where $x(t) \in \mathbf{R}^n$, U is a closed and convex set in $\mathbf{R}^m$, $g : \mathbf{R}^n \times \mathbf{R}^m \to \mathbf{R}$, $f : \mathbf{R}^n \times \mathbf{R}^m \to \mathbf{R}^n$, and a is a fixed vector in $\mathbf{R}^n$. Throughout L^∞ is the space of essentially bounded vector

functions in [0, 1] with the norm $\| u \|_{L^\infty} = \operatorname{ess\,sup}\{|u(t)| : 0 \le t \le 1\}$ and $W^{1,\infty}$ is the space of functions with values in $\mathbf{R}^n$ that are Lipschitz continuous on [0, 1] equipped with the norm $\| x \|_{W^{1,\infty}} = \| x \|_{L^\infty} + \| \dot{x} \|_{L^\infty}$. We denote by $| \cdot |$ any norm in $\mathbf{R}^n$ and by the superscript ^{T} the transposition.

Assuming that the functions f and g are continuously differentiable, we write the first-order conditions (Pontryagin maximum principle) as a variational inequality of the form

$$\dot{x}(t) = f(x(t), u(t)), \quad x(0) = a; \tag{2}$$

$$\dot{\lambda}(t) = -\nabla_x H(x(t), u(t), \lambda(t)), \quad \lambda(1) = 0; \tag{3}$$

$$\nabla_u H(x(t), u(t), \lambda(t)) \in N(U; u(t)), \tag{4}$$

for a.e. $t \in [0, 1]$, where λ is the adjoint variable, H is the Hamiltonian, $H(x, u, \lambda) = g(x, u) + \lambda^T f(x, u)$, $\nabla_x H$ is the derivative of H with respect to x, and $N(U; u)$ is the normal cone to the set U at the point u; that is,

$$N(U; u) = \begin{cases} \{y \in \mathbf{R}^m : y^T(v - u) \le 0 \text{ for each } v \in U\} & \text{if } u \in U, \\ \emptyset & \text{if } u \notin U. \end{cases}$$

Suppose that to solve problem (2)–(4) we use a discrete approximation provided by the Euler scheme. More specifically, let N be a natural number; let $h = 1/N$ be the mesh spacing; let $t_i = ih$; and let x_i, u_i, λ_i denote approximations of $x(t)$, $u(t)$, and $\lambda(t)$, respectively, at $t = t_i$. The Euler scheme applied to the variational inequality (2)–(4) results in a finite-dimensional variational inequality. There are various numerical techniques for solving such problems; in this paper we shall not discuss this topic. We suppose that, after applying a numerical procedure with certain accuracy, a sequence of vectors $(x^N, u^N, \lambda^N) \in \mathbf{R}^{Nn} \times \mathbf{R}^{Nm} \times \mathbf{R}^{Nn}$ is available that satisfy the following approximation to (2)–(4):

$$x_{i+1} = x_i + hf(x_i, u_i) + h\delta_i^N, \quad x_0 = a; \tag{5}$$

$$\lambda_i = \lambda_{i+1} + h\nabla_x H(x_i, u_i, \lambda_{i+1}) + h\eta_i^N, \quad \lambda_N = \sigma^N; \tag{6}$$

$$\nabla_u H(x_i, u_i, \lambda_{i+1}) + \kappa_i^N \in N(U; u_i), \quad i = 0, 1, \ldots, N - 1. \tag{7}$$

Here the vector $\epsilon_i^N = (\delta_i^N, \eta_i^N, \sigma^N, \kappa_i^N)$, $\delta_i^N \in \mathbf{R}^n$, $\eta_i^N \in \mathbf{R}^n$, $\kappa_i^N \in \mathbf{R}^m$, $i = 0, 1, \ldots, N - 1$, $\sigma^N \in \mathbf{R}^n$, represents the accuracy of the algorithm used for solving the discretized problem. We denote by $x^N(\cdot)$ and $\lambda^N(\cdot)$ the piecewise linear and continuous extensions over [0, 1] of x^N and λ^N, respectively, and by $u_N(\cdot)$ the piecewise constant extension of u^N over [0, 1], which is continuous from the right across the grid points t_i.

In our previous paper with W. Hager [21] we showed that if a given optimal control u^* and the corresponding state x^* and adjoint variable λ^* for the continuous problem (1) satisfy certain conditions, then there exists a solution of the discretized problem that is "close" to (u^*, x^*, λ^*). In this paper we are concerned with the converse estimate; namely, we consider the distance from a given sequence of solutions of the approximating problem (5)–(7) to the set of solutions of the continuous problem (1). More precisely, in Theorem 1 we give an answer to the question of under what conditions on a sequence of successive approximations x^N, u^N, λ^N there exists an optimal control u^* of the original problem (1) such that its L^∞ distance from $u^N(\cdot)$ is proportional to the step size h and to the error ϵ^N.

THEOREM 1. *Assume that the sequence $(x_i^N, u_i^N, \lambda_i^N)$ is contained in a compact set $\mathcal{X} \subset \mathbf{R}^n \times \mathbf{R}^m \times \mathbf{R}^n$ for all $i = 0, 1, \ldots, N$ and for all N and that the functions f and g are twice*

continuously differentiable in an open set containing $\mathcal{X}$. *Let there exist a constant* $\alpha > 0$ *such that for every sufficiently large* N

$$\int_0^1 [x^T(t)Q_N(t)x(t) + 2x^T(t)S_N(t)u(t) + u^T(t)R_N(t)u(t)]dt \geq \alpha \int_0^1 |u(t)|^2 dt \tag{8}$$

for all $x(\cdot) \in W^{1,2}, u(\cdot) \in L^2, x(0) = 0, \dot{x}(t) = A_N(t)x(t) + B_N(t)u(t), u(t) \in U - U$ *a.e. in* $[0, 1]$, *where* $A_N = \nabla_x f(x^N, u^N)$, $B_N = \nabla_u f(x^N, u^N)$, $R_N = \nabla^2_{uu} H(x^N, u^N, \lambda^N)$, $S_N = \nabla^2_{xu} H(x^N, u^N, \lambda^N)$, $Q_N = \nabla^2_{xx} H(x^N, u^N, \lambda^N)$. *Then there exist positive constants* c, δ *and an integer* N^* *such that for every* $N \geq N^*$ *for which*

$$\max_{0 \leq i \leq N-1} |\epsilon_i^N| \leq \delta, \tag{9}$$

there exist an isolated local minimizer $(x^{*N}(\cdot), u^{*N}(\cdot))$ *of the continuous problem* (1) *and a corresponding adjoint variable* $\lambda^{*N}(\cdot)$ *such that*

$$\begin{aligned} &\| x^{*N}(\cdot) - x^N(\cdot) \|_{W^{1,\infty}} + \| \lambda^{*N}(\cdot) - \lambda^N(\cdot) \|_{W^{1,\infty}} \\ &\qquad + \| u^{*N}(\cdot) - u^N(\cdot) \|_{L^\infty} \leq c(h + \max_{0 \leq i \leq N-1} |\epsilon_i^N|). \end{aligned} \tag{10}$$

In the statement of the theorem we use the uniform grid in [0, 1], i.e. with a constant step size h. The same result holds for any regular partition of [0, 1] in which the maximal step size goes to zero. From Theorem 1 we obtain the following corollary.

COROLLARY 1. *Let problem* (1) *have no more than one optimal solution, let*

$$\lim_{N \to \infty} \max_{0 \leq i \leq N-1} |\epsilon_i^N| = 0,$$

and let for every regular partition of $[0, 1]$ *in* N *intervals the sequence* (x^N, u^N, λ^N) *obtained from* (5)–(7) *satisfy coercivity condition* (8). *Then there exists a (unique) optimal control for* (1), *which is Riemann integrable.*

Proof. Theorem 1 implies that problem (1) has a solution (x^*, u^*) that is unique and satisfies (10). Then for every regular partition $\{t_i\}_{i=0}^N$,

$$\max_{0 \leq i \leq N-1} \sup_{t_i \leq t < t_{i+1}} |u^*(t) - u^*(t_i)| \to 0 \quad \text{as } N \to \infty,$$

which implies Riemann integrability of u^*. □

The coercivity condition (8) is a stability-type condition which implies that the inverse of the linearization of (5)–(7) is Lipschitzian around the reference sequence uniformly in N. For instance, it holds when the Hamiltonian is convex in x and strongly convex in u in a neighborhood of a solution and the sequence of successive approximations is in this neighborhood. Practically, during computations one may check whether there exists a constant $\alpha > 0$ such that

$$(x^T, u^T) \begin{pmatrix} Q_N(t) & S_N^T(t) \\ S_N(t) & R_N(t) \end{pmatrix} \begin{pmatrix} x \\ u \end{pmatrix} \geq \alpha |u|^2$$

for all N, x, u, and t, which is a computationally available procedure. The consistency condition (9) means that the error of solving the discretized problems is to be sufficiently small when increasing the number N. Note that a finer discretization results in higher dimensions of the discrete problem and, in turn, is more likely to lead to accumulation of various errors accompanying the computations. The practical validity of the error model adopted in Theorem 1 may vary from problem to problem and from computer to computer.

3. Proof of Theorem 1. The proof is based on the following abstract inverse-function-type result for a sequence of set-valued maps.

LEMMA 1. *Let (X, ρ) be a complete metric space, let Y be a linear normed space, and let $B_a(x)$ be the closed ball centered at x with radius a. Let ξ_N be a sequence in X, let Θ_N be a sequence of set-valued maps from X to Y with $0 \in \Theta_N(\xi_N)$ for all N, and let $\phi_N : X \to Y$ be a sequence of functions. Suppose that for each N there exists a function $\Psi_N : Y \to X$ with the following properties.*

(A1) $\xi_N = \Psi_N(0)$ *and there exists a constant $\beta > 0$ such that for every N*

$$\Psi_N(y) \in \Theta_N^{-1}(y) \text{ for every } y \in B_\beta(0).$$

(A2) *There exists a constant $\gamma > 0$ such that Ψ_N is Lipschitz in $B_\beta(0)$ with constant γ for every N.*

(A3) *For every $\epsilon > 0$ there exists $\alpha > 0$ such that for every N*

$$\| \phi_N(u) - \phi_N(v) \| \leq \epsilon \rho(u, v)$$

whenever $u, v \in B_\alpha(\xi_N)$, $N = 1, 2, \ldots$.

Then for every $c > \gamma$ there exists $\Delta > 0$ such that for every N for which

$$\| \phi_N(\xi_N) \| \leq \Delta$$

there exists $\xi_N^* \in (\Theta_N - \phi_N)^{-1}(0)$ satisfying

$$\rho(\xi_N^*, \xi_N) \leq c \| \phi_N(\xi_N) \| . \tag{11}$$

Moreover, if Θ_N^{-1} is single-valued near 0, then there exists exactly one ξ_N^* with the above properties.

Proof of Lemma 1. Let $c > \gamma$ and let $\epsilon > 0$ be so small that

$$0 < \gamma\epsilon < 1 \quad \text{and} \quad \frac{\gamma}{1 - \epsilon\gamma} \leq c. \tag{12}$$

Let $\Delta > 0$ be such that

$$\Delta \leq \min\left\{ \frac{\beta}{c\epsilon + 1}, \frac{\alpha}{c} \right\}, \tag{13}$$

and let

$$r_N = c \| \phi_N(\xi_N) \| . \tag{14}$$

Define the function

$$\Phi_N(x) = \Psi_N(\phi_N(x)).$$

Let N be such that $\| \phi_N(\xi_N) \| \leq \Delta$, and let $x \in B_{r_N}(\xi_N)$. Using (A3), (13), and (14) we have

$$\| \phi_N(x) \| \leq \| \phi_N(x) - \phi_N(\xi_N) \| + \| \phi_N(\xi_N) \| \leq \epsilon r_N + \Delta \leq \Delta(1 + c\epsilon) \leq \beta.$$

Then from (A2), (A3), (12), and (14) we obtain

$$\begin{aligned} \rho(\xi_N, \Phi_N(x)) &= \rho(\Psi_N(0), \Psi_N(\phi_N(x))) \leq \gamma \| \phi_N(x) \| \\ &\leq \gamma \| \phi_N(x) - \phi_N(\xi_N) \| + \gamma \| \phi_N(\xi_N) \| \leq \gamma\epsilon r_N + \gamma r_N / c \leq r_N. \end{aligned}$$

Hence, Φ_N maps $B_{r_N}(\xi_N)$ into itself. Moreover, if $x', x'' \in B_{r_N}(\xi_N)$, then

$$\rho(\Phi_N(x'), \Phi_N(x'')) = \rho(\Psi_N(\phi_N(x')), \Psi_N(\phi_N(x'')))$$
$$\leq \gamma \parallel \phi_N(x') - \phi_N(x'') \parallel \leq \gamma\epsilon\rho(x', x'') < \rho(x', x'').$$

Thus Φ_N is a contraction from $B_{r_N}(\xi_N)$ to $B_{r_N}(\xi_N)$. By the contraction mapping principle for every N there exists $\xi_N^* \in B_{r_N}(\xi_N)$ such that $\xi_N^* = \Phi_N(\xi_N^*)$. The definition of Φ_N yields that $\xi_N^* \in (\Theta_N - \phi_N)^{-1}(0)$. If Θ_N^{-1} is locally single-valued near 0, then ξ_N^* is the unique fixed point of Φ_N in $B_{r_N}(\xi_N)$. This completes the proof of Lemma 1. □

Proof of Theorem 1. We apply Lemma 1 with the specifications

$$X = \{\xi = (x, \lambda, u) \in W^{1,\infty} \times W^{1,\infty} \times L^\infty, x(0) = a\}, \quad Y = L^\infty \times \mathbf{R}^n,$$

$$\phi_N(\xi) = -\begin{pmatrix} \dot{x} - f(x,u) - (\dot{x} - \dot{x}^N) + A_N(x - x^N) + B_N(u - u^N) \\ \dot{\lambda} + \nabla_x H(x,u,\lambda) - (\dot{\lambda} - \dot{\lambda}^N) - A_N^T(\lambda - \lambda^N) - Q_N(x - x^N) - S_N(u - u^N) \\ -\nabla_u H(x,u,\lambda) + \nabla_u H^N + R_N(u - u^N) + S_N^T(x - x^N) + B_N^T(\lambda - \lambda^N) - \kappa^N \\ \sigma^N \end{pmatrix},$$

$$\Theta_N(\xi) = \begin{pmatrix} (\dot{x} - \dot{x}^N) - A_N(x - x^N) - B_N(u - u^N) \\ (\dot{\lambda} - \dot{\lambda}^N) + A_N^T(\lambda - \lambda^N) + Q_N(x - x^N) + S_N(u - u^N) \\ -\nabla_u H^N - R_N(u - u^N) - S_N^T(x - x^N) - B_N^T(\lambda - \lambda^N) + \kappa^N + N(U; u) \\ \lambda(1) - \sigma^N \end{pmatrix},$$

where $\nabla_u H^N(t) = \nabla_u H(x^N(t_i), u^N(t), \lambda^N(t_{i+1}))$ for $t \in [t_i, t_{i+1})$ and $\delta^N, \eta^N, \kappa^N$ are assumed piecewise constant and continuous from the right across the time grid. Clearly, $0 \in \Theta_N(\xi_N)$.

Let $(p, q, r) \in L^\infty, s \in \mathbf{R}^n$, and denote $y = (p, q, r, s)$. Then $\xi \in \Theta_N^{-1}(y)$ if and only if $\xi = (x, \lambda, u)$ satisfies the relations

$$\dot{x} = A_N x + B_N u + p + \alpha_N, \quad x(0) = a; \tag{15}$$

$$\dot{\lambda} = -A_N^T \lambda - Q_N x - S_N u + q + \beta_N, \quad \lambda(1) = s + \sigma^N; \tag{16}$$

$$R_N u + S_N^T x + B_N^T \lambda + r + \gamma_N \in N(U; u) \tag{17}$$

for a.e. $t \in [0, 1]$, where $\alpha_N = \dot{x}^N - A_N x^N - B_N u^N, \beta_N = \dot{\lambda}^N + A_N^T \lambda^N + Q_N x^N + S_N u^N, \gamma_N = \nabla_u H^N - R_N u^N - S_N^T x^N - B_N^T \lambda^N - \kappa^N$. We show first that there exists a function $\Psi_N(y) = (x_N(y), \lambda_N(y), u_N(y)) \in \Theta_N^{-1}(y)$ that satisfies conditions (A1), (A2) of Lemma 1.

Under the coercivity condition (8) the system (15)–(17) is equivalent to the linear-quadratic problem of minimizing

$$-x(1)^T(s+\sigma^N) + 0.5 \int_0^1 [x^T Q_N x + u^T R_N u + 2x^T S_N u - (q+\beta_N)^T x + (r+\gamma_N)^T u] dt \tag{18}$$

subject to

$$\dot{x} = A_N x + B_N u + p + \alpha_N, \quad u(t) \in U \text{ for a.e. } t \in [0, 1], \quad x(0) = a. \tag{19}$$

Let $w_N(p)$ be the solution of

$$\dot{w} = A_N w + p + \alpha_N, \qquad w(0) = a.$$

Changing the state variable $x = z + w_N(p)$ we obtain the following problem equivalent to (18): minimize

$$-z(1)^T(s + \sigma^N) + 0.5 \int_0^1 [z^T Q_N z + u^T R_N u + 2z^T S_N u$$

$$-(q + \beta_N - 2Q_N w_N(p))^T z + (r + \gamma_N + 2S_N^T w_N(p))^T u]dt \tag{20}$$

subject to

$$\dot{z} = A_N z + B_N u, \quad u(t) \in U, \text{ a.e. } t \in [0, 1], \quad z(0) = 0. \tag{21}$$

Let $\mathcal{L}_N : L^2 \to L^2$ be the linear and bounded input–state map for system (21); that is,

$$(\mathcal{L}_N u)(t) = \int_0^t \Phi_N(t, \tau) B_N(\tau) u(\tau) d\tau,$$

where Φ_N is the fundamental matrix solution to $\dot{z} = A_N z$. Note that the conjugate map is

$$(\mathcal{L}_N^T x)(t) = \int_t^1 B_N(t)^T \Phi_N(\tau, t)^T x(\tau) d\tau,$$

and, since the components of A_N and B_N are bounded in L^∞, there exists a constant c_1 independent of N such that the operator norm satisfies

$$\| \mathcal{L}_N \| \leq c_1. \tag{22}$$

Denote

$$c_N[s](t) = -B_N^T(t)\Phi_N(1, t)^T(s + \sigma_N),$$

$$v_N(y) = \mathcal{L}_N^T(-q - \beta_N + 2Q_N w_N(p)) + r + \gamma_N + 2S_N^T w_N(p) + c_N(s),$$

$$\mathcal{R}_N = \mathcal{L}_N^T Q_N \mathcal{L}_N + 2\mathcal{L}_N^T S_N + R_N; \tag{23}$$

and let $\Omega = \{u \in L^2 : u(t) \in U \text{ for a.e. } t \in [0, 1]\}$. Then problem (20) can be rewritten as

$$\text{minimize } 0.5\langle u, \mathcal{R}_N u\rangle + \langle v_N(y), u\rangle \text{ subject to } u \in \Omega, \tag{24}$$

where $\langle \cdot, \cdot \rangle$ is the L^2 scalar product. The set Ω is a closed and convex subset of the space L^2 and the coercivity condition (8) is equivalent to

$$\langle u, \mathcal{R}_N u\rangle \geq \alpha \| u \|_{L^2}^2 \qquad \text{for all } u \in \Omega - \Omega. \tag{25}$$

It is a standard observation that, under (25), for every $y \in L^\infty \times \mathbf{R}^n$ there exists a unique solution $u_N(y)$ of the problem (24). Thus there exist an unique optimal state $x_N(y)$ and an unique optimal adjoint variable $\lambda_N(y)$; that is, the function $\Psi_N(y) = (x_N(y), \lambda_N(y), u_N(y))$ is well defined for all $y \in L^\infty \times \mathbf{R}^n$. Hence assumption (A1) of Lemma 1 holds. To show that

$\Psi_N(y)$ is Lipschitzian we apply a well-known argument; see, e.g., [18, Ch. 2]. For any $y', y'' \in Y$ the corresponding solutions u'_N, u''_N satisfy

$$\langle \mathcal{R}_N u' + v_N(y'), u'' - u' \rangle \geq 0,$$

$$\langle \mathcal{R}_N u'' + v_N(y''), u' - u'' \rangle \geq 0.$$

Combining these two inequalities with (25) we obtain that

$$\| u'_N - u''_N \|_{L^2} \leq \frac{1}{\alpha} \| v_N(y') - v_N(y'') \|_{L^2} . \tag{26}$$

Using (22) and the boundedness in L^∞ of the matrices A_N, B_N, Q_N, S_N we conclude that for every $y \in Y$ there exists a unique optimal control $u_N(y)$ of problem (18) that is Lipschitzian in y from L^∞ to L^2 with a Lipschitz constant independent of N. The Gronwall lemma and (22) applied to the state and adjoint equations yield that the optimal state $x_N(y)$ and the optimal adjoint variable $\lambda_N(y)$ are Lipschitzian with respect to y from $L^\infty \times \mathbf{R}^n$ to $W^{1,2}$ uniformly in N. Furthermore, the coercivity condition (8) implies that for some $\alpha_1 > 0$,

$$u^T R_N(t) u \geq \alpha_1 |u|^2 \quad \text{for a.e. } t \in [0, 1],$$

whenever $u \in U - U$; see [27]. By repeating the argument in deriving (26) for optimality condition (17), we obtain that the optimal control $u_N(y)$ is Lipschitzian in y from L^∞ to L^∞ uniformly in N. The Gronwall lemma applied to the state and adjoint equations yields that $x_N(y)$ and $\lambda_N(y)$ are Lipschitzian in y from $L^\infty \times \mathbf{R}^n$ to $W^{1,\infty}$ uniformly in N. Hence, condition (A2) of Lemma 1 is satisfied.

Let us show that ϕ_N satisfies (A3) at $\xi_N(\cdot) = (x^N(\cdot), \lambda^N(\cdot), u^N(\cdot))$ uniformly in N as a function from $W^{1,\infty} \times W^{1,\infty} \times L^\infty \times \mathbf{R}^n$ to L^∞. Denote $\zeta = (x, u)$ and consider the first component of ϕ_N. From the continuity of the derivative ∇f it follows that for any $\epsilon > 0$ there exists $\alpha > 0$ such that for every $\bar{\zeta}$ with $\| \bar{\zeta} - \zeta_N \|_{L^\infty} \leq \alpha$,

$$\| \nabla f(\bar{\zeta}) - \nabla f(\zeta_N) \|_{L^\infty} \leq \epsilon.$$

If $\zeta_1, \zeta_2 \in B_\alpha(\zeta_N)$, then

$$\| f(\zeta_1) - f(\zeta_2) - \nabla f(\zeta_N)(\zeta_1 - \zeta_2) \|_{L^\infty} \leq \epsilon \| \zeta_1 - \zeta_2 \|_{W^{1,\infty} \times L^\infty} .$$

The proof of (A3) for the remaining components of ϕ_N is completely analogous.

Thus we can apply Lemma 1, obtaining that there exist constants c and Δ such that if $\| \phi_N(\xi_N) \| \leq \Delta$, then there exists $\xi_N^* \in (\Theta_N - \phi_N)^{-1}(0)$ satisfying (11). It remains to estimate $\| \phi_N(\xi_N) \|$. The relations (5)–(7) imply that $\xi_N \in X$ and satisfies

$$\dot{x}(t) = f(x(t_i), u(t)) + \delta^N(t);$$

$$\dot{\lambda}(t) = -\nabla_x H(x(t_i), u(t), \lambda(t_{i+1})) + \eta^N(t), \quad \lambda(1) = \sigma^N;$$

$$\nabla_u H(x(t_i), u(t), \lambda(t_{i+1})) + \kappa^N(t) \in N(U; u(t))$$

for $t \in [t_i, t_{i+1})$, $i = 0, 1, \ldots, N-1$. Applying the Gronwall lemma to the adjoint equation and using the assumption that $x^N(\cdot)$, $u^N(\cdot)$ are bounded in L^∞ and f, g and their derivatives are continuous, we obtain that $\lambda^N(\cdot)$ is bounded in L^∞. Hence, the sequence of the derivatives $(\dot{x}^N(\cdot), \dot{\lambda}^N(\cdot))$ is bounded in L^∞. Then

$$\begin{aligned}\| \phi_N(\xi_N) \|_{L^\infty} &\le \max_{0\le i\le N-1} \sup_{t_i\le t\le t_{i+1}} \{[|f(x^N(t_i), u^N(t)) - f(x^N(t), u^N(t))| \\ &\quad + |\nabla_x H(x^N(t_i), u^N(t), \lambda^N(t_{i+1})) - \nabla_x H(x^N(t), u^N(t), \lambda^N(t))| \\ &\quad + |\nabla_u H(x^N(t_i), u^N(t), \lambda^N(t_{i+1})) - \nabla_u H^N(x(t), u^N(t), \lambda^N(t))|] \\ &\quad + |\kappa_i^N| + |\sigma^N|\} \\ &\le c_2 h + \max_{0\le i\le N-1} |\epsilon_i^N|,\end{aligned}$$

where c_2 is a constant independent of N. Take $\delta > 0$ and N^* such that $c_2/N^* + \delta \le \Delta$. From Lemma 1, if $N \ge N^*$ and $\max_{0\le i\le N-1} |\epsilon_i^N| \le \delta$, then there exist x^{*N}, u^{*N}, and λ^{*N} satisfying the estimate (10) and the maximum principle (2)–(4). The last step of the proof is to show that (x^{*N}, u^{*N}) is an isolated local solution of (1). Clearly, the values of the derivatives of f and H at $(x^{*N}, u^{*N}, \lambda^{*N})$, denoted A_N^*, B_N^*, Q_N^*, S_N^*, R_N^*, are close in L^∞ to the values of the corresponding matrix functions A_N, B_N, Q_N, S_N, R_N defined in the statement of the theorem. Then the operator $\mathcal{R}_N^*$ defined as in (23), where A_N, B_N, Q_N, S_N, R_N are replaced by A_N^*, B_N^*, Q_N^*, S_N^*, R_N^*, satisfies (25). It is known that (8) (or, equivalently, (25)), together with the maximum principle (2)–(4), is a second-order sufficient condition for an isolated local minimum; see, e.g., [21, App. 1]. The proof is complete. □

4. A computational example. If the final state in problem (1) is fixed, e.g. $x(1) = b$, then using Lemma 1 one can easily prove a result completely analogous to that in Theorem 1 on the additional assumption that there exists $c > 0$ such that the ball $B_c(b)$ is in the reachable set of the linearized system (15) for all N (for a related analysis see [22]). As an illustration we consider the problem

$$\text{minimize } 0.5 \int_0^2 u(t)^2 dt$$

subject to

$$\begin{aligned}&\dot{x}_1 = x_2, \\ &\dot{x}_2 = u, \\ &x_1(0) = 0, \qquad x_1(2) = 5/6, \\ &x_2(0) = 0, \qquad x_1(2) = 1/2, \\ &u \ge 0, \quad t \in [0, 2].\end{aligned}$$

The optimal control is a nonsmooth function in time, that is,

$$u^*(t) = \begin{cases} 1 - t & \text{for } t \in [0, 1), \\ 0 & \text{for } t \in [1, 2]; \end{cases}$$

and the first-order optimality conditions result in a boundary-value problem with nonsmooth right-hand side

$$\begin{aligned}&\dot{x}_1 = x_2, \\ &\dot{x}_2 = \max\{0, \lambda_2\}, \\ &\dot{\lambda}_1 = 0,\end{aligned}$$

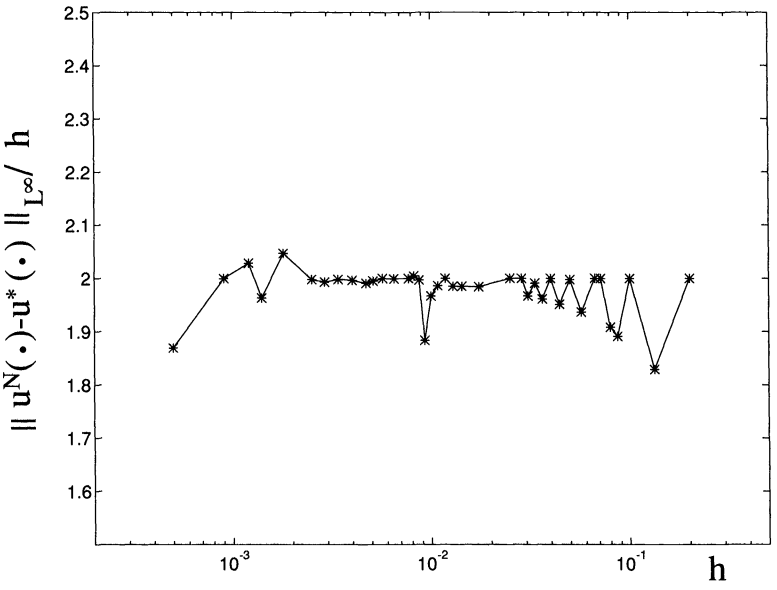

FIG. 1. *The dependence of the relative accuracy on h for* $\epsilon = 10^{-6}$.

$$\dot{\lambda}_2 = -\lambda_1.$$
$$x_1(0) = 0, \qquad x_1(2) = 5/6,$$
$$x_2(0) = 0, \qquad x_1(2) = 1/2, \tag{27}$$

We applied the Euler discretization scheme to the latter problem and solved the resulting finite-dimensional problem by the shooting method with a quadratic penalty. The unconstrained optimization problem is solved with the help of the BFGS code of MATLAB on HP Apollo workstation 715/50.

It turns out that even for the simple linear-quadratic problem considered one observes effects in the line of the theoretical analysis. Figure 1 shows the dependence of the relative accuracy $\| u^*(\cdot)-u^N(\cdot) \|_{L^\infty} / h$ on the mesh spacing h when the tolerance in the stopping test is $\epsilon = 10^{-6}$. We see that this relative accuracy is bounded, hence the convergence rate is $O(h)$ as proved theoretically. Note that the computational time for $h = 5 \times 10^{-4}$ was 1.9542×10^4 sec. In Fig. 2 the same dependence is obtained for the tolerance $\epsilon = 10^{-3}$. In this case, for $h \leq 5 \times 10^{-3}$ the relative accuracy significantly increases; that is, for a tolerance comparable with the mesh spacing, there is no first-order convergence. Figure 3 shows the exact and the approximate optimal controls for $\epsilon = 10^{-6}$ and $h = 0.05$.

An area for future research is error analysis of higher order approximations (e.g., Runge–Kutta schemes) applied to *constrained* optimal control problems. We did some computations for problem (27) with the standard second-order Runge–Kutta scheme. The dependence of the relative accuracy on h is given in Fig. 4; it indicates $O(h^2)$ convergence.

In the author's opinion the abstract result in Lemma 1 can be applied to variational problems with integral state and control constraints, as well as with systems governed by abstract (functional or partial) differential equations. The main steps in such an analysis will be to prove the consistency and stability of the approximation considered. A direct application of the abstract scheme may fail for stiff systems where, in general, the stability condition fails.

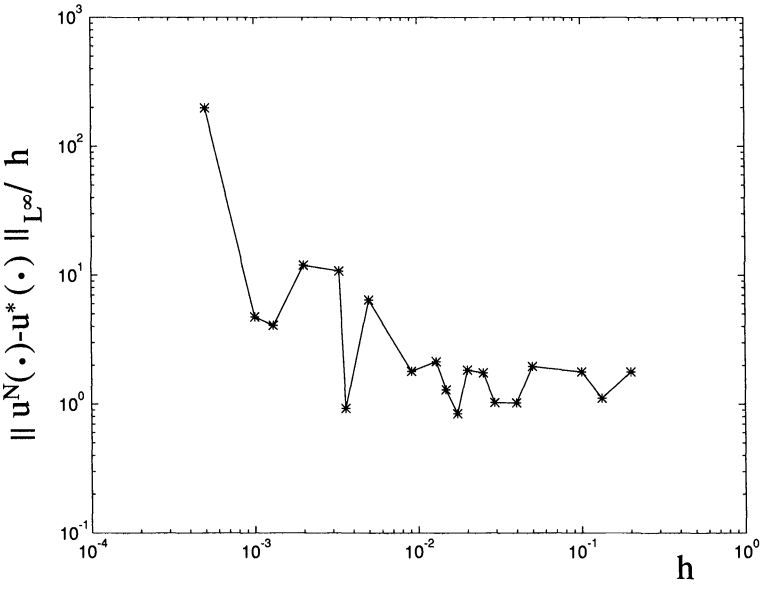

FIG. 2. *The dependence of the relative accuracy on h for* $\epsilon = 10^{-3}$.

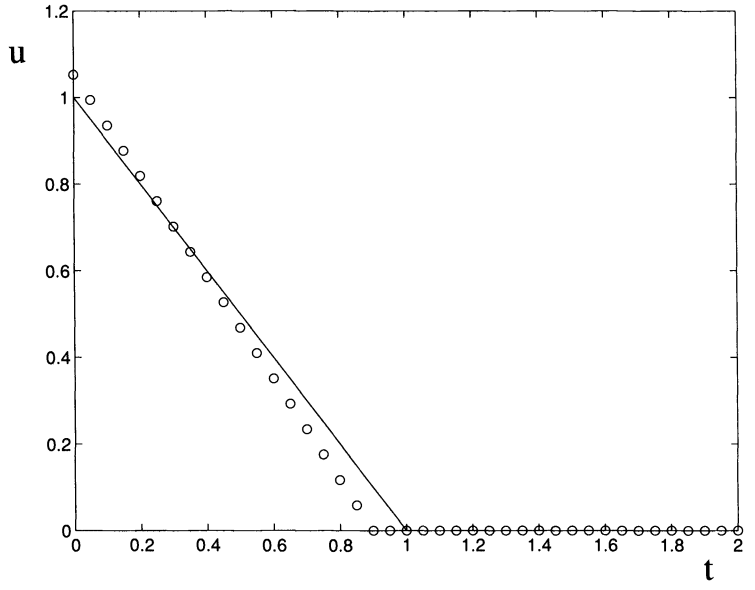

FIG. 3. *The exact and approximate optimal controls for* $h = 0.05$ *and* $\epsilon = 10^{-6}$.

The presence of state constraints considerably complicates the analysis of nonlinear optimal control problems. The main difficulty here is to find a compromise between the requirements for differentiability of the functions involved and the coercivity conditions guaranteeing stability. An $O(h)$ estimate for the L^2 norm of the error for the optimal control was obtained in [17] for a convex problem with linear inequality state and control constraints. We do not know whether such an estimate holds with a stronger norm, for example, in L^∞.

A NEVANLINNA–PICK APPROACH TO TIME-DOMAIN CONSTRAINED $\mathcal{H}_\infty$ CONTROL*

HÉCTOR ROTSTEIN†

Abstract. In this paper, generalized Nevanlinna–Pick theory is used to solve a time-domain constrained $\mathcal{H}_\infty$ control problem for linear time-invariant discrete-time systems. First it is shown that if constraints are imposed only over a finite horizon (i.e., only on the first n samples), then the problem reduces to a finite-dimensional convex minimization problem. Subsequently it is shown that if these problems are conveniently modified, then letting the horizon length go to infinity produces a solution to the infinite-horizon problem.

Key words. $\mathcal{H}_\infty$ control, interpolation theory, time-domain constraints

AMS subject classifications. 93B36, 93B28

1. Introduction.

Consider the standard setup for linear time-invariant $\mathcal{H}_\infty$ control illustrated in Fig. 1. The objective is to design a controller that minimizes the worst-case l_2-norm of the controlled variable y, assuming that the disturbance w lies in a (weighted) ball of l_2 signals. Numerous control problems can be reduced to this setup, including problems of disturbance rejection, robust stability, and signal tracking [6, 7]. Suppose, for instance, that one wants to track a given signal r with the output y. In order to formulate this as an $\mathcal{H}_\infty$ problem, one starts by modeling the input by the set

$$\mathcal{W} \doteq \{\hat{r} = Ww \text{ s.t. } \|w\|_2 \leq 1\},$$

where W is a stable weighting function reflecting the frequency content of r, and $r \in \mathcal{W}$. Then, if $T_{e\hat{r}}$ denotes the closed-loop transfer function between $\hat{r}$ and $\hat{r} - y$, the $\mathcal{H}_\infty$ objective becomes the minimization of the $\mathcal{H}_\infty$ norm of $WT_{e\hat{r}}$. (The energy of the control action is usually also penalized to guarantee the properness of the optimal controller.) If the resulting norm is "small," then good tracking can be guaranteed for all signals in $\mathcal{W}$ and hence, in particular, for r. This procedure has two main drawbacks. First, since performance for a *fixed* signal r is replaced by performance for a set of signals $\mathcal{W}$, the result will be generically conservative. This difficulty can be partially alleviated by taking the tracking signal into account when formulating the $\mathcal{H}_\infty$ objective, as proposed in [3]. Second, the $\mathcal{H}_\infty$ norm provides a bound on the l_2-norm of the tracking error, but very little can be inferred about the time response of the signal, in particular over the first few samples.

Specifications for the time responses of the closed-loop system, such as the one considered in the previous paragraph, are not amicable to standard $\mathcal{H}_\infty$ control. Therefore, until recently, one was left with a trial-and-error procedure, by which weighting functions (such as W in the example above) were iteratively adjusted in an attempt to enforce the specifications. In the absence of a formal procedure for constructing weighting functions from time-domain specifications, this trial-and-error procedure may become arduous and time consuming, without guarantees of producing a solution, even if one exists. This problem gave rise to interest in a theory that would include both the $\mathcal{H}_\infty$ objective and time-domain constraints. The first attempts in this direction were to use the Youla lemma [6] to parameterize all feasible (i.e., resulting from stabilizing controllers) closed-loop transfer functions and then compute the free variable in the parameterization through a constrained optimization procedure [2, 13]. Although this constitutes in principle a reasonable approach, it is not completely satisfactory

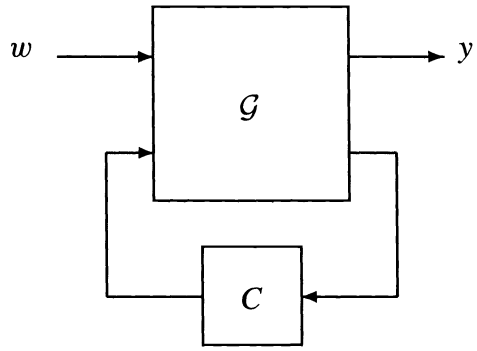

FIG. 1. *Standard $\mathcal{H}_\infty$ setup.*

since it provides little insight into the problem and the computation of a solution becomes very expensive, even for relatively modest problems.

A different approach to the $\mathcal{H}_\infty$ constrained problem was initiated by Helton and Sideris in [8], where Lawson's algorithm for solving the Nehari problem was modified to accommodate time-domain constraints. The resulting program is a combination of Lawson's and quadratic programming steps; it is in the latter that constraints appear. The original idea had several drawbacks, including the lack of a proof of convergence and the fact that it was tailored for a specific $\mathcal{H}_\infty$ problem and cannot be extended directly into the general setup. Also, the approach was based on imposing the constrains only over a finite horizon, i.e., up to a time instant $n-1$. Although this is intuitively plausible, since by stability one expects that the responses will achieve some steady-state value for n sufficiently large, it turned out to be problematic in the subsequent developments. The first two difficulties were largely overcome in [14, 15, 17]. In [17] the problem considered by Helton and Sideris, i.e., a scalar one-block $\mathcal{H}_\infty$ problem with constraints imposed over a finite horizon, was solved by resorting to Nehari's theorem. In addition to providing a better understanding of some of its properties, the approach reduced the problem to a finite-dimensional convex minimization, thus establishing the convergence issue. Also, the special structure of the objective function was exploited to obtain an algorithm for solving the minimization with relatively low computational complexity. Subsequently, in [15], the setup of Fig. 2 was considered. Here the objective is to guarantee an $\mathcal{H}_\infty$ norm bound between w_f and y_f while satisfying some time-domain specifications between w_t and y_t. It was shown that, although technically more involved, the general problem can be reduced to a generalized version of the one considered in [17], and hence it inherits its main properties, including convexity and the bound on the computational complexity. It is interesting to remark that previous approaches to the problem scaled badly to the multivariable case. The original problem has been extended in several different directions; for instance, in [19–21] a mixed $l_\infty/\mathcal{H}_\infty$ problem is solved by using similar techniques.

The aim of the present paper is to solve the time-domain constrained $\mathcal{H}_\infty$ problem by using existing results in interpolation theory. The study was motivated by the facts that a variety of solution techniques have been used to solve the standard $\mathcal{H}_\infty$ problem and that the interplay of the various approaches has provided considerable additional knowledge. In particular, the interested reader may consult [12] for a pointer to relevant literature in interpolation theory and its role in the progress of the field. Since the main motivation of this paper is to obtain further insights into the problem, a simple instance of the setup illustrated in Fig. 2 will be considered, thus sacrificing generality in order to get cleaner results.

The paper is organized as follows. Section 2 is devoted to a review of relevant results in interpolation theory, more specifically a particular generalization of the Nevanlinna–Pick

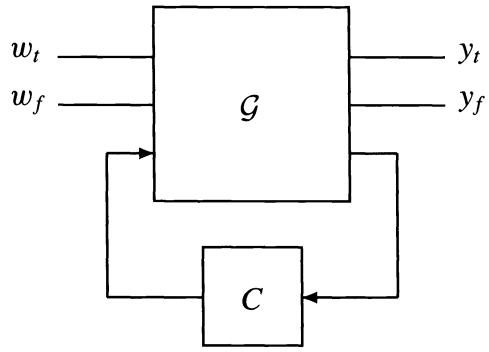

FIG. 2. *Time-domain constrained $\mathcal{H}_\infty$ setup.*

theory borrowed from [1]. Section 3 describes the prototype problem which is studied in this paper. Section 4 contains the solution of the problem when constraints are imposed only over a finite number of sample points, and constitutes the interpolation counterpart of [17]. Section 5 contains the major new contribution of this paper, namely, the construction of a solution when constraints are imposed over an infinite horizon, i.e., for all sampling instants. It is worth stressing that this result does not follow in a straightforward manner from the finite-horizon case considered in [17] and [15]. In fact, it is not clear at this point that just letting the horizon length go to infinity will eventually produce a solution to the original problem, and a special construction is required to guarantee this fact. Section 6 contains the conclusions and a brief discussion of other approaches to the infinite-horizon problem.

2. Preliminaries on interpolation theory. It is well known that interpolation theory can be used to solve numerous linear system problems. For instance, [9, 10] used a result of Nevanlinna–Pick to study the robust stabilization problem, while [11] used the same tool to solve a version of the $\mathcal{H}_\infty$ problem. A common simplifying assumption in these works is that all interpolation points have multiplicity one; since in the present case some multiplicities are assumed to be larger than one (see the discussion below), a result which is more general than the standard is required and reviewed next, adapted from the comprehensive book [1].

Some notation is needed in order to formulate the problem and its solution. Consider the closed unit disk $\mathcal{D} = \{z : |z| \leq 1\}$ and let $\mathcal{H}_\infty$ denote the set of complex functions analytic on the interior of $\mathcal{D}$ and essentially bounded on $\mathcal{D}$. Let $f(z) \in \mathcal{H}_\infty$; then $\|f(z)\|_\infty \doteq \text{ess sup}_\theta |f(e^{j\theta})|$, and the closed unit ball in $\mathcal{H}_\infty$ is denoted by $\overline{\mathcal{BH}}_\infty$. Let $\mathcal{RH}_\infty$ denote the subset of real rational transfer function of $\mathcal{H}_\infty$ and $\mathcal{BRH}_\infty$ ($\overline{\mathcal{BRH}}_\infty$) denote the set of functions in $\mathcal{RH}_\infty$ with norm less than (less than or equal to) 1. Finally, let l_1 denote the set of absolutely summable sequences; i.e., if $f = \{f_1, f_2, \ldots\} \in l_1$, then $\|f\|_1 = \sum_{i=0}^{\infty} |f_i| < \infty$.

In the original Nevanlinna–Pick formulation, the data are given by some points $z_1, z_2, \ldots, z_r$ in the interior of $\mathcal{D}$, $z_i \neq z_j$ for $i \neq j$, and some interpolation values $w_1, w_2, \ldots, w_r$. The aim is then to find conditions under which there exists a function $f \in \mathcal{BRH}_\infty$ (or $\overline{\mathcal{BRH}}_\infty$) such that $f(z_i) = w_i$ and possibly to parameterize all such solutions. A related classical problem is the Carathéodory interpolation problem, in which the data are a polynomial of the form

$$\hat{f}(z) = f_0 + f_1 z + \cdots + f_n z^n$$

and the objective is to find necessary and sufficient conditions for the existence of a function $f \in \mathcal{BRH}_\infty$ (or $\overline{\mathcal{BRH}}_\infty$) such that

$$f(z) = f_0 + f_1 z + \cdots + f_n z^n + z^{n+1} f^n(z)$$

for some $f^n(z) \in \mathcal{RH}_\infty$.

Nevanlinna–Pick and Carathéodory problems may be considered in a unified way by introducing the following formulation.

PROBLEM 1. *Find necessary and sufficient conditions under which there exists an* $f \in \mathcal{BRH}_\infty$ *(or* $\overline{\mathcal{BRH}}_\infty$*) such that*

$$\sum_{z_o \in \mathcal{D}} Res_{z=z_o} f(z) C_-(zI - A)^{-1} = C_+. \tag{1}$$

Problem 1 is a special case of the much broader theory considered in [1] but suffices for the purposes of this paper. The next two examples (see also Examples 18.5.1 and 22.2.1 in [1]) show that the claim that the interpolation condition (1) includes the original Nevanlinna–Pick and Carathéodory problems as special cases is indeed justified. These examples are instrumental in solving the time-domain constrained $\mathcal{H}_\infty$ problem.

Example 2.1. Let $\Gamma = \operatorname{diag}\{z_i\} \in \mathbb{C}^{r\times r}$, and take

$$\begin{aligned} A &= \Gamma, \\ C_- &= \mathbb{1}^T = [1\ 1\ \cdots\ 1] \in \mathbb{R}^r, \\ C_+ &= [w_1\ w_2\ \cdots\ w_r]; \end{aligned}$$

then the interpolation constraint 1 is satisfied if and only if

$$f(z_i) = w_i, \quad i = 1, \ldots, r. \tag{2}$$

Example 2.2. Let $I_{n\times n}$ denote the $n \times n$ identity matrix, and $A_f \in \mathbb{R}^{(n+1)\times(n+1)}$,

$$A_f = \begin{bmatrix} 0 & I_{n\times n} \\ 0 & 0 \end{bmatrix}.$$

Take

$$\begin{aligned} A &= A_f, \\ C_- &= e_1^T = [1\ 0\ \cdots\ 0] \in \mathbb{R}^{n+1}, \\ C_+ &= [f_0\ f_1\ \cdots\ f_n]; \end{aligned}$$

then the interpolation constraint (1) is satisfied if and only if $f(z)$ can be written as

$$f(z) = f_0 + f_1 z + f_2 z^2 + \cdots + f_n z^n + \cdots. \tag{3}$$

Now consider the Stein (or discrete-time Lyapunov) equation

$$M = A^T M A + C_-^T C_- - C_+^T C_+. \tag{4}$$

Under the condition that A has all its eigenvalues in $\mathcal{D}$, a Hermitian solution to (4) exists and is unique. The solution M is called the generalized Pick matrix associated with Problem 1 and plays a key role for finding necessary and sufficient conditions for the solvability of the interpolation problem.

THEOREM 2.3. *Let* M *solve* (4). *Then there exist a transfer function* $f(z) \in \mathcal{BRH}_\infty$ *(*$\overline{\mathcal{BRH}}_\infty$*) such that* (1) *is satisfied if and only if* M *is positive definite (positive semidefinite).*

Proof. See Theorem 18.5.1 of [1] and the note on page 404 therein. □

It is also possible to parameterize all solutions to the interpolation problem cited above, but Theorem 2.3 suffices for the purposes of the present paper. Necessary and sufficient conditions for the existence of a solution to the Nevanlinna–Pick and Carathéodory interpolation problems follow easily from the theorem.

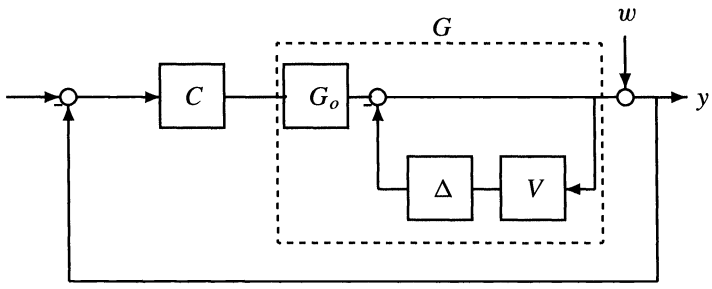

FIG. 3. *The prototype problem.*

COROLLARY 2.4. *Let P be the standard Pick matrix*

$$P = \left[\frac{1 - w_i w_j}{1 - z_i z_j}\right]_{ij}. \tag{5}$$

Then there is a transfer function $f(z) \in \mathcal{BRH}_\infty$ such that (2) is satisfied if and only if P is positive definite.

Proof. Some simple algebra shows that P given by (5) satisfies (4) for A, C_-, and C_+ considered in Example 2.1. □

COROLLARY 2.5. *Let $\mathcal{F}_n$ be the matrix*

$$\mathcal{F}_n = \begin{bmatrix} f_0 & f_1 & \cdots & f_n \\ 0 & f_0 & \cdots & f_{n-1} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & f_0 \end{bmatrix}. \tag{6}$$

Then there is a transfer function $f(z) \in \overline{\mathcal{BRH}}_\infty$ such that (3) is satisfied if and only if $\mathcal{F}_n$ is a contraction (i.e., $\overline{\sigma}(\mathcal{F}_n) \leq 1$).

Proof. Again, some simple algebra shows that $M_c = I - \mathcal{F}_n^T \mathcal{F}_n$ solves (4) for A, C_-, and C_+ considered in Example 2.2. Since this matrix is positive semidefinite if and only if $\overline{\sigma}(\mathcal{F}_n) \leq 1$, the corollary follows from Theorem 2.3. □

3. The control problem and its formulation. The purpose of this section is twofold. First the control problem which will be studied in the rest of the paper is introduced. Then the problem is formulated to resemble an interpolation problem.

3.1. Prototype problem. As anticipated in the introduction, the example to be considered next is not introduced due to its intrinsic significance but rather because it allows a transparent derivation while keeping technical details and notation as simple as possible. More general cases, like problems involving multivariable one-block $\mathcal{H}_\infty$ objectives or time-domain constraints over several transfer functions, can be derived by using a generalized version of the interpolation theory reviewed in the previous section and a more involved notation.

Consider the disturbance rejection problem illustrated in Fig. 3. Here $G = G_o/(1 + \Delta V^{-1})$ is a linear time-invariant discrete-time plant with nominal finite-dimensional transfer function G_o. Δ is assumed to be stable and such that $\|\Delta\| < 1$ but otherwise unknown. V is a weighting function assumed to be finite dimensional and outer (i.e., both V and $V^{-1} \in \mathcal{RH}_\infty$). Let $t(z) = 1/(1 + G_o C)$ denote the *nominal* transfer function from w to y. If C stabilizes the nominal closed loop, then $t(z)$ can be expanded as $t(z) = \sum_{k=0}^{\infty} t_k z^k$.

The prototype control problem considered in this paper is to design a controller $C(z)$ such that

O1) C internally stabilizes the closed loop for all Δ's that satisfy the conditions stated above.

O2) The nominal closed-loop transfer function from w to y is such that, for every k,

$$lb_k \leq t_k \leq ub_k, \tag{7}$$

where the two sequences $lb = \{lb_0, lb_1, \ldots\}$ and $ub = \{ub_0, ub_1, \ldots\}$ are assumed to be in l_1. The control problem is hence a combination of robust stabilization O1 and nominal performance O2. Necessary and sufficient conditions for the existence of a controller satisfying O1 are well documented in the literature.

LEMMA 3.1. *A controller C satisfies* O1 *if and only if*

$$\|V^{-1}/(1 + G_oC)\|_\infty \leq 1. \tag{8}$$

Proof. See, for instance, [5]. □

It follows from the lemma that O1 gives rise to an $\mathcal{H}_\infty$ control problem, while O2 imposes time-domain constraints.

3.2. Problem formulation. Given G_o and V_o as above, the robust stabilization problem is said to be solvable (strictly solvable) if there exists a controller C such that (8) holds (respectively, holds with strict inequality). Necessary and sufficient conditions for solvability using interpolation theory have been known for some time.

LEMMA 3.2. *Let G_o have r_z zeros $z_1, \ldots, z_{r_z}$ and r_p poles $z_{r_z+1}, \ldots, z_{r_z+r_p}$ in the interior of $\mathcal{D}$, $z_i \neq z_j$ for $i \neq j$, and V be as above. Then the robust stabilization problem is solvable (strictly solvable) if and only if the Pick matrix* (5) *is positive semidefinite (positive definite), with $w_i = V^{-1}(z_i)$, $i = 1, \ldots, r_z$, $w_i = 0$, $i = r_z + 1, \ldots, r = r_z + r_p$.*

For further discussion on the relationship between interpolation theory and robust stabilization, see [12].

The next step is to reformulate the control problem into a form that resembles the generalized Nevanlinna–Pick problem reviewed in §2.

THEOREM 3.3. *Let G_o have r_z zeros $z_1, \ldots, z_{r_z}$ and r_p poles $z_{r_z+1}, \ldots, z_{r_z+r_p}$ in the interior of $\mathcal{D}$, $z_i \neq z_j$ for $i \neq j$. Then the control problem considered in the previous section has a solution if and only if there exist $f \in \overline{\mathcal{BRH}}_\infty$ such that*

$$f(z_i) = V^{-1}(z_i) \doteq w_i, \quad i = 1, \ldots, r_z, \tag{9}$$

$$f(z_i) = 0, \quad i = r_z + 1, \ldots, r_z + r_p, \tag{10}$$

$$lb_k \leq t_k \leq ub_k \quad \forall k, \tag{11}$$

and $t(z) = V(z)f(z)$.

Proof. Let $f(z) \doteq V^{-1}(z)\frac{1}{1+G_o(z)C(z)}$ denote the weighted sensitivity transfer function. Then, from Lemma 3.2, $f \in \mathcal{H}_\infty$, $\|f\| \leq 1$, and conditions (9), (10) are equivalent to the robust stability of the closed loop. Finally, condition (11) is a restatement of (7). □

The problem considered in Theorem 3.3 is similar to an interpolation problem, except that the coefficients f_k are not given some specific values (as in a Carathéodory problem) or left unspecified (as in a Nevanlinna–Pick problem) but are constrained by inequalities. For this reason, it is referred to as a *constrained interpolation problem* (CIP). In the next section, it is shown that Theorem 2.3 can be used to obtain necessary and sufficient conditions for the solvability of the CIP if constraints are imposed only over a finite horizon. For future reference let $r = r_z + r_u$.

4. The finite-horizon case. Suppose that one wants to impose the constraint $lb_k \leq t_k \leq ub_k$ only for $k \leq n < \infty$ or, equivalently, that there exists an n in (11) such that $-lb_k$ and ub_k

are arbitrarily large for $k > n$. By the causality of $V(z) = \sum_{i=0}^{\infty} v_i z^i$, (11) may be written as the matrix inequality

$$\begin{bmatrix} lb_0 \\ lb_1 \\ \cdots \\ lb_n \end{bmatrix} \le \begin{bmatrix} v_0 & 0 & \cdots & 0 \\ v_1 & v_0 & \ddots & 0 \\ \vdots & \ddots & \ddots & \vdots \\ v_n & v_{n-1} & \cdots & v_0 \end{bmatrix} \begin{bmatrix} f_0 \\ f_1 \\ \vdots \\ f_n \end{bmatrix} \le \begin{bmatrix} ub_0 \\ ub_1 \\ \cdots \\ ub_n \end{bmatrix}$$

or, in a compact notation,

$$\mathbf{lb_n} \le \mathbf{V_n f_n} \le \mathbf{ub_n}. \tag{12}$$

The value n is referred to as the horizon length, and the corresponding constrained interpolation problem is called CIP_n. Note that in a CIP_n, constraints are imposed over $n+1$ samples. With a small abuse of notation, the original problem CIP is said to have constraints over an infinite horizon, while the robust stabilization problem is referred to as the unconstrained problem.

From (12), CIP_n has only a finite number of constraints; as shown in the following theorem, this implies that it can be reduced to a finite-dimensional minimization problem.

THEOREM 4.1. *Let G_o, V be as above, and assume that the unconstrained problem is strictly solvable. Then the CIP_n has a solution if and only if there exists a vector $\mathbf{f_n} = [f_0\ f_1 \cdots f_n]^T \in \mathbb{R}^{n+1}$ satisfying (12) such that $\overline{\sigma}(\hat{M}(\mathbf{f_n})) \le 1$, where $\overline{\sigma}(\hat{M}(\mathbf{f_n})$ denotes the largest singular value of the matrix*

$$\hat{M}(\mathbf{f_n}) = \begin{bmatrix} \mathcal{F}_n \\ P^{-1/2}(S^o - S^l \mathcal{F}_n) \end{bmatrix}, \tag{13}$$

with

$$S^o = \begin{bmatrix} 1 & z_1 & z_1^2 & \cdots & z_1^n \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ 1 & z_{r_z} & z_{r_z}^2 & \cdots & z_{r_z}^n \\ 1 & z_{r_z+1} & z_{r_z+1}^2 & \cdots & z_{r_z+1}^n \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ 1 & z_r & z_r^2 & \cdots & z_r^n \end{bmatrix},$$

$$S^l = \begin{bmatrix} w_1 & w_1 z_1 & w_1 z_1^2 & \cdots & w_1 z_1^n \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ w_{r_z} & w_{r_z} z_{r_z} & w_{r_z} z_{r_z}^2 & \cdots & w_{r_z} z_{r_z}^n \\ & & 0 & & \end{bmatrix},$$

$$\mathcal{F}_n = \begin{bmatrix} f_0 & f_1 & \cdots & f_n \\ 0 & f_0 & \cdots & f_{n-1} \\ \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & f_0 \end{bmatrix},$$

and P is the Pick matrix (5).

Proof. Assuming that the f_i's are fixed, CIP_n reduces to the generalized Nevanlinna–Pick interpolation problem of finding $f \in \mathcal{BRH}_\infty$ such that

$$\begin{aligned} f(z_i) &= w_i, \quad i = 1, \ldots, r_z, \\ f(z_i) &= 0, \quad i = r_z + 1, \ldots, r, \\ f(z) &= f_0 + f_1 z + f_2 z^2 + \cdots + f_n z^n + \cdots. \end{aligned}$$

Let $A = \left[\begin{smallmatrix} \Gamma & 0 \\ 0 & A_f \end{smallmatrix}\right]$, where Γ and A_f are as defined in Examples 2.1 and 2.2, respectively. Let

$$\begin{aligned} C_- &= [\mathbb{1}^T \; e_1^T], \\ C_+ &= [w_1 \; w_2 \; \cdots \; w_r \; f_0 \; f_1 \; \cdots \; f_n]. \end{aligned}$$

From Examples 2.1 and 2.2, the interpolation problem has a solution if and only the corresponding generalized Pick matrix $M(\mathbf{f_n})$ in Theorem 2.3 is positive definite. It is claimed that

$$M(\mathbf{f_n}) = \begin{bmatrix} P & S^o - S^l\mathcal{F}_n \\ (S^o - S^l\mathcal{F}_n)^T & I - \mathcal{F}_n^T\mathcal{F}_n \end{bmatrix}. \tag{14}$$

To see this, begin by partitioning M as

$$M = \begin{bmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{bmatrix},$$

compatible with the structure of A. Then if M satisfies the Stein equation (4),

$$M_{11} = \Gamma M_{11}\Gamma + \mathbb{1}\mathbb{1}^T - \mathbf{w}\mathbf{w}^T, \tag{15}$$

$$M_{22} = A_f^T M_{22} A_f + e_1 e_1^T - \mathbf{f_n}\mathbf{f_n}^T, \tag{16}$$

$$M_{12} = \Gamma M_{12} A_f + \mathbb{1} e_1^T - \mathbf{w}\mathbf{f_n}^T, \tag{17}$$

where $\mathbf{w_n} = [w_1 \; \cdots \; w_{r_z} \; 0 \; \cdots 0]^T$. From (15), (16), and Examples 2.1 and 2.2,

$$\begin{aligned} M_{11} &= P, \\ M_{22} &= I - \mathcal{F}_n^T\mathcal{F}_n, \end{aligned}$$

Multiplying the left-hand side of (17) by e_1,

$$M_{12}e_1 = \mathbb{1} - \mathbf{w}f_0,$$

and by e_2,

$$M_{12}e_2 = \Gamma M_{12}e_1 - \mathbf{w}f_1 = \Gamma\mathbb{1} - \Gamma\mathbf{w}f_0 - \mathbf{w}f_1.$$

Continuing this process, one gets

$$M_{12} = S^o - S^l\mathcal{F}_n$$

as required. Note that $M(\cdot)$ depends quadratically on $\mathbf{f_n} = [f_0 \; f_1 \cdots f_n]^T$.

By Lemma 3.2 and the assumption on strict solvability of the unconstrained problem, P is positive definite and hence invertible. M is then positive semidefinite if and only if

$$I - \mathcal{F}_n^T\mathcal{F}_n - (S^o - S^l\mathcal{F}_n)^T P^{-1}(S^o - S^l\mathcal{F}_n) \geq 0,$$

which is equivalent to

$$\rho\left(\mathcal{F}_n^T\mathcal{F}_n - (S^o - S^l\mathcal{F}_n)^T P^{-1}(S^o - S^l\mathcal{F}_n)\right) \geq 1,$$

where ρ denotes the spectral radius, or to

$$\overline{\sigma}\left(\begin{bmatrix} \mathcal{F}_n \\ P^{-1/2}(S^o - S^l\mathcal{F}_n) \end{bmatrix}\right) \leq 1. \tag{18}$$

It follows from these calculations that CIP_n has a solution if and only if there exists a vector $\mathbf{f_n}$ satisfying (12) such that (18) holds. □

The block diagonal terms of M in (14) show that if the CIP is solvable, then the associated Nevanlinna–Pick and Carathéodory problems also have a solution; the condition is *not* sufficient, because of the off-diagonal terms in M.

Theorem 4.1 reduces the solution of an $\mathcal{H}_\infty$ optimization problem with constraints over a finite horizon to a finite-dimensional optimization problem, namely, the minimization of the largest singular value of $N(\mathbf{f_n})$ subject to constraints on $\mathbf{f_n}$. Given the linear dependence of $N(\mathbf{f_n})$ on $\mathbf{f_n}$, and the linearity of the constraints, the optimization problem is convex but in general nondifferentiable. Since, in addition, a large number of variables and constraints are usually involved, solving this problem can be difficult; in particular, general procedures for nondifferentiable programming may not produce a solution at a reasonable cost. An algorithm for solving this type of problems based on the ellipsoid algorithm was outlined in [14, 15, 17].

5. The infinite-horizon case. A first approach to solving the infinite horizon problem would be to take a horizon length n large and compute a vector $\mathbf{f_n}$ that satisfies the constraints (12) and minimizes $\overline{\sigma}(\hat{M}(\mathbf{f_n}))$. Letting $\mu_n \doteq \overline{\sigma}(\hat{M}(\mathbf{f_n}))$, if $\mu_n > 1$, then no solution to CIP exists; but if $\mu_n \leq 1$, then one could construct a solution $f^n(z)$ to CIP_n and then check whether (7) is also satisfied for $k > n$. Note, however, that for $\mu_n < 1$ the solution is highly nonunique and there is no systematic way of selecting $f^n(z)$ so that the violation of the constraints is minimized or driven to zero. To circumvent this difficulty, one could select a particular solution (e.g., the minimum entropy one) to the CIP_n and keep increasing the horizon length in the hope that constraints for all time instants will eventually be satisfied.

Unfortunately, research on the finite-horizon problem using a Nehari approach [15, 17] shows that the infinite-horizon case may not always be addressed directly by taking the limit for the horizon length going to infinity. This is because little can be said about the time-domain behavior after the horizon (i.e., for $k > n$), which turns out to be unacceptable if the optimal solution (in terms of the $\mathcal{H}_\infty$ norm) is pursued. This difficulty was circumvented by solving an approximate problem in which the closed-loop poles are constrained to lie in a disk of radius $\rho < 1$; the fact that all poles have an absolute value strictly less than 1 induces a decay rate on the time responses and hence implies a good (i.e., small) behavior for $k > n$ if the horizon length n is taken to be larger than some precomputable bound. One can then argue that under some suitable continuity condition, letting $\rho \to 1$ would produce in the limit a solution to the infinite-horizon problem. However, since continuity properties are hard to ascertain (note that both the $\mathcal{H}_\infty$ problem *and* the constraints should be continuous in some sense), a more direct approach is pursued in this section.

LEMMA 5.1. *The set of transfer functions $f(z)$ such that $t(z) = V(z)f(z)$ satisfies the time-domain constraints* (7) *is compact as a subset of $\mathcal{H}_\infty$.*

Proof. The proof is based on the fact that both ub and lb are assumed to be in l_1. Let

$$\mathcal{FS} = \left\{ t(z) = \sum_{k=0}^{\infty} t_k z^k \text{ s.t. } lb_k \leq t_k \leq ub_k \ \forall k \right\} \subset \mathcal{H}_\infty.$$

The first step is to show that $\mathcal{FS}$ is compact as a subset of l_1; since the l_1 norm bounds the $\mathcal{H}_\infty$ norm, the lemma will follow.

The space l_1 is complete and $\mathcal{FS}$ is closed, and hence it suffices to show that for every $\epsilon > 0$ it is possible to cover $\mathcal{FS}$ with a finite number of balls of l_1 with radius ϵ [4, p. 59]. Thus, let $\epsilon > 0$ be given. By the assumption $\sum_{k=0}^{\infty} |lb_k| < \infty$, $\sum_{k=0}^{\infty} |ub_k| < \infty$, there exists an N such that

$$\sum_{k=N}^{\infty} |lb_k| < \epsilon/4, \tag{19}$$

$$\sum_{k=N}^{\infty} |ub_k| < \epsilon/4, \tag{20}$$

implying $\sum_{k=N}^{\infty} |t_k| < \epsilon/2 \ \forall\, t \in \mathcal{FS}$. Now consider the set

$$\mathcal{FS}_N \doteq \{[t_0\, t_1\, \cdots\, t_{N-1}] \in \mathbb{R}^N \text{ s.t. } lb_k \le t_k \le ub_k,\ 0 \le k < n\}.$$

$\mathcal{FS}_N$ is a closed and bounded set in $\mathbb{R}^N$, and hence there exist a finite number of balls $\mathcal{B}(\hat{t}^i, \epsilon/2)$, with center at $\hat{t}^i \doteq [t_0^i\, t_1^i\, \cdots\, t_{N-1}^i]$ and radius $\epsilon/2$ that cover $\mathcal{FS}_N$. Define

$$t^i \doteq [t_0^i\, t_1^i\, \cdots\, t_{N-1}^i\, 0\, 0\, \cdots],$$

and consider the balls $\mathcal{B}(t^i, \epsilon) \subset l_1$. Consider now any $t \in \mathcal{FS}$. By construction, there exists an i_o such that $\sum_{k=0}^{N-1} |t_k - t_k^{i_o}| < \epsilon/2$, and then

$$\begin{aligned} \|t - t^{i_o}\|_1 &\le \sum_{k=0}^{N-1} |t_k - t_k^{i_o}| + \sum_{k=N}^{\infty} |t_k| \\ &< \epsilon/2 + \epsilon/2 = \epsilon. \end{aligned}$$

Since the finite number of balls $\mathcal{B}(f^i, \epsilon)$ covers $\mathcal{FS}$, the set is compact. Since $V^{-1} \in \mathcal{RH}_\infty$, the proof follows. □

Let $f^{(n)}(z)$ denote the minimum entropy solution to CIP$_n$, and let $\hat{f}^{(n)}(z)$ denote

$$\hat{f}^{(n)} = f_0^n + f_1^n z^1 + f_2^n z^2 + \cdots + f_n^n z^n,$$

i.e., its projection over the space generated by $\{1, z, \ldots, z^n\}$. From Lemma 5.1, an accumulation point for the sequence of transfer functions $\{\hat{f}^{(n)}\}$ constitutes a natural candidate for solving the infinite-horizon problem. Unfortunately, the resulting accumulation point does not necessarily satisfy the interpolation constraints (9), (10), which are satisfied by $f^{(n)}$ and *not* by $\hat{f}^{(n)}$. One could enforce constraints (9), (10) on $\hat{f}^{(n)}$ by modifying the minimization problem to include the constraints explicitly, but it is not clear how this would affect the convergence to the optimal solution. Instead, if the CIP$_n$ are modified so that (9), (10) are only approximately satisfied by $\hat{f}^{(n)}$, it is possible to establish that a solution to the infinite-horizon problem can be computed by letting the horizon length n go to infinity. More explicitly, consider the following modification of the CIP$_n$ problem.

PROBLEM 2 (MCIP$_n$). *Find* $f \in \mathcal{BRH}_\infty$ *such that*

$$\begin{aligned} f(z_i) &= w_i, \qquad i = 1, \ldots, r_z, \\ f(z_i) &= 0, \qquad i = r_z + 1, \ldots, r_z + r_s, \\ lb_k &\le t_k \le ub_k, \quad 0 \le k \le n, \end{aligned}$$

$$\left| \sum_{k=0}^{n} f_k z_i^k - w_i \right| \le \epsilon^n, \qquad i = 1, \ldots, r_z, \tag{21}$$

$$\left| \sum_{k=0}^{n} f_k z_i^k \right| \le \epsilon^n, \qquad i = r_z + 1, \ldots, r, \tag{22}$$

where $\epsilon < 1$.

A careful choice of ϵ now shows that the solvability of the MCIP$_n$ eventually implies the solvability of the infinite-horizon problem.

THEOREM 5.2. *Let* $1 > \epsilon > \max_{i=1,\ldots,r} |z_i|$. *Then the infinite-horizon problem is solvable if and only if there exists an* N *such that the MCIP*$_n$ *is solvable for all* $n > N$.

Proof. Suppose that there exists N such that the MCIP$_n$ is solvable for all $n > N$, and let $f^{(n)}$ denote a solution for the MCIP$_n$. As before, $f^{(n)}$ can be the minimum entropy solution for definiteness. Let $\hat{f}^{(n)}$ be defined as in the proof of Lemma 5.1:

$$\hat{f}_k^{(n)} = \left\{ \begin{array}{ll} f_k^{(n)} & \text{if } k \leq n \\ 0 & \text{if } k > n \end{array} \right\}$$

(i.e., $\hat{f}^{(n)}$ is found by truncating $f^{(n)}$), and consider the sequence of functions $\{\hat{f}^{(n)}\}_n$. It is clear that $\hat{f}^{(n)}$ satisfies the constraint (11) for all n, and hence Lemma 5.1 implies that there exists a convergent subsequence $\{\hat{f}^{n_k}\}$. Let $f \doteq \lim_{k\to\infty} \hat{f}^{n_k}$. Then it is claimed that f solves the infinite-horizon problem. To see this, note that the interpolation constraints (9) and (10), are satisfied in the limit due to the additional constraints (21) and (22) in the MCIP$_n$. The constraint (11) is also satisfied because all $\hat{f}^{(n)}$ do satisfy it, and the conditions on lb and ub imply that $f \in \mathcal{H}_\infty$. Finally $\|f\| \leq 1$ because $\overline{\sigma}(\mathcal{F}_n) \to \|f\|$ for $n \to \infty$.

To prove the converse, assume that f solves the CIP. Then f is a feasible point for the CIP$_n$ for all n, and hence it suffices to show that there exists an N such that f also satisfies (21) and (22) for each $n \geq N$. Since f satisfies (11), $\sum_{j=0}^{\infty} f_j z_i^j = 0$ for $i = r_z + 1, \ldots, r$, and

$$\left| \sum_{j=n+1}^{\infty} f_j z_i^j \right| \leq |z_i|^{n+1} \sum_{j=n}^{\infty} |f_j|, \qquad i = r_z + 1, \ldots, r.$$

Since f satisfies the time-domain constraints, $\sum_{j=0}^{\infty} |f_j| < \infty$, implying that there exists an N such that $\sum_{j=N+1}^{\infty} |f_j| < 1$. Then, if $n > N$,

$$\left| \sum_{n+1}^{\infty} f_k z_i^k \right| \leq |z_i|^n \leq \epsilon^n$$

or

$$\left| \sum_{k=0}^{n} f_k z_i^k \right| \leq \epsilon^n$$

for all $i = r_z, \ldots, r$; hence f satisfies the additional constraint (22). A similar argument proves that f satisfies (21), and hence the MCIP$_n$ is feasible for all $n \geq N$. This concludes the proof. □

The condition in Theorem 5.2 is hard to check, since it involves the solution of MCIP$_n$ for arbitrarily large values of n, and solving the associated optimization problem becomes progressively more expensive as n increases. In practice, this inconvenience can be circumvented as follows. First, solve the optimization problem associated with MCIP$_n$ for n large; the horizon length is related to the location of the singularities z_i, $i = 1, \ldots, r$. Then check if either $\hat{f}^{(n)}$, perturbed to satisfy the interpolation constraints, also satisfies the norm bound or $f^{(n)}$ has a reasonable time behavior after the horizon. The first choice is justified by Theorem 5.2, since it implies that the finite impulse response solution $\hat{f}^{(n)}$ to the corresponding MCIP$_n$ eventually provides an approximate solution to the infinite-horizon problem. On the other hand, numerical experience suggests that picking $f^{(n)}$ often yields a solution to the infinite-horizon problem, specially if μ^n is significantly smaller than one.

6. Conclusions. In this paper the time-domain constrained $\mathcal{H}_\infty$ problem has been studied, using interpolation theory. If constraints are imposed over a finite horizon, then a generalized Nevanlinna–Pick theorem from [1] can be used to reduce the problem into a finite-dimensional, convex minimization. Theorem 4.1 shows that the solution to this problem is less than or equal to 1 if and only if there exists a solution to the original constrained $\mathcal{H}_\infty$ problem. If constraints are imposed over an infinite horizon, then Theorem 5.2 shows that a solution exists if and only if the solution to a sequence of finite-dimensional convex problems is bounded by one. It is worth stressing that the additional insight provided by the interpolation theory approach allowed the solution to the infinite-horizon case, since previous works have concentrated on the finite-horizon problem. After the submission of this manuscript, substantial progress has been achieved in the solution to the infinite-horizon problem, partially fueled by the convergence theorem presented in §5. For instance, in [16] the normal convergence of the finite-horizon solutions is established under no assumptions on the bounds ub and lb and without introducing additional constraints. In [18] the assumptions are stronger, but again convergence is established without resorting to the approximate interpolation constraints.

This work can be extended in several directions. First, although attention has been focused in finding necessary and sufficient conditions for the solvability of the constrained problem, state-space formulas for the computation of an actual solution (i.e., a controller) may be given by using the corresponding results in interpolation theory. Then, the one-block multivariable $\mathcal{H}_\infty$ problem can be solved, and the feasibility of solving the general four-block $\mathcal{H}_\infty$ could be investigated. Also, the problem of imposing time-domain constraints on a transfer function while bounding the $\mathcal{H}_\infty$-norm of another transfer function can be addressed. Although the finite-horizon problem is apparently easy to extend to this case as well, it is not clear at this point if the infinite-horizon result will extend as nicely. This is also true for the multivariable case and is currently under investigation.

Acknowledgments. The author wishes to thank Prof. Athanasios Sideris for his suggestion of using approximate interpolation constraints for the infinite-horizon problem, and the anonymous reviewers for their remarks and suggestions.

PARTIALLY OBSERVED DIFFERENTIAL GAMES, INFINITE-DIMENSIONAL HAMILTON–JACOBI–ISAACS EQUATIONS, AND NONLINEAR H_∞ CONTROL*

M. R. JAMES† AND J. S. BARAS‡

Abstract. This paper presents new results for partially observed nonlinear differential games. Using the concept of *information state*, we solve this problem in terms of an infinite-dimensional partial differential equation, which turns out to be the Hamilton–Jacobi–Isaacs (HJI) equation for partially observed differential games. We give definitions of smooth and viscosity solutions and prove that the value function is a viscosity solution of the HJI equation. We prove a verification theorem, which implies that the optimal controls are separated in that they depend on the observations through the information state. This constitutes a separation principle for partially observed differential games. We also present some new results concerning the certainty equivalence principle under certain standard assumptions. Our results are applied to a nonlinear output feedback H_∞ robust control problem.

Key words. partially observed differential games, infinite-dimensional partial differential equations, viscosity solutions, nonlinear H_∞ robust control

1. Introduction.

The nonlinear H_∞ robust control problem has generated considerable activity in recent years, and important contributions have been made by a number of authors; see [1]–[3], [5], [8], [9], [12], [16], [20]–[24], [26], [29]–[35]. The state feedback problem is reasonably well understood, although the issue of controller synthesis for continuous-time systems remains outstanding. This is because the value functions solving the various partial differential equations (PDEs) that have been proposed need not be smooth—a standard difficulty even for simple deterministic optimal control problems. The output feedback problem is much more difficult, and various approaches have been suggested in the literature. Perhaps the most general of these approaches was initiated in [24], [25], where the concept of *information state* was used to solve a partially observed dynamic game, and applied in [23] to solve the output feedback H_∞ problem (see also the discussion in [6]). The results in [24], [23] are presented in the discrete-time context for technical simplicity, although the system-theoretic ideas are valid in continuous-time also; ideed, the key equations were presented in [25], [32] and later in [6]. The purpose of this paper is to commence the task of developing a mathematical theory for continuous-time partially observed differential games and output feedback H_∞ robust control.

The information state $p_t = p_t(x)$ is the solution of a first-order PDE and takes values in a suitable infinite-dimensional Banach space $p_t \in \mathcal{X}$ (here, $x \in \mathbf{R}^n$ is the state of the system being controlled, so $\mathcal{X}$ is a space of real-valued functions of x). The partially observed differential game that we consider can be transformed into an equivalent game with full state information, and this leads via dynamic programming to a value or optimal cost function $W(p, t)$ that "solves" a PDE on $\mathcal{X} \times [0, T]$. This PDE is a nonlinear first-order equation and is the correct Hamilton–Jacobi–Isaacs (HJI) equation for partially observed differential games. This HJI equation appears to be new, and we are not aware of any results in the literature concerning this type of infinite-dimensional PDE. It is not clear what if anything the results in [7] have to say about this HJI equation. In the case of partially observed stochastic control,

the idea of information state is familiar, a theory has been developed [14], [17], [27], and the dynamic programming equation is an infinite-dimensional nonlinear second-order PDE.

The particular class of problems that we consider in this paper is presented in §2. This class should be regarded as a prototype class, and the ideas and principles we develop are expected to apply in much more general contexts. The relevant information state is defined in §3, and some if its properties are analyzed for use in later sections. In particular, the key representation theorem is given. In §4, the value function and HJI equation are defined and studied. Definitions of smooth and viscosity solutions are given. We prove that the value function is a viscosity solution of the HJI equation. We do not know a proof of a uniqueness or comparison theorem for equations of this type, and consequently our definition of viscosity solution should be regarded as a provisional one. While in general it is not expected that smooth solutions will exist, a verification theorem is proven in §5 assuming a smooth solution exists, yielding that the optimal control is a separated control in the sense that it depends on the observations via the information state. The certainty equivalence principle proposed in [5] and [9] is considered in §6. We explain how this principle fits into the general information state framework and show that, under a generalization of the standard assumptions, the certainty equivalence controller can be optimal at certain values of the information state. The standard assumptions are very stringent and are unlikely to hold in general, and we explain what can happen in such an event. In §7, we apply our results to a relatively simple nonlinear H_∞ control problem, viz., finite horizon disturbance attenuation. The solution is expressed in terms of two PDEs, a finite-dimensional one for the information state and an infinite-dimensional equation for the value function. Infinite horizon H_∞ problems are closely related to the theory of dissipative systems [18], [36], and we present the relevant partial differential inequality (PDI) for the output feedback problem. Finally, we make some comments concerning more general cases.

2. Problem formulation. We consider the class of nonlinear partially observed deterministic systems described by the state space equations

$$\begin{cases} \dot{x}(t) = f(x(t), u(t)) + g(x(t), w(t)), \\ y(t) = h(x(t)) + w(t). \end{cases} \tag{2.1}$$

Here, $x(t) \in \mathbf{R}^n$ denotes the state of the system and is not directly measurable; instead, an output quantity $y(t) \in \mathbf{R}^p$ is observed. The control input is $u(t) \in U \subset \mathbf{R}^m$, and $w(t) \in \mathbf{R}^p$ is regarded as an opposing disturbance input. The functions $f : \mathbf{R}^n \times \mathbf{R}^m \to \mathbf{R}^n$, $g : \mathbf{R}^n \times \mathbf{R}^p \to \mathbf{R}^{n\times m}$, and $h : \mathbf{R}^n \to \mathbf{R}^n$ are assumed bounded and smooth with bounded derivatives of orders up to three, say. The set U is compact.

Most of this paper is concerned with a differential game problem on a finite-time horizon $[0, T]$, and we use the following type of admissible strategies. The admissible disturbances are the square integrable functions

$$w \in \mathcal{W}(t) = L_2([t, T], \mathbf{R}^p),$$

while the admissible controls are the nonanticipating (causal) maps

$$\mathbf{u} : \mathcal{Y}(t) \to \mathcal{U}(t),$$

where

$$\mathcal{U}(t) = L_2([t, T], U), \quad \mathcal{Y}(t) = L_2([t, T], \mathbf{R}^p).$$

The nonanticipating property means that if $y_1, y_2 \in \mathcal{Y}(t)$ and $y_1(r) = y_2(r)$ a.e. $r \in [t, s]$, then $\mathbf{u}[y_1](r) = \mathbf{u}[y_2](r)$ a.e. $r \in [t, s]$ (cf. the Elliott–Kalton notion of strategy [10], [11]).

We will denote by $\mathbf{U}(t)$ the class of such nonanticipating strategies for which (2.1) and (3.2) (for $u = \mathbf{u}[y]$) have unique solutions.

We next introduce several function spaces that will be used in the sequel. The Banach space of continuous functions with at most linear growth is denoted

$$\mathcal{X} = \{p \in C(\mathbf{R}^n) \ : \| \ p \ \| < \infty\},$$

where the norm is defined by

$$\| \ p \ \| = \sup_{x \in \mathbf{R}^n} \frac{|p(x)|}{1 + |x|}.$$

Denote by

$$\mathcal{X}^1 = \{p \in C^1(\mathbf{R}^n) \ : \| \ p \ \|_1 < \infty\}$$

the Banach space of continuously differentiable functions with bounded derivatives equipped with norm

$$\| \ p \ \|_1 = \sup_{x \in \mathbf{R}^n} \frac{|p(x)|}{1 + |x|} + \sup_{x \in \mathbf{R}^n} |\nabla_x p(x)|,$$

where $\nabla_x p$ is the gradient of p. Also, we need to define the function space

$$\mathcal{D} = \{p \in C(\mathbf{R}^n) \ : \ p(x) \leq -c_1|x| + c_2 \ \forall x \in \mathbf{R}^n, \text{ for some } c_1 > 0, c_2 \in \mathbf{R}\}.$$

Note that the subsets $\mathcal{D} \cap \mathcal{X} \subset \mathcal{X}$ and $\mathcal{D} \cap \mathcal{X}^1 \subset \mathcal{X}^1$ are open in their respective topologies. As sets, $\mathcal{X}^1 \subset \mathcal{X}$, but $\mathcal{X}^1$ is not a subspace of $\mathcal{X}$ as Banach spaces.

The minimax differential game is defined as follows. The payoff is

$$J(\mathbf{u}, w, x_0) = \alpha(x_0) + \int_0^T [L(x(t), \mathbf{u}[y](t)) - \gamma^2 \ell(w(t))] \, dt + \Phi(x(T)),$$

where the initial state $x(0) = x_0$ is in general unknown. The functions $L : \mathbf{R}^n \times \mathbf{R}^m \to \mathbf{R}$, $\ell : \mathbf{R}^p \to \mathbf{R}$, and $\Phi : \mathbf{R}^n \to \mathbf{R}$ are assumed bounded and smooth with bounded derivatives of orders up to three, and $\alpha \in \mathcal{D} \cap \mathcal{X}$. The assumptions imply that J is well defined and bounded uniformly in $w \in \mathcal{W}(0)$ and $\mathbf{u} \in \mathbf{U}(0)$. We will also assume that $L \geq 0$, $\ell \geq 0$, $\Phi \geq 0$. The controller's objective is to minimize J, while the disturbances attempt to maximize J. For $\mathbf{u} \in \mathbf{U}(0)$ define the functional

$$J(\mathbf{u}) = \sup_{w \in \mathcal{W}(0), \ x_0 \in \mathbf{R}^n} J(\mathbf{u}, w, x_0).$$

The problem addressed in this paper is that of minimizing $J(\mathbf{u})$ over $\mathbf{u} \in \mathbf{U}(0)$. This is a partially observed minimax differential game. Note that x_0 is regarded as an unknown opponent also.

3. Information state. The key to solving the partially observed game is to replace it by an equivalent one with full state information. The difficulty is that the new state is infinite dimensional in general.

To this end, for fixed output path $y \in \mathcal{Y}(0)$ and control $u \in \mathcal{U}(0)$, define the *information state* by

$$p_t(x) = \alpha(x_0) + \int_0^t [L(x(s), u(s)) - \gamma^2 \ell \, (y(s) - h(x(s)))] \, ds, \tag{3.1}$$

where $x(\cdot)$ is the solution of

$$\dot{x}(s) = f(x(s), u(s)) + g(x(s), y(s) - h(x(s))), \qquad 0 < s < t, \tag{3.2}$$

with terminal condition $x(t) = x$. This quantity describes the worst-case performance up to time t using the control u, which is consistent with the observed output and the constraint $x(t) = x$. It summarizes the observed information in a way that is suitable for fulfilling the control objective. The information state evolves according to the dynamics

$$\begin{cases} \dot{p}_t = F(p_t, u(t), y(t)), \\ p_0 = \alpha, \end{cases} \tag{3.3}$$

where F is the differential operator

$$F(p, u, y) = -\nabla_x p \cdot (f(\cdot, u) + g(\cdot, y - h)) + L(\cdot, u) - \gamma^2 \ell(y - h), \tag{3.4}$$

defined on a domain in $\mathcal{X} \times \mathbf{R}^m \times \mathbf{R}^p$ mapping into $\mathcal{X}$. (Note that F is not continuous on $\mathcal{X} \times \mathbf{R}^m \times \mathbf{R}^p$ but is continuous from $\mathcal{X}^1 \times \mathbf{R}^m \times \mathbf{R}^p$ to $\mathcal{X}$.)

The smoothness of $p_t(x)$ and consequently the sense in which (3.3) is to be understood depends on the smoothness of the initial data α (the other data are assumed smooth) and on the regularity of $u(\cdot)$ and $y(\cdot)$.

DEFINITION 3.1. *We say that a function $p_t(x)$ is a* smooth solution *of the dynamics* (3.3) *if $\alpha \in \mathcal{D} \cap \mathcal{X}^1$; and when $u \in \mathcal{U}(0)$ and $y \in \mathcal{Y}(0)$ are continuous,*

(i) *$p_t(x)$ is of class $C^1(\mathbf{R}^n \times [0, T])$ and*

(ii) *$p_t(x)$ satisfies* (3.3) *in $\mathbf{R}^n \times (0, T)$ in the usual sense.*

LEMMA 3.2. *If $\alpha \in \mathcal{D} \cap \mathcal{X}^1$, then $p_t(x)$ is the unique smooth solution of* (3.3), *and for any $u \in \mathcal{U}(0)$ and $y \in \mathcal{Y}(0)$, the information state p_t evolves in $\mathcal{D} \cap \mathcal{X}^1$ as*

$$p_t \in \mathcal{D} \cap \mathcal{X}^1, \qquad t \in [0, T], \tag{3.5}$$

whenever $\alpha \in \mathcal{D} \cap \mathcal{X}^1$. Moreover, the map $t \mapsto p_t$ from $[0, T]$ into $\mathcal{D} \cap \mathcal{X}^1$ is continuous, with modulus of continuity independent of $u \in \mathcal{U}(0)$, $y \in \mathcal{Y}(0)$.

Proof. 1. Let $\alpha \in \mathcal{D} \cap \mathcal{X}^1$, $u \in \mathcal{U}(0) \cap C([0, T], \mathbf{R}^m)$, and $y \in \mathcal{Y}(0) \cap C([0, T], \mathbf{R}^p)$. Then by the method of characteristics (see, e.g., [13]), we see that (3.3) has a unique solution given by (3.1) that is of class C^1, and moreover, the gradient has the representation

$$\begin{aligned} \nabla_x p_t(x) &= \nabla_x \alpha(x(0)) \\ &\quad + \int_0^t [\nabla_x L(x(s), u(s)) + \gamma^2 \nabla_w \ell\,(y(s) - h(x(s)))\, \nabla_x h(x(s))] \Xi(s)\, ds, \end{aligned} \tag{3.6}$$

where $x(\cdot)$ is the solution of (3.2) and

$$\begin{aligned} \dot{\Xi}(s) = [&\nabla_x f(x(s), u(s)) + \nabla_x g(x(s), y(s) - h(x(s))) \\ &- \nabla_w g(x(s), y(s) - h(x(s)) \nabla_x h(x(s))] \Xi(s), \end{aligned} \tag{3.7}$$

$0 \le s \le t$, where $\Xi(t) = I$.

2. These formulas are also valid for $u \in \mathcal{U}(0)$, $y \in \mathcal{Y}(0)$, by an approximation argument using continuous functions, as follows. Let $u^i \to u$ in $\mathcal{U}(0)$ and $y^i \to y$ in $\mathcal{Y}(0)$ as $i \to \infty$, where each u^i and y^i is continuous. We claim that

$$\lim_{i \to \infty} \sup_{0 \le t \le T} \| p_t^i - p_t \|_1 = 0, \tag{3.8}$$

where $p_\cdot^i$ and $p_\cdot$ denote the corresponding solutions of (3.3) with initial data α.

To prove this, let $x^i(\cdot)$ and $x(\cdot)$ denote the corresponding solutions of (3.2) with terminal data $x^i(t) = x, x(t) = x$. Then a standard estimate using the Gronwall and Holder inequalities gives

$$|x^i(s) - x(s)| \leq K(\| u^i - u \|_{L_2} + \| u^i - u \|_{L_2}),$$

for $s \in [0, t]$, where $K > 0$ is independent of $t \in [0, T]$, $x \in \mathbf{R}^n$. This implies

$$\begin{aligned}
|p_t^i(x) - p_t(x)| &\leq |\alpha(x^i(0)) - \alpha(x(0))| \\
&+ \int_0^t [|L(x^i(s), u^i(s)) - L(x(s), u(s))| + |\ell(y^i(s) - h(x^i(s))) - \ell(y(s) - h(x(s)))|]\, ds \\
&\leq \rho_\alpha(|x^i(0) - x(0)|) + K \int_0^t [|x^i(s) - x(s)| + |u^i(s) - u(s)| + |y^i(s) - y(s)|]\, ds \\
&\leq K(\| u^i - u \|_{L_2} + \| y^i - y \|_{L_2}),
\end{aligned}$$

uniformly, where ρ_α is a modulus of continuity function for α. A similar estimate for $|\nabla_x p_t^i(x) - \nabla_x p_t(x)|$ can be obtained using (3.6). This proves (3.8).

3. Note that by assumption and (3.6), $\nabla_x p_t(x)$ is bounded uniformly in $(x, t) \in \mathbf{R}^n \times [0, T]$. This implies $p_t \in \mathcal{X}^1$. The fact that $p_t \in \mathcal{D} \cap \mathcal{X}^1$ follows from the estimate (3.13).

4. Finally, we claim that there exists a modulus function ρ depending on α but independent of u and y such that

$$\| p_{t^2} - p_{t^1} \|_1 \leq \rho(|t^2 - t^1|). \tag{3.9}$$

To prove (3.9), assume $t^1 \leq t^2$. Let $x^i(\cdot)$ $(i = 1, 2)$ denote the solution of (3.2) with terminal data $x^i(t^i) = x$. Now

$$|x^2(t^1) - x| \leq K|t^2 - t^1|,$$

and for $0 \leq s \leq t^1$, using Gronwall's inequality,

$$|x^1(s) - x^2(s)| \leq K|x^1(t^1) - x^2(t^1)| \leq K|t^2 - t^1|.$$

Therefore

$$\begin{aligned}
|p_{t^2}(x) - p_{t^1}(x)| &\leq |\alpha(x^2(0)) - \alpha(x^1(0))| + \int_0^{t^1} [|L(x^2(s), u(s)) - L(x^1(s), u(s))| \\
&\quad + K|\ell(y(s) - h(x^2(s))) - \ell(y(s) - h(x^1(s)))|]\, ds \\
&\quad + \int_{t^1}^{t^2} [|L(x^2(s), u(s))| + K|g(x^2(s), y(s) - h(x^2(s)))|]\, ds \\
&\leq \rho_\alpha(|x^2(0) - x^1(0)|) + K \int_0^{t^1} |x^2(s) - x^1(s)|\, ds + K|t^2 - t^1| \\
&\leq \rho_\alpha(K|t^2 - t^1|) + K|t^2 - t^1|,
\end{aligned}$$

uniformly in x, u, y. A similar estimate for $|\nabla_x p_{t^2}(x) - \nabla_x p_{t^1}(x)|$ can be obtained using (3.6). This completes the proof. □

If α is not differentiable, then (3.3) can be interpreted in the viscosity sense [13], [28].

DEFINITION 3.3. *We say that a function $p_t(x) \in C(\mathbf{R}^n \times [0, T])$ is a* viscosity subsolution *of the dynamics* (3.3) *if $\alpha \in \mathcal{D} \cap \mathcal{X}$, and if for all $\phi \in C^\infty(\mathbf{R}^n)$, $\psi \in L^1[0, T]$, whenever there*

exists $(x', t') \in \mathbf{R}^n \times (0, T)$ *with* $p_{t'}(x') + \int_0^{t^1} \psi(s)\,ds - \phi(x') = \max_{(x,t)\in\mathbf{R}^n\times[0,T]}(p_t(x) + \int_0^t \psi(s)\,ds - \phi(x))$, *then*

$$\lim_{\delta\to 0} \inf_{|t-t'|<\delta} \operatorname{ess\,inf}\{\psi(t) - \lambda\cdot(f(x,u(t)) + g(x,y(t)-h(x))) + L(x,u(t)) - \gamma^2\ell(y(t)-h(x)) \;:\; |x-x'|<\delta,\ |\lambda - \nabla_x\phi(x')|\le\delta\} \ge 0; \tag{3.10}$$

or a viscosity supersolution *of the dynamics* (3.3) *if* $\alpha \in \mathcal{D}\cap\mathcal{X}$, *and if for all* $\phi \in C^\infty(\mathbf{R}^n)$, $\psi \in L^1[0,T]$, *whenever there exists* $(x', t') \in \mathbf{R}^n\times(0,T)$ *with* $p_{t'}(x') + \int_0^{t^1}\psi(s)\,ds - \phi(x') = \min_{(x,t)\in\mathbf{R}^n\times[0,T]}(p_t(x) + \int_0^t \psi(s)\,ds - \phi(x))$, *then*

$$\lim_{\delta\to 0} \sup_{|t-t'|<\delta} \operatorname{ess\,sup}\{\psi(t) - \lambda\cdot(f(x,u(t)) + g(x,y(t)-h(x))) + L(x,u(t)) - \gamma^2\ell(y(t)-h(x)) \;:\; |x-x'|<\delta,\ |\lambda - \nabla_x\phi(x')|\le\delta\} \le 0; \tag{3.11}$$

or a viscosity solution *if it is both a subsolution and a supersolution.*

LEMMA 3.4. *If* $\alpha \in \mathcal{D}\cap\mathcal{X}$, *then* $p_t(x)$ *is the unique viscosity solution of* (3.3). *Moreover, for any* $u \in \mathcal{U}(0)$ *and* $y \in \mathcal{Y}(0)$, *the information state* p_t *evolves in* $\mathcal{D}\cap\mathcal{X}$ *as*

$$p_t \in \mathcal{D}\cap\mathcal{X}, \qquad t \in [0,T], \tag{3.12}$$

whenever $\alpha \in \mathcal{D}\cap\mathcal{X}$.

Proof. Let $\alpha \in \mathcal{D}\cap\mathcal{X}$, $u \in \mathcal{U}(0)$, and $y \in \mathcal{Y}(0)$. From the formula (3.1) and from well-known continuity properties of ODEs, it is not hard to show that $p_t(x) \in C(\mathbf{R}^n\times[0,T])$, and we omit the details. The fact that $p_t(x)$ is the unique viscosity solution of (3.3) follows from the results in [28].

To show that $p_t \in \mathcal{D}\cap\mathcal{X}$, we must prove the estimate

$$-\underline{c}_1|x| - \underline{c}_2 \le p_t(x) \le -\bar{c}_1|x| + \bar{c}_2 \quad \text{for all } x \in \mathbf{R}^n,\ 0 \le t \le T, \tag{3.13}$$

where the constants are independent of $u \in \mathcal{U}(0)$, $y \in \mathcal{Y}(0)$ but may depend on α. To this end, let $x(\cdot)$ be the solution of (3.2). Then for $0 \le r \le s \le t \le T$, we have

$$|x(s)| \le |x(r)| + K|s-r| \tag{3.14}$$

for some constant $K > 0$. A similar inequality holds if $s \le r$. Therefore,

$$\begin{aligned} p_t(x) &\le \alpha(x(0)) + KT \\ &\le -c_1|x(0)| + c_2 + KT \\ &\le -c_1|x| + c_1KT + c_2 + KT. \end{aligned}$$

This proves the upper bound in (3.13). The lower bound is proven similarly. □

LEMMA 3.5. *The map* $(p,t) \mapsto p_T$ *from* $\mathcal{D}\cap\mathcal{X}\times[0,T]$ *into* $\mathcal{D}\cap\mathcal{X}$ *is continuous, where* p_T *denotes the solution of* (3.3) *at time* T *with initial data* $p_t = p$. *In addition, if* $u \in \mathcal{U}(0)$ *and* $y \in \mathcal{Y}(0)$ *are continuous, then the map* $t \mapsto p_t$ *from* $[0,T]$ *into* $\mathcal{X}$ *is* $\mathcal{X}$*-Frechet differentiable with continuous derivative* $t \mapsto F(p_t, u(t), y(t))$.

Proof. 1. Proof of first assertion. Fix $p^1 \in \mathcal{D}\cap\mathcal{X}$, and consider $p^2 \in \mathcal{D}\cap\mathcal{X}$ and $0 \le t^1 \le t^2 \le T$. If $u \in \mathcal{U}(t^1)$, $y \in \mathcal{Y}(t^1)$, then the natural truncations of u and y belong to $\mathcal{U}(t^2)$ and $\mathcal{Y}(t^2)$, respectively. Similarly, if $u \in \mathcal{U}(t^2)$, $y \in \mathcal{Y}(t^2)$ are given, then one can extend them to elements of $\mathcal{U}(t^1)$ and $\mathcal{Y}(t^1)$ by setting them equal to arbitrary but fixed elements of U and $\mathbf{R}^p$, respectively, on $[t^1, t^2]$. We use this convention to avoid any ambiguity in the sequel. We claim that there exist a constant $K > 0$ and modulus function ρ that may depend on p^1 such that

$$\| p_T^1 - p_T^2 \| \le K \| p^1 - p^2 \| + \rho(|t^2 - t^1|), \tag{3.15}$$

where p_T^i $(i = 1, 2)$ denotes the solution of (3.3) at time T with initial data $p_{t^i}^i = p^i$, and inputs $u(\cdot)$, $y(\cdot)$, with interpretations as explained above. This inequality implies that $(p, t) \mapsto p_T$ is continuous at $(p^1, t^1) \in \mathcal{D} \cap \mathcal{X} \times [0, T]$ (since (3.15) holds also if $t^2 \leq t^1$).

Fix x and let $x^i(\cdot)$ denote the corresponding solutions of (3.2) with terminal data $x^i(T) = x$. Then $x^1(s) = x^2(s)$ for $t^2 \leq s \leq T$ (in particular $x^1(t^2) = x^2(t^2)$),

$$|x^1(t^1) - x^1(t^2)| \leq K|t^2 - t^1|$$

and

$$|x^2(t^2)| \leq |x| + K.$$

Using these estimates,

$$\begin{aligned}
|p_T^1(x) - p_T^2(x)| &\leq |p^1(x^1(t^1)) - p^2(x^2(t^2))| \\
&\quad + \int_{t^1}^{t^2} |L(x^1(s), u(s)) - \gamma^2 \ell(y(s) - h(x^1(s)))|\, ds \\
&\leq |p_1(x^1(t^1)) - p_1(x^2(t^2))| + |p_1(x^2(t^2)) - p^2(x^2(t^2))| + K|t^2 - t^1| \\
&\leq \rho_{p^1}(|x^1(t^1) - x^2(t^2))|) + \| p^1 - p^2 \| (1 + |x^2(t^2)) + K|t^2 - t^1| \\
&\leq \rho_{p^1}(K|t^2 - t^1|) + K \| p^1 - p^2 \| (1 + |x|) + K|t^2 - t^1|.
\end{aligned}$$

This estimate implies (3.15) with $\rho(s) = \rho_{p^1}(K|s|) + K|s|$.

2. Proof of second assertion. Let $\alpha \in \mathcal{D} \cap \mathcal{X}^1$, and assume that u and y are continuous. We must prove that

$$\lim_{\delta \to 0} \frac{\| p_{t+\delta} - p_t - F(p_t, u(t), y(t))\delta \|}{\delta} = 0. \tag{3.16}$$

Since $p_t(x)$ is of class C^1, we have

$$\begin{aligned}
&\frac{|p_{t+\delta}(x) - p_t(x) - F(p_t, u(t), y(t))(x)\delta|}{\delta} \\
&\quad = \left| \frac{1}{\delta} \int_t^{t+\delta} [F(p_s, u(s), y(s))(x) - F(p_t, u(t), y(t))(x)]\, ds \right| \\
&\quad \leq \frac{1}{\delta} \int_t^{t+\delta} [|\nabla_x p_s(x) - \nabla_x p_t(x)||f(x, u(s)) + g(x, y(s) - h(x))| \\
&\qquad + |\nabla_x p_t(x)||f(x, u(s)) - f(x, u(t)) + g(x)(y(s) - y(t))| \\
&\qquad + |L(x, u(s)) - L(x, u(t))| + \gamma^2 K|y(s) - y(t)|]\, ds \\
&\quad \leq \frac{1}{\delta} \int_t^{t+\delta} [K|\nabla_x p_s(x) - \nabla_x p_t(x)| \\
&\qquad + K|f(x, u(s)) - f(x, u(t))| + K(1 + \gamma^2)|y(s) - y(t)| \\
&\qquad + |L(x, u(s)) - L(x, u(t))|]\, ds \\
&\quad \leq \frac{1}{\delta} \int_t^{t+\delta} C\rho(|s - t|)\, ds \ \to 0,
\end{aligned}$$

as $\delta \to 0$ uniformly, where ρ denotes a suitable modulus of continuity function. This follows because of our assumptions on the data and using (3.6), and is enough to prove (3.16). □

Using the definition (3.1), we have the following key representation theorem.

THEOREM 3.6. *For any* $\mathbf{u} \in \mathbf{U}(0)$ *we have*

$$J(\mathbf{u}) = \sup_{y \in \mathcal{Y}(0)} \{(p_T, \Phi) \,:\, p_0 = \alpha\}, \tag{3.17}$$

where $(p, \Phi) = \sup_{x \in \mathbf{R}^n}(p(x) + \Phi(x))$ *is the "sup-pairing"* [24].

Proof. For any $w \in \mathcal{W}(0)$, an output $y \in \mathcal{Y}(0)$ can be defined by solving the ODE (2.1) with $u(t) = \mathbf{u}[y](t)$, $0 \le t \le T$. Conversely, given any $y \in \mathcal{Y}(0)$, a disturbance $w \in \mathcal{W}(0)$ is defined by solving the ODE (3.2) with $u(t) = \mathbf{u}[y](t)$, $0 \le t \le T$, and setting $w(t) \triangleq -h(x(t)) + y(t)$, $0 \le t \le T$. Therefore there is a natural bijection between $\mathcal{W}(0)$ and $\mathcal{Y}(0)$ (for each $\mathbf{u}$). Consequently,

$$\begin{aligned}
J(\mathbf{u}) &= \sup_{w \in \mathcal{W}(0),\ x_0 \in \mathbf{R}^n} \left\{ \alpha(x_0) + \int_0^T [L(x(t), \mathbf{u}[y](t)) - \gamma^2 \ell(w(t))]\, dt + \Phi(x(T)) \right\} \\
&= \sup_{y \in \mathcal{Y}(0),\ x_0 \in \mathbf{R}^n} \left\{ \alpha(x_0) + \int_0^T [L(x(t), \mathbf{u}[y](t)) - \gamma^2 \ell(y(t) - h(x(t)))]\, dt + \Phi(x(T)) \right\} \\
&= \sup_{y \in \mathcal{Y}(0),\ x \in \mathbf{R}^n} \left\{ \alpha(x_0) + \int_0^T [L(x(t), \mathbf{u}[y](t)) - \gamma^2 \ell(y(t) - h(x(t)))]\, dt + \Phi(x(T)) \right. \\
&\qquad\qquad \left. :\, x(T) = x \right\} \\
&= \sup_{y \in \mathcal{Y}(0),\ x \in \mathbf{R}^n} \{p_T(x) + \Phi(x)\} \\
&= \sup_{y \in \mathcal{Y}(0)} \{(p_T, \Phi) \,:\, p_0 = \alpha\}. \qquad \square
\end{aligned}$$

The equivalent differential game with full state information is to minimize the right-hand side of (3.17) over $\mathbf{u} \in \mathbf{U}(0)$ subject to the infinite-dimensional dynamics (3.3).

We conclude this section with a brief discussion of an "adjoint" information state q_t, which runs backward in time and has the interesting property that the sup-pairing (p_t, q_t) is constant [24]. The *adjoint information state* is defined for fixed $u \in \mathcal{U}(t)$ and $y \in \mathcal{Y}(t)$ by

$$q_t(x) = \int_t^T [L(x(s), u(s)) - \gamma^2 \ell\,(y(s) - h(x(s)))]\, ds + \Phi(x(T)), \tag{3.18}$$

where $x(\cdot)$ is the solution of (3.2) on $[t, T]$ with initial data $x(t) = x$. The dynamics for the adjoint information state are

$$\begin{cases} \dot{q}_s &= -F(-q_s, u(s), y(s)), \qquad s \in [t, T], \\ q_T &= \Phi. \end{cases} \tag{3.19}$$

THEOREM 3.7. *The sup-pairing of the information state and the adjoint information state is constant and expressed as*

$$(p_t, q_t) \text{ is independent of } t \in [0, T]. \tag{3.20}$$

Proof. The assertion can be verified easily by combining the definitions (3.1) and (3.18). Alternatively, suppose p_t and q_t are smooth solutions of (3.3) and (3.19), respectively. Define $v(t) = (p_t, q_t) = p_t(\bar{x}(t)) + q(\bar{x}(t))$. Then $\nabla_x p_t(\bar{x}(t)) = -\nabla_x q_t(\bar{x}(t))$ and

$$\begin{aligned}\dot{v}(t) &= \frac{\partial p_t}{\partial t}(\bar{x}(t)) + \frac{\partial q_t}{\partial t}(\bar{x}(t)) \\ &= -\nabla_x p_t(\bar{x}(t)) \cdot (f(\bar{x}(t), u(t)) + g(\bar{x}(t), y(t) - h(\bar{x}(t)))) \\ &\quad + L(\bar{x}(t), u(t)) - \gamma^2 \ell(y - h(\bar{x}(t))) \\ &\quad - \nabla_x q_t(\bar{x}(t)) \cdot (f(\bar{x}(t), u(t)) + g(\bar{x}(t), y(t) - h(\bar{x}(t)))) \\ &\quad - L(\bar{x}(t), u(t)) + \gamma^2 \ell(y - h(\bar{x}(t))) = 0.\end{aligned}$$

This shows that $v(t) = (\alpha, q_0) = (p_T, \Phi)$ is constant, as required. □

4. Value function and the HJI equation. Given Theorem 3.6, one can now apply dynamic programming methods to solve the equivalent problem and, hence, the original partially observed problem. The value function is defined for $(p, t) \in \mathcal{D} \cap \mathcal{X} \times [0, T]$ by

$$W(p, t) = \inf_{\mathbf{u} \in \mathbf{U}(t)} \sup_{y \in \mathcal{Y}(t)} \{(p_T, \Phi) : p_t = p\}. \tag{4.1}$$

This function is finite, as the following lemma shows.

LEMMA 4.1. *For all* $(p, t) \in \mathcal{D} \cap \mathcal{X} \times [0, T]$ *we have*

$$(p, 0) - K \leq W(p, t) \leq K + (p, 0) \tag{4.2}$$

for some constant $K > 0$.

Proof. For any $\mathbf{u} \in \mathbf{U}(t)$ and $y \in \mathcal{Y}(t)$ we have

$$\begin{aligned}p_T(x(T)) + \Phi(x(T)) &= p(x(t)) + \int_t^T [L(x(s), \mathbf{u}[y](s)) - \gamma^2 \ell(y(s) - h(x(s)))]\, ds + \Phi(x(T)) \\ &\leq p(x(t)) + K,\end{aligned}$$

where $K > 0$ does not depend on $\mathbf{u}$, y, and hence

$$(p_T, \Phi) = \sup_{x(T)} \{p(x(T)) + \Phi(x(T))\} \leq \sup_{x(t)} \{p(x(t)) + K\} = (p, 0) + K.$$

This proves the upper bound in (4.2).

To obtain the lower estimate in (4.2), select $x \in \operatorname{argmax} p$. Then

$$(p_T, \Phi) \geq p(x) + \int_t^T [L(x(s), \mathbf{u}[y](s)) - \gamma^2 \ell(y(s) - h(x(s)))]\, ds + \Phi(x(T)) \geq (p, 0) - K,$$

where $x(\cdot)$ is the solution of (2.1) with initial data $x(t) = x$. □

In the next lemma, $B(0, R)$ denotes the ball of radius R centered at 0 in $\mathbf{R}^n$.

LEMMA 4.2. *Fix* $p^1 \in \mathcal{D} \cap \mathcal{X}$. *Then there exist* $\delta^1 > 0$ *and* $R^1 > 0$ *such that* $\| p^2 - p^1 \| < \delta^1$ *implies that* $\operatorname{argmax}_{x \in \mathbf{R}^n} (p^2(x) + \Phi(x)) \subset B(0, R^1)$.

Proof. Since $p^1 \in \mathcal{D}$ and Φ is bounded, $p^1(x) + \Phi(x) \leq -c_1|x| + c_2 + K$. Then for $p^2 \in \mathcal{X}$,

$$p^2(x) + \Phi(x) = p^1(x) + \Phi(x) + (p^2(x) - p^1(x)) \leq -c_1|x| + c_2 + K + \| p^2 - p^1 \| (1 + |x|).$$

Set $\delta^1 = c_1/2$. Then for $\| p^2 - p^1 \| < \delta^1$,

$$p^2(x) + \Phi(x) \leq -c_1'|x| + c_2', \tag{4.3}$$

where $c_1' = c_1/2$, $c_2' = c_2 + K + \delta^1$.

Next, select a sequence x_i such that $\lim_{i\to\infty} p^2(x_i) = \sup_{x\in\mathbf{R}^n} p^2(x) = (p^2, 0) < +\infty$. Fix $\varepsilon > 0$. Then for all large i,

$$(p^2, \Phi) - \varepsilon \le p^2(x_i) \le -c_1'|x_i| + c_2',$$

and hence

$$|x_i| \le R^1 \tag{4.4}$$

for some constant $R^1 > 0$ depending on p^1 and δ^1. Thus the sequence x_i is bounded, and any limit point x^2 satisfies $|x^2| \le R^1$. Hence $\operatorname{argmax}_{x\in\mathbf{R}^n}(p^2(x) + \Phi(x)) \subset B(0, R^1)$. □

THEOREM 4.3. *The value function $W(p, t)$ defined by* (4.1) *is continuous, denoted*

$$W \in C(\mathcal{D} \cap \mathcal{X} \times [0, T]).$$

Proof. Fix $(p^1, t^1) \in \mathcal{D} \cap \mathcal{X} \times [0, T]$. Given $\varepsilon > 0$, we will show that there exists $\delta > 0$ (depending on p^1) such that $\| p^2 - p^1 \| < \delta$ and $|t^2 - t^1| < \delta$ imply

$$|W(p^1, t^1) - W(p^2, t^2)| \le \varepsilon. \tag{4.5}$$

The proof of this assertion is based on the proof of [11, Thm. 3.2].

Assume that $0 \le t^1 \le t^2 \le T$ and $0 < \delta < \delta^1$, where δ^1, R^1 are as in Lemma 4.2, and that $\| p^2 - p^1 \| < \delta$, $|t^2 - t^1| < \delta$.

Choose $\mathbf{u} \in \mathbf{U}(t^1)$ such that

$$W(p^1, t^1) \ge \sup_{y\in\mathcal{Y}(t^1)} \{(p_T^1, \Phi)\} - \varepsilon/3,$$

where p_s^1 is the solution of (3.3) with initial data $p_{t^1}^1 = p^1$ and using this $\mathbf{u}$ and any y. For any $y \in \mathcal{Y}(t^2)$ define $\tilde{y} \in \mathcal{Y}(t^1)$ by

$$\tilde{y}(s) = \begin{cases} 0, & t^1 \le s < t^2, \\ y(s), & t^2 \le s \le T. \end{cases}$$

Define $\tilde{\mathbf{u}} \in \mathbf{U}(t^2)$ by

$$\tilde{\mathbf{u}}[y] = \mathbf{u}[\tilde{y}] \quad \text{for all } y \in \mathcal{Y}(t^2).$$

Select $y \in \mathcal{Y}(t^2)$ such that

$$W(p^2, t^2) \le (p_T^2, \Phi) + \varepsilon/3,$$

where p_s^2 is the solution of (3.3) with initial data $p_{t^2}^2 = p^2$ and using $\tilde{\mathbf{u}}$ and y. Then

$$W(p^2, t^2) - W(p^1, t^1) \le (p_T^2, \Phi) - (p_T^1, \Phi) + 2\varepsilon/3 = p_T^2(x^2) - p_T^1(x^2) + 2\varepsilon/3, \tag{4.6}$$

where $x^2 \in \operatorname{argmax}\{p^2 + \Phi\}$. By Lemma 4.2, since Φ is bounded, $|x^2| \le R^1$. Then using $u(s) = \mathbf{u}[\tilde{y}](s)$ and $\tilde{y}(s)$, $s \in [t^1, T]$, and $s \in [t^2, T]$, inequality (3.15) of Lemma 3.5 implies that

$$p_T^2(x^2) - p_T^1(x^2) \le (K\delta + \rho(|t^2 - t^1|))(1 + |x^2|) \le (K\delta + \rho(|t^2 - t^1|))(1 + R^1).$$

Therefore there exists $\delta^2 < \delta^1$ such that $\delta < \delta^2$ implies, using (4.6),

$$W(p^2, t^2) - W(p^1, t^1) \le \varepsilon. \tag{4.7}$$

The proof of the opposite inequality is similar. Choose $\mathbf{u} \in \mathbf{U}(t^2)$ such that

$$W(p^2, t^2) \geq \sup_{y \in \mathcal{Y}(t^2)} \{(p_T^2, \Phi)\} - \varepsilon/3,$$

where p_s^2 is the solution of (3.3) with initial data $p_{t^2}^2 = p^2$ and using $\mathbf{u}$ and any y. For all $y \in \mathcal{Y}(t^1)$, define $\tilde{y} \in \mathcal{Y}(t^2)$ by $\tilde{y} = y$ on $[t^2, T]$. Fix $u_0 \in U$. Define $\tilde{\mathbf{u}} \in \mathbf{U}(t^1)$ by

$$\tilde{\mathbf{u}}[y] = \begin{cases} u_0, & t^1 \leq s \leq t^2, \\ \mathbf{u}[\tilde{y}](s), & t^2 \leq s \leq T. \end{cases}$$

Now choose $y \in \mathcal{Y}(t^1)$ such that

$$W(p^1, t^1) \leq (p_T^1, \Phi) + \varepsilon/3,$$

where p_s^1 is the solution of (3.3) with initial data $p_{t^1}^1 = p^1$ and using $\tilde{\mathbf{u}}$ and y. Therefore,

$$W(p^1, t^1) - W(p^2, t^2) \leq (p_T^1, \Phi) - (p_T^2, \Phi) + 2\varepsilon/3,$$

and proceeding as above there exists $\delta^3 \leq \delta^2$ such that $\delta < \delta^3$ implies

$$W(p^1, t^1) - W(p^2, t^2) \leq \varepsilon. \tag{4.8}$$

Inequalities (4.7) and (4.8) are both valid for $\delta < \delta^3$, hence (4.5). □

The principle of optimality (dynamic programming principle) for this problem is as follows.

THEOREM 4.4. *For any* $0 \leq t \leq r \leq T$ *we have*

$$W(p, t) = \inf_{\mathbf{u} \in \mathbf{U}(t)} \sup_{y \in \mathcal{Y}(t)} \{W(p_r, r) \,:\, p_t = p\}. \tag{4.9}$$

Proof. The proof uses the same methods as in [10], [11].

Indeed, let $R(p, t)$ denote the right-hand side of (4.9), and fix $\varepsilon > 0$. Choose $\mathbf{u}^1 \in \mathbf{U}(p, t)$ such that

$$R(p, t) \geq \sup_{y \in \mathcal{Y}(t)} \{W(p_r, r)\} - \varepsilon.$$

For any $q \in \mathcal{D} \cap \mathcal{X}$ there exists $\mathbf{u}^2 \in \mathbf{U}(q, r)$ such that

$$W(q, r) \geq \sup_{y \in \mathcal{Y}(t)} \{(p_T, \Phi)\} - \varepsilon,$$

where $p_r = q$. Define $\mathbf{u}^3 \in \mathbf{U}(p, t)$ by

$$\mathbf{u}^3(y)(s) = \begin{cases} \mathbf{u}^1(p, y)(s), & t \leq s \leq r, \\ \mathbf{u}^2(p_r, y)(s), & r \leq s \leq T. \end{cases}$$

Then for any $y \in \mathcal{Y}(t)$ we have, using the control $\mathbf{u}^3$,

$$\begin{aligned} R(p, t) &\geq W(p_r, r) - \varepsilon \\ &\geq (p_T, \Phi) - 2\varepsilon; \end{aligned}$$

hence

$$(p_T, \Phi) \leq R(p, t) + 2\varepsilon \quad \text{for all } y \in \mathcal{Y}(t).$$

Therefore

$$\sup_{y\in\mathcal{Y}(t)}\{(p_T,\Phi)\}\le R(p,t)+2\varepsilon \quad (\text{using } \mathbf{u}^3).$$

This implies

$$W(p,t)\le R(p,t)+2\varepsilon. \tag{4.10}$$

To prove the opposite inequality, choose $\mathbf{u}\in\mathbf{U}(p,t)$ such that

$$W(p,t)\ge \sup_{y\in\mathcal{Y}(t)}\{(p_T,\Phi)\}-\varepsilon. \tag{4.11}$$

Then

$$R(p,t)\le \sup_{y\in\mathcal{Y}(t)}\{W(p_r,r)\},$$

and there exists $y^1\in\mathcal{Y}(t)$ such that

$$R(p,t)\le W(p_r,r)+\varepsilon.$$

For each $y\in\mathcal{Y}(r)$, define $\tilde{y}\in\mathcal{Y}(t)$ by

$$\tilde{y}(s)=\begin{cases} y^1(s), & t\le s\le r,\\ y(s), & r\le s\le T.\end{cases}$$

Then define $\tilde{\mathbf{u}}\in\mathbf{U}(q,r)$ ($q=p_r$ results from $\mathbf{u}$, y^1, and $p_t=p$) by $\tilde{\mathbf{u}}(y)(s)=\mathbf{u}(\tilde{y})(s)$, $r\le s\le T$. Then

$$W(p_r,r)\le \sup_{y\in\mathcal{Y}(r)}\{(p_T,\Phi)\ :\ p_r=q\},$$

and there exists $y^2\in\mathcal{Y}(r)$ such that

$$W(p_r,r)\le (p_T,\Phi)+\varepsilon.$$

Define $y^3\in\mathcal{Y}(t)$ by

$$y^3(s)=\begin{cases} y^1(s), & t\le s\le r,\\ y^2(s), & r\le s\le T.\end{cases}$$

Therefore we have

$$R(p,t)\le W(p_r,r)+\varepsilon\le (p_T,\Phi)+2\varepsilon,$$

which implies, by (4.11),

$$R(p,t)\le \sup_{y\in\mathcal{Y}(t)}\{(p_T,\Phi)\}+2\varepsilon\le W(p,t)+3\varepsilon. \tag{4.12}$$

Since $\varepsilon>0$ was arbitrary, inequalities (4.10) and (4.12) imply (4.9). □

Equation (4.9) leads to the dynamic programming equation (DPE)

$$\begin{cases} \dfrac{\partial W}{\partial t}+\inf\limits_{u\in U}\sup\limits_{y\in\mathbf{R}^p}\langle\nabla_p W(p,t),F(p,u,y)\rangle = 0 \quad \text{in } \mathcal{D}\cap\mathcal{X}^1\times(0,T),\\ W(p,T) = (p,\Phi) \quad \text{in } \mathcal{D}\cap\mathcal{X}.\end{cases} \tag{4.13}$$

In (4.13), $\nabla_p W(p,t)$ denotes the gradient of W with respect to p and, if it exists, belongs to the dual space $\mathcal{X}^*$ and $\langle\lambda,p\rangle$ denotes the value of $\lambda\in\mathcal{X}^*$ at $p\in\mathcal{X}$. In view of the structure of F (see (3.4)), the order of inf and sup in (4.13) is immaterial; i.e., the Isaacs condition holds.

The DPE (4.13) is the appropriate Hamilton–Jacobi–Isaacs (HJI) equation for the partially observed differential game.

We will make use of two classes $\mathcal{C}^1 \subset \mathcal{C} \subset C(\mathcal{D} \cap \mathcal{X} \times [0, T])$ of test functions. We take $\phi \in \mathcal{C}$ to mean that

(i) ϕ is $\mathcal{X}$-Frechet differentiable, with derivative denoted $(\nabla_p \phi, \frac{\partial \phi}{\partial t})$;

(ii) the Frechet derivative $(\nabla_p \phi, \frac{\partial \phi}{\partial t})$ is continuous on $\mathcal{D} \cap \mathcal{X} \times [0, T]$; and $\phi \in \mathcal{C}^1$ means that in addition

(iii) the Frechet derivative $(\nabla_p \phi, \frac{\partial \phi}{\partial t})$ is continuous on $\mathcal{D} \cap \mathcal{X}^1 \times [0, T]$.

These classes of functions will be used to define smooth and viscosity solutions of (4.13).

LEMMA 4.5. *Let $p \in \mathcal{D} \cap \mathcal{X}^1$ so that $p_r(x)$ is a smooth solution of* (3.3) *on $[t, T]$ with initial data $p_t = p$, and let $\phi \in \mathcal{C}$. Then we have the following version of the fundamental theorem of calculus:*

$$\phi(p_r, r) = \phi(p_t, t) + \int_t^r \left[\frac{\partial \phi}{\partial t}(p_s, s) + \langle \nabla_p \phi(p_s, s), F(p_s, u(s), y(s)) \rangle \right] ds. \tag{4.14}$$

Proof. Let u and y be continuous. Then the function $r \mapsto \phi(p_r, r)$ is continuously differentiable, and so by the usual fundamental theorem of calculus, (4.14) holds.

By an approximation argument, (4.14) holds for all $u \in \mathcal{U}(t)$, $y \in \mathcal{Y}(t)$ as follows. Let $u^i \to u$ in $\mathcal{U}(0)$ and $y^i \to y$ in $\mathcal{Y}(0)$ as $i \to \infty$, where each u^i and y^i is continuous. Then

$$\phi(p_r^i, r) = \phi(p_t^i, t) + \int_t^r \left[\frac{\partial \phi}{\partial t}(p_s^i, s) + \langle \nabla_p \phi(p_s^i, s), F(p_s^i, u^i(s), y^i(s)) \rangle \right] ds. \tag{4.15}$$

We claim that

$$\lim_{i \to \infty} \phi(p_r^i, r) = \phi(p_r, r), \qquad \lim_{i \to \infty} \phi(p_t^i, t) = \phi(p_t, t), \tag{4.16}$$

and

$$\begin{aligned} &\lim_{i \to \infty} \int_t^r \left[\frac{\partial \phi}{\partial t}(p_s^i, s) + \langle \nabla_p \phi(p_s^i, s), F(p_s^i, u^i(s), y^i(s)) \rangle \right] ds \\ &\quad = \int_t^r \left[\frac{\partial \phi}{\partial t}(p_s, s) + \langle \nabla_p \phi(p_s, s), F(p_s, u(s), y(s)) \rangle \right] ds, \end{aligned} \tag{4.17}$$

where $p_\cdot^i$ and $p_\cdot$ denote the corresponding solutions of (3.3) with initial data $p \in \mathcal{D} \cap \mathcal{X}^1$ at time t. By (3.8) in Lemma 3.2, (4.16) follows directly by continuity. Thus it remains to prove (4.17). This can be done by showing that

$$\begin{aligned} &\left| \int_t^r \left[\frac{\partial \phi}{\partial t}(p_s^i, s) + \langle \nabla_p \phi(p_s^i, s), F(p_s^i, u^i(s), y^i(s)) \rangle \right. \right. \\ &\qquad \left. \left. - \frac{\partial \phi}{\partial t}(p_s, s) - \langle \nabla_p \phi(p_s, s), F(p_s, u(s), y(s)) \rangle \right] ds \right| \\ &\quad \le \int_t^r \left| \frac{\partial \phi}{\partial t}(p_s^i, s) - \frac{\partial \phi}{\partial t}(p_s, s) \right| + |\langle \nabla_p \phi(p_s^i, s) - \nabla_p \phi(p_s, s), F(p_s, u(s), y(s)) \rangle| \\ &\qquad + |\langle \nabla_p \phi(p_s^i, s), F(p_s^i, u^i(s), y^i(s)) - F(p_s, u(s), y(s)) \rangle|] \, ds \\ &\quad \le \int_t^r \left| \frac{\partial \phi}{\partial t}(p_s^i, s) - \frac{\partial \phi}{\partial t}(p_s, s) \right| + \| \nabla_p \phi(p_s^i, s) - \nabla_p \phi(p_s, s) \|_* \| F(p_s, u(s), y(s)) \| \\ &\qquad + \| \nabla_p \phi(p_s^i, s) \|_* \| F(p_s^i, u^i(s), y^i(s)) - F(p_s, u(s), y(s)) \|] \, ds \to 0 \end{aligned} \tag{4.18}$$

as $i \to \infty$. Here, $\| \cdot \|$ denotes the norm on $\mathcal{X}$ as in §2 and $\| \cdot \|_*$ indicates the norm on the dual space $\mathcal{X}^*$. We treat each term as follows.

Given $\varepsilon > 0$, the compactness of $[t, r]$, the assumed continuity of the partial derivatives, and the uniform convergence (3.8) imply that for i sufficiently large,

$$\begin{aligned} &\sup_{t \le s \le r} \| \nabla_p \phi(p_s^i, s) - \nabla_p \phi(p_s, s) \|_* \le \varepsilon, \\ &\sup_{t \le s \le r} \left| \frac{\partial \phi}{\partial t}(p_s^i, s) - \frac{\partial \phi}{\partial t}(p_s, s) \right| \le \varepsilon. \end{aligned} \tag{4.19}$$

This also implies

$$\sup_{t \le s \le r} \| \nabla_p \phi(p_s^i, s) \|_* \le K. \tag{4.20}$$

Next, because of (3.8) and the assumed bounds on the problem data, we have

$$\sup_{t \le s \le r} \| F(p_s, u(s), y(s)) \| \le K. \tag{4.21}$$

Finally, it is not hard to verify the estimate

$$\begin{aligned} &\int_r^t \| F(p_s^i, u^i(s), y^i(s)) - F(p_s, u(s), y(s)) \| \, ds \\ &\le K \sup_{t \le s \le r} \| p_s^i - p_s \|_1 + K \left(1 + \sup_{t \le s \le r} \| p_s^i \|_1 \right) \\ &\quad \cdot \int_t^r [|u^i(s) - u(s)| + |y^i(s) - y(s)|] \, ds \end{aligned} \tag{4.22}$$

Therefore using (4.19), (4.20), (4.21), (4.22) in (4.18), we have

$$(4.18) \le T\varepsilon + TK\varepsilon + K \int_t^r [|u^i(s) - u(s)| + |y^i(s) - y(s)|] \, ds \le K\varepsilon$$

for all i sufficiently large, for a suitable constant $K > 0$ not depending on i. This completes the proof. □

DEFINITION 4.6. *A function* $W : \mathcal{D} \cap \mathcal{X} \times [0, T] \to \mathbf{R}$ *is called a* smooth solution *of the DPE* (4.13) *if*

(i) $W \in C^1$;

(ii) W *satisfies* (4.13) *in* $\mathcal{D} \cap \mathcal{X}^1 \times (0, T)$ *in the usual sense.*

In general, it is too much to expect that the DPE will have smooth solutions, and so one must appeal to a weaker notion of solution. To this end, we will show that the value function W is a viscosity solution of (4.13) in a suitable sense. The definition we provide below is consistent with our definition of smooth solution and is a generalization of it. We do not know a proof of uniqueness, and it may be the case that the definition has to be modified to achieve this. Consequently, Definition 4.7 is a provisional one. An abstract formulation of the viscosity solution definition is given in [13]. It is not clear at present how our definition relates to those appearing in [7], [17], [27]; indeed, the PDE (4.13) does not appear to be covered by existing theory.

DEFINITION 4.7 (provisional viscosity solution). *We say that a function* $W \in C(\mathcal{D} \cap \mathcal{X} \times [0, T])$ *is a* viscosity subsolution *of the DPE* (4.13) *if for all* $\phi \in C$, *whenever there exists* $(p', t') \in \mathcal{D} \cap \mathcal{X}^1 \times (0, T)$ *with* $W(p', t') - \phi(p', t') = \max_{(p,t) \in \mathcal{D} \cap \mathcal{X} \times [0,T]} (W(p, t) - \phi(p, t)) = 0$, *then*

$$\frac{\partial \phi}{\partial t}(p', t') + \inf_{u \in U} \sup_{y \in \mathbf{R}^p} \langle \nabla_p \phi(p', t'), F(p', u, y) \rangle \ge 0; \tag{4.23}$$

a viscosity supersolution *of the DPE* (4.13) *if for all* $\phi \in \mathcal{C}$, *whenever there exists* $(p', t') \in \mathcal{D} \cap \mathcal{X}^1 \times (0, T)$ *with* $W(p', t') - \phi(p', t') = \min_{(p,t)\in\mathcal{D}\cap\mathcal{X}\times[0,T]}(W(p,t) - \phi(p,t)) = 0$, *then*

$$\frac{\partial \phi}{\partial t}(p', t') + \inf_{u\in U} \sup_{y\in\mathbf{R}^p} \langle \nabla_p \phi(p', t'), F(p', u, y)\rangle \leq 0; \tag{4.24}$$

and a viscosity solution *if it is both a subsolution and a supersolution.*

The proof that W is a viscosity solution of (4.13) requires the following result (cf. [11, Lem. 4.3]).

LEMMA 4.8. *Let* $\phi \in \mathcal{C}$. *Assume that* ϕ *satisfies*

$$\frac{\partial \phi}{\partial t}(p', t') + \inf_{u\in U} \sup_{y\in\mathbf{R}^p} \langle \nabla_p \phi(p', t'), F(p', u, y)\rangle \leq -\theta, \tag{4.25}$$

where $\theta > 0$, $p' \in \mathcal{D} \cap \mathcal{X}^1$, $t' \in [0, T]$. *Then there exists* $\delta_0 > 0$, $\mathbf{u} \in \mathbf{U}(t')$ *such that for all* $\delta < \delta_0$, $y \in \mathcal{Y}(t')$

$$\int_{t'}^{t'+\delta} \left[\frac{\partial \phi}{\partial t}(p_s, s) + \langle \nabla_p \phi(p_s, s), F(p_s, \mathbf{u}[y](s), y(s))\rangle\right] ds \leq -\delta\theta/2. \tag{4.26}$$

Similarly, if ϕ *satisfies*

$$\frac{\partial \phi}{\partial t}(p', t') + \inf_{u\in U} \sup_{y\in\mathbf{R}^p} \langle \nabla_p \phi(p', t'), F(p', u, y)\rangle \geq \theta, \tag{4.27}$$

where $\theta > 0$, $p' \in \mathcal{D} \cap \mathcal{X}^1$, $t' \in [0, T]$, *then there exists* $\delta_1 > 0$, $y \in \mathcal{Y}(t')$ *such that for all* $\delta < \delta_1$, $\mathbf{u} \in \mathbf{U}(t')$

$$\int_{t'}^{t'+\delta} \left[\frac{\partial \phi}{\partial t}(p_s, s) + \langle \nabla_p \phi(p_s, s), F(p_s, \mathbf{u}[y](s), y(s))\rangle\right] ds \geq \delta\theta/2. \tag{4.28}$$

Proof. Write

$$\Lambda(p, t, u, y) = \frac{\partial \phi}{\partial t}(p, t) + \langle \nabla_p \phi(p, t), F(p, u, y)\rangle.$$

Since $\phi \in \mathcal{C}$, $\Lambda : \mathcal{D} \cap \mathcal{X}^1 \times [0, T] \times U \times \mathbf{R}^p \to \mathbf{R}$ is continuous. In fact, for $\| p - p' \|_1 < \nu$, $|t - t'| < \nu$ ($\nu > 0$ small), we have the estimate

$$\begin{aligned} |\Lambda(p, t, u, y) - \Lambda(p', t', u', y')| \leq{}& \left|\frac{\partial \phi}{\partial t}(p, t) - \frac{\partial \phi}{\partial t}(p', t')\right| \\ &+ K \| \nabla_p \phi(p, t) - \nabla_p \phi(p', t') \|_* + K(\| p - p' \|_1 + |u - u'| + |y - y'|), \end{aligned} \tag{4.29}$$

where $K > 0$ depends on p', t', and ν.

By (4.25), $\inf_u \sup_y \Lambda(p', t', u, y) \leq -\theta$. Select $u_0 \in \operatorname{argmin}_u \sup_y \Lambda(p', t', u, y)$, which does not depend on y because the Isaacs condition holds. Therefore

$$\Lambda(p', t', u_0, y) \leq -\theta \quad \text{for all } y \in \mathbf{R}^p.$$

Define $\mathbf{u} \in \mathbf{U}(t')$ by $\mathbf{u}[y] \equiv u_0$. Let $y \in \mathcal{Y}(t')$. As in (3.9), Lemma 3.2, the map $s \mapsto p_s$ from $[t', T]$ into $\mathcal{D} \cap \mathcal{X}^1$ is continuous, with modulus of continuity independent of u, y. Thus there exists $\delta_0 > 0$ such that if $\delta < \delta_0$ and $t' \leq s \leq t' + \delta$, then

$$\Lambda(p_s, s, \mathbf{u}[y](s), y(s)) \leq -\theta/2.$$

Integrating from t' to $t' + \delta$ gives (4.26).

To prove (4.28), we note that (4.27) implies the existence of $y_0 \in \mathbf{R}^p$ (independent of u) such that

$$\Lambda(p', t', u, y_0) \geq \theta \quad \text{for all } u \in U.$$

Define $y \in \mathcal{Y}(t')$ by $y \equiv y_0$, and let $\mathbf{u} \in \mathbf{U}(t')$. Then by continuity, with $\delta < \delta_1$ (some $\delta_1 > 0$), $t' \leq s \leq t' + \delta$ implies

$$\Lambda(p_s, s, \mathbf{u}[y](s), y(s)) \geq \theta/2.$$

Integrating from t' to $t' + \delta$ gives (4.28). □

THEOREM 4.9. *The value function $W(p, t)$ defined by* (4.1) *is a continuous viscosity solution of the DPE* (4.13).

Proof. To show that $W(p, t)$ is a viscosity subsolution, assume there exist $\phi \in \mathcal{C}$, $(p', t') \in \mathcal{D} \cap \mathcal{X}^1 \times (0, T)$ with $W(p', t') - \phi(p', t') = \max_{(p,t)\in\mathcal{D}\cap\mathcal{X}\times[0,T]}(W(p, t) - \phi(p, t)) = 0$. We must show that ϕ satisfies (4.23). If not, then there exists $\theta > 0$ such that (4.25) holds. By Lemma 4.8, (4.26) holds, which implies

$$(4.30)\quad \inf_{\mathbf{u}\in\mathbf{U}(t')} \sup_{y\in\mathcal{Y}(t')} \left\{ \int_{t'}^{t'+\delta} \left[\frac{\partial \phi}{\partial t}(p_s, s) + \langle \nabla_p \phi(p_s, s), F(p_s, \mathbf{u}[y](s), y(s)) \rangle \right] ds \right\} \leq -\delta\theta/2.$$

Now

$$W(p', t') = \phi(p', t') \quad \text{and} \quad W(p, t) \leq \phi(p, t);$$

hence the dynamic programming principle (4.9) with $t = t'$, $r = t' + \delta$ implies

$$0 \leq \inf_{\mathbf{u}\in\mathbf{U}(t')} \sup_{y\in\mathcal{Y}(t')} \{\phi(p_{t'+\delta}, t' + \delta) - \phi(p', t')\}.$$

Since $\phi \in \mathcal{C}$, Lemma 4.5 and this inequality imply

$$(4.31)\quad 0 \leq \inf_{\mathbf{u}\in\mathbf{U}(t')} \sup_{y\in\mathcal{Y}(t')} \left\{ \int_{t'}^{t'+\delta} \left[\frac{\partial \phi}{\partial t}(p_s, s) + \langle \nabla_p \phi(p_s, s), F(p_s, \mathbf{u}[y](s), y(s)) \rangle \right] ds \right\}.$$

But (4.31) contradicts (4.30), hence (4.23) is valid. Therefore $W(p, t)$ is a viscosity subsolution of (4.13).

Now suppose there exists $\phi \in \mathcal{C}$, $(p', t') \in \mathcal{D} \cap \mathcal{X}^1 \times (0, T)$ with

$$W(p', t') - \phi(p', t') = \min_{(p,t)\in\mathcal{D}\cap\mathcal{X}\times[0,T]} (W(p, t) - \phi(p, t)) = 0.$$

If (4.24) does not hold, then there exists $\theta > 0$ such that (4.27) holds. Then by Lemma 4.8, (4.28) holds, implying

$$(4.32)\quad \inf_{\mathbf{u}\in\mathbf{U}(t')} \sup_{y\in\mathcal{Y}(t')} \left\{ \int_{t'}^{t'+\delta} \left[\frac{\partial \phi}{\partial t}(p_s, s) + \langle \nabla_p \phi(p_s, s), F(p_s, \mathbf{u}[y](s), y(s)) \rangle \right] ds \right\} \geq \delta\theta/2.$$

Now

$$W(p', t') = \phi(p', t') \quad \text{and} \quad W(p, t) \geq \phi(p, t),$$

and by dynamic programming,

$$0 \geq \inf_{\mathbf{u}\in\mathbf{U}(t')} \sup_{y\in\mathcal{Y}(t')} \{\phi(p_{t'+\delta}, t' + \delta) - \phi(p', t')\}.$$

This implies

$$(4.33)\quad 0 \geq \inf_{\mathbf{u}\in\mathbf{U}(t')} \sup_{y\in\mathcal{Y}(t')} \left\{ \int_{t'}^{t'+\delta} \left[\frac{\partial \phi}{\partial t}(p_s, s) + \langle \nabla_p \phi(p_s, s), F(p_s, \mathbf{u}[y](s), y(s)) \rangle \right] ds \right\},$$

contradicting (4.32). Therefore $W(p, t)$ is a viscosity supersolution of (4.13). □

5. Verification theorem. The main reason for defining value functions and using dynamic programming is to determine optimal controls. Typically, some type of smoothness is required. The following theorem says essentially that if both (3.3) and (4.13) have smooth solutions, then the optimal control is obtained by finding the control value $\mathbf{u}^*(p,t)$ that attains the minimum in (4.13) as

$$\mathbf{u}^*[y](t) = \mathbf{u}^*(p[y]_t, t). \tag{5.1}$$

This control is an *information state feedback* controller and depends on the output y via the information state. This is a type of *separation principle* for this partially observed differential game.

THEOREM 5.1. *Assume that there exists a smooth solution $\tilde{W}$ of the DPE* (4.13). *If there exist $\mathbf{u}^* \in \mathbf{U}(t)$, $y^* \in \mathcal{Y}(t)$ such that*

$$\mathbf{u}^*(s) \in \operatorname*{argmin}_{u\in U}\{\langle \nabla_p W(p_s, s), -\nabla_x p_s \cdot f(\cdot, u) + L(\cdot, u)\rangle\}, \tag{5.2}$$

$$y^*(s) \in \operatorname*{argmax}_{y\in \mathbf{R}^p}\{\langle \nabla_p W(p_s, s), -\nabla_x p_s \cdot g(\cdot, y-h) - \gamma^2 \ell(y-h)\rangle\} \tag{5.3}$$

for a.e. $s \in [t,T]$, then $\mathbf{u}^*$ is optimal for the initial data $(p,t) \in \mathcal{D}\cap\mathcal{X}^1 \times [0,T]$ and $\tilde{W}(p,t) = W(p,t)$, where $(p,t) \in \mathcal{D}\cap\mathcal{X}^1$. In particular, for $(p,t) = (\alpha, 0) \in \mathcal{D}\cap\mathcal{X}^1 \times [0,T]$ the control $\mathbf{u}^*$ solves the partially observed minimax differential game.

Proof. Since $p_t(x)$ and $\tilde{W}(p,t)$ are smooth solutions ($t \le r \le T$, $p_t = p \in \mathcal{D}\cap\mathcal{X}^1$), Lemma 4.5 implies

$$\tilde{W}(p_r, r) = \tilde{W}(p_t, t) + \int_t^r \left[\frac{\partial \tilde{W}}{\partial t}(p_s, s) + \langle \nabla_p \tilde{W}(p_s, s), F(p_s, u(s), y(s))\rangle\right] ds. \tag{5.4}$$

Fix $y^* \in \mathcal{Y}(t)$ as in (5.3). Then for any $\mathbf{u} \in \mathbf{U}(t)$, we have, using the DPE (4.13) and (5.4) with $r = T$,

$$\begin{aligned}\tilde{W}(p,t) &= -\int_t^T \left[\frac{\partial \tilde{W}}{\partial t}(p_s, s) + \langle \nabla_p \tilde{W}(p_s, s), F(p_s, \mathbf{u}[y^*](s), y^*(s))\rangle\right] ds + (p_T, \Phi) \\ &\le (p_T, \Phi),\end{aligned}$$

with equality for $\mathbf{u} = \mathbf{u}^*$ as in (5.2). Therefore $\tilde{W}(p,t) \le W(p,t)$.

Conversely, let $\mathbf{u} = \mathbf{u}^*$ and $\varepsilon > 0$. Then there exists $y \in \mathcal{Y}(t)$ such that

$$W(p,t) \le (p_T, \Phi) + \varepsilon.$$

Using (5.4) and $r = T$, this gives

$$\begin{aligned}W(p,t) &\le \tilde{W}(p,t) + \int_t^T \left[\frac{\partial \tilde{W}}{\partial t}(p_s, s) + \langle \nabla_p \tilde{W}(p_s, s), F(p_s, u^*(s), y(s))\rangle\right] ds + \varepsilon \\ &\le \tilde{W}(p,t) + \int_t^T \left[\frac{\partial \tilde{W}}{\partial t}(p_s, s) + \langle \nabla_p \tilde{W}(p_s, s), F(p_s, u^*(s), y(s))\rangle\right] ds + \varepsilon \\ &\le \tilde{W}(p,t) + \varepsilon.\end{aligned}$$

Hence $W(p,t) \le \tilde{W}(p,t)$.

We conclude that $W(p,t) = \tilde{W}(p,t)$, and in fact

$$\tilde{W}(\alpha, 0) = J(\mathbf{u}^*) = \inf_{\mathbf{u}\in\mathbf{U}(0)} J(\mathbf{u}),$$

proving the optimality of $\mathbf{u}^*$. □

6. Relation to certainty equivalence. In this section we explain how the certainty equivalence principle [5], [9], [6] fits into the general framework developed in this paper. This issue was treated in discrete-time in [24], [21] and in the case of continuous-time bilinear systems in [32], [33]; see also [6]. The certainty equivalence principle is as follows.

Consider a state feedback differential game with value function $V(x,t)$ satisfying the DPE

$$\begin{cases} \dfrac{\partial V}{\partial t} + \inf\limits_{u\in U}\sup\limits_{w\in\mathbf{R}^p}\{\nabla_x V\cdot(f(x,u)+g(x,w)) - \gamma^2\ell(w) + L(x,u)\} = 0 \text{ in } \mathbf{R}^n\times(0,T), \\ V(x,T) = \Phi(x) \quad \text{in } \mathbf{R}^n. \end{cases} \tag{6.1}$$

Equation (6.1) is a nonlinear first-order PDE and need not possess smooth solutions; thus (6.1) must also be interpreted in the viscosity sense in general. The value function $V(x,t)$ is the unique viscosity solution of (6.1) and is bounded Lipschitz continuous. Let $u^s(x,t)$ denote the optimal state feedback control (if it exists), i.e., the control value attaining the minimum in (6.1). The *minimum stress estimate* is defined by

$$\bar{x}(t) \in \operatorname*{argmax}_{x\in\mathbf{R}^n}(p_t(x) + V(x,t)). \tag{6.2}$$

In [9] it is proven (for a closely related problem) that the *certainty equivalence* controller

$$u^{ce}(t) = u^s(\bar{x}(t),t) \tag{6.3}$$

is optimal provided (i) $p_t(x)$ is a smooth solution of (3.3), (ii) $V(x,t)$ is a smooth solution of (6.1), and, most significantly, (iii) $\bar{x}(t)$ is *unique*.

The following theorem provides a new interpretation of the certainty equivalence controller (see also [6], [21], [24], [32], [33]).

THEOREM 6.1. *Fix a point* $(p^1,t^1)\in\mathcal{D}\cap\mathcal{X}^1\times(0,T)$, *and assume that*

(i) $V(x,t) = V_t(x)$ *is a smooth solution of* (6.1);

(ii) *the quantity*

$$\bar{x}_{t^1}(p^1) = \operatorname*{argmax}_{x\in\mathbf{R}^n}(p^1(x) + V_{t^1}(x)) \tag{6.4}$$

is unique (i.e., the maximum is attained at a unique point).
Then the function $\tilde{W}\in C(\mathcal{D}\cap\mathcal{X}\times[0,T])$ *defined by*

$$\tilde{W}(p,t) = (p, V_t) \tag{6.5}$$

(sup-pairing) is $\mathcal{X}$*-Gateaux differentiable at* (p^1,t^1) *and satisfies the DPE* (4.13) *at* (p^1,t^1). *Further, the optimal control at the point* (p^1,t^1) *is given by*

$$\mathbf{u}^*_{t^1}(p^1) = u^s(\bar{x}_{t^1}(p^1),t^1) = u^{ce}(t^1). \tag{6.6}$$

Proof. 1. We claim first that the Gateaux derivative $\partial_p\tilde{W}(p^1,t^1)$ is given by

$$\partial_p\tilde{W}(p^1,t^1) = E_{\bar{x}_{t^1}(p^1)}, \tag{6.7}$$

where $E_x\in\mathcal{X}^*$ is the evaluation map

$$\langle E_x, q\rangle = q(x), \quad (q\in\mathcal{X}). \tag{6.8}$$

For brevity, write $\bar{x} = \bar{x}_{t^1}(p^1)$, $\phi(p) = (p,V)$, $V(x) = V_{t^1}(x)$, and let $q\in\mathcal{X}$, $\varepsilon>0$. Since $p^1\in\mathcal{D}\cap\mathcal{X}$, $\phi(p^1+\varepsilon q)$ is finite for all ε sufficiently small, and $\phi(p^1+\varepsilon q)\to f(p^1)$,

$\bar{x}^\varepsilon \to \bar{x}$ as $\varepsilon \to 0$ by hypothesis (iii), where $\bar{x}^\varepsilon \in \operatorname{argmax}_{x\in\mathbf{R}^n}(p^1(x) + \varepsilon q(x) + V_{t^1}(x))$. We must show that

$$\lim_{\varepsilon\to 0} \frac{\phi(p^1 + \varepsilon q) - \phi(p^1)}{\varepsilon} = q(\bar{x}). \tag{6.9}$$

Now

$$\phi(p^1 + \varepsilon q) - \phi(p^1) \geq p^1(\bar{x}) + \varepsilon q(\bar{x}) + V(\bar{x}) - (p^1(\bar{x}) + V(\bar{x})) = \varepsilon q(\bar{x}),$$

and hence

$$\liminf_{\varepsilon\to 0} \frac{\phi(p^1 + \varepsilon q) - \phi(p^1)}{\varepsilon} \geq q(\bar{x}).$$

Similarly,

$$\phi(p^1 + \varepsilon q) - \phi(p^1) \leq p^1(\bar{x}^\varepsilon) + \varepsilon q(\bar{x}^\varepsilon) + V(\bar{x}^\varepsilon) - (p^1(\bar{x}^\varepsilon) + V(\bar{x}^\varepsilon)) = \varepsilon q(\bar{x}^\varepsilon),$$

and hence

$$\limsup_{\varepsilon\to 0} \frac{\phi(p^1 + \varepsilon q) - \phi(p^1)}{\varepsilon} \leq q(\bar{x}).$$

These two inequalities prove (6.9), establishing the claim.

2. It follows from Danskin's theorem (see [5, App.]) that

$$\begin{aligned} \frac{\partial \tilde{W}}{\partial t}(p^1, t^1) &= \frac{\partial V}{\partial t}(\bar{x}, t^1), \\ \nabla_x V(\bar{x}, t^1) &= -\nabla_x p^1(\bar{x}). \end{aligned} \tag{6.10}$$

The gradient $\nabla_x p^1$ is well defined since $p^1 \in \mathcal{X}^1$.

3. Next substitute the derivatives calculated above into the left-hand side of DPE (4.13) to yield

$$\begin{aligned} &\frac{\partial \tilde{W}}{\partial t}(p^1, t^1) + \inf_{u\in U} \sup_{y\in\mathbf{R}^p} \langle \partial_p \tilde{W}(p^1, t^1), F(p^1, u, y)\rangle \\ &= \frac{\partial V}{\partial t}(\bar{x}, t^1) + \inf_{u\in U} \sup_{y\in\mathbf{R}^p} \langle E_{\bar{x}}, -\nabla_x p^1 \cdot (f(\cdot, u) + g(\cdot, y-h)) + L(\cdot, u) - \gamma^2 \ell(h-y)\rangle \\ &= -\inf_{u\in U} \sup_{w\in\mathbf{R}^p} \left[\nabla_x V(\bar{x}, t^1) \cdot (f(\bar{x}, u) + g(\bar{x}, w)) - \gamma^2 \ell(w) + L(\bar{x}, u)\right] \\ &\quad + \inf_{u\in U} \sup_{y\in\mathbf{R}^p} \left[\nabla_x V(\bar{x}, t^1) \cdot (f(\bar{x}, u) + g(\bar{x}, y-h)) - \gamma^2 \ell(y-h) + L(\bar{x}, u)\right] \\ &= 0. \end{aligned} \tag{6.11}$$

This proves that $\tilde{W}$ satisfies the DPE at (p^1, t^1).

4. Finally, the above calculation yields explicitly the formula (6.6). □

Remark 6.2. If the minimum stress estimate (6.4) is not unique, i.e. contains more than one point, then in general the function $\tilde{W}(p, t)$ defined by (6.5) is not a solution of (4.13). To see this, we know from Lemma 4.2 that $\bar{x} = \bar{x}_{t^1}(p^1)$ is compact. The proof of Theorem 6.1 shows that

$$\partial_p \tilde{W}(p^1, t^1) \geq \max_{x\in\bar{x}_{t^1}(p^1)} E_x. \tag{6.12}$$

Hence in place of (6.11), Theorem 6.1, we have (for $x \in \bar{x}$)

$$\begin{aligned}
&\frac{\partial \tilde{W}}{\partial t}(p^1, t^1) + \inf_{u\in U} \sup_{y\in \mathbf{R}^p} \langle \partial_p \tilde{W}(p^1, t^1), F(p^1, u, y)\rangle \\
&\geq \frac{\partial V}{\partial t}(x, t^1) + \inf_{u\in U} \sup_{y\in \mathbf{R}^p} \sup_{x\in \bar{x}} \langle E_x, -\nabla_x p^1 \cdot (f(\cdot, u) + g(\cdot, y-h)) + L(\cdot, u) - \gamma^2 \ell(h-y)\rangle \\
&= -\inf_{u\in U} \sup_{w\in \mathbf{R}^p} \left[\nabla_x V(x, t^1)\cdot (f(x,u) + g(x,w)) - \gamma^2 \ell(w) + L(x,u)\right] \\
&\quad + \inf_{u\in U} \sup_{y\in \mathbf{R}^p} \sup_{x\in \bar{x}} \left[\nabla_x V(x, t^1)\cdot (f(x,u) + g(x,y-h)) - \gamma^2 \ell(y-h) + L(x,u)\right] \\
&\geq -\inf_{u\in U} \sup_{w\in \mathbf{R}^p} \left[\nabla_x V(x, t^1)\cdot (f(x,u) + g(x,w)) - \gamma^2 \ell(w) + L(x,u)\right] \\
&\quad + \sup_{x\in \bar{x}} \inf_{u\in U} \sup_{y\in \mathbf{R}^p} \left[\nabla_x V(x, t^1)\cdot (f(x,u) + g(x,y-h)) - \gamma^2 \ell(y-h) + L(x,u)\right] \\
&\geq 0.
\end{aligned} \tag{6.13}$$

This inequality can be strict in general. This calculation suggests that $\tilde{W}(p, t)$ is a *subsolution* of (4.13), but not in general a solution, and consequently

$$W(p, t) \geq \tilde{W}(p, t). \tag{6.14}$$

7. H_∞ control. As an application of the above results, we consider a relatively simple nonlinear H_∞ control problem, viz. finite-horizon disturbance attenuation. Some comments on the infinite-horizon problem will be made in §8.2. We follow closely the approach initiated in [4], [23]. We emphasize that we provide both necessary and sufficient conditions in terms of two PDEs—one defined on a finite-dimensional space $\mathbf{R}^n$, the other defined on an infinite-dimensional space $\mathcal{D} \cap \mathcal{X}$.

Associated with the system (2.1) is the performance output z (not measured) given by

$$z(t) = l(x(t), u(t)). \tag{7.1}$$

To maintain consistency with earlier notation, we set $L(x, u) = \frac{1}{2}|l(x, u)|^2$ and $\Phi = 0$. We assume that zero is an equilibrium; that is, $f(0, 0) = 0$, $g(0, 0) = 0$, $h(0) = 0$, $l(0, 0) = 0$.

Given $\gamma > 0$ and a fixed time interval $[0, T]$, the disturbance attenuation H_∞ problem is to find an output feedback control $\mathbf{u} \in \mathbf{U}(0)$ such that the resulting closed loop system $\Sigma^{\mathbf{u}}$ is *finite gain* $[0, T]$, i.e.,

$$\left\{\frac{1}{2}\int_0^T |z(t)|^2\, dt \leq \frac{\gamma^2}{2}\int_0^T \ell(w(t))\, dt + \beta(x_0) \quad \text{for all } w \in \mathcal{W}(0),\right. \tag{7.2}$$

for some function $\beta(x) \geq 0$, $\beta(0) = 0$, $-\beta \in \mathcal{D} \cap \mathcal{X}$.

Clearly, $\Sigma^{\mathbf{u}}$ is finite gain on $[0, T]$ if and only if

$$J(\mathbf{u}) \leq 0 \text{ for } p_0 = \alpha = -\beta. \tag{7.3}$$

THEOREM 7.1. *If there exists a solution of the finite-time H_∞ problem, then there exist solutions of the PDEs* (3.3) *and* (4.13) *such that $p_0 = -\beta$ and $W(-\beta, 0) = 0$ for some $\beta(x) \geq 0$ with $\beta(0) = 0$. Conversely, if there exist smooth solutions of the PDEs* (3.3) *and* (4.13) *such that $p_0 = -\beta$ and $W(-\beta, 0) = 0$, for some $\beta(x) \geq 0$ with $\beta(0) = 0$, then the controller $\mathbf{u}^*$ defined by* (5.1), (5.2) *solves the finite-time H_∞ problem.*

Proof. 1. Assume that a control $\mathbf{u}^o \in \mathbf{U}(0)$ solves the finite-time H_∞ problem, and set $p_0 = -\beta^{\mathbf{u}^o}$. Then

$$J(\mathbf{u}^o) \leq 0,$$

and in fact

$$0 = (-\beta^{\mathbf{u}^o}, 0) \leq W(-\beta^{\mathbf{u}^o}, 0) \leq 0,$$

as in Lemma 4.1. Thus $W(-\beta^{\mathbf{u}^o}, 0) = 0$. Solutions to the PDEs (3.3) and (4.13) exist according to the results in earlier sections in the viscosity sense.

2. Conversely, if (3.3) and (4.13) have smooth solutions, then the verification Theorem 5.1 implies that the control $\mathbf{u}^*$ given by (5.1), (5.2) is optimal. Therefore, with $p_0 = -\beta$,

$$J(\mathbf{u}^*) = W(-\beta, 0) = 0,$$

which implies that $\Sigma^{\mathbf{u}^*}$ is finite gain on $[0, T]$. □

8. Remarks.

8.1. General partially observed differential games. We expect that the results developed in this paper will extend to much more general situations. However, additional technical difficulties arise. For instance, suppose (2.1) is replaced by

$$\begin{cases} \dot{x}(t) = f(x(t), u(t)) + g(x(t), w(t)), \\ y(t) = h(x(t)) + v(t), \end{cases} \tag{8.1}$$

where $v(\cdot)$ is a second independent and unknown disturbance input. In this case, the function $F(p, u, y)$ governing the information state dynamics is nonlinear:

$$F(p, u, y) = \sup_w \{-\nabla_x p \cdot (f(\cdot, u) + g(\cdot, w)) + L(\cdot, u) - \gamma^2 \ell(w, y - h)\}. \tag{8.2}$$

A consequence of this is that (3.3) does not in general have smooth solutions (even if α is smooth). This complicates substantially the proof that the value function $W(p, t)$ is a viscosity solution of the corresponding HJI equation (4.13).

8.2. Infinite-horizon H_∞ control. The theory of dissipative systems [18], [36] provides a powerful framework for treating infinite-horizon H_∞ problems, and many of the articles listed in the reference section make use of this theory. In the state feedback case, one is led to a partial differential inequality (PDI); see, e.g., [2], [18], [20], [34], [36]. In particular, it is shown in [2] and [20] that the PDI can be interpreted in the viscosity sense.

In the discrete-time case, the infinite-horizon output feedback H_∞ problem was discussed in [23], and an infinite-dimensional dissipation inequality was used. The continuous-time analogue of this inequality is an infinite-dimensional PDI, closely related to the steady-state version of (4.13). The PDI is

$$\begin{cases} \inf_{u \in U} \sup_{y \in \mathbf{R}^p} \langle \nabla_p W, F(p, u, y) \rangle \leq 0 \text{ in } \mathcal{D} \cap \mathcal{X}^1, \\ W(p) \geq (p, 0) \text{ in } \mathcal{D} \cap \mathcal{X}, \\ W(-\beta) = 0. \end{cases} \tag{8.3}$$

A theory of infinite-horizon H_∞ control can be developed using this type of equation; see [16]. It is possible to prove the existence of a function $W(p)$ satisfying (8.3) in the viscosity sense (i.e., as a viscosity supersolution), using a stationary version of the definition given in §4. An explicit storage function for the closed-loop system is defined in [15].

Acknowledgment. We wish to thank Professor W. H. Fleming for some interesting and useful discussions.

INVERSE OPTIMALITY IN ROBUST STABILIZATION*

R. A. FREEMAN† AND P. V. KOKOTOVIC†

Abstract. The concept of a robust control Lyapunov function (rclf) is introduced, and it is shown that the existence of an rclf for a control-affine system is equivalent to robust stabilizability via continuous state feedback. This extends Artstein's theorem on nonlinear stabilizability to systems with disturbances. It is then shown that every rclf satisfies the steady-state Hamilton–Jacobi–Isaacs (HJI) equation associated with a meaningful game and that every member of a class of pointwise min-norm control laws is optimal for such a game. These control laws have desirable properties of optimality and can be computed directly from the rclf without solving the HJI equation for the upper value function.

Key words. nonlinear systems, robust stabilization, control Lyapunov functions, input-to-state stability, differential games

1. Introduction.

The relationship between stability and optimality has been a central issue in the optimal stabilization problem ever since the advent of the steady-state Hamilton–Jacobi–Bellman (HJB) equation. Optimal feedback systems enjoy many desirable properties beyond stability, provided the optimality is meaningful, that is, provided the associated cost functional places suitable penalty on the state and control. For example, linear-quadratic optimal control systems have favorable gain and phase margins and reduced sensitivity [1]. Similar robustness properties have been shown to hold also for nonlinear control systems that are optimal with respect to meaningful cost functionals [14]. Another consequence of optimality is that control effort is not wasted to counteract beneficial nonlinearities. Optimality is thus a discriminating measure by which to select from among the entire set of stabilizing control laws those with desirable properties. Unfortunately, its usefulness as a synthesis tool for nonlinear systems is hampered by the computational burden associated with the HJB equation. In this paper we explore the links between stability and optimality with the aim of developing a synthesis strategy that achieves the desirable properties of optimality but avoids HJB computations.

An important link between stability and optimality is well known; the value function for a meaningful optimal stabilization problem is also a Lyapunov function for the closed-loop system. In short,

- *Every meaningful value function is a Lyapunov function.*

One purpose of this paper is to establish the converse link. We show that every Lyapunov function for every stable closed-loop system is also a value function for a meaningful optimal stabilization problem. In short,

- *Every Lyapunov function is a meaningful value function.*

While the first link has implications for the *analysis* of optimal feedback control systems, this converse link will have implications for their *synthesis*.

For systems with control inputs, the property of interest is stabilizability rather than stability. We therefore base our theory on the *control Lyapunov function* (clf) [2, 39, 34] rather than the Lyapunov function. Although quite old, the clf concept was not formalized until Artstein proved that the existence of a clf for a control-affine system is equivalent to

*Received by the editors November 18, 1993; accepted for publication (in revised form) April 17, 1995. stabilizability via continuous (ordinary) state feedback [2]. The above converse link between stability and optimality can be restated as

- *Every* clf *is a meaningful value function.*

This will be a corollary of a more general result that we prove for the *robust* stabilizability of systems with both control and disturbance inputs. We first extend Artstein's theorem to such systems by introducing the *robust control Lyapunov function* (rclf) and showing that its existence is equivalent to robust stabilizability via continuous state feedback. We then show that every rclf is an upper value function for a meaningful two-person zero-sum differential game, the opposing players being the control and the disturbance. In short,

- *Every* rclf *is a meaningful upper value function.*

To prove this, we show that every rclf solves the steady-state Hamilton–Jacobi–Isaacs (HJI) equation associated with a meaningful game. As a consequence of this result, if an rclf is known, we can construct a feedback law that is optimal with respect to a meaningful cost functional. Moreover, we can accomplish this *without* solving the HJI equation for the upper value function. In fact, we do not even need to construct the cost functional because we can calculate the optimal feedback directly from the rclf without recourse to the HJI equation. Indeed, we provide a formula that generates a class of such optimal control laws and that involves only the rclf, the system equations, and design parameters. The control laws given by our formula are called *pointwise min-norm* control laws, and each one inherits the desirable properties of optimality because

- *Every pointwise min-norm control law is optimal for a meaningful game.*

Let us now summarize the synthesis strategy suggested by our results. The first step is to find an rclf for our system. Fortunately, techniques for the systematic construction of rclfs for many classes of nonlinear systems are beginning to appear [28, 25, 32, 7, 29, 12, 26]. Even feedback linearization can be viewed as such a technique for systems with no disturbances [13]. Once an rclf is known, we choose design parameters and use our formula to generate a pointwise min-norm control law. This control law will have the desirable properties of optimality even though its construction is independent of any cost functional or HJI equation.

Our results represent a missing ingredient in Lyapunov design. We provide a systematic, optimality-based method for choosing a control law once an rclf is known. To fully appreciate the importance of this contribution, one should recall that other methods for choosing the control law, based on the cancellation or domination of nonlinear terms, do not necessarily possess the desirable properties of optimality and may lead to poor robustness and wasted control effort. Let us illustrate this point on an elementary example. Suppose we wish to robustly stabilize the first-order system

$$\dot{x} = -x^3 + u + wx, \tag{1}$$

where u is the control input and w is the disturbance input satisfying $|w(t)| \leqslant 1$. A control law suggested by feedback linearization would cancel the nonlinearity $-x^3$ as

$$u = x^3 - 2x. \tag{2}$$

This control law obviously (globally) asymptotically stabilizes the equilibrium at $x = 0$ for any admissible disturbance $w(t)$. However, it is an absurd choice because the term x^3 in (2) represents control effort wasted to cancel a beneficial nonlinearity. Moreover, this term is actually *positive* feedback that increases the risk of instability. It is easy to find a better control law for this simple system, but what we desire is a *systematic* method for choosing the control law that prevents wasteful mistakes like (2). The method we propose in this paper is based on the pointwise min-norm control law. For this example, the simplest pointwise min-norm

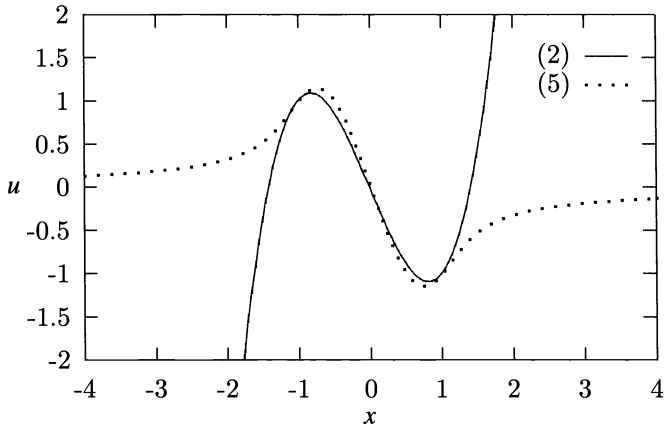

FIG. 1. *A comparison between the control laws* (2) *and* (5).

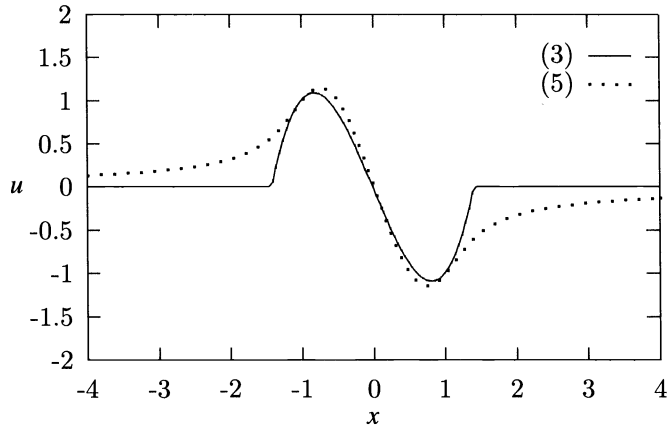

FIG. 2. *A comparison between the control laws* (3) *and* (5).

control law is

$$u = \begin{cases} x^3 - 2x & \text{when } x^2 < 2, \\ 0 & \text{when } x^2 \geqslant 2. \end{cases} \tag{3}$$

For the sake of comparison, we also solved the HJI equation associated with the system (1) and the cost functional

$$J = \int_0^\infty [x^2 + u^2]dt. \tag{4}$$

The resulting optimal feedback law is

$$u = x^3 - x - x\sqrt{x^4 - 2x^2 + 2}. \tag{5}$$

The three control laws (2), (3), and (5) are plotted in Figs. 1 and 2. We see that the control laws (3) and (5), both of which are optimal with respect to a meaningful cost functional, are very similar. They both recognize the benefit of the nonlinearity $-x^3$ in (1) and accordingly expend little control effort for large signals; moreover, these control laws are never positive

feedback. The main difference between them lies in their synthesis. The pointwise min-norm control law (3) came from a simple formula, while the control law (5) required the solution of an HJI equation. In general, the pointwise min-norm calculation is feasible, but the HJI calculation is not.

We can interpret our results in this paper as a solution to an *inverse optimal stabilization problem* in a differential game setting. The first inverse problem to be formulated and solved was for linear time-invariant systems [17, 1], where the authors identified those stabilizing gain matrices that were also optimal with respect to some quadratic cost. Inverse problems for nonlinear systems have since been considered but with more limited success. As described in the survey paper [14], the task is to choose a candidate value function and then to construct a meaningful cost functional so that the corresponding HJB equation holds. For open-loop stable nonlinear systems, one can obtain a solution by choosing the candidate value function to be a Lyapunov function for the open-loop system [16, 14]. In this paper, we extend this result to open-loop *unstable* systems by choosing the candidate value function to be a clf for the system. We provide a further generalization by solving an inverse optimal *robust* stabilization problem for systems with disturbances; we show that every rclf is an upper value function for a meaningful game.

This paper is organized as follows. We briefly list some notation and terminology in §2. This includes a review of continuity concepts for set-valued maps and statement of Michael's selection theorem. We use set-valued maps throughout this paper for three reasons. First, they arise naturally in optimization problems as the subdifferentials of convex functions; second, they allow us to weaken some assumptions; and third, they generate more concise notation.

In §3 we formulate the robust stabilization problem of achieving the *guaranteed global stability* of the closed-loop system in the presence of any admissible disturbance. In this formulation, we assume knowledge of a *bounded* set in which the disturbance is allowed to take its values. The guaranteed stability formulation has a long history (see for example [20, 15, 11, 6, 8] and the references therein), and it includes as a special case the *quadratic stability* of linear systems (see the recent survey [10] for references). In §4 we introduce the rclf and prove that its existence is sufficient for a system to be robustly stabilizable via continuous state feedback. In §5 we show that the existence of an rclf is also necessary for robust stabilizability. This necessity result relies on a converse Lyapunov theorem recently proved in [24]. Many Lyapunov-based controller designs for guaranteed stability can be cast in our rclf framework [20, 15, 11, 6–8, 28, 25, 32, 29, 12]; in particular, the control Lyapunov function defined in [31] for quadratic stability is a special kind of rclf.

In §6 we do *not* assume knowledge of a bounded set in which the disturbance is allowed to take its values. We instead consider the design objective of achieving the *input-to-state stability* of the closed-loop system (with the disturbance regarded as the input). This type of stability was introduced in [33] and is becoming a popular tool in the Lyapunov design and analysis of nonlinear systems. In §6 we show that input-to-state stabilizability is equivalent to the existence of an rclf for an auxiliary system.

In §7 we define the class of pointwise min-norm control laws described above. Our formula for this class of control laws generates those values of the control that minimize the instantaneous control effort while maintaining some desired negativity of the worst case Lyapunov derivative. In §§8–10 we show that each pointwise min-norm control law is optimal for a meaningful game and that every rclf solves the steady-state HJI equation associated with such a game. In §§8 and 9 we consider cost functionals defined over the infinite horizon, in which case we require the disturbances to vanish at the equilibrium. In §10 we allow persistent disturbances and consider cost functionals defined over a finite horizon determined by the time required to reach a given target set.

2. Notation and terminology. In what follows, Z and Y are metric spaces with both metrics denoted by $d(\cdot, \cdot)$ and X is a Hilbert space with inner product $\langle \cdot, \cdot \rangle$ (or $\cdot^T \cdot$) and norm $\| \cdot \|$.

For a subset $C \subset Z$ and a point $z \in Z$, we let either $d(z, C)$ or $|z|_C$ denote the number $\inf\{d(z, \xi) : \xi \in C\}$. We let $\overline{C}$ denote the closure of C, we let $\operatorname{int} C$ denote the interior of C, and we let $\partial C = \overline{C} \setminus \operatorname{int} C$ denote the boundary of C. For a sequence $\{C_i\}$ of subsets of Z, we let $\operatorname{Limsup} C_i$ denote the set $\{z \in Z : \liminf d(z, C_i) = 0\}$ of cluster points of sequences $z_i \in C_i$.

By $A : Z \rightsquigarrow Y$ we mean a set-valued map A mapping points in Z to subsets of Y. For such maps we let $\operatorname{Graph}(A)$ denote the set $\{(z, y) \in Z \times Y : y \in A(z)\}$. We say A is upper semicontinuous (usc) at a point $z \in Z$ when for every open set $N \subset Y$ satisfying $A(z) \subset N$ there exists an open neighborhood M of z such that $A(\xi) \subset N$ for all $\xi \in M$. We say A is lower semicontinuous (lsc) at a point $z \in Z$ when for every open set $N \subset Y$ satisfying $A(z) \cap N \neq \emptyset$ there exists an open neighborhood M of z such that $A(\xi) \cap N \neq \emptyset$ for all $\xi \in M$ (where $\emptyset$ denotes the empty set). An equivalent definition of lower semicontinuity is as follows ([5, Def. 1.4.2; 19, Thm. II.2.9]). A is lsc at a point $z \in Z$ when for every sequence $\{z_i\} \in Z$ converging to z and every $y \in A(z)$ there exists a sequence $\{y_i\} \in Y$ converging to y and $N \geqslant 1$ such that $y_i \in A(z_i)$ for all $i \geqslant N$. We say A is continuous at a point $z \in Z$ when it is both usc and lsc at z. We say A is locally Lipschitz when for each $z \in Z$ there exists an open neighborhood M of z and a constant $L \geqslant 0$ such that for all $\xi_1, \xi_2 \in M$ we have $y \in A(\xi_1)$ implies $d(y, A(\xi_2)) \leqslant L \cdot d(\xi_1, \xi_2)$. Michael's selection theorem [19, Thm. II.4.1] states that if Y is a Banach space and A is lsc with nonempty closed convex values, then A admits a continuous selection, that is, there exists a continuous (single-valued) function $a : Z \to Y$ such that $a(z) \in A(z)$ for all $z \in Z$.

We let B_X denote the closed unit ball of X, abbreviated B when no confusion is likely to arise. For a subset $D \subset X$ we let $\|D\|$ denote the number $\sup\{\|x\| : x \in D\}$. For $\lambda \in R$ we let λD denote the set $\{\lambda x : x \in D\}$. We let $\operatorname{co}(D)$ denote the convex hull of D, and we let $\overline{\operatorname{co}}(D)$ denote the closed convex hull of D. We let $D^\perp$ denote the set $\{x \in X : \langle x, D \rangle = \{0\}\}$. If D is convex and $x \in D$, we let $N_D(x) \subset X$ denote the normal cone to D at x. For $x \in X \setminus \{0\}$ we let $\operatorname{sgn}(x)$ denote the vector $x/\|x\|$. If W is another normed space, we let $\mathcal{B}(X, W)$ denote the normed space of bounded linear operators from X to W. For a convex function $h : X \to R$ we let $\partial h : X \rightsquigarrow X$ denote the subdifferential of h. We let R_+ denote the closed interval $[0, \infty)$. We say a function $\chi : R_+ \to R_+$ is of class $\mathcal{K}$ when χ is continuous, strictly increasing, and $\chi(0) = 0$. We say χ is of class $\mathcal{K}_\infty$ when χ is of class $\mathcal{K}$ and satisfies $\chi(r) \to \infty$ as $r \to \infty$. We say a function $\beta : R_+ \times R_+ \to R_+$ is of class $\mathcal{KL}$ when $\beta(\cdot, t)$ is of class $\mathcal{K}$ for each fixed $t \in R_+$ and $\beta(r, t)$ decreases to zero as $t \to \infty$ for each fixed $r \in R_+$. By C^1 we mean having a continuous (first) derivative, and by smooth we mean having continuous derivatives of any order.

3. Robust stabilizability. Let us consider three finite-dimensional Euclidean spaces: the *state space* $\mathcal{X}$, the *control space* $\mathcal{U}$, and the *disturbance space* $\mathcal{W}$. Given a continuous function $f : \mathcal{X} \times \mathcal{U} \times \mathcal{W} \to \mathcal{X}$ we define the differential equation

$$\dot{x} = f(x, u, w), \tag{6}$$

where $x(t)$ is the state trajectory taking values in $\mathcal{X}$ and satisfying an initial condition $x(0) = x_0$, $u(t)$ is the control input taking values in $\mathcal{U}$, and $w(t)$ is the disturbance input taking values in $\mathcal{W}$. Associated with the control and disturbance are constraints given by set-valued maps $U : \mathcal{X} \rightsquigarrow \mathcal{U}$ and $W : \mathcal{X} \rightsquigarrow \mathcal{W}$, respectively. The *system* Σ is (6) together with these constraints, $\Sigma := (f, U, W)$. Our standing assumptions on Σ are as follows.

A1. For each $(x, w) \in \mathcal{X} \times \mathcal{W}$, the mapping $u \mapsto f(x, u, w)$ is affine.

A2. The control constraint U is lsc with nonempty closed convex values.

A3. The disturbance constraint W is usc with nonempty compact values.

Our most restrictive assumption is A1, which requires that the system be affine in the control variable. It may be possible to remove this assumption by considering *relaxed controls* as in [2].

A *control law* for Σ is a continuous function $k : \mathcal{X} \to \mathcal{U}$ that satisfies the control constraint U; that is, for each $x \in \mathcal{X}$ we have $k(x) \in U(x)$. Assumption A2 together with Michael's theorem guarantee the existence of a control law for Σ. Each control law k for Σ defines a closed-loop differential equation

$$\dot{x} = f(x, k(x), w). \tag{7}$$

We let $\mathcal{C}(\Sigma)$ denote the set of all functions $u_g : \mathcal{X} \times R_+ \to \mathcal{U}$ such that $u_g(x, t)$ is continuous in x for each fixed $t \in R_+$ and locally bounded and (Lebesgue) measurable in t for each fixed $x \in \mathcal{X}$. These functions u_g are called *generic controls*, and they need not satisfy the control constraint U. We give the obvious meaning to the abuse of notation $k(x) \in \mathcal{C}(\Sigma)$ for a control law k defined on $\mathcal{X}$ so that the set of control laws for Σ can be regarded as a subset of the set of generic controls $\mathcal{C}(\Sigma)$. Similarly, we let $\mathcal{D}(\Sigma)$ denote the set of all functions $w_a : \mathcal{X} \times \mathcal{U} \times R_+ \to \mathcal{W}$ such that $w_a(x, u, t)$ is continuous in (x, u) for each fixed $t \in R_+$ and measurable in t for each fixed $(x, u) \in \mathcal{X} \times \mathcal{U}$, and furthermore $w_a(x, u, t) \in W(x)$ for all $(x, u, t) \in \mathcal{X} \times \mathcal{U} \times R_+$. These functions w_a are called *admissible disturbances*, and they are required to satisfy the disturbance constraint W. Again, we allow the abuse of notation $w_a(t) \in \mathcal{D}(\Sigma)$ and $w_a(x, u) \in \mathcal{D}(\Sigma)$ for functions defined on R_+ and $\mathcal{X} \times \mathcal{U}$, respectively. Implicit throughout this paper is the assumption that $\mathcal{D}(\Sigma)$ is nonempty.

It follows from assumption A3 [19, Prop. II.2.3] and standard existence theorems that for every generic control $u_g \in \mathcal{C}(\Sigma)$ and every admissible disturbance $w_a \in \mathcal{D}(\Sigma)$, solutions to the differential equation

$$\dot{x} = f\big(x,\ u_g(x, t),\ w_a(x, u_g(x, t), t)\big) \tag{8}$$

exist locally from every initial condition and bounded solutions can be extended for all $t \geqslant 0$. Note that we are *not* requiring the uniqueness of solutions. To summarize, we have defined *generic controls* that need not satisfy the constraint U, and we have defined *control laws* and *admissible disturbances* that are required to satisfy the constraints U and W, respectively.

Our formulation allows the constraint sets U and W to vary with the state x as in [3]. Sometimes we can parameterize these set-valued maps to obtain an equivalent formulation with *constant* constraints. For example, suppose $\mathcal{X} = \mathcal{W} = R$ and $W(x) = [-x^2, x^2]$ for all $x \in R$. We can parameterize W by setting $w = \widehat{w}\, x^2$ with $\widehat{w} \in [-1, 1]$; we then obtain an equivalent formulation with a constant disturbance constraint $\widehat{W} := [-1, 1]$. Continuous parameterizations always exist for continuous set-valued maps with nonempty compact convex values [4, Thm. 1.7.2]. However, even if such a parameterization for U exists, it may lead to an equivalent formulation that violates assumption A1. Furthermore, by allowing state-varying control constraints, we can sometimes satisfy assumption A1 by redefining the control *without* introducing less practical relaxed controls. For example, suppose we have $\mathcal{X} = \mathcal{U} = R$ and $\dot{x} = f_0(x, w) + (x + u)^3$ where $U = [-1, 1]$ is a constant control constraint. This system is not affine in the control u. However, if we redefine the control by setting $\widehat{u} := (x + u)^3$, we obtain a system that is now affine in the control $\widehat{u}$ but that has a state-varying control constraint $\widehat{U}(x) := \big[(x - 1)^3,\ (x + 1)^3\big]$.

Given a control law k for Σ, we will consider two types of robust stability for the closed-loop system (7). If $f(0, k(0), w) = 0$ for every $w \in W(0)$, then the system has a robust equilibrium solution $x(t) \equiv 0$ and we can possibly achieve the global uniform asymptotic

stability of this equilibrium solution. Otherwise we can only hope to achieve convergence to some compact *residual set* Ω containing the point $x = 0$.

DEFINITION 3.1. *Let Ω be a compact subset of $\mathcal{X}$ such that $0 \in \Omega$. The solutions of* (7) *are* robustly globally uniformly asymptotically stable with respect to Ω (RGUAS-Ω) *when there exists a class $\mathcal{KL}$ function β such that for any initial condition $x_0 \in \mathcal{X}$ and any admissible disturbance $w = w_a \in \mathcal{D}(\Sigma)$, all solutions $x(t)$ starting from x_0 exist for all $t \geqslant 0$ and satisfy $|x(t)|_\Omega \leqslant \beta(|x_0|_\Omega, t)$ for all $t \geqslant 0$. The solutions of* (7) *are* RGUAS *when they are* RGUAS-$\{0\}$.

This type of robust stability, defined for example in [24], is uniform with respect to admissible disturbances. Note that RGUAS-Ω implies that the residual set Ω is (robustly) positively invariant. We next define three types of stabilizability for the system Σ in the order of decreasing restrictiveness.

DEFINITION 3.2. *The system Σ is* robustly asymptotically stabilizable (RAS) *when there exists a control law k such that the solutions of* (7) *are* RGUAS. *The system Σ is* robustly practically stabilizable (RPS) *when for every $\varepsilon > 0$ there exists a control law k and a compact set $\Omega \subset \mathcal{X}$ satisfying $0 \in \Omega \subset \varepsilon B$ such that the solutions of* (7) *are* RGUAS-Ω. *The system Σ is* robustly stabilizable (RS) *when there exists a control law k and a compact set $\Omega \subset \mathcal{X}$ satisfying $0 \in \Omega$ such that the solutions of* (7) *are* RGUAS-Ω.

Clearly RAS $\Rightarrow$ RPS $\Rightarrow$ RS. The difference between RPS and RS is that if the system is RPS, then the residual set Ω can be made arbitrarily small by choice of the control law, whereas if the system is only RS, then there is a lower limit on the size of Ω. However, even if the system is only RS, we can often make Ω arbitrarily small in some directions by allowing it to grow in others.

Although we have described our system in finite-dimensional spaces $\mathcal{X}, \mathcal{U}$, and $\mathcal{W}$, many of the results in this paper can easily be modified to be valid also in infinite dimensions. For example, the results in §4 can be extended to the case where $\mathcal{X}$ and $\mathcal{U}$ are Banach spaces and $\mathcal{W}$ is a metric space, provided one assumes or can guarantee the existence of solutions to (8). Likewise, the results in §§7–10 can be extended to the case where $\mathcal{X}$ is a Banach space and $\mathcal{W}$ is a metric space.

4. Robust control Lyapunov functions. Our main tool is the *robust control Lyapunov function* (rclf) defined for a system Σ. The rclf represents an extension of the control Lyapunov function (clf) [2, 39, 34] to systems with disturbances. In this section we show that the existence of an rclf implies robust stabilizability, and in §5 we show that its existence is necessary for robust stabilizability. These results extend Artstein's theorem [2, Thm. 5.1] to systems with disturbances.

Let $\mathcal{A}(\mathcal{X})$ denote the class of continuous positive definite functions on $\mathcal{X}$, that is, continuous functions $\alpha : \mathcal{X} \to R_+$ such that $\alpha(0) = 0$ and $\alpha(x) > 0$ for $x \in \mathcal{X} \setminus \{0\}$. Let $\mathcal{A}_\kappa(\mathcal{X})$, respectively $\mathcal{A}_\infty(\mathcal{X})$, denote the set of those functions $\alpha \in \mathcal{A}(\mathcal{X})$ for which there exists a class $\mathcal{K}$, respectively class $\mathcal{K}_\infty$, function χ such that $\alpha(x) \geqslant \chi(\|x\|)$ for all $x \in \mathcal{X}$. To each C^1 function $V \in \mathcal{A}(\mathcal{X})$ we associate the *Lyapunov derivative* $L_f V : \mathcal{X} \times \mathcal{U} \times \mathcal{W} \to R$ defined by $L_f V(x, u, w) := \nabla V(x) \cdot f(x, u, w)$. Because V has a minimum at $x = 0$, we have $L_f V(0, u, w) = 0$ for all $(u, w) \in \mathcal{U} \times \mathcal{W}$. Given $c \in R_+$, we let $\Omega_c(V) := \{x \in \mathcal{X} : V(x) \leqslant c\}$ denote the c-sublevel set of V. Note that if $V \in \mathcal{A}_\infty(\mathcal{X})$, then $\Omega_c(V)$ is compact for all $c \in R_+$.

DEFINITION 4.1. *A C^1 function $V \in \mathcal{A}_\infty(\mathcal{X})$ is an* rclf *for the system Σ when there exists $c \in R_+$ such that*

$$\inf_{u \in U(x)} \sup_{w \in W(x)} L_f V(x, u, w) < 0 \tag{9}$$

for all $x \in \mathcal{X} \setminus \Omega_c(V)$. We let $c_V \in R_+$ denote the smallest value of c for which (9) *is satisfied for all $x \in \mathcal{X} \setminus \Omega_c(V)$.*

Definition 4.1 reduces to the usual clf definition when $c = 0$, $U(x)$ is constant, and $W(x) \equiv \{0\}$ (no disturbances). The main result of this section is the following.

THEOREM 4.2. *Let* Σ *satisfy assumptions* A1–A3. *If there exists an* rclf V *for* Σ, *then* Σ *is* RS. *If furthermore* $c_V = 0$, *then* Σ *is* RPS.

We will prove this theorem through a series of simple propositions. Let V be an rclf for Σ; then $L_f V$ is continuous, which together with A3 implies that we can define the *worst case Lyapunov derivative* $D_f V : \mathcal{X} \times \mathcal{U} \to R$ by the maximum

$$D_f V(x,u) := \max_{w \in W(x)} L_f V(x,u,w). \tag{10}$$

Note that $D_f V(0,u) = 0$ for all $u \in \mathcal{U}$.

PROPOSITION 4.3. $D_f V$ *is usc and for each* $x \in \mathcal{X}$, *the mapping* $u \mapsto D_f V(x,u)$ *is convex. Furthermore, there exists a continuous function* $\alpha : \mathcal{X} \to R_+$ *such that* $\alpha(0) = 0$ *and for all* $x \in \mathcal{X} \setminus \Omega_{c_V}(V)$ *we have*

$$\inf_{u \in U(x)} D_f V(x,u) < -\alpha(x) < 0. \tag{11}$$

Proof. The upper semicontinuity of $D_f V$ follows from A3 and [5, Thm. 1.4.16]. Now for each fixed $x \in \mathcal{X}$, the function $D_f V(x,u)$ is the pointwise maximum of the family of affine functions $\{L_f V(x,u,w) : w \in W(x)\}$ (assumption A1), and it follows that $D_f V(x,u)$ is convex in u. Next, it follows from [5, Thm. 1.4.16] and (9) that the left-hand side of (11) is usc and strictly negative on $\mathcal{X} \setminus \Omega_{c_V}(V)$. The existence of a function α satisfying (11) can then be deduced from [18, Prob. 5X]. □

At each point $x \in \mathcal{X} \setminus \Omega_{c_V}(V)$, the negative number $-\alpha(x)$ in Proposition 4.3 represents a certain level of negativity of the worst case Lyapunov derivative that can be guaranteed by values of the control in $U(x)$. This *negativity margin* α is not unique and will be regarded as a design parameter in later sections. Note that $\alpha \in \mathcal{A}(\mathcal{X})$ when $c_V = 0$. Given an rclf V for Σ and a negativity margin α as in Proposition 4.3, we define set-valued maps $L_V, K_V : \mathcal{X} \rightsquigarrow \mathcal{U}$ as

$$L_V(x) := \{u \in \mathcal{U} : D_f V(x,u) \leqslant -\alpha(x)\}, \tag{12}$$

$$K_V(x) := U(x) \cap L_V(x). \tag{13}$$

At each $x \in \mathcal{X}$, the set $K_V(x) \subset U(x) \subset \mathcal{U}$ is the set of all possible values of the control that satisfy the control constraint *and* make the worst-case Lyapunov derivative at least as negative as $-\alpha(x)$. Therefore, if we can find a control law k for Σ such that $k(x) \in K_V(x)$ for all $x \in \mathcal{X} \setminus \Omega_c(V)$, then k will render the solutions of (7) RGUAS-$\Omega_c(V)$. Our goal is to show that such a k exists.

PROPOSITION 4.4. K_V *is lsc with nonempty closed convex values on* $\mathcal{X} \setminus \Omega_{c_V}(V)$.

Proof. We define the set-valued map $K_V^\circ : \mathcal{X} \rightsquigarrow \mathcal{U}$ by

$$K_V^\circ(x) := U(x) \cap \{u \in \mathcal{U} : D_f V(x,u) < -\alpha(x)\}. \tag{14}$$

From Proposition 4.3 and [4, Prop. 1.10.4] we see that K_V° is lsc with nonempty convex values on $\mathcal{X} \setminus \Omega_{c_V}(V)$. Fix $x_0 \in \mathcal{X} \setminus \Omega_{c_V}(V)$. Let $\mathcal{I}(u)$ denote the convex indicator function of the set $U(x_0)$; then $\mathcal{I}$ is closed and proper (in the sense of convex analysis) because $U(x_0)$ is closed and nonempty. It follows from [30, Thms. 9.3 and 9.4] that the mapping $u \mapsto D_f V(x_0,u) + \mathcal{I}(u)$ is closed and proper. It then follows from [30, Thm. 7.6] that $\overline{K_V^\circ(x_0)} = \overline{\{u \in \mathcal{U} : D_f V(x_0,u) + \mathcal{I}(u) < -\alpha(x_0)\}} = \{u \in \mathcal{U} : D_f V(x_0,u) + \mathcal{I}(u) \leqslant -\alpha(x_0)\} =$

$K_V(x_0)$. Now any set-valued map whose values are the closures of the values of a lsc map is itself lsc, and thus K_V is lsc with nonempty closed convex values on $\mathcal{X} \setminus \Omega_{c_V}(V)$. □

PROPOSITION 4.5. *For every $c > c_V$ there exists a control law k for Σ such that $k(x) \in K_V(x)$ for all $x \in \mathcal{X} \setminus \Omega_c(V)$.*

Proof. It follows from Proposition 4.4 and Michael's theorem that there exists a continuous function $\phi : \mathcal{X} \setminus \Omega_{c_V}(V) \to \mathcal{U}$ such that $\phi(x) \in K_V(x)$ for every $x \in \mathcal{X} \setminus \Omega_{c_V}(V)$. Fix $c > c_V$ and consider the set-valued map $K_c : \mathcal{X} \rightsquigarrow \mathcal{U}$ defined by

$$K_c(x) := \begin{cases} U(x) & \text{when } x \in \operatorname{int} \Omega_c(V), \\ \{\phi(x)\} & \text{when } x \in \mathcal{X} \setminus \operatorname{int} \Omega_c(V). \end{cases} \tag{15}$$

It follows from A2 that K_c is lsc with nonempty closed convex values and thus admits a continuous selection k (Michael's theorem). Now $k(x) \in U(x)$ for all $x \in \mathcal{X}$, which means k is a control law for Σ; moreover, $k(x) = \phi(x) \in K_V(x)$ for $x \in \mathcal{X} \setminus \Omega_c(V)$. □

Proof of Theorem 4.2. Fix $c > c_V$ and let k be as in Proposition 4.5. Then for all $x \in \mathcal{X} \setminus \Omega_c(V)$ we have $D_f V(x, k(x)) \leqslant -\alpha(x)$. It follows that $\dot{V}(t) \leqslant -\alpha(x(t))$ (for almost all t) along solutions $x(t)$ of (7) that lie outside $\Omega_c(V)$, and standard Lyapunov arguments show that the solutions of (7) are RGUAS-$\Omega_c(V)$. We thus conclude that Σ is RS. If $c_V = 0$, then for any $\varepsilon > 0$ we can choose $c > 0$ above such that $\Omega_c(V) \subset \varepsilon B$, and we then conclude that Σ is RPS. □

When $c_V = 0$, we can prove that Σ is RAS rather than RPS provided V has the following additional property [2, 39, 34].

DEFINITION 4.6. *An* rclf V *for* Σ *satisfies the* continuous control property (ccp) *when* $c_V = 0$ *and there exists* $u^\circ \in U(0)$ *such that for every* $\varepsilon > 0$ *there exists* $\delta > 0$ *such that* $0 < \|x\| < \delta$ *implies*

$$\inf \left\{ D_f V(x, u) \,:\, u \in U(x),\ \|u - u^\circ\| < \varepsilon \right\} < 0. \tag{16}$$

V *satisfies the* small control property (scp) *when it satisfies the* ccp *with* $u^\circ = 0$.

COROLLARY 4.7. *If there is an* rclf *for* Σ *that satisfies the* ccp, *then* Σ *is* RAS.

Proof. Let ρ be a class $\mathcal{K}$ function such that $\rho(\varepsilon) < \delta$ for each (ε, δ)-pair described in Definition 4.6. We define a new control constraint $\widehat{U} : \mathcal{X} \rightsquigarrow \mathcal{U}$ as

$$\widehat{U}(x) := \begin{cases} U(x) & \text{when } \|x\| > \rho(1), \\ U(x) \cap \left[u^\circ + \rho^{-1}(\|x\|)B\right] & \text{when } \|x\| \leqslant \rho(1). \end{cases} \tag{17}$$

It follows from Definition 4.6 that $\widehat{U}$ is lsc with nonempty closed convex values (see [19, Prop. II.2.4]) and that V is an rclf for the new system $\widehat{\Sigma} := (f, \widehat{U}, W)$ with $c_V = 0$. The corresponding set-valued map $\widehat{K}_V$ is then lsc with nonempty closed convex values on all of $\mathcal{X}$, and it follows from Michael's theorem that there exists a control law k for $\widehat{\Sigma}$ such that $k(x) \in \widehat{K}_V(x)$ for all $x \in \mathcal{X}$. Now k is also a control law for the original system Σ, and standard Lyapunov arguments show that the solutions of the resulting closed-loop system are RGUAS. □

Note that the control law k given in the above proof satisfies $k(0) = u^\circ$. If V satisfies the scp, then by taking $u^\circ = 0$ we obtain a robustly asymptotically stabilizing control law k with $k(0) = 0$.

We conclude this section by mentioning that if the control constraint U has nonempty interior for all $x \in \mathcal{X}$ (in addition to satisfying assumption A2), then the control law k in Theorem 4.2 and Corollary 4.7 can be chosen to be *smooth* except possibly at the point $0 \in \mathcal{X}$. The proof of this fact is similar to Artstein's original proof in [2].[1] However, such smoothness cannot be achieved in general when $\mathcal{X}$ is an infinite-dimensional Banach space.

[1] We thank the anonymous reviewer for showing us this smooth version of our results.

5. Necessary conditions. Theorem 4.2 and Corollary 4.7 provide sufficient conditions for robust stabilizability in terms of the existence of an rclf. In this section we explore the necessity of these conditions using the recent converse Lyapunov theorem of [24], which was proved under the assumption that the closed-loop system is locally Lipschitz. We make this assumption in the following theorem, but we believe that it can be removed by modifying the proof in [24].

THEOREM 5.1. *Suppose the disturbance constraint W is locally Lipschitz with nonempty compact convex values, and suppose Σ is* RS *via a control law k that renders locally Lipschitz the mapping $(x, w) \to f(x, k(x), w)$. Then there is a smooth* rclf V *for Σ. If in addition Σ is* RAS *via such a control law k, then there is a smooth* rclf V *for Σ that satisfies the* ccp.

Proof. It follows from [5, Thm. 9.6.2] that we may assume $W(x) \equiv B$ without loss of generality. Let Ω denote the compact residual set in the definition of RS. It follows from [24, Thm. 2] that there exists a smooth function $V_0 : \mathcal{X} \to R_+$ and class $\mathcal{K}_\infty$ functions χ_1, χ_2, and χ_3 such that $\chi_1(|x|_\Omega) \leqslant V_0(x) \leqslant \chi_2(|x|_\Omega)$ for all $x \in \mathcal{X}$ and furthermore $D_f V_0(x, k(x)) \leqslant -\chi_3(|x|_\Omega)$ for all $x \in \mathcal{X} \setminus \Omega$. Because Ω is compact, there exists $c > 0$ and a smooth function $V \in \mathcal{A}_\infty(\mathcal{X})$ such that $V(x) = V_0(x)$ for all $x \in \mathcal{X} \setminus \Omega_c(V)$. It follows that V is an rclf for Σ. If Σ is RAS via such a control law k, then we take $\Omega = \{0\}$ and $V \equiv V_0$ to obtain a smooth rclf that satisfies the ccp. □

Note that in this theorem, assumptions A1–A3 have been replaced by an assumption on the disturbance constraint W alone. This theorem establishes the necessity of the existence of an rclf for both robust stabilizability and robust asymptotic stabilizability. The key part of our formulation that leads to this necessity is that there are no restrictions (other than measurability) on the time-variation of the admissible disturbances. In contrast, adaptive control formulations require the disturbances to be constant or slowly varying. If we were to so restrict the time-variation of the admissible disturbances, then the existence of an rclf would become a sufficient, but not necessary, condition for robust stabilizability.

6. Input-to-state stabilizability. In this section we describe an alternative problem formulation using the definition of *input-to-state stability* in [33]. Rather than consider disturbances that take values in a known compact set, we instead assume no knowledge of such a set and look for a control law that renders the closed-loop system input-to-state stable (ISS) with respect to the disturbance input. The ISS property is stronger than bounded-input/bounded-state stability together with the global asymptotic stability of the nominal (zero-input) system [36]. It is closely related to Lyapunov stability, and many authors have used the ISS property in conjunction with the Lyapunov-based design and analysis of nonlinear systems [35, 24, 27, 38, 40, 37]. In this section we show that ISS-stabilizability is equivalent to the existence of an rclf for an auxiliary system.

In Definition 6.1 and Corollaries 6.2 and 6.3, we consider disturbances $w(t)$ in the set $\mathcal{L}_\infty(\mathcal{W})$ of all measurable essentially bounded functions from R_+ to $\mathcal{W}$, with the essential supremum denoted by $\|\cdot\|_\infty$. Given a continuous function f describing the system dynamics and a control constraint U, we define the ISS-stabilizability of the pair (f, U) as follows.

DEFINITION 6.1. *The closed-loop system* (7) *is* globally input-to-state stable (ISS) *when there exists a class $\mathcal{KL}$ function β and a class $\mathcal{K}$ function χ such that for any $x_0 \in \mathcal{X}$ and any disturbance $w \in \mathcal{L}_\infty(\mathcal{W})$, all solutions $x(t)$ starting from x_0 exist for all $t \geqslant 0$ and satisfy $\|x(t)\| \leqslant \beta(\|x_0\|, t) + \chi(\|w\|_\infty)$ for all $t \geqslant 0$. The pair (f, U) is* ISS-stabilizable *when there exists a control law k such that the closed-loop system* (7) *is* ISS.

Given a class $\mathcal{K}_\infty$ function ρ, we let $W_\rho : \mathcal{X} \rightsquigarrow \mathcal{W}$ denote the set-valued map defined by $W_\rho(x) := \rho(\|x\|)B$; note that W_ρ satisfies A3. We associate with the pair (f, U) the *auxiliary system* $\Sigma_\rho := (f, U, W_\rho)$. Our first result is a consequence of Corollary 4.7 and states that the existence of an rclf for some such auxiliary system Σ_ρ implies the ISS-stabilizability of (f, U).

COROLLARY 6.2. *Let the pair* (f, U) *satisfy assumptions* A1 *and* A2. *Suppose there exists a class* $\mathcal{K}_\infty$ *function* ρ *such that the system* $\Sigma_\rho = (f, U, W_\rho)$ *has an* rclf V *that satisfies the* ccp. *Then the pair* (f, U) *is* ISS-*stabilizable.*

Proof. It follows from the proof of Corollary 4.7 that there exists a control law k for Σ_ρ and a negativity margin $\alpha \in \mathcal{A}(\mathcal{X})$ such that $D_f V(x, k(x)) \leqslant -\alpha(x)$ for all $x \in \mathcal{X}$. In other words, $w \in W_\rho(x)$ implies $L_f V(x, k(x), w) \leqslant -\alpha(x)$. From the definition of W_ρ, we know that $w \in W_\rho(x)$ if and only if $\|w\| \leqslant \rho(\|x\|)$. Thus for all $(x, w) \in \mathcal{X} \times \mathcal{W}$, $\|x\| \geqslant \rho^{-1}(\|w\|)$ implies $L_f V(x, k(x), w) \leqslant -\alpha(x)$. In the terminology of [24, 21], the function V is an ISS-Lyapunov function for (7), and it follows from [21, Prop. 3.1.7] that the closed-loop system (7) is ISS. □

We next use [24, Thm. 3] to prove a converse of the previous result.

COROLLARY 6.3. *Suppose the pair* (f, U) *is* ISS-*stabilizable via a control law* k *that renders locally Lipschitz the mapping* $(x, w) \to f(x, k(x), w)$. *Then there exists a class* $\mathcal{K}_\infty$ *function* ρ *such that the system* $\Sigma_\rho := (f, U, W_\rho)$ *has a smooth* rclf V *that satisfies the* ccp.

Proof. It follows from the converse ISS-Lyapunov theorem [24, Thm. 3] that there exists an ISS-Lyapunov function for (7), namely, that there exists a smooth function $V \in \mathcal{A}_\infty(\mathcal{X})$ and class $\mathcal{K}_\infty$ functions χ_3 and ζ such that for all $(x, w) \in \mathcal{X} \times \mathcal{W}$, $\|x\| \geqslant \zeta(\|w\|)$ implies $L_f V(x, k(x), w) \leqslant -\chi_3(\|x\|)$. If we define the class $\mathcal{K}_\infty$ function $\rho := \zeta^{-1}$, then $w \in W_\rho(x)$ implies $L_f V(x, k(x), w) \leqslant -\chi_3(\|x\|)$. It follows that $D_f V(x, k(x)) \leqslant -\chi_3(\|x\|)$ for all $x \in \mathcal{X}$. We conclude that V is an rclf for Σ_ρ that satisfies the ccp. □

7. Pointwise min-norm control laws. We have shown that the existence of an rclf implies robust stabilizability, but how do we use our knowledge of an rclf to construct a robustly stabilizing control law k? For systems without disturbances, constructive proofs of Artstein's theorem with explicit formulas for k are given in [39, 34, 23, 22, 21]. In these papers, different formulas are given for different *constant* control constraints (a formula for the unconstrained control case $U(x) \equiv \mathcal{U}$ is given in [39, 34], a formula for the control constraint $U(x) \equiv B$ is given in [23], and a formula for the constraint of positive controls is given in [22]). In this section our goal is to provide a formula for k that results in a *robustly* stabilizing control law for systems with disturbances, works for a general nonconstant control constraint $U(x)$, and naturally incorporates the negativity margin α as a design parameter. Moreover, we will show in following sections that the control laws generated by our formula, called pointwise min-norm control laws, are in fact optimal for meaningful games. We introduce the following additional assumptions on the system Σ:

A4. The control constraint U is such that Graph(U) is closed.

A5. The disturbance constraint W is lsc.

Let V be an rclf for Σ, and let L_V and K_V be the set-valued maps defined in (12) and (13). It follows from Proposition 4.4 that we can define $m_V : \mathcal{X} \to \mathcal{U}$ by

$$m_V(x) := \begin{cases} \arg\min \{\|u\| : u \in K_V(x)\} & \text{when } x \in \mathcal{X} \setminus \Omega_{c_V}(V), \\ 0 & \text{when } x \in \Omega_{c_V}(V). \end{cases} \tag{18}$$

This is called a *minimal selection for* V. It is not unique because the definition of K_V depends on the choice of the negativity margin α in Proposition 4.3.

PROPOSITION 7.1. *Let* Σ *satisfy assumptions* A1–A5, *and let* V *be an* rclf *for* Σ. *Then every minimal selection* m_V *for* V *is continuous on* $\mathcal{X} \setminus \Omega_{c_V}(V)$. *If furthermore* V *satisfies the* scp, *then there is a minimal selection* m_V *for* V *that is continuous on* $\mathcal{X}$.

Proof. It follows from A5, Proposition 4.3, and [5, Thm. 1.4.16] that $D_f V$ is continuous. Thus from A4 we see that Graph(K_V) = Graph$(U) \cap$ Graph(L_V) is closed. Now from Proposition 4.4 we know that K_V is lsc on $\mathcal{X} \setminus \Omega_{c_V}(V)$, and it follows from [5, Prop. 9.3.2] that Graph(m_V) is closed relative to $\mathcal{X} \setminus \Omega_{c_V}(V) \times \mathcal{U}$. Also, it follows from [5, Lem. 9.3.1] that

the mapping $x \mapsto \|m_V(x)\|$ is usc on $\mathcal{X} \setminus \Omega_{c_V}(V)$, which implies that m_V is locally bounded on $\mathcal{X} \setminus \Omega_{c_V}(V)$. Because the dimension of $\mathcal{U}$ is finite, the closedness of Graph(m_V) and the local boundedness of m_V on $\mathcal{X} \setminus \Omega_{c_V}(V)$ imply the continuity of m_V on $\mathcal{X} \setminus \Omega_{c_V}(V)$. Next suppose V satisfies the scp; then from the the proof of Corollary 4.7 there exists a choice for α in Proposition 4.3 such that K_V admits a continuous selection k with $k(0) = 0$. From (18) we have $0 \leqslant \|m_V(x)\| \leqslant \|k(x)\|$ for all $x \in \mathcal{X}$, and therefore m_V is continuous at $x = 0$. □

As a result of Proposition 7.1, minimal selections m_V for V can be used to generate robustly stabilizing control laws for Σ.

DEFINITION 7.2. *Let V be an* rclf *for Σ. If V satisfies the* scp, *then every control law k for Σ that is also a minimal selection for V is called* pointwise min-norm for V. *If V does not satisfy the* scp, *then every control law k for Σ that satisfies $k(x) = m_V(x)$ for all $x \in \mathcal{X} \setminus \Omega_c(V)$ for some $c > c_V$ and some minimal selection m_V for V is called pointwise min-norm for V.*

Pointwise min-norm control laws are so named because at each point x (except possibly inside some sublevel set of V), their value is the unique element of $\mathcal{U}$ of minimum norm that satisfies the control constraint $U(x)$ and makes the worst case Lyapunov derivative at least as negative as $-\alpha(x)$. These control laws naturally incorporate the negativity margin α as a design parameter. Note that if V satisfies the scp, then only those choices for the negativity margin α that lead to *continuous* minimal selections m_V for V will generate pointwise min-norm control laws for V.

We can compute the value of a pointwise min-norm control law at any point x by solving the static minimization problem (18). This is a convex programming problem on the control space $\mathcal{U}$ and is completely determined by the data Σ, V, and α. One of the constraints in this problem depends on $D_f V$, and the calculation of $D_f V(x, u)$ in (10) for any fixed $(x, u) \in \mathcal{X} \times \mathcal{U}$ is itself a static nonlinear programming problem on the disturbance space $\mathcal{W}$. We will show in the next sections that every pointwise min-norm control law is optimal for a meaningful differential game, and therefore our formula (18) allows us to compute such a control law by solving a static rather than dynamic programming problem. Furthermore, this static programming problem has a simple explicit solution in the following special cases.

Jointly affine systems. Suppose the function f is jointly affine in the control and disturbance; that is, suppose the system (6) can be written as

$$\dot{x} = f_0(x) + f_1(x)\,u + f_2(x)\,w \tag{19}$$

for continuous functions $f_0 : \mathcal{X} \to \mathcal{X}$, $f_1 : \mathcal{X} \to \mathcal{B}(\mathcal{U}, \mathcal{X})$, and $f_2 : \mathcal{X} \to \mathcal{B}(\mathcal{W}, \mathcal{X})$. Suppose also that the control and disturbance constraints are given by $U(x) \equiv \mathcal{U}$ and $W(x) \equiv B$, respectively. Let V be an rclf for this system; then from (10) we have

$$D_f V(x, u) = \nabla V(x) \cdot f_0(x) + \nabla V(x) \cdot f_1(x)\,u + \left\|\nabla V(x) \cdot f_2(x)\right\|. \tag{20}$$

We choose a negativity margin α according to (11) and use (20) to write

$$D_f V(x, u) + \alpha(x) = \psi_0(x) + \psi_1^T(x)\,u \tag{21}$$

with $\psi_0(x) := \nabla V(x) \cdot f_0(x) + \left\|\nabla V(x) \cdot f_2(x)\right\| + \alpha(x)$ and $\psi_1(x) := \left[\nabla V(x) \cdot f_1(x)\right]^T$. Then from (13) we have

$$K_V(x) = \left\{u \in \mathcal{U} : \psi_0(x) + \psi_1^T(x)\,u \leqslant 0\right\}. \tag{22}$$

It now follows from (18) and the projection theorem that

$$m_V(x) = \begin{cases} -\dfrac{\psi_0(x)\,\psi_1(x)}{\psi_1^T(x)\,\psi_1(x)} & \text{when } x \in \mathcal{X} \setminus \Omega_{c_V}(V) \text{ and } \psi_0(x) > 0, \\ 0 & \text{when } x \in \Omega_{c_V}(V) \text{ or } \psi_0(x) \leqslant 0. \end{cases} \tag{23}$$

This explicit formula for m_V depends on the negativity margin α through the function ψ_0 and has the continuity properties described in Proposition 7.1. Note that there is never division by zero in this expression because the set $K_V(x)$ is nonempty for all $x \in \mathcal{X} \setminus \Omega_{c_V}(V)$ (Proposition 4.4). Because of the symmetry of the unit ball, this expression is also valid under control constraints of the form $U(x) = p(x)B$ for a continuous function $p : \mathcal{X} \to R_+$.

This formula (23) generates the control law (3) for the system (1) in §1 as follows. For this system we have $f_0(x) = -x^3$, $f_1(x) = 1$, and $f_2(x) = x$. We choose $V(x) = \frac{1}{2}x^2$ so that $\nabla V(x) = x$, and we choose $\alpha(x) = x^2$. Then we obtain $\psi_0(x) = -x^4 + 2x^2$ and $\psi_1(x) = x$, and the formula (23) yields the control law (3).

Feedback linearizable systems. We now apply the formula (23) to the class of (globally) feedback linearizable systems with no disturbances. Suppose there are coordinates in which our system is

$$\dot{x} = Fx + G\big[\ell_0(x) + \ell_1(x)\,u\big], \tag{24}$$

where the matrix pair (F, G) is stabilizable and the continuous functions $\ell_0 : \mathcal{X} \to \mathcal{U}$ and $\ell_1 : \mathcal{X} \to \mathcal{B}(\mathcal{U}, \mathcal{U})$ are such that $\ell_0(0) = 0$ and $\ell_1(x)$ is nonsingular for all $x \in \mathcal{X}$. Suppose also that the control constraint is $U(x) \equiv \mathcal{U}$. The control law suggested by feedback linearization would cancel nonlinearities and apply linear feedback as

$$k(x) = \big[\ell_1(x)\big]^{-1}\big[-\ell_0(x) + Kx\big], \tag{25}$$

where K is a stabilizing gain matrix for the pair (F, G). Unfortunately, this control law (25) may not have good robustness properties and might waste control effort to counteract beneficial nonlinearities. We instead construct a pointwise min-norm control law by using the formula (23) as follows. We first choose symmetric positive definite matrices P and Q such that the Lyapunov matrix equation

$$P\big(F + GK\big) + \big(F + GK\big)^T P = -Q \tag{26}$$

is satisfied. Then $V(x) := x^T Px$ is a clf that satisfies the scp, and an appropriate choice for the negativity margin is $\alpha(x) := \varepsilon x^T Qx$ for some $\varepsilon \in (0, 1)$. In this case, the function ψ_0 above is

$$\psi_0(x) = 2x^T P\big[Fx + G\,\ell_0(x)\big] + \varepsilon x^T Qx \tag{27}$$

and the formula (23) becomes

$$m_V(x) = \begin{cases} -\dfrac{\psi_0(x)\,\ell_1^T(x)G^T Px}{2x^T PG\,\ell_1(x)\,\ell_1^T(x)G^T Px} & \text{when } \psi_0(x) > 0, \\ 0 & \text{when } \psi_0(x) \leqslant 0. \end{cases} \tag{28}$$

The design parameters in this expression are ε, P, and Q; and their choices are constrained by $\varepsilon \in (0, 1)$ and the Lyapunov matrix equation (26). This minimal selection m_V is continuous everywhere (Proposition 7.1) and, therefore, defines a pointwise min-norm control law $k(x) := m_V(x)$. Although both control laws (28) and (25) globally asymptotically stabilize the system (24), the control law (28) is optimal with respect to a meaningful cost functional (as shown in the next sections) whereas the control law (25) is not (in general). The potential advantage of (28) over (25) was illustrated in the comparison of the control laws (3) and (2) in §1.

We end this section with a discussion of the role of the negativity margin α. This function represents the desired negativity of the Lyapunov derivative and can be adjusted to achieve a trade-off between the control effort and the rate of convergence of the state to zero. For example, if α is a negativity margin, then so is $\varepsilon\alpha$ for every $\varepsilon \in (0, 1)$. For each such ε we then obtain a different pointwise min-norm control law k for Σ. In general, smaller values of ε will lead to smaller control magnitudes and slower convergence. Moreover, by adjusting the shape of α we can place more cost on some states and less cost on others. Thus the function α should be regarded as a design parameter to be adjusted according to design specifications.

8. Inverse optimal robust stabilization. Our goal in the next three sections is to show that every pointwise min-norm control law is optimal for a meaningful game. We accomplish this by showing that every rclf solves the steady-state HJI equation associated with such a game. These results represent a solution to an inverse optimal robust stabilization problem for nonlinear systems with disturbances. As a consequence of these results, we can use formulas (18) and (23) to compute optimal robustly stabilizing control laws *without* solving the HJI equation for the upper value function, provided an rclf is known.

In this section and the next, we assume that the scp is satisfied, which in particular implies that the disturbances vanish at the equilibrium point. In this case our system is RAS and we can therefore consider cost functionals defined over the infinite horizon. In §10 we remove the scp assumption and allow persistent disturbances, in which case we must consider cost functionals defined over a finite horizon determined by the time required to reach a given target set.

We assume that the system Σ satisfies A1–A5 plus the following assumption on the control constraint.

A6. There exists a continuous function $\pi : \mathcal{X} \to R_+$ such that $\pi(x) > 0$ and $\pi(x)B \subset U(x)$ for all $x \in \mathcal{X}$.

One can show that, under assumption A2, assumption A6 is equivalent to the assumption that $0 \in \operatorname{int} U(x)$ for all $x \in \mathcal{X}$. Our cost functionals will be characterized by functions $q : \mathcal{X} \to R_+$ and $r : \mathcal{X} \times \mathcal{U} \to R_+$, which satisfy the following specifications.

S1. q satisfies $q \in \mathcal{A}_\kappa(\mathcal{X})$.

S2. r is continuous, and for each fixed $x \in \mathcal{X}$ we have $r(x, u) = \gamma_x(\|u\|_x)$ for some convex class $\mathcal{K}$ function γ_x and some norm $\|\cdot\|_x$

Using such a pair (q, r), we form a two-person zero-sum differential game $\mathcal{G}(q, r)$ by considering a cost functional J parameterized by the initial condition $x_0 \in \mathcal{X}$. In this game, the control tries to minimize J and the disturbance tries to maximize J. Given $x_0 \in \mathcal{X}$, $u_g \in \mathcal{C}(\Sigma)$, and $w_a \in \mathcal{D}(\Sigma)$ we define the cost

$$J(u_g, w_a, x; x_0) := \int_0^\infty [q(x) + r(x, u_g)]dt, \tag{29}$$

where the integration is taken along the solution $x(t)$ of the differential equation (8) starting from the initial condition x_0. Because such solutions are not necessarily unique, we included in our notation $J(u_g, w_a, x; x_0)$ the dependence on the particular state trajectory x along which we integrate. If the solution $x(t)$ cannot be extended for all $t \geqslant 0$, then we set $J(u_g, w_a, x; x_0) := \infty$. Also, because q is bounded from below by a class $\mathcal{K}$ function of the norm, $J < \infty$ implies $x(t) \to 0$ as $t \to \infty$. We define the *upper value function* $\bar{J} : \mathcal{X} \to R_+ \cup \{\infty\}$ of the game by the equation

$$\bar{J}(x_0) := \inf_{u_g} \sup_{w_a} \sup_{x} J(u_g, w_a, x; x_0). \tag{30}$$

The first supremum is taken over all solutions $x(t)$ of (8) starting from x_0 (this supremum is superfluous if solutions are unique), the second supremum is taken over all admissible

disturbances $w_a \in \mathcal{D}(\Sigma)$, and the infimum is taken over all generic controls $u_g \in \mathcal{C}(\Sigma)$. When this infimum is achieved by some $u_g^* \in \mathcal{C}(\Sigma)$ for some $x_0 \in \mathcal{X}$ such that $J(x_0) < \infty$, we say that u_g^* is *optimal from* x_0. We say a control law k^* for Σ is *optimal for* $\mathcal{G}(q, r)$ when k^* is optimal from every $x_0 \in \mathcal{X}$. Such an optimal control law minimizes the worst case cost for every initial condition. Also, because $J < \infty$ only if $x(t) \to 0$ as $t \to \infty$, every optimal control law drives the state (robustly) to zero from any initial condition.

Before we proceed, we introduce the notion of a strong rclf. If V is an rclf for Σ, then Proposition 4.3 guarantees the existence of a negativity margin α that is nonzero outside some compact set. We say that V is a *strong* rclf when α can be chosen to be *bounded away from zero* outside some compact set. If $c_V = 0$, this means that we can choose $\alpha \in \mathcal{A}_\kappa(\mathcal{X})$ instead of merely $\alpha \in \mathcal{A}(\mathcal{X})$. We will see below that this stronger property will lead to a function q in (29) that belongs to $\mathcal{A}_\kappa(\mathcal{X})$ rather than just to $\mathcal{A}(\mathcal{X})$, thus guaranteeing that $J < \infty$ only if $x(t) \to 0$ as $t \to \infty$. The restriction to strong rclf's is not important in practice; it follows from results in [33] that if an rclf is known, then the construction of a strong rclf is straightforward.

Let V be a strong rclf for Σ that satisfies the scp, and let k^* be a pointwise min-norm control law for V associated with a negativity margin $\alpha \in \mathcal{A}_\kappa(\mathcal{X})$. Theorem 8.1 states that there exists a pair (q, r) satisfying S1 and S2 such that k^* is optimal for $\mathcal{G}(q, r)$ with V being the corresponding upper value function. In simple terms, every pointwise min-norm control law is optimal and every (strong) rclf is an upper value function. This theorem is only of interest when such a game $\mathcal{G}(q, r)$ is meaningful, and we claim that this is indeed the case. First of all, it follows from S1 and S2 that the integrand in (29) is bounded below by a class $\mathcal{K}$ function of $\|x\|$; thus $J < \infty$ only if the objective of driving the state to zero is achieved. Furthermore, for each fixed $x \in \mathcal{X}$ the integrand is a convex function of u with a global minimum at the point $u = 0$; thus there is always a higher penalty for values of u further away from zero and there are no local minima other than $u = 0$. In fact, integrands satisfying S1 and S2 are a generalization of the familiar quadratic integrand $x^T Q x + u^T R u$ for symmetric positive definite matrices Q and R. Next, the disturbance w is given two advantages in the game consistent with the goal of robust stabilization. First, there is no direct cost on w in (29); and second, w is allowed to base its strategy on knowledge of the strategy of the control u (we consider the *upper* value of the game). Finally, the control law k^* is optimal with respect to *all* generic controls $u_g \in \mathcal{C}(\Sigma)$, not just those that satisfy the control constraint; in other words, we do not allow the possibility of reducing the guaranteed cost by relaxing the control constraint.

To prove optimality rather than suboptimality, we need to assume that the effect of a certain *worst case disturbance* (one that maximizes the Lyapunov derivative) can be approximated arbitrarily closely by admissible disturbances. A worst case disturbance is a function $w^* : \mathcal{X} \times \mathcal{U} \to \mathcal{W}$ such that $L_f V(x, u, w^*(x, u)) = D_f V(x, u)$ and $w^*(x, u) \in W(x)$ for all $(x, u) \in \mathcal{X} \times \mathcal{U}$. Such a function w^* may be discontinuous and thus not belong to the set $\mathcal{D}(\Sigma)$ of admissible disturbances. Our approximation condition is as follows.

DC. For every $x_0 \in \mathcal{X}$, every $u_g \in \mathcal{C}(\Sigma)$, and every $\Delta > 0$ there exists $w_\Delta \in \mathcal{D}(\Sigma)$ and a solution $x_\Delta(t)$ of (8) starting from x_0 (with $w_a = w_\Delta$) such that either $J(u_g, w_\Delta, x_\Delta; x_0) = \infty$ or for every $T \geqslant 0$ we have

$$\int_0^T L_f V(x_\Delta, u_g, w_\Delta)\, dt \geqslant \int_0^T D_f V(x_\Delta, u_g)\, dt - \Delta. \tag{31}$$

If this condition is not true for our system, then we can only prove suboptimality. We now state one of the main results of this paper.

THEOREM 8.1. *Let* Σ *satisfy assumptions* A1–A6, *let* V *be a strong* rclf *for* Σ *which satisfies the* scp, *and let* k^* *be a pointwise min-norm control law for* V *associated with a*

negativity margin $\alpha \in \mathcal{A}_\kappa(\mathcal{X})$. *Then there exists a pair* (q, r) *satisfying* S1 *and* S2 *such that* $J(k^*, w_a, x; x_0) \leqslant V(x_0)$ *for every* $x_0 \in \mathcal{X}$, *every* $w_a \in \mathcal{D}(\Sigma)$, *and every solution* $x(t)$ *of the closed-loop system*

$$\dot{x} = f(x, k^*(x), w_a) \tag{32}$$

starting from x_0. *If, furthermore,* DC *is true, then* $\bar{J}(x_0) = V(x_0)$ *for all* $x_0 \in \mathcal{X}$, *which means* k^* *is optimal for* $\mathcal{G}(q, r)$.

The proof of this theorem involves several steps and will be presented in the next section. The main idea is to construct the functions q and r in such a way that V satisfies the steady-state HJI equation

$$0 = \min_{u \in \mathcal{U}} \max_{w \in W(x)} [q(x) + r(x, u) + L_f V(x, u, w)] \tag{33}$$

for all $x \in \mathcal{X}$. We accomplish this by constructing a continuous function r that satisfies S2 and that has two additional properties. First, r must be such that the function q defined by

$$0 = q(x) + r(x, k^*(x)) + D_f V(x, k^*(x)) \tag{34}$$

satisfies S1; and second, r must be such that the equality

$$\min_{u \in \mathcal{U}} [r(x, u) + D_f V(x, u)] = r(x, k^*(x)) + D_f V(x, k^*(x)) \tag{35}$$

holds for all $x \in \mathcal{X}$. Once we find such a function r, it will follow from (34) and (35) that the HJI equation (33) is true.

9. Proof of Theorem 8.1. We begin with a careful construction of the function r in (29). We first define a set-valued map $C : \mathcal{X} \rightsquigarrow \mathcal{U}$ as

$$C(x) = \operatorname{co}\big([\pi(x)B] \cup \{k^*(x), -k^*(x)\} \big). \tag{36}$$

The values of C are compact and convex, and for each $x \in \mathcal{X}$ we have $0 \in \operatorname{int} C(x)$ and $C(x) = -C(x)$. Furthermore, it follows from [19, Thms. II.2.7 and II.2.10] that C is continuous on $\mathcal{X}$. Associated with C is the Minkowski distance functional $\sigma : \mathcal{X} \times \mathcal{U} \to R_+$ defined as

$$\sigma(x, u) := \inf \{\lambda \geqslant 0 : u \in \lambda C(x)\}. \tag{37}$$

PROPOSITION 9.1. *For each* $x \in \mathcal{X}$, $\sigma(x, \cdot)$ *is a norm on* $\mathcal{U}$. *Also,* σ *is continuous on* $\mathcal{X} \times \mathcal{U}$.

Proof. The first statement follows from [30, Thm. 15.2], and we have left to prove that σ is continuous. Fix $(x_0, u_0) \in \mathcal{X} \times \mathcal{U}$ and let $\{(x_i, u_i)\} \in \mathcal{X} \times \mathcal{U}$ be a sequence converging to (x_0, u_0). Define $\sigma_i := \sigma(x_i, u_i)$ and $\sigma_0 := \sigma(x_0, u_0)$; we need to show that $\sigma_i \to \sigma_0$ or, equivalently, that every subsequence of $\{\sigma_i\}$ has in turn a subsequence that converges to σ_0. Let $\{\sigma_{i_j}\}$ be a subsequence of $\{\sigma_i\}$, and define $C_j := C(x_{i_j})$ and $C_0 := C(x_0)$. It follows from (37) that there exists a sequence $\{w_j\} \in \mathcal{U}$ such that $w_j \in \partial C_j$ and $u_{i_j} = \sigma_{i_j} w_j$ for all $j \geqslant 1$. It then follows from [19, Thm. II.2.2] that the sequence $\{w_j\}$ has a subsequence $\{w_{j_k}\}$ that converges to some $w_0 \in C_0$. We claim that $w_0 \in \partial C_0$. Indeed, because $w_{j_k} \in \partial C_{j_k}$, we know there exists a sequence of unit vectors $\{v_k\} \in \mathcal{U}$ such that $v_k \in N_{C_{j_k}}(w_{j_k})$ for all $k \geqslant 1$. The unit sphere in $\mathcal{U}$ is compact, and thus Limsup $N_{C_{j_k}}(w_{j_k})$ contains a unit vector. It then follows from [5, Cor. 7.6.5] that $N_{C_0}(w_0) \neq \{0\}$, which means $w_0 \in \partial C_0$. We can now show that $\sigma_{i_{j_k}} \to \sigma_0$. First suppose $u_0 = 0$; then $\sigma_0 = 0$ and $u_{i_{j_k}} = \sigma_{i_{j_k}} w_{j_k} \to 0$, and because $w_{j_k} \to w_0 \neq 0$, it follows that $\sigma_{i_{j_k}} \to 0 = \sigma_0$. Next suppose $u_0 \neq 0$. By the continuity of the inner product and the

continuity of $\operatorname{sgn}(\cdot)$ away from zero, we have $\langle \operatorname{sgn}(w_0), \operatorname{sgn}(u_{i_{j_k}})\rangle = \langle \operatorname{sgn}(w_0), \operatorname{sgn}(w_{j_k})\rangle \to \langle \operatorname{sgn}(w_0), \operatorname{sgn}(w_0)\rangle = 1$ and $\langle \operatorname{sgn}(w_0), \operatorname{sgn}(u_{i_{j_k}})\rangle \to \langle \operatorname{sgn}(w_0), \operatorname{sgn}(u_0)\rangle$, and it follows that $u_0 = \lambda w_0$ for some $\lambda > 0$. Because $w_0 \in \partial C_0$, we have $\lambda = \sigma_0$, and thus $u_{i_{j_k}} \to u_0$ implies $\sigma_{i_{j_k}} w_{j_k} \to \sigma_0 w_0$. Now because $w_{j_k} \to w_0 \neq 0$, we have $\sigma_{i_{j_k}} \to \sigma_0$ as desired. □

We next define a set-valued map $D : \mathcal{X} \rightsquigarrow \mathcal{U}$ as

$$D(x) := \partial_u D_f V(x, k^*(x))$$

$$= \{w \in \mathcal{U} : D_f V(x,u) \geqslant D_f V(x, k^*(x)) + \langle w, u - k^*(x)\rangle \quad \forall u \in \mathcal{U}\}. \tag{38}$$

Thus $D(x)$ is the partial (convex) subdifferential with respect to u of the worst case Lyapunov derivative $D_f V$, evaluated at $(x, k^*(x))$. It follows from Lemma 12.1 and [19, Cor. II.2.1] that D is usc on $\mathcal{X}$ and has nonempty, convex, compact values. The next two propositions follow from the pointwise min-norm property of k^*.

PROPOSITION 9.2. *If $x \in \mathcal{X}$ is such that $k^*(x) \neq 0$, then $D_f V(x, k^*(x)) = -\alpha(x)$ and $0 \notin D(x)$.*

Proof. Recall that k^* is the minimal selection for V associated with α. Fix $x \in \mathcal{X}$ and suppose $k^*(x) \neq 0$. It follows from A6, (13), and (18) that $D_f V(x, 0) > -\alpha(x)$. Because the mapping $u \mapsto D_f V(x,u)$ is continuous and $U(x)$ is convex, the intermediate value theorem gives $D_f V(x, k^*(x)) = -\alpha(x)$. Suppose $0 \in D(x)$; then from (38) we have $-\alpha(x) = D_f V(x, k^*(x)) \leqslant D_f V(x,u)$ for all $u \in \mathcal{U}$, but this contradicts (11) because $k^*(x) \neq 0$ implies $x \in \mathcal{X} \setminus \Omega_{c_V}(V)$. □

PROPOSITION 9.3. *There exist continuous functions $\mu, \nu : \mathcal{X} \to R_+$ such that $\mu(x) \leqslant d(0, D(x))$ and $\|D(x)\| < \nu(x)$ for all $x \in \mathcal{X}$, with μ having the additional property that $\mu(x) > 0$ if and only if $k^*(x) \neq 0$.*

Proof. Because D is usc with nonempty bounded values, it follows from [5, Lem. 9.3.1] that the map $x \mapsto \|D(x)\|$ is usc on $\mathcal{X}$ and the map $x \mapsto d(0, D(x))$ is lsc on $\mathcal{X}$. The existence of ν then follows from [18, Prob. 5X]. Let $G \subset \mathcal{X}$ denote the open set $G = \{x \in \mathcal{X} : k^*(x) \neq 0\}$; it then follows from Proposition 9.2 and [18, Prob. 5X] that there exists a continuous function $\mu_0 : G \to R_+$ such that $0 < \mu_0(x) \leqslant d(0, D(x))$ for all $x \in G$. We define μ by setting $\mu(x) := 0$ when $k^*(x) = 0$ and otherwise

$$\mu(x) := \frac{\|k^*(x)\|}{1 + \|k^*(x)\| + \mu_0(x)}\, \mu_0(x). \tag{39}$$

This function μ has the desired properties. □

These functions μ and ν should be regarded as continuous "lower" and "upper" bounds (respectively) on the set-valued map D. We will now use them to construct the function r in the cost functional (29). Let $\alpha_0 \in \mathcal{A}(\mathcal{X})$ be such that $(\alpha - \alpha_0) \in \mathcal{A}_\kappa(\mathcal{X})$; for example, take $\alpha_0 := \varepsilon\alpha$ for some $\varepsilon \in (0,1)$. We next construct continuous functions $a, b : \mathcal{X} \to R_+$ as

$$a(x) := \begin{cases} \min\left\{\mu(x)\pi(x),\ \dfrac{\alpha_0(x)}{\sigma(x, k^*(x))}\right\} & \text{when } k^*(x) \neq 0, \\ 0 & \text{when } k^*(x) = 0; \end{cases} \tag{40}$$

$$b(x) := \nu(x) \max\left\{\|k^*(x)\|,\ \pi(x)\right\}. \tag{41}$$

It follows from Propositions 9.1 and 9.3 that a is continuous with $a(x) > 0$ whenever $k^*(x) \neq 0$. Also, we see from Proposition 9.3 that b is continuous with $b(x) > 0$ for all $x \in \mathcal{X}$. Furthermore, for all $x \in \mathcal{X}$ we have $0 \leqslant a(x) \leqslant \mu(x)\pi(x) < \nu(x)\pi(x) \leqslant b(x)$. We use a and b to define a function $\gamma : \mathcal{X} \times R_+ \to R_+$ as

$$\gamma(x,s) := \begin{cases} a(x)s & \text{when } 0 \leqslant s \leqslant \sigma(x, k^*(x)), \\ b(x)s + \sigma(x, k^*(x))\big[a(x) - b(x)\big] & \text{when } \sigma(x, k^*(x)) < s. \end{cases} \tag{42}$$

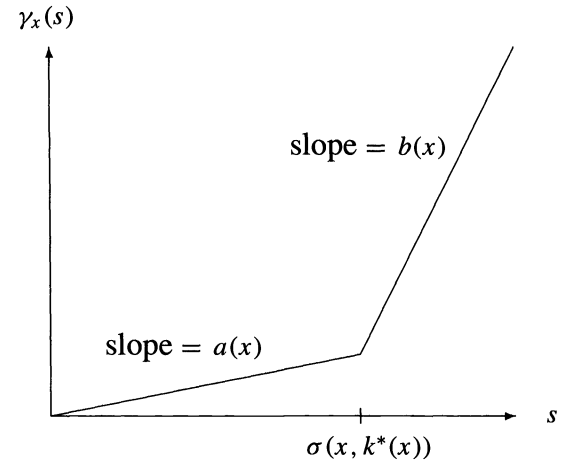

FIG. 3. *The function $\gamma_x(s)$ when $k^*(x) \neq 0$.*

It follows from the continuity of a, b, σ, and k^* that γ is continuous. Now fix $x \in \mathcal{X}$ and consider the function $\gamma_x : R_+ \to R_+$ given by $\gamma_x(s) = \gamma(x, s)$. Suppose $k^*(x) = 0$; then for all $s \geqslant 0$ we have $\gamma_x(s) = b(x)s$ with $b(x) > 0$, and thus γ_x is a (linear) convex class $\mathcal{K}$ function. Now suppose $k^*(x) \neq 0$; then $0 < a(x) < b(x)$ and we see from (42) that γ_x is a (piecewise-linear) convex class $\mathcal{K}$ function (see Fig. 3). Our choice for γ is not unique; in fact, redefining γ for $s \geqslant \sigma(x, k^*(x)) + 1$ to be anything preserving convexity and continuity (for example, replacing the linear growth with quadratic growth) will not alter our results.

We now choose the functions q and r in (29) as

$$r(x, u) := \gamma(x, \sigma(x, u)), \tag{43}$$

$$q(x) := -r(x, k^*(x)) - D_f V(x, k^*(x)) \tag{44}$$

for all $(x, u) \in \mathcal{X} \times \mathcal{U}$. Clearly q and r are continuous, and it follows from Proposition 9.1 and the properties of γ discussed above that r satisfies S2. We next show that q satisfies S1. We see from (42) and (40) that $r(x, k^*(x)) = a(x)\sigma(x, k^*(x)) \leqslant \alpha_0(x)$ for all $x \in \mathcal{X}$. Now $D_f V(x, k^*(x)) \leqslant -\alpha(x)$ for all $x \in \mathcal{X}$, and it follows from (44) that $q(x) \geqslant \alpha(x) - \alpha_0(x)$ for all $x \in \mathcal{X}$. By inspection we have $q(0) = 0$, and because $(\alpha - \alpha_0) \in \mathcal{A}_\kappa(\mathcal{X})$, it follows that $q \in \mathcal{A}_\kappa(\mathcal{X})$. We now show that the function r satisfies the key equation (35).

PROPOSITION 9.4. *It is true for all $x \in \mathcal{X}$ that*

$$\min_{u \in \mathcal{U}} [r(x, u) + D_f V(x, u)] = r(x, k^*(x)) + D_f V(x, k^*(x)). \tag{45}$$

Proof. We fix $x \in \mathcal{X}$. Because $r + D_f V$ is convex in u, (45) is true if and only if $0 \in \partial_u(r + D_f V)(x, k^*(x))$, where ∂_u denotes the partial subdifferential with respect to u. From [30, Thm. 23.8] and (38) we see that this condition is equivalent to the condition $0 \in \partial_u r(x, k^*(x)) + D(x)$.

First suppose $k^*(x) = 0$. Then from (36) we have $C(x) = \pi(x)B$, and it follows from (37) that $\sigma(x, u) = \|u\|/\pi(x)$ for all $u \in \mathcal{U}$. Thus $\partial_u \sigma(x, 0) = (1/\pi(x))B$. Now we have $\sigma(x, k^*(x)) = \sigma(x, 0) = 0$, which means $\gamma(x, s) = b(x)s$ for all $s \geqslant 0$; and it follows from (43) and (41) that $\partial_u r(x, k^*(x)) = b(x)\,\partial_u \sigma(x, k^*(x)) = (b(x)/\pi(x))B = \nu(x)B$. Now $\|D(x)\| < \nu(x)$ and so $0 \in [\nu(x)B] + D(x) = \partial_u r(x, k^*(x)) + D(x)$ as desired.

Next suppose $k^*(x) \neq 0$. We need to compute $\partial_u r(x, k^*(x))$. Now $\sigma(x, k^*(x)) > 0$, and it follows immediately from (42) (see Fig. 3) that

$$\partial_s \gamma\big(x, \sigma(x, k^*(x))\big) = \big[a(x),\ b(x)\big], \tag{46}$$

where ∂_s denotes the partial subdifferential with respect to s. We next compute $\partial_u \sigma(x, k^*(x))$. Let $E := \big\{u \in \mathcal{U} : \sigma(x, u) \leqslant \sigma(x, k^*(x))\big\}$ denote the sublevel set of σ at $k^*(x)$, and let N_E denote the normal cone to E at $k^*(x)$. From (36) and (37) we have $E \subset \|k^*(x)\| B$, and it follows that $k^*(x) \in N_E$. It then follows from [30, Cor. 23.7.1] that there exists $\lambda > 0$ such that $\lambda \operatorname{sgn}(k^*(x)) \in \partial_u \sigma(x, k^*(x))$. We now calculate the value of λ. From the definition of the subdifferential, it follows that $\sigma(x, \xi) \geqslant \sigma(x, k^*(x)) + \big\langle \lambda \operatorname{sgn}(k^*(x)),\ \xi - k^*(x)\big\rangle$ for all $\xi \in \mathcal{U}$. Setting $\xi = 0$ we obtain $0 \geqslant \sigma(x, k^*(x)) + \big\langle \lambda \operatorname{sgn}(k^*(x)),\ -k^*(x)\big\rangle$, which implies $\sigma(x, k^*(x)) \leqslant \lambda \|k^*(x)\|$. Setting $\xi = 2k^*(x)$ we obtain $2\sigma(x, k^*(x)) \geqslant \sigma(x, k^*(x)) + \big\langle \lambda \operatorname{sgn}(k^*(x)),\ k^*(x)\big\rangle$, which implies $\sigma(x, k^*(x)) \geqslant \lambda \|k^*(x)\|$. We have thus shown that $\lambda = \sigma(x, k^*(x))/\|k^*(x)\|$. Now if $\|k^*(x)\| \leqslant \pi(x)$ we have $\sigma(x, k^*(x)) = \|k^*(x)\|/\pi(x)$ and thus $\lambda = 1/\pi(x)$. Otherwise $\|k^*(x)\| > \pi(x)$, which means $\sigma(x, k^*(x)) = 1$ and we have $\lambda = 1/\|k^*(x)\|$. It follows from (41) that $\lambda = \nu(x)/b(x)$, and thus from Lemma 12.2 we obtain

$$\partial_u \sigma(x, k^*(x)) = N_E \cap \left[\frac{\nu(x)}{b(x)} \operatorname{sgn}(k^*(x)) + \big\{k^*(x)\big\}^{\perp}\right]. \tag{47}$$

It then follows from the projection theorem that $d(0, \partial_u \sigma(x, k^*(x))) = \nu(x)/b(x)$. We next show that $\|\partial_u \sigma(x, k^*(x))\| \leqslant 1/\pi(x)$. If $\|k^*(x)\| \leqslant \pi(x)$, then $\partial_u \sigma(x, k^*(x))$ is a singleton, which means $\|\partial_u \sigma(x, k^*(x))\| = d(0, \partial_u \sigma(x, k^*(x))) = \nu(x)/b(x) = 1/\pi(x)$. Next suppose $\|k^*(x)\| > \pi(x)$ and let $w \in \partial_u \sigma(x, k^*(x))$; then from (47) we have $w \in N_E \backslash \{0\}$, which means $H := \big[k^*(x) + \{w\}^{\perp}\big]$ is a supporting hyperplane of E. Let $v = d(0, H) \operatorname{sgn}(w)$; then from the projection theorem we have $v \in H$, which means $H = \big[v + \{w\}^{\perp}\big]$. Because $\pi(x) B \subset E$ we have $\|v\| = d(0, H) \geqslant \pi(x) > 0$, which means $H = \big[v + \{v\}^{\perp}\big]$. Now $\nu(x)/b(x) = 1/\|k^*(x)\|$ for $\|k^*(x)\| > \pi(x)$, and it follows from (47) that $w = \operatorname{sgn}(k^*(x))/\|k^*(x)\| + w_1$ for some $w_1 \in \big\{k^*(x)\big\}^{\perp}$. Thus $\big\langle w,\ k^*(x)\big\rangle = \big\langle \operatorname{sgn}(k^*(x))/\|k^*(x)\|,\ k^*(x)\big\rangle = 1$. Also, because $k^*(x) \in H$, we have $k^*(x) = v + v_1$ for some $v_1 \in \{v\}^{\perp}$ and so $\big\langle v,\ k^*(x)\big\rangle = \langle v, v\rangle = \|v\|^2$. Now $\operatorname{sgn}(w) = \operatorname{sgn}(v)$, which means $\big\langle w,\ k^*(x)\big\rangle / \|w\| = \big\langle v,\ k^*(x)\big\rangle / \|v\|$, and substituting from above we obtain $1/\|w\| = \|v\|$. Because $\|v\| \geqslant \pi(x)$, we have $\|w\| \leqslant 1/\pi(x)$; and because w was arbitrary we conclude that $\|\partial_u \sigma(x, k^*(x))\| \leqslant 1/\pi(x)$. We summarize these results as

$$\frac{\nu(x)}{b(x)} = d(0, \partial_u \sigma(x, k^*(x))) \leqslant \|\partial_u \sigma(x, k^*(x))\| \leqslant \frac{1}{\pi(x)}. \tag{48}$$

It follows from (43), (46), and the chain rule [9, Thm. 2.3.9] that

$$\begin{aligned} \partial_u r(x, k^*(x)) &= \overline{\operatorname{co}}\{\eta\zeta : \eta \in \partial_s \gamma(x, \sigma(x, k^*(x))),\ \zeta \in \partial_u \sigma(x, k^*(x))\} \\ &= \overline{\operatorname{co}}\{\eta\zeta : \eta \in \big[a(x),\ b(x)\big],\ \zeta \in \partial_u \sigma(x, k^*(x))\}. \end{aligned} \tag{49}$$

We now use (48) and (49) to show that

$$N_E \cap \{u \in \mathcal{U} : \mu(x) \leqslant \|u\| \leqslant \nu(x)\} \subset \partial_u r(x, k^*(x)). \tag{50}$$

Let $w \in N_E$ be such that $\mu(x) \leqslant \|w\| \leqslant \nu(x)$. Because $k^*(x) \neq 0$, we have $\mu(x) > 0$, which means $w \neq 0$. It then follows from [30, Cor. 23.7.1] that there exists $\delta > 0$ such that

$\delta w \in \partial_u \sigma(x, k^*(x))$. From (48) we have $\delta\mu(x) \leqslant \delta\|w\| \leqslant 1/\pi(x)$, and it follows from (40) that $(1/\delta) \geqslant \mu(x)\pi(x) \geqslant a(x)$. Also from (48) we have $\nu(x)/b(x) \leqslant \delta\|w\| \leqslant \delta\nu(x)$, which means $(1/\delta) \leqslant b(x)$. Thus $(1/\delta) \in [a(x), b(x)]$, and it follows from (49) that $w = (1/\delta)\delta w \in \partial_u r(x, k^*(x))$. The choice for w was arbitrary, and thus (50) is true.

Now $k^*(x) \neq 0$, and it follows from Proposition 9.2 that $D_f V(x, k^*(x)) = -\alpha(x)$. It thus follows from (12) that $L_V(x) = \{u \in \mathcal{U} : D_f V(x, u) \leqslant D_f V(x, k^*(x))\}$ is the sublevel set of $D_f V$ at $k^*(x)$. Let N_L denote the normal cone to $L_V(x)$ at $k^*(x)$, let N_U denote the normal cone to $U(x)$ at $k^*(x)$, and let N_K denote the normal cone to $K_V(x)$ at $k^*(x)$. Now it follows from (11) that $0 \in \operatorname{int}[L_V(x) - U(x)]$, and so from (13) and [5, Table 4.3] we have $N_K = N_U + N_L$. Recall that $k^*(x)$ is the element of $K_V(x)$ of minimum norm; this together with the projection theorem implies $-k^*(x) \in N_K$. Also, it follows from A6 and (36) that $E \subset C(x) \subset U(x)$, and therefore $N_U \subset N_E$. It then follows that $-k^*(x) \in N_E + N_L$. Thus there exist $v_E \in N_E$ and $v_L \in N_L$ such that $-k^*(x) = v_E + v_L$. Our goal is to show that $-v_L \in N_E \setminus \{0\}$. Now $-k^*(x) \notin N_E$, which means $v_L \neq 0$. Suppose $v_E = 0$; then $-v_L = k^*(x) \in N_E$. Otherwise we use the linearity of the inner product to obtain $\langle v_E, \operatorname{sgn}(k^*(x))\rangle + \langle v_L, \operatorname{sgn}(k^*(x))\rangle = \langle -k^*(x), \operatorname{sgn}(k^*(x))\rangle = -\|k^*(x)\|$, and thus

$$\begin{aligned}\langle \operatorname{sgn}(-v_L), \operatorname{sgn}(k^*(x))\rangle &= \frac{\|v_E\|\langle \operatorname{sgn}(v_E), \operatorname{sgn}(k^*(x))\rangle + \|k^*(x)\|}{\|v_L\|} \\ &\geqslant \frac{\|v_E\|\langle \operatorname{sgn}(v_E), \operatorname{sgn}(k^*(x))\rangle + \|k^*(x)\|}{\|v_E\| + \|k^*(x)\|} \\ &\geqslant \langle \operatorname{sgn}(v_E), \operatorname{sgn}(k^*(x))\rangle.\end{aligned}$$

Thus the angle between $-v_L$ and $k^*(x)$ is smaller than the angle between v_E and $k^*(x)$. Now $v_E \in N_E$, and it follows from the convexity of N_E and the symmetry of N_E around $k^*(x)$ that $-v_L \in N_E$. We have thus shown that $-v_L \in N_E \setminus \{0\}$.

Now $v_L \in N_L \setminus \{0\}$, and it follows from [30, Cor. 23.7.1] that there exists $\delta > 0$ such that $\delta v_L \in D(x)$. From Proposition 9.3 we have $\mu(x) \leqslant \|\delta v_L\| \leqslant \nu(x)$; and because $-\delta v_L \in N_E$, we have from (50) that $-\delta v_L \in \partial_u r(x, k^*(x))$. Therefore $0 = -\delta v_L + \delta v_L \in \partial_u r(x, k^*(x)) + D(x)$, and the proof is complete. □

An immediate consequence of (44) and Proposition 9.4 are the equalities

$$0 = q(x) + r(x, k^*(x)) + D_f V(x, k^*(x)), \tag{51}$$

$$= q(x) + \min_{u \in \mathcal{U}} [r(x, u) + D_f V(x, u)], \tag{52}$$

$$= \min_{u \in \mathcal{U}} \max_{w \in W(x)} [q(x) + r(x, u) + L_f V(x, u, w)], \tag{53}$$

which hold for all $x \in \mathcal{X}$. Therefore, the rclf V satisfies the steady-state HJI equation associated with the cost functional J. We are now ready to prove Theorem 8.1.

Let $J_T(u_g, w_a, x; x_0)$ denote the cost J in (29) truncated at time T, again setting $J_T := \infty$ when the solution does not exist over $[0, T]$:

$$J_T(u_g, w_a, x; x_0) := \int_0^T [q(x) + r(x, u_g)]dt. \tag{54}$$

Fix $x_0 \in \mathcal{X}$ and $w_a \in \mathcal{D}(\Sigma)$, and let $x(t)$ be a solution of the closed-loop system (32) starting from x_0. Because k^* renders the solutions of (32) RGUAS, the solution $x(t)$ exists for all

$t \geqslant 0$ and furthermore $x(t) \to 0$ as $t \to \infty$. Thus we can integrate $L_f V$ along $x(t)$ and use (10) and (51) to obtain for all $T \geqslant 0$

$$\begin{aligned} V(x_0) &= V(x(T)) - \int_0^T L_f V(x, k^*(x), w_a)\, dt \\ &\geqslant V(x(T)) - \int_0^T D_f V(x, k^*(x))\, dt \\ &\geqslant V(x(T)) + \int_0^T [q(x) + r(x, k^*(x))] dt. \end{aligned} \tag{55}$$

Thus $V(x(T)) + J_T(k^*, w_a, x; x_0) \leqslant V(x_0)$ for all $T \geqslant 0$; and because $V(x(T)) \to 0$ as $T \to \infty$, we can take the limit to obtain $J(k^*, w_a, x; x_0) \leqslant V(x_0)$.

Next fix $x_0 \in \mathcal{X}$, $u_g \in \mathcal{C}(\Sigma)$, and $\Delta > 0$, and suppose condition DC is true. Then there exists $w_\Delta \in \mathcal{D}(\Sigma)$ and a solution $x_\Delta(t)$ of (8) starting from x_0 (with $w_a = w_\Delta$) such that either $J(u_g, w_\Delta, x_\Delta; x_0) = \infty$ or for every $T \geqslant 0$ we have

$$\int_0^T L_f V(x_\Delta, u_g, w_\Delta)\, dt \geqslant \int_0^T D_f V(x_\Delta, u_g)\, dt - \Delta. \tag{56}$$

If $J(u_g, w_\Delta, x_\Delta; x_0) = \infty$, then trivially we have $J(u_g, w_\Delta, x_\Delta; x_0) \geqslant V(x_0) - \Delta$. Otherwise $x_\Delta(t) \to 0$ as $t \to \infty$ and we can integrate $L_f V$ along the solution x_Δ as above and use (56) and (52) to obtain for all $T \geqslant 0$

$$\begin{aligned} V(x_0) &= V(x_\Delta(T)) - \int_0^T L_f V(x_\Delta, u_g, w_\Delta)\, dt \\ &\leqslant V(x_\Delta(T)) + \Delta - \int_0^T D_f V(x_\Delta, u_g)\, dt \\ &\leqslant V(x_\Delta(T)) + \Delta + \int_0^T [q(x_\Delta) + r(x_\Delta, u_g)] dt. \end{aligned} \tag{57}$$

Thus $V(x_\Delta(T)) + J_T(u_g, w_\Delta, x_\Delta; x_0) \geqslant V(x_0) - \Delta$ for all $T \geqslant 0$; and because $V(x_\Delta(T)) \to 0$ as $T \to \infty$, we obtain $J(u_g, w_\Delta, x_\Delta; x_0) \geqslant V(x_0) - \Delta$ in the limit. Because Δ was arbitrary, it follows from (30) that $\bar{J}(x_0) \geqslant V(x_0)$. Recall from above that k^* guarantees $J \leqslant V(x_0)$; it follows that $\bar{J}(x_0) = V(x_0)$ and that k^* is optimal from x_0. The initial condition x_0 was arbitrary, and the proof is complete.

10. Inverse optimal robust stabilization: finite horizon. We next extend the results of the previous two sections to the case where the scp is *not* satisfied. In this case, persistent disturbances may make convergence to the origin impossible, and so to obtain finite costs we introduce a *terminal time* for our game. Given a nonempty bounded *target set* $\Lambda \subset \mathcal{X}$ and a solution $x(t)$ of the differential equation (8), we define the terminal time T_Λ as

$$T_\Lambda := \inf\{T \geqslant 0 : x(t) \in \Lambda \text{ for all } t \geqslant T\}. \tag{58}$$

Thus T_Λ represents the first time the solution enters the target set Λ *without ever again leaving*. If the solution $x(t)$ does not exist for all $t \geqslant 0$ or is not eventually contained in Λ, then we set $T_\Lambda := \infty$. In addition to a terminal time for our game, we introduce a terminal cost $q_f : \mathcal{X} \to R_+$ according to the following specification.

S3. q_f satisfies $q_f \in \mathcal{A}_\kappa(\mathcal{X})$.

Using a triple (q, r, q_f) satisfying S1–S3, we will define a game $\mathcal{G}_\Lambda(q, r, q_f)$ for each nonempty bounded set $\Lambda \subset \mathcal{X}$ by considering a cost functional J_Λ parameterized by the initial condition $x_0 \in \mathcal{X}$. Given $x_0 \in \mathcal{X}$, $u_g \in \mathcal{C}(\Sigma)$, and $w_a \in \mathcal{D}(\Sigma)$ we define

$$J_\Lambda(u_g, w_a, x; x_0) := q_f(x(T_\Lambda)) + \int_0^{T_\Lambda} [q(x) + r(x, u_g)]dt, \tag{59}$$

where the integration is taken along the (possibly nonunique) solution $x(t)$ of the differential equation (8) starting from the initial condition x_0. If $T_\Lambda = \infty$, then we set $J_\Lambda(u_g, w_a, x; x_0) := \infty$. We define the upper value function $\bar{J}_\Lambda : \mathcal{X} \to R_+ \cup \{\infty\}$ of the game by the equation

$$\bar{J}_\Lambda(x_0) := \inf_{u_g} \sup_{w_a} \sup_{x} J_\Lambda(u_g, w_a, x; x_0). \tag{60}$$

The first supremum is taken over all solutions $x(t)$ of (8) starting from x_0 (this supremum is superfluous if solutions are unique), the second supremum is taken over all admissible disturbances $w_a \in \mathcal{D}(\Sigma)$, and the infimum is taken over all generic controls $u_g \in \mathcal{C}(\Sigma)$. When the infimum in (60) is achieved by some $u_g^* \in \mathcal{C}(\Sigma)$ for some $x_0 \in \mathcal{X}$ such that $\bar{J}_\Lambda(x_0) < \infty$, we say that u_g^* is *optimal from* x_0. We say a control law k^* for Σ is *optimal for* $\mathcal{G}_\Lambda(q, r, q_f)$ when k^* is optimal from every $x_0 \in \mathcal{X}$. Note that every optimal control law is robustly stabilizing in the sense that every closed-loop trajectory is eventually contained in Λ.

Let V be a strong rclf for Σ. We say a nonempty bounded set $\Lambda \subset \mathcal{X}$ is an *admissible target set for* V when there exists $c > c_V$ such that $\Omega_c(V) \subset \Lambda$. If $c_V = 0$, then any bounded set Λ containing a neighborhood of the origin is an admissible target set for V; this is consistent with practical stabilizability. For each admissible target set Λ^* for V, we define a nonempty set $K(V, \Lambda^*)$ of pointwise min-norm control laws as follows. We say a control law k for Σ belongs to $K(V, \Lambda^*)$ when it is pointwise min-norm for V with the associated constant $c > c_V$ satisfying $\Omega_c(V) \subset \Lambda^*$ and the associated negativity margin α being bounded away from zero outside some compact set. Theorem 10.1 states that for every control law $k^* \in K(V, \Lambda^*)$ there exists a triple (q, r, q_f) satisfying S1–S3 such that k^* is optimal for $\mathcal{G}_\Lambda(q, r, q_f)$ for every $\Lambda \supset \Lambda^*$, with V being the corresponding upper value function. Each game $\mathcal{G}_\Lambda(q, r, q_f)$ is meaningful for the same reasons the game of §8 was meaningful; the difference here is the terminal time T_Λ and the terminal cost q_f. Our choice for the terminal time in (58) is consistent with the stabilization objective: the game ends when we enter the target set Λ permanently. If we enter and then leave again, the game continues. We must allow for the possibility of the trajectory leaving Λ because there does not necessarily exist a control that renders Λ positively invariant. Our technical condition on the admissible disturbances now depends on Λ as follows:

DC$_\Lambda$. For every $x_0 \in \mathcal{X}$, every $u_g \in \mathcal{C}(\Sigma)$, and every $\Delta > 0$ there exists $w_\Delta \in \mathcal{D}(\Sigma)$ and a solution $x_\Delta(t)$ of (8) starting from x_0 (with $w_a = w_\Delta$) such that either $J_\Lambda(u_g, w_\Delta, x_\Delta; x_0) = \infty$ or

$$\int_0^{T_\Lambda} L_f V(x_\Delta, u_g, w_\Delta)\, dt \geqslant \int_0^{T_\Lambda} D_f V(x_\Delta, u_g)\, dt - \Delta. \tag{61}$$

As in the previous section, if DC$_\Lambda$ is not true, then we may achieve suboptimality rather than optimality. We now state the main result of this section.

THEOREM 10.1. *Let* Σ *satisfy assumptions* A1–A6, *let* V *be a strong* rclf *for* Σ, *let* Λ^* *be an admissible target set for* V, *and let* $k^* \in K(V, \Lambda^*)$. *Then there exists a triple* (q, r, q_f) *satisfying* S1–S3 *such that* $J_\Lambda(k^*, w_a, x; x_0) \leqslant V(x_0)$ *for every admissible target set* $\Lambda \supset \Lambda^*$,

every $x_0 \in \mathcal{X}$, *every* $w_a \in \mathcal{D}(\Sigma)$, *and every solution* $x(t)$ *of* (32) *starting from* x_0. *If furthermore* DC_Λ *is true, then* $\bar{J}_\Lambda(x_0) = V(x_0)$ *for all* $x_0 \in \mathcal{X}$, *which means* k^* *is optimal for* $\mathcal{G}_\Lambda(q, r, q_f)$.

The proof of this theorem is similar to the proof of Theorem 8.1. From Definition 7.2 and the definition of $K(V, \Lambda^*)$ above, there exist $c > c_V$ and a minimal selection m_V of V such that $\Omega_c(V) \subset \Lambda^*$ and $k^*(x) = m_V(x)$ for all $x \in \mathcal{X} \setminus \Omega_c(V)$, with the associated negativity margin α being bounded away from zero outside some compact set. We choose $q_f(x) := V(x)$ for all $x \in \mathcal{X}$; this choice satisfies S3. We define $C(x)$, $\sigma(x, u)$, and $D(x)$ as in (36)–(38). Proposition 9.1 remains true, but Propositions 9.2 and 9.3 become weaker as follows (we omit their proofs).

PROPOSITION 10.2. *If* $x \in \mathcal{X} \setminus \Omega_c(V)$ *and* $k^*(x) \neq 0$, *then* $D_f V(x, k^*(x)) = -\alpha(x)$ *and* $0 \notin D(x)$.

PROPOSITION 10.3. *There exist continuous functions* $\mu, \nu : \mathcal{X} \to R_+$ *such that* $\mu(x) \leqslant d(0, D(x))$ *for all* $x \in \mathcal{X} \setminus \Omega_c(V)$ *and* $\|D(x)\| < \nu(x)$ *for all* $x \in \mathcal{X}$, *with* μ *having the additional property that* $\mu(x) > 0$ *if and only if* $k^*(x) \neq 0$.

Because α is bounded away from zero outside a compact set, it follows from (11) that there exist $\alpha_0 \in \mathcal{A}(\mathcal{X})$ and $\widehat{\alpha} > 0$ such that $\alpha(x) - \alpha_0(x) \geqslant \widehat{\alpha}$ for all $x \in \mathcal{X} \setminus \Omega_c(V)$. We then define $a(x)$, $b(x)$, $\gamma(x, s)$, and $r(x, u)$ as in (40)–(43). It follows that r satisfies S2. Our next task is to construct the function q. We first show that there exist continuous functions $d_1, d_2 : \mathcal{X} \to R$ such that $d_1(x) > 0$ for all $x \in \mathcal{X}$ and

$$r(x, u) + D_f V(x, u) \geqslant d_1(x)\,\|u\| + d_2(x) \tag{62}$$

for all $(x, u) \in \mathcal{X} \times \mathcal{U}$. First, it follows from (37) and (41) that $b(x)\,\sigma(x, u) \geqslant \nu(x)\,\|u\|$ for all $(x, u) \in \mathcal{X} \times \mathcal{U}$. It then follows from (42) and (43) that

$$\begin{aligned} r(x, u) &\geqslant b(x)\,\sigma(x, u) + \sigma(x, k^*(x))\big[a(x) - b(x)\big] \\ &\geqslant \nu(x)\,\|u\| + \sigma(x, k^*(x))\big[a(x) - b(x)\big] \end{aligned} \tag{63}$$

for all $(x, u) \in \mathcal{X} \times \mathcal{U}$. For each $x \in \mathcal{X}$ choose $w_x \in D(x)$; then it follows from (38) and Proposition 10.3 that

$$\begin{aligned} D_f V(x, u) &\geqslant D_f V(x, k^*(x)) + \langle w_x, u - k^*(x)\rangle \\ &\geqslant D_f V(x, k^*(x)) - \|w_x\| \cdot \|u\| - \|w_x\| \cdot \|k^*(x)\| \\ &\geqslant D_f V(x, k^*(x)) - \|D(x)\| \cdot \|u\| - \nu(x)\,\|k^*(x)\| \end{aligned} \tag{64}$$

for all $(x, u) \in \mathcal{X} \times \mathcal{U}$. We add the inequalities (63) and (64) to obtain

$$\begin{aligned} r(x, u) + D_f V(x, u) \geqslant\ & [\nu(x) - \|D(x)\|]\|u\| + \sigma(x, k^*(x))\big[a(x) - b(x)\big] \\ & + D_f V(x, k^*(x)) - \nu(x)\,\|k^*(x)\| \end{aligned} \tag{65}$$

for all $(x, u) \in \mathcal{X} \times \mathcal{U}$. It follows from Proposition 10.3, [18, Prob. 5X], and the lower semicontinuity of the mapping $x \mapsto \nu(x) - \|D(x)\|$ that there exists a continuous function $d_1 : \mathcal{X} \to R$ such that $0 < d_1(x) \leqslant \nu(x) - \|D(x)\|$ for all $x \in \mathcal{X}$. Thus if we define $d_2(x) := \sigma(x, k^*(x))\big[a(x) - b(x)\big] + D_f V(x, k^*(x)) - \nu(x)\,\|k^*(x)\|$ for all $x \in \mathcal{X}$, then d_2 is continuous and (65) implies (62).

We next define a function $\omega : \mathcal{X} \to R_+$ for all $x \in \mathcal{X}$ as

$$\omega(x) := \frac{r(x, k^*(x)) + D_f V(x, k^*(x)) - d_2(x)}{d_1(x)}. \tag{66}$$

Thus ω is continuous and it follows from (62) that $\|k^*(x)\| \leqslant \omega(x)$ for all $x \in \mathcal{X}$. Also, from (62) we see that for all $(x, u) \in \mathcal{X} \times \mathcal{U}$ such that $\|u\| > \omega(x)$ we have $r(x, u) + D_f V(x, u) \geqslant d_1(x)\|u\| + d_2(x) > r(x, k^*(x)) + D_f V(x, k^*(x))$. Therefore

$$\begin{aligned} \inf_{u \in \mathcal{U}} [r(x, u) + D_f V(x, u)] &= \inf_{u \in \omega(x)B} [r(x, u) + D_f V(x, u)] \\ &= \min_{u \in \omega(x)B} [r(x, u) + D_f V(x, u)] \end{aligned} \tag{67}$$

for all $x \in \mathcal{X}$, where the second line follows from the continuity of $r + D_f V$ and the compactness of $\omega(x)B$. Now [5, Thm. 1.4.16] implies that the right-hand side of (67) is continuous on $\mathcal{X}$, and so the mapping

$$x \mapsto \min_{u \in \mathcal{U}} [r(x, u) + D_f V(x, u)] \tag{68}$$

is well defined and continuous on $\mathcal{X}$. Let $\alpha_1 \in \mathcal{A}_\kappa(\mathcal{X})$ be such that $\alpha_1(x) \leqslant \widehat{\alpha}$ for all $x \in \mathcal{X}$. We define q for all $x \in \mathcal{X}$ as

$$q(x) := \max \left\{ \alpha_1(x), \ -\min_{u \in \mathcal{U}} [r(x, u) + D_f V(x, u)] \right\}. \tag{69}$$

Thus q is continuous with $q(0) = 0$ and $q \geqslant \alpha_1$, and it follows that $q \in \mathcal{A}_\kappa(\mathcal{X})$ as required in S1. With this choice for q, it is true for all $x \in \mathcal{X}$ that

$$q(x) + \min_{u \in \mathcal{U}} [r(x, u) + D_f V(x, u)] \geqslant 0. \tag{70}$$

One can use Propositions 10.2 and 10.3 in the proof of Proposition 9.4 to show that (45) is true for $x \in \mathcal{X} \setminus \Omega_c(V)$, and so we have

$$q(x) = \max\{\alpha_1(x), \ -r(x, k^*(x)) - D_f V(x, k^*(x))\} \tag{71}$$

for all such x. Now $-r(x, k^*(x)) - D_f V(x, k^*(x)) \geqslant \alpha(x) - \alpha_0(x) \geqslant \widehat{\alpha} \geqslant \alpha_1(x)$ for all such x, which means

$$q(x) = -r(x, k^*(x)) - D_f V(x, k^*(x)) \tag{72}$$

for all such x. Therefore, it is true for all $x \in \mathcal{X} \setminus \Omega_c(V)$ that

$$0 = q(x) + r(x, k^*(x)) + D_f V(x, k^*(x)) \tag{73}$$

$$= q(x) + \min_{u \in \mathcal{U}} [r(x, u) + D_f V(x, u)]. \tag{74}$$

Thus the HJI *inequality* (70) is true for all $x \in \mathcal{X}$, whereas the HJI *equality* (74) is true whenever $x \in \mathcal{X} \setminus \Omega_c(V)$. We are now ready to prove Theorem 10.1.

Proof of Theorem 10.1. Let $\Lambda \supset \Lambda^*$ be an admissible target set for V, let $x_0 \in \mathcal{X}$, let $w_a \in \mathcal{D}(\Sigma)$, and let $x(t)$ be a solution of the closed-loop system (32) starting from x_0. Because k^* renders the solutions of (32) RGUAS-$\Omega_c(V)$ and $\Omega_c(V) \subset \Lambda$, it follows from (58) that $T_\Lambda < \infty$. Thus we can integrate $L_f V$ along $x(t)$ to obtain

$$0 = V(x_0) - V(x(T_\Lambda)) + \int_0^{T_\Lambda} L_f V(x, k^*(x), w_a)\, dt. \tag{75}$$

Because $q_f = V$, we can add this zero quantity (75) to (59) and use (10) to obtain

$$J_\Lambda(k^*, w_a, x; x_0) = V(x_0) + \int_0^{T_\Lambda} [q(x) + r(x, k^*(x)) + L_f V(x, k^*(x), w_a)]dt$$

$$\leqslant V(x_0) + \int_0^{T_\Lambda} [q(x) + r(x, k^*(x)) + D_f V(x, k^*(x))]dt. \tag{76}$$

Now k^* renders the set $\Omega_c(V)$ robustly positively invariant, and so from (58) we have $x(t) \in \mathcal{X} \setminus \Omega_c(V)$ for all $t \in [0, T_\Lambda)$. It then follows from (73) that the integrand in (76) is zero for all $t \in [0, T_\Lambda)$, and thus we have $J_\Lambda(k^*, w_a, x; x_0) \leqslant V(x_0)$.

Next fix $x_0 \in \mathcal{X}$, $u_g \in \mathcal{C}(\Sigma)$, and $\Delta > 0$, and suppose condition DC_Λ is true. Then there exists $w_\Delta \in \mathcal{D}(\Sigma)$ and a solution $x_\Delta(t)$ of (8) starting from x_0 (with $w_a = w_\Delta$) such that either $J_\Lambda(u_g, w_\Delta, x_\Delta; x_0) = \infty$ or

$$\int_0^{T_\Lambda} L_f V(x_\Delta, u_g, w_\Delta)\, dt \geqslant \int_0^{T_\Lambda} D_f V(x_\Delta, u_g)\, dt - \Delta. \tag{77}$$

If $J_\Lambda(u_g, w_\Delta, x_\Delta; x_0) = \infty$, then trivially we have $J_\Lambda(u_g, w_\Delta, x_\Delta; x_0) \geqslant V(x_0) - \Delta$. Otherwise $T_\Lambda < \infty$ and we can integrate $L_f V$ along the solution x_Δ as above and use (77) and (70) to obtain

$$J_\Lambda(u_g, w_\Delta, x_\Delta; x_0) = V(x_0) + \int_0^{T_\Lambda} [q(x_\Delta) + r(x_\Delta, u_g) + L_f V(x_\Delta, u_g, w_\Delta)]dt$$

$$\geqslant V(x_0) - \Delta + \int_0^{T_\Lambda} [q(x_\Delta) + r(x_\Delta, u_g) + D_f V(x_\Delta, u_g)]dt$$

$$\geqslant V(x_0) - \Delta. \tag{78}$$

Because Δ was arbitrary, it follows from (60) that $\bar{J}_\Lambda(x_0) \geqslant V(x_0)$. Recall from above that k^* guarantees $J_\Lambda \leqslant V(x_0)$; it follows that $\bar{J}_\Lambda(x_0) = V(x_0)$ and that k^* is optimal from x_0. The initial condition x_0 was arbitrary, and the proof is complete. □

11. Conclusion. We have introduced the robust control Lyapunov function and shown that its existence is equivalent to robust stabilizability. Also, we have solved an inverse optimal robust stabilization problem by showing that every rclf is an upper value function for a meaningful game and that every pointwise min-norm control law is optimal for such a game. Our formulas (18) and (23) can be used to generate control laws that have the desirable properties of optimality but do not require the solution of an HJI equation.

Our results motivate further research in the development of methods for the construction rclf 's for uncertain nonlinear systems. Recent breakthroughs in this area include recursive backstepping techniques [25, 32, 29]. In this paper we provided a method for choosing a reasonable control law given an rclf, but the overall system performance will ultimately be determined by the choice of the rclf itself. This point is illustrated in [12], where it is shown that an improper choice of the rclf can lead to undesirable behavior no matter how the associated control law is chosen. Methods for improving the choices of rclf 's, when combined with the results in this paper on choosing control laws, will constitute a promising strategy for the design of controllers for uncertain nonlinear systems.

12. Appendix. We include here two simple lemmas whose proofs we could not find elsewhere.

LEMMA 12.1. *Let Z be a metric space, let Y be a finite-dimensional Hilbert space, and let $h : Z \times Y \to R$ be continuous. If the mapping $y \mapsto h(z, y)$ is convex for every $z \in Z$,*

then the partial subdifferential $\partial_y h : Z \times Y \rightsquigarrow Y$ is usc on $Z \times Y$ and has nonempty, convex, compact values.

Proof. It follows from [30, Thm. 23.4] that $\partial_y h$ has nonempty, convex, compact values. To prove upper semicontinuity, fix $(z_0, y_0) \in Z \times Y$ and let $\{(z_i, y_i)\} \in Z \times Y$ converge to (z_0, y_0). Let $\{w_i\} \in Y$ be any sequence such that $w_i \in \partial_y h(z_i, y_i)$ for all $i \geqslant 1$. It follows from [19, Thm. II.2.2] that we need only show that $\{w_i\}$ has a subsequence converging to some $w_0 \in \partial_y h(z_0, y_0)$. First we show that $\{w_i\}$ is bounded. From the definition of $\partial_y h$ we have $\langle w_i, v - y_i \rangle \leqslant h(z_i, v) - h(z_i, y_i)$ for all $v \in Y$ and all $i \geqslant 1$. It follows from the continuity of h and the compactness of the unit sphere in Y that there exists $M \in R$ such that $\langle w_i, e \rangle \leqslant M$ for all unit vectors $e \in Y$ and all $i \geqslant 1$, and we conclude that $\{w_i\}$ is bounded. Let $\{w_{i_j}\}$ be a convergent subsequence of $\{w_i\}$ with limit $w_0 \in Y$. Fix $v \in Y$; then for all $j \geqslant 1$ we have $\langle w_{i_j}, v - y_{i_j} \rangle \leqslant h(z_{i_j}, v) - h(z_{i_j}, y_{i_j})$. It follows from the continuity of the inner product and h that $\langle w_0, v - y_0 \rangle \leqslant h(z_0, v) - h(z_0, y_0)$. This holds for all $v \in Y$, and so $w_0 \in \partial_y h(z_0, y_0)$ as desired. □

LEMMA 12.2. *Let Y be a finite-dimensional Hilbert space, and let $h : Y \to R$ be a sublinear functional. For each $y \in Y$, let $E_y = \{\xi \in Y : h(\xi) \leqslant h(y)\}$ denote the sublevel set of h at y and $N_E(y)$ denote the normal cone to E_y at y. Then $\partial h(y) \neq \emptyset$ for all $y \in Y$, and for every $y \in Y$ such that $h(y) \neq 0$ we have*

$$\partial h(y) = N_E(y) \cap \left[p + \{y\}^{\perp} \right], \tag{79}$$

where p is any member of $\partial h(y)$.

Proof. It follows from [30, Thm. 23.4] that $\partial h(y)$ is nonempty for all $y \in Y$. Let $y \in Y$ be such that $h(y) \neq 0$, and let $p \in \partial h(y)$. We first show that $\langle w, y \rangle = h(y)$ for all $w \in \partial h(y)$. Indeed, $w \in \partial h(y)$ implies $h(\xi) \geqslant h(y) + \langle w, \xi - y \rangle$ for all $\xi \in Y$. Taking $\xi = 0$ we obtain $0 \geqslant h(y) + \langle w, -y \rangle$, which means $\langle w, y \rangle \geqslant h(y)$, and taking $\xi = 2y$ we obtain $h(2y) = 2h(y) \geqslant h(y) + \langle w, y \rangle$, which means $\langle w, y \rangle \leqslant h(y)$. It then follows that for any $w \in \partial h(y)$ we have $\langle w - p, y \rangle = h(y) - h(y) = 0$, which means $w \in [p + \{y\}^{\perp}]$. Now because h is sublinear and $h(y) \neq 0$, we know that y does not minimize h, and it follows from [30, Cor. 23.7.1] that $\partial h(y) \subset N_E(y)$. We have thus shown that $\partial h(y) \subset N_E(y) \cap [p + \{y\}^{\perp}]$.

Next suppose $w \in N_E(y) \cap [p + \{y\}^{\perp}]$. Because $\langle p, y \rangle = h(y) \neq 0$, we have $0 \notin [p + \{y\}^{\perp}]$, which means $w \neq 0$. It then follows from [30, Cor. 23.7.1] that $\lambda w \in \partial h(y)$ for some $\lambda > 0$. From above we have $\lambda w \in [p + \{y\}^{\perp}]$, and it follows that $(\lambda w - w) \in \{y\}^{\perp}$ and so $(\lambda - 1)\langle w, y \rangle = 0$. Now $\langle w, y \rangle = \langle \lambda w, y \rangle / \lambda = h(y)/\lambda \neq 0$, and it follows that $\lambda = 1$. Therefore $w = \lambda w \in \partial h(y)$, and we have shown that $N_E(y) \cap [p + \{y\}^{\perp}] \subset \partial h(y)$. □

Acknowledgments. This work was initiated in part through discussions with Tamer Başar, and we thank him for his useful comments. Also, we thank Eduardo Sontag for providing us with an early copy of the paper [24], the results of which enabled us to prove the necessary conditions in §§5 and 6.

THE STRUCTURED SINGULAR VALUE FOR LINEAR INPUT/OUTPUT OPERATORS*

HARI BERCOVICI†, CIPRIAN FOIAS†, AND ALLEN TANNENBAUM‡

Abstract. In this paper, we employ our lifting method to study the structured singular value applied to input/output operators of control systems. We moreover give a new criterion which guarantees that the structured singular value equals its upper bound defined by D-scalings.

Key words. structured singular value, time-varying perturbations, lifting, robust control

AMS subject classifications. 93B35, 93C05

1. Introduction.

Let A be a linear operator on a Hilbert space $\mathcal{E}$, and let Δ be an algebra of operators on $\mathcal{E}$. The structured singular value of A (relative to Δ) is the number

$$\mu_\Delta(A) = 1/\inf\{\|X\| : X \in \Delta,\ -1 \in \sigma(AX)\}\,.$$

This quantity was introduced by Doyle and Safonov [6, 12] under a more restrictive context, and it has proved to be a powerful tool in robust system analysis and design. In system analysis, the structured singular value gives a measure of robust stability with respect to certain perturbation measures. Unfortunately, $\mu_\Delta(A)$ is very difficult to calculate, and in practice an upper bound for it is used. This upper bound is defined by

$$\widehat{\mu}_\Delta(A) := \inf\{\|XAX^{-1}\| : X \in \Delta',\ X \text{ invertible}\},$$

where Δ' is the commutant of the algebra Δ.

In [1, 5], we formulated a lifting technique for the study of the structured singular value. The basic idea is that $\widehat{\mu}_\Delta(A)$ can be shown to be equal to the structured singular value of an operator on a bigger Hilbert space. (In [1] this was done for finite-dimensional Hilbert spaces, and then in [5] this was extended to the infinite-dimensional case.) The problem with these results is that the size of the ampliation necessary to get $\widehat{\mu}_\Delta(A)$ equal to a structured singular value was equal to the dimension of the underlying Hilbert space. Hence in the infinite-dimensional case we needed an infinite ampliation. In this work, we will show that in fact one can always get by with a finite lifting. (Note that in this paper we will be using the terms "ampliation" and "lifting" interchangeably.) For the block diagonal algebras of interest in robust control, the ampliation only depends on the number of blocks of the given perturbation structure. (See Theorem 4.1 below.) We moreover give a new result when $\widehat{\mu}_\Delta(A) = \mu_\Delta(A)$, that is, when no lifting is necessary and so $\widehat{\mu}_\Delta(A)$ gives a nonconservative measure of robustness. (See Theorem 5.3.) This is then used to derive an elegant result of Shamma [13, 14] on Toeplitz operators. See also [7, 9, 10] for related work in this area.

We now briefly sketch the contents of this paper. In §2, we give some background results which will be needed in the proof of Theorem 4.1. In §3, we derive a number of useful facts about the relative numerical range. Then in §4, we state and prove our new version of the lifting theorem relating the structured singular value and its upper bound. In §5, we give new conditions when $\mu = \hat{\mu}$. These are applied in §6 to give a new proof of the aforementioned result of Shamma. Finally, in §7, we give a system-theoretic interpretation of our lifting methodology.

2. Preliminary results. Denote by $\mathcal{L}(\mathcal{E})$ the algebra of all bounded linear operators on the (complex, separable) Hilbert space $\mathcal{E}$. Fix an operator $A \in \mathcal{L}(\mathcal{E})$ and a subalgebra $\Delta \subset \mathcal{L}(\mathcal{E})$. The numbers $\mu_\Delta(A)$ and $\widehat{\mu}_\Delta(A)$ have already been defined in the Introduction. Observe that $\Delta \subset \Delta''$ and $\Delta''' = (\Delta'')' = \Delta'$ so that we have the inequalities

$$\mu_\Delta(A) \le \mu_{\Delta''}(A), \quad \widehat{\mu}_\Delta(A) = \widehat{\mu}_{\Delta''}(A) .$$

Observe that the algebras Δ considered in [6] consisted of block diagonal matrices, so our approach is more general in this respect. In the following proposition we summarize some of the elementary properties of μ_Δ; see Doyle [6] or [1] for proofs. We will denote by $\|T\|_{\mathrm{sp}}$ the spectral radius of the operator T.

LEMMA 2.1. (i) $\mu_\Delta(A) = \sup\{\|AX\|_{\mathrm{sp}} : X \in \Delta, \ \|X\| \le 1\}$;

(ii) μ_Δ *is upper semicontinuous*;

(iii) *if* $\mathcal{E}$ *is finite dimensional, then* μ_Δ *is continuous*;

(iv) $\mu_\Delta(A) \le \widehat{\mu}_\Delta(A)$.

In our study we will need further singular values which we now define. For $n \in \{1, 2, \ldots, \infty\}$ we denote by $\mathcal{E}^{(n)}$ the orthogonal sum of n copies of $\mathcal{E}$ and by $T^{(n)}$ the orthogonal of n copies of $T \in \mathcal{L}(\mathcal{E})$. Operators on $\mathcal{E}^{(n)}$ can be represented as $n \times n$ matrices of operators in $\mathcal{L}(\mathcal{E})$, and $T^{(n)}$ is represented by a diagonal matrix, with diagonal entries equal to T.

Denote by Δ_n the algebra of all operators on $\mathcal{E}^{(n)}$ whose matrix entries belong to Δ, and observe that $(\Delta_n)'' = (\Delta'')_n$ and $(\Delta_n)' = (\Delta')^{(n)} = \{T^{(n)} : T \in \Delta'\}$. Therefore we will denote these algebras by Δ_n'' and Δ_n', respectively.

LEMMA 2.2. *For every finite number n we have*

$$\mu_\Delta(A) \le \mu_{\Delta_n}(A^{(n)}) \le \mu_{\Delta_{n+1}}(A^{(n+1)}) \le \mu_{\Delta_\infty}(A^{(\infty)}) \le \widehat{\mu}_\Delta(A)$$

and

$$\mu_{\Delta''}(A) \le \mu_{\Delta_n''}(A^{(n)}) \le \mu_{\Delta_{n+1}''}(A^{(n+1)}) \le \mu_{\Delta_\infty''}(A^{(\infty)}) \le \widehat{\mu}_\Delta(A) .$$

Proof. It is clearly sufficient to prove the first sequence of inequalities. Observe that for every $X \in \Delta_n$ and for $m > n$ we can define an operator $Y \in \Delta_m$ by $Y = X \oplus 0$. Clearly $\sigma(A^{(n)}X) = \sigma(A^{(m)}Y) \cup \{0\}$ and hence $-1 \in \sigma(A^{(n)}X)$ implies $-1 \in \sigma(A^{(m)}Y)$. Since $\mu_\Delta(A) = \mu_{\Delta_1}(A^{(1)})$, this proves the first three inequalities. The last one follows because $\mu_{\Delta_\infty}(A^{(\infty)}) \le \widehat{\mu}_{\Delta_\infty}(A^{(\infty)}) = \widehat{\mu}_\Delta(A)$. □

We will now state (without proof) several results from [1–5] which we will need.

LEMMA 2.3 (see [5]). *Let A be a finite-dimensional* $\mathbf{C}^*$*-algebra. Then A has only finitely many equivalence classes of cyclic representations.*

LEMMA 2.4 (see [5]). *Let the sequence* Y_j *of operators on* $\mathcal{H}$ *and the sequence* $h_j \in \mathcal{H}$ *satisfy*

(i) $\sup_j \operatorname{rank} Y_j < \infty$, $\sup_j \|Y_j\| < \infty$;

(ii) $\lim_{j\to\infty} \|(Y_j - I)h_j\| = 0$;

(iii) $\lim_{j\to\infty} \|h_j\| = 1$.

Then $\liminf_{n\to\infty} \|Y_j\|_{\mathrm{sp}} \ge 1$.

LEMMA 2.5 (see [4]). *Let* $\mathcal{H}$ *be a Hilbert space,* $T \in \mathcal{L}(\mathcal{H})$*, and* $D_j \in \mathcal{L}(\mathcal{H})$ *be invertible so that*

$$T_0 = \lim_{j\to\infty} D_j T D_j^{-1}.$$

If the set $\{D_j, D_j^{-1} : j = 1, 2, \ldots\}$ *is contained in a finite-dimensional subspace, then* $\|T_0\|_{\mathrm{sp}} = \|T\|_{\mathrm{sp}}$.

3. Relative numerical range. We will also need some results in what follows about the relative numerical range. Let $\mathcal{H}$ be a complex separable Hilbert space, and let $\mathcal{L}(\mathcal{H})$ denote the set of bounded linear operators on $\mathcal{H}$. Let $T_1, \dots, T_m, Q \in \mathcal{L}(\mathcal{H})$. Then we define the following *relative numerical ranges*:

$$W_Q(T_1, \dots, T_m) := \Big\{\lambda \in \mathbf{C}^n,\ \lambda = \lim_{n\to\infty} (\langle T_j h_n, h_n\rangle)_{j=1}^m :$$
$$h_n \in \mathcal{H}, \|h_n\| = 1, \lim_{n\to\infty} \|Qh_n\| = 0\Big\}$$

and

$$W_Q^0(T_1, \dots, T_m) := \Big\{\lambda \in \mathbf{C}^n,\ \lambda = \lim_{n\to\infty} (\langle T_j h_n, h_n\rangle)_{j=1}^m :$$
$$h_n \in \mathcal{H}, \|h_n\| = 1, \lim_{n\to\infty} \|Qh_n\| = 0, h_n \to 0 \text{ weakly}\Big\}.$$

LEMMA 3.1. *$W_Q^0(T_1, \dots, T_m)$ is a compact convex subset of $\mathbf{C}^m$.*

Proof. The compactness is immediate since $W_Q^0(T_1, \dots, T_m)$ is a closed bounded subset of $\mathbf{C}^m$. As for the convexity, let $\lambda = (\lambda_1, \dots, \lambda_m)$, $\mu = (\mu_1, \dots, \mu_m) \in W_Q^0(T_1, \dots, T_m)$, and let the sequences of unit vectors

$$\{h_n\}_{n=1}^\infty,\ \{k_n\}_{n=1}^\infty \subset \mathcal{H}$$

satisfy

$$\lambda_j = \lim_{n\to\infty} \langle T_j h_n, h_n\rangle,$$
$$\mu_j = \lim_{n\to\infty} \langle T_j k_n, k_n\rangle, \qquad j = 1, \dots, m,$$
$$\lim_{n\to\infty} \|Qh_n\| = 0 = \lim_{n\to\infty} \|Qk_n\|,\ h_n \to 0,\ k_n \to 0 \text{ weakly}.$$

Next for n fixed choose $N_n \geq n$ such that

$$|\langle h_n, k_{N_n}\rangle| \leq \frac{1}{n},\ |\langle T_j h_n, k_{N_n}\rangle| + |\langle T_j^* h_n, k_{N_n}\rangle| \leq \frac{1}{n}, \qquad j = 1, 2, \dots, m.$$

Then for any $\theta \in [0, 1]$,

$$g_n := \sqrt{\theta} h_n + \sqrt{1-\theta} k_{N_n}, \qquad n \geq 2,$$

satisfies the following conditions:

$$\|g_n\|^2 = 1 + 2\sqrt{\theta(1-\theta)}\Re\langle h_n, k_{N_n}\rangle \to 1, \qquad \|g_n\|^2 \geq \frac{1}{2},$$
$$g_n \to 0 \text{ weakly}, \qquad \|Qg_n\| \to 0,$$
$$|\langle T_j g_n, g_n\rangle - \theta\lambda_j - (1-\theta)\mu_j| \leq \theta|\langle T_j h_n, h_n\rangle - \lambda_j| + (1-\theta)|\langle T_j k_{N_n}, k_{N_n}\rangle - \mu_j|$$
$$+\sqrt{\theta(1-\theta)}\frac{1}{n} \to 0 \text{ as } n \to \infty.$$

Thus replacing the g_n by $g_n/\|g_n\|$ we immediately conclude that

$$\theta\lambda + (1-\theta)\mu \in W_Q^0(T_1, \dots, T_m),$$

as required. □

LEMMA 3.2. *$W_Q(T_1, \ldots, T_m)$ is the union of all segments*

$$\{\theta\lambda + (1-\theta)\mu : 0 \le \theta \le 1\},$$

where $\lambda \in W_Q^0(T_1, \ldots, T_m)$ and $\mu = (\langle T_j h, h\rangle)_{j=1}^m$ for some $h \in \ker Q$, $\|h\| = 1$.

Proof. Let $\theta, \lambda = (\lambda_j)_{j=1}^m, \mu = (\mu_j)_{j=1}^m$ be as above and let the sequence $\{h_n\}_{n=1}^\infty \subset \mathcal{H}$ satisfy $\|h_n\| = 1$, $h_n \to 0$ weakly, $Qh_n \to 0$ strongly, and $\langle T_j h_n, h_n\rangle \to \lambda_j$ for $j = 1, \ldots, m$. Then as in the proof of Lemma 3.1, we obtain that

$$g_n = \sqrt{\theta} h_n + \sqrt{1-\theta} h, \qquad n = 1, 2, \ldots$$

satisfies the conditions

$$\|g_n\| \to 1, \qquad \|Qg_n\| \to 0,$$

and

$$\langle T_j g_n, g_n\rangle \to \theta\lambda_j + (1-\theta)\mu_j, \qquad j = 1, \ldots, m.$$

Therefore

$$\theta\lambda + (1-\theta)\mu \in W_Q(T_1, \ldots, T_m).$$

Conversely, if $\psi = (\psi_j)_{j=1}^m \in W_Q(T_1, \ldots, T_m)$, then

$$\psi_j = \lim_{n\to\infty} \langle T_j g_n, g_n\rangle, \qquad j = 1, \ldots, m,$$

for some sequence $\{g_n\}_{n=1}^\infty \subset \mathcal{H}$ such that $\|g_n\| = 1$, $\|Qg_n\| \to 0$. Without loss of generality we can assume that g_n converges weakly to some $h' \in \ker Q$.

If $\|h'\| = 1$, then g_n converges strongly to h' and $\psi_j = \langle T_j h', h'\rangle$, $j = 1, 2, \ldots, m$. Clearly then

$$\psi = \theta\lambda + (1-\theta)(\langle T_j h, h\rangle)_{j=1}^m$$

with $h = h', \theta = 0$, and $\lambda \in W_Q^0(T_1, \ldots, T_m)$. If $\|h'\| = 0$, then ψ belongs to $W_Q^0(T_1, \ldots, T_m)$ and hence $\psi = \theta\psi + (1-\theta)\mu$ with $\theta = 1$ and μ arbitrary. Finally we consider the case when $h' \neq 0$ and $\|h'\| \neq 1$. The vectors $h_n = (g_n - h')/\|g_n - h'\|$ converge weakly to zero, $\|Qh_n\| \to 0$, and $h = h'/\|h'\|$ is a unit vector in $\ker Q$. Clearly then

$$\psi_j = (1 - \|h\|^2) \lim_{n\to\infty} \langle T_j h_n, h_n\rangle + \|h\|^2 \langle T_j h, h\rangle, \qquad j = 1, \ldots, m,$$

and therefore

$$\psi \in \{\theta\lambda + (1-\theta)(\langle T_j h, h\rangle)_{j=1}^m : 0 \le \theta \le 1\},$$

where

$$\lambda := \lim_{n\to\infty} (\langle T_j h_n, h_n\rangle)_{j=1}^m \in W_Q^0(T_1, \ldots, T_m).$$

This concludes the proof. □

COROLLARY 3.3. *For all $T, Q \in \mathcal{L}(\mathcal{H})$, the set*

$$W_Q(T) = \left\{\lambda = \lim_{n\to\infty} \langle Th_n, h_n\rangle : h_n \in H\ ,\ \|h_n\| = 1\ ,\ \lim_{n\to\infty} \|Qh_n\| = 0\right\}$$

is a compact convex set.

Proof. First notice that by an application of the classical Toeplitz–Hausdorff theorem to $T_Q := PT|\ker Q$, where P denotes the orthogonal projection of $\mathcal{H}$ onto $\ker Q$, we see that the set

$$W(T_Q) = \{\langle Th, h\rangle : \|h\| = 1,\ h \in \ker Q\}$$

is compact and convex. Therefore the convex hull of

$$W_Q^0(T) \cup W(T_Q)$$

is the union of all segments

$$\{\theta\lambda + (1-\theta)\mu : 0 \leq \theta \leq 1\},$$

where λ and μ run over $W_Q^0(T)$ and $W(T_Q)$, respectively. But according to Lemma 3.2, this union is precisely $W_Q(T)$. □

Remark. Corollary 3.3 was proven in [3] using a completely different argument that was based on an approximation lemma, which is of independent interest.

Finally, for the proof of our lifting theorem (to be given in §4), we will need the following elementary fact.

LEMMA 3.4. *Let $\mathcal{Z}$ denote a finite-dimensional normed space and S be a set of linear functionals on $\mathcal{Z}$. Suppose that for every $z \in \mathcal{Z}$ there exists a sequence $\ell_n \in S$ such that $\lim_{n\to\infty} \ell_n(z) = 0$. Then there exists a sequence ℓ_n in the convex hull of S such that $\lim_{n\to\infty} \|\ell_n\| = 0$.*

Proof. Since $\mathcal{Z}$ is finite dimensional, S is contained in the dual $\mathcal{Z}'$ of $\mathcal{Z}$. We may also assume that S is a convex set. To prove the lemma we must show that the closure of S contains zero. If it did not then the Hahn–Banach theorem would imply the existence of a vector $z \in \mathcal{Z}$ and of a number $\varepsilon > 0$ such that $\Re\ell(z) > \varepsilon$ for all $\ell \in S$. This is contrary to the assumption of the lemma. □

4. Ampliations of perturbations. In this section, we will formulate and prove a new lifting result relating $\mu_\Delta(A)$ and $\widehat{\mu}_\Delta(A)$. For finite-dimensional $\mathcal{E}$, a lifting result of this type was first proven in [1]. The result was then generalized to the infinite-dimensional case in [5]. (For another proof of this type of lifting result in finite dimensions, see [7].) In these theorems, the lifting or ampliation of the operator A and perturbation structure Δ depends on the dimension of $\mathcal{E}$. Thus if $\mathcal{E}$ is infinite dimensional, we get an infinite lifting. In the new result proven below, we only have to lift up to the dimension of Δ', which in the cases of interest in the control applications of this theory only depends on the number of blocks of the given perturbation structure.

The notation will be that used in §2.

THEOREM 4.1. *Assume that Δ' is a $*$-algebra of finite dimension n. Then*

$$\widehat{\mu}_\Delta(A) = \mu_{\Delta_n''}(A^{(n)}),$$

for every $A \in \mathcal{L}(\mathcal{E})$.

Proof. The argument starts as in the proof of Theorem 3 in [1] and of Theorem 1 of [5]. Without loss of generality, we may assume that $\widehat{\mu}_\Delta(A) = 1$. We must show that $\mu_{\Delta_n''}(A^{(n)}) \geq 1$. Choose a sequence of invertible operators $X_j \in \Delta'$ such that $\|X_j A X_j^{-1}\| \to \widehat{\mu}_\Delta(A)$. Since $X_j A X_j^{-1}$ belongs to the finite-dimensional space generated by $\Delta' A \Delta'$, we may assume that the sequence $X_j A X_j^{-1}$ converges to some operator A_0 such that $\|A_0\| = 1$. Obviously $\|X A_0 X^{-1}\| \geq \|A_0\|$ for every invertible operator $X \in \Delta'$. In particular we have

$$\|(I - X)A_0(I + X + X^2 + \cdots)\| \geq 1,$$

for $X \in \Delta'$ with $\|X\| < 1$. Fix an operator $X \in \Delta'$ and a sequence $\varepsilon_j > 0$ converging to zero. There exist vectors $h_j \in \mathcal{E}$ with $\|h_j\| = 1$ such that

$$\|(I - \varepsilon_j X)A_0(I + \varepsilon_j X + \varepsilon_j^2 X^2 + \cdots)h_j\|^2 \geq 1 - \varepsilon_j^2 .$$

This can be rewritten as

$$\langle A_0^* A_0 h_j, h_j\rangle + 2\varepsilon_j \Re\langle A_0^*(A_0 X - X A_0)h_j, h_j\rangle + O(\varepsilon_j^2) \geq 1 - \varepsilon_j^2$$

or, equivalently,

$$2\varepsilon_j \Re\langle A_0^*(A_0 X - X A_0)h_j, h_j\rangle + O(\varepsilon_j^2) \geq \langle (I - A_0^* A_0)h_j, h_j\rangle - \varepsilon_j^2 \geq -\varepsilon_j^2.$$

Dividing by ε_j and letting $\varepsilon_j \to 0$ as $j \to \infty$, we see from the last equation that

$$\langle (I - A_0^* A_0)h_j, h_j\rangle \to 0, \tag{1}$$

$$\liminf_{j\to\infty} \Re\langle A_0^*(A_0 X - X A_0)h_j, h_j\rangle \geq 0. \tag{2}$$

We easily conclude that

$$\liminf_{j\to\infty} \Re\langle (X - A_0^* X A_0)h_j, h_j\rangle \geq 0. \tag{3}$$

Set

$$Q = I - A_0^* A_0, \quad T = X - A_0^* X A_0.$$

Then from (1), (3), we see that

$$Qh_j \to 0, \quad \liminf_{j\to\infty} \Re\langle T h_j, h_j\rangle \geq 0. \tag{4}$$

Applying the above argument to ζX for any $\zeta \in \partial\mathbf{D}$ (the unit circle), we see that there exists a sequence $h_j^{(\zeta)}$, $\|h_j^{(\zeta)}\| = 1$, such that

$$Qh_j^{(\zeta)} \to 0, \quad \liminf_{j\to\infty} \Re\zeta\langle T h_j, h_j\rangle \geq 0. \tag{5}$$

We claim that $0 \in W_{Q,0}(T)$. Indeed, if this were not the case, Corollary 3.3 would imply the existence of $\zeta \in \partial\mathbf{D}$ such that

$$\liminf_{j\to\infty} \Re\zeta\langle T h_j, h_j\rangle < 0,$$

for all sequences of unit vectors h_j such that $Qh_j \to 0$, which would contradict (5).

Thus, we have shown that for each $X \in \Delta'$, there exists a sequence of unit vectors $h_j \in \mathcal{E}$ such that

$$(I - A_0^* A_0)h_j \to 0 \text{ and } \langle (X - A_0^* X A_0)h_j, h_j\rangle \to 0. \tag{6}$$

Let

$$\Delta'_{\text{sa}} := \{X = X^* : X \in \Delta'\}.$$

Consider now a subspace $D \subset \Delta'_{\text{sa}}$ of real dimension $n - 1$ such that $\Delta'_{\text{sa}} = D + \mathbf{R}I$. Set $\mathcal{Z} = \{X - A_0^* X A_0 : X \in D\}$, and for every unit vector $h \in \mathcal{E}$ define a linear functional

$\ell(h)$ on $\mathcal{Z}$ by $\ell(h)(T) = \langle Th, h\rangle$, $T \in \mathcal{Z}$. Then Lemma 3.4 applied to the set $S_k = \{\ell(h) : \|(I - A_0^*A_0)h\| \leq 1/k\}$ implies the existence of linear functionals ℓ_k in the convex hull of S_k such that $\|\ell_k\| \leq 1/k$. Observe furthermore that the real dimension of $\mathcal{Z}$ is at most $n - 1$. Then from a standard result (see, e.g., [11, p. 73], each ℓ_k is a convex combination of at most n functionals $\ell(h)$, say $\ell_k = \sum_{j=1}^n \alpha_j^{(k)} \ell(h_j^{(k)})$, where $\alpha_j^{(k)} \geq 0$, $\sum_{j=1}^n \alpha_j^{(k)} = 1$, and the $h_j^{(k)}$ are unit vectors in $\mathcal{E}$, such that

$$\|(I - A_0^*A_0)h_j^{(k)}\| \leq 1/k.$$

Let us define unit vectors $u_k \in \mathcal{E}^{(n)}$ by

$$u_k = \bigoplus_{j=1}^n (\alpha_j^{(k)})^{1/2} h_j^{(k)} \tag{7}$$

and observe that $\lim_{k\to\infty}\langle (X^{(n)} - A_0^{*(n)}X^{(n)}A_0^{(n)})u_k, u_k\rangle = 0$, for every $X \in \Delta'$. Taking $X = Y^*Y$ we obtain

$$\lim_{k\to\infty} (\|Y^{(n)}A_0^{(n)}u_k\| - \|Y^{(n)}u_k\|) = 0, \tag{8}$$

for every $Y \in \Delta'$.

Consider now the spaces $\mathcal{H}_k = \Delta_n' A_0^{(n)} u_k$ and $\mathcal{K}_k = \Delta_n' u_k$. Lemma 2.3 implies that, by passing to appropriate subsequences, we may assume that all the representations $X \to X^{(n)}|\mathcal{H}_k$ (respectively $X \to X^{(n)}|\mathcal{K}_k$) are unitarily equivalent. It follows that we can find partial isometries U_k, V_k in Δ_n'' such that $U_k\mathcal{H}_k = \mathcal{H}_1$ and $V_k\mathcal{K}_k = \mathcal{K}_1$. Dropping again to appropriate subsequences, we may assume that the limits $u = \lim_{k\to\infty} U_k A_0^{(n)} u_k$ and $v = \lim_{k\to\infty} V_k u_k$ exist. Then (8) implies that

$$\|Y^{(n)}u\| = \|Y^{(n)}v\|,$$

for every $Y \in \Delta'$. Therefore there exists a partial isometry $W \in \Delta_n''$ such that

$$WY^{(n)}u = Y^{(n)}v,$$

for every $Y \in \Delta'$. Of course, W can be chosen to be equal to zero on the orthogonal complement of $\Delta_n' u$ and thus to have finite rank at most n. The partial isometries $R_k := V_k^* W U_k$ are in Δ_n'', they have uniformly bounded rank, and

$$\lim_{k\to\infty} (R_k A_0^{(n)} - I)u_k = \lim_{k\to\infty} V_k^*(WU_k A_0^{(n)} u_k - V_k u_k) = 0.$$

Therefore Lemma 2.4 implies that

$$\liminf_{k\to\infty} \|R_k A_0^{(n)}\|_{\mathrm{sp}} \geq 1.$$

Finally, since R_k commutes with $X^{(n)}$, $X \in \Delta'$, and we have

$$X_j^{(n)} R_k A^{(n)} X_j^{(n)-1} \to R_k A_0^{(n)}$$

in norm as $j \to \infty$. Lemma 2.5 shows that

$$\|R_k A_0^{(n)}\|_{\mathrm{sp}} = \|R_k A^{(n)}\|_{\mathrm{sp}}.$$

Consequently, we have

$$\liminf_{k\to\infty} \|R_k A^{(n)}\|_{\mathrm{sp}} = \liminf_{k\to\infty} \|R_k A_0^{(n)}\| \geq 1.$$

Thus,

$$\mu_{\Delta_n''}(A^{(n)}) \geq \liminf_{k\to\infty} \|A^{(n)} X_k\|_{\mathrm{sp}} \geq 1 = \widehat{\mu}_{\Delta}(A),$$

which completes the proof of the theorem. □

Remark. In the cases of interest in control,

$$\Delta'' = \Delta,$$

and so one has from Theorem 4.1 that

$$\mu_{\Delta_n}(A) = \hat{\mu}_{\Delta}(A).$$

5. Conditions for $\mu = \hat{\mu}$. In this section, we will discuss some new conditions when $\mu = \hat{\mu}$ without any need for lifting or ampliation. In the finite-dimensional case, there have been some results of this kind, the most famous of which is that of Doyle [6], who showed that no lifting is necessary for perturbation structures with three or fewer blocks.

We begin by noting that in the proof of Theorem 4.1, we established a useful property of the critical operators A_0 in the closed Δ' similarity orbit

$$\overline{\mathcal{O}_{\Delta'}(A)} = \overline{\{XAX^{-1} : X \in \Delta'\}}$$

of A. Namely, if we call *critical* any $A_0 \in \overline{\mathcal{O}_{\Delta'}(A)}$ satisfying

$$\limsup_{\epsilon\downarrow 0} \|(I - \epsilon X)A_0(I - \epsilon X)^{-1}\| \geq \|A_0\|, \ \forall X \in \Delta',$$

then the first part of the proof of Theorem 4.1 establishes the following.

LEMMA 5.1. *If A_0 is a critical operator in $\overline{\mathcal{O}_{\Delta'}(A)}$, then it enjoys the following property $(\mathcal{O})$:*

$$0 \in W_Q(\|A_0\|^2 X - A_0^* X A_0), \qquad X \in \Delta',$$

where $Q = \|A_0\|^2 I - A_0^* A_0$.

Indeed, property $(\mathcal{O})$ is a reformulation of equation (6) in the case in which the norm of A_0 may be different from 1.

The next lemma is the key step in adapting the proof of Theorem 4.1 to show that

$$\mu_{\Delta}(A) = \widehat{\mu}_{\Delta}(A)$$

in several interesting cases.

LEMMA 5.2. *Let A_0 be an operator on $\mathcal{E}$ which satisfies the essential version of property $(\mathcal{O})$, property $(\mathcal{O}^0)$, namely,*

$$0 \in W_Q^0(\|A_0\|^2 X - A_0^* X A_0), \qquad X \in \Delta',$$

where $Q = \|A_0\|^2 I - A_0^* A_0$. Then there exists a sequence $\{h_k\}_{k=1}^{\infty} \subset \mathcal{E}$, $\|h_k\| = 1$, $k = 1, 2, \ldots$, such that

$$Qh_k \to 0 \text{ strongly and } \langle(\|A_0\|^2 X - A_0^* X A_0)h_k, h_k\rangle \to 0,$$

for all $X \in \Delta'$.

Proof. Without loss of generality we can assume that $\|A_0\| = 1$. Let $X_1, \dots, X_n$ be an algebraic basis of Δ'. (Note that Δ' is finite dimensional.) Set $T_j := X_j - A_0^* X_j A_0$, $j = 1, \dots, n$. Then by virtue of Lemma 3.1, $W_Q^0(T_1, \dots, T_n)$ is convex and compact. If $0 \notin W_Q^0(T_1, \dots, T_n)$, there exists $\psi = (\psi_1, \dots, \psi_n) \in \mathbf{C}^n$ and $\epsilon > 0$ such that

$$\Re \sum_{j=1}^{n} \psi_j \lambda_j \geq \epsilon, \quad \forall \lambda = (\lambda_1, \dots, \lambda_n) \in W_Q^0(T_1, \dots, T_n).$$

Set

$$T = \sum_{j=1}^{n} \psi_j T_j.$$

Property $(\mathcal{O}^0)$ implies that there exists a sequence $\{g_k\}_{k=1}^{\infty} \subset \mathcal{E}$, $\|g_k\| = 1$, $g_k \to 0$ weakly such that $\langle T g_k, g_k \rangle \to 0$. Without loss of generality (by passing to a subsequence if necessary), we can assume that

$$\langle T_j g_k, g_k \rangle \to \lambda_j, \quad j = 1, \dots, n,$$

for $k \to \infty$. Thus

$$\lambda = (\lambda_1, \dots, \lambda_n) \in W_Q^0(T_1, \dots, T_n).$$

Hence

$$0 \leftarrow \Re \langle T g_k, g_k \rangle = \Re \sum_{j=1}^{n} \psi_j \langle T_j g_k, g_k \rangle \to \Re \sum_{j=1}^{n} \psi_j \lambda_j \geq \epsilon,$$

which is a contradiction. We therefore conclude that $0 \in W_Q^0(T_1, \dots, T_n)$, i.e., there exists a sequence $\{h_k\}_{k=1}^{\infty} \subset \mathcal{E}$ satisfying the properties $\|h_k\| = 1$, $k = 1, 2, \dots$, $\|Q h_k\| \to 0$, $h_k \to 0$ weakly, and

$$\langle (X_j - A_0^* X_j A_0) h_k, h_k \rangle = \langle T_j h_k, h_k \rangle \to 0,$$

for all $j = 1, 2, \dots, n$. This implies that

$$\langle (X - A_0^* X A_0) h_k, h_k \rangle \to 0,$$

for all $X \in \Delta'$. □

We can now state the second main result of this paper.

THEOREM 5.3. *If there exists a critical operator A_0 satisfying property $\mathcal{O}^0$ in the closed Δ'-orbit of A, then*

$$\mu_{\Delta''}(A) = \hat{\mu}_{\Delta}(A).$$

Proof. We only have to note that because of Lemma 5.2, we need not take direct sums in the proof of Theorem 4.1. More precisely, referring to equation (7) in the proof of Theorem 4.1, we can take $u_k = h_k$, where

$$\{h_k\}_{k=1}^{\infty}$$

is the sequence provided by Lemma 5.2. The proof then proceeds exactly as in Theorem 4.1 with A_0 replacing $A_0^{(n)}$, X replacing $X^{(n)}$, and Y replacing $Y^{(n)}$. □

Remark. Under the hypotheses of Theorem 5.3, when $\Delta'' = \Delta$ (which happens in all cases of interest in control), we have that

$$\mu_\Delta(A) = \hat{\mu}_\Delta(A).$$

Let $L(\Delta' A \Delta')$ denote the linear space generated by

$$\Delta' A \Delta' = \{XAY : X, Y \in \Delta'\}.$$

Obviously $L(\Delta' A \Delta')$ is finite dimensional and therefore closed. Hence $\overline{\mathcal{O}_{\Delta'}(A)} \subset L(\Delta' A \Delta')$.

COROLLARY 5.4. *If for every $B \in L(\Delta' A \Delta')$, $B \neq 0$, the norm of B is not attained (that is, there is no $h \in \mathcal{H}$ such that $\|Bh\| = \|B\|\|h\| \neq 0$), then*

$$\mu_{\Delta''}(A) = \hat{\mu}_\Delta(A).$$

Proof. The critical operator A_0 constructed in the first part of the proof of Theorem 4.1 belongs to $L(\Delta' A \Delta')$, and therefore its norm is not attained. However in equation (6), we can assume that the sequence $\{h_j\}_{j=1}^\infty$ is weakly convergent, say $h_j \to h$ weakly. Without loss of generality, we may assume that $\|A_0\| = 1$. Then (6) shows that

$$(I - A_0^* A_0)h = 0.$$

Therefore if $h \neq 0$, we would have

$$\|A_0 h\|^2 = \|h\|^2 = \|A_0\|^2 \|h\|^2 \neq 0,$$

and so the norm of A_0 would be attained. We conclude that $h_j \to 0$ weakly, and so A_0 satisfies property $(\mathcal{O}^0)$. The required result now follows by Theorem 5.3. □

Remark. Note that Corollary 5.4 applies only to infinite-dimensional Hilbert spaces $\mathcal{E}$.

Example. We would like to give an explicit example to which Corollary 5.4 applies. Let A_j be an operator on a Hilbert space $\mathcal{E}_j$ $(j = 1, \ldots, n)$ for which the norm is not attained. (For example, take $\mathcal{E}_j = L^2((0, 1))$ and let A_j be the muliplication operator $f(x) \mapsto xf(x)$ for $x \in (0, 1)$ and $f \in L^2((0, 1))$.) Set

$$\mathcal{E} := \mathcal{E}_1 \oplus \cdots \oplus \mathcal{E}_n,$$

and let Δ be the algebra of operators on $\mathcal{E}$ of the form

$$\begin{bmatrix} X_1 & 0 & \ldots & 0 \\ 0 & X_2 & \ldots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & X_n \end{bmatrix},$$

with $X_j \in \mathcal{L}(\mathcal{E}_j)$, $j = 1, 2, \ldots, n$. Then Δ' is formed by the diagonal operators

$$\begin{bmatrix} \lambda_1 I_{\mathcal{E}_1} & 0 & \ldots & 0 \\ 0 & \lambda_2 I_{\mathcal{E}_2} & \ldots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & \lambda_n I_{\mathcal{E}_n} \end{bmatrix},$$

for $\lambda_j \in \mathbf{C}$, $j = 1, 2, \ldots, n$, and $I_{\mathcal{E}_j}$ denotes the identity operator on $\mathcal{E}_j$, $j = 1, 2, \ldots, n$. Let A be any operator on $\mathcal{E}$, the $n \times n$ block matrix representation of which has entries in the set $\{0, A_1, \ldots, A_n\}$ with only one nonzero entry in each row and column. Then it is easy to check that $L(\Delta' A \Delta')$ has the property required in Corollary 5.4, and therefore

$$\mu_{\Delta''}(A) = \hat{\mu}_\Delta(A).$$

6. Toeplitz operators. In this section, we want to use our lifting methodology to derive a beautiful result of Shamma [13, 14] on the structured singular value of a Toeplitz operator, i.e., a linear time-invariant system.

Accordingly, set $\mathcal{E} = H^2(\mathbf{C}^n)$ and let A denote the multiplication (analytic Toeplitz) operator on $\mathcal{E}$ defined by

$$(Ah)(z) = A(z)h(z), \qquad |z| < 1, \ h \in \mathcal{E},$$

where

$$A(z) = [a_{jk}]_{j,k=1}^{n}, \qquad |z| < 1,$$

has H^∞ entries. Let Δ' be any $*$-subalgebra of $\mathcal{L}(\mathbf{C}^n)$, the elements of which are regarded as multiplication operators on $\mathcal{E}$. Note that in this case, $\Delta'' = \Delta$ is the algebra generated by operators of the form

$$(Bh)(z) = B(z)h(z), \qquad |z| < 1, \ h \in \mathcal{E},$$

with $B(z)X = XB(z)$, $|z| < 1$, $X \in \Delta'$, as well as of the form

$$B \begin{bmatrix} h_1 \\ h_2 \\ \vdots \\ h_n \end{bmatrix} = \begin{bmatrix} Yh_1 \\ Yh_2 \\ \vdots \\ Yh_n \end{bmatrix},$$

with $Y \in \mathcal{L}(H^2(\mathbf{C}))$ arbitrary. We can now state the following lemma.

LEMMA 6.1. *Let A_0 be an analytic Toeplitz operator. Then if A_0 has property $(\mathcal{O})$, it also has property $(\mathcal{O}^0)$.*

Proof. Without loss of generality we may assume $\|A_0\| = 1$. Let $X \in \Delta'$ and let h_j, $j = 1, 2, \ldots$ be a sequence of unit vectors satisfying

$$\|(I - A_0^* A_0)h_j\|^2 \to 0, \quad \langle (X - A_0^* X A_0)h_j, h_j \rangle \to 0. \tag{9}$$

Note that since $I - A_0^* A_0 \geq 0$, the first condition in (9) is equivalent to

$$\langle (I - A_0^* A_0)h_j, h_j \rangle \to 0.$$

Let U denote the canonical unilateral shift on $\mathcal{E} = H^2(\mathbf{C}^n)$, that is,

$$(Uh)(z) := zh(z), \qquad |z| < 1, \ h \in \mathcal{E}.$$

As is well known, we can view $H^2(\mathbf{C}^n)$ as a subspace of $L^2(\mathbf{C}^n)$. In particular, in this representation the relations (9) are equivalent to

$$\int_0^{2\pi} (\|h_j(e^{it})\|^2 - \|A_0(e^{it})h_j(e^{it})\|^2)dt \to 0,$$

$$\int_0^{2\pi} [\langle Xh_j(e^{it}), h_j(e^{it}) \rangle - \langle XA_0(e^{it})h_j(e^{it}), h_j(e^{it}) \rangle]dt \to 0. \tag{10}$$

Note that X is an $n \times n$ matrix with constant coefficients. Therefore in (10), h_j can be replaced by $U^k h_j$ for any $k \geq 0$ without changing the values of the integrals. We infer that

$$\|(I - A_0^* A_0)U^{k_j} h_j\|^2 \to 0, \qquad \langle (X - A_0^* X A_0)U^{k_j} h_j, U^{k_j} h_j \rangle \to 0,$$

for any sequence $\{k_j\}_{j=1}^{\infty}$ of natural numbers. Since for any $g, h \in \mathcal{E}$,

$$|\langle U^k g, h\rangle| = |\langle g, U^{*k} h\rangle| \leq \|g\|\|U^{*k} h\| \to 0, \quad k \to \infty,$$

we can choose k_j sufficiently large to guarantee that

$$|\langle U^{k_j} h_j, h\rangle| \leq \frac{1}{2^j},$$

for any h of the form

$$h = (z^m \delta_{pk})_{k=1}^n, \qquad 0 \leq m \leq j,\ 1 \leq p \leq n, \tag{11}$$

where δ_{pk} is the Kronecker delta. Thus

$$\langle U^{k_j} h_j, h\rangle \to 0 \text{ as } j \to \infty,$$

for all vectors of the form (11). Since these vectors form an orthonormal basis of $\mathcal{E}$, we see that $U^{k_j} h_j \to 0$ weakly, which concludes the proof of the lemma. □

COROLLARY 6.2 (see [13, 14]). *For A and Δ' as above, we have that*

$$\mu_{\Delta}(A) = \hat{\mu}_{\Delta}(A).$$

Proof. First, note that any operator B in $L(\Delta' A \Delta')$ is also an analytic Toeplitz operator. In particular, the critical operator A_0 obtained in the proof of Theorem 4.1 is a multiplication operator given by

$$A_0(z) = [a_{jk}^0(z)]_{j,k=1}^n, \qquad |z| < 1.$$

By Lemma 5.1, the operator A_0 has property $(\mathcal{O})$ and thus also property $(\mathcal{O}^0)$, by virtue of Lemma 6.1. The conclusion now follows from Theorem 5.3. □

7. Structured singular value of input/output operators. In this section, we will put some of the above results into a system-theoretic framework. Accordingly, let ℓ_+^2 be the space of square summable one-sided sequences in $\mathbf{C}$, let $\mathcal{C}$ denote the set of all bounded linear operators on ℓ_+^2. Further, let $A : \ell_+^2(\mathbf{C}^n) \to \ell_+^2(\mathbf{C}^n)$ be an arbitrary bounded linear operator. Thus A defines a (possibly) time-varying system. (Here $\ell_+^2(\mathbf{C}^n)$ denotes the space of square summable sequences in $\mathbf{C}^n$, i.e., the space of finite energy vector-valued signals with n components.) Then we want to interpret $\hat{\mu}_{\Delta}(A)$ as a structured singular value on an extended space with an enhanced perturbation structure. Note $\mathcal{E}$ in this case is the Hilbert space $\ell_+^2(\mathbf{C}^n)$.

Define the algebra of perturbations

$$\Delta := \left\{ \begin{bmatrix} \delta_1 & 0 & \dots & 0 \\ 0 & \delta_2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \delta_n \end{bmatrix} : \delta_i \in \mathcal{C}, i = 1, \dots, n \right\}.$$

Then the commutant of Δ is the finite-dimensional C^*-algebra

$$\Delta' := \left\{ \begin{bmatrix} d_1 & 0 & \dots & 0 \\ 0 & d_2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & d_n \end{bmatrix} : d_i \in \mathbf{C}, i = 1, \dots, n \right\}.$$

Note that a constant $d \in \mathbf{C}$ defines an operator on ℓ_+^2 via multiplication.

From Theorem 4.1, it follows that the μ upper bound given by the infimum of $\|XAX^{-1}\|$ over all constant X-scales equals $\bar{\mu}_\Delta(A)$. We now have the following interpretation of $\widehat{\mu}_\Delta(A)$. We lift A to $A^{(n)} : \mathcal{E}^{(n)} \to \mathcal{E}^{(n)}$. Then

$$(\Delta_n)'' \cong \left\{ \begin{bmatrix} \tilde{\Delta}_1 & 0 & 0 & 0 \\ 0 & \tilde{\Delta}_2 & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \tilde{\Delta}_n \end{bmatrix} : \tilde{\Delta}_j \in \Delta \right\}.$$

$(\Delta_n)''$ is a space of time-varying perturbations and we have from Theorem 4.1 that

$$\widehat{\mu}_\Delta(A) = \mu_{\Delta_n''}(A^{(n)}).$$

This is true for *arbitrary time-varying systems* A. When A is Toeplitz, i.e., the system is time invariant, then as we have seen (Corollary 6.2, [13, 14]),

$$\widehat{\mu}_\Delta(A) = \mu_\Delta(A).$$

A TURNPIKE THEORY FOR INFINITE-HORIZON OPEN-LOOP COMPETITIVE PROCESSES*

D. CARLSON† AND A. HAURIE‡

Abstract. This paper deals with a class of dynamic discrete time open-loop games played over an infinite time horizon. The equilibrium concept is defined in the sense of overtaking optimal responses by the players to the program choices of the opponents. We extend to this dynamic game framework the results obtained by Rosen for concave static games. We prove existence, uniqueness, and asymptotic stability (also called the turnpike property) of overtaking equilibrium programs for a class of games satisfying a strong concavity assumption (strict diagonal concavity).

Key words. dynamic games, overtaking equilibrium, infinite-horizon dynamic games, open-loop equilibrium

AMS subject classifications. 49J99, 49N40, 90D06, 90D10, 90D50

1. Introduction.

This paper deals with a class of dynamic competitive process models defined over an infinite time horizon. We use overtaking optimality to deal with unbounded payoffs. This optimality concept has been used to study optimal economic growth models in [28], [21], [3], [7] and in dynamic games [4], [18], [25], [20]. We prove existence and uniqueness of open-loop equilibria and asymptotic stability of the equilibrium programs under a *strict diagonal concavity–convexity* assumption for the Hamiltonians associated with the extremal dynamic programs of each player. This assumption is very close to the one introduced by Rosen [26] in his study of static concave games.

The theory of asymptotic optimality of dynamical systems has been mainly motivated by the modeling of optimal economic growth processes. Von Weizäcker [28] was the first to propose the use of the overtaking optimality concept to compare accumulation programs over infinite time horizons. These economic growth models developed under two formulations: either in continuous time (see, e.g., [9], [10], [12], [5]) or in discrete time (see, e.g., [3], [21]). A major result in these theories is the *turnpike property* which links existence as well as necessary and sufficiency conditions with the asymptotic stability of the solutions of an associated Hamiltonian system. This property is easily derived from the convexity–concavity of the Hamiltonian [23], when the stream of payoffs is undiscounted. For the discounted case, Cass and Shell [12], Brock and Scheinkman [6], and Rockafellar [24] have obtained the same property under a stricter *curvature assumption*. The whole theory extends to optimal control, both in the deterministic and stochastic frameworks, as exposed in [7], [17].

The class of competitive processes considered encompasses the oligopoly paradigm, representing the competition among a few firms on a single market, which is a cornerstone of microeconomic theory (see, e.g., [15]). The Cournot equilibrium [13], extended by Nash [22] to a general game format, has been used in many economic models. Rosen [26], in a seminal paper gave a condition, called *strict diagonal concavity*, for existence, uniqueness, and stability of a gradient-path following method for Nash–Cournot equilibria in static m-player games. Linking game theory and asymptotic economic growth models has been attempted in several papers. Brock [4] proposed the first study, in continuous time, of differential games with infinite time horizon. In a more general setting, the asymptotic stability of the solutions

*Received by the editors March 24, 1994; accepted for publication (in revised form) April 25, 1995. of the *pseudo Hamiltonian* systems associated with open-loop differential games was studied in [18]. More recently, in [19], a continuous time piecewise deterministic differential game model of oligopoly has been studied and conditions for asymptotic stability have been stated.

In the present paper we consider a dynamic competitive process modeled in discrete time and we provide a complete theory of existence, uniqueness, and asymptotic stability. We obtain these results under conditions very similar to Rosen's strict diagonal concavity. In a sense, the present paper can be seen as an extension of Rosen's work to a dynamic setting.

We would like now to address those "mathematical economists" who don't read further as soon as they have detected that a paper deals with an open-loop equilibrium concept on an infinite horizon. The recent polarization of interest on *subgame perfectness* in dynamic games (see [27] for a definition of this concept) and the famous *Folk theorem* for infinite-horizon games (see [16] for a discussion of modern game theory) have indeed diminished the interest of economists for the open-loop equilibrium solution concept. The first concept is close to, in spirit, but more general than the *feedback-Nash* equilibrium solution (see [1] for a complete discussion of this concept); it is of limited applicability in a truly dynamical setting (i.e., not a repeated game setting) since a complete and general theory of feedback-Nash equilibria is still to be developed. The Folk theorem (see [20] for a statement in the realm of multistage games) establishes that, on an infinite time horizon, any solution dominating the feedback-Nash equilibrium solution can be transformed into a subgame perfect equilibrium; this result is based on an information structure allowing the players to remember a preplay agreement and to retaliate if the agreed upon trajectory is not implemented. Both concepts present attractive features. We claim, however, that the exploration of the properties of open-loop solutions deserves continuing interest.

To give full mathematical respectability to open-loop equilibria we only have to assume an information structure whereby each player knows only the initial state of the process and has to choose a control for the entire infinite time horizon. Then the open-loop equilibrium solution is similar to a static game concept, except that the players' actions are now described as functions of time.

In [19] it is shown how this paradigm can be used in a more complex information structure, called *piecewise deterministic games*, where the information on the state occurs at "random stopping time" as the outcome of a random jump process. The game studied in [19] is akin to a *sequential game* with continuous state and action spaces. It has been shown in [19] that the dynamic programming solution of this type of game is closely linked with the turnpike property of an associated class of infinite-horizon open-loop games.

This gives already two good reasons for studying this interesting class of equilibria. A third one is more operational. Most of the large-scale *computable* market models which have been developed in operations research studies have been based on the open-loop equilibrium concept. This has been the case in the modeling of energy markets and this is the current trend when dealing with the modeling of environmental management. Of course, the feedback-Nash concept usually does not lend itself to a numerical computation with the exception of two extreme cases: the *linear quadratic* game structure (with some difficulties for the infinite-horizon case, see, e.g., [8]) and the *affine dynamics* one (see [2] for a discussion of the difficulties in solving dynamic programming equilibrium equations). Therefore the operational representation of competition through capital accumulation or capacity expansion for large-scale models remains, for the moment, in the realm of open-loop games.

As in the economic growth problem, the justification for considering an infinite time horizon stems from the necessity to give, at the end of any finite horizon, a bequest value to the accumulated stocks (capital goods). These values should express the utility of these stocks in further economic activity, hence providing a justification for a never-ending process. From

an operational viewpoint, the theory developed in the present paper would give a theoretical justification for adopting as approximate terminal conditions for a long but finite-horizon model the steady-state equilibrium, which should be the attractor if the horizon is infinite.

The paper is organized as follows. In §2 we explore the turnpike property for a general class of competitive process models, permitting, as in [21] for the single-player case, a nonautonomous dynamic. In §3 we show that the conditions used to insure asymptotic stability also imply existence of overtaking equilibria. In §4 we show that, in addition we get uniqueness. Finally in §5 we present a class of examples to which the results given below are applicable.

2. Turnpikes for discrete time overtaking equilibria. In this section we define the concept of an *overtaking equilibrium* for a class of games which represent infinite-horizon dynamic competition among m firms. We give conditions under which all the overtaking equilibrium programs, emanating from different initial states, bunch together at infinity.

2.1. Competitive programs. We consider a competitive process defined by the following data:

(i) There is an infinite sequence of stages or time periods $k = 0, 1, 2, \ldots$.

(ii) A set $M \doteq \{1, \ldots, m\}$ of m players (or firms) is represented at period k by a state $x_j^k \in \mathbb{R}^{n_j}$, where n_j is a given positive integer (we denote $n \doteq n_1 + \cdots + n_m$). This state is, e.g., the production capacity of firm j.

(iii) For each $j \in M$, a program for player j is defined as an infinite sequence $\mathbf{x}_j = (x_j^k \in \mathbb{R}^{n_j} : k = 0, 1, \ldots)$. An M-program is defined as $\mathbf{x} = (x^k : k = 0, 1, \ldots) \doteq ((x_j{}^k)_{j\in M} : k = 0, 1, \ldots)$.

(iv) Along an M-program, the reward accumulation process for player j is defined as

$$\phi_j^K(\mathbf{x}) = \sum_{k=0}^{K-1} (\beta_j)^k L_j^k(x^k, \Delta x_j^k), \quad K = 1, 2, \ldots, \tag{1}$$

where $\beta_j \in (0, 1]$ is the discount factor for player j ($(\beta_j)^k$ denotes the kth power of β_j), $L_j^k : \mathbb{R}^n \times \mathbb{R}^{n_j} \mapsto \mathbb{R} \cup \{-\infty\}$, $j \in M$, are given functions and $\Delta x_j^k = x_j^{k+1} - x_j^k$. The expression $L_j^k(x^k, \Delta x_j^k)$ represents, e.g., the net income to firm j when the market price is a function of total supply $\sum_{j\in M} x_j^k$ minus the cost for the capacity adjustment Δx_j^k.

2.2. Optimality. Given an M-program $\mathbf{x}^*$ we denote by $[\mathbf{x}^{*(j)}; \mathbf{x}_j]$ the M-program obtained when player j changes unilaterally his program to $\mathbf{x}_j$.

DEFINITION 2.1. *An M-program $\mathbf{x}^*$ is an* equilibrium *at x^o if*

1. $x^{0^*} = x^o$,
2. $\lim_{K\to\infty} \phi_j^K(\mathbf{x}^*) < \infty$ *for all* $j \in M$,
3. $\liminf_{K\to\infty}(\phi_j^K(\mathbf{x}^*) - \phi_j^K([\mathbf{x}^{*(j)}; \mathbf{x}_j])) \geq 0$ *for all programs* $\mathbf{x}_j$ *such that* $x_j^0 = x_j^o$ *for all* $j \in M$.

If only the first and third conditions hold, the M-program $\mathbf{x}^*$ is called an overtaking equilibrium *at x^o.*

2.3. Optimality conditions. Let us introduce for $j \in M$ and $p_j \in \mathbb{R}^{n_j}$ the *Hamiltonians* $H_j^k : \mathbb{R}^n \times \mathbb{R}^{n_j} \mapsto \mathbb{R} \cup \{\infty\}$, defined as

$$H_j^k(x, p_j) = \sup_{z_j}\{L_j^k(x, z_j) + p_j' z_j\}. \tag{2}$$

Here p_j is called a *j-supporting price* vector. A sequence

$$\mathbf{p} \doteq (p^k : k = 0, 1, \ldots) \doteq ((p_j{}^k)_{j\in M} : k = 0, 1, \ldots)$$

will be called an *M-price schedule.*

Assumption 2.2. We assume that the Hamiltonians H_j^k are concave in x_j, convex in p_j.

For an (overtaking) equilibrium the following necessary conditions hold.

THEOREM 2.3. *Under Assumption* 2.2, *if* $\mathbf{x}^*$ *is an* overtaking equilibrium *at initial state* x^o, *then there exists an* M*-price schedule* $\mathbf{p}^*$ *such that*

$$\Delta x_j^{k^*} \in \partial_{p_j} H_j^k(x^{k^*}, p_j^{k+1^*}), \tag{3}$$

$$\Delta p_j^{k^*} + \alpha_j\, p_j^{k+1^*} \in -\partial_{x_j} H_j^k(x^{k^*}, p_j^{k+1^*}), \tag{4}$$

for all $j \in M$, *where we have denoted* $\alpha_j = (1 - \frac{1}{\beta_j})$.

Proof. See [3], [21] for a proof of Theorem 2.3. □

Equations (3), (4) were called pseudo-Hamiltonian systems in [18]. These conditions are incomplete since only initial conditions are specified for the M-programs and not their associated M-price schedules. In the single-player case, this system is made complete by invoking the turnpike property, which provides an asymptotic transversality condition. Due to the coupling among the players, the system (3), (4) considered here does not fully enjoy the rich geometric structure found in the classical optimization setting (for instance the saddle point behavior of Hamiltonian systems in the autonomous case). In the next two sections we provide conditions under which the turnpike property holds for these pseudo-Hamiltonian systems.

2.4. A Turnpike result for the undiscounted case. Let us first consider the case where $\beta_j \equiv 1$ for all $j \in M$. Then, clearly, we have to deal with overtaking equilibria since the sequence of accumulated rewards can be unbounded.

Assumption 2.4 (strict diagonal concavity–convexity assumption (SDCCA)). We assume that the combined Hamiltonian $\sum_{j\in M} H_j^k(x, p_j)$ is strictly diagonally concave in x, convex in p. That is,

$$\sum_{j\in M}\Big[(\hat{p}_j - \tilde{p}_j)'(\hat{\pi}_j - \tilde{\pi}_j) + (\hat{x}_j - \tilde{x}_j)'(\hat{\xi}_j - \tilde{\xi}_j)\Big] > 0, \tag{5}$$

for all $(\hat{x}_j, \tilde{x}_j, \hat{p}_j, \tilde{p}_j)$ and $(\hat{\pi}_j, \tilde{\pi}_j, \hat{\xi}_j, \tilde{\xi}_j)$, such that

$$\hat{\pi}_j \in \partial_{p_j} H_j^k(\hat{x}, \hat{p}_j), \quad \tilde{\pi}_j \in \partial_{p_j} H_j^k(\tilde{x}, \tilde{p}_j), \tag{6}$$

$$\hat{\xi}_j \in -\partial_{x_j} H_j^k(\hat{x}, \hat{p}_j), \quad \tilde{\xi}_j \in -\partial_{x_j} H_j^k(\tilde{x}, \tilde{p}_j). \tag{7}$$

LEMMA 2.5. *Assume* $\beta_j \equiv 1$ *for all* $j \in M$. *Let* $\hat{\mathbf{x}}$ *and* $\tilde{\mathbf{x}}$ *be two (overtaking) equilibria at* $\hat{x}^o$ *and* $\tilde{x}^o$, *respectively, with their respective associated* M*-price schedules* $\hat{\mathbf{p}}$ *and* $\tilde{\mathbf{p}}$. *Then under Assumptions* 2.2 *and* 2.4 *the following inequality holds:*

$$\sum_{j\in M}\Big[(\Delta\hat{p}_j^k - \Delta\tilde{p}_j^k)'(\hat{x}_j^k - \tilde{x}_j^k) + (\hat{p}_j^{k+1} - \tilde{p}_j^{k+1})'(\Delta\hat{x}_j^k - \Delta\tilde{x}_j^k)\Big] > 0. \tag{8}$$

Proof. According to Theorem 2.3 we have

$$\Delta\hat{x}_j^k \in \partial_{p_j} H_j^k(\hat{x}^k, \hat{p}_j^{k+1}), \tag{9}$$

$$\Delta\hat{p}_j^k \in -\partial_{x_j} H_j^k(\hat{x}^k, \hat{p}_j^{k+1}), \tag{10}$$

$$\Delta\tilde{x}_j^k \in \partial_{p_j} H_j^k(\tilde{x}^k, \tilde{p}_j^{k+1}), \tag{11}$$

$$\Delta\tilde{p}_j^k \in -\partial_{x_j} H_j^k(\tilde{x}^k, \tilde{p}_j^{k+1}). \tag{12}$$

Then (8) follows directly from Assumption 2.4. □

We now prove the turnpike theorem, under Assumption 2.4, for the class of *strongly diagonally supported* (overtaking) equilibria defined below.

DEFINITION 2.6. *We say that the (overtaking) equilibrium M-program* $\hat{\mathbf{x}}$ *is strongly diagonally supported by the M-price schedule* $\hat{\mathbf{p}}$ *if, for every* $\varepsilon > 0$, *there exists a* $\delta > 0$ *such that for all* $k = 0, 1, \ldots, \|x - \hat{x}^k\| + \|p - \hat{p}^k\| > \varepsilon$ *implies*

$$\sum_{j \in M} \left[(\hat{p}_j^{k+1} - p_j)'(\Delta \hat{x}_j^k - \pi_j) + (\hat{x}_j^k - x_j)'(\Delta \hat{p}_j^k - \xi_j) \right] > \delta, \tag{13}$$

for all (x_j, p_j) *and* (π_j, ξ_j), *such that*

$$\pi_j \in \partial_{p_j} H_j^k(x, p_j), \tag{14}$$

$$\xi_j \in -\partial_{x_j} H_j^k(x, p_j). \tag{15}$$

Remark 2.7. In the autonomous case, treated in more detail in §2.7, the stricter inequality (13) is obtained as a consequence of Assumption 2.4 or inequality (5) when the state variable x remains in a compact set (this is known as the Atsumi lemma in the single-player case). In the general nonautonomous case, the condition (13) is certainly more restrictive and not always easy to verify. The case of discounted payoffs is a special case of the general nonautonomous case and it exhibits a special structure that permits these strong support properties to be modified in such as way as to be useful. This is particularly true if this nonautonomy arises only as a result of the discounting. We pursue these developments in §§2.6 and 2.7 below.

THEOREM 2.8. *Suppose Assumptions* 2.2 *and* 2.4 *hold. Assume* $\beta_j \equiv 1$ *for all* $j \in M$. *Let* $\hat{\mathbf{x}}$, *with its associated M-price schedule* $\hat{\mathbf{p}}$, *be a strongly diagonally supported (overtaking) equilibrium at* $\hat{x}^o$ *such that*

$$\limsup_{k \to \infty} \|(\hat{x}^k, \hat{p}^k)\| < \infty.$$

Let $\tilde{\mathbf{x}}$ *be another (overtaking) equilibrium at* $\tilde{x}^o$ *with* $\tilde{\mathbf{p}}$ *its associated M-price schedule such that*

$$\limsup_{k \to \infty} \|(\tilde{x}^k, \tilde{p}^k)\| < \infty.$$

Then

$$\lim_{k \to \infty} \|(\hat{x}^k - \tilde{x}^k, \hat{p}^k - \tilde{p}^k)\| = 0. \tag{16}$$

Proof. Assume (16) does not hold. Then, according to equation (13) of Definition 2.6 we have

$$\lim_{K \to \infty} \sum_{k=0}^{K} \sum_{j \in M} \left[(\Delta \hat{p}_j^k - \Delta \tilde{p}_j^k)'(\hat{x}_j^k - \tilde{x}_j^k) + (\hat{p}_j^{k+1} - \tilde{p}_j^{k+1})'(\Delta \hat{x}_j^k - \Delta \tilde{x}_j^k) \right] = \infty. \tag{17}$$

However the left-hand side of the above expression is also equal to $\lim_{K \to \infty} V(K)$, where

$$V(K) \doteq \sum_{j \in M} \left[(\hat{p}_j^{K+1} - \tilde{p}_j^{K+1})'(\hat{x}_j^{K+1} - \tilde{x}_j^{K+1}) - (\hat{p}_j^0 - \tilde{p}_j^0)'(\hat{x}_j^0 - \tilde{x}_j^0) \right]. \tag{18}$$

If the M-programs and their associated M-price schedules are bounded, then so should be $V(K)$ for all K. This contradicts (17). □

Remark 2.9. This turnpike result is very much in the spirit of McKenzie [21] since it is established for nonautonomous systems as well as a nonconstant turnpike. The special case of autonomous systems will be considered in more detail in §2.7.

2.5. Conditions for SDCCA.

LEMMA 2.10. *Assume $L_j^k(x, z_j)$ is concave in (x_j, z_j) and assume that the total reward function $\sum_{j\in M} L_j^k(x, z_j)$ is diagonally strictly concave in (x, z), i.e., it verifies*

$$\sum_{j\in M}[(z_j^1 - z_j^0)'(\zeta_j^1 - \zeta_j^0) + (x_j^1 - x_j^0)(\eta_j^1 - \eta_j^0)] < 0, \tag{19}$$

for all

$$\eta_j^1 \in \partial_{x_j} L_j^k(x^1, z_j^1), \quad \zeta_j^1 \in \partial_{z_j} L_j^k(x^1, z_j^1),$$
$$\eta_j^0 \in \partial_{x_j} L_j^k(x^0, z_j^0), \quad \zeta_j^0 \in \partial_{z_j} L_j^k(x^0, z_j^0).$$

Then Assumption 2.4 *holds true.*

Proof. The concavity of $L_j^k(x, z_j)$ in (x_j, z_j) implies that each Hamiltonian

$$H_j^k(x, p_j) = \sup_{z_j}\{L_j^k(x, z_j) + p_j' z_j\}$$

defined in (2) is convex in p_j, for $j \in M$. This property with (19) imply that (5) holds true for all $(\hat{x}_j, \tilde{x}_j, \hat{p}_j, \tilde{p}_j)$ and $(\hat{\pi}_j, \tilde{\pi}_j, \hat{\xi}_j, \tilde{\xi}_j)$, such that (6) and (7) are satisfied. □

Remark 2.11. In the special case when the functions $L_j^k(\cdot, \cdot)$ are twice continuously differentiable the strict diagonal concavity in (x, z) of the total reward function $\sum_{j\in M} L_j^k(x, z)$ may be verified by applying the conditions given in Rosen [26, Thm. 6, p. 528].

2.6. The turnpike property with discounting. We have seen that concavity–convexity of the Hamiltonians and SDCCA, when combined with the strong support property, imply the turnpike property for overtaking equilibria when the infinite-horizon payoffs are not discounted. Discounting the payoffs could be considered as a form of a nonautonomous system. However, in that case, the condition of strong diagonal support will not be easily satisfied. To give a workable turnpike theorem for the discounted case, i.e., when $\beta_j < 1$ for at least one j, we must strengthen the support property of Definition 2.6 by a curvature condition.

THEOREM 2.12. *Suppose Assumptions* 2.2 *and* 2.4 *hold. Let $\hat{\mathbf{x}}$ and $\tilde{\mathbf{x}}$ be two overtaking equilibria at $\hat{x}^o$ and $\tilde{x}^o$, respectively, with associated M-price schedules $\hat{\mathbf{p}}$ and $\tilde{\mathbf{p}}$ such that*

$$\limsup_{k\to\infty} \| (\hat{x}^k, \hat{p}^k) \| < \infty \text{ and } \limsup_{k\to\infty} \| (\tilde{x}^k, \tilde{p}^k) \| < \infty$$

and additionally satisfy the following property.

For each $\epsilon > 0$ there exists $\delta > 0$ so that whenever

$$\| (\hat{x}^k - \tilde{x}^k, \hat{p}^k - \tilde{p}^k) \| > \epsilon,$$

one has

$$\sum_{j\in M}\left[\left(\hat{p}_j^{k+1} - \tilde{p}_j^{k+1}\right)'\left(\Delta\hat{x}_j^k - \Delta\tilde{x}_j^k\right) + \left(\hat{x}_j^k - \tilde{x}_j^k\right)'\left(\hat{\xi}_j^k - \tilde{\xi}_j^k\right)\right]$$
$$> \delta + \sum_{j\in M}\alpha_j\left(\hat{x}_j^k - \tilde{x}_j^k\right)'\left(\hat{p}_j^k - \tilde{p}_j^k\right) \tag{20}$$

for all

$$\hat{\xi}_j^k \in -\partial_{x_j} H_j^k(\hat{x}^k, \hat{p}_j^{k+1}), \tag{21}$$

$$\tilde{\xi}_j^k \in -\partial_{x_j} H_j^k(\tilde{x}^k, \tilde{p}_j^{k+1}). \tag{22}$$

Then

$$\lim_{k\to\infty} \| (\hat{x}^k - \tilde{x}^k, \hat{p}^k - \tilde{p}^k) \| = 0.$$

Proof. The proof of this result is a straightforward adaptation of the proof of Theorem 2.8. □

Remark 2.13. The condition (20) is clearly a strengthening of (13). This condition indeed is analogous to the conditions found in the papers of Cass and Shell, Brock and Scheinkman, and Rockafellar, et. al., which are nicely collected in [11].

2.7. The autonomous case. We now focus our study on the case when the functions L_j^k are independent of time k (i.e., $L_j^k(x, z_j) \equiv L_j(x, z_j)$). In this case, the optimality conditions become

$$\Delta x_j^k \in \partial_{p_j} H_j(x^k, p_j^{k+1}),$$
$$\Delta p_j^k + \alpha_j p_j^{k+1} \in -\partial_{x_j} H_j(x^k, p_j^{k+1}),$$

where

$$H_j(x, p_j) = \sup_{z_j \in \mathbb{R}^{n_j}} \{L_j(x, z_j) + p_j' z_j\}.$$

The above conditions define an autonomous pseudo-Hamiltonian system and the possibility arises that there exists a *steady-state equilibrium.* That is, a pair $(\bar{x}, \bar{p}) \in \mathbb{R}^n \times \mathbb{R}^n$ which satisfies

$$0 \in \partial_{p_j} H_j(\bar{x}, \bar{p}_j),$$
$$\alpha_j \bar{p}_j \in -\partial_{x_j} H_j(\bar{x}, \bar{p}_j).$$

When a unique steady-state equilibrium exists, the turnpike properties discussed above provide conditions when the pair $(\bar{x}, \bar{p})$ becomes an attractor for all bounded (overtaking) equilibria. Moreover, in this case, the support properties and curvature assumptions along a trajectory described on the nonautonomous case become simpler.

DEFINITION 2.14. *Let $(\bar{x}, \bar{p})$ be a steady-state equilibrium. We say that the strong diagonal support property for $(\bar{x}, \bar{p})$ holds if for each $\epsilon > 0$ there exists $\delta > 0$ so that whenever $\|x - \bar{x}\| + \|p - \bar{p}\| > \epsilon$, one has*

$$\sum_{j \in M} \left[(p_j - \bar{p}_j)' \pi_j + (x_j - \bar{x}_j)' (\xi_j - \alpha_j \bar{p}_j) \right]$$
$$> \delta + \sum_{j \in M} \alpha_j (x_j - \bar{x}_j)' (p_j - \bar{p}_j), \tag{23}$$

for all $j \in M$ and pairs (π_j, ξ_j) satisfying

$$\pi_j \in \partial_{x_j} H_j(x, p_j) \text{ and } \xi_j \in -\partial_{p_j} H_j(x, p_j).$$

Remark 2.15. If $\mathbf{x}$ is an M-program with an associated M-price schedule $\mathbf{p}$ such that

$$\|x^k - \bar{x}\| + \|p^k - \bar{p}\| > \epsilon,$$

then making the substitutions $x_j = x_j^k$, $p_j = p_j^{k+1}$, $\pi_j = \Delta x_j^k$, and $\xi_j = \Delta x_j^k$ in (23) immediately shows that the steady state $(\bar{x}, \bar{p})$ satisfies (20). This leads immediately to the following result.

THEOREM 2.16. *Assume that $(\bar{x}, \bar{p})$ is a unique steady-state equilibrium that has the strong diagonal support property given by* (23). *Then for any M-program $\mathbf{x}$ with an associated M-price schedule $\mathbf{p}$ that satisfies*

$$\limsup_{k \to \infty} \| (x^k, p^k) \| < \infty,$$

we have

$$\lim_{k\to\infty} \| \left(x^k - \bar{x}, p^k - \bar{p}\right) \| = 0.$$

Proof. Theorem 2.16 follows immediately from the above remark and Theorem 2.12. □

In a discrete time infinite-horizon optimal control problem with discount factor $\beta \in (0, 1]$, a steady-state equilibrium $\bar{x}$ is assured to be an attractor of overtaking equilibria by requiring the Hamiltonian of the system to be a-concave in x and b-convex in p for values of $a > 0$ and $b > 0$ for which the inequality

$$\left(1 - \frac{1}{\beta}\right)^2 < 4ab$$

holds (see, e.g., Rockafellar [24] or Brock and Scheinkman [6]). We conclude this section by extending this result to the case considered here.

DEFINITION 2.17. *Let $a = (a_1, a_2, \ldots, a_m)$ and $b = (b_1, b_2, \ldots, b_m)$ be two vectors in $\mathbb{R}^m$ with $a_j > 0$ and $b_j > 0$ for all $j \in M$. We say that the combined Hamiltonian $\sum_{j\in M} H_j\left(x, p_j\right)$ is strictly diagonally a-concave in x, b-convex in p if*

$$\sum_{j\in M}\left[H_j(x, p_j) + \frac{1}{2}\left(a_j\|x_j\|^2 - b_j\|p_j\|^2\right)\right]$$

is strictly diagonally concave in x, convex in p.

THEOREM 2.18. *Assume that there exists a unique steady-state equilibrium, $(\bar{x}, \bar{p})$. Let $a = (a_1, a_2, \ldots, a_m)$ and $b = (b_1, b_2, \ldots, b_m)$ be two vectors in $\mathbb{R}^m$ with $a_j > 0$ and $b_j > 0$ for all $j \in M$, and assume that the combined Hamiltonian is strictly diagonally a-concave in x, b-convex in p. Further, let* **x** *be a bounded equilibrium M-program with an associated M-price schedule* **p** *that also remains bounded. Then, if the discount rates β_j, $j \in M$, satisfy the inequalities*

$$\alpha_j^2 = \left(1 - \frac{1}{\beta_j}\right)^2 < 4a_jb_j, \tag{24}$$

the M-program **x** *converges to $\bar{x}$.*

Proof. Let **x** be a bounded M-program and let **p** be its associated M-price schedule (which is also bounded). Then we have the following inclusions for all $k \in \mathbb{N}$ and $j \in M$:

$$\Delta x_j^k - b_j p^{k+1} \in \partial_{p_j}\left[H_j(x^k, p_j^{k+1}) + \frac{1}{2}\left(a_j\|x_j^k\|^2 - b_j\|p_j^{k+1}\|^2\right)\right],$$

$$\Delta p_j^k + \alpha_j p_j^k - a_j x_j^k \in -\partial_{x_j}\left[H_j(x^k, p_j^{k+1}) + \frac{1}{2}\left(a_j\|x_j^k\|^2 - b_j\|p_j^{k+1}\|^2\right)\right],$$

$$-b_j\bar{p} \in \partial_{p_j}\left[H_j(\bar{x}, \bar{p}_j) + \frac{1}{2}\left(a_j\|\bar{x}_j\|^2 - b_j\|\bar{p}_j\|^2\right)\right],$$

$$\alpha_j\bar{p}_j - a_j\bar{x}_j \in -\partial_{x_j}\left[H_j(\bar{x}, \bar{p}_j) + \frac{1}{2}\left(a_j\|\bar{x}_j\|^2 - b_j\|\bar{p}_j\|^2\right)\right].$$

Thus, as a consequence of our SDCCAs, we have for each $k \in \mathbb{N}$ that

$$0 < \sum_{j\in M}\left[\left(p_j^{k+1} - \bar{p}_j\right)'\left(\Delta x_j^k - b_j p^{k+1} + b_j\bar{p}\right)\right.$$

$$\left. + \left(x_j^k - \bar{x}_j\right)'\left(\Delta p_j^k + \alpha_j p_j^{k+1} - a_j x_j^k - \left(\alpha_j\bar{p}_j - a_j\bar{x}_j\right)\right)\right]$$

$$= \sum_{j\in M}\left[\left(p_j^{k+1}-\bar{p}_j\right)'\Delta x_j^k + \left(x_j^k-\bar{x}_j\right)'\Delta p_j^k\right]$$
$$- \sum_{j\in M}\left[b_j\|p_j^{k+1}-\bar{p}_j\|^2 - \alpha_j\left(p_j^{k+1}-\bar{p}_j\right)'\left(x_j^k-\bar{x}_j\right) + a_j\|x_j^k-\bar{x}_j\|^2\right].$$

Summing from $k=0$ to $k=K$ we may write

$$V(K) > \sum_{k=0}^{K}\sum_{j\in M}\left[b_j\|p_j^{k+1}-\bar{p}_j\|^2 - \alpha_j\left(p_j^{k+1}-\bar{p}_j\right)'\left(x_j^k-\bar{x}_j\right) + a_j\|x_j^k-\bar{x}_j\|^2\right],$$

where, as before,

$$V(K) = \sum_{k=0}^{K}\sum_{j\in M}\left[\left(p_j^{k+1}-\bar{p}_j\right)'\Delta x_j^k + \left(x_j^k-\bar{x}_j\right)'\Delta p_j^k\right].$$

This inequality may be equivalently written as

$$V(K) > \sum_{k=0}^{K}\sum_{j\in M} b_j\left\|\left(p_j^{k+1}-\bar{p}_j\right) - \frac{\alpha_j}{2b_j}\left(x_j^k-\bar{x}\right)\right\|^2$$
$$- \left(\frac{\alpha_j^2}{4b_j} - a_j\right)\|x_j^k-\bar{x}\|^2$$
$$> \sum_{k=0}^{K}\sum_{j\in M}\left(a_j - \frac{\alpha_j^2}{4b_j}\right)\|x_j^k-\bar{x}\|^2.$$

To conclude this proof we see, from above, that if the M-program $\mathbf{x}$ does not converge to $\bar{x}$, then $\lim_{K\to\infty} V(K) = \infty$ because of (24). This, however, is a contradiction since we may equivalently write

$$V(K) = \sum_{j\in M}\left(\left(p_j^{K+1}-\bar{p}_j\right)'\left(x_j^{K+1}-\bar{x}_j\right) - \left(p_j^0-\bar{p}_j\right)'\left(x_j^0-\bar{x}_j\right)\right),$$

showing that $V(K)$ must remain bounded for all K. □

Remark 2.19. In the above results we have extended the classical asymptotic turnpike theory to a dynamic game framework with separated dynamics. The fact that each firm controls a distinct dynamical system and that the coupling between the players occurs only through the rewards is essential. An indication of the increased complexities of coupled dynamics is given in Haurie and Leitmann [18].

Remark 2.20. The assumption of the existence and uniqueness of the steady-state equilibrium $(\bar{x}, \bar{p})$ requires the solution of a nonlinear system of inclusions. In the single-player case, the study of solutions of these systems was considered by Rockafellar [24] (see in particular Theorem 5). In particular, he showed that if the Hamiltonian is a-concave in x and b-convex in p, and if there exists a unique steady-state equilibrium for the undiscounted case $\alpha = 0$ (i.e., $\beta = 1$), then for all $\alpha > 0$ sufficiently small there exists a unique steady-state equilibrium pair $(\bar{x}_\alpha, \bar{p}_\alpha)$. This theory has yet to be developed for the multi-player case considered here. In addition, the relationship between the steady-state equilibrium and the solution of a related family of mathematical programming problems was studied, again in the single-player case, by Feinstein and Luenberger [14]. In that work the "implicit programming problem" is defined and the solutions to this optimization problem are shown to correspond to a steady-state equilibrium pair. For the multi-player case, we direct the reader to [19] in which an "implicit static equilibrium" is defined with properties analogous to those presented in [14].

3. Existence of equilibria. In this section we extend Rosen's approach to show existence of equilibria in dynamic autonomous competitive processes, under sufficient smoothness and compactness conditions. Basically we reduce the existence proof to a fixed-point argument for a point-to-set mapping constructed from an associated class of infinite-horizon concave optimization problems.

3.1. Existence of overtaking equilibria in the undiscounted case. Our proof of existence of an overtaking equilibrium for undiscounted dynamic competitive processes uses extensively sufficient overtaking optimality conditions for single-player optimization problems (see [7, Chap. 2]). For this appeal to sufficiency conditions the existence of a bounded attractor to all good programs is important. This is the reason why our existence theory is restricted to autonomous systems for which a steady-state equilibrium provides such an attractor.

Remark 3.1. Existence of overtaking optimal control for autonomous systems (discrete or continuous time) can be established through a reduction to finite cost argument (see, e.g., [7]). There is a difficulty in extending this approach to the case of dynamic open-loop games. It comes from the inherent time-dependency introduced by the other players' decisions. Our approach circumvents this difficulty by implementing a reduction to finite costs for an associated class of infinite-horizon concave optimization problems.

We first make the following assumptions.

Assumption 3.2. The functions $L_j : \mathbb{R}^n \times \mathbb{R}^{n_j} \to \mathbb{R}$ are strictly concave in (x_j, z_j) and additionally we have that $\frac{\partial L_j}{\partial x_j}$ and $\frac{\partial L_j}{\partial z_j}$ are continuous on $\mathcal{R}^n \times \mathbb{R}^{n_j}$ for each $j \in M$.

Assumption 3.3. There exists a unique steady-state equilibrium $\bar{x} \in \mathbb{R}^n$ and a corresponding constant M-price schedule $\bar{p} \in \mathbb{R}^n$ satisfying

$$\begin{aligned} 0 &\in \partial_{p_j} H_j(\bar{x}, \bar{p}_j), \\ 0 &\in \partial_{x_j} H_j(\bar{x}, \bar{p}_j). \end{aligned} \tag{25}$$

To achieve our result we must assure that all admissible M-programs lie in a compact set. Thus we make the following additional assumption.

Assumption 3.4. For each $j \in M$ there exists a closed bounded set $X_j \subset \mathbb{R}^{n_j}$ such that each M-program, $\mathbf{x}$, satisfies $x_j^k \in X_j$ for each $k \in \mathbb{N}$. Additionally we introduce the following notation.

(i) We let Ω denote the set of all M-programs that start at x^o and converge to $\bar{x}$, the unique steady-state equilibrium.

(ii) We define the family of functionals $\rho^K : \Omega \times \Omega \to \mathbb{R}$, $K \in \mathbb{N}$, by the formula

$$\rho^K(\mathbf{x}, \mathbf{y}) \doteq \sum_{k=0}^{K} \sum_{j \in M} \left[L_j \left(\left[\mathbf{x}^j, y_j \right]^k, \Delta y_j^k \right) \right].$$

We view Ω as a subset of all bounded sequences in $\mathbb{R}^n$ endowed with the topology of pointwise convergence.

DEFINITION 3.5. *Let* $\mathbf{x}, \mathbf{y} \in \Omega$. *We say that* $\mathbf{y} \in \Gamma(\mathbf{x})$ *if*

$$\liminf_{K \to \infty} \left(\rho^K(\mathbf{x}, \mathbf{y}) - \rho^K(\mathbf{x}, \mathbf{z}) \right) \geq 0,$$

for all M*-programs* $\mathbf{z}$ *such that* $z_j^0 = x_j^0$. *That is,* $\mathbf{y}$ *is an overtaking optimal solution of the infinite-horizon optimization problem whose objective functional is defined by* $\rho^K(\mathbf{x}, \cdot)$. *Hence* $\Gamma(\mathbf{x})$ *can be viewed as the set of* optimal responses *by all players to an* M*-program* $(\mathbf{x})$.

THEOREM 3.6. *Under the above assumptions, there exists an overtaking equilibrium for the infinite-horizon dynamic game.*

Proof. To prove our result we prove that the set-valued map $\Gamma : \Omega \to 2^{\Omega}$ has a fixed point using the Kakutani fixed-point theorem. To do this we need to show that

1. for each $x \in \Omega$, the set $\Gamma(\mathbf{x})$ is nonempty, convex, and compact.
2. the map $\Gamma(\cdot)$ has a closed graph. That is, if $(\mathbf{y}_l, \mathbf{x}_l)$ is a sequence in $\Omega \times \Omega$ that converges to $(\mathbf{y}, \mathbf{x})$ and additionally satisfies

$$\mathbf{y}_l \in \Gamma(\mathbf{x}_l)$$

for all $l = 1, 2, \ldots$, then $\mathbf{y} \in \Gamma(\mathbf{x})$.

We begin by first showing, for each $\mathbf{x} \in \Omega$, that $\Gamma(\mathbf{x})$ is nonempty. To see this we fix $\mathbf{x} \in \Omega$, let $(\theta_l)_{l=1}^{\infty}$ be an unbounded strictly increasing sequence of positive integers, and define for each $l = 1, 2, \ldots$, the M-programs $\mathbf{x}_l$ as

$$x_l^k = \begin{cases} x^k & \text{if } k < \theta_l, \\ \bar{x} & \text{if } k \geq \theta_l, \end{cases}$$

for $k = 1, 2, \ldots$. Now consider the problem of maximizing the functional $\gamma(\mathbf{x}_l, \cdot)$ defined by the formula

$$\begin{aligned} \gamma(\mathbf{x}_l, \mathbf{z}) &\doteq \sum_{k=0}^{\infty} \sum_{j \in M} \left[L_j \left(\left[\mathbf{x}_l^j, z_j \right]^k, \Delta z_j^k \right) - L_j(\bar{\mathbf{x}}, 0) + \bar{p}_j \Delta z_j^k \right] \\ &= \sum_{k=0}^{\theta_l - 1} \sum_{j \in M} \left[L_j \left(\left[\mathbf{x}_l^j, y_j \right]^k, \Delta y_j^k \right) - L_j(\bar{\mathbf{x}}, 0) + \bar{p}_j \Delta y_j^k \right] \\ &\quad + \sum_{k=\theta_l}^{\infty} \sum_{j \in M} \left[L_j \left(\left[\bar{\mathbf{x}}^j, y_j \right]^k, \Delta y_j^k \right) - L_j(\bar{\mathbf{x}}, 0) + \bar{p}_j \Delta y_j^k \right], \end{aligned}$$

over all M-programs starting at x^o. Observe that for each $k > \theta_l$, the terms of $\gamma(\mathbf{x}_l, \mathbf{z})$ are nonpositive and in fact equal zero whenever we take $z_j^k = \bar{x}_j$. From this it follows easily that there exists an M-program, say $\mathbf{z}$, for which $\gamma(\mathbf{x}_l, \mathbf{z}) > -\infty$ and, moreover, since each term of an M-program lies in a compact subset of $\mathbb{R}^n$, it also follows that $\gamma(\mathbf{x}_l, \mathbf{z})$ is bounded above. Therefore, there exists an M-program $\mathbf{y}_l$ that maximizes $\gamma(\mathbf{x}_l, \mathbf{z})$ as desired. Furthermore, as a result of the strict concavity assumptions given above, it follows that $\mathbf{y}_l \in \Gamma(\mathbf{x}_l)$ and we also have

$$\lim_{k \to \infty} y_l^k = \bar{x}.$$

This asymptotic stability property was proved by Brock in [3] (see also [7]). In this way we generate the sequence $(\mathbf{y}_l)$ in Ω, a compact set. Thus we can assume that the sequence $(\mathbf{y}_l)$ converges to an M-program $\mathbf{y} \in \Omega$. Additionally, we also know that the sequence $(\mathbf{x}_l)$ converges to our original M-program $\mathbf{x}$. We now show that $\mathbf{y} \in \Gamma(\mathbf{x})$. To this end we note that for each $l = 1, 2, \ldots$, there exists an M-price schedule $\mathbf{p}_l$ such that

$$\begin{aligned} \Delta y_{lj}^k &\in \partial_{p_j} H_j \left([x_l^{(j)}, y_{lj}]^k, p_{lj}^{k+1} \right), \\ \Delta p_{lj}^k &\in -\partial_{x_j} H_j \left([x_l^{(j)}, y_{lj}]^k, p_{lj}^{k+1} \right) \end{aligned}$$

or equivalently that

$$\begin{aligned} p_{lj}^{k+1} &= -\frac{\partial}{\partial z_j} L_j \left([x_l^{(j)}, y_{lj}]^k, \Delta y_{lj}^k \right), \\ \Delta p_{lj}^k &= -\frac{\partial}{\partial x_j} L_j \left([x_l^{(j)}, y_{lj}]^k, \Delta y_{lj}^k \right). \end{aligned} \tag{26}$$

Holding $k \in \mathbb{N}$ fixed and letting $l \to \infty$ in the above gives us that

$$p_j^{k+1} \doteq \lim_{l\to\infty} p_{lj}^{k+1} = -\frac{\partial}{\partial z_j} L_j\left([x^{(j)}, y_j]^k, \Delta y_j^k\right) \tag{27}$$

and

$$\Delta p_j^k = -\frac{\partial}{\partial x_j} L_j\left([x^{(j)}, y_j]^k, \Delta y_j^k\right). \tag{28}$$

That is, we can associate with $\mathbf{y} \in \Omega$ an M-price schedule $\mathbf{p}$ and, moreover, since $\mathbf{x}, \mathbf{y} \in \Omega$ we have $\lim_{k\to\infty} p_j^k = \bar{p}_j$ as well. Therefore, by appealing to standard sufficient conditions for overtaking optimality we obtain $\mathbf{y} \in \Gamma(\mathbf{x})$ as desired. Further it is easy to see that, as a result of our concavity assumptions on L_j, $\Gamma(\mathbf{x})$ is a convex set.

Since $\Gamma(\mathbf{x})$ is a subset of Ω, a compact set, the compactness of $\Gamma(\mathbf{x})$ follows immediately once we show that it is closed. To see this let $(\mathbf{y}_l)$ be a sequence in $\Gamma(\mathbf{x})$ that converges to $\mathbf{y}$ and let $(\mathbf{p}_l)$ be the sequence of corresponding M-price schedules. By a direct adaptation of the above argument it can be shown that there is an M-price schedule $\mathbf{p}$ associated with $\mathbf{y}$ that converges to $\bar{p}$ as $k \to \infty$. Hence $\mathbf{y} \in \Gamma(\mathbf{x})$, giving us the desired compactness condition.

It remains to prove that the graph of Γ is closed. To see this let $(\mathbf{y}_l, \mathbf{x}_l) \to (\mathbf{y}, \mathbf{x})$ as $l \to \infty$ be such that $\mathbf{y}_l \in \Gamma(\mathbf{x}_l)$ for each $l \in \mathbb{N}$. Further we let $(\mathbf{p}_l)$ be a sequence of associated M-price schedules, satisfying (26). Then, once again, letting $l \to \infty$ one sees that there exists an M-price schedule $\mathbf{p}$ associated with $\mathbf{x}$ such that $\mathbf{p}_l \to \mathbf{p}$. Thus proceeding as above we see that $\mathbf{y} \in \Gamma(\mathbf{x})$, which gives us the closed graph property.

We have just shown that the conditions needed to apply Kakutani's fixed-point theorem are satisfied. Therefore there exists $\mathbf{x}^* \in \Gamma(\mathbf{x}^*)$. The proof that the M-program $\mathbf{x}^*$ is an overtaking equilibrium now follows as in Rosen [26, Thm. 1]. □

3.2. Existence of equilibria in discounted competitive processes. Under the assumptions made above to establish the existence of an overtaking equilibrium, it is easy to treat the case of autonomous games with discounting. Indeed, by requiring all admissible M-programs to satisfy the compact constraints $x_j^k \in X_j$ for all $j \in M$ and $k \in \mathbb{N}$ and having $\beta_j \in (0, 1)$, it follows that the functionals $\rho^K : \Omega \times \Omega \to \mathbb{R}$, $K \in \mathbb{N}$, now given by

$$\rho^K(\mathbf{x}, \mathbf{y}) \doteq \sum_{k=0}^{K} \sum_{j\in M} \left[(\beta_j)^k L_j\left(\left[\mathbf{x}^j, y_j\right]^k, \Delta y_j^k\right)\right]$$

are bounded both above and below for all $K \in \mathbb{N}$. Thus, the existence of an equilibrium can be assured by an easy modification of the above argument. To do this we enlarge Ω to be the set of all M-programs satisfying the initial condition x^o and now define $\Gamma : \Omega \to 2^\Omega$ as follows:

> For an M-program $\mathbf{x} \in \Omega$ we let $\Gamma(\mathbf{x})$ denote the set of all M-programs $\mathbf{y} \in \Omega$ such that
>
> $$\rho^K(\mathbf{x}, \mathbf{y}) = \max_{\mathbf{z}\in\Omega} \rho^K(\mathbf{x}, \mathbf{z}).$$

Further, the positive discounting eliminates the need to define the associated problems using the functional $\gamma(\cdot, \cdot)$. Therefore we state the following result without proof.

THEOREM 3.7. *Let $\beta_j > 0$ for $j \in M$ and let Assumptions* 3.2–3.4 *hold. Then there exists an overtaking equilibrium for the discounted autonomous infinite-horizon dynamic game.*

Remark 3.8. Both of the existence results given above are for autonomous dynamic games only. We observe however that our arguments would be applicable in the nonautonomous case

if one could assume that the sets $\Gamma(\mathbf{x})$ are nonempty. To make this conclusion would require one to appeal to corresponding nonautonomous existence theorems for optimality (overtaking optimality in the discounted case). This of course would require some growth restrictions on the functions $L_j^k(\cdot,\cdot)$ (e.g., $|L_j^k(x, z_j)| \le \Lambda_j$ for all (x, z_j), $j \in M$, and $k \in \mathbb{N}$).

4. Uniqueness of equilibria. In Rosen's paper [26], the strict diagonal concavity condition was introduced essentially to assure uniqueness of equilibria. In §2 we introduced a similar assumption to get asymptotic stability of equilibrium programs. Indeed this condition also leads to uniqueness.

THEOREM 4.1. *If the assumptions of Theorem* 2.8 *hold and there exists an overtaking equilibrium at* x^o, *then it is unique.*

Proof. Assume that $\hat{\mathbf{x}}$ and $\tilde{\mathbf{x}}$ are two distinct equilibria at x^o, with their respective M-price schedules $\hat{\mathbf{p}}$ and $\tilde{\mathbf{p}}$. According to the necessary conditions, for all $k = 0, 1, \ldots$, there exist

$$\hat{\pi}_j^k \in \partial_{p_j} H_j^k(\hat{x}, \hat{p}_j), \quad \tilde{\pi}_j^k \in \partial_{p_j} H_j^k(\tilde{x}, \tilde{p}_j), \tag{29}$$

$$\hat{\xi}_j^k \in -\partial_{x_j} H_j^k(\hat{x}, \hat{p}_j), \quad \tilde{\xi}_j^k \in -\partial_{x_j} H_j^k(\tilde{x}, \tilde{p}_j) \tag{30}$$

such that

$$\sum_{j\in M}\Big[(\hat{p}_j^{k+1} - \tilde{p}_j^{k+1})'(\hat{\pi}_j^k - \Delta\hat{x}_j^k - \tilde{\pi}_j^k + \Delta\tilde{x}_j^k) + (\hat{x}_j^k - \tilde{x}_j^k)'(\hat{\xi}_j^k - \Delta\hat{p}_j^k - \tilde{\xi}_j^k + \Delta\tilde{p}_j^k)\Big] = 0. \tag{31}$$

Adding over $k = 0, \ldots, K$ we get

$$\sum_{k=0}^{K}\sum_{j\in M}\Big[(\Delta\hat{p}_j^k - \Delta\tilde{p}_j^k)'(\hat{x}_j^k - \tilde{x}_j^k) + (\hat{p}_j^{k+1} - \tilde{p}_j^{k+1})'(\Delta\hat{x}_j^k - \Delta\tilde{x}_j^k)\Big]$$

$$= \sum_{k=0}^{K}\sum_{j\in M}\Big[(\hat{p}_j^{k+1} - \tilde{p}_j^{k+1})'(\hat{\pi}_j^k - \tilde{\pi}_j^k) + (\hat{x}_j^k - \tilde{x}_j^k)'(\hat{\xi}_j^k - \tilde{\xi}_j^k)\Big]. \tag{32}$$

Now, when $K \to \infty$, the right-hand side of (32) tends to a strictly positive number, due to SDCCA, whereas the left-hand side, which collapses to

$$\sum_{j\in M}\Big[(\hat{p}_j^{K+1} - \tilde{p}_j^{K+1})'(\hat{x}_j^{K+1} - \tilde{x}_j^{K+1}) + (\hat{p}_j^0 - \tilde{p}_j^0)'(\hat{x}_j^0 - \tilde{x}_j^0)\Big], \tag{33}$$

goes to zero, due to the turnpike property. This is a contradiction; hence the overtaking equilibrium is unique. □

5. Example. We consider the following class of games as an example where the conditions stated in this paper are easy to check. We assume that $L_j : \mathbb{R}^n \times \mathbb{R}^{n_j} \to \mathbb{R}$ has the form

$$L_j(x, z_j) = g_j(x_j, z_j) + G_j(x),$$

for $j = 1, 2, \ldots m$. Thus the accumulated reward for the jth player over $[0, K]$, $K > 0$ an integer, is given as

$$\phi_j^K(\mathbf{x}) = \sum_{k=0}^{K-1}(\beta_j)^k\left[g_j(x_j^k, \Delta x_j^k) + G_j(x^k)\right].$$

In this formulation there is a separation between the control of each player and the state variables of the other players. We assume that the functions $g_j(\cdot, \cdot)$ are concave and that the combined G's are strictly diagonally concave. In this way it is easy to see that the combined Hamiltonians, defined by

$$\begin{aligned} H_j(x, p_j) &= \sup_{z \in \mathbb{R}^{n_j}} \{L_j(x, z) + p_j \cdot z\} \\ &= \sup_{z \in \mathbb{R}^{n_j}} \{g_j(x_j, z) + p_j \cdot z\} + G_j(x) \\ &= \tilde{H}_j(x_j, p_j) + G_j(x), \end{aligned}$$

are strictly diagonally concave in x and convex in p since each of the Hamiltonians, $\tilde{H}$, are concave in x_j and convex in p_j. We further observe that the Hamiltonian dynamical system that is necessary for an equilibrium becomes, when $\beta_j \equiv 1$,

$$\begin{aligned} \Delta x_j^k &\in \partial_{p_j} \tilde{H}_j(x_j^k, p_j^k), \\ \Delta p_j^k + \nabla_{x_j} G_j(x^k) &\in -\partial_{x_j} \tilde{H}_j(x_j^k, p_j^k). \end{aligned}$$

The conditions for a steady-state equilibrium become

$$\begin{aligned} 0 &\in \partial_{p_j} \tilde{H}_j(\bar{x}_j, \bar{p}_j), \\ -\nabla_{x_j} G_j(\bar{x}) &\in -\partial_{x_j} \tilde{H}_j(\bar{x}_j, \bar{p}). \end{aligned}$$

Thus to insure that the turnpike property holds, we require this steady state $\bar{x}$ to be *strongly diagonally supported* by $\bar{p}$. That is, for each $\epsilon > 0$ there exists $\delta > 0$ so that if $\|x - \bar{x}\| + \|p - \bar{p}\| > \epsilon$, one has

$$\sum_{j \in M} \left[(p_j - \bar{p}_j)' \pi_j + (x_j - \bar{x}_j)' \eta_j\right] + \sum_{j \in M} (x_j - \bar{x}_j)' (\nabla_{x_j} G_j(x) - \nabla_{x_j} G_j(\bar{x})) > \delta$$

for all (π_j, η_j), $j \in M$, satisfying

$$\begin{aligned} \pi_j &\in \partial_{p_j} \tilde{H}_j(x_j, p_j), \\ \eta_j &\in -\partial_{x_j} \tilde{H}_j(x_j, p_j). \end{aligned}$$

This condition is insured if the steady-state equilibrium is unique and the programs remain in a compact set. Indeed this is a consequence of the strict diagonal concavity for the combined G's and of the concavity–convexity property of each $\tilde{H}_j$. The fact that the strong support property is a consequence of compactness and strict diagonal concavity would be an easy adaptation of Atsumi's lemma (see [7]).

6. Conclusion. In this paper we have shown that, for infinite-horizon competitive processes defined over dynamical systems where the players only interact through the payoff functionals but control their own separate dynamics, an assumption very similar to the one made by Rosen in his seminal study of uniqueness of equilibria in static concave games brings together global asymptotic stability of equilibrium trajectories, existence, and uniqueness of overtaking equilibria at each initial state. This extends the so-called turnpike theory of optimal economic processes to a competitive case.

Acknowledgment. We would like to acknowledge the fruitful discussions with and comments from our colleague Professor Arie Leizarowitz throughout the development of this work.

THE GENERALIZED SOLUTIONS OF NONLINEAR OPTIMIZATION PROBLEMS WITH IMPULSE CONTROL*

BORIS M. MILLER†

Abstract. The optimal control problem described by a nonlinear ordinary differential equation is considered with unbounded controls. The aim of this paper is to provide a representation of generalized (discontinuous) solutions in terms of differential equations with a measure. By using the method of discontinuous time change the problem with nonlinear dependence on the unbounded controls can be reduced to the simpler one with bounded controls. These results are applied to solving the problem of generalized (discontinuous) solution representation in the dynamic system with impulse-type controls.

Key words. nonlinear systems, impulse control, generalized solutions, discontinuous time change

AMS subject classification. 49B05

1. Introduction.

In this paper we discuss the control of a nonlinear dynamic system whose state is governed by the nonlinear differential equation

$$\dot{x}(t) = F(x(t), u(t), w(t), t), \tag{1}$$

where $F(x(t), u(t), w(t), t)$ is a given function, $x(t) \in R^n$, $t \in [0, T]$, $x(t) = x_0$ is an initial condition, and $u(t)$ and $w(t)$ are measurable controls on $[0, T]$: $u(t) \in R^k$ is an ordinary control component, and $w(t) \in R^m$ is a generalized one. The former component corresponds to the bounded control

$$u(t) \in U \subset R^k, \tag{2}$$

where U is a closed and bounded subset of R^k, and the latter corresponds to control which is unbounded in the norm but bounded in the integral sense so that

$$w(t) \in W \subset R^m, \tag{3}$$

$$\int_o^T \|w(t)\| dt \leq M < \infty, \tag{4}$$

where W is a subset of R^m and M is a constant.

The optimization problems with impulse and ordinary controls occur in flight dynamics [5], [7], [8]: for example, the positions of the exhaust vanes of the space vehicle can be considered the bounded control inputs, and the jet flow rate could be impulse (unbounded) controls. Another example of such type of optimization problem is one of observation control [2], [8] for discrete-continuous systems where two different types of observation controls characterize the possibility of controlling both the composition of observations and their timing and density.

Condition (4) means that the admissible controls can be taken as functions that are as close as desired to the impulse or generalized functions. As a result, the solution of the optimal control problem in system (1) with absolutely continuous paths $\{x(\cdot)\}$ under constraints (2)–(4) may not exist within the class of measurable ordinary or relaxed control functions. Thus,

the concept of a solution should be extended to consider the possible discontinuous behavior of the optimal path under the impulse control action.

If the function $F(x, u, w, t)$ is linear on w, i.e.,

$$F(x, u, w, t) = f(x, u, t) + B(t)w,$$

where the matrix-valued function $B(\cdot)$ is continuous, the concept of solution can be easily extended, interpreting equation (1) as one with measure of the following type [6], [16]:

$$dx(t) = f(x(t), u(t), t)dt + B(t)d\mu(t).$$

However, if the function $B(\cdot)$ is discontinuous or depends on the other control $u(\cdot)$, i.e., $B = B(t, u)$, then the representation of the optimal solution by the above equation can be incorrect without a special "constancy" condition. For the investigation of optimization problems with impulse controls in the system

$$dx(t) = f(x(t), u(t), t)dt + B(t, u(t))d\mu(t),$$

the special method that we refer to as the *method of discontinuous time change* was introduced by Rishel [15]. Rishel's approach is to introduce a new independent variable with respect to which trajectories become absolutely continuous. This leads to the consideration of an auxiliary control problem with bounded controls in which the time variable plays the role of a component of the state variable. This approach enables us to reduce the original optimization problem to the equivalent auxiliary one with bounded controls and to deduce optimality conditions for the original optimal process.

The general approach, based on the idea of replacing time with a new independent variable, was applied to the class of nonlinear systems by Warga [20]–[22], who considered nonlinear systems with an arbitrary dependence on unbounded components of control. Warga's approach provides an effective tool for the investigation of the optimization problems and gives the general representation of optimal paths by the discontinuous time change. We are going to give a further extension of this method, namely, to derive the representation of generalized (discontinuous) solution in optimization problems in terms of differential equations with a measure.

Some results in this area were obtained for special classes of systems, for example, when $B(\cdot)$ depends on the state variable x and t only, i.e., $B = B(x, t)$. If $B(x, t)$ satisfies the Frobenius-type condition [1], [9], [11], [14], [18], it is possible to derive the representation of a generalized solution in the form of a nonlinear differential equation with a measure.

In recent works [10], [12], [13] this representation was obtained for nonlinear systems with the function $F(x, u, w, t)$ in (1) in the form

$$F(x, u, w, t) = f(x, u, v, t) + B(x, u, v, t)w$$

with additional variable v, which satisfies the equation

$$\dot{v} = \|w(s)\|$$

and can be used to describe the dependence of state variables and constraints upon the varying control resource. The complete survey of results concerning the applications of the discontinuous time change method to representation of the generalized solutions and derivation of the optimality conditions can be found in [11].

However, if the function $F(x, u, w, t)$ is nonlinear with respect to w or there are special constraints on variations of state variables, we need a further investigation of this concept to obtain the representation of generalized solutions by differential equation with a measure.

In this paper we consider the concept of a generalized solution as a pointwise limit of some sequence of ordinary solutions on the set of continuity of this generalized solution. The application of Warga's approach [20], [21] to the problem with constraint (4) gives a very natural form of auxiliary system for representation of the generalized solution with an additional variable "new time." In this case the function φ in the equation for the "new time" can be taken in the form $\varphi = 1 + \|w\|$, as in the cases mentioned above [10]–[13]. Then, our next steps in the representation of generalized solution, such as Theorems 3.1, 3.2, and 3.3, follow directly from the results presented in [21] with slight modifications. Section 4 is devoted to the study of representation problem for the right-hand side of the auxiliary system in the "control" form along the lines of [22]. This is the key problem for the representation of the generalized solution by the sampling of some control in the auxiliary system. Here, the main result shows that in the case of the regular behavior of $F(x, u, w, t)$ at infinity, we can obtain this representation of the right-hand side of auxiliary system. Now, in the regular case we can derive the differential equation with a measure for any generalized solution of system (1). Results presented in §5 (Theorems 5.1 and 5.3) yield the representation of any generalized solution in the form of a generalized equation with a measure, that is, similarly to the representation of weak solutions for the controlled systems, described by the ordinary differential equations with a nonconvex right-hand side [6]. Finally, in §6 we return to the original optimization problem to formulate the existence condition for the optimal generalized solution.

2. Problem statement and assumptions. Let the controllable system be described by (1) with the state variable $x(t) \in R^n$ and controls $\{u(t), w(t)\}$ satisfying (2)–(4).

We shall assume that vector function F is continuous with respect to $(x, u, w, t) \in R^{n+k+m+1}$ and that for any $(u, w, t) \in U \times W \times [0, T]$ the function F satisfies a Lipschitz condition, i.e.,

$$\|F(x_1, u, w, t) - F(x_2, u, w, t)\| \leq L_1(1 + \|w\|)(\|x_1 - x_2\|) \tag{5}$$

for any $x_1, x_2 \in R^n$ with constant $L_1 > 0$.

We shall also assume that $F(x, u, w, t)$ has linear growth in both x and w, i.e.,

$$\|F(x, u, w, t)\| \leq L_2(1 + \|x\|)(1 + \|w\|) \tag{6}$$

for any (x, u, w, t) with constant $L_2 > 0$.

Our purpose is to consider the optimal control problem for system (1) with the following performance criterion, which must be minimized:

$$J[x(\cdot), u(\cdot), w(\cdot)] = \varphi_0(x(0), x(t)), \tag{7}$$

where φ_0 is continuous with respect to all the variables, and controls $\{u(\cdot), w(\cdot)\}$ satisfy the constraints (2)–(4) also to the following terminal and phase constraints:

$$h(x(0), x(T)) = 0, \qquad S(x(0), x(T)) \leq 0, \tag{8}$$

$$g(x(t), t) \leq 0 \qquad \text{for} \quad t \in [0, T]. \tag{9}$$

Here h, S, and g are R^{N_1}-, R^{N_2}-, and R^{N_3}-valued continuous functions, respectively, and (8) and (9) can be understood as componentwise relations.

To take into account the possible impulse behavior of the control component $w(\cdot)$ we shall consider the following definition of generalized (discontinuous) solution of system (1).

DEFINITION 2.1. *A right continuous function $x(\cdot)$ of bounded variation on the interval $[0, T]$ is said to be a* generalized solution *of the system* (1) *if there exists a sequence of*

admissible controls $\{u^n(\cdot), w^n(\cdot)\}$ *satisfying the constraints* (2)–(4) *such that the corresponding sequence* $\{x^n(\cdot)\}$ *of solutions of* (1) *with the initial condition* $x^n(0) = x(0-)$ *converges to* $x(\cdot)$ *at all the points of its continuity.*

In other words the generalized solution is a limit of sequence of ordinary solutions in the sense of weak-$\star$ topology in the space of right continuous functions with bounded variation.

A solution of optimization problem will be sought in the class of generalized solutions. We shall require that constraints (8) and (9) hold for a generalized solution, whereas (8) and (9) hold only in the limit for the sequence of ordinary solutions that approximates the former one.

DEFINITION 2.2. *A right continuous function* $x(\cdot)$ *of bounded variation on the interval* $[0, T]$ *is said to be the* admissible generalized solution *of the system* (1) *under the constraints* (8) *and* (9) *if*

(i) $\{x(\cdot)\}$ *satisfies the constraints* (8) *and* (9) *in the sense*

$$h(x(0-), x(T)) = 0, \qquad S(x(0-), x(T)) \le 0,$$
$$g(x(t), t) \le 0 \qquad \text{for} \quad t \in [0, T];$$

(ii) *there exists a sequence of admissible controls* $\{u^n(\cdot), w^n(\cdot)\}$ *satisfying the constraints* (2)–(4) *such that the corresponding sequence* $\{x^n(\cdot)\}$ *of solutions of system* (1) *converges to* $x(\cdot)$ *at all points of continuity and, in addition,*

$$\lim_n x^n(0) = x(0-), \qquad \lim_n x^n(T) = x(T),$$
$$\lim_n \sup_{[0,T]} g_k(x^n(t), t) \le 0 \qquad \textit{for} \quad k = 1, \dots, N_3.$$

DEFINITION 2.3. *An admissible generalized solution* $\{x^0(\cdot)\}$ *is said to be the* optimal generalized solution *if the inequality*

$$\varphi_0(x^0(0-), x^0(T)) \le \varphi_0(x(0-), x(T))$$

takes place for any admissible generalized solution $\{x(\cdot)\}$.

Remark 2.1 These definitions are in accord with the definition of the solution of general optimization problem formulated in [21, Thm. VI.4.2].

Our purpose is to characterize the generalized solution with the aid of auxiliary control system by the method of the discontinuous time change. The next step is to derive the equation for the generalized solution in the form of special differential inclusion with a measure and, finally, to prove the existence theorem for the solution of the optimization problem.

3. Generalized solutions and their representation by discontinuous time change. The application of discontinuous time change for the representation of generalized solutions of system (1) needs the consideration of some auxiliary controlled system whose right-hand side is bounded for arbitrary state variables.

Consider the auxiliary controllable system of differential equations for the pair $y(s) \in R^n$ and $\eta(s) \in R^1$, defined on the interval $[0, T_1]$, where $T_1 \le T + M$:

$$(10) \qquad \begin{pmatrix} \dot{y}(s) \\ \dot{\eta}(s) \end{pmatrix} = \begin{pmatrix} \dfrac{F(y(s), u_1(s), w_1(s), \eta(s))}{1 + \|w_1(s)\|} \\ \dfrac{1}{1 + \|w_1(s)\|} \end{pmatrix} = \tilde{F}(y(s), u_1(s), w_1(s), \eta(s))$$

with the initial conditions

$$y(0) = x(0), \qquad \eta(0) = 0$$

and the controls in the form of functions $u_1(s)$ and $w_1(s)$, which satisfy the constraints

$$u_1(s) \in U, \qquad w_1(s) \in W. \tag{11}$$

In the auxiliary system (10) and (11) the function $F(x, u, w, t)$, sets U and W, and constants T and M are the same as in (1)–(4).

Remark 3.1. This choice of auxiliary system corresponds to the one of function φ [20], [21], which is a "rate" of time change, in the form

$$\varphi(x, u, w, t) = 1 + \|w\|.$$

The right-hand side of (10) satisfies a Lipschitz condition with respect to y, and it has linear growth in the usual sense, as follows from the inequalities (5) and (6).

There exists an interconnection between the systems (1) and (10) and their solutions, specified by the following theorems.

THEOREM 3.1. *Let the triple of functions* $\{x(\cdot), u(\cdot), w(\cdot)\}$ *satisfy* (1) *and the controls* $\{u(\cdot), w(\cdot)\}$ *be measurable and satisfy the constraints* (2)–(4).

Then there exist the set of functions $\{y(\cdot), \eta(\cdot), u_1(\cdot), w_1(\cdot)\}$ *defined on some interval* $[0, T_1]$, *where*

$$\eta(T_1) = T,$$

which satisfy the system (10) *with the initial condition* $y(0) = x(0)$, *and the measurable controls* $\{u_1(\cdot), w_1(\cdot)\}$, *which satisfy the constraints* (11) *such that for any* $t \in [0, T]$

$$x(t) = y(\Gamma(t)), \tag{12}$$

where

$$\Gamma(t) = \inf\{s : \eta(s) > t\}. \tag{13}$$

THEOREM 3.2. *Let* $x(\cdot)$ *be a generalized solution of system* (1). *Then there exists a sequence of admissible controls* $\{u_1^n(\cdot), w_1^n(\cdot)\}$ *satisfying* (11), *on some interval* $[0, T_1]$, $T_1 \leq T + M$, *such that the corresponding sequence of solutions of the system* (10) *with initial conditions*

$$y^n(0) = x(0-), \qquad \eta^n(0) = 0$$

converges uniformly on $[0, T_1]$ *to the pair of functions* $\{y(\cdot), \eta(\cdot)\}$, *and the generalized solution* $x(\cdot)$ *can be represented on* $[0, T]$ *by the relation* (12), *where the function* $\Gamma(\cdot)$ *is defined by* (13), *and* $\Gamma(T) = T_1$ *by definition.*

Remark 3.2. These results follow directly from theorems VI.4.4 and VI.4.5 in Warga's book [21] if the original system is autonomous, i.e., $F(x, u, w, t) = F(x, w, u)$. However, Warga's arguments remain valid in the nonautonomous case without any change. For our problem the assumptions of theorem VI.4.4 [21] follow by choosing, in Warga's notation, $\varphi(v, u, b) = 1 + \|w\|$, where Warga's u represents our (u, w). (Note that all the solutions of original and transformed problems are confined to a compact set, due to assumptions (4) and (5).) The assumptions of theorem VI.4.5 should be slightly modified; namely, the condition

$$\|F(x_1, u, w) - F(x_2, u, w)\| \leq L_1\|x_1 - x_2\| \tag{14}$$

is replaced by

$$\|F(x_1, u, w, t) - F(x_2, u, w, t)\| \leq L_1(1 + \|w\|)\|x_1 - x_2\|. \tag{15}$$

However, the proof of Warga's theorem VI.4.5 [21] remains valid with slight modifications if assumption (14) is replaced by (15). To modify the proof of theorem VI.4.5 [21] we should (using the notation of [21])

(i) replace c_1 in (2) with $2c_1(L+1)$—here L is the upper bound of the variation of the system (1) solution;

(ii) replace c_1 in (5) with $c_1(1+\|w(t)\|)$;

(iii) and replace, in step 2, in the first inequality for $e(s)$

$$\int_0^s e(\tau)d\tau \quad \text{with} \quad \int_0^s (1+\|w(\tau)\|)e(\tau)d\tau,$$

which (using Holder's inequality) yields relation (7) in the form

$$e(s) \le |1-\alpha_j^{-1}|Lc',$$

where (in Warga's notation)

$$c'' = 2c_1\int_0^1 (1+|w(t)|)dt, \quad c' = c''\exp(c'') \le 2(L+1)c_1\exp(2(L+1)c_1).$$

Now, for every generalized solution of the system (1) we have the representation by the sequence of ordinary solutions of the auxiliary system (10). However, for the solution of the optimization problem we should find more appropriate representation of generalized solution. Again, consider the sequence of solutions of the auxiliary system (10), which converges uniformly to some pair of functions $\{y(\cdot), \eta(\cdot)\}$. As follows from the theory of differential inclusions and by virtue of continuity properties of function $\tilde{F}(y, u, w, \eta)$ [6] this pair satisfies the differential inclusion

$$\begin{pmatrix} \dot{y}(s) \\ \dot{\eta}(s) \end{pmatrix} \in \overline{\text{conv}}\,(\tilde{F}(y_1(s), u_1, w_1, \eta(s)) \mid u_1 \in U, w_1 \in W), \tag{16}$$

where the set in the right-hand side of (16) is a closed convex hull of the right-hand sides of the system (10) for every (y, η).

Assume that there exists an appropriate representation of the set in the right-hand side of (16); i.e., there exists the R^{n+1}-valued vector-function $G(y, \omega, \eta)$ and some closed bounded set Ω in a vector space of appropriate dimension such that for any $(y, \eta) \in R^{n+1}$

$$\begin{aligned} \overline{\text{conv}}\,(\tilde{F}(y, u_1, w_1, \eta) \mid u_1 \in U, w_1 \in W) &= \overline{\text{conv}}\,(\tilde{F}(y, U, W, \eta) \\ &= G(y, \Omega, \eta) = \{G(y, \omega, \eta) \mid \omega \in \Omega\}. \end{aligned} \tag{17}$$

In addition, assume that $G(y, \omega, \eta)$ is continuous with respect to (y, ω, η) and for any fixed $\omega \in \Omega$ this function satisfies the Lipschitz condition and has a linear growth with respect to (y, η), i.e.,

$$\|G(y_1, \omega, \eta_1) - G(y_2, \omega, \eta_2)\| \le L\{\|y_1 - y_2\| + |\eta_1 - \eta_2|\} \tag{18}$$

and

$$\|G(y, \omega, \eta)\| \le L(1 + \|y\| + |\eta|) \tag{19}$$

for any $y_1, y_2 \in R^n$, $\eta_1, \eta_2 \in R^1$ with some constant $L > 0$.

Then, due to convexity of the set $G(y, \Omega, \eta)$ and the boundedness of the set Ω for any solution $\{y(\cdot), \eta(\cdot)\}$ satisfying the differential inclusion (16), there exists a measurable control $\omega(\cdot)$ such that $\omega(s) \in \Omega$ almost everywhere on $[0, T_1]$ and $\{y(\cdot), \eta(\cdot)\}$ satisfy the system

$$\begin{pmatrix} \dot{y}(s) \\ \dot{\eta}(s) \end{pmatrix} = G(y(s), \omega(s), \eta(s))$$

on $[0, T_1]$ [6].

Now it is possible to formulate the following result concerning representation of the generalized solution.

THEOREM 3.3. *Let there exist the vector function $G(y, \omega, \eta)$ and the set Ω satisfying the conditions* (17)–(19). *Then for any generalized solution $x(\cdot)$ of the system* (1) *there exists a control $\omega(s) \in \Omega$ defined on some interval $[0, T_1]$ such that*

$$x(t) = y(\Gamma(t)),$$

where

$$\Gamma(t) = \inf\{s : \eta(s) > t\}$$

and the pair of functions $\{y(\cdot), \eta(\cdot)\}$ satisfies the differential equation

$$\begin{pmatrix} \dot{y}(s) \\ \dot{\eta}(s) \end{pmatrix} = G(y(s), \omega(s), \eta(s))$$

with the initial conditions

$$y(0) = x(0-), \qquad \eta(0) = 0$$

and terminal condition

$$\eta(T_1) = T.$$

Assumptions concerning the existence of appropriate function $G(y, \omega, \eta)$ and the set Ω seem to be very artificial; however, it is possible to demonstrate that in the "regular" case they are fulfilled.

4. Existence of the G function in the regular case. We shall say that we consider the "regular" case if the function $F(x, u, w, t)$ demonstrates the regular behavior for large values of variable w.

DEFINITION 4.1. *$F(x, u, w, t)$ is said to be* regular at infinity *if*

(i) *it is continuous with respect to all variables and has a Lipschitz property with respect to x and t, i.e.,*

$$\|F(x', u, w, t') - F(x, u, w, t)\| \leq L(1 + \|w\|)(\|x - x'\| + |t - t'|)$$

for any $x', x \in R^n, t', t \in [0, T], u \in U, w \in W$;

(ii) *for any pair of vectors (u, e): $u \in U, e \in E = \{\|e\| = 1\}$ there exists*

$$\lim_n \frac{F(x, u_n, w_n, t)}{1 + \|w_n\|} = \Phi(x, u, e, t) \tag{20}$$

if

$$u_n \to u, \qquad \frac{w_n}{1 + \|w_n\|} \to e, \qquad \|w_n\| \to \infty, \qquad u_n \in U, \qquad w_n \in W,$$

where $\Phi(x, u, e, t)$ *is continuous with respect to all the variables and the limit in* (20) *is independent of the choice of sequence* $\{u_n, w_n\}$.

In this case, introduce the new control variable ω, defined by the relation

$$\omega = \omega(w) = \frac{w}{1 + \|w\|}. \tag{21}$$

Function (21) maps the unbounded set W in a one-to-one manner to the set $\omega(W)$, which is a subset of interior of the unit ball in R^m. The map that is inverse to (21) is

$$w(\omega) = \frac{\omega}{1 - \|\omega\|}.$$

This inverse map is defined and continuous on the interior of the unit ball in R^m.

Substitution of the control $\omega \in \omega(W)$ instead of $w \in W$ into (10) for $\tilde{F}$ gives

$$\tilde{F}(y, u_1, w_1, \eta) = \left\{ \begin{array}{l} (1 - \|\omega\|) F\left(y, u_1, \dfrac{\omega}{1 - \|\omega\|}, \eta\right) \\ 1 - \|\omega\| \end{array} \right\} = \tilde{G}(y, u_1, \omega, \eta).$$

Now we can demonstrate that in the regular case $\tilde{G}$ is almost the same as desired by Theorem 3.3. First, one can prove that $\tilde{G}(y, u_1, \omega, \eta)$ is continuous with respect to $(y, \eta, u_1, \omega) \in R^n \times R^1 \times U \times \overline{\omega(W)}$. (Here the last set is the closure of the set $\omega(W)$.) The continuity of this function is evident if $\|\omega\| < 1$ due to continuity of superposition of continuous functions. Thus, if we consider an arbitrary point (y, η, u_1, ω), where $\|\omega\| = 1$ and $\omega \in \overline{\omega(W)}$, then there exists a sequence $\{u_1^n, \omega^n\}$, such that $u_1^n \in U$, $\|\omega^n\| < 1$, $\omega^n \in \omega(W)$, and $u_1^n \to u_1$, $\omega^n \to \omega$. Moreover, for every $\omega^n \in \omega(W)$ we can define

$$w^n = \frac{\omega^n}{1 - \|\omega^n\|} \in W$$

such that

$$\|w^n\| \to \infty, \qquad \frac{w^n}{1 + \|w^n\|} \to \omega,$$

and

$$\tilde{G}(y, u^n, \omega^n, \eta) = \tilde{F}(y, u^n, w^n, \eta). \tag{22}$$

By regularity condition, the function in the right-hand side of (22) has a limit if $u^n \to u$ and $w^n/(1 + \|w^n\|) \to \omega$, and this limit is independent of the sequence $\{u^n, w^n\}$ choice. Therefore, $\tilde{G}$ can be extended by continuity to the closure of the set $\omega(W)$. We will use the same symbol $\tilde{G}$ for the extended function.

Consider the relation

$$\begin{aligned} &\|\tilde{G}(y', u_1', \omega', \eta') - \tilde{G}(y, u_1, \omega, \eta)\| \\ &\quad \le \|\tilde{G}(y_1', u_1', \omega', \eta') - \tilde{G}(y, u_1', \omega', \eta)\| + \|\tilde{G}(y, u_1', \omega', \eta) - \tilde{G}(y, u_1, \omega, \eta)\|. \end{aligned} \tag{23}$$

The first term in the right-hand side of (23) can be estimated by the value $L(\|y_m' - y\| + |\eta' - \eta|)$, due to the Lipschitz property of original function $F(x, u, w, t)$, and the last term tends to zero if $(u_1', \omega') \to (u_1, \omega)$ because of the regularity condition. Hence $\tilde{G}(y', u_1', \omega', \eta') \to \tilde{G}(y, u_1, w, \eta)$ if $(y', u_1', \omega', \eta') \to (y, u_1, w, \eta)$, and the function G is continuous. Moreover, it is a Lipschitz one and has a linear growth.

Now for the final construction of the requested function $G(y, \overline{\omega}, \eta)$ we can use an analytical description of convex hall of the bounded set $\tilde{G}(y, U, \overline{\omega(W)}, \eta)$ by the Carathéodory theorem [6]. Hence, the function $G(y, \overline{\omega}, \eta)$ and set Ω can be represented in the form

$$\Omega = \left\{ \overline{\omega} = [u_i, \omega_i, \alpha_i, i = 1, \ldots, n+2] \mid u_i \in U, \omega_i \in \overline{\omega(W)}, \alpha_i \geq 0, \sum_{i=1}^{n+2} \alpha_i = 1 \right\},$$

$$G(y, \overline{\omega}, \eta) = \sum_{i=1}^{n+2} \alpha_i \tilde{G}(y, u_i, \omega_i, \eta).$$

Remark 4.1. Following the results of [20], [21], we note that the homeomorphism $w \to \omega(w) = w/(1 + \|w\|)$ of W onto its image $\omega(W)$ defines a metric compactification $(\bar{Z}, Z, \Phi)$ of W in the terminology of Warga's book [21]. However, we consider it possible to bring in the construction procedure to clarify it in our specific case.

As an example of application of this procedure we can handle control problems for the system, which is sublinear with respect to unbounded control [1], [3], [10], [12]–[14], [17], [18]. Let it be described by the equations

$$\dot{x}(t) = f(x(t), v(t), u(t), t) + B(x(t), v(t), u(t), t)w,$$
$$\dot{v}(t) = \|w(t)\|,$$

where $u \in U$, $w \in K$, U is a compact subset, and K is a convex cone, and the functions f and B are continuous. Then for all $e \in \{\|e\| = 1\}$ there exists a limit

$$\lim \frac{f + Bw}{1 + \|w\|} = Be$$

if $\|w\| \to \infty$, $w/(1 + \|w\|) \to e$, and the right-hand side of auxiliary system is described by the function

$$\tilde{G}(y, z, u, \eta, \omega) = \begin{cases} (1 - \|\omega\|)\left[f + B\dfrac{\omega}{1 - \|\omega\|} \right] = (1 - \|\omega\|)f + B\omega, \\ \|\omega\|, \\ 1 - \|\omega\|, \end{cases}$$

where $0 \leq \|\omega\| \leq 1$. If the set

$$\tilde{G}(y, z, U, \eta, \overline{\omega(K)}) = \{l \in R^{n+2} : l = \tilde{G}(y, z, u, \eta, \omega) \mid u \in U, \omega \in K \cap \{\|\omega\| \leq 1\}\}$$

is convex for any y, z, and η, then one can introduce a new pair of control variables $\{(\alpha, e) : 0 \leq \alpha \leq 1, e \in K \cap \{\|e\| \leq 1\}$, which describes the set $\tilde{G}(y, z, U, \eta, \overline{\omega(K)})$ in the following way:

$$\tilde{G}(y, z, U, \eta, \overline{\omega(K)}) = \left\{ \begin{array}{l|l} \alpha f + (1 - \alpha)Be & \alpha \in [0, 1] \\ (1 - \alpha)\|e\| & e \in K \cap \{\|e\| \leq 1\} \\ \alpha & u \in U \end{array} \right\}.$$

This gives the following description of auxiliary system with the right-hand side:

$$G(y, z, \overline{\omega}, \eta) = \begin{pmatrix} \alpha f(y, z, u, \eta) + (1 - \alpha)B(y, z, u, \eta)e \\ (1 - \alpha)\|e\| \\ \alpha \end{pmatrix},$$

where

$$\overline{\omega} = (\alpha, e, u)$$

such that

$$\overline{\omega} \in \Omega = \{0 \leq \alpha \leq 1,\ e \in K \cap \{\|e\| \leq 1\},\ u \in U\}.$$

If the set $G(y, z, \Omega, \eta)$ is convex for any y, z, and η, we shall obtain the desired representation; otherwise we should use the procedure of convexification using the Carathéodory theorem [6].

5. Representation of the generalized solution via the differential equation with measure. This part of the paper is devoted to the representation of generalized solutions by the special type of differential equations with a measure.

Let us consider the function $x(\cdot)$, which is the generalized solution of the system (1) on the interval $[0, T]$. The function $x(\cdot)$ has the bounded variation and is continuous from the right; thus it admits the representation [4]

$$x(t) = x(0) + x^c(t) + \sum_{\tau \leq t} \Delta x(\tau), \tag{24}$$

where

$$\Delta x(\tau) = x(\tau) - x(\tau -)$$

and $x^c(\cdot)$ is a continuous function. For all components in (24) one can derive the representation in the form of special differential inclusion.

To formulate this result, we introduce the set $G^1(y, \eta) \in R^n$, where $l_1 \in G^1(y, \eta)$ if the extended vector $(l_1, 0) \in G(y, \Omega, \eta)$, i.e.,

$$G^1(y, \eta) = \left\{ l_1 \in R^n : \quad l_1 = \left(\begin{array}{l|l} G_1(y, \omega, \eta) & \\ G_2(y, \omega, \eta) & \omega \in \Omega, \\ \vdots & G_{n+1}(y, \omega, \eta) = 0 \\ G_n(y, \omega, \eta) & \end{array} \right) \right\}.$$

This set is nonempty, because it contains all the partial limits of sequences of the type

$$\left\{ \frac{F(y, u_i, w_i, \eta)}{1 + \|w_i\|} \right\}$$

such that $u_i \in U$, $w_i \in W$, and $\|w_i\| \to \infty$. Any of such sequences is uniformly bounded for fixed (y, η) by virtue of the inequalities (6), and hence, the set of its all partial limits is nonempty. By definition of $G(y, \omega, \eta)$ and Ω, the set $G(y, \Omega, \eta)$ contains all partial limits of the sequences

$$\begin{pmatrix} l_1^i \\ l_{n+1}^i \end{pmatrix} = \left\{ \begin{array}{ll|l} l_1^i \in R^n & l_1^i = \dfrac{F(y, u_i, w_i, \eta)}{1 + \|w_i\|} & u_i \in U \\ l_{n+1}^i \in R^1 \quad : & l_{n+1}^i = \dfrac{1}{1 + \|w_i\|} & w_i \in W \end{array} \right\};$$

hence it contains all partial limits with $\|w_i\| \to \infty$ and $l_{n+1}^i \to 0$.

The set $G^1(y, \eta)$ is convex and closed for all (y, η), because it is the cross section of the convex and closed set $G(y, \Omega, \eta)$.

Let us also introduce the conic hull of the set $G^1(y, \eta)$, denoted by con $G^1(y, \eta)$, where

$$\operatorname{con} G^1(y, \eta) = \left\{ l \in R^n \mid l = \sum_{i=1}^{k} \beta_i l_i, \quad \beta_i \geq 0, \quad k \geq 1, \quad l_i \in G^1(y, \eta) \right\}.$$

The next theorem yields the representation of a generalized solution.

THEOREM 5.1. *Let the set of right-hand sides of the system* (10) *be represented in the form* (17) *with the appropriate function* $G(y, \omega, \eta)$ *and set* Ω. *Then for any generalized solution* $x(\cdot)$ *there exists a scalar nonnegative regular measure* $V(dt)$, *defined on the Borel subsets of the interval* $[0, T]$ *such that the function*

$$v(t) = V\{[0, t]\}$$

has the representation

$$v(t) = \int_0^t \dot{v}(s)ds + v^s(t) + \sum_{\tau \le t} \Delta v(\tau),$$

where $\dot{v}(t)$ *is the derivative of* $v(\cdot)$ *defined almost everywhere in* $[0, T]$; $v^s(t)$ *is a continuous nondecreasing function whose set of growth points has zero Lebesgue measure (i.e., the corresponding measure* $V^s(dt)$ *is singular with respect to the Lebesgue measure);* $\Delta v(\tau) = v(\tau) - v(\tau -)$ *are the jumps of the function* $v(\cdot)$; *and*

$$v(T) = V\{[0, T]\} \le M$$

such that the generalized solution $x(\cdot)$ *can be represented in the form*

$$x(t) = x(0-) + x^a(t) + x^s(t) + \sum_{\tau \le t} \Delta x(\tau),$$

where

(i) $x^a(t)$ *is absolutely continuous with respect to the Lebesgue measure and its derivative satisfies the differential inclusion*

$$\dot{x}^a(t) \in \overline{\text{conv}}\, F(x(t), U, W, t) + \text{con}\, G^1(x(t), t) \quad \text{a.e. in } [0, T]; \tag{25}$$

(ii) $x^s(t)$ *is absolutely continuous with respect to the measure* $V^s(dt)$ *and its derivative with respect to the measure* $V^s(dt)$ *satisfies the differential inclusion*

$$\frac{dx^s(t)}{dv^s(t)} \in G^1(x(t), t) \quad \text{a.e. in } [0, T] \quad \text{with respect to } V^s(dt); \tag{26}$$

(iii) *and*

$$\Delta x(\tau) = x(\tau) - x(\tau -) = y_\tau(\Delta v(\tau)) - x(\tau -),$$

where $y_\tau(\cdot)$ *satisfies, on the interval* $[0, \Delta v(\tau)]$, *the differential inclusion*

$$\dot{y}_\tau(s) \in G^1(y_\tau(s), \tau)$$

with the initial condition

$$y_\tau(0) = x(\tau -).$$

Proof. According to Theorem 3.3, $x(t) = y(\Gamma(t))$, where $\Gamma(t) = \inf\{s \in [0, T_1] : \eta(s) > t\}$ and the pair $(y(s), \eta(s))$ satisfies the differential equation

$$\begin{pmatrix} \dot{y}(s) \\ \dot{\eta}(s) \end{pmatrix} = G(y(s), \omega(s), \eta(s)), \qquad y(0) = x(0-), \qquad \eta(0) = 0,$$

with some measurable control $\omega(s) \in \Omega$ a.e. in $[0, T_1]$. By virtue of results obtained in [9], $\Gamma(\cdot)$ is right continuous and monotonically increasing; therefore, it admits the representation

$$\Gamma(t) = \int_0^t \dot{\Gamma}(s)ds + \Gamma^s(t) + \sum_{\tau \le t} \Delta\Gamma(\tau),$$

where $\dot{\Gamma}(t)$ is a derivative of $\Gamma(\cdot)$, $\Gamma^s(t)$ is a continuous nondecreasing function such that the corresponding measure $\Gamma^s(dt)$ is singular with respect to the Lebesgue measure, and

$$\Delta\Gamma(\tau) = \Gamma(\tau) - \Gamma(\tau-).$$

The interval $[0, T]$ can be represented as a union of three disjoint subsets:

$$[0, T] = D_\Gamma^a \cup D_\Gamma^s \cup D_\Gamma^d,$$

where D_Γ^a is a support of absolutely continuous component of the measure $\Gamma(dt)$, D_Γ^s is a support of the measure $\Gamma^s(dt)$, and D_Γ^d is a union of no more than countable set of points τ such that $\Gamma(\tau) - \Gamma(\tau-) > 0$.

The generalized solution satisfies the integral relation

$$x(t) = y(\Gamma(t)) = x(0) + \int_0^{\Gamma(t)} \dot{y}(s)ds,$$

which can be rewritten

$$\begin{aligned} x(t) &= x(0) + \int_0^{\Gamma(t)} \dot{y}(s) I\{s : \eta(s) \overline{\in} D_\Gamma^d\} ds + \int_0^{\Gamma(t)} \dot{y}(s) I\{s : \eta(s) \in D_\Gamma^d\} ds \\ &= x(0) + \int_0^{\Gamma(t)} \dot{y}(s) I\{s : \eta(s) \overline{\in} D_\Gamma^d\} ds + \sum_{\tau \le t} \int_{\Gamma(\tau-)}^{\Gamma(\tau)} \dot{y}(s) ds \\ &= x(0) + \int_0^{\Gamma(t)} \dot{y}(s) I\{s : \eta(s) \overline{\in} D_\Gamma^d\} ds + \sum_{\tau \le t} \Delta x(\tau), \end{aligned} \tag{27}$$

where $I\{\cdot\}$ means the indicator function.

Substituting the variable $\tau = \eta(s)$ into the first integral in (27) and using the relation $\Gamma(\eta(s)) = s$, which is valid if $\eta(s) \overline{\in} D_\Gamma^d$, we obtain

$$\begin{aligned} &\int_0^{\Gamma(t)} \dot{y}(s) I\{s : \eta(s) \overline{\in} D_\Gamma^d\} ds = \int_0^{\Gamma(t)} \dot{y}(\Gamma(\eta(s))) I\{s : \eta(s) \overline{\in} D_\Gamma^d\} ds \\ &= \int_0^{\eta(\Gamma(t))} \dot{y}(\Gamma(t)) I\{\tau : \tau \overline{\in} D_\Gamma^d\} d\Gamma(\tau) = \int_0^t \dot{y}(\Gamma(\tau)) I\{\tau : \tau \overline{\in} D_\Gamma^d\} d\Gamma(\tau) \\ &= \int_0^t \dot{y}(\Gamma(\tau))(\dot{\Gamma}(\tau)d\tau + d\Gamma^s(\tau)) \\ &= \int_0^t \dot{y}(\Gamma(\tau))\dot{\Gamma}(\tau)d\tau + \int_0^t \dot{y}(\Gamma(\tau))d\Gamma^s(\tau) = x^a(t) + x^s(t). \end{aligned} \tag{28}$$

The union of relations (27) and (28) gives the following representation for $x(t)$:

$$x(t) = x(0-) + x^a(t) + x^s(t) + \sum_{\tau \le t} \Delta x(\tau),$$

where

$$x^a(t) = \int_0^t \dot{y}(\Gamma(\tau))\dot{\Gamma}(\tau)d\tau \tag{29}$$

and $x^a(\cdot)$ is absolutely continuous with respect to the Lebesgue measure;

$$x^s(t) = \int_0^t \dot{y}(\Gamma(\tau))d\Gamma^s(\tau), \tag{30}$$

and $x^s(\cdot)$ is absolutely continuous with respect to measure $\Gamma^s(dt)$; and

$$\Delta x(\tau) = y(\Gamma(\tau)) - y(\Gamma(\tau-)) = \int_{\Gamma(\tau-)}^{\Gamma(\tau)} \dot{y}(s)ds$$

is the jump of the function $x(\cdot)$ at the point $\tau \in D_\Gamma^d$.

We are able to show that $x^a(\cdot)$, $x^s(\cdot)$, and jumps $\Delta x(\tau)$ are the same as claimed in the theorem. First, define the measure $V(dt)$ by the relation

$$V\{(a, b]\} = \Gamma\{(a, b]\} - (b - a). \tag{31}$$

Since

$$\Gamma\{(a, b]\} \geq (b - a),$$

the measure $V(dt)$ is regular and nonnegative. Further,

$$V\{[0, T]\} = \Gamma(T) - T \leq M$$

and

$$V^s(dt) = \Gamma^s(dt), \qquad \Delta v(\tau) = V\{\tau\} = \Delta\Gamma(\tau).$$

Consider (29). As on the subset D_Γ^a the derivative of $\Gamma(\cdot)$ exists a.e. and satisfies inequalities

$$0 < \dot{\Gamma}(t) = \frac{1}{\dot{\eta}(\Gamma(t))} < \infty,$$

then $\dot{\eta}(\Gamma(t)) > 0$ a.e. in $[0, T]$, and the derivative of $x^a(\cdot)$ exists and satisfies the relation

$$\dot{x}^a(t) = \frac{\dot{y}(\Gamma(t))}{\dot{\eta}(\Gamma(t))} \quad \text{a.e. in } [0, T].$$

Now we prove that $\dot{x}^a(t)$ satisfies the inclusion (25). As was proven in [12], the control function $\omega(\Gamma(t))$ is Lebesgue measurable; hence,

$$\begin{pmatrix} \dot{y}(\Gamma(t)) \\ \dot{\eta}(\Gamma(t)) \end{pmatrix} = G(y(\Gamma(t)), \omega(\Gamma(t)), \eta(\Gamma(t))) = G(x(t), \omega(\Gamma(t)), t) \tag{32}$$

a.e. in $[0, T]$.

The set $G(x, \Omega, t)$ is the convex hull of closure of the set $\tilde{F}(x, v, w, t)$; hence by the Carathéodory theorem [6] for all $\omega \in \Omega$ the set $\{(\alpha_i, l_i), i = 1, \ldots, n + 2\}$ exists such that

$$\alpha_i \geq 0, \qquad \sum_{i=1}^{n+2} \alpha_i = 1, \qquad l_i \in \overline{\tilde{F}(x, v, w, t)},$$

and

$$G(x, \omega, t) = \sum_{i=1}^{n+2} \alpha_i l_i = \sum_{i=1}^{n+2} \alpha_i \begin{pmatrix} l_i^1 \\ l_i^2 \end{pmatrix}, \tag{33}$$

where l_i^1 is a vector of the first n components of vector l_i and l_i^2 is the $(n+1)$-th component of this vector.

If $l_i^2 > 0$, then, due to continuity of $\tilde{F}(x, u, w, t)$, there exists a pair (u_i, w_i), $u_i \in U$, $w_i \in W$, such that

$$\begin{pmatrix} l_i^1 \\ l_i^2 \end{pmatrix} = \tilde{F}(x, u_i, w_i, t).$$

If $l_i^2 = 0$, then $l_i^1 \in G^1(x, t)$ by the definition of the set $G^1(x, t)$. Now we can derive the representation

$$G(x(t), \omega(\Gamma(t)), t) = \sum_{i=1}^{n+2} \alpha_i(t) \begin{pmatrix} l_i^1(t) \\ l_i^2(t) \end{pmatrix} I\{i : l_i^2(t) > 0\} + \sum_{i=1}^{n+2} \alpha_i(t) \begin{pmatrix} l_i^1(t) \\ l_i^2(t) \end{pmatrix} I\{i : l_i^2(t) = 0\}$$

with some Lebesgue-measurable function $\{\alpha_i(t), l_i^1(t), l_i^2(t)\}$, $i = 1, \ldots, n+2$. Hence the derivative of $x^a(t)$ is equal to

$$\dot{x}^a(t) = \frac{\sum_{i=1}^{n+2} \alpha_i(t) l_i^1(t)}{\sum_{i=1}^{n+2} \alpha_i(t) l_i^2(t)} \qquad \text{a.e. in} \quad [0, T],$$

and one can derive the following representation for $\dot{x}^a(t)$:

$$\dot{x}^a(t) = \sum_{i=1}^{n+2} \frac{\alpha_i(t) l_i^2(t)}{\sum_{i=1}^{n+2} \alpha_i(t) l_i^2(t)} \frac{l_i^1(t)}{l_i^2(t)} I\{i : l_i^2(t) > 0\} + \sum_{i=1}^{n+2} \frac{\alpha_i(t)}{\sum_{i=1}^{n+2} \alpha_i(t) l_i^2(t)} l_i^1(t) I\{i : l_i^2(t) = 0\}. \tag{34}$$

Denote

$$\beta_i^1(t) = \frac{\alpha_i(t) l_i^2(t)}{\sum_{i=1}^{n+2} \alpha_i(t) l_i^2(t)} I\{i : l_i^2(t) > 0\} \tag{35}$$

and

$$\beta_i^2(t) = \frac{\alpha_i(t)}{\sum_{i=1}^{n+2} \alpha_i(t) l_i^2(t)} I\{i : l_i^2(t) = 0\}. \tag{36}$$

Then

$$\beta_i^1(t) \geq 0, \qquad \sum_{i=1}^{n+2} \beta_i^1(t) = 1, \tag{37}$$

and

$$\beta_i^2(t) \geq 0. \tag{38}$$

Vectors $l_i^1(t)/(l_i^2(t))$ in the first sum of (34) satisfy the inclusion

$$\frac{l_i^1(t)}{l_i^2(t)} \in F(x(t), U, W, t),$$

and vectors $l_i^1(t)$ in the second sum satisfy the inclusion

$$l_i^1(t) \in G^1(x(t), t).$$

Hence the derivative $\dot{x}^a(t)$ has the representation

$$\dot{x}^a(t) = \sum_{i=1}^{n+2} \beta_i^1(t) F(x(t), u_i(t), w_i(t), t) + \sum_{i=1}^{n+2} \beta_i^2(t) l_i^1(t),$$

where $l_i^1(t) \in G^1(x(t), t)$ and functions $\beta_i^1(t)$, $\beta_i^2(t)$ satisfy the relations (37), (38). This proves the theorem's claim for the component $x^a(t)$.

Now we consider the function $x^s(t)$ represented by the equation (30) and note that $\dot{\eta}(\Gamma(t)) = 0$ on the subset $D_\Gamma^s = D_V^s$. Then, similar consideration applied to the component $x^s(t)$ gives the inclusion

$$\dot{y}^s(\Gamma(t)) \in G^1(x(t), t)$$

and the relation

$$x^s(t) = \int_0^t l^1(\tau) dv^s(\tau), \qquad l^1(\tau) \in G^1(x(\tau), \tau),$$

proves the theorem for the component $x^s(t)$.

Since on the interval $[\Gamma(\tau-), \Gamma(\tau)]$, where $\eta(s) = \tau \in D_V^d = D_\Gamma^d$, the derivative of $\eta(s)$ is also equal to zero,

$$\dot{y}(s) \in G^1(y(s), \tau).$$

Therefore, if $s \in [\Gamma(\tau-), \Gamma(\tau)]$, then $y(s)$ satisfies the above differential inclusion with the initial condition $y(\Gamma(\tau-) = x(\tau-)$. Letting

$$y_\tau(s) = y(\Gamma(\tau-) + s)$$

for $s \in [0, \Delta v(\tau)] = [0, \Delta\Gamma(\tau)]$, we obtain the assertion of the theorem for the jumps of $x(\cdot)$. This completes the proof. □

In the case of the regular function $F(x, u, w, t)$ we can give a more precise statement about the representation of the generalized solution. First we prove the theorem concerning the description of the set $G^1(x, t)$.

THEOREM 5.2. *If $F(x, u, w, t)$ is regular at infinity, then*

$$G^1(x, t) = \operatorname{conv} \Phi(x, U, E, t),$$

where

$$\Phi(x, U, E, t) = \{l \in R^n : l = \Phi(x, u, e, t) | \quad u \in U, \quad e \in E = \{\|e\|\} = 1\}.$$

Proof. By the definition of regularity, if vector $l \in \Phi(x, U, E, t)$, i.e., there exist $u \in U$ and $e \in E$ such that $l = \Phi(x, u, e, t)$, then for any sequence $w_n \in W$ such that $\|w_n\| \to \infty$, $w_n/(1 + \|w_n\|) \to e$, we have

$$l = \lim_n \frac{F(x, u, w_n, t)}{1 + \|w_n\|} = \Phi(x, u, e, t).$$

Since $\|w_n\| \to \infty$, $\lim_n 1/(1 + \|w_n\|) = 0$.

Hence, the extended vector

$$\begin{pmatrix} l \\ 0 \end{pmatrix} \in G(x, \Omega, t),$$

where $l \in G^1(x, t)$ by definition of the set $G^1(x, t)$. Therefore, by convexity of $G^1(x, t)$

$$\operatorname{conv} \Phi(x, U, E, t) \subseteq G^1(x, t). \tag{39}$$

To prove the inverse inclusion, note that if $l \in G^1(x, t)$, then

$$\begin{pmatrix} l \\ 0 \end{pmatrix} \in G(x, \Omega, t) = \overline{\operatorname{conv}} \tilde{F}(x, U, W, t).$$

Hence there exists the set of pairs $\{\alpha_i, l_i\}$, $i = 1, \ldots, n + 2$, such that

$$\alpha_i > 0, \quad \sum_{i=1}^{n+2} \alpha_i = 1, \quad \begin{pmatrix} l_i^1 \\ 0 \end{pmatrix} \in \overline{\tilde{F}(x, U, W, t)},$$

and

$$\begin{pmatrix} l \\ 0 \end{pmatrix} = \sum_{i=1}^{n+2} \alpha_i \begin{pmatrix} l_i^1 \\ 0 \end{pmatrix}. \tag{40}$$

Then for every i there exists the sequence $\{u_n^i, w_n^i\}$, $u_n^i \in U$, $w_n^i \in W$, such that

$$\begin{pmatrix} l_i^1 \\ 0 \end{pmatrix} = \lim_n \begin{pmatrix} \dfrac{F(x, u_n^i, w_n^i, t)}{1 + \|w_n^i\|} \\ \dfrac{1}{1 + \|w_n^i\|} \end{pmatrix},$$

and due to uniform boundedness of sequence $\{u_n^i, w_n^i/(1 + \|w_n^i\|)\}$ one can extract the subsequence $\{u_{n_k}^i, w_{n_k}^i\}$ such that

$$u_{n_k}^i \to u^i \in U \quad \text{and} \quad \frac{w_{n_k}^i}{1 + \|w_{n_k}^i\|} \to e^i \in E \quad \text{if} \quad k \to \infty.$$

Then $l_i^1 = \Phi(x, u^i, e^i, t)$, and with (40) it means

$$\begin{pmatrix} l \\ 0 \end{pmatrix} \in \begin{pmatrix} \operatorname{conv} \Phi(x, U, E, t) \\ 0 \end{pmatrix}.$$

Hence

$$G^1(x, t) \subseteq \operatorname{conv} \Phi(x, U, E, t), \tag{41}$$

and combining (39) with (41) we complete the proof. □

We can now formulate the result concerning the representation of generalized solution by the differential equation with a measure.

THEOREM 5.3. *Let the function $F(x, u, w, t)$ be regular and the set of vectors*

$$\mathcal{L} = \left\{ l = \begin{pmatrix} l_1 \\ l_2 \end{pmatrix} \in R^{n+1} \;\middle|\; \begin{array}{l} l_1 = F(x, u, w, t) \\ l_2 = \|w\| \end{array} \;\middle|\; \begin{array}{l} u \in U \\ w \in W \end{array} \right\} \tag{42}$$

be convex for any (x, t).

Then for any generalized solution $x(\cdot)$ of the system (1) *there exist*

(i) *the regular nonnegative measure $V(dt)$ on the interval $[0, T]$, which satisfies the constraint*

$$V\{[0, T]\} \leq M;$$

(ii) *the set of both Lebesgue- and V-measurable controls*

$$\{u_0(t), w_0(t), \beta_i^0(t), \beta_i^s(t), u_i(t), e_i(t)\}, \qquad i = 1, \ldots, n+2,$$

which satisfy the constraints

$$u_0(t) \in U, \quad w_0(t) \in W, \quad \beta_i^0(t) \geq 0,$$

$$u_i(t) \in U, \quad e_i(t) \in E, \quad \beta_i^s(t) \geq 0, \quad \sum_{i=1}^{n+2} \beta_i^s(t) = 1,$$

a.e. in the interval $[0, T]$;

(iii) *the set of Lebesgue-measurable controls*

$$\{u_i^\tau(s), e_i^\tau(s), \beta_i^\tau(s)\}, \qquad i = 1, \ldots, n+2,$$

which are defined on every interval $[0, \Delta v(\tau)]$ for all $\tau \in D_V^d$ and satisfy the constraints

$$u_i^\tau(s) \in U, \qquad e_i^\tau(s) \in E, \qquad \beta_i^\tau(s) \geq 0, \qquad \sum_{i=1}^{n+2} \beta_i^\tau(s) = 1,$$

a.e. in the interval $[0, \Delta v(\tau)]$
such that the generalized solution $x(t)$ and the function $v(t) = V\{[0, t]\}$ satisfy the equations

$$\begin{aligned} x(t) = x(0) &+ \int_0^t F(x(\tau), u_0(\tau), w_0(\tau), \tau) d\tau \\ &+ \int_0^t \sum_{i=1}^{n+2} \beta_i^0(\tau) \Phi(x(\tau), u_i(\tau), e_i(\tau), \tau) d\tau \\ &+ \int_0^t \sum_{i=1}^{n+2} \beta_i^s(\tau) \varphi(x(\tau), u_i(\tau), e_i(\tau), \tau) dv^s(\tau) + \sum_{\tau \leq t} \Delta x(\tau), \end{aligned} \tag{43}$$

where

$$\Delta x(\tau) = y_\tau(\Delta v(\tau)) - x(\tau -)$$

and $y_\tau(s)$ is the solution of the differential equation

$$\dot{y}_\tau(s) = \sum_{i=1}^{n+2} \beta_i^\tau(s) \Phi(y_\tau(s), u_i^\tau(s), e_i^\tau(s), \tau) \tag{44}$$

with the initial condition $y_\tau(0) = x(\tau-)$, *and*

$$v(t) = \int_0^t \|w_0(\tau)\| d\tau + \int_0^t \sum_{i=1}^{n+2} \beta_i^0(\tau) d\tau + v^s(t) + \sum_{\tau \le t} \Delta v(\tau). \tag{45}$$

Proof. By definition of the measure $V(dt)$, according to (31), the derivative of $v(t) = V\{[0, t]\}$ is equal to

$$\dot{v}(t) = \dot{\Gamma}(t) - 1,$$

and, as follows from (32) and (33), the pair of functions $\{x^a(\cdot), v^a(\cdot)\}$ satisfies the equations

$$\begin{aligned} \dot{x}^a(t) &= \sum_{i=1}^{n+2} \beta_i^1(t) \frac{l_i^1(t)}{l_i^2(t)} I\{i : l_i^2(t) > 0\} + \sum_{i=1}^{n+2} \beta_i^2(t) l_i^1(t) I\{i : l_i^2(t) = 0\}, \\ \dot{v}^a(t) &= \sum_{i=1}^{n+2} \beta_i^1(t) \frac{1 - l_i^2(t)}{l_i^2(t)} I\{i : l_i^2(t) > 0\} + \sum_{i=1}^{n+2} \beta_i^2(t), \end{aligned} \tag{46}$$

where $l_i^1(t)$ and $l_i^2(t)$ are the components of the vector function $G(x(t), \omega(\Gamma(t)), t)$, i.e.,

$$\begin{pmatrix} l_i^1(t) \\ l_i^2(t) \end{pmatrix} = G(x(t), \omega(\Gamma(t)), t),$$

and the assembly of coefficients $\beta_i^1(t)$ and $\beta i^2(t)$ is defined by (35), (36).

If $l_i^2(t) > 0$, then there exists a pair of vectors $u_i(t) \in U$, $w_i(t) \in W$, such that

$$\frac{l_i^1(t)}{l_i^2(t)} = F(x(t), u_i(t), w_i(t), t) \tag{47}$$

and

$$\frac{1 - l_i^2(t)}{l_i^2(t)} = \|w_i(t)\|, \tag{48}$$

and if $l_i^2(t) = 0$, then

$$l_i^1(t) \in G^1(x(t), t) = \operatorname{conv} \Phi(x(t), U, E, t). \tag{49}$$

The substitution of relations (47)–(49) into (46) gives

$$\begin{pmatrix} \dot{x}^a(t) \\ \dot{v}^a(t) \end{pmatrix} = \sum_{i=1}^{n+2} \beta_i^1(t) \begin{pmatrix} F(x(t), u_i(t), w_i(t), t) \\ \|w_i(t)\| \end{pmatrix} + \sum_{i=1}^{n+2} \beta_i^2(t) \begin{pmatrix} l_i^1(t) \\ 1 \end{pmatrix}. \tag{50}$$

For the first term in the right-hand side of (50), due to convexity of the set (42) and the relation (37), there exists a pair of functions $\{u_0(t), w_0(t)\}$, such that $u_0(t) \in U$, $w_0(t) \in W$ a.e. in $[0, T]$, and

$$\sum_{i=1}^{n+2} \beta_i^1(t) \begin{pmatrix} F(x(t), u_i(t), w_i(t), t) \\ \|w_i(t)\| \end{pmatrix} = \begin{pmatrix} F(x(t), u_0(t), w_0(t), t) \\ \|w_0(t)\| \end{pmatrix}. \tag{51}$$

Using the standard procedure of measurable selection [23], this functions $\{u_0(t)\}$, $\{w_0(t)\}$ can be shown to be measurable with respect to Lebesgue measure.

The second term in the right-hand side of (51) can be represented in the form

$$\sum_{i=1}^{n+2} \beta_i^2(t) \begin{pmatrix} l_i^1(t) \\ 1 \end{pmatrix} = \left(\sum_{i=1}^{n+2} \beta_i^2(t) \right) \sum_{i=1}^{n+2} \frac{\beta_i^2(t)}{\sum_{i=1}^{n+2} \beta_i^2(t)} \begin{pmatrix} l_i^1(t) \\ 1 \end{pmatrix},$$

where the components in the sum satisfy the inclusion

$$\begin{pmatrix} l_i^1(t) \\ 1 \end{pmatrix} \in \begin{pmatrix} G^1(x(t), t) \\ 1 \end{pmatrix}$$

because of its convexity. Then there exists an assembly of functions

$$\{\gamma_k(t), u_k(t), e_k(t), \quad k = 1, \ldots, n+2\}$$

which satisfy the constraints $\gamma_k(t) \geq 0$, $\sum_{k=1}^{n+2} \gamma_k(t) = 1$, $u_k(t) \in U$, $e_k(t) \in E$ a.e. in $[0, T]$ such that

$$\sum_{i=1}^{n+2} \frac{\beta_i^2(t)}{\sum_{i=1}^{n+2} \beta_i^2(t)} \begin{pmatrix} l_i^1(t) \\ 1 \end{pmatrix} = \sum_{k=1}^{n+2} \gamma_k(t) \begin{pmatrix} \Phi(x(t), u_k(t), e_k(t), t) \\ 1 \end{pmatrix}$$

and

$$\sum_{i=1}^{n+2} \beta_i^2(t) \begin{pmatrix} l_i^1(t) \\ 1 \end{pmatrix} = \sum_{i=1}^{n+2} \beta_i^0(t) \begin{pmatrix} \Phi(x(t), u_i(t), e_i(t), t) \\ 1 \end{pmatrix}, \tag{52}$$

where

$$\beta_i^0(t) = \gamma_i(t) \sum_{k=1}^{n+2} \beta_k^2(t).$$

If the functions $\{\beta_i^0, u_i, e_i\}$ are selected to be Lebesgue measurable, then substitution of relation (50) and (52) into (46) proves the representations (43) and (45) for the absolutely continuous part of functions $\{x(\cdot), v(\cdot)\}$.

By the same arguments we can prove the representation for the singular components of functions $\{x(\cdot), v(\cdot)\}$. From the relations (26) it follows that the derivative of the function $x^s(t)$ with respect to the measure $V^s(dt)$ equals

$$\frac{dx^s(t)}{dv^s(t)} = \sum_{i=1}^{n+2} \beta_i^s(t) \Phi(x(t), u_i(t), e_i(t), t),$$

where the functions $u_i(t)$, $e_i(t)$ are V^s-measurable and

$$\beta_i^s(t) \geq 0, \qquad \sum_{i=1}^{n+2} \beta_i^s(t) = 1.$$

Therefore, if we complete the definition of Lebesgue-measurable functions $\{u_i(t), e_i(t)\}$ in relation (52), which are defined on the set D_V^a, by V^s-measurable functions $\{u_i(t), e_i(t)\}$, we obtain statement (ii) of this theorem. The proof of statement (iii) can be obtained by the same arguments. □

Now we can return to the original optimization problem. The results obtained above give us the opportunity to prove the theorem, which ensures the existence of the generalized solution for the original optimization problem.

6. Existence of a solution for problem of generalized optimization. Here, we shall use the approach based on the auxiliary control problem. Consider the auxiliary control problem for the system

$$\begin{pmatrix} \dot{y}(s) \\ \dot{\eta}(s) \end{pmatrix} = G(y(s), \omega(s), \eta(s)) \tag{53}$$

with control which subjects it to the constraint

$$\omega(s) \in \Omega \tag{54}$$

on the interval $[0, T_1]$, with T_1 satisfying the inequality

$$T_1 \leq T + M \tag{55}$$

with the terminal and phase constraints

$$S(y(0), y(T_1)) \leq 0, \qquad h(y(0), y(T_1)) = 0, \qquad \eta(T_1) = T, \tag{56}$$

$$g(y(s), \eta(s)) \leq 0 \text{ for any } s \in [0, T_1], \tag{57}$$

and the following performance criterion, which should be minimized:

$$J'[y(\cdot), \omega(\cdot), T_1] = \varphi_0(y(0), y(T_1)). \tag{58}$$

If the set of admissible controls in the original optimization problem is nonempty, then the set of controls satisfying the constraints (54)–(57) is also nonempty, and one can prove the equivalence of the original and auxiliary problems.

THEOREM 6.1. *Let the set of generalized solutions of the system* (1) *under constraints* (2), (3) *and* (8), (9) *be bounded and nonempty. Then there exists an optimal generalized solution.*

Both in the regular case and in the case of convexity of the set (42), this optimal solution admits the representation by the differential equation with a measure in the form (43), (44) and appropriate elements (i), (ii), (iii) that could be understood as the generalized controls.

THEOREM 6.2. *The optimization problem* (1)–(3), (7)–(9) *and the auxiliary problem* (53)–(58) *are equivalent; i.e., if the pair* $\{y^0(\cdot), \eta^0(\cdot)\}$ *is the solution of auxiliary problem, then the path* $x^0(t) = y^0(\Gamma^0(t))$ *is the optimal generalized solution of the original problem.*

Conversely, if the assumptions of Theorem 5.3 *hold and if* $x^0(\cdot)$ *is the optimal generalized solution of the original problem, then there exists the optimal solution of the auxiliary problem* $\{y^0(\cdot), \eta^0(\cdot)\}$ *such that the relations* (12) *and* (13) *take place.*

Remark 6.1. These two theorems follow directly from the results of theorems VI.4.4 and VI.4.5 in [21] and Theorems 3.2 and 5.3.

Remark 6.2. This result can be considered the main result of our work because it gives a very useful tool for investigation of the generalized optimization problems. One of the most useful features of this approach is that it gives the opportunity to derive necessary and sufficient conditions of optimality. Examples of its application in this area can be found in [1], [11], [15], [16], [20], [22], where the method of discontinuous time change was used for derivation of necessary conditions of optimality in the maximum principle form.

Acknowledgments. The author is very grateful to the anonymous referees for their valuable comments and suggestions, which strengthened this paper.

A DIFFERENTIAL GAME WITH TWO PLAYERS AND ONE TARGET*

PIERRE CARDALIAGUET†

Abstract. We study a two-player differential game in which one of the players wants the state of the system to reach an open target, while the other player wants the state of the system to avoid this target. We show that the victory domains of the players form a partition of the complement of the target. One of them can be characterized by the mean of geometrical conditions (as a "discriminating domain"). Finally we show that the common boundary of the victory domains enjoys a semipermeability property.

Key words. differential games, pursuit-and-evasion games, viability theory

AMS subject classifications. 49J24, 49J52, 90J25, 90J26

Let

$$(1)\qquad \begin{cases} x'(t) = f(x(t), u(t), v(t)), \text{ for almost every } t \geq 0, \\ u(t) \in U,\ v(t) \in V, \\ x(0) = x_0 \end{cases}$$

be a two-controlled dynamical system and Ω be an open subset of $\mathbb{R}^N$. The open set Ω shall be called the *target*. In this paper, we investigate the differential game where the first player—Ursula, playing with u—wants the state of the system to reach Ω in finite time. The second player—Victor, playing with v—wants the state of the system to avoid Ω forever. So Ursula wins if the trajectory $x(\cdot)$ reaches the target Ω in finite time, while Victor wins if the trajectory avoids the target forever. This game is called the target problem.

The target problem has been studied often since Isaacs' pioneer work [21]. It is one of the most interesting *game of kind* (by opposition, in Isaacs' terminology, to the *games of degree*). Many examples of application can be found in [21] and also in [20], [8], and [6]. In their monographs [22], [23], Krasovskii and Subbotin have proved that, from any initial position x_0, either Ursula or Victor wins against any action of her (his) adversary. This result is called the alternative theorem. In Krasovskii and Subbotin's result, the game is played in the framework of the positional strategies. Specifically, in equation (1), the controls $u(t)$ and $v(t)$ are replaced by positional strategies, i.e., maps (without a priori regularity) $\tilde{u} : \mathbb{R}^+ \times \mathbb{R}^N \to U$ and $\tilde{v} : \mathbb{R}^+ \times \mathbb{R}^N \to V$. Then the differential equation (1) has in general no solution and Krasovskii and Subbotin had to provide another definition of solution for the differential equation; these solutions are called the constructive motions. In general, they are not solutions to (1) in the Carathéodory sense, but they are limits of step-by-step motions which are solutions to equation (1). So, for the initial differential system, the alternative theorem gives information only on an *approximated game*.[1]

Our main purpose in this paper is to show that, starting from any initial position, either Ursula or Victor can realize *exactly* her (his) objective, against any action of her (his) opponent, provided that the game is played in the framework of Elliot–Kalton nonanticipative strategies (we recall the definition below). The nonanticipative strategies cannot be played simultaneously by Ursula and Victor because the player who plays the nonanticipative strategy needs knowledge of the control played by his opponent to play. So the game cannot be put in the so-called normal form unlike differential games in the class of positional strategies. But this is

*Received by the editors August 1, 1994; accepted for publication (in revised form) April 26, 1995.

†CEREMADE, Université Paris-Dauphine, Place du Maréchal de Lattre de Tassigny, 75775 Paris cedex 16, France.

[1] In Krasovskii and Subbotin's terminology, this approximated problem is called the game of $(\mathcal{M}^\epsilon, \mathcal{N}^\epsilon)$ approach, ϵ denoting a small positive parameter of approximation.

not surprising because we show below that knowledge of the opponent's strategy is in general necessary for Victor to realize exactly his objective, while it is useless for Ursula. This fact was pointed out in several examples of differential games since Isaacs.

We also intend to characterize, by geometric conditions, the set of initial positions x_0 from which Ursula (resp., Victor) may win against any action of her (resp., his) adversary; this set is called Ursula's (resp., Victor's) victory domain.[2] The characterization of the victory domains enables us to solve numerically the target problem (see the joint work [9]). It is also close to one of the characterizations of the stable bridges (see [23]) for the problem of the $(\mathcal{M}, \mathcal{N})$ approach. Our systematic use of the geometric conditions to study the victory domains distinguishes this investigation from previous studies.

Thanks to this characterization we shall provide a proof of the barrier phenomenon. This phenomenon is the key point in Isaacs' construction of the victory domains of the target problem. It is shown in [21] that, if the boundary of the victory domains is smooth, then each player can prevent the state of the system from crossing this boundary in one direction. Since then, this result has been generalized under less restrictive assumptions on the regularity of the boundary. It has also been proved in the case of control theory, without any assumption on regularity of the boundary (see Quincampoix [25]). Our result is an extension of this last one to the two-player differential games.

We make some remarks about the proofs. The proof of the main theorem (Theorem 2.1) uses some results of viability theory [4] and in particular the measurable viability theorem (see [18]). In the characterization of one of the victory domains, we use the same considerations previously used in the method of program iterations developed by Čencov (see [11]–[13]). The proof of Theorem 2.3 seems to be closely related to the proofs of Krasovskii and Subbotin for the characterization of the stable bridges. Let us finally emphasize that Theorems 2.1 and 2.3 have been discovered, independently and simultaneously, by a Polish mathematician, Plaskacz. The proof of Lemma 4.1 is basically his proof.

This paper is organized as follows. In §1, we define the nonanticipative strategies and some sets that play a central role throughout the paper: the discriminating and leadership domains and the discriminating and leadership kernel of a closed set. The main results of this paper are concerned with the interpretation theorems of the discriminating and leadership domains and of the characterization theorems of the discriminating and leadership kernels for the nonanticipative strategies (§2). These results shall be applied in §3 to the target problem. We show that the victory domains of the players can be characterized by means of the discriminating and leadership kernels. Moreover, we prove that the victory domains form a partition of the complement of the target. We also prove a so-called barrier phenomenon which states that some particular trajectories starting from the boundary of the victory domains remain in a neighbourhood of this boundary.

Finally, §§4 and 5 are devoted, respectively, to the proofs of the interpretation theorems and of the characterization theorems.

1. Definitions, assumptions, and notation.

1.1. The nonanticipative strategies. The first definitions of nonanticipative strategies can be found in [27], [28]. Such strategies have been intensively studied (see for instance [14], [15], [20], [16], [19]), but they were mainly applied to problems of games of degree.

Let us now recall the definition of the nonanticipative strategies. If we denote by

$$\text{(2)} \qquad \begin{cases} \mathcal{U} = \{u(\cdot) : [0, +\infty[\to U, \text{ measurable application } \}, \\ \mathcal{V} = \{v(\cdot) : [0, +\infty[\to V, \text{ measurable application } \} \end{cases}$$

[2] We give a rigorous definition of the victory domains in §3. This set plays a major role in the target problem.

the sets of time-measurable controls, nonanticipative strategies are defined in the following way.

DEFINITION 1.1. *We say that a map $\alpha : \mathcal{V} \to \mathcal{U}$ is a nonanticipative strategy (for Ursula) if it satisfies the following condition. For any $s \geq 0$ and for any $v_1(\cdot)$ and $v_2(\cdot)$ belonging to $\mathcal{V}$, such that $v_1(\cdot)$ and $v_2(\cdot)$ coincide almost everywhere on $[0, s]$, the images $\alpha(v_1(\cdot))$ and $\alpha(v_2(\cdot))$ coincide almost everywhere on $[0, s]$.*

Nonanticipative strategies $\beta : \mathcal{U} \to \mathcal{V}$ (for Victor) are defined in the same way. Namely, for any $s \geq 0$ and for any $u_1(\cdot)$ and $u_2(\cdot)$ belonging to $\mathcal{U}$, such that $u_1(\cdot)$ and $u_2(\cdot)$ coincide almost everywhere on $[0, s]$, the images $\beta(u_1(\cdot))$ and $\beta(u_2(\cdot))$ coincide almost everywhere on $[0, s]$.

1.2. The proximal normals. Proximal normals generalize to the closed sets the usual definition of the outward normals.

DEFINITION 1.2. *Let K be a closed subset of $\mathbb{R}^N$ and x belong to K. A vector $p \in \mathbb{R}^N$ is a* proximal normal *to K at x if*

$$d_K(x + p) = \|p\|,$$

where $d_K(y) := \min_{z \in K} \|z - y\|$.

The set of proximal normals to a closed set K at a point x is denoted by $NP_K(x)$. (Note that $\|\cdot\|$ always denotes the Euclidean norm.)

So a vector p is a proximal normal to a closed set K at a point $x \in K$ if the open ball centered in $x + p$ and of radius $\|p\|$ does not intersect K. Let us point out that the closed ball centered in $x + p$ and of radius $\|p\|$ intersects K at least at the point x. Roughly speaking, this ball is tangent to K at x.

1.3. The discriminating and leadership domains and kernels.

DEFINITION 1.3. *Let $H : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}$ be a map. A closed set D is a* domain for H *if D satisfies*

$$\forall x \in D, \ \forall p \in NP_D(x), \ H(x, p) \leq 0.$$

We shall study in detail the following two cases:

- If the map H is defined by

$$H(x, p) := \sup_u \inf_v \langle f(x, u, v), p \rangle, \tag{3}$$

then the domains for H are called *discriminating domains* for f. (See [1], [3], [4] for an equivalent definition.)

- If H is defined by

$$H(x, p) := \inf_v \sup_u \langle f(x, u, v), p \rangle, \tag{4}$$

then the domains for H are called *leadership domains* for f (see [10]). Leadership domains are always discriminating domains. The converse is false in general.

In [10], we proved the following theorem.

THEOREM 1.1. *Let $H : \mathbb{R}^N \times \mathbb{R}^N$ be a lower semicontinuous map. Any closed subset K of $\mathbb{R}^N$ contains a largest closed domain for H. This set is called the* kernel of K for H.

So any closed domain for H contained in a closed K is contained in the kernel of K for H. Moreover, this kernel is itself a domain for H. The kernel of K for H may be empty if K does not contain any domain for H.

• If the map H is defined by (3), then the kernel of K for H is called the *discriminating kernel* of K for f and is denoted by $Disc_f(K)$.

• If the map H is defined by (4), then the kernel of K for H is called the *leadership kernel* of K for f and is denoted by $Lead_f(K)$.

Note in particular that for any closed set K, $Lead_f(K) \subset Disc_f(K)$.

1.4. Assumptions and notation. We summarize here the assumptions we shall need on the dynamics throughout this paper. The first ones are concerned with the regularity properties of f:

$$\text{(5)} \qquad \begin{cases} \text{(i)} & \text{U and V are metric compact spaces,} \\ \text{(ii)} & f : \mathbb{R}^N \times U \times V \to \mathbb{R}^N \text{ is continuous,} \\ \text{(iii)} & f(\cdot, u, v) \text{ is an } \ell\text{-Lipschitz map for any } u \text{ and } v. \end{cases}$$

For the study of the discriminating domains and kernels, we also require some convexity properties[3]:

$$\text{(6)} \qquad \begin{cases} \text{(i)} & V \text{ is a convex compact subset of } \mathbb{R}^d \ (d \in \mathbb{N}^*), \\ \text{(ii)} & f \text{ is affine in } v. \end{cases}$$

When (5) is satisfied, we shall denote by $x[x_0, u(\cdot), v(\cdot)]$ the unique solution of the differential equation

$$\text{(7)} \qquad \begin{cases} x'(t) = f(x(t), u(t), v(t)) \text{ for almost every } t \geq 0, \\ x(0) = x_0, \end{cases}$$

where $x_0 \in \mathbb{R}^N$, $u(\cdot) \in \mathcal{U}$, and $v(\cdot) \in \mathcal{V}$.

We shall also denote by B the closed unit ball of the state space $\mathbb{R}^N$, while $\overset{o}{B}$ shall denote the open unit ball. Moreover, the distance map to a closed set K shall be denoted by d_K:

$$d_K(x) := \min_{y \in K} \|y - x\|.$$

For any positive ϵ, $K + \epsilon B$ shall denote the closed set

$$K + \epsilon B := \{y \in \mathbb{R}^N \mid d_K(y) \leq \epsilon\}.$$

2. Statement of the main results.

2.1. Discriminating domains and kernels. We first provide an interpretation of discriminating domains for nonanticipative strategies.

The following theorem states that the discriminating domains are sets in which Victor can ensure that the state of the system remains as soon as he knows what Ursula plays.

THEOREM 2.1 (interpretation theorem). *Assume that f satisfies* (5) *and* (6) *and that D is a closed subset of $\mathbb{R}^N$. Then, the closed set D is a discriminating domain for f if and only if, for any x_0 belonging to D, there exists a nonanticipative strategy β, such that, for any $u(\cdot)$ belonging to $\mathcal{U}$, the solution $x[x_0, u(\cdot), \beta(u(\cdot))]$ remains in D on $[0, +\infty)$. Namely,*

$$\forall t \geq 0, \ x[x_0, u(\cdot), \beta(u(\cdot))](t) \in D.$$

[3]By *affine*, we mean of the form

$$f(x, u, v) = a(x, u) + B(x, u)v.$$

(Recall that $x[x_0, u(\cdot), \beta(u(\cdot))]$ *is the solution to* (7) *with* $v(\cdot) := \beta(u(\cdot))$.*)*

Section 4 is devoted to the proof of Theorem 2.1.

Remark. Theorem 2.1 still holds true even if we only assume that D is a *locally compact set.* But in this case, we have to modify the statement of the theorem: A locally compact set D is a discriminating domain if and only if there exist a nonanticipative strategy β *and a positive time* T, such that, for any control $u(\cdot)$ belonging to $\mathcal{U}$, the solution $x[x_0, u(\cdot), \beta(u(\cdot))]$ remains in D *on* $[0, T]$.

If a discriminating domain D is contained in a closed set K, then Victor can ensure that the state of the system remains in D and so in K. This is in particular the case for the discriminating kernel of K. We prove here a kind of converse: If Victor can ensure that the state of the system remains in K, then the initial position of the system necessarily belongs to the discriminating kernel of K.

THEOREM 2.2 (characterization theorem). *Let* K *be a closed subset of* $\mathbb{R}^N$ *and* f *satisfy* (5) *and* (6). *Then, the discriminating kernel of* K *for* f *is equal to the set of points* x_0 *belonging to* K *for which there exists a nonanticipative strategy* $\beta : \mathcal{U} \to \mathcal{V}$ *such that, for any* $u(\cdot) \in \mathcal{U}$, *the solution* $x[x_0, u(\cdot), \beta(u(\cdot))]$ *remains in* K.

Proof of Theorem 2.2. From Theorem 2.1, for any x_0 belonging to $Disc_f(K)$, there exists a nonanticipative strategy $\beta : \mathcal{U} \to \mathcal{V}$ such that, for any $u(\cdot) \in \mathcal{U}$, the solution $x[x_0, u(\cdot), \beta(u(\cdot))]$ remains in $Disc_f(K)$ on $[0, +\infty)$, and so in K.

To prove the converse, let x_0 belong to K but not to $Disc_f(K)$. Let β be a nonanticipative strategy for Ursula. We have to construct a control $u(\cdot) \in \mathcal{U}$ such that the solution $x[x_0, u(\cdot), \beta(u(\cdot))]$ leaves K in finite time.

For that purpose, let us recall that the viability kernel of a closed set C for a Marchaud set-valued map[4] $F : \mathbb{R}^N \to \mathbb{R}^N$ is the set of initial positions from which starts at least a solution of the differential inclusion for F which remains in K forever. The viability kernel of K for F is a (maybe empty) closed subset of K. It is denoted by $Viab_F(K)$. (Most results on viability theory can be found in Aubin's monograph [4].)

In [10], we have proved that the discriminating kernel of a closed set can be obtained as decreasing intersections of viability kernels. Namely, if we define the sequence of closed sets

$$\begin{cases} K_1 := K, \\ K_{i+1} := \bigcap_{u \in U} Viab_{f(\cdot,u,V)}(K_i), \end{cases}$$

where $f(\cdot, u, V)$ denotes the set-valued map $x \rightsquigarrow \bigcup_{v \in V} f(x, u, v)$, then

$$\bigcap_i K_i = Disc_f(K).$$

Since $x_0 \notin Disc_f(K)$, there is some $i_0 \in \mathbb{N}^*$ such that x_0 belongs to K_{i_0} but not to K_{i_0+1}.

From the very definition of K_{i_0+1}, there exists $u_1 \in U$, such that x_0 does not belong to $Viab_{f(\cdot,u_1,V)}(K_{i_0})$. Thus any solution to the differential inclusion for $f(\cdot, u_1, V)$ starting from x_0 leaves K_{i_0} in finite time. The solution $x[x_0, u_1, \beta(u_1)]$ is a solution to the differential inclusion for $f(\cdot, u_1, V)$, so there is a time t_1 such that $x[x_0, u_1, \beta(u_1)](t_1)$ does not belong to K_{i_0}.

We set $u(\cdot) := u_1$ on $[0, t_1]$. If $x_1 := x[x_0, u(\cdot), \beta(u(\cdot))](t_1)$ does not belong to K_{i_0-1}, then we set $t_2 := t_1$. Otherwise, x_1 belongs to K_{i_0-1}, but not to K_{i_0}. So there exists $u_2 \in U$ such that x_1 does not belong to $Viab_{f(\cdot,u_2,V)}(K)$. We define an intermediate control $\bar{u}(\cdot)$ by $\bar{u}(s) := u(s)$ on $[0, t_1]$ and $\bar{u}(s) := u_2$ on $[t_1, +\infty)$. Since β is nonanticipative, $x[x_0, \bar{u}(\cdot), \beta(\bar{u}(\cdot))](t_1)$ equals x_1. Moreover, $x[x_0, \bar{u}(\cdot), \beta(\bar{u}(\cdot))]$ is a solution to the

[4] I.e., an upper semicontinuous set-valued map, with closed convex values and a linear growth (see [4]).

differential inclusion for $f(\cdot, u_2, V)$ on $[t_1, +\infty)$. Thus there is a time $t_2 \geq t_1$ such that $x[x_1, \bar{u}(\cdot), \beta(\bar{u}(\cdot))](t_2)$ does not belong to K_{i_0-1}. Now set $u(s) = \bar{u}(s)$ on $[t_1, t_2]$. Since $\bar{u}(\cdot)$ and $u(\cdot)$ coincide on $[0, t_2]$ and since β is nonanticipative, $x[x_0, u(\cdot), \beta(u(\cdot))](t_2)$ does not belong to K_{i_0-1}.

Thus it is possible to define by induction a nondecreasing sequence (t_i) and a control $u(\cdot)$ on $[0, t_i]$ such that $x[x_0, u(\cdot), \beta(u(\cdot))](t_i)$ does not belong to K_{i_0+1-i}. In particular, for $i = i_0$, $x[x_0, u(\cdot), \beta(u(\cdot))](t_{i_0})$ does not belong to $K_1 = K$. So we have constructed a control $u(\cdot)$ such that the solution $x[x_0, u(\cdot), \beta(u(\cdot))]$ leaves K in finite time. □

2.2. Leadership domains and kernels. If Ursula has a spy (she plays nonanticipative strategies), then leadership domains are the sets in which Victor can almost ensure that the state of the system remains.

THEOREM 2.3 (interpretation theorem). *Assume that f satisfies* (5) *and that D is a closed subset of $\mathbb{R}^N$. Then, the closed set D is a leadership domain for f if and only if, for any x_0 belonging to D, for any nonanticipative strategy $\alpha : \mathcal{V} \to \mathcal{U}$, for any positive ϵ, and for any time $T \geq 0$, there exists a control $v(\cdot) \in \mathcal{V}$ such that the solution $x[x_0, \alpha(v(\cdot)), v(\cdot)]$ remains*[5] *in $D + \epsilon B$ on $[0, T]$.*

The proof of Theorem 2.3 is provided in §4.

Remark. (1) Unfortunately, it is sometimes impossible to find a time-measurable control $v(\cdot)$ such that $x[x_0, \alpha(v(\cdot)), v(\cdot)]$ remains in the leadership domain D. For example, set $D := \{0\}$ (subset of $\mathbb{R}$) and $f(x, u, v) := \{u + v\}$, where u and v belong to $[-1, 1]$. If the nonanticipative strategy is

$$\begin{cases} \alpha(v(\cdot))(t) = v(t) \text{ if } v(t) \neq 0, \\ \alpha(v(\cdot))(t) = 1 \text{ if } v(t) = 0, \end{cases} \tag{8}$$

then there is no control $v(\cdot)$ such that the solution $x(\cdot) := x[0, \alpha(v(\cdot)), v(\cdot)]$ remains in D (because $x'(t) \neq 0$ for almost every $t \geq 0$).

So, in general, Victor needs knowledge of Ursula's control to prevent the state of the system from leaving K.

(2) Theorem 2.3 still holds true even if we only assume that D is a *locally compact set.* But in this case, we have to modify the statement of the theorem: A locally compact set D is a leadership domain if and only if, for any x_0 belonging to D, *there exists a positive T* such that, for any nonanticipative strategy α and for any $\epsilon > 0$, there is some control $v(\cdot) \in \mathcal{V}$ such that the solution $x[x_0, \alpha(v(\cdot)), v(\cdot)]$ remains in $D + \epsilon B$ on $[0, T]$.

We now characterize the leadership kernel of a closed set.

THEOREM 2.4 (characterization theorem). *Let K be a closed subset of $\mathbb{R}^N$ and f satisfy* (5). *Then, the leadership kernel of K for f is equal to the set of points x_0 belonging to K such that, for any nonanticipative strategy $\alpha : \mathcal{V} \to \mathcal{U}$, for any $\epsilon > 0$, and for any $T \geq 0$, there exists a control $v(\cdot) \in \mathcal{V}$ such that the solution $x[x_0, \alpha(v(\cdot)), v(\cdot)]$ remains in $K + \epsilon B$ on $[0, T]$.*

Theorem 2.4 yields, in particular, Corollary 2.1.

COROLLARY 2.1. *If x_0 belongs to K but not to $Lead_f(K)$, there exist positive T and ϵ and a nonanticipative strategy $\alpha : \mathcal{V} \to \mathcal{U}$, such that for any control $v(\cdot) \in \mathcal{V}$, the solution $x[x_0, \alpha(v(\cdot)), v(\cdot)]$ leaves $K + \epsilon B$ before T (i.e., there is a time $t \leq T$ such that $d_K(x[x_0, \alpha(v), v](t))$ is larger than ϵ).*

The proof of Theorem 2.4 is provided in §5.

3. Applications for the target problem. Let Ω be an open target of $\mathbb{R}^N$ and f satisfy (5), (6). We recall briefly the target problem. Two players, Ursula and Victor, control the

[5] Let us recall that we denote by $D + \epsilon B$ the set of points x such that $d_D(x) \leq \epsilon$.

dynamical system

$$x'(t) = f(x(t), u(t), v(t)).$$

Ursula, acting on u, wants the state of the system to reach the target Ω, while Victor, acting on v, wants the state of the system to avoid Ω.

3.1. The alternative theorem. Let us define now the victory domains of each player.

DEFINITION 3.1 (victory domains).

• Victor's victory domain *is the set of initial positions* $x_0 \notin \Omega$ *for which Victor can find a nonanticipative strategy* $\beta : \mathcal{U} \to \mathcal{V}$ *such that for any time-measurable control* $u(\cdot) \in \mathcal{V}$ *played by Ursula, the solution* $x[x_0, u(\cdot), \beta(u(\cdot))]$ *avoids* Ω *for any* $t \geq 0$, *i.e.,*

$$\forall t \geq 0,\ x[x_0, u(\cdot), \beta(u(\cdot))](t) \notin \Omega.$$

• Ursula's victory domain *is the set of initial positions* $x_0 \notin \Omega$ *for which Ursula can find a nonanticipative strategy* $\alpha : \mathcal{V} \to \mathcal{U}$, *positive* ϵ, *and* T *such that, for any* $v(\cdot) \in \mathcal{U}$ *played by Victor, the solution* $x[x_0, \alpha(v(\cdot)), v(\cdot)]$ *reaches the set* $\Omega_\epsilon := \{x \mid d_{\Omega^c}(x) \geq \epsilon\}$ *before* T. *Namely,*

$$\exists t \leq T,\ d_{\Omega^c}(x[x_0, \alpha(v(\cdot)), v(\cdot)](t)) \geq \epsilon.$$

Remark. Note that $\Omega_\epsilon \subset \Omega$.

Theorems 2.2 and 2.4 yield the following results.

THEOREM 3.1 (alternative theorem). *Assume that* f *satisfies* (5) *and* (6). *Set* $K := \mathbb{R}^N \backslash \Omega$. *Then*

• *Victor's victory domain is equal to* $Disc_f(K)$.

• *Ursula's victory domain is equal to* $K \backslash Lead_f(K)$.

Assume moreover that

$$Lead_f(K) = Disc_f(K). \tag{9}$$

Then the victory domains of the two players form a partition of the closed set K.

Note that equality (9) is fulfilled as soon as Isaacs' condition holds:

$$\forall (x, p) \in \mathbb{R}^{2N},\ \sup_u \inf_v \langle f(x, u, v), p\rangle = \inf_v \sup_u \langle f(x, u, v), p\rangle.$$

If equality (9) does not hold true, there are initial conditions x_0 (where x_0 belongs to $Disc_f(K)$ but not to $Lead_f(K)$) from which Victor wins if he knows Ursula's control and from which Ursula wins if she knows Victor's control.

Let us recall that a similar alternative theorem has been obtained by Krasovskii and Subbotin in the framework of the positional strategies (see [23]).

Here we characterize the victory domains by means of geometric conditions (as discriminating and leadership kernels of a closed set). This characterization is used in the joint work with Quincampoix and Saint-Pierre [9] to compute numerically the victory domains (see also [30] and [26] in the framework of control theory).

3.2. The barrier phenomenon. Since the kernel of a closed set for a map $H : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}$ is the maximal domain for H contained in K, it enjoys some particular properties at its boundary. We have proved in [10] the following theorem.

THEOREM 3.2. *Assume that the map* $H : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}$ *is continuous and positively homogeneous in the second variable. Let* D *denote the kernel of a closed set* K *for* H. *Assume that a point* x *belongs to* ∂D *but not to* ∂K. *Then*

(1) *if* $v \in NP_D(x)$,

$$H(x, v) \leq 0.$$

(2) *if* $\mu \in NP_{\overline{\mathbb{R}^N \setminus D}}(x)$,

$$H(x, -\mu) \geq 0.$$

Let us point out that (1) follows from the very definition of the domains for H (recall that D is itself a domain for H). So the important part of the theorem is the second assertion.

Let us further point out that, if $\mu \in NP_{\overline{\mathbb{R}^N \setminus D}}(x)$, then the ball $x + \mu + \|\mu\| B$ is contained in D. Roughly speaking, μ is an inward proximal normal. So, if the boundary of D has nonzero outward and inward proximal normals ($\mu = -\nu$ up to a positive multiplicative coefficient), then $H(x, \nu) = 0$. In the case when $H(x, p) := \sup_u \inf_v \langle f(x, u, v), p\rangle$, (1) and (2) can be interpreted as a generalized definition of Isaacs' equation:

$$\sup_u \inf_v \langle f(x, u, v), p\rangle = 0, \tag{10}$$

where p is an outward normal to the smooth boundary of the victory domains.

Isaacs' equation plays a main role in two-player differential game theory. See for instance [21], [7] and the references therein. Smooth surfaces satisfying (10) are called semipermeable surfaces by Isaacs. The reason is that both players can prevent the state of the system from crossing this surface in one direction. In general, the boundary of the victory domains is not smooth, and Isaacs' methods do not work anymore. We prove below that, in any case, the boundary of the victory domains is almost semipermeable. Similar results have been obtained by Quincampoix in the framework of control theory[6] (see [25]).

THEOREM 3.3. *Assume that f satisfies* (5) *and* (6). *Let x_0 belong to $\partial Disc_f(K)$ but not to ∂K. If $\beta : \mathcal{U} \to \mathcal{V}$ is a winning nonanticipative strategy*[7] *for Victor, then there is a time $T > 0$ such that, for any positive ϵ, Ursula can find a control $u(\cdot) \in \mathcal{U}$ such that the solution $x[x_0, u(\cdot), \beta(u(\cdot))]$ remains in $\partial Disc_f(K) + \epsilon B$ on $[0, T]$, i.e.,*

$$\forall t \leq T,\ d_{\partial Disc_f(K)}(x[x_0, u(\cdot), \beta(u(\cdot))](t)) \leq \epsilon.$$

So Ursula can ensure that the state of the system almost remains on the boundary of her victory domain.

Proof of Theorem 3.3. The proof of this result is a direct application of the second remark following Theorem 2.1 applied to the dynamics g defined by

$$\forall x \in \mathbb{R}^N,\ \forall \tilde{u} \in \tilde{U},\ \forall \tilde{v} \in \tilde{V},\ g(x, \tilde{u}, \tilde{v}) := f(x, \tilde{v}, \tilde{u}),$$

where $\tilde{U} := V$ and $\tilde{V} := U$. Indeed, choose $x_0 \in \partial Disc_f(K) \setminus \partial K$ and $R > 0$ such that $x_0 + RB$ is contained in K. From Theorem 3.2, the set $\hat{D} := \overline{Disc_f(K) \setminus K}$ satisfies the following condition on $x_0 + RB$:

$$\forall x \in x_0 + R\overset{o}{B},\ \forall p \in NP_{\hat{D}}(x),\ \sup_u \inf_v \langle f(x, u, v), -p\rangle \geq 0.$$

Since $\sup_u \inf_v \langle f(x, u, v), -p\rangle = -\inf_{\tilde{u}} \sup_{\tilde{v}} \langle g(x, \tilde{u}, \tilde{v}), p\rangle$, we have proved that the locally compact set $\hat{D} \cap (x_0 + R\overset{o}{B})$ is a leadership domain. So the second remark following Theorem 2.1 can be applied. □

[6] Quincampoix's results are concerned with the boundary of the viability kernel and of the invariance kernel (see also the monograph [4]). The reader may refer to [29] for the case where the dynamics are only upper semicontinuous.

[7] A winning nonanticipative strategy for Victor is a strategy which ensures that the state of the system remains in K forever, and so in $Disc_f(K)$.

4. Proof of the interpretation theorems. We prove in this section Theorems 2.1 and 2.3. The proof for the discriminating domains involves results of viability theory. The proof for the leadership domains uses more technical estimates.

4.1. Proof for the discriminating domains.

4.1.1. Necessary condition. Let D be a closed set which enjoys the discriminating property. By definition, for any $x_0 \in D$, there exists a nonanticipative strategy $\beta : \mathcal{U} \to \mathcal{V}$ such that for any $u(\cdot) \in \mathcal{U}$, the solution $x[x_0, u(\cdot), \beta(u(\cdot))]$ remains in D. Let us show that D is a discriminating domain.

For that purpose, fix $x_0 \in D$, β a nonanticipative strategy as above, and $p \in NP_D(x_0)$. We have to prove that $\sup_u \inf_v \langle f(x_0, u, v), p\rangle \leq 0$. Assume on the contrary that

$$\sup_u \inf_v \langle f(x_0, u, v), p\rangle \geq a > 0.$$

There is some $\bar{u} \in U$ such that

$$\forall v \in V, \ \inf_v \langle f(x_0, \bar{u}, v), p\rangle \geq a. \tag{11}$$

If we set $u(t) = \bar{u}$ for any t, the solution $x(\cdot) := x[x_0, u(\cdot), \beta(u(\cdot))]$ remains in D forever from the very definition of β. Since the open ball centered in $x_0 + p$ and of radius $\|p\|$ does not intersect D (p is a proximal normal to D at x_0), $x(\cdot)$ satisfies

$$\forall t \geq 0, \ \|x(t) - (x_0 + p)\| \geq \|p\|. \tag{12}$$

Let us compute now the derivative of $\|x(t) - (x_0 + p)\|^2$:

$$\begin{aligned}
\frac{d}{dt}\frac{1}{2}\|x(t) - (x_0 + p)\|^2 &= \langle x'(t), x(t) - (x_0 + p)\rangle \\
&= \langle f(x(t), \bar{u}, \beta(u)(t)), x(t) - x_0\rangle \\
&\qquad -\langle f(x(t), \bar{u}, \beta(u)(t)), p\rangle \\
&\leq \|x(t) - x_0\|(\|f(x(t), \bar{u}, \beta(u)(t))\| + \ell\|p\|) \\
&\qquad -\langle f(x_0, \bar{u}, \beta(u)(t)), p\rangle \\
&\leq -a/2
\end{aligned}$$

for almost every t small enough (recall that f is ℓ-Lipschitz and satisfies (11)). Thus

$$\|x(t) - (x_0 + p)\|^2 \leq \|p\|^2 - (at)/2 < \|p\|^2$$

for t small enough. This contradicts (12). Thus we have proved that any closed set D satisfying the discriminating property satisfies also $\sup_u \inf_v \langle f(x_0, u, v), p\rangle \leq 0$, for any $x_0 \in D$ and any proximal normal p to D at x. This means that D is a discriminating domain. □

4.1.2. Sufficient condition. Assume now that D is a discriminating domain. Let x_0 belong to D. We want to define a nonanticipative strategy $\beta : \mathcal{U} \to \mathcal{V}$, such that for any $u(\cdot)$ belonging to $\mathcal{U}$, the solution $x[x_0, u(\cdot), \beta(u(\cdot))]$ remains in D.

For that purpose, we introduce the following set-valued map:

$$B(u(\cdot)) = \{v(\cdot) \in \mathcal{V} \mid x[x_0, u(\cdot), v(\cdot)] \text{ remains in } D\}.$$

The set-valued map $B(\cdot) : \mathcal{U} \rightsquigarrow \mathcal{V}$ has nonempty values. Indeed D is a discriminating domain

and the measurable viability theorem[8] [18] states that, for any $x_0 \in D$, for any $u(\cdot) : \mathbb{R}^+ \to U$ measurable, there exists a solution $x(\cdot)$ of the differential inclusion

$$\text{(13)} \qquad \begin{cases} x'(t) \in f(x(t), u(t), V) \text{ for almost all } t \geq 0, \\ x(0) = x_0, \end{cases}$$

which remains in D. Usual selections theorems state (see also Theorem 3.1.1 of [17]) that the solutions to (13) are the same as the solutions to

$$\begin{cases} x'(t) = f(x(t), u(t), v(t)) \text{ for almost all } t \geq 0, \\ v(t) \in V \text{ for almost all } t \geq 0, \\ x(0) = x_0. \end{cases}$$

Thus there exists a control $v(\cdot)$ belonging to $\mathcal{V}$ such that $x(\cdot) = x[x_0, u(\cdot), v(\cdot)]$, i.e., $v(\cdot) \in B(u(\cdot))$.

We claim that $B(\cdot)$ has compact values for the weak topology of the Hilbert space $L^2([0, +\infty[, \mathbb{R}^d, e^{-t})$ (which is $L^2([0, +\infty), \mathbb{R}^d)$ supplied with the Euclidean norm $\|v(\cdot)\|_{L^2} := \int_0^{+\infty} \|v(t)\|^2 e^{-t} dt$) and that $B(\cdot)$ is a nonanticipative set-valued map. Recall that $V \subset \mathbb{R}^d$.

$B(\cdot)$ has weakly compact values. Since V is a convex compact subset of $\mathbb{R}^d$, $\mathcal{V}$ is weakly compact. Let $v_p(\cdot)$ belong to $B(u(\cdot))$. Up to a subsequence (again denoted by $v_p(\cdot)$), $v_p(\cdot)$ converges for the weak topology to some control $v(\cdot)$ belonging to $\mathcal{V}$. Thus, from Alaoglu and Ascoli theorems, the solutions $x[x_0, u(\cdot), v_p(\cdot)]$ converge to the solution $x[x_0, u(\cdot), v(\cdot)]$ for the compact convergence because f is affine in v (for more details, see for instance the proof of the Convergence Theorem 2.4.4 in [4]). Thus $x[x_0, u(\cdot), v(\cdot)]$ remains in D on $[0, +\infty)$, i.e., $v(\cdot)$ belongs to $B(u(\cdot))$. So $B(\cdot)$ has nonempty, compact values.

The set-valued map $B(\cdot)$ is nonanticipative. We say that the set-valued map $B : \mathcal{U} \rightsquigarrow \mathcal{V}$ is nonanticipative if, for any $s \geq 0$, u_1 and u_2 belonging to $\mathcal{U}$ coincide almost everywhere on $[0, s]$, then, for any v_1 belonging to $B(u_1)$, one can find v_2 belonging to $B(u_2)$ which coincides with v_1 almost everywhere on $[0, s]$. We now check that the set-valued map $B(\cdot)$ is nonanticipative.

Indeed, since u_1 and u_2 coincide almost everywhere on $[0, T]$, $x[x_0, u_2, v_1]$ remains in D on $[0, T]$, from the very definition of v_1. Set $v_2(\cdot) := v_1(\cdot)$ on $[0, T]$. The measurable viability theorem yields the existence of a control $v(\cdot)$ such that the solution to the differential equation for $f(\cdot, u_2(t), v(t))$, starting at time T from $x[x_0, u_1, v_1](T)$, remains in D. Set $v_2(\cdot) := v(\cdot)$ on $(T, +\infty)$. Then $v_2(\cdot)$ belongs to $B(u_2(\cdot))$ and coincides almost everywhere on $[0, T]$ with $v_1(\cdot)$.

Thus, to prove Theorem 2.1, it is enough to find a nonanticipative selection of $B(\cdot)$, i.e., a nonanticipative map $\beta : \mathcal{U} \to \mathcal{V}$ such that

$$\forall u(\cdot) \in \mathcal{U}, \ \beta(u(\cdot)) \in B(u(\cdot)).$$

The following lemma provides the existence of a nonanticipative selection of nonanticipative set-valued maps. This lemma is due to Plaskacz [24].

LEMMA 4.1 (Plaskacz). *Let $B(\cdot) : \mathcal{U} \to \mathcal{V}$ be a nonanticipative set-valued map with nonempty, closed values for the weak topology of $L^2(\mathbb{R}^+, V, e^{-t})$. Then there is a nonanticipative selection $\beta(\cdot)$ of $B(\cdot)$.*

---

[8] To apply this result, we have to recall that, under assumptions (5) and (6), the following statements are equivalent (see [10]):

(1) D is a discriminating domain for f.

(2) $\forall x \in D, \ \forall u \in U, \ f(x, u, V) \cap T_D(x) \neq \emptyset$, where $T_D(x) := \{v \in \mathbb{R}^N \mid \liminf_{h \to 0^+} d_D(x + hv)/h = 0\}$.

Thus, if D is a discriminating domain, for any $u(\cdot) \in \mathcal{U}$, the following condition is fulfilled:

$$\forall x \in D, \ f(x, u(t), V) \cap T_D(x) \neq \emptyset \text{ for almost every } t \geq 0.$$

So we can apply Theorem 1 of [18].

Since this result is still unpublished, we provide a proof of Lemma 4.1 in the Appendix for the convenience of the reader.

4.2. Proof for the leadership domains. Let us now prove Theorem 2.3.

4.2.1. Sufficient condition. Suppose that D is not a leadership domain. We have to contradict the conclusion of Theorem 2.3, i.e., to find some x_0 belonging to D and some positive ϵ and T and we have to build a nonanticipative strategy $\alpha(\cdot)$, such that, for any v belonging to $\mathcal{V}$, the solution $x[x_0, \alpha(v), v]$ leaves $D + \epsilon B$ before T.

Since D is not a leadership domain, there are some $x_0 \in D$ and some proximal normal $\nu \in NP_D(x_0)$ such that

$$\inf_v \sup_u \langle f(x_0, u, v), \nu \rangle \;=\; 2a \;>\; 0.$$

Without loss of generality, we can assume that $\|\nu\| \leq 1$. (Recall that $NP_D(x_0)$ is closed and convex and that 0 belongs to $NP_D(x_0)$.)

Since the maps $f(\cdot, u, v)$ are ℓ-Lipschitz for any u and v,

$$\forall y \in \left[x_0 + \frac{a}{\ell} B\right], \;\; \inf_v \sup_u \langle f(y, u, v), \nu \rangle \;\geq\; a.$$

The set-valued map

$$v \rightsquigarrow \left\{ u \in U \mid \inf_{y \in x_0 + \frac{a}{\ell} B} \langle f(y, u, v), \nu \rangle \;\geq\; a \right\}$$

is measurable and has nonempty closed values. (It has a closed graph.) Thus Measurable Selection Theorem 8.1.3 of [5] states that there exists a measurable selection $\pi : V \to U$ of this set-valued map.

Define now the map $\alpha(\cdot) : \mathcal{V} \to \mathcal{U}$ in the following way:

$$\forall v(\cdot) \in \mathcal{V}, \;\; \alpha(v(\cdot))(t) = \pi(v(t)).$$

Note that $\alpha(v(\cdot))$ is measurable because it is the composition of two measurable maps. Moreover, $\alpha(\cdot)$ is obviously a nonanticipative strategy.

Let M be a bound of $\|f(\cdot, \cdot, \cdot)\|$ on $[x_0 + \frac{a}{\ell} B] \times U \times V$. Fix $v(\cdot) \in \mathcal{V}$ and set $x(\cdot) := x[x_0, \alpha(v(\cdot)), v(\cdot)]$. We claim that, for any $t \in [0, \frac{a}{M\ell}]$,

$$\langle x(t) - x_0, \nu \rangle \geq at \;\text{ and }\; \|x(t) - x_0\| \leq Mt. \tag{14}$$

If our claim holds true, we can make the following statement.

LEMMA 4.2. *Let D be a closed subset of $\mathbb{R}^N$ and x belong to D. Assume that ν is a proximal normal to D at x. Let M and a be positive. Then, for any $0 < t < \frac{2a}{M^2}$, one has*

$$\left.\begin{array}{l} \|y - x\| \leq Mt, \\ \langle y - x, \nu \rangle \geq at \end{array}\right\} \Rightarrow \;\; d_D(y) \;\geq at - \frac{M^2 t^2}{2}.$$

Set $\bar{t} := \inf\{\frac{a}{M\ell}, \frac{2a}{M^2}\}$ and $\epsilon := [a - \frac{M^2 \bar{t}}{2}]\bar{t}$. (Note that both $\bar{t}$ and ϵ are positive.) Combining equation (14) with Lemma 4.2 yields $d_D(x(\bar{t})) \geq \epsilon$. Since $\bar{t}$ and ϵ do not depend on $v(\cdot)$, we have defined a nonanticipative strategy $\alpha(\cdot)$ such that, for any $v(\cdot)$ belonging to $\mathcal{U}$, the solution to $x[x_0, \alpha(v(\cdot)), v(\cdot)]$ leaves $D + \epsilon B$ before $\bar{t}$. This is the desired conclusion.

To prove that (14) holds true, note that, for $t \leq \frac{a}{M\ell}$, $x(t)$ belongs to $x_0 + \frac{a}{\ell}$. Thus the following estimates hold:

$$\langle x'(t), v\rangle \geq a \text{ and } \|x'(t)\| \leq M \text{ for almost all } t \in \left[0, \frac{a}{M\ell}\right].$$

We obtain (14) after integration, using the fact that $(\|x(t)\|)' \leq \|x'(t)\|$ for almost every $t \geq 0$. □

Proof of Lemma 4.2. Let us first prove that, if y and t are as in Lemma 4.2, then y belongs to the ball $x + v + \|v\|B$:

$$\|x + v - y\|^2 = \|x - y\|^2 - 2\langle y - x, v\rangle + \|v\|^2 \leq \|v\|^2 + M^2t^2 - 2at.$$

Thus, for $t \in (0, \frac{2a}{M^2})$, $\|x + v - y\|$ is not greater than $\|v\|$, which means that y belongs to $x + v + \|v\|B$.

Since v is a proximal normal, the distance from y to D is less than or equal to the distance from y to the complement of $x + v + \|v\|B$. Thus

$$d_D(y) \geq \|v\| - \|x + v - y\| \geq \|v\| - [\|v\|^2 + M^2t^2 - 2at]^{\frac{1}{2}}.$$

Since, for $s \in [-1, 0]$, one has $1 - [1 + s]^{\frac{1}{2}} \geq -\frac{s}{2}$, the proof is complete. □

4.2.2. Necessary condition. We now suppose that D is a leadership domain. Fix $x_0 \in D$, α a nonanticipative strategy, $\epsilon > 0$, and $T > 0$. We construct a control $v(\cdot)$ such that the solution $x[x_0, \alpha(v(\cdot)), v(\cdot)]$ remains in $D + \epsilon B$ on $[0, T]$.

The proof is divided into three steps. We first state two lemmas. Then we construct the control $v(\cdot)$. Finally, we prove that $v(\cdot)$ satisfies the required condition.

Preliminary lemmas. Throughout the proof, we keep the notation of the following lemma, which shall be proved later.

LEMMA 4.3. *With the notation and the assumptions of Theorem* 2.1, *there is some radius R such that, for any $u(\cdot)$ belonging to $\mathcal{U}$ and any $v(\cdot)$ belonging to $\mathcal{V}$, the solution $x[x_0, u(\cdot), v(\cdot)]$ remains in $x_0 + RB$ on $[0, 2T]$. We denote by M a bound of $\|f(\cdot, \cdot, \cdot)\|$ on $(x_0 + RB) \times U \times V$.*

In particular, Lemma 4.3 states that we can proceed as if f is bounded by M, because we study the solutions only on $[0, T]$.

We now need the following lemma.

LEMMA 4.4. *Assume that the map f satisfies* (5) *and is bounded by M. Let D be a leadership domain. Let $\bar{x} \notin D$ and y belong to the projection of $\bar{x}$ onto D. Choose $\bar{v} \in V$ such that*

$$\sup_u \langle f(\bar{x}, u, \bar{v}), \bar{x} - y\rangle \leq 0.$$

There are positive constants c and τ (which depend only on ℓ and M) such that, for any $u(\cdot) \in \mathcal{U}$, the following estimate holds true:

$$\forall t \leq \tau,\ d_D(x[\bar{x}, u(\cdot), \bar{v}](t))^2 \leq ct^2 + d_D^2(\bar{x})e^{2\ell t}.$$

Lemma 4.4 is proved below.

We are now ready to construct the control $v(\cdot)$. (We keep the notation of Lemmas 4.3 and 4.4.)

Construction of $v(\cdot)$. Fix $a \in (0, \tau)$ small enough such that

$$M^2a^2e^{2T\ell} + ca^2\frac{e^{2T\ell} - 1}{e^{2\ell a} - 1} < \epsilon^2.$$

Let $(t_p = ap)_{p \le T/a}$ be a subdivision of $[0, T]$. We define $v(\cdot)$ recursively, in such a way that $v(\cdot)$ is constant on any interval $[t_p, t_{p+1})$.

On $[0, t_1)$, we set $v(t) = v_1$, where v_1 is any element of V.

Assume we have defined $v(\cdot)$ on $[0, t_p)$. For simplicity, we set $x_p := x[x_0, \alpha(v), v](t_p)$. Since α is nonanticipative, x_p only depends on the restriction of $v(\cdot)$ to $[0, t_p]$.

• If x_p belongs to D, we set $v(t) := v_{p+1}$ on $[t_p, t_{p+1})$, where v_{p+1} is any element of V.

• If x_p does not belong to D, then let y_p be a projection of x_p onto D. Since D is a leadership domain and $x_p - y_p$ is a proximal normal to D at y_p, there exists v_{p+1} such that $\sup_u \langle f(y_p, u, v_{p+1}) , x_p - y_p \rangle \le 0$. Then we set $v(\cdot) := v_{p+1}$ on $[t_p, t_{p+1})$.

From now on, we set $x(t) := x[x_0, \alpha(v), v](t)$.

$d_D(x(t)) \le \epsilon$ *for* $t \in [0, T]$. To show this, we apply Lemma 4.4 with $u(\cdot) := \alpha(v(\cdot))$. Note that in the worst case (i.e., the case when $\sup_{t\in[0,T]} d_D(x(t))$ is maximum), the $x(t_p)$ do not belong to D once $p \ge 1$.

If t belongs to $[t_p, t_{p+1})$, then $v(t) = v_{p+1}$, where v_{p+1} satisfies

$$\sup_u \langle f(y_p, u, v_{p+1}), x_p - y_p \rangle \le 0.$$

Since y_p is a projection of x_p onto D, we can apply Lemma 4.4 to get

$$d_D^2(x(t)) \le c(t - t_p)^2 + d_D^2(x_p) e^{2\ell a}$$

because $a \le \tau$.

Applying Lemma 4.4 again yields

$$d_D^2(x_p) \le ca^2 + d_D^2(x_{p-1}) e^{2\ell a}.$$

By induction we obtain

$$d_D(x_p)^2 \le d_D^2(x_1) e^{2p\ell a} + ca^2 \sum_{j=0}^{i-1} e^{2j\ell a}.$$

Note that, for any $t \le T$, there is $p \le T/a$ such that $t_p \le t < t_{p+1}$. Moreover,

$$d_D^2(x_1) \le \|x_0 - x_1\|^2 \le M^2 a^2$$

because f is bounded by M. So we have finally proved that

$$\forall t \le T, \quad d_D(x(t))^2 \le M^2 a^2 e^{2T\ell} + ca^2 \frac{e^{2T\ell} - 1}{e^{2\ell a} - 1}.$$

From the very definition of a, the right-hand side is smaller than ϵ^2. Thus, we have constructed a control $v(\cdot)$ such that, on $[0, T]$,

$$d_D(x[x_0, \alpha(v(\cdot)), v(\cdot)](t)) \le \epsilon,$$

as desired. □

Proof of Lemma 4.3. For simplicity, we set $x(\cdot) := x[x_0, u(\cdot), v(\cdot)]$, and $\lambda := \sup_u \sup_v \|f(x_0, u, v)\|$. The derivative of $\|x(t) - x_0\|$ is not larger than $\|x'(t)\|$ for almost every t. Thus, for almost every t, one has

$$\begin{aligned} \frac{d}{dt}\|x(t) - x_0\| &\le \|x'(t)\| \\ &\le \|f(x(t), u(t), v(t))\| \\ &\le \lambda + \ell\|x(t) - x_0\| \end{aligned}$$

because f is ℓ-Lipschitz. Gronwall's lemma yields

$$\|x(t) - x_0\| \leq \frac{\lambda}{\ell}[e^{\ell t} - 1].$$

Thus, if we set $R := \frac{\lambda}{\ell}[e^{\ell 2T} - 1]$, Lemma 4.3 follows. □

Proof of Lemma 4.4. For simplicity, set $x(t) := x[x, u(\cdot), \bar{v}](t)$. Let $t \leq T$ for which the derivative of $x(\cdot)$ exists and is equal to $f(x(t), u(t), \bar{v})$. Recall also that f is ℓ-Lipschitz and bounded by M. So we have the following estimate:

$$\begin{aligned}\left(\frac{1}{2}\|x(t) - y\|^2\right)' &= \langle f(x(t), u(t), \bar{v}) \ , \ x(t) - y\rangle \\ &\leq \langle f(y, u(t), \bar{v}), x(t) - y\rangle + \ell\|x(t) - y\|^2 \\ &\leq \langle f(y, u(t), \bar{v}), \bar{x} - y\rangle + M\|x(t) - \bar{x}\| + \ell\|x(t) - y\|^2.\end{aligned}$$

Recall that $\langle f(y, u, \bar{v}) \ , \ \bar{x} - y\rangle \leq 0$ for any u of U. Since $\|f(\cdot, \cdot, \cdot)\|$ is bounded by M, the distance between $x(t)$ and $\bar{x}$ is not larger than Mt. Thus

$$\left(\frac{1}{2}\|x(t) - y\|^2\right)' \leq M^2 t + \ell\|x(t) - y\|^2.$$

This inequality is fulfilled for almost every $t \geq 0$. Gronwall's lemma yields

$$\forall t \geq 0, \ \|x(t) - y\|^2 \leq \|\bar{x} - y\|^2 e^{2\ell t} - \frac{M^2}{\ell}t + \frac{M^2}{2\ell^2}[e^{2\ell t} - 1]. \tag{15}$$

Note that the map $\phi : t \to -\frac{M^2}{\ell}t + \frac{M^2}{2\ell^2}[e^{2\ell t} - 1]$ vanishes at $t = 0$, and $\phi'(0) = 0$. Thus there are positive constants c and τ (which depend only on M and ℓ) such that

$$\forall t \in [0, \tau], \ -\frac{M^2}{\ell}t + \frac{M^2}{2\ell^2}[e^{2\ell t} - 1] \leq ct^2.$$

In particular, (15) yields

$$\forall t \in [0, \tau), \ d_D^2(x(t)) \leq \|x(t) - y\|^2 \leq d_D^2(\bar{x})e^{2\ell t} + ct^2.$$

So we have proved Lemma 4.4. □

5. Proof of the characterization theorem for the leadership kernel. In this section, we prove Theorem 2.4.

From now on, symbols involving α (like $\alpha(\cdot), \bar{\alpha}(\cdot)$), always denote nonanticipative strategies from $\mathcal{V}$ to $\mathcal{U}$.

Set

$$\begin{aligned}L := \{x_0 \in K \mid \forall \alpha(\cdot), \ \forall \epsilon > 0, \ \forall T > 0, \\ \exists v(\cdot) \in \mathcal{V} \text{ such that} \\ \forall t \leq T, \ x[x_0, \alpha(v(\cdot)), v(\cdot)](t) \in K + \epsilon B\}.\end{aligned}$$

We have to show that $L = Lead_f(K)$.

Inclusion $Lead_f(K) \subset L$ follows directly from Theorem 2.1. To prove the opposite inclusion, it is sufficient to show that L is a leadership domain, because $Lead_f(K)$ contains any leadership domain contained in K. For that purpose, we first prove that L is closed and then that L is a leadership domain.

L is closed. This claim is a consequence of the following lemma.

LEMMA 5.1. *If x belongs to K but not to L, there exist positive η, ϵ, and T and a nonanticipative strategy α such that, for any $y \in x + \eta B$, for any control $v(\cdot) \in \mathcal{V}$, the solution $x[y, \alpha(v), v]$ leaves $K + \epsilon B$ before T.*

In particular, the complement of L is open, and thus L is closed.

Proof of Lemma 5.1. From the very definition of L, there are positive ϵ and T and a nonanticipative strategy α, such that for any control v of $\mathcal{V}$, there is some $t \leq T$ with $x[x, \alpha(v), v](t) \notin K + 2\epsilon B$.

Since f is Lipschitz and V is compact, by Gronwall's lemma, there exists some $\eta > 0$ such that, for any $v \in \mathcal{N}$, for any $y \in x + \eta B$,

$$\|x[y, \alpha(v), v](t) - x[x, \alpha(v), v](t)\| \leq \epsilon, \text{ for } t \leq T.$$

Thus

$$\begin{aligned} &d_K(x[y, \alpha(v), v](t)) \\ &\quad \geq d_K(x[x_0, \alpha(v), v](t)) - \|x[y, \alpha(v), v](t) - x[x_0, \alpha(v), v](t)\| \geq \epsilon. \end{aligned}$$

This proves the lemma. □

L is a leadership domain. Assume that L is *not* a leadership domain. Then there is some $x_0 \in L$ such that

$$\text{(16)} \qquad \begin{cases} \exists \alpha(\cdot),\ \epsilon > 0,\ T > 0, \text{ such that } \forall v(\cdot) \in \mathcal{V} \\ \quad \exists t \leq T \text{ with } x[x_0, \alpha(v(\cdot)), v(\cdot)](t) \notin L + \epsilon B. \end{cases}$$

We are going to prove that, if x_0 satisfies (16), then it satisfies

$$\text{(17)} \qquad \begin{cases} \exists \bar{\alpha}(\cdot),\ \bar{\epsilon} > 0,\ \bar{T} > 0, \text{ such that } \forall v(\cdot) \in \mathcal{V} \\ \quad \exists t \leq \bar{T} \text{ with } x[x_0, \bar{\alpha}(v(\cdot)), v(\cdot)](t) \notin K + \bar{\epsilon} B. \end{cases}$$

Since (17) contradicts $x_0 \in L$, L is necessarily a leadership domain.

Let x_0 belong to L, and assume that x_0 satisfies (16). Let E be the closure of

$$\{y \notin L + \epsilon B \mid \exists v \in \mathcal{V} \text{ and } t \leq T \text{ with } y = x[x_0, \alpha(v), v](t)\}.$$

The set E is compact, because f has a linear growth. Moreover, $E \cap L = \emptyset$. For $x \in E$, we define $\eta_x > 0$, $\epsilon_x > 0$, $T_x > 0$, and $\alpha_x(\cdot)$ by the following statements:

- If $x \notin K$, then $\eta_x := d_K(x)/2$, $\epsilon_x := \eta_x$, $T_x := 0$, and $\alpha_x(\cdot) := \alpha(\cdot)$. (Recall that $\alpha(\cdot)$ is defined by (16).)
- If $x \in K$, then η_x, ϵ_x, T_x, and $\alpha_x(\cdot)$ are defined as in Lemma 5.1.

Note that $E \subset \bigcup_{x \in E}(x + \eta_x B)$. Thus there exist $x_1, \ldots, x_p$ belonging to E such that

$$\text{(18)} \qquad E \subset \bigcup_{i=1}^{p}(x_i + \eta_{x_i} B).$$

We are now ready to define

$$\bar{\epsilon} := \min_{i=1,\ldots,p} \epsilon_{x_i} \text{ and } \bar{T} := T + \max_{i=1,\ldots,p} T_{x_i}.$$

To define $\bar{\alpha}$, let us first define the hitting time of E:

$$\forall v(\cdot) \in \mathcal{V},\ \rho(v(\cdot)) := \inf\{t \geq 0 \mid x[x_0, \alpha(v), v](t) \in E\}.$$

Assumption (16) yields that $\rho(v(\cdot)) \leq T$ for any $v(\cdot)$ belonging to $\mathcal{V}$. Moreover, $x[x_0, \alpha(v(\cdot)), v(\cdot)](\rho(v(\cdot)))$ belongs to E, because E is closed.

We are now ready to define $\bar{\alpha}(v(\cdot))$.

• On $[0, \rho(v(\cdot))[$, we set $\bar{\alpha}(v(\cdot))(t) := \alpha(v(\cdot))(t)$.

• On $[\rho(v(\cdot)), +\infty)$, we set $\bar{\alpha}(v(\cdot))(t) := \alpha_i(v(\cdot))(t - \rho(v(\cdot)))$, where i is the smallest integer for which $x[x_0, \alpha(v), v](\rho(v(\cdot)))$ belongs to $x_i + \eta_i B$ (such an i exists from (18)).

We have to prove that $\bar{\alpha}$ is a nonanticipative strategy and that $\bar{\eta}$, $\bar{\epsilon}$, $\bar{T}$, and $\bar{\alpha}(\cdot)$ satisfy the conclusion of (17), i.e.,

$$\forall v(\cdot) \in \mathcal{V}, \ \exists t \leq \bar{T}, \text{ such that } x[x_0, \bar{\alpha}(v(\cdot)), v(\cdot)](t) \notin K + \bar{\epsilon}B.$$

$\bar{\alpha}$ is a nonanticipative strategy. Let $t > 0$ and let v_1 and v_2 belong to $\mathcal{V}$, such that v_1 and v_2 coincide almost everywhere on $[0, t]$. Let

$$t' = \max\{s \leq t \mid \bar{\alpha}(v_1) \equiv \bar{\alpha}(v_2) \text{ on } [0, s]\}.$$

Note that $x[x_0, \bar{\alpha}(v_1), v_1]$ and $x[x_0, \bar{\alpha}(v_2), v_2]$ coincide on $[0, t']$. We have to prove that $t' = t$. For that purpose, we have to discuss two cases.

(i) Assume that $t' < \rho(v_1)$. Then for any $s \leq t'$, $x[x_0, \bar{\alpha}(v_1), v_1](s) = x[x_0, \bar{\alpha}(v_2), v_2](s)$ does not belong to E. Since E is closed, there is $\theta > 0$ such that $\rho(v_1) \geq t' + \theta$ and $\rho(v_2) \geq t' + \theta$.

From the very definition of $\bar{\alpha}$, $\bar{\alpha}(v_1)$ equals $\alpha(v_1)$ on $[0, t' + \theta]$, and $\bar{\alpha}(v_2)$ equals $\alpha(v_2)$ on $[0, t' + \theta]$. Since α is nonanticipative, $\bar{\alpha}(v_1)$ and $\bar{\alpha}(v_2)$ coincide almost everywhere on $[0, \min(t, t' + \theta)]$. So $t' = \min(t, t' + \theta)$, and thus $t' = t$.

(ii) Assume now that $t' \geq \rho(v_1)$. Since $\bar{\alpha}(v_1)$ and $\bar{\alpha}(v_2)$ coincide almost everywhere on $[0, t']$, one has $\rho(v_1) = \rho(v_2)$. We denote by ρ this common value. Let i be the smallest integer such that $x[x_0, \bar{\alpha}(v_1), v_1](\rho) = x[x_0, \bar{\alpha}(v_2), v_2](\rho)$ belongs to $x_i + \eta_i B$.

From the very definition of $\bar{\alpha}$, $\bar{\alpha}(v_1)(t) = \alpha_i(v_1)(t - \rho)$ on $[\rho, \infty)$ and $\bar{\alpha}(v_2)(t) = \alpha_i(v_2)(t - \rho)$ on $[\rho, \infty)$. Since α_i is nonanticipative and since v_1 and v_2 coincide almost everywhere on $[\rho, t]$, $\bar{\alpha}(v_1)$ and $\bar{\alpha}(v_2)$ coincide almost everywhere on $[\rho, t]$. Thus $t = t'$.

In both cases we have proved that, for any $t \geq 0$, if v_1 and v_2 coincide almost everywhere on $[0, t]$, then $\bar{\alpha}(v_1)$ and $\bar{\alpha}(v_2)$ coincide almost everywhere on $[0, t]$. So $\bar{\alpha}$ is nonanticipative.

$\bar{\eta}$, $\bar{\epsilon}$, $\bar{T}$, and $\bar{\alpha}(\cdot)$ satisfy (17). Let v belong to $\mathcal{V}$. We want to prove that $x(\cdot) := x[x_0, \bar{\alpha}(v), v]$ leaves $K + \bar{\epsilon}$ before $\bar{T}$.

From the very definitions of $\bar{\alpha}(v)$ and α, $x(\cdot)$ reaches E at a time $\rho(v) \leq T$. Let i be the smallest integer such that $x(\rho(v))$ belongs to $x_i + \eta_i B$. Suppose either $x_i \notin K$ or $x_i \in K$. If $x_i \notin K$, then

$$d_K(x(\rho(v))) \geq d_K(x_i) - \|x_i - x(\rho(v))\| \geq 2\eta_i - \eta_i \geq \bar{\epsilon}.$$

If $x_i \in K$, then since $\bar{\alpha}(v)(\cdot) = \alpha_i(\cdot - \rho(v))$ on $[\rho(v), \infty)$, $x(\cdot)$ leaves $K + \epsilon_i B$ before $\rho(v) + T_i \leq \bar{T}$; this follows from Lemma 5.1 and from the very definition of $\alpha_i(\cdot)$. In both cases, $x(\cdot)$ leaves $K + \bar{\epsilon}B$ before $\bar{T}$.

So we have proved that (16) implies (17) and so the proof is complete. □

6. Appendix. We now provide a proof of the following lemma.

LEMMA 6.1 (Plaskacz). *Let $B(\cdot) : \mathcal{U} \to \mathcal{V}$ be a nonanticipative set-valued map with nonempty, closed values for the weak topology of $L^2(\mathbb{R}^+, V, e^{-t})$. There is a nonanticipative selection $\beta(\cdot)$ of $B(\cdot)$.*

Proof of Lemma 6.1. Let $\mathcal{B}$ be the set of the set-valued maps $A : \mathcal{U} \rightsquigarrow \mathcal{V}$ with weakly compact nonempty values, which are nonanticipative and which moreover satisfy $A(u(\cdot)) \subset B(u(\cdot))$ for any $u(\cdot)$ belonging to $\mathcal{M}$.

There is a natural partial order on $\mathcal{B}$:

$$[A_1 \preceq A_2] \Leftrightarrow [\forall u(\cdot) \in \mathcal{M},\ A_1(u(\cdot)) \subset A_2(u(\cdot))].$$

The proof is divided into two steps. In the first step, we prove that the order $\preceq$ is inductive. Then Zorn's lemma yields the existence of minimal set-valued maps for $\preceq$. In the second step, we show that minimal set-valued maps are maps, which achieves the proof.

$\preceq$ *is inductive.* For this purpose, let $(A_\lambda)_{\lambda\in\Lambda}$ be a totally ordered subset of $\mathcal{B}$. We denote by A the set-valued map

$$\forall u(\cdot) \in \mathcal{U},\ A(u(\cdot)) := \bigcap_{\lambda\subset\Lambda} A_\lambda(u(\cdot)).$$

Then obviously, $A \preceq A_\lambda$ for any $\lambda \in \Lambda$. We have to prove that A belongs to $\mathcal{B}$. So we have to show that (1) for any $u(\cdot) \in \mathcal{U}$, $A(u(\cdot))$ is nonempty, weakly compact, and contained in $B(u(\cdot))$ and (2) A is a nonanticipative set-valued map.

(1) For any $u(\cdot) \in \mathcal{U}$, $A_\lambda(u(\cdot))$ is a nonempty and weakly compact set, and the family $(A_\lambda(u(\cdot)))$ is totally ordered for the inclusion. Since the decreasing intersection of nonempty compact sets is nonempty and compact, A has nonempty weakly compact values. For any $u(\cdot) \in \mathcal{U}$, for any $\lambda \in \Lambda$, $A_\lambda(u(\cdot))$ is contained in $B(u(\cdot))$. Thus $A(u(\cdot))$ is contained in $B(u(\cdot))$.

(2) It remains to prove that A is nonanticipative. Let $s \geq 0$, and assume that $u_1(\cdot)$ coincides with $u_2(\cdot)$ on $[0, s]$. Let $v_1(\cdot)$ belong to $A(u_1(\cdot))$. We have to find $v_2(\cdot) \in A(u_2(\cdot))$ which coincides with $v_1(\cdot)$ on $[0, s]$.

Since $v_1(\cdot)$ belongs to $A(u_1(\cdot))$, $v_1(\cdot)$ belongs to $A_\lambda(u_1(\cdot))$ for any $\lambda \in \Lambda$. The set-valued maps A_λ are nonanticipative, so, for each λ, there exists $v_2^\lambda(\cdot) \in A_\lambda(u_2(\cdot))$, which coincides with $v_1(\cdot)$ on $[0, s]$.

Fix $\lambda \in \Lambda$, and set

$$P_\lambda := \text{closure}\{v_2^{\lambda'}(\cdot) \mid A_{\lambda'} \preceq A_\lambda\},$$

where the closure denotes the weak closure. Note that, for any $w(\cdot)$ belonging to $\{v_2^{\lambda'}(\cdot) \mid A_{\lambda'} \preceq A_\lambda\}$, $w(\cdot)$ coincides with $v_1(\cdot)$ on $[0, s]$. We use the following lemma to prove that this property also holds true for any $w(\cdot) \in P_\lambda$.

LEMMA 6.2. *Let E be a subset of $\mathcal{V}$ such that there exist $v_1(\cdot) \in \mathcal{V}$ and $s > 0$ with*

$$\forall w \in E,\ w \equiv v_1 \text{ almost everywhere on } [0, s].$$

Then the weak closure $\bar{E}$ of E also enjoys the following property:

$$\forall w \in \bar{E},\ w \equiv v_1 \text{ almost everywhere on } [0, s].$$

Proof. Let w belong to $\bar{E}$. There exists a sequence $w_p \in E$ which converges weakly to w. Thus,

$$\forall t \leq s,\ \int_0^t w_p(\sigma)d\sigma \to \int_0^t w(\sigma)d\sigma.$$

Since, by assumption, w_p and v_1 coincide on $[0, s]$, one has

$$\forall t \in [0, s],\ \int_0^t w_p(\sigma)d\sigma = \int_0^t v_1(\sigma)d\sigma.$$

So,

$$\forall t \in [0, s], \int_0^t w(\sigma)d\sigma = \int_0^t v_1(\sigma)d\sigma.$$

Thus w coincides with v_1 almost everywhere on $[0, s]$. □

Lemma 6.2 states that the elements of P_λ coincide with $v_1(\cdot)$ on $[0, s]$. The family P_λ is a decreasing family of weakly compact sets and P_λ is contained in $A_\lambda(u_2(\cdot))$ for any λ. Thus the set P defined by

$$P := \bigcap_{\lambda \in \Lambda} P_\lambda$$

is nonempty and compact. Moreover,

$$[\forall \lambda \in \Lambda,\ P_\lambda \subset A(u_2(\cdot))] \Rightarrow \left[P \subset \bigcap_{\lambda \in \Lambda} A_\lambda(u_2(\cdot)) = A(u_2(\cdot)) \right].$$

Since, for any $v_2(\cdot)$ belonging to P, $v_2(\cdot)$ belongs to P_λ, $v_2(\cdot)$ coincides with $v_1(\cdot)$ almost everywhere on $[0, s]$. So there exists $v_2(\cdot)$ which belongs to $A(u_2(\cdot))$ and coincides with $v_1(\cdot)$ on $[0, s]$.

For any $s \geq 0$, for any $u_1(\cdot)$ and $u_2(\cdot)$ which coincide almost everywhere on $[0, s]$, for any $v_1(\cdot)$ belonging to $A(u_1(\cdot))$, there exists $v_2(\cdot) \in A(u_2(\cdot))$ which coincides with $v_1(\cdot)$ almost everywhere on $[0, s]$. Thus A is nonanticipative, with nonempty compact values, and with a graph contained in the graph of B, i.e., A belongs to $\mathcal{B}$.

We have proved that the partial order on $\mathcal{B}$ is inductive. Zorn's lemma states that there exist minimal elements for this order. Let $\beta(\cdot) \in \mathcal{B}$ be such a minimal element. We claim that $\beta(\cdot)$ is a map. If our claim holds true, $\beta(\cdot)$ is a nonanticipative selection of B from the very definition of $\mathcal{B}$, and the proof of Lemma 6.1 is complete.

Minimal set-valued maps for $\preceq$ are maps. Assume that, contrary to our claim, the minimal set-valued map β is not a map. There exists $\bar{u}(\cdot) \in \mathcal{U}$, such that the cardinal of $\beta(\bar{u}(\cdot))$ is larger than 1. Let $\bar{v}(\cdot)$ belong to $\beta(\bar{u}(\cdot))$. We are going to construct a set-valued map $A \in \mathcal{B}$, such that $A \preceq \beta$ and $A(\bar{u}(\cdot)) = \{\bar{v}(\cdot)\}$ (in particular, $A \neq \beta$). Thus we obtain a contradiction, because, from the assumption, β is supposed to be minimal.

For any $u(\cdot) \in \mathcal{U}$, we define $A(u(\cdot))$ in the following way.

- If $u(\cdot) = \bar{u}(\cdot)$, we set $A(\bar{u}(\cdot)) := \{\bar{v}(\cdot)\}$.
- If $u(\cdot)$ does not coincide with $\bar{u}(\cdot)$ on any interval $[0, s]$ $(s > 0)$, then we set $A(u(\cdot)) := \beta(u(\cdot))$.
- If $u(\cdot)$ coincides with $\bar{u}(\cdot)$ on some interval $[0, t]$, let $[0, s]$ be the maximal interval on which $\bar{u}(\cdot)$ and $u(\cdot)$ coincide. Then we set

$$A(u(\cdot)) := \{w(\cdot) \in \beta(u(\cdot)) \mid w(\cdot) \equiv \bar{v}(\cdot) \text{ a.e. on } [0, s]\}.$$

Note that $A(u(\cdot)) \subset \beta(u(\cdot))$ for any $u(\cdot)$ belonging to $\mathcal{M}$ and that $A(\bar{u}(\cdot)) = \{\bar{v}(\cdot)\}$. So it remains to prove that A belongs to $\mathcal{B}$.

Since β is nonanticipative and has nonempty values, A has nonempty values. The graph of A is contained in the graph of β, and thus is contained in the graph of B. Moreover, the values of β are weakly compact, so by Lemma 6.2 the values of A are also weakly compact.

Next we prove that A is nonanticipative. For this purpose, let $s > 0$ and assume that $u_1(\cdot)$ and $u_2(\cdot)$ coincide almost everywhere on $[0, s]$. Without loss of generality, we also assume that $[0, s]$ is the maximal interval on which $u_1(\cdot)$ and $u_2(\cdot)$ coincide. Let v_1 belong to $A(u_1(\cdot))$. We have to find $v_2(\cdot) \in A(u_2(\cdot))$ which coincides with $v_1(\cdot)$ on $[0, s]$. There are two cases.

(1) $u_1(\cdot)$ does not coincide with $\bar{u}(\cdot)$ on any interval $[0, t]$ $(t > 0)$. In this case, $v_1(\cdot)$ belongs to $\beta(u_1(\cdot))$. Note moreover that $u_2(\cdot)$ does not coincide with $\bar{u}(\cdot)$ on any interval $[0, t]$ $(t > 0)$, because $u_1(\cdot)$ and $u_2(\cdot)$ coincide on $[0, s]$. Since β is nonanticipative, there is $v_2(\cdot)$ which belongs to $\beta(u_2(\cdot)) = A(u_2(\cdot))$ and which coincides with $v_1(\cdot)$ on $[0, s]$.

(2) $u_1(\cdot)$ coincides with $\bar{u}(\cdot)$ on $[0, t]$. We denote by $[0, t_1]$ the maximal interval on which $u_1(\cdot)$ and $\bar{u}(\cdot)$ coincide and by $[0, t_2]$ the maximal interval on which $u_2(\cdot)$ and $\bar{u}(\cdot)$ coincide. Note that, from the construction of A, $v_1(\cdot)$ and $\bar{v}(\cdot)$ coincide on $[0, t_1]$.

We have to find $v_2(\cdot) \in A(u_2(\cdot))$ which coincides with $v_1(\cdot)$ almost everywhere on $[0, s]$. From the construction of A, this is equivalent to finding $v_2(\cdot) \in \beta(u_2(\cdot))$ which coincides with $v_1(\cdot)$ on $[0, s]$ and with $\bar{v}(\cdot)$ on $[0, t_2]$.

We first prove that, in the set $\{s, t_1, t_2\}$, there are two elements that are equal and smaller than or equal to the third one. Indeed, assume for instance that $s \geq t_1 \geq t_2$. Then

$$\left.\begin{array}{l} u_1(\cdot) \equiv u_2(\cdot) \text{ on } [0, s], \\ u_1(\cdot) \equiv \bar{u}(\cdot) \text{ on } [0, t_1] \end{array}\right\} \Rightarrow u_2(\cdot) \equiv \bar{u}(\cdot) \text{ on } [0, t_1].$$

So $t_2 = t_1$. The other cases (i.e., $t_1 \geq t_2 \geq s$, and so on) can be treated in the same way. To find the desired $v_2(\cdot)$, we have to study three cases.

(1) $s \geq t_1 = t_2$. Since β is nonanticipative, we can find $v_2(\cdot) \in \beta(u_2(\cdot))$ which coincides with $v_1(\cdot)$ on $[0, s]$. Since $v_1(\cdot)$ coincides with $\bar{v}(\cdot)$ on $[0, t_1]$, $v_2(\cdot)$ coincides with $\bar{v}(\cdot)$ on $[0, t_2]$ because $t_1 = t_2$ and $s \geq t_2$. Thus $v_2(\cdot)$ belongs to $A(u_2(\cdot))$ and coincides with $v_1(\cdot)$ on $[0, s]$.

(2) $t_1 \geq s = t_2$. The same argument applies.

(3) $t_2 \geq s = t_1$. Since β is nonanticipative, we can find $v_2(\cdot) \in \beta(u_2(\cdot))$ which coincides with $\bar{v}(\cdot)$ on $[0, t_2]$. In particular, $v_2(\cdot)$ belongs to $A(u_2(\cdot))$ from the construction of A. Since $\bar{v}(\cdot)$ coincides with $v_1(\cdot)$ on $[0, t_1]$, $v_2(\cdot)$ and $v_1(\cdot)$ coincide on $[0, s]$ because $s = t_1$ and $s \leq t_2$.

So in any case, we have found $v_2(\cdot) \in A(u_2(\cdot))$ which coincides with $v_1(\cdot)$ on $[0, s]$. Thus A is nonanticipative, which completes the proof. □

INFORMATION CAPACITY OF CHANNELS WITH PARTIALLY UNKNOWN NOISE. II. INFINITE-DIMENSIONAL CHANNELS*

C. R. BAKER† AND I.-F. CHAO‡

Abstract. Information capacity is considered for a communication channel in which the noise is the sum of a known Gaussian component and an independent component with unknown statistical distributions. A lower bound on capacity is sought; the unknown noise component is thus assumed to be under the control of an adversary—a jammer. The problem is modeled as a zero-sum two-person game with mutual information as the payoff function. Appropriate constraints are determined on the transmitted signal and the unknown noise component. Although the usual conditions sufficient for application of the general form of the von Neumann minimax theorem are shown not to hold, a solution is obtained for the game: a saddle value, saddle point, and minimax strategy for the jammer are obtained. The essential effect of jamming is to convert the infinite-dimensional channel into a finite-dimensional channel having the same constraints, with the dimensionality depending upon the problem parameters: the covariance of the known Gaussian noise component and the constraints on the transmitted signal and the unknown noise component.

Key words. Shannon theory, channel capacity, information capacity, jamming

AMS subject classifications. 94A15, 94A40, 90D80

1. Introduction.

The subject of this paper is a communication channel in which the noise is the sum of a known Gaussian component and an independent component with unknown statistical distributions. An example is when the interference is the sum of a Gaussian receiver noise and an unknown noise in the transmission medium. One may then ask for the worst-case capacity of the channel; that is, when "nature" chooses the unknown noise component to be that which is least favorable to the channel user, or coder. A natural way to view this problem is that of a jamming channel, where the unknown noise is controlled by a hostile jammer who seeks to minimize the information capacity of the channel.

Information capacity of such a channel is determined in [7] under the assumption that the channel is finite dimensional. By "information capacity" we mean here a saddle point solution to a zero-sum two-person game in which mutual information is the payoff function and the admissible strategies for coder and jammer are determined by constraints on the stochastic signals of the coder and jammer.

In this paper this problem is solved for the infinite-dimensional channel: a channel in which all sample paths belong to a real separable Hilbert space, H, with inner product $\langle \cdot, \cdot \rangle$ and norm $\| \cdot \|$. A concrete example is when H is the M-fold product of $L_2[0, T]$; f in H is of the form $f = (f_1, f_2, \ldots, f_M)$, each f_i belonging to $L_2[0, T]$; and $\|f\| = [\sum_{i=1}^{M} \int_0^T f_i^2(t)dt)]^{1/2}$.

Very substantial differences exist between this problem and that for the finite-dimensional channel. In the latter, the initial problem can be reformulated so that a saddle point solution is guaranteed by the von Neumann minimax theorem. Moreover, the solution can be obtained, after some development, by application of constrained optimization and the Kuhn–Tucker conditions. For the infinite-dimensional channel, it will be seen that the von Neumann theorem cannot be applied. Thus, one does not know in advance whether a saddle value exists, much less a saddle point. Moreover, constrained optimization is not available. Nevertheless, we shall prove the existence of a saddle point, obtain the saddle value, and in the process give a minimax strategy for the jammer.

The results have potential interest from several viewpoints. One, of course, is that mutual information is a mathematical quantity that accompanies every finite measure on a measurable product space. Game-theoretic formulations with mutual information as payoff function may be of interest to model and analyze various competitions (e.g., in economics), quite aside from communication over noisy channels. For such applications, more general models than those suitable for an additive-interference communication channel may be needed; some results in this direction are given in [1]. Additional generality can be added in various ways; for example, as in [5], finitely additive measures can be included. The problem in a communication channel framework is of long standing, first enunciated by Blachman [10] and Dobrushin [12] as an intrinsic measure of a channel's ability to convey information. A sufficient rationale for the present work and [7] is to give a solution to the game-theoretic problem first described by these authors over 35 years ago.

The results may also have practical use in obtaining coding capacity of communication channels. Information capacity is often used to obtain coding capacity in the sense that the former is typically an upper bound on the latter, and for Gaussian channels, the two are equal, at least for dimension-limited channels [4], [5], where the elements of the code word set must each satisfy an energy constraint. The finite-dimensional results of [7] are sufficient for this purpose in the case of the discrete-time channel. However, for continuous-time channels, one obtains the upper bound on coding capacity in the classical approach by computing the information capacity for each value of T, thus obtaining a quantity C_T, and then taking $\limsup_{T\to\infty} C_T/T$. C_T is computed for the channel having sample functions in $L_2[0, T]$ or its M-fold product.

Another approach to coding capacity of continuous-time channels is given in [4] and [5], where, rather than having the transmission time period increase and included in the constraint, the length of transmission is fixed and the dimensionality of the code word set is incorporated into the constraint. The motivation is that complexity can be as important in cost analysis as the time of transmission—perhaps more so—and that implemented communication channels are necessarily time limited. In this framework, the development involves computation of $\limsup_{n\to\infty} C(n)/n$, where n is the permitted dimensionality of the code word set and $C(n)$ is the capacity of the $L_2[0,T]$ channel when the coder is subject to this constraint.

For solving the first of the two problems just described, knowledge of the information capacity for the infinite-dimensional channel appears necessary; for the second, it seems at least helpful. Thus, the solution of the problem considered here appears to be a useful—perhaps essential—step in order to obtain coding capacity for continuous-time channels subject to jamming. Finally, we note that the basic problem—a channel where the noise is the sum of a known Gaussian component and an independent component with unknown distributions—arises very frequently in applications.

Channels such as those analyzed here are usually characterized as "compound," which refers to a channel known only to the extent that it belongs to a specified family. The family of channels admitted here is defined by energy-type constraints on the jammer and the coder which take into account the properties of the ambient Gaussian noise.

Recent work on the game-theoretic analysis of information capacity has primarily been done by McEliece and his collaborators [11], [18], [19]. Although their work includes analysis of some quantized channels, its intersection with our work is for an essentially one-dimensional Gaussian channel in which the jammer controls all of the noise.

The present work is for the general channel; there is no limitation such as stationarity, memory, or univariate nature. It is anticipated that $\lim_{T\to\infty} C_T/T$ can be given in terms of spectral densities for the stationary Gaussian channel subject to jamming. This can presumably be obtained through limiting arguments based on the results given here, in the same way that

the results of [3] have been used to obtain $\lim_{T\to\infty} C_T/T$ of stationary Gaussian channels without jamming [6].

Previous publications on analysis of channels subject to jamming include papers in which either coding capacity or minimization of mean-square signal distortion is the criterion. Among the former is the Gaussian arbitrarily varying channel (AVC). As analyzed in the existing literature (e.g., [14], [15]), this is an inherently discrete-parameter channel in which the noise is the sum of a known Gaussian process with independent components and (usually) constant variance and a jamming process with unknown statistical properties, with the transmitted signal and the jamming process subject to average or peak power constraints. Comparisons with our approach will thus first require applications of the results of [7] to obtain coding capacity for discrete-time channels. However, extension of the published AVC models and methods to general infinite-dimensional channels is not immediately obvious, especially for continuous-time channels.

An approach to modeling and analysis of jamming channels that can be applied to continuous-time channels has been taken by Basar and Basar [9]. Their work involves the use of mean-square signal distortion as the criterion of optimality and is not directly comparable to our approach.

Additional discussion of related work is contained in [7].

2. Mathematical model. The channel sample paths are described by $Y = X + W + J$, where X is the coder's signal, W is the ambient Gaussian noise, and J is the noise component controlled by the jammer. X, W, and J are mutually independent. These quantities are described by the probabilities μ_X, μ_W, and μ_J on the Borel sets of H; all are assumed countably additive and second order (i.e., $\int_H \|x\|^2 d\mu(x) < \infty$) so that their covariance operators are necessarily trace class. The (average) mutual information of interest is

$$I(X, Y) = I(\mu_{XY}) = \int_{H\times H} \left[\log \frac{d\mu_{XY}}{d\mu_X \otimes \mu_Y}(x, y)\right] d\mu_{XY}(x, y),$$

where $\mu_X \otimes \mu_Y$ denotes product measure and $\mu_{XY}(A) = \mu_X \otimes \mu_W \otimes \mu_J\{(x, w, v) : (x, x + w + v) \in A\}$. $I(\mu_{XY}) \equiv \infty$ when μ_{XY} is not absolutely continuous with respect to $\mu_X \otimes \mu_Y$.

Under these assumptions, μ_X, μ_W, and μ_J have covariance operators R_X, R_W, and R_J: e.g., $\langle R_W u, v\rangle = \int_H \langle x, u\rangle \langle x, v\rangle d\mu_W(x)$. We assume without loss of generality (WLOG) that R_W is strictly positive on H and that all probabilities are zero-mean.

The assumptions imply the existence of a self-adjoint operator S, possibly unbounded, satisfying $R_W + R_J = R_W^{1/2}(I + S)R_W^{1/2}$ or, equivalently, $R_J = R_W^{1/2} S R_W^{1/2}$, where $\text{range}(R_W^{1/2}) \subset \mathcal{D}(S)$, the domain of S [3]. The operator $(I + S)^{-1}$ exists, since S is nonnegative and necessarily bounded, since $\text{range}(R_W^{1/2}) \subset \text{range}(R_W + R_J)^{1/2}$. $R_W = \sum_{n\geq 1} \lambda_n e_n \otimes e_n$, where $\lambda_n > 0$ and $\lambda_n \geq \lambda_{n+1}$ for all $n \geq 1$, $\sum_{n\geq 1} \lambda_n < \infty$, $\{e_n, n \geq 1\}$ is a complete orthonormal set (CONS) for H, and $(e_n \otimes e_n)v \equiv \langle e_n, v\rangle e_n$.

The constraints on the coder are given by $\mu_X[\text{range}(R_W^{1/2})] = 1$ and $E_{\mu_X}\|x\|_W^2 \leq P_1$, where for x in $\text{range}(R_W^{1/2})$, $\|x\|_W^2 \equiv \|R_W^{-1/2}x\|^2$. Such constraints are necessary for the capacity without jamming to be finite [2]. This constraint amounts to a RKHS (reproducing kernel Hilbert space) constraint on the coder's energy in terms of the RKHS of the ambient channel noise covariance. As such, it limits the amount of energy that the coder can place into regions where the ambient noise energy is small.

The jammer's constraint is given by $E_{\mu_J}\|x\|^2 \leq P_2$. The stronger constraints $\mu_J[\text{range}(R_W^{1/2})] = 1$ and $E_{\mu_J}\|x\|_W^2 \leq P_2$ might be thought reasonable, since they are consistent with those imposed on the coder. However, they are too strong; the jammer would not be

able to have any effect on the information capacity under these constraints. This can be seen from the results of [3]; from Theorem 3 of that paper, if S is nonnegative and has zero as the only limit point of its spectrum, then the capacity is equal to $P_1/2$. This situation would hold if one used the constraints $\mu_J[\text{range}(R_W^{1/2})] = 1$ and $E_{\mu_J}\|x\|_W^2 \leq P_2$, since the inequality (using the fact that $R_J = R_W^{1/2} S R_W^{1/2}$) is the same as Trace $S \leq P_2$. Thus, the jammer's constraint must be weaker than that of the coder.

The constraint $E_{\mu_J}\|x\|^2 \leq P_2$ places a constraint on the total jammer energy but not on the relative jammer/noise energy. In terms of frequency, this means that the jammer can use signals that have relatively large energy compared to the noise energy in appropriate frequency ranges. Such a constraint has an immediate intuitive interpretation. The jammer's optimum policy should be that of adding the available energy to the ambient noise energy in such a way that the sum provides maximum interference to the coder. The jammer will thus want to place the available energy in regions available to the coder in which the noise energy is small, and this is provided by the above constraint. The use of the RKHS constraint $E_{\mu_J}\|x\|_W^2 \leq P_2$ would permit the jammer to place the available energy in regions that are available to the coder and with the same flexibility as permitted to the coder. However, it also limits the jammer's energy relative to the ambient noise energy and is evidently too strong for the jammer to have an effect. This may be regarded as somewhat surprising and is one of the first differences that one sees in going from the finite-dimensional to the infinite-dimensional channel. It means that, with the coder selecting the optimum strategy, the jammer cannot reduce the information capacity if the energy limitation on the jammer is subject to the same type of RKHS constraint as that applied to the coder, regardless of the value of P_2, i.e., regardless of the total amount of energy available to the jammer. As already mentioned, the constraint applied to the coder is implied by any constraint that gives finite information capacity in the absence of jamming.

In the form given above, there is no constraint on the probability distribution of the jammer's signal other than $E_{\mu_J}\|x\|^2 \leq P_2$. However, it follows from [16] that for a given R_J, the information capacity (coder's viewpoint) will be minimized by taking μ_J to be Gaussian. *Thus, the jammer should always choose μ_J to be Gaussian, and this will be assumed henceforth.* With this assumption, the jamming channel is a special case of the mismatched Gaussian channel: a Gaussian channel such that the constraint covariance R_W is not the same as the noise covariance [3].

The jammer's strategy is now uniquely determined by the choice of the operator S. For a given strategy, the mutual information can be expressed as [3]

$$I(\mu_{XY}) = F(\mathbf{z}, \alpha) = \frac{1}{2}\sum_n \log\left[1 + z_n(1+\alpha_n)^{-1}\right],$$

where (z_n) and (α_n) are defined as follows. The coder's covariance operator R_X is given by

$$R_X = \sum_n \tau_n (R_W + R_J)^{\frac{1}{2}} u_n \otimes (R_W + R_J)^{\frac{1}{2}} u_n,$$

where $\{u_n, n \geq 1\}$ is a CONS in H, $\tau_n > 0$ for $n \geq 1$, and $\sum_n \tau_n < \infty$. Then

$$\alpha_n \equiv \left\langle SU^* u_n, U^* u_n \right\rangle \qquad \text{and} \qquad z_n \equiv \tau_n \|(I+S)^{\frac{1}{2}} U^* u_n\|^2,$$

where U^* is the unitary operator satisfying $(R_W + R_J)^{1/2} = R_W^{1/2}(I+S)^{1/2}U^*$.

The problem to be considered is to determine if there exists a saddle value for the zero-sum two-person game with $I(\mu_{X,Y})$ as the payoff function; further, if a saddle value exists, then determine whether a saddle point exists; if such a point exists, then give its definition. That

is, we seek to determine whether

$$\sup_{z} \inf_{\alpha} F(\mathbf{z}, \alpha) = \inf_{\alpha} \sup_{z} F(\mathbf{z}, \alpha), \tag{1}$$

where the sup and inf are taken over the admissible signals for the coder and jammer, respectively. If this equality holds, then it defines the saddle value. In that case, one seeks to determine if the saddle value is actually attained by an admissible pair $(\mathbf{z}, \alpha)$, i.e., if a saddle point exists.

The admissible strategies for the coder and the jammer are given by the two constraints defined above. For the coder, the constraint is given by $\sum_n z_n \leq P_1$. Let $\mathcal{C}$ be the set of all densely defined symmetric nonnegative linear operators S on H such that the domain of S contains the range of $R_W^{1/2}$.The constraint on the jammer is that $R_J = R_W^{1/2} S R_W^{1/2}$ for some S in $\mathcal{C}$ such that Trace $R_W^{1/2} S R_W^{1/2} \leq P_2$.

The smallest limit point of the spectrum of S will be denoted by θ. The set of limit points of the spectrum ($\equiv$ the essential spectrum, $\sigma_{\text{ess}}(S)$) of S consists of all eigenvalues of infinite multiplicity, limit points of distinct eigenvalues, and other points of the continuous spectrum. As usual, S is said to have pure point spectrum if it has a CONS of eigenvectors. In this case, the continuous spectrum may not be empty, since any limit point of distinct eigenvalues which is itself not an eigenvalue will belong to the continuous spectrum. The sequence (γ_n) will denote the eigenvalues of S that are strictly less than θ, repeated according to their multiplicity; $\{v_n, n \geq 1\}$ will denote the corresponding eigenvectors. The following result is essential to our development.

LEMMA 1 (see [3, Thm. 3 and Cor. 4]). *Suppose that the jammer's strategy is fixed and (WLOG) order (γ_n) as a nondecreasing sequence.*

(1) *Suppose that $\theta < \infty$. The information capacity $C_W(P_1)$ is then given as follows.*

(a) *If $\{\gamma_n, n \geq 1\}$ is not empty and $\sum_n (\theta - \gamma_n) \leq P_1$, then*

$$C_W(P_1) = \frac{1}{2} \sum_{n=1}^{K} \log \left[\frac{1+\theta}{1+\gamma_n} \right] + \frac{1}{2} \frac{P_1 + \sum_{m=1}^{K} (\gamma_m - \theta)}{1+\theta}$$

(b) *If $\{\gamma_n, n \geq 1\}$ is empty, then $C_W(P_1) = P_1/[2(1+\theta)]$.*

(c) *In* (a), *the capacity can be attained if and only if $P_1 = \sum_{n \geq 1} (\theta - \gamma_n)$. In that case, it is uniquely attained by a Gaussian μ_X with covariance $R_X = \sum_{n \geq 1} \tau_n R_N^{1/2} u_n \otimes R_N^{1/2} u_n$, where $u_n = U v_n$ and $\tau_n = (\theta - \gamma_n)(1+\gamma_n)^{-1}$; for all $n \geq 1$ if (γ_n) is an infinite sequence; for $1 \leq n \leq K$ and $\tau_n = 0$ for $n > K$ when (γ_n) is a finite sequence with K elements. If $P_1 > \sum_{n \geq 1} (\theta - \gamma_n)$, then capacity can be approached as closely as desired by using a covariance R_X of the above form. In (b), the capacity cannot be attained.*

(d) *If $\{\gamma_n, n \geq 1\}$ is not empty, (γ_n) is an infinite sequence, and $P_1 < \sum_n (\theta - \gamma_n)$, then an integer M exists such that $M\gamma_{M+1} > P_1 + \sum_{i=1}^{M} \gamma_i \geq M\gamma_M$ and then*

$$C_W(P_1) = \frac{1}{2} \sum_{i=1}^{M} \left[\frac{P_1 + \sum_{k=1}^{M} \gamma_k + M}{M(1+\gamma_i)} \right].$$

(e) *If $\{\gamma_n, n \geq 1\}$ is not empty, (γ_n) is a finite sequence containing exactly L elements, and $P_1 < \sum_n (\theta - \gamma_n)$, then the following hold:*

(i) *If $P_1 + \sum_{i=1}^{L} \gamma_i \geq L\gamma_L$, then the capacity is given as in* (d), *with $M = L$;*

(ii) *If $M\gamma_{M+1} > P_1 + \sum_{i=1}^{M} \gamma_i \geq M\gamma_M$ for some $M < L$, then the capacity is given as in* (d).

(2) *If $\theta = \infty$, then the information capacity is obtained (and only obtained) by using a Gaussian μ_X having M-dimensional support, with M the smallest integer such that $M\gamma_{M+1} > P_1 + \sum_{i=1}^{M} \gamma_i \geq M\gamma_M$. The capacity $C_W(P_1)$ is then given by*

$$C_W(P_1) = \frac{1}{2} \sum_{i=1}^{M} \left[\frac{P_1 + \sum_{k=1}^{M} \gamma_k + M}{M(1+\gamma_i)} \right].$$

LEMMA 2. *A minimax strategy for the jammer, if it exists, requires an operator S having pure point spectrum with $\theta < \infty$ and all eigenvalues $\leq \theta$ with only a finite number being zero. If $\{\gamma_n, n \geq 1\}$ is not empty, then a minimax strategy requires that $P_1 \geq \sum_{n\geq 1}(\theta - \gamma_n)$ and that $P_1 + \sum_1^M \gamma_n \geq M\gamma_M$ for all γ_M.*

Proof. If the smallest limit point of the spectrum is infinite, then it must occur as a limit point of eigenvalues and then S has pure point spectrum. Suppose that $\gamma_n \nearrow \theta = \infty$. Applying the expression for information capacity given in (2) of Lemma 1, let M be the smallest integer such that $M\gamma_{M+1} > P_1 + \sum_{i=1}^{M} \gamma_i \geq M\gamma_M$. Let $K < M$ be such that $\gamma_K < \gamma_M$. (If no such K exists, then the following argument applies with γ_K replaced by γ_M, since then $P_1 + \sum_{i=1}^{M} \gamma_i > M\gamma_M$.) An increase of ε in the value of γ_K will result in a strict decrease in the value of $C_W(P_1)$. Define a sequence (γ_n') such that $\gamma_n' = \gamma_n$ for $n \notin \{K, M+1\}$, $\gamma_K' = \gamma_K + \varepsilon$, $\gamma_{M+1}' = \gamma_{M+1} - \delta$, with ε and δ satisfying $M(\gamma_{M+1} - \delta) > P_1 + \sum_{i=1}^{M} \gamma_i + \varepsilon \geq \max(M\gamma_M, M\gamma_K + M\varepsilon)$. A jammer covariance defined by the operator S' having eigenvalues (γ_n') will give the same value of the integer M defined in (2) of Lemma 1 as given by the original S. To ensure that the constraint on the jammer remains satisfied by the new sequence (γ_n'), one notes that for $R_W^{1/2} S R_W^{1/2}$ trace-class, its trace equals that of $S^{1/2} R_W S^{1/2}$ [21, p. 31] so that the sequence (γ_n) affects the constraint only through the value of $\sum_{k\geq 1} \gamma_k \langle R_W v_k, v_k \rangle$. Thus, selecting strictly positive ε and δ such that the two preceding inequalities are satisfied and $\delta/\varepsilon \geq \langle R_W v_K, v_K \rangle / \langle R_W v_{M+1}, v_{M+1} \rangle$, the operator S' having eigenvalues (γ_n') will still satisfy the constraint on the jammer and will provide a strictly smaller value of $C_W(P_1)$. This shows that $\theta < \infty$ is necessary for a minimax strategy. A similar argument shows that a jammer strategy as in parts (d) and (e) of (1) of Lemma 1 cannot be minimax. Thus, a minimax strategy requires that $P_1 \geq \sum_n (\theta - \gamma_n)$ if (γ_n) is not empty; from [3, Lem. 4], this implies the inequality $P_1 + \Sigma_1^M \gamma_n \geq M\gamma_M$ for all γ_M.

Attention can now be restricted to jammer strategies such that $\theta < \infty$. Moreover, since only those eigenvalues of S that are $\leq \theta$ affect (by (1) of Lemma 1) the value of $C_W(P_1)$, a minimax strategy requires that all eigenvalues of S not exceed θ; otherwise, eigenvalues that exceed θ will require part of the jammer's energy while not contributing to the reduction in mutual information. Since $\theta \geq 0$, it follows from Lemma 1(1) that θ should be strictly positive and thus that only a finite number of eigenvalues can equal zero.

Finally, to see that S must have pure point spectrum to provide a minimax policy, suppose that θ is in the continuous spectrum of S. If θ is the only point in the continuous spectrum, then it must occur as the limit of distinct eigenvalues, since if θ is in the continuous spectrum, then every interval containing θ must contain a point of the spectrum that is distinct from θ [20, p. 364]. In that case, those eigenvalues must obviously be less than θ if S is to be a minimax strategy.

Now suppose that S is any nonnegative and symmetric operator satisfying the constraint on the jammer and such that θ, the smallest value in $\sigma_{\text{ess}}(S)$, is a point of the continuous spectrum and not a limit point of distinct eigenvalues. The eigenvalues of S that are less than θ must then be finite in number. Let $\{v_i, i \geq 1\}$ be a CONS in H and $\{v_1, \ldots, v_K\}$ the eigenvectors of S corresponding to its eigenvalues $\{\gamma_1, \ldots, \gamma_K\}$. Define the operator S_1 to have pure point spectrum with eigenvectors $\{v_i, i \geq 1\}$ and eigenvalues given by $\{\gamma_1, \ldots, \gamma_K, \theta_1, \ldots \theta_1, \ldots\}$;

that is, θ_1 is an eigenvalue of infinite multiplicity corresponding to the eigenvectors $\{v_n, n \geq K+1\}$. Suppose first that $\theta_1 = \theta$ and $K > 0$. The operator $S - S_1$ is symmetric and nonnegative so that $R_W^{1/2}(S-S_1)R_W^{1/2}$ is self-adjoint, nonnegative, and trace-class. If the latter operator has trace equal to zero, then it is identically zero, and this would then require that $R_W^{1/2}SR_W^{1/2} = R_W^{1/2}S_1R_W^{1/2}$. Since range $(R_W^{1/2})$ is dense in H, this last equality would require that $S = S_1$ on H. As this is false, $P_2 \geq \sum_{j\geq 1}\langle R_W^{1/2}SR_W^{1/2}v_j, v_j\rangle > \sum_{j\geq 1}\langle R_W^{1/2}S_1R_W^{1/2}v_j, v_j\rangle$. From the last two inequalities, the K smallest eigenvalues of S_1 can be increased with S_1 still satisfying the constraint on the jammer and decreasing (from (1(a)) of Lemma 1) the mutual information in comparison with that obtained using the operator S. If $K = 0$, then θ_1 can be taken strictly greater than θ while satisfying the constraint on the jammer and again reducing (from (1(b)) of Lemma 1) the mutual information from that obtained using S. Thus, in order that S define a minimax strategy for the jammer, it is necessary that the continuous spectrum of S be empty except when S has an infinite sequence of eigenvalues and θ is the limit point of those eigenvalues (from below) and not an eigenvalue of S; θ is then the only point in the continuous spectrum. □

Applying Lemma 2 and Lemma 1(1), the coder's optimum strategy (when it exists) requires choosing a Gaussian signal process with the covariance operator R_X defined in terms of the eigenvalues of the ambient noise covariance R_W, the eigenvalues and associated orthonormal eigenvectors of the operator S defining the jamming covariance $R_J = R_W^{1/2}SR_W^{1/2}$, and the unitary operator U satisfying $(R_W + R_J)^{1/2} = R_W^{1/2}(I+S)^{1/2}U^*$. The problem now reduces to determining the jammer's minimax strategy (if it exists), which is to select a Gaussian jamming process with covariance operator R_J such that the value of $C_W(P_1)$ is minimized. Lemma 2 defines properties that the operator S must satisfy if a minimax strategy is to be realized.

An important question at this point is whether the game has a solution. Does a saddle value exist? If so, is there a saddle point? Such questions are usually answered by appealing to the von Neumann minimax theorem, which we now consider.

General forms of the von Neumann minimax theorems are given, for example, in [8]. For a concave/convex function such as F, a saddle value will exist if the set of admissible $\mathbf{z}$ constitutes a compact convex set in a linear topological space H_1, the set of admissible α constitutes a compact convex subset of a linear topological space H_2, and (on the set of admissible $(\mathbf{z}, \alpha)$) F is continuous in $\mathbf{z}$ (resp., α) for each fixed α (resp., $\mathbf{z}$) [8, Thm. 3.5]. For reflexive spaces H_1 and H_2, this criterion can be satisfied by using the weak topology. From [8, Cor. 3.7], both a saddle value and a saddle point will exist if the spaces H_1 and H_2 are reflexive Banach spaces *and* if the set of admissible $\mathbf{z}$ (resp., admissible α) is a closed and bounded subset of H_1 (resp., H_2). As defined, the continuity conditions are satisfied by F and the set of admissible $\mathbf{z}$ constitutes a closed and bounded subset of the nonreflexive space ℓ_1. Of course, the admissible $\mathbf{z}$ constitute a bounded set in the reflexive space ℓ_p for $1 < p < \infty$. However, this set is not closed in any of the reflexive ℓ_p spaces. This can be proven by a construction and argument based on the Baire category theorem. A more general result is given by the following proposition.

PROPOSITION 1. *The set of admissible* $\mathbf{z}$ *is not a closed and bounded subset of any reflexive Banach space.*

Proof. First, for reflexive Banach spaces, convergence in the weak* topology [13, p. 420] is the same as convergence in the weak topology from the definitions of the two topologies. Thus, from [17, Thm. 2.e.7], if a separable Banach space Y is reflexive, then there exists no bounded linear operator T: $\ell_1 \to Y$ having bounded inverse (on the range of T in Y). Let Y be any reflexive Banach space—not necessarily separable—containing the set of admissible $\mathbf{z}$. By linearity, it is seen that Y must contain all of ℓ_1. Let T be the natural injection from

ℓ_1 into Y : Tx is x viewed as an element of Y. *Suppose* that T maps the set of admissible $\mathbf{z}$ into a bounded and closed set in Y. Applying linearity, T must then also map the unit ball $B_1 \equiv \{\mathbf{z} : \sum_{k\geq 1} |z_k| \leq 1\}$ into a bounded and closed set in Y. T is then continuous on ℓ_1; this fact, the separability of ℓ_1, and the fact that $T[B_1]$ is closed imply that $T[B_1]$ is a complete separable metric space under the Y norm metric. By the open mapping theorem [13, p. 57], the operator T^{-1} is continuous on $T[B_1]$ and, by linearity and the definition of B_1, must be continuous on the range of T. The closure of range (T) is separable, since range (T) is separable and T is continuous; reflexive [13, p. 67]; and thus a separable reflexive Banach space under the Y norm, contains ℓ_1 as a subspace, and T^{-1} is continuous on ℓ_1. This contradicts Theorem 2.e.7 of [17]. □

This result shows that the general form of the von Neumann minimax theorem cannot be applied to guarantee the existence of a saddle point (or even a saddle value). We shall prove, however, that a saddle point exists, determine the saddle value, and give a minimax strategy for the jammer.

LEMMA 3 (see [7]). *Define* $(\gamma_{K,i}^m)$, (z_i^m), θ_K^m, g_K^m, *and* T_K^m *as follows, for* $K \geq 0, m \geq K+1$:

$$g_K^m(\theta) = \left[\sum_{i=K+1}^{m} \frac{\lambda_i}{P_2 + \sum_{k=K+1}^{m} \lambda_k + (P_1 - K\theta)\lambda_i}\right]^{-1}, \qquad 0 \leq \theta \leq P_1/K,$$

$$T_K^m = \frac{P_1 \lambda_{K+1}}{P_2 + \sum_{i=K+1}^{m} \lambda_i + K\lambda_{K+1}},$$

$$1 + \gamma_{K,i}^m = \frac{(P_2 + \sum_{k=K+1}^{m} \lambda_k)(1 + \theta_K^m)}{P_2 + \sum_{j=K+1}^{m} \lambda_j + (P_1 - K\theta_K^m)\lambda_i}, \qquad i \geq K+1,$$

$$\gamma_{K,i}^m = 0, \qquad i \leq K,$$

where θ_K^m *is the solution to* $1 + \theta = g_K^m(\theta)$, *and*

$$z_i^m \equiv \theta_K^m - \gamma_{K,i}^m, \qquad i \geq 1.$$

A unique solution exists for θ_K^m. *If* $P_1 < (m-1)P_2/\lambda_m$ *and it is required that the coder's covariance satisfy* $z_n = 0$ *for all* $n \geq m+1$, *then the jamming problem has a saddle point* $(\mathbf{z}^*, \gamma^*)$, *with* $\gamma_i^m = \gamma_{K(m),i}^m$ *for* $i \leq m$ *and* $\gamma_i^* = 0$ *for* $i > m$; $z_i^* = z_i^m$ *for* $i \leq m$ *and* $z_i^* = 0$ *for* $i > m$; *and* $K(m)$ *the smallest integer* k *such that* $\theta_k^m > T_k^m$. *This* $K(m)$ *satisfies* $K(m) \leq m-2$, *and* $P_1 \geq K(m)P_2/\sum_{j=K(m)+1}^{m} \lambda_j$.

The condition $P_1 < (m-1)P_2/\lambda_m$ assumed in Lemma 3 will of course be satisfied for all sufficiently large m; in fact, for all $m \geq k$, where k is such that $P_1 \leq kP_2/(\sum_{j=k+1}^{\infty} \lambda_j)$.

LEMMA 4. *If* K *is any integer* ≥ 0 *such that* $P_1 < (K+1)P_2/\sum_{i\geq K+2} \lambda_i$, *then* $\theta_K^m > T_K^m$ *for all* $m \geq K+1$.

Proof. We will show that $g_K^m(T_K^m) > 1 + T_K^m$ for all $m \geq K+1$. This will prove the statements, since otherwise one would have $\theta_K^m \leq T_K^m$ for some m; since $g_K^m(\theta)$ is a strictly decreasing function of θ for fixed m and K, this would give

$$1 + T_K^m \geq 1 + \theta_K^m = g_K^m(\theta_K^m) \geq g_K^m(T_K^m) > 1 + T_K^m.$$

To see that $g_K(T_K^m) > 1 + T_K^m$, this inequality is equivalent to

$$\sum_{i=K+1}^{m} \frac{\lambda_i[P_2 + \sum_{j=K+1}^{m} \lambda_j + K\lambda_{K+1}]}{(P_2 + \sum_{k=K+1}^{m} \lambda_k)[P_2 + \sum_{n=K+1}^{m} \lambda_n + K\lambda_{K+1} + P_1\lambda_i]} < \frac{P_2 + \sum_{j=K+1}^{m} \lambda_j + K\lambda_{K+1}}{P_2 + \sum_{k=K+1}^{m} \lambda_k + (P_1 + K)\lambda_{K+1}}$$

or

$$\sum_{i=K+1}^{m} \lambda_i \left\{ 1 + \frac{P_1(\lambda_{K+1} - \lambda_i)}{P_2 + \sum_{j=K+1}^{m} \lambda_j + K\lambda_{K+1} + P_1\lambda_i} \right\} < P_2 + \sum_{k=K+1}^{m} \lambda_k.$$

This holds if

$$P_1\lambda_{K+1} \sum_{i=K+2}^{m} \lambda_i < P_2 \left[P_2 + \sum_{j=K+2}^{m} \lambda_j + (K+1)\lambda_{K+1} \right],$$

which is satisfied, since $LHS \leq P_2\lambda_{K+1}(K+1)$. □

Now define T_K and g_K by

$$T_K = \frac{P_1\lambda_{K+1}}{P_2 + \sum_{j=K+1}^{\infty} \lambda_j + K\lambda_{K+1}},$$

$$g_K(\theta) = \left[\sum_{i=K+1}^{\infty} \frac{\lambda_i}{P_2 + \sum_{j=K+1}^{\infty} \lambda_j + (P_1 - K\theta)\lambda_i} \right]^{-1}, \qquad 0 \leq \theta \leq P_1/K,$$

and let θ_K be the solution to $1 + \theta = g_K(\theta)$. It is obvious that $T_K = \lim_m T_K^m$; we now show that the equation $1 + \theta = g_K(\theta)$ has a unique solution, θ_K, and that $\theta_K = \lim_m \theta_K^m$.

LEMMA 5. (a) *$g_K^m(\theta)$ is a strictly decreasing function of m for fixed K and θ.*

(b) *θ_K^m is a strictly decreasing function of m.*

(c) *θ_K is uniquely defined and $\theta_K = \lim_{m\to\infty} \theta_K^m$.*

(d) *$\theta_K \geq T_K$ if and only if*
$\sum_{i=K+1}^{\infty} [P_1(\lambda_{K+1} - \lambda_i)\lambda_i][P_2 + \sum_{j=K+1}^{\infty} \lambda_j + K\lambda_{K+1} + P_1\lambda_i]^{-1} \leq P_2$.

(e) *$\theta_K \geq T_K$ if and only if $\theta_K^m > T_K^m$ for all $m \geq K+1$.*

Proof. (a) It is immediate that $[g_K^{m+1}(\theta)]^{-1} > [g_K^m(\theta)]^{-1}$ if $\theta \leq P_1/K$.

(b) Since $g_K^m(\theta)$ is a strictly decreasing function of m, the solution to $1 + \theta = g_K^{m+1}(\theta)$ must be strictly less than the solution to $1 + \theta = g_K^m(\theta)$.

(c) Let $f(\theta) = 1 + \theta$. f is continuous and strictly monotone increasing. g_K is continuous and strictly monotone decreasing, and $f(0) = 1 < g_K(0)$. If $P_1/K \geq P_2/\sum_{j\geq K+1} \lambda_j$, then $f(P_1/K) = 1 + P_1/K \geq 1 + P_2/\sum_{j\geq K+1} \lambda_j = g_K(P_1/K)$. Thus a unique solution exists to $f = g_K$ if $P_1/K \geq P_2/\sum_{j\geq K+1} \lambda_j$. If $P_1/K < P_2/\sum_{j\geq K+1} \lambda_j$, then the same result holds, since then $f(P_2/\sum_{j\geq K+1} \lambda_j) > g(P_2/\sum_{j\geq K+1} \lambda_j)$.

Since (θ_K^m) is monotone decreasing as m increases and is bounded below by zero, $\lim_m \theta_K^m \equiv \theta_0$ exists. Since $g_K(\theta) = \lim_m g_K^m(\theta)$ for $\theta > 0$, $g_K(\theta_0) = \lim_m g_K^m(\theta_0) \geq \limsup_m g_K^m(\theta_K^m) = \limsup_m (1+\theta_K^m) = 1+\theta_0$. Conversely, $g_K(\theta_0) = \lim_m g_K(\theta_K^m) \leq \limsup_m g_K^m(\theta_K^m) = 1+\theta_0$. Thus, $1 + \theta_0 = g_K(\theta_0)$; since this solution is unique, $\theta_0 = \theta_K$.

(d) $g_K(T_K) \geq 1 + T_K$, since otherwise (proceeding as in the proof of part (c)) the solution to $g_K(\theta) = 1 + \theta$ will occur for $\theta < T_K$. The inequality of (d) then follows from $g_K^{-1}(T_K) \leq (1 + T_K)^{-1}$.

(e) As in the proof of (*d*), $\theta_K^m > T_K^m$ if and only if $g_K^m(T_K^m) > 1 + T_K^m$, and this occurs if and only if

$$\sum_{i=K+1}^{m} \frac{P_1(\lambda_{K+1} - \lambda_i)\lambda_i}{P_2 + \sum_{j=K+1}^{m} \lambda_j + K\lambda_{K+1} + P_1\lambda_i} < P_2.$$

The left-hand side of this inequality is a strictly increasing function of m. Moreover,

$$g_K^{K+1}(\theta_K^{K+1}) = 1 + \theta_K^{K+1} = \left[\frac{\lambda_{K+1}}{P_2 + \left[P_1 - K\theta_K^{K+1} + 1\right]\lambda_{K+1}} \right]^{-1}$$

so that

$$\theta_K^{K+1} = \frac{P_2 + P_1\lambda_{K+1}}{(K+1)\lambda_{K+1}} > \frac{P_1\lambda_{K+1}}{P_2 + (K+1)\lambda_{K+1}} = T_K^{K+1}.$$

Thus, $\lim_{m\to\infty} \theta_K^m \geq \lim_{m\to\infty} T_K^m <=> \theta_K^m \geq T_K^m$ for all $m \geq K+1$. □

The following theorem is the main result of this paper. It will be seen (in Remark 2 below) that the effect of the jammer is essentially to convert the infinite-dimensional channel into a channel of dimension $\leq K+1$ $(0 \leq K < \infty)$. This integer K will be defined in terms of P_1, P_2, and the eigenvalues (λ_n) of R_W.

THEOREM 1. *The jamming problem has a saddle value and a saddle point. The saddle value is given by*

$$I(\mu_{XY}) = \frac{1}{2}\sum_{n\geq K+1} \log\left[1 + \frac{(P_1 - K\theta_K)\lambda_n}{P_2 + \sum_{i\geq K+1}\lambda_i}\right] + \frac{K}{2}\log(1+\theta_K),$$

where θ_K is the unique solution of

$$1 + \theta = \left[\sum_{n\geq K+1} \frac{\lambda_n}{P_2 + \sum_{j\geq K+1}\lambda_j + (P_1 - K\theta)\lambda_n}\right]^{-1}$$

for $0 \leq \theta \leq P_1/K$ and K is the smallest integer $k \geq 0$ such that

$$\sum_{i=k+1}^{\infty} \frac{P_1(\lambda_{k+1} - \lambda_i)\lambda_i}{P_2 + \sum_{j=k+1}^{\infty}\lambda_j + k\lambda_{k+1} + P_1\lambda_i} \leq P_2.$$

A saddle point is given by $(\mathbf{z}^*, \gamma^*)$, where $z_i^* = \theta_K - \gamma_i^*$ for all $i \geq 1$, $\gamma_i^* = 0$ for $i \leq K$, and

$$1 + \gamma_i^* = \frac{[P_2 + \sum_{j\geq K+1}\lambda_j](1+\theta_K)}{P_2 + \sum_{i\geq K+1}\lambda_i + (P_1 - K\theta_K)\lambda_i} \quad \text{for} \quad i \geq K+1.$$

A minimax strategy for the jammer is to choose S to have pure point spectrum with eigenvalues (γ_n^*) and corresponding eigenvectors $\{e_n, n \geq 1\}$. The resulting maximin strategy for the coder is given by (1(c)) *of Lemma* 1.

Proof. Define $Z = \{(z_i) : z_i \geq 0$ for $i \geq 1$ and $\sum_{i\geq 1} z_i \leq P_1\}$. For m such that $P_1 < mP_2/\sum_{i\geq m}\lambda_i$, $Z^m \equiv \{(z_i) \in Z : z_i = 0$ for $i > m\}$. $\Gamma \equiv \{(\gamma_i) : \gamma_i = \langle Sv_i, v_i\rangle$ for a CONS $\{v_i, i \geq 1\}$, $S \in \mathcal{C}$, $\sum_{i\geq 1}\lambda_i\langle Se_i, e_i\rangle \leq P_2\}$, $\Gamma^m = \{(\gamma_i) \in \Gamma : \gamma_j = 0$ for $j > m\}$, where $\mathcal{C}$ is the set of all densely defined symmetric nonnegative linear operators whose domain contains the range of $R_W^{1/2}$. To prove the existence of a saddle value, it is sufficient [8] to show that $\sup_Z \inf_\Gamma F(\mathbf{z}, \gamma) \geq \inf_\Gamma \sup_Z F(\mathbf{z}, \gamma)$. Note that $\sup_Z \inf_\Gamma F(\mathbf{z}, \gamma) \geq \sup_{Z^m} \inf_\Gamma F(\mathbf{z}, \gamma) = \sup_{Z^m} \inf_{\Gamma^m} F(z, \gamma) = F(\mathbf{z}^m, \gamma_{k(m)}^m)$, where $(\mathbf{z}^m, \gamma_{k(m)}^m)$ is defined in Lemma 3.

Thus, $\sup_Z \inf_\Gamma F(\mathbf{z}, \gamma) \geq \liminf_{m\to\infty} F(\mathbf{z}^m, \gamma_{k(m)}^m) = \liminf_{m\to\infty} \frac{1}{2}\Sigma_{i\geq 1}\log[1 + z_i^m/(1+\gamma_{k(m),i}^m)]$. Define $k_0 \equiv \liminf_{m\to\infty} k(m) = \liminf_{m\to\infty}\{k : \theta_k^m > T_k^m\} = K$ (Lemma 5), with K defined as in the theorem. From the definitions of $\gamma_{k(m)}^m$, $\mathbf{z}^m$, γ^*, and $\mathbf{z}^*$, $\lim_n \theta_K^n = \theta_K$ implies $\gamma_{K(m),i}^m \to \gamma_i^*$ and $z_i^m \to z_i^*$ for all $i \geq 1$ as $m \to \infty$. By Fatou's lemma,

$$\liminf_{m\to\infty} \frac{1}{2}\sum_{i=1}^{\infty} \log\left[1 + \frac{z_i^m}{1+\gamma_{K,i}^m}\right] \geq \frac{1}{2}\sum_{i=1}^{\infty}\log\left[1 + \frac{z_i^*}{1+\gamma_i^*}\right]. \tag{2}$$

Thus, $\sup_Z \inf_\Gamma F(\mathbf{z}, \gamma) \geq F(\mathbf{z}^*, \gamma^*) = I(\mu_{XY})$, as given in the theorem.

Conversely, one notes that $\gamma_i^* \nearrow \theta_K$ and that $\sum_{i=1}^{\infty}(\theta_K - \gamma_i^*) = P_1$. Thus, by (1(a)) of Lemma 1, $F(\mathbf{z}^*, \gamma^*) = \sup_Z F(\mathbf{z}, \gamma^*) \geq \inf_\Gamma \sup_Z F(\mathbf{z}, \gamma)$. This shows that

$$\inf_\Gamma \sup_Z F(\mathbf{z}, \gamma) \leq F(\mathbf{z}^*, \gamma^*) \leq \sup_Z \inf_\Gamma F(\mathbf{z}, \gamma)$$

and completes the proof of existence of a saddle value and saddle point and their definitions as given in the theorem. The stated minimax strategy for the jammer is obvious and then determines the coder's optimum strategy from Lemma 1(1). □

Remark 1. The integer K defined in the theorem must be smaller than the smallest integer k satisfying $P_1 < (k+1)P_2/\sum_{j=k+2}^{\infty}\lambda_j$. This follows from Lemma 4 and Theorem 3 of [7] and yields the following result.

COROLLARY 1. *The saddle value of F on Λ has the upper bound*

$$F(\mathbf{z}, \gamma) < \frac{K+1}{2}\log\left[1 + \frac{P_1}{K+1}\right],$$

where K is the smallest integer k satisfying $P_1 < (k+1)P_2/\sum_{j=k+2}^{\infty}\lambda_j$.

Proof. From (1(a)) of Lemma 1, the right side of the first inequality is the value of the channel capacity that would be obtained if the jammer used (γ_n) such that $\gamma_n = 0$ for $n \leq K+1$ and $\gamma_n = P_1/(K+1)$ for $n > K+1$. In that case, $\sum_{n=1}^{\infty}\gamma_n\lambda_n = \sum_{n=K+2}^{\infty}\gamma_n\lambda_n = (P_1/[K+1])\sum_{n\geq K+2}^{\infty}\lambda_n < P_2$. This γ is thus an admissible strategy for the jammer, and the result follows. □

Remark 2. The capacity of the channel in the absence of jamming is $P_1/2$; see [2] or [3]. Since $P_1/2 = \lim_K \frac{1}{2}(K+1)\log[1 + P_1/(K+1)]$, one sees that the minimum effect of jamming can be immediately gauged by determining the value of K, the largest integer such that $P_1 > KP_2/\sum_{n=K+1}^{\infty}\lambda_n$, and applying the above corollary. Since the capacity of the $(K+1)$-dimensional channel in the absence of jamming is $\frac{1}{2}(K+1)\log[1 + P_1/(K+1)]$, one can view the effect of jamming as converting the infinite-dimensional channel into a finite-dimensional channel. The value of this K depends on all the channel parameters: the coder's constraint P_1, the jammer's constraint P_2, and the covariance operator of the ambient Gaussian noise.

COROLLARY 2. *The jammer's minimax strategy satisfies $P_1 = \sum_{n\geq 1}(\theta_K - \gamma_n^*)$.*

Remark 3. The statement of the theorem can be interpreted by considering the sum of the jamming and the ambient noise when the jammer selects the minimax strategy given in the theorem. Define K as in the theorem; K is the largest integer k such that $\gamma_k^* = 0$. Corresponding to the eigenvectors $\{e_n, n \geq 1\}$ of $R_W + R_J$, the eigenvalues are given by λ_j for $j \leq K$, while for $j > K$ the eigenvalues are equal to $\lambda_j(1 + \gamma_j^*)$. Thus, as $j \to \infty$, the eigenvalues converge upward to $\lambda_j(1 + \theta_K)$. Since the coder will typically wish to place the transmitted signal energy, as much as possible, according to smaller eigenvalues of the total channel noise, the effect of the jamming is to increase those smaller eigenvalues by a factor that converges upward to $(1 + \theta_K)$.

3. Concluding comments. The above development and that of [7] provide a complete solution for the information capacity of the Gaussian channel with jamming in which the coder's constraint covariance is matched to the ambient noise covariance. An extension of interest is to obtain similar results when the coder constraint and the ambient noise covariance are mismatched.

In addition to the main result, several of the results may be regarded as unexpected and/or of particular interest. They include the following:

1. The constraint applied to the jammer must be of a weaker type than that applied to the coder. This can be interpreted to mean that the jammer must have more flexibility in choosing

the distribution of the available jamming energy as a function of frequency. If this flexibility is the same as that of the coder, then the jammer cannot decrease the information capacity of the channel, regardless of the amount of available jamming energy.

2. With the constraints applied in this paper, which enable the jammer to reduce the information capacity, the usual sufficient conditions [8] for application of the von Neumann minimax theorem are not satisfied: thus, existence of a saddle point (or even a saddle value) is not guaranteed by applying the von Neumann theorem. Nevertheless, a solution is shown to exist, and the saddle value, a saddle point, and a minimax strategy for the jammer are obtained.

3. The essential effect of jamming is to convert the infinite-dimensional channel into a finite-dimensional channel with the same energy limitations on coder and jammer. The "effective dimensionality" of the channel is determined by the problem parameters: the noise covariance and the constraints.

A UNIQUENESS RESULT FOR THE LINEAR SYSTEM OF ELASTICITY AND ITS CONTROL THEORETICAL CONSEQUENCES*

ENRIQUE ZUAZUA†

Abstract. We consider the time-dependent linear system of three-dimensional elasticity for an homogeneous and isotropic elastic body Ω with Dirichlet boundary conditions. We prove that when the domain Ω is of class C^2 and is not symmetric with respect to a plane parallel to $x_3 = 0$, any solution whose first two components vanish in some open subset of Ω for a large enough time interval has to be identically zero. The proof of this uniqueness result can be reduced to show that solutions of the scalar wave equation with zero Dirichlet boundary conditions that are of the form $u(x, y, z, t) = \varphi(x, y, t) + \psi(z, t)$ have to be identically zero. This result depends not only on the length of the time interval but also on the geometry of the domain. As a consequence of this uniqueness result we prove that the linear system of elasticity is approximately controllable by means of planar volume forces with zero third component. We show that these results fail for some Lipschitz domains that are piecewise smooth and symmetric with respect to the plane $x_3 = 0$.

1. Introduction and main results.

Let us consider an homogeneous and isotropic elastic n-dimensional body occupying a bounded domain Ω of $\mathbb{R}^n$ ($n = 2, 3$) of class C^2. ($\Gamma = \partial\Omega$ is of class C^2, and Ω is locally at one side of $\partial\Omega$.)

Let ω be an open and nonempty subset of Ω and $T > 0$. We denote by χ_ω the characteristic function of ω.

We consider the system of linear elasticity with a control (volume force) supported in ω and with homogeneous boundary conditions of Dirichlet type:

$$\begin{cases} u_{tt} - \mu\Delta u - (\lambda + \mu)\nabla \mathrm{div} u = f\chi_\omega & \text{in } \Omega \times (0, T), \\ u = 0 & \text{on } \Gamma \times (0, T), \\ u(0) = u^0, u_t(0) = u^1 & \text{in } \Omega, \end{cases} \tag{1.1}$$

where $\mu, \lambda > 0$ are Lamé's constants.

We assume that $f \in (L^2(\Omega \times (0, T)))^n$ is of the form

$$f = (f_1, \ldots, f_{n-1}, 0), \tag{1.2}$$

i.e., the nth component of f vanishes.

The initial data (u^0, u^1) are supposed to be in $H = (H_0^1(\Omega))^n \times (L^2(\Omega))^n$. Under these conditions, system (1.1) admits a unique solution $(u, u_t) \in C([0, T]; H)$.

We are interested in the controllability properties of this system under restriction (1.2) on the set of controls. More precisely, we investigate its approximate controllability. In other words, we want to know whether, for T large enough, the set

$$R(T) = \{(u(T), u_t(T)) : f \in (L^2(\Omega \times (0, T)))^n \text{ satisfying (1.2)}\}$$

is dense in H for all initial data $(u^0, u^1) \in H$.

†Matemática Aplicada, Universidad Complutense, 28040 Madrid, Spain (zuazua@sunma4.mat.ucm.es).

Thus, for instance in three space dimensions, we are trying to understand the final configurations that an elastic body may reach by means of the action of arbitrary planar volume forces.

In the absence of restriction (1.2) on the set of controls, the approximate controllability is well known and is a consequence of the following uniqueness result, which turns out to be an immediate corollary of Holmgren's uniqueness theorem: If φ is a solution of

$$\begin{cases} \varphi_{tt} - \mu\Delta\varphi - (\lambda+\mu)\nabla\mathrm{div}\varphi = 0 & \text{in } \Omega \times (0,T), \\ \varphi = 0 & \text{on } \Gamma \times (0,T) \end{cases} \tag{1.3}$$

in the class $C([0,T];(L^2(\Omega))^n) \cap C^1([0,T];(H^{-1}(\Omega))^n)$ such that

$$\varphi_1 \equiv \cdots \equiv \varphi_{n-1} \equiv \varphi_n \equiv 0 \text{ in } \omega \times (0,T)$$

and T is large enough, then $\varphi \equiv 0$ in $\Omega \times (0,T)$.

In that case (i.e., without restriction (1.2)) the control time is

$$T(\Omega) = \frac{2\delta_n(\Omega;\omega)}{\sqrt{\mu}},$$

the quantity δ_n being defined as follows. For any open subset $\mathcal{O}$ of Ω,

$$\delta_n(\Omega;\mathcal{O}) = \sup_{x\in\Omega\setminus\mathcal{O}} \inf_{\gamma\in\xi(x;\mathcal{O})} \ell(\gamma), \tag{1.4}$$

where $\xi(x;\mathcal{O})$ denotes the set of curves in Ω joining x and $\overline{\mathcal{O}}$ and $\ell(.)$ denotes the length of the curve. We set $\delta_n(\Omega;\emptyset) = \infty$.

Since Ω is bounded and smooth, it is clear that $\delta_n(\Omega;\mathcal{O})$ is finite for any open and nonempty subset $\mathcal{O}$ of Ω.

When restriction (1.2) is introduced in the set of controls, the approximate controllability cannot be obtained directly from Holmgren's uniqueness theorem, and we are led to investigate the following uniqueness or unique continuation problem: If φ is a solution of (1.3) in the class $C([0,T];(L^2(\Omega))^n) \cap C^1([0,T];(H^{-1}(\Omega))^n)$ such that

$$\varphi_1 \equiv \cdots \equiv \varphi_{n-1} \equiv 0 \text{ in } \omega \times (0,T) \tag{1.5}$$

and T is large enough, can we deduce that, necessarily, $\varphi \equiv 0$ in $\Omega \times (0,T)$?

In this paper we give the following positive answer to this problem.

THEOREM 1.1. *Suppose that Ω is a bounded domain of class C^2. When $n = 3$, we assume also that either*

(i) *an open subset of $\partial\Omega$ is contained in a plane of the form $x_3 = c$*

or

(ii) *Ω is not symmetric with respect to a plane parallel to $x_3 = 0$.*

Then there exists some $T^*(\Omega) \geq 0$ such that if φ is a solution of (1.3) *in the class $C([0,T];(L^2(\Omega))^n) \cap C^1([0,T];(H^{-1}(\Omega))^n)$ satisfying* (1.5) *with*

$$T > \frac{2\delta_n(\Omega;\omega)}{\sqrt{\mu}} + T^*(\Omega),$$

then $\varphi \equiv 0$ in $\Omega \times (0,T)$.

As a consequence of Holmgren's uniqueness theorem, the proof of Theorem 1.1 can be reduced to the following uniqueness result for scalar wave equations.

THEOREM 1.2. *Let us suppose that Ω satisfies the assumptions of Theorem* 1.1. *Assume that $T > T^*(\Omega)$. Then, if*

$$\psi(x,t) = a(x_1, \dots, x_{n-1}, t) + b(x_n, t)$$

is a solution of the scalar wave equation

$$\begin{cases} \psi_{tt} - \mu\Delta\psi - (\lambda+\mu)\frac{\partial^2\psi}{\partial x_n^2} = 0 \ \text{in } \Omega \times (0,T), \\ \psi = 0 \ \text{on } \partial\Omega \times (0,T), \end{cases} \tag{1.6}$$

necessarily $\psi \equiv 0$ in $\Omega \times (0,T)$.

The proof of Theorem 1.2 can be reduced to the following elliptic version of it.

THEOREM 1.3. *Let us suppose that Ω satisfies the assumptions of Theorem* 1.1. *Then, if*

$$\phi(x) = p(x_1, \dots, x_{n-1}) + \alpha \cos\left(\frac{\kappa}{\sqrt{\lambda+2\mu}} x_n + \beta\right) \tag{1.7}$$

is an eigenfunction of the elliptic eigenvalue problem

$$\begin{cases} -\mu\Delta\phi - (\lambda+\mu)\frac{\partial^2\phi}{\partial x_n^2} = \kappa^2\phi \ \text{in } \Omega, \\ \phi = 0 \ \text{on } \partial\Omega \end{cases} \tag{1.8}$$

for some $\alpha, \beta, \kappa \in \mathbb{R}$ necessarily, $\phi \equiv 0$ in Ω.

Remark 1.4. Observe that in Theorem 1.1 the uniqueness time for the system of elasticity under the weak restriction (1.5) is, in general, larger than the classical uniqueness time that one obtains when all components vanish (i.e., larger than $2\delta_n(\Omega;\omega)/\sqrt{\mu}$). Indeed, under restriction (1.5) the uniqueness time is increased by the quantity $T^*(\Omega)$. We will give below some sharp estimates on this quantity that depend strongly on the geometry of the domain (not only on its size!). In some cases $T^*(\Omega) = 0$ so that the uniqueness time under restriction (1.5) coincides with the classical one. But in general, $T^*(\Omega) > 0$.

Note that when $\omega = \Omega$, the uniqueness time in Theorems 1.1 and 1.2 coincide since $\delta_n(\Omega;\Omega) = 0$.

Remark 1.5. The assumption on the C^2 regularity on the domain Ω is sharp in the sense that the results above fail for some piecewise C^2 domains.

For instance, as we will see in §7, in dimension $n = 2$ when Ω is the polygonal domain

$$\Omega = \Big\{(x_1,x_2) \in \Big(-\sqrt{\mu/(\lambda+2\mu)}, \sqrt{\mu/(\lambda+2\mu)}\Big) \times (-1,1) : \\ |\sqrt{\lambda+2\mu}x_1/\sqrt{\mu}| - 1 < x_2 < 1 - |\sqrt{\lambda+2\mu}x_1/\sqrt{\mu}|\Big\}, \tag{1.9}$$

Theorems 1.1, 1.2, and 1.3 do not hold. Moreover, Theorems 1.1 and 1.2 do not hold for any time $T > 0$.

As we will see below analogous counterexamples may be constructed in three space dimensions (see §7).

However, there is a way of relaxing the C^2 assumption on Ω, as we will see in Theorem 1.8 below.

When $n = 3$, we need the nonsymmetry assumption in order to prove Theorem 1.3. This assumption is not sharp. Indeed, we can construct C^2 domains which are symmetric with respect to the plane $x_3 = 0$ and where the results above hold. Given Ω we define the domain

$$\mathcal{W} = \left\{x \in R^3 : \left(x_1, x_2, \sqrt{\lambda+2\mu}x_3/\sqrt{\mu}\right) \in \Omega\right\}.$$

Let us choose an ellipsoid Ω such that the corresponding $\mathcal{W}$ is a ball of $\mathbb{R}^3$. Observe that if there exists ϕ defined in Ω satisfying (1.7), (1.8), then

$$\varphi(x) = \phi\left(x_1, x_2, \sqrt{\lambda + 2\mu}x_3/\sqrt{\mu}\right) = p(x_1, \ldots, x_{n-1}) + \alpha\cos\left(\frac{\kappa}{\sqrt{\mu}}x_n + \beta\right)$$

is an eigenfunction of the elliptic eigenvalue problem

$$\begin{cases} -\mu\Delta\varphi = \kappa^2\phi \text{ in } \mathcal{W}, \\ \varphi = 0 \text{ on } \partial\mathcal{W}. \end{cases}$$

Such an eigenfunction does not exist since, as is well known, when $\mathcal{W}$ is a ball of $\mathbb{R}^3$, the eigenfunctions are of the form $\varphi(x) = a(|x|)b(\theta)$, where b is an eigenfunction of the Laplacian over the unit sphere.

We have constructed an ellipsoid which is smooth and symmetric with respect to $x_3 = 0$, where the results above hold. In §5 we will discuss with more detail the assumption on the nonsymmetry of the domain. □

In order to give an estimate on the time $T^*(\Omega)$ it is convenient to introduce some notation.

By $\Omega^{n-1} \subset \mathbb{R}^{n-1}$ and $\Omega_1 \subset \mathbb{R}$ we denote respectively the projections of Ω on the hyperplane $x_n = 0$ and on the axis Ox_n. On the other hand, by $\mathcal{U}^{n-1} \subset \mathbb{R}^{n-1}$ (resp., $\mathcal{U}_1 \subset \mathbb{R}$) we denote the union of the projections on the hyperplane $x_n = 0$ (resp., on the axis Ox_n) of all those components of the boundary $\partial\Omega$ that can be written in the form $x_n = h(x_1, \ldots, x_{n-1})$ with h of class C^2 and such that

$$|\nabla' h(x_1, \ldots, x_{n-1})|^2 \neq \frac{\lambda + 2\mu}{\mu}$$

or

$$\Delta' h(x_1, \ldots, x_{n-1}) \neq 0.$$

By ∇' and Δ' we denote the gradient and Laplacian in the variables $(x_1, \ldots, x_{n-1})$.

The following proposition provides an estimate on the value $T^*(\Omega)$.

PROPOSITION 1.6. *Let us suppose that Ω satisfies the assumptions of Theorem* 1.1. *Then the results above hold with*

$$T^*(\Omega) = 2\min\left(\frac{1}{\sqrt{\mu}}\delta_{n-1}(\Omega^{n-1}; \mathcal{U}^{n-1}), \frac{1}{\sqrt{\lambda + 2\mu}}\delta_1(\Omega_1; \mathcal{U}_1)\right).$$

By δ_{n-1} and δ_1 we denote the $(n-1)$- and one-dimensional versions of the quantity δ_n defined in (1.4).

Since Ω is of class C^2 (to be of class C^1 would suffice), it is clear that $\mathcal{U}^{n-1}$ is nonempty and therefore $T^*(\Omega)$ is finite.

Remark 1.7. When dealing with a particular domain Ω the estimate above on $T^*(\Omega)$ might be eventually improved. However, in §6 we will show that the value given to $T^*(\Omega)$ in Proposition 1.6 is, in general, sharp. □

The proof of Theorem 1.1 shows, roughly, that Theorem 1.1 holds if and only if the uniqueness result for the elliptic problem (1.7), (1.8) of Theorem 1.3 holds. A careful analysis of this elliptic problem allows us to relax C^2 regularity assumption on Ω. Indeed, we have the following result.

THEOREM 1.8. *The results above hold if Ω satisfies the following four conditions:*

a) *Ω is a piecewise C^2-bounded domain.*

b) *Some open and nonempty C^2 component of Γ can be written in the form $x_n = h(x_1, \ldots, x_{n-1})$ with $|\nabla' h|^2 \neq (\lambda + 2\mu)/\mu$ or $\Delta' h \neq 0$ everywhere on that component.*

c) *There exists a point of a* C^2 *component of the boundary of* Ω *where the tangent hyperplane to* Ω *exists, and it is parallel to the axis* Ox_n.

d) *When* $n = 3$, *either*

d_1) *an open subset of the boundary of* Ω *is contained on a plane of the form* $x_3 = c$ *or*

d_2) Ω *is not symmetric with respect to a plane of the form* $x_3 = c$.

Moreover, under these conditons, the definition of $T^*(\Omega)$ *given in Proposition* 1.6 *remains valid.*

As a consequence of Theorems 1.1 and 1.8 we have the following approximate controllability result.

THEOREM 1.9. *Let us suppose that* Ω *satisfies the assumptions of Theorem* 1.8. *Then, if*

$$T > 2\frac{\delta(\Omega;\omega)}{\sqrt{\mu}} + T^*(\Omega),$$

system (1.1) *is approximately controllable at time* T *under the constraint* (1.2). *More precisely, for all* (u^0, u^1) *and* (v^0, v^1) *in* H *and* $\varepsilon > 0$ *there exists* $f \in (L^2(\Omega \times (0,T)))^n$ *obeying* (1.2) *such that the solution of* (1.1) *satisfies*

$$\left[\|u(T) - v^0\|^2_{H_0^1(\Omega))^n} + \|u_t(T) - v^1\|^2_{L^2(\Omega))^n}\right]^{1/2} \leq \varepsilon. \tag{1.10}$$

In other words, $R(T)$ *is dense in* H.

The fact that Theorems 1.1 and 1.8 imply Theorem 1.9 can be proven by rather classical arguments in control theory.

Remark 1.10. According to Theorem 1.8, the results above hold when Ω is the n-dimensional cube $\Omega = (0,1)^n$ with $T^*(\Omega) = 0$. In fact, they hold in any cylinder $\Omega = \Theta \times (0, l)$, where Θ is a bounded and piecewise C^2 domain of $\mathbb{R}^{n-1}$.

In this case, when Dirichlet boundary conditions are replaced by periodic ones, it is easy to check explicitly that the exact controllability does not hold with L^2-controls satisfying (1.2), i.e., $R(T) \neq H$ (see §9). In other words, (1.10) does not hold with $\varepsilon = 0$ for all initial and final data. We do not have an explicit counterexample for Dirichlet boundary conditions, but very probably the same happens.

Without the constraint (1.2), exact controllability with $(L^2(\Omega \times (0,T)))^n$-controls holds for a certain class of ω's. For instance, if ω is a neighborhood of the boundary of Ω exact controllability holds with control time, $T(\Omega) = \operatorname{diam}(\Omega \setminus \omega)/\sqrt{\mu}$ (see [4]). In fact, in order to have exact controllability, it is sufficient to take as support of the controls a set ω of the form $\omega = \Omega \cap \mathcal{O}$, where $\mathcal{O}$ is an open neighborhood in $\mathbb{R}^n$ of a subset of the boundary of Ω of the form

$$\Gamma(x^0) = \{x \in \Gamma : (x - x^0) \cdot \nu(x) > 0\}$$

for any $x^0 \in \mathbb{R}^n$. (By $\nu(x)$ we denote the outward unit normal to Ω at $x \in \Gamma$.) □

Remark 1.11. The same type of example shows that Theorem 1.1 and its counterpart in the more general setting of Theorem 1.8 are sharp in the sense that if, instead of (1.5), we impose the weaker condition

$$\varphi_1 \equiv \cdots \equiv \varphi_{n-2} \equiv 0 \quad \text{in } \omega \times (0,T)$$

and periodic boundary conditions, then uniqueness fails (see §9.2). □

The rest of this paper is organized as follows. In §2 we prove the elliptic version of the uniqueness result, i.e., Theorem 1.3. In §3 we prove Theorem 1.2. In §4 we prove the main

uniqueness results for the system of elasticity, Theorems 1.1 and 1.8. In §5 we discuss the assumption on the nonsymmetry of the domain and formulate some open problems that may lead to the characterization of those symmetric domains where the results above hold. In §6 we show that the uniqueness time in Theorem 1.1 and the estimate on $T^*(\Omega)$ given in Proposition 1.6 are sharp. In §7 we discuss how to extend the counterexample of Remark 1.5 to three space dimensions. In §8 we derive the controllability result stated in Theorem 1.9. Finally, in §9 we give two examples of noncontrollability as mentioned in Remarks 1.10 and 1.11.

In the sequel we will denote by ∇', Δ', div′, and curl′ the $(n-1)$-dimensional gradient, Laplacian, divergence, and curl operators in the variables $(x_1, \dots, x_{n-1})$.

Some of the results of this article were announced in [6].

2. Proof of Theorem 1.3. First, we prove Theorem 1.3 in the case $n = 3$ under the additional assumption d). Then, we prove it when $n = 2$ under the more general assumptions.

2.1. The case $n = 3$. Due to the Dirichlet boundary conditions it is obvious that if $\alpha = 0$, then $\phi \equiv 0$. Thus, without loss of generality we can assume that $\alpha = -1$.

On the other hand, if an open subset of the boundary of Ω is contained on a plane of the form $x_3 = c$, then necessarily, p is constant on an open subset of Ω^2, the projection of Ω on $x_3 = 0$. Since p satisfies the elliptic equation

$$-\mu\Delta' p = \kappa^2 p \quad \text{in } \Omega^2$$

by elliptic unique continuation, we deduce that p is constant everywhere in Ω^2. But then $\phi = \phi(x_3)$, and since it satisfies Dirichlet boundary conditions on Γ, we deduce that $\phi \equiv 0$.

Let us consider the case where Ω is not symmetric with respect to a plane parallel to $x_3 = 0$. Let $x^0 = (x_1^0, x_2^0, x_3^0)$ be a point of a C^2 component of $\partial\Omega$ where the tangent plane to $\partial\Omega$ is parallel to the axis Ox_3. Obviously, such a point exists when Ω is bounded and of class C^1. Without loss of generality we may assume that $x_3^0 = 0$.

Let us introduce the cross section of Ω at the level $x_3 = x_3^0 = 0$, i.e., the set

$$\Omega_0 = \{(x_1, x_2) \in \mathbb{R}^2 : (x_1, x_2, 0) \in \Omega\}.$$

Clearly, Ω_0 is a two-dimensional domain of class C^2 in a neighborhood of $(x_1, x_2) = (x_1^0, x_2^0) = y^0$.

Let us now consider a small neighborhood of y^0 in Ω_0,

$$\mathcal{N}_\varepsilon = \{(x_1, x_2) \in \Omega_0 : |(x_1 - x_1^0, x_2 - x_2^0)| < \varepsilon\},$$

and a C^2 trajectory

$$\tau \in [0, 1] \to \theta(\tau) = (x_1(\tau), \dots, x_{n-1}(\tau)) \in \overline{\mathcal{N}_\varepsilon}$$

such that $\theta(0)$ belongs to the interior of $\mathcal{N}_\varepsilon$, $\theta(1) = (x_1^0, x_2^0)$, and $\theta'(1) = \vec{n}$, the outward unit normal vector to $\partial\Omega_0$. This trajectory is the projection on Ω_0 of a C^2-trajectory on $\partial\Omega$ (which we denote by $\sigma = \sigma(\tau) = (x_1(\tau), x_2(\tau), x_3(\tau))$) such that $\sigma(1) = x^0$.

Taking into account that the tangent hyperplane to Ω at x^0 is parallel to the Ox_3 axis, we deduce that, necessarily,

$$\left|\frac{dx_3(\tau)}{d\tau}\right| \to \infty \quad \text{as } \tau \to 1^-. \tag{2.1}$$

In view of the structure of the eigenfunction ϕ and the fact that ϕ vanishes on $\partial\Omega$, along this trajectory $\sigma = \sigma(\tau)$ we have

$$x_3(\tau) = \frac{\sqrt{\lambda + 2\mu}}{\kappa}[\arccos(p(x_1(\tau), x_2(\tau))) - \beta]. \tag{2.2}$$

Then

$$\frac{dx_3(\tau)}{d\tau} = -\frac{\sqrt{\lambda+2\mu}\big(\nabla' p(x_1(\tau), x_2(\tau)) \cdot (x_1'(\tau), x_2'(\tau))\big)}{\kappa\sqrt{1- \mid p(x_1(\tau), x_2(\tau))) \mid^2}}. \tag{2.3}$$

We now observe that p solves the following elliptic equation in Ω_0:

$$-\mu\Delta' p = \kappa^2 p \quad \text{in } \Omega_0, \qquad p = \cos(\beta) \quad \text{on } \partial\Omega_0. \tag{2.4}$$

Since Ω_0 is locally of class C^2 at $y^0 = (x_1^0, x_2^0)$, the classical regularity theory for elliptic equations (see, for instance, [2, §8.11]) guarantees that $p \in C^{1,\alpha}(\overline{\mathcal{N}_\varepsilon})$. Therefore $\nabla' p$ remains bounded as $(x_1, x_2) \to y^0$. Thus, in view of (2.1) and (2.3) we deduce that $|p(y^0)| = 1$. Without loss of generality we may assume that $p(y^0) = 1$. But then $\beta = 2k\pi$ for some $k \in \mathbf{Z}$ and the function ϕ is even with respect to x_3.

On the other hand, over Γ we have

$$x_3 = \frac{\sqrt{\lambda+2\mu}}{\kappa}[\arccos(p(x_1, x_2)) - \beta]. \tag{2.5}$$

This implies that Ω is symmetric with respect to $x_3 = 0$ in the set where $p(x_1, x_2) > -1$. Thus, if $\inf_{\Omega_0} p > -1$, Ω is symmetric with respect to $x_3 = 0$, and this contradicts the nonsymmetry assumption. Then, necessarily, there exists a point y^1 in the interior of Ω_0 where $p(y^1) = -1$ and $\nabla' p(y^1) = 0$. In this case, the symmetry of Ω has to be analyzed with more care. Indeed, in principle, the symmetry of the domain may be broken since, for instance, on the upper half of Γ, x_3 may achieve its maximum at this point y^1 of Ω_0 but at the lower half of Γ, x_3 may keep decreasing in a neighborhood of y^1 by switching from one branch to another of the function arc cos. It is easy to see that this second possibility may not arise without introducing discontinuities on the boundary of Ω.

Thus, Ω is symmetric. This concludes the proof of Theorem 1.3 when $n = 3$. □

Remark 2.1. Note that if $p(y^1) = -1$ at the upper point of the boundary where x_3 achieves its maximum, we have

$$\frac{\partial x_3}{\partial x_\alpha} = -\frac{\sqrt{\lambda+2\mu}}{\kappa}\frac{\partial p(y^1)/\partial x_\alpha}{\sqrt{1- |p(y^1))|^2}}$$

for $\alpha = 1, 2$. But these quantities are not well defined since both numerator and denominator vanish. Applying l'Hôpital's rule we obtain

$$\begin{aligned} l_\alpha = \lim_{(x_1,x_2)\to y^1} \frac{\partial x_3}{\partial x_\alpha} &= -\frac{\sqrt{\lambda+2\mu}}{\kappa}\frac{\partial^2 p(y^1)/\partial x_\alpha^2}{-p(y^1)\partial p(y^1)/\partial x_\alpha/\sqrt{1- |p(y^1))|^2}} \\ &= -\frac{\lambda+2\mu}{\kappa^2}\frac{\partial^2 p(y^1)/\partial x_\alpha^2}{p(y^1) l_\alpha} = \frac{\lambda+2\mu}{\kappa^2}\frac{\partial^2 p(y^1)/\partial x_\alpha^2}{l_\alpha}. \end{aligned}$$

Thus,

$$|\nabla' x_3(y^1)|^2 = l_1^2 + l_2^2 = \frac{\lambda+2\mu}{\kappa^2}\Delta' p(y^1) = -\frac{\lambda+2\mu}{\mu} p(y^1) = \frac{\lambda+2\mu}{\mu} \neq 0.$$

Thus the surface Γ may not be C^1 in a neighborhood of this point in which x_3 achieves its maximal value with $p(y^1) = -1$. Indeed, if it were C^1, we would have $|\nabla' x_3(y^1)| = 0$. The computation above is justified since y^1 is in the interior of Ω_0 and therefore p is C^∞ in a neighborhood of y^1. □

Remark 2.2. Observe that this proof applies under the following assumptions:

a) Ω is piecewise of class $C^{1,\alpha}$.

b) There exists a point on a $C^{1,\alpha}$ component of $\partial\Omega$ where the plane tangent to Ω is parallel to the plane $x_3 = 0$.

c) Ω is not symmetric with respect to a plane of the form $x_3 = c$.

Therefore, in particular, it applies under the assumptions of Theorem 1.8. □

2.2. The case $n = 2$. The proof of the case $n = 3$ applies as well and reduces the analysis to the situation where $|p(y^0)| = 1$. (Note that y^0 reduces to $y^0 = x_1^0$.) Let us assume, without loss of generality, that $p(x_1^0) = 1$. Note that since p solves the one-dimensional version of (2.4), $p(x_1) = \gamma \cos(\kappa x_1/\sqrt{\mu} + \theta)$ for some $\gamma \geq 1$ and real θ. If $\gamma = 1$, then $p'(x_1^0) = 0$, and therefore, by the computation of Remark 2.1, we deduce that

$$|\partial x_2(x_1^0)/\partial x_1|^2 = \frac{\lambda + 2\mu}{\mu},$$

which is finite. This contradicts (2.1).

Suppose now that $\gamma > 1$. Taking into account that $|p| \leq 1$ for all x_1 in Ω_0, we deduce that x_1 has to lie in an interval to one side of x_1^0 where $|\cos(\kappa x_1/\sqrt{\mu} + \theta)| \leq 1/\gamma$. But then

$$x_2 = \frac{\sqrt{\lambda + 2\mu}}{\kappa}[\arccos(p(x_1)) - \beta]$$

is monotonous, and therefore the boundary of Ω is included in a set that does not contain any closed curve. This concludes the proof of Theorem 1.3 when $n = 2$. □

Remark 2.3. Note that when $n = 2$, we do not need any symmetry assumption on Ω because the sole solution of the one-dimensional version of (2.4) such that $p = 1$ on the boundary of a one-dimensional interval and takes values $|p| \leq 1$ everywhere satisfies $p' = 0$ on the boundary. As we will see in §5, the two-dimensional version of this property seems to be much more delicate (it could be even false), and therefore we require the extra nonsymmetry assumption when $n = 3$. □

3. Proof of Theorem 1.2. First we observe that, under the assumptions of Theorem 1.2, ψ may be written as

$$\psi = a(x_1, \ldots, x_{n-1}, t) + b(x_n, t),$$

where a and b are solutions of the following wave equation in space dimensions $n - 1$ and 1, respectively:

$$a_{tt} - \mu\Delta' a = 0 \text{ in } \Omega^{n-1} \times (0, T), \tag{3.1}$$

$$b_{tt} - (\lambda + 2\mu)\frac{\partial^2 b}{\partial x_n^2} = 0 \text{ in } \Omega_1 \times (0, T), \tag{3.2}$$

where Ω^{n-1} and $\Omega_1 = (l_1, l_2)$ are, respectively, the projections of Ω on the hyperplane $x_n = 0$ and the axis Ox_n.

In order to prove Theorem 1.2, in view of Theorem 1.3, it is sufficient to show that ψ is a solution of the wave equation (1.6) in separated variables. More precisely, it is sufficient to prove that ψ is of the form

$$\psi(x, t) = A(t)\phi(x)$$

with A such that

$$-A'' = \kappa^2 A$$

and with ϕ as in (1.7), (1.8).

Let γ be an open and nonempty subset of Γ that can be represented as $x_n = h(x_1, \dots, x_{n-1})$ for $(x_1, \dots, x_{n-1})$ in some open subset $\mathcal{U}$ of Ω^{n-1} with

$$|\nabla' h(x_1, \dots, x_{n-1})|^2 \neq \frac{\lambda + 2\mu}{\mu} \quad \text{or } \Delta' h \neq 0 \quad \text{for all } (x_1, \dots, x_{n-1}) \in \mathcal{U}. \tag{3.3}$$

Obviously, as soon as Ω is bounded and of class C^2, such a subset exists. Note also that, by hypothesis, this set exists if Ω is in the conditions of Theorem 1.8.

Since ψ vanishes on the boundary of Ω, we have

$$a(x_1, \dots, x_{n-1}, t) = -b(h(x_1, \dots, x_{n-1}), t) \quad \forall (x_1, \dots, x_{n-1}) \in \mathcal{U},\ 0 < t < T. \tag{3.4}$$

We distinguish two cases.

Case 1. The image of $h : \mathcal{U} \to \mathbb{R}$ reduces to a point; i.e., h is constant in $\mathcal{U}$, and thus the subset of the boundary that we are considering is a hyperplane parallel to $x_n = 0$.

Case 2. The image of h contains an interval (x_n^0, x_n^1) with $x_n^0 < x_n^1$.

Let us discuss these two cases separately.

Case 1: In view of (3.4) we have

$$a = a(t) \quad \text{in the cylinder } \mathcal{U} \times (0, T).$$

According to (3.1), we have $a_{tt} = 0$, and therefore a is linear in t, i.e.,

$$a = \alpha t + \beta \quad \text{in } \mathcal{U} \times (0, T)$$

for some $\alpha, \beta \in \mathbb{R}$. Thus

$$\psi = \tilde{b}(x_n, t) \quad \text{in } \mathcal{U} \times (0, T),$$

where $\tilde{b} = b + \alpha t + \beta$ is a (new) solution of (3.2). In other words, in the set $\mathcal{U} \times (0, T)$, ψ depends only on x_n and t.

If $\Omega \subset \mathcal{U} \times \mathbb{R}$, since $\psi = 0$ on $\partial\Omega \times (0, T)$, this clearly implies that $\psi \equiv 0$. If not, we observe that by Holmgren's uniqueness theorem (see [3] or [4, Chap. 1]) a has to be of the same form in a larger set. The latter contains

$$\Omega^{n-1} \times \left(\frac{\delta_{n-1}(\Omega^{n-1}; \mathcal{U})}{\sqrt{\mu}}, T - \frac{\delta_{n-1}(\Omega^{n-1}; \mathcal{U})}{\sqrt{\mu}} \right)$$

as soon as $T > 2\delta_{n-1}(\Omega^{n-1}; \mathcal{U})/\sqrt{\mu}$. Since $\Omega \subset \Omega^{n-1} \times \mathbb{R}$, we deduce that

$$\psi = b(x_n, t) \quad \text{everywhere in } \Omega \times \left(\frac{\delta_{n-1}(\Omega^{n-1}; \mathcal{U})}{\sqrt{\mu}}, T - \frac{\delta_{n-1}(\Omega^{n-1}; \mathcal{U})}{\sqrt{\mu}} \right), \tag{3.5}$$

and, in view of the boundary conditions that ψ satisfies, this implies that $\psi \equiv 0$.

Case 2: Since a and b solve the wave equations (3.1) and (3.2), respectively, we have

$$\begin{aligned} &(\lambda + 2\mu - \mu \mid \nabla' h(x_1, \dots, x_{n-1}) \mid^2) \frac{\partial^2 b}{\partial x_n^2}(h(x_1, \dots, x_{n-1}), t) \\ &\quad -\mu \Delta' h(x_1, \dots, x_{n-1}) \frac{\partial b}{\partial x_n}(h(x_1, \dots, x_{n-1}), t) = 0 \end{aligned} \tag{3.6}$$

for all $(x_1, \dots, x_{n-1}) \in \mathcal{U}$ and $t \in (0, T)$.

From (3.3) and (3.6) we deduce immediately that b is of the form

$$b(x_n, t) = A(t)B(x_n) + C(t) \quad \text{in } \mathcal{U} \times (0, T). \tag{3.7}$$

Since b solves the wave equation (3.2) we have

$$A''(t)B(x_n) - (\lambda + 2\mu)A(t)B''(x_n) + C''(t) = 0.$$

Taking one derivative of this equation with respect to x_n we see that

$$A''(t)B'(x_n) - (\lambda + 2\mu)A(t)B'''(x_n) = 0.$$

Thus A and B satisfy

$$A''(t) = -(\lambda + 2\mu)\xi^2 A(t) \tag{3.8}$$

and

$$-B''' = \xi^2 B' \tag{3.9}$$

for some real number ξ^2, and therefore they are necessarily of the form

$$A(t) = \alpha_1 e^{i\xi\sqrt{\lambda+2\mu}t} + \beta_1 e^{-i\xi\sqrt{\lambda+2\mu}t}$$

and

$$B(x_n) = \alpha_2 e^{i\xi x_n} + \beta_2 e^{-i\xi x_n} + \gamma$$

for some complex numbers $\alpha_1, \alpha_2, \beta_1, \beta_2, \gamma$, and ξ.

It is also easy to check that $C = C(t)$ has to be a linear function of t.

On the other hand, (3.4) implies

$$a(x_1, \dots, x_{n-1}, t) = -A(t)D(x_1, \dots, x_{n-1}) - C(t) \quad \text{in } \mathcal{U} \times (0, T), \tag{3.10}$$

where $D(x_1, \dots, x_{n-1}) = B(h(x_1, \dots, x_{n-1}))$.

Since a satisfies the wave equation (3.1), the function $D = D(x_1, \dots, x_{n-1})$ has to satisfy the elliptic equation

$$-\Delta' D = \frac{\lambda + 2\mu}{\mu}\xi^2 D. \tag{3.11}$$

All this implies, in particular, that ψ has the form

$$\begin{cases} \psi(x_1, \dots, x_n, t) = A(t)\phi(x) & \text{in } \mathcal{U} \times (x_n^0, x_n^1) \times (0, T), \\ \phi(x) = D(x_1, \dots, x_{n-1}) + B(x_n) \end{cases} \tag{3.12}$$

as in Theorem 1.3.

By Holmgren's uniqueness theorem it is easy to see that ψ has to preserve this form in a larger set. Indeed, since b satisfies the wave equation (3.2) and has the form (3.7) with A and B satisfying (3.8) and (3.9), by unique continuation of solutions of the one-dimensional wave equation, b has to preserve this structure in the set

$$\mathcal{Q}_1 = \Omega_1 \times \left(\frac{\max(l_2 - x_n^1, x_n^0 - l_1)}{\sqrt{\lambda + 2\mu}}, T - \frac{\max(l_2 - x_n^1, x_n^0 - l_1)}{\sqrt{\lambda + 2\mu}} \right) \tag{3.13}$$

if

$$T > \frac{2}{\sqrt{\lambda+2\mu}}\max(l_2 - x_n^1, x_n^0 - l_1).$$

Note that $\max(l_2 - x_n^1, x_n^0 - l_1) = \delta_1(\Omega_1, (x_n^0, x_n^1))$.

According to (3.10), (3.11) and taking into account that a solves the wave equation (3.1), by Holmgren's uniqueness theorem it is easy to see that a keeps the same structure in the set

$$\mathcal{Q}_2 = \Omega^{n-1} \times \left(\frac{1}{\sqrt{\mu}}\delta_{n-1}(\Omega^{n-1}; \mathcal{U}), T - \frac{1}{\sqrt{\mu}}\delta_{n-1}(\Omega^{n-1}; \mathcal{U})\right) \tag{3.14}$$

as soon as

$$T > \frac{2}{\sqrt{\mu}}\delta_{n-1}(\Omega^{n-1}; \mathcal{U}).$$

Suppose that

$$T > T_0 \quad \text{with } T_0 = 2\min\left(\frac{1}{\sqrt{\mu}}\delta_{n-1}(\Omega^{n-1}; \mathcal{U}), \frac{1}{\sqrt{\lambda+2\mu}}\delta_1(\Omega_1; (x_n^0, x_n^1))\right). \tag{3.15}$$

Then either a is of the form (3.10), (3.11) in the set (3.14) or b is of the form (3.7) in the set (3.13). In any case, as soon as (3.15) holds, ψ is of the form (3.12) in $\Omega \times (T_0, T - T_0)$.

The analysis of the two different cases above shows that the minimal time for uniqueness is the quantity $T^*(\Omega)$ introduced in Proposition 1.6. Indeed, if in (3.15) we take, instead of $\mathcal{U}$ (resp., (x_n^0, x_n^1)) the union of all sets $\mathcal{U}$ (resp., all intervals (x_n^0, x_n^1)) where the above applies, the time T_0 defined in (3.15) coincides with $T^*(\Omega)$.

4. Proof of Theorem 1.1. In view of (1.5) we have

$$\operatorname{div}\varphi = \frac{\partial \varphi_n}{\partial x_n} \quad \text{in } \omega \times (0, T). \tag{4.1}$$

Using the first $n-1$ equations of (1.3) we deduce that

$$\frac{\partial \operatorname{div}\varphi}{\partial x_j} = \frac{\partial^2 \varphi_n}{\partial x_j \partial x_n} = 0 \quad \text{in } \omega \times (0, T) \tag{4.2}$$

for $j = 1, \ldots, n-1$.

Combining (4.2) with the fact that

$$\frac{\partial^2 \varphi_i}{\partial x_j \partial x_n} = 0 \quad \text{in } \omega \times (0, T) \quad \text{for } i, j = 1, \ldots, n-1$$

we see that

$$\frac{\partial^2 \varphi}{\partial x_j \partial x_n} = 0 \quad \text{in } \omega \times (0, T) \quad \text{for } j = 1, \ldots, n-1.$$

For each $j \in \{1, \ldots, n-1\}$, the vector-valued function $\partial^2\varphi/\partial x_j \partial x_n$ solves the system of elasticity (1.3). Thus, applying Holmgren's uniqueness theorem we deduce that

$$\frac{\partial^2 \varphi}{\partial x_j \partial x_n} \equiv 0 \quad \text{in } Q_1 = \Omega \times \left(\frac{\delta_n(\Omega; \omega)}{\sqrt{\mu}}, T - \frac{\delta_n(\Omega; \omega)}{\sqrt{\mu}}\right).$$

Therefore,

$$\varphi = \rho(x_1, \dots, x_{n-1}, t) - \sigma(x_n, t) \text{ in } Q_1 \tag{4.3}$$

with $\rho = (\rho_1, \dots, \rho_n)$ and $\sigma = (\sigma_1, \dots, \sigma_n)$.

From (1.5) we deduce that

$$\rho_j \text{ and } \sigma_j \text{ are independent of } x \text{ in } \omega \times (0, T) \text{ for } j = 1, \dots, n-1. \tag{4.4}$$

On the other hand, $\phi = \operatorname{div}\varphi$ solves the scalar wave equation

$$\phi_{tt} - (\lambda + 2\mu)\Delta\phi = 0 \text{ in } \Omega \times (0, T). \tag{4.5}$$

Since

$$\frac{\partial\phi}{\partial x_j} = \frac{\partial \operatorname{div}\varphi}{\partial x_j} = \frac{\partial^2\varphi}{\partial x_j \partial x_n} = 0 \quad \text{in } \omega \times (0, T) \text{ for } j = 1, \dots, n-1$$

as a consequence of Holmgren's uniqueness theorem (this time applied to (4.5)) we deduce that

$$\frac{\partial\phi}{\partial x_j} = 0 \quad \text{in } Q_2 = \Omega \times \left(\frac{\delta_n(\Omega; \omega)}{\sqrt{\lambda + 2\mu}}, T - \frac{\delta_n(\Omega; \omega)}{\sqrt{\lambda + 2\mu}} \right)$$

for $j = 1, \dots, n-1$, i.e., $\phi = \phi(x_n, t)$ in Q_2.

But, according to (4.3),

$$\phi = \operatorname{div}'(\rho_1, \dots, \rho_{n-1}) - \frac{\partial\sigma_n}{\partial x_n}$$

in $Q_1 = Q_1 \cap Q_2$. Therefore, $\operatorname{div}'(\rho_1, \dots, \rho_{n-1})$ is independent of $(x_1, \dots, x_{n-1})$, i.e.,

$$\frac{\partial\rho_1}{\partial x_1} + \cdots + \frac{\partial\rho_{n-1}}{\partial x_{n-1}} = c(t) \text{ in } Q_1. \tag{4.6}$$

We now distinguish dimensions $n = 2$ and $n = 3$.

When $n = 3$, $w = \operatorname{curl}\varphi$ satisfies the wave equation

$$w_{tt} - \mu\Delta w = 0 \text{ in } \Omega \times (0, T). \tag{4.7}$$

Moreover, (1.5) implies that w_3 vanishes in $\omega \times (0, T)$. Thus, by Holmgren's uniqueness theorem we deduce that

$$w_3 \equiv 0 \text{ in } Q_1. \tag{4.8}$$

But

$$w_3 = \operatorname{curl}'(\rho_1, \rho_2).$$

Therefore, (4.8) implies the existence of a potential $p = p(x_1, x_2, t)$ such that $(\rho_1, \rho_2) = \nabla' p$. In view of (4.4) and (4.6) we see that p obeys

$$\begin{cases} \Delta' p = c(t) & \text{in } Q_1, \\ p = \gamma(t) \cdot (x_1, x_2) + q(t) & \text{in } \{(x, t) \in Q_1 : x \in \omega\}. \end{cases}$$

Thus, by elliptic unique continuation,

$$p = \gamma(t) \cdot (x_1, x_2) + q(t) \quad \text{in } Q_1$$

and then

$$\nabla' p = (\rho_1, \rho_2) \equiv \gamma(t) \qquad \text{in } Q_1.$$

Therefore,

$$\varphi_j = \gamma_j(t) - \sigma_j(x_3, t) \qquad \text{in } Q_1$$

for $j = 1, 2$. But since φ satisfies Dirichlet boundary conditions, we deduce that

$$\varphi_j \equiv 0 \text{ in } Q_1 \text{ for } j = 1, 2.$$

When $n = 2$, (4.6) implies that $\rho_1 = c(t)x_1 + d(t)$ in Q_1 and therefore $\varphi_1(x_1, x_2, t) = c(t)x_1 + d(t) - \sigma_1(x_2, t)$ in Q_1. But then φ_1 cannot be identically zero on the boundary of the bounded domain Ω except if $\varphi_1 \equiv 0$ in Q_1.

Thus, in both cases, it is sufficient to prove that $\varphi_n \equiv 0$ in Q_1. Indeed, if $\varphi_n \equiv 0$ in Q_1, then the initial data for φ at time $t = T/2$ are identically zero, i.e., $\varphi(x, T/2) \equiv \varphi_t(x, T/2) \equiv 0$. The system (1.3) being reversible in time, by uniqueness of solutions, we deduce $\varphi \equiv 0$ everywhere.

We have

$$\varphi_{n,tt} - \mu\Delta\varphi_n - (\lambda + \mu)\partial^2\varphi_n/\partial x_n^2 = 0 \quad \text{in } Q_1,$$

$$\varphi_n = \rho_n(x_1, \ldots, x_{n-1}, t) - \sigma_n(x_n, t) \quad \text{in } Q_1,$$

$$\varphi_n = 0 \quad \text{on } \Gamma \times (0, T).$$

But then, as an immediate consequence of Theorem 1.2, $\varphi_n \equiv 0$ in Q_1.

5. Discussion on the nonsymmetry assumption. In this section we analyze the nonsymmetry assumption that we have introduced in dimension $n = 3$. As was pointed out in Remark 1.5, the nonsymmetry assumption is required only for the proof of Theorem 1.3.

When analyzing the uniqueness property stated in Theorem 1.3 for a smooth domain Ω of $\mathbb{R}^3$ which is symmetric with respect to $x_3 = 0$, the proof of Theorem 1.3 leads naturally to the following question: Is there any smooth domain $\mathcal{O}$ (of class C^2) of $\mathbb{R}^2$ such that for some $\kappa \in \mathbb{R}$ the elliptic problem

$$-\mu\Delta' p = \kappa^2 p \text{ in } \mathcal{O}, \qquad p = 1 \text{ on } \partial\mathcal{O}, \tag{5.1}$$

admits a solution of class C^2 such that

$$\|p\|_\infty = 1, \qquad \nabla' p \neq 0 \text{ everywhere on } \partial\mathcal{O}? \tag{5.2}$$

If such a domain $\mathcal{O}$ and function p exist with $-1 < p < 1$ in the interior of $\mathcal{O}$, we can construct a smooth domain Ω of R^3, symmetric with respect to $x_3 = 0$, $\mathcal{O}$ being its cross section at the level $x_3 = 0$, and where the uniqueness property of Theorem 1.3 fails. Indeed, it is sufficient to define the upper half of the boundary of Ω as being given by the graph of the function

$$x_3 = \frac{\sqrt{\lambda + 2\mu}}{\kappa}[\arccos(p(x_1, x_2)) - \beta] \tag{5.3}$$

with β such that $\cos\beta = 1$. In this case, the function

$$\phi(x) = p(x_1, x_2) - \cos\left(\frac{\kappa}{\sqrt{\lambda + 2\mu}} x_n + \beta\right) \tag{5.4}$$

satisfies (1.8) in this domain Ω without being identically zero.

When p achieves the extremal values 1 and/or -1 in the interior of $\mathcal{O}$, the same can be done. But in this case the surface $\partial\Omega$ is not of class C^1 at those points where (x_1, x_2) are such that p achieves those values, as the computations of Remark 2.1 show.

Therefore, the existence of this type of domain $\mathcal{O}$ and function p satisfying (5.1) and (5.2) is relevant to understand the uniqueness property stated in Theorem 1.3 in the frame of symmetric domains.

In dimension $n = 2$, one has to analyze the one-dimensional version of (5.1), (5.2). As we pointed out in Remark 2.3, there is no open connected domain $\mathcal{O}$ in $\mathbb{R}$ where these properties hold. Thus, Theorem 1.3 holds without nonsymmetry assumptions.

This question may be addressed in a different way. Assume that Ω is a C^2 domain of $\mathbb{R}^3$ and symmetric with respect to the plane $x_3 = 0$. Suppose that the upper surface of $\partial\Omega$ is the graph of a function $h = h(x_1, x_2)$. Then, taking into account that

$$\phi(x) = p(x_1, x_2) - \cos\left(\frac{\kappa}{\sqrt{\lambda + 2\mu}} x_3 + \beta\right)$$

vanishes on the boundary, we have

$$p(x_1, x_2) = \cos\left(\frac{\kappa}{\sqrt{\lambda + 2\mu}} h(x_1, x_2) + \beta\right).$$

Since β has to be such that $\cos\beta = 1$, we can assume that $\beta = 0$. Taking into account that $-\mu\Delta' p = \kappa^2 p$ in $\mathcal{O}$ we deduce that

$$-\mu\sqrt{\lambda + 2\mu}\,\Delta' h + \kappa(\lambda + 2\mu - \mu|\nabla' h|^2)\operatorname{cotg}\left(\frac{\kappa}{\sqrt{\lambda + 2\mu}} h(x_1, x_2)\right) \text{ in } \mathcal{O} = 0. \tag{5.5}$$

In order to understand the uniqueness property of Theorem 1.3 without the symmetry assumption we have to analyze the existence of κ and h such that (5.5) has a smooth solution so that $\partial h/\partial\vec{n} = -\infty$ on $\partial\mathcal{O}$. (By $\vec{n}$ we denote the normal outward unit vector to $\partial\mathcal{O}$.)

In one space dimension (when $\mathcal{O}$ is an interval of $\mathbb{R}$), it is easy to see that all solutions of (5.5) develop singularities so that they are not Lipschitz.

6. Optimality of the time of uniqueness. In this section we prove that, in general, the uniqueness times given in Theorems 1.1 and 1.2 are sharp.

6.1. Scalar wave equations. In this section we prove the optimality of the uniqueness time $T^*(\Omega)$ given in Proposition 1.6. For the sake of simplicity we consider the bidimensional case $n = 2$.

Let us consider the following polygonal domain in $\mathbb{R}^2$ (see Figure 1):

$$\Omega = \left\{(x_1, x_2) \in \left(\frac{\gamma}{2}, \frac{3\gamma}{2}\right) \times \left(-\frac{1}{2}, \frac{1}{2}\right) : \frac{x_1}{2\gamma} - \frac{3}{4} < x_2 < \frac{3}{4} - \frac{x_1}{2\gamma}\right\}$$

$$\cup \left\{(x_1, x_2) \in \left(-\gamma, \frac{\gamma}{2}\right) \times (-1, 1) : \left|\frac{x_1}{\gamma}\right| - 1 < x_2 < 1 - \left|\frac{x_1}{\gamma}\right|\right\}, \tag{6.1}$$

where $\gamma = \sqrt{\mu/(\lambda + 2\mu)}$.

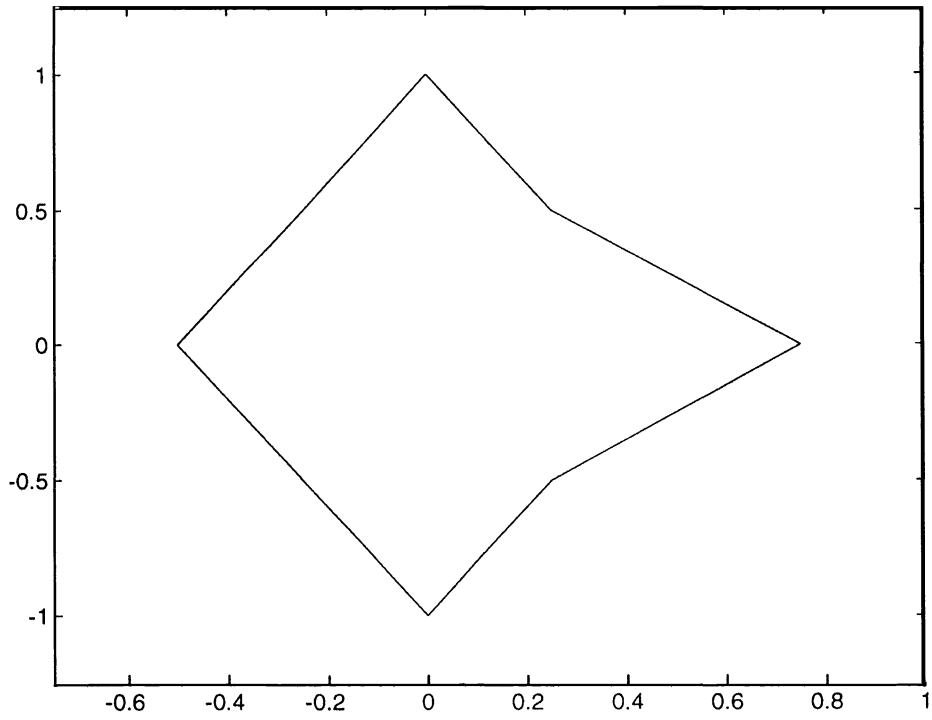

FIG. 1. *Polygonal domain* Ω *as in* (6.1) *with* $\lambda = 2$ *and* $\mu = 1$.

In this case

$$\Omega^{n-1} = \Omega^1 = (-\gamma, 3\gamma/2), \qquad \mathcal{U}^{n-1} = \mathcal{U}^1 = \left(\frac{\gamma}{2}, \frac{3\gamma}{2}\right),$$

$$\Omega_1 = (-1, 1), \qquad \mathcal{U}_1 = \left(-\frac{1}{2}, \frac{1}{2}\right).$$

Then

$$\delta_1(\Omega^1, \mathcal{U}^1) = 3\gamma/2, \qquad \delta_1(\Omega_1, \mathcal{U}_1) = \frac{1}{2},$$

and therefore

$$T^*(\Omega) = \frac{1}{\sqrt{\lambda + 2\mu}}.$$

Let us prove that this uniqueness time $T^*(\Omega)$ is optimal in the context of Theorem 1.2. Let b be an even and x-periodic function with period γ that solves the wave equation

$$b_{tt} - \mu b_{xx} = 0.$$

Let us choose b so that its support in the interval $[-\gamma, \gamma]$ is concentrated in the union of two very small intervals to the right of $-\gamma$ and 0, respectively, i.e.,

$$\text{supp}(b) \subset [-\gamma, -\gamma + \varepsilon] \cup [0, \varepsilon].$$

Then set

$$\psi(x_1, x_2, t) = b(x_1, t) - b(\gamma x_2, t).$$

It is easy to check that ψ solves (1.6) in the cylinder

$$\Omega \times \left(-\frac{(\gamma - \varepsilon)}{2\sqrt{\mu}}, \frac{(\gamma - \varepsilon)}{2\sqrt{\mu}} \right).$$

Since this is true for any $\varepsilon > 0$ and $T^*(\Omega) = \gamma/\sqrt{\mu}$, this implies that the uniqueness time $T^*(\Omega)$ is sharp.

Note that ψ does not satisfy the boundary conditions at the part of the boundary of Ω lying in the strip $\gamma/2 < x_1 < 3\gamma/2$ as soon as the support of $b(\cdot, t)$ enters this region.

As pointed out in Remark 1.4, this shows that the uniqueness time given in Theorem 1.1 is sharp when $\omega = \Omega$.

6.2. System of elasticity. In this section we prove that, in general, the uniqueness time given in Theorem 1.1 is optimal.

Let Ω be the unit ball of $\mathbb{R}^3$. It is easy to check that $T^*(\Omega) = 0$. Then the uniqueness time in Theorem 1.1 reduces to the classical one:

$$T(\Omega) = \frac{2\delta_3(\Omega; \omega)}{\sqrt{\mu}}.$$

Suppose that ω is a neighborhood of the boundary:

$$\omega = \{x \in \Omega : 1 - r < | x | \}$$

with $r < 1$. Then $T(\Omega) = 2(1 - r)/\sqrt{\mu}$.

Let φ be a solution of (1.3) with data at time $t = 0$ with support contained in a small ball around the origin of radius ε. It is easy to see that φ vanishes on ω on the time interval $(-(1 - r - \varepsilon)/\sqrt{\mu}, (1 - r - \varepsilon)/\sqrt{\mu})$. Since ε is arbitrarily small, this implies that $T(\Omega)$ is sharp.

7. Counterexamples to the uniqueness results. In this section we develop the two-dimensional counterexample mentioned in Remark 1.5. We also show how it can be extended to three space dimensions.

7.1. Dimension $n = 2$. Let us consider the following polygonal domain Ω in dimension $n = 2$ (see Figure 2):

$$\Omega = \Big\{ (x_1, x_2) \in \left(-\sqrt{\mu/(\lambda + 2\mu)}, \sqrt{\mu/(\lambda + 2\mu)} \right) \times (-1, 1) : \tag{7.1}$$
$$| \sqrt{\lambda + 2\mu} x_1/\sqrt{\mu} | - 1 < x_2 < 1 - | \sqrt{\lambda + 2\mu} x_1/\sqrt{\mu} | \Big\}.$$

Let b be an even and x-periodic function with period $\sqrt{\mu/(\lambda + 2\mu)}$ that solves the wave equation

$$b_{tt} - \mu b_{xx} = 0.$$

Then

$$\psi(x_1, x_2, t) = b(x_1, t) - b\left(\frac{\sqrt{\mu} x_2}{\sqrt{\lambda + 2\mu}}, t \right)$$

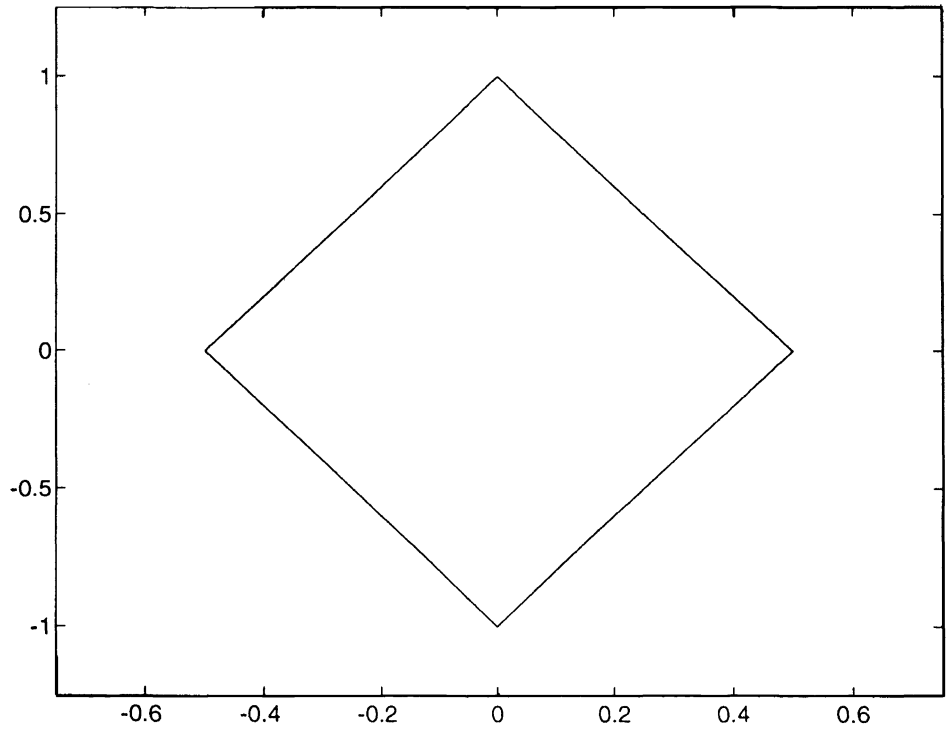

FIG. 2. *Polygonal domain* Ω *as in* (7.1) *with* $\lambda = 2$ *and* $\mu = 1$.

solves (1.6) for all $t > 0$. This shows that Theorem 1.2 does not hold in this domain Ω for any $T > 0$.

On the other hand, $\varphi = (0, \psi)$ is a nontrivial solution of (1.3) that satisfies (1.5) for any $T > 0$. Thus Theorem 1.1 does not hold either.

In a similar way, the function

$$\phi(x) = \cos\left(\frac{2\pi\sqrt{\lambda + 2\mu}}{\sqrt{\mu}} x_1\right) - \cos(2\pi x_2)$$

solves the elliptic eigenvalue problem (1.8) in this domain for

$$\kappa^2 = 4\pi^2(\lambda + 2\mu).$$

This shows that Theorem 1.3 also fails.

7.2. Dimension $n = 3$. In this section we show how the example above can be extended to dimension $n = 3$.

Let us denote by Θ a planar bounded and piecewise smooth domain of $\mathbb{R}^2$. Let $p = p(x_1, x_2)$ be the first eigenfunction of $-\Delta'$ in $H_0^1(\Theta)$, i.e.,

$$\begin{cases} -\mu\Delta' p = \kappa^2 p & \text{in } \Theta, \\ p = 0 & \text{on } \partial\Theta, \end{cases}$$

κ^2 being the first eigenvalue. Since p is bounded, we can assume that $\|p\|_{L^\infty(\Theta)} = 1$. Note that $p > 0$ in Θ.

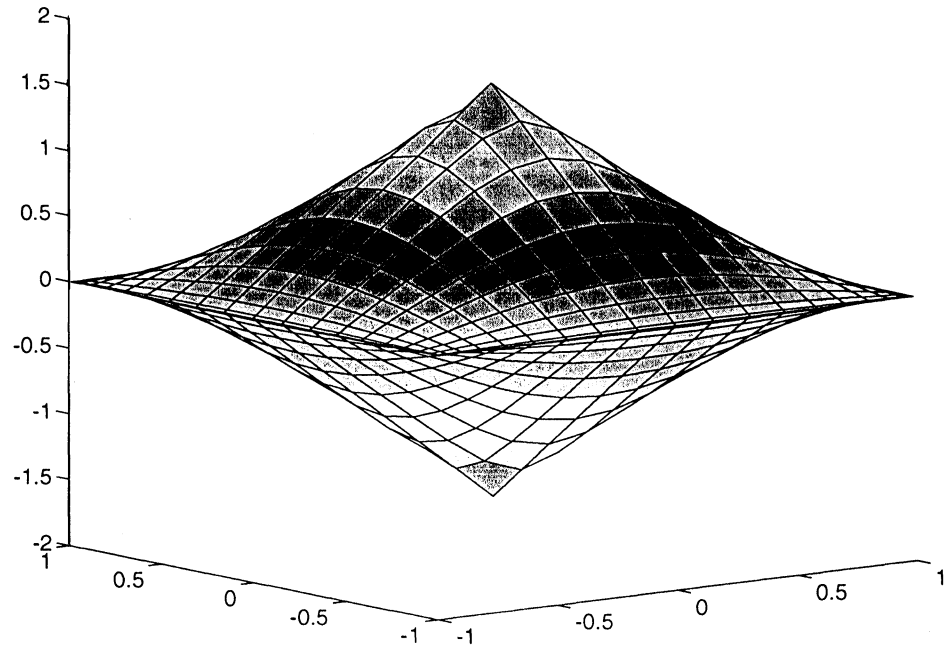

FIG. 3. *Domain* Ω *as in* (7.2) *when* $\Theta = (-1, 1) \times (-1, 1)$ *with* λ *and* μ *such that* $\lambda + 2\mu = \kappa^2$.

Let us consider the function

$$\phi(x_1, x_2, x_3) = p(x_1, x_2) - \sin\Big(\frac{\kappa}{\sqrt{\lambda + 2\mu}} x_3\Big).$$

It is easy to check that ϕ satisfies

$$-\mu\Delta\phi - (\lambda + \mu)\frac{\partial^2\phi}{\partial x_3^2} = \kappa^2\phi \quad \text{in } \Theta \times \mathbb{R}.$$

Let us consider now the surfaces S_1 and S_2 in $\mathbb{R}^3$ corresponding to the graphs of the folowing two functions:

$$x_3 = \frac{\sqrt{\lambda + 2\mu}}{\kappa}\arcsin(p(x_1, x_2)) \quad \text{and} \quad x_3 = -\frac{\sqrt{\lambda + 2\mu}}{\kappa}\arcsin(p(x_1, x_2)). \tag{7.2}$$

These two surfaces define the upper and lower boundaries of a piecewise smooth bounded domain Ω of $\mathbb{R}^3$ which is contained in $\Theta \times (-\pi/2, \pi/2)$. By definition $\phi = 0$ on $\partial\Omega$. Therefore Theorem 1.3 does not hold in this domain.

This type of set Ω reproduces the structure of the polygonal domain given in §7.1.

In these domains Ω the hypothesis c) of Theorem 1.8 fails since there is no point of the boundary of Ω where the tangent plane is orthogonal to the plane $x_3 = 0$. Note that, at the points of the boundary of Ω where $x_3 = 0$, the tangent plane does not exist since the tangent planes of the upper and lower surfaces S_1 and S_2 do not match.

In Figures 3 and 4 we see the domain Ω when Θ is an square and a disk of $\mathbb{R}^2$.

Note that when Θ is smooth, the corresponding domain Ω is Lipschitz. This can be proven easily by using the fact that the normal derivative of p at $\partial\Theta$ is strictly negative. However, as is seen in Figure 3, when Θ is the square, the corresponding domain Ω is not Lipschitz. This is due to the fact that the derivative of the eigenfunction p in the direction of a diagonal of Θ vanishes at the corner.

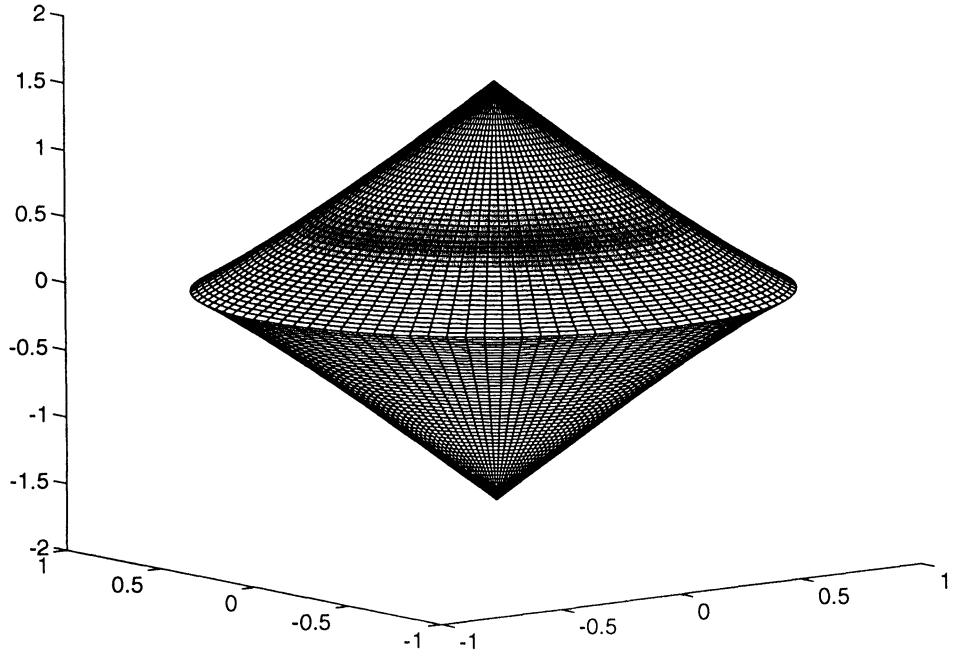

FIG. 4. *Domain Ω as in (7.2) when Θ is the unit disk of $\mathbb{R}^2$ with λ and μ such that $\lambda + 2\mu = \kappa^2$.*

8. Proof of Theorem 1.9. We prove Theorem 1.9 following the approach of Lions [5] and Fabre, Puel, and Zuazua [1].

First we observe that it is sufficient to consider the case where $u^0 \equiv u^1 \equiv 0$. Indeed, given any initial and final data (u^0, u^1), $(v^0, v^1) \in H$ and any $\varepsilon > 0$, let w be the solution of (1.1) with initial data (u^0, u^1) and right-hand side $f = 0$. Then, set $\hat{u} = u - w$. It is easy to check that finding $f \in (L^2(\Omega \times (0, T)))^n$ such that (1.10) holds is equivalent to finding $f \in (L^2(\Omega \times (0, T)))^n$ so that the solution $\hat{u}$ of (1.1) with this control and zero initial data satisfies

$$\left(\|\hat{u}(T) - v^0 + w(T)\|^2_{(H_0^1(\Omega))^n} + \|\hat{u}_t(T) - v^1 + w_t(T)\|^2_{(L^2(\Omega))^n}\right)^{1/2} \leq \varepsilon.$$

Therefore, in the sequel we will assume that $u^0 \equiv u^1 \equiv 0$.

Given any $(v^0, v^1) \in H$ and $\varepsilon > 0$ we introduce the functional $J : \mathcal{H} = (L^2(\Omega))^n \times (H^{-1}(\Omega))^n \to \mathbb{R}$, defined as follows:

$$J(\varphi^0, \varphi^1) = \frac{1}{2}\int_0^T \int_\omega \left(|\varphi_1|^2 + \cdots + |\varphi_{n-1}|^2\right) dx dt - \int_\Omega v^1 \cdot \varphi^0 dx + \langle v^0, \varphi^1 \rangle$$
$$+\varepsilon \|(\varphi^0, \varphi^1)\|_{(L^2(\Omega))^n \times (H^{-1}(\Omega))^n}, \tag{8.1}$$

where $\langle \cdot, \cdot \rangle$ denotes the duality product between $(H_0^1(\Omega))^n$ and $(H^{-1}(\Omega))^n$ and φ is the solution of

$$\begin{cases} \varphi_{tt} - \mu\Delta\varphi - (\lambda + \mu)\nabla \mathrm{div}\varphi = 0 & \text{in } \Omega \times (0, T), \\ \varphi = 0 & \text{on } \Gamma \times (0, T), \\ \varphi(x, T) = \varphi^0(x), \ \varphi_t(x, T) = \varphi^1(x) & \text{in } \Omega. \end{cases} \tag{8.2}$$

The functional J is coercive in $\mathcal{H}$. More precisely, we have the following result.

LEMMA 8.1. *Under the assumptions of Theorem* 1.8,

$$\liminf_{\|(\varphi^0,\varphi^1)\|_{\mathcal{H}}\to\infty} \frac{J(\varphi^0,\varphi^1)}{\|(\varphi^0,\varphi^1)\|_{\mathcal{H}}} \geq \varepsilon. \tag{8.3}$$

Proof. Let us consider a sequence $(\varphi_j^0, \varphi_j^1)$ in $\mathcal{H}$ such that

$$N_j = \|(\varphi_j^0, \varphi_j^1)\|_{\mathcal{H}} \to \infty \text{ as } j \to \infty.$$

We introduce the normalized initial data

$$(\hat{\varphi}_j^0, \hat{\varphi}_j^1) = (\varphi_j^0, \varphi_j^1)/N_j$$

and the corresponding solutions of (8.2):

$$\hat{\varphi}_j = \varphi_j/N_j.$$

We have

$$\frac{I_j}{N_j} = \frac{J(\varphi_j^0,\varphi_j^1)}{N_j} = \frac{N_j}{2}\int_\omega \left(|\hat{\varphi}_{j,1}|^2 + \cdots + |\hat{\varphi}_{j,n-1}|^2\right) dxdt - \int_\Omega v^1.\hat{\varphi}_j^0 dx + \langle v^0, \hat{\varphi}_j^1\rangle + \varepsilon.$$

We distinguish the following two cases:

(i)

$$\liminf_{j\to\infty} \int_0^T \int_\omega \left(|\hat{\varphi}_{j,1}|^2 + \cdots + |\hat{\varphi}_{j,n-1}|^2\right) dxdt > 0.$$

(ii) there exists a subsequence (denoted by the index j to simplify the notation) such that

$$\int_0^T \int_\omega \left(|\hat{\varphi}_{j,1}|^2 + \cdots + |\hat{\varphi}_{j,n-1}|^2\right) dxdt \to 0 \text{ as } j \to \infty. \tag{8.4}$$

In the first case we clearly have

$$\liminf_{j\to\infty} I_j/N_j = \infty.$$

Let us consider the second case. Since $(\hat{\varphi}_j^0, \hat{\varphi}_j^1)$ is bounded in $\mathcal{H}$, we can extract a subsequence (still denoted by the index j) such that $(\hat{\varphi}_j^0, \hat{\varphi}_j^1) \to (\hat{\varphi}^0, \hat{\varphi}^1)$ weakly in $\mathcal{H}$ as $j \to \infty$. Let us denote by $\hat{\varphi}$ the corresponding solutions of (8.2). In view of (8.4) we have

$$\hat{\varphi}_1 \equiv \cdots \equiv \hat{\varphi}_{n-1} \equiv 0 \text{ in } \omega \times (0, T)$$

and therefore, as a consequence of Theorem 1.8, $(\hat{\varphi}^0, \hat{\varphi}^1) \equiv 0$. Thus

$$(\hat{\varphi}_j^0, \hat{\varphi}_j^1) \to (0, 0) \text{ weakly in } \mathcal{H}. \tag{8.5}$$

From (8.5) we deduce that

$$\liminf_{j\to\infty} \frac{I_j}{N_j} = \liminf_{j\to\infty} \frac{N_j}{2}\int_0^T \int_\omega \left(|\hat{\varphi}_{j,1}|^2 + \cdots + |\hat{\varphi}_{j,n-1}|^2\right) dxdt + \varepsilon \geq \varepsilon. \tag{8.6}$$

Therefore, (8.3) holds. □

As a consequence of the coercivity property (8.3), it is easy to check that the infimum of J over $\mathcal{H}$ is achieved at some $(\hat{\varphi}^0, \hat{\varphi}^1) \in \mathcal{H}$. At this minimizer $(\hat{\varphi}^0, \hat{\varphi}^1)$ the optimality conditions

$$(8.7)\quad \left| \int_0^T \int_\omega \left(\hat{\varphi}_1\rho_1 + \cdots + \hat{\varphi}_{n-1}\rho_{n-1}\right) dxdt - \int_\Omega v^1 \cdot \rho^0 dx + \langle v^0, \rho^1 \rangle \right| \leq \varepsilon \|(\rho^0, \rho^1)\|_{\mathcal{H}}$$

are satisfied for all $(\rho^0, \rho^1) \in \mathcal{H}$, where $\hat{\varphi}$ denotes the solution of (8.2) corresponding to the minimizer $(\hat{\varphi}^0, \hat{\varphi}^1)$ and ρ is the solution of (8.2) with data (ρ^0, ρ^1).

Observe that if u solves (1.1) with $u^0 \equiv u^1 \equiv 0$ and $f = \hat{\varphi}$, then

$$(8.8)\quad \int_0^T \int_\omega \left(\hat{\varphi}_1\rho_1 + \cdots + \hat{\varphi}_{n-1}\rho_{n-1}\right) dxdt = \int_\Omega u_t(T) \cdot \rho^0 dx - \langle u(T), \rho^1 \rangle.$$

Combining (8.7) and (8.8) we obtain

$$\left| -\int_\Omega (v^1 - u_t(T)) \cdot \rho^0 \, dx + \langle v^0 - u(T), \rho^1 \rangle \right| \leq \varepsilon \|(\rho^0, \rho^1)\|_{\mathcal{H}}$$

for all $(\rho^0, \rho^1) \in \mathcal{H}$, and this is equivalent to

$$\|(u(T) - v^0, u_t(T) - v^1)\|_H \leq \varepsilon.$$

9. Two examples of noncontrollability. In this section we develop the examples mentioned in Remarks 1.10 and 1.11 that can be constructed explicitly for periodic boundary conditions. The first one shows that, in general, exact controllability does not hold with L^2-controls obeying (1.2) and periodic boundary conditions. We do not have a counterexample for Dirichlet boundary conditions, but the situation is probably the same in this respect. The second example shows that if we impose further restrictions on the control, the approximate controllability may be lost. However, this result may depend on the type of boundary conditions and cannot be considered a serious indication for Dirichlet boundary conditions.

Throughout this section we assume that the Dirichlet boundary conditions are replaced by the periodic ones.

9.1. An example of nonexact controllability. The exact controllability with controls f in $(L^2(\Omega \times (0, T)))^n$ obeying (1.2) is equivalent to the following estimate for the adjoint system (1.3) (see [4]):

$$(9.1)\quad \|\varphi(0)\|^2_{(L^2(\Omega))^n} + \|\varphi_t(0)\|^2_{(H^{-1}(\Omega))^n} \leq C \int_0^T \int_\omega \left[|\varphi_1|^2 + \cdots + |\varphi_{n-1}|^2\right] dxdt.$$

Let us prove that, in general, (9.1) does not hold even if $\omega = \Omega$.

Let us assume that Ω is the three-dimensional cube $\Omega = (0, \pi)^3$. Let us consider divergence-free solutions of the form

$$\varphi(x, t) = c \sin(k \cdot x) \cos(\sqrt{\mu}\,|k|\,t)$$

with $c \in \mathbb{R}^n$ and $k \in \mathbf{Z}^n$ such that $c \cdot k = 0$. It is easy to check that φ satisfies (1.3). Actually, since $c \cdot k = 0$, we have $\operatorname{div}\varphi = 0$. Therefore, (1.3) reduces to the diagonal system of wave equations

$$\varphi_{tt} - \mu\Delta\varphi = 0.$$

Let us now analyze inequality (9.1) in the case where $\omega = \Omega$. It is a simple computation to check that the energy of the initial data (i.e., the left-hand side of (9.1)) equals $|c|^2/2$. The

integral on the right-hand side, which measures the energy of the first two components of the solution, equals

$$\frac{|c'|^2}{2}\left(T+\frac{\sin(\sqrt{\mu}\,|k|\,T)}{\sqrt{\mu}\,|k|}\right),$$

where $c'=(c_1,c_2)$. For any $T>0$ the quantity

$$\frac{|c|^2}{|c'|^2}\left(T+\frac{\sin(\sqrt{\mu}\,|k|\,T)}{\sqrt{\mu}\,|k|}\right)^{-1}=\left(1+\frac{c_3^2}{|c'|^2}\right)\left(T+\frac{\sin(\sqrt{\mu}\,|k|\,T)}{\sqrt{\mu}\,|k|}\right)^{-1}$$

(which is the quotient between the left- and right-hand sides of (9.1)) may be arbitrarily large. Indeed, since $c\cdot k=0$, we have $c_3=-c'\cdot k'/k_3$ with $k'=(k_1,k_2)$. Thus,

$$1+\frac{c_3^2}{|c'|^2}=1+\frac{|c'\cdot k'|^2}{|c'|^2\,k_3^2}.$$

We see that given $k_3\in\mathbf{Z}$ and $c'\in\mathbb{R}^2$, we may choose $k'\in\mathbf{Z}^2$ so that this quantity becomes arbitrarily large. On the other hand,

$$\left(T+\frac{\sin(\sqrt{\mu}\,|k|\,T)}{\sqrt{\mu}\,|k|}\right)\to T\quad\text{as } |k|\to\infty.$$

Thus (9.1) does not hold. □

Let us recall that if all the components of the control are nonzero, exact controllability with $(L^2(\Omega\times(0,T)))^3$ controls holds for a certain class of ω's. For instance, if ω is a neighborhood of the boundary of Ω, exact controllability holds with control time $T(\Omega)=\operatorname{diam}(\Omega\setminus\omega)/\sqrt{\mu}$ (see [4]).

9.2. An example of nonapproximate controllability under further constraints on the control. In view of Theorem 1.9 it is natural to study if approximate controllability holds when two components of the control are constrained to be identically zero. Thus let us suppose that the control function f is of the form

$$f=(f_1,\dots,f_{n-2},0,0). \tag{9.2}$$

This problem can be formulated in an equivalent way in terms of a uniqueness property for the adjoint system (1.3). This time, the uniqueness property to be understood is the following: If φ is a solution of (1.3) in the class $C([0,T];(L^2(\Omega))^n)\cap C^1([0,T];(H^{-1}(\Omega))^n)$ such that

$$\varphi_1\equiv\dots\equiv\varphi_{n-2}\equiv 0 \text{ in } \omega\times(0,T) \tag{9.3}$$

and T is large enough, can we deduce that, necessarily, $\varphi\equiv 0$ in $\Omega\times(0,T)$? It is easy to check that in dimension $n=3$ when $\Omega=(0,\pi)^3$ this uniqueness result does not hold even when $\omega=\Omega$.

Indeed, we can construct solutions of the form

$$\varphi(x,t)=c\sin(k\cdot x)\cos(\sqrt{\mu}\mid k\mid t)$$

with $c\in\mathbb{R}^3$, $k\in\mathbf{Z}^3$, $k\neq 0$ such that $c\cdot k=0$, $c_1=0$, $c'\neq 0$ so that $\varphi_1\equiv 0$ everywhere but φ is nontrivial. Thus we cannot expect approximate controllability results in three space dimensions with controls of the form $f=(f_1,0,0)$. □

Acknowledgments. The author acknowledges Caroline Fabre for a fruitful discussion on the proof of Theorem 1.3.

NEW NECESSARY CONDITIONS FOR THE GENERALIZED PROBLEM OF BOLZA*

P. D. LOEWEN† AND R. T. ROCKAFELLAR‡

Abstract. Problems of optimal control are considered in the neoclassical Bolza format, which centers on states and velocities and relies on nonsmooth analysis. Subgradient versions of the Euler–Lagrange equation and the Hamiltonian equation are shown to be necessary for the optimality of a trajectory, moreover in a newly sharpened form that makes these conditions equivalent to each other. At the same time, the assumptions on the Lagrangian integrand are weakened substantially over what has been required previously in obtaining such conditions.

Key words. optimal control, calculus of variations, nonsmooth analysis, problem of Bolza, Euler–Lagrange condition, Hamiltonian condition, transversality condition

AMS subject classifications. 49K15, 49K05, 49K24

1. Introduction. Among the classical problems in the calculus of variations, that of Bolza marked a high point of complication, involving all the kinds of side conditions then viewed as important. With deceptive simplicity, the *generalized* problem of Bolza can be stated in one line:

$$(\mathcal{P}) \qquad \text{minimize } \Lambda[x] := l(x(a), x(b)) + \int_a^b L(t, x(t), \dot{x}(t))\, dt,$$

where the minimization takes place over all absolutely continuous functions ("arcs") $x\colon [a, b] \to \mathbb{R}^n$. Its generality rests on allowing l and L to be extended real valued, hence not necessarily differentiable or even continuous.

The tactic of admitting such a broad range of choices for l and L, first adopted in Rockafellar [21], enables $(\mathcal{P})$ to encompass a vast array of dynamic optimization problems, including those governed by controlled differential equations, differential inclusions, and incorporating endpoint constraints of every conceivable form. For example, $(\mathcal{P})$ subsumes the problem

$$(\mathcal{P}_1) \qquad \begin{aligned} &\text{minimize } \Lambda_1[x] := l_1(x(a), x(b)) + \int_a^b L_1(t, x(t), \dot{x}(t))\, dt \\ &\text{subject to } (x(a), x(b)) \in S \text{ and } \dot{x}(t) \in F(t, x(t)) \text{ a.e. } t \in [a, b] \end{aligned}$$

for a set $S \subset \mathbb{R}^n \times \mathbb{R}^n$ and a multifunction $F : [a, b] \times \mathbb{R}^n \rightrightarrows \mathbb{R}^n$. Indeed, it suffices to take $l = l_1 + \Psi_S$ and $L = L_1 + \Psi_{\text{gph}\, F}$, where Ψ_S and $\Psi_{\text{gph}\, F}$ are the indicators of S and the graph of F (having the value 0 on these sets but ∞ outside). In the classical problem of Bolza, S and the graph of F were specified by side conditions of the kind $l_i(x(a), x(b)) = 0$ and $L_j(t, x(t), \dot{x}(t)) = 0$, with i and j in given finite index sets, all functions being assumed smooth (cf. Bliss [2, p. 189]); eventually the equations were supplemented by inequalities, and "isoperimetric" constraints were listed too (cf. Hestenes [8, p. 348]). Isoperimetric constraints fit into $(\mathcal{P}_1)$ by the trick of adding more state variables and modifying S and F accordingly. (In these classical formulations the interval $[a, b]$ was permitted to vary, and this could be built into $(\mathcal{P}_1)$ and $(\mathcal{P})$ as well, but we focus on the fixed-interval case here, reserving the variable-interval extension for elsewhere.)

On the other hand, problems in optimal control of the wide form below can also be fitted into the pattern of $(\mathcal{P})$:

$$(\mathcal{P}_C)\qquad \begin{aligned} &\text{minimize } \Phi[x,u] := \phi(x(a),x(b)) + \int_a^b f(t,x(t),u(t))\,dt \\ &\text{subject to } \dot{x}(t) \in F(t,x(t),u(t)),\ u(t) \in U(t,x(t)) \text{ a.e. } t \in [a,b], \\ &\qquad \text{and } (x(a),x(b)) \in S. \end{aligned}$$

To arrange this, simply take $l = \phi + \Psi_S$ as before and

$$L(t,x,v) = \inf_u \{f(t,x,u) \,:\, u \in U(t,x),\ v \in F(t,x,u)\},$$

interpreting the right side as ∞ when there is no u in $U(t,x)$ for which $F(t,x,u)$ contains v. Note that the dynamics here involve a controlled differential inclusion and that the set of admissible controls displays explicit state dependence—two features beyond the scope of the classical theory. It is more difficult to force $(\mathcal{P}_C)$ into the framework of $(\mathcal{P}_1)$, which underscores the importance of $(\mathcal{P})$ as the model of choice when a full spectrum of control applications is envisioned. For more on this approach to optimal control, see [24] and [29].

Our aim is to establish necessary conditions for optimality in $(\mathcal{P})$ that retain both the form and the power of their classical precursors, the equations of Euler–Lagrange and Hamilton, despite the nonsmooth, extended-real-valued setting. This program for the generalized problem of Bolza is not new: it began with Rockafellar's work in the case where both functions l and $L(t,\cdot,\cdot)$ are convex [21–23, 25], and it was greatly advanced beyond such full convexity by Clarke [3–6] and others. Most recently there have been contributions by Loewen and Rockafellar [13, 14], Mordukhovich [19], and Ioffe and Rockafellar [10].

The current work has two especially distinguishing features. First, it provides a sharpened version of the Hamiltonian optimality condition that is *equivalent* to the sharpened form of the Euler–Lagrange condition we introduced in [14]. Second, it assumes significantly less than before about the Lagrangian L; it does not demand that L have the form $L_1 + \Psi_{\text{gph}\,F}$ in which Lipschitz properties are expected of L_1 and F, as, for instance, in [13]. It does ask for the convexity of L in the velocity argument, in contrast to the recent papers [19] and [10], but those works are more restrictive in other respects and anyway concern the Euler–Lagrange condition only.

The convexity of L in the velocity argument is essential for the equivalence between the Euler–Lagrange condition and the Hamiltonian condition, whatever their versions. Indeed, aside from the classical case of a smooth function L, or the fully convex case where L is convex in the state and velocity arguments together and some other special cases covered by [30], results asserting the simultaneous necessity of both conditions were elusive. The best that could be claimed, in [14], was the existence of at least one adjoint arc for which both conditions in a certain form were satisfied. (Other adjoint arcs might fulfill just one of the two.)

The sharpened Euler–Lagrange condition that we use in relating an extremal arc $\overline{x}$ to an adjoint arc p asserts that

$$\dot{p}(t) \in \operatorname{co}\left\{v \,:\, (v,p(t)) \in \partial L(t,\overline{x}(t),\dot{\overline{x}}(t))\right\} \text{ a.e. } t \in [a,b]. \tag{1.1}$$

Here ∂ refers to the possibly nonconvex *limiting subgradient* set (see Loewen [12] for notation and terminology), known also under various other names: limiting proximal subgradient set in Clarke [6], approximate subdifferential in Ioffe [9], subdifferential in Mordukhovich [19], subgradient set in the general sense in Rockafellar [31]. (The subgradients are those of $L(t,\cdot,\cdot)$ with t fixed.) Under the hypotheses of this paper (see §2), the inclusion (1.1) implies that for almost all t the vector $\dot{\overline{x}}(t)$ maximizes the function $v \mapsto \langle p(t)\,,\, v\rangle - L(t,\overline{x}(t),v)$.

The sharpened Hamiltonian condition that we establish for the first time as necessary for optimality, by virtue of its equivalence to (1.1), is

$$\dot{p}(t) \in \operatorname{co}\left\{w \,:\, (-w, \dot{\overline{x}}(t)) \in \partial H(t, \overline{x}(t), p(t))\right\} \text{ a.e. } t \in [a, b]. \tag{1.2}$$

The Hamiltonian H is, as usual, the Legendre–Fenchel transform of the Lagrangian L in its velocity variable:

$$H(t, x, p) := \sup\left\{\langle p\,,\, v\rangle - L(t, x, v) \,:\, v \in \mathbb{R}^n\right\}.$$

Clearly, (1.2) is a strict improvement on the form $(-\dot{p}(t), \dot{\overline{x}}(t)) \in \operatorname{co} \partial H(t, \overline{x}(t), p(t))$, taken as standard until now, since it convexifies only in the first argument. It implies, in particular, that for almost all t, the vector $p(t)$ maximizes the function $q \mapsto \langle q\,,\, \dot{\overline{x}}(t)\rangle - H(t, \overline{x}(t), q)$.

The weakened assumptions on L that suffice for these developments are set out in hypotheses (H4) and (H5) of §2. The first of these is a very mild "epi-continuity" assumption. Geometrically it amounts to insisting that, for each fixed t, the set epi $L(t, x, \cdot)$ should vary continuously with x. The second is a growth condition on subgradients, reducing when $L(t, x, v)$ is smooth to a local inequality of the form $|\nabla_x L| \le \kappa\big(1 + |\nabla_v L|\big)$. It implies, through a result of Mordukhovich [18], the Aubin ("pseudo-Lipschitz") continuity of the multifunction $x \rightrightarrows$ epi $L(t, x, \cdot)$ near the optimal arc. Our need for Aubin continuity on a tube of uniform size around the minimizing trajectory makes it necessary to formulate a quantitative generalization of Mordukhovich's result in §4.

We give special attention in §7 to the Lipschitz-plus-indicator case where $L = L_1 + \Psi_{\text{gph}\, F}$, showing for that version of the problem that the present results yield a full suite of (sharpened) Lagrangian and Hamiltonian necessary conditions for optimality in both normal and abnormal forms beyond what we had previously obtained in [13] and [14]. This recalls the work of Smirnov [32], who proposed the version of (1.1) for $L = \Psi_{\text{gph}\, F}$ as a necessary condition in 1991 but whose requirements that F be bounded and autonomous are significantly relaxed here. (Smirnov's result and proof are linked to prior work of Mordukhovich [15–17], who has recently given conditions [19] under which the necessity of (1.1) can be established in the absence of convexity hypotheses.) The main thrust of our effort, however, goes the other way: we demonstrate how to transform $(\mathcal{P})$ in its full generality into an instance of the differential inclusion problem in [14], and with some new machinery we then apply the results in that paper in combination with the Lagrangian–Hamiltonian equivalence theorem in [31].

State constraints requiring $x(t)$ to belong to a set $X(t) \subset \mathbb{R}^n$ can in principle be incorporated into problem $(\mathcal{P})$ by adding an indicator term in the specification of L, but for technical reasons it is better, at least in the theory as it now stands, to keep them explicit. The treatment of such constraints is taken up in §6.

2. The main result. Our main result is Theorem 2.1, a set of necessary conditions for an arc $\overline{x}$ to provide a local minimum in problem $(\mathcal{P})$. So let $\overline{x}$ be given, and fix some $\varepsilon > 0$ in order to define a suitable neighbourhood of $\overline{x}$:

$$\Omega := \{(t, x) \,:\, t \in [a, b],\ |x - \overline{x}(t)| < \varepsilon\},$$
$$\Omega_t := \{x \,:\, |x - \overline{x}(t)| < \varepsilon\}, \quad a \le t \le b.$$

We impose five conditions on $\overline{x}$ and the functions l and L relative to the set Ω; they are described below as (H1)–(H5). For simplicity in dealing with subgradients of $L(t, x, v)$ and $H(t, x, p)$ we use the notation ∂L and ∂H instead of the more cumbersome (but precise) $\partial_{(x,v)} L$ and $\partial_{(x,p)} H$. In general, as already mentioned, we write $\partial f(z)$ for the set of limiting subgradients associated with a lower semicontinuous function f at the point z; the singular counterpart to this set is $\partial^\infty f(z)$. See Loewen [12] for details.

THEOREM 2.1. *Assume* (H1)–(H5). *Suppose that for every arc x with graph in Ω, one has $\Lambda[x] \geq \Lambda[\overline{x}]$. Then either the normal conditions or the degenerate conditions given below are valid.*

Normal conditions: For some arc p on $[a, b]$,

(a) $\dot{p}(t) \in \operatorname{co}\{v : (v, p(t)) \in \partial L(t, \overline{x}(t), \dot{\overline{x}}(t))\}$ *a.e.* $t \in [a, b]$,

(b) $(p(a), -p(b)) \in \partial l(\overline{x}(a), \overline{x}(b))$.

Degenerate conditions: For some nonzero arc p on $[a, b]$,

(a^∞) $\dot{p}(t) \in \operatorname{co}\{v : (v, p(t)) \in \partial^\infty L(t, \overline{x}(t), \dot{\overline{x}}(t))\}$ *a.e.* $t \in [a, b]$,

(b^∞) $(p(a), -p(b)) \in \partial^\infty l(\overline{x}(a), \overline{x}(b))$.

(In particular, if the only arc p on $[a, b]$ satisfying conditions (a^∞)–(b^∞) *is the zero arc, then the normal conditions are satisfied.) In the normal conditions, assertion* (a) *is equivalent to*

(a′) $\dot{p}(t) \in \operatorname{co}\{w : (-w, \dot{\overline{x}}(t)) \in \partial H(t, \overline{x}(t), p(t))\}$ *a.e.* $t \in [a, b]$.

Also, conditions (a) *and* (a′) *imply that for almost all t in $[a, b]$,*

(c) $p(t) \in \partial_v L(t, \overline{x}(t), \dot{\overline{x}}(t)) = \operatorname{argmax}_{q \in \mathbb{R}^n} \{\langle q, \dot{\overline{x}}(t)\rangle - H(t, \overline{x}(t), q)\}$, *and*
$\dot{\overline{x}}(t) \in \partial_p H(t, \overline{x}(t), p(t)) = \operatorname{argmax}_{v \in \mathbb{R}^n} \{\langle p(t), v\rangle - L(t, \overline{x}(t), v)\}$.

Hypotheses. The terms in the Bolza functional Λ are required to have the following properties, expressed in terms of the constant $\varepsilon > 0$ in the definition of Ω and two positive-valued integrable functions δ and κ on $[a, b]$.

(H1) The endpoint cost function $l(x_a, x_b)$: $\mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R} \cup \{\infty\}$ is lower semicontinuous on $\Omega_a \times \Omega_b$.

(H2) The integrand $L(t, x, v)$: $\Omega \times \mathbb{R}^n \to \mathbb{R} \cup \{\infty\}$ is measurable with respect to the σ-field $\mathcal{L} \times \mathcal{B}$ generated by products of Lebesgue subsets of $[a, b]$ with Borel subsets of $\mathbb{R}^n \times \mathbb{R}^n$.

(H3) For each fixed pair (t, x) in Ω, the function $v \mapsto L(t, x, v)$ is convex.

(H4) For almost every t in $[a, b]$, the function $(x, v) \mapsto L(t, x, v)$ is lower semicontinuous on $\Omega_t \times \mathbb{R}^n$ and has the following epi-continuity property: for any point $(\widehat{x}, \widehat{v})$ where $|\widehat{x} - \overline{x}(t)| < \varepsilon$ and $L(t, \widehat{x}, \widehat{v})$ is finite, and for any sequence $x_k \to \widehat{x}$ in Ω_t, there exists a sequence $v_k \to \widehat{v}$ along which $L(t, x_k, v_k) \to L(t, \widehat{x}, \widehat{v})$.

(H5) The ratio $\kappa(t)/\delta(t)$ is essentially bounded. For almost all t in $[a, b]$, one has

$$|w| \leq \kappa(t)\,(1 + |p|) \text{ for all } (w, p) \in \partial L(t, x, v),$$

whenever $|x - \overline{x}(t)| < \varepsilon$, $\left|(v, L(t, x, v)) - (\dot{\overline{x}}(t), L(t, \overline{x}(t), \dot{\overline{x}}(t)))\right| < \delta(t)$.

As the absence of measures in the statement of Theorem 2.1 signals, state constraints cannot be implicit in the instance of $(\mathcal{P})$ under consideration at this stage. To see how such restrictions are ruled out, note that (H4) makes the set

$$G_t = \{x \in \Omega_t : L(t, x, v) < \infty \text{ for some } v \text{ with } |v - \dot{\overline{x}}(t)| < \delta(t)\}$$

be *open* for almost all t. Indeed, (H4) says that no point $\widehat{x}$ in G_t can be a boundary point. Of course, $\overline{x}(t)$ lies in G_t. Thus our paradigm allows L to impose certain velocity constraints through the use of infinite penalties but does not allow unilateral state constraints to be covered in the same way. State constraints in the explicit form $x(t) \in X(t)$ $\forall t$ can nonetheless be handled by our methods, as will be explained in §6.

Hypothesis (H5) can be viewed as a combined growth condition and Lipschitz condition. As a growth condition, it resembles the "condition of Morrey type" underlying Clarke and Vinter's Proposition 3.2 in [7], a result which establishes the validity of the Euler–Lagrange equation in the calculus of variations without the a priori assumption that the minimizing arc is Lipschitzian. Indeed, in the special case where $L(t, \cdot, \cdot)$ is continuously differentiable on Ω_t, (H5) reduces to

$$|\nabla_x L(t, x, v)| \leq \kappa(t)\big(1 + |\nabla_v L(t, x, v)|\big) \qquad \forall (x, v) \in \Omega_t.$$

As a Lipschitz condition, (H5) is a subgradient characterization of the Aubin continuity of the epigraphical multifunction associated with L, as we shall see in §4. A Hamiltonian formulation of this assumption is derived in §5, where its relationship to Clarke's "strong Lipschitz condition" [4] is easiest to discern.

Note that the seemingly weaker form of (H5) obtained by substituting the proximal subgradient set $\widehat{\partial} L$ for ∂L is actually equivalent to the form stated here, because ∂L is defined by taking limits of proximal subgradients.

The method of proof. There is a well-known equivalence between Bolza problems and Mayer problems, mediated by the technique of state augmentation. Indeed, consider the domain $\widetilde{\Omega} = \Omega \times \mathbb{R}$ in one more state dimension, the extra state variable being denoted by y, and define the epigraphical multifunction $E : \widetilde{\Omega} \rightrightarrows \mathbb{R}^{n+1}$ by

$$E(t, x, y) := \operatorname{epi} L(t, x, \cdot).$$

(The set $E(t, x, y)$ does not actually depend on y.) If the arc $\overline{x}$ figuring in our hypotheses solves $(\mathcal{P})$, then the arc $(\overline{x}, \overline{y})$, with

$$\overline{y}(t) := \int_a^t L(r, \overline{x}(r), \dot{\overline{x}}(r))\, dr,$$

solves the following differential inclusion problem:

$$(\mathcal{P}') \qquad \begin{array}{l} \text{minimize } k\big(x(a), y(a), x(b), y(b)\big) := l(x(a), x(b)) + y(b) + \Psi_{\{0\}}(y(a)) \\ \text{subject to } (\dot{x}(t), \dot{y}(t)) \in E(t, x(t), y(t)) \text{ a.e. } t \in [a, b]. \end{array}$$

The right side in the dynamic constraint here is unbounded. Necessary conditions for optimality in problems of this sort were the subject of a previous paper [14]. Our procedure in the current paper is basically to check the hypotheses in [14] and then to translate the conclusions of that work into the context of $(\mathcal{P})$. Checking the hypotheses takes a certain amount of work, since the transition from the subgradient hypothesis (H5) to the Lipschitz conditions required by [14] is not completely straightforward (see §4). Likewise, an additional state-augmentation argument is necessary to reduce the case of a general lower semicontinuous endpoint cost l to the Lipschitz-plus-indicator form treated in [14] (see the proof of Theorem 3.1). Finally, it is insufficient simply to transcribe the conclusions of [14]: the sharpened Hamiltonian inclusion featured here relies on a careful analysis of the relationship between the Hamiltonian and Eulerian forms of the necessary conditions, as carried out by Rockafellar [31].

3. Proof of the main result. To prove Theorem 2.1, we shall apply an intermediate result for unbounded differential inclusions which is readily derived from [14, Thm. 4.3]. The reformulated problem $(\mathcal{P}')$ under consideration fits the general pattern:

$$(\overline{\mathcal{P}}) \qquad \begin{array}{l} \text{minimize } k(z(a), z(b)) \\ \text{subject to } \dot{z}(t) \in E(t, z(t)) \text{ a.e. } t \in [a, b]. \end{array}$$

The hypotheses of [14] for this kind of problem refer to a distinguished arc $\overline{z}$ and, for some fixed $\eta > 0$, its "graphical neighbourhood"

$$U = \{(t, z) : t \in [a, b],\ |z - \overline{z}(t)| < \eta\},$$
$$U_t = \{z : |z - \overline{z}(t)| < \eta\}, \quad a \le t \le b.$$

They read as follows:

(h1) The endpoint cost function $k: U_a \times U_b \to \mathbb{R} \cup \{\infty\}$ is lower semicontinuous.

(h2) The sets $E(t, z)$ are nonempty, closed, and convex for each (t, z) in U and empty for each (t, z) outside U.

(h3) The multifunction E is measurable with respect to the σ-field $\mathcal{L} \times \mathcal{B}$ generated by products of Lebesgue subsets of $[a, b]$ with Borel subsets of $\mathbb{R}^m$.

(h4) There are integrable functions δ and K on $[a, b]$, with K/δ essentially bounded, such that almost every t in $[a, b]$ obeys

$$E(t, y) \cap (\dot{\overline{z}}(t) + \delta(t)\mathbb{B}) \subseteq E(t, z) + K(t)|y - z|\mathbb{B} \quad \forall y, z \in U_t.$$

Here and elsewhere in this paper, $\mathbb{B}$ denotes the closed unit ball in the Euclidean space of appropriate dimension.

THEOREM 3.1 (see [14]). *If hypotheses* (h1)–(h4) *hold and* $\overline{z}$ *solves problem* $(\overline{\mathcal{P}})$, *then there exists an arc* q *on* $[a, b]$ *such that*

(a) $\dot{q}(t) \in \operatorname{co}\left\{w : (w, q(t)) \in N_{\operatorname{gph} E(t,\cdot)}\left(\overline{z}(t), \dot{\overline{z}}(t)\right)\right\}$ *a.e.* $t \in [a, b]$; *and*

(b) *one of the following transversality conditions holds:*

(i) $(q(a), -q(b)) \in \partial k(\overline{z}(a), \overline{z}(b))$, *or*

(ii) $(q(a), -q(b)) \in \partial^\infty k(\overline{z}(a), \overline{z}(b))$, *with* q *not identically zero.*

Proof. A simple trick reduces the general lower semicontinuous endpoint cost function k to one in the Lipschitz-plus-indicator form analyzed in [14]. Indeed, it suffices to define the constant arc $\overline{r} = k(\overline{z}(a), \overline{z}(b))$ and then to observe that the pair $(\overline{z}, \overline{r})$ solves the problem

$$\begin{aligned} &\text{minimize } r(b) \\ &\text{subject to } (z(a), z(b), r(a)) \in \operatorname{epi} k, \quad r(b) \in \mathbb{R}, \\ &\qquad (\dot{z}(t), \dot{r}(t)) \in E(t, z(t)) \times \{0\} \text{ a.e. } t \in [a, b]. \end{aligned}$$

The stated result follows from conditions (b) and (d) of [14, Thm. 4.3] by elementary subgradient calculus.

Note that although the statement of [14, Thm. 4.3] involves stronger Lipschitz conditions on the multifunction E specifically tailored to the modulus of integrability of the function $\dot{\overline{z}}$, they are present only to facilitate a statement free of explicit references to the quantity $\dot{\overline{z}}(t)$. In fact, the conditions of [14, Prop. 2.2] are sufficient for the conclusions of [14, Thm. 4.3], and it is these we have applied here—taking $R = \delta$ and $m = K$. □

Leaving aside the verification of hypotheses (h1)–(h4) for now, let us derive the conclusions of Theorem 2.1 from those of Theorem 3.1. To apply the latter result, we take $m = n+1$, with $z = (x, y)$ as a pattern and $\overline{z} = (\overline{x}, \overline{y})$ as the optimal arc. Of course, $E(t, z) = E(t, x, y)$ and $k(x_a, y_a, x_b, y_b) = l(x_a, x_b) + y_b + \Psi_{\{0\}}(y_a)$. Observe that

$$\begin{aligned} \partial k(\overline{z}(a), \overline{z}(b)) &= \{(\alpha, \zeta, \beta, 1) : (\alpha, \beta) \in \partial l(\overline{x}(a), \overline{x}(b)),\ \zeta \in \mathbb{R}\}, \\ \partial^\infty k(\overline{z}(a), \overline{z}(b)) &= \left\{(\alpha, \zeta, \beta, 0) : (\alpha, \beta) \in \partial^\infty l(\overline{x}(a), \overline{x}(b)),\ \zeta \in \mathbb{R}\right\}. \end{aligned}$$

In terms of these data, Theorem 3.1 provides an adjoint arc (p, q): $[a, b] \to \mathbb{R}^n \times \mathbb{R}$ satisfying two conditions. First, the transversality condition 3.1(b) implies that either $q(b) = -1$ and $(p(a), -p(b)) \in \partial l(\overline{x}(a), \overline{x}(b))$ or $q(b) = 0$ and $(p(a), -p(b)) \in \partial^\infty l(\overline{x}(a), \overline{x}(b))$ with (p, q) not identically zero. Second, the Euler–Lagrange condition 3.1(a) asserts that for almost all t in $[a, b]$,

$$(\dot{p}(t), \dot{q}(t)) \in \operatorname{co}\left\{(v, w) : (v, w, p(t), q(t)) \in N_{\operatorname{gph} E(t,\cdot)}\left(\overline{x}(t), \overline{y}(t), \dot{\overline{x}}(t), \dot{\overline{y}}(t)\right)\right\}. \tag{3.1}$$

Now for fixed t, one has

$$\operatorname{gph} E(t, \cdot) = \{(x, y, v, r) : (x, v, r) \in \operatorname{epi} L(t, \cdot, \cdot),\ y \in \mathbb{R}\}.$$

In terms of $\overline{L}(t) = L(t, \overline{x}(t), \dot{\overline{x}}(t))$, this implies

$$\begin{aligned} &N_{\operatorname{gph} E(t,\cdot)}\left(\overline{x}(t), \overline{y}(t), \dot{\overline{x}}(t), \dot{\overline{y}}(t)\right) \\ &\qquad = \left\{(v, 0, \pi, -\rho) : (v, \pi, -\rho) \in N_{\operatorname{epi} L(t,\cdot,\cdot)}\left(\overline{x}(t), \dot{\overline{x}}(t), \overline{L}(t)\right)\right\}. \end{aligned}$$

Using this relation in (3.1), we get

$$(\dot{p}(t), \dot{q}(t)) \in \operatorname{co}\left\{v : (v, p(t), q(t)) \in N_{\operatorname{epi} L(t,\cdot,\cdot)}\left(\overline{x}(t), \dot{\overline{x}}(t), \overline{L}(t)\right)\right\} \times \{0\}. \tag{3.2}$$

In particular, the second component of this inclusion implies that $\dot{q}(t) = 0$ almost everywhere. Thus q is a constant function whose value is either 0 or -1. In the case where $q = -1$, one has the normal conditions of Theorem 2.1:

(a) $\dot{p}(t) \in \operatorname{co}\left\{v : (v, p(t)) \in \partial L(t, \overline{x}(t), \dot{\overline{x}}(t))\right\}$ a.e. $t \in [a, b]$, and

(b) $(p(a), -p(b)) \in \partial l(\overline{x}(a), \overline{x}(b))$.

In the case where $q = 0$, the degenerate conditions of Theorem 2.1 follow instead:

(a$^\infty$) $\dot{p}(t) \in \operatorname{co}\left\{v : (v, p(t)) \in \partial^\infty L(t, \overline{x}(t), \dot{\overline{x}}(t))\right\}$ a.e. $t \in [a, b]$, and

(b$^\infty$) $(p(a), -p(b)) \in \partial^\infty l(\overline{x}(a), \overline{x}(b))$, and p is not the zero arc.

In [31, Thm. 1.1], Rockafellar proves that the inclusions (a) and (a′) in Theorem 2.1 are equivalent for each fixed t with the properties described in (H4), provided that every such t also satisfies the condition

$$(w, 0) \in \partial^\infty L(t, \overline{x}(t), \dot{\overline{x}}(t)) \implies w = 0. \tag{3.3}$$

Note that (3.3) holds for almost all t, by (H5). Indeed, any point $(w, 0)$ in the cone $\partial^\infty L(t, \overline{x}(t), \dot{\overline{x}}(t))$ must have the form $(w, 0) = \lim_{\nu\to\infty} r_\nu(w_\nu, p_\nu)$ for sequences $r_\nu \to 0^+$ and $(w_\nu, p_\nu) \in \hat{\partial} L(t, x_\nu, v_\nu)$ along which $(x_\nu, v_\nu) \underset{L}{\to} (\overline{x}(t), \dot{\overline{x}}(t))$. Since $\hat{\partial} L \subseteq \partial L$ always, (H5) implies that for all ν sufficiently large,

$$|r_\nu w_\nu| \le \kappa\,(|r_\nu p_\nu| + r_\nu).$$

In the limit as $\nu \to \infty$, it follows that $|w| \le 0$, so (3.3) holds. Under the same hypotheses, Rockafellar [31] shows that the equivalent conditions (a) and (a′) both imply the argmax conditions in (c).

To complete the proof of Theorem 2.1, we must demonstrate that Theorem 3.1 is truly applicable—by checking hypotheses (h1)–(h4). Conditions (h1)–(h3) hold for any $\eta \in (0, \varepsilon]$ as obvious consequences of the corresponding hypotheses (H1)–(H3) on l and L. The real issue is hypothesis (h4), which calls for the Aubin continuity of the multifunction E (see Aubin [1]) with respect to a certain restricted tube around $\overline{z}$. This condition follows from hypothesis (H5) and Theorem 4.3 in the next section.

To see this, fix a time t in $[a, b]$ at which the conditions in (H4)–(H5) hold. Since t will be fixed throughout this argument, and since E does not actually depend on y, we suppress both the t- and y-dependence of E and L, writing simply $E(x) = \operatorname{epi} L(x, \cdot)$ for $|x - \overline{x}| < \varepsilon$. (We also write $\dot{\overline{x}}$ instead of $\dot{\overline{x}}(t)$ and use the shorthand $\overline{L} = L(\overline{x}, \dot{\overline{x}})$.) As noted above, $\operatorname{gph} E = \operatorname{epi} L$; thus (H4) implies that $\operatorname{gph} E$ is closed and that condition (i) of Theorem 4.3 holds. Condition (ii), on the other hand, requires that

$$|w| \le R|(p, -\lambda)| \text{ for all } (w, p, -\lambda) \in N_{\operatorname{epi} L}(x, v, r), \quad \text{whenever } |x - \overline{x}| < \varepsilon \text{ and } \left|(v, r) - (\dot{\overline{x}}, \overline{L})\right| < \delta.$$

Now the "proximal subgradient formula" [26, 11] asserts that every nonzero vector $(w, p, -\lambda)$ in $N_{\operatorname{epi} L}(x, v, r)$ can be realized as the limit of a sequence of proximal normals $(w_\nu, p_\nu, -\lambda_\nu)$ in $\hat{N}_{\operatorname{epi} L}(x_\nu, v_\nu, r_\nu)$ for which $\lambda_\nu > 0$ and the corresponding base points obey $(x_\nu, v_\nu, r_\nu) \underset{\operatorname{epi} L}{\to} (x, v, r)$. For every term in such a sequence, one has $(w_\nu/\lambda_\nu, p_\nu/\lambda_\nu) \in \hat{\partial} L(x_\nu, v_\nu)$, so (H5) gives

$$|w_\nu/\lambda_\nu| \le \kappa\,(1 + |p_\nu/\lambda_\nu|).$$

Multiplying through by $\lambda_\nu > 0$ and letting $\nu \to \infty$, we obtain

$$|w| \leq \kappa\,(|p| + |\lambda|) \leq 2\kappa|(p, -\lambda)|.$$

This argument applies to every triple $(w, p, -\lambda)$ in $N_{\text{epi}\,L}\,(x, v, r)$, so condition (ii) of Theorem 4.3 holds with $R = 2\kappa$. The conclusion of Theorem 4.3 establishes (h4), with $K(t) = \sqrt{1 + 4\kappa(t)^2}$, any constant $0 < \eta \leq \varepsilon_0(t) := \min\{\varepsilon, \delta(t)/(9K(t))\}$, and $\delta(t)$ equal to one sixth of the value of the $\delta(t)$ provided in (H5). (The function ε_0 is bounded away from zero because $\kappa/\delta \in L^\infty$ by (H5).) This completes the proof of Theorem 2.1.

4. On uniform Aubin continuity. This section and the next furnish technical support for the proof and interpretation of Theorem 2.1 above. Both are intended, though, to stand alone as having independent interest: they involve functions and constants whose names are deliberately suggestive but are logically distinct from those identified in §§1–3 and 6–7.

DEFINITION 4.1. *Let* $\Gamma\colon \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ *be a multifunction and* $(\overline{x}, \overline{y})$ *be a point in* $\operatorname{gph}\Gamma$. *To say that* Γ *is Aubin continuous at* $(\overline{x}, \overline{y})$ *with parameters* $\varepsilon > 0$, $\delta > 0$, *and* $K > 0$ *means that one has*

$$\Gamma(x) \cap (\overline{y} + \delta\mathbb{B}) \subseteq \Gamma(y) + K|y - x|\mathbb{B} \qquad \forall x, y \in \overline{x} + \varepsilon\mathbb{B}. \tag{4.1}$$

The modulus of Aubin continuity for a given multifunction Γ at a point $(\overline{x}, \overline{y})$ in $\operatorname{gph}\Gamma$ is the number $\kappa_\Gamma(\overline{x}, \overline{y})$, defined as the infimum of all $K > 0$ satisfying (4.1) for some $\varepsilon > 0$ and $\delta > 0$. Mordukhovich [18, Thm. 5.7] has shown that if $\operatorname{gph}\Gamma$ is closed, then

$$\kappa_\Gamma(\overline{z}, \overline{y}) = \sup\left\{|\alpha| \,:\, (\alpha, \beta) \in N_{\operatorname{gph}\Gamma}\,(\overline{x}, \overline{y})\,,\ |\beta| \leq 1\right\}.$$

For the purposes of this paper, Aubin continuity with some fixed $\delta > 0$ is required at every point in some ε-neighbourhood of a given arc, and knowing only that κ_Γ is finite at every point along the arc is not sufficient. We need quantitative estimates of the constants ε, δ, and K in terms of a neighbourhood of $(\overline{x}, \overline{y})$ in which the (generalized) slope of vectors normal to the graph of Γ is bounded.

Our approach to this problem is patterned on that introduced in Rockafellar [28, Rem. 3.14]: we prove that Γ has the desired Aubin continuity properties by showing that the function d_Γ defined in the following lemma satisfies a corresponding Lipschitz continuity condition. This in turn is accomplished by using Rockafellar's 1985 results [27] for estimating the subgradients of marginal functions. (Although the facts we appropriate from these earlier papers were phrased in terms of Clarke subgradients, they apply equally well to the limiting subgradients we are working with here.)

LEMMA 4.2. *Given a multifunction* Γ *with closed graph* G, *consider* $d_\Gamma(x, v) := d_{\Gamma(x)}\,(v)$. *If* d_Γ *is Lipschitz of rank* K *on the set* $(\overline{x} + \varepsilon\mathbb{B}) \times (\overline{y} + \delta\mathbb{B})$ *for some constants* $\varepsilon > 0$, $\delta > 0$, *then condition* (4.1) *holds, with the same constants.*

Proof. This is elementary—see Rockafellar [28, Thm. 2.3, (b)⇒(a)]. □

THEOREM 4.3. *Let* $\Gamma\colon \mathbb{R}^n \rightrightarrows \mathbb{R}^m$ *be a multifunction; write* $G = \operatorname{gph}\Gamma$, *and assume that* G *is a closed set. Let* $(\overline{x}, \overline{y})$ *in* G *be a point for which some constants* $\varepsilon > 0$, $\delta > 0$, *and* $R > 0$ *satisfy two conditions*:

(i) *For any point* (x, y) *in* G *with* $|x - \overline{x}| < \varepsilon$ *and* $|y - \overline{y}| < \delta$, *and for any sequence* $x_k \to x$, *there is a sequence* $y_k \in \Gamma(x_k)$ *such that* $y_k \to y$.

(ii) $|\alpha| \leq R|\beta|$ *for all* $(\alpha, \beta) \in N_{\operatorname{gph}\Gamma}\,(x, y)$ *whenever* $|x - \overline{x}| < \varepsilon$ *and* $|y - \overline{y}| < \delta$.

Then Γ *is Aubin continuous at* $(\overline{x}, \overline{y})$ *with parameters* $K = \sqrt{1 + R^2}$, $\delta_0 = \delta/6$, *and* $\varepsilon_0 = \min\{\varepsilon, \delta/(9K)\}$, *i.e.,*

$$\Gamma(y) \cap (\overline{x} + \delta_0\mathbb{B}) \subseteq \Gamma(x) + K|y - x|\mathbb{B} \qquad \forall x, y \in \overline{x} + \varepsilon_0\mathbb{B}. \tag{4.2}$$

Proof. According to Lemma 4.2, we only have to show that d_Γ is Lipschitz continuous of rank K on the set $(\overline{x} + \varepsilon_0 \mathbb{B}) \times (\overline{\gamma} + \delta_0 \mathbb{B})$. To accomplish this, it suffices to show that $\partial d_\Gamma(x, v) \subseteq K\mathbb{B}$ for all (x, v) in this set. We therefore set out to estimate ∂d_Γ, relying on Rockafellar [27].

A convenient characterization of d_Γ, valid for all x and v without restriction, is

$$\begin{aligned} d_\Gamma(x, v) &= \min\{|v - \gamma| \,:\, (x, \gamma) \in G\} \\ &= \min\left\{ f(x, v, \gamma) \,:\, (x, v, \gamma) \in S \right\}, \end{aligned} \tag{4.3}$$

where $f(x, v, \gamma) = |x - \gamma|$ and $S = \{(x, v, \gamma) \,:\, (x, \gamma) \in G,\ v \in \mathbb{R}^m\}$. In the latter form, d_Γ is revealed as the marginal function associated with an optimization problem depending on parameters (x, v). Such functions have been studied extensively, in particular by Rockafellar [27], whose results we shall employ here. Let us denote by $\Sigma(x, v)$ the set of minimizing vectors γ in (4.3) above. Theorem 8.3 of [27] implies that any point (x, v) has a neighbourhood in which d_Γ is Lipschitzian and satisfies the following estimate for limiting subgradients:

$$\partial d_\Gamma(x, v) \ \subseteq\ \{(\xi, \eta) \,:\, (\xi, \eta, 0) \in \partial f(x, v, \gamma) + N_S(x, v, \gamma)\ \exists \gamma \in \Sigma(x, v)\}.$$

(The hypotheses of Rockafellar's result are easy to verify, because the function f here is Lipschitzian, so $\partial^\infty f \equiv \{0\}$, and because f grows rapidly enough to make the inf-compactness condition obvious.) We note that whenever $\gamma \in \Sigma(x, v)$,

$$\begin{aligned} \partial f(x, v, \gamma) &\subseteq \{(0, u, -u) \,:\, |u| \le 1\}, \\ N_S(x, v, \gamma) &= \left\{ (\alpha, 0, \beta) \,:\, (\alpha, \beta) \in N_G(x, \gamma) \right\}. \end{aligned}$$

(A sharper version of the first inclusion is possible, but this one is adequate for our purposes.) It follows that any point (ξ, η) in $\partial d_\Gamma(x, v)$ obeys

$$(\xi, \eta, 0) = (0, u, -u) + (\alpha, 0, \beta) \text{ for some } \gamma \in \Sigma(x, v),\ (\alpha, \beta) \in N_G(x, \gamma),\ u \in \mathbb{B}.$$

Thus

$$\partial d_\Gamma(x, v) \subseteq \{(\alpha, \beta) \in N_G(x, \gamma) \,:\, \gamma \in \Sigma(x, v),\ |\beta| \le 1\}.$$

For those points (x, v) where all the pairs (x, γ) with $\gamma \in \Sigma(x, v)$ lie in the set specified by hypothesis (ii), that condition implies that every pair (α, β) on the right side has $|\alpha| \le R$ and $|\beta| \le 1$, so $|(\alpha, \beta)|^2 \le (R^2 + 1) = K^2$. Thus

$$\{x\} \times \Sigma(x, v) \subseteq (\overline{x} + \varepsilon\mathbb{B}) \times (\overline{\gamma} + \delta\mathbb{B}) \implies \partial d_\Gamma(x, v) \subseteq K\mathbb{B}. \tag{4.4}$$

This reveals the key to the result: the location of the set $\Sigma(x, v)$.

CLAIM. *Fix $(\widehat{x}, \widehat{\gamma})$ in G with $|\widehat{x} - \overline{x}| < \varepsilon$, $|\widehat{\gamma} - \overline{\gamma}| < \delta$. Then for some $\mu > 0$, one has $\Sigma(x, v) \subseteq \overline{\gamma} + \delta\mathbb{B}$ whenever $|x - \widehat{x}| < \mu$, $|v - \widehat{\gamma}| < (\delta - |\widehat{\gamma} - \overline{\gamma}|)/3$.*

To prove this, suppose not: then there are sequences $x_k \to \widehat{x}$ and v_k for which

$$|v_k - \widehat{\gamma}| < \frac{\delta - |\widehat{\gamma} - \overline{\gamma}|}{3} \tag{4.5}$$

and yet $\Sigma(x_k, v_k)$ contains some point outside $\overline{\gamma} + \delta\mathbb{B}$. Call this point π_k. Then $|\pi_k - \overline{\gamma}| > \delta$ and consequently

$$\begin{aligned} d_{\Gamma(x_k)}(v_k) &= |(\pi_k - \overline{\gamma}) - (v_k - \overline{\gamma})| \\ &\ge |\pi_k - \overline{\gamma}| - |v_k - \overline{\gamma}| \\ &> \delta - |v_k - \widehat{\gamma}| - |\widehat{\gamma} - \overline{\gamma}|. \end{aligned} \tag{4.6}$$

But the semicontinuity property (i) provides a sequence $\gamma_k \in \Gamma(x_k)$ such that $\gamma_k \to \widehat{\gamma}$. For this sequence,

$$d_{\Gamma(x_k)}(v_k) \le |v_k - \gamma_k| \le |v_k - \widehat{\gamma}| + |\widehat{\gamma} - \gamma_k|. \tag{4.7}$$

Concatenating inequalities (4.6) and (4.7) and applying condition (4.5) yield

$$\begin{aligned} 2|v_k - \widehat{\gamma}| &\ge \delta - |\widehat{\gamma} - \overline{\gamma}| - |\widehat{\gamma} - \gamma_k| \\ &> 3|v_k - \widehat{\gamma}| - |\widehat{\gamma} - \gamma_k|, \end{aligned}$$

whence $|v_k - \widehat{\gamma}| < |\gamma_k - \widehat{\gamma}|$. In particular, $v_k \to \widehat{\gamma}$. Taking the limit in the previous inequality then gives $0 \ge \delta - |\widehat{\gamma} - \overline{\gamma}|$. This is a contradiction, since the right side here is positive by construction. The claim holds.

We apply the claim first to the point $(\widehat{x}, \widehat{\gamma}) = (\overline{x}, \overline{\gamma})$. In view of (4.4), this shows that ∂d_Γ is bounded by K throughout the interior of some set $(\overline{x} + \mu\mathbb{B}) \times (\overline{\gamma} + (\delta/3)\mathbb{B})$ but provides no information about the size of $\mu > 0$. To balance the need for quantitative information in both directions, consider

$$\widehat{\mu} = \sup\{\mu \in (0, \varepsilon) \,:\, \partial d_\Gamma(x, v) \subseteq K\mathbb{B} \;\forall x \in \overline{x} + \mu\mathbb{B},\; v \in \overline{\gamma} + \delta_0\mathbb{B}\},$$

where δ_0 is defined in the theorem statement. Note that for every (x, v) where $|x - \overline{x}| < \widehat{\mu}$ and $|v - \overline{\gamma}| \le \delta_0$, one has $\partial d_\Gamma(x, v) \subseteq K\mathbb{B}$. Thus d_Γ is Lipschitz continuous of rank K on the set just described. In particular, Γ is Aubin continuous there, and consequently every y with $|y - \overline{x}| < \widehat{\mu}$ obeys

$$\begin{aligned} \overline{\gamma} \in \Gamma(\overline{x}) \cap (\overline{\gamma} + \delta_0\mathbb{B}) \subseteq \Gamma(y) + K|y - \overline{x}|\mathbb{B}, \text{ i.e.,} \\ \Gamma(y) \cap (\overline{\gamma} + K|y - \overline{x}|\mathbb{B}) \ne \emptyset. \end{aligned} \tag{4.8}$$

The closed-graph property of Γ makes it elementary to extend (4.8) to all y in the closed set $\overline{x} + \widehat{\mu}\mathbb{B}$.

Let us prove that $\widehat{\mu} \ge \varepsilon_0$. Suppose this statement is false, i.e., $\widehat{\mu} < \varepsilon_0$: then every sufficiently large integer k admits a corresponding point (x_k, v_k) with $|x_k - \overline{x}| < \widehat{\mu} + 1/k < \varepsilon$, $|v_k - \overline{\gamma}| \le \delta_0$, but $\partial d_\Gamma(x, v) \not\subseteq K\mathbb{B}$. By passing to a subsequence if necessary we can assume that (x_k, v_k) converges to some point $(\widehat{x}, \widehat{v})$ satisfying $|\widehat{x} - \overline{x}| \le \widehat{\mu} < \varepsilon_0$ and $|\widehat{v} - \overline{\gamma}| \le \delta_0 = \delta/6$. From the strong form of (4.8) described in the previous paragraph there exists some point $\widehat{\gamma}$ in $\Gamma(\widehat{x})$ such that $|\widehat{\gamma} - \overline{\gamma}| \le K|\widehat{x} - \overline{x}|$. Our claim applies to the point $(\widehat{x}, \widehat{\gamma})$: it says that the estimate $\partial d_\Gamma \subseteq K\mathbb{B}$ holds throughout some set of the form

$$(\widehat{x} + \mu\mathbb{B}) \times \left(\widehat{\gamma} + \frac{\delta - |\widehat{\gamma} - \overline{\gamma}|}{3}\mathbb{B}\right),$$

where $\mu > 0$ and (by choice of ε_0)

$$\frac{\delta - |\widehat{\gamma} - \overline{\gamma}|}{3} \ge \frac{\delta - K|\widehat{x} - \overline{x}|}{3} \ge \frac{\delta - K\left(\frac{\delta}{9K}\right)}{3} = \frac{8\delta}{27}.$$

But the point $(\widehat{x}, \widehat{v})$ satisfies

$$\begin{aligned} |\widehat{v} - \widehat{\gamma}| \le |\widehat{v} - \overline{\gamma}| + |\overline{\gamma} - \widehat{\gamma}| &\le \frac{\delta}{6} + K|\widehat{x} - \overline{x}| \\ &\le \frac{\delta}{6} + K\left(\frac{\delta}{9K}\right) = \frac{5\delta}{18}. \end{aligned}$$

Now $\frac{8\delta}{27} > \frac{5\delta}{18}$, so these two estimates show that $(\widehat{x}, \widehat{v})$ lies in the *interior* of a set in which ∂d_Γ is bounded by K. This contradicts the stated properties of the sequence (x_k, v_k) and completes our justification that $\widehat{\mu} \geq \varepsilon_0$.

These arguments show that d_Γ is Lipschitz with rank K on a set containing $(\overline{x} + \varepsilon_0\mathbb{B}) \times (\overline{\gamma} + \delta_0\mathbb{B})$. The desired result now follows from Lemma 4.2. □

5. Aubin continuity in Lagrangian and Hamiltonian terms. Like §4, this section is logically independent of the others in the paper, although the similarity of the notation is deliberate.

Given $\overline{x}$ in $\mathbb{R}^n$ and $\varepsilon > 0$, write $\Omega = \overline{x} + \varepsilon\mathbb{B}$ and consider a Lagrangian $L: \Omega \times \mathbb{R}^n \to \mathbb{R} \cup \{\infty\}$. Assume that for every $x \in \Omega$, the function $v \mapsto L(x, v)$ is closed, proper, and convex. Use L to define the multifunction $E(x) := \operatorname{epi} L(x, \cdot)$. Note that for every $x \in \Omega$, this multifunction has nonempty closed convex values. In this section we characterize the Aubin continuity of E near $(\overline{x}, \overline{v})$ in terms of conditions on L and its associated Hamiltonian $H(x, p) := \sup\{\langle p, v\rangle - L(x, v) : v \in \mathbb{R}^n\}$.

THEOREM 5.1. *Fix any point $(\overline{v}, \overline{L})$ in $E(\overline{x})$, along with scalars $\varepsilon > 0$, $K \geq 0$. Write $\mathbb{B}' = \mathbb{B} \times [-1, 1]$ for the unit ball in in $\mathbb{R}^n \times \mathbb{R}$. Then for any $x, y \in \overline{x} + \varepsilon\mathbb{B}$, conditions* (a)–(c) *below are equivalent*:

(a) $E(x) \cap ((\overline{v}, \overline{L}) + \delta\mathbb{B}') \subseteq E(y) + K|y - x|\mathbb{B}'$.

(b) *For any $u \in \overline{v} + \delta\mathbb{B}$ obeying $L(x, u) \leq \overline{L} + \delta$, there exists $v \in \mathbb{R}^n$ satisfying*

(i) $|v - u| \leq K|y - x|$, *and*

(ii) $L(y, v) \leq \max\{\overline{L} - \delta, L(x, u)\} + K|y - x|$.

(c) *For any $p \in \mathbb{R}^n$,*

$$\inf_{\substack{p' \in \mathbb{R}^n \\ \theta > 0}} \{\theta H(x, p'/\theta) + \delta|p' - p| + \delta|\theta - 1| + \langle p - p', \overline{v}\rangle + (\theta - 1)\overline{L}\} \leq H(x, p) + K(1 + |p|)|y - x|. \tag{5.1}$$

Proof. (a⇒b) Suppose that (a) holds. If $u \in \mathbb{R}^n$ satisfies $L(x, u) \leq \overline{L} + \delta$, then the point $(u, \max\{\overline{L} - \delta, L(x, u)\})$ lies in the left side shown in condition (a); thus

$$(u, \max\{\overline{L} - \delta, L(x, u)\}) \in E(y) + K|y - x|\mathbb{B}'.$$

In particular, there has to be a point (h, r) with $\max\{|h|, |r|\} \leq K|y - x|$ such that

$$(u, \max\{\overline{L} - \delta, L(x, u)\}) + (h, r) \in E(y).$$

The special shape of the epigraph set $E(y)$ allows us to replace r with the larger value $K|y - x|$ on the left side: in this case, defining $v = u + h$ gives $|v - u| \leq K|y - x|$ and

$$(v, \max\{\overline{L} - \delta, L(x, u)\} + K|y - x|) \in E(y), \quad \text{i.e., } L(y, v) \leq \max\{\overline{L} - \delta, L(x, u)\} + K|y - x|.$$

(b⇒a) Suppose that (b) holds. Let (u, r) be a vector on the left side in (a). Then $L(x, u) \leq r$ and $\overline{L} - \delta \leq r \leq \overline{L} + \delta$, so (b) provides a vector v such that

(i′) $|v - u| \leq K|y - x|$,

(ii′) $L(y, v) \leq \max\{\overline{L} - \delta, L(x, u)\} + K|y - x| \leq r + K|y - x|$.

Thus $r \geq L(y, v) - K|y - x|$: the special shape of the epigraph set $E(y)$ ensures that $(u, r) \in E(y) + K|y - x|\mathbb{B}$, as required.

(c⇔a) The right side in (a) is a nonempty, closed convex set, since it arises as the sum of a closed convex set and a compact convex set. A separation theorem customized for epigraphs implies that an equivalent formulation of (a) is

$$\sigma_{\mathrm{LS}}(p, -1) \leq \sigma_{\mathrm{RS}}(p, -1) \quad \forall p \in \mathbb{R}^n. \tag{5.2}$$

We calculate

$$\begin{aligned}\sigma_{\mathrm{RS}}(p,-1) &= \sigma_{E(y)}(p,-1) + K|y-x|\sigma_{\mathbb{B}'}(p,-1)\\ &= H(t,y,p) + K\|(p,-1)\|_*|y-x|,\end{aligned} \tag{5.3}$$

where $\|(v,r)\|_* = |v| + |r|$ is the norm on $\mathbb{R}^n \times \mathbb{R}$ dual to the one defining $\mathbb{B}'$ there.

Basic convex analysis (Rockafellar [20, Chap. 16]) affirms that for any nonempty convex sets C and D, with D compact, one has

$$\sigma_{C\cap D} = \mathrm{cl}(\sigma_C \,\square\, \sigma_D) = \sigma_C \,\square\, \sigma_D.$$

(The second equation here holds because the convex function $\sigma_C \,\square\, \sigma_D$ is finite, and hence continuous, on the whole space.) It follows that

$$\begin{aligned}&\sigma_{\mathrm{LS}}(p,-1)\\ &\quad= \left(\sigma_{E(x)} \,\square\, \sigma_{(\overline{v},\overline{L})+\delta\mathbb{B}'}\right)(p,-1)\\ &\quad= \inf_{(p',q')} \left\{\sigma_{E(x)}(p',q') + \delta\left\|(p,-1)-(p',q')\right\|_* + \left\langle p-p',\,\overline{v}\right\rangle + (-1-q')\overline{L}\right\}.\end{aligned}$$

Now $\sigma_{E(x)}(p',q') = \infty$ whenever $q' > 0$, so the latter infimum can be restricted to those points where $q' \le 0$. Furthermore, at any point (p',q') where $q' = 0$, the special features of epigraph sets imply that the quantity $\sigma_{E(x)}(p',0) + \delta\left\|(p,-1)-(p',0)\right\|_*$ can be realized as a limit of some sequence $\sigma_{E(x)}(p'_k,q'_k) + \delta\left\|(p,-1)-(p'_k,q'_k)\right\|_*$ with $q'_k < 0$. Thus the infimum can be restricted to points where $q' < 0$. So we write $\theta = -q' > 0$ and use the observation that

$$\sigma_{E(x)}(p',-\theta) = \theta\sigma_{E(x)}(p'/\theta,-1) = \theta H(x,p'/\theta)$$

to obtain

$$\sigma_{\mathrm{LS}}(p,-1) = \inf_{\substack{p'\in\mathbb{R}^n\\ \theta>0}} \left\{\theta H(x,p'/\theta) + \delta\left\|(p'-p,\theta-1)\right\|_* + \left\langle p-p',\,\overline{v}\right\rangle + (\theta-1)\overline{L}\right\}. \tag{5.4}$$

Equations (5.3) and (5.4) reveal that condition (5.2) is equivalent to (c), whereas (5.2) is equivalent to (a) by construction. □

Clarke's strong Lipschitz condition. In treating the generalized problem of Bolza in [4, Chap. 4], Clarke imposes a Hamiltonian requirement called the "strong Lipschitz condition," which asks that for all x and y in some large enough ball,

$$H(y,p) \le H(x,p) + K\,(1+|p|)\,|y-x| \qquad \forall p \in \mathbb{R}^n. \tag{5.5}$$

Our next corollary shows that Aubin continuity of the sort utilized here is a less demanding hypothesis.

COROLLARY 5.2. *If H satisfies the strong Lipschitz condition* (5.5)*, then H satisfies each of the equivalent conditions* (a)–(c) *in Theorem* 5.1 *for every $\delta > 0$.*

Proof. Choose $p' = p$, $\theta = 1$ in (5.1) to see that the right side of (5.1) is majorized by the right side of (5.5). Thus (5.5) implies condition (c) of Theorem 5.1. □

To see that (5.1) can be strictly weaker than (5.5), consider the example of $L(x,v) = \frac{1}{2}[v^2 + x^2v^2]$. It is easy to compute that $H(x,p) = \frac{1}{2}p^2/(1+x^2)$. For any $\varepsilon > 0$, then, there is a constant $\sigma_\varepsilon > 0$ such that $|H_x(x,p)| \ge \sigma_\varepsilon|p|^2$ for some x in $[-\varepsilon,\varepsilon]$. In particular,

the strong Lipschitz condition (5.5) fails. However, for any fixed x, y in $[-\varepsilon, \varepsilon]$, the choices $\theta = 1$ and $p' = p\sqrt{1+y^2}/\sqrt{1+x^2}$ in (5.1) give

$$\text{LS}(5.1) \le H(x,p) + \delta\left|p\frac{\sqrt{1+y^2}}{\sqrt{1+x^2}} - p\right| \le H(x,p) + (\delta\sqrt{1+x^2})|p||y-x|.$$

Thus inequality (5.1) holds for any $\delta > 0$, with $K = \delta\sqrt{1+\varepsilon^2}$.

In his later treatment of the generalized problem of Bolza in [5], Clarke replaces his "strong Lipschitz condition" with a "weak Lipschitz condition." Although the latter condition is difficult to compare to our Aubin continuity assumption, it does hold for the simple example introduced above.

6. Problems with explicit state constraints. In deriving Theorem 3.1 from Loewen and Rockafellar [14], we have transcribed only the conclusions that pertain in the absence of explicit state constraints. Such constraints are handled in [14], however, and a proof perfectly analogous to the one given in §3 allows us to incorporate them into the main result of this paper as well. In this section we summarize the new ideas required in this broader context and develop the associated enlargement of Theorem 2.1. Fuller explanations of the new ingredients and ideas appear in [13, 14].

Consider the following extension of problem $(\mathcal{P})$ in which state constraints now explicitly enter:

$$(\mathcal{P}^*) \qquad \begin{aligned} &\text{minimize } \Lambda[x] := l(x(a), x(b)) + \int_a^b L(t, x(t), \dot{x}(t))\,dt \\ &\text{subject to } x(t) \in X(t) \ \forall t \in [a,b]. \end{aligned}$$

We retain hypotheses (H1)–(H5) of §2 and impose the following conditions on the state constraint multifunction X:

(H6) Each set $X(t)$ is closed, and the multifunction $t \rightrightarrows X(t)$ is lower semicontinuous, which means that for every point $(t_0, x_0) \in \Omega \cap (\text{gph } X)$ and for every sequence $t_k \to t_0$ in $[a,b]$, there exists a sequence $x_k \to x_0$ with $x_k \in X(t_k)$ for all k.

For each (t,x) in $\Omega \cap (\text{gph } X)$ let

$$\begin{aligned} \overline{N}_X(t,x) = \text{cl co}\big\{v \in \mathbb{R}^n \ : v = \lim_{k\to\infty} v_k \text{ for some sequences} \\ v_k \in \hat{\hat{N}}_{X(t_k)}(x_k),\ (t_k,x_k) \xrightarrow[\text{gph } X]{} (t,x)\big\}. \end{aligned} \tag{6.1}$$

This closed convex cone specifies the directions in which the adjoint function p is allowed to jump when the state constraint is active. Recall that a vector-valued measure dp is called $\overline{N}_X(t, \bar{x}(t))$-valued when dp can be written as $v(t)\,d\mu(t)$ for some nonnegative measure μ on $[a,b]$ with $dp \ll \mu$ and some measurable selection $v(t) \in \overline{N}_X(t, \bar{x}(t))$ μ-a.e.

With these additional ingredients, our main result takes the form stated below. This version differs from the original one, Theorem 2.1, primarily in that its adjoint function p is only of bounded variation, not absolutely continuous as it must be when $X \equiv \mathbb{R}^n$. In particular, the endpoints $p(a)$ and $p(b)$ may differ from the one-sided limits $p(a+)$ and $p(b-)$ in cases where the measure dp has an atom at one or both ends of the interval $[a,b]$.

THEOREM 6.1. *Assume* (H1)–(H6). *Suppose that the arc* $\bar{x}$ *solves problem* $(\mathcal{P}^*)$ *and that the constraint qualification below is satisfied*:

$$\text{(CQ)} \qquad \textit{the cone } \overline{N}_X(t, \bar{x}(t)) \textit{ is pointed for all } t \textit{ in } [a,b].$$

Then either the normal conditions or the degenerate conditions below are satisfied by some function $p \in BV([a,b];\mathbb{R}^n)$ *for which the singular part of the measure* dp *is* $\overline{N}_X(t,\overline{x}(t))$*-valued, and hence in particular is supported on the set*

$$\left\{t \,:\, \overline{N}_X(t,\overline{x}(t)) \neq \{0\}\right\} = \{t \in [a,b] \,:\, (t,\overline{x}(t)) \in \operatorname{bdy} \operatorname{gph} X\}\,.$$

Normal conditions:

(a) $\dot{p}(t) \in \operatorname{co}\left\{w \,:\, (w,p(t)) \in \partial L(t,\overline{x}(t),\dot{\overline{x}}(t))\right\} + \overline{N}_X(t,\overline{x}(t))$ *a.e.* $t \in [a,b]$,

(b) $(p(a),-p(b)) \in \partial l(\overline{x}(a),\overline{x}(b))$.

Singular conditions: The function p *is nonzero, and*

(a^∞) $\dot{p}(t) \in \operatorname{co}\left\{w \,:\, (w,p(t)) \in \partial^\infty L(t,\overline{x}(t),\dot{\overline{x}}(t))\right\} + \overline{N}_X(t,\overline{x}(t))$ *a.e.* $t \in [a,b]$,

(b^∞) $(p(a),-p(b)) \in \partial^\infty l(\overline{x}(a),\overline{x}(b))$.

(*In particular, if the only such function* p *satisfying conditions* (a^∞)–(b^∞) *is identically zero, then the normal conditions are satisfied.*) *In the normal conditions, assertion* (a) *is equivalent to*

(a′) $\dot{p}(t) \in \operatorname{co}\left\{w \,:\, (-w,\dot{\overline{x}}(t)) \in \partial H(t,\overline{x}(t),p(t))\right\} + \overline{N}_X(t,\overline{x}(t))$ *a.e.* $t \in [a,b]$.

Also, conditions (a) *and* (a′) *imply that for almost all* t *in* $[a,b]$,

(c) $p(t) \in \partial_v L(t,\overline{x}(t),\dot{\overline{x}}(t)) = \operatorname{argmax}_{q\in\mathbb{R}^n}\left\{\langle q\,,\,\dot{\overline{x}}(t)\rangle - H(t,\overline{x}(t),q)\right\}$, *and*

$\dot{\overline{x}}(t) \in \partial_p H(t,\overline{x}(t),p(t)) = \operatorname{argmax}_{v\in\mathbb{R}^n}\{\langle p(t)\,,\,v\rangle - L(t,\overline{x}(t),v)\}$.

7. Application: The Lipschitz-plus-indicator case. Many practical problems permit a clear distinction to be drawn between the constraints and the costs. They can thus be expressed in the form of ($\mathcal{P}_1$) in §1. To this model we can now add the possibility of explicit state constraints. We focus then on the problem

$$(\mathcal{P}_1^*)\qquad \begin{aligned} &\text{minimize } \Lambda_1[x] := l_1(x(a),x(b)) + \int_a^b L_1(t,x(t),\dot{x}(t))\,dt \\ &\text{subject to } (x(a),x(b)) \in S \text{ and } \dot{x}(t) \in F(t,x(t)) \text{ a.e. } t \in [a,b] \\ &\text{along with } x(t) \in X(t)\ \forall t \in [a,b], \end{aligned}$$

in which the endpoint cost function l_1 and, for each t, the running cost function $L_1(t,\cdot,\cdot)$ are assumed to be locally Lipschitz continuous. To display this problem as an instance of the general problem's state-constrained version ($\mathcal{P}^*$) treated in §6, it suffices, as we have noted above, to take $l = l_1 + \Psi_S$ and $L = L_1 + \Psi_{\operatorname{gph} F}$, where Ψ_S and $\Psi_{\operatorname{gph} F}$ are the indicators of S and the graph of the multifunction F.

Suitable hypotheses on l_1 and S, as well as L_1 and F, are as follows. Again, they refer to the constant $\varepsilon > 0$ appearing in the definition of Ω and to two positive-valued integrable functions δ and κ.

($H1^+$) The endpoint cost function $l_1\colon \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$ is locally Lipschitzian on $\Omega_a \times \Omega_b$; the target set $S \subseteq \mathbb{R}^n \times \mathbb{R}^n$ is closed.

($H2^+$) The integrand $L_1\colon \Omega \times \mathbb{R}^n \to \mathbb{R}$ and the multifunction $F\colon \Omega \rightrightarrows \mathbb{R}^n$ are $\mathcal{L} \times \mathcal{B}$-measurable.

($H3^+$) For each fixed pair (t,x) in Ω, the function $v \mapsto L_1(t,x,v)$ is convex on $\mathbb{R}^n$, while the set $F(t,x)$ is convex.

($H4^+$) For almost every t in $[a,b]$, the function $(x,v) \mapsto L_1(t,x,v)$ is finite-valued and lower semicontinuous on $\Omega_t \times \mathbb{R}^n$, while the multifunction $x \rightrightarrows F(t,x)$ has closed graph. Furthermore, one has the following epi-continuity property: for any point $(\widehat{x},\widehat{v})$ in $\operatorname{gph} F$ where $|\widehat{x} - \overline{x}(t)| < \varepsilon$ and for any sequence $x_k \to \widehat{x}$ in Ω_t, there exists a sequence $v_k \to \widehat{v}$ satisfying both $v_k \in F(t,x_k)$ and $L_1(t,x_k,v_k) \to L_1(t,\widehat{x},\widehat{v})$.

($H5^+$) The ratio $\kappa(t)/\delta(t)$ is essentially bounded. For almost all t in $[a,b]$, the function $(x,v) \mapsto L_1(t,x,v)$ is Lipschitz of rank $\kappa(t)$ on the set $(\overline{x}(t) + \varepsilon\mathbb{B}) \times (\dot{\overline{x}}(t) + \delta(t)\mathbb{B})$, while

the multifunction F satisfies

$$|w| \leq \kappa(t)\,(1 + |p|) \text{ for all } (w, p) \in N_{\operatorname{gph} F(t,\cdot)}(x, v)$$

whenever $|x - \overline{x}(t)| < \varepsilon$, $\left|v - \dot{\overline{x}}(t)\right| < \delta(t)$.

This case is especially interesting because the Lipschitz continuity of l_1 and L_1 ensures that the singular subgradients of l and L coincide with the usual subgradients of the reduced functions $l_0 = \Psi_S$ and $L_0(t, x, v) = \Psi_{\operatorname{gph} F}(t, x, v)$. This makes it possible to expand the degenerate conditions of Theorem 6.1, which now take the form

(a^∞) $\dot{p}(t) \in \operatorname{co}\left\{v : (v, p(t)) \in \partial L_0(t, \overline{x}(t), \dot{\overline{x}}(t))\right\} + \overline{N}_X(t, \overline{x}(t))$ a.e.,

(b^∞) $(p(a), -p(b)) \in \partial l_0(\overline{x}(a), \overline{x}(b)) = N_S(\overline{x}(a), \overline{x}(b))$.

Rockafellar's equivalence results in [31] certainly apply to L_0 as well as to L, and consequently condition (a^∞) has the equivalent Hamiltonian form

$$\dot{p}(t) \in \operatorname{co}\left\{w : (-w, \dot{\overline{x}}(t)) \in \partial H_0(t, \overline{x}(t), p(t))\right\} \text{ a.e. } t \in [a, b],$$

where, of course, $H_0(t, x, p) := \sup\{\langle p, v\rangle : v \in F(t, x)\}$ is the Hamiltonian corresponding to L_0. Either of the equivalent forms of (a^∞) implies a corresponding argmax condition analogous to (c) in Theorem 6.1.

To summarize these developments, define the Lagrangian and Hamiltonian of index λ, for any $\lambda \geq 0$, by

$$L_\lambda(t, x, v) := \lambda L_1(t, x, v) + \Psi_{\operatorname{gph} F}(t, x, v),$$
$$H_\lambda(t, x, p) := \sup\{\langle p, v\rangle - \lambda L_1(t, x, v) : v \in F(t, x)\}.$$

Then the following result holds.

THEOREM 7.1. *Assume* ($H1^+$)–($H5^+$) *and* (H6). *Suppose that the arc* $\overline{x}$ *solves problem* $(\mathcal{P}_1^*)$ *and that the constraint qualification* (CQ) *of Theorem* 6.1 *is satisfied. Then there exist* $p \in BV([a, b]; \mathbb{R}^n)$ *and a constant* $\lambda \in \{0, 1\}$, *not both zero, such that for almost all* t *in* $[a, b]$,

(a) $\dot{p}(t) \in \operatorname{co}\left\{w : (-w, \dot{\overline{x}}(t)) \in \partial H_\lambda(t, \overline{x}(t), p(t))\right\} + \overline{N}_X(t, \overline{x}(t))$,

(b) $\dot{p}(t) \in \operatorname{co}\left\{w : (w, p(t)) \in \partial L_\lambda(t, \overline{x}(t), \dot{\overline{x}}(t))\right\} + \overline{N}_X(t, \overline{x}(t))$,

(c) $p(t) \in \partial_v L_\lambda(t, \overline{x}(t), \dot{\overline{x}}(t)) = \operatorname{argmax}_{q \in \mathbb{R}^n}\left\{\left\langle q, \dot{\overline{x}}(t)\right\rangle - H_\lambda(t, \overline{x}(t), q)\right\}$,

$\dot{\overline{x}}(t) \in \partial_p H_\lambda(t, \overline{x}(t), p(t)) = \operatorname{argmax}_{v \in F(t, \overline{x}(t))}\{\langle p(t), v\rangle - \lambda L_1(t, \overline{x}(t), v)\}$.

Furthermore,

(d) $(p(a), -p(b)) \in \partial\,(\lambda l_1 + \Psi_S)\,(\overline{x}(a), \overline{x}(b)) \subseteq \lambda \partial l_1(\overline{x}(a), \overline{x}(b)) + N_S(\overline{x}(a), \overline{x}(b))$,

(e) *the singular part of the measure* dp *is* $\overline{N}_X(t, \overline{x}(t))$*-valued and thus is supported on the set* $\left\{t : \overline{N}_X(t, \overline{x}(t)) \neq \{0\}\right\} = \{t : (t, \overline{x}(t)) \in \operatorname{bdy} \operatorname{gph} X\}$.

Note that when $L_1 \equiv 0$, problem $(\mathcal{P}_1^*)$ reproduces the unbounded differential inclusion control problem of Loewen and Rockafellar [14]. The conclusions of Theorem 7.1 then correspond exactly to those of [14, Thm. 4.3] but with three major improvements: they allow for a nonzero integrand L_1, offer the alternative formulation of the Aubin continuity hypothesis in ($H5^+$), and present a sharper Hamiltonian inclusion in (a).

BOUNDARY EXACT CONTROLLABILITY OF INTERFACE PROBLEMS WITH SINGULARITIES I: ADDITION OF THE COEFFICIENTS OF SINGULARITIES*

SERGE NICAISE†

Abstract. We prove the exact controllability by boundary action of hyperbolic interface problems with singularities. The idea is to replace the classical space of controls with the space of their regular parts, which is augmented with the coefficents of singularities. This leads to a classical boundary control but with an internal control, which is a distribution with a support equal to the singular vertices.

Key words. interface problems, singularities, control

AMS subject classifications. 93C20, 35B37, 35L67

1. Introduction.

The description of various models of multiple-link flexible structures consisting of finitely many interconnected flexible elements, such as strings, beams, plates, shells, or combinations of them, recently has been the subject of great interest [10, 3, 12, 13]. The problem of controllability, or even stabilizability, of such structures has been considered very little. Let us quote the works of Lagnese, Leugering, and Schmidt [25, 11, 12] for one-dimensional (1-d) networks; the books of Lagnese, Leugering, and Schmidt [12, Chap. VII] and J.-L. Lions [15, Chap. VI] about transmission problems excluding singularities; and finally, the papers of Puel and Zuazua [24] and the author [20, 21] for multidimensional structures. In all these works, either no singularity occurs or, if there are some singularities, they are cancelled by an appropriate choice of the multiplier. In the present papers, we show with simple examples of multilink structures—namely, the wave equation in two-dimensional (2-d) networks (see below for a precise definition; also [4, 22])—how to manage the presence of singularities and the controllability problem using the Hilbert uniqueness method of J.-L. Lions [15]. Indeed, this method usually needs the regularity $H^{3/2+\varepsilon}$ for some $\varepsilon > 0$ (in our case, it means $H^{3/2+\varepsilon}(P_i)$ for all faces P_i), which is, in general, not satisfied for 2-d networks. For the classical wave equation in the plane (or in the space), i.e., without transmission, different strategies were proposed to overcome this difficulty: Grisvard [7] imposed strong geometrical assumptions in order to adapt the multipliers method; to avoid these geometrical conditions, Niane and Seck [18, 19] and Heibig and Moussaoui [8] proposed using classical boundary controls whose support stays far from the singular points and adding internal controls located in a small neighbourhood of the singular vertices. Here, for interface problems, we proposed the following slightly different method: we replace the boundary control with its regular part and add to the space of controls the coefficients of the singularities. This leads to a classical boundary control but with an internal control, which is a distribution with a support equal to the singular vertices.

The second part will propose two other methods consisting of acting by a classical boundary control whose support does not contain a neighbourhood of the singular points and adding internal controls located near these singular points (more in the spirit of [18, 8, 19], where such a method was introduced).

The structure of this paper is as follows: In §2, we recall some notations and definitions concerning 2-d networks. We also give the decomposition into a regular part and a singular one for elements from the domain of the Laplace operator. Section 3 is devoted to the solution of the wave equation and the regularity of its coefficients of the singularities. This is made

*Received by the editors February 27, 1995; accepted for publication April 12, 1995.

by using a localization procedure and Bessel functions as Moussaoui and Sadallah [16] and Moussaoui and Tran [17] made in the non-transmission case. In §4, we establish an identity with multiplier, different from the usual one since a remainder depending on the coefficients of singularities appears. This identity yields an estimate of the energy. The weak solution of the wave equation is considered in §5, as is its interpretation in terms of partial differential equations. Section 6 is devoted to the setting of the Hilbert uniqueness method. Finally, we give in §7 an example of a 2-d network for which we do not have exact controllability by exterior boundary control. As for 1-d networks [12, § II.5.2], this network contains circuits.

2. Preliminaries. Let us fix Ω, a 2-d polygonal topological network (for short, a 2-d network; see [4, 22] for more details) which is a subset of $\mathbf{R}^n$ (n fixed ≥ 2) formed by a finite union of disjoint nonempty subsets P_i, $i \in \mathcal{I}$ such that

(i) each P_i is a simply connected open subset of a plane Π_i of $\mathbf{R}^n$, P_i being a polygonal domain of Π_i;

(ii) $\cup_{i\in\mathcal{I}} \overline{P_i}$ is connected;

(iii) for all $i, j \in \mathcal{I}$, $i \neq j$, $\overline{P_i} \cap \overline{P_j}$ either is empty or is a common vertex or is a whole common side.

For all $i \in \mathcal{I}$, we can fix once and for all a system of Cartesian coordinates in the plane Π_i. We assume that the boundary of P_i is the union of a finite number of linear segments $\overline{\Gamma}_{ij}$, $j \in \{1, \ldots, N_i\}$, numbered according to the trigonometric orientation. S_{ij} denotes the common vertex between $\overline{\Gamma}_{ij}$ and $\overline{\Gamma}_{ij+1}$, and ω_{ij} is the interior angle at S_{ij} between Γ_{ij} and Γ_{ij+1}. Now, ν_{ij} denotes the unitary outer normal vector on Γ_{ij} and τ_{ij} is the unitary tangent vector to Γ_{ij} so that (ν_{ij}, τ_{ij}) is a direct orthonormal basis.

The vertices of Ω will denote the vertices of all P_i's, and in the same way, the edges will be the sides of all P_i's. The faces will be the P_i's. We shall denote by $\mathcal{A}$ (resp., $\mathcal{S}$) the set of edges (resp., vertices) of Ω. For a fixed $S \in \mathcal{S}$, $\mathcal{I}(S)$ will denote the set of adjacent faces to S, i.e., $\mathcal{I}(S) = \{i \in \mathcal{I} : S \in \overline{P_i}\}$. Similarly, $\mathcal{A}(S)$ will be the set of adjacent edges to S, i.e., $\mathcal{A}(S) = \{A \in \mathcal{A} : S \in \overline{A}\}$. Finally, for $A \in \mathcal{A}$, $\mathcal{I}_A$ will be the set of adjacent faces to A, i.e., $\mathcal{I}_A = \{i \in \mathcal{I} : \exists j \in \{1, \ldots, N_i\}$ such that $\Gamma_{ij} = A\}$; moreover, for any $i \in \mathcal{I}_A$, (ν_i, τ_i) will denote (ν_{ij}, τ_{ij}) for the unique $j \in \{1, \ldots, N_i\}$ such that $\Gamma_{ij} = A$, when no confusion is possible.

Later, γ_{ij} will denote on P_i the trace operator on the edge Γ_{ij}. For a function u defined on Ω, u_i will be the restriction of u on the face P_i:

$$u_i : P_i \to \mathbf{C} : x \mapsto u(x).$$

For the sake of simplicity, we shall write

$$\int_\Omega u \, dx = \sum_{i\in\mathcal{I}} \int_{P_i} u_i(x) \, dx.$$

We now recall the definition of Sobolev spaces on Ω.

DEFINITION 2.1. *Let s be a nonnegative real number. Then*

$$\mathcal{H}^s(\Omega) = \prod_{i\in\mathcal{I}} H^s(P_i), \tag{2.1}$$

where $H^s(P_i)$ is the usual Sobolev space on P_i [6] with norm denoted by $\|\cdot\|_{s,P_i}$. $\mathcal{H}^s(\Omega)$ is a Hilbert space for the product norm:

$$\|u\|_{s,\Omega} = \left(\sum_{i\in\mathcal{I}} \|u_i\|^2_{s,P_i} \right)^{1/2}. \tag{2.2}$$

In the following discussion, for the sake of simplicity, we shall write H for $L^2(\Omega) := \mathcal{H}^0(\Omega)$.

Let us fix a partition of the set of edges $\mathcal{A}$ into two subsets $\mathcal{N}$ and $\mathcal{D}$. ($\mathcal{D}$ will be the part of the "boundary" where we shall consider Dirichlet boundary conditions, while $\mathcal{N}$ will be the part where we shall consider Neumann or transmission conditions.) For convenience, we suppose that $\mathcal{D}$ is not empty. We also fix a sequence of positive real numbers $\{\alpha_i\}_{i\in\mathcal{I}}$ and denote by α the function defined on Ω by $\alpha_i(x) = \alpha_i$ for all $x \in P_i$.

We consider the following boundary value problem: given $f \in L^2(\Omega)$, let u be a solution of

$$-\Delta u_i = f_i \text{ in } P_i \quad \forall i \in \mathcal{I}, \tag{2.3}$$

$$\gamma_{ij} u_i = 0 \text{ on } \Gamma_{ij} \quad \forall\, \Gamma_{ij} \in \mathcal{D}, \tag{2.4}$$

$$\gamma_{ij} u_i = \gamma_{kl} u_k \quad \text{when } \Gamma_{ij} = \Gamma_{kl}, \tag{2.5}$$

$$\sum_{i\in\mathcal{I}:\exists j:\Gamma_{ij}=A} \alpha_i \gamma_{ij} \frac{\partial u_i}{\partial \nu_{ij}} = 0 \text{ on } A \quad \text{when } A \in \mathcal{N}. \tag{2.6}$$

When Ω is a polygon of the plane, the union of several polygons P_i, problem (2.3)–(2.6) is called a transmission problem, which was studied by Kellogg [9], Lemrabet [14], and Dobrowolski [5]. The extension to 2-d networks was considered in [4, 22].

The problem (2.3)–(2.6) admits the next variational formulation, (2.7): introduce the Hilbert space

$$V = \{u \in \mathcal{H}^1(\Omega) \text{ fulfilling (2.4) and (2.5)}\}$$

and the continuous bilinear form on V:

$$a(u, v) = \sum_{i\in\mathcal{I}} \alpha_i \int_{P_i} \nabla u_i \cdot \nabla v_i \, dx \quad \forall u, v \in V.$$

Therefore, we shall say that u is a weak solution of problem (2.3)–(2.6) if $u \in V$ satisfies

$$a(u, v) = \int_\Omega f v \, dx \quad \forall v \in V. \tag{2.7}$$

Since $\mathcal{D}$ is nonempty, the form a is V-coercive. Consequently, the existence and uniqueness of the solution of (2.7) follow from the Lax–Milgram lemma. Moreover, since V is dense and compactly imbedded into $L^2(\Omega)$ and the form a is symmetric, it also induces a positive self-adjoint operator A from $L^2(\Omega)$ into $L^2(\Omega)$, with a compact inverse, defined by

$$\begin{cases} D(A) = \{u \in V : \exists f \in H : a(u, v) = \int_\Omega f v \, dx, \forall v \in V\}, \\ Au = f \quad \forall u \in D(A). \end{cases} \tag{2.8}$$

According to [9, 14, 22], $u \in D(A)$ does not have, in general, the optimal regularity $\mathcal{H}^2(\Omega)$ and admits a decomposition into a regular part and a singular part. To describe this decomposition, we recall the following notation (see [22, §1.6]): For a fixed vertex $S \in \mathcal{S}$ of Ω and any $i \in \mathcal{I}(S)$, let us denote by $\omega_i(S)$ the interior opening of P_i at S. We now introduce polar coordinates (r_i, θ_i) on Π_i centred at S such that the half-lines $\theta_i = 0$ and $\theta_i = \omega_i(S)$ contain the two edges of P_i of extremity S. The 1-d network $\mathcal{R}(S)$ associated with S is then defined by

$$\mathcal{R}(S) = \bigcup_{i\in\mathcal{I}(S)} \{(\cos\theta_i, \sin\theta_i) \in \Pi_i : 0 < \theta_i < \omega_i(S)\}.$$

Roughly speaking, we can identify the nodes of $\mathcal{R}(S)$ with the edges of Ω adjacent to S. We are now able to introduce the Laplace–Beltrami operator Δ_S on $\mathcal{R}(S)$: $D(\Delta_S) = \{(u_i)_{i\in\mathcal{I}(S)} : u_i \in H^2(]0, \omega_i(S)[)$ satisfying (2.9), (2.10) and (2.11) below$\}$, and for any $u = (u_i)_{i\in\mathcal{I}(S)} \in D(\Delta_S)$, we set $\Delta_S u = (-u_i'')_{i\in\mathcal{I}(S)}$:

$$u_i(A) = 0 \quad \forall A \in \mathcal{A}(S) \cap \mathcal{D}, \tag{2.9}$$

$$u_i(A) = u_j(A) \quad \forall A \in \mathcal{A}(S), \quad i, j \in \mathcal{I}_A, \tag{2.10}$$

$$\sum_{i\in\mathcal{I}_A} \alpha_i \frac{\partial u_i}{\partial \nu_i}(A) = 0 \quad \forall A \in \mathcal{A}(S) \cap \mathcal{N}. \tag{2.11}$$

According to the results of §1.6 of [22], Δ_S is a nonnegative self-adjoint operator on $L^2(\mathcal{R}(S))$ (equipped with the inner product

$$(u, v)_{\mathcal{R}(S),\alpha} := \sum_{i\in\mathcal{I}(S)} \alpha_i \int_0^{w_i(S)} u_i(\theta_i) v_i(\theta_i)\, d\theta_i)$$

with a discrete set of eigenvalues $\{\lambda_{S,n}^2\}_{n\in\mathbf{N}^*}$ repeated according to their multiplicity (for convenience, $\lambda_{S,n}$ is always supposed to be nonnegative) and of associated eigenvectors $\{\varphi^{S,n}\}_{n\in\mathbf{N}^*}$ satisfying the orthogonality conditions

$$(\varphi^{S,n}, \varphi^{S,m})_{\mathcal{R}(S),\alpha} = \delta_{nm} \quad \forall n, m \in \mathbf{N}^*. \tag{2.12}$$

Theorem 2.27 of [22] yields the following theorem.

THEOREM 2.2. *Let $u \in D(A)$. Then it admits the decomposition*

$$u = u_R + \sum_{S\in\mathcal{S}} \sum_{0<\lambda_{S,n}\le 1/2} c_{S,n} S^{S,n}, \tag{2.13}$$

where $u_R \in \mathcal{H}^{3/2+\varepsilon}(\Omega)$, for $\varepsilon > 0$ small enough, is the regular part of u; $S^{S,n} = \eta_S r^{\lambda_{S,n}} \varphi^{S,n}(\theta)$ are the so-called singular functions of the operator A; η_S is a cutoff function such that $\eta_S = 1$ (resp., 0) near S (resp., near the other vertices); and finally $c_{S,n} \in \mathbf{C}$ is the coefficient of the singularity $S^{S,n}$, which admits the expression

$$c_{S,n} = -\int_\Omega Au \cdot K^{S,n}\, dx \tag{2.14}$$

for some function $K^{S,n} \in L^2(\Omega)$, which behaves like $r^{-\lambda_{S,n}}$ near S.

In the following discussion, for the sake of brevity, we shall write $\sum_{S,n}$ for $\sum_{S\in\mathcal{S}} \sum_{0<\lambda_{S,n}\le 1/2}$.

3. The wave equation. Since H, V, and the form a fulfill the hypotheses of Remark 4.4 of [20], Theorems 4.1–4.3 of [20] may be applied to A. In particular, we have the following theorem.

THEOREM 3.1. *Let $\varphi_0 \in D(A^s)$, $\varphi_1 \in D(A^{s-1/2})$ and $f \in L^1(0, T; D(A^{s-1/2}))$, with $s \ge 1/2$. Then the problem*

$$\begin{cases} \varphi''(t) + A\varphi(t) = f(t), & t \in [0, T], \\ \varphi(0) = \varphi_0, \\ \varphi'(0) = \varphi_1, \end{cases} \tag{3.1}$$

has a unique solution $\varphi \in C([0, T], D(A^s)) \cap C^1([0, T], D(A^{s-1/2}))$ *fulfilling*

$$\begin{aligned}(3.2)\qquad &\|\varphi\|_{C([0,T],D(A^s))} + \|\varphi\|_{C^1([0,T],D(A^{s-1/2}))}\\ &\le C\{\|\varphi_0\|_{D(A^s)} + \|\varphi_1\|_{D(A^{s-1/2})} + \|f\|_{L^1(0,T;D(A^{s-1/2}))}\}\end{aligned}$$

for some constant $C > 0$ *independent of* φ.

In the particular case $s = 1$, the solution φ satisfies $\varphi \in C([0, T], D(A))$; consequently, by Theorem 2.2, $\varphi(t)$ admits the decomposition (2.13) for all t, with coefficients $c_{S,n}(t)$ depending on t. Our next aim is to give regularity results for these coefficients $c_{S,n}(t)$. Following [16, 17], we first work in a neighbourhood of a vertex and use an explicit basis of the eigenfunctions of the Laplace operator. More precisely, for a fixed vertex $S \in \mathcal{S}$, let us introduce the 2-d network

$$\Omega_S = \bigcup_{i \in \mathcal{I}(S)} \Omega_{Si},$$

where $\Omega_{Si} = \{(r_i \cos\theta_i, r_i \sin\theta_i) \in \Pi_i : 0 < r_i < 1, 0 < \theta_i < \omega_i(S)\}$. Remark that Ω_S coincides with Ω in a neighbourhood of S. Similarly, we shall denote by Γ_{Sij} the segment $\{(r_i \cos\eta_i, r_i \sin\eta_i) \in \Pi_i : 0 < r_i < 1\}$, with $\eta_i = 0$ or $\omega_i(S)$, which coincides with Γ_{ij} near S. As before, the Laplace operator A_S on Ω_S corresponds to the following data: $V_S = \{u \in \mathcal{H}^1(\Omega_S)$ fulfilling (2.4), (2.5) on Γ_{Sij} and $u_i(1, \theta_i) = 0$, for a.e. $\theta_i \in]0, \omega_i(S)[$, and all $i \in \mathcal{I}(S)\}$ and

$$a_S(u, v) = \sum_{i \in \mathcal{I}(S)} \alpha_i \int_{\Omega_{Si}} \nabla u_i \nabla v_i \, dx \quad \forall u, v \in V_S.$$

Using the method of separation of variables, one can prove the following lemma.

LEMMA 3.2. *For all* $n, k \in \mathbb{N}^*$, $\lambda_{n,k} := (j_{\lambda_{S,n};k})^2$ *is an eigenvalue of* $\alpha_S^{-1} A_S$ *(obviously* α_S *is the function defined on* Ω_S *by* $\alpha_i(x) = \alpha_i$ *for all* $x \in \Omega_{Si}$*) of associated eigenvector*

$$(3.3)\qquad w^{n,k} = \alpha_{n,k} J_{\lambda_{S,n}}(j_{\lambda_{S,n};k} r)\varphi^{S,n}(\theta),$$

where $J_\gamma(s)$ *is the Bessel function of index* γ *and* $j_{\gamma;k}$ *is its* k*th positive zero. The real number* $\alpha_{n,k}$ *is a normalization factor chosen so that*

$$(3.4)\qquad \sum_{i \in \mathcal{I}(S)} \int_{\Omega_{Si}} \alpha_i |w_i^{n,k}(x)|^2 \, dx = 1.$$

Moreover $\{\sqrt{\alpha_S} w^{n,k}\}_{n,k \in \mathbb{N}^*}$ *is an orthonormal basis of* $L^2(\Omega_S)$ *equipped with the inner product* $(\cdot, \cdot)_{S,\alpha}$ *defined by*

$$(u, v)_{S,\alpha} = \sum_{i \in \mathcal{I}(S)} \alpha_i \int_{\Omega_{Si}} u_i(x) v_i(x) \, dx.$$

Since $J_\gamma(s) \cong s^\gamma$ near $s = 0$, we may see that $w^{n,k} \in \mathcal{H}^2(\Omega_S)$ iff $\lambda_{S,n} > 1$. Consequently, only the eigenvectors $w^{n,k}$ with $0 \le \lambda_{S,n} \le 1$ will arise in the computation of the coefficient $c_{s,n}$ in the decomposition (2.13). As in [16, 17], we need the following technical step.

LEMMA 3.3. *If* $0 \le \lambda_{S,n} \le 1$, *there exist* $C_1, C_2 > 0$ *(depending on* n *but not on* k*) such that*

$$(3.5)\qquad C_1 k^2 \le \lambda_{n,k} \le C_2 k^2,$$

$$(3.6)\qquad C_1 \sqrt{k} \le |\alpha_{n,k}| \le C_2 \sqrt{k} \quad \forall k \in \mathbb{N}^*.$$

Proof. Equation (3.5) is a direct consequence of MacMahon formula [1, p. 371], which says that

$$j_{\gamma;k} = \left(k + \frac{\gamma}{2} - \frac{1}{4}\right)\pi + \bigcirc\left(\frac{1}{k}\right) \tag{3.7}$$

for a fixed γ. The estimates (3.6) follow from simple properties of Bessel functions and remarking that (3.4) is equivalent to

$$|\alpha_{n,k}|^2 \int_0^1 |J_{\lambda_{S,n}}(j_{\lambda_{S,n};k} r)|^2 \, r dr = 1. \qquad \square$$

We are now able to clarify the regularity of the eigenvectors $w^{n,k}$.

PROPOSITION 3.4. *For all $n \in \mathbf{N}^*$, we have*

$$w^{n,k} = w_R^{n,k} + a_{n,k} S^{S,n}, \tag{3.8}$$

where $w_R^{n,k} \in \mathcal{H}^{3/2+\varepsilon}(\Omega_S)$ for some $\varepsilon > 0$; $a_{n,k} = 0$ if $\lambda_{S,n} > 1/2$ or if $\lambda_{S,n} = 0$. Otherwise there exist $C_1, C_2 > 0$ (depending on n but not on k) such that

$$C_1 (\lambda_{n,k})^{\frac{\lambda_{S,n}}{2}+\frac{1}{4}} \le |a_{n,k}| \le C_2 (\lambda_{n,k})^{\frac{\lambda_{S,n}}{2}+\frac{1}{4}} \quad \forall k \in \mathbf{N}^*. \tag{3.9}$$

Proof. As $w^{n,k} \in V_S$ is solution of $A_S w^{n,k} = \alpha_S \lambda_{n,k} w^{n,k} \in L^2(\Omega_S)$, Theorem 2.2 implies

$$w^{n,k} = w_R^{n,k} + \sum_{0<\lambda_{S,m}\le 1/2} a_{n,k,m} S^{S,m}, \tag{3.10}$$

where $w_R^{n,k} \in \mathcal{H}^{3/2+\varepsilon}(\Omega_S)$ for $\varepsilon > 0$ small enough. Moreover, with the help of Theorem 2.27 of [22], we can show that (see also Theorem 2.2)

$$a_{n,k,m} = -\lambda_{n,k} \sum_{i \in \mathcal{I}(S)} \alpha_i \int_{\Omega_{Si}} w_i^{n,k} K_i^{S,m} \, dx,$$

where $K^{S,m} = \frac{1}{\lambda_{S,m}}(r^{-\lambda_{S,m}} - r^{\lambda_{S,m}})\varphi^{S,m}$. Using the expression of $w^{n,k}$ and the orthogonality properties (2.12) of the $\varphi^{S,m}$'s, we arrive at

$$a_{n,k,m} = -\delta_{nm} \frac{\alpha_{n,k}\lambda_{n,k}}{\lambda_{S,m}} \int_0^1 J_{\lambda_{S,n}}(j_{\lambda_{S,n};k} r)(r^{-\lambda_{S,m}} - r^{\lambda_{S,m}}) r dr. \tag{3.11}$$

This leads to (3.8). The asymptotic behaviour of $a_{n,k}$ comes from (3.11), the properties of the Bessel functions, and Lemma 3.3. $\square$

Let us return to the wave equation (3.1).

THEOREM 3.5. *Let $\varphi_0 \in D(A)$, $\varphi_1 \in V$, and $f \in L^2(0, T; V)$. If $T > 2$, then the solution $\varphi \in C([0, T], D(A)) \cap C^1([0, T], V)$ of (3.1) admits the decomposition*

$$\varphi = \varphi_R + \sum_{S,n} c_{S,n} S^{S,n}, \tag{3.12}$$

where $\varphi_R \in C([0, T], \mathcal{H}^{3/2+\varepsilon}(\Omega)) \cap H^1(0, T; V)$ for some $\varepsilon > 0$ and $c_{S,n} \in H^s(0, T)$, for any $s \le \frac{3}{2} - \lambda_{S,n}$ with norms depending continuously on $\|\varphi_0\|_{D(A)} + \|\varphi_1\|_V + \|f\|_{L^2(0,T;V)}$.

Proof. Multiplying φ by the cutoff function η_S, we are reduced to the case $\Omega = \Omega_S$. Writing φ in the basis $\{w^{n,k}\}_{n,k\in\mathbb{N}^*}$ and using (3.8), we arrive at (3.12) with

$$c_{S,n}(t) = \sum_{k\in\mathbb{N}^*} a_{n,k} \left\{ \cos(t\sqrt{\lambda_{n,k}})(\varphi_0, w^{n,k})_{S,\alpha} + \frac{\sin(t\sqrt{\lambda_{n,k}})}{\sqrt{\lambda_{n,k}}}(\varphi_1, w^{n,k})_{S,\alpha} + \int_0^t \frac{\sin((t-s)\sqrt{\lambda_{n,k}})}{\sqrt{\lambda_{n,k}}}(f(s), w^{n,k})_{S,\alpha}\, ds \right\}, \tag{3.13}$$

where φ_R is the remainder. To prove the inclusion $c_{S,n} \in H^s(0,T)$, we use Ingham's inequalities [2] in each of the three series in the right-hand side of (3.13). Indeed applying Theorem 2.1 of [2] to

$$w := \sum_{k\in\mathbb{N}^*} \lambda_{n,k}^{s/2} a_{n,k} \cos(t\sqrt{\lambda_{n,k}})(\varphi_0, w^{n,k})_{S,\alpha},$$

we get the existence of a constant $C > 0$ such that

$$\int_0^T |w(t)|^2\, dt \le C\|\varphi_0\|^2_{D(A)}$$

if $T > 2$ because (3.7) yields assumption (2.1) of [2] with $\gamma = \pi$. Other terms are treated similarly. □

In the above theorem, the assumption $f \in L^2(0,T;V)$ is not satisfactory for our next applications. We prefer $f \in L^1(0,T;V)$, which is unfortunately unavailable; therefore, we replace it with $f \in L^1(0,T;D(A))$.

THEOREM 3.6. *Let $\varphi \in C([0,T], D(A^{3/2})) \cap C^1([0,T], D(A))$ be the solution of* (3.1) *with $\varphi_0 = \varphi_1 = 0$ and $f \in L^1(0,T;D(A))$. Then it admits the decomposition* (3.12)*, where $\varphi_R \in C^1([0,T], \mathcal{H}^{3/2+\varepsilon}(\Omega))$ for some $\varepsilon > 0$ and $c_{S,n} \in C^1([0,T])$, with norms depending continuously on $\|f\|_{L^1(0,T;D(A))}$.*

Proof. Since $D(A^{3/2}) \hookrightarrow D(A)$, $\varphi(t)$ clearly has the expansion (3.12). The conclusion follows from the expression (2.14) of $c_{S,n}(t)$, the regularity $\varphi \in C^1([0,T], D(A))$, and Lebesgue's bounded convergence theorem. □

4. Estimate of the energy. As usual [15, 7], the estimate of the energy is based on an identity with multiplier, which, in our case, takes a slightly different form since we multiply the equation $\varphi'' + A\varphi = 0$ by $m \cdot \nabla\varphi_R$ instead of $m \cdot \nabla\varphi$. (Due to the singular behaviour of φ, the factor $m \cdot \nabla\varphi$ is too singular.) This will be made in several technical steps.

It is quite natural that the boundary control is applied only on the exterior boundary of the domain. This means that we have to distinguish between "interior" and "exterior" Neumann edges: more precisely, we set

$$\begin{aligned} \mathcal{N}_{\text{int}} &= \{A \in \mathcal{N} : \#\mathcal{I}_A \ge 2\}, \\ \mathcal{N}_{\text{ext}} &= \{A \in \mathcal{N} : \#\mathcal{I}_A = 1\}. \end{aligned}$$

Dirichlet edges, on the contrary, may always be seen as exterior edges. For $A \in \mathcal{N}_{\text{ext}} \cup \mathcal{D}$, we then denote by i_A the unique element of $\mathcal{I}_A$.

For fixed points $x_{0i} \in \Pi_i$, $i \in \mathcal{I}$, we define the function m on Ω by $m_i(x) = x - x_{0i}$.

From now on, we suppose that the following geometrical conditions are satisfied (see the end of this section for some examples):

(H1) $\sum_{i\in\mathcal{I}_A} m_i \cdot \nu_i = 0$ on $A\ \forall A \in \mathcal{N}_{\text{int}}$.

(H2) $m_i \cdot \tau_i = m_j \cdot \tau_i$ on $A\ \forall i, j \in \mathcal{I}_A$, $A \in \mathcal{N}_{\text{int}}$.

(H3) $\sum_{i\in\mathcal{I}_A} \alpha_i m_i \cdot \nu_i \geq 0$ on $A\ \forall A \in \mathcal{N}_{\text{int}}$.

(H4) For all $A \in \mathcal{N}_{\text{int}}$ and any $w \in \mathbf{R}^{\#\mathcal{I}_A}$ such that $\sum_{i\in\mathcal{I}_A} \alpha_i w_i = 0$, we have

$$\sum_{i\in\mathcal{I}_A} \alpha_i m_i \cdot \nu_i (w_i)^2 \leq 0 \text{ on } A.$$

LEMMA 4.1. *Let $\varphi \in \mathcal{H}^{3/2+\varepsilon}(\Omega) \cap D(A)$ for some $\varepsilon > 0$. Then the following inequality holds:*

$$\begin{aligned}\int_\Omega A\varphi m \cdot \nabla\varphi dx \geq & -\frac{1}{2}\sum_{A\in\mathcal{D}}\int_A \alpha_{i_A} m_{i_A}\cdot\nu_{i_A}\left(\frac{\partial\varphi_{i_A}}{\partial\nu_{i_A}}\right)^2 d\sigma \\ & + \frac{1}{2}\sum_{A\in\mathcal{N}_{\text{ext}}}\int_A \alpha_{i_A} m_{i_A}\cdot\nu_{i_A}\left(\frac{\partial\varphi_{i_A}}{\partial\tau_{i_A}}\right)^2 d\sigma.\end{aligned} \tag{4.1}$$

Proof. The regularity of φ allows us to apply Green's formula on each P_i, which leads to (see Lemma 3.3 of [7])

$$\begin{aligned}\int_{P_i} \Delta\varphi_i m_i \cdot \nabla\varphi_i\, dx = \sum_{j=1}^{N_i}\Bigg\{ & -\frac{1}{2}\int_{\Gamma_{ij}} m_i\cdot\nu_{ij}|\nabla\varphi_i|^2\, d\sigma \\ & + \int_{\Gamma_{ij}} \frac{\partial\varphi_i}{\partial\nu_{ij}} m_i\cdot\nabla\varphi_i\, d\sigma\Bigg\}.\end{aligned}$$

Multiplying this identity by α_i and summing on $i \in \mathcal{I}$, we get

$$\begin{aligned}\int_\Omega A\varphi m\cdot\nabla\varphi dx = \sum_{i\in\mathcal{I}}\sum_{j=1}^{N_i}\Bigg\{ & \frac{1}{2}\int_{\Gamma_{ij}} \alpha_i m_i\cdot\nu_{ij}|\nabla\varphi_i|^2\, d\sigma \\ & - \int_{\Gamma_{ij}} \alpha_i \frac{\partial\varphi_i}{\partial\nu_{ij}}\left(m_i\cdot\nu_{ij}\frac{\partial\varphi_i}{\partial\nu_{ij}} + m_i\cdot\tau_{ij}\frac{\partial\varphi_i}{\partial\tau_{ij}}\right) d\sigma\Bigg\}.\end{aligned} \tag{4.2}$$

Using the condition (H2) and the fact that φ satisfies (2.4), (2.5), and (2.6), we show that

$$\sum_{i\in\mathcal{I}}\sum_{j=1}^{N_i}\int_{\Gamma_{ij}} \alpha_i \frac{\partial\varphi_i}{\partial\nu_{ij}}\frac{\partial\varphi_i}{\partial\tau_{ij}} m_i\cdot\tau_{ij}\, d\sigma = 0.$$

Consequently, the right-hand side of (4.2) is reduced to

$$\frac{1}{2}\sum_{A\in\mathcal{A}}\int_A\sum_{i\in\mathcal{I}_A}\alpha_i m_i\cdot\nu_i\left\{-\left(\frac{\partial\varphi_i}{\partial\nu_i}\right)^2 + \left(\frac{\partial\varphi_i}{\partial\tau_i}\right)^2\right\} d\sigma.$$

The terms corresponding to $A \in \mathcal{D}\cup\mathcal{N}_{\text{ext}}$ are those of the right-hand side of (4.1) due to (2.4) and (2.6). For $A \in \mathcal{N}_{\text{int}}$, since φ satisfies (2.6), assumptions (H3) and (H4) yield

$$\int_A \sum_{i\in\mathcal{I}_A}\alpha_i m_i\cdot\nu_i\left\{-\left(\frac{\partial\varphi_i}{\partial\nu_i}\right)^2 + \left(\frac{\partial\varphi_i}{\partial\tau_i}\right)^2\right\} d\sigma \geq 0.$$

This proves (4.1). □

The inequality (4.1) can be applied to the solution of the wave equation in the following way.

PROPOSITION 4.2. *Let* $\varphi \in C([0,T], D(A)) \cap C^1([0,T], V) \cap C^2([0,T], H)$ *be a solution of* (3.1) *with* $f = 0$. *Then setting* $Q = \Omega \times (0,T)$, $\Sigma_A = A \times (0,T)$ *for all* $A \in \mathcal{A}$, *we have*

$$\int_Q (D_t\varphi_R)^2\,dxdt \le \frac{1}{2}\sum_{A\in\mathcal{D}}\int_{\Sigma_A}\alpha_{i_A}m_{i_A}\cdot\nu_{i_A}\left(\frac{\partial\varphi_{Ri_A}}{\partial\nu_{i_A}}\right)^2 d\sigma dt \tag{4.3}$$
$$-\frac{1}{2}\sum_{A\in\mathcal{N}_{\text{ext}}}\int_{\Sigma_A}\alpha_{i_A}m_{i_A}\cdot\nu_{i_A}\left(\frac{\partial\varphi_{Ri_A}}{\partial\tau_{i_A}}\right)^2 d\sigma dt$$
$$+\frac{1}{2}\sum_{A\in\mathcal{N}_{\text{ext}}}\int_{\Sigma_A}m_{i_A}\cdot\nu_{i_A}\left(D_t\varphi_{Ri_A}\right)^2 d\sigma dt + R,$$

where φ_R *is the regular part of* φ *appearing in its decomposition* (3.12) *and* R *is a remainder given by*

$$R = -\int_\Omega D_t\varphi m\cdot\nabla\varphi_R\,dx\,|_0^T \tag{4.4}$$
$$+\sum_{S,n}\int_Q [D_t c_{S,n}\{2S^{S,n} + m\cdot\nabla S^{S,n}\}D_t\varphi_R - c_{S,n}AS^{S,n}m\cdot\nabla\varphi_R]dxdt.$$

Proof. For such a solution φ, an integration by parts with respect to the variable t in $(0,T)$ and the expansion (3.12) of φ lead to

$$\int_Q D_t^2\varphi m\cdot\nabla\varphi_R\,dxdt = \int_\Omega D_t\varphi m\cdot\nabla\varphi_R\,dx\,|_0^T \tag{4.5}$$
$$-\int_Q D_t\varphi m\cdot\nabla D_t\varphi_R\,dxdt = \int_\Omega D_t\varphi m\cdot\nabla\varphi_R\,dx\,|_0^T$$
$$-\int_Q D_t\varphi_R m\cdot\nabla D_t\varphi_R\,dxdt - \sum_{S,n}\int_Q D_t c_{S,n}S^{S,n}m\cdot\nabla D_t\varphi_R\,dxdt.$$

The second term of this right-hand side is transformed, using Green's formula in P_i for all $i \in \mathcal{I}$ (allowed thanks to Theorem 3.5). This leads to

$$\int_Q D_t\varphi_R m\cdot\nabla D_t\varphi_R\,dxdt = -\int_Q (D_t\varphi_R)^2 dxdt$$
$$+\frac{1}{2}\sum_{A\in\mathcal{A}}\int_{\Sigma_A}(D_t\varphi_R)^2\left(\sum_{i\in\mathcal{I}_A}m_i\cdot\nu_i\right)d\sigma dt.$$

Since φ_R satisfies (2.4) and taking into account assumption (H1), we arrive at

$$\int_Q D_t\varphi_R m\cdot\nabla D_t\varphi_R\,dxdt = -\int_Q (D_t\varphi_R)^2 dxdt \tag{4.6}$$
$$+\frac{1}{2}\sum_{A\in\mathcal{N}_{\text{ext}}}\int_{\Sigma_A}(D_t\varphi_R)^2 m_{i_A}\cdot\nu_{i_A}d\sigma dt.$$

The third term of the right-hand side of (4.5) is treated similarly; i.e., we first apply Green's formula on each P_i, use the fact that $S^{S,n}$ and φ_R satisfy (2.5), and take into account hypothesis (H1). This yields

$$\int_Q D_t c_{S,n}S^{S,n}m\cdot\nabla D_t\varphi_R\,dxdt = -R^1_{S,n}, \tag{4.7}$$

where we set

$$R^1_{S,n} := \int_Q D_t c_{S,n}\{2S^{S,n} + m \cdot \nabla S^{S,n}\} D_t \varphi_R \, dxdt.$$

The two identities (4.6) and (4.7) into (4.5) give

$$\int_Q D_t^2 \varphi m \cdot \nabla \varphi_R \, dxdt = \int_\Omega D_t \varphi m \cdot \nabla \varphi_R \, dx \,|_0^T + \int_Q (D_t \varphi_R)^2 dxdt - \frac{1}{2} \sum_{A \in \mathcal{N}_{\text{ext}}} \int_{\Sigma_A} (D_t \varphi_R)^2 m_{i_A} \cdot \nu_{i_A} d\sigma dt + \sum_{S,n} R^1_{S,n}. \tag{4.8}$$

Using the expansion (3.12) of φ, we may write

$$\int_Q A\varphi m \cdot \nabla \varphi_R \, dxdt = \int_Q A\varphi_R m \cdot \nabla \varphi_R \, dxdt + \sum_{S,n} R^2_{S,n},$$

where $R^2_{S,n} = \int_Q c_{S,n} A S^{S,n} m \cdot \nabla \varphi_R \, dxdt$. The application of Lemma 4.1 to φ_R yields

$$\int_Q A\varphi m \cdot \nabla \varphi_R \, dxdt \geq \sum_{S,n} R^2_{S,n} - \frac{1}{2} \sum_{A \in \mathcal{D}} \int_{\Sigma_A} \alpha_{i_A} m_{i_A} \cdot \nu_{i_A} \left(\frac{\partial \varphi_{Ri_A}}{\partial \nu_{i_A}} \right)^2 d\sigma dt + \frac{1}{2} \sum_{A \in \mathcal{N}_{\text{ext}}} \int_{\Sigma_A} \alpha_{i_A} m_{i_A} \cdot \nu_{i_A} \left(\frac{\partial \varphi_{Ri_A}}{\partial \tau_{i_A}} \right)^2 d\sigma dt. \tag{4.9}$$

The sum of (4.8) and (4.9) is the inequality (4.3). □

Let us now set

$$\mathcal{D}^+ = \{A \in \mathcal{D} : m_{i_A} \cdot \nu_{i_A} > 0 \text{ on } A\},$$
$$\mathcal{N}^+_{\text{ext}}(\text{resp.}, \mathcal{N}^-_{\text{ext}}) = \{A \in \mathcal{N}_{\text{ext}} : m_{i_A} \cdot \nu_{i_A} > 0 \text{ (resp., } < 0) \text{ on } A\}.$$

For any $\{\varphi_0, \varphi_1\} \in D(A) \times V$, let $\varphi \in C([0, T], D(A)) \cap C^1([0, T], V)$ be the solution of (3.1) with $f = 0$, which admits the decomposition (3.12), and define

$$|||\{\varphi_0, \varphi_1\}|||^2 = \sum_{A \in \mathcal{D}^+} \int_{\Sigma_A} \left(\frac{\partial \varphi_{Ri_A}}{\partial \nu_{i_A}} \right)^2 d\sigma dt + \sum_{A \in \mathcal{N}^-_{\text{ext}}} \int_{\Sigma_A} \left(\frac{\partial \varphi_{Ri_A}}{\partial \tau_{i_A}} \right)^2 d\sigma dt + \sum_{A \in \mathcal{N}^+_{\text{ext}}} \int_{\Sigma_A} \left(D_t \varphi_{i_A} \right)^2 d\sigma dt + \sum_{S,n} \|c_{S,n}\|^2_{1,(0,T)}. \tag{4.10}$$

We are now ready to establish the main result of this section.

PROPOSITION 4.3. *Let $\varphi \in C([0, T], D(A)) \cap C^1([0, T], V) \cap C^2([0, T], H)$ be a solution of* (3.1) *with $f = 0$. Then there exists a minimal time $T_0 > 0$ such that for all $T > T_0$, there exists a constant $C > 0$ (depending on T but not on φ_0, φ_1) such that*

$$(T - T_0) E_0 \leq C |||\{\varphi_0, \varphi_1\}|||^2, \tag{4.11}$$

where E_0 denotes the energy of φ at time $t = 0$, namely,

$$E_0 = \frac{1}{2}\{\|\varphi_1\|_H^2 + a(\varphi_0, \varphi_0)\}.$$

Proof. According to Theorem 4.3, Remark 4.4, and identity (4.24) of [20], we may write

$$\int_Q |D_t\varphi|^2 dxdt = TE_0 + \frac{1}{2}\int_\Omega D_t\varphi\varphi \, dx \,|_0^T . \tag{4.12}$$

Using the expansion (3.12) of φ, (4.12) becomes

$$\begin{aligned} TE_0 &\le -\frac{1}{2}\int_\Omega D_t\varphi\varphi \, dx \,|_0^T \\ &+ C_1\int_Q |D_t\varphi_R|^2 dxdt + C_1\sum_{S,n}\int_Q |D_t c_{S,n} S^{S,n}|^2 dxdt, \end{aligned}$$

where $C_1 > 0$ depends only on the number of eigenvalues $\lambda_{S,n}$ in $]0, 1/2]$. In view of the inequality (4.3), it remains to be shown that

$$R - \frac{1}{2}\int_\Omega D_t\varphi\varphi \, dx \,|_0^T \le C\{|||\{\varphi_0, \varphi_1\}|||^2 + E_0\}. \tag{4.13}$$

The estimate of the term $\int_\Omega D_t\varphi\varphi \, dx \,|_0^T$ with respect to E_0 is classical (see [15, 7]) and is thus omitted. Let us proceed to the estimation of R. Applying Cauchy–Schwarz's inequality, the first term is estimated as follows:

$$\begin{aligned} &\left|\int_\Omega D_t\varphi m\cdot\nabla\varphi_R \, dx \,|_0^T\right| \le C\sum_{t=0,T}\left(\int_\Omega |D_t\varphi(t)|^2 dx\right)^{1/2}\left(\int_\Omega |\nabla\varphi_R(t)|^2 dx\right)^{1/2} \\ &\le CE_0^{1/2}\sum_{t=0,T}\left\{\left(\int_\Omega |D_t\varphi(t)|^2 dx\right)^{1/2} + \sum_{S,n}|c_{S,n}(t)|\left(\int_\Omega |\nabla S^{S,n}|^2 dx\right)^{1/2}\right\}. \end{aligned}$$

Accordingly, the continuous imbedding $H^1(0, T) \hookrightarrow C([0, T])$ (Sobolev imbedding theorem) and the usual estimate

$$ab \le \frac{1}{2}(a^2 + b^2) \quad \forall a, b \in \mathbf{R} \tag{4.14}$$

lead to

$$\begin{aligned} \left|\int_\Omega D_t\varphi m\cdot\nabla\varphi_R \, dx \,|_0^T\right| &\le C\left\{E_0 + \sum_{S,n}\|c_{S,n}\|_{1,(0,T)}^2\right\} \\ &\le C\{E_0 + |||\{\varphi_0, \varphi_1\}|||^2\}. \end{aligned}$$

Let us estimate $R_{S,n}^1$. The treatment of $R_{S,n}^2$ is similar and then omitted. Cauchy–Schwarz's inequality and the expansion (3.12) of φ yield

$$\begin{aligned} |R_{S,n}^1| &\le C\|c_{S,n}\|_{1,(0,T)}\left\{\left(\int_Q |D_t\varphi|^2 dxdt\right)^{1/2} + \sum_{T,m}\|c_{T,m}\|_{1,(0,T)}\right\} \\ &\le C\left\{\sum_{T,m}\|c_{T,m}\|_{1,(0,T)}^2 + \|c_{S,n}\|_{1,(0,T)}T^{1/2}E_0^{1/2}\right\}, \end{aligned}$$

due to the conservation of energy. Applying the estimate (4.14) with $a = \|c_{S,n}\|_{1,(0,T)}T^{1/2}$ and $b = E_0^{1/2}$, one gets

$$|R^1_{S,n}| \le C\left\{(1+T)\sum_{T,m}\|c_{T,m}\|^2_{1,(0,T)} + E_0\right\}.$$

This completes the proof. □

Let us now fix $T > T_0$ such that the inequality (4.11) holds. Then the application

$$D(A) \times V \to \mathbf{R}^+ : \{\varphi_0, \varphi_1\} \to |||\{\varphi_0, \varphi_1\}|||$$

is a norm stronger than the norm induced by $V \times H$, due to Proposition 4.3. As in [15, 7, 20], we define F as the closure of $D(A) \times V$ for this new norm (obviously, F depends on the points x_{0i} and T), and we have the algebraic and topological inclusions

$$D(A) \times V \hookrightarrow F \hookrightarrow V \times H. \tag{4.15}$$

For the inhomogeneous wave equation (3.1) (i.e., f not necessarily equal to 0), we can now state the following proposition.

PROPOSITION 4.4. *Let $\{\varphi_0, \varphi_1\} \in F$ and $f \in L^1(0, T; D(A))$. Then the unique solution φ of* (3.1) *admits the decomposition* (3.12) *and fulfills*

$$\frac{\partial \varphi_{Ri_A}}{\partial \nu_{i_A}} \in L^2(\Sigma_A) \quad \forall A \in \mathcal{D}^+, \tag{4.16}$$

$$\frac{\partial \varphi_{Ri_A}}{\partial \tau_{i_A}} \in L^2(\Sigma_A) \quad \forall A \in \mathcal{N}^-_{\text{ext}}, \tag{4.17}$$

$$D_t\varphi_{i_A} \in L^2(\Sigma_A) \quad \forall A \in \mathcal{N}^+_{\text{ext}}, \tag{4.18}$$

$$c_{S,n} \in H^1(0,T) \quad \forall S \in \mathcal{S},\ 0 < \lambda_{S,n} \le 1/2. \tag{4.19}$$

Moreover, there exists a constant $C > 0$ (independent of $\{\varphi_0, \varphi_1\}$ and f) such that

$$\begin{aligned}&\left\{\sum_{A\in\mathcal{D}^+}\int_{\Sigma_A}\left(\frac{\partial\varphi_{Ri_A}}{\partial\nu_{i_A}}\right)^2 d\sigma dt + \sum_{A\in\mathcal{N}^-_{\text{ext}}}\int_{\Sigma_A}\left(\frac{\partial\varphi_{Ri_A}}{\partial\tau_{i_A}}\right)^2 d\sigma dt\right.\\ &\left.+\sum_{A\in\mathcal{N}^+_{\text{ext}}}\int_{\Sigma_A}\left(D_t\varphi_{i_A}\right)^2 d\sigma dt + \sum_{S,n}\|c_{S,n}\|^2_{1,(0,T)}\right\}^{1/2}\\ &\le C\{|||\{\varphi_0,\varphi_1\}||| + \|f\|_{L^1(0,T;D(A))}\}.\end{aligned} \tag{4.20}$$

Proof. We argue as in Theorem 5.6 of [7]: Using the uniqueness of the solution of (3.1) and the linearity of the wave equation, we may write $\varphi = \varphi^{(1)} + \varphi^{(2)}$, where $\varphi^{(1)}$ (resp., $\varphi^{(2)}$) corresponds to the Cauchy data $\{\varphi_0, \varphi_1\}$ (resp., the right-hand side f). The conclusion for $\varphi^{(1)}$ follows from the definition of the space F. On the other hand, Theorem 3.6 and the usual trace theorems yield the desired properties of $\varphi^{(2)}$. □

We finish this section by giving two examples of 2-d networks for which the conditions (H1)–(H4) are satisfied.

Example 1. First we recall the example considered in [23]. Let $\Omega = P_1 \cup P_2$ be a bounded polygonal domain of $\mathbf{R}^2$, divided into two connected parts, P_1 and P_2, separated by a piecewise polygonal line I (one can readily check that Ω is then a 2-d network). If $m_1(x) = m_2(x) = x - x_0$ for some $x_0 \in \mathbf{R}^2$, one can check that the conditions (H1)–(H4) are reduced to

$$m_1 \cdot \nu_1(\alpha_1 - \alpha_2) \ge 0 \text{ on } I.$$

This condition means that $m_1 \cdot \nu_1$ has to keep the same sign as $(\alpha_1 - \alpha_2)$ along I. Examples of domains P_1, P_2 for which this condition is fulfilled are then easily built.

Example 2. Let $\Omega = \cup_{i=1}^5 P_i$ be included in $\mathbf{R}^3$, where the P_i's are defined by

$$P_i = \{(x, y, 0) : 0 < y < 1,\ i - 2 < x < i - 1\}, \qquad i = 1, 2, 3,$$
$$P_i = \{(i - 4, y, z) : 0 < y < 1,\ 0 < z < 1\}, \qquad i = 4, 5.$$

Take $X_0 = (x_0, y_0, 0) \in \mathbf{R}^3$ and $m_i(x) = \text{proj}_{\Pi_i}(x - X_0)$ (proj_{Π_i} means the orthogonal projection on the plane Π_i). If $\alpha_3 \leq \alpha_2 \leq \alpha_1$, then one can check that (H1)–(H4) are satisfied if $x_0 \leq 0$.

5. Weak solutions of the wave equation. We transpose Proposition 4.4 to get the next theorem.

THEOREM 5.1. *For all $u_0 \in H$, $u_1 \in V'$, $w_A \in L^2(\Sigma_A)$, $A \in \mathcal{D}^+ \cup \mathcal{N}_{\text{ext}}^+ \cup \mathcal{N}_{\text{ext}}^-$, and all $w_{S,n} \in H^1(0, T)$, $S \in \mathcal{S}$, $0 < \lambda_{S,n} \leq 1/2$, there exist unique $u \in L^\infty(0, T; D(A)')$, $\{\psi_1, \psi_0\} \in F'$, which are solutions of*

$$\begin{aligned}(5.1)\qquad &\int_0^T \langle u(t), f(t)\rangle_{D(A)'-D(A)} dt + \langle\{\psi_1, \psi_0\}, \{\varphi_0, -\varphi_1\}\rangle_{F'-F} \\ &= \langle u_1, \varphi(0)\rangle_{V'-V} - \langle u_0, \varphi'(0)\rangle_{H'-H} - \sum_{A\in\mathcal{D}^+} \int_{\Sigma_A} w_A \frac{\partial \varphi_{Ri_A}}{\partial \nu_{i_A}}\, d\sigma dt \\ &- \sum_{A\in\mathcal{N}_{\text{ext}}^-} \int_{\Sigma_A} w_A \frac{\partial \varphi_{Ri_A}}{\partial \tau_{i_A}}\, d\sigma dt - \sum_{A\in\mathcal{N}_{\text{ext}}^+} \int_{\Sigma_A} w_A D_t \varphi_{i_A}\, d\sigma dt \\ &- \sum_{S,n} \int_0^T \{w_{S,n} c_{S,n} + w'_{S,n} c'_{S,n}\} dt\end{aligned}$$

for all $f \in L^1(0, T; D(A))$, $\{\varphi_0, -\varphi_1\} \in F$, where $\varphi = \varphi_R + \sum_{S,n} c_{S,n} S^{S,n}$ is the unique solution of

$$(5.2)\qquad \begin{cases} \varphi \in C([0, T], V) \cap C^1([0, T], H), \\ \varphi''(t) + A\varphi(t) = f(t), t \in [0, T], \\ \varphi(T) = \varphi_0, \varphi'(T) = \varphi_1. \end{cases}$$

The interpretation of (5.1) in terms of partial differential equations is delicate and will be given for more regular data. First we need a density result.

LEMMA 5.2. *Let us denote*

$$K = \{w \in C^\infty([0, T]) : w'''(0) = w'(0) = w'(T) = 0 \text{ and } w''(0) = w(0)\}.$$

Then K is dense in $H^1(0, T)$.

Proof. Let $u \in K^\perp$. Then it fulfills

$$u'' - u = 0 \text{ in } \mathcal{D}'(0, T).$$

Consequently, $u \in C^\infty([0, T])$ and is then a linear combination of e^t and e^{-t}. Since the mapping

$$K \to \mathbf{R}^2 : w \longmapsto (w(0), w(T))$$

is onto, we conclude that $u \equiv 0$. □

The next trace lifting result is easily proved by using the simple geometry of Ω and is left to the reader.

LEMMA 5.3. *Let* $w_A \in \mathcal{D}(\Sigma_A)$, $A \in \mathcal{D}^+ \cup \mathcal{N}_{\text{ext}}^+ \cup \mathcal{N}_{\text{ext}}^-$. *Then there exists* $v \in \mathcal{D}(0, T, \prod_{i\in\mathcal{I}} C^\infty(\overline{P}_i))$ *fulfilling* (2.5) *and* (2.6) *for all* $A \in \mathcal{N}_{\text{int}}$, *and*

$$v_{i_A} = \begin{cases} \alpha_{i_A}^{-1} w_A \text{ on } A \quad \forall A \in \mathcal{D}^+, \\ 0 \text{ on } A \quad \forall A \in \mathcal{D} \setminus \mathcal{D}^+. \end{cases} \tag{5.3}$$

$$\frac{\partial v_{i_A}}{\partial \nu_{i_A}} = \begin{cases} \alpha_{i_A}^{-1} D_t w_A \text{ on } A \quad \forall A \in \mathcal{N}_{\text{ext}}^+, \\ \alpha_{i_A}^{-1} \frac{\partial w_A}{\partial \tau_{i_A}} \text{ on } A \quad \forall A \in \mathcal{N}_{\text{ext}}^-, \\ 0 \text{ on } A \quad \forall A \in \mathcal{N}_{\text{ext}} \setminus (\mathcal{N}_{\text{ext}}^+ \cup \mathcal{N}_{\text{ext}}^-). \end{cases} \tag{5.4}$$

THEOREM 5.4. *Let* $u \in L^\infty(0, T; D(A)')$, $\{\psi_1, \psi_0\} \in F'$ *be the unique solutions of* (5.1) *with data* $u_0 \in V$, $u_1 \in H$, $w_A \in \mathcal{D}(\Sigma_A)$, $A \in \mathcal{D}^+ \cup \mathcal{N}_{\text{ext}}^+ \cup \mathcal{N}_{\text{ext}}^-$, *and* $w_{S,n} \in K$, $S \in \mathcal{S}$, $0 < \lambda_{S,n} \le 1/2$. *Then* $u \in C^1([0, T], H)$ *satisfies* (5.3) *and* (5.5)–(5.7):

$$u_i'' - \alpha_i \Delta u_i = 0 \text{ in } \mathcal{D}'(P_i \times (0, T)) \quad \forall i \in \mathcal{I}, \tag{5.5}$$

$$u(0) = u_0, \qquad u'(0) = u_1, \tag{5.6}$$

$$u(T) = \psi_0, \qquad u'(T) = \psi_1. \tag{5.7}$$

Proof. We proceed as in Theorem 5.3 of [20] with the necessary adaptations. Let us fix $v \in \mathcal{D}(0, T, \prod_{i\in\mathcal{I}} C^\infty(\overline{P}_i))$ obtained in Lemma 5.3 and set

$$\begin{aligned} \hat{w}_{S,n} &= w_{S,n} - w_{S,n}'' \\ &\quad - \sum_{A\in\mathcal{D}^+} \int_A w_A \frac{\partial S^{S,n}}{\partial \nu_{i_A}} d\sigma - \sum_{A\in\mathcal{N}_{\text{ext}}^-} \int_A w_A \frac{\partial S^{S,n}}{\partial \tau_{i_A}} d\sigma. \end{aligned} \tag{5.8}$$

Since the w_A's are regular and $w_{S,n} \in C^\infty([0, T])$, $\hat{w}_{S,n}$ also belongs to $C^\infty([0, T])$. Let $K^{S,n} \in L^2(\Omega)$ be the dual singular function defined in [22] and recalled in Theorem 2.2, and define

$$f_i = v_i'' - \alpha_i \Delta v_i + \sum_{S,n} \hat{w}_{S,n}'' K_i^{S,n} \quad \forall i \in \mathcal{I}.$$

Since $f \in L^2(0, T; H)$, Lemma I.3.4 of [15] guarantees the existence of a unique solution $\psi \in C([0, T], V) \cap C^1([0, T], H) \cap H^2(0, T; V')$ of

$$\begin{cases} \langle \psi''(t), w \rangle + a(\psi(t), w) \\ \qquad = -\int_\Omega f(t) w dx, \text{ a.e. } t \in [0, T], \quad \forall w \in V, \\ \psi(0) = u_0, \quad \psi'(0) = u_1. \end{cases} \tag{5.9}$$

Let us now show that

$$u = \psi + v + \sum_{S,n} \hat{w}_{S,n} K^{S,n} \tag{5.10}$$

is the unique solution of (5.1) when $\psi_0 = u(T)$, $\psi_1 = u'(T)$. Note that the inclusion $w_{S,n} \in K$ leads to the initial conditions

$$u(0) = \psi(0) = u_0, \qquad u'(0) = \psi'(0) = u_1,$$

which is (5.6).

From the density of $\mathcal{D}(0, T; D(A^{3/2}))$ into $L^1(0, T; D(A))$, it suffices to check (5.1) for $\varphi \in C([0, T], D(A^2)) \cap C^1([0, T], D(A^{3/2})) \cap C^2([0, T], D(A))$. Since $\psi \in H^2(0, T; V')$, the integrations by parts over $(0, T)$ are allowed. Taking into account the initial conditions satisfied by φ and u, we get

$$\begin{aligned}(5.11)\qquad &\int_0^T \langle u(t), \varphi''(t) + A\varphi(t)\rangle dt - \langle u(T), \varphi_1\rangle + \langle u'(T), \varphi_0\rangle \\ &= \langle u_1, \varphi(0)\rangle - \langle u_0, \varphi'(0)\rangle \\ &+ \int_0^T \{\langle u''(t), \varphi(t)\rangle + \langle u(t), A\varphi(t)\rangle_{D(A)'-D(A)}\} dt.\end{aligned}$$

Let us now transform the term $\langle u(t), A\varphi(t)\rangle_{D(A)'-D(A)}$: from the expansion (5.10) of u, we may write

$$\begin{aligned}(5.12)\qquad \langle u, A\varphi\rangle_{D(A)'-D(A)} &= a(\psi, \varphi) + \int_\Omega vA\varphi \, dx \\ &+ \sum_{S,n} \hat{w}_{S,n} \int_\Omega K^{S,n} A\varphi \, dx.\end{aligned}$$

Since v vanishes in a neighbourhood of the vertices, Green's formula and Lemma 5.3 yield

$$\begin{aligned}\int_\Omega vA\varphi \, dx &= \int_\Omega Av\varphi \, dx + \sum_{A\in\mathcal{N}_{\text{ext}}^+} \int_A D_t w_A \varphi_{i_A} d\sigma \\ &+ \sum_{A\in\mathcal{N}_{\text{ext}}^-} \int_A \frac{\partial w_A}{\partial \tau_{i_A}} \varphi_{i_A} d\sigma - \sum_{A\in\mathcal{D}^+} \int_A w_A \frac{\partial \varphi_{i_A}}{\partial \nu_{i_A}} d\sigma.\end{aligned}$$

Integrating this identity with respect to t and applying some integrations by parts on Σ_A, we arrive at

$$\begin{aligned}(5.13)\qquad \int_Q vA\varphi \, dxdt &= \int_Q Av\varphi \, dxdt - \sum_{A\in\mathcal{N}_{\text{ext}}^+} \int_{\Sigma_A} w_A D_t \varphi_{i_A} d\sigma dt \\ &- \sum_{A\in\mathcal{N}_{\text{ext}}^-} \int_{\Sigma_A} w_A \frac{\partial \varphi_{i_A}}{\partial \tau_{i_A}} d\sigma dt - \sum_{A\in\mathcal{D}^+} \int_{\Sigma_A} w_A \frac{\partial \varphi_{i_A}}{\partial \nu_{i_A}} d\sigma dt.\end{aligned}$$

Moreover, Theorem 2.2 implies that

$$(5.14)\qquad \int_\Omega A\varphi K^{S,n} dx = -c_{S,n},$$

when φ admits the decomposition (3.12).

Taking into account (5.12)–(5.14), the identity (5.11) becomes

$$\begin{aligned}(5.15)\qquad &\int_0^T \langle u(t), \varphi'' + A\varphi\rangle dt - \langle u(T), \varphi_1\rangle + \langle u'(T), \varphi_0\rangle \\ &= \langle u_1, \varphi(0)\rangle - \langle u_0, \varphi'(0)\rangle - \sum_{A\in\mathcal{N}_{\text{ext}}^+} \int_{\Sigma_A} w_A D_t \varphi_{i_A} d\sigma dt \\ &- \sum_{A\in\mathcal{N}_{\text{ext}}^-} \int_{\Sigma_A} w_A \frac{\partial \varphi_{i_A}}{\partial \tau_{i_A}} d\sigma dt - \sum_{A\in\mathcal{D}^+} \int_{\Sigma_A} w_A \frac{\partial \varphi_{i_A}}{\partial \nu_{i_A}} d\sigma dt \\ &- \sum_{S,n} \int_0^T \hat{w}_{S,n}(t) c_{S,n}(t) \, dt.\end{aligned}$$

This proves that u is the solution of (5.1) with $u(T) = \psi_0$, $u'(T) = \psi_1$ if we show that

$$\sum_{A\in\mathcal{N}_{\text{ext}}^-}\int_{\Sigma_A} w_A\frac{\partial\varphi_{i_A}}{\partial\tau_{i_A}}d\sigma dt + \sum_{A\in\mathcal{D}^+}\int_{\Sigma_A} w_A\frac{\partial\varphi_{i_A}}{\partial\nu_{i_A}}d\sigma dt$$
$$+\sum_{S,n}\int_0^T \hat{w}_{S,n}(t)c_{S,n}(t)\,dt = \sum_{A\in\mathcal{D}^+}\int_{\Sigma_A} w_A\frac{\partial\varphi_{Ri_A}}{\partial\nu_{i_A}}d\sigma dt$$
$$+\sum_{A\in\mathcal{N}_{\text{ext}}^-}\int_{\Sigma_A} w_A\frac{\partial\varphi_{Ri_A}}{\partial\tau_{i_A}}d\sigma dt + \sum_{S,n}\int_0^T (w_{S,n}(t)c_{S,n}(t) + w'_{S,n}(t)c'_{S,n}(t))\,dt.$$

This last identity is proved using the expansion (3.12) of φ, an integration by parts in time (taking into account the boundary conditions $w'_{S,n}(0) = w'_{S,n}(T) = 0$, due to the inclusion $w_{S,n} \in K$) and the expression (5.8) of $\hat{w}_{S,n}$.

Let us finally note that the boundary conditions (5.3) come from (5.10); the boundary conditions (5.3) which are fulfilled by v and the fact that ψ and $K^{S,n}$ both satisfy (2.4). □

Roughly speaking, ψ introduced in the above proof satisfies (2.6); therefore, one can say that u satisfies (2.6) for all $A \in \mathcal{N}_{\text{int}}$ and (5.4) in a weak sense.

Up to now, the functions $w_{S,n}$ appear neither in the partial differential equation (5.5) nor in the boundary conditions (5.3) and (5.4) fulfilled by u. This is because we were working in the setting of $\mathcal{D}'(P_i \times (0, T))$.

DEFINITION 5.5. *Let $D := \{\varphi = \Phi_{|\Omega} : \Phi \in \mathcal{D}(\mathbf{R}^n)\}$, and for all $S \in \mathcal{S}$, $0 < \lambda_{S,n} \le 1/2$, introduce the distribution $T^{S,n}$ in D' by*

$$\langle T^{S,n}, \varphi\rangle = \int_\Omega \alpha K^{S,n}\triangle\varphi\,dx - \sum_{A\in\mathcal{N}}\int_A \sum_{i\in\mathcal{I}_A}\alpha_i\frac{\partial\varphi_i}{\partial\nu_i}K_i^{S,n}\,d\sigma$$
$$+\sum_{A\in\mathcal{D}}\int_A \alpha_{i_A}\frac{\partial K_{i_A}^{S,n}}{\partial\nu_{i_A}}\left(\varphi_{i_A} - \eta_S\varphi_{i_A}(S)\right)d\sigma. \tag{5.16}$$

Note that $T^{S,n}$ is well defined due to the decomposition (2.73) in [22] of $K^{S,n}$.

LEMMA 5.6. *For all $S \in \mathcal{S}$, $0 < \lambda_{S,n} \le 1/2$, we have*

$$\langle T^{S,n}, \varphi\rangle = c_{S,n} \tag{5.17}$$

for any $\varphi \in D(A)$, where $c_{S,n}$ is the coefficient of the singularity $S^{S,n}$ of φ appearing in its decomposition (2.13).

The support of $T^{S,n}$ is equal to S in the sense that for any $\varphi \in D$ such that $\varphi \equiv 0$ in a neighbourhood of S, we have

$$\langle T^{S,n}, \varphi\rangle = 0. \tag{5.18}$$

Proof. Since $\varphi \in D(A)$ satisfies (2.4), (2.5), (2.6), and $\varphi_{i_A}(S) = 0$, for all $S \in \bar{A}$ such that $A \in \mathcal{D}$, we get

$$\langle T^{S,n}, \varphi\rangle = \int_\Omega \alpha K^{S,n}\triangle\varphi\,dx = c_{S,n}$$

due to Theorem 2.2.

On the other hand, for any $\varphi \in D$ such that $\varphi = 0$ on $B(S, \delta) \cap \Omega$ for some $\delta > 0$, applying Green's formula on $P_i \setminus B(S, \delta/2)$ for all $i \in \mathcal{I}$, one gets (5.18). □

According to Lemma 5.6, the identity (5.15) implies that

$$\begin{aligned}(5.19)\qquad &\int_0^T \langle u(t), \varphi'' + A\varphi\rangle dt - \langle u(T), \varphi_1\rangle + \langle u'(T), \varphi_0\rangle \\ &= \langle u_1, \varphi(0)\rangle - \langle u_0, \varphi'(0)\rangle - \sum_{A\in\mathcal{N}_{\text{ext}}^+}\int_{\Sigma_A} w_A D_t\varphi_{i_A} d\sigma dt \\ &- \sum_{A\in\mathcal{N}_{\text{ext}}^-}\int_{\Sigma_A} w_A \frac{\partial\varphi_{i_A}}{\partial\tau_{i_A}} d\sigma dt - \sum_{A\in\mathcal{D}^+}\int_{\Sigma_A} w_A \frac{\partial\varphi_{i_A}}{\partial\nu_{i_A}} d\sigma dt \\ &- \sum_{S,n}\int_0^T \hat{w}_{S,n}(t)\langle T^{S,n}, \varphi\rangle\, dt \quad \forall\varphi\in C^\infty([0,T], D).\end{aligned}$$

This means that u satisfies

$$(5.20)\qquad u'' + Au = -\sum_{S,n}\hat{w}_{S,n}T^{S,n} \text{ in } C^\infty([0,T], D)'$$

if we admit that u satisfies (5.3) and (5.4).

Let us remark that (5.20) covers (5.5) since

$$\langle T^{S,n}, \varphi\rangle = 0 \quad \forall\varphi\in\prod_{i\in\mathcal{I}}\mathcal{D}(P_i\times(0,T)).$$

All these considerations lead us to call the solution u of (5.1) the weak solution of (5.20), (5.6), (5.3), and (5.4). In order to give a meaning to the final conditions (5.7), we need the next regularity result.

THEOREM 5.7. *Under the assumption of Theorem* 5.1, *let* u, $\{\psi_1, \psi_0\}$ *be the solutions of* (5.1). *Then* $u\in C([0,T], D(A)')\cap C^1([0,T], D(A^{3/2})')$ *and* u *satisfies the final conditions* (5.7).

Proof. We argue as at the end of paragraph 5 of [20]: first we reduce the wave equation to the first-order equation

$$(5.21)\qquad \begin{cases}\Phi' + B\Phi = g,\\ \Phi(0) = \Phi_0,\end{cases}$$

where B is an operator from $\mathcal{H} = V\times H$ into itself defined by $D(B) = D(A)\times V$ and for all $\Phi = (\varphi, \xi)\in D(B)$, $B\Phi = (-\xi, A\varphi)$. Using Lemma 5.4 of [20] and Theorems 3.5 and 3.6, we can show that if $\Phi = (\varphi, \xi)\in C([0,T], \mathcal{H})$ is the unique solution of (5.21) with $\Phi_0\in F$ and $g\in L^1(0,T; D(A^{3/2})\times D(A))$, then φ admits the decomposition (3.12) and satisfies

$$\begin{aligned}&\left\{\sum_{A\in\mathcal{D}^+}\int_{\Sigma_A}\left(\frac{\partial\varphi_{Ri_A}}{\partial\nu_{i_A}}\right)^2 d\sigma dt + \sum_{A\in\mathcal{N}_{\text{ext}}^-}\int_{\Sigma_A}\left(\frac{\partial\varphi_{Ri_A}}{\partial\tau_{i_A}}\right)^2 d\sigma dt\right.\\ &\left.+\sum_{A\in\mathcal{N}_{\text{ext}}^+}\int_{\Sigma_A}\left(D_t\varphi_{i_A}\right)^2 d\sigma dt + \sum_{S,n}\|c_{S,n}\|^2_{1,(0,T)}\right\}^{1/2}\\ &\le C\{|||\Phi_0||| + \|g\|_{L^1(0,T;D(A^{3/2})\times D(A))}\}.\end{aligned}$$

By transposition and density, we arrive at the conclusion. □

6. The Hilbert uniqueness method. The application of the Hilbert uniqueness method of J.-L. Lions [15] is now standard: first, by Proposition 4.4, for $\{\varphi_0, \varphi_1\} \in F$, there exists a unique solution $\varphi \in C([0,T], V) \cap C^1([0,T], H)$ of (3.1) with $f = 0$ satisfying (4.20). Second, consider $\psi \in L^\infty(0,T, D(A)')$, $\{\chi_1, -\chi_0\} \in F'$, the unique solutions of

$$
\begin{aligned}
(6.1)\qquad & \int_0^T \langle \psi(t), g(t)\rangle dt - \langle \{\chi_1, -\chi_0\}, \{\eta_0, \eta_1\}\rangle \\
&= -\sum_{A\in\mathcal{D}^+} \int_{\Sigma_A} \frac{\partial \varphi_{Ri_A}}{\partial \nu_{i_A}} \frac{\partial \eta_{Ri_A}}{\partial \nu_{i_A}}\, d\sigma dt - \sum_{A\in\mathcal{N}^-_{\text{ext}}} \int_{\Sigma_A} \frac{\partial \varphi_{Ri_A}}{\partial \tau_{i_A}} \frac{\partial \eta_{Ri_A}}{\partial \tau_{i_A}}\, d\sigma dt \\
&\quad - \sum_{A\in\mathcal{N}^+_{\text{ext}}} \int_{\Sigma_A} D_t\varphi_{i_A} D_t\eta_{i_A}\, d\sigma dt - \sum_{S,n} \int_0^T (c_{S,n} d_{S,n} + c'_{S,n} d'_{S,n})\, dt
\end{aligned}
$$

for all $g \in L^1(0,T; D(A))$, $\{\eta_0, \eta_1\} \in F$, where $\eta = \eta_R + \sum_{S,n} d_{S,n} S^{S,n}$ is the unique solution of

$$
(6.2)\qquad \begin{cases} \eta \in C([0,T], V) \cap C^1([0,T], H), \\ \eta''(t) + A\eta(t) = g(t), t \in [0,T], \\ \eta(0) = \eta_0, \qquad \eta'(0) = \eta_1. \end{cases}
$$

Its existence comes from Theorem 5.1, inverting the order of time; moreover, Theorem 5.7 gives a meaning to the initial conditions

$$
\psi(0) = \chi_0, \qquad \psi'(0) = \chi_1.
$$

Accordingly, the next operator,

$$
\Lambda : F \to F' : \{\varphi_0, \varphi_1\} \to \{\chi_1, -\chi_0\},
$$

is well defined and is an isomorphism, because the identity (6.1) with $\eta = \varphi$ yields

$$
\langle \Lambda\{\varphi_0, \varphi_1\}, \{\varphi_0, \varphi_1\}\rangle = |||\{\varphi_0, \varphi_1\}|||^2 \quad \forall \{\varphi_0, \varphi_1\} \in F.
$$

This leads to the main result of this paper.

THEOREM 6.1. *For all $u_0 \in H$, $u_1 \in V'$, there exist $w_A \in L^2(\Sigma_A)$, $A \in \mathcal{D}^+ \cup \mathcal{N}^+_{\text{ext}} \cup \mathcal{N}^-_{\text{ext}}$, and $w_{S,n} \in H^1(0,T)$, $S \in \mathcal{S}$, $0 < \lambda_{S,n} \le 1/2$ such that the weak solution $u \in C([0,T], D(A)') \cap C^1([0,T], D(A^{3/2})')$ of the wave equation* (6.3) (*in the sense of* (5.1)) *satisfies $u(T) = u'(T) = 0$:*

$$
(6.3)\qquad \begin{cases} u''(t) + Au(t) = -\sum_{S,n} \hat{w}_{S,n}(t) T^{S,n}, \qquad t \in [0,T], \\ u(0) = u_0, \qquad u'(0) = u_1, \\ u_{i_A} = \begin{cases} \alpha_{i_A}^{-1} w_A \text{ on } A \quad \forall A \in \mathcal{D}^+, \\ 0 \text{ on } A \quad \forall A \in \mathcal{D} \setminus \mathcal{D}^+, \end{cases} \\ \dfrac{\partial u_{i_A}}{\partial \nu_{i_A}} = \begin{cases} \alpha_{i_A}^{-1} D_t w_A \text{ on } A \quad \forall A \in \mathcal{N}^+_{\text{ext}}, \\ \alpha_{i_A}^{-1} \dfrac{\partial w_A}{\partial \tau_{i_A}} \text{ on } A \quad \forall A \in \mathcal{N}^-_{\text{ext}}, \\ 0 \text{ on } A \quad \forall A \in \mathcal{N}_{\text{ext}} \setminus (\mathcal{N}^+_{\text{ext}} \cup \mathcal{N}^-_{\text{ext}}). \end{cases} \end{cases}
$$

Recall that in the case of smoother controls w_A and $w_{S,n}$, $\hat{w}_{S,n}$ is given by (5.8) (*see Theorem* 5.4).

Proof. Since $\{u_1, -u_0\} \in V' \times H \subset F'$, there exists a unique solution $\{\varphi_0, \varphi_1\} \in F$ of

$$\Lambda\{\varphi_0, \varphi_1\} = \{u_1, -u_0\}.$$

We take the solution φ of (3.1) with $f = 0$, which admits the decomposition (3.12) and then the solution ψ of (6.1). The conclusion follows with $u = \psi$, $w_A = \frac{\partial \varphi_{Ri_A}}{\partial \nu_{i_A}}$ for all $A \in \mathcal{D}^+$, $w_A = D_t \varphi_{i_A}$ for all $A \in \mathcal{N}^+_{\text{ext}}$, $w_A = \frac{\partial \varphi_{Ri_A}}{\partial \tau_{i_A}}$ for all $A \in \mathcal{N}^-_{\text{ext}}$, and $w_{S,n} = c_{S,n}$ for all $S \in \mathcal{S}, 0 < \lambda_{S,n} \leq 1/2$, because of the reversibility of the wave equation and Proposition 4.4. □

Remark. In the above theorem, the boundary controls are classical. The influence of the singularities is translated through the terms $\hat{c}_{S,n}(t)T^{S,n}$, and each of them can be seen as a distributional internal control with a support concentrated at the singular vertex S (due to Lemma 5.6). The introduction of these terms is the price to pay to avoid the regularity hypothesis $D(A) \hookrightarrow \mathcal{H}^{3/2+\varepsilon}(\Omega)$ for some $\varepsilon > 0$ leading to strong geometrical conditions on the domains Ω [12, Chaps. 4 and 7]. On the other hand, the conditions (H1)–(H4) that we imposed are not related to the singularities but linked to the multiplier method, since they were introduced to avoid internal control. Consequently, they also appear for transmission problems without singularities [15, Chap. VI].

7. Lack of controllability for 2-d networks with circuits. In this section, we shall give an example of a 2-d network for which we do not have exact controllability by boundary control on the exterior edges with the help of the Hilbert uniqueness method. Inspired by the results of Lagnese, Leugering, and Schmidt for 1-d networks [12, § II.5.2], we choose a network with circuits. More precisely, let us define $\Omega \subset \mathbf{R}^3$ by

$$\Omega = \bigcup_{i=-5}^{5} P_i,$$

where

$$\begin{aligned}
&P_0 = (0,1) \times (0,1) \times \{0\}, \qquad P_5 = (-1,0) \times (0,1) \times \{1\},\\
&P_1 = \{0\} \times (0,1) \times (0,1), \qquad P_3 = \{-1\} \times (0,1) \times (0,1),\\
&P_2 = (-1,0) \times \{1\} \times (0,1), \qquad P_4 = (-1,0) \times \{0\} \times (0,1),\\
&P_{-k} = \{(x_1, x_2, -x_3) : (x_1, x_2, x_3) \in P_k\}.
\end{aligned}$$

The exterior edges of Ω are the exterior edges of P_0, i.e.,

$$\begin{aligned}
\Gamma_{01} &= (0,1) \times \{0\} \times \{0\},\\
\Gamma_{02} &= \{1\} \times (0,1) \times \{0\},\\
\Gamma_{03} &= (0,1) \times \{1\} \times \{0\}.
\end{aligned}$$

We take $\mathcal{D} = \{\Gamma_{0i}\}_{i=1,2,3}$, which means that we consider Dirichlet boundary conditions on the exterior boundary of Ω. Finally, for simplicity, we fix $\alpha_i \equiv 1$ for all $i \in \mathcal{I} := \{-5, \ldots, 5\}$.

As in [12], the lack of controllability comes from the existence of a special eigenvector $w \neq 0$ of the Laplace operator A on Ω of eigenvalue $\lambda > 0$ then fulfilling

$$-\triangle w_i = \lambda w_i \text{ in } P_i \quad \forall i \in \mathcal{I} \tag{7.1}$$

and the boundary and interface conditions (2.4)–(2.6) and also the supplementary conditions

$$\frac{\partial w_0}{\partial \nu} = 0 \text{ on } \Gamma_{0i} \quad \forall i = 1, 2, 3. \tag{7.2}$$

Indeed, let us consider the 2-d network $\tilde{\Omega} = \cup_{i=1}^{5} P_i$ (with the same P_i as in the definition of Ω). Consider the Laplace operator $\tilde{A}$ on $\tilde{\Omega}$ with Dirichlet boundary conditions on its exterior boundary (corresponding to the edges of the P_i's included in the plane $x_3 = 0$). Take $\tilde{w} = (w_i)_{i=1,\dots,5}$, an eigenvector $\neq 0$ of $\tilde{A}$ of eigenvalue $\lambda > 0$. (In other words, $\tilde{w}$ satisfies (7.1) for $i = 1, \dots, 5$ and Dirichlet boundary conditions.) From Theorem 2.27 of [22], one can show that $\tilde{w} \in \mathcal{H}^{3/2+\varepsilon}(\tilde{\Omega})$ for some $\varepsilon > 0$. We now define w on the whole of Ω by antisymmetry:

$$w_0 \equiv 0,\ w_{-k}(x_1, x_2, -x_3) = -w_k(x_1, x_2, x_3) \quad \forall (x_1, x_2, x_3) \in P_k, \qquad k = 1, \dots, 5.$$

From the inclusion $\tilde{w} \in D(\tilde{A})$, we readily check that $w \in D(A)$ and satisfies (7.1). The property (7.2) is immediate since $w_0 \equiv 0$ in P_0. Finally, w is inherited from $\tilde{w}$ of the regularity $\mathcal{H}^{3/2+\varepsilon}(\Omega)$ for some $\varepsilon > 0$.

We now say that we have exact controllability at time $T > 0$ by Dirichlet control on $\mathcal{D}$ with the help of the Hilbert uniqueness method if there exists a Hilbert space F such that (4.15), Proposition 4.4 and Theorem 5.1 hold (with $\mathcal{D}^+ = \mathcal{D}, \mathcal{N}_{\text{ext}} = \emptyset$) and if moreover the continuous mapping

$$C_T : \prod_{A \in \mathcal{D}} (L^2(\Sigma_A)) \times \prod_{S,n} H^1(0, T) \longrightarrow F' : (w_A)_{A \in \mathcal{D}} \times (w_{S,n})_{S,n} \longmapsto \{\psi_1, \psi_0\},$$

where u, $\{\psi_1, \psi_0\}$ are the unique solutions of (5.1) with $u_0 = u_1 = 0$, is surjective.

From (5.1), we directly see that

$$C_T^*(\{\varphi_0, -\varphi_1\}) = \left(\frac{\partial \varphi_{Ri_A}}{\partial \nu_{i_A}} \right)_{A \in \mathcal{D}} \times (c_{S,n})_{S,n}$$

when $\varphi = \varphi_R + \sum_{S,n} c_{S,n} S^{S,n}$ is the unique solution of (5.2) with $f = 0$.

If C_T is surjective, then $\ker C_T^* = \{0\}$, which, in our case, is impossible because the pair $\{w, 0\} \in D(A) \times V \hookrightarrow F$ belongs to $\ker C_T^*$. Indeed the unique solution η of

$$\begin{cases} \eta''(t) + A\eta(t) = 0, & t \in [0, T], \\ \eta(T) = w, \qquad \eta'(T) = 0 \end{cases}$$

is given by $\eta(t) = w \cos(\sqrt{\lambda}(T - t))$. Consequently, the property (7.2) satisfied by w and its regularity leads to

$$\frac{\partial \eta_{i_A}}{\partial \nu_{i_A}} = 0 \text{ on } A \quad \forall A \in \mathcal{D},$$

$$c_{S,n} = 0 \quad \forall S \in \mathcal{S},\ 0 < \lambda_{S,n} \leq 1/2.$$

APPROXIMATE FEEDBACK LINEARIZATION: A HOMOTOPY OPERATOR APPROACH*

ANDRZEJ BANASZUK† AND JOHN HAUSER‡

Abstract. In this paper, we present an approach for finding feedback linearizable systems that approximate a given single-input nonlinear system on a given compact region of the state space. First, we show that if the system is close to being involutive, then it is also close to being linearizable. Rather than working directly with the characteristic distribution of the system, we work with characteristic one-forms, i.e., with the one-forms annihilating the characteristic distribution. We show that homotopy operators can be used to decompose a given characteristic one-form into an exact and an antiexact part. The exact part is used to define a change of coordinates to a normal form that looks like a linearizable part plus nonlinear perturbation terms. The nonlinear terms in this normal form depend continuously on the antiexact part, and they vanish whenever the antiexact part does. Thus, the antiexact part of a given characteristic one-form is a measure of nonlinearizability of the system. If the nonlinear terms are small, by neglecting them we obtain a linearizable system approximating the original system. One can design control for the original system by designing it for the approximating linearizable system and applying it to the original one. We apply this approach for design of locally stabilizing feedback laws for nonlinear systems that are close to being linearizable.

1. Introduction.

Consider a single-input system

$$\dot{x} = f(x) + g(x)u, \tag{1}$$

where f and g are smooth vector fields defined on a compact contractible region $\mathcal{M}$ of R^n containing the origin. (Typically, $\mathcal{M}$ is a closed ball in R^n.) We assume that $f(0) = 0$, i.e., that the origin is an equilibrium for $\dot{x} = f(x)$. The classical problem of feedback linearization can be stated as follows: find in a neighborhood of the origin a smooth change of coordinates $z = \Phi(x)$ (a local diffeomorphism) and a smooth feedback law $u = k(x) + l(x)u_{\text{new}}$ such that the closed-loop system in the new coordinates with new control is linear,

$$\dot{z} = Az + Bu_{\text{new}}, \tag{2}$$

and controllable. We usually require that $\Phi(0) = 0$.

We assume that the system (1) has *the linear controllability* property

$$\dim \operatorname{span} \{g, ad_f g, \ldots, ad_f^{n-1} g\} = n \ \forall x \in \mathcal{M} \tag{3}$$

(where $ad_f^i g$ are iterated Lie brackets of f and g). We define the *characteristic distribution* for (1):

$$D := \operatorname{span} \{g, ad_f g, \ldots, ad_f^{n-2} g\}. \tag{4}$$

(It is an $n-1$-dimensional smooth distribution by assumption of linear controllability (3).) We shall call any nowhere vanishing one-form ω annihilating D a *characteristic one-form for* (1). All the characteristic one-forms for (1) can be represented as multiples of some fixed

characteristic one-form ω_0 by a smooth nowhere vanishing function (zero-form) β. Suppose that there is a nonvanishing β so that $\beta\omega_0$ is exact, i.e., $\beta\omega_0 = d\alpha$ for some smooth function α. (d denotes the exterior derivative.) Then ω_0 is called *integrable* and β is called an *integrating factor for* ω_0. The following result is standard [14, 15].

THEOREM 1.1. *Suppose that the system* (1) *has the linear controllability property* (3) *on* $\mathcal{M}$. *Let* D *be the characteristic distribution and* ω_0 *be a characteristic one-form for* (1). *The following statements are equivalent:*

1. *Equation* (1) *is feedback linearizable in a neighborhood of the origin in* $\mathcal{M}$.
2. D *is involutive in a neighborhood of the origin in* $\mathcal{M}$.
3. ω_0 *is integrable in a neighborhood of the origin in* $\mathcal{M}$.

As is well known, a generic nonlinear system is not feedback linearizable for $n > 2$. However, in some cases, it may make sense to consider *approximate* feedback linearization. Namely, if one can find a feedback linearizable system *close* to (1), there is hope that a control designed for the feedback linearizable system and applied to (1) will give satisfactory performance if the feedback linearizable system is *close* enough to (1). The first attempt in this direction goes back to [16], where it was proposed to apply to (1) a change of variables and feedback that yield a system of the form

$$\dot{z} = Az + Bu_{\text{new}} + \mathcal{O}(z, u_{\text{new}}), \tag{5}$$

where the term $\mathcal{O}(z, u_{\text{new}})$ contains higher-order terms. The aim was to make $\mathcal{O}(z, u_{\text{new}})$ of as high order as possible. Then we can say that the system (1) is approximately feedback linearized in a small neighborhood of the origin. Reference [13] introduced a new algorithm to achieve the same goal with fewer steps.

Another idea has been investigated in [11]. Roughly speaking, the idea was to neglect nonlinearities in (1) responsible for the failure of the involutivity condition in Theorem 1.1. This approach happened to be successful in the *ball-and-beam* system, when neglect of centrifugal force acting on ball yielded a feedback linearizable system. Application of a control scheme designed for the system with centrifugal force neglected to the original system gave much better results than applying a control scheme based on classical Jacobian linearization. This approach has been further investigated in [10, 18, 19] for the purpose of approximate feedback linearization about the manifold of constant operating points. However, a general approach to deciding which nonlinearities should be neglected to get the best approximation has not been set forth.

In [17] a design of a control law for the systems with cubic nonlinearities is proposed which uses a change of variables that directly minimizes the terms P and Q in L_2.

All of the above-mentioned work (except [17]) dealt with applying a change of coordinates and a preliminary feedback so that the resulting system looks like linearizable part plus nonlinear terms of highest possible order around an equilibrium point or an equilibrium manifold. However, in many applications one requires a large region of operation for the nonlinearizable system. In such a case, demanding the nonlinear terms to be neglected to be of highest possible order may, in fact, be quite undesirable. One might prefer that the nonlinear terms to be neglected be small in a uniform sense over the region of operation. In the present paper we propose an approach to approximate feedback linearization that uses a change of coordinates and a preliminary feedback to put a system (1) in *a perturbed Brunovsky form*,

$$\dot{z} = Az + Bu_{\text{new}} + P(z) + Q(z)u_{\text{new}}, \tag{6}$$

where $P(z)$ and $Q(z)$ vanish at $z = 0$ and are "small" on $\mathcal{M}$. We obtain upper bounds on uniform norms of P and Q (depending on some measures of noninvolutivity of D) on any compact, contractible $\mathcal{M}$.

Our approach is an indirect one. We begin with approximating characteristic one-forms by exact forms using *homotopy operators*. Namely, on any contractible region $\mathcal{M}$ one can define a linear operator H that satisfies

$$\omega = d(H\omega) + Hd\omega \tag{7}$$

for any form ω.

Note that the homotopy identity (7) allows to decompose any given one-form into the *exact part* $d(H\omega)$ and an "error" part $\epsilon := Hd\omega$, which we will call the *antiexact part of* ω. For given ω_0 annihilating D and a scaling factor β we define $\alpha_\beta := H\beta\omega_0$ and $\epsilon_\beta := Hd\beta\omega_0$. Note that the one-form ϵ_β measures how exact $\omega_\beta := \beta\omega_0$ is. If it is zero, then ω_β is exact and the system (1) is linearizable, and the zero-form α_β and its first $n-1$ Lie derivatives along f are the new coordinates. In the case that ω_0 is not exactly integrable, i.e., when no exact integrating factor β exists, we choose β so that $d\beta\omega_0$ is *smallest* in some sense (because this also makes ϵ_β small). We will call this β an *approximate integrating factor for* ω_0. We will use the zero-form α_β and its first $n-1$ Lie derivatives along f as the new coordinates as in the linearizable case. In those new coordinates the system (1) is in the form

$$\dot{z} = Az + Bru + Bp + Eu, \tag{8}$$

where r and p are smooth functions, $r \neq 0$ around the origin, and the term E (the obstruction to linearizablity) depends *linearly* on ϵ_β and some of its derivatives. (In particular, E vanishes whenever ϵ_β does.) We choose $u = r^{-1}(u_{\text{new}} - p)$, where u_{new} is a new control variable. After this change of coordinates and control variable the system is of the form (6) with $Q := r^{-1}E$, $P := -r^{-1}pE$. We obtain estimates on the uniform norm of Q and P (via estimates on r, p, and E) in terms of the error one-form ϵ_β, for any fixed β, on any compact, contractible region $\mathcal{M}$. Most important is that Q and P depend in a continuous way on ϵ_β and some of its derivatives, and they vanish whenever ϵ does.

From another point of view our approach can be viewed as a robustness analysis of exact feedback linearization. It is of obvious interest to analyze what happens to an exactly linearizable system subject to a small perturbation that destroys the property of being linearizable. One can expect that if linearization was used as an intermediate tool to achieve stabilization, tracking, disturbance rejection, and so on, a small perturbation, yielding a system "close" to being linearizable, still allows one to apply the control designed for the original linearizable system, guaranteeing satisfactory performance. In the present paper we propose some tools to measure a distance of a nonlinearizable perturbed system from a linearizable one, thus allowing us to measure how small the small perturbation is. In particular, we provide analysis of robustness of stabilizing feedback design based on feedback linearization.

We anticipate many applications of transforming (1) into (6). The idea behind making Q and P small is to neglect them in design. Intuitively speaking, we can neglect them if they are "small enough." What "small enough" means will depend on the particular application.

We should warn that one cannot expect that an exact or approximate feedback linearization will always help improve performance. The point is that the idea of linearization is to get rid of nonlinearities because we don't know how to deal with them. It may happen, though, that removing of some nonlinear terms may negatively affect the performance of the system. For instance, consider the problem of stabilization of the feedback linearizable system $\dot{x} = -x^3 + u$. One can remove the nonlinear term $-x^3$ using feedback, but this doesn't help stabilization at all. The term $-x^3$ actually helps to stabilize the system, especially for large initial conditions. Still, there are enough examples of systems in which nonlinear terms cause problems to justify the present study.

The paper is organized as follows. In §2 we introduce notation and some auxiliary results. We also explain construction of characteristic one-forms. In §3 we discuss the problem of optimal scaling of the characteristic one-forms. We review the construction of exact integrating factors and introduce and study best approximate L^p integrating factors. In §4 we show how homotopy operators can be use to decompose characteristic one-forms into exact and antiexact parts. In §5 we prove that a change of coordinates based on the exact part of any characteristic one-form obtained with a homotopy operator having its center at the origin defines a local diffeomorphism that takes the system (1) to a normal form that looks like a linearizable part perturbed by some nonlinear terms. The nonlinear perturbation terms depend linearly on the antiexact part of the characteristic one-form. In §6 we obtain some upper bounds on nonlinear perturbation terms using the antiexact part of a characteristic one-form and thus establish a continuity relationships between some measures of noninvolutivity and nonlinearizability. In §7 we apply the results of the paper to study locally linearizing feedback laws for the system (1).

2. Notation and auxiliary results. In the present paper we apply the theory of differential alternating forms. We refer to standard texts such as [1, 7, 8, 9, 12] for all the notions not defined here.

We denote by $T\mathcal{M}$ the tangent bundle to $\mathcal{M}$ and by $\Omega^k(\mathcal{M})$ the set of all alternating k-forms on $\mathcal{M}$, i.e., the space of all k-linear antisymmetric functionals on $T\mathcal{M}$. $\Omega(\mathcal{M})$ will denote the direct sum of all $\Omega^k(\mathcal{M})$. Let $\zeta \in \Omega(\mathcal{M})$ and $v \in T\mathcal{M}$. Then $d\zeta$ will denote the exterior derivative of ζ, and $L_v\zeta$ will denote the Lie derivative of ζ along v.

By $i_v(\xi)$ we will mean the interior product (contraction) of a vector field v with a k-form ξ, which is a $k-1$ form defined by

$$i_v(\xi)(v_1, v_2, \ldots, v_{k-1}) := \xi(v, v_1, v_2, \ldots, v_{k-1}).$$

Note that if ξ is a one-form, then $i_v(\xi) = \xi(v)$. Below we summarize some properties of interior and exterior (wedge) products and exterior and Lie derivatives.

PROPOSITION 2.1. *Let $\xi_1 \in \Omega^k(\mathcal{M})$, $\xi_2 \in \Omega(\mathcal{M})$, and $v \in T\mathcal{M}$ be arbitrary. Then*

1. $i_v(\xi_1 \wedge \xi_2) = (i_v\xi_1) \wedge \xi_2 + (-1)^k \xi_1 \wedge (i_v\xi_2)$.
2. $i_v i_v \xi_2 = 0$.
3. $d(\xi_1 \wedge \xi_2) = (d\xi_1) \wedge \xi_2 + (-1)^k \xi_1 \wedge (d\xi_2)$.
4. $d(L_v\xi_2) = L_v(d\xi_2)$.

While we did not need any additional structure except the differential one to study the problem of finding exact integrating factors, in the case of approximate integrating factors we need some means of measuring the distance between k-forms (for instance, ω_0 from an exact form $d\alpha$, or $d\beta\omega_0$ from 0), both at a point and globally (on $\mathcal{M}$). For this, we use a Riemannian metric, i.e., a positive definite (pointwise) inner product $\langle , \rangle$ on the tangent space to $\mathcal{M}$. This inner product induces an inner product on p-forms (see [1, §6.2]), which we will denote by the same symbol. Namely, let $\{e^i\}$, $i = 1, \ldots, n$, be an orthonormal basis for $\Omega^1(\mathcal{M})$. Then the inner product on p-forms is uniquely defined by requiring $\{e^{i_1} \wedge \cdots \wedge e^{i_p} | i_1 < \cdots < i_p\}$ to be an orthonormal basis for $\Omega^p(\mathcal{M})$. The corresponding pointwise norm will be denoted by $|\cdot|$. We obtain a global inner product $\langle\langle , \rangle\rangle$ of p-forms on $\mathcal{M}$ by integrating the pointwise one over $\mathcal{M}$. A standard metric associated with coordinate system $x_1, x_2, \ldots, x_n$ is the one in which the vector fields $\frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_2}, \ldots, \frac{\partial}{\partial x_n}$ and thus the one-forms $dx_1, dx_2, \ldots, dx_n$ are orthonormal. The standard (in coordinates x_i) volume element on $\mathcal{M}$ is

$$\mu := dx_1 \wedge dx_2 \wedge \cdots \wedge dx_n.$$

For any one-form η we will denote by $\eta^\#$ the dual vector field to η, i.e., the unique smooth vector field satisfying $\langle \xi, \eta \rangle = i_{\eta^\#}(\xi) = \xi(\eta^\#)$ for any one-form ξ. For instance, if we use the

standard metric, we have $(\sum_{i=1}^{n} \eta_i dx_i)^{\#} = \sum_{i=1}^{n} \eta_i \frac{\partial}{\partial x_i}$. We have the following elementary result.

PROPOSITION 2.2. *Let* $\xi_1, \xi_2 \in \Omega^1(\mathcal{M})$ *and* $\zeta \in \Omega^2(\mathcal{M})$. *Then*

$$\langle \xi_1 \wedge \xi_2, \zeta \rangle = \langle \xi_2, i_{\xi_1^{\#}} \zeta \rangle = \zeta(\xi_1^{\#}, \xi_2^{\#}).$$

Let $\zeta \in \Omega^p(\mathcal{M})$ and $\xi \in \Omega^{m-p}(\mathcal{M})$. In the following discussion we will deal with the operator $W_\xi : \Omega^p(\mathcal{M}) \mapsto \Omega^m(\mathcal{M})$ defined by $W_\xi \zeta := \zeta \wedge \xi$.

To obtain a one-form annihilating an $n-1$-dimensional distribution D in $\mathcal{M}$, we contract any volume element of $\mathcal{M}$ by any basis of D. For instance, we may choose

$$\omega_0 := i_g i_{ad_f g} \ldots i_{ad_f^{n-2} g} \mu, \tag{9}$$

where μ is the standard volume element in coordinates x_i.

3. Approximate integrating factors. Before we discuss the approximate integrating factors for nonintegrable characteristic one-form ω_0, let us remind the reader how, given an integrable characteristic one-form ω_0, one constructs an exact integrating factor for ω_0. The construction will suggest what can be done in the case of nonintegrable characteristic one-form ω_0. Let us begin with following standard result (see, e.g., [1, §6.4; 8, §4.2]).

PROPOSITION 3.1. *Let* ω_0 *be a nonvanishing one-form on* $\mathcal{M}$. *The following statements are equivalent:*

1. ω_0 *is integrable.*
2. *There is a one-form* γ *such that*

$$d\omega_0 = \gamma \wedge \omega_0. \tag{10}$$

3. *There is a zero-form* θ *such that*

$$d\omega_0 = d\theta \wedge \omega_0. \tag{11}$$

4. ω_0 *satisfies*

$$d\omega_0 \wedge \omega_0 = 0. \tag{12}$$

Note that statement 4 provides a test for integrability of ω_0 and thus for linearizability of the system (1). Let us present one possible way of proving $4 \Rightarrow 2$.

Let X be any smooth vector field on $\mathcal{M}$ satisfying $i_X(\omega_0) = \omega_0(X) = 1$. Then (see Proposition 2.1, statement 1)

$$0 = i_X(d\omega_0 \wedge \omega_0) = i_X(d\omega_0) \wedge \omega_0 + d\omega_0 \wedge i_X(\omega_0) = i_X(d\omega_0) \wedge \omega_0 + d\omega_0.$$

Choosing $\gamma := -i_X(d\omega_0)$, we see that $4 \Rightarrow 2$. Even though it is not immediately seen, one can choose X so that $i_X(\omega_0) = 1$ and $-i_X(d\omega_0) = d\theta$ for some zero-form θ, thus proving (3). The condition (3) is most important in construction of the integrating factor for ω_0. Namely, once we know the zero-form θ, choosing $\beta := e^{-\theta}$, we obtain $d\beta\omega_0 = 0$ and $\beta > 0$ as required. Note that an integrating factor β obtained in that way is not unique. Namely, if $\beta\omega_0 = d\alpha$ for some zero-form α, one can replace β with $h(\alpha)\beta$, where $h(\alpha)$ is smooth and positive. It is now easily checked that $dh(\alpha)\beta\omega_0 = 0$ so that $h(\alpha)\beta$ is an integrating factor for ω_0 whenever β is.

Given a nonintegrable characteristic one-form ω_0, we try to find a *best possible* integrating factor for it. Let us recall that the goal is to make $d\beta\omega_0$ "as small as possible." Below we define some precise meaning for making $d\beta\omega_0$ "small" by an appropriate choice of β. We

want to avoid the trivial solution $\beta = 0$. To the contrary, we want to formulate the problem of construction of best approximate integrating factor so that the solution yields $\beta > 0$ for all $x \in \mathcal{M}$. In coordinates, minimization of $d\beta\omega_0$ can be understood as making the differences of the mixed partial derivatives $\frac{\partial \beta\omega_{0i}}{\partial x_j} - \frac{\partial \beta\omega_{0j}}{\partial x_i}$ as small as possible.

We will first establish a pointwise measure of exactness for $\beta\omega_0$ and then construct a global one from the pointwise one. Let

$$\kappa(\omega_0)(x) := \frac{|(d\omega_0)(x)|}{|(\omega_0)(x)|}, \tag{13}$$

where $|\cdot|$ is the pointwise norm of a form given by the Riemannian metric. Note that such a measure of exactness of ω_0 is invariant under scaling of the one-form ω_0 by a constant, nonzero function. Now we define global measures of exactness of ω_0. A uniform measure can be obtained by taking the supremum of $\kappa(\omega_0)(x)$ over $\mathcal{M}$,

$$\chi_\infty(\omega_0) := \sup\{\kappa(\omega_0)(x), x \in \mathcal{M}\}. \tag{14}$$

Note that the supremum exists since $\mathcal{M}$ is compact (by assumption).

An average measure of integrability is obtained by integrating $\kappa(\omega_0)(x)$ over $\mathcal{M}$. Let $p > 0$. Then

$$\chi_p(\omega_0) := \left(\int_{\mathcal{M}} (\kappa(\omega_0)(x))^p \mu\right)^{1/p}, \tag{15}$$

where μ is the volume element associated with the Riemannian metric. Now, for $1 \leq p \leq \infty$, we can define the best approximate L^p integrating factor β for ω_0 as the zero-form that minimizes $\chi_p(\beta\omega_0)$.

The best situation that one might hope for when facing the problem of construction of the best approximate integrating factor is that there is a single function β that is, in fact, the best L^p approximate integrating factor for every $1 \leq p \leq \infty$. This will be the case if we can find a function β that minimizes $\kappa(\beta\omega_0)(x)$ at every point $x \in \mathcal{M}$. In certain special cases there is, in fact, an easy solution to this problem.

Let ω_0 be a given one-form on $\mathcal{M}$, and consider the decomposition

$$d\omega_0 = \gamma \wedge \omega_0 + \tau. \tag{16}$$

This equation should be interpreted as an "approximation" to (10) with the two-form τ playing the role of an error term. There are infinitely many ways of decomposing $d\omega_0$ as above, because for any γ, one can simply choose $\tau := d\omega_0 - \gamma \wedge \omega_0$. We know from Proposition 3.1 that we can choose $\tau = 0$ in the case of integrable ω_0. If ω_0 fails to be integrable, we will try to choose γ and τ in (16) so that the two-form τ is smallest possible in a least-squares sense, i.e., with respect to the (global) L^2 norm of forms on $\mathcal{M}$,

$$\|\xi\| := \left(\int_{\mathcal{M}} |\xi|^2 \mu\right)^{1/2} \quad \text{for } \xi \in \Omega(\mathcal{M}). \tag{17}$$

Note that this smallest possible τ measures how far ω_0 is from being closed (and thus exact).

It happens that the problem of finding γ and τ satisfying (16) with $\|\tau\|$ minimal can be solved pointwise.

As in the case of integrable ω_0, we will use an interior product of a vector field X satisfying $i_X(\omega_0) = \omega_0(X) = 1$ with $d\omega_0 \wedge \omega_0$ to obtain a decomposition of type (16). We have (see Proposition 2.1, statement 1)

$$i_X(d\omega_0 \wedge \omega_0) = i_X(d\omega_0) \wedge \omega_0 + d\omega_0 \wedge i_X(\omega_0) = i_X(d\omega_0) \wedge \omega_0 + d\omega_0$$

so that

$$d\omega_0 = (-i_X(d\omega_0)) \wedge \omega_0 + i_X(d\omega_0 \wedge \omega_0).$$

This relation has the required form (16) with $\gamma := -i_X(d\omega_0)$, $\tau := i_X(d\omega_0 \wedge \omega_0)$.

We will denote by $\tau_{\min}$ the two-form τ satisfying (16) for some γ with a minimum pointwise norm $|\tau(x)|$ at every $x \in \mathcal{M}$. (It is clear that this will also be the two-form with minimal global norm $\|\cdot\|$ among all two-forms τ satisfying (16).) Below we give an explicit formula for $\tau_{\min}$.

PROPOSITION 3.2. *Put* $X_0 := |\omega_0|^{-2}\omega_0^{\#}$. *Then* $i_{X_0}(\omega_0) = 1$ *and*

$$\tau_{\min} = i_{X_0}(d\omega_0 \wedge \omega_0). \tag{18}$$

Among all γ *satisfying* (16) *for* $\tau = \tau_{\min}$, *the one with a minimal norm is*

$$\gamma_{\min} := -i_{X_0}(d\omega_0). \tag{19}$$

$\gamma_{\min}$ *is pointwise orthogonal to* ω_0. *All other one-forms* γ *satisfying* (16) *can be represented as* $\gamma_\eta = \gamma_{\min} + \eta\omega_0$ *for some zero-form* η.

Proof. First, note that $\tau = \tau_{\min}$ if and only if $\langle \xi \wedge \omega_0, \tau\rangle = 0$ pointwise on $\mathcal{M}$ for any one-form ξ. (This follows from the fact that by a standard least-squares argument $\tau_{\min}$ must be orthogonal to the space $R(W_{\omega_0}) = \{\xi \wedge \omega_0 | \xi \in \Omega^1(\mathcal{M})\}$.) Note also that $i_{X_0}(\omega_0) = |\omega_0|^{-2}\omega_0(\omega_0^{\#}) = |\omega_0|^{-2}\langle\omega_0, \omega_0\rangle = 1$. Thus, it is immediately seen that (16) is satisfied for τ and γ given by (18) and (19). To see that τ defined by (18) is actually $\tau_{\min}$ we will show that $\langle \xi \wedge \omega_0, \tau\rangle = 0$ pointwise on $\mathcal{M}$ for any one-form ξ. Using Propositions 2.2 and 2.1, statement 2, we have

$$\langle \xi \wedge \omega_0, \tau\rangle = -\langle \omega_0 \wedge \xi, i_{X_0}(d\omega_0 \wedge \omega_0)\rangle = -|\omega_0|^{-2}\langle \xi, i_{\omega_0^{\#}} i_{\omega_0^{\#}}(d\omega_0 \wedge \omega_0)\rangle = 0.$$

We have shown that $\tau = \tau_{\min}$.

To prove that $\gamma_{\min}$ is pointwise orthogonal to ω_0, note that $\langle \omega_0, \gamma_{\min}\rangle = i_{\omega_0^{\#}}\gamma_{\min} = -|\omega_0|^{-2} i_{\omega_0^{\#}} i_{\omega_0^{\#}}(d\omega_0) = 0$. □

Note that $\tau_{\min} = 0$ is zero on $\mathcal{M}$ if and only if ω_0 is integrable on $\mathcal{M}$, and $\tau_{\min} = 0$ and $\gamma_{\min} = 0$ on $\mathcal{M}$ if and only if ω_0 is exact on $\mathcal{M}$. Let $\beta \in \Omega^0(\mathcal{M})$. We have

$$d\beta\omega_0 = (d\beta + \beta\gamma_{\min}) \wedge \omega_0 + \beta\tau_{\min}. \tag{20}$$

Now we can obtain the following pointwise lower bound for $\kappa(\beta\omega_0)$.

PROPOSITION 3.3. *For any* $x \in \mathcal{M}$ *and* $\beta \in \Omega^0(\mathcal{M})$ *we have*

$$\kappa(\beta\omega_0)(x) \geq \frac{|\tau_{\min}(x)|}{|\omega_0(x)|}. \tag{21}$$

Proof. Since the two-forms $(d\ln\beta + \gamma_{\min}) \wedge \omega_0$ and $\tau_{\min}$ are pointwise orthogonal for every β (see the proof of Proposition 3.2), we have

$$\begin{aligned}
\kappa(\beta\omega_0)(x) &= \frac{|d\beta \wedge \omega_0 + \beta d\omega_0|}{|\beta\omega_0|} = \frac{|d\beta \wedge \omega_0 + \beta(\gamma_{\min} \wedge \omega_0) + \beta\tau_{\min}|}{|\beta\omega_0|} \\
&= \frac{|(d\beta + \beta\gamma_{\min}) \wedge \omega_0 + \beta\tau_{\min}|}{|\beta\omega_0|} = \frac{|(d\ln\beta + \gamma_{\min}) \wedge \omega_0 + \tau_{\min}|}{|\omega_0|} \\
&= \left(\left(\frac{|(d\ln(\beta) + \gamma_{\min}) \wedge \omega_0|}{|\omega_0|}\right)^2 + \left(\frac{|\tau_{\min}|}{|\omega_0|}\right)^2\right)^{1/2} \geq \frac{|\tau_{\min}|}{|\omega_0|}.
\end{aligned}$$

□

The best that we can hope for is that the lower bound for $\kappa(\beta\omega_0)(x)$ obtained above is sharp; i.e., there is a zero-form β such that $\kappa(\beta\omega_0)(x) = \frac{|\tau_{\min}(x)|}{|\omega_0(x)|}$ for every $x \in \mathcal{M}$. This will be the case if $(d\ln(\beta) + \gamma_{\min}) \wedge \omega_0 = 0$ for some choice of β. A necessary and sufficient condition for this is $\gamma_\eta := \gamma_{\min} + \eta\omega_0 = d\theta$ for some zero-forms η and θ. Then we choose $\beta := e^{-\theta}$ and obtain $(d\ln\beta + \gamma_\eta) \wedge \omega_0 = 0$. Note that the zero-form β is everywhere strictly positive, as required.

Example 3.1. Consider

$$\begin{aligned} \dot{x}_1 &= x_2 + h_1(x_3) + h_2(x_1, x_2), \\ \dot{x}_2 &= x_3 + h_3(x_3) + h_4(x_1, x_2), \\ \dot{x}_3 &= u, \end{aligned} \tag{22}$$

where $h_i(\cdot)$ are any smooth functions with $h_i(0) = \frac{\partial h_i}{\partial x_j}(0) = 0$. We have $g = \frac{\partial}{\partial x_3}$, $f = (x_2 + h_1(x_3) + h_2(x_1, x_2))\frac{\partial}{\partial x_1} + (x_3 + h_3(x_3) + h_4(x_1, x_2))\frac{\partial}{\partial x_2}$, $ad_f g := [f, g] = (-h_1'(x_3))\frac{\partial}{\partial x_1} - (1 + h_3'(x_3))\frac{\partial}{\partial x_2}$, $\omega_0 = (1 + h_3'(x_3))dx_1 - h_1'(x_3)dx_2$, $d\omega_0 = h_1''(x_3)dx_2 \wedge dx_3 - h_3''(x_3)dx_1 \wedge dx_3$, and $d\omega_0 \wedge \omega_0 = (h_1''(x_3)dx_2 \wedge dx_3 - h_3''(x_3)dx_1 \wedge dx_3) \wedge ((1 + h_3'(x_3))dx_1 - h_1'(x_3)dx_2) = ((1 + h_3'(x_3))h_1''(x_3) - h_1'(x_3)h_3''(x_3))dx_1 \wedge dx_2 \wedge dx_3$. We see that the system is exactly feedback linearizable in a neighborhood of the origin if and only if $(1 + h_3'(x_3))h_1''(x_3) - h_1'(x_3)h_3''(x_3) = 0$, which is the case if $h_1(\cdot) = 0$.

It happens that for this system we can actually construct the best approximate L^p integrating factor β in above-mentioned sense, i.e., the one that works for every $1 \le p \le \infty$. Suppose that we use the standard metric in coordinates x_1, x_2, x_3. We have

$$\gamma_{\min} = \frac{h_1'(x_3)h_1''(x_3) + (1 + h_3'(x_3))h_3''(x_3)}{h_1'(x_3)^2 + (1 + h_3'(x_3))^2} dx_3,$$

$$\tau_{\min} = \frac{(h_1''(x_3) + h_3'(x_3)h_1''(x_3) - h_1'(x_3)h_3''(x_3))}{h_1'(x_3)^2 + (1 + h_3'(x_3))^2}((1 + h_3'(x_3))dx_2 \wedge dx_3 + h_1'(x_3)dx_1 \wedge dx_3).$$

Note that $\gamma_{\min}$ depends only on x_3, and thus it is exact. One can check that $\gamma_{\min} = d\theta$ for $\theta = \ln(h_1'(x_3)^2 + (1 + h_3'(x_3))^2)^{1/2}$. The best approximate integrating factor in above-mentioned sense is $\beta_0 = e^{-\theta} = (h_1'(x_3)^2 + (1 + h_3'(x_3))^2)^{-1/2} = |\omega_0|^{-1}$. (Note that this choice makes the pointwise length of $\beta_0\omega_0$ equal to 1 everywhere.) □

In [2] we show that the lower bound for $\kappa(\beta\omega_0)(x)$ is always sharp if the metric is the standard metric in some special coordinates. There are, however, examples of systems for which the lower bound for $\kappa(\beta\omega_0)(x)$ is not sharp. In this case a more sophisticated analysis is required (cf. [6, 4]), which leads to some variational problems whose solutions for β are given as solutions of elliptic eigenvalue problems. A simple alternative would be an approximation of γ_η by an exact form $dH\gamma_\eta$ using a homotopy operator H (see the next section).

Note that even though the minimal $\chi_p(\beta\omega_0)$ seems to be a natural measure of integrability of ω_0 and thus also a measure of noninvolutivity of the characteristic distribution D, it may not be a sufficient measure for the problem of approximate linearization. There are some indications that one should actually minimize $d(\beta\omega_0)$ *together* with its first $n-1$ Lie derivatives along f. This problem is addressed in [6, 5].

4. Homotopy operator. On any contractible region $\mathcal{M}$ one can define a linear operator $H : \Omega^k(\mathcal{M}) \mapsto \Omega^{k-1}(\mathcal{M})$ that partially inverts the exterior derivative, i.e.,

$$\omega = (dH + Hd)\omega \quad \forall\omega \in \Omega^k(\mathcal{M}) \tag{23}$$

or, in other words,

$$\omega = d(H\omega) + Hd\omega. \tag{24}$$

Any operator with such property will be called a *homotopy* operator. Following [9], we present a construction of such an operator. Consider the *cylinder* $I \times \mathcal{M}$ where $I := [0, 1]$, and define a family of maps $j_\lambda : \mathcal{M} \mapsto I \times \mathcal{M}$ by $j_\lambda(x) = (\lambda, x)$ for $\lambda \in I$. Note that k-forms on the cylinder can be represented in coordinates $\lambda, x_1, \ldots, x_n$ as sums of monomials of two types: $a(\lambda, x)dx_{i_1} \wedge dx_{i_2} \wedge \cdots \wedge dx_{i_k}$ and $a(\lambda, x)d\lambda \wedge dx_{i_1} \wedge \cdots \wedge dx_{i_{k-1}}$. We now define a linear operator $K : \Omega^k(I \times \mathcal{M}) \mapsto \Omega^{k-1}(\mathcal{M})$ such that its action on these two types of monomials is given by

$$K(a(\lambda, x)dx_{i_1} \wedge dx_{i_2} \wedge \cdots \wedge dx_{i_k}) = 0, \tag{25}$$

$$K(a(\lambda, x)d\lambda \wedge dx_{i_1} \wedge \cdots \wedge dx_{i_{k-1}}) = \left(\int_0^1 a(\lambda, x)d\lambda\right) dx_{i_1} \wedge \cdots \wedge dx_{i_{k-1}}. \tag{26}$$

The operator K satisfies ([9, §3.6])

$$K(d\omega) + d(K\omega) = j_1^*\omega - j_0^*\omega, \tag{27}$$

where $j_\lambda^* : \Omega^k(I \times \mathcal{M}) \mapsto \Omega^k(\mathcal{M})$ is the pullback induced by j_λ. Note that the above result doesn't require $\mathcal{M}$ to be contractible. Now, by definition, $\mathcal{M}$ is contractible iff there is a smooth mapping $\phi : I \times \mathcal{M} \mapsto \mathcal{M}$ such that $\phi(1, x) = x, \phi(0, x) = x^0$, where x^0 is a distingushed point in $\mathcal{M}$. Such a mapping ϕ is called a *homotopy* or *contraction* (of $\mathcal{M}$ to x^0). The point x^0 is called the homotopy center. Since we have $(\phi \circ j_1)(x) = x$ and $(\phi \circ j_0)(x) = x^0$ $\forall x \in \mathcal{M}$, the pullback $\phi^* : \Omega^k(\mathcal{M}) \mapsto \Omega^k(I \times \mathcal{M})$ induced by the mapping ϕ satisfies

$$j_1^*(\phi^*\omega) = \omega, \ j_0^*(\phi^*\omega) = 0. \tag{28}$$

Therefore, (27), (28), and the fact that the exterior derivative commutes with a pullback together imply

$$K\phi^*(d\omega) + d(K\phi^*\omega) = \omega. \tag{29}$$

Thus, the operator $H := K \circ \phi^*$ satisfies (24) so that it is a homotopy operator.

Note that different choices of homotopy centers x^0 and homotopies ϕ yield different homotopy operators. The one we will use is probably the simplest one: it will act on one-forms by integrating them along straight lines (in coordinates x_i) from a distingushed point x^0 in $\mathcal{M}$ (usually the origin). Such a homotopy operator will be called *radial* (see, e.g., [8, §5.3] and [9, §3.7]). If $\mathcal{M}$ is star shaped in coordinates x_i with respect to x^0 (i.e., $\mathcal{M}$ can be contracted to x^0 by straight lines lying entirely in $\mathcal{M}$), a simple choice for a homotopy ϕ is $\phi(\lambda, x) = x^0 + \lambda(x - x^0)$. Let $\omega = \sum_{i_1 \ldots i_k} \omega^{i_1 \ldots i_k}(x)dx_{i_1} \wedge dx_{i_2} \wedge \cdots \wedge dx_{i_k}$. Now, one can explicitly calculate the pullback ϕ^*,

$$\begin{aligned}
\phi^*\omega &= \sum_{i_1,\ldots,i_k} \omega^{i_1,\ldots,i_k}(x^0 + \lambda(x - x^0))d(x_{i_1}^0 + \lambda(x_{i_1} - x_{i_1}^0)) \\
&\quad \wedge d(x_{i_2}^0 + \lambda(x_{i_2} - x_{i_2}^0)) \wedge \cdots \wedge d(x_{i_k}^0 + \lambda(x_{i_k} - x_{i_k}^0)) \\
&= \sum_{i_1,\ldots,i_k} \omega^{i_1,\ldots,i_k}(x^0 + \lambda(x - x^0))((x_{i_1} - x_{i_1}^0)d\lambda + \lambda dx_{i_1}) \\
&\quad \wedge ((x_{i_2} - x_{i_2}^0)d\lambda + \lambda dx_{i_2}) \wedge \cdots \wedge ((x_{i_k} - x_{i_k}^0)d\lambda + \lambda dx_{i_k}),
\end{aligned} \tag{30}$$

and we can express the action of the radial homotopy operator as

$$(H\omega)(x) = \sum_{i_1,\dots,i_k} \left(\sum_{i_j} ((-1)^{j+1}(x_{i_j} - x^0_{i_j}) \right.$$
$$\left. \int_0^1 \lambda^{k-1} \omega^{i_1,\dots,i_k}(x^0 + \lambda(x - x^0))d\lambda) \right) dx_{i_1} \wedge \cdots \wedge \widehat{dx_{i_j}} \cdots \wedge dx_{i_k},$$

(31)

where the symbol $\widehat{\ }$ over dx_{i_j} indicates that it is omitted.

Once again consider the system of Example 3.1. Choose $\omega_0 = (1 + h_3'(x_3))dx_1 - h_1'(x_3)dx_2$ and $\beta = 1$. Then, for $x_0 = 0$, we see that

$$\alpha = \int_0^1 (x_1(1 + h_3'(\lambda x_3)) - x_2 h_1'(\lambda x_3))d\lambda = x_1 - \frac{x_2 h_1(x_3)}{x_3} + \frac{x_1 h_3(x_3)}{x_3},$$

and the error one-form ϵ is given by

$$\epsilon = -(h_3(x_3) - x_3 h_3'(x_3))/x_3^2 dx_1 + (h_1(x_3) - x_3 h_1'(x_3))/x_3^2 dx_2$$
$$+ (x_2 h_1(x_3) - x_1 h_3(x_3) - x_2 x_3 h_1'(x_3) + x_1 x_3 h_3'(x_3))/x_3^2 dx_3.$$

(Alternatively, once α is known, one can use the formula $\epsilon = \beta\omega_0 - d\alpha$ instead of $\epsilon = Hd\beta\omega_0$ to obtain the error one-form ϵ.)

Let $|\cdot|$ denote the pointwise norm of a form induced by the standard metric in x_i coordinates. We have shown in the previous section that the best approximate integrating factor for the above system in the sense of minimizing $\frac{|(d\beta\omega_0)(x)|}{|(\beta\omega_0)(x)|}$ pointwise everywhere is $\beta_0 = |\omega_0|^{-1} = (h_1'(x_3)^2 + (1 + h_3'(x_3))^2)^{-1/2}$. Contrary to the case $\beta = 1$ it is now impossible to evaluate $H\beta_0\omega_0$ and $Hd\beta_0\omega_0$ explicitly. The integration must be performed case by case for specific functions $h_1(\cdot)$ and $h_3(\cdot)$. We don't expect to be always able to perform the integration symbolically, because the result might not be an elementary function.

The homotopy operator that we will use in subsequent discussion uses the origin in coordinates x_i as the homotopy center. One can obtain other homotopy operators choosing different homotopy centers x_0. Moreover, one doesn't have to integrate over straight lines from the center. Note that the notion of a straight line is associated with specific choice of coordinates. Hence, if we change coordinates, we immediately obtain a homotopy operator, namely, the radial homotopy operator in the new coordinates. Moreover, an arithmetic mean of homotopy operators is again a homotopy operator. For exactly linearizable systems, once we have found an exact integrating factor for a characteristic one-form ω, any homotopy operator will give the same exact part and zero antiexact part. However, for nonlinearizable systems the choice of a homotopy operator will make a difference. Apparently, the choice of a particular homotopy operator will influence the exact and antiexact parts of a characteristic one-form ω. It is not clear to us yet what should be the best choice for approximate feedback linearization. This issue is currently under investigation. One may expect that the optimal homotopy operator might be rather complicated. Hence, even though there is no reason to believe that the radial homotopy operator in the original coordinates will be the best one (i.e., yielding the smallest antiexact part of ω), there is a good chance that it will be the simplest one to apply. Moreover, any homotopy operator with the center at the origin that satisfies $\phi(\lambda, 0) \equiv 0$ (in particular the radial one) will always yield $\epsilon(0) = 0$. Since ϵ is a smooth one-form vanishing at the origin, it will be small in a neighborhood of the origin.

The following result shows some that there are some limitations to what can be achieved in approximating nonexact characteristic forms by exact ones.

THEOREM 4.1. *Let H be any homotopy operator on $\mathcal{M}$ and ω be any characteristic one-form for the system* (1). *Let $\alpha_H := H\omega$ and $\epsilon_H := Hd\omega$. Then for any closed curve c in $\mathcal{M}$ we have*

$$\int_c L_f^i \epsilon_H = \int_c L_f^i \omega$$

for $i = 0, 1, \ldots$.

Proof. Note that $L_f^i\omega = L_f^i(d\alpha_H + \epsilon_H) = dL_f^i\alpha_H + L_f^i\epsilon_H$. Now, the proof follows from the fact that the integral of an exact form over any closed curve is zero. □

The above result is a law of preservation of hassle. No matter how one chooses a homotopy operator H, the average value of ("a component along c" of) $\epsilon_H := Hd\omega$ on any closed curve c is constant. Different homotopy operators may only distribute ϵ along c in a different way. A similar result holds true for any Lie derivative (of any order) of ϵ along any vector field.

This result can be used to obtain lower bounds for the uniform norm of the error one-form ϵ_H and its Lie derivatives along f on $\mathcal{M}$, independent of the choice of homotopy.

Let us conclude the section by an example of a homotopy operator that is optimal in some precise sense. Let ω be a one-form. The so-called Hodge decomposition of ω is a decomposition of the form $\omega = d\alpha + \epsilon$, where $d\alpha$ is the best L^2 approximation of ω among exact one-forms (cf. [1, §7.5; 3, 4, 5, 6]). Let δ denote the formal adjoint operator to the exterior derivative d and $\Delta := \delta d + d\delta$ denote the Laplace–De Rham operator ([1, §7.5]). One can show that $\Delta\alpha = \delta\omega$ and $\Delta\epsilon = \delta d\omega$. These equations (together with some boundary conditions) allow us to find α and ϵ appearing in the Hodge decomposition of ω. Thus, formally $\alpha = \Delta^{-1}\delta\omega$ and $\epsilon = \Delta^{-1}\delta d\omega$. Therefore, the operator $H_\Delta = \Delta^{-1}\delta$ (formally) satisfies $\omega = d(H_\Delta\omega) + H_\Delta d\omega$ so that it is a homotopy operator. Note that one has to solve a boundary value problem to obtain the zero-form α such that $d\alpha$ best approximates ω in L^2. This should be contrasted with the radial homotopy operator, which requires only simple integration with respect to a parameter. For instance, if the system (1) has polynomial nonlinearities in the original coordinates, the characteristic one-form ω_0 given by (9) will also have polynomial coefficients and thus the integration in (31) can be easily performed, yielding polynomial expressions for α and ϵ. The situation is usually much more difficult after applying an optimal approximate integrating factor β_0. The optimal characteristic one-form $\beta_0\omega$ will rarely be polynomial, and the result of integration in (31) might not be expressed in terms of elementary functions. This is one reason why we might not always be able to apply the optimal approximate integrating factor in practice, even if we find one.

5. Change of coordinates. In this section we prove that a change of coordinates based on the exact part of any characteristic one-form ω obtained with a homotopy operator H having its center at the origin defines a local diffeomorphism that takes the system (1) to a normal form that looks like a linearizable part perturbed by some nonlinear terms that depend linearly on the error one-form $\epsilon := Hd\omega$. This approach can be applied to both linearizable and nonlinearizable systems.

For exactly linearizable systems (1), we proceed as follows. First, we construct a characteristic one-form ω_0. Then we choose an exact integrating factor β and obtain a new characteristic form $\omega := \beta\omega_0$ such that $d\omega = 0$. We apply a homotopy operator H to get the zero form $\alpha := H\omega$. Then we use change of variables

$$\begin{aligned} z_1 &= \alpha, \\ z_2 &= L_f\alpha, \\ &\vdots \\ z_n &= L_f^{n-1}\alpha. \end{aligned} \tag{32}$$

The system (8) in new coordinates is

$$\begin{aligned} \dot{z}_1 &= z_2, \\ \dot{z}_2 &= z_3, \\ &\vdots \\ \dot{z}_{n-1} &= z_n, \\ \dot{z}_n &= p + ru, \end{aligned} \tag{33}$$

where

$$r = L_g L_f^{n-1}\alpha, \qquad p = L_f^n \alpha,$$

and the feedback $u = r^{-1}(u_{\text{new}} - p)$ makes it linear.

For a nonlinearizable system we proceed as follows. First, we construct a characteristic one-form ω_0. Then we choose an integrating factor β, either optimal or not, and obtain a new characteristic one-form $\omega := \beta\omega_0$. We apply a homotopy operator H to get the zero form $\alpha := H\omega$ and the corresponding error one-form $\epsilon := Hd\omega$. Then we use change of variables (32) (as for exactly linearizable systems) to get a normal form

$$\begin{aligned} \dot{z}_1 &= z_2 + e_1 u, \\ \dot{z}_2 &= z_3 + e_2 u, \\ &\vdots \\ \dot{z}_{n-1} &= z_n + e_{n-1} u, \\ \dot{z}_n &= p + ru + e_n u, \end{aligned} \tag{34}$$

where

$$\begin{aligned} e_1 &= L_g \alpha, \\ e_2 &= L_g L_f \alpha, \\ &\vdots \\ e_n &= L_g L_f^{n-1}\alpha - (-1)^{n-1}\omega(ad_f^{n-1} g), \\ r &= (-1)^{n-1}\omega(ad_f^{n-1} g), \\ p &= L_f^n \alpha. \end{aligned} \tag{35}$$

In the subsequent discussion we will need the following result.

LEMMA 5.1. *Let ω be any characteristic one-form for the system* (1). *Let i and j be nonnegative integers. Then*

1. $(L_f^i \omega)(ad_f^j g) = 0$ *for* $i + j < n - 1$.
2. $(L_f^i \omega)(ad_f^{n-1-i} g) = (-1)^i \omega(ad_f^{n-1} g)$ *for* $i = 0, 1, \ldots, n-1$.

Proof. 1. One can prove by induction the formula

$$(L_X^i \eta)(Y) = \sum_{l=0}^{l=i} (-1)^l \binom{i}{l} L_X^{i-l}(\eta(ad_X^l Y)). \tag{36}$$

In particular,

$$\begin{aligned} (L_f^i \omega)(ad_f^j g) &= \sum_{l=0}^{l=i} (-1)^l \binom{i}{l} L_X^{i-l}(\omega(ad_f^l(ad_f^j g))) \\ &= \sum_{l=0}^{l=i} (-1)^l \binom{i}{l} L_X^{i-l}(\omega(ad_f^{l+j} g)). \end{aligned} \tag{37}$$

Note that $\omega(ad_f^{l+j} g) = 0$ for $l = 0, \ldots, i$ if $i + j \leq n - 1$.

2. Apply the formula (37) for $j = n - 1 - i$, and note that all the terms $\omega(ad_f^{l+n-1-j}g)$ vanish except when $l = i$. □

To establish continuity relationships between noninvolutivity and nonlinearizability we express the nonlinear perturbation terms e_i in terms of the error one-form ϵ.

PROPOSITION 5.2. *Let ω be a characteristic form for* (1), *H be a homotopy operator on $\mathcal{M}$, $\alpha := H\omega$, and $\epsilon := Hd\omega$. Let $e_i, i = 1, \ldots, n$, and p be given by* (35). *Then*

$$
\begin{aligned}
e_1 &= -\epsilon(g), \\
e_2 &= -(L_f\epsilon)(g), \\
&\vdots \\
e_{n-1} &= -(L_f^{n-2}\epsilon)(g), \\
e_n &= -(L_f^{n-1}\epsilon)(g).
\end{aligned} \tag{38}
$$

Proof. It is a straightforward calculation using Lemma 5.1. □

Note that the above choice for e_n and r is not the only one possible. Actually, any choice that guarantees $r + e_n = L_g L_f^{n-1}\alpha$ with $e_n(0) = 0$ could be considered, for instance, $e_n = 0$ and $r = L_g L_f^{n-1}\alpha$. Our choice is dictated by the fact that it guarantees $r \neq 0$ on the whole $\mathcal{M}$ and $e_n = -(L_f^{n-1}\epsilon)(g)$.

One can also express the function $p := L_f^n\alpha$ using the error one-form ϵ as $p = (L_f^{n-1}\omega)(f) - (L_f^{n-1}\epsilon)(f)$.

A natural question to ask is whether the zero-form α together with its $n-1$ Lie derivatives along f is a well-defined change of coordinates. The main result of this section says that in a neighborhood of the origin, (32) indeed defines a local diffeomorphism. Before we prove it, we need some preliminary results.

LEMMA 5.3. *Let η be any smooth one-form and X and Y be any smooth vector fields on $\mathcal{M}$. Then*

1. $(L_X\eta)(Y) = L_X(\eta(Y)) - \eta([X, Y])$.
2. *If $\eta(0) = 0$ and $X(0) = 0$, then $(L_X^i\eta)(Y)(0) = 0$ for $i = 0, 1, 2, \ldots$.*

Proof. 1. See [12, §7.3].

2. For $i = 0$ the formula is true as $(L_X^0\eta)(Y)(0) = \eta(Y)(0) = 0$. Assume that the formula is true for $i = 0, \ldots, m$. Using statement 1 one easily shows that $(L_X^{m+1}\eta)(Y)(0) = d((L_X^m\eta)(Y))(X)(0) - (L_X^m\eta)([X, Y])(0)$. The first part of this expression is zero because $X(0) = 0$, and the second by assumption. By induction, the formula holds for all nonnegative i. □

PROPOSITION 5.4. *Assume that* $\dim \operatorname{span}\{g, ad_f g, \ldots, ad_f^{n-1}g\} = n \ \forall x$ *in a neighborhood of* 0 *in $\mathcal{M}$ (linear controllability). Let ω be any characteristic one-form for the system* (1). *Then the one-forms $\omega, L_f\omega, \ldots, L_f^{n-1}\omega$ are linearly independent in a neighborhood of the origin.*

Proof. It is sufficient to show that $(L_f^{n-1}\omega \wedge L_f^{n-2}\omega \wedge \cdots \wedge \omega)(0) \neq 0$. Since this form is smooth, it is enough to check that $(L_f^{n-1}\omega \wedge L_f^{n-2}\omega \wedge \cdots \wedge \omega)(g, ad_f g, \ldots, ad_f^{n-1}g)(0) \neq 0$. For this, note that $(L_f^{n-1}\omega \wedge L_f^{n-2}\omega \wedge \cdots \wedge \omega)(g, ad_f g, \ldots, ad_f^{n-1}) = \det S$, where S is an $n \times n$ matrix whose (i, j) entry is $(L_f^{i-1}\omega)(ad_f^{j-1}g)$. Now, by Lemma 5.1, S is an upper triangular matrix whose ith diagonal element is $(-1)^{n-i}\omega(ad_f^{n-1}g)$. Therefore, $\det S = (-1)^n(\omega(ad_f^{n-1}g))^n \neq 0$. □

Now we are ready to prove the main result of this section.

THEOREM 5.5. *Assume that* $\dim \operatorname{span}\{g, ad_f g, \ldots, ad_f^{n-1}g\} = n \ \forall x$ *in a neighborhood of 0 in $\mathcal{M}$ (linear controllability). Let H be any homotopy operator on $\mathcal{M}$ with the center at the origin such that $\phi(\lambda, 0) \equiv 0$ and ω be any characteristic one-form for the system* (1). *Set $\alpha := H\omega$. Then* (32) *defines a local diffeomorphism in a neighborhood of the origin.*

Proof. We will show that the differentials of the zero-forms $\alpha, L_f\alpha, \ldots, L_f^{n-1}\alpha$ are linearly independent at the origin (and thus, in a neighborhood of the origin). Let $\epsilon := Hd\omega$. Since $\omega = d\alpha + \epsilon$ and the Lie and exterior derivatives commute, we have $dL_f^i\alpha = L_f^i d\alpha = L_f^i(\omega - \epsilon) = L_f^i\omega - L_f^i\epsilon$. Hence, $dL_f^i\alpha(0) = L_f^i\omega(0) - L_f^i\epsilon(0)$. Note that $\epsilon(0) := (Hd\omega)(0) = 0$, since H is a homotopy operator with the center at 0 such that $\phi(\lambda, 0) \equiv 0$. Now, it follows from Lemma 5.3, statement 2, that $\epsilon, L_f\epsilon, \ldots, L_f^{n-1}\epsilon$ all vanish at the origin and hence $dL_f^i\alpha(0) = L_f^i\omega(0)$. Now the result follows from Proposition 5.4. □

We usually cannot guarantee a priori that the change of coordinates (32) will be valid in the whole $\mathcal{M}$. Some conditions for a map to be a global diffeomorphism are quoted in [14] and [20]. Below, we show an example of a system that admits a global transformation in R^3 to the normal form (6).

Example 5.1. Consider the system

$$\begin{aligned} \dot{x}_1 &= x_2 + h_1(x_3), \\ \dot{x}_2 &= x_3, \\ \dot{x}_3 &= u, \end{aligned} \tag{39}$$

where $h_1(\cdot)$ is any smooth function with $h_1'(0) = 0$. We have

$$\begin{aligned} \omega_0 &= dx_1 - h_1'(x_3)dx_2, \\ \alpha &= H\beta\omega_0 = x_1 - \frac{x_2 h_1(x_3)}{x_3}, \\ \epsilon &= \left(\frac{h_1(x_3) - x_3 h_1'(x_3)}{x_3^2}\right)(x_3 dx_2 - x_2 dx_3), \\ L_f\epsilon &= L_f^2\epsilon = 0. \end{aligned}$$

The system can be transformed by a global diffeomorphism

$$\begin{aligned} z_1 &= \alpha &&= x_1 - \frac{x_2 h_1(x_3)}{x_3}, \\ z_2 &= L_f\alpha &&= x_2, \\ z_3 &= L_f^2\alpha &&= x_3 \end{aligned} \tag{40}$$

to the form

$$\begin{aligned} \dot{z}_1 &= z_2 + \frac{z_2(h_1(z_3) - z_3 h_1'(z_3))}{z_3^2}u, \\ \dot{z}_2 &= z_3, \\ \dot{z}_3 &= u. \end{aligned} \tag{41}$$

The inverse transformation given by

$$\begin{aligned} x_1 &= z_1 + \frac{z_2 h_1(z_3)}{z_3}, \\ x_2 &= z_2, \\ x_3 &= z_3. \end{aligned} \tag{42}$$

□

In the case when the change of coordinates is not valid on the whole region $\mathcal{M}$, we have to restrict to a region on which the change of coordinates is valid. In the following discussion we assume that this has been done, and the restricted region is also called $\mathcal{M}$.

6. Estimates of the nonlinear part. In this section we estimate the nonlinear perturbation terms $e_1, \ldots, e_n$ using the error one-form ϵ. First, let us rewrite the equations (34) (in the usual matrix-vector notation) as

$$\dot{z} = Az + Bru + Bp + Eu, \tag{43}$$

where A and B are in the Brunovsky form, that is,

$$A = \begin{bmatrix} 0 & 1 & 0 & \cdots & 0 \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ \vdots & & \ddots & 1 & 0 \\ \vdots & & & 0 & 1 \\ 0 & \cdots & \cdots & \cdots & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ \vdots \\ \vdots \\ 0 \\ 1 \end{bmatrix},$$

and $E = (e_1, e_2, \ldots, e_n)^T$. ($e_i's$, r, and p are defined by (35).) We see that $r \neq 0$ on $\mathcal{M}$ (under the assumption that linear controllability holds on $\mathcal{M}$) and E depends *linearly* on ϵ and vanishes whenever ϵ does. We will choose $u = r^{-1}(u_{\text{new}} - p)$, where u_{new} is a new control variable. After this change of coordinates and control variable the system is of the form (6) with $Q := r^{-1}E$, $P := -r^{-1}pE$. In this section we obtain estimates on the uniform norm of Q and P (via estimates on r, p, and E) in terms of the error one form ϵ_β for any fixed β on any compact, contractible region $\mathcal{M}$.

Let h be a smooth vector field on $\mathcal{M}$ and l be a nonnegative integer. Let ζ be a k-form on $\mathcal{M}$. We define the C^0 norm $\|\zeta\|^0$ of ζ as $\|\zeta\|^0 := \sup|\zeta(x)|$ for $x \in \mathcal{M}$ (uniform norm on $\mathcal{M}$) and the C^l_h norm $\|\zeta\|^l_h$ as $\|\zeta\|^l_h := \sup(|\zeta(x)|^2 + |L_h\zeta(x)|^2 + \cdots + |L^l_h\zeta(x)|^2)^{1/2}$ for $x \in \mathcal{M}$ (uniform norm on $\mathcal{M}$, together with the first l Lie derivatives along h). It is immediately seen from Proposition 5.2 that whenever the one-forms $\epsilon, L_f\epsilon, \ldots, L^{n-1}_f\epsilon$ are small on $\mathcal{M}$, so is the term E on $\mathcal{M}$.

THEOREM 6.1. *Let ω be any characteristic one-form for the system* (1) *and ϵ be the error one-form corresponding to a given homotopy operator. Then the mapping $\epsilon \mapsto E$ is a continuous mapping from the space of smooth one forms equipped with the C^{n-1}_f norm on $\mathcal{M}$ into the space of smooth vector fields on $\mathcal{M}$ equipped with the C^0 norm (uniform norm on $\mathcal{M}$). In particular,*

$$\|E\|^0 \leq \|\epsilon\|^{n-1}_f \|g\|^0.$$

Proof. The proof is immediate in view of Proposition 5.2. □

Note that in the above result we could substitute for $\epsilon, L_f\epsilon, \ldots, L^{n-1}_f\epsilon$ their evaluations at (contractions by) the vector field g. Let h and v be smooth vector fields on $\mathcal{M}$ and l be a nonnegative integer. Let us define the $C^l_{h,v}$ seminorm $\|\zeta\|^l_{h,v}$ of a one-form ζ on $\mathcal{M}$ as $\|\zeta\|^l_{h,v} := \sup(|\zeta(v)(x)|^2 + |L_h\zeta(v)(x)|^2 + \cdots + |L^l_h\zeta(v)(x)|^2)^{1/2}$ over $x \in \mathcal{M}$. Note that $C^l_{h,v}$ is not quite a norm, since it may happen that $\|\zeta\|^l_{h,v} = 0$ even though $\zeta \neq 0$ (for example, $\|\omega_0\|^0_{f,g}$ for ω_0 being a characteristic one-form for (1)). However, it happens that for the one-forms on $\mathcal{M}$, the $C^{n-1}_{f,g}$ seminorm becomes a norm if the vector fields f and g satisfy the linear controllability condition of Theorem 1.1. This follows from the following result.

PROPOSITION 6.2. *Let ζ be a one-form on $\mathcal{M}$ and the vector fields f and g satisfy the linear controllability condition of Theorem* 1.1. *Then $\zeta = 0$ if and only if $\|\zeta\|^{n-1}_{f,g} = 0$.*

Proof. ($\Rightarrow$) The proof is obvious.

($\Leftarrow$) Note that $L^i_f\zeta(g) = L_f(L^{i-1}_f\zeta(g)) - L^{i-1}_f\zeta(ad_f g)$. We have $L^i_f\zeta(g) = 0$ for $i = 0, 1, \ldots, n-1$. In particular, $\zeta(g) = 0$. Thus, using Lemma 5.3, statement 1, we get

$0 = (L_f\zeta)(g) = L_f(\zeta(g)) - \zeta(ad_f g) = -\zeta(ad_f g)$. Continuing in the same fashion, we obtain $\zeta(ad_f^i g) = 0$ for $i = 0, 1, \ldots, n-1$. By the linear controllability assumption, the vector fields $ad_f^i g$ for $i = 0, 1, \ldots, n-1$ are linearly independent. The one-form ζ annihilates n linearly independent fields on an n-dimensional manifold. Thus $\zeta = 0$. □

The above result, when applied to the error one-form ϵ, yields an obvious fact that the $\epsilon = 0$ is equivalent with (32) being the linearizing change of coordinates for (1). The fact that we wanted to emphasize here is that, because of (38), the nonlinear perturbation terms e_i can be used to define a norm for the error one-form ϵ, thus making the relationship between a measure of noninvolutivity of the characteristic distribution D and a direct measure of nonlinearity of the system (1) in new coordinates explicit. Namely, we have the following proposition.

PROPOSITION 6.3. $\|E\|^0 = \|\epsilon\|_{f,g}^{n-1}$.

We conclude this section with establishing some upper bounds on the uniform norms $\|P\|^0$ and $\|Q\|^0$ of the nonlinear terms $Q := r^{-1}E$, $P := -r^{-1}pE$ in the system (6) after change of coordinates and preliminary feedback.

PROPOSITION 6.4. *Let ω be any characteristic form for the system* (1), $\alpha := H\omega$, $\epsilon := Hd\omega$. *Let* $\rho := \inf |\omega(ad_f^{n-1}g)(x)|$ *over* $x \in \mathcal{M}$ *and* $\varrho := \sup |L_f^n\alpha(x)|$ *over* $x \in \mathcal{M}$. *Then*

1.

$$\|P\|^0 \leq \frac{\varrho\|\epsilon\|_{f,g}^{n-1}}{\rho}. \tag{44}$$

2.

$$\|Q\|^0 \leq \frac{\|\epsilon\|_{f,g}^{n-1}}{\rho}. \tag{45}$$

Proof. The proof is immediate, in view of Proposition 6.3 and (35). □

7. Application to stabilization. In this section we will use the results of the previous section to study various locally stabilizing feedback laws for the system (1). The laws that we have in mind will be linear in new coordinates (32), with the gains chosen so that the linear part of the system (6) is asymptotically stable. We will then study robustness of such control laws when applied to the system (6). We will accomplish that studying Lyapunov functions that are quadratic in new coordinates. We shall examine how the nonlinear part of (6) affects the time derivative of the Lyapunov function. The continuity result of Theorem 6.1 will allow us to formulate some robustness criteria for stabilization.

The idea behind transforming a linearizable system (1) to an equivalent form (2) is to design control schemes for (2), which is much easier to analyze and control, and apply them to (1). For example, if Φ happens to be a global diffeomorphism from R^n into R^n, one can globally asymptotically stabilize the system (1). For this, one can choose new control variable $u_{\text{new}} = Kz$ (linear feedback in new variables) so that the closed-loop system

$$\dot{z} = (A + BK)z \tag{46}$$

is globally asymptotically stable. (Controllability of (2) is equivalent to possibility of arbitrary assignment of the eigenvalues of $(A + BK)$ by an appropriate choice of the feedback gain K.) Then $u = k(x) + l(x)u_{\text{new}} = k(x) + l(x)K\Phi(x)$ makes the closed-loop system

$$\dot{x} = f(x) + g(x)(k(x) + l(x)K\Phi(x)) \tag{47}$$

globally asymptotically stable, since Φ^{-1} is a diffeomorphism preserving the equilibrium point at the origin.

For nonlinearizable systems the best we can hope for using our approach is to transform (1) to (6) with P and Q small. Then we will try to use the new form (6) to design a locally stabilizing feedback—in this case we expect to improve the basin of attraction of the origin of the closed-loop system. We will choose $u_{\text{new}} = Kz$ (a feedback law linear in new variables) so that the mapping $A + BK$ is stable (has all eigenvalues with negative real parts) and analyze its robustness as a stabilizing law for (6); bounds on uniform norms for Q and P should help us to do so. Let us stress that we will actually use new coordinates z and new control u_{new} only as intermediate tools, and the control law $u = r^{-1}(u_{\text{new}} - p) = r^{-1}(Kz - p)$ will be expressed in the old coordinates x as $u = k_1(x)$ (where $k_1(x) := r(\Phi(x))^{-1}(K\Phi(x) - p(\Phi(x)))$) and applied to (1). Since Φ^{-1} is a diffeomorphism preserving the equilibrium point at the origin, it maps the basin of attraction of the equilibrium for

$$\dot{z} = (A + BK)z + P(z) + Q(z)Kz \tag{48}$$

to the basin of attraction of the equilibrium for

$$\dot{x} = f(x) + g(x)k_1(x). \tag{49}$$

Observe that, to express the feedback laws computed in new coordinates z in the original coordinates x, we don't even need to find the form (6) explicitly. It would be actually very difficult, if not impossible, to do so in general, since we would have to know the inverse transformation $x = \Phi^{-1}(z)$ in order to obtain the form (6).

Of course, we might not always be able to find the best integrating factor β_0 for ω_0 annihilating $D := \text{span}\{g, ad_f g, \ldots, ad_f^{n-2} g\}$ to begin with. Still, for any scaling factor β we can choose the corresponding zero-form α_β and its Lie derivatives along f as new coordinates. We can also find the corresponding error one-form ϵ_β and verify the bounds on the corresponding terms Q and P in (6) and decide if they are sufficiently small for our purpose.

THEOREM 7.1. *Assume that $z = \Phi(x)$ is a (global) diffeomorphism of $\mathcal{M}$ onto its image given by* (32). *Let $u_{\text{new}} = Kz$ be any linear feedback in new variables so that the linear part*

$$\dot{z} = (A + BK)z \tag{50}$$

of the system (6) *obtained from* (1) *after change of coordinates and preliminary feedback is asymptotically stable. Let N be a positive definite $n \times n$ matrix and M be the unique positive semidefinite solution of the Lyapunov equation*

$$(A + BK)^T M + M(A + BK) + N = 0. \tag{51}$$

Let

$$E(z) := P(z) + Q(z)Kz \tag{52}$$

and $\Omega_r = \{0\} \cup \{z \in \Phi(\mathcal{M}) : \langle z, Mz\rangle < r$ and $\langle z, Nz\rangle - 2\langle z, ME(z)\rangle > 0\}$. Define $r_{\max} := \sup\{r \geq 0 : \Omega_r \subseteq \Phi(\mathcal{M})\}$. Then $\Phi^{-1}(\Omega_{r_{\max}})$ is an invariant set contained in the basin of attraction of the origin of the system

$$\dot{x} = f(x) + g(x)k_1(x), \tag{53}$$

where $k_1(x) := r(\Phi(x))^{-1}(K\Phi(x) - p(\Phi(x)))$ (p and q are defined by (35)).

Proof. The linearizable part of the system in new coordinates z can be made asymptotically stable by feedback $u_{\text{new}} = Kz$ linear in new coordinates. One can define a quadratic Lyapunov

function $V(z) := \langle z, Mz\rangle$ with a negative time derivative $\dot{V}(z) = -\langle z, Nz\rangle$ solving the Lyapunov equation (51). The sets Ω_r are invariant sets for the closed-loop linear part (50). Now, the time derivative of Lyapunov function for the true system in new coordinates is $\dot{V}(z) = -(\langle z, Nz\rangle - 2\langle z, ME(z)\rangle)$. If this is negative, the sets $\Phi^{-1}(\Omega_{r_{\max}})$ are invariant sets for the closed-loop system (53). □

The above result simply states a sufficient condition for a region of $\mathcal{M}$ to be an invariant set contained in the basin of attraction of the origin of the system $\dot{x} = f(x) + g(x)k_1(x)$ and is well known. What is nice about the above result is that we can actually estimate the set $\Phi^{-1}(\Omega_{r_{\max}})$ in our approach. Namely, since we have estimates on the uniform norms $\|P(z)\|$ and $\|Q(z)\|$ of the nonlinear terms in the system (6), we obtain an upper bound on the uniform norm $E(z) = P(z) + Q(z)Kz$. Thus, we can check if the time derivative $-(\langle z, Nz\rangle + 2\langle z, ME(z)\rangle)$ of the Lyapunov function is negative on the region of interest. Moreover, since we expect $P(z)$ and $Q(z)$ to be small, so will $E(z)$. Since the first term in $-(\langle z, Nz\rangle + 2\langle z, ME(z)\rangle)$ is negative and the second term is small, the whole expression is negative in some neighborhood of the origin.

Let us define yet another measure of nonlinearity in new coordinates that is particularly suited for studying stabilization:

$$\eta_{afl}(z) := \frac{2\langle z, ME(z)\rangle}{\langle z, Nz\rangle} \text{ for } z \neq 0, \ \eta_{afl}(0) := 0. \tag{54}$$

Now we can replace the condition

$$2\langle z, ME(z)\rangle < \langle z, Nz\rangle \text{ for } z \neq 0 \tag{55}$$

with

$$\eta_{afl}(z) < 1. \tag{56}$$

Note that the quantity η_{afl} actually depends on the choice of characteristic one-form, the particular homotopy operator, the stabilizing feedback gain matrix K, and the matrix N. Observe that $|\eta_{afl}(z)| < 1$ means that the linear term dominates the nonlinear one in the time derivative $\dot{V}(z) = -(\langle z, Nz\rangle + 2\langle z, ME(z)\rangle)$ of the Lyapunov function $V(z) := \langle z, Mz\rangle$ at the particular point z, guaranteeing its negative sign. On the other hand $0 < \eta_{afl}(z)$ means that the nonlinearities contribute to making $\dot{V}(z)$ more positive and thus have a destibilizing effect, while $\eta_{afl}(z) < 0$ means that the nonlinearities try to make $\dot{V}(z)$ more negative and hence help to stabilize the system. Therefore, the following terminology is justified: we will say that the nonlinearities are *weak* (respectively, *strong*) at z if $|\eta_{afl}(z)| < 1$ (respectively, $|\eta_{afl}(z)| > 1$) and *friendly* (respectively, *unfriendly*) if $\eta_{afl}(z) < 0$ (respectively, $0 < \eta_{afl}(z)$).

Let us express this condition in terms of system (6) and (8). We have $E(z) = P(z) + Q(z)Kz = (Kz - p(z))(r^{-1}(z)E(z))$. Thus $2\langle z, ME(z)\rangle = 2\langle z, M(Kz - p(z))(r^{-1}(z)E(z))\rangle$, and (56) is equivalent to

$$\frac{2\langle z, M(Kz - p(z))(r^{-1}(z)E(z))\rangle}{\langle z, Nz\rangle} < 1 \text{ for } z \neq 0. \tag{57}$$

Using bounds on $\|P(z)\|$ and $\|Q(z)\|$ obtained in the previous section, one can formulate the following inequality, which implies the previous ones:

$$2\frac{(\varrho + |K||z|)\|\epsilon\|_{f,g}^{n-1}}{\rho} < \frac{\inf \sigma(N)}{\sup \sigma(M)}|z| \text{ for } z \neq 0, \tag{58}$$

where $\sigma(\cdot)$ denotes a spectrum of a matrix.

It is possible to combine the problems of designing a stabilizing feedback for the linear part of of the system (6) obtained from (1) after change of coordinates and preliminary feedback and construction of a Lyapunov function in a linear quadratic optimal control design: find u_{new} minimizing

$$\int_0^\infty (\langle z(t), Nz(t)\rangle + \langle u_{\text{new}}(t), Ru_{\text{new}}(t)\rangle)dt$$

for strictly positive definite R and a positive definite N. (To make life easier, we will assume that N is also strictly positive definite.) It is well known that the optimal control u_{new} has the form of linear feedback $u_{\text{new}} = Kz$ for $K = -R^{-1}B^TM$, where M is the unique positive definite solution of the Riccati equation

$$A^TM + MA - MBR^{-1}B^TM + N = 0. \tag{59}$$

Then $V(z) := \langle z(t), Mz(t)\rangle$ is the Lyapunov function for the closed-loop system (50) and $\dot V(z) = -\langle z(t), (N + MBR^{-1}B^TM)z(t)\rangle$.

Example 7.1. Consider the system

$$\begin{aligned} \dot x_1 &= x_2 + ax_3^3 + bx_1^3, \\ \dot x_2 &= x_3 + cx_1^2x_2, \\ \dot x_3 &= u. \end{aligned} \tag{60}$$

□

Note this is a particular case of the system considered in Example 3.1. We have $\omega_0 = dx_1 - 3ax_3^2dx_2$ and $d\omega_0 = 6ax_3dx_2 \wedge dx_3$. For scaling factor $\beta = 1$ we get $\alpha := H\omega = x_1 - ax_2x_3^2, \epsilon := Hd\omega = (2ax_3)(x_2dx_3 - x_3dx_2)$. New coordinates $z = \Phi(x)$ are given by $z_1 := \alpha = x_1 - ax_2x_3^2, z_2 := L_f\alpha = x_2 + bx_1^3 - acx_1^2x_2x_3^2, z_3 := L_f^2\alpha = x_3 + 3b^2x_1{}^5 + 3bx_1{}^2x_2 + cx_1{}^2x_2 - 2abcx_1{}^4x_2x_3{}^2 - ac^2x_1{}^4x_2x_3{}^2 - 2acx_1x_2{}^2x_3{}^2 + 3abx_1{}^2x_3{}^3 - acx_1{}^2x_3{}^3 - 2a^2cx_1x_2x_3{}^5$. Note that $\Phi(x)$ is only a local diffeomorphism around the origin, and it is impossible to find an inverse transformation. Thus, in the following discussion we express the nonlinear terms $E(z)$, $r(z)$, and $p(z)$ in old coordinates: $E(\Phi(x)) = [-2ax_2x_3, -2acx_1{}^2x_2x_3, -2acx_1x_2x_3\,(2bx_1{}^3 + cx_1{}^3 + 2x_2 - 4ax_3{}^3)]^T$,

$$\begin{aligned} r(\Phi(x)) &:= 1 + 9abx_1{}^2x_3{}^2 - 3acx_1{}^2x_3{}^2 - 18a^2cx_1x_2x_3{}^4, \\ p(\Phi(x)) &:= 15b^3x_1{}^7 + 21b^2x_1{}^4x_2 + 5bcx_1{}^4x_2 + c^2x_1{}^4x_2 + 6bx_1x_2{}^2 \\ &\quad + 2cx_1x_2{}^2 + 3bx_1{}^2x_3 + cx_1{}^2x_3 - 8ab^2cx_1{}^6x_2x_3{}^2 - 6abc^2x_1{}^6x_2x_3{}^2 \\ &\quad - ac^3x_1{}^6x_2x_3{}^2 - 10abcx_1{}^3x_2{}^2x_3{}^2 - 8ac^2x_1{}^3x_2{}^2x_3{}^2 - 2acx_2{}^3x_3{}^2 \\ &\quad + 21ab^2x_1{}^4x_3{}^3 - 4abcx_1{}^4x_3{}^3 - ac^2x_1{}^4x_3{}^3 + 12abx_1x_2x_3{}^3 \\ &\quad - 4acx_1x_2x_3{}^3 - 10a^2bcx_1{}^3x_2x_3{}^5 - 6a^2c^2x_1{}^3x_2x_3{}^5 - 4a^2cx_2{}^2x_3{}^5 \\ &\quad + 6a^2bx_1x_3{}^6 - 4a^2cx_1x_3{}^6 - 2a^3cx_2x_3{}^8. \end{aligned}$$

(All computations were done using Mathematica.) To design a locally stabilizing feedback, we have solved the linear quadratic regulator problem for the linear part of the system as mentioned above for N being the 3×3 identity matrix and $R = 1$. The optimal feedback gain matrix was $K = [-1, -2.41421, -2.41421]$, and eigenvalues of $A + BK$ were $-1, -0.707107 + i0.707107, -0.707107 - i0.707107$. The feedback law applied to the original system (1) was $u_{afl} := r(\Phi(x))^{-1}(K\Phi(x) - p(\Phi(x)))$. We choose the values of parameters $a = 0.01, b = 1, c = 5$, and $\mathcal{M} := \{|x_i| < 0.36, i = 1, 2, 3\}$. We checked that the condition (57) was satisfied on $\mathcal{M}$, with $\sup \eta_{afl}(\Phi(x)) \approx 0.45$. Thus, by Theorem 7.1, the corresponding set $\Phi^{-1}(\Omega_{r_{\max}})$ (defined in the formulation of Theorem 7.1) is in the basin of attraction of the

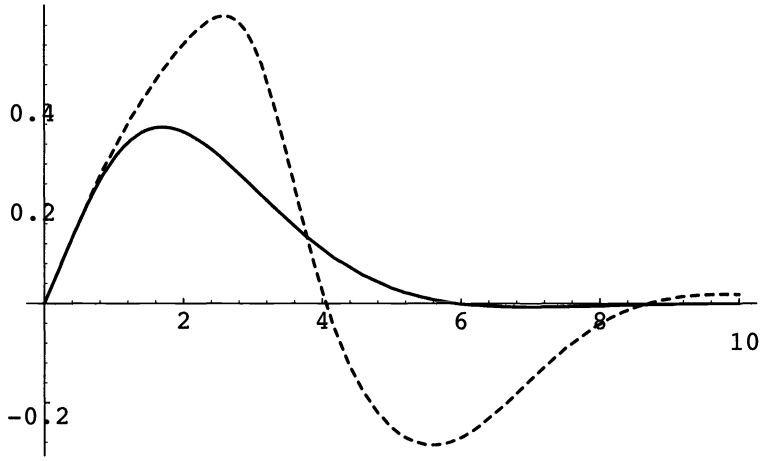

FIG. 1. $x_1(t)$ *for* $x_1(0) = 0, x_2(0) = 0.3, x_3(0) = 0.3$.

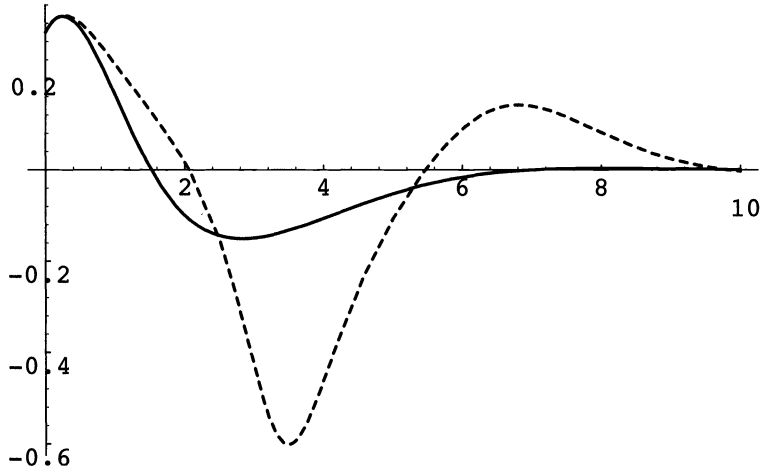

FIG. 2. $x_2(t)$ *for* $x_1(0) = 0, x_2(0) = 0.3, x_3(0) = 0.3$.

origin. As we have checked, the whole $\mathcal{M}$ was in the basin of attraction of the origin. The basin of attraction was actually much larger than $\mathcal{M}$, even though the condition (57) was not satisfied. (Note that Theorem 7.1 gives only an underestimate of the actual stability region.) For comparison, we considered the control based on Jacobian linearization $u_{\text{jac}} := Kx$ for the same gain matrix K. Note that the x and z coordinates agree up to first order and that both control schemes u_{afl} and u_{jac} yield the same linear part of the closed-loop system with eigenvalues $-1, -0.707107 + i0.707107, -0.707107 - i0.707107$. We checked that for u_{jac} condition (57) failed to hold on $\mathcal{M}$, with $\sup \eta_{\text{jac}}(x) \approx 5.6$ (11 times more than for u_{afl}), where $\eta_{\text{jac}}(x) := \frac{2\langle x, M(Kx)(E_{\text{jac}}(x))\rangle}{\langle x, Nx\rangle}$, $E_{\text{jac}} := [ax_3^3 + bx_1^3, cx_1^2x_2, 0]^T$. Not whole $\mathcal{M}$ was in the region of stability for u_{jac}, and the region of stability for u_{jac} was strictly contained in the the region of stability for u_{afl}. We present (in Figures 1–3) typical plots of the state variables as functions of time. (The continuous lines represent the time responses for u_{afl}, the dashed lines for u_{jac}.) Comparing those responses of our system for both control schemes, we see that u_{afl} offered faster convergence to the origin and less oscillatory responses than u_{jac}. We also plot (in Figures 4 and 5) the terms $\eta_{afl}(\Phi(x))$ and $\eta_{\text{jac}}(x)$ along trajectories, because they in some sense measure nonlinearity of the corresponding closed-loop systems. Observe that the strong and unfriendly nonlinearities prevail in the closed-loop system with u_{jac} control when compared to weak nonlinearities in the closed-loop system with u_{afl} control.

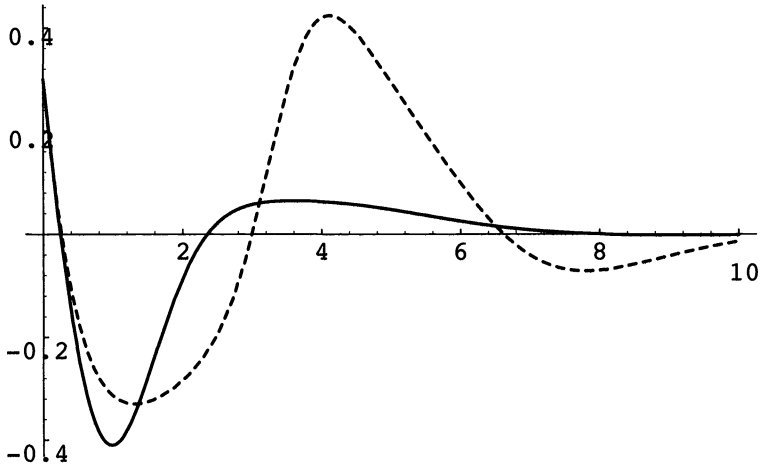

FIG. 3. $x_3(t)$ *for* $x_1(0) = 0, x_2(0) = 0.3, x_3(0) = 0.3$.

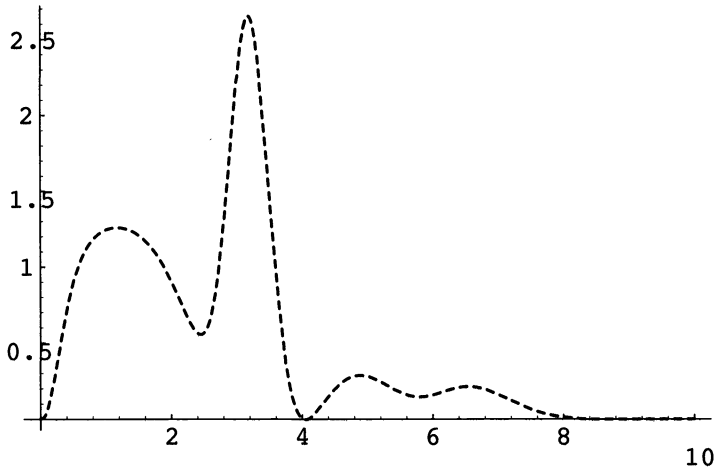

FIG. 4. η_{jac} *for* $x_1(0) = 0, x_2(0) = 0.3, x_3(0) = 0.3$.

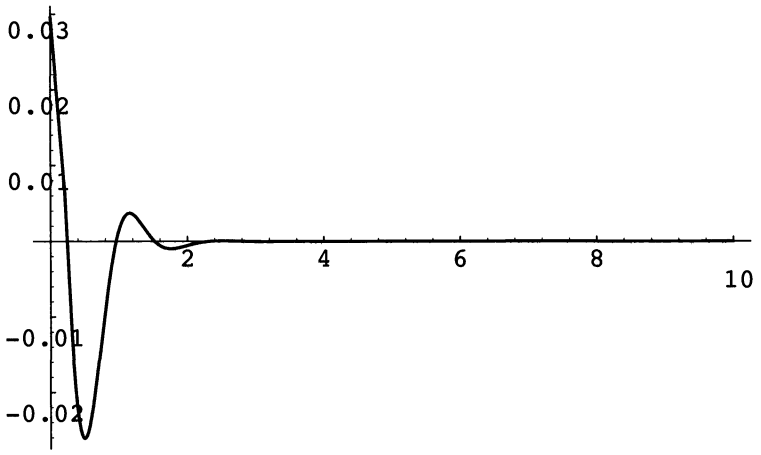

FIG. 5. η_{afl} *for* $x_1(0) = 0, x_2(0) = 0.3, x_3(0) = 0.3$.

Note that from §3 we actually know that the optimal integrating factor for $\omega_0 = dx_1 - ax_3^2 dx_2$ is $\beta = |\omega_0|^{-1} = (1 + a^2 x_3^4)^{-1/2}$. Observe that, with $a = 0.01$ and $|x_3| < 0.36$, we have $\beta \approx 1$ up to six decimal places. We have found the coresponding change of coordinates and performed simulations, but the results were indistinguishable from the case $\beta = 1$.

8. Conclusion. In this paper, we presented an approach for finding feedback linearizable systems that approximate a given single-input nonlinear system on a given compact region of the state space. We have shown that if the system is close to being involutive, then it is also close to being linearizable. We have applied this approach for design of locally stabilizing feedback laws for nonlinear systems that are close to being linearizable. The main idea was to study the characteristic one-forms rather than deal with the characteristic distribution directly. In this approach two issues have occurred: first, how to scale characteristic forms; second, how to approximate them by exact forms. We have presented some ideas on that subject and indicated some open problems.

PERTURBED OPTIMIZATION IN BANACH SPACES III: SEMI-INFINITE OPTIMIZATION*

J. FRÉDÉRIC BONNANS† AND ROBERTO COMINETTI‡

Abstract. This paper is devoted to the study of perturbed semi-infinite optimization problems, i.e., minimization over $\mathbb{R}^n$ with an infinite number of inequality constraints. We obtain the second-order expansion of the optimal value function and the first-order expansion of approximate optimal solutions in two cases: (i) when the number of binding constraints is finite and (ii) when the inequality constraints are parametrized by a real scalar.

These results are partly obtained by specializing the sensitivity theory for perturbed optimization developed in part I (cf. [*SIAM J. Control Optim.*, 34 (1996), pp. 1151–1171]) and deriving specific sharp lower estimates for the optimal value function which take into account the curvature of the positive cone in the space $C(\Omega)$ of continuous real-valued functions.

Key words. sensitivity analysis, marginal function, approximate solutions, directional constraint qualification, semi-infinite programming, epilimits

1. Introduction.

This paper is the last of a trilogy devoted to the analysis of parametric optimization problems of the form

$$\min_x \{f(x,u) : G(x,u) \in K\},$$

with X and Y Banach spaces, K a closed convex subset of Y, and $f(x,u)$ and $G(x,u)$ mappings of class $\mathcal{C}^2$ from $X \times \mathbb{R}$ into $\mathbb{R}$ and Y, respectively. This third part is devoted to the study of the parametric semi-infinite optimization problem

$$(\mathrm{P}_u) \qquad \min_x \{f(x,u) : G(x,u)_\omega \geq 0, \ \forall \omega \in \Omega\},$$

where Ω is a compact metric space; $G(x,u) := \{G(x,u)_\omega\}_{\omega\in\Omega}$ belongs to $C(\Omega)$, the space of continuous functions on Ω endowed with the max norm; and the mapping $(x,u) \to (f(x,u), G(x,u))$ is of class $\mathcal{C}^2$ from $\mathbb{R}^n \times \mathbb{R}^+$ into $\mathbb{R} \times C(\Omega)$. Since

$$C_+(\Omega) := \{y \in C(\Omega) \ : \ y \geq 0\}$$

is a closed convex cone in the Banach space $C(\Omega)$, it follows that (P_u) is a particular case of the above abstract optimization problem.

Semi-infinite optimization problems occur in robust control theory, the design of filters, the design of devices having to respect some specifications in a certain range of pressure and temperature, and optimal control problems when the control has a finite-dimensional parametrization; see [16]. However, the wealth of applications is not the only motivation for studying semi-infinite optimization. In the past few years, a rather complete perturbation theory has been developed for optimization problems with a finite number of constraints, the so-called perturbed nonlinear programming problem; see [2], [6], [8], [19]. The theory of perturbed semi-infinite optimization problems, although it seems much easier than the general perturbation problem in Banach space, includes an essential difficulty related to the curvature of $C_+(\Omega)$. As a consequence, the standard second-order upper and lower estimates for the cost

do not, in general, coincide. Our main contribution here is to exhibit a sharp lower estimate that, in some cases, is equal to the parabolic upper estimate.

There is already a large body of literature on semi-infinite optimization; see the early references [3] and [11]. The recent review [9] describes in particular the so-called *reduction theory* that reduces (P_u) to an optimization problem with a finite number of constraints (see also [13]). This reduction is possible when the contact set includes a finite number of points and each of them can be expressed locally as a function of the data, typically a local solution of an optimization problem with finitely many constraints. Then the perturbation theory for nonlinear programming can be applied for deriving optimality conditions as well as for conducting a perturbation analysis; see the early reference [18].

In this paper we do not use any reduction device. In this way we may handle some cases where there is a continuum of binding constraints, especially when Ω is a one-dimensional interval. We are also able to treat the case of a finite number of binding constraints in cases where the reduction theory does not apply.

The paper is organized as follows. In §2 we discuss the directional qualification condition introduced in part I. We characterize it and show how to deduce a first-order upper estimate. Section 3 is devoted to the parabolic (second-order) upper estimates. There we combine the technique of parabolic estimates with the directional qualification condition and a characterization of second-order tangent sets to $C_+(\Omega)$, recently obtained in [7]. This upper estimate combined with the strong quadratic growth condition implies the upper Lipschitz property for the set of solutions. In §4 we discuss some sharp lower estimates. We use there specific properties of semi-infinite optimization, among them the fact that an extremal multiplier has a finite support. Then in §5 we recapitulate and state our main result.

2. Directional qualification. We start with some notations. The feasible set, value function, and set of solutions of (P_u) are denoted

$$F(u) := \{x \in \mathbb{R}^n \ : \ G(x,u) \geq 0\},$$
$$v(u) := \inf\{f(x,u) \ : \ x \in F(u)\},$$
$$S(u) := \{x \in F(u) \ : \ f(x,u) = v(u)\}.$$

Similarly, given any optimization problem (P), we define F(P), v(P), and S(P) as the feasible set, value function, and set of solutions of (P).

We recall that the dual space of $C(\Omega)$ is the set $M(\Omega)$ of bounded measures; see, e.g., [22]. If $(\lambda, y) \in M(\Omega) \times C(\Omega)$, then $\langle \lambda, y \rangle = \int_\Omega y(\omega) d\lambda(\omega)$. The support of $\lambda \in M(\Omega)$, denoted supp(λ), is defined as the complement of the greatest open subset of Ω over which $|\lambda|$ is null. The negative cone of $M(\Omega)$ is denoted $M_-(\Omega)$.

The Lagrangian function associated with (P_u) is

$$\mathcal{L}(x,\lambda,u) = f(x,u) + \int_\Omega G(x,u)_\omega d\lambda(\omega).$$

With $x \in F(u)$ we associate the set of Lagrange multipliers

$$\Lambda_u(x) := \{\lambda \in M_-(\Omega) \ : \ \text{supp}(\lambda) \subset Z(G(x,u)) \text{ and } \mathcal{L}'_x(x,\lambda,u) = 0\},$$

where, for $y \in C(\Omega)$, the set $Z(y)$ is the contact set defined as

$$Z(y) := \{\omega \in \Omega \ : \ y(\omega) = 0\}.$$

Let us fix a particular solution $x_0 \in S(0)$ and denote $\Lambda_0 := \Lambda_0(x_0)$ and $Z_0 := Z(G(x_0,0))$. The problem with linearized data (L) and its dual (D) are

$$\text{(L)} \qquad \min_d \{f'(x_0,0)(d,1) \ : \ G'(x_0,0)(d,1) \geq 0 \text{ on } Z_0\},$$

$$\text{(D)} \qquad \max_{\lambda \in \Lambda_0} \mathcal{L}'_u(x_0,\lambda,0).$$

We consider the directional qualification hypothesis

$$\text{(DCQ)} \qquad \exists\, \hat{d} \in \mathbb{R}^n \ : \ G'(x_0, 0)(\hat{d}, 1) > 0 \text{ on } Z_0,$$

which is to be compared to the standard qualification hypothesis (see [12])

$$\text{(CQ)} \qquad \exists\, \tilde{d} \in \mathbb{R}^n \ : \ G'_x(x_0, 0)\tilde{d} > 0 \text{ on } Z_0.$$

The following is essentially known.

LEMMA 2.1. *Condition* (CQ) *is equivalent to each of the following two conditions:*

(i) *There exists* $\tilde{d} \in \mathbb{R}^n$ *such that*

$$G(x_0, 0) + G'_x(x_0, 0)\tilde{d} > 0 \text{ on } \Omega.$$

(ii) *The set* Λ_0 *is nonempty and bounded.*

Proof. The equivalence between (CQ) and (i) is proven in [20]. That (CQ) implies (ii) follows from [23]. Let us prove that (ii) implies (CQ). If (CQ) does not hold, then the linear semi-infinite optimization problem

$$\min_{d,z}\{z : G'(x_0, 0)_\omega(d, 0) + z \geq 0, \ \forall \omega \in Z_0\}$$

has value 0. It follows that $(d, z) = (0, 0)$ is a solution of this problem at which the qualification condition is satisfied by the direction $(0, 1)$. By (i) $\Rightarrow$ (ii), there exists at least one multiplier $\hat{\lambda}$. Expressing the optimality conditions, we find that $\hat{\lambda} \in M_-(\Omega) \setminus \{0\}$, $\text{supp}(\hat{\lambda}) \subset Z_0$, and $\hat{\lambda} \circ G'_x(x_0, 0) = 0$. It follows that whenever $\lambda \in \Lambda_0$ and $t \in \mathbb{R}_+$, then $\lambda + t\hat{\lambda} \in \Lambda_0$, in contradiction to (ii). □

A similar result holds for condition (DCQ).

LEMMA 2.2. *Condition* (DCQ) *is equivalent to*

(i) *there exist* $\varepsilon > 0$ *and* $\tilde{d} \in \mathbb{R}^n$ *such that*

$$G(x_0, 0) + \varepsilon G'(x_0, 0)(\tilde{d}, 1) > 0 \text{ on } \Omega.$$

If in addition $\Lambda_0 \neq \emptyset$, *then* (DCQ) *is equivalent to*

(ii) *the set* $S(\mathrm{D})$ *is nonempty and bounded.*

Proof. Noting that (DCQ) is nothing but the standard qualification condition for the set of constraints $\{G(x, u) \geq 0; \ u \geq 0\}$, and applying Lemma 2.1, we obtain the equivalence of (DCQ) and (i).

Now assume that $\Lambda_0 \neq \emptyset$. That (DCQ) implies (ii) follows from [4, Prop. 3.1]. Conversely, if (DCQ) does not hold, we have

$$\alpha := \min_{d,z}\{z : G'(x_0, 0)_\omega(d, 1) + z \geq 0, \ \forall \omega \in Z_0\} \geq 0.$$

Considering the perturbation function

$$\varphi((d, z), h) = \begin{cases} z & \text{if } h(\omega) + G'(x_0, 0)_\omega(d, 1) + z \geq 0, \ \forall \omega \in Z_0 \\ +\infty & \text{otherwise,} \end{cases}$$

we obtain the dual problem

$$\min_{\lambda}\left\{-\int_\Omega G'_u(x_0, 0)d\lambda : \lambda \in M_-(\Omega), \text{supp}(\lambda) \subset Z_0, \int_\Omega d\lambda = -1, \lambda \circ G'_x(x_0, 0) = 0\right\}.$$

Applying [4, Thm. A2] we get the existence of an optimal solution $\hat{\lambda}$ for this problem, and we have

$$\int_\Omega G'_u(x_0, 0)d\hat{\lambda} = \alpha \geq 0.$$

It follows that for each $\lambda \in S(\mathrm{D})$ and every $t > 0$ we have $\lambda + t\hat{\lambda} \in S(\mathrm{D})$, contradicting the boundedness of $S(\mathrm{D})$ stated in (ii). □

From the above lemma and [5, Prop. 5.2], it follows that (DCQ) is a particular case of the abstract directional constraint qualification of part I.

PROPOSITION 2.3. *If* (DCQ) *holds, then*

$$\limsup_{u\downarrow 0} \frac{v(u) - v(0)}{u} \leq v(\mathrm{D}) = v(\mathrm{L}).$$

Proof. This follows from Propositions 2.1 and 3.1 in [4] and Lemma 2.2 above. □

Remark. The above statements hold when f and G are merely of class C^1.

3. Second-order upper estimates. Define a *path* as a mapping $u \to x_u$ from $\mathbb{R}_+$ to X, with $x_u \to x_0$ when $u \downarrow 0$. The path is said to be feasible if $G(x_u, u) \in K$ for u small enough. In the study of second-order upper estimates, we analyze feasible paths of the form

$$x_u := x_0 + ud + \frac{u^2}{2}z + o(u^2).$$

Feasibility of x_u implies some relations between the expansion of $G(x_u, u)$ and the geometry of $C_+(\Omega)$. Given a convex subset K of a Banach space Y, we define the first-order tangent set at $y \in K$ as

$$T_K(y) := \{h \in Y : \text{ there exists } o(t) \text{ such that } y + th + o(t) \in K\}.$$

Similarly, the second-order tangent set at $y \in K$ in the direction $h \in T(y)$ is

$$T_K^2(y, h) := \left\{z \in Y : \text{ there exists } o(t^2) \text{ such that } y + th + \frac{t^2}{2}z + o(t^2) \in K\right\}.$$

For the sake of simplicity we write $T := T_{C_+(\Omega)}$ and $T^2 := T^2_{C_+(\Omega)}$ and denote the terms of the second-order expansion of $f(x_u, u)$ and $G(x_u, u)$ as

$$\Psi_f(z, d) := f'_x(x_0, 0)z + f''(x_0, 0)(d, 1)(d, 1),$$

$$\Psi_G(z, d) := G'_x(x_0, 0)z + G''(x_0, 0)(d, 1)(d, 1).$$

Expanding $G(x_u, u)$ we obtain that if x_u is a feasible path, then

$$G'(x_0, 0)(d, 1) \in T(G(x_0, 0)), \tag{1}$$

$$\Psi_G(z, d) \in T^2(G(x_0, 0), G'(x_0, 0)(d, 1)), \tag{2}$$

and, when $d \in S(\mathrm{L})$, we get

$$v(u) \leq v(0) + uv(L) + \frac{u^2}{2}\Psi_f(z, d) + o(u^2). \tag{3}$$

In [4], it was shown that an upper estimate of the second-order variation of the cost is obtained by minimizing $\Psi_f(z, d)$ over those z satisfying (2). The purpose of this section is

to make explicit this bound in the case of semi-infinite programming. In the statement of our result, we use some expressions for the tangent sets of $K = C_+(\Omega)$. The first-order tangent cone is well known (see, e.g., [20]):

$$T(y) = \{h \in C(\Omega) : h \geq 0 \quad \text{on} \quad Z(y)\}.$$

In particular, the tangent cone at $G(x_0, 0)$ is

$$T(G(x_0, 0)) = \{h \in C(\Omega) : h \geq 0 \quad \text{on} \quad Z_0\}.$$

A formula for the second-order tangent set has been recently obtained in [7]. This formula uses the concept of lower epilimit that we now recall, referring to [1] for a detailed exposition. Let $(A_t)_{t>0}$ be a family of subsets of a Banach space Y. The upper limit of $(A_t)_{t>0}$ at $t = 0$ in the sense of Painlevé–Kuratowski is defined as

$$\limsup_{t\downarrow 0} A_t := \left\{ y \in Y : \liminf_{t\downarrow 0} d(y, A_t) = 0 \right\}.$$

The lower epilimit of a family $(f_t)_{t>0}$ of extended real-valued functions on the topological space K is defined as the function whose epigraph is $\limsup_{t\downarrow 0} \operatorname{epi} f_t$, where

$$\operatorname{epi} f_t := \{(x, r) \in K \times \mathbb{R} : f_t(x) \leq r\}$$

is the epigraph of f_t. An alternative characterization is given by

$$\text{e-}\liminf_{t\downarrow 0} f_t(x) = \sup_{V \in \mathcal{N}(x)} \liminf_{t\downarrow 0} \inf_{y \in V} f_t(y) = \liminf_{(t,y)\to(0^+,x)} f_t(y),$$

where $\mathcal{N}(x)$ is the set of neighborhoods of x.

PROPOSITION 3.1 (cf. [7]). *Let $y \in C_+(\Omega)$ and $h \in T(y)$. Then*

$$T^2(y, h) = \{h \in C(\Omega) : \ h + \tau(y, h) \geq 0\},$$

where $\tau(f, v)$ is the lower semicontinuous extended real-valued function defined by

$$\tau(f, v) := \text{e-}\liminf_{t\downarrow 0} \left[\frac{f + tv}{t^2/2} \right].$$

Equivalently, $\tau(f, v)$ is given by the formula

$$\tau(f, v)(\omega) = \begin{cases} 0 & \text{if } \omega \in \operatorname{int} Z(f) \text{ and } v(\omega) = 0, \\ -\theta(\omega) & \text{if } \omega \in \operatorname{bd} Z(f) \text{ and } v(\omega) = 0, \\ +\infty & \text{otherwise,} \end{cases} \tag{4}$$

where

$$\theta(\omega) := \limsup_{\substack{y\to\omega \\ f(y)>0}} \frac{[-v(y)]_+^2}{2f(y)}. \tag{5}$$

In view of this result, defining

$$\Xi(d, u)_\omega := \frac{G(x_0, 0)_\omega + uG'(x_0, 0)_\omega(d, 1)}{u^2/2},$$

$$\tau_d(\omega) := \text{e-}\liminf_{u\downarrow 0} \Xi(d, u)_\omega,$$

we get the characterization

$$T^2(G(x_0,0);G'(x_0,0)(d,1)) = \{h \in C(\Omega) :\ h + \tau_d \geq 0\}.$$

Writing $T^2(d)$ for the above set for brevity, we see that $T^2(d) \neq \phi$ if and only if $\tau_d > -\infty$. In such a case the support function of $T^2(d)$ can be characterized as

$$\sigma(\lambda, T^2(d)) := \sup\left\{\int_\Omega h(\omega)d\lambda(\omega) : h \in T^2(d)\right\} = -\int_\Omega \tau_d(\omega)d\lambda(\omega)$$

for all $\lambda \in S(D)$. (Since $\lambda \leq 0$ and τ_d is lower semicontinuous and nonpositive on $\mathrm{supp}(\lambda)$, the integral on the right-hand side above is well defined.) To make this equality always valid we define $\int_\Omega \tau_d(\omega)d\lambda(\omega) := +\infty$ whenever τ_d takes the value $-\infty$.

The function $-\tau_d$ may be interpreted as an *upper curvature function.*

Given $d \in S(\mathrm{L})$, the relations (1)–(3) suggest consideration of the subproblem

$$(\mathrm{L}_d) \qquad \min_z\{\Psi_f(z,d) : \Psi_G(z,d) + \tau_d \geq 0\},$$

with which we associate a dual formulation

$$(\mathrm{D}_d) \qquad \max_{\lambda \in S(\mathrm{D})} \mathcal{L}''(x_0,\lambda,0)(d,1)(d,1) + \int_\Omega \tau_d(\omega)d\lambda(\omega).$$

We also introduce the problem

$$(\mathrm{Q}) \qquad \min\{v(\mathrm{L}_d) : d \in S(\mathrm{L})\}.$$

Whenever $v'(0)$ exists, we define the upper and lower second-order Dini derivatives

$$(6) \qquad v''_+(0) := \limsup_{u\downarrow 0} 2[v(u) - v(0) - uv'(0)]/u^2,$$

$$(7) \qquad v''_-(0) := \liminf_{u\downarrow 0} 2[v(u) - v(0) - uv'(0)]/u^2.$$

PROPOSITION 3.2. *If* (DCQ) *holds, then* $v(\mathrm{L}_d) = v(\mathrm{D}_d)$ *for all* $d \in S(\mathrm{L})$, *and we have* $v(\mathrm{Q}) < +\infty$ *iff there exists* $d \in S(\mathrm{L})$ *such that* $\tau_d(\omega) > -\infty$ *for all* $\omega \in \Omega$. *Moreover, if* $S(\mathrm{L})$ *is nonempty and* $v(\mathrm{Q}) > -\infty$, *we then have*

$$(8) \qquad v(u) \leq v(0) + uv(\mathrm{L}) + \frac{u^2}{2}v(Q) + o(u^2).$$

In particular, if there exists $v'(0) = v(\mathrm{L})$, *we get*

$$(9) \qquad v''_+(0) \leq \inf_{d\in S(\mathrm{L})} \max_{\lambda\in S(\mathrm{D})} \left\{\mathcal{L}''(x_0,\lambda,0)(d,1)(d,1) + \int_\Omega \tau_d(\omega)d\lambda(\omega)\right\}.$$

Proof. This is a consequence of Propositions 2.1, 2.2, and 4.2 in [4]. □

By the above Proposition, $v(\mathrm{Q}) < +\infty$ iff $\tau_d > -\infty$ for some $d \in S(\mathrm{L})$. We show that a sufficient condition for this is a quadratic growth condition, recently introduced in [20].

LEMMA 3.3. *Suppose that* $G'(x_0,0)$ *is Lipschitz with respect to* ω *and assume that* $G(x_0,0)$ *satisfies the quadratic growth condition*

$$(\mathrm{QGC}) \qquad \exists\, c > 0 \text{ such that } G(x_0,0)_\omega \geq c\,\mathrm{dist}(\omega, Z_0)^2.$$

Then $\tau_d > -\infty$ *for all* $d \in S(\mathrm{L})$.

Proof. Using (4) it suffices to show that for all $\omega \in \text{bd } Z_0$ with $G'(x_0, 0)(d, 1)_\omega = 0$ we have $\theta(\omega) < +\infty$. To this end let L be a Lipschitz constant for $\omega \to G'(x_0, 0)(d, 1)_\omega$. For each $\omega \notin Z_0$ let ω_0 be a projection of ω onto Z_0. Then ω_0 lies on the boundary of Z_0 so that $G(x_0, 0)_{\omega_0} = 0$, and since $G'(x_0, 0)(d, 1) \in T(G(x_0, 0))$ we deduce $G'(x_0, 0)(d, 1)_{\omega_0} \geq 0$. We obtain

$$-G'(x_0, 0)(d, 1)_\omega \leq -G'(x_0, 0)(d, 1)_{\omega_0} + L\, d(\omega, w_0) \leq L\ \text{dist}(\omega, Z_0).$$

From this and (QGC) we deduce

$$[-G'(x_0, 0)(d, 1)_\omega]_+^2 \leq L^2\ \text{dist}(\omega, Z_0)^2 \leq \frac{L^2}{c} G(x_0, 0)_\omega,$$

which implies $\theta(\omega) \leq L^2/(2c) < +\infty$. □

Remark. Assuming (DCQ), we know by Lemma 2.2 that $S(\mathrm{D})$ is bounded. Let $d \in S(\mathrm{L})$. If (QGC) holds, as a consequence of the bound established for $\theta(\omega)$, the amount $\int_\Omega \tau_d(\omega) d\lambda(\omega)$ is bounded uniformly for $\lambda \in S(\mathrm{D})$, so $v(\mathrm{D}_d)$ is finite.

4. Stability of solutions. We state next a sufficient condition for ensuring a Lipschitz behavior of the (sub)optimal paths x_u of the perturbed problems. The result, which is a rather straightforward application of the preceding discussion and [4, Prop. 6.3], is based on the strong second-order sufficient condition

$$\text{(SOC)} \qquad \max_{\lambda \in S(\mathrm{D})} \mathcal{L}''_x(x_0, \lambda, 0)dd > 0 \ \text{ for all } d \text{ in } C \backslash \{0\},$$

where C denotes the critical cone

$$C := \{d \in \mathbb{R}^n \ :\ f'_x(x_0, 0)d \leq 0 \ \text{ and } \ G'_x(x_0, 0)d \geq 0 \text{ on } Z_0\}.$$

PROPOSITION 4.1. *Suppose that*

(i) (DCQ) *holds and* $\Lambda_0 \neq \emptyset$.

(ii) *There exists* $d \in S(\mathrm{L})$ *such that* $\tau_d(\omega) > -\infty\ \forall \omega \in \Omega$.

(iii) (SOC) *holds.*

Then every $O(u^2)$*-optimal path* x_u *satisfies* $x_u = x_0 + O(u)$.

Remark. Combining Lemma 3.3 and Proposition 4.1, we obtain a sufficient condition for Lipschitz behavior of solutions, similar to the result of [20].

Remark. Following [10], we may introduce the strong quadratic growth condition

$$\text{(SQG)} \qquad \exists \alpha > 0, c > 0,\ F(x, u) \geq v(0) + uv(L) + \alpha\, \text{dist}(x, S_0)^2 - cu^2,$$

where

$$F(x, u) := \begin{cases} f(x, u) & \text{if } G(x, u) \geq 0, \\ +\infty & \text{if not.} \end{cases}$$

Then we can show that (SOC) $\Rightarrow$ (SQG), and Proposition 4.1 is still valid if we replace assumption (iii) by (SQG).

5. Lower estimates. We recall for reference the following standard lower estimate, which is in fact a particular case of the general lower estimate of part I.

LEMMA 5.1. *Let us assume* (DCQ) *and suppose that there exists a path of* $o(u^2)$*-optimal solutions* x_u *satisfying* $x_u = x_0 + O(u)$. *Then* $\Lambda_0 \neq \emptyset$, $v'(0)$ *exists with* $v'(0) = v(\mathrm{L}) = v(\mathrm{D})$, $S(\mathrm{L}) \neq \emptyset$, *and we have*

$$v''_-(0) \geq \inf_{d \in S(\mathrm{L})} \max_{\lambda \in S(\mathrm{D})} \mathcal{L}''(x_0, \lambda, 0)(d, 1)(d, 1).$$

Proof. The existence of $v'(0)$, as well as the equality $v'(0) = v(\mathrm{L}) = v(\mathrm{D})$, follows from [4, Prop. 3.2]. The finiteness of $v'(0) = v(\mathrm{D})$ implies that $\Lambda_0 \neq \emptyset$, and [4, Prop. 3.3] gives $S(\mathrm{L}) \neq \emptyset$. The lower estimate on $v''_-(0)$ is then obtained by applying [4, Prop. 4.3(b)]. □

Comparing the previous lower estimate to the upper estimate (9) in §3, we observe a gap due to the curvature of $C_+(\Omega)$ at $G(x_0, 0)$. More precisely, if

$$\tau_d = 0 \text{ on } \operatorname{supp}(\lambda) \quad \forall \lambda \in S(\mathrm{D}),$$

then the two estimates coincide, but as one can see from (4) and (5), this may occur only in some very special situations.

We are then led to search for sharper lower estimates. We will obtain a lower estimate on $v''_-(0)$ involving the upper epilimit of $\Xi(d, u)$.

We recall the concept of upper epilimit, for which we refer again to [1]. Let $(A_t)_{t>0}$ be a family of subsets of a Banach space Y. The lower limit of $(A_t)_{t>0}$ at $t = 0$ in the sense of Painlevé–Kuratowski is defined as

$$\liminf_{t\downarrow 0} A_t := \left\{ y \in Y : \limsup_{t\downarrow 0} d(y, A_t) = 0 \right\}.$$

The upper epilimit of a family $(f_t)_{t>0}$ of extended real-valued functions on the topological space K is defined as the function whose epigraph is $\liminf_{t\downarrow 0} \operatorname{epi} f_t$. A useful formula is

$$\text{e-}\limsup_{t\downarrow 0} f_t(x) = \sup_{V\in\mathcal{N}(x)} \limsup_{t\downarrow 0} \inf_{y\in V} f_t(y). \tag{10}$$

When the upper and lower epilimits coincide at a given point, we shall say that the family of functions *epiconverges* at that point, and we shall denote

$$\text{e-}\lim_{t\downarrow 0} f_t(x) = \text{e-}\liminf_{t\downarrow 0} f_t(x) = \text{e-}\limsup_{t\downarrow 0} f_t(x).$$

We shall say that the family of functions epiconverges on a subset $K_0 \subset K$ if it epiconverges at each point of K_0.

The next proposition makes use of the set of extreme points of $S(\mathrm{D})$, which will be denoted $S^*(\mathrm{D})$. The result will be derived under a technical assumption ($\mathrm{H}_{\hat\omega}$), which will be further clarified afterwards. $B(\hat\omega, r)$ denotes the ball of center $\hat\omega$ and radius r.

PROPOSITION 5.2. *Assume* (DCQ) *and suppose that there exists an $o(u^2)$-optimal path such that $x_u = x_0 + O(u)$. Let $G(x_0, 0)$, $G'(x_0, 0)$, and $G''(x_0, 0)$ be Lipschitz with respect to ω and assume also that for every $d \in S(\mathrm{L})$, each $\lambda \in S^*(\mathrm{D})$, and every $\hat\omega \in \operatorname{supp}(\lambda)$, one has*

$$(\mathrm{H}_{\hat\omega}) \qquad \exists\, V \in \mathcal{N}(\hat\omega), \exists\, r > 0 \text{ s.t. } \inf_{\omega\in V} \Xi(d, u)_\omega = \inf_{\omega\in B(\hat\omega, ru)} \Xi(d, u)_\omega + o(1),$$

with $o(1)$ converging to 0 uniformly as $u \downarrow 0$. Then

$$v''_-(0) \geq \inf_{d\in S(L)} \max_{\lambda\in S(\mathrm{D})} \left\{ \mathcal{L}''(x_0, \lambda, 0)(d, 1)(d, 1) + \int_\Omega \bar\tau_d(\omega) d\lambda(\omega) \right\}, \tag{11}$$

where

$$\bar\tau_d(\omega) := \text{e-}\limsup_{u\downarrow 0} \Xi(d, u)_\omega.$$

For $\int_\Omega \bar\tau_d(\omega) d\lambda(\omega)$ we adopt the same convention as in §3: its value is the usual integral when $\bar\tau_d > -\infty$, and $+\infty$ when $\bar\tau_d$ takes the value $-\infty$. With this convention

$$\int_\Omega \bar{\tau}_d(\omega)d\lambda(\omega) = -\sigma(\lambda, \{h \in C(\Omega); h + \bar{\tau}_d \geq 0\}),$$

which is an upper semicontinuous function of $\lambda \in S(\mathrm{D})$.

The function $-\bar{\tau}_d$ may be interpreted as a *lower-curvature function.*

We discuss some consequences of this proposition, postponing the proof until the end of the section.

Comparing the bounds obtained for $v''_+(0)$ and $v''_-(0)$ in Propositions 3.2 and 5.2, we see that the only difference is between the terms $\text{e-lim inf}_{u\downarrow 0}\, \Xi(d, u)$ and $\text{e-lim sup}_{t\downarrow 0}\, \Xi(d, u)$. The statement below follows.

COROLLARY 5.3. *In addition to the assumptions of Proposition* 5.2, *let us suppose that* $\Xi(d, u)$ *epiconverges on* $\mathrm{supp}(\lambda)$ *for each* $\lambda \in S^*(\mathrm{D})$ *and* $d \in S(\mathrm{L})$. *Then there exists*

$$v''(0) = \inf_{d\in S(L)} \max_{\lambda\in S(\mathrm{D})} \left\{ \mathcal{L}''(x_0, \lambda, 0) + \int_\Omega \text{e-lim}_{u\downarrow 0}\, \Xi(d, u)_\omega d\lambda(\omega) \right\}.$$

It remains to find sufficient conditions to ensure the technical assumption $(\mathrm{H}_{\hat{\omega}})$ in Proposition 5.2. Lemma 5.5 below gives a result in this direction. We first need a technical lemma which describes the structure of extreme points of $S(\mathrm{D})$.

LEMMA 5.4. *Suppose* (DCQ) *and* $\Lambda_0 \neq \emptyset$. *Then* $S(\mathrm{D})$ *is the closed convex hull of* $S^*(\mathrm{D})$, *and any* $\lambda \in S^*(\mathrm{D})$ *is of the form*

$$\lambda = \sum_{i=1}^{p} \lambda_{\omega_i} \delta_{\omega_i} \tag{12}$$

with $p \leq n$, $\lambda_{\omega_i} < 0$, *and* δ_{ω_i} *being the Dirac mass at* ω_i. (*Recall that* n *is the dimension of the space to which* x *belongs.*)

Proof. By Lemma 2.2, the set $S(\mathrm{D})$ is nonempty and bounded. Being closed, it is weak* compact. The Krein–Milman theorem implies that $S(\mathrm{D})$ is the closed convex hull of its extreme points (see, e.g., [22]). Now, $S(\mathrm{D})$ is a face of Λ_0 so that the points in $S^*(\mathrm{D})$ are also extreme points of Λ_0, and the latter are known to be the sum of at most n Dirac masses (see [20]). □

LEMMA 5.5. *Suppose that* $G(x_0, 0)$, $G'(x_0, 0)$, *and* $G''(x_0, 0)$ *are Lipschitz with respect to* ω *and* (QGC) *holds. Under each of the following conditions, property* $(\mathrm{H}_{\hat{\omega}})$ *is satisfied* $\forall\, \hat{\omega} \in \mathrm{supp}(\lambda)$, $\forall\, \lambda \in S^*(\mathrm{D})$, $\forall\, d \in S(\mathrm{L})$:

(i) Z_0 *is a finite set.*

(ii) Ω *is an interval, and* Z_0 *is the union of finitely many intervals.*

Proof. By the previous lemma, $\lambda \in S^*(D)$ has a finite support included in Z_0. Then, using $d \in S(\mathrm{L})$, we obtain

$$G(x_0, 0)_{\hat{\omega}} = G'(x_0, 0)(d, 1)_{\hat{\omega}} = 0 \quad \forall\, \hat{\omega} \in \mathrm{supp}(\lambda).$$

From this we deduce that for all $V \in \mathcal{N}(\hat{\omega})$ we have for all $r > 0$, $u > 0$ small enough

$$\inf_{\omega\in V} \Xi(d, u)_\omega \leq \inf_{\omega\in B(\hat{\omega}, ru)} \Xi(d, u)_\omega \leq \Xi(d, u)_{\hat{\omega}} = 0. \tag{13}$$

Let V be a closed neighborhood of $\hat{\omega}$ such that $\mathrm{dist}(\omega, Z_0) = d(\omega, \hat{\omega})$ whenever $\omega \in V \setminus Z_0$: this is possible by (i) or (ii). Let us consider a Lipschitz constant L for

$$g(\omega) := G'(x, 0)(d, 1)_\omega,$$

and let ω_u minimize $\Xi(d, u)_\omega$ over $\omega \in V$. If $\omega_u \in Z_0$, then we get $\Xi(d, u)_{\omega_u} \geq 0$, which combined with (13) gives $(\mathrm{H}_{\hat{\omega}})$ with $o(1) \equiv 0$ and $r > 0$ arbitrary. Let us then assume that

$\omega_u \notin Z_0$. Then we may use (QGC) and (13) to obtain

$$c\ \mathrm{dist}(\omega_u, Z_0)^2 + ug(\omega_u) \le G(x_0, 0)_{\omega_u} + ug(\omega_u) = \frac{u^2}{2}\Xi(d, u)_{\omega_u} \le \frac{u^2}{2}\Xi(d, u)_{\hat{\omega}} = ug(\hat{\omega}).$$

Since $g(\omega)$ is Lipschitzian, we get

$$c\, d(\omega_u, \hat{\omega})^2 \le u(g(\hat{\omega}) - g(\omega_u)) \le uL\, d(\omega_u, \hat{\omega}),$$

and then $d(\omega_u, \hat{\omega}) \le uL/c$. This proves that minimizing $\Xi(d, u)_\omega$ over $\omega \in V$ is equivalent to minimizing it over $B(\hat{\omega}, uL/c)$, proving $(H_{\hat{\omega}})$ with $r = L/c$ and $o(1) \equiv 0$. □

We now return to the proof of Proposition 5.2, starting with the following lemma, which does not use the specific properties of semi-infinite optimization.

LEMMA 5.6. *Assume* (DCQ) *and suppose that there exists an* $o(u^2)$*-optimal path such that* $x_u = x_0 + O(u)$. *Then there exists* $u_k \downarrow 0$ *and* $d \in S(\mathrm{L})$ *such that for any* $\lambda \in S(\mathrm{D})$

$$v''_-(0) = \mathcal{L}''(x_0, \lambda, 0)(d, 1)(d, 1) - \lim_{k\to\infty} \int_\Omega \Psi_G(z^k, d)_\omega d\lambda(\omega), \tag{14}$$

where

$$z^k := \frac{x_{u_k} - x_0 - u_k d}{u_k^2/2}. \tag{15}$$

Proof. Let us take a sequence $u_k \downarrow 0$ such that

$$2(v(u_k) - v(0) - u_k v(L))/u_k^2 \to v''_-(0). \tag{16}$$

Denoting $x^k = x_{u_k}$ and passing to a subsequence we may also assume that

$$(x^k - x_0)/u_k \to d \tag{17}$$

for some $d \in \mathbb{R}^n$, which, by [4, Prop. 3.3], satisfies $d \in S(\mathrm{L})$.

Since $x_u = x_0 + O(u)$, a second-order expansion of G gives

$$G(x^k, u_k) = G(x_0, 0) + u_k G'(x_0, 0)(d, 1) + \frac{u_k^2}{2}\Psi_G(z^k, d) + o(u_k^2).$$

Since $d \in S(\mathrm{L})$ and $\lambda \in S(\mathrm{D})$ we have

$$\langle \lambda, G(x_0, 0)\rangle = \langle \lambda, G'(x_0, 0)(d, 1)\rangle = 0,$$

from which we get

$$\langle \lambda, G(x^k, u_k)\rangle = \frac{u_k^2}{2}\langle \lambda, \Psi_G(z^k, d)\rangle + o(u_k^2).$$

Taking into account that $\mathcal{L}(x_0, \lambda, 0) = v(0)$, $\mathcal{L}'_x(x_0, \lambda, 0) = 0$, and $\mathcal{L}'_u(x_0, \lambda, 0) = v'(0)$, we deduce

$$v(u_k) = f(x^k, u_k) + o(u_k^2) = \mathcal{L}(x^k, \lambda, u_k) - \langle \lambda, G(x^k, u_k)\rangle + o(u_k^2)$$

$$= v(0) + u_k v'(0) + \frac{u_k^2}{2}[\mathcal{L}''(x_0, \lambda, 0)(d, 1)(d, 1) - \langle \lambda, \Psi_G(z^k, d)\rangle] + o(u_k^2),$$

from which the conclusion follows. □

In order to get the best lower estimate, and recalling that the multiplier is nonpositive, we must minorize $\Psi_G(z^k, d)$ efficiently. Note that by expanding $G(x^k, u_k)$, we get the following relation, which we shall use later:

$$\Psi_G(z^k, d) + \Xi(d, u^k) \geq o(1), \tag{18}$$

where the inequality is to be understood in $C(\Omega)$, i.e., $o(1) \to 0$ uniformly when $u \downarrow 0$.

We now proceed with the proof of Proposition 5.2.

Proof. Let u_k, d, z^k be chosen as in Lemma 5.6. Consider the problem

$$\max_{\lambda \in S(\mathrm{D})} \left\{ \mathcal{L}''(x_0, \lambda, 0)(d, 1)(d, 1) + \int_\Omega \bar{\tau}_d(\omega) d\lambda(\omega) \right\}.$$

As the cost function is affine and upper semicontinuous and $S(\mathrm{D})$ is weak* compact, the maximum is attained at an extreme point $\lambda^* \in S^*(\mathrm{D})$. By Lemma 5.4, $\lambda^* = \sum_{i=1}^p \lambda_{\omega_i} \delta_{\omega_i}$.

Let us take $\hat{\omega} = w_i$. From (18) we have

$$\Psi_G(z^k, d)_{\hat{\omega}} + \Xi(d, u_k)_\omega \geq \Psi_G(z^k, d)_{\hat{\omega}} - \Psi_G(z^k, d)_\omega + o(1),$$

with $o(1)$ uniform with respect to ω. Minimize the right-hand side first and then the left-hand side for $\omega \in B(\hat{\omega}, ru_k)$ to obtain

$$\Psi_G(z^k, d)_{\hat{\omega}} + \inf_{\omega \in B(\hat{\omega}, ru_k)} \Xi(d, u_k)_\omega \geq \Psi_G(z^k, d)_{\hat{\omega}} - \sup_{\omega \in B(\hat{\omega}, ru_k)} \Psi_G(z^k, d)_\omega + o(1).$$

Now if we fix $r > 0$, because $G'(x_0, 0)$ and $G''(x_0, 0)$ are Lipschitzian, using the fact that $u_k z^k \to 0$, we get

$$\Psi_G(z^k, d)_{\hat{\omega}} - \sup_{\omega \in B(\hat{\omega}, ru_k)} \Psi_G(z^k, d)_\omega \geq O(u_k)\|z^k\| + o(1) = o(1),$$

which combined with the previous estimate gives

$$\Psi_G(z^k, d)_{\hat{\omega}} + \inf_{\omega \in B(\hat{\omega}, ru_k)} \Xi(d, u_k)_\omega \geq o(1).$$

Invoking assumption $(\mathrm{H}_{\hat{\omega}})$, we may select $V \in \mathcal{N}(\hat{\omega}), r > 0$ such that

$$\liminf_{k \to +\infty} \Psi_G(z^k, d)_{\hat{\omega}} + \limsup_{u \downarrow 0} \inf_{\omega \in V} \Xi(d, u)_\omega \geq 0,$$

and therefore, by (10)

$$\liminf_{k \to +\infty} \Psi_G(z^k, d)_{\hat{\omega}} + \bar{\tau}_d(\hat{\omega}) \geq 0.$$

Combining this estimate with (14) and noting that $\lambda_{\omega_i} < 0$, we obtain (11) as required. □

6. Conclusion. Let us assume that the original problem (P_0) has a unique solution

$$S(0) = \{x_0\} \tag{H1}$$

and that we have the uniform boundedness of solutions:

$$\exists\, r > 0,\ u_0 > 0 \text{ such that for all } u \leq u_0,\ S(u) \neq \emptyset \text{ and } S(u) \subset B(0, r). \tag{H2}$$

THEOREM 6.1 (main result). *Let us assume* (H1), (H2), (DCQ), (QGC), (SOC), *and* $S(\mathrm{L}) \neq \emptyset$. *Suppose also that* $G(x_0, 0)$, $G'(x_0, 0)$, *and* $G''(x_0, 0)$ *are Lipschitz with respect to*

ω. Suppose finally that for each $d \in S(\mathrm{L})$ *there exists* $\text{e-lim}_{u \downarrow 0} \Xi(d, u)$ *and also that one of the following conditions holds:*

(i) Z_0 *is finite.*

(ii) Ω *is an interval, and* Z_0 *is the union of finitely many intervals.*

Then we have

(a) *The value function has first- and second-order (right) derivatives given by* $v'(0) = v(L)$, $v''(0) = v(Q)$. *Moreover, if* $v(Q) > -\infty$, *we have the expansion*

$$v(u) = v(0) + uv(L) + \frac{u^2}{2} v(Q) + o(u^2).$$

(b) *The set of all limit points of* $(x_u - x_0)/u$, *where* x_u *ranges over all paths of* $o(u^2)$*-optimal solutions, is included in* $S(\mathrm{Q})$. *In particular, if* $S(\mathrm{Q})$ *is a singleton, i.e.,* $S(\mathrm{Q}) = \{d\}$, *and* x_u *is as above, then* $x_u = x_0 + ud + o(u)$.

(c) *Let* $d \in S(Q)$. *If there exists* $z \in S(\mathrm{L}_d)$ *(this is always the case when* (i) *holds), then there exists an* $o(u^2)$*-optimal path* $x_u = x_0 + ud + o(u)$.

(d) *Let* λ_u *be a multiplier associated with a solution* x_u *of* (P_u). *Then all weak* limit points of* λ_u *belong to* $S(\mathrm{D})$.

Proof. From (H1) and (H2) there exists $x_u \in S(u)$ which satisfies $x_u \to x_0$ when $u \downarrow 0$. Then, from Proposition 4.1 we get $x_u = x_0 + O(u)$, and part (a) follows by combining Lemmas 5.1 and 5.5 with Corollary 5.3.

If x_u is a path of $o(u^2)$-optimal solutions, expanding $f(x_u, u)$ as in the proof of Lemma 5.6, we obtain the first statement in (b). The second statement is an immediate consequence of the first.

We now prove (c). Let $d \in S(\mathrm{Q})$ and $z \in S(\mathrm{L}_d)$. Then there exists a feasible path $x_u = x_0 + ud + \frac{u^2}{2} z + o(u^2)$. Expanding $f(x_u, u)$ and $G(x_u, u)$, we obtain $v(\mathrm{Q}) = \Psi_f(z, d)$ as well as (2). The conclusion follows.

Assertion (d) is a consequence of [4, Prop. 3.3]. □

Concluding remarks. Our final result is an extension to semi-infinite optimization of the results of the sequence of papers [8], [19], [2], and [6] in the following sense: if Ω is a finite set, then we exactly recover the above-mentioned results up to the presence of equality constraints. However, there is no difficulty in adding a finite number of equality constraints to our formulation. We avoided it for the sake of clarity of exposition and in order to concentrate on the real difficulty, which is to handle an infinite number of constraints.

Some of our hypotheses, however, may seem unduly strong. First of all, we assume that $S(\mathrm{L})$ is nonempty. While this hypothesis is automatically satisfied when the contact set is finite (due to the standard theory of linear programming), we are not aware of general criteria allowing to check nonemptyness of $S(\mathrm{L})$ for semi-infinite programming. Performing an analysis of the variation of the solutions when $S(\mathrm{L})$ is empty is an open problem. Some of the results of part II might be useful for dealing with this case.

The other hypothesis that seems excessively strong is the alternative (i) or (ii). We need it in order to satisfy the geometrical hypothesis $(\mathrm{H}_{\hat{\omega}})$. Still, the most important contribution of this paper is to present a new way of obtaining sharp lower estimates of the cost, and we hope that the technique presented here can be improved in order to deal with more general contact sets.

VISCOSITY SOLUTIONS AND VISCOSITY SUBDERIVATIVES IN SMOOTH BANACH SPACES WITH APPLICATIONS TO METRIC REGULARITY*

JONATHAN M. BORWEIN† AND QIJI J. ZHU‡

Abstract. In Gâteaux or bornologically differentiable spaces there are two natural generalizations of the concept of a Fréchet subderivative. In this paper we study the viscosity subderivative (which is the more robust of the two) and establish refined fuzzy sum rules for it in a smooth Banach space. These rules are applied to obtain comparison results for viscosity solutions of Hamilton–Jacobi equations in smooth spaces. A unified treatment of metric regularity in smooth spaces completes the paper. This illustrates the flexibility of viscosity subderivatives as a tool for analysis.

Key words. viscosity subderivative, fuzzy sum rule, viscosity solutions, Hamilton–Jacobi equations, smooth spaces, metric regularity

AMS subject classifications. 49J52, 49L25, 49J40, 49J50, 58C20

1. Introduction.

It is well known that the proximal limit formula for generalized derivatives plays a crucial role in Hilbert space nonsmooth and variational analysis. The reason is twofold: many properties of a nonsmooth function are determined by the (densely existing) proximal subderivatives, and proximal subderivatives are easier to handle than various other generalized derivatives. However, the proximal derivative concept depends crucially on the analysis of nearest points and, therefore, relies heavily on the inner product structure of the underlying space. Recent research [8, 10, 19] shows that, in fact, what is essential in this context is a "smooth" support function (rather than a nearest point) that corresponds to the "viscosity" (as opposed to the limit) subderivative concept. This makes it possible to do nonsmooth and variational analysis in smooth Banach spaces by using bornological subderivatives (compatible to the smoothness of the underlying space). Such a new technology is crucially important in studying problems on non–Fréchet-smooth spaces (see, for example, [10]).

One of the most important properties of the proximal subderivatives (and that of other generalized derivatives) is the sum rule. There is extensive research on this topic. We refer to Aubin and Frankowska [1], Clarke [11, 12], Deville and Haddad [20], Fabian [21], Ioffe [25, 26, 27, 28, 30], Jourani and Thibault [31], Kruger and Mordukhovich [32], Loewen [34], Mordukhovich [37], Mordukhovich and Shao [38], Rockafellar [41], Thibault [42], Ward and Borwein [43], and Warga [44, 45] and the references therein for sum rules for various generalized derivatives. The main purpose of this paper is to establish refined versions of the "fuzzy" sum rule given in [8] for viscosity bornological subderivatives and discuss its applications to viscosity solutions of Hamilton–Jacobi (HJ) equations and to the metric regularity problem. Roughly speaking, the major difference between our sum rules and that of [8] is the following observation: we can have certain control on the "size" of the bornological subderivatives in the sum. This observation is new even for sum rules in finite-dimensional spaces and is important for applications (e.g., in viscosity solution theory). A crucial tool in proving our "fuzzy" sum rules is the smooth variational principle proven in [9] that requires the underlying space to have a smooth equivalent norm. In most of the following results this condition can be weakened by using the smooth variational principle proven by Deville, Godefroy, and Zizler [18]: it suffices that the space has a smooth bump function.

Viscosity solutions were introduced by Crandall and Lions [15] to handle partial differential equations (in particular, HJ equations) that do not have any classical solution. Naturally the uniqueness of viscosity solution is one of the most important issues in the viscosity solution theory. The basic uniqueness result for finite-dimension problems was established in the pioneering paper of Crandall and Lions [15] and then developed in [13]. It is extended to Banach spaces with the Radon–Nikodým property in [16, part I]. In [19] and [20] uniqueness results are derived for HJ equations in smooth spaces with elegant short proofs using the smooth variational principle and fuzzy sum rules for viscosity subderivatives. However, the results in [19] and [20] require restrictive uniform continuity conditions to be imposed on the Hamiltonian. For HJ equations corresponding to optimal control problems involving general control equations, these uniform continuity conditions are not satisfied. By using our refined fuzzy sum rule we can prove a uniqueness theorem for an HJ equation under less restrictive conditions. It is applicable to infinite-horizon optimal control problems with a control equation that satisfies the usual Lipschitz condition in the state variable. We then apply this result to show that the value function of a class of infinite-horizon optimal control problems in a β-smooth space is the unique β-viscosity solution of the corresponding HJ equation. These results in particular applies to such a problem in L^1 which has a weak Hadamard smooth equivalent norm [6].

We also apply these fuzzy sum rules to give a unified treatment of metric regularity in smooth spaces. We prove a dual sufficient condition for metric regularity that is parallel to the dual conditions given in Ioffe [27] and Ginsburg and Ioffe [23] and deduce a primal condition that improves a similar condition in Borwein and Strojwas [5]. Then we show that various primal conditions discussed in [1, 2, 3, 5] can be deduced from our primary conditions. This illustrate the flexibility of viscosity subderivatives as a tool for analysis.

We introduce terminology and prove our refined fuzzy sum rules (Theorems 2.9–2.12) in §2. In §3 we discuss viscosity solutions to the HJ equations in smooth spaces, and in §4 we discuss metric regularity.

Finally let us remark that in bornologically differentiable spaces there are two natural generalizations of a Fréchet subderivative. It seems to us that in such spaces the viscosity subderivative (Definition 2.1) is usually the right generalization to use, rather than the limit definition.

2. Viscosity subderivatives and fuzzy sum formulae. Let X be a real Banach space with closed unit ball B and dual X^*. For a set S in X, we denote its diameter by $\operatorname{diam}(S) := \sup\{||x - y|| : x, y \in S\}$. A *bornology* β of X is a family of closed bounded and centrally symmetric subsets of X whose union is X, which is closed under multiplication by scalars and is directed upward (that is, the union of any two members of β is contained in some member of β). We will denote by X^*_β the dual space of X endowed with the topology of uniform convergence on β-sets. The most important bornologies are those formed by all (symmetric) bounded sets (the Fréchet bornology, denoted by F), weak compact sets (the weak Hadamard bornology, denoted by WH), compact sets (the Hadamard bornology, denoted by H), and finite sets (the Gâteaux bornology, denoted by G).

We will define a *convex bornology* as one that also contains all convex closures of the sets in the corresponding bornology. (In particular, any finite-dimensional subspace is included in the subspace spanned by some element of the convex bornology.) Note that the convex Gâteaux bornology lies strictly between the Gâteaux and Hadamard bornology, while for the Fréchet, weak Hadamard, and Hadamard bornologies the convex and nonconvex definitions are the same.

By a *function* we always mean an *extended-real-valued* function, usually lower (upper) semicontinuous and *proper* (that is to say, not everywhere equal to $+\infty$ ($-\infty$) and nowhere

equal to $-\infty$ ($+\infty$)). Given a function f on X, we say that f is β-differentiable at x and has a β-derivative $\nabla^\beta f(x)$ if $f(x)$ is finite and

$$t^{-1}(f(x+tu) - f(x) - t\langle \nabla^\beta f(x), u\rangle) \to 0$$

as $t \to 0$ uniformly in $u \in V$ for every $V \in \beta$. We say that a function f is β-smooth at x if $\nabla^\beta f : X \to X^*_\beta$ is continuous in a neighbourhood of x. It is not hard to check that a convex function f is β-smooth at x if and only if f is β-differentiable on a convex neighbourhood of x. Now we can define β-viscosity subderivatives and superderivatives.

DEFINITION 2.1. *Let f be a lower semicontinuous function and $f(x) < +\infty$. We say f is* β-viscosity subdifferentiable *and x^* is a* β-viscosity subderivative *of f at x if there exists a locally Lipschitz function g such that g is β-smooth at x, $\nabla^\beta g(x) = x^*$, and $f - g$ attains a local minimum at x. We denote the set of all β-viscosity subderivatives of f at x by $D_\beta f(x)$.*

Let f be a upper semicontinuous function and $f(x) > -\infty$. We say f is β-viscosity superdifferentiable *and x^* is a* β-viscosity superderivative *of f at x if there exists a locally Lipschitz function g such that g is β-smooth at x, $\nabla^\beta g(x) = x^*$, and $f - g$ attains a local maximum at x. We denote the set of all β-viscosity superderivatives of f at x by $D^\beta f(x)$.*

Remark 2.2. The concepts of viscosity subderivatives and superderivatives are introduced in [19] in slightly different forms where the β-smooth function g is required only to be upper semicontinuous and lower semicontinuous, respectively. We require g to be locally Lipschitz because it seems more convenient for applications.

Remark 2.3. By adding a constant we may always assume that the β-smooth function g in the above definition satisfies $g(x) = f(x)$.

Remark 2.4. The limit definition of the β-subdifferential $\partial_\beta f(x)$ of f at x is as follows: $x^* \in \partial_\beta f(x)$ if, for any $\varepsilon > 0$ and any $V \in \beta$, there exists a $\eta > 0$ such that

$$t^{-1}(f(x+th) - f(x)) - \langle x^*, h\rangle > -\varepsilon \quad \forall t \in (0, \eta),\ h \in V.$$

One can check that $D_\beta f(x) \subset \partial_\beta f(x)$. It is proven in [18] that $D_F f(x) = \partial_F f(x)$, provided that there exists a Lipschitz Fréchet-smooth bump function on X. However, the two concepts are different in general as shown by the following example.

Example 2.5. Let $f : R^n \to R$ ($n \geq 2$) be continuous, and suppose that f is Gâteaux but not Fréchet (weak Hadamard) differentiable at 0 (e.g., $f : R^2 \to R$ defined by $f(x, y) = xy^3/(x^2 + y^4)$ when $(x, y) \neq (0, 0)$ and $f(0, 0) = 0$ at point $(0, 0)$). Let $g(h) := -|f(h) - f(0) - \nabla^G f(0)h|$. Then g is locally uniformly continuous and

(1) $\partial_G g(0) = \{0\}$;

(2) $D_G g(0) = \emptyset$.

Proof. In fact, we can directly check that $\nabla^G g(0) = 0$; hence $\partial_G g(0) = \{0\}$. Since we always have $D_G g(0) \subset \partial_G g(0)$, either (2) is true or else $D_G g(0) = \{0\}$. In the latter case, there exists a locally Lipschitz and Gâteaux-differentiable (and therefore Fréchet-differentiable) function k such that $k(0) = g(0) = 0$, $\nabla^G k(0) = \nabla^G g(0) = 0$, and $k \leq g$ in a neighbourhood of 0. Thus,

$$\frac{|f(0+h) - f(0) - \nabla^G f(0)h|}{\|h\|} \leq -\frac{k(h) - k(0)}{\|h\|} \leq \frac{|k(h) - k(0)|}{\|h\|},$$

which implies that f is Fréchet differentiable at 0, a contradiction. □

DEFINITION 2.6 (see [8]). *Let $f_1, \ldots, f_N$ be lower semicontinuous functions and E be a closed subset of X. We say that $(f_1, \ldots, f_N)$ is* uniformly lower semicontinuous *on E if*

$$\inf_{x \in E} \sum_{n=1}^N f_n(x) \leq \liminf_{\varepsilon \to 0} \left\{ \sum_{n=1}^N f_n(x_n) : \|x_n - x_m\| \leq \varepsilon, x_n, x_m \in E, n, m = 1, \ldots, N \right\}.$$

We say that $(f_1, \dots, f_N)$ *is* locally uniformly lower semicontinuous *if, for any* $x \in \cap_{n=1}^N \operatorname{dom}(f_n)$, $(f_1, \dots, f_N)$ *is uniformly lower semicontinuous on a closed ball centered at* x.

The next useful proposition follows directly from the definition.

PROPOSITION 2.7. *Let* $(f_1, \dots, f_N)$ *be lower semicontinuous functions on* X *and* E *be a closed subset of* X. *Then the following conditions are sufficient for* $(f_1, \dots, f_N)$ *to be uniformly lower semicontinuous on* E:

1. *all but one of the functions are uniformly continuous on* E;
2. *one of the functions has compact level sets when restricted to* E;
3. X *is finite dimensional and* E *is bounded.*

The following lemma, first used in [8] in a different form, is an infinite-dimensional extension of the smooth penalization result [14, Lem. 3.1].

LEMMA 2.8. *Let* $(f_1, \dots, f_N)$ *be lower semicontinuous functions and* E *be a closed subset of* X. *Suppose that* $(f_1, \dots, f_N)$ *is uniformly lower semicontinuous on* E. *Define, for* $t > 0$,

$$M_t = \inf_{(x_1,\dots,x_N)\in E^N} \left[\sum_{n=1}^N f_n(x_n) + t \sum_{n,m=1}^N \|x_n - x_m\|^2 \right].$$

Assume that $(x_1^t, \dots, x_N^t)$ *satisfies*

$$\lim_{t\to\infty} \left(M_t - \left[\sum_{n=1}^N f_n(x_n^t) + t \sum_{n,m=1}^N \|x_n^t - x_m^t\|^2 \right] \right) = 0.$$

Then

(i) $\lim_{t\to\infty} t[\operatorname{diam}(\{x_1^t, \dots, x_N^t\})]^2 = 0$;

(ii) $\lim_{t\to\infty} M_t = \inf_{x\in E} \sum_{n=1}^N f_n(x)$.

Proof. Set

$$d_t := M_t - \left[\sum_{n=1}^N f_n(x_n^t) + t \sum_{n,m=1}^N \|x_n^t - x_m^t\|^2 \right].$$

Then $\lim_{t\to\infty} d_t = 0$. Evidently M_t increases with t and $M_t \le \inf_{x\in E} \sum_{n=1}^N f_n(x)$. Therefore, $M := \lim_{t\to\infty} M_t$ exists and $M \le \inf_{x\in E} \sum_{n=1}^N f_n(x)$. Moreover,

$$\begin{aligned} M_{t/2} &\le \sum_{n=1}^N f_n(x_n^t) + \frac{t}{2} \sum_{n,m=1}^N \|x_n^t - x_m^t\|^2 \\ &= \sum_{n=1}^N f_n(x_n^t) + t \sum_{n,m=1}^N \|x_n^t - x_m^t\|^2 - \frac{t}{2} \sum_{n,m=1}^N \|x_n^t - x_m^t\|^2 \\ &= M_t - d_t - \frac{t}{2} \sum_{n,m=1}^N \|x_n^t - x_m^t\|^2 \end{aligned}$$

or

$$2(M_t - M_{t/2} - d_t) \ge t \sum_{n,m=1}^N \|x_n^t - x_m^t\|^2 \ge t[\operatorname{diam}(\{x_1^t, \dots, x_N^t\})]^2.$$

Thus,

$$\lim_{t\to\infty} t[\operatorname{diam}(\{x_1^t, \dots, x_N^t\})]^2 = 0.$$

It remains to show that $M \geq \inf_{x\in E} \sum_{n=1}^N f_n(x)$. To do so, observe that $\|x_n^t - x_m^t\| \to 0$ when $t \to \infty$ and $(f_1, \ldots, f_N)$ is uniformly lower semicontinuous on E. Therefore,

$$M = \lim_{t\to\infty} \left(\sum_{n=1}^N f_n(x_n^t) + t \sum_{n,m=1}^N \|x_n^t - x_m^t\|^2 \right)$$
$$\geq \liminf_{t\to\infty} \sum_{n=1}^N f_n(x_n^t) \geq \inf_{x\in E} \sum_{n=1}^N f_n(x). \qquad \square$$

The next theorem is a refined fuzzy sum rule for the sum of several functions at its minimum. It refines [8, Prop. 4] in that it gives a bound for the β-subderivatives in the fuzzy sum. This bound is new even for fuzzy sum rules in finite-dimensional spaces and is important in application to the uniqueness result for HJ equations.

THEOREM 2.9. *Let X be a Banach space with an equivalent β-smooth norm and $f_1, \ldots, f_N$ be lower semicontinuous functions on X. Suppose that $(f_1, \ldots, f_N)$ is locally uniformly lower semicontinuous and $\sum_{n=1}^N f_n$ attains a local minimum at x. Then, for any $\varepsilon > 0$, there exist $x_n \in x + \varepsilon B$ and $x_n^* \in D_\beta f_n(x_n), n = 1, \ldots, N$, such that $|f_n(x_n) - f_n(x)| < \varepsilon$, $\|x_n^*\|\operatorname{diam}(\{x_1, \ldots, x_N\}) < \varepsilon, n = 1, 2, \ldots, N$, and*

$$\left\| \sum_{n=1}^N x_n^* \right\| < \varepsilon.$$

Proof. Let $\varepsilon > 0$ be given. Taking a smaller ε if necessary, we may assume that $(f_1, \ldots, f_N)$ is uniformly lower semicontinuous on $x+\varepsilon B$ and that $\sum_{n=1}^N f_n$ attains a minimum at x over $x + \varepsilon B$. Define

$$w_t(y_1, \ldots, y_N) := \sum_{n=1}^N f_n(y_n) + t \sum_{n,m=1}^N \|y_n - y_m\|^2.$$

Then, by Lemma 2.8,

$$\lim_{t\to\infty} \inf\{w_t(y_1, \ldots, y_N) : y_n \in x + \varepsilon B, n = 1, \ldots, N\}$$
$$= \inf_{y\in x+\varepsilon B} \sum_{n=1}^N f_n(y) = \sum_{n=1}^N f_n(x) = w_t(x, \ldots, x). \tag{1}$$

Choose $t_i \to \infty$ such that

$$w_{t_i}(x, \ldots, x) < \inf\{w_{t_i}(y_1, \ldots, y_N) : y_n \in x + \varepsilon B, n = 1, \ldots, N\} + \frac{\varepsilon^2}{Ni}.$$

Then by the Borwein–Preiss smooth variational principle [9], for each i there exist a β-smooth function ϕ_i and $x_n^i, n = 1, \ldots, N$, such that $w_{t_i} + \phi_i$ attains a local minimum at $(x_1^i, \ldots, x_N^i)$, $\|\nabla^\beta \phi_i\| < \varepsilon/N$, $\|x_n^i - x\| < \varepsilon/i$, and

$$w_{t_i}(x_1^i, \ldots, x_N^i) < \inf\{w_{t_i}(y_1, \ldots, y_N) : y_n \in x + \varepsilon B, n = 1, \ldots, N\} + \frac{\varepsilon^2}{Ni}. \tag{2}$$

For each n, the function

$$y \to w_{t_i}(x_1^i, \ldots, x_{n-1}^i, y, x_{n+1}^i, \ldots, x_N^i) + \phi_i(x_1^i, \ldots, x_{n-1}^i, y, x_{n+1}^i, \ldots, x_N^i)$$

attains a local minimum at $y = x_n^i$. Thus

$$x_{n_i}^* := -\nabla_{x_n}^{\beta} \phi_i(x_1^i, \ldots, x_N^i) - 2t_i \sum_{m=1}^{N} \nabla^{\beta} \|\cdot\|^2 (x_n^i - x_m^i) \in D_{\beta} f_n(x_n^i). \tag{3}$$

Summing $x_{n_i}^*$, $n = 1, \ldots, N$, yields

$$\sum_{n=1}^{N} x_{n_i}^* = -\sum_{n=1}^{N} \nabla_{x_n}^{\beta} \phi_i(x_1^i, \ldots, x_N^i) - 2t_i \sum_{n=1}^{N} \sum_{m=1}^{N} \nabla^{\beta} \|\cdot\|^2 (x_n^i - x_m^i).$$

Observing that $\| - \sum_{n=1}^{N} \nabla_{x_n}^{\beta} \phi_i(x_1^i, \ldots, x_N^i)\| \le \varepsilon$ and

$$\nabla^{\beta} \|\cdot\|^2 (x_n^i - x_m^i) + \nabla^{\beta} \|\cdot\|^2 (x_m^i - x_n^i) = 0$$

so that the double sum in the previous inclusion vanishes, we obtain

$$\left\| \sum_{n=1}^{N} x_{n_i}^* \right\| \le \varepsilon.$$

By (1) and (2)

$$\sum_{n=1}^{N} f_n(x) = \lim_{i \to \infty} \sum_{n=1}^{N} f_n(x_n^i).$$

Since f_n, $n = 1, \ldots, N$, are lower semicontinuous

$$\lim_{i \to \infty} f_n(x_n^i) = f_n(x), \quad n = 1, \ldots, N.$$

Moreover, Lemma 2.8 and (2) imply

$$\lim_{i \to \infty} t_i [\operatorname{diam}(\{x_1^i, \ldots, x_N^i\})]^2 = 0. \tag{4}$$

Since $\nabla^{\beta} \|\cdot\|^2(x)$ is bounded by $2\|x\|$, combining (4) and (3) yields

$$\lim_{i \to \infty} \|x_{n_i}^*\| \operatorname{diam}(\{x_1^i, \ldots, x_N^i\}) = 0 \quad \text{for } n = 1, \ldots, N.$$

Thus, when i is sufficiently large,

$$\|x_n^i - x\| < \varepsilon, \quad |f_n(x_n^i) - f_n(x)| < \varepsilon, \quad \text{and} \quad \|x_{n_i}^*\| \operatorname{diam}(\{x_1^i, \ldots, x_N^i\}) < \varepsilon$$

for $n = 1, 2, \ldots, N$. It remains to take $x_n = x_n^i$ and $x_n^* = x_{n_i}^*$, $n = 1, \ldots, N$. □

The next three theorems provide general forms of sum rules for β-viscosity subderivatives.

THEOREM 2.10. *Let X be a Banach space with an equivalent β-smooth norm. Let $f_1, \ldots, f_N$ be lower semicontinuous functions on X, with $x \in \cap_{n=1}^{N} \operatorname{dom}(f_n)$. Then, for any $x^* \in D_{\beta}(\sum_{n=1}^{N} f_n)(x)$, $\varepsilon > 0$, and any weak-star neighbourhood V of 0 in X^*, there exist $x_n \in x + \varepsilon B$, $x_n^* \in D_{\beta} f_n(x_n)$, $n = 1, \ldots, N$, such that $|f_n(x_n) - f_n(x)| < \varepsilon$, $\|x_n^*\| \operatorname{diam}(\{x_1, \ldots, x_N\}) < \varepsilon$, $n = 1, 2, \ldots, N$, and*

$$x^* \in \sum_{n=1}^{N} x_n^* + V.$$

Proof. Let $\varepsilon > 0$ and V be a weak-star neighbourhood of 0 in X^*. Fix $r > 0$, L a finite-dimensional subspace of X containing x, and V_β a β-neighbourhood of 0 in X^*_β such that $V_\beta + L^\perp + rB_{X^*} \subset V$. Since $x^* \in D_\beta(\sum_{n=1}^N f_n)(x)$, there exists a locally Lipschitz function g such that g is β smooth at x with $\nabla^\beta g(x) = x^*$ and $\sum_{n=1}^N f_n - g$ attains a local minimum at x. Choose $0 < \eta < \min(\varepsilon, r)$ such that $\|y - x\| < \eta < \varepsilon$ implies that $\nabla^\beta g(x) - \nabla^\beta g(y) \in V_\beta$, and let δ_L be the indicator function of L. Then $\sum_{n=1}^N f_n - g + \delta_L$ attains a local minimum at x. By Proposition 2.7 $(f_1, \ldots, f_N, -g, \delta_L)$ is locally uniformly lower semicontinuous. Applying Theorem 2.9 yields the existence of x_n, $n = 1, \ldots, N+2$, such that $\|x_n - x\| < \eta < \varepsilon, n = 1, \ldots, N+2, x_n^* \in D_\beta f(x_n), n = 1, \ldots, N, x_{N+1}^* = -\nabla^\beta g(x_{N+1})$, and $x_{N+2}^* \in D_\beta \delta_L(x_{N+2})$ satisfying the conclusion of Theorem 2.9, i.e., $|f_n(x_n) - f_n(x)| < \eta < \varepsilon$, $\|x_n^*\| \operatorname{diam}(\{x_1, \ldots, x_N\}) \le \|x_n^*\| \operatorname{diam}(\{x_1, \ldots, x_{N+2}\}) < \eta < \varepsilon$ for $n = 1, \ldots, N$, $|\delta_L(x_{N+2}) - \delta_L(x)| < \eta$, i.e., $x_{N+2} \in L$, and

$$\sum_{n=1}^N x_n^* - \nabla^\beta g(x_{N+1}) + x_{N+2}^* \in rB_{X^*}.$$

Note that $D_\beta \delta_L(x_{N+2}) = L^\perp$ and $x^* - \nabla^\beta g(x_{N+1}) \in V_\beta$. □

Using the method in [8], we can prove the following stronger result.

THEOREM 2.11. *Let β be a convex bornology and X be a Banach space with an equivalent β-smooth norm. Let $f_1, \ldots, f_N$ be lower semicontinuous functions and $x \in \cap_{n=1}^N \operatorname{dom}(f_n)$. Then, for any $x^* \in \partial_\beta(\sum_{n=1}^N f_n)(x)$, $\varepsilon > 0$, and any weak-star neighbourhood V of 0 in X^*, there exist $x_n \in x + \varepsilon B, x_n^* \in D_\beta f_n(x_n), n = 1, \ldots, N$, such that $|f_n(x_n) - f_n(x)| < \varepsilon$, $\|x_n^*\| \operatorname{diam}(\{x_1, \ldots, x_N\}) < \varepsilon, n = 1, 2, \ldots, N$, and*

$$x^* \in \sum_{n=1}^N x_n^* + V.$$

Proof. Let $\varepsilon > 0$ and V be a weak-star neighbourhood of 0 in X^*. Fix $r > 0$ and L a finite-dimensional subspace of X containing x such that $L^\perp + 2rB_{X^*} \subset V$. Let $x^* \in \partial_\beta(\sum_{n=1}^N f_n)(x)$. Then, for any $K \in \beta$,

$$\liminf_{t \to 0^+} \inf_{h \in tK} t^{-1} \left[\sum_{n=1}^N (f_n(x+h) - f_n(x)) - \langle x^*, h \rangle \right] \ge 0. \tag{5}$$

Choose a $K \in \beta$ containing the intersection of L with a ball around zero. Then (5) in particular implies that

$$\liminf_{t \to 0^+} \inf_{h \in tB \cap L} t^{-1} \left[\sum_{n=1}^N (f_n(x+h) - f_n(x)) - \langle x^*, h \rangle \right] \ge 0.$$

Since L is a finite-dimensional space, this is equivalent to

$$\liminf_{\|y-x\| \to 0} \inf_{y - x \in L} \|y - x\|^{-1} \left[\sum_{n=1}^N (f_n(y) - f_n(x)) - \langle x^*, y - x \rangle \right] \ge 0.$$

Thus, there exists $\eta < r$ such that the function

$$y \to \sum_{n=1}^N f_n(y) - \langle x^*, y \rangle + r\|y - x\| + \delta_L(y)$$

attains a minimum over $y \in x + \eta B$ at $y = x$.

By Proposition 2.7, the mapping $y \to (f_1(y), \dots, f_N(y), -\langle x^*, y\rangle, r\|y - x\|, \delta_L(y))$ is locally uniformly lower semicontinuous. Applying Theorem 2.9 yields that there exist $x_n, n = 1, \dots, N+3$, with $\|x_n - x\| < \eta < \varepsilon, n = 1, \dots, N+3$; $x_n^* \in D_\beta f(x_n), n = 1, \dots, N$; $x_{N+1}^* = -x^*$, $x_{N+2}^* \in rD_\beta\|x_{N+2} - x\|$, and $x_{N+3}^* \in D_\beta\delta_L(x_{N+3})$ such that $|f_n(x_n) - f_n(x)| < \eta < \varepsilon$, $\|x_n^*\|\text{diam}(\{x_1, \dots, x_N\}) \le \|x_n^*\|\text{diam}(\{x_1, \dots, x_{N+3}\}) < \eta < \varepsilon$ for $n = 1, \dots, N$, $|\delta_L(x_{N+3}) - \delta_L(x)| < \eta$, i.e., $x_{N+3} \in L$ and

$$\sum_{n=1}^{N} x_n^* - x^* + x_{N+2}^* + x_{N+3}^* \in rB_{X^*}.$$

Observing that $D_\beta\delta_L(x_{N+3}) = L^\perp$ and $rD_\beta\|x_{N+2} - x\| \subset rB_{X^*}$, we obtain

$$x^* \in \sum_{n=1}^{N} x_n^* + L^\perp + 2rB_{X^*} \subset \sum_{n=1}^{N} x_n^* + V. \qquad \square$$

THEOREM 2.12. *Let X be a Banach space with an equivalent β-smooth norm. Let $f_1, \dots, f_N$ be lower semicontinuous functions, with all but one of $f_n, n = 1, \dots, N$, locally uniformly continuous and $x \in \cap_{n=1}^N \text{dom}(f_n)$. Then, for any $x^* \in D_\beta(\sum_{n=1}^N f_n)(x)$, $\varepsilon > 0$, and any β-neighbourhood V of 0 in X_β^*, there exist $x_n \in x + \varepsilon B$, $x_n^* \in D_\beta f_n(x_n), n = 1, \dots, N$, such that $|f_n(x_n) - f_n(x)| < \varepsilon$, $\|x_n^*\|\text{diam}(\{x_1, \dots, x_N\}) < \varepsilon, n = 1, 2, \dots, N$, and*

$$x^* \in \sum_{n=1}^{N} x_n^* + V.$$

Proof. Let $\varepsilon > 0$ and V be a neighbourhood of 0 in X_β^*. Let $r > 0$, U be a neighbourhood of $0 \in X_\beta^*$ such that $U + rB_{X^*} \subset V$. Let $x^* \in D_\beta(\sum_{n=1}^N f_n)(x)$. Then there exists a β smooth function g such that $\nabla^\beta g(x) = x^*$ and $\sum_{n=1}^N f_n - g$ attains a local minimum at x. Choose $0 < \eta < \varepsilon$ such that $\|y - x\| < \eta < \varepsilon$ implies that $\nabla^\beta g(x) - \nabla^\beta g(y) \in U$. By Proposition 2.7 $(f_1, \dots, f_N, -g)$ is locally uniformly lower semicontinuous. Applying Theorem 2.9 yields that there exist $x_n, n = 1, \dots, N+1$, with $\|x_n - x\| < \eta < \varepsilon, n = 1, \dots, N+1$, $x_n^* \in D_\beta f_n(x_n), n = 1, \dots, N$, and $x_{N+1}^* = -\nabla^\beta g(x_{N+1})$ such that $|f_n(x_n) - f_n(x)| < \eta < \varepsilon$, $\|x_n^*\|\text{diam}(\{x_1, \dots, x_N\}) < \varepsilon, n = 1, \dots, N$, and

$$\left\| \sum_{n=1}^{N} x_n^* - \nabla^\beta g(x_{N+1}) \right\| < r.$$

Thus,

$$\begin{aligned} x^* &\in \sum_{n=1}^{N} x_n^* + \nabla^\beta g(x) - \nabla^\beta g(x_{N+1}) + rB_{X^*} \\ &\subset \sum_{n=1}^{N} x_n^* + U + rB_{X^*} \subset \sum_{n=1}^{N} x_n^* + V. \qquad \square \end{aligned}$$

Remark 2.13. As in [9] we call a lower semicontinuous function $f : X \to [-\infty, \infty]$ *s-Hölder subdifferentiable* at x ($s \in (0, 1]$) with subderivative $x^* \in X^*$ if f is finite at x and there exists a positive constant C_x such that

$$f(y) - f(x) - \langle x^*, y - x\rangle \ge -C_x\|y - x\|^{1+s}$$

for all y in a neighbourhood of x. We denote the set of s-Hölder subderivatives of f at x by $\partial^{H(s)} f(x)$. When $s = 1$, such subderivatives are called *Lipschitz smooth*, and in Hilbert space they coincide with Rockafellar's *proximal subderivatives*, written $\partial^{\pi} f(x)$ in [40]. Then all the above statements and proofs will still hold true in a Banach space with a power modulus of smoothness t^p [33] if we replace β with $H(p-1)$.

Remark 2.14. By the same argument as in [18, §VIII, Lem. 1.3] we can prove the following result.

LEMMA 2.15. *Let X be a Banach space that admits a bump function which is Lipschitzian and β-smooth. Then there exist a function $d : X \to R^+$ and a scalar $K > 1$ such that*

i) *d is bounded, Lipschitzian on X, and β-smooth on $X\backslash\{0\}$.*

ii) *$\|x\| \le d(x) \le K\|x\|$ if $\|x\| \le 1$ and $d(x) = 2$ if $\|x\| \ge 1$.*

Then, observing that we can replace the $\|\cdot\|^2$ term in Lemma 2.8 and Theorem 2.9 and their proofs with $d(\cdot)^2$ and using the Deville–Godefroy–Zizler smooth variational principle (cf. [18, 39]) in place of the Borwein–Preiss smooth variational principle, the condition that X has a β-smooth norm can be replaced by the weaker condition that X has a β-smooth Lipschitzian bump function.

Remark 2.16. Ioffe [25, 26] named Banach spaces that have the fuzzy sum rules for lower semicontinuous functions for the ε-Fréchet-subderivative and the ε-Dini-subderivative trustworthy (T) and weak trustworthy (WT) spaces, respectively. He proved that if a Banach space has a Fréchet- or Gâteaux-smooth norm, then it has property (T) or (WT). It is also known that (T) or (WT) is equivalent to the dense ε-Fréchet-subdifferentiability (S) or dense ε-Dini-subdifferentiability (WS) of lower semicontinuous functions [21]. In this spirit we will call a Banach space β-trustworthy (T_β) if it has the property stated in the conclusion of Theorem 2.10 (without requiring the bound on the β-subderivatives in the sum) and say that a Banach space is a (strong) dense β-subdifferentiability space if, for any lower semicontinuous function f, the set $((x, f(x)) \in \text{graph}(f))\, x \in \text{dom}(f)$ for which $D_\beta f(x) \neq \emptyset$ is dense in the (graph) domain of f. We will use notations S_β^+ and S_β for strong β-subdifferentiability and β-subdifferentiability spaces, respectively. We will denote the properties "has a β-smooth norm" and "has a β-smooth Lipschitz bump function" by H_β and H_β^-, respectively. Then Theorem 2.10 and Remark 2.14 tell us that $H_\beta \Longrightarrow H_\beta^- \Longrightarrow T_\beta$. It is obvious that $S_\beta^+ \Longrightarrow S_\beta$. Let f be a lower semicontinuous function in a T_β space. Then, for any $x \in \text{dom}(f)$, applying the T_β property to $f + \delta_{\{x\}}$ yields S_β^+. Therefore, we have

$$H_\beta \Longrightarrow H_\beta^- \Longrightarrow T_\beta \Longrightarrow S_\beta^+ \Longrightarrow S_\beta.$$

In [21] it is shown that $T \Longleftrightarrow S$ and $WT \Longleftrightarrow WS$. Using similar arguments we can show that $T_\beta \Longleftrightarrow S_\beta^+$. However, it is not clear if $S_\beta \Longleftrightarrow S_\beta^+$. Since conditions H_β and H_β^- are easier to check than S_β and S_β^+ and can yield a bound on the β-subderivatives in the fuzzy sum, we will not pursue this topic further here.

Adapting the arguments in [7, 8] and using Theorem 2.9 we can obtain corresponding viscosity versions of the sequential limit formulae for the g-subdifferential of a function and the g-normal cone of a closed set. In the following theorems, ∂_g, ∂_c, N_g, and N_c signify the g-subdifferential, Clarke generalized gradient, g-normal cone, and Clarke normal cone, respectively, and we refer the reader to [8] and the references therein for their definitions.

THEOREM 2.17. *Let X be a Banach space with an equivalent β-smooth norm. Let f be a lower semicontinuous proper function on X. Then for any $x \in X$*

$$\partial_g f(x) = \text{cl}^* \bigcup_{k=1}^{\infty} \{\text{w}^* - \lim_{n\to\infty} x_n^* : x_n^* \in D_\beta^k f(x_n),\ x_n \to_f x\}$$

and

$$\partial_c f(x) = \mathrm{cl}^* co \bigcup_{k=1}^{\infty} \{w^* - \lim_{n\to\infty} x_n^* : x_n^* \in D_\beta^k f(x_n),\ x_n \to_f x\} + \partial_c^\infty f(x).$$

where $D_\beta^k f(x)$ is the subset of $D_\beta f(x)$ for which the support function in the definition has a Lipschitz constant no greater than k.

THEOREM 2.18. *Let X be a Banach space with an equivalent β-smooth norm. Let S be a closed subset of X. Then for any $x \in S$*

$$N_g(S, x) = \mathrm{cl}^* \bigcup_{k=1}^{\infty} \{w^* - \lim_{n\to\infty} x_n^* : x_n^* \in kD_\beta d(S, x_n),\ x_n \to_S x\}$$

and

$$N_c(S, x) = \mathrm{cl}^* co \bigcup_{k=1}^{\infty} \{w^* - \lim_{n\to\infty} x_n^* : x_n^* \in kD_\beta d(S, x_n),\ x_n \to_S x\}.$$

In the following discussion we will use the formulae given in the above theorems as equivalent definitions for the g-normal cone in a β-smooth space. These formulae also have corresponding s-Hölder versions. For details see [10].

3. Viscosity solutions to HJ equations. Consider the partial differential equation

$$F(x, u, Du) = 0. \tag{6}$$

This equation encompasses the usual HJ equation associated with the optimal value function of certain optimal control problems. In general, (6) does not have a classical solution. Viscosity solutions were introduced by Crandall and Lions [15] to replace classical solutions. The original definition of viscosity solutions (cf. [15, 16]) is based on the Fréchet-subderivative. In [19], β-viscosity solutions are defined for problems on non–Fréchet-smooth spaces. We recall this definition below.

DEFINITION 3.1 (see [19]). *Let X be a Banach space with an equivalent β-smooth norm. A function $u : X \to R$ is a* β-viscosity subsolution *of* (6) *if u is upper semicontinuous and, for every $x \in X$ and every $x^* \in D^\beta u(x)$,*

$$F(x, u(x), x^*) \le 0.$$

A function $u : X \to R$ is a β-viscosity supersolution *of* (6) *if u is lower semicontinuous and, for every $x \in X$ and every $x^* \in D_\beta u(x)$,*

$$F(x, u(x), x^*) \ge 0.$$

A continuous function u is called a β-viscosity solution *if u is both a β-viscosity subsolution and a β-viscosity supersolution.*

Now we prove the main result of this section.

THEOREM 3.2. *Let X be a Banach space with an equivalent β-smooth norm. Suppose that $\gamma > 0$, $F(x, u, x^*) = \gamma u + H(x, x^*)$, and $H : X \times X_\beta^* \to R$ satisfy the following assumption:*

(A) *for any $x_1, x_2 \in X$ and $x_1^*, x_2^* \in X_\beta^*$,*

$$|H(x_1, x_1^*) - H(x_2, x_2^*)| \le \omega(x_1 - x_2, x_1^* - x_2^*) + M \max(||x_1^*||, ||x_2^*||)||x_1 - x_2||,$$

where $M > 0$ is a constant and $\omega : X \times X_\beta^* \to R$ is a continuous function with $\omega(0, 0) = 0$.

Let u and v be two uniformly continuous functions such that v is bounded below and u is bounded above. If u is a β-viscosity subsolution of (6) *and v is a β-viscosity supersolution of* (6), *then $u \le v$.*

Proof. Let $\varepsilon > 0$ be an arbitrary positive number. By assumption (A) there exist $\eta \in (0, \varepsilon)$ and a neighbourhood V of 0 in X_β^* such that $\|x_1 - x_2\| < 2\eta$ and $x_1^* - x_2^* \in V$ implies that

$$|H(x_1, x_1^*) - H(x_2, x_2^*)| < \varepsilon + M \max(||x_1^*||, ||x_2^*||)||x_1 - x_2||.$$

The function $v - u$ is uniformly continuous and bounded below. By the smooth variational principle there exist $x \in X$ and $x^* \in D_\beta(v-u)(x)$ such that $x^* + \frac{1}{2}V \subset V$ and $(v-u)(x) < \inf_X(v-u) + \varepsilon$. By Theorem 2.12 with $f_1 = v$ and $f_2 = -u$, there exist $x_1, x_2 \in X$, $x_1^* \in D_\beta v(x_1)$, and $x_2^* \in D^\beta u(x_2)$ satisfying

(i) $\|x_1 - x\| < \eta$ and $\|x_2 - x\| < \eta$;
(ii) $|v(x_1) - v(x)| < \varepsilon$ and $|u(x_2) - u(x)| < \varepsilon$;
(iii) $||x_1^*||||x_1 - x_2|| < \varepsilon$ and $||x_2^*||||x_1 - x_2|| < \varepsilon$;
(iv) $x_1^* - x_2^* - x^* \in \frac{1}{2}V$.

Since the function u is a viscosity subsolution of (6) we have

$$F(x_1, u(x_1), x_1^*) = \gamma u(x_1) + H(x_1, x_1^*) \le 0.$$

Similarly

$$F(x_2, v(x_2), x_2^*) = \gamma v(x_2) + H(x_2, x_2^*) \ge 0.$$

Therefore, observing that $||x_1 - x_2|| < 2\eta$ and $x_1^* - x_2^* \in V$,

$$\begin{aligned}\inf_X(v-u) &> (v-u)(x) - \varepsilon > v(x_2) - u(x_1) - 3\varepsilon \\ &\ge \gamma^{-1}[H(x_1, x_1^*) - H(x_2, x_2^*)] - 3\varepsilon \\ &\ge -\gamma^{-1}[\varepsilon + M \max(||x_1^*||, ||x_2^*||)||x_1 - x_2||] - 3\varepsilon \\ &\ge -[\gamma^{-1}(1+M) + 3]\varepsilon.\end{aligned}$$

As ε is arbitrary, $\inf_X(v-u) \ge 0$. □

COROLLARY 3.3. *Under the assumptions of Theorem* 3.2 *any uniformly continuous bounded β-viscosity solution to* (6) *is unique.*

Remark 3.4. Condition (A) is significantly weaker than the uniform continuity conditions imposed in [19, 20]. This allows us to apply Corollary 3.3 to the HJ equation corresponding to a general optimal control problem $P(x)$ in the sequel. In [16, part I], a uniqueness result is established for HJ equations in Banach spaces with the Radon–Nikodým property under somewhat weaker (but rather technical) conditions. How much we can weaken our requirements for the Hamiltonian in a β-smooth space is an interesting problem that we will not pursue further in this paper.

Remark 3.5. Definition 3.1 is slightly different from the original definition in [19] in that we require X to be β-smooth. We make this modification to avoid the following pathological examples.

Example 3.6. Let X be a β'-differentiable Banach space with a nowhere β-differentiable norm $\|\cdot\|$. Consider the case of (6) where F is the constant function 1. Then obviously this equation does not have any β'-viscosity solution, but $u(x) = (\|x\| + 2)/(\|x\| + 1)$ is a uniformly continuous bounded β-viscosity solution in the sense of [19, Def. III.2]. To see this, observe that u is trivially a supersolution. Since $u(x)$ is convex and nowhere β-differentiable

(otherwise $\|x\| = (2 - u(x))/(u(x) - 1)$ would be β-differentiable), $D^\beta u(x) = \emptyset$ for all $x \in X$. Thus, u is also a β-viscosity subsolution and, therefore, a β-viscosity solution in the sense of [19, Def. III.2].

Example 3.7. In Banach space X consider

$$V(x) + \|DV(x)\| = 0. \tag{7}$$

Assume that the norm $\|\cdot\|$ of X is nowhere β-differentiable and X has an equivalent β'-smooth norm. Then, in the sense of [19, Def. III.2],

1. $V = 0$ is the unique uniformly continuous bounded β'-viscosity solution of (7);
2. $V(x) = (\|x\| + 2)/(\|x\| + 1)$ is a uniformly continuous bounded β-viscosity solution of (7).

Proof. Step 1. If V is a uniformly continuous bounded β'-viscosity solution of (7), then u is nonnegative. In fact, if $-\Delta = \inf_X V < 0$, then since X has an equivalent β'-smooth norm, by the Borwein–Preiss smooth variational principle, there exists an $x \in X$ and a $p \in X^*$ such that

$$V(x) < \inf_X V + \frac{\Delta}{2}$$

and

$$p \in D_{\beta'} V(x), \quad \|p\| < \frac{\Delta}{2}.$$

This implies

$$V(x) + \|p\| < 0$$

so that V is not a β'-viscosity supersolution of (7), which is absurd.

Step 2. If V is a nonnegative β'-viscosity solution of (7), then V is a nonnegative β'-viscosity subsolution of (7). Thus, $D^{\beta'} V(x) = \{0\}$ whenever it is nonempty. By [10, Thm. 6.3] u is a constant. It is then obvious that V must be the zero function. This completes the proof of 1.

Step 3. We prove 2. It is trivial to observe that $V(x) = (\|x\|+2)/(\|x\|+1)$ is a β-viscosity supersolution of (7). Since $V(x)$ is convex and nowhere β-differentiable, $D^\beta V(x) = \emptyset$ for all $x \in X$. Thus, V is also a β-viscosity subsolution and, therefore, a β-viscosity solution of (7) according to [19, Def. III.2]. □

Note that (7) is the HJ equation corresponding to the optimal control problem

$$\text{minimize } J(x, u) := \int_0^\infty e^{-s} f(x(s), u(s)) ds$$

$$\text{subject to } \dot{x}(s) = u(s),$$

$$x(0) = x, \ u(s) \in B_X,$$

with $f = 0$. Since the optimal value function for this problem is identically 0, it is reasonable to expect 0 to be the unique viscosity solution of (7). Thus, it is reasonable to require X to be β-smooth in the definition of β-viscosity solutions.

As concrete examples of the spaces in Examples 3.6 and 3.7,

a. the sup norm of $C[0, 1]$ is Gâteaux smooth but nowhere weak Hadamard differentiable [6].

b. $L_1[0, 1]$ or $l_1(N)$ has an equivalent weak Hadamard smooth norm [6] but is not Asplund and, therefore, has a nowhere Fréchet-differentiable norm. Moreover, $L_1[0, 1]$ fails to have the Radon–Nikodým property.

Remark 3.8. Let X be a Banach space with a β-smooth equivalent norm. Then this norm is also β'-smooth for any $\beta' \subset \beta$. Thus, in Theorem 3.2 and Corollary 3.3 we can always reduce the requirement on the smoothness of the space by using a smaller bornology. However, the price to pay is that we have to impose stronger continuity conditions on F.

Let X be a Banach space with a β-smooth norm and U be a metric space. We now consider the following optimal control problem in X:

$$P(x): \quad \text{minimize } J(x, u) := \int_0^\infty e^{-\gamma s} f(x(s), u(s))ds$$
$$\text{subject to } \dot{x}(s) = g(x(s), u(s)),$$
$$x(0) = x, \ u \in \mathcal{U},$$

where $g : X \times U \to R$ is continuous and Lipschitz in x uniformly in U and there exists $K \in \beta$ such that $g(x, U) \subset K$ for all $x \in X$, $f : X \times U \to R$ is continuous, bounded, continuous in x uniformly in U, and

$$\mathcal{U} := \{u : u \text{ is measurable and } u(t) \in U \text{ for } t \in [0, \infty) \text{ a. e.}\}.$$

Under our assumptions, for given $x \in X$ and $u \in \mathcal{U}$, $\dot{x}(s) = g(x(s), u(s))$, $x(0) = x$ has a unique solution defined on $[0, \infty)$, denoted by $x(s, x, u)$.

Since f is bounded, the problem is well defined. We denote the value function of $P(x)$ by $V(x)$. Then we have the following.

THEOREM 3.9 (dynamic programming principle). *For any $t > 0$,*

$$V(x) = \inf_{u \in \mathcal{U}} \left\{ \int_0^t e^{-\gamma s} f(x(s, x, u), u(s))ds + e^{-\gamma t} V(x(t, x, u)) \right\}.$$

This theorem is standard; for a proof see, for example, [22].

Define $H : X \times X^* \to R$ by

$$H(x, p) = \sup_{u \in U} \{-\langle p, g(x, u)\rangle - f(x, u)\}.$$

We prove the following theorem.

THEOREM 3.10. *V is the unique β-viscosity solution of the HJ equation*

$$\gamma V(x) + H(x, DV(x)) = 0. \tag{8}$$

Proof. Since f is bounded, so is V. Using Gronwall's inequality, since f is continuous in x uniformly in U, we can show that V is uniformly continuous. One can directly check that $H(x, p)$ satisfies assumption (A). Therefore, uniqueness is a direct consequence of Corollary 3.3. We need only to show that V is a β-viscosity solution of (8).

a. Subsolution. Let y be an element of X such that $p \in D^\beta V(y)$. Then there exists a β-smooth locally Lipschitz function w such that $\nabla^\beta w(y) = p$, y is a (local) maximum of $V - w$, and $0 = (V - w)(y)$. Note that w depends only on y and p and is fixed in the subsequent discussion. By the dynamic programming principle, for any $u \in \mathcal{U}$ and $t > 0$,

$$w(y) = V(y) \le \int_0^t e^{-\gamma s} f(x(s, y, u), u(s))ds + e^{-\gamma t} V(x(t, y, u)). \tag{9}$$

Since w is β-smooth and locally Lipschitz at x, there exists $\eta > 0$ such that w is Lipschitz and $\nabla^\beta w$ exist in $y + \eta B$. Therefore, w is at least Hadamard differentiable and $\nabla^\beta w = \nabla^H w$ in $y + \eta B$. Observing that $\{x(s, y, u) : s \in [0, 1]\}$ is compact, when $t > 0$ is sufficiently small, we have

$$\frac{d}{dt}[e^{-\gamma t} w(x(t, y, u))] = -e^{-\gamma t}\gamma w(x(t, y, u)) + e^{-\gamma t}\langle \nabla^\beta w(x(t, y, u)), g(x(t, y, u), u(t))\rangle.$$

Thus, we can write (9) as

$$t^{-1}\int_0^t e^{-\gamma s}[\gamma w(x(s, y, u)) - \langle \nabla^\beta w(x(s, y, u)), g(x(s, y, u), u(s))\rangle - f(x(s, y, u), u(s))]ds \le 0.$$

Fixing an arbitrary $v \in U$ and setting $u(s) = v$ for all $s \in [0, t]$ yield

$$t^{-1}\int_0^t e^{-\gamma s}[\gamma w(x(s, y, u)) - \langle \nabla^\beta w(x(s, y, u)), g(x(s, y, u), v)\rangle - f(x(s, y, u), v)]ds \le 0.$$

Taking limits when $t \to 0$, observing that the integrand is continuous in s and $x(0, y, u) = y$, we obtain

$$\gamma V(y) - \langle p, g(y, v)\rangle - f(y, v) = \gamma w(y) - \langle \nabla^\beta w(y), g(y, v)\rangle - f(y, v) \le 0.$$

Therefore,

$$\gamma V(y) + H(y, p) \le 0,$$

that is to say, V is a β-viscosity subsolution of (8).

b. Supersolution. Now let y be an element of X such that $p \in D_\beta V(y)$. Then there exists a β-smooth function w such that $\nabla^\beta w(y) = p$, y is a (local) minimum of $V - w$, and $0 = (V - w)(y)$. By the dynamic programming principle, for each integer i, there exists $u^i \in \mathcal{U}$ such that

$$w(y) + \frac{1}{i^2} = V(y) + \frac{1}{i^2} \ge \int_0^{1/i} e^{-\gamma s} f(x(s, y, u^i), u^i(s))ds + e^{-\gamma/i} V\left(x\left(\frac{1}{i}, y, u^i\right)\right). \tag{10}$$

Arguments similar to those in the previous paragraph yield

$$\frac{1}{i} + i\int_0^{1/i} e^{-\gamma s}[\gamma w(x(s, y, u^i)) - \langle \nabla^\beta w(x(s, y, u^i)), g(x(s, y, u^i), u^i(s))\rangle - f(x(s, y, u^i), u^i(s))]ds \ge 0.$$

We rewrite this inequality as

$$\gamma w(y) + i\int_0^{1/i} [-\langle \nabla^\beta w(y), g(y, u^i(s))\rangle - f(y, u^i(s))]ds \ge h(i),$$

where

$$h(i) = -\frac{1}{i} + h_1(i) + h_2(i) + h_3(i)$$

and the h_j's are defined as follows:

$$h_1(i) := \gamma w(y) - i\int_0^{1/i} e^{-\gamma s}\gamma w(x(s, y, u^i))ds,$$

$$h_2(i) := i \int_0^{1/i} [e^{-\gamma s} \langle \nabla^\beta w(x(s, y, u^i)), g(x(s, y, u^i), u^i(s)) \rangle - \langle \nabla^\beta w(y), g(y, u^i(s)) \rangle] ds,$$

and

$$h_3(i) := i \int_0^{1/i} [e^{-\gamma s} f(x(s, y, u^i), u^i(s)) - f(y, u^i(s))] ds.$$

It is obvious that

$$-\langle \nabla^\beta w(y), g(y, u^i(s)) \rangle - f(y, u^i(s)) \leq H(y, p)$$

and, therefore,

$$\gamma V(y) + H(y, p) \geq h(i). \tag{11}$$

Since

$$\sup \left\{ \|x(s, y, u^i) - y\| : s \in \left[0, \frac{1}{i}\right] \right\} \to 0$$

when $i \to \infty$, $\lim_{i\to\infty} h_1(i) = \lim_{i\to\infty} h_3(i) = 0$. Observing that g is Lipschitz in x uniformly in U and $g(y, u^i(s))$ is in the β-set K, the β-smoothness of w at y yields $\lim_{i\to\infty} h_2(i) = 0$. Therefore, $\lim_{i\to\infty} h(i) = 0$. Sending i to infinity in (11), we obtain that V is a β-viscosity supersolution of (8) and, hence, a β-viscosity solution of (8). □

4. Metric regularity. Metric regularity is closely related to the open mapping property and plays an important role in studying exact penalization and necessary conditions for constrained minimization problems. In this section we apply the fuzzy sum rules derived in §2 to derive a necessary condition for metric regularity to fail; contraposition produces a sufficient condition for a function to be metrically regular at a given point. We deduce a dual condition parallel to the dual conditions given in Ioffe [27] and Ginsburg and Ioffe [23] and a β-smooth space version of the primal condition discussed in Borwein and Strojwas [5]. Many authors have discussed primal sufficient conditions. The condition that we give below (Theorem 4.9) appears to be the weakest (in β-smooth spaces) up to now. Various primal conditions discussed in [1, 2, 3, 5] are deduced as corollaries. To avoid complications in the notations we consider metric regularity for a single-valued function with respect to a closed set. This is in fact an entirely general formulation (see [1] and [29]). There are many discussions about regularity of multifunctions (see, for example, [31, 35] and the references therein). We will indicate at the end of this section how to handle multifunctions with our results. We recall the following definition of metric regularity.

DEFINITION 4.1. *Let X and Y be Banach spaces. One says that $h : X \to Y$ is* regular with respect to S at x_0 *if there exist positive constants ε and K such that, for all $x \in S \cap (x_0 + \varepsilon B)$ and $\xi \in h(x_0) + \varepsilon B$,*

$$d(x, S \cap h^{-1}(\xi)) \leq K \|h(x) - \xi\|.$$

DEFINITION 4.2. *Let X and Y be Banach spaces with β-smooth norms, S be a closed subset of X, and $h : X \to Y$ be differentiable at x_0. We say that x_0 is an* extremal with respect to (h, S) *if, for any $\eta > 0$, there exist a unit vector y^*, $y \in (x_0 + \eta B) \cap S$, and a constant L such that*

$$0 \in (\nabla h(x_0))^* y^* + L D_\beta d(y, S) + \eta B_{X^*}.$$

The next theorem shows that a function is not metrically regular at a point corresponding to the fuzzy extremal condition described above at the given point. The essential part of the proof is an application of the Ekeland variational principle that was first introduced in [24] for handling metric regularity problems and now becomes quite standard. Before stating the theorem, let us recall that a mapping $f : X \to Y$ is called strictly differentiable at x, provided that f is (Fréchet) differentiable at x, for each v,

$$\lim_{x' \to x, t \to 0^+} \left\| \frac{f(x' + tv) - f(x')}{t} - \langle \nabla f(x), v \rangle \right\| = 0,$$

and the convergence is uniform for $v \in B_X$. Note that f is strictly differentiable at x implies that f is locally Lipschitz at x.

THEOREM 4.3. *Let X and Y be Banach spaces with β-smooth norms, S be a closed subset of X, and $x_0 \in S$. Assume that $h : X \to Y$ is strictly differentiable at x_0. Then h is not regular with respect to S at x_0 implies that x_0 is an extremal with respect to (h, S).*

Proof. Let η be an arbitrary positive constant in $(0, 1)$. Since h is strictly differentiable at x_0, for any $d \in B_X$, there exists $\eta_1 < \eta/4$ such that $\|x - x_0\| < \eta_1$ and $t \in (0, \eta_1)$ implies that

$$\frac{h(x + td) - h(x)}{t} - \nabla h(x_0)d \in \frac{\eta}{2} B_Y \tag{12}$$

and

$$\|h(x) - h(x_0)\| < \frac{\eta^2}{128}.$$

Suppose h is not regular with respect to S at x_0. Then there exist an $s \in S \cap (x_0 + \frac{\eta_1}{4} B)$ and a $\xi \in h(x_0) + \frac{\eta^2}{128} B$ such that

$$d(s, S \cap h^{-1}(\xi)) > \frac{1}{\eta} ||h(s) - \xi||. \tag{13}$$

By inequality (13) $d(s, S \cap h^{-1}(\xi)) > 0$ and, therefore, $\|h(s) - \xi\| > 0$. Apply Ekeland's principle with

$$f(x) := ||h(x) - \xi||, \qquad \varepsilon := ||h(s) - \xi|| \leq \frac{\eta^2}{64},$$

$$\lambda := \frac{\eta}{8}, \qquad \bar{x} := s.$$

Then there exist $v \in S$ such that

1. $||s - v|| \leq \frac{\eta}{8}$.
2. v minimizes

$$x \to ||h(x) - \xi|| + \frac{\varepsilon}{\lambda} ||x - v||$$

on S.

Since h is strictly differentiable at x_0, it is locally Lipschitz at x_0. Let L' be a local Lipschitz constant for h at x_0. Then $L := L' + 1$ is a local Lipschitz constant for $x \to ||h(x)|| + \frac{\varepsilon}{\lambda} ||x - v||$. Thus, using the penalization result of Clarke [11] we have

2′. v locally minimizes

$$x \to ||h(x) - \xi|| + \frac{\varepsilon}{\lambda}||x - v|| + L \cdot d(x, S).$$

By Theorem 2.9 there exist y, z, and w such that

$$\begin{aligned} 0 &\in D_\beta||h(\cdot) - \xi||(y) + \frac{\varepsilon}{\lambda}D_\beta||w - v|| + LD_\beta d(z, S) + \frac{\eta}{8}B_{X^*} \\ &\subset D_\beta||h(\cdot) - \xi||(y) + LD_\beta d(z, S) + \frac{\eta}{4}B_{X^*}, \end{aligned} \tag{14}$$

where $\|y - v\| < \frac{\eta_1}{4}$ and $\|z - v\| < \frac{\eta_1}{4}$ and, therefore, $\|y - x_0\| < \eta_1$ and $\|z - x_0\| < \eta_1$. Without loss of generality we may assume that y were chosen close enough to s such that $\|h(y) - \xi\| > 0$. Then, for any $d \in B$, when t is small enough, $y_t^*(d) := \nabla^\beta||.||(h(y+td)-\xi)$ exists. Since $\|y_t^*(d)\| = 1$, by (12), for any $d \in B_X$, when t is sufficiently small,

$$\begin{aligned} \frac{\eta}{2} &\geq \left\langle y_t^*(d), \frac{h(y + td) - h(y)}{t} - \nabla h(x_0)d \right\rangle \\ &= \left\langle y_t^*(d), \frac{(h(y + td) - \xi) - (h(y) - \xi)}{t} \right\rangle - \langle y_t^*(d), \nabla h(x_0)d \rangle \\ &\geq \frac{||h(y + td) - \xi|| - ||h(y) - \xi||}{t} - \langle y_t^*(d), \nabla h(x_0)d \rangle. \end{aligned} \tag{15}$$

By inclusion (14) there exists $z^* \in LD_\beta d(z, S)$ such that $z^* = -u^* + v^*$, where $u^* \in D_\beta||h(.) - \xi||(y)$ and $v^* \in \frac{\eta}{4}B_{X^*}$. Observe that, for a fixed d, there exists a t_d such that when $t \in (0, t_d)$,

$$\frac{||h(y + td) - \xi|| - ||h(y) - \xi||}{t} > \langle u^*, d \rangle - \frac{\eta}{4} \geq \langle z^*, d \rangle - \frac{\eta}{2}.$$

Combining this with (15) we obtain that when $t \in (0, t_d)$

$$\eta \geq -\langle y_t^*(d), \nabla h(x_0)d \rangle - \langle z^*, d \rangle.$$

Denote $y^* = \nabla^\beta||.||(h(y) - \xi)$. Then $y_t^*(d) = \nabla^\beta||.||(h(y + td) - \xi) \rightharpoonup_{w^*} y^*$ as $t \to 0^+$ and $||y^*|| = 1$. (In fact, $y_t^*(d)$ converges to y^* in Y_β^*.) Taking limits in the above inequality as $t \to 0^+$ yields

$$\eta \geq -\langle y^*, \nabla h(x_0)d \rangle - \langle z^*, d \rangle.$$

Since this is true for all $d \in B$, we obtain

$$(\nabla h(x_0))^* y^* + z^* \in \eta B_{X^*}$$

or

$$0 \in (\nabla h(x_0))^* y^* + LD_\beta d(y, S) + \eta B_{X^*},$$

as was to be shown. □

We now turn to some sufficient conditions for h to be regular with respect to S at x_0. We consider a dual condition first. To do so we need the following definitions.

DEFINITION 4.4. *Let X be a Banach space with a β-smooth norm and S be a closed subset of X. We define the* β-normal cone (*denoted by $N_\beta(x, S)$*) *and the* β-tangent cone (*denoted by $T_\beta(x, S)$*) *of S at $x \in S$ by*

$$N_\beta(x, S) := \bigcup_{L>0} L \cdot D_\beta d\,(x, S)$$

and

$$T_\beta(x, S) := (N_\beta(x, S))^0.$$

Here we adopt the convention that $(\emptyset)^0 = X$.

Remark 4.5. Recall that the contingent cone $T_b(x, S)$ and the Clarke tangent cone $T_c(x, S)$ of S at $x \in S$ are defined by

$$T_b(x, S) := \left\{u : \liminf_{t\to 0^+} \frac{d(x + tu, S)}{t} = 0\right\}$$

and

$$T_c(x, S) := \left\{u : \limsup_{t\to 0^+, y\to x} \frac{d(y + tu, S)}{t} = 0\right\},$$

respectively. It is easy to see that $T_c(x, S) \subset T_b(x, S) \subset T_\beta(x, S)$ for any bornology β. Note also that $N_\beta(x, S)$ need not be closed. Also, it is known [8] that $T_c(x, S) = (N_g(x, S))^0$.

The next definition is a β-normal version of the finite-codimension condition defined in [23]. In a β-smooth space this condition is less restrictive than the definition in [23].

DEFINITION 4.6. *Let X be a Banach space with an equivalent β-smooth norm and Y be a Banach space. We say that $f : X \to Y$ has the* β-finite codimension property *with respect to S at x_0 if there is a weak-star closed subspace $V^* \subset Y^*$ of finite codimension and constants $\varepsilon, c > 0$ such that if*

(1) $x \in S$ *and* $\|x - x_0\| < \varepsilon$,

(2) $x^* \in N_\beta(x, S)$,

(3) $\|y^*\| = 1, d(y^*, V^*) < \varepsilon$,

then

$$\|(\nabla f(x_0))^* y^* + x^*\| \geq c.$$

The next theorem can be deduced from [23, Thm. 2.7]. We give a self-contained proof by using Theorem 4.3.

THEOREM 4.7. *Let X and Y be Banach spaces with β-smooth norms and S be a closed subset of X. Assume that h is strictly differentiable at x_0 and has the β-finite-codimension property with respect to S at x_0. Then*

$$cl\nabla h(x_0) T_c(x_0, S) = Y \tag{16}$$

implies that h is regular with respect to S.

Proof. In light of Theorem 4.3 we need only to show that x_0 is not an extremal with respect to (h, S). Assume on the contrary that x_0 is an extremal with respect to (h, S). Then, for each n, there exist a unit vector y_n^* and $y_n \in (x_0 + \frac{1}{n}B) \cap S$ such that

$$0 \in (\nabla h(x_0))^* y_n^* + L D_\beta d(y_n, S) + \frac{1}{n} B_{X^*}. \tag{17}$$

We may assume that $y_n^* \to_{w^*} y^*$. Then by the definition of the g-normal cone

$$-(\nabla h(x_0))^* y^* \in N_g(x_0, S).$$

In other words, y^* is normal to $\nabla h(x_0) T_c(x_0, S)$ (because $T_c(x_0, S) = N_g(x_0, S)^0$), which, together with (16), yields $y^* = 0$. Since h has the β-finite-codimension property with respect to S at x_0, there exists a weak-star closed subspace V^* of Y^* such that h, S, and V^* satisfy the conditions in Definition 4.4. Write $Y^* = V^* + W^*$, where W^* is a finite-dimensional space with $V^* \cap W^* = \{0\}$ and $y_n^* = v_n^* + w_n^*$ with $v_n^* \in V^*$ and $w_n^* \in W^*$. Since W^* is finite dimensional and $\|w_n^*\| \le \|y_n^*\| = 1$, without loss of generality we may assume that $w_n^* \to w^*$. Since $y^* = 0$, we have $w^* = 0$. Thus, $d(V^*, y_n^*) \to 0$. Observe that (17) implies that, for each n, there exists an $e_n^* \in \frac{1}{n} B_{X^*}$ such that

$$u_n^* := -(\nabla h(x_0))^* y_n^* + e_n^* \in L D_\beta d(y_n, S) \subset N_\beta(y_n, S).$$

When n is sufficiently large, the β-finite-codimension property of h with respect to S at x_0 implies that

$$0 < c \le \|(\nabla h(x_0))^* y_n^* + u_n^*\| = \|e_n^*\| \le \frac{1}{n} \quad \forall n,$$

which is a contradiction. □

Remark 4.8. Since $N_\beta(x, S) \subset N_g(x, S)$, a function f which satisfies the codimension condition in [23] also satisfies the β-finite-codimension property. Thus, the β-finite-codimension property is less restrictive than the codimension condition in [23]. However, we should note that the result in [23] was proven without the smoothness assumption on the underlying space.

Now we turn to a β-smooth space version of the primal condition discussed in [5].

THEOREM 4.9. *Let X and Y be Banach spaces with β-smooth norms and S be a closed subset of X. Assume that $h : X \to Y$ is strictly differentiable at x_0. Suppose that*

(i) $\operatorname{cl} \nabla h(x_0) T_c(x_0, S) = Y$,

(ii) *there exists a nonempty compact set $K \subset Y$ and positive numbers α, γ, and η such that $\alpha < \gamma$ and, for all $\|x - x_0\| \le \eta$,*

$$\gamma B_Y \subset \operatorname{cl} \{\nabla h(x_0)(T_\beta(x, S) \cap B_X) + \alpha B_Y\} + K.$$

Then h is regular with respect to S at x_0.

Proof. We need only to show that the condition of this theorem implies that of Theorem 4.7. Suppose that conditions (i) and (ii) are satisfied. By [4, Lem. 2.1] we may assume that K is finite dimensional. Let $V := \operatorname{span}(K)$ and

$$V^* := \{y^* \in Y^* : y^* \perp V\}.$$

Then V^* is of finite codimension. Let

$$\varepsilon := \min\left\{\eta, \frac{\gamma - \alpha}{2 \sup\{\|k\| : k \in K\}}\right\}$$

and $c := \gamma - \varepsilon \sup\{\|k\| : k \in K\} - \alpha$. Consider x, x^*, and y^* satisfying (1), (2), and (3) in Definition 4.12. Let ξ be an arbitrary element of γB_Y. Then by condition (ii), for any $\alpha' > \alpha$, there exist $u \in T_\beta(x, S) \cap B_X$, $b \in B_Y$, and $k \in K$ such that

$$\xi = \nabla h(x_0) u + \alpha' b + k.$$

Then

$$\begin{aligned}\langle y^*, -\xi\rangle &= \langle(\nabla h(x_0))^* y^*, -u\rangle + \alpha'\langle y^*, -b\rangle + \langle y^*, -k\rangle \\ &= \langle(\nabla h(x_0))^* y^* + x^*, -u\rangle + \langle x^*, u\rangle + \alpha'\langle y^*, -b\rangle + \langle y^*, -k\rangle \\ &\le \|(\nabla h(x_0))^* y^* + x^*\| + \alpha' + \varepsilon \sup\{\|k\| : k \in K\}.\end{aligned}$$

Taking the supremum on the left-hand side and letting $\alpha' \to \alpha$ lead to

$$\gamma \le \|(\nabla h(x_0))^* y^* + x^*\| + \alpha + \varepsilon \sup\{\|k\| : k \in K\}$$

or

$$c \le \|(\nabla h(x_0))^* y^* + x^*\|. \qquad \square$$

Remark 4.10. Since $T_c(x, S) \subset T_b(x, S) \subset T_\beta(x, S)$, the condition of this theorem is weaker than that of [5, Thm. 4.1] in β-smooth spaces. We should note that the results of [5, Thm. 4.1] are proven without the β-smoothness assumption. The same remark also applies to the corollaries below.

As shown in Borwein and Strojwas [5], in a β-smooth space, conditions (i) and (ii) in Theorem 4.9 are weaker than the sufficient conditions for regularity given in Borwein [3] for the cases where (i) Y is a finite-dimensional space, (ii) S is convex, and (iii) S is epi-Lipschitz-like (see [5] for the definition). Therefore we have the following corollary.

COROLLARY 4.11 (see [3, 5]). *Let X and Y be Banach spaces with β-smooth norms and S be a closed subset of X. Assume that $h : X \to Y$ is strictly differentiable at $x_0 \in S$. Then h is regular with respect to S at x_0, provided that one of the following conditions is satisfied:*

a. *S is convex and $0 \in \operatorname{core}\nabla h(x_0)(S - x_0)$.*

b. *S is epi-Lipschitz-like and $\nabla h(x_0)T_c(x_0, S) = Y$.*

c. *Y is finite dimensional and $\nabla h(x_0)T_c(x_0, S) = Y$.*

Next we show that the sufficient condition for regularity in terms of uniform sleekness of the set S given by Aubin and Frankowska [1] is also a direct consequence of Theorem 4.9. First we recall the definitions of sleekness and uniform sleekness.

DEFINITION 4.12. *We say S is* β-sleek *at x if*

$$\liminf_{y \to x} T_\beta(y, S) \supset T_b(x, S).$$

We say S is uniformly β-sleek *at x if, for $u \in T_b(x, S) \cap B$,*

$$\lim_{y \to x} d(u, T_\beta(y, S)) = 0$$

uniformly.

Remark 4.13. (a) By Remark 4.5 β-sleekness is weaker than sleekness defined in [1].

(b) Borwein and Ioffe [8] have shown that

$$T_c(x, S) \supset \liminf_{y \to x} T_\beta(y, S).$$

It is well known that $T_c(x, S) \subset T_b(x, S)$. Thus, if S is β-sleek at x, then $T_c(x, S) = T_b(x, S)$ (i.e., S is b-tangentially regular at x).

COROLLARY 4.14. *Let X and Y be Banach spaces with β-smooth norms and S be a closed subset of X. Assume that S is uniformly β-sleek at x_0 and $h : X \to Y$ is strictly differentiable at $x_0 \in S$. Then*

$$\nabla h(x_0)T_c(x_0, S) = Y \tag{18}$$

implies that h is regular with respect to S at x_0.

Proof. We need only to show that h and S satisfy condition (ii) in Theorem 4.9. By the Robinson–Ursescu theorem (see [1]) there exists a $\gamma > 0$ such that

$$\gamma B_Y \subset \nabla h(x_0)\left(T_c(x_0, S) \cap \frac{1}{2}B_X\right).$$

Take an $\varepsilon < \frac{1}{2}$ such that $\alpha := \varepsilon\|\nabla h(x_0)\| < \gamma$. The uniform sleekness of S at x_0 implies that there exists an η such that $\|x - x_0\| \leq \eta$ implies that

$$T_c(x_0, S) \cap \frac{1}{2}B_X \subset T_\beta(x, S) \cap B_X + \varepsilon B_X.$$

Therefore

$$\gamma B_Y \subset \nabla h(x_0)\left(T_c(x_0, S) \cap \frac{1}{2}B_X\right) \subset \operatorname{cl}\{\nabla h(x_0)(T_\beta(x, S) \cap B_X) + \alpha B_Y\},$$

as was to be shown. □

Recently Azé and Chou [2] derived a primal sufficient condition in terms of equi-circatangent cones. It turns out this condition can also be deduced directly from Theorem 4.9.

DEFINITION 4.15 (see [2]). *A cone $K \subset X$ is said to be* equi-circatangent *to S at $x \in S$ if*

$$\lim_{t \to 0^+, y \to_S x} e(K \cap B_X, t^{-1}(S - y)) = 0,$$

where $e(A, S) := \inf\{\lambda > 0 : A \subset S + \lambda B_X\}$.

The primal condition discussed in [2] (as specialized for single-valued functions) can be stated as the following corollary.

COROLLARY 4.16. *Let X and Y be Banach spaces with β-smooth norms and S be a closed convex subset of X. Assume that $h : X \to Y$ is strictly differentiable at x_0. Let K be an equi-circatangent cone of S at x_0. Suppose that*

$$\nabla h(x_0)K = Y.$$

Then h is regular with respect to S at x_0.

Proof. We show that the conditions of this corollary imply those of Theorem 4.9. Condition (i) is obvious. To show condition (ii), invoke the Robinson–Ursescu theorem: there exists a positive constant γ such that

$$\gamma B_X \subset \nabla h(x_0)\left(K \cap \frac{1}{2}B_X\right).$$

By the definition of K there exists $\eta > 0$ such that, for all $t \in (0, \eta)$ and $x \in (x_0 + \eta B_X) \cap S$,

$$K \cap B_X \subset \frac{S - x}{t} + \varepsilon B_X,$$

where $\varepsilon := \min(\frac{\gamma}{2\|\nabla h(x_0)\|}, \frac{1}{2})$. Then

$$K \cap \frac{1}{2}B_X \subset T_\beta(x, S) \cap B_X + \varepsilon B_X.$$

Therefore

$$\begin{aligned}\gamma B_Y &\subset \nabla h(x_0)\left(K \cap \frac{1}{2}B_X\right)\\ &\subset \nabla h(x_0)(T_\beta(x, S) \cap B_X) + \varepsilon \nabla h(x_0)B_X\\ &\subset \nabla h(x_0)(T_\beta(x, S) \cap B_X) + \frac{\gamma}{2}B_X. \qquad \square\end{aligned}$$

Finally let us discuss regularity for multifunctions.

DEFINITION 4.17. *Let X and Y be Banach spaces and F be a multifunction from X to Y. We say that F is* regular *at $(x_0, y_0) \in Gr(F)$ if there exist positive constants ε and γ such that, for all $x \in x_0 + \varepsilon B$, $y \in y_0 + \varepsilon B$, and $d(y_0, F(x)) < \varepsilon$,*

$$d(x, F^{-1}(y)) \leq \gamma d(y, F(x)).$$

The following well-known lemma (see, e.g., [1, 29]) will enable us to connect the regularity of a multifunction to that of a single-valued function and derive sufficient conditions for a multifunction to be regular through various of the results discussed before. We include a proof here for completeness.

LEMMA 4.18. *Let $p : X \times Y \to Y$ be defined by $p(x, y) = y$. For a multifunction F from X to Y to be regular at $(x_0, y_0) \in Gr(F)$, it suffices that p be regular with respect to $Gr(F)$ at (x_0, y_0).*

Proof. Since p is regular with respect to $Gr(F)$ at (x_0, y_0), there exist positive constants ε and γ such that, for all $(x, z) \in ((x_0, y_0) + \varepsilon B) \cap Gr(F)$ and $y \in y_0 + \varepsilon B$,

$$d((x, z), Gr(F) \cap p^{-1}(y)) \leq \gamma \|z - y\|.$$

We may assume that $\gamma > 1$. Let $\varepsilon_1 = \varepsilon/2$. If $\|x - x_0\| < \varepsilon_1$, $\|y - y_0\| < \varepsilon_1$, and $d(y_0, F(x)) < \varepsilon_1$, then taking the infimum with respect to $z \in F(x)$ yields

$$\begin{aligned}
\gamma d(y, F(x)) &= \gamma \inf\{\|z - y\| : z \in F(x)\} \\
&= \gamma \inf\{\|z - y\| : z \in F(x), \|z - y_0\| < \varepsilon\} \\
&\geq \inf_{z \in F(x)} d((x, z), Gr(F) \cap p^{-1}(y)) \\
&= \inf_{z \in F(x)} \inf\{\|x - x'\| + \|z - y'\| : x' \in F^{-1}(y'), y' = y\} \\
&= \inf_{z \in F(x)} \{d(x, F^{-1}(y)) + \|z - y\|\} \\
&= d(x, F^{-1}(y)) + d(y, F(x)).
\end{aligned}$$

Thus,

$$d(x, F^{-1}(y)) \leq (\gamma - 1) d(y, F(x)). \qquad \square$$

Using this lemma and the various sufficient conditions that we discussed before will lead to sufficient conditions for a multifunction to be regular. For example, combining Lemma 4.18 with Theorem 4.9 we get the following theorem.

THEOREM 4.19. *Let X and Y be Banach spaces with β-smooth norms, F be a multifunction from X to Y, and p be the projection defined in Lemma* 4.18. *Suppose that*

(i) $\operatorname{cl}[p(T_c(x_0, y_0; Gr(F)))] = Y$,

(ii) *there exists a nonempty compact set $K \subset Y$ and positive numbers α, γ, and η such that $\alpha < \gamma$ and*

$$\gamma B_Y \subset \operatorname{cl}\{p(T_c(x_0, y_0; Gr(F))) \cap B_X + \alpha B_Y\} + K$$

whenever $\|x - x_0\| \leq \eta$ and $\|y - y_0\| \leq \eta$.

Then F is regular at (x_0, y_0).

Acknowledgments. We thank P. D. Loewen, A. Ioffe, L. Thibault, and the referees for their helpful comments and criticism regarding an earlier version of this paper.

OPTIMAL RELAXED CONTROLS FOR INFINITE-DIMENSIONAL STOCHASTIC SYSTEMS OF ZAKAI TYPE*

N. U. AHMED†

Abstract. In this paper, we present some new results on partially observed control problems for infinite-dimensional stochastic systems in Hilbert space using a fundamental result of Da Prato and Zabczyk on an infinite-dimensional Kolmogorov operator. We prove the existence of optimal relaxed controls for an infinite-dimensional Zakai equation following a semigroup approach and the theory of measurable selections. This result is also extended to differential inclusion. We also present some necessary conditions of optimality.

Key words. partially observed, infinite-dimensional stochastic systems, Zakai equations and inclusions, optimal relaxed controls, existence, necessary conditions

1. Introduction.

We consider the following controlled system governed by a pair of stochastic differential equations as described below:

$$\begin{aligned} dx &= Axdt + F(x)dt + B(x, u(t, y))dt + \sqrt{Q}dW, \qquad x(0) = x_0, \\ dy &= h(x, y)dt + \sigma_0(y)dw^0, \qquad y(0) = 0, \end{aligned} \tag{1.1}$$

where the first equation is defined on an infinite-dimensional Hilbert space H and the second is defined on a finite-dimensional Euclidian space R^d. The process x, which is generally not observable, is controlled through a controller u which exercises its control actions on the basis of available information about the process y which is physically measurable. The fundamental objective is to find from a suitable class of operators or maps, to be introduced shortly, a control law which minimizes the following cost functional:

$$J(u) \equiv E \int_I \ell(t, y(t), x(t), u(t, y))dt. \tag{1.2}$$

Generally A is an unbounded operator with domain and range in a separable Hilbert space H, F is a nonlinear continuous bounded operator in H, and B is also a continuous bounded map from $H \times \mathcal{Z}$ to H, where $\mathcal{Z}$ is a suitable set to be defined shortly. The map Q is a symmetric positive operator in H and W is a cylindrical Brownian motion with values in H. The operator h is a continuous bounded map from $H \times R^d$ to R^d and σ_0 is a continuous bounded map from R^d to the space of symmetric $d \times d$ matrices. Precise hypotheses will be introduced shortly.

Partially observed finite-dimensional control problems have been studied extensively by many authors over the last two decades [12]–[17], including the recent (1992) excellent book by Bensoussan [16] and the references therein. Fully observed infinite-dimensional control problems have been extensively studied by Barbu and Da Prato and Da Prato and his school through Hamilton–Jacobi–Bellman (HJB) equations [2, 3, 4]. Recently Zhu and Ahmed [5] considered HJB equations on Banach spaces related to fully observed stochastic control problems. However very little is known on infinite-dimensional partially observed control problems [7, 9]. In [9] the author considers partially observed stochastic differential inclusions using the theory of monotone operators and uses a stochastic approach. Recently Da Prato and Zabczyk discovered some very interesting results [1] regarding Kolmogorov operators and

†Department of Electrical Engineering, Department of Mathematics, University of Ottawa, Ottawa, ON, K1N 6N5, Canada.

the associated semigroups for infinite-dimensional stochastic differential equations on Hilbert spaces. This opens up the prospects of treating nonlinear filtering and control with partial information using an analytic approach in contrast to a stochastic approach [9]. Using their results Ahmed and Zabczyk [6] recently obtained some new results on nonlinear filtering of infinite-dimensional processes with finite-dimensional observation. In this paper we use the results of Da Prato and Zabczyk and those of Ahmed and Zabczyk as the starting point to study partially observed stochastic control problems in infinite-dimension, as stated above.

The rest of the paper is organized as follows: In §2 we discuss motivation and present some physical examples followed by basic notations. In §3, basic assumptions and some fundamental results due to Da Prato and Zabczyk and to Ahmed and Zabczyk are quoted for the convenience of readers. In §4, admissible controls are introduced and the partially observed control problem is transformed into a fully observed one. In §5, existence of optimal controls is proved. In §6, a similar result is proved for evolution inclusions. In §7, some necessary conditions of optimality are presented. We conclude the paper with §8 discussing the applicability and limitations of our results.

2. Motivation. The general problem of controlling the behavior of an unobservable random process based on the observation of a physically measurable process is known as a partially observed control problem. This is a general problem and arises in many physical situations. A classical example is an electrical communication problem where the received signal is corrupted by noise picked up from the source itself or (and) from the communication channel. The receiver is required to estimate the true message from the corrupted one. Often feedback communication is used to control the shape of the message signals in order to minimize error estimates at the receiver. This is a classical problem in finite-dimensional space that led to the Winer–Hoff equation and later Kalman filtering for linear dynamic systems and Kushner and Zakai equations for nonlinear systems. We present here two infinite-dimensional examples: one arising from ecological problems and another from an electromagnetic interference problem.

Ecological problem. Consider an aquatic system, like the Great Lakes, inhabited by various species of marine life, which is naturally affected by the presence of organic and inorganic agents. The concentration of organic and inorganic agents such as pollutants and nutrients in the water body can be described by a partial differential equation (PDE) as follows:

$$\begin{aligned} &\frac{\partial C}{\partial t} - D\Delta C + (\nabla C)v = b(C,u) + N, \qquad t \geq 0, \quad \xi \in \Omega, \\ &C|_{\partial\Omega} = 0, C(0,\xi) = C_0(\xi), \qquad \xi \in \Omega, \end{aligned} \tag{2.1}$$

where Ω is assumed to be an open, connected, bounded domain representing the aquatic body. C represents the concentration level of, say, m different organic and inorganic agents such as pollutants and nutrients. The function b represents the interactions between s different control agents u and the m different pollutants and nutrients C. The control may take the form of organized application of biological and biochemical agents reacting with the pollutants or simply physical removal of visible objects such as solid waste, algae, and other phytoplanktons. N is the distributed noise representing the additive effect of land run-offs from surrounding farmlands, summer cottages, acid rain, accidental oil spills, etc. The third term on the left of the equation represents transport of C due to water movement, where v is the given velocity vector as a function of space–time. For simplicity we shall assume that v is the steady-state velocity, that is, $v(t,x) = v(x)$ independent of time. The aquatic system is also inhabited by much important marine life such as microorganisms and fish. The stock of fish is subject to regulation by the Department of Fisheries. Assuming d different species of population and

denoting their biomass per unit volume by the d-vector y, a simplified model is given by

$$(d/dt)y = h(C, y) + N_0, \qquad t \geq 0, \tag{2.2}$$
$$y(0) = y_0,$$

where h represents the growth vector and N_0 the noise vector. For h we take the standard logistic growth function given by

$$h_i(C, y) \equiv \begin{cases} 0 & \text{for } y_i < 0; \\ r_i y_i(1 - (y_i/K_i)), & 0 \leq y_i \leq K_i; \\ \text{Exp}(-\delta_i K_i)(e^{-\delta_i(y_i - K_i)} - 1), & y_i > K_i, \end{cases} \tag{2.3}$$
$$K_i = K_i(C), \qquad i = 1, 2, \ldots, d.$$

The coefficient r_i is a positive constant representing the intrinsic growth rate of the ith species and the coefficient K_i, known as the environmental carrying capacity, is also positive and a nonincreasing (possibly decreasing) function of the concentration level of pollutants and nondecreasing (possibly increasing) function of the concentration level of nutrients in C. Above the carrying capacity the population decreases exponentially at the rate $\delta_i > 0$. The Department of Fisheries and Environment is interested in introducing a control program to promote marine life and water quality. For this purpose one may consider a simple cost integrand such as

$$\ell(y, C, u) \equiv \int_\Omega (Q_1(\xi)C(t, \xi), C(t, \xi))d\xi - \int_\Omega (Q_2(\xi)C(t, \xi), C(t, \xi))d\xi - (Q_3 y, y) + (Q_4 u, u),$$

where Q_1, Q_2 are symmetric, positive, semidefinite $m \times m$ matrix-valued functions bounded on Ω, Q_3 is a symmetric $d \times d$ positive, semidefinite matrix, and Q_4 is a positive definite $r \times r$ matrix. The r-dimensional control signifies r-different control actions including application of antipollutants, biological agents predating unwanted microorganisms, physical removal of solid waste, algae, etc. The cost functional may be taken as

$$J(u) \equiv E \int_I \ell(y, C, u)dt, \tag{2.4}$$

which is to be minimized. The first term promotes selective removal, the second promotes growth of possibly nutrient contents in C considered healthy for marine life, the third term promotes selective growth of marine life (like edible fish), and the fourth term represents the cost of administering controls.

The system (2.1)–(2.2) can be written as the abstract stochastic system (1.1) by choosing $H = L_2(\Omega, R^m)$, and A as the operator given by

$$D(A) \equiv \{\phi \in H : D\Delta\phi - (\nabla\phi)v \in H, \phi|_{\partial\Omega} = 0\}$$
$$= H^2(\Omega, R^m) \cap H_0^1(\Omega, R^m),$$

and setting

$$A\phi = D\Delta\phi - (\nabla\phi)v \text{ for } \phi \in D(A).$$

Define B as the Nemytskii operator corresponding to the vector function b by

$$(B(\phi, u), \psi) = \int_\Omega (b(\phi(\xi), u(\xi)), \psi(\xi))d\xi, \qquad \psi \in H,$$

and

$$E(N(t,\xi)N'(s,\eta)) = \delta(t-s)q(\xi,\eta), \qquad \xi,\eta \in \Omega,$$

where q is a positive symmetric kernel and δ is the Dirac measure. Let Q denote the integral operator

$$(Qz)(\xi) \equiv \int_\Omega q(\xi,\eta)z(\eta)d\eta, \qquad z \in H.$$

It is assumed that Q is a positive nuclear operator in H. For N_0, we take standard white noise in R^d so that

$$E(N_0(t)N_0'(s)) = \delta(t-s)I.$$

Hence the system (2.1)–(2.2) can be written as an abstract stochastic differential equation in $H \times R^d$ given by

$$\begin{aligned} dx &= Axdt + B(x,u)dt + \sqrt{Q}dW, \\ dy &= h(x,y)dt + dw^0, \end{aligned} \tag{2.5}$$

where W is a cylindrical Brownian motion in H and w^0 is a standard Brownian motion in R^d associated with the white noise N_0.

Electromagnetic interference. Power line harmonics interfere with nearby telephone lines. Similarly high-density multilayered printed circuit boards and multicored electrical cables experience (interline) interference. This kind of interference is known as "crosstalk" (see Khan and Costache [27, p. 9]). The mathematical model proposed for such systems can be described by a $2m$-dimensional first-order hyperbolic differential equation for currents and voltages associated with m transmission lines (of length l) subject to crosstalk as described below:

$$\begin{aligned} \partial i/\partial t &= -L^{-1}D_\xi v - L^{-1}Ri, \\ \partial v/\partial t &= -C^{-1}D_\xi i - C^{-1}Gv, \qquad t \geq 0, \xi \in (0,l) \equiv \Omega, \end{aligned} \tag{2.6}$$

where D_ξ denotes the first partial with respect to the spatial coordinate ξ; L, C, R, G are constant matrices representing the inductance, capacitance, resistance, and conductance parameters per unit length. For example, $L = L_0 + \tilde{L}$, $C = C_0 + \tilde{C}$, where L_0 is the self-inductance matrix (diagonal) and $\tilde{L}$ is the mutual inductance matrix. The boundary conditions are given by

$$\begin{aligned} v(t,0) + R_0 i(t,0) &= E(t), \\ C_1 \partial v(t,l)/\partial t + g(v(t,l)) &= i(t,l), \end{aligned} \tag{2.7}$$

where g represents the nonlinear $(i - v)$-characteristic of the n-vector terminal load and R_0 is the source-resistance matrix (diagonal) and E the source-voltage vector. Defining $I \equiv i$, $V \equiv v - E$, the first boundary condition in equation (2.7) can be reduced to a homogeneous boundary condition. Assuming distributed noise in the lines and boundary noise due to uncertain fluctuation of the demand and equipment noise, the system takes the form

$$\begin{aligned} \partial I/\partial t &= -L^{-1}D_\xi V - L^{-1}RI + N_1, \\ \partial V/\partial t &= -C^{-1}D_\xi I - C^{-1}GV + u_1(t) + N_2, \end{aligned} \tag{2.8}$$

with boundary conditions given by

(2.9)
$$V(t,0) + R_0 I(t,0) = 0,$$
$$\partial V(t,l)/\partial t + C_1^{-1} g(V(t,l) - G^{-1}C(u_1(t) + C_1^{-1}u_2(t)) + C_1^{-1}u_2(t) = C_1^{-1}I(t,l) + N_3,$$

where

$$\begin{aligned} u_1 &\equiv -C^{-1}GE - \dot{E}, \\ u_2 &\equiv C_1\dot{E}. \end{aligned} \tag{2.10}$$

Current probes placed at d-different locations along the transmission line can be used to measure the level of interference. This is described by a set of d-ordinary differential equations

$$\ell_k(d/dt)i_k = h_k(I, V) + \gamma_k, k = 1, 2, \ldots, d, \tag{2.11}$$

where h_k denotes the voltage induced in the induction coil of the current probe at the kth location and i_k is the current measured, where ℓ_k is the self-inductance of the coil and γ_k is the measurement noise.

The objective here is to choose the control signal $u \equiv \binom{u_1}{u_2}$ so that crosstalk is minimized while satisfying the desired electrical demand. The integrand of such an objective function can be taken as

$$\begin{aligned} \ell(y, I, V, \theta, , u) \equiv (1/2)\int_\Omega \{(\tilde{L}I, I) + (\tilde{C}V, V)\}d\xi + (1/2) \parallel \theta(t) - \theta_d(t) \parallel^2_{R^m} \\ + (1/2) \parallel u \parallel^2_{R^{2m}}, \end{aligned}$$

where $\tilde{L}, \tilde{C}$ are the coupling matrices of inductance and capacitance, $\theta(t) = V(t, l)$, θ_d is the desired load voltage, and u is the source signal. The first two terms give a measure of crosstalk (electromagnetic interference) which is measured in terms of electromagnetic energy and the remaining terms have the standard meaning. The cost functional is given by

$$J(u) = E\int_0^T \ell(y, I, V, \theta, u)dt.$$

Again we can write the system of equations (2.8)–(2.11) as an abstract stochastic differential equation of the form (1.1).

For the nonlinear $(i - v)$-characteristic of the terminal load we assume that g is Lipschitz continuous and there exists a symmetric positive definite matrix K and a number $\beta > 0$ such that

$$\sup\{\parallel g(\theta + z) - K\theta \parallel_{R^m}, \theta \in R^m\} \leq \beta(1 + \parallel z \parallel) \tag{2.12}$$

for all $z \in R^m$. For a mild nonlinear characteristic of the load, this is a reasonable approximation. Define $H \equiv L_2(\Omega, R^m) \times L_2(\Omega, R^m) \times R^m$ with the natural scalar product, and the operator A by

$$D(A) \equiv \{(\phi, \psi, \theta) \in H : \phi, \psi \in H^1(\Omega, R^m), \psi(0) + R_0\phi(0) = 0, \theta = \psi(l)\} \tag{2.13}$$

and

$$A(\phi, \psi, \theta) \equiv \begin{pmatrix} -L^{-1}R\phi - L^{-1}D_\xi\psi \\ -C^{-1}D_\xi\phi - C^{-1}G\psi \\ C_1^{-1}(\phi(l) - K\theta) \end{pmatrix}. \tag{2.14}$$

Define

$$
\begin{aligned}
b(\phi, \psi, \theta, u) &\equiv \begin{pmatrix} 0 \\ u_1 \\ -C_1^{-1} g(\theta - G^{-1} C(u_1 + C_1^{-1} u_2)) + C_1^{-1} K\theta - C_1^{-1} u_2 \end{pmatrix} \\
&\equiv \begin{pmatrix} 0 \\ u_1 \\ \tilde{g}(\theta, u) \end{pmatrix}, \\
N &\equiv \begin{pmatrix} N_1 \\ N_2 \\ N_3 \end{pmatrix}, \\
u &\equiv \begin{pmatrix} u_1 \\ u_2 \end{pmatrix}.
\end{aligned} \tag{2.15}
$$

Let $x(t) \equiv \operatorname{col}(I(t, \cdot), V(t, \cdot), \theta(t))$ denote the state vector at time t taking values from H, and $B(x, u)$ denote the Nemytskii operator associated with b. Assume that the transmission line noises (N_1, N_2) are independent of the electrical load (demand) noise N_3 and that the covariance operator Q corresponding to N is a positive nuclear operator in H. Let $y \equiv \operatorname{col}(i_1, i_2, \ldots, i_d)$ denote the measurement process governed by equation (2.11) and w^0 is the standard Brownian motion corresponding to the measurement noise $N_0 \equiv \operatorname{col}(\gamma_1, \gamma_2, \ldots, \gamma_d)$, $h \equiv \operatorname{col}((1/\ell_k)h_k, k = 1, 2, \ldots, d)$ and $\sigma_0 \equiv \operatorname{diag}((1/\ell_1), (1/\ell_2), \ldots, (1/\ell_d))$. Using the above notations we can rewrite the system of equations (2.8)–(2.11) as an abstract stochastic differential equation in $H \times R^d$:

$$
\begin{aligned}
dx &= Ax\,dt + B(x, u)dt + \sqrt{Q}\,dW, \\
dy &= h(x)dt + \sigma_0 dw^0.
\end{aligned} \tag{2.16}
$$

Further discussion of these examples is given in §8.

Basic Notations. For any pair of Banach spaces X, Y, $\mathcal{L}(X, Y)$ will denote the space of bounded linear operators from X to Y and $\mathcal{L}(X) \equiv \mathcal{L}(X, X)$. For any interval $I \equiv [0, T]$, $C(I, X)$ will denote the Banach space of continuous functions on I with values in X. Let H denote a separable Hilbert space, and $C_b(H)(B_b(H))$ the space of bounded continuous (measurable) functions on H. $\mathcal{M}_b(H)$ is the space of countably additive, bounded, signed measures on the measurable space $(H, \mathcal{B}(H))$ and $\mathcal{M}(H) \subset \mathcal{M}_b$ is the space of probability measures. For $\mu \in \mathcal{M}_b(H)$ and $\phi \in B_b(H)$ we use $\mu(\phi)$ to denote the functional $\int_H \phi(x)\mu(dx)$. For any topological space $\mathcal{Z}$, $2^{\mathcal{Z}} \setminus \emptyset$ will denote the space of nonempty subsets of $\mathcal{Z}$, and $c(\mathcal{Z})$, $(cc(\mathcal{Z}), cbc(\mathcal{Z}), kc(\mathcal{Z}))$ denotes the class of nonempty closed (closed convex, closed bounded convex, compact convex) subsets of $\mathcal{Z}$.

Let $(\Sigma, \mathcal{P})$ be an arbitrary measurable space and X a Polish space. A multifunction $F : \Sigma \longrightarrow 2^X \setminus \emptyset$ is said to be measurable (weakly measurable) if for every closed (open) set $C \subset X$ the set $F^-(C) \equiv \{\sigma \in \Sigma : F(\sigma) \cap C \neq \emptyset\} \in \mathcal{P}$.

Let X, Y be any two topological spaces and $F : X \mapsto c(Y)$ is a multifunction. F is said to be upper (lower) semicontinuous with respect to inclusion if for every $x_0 \in X$ and every open set $V \subset Y$ satisfying $F(x_0) \subset V$ $(V \cap F(x_0) \neq \emptyset)$, there exists an open set $U \subset X$ containing x_0 such that $F(x) \subset V$ $(F(x) \cap V \neq \emptyset)$ for all $x \in U$. If Y is a metric space with metric d, then one can introduce a metric d_H, called the Hausdorff metric, on $c(Y)$ as follows:

$$
d_H(C, D) \equiv \operatorname{Max}\{\operatorname{Sup}_{y \in D} d(C, y), \operatorname{Sup}_{z \in C} d(z, D)\}
$$

for $C, D \in c(Y)$. If (Y, d) is complete, then so is $(c(Y), d_H)$. $F : X \mapsto c(Y)$ is said to be continuous in the Hausdorff metric if, whenever $x_n \longrightarrow x$ in the topology of X,

$$\mathrm{Lim}_{n\to\infty} d_H(F(x_n), F(x)) = 0,$$

and it is said to be mild or quasi-upper semicontinuous if

$$\mathrm{Lim}_{n\to\infty} d^*(F(x_n), F(x)) \equiv \mathrm{Sup}\{d(z, F(x)), z \in F(x_n)\} \longrightarrow 0.$$

For other types of continuity see [20, 21].

Let $(\Omega, \mathcal{F}, \mathcal{F}_t \uparrow\subset \mathcal{F}, t \geq 0, P)$ denote a complete probability space furnished with an increasing family of right continuous complete sub σ-algebras $\mathcal{F}_t \subset \mathcal{F}$. All random processes considered in the paper will be assumed to be strongly $\mathcal{F}_t$-predictable processes unless stated otherwise.

3. Basic assumptions. For study of the control problem we shall make critical use of the Da Prato–Zabczyk semigroup [1] which is an extension of the Markov transition operator corresponding to the stochastic evolution equation

$$\begin{aligned} dx &= Axdt + F(x)dt + \sqrt{Q}dW, \\ x(0) &= x_0. \end{aligned} \tag{3.1}$$

For this we need the following assumptions:

(H1)

(a) A is the infinitesimal generator of a C_0-semigroup, $T(t), t \geq 0$ in H satisfying

$$\| T(t) \|_{\mathcal{L}(H)} \leq Me^{-\omega t}, \qquad t \geq 0, \omega > 0, M \geq 1.$$

(b) Q is a positive, symmetric, bounded operator in H so that the operator Q_t given by

$$Q_t x \equiv \int_0^t T(s)QT^*(s)xds, \qquad x \in H, t \geq 0$$

is nuclear for all $t \geq 0$ and $\mathrm{Sup}_{t\geq 0} Tr\, Q_t < \infty$.

(c) W is a cylindrical Wiener process with values in H with $\mathrm{Cov} W(1) = I$.

(H2) F is a bounded Lipschitz mapping from H to H.

(H3) For all $t \geq 0$, $\mathrm{Range}(T(t)) \subset \mathrm{Range}(Q_t^{1/2})$.

(H4) The operator-valued function $\Gamma(t) \equiv (Q_t^{-1/2}T(t)), t \geq 0$, is Laplace transformable.

Let $D\phi$ and $D^2\phi$ denote the first and the second Fréchet derivatives of the function $\phi : H \longrightarrow R^1$, whenever they exist as elements of H and $\mathcal{L}(H)$, respectively. Define the operators $\mathcal{A}_0$ and $\mathcal{A}$ by

$$\begin{aligned} \mathcal{A}_0\phi &\equiv (1/2)Tr(QD^2\phi) + (x, A^*D\phi), x \in H, \\ D(\mathcal{A}_0) &\equiv \{\phi \in C_b^2(H) : D^2\phi \in \mathcal{L}_1(H),\ \mathrm{Sup}_{x\in H} \| D^2\phi \|_{\mathcal{L}_1(H)} < \infty \\ &\qquad \text{and there exists } \psi \in C_b^2(H) : \phi(x) = \psi(A^{-1}x), x \in H\}, \\ \mathcal{B}\phi &\equiv \langle F(\cdot), D\phi(\cdot)\rangle, \phi \in W^{1,2}(H, \mu^0), \text{ and} \\ \mathcal{A} &\equiv (\bar{\mathcal{A}}_0 + \mathcal{B}), D(\mathcal{A}) = D(\bar{\mathcal{A}}_0), \end{aligned}$$

where $\mathcal{L}_1(H)$ is the space of nuclear operators in H and $C_b^k(H)$ is the space of bounded k-times Frechet differentiable functions on H. We consider the semigroup $S(t), t \geq 0$, corresponding

to the Kolmogorov operator associated with the nonlinear stochastic evolution equation (1.1). The following result is fundamental.

THEOREM 3.1. *Suppose the assumptions* (H1)–(H4) *hold. Then* (a) *the linear version of* (3.1), *with* $F = 0$, *has a unique invariant Gaussian measure* μ^0 *on* $\mathcal{B}(H)$; (b) *the operator* $\mathcal{A}$ *generates a* C_0*-semigroup of bounded linear operators,* $S(t), t \geq 0$, *in* $L_2(H, \mu^0)$ *and it is the extension of the original Markov transition operator (corresponding to system* (3.1)*) from* $B_b(H)$ *to* $L_2(H, \mu^0)$. *Further,* $D(\mathcal{A}) \subset W^{1,2}(H, \mu^0)$ *and for* $t > 0$, $S(t)$ *is a family of compact operators in* $L_2(H, \mu^0)$.

Proof. See Da Prato and Zabczyk [1, Thm. 2.10].

Consider the controlled system

$$\begin{aligned} dx &= Axdt + F(x)dt + B(x, u(t, y))dt + \sqrt{Q}dW, \qquad x(0) = x_0, \\ dy &= h(x, y)dt + \sigma_0(y)dw^0, \qquad y(0) = 0. \end{aligned} \tag{3.2}$$

To solve the control problem we need the solution of the associated filtering problem. Let $\mathcal{F}_t^y \equiv \sigma\{y(s), s \leq t\}$ denote the smallest σ-algebra generated by the observed process y up to time $t, t \geq 0$. Let $\phi : H \longrightarrow R$ be any continuous bounded function. The filtering problem is to find an $\mathcal{F}_t^y$-measurable process $\{\eta(t), t \geq 0\}$, such that

$$E\{(\eta(t) - \phi(x(t))^2 | \mathcal{F}_t^y\} = \min \quad \text{for all } t \in I \equiv [0, T].$$

It is well known that the best filter is given by

$$\begin{aligned} \eta^0(t) &= E\{\phi(x(t)) | \mathcal{F}_t^y\} \\ &= \int_H \phi(\xi) Q_t^y(d\xi) \equiv Q_t^y(\phi), \end{aligned} \tag{3.3}$$

where

$$Q_t^y(\chi_\Gamma) = P\{x(t) \in \Gamma | \mathcal{F}_t^y\}$$

for $\Gamma \in B(H)$ with $B(H)$ denoting the σ-algebra of Borel subsets of H. This solution suggests that we must find the conditional probability measure Q_t^y which is an $\mathcal{F}_t^y$-adapted (probability) measure-valued stochastic process. Recently it was proved [6] on the basis of the Da Prato–Zabczyk semigroup that Q_t^y satisfies the Kushner equation (in the weak sense) which is a nonlinear stochastic PDE in an infinite-dimensional space.

Let $I \equiv [0, T]$, $T < \infty$, and define $H_d \equiv H \times R^d$ with the obvious scalar product. Let $\mathcal{Z}$ denote a Polish space (a Hausdorff topological space for which there exists a metric, of countable type compatible with the topology, with respect to which it is a complete separable metric space). We introduce the following hypotheses:

(H5) B and $Q^{-1/2}B : H \times \mathcal{Z} \longrightarrow H$ are bounded Borel-measurable maps, Lipschitz in the first variable and continuous in the second.

(H6) $h : H_d \longrightarrow R^d$ is a bounded Lipschitz map and $\sigma_0 : R^d \longrightarrow \mathcal{L}(R^d)$ is a bounded Lipschitz map having bounded inverse.

Consider the canonical space $C(I, H_d) \equiv C$ and let $\mathcal{B}(C)$ denote the σ-algebra of Borel subsets of the topological space C. We shall need the following lemma.

LEMMA 3.2. *Suppose the hypotheses* (H1)–(H6) *hold and let* $u \in \mathcal{U}_{ad}$. *Let* ν^1 *denote the measure induced by the solution process of* (1.1) *on the measurable space* $(C, \mathcal{B}(C))$ *and* ν^0 *the measure induced by the same system with* $B = 0, h = 0$. *Then* ν^1 *is absolutely continuous with respect to* ν^0 *and* $d\nu^1 = q_T d\nu^0$, *where* q *denotes the Radon–Nikodým derivative and is given by*

$$q_t = \operatorname{Exp}\left\{\int_0^t \{(Q^{-1/2}B, dW) - (1/2) \parallel Q^{-1/2}B \parallel_H^2 dt\} + \int_0^t \{\langle \Gamma_0^{-1}h, dy\rangle - (1/2)\langle \Gamma_0^{-1}h, h\rangle dt\}\right\} \tag{3.4}$$

for all $t \in I \equiv [0, T]$, *where* $\Gamma_0 = \sigma_0\sigma_0^*$. *The process* $q_t, t \geq 0$, *is a continuous square integrable* $\mathcal{F}_t$*-martingale and* $E^0(q_t) = 1$ *for all* $t \geq 0$.

Proof. The proof is basically a consequence of the Girsanov theorem extended to Hilbert spaces (see [3]).

Conditioning with respect to the σ-algebra $\mathcal{F}_t^y$, we have

$$Q_t^y(\phi) = E^1(\phi(x(t))|\mathcal{F}_t^y) = \frac{E^0\{\phi(x(t))q_t|\mathcal{F}_t^y\}}{E^0\{q_t|\mathcal{F}_t^y\}} \equiv \frac{\mu_t^y(\phi)}{\mu_t^y(1)}. \tag{3.5}$$

The process μ_t^y is a measure-valued stochastic process possibly taking values from the Banach space of countably additive, bounded, signed measures, $\mathcal{M}_b(H)$. This is the unnormalized measure-valued process. It was shown in [6] that this process satisfies the so-called Zakai equation which is a linear stochastic PDE in an infinite-dimensional space.

THEOREM 3.3. *Under the assumptions* (H1)–(H6), *for any given* $\mathcal{F}_t^y$*-measurable control law* u *taking values from* $\mathcal{Z}$, *the measure-valued process* $\{\mu_t^y, t \geq 0\}$ *satisfies the following stochastic (partial) differential equation in the weak sense:*

$$\begin{aligned} d\mu_t(\phi) &= \mu_t(\mathcal{A}\phi)dt + \mu_t(L_u\phi)dt + \langle \mu_t(\phi h), \Gamma_0^{-1}(y(t))dy(t)\rangle \\ \mu_0(\phi) &= \Pi_0(\phi) \text{ for each test function } \phi \in D(\mathcal{A}), \end{aligned} \tag{3.6}$$

where $\Pi_0 \in \mathcal{M}(H)$ *is the probability law induced by the random variable* x_0 *and*

$$(L_u\phi)(x) \equiv (D\phi(x), B(x, u))_H. \tag{3.7}$$

Proof. Given a fixed $\mathcal{F}_t^y$-adapted control law, the proof is essentially the same as in [6].

Under suitable assumptions, equation (3.6) is equivalent to a stochastic evolution equation in the Hilbert space $L_2(H, \mu^0)$. This is given in the following result.

THEOREM 3.4. *Suppose the hypotheses* (H1)–(H6) *hold and the initial measure* Π_0 *is absolutely continuous with respect to the invariant measure* μ^0 *having a density* $\rho_0 \in L_2(H, \mu^0)$. *Then the Zakai equation* (3.6) *is equivalent to the stochastic evolution equation*

$$\begin{aligned} d\rho(t) &= \mathcal{A}^*\rho(t)dt + L_u^*(\rho(t))dt + G(\rho(t))dy(t), \qquad t \in I, \\ \rho(0) &= \rho_0 \end{aligned} \tag{3.8}$$

in the Hilbert space $L_2(H, \mu^0)$, *where* $G(\rho) \equiv \rho\Gamma_0^{-1}h$.

Proof. For proof see [6].

Later in the discussion we shall discuss the questions of existence and uniqueness of solutions of this equation. The major difficulty here, unlike in [6], where L_u^* does not arise, is that even though L_u is a nice operator mapping $W^{1,2}(H, \mu^0) \longrightarrow L_2(H, \mu^0)$, L_u^* is not.

4. Conversion to a fully observed control problem. In this section we prove that the partially observed control problem (1.1)–(1.2) is equivalent to a fully observed control problem on $L_2(H, \mu^0) \equiv \mathcal{H}$ involving the Zakai equation. Now we shall formally introduce the class of admissible controls.

Admissible Controls. Recall that a topological space $\mathcal{Z}$ is called a Polish space if it is metrizable of countable type and if there exists a metric, compatible with the topology of $\mathcal{Z}$, with respect to which $\mathcal{Z}$ is complete. In other words, embedded in a Polish space there may be more than one complete separable metric space. Let Γ be a Polish space, for example, a

closed subspace of $\mathcal{Z}$, and $\mathcal{M}(\Gamma)$ the space of Radon probability measures. This is also a Polish space. Let $Y \equiv C(I, R^d)$ and $\mathcal{B}(Y)$ denote the Borel σ-algebra on Y and for each $t \in I$, $\mathcal{B}_t(Y)$ denote the family of increasing subσ-algebras of the σ-algebra $\mathcal{B}(Y)$. Let $\mathcal{P} \equiv \mathcal{P}_\Sigma$ denote the σ-algebra of predictable (nonanticipating) subsets of the set $I \times Y \equiv \Sigma$. Let η be a probability measure on $\mathcal{B}(Y)$ and $\hat{\eta}$ the restriction of the product measure $dt \times \eta(dy)$ on the predictable σ-field $\mathcal{P}$. We assume that $\mathcal{P}$ has been completed with respect to the measure $\hat{\eta}$. Let $\mathcal{U}(\Sigma, \mathcal{M}(\Gamma))$ denote the class of functions (equivalence classes) from Σ to $\mathcal{M}(\Gamma)$ which are w^*-measurable with respect to the predictable σ-field $\mathcal{P}$. Let $cc(\mathcal{M}(\Gamma))$ denote the class of nonempty, closed, convex subsets of $\mathcal{M}(\Gamma)$ and $U : \Sigma \longrightarrow cc(\mathcal{M}(\Gamma))$ is a $\mathcal{P}$-measurable (nonanticipative) multifunction. Note that $U(t, y) = U(t, z)$ for all $y, z \in Y$ satisfying $y(s) = z(s)$ for $0 \leq s \leq t$. We take for the admissible controls the set

$$(4.1)\quad \mathcal{U}_{ad} \equiv \{u \in \mathcal{U}(\Sigma, \mathcal{M}(\Gamma)); u(t, y) \in U(t, y), \ \hat{\eta} \text{ almost everywhere (a.e.) on } \Sigma\}.$$

In other words, the admissible controls are given by the $\mathcal{P}$-measurable selections of the multifunction U.

Throughout the rest of the paper we assume that the operator B and the the cost integrand ℓ have the forms

$$(4.2)\quad \begin{aligned} B(x, u) &\equiv \int_\Gamma \tilde{B}(x, \gamma) u(d\gamma) \ \text{ for } x \in H \ \text{ and } \ u \in \mathcal{M}(\Gamma), \\ \ell(t, y, x, u) &\equiv \int_\Gamma \tilde{\ell}(t, y, x, \gamma)\, u(d\gamma) \ \text{ for } t \in I, y \in R^d, x \in H, u \in \mathcal{M}(\Gamma), \end{aligned}$$

where $\tilde{B} : H \times \Gamma \longrightarrow H$ and $\tilde{\ell} : I \times R^d \times H \times \Gamma \longrightarrow R \cup \{+\infty\}$ are generally Borel-measurable maps to be specified later.

Remark. Before we start with the control problem, some discussion on the choice of control space is warranted. The space $\mathcal{M}(\Gamma)$ has three possible choices. If Γ is an arbitrary set (even without any topology), one may choose $\mathcal{M}(\Gamma) \equiv M_{ba}(\Gamma)$, the space of bounded finitely additive (positive) measures, and in this case both $r \mapsto \tilde{B}(x, r)$ and $r \mapsto \tilde{\ell}(t, y, x, r)$ must be bounded H and scalar-valued functions, respectively. In case Γ is a normal topological space, one takes $\mathcal{M}(\Gamma) \equiv M_{rba}(\Gamma)$, the space of regular bounded finitely additive (positive) measures on the field generated by closed subsets of Γ. In this case the maps defined above must be continuous and bounded. In case Γ is a compact topological Hausdorff space, $\mathcal{M}(\Gamma) \equiv M_{rca}(\Gamma)$, regular countably additive (positive) measures on the σ-algebra of Borel subsets of Γ. In this case the maps defined above are merely continuous. For an excellent discussion on this topic see Fattorini [11]; Cutland and Lindstrom [14]. Since we consider Γ to be a Polish space which is clearly a normal topological space, either of the last two spaces are admissible in our case.

Now we are prepared to recast our original partially observed control problem as a fully observed control problem. Consider the stochastic differential equation

$$(4.3)\qquad dy = \sigma_0(y) dw^0, \ y(0) = 0.$$

Let η denote the measure induced by y on the path space Y or any other measure which is absolutely continuous with respect to η.

THEOREM 4.1. *Suppose that the hypotheses* (H1)–(H6) *hold and that the initial measure* Π_0 *is absolutely continuous with respect to the invariant measure* μ^0. *Then the partially observed control problem* (1.1)–(1.2) *is equivalent to the following fully observed control problem on the Hilbert space* $\mathcal{H} \equiv L_2(H, \mu^0)$: *find a control* $u \in \mathcal{U}_{ad}$ *such that*

$$(4.4)\qquad J(u) \equiv \int_Y \int_{I \times H} \{\ell(t, y(t), x, u(t, y)) \rho_t(x)\} \mu^0(dx) dt\, \eta(dy) \Longrightarrow \text{Inf},$$

where ρ *is the solution of the evolution equation*

$$d\rho(t) = \mathcal{A}^*\rho(t)dt + L_u^*\rho(t)dt + G(\rho(t))dy(t), t \geq 0, \rho(0) = \rho_0 \tag{4.5}$$

on the Hilbert space $L_2(H, \mu^0)$ *corresponding to the control law* u.

Proof. Let E^1 and E^0 denote the integrations with respect to the measures ν^1 and ν^0, respectively, on the canonical space $C \equiv C(I, H_d)$. Then in view of Lemma 3.2, we can write

$$\begin{aligned} J(u) &= E^1\left\{\int_I \ell(t, y(t), x(t), u(t, y))dt\right\} \\ &= E^0\left\{\left(\int_I \ell(t, y(t), x(t), u(t, y))dt\right) q_T(x, y, u)\right\} \\ &= E^0 \int_I \{E^0\{\ell(t, y(t), x(t), u(t, y))q_T(x, y, u)|\mathcal{F}_t\}\}dt \\ &= E^0 \int_I \{\ell(t, y(t), x(t), u(t, y))E^0\{q_T(x, y, u)|\mathcal{F}_t\}\}dt \\ &= E^0 \int_I \{\ell(t, y(t), x(t), u(t, y))q_t(x, y, u)\}dt. \end{aligned} \tag{4.6}$$

The first and the second equalities follow from Lemma 3.2 and the definition of the measures ν^1 and ν^0, respectively. The third and the fourth follow from the properties of conditional expectations and the $\mathcal{F}_t$-measurability of $\ell(t, y(t), x(t), u(t, y))$. The fifth follows from the fact that $q_t, t \geq 0$ is an $\mathcal{F}_t$-martingale (see Lemma 3.2). Now conditioning with respect to the σ-algebra $\mathcal{F}_t^y$ and recalling that

$$Q_t^y(\phi) = E^1(\phi(x(t))|\mathcal{F}_t^y) = \frac{E^0\{\phi(x(t))q_t|\mathcal{F}_t^y\}}{E^0\{q_t|\mathcal{F}_t^y\}} \equiv \frac{\mu_t^y(\phi)}{\mu_t^y(1)},$$

we can express $J(u)$ as

$$\begin{aligned} J(u) &= E^0 \int_I E^0\{\ell(t, y(t), x(t), u(t, y))q_t(x, y, u)|\mathcal{F}_t^y\}dt \\ &= E^0 \int_I \{\mu_t^y(\ell(t, y(t), x, u(t, y)))\}dt, \end{aligned} \tag{4.7}$$

where μ is any solution of the Zakai equation (3.6) of Theorem 3.3 corresponding to the control law u. Since by our assumption, Π_0 is absolutely continuous with respect to the invariant measure μ^0, it follows from Theorem 3.3 that $d\mu_t^y = \rho_t^y d\mu^0$, where ρ is the solution of equation (3.8) corresponding to the control u. Hence it follows from (4.7) that the cost-functional J can be written as

$$J(u) = E^0 \int_{I\times H} \{\ell(t, y(t), x, u(t, y))\rho_t^y(x)\}\mu^0(dx)dt. \tag{4.8}$$

Under the measure ν^0 the process x is independent of the process y and y is governed by the stochastic differential equation $dy = \sigma_0(y)dw^0$. Using the measure η as discussed earlier and Fubini's theorem, equation (4.8) can be rewritten as

$$\begin{aligned} J(u) &= \int_Y \left(\int_{I\times H} \{\ell(t, y, x, u(t, y))\rho_t^y(x)\}\mu^0(dx)dt\right)\eta(dy) \\ &= \int_\Sigma \left(\int_H \{\ell(t, y, x, u(t, y))\rho_t^y(x)\}\mu^0(dx)\right)\hat{\eta}(dtdy). \end{aligned} \tag{4.9}$$

The converse is easy and can be proved by reversing the above arguments. This completes the proof.

In the following section we shall prove that this control problem has a solution. Throughout the rest of the paper we assume that the measure $\hat{\eta}$ of (4.1) is constructed from the measure η induced by the process y as in the previous theorem or any other measure absolutely continuous with respect to η.

5. Existence of optimal controls. In this section we shall prove the existence of optimal relaxed feedback controls under the assumption that the operator A is merely the infinitesimal generator of a C_0-semigroup of negative type in H as given in (H1)(a). For this we must establish the existence of a solution of equation (4.5) under some general conditions. For convenience of notation we shall denote the Hilbert and Sobolev spaces introduced by Da Prato–Zabczyk [1] as follows:

Let $\mathcal{H} \equiv L_2(H, \mu^0)$, $V \equiv W^{1,2}(H, \mu^0)$, and let V^* denote the topological dual of V. Since the embedding $V \hookrightarrow \mathcal{H}$ is continuous and dense, identifying $\mathcal{H}$ with its own dual we obtain the Gelfand triple

$$V \hookrightarrow \mathcal{H} \hookrightarrow V^*,$$

where the embeddings are actually compact. Let $\langle \cdot, \cdot \rangle_{V^*,V}$ denote the duality pairing of elements of V^* with those of V, and $(\cdot, \cdot)_{\mathcal{H}}$ the scalar product in $\mathcal{H}$. Clearly, for $\xi, \zeta \in \mathcal{H}$,

$$(\xi, \zeta)_{\mathcal{H}} \equiv \int_H \xi(x)\bar{\zeta}(x)\mu^0(dx).$$

Note that for $\xi \in \mathcal{H}$ and $v \in V$, $\langle \xi, v \rangle_{V^*,V} = (\xi, v)_{\mathcal{H}}$. Let $L_2^e(I, \mathcal{H}) \equiv L_2^e(\mathcal{H})$ and $L_2^e(I, V^*) \equiv L_2^e(V^*)$ denote the Banach spaces of $\mathcal{F}_t^y$-predictable $\mathcal{H}$ and V^*-valued processes with respective norm topologies given by

$$\begin{aligned} \| \lambda \|_{L_2^e(\mathcal{H})} &\equiv \left(E \int_I \| \lambda(t) \|_{\mathcal{H}}^2 \, dt \right)^{1/2} \quad \text{for } \lambda \in L_2^e(\mathcal{H}), \\ \| \beta \|_{L_2^e(V^*)} &\equiv \left(E \int_I \| \beta(t) \|_{V^*}^2 \, dt \right)^{1/2} \quad \text{for } \beta \in L_2^e(V^*). \end{aligned} \tag{5.1}$$

Let $M_2(\mathcal{H})$ denote the class of $\mathcal{F}_t^y$-predictable $\mathcal{H}$-valued processes furnished with norm topology given by

$$\| \lambda \|_{M_2} \equiv \operatorname{Sup}\{(E \| \lambda(t) \|_{\mathcal{H}}^2)^{1/2}, t \in I\}.$$

It is easy to verify that M_2 is a Banach space.

Let us first consider the system

$$d\rho(t) = \mathcal{A}^*\rho(t)dt + \beta(t)dt + G(\rho(t))dy(t), \qquad t \geq 0, \rho(0) = \rho_0, \tag{5.2}$$

where $\beta \in L_2^e(V^*)$. We need the following lemma.

LEMMA 5.1. *Suppose the assumptions* (H1)–(H6) *hold and, in addition, with reference to assumption* (H4), *there exists a constant* $c > 0$ *and* $\alpha \in (0, 1/2)$ *so that*

$$\| \Gamma(t) \|_{\mathcal{L}(H)} \leq c/t^{\alpha} \quad \text{for } t > 0. \tag{5.3}$$

Consider the system (5.2) *with initial state* $\rho_0 \in \mathcal{H}$. *Then for every* $\beta \in L_2^e(V^*)$, *equation* (5.2) *has a unique mild solution* $\rho \in M_2(\mathcal{H})$. *Further, the solution map* $\beta \mapsto \rho$ *denoted by* $\rho = \Phi(\beta)$, *with values*

$$\rho(t) \equiv \Phi_t(\beta), \qquad t \in I$$

is weakly continuous from $L_2^e(V^*)$ *to* $M_2(\mathcal{H})$, *and* $\rho \in C(I, \mathcal{H})$ P *almost surely (a.s.).*

Proof. Using the dual semigroup $S^*(t), t \geq 0$ of the Da Prato–Zabczyk semigroup $S(t), t \geq 0$ corresponding to the infinitesimal generator $\mathcal{A}$ as defined here, we can write the evolution equation as an integral equation:

$$\rho(t) = S^*(t)\rho_0 + \int_0^t S^*(t-\tau)\beta(\tau)d\tau + \int_0^t S^*(t-\tau)G(\rho(\tau))dy(\tau). \tag{5.4}$$

We prove that this equation has a unique solution having the properties as stated in the theorem. Define

$$z(t) \equiv S^*(t)\rho_0 + \int_0^t S^*(t-\tau)\beta(\tau)d\tau, \qquad t \geq 0. \tag{5.5}$$

It is clear that the first term belongs to $M_2(\mathcal{H})$. For the second term, it follows from Theorem 2.10 of Da Prato–Zabczyk [1] that for $t > 0$, the semigroup $S(t) : \mathcal{H} \longrightarrow V$ is a bounded linear map. Hence for $t > 0$, the adjoint semigroup $S^*(t)$ is also a bounded linear map from V^* to $\mathcal{H}$. Further, by virtue of the assumption on the operator $\Gamma(t), t > 0$ (see (5.3)), it follows from some computation, using the perturbation series $S(t) \equiv \sum_{n\geq 0} S_n(t)$ as in [1, Prop. 2.8, Thm. 2.10], that

$$\int_I \| S^*(t) \|^2_{\mathcal{L}(V^*,\mathcal{H})}\, dt \leq c_2 < \infty,$$

where c_2 is a constant depending on c, α, and T. This justifies the following estimate:

$$\mathrm{Sup}\{E \| z(t) \|^2_{\mathcal{H}}, t \in I\} \leq 2M^2 \| \rho_0 \|^2_{\mathcal{H}} + 2c_2 \| \beta \|^2_{L_2^e(V^*)}, \tag{5.6}$$

where $M \equiv \mathrm{Sup}\{\| S(t) \|_{\mathcal{L}(\mathcal{H})}, t \in I\}$. Hence $z \in M_2(\mathcal{H})$. Using this fact and the uniform bound of $\Gamma_0^{-1}h$ over $H \times R^d$, one can establish that the right-hand expression of equation (5.4) defines an operator Ψ whose mth iterate, for m sufficiently large, is a contraction in $M_2(\mathcal{H})$ and hence it has a unique fixed point, thereby proving that equation (5.4) has a unique solution. Thus the solution map Φ is well defined on $L_2^e(V^*)$. For continuity, it is easy to verify that for any pair of data $\gamma, \beta \in L_2^e(V^*)$, the solutions $\Phi(\gamma), \Phi(\beta)$ satisfy the following inequality:

$$\mathrm{Sup}\{E(\| \Phi_t(\gamma) - \Phi_t(\beta) \|^2_{\mathcal{H}}), t \in I\} \leq K \| \gamma - \beta \|^2_{L_2^e(V^*)}, \tag{5.7}$$

where $K > 0$ is a suitable constant depending only on M, T, $\mathrm{Sup} \| \Gamma_0^{-1}h \|$. Thus Φ is a continuous map from $L_2^e(V^*)$ to $M_2(\mathcal{H})$. Since Φ is an affine map, this implies that it is also weakly continuous. In particular, Φ is also weakly continuous from $L_2^e(V^*)$ to $L_2^e(\mathcal{H})$. For almost sure continuity of the trajectories, we use the C_0-property of the semigroup S^* and the Lebesgue-dominated convergence theorem and the fact that $\int_0^t S^*(t-s)\beta(s)ds \in \mathcal{H}$, P a.s. for each $\beta \in L_2^e(V^*), t \in I$. This completes the proof of the Lemma.

Remark. If the assumption on α in Lemma 5.1 is relaxed by $\alpha \in (0, 1)$ then z, given by

$$z(t) \equiv \int_0^t S^*(t-s)\beta(s)ds, t \in I, \beta \in L_2^e(V^*),$$

only belongs to $L_2^e(\mathcal{H})$ and in this case we can only prove that equation (5.2) has a unique solution in $L_2^e(\mathcal{H})$ and the solution map $\beta \longrightarrow \Phi(\beta)$ is weakly continuous from $L_2^e(V^*)$ to $L_2^e(\mathcal{H})$. Assumption (5.3) is not required for weak solutions [28].

In the next theorem we present an existence result for the system (4.5) and prove that the family of solutions

$$\Xi \equiv \{\rho^u, u \in \mathcal{U}_{ad}\}$$

of the system (4.5) corresponding to the set of admissible controls $\mathcal{U}_{ad}$ is a bounded subset of $M_2(\mathcal{H})$.

THEOREM 5.2. *Under the assumptions of Lemma* 5.1, *for each initial state* $\rho_0 \in \mathcal{H}$ *and admissible control* $u \in \mathcal{U}_{ad}$, *the system* (4.5) *has a unique mild solution* $\rho \in M_2(\mathcal{H})$. *Further, the solution family* Ξ *corresponding to the set of admissible controls* $\mathcal{U}_{ad}$ *is a bounded subset of* $M_2(\mathcal{H})$.

Proof. Under the hypothesis (H5), for each $v \in M(\Gamma)$, the operator L_v given by

$$(L_v\phi)(x) \equiv (D\phi(x), B(x, v))_H \equiv \int_\Gamma ((D\phi)(x), \tilde{B}(x, \gamma))_H \, v(d\gamma), \qquad x \in H$$

is a bounded linear operator from V to $\mathcal{H}$. Indeed there exists a constant b independent of v such that

$$\| L_v\phi \|_{\mathcal{H}} \leq b \| D\phi \|_{\mathcal{H}} \leq b \| \phi \|_V \quad \text{for all } \phi \in V \text{ and } v \in M(\Gamma).$$

Hence the dual operator L_v^* is also a bounded linear operator from $\mathcal{H}$ to V^*. Indeed, for all $v \in M(\Gamma)$, we have

$$|\langle L_v^*\lambda, \phi\rangle_{V^*,V}| = |\langle \lambda, L_v\phi\rangle_{\mathcal{H}}| \leq b \| \lambda \|_{\mathcal{H}} \| \phi \|_V \quad \text{for all } \phi \in V \text{ and } \lambda \in \mathcal{H}.$$

Hence, for each $u \in \mathcal{U}_{ad}$, it follows from measurability of u and continuity of B that for each $\lambda \in L_2^e(\mathcal{H})$, $\beta \equiv L_u^*\lambda$ is weakly measurable, and hence by virtue of separability of the Gelfand triple, it is strongly measurable. Thus it follows from the above inequality that $\beta \equiv L_u^*\lambda \in L_2^e(V^*)$ and $\| L_u^*\lambda \|_{L_2^e(V^*)} \leq b \| \lambda \|_{L_2^e(\mathcal{H})}$. Thus the existence and uniqueness of a solution $\rho^u \in M_2$ corresponding to any given admissible control u follows from application of Lemma 5.1. Indeed using the map Φ as introduced in Lemma 5.1, one can easily verify that the question of existence and uniqueness of solution of equation (4.5) is equivalent to the question of existence of a unique fixed point of the composition operator $\Psi \equiv \Phi o L_u^*$. By repeated iteration one can verify that the nth iterate of Ψ, for n large enough, is a contraction in the Banach space M_2 and hence the existence and uniqueness follows. For boundedness of the solution family Ξ, one can verify using equation (5.4) and replacing β by $L_u^*(\rho)$ that

$$E\big(\| \rho^u(t) \|_{\mathcal{H}}^2\big) \leq 9 \left\{ M^2 \| \rho_0 \|_{\mathcal{H}}^2 + (b^2c_2 + c_3) \int_0^t E(\| \rho^u(s) \|_{\mathcal{H}}^2) ds \right\}, \quad t \in I, \tag{5.8}$$

where

$$b \equiv \operatorname{Sup}\{\| B(x, v) \|, x \in H, v \in \mathcal{M}(\Gamma)\},$$

$$c_2 \equiv \int_I \| S^*(t) \|_{\mathcal{L}(V^*,\mathcal{H})}^2 \, dt,$$

$$c_3 \equiv \operatorname{Sup}\{|\sigma_0^{-1}(z)h(x, z)|_{R^d}^2, x \in H, z \in R^d\}.$$

The inequality (5.8) holds uniformly with respect to $u \in \mathcal{U}_{ad}$. Hence by Gronwall's lemma, it follows from (5.8) that there exists a constant $c_4 > 0$ such that

$$\operatorname{Sup}\{E \| \rho^u(t) \|_{\mathcal{H}}^2, t \in I, u \in \mathcal{U}_{ad}\} \leq c_4 < \infty.$$

In other words Ξ is a bounded subset of M_2. This completes the proof. See also [28] for weak solutions.

Now we are prepared to consider the question of existence of optimal controls. Define for $t \in I$, $y \in Y$, $\lambda \in \mathcal{H}$, $v \in \mathcal{M}(\Gamma)$,

$$\begin{aligned} \hat{\ell}(t, y, \lambda, v) &\equiv \int_H \ell(t, y, x, v)\lambda(x)\mu^0(dx) \\ &\equiv \int_H \int_\Gamma \tilde{\ell}(t, y, x, \gamma)v(d\gamma)\lambda(x)\mu^0(dx). \end{aligned} \tag{5.9}$$

Thus the control problem (4.4)–(4.5), as stated in Theorem 4.1, is equivalent to the following: find a control $u \in \mathcal{U}_{ad}$ such that

$$J(u) \equiv \int_{\Sigma} \{\hat{\ell}(t, y, \rho_t, u(t, y))\}\hat{\eta}(dt, dy) \Longrightarrow \text{Inf}, \tag{5.10}$$

where ρ is the solution of the evolution equation

$$d\rho(t) = \mathcal{A}^*\rho(t)dt + L_u^*\rho(t)dt + G(\rho(t))dy(t), \qquad t \geq 0, \rho(0) = \rho_0. \tag{5.11}$$

For an arbitrary $v \in \mathcal{M}(\Gamma)$, recall the definition of the operator L_v and its dual L_v^*:

$$L_v\phi \equiv (D\phi(\cdot), B(\cdot, v))_H \equiv \int_{\Gamma} (D\phi(\cdot), \tilde{B}(\cdot, r))_H \, v(dr) \text{ for } \phi \in V,$$

$$L_v^*\lambda \equiv \beta \text{ for } \lambda \in \mathcal{H} \text{ such that } \langle \beta, \phi \rangle_{V^*,V} = (\lambda, L_v\phi)_{\mathcal{H}} \text{ for all } \phi \in V.$$

Define the set-valued map $\mathcal{Q} : \Sigma \times \mathcal{H} \longrightarrow 2^{R \times V^*} - \emptyset$ as follows:

(5.12)

$$\mathcal{Q}(t, y, \lambda) \equiv \{(r, \beta) \in R \times V^* : r \geq \hat{\ell}(t, y, \lambda, v) \text{ and } \beta = L_v^*\lambda \text{ for some } v \in U(t, y)\}.$$

For any $\lambda^0 \in \mathcal{H}$, let $N_\epsilon(\lambda^0)$ denote the ϵ-neighborhood of λ^0 in $\mathcal{H}$. The multifunction $\mathcal{Q}$ is said to satisfy the weak Cesari property on $\Sigma \times \mathcal{H}$ if, for each $\lambda^0 \in \mathcal{H}$,

$$\bigcap_{\epsilon > 0} C\ell Co\, \mathcal{Q}(t, y, N_\epsilon(\lambda^0)) \subset \mathcal{Q}(t, y, \lambda^0), \quad \text{for } (t, y) \in \Sigma.$$

If a multifunction satisfies the Cesari property then it must necessarily be closed convex-valued. On the other hand a closed, convex-valued, Hausdorff continuous multifunction always satisfies the Cesari property. In fact, the Cesari property holds for upper semicontinuous (even less, quasi-upper semicontinuous), closed, convex-valued multifunctions [20, 21]. Our first existence result is given in the following theorem. For its proof we adopt a similar procedure as in [8, 9].

THEOREM 5.3. *Consider the optimal control problem* (5.10)–(5.11) *and suppose the following assumptions hold in addition to the basic hypotheses* (H1)–(H6)*:*

(a1) $U : (\Sigma, \mathcal{P}) \longmapsto cc(\mathcal{M}(\Gamma))$ *is weakly measurable.*

(a2) *The integrand* $\hat{\ell}(t, y, \lambda, v)$ *is* $\mathcal{P}$*-measurable in the first two variables, and continuous in the last two arguments, and further there exists a real number* $\delta \geq 0$ *and an* $h \in L_1(\Sigma, \hat{\eta}; R)$ *such that*

$$\hat{\ell}(t, y, \lambda, v) + \delta \parallel \lambda \parallel_{\mathcal{H}}^2 \geq h(t, y), \quad \hat{\eta}\text{-a.e. } \textit{for all} \quad \lambda \in \mathcal{H} \quad \textit{and } v \in U(t, y).$$

(a3) *The set-valued map* $\mathcal{Q}$ *satisfies the weak Cesari property on* $\Sigma \times \mathcal{H}$*. Then there exists an optimal control for the problem.*

Proof. First note that for $\rho \in L_2^e(\mathcal{H})$ and $u \in \mathcal{U}_{ad}$, the functional

$$\tilde{J}(u, \rho) \equiv \int_{\Sigma} \hat{\ell}(t, y, \rho, u)\hat{\eta}(dt, dy)$$

is a well-defined, extended, real-valued function on $\mathcal{U}_{ad} \times L_2^e(\mathcal{H})$. Let Φ denote the solution map as defined in Lemma 5.1 and

$$\mathcal{D} \equiv \{(u, \rho) \in \mathcal{U}_{ad} \times \Xi : \rho = \Phi(\mathbf{L}_{\mathbf{u}}^*\rho)\}$$

denote the set of admissible control-state pairs. Clearly the cost functional J is the restriction of $\tilde{J}$ to $\mathcal{D}$. Thus it suffices to prove the existence of a pair $(u^0, \rho^0) \in \mathcal{D}$ such that

$$\tilde{J}(u^0, \rho^0) \leq \tilde{J}(u, \rho) \quad \text{for all} \quad (u, \rho) \in \mathcal{D}.$$

Since the solution set Ξ is a bounded subset of $L_2^e(\mathcal{H})$, it follows from assumptions (a1) and (a2) that

$$\text{Inf}\{\tilde{J}(u, \rho), (u, \rho) \in \mathcal{D}\} \equiv m_0 > -\infty.$$

Clearly if $m_0 = +\infty$ there is nothing to prove. So we assume that $m_0 < +\infty$. Let $(u^n, \rho^n) \in \mathcal{D}$ be a minimizing sequence for the functional $\tilde{J}$ restricted to $\mathcal{D}$. That is,

$$\lim_{n\to\infty} \tilde{J}(u^n, \rho^n) = m_0. \tag{5.13}$$

Define $\beta^n \equiv L^*_{u^n}\rho^n$ so that $\rho^n = \Phi(\beta^n)$. Since the operator L^*_u is a bounded operator from $L_2^e(\mathcal{H})$ to $L_2^e(V^*)$ uniformly with respect to $u \in \mathcal{U}_{ad}$, as observed in the proof of Theorem 5.2, $\{\beta^n\}$ is contained in a bounded subset of $L_2^e(V^*)$. Note that $L_2^e(V^*)$ is a reflexive Banach space, in fact, a Hilbert space. Thus there exists a subsequence of the sequence $\{\beta^n\}$, relabeled as $\{\beta^n\}$, and an element $\beta^0 \in L_2^e(V^*)$ such that

$$\beta^n \xrightarrow{w} \beta^0 \text{ in } L_2^e(V^*). \tag{5.14}$$

Clearly by virtue of weak continuity of the solution map Φ (see Lemma 5.1), we also have

$$\rho^n \equiv \Phi(\beta^n) \xrightarrow{w} \Phi(\beta^0) \equiv \rho^0 \text{ in } L_2^e(\mathcal{H}). \tag{5.15}$$

Thus by Mazur's theorem there exists a finite convex combination of $\{\beta^n\}$ that converges strongly to β^0 in $L_2^e(V^*)$. In particular, for each integer k, there exists an integer n_k, a set of integers $\{i = 1, 2, \ldots, m(k)\}$ and a set of nonnegative numbers $\{\alpha_{k,i}, 1 = 1, 2, 3, \ldots, m(k)\}$ satisfying

$$\sum_{i=1}^{m(k)} \alpha_{k,i} = 1 \quad \text{for all } k$$

such that

$$\psi_k \xrightarrow{s} \beta^0 \text{ in } L_2^e(V^*), \tag{5.16}$$

where

$$\psi_k(t, y) \equiv \sum_{i=1}^{m(k)} \alpha_{k,i}\, \beta^{n_k+i}(t, y), \quad (t, y) \in \Sigma.$$

Corresponding to the above sequence, define the sequence $\{C_k \equiv C_k(t, y), (t, y) \in \Sigma\}$ as follows:

$$\begin{aligned} C_{n_k+i}(t, y) &\equiv \hat{\ell}\big(t, y, \Phi(\beta^{n_k+i})(t, y), u^{n_k+i}(t, y)\big), \\ C_k(t, y) &\equiv \textstyle\sum_{i=1}^{m(k)} \alpha_{k,i}\, C_{n_k+i}(t, y). \end{aligned} \tag{5.17}$$

Define

$$C_0(t, y) \equiv \liminf_{k\to\infty} C_k(t, y), \qquad (t, y) \in \Sigma. \tag{5.18}$$

Using assumption (a2) and the boundedness of the set Ξ, it is easy to verify that $\liminf C_k(t, y)$ is well-defined $\hat{\eta}$-a.e. on Σ. Therefore by Fatou's lemma we have

$$\int_\Sigma C_0(t, y)\hat{\eta}(dt, dy) \leq \liminf_{k\to\infty} \int_\Sigma C_k(t, y)\hat{\eta}(dt, dy). \tag{5.19}$$

Clearly by virtue of (5.13)

$$\tilde{J}(u^{n_k+i}, \rho^{n_k+i}) \overset{k\to\infty}{\longrightarrow} m_0,$$

and hence it follows from (5.17) that

$$\lim_{k\to\infty} \int_\Sigma C_k(t, y)\hat{\eta}(dt, dy) = m_0. \tag{5.20}$$

Thus from (5.19) and (5.20) we obtain

$$\int_\Sigma C_0(t, y)\hat{\eta}(dt, dy) \leq m_0. \tag{5.21}$$

On the other hand it follows from our assumption (a2) and the boundedness of the set Ξ that there exists an $\tilde{h} \in L_1(\Sigma, \hat{\eta}; R)$ dependent on h such that $C_0(t, y) \geq \tilde{h}(t, y)$, $\hat{\eta}$-a.e. Using this fact along with (5.21) we have $C_0 \in L_1(\Sigma, \hat{\eta}; R)$. Now we show that

$$(C_0(t, y), \beta^0(t, y)) \in \mathcal{Q}(t, y, \Phi(\beta^0)) \equiv \mathcal{Q}(t, y, \rho^0(t, y)), \quad \hat{\eta}\text{-a.e.}$$

Define

$$N_1 \equiv \{(t, y) \in \Sigma : |C_0(t, y)| < \infty \text{ and } \lim_{k\to\infty} \| \psi_k(t, y) - \beta^0(t, y) \|_{V^*} = 0\},$$
$$M_k \equiv \{(t, y) \in \Sigma : u^k(t, y) \notin U(t, y)\} \text{ and } N_0 \equiv \bigcup_{k\geq 1} M_k.$$

Since $C_0 \in L_1(\Sigma, \hat{\eta}; R)$ and $\psi_k \overset{s}{\longrightarrow} \beta^0$ we have $\hat{\eta}(\Sigma \setminus N_1) = 0$. Set $N_2 \equiv (\Sigma \setminus N_0)$ and $N_3 \equiv N_1 \cap N_2$. By the definition of admissible controls, $\hat{\eta}(N_0) = 0$. Thus $\hat{\eta}(\Sigma \setminus N_3) = 0$. In other words $\hat{\eta}(N_3) = \hat{\eta}(\Sigma)$. Define $\Sigma_0 \equiv N_3 \bigcap \{(t, y) \in \Sigma : t \neq \{0, T\}\}$. Therefore, for $(t, y) \in \Sigma_0$, there exists a subsequence, possibly dependent on (t, y), of the sequence $\{C_k\}$, again denoted by $\{C_k\}$, such that

$$C_k(t, y) \longrightarrow C_0(t, y) \quad \text{for } (t, y) \in \Sigma_0. \tag{5.22}$$

Choosing the corresponding subsequence for the sequence $\{\psi_k\}$, we have

$$\psi_k(t, y) \overset{s}{\longrightarrow} \beta^0(t, y) \text{ in } V^* \quad \text{for } (t, y) \in \Sigma_0. \tag{5.23}$$

Thus for every $(t, y) \in \Sigma_0$ and $\epsilon > 0$, there exists an integer $\tilde{k} \equiv \tilde{k}(t, y)$ such that, for $k > \tilde{k}$,

$$\Phi(\beta^{n_k+i})(t, y) \in N_\epsilon(\Phi(\beta^0)(t, y)),$$

where $N_\epsilon(\lambda)$ denotes the ϵ-neighborhood of any point $\lambda \in \mathcal{H}$. Clearly

$$\mathcal{Q}(t, y, \Phi(\beta^{n_k+i})) \subset \mathcal{Q}(t, y, N_\epsilon(\Phi(\beta^0))) = \mathcal{Q}(t, y, N_\epsilon(\rho^0)) \quad \text{for } k > \tilde{k} \text{ and } (t, y) \in \Sigma_0.$$

It follows from the definition of $\mathcal{Q}$ that

$$(C_{n_k+i}(t, y), \beta^{n_k+i}(t, y)) \in \mathcal{Q}(t, y, \Phi(\beta^{n_k+1})(t, y)).$$

Thus for $k > \tilde{k}$, using (5.16)–(5.17), we obtain

$$(C_k(t, y), \psi_k(t, y)) \in Co\ \mathcal{Q}(t, y, N_\epsilon(\Phi(\beta^0)(t, y)) \quad \text{for } (t, y) \in \Sigma_0.$$

Using these facts, it follows from (5.22) and (5.23) that for $(t, y) \in \Sigma_0$,

$$(C_0(t, y), \beta^0(t, y)) \in C\ell Co\ \mathcal{Q}\ (t, y, N_\epsilon(\Phi(\beta^0)(t, y)))$$

for every $\epsilon > 0$, and hence

$$(C_0(t, y), \beta^0(t, y)) \in \bigcap_{\epsilon>0} C\ell Co\ \mathcal{Q}(t, y, N_\epsilon(\Phi(\beta^0)(t, y)).$$

Therefore, by the weak Cesari property (a3),

$$(C_0(t, y), \beta^0(t, y)) \in \mathcal{Q}(t, y, \Phi(\beta^0)(t, y)) = \mathcal{Q}(t, y, \rho^0(t, y)) \text{ for all } (t, y) \in \Sigma_0,$$

and hence $\hat{\eta}$-a.e. on Σ. This implies that for every $(t, y) \in \Sigma_0$ there exists $\tilde{u}(t, y) \in U(t, y)$ such that

$$C_0(t, y) \geq \hat{\ell}(t, y, \rho^0(t, y), \tilde{u}(t, y)) \text{ for } (t, y) \in \Sigma_0,$$
$$\beta^0(t, y) = (L^*_{\tilde{u}}\, \rho^0)(t, y) \text{ for } (t, y) \in \Sigma_0.$$

Since $\hat{\eta}(\Sigma_0) = \hat{\eta}(\Sigma)$, we have

$$C_0(t, y) \geq \hat{\ell}(t, y, \rho^0(t, y), \tilde{u}(t, y)), \ \hat{\eta}\text{-a.e. on } \Sigma,$$
$$\beta^0(t, y) = (L^*_{\tilde{u}}\, \rho^0)(t, y) \ \hat{\eta}\text{-a.e. on } \Sigma.$$

In view of (5.21), the question that remains to be settled is whether or not a $\mathcal{P}$-measurable substitute for $\tilde{u}$ can be found. We prove this using the theory of measurable selections. Define for $(t, y) \in \Sigma_0$, the set-valued map

$$\Lambda(t, y) \equiv \left\{v \in U(t, y) : C_0(t, y) \geq \hat{\ell}(t, y, \rho^0(t, y), v) \text{ and } \beta^0(t, y) = (L^*_v(\rho^0))(t, y)\right\}.$$

Clearly this set is nonempty. We prove that it has a $\mathcal{P}$-measurable selection. A most general result in this direction states that a weakly measurable set-valued function (for definition see §2) with closed values, from an arbitrary measurable space to a Polish space, has measurable selection [10, Thm. 4.1, pp. 867]. Since $\mathcal{M}(\Gamma)$ is a Polish space, it suffices to verify that Λ is closed valued and weakly measurable. To prove closedness, let $v_n \in \Lambda(t, y)$ and suppose $v_n \xrightarrow{w^*} v_0$ in $\mathcal{M}(\Gamma)$. Since $U(t, y) \in cc(\mathcal{M}(\Gamma))$ we have $v_0 \in U(t, y)$. Further, it follows from continuity of $\nu \longrightarrow \hat{\ell}(t, y, \lambda, \nu)$ that

$$\hat{\ell}(t, y, \rho^0(t, y), v_n) \longrightarrow \hat{\ell}(t, y, \rho^0(t, y), v_0), \ \hat{\eta}\text{-a.e.}$$

Similarly for any $\phi \in V$, we have

$$\begin{aligned}\langle \beta^0(t, y), \phi\rangle_{V^*,V} &= \langle L^*_{v_n} \rho^0(t, y), \phi\rangle_{V^*,V} \\ &= (\rho^0(t, y), L_{v_n}\phi)_{\mathcal{H}} \longrightarrow (\rho^0(t, y), L_{v_0}\phi)_{\mathcal{H}} \\ &= \langle L^*_{v_0}\rho^0, \phi\rangle_{V^*,V}\ \hat{\eta}\text{-a.e.}\end{aligned}$$

Since $\phi \in V$ is arbitrary, this implies that Λ has closed values. In fact $\Lambda : \Sigma \longrightarrow cc(\mathcal{M}(\Gamma))$. Now we prove measurability. For simplicity of notation, we denote $\sigma \equiv (t, y) \in \Sigma$. Define the multifunctions

$$\Lambda_0(\sigma) \equiv \{v \in \mathcal{M}(\Gamma) : \hat{\ell}(\sigma, \rho^0(\sigma), v) - C_0(\sigma) \leq 0\},\ \sigma \in \Sigma,$$
$$\Lambda_1(\sigma) \equiv \{v \in \mathcal{M}(\Gamma) : (L^*_v\rho^0)(\sigma) - \beta^0(\sigma) = 0\},\ \sigma \in \Sigma.$$

Then

$$\Lambda(\sigma) = \big(\Lambda_0(\sigma) \cap U(\sigma)\big) \bigcap \big(\Lambda_1(\sigma) \cap U(\sigma)\big). \tag{5.24}$$

We show that each component is $\mathcal{P}$-measurable. Let $M_0 \subset \mathcal{M}(\Gamma)$ be any closed subset. Since $\mathcal{M}(\Gamma)$ is a Polish space, there exists a countable dense subset M_{00} of M_0 so that we have

$$\begin{aligned} \Lambda_0^-(M_0) &\equiv \{\sigma \in \Sigma : \Lambda_0(\sigma) \cap M_0 \neq \emptyset\} \\ &= \bigcup_{v \in M_{00}} \{\sigma \in \Sigma : \hat{\ell}(\sigma, \rho^0(\sigma), v) - C_0(\sigma) \leq 0\}. \end{aligned} \tag{5.25}$$

Since ρ^0 and C_0 are $\mathcal{P}$-measurable it follows from our assumption (a2) that each of the components in (5.25) is $\mathcal{P}$-measurable and hence $\Lambda_0^-(M_0) \in \mathcal{P}$. Similarly, using the separability of V we can also write

$$\begin{aligned} \Lambda_1^-(M_0) &\equiv \{\sigma \in \Sigma : \Lambda_1(\sigma) \cap M_0 \neq \emptyset\} \\ &= \bigcup_{v \in M_{00}} \bigcap_{\phi \in V_0} \big\{\sigma \in \Sigma : \langle (L_v^* \rho^0)(\sigma), \phi \rangle = \langle \beta^0(\sigma), \phi \rangle\big\}, \end{aligned} \tag{5.26}$$

where V_0 is a countable dense subset of V. This shows that both Λ_0 and Λ_1 are $\mathcal{P}$-measurable. Since for set-valued maps measurability implies weak measurability and by our assumption U is weakly measurable, we conclude that Λ, given by (5.24), is weakly measurable. Thus there exists a $\mathcal{P}$-measurable selection u^* of Λ which is a substitute for $\tilde{u}$. This completes the proof.

Remark. Assumption (5.3) of Lemma 5.1 can be replaced by hypothesis 5 of Da Prato and Zabczyk [1], in which case the operator $-\mathcal{A}$ is coercive with respect to the triple $\{V, \mathcal{H}, V^*\}$. In this case weak solutions can be exploited instead of mild solutions.

6. Optimal control of Zakai inclusion. So far we have considered the map $B(x, u)$ to be single valued. If it is a multivalued map, equation (1.1) turns into a stochastic differential inclusion:

$$\begin{aligned} &dx \in Axdt + F(x)dt + B(x, u(t, y))dt + \sqrt{Q}dW, x(0) = x_0, \\ &dy = h(x, y)dt + \sigma_0(y)dw^0, y(0) = 0. \end{aligned} \tag{6.1}$$

We consider F to be single valued and B a multivalued map. This class of systems may arise from evolution inequalities or from parametric uncertainty of system coefficients [9, 18]. Here we shall use the notion of a solution for differential inclusions as given in Ahmed [8, 9]. Corresponding to an admissible control u, a process x is a mild solution of (6.1) if there exists a predictable process $z \in L_2^e(H)$ such that x is a mild solution of (1.1) with z substituted for B and that $z(t) \in B(x(t), u(t, y))$ for almost all $t \in I$ -P a.s.

We present here an existence result similar to Theorem 5.2. First we translate the above problem into a differential inclusion of Zakai type.

For each $v \in M(\Gamma)$, define

$$\mathcal{B}(v) \equiv \{\text{ all } \mu^0\text{-measurable Borel selections } b : b(x) \in B(x, v), \mu^0 \text{ a.e. on } H\}.$$

We assume that for each $v \in M(\Gamma)$, the set $\mathcal{B}(v)$ is nonempty. A sufficient condition for this is that there exists $\zeta \in L_1(H, \mu^0)$ such that

$$\| B(x, v) \|^0 \equiv \text{ Sup}\{\| \beta \|_H, \beta \in B(x, v)\} \leq \zeta(x), x \in H.$$

Then define the multivalued operator $L_{\mathcal{B}(v)}$ as follows: for each $\phi \in V$,

$$L_{\mathcal{B}(v)}\phi \equiv \{g \in \mathcal{H} : g = (D\phi(\cdot), b(\cdot))_H \equiv L_b\phi \text{ for some } b \in \mathcal{B}(v)\}.$$

The corresponding adjoint family $L^*_{\mathcal{B}(v)}$ is given by

$$L^*_{\mathcal{B}(v)}\zeta \equiv \{\beta \in V^* : \langle \beta, \phi\rangle_{V^*,V} = (\zeta, L_b\phi)_{\mathcal{H}}, \text{ for some } b \in \mathcal{B}(v) \text{ for all } \phi \in V\}, \qquad \zeta \in \mathcal{H}.$$

The equation (5.11) now turns into an inclusion. For any admissible control law u we have the differential inclusion in $\mathcal{H}$:

$$d\lambda \in \mathcal{A}^*\lambda dt + L^*_{\mathcal{B}(u(t,y))}\lambda dt + G(\lambda)dy, \lambda(0) = \rho_0, \qquad t \in I, \tag{6.2}$$

which is associated with the differential inclusion (6.1) in H. An element $\rho \in M_2(\mathcal{H}) \subset L^e_2(\mathcal{H})$ is a mild solution of the evolution inclusion (6.2) if there exists a $\beta \in L^e_2(V^*)$ such that

$$\begin{aligned} &d\rho = \mathcal{A}^*\rho dt + \beta dt + G(\rho)dy, \qquad \rho(0) = \rho_0 \\ &\text{and } \beta(t) \in (L^*_{\mathcal{B}(u)}\rho)(t) \ \hat{\eta}\text{-a.e.} \end{aligned} \tag{6.3}$$

Let $\Phi : \beta \mapsto \rho$ denote the solution map giving $\rho = \Phi(\beta)$ as the solution of the first equation of (6.3) corresponding to any $\beta \in L^e_2(V^*)$. For each $u \in \mathcal{U}_{ad}$, define the multivalued map

$$\hat{C}_u(\beta) \equiv \{\gamma \in L^e_2(V^*) : \gamma(t) \in (L^*_{\mathcal{B}(u(t,y))}\Phi(\beta))(t), \ \hat{\eta}\text{-a.e.}\}.$$

The question of existence of a solution of the evolution inclusion (6.2) is equivalent to the question of existence of a fixed point of the multivalued map $\hat{C}_u$. We present here the following existence result for optimal control of (6.2) and (5.10).

THEOREM 6.1. *Consider the system* (6.2) *along with the cost functional* (5.10). *In addition to the assumptions* (H1)–(H6), *suppose the following assumptions hold:*

(b1) $U : (\Sigma, \mathcal{P}) \mapsto cc(\mathcal{M}(\Gamma))$ *is measurable.*

(b2) $B : H \times \mathcal{M}(\Gamma) \mapsto cbc(H)$ *and there exists a constant* $b_0 < \infty$ *such that* $\| B \|^0 \equiv \text{Sup}\{\| b(x) \|_H, x \in H, b \in \mathcal{B}(v), v \in \mathcal{M}(\Gamma)\} \le b_0$.

(b3) *The cost integrand* $\hat{\ell}$ *satisfies* (a2) *of Theorem* 5.3.

(b4) *The set-valued map* $\mathcal{Q}$ *given by*

$$\mathcal{Q}(t, y, \lambda) \equiv \{(r, \beta) \in R \times V^* : r \ge \hat{\ell}(t, y, \lambda, v) \text{ and } \beta \in L^*_{B(v)}\lambda \text{ for some } v \in U(t, y)\} \tag{6.4}$$

satisfies the weak Cesari property. Then there exists an optimal control for the problem.

Proof. The major part of the proof is identical to that of Theorem 5.3. It is required only to show that the evolution inclusion (6.2) has solutions. This follows if, for every admissible control u, the fixed point set $Fix(\hat{C}_u)$ of the multivalued map $\hat{C}_u$ is nonempty. Under the assumptions on B and U, it can be shown that $\hat{C}_u : L^e_2(V^*) \mapsto cbc(L^e_2(V^*))$. Further $\beta \longrightarrow \hat{C}_u(\beta)$ is upper semicontinuous with respect to inclusion. By virtue of boundedness of the set-valued map B, (see assumption (b2)), there exists a constant $0 < r < \infty$ independent of u such that $\hat{C}_u : D_r \subset L^e_2(V^*) \mapsto D_r$, where D_r is a closed ball of radius r in $L^e_2(V^*)$ with its center at the origin. Hence $\hat{C}_u(\beta) \cap D_r \neq \emptyset$ for all $\beta \in D_r$ and $u \in \mathcal{U}_{ad}$. Since $L^e_2(V^*)$ is a reflexive Banach space endowed with the weak topology, it is a locally convex, topological vector space. Hence it follows from a generalized version of the Kakutani–Fan fixed-point theorem [19, Thm. 9.B, p. 452] that the fixed-point set, $Fix(\hat{C}_u)$ is nonempty for every $u \in \mathcal{U}_{ad}$. Hence, for each $u \in \mathcal{U}_{ad}$, the evolution inclusion (6.2) has solutions. Let

$$\Xi \equiv \{\rho \in L^e_2(\mathcal{H}) : \rho = \Phi(\beta), \text{ for } \beta \in Fix(\hat{C}_u), u \in \mathcal{U}_{ad}\}$$

denote the solution set. Then the set of admissible control-state pairs is given by

$$\mathcal{D} \equiv \{(u, \rho) \in \mathcal{U}_{ad} \times \Xi : \rho = \Phi(\beta), \beta \in \hat{\mathbf{C}}_{\mathbf{u}}(\beta)\}. \tag{6.5}$$

From here on, the rest of the proof is identical to that of Theorem 5.3. This completes the proof.

Remark. In case the evolution inclusion arises from parametric uncertainty, it is natural to consider the min-max problem (see [18]) rather than the minimum problem considered here in Theorem 6.1. One defines the solution set corresponding to a fixed admissible control law u as follows:

$$\mathcal{X}(u) \equiv \{\rho \in L_2^e(\mathcal{H}) : \rho = \Phi(\beta) \text{ for some } \beta \in Fix(\hat{C}_u)\}.$$

The cost functional is then given by

$$J_0(u) \equiv \text{Sup}\{J(u, \rho), \rho \in \mathcal{X}(u)\}.$$

The problem is to find a control law that minimizes this functional. In other words optimal control is the one that minimizes the maximum risk.

Remark. If h of equation (6.1) is multivalued, the operator G of the inclusion (6.2) is also multivalued. This situation may arise if the measurement dynamics also has parametric uncertainties. Since this appears in the diffusion term the problem becomes much more difficult.

7. Necessary condions of optimality. In this section we present a result on the necessary conditions of optimality. This is essentially a stochastic minimum principle. We shall only state the result without proof. In principle the proof is based on arguments similar to those of [22]–[25].

Set $\sigma \equiv (t, y) \in \Sigma$ and define the Hamiltonian

$$H(\sigma, \rho, \phi, v) \equiv \langle \rho, L_v\phi\rangle_{\mathcal{H}} + \hat{\ell}(\sigma, \rho, v) \equiv \int_\Gamma \{\langle \rho, (B(\cdot, \xi), D\phi)\rangle + \bar{\ell}(\sigma, \rho, \xi)\}v(d\xi), \tag{7.1}$$

where $\bar{\ell}(\sigma, \rho, \xi) \equiv \int_H \tilde{\ell}(\sigma, x, \xi)\rho(x)\mu^0(dx)$. Introduce the function

$$g(\sigma, x) \equiv \int_\Gamma \tilde{\ell}(\sigma, x, \xi)u^o(\sigma)(d\xi),$$

where u^0 is the optimal control law, and define the abstract vector-valued function

$$g^o(\sigma) \equiv g(\sigma, \cdot),$$

taking values from $L_1((\Sigma, \hat{\eta}), \mathcal{H})$. The Hamiltonian

$$H : \Sigma \times \mathcal{H} \times V \times M(\Gamma) \longrightarrow R \cup \{+\infty\}.$$

THEOREM 7.1. *Let $\{u^o, \rho^o\} \in \mathcal{U}_{ad} \times L_2^e(\mathcal{H})$. In order that $\{u^o, \rho^o\}$ be an optimal pair, it is necessary that there exists an element $\phi^o \in L_2^e(V)$ so that*

$$\int_\Sigma H(\sigma, \rho^o, \phi^o, u)\hat{\eta}(d\sigma) \geq \int_\Sigma H(\sigma, \rho^o, \phi^o, u^o)\hat{\eta}(d\sigma) \text{ for all } u \in \mathcal{U}_{ad}, \tag{7.2}$$

where the pair $\{\rho^o, \phi^o\}$ are the mild solutions of the following equations:

$$\begin{aligned} d\rho &= \mathcal{A}^*\rho dt + L^*_{u^o}\rho dt + G(\rho)dy, \qquad t \geq 0, \rho(0) = \rho_0, \\ d\phi &= -(\mathcal{A}\phi + L_{u^o}\phi)dt + g^o dt - G(\phi)dy, \qquad \phi(T) = 0. \end{aligned} \tag{7.3}$$

Remark. The last equation in (7.3) is a backward stochastic evolution equation which naturally arises whenever one attempts to develop a stochastic minimum principle as the necessary condition of optimality. The question of existence of solutions of such equations has been considered in several papers. For details see [22]–[25].

Pointwise necessary conditions of optimality can be derived from (7.2) provided certain conditions are met. Let $\mathcal{B}(R^d)$ denote the σ-algebra of Borel subsets of R^d, and set $\Theta(t)(G) \equiv P\{y(t) \in G\}$ for any $G \in \mathcal{B}(R^d)$, where y is the unique solution of the stochastic differential equation $dy = \sigma_0(y)dw^0$, $y(0) = 0$. Define the Young measure $\hat{\Theta}$ on $\mathcal{B}(I \times R^d)$ as follows: for any $K \in \mathcal{B}(I \times R^d)$,

$$\int_K \hat{\Theta}(dtd\zeta) = \int_K \Theta(t)(d\zeta)dt.$$

Let Γ be a compact Polish space and $U : I \times R^d \longrightarrow cc(M(\Gamma))$ be a measurable multifunction. For the admissible controls we take

$$\mathcal{U}_{ad} \equiv \{u : I \times R^d \longrightarrow M(\Gamma) \text{ so that } u \text{ is } w^*\text{-measurable and } u(t, y) \in U(t, y)\ \hat{\Theta}\text{-a.s.}\}.$$

Define the Hamiltonian as follows:

$$H(t, y, \rho, \phi, v) \equiv \langle \rho, L_v\phi \rangle + \hat{\ell}(t, y, \rho, v),\ v \in U(t, y).$$

Note that H maps $I \times R^d \times \mathcal{H} \times V \times M(\Gamma)$ to $R \cup \{+\infty\}$. Then, for the given admissible controls, one can use (7.2) to derive the pointwise necessary condition of optimality given by

$$(7.5)\ H(t, y, \rho^o(t), u, \phi^o(t)) \geq H(t, y, \rho^o(t), u^o(t, y), \phi^o(t)) \quad \text{for all } u \in U(t, y),\ \hat{\Theta}\text{-a.e.}$$

8. Comments on applications.

Ecological problem. Considering the ecological problem, it is not difficult to verify that if $\beta \equiv \sup\{\| v(\xi) \|, \xi \in \Omega\} < \infty$, and $D \equiv \operatorname{diag}(d_1, d_2, \ldots, d_m)$ with $d_k > 0, k = 1, 2, \ldots, m$, then the operator A, as defined in this example, is the infinitesimal generator of an analytic semigroup $T(t), t \geq 0$ in H. If β is sufficiently small then the semigroup is exponentially stable and condition (H1)(a) is satisfied. For this problem, considering the source of noise, the covariance Q is practically nuclear and hence by virtue of exponential stability of the semigroup T, Q_t satisfies (H1)(b). (H1)(c) is an assumption of the model. Hence the existence of a unique invariant measure μ^0 follows. For this example, $F = 0$ and (H2) is trivially satisfied. Assumptions (H3) and (H4) are rather technical and are required for the proof of the main result of Da Prato and Zabczyk [1, Thm. 3.1] on which our result is based. Since the environmental agencies monitoring the system will never permit growth of C beyond a certain predetermined level, for all practical purposes we can assume B to satisfy assumption (H5). For example, we can replace B by $B_r(x, u) \equiv B(P_r(x), u)$, where P_r is the retraction of the ball $S_r \equiv \{x \in H : \| x \| \leq r\}$ defined as

$$P_r(x) \equiv \begin{cases} x & \text{for } x \in S_r, \\ (r/\| x \|)x & \text{otherwise.} \end{cases}$$

One can choose the ceiling r as large as required. With this modification we can admit any function $B(x, u)$ which is locally Lipschitz in $x \in H$ and continuous and bounded in u on closed bounded sets $\Gamma \subset L_\infty(\Omega, R^s_+)$, where R^s_+ denotes the positive orthant of R^s and s is the number of distinct control agents as described in §2. Clearly the function h as defined by

equation (2.3) is bounded and Lipschitz. Since $L_1(\Omega, R^s)$ is separable, any closed bounded set $\Gamma \subset L_\infty(\Omega, R^s_+)$ with the relative w^* topology is a Polish space. Thus with relaxed controls, all the conditions (a1)–(a3) of Theorem 5.3 hold. Conditions (a1) and (a2) are trivial. For (a3), note that continuity of the maps B and the cost integrand ℓ with respect to the state and control, all convexified by relaxed controls, imply that the Cesari map $\mathcal{Q}$ (see equation (5.12)) is continuous in the Hausdorff metric and closed convex-valued and hence satisfies the weak Cesari property.

Electrical problem. Now we consider the electrical "crosstalk" problem. The standard norm for $H \equiv L_2(\Omega, R^m) \times L_2(\Omega, R^m) \times R^m$ is induced by the scalar product

$$(y, z) \equiv (y_1, z_1)_{L_2(\Omega, R^m)} + (y_2, z_2)_{L_2(\Omega, R^m)} + (y_3, z_3)_{R^m}.$$

For the electrical problem, however, it is convenient to use the energy norm induced by the scalar product

$$(y, z)_e \equiv (Ly_1, z_1)_{L_2(\Omega, R^m)} + (Cy_2, z_2)_{L_2(\Omega, R^m)} + (C_1 y_3, z_3)_{R^m}.$$

Since the matrices L, C, C_1 are symmetric and positive definite, the two norms are equivalent. We assume that H is furnished with the energy-related scalar product $(y, z) \equiv (y, z)_e$ and omit the subscript e. It is easy to verify that the operator A (see §2, electrical problem) is closed and densely defined with domain and range in H and that it is strictly m-dissipative. Hence by the Lumer–Phillips theorem (see [26]), A is the infinitesimal generator of a C_0-semigroup, $T(t), t \geq 0$, of contractions in H. Further, by use of the energy norm, it is not difficult to verify that

$$(Ay, y) = -(Ry_1, y_1)_{L_2(\Omega, R^m} - (Gy_2, y_2)_{L_2(\Omega, R^m)} - (R_0 y_1(0), y_1(0))_{R^m} - (Ky_3, y_3)_{R^m}.$$

Since $\{R, G, R_0, K\}$ are all symmetric and positive definite and the two norms are equivalent, there exists an $\alpha > 0$ such that

$$(Ay, y) \leq -\alpha \parallel y \parallel^2 \quad \text{for all } y \in D(A).$$

Hence A generates a C_0-semigroup $T(t), t \geq 0$ of contractions satisfying $\parallel T(t) \parallel \leq e^{-\alpha t}$, for all $t \geq 0$. For this problem, the controls are finite dimensional and we may assume that u takes values from a closed bounded set $\Gamma \subset R^{2m}$, not necessarily convex. Since $\tilde{g}$ is Lipschitz and bounded, the operator $B(x, u)$ is Lipschitz and bounded on $H \times \Gamma$. The function h in equation (2.16) may not be uniformly bounded on H. In fact the voltages induced in the induction coils of the probe may increase with the increase of currents and voltages on the transmission lines and the frequency. But in all practical instrumentation, the measurement devices saturate if overdriven and hence whenever line currents and voltages exceed a certain limit, the induced voltages h_k will saturate. Hence for all practical purposes, h can be replaced by $\tilde{h}_r(x) \equiv h(P_r x)$ for a suitable $0 < r < \infty$, where, again, P_r denotes the retraction map with respect to the ball $S_r \equiv \{x \in H : \parallel x \parallel \leq r\}$. With these modifications all the assumptions of Theorem 5.3 hold with relaxed controls replacing the ordinary controls.

Remark. Even though from practical considerations, the theoretical results developed here are applicable to many applied problems, from a theoretical standpoint the theory is certainly not completely satisfactory. The main limitation arises from the assumption of boundedness of the operator-valued functions B and h. But this limitation of the theory has not been overcome even for finite-dimensional problems. As an example, for unbounded h, no satisfactory existence theorem for the solution of the Zakai equation is known. Thus it remains an open problem to develop theoretical results that allow unbounded operators B and h.

STABILIZATION BY CONSTRAINED CONTROLS*

GEORGI V. SMIRNOV†

Abstract. A stabilization problem for a general nonlinear control system is considered. In particular the control corresponding to the equilibrium position may belong to the boundary of the control set. A linear control system is considered as a first approximation for the original problem. The right-hand side of the linear system generates a set-valued map of a special type known as a convex process. This set-valued map has a number of properties similar to those of a linear operator. They allow one to establish necessary and sufficient conditions for solvability of the regulator design problem for the first approximation and to construct a Lyapunov function. Based on these results the nonlinear stabilization problem is investigated. Different statements of the regulator design problem are studied. Stabilization problems for some mechanical systems are considered to illustrate the regulator design techniques. The properties of transient characteristics (the "peak" effect) are discussed for a linear stabilization problem under controllability conditions.

Key words. stabilization, Lyapunov function, constrained control, discontinuous right-hand side

Introduction.

Consider a control system

$$\dot{x} = f(x, u), \ u \in U, \tag{1}$$

where U is the control set. Assume that there exists $u_0 \in U$ such that $f(0, u_0) = 0$. In this case we say that $x = 0$ is an equilibrium position of system (1) and u_0 is a control corresponding to the equilibrium position. Our aim is to find a function $u = u(x)$ defined in a neighborhood of the origin and satisfying the following conditions:

1. $u(0) = u_0$, and
2. all trajectories of the differential equation

$$\dot{x} = f(x, u(x)) \tag{2}$$

starting at a neighborhood of the origin tend to the equilibrium position $x = 0$.

The function $u(x)$ is referred to as a regulator or a stabilizer, and the problem of its construction is called a regulator design or stabilization problem.

The regulator design problem has been largely studied in the case of control systems where controls range over a vector space. Such problems serve as mathematical models for a large number of applications, and rather developed and satisfactory theory is now available for them (see Bacciotti [3], for example). This theory is also applicable in the presence of the control constraint $u \in U$ if the control u_0 corresponding to the equilibrium position is an interior point of the set U. Indeed, since the stabilization problem is of local nature we can expect that the stabilizer $u(x)$ varies in a neighborhood of u_0, and the constraint $u \in U$ is of no importance. However, in many technological applications processes possessing some extreme properties are of great interest. The main characteristic feature of the regulator design problem for such processes is that the control corresponding to the equilibrium position belongs to the boundary of the set U. In this case the control constraint is inevitably involved, and the problem is considerably more difficult. This paper is devoted to problems of this type.

There are many motivations that lead researchers to consider such problems. First of all, the Pontryagin maximum principle tells us that stabilization of optimal processes is a problem of this type. Usually optimal processes are not stabilizable and it is very important to determine

*Received by the editors January 26, 1994; accepted for publication (in revised form) May 12, 1995.

†Departamento de Matematica, Universidade de Evora, Apartado 94, P-7001 Evora codex, Portugal (smirnov@uevora.pt).

the set of deviations starting at which the system can be stabilized to the optimal process. The stabilization problem studied here can be considered as the first step in this direction.

A similar problem arises if we deal with a mechanical system subjected to a unilateral force. Consider, for instance, an oscillator and suppose that we have to stabilize it applying a force only in one direction. The corresponding mathematical model is

$$\ddot{x} = -x + u,$$
$$0 \le u \le 1.$$

The control $u_0 = 0$ corresponding to the equilibrium position $x = 0$ belongs to the boundary of the control set.

Now consider a guided missile which moves in a plane. We can vary the thrust of its jet propulsion in value and direction. If we neglect the angular motion and size of the missile and suppose that the velocity of the missile is always directed along the longitudinal axis, then the motion of the missile's mass center is described by the following equations:

$$\ddot{x} = -\sigma\dot{x} + \frac{u^1\dot{x} - u^2\dot{y}}{\sqrt{\dot{x}^2 + \dot{y}^2}},$$
$$\ddot{y} = -\sigma\dot{y} + \frac{u^1\dot{y} + u^2\dot{x}}{\sqrt{\dot{x}^2 + \dot{y}^2}},$$
$$(u^1, u^2) \in U = \left\{(u^1, u^2) \mid \sqrt{(u^1)^2 + (u^2)^2} \le b,\ \frac{u^2}{u^1} \le \tan\eta,\ u^1 \ge 0\right\},$$

where $\sigma > 0$ stands for a coefficient of air resistance, b is the maximal thrust, and η is the maximal angle between the longitudinal axis of the missile and that of the jet propulsion. Our aim is to stabilize the motion of the object along the x-axis with the constant maximal speed $\dot{x} = b/\sigma$. Thus we again obtain a stabilization problem where control $(u_0^1, u_0^2) = (b, 0)$ corresponding to the equilibrium position belongs to the boundary of the control set.

In mathematical biology and economics we also face stabilization problems with constrained controls (see Gouzé [10] and Berman, Neumann, and Stern [5]).

Classic regulator design theory cannot be applied to the above problems because of control constraints. The optimal control theory involves control constraints, but the problem of construction of the feedback control $u(x)$ that guarantees optimality of trajectories in a certain sense is too complex to be solved analytically, applying the Pontryagin maximum principle or studying the Bellman equation. Computational methods of optimal control theory are more suitable to finding optimal trajectories than to solving synthesis problems. Thus it is not worth considering the regulator design problem in the frame of optimal control theory. Therefore a reasonable statement of the regulator design problem and a rational combination of analytical and computational methods are required in order to solve the problem.

In classic stabilization theory we meet the statement of the problem where neither optimality nor finiteness of the stabilization time are required. The only requirement the regulator has to satisfy is that the equilibrium position is asymptotically stable. It seems natural to develop mathematical theory for this "weak" statement of the regulator design problem, if we aim to consider control systems of general type (1).

The origin of this setting of the problem and the method of its solution is the classical Lyapunov [14] stability theory. For practical problems it is important to consider not only the fact of asymptotic stability of an equilibrium position but also an estimate of a region of attraction, that is, the set of initial points starting at which trajectories tend to zero. It is possible with the help of the Lyapunov functions method. Unfortunately, there are no methods

to construct a Lyapunov function for a control system of general type. Therefore we have to "simplify" the system under consideration, that is, to find a less complex control system which is close to the original one in a neighborhood of the origin. To this end we consider the "first approximation" of system (1), that is, the linear control system

$$\dot{x} = Cx + w, \quad w \in K, \tag{3}$$

where $C = \nabla_x f(0, u_0)$ is an $n \times n$ matrix and K is a convex cone spanned by the set $f(0, U)$. Control systems of this type were first studied by Korobov and his students [12, 13] and then in more general form by Aubin, Frankowska, and Olech [2]. For control system (3) we derive necessary and sufficient conditions guaranteeing the existence of a Lyapunov function and prove that the latter is equivalent to the solvability of the regulator design problem for system (3). The proof is based on an investigation of the set-valued map $x \to Cx + K$. A map of this type, referred to as a convex process (see Rockafellar [16]), is a multivalued analogy of a linear operator. A number of properties similar to the Jordan theorem are established for it. The analysis of the structure of the convex process $x \to Cx + K$ is the basis for the construction of a Lyapunov function $V(x)$. To solve the regulator design problem we can choose the control $u(x)$ at the point x from the following condition:

$$V(x + \tau f(x, u(x))) = \min_{u \in U} V(x + \tau f(x, u)), \tag{4}$$

where $\tau > 0$.

A multivalued version of the Jordan theorem for convex processes of general type appeared in Smirnov [18], where it was applied to solve the regulator design problem for differential inclusions. Here we specify the results from [18] for the case of control systems. This allows us to simplify the proofs and to establish many new properties of the developed regulator design techniques. Computational aspects of this approach are discussed in Bushenkov and Smirnov [7, 8], where many examples are considered.

The regulator design method derived from our analysis contains many parameters which we can dispose of as needed. Optimization methods or heuristics allow one to obtain a regulator with required transient characteristics. For example, in the case of the single-input linear control system

$$\dot{x} = Ax + bu, \quad u \in R, \tag{5}$$

under controllability condition, we obtain a regulator which is a linear feedback control $u(x) = \langle d, x \rangle$ such that the spectrum of the linear system

$$\dot{x} = (A + bd^T)x \tag{6}$$

is concentrated at any given point $\lambda \in R$. A linear stabilizer of this type satisfies the following extremal property. It ensures a minimal overshoot among linear feedback control laws with the spectra of (6) $\{\lambda_1, \ldots, \lambda_n\}$ satisfying the conditions: $\mathrm{Re}\lambda_i \leq \lambda$ and $|\lambda_i - \lambda| < \epsilon$, where $\epsilon > 0$ is sufficiently small.

The paper is organized as follows. In §1 we discuss different statements of the stabilization problem. Section 2 is devoted to the regulator design problem for the first approximation. The nonlinear stabilization problem is considered in §3. Examples are given in §4. In §5 we consider the stabilization problem for the first approximation under controllability conditions. The connection between stabilizability and weak asymptotic stability is discussed in §6.

Throughout this paper we denote by R the set of real numbers and by R^n the usual n-dimensional space of vectors $x = (x^1, \ldots, x^n)$, where $x^i \in R$, $i = \overline{1, n}$. The inner product

of two vectors x and y in R^n is expressed by $\langle x, y\rangle = x^1y^1 + \cdots + x^ny^n$. The norm of a vector $x \in R^n$ is defined by $|x| = \langle x, x\rangle^{1/2}$. If C is an $m \times n$ real matrix, then the transposed matrix is denoted by C^T. The unit linear operator from R^n to R^n will be denoted by E. We denote by B_n the unit ball in R^n: $B_n = \{x \in R^n \mid |x| \leq 1\}$. The open unit ball in R^n is denoted by $\overset{\circ}{B}_n = \{x \in R^n \mid |x| < 1\}$. Let $A \subset R^n$. The distance function $d(\cdot, A) : R^n \to R$ is denoted by $d(x, A) = \inf\{|x - a| \mid a \in A\}$. Let $\lambda \in R$. Then put $\lambda A = \{\lambda a \mid a \in A\}$. For two sets A and B in R^n, their sum is denoted by $A + B = \{a + b \mid a \in A,\ b \in B\}$. The closure and interior of A are denoted by $\mathrm{cl}A$ and $\mathrm{int}A$, respectively. The boundary of A is denoted by $\mathrm{bd}A = \mathrm{cl}A \setminus \mathrm{int}A$. The convex hull of A is denoted by $\mathrm{co}A$. The support function of a set A is denoted by

$$S(x^*, A) = \sup\{\langle x^*, a\rangle \mid a \in A\}.$$

Let $K \subset R^n$ be a convex cone. The conjugate cone of K is defined by

$$K^* = \{x^* \mid \langle x, x^*\rangle \geq 0,\ \forall x \in K\}.$$

Let $f : R^n \to R$ be a function. The directional derivative of f at x with respect to a vector v is denoted by

$$Df(x)(v) = \lim_{\lambda \downarrow 0} \frac{f(x + \lambda v) - f(x)}{\lambda}$$

if it exists.

Let $f : R \to R$ be a continuous function. The Lyapunov exponent (see Lyapunov [14]) of f is defined by

$$\chi[f(\cdot)] = -\limsup_{t \to \infty} \frac{1}{t} \ln |f(t)|.$$

The Lyapunov exponent has the following properties:

1. $\chi[(f + \varphi)(\cdot)] \geq \min\{\chi[f(\cdot)], \chi[\varphi(\cdot)]\}$,
2. $\chi[(f\varphi)(\cdot)] \geq \chi[f(\cdot)] + \chi[\varphi(\cdot)]$,
3. $\chi[(f\varphi)(\cdot)] = \chi[f(\cdot)]$, where $0 < a \leq \varphi(t) \leq b < \infty$.

If $f : R \to R^n$ is a vector function, then the Lyapunov exponent is defined as the minimal value of the Lyapunov exponents of the components

$$\chi[f(\cdot)] = \min\{\chi[f^1(\cdot)], \ldots, \chi[f^n(\cdot)]\}.$$

1. Statement of the problem. Consider a control system

$$\dot{x} = f(x, u), \quad u \in U \subset R^k. \tag{7}$$

Assume that $f : R^n \times U \to R^n$ is a continuous function differentiable with respect to x and that for any arbitrary compact set $X \in R^n$ there exists a constant $l > 0$ such that $|\nabla_x f(x, u)| \leq l$ for all $(x, u) \in X \times U$. Let $f(x, U) \subset R^n$ be a convex set for all $x \in R^n$, and let $u_0 \in U$ be a point such that $f(0, u_0) = 0$. Our aim is to find a map $u : R^n \to U$ defined in a neighborhood of the origin and satisfying the following conditions:

1. $u(0) = u_0$,
2. the equilibrium point $x = 0$ of the differential equation

$$\dot{x} = f(x, u(x)) \tag{8}$$

is asymptotically stable.

The regulator design problem described above is very general and intuitive and is not yet suitable for a mathematical consideration. We should specify the exact meaning of "asymptotic stability" and what we mean by "solution" of (8). As we will see, different specifications of these notions can lead to substantially different developments.

The first issue we must consider is how smooth the stabilizer $u = u(x)$ should be. In classic regulator design theory (see Sontag [19], for example) the control system

$$\dot{x} = g(x, u), \quad u \in R^k, \tag{9}$$

is studied. Suppose that the function g is smooth. Consider the following linear control system associated with (9):

$$\dot{x} = Cx + Bw, \quad w \in R^k, \tag{10}$$

where $C = \nabla_x g(0, u_0)$ and $B = \nabla_u g(0, u_0)$. System (10) is stabilizable if and only if there exists a matrix D such that the equilibrium position $x = 0$ of the linear system

$$\dot{x} = (C + BD)x$$

is asymptotically stable. If (10) is stabilizable, then any linear feedback law $w(x) = Dx$ which stabilizes (10) provides a local stabilizer for system (9): $u(x) = u_0 + Dx$. Thus, we can expect that under suitable assumptions a smooth and even an analytical regulator exists for control system (9).

The situation completely changes as soon as control constraints are involved. Let us consider the following example.

Example: Absence of smooth stabilizability. Suppose that the stabilization problem for the control system

$$\begin{aligned} \dot{x}^1 &= x^2 + u^1, \\ \dot{x}^2 &= x^1 + u^2, \end{aligned} \tag{11}$$

where $u = (u^1, u^2) \in U = \{(u^1, u^2) \mid u^1 \leq 0, \ u^2 \geq 0\}$ has a smooth solution, that is, there exists a smooth regulator $u = u(x) = (u^1(x^1, x^2), u^2(x^1, x^2))$ such that $u(0) = 0$, and the equilibrium position $x^1 = 0, \ x^2 = 0$ of the system

$$\begin{aligned} \dot{x}^1 &= x^2 + u^1(x^1, x^2), \\ \dot{x}^2 &= x^1 + u^2(x^1, x^2) \end{aligned} \tag{12}$$

is asymptotically stable. Show that $\nabla_x u(0) = 0$. Assume that there exists $x_0 \in R^2$ such that $\nabla_x u(0)x_0 = w \neq 0$. Then $\nabla_x u(0)(-x_0) = -w$. Assume for the sake of being definite that $w^1 \neq 0$, and consider the function $\varphi(\tau) = u^1(\tau x_0)$. Observe that $\varphi'(0) = w^1 \neq 0$. By the inverse function theorem there exists φ^{-1} defined in a neighborhood of zero. This implies that $u^1(\tau x_0)$ changes sign, if τ changes sign. Since the set U does not contain vectors (u^1, u^2) with $u^1 > 0$, we come to a contradiction. Hence $\nabla_x u(0) = 0$. Thus we conclude that the linearization of system (12) at zero is

$$\begin{aligned} \dot{x}^1 &= x^2, \\ \dot{x}^2 &= x^1. \end{aligned}$$

The matrix of this system has the eigenvalue 1, that is, system (12) is not stable. Consequently, there is no smooth stabilizer for system (11). As we shall see from Theorem 7 there exists a Lipschitz continuous stabilizer for this system.

Different statements of the problem. The example shows that we can expect the existence of at most a Lipschitz continuous stabilizer, if control constraints are involved. Therefore, the first reasonable statement of the regulator design problem is to find a *Lipschitzian control* $u(x)$ that guarantees asymptotic stability of zero solution to differential equation (8). Lipschitz continuity of $u(x)$ implies that equation (8) has a unique, classical solution for each initial condition.

Another, weaker statement of the stabilization problem can be obtained if the Lipschitz condition is replaced by the continuity of $u(x)$. The latter implies that equation (8) has a classical solution (not unique, in general) for each initial point. In this case we mean by asymptotic stability the following: the equilibrium point $x = 0$ of differential equation (8) is said to be asymptotically stable if for any $\epsilon > 0$ there exists $\delta > 0$ such that for all $x_0 \in \delta B_n$ *each* solution to differential equation (8) with $x(0) = x_0$ exists for $t \in [0, \infty)$ and satisfies the conditions $|x(t)| < \epsilon$ for all $t \in [0, \infty)$ and $\lim x(t) = 0$ as $t \to \infty$.

The above problems can be solved only under rather restrictive assumptions on the map $u \to f(x, u)$. Therefore, a quite natural goal is to find a control $u(x)$ such that the function $x \to f(x, u(x))$ is *continuous* and the equilibrium position $x = 0$ of differential equation (8) is asymptotically stable.

Practical experience shows that discontinuous control laws are of great importance. For example, optimal synthesis is usually discontinuous, relay stabilization systems are widely used in engineering, etc. For this reason we are interested in considering regulators such that the function $x \to f(x, u(x))$ is not continuous in general. To this end we invoke Filippov's notion of solution to a differential equation with discontinuous right-hand side (see Aubin and Cellina [1] and Filippov [9]).

The problem we shall mainly consider is to find a control $u(x)$ such that the equilibrium position $x = 0$ of a differential equation with *discontinuous* right-hand side (8) is asymptotically stable.

Recall the definition of the Filippov solution and the notion of asymptotic stability for discontinuous differential equations. Let $\varphi : R^n \to R^n$ be a bounded function satisfying $\varphi(0) = 0$, and let $\Phi : R^n \to R^n$ be the set-valued map defined by

$$\Phi(x) = \bigcap_{\eta > 0} \operatorname{cl} \operatorname{co} \varphi(x + \eta B_n).$$

An absolutely continuous function $x(\cdot)$ is called a Filippov solution to the differential equation

$$\dot{x} = \varphi(x) \tag{13}$$

if and only if it satisfies the differential inclusion

$$\dot{x} \in \Phi(x)$$

almost everywhere.

The equilibrium point $x = 0$ of the differential equation (13) is said to be asymptotically stable if, for any $\epsilon > 0$, there exists $\delta > 0$ such that for all $x_0 \in \delta B_n$, each Filippov solution to the differential equation (13) with $x(0) = x_0$ exists for $t \in [0, \infty)$ and satisfies the conditions $|x(t)| < \epsilon$ for all $t \in [0, \infty)$ and $\lim x(t) = 0$ as $t \to \infty$.

From now on, by the *stabilization* or *regulator design* problem we mean this formulation, if there is no other specification.

In technological applications a piecewise constant control law is usually used instead of the stabilizer $u(x)$ we dealt with before. The control is chosen in discrete moments of time $0, \sigma, 2\sigma, \ldots$, where $\sigma > 0$, and we have

$$u_\sigma(t) \equiv u(x(k\sigma)), \quad t \in [k\sigma, (k+1)\sigma).$$

This leads us to another problem where the goal is to find a control $u(x)$ such that all the trajectories of the nonautonomous differential equation

$$\dot{x} = f(x, u_\sigma(t))$$

tend to zero. This statement of the problem is also very important, since it substantiates practical realizations of stabilizers, and we discuss it in detail in §3.

Informal outline of the approach. First, we investigate the stabilization problem for the first approximation of system (7), that is, for the linear control system

$$\dot{x} = Cx + w, \quad w \in K, \tag{14}$$

where $C = \nabla_x f(0, u_0)$ is an $n \times n$ matrix and K is the closed convex cone spanned by the set $f(0, U)$. Consider the set-valued map $x \to Cx + K$ associated with control system (14). The properties of this map are similar to those of a linear operator. In particular, a multivalued version of the Jordan theorem can be established. More precisely, there exists a minimal invariant subspace I, that is, a minimal subspace such that for any $x \in I$ we have $Cx + K \subset I$. The map $x \to Cx + K$ considered as a map from the factor space R^n/I into R^n/I is a linear operator denoted by $\tilde{C}$. The meaning of I in terms of control is that only movements in linear manifolds parallel to I are affected by a control, while movements in the factor space R^n/I are completely determined by properties of $\tilde{C}$. Asymptotic stability of $\tilde{C}$ is necessary for the first approximation to be stabilizable. If this operator is not asymptotically stable, the control system (14) cannot be stabilized by any control $w(x)$.

Consider the structure of I. For the sake of simplicity suppose that $I = R^n$. Let λ_0 be the maximal real eigenvalue of C^T that corresponds to an eigenvector contained in the polar cone K^*. Assume that $\lambda > \lambda_0$. Then for any x there exist vectors $y_0, \ldots, y_k$ such that

$$\begin{aligned} y_0 &\in -K, \\ \lambda y_1 &\in Cy_1 + K, \\ y_1 + \lambda y_2 &\in Cy_2 + K, \\ &\vdots \\ y_{k-1} + \lambda y_k &\in Cy_k + K, \\ x &= y_k + y_0. \end{aligned} \tag{15}$$

We can interpret inclusions (15) as follows. Vectors y_1 and y_j, $j > 1$, can be considered as an eigenvector and joined (principal) vectors of the set-valued map $x \to Cx + K$, respectively. Inclusions (15) imply that the subspace I is a "cyclic" subspace of the set-valued map $x \to Cx + K$ corresponding to one "Jordan block."

Now we are in a position to explain how to choose the control $w(x)$ to stabilize the control system (14). We establish that the stabilizability of (14) is equivalent to the condition $\lambda_0 < 0$. If the first approximation is stabilizable, we fix $\lambda \in (\lambda_0, 0)$. For any $x \in R^n$ we find a finite set of vectors $y_0, \ldots, y_k$ satisfying (15).

Suppose, first, that $y_k = 0$. Then $x = y_0 \in -K$. Consequently, for any $\epsilon > 0$ we can choose $\tau > 0$ such that $\tau Cx \in \epsilon B_n$. Put $w_0(x) = -\frac{1}{\tau}x$. Then we have $w_0(x) \in K$ and

$$x + \tau(Cx + w_0(x)) \in \epsilon B_n.$$

It means that there exists a velocity of system (14) almost exactly directed from x to the origin.

Now assume that $y_0 = 0$, that is, $x = y_k$. Suppose that $k = 1$, which implies that x is an eigenvector of the set-valued map $x \to Cx + K$. Since $\lambda < 0$, we conclude that there exists

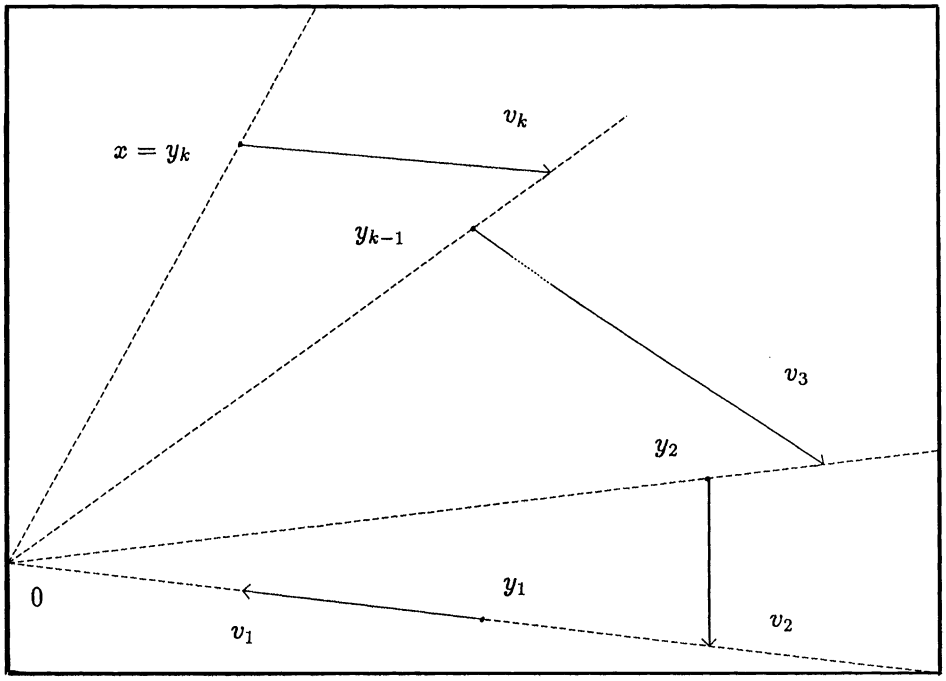

FIG. 1. *Choosing stabilizing controls.*

a vector v_1, a velocity of (14), directed from x to the origin. Indeed, let $w_1(x) = \lambda x - Cx$. Then we obtain $w_1(x) \in K$ and

$$x + \frac{1}{|\lambda|}(Cx + w_1(x)) = 0.$$

Consider the case $k > 1$. Since $\lambda < 0$, we have

$$\frac{1}{|\lambda|} y_{k-1} \in y_k + \frac{1}{|\lambda|}(Cy_k + K)$$

or, in other words,

$$\frac{1}{|\lambda|} y_{k-1} = y_k + \frac{1}{|\lambda|}(Cy_k + w_k(x)),$$

where $w_k(x) \in K$. This implies that there exists a vector v_k, a velocity of (14), directed from the point y_k to the ray spanned by y_{k-1}. The same is true for the vectors $y_{k-1}, \ldots, y_2$. Thus, starting at $x = y_k$ and choosing a suitable control we can reach the ray spanned by the eigenvector y_1 and then move along it (see Figure 1). In the general case when $x = y_k + y_0$ with nonzero y_k and y_0, we take $w(x)$ as a convex combination of $w_k(x)$ and $w_0(x)$. Since K is a convex cone, we have $w(x) \in K$. It is clear intuitively that trajectories of the system

$$\dot{x} = Cx + w(x)$$

tend to zero. The above informal considerations show the main ideas of the regulator design method we use in this paper.

We use similar reasoning to prove the existence of a Lyapunov function $V(x)$ in R^n and a number $\theta > 0$ satisfying the following condition: for all $x \in R^n$ there exists a vector $v \in Cx + K$ such that $DV(x)(v) + \theta V(x) \leq 0$. If $|x|$ is sufficiently small, then there exists a vector $v \in f(x, U)$ such that $DV(x)(v) + \frac{1}{2}\theta V(x) \leq 0$. The map $u(x)$ is defined to make $V(x)$ a Lyapunov function for differential equation (8). This implies the asymptotic stability of the equilibrium point $x = 0$. The proof of the existence of the function $V(x)$ is constructive and can serve as the basis for a numerical regulator design algorithm.

2. The first approximation. In this section we investigate the first approximation of system (7), that is, the linear control system

$$\dot{x} = Cx + w, \quad w \in K, \tag{16}$$

where $C = \nabla_x f(0, u_0)$ is an $n \times n$ matrix and K is the closed convex cone spanned by the set $f(0, U)$. For control system (16) we derive necessary and sufficient conditions guaranteeing the existence of a number $\theta > 0$ and a convex positive, positively homogeneous function $V(x)$ in R^n satisfying the following condition: for any $x \in R^n$ there exists a vector $v \in Cx + K$ such that $DV(x)(v) + \theta V(x) \leq 0$.

We now consider the linear differential equation

$$\dot{x} = -C^T x. \tag{17}$$

Let Λ^+ be the subspace such that a solution to (17) with the initial condition $x(0) = x \in \Lambda^+$ has a nonnegative Lyapunov exponent.

The following result contains necessary and sufficient conditions of solvability for the regulator design problem for linear system (16).

THEOREM 1. *The following conditions are equivalent:*

1. *The regulator design problem for control system* (16) *is solvable.*
2. *For any $x_0 \in R^n$ there exists a trajectory $x(\cdot)$ of system* (16) *such that $x(t) \to 0$ as $t \to \infty$.*
3. *The matrix C^T has neither eigenvectors which correspond to nonnegative real eigenvalues and are contained in the cone K^* nor proper invariant subspaces contained in the subspace $\Lambda^+ \cap K^* \cap -K^*$.*
4. *There exist numbers $\tau > 0$, $\delta \in (0, 1)$ and a convex positively homogeneous function $V(x)$ such that $V(0) = 0$, $V(x) > 0$, if $x \neq 0$, and for any $x \in R^n$ a vector $w \in K$ satisfying*

$$V(x + \tau(Cx + w)) \leq \delta V(x)$$

can be found.

First we prove auxiliary results.

LEMMA 1. *Assume that for any $x_0 \in R^n$ there exists a trajectory $x(\cdot)$ of system* (16) *with $x(0) = 0$ such that $x(t) \to 0$ when $t \to \infty$. Then there exist numbers $a > 0$ and $\gamma > 0$ such that for any point $x_0 \in R^n$ a trajectory of system* (16) *with $x(0) = x_0$ satisfying the condition*

$$|x(t)| \leq a|x_0|e^{-\gamma t}, \ t \geq 0, \tag{18}$$

can be found.

Proof. Let us consider a simplex $\Sigma = \text{co}\{z_0, \ldots, z_n\}$ containing a unit ball centered at zero. There are trajectories $x_k(\cdot)$ satisfying the conditions

$$x_k(0) = z_k, \quad \lim_{t \to \infty} x_k(t) = 0, \quad k = \overline{0, n}.$$

There exists a number $\tau \geq 0$ such that $|x_k(\tau)| \leq 1/e$ for all $k = \overline{0, n}$. Let $y \in \operatorname{bd} B_n$. Then there exist numbers $\lambda_k \geq 0$, $k = \overline{0, n}$, such that $\sum_{k=0}^{n} \lambda_k = 1$ and $y = \sum_{k=0}^{n} \lambda_k z_k$. Obviously, the function $x(\cdot, y) = \sum_{k=0}^{n} \lambda_k x_k(\cdot)$ is a trajectory of system (16) and satisfies the inequality $|x(\tau, y)| \leq 1/e$. Hence, for any $y \in R^n$ the function $x_y(\cdot) = |y| x(\cdot, y/|y|)$ is a trajectory of system (16) and satisfies the inequality $|x_y(\tau)| \leq |y|/e$. Set

$$\gamma = 1/\tau, \quad a = e \max\{|x_k(t)| \mid t \in [0, \tau], \ k = \overline{0, n}\}.$$

For every $x_0 \in R^n$ we define a trajectory $x(\cdot)$ of system (16) satisfying the initial condition $x(0) = x_0$ as follows:

$$x(t) = x_{x(m\tau)}(t - m\tau), \quad t \in [m\tau, (m+1)\tau], \ m = 0, 1, \ldots.$$

It is easy to check that the trajectory $x(\cdot)$ satisfies condition (18). □

Let us study some properties of the set-valued map $x \to Cx + K$. Denote by J the maximal invariant subspace of C^T contained in $K^* \cap -K^*$ and by I the orthogonal complement to J.

The subspace I turns out to be invariant by the set-valued map $x \to Cx + K$ in the following sense.

LEMMA 2. *For all $x \in I$ we have*

$$Cx + K \subset I.$$

Proof. Let $x \in I$, $x^* \in J$, $w \in K$. Since $C^T x^* \in J$, $x^* \in J \subset K^* \cap -K^*$, we have

$$\langle x^*, Cx + w \rangle = \langle C^T x^*, x \rangle + \langle x^*, w \rangle = 0. \qquad \square$$

Remark. A description of the minimal invariant subspace for convex processes of general form appeared in Aubin, Frankowska, and Olech [2].

It follows from Lemma 2 that $K \subset I$ and the subspace I is invariant by the linear operator C. We denote by C_I the restriction of C to the subspace I, i.e., $C_I = C \mid_I$. Let C_J be the transposed operator of the restriction of C^T to the subspace J, i.e., $C_J = (C^T \mid_J)^T$. The cone K considered as a subset of I is denoted by K_I. The unit linear operator from I to I is denoted by E_I. Since $R^n = I \times J$, every $x \in R^n$ can be represented as $x = (x_I, x_J)$, where $x_I \in I$ and $x_J \in J$.

LEMMA 3. *The linear operator C_I^T has no nontrivial invariant subspaces contained in the cone K_I^*.*

Proof. Suppose there is a nontrivial subspace $L \subset K_I^* \cap -K_I^*$ invariant by the linear operator C_I^T. Let us prove that $C^T(L, J) \subset (L, J)$. Since $(L, J) \subset (K_I^* \cap -K_I^*, J) = K^* \cap -K^*$, this will contradict the definition of J as the maximal invariant by C^T subspace contained in the subspace $K^* \cap -K^*$. Let $x_I^* \in L$, $x_I \in L^\perp$. Then

$$\langle C^T(x_I^*, 0), (x_I, 0) \rangle = \langle (x_I^*, 0), C(x_I, 0) \rangle = \langle (x_I^*, 0), (C_I x_I, 0) \rangle$$

$$= \langle x_I^*, C_I x_I \rangle = \langle C_I^T x_I^*, x_I \rangle = 0.$$

Since $C^T(0, J) \subset (0, J)$, we obtain $C^T(L, J) \subset (L, J)$. This achieves the proof. □

Denote by λ_0 the maximal real eigenvalue of C^T which corresponds to an eigenvector contained in the cone K^*. If there is no such eigenvector, we put $\lambda_0 = -\infty$.

LEMMA 4. *Suppose that μ is a real eigenvalue of C_I^T which corresponds to an eigenvector y_I^* contained in K_I^*. Then $\mu \leq \lambda_0$.*

Proof. If μ is an eigenvalue of C^T corresponding to an eigenvector from J, then we have nothing to prove. If this is not the case, then $(C^T - \mu E)J = J$.

Observe that for all $y_I \in I$

$$\langle C^T(y_I^*, 0) - \mu(y_I^*, 0), (y_I, 0)\rangle = \langle (y_I^*, 0), C(y_I, 0)\rangle - \mu\langle y_I^*, y_I\rangle$$

$$= \langle (y_I^*, 0), (C_I y_I, 0)\rangle - \mu\langle y_I^*, y_I\rangle = \langle C_I^T y_I^*, y_I\rangle - \mu\langle y_I^*, y_I\rangle = 0.$$

Thus, $\mu(y_I^*, 0) = C^T(y_I^*, 0) + (0, z_J^*)$ for some $z_J^* \in J$. In other words, $C^T(y_I^*, 0) - \mu(y_I^*, 0) \in J$.

There exists a vector p_J^* such that $(0, z_J^*) = (C^T - \mu E)(0, p_J^*)$. This implies that

$$\mu(y_I^*, p_J^*) = C^T(y_I^*, p_J^*).$$

Consequently, $\mu \leq \lambda_0$. □

LEMMA 5. *Let $y = Cx$, where $y = (y_I, y_J)$, $x = (0, x_J)$. Then $y_J = C_J x_J$.*

Proof. Let x_J, $x_J^* \in J$. Then

$$\langle C(0, x_J), (0, x_J^*)\rangle = \langle (0, x_J), C^T(0, x_J^*)\rangle$$

$$= \langle (0, x_J), (0, C^T|_J\, x_J^*)\rangle = \langle C_J x_J, x_J^*\rangle$$

$$= \langle (0, C_J x_J), (0, x_J^*)\rangle.$$

Since x_J, $x_J^* \in J$ are arbitrary, the proof ensues. □

For all real λ we define convex cones

$$L_k(\lambda) = -\mathrm{co}\bigcup_{i=0}^{k}(C_I - \lambda E_I)^{-i} K_I, \qquad k = \overline{0, \infty},$$

contained in the subspace I. We observe that $L_k(\lambda) \subset L_m(\lambda)$ if $k < m$.

We shall use the following generalization of the well-known Perron positive matrix theorem (see Berman and Plemmons [4], for example).

THEOREM 2. *Let $K \subset R^n$ be a nonzero convex closed cone which does not contain a line and let $C : R^n \to R^n$ be a linear operator. If $Cx \in K$ for all $x \in K$ then there exists an eigenvector of C contained in the cone K and corresponding to a nonnegative eigenvalue.*

THEOREM 3. *If $\lambda > \lambda_0$, then there exists a number k such that the equality*

$$L_k(\lambda) = I$$

holds.

Proof. Since a polyhedron can be chosen as a neighborhood of the origin in the subspace I, it is sufficient to prove that

$$L_\infty(\lambda) = I.$$

The latter is equivalent with the equality

$$L_\infty^*(\lambda) = \{0\}.$$

Suppose this equality is not true. Since $\lambda > \lambda_0$, we have

$$(C_I - \lambda E_I)I - K_I = I. \tag{19}$$

Indeed, if $(C_I - \lambda E_I)I - K_I \neq I$, then there exists a nonzero vector $x^* \in I$ such that $\langle (C_I - \lambda E_I)x, x^*\rangle \leq \langle z, x^*\rangle$ for all $x \in I$, $z \in K_I$. Taking $x = 0$, we obtain $x^* \in K_I^*$. Let $z = 0$. Then we have $\langle x, (C_I^T - \lambda E_I)x^*\rangle = 0$ whenever $x \in I$. Hence $x^* \in K_I^*$ is an eigenvector of C_I^T corresponding to the eigenvalue λ. By Lemma 4, $\lambda \leq \lambda_0$, a contradiction.

From (19) we obtain

$$(C_I - \lambda E_I)I - L_k(\lambda) = I.$$

By Corollary 16.3.2 in [16, p. 143] and Corollary 16.4.2 in [16, p. 146], we have

$$L^*_{k+1}(\lambda) \subset ((C_I - \lambda E_I)^{-1}\mathrm{cl}L_k(\lambda) - K)^* = (C_I^* - \lambda E_I)L_k^*(\lambda) \cap -K^*, \quad k = \overline{0, \infty}.$$

Obviously,

$$(C_I^T - \lambda E_I)^{-1}L^*_\infty(\lambda) \subset L^*_\infty(\lambda). \tag{20}$$

The cone $L^*_\infty(\lambda)$ does not contain a line. Indeed, if L is the maximal subspace contained in $L^*_\infty(\lambda)$, then $(C_I^T - \lambda E_I)^{-1}L \subset L$. This implies that L is invariant by the linear operator C_I^T. Since $L^*_\infty(\lambda) \subset K_I^*$, invoking Lemma 3, we derive a contradiction.

From inclusion (20) and Theorem 2 it follows that there exists a nonzero vector $x_I^* \in L^*_\infty(\lambda)$ and a number $\mu \geq 0$ such that

$$(C_I^T - \lambda E_I)^{-1}x_I^* = \mu x_I^*.$$

Since $\lambda > \lambda_0$, we conclude that $\mu \neq 0$. Consequently,

$$C_I^T x_I^* = \left(\lambda + \frac{1}{\mu}\right)x_I^*.$$

By Lemma 4, $\lambda + 1/\mu \leq \lambda_0$, a contradiction. □

Proof of Theorem 1. Condition 2 is a trivial consequence of the first condition. Assume that Condition 2 is fulfilled. Suppose that the third condition does not hold. This implies that the differential equation

$$\dot{x}^*(t) = -C^T x^*(t)$$

has a nontrivial solution satisfying the inclusion $x^*(t) \in K^*$, for all $t \geq 0$, and such that $\chi[x^*(\cdot)] \geq 0$. Let $x_0 \in R^n$. By Lemma 1 there exists a trajectory $x(\cdot)$ of (16) with $x(0) = x_0$ such that $\chi[x(\cdot)] > 0$. Let $w(\cdot)$ be a control corresponding to the trajectory $x(\cdot)$. We observe that

$$\langle x(t), x^*(t)\rangle = \langle x_0, x^*(0)\rangle + \int_0^t \frac{d}{ds}\langle x(s), x^*(s)\rangle ds$$

$$= \langle x_0, x^*(0)\rangle + \int_0^t (\langle Cx(s) + w(s), x^*(s)\rangle + \langle x(s), -C^T x^*(s)\rangle) ds$$

$$= \langle x_0, x^*(0)\rangle + \int_0^t \langle w(s), x^*(s)\rangle ds \geq \langle x_0, x^*(0)\rangle.$$

Since

$$\langle x(t), x^*(t)\rangle \leq |x(t)|\,|x^*(t)| \to 0 \text{ as } t \to \infty,$$

we obtain $0 \geq \langle x_0, x^*(0)\rangle$. Since x_0 is an arbitrary vector we conclude that $x^*(0) = 0$. This contradicts the nontriviality of $x^*(\cdot)$. Thus, the third condition is a consequence of the second one.

Now, suppose that the third condition holds. We shall derive Condition 4 from it. The third condition means that $\lambda_0 < 0$. Fix $\lambda \in (\lambda_0, 0)$. Let $\Sigma \subset I$ be a polyhedron containing

the ball $B_I = B_n \cap I$. Denote by x_i^Σ, $i = \overline{0, m}$, the vertices of the polyhedron. By Theorem 3, $x_i^\Sigma \in L_{k_i}(\lambda)$ for some k_i. Moreover, x_i^Σ does not belong to $L_k(\lambda)$, if $k < k_i$. From the definition of the cones $L_{k_i}(\lambda_i)$ we derive the existence of a finite set of nonzero vectors $\{y_{i,j}\}_{j=0}^{k_i}$ in I that satisfy the following inclusions:

$$
\begin{aligned}
y_{i,0} &\in -K_I, \\
\lambda y_{i,1} &\in C_I y_{i,1} + K_I, \\
y_{i,1} + \lambda y_{i,2} &\in C_I y_{i,2} + K_I, \\
&\vdots \\
y_{i,k_i-1} + \lambda y_{i,k_i} &\in C_I y_{i,k_i} + K_I, \\
x_i^\Sigma &= y_{i,k_i} + y_{i,0}.
\end{aligned} \tag{21}
$$

Fix a number $\alpha > 1$. Let M_I be the convex hull of the points

$$
z_{i,0} = y_{i,0}, \quad i = \overline{0, m};
$$

$$
z_{i,j} = (\alpha/|\lambda|)^{k_i - j} y_{i,j}, \quad j = \overline{1, k_i}, \quad i = \overline{0, m}.
$$

Let us consider the linear operator $C_J : J \to J$. The third condition implies that C_J is an asymptotically stable linear operator. There exists a positive definite quadratic form $W : J \to R$ which is a Lyapunov function for the differential equation

$$
\dot{x}_J = C_J x_J
$$

(see Lyapunov [14]). Denote by M_J the ellipsoid $\{x \in J \mid W(x) \leq 1\}$. Let $\omega > 0$. Consider the convex compact set

$$
\mathcal{M}_\omega = M_I \times \omega M_J \subset I \times J = R^n.
$$

We shall prove that the Minkowski function $V(x)$ of the set $\mathcal{M}_\omega$ is the function to be found whenever $\omega > 0$ is sufficiently small.

Since $B_I \subset \Sigma$, we conclude that $\frac{1}{2} B_I \subset M_I$. Obviously, $w_{i,0} = -4|C_I z_{i,0}| z_{i,0} \in K_I$ and

$$
z_{i,0} + \frac{1}{(4|C_I z_{i,0}|)} (C_I z_{i,0} + w_{i,0}) \in \frac{1}{4} B_I \subset \operatorname{int} M_I
$$

when $i = \overline{0, m}$. For each $i = \overline{0, m}$, the vector $w_{i,1} = \lambda z_{i,1} - C_I z_{i,1}$ belongs to the cone K_I and satisfies the inclusion

$$
z_{i,1} + |\lambda|^{-1} (C_I z_{i,1} + w_{i,1}) = 0 \in \operatorname{int} M_I.
$$

For all points $z_{i,j}$, $j > 1$, $i = \overline{0, m}$, we consider the vectors $w_{i,j} = (1/\alpha)|\lambda| z_{i,j-1} + \lambda z_{i,j} - C_I z_{i,j}$. Obviously, we have $w_{i,j} \in K_I$ and

$$
z_{i,j} + |\lambda|^{-1} (C_I z_{i,j} + w_{i,j}) = \frac{1}{\alpha} z_{i,j-1} \in \operatorname{int} M_I.
$$

From the above reasoning we conclude that there exist numbers $\tau_I > 0$ and $\delta_I \in (0, 1)$ such that for each $x_I \in \operatorname{bd} M_I$ there exists a vector $w \in K_I$ satisfying the inclusion

$$
x_I + \tau_I (C_I x_I + w) \in \delta_I M_I.
$$

Moreover, there exist numbers $\tau_J > 0$ and $\delta_J \in (0, 1)$ such that for all $x_J \in \operatorname{bd} M_J$ the inclusion

$$
x_J + \tau_J C_J x_J \in \delta_J M_J
$$

is fulfilled. Set $\tau = \min\{\tau_I, \tau_J\}$, $\delta = \max\{\delta_I, \delta_J\}$ and choose ω from the interval $(0, (1 - \delta)/(4\tau|C|b))$, where $b = \max\{|x_J| \mid x_J \in \mathrm{bd}M_J\}$.

Let $x = (x_I, x_J) \in \mathrm{bd}\mathcal{M}_\omega$. Then there exists a number $\eta \in [0, 1]$ such that $x_I \in \mathrm{bd}(\eta M_I)$. Observe that there exists a vector $w \in K$ satisfying the inclusion

$$(x_I, 0) + \tau(C(x_I, 0) + w) \in (\delta\eta M_I, 0) \subset (\delta M_I, 0). \tag{22}$$

On the other hand, by Lemma 5 we have

$$(0, x_J) + \tau C(0, x_J) = (0, x_J) + \tau(y_I, C_J x_J) \in \tau(y_I, 0) + (0, \delta\omega M_J). \tag{23}$$

Since

$$|y_I| \le |C(0, x_J)| \le |C|\omega b \le \frac{1 - \delta}{4\tau},$$

we conclude that $\tau y_I \in \frac{1}{2}(1 - \delta)M_I$. Summation of (22) and (23) yields

$$x + \tau(Cx + w) \in \left(\frac{1 + \delta}{2} M_I, \delta\omega M_J\right) \subset \frac{1 + \delta}{2}\mathcal{M}_\omega.$$

Thus, we obtain Condition 4 of the theorem.

Finally, let Condition 4 be fulfilled. We shall derive Condition 1. Consider the set-valued maps

$$G(x) = \{v \in R^n \mid x + \tau v \in \delta V(x)\mathcal{M}\} \quad \text{and} \quad H(x) = G(x) \cap (Cx + K),$$

where $\mathcal{M} = \{x \in R^n \mid V(x) \le 1\}$. Condition 4 implies $H(x) \ne \emptyset$ for all $x \in R^n$. Let $w : R^n \to K$ be an arbitrary function satisfying the inclusion $Cx + w(x) \in G(x)$. Obviously, $|Cx + w(x)| \le LV(x)$, where $L = \tau^{-1} \max\{V(x) \mid \delta z - x/V(x)| \mid z \in \mathcal{M},\ x \in \mathrm{bd}\mathcal{M}\}$. Consider the set-valued map

$$W(x) = \bigcap_{\eta > 0} \mathrm{cl\ co}\ w(x + \eta B_n).$$

Let $w \in W(x)$. Then we have

$$DV(x)(Cx + w) \le \frac{[V(x + \tau(Cx + w)) - V(x)]}{\tau} \le -\frac{1 - \delta}{\tau} V(x).$$

Hence any Filippov solution $x(\cdot)$ to the differential equation

$$\dot{x} = Cx + w(x) \tag{24}$$

satisfies

$$V(x(t)) \le V(x(0))e^{-\theta t}, \quad t \ge 0,$$

where $\theta = (1 - \delta)/\tau$. Consequently, the zero equilibrium position of differential equation (24) is asymptotically stable. This ends the proof. □

COROLLARY 1. *Assume that the matrix C^T has no proper invariant subspaces contained in the subspace $K^* \cap -K^*$ and one of the following conditions holds:*

1. *The matrix C^T has no eigenvectors corresponding to nonnegative real eigenvalues and contained in the cone K^*.*

2. *There exist $\lambda < 0$ and k such that $L_k(\lambda) = R^n$.*

Then the regulator design problem for control system (16) *is solvable.*

Proof. Since the matrix C^T has no proper invariant subspaces contained in the subspace $K^* \cap -K^*$, we see that $I = R^n$. The reasoning used to prove the implication $3 \Rightarrow 4$ achieves the proof. □

Remark 1. The proof of the implication $3 \Rightarrow 4$ can be modified as follows. Consider negative numbers $\lambda_1, \ldots, \lambda_m$ such that $\lambda_i \geq \lambda_0$, $i = \overline{1, m}$. Assume that vectors $y_{i,0}, \ldots, y_{i,k_i}$ satisfy (21) with $\lambda = \lambda_i$. Then we can continue the proof without any changes. Different collections $\lambda_1, \ldots, \lambda_m$ yield different Lyapunov functions and hence different stabilizers. The choice of these parameters provides additional possibilities for generating regulators with desired transient characteristics.

Remark 2. If $\lambda > \lambda_0$ we derive from Theorem 3 that the system of inclusions (21) is compatible for a finite k_i. To estimate the number of operations needed to construct a regulator we have to estimate $k = \max\{k_i \mid i = \overline{1, m}\}$. From now on the number $k = k(\lambda)$ is called the λ-*dimension* of the subspace I with respect to the set-valued map $x \to Cx + K$. In §5 we derive an estimate for $k(\lambda)$ in a general case. Here we only note that if the cone K is a subspace, then $\sum_{i=0}^{n-1} (C_I - \lambda E_I)^{-i} K_I$ spans the whole subspace I, thanks to the Cayley–Hamilton theorem. This implies that $k(\lambda) \leq n - 1$.

3. Stabilization of nonlinear systems. We now proceed to consider the regulator design problem for a nonlinear control system

$$\dot{x} = f(x, u), \quad u \in U. \tag{25}$$

The main stabilization problem. The following theorem contains sufficient conditions for stabilizability of system (25) at first approximation.

THEOREM 4. *Assume that the regulator design problem for the first approximation is solvable. Then there exist a neighborhood Ω of the origin and a map $u : \Omega \to U$ that satisfies the following conditions:*

1. $u(0) = u_0$.
2. *The equilibrium point $x = 0$ of the differential equation*

$$\dot{x} = f(x, u(x)) \tag{26}$$

is asymptotically stable; moreover, there exist constants $a > 0$ and $\theta > 0$ such that

$$|x(t)| \leq a|x(0)|e^{-\theta t}, \quad t \geq 0, \tag{27}$$

$$|\dot{x}(t)| \leq a|x(0)|e^{-\theta t}, \quad t \geq 0 \tag{28}$$

for any solution $x(\cdot)$ to (26) with sufficiently small $|x(0)|$.

Proof. By Theorem 1 there exist numbers $\tau > 0$, $\delta \in (0, 1)$, and a convex positively homogeneous function $V(x)$ such that $V(0) = 0$, $V(x) > 0$, if $x \neq 0$, and for any $x \in \mathrm{bd}\mathcal{M}$ ($\mathcal{M} = \{x \mid V(x) \leq 1\}$) there exists a vector $v \in Cx + K$ satisfying $x + \tau v \in \delta\mathcal{M}$.

Let x_0 and v_0 be vectors from the sets $\mathrm{bd}\mathcal{M}$ and $Cx_0 + K$, respectively, which satisfy $x_0 + \tau v_0 \in \delta\mathcal{M}$. If $\epsilon_1 > 0$ is sufficiently small, then the inclusions $x \in x_0 + \epsilon_1 B_n$, $v \in v_0 + \epsilon_1 B_n$ imply that $x + \tau v \in \frac{1}{2}(1 + \delta)\mathcal{M}$.

We need the following technical lemma.

LEMMA 6. *For any $v_0 \in Cx_0 + K$ the equality*

$$\lim_{\rho \downarrow 0,\ x \to x_0} \rho^{-1} d(\rho v_0,\ f(\rho x, U)) = 0$$

is fulfilled.

Proof. Let $\eta > 0$. There exist $u \in U$ and $\beta > 0$ such that $|v_0 - Cx_0 - \beta f(0,u)| < \eta$. If $\rho\beta < 1$, then taking into account convexity of the set $f(\rho x_0, U)$ and the inequality $|\nabla_x f(x,u)| \le l$, $x \in B_n$, we have

$$d(\rho v_0, f(\rho x, U)) \le d(\rho(Cx_0 + \beta f(0,u)), f(\rho x_0, U))$$
$$+\rho\eta + \rho l|x - x_0| \le |\rho\nabla_x f(0,u_0)x_0 + \rho\beta f(0,u)$$
$$-f(\rho x_0, u_0) - \rho\beta(f(\rho x_0, u) - f(\rho x_0, u_0))| + \rho\eta + \rho l|x - x_0|$$
$$\le |\rho\nabla_x f(0,u_0)x_0 - f(\rho x_0, u_0)| + \rho\beta(|f(0,u) - f(\rho x_0, u)|$$
$$+|f(\rho x_0, u_0)|) + \rho\eta + \rho l|x - x_0|.$$

Since η is an arbitrary positive number, dividing by ρ and taking the limit as $\rho \downarrow 0$ and $x \to x_0$, we obtain the result. □

End of the proof of Theorem 4. By the above lemma there exists $\epsilon_2 > 0$ such that the inequality

$$\rho^{-1} d(\rho v_0,\ f(\rho x, U)) \le \epsilon_1$$

holds for all $x \in x_0 + \epsilon_2 B_n$, $\rho \in (0, \epsilon_2)$. Set $\epsilon_0 = \min\{\epsilon_1, \epsilon_2\}$. Let $x \in \mathrm{bd}\mathcal{M} \cap (x_0 + \epsilon_0 B_n)$, $\rho \in (0, \epsilon_0)$. Then there exists a vector $v(\rho, x) \in f(\rho x, U)$ satisfying $|v_0 - \rho^{-1} v(\rho, x)| \le \epsilon_1$. We observe that

$$x + \tau\rho^{-1} v(\rho, x) \in \frac{1+\delta}{2}\mathcal{M}.$$

Now, we cover every point $x_0 \in \mathrm{bd}\mathcal{M}$ by such an ϵ_0-neighborhood and choose a finite subcovering. Let $\bar{\epsilon}$ be the minimal radius of a subcovering element. If $V(x) < \bar{\epsilon}$, then by the above considerations we conclude that there is a vector $v \in f(x, U)$ satisfying

$$x + \tau v \in \frac{1+\delta}{2} V(x)\mathcal{M}.$$

Let us consider the set-valued maps

$$G(x) = \left\{ v \in R^n \mid x + \tau v \in \frac{1+\delta}{2} V(x)\mathcal{M} \right\}, \quad H(x) = G(x) \cap f(x, U)$$

defined on the set $\Omega = \{x \mid V(x) < \bar{\epsilon}\}$. We take any single-valued map $\varphi(x) \in H(x)$. Since $\varphi(0) = 0$, there exists a map $u : \Omega \to U$ satisfying the conditions $u(0) = u_0$ and $\varphi(x) = f(x, u(x))$.

Consider the set-valued map

$$\Phi(x) = \bigcap_{\eta > 0} \mathrm{cl\ co}\ \varphi(x + \eta B_n).$$

Let $v \in \Phi(x)$. Then we have

$$DV(x)(v) \le \frac{[V(x + \tau v) - V(x)]}{\tau} \le -\theta V(x),$$

where $\theta = (1-\delta)/(2\tau)$. Hence any Filippov solution $x(\cdot)$ to differential equation (26) satisfies

$$V(x(t)) \le V(x(0))e^{-\theta t}, \quad t \ge 0, \tag{29}$$

whenever $x(0) \in \Omega$. By construction

$$\dot{x}(t) \in G(x) = \tau^{-1}\left(\frac{1+\delta}{2}V(x(t))\mathcal{M} - x(t)\right)$$

$$\subset \tau^{-1}e^{-\theta t}V(x(0))\left(\frac{1+\delta}{2}\mathcal{M} - \mathcal{M}\right). \tag{30}$$

From (29) and (30) we see that there exists a constant $a > 0$ such that (27) and (28) are satisfied for any solution $x(\cdot)$ to (26) with sufficiently small $|x(0)|$. The theorem is proved. □

Remark. For example, $\varphi(x) \in f(x, U)$ can be chosen from the condition

$$\min_{u \in U} V(x + \tau f(x, u)) = V(x + \tau\varphi(x))$$

if U is a compact. For many control systems this minimization problem can be easily solved using numerical methods (see [7, 8]).

An estimate for the region of attraction. Theorem 4 contains sufficient conditions for solvability of the regulator design problem. However it does not allow one to estimate the *region of attraction*, that is, the domain where the regulator is defined. Below we obtain such an estimate under additional assumptions on the control system. Assume that

1. the function $f(\cdot, u)$ is twice differentiable and $|\nabla_x f(x, u)| \le l$ and $|\nabla_{xx} f^i(x, u)| \le M$ for all $(x, u) \in R^n \times U$, $i = \overline{1, n}$;

2. the set U is compact and

$$0 < \sigma = \min\{|v| \mid v \in f(0, U),\ W(v) = 1\},$$

where W is the Minkowski function of the set $f(0, U)$.

Note that the latter assumption is fulfilled if $f(0, U)$ is a polyhedron, for example.

Under the assumptions of Theorem 4 there exist numbers $\tau > 0$, $\delta \in (0, 1)$, and a convex positively homogeneous function $V(x)$ such that $V(0) = 0$, $V(x) > 0$, if $x \neq 0$, and for any $x \in \mathrm{bd}\mathcal{M}$ ($\mathcal{M} = \{x \mid V(x) \le 1\}$) there is a vector $v \in Cx + K$ satisfying $x + \tau v \in \delta\mathcal{M}$.

Observe that there exist numbers $a > 0$ and $b > 0$ such that

$$aB_n \subset \mathcal{M} \subset bB_n.$$

For the Minkowski function $V(x)$ we have

$$\frac{|x|}{b} \le V(x) \le \frac{|x|}{a}.$$

Set

$$\bar{\rho} = \frac{a(1-\delta)\sigma}{b^2(\sqrt{n}M\tau\sigma + (4l + a/(\tau b))(\delta + |E + \tau C|))}.$$

THEOREM 5. *Assume that the conditions of Theorem* 4 *and Assumptions* 1 *and* 2 *are satisfied. Then for all* $x \in \rho\mathcal{M}$ *there exists* $u(x) \in U$ *such that*

$$x + \tau f(x, u(x)) \in \frac{1+\delta}{2}V(x)\mathcal{M}.$$

Proof. Let $\rho \in (0, \bar{\rho}]$ and $x \in \mathrm{bd}\rho\mathcal{M}$. There exist $x_0 \in \mathrm{bd}\mathcal{M}$ and $v_0 \in Cx_0 + K$ satisfying $x = \rho x_0$ and $x_0 + \tau v_0 \in \delta\mathcal{M}$, respectively. We claim that there exist $\beta \ge 0$ and

$u \in U$ such that $v_0 = Cx_0 + \beta f(0, u)$ and $W(f(0, u)) = 1$. Indeed, the vector $v_0 - Cx_0$ can be represented as $\lim \beta_i f(0, u_i)$, where $\beta_i \geq 0$, $u_i \in U$, and $W(f(0, u_i)) = 1$. We observe that $|f(0, u_i)| \geq \sigma > 0$. Consequently, the sequence β_i is bounded from above and, without loss of generality, converges to β. Since the set U is compact, taking the limit, we obtain the required statement.

Now we prove the inequality

$$d(v_0,\ \rho^{-1} f(\rho x_0, U)) \leq a\frac{1-\delta}{2\tau}. \tag{31}$$

Since the set $f(\rho x_0, U)$ is convex, we have

$$\begin{aligned} &d(Cx_0 + \beta f(0, u),\ \rho^{-1} f(\rho x_0, U)) \\ &\leq |Cx_0 + \beta f(0, u) - \rho^{-1}(\alpha f(\rho x_0, u) + (1-\alpha) f(\rho x_0, u_0))|, \end{aligned} \tag{32}$$

where $\alpha \in [0, 1]$.

The inclusion $x_0 + \tau(Cx_0 + \beta f(0, u)) \in \delta\mathcal{M}$ implies that $|x_0 + \tau(Cx_0 + \beta f(0, u))| \leq \delta b$. Hence

$$\tau\beta|f(0, u)| \leq |x_0 + \tau(Cx_0 + \beta f(0, u))| + |x_0 + \tau Cx_0| \leq \delta b + |E + \tau C|b.$$

Thus,

$$\beta \leq (\delta + |E + \tau C|)(\tau\sigma)^{-1} b. \tag{33}$$

Observe that $\beta\rho < 1$.

Set $\alpha = \beta\rho$. The right side of (32) is less than or equal to

$$\begin{aligned} &|Cx_0 - \rho^{-1} f(\rho x_0, u_0)| + \beta|f(0, u) - f(\rho x_0, u)| + \beta|f(\rho x_0, u_0)| \\ &\leq \rho\left(\frac{\sqrt{n}}{2}|x_0|^2 M + 2\beta|x_0|l\right) \leq \rho\left(\frac{\sqrt{n}}{2} b^2 M + 2\beta bl\right). \end{aligned}$$

Combining this inequality with (33) we derive (31).

Thus, there exists $v \in f(\rho x_0, U)$ such that $x_0 + (\tau/\rho)v \in \frac{1}{2}(1+\delta)\mathcal{M}$ or, in other words,

$$x + \tau f(x, u(x)) \in \frac{1+\delta}{2} V(x)\mathcal{M}.$$

The theorem is proved. □

Continuous stabilizers. Theorem 4 shows that there exists a stabilizer $u(x)$ such that the origin is the asymptotically stable equilibrium point of differential equation (26) with a discontinuous right-hand side. A natural question arises: is there a stabilizer which makes the right-hand side of (26) a continuous function? A positive answer is given by the following theorem.

THEOREM 6. *Assume that in addition to the conditions of Theorem* 4 *the set* $f(x, U)$ *is closed for any* x. *Then there exists a regulator* $u(x)$ *such that the map* $x \to f(x, u(x))$ *is continuous.*

Proof. As in the proof of Theorem 4 we observe that there exist numbers $\tau > 0, \delta \in (0, 1)$, and a convex positively homogeneous function $V(x)$ such that $V(0) = 0$, $V(x) > 0$, if $x \neq 0$, and for any x from the neighborhood of the origin Ω the set-valued map

$$H(x) = \tau^{-1}\left(\frac{1+\delta}{2} V(x)\mathcal{M} - x\right) \bigcap f(x, U),$$

where $\mathcal{M} = \{x \mid V(x) \leq 1\}$, is nonempty. Let us consider the set-valued map

$$\tilde{H}(x) = \tau^{-1}\left(\frac{3+\delta}{4}V(x)\mathcal{M} - x\right) \bigcap f(x, U).$$

Obviously, the map $\tilde{H}(x)$ is upper semicontinuous and has convex compact values. Let $v(x)$ be the projection of the origin onto $\tilde{H}(x)$. By Theorem 1.2.3 in [1, p. 49] $\tilde{H}(x)$ is lower semicontinuous. From Theorem 1.7.1 in [1, p. 70] we see that $v(x)$ is a continuous function. Hence there exists $u(x) \in U$ satisfying $v(x) = f(x, u(x))$. Asymptotic stability of the zero equilibrium position of the differential equation

$$\dot{x} = v(x) = f(x, u(x))$$

can be proved similarly to the last part of Theorem 4. □

Remark. From the computational point of view the construction of such a regulator $u(x)$ is much more complex than the procedure described in the remark after Theorem 4.

Under more restrictive assumptions on the map $u \to f(x, u)$ it is possible to establish continuity of the stabilizer $u(x)$. For example, applying the inverse function theorem we immediately obtain the following result.

COROLLARY 2. *Assume, in addition to the conditions of Theorem 6, that the map $u \to f(x, u)$ is differentiable. If there exists an inverse linear operator $(\nabla_u f(0, u_0))^{-1}$, then there exists a continuous stabilizer $u(x)$.*

Lipschitzian stabilizers. Now let us establish sufficient conditions for the existence of a Lipschitzian stabilizer.

We need the following auxiliary result.

Let $X \subset R^n$ be a compact set and let $U \subset R^k$ and $M \subset R^m$ be convex sets. Let $f : R^n \to R^m$ be a continuous function and let $\Lambda : R^k \to R^m$ be a linear operator.

LEMMA 7. *Assume that for any $x \in X$ there exists $u \in U$ satisfying*

$$f(x) + \Lambda u \in M.$$

Then for any $\epsilon > 0$ there exists a Lipschitzian map $u : X \to U$ such that

$$f(x) + \Lambda u(x) \in M + \epsilon B_m$$

whenever $x \in X$.

Proof. Let $\epsilon > 0$. Consider a point $x_0 \in X$. There exists $u_0 \in U$ satisfying

$$f(x_0) + \Lambda u_0 \in M.$$

Since f is continuous, there exists $\delta_0 > 0$ such that $|f(x) - f(x_0)| < \epsilon$ whenever $|x - x_0| < \delta_0$. We cover every point $x_0 \in X$ by such a δ_0-neighborhood and choose a finite subcovering $\{\Omega_i = x_i + \delta_i \overset{\circ}{B}_n\}_{i=1}^I$. Let $\{u_i\}_{i=1}^I$ be the corresponding vectors from U.

There exists a Lipschitz partition of unity $\{p_i(x)\}_{i=1}^I$ subordinated to this subcovering (see [1, Thm. 0.1.2]), that is, a family of functions $\{p_i(x)\}_{i=1}^I$ defined on X and satisfying the following conditions:

1. $p_i(\cdot)$ is Lipschitz for all $i = \overline{1, I}$;
2. $p_i(x) > 0$ for $x \in \Omega_i \cap X$ and $p_i(x) = 0$ for $x \in X \setminus \Omega_i$;
3. for each $x \in X$, $\sum_{i=1}^I p_i(x) = 1$.

Set

$$u(x) = \sum_{i=1}^{I} p_i(x) u_i.$$

Let $x \in X$. Then $p_i(x) > 0$ if and only if $|x - x_i| < \delta_i$. Hence

$$f(x) + \Lambda u(x) = \sum_{i=1}^{I} p_i(x)(f(x) + \Lambda u_i) \in \sum_{i=1}^{I} p_i(x)(f(x_i) + \Lambda u_i + \epsilon B_m)$$
$$\subset \sum_{i=1}^{I} p_i(x)(M + \epsilon B_m) = M + \epsilon B_m.$$

The lemma is proved. □

Assume that the right-hand side of (25) is affine, that is,

$$f(x, u) = f_0(x) + \sum_{q=1}^{N} u^q f_q(x) \tag{34}$$

with $u = (u^1, \ldots, u^N) \in U$, where $U \subset R^N$ is convex. Denote by $F(x)$ the matrix whose columns are the vectors $f_1(x), \ldots, f_N(x)$.

THEOREM 7. *Assume that the regulator design problem for the first approximation of system* (25) *with affine right-hand side* (34) *is solvable. Then there exists a Lipschitzian regulator* $u(x)$.

Proof. Consider the control system

$$\dot{x} = Cx + F(0)(u - u_0), \ u \in U.$$

By Theorem 1 there exist a convex positively homogeneous function $V(x)$, numbers $\tau > 0$, $\delta \in (0, 1)$, and a map $\tilde{u} : \mathcal{M} \to U$ $(\mathcal{M} = \{x \mid V(x) \leq 1\})$ such that $V(0) = 0$, $V(x) > 0$, if $x \neq 0$ and

$$x + \tau(Cx + F(0)(\tilde{u}(x) - u_0)) \in \delta\mathcal{M}$$

whenever $x \in \mathrm{bd}\mathcal{M}$. By Lemma 7 there exists a Lipschitzian map $\hat{u} : \mathrm{bd}\mathcal{M} \to U$ such that

$$x + \tau(Cx + F(0)(\hat{u}(x) - u_0)) \in \frac{1+\delta}{2}\mathcal{M}$$

for all $x \in \mathrm{bd}\mathcal{M}$. Let $V(x) < 1$. Then

$$x + \tau\left(Cx + V(x)F(0)\left(\hat{u}\left(\frac{x}{V(x)}\right) - u_0\right)\right) \in \frac{1+\delta}{2}V(x)\mathcal{M}.$$

Set

$$u(x) = (1 - V(x))u_0 + V(x)\hat{u}\left(\frac{x}{V(x)}\right).$$

If $V(x)$ is sufficiently small, then we have

$$f_0(x) + F(x)u_0 - Cx \in \frac{1-\delta}{8}V(x)\mathcal{M}$$

and

$$V(x)(F(x) - F(0))\left(\hat{u}\left(\frac{x}{V(x)}\right) - u_0\right) \in \frac{1-\delta}{8}V(x)\mathcal{M}.$$

Therefore

$$x + \tau(f_0(x) + F(x)u(x))$$

$$= x + \tau\left(f_0(x) + F(x)u_0 + V(x)F(x)\left(\hat{u}\left(\frac{x}{V(x)}\right) - u_0\right)\right)$$

$$\in x + \tau\left(Cx + V(x)F(0)\left(\hat{u}\left(\frac{x}{V(x)}\right) - u_0\right)\right) + \frac{1-\delta}{4}V(x)\mathcal{M} \subset \frac{3+\delta}{4}V(x)\mathcal{M}.$$

Consequently $V(x)$ is a Lyapunov function for the differential equation

$$\dot{x} = f_0(x) + F(x)u(x).$$

The theorem is proved. □

Note that the right-hand side of the first approximation is always affine. Therefore we obtain the following corollary.

COROLLARY 3. *Assume that the regulator design problem for the first approximation* (16) *is solvable. Then there exists a Lipschitzian stabilizer* $w(x)$ *for system* (16).

Now apply Theorem 7 to the general case. Suppose that the right-hand side of (25) is differentiable in u, and that U is a convex set. Consider the system

$$\dot{x} = f(x, u_0) + \nabla_u f(x, u_0)(u - u_0), \quad u \in U. \tag{35}$$

COROLLARY 4. *Assume that the regulator design problem for the first approximation of system* (35) *is solvable. Then there exists a Lipschitzian stabilizer* $u(x)$ *that solves the regulator design problem for system* (25).

Proof. By Theorems 1 and 7 there exist a convex positively homogeneous function $V(x)$, numbers $\tau > 0$, $\delta \in (0, 1)$, and a Lipschitzian map $u : \mathcal{M} \to U$ $(\mathcal{M} = \{x \mid V(x) \leq 1\})$ such that $V(0) = 0$, $V(x) > 0$, if $x \neq 0$ and

$$x + \tau(f(x, u_0) + \nabla_u f(x, u_0)(u(x) - u_0)) \in \delta V(x)\mathcal{M}$$

for all x sufficiently close to zero. If $V(x)$ is sufficiently small, then we have

$$x + \tau f(x, u(x)) = x + \tau(f(x, u_0) + f(x, u(x)) - f(x, u_0))$$

$$\in x + \tau(f(x, u_0) + \nabla_u f(x, u_0)(u(x) - u_0)) + \frac{1-\delta}{2}V(x)\mathcal{M} \subset \frac{1+\delta}{2}V(x)\mathcal{M}.$$

Consequently, $V(x)$ is a Lyapunov function for the differential equation

$$\dot{x} = f(x, u(x)). \qquad \square$$

Piecewise constant controls. In practical problems a piecewise constant control law is usually used instead of the stabilizer $u(x)$ considered before. The control is chosen in discrete moments of time $0, \sigma, 2\sigma, \ldots$, where $\sigma > 0$, and we have

$$u_\sigma(t) \equiv u(x(k\sigma)), \quad t \in [k\sigma, (k+1)\sigma),$$

where $u(x)$ is the regulator constructed in Theorem 4. The following theorem substantiates this control law.

THEOREM 8. *If $\sigma > 0$ is sufficiently small, then any trajectory $x(\cdot)$ of the differential equation*

$$\dot{x} = f(x, u_\sigma(t)) \tag{36}$$

tends to zero whenever $|x(0)|$ is sufficiently small.

Proof. Let $x(\cdot)$ be a solution to (36) and $t \in [k\sigma, (k+1)\sigma)$. Since $V(x) \le |x|/a$, the function $V(x)$ is Lipschitzian with the constant $1/a$. Indeed,

$$V(x_1) = V(x_2 + x_1 - x_2) \le V(x_2) + V(x_1 - x_2) \le V(x_2) + \frac{|x_1 - x_2|}{a}.$$

If $x(t)$ is sufficiently close to zero, then we have

$$\frac{d}{dt}V(x(t)) \le \frac{1}{\tau}[V(x(t) + \tau f(x(t), u_\sigma(t))) - V(x(t))]$$

$$\le \frac{1}{\tau}[V(x(k\sigma) + \tau f(x(k\sigma), u(x(k\sigma)))) - V(x(k\sigma))] + \frac{2+\tau l}{a\tau}|x(t) - x(k\sigma)|$$

$$\le -\frac{1-\delta}{2\tau}V(x(k\sigma)) + \frac{2+\tau l}{a\tau}|x(t) - x(k\sigma)|$$

(see the proof of Theorem 4). Since

$$|x(t) - x(k\sigma)| \le l\int_{k\sigma}^{t} |x(s) - x(k\sigma)|ds + \sigma|f(x(k\sigma), u(x(k\sigma))|,$$

we derive from the Gronwall inequality

$$|x(t) - x(k\sigma)| \le \sigma|f(x(k\sigma), u(x(k\sigma))|e^{l\sigma}.$$

Moreover, if N is a sufficiently large number, then $|f(x, u(x))| \le NV(x)$ for all $x \in \Omega$. Thus we obtain

$$\frac{d}{dt}V(x(t)) \le -\frac{1-\delta}{2\tau}V(x(k\sigma)) + \sigma\frac{2+\tau l}{a\tau}Ne^{l\sigma}V(x(k\sigma)).$$

Let $\sigma = \min\{1,\ (1-\delta)ae^{-l}/(4(2+\tau l)N)\}$. Then we have

$$\frac{d}{dt}V(x(t)) \le -\frac{1-\delta}{4\tau}V(x(k\sigma)), \quad \text{if } t \in [k\sigma, (k+1)\sigma).$$

This implies that $V(x(t)) < V(x(k\sigma))$, if $t \in (k\sigma, (k+1)\sigma)$. Consequently we obtain

$$\frac{d}{dt}V(x(t)) \le -\frac{1-\delta}{4\tau}V(x(t)).$$

Thus, any trajectory $x(\cdot)$ of differential equation (36) tends to zero whenever $|x(0)|$ is sufficiently small. □

4. Examples. In this section we study the regulator design problem for two simple control systems considered in the introduction.

Stabilization of an oscillator subjected to a unilateral force. The motion of an oscillator subjected to a unilateral force is described by the following equations:

$$\begin{aligned} &\dot{x}^1 = x^2, \\ &\dot{x}^2 = -x^1 + u, \\ &0 \le u \le 1. \end{aligned} \tag{37}$$

The control $u_0 = 0$ corresponds to the equilibrium position. Thus the first approximation of system (37) is given by

$$\begin{aligned} &\dot{x}^1 = x^2, \\ &\dot{x}^2 = -x^1 + w, \\ &w \ge 0. \end{aligned}$$

In this case

$$C = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$$

and

$$K = \{(w^1, w^2) \mid w^1 = 0,\ w^2 \ge 0\}.$$

The transposed matrix C^T has neither nontrivial subspaces nor eigenvectors contained in the conjugate cone $K^* = \{(w^{1*}, w^{2*}) \mid w^{2*} \ge 0\}$. Therefore, by Theorem 3 for all negative λ the cone $L_k(\lambda)$ coincides with the hole space for some $k = k(\lambda)$. By Corollary 1 and Theorem 4 the stabilization problem for system (37) is solvable.

Let us show that $k(\lambda) \to \infty$ as $\lambda \to \infty$. Indeed, by definition

$$L_k(\lambda) = -\operatorname{co} \bigcup_{i=0}^{k} (C - \lambda E)^{-i} K.$$

If $\lambda < 0$, then we have

$$(C - \lambda E)^{-i} = \left(\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} + |\lambda| \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \right)^{-i}$$

$$= \left(\frac{1}{\lambda^2 + 1} \right)^i \left(\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} + |\lambda| \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \right)^i = \left(\frac{1}{\lambda^2 + 1} \right)^i \sum_{j=0}^{i} C_i^j |\lambda|^{i-j} \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}^j$$

$$= \left(\frac{1}{\lambda^2 + 1} \right)^i \left[\left(\sum_{p=0} (-1)^p C_i^{2p} |\lambda|^{i-2p} \right) \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \right.$$

$$\left. + \left(\sum_{p=0} (-1)^p C_i^{2p+1} |\lambda|^{i-2p-1} \right) \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \right]. \tag{38}$$

Denote $e_1 = (1, 0)$, $e_2 = (0, 1)$, $l_i(\lambda) = -(C - \lambda E)^{-i} e_2$. Observe that the cone $L_k(\lambda)$ is spanned by the convex hull of the points $\{l_0(\lambda), \ldots, l_k(\lambda)\}$. From (38) we obtain

$$\langle e_1, l_i(\lambda) \rangle = \left(\frac{1}{\lambda^2 + 1} \right)^i \left(\sum_{p=0} (-1)^p C_i^{2p+1} |\lambda|^{i-2p-1} \right).$$

Obviously, for any k there exists a $\Lambda < 0$ such that $\langle e_1, l_i(\lambda) \rangle \ge 0$, $i = \overline{1, k}$, whenever $\lambda < \Lambda$. Hence $L_k(\lambda) \ne R^2$. Thus $k(\lambda) \to \infty$ as $\lambda \to -\infty$.

Stabilization of a missile uniform motion. Now consider the model of a missile (see the introduction). The motion of the missile's mass center is described by the following equations:

$$
\begin{aligned}
&\ddot{z}^1 = -\sigma \dot{z}^1 + \frac{u^1 \dot{z}^1 - u^2 \dot{z}^2}{\sqrt{(\dot{z}^1)^2 + (\dot{z}^2)^2}},\\
&\ddot{z}^2 = -\sigma \dot{z}^2 + \frac{u^1 \dot{z}^2 + u^2 \dot{z}^1}{\sqrt{(\dot{z}^2)^2 + (\dot{z}^2)^2}},\\
&(u^1, u^2) \in U = \{(u^1, u^2) \mid \sqrt{(u^1)^2 + (u^2)^2} \le b,\ \frac{u^2}{u^1} \le \tan \eta,\ u^1 \ge 0\},
\end{aligned}
\tag{39}
$$

where $\sigma > 0$ stands for a coefficient of air resistance, b is the maximal thrust, and η is the maximal angle between the longitudinal axis of the missile and that of the jet propulsion. Our aim is to stabilize the uniform motion of the object under consideration along the z^1-axis with the constant maximal speed $\dot{z}^1 = b/\sigma$. The control $(u_0^1, u_0^2) = (b, 0)$ corresponds to the uniform motion we are to stabilize.

Let us introduce new variables $x^1 = \dot{z}^1 - b/\sigma$, $x^2 = z^2$, $x^3 = \dot{z}^2$. System (39) now can be written in the form

$$
\begin{aligned}
&\dot{x}^1 = -\sigma \left(x^1 + \frac{b}{\sigma}\right) + \frac{u^1 (x^1 + \frac{b}{\sigma}) - u^2 x^3}{\sqrt{(x^1 + \frac{b}{\sigma})^2 + (x^3)^2}},\\
&\dot{x}^2 = x^3,\\
&\dot{x}^3 = -\sigma x^3 + \frac{u^1 x^3 + u^2 (x^1 + \frac{b}{\sigma})}{\sqrt{(x^1 + \frac{b}{\sigma})^2 + (x^3)^2}},\\
&(u^1, u^2) \in U,
\end{aligned}
\tag{40}
$$

and we obtain the regulator design problem in the usual form: to find a control $u(x)$ stabilizing system (40) to the zero equilibrium position.

Consider the first approximation of system (40)

$$
\begin{pmatrix} \dot{x}^1 \\ \dot{x}^2 \\ \dot{x}^3 \end{pmatrix} = \begin{pmatrix} -\sigma & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} x^1 \\ x^2 \\ x^3 \end{pmatrix} + \begin{pmatrix} w^1 \\ w^2 \\ w^3 \end{pmatrix}, \tag{41}
$$

where $(w^1, w^2, w^3) \in K = \{(w^1, w^2, w^3) \mid w^1 \le 0,\ w^2 = 0\}$. Obviously, the transposed matrix

$$
C^T = \begin{pmatrix} -\sigma & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}
$$

has the eigenvector $(-1,0,0)$ corresponding to the eigenvalue $-\sigma$, the eigenvector $(0,0,1)$ corresponding to the eigenvalue 0, and the invariant subspace spanned by the vectors $(0,0,1)$ and $(0,1,0)$ corresponding to one Jordan block of the matrix C^T with the eigenvalue 0. Since

$$
K^* = \{(w^{1*}, w^{2*}, w^{3*}) \mid w^{1*} \le 0,\ w^{3*} = 0\},
$$

we observe that the invariant space spanned by the vectors $(0, 0,1)$ and $(0,1,0)$ is not contained in the cone K^*. The vector $(-1,0,0)$ belongs to the cone K^*, but it corresponds to the negative eigenvalue $-\sigma$. By Corollary 1 and Theorem 4 the regulator design problem for system (40) is solvable.

In the previous example the λ-dimension depends on λ. In the example under consideration, for all $\lambda \in (-\sigma, 0)$ we have

$$L_1(\lambda) = \{(y^1, y^2, y^3) \mid \lambda y^2 = y^3,\ (\sigma + \lambda)y^1 \leq 0\} - K = R^3.$$

The results of computer simulation for these two examples can be found in [7, 8].

5. Regulator design under controllability conditions. In this section we consider the regulator design problem for the linear control system

$$\dot{x} = Cx + u,\ u \in K, \tag{42}$$

where K is a closed convex cone. We suppose that system (42) is controllable.

Recall the following result (Korobov [12] and Aubin, Frankowska, and Olech [2]).

THEOREM 9. *The following conditions are equivalent:*

1. *Linear control system* (42) *is controllable.*
2. *The matrix C^T has neither eigenvectors in K^* nor proper invariant subspaces contained in K^*.*

Remark. Another necessary and sufficient condition of controllability appeared in Brammer [6]. The case of a single-input system was considered by Saperstone and Yorke [17].

Theorem 9 combined with Corollary 1 implies that the regulator design problem for system (42) is solvable. Moreover, by Theorem 3 for any $\lambda < 0$ there exists a positive integer $k = k(\lambda)$ such that

$$L_k(\lambda) = -\operatorname{co}\bigcup_{i=0}^{k}(C - \lambda E)^{-i}K = R^n.$$

As was pointed out in Remark 2 at the end of §2, the λ-dimension characterizes the efficiency of the regulator design method. Our goal is to estimate the λ-dimension of R^n with respect to the set-valued map $x \to Cx + K$.

An estimate for the λ-dimension. To clarify the idea of the estimate note that for $\lambda < 0$ the cone

$$L_k(\lambda) = -\sum_{i=0}^{k}(C - \lambda E)^{-i}K = -\sum_{i=0}^{k}(E + |\lambda|^{-1}C)^{-i}\left(\bigcup_{\alpha \geq 0}\alpha W\right),$$

where $W = K \cap B_n$, can be considered as a cone spanned by the reachable set of the discrete control system

$$x_{i+1} = \left(E + \frac{1}{|\lambda|}C\right)^{-1}x_i - \frac{1}{|\lambda|}u,\ u \in W,\ i = \overline{0, k-1}. \tag{43}$$

The discrete system (43) approximates the control system

$$\dot{x} = -Cx - u,\ u \in W,\ t \in [0, T]. \tag{44}$$

The system

$$\dot{x} = Cx + u,\ u \in W, \tag{45}$$

is locally controllable (see [2, Lem. 5.7]). For systems (43) and (44) we denote the sets reachable from the origin by $\mathcal{A}_k(0)$ and $\mathcal{A}_T(0)$, respectively. Since system (45) is controllable,

there exist $T > 0$ and $\eta > 0$ such that $\eta B_n \subset \mathcal{A}_T(0)$. If k and $|\lambda|$ are sufficiently large, then $0 \in \operatorname{int}\mathcal{A}_k(0)$. The latter amounts to saying $L_k(\lambda) = R^n$. Thus, we can estimate the number $k = k(\lambda)$ via the time T.

Consider a linear control system

$$\dot{x} = Cx + u, \ u \in U, \tag{46}$$

where C is an $n \times n$ matrix and U is a convex compact set satisfying $U \subset B_n$. Consider the discrete control system

$$x_{i+1} = (E - \tau C)^{-1}x_i + \tau u_i, \ u_i \in U, \ i = \overline{0, k-1}. \tag{47}$$

The following lemma shows that any trajectory $x(\cdot)$ of system (46) can be approximated by a trajectory of discrete system (47).

LEMMA 8. *Let a number $\tau > 0$ and a positive integer k be such that $T/\tau < k \le (T/\tau)+1$ and $T/k < |C|^{-1}$. Then for any trajectory $x(\cdot)$ of system* (46) *with $x(0) = 0$ there exists a trajectory of discrete system* (47) $x_0, \dots, x_k$, $x_0 = 0$ *such that*

$$|x_k - x(T)| \le \frac{T}{k}(2 + |C|)^2 e^{2|C|T}.$$

Proof. Let $x(\cdot)$ be a trajectory of (46) with $x(0) = 0$. Applying the mean value theorem, from (46) we have

$$\begin{aligned} x(i\tau + \tau) - x(i\tau) &\in C\int_{i\tau}^{i\tau+\tau} x(t)dt + \tau U \\ &= C\int_{i\tau}^{i\tau+\tau}(x(i\tau+\tau) + \int_{i\tau+\tau}^{t}\dot{x}(s)ds)dt + \tau U \\ &= \tau C x(i\tau+\tau) + \tau U + C\int_{i\tau}^{i\tau+\tau}\int_{i\tau+\tau}^{t}\dot{x}(s)dsdt \end{aligned} \tag{48}$$

for all $i = \overline{0, k-1}$. Obviously,

$$|\dot{x}| \le |C|\int_0^t e^{(t-s)|C|}ds + 1 = e^{t|C|}. \tag{49}$$

From (48) and (49) we have

$$\begin{aligned} &x(i\tau+\tau) \\ &\in (E-\tau C)^{-1}x(i\tau) + \tau(E-\tau C)^{-1}U + (E-\tau C)^{-1}|C|\int_{i\tau}^{i\tau+\tau}\int_{t}^{i\tau+\tau} e^{s|C|}dsdtB_n \\ &\subset (E-\tau C)^{-1}x(i\tau) + \tau U + \tau(\tau|C| + \tau^2|C|^2 + \cdots)B_n \\ &+ |E-\tau C|^{-1}e^{T|C|}(\tau - |C|^{-1}(1 - e^{-\tau|C|}))B_n \subset (E-\tau C)^{-1}x(i\tau) + \tau U + \tau^2\gamma B_n, \end{aligned}$$

where $\gamma = |C|(1 + \exp(T|C|))/(1 - \tau|C|)$.

Define the trajectory $x_0, \dots, x_k$ of discrete system (47) approximating the trajectory $x(\cdot)$ by induction. Set $x_0 = 0$. If x_i is already determined, we choose $x_{i+1} \in (E - \tau C)^{-1}x_i + \tau U$ from the condition

$$|x_{i+1} - x(i\tau+\tau)| = d(x(i\tau+\tau), (E-\tau C)^{-1}x_i + \tau U).$$

Observe that

$$\begin{aligned} |x_{i+1} - x(i\tau+\tau)| &\le |(E-\tau C)^{-1}||x_i - x(i\tau)| + \tau^2\gamma \\ &\le (1 - \tau|C|)^{-1}|x_i - x(i\tau)| + \tau^2\gamma. \end{aligned}$$

By induction we have

$$|x_k - x(T)| \le ((1-\tau|C|)^{-(k-1)} + \cdots + (1-\tau|C|)^{-1} + 1)\tau^2\gamma$$
$$= \tau^2\gamma\frac{(1-\tau|C|)^{-k}-1}{(1-\tau|C|)^{-1}-1} \le \frac{T}{k}(2+|C|)^2 e^{2|C|T}.$$

The lemma is proved. □

THEOREM 10. *Assume that there exist* $T > 0$ *and* $\eta > 0$ *such that* $\eta B_n \subset \mathcal{A}_T(0)$. *If* $\lambda < -\max\{|C|, \eta^{-1}(2+|C|)^2\exp(2|C|T)\}$ *and* $k > T|\lambda|$, *then*

$$L_k(\lambda) = R^n.$$

Proof. For any point $b \in \eta B_n$ one can find a trajectory $x(\cdot)$ of control system (44) with $x(0) = 0$ and satisfying $x(T) = b$. Lemma 8 implies that the reachable set $\mathcal{A}_k(0)$ of discrete system (43) satisfies $\eta B_n \subset \mathcal{A}_k(0) + \beta B_n$, where $\beta < \eta$. Let $x^* \in \mathrm{bd}B_n$. Then we have

$$S(x^*, (\eta-\beta)B_n) = \eta - \beta = S(x^*, \eta B_n) - \beta \le S(x^*, \mathcal{A}_k(0) + \beta B_n) - \beta$$
$$= S(x^*, \mathcal{A}_k(0)) + S(x^*, \beta B_n) - \beta = S(x^*, \mathcal{A}_k(0)).$$

Hence, $(\eta-\beta)B_n \subset \mathcal{A}_k(0)$. Consequently, $L_k(\lambda) = \mathrm{cone}\mathcal{A}_k(0) = R^n$. □

Remark. We have reproved Theorem 3 for $\lambda_0 = -\infty$.

Single-input control systems. Now we proceed to study the regulator design problem for a single-input linear control system

$$\dot{x} = Cx + bu, \quad u \in R, \tag{50}$$

where $b \in R^n$ is a vector. We suppose that system (50) is controllable. By Kalman's criterion the controllability is equivalent with the linear independence of the vectors $b, Cb, \ldots, C^{n-1}b$. Let Σ be a polyhedron satisfying $0 \in \mathrm{int}\Sigma$. Following the proof of Theorem 1, for any $\lambda < 0$ we generate a polyhedron $\mathcal{M}$. Let $V(x)$ be the Minkowski function of $\mathcal{M}$. For system (50) we can analytically solve the minimization problem

$$\min_{u\in R} V(x + \tau(Cx + bu)) \tag{51}$$

considered in §3 (see the remark after Theorem 4) to determine the stabilizer $u(x)$. The result is contained in the following theorem.

THEOREM 11. *Let* $\lambda < 0$ *and* $\tau = 1/|\lambda|$. *Assume that the matrix* $C - \lambda E$ *is nonsingular. Then the regulator obtained as the solution to minimization problem* (51) *is a linear feedback* $u(x) = \langle c, x\rangle$ *such that the linear system*

$$\dot{x} = (C + bc^T)x \tag{52}$$

has the spectrum $\lambda_1 = \lambda_2 = \cdots = \lambda_n = \lambda$.

Proof. Since system (50) is controllable, the vectors $b_i = (C-\lambda E)^{-i}b$, $i = \overline{0, n-1}$, form a basis in R^n. Indeed, by Theorem 3 there exists a positive integer k such that

$$\mathrm{co}\bigcup_{i=0}^{k}(C-\lambda E)^{-k}(Rb) = R^n.$$

From the Cayley–Hamilton theorem $k = n-1$. Thus, for any $x \in R^n$ there exist β^i, $i = \overline{0, n-1}$ such that

$$x = \sum_{i=0}^{n-1}\beta^i b_i. \tag{53}$$

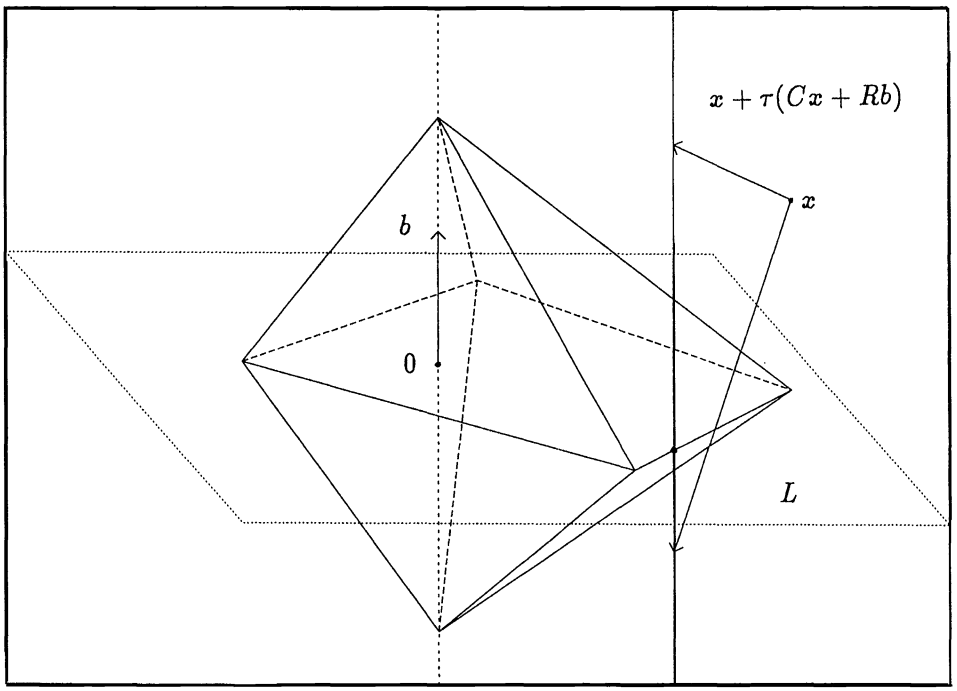

FIG. 2. *The stabilizer for a single-input system.*

Thus any vertex of the polyhedron Σ can be represented in the form (53). This implies that the polyhedron $\mathcal{M}$ is the convex hull of a polyhedron contained in the subspace L spanned by the vectors $b_1, \ldots, b_{n-1}$ and of two points contained in the one-dimensional subspace spanned by $b_0 = b$. Consequently, the Minkowski function V in (51) has the minimum at the point $u(x)$ such that the vector $x + \tau(Cx + bu(x))$ belongs to the subspace L (see Figure 2). To determine $u(x)$ observe that for all $i = \overline{0, n-1}$ we have

$$Cb_i = \sum_{k=0}^{n-1} \gamma_i^k b_k. \tag{54}$$

From (53) and (54) we have

$$x + \tau(Cx + bu)$$
$$= \sum_{i=1}^{n-1} \beta^i b_i + \tau \sum_{i=0}^{n-1} \beta^i \sum_{k=1}^{n-1} \gamma_i^k b_k + \left(\beta^0 + \tau \sum_{i=0}^{n-1} \beta^i \gamma_i^0 + \tau u \right) b_0.$$

Hence

$$u(x) = -\sum_{i=0}^{n-1} \beta^i \gamma_i^0 - \beta^0/\tau. \tag{55}$$

Thus $u(x)$ is a linear function of x, i.e., $u(x) = \langle c, x \rangle$ for some $c \in R^n$. Differentiating (53) and using (54) and (55), we obtain

$$\sum_{i=0}^{n-1} \dot{\beta}^i b_i = \sum_{i=0}^{n-1} \beta^i \sum_{k=1}^{n-1} \gamma_i^k b_k - \beta^0 b_0/\tau. \tag{56}$$

Since the vectors b_i, $i = \overline{0, k}$, are linear independent, from (56) we have

$$\dot{\beta}^0 = -\beta^0/\tau, \tag{57}$$

$$\dot{\beta}^i = \sum_{j=0}^{n-1} \beta^j \gamma_j^i, \qquad i = \overline{1, n-1}. \tag{58}$$

Subtracting λb_i from both sides of (54), we obtain

$$b_{i-1} = \sum_{k=0}^{n-1} \gamma_i^k b_k - \lambda b_i.$$

Consequently, $\gamma_i^i = \lambda$, $\gamma_i^{i-1} = 1$, $i = \overline{1, n-1}$, and $\gamma_i^k = 0$, $k = \overline{1, n-1}$, $i = \overline{1, n-1}$, $k \neq i$, $k \neq i-1$. Since $\tau = 1/|\lambda|$, (57) and (58) can be written in the form

$$\frac{d}{dt}\begin{pmatrix} \beta^0 \\ \beta^1 \\ \vdots \\ \vdots \\ \beta^{n-1} \end{pmatrix} = \begin{pmatrix} \lambda & 0 & 0 & \dots & 0 \\ \gamma_0^1 & \lambda & 1 & \dots & 0 \\ \vdots & & \ddots & \ddots & \vdots \\ \vdots & & & \ddots & 1 \\ \gamma_0^{n-1} & 0 & 0 & \dots & \lambda \end{pmatrix} \begin{pmatrix} \beta^0 \\ \beta^1 \\ \vdots \\ \vdots \\ \beta^{n-1} \end{pmatrix}.$$

The spectrum of the system is, obviously, $\lambda_1 = \lambda_2 = \cdots = \lambda_n = \lambda$. □

There exists a linear feedback $u(x) = \langle c, x \rangle$ such that the closed-loop system

$$\dot{x} = (C + bc^T)x \tag{59}$$

has an arbitrary given spectrum (see [19, Thm. 4.1.7], for example). Consequently the solutions of (59) can damp to the zero equilibrium position with an arbitrary given speed determined by the real parts of the spectrum. It turns out that the trajectories of closed-loop systems with fast damping significantly deviate from the equilibrium position during a short initial time interval. In other words, trajectories have "peaks" before fast damping. This effect has been largely studied (see Polotski [15], Izmailov [11], and Sussmann and Kokotovic [20], for example). Let us show that the regulator obtained as the solution to (51) ensures a minimal overshoot among linear feedback control laws with the spectra $\{\lambda_1, \dots, \lambda_n\}$ satisfying the conditions $\mathrm{Re}\lambda_i \leq \lambda < 0$, $|\lambda_i - \lambda| < \epsilon$, where $\epsilon > 0$ is sufficiently small.

Recall the following result from Izmailov [11].

Denote by $x(t, x_0)$ the solution to (59) satisfying $x(0, x_0) = x_0$.

THEOREM 12. *There exists $\gamma = \gamma(C, b) > 0$ such that if the spectrum $\{\lambda_1, \dots, \lambda_n\}$ of system* (59) *satisfies* $\mathrm{Re}\lambda_i \leq \lambda < 0$, $i = \overline{1, n}$, *then we have*

$$\sup_{0 \leq t \leq 1/\lambda} \sup_{x_0 \in \mathrm{bd} B_n} |x(t, x_0)| \geq \gamma \frac{|\lambda_1 \dots \lambda_n|}{\max |\lambda_i|}.$$

As follows from Theorem 12, the "peak" effect always takes place in linear systems. An important practical problem is to choose a linear feedback with the minimal overshoot and the damping speed greater than or equal to a given value. This problem is very complex and its complete solution is unknown, but some results in this direction have been obtained by Polotski [15]. The following two theorems can be proved with the help of techniques similar to the ones developed in [15].

Consider linear control system (50). Let the linear feedback $u = \langle c, x \rangle$ be such that linear system (59) has the spectrum $\{\lambda_1, \dots, \lambda_n\}$, where $\lambda_1, \dots, \lambda_n$ are different complex numbers. Denote the matrix $A = C + bc^T$ by $A(\lambda_1, \dots, \lambda_n)$ to emphasize its dependence on $\lambda_1, \dots, \lambda_n$.

To characterize the "peak" effect introduce the function

$$p(\lambda_1, \ldots, \lambda_n) = \max_{t \geq 0} \max_{|x| \leq 1} |e^{A(\lambda_1, \ldots, \lambda_n)t} x|$$

defined for complex numbers satisfying $\mathrm{Re}\lambda_i < 0$, $i = \overline{1, n}$. The norm in the definition of p is not necessarily Euclidean.

THEOREM 13. *If* $\lambda_1 = \cdots = \lambda_n = \lambda < 0$, *then we have*

$$p(\lambda, \ldots, \lambda) \leq (\mathrm{const})\lambda^{n-1}.$$

Theorem 12 shows that

$$p(\lambda_1, \ldots, \lambda_n) \geq (\mathrm{const})\lambda^{n-1}$$

whenever the spectrum $\{\lambda_1, \ldots, \lambda_n\}$ satisfies $\mathrm{Re}\lambda_i \leq \lambda < 0$. Thus, from Theorem 13 we see that the spectrum $\lambda_1 = \cdots = \lambda_n = \lambda$ guarantees the minimal overshoot at least up to a factor. It is natural to expect that for any spectrum $\{\lambda_1, \ldots, \lambda_n\}$ satisfying $\mathrm{Re}\lambda_i \leq \lambda < 0$ we have

$$p(\lambda, \ldots, \lambda) \leq p(\lambda_1, \ldots, \lambda_n)$$

whenever $|\lambda|$ is sufficiently large. Unfortunately, we have no proof of this hypothesis, but its local variant can be proved.

Note that the function $p(\cdot)$ is directionally differentiable.

THEOREM 14. *For any complex vector* $(\lambda_1, \ldots, \lambda_n)$ *satisfying* $\mathrm{Re}\lambda_i \leq 0$ *and any real number* $\lambda < 0$ *there exists a number* $\nu < 0$ *such that*

$$Dp(\lambda, \ldots, \lambda)(\lambda_1, \ldots, \lambda_n) = \nu \frac{\mathrm{Re}\lambda_1 + \cdots + \mathrm{Re}\lambda_n}{n}$$

whenever $|\lambda|$ *is sufficiently large.*

From this theorem we derive a local variant of the optimality hypothesis.

COROLLARY 5. *Let* $\lambda_1, \ldots, \lambda_n$ *be a spectrum. If* $\mathrm{Re}\lambda_i < 0$ *and* $\lambda < 0$, *then*

$$Dp(\lambda, \ldots, \lambda)(\lambda_1, \ldots, \lambda_n) > 0$$

whenever $|\lambda|$ *is sufficiently large.*

We know from Theorem 11 that in the case under consideration the regulator design algorithm (51) generates a linear feedback corresponding to the spectrum $\{\lambda, \ldots, \lambda\}$ and, hence, generates a linear feedback with the *minimal overregulation*, at least in a local sense.

6. Weak asymptotic stability and stabilizability. In this section we investigate the connection between weak asymptotic stability and stabilizability and describe the class of control systems stabilizable at first approximation.

Recall the notion of weak asymptotic stability (see [9] for details). The equilibrium position $x = 0$ of a control system

$$\dot{x} = f(x, u), \quad u \in U \tag{60}$$

is called *weakly asymptotically stable* if, given $\epsilon > 0$, there exists $\delta > 0$ such that for any $x_0 \in \delta B_n$ *at least one* trajectory $x(\cdot)$ of (60) with $x(0) = x_0$ satisfies the conditions $|x(t)| < \epsilon$ for all $t \geq 0$ and $\lim x(t) = 0$ as $t \to \infty$.

Obviously, if the stabilization problem for system (60) is solvable, then the origin is its weakly asymptotically stable equilibrium position. As we know from Theorem 1, for the first

approximation these conditions are equivalent. In general stabilizability cannot be derived from weak asymptotic stability.

Example. Consider the following control system with the control set consisting of one point:

$$(\dot{x}^1, \dot{x}^2) = \begin{cases} (x^1, x^1(x^2)^{1/3}), & (x^1, x^2) \in \Omega_1, \\ -(x^1, x^2), & (x^1, x^2) \in \Omega_2, \end{cases} \tag{61}$$

where $\Omega_1 = \{(x^1, x^2) \mid x^1 \geq 0,\ |x^2| < (x^1)^2\}$, $\Omega_2 = R^2 \setminus \Omega_1$. Let $(x_0^1, x_0^2) \in \Omega_2$. Then the trajectory

$$(x^1(t), x^2(t)) = e^{-t}(x_0^1, x_0^2)$$

of system (61) obviously tends to zero when $t \to \infty$.

Let $(x_0^1, x_0^2) \in \Omega_1$ and $x_0^2 \geq 0$ (the case $x_0^2 \leq 0$ is similar to that one). Then the trajectory

$$(x^1(t), x^2(t)) = (x_0^1 e^t, \left(\frac{2}{3}\left(x_0^1(e^t - 1) + \frac{3}{2}(x_0^2)^{2/3}\right)^{3/2}\right)$$

satisfies $x^2(t) = (\frac{2}{3}(x^1(t) + \frac{3}{2}(x_0^2)^{2/3} - x_0^1))^{3/2}$. We see that there exists t^* such that $x^2(t^*) = (x^1(t^*))^2$ if (x_0^1, x_0^2) is sufficiently close to the origin. Hence $(x^1(t^*), x^2(t^*)) \in \Omega_2$. Thus, the equilibrium position $(x^1, x^2) = (0, 0)$ of system (61) is weakly asymptotically stable. Nevertheless, it is not asymptotically stable. Indeed, let $x_0^1 > 0$. Then the trajectory $(e^t x_0^1, 0)$ of system (61) does not tend to the origin. Thus the stabilization problem is not solvable.

In order to derive stabilizability from a stability concept we introduce the following definition. We say that the equilibrium position $x = 0$ of control system (60) is *weakly exponentially stable* if there exist positive constants a, θ, and δ such that for each $x_0 \in \delta B_n$ *at least one* trajectory $x(\cdot)$ of system (60) with $x(0) = x_0$ satisfies

$$|x(t)| \leq a|x_0|e^{-\theta t}, \quad t \geq 0,$$

$$|\dot{x}(t)| \leq a|x_0|e^{-\theta t}, \quad t \geq 0.$$

From Theorem 4 we see that if a system is stabilizable at first approximation, then its zero equilibrium position is weakly exponentially stable. Below we prove an inverse statement.

THEOREM 15. *Let the right-hand side of system* (60) *be twice differentiable in x, and let the derivatives $\nabla_x f(x, u)$ and $\nabla^2_{xx} f(x, u)$ be continuous in (x, u). Assume that U is a compact set and that there exists a unique $u_0 \in U$ satisfying $f(0, u_0) = 0$. If the equilibrium position $x = 0$ of system* (60) *is weakly exponentially stable, then the stabilization problem for the first approximation is solvable.*

Proof. Let $\bar{x} \in R^n$. Since the equilibrium position $x = 0$ is weakly exponentially stable, there exist trajectories $x_k(\cdot)$ of system (60) with $x_k(0) = \bar{x}/k$ satisfying

$$|x_k(t)| \leq \frac{a}{k}|\bar{x}|e^{-\theta t}, \quad t \geq 0, \tag{62}$$

$$|\dot{x}_k(t)| \leq \frac{a}{k}|\bar{x}|e^{-\theta t}, \quad t \geq 0, \tag{63}$$

where $a > 0$ and $\theta > 0$ and k is large enough. Introduce a new time $\tau = 1 - (t + 1)^{-1}$. Obviously τ varies in $[0, 1)$ when t varies in $[0, \infty)$. Let

$$y_k(\tau) = x_k(t(\tau)), \quad \tau \in [0, 1), \ k = 1, 2, \ldots.$$

Then we have

$$\frac{d}{d\tau}y_k(\tau) = (1-\tau)^{-2} f(y_k(\tau), u_k(t(\tau))), \tag{64}$$

where $u_k(\cdot)$, $k = 1, 2, \ldots$, are the controls corresponding to $x_k(\cdot)$. From (62) and (63) we obtain

$$|y_k(\tau)| \le \frac{a}{k}|\bar{x}|e^{-\theta((1-\tau)^{-1}-1)}, \quad \tau \in [0, 1), \tag{65}$$

$$|\dot{y}_k(\tau)| \le \frac{a}{k}|\bar{x}|(1-\tau)^{-2}e^{-\theta((1-\tau)^{-1}-1)}, \quad \tau \in [0, 1). \tag{66}$$

Consequently $y_k(\tau) \to 0$ and $\dot{y}_k(\tau) \to 0$ as $\tau \to 1$. Put by definition $y_k(1) = 0$, $k = 1, 2, \ldots$. From (65) and (66) we see that the sequence $\{ky_k(\cdot)\}_{k=1}^{\infty}$ is bounded in sup-norm and is equicontinuous. By the Ascoli–Arzelà theorem it contains a uniformly convergent subsequence. Without loss of generality $ky_k(\cdot)$ uniformly converge to a continuous function $y(\cdot)$.

From (64) and (66) we see that there exists $M > 0$ such that

$$k\dot{y}_k(\tau) \in k(1-\tau)^{-2} f(y_k(\tau), U) \cap MB_n$$

$$\subset k(1-\tau)^{-2}(f(k^{-1}y(\tau), U) + l|y_k(\tau) - k^{-1}y(\tau)|B_n) \cap MB_n. \tag{67}$$

Let $\tau \in (0, 1)$ be such that all functions $y(\cdot)$ and $y_k(\cdot)$, $k = 1, 2, \ldots$, are differentiable at τ. From (67) we see that there exist $v_k(\tau)$, $k = 1, 2, \ldots$, such that

$$v_k(\tau) \in k(1-\tau)^{-2} f(k^{-1}y(\tau), U), \quad k = 1, 2, \ldots,$$

and

$$k\dot{y}_k(\tau) \in v_k(\tau) + (1-\tau)^{-2} l|ky_k(\tau) - y(\tau)|B_n, \quad k = 1, 2, \ldots.$$

Let $w_k(\tau) \in U$, $k = 1, 2, \ldots$, be such that

$$v_k(\tau) = k(1-\tau)^{-2} f(k^{-1}y(\tau), w_k(\tau)), \quad k = 1, 2, \ldots.$$

Since U is compact, without loss of generality $w_k(\tau) \to w_\infty(\tau) \in U$. Observe that $v_k(\tau)$ are bounded. Hence we have

$$f(0, w_\infty(\tau)) = \lim_{k\to\infty} f(k^{-1}y(\tau), w_k(\tau)) = \lim_{k\to\infty} k^{-1}v_k(\tau)(1-\tau)^2 = 0.$$

Since $u_0 \in U$ is a unique solution to the equation $f(0, u_0) = 0$, we obtain $w_\infty(\tau) = u_0$.

From (67) and the equality

$$v_k(\tau) = k(1-\tau)^{-2}[f(k^{-1}y(\tau), u_0) + (f(0, w_k(\tau)) - f(0, u_0))$$

$$+ (f(k^{-1}y(\tau), w_k(\tau)) - f(0, w_k(\tau))) - (f(k^{-1}y(\tau), u_0) - f(0, u_0))]$$

$$= k(1-\tau)^{-2}[k^{-1}Cy(\tau) + (f(0, w_k(\tau)) - f(0, u_0))$$

$$+ k^{-1}(\nabla_x f(0, w_k(\tau)) - \nabla_x f(0, u_0))y(\tau) + r(k, \tau)],$$

where $\lim_{k\to\infty} \sup_\tau kr(k,\tau) = 0$, we have

$$k\dot{y}_k(\tau) \in (1-\tau)^{-2}(Cy(\tau)+K) \cap MB_n + \epsilon_k(\tau)B_n,$$

where $\epsilon_k(\tau) \to 0$ as $k \to \infty$. Applying Lemma 2.7.3 in [9, p. 82], we obtain

$$\dot{y}(\tau) \in (1-\tau)^{-2}(Cy(\tau)+K), \ \tau \in [0,1).$$

From (65) we have

$$|y(\tau)| \le a|\bar{x}|e^{-\theta((1-\tau)^{-1}-1)}, \quad \tau \in [0,1).$$

Thus, the function $x(t) = y(\tau(t))$ satisfies

$$\dot{x}(t) \in Cx(t) + K$$

and

$$|x(t)| \le a|\bar{x}|e^{-\theta t}, \quad t \ge 0.$$

Applying Theorem 1, we obtain the result. □

Remark. The uniqueness of $u_0 \in U$ satisfying $f(0,u_0) = 0$ is essential. Indeed, the zero equilibrium position of the control system $\dot{x} = ux$, $|u| \le 1$, $u_0 = 0$, is weakly asymptotically stable. The control $u \equiv -1$ is a constant stabilizer. Nevertheless the first approximation is $\dot{x} = 0$.

COROLLARY 6. *Under the conditions of Theorem* 15 *the stabilization problem for system* (60) *is solvable.*

MINIMAX RENDEZVOUS ON THE LINE*

WEI SHI LIM† AND STEVE ALPERN‡

Abstract. Suppose that n players are placed randomly on the real line at consecutive integers, and faced in random directions. Each player has maximum speed one, cannot see the others, and doesn't know his relative position. What is the minimum time M_n required to ensure that all the players can meet together at a single point, regardless of their initial placement? We prove that $M_2 = 3$, $M_3 = 4$, and M_n is asymptotic to $n/2$. We also consider a variant of the problem which requires players who meet to stick together, and find in this case that three players require 5 time units to ensure a meeting. This paper is thus a minimax version of the rendezvous search problem, which has hitherto been studied only in terms of minimizing the expected meeting time.

Key words. rendezvous, search game

AMS subject classifications. 90B40, 90D26

1. Introduction.

In this paper we ask how much time is needed to ensure that n players, placed randomly onto consecutive integers on the line, can all meet together at a single point. We assume that they cannot see each other and can move at unit speed. We also assume that they have no common notion of a positive direction on the line, or equivalently are each placed pointing in a random direction. We seek the minimum time M_n by which some n-tuple of strategies guarantees a group meeting regardless of the initial placement of the players. For example, it is clear that $M_2 \leq 3$ because if one player remains still while the other goes, say, one unit to the right followed by two to the left, then the meeting time is 1 or 3.

The problem considered here is a search game, and fits into the framework of [5] and [9], except that our problem is far from being zero sum. More specifically, our problem can be seen as a minimax version of the *rendezvous search problem* [1] which has previously been analyzed only in terms of expected-time minimization. However there are many applications in search theory where expected-time minimization is not the most appropriate solution concept, and minimax is one of several others that have been studied in various contexts. It seems that minimax is appropriate even in the original rendezvous problem of Schelling [10], where two parachutists have to meet after a simultaneous landing in a large field. If the overall plan involves their moving out together from this field at time t_1, then they must be dropped into the field no later than t_1 minus the minimax rendezvous time. For a simulation approach to Schelling's problem, see [12].

As the search region is the line, our work may be compared to several recent investigations of rendezvous search on the line in an expected-time context. The line as the search region was first studied in the original paper on rendezvous search [1] and improved on in [3], but only in a "symmetric" version in which the two players were required to use the same mixed strategy. Clearly the symmetric version of the rendezvous problem is not appropriate to the minimax context because it allows the possibility that both players might use the same pure strategy. (They would never meet in the case where they are initially pointed in the same direction.) The asymmetric version of rendezvous search on the line was first studied in [2], where it was shown that two players initally placed one unit apart could meet in least expected time 13/8. From our current perspective it is worth noting that the optimal strategies in that context had a maximum meeting time of 3. (It is interesting to note that two-person rendezvous on the line is in some sense dual to *high-low search* [4], since in the former the searcher knows the distance

but not the direction of the other player, while in the latter the direction but not the distance is learned after each guess.) More recently the problem of three-player rendezvous on the line was studied in [6]. No exact value was obtained for the least expected time required for all three to meet, but it was shown that two (out of three) could meet in least expected time 47/48.

The present paper finds the first exact value for a full three-player rendezvous problem, i.e., the time needed for all three to meet at a single point. We do this in a minimax context and find that 4 is the least time required to ensure that three players placed at unit distances apart can meet, that is $M_3 = 4$. In order for all three to meet this quickly, the two players who first meet must in some cases split up to find the remaining player, before regrouping in a threesome. The problem facing the two who meet first is thus similar to that studied in a different context [11], [7], [8]. We also consider an important variant of the problem, namely "sticky" rendezvous, where players who meet are required to remain together. We find that when players' strategies are thus restricted, they need 5 time units to ensure full three-player rendezvous. Our final result concerns the behavior of M_n for large values of n, the time required for large numbers of players to meet. We find that M_n is asymptotic to $n/2$. This asymptotic value is the same as for the least expected time in the symmetric problem, as proved in [6], although of course the problem and solution concept are entirely different.

The paper is organized as follows. In §2 we give a precise formulation of the minimax rendezvous problem, in its unrestricted and "sticky" forms. In §3 we analyze the two-player problem in an extended form that will arise for three players after two of them meet. In particular we establish that $M_2 = 3$. In §4 we solve the sticky version of the three-person problem, proving that sticky players require 5 time units to guarantee a three-way meeting. In §5 we use similar arguments to show that without this restriction three players can meet in 4 time units, $M_3 = 4$. The final section, §6, establishes the asymptotic result that $\lim_{n\to\infty} M_n/n = 1/2$.

2. The minimax rendezvous time. In this section we give the definitions of the n-player rendezvous problems Γ_n and the associated minimax rendezvous time M_n. We also define their "sticky" counterparts, in which players who meet must thenceforth remain together.

The problem (or game) Γ_n begins with a random placement of the n players onto the first n integers (or, equivalently, any n consecutive integers). The initial position of player i is denoted by c_i, where $\{c_1, c_2, \ldots, c_n\} = \{1, 2, \ldots, n\}$. Since the players do not have a common notion of a positive direction on the real line, we assume they are initially faced in independent random directions. We use c_{n+i} to denote the direction that player i is initially pointing, from an observer's fixed global view, where $c_{n+i} \in \{+1, -1\}$. Let $C = C_n$ denote the set of all $n!2^n$ *initial configurations* of the form $c = \{c_1, c_2, \ldots, c_{2n}\}$. Note that the first n coordinates denote position, while the next n denote direction.

A strategy for player i in the game Γ_n is a rule that gives his motion (relative to his starting point and starting direction) as a function of the information he receives from players he may meet. A strategy profile is simply an n-tuple of strategies, one for each player. A strategy profile together with an initial configuration determines completely the motions of all the players. If $\bar{S}$ is a strategy profile and c is an initial configuation, we define $T_c(\bar{S})$ to be the first time (if any) that all n players following the profile $\bar{S}$ meet together at a single point, when the initial configuration is c.

In particular, a strategy for player i must say how that player should move before he meets anyone. This part of the strategy is called the Stage 1 strategy. A Stage 1 strategy s_i is a (speed-one) path belonging to the set

$$P = \left\{p : \Re^+ \to \Re,\ p(0) = 0,\ |p(t_1) - p(t_2)| \le |t_1 - t_2|\right\}.$$

The Stage 1 path of a player following strategy s_i when the initial configuration is c is given by $c_i + c_{n+i}s_i(t)$. In a recent paper [6] it is shown that when initial distances between adjacent

players are integers, any strategy profile can be modified to one in a subset of P called P^* where players have piecewise linear paths, with slopes ± 1, and which turn only at times $k/2$, where k is an integer. This modification does not postpone any meeting between players and hence does not postpone the final meeting of all the players. For this reason we will further assume that throughout the game all players are restricted to paths in P^*. Observe that this assumption implies that $T_c(\bar{S})$ is always half of an integer. A useful notational device for describing Stage 1 strategies in P^* is simply to list the slopes in successive half-units of time. Thus $s = [+1, -1, +1, -1, \ldots]$ describes a path that oscillates between its starting point and a point a half-unit above the start. More generally, if $s = [x_1, x_2, \ldots]$ then we have (with [ ] denoting integer part)

$$s(t) = \frac{1}{2}\sum_{m=1}^{[2t]} x_m + x_{[2t]+1}\left(\frac{2t - [2t]}{2}\right).$$

One final remark regarding player strategies in Γ_n is that we may assume without loss of generality that they all begin with $+1$, that is, they go in the forward direction for the first half-unit of time. This assumption is valid because it does not restrict the actual player motion, since the player may be initially pointed either way.

The maximum rendezvous time for a strategy profile $\bar{S}$, denoted simply $T(\bar{S})$, is defined as

$$T(\bar{S}) = \max_{c \in C} T_c(\bar{S}).$$

Then we may define the minimax rendezvous time M_n as

$$M_n = \min_{\bar{S}} T(\bar{S}),$$

where the minimum is taken over all strategy profiles $\bar{S}$. We note that the index n does not appear on the right side of the above equation, but of course the player-number parameter n is implicit in all the definitions in this section. The existence of the minimum follows from our assumption that all player paths must belong to P^*.

In §4 we will consider a further restriction on player paths, namely, that when players meet they stick together. All the above definitions remain valid, with this assumption. The sticky version of the n-player game is denoted $\tilde{\Gamma}_n$ and the sticky minimax time is denoted $\tilde{M}_n$.

3. Two-player minimax rendevous. In this section we consider the minimax rendezvous problem on the line for the case of two players. In passing, we will prove that the minimax rendezvous time for the standard two-player problem Γ_2 is 3, but we will mainly be concerned with a more general two-person problem denoted $\Gamma(\alpha, \beta)$. We are forced to consider this more general problem because this is what the three-player "sticky" problem (discussed in the next section) collapses to after two players meet.

The problem $\Gamma(\alpha, \beta)$ is an asymmetric information rendezvous game defined as follows. Player I is placed at some point of the line (which we take as the origin 0) and pointed facing up (the line is taken to be vertical). Player II is then faced in a random direction either a distance α above player I or a distance β below player I (i.e., at α or at $-\beta$). Thus player II knows only that his partner is a distance α or β away, while player I knows that his partner is either α above (forward) or β below. If $\alpha = \beta = 1$ then the information is symmetric and indeed $\Gamma(1, 1)$ is the same as the problem we called Γ_2. If player I chooses a strategy $s_1 = f \in P$ and player II chooses a strategy $s_2 = g \in P$ (we cannot restrict strategies to P^* unless α and

β are integers) then the maximum rendezvous time $T^{\alpha,\beta}(f, g)$ is the first time t when the path $f(t)$ has intersected the four paths given below:

$$L_1(t) = \alpha - g(t),$$
$$L_2(t) = \alpha + g(t),$$
$$L_3(t) = -\beta - g(t),$$
$$L_4(t) = -\beta + g(t).$$

That is, $T^{\alpha,\beta}(f, g)$ is the maximum of $t_j = t_j(f, g) = \min\{t : f(t) = L_j(t)\}$ $\forall j = 1, \ldots, 4$. The minimax rendezvous time for $\Gamma(\alpha, \beta)$ is the minimum of $T^{\alpha,\beta}$ $\forall (f, g) \in P \times P$.

Note that any strategy pair (f, g) determines an ordering of the meeting times t_j, i.e., there is a permutation $\sigma = \sigma(f, g)$ of $\{1, 2, 3, 4\}$ such that

$$t_{\sigma(1)} \leq t_{\sigma(2)} \leq t_{\sigma(3)} \leq t_{\sigma(4)} = T^{\alpha,\beta}(f, g).$$

In such a case we will say that (f, g) has permutation type σ. If α and β are integers and $(f, g) \in P^* \times P^*$ then the permutation type is unique and $t_{\sigma(j+1)} \geq t_{\sigma(j)} + .5$.

There is a complementary notion (introduced in [2]) by which each permutation σ determines a canonical strategy pair (F_σ, G_σ), such that in the interval $t_{\sigma(j-1)} < t < t_{\sigma(j)}$, $j = 1, \ldots, 4$ (with $\sigma(0)$ defined as 0), the path F_σ and the path $L_{\sigma(j)}$ (which depends on G_σ) are moving towards each other at maximum speed. It is shown in [2, Thm. 3 and its proof] that *the canonical strategy pair (F_σ, G_σ) minimizes all the meeting times t_j, within the class of strategy pairs of permutation type σ*. It follows that the minimax rendezvous time, as well as the least expected rendezvous time, will be attained for some canonical strategy. However, there may also be noncanonical strategy pairs which achieve the minimax rendezvous time.

To see how this definition defines a unique strategy pair (F_σ, G_σ), we illustrate the construction for the identity permutation $\bar{\sigma}$, using the simpler notation $\bar{f} = F_{\bar{\sigma}}$ and $\bar{g} = G_{\bar{\sigma}}$. The path $\bar{f}$ is pictured in Figure 1 for the parameters $\alpha = 1$ and $\beta = 2$, where it is called f_1 (the meeting times there are .5, 1, 2.5, and 4). The strategies begin with the player I path $\bar{f}$ and the player II possible path $L_1(t) = \alpha - \bar{g}(t)$ moving towards each other at maximum speed. Since L_1 is above $\bar{f}$ at time zero, this means that $\bar{f}' = 1$ and $L_1' = -1$, or $\bar{g}' = +1$, from time zero until the first meeting time $t_1 = \alpha/2$. At this time L_2 is above $\bar{f}$ and so $\bar{f}' = +1$ and $L_2' = -1$, or $\bar{g}' = -1$, from time $t_1 = \alpha/2$ until $\bar{f}$ meets L_2 at time $t_2 = \alpha$. Note that $\bar{f}(\alpha) = \alpha$ and $\bar{g}(\alpha) = 0$. At time $t_2 = \alpha$, $L_3(\alpha) = -\beta - \bar{g}(\alpha) = -\beta$ is below $\bar{f}(\alpha) = \alpha$ and so for the next time interval,

$$t_2 < t < t_3 = t_2 + (\alpha - (-\beta))/2 = (3\alpha + \beta)/2,$$

$\bar{f}' = -1$, and $L_3' = +1$, or $\bar{g}' = -1$. At time t_3, $\bar{f}$ is at $(\alpha - \beta)/2$, while L_4 is lower, at $-(\alpha + 3\beta)/2$. Hence $\bar{f}$ goes down and L_4 goes up (or $\bar{g}$ goes up) throughout the interval

$$t_3 < t < t_4 = t_3 + \left(\frac{\alpha - \beta}{2} - \left(-\frac{\alpha + 3\beta}{2}\right)\right)/2 = 2\alpha + \beta.$$

The data just derived are presented in the first data row of Table 1 which gives the four meeting times $t_{\sigma(j)}$ for the canonical strategies (F_σ, G_σ) corresponding to various permutations. While this table contains just six of the $4! = 24$ possible permutations, it will in fact be sufficient to calculate the minimax rendezvous time. The data in this table will be useful in the following theorem.

THEOREM 1. *The minimax rendezvous time for the problem $\Gamma(\alpha, \beta)$, $\alpha \leq \beta$, is*

$$\min_{f,g \in P \times P} T^{\alpha,\beta}(f, g) = 2\alpha + \beta.$$

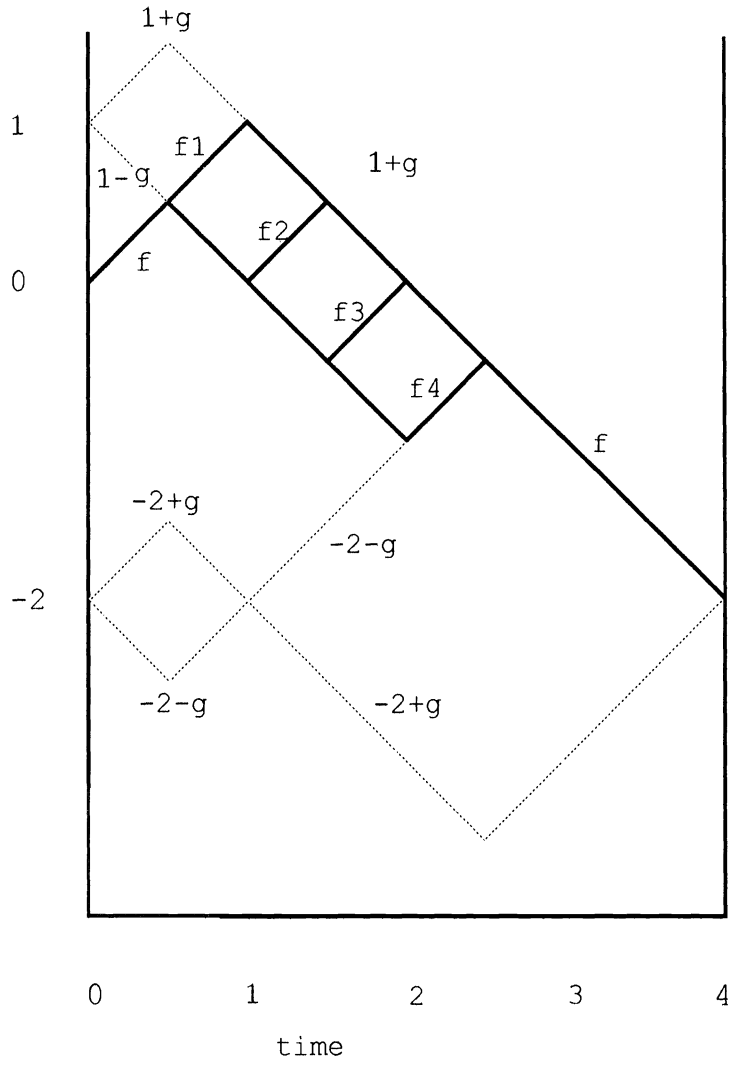

FIG. 1. *Optimal strategies for the problem* $\Gamma(1, 2)$.

TABLE 1
Meeting times for canonical strategies (F_σ, G_σ).

σ	$t_{\sigma(1)}$	$t_{\sigma(2)}$	$t_{\sigma(3)}$	$t_{\sigma(4)} = T^{\alpha,\beta}(F_\sigma, G_\sigma)$
(1, 2, 3, 4)	$\alpha/2$	α	$(3\alpha+\beta)/2$	$2\alpha+\beta$
(1, 2, 4, 3)	$\alpha/2$	α	$(3\alpha+\beta)/2$	$2\alpha+\beta$
(1, 3, 2, 4)	$\alpha/2$	$(2\alpha+\beta)/2$	$(3\alpha+\beta)/2$	$2\alpha+\beta$
(1, 3, 4, 2)	$\alpha/2$	$(2\alpha+\beta)/2$	$\alpha+\beta$	$(3\alpha+3\beta)/2$
(1, 4, 2, 3)	$\alpha/2$	$(\alpha+\beta)/2$	$\alpha+\beta$	$(3\alpha+3\beta)/2$
(1, 4, 3, 2)	$\alpha/2$	$(\alpha+\beta)/2$	$\alpha+\beta$	$(3\alpha+3\beta)/2$

Furthermore, if $T^{\alpha,\beta}(f, g) = 2\alpha + \beta$ *and* $\alpha < \beta$, *then the permutation type of* (f, g) *is* (1, 2, 3, 4), (1, 2, 4, 3), *or* (1, 3, 2, 4).

Proof. According to the result of [2] quoted above, the minimax rendezvous time is the minimum of $T^{\alpha,\beta}(F_\sigma, G_\sigma)$ as σ varies over the permutations of $\{1, 2, 3, 4\}$. We claim that

it is sufficient to consider only the six permutations listed in Table 1 (those where the player II path $\alpha - g(t)$ is intersected first), where the minimum (given that $\alpha \leq \beta$) is $2\alpha + \beta$. The cases which intersect the player II path $\alpha + g(t)$ first will give the same results, that is, the same meeting times $t_{\sigma(j)}$, the same F, and a sign reversal for G. The cases which intersect either of the paths $-\beta \pm g(t)$ first will give a similar table with α and β interchanged. So the only new maximum rendezvous time appearing in such a table would be $2\beta + \alpha$, which is not less than $2\alpha + \beta$. When $\alpha < \beta$, only the first three data rows of the table give the minimum $2\alpha + \beta$. □

As a special case of the above result when $\alpha = \beta = 1$, we have the following solution to the standard two-person minimax rendezvous problem.

COROLLARY 1. $M_2 = 3$.

The three-person "sticky" rendezvous problem $\tilde{\Gamma}_3$ to be analyzed in the next section may reduce to the problem $\Gamma(1, 2)$ in certain cases. For this reason we explicitly give the four optimal player I strategies in P^* for $\Gamma(1, 2)$ in the following result.

COROLLARY 2. *The minimax rendezvous value for the problem* $\Gamma(1, 2)$ *is* 4. *Furthermore if* $T^{1,2}(f, g) = 4$, *for* $(f, g) \in P^* \times P^*$ *then* f *is one of the four strategies in* P^* *which satisfy*

$$f(1/2) = 1/2, \quad f(2.5) = -.5, \quad \textit{and} \quad f(4) = -2, \quad \textit{i.e.},$$

$$\begin{aligned} f_1 &= [+1, +1, -1, -1, -1, -1, -1, -1], \\ f_2 &= [+1, -1, +1, -1, -1, -1, -1, -1], \\ f_3 &= [+1, -1, -1, +1, -1, -1, -1, -1], \\ f_4 &= [+1, -1, -1, -1, +1, -1, -1, -1]. \end{aligned}$$

Each of these has maximum rendezvous time of 4 *when paired with the player* II *strategy* $g = [+1, -1, -1, -1, -1, +1, +1, +1]$. *(See Figure* 1.*)*

Proof. The reader should first verify the obvious fact that the f_k are indeed the only four strategies in P^* which satisfy the three conditions (including of course $f(0) = 0$, which is part of the definition of P^*). According to Theorem 1 we can only find optimal strategies for the permutation types (1, 2, 3, 4), (1, 2, 4, 3), and (1, 3, 2, 4).

Case 1, σ *is* (1, 2, 3, 4) *or* (1, 2, 4, 3). Suppose $T^{1,2}(f, g) = 4$ for $(f, g) \in P^* \times P^*$, and

$$t_1 < t_2 < t_3, t_4.$$

We may assume that $t_1 = .5$ and $f(.5) = g(.5) = .5$ because in the alternative case that $f(.5) = -.5$ the resulting problem at time .5 is either $\Gamma(1, 2)$ (if I is told that II moved down) or $\Gamma(2, 1)$ (if I is told that II moved up), and therefore (by Theorem 1) requires an *additional* 4 units of time to ensure meeting. Since $g(.5) = .5$ it follows that $g(t) \geq .5 - (t - .5) = 1 - t$, for $t \geq .5$. Hence after f has intercepted $1 + g(t)$ at time t_2, we must have that

$$f(t) \geq 2 - t \text{ for } t \geq t_2. \tag{1}$$

Since f intersects $1 + g$ at time t_2 and $-2 + g$ at time $t_4 \leq 4$, and speeds are bounded by 1, we must have

$$t_4 - t_2 \geq |(1 + g(t_2)) - (-2) + g(t_2)|/2 = 1.5 \text{ or } t_2 \leq t_4 - 1.5 \leq 2.5. \tag{2}$$

Suppose that strict inequality holds in (1), that $f(s) = 2 - s + p$ for some $p > 0$ and some time $s < 4$. Then a player I starting at position $2 + p$ at time zero, following path $2 - t + p$ until time $t = s$, and then following path f, could ensure meeting paths $-2 \pm g$ by time 4. But this

would mean that the minimax rendezvous time for the problem $\Gamma(0, 4+p) = \Gamma(4+p, 0)$ is not more than 4, whereas Theorem 1 says it is equal to $4+p$. Hence our assumption that $f(t)$ could be larger than $2-t$ was false, and (1) must hold with equality, that is,

$$f(t) = 2 - t \text{ for } t \geq 2.5. \tag{3}$$

We showed earlier that $f \in P^*$ must go through (.5,.5) and (3) shows further that it must go through (2.5, −.5) and (4, −2). It follows that it must be one of the four strategies f_k. (Actually it cannot be f_4 in this case, but we do not need to prove this fact.)

Case 2, σ *is* (1, 3, 2, 4). Suppose $T^{1,2}(f, g) = 4$ for $(f, g) \in P^* \times P^*$, and

$$t_1 < t_3 < t_2 < t_4 = 4.$$

Since speeds are bounded by 1, it follows that

$$\begin{aligned} 4 - t_2 = t_4 - t_2 \geq |L_4(t_2) - L_2(t_2)|/2 = |(-2 + g(t_2) - (1 + g(t_2)))| = 1.5, \text{ or} \\ t_2 \leq 2.5, \text{ and hence } t_3 \leq t_2 - .5 \leq 2. \end{aligned} \tag{4}$$

By the same reasoning as (4), we have

$$t_3 - t_1 \geq 1.5, \quad \text{so } t_3 \geq t_1 + 1.5 \geq 2. \tag{5}$$

The only solution to (4) and (5) is $t_1 = .5$, $t_3 = 2$, $t_2 = 2.5$, $t_4 = 4$, which are the times for the canonical strategy pair with this permutation. Hence f must be $F_\sigma = f_4$. □

The optimal strategies for the problem $\Gamma(1, 2)$ are drawn in Figure 1. They are also drawn in a stacked form in Figure 3, which will be discussed later.

We conclude this section with an analysis of some two-person rendezvous problems where one of the players (taken to be I) knows the direction of the other. Since this person will clearly move at speed one in this direction, these are really one-person problems. The only strategic variable is the path of player II. These results are called lemmas because they will be used in §5 in the following way: When two players meet and do not know the direction of the other, they will each be assigned a direction and will assume the remaining player lies in that direction. A lower bound on the maximum time taken to find the remaining player, assuming he is in this direction, is the minimax value of the game in which the direction is known. It is these minimax values that we now calculate. These are all very simple results.

LEMMA 1. *Suppose that player* I *is placed facing up at* 0 *and player* II *is either placed facing down at* 1 *or facing up at* 2. *Then the minimax rendezvous time is* 3/2. *Furthermore this maximum meeting time occurs if and only if* I *moves up at speed one and* II *uses a strategy* $h \in P$ *satisfying* $h(3/2) = -1/2$. *There are three strategies* $h \in P^*$, *defined up to time* 3/2, *satisfying this condition. In the notation giving the slopes of the paths in successive time intervals of length* 1/2 *these paths* (*as shown in Figure* 2) *are as follows:*

$$\begin{aligned} h_1 &= [+1, -1, -1], \\ h_2 &= [-1, -1, +1], \\ h_3 &= [-1, +1, -1]. \end{aligned}$$

Proof. If player II uses strategy h, the maximum meeting time $T(h)$ is the time required for the path t (of player I) to meet both possible paths of II, that is, $1 - h(t)$ and $2 + h(t)$. This is the same as the time required for $h \in P$ to meet both $1 - t$ and $t - 2$. Clearly if $h(3/2) = -1/2$, then it meets both these paths at time 3/2. If it meets either of these paths before this time, the earliest it can meet the other is 3/2, since these two paths are approaching each other at combined speed 2. Furthermore if $h(3/2) > -1/2$, then it cannot yet have

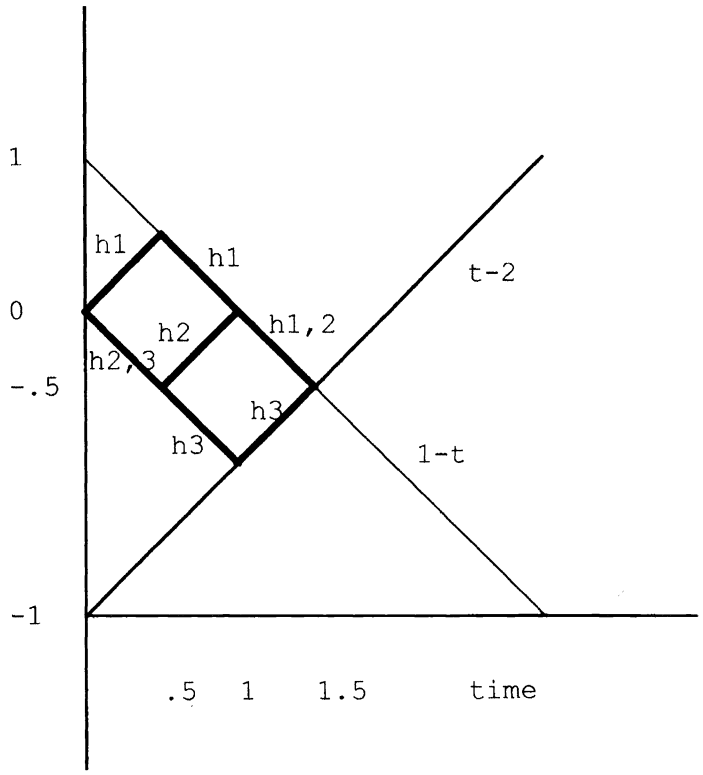

FIG. 2. *Optimal paths derived in Lemma* 1.

intersected $t-2$; if $h(3/2) < -1/2$, then it cannot yet have intersected $1-t$. Thus only paths with $h(3/2) = -1/2$ can achieve a maximum meeting time of $3/2$. The three paths stated in the lemma are the only ones in P^* satisfying this condition. These paths are drawn in bold in Figure 2. □

The following two lemmas are even easier, as they give minimax times when player I knows not only the direction but also the initial distance to player II. They may appear too obvious to bother stating, but we do so because they will be used repeatedly in §5, without specific mention. (The first is actually a corollary of Theorem 1, with $\alpha = 0$.)

LEMMA 2. *If player* I *is placed (at time* 0*) facing up at position* 0 *and player* II *is placed in a random direction at position* $\beta > 0$*, at any time prior to time* β*, then the minimax rendezvous time is* β*. Call this problem* $\Gamma'(\beta)$.

LEMMA 3. *If player* I *is placed (at time* 0*) facing up at position* 0 *and player* II *is placed in a known direction (say up) at position* $\beta > 0$*, at time* δ*,* $-\beta \leq \delta \leq \beta$*, then the minimax rendezvous time is* $(\beta + \delta)/2$*. Call this problem* $\Gamma''(\beta, \delta)$.

4. Sticky three-person rendezvous. We are now in a position to attack the problem $\tilde{\Gamma}_3$. Recall that in this problem three players are randomly placed onto the integers 1, 2, and 3, and faced in random directions. Once two players meet, they must stick together while trying to locate the third. The players' strategy paths are assumed to belong to P^*. The main result of this section is the determination of the minimax rendezvous time $\tilde{M}_3$ for this problem.

THEOREM 2. *The minimax rendezvous time* $\tilde{M}_3$ *for the sticky three-person problem* $\tilde{\Gamma}_3$ *is* 5.

Proof. We first show that $\tilde{M}_3 \leq 5$ by exhibiting a simple strategy triple which guarantees three-player rendezvous by time 5. The simplest version is that two of the players remain still

(until they are met by the moving player) while the third moves forward, taking along any player he meets, until he reaches an integer location with no player on it. He then reverses direction, similarly taking along any player he meets, until he has accumulated both of the other players. The case with maximum rendezvous time is when the moving player starts in the middle, and in this case the rendezvous time is 5. Since the strategy of staying still in Stage 1 does not belong to P^*, it has to be modified. The modification is simply to oscillate between the starting point and a point 1/2 unit forward. The analysis for the modified strategy is essentially the same and it also has a maximum rendezvous time of 5.

To demonstrate that $\tilde{M}_3 \geq 5$, we assume that there is a strategy triple S^* with $T(S^*) = 4.5$, and then show that this assumption leads to a contradiction. Since for strategies involving paths in P^* intersections can occur only at integer multiples of $1/2$, this will establish that $\tilde{M}_3 \geq 5$.

Let $S = (s_1, s_2, s_3)$ be the Stage 1 strategies for S^*. We may assume that each is simply the identity function t for $t \leq 1/2$. Observe that for any of the three players $j = 1, 2, 3$, there is an initial configuration $c = c(j)$ for which the two players other than j meet at time .5. (For example $c(2) = (1, 3, 2, +1, +1, -1)$.) Let g_j denote the strategy (path) followed by the two who meet in case $c(j)$ from time 1/2 onwards. We normalize this so that the position of these two players at time $t + 1/2$ is $g_j(t)$ plus their position when they meet at time .5. Thus g_j belongs to P^* (takes value 0 at 0). Similarly let $\tilde{s}_j$ denote the remainder of player j's path from time $1/2$ onwards, $\tilde{s}_j(t) = s_j(t + 1/2) - s_j(1/2)$. Thus $\tilde{s}_j$ also belongs to P^* (takes value 0 at 0). Note that the situations of player j and of the remaining two players are the same as that of players I and II in the game $\Gamma(1, 2)$; the paired players are either 1 unit above player j (that is in the direction he was initially pointed) or 2 units below him. Hence it follows that

$$T_{c(j)}(S^*) = 1/2 + T^{1,2}(\tilde{s}_j, g_j),$$

where $T^{1,2}$ is the minimax rendezvous time defined in the previous section for the game $\Gamma(1, 2)$. Our assumption that $T(S^*) = 4.5$ implies that $T_{c(j)}(S^*) \leq 4.5$ and by the above that $T^{1,2}(\tilde{s}_j, g_j) \leq 4$. It follows from Corollary 2 that $T^{1,2}(\tilde{s}_j, g_j) = 4$ and that $\tilde{s}_j$ belongs to the set of optimal strategies for player I in $\Gamma(1, 2)$, that is, to the set $\{f_1, f_2, f_3, f_4\}$.

Since the above argument holds for each player $j = 1, 2, 3$, we have shown that the Stage 1 paths of S^* must be optimal for the problem $\Gamma(1, 2)$ from time $1/2$ onwards, that is,

$$\tilde{s}_j \in \{f_1, f_2, f_3, f_4\}, \quad \text{for } j = 1, 2, 3.$$

It now follows that there is a case $\bar{c}$ for which none of the three players meet (not even two of them) by time 4.5, that is $T_{\bar{c}}(S^*) > 4.5$, which contradicts our assumption. To see that such a case (initial configuration) $\bar{c}$ exists, first look at Figure 3. This shows a drawing of the four paths f_1, f_2, f_3, f_4 with each preceeded by a slope 1 diagonal for time $1/2$. The lower-indexed functions are started at higher positions on the line, and there are no intersections by time 4.5. The general algorithm for choosing $\bar{c}$ as a function of (s_1, s_2, s_3) is very simple: point all the players up, and place the players using lower-indexed $\tilde{f}_k$'s higher. If two players are using the same f_k, then of course it doesn't matter which of these is placed higher. For example, if $(\tilde{s}_1, \tilde{s}_2, \tilde{s}_3) = (f_1, f_4, f_3)$, then $\bar{c} = (3, 1, 2, +1, +1, +1)$. □

5. Three-player rendezvous (unrestricted). In this section we show that three players placed on adjacent integers can ensure a three-way meeting by time 4, that is $M_3 = 4$. This is a savings of 1 time unit over the 5 needed in the sticky case considered in the previous section. The novel feature considered here is that players who meet can separate to find the third (although the game does not end until all three are together).

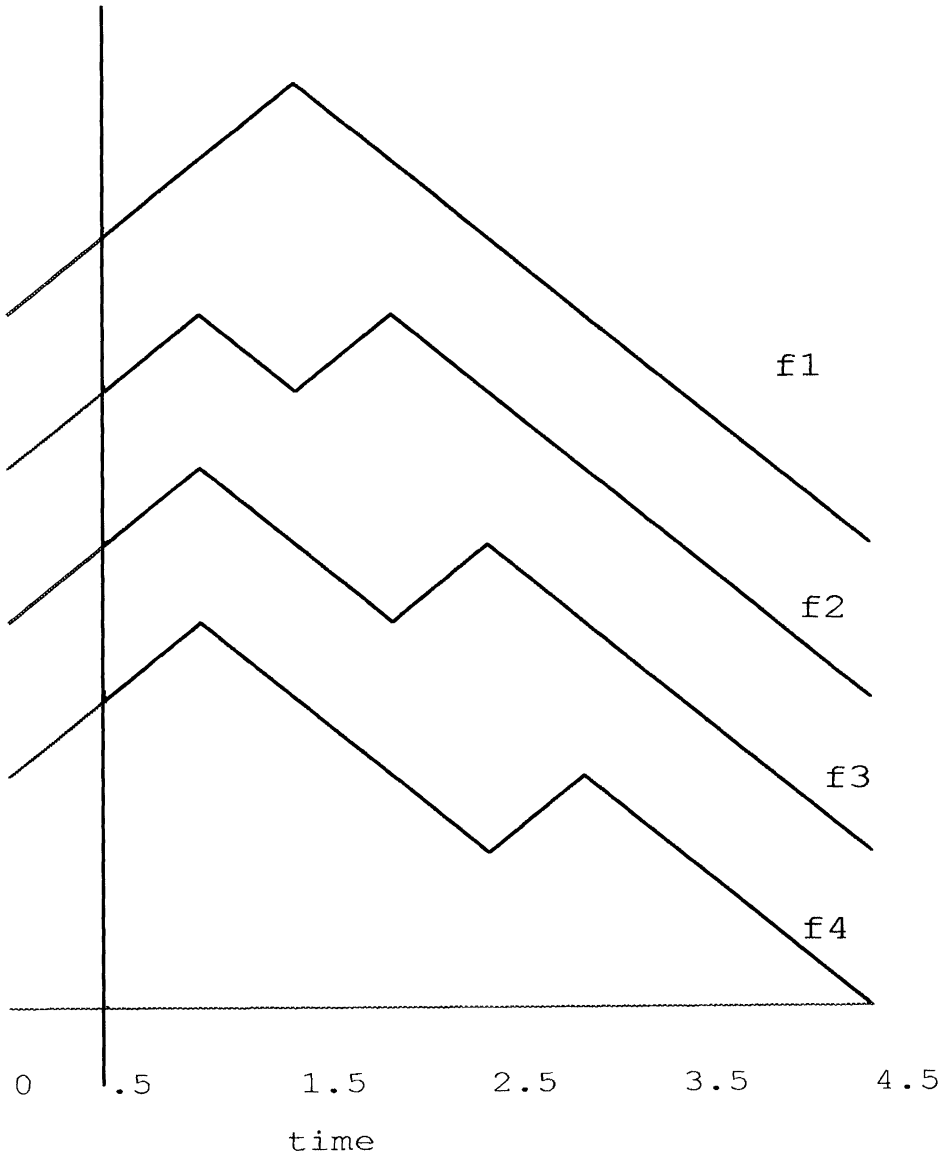

FIG. 3. *A nonintersecting stacking of the strategies f_k, starting at time .5.*

LEMMA 4. $M_3 \leq 4$.

Proof. We exhibit a strategy profile with a maximum rendezvous time of 4. The Stage 1 strategies are the same as for the optimal sticky rendezvous: Player I follows the path (given in slope form for a half-unit time interval) $[+1, +1, -1, -1, -1, -1]$ up to time 3. The other two players follow a path which oscillates between their start and a point half a unit away, such as $[+1, -1, +1, -1, +1, -1, +1, -1]$. If player I has not met another player by time 1, then he can conclude the other players were both behind him, so when he reverses direction at time 1 he continues forever in this direction, bringing with him the first player he meets (at time 3), and meeting the second at time 4. If he first meets another player at time 1, the two who meet know that the remaining player is either 1 above or 2 below, and will be there at every integer time. So one of them (say player I) goes 1 above and then reverses, while the

other goes 2 below and then reverses. If either finds the remaining player he asks that player to stick with him. Thus the two who originally met will meet again in 3 more time units, at player I's starting point. Furthermore one of the two is sure to have brought the remaining player along with him. Finally, if player I first meets a player at time 1/2, he can ignore this and bring that player back to that player's start. This puts the two who met in the situation analyzed above. Thus in any case the rendezvous time is not more than 4. □

LEMMA 5. *$M_3 \geq 3.5$. Furthermore any strategy profile for the game Γ_3 which has a maximum rendezvous time of 3.5 must have all its Stage 1 paths, up to time 2, belonging to the set $\{\tilde{h}_1 \tilde{h}_2, \tilde{h}_3\}$ defined as follows. The path $\tilde{h}_k$ is the path h_k of Lemma 1, preceded by a forward speed-one motion for $t \leq 1/2$. That is, $\tilde{h}_k(t) = t$, $t \leq 1/2$, and $\tilde{h}_k(t) = 1/2 + h_k(t - 1/2)$, $t \geq 1/2$. In the notation giving the slope in each half-unit of time, these paths are*

$$\begin{aligned} \tilde{h}_1 &= [+1, +1, -1, -1], \\ \tilde{h}_2 &= [+1, -1, -1, +1], \\ \tilde{h}_3 &= [+1, -1, +1, -1]. \end{aligned}$$

Proof. As in the proof of Theorem 2, we begin by assuming an initial configuration such that the two players other than player j meet each other at time $1/2$. One of these players (call each of these player I) must go up to find the remaining player j (call him player II). Renormalize the line so that the origin (0) is where the two players have met. Assuming II is above this, he is either at 1 facing down (if he started facing down) or at 2 facing up (if he started facing up). Hence by Lemma 1 the earliest that the player I who goes up can guarantee finding II, assuming he is up, is (additional) time 1.5. It follows that the earliest the two agents of Player I (the one going up and the one going down) can meet together, bringing along player II, is $T = 1/2 + 2(1.5) = 3.5$. Furthermore, it follows from the second part of Lemma 1 that in order for this time to be achieved, player II must be following one of the paths h_k from time $1/2$. Since we are assuming that strategies for Γ_3 begin by going up for time $1/2$, it follows that the player we are calling II and j must use a strategy $\tilde{h}_k$ up to time 2. But since this argument applied to any player $j = 1, 2, 3$, we are done. □

LEMMA 6. *Any strategy for the game Γ_3, whose Stage 1 paths (up to time 2) belong to the set $\{\tilde{h}_1, \tilde{h}_2, \tilde{h}_3\}$, has maximum rendezvous time at least $M = 4$.*

Proof. Since order does not matter, there are ten strategy triples in $\{\tilde{h}_1, \tilde{h}_2, \tilde{h}_3\}^3$. We divide these into four types. For each type we stop the action at some time T_0 and assume a certain set of initial configurations. We then give a lower bound on the maximum remaining time, which when added to T_0 is at least 4.

Type 1: All three use the same strategy. This type covers the three strategy profiles $(\tilde{h}_k, \tilde{h}_k, \tilde{h}_k)$, $k = 1, 2, 3$. For strategy profiles of this type the first integer q such that some players have a different Stage 1 strategy for the time interval $[q/2, (q+1)/2]$ satisfies $q \geq 4$.

Assume that all three players start facing up. Then at time $T_0 = q/2$ they are back at their original positions, and the top and bottom players are at distance 2. By the definition of q, there are two players who move in opposite directions in the interval $[q/2, (q+1)/2]$. So for some initial configuration the player starting at 3 will move up throughout this interval and the player starting at 1 will move down. Hence at time $(q+1)/2$ the players at the ends will be at distance 3. Therefore the earliest these two player can meet is at time $(q+1)/2 + 3/2 \geq (4+1)/2 + 3/2 = 4$.

Type 2: The strategy $(\tilde{h}_1, \tilde{h}_2, \tilde{h}_2)$ is used. Consider two initial configurations $c' = \{3, 2, 1, +1, +1, +1\}$ and $c'' = \{3, 2, 1, +1, -1, -1\}$. In each of these configurations player 1, who we now call player I, starts at 3 and is back at 3 at time $T_0 = 2$. Player 3, who we now call player II, starts at 1 and is back at 1 at time 2. In both cases no players have met, so they

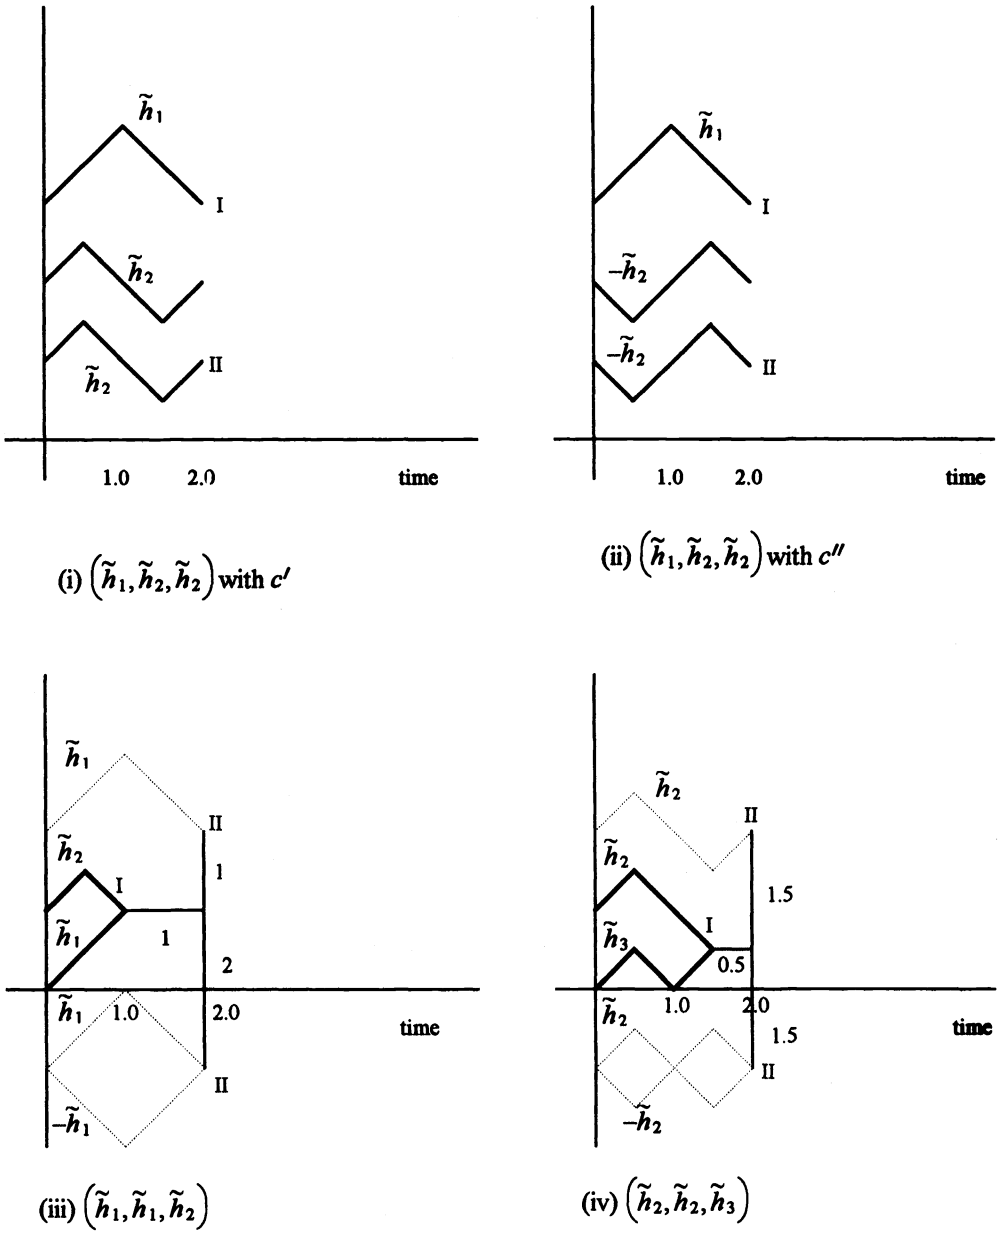

FIG. 4. *Strategies with* $s_j \in \{\tilde{h}_1, \tilde{h}_2, \tilde{h}_3\}$ *have* $T \geq 4$.

cannot determine by time 2 which of these (c' or c'') is the actual initial configuration. In case c', player II is pointing up at time T_0, while in case c'' he is pointing down. Hence by Lemma 2 with $\beta = 2$, players cannot meet before time $T_0 + \beta = 2 + 2 = 4$. This case is illustrated in Figures 4(i) and 4(ii).

For the remaining Types 3 and 4, the analysis will be as follows. For each of the two types we give a set of initial configurations. Then for each strategy profile of that type, we give a time T_0 at which two players meet (who we then call player I) but cannot distinguish between the configurations in the given set. The problem of finding player II above them is called Γ_{up} and the minimax time to find him (or turn back) is denoted by T_{up}, which can be

calculated using Lemma 2 or 3, depending on the nature of Γ_{up}. If the remaining player (II) is below then the associated problem and minimax time are denoted by Γ_{down} and T_{down}. Thus the maximum meeting time T satisfies

$$T \geq T_0 + T_{up} + T_{down}. \tag{6}$$

Examples of Types 3 and 4 are illustrated in Figures 4(iv) and 4(iii), respectively. The paths of the two players who meet at time T_0 are drawn in bold up to time T_0; the three possible paths of the remaining player (each corresponding to some initial configuation in the given set) are drawn in a dashed line up to time $2 = T_0 + \delta$; the parameters β and δ of the games Γ' and Γ'' of Lemmas 2 and 3 are drawn from player I's position at time T_0 in thin lines.

Type 3: *The strategies* $(\tilde{h}_2, \tilde{h}_2, \tilde{h}_3)$ *or* $(\tilde{h}_2, \tilde{h}_3, \tilde{h}_3)$ *are used.* Consider the set of configurations

$$C_3 = \{(1, 3, 2, +1, +1, +1), (3, 1, 2, +1, -1, -1), (3, 2, 1, +1, +1, +1)\}.$$

For these two strategy profiles and any of these configurations, a player using $\tilde{h}_2$ will meet a player using $\tilde{h}_3$ at time $T_0 = 1.5$, and they will then be unable to distinguish between these three initial configurations. Call this pair player I. For either profile we can take Γ_{up} to be $\Gamma''(1.5, .5)$ and so $T_{up} = 1$ by Lemma 3. Similarly for either profile $\Gamma_{down} = \Gamma'(1.5)$ so $T_{down} = 1.5$. Thus by (6) we have $T \geq 1.5 + 1 + 1.5 = 4$. To aid the reader we give the full analysis for the profile $(\tilde{h}_2, \tilde{h}_2, \tilde{h}_3)$, which is illustrated in Figure 4(iv). At time T_0 we normalize the time back to zero and let the meeting point be the new origin. With respect to this framework, the position of player II if above is 1.5 units above player I (i.e., the two players who met) at time .5 (at actual time 2) and facing up. Hence as claimed above, $\Gamma_{up} = \Gamma''(1.5, .5)$. If player II is below player I, then he is 1.5 units below in additional time .5, and can be facing either way, depending on the configuration. Hence, as claimed, $\Gamma_{down} = \Gamma'(1.5)$.

Type 4: *One of the strategies* $(\tilde{h}_1, \tilde{h}_1, \tilde{h}_2)$, $(\tilde{h}_1, \tilde{h}_1, \tilde{h}_3)$, $(\tilde{h}_1, \tilde{h}_3, \tilde{h}_3)$, $(\tilde{h}_1, \tilde{h}_2, \tilde{h}_3)$ *is used.* For these strategy profiles, consider the following set of configurations:

$$C_4 = \{(1, 3, 2, +1, +1, +1), (2, 1, 3, +1, +1, +1), (2, 1, 3, +1, -1, +1)\}.$$

In each of these profiles, two players meet at time $T_0 = 1$, $\Gamma_{up} = \Gamma''(1, 1)$ so $T_{up} = 1$ by Lemma 3, and $\Gamma_{down} = \Gamma'(2)$, so $T_{down} = 2$ by Lemma 2. Hence in all these cases, $T \geq 1 + 1 + 2 = 4$. □

THEOREM 3. $M_3 = 4$. *That is, the minimax rendezvous time for three players placed in random directions on consecutive integers is* 4.

Proof. Lemma 4 says that $M_3 \leq 4$, so we need only show that $M_3 \geq 4$. Since we are assuming that all paths belong to P^*, it is sufficient to show that $M_3 > 3.5$. Lemma 5 says that any strategy with maximum rendezvous time ≤ 3.5 must have all of its Stage 1 paths belonging to the set $\{\tilde{h}_1, \tilde{h}_2, \tilde{h}_3\}$. However, Lemma 6 says that any strategy triple with this property must have maximum rendezvous time of at least 4. □

6. Asymptotic value of M_n. In this section we estimate the value of the minimax rendezvous time M_n for the n-player game Γ_n when n is large. Clearly a lower bound for M_n is $(n-1)/2$, since the distance between the players initially placed at 1 and n is $n-1$. The main work of this section is the presentation and analysis of a class of strategy profiles $S(n, m)$ for the games Γ_n which have maximum rendezvous times asymptotic to $n/2$. This analysis thus gives the main result of this section (Theorem 4), that M_n is asymptotic to $n/2$.

We now define the strategy profile $S(n, m)$ for the games Γ_n. Up to time $T_0 = 3m + 1$ the players adopt *adjacency search* paths called g_k. (The paths g_1, g_2, g_3 are drawn in Figure 5, for players initially pointed to the right.) These paths remain at a player's starting point

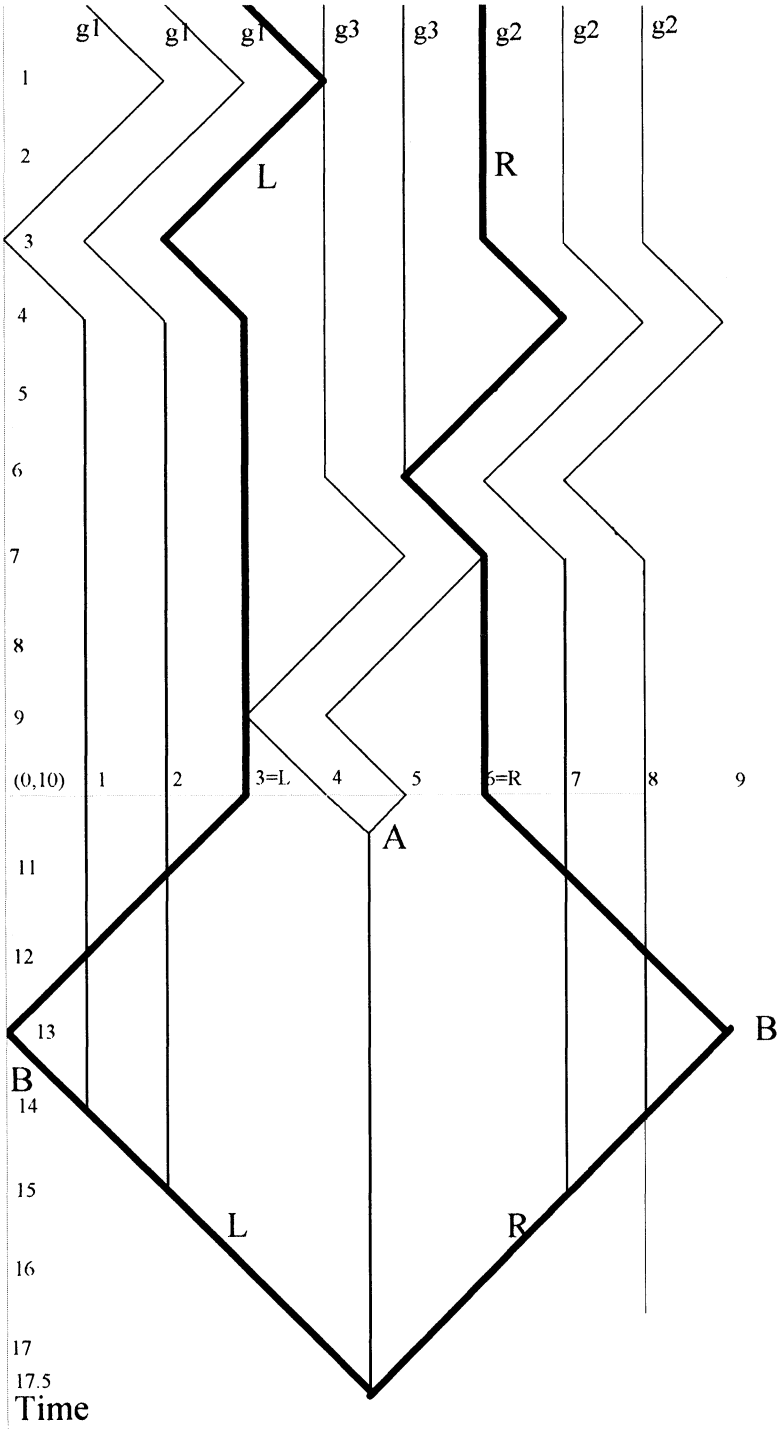

FIG. 5. $T(S(8,3)) = 17.5$.

except during the time interval $[3(k-1), 3k+1]$ of length 4, when they search first forward 1 unit, then backwards 2 units, and then forward again to return to the starting point. This path will meet any adjacent player who is stationary at their starting point during this period

(in particular at times $3(k-1)+1$ and $3(k-1)+3$). More formally these *adjacency search* paths are defined as

$$g_k(j) = \begin{cases} 1 & \text{if } j = 3(k-1)+1, \\ -1 & \text{if } j = 3(k-1)+3, \\ 0 & \text{otherwise.} \end{cases}$$

Observe that if $k < k'$ and two adjacent players are using *adjacency search* paths g_k and $g_{k'}$, then they will meet at time $3(k-1)+1$ or $3(k-1)+3$, and in any case by time $3(k-1)+3$.

In the strategy profile $S(n, m)$ the players use the first m *adjacency search* paths $g_1, \ldots, g_n$, in as equal numbers as possible. We will take as an example $S(8, 3)$, which is illustrated in Figure 5. Let $n = am + b$, $0 \le b < m$, and let exactly $a+1$ players use each strategy g_k, $k = 1, \ldots, b$, and let exactly a players use each *adjacency search* path g_k, $k = b+1, \ldots, m$, for times $0 \le t \le T_0 = 3m + 1$, disregarding (for the time being) any players they may meet. Note that $a = \text{Int}(n/m)$. (In the example, $a = 2$ and three players use g_1, three use g_2, and two use g_3.) Observe that at time $T_0 = 3m + 1$ (10, in the example) all the players are back at their starting points and that any pair of adjacent players who are using distinct strategies g_k will have already met each other, regardless of the directions in which they are initially pointed. Once the players have been placed on the integers $1, \ldots, n$, name them according to the integer where they start. We use a horizontal description of the line on which the players are placed. Let L denote the leftmost player for which the adjacent player on the right is using a different initial strategy g_k. Let R denote the rightmost player such that the player on his left is using a different strategy. (In the example $L = 3$ and $R = 6$.) Since there are at most a players to the left of L (who are using the same strategy g_k as player L) and similarly at most a players to the right of player R, we have

$$L \le a + 1 \text{ and } R \ge n - a. \tag{7}$$

Note that equality holds in the above if and only if the first $a+1$ players are all using the same strategy and the last $a+1$ players are all using the same strategy, and these end groups are initially pointed in a common direction. This configuration (shown in Figure 5) produces the maximum meeting time T.

We now describe the strategies the players adopt from time $T_0 = 3m + 1$. At this time the players have met either no adjacent players, two adjacent players, or exactly one adjacent player. (In the example of Figure 5, players 1, 2, 7, and 8 are of the first type, nobody is of the second type, and players 3, 4, 5, and 6 are of the third type.) Players of the first two types should remain still at their starting points until they meet a player who says, "follow me." Players of the third type, who have met an adjacent player in only one direction, should go in the opposite direction (at speed one) until they either (A) meet another moving player or (B) reach an unoccupied integer location (relative to their starting point). In case (A) they stop and remain still until someone says, "follow me." In case (B) they can conclude they are at position 0 or $n+1$ and hence they reverse direction and go at speed one, telling anyone they meet to follow them, until the game ends. (In the example of Figure 5, players L = 3 and R = 6 reach situation (B) at time 13, while players 4 and 5 reach situation (A) at time 10.5.) In general, it follows from the inequalities (7) that players L and R reach positions 0 and $n+1$, respectively (situation (B)), by time $(3m+1)+(a+1)$. They then meet each other, together with everyone else, by maximum T, where

$$T = T_n \le (3m+1) + (a+1) + (n+1)/2. \tag{8}$$

(In the example of Figure 5, this gives a worst case of 17.5.)

Suppose we define $m = \text{Int}(\log\ n)$ so that $a = \text{Int}(n/\text{Int}(\log\ n))$. It follows that

$$\frac{T_n}{n} \leq \frac{3\,\text{Int}(\log\ n) + 2 + \text{Int}(n/\text{Int}(\log\ n)) + 1/2}{n} + \frac{1}{2} \underset{n\to\infty}{\longrightarrow} \frac{1}{2}.$$

Consequently the minimax rendezvous time M_n satisfies

$$\frac{1}{2} = \lim_{n\to\infty} \frac{(n-1)/2}{n} \leq \lim_{n\to\infty} \frac{M_n}{n} \leq \lim_{n\to\infty} \frac{T_n}{n} = \frac{1}{2}, \text{ or } \lim_{n\to\infty} \frac{M_n}{n} = \frac{1}{2}.$$

Thus we have proved our final result.

THEOREM 4. *The minimax rendezvous time M_n, required for n players placed on adjacent integers to meet together at a single point, is asymptotic to $n/2$.*

POLYNOMIAL FILTERING FOR LINEAR DISCRETE TIME NON-GAUSSIAN SYSTEMS*

FRANCESCO CARRAVETTA†, ALFREDO GERMANI‡, AND MASSIMO RAIMONDI§

Abstract. In this work we propose a new filtering approach for linear discrete time non-Gaussian systems that generalizes a previous result concerning quadratic filtering [A. De Santis, A. Germani, and M. Raimondi, *IEEE Trans. Automat. Control*, 40 (1995) pp. 1274–1278]. A recursive νth-order polynomial estimate of finite memory Δ is achieved by defining a suitable extended state which allows one to solve the filtering problem via the classical Kalman linear scheme. The resulting estimate will be the mean square optimal one among those estimators that take into account ν-polynomials of the last Δ observations. Numerical simulations show the effectiveness of the proposed method.

Key words. nonlinear filtering, polynomial estimates, recursive estimates, non-Gaussian systems

AMS subject classifications. 93E10, 93E11

1. Introduction.

In this paper the state estimation problem for linear non-Gaussian systems is considered. In many important technical areas the widely used Gaussian assumption cannot be accepted as a realistic statistical description of the random quantities involved. As shown in various papers (see for instance [1, 2]), increasing attention has been paid in control engineering to non-Gaussian systems, and the importance of parameters and state estimation problems is plainly evidenced. In these cases the conditional expectation, which gives the optimal minimum variance estimate, cannot be generally computed, so that it is necessary to look for suboptimal estimates that are easier to achieve, such as the optimal linear one. In recent years, the signal filtering and detection problems in the presence of non-Gaussian noise have been widely investigated with different signal models and statistical settings. Non-Gaussian problems often arise in digital communications when the noise interference includes noise components that are essentially non-Gaussian (this is a common situation below 100 MHz) [6]. Neglecting these components is a major source of error in communication system design. In [3, 4] the existence of stable filters for a class of nonlinear stochastic systems is studied, where the nonlinearity is defined not by its deterministic structure but by its statistical properties. In [5] the Bayesian approach to nonlinear parameter estimation is considered and the cost of computing the posterior density description is investigated when the Bayes formula is recursively applied. In telecommunication systems the detection problem in the presence of non-Gaussian noises is extensively addressed in [6]–[12], while in [13] a general abstract setting is considered for high-order statistical processing (Volterra filters). A first attempt in the definition of a polynomial filter, which in some sense generalizes the Kalman approach, is described in [14], where, in particular, an instantaneous polynomial function of the innovation process constitutes the forcing term for the linear dynamic of the filter. The computation of the polynomial coefficients, which generalizes the Kalman gain to the non-Gaussian case, remains the main problem. In [15] the linear recursive estimation is dealt with for stochastic signals having multiplicative noise and in [16] for linear discrete time systems with stochastic parameters. In [17] an asymptotic minimum variance algorithm is described for parameter estimation in non-Gaussian moving average (MA) and autoregressive moving average (ARMA)

processes, using sample high-order statistics. The same problem is studied in [18] by using a fixed set of output cumulants. In [19], on the basis of the knowledge of the output process together with its Kronecker square products, a linear filter with respect to such information process is defined.

In this paper we consider the more general polynomial case, where past values of the output process are also considered.

The paper is organized as follows: in §2 we recall some definitions and properties on the estimation theory in a geometric framework. Moreover, some results on the Kronecker algebra are given. In §3 the non-Gaussian filtering problem is formulated with reference to a linear discrete time system. The augmented state and the corresponding dynamical model generating process are defined. In §4 some theoretical results useful for the practical implementation of the proposed algorithm are reported. Finally in §5 some numerical examples of application are presented, showing high performance of the proposed filter with respect to the Kalman one. The paper ends with a concluding remark in §6.

2. Preliminaries.

2.1. Estimates as projections. In this section, we will consider the mean square optimal (and suboptimal) estimate of a partially observed random variable as a projection onto a suitable L^2-subspace.

Let $(\Omega, \mathcal{F}, P)$ be a probability space. For any given sub σ-algebra $\mathcal{G}$ of $\mathcal{F}$ let us denote by $L^2(\mathcal{G}, n)$ the Hilbert space of the n-dimensional, $\mathcal{G}$-measurable, random variables with finite second moment as

$$L^2(\mathcal{G}, n) = \left\{ X : \Omega \to \mathbb{R}^n,\ \mathcal{G}\text{-measurable},\ \int_\Omega \|X(\omega)\|^2 dP(\omega) < +\infty \right\},$$

where $\|\cdot\|$ is the euclidean norm in $\mathbb{R}^n$. Moreover, when $\mathcal{G}$ is the σ-algebra generated by a random variable $Y : \Omega \to \mathbb{R}^m$, that is, $\mathcal{G} = \sigma(Y)$, we will use the notation $L^2(Y, n)$ to indicate $L^2(\sigma(Y), n)$. Finally if M is a closed subspace of $L^2(\mathcal{F}, n)$, we will use the symbol $\Pi(X/M)$ to indicate the orthogonal projection of $X \in L^2(\mathcal{F}, n)$ onto M.

As is well known, the optimal minimum variance estimate of a random variable $X \in L^2(\mathcal{F}, n)$ with respect to a random variable Y, that is, $\Pi(X/L^2(Y, n))$, is given by the conditional expectation (C.E.) $E(X/Y)$. If X and Y are jointly Gaussian, then the C.E. is the following affine transformation of Y:

$$E(X/Y) = E(X) + E(X\tilde{Y}^T)E(\tilde{Y}\tilde{Y}^T)^{-1}\tilde{Y}, \tag{2.1.1}$$

where $\tilde{Y} = Y - E(Y)$.

Moreover, defining

$$Y' = \begin{bmatrix} 1 \\ Y \end{bmatrix},$$

(2.1.1) can be also interpreted as the projection on the subspace

$$\mathcal{L}(Y', n) = \{Z : \Omega \to \mathbb{R}^n \,/\, \exists\ A \in \mathbb{R}^{n\times(m+1)} \text{ such that } Z = AY'\} \subset L^2(Y', n) = L^2(Y, n).$$

Unfortunately in the non-Gaussian case, no simple characterization of the C.E. can be achieved. Consequently it is worthwhile to consider suboptimal estimates which have a simpler mathematical structure that allows the treatment of real data. The simplest suboptimal estimate is the optimal affine one, that is, $\Pi(X/\mathcal{L}(Y', n))$, which is given again by the right-hand side (R.H.S.) of (2.1.1). In the following discussion such an estimate will be denoted with $\hat{X}$ and

shortly called an optimal linear one. Intermediate estimates between the optimal linear and the C.E. can be considered by projecting onto subspaces greater than $\mathcal{L}(Y', n)$, like subspaces of polynomial transformations of Y. In order to proceed this way, we need to state some results on the Kronecker products [20] that constitute a powerful tool in treating vector polynomials.

2.2. The Kronecker algebra.

DEFINITION 2.2.1. *Let M and N be matrices of dimensions $r \times s$ and $p \times q$ respectively. Then the Kronecker product $M \otimes N$ is defined as the $(r \cdot p) \times (s \cdot q)$ matrix*

$$M \otimes N = \begin{bmatrix} m_{11}N & \dots & m_{1s}N \\ \dots\dots\dots\dots & & \\ m_{r1}N & \dots & m_{rs}N \end{bmatrix},$$

where the m_{ij} are the entries of M. Of course this kind of product is not commutative.

DEFINITION 2.2.2. *Let M be the $r \times s$ matrix*

$$M = [\, m_1 \quad m_2 \quad \dots \quad m_s \,], \tag{2.2.1}$$

where m_i denotes the ith column of M. Then the stack of M is the $r \cdot s$ vector

$$st(M) = \begin{bmatrix} m_1 \\ m_2 \\ \vdots \\ m_s \end{bmatrix}. \tag{2.2.2}$$

Observe that a vector as in (2.2.2) can be reduced to a matrix M as in (2.2.1) by considering the inverse operation of the stack denoted by st^{-1}. We refer to [20, Chap. 12] for the main properties of the Kronecker product and stack operation. It is easy to verify that for $u \in \mathbb{R}^r$, $v \in \mathbb{R}^s$, the ith entry of $u \otimes v$ is given by

$$(u \otimes v)_i = u_l \cdot v_m, \quad l = \left[\frac{i-1}{s}\right] + 1, \quad m = |i-1|_s + 1, \tag{2.2.3}$$

where $[\cdot]$ and $|\cdot|_s$ denote integer part and s-modulo, respectively. Moreover, the Kronecker power of M is defined as

$$M^{[0]} = 1 \in \mathbb{R},$$
$$M^{[l]} = M \otimes M^{[l-1]}, \quad l \geq 1.$$

Even if the Kronecker product is not commutative in general, the following result holds [24].

THEOREM 2.2.3. *For any given pair of matrices $A \in \mathbb{R}^{r \times s}$, $B \in \mathbb{R}^{n \times m}$, we have*

$$B \otimes A = C_{r,n}^T (A \otimes B) C_{s,m}, \tag{2.2.4}$$

where $C_{r,n}$, $C_{s,m}$ are suitable $0-1$ matrices.

It is possible to show that $C_{u,v}$ is the $(u \cdot v) \times (u \cdot v)$ matrix such that its (h, l) entry is given by

$$\{C_{u,v}\}_{h,l} = \begin{cases} 1 & \text{if } l = (|h-1|_v)u + \left(\left[\dfrac{h-1}{v}\right] + 1\right); \\ 0 & \text{otherwise.} \end{cases} \tag{2.2.5}$$

Observe that $C_{1,1} = 1$, hence in the vector case when $a \in \mathbb{R}^r$ and $b \in \mathbb{R}^n$, (2.2.4) becomes

$$b \otimes a = C_{r,n}^T (a \otimes b). \tag{2.2.6}$$

Moreover, in the vector case the commutation matrices also satisfy the following recursive formula.

LEMMA 2.2.4. *For any $a, b \in \mathbb{R}^n$ and for any $l = 1, 2 \ldots$, let $G_l = C^T_{n,n^l}$ so that*

$$b^{[l]} \otimes a = G_l(a \otimes b^{[l]}). \tag{2.2.7}$$

Then the sequence $\{G_l\}$ satisfies the following equations:

$$G_1 = C^T_{n,n}, \tag{2.2.8}$$

$$G_l = (I_1 \otimes G_{l-1}) \cdot (G_1 \otimes I_{l-1}), \quad l > 1, \tag{2.2.9}$$

where I_r is the identity matrix in $\mathbb{R}^{n^r}$.

Proof. Equation (2.2.6) assures the existence of the G_l's and implies (2.2.8). Moreover, using the associative property of the Kronecker product and recalling the identity

$$(A \cdot C) \otimes (B \cdot D) = (A \otimes B) \cdot (C \otimes D)$$

with $A = I_1$, we have

$$\begin{aligned} b^{[l]} \otimes a &= b \otimes b^{[l-1]} \otimes a \\ &= b \otimes \left(G_{l-1}(a \otimes b^{[l-1]})\right) \\ &= (I_1 \otimes G_{l-1}) \cdot (b \otimes a \otimes b^{[l-1]}) \\ &= (I_1 \otimes G_{l-1}) \cdot \left((G_1(a \otimes b)) \otimes b^{[l-1]}\right) \\ &= (I_1 \otimes G_{l-1}) \cdot (G_1 \otimes I_{l-1}) \cdot (a \otimes b^{[l]}). \end{aligned}$$

Then equation (2.2.9) follows immediately by using (2.2.7). □

We can also find a binomial formula for the Kronecker power which generalizes the classical Newton one.

THEOREM 2.2.5. *For any integer $h \geq 0$ the matrix coefficients of the binomial power formula*

$$(a + b)^{[h]} = \sum_{k=0}^{h} M_k^h (a^{[k]} \otimes b^{[h-k]}) \tag{2.2.10}$$

constitute a set of matrices $\{M_0^h, \ldots, M_h^h\}$ such that

$$M_h^h = M_0^h = I_h, \tag{2.2.11}$$

$$M_j^h = (M_j^{h-1} \otimes I_1) + (M_{j-1}^{h-1} \otimes I_1) \cdot (I_{j-1} \otimes G_{h-j}), \quad 1 \leq j \leq h-1, \tag{2.2.12}$$

where G_l and I_l are as in Lemma 2.2.4.

Proof. Equation (2.2.11) is obviously true for any h.

We will prove (2.2.12) by induction for $h \geq 2$. For $h = 2$ it results in

$$\begin{aligned} (a + b)^{[2]} &= a^{[2]} + a \otimes b + b \otimes a + b^{[2]} \\ &= a^{[2]} + (I_2 + G_1)(a \otimes b) + b^{[2]}, \end{aligned} \tag{2.2.13}$$

where (2.2.7) has been used. Moreover, using (2.2.12) we obtain

$$M_1^2 = (M_1^1 \otimes I_1) + (M_0^1 \otimes I_1)(I_0 \otimes G_1) = I_2 + I_2 G_1 = I_2 + G_1$$

so that the matrix coefficient of $a \otimes b$ in (2.2.10) (which is equal to $I_2 + G_1$ by (2.2.13)) agrees with the matrix M_1^2 computed by using (2.2.12). Now suppose that (2.2.12) is true for $h \geq 2$. Then we will prove that it is true for $h+1$. We have

$$\begin{aligned}
(a+b)^{[h+1]} &= (a+b)^{[h]} \otimes (a+b) \\
&= \left(\sum_{k=0}^{h} M_k^h (a^{[k]} \otimes b^{[h-k]}) \right) \otimes (a+b) \\
&= \sum_{k=0}^{h} \left((M_k^h \otimes I_1) \cdot (a^{[k]} \otimes b^{[h-k]} \otimes a) + (M_k^h \otimes I_1) \cdot (a^{[k]} \otimes b^{[h+1-k]}) \right) \\
&= \sum_{k=0}^{h} \Big((M_k^h \otimes I_1) \cdot \big(a^{[k]} \otimes \big(G_{h-k}(a \otimes b^{[h-k]})\big)\big) \\
&\qquad + (M_k^h \otimes I_1) \cdot (a^{[k]} \otimes b^{[h+1-k]}) \Big) \\
&= \sum_{k=0}^{h} (M_k^h \otimes I_1) \cdot (I_k \otimes G_{h-k}) \cdot (a^{[k+1]} \otimes b^{[h-k]}) \\
&\qquad + \sum_{k=0}^{h} (M_k^h \otimes I_1) \cdot (a^{[k]} \otimes b^{[h+1-k]}).
\end{aligned}$$

Hence, taking into account (2.2.10) we have

$$M_j^{h+1} = (M_j^h \otimes I_1) + (M_{j-1}^h \otimes I_1) \cdot (I_{j-1} \otimes G_{h+1-j}), \quad 1 \leq j \leq h. \qquad \square$$

2.3. Polynomial estimates. Let $X \in L^2(\mathcal{F}, n)$, $Y \in L^2(\mathcal{F}, m)$ be random variables and, moreover, suppose that for some integer i, $\int_\Omega \|Y\|^{2i} dP < +\infty$. Then we can define the ith-order polynomial estimate of X as $\Pi(X/\mathcal{L}(\mathcal{Y}_i, n))$, where $\mathcal{Y}_i \in L^2(\mathcal{F}, 1 + m + \cdots + m^i)$ is given by

$$\mathcal{Y}_i = \begin{bmatrix} 1 \\ Y \\ \vdots \\ Y^{[i]} \end{bmatrix}.$$

Note that $\mathcal{L}([\begin{smallmatrix} 1 \\ Y \end{smallmatrix}], n) = \mathcal{L}(\mathcal{Y}_1, n) \subset \cdots \subset \mathcal{L}(\mathcal{Y}_{i-1}, n) \subset \mathcal{L}(\mathcal{Y}_i, n)$ so that a polynomial estimate improves (in terms of error variance) the performance of the linear one. Observe, moreover, that the previous estimate has the form

$$\sum_{l=0}^{i} c_l Y^{[l]}, \quad c_l \in \mathbb{R}^{n \times m^l}, \tag{2.3.1}$$

which justifies the term polynomial used in this paper. If $\int_\Omega \|Y\|^{2i} dP < +\infty \ \forall i \in \mathbb{N}$, let $\mathcal{H}$ be defined as the L^2-closure of $\cup_{i=0}^{+\infty} \mathcal{L}(\mathcal{Y}_i, n)$. Then the C.E. can be decomposed as

$$E(X/Y) = \Pi(X/\mathcal{H}) + \Pi(X/\mathcal{H}^\perp), \tag{2.3.2}$$

where the first term of the R.H.S. of (2.3.2) is the L^2-limit of a sequence of polynomials of Y. In particular such a sequence can be obtained by projecting X on the subspaces $\mathcal{L}(\mathcal{Y}_i, n)$,

so that the difficulty in computing the C.E. is moved to the second part of the R.H.S. of (2.3.2). In any case we can compute the coefficients in (2.3.1) of any finite-rank polynomial approximation of the term $\Pi(X/\mathcal{H})$ by using the linear estimate formula given by the R.H.S. of (2.1.1).

3. Problem formulation.

3.1. The system to be filtered. Let us consider the filtering problem for the following class of linear discrete time systems:

$$x(k+1) = Ax(k) + FN(k), \qquad x(0) = \bar{x}, \tag{3.1.1}$$

$$y(k) = Cx(k) + GN(k), \tag{3.1.2}$$

where $x(k) \in \mathbb{R}^n$, $y(k) \in \mathbb{R}^m$, $N(k) \in \mathbb{R}^u$, $A \in \mathbb{R}^{n\times n}$, $C \in \mathbb{R}^{m\times n}$, $F \in \mathbb{R}^{n\times u}$, $G \in \mathbb{R}^{m\times u}$. The random variable $\bar{x}$ (the initial condition) and the random sequence $\{N(k)\}$ satisfy the following conditions for $k \geq 0$:

i) $E\{\bar{x}\} = 0$, $E\{N(k)\} = 0$;

ii) there exists an integer $\nu \geq 1$ such that for any given multiindex $i_1, \ldots, i_L \in \{1, \ldots, u\}$, $j_1, \ldots, j_L \in \{1, \ldots, n\}$, $1 \leq L \leq 2\nu$ we have

$$F(i_1, \ldots, i_L) \triangleq E\{|N_{i_1}(k)N_{i_2}(k) \cdot \cdots \cdot N_{i_L}(k)|\} < \infty, \tag{3.1.3}$$

$$X(j_1, \ldots, j_L) \triangleq E\left\{|\bar{x}_{j_1}\bar{x}_{j_2} \cdot \cdots \cdot \bar{x}_{j_L}|\right\} < \infty; \tag{3.1.4}$$

iii) the sequence $\{N(k)\}$ forms with $\bar{x}$ a family of independent random variables.

3.2. Recursive estimates. It is well known that the optimal mean square state estimate for the state $x(k)$ of the linear system (3.1.1), (3.1.2) with respect to the observations up to the time k is given by the conditional expectation

$$\hat{x}(k) = E(x(k)/\mathcal{F}_k^y), \tag{3.2.1}$$

where $\mathcal{F}_k^y$ is the σ-algebra generated by $\{y(\tau),\ \tau \leq k\}$. Hence there exists a Borel function F such that

$$\hat{x}(k) = F(y(\tau),\ \tau \leq k).$$

As we have already seen in §2, the computation of F could be very difficult and, in general, does not produce a recursive algorithm, so it does not turn out to be very useful from an application point of view. If we are interested only in an optimal linear estimate, then we can also express the above estimate in the general recursive form,

$$\hat{x}(k) = F(k, \hat{x}(k-1), y(k)). \tag{3.2.2}$$

In fact the well-known Kalman filter, which gives the optimal linear estimate of the state, is expressed as in (3.2.2) with a linear transformation F. More generally we can consider the set of the recursive Borel transformations of finite memory Δ, that is,

$$\hat{x}(k) = \rho(k, \hat{x}(k-1), y(k), y(k-1), \ldots, y(k-\Delta)). \tag{3.2.3}$$

In order to realize (3.2.3) we will adopt the larger class of recursive functions

$$\begin{aligned} &\hat{x}(k) = \mathcal{T}\xi(k), \\ &\xi(k) = \varrho(k, \xi(k-1), y(k), y(k-1), \ldots, y(k-\Delta)), \end{aligned} \tag{3.2.4}$$

where $\xi(k) \in L^2(\mathcal{F}, n')$, $n' \geq n$, and $\mathcal{T}$ is the (linear) operator that extracts the first n components of $\xi(k)$. In particular the method that will be proposed will allow us to obtain an estimate in the form

$$\begin{aligned} &\hat{x}(k) = \mathcal{T}\xi(k), \\ &\xi(k) = L(k)\xi(k-1) + \mathcal{P}(y(k), y(k-1), \ldots, y(k-\Delta)), \end{aligned} \tag{3.2.5}$$

where $L(k) \in \mathbb{R}^{n' \times n'}$ and $\mathcal{P}$ is a polynomial transformation. One way to justify (3.2.5) is that a similar form is optimal in some interesting cases [25].

3.3. The extended system. In order to obtain a recursive estimate like in (3.2.5), as a first step we introduce the following extended vectors:

$$x_e(k) = \begin{bmatrix} x(k) \\ y(k-1) \\ \vdots \\ y(k-\Delta) \end{bmatrix} \in \mathbb{R}^q, \qquad y_e(k) = \begin{bmatrix} y(k) \\ y(k-1) \\ \vdots \\ y(k-\Delta) \end{bmatrix} \in \mathbb{R}^p, \tag{3.3.1}$$

with $q = n + m\Delta$ and $p = (\Delta + 1)m$. The model equations (3.1.1), (3.1.2) become

$$x_e(k+1) = A_e x_e(k) + F_e N(k), \quad x_e(0) = \bar{x}_e, \tag{3.3.2}$$

$$y_e(k) = C_e x_e(k) + G_e N(k), \tag{3.3.3}$$

where

$$A_e = \begin{bmatrix} A & 0 & \ldots & \ldots & 0 \\ C & 0 & \ldots & \ldots & 0 \\ 0 & I & \ddots & & \vdots \\ \vdots & & \ddots & \ddots & \vdots \\ 0 & \ldots & \ldots & I & 0 \end{bmatrix}, \quad F_e = \begin{bmatrix} F \\ G \\ 0 \\ \vdots \\ 0 \end{bmatrix}, \quad \bar{x}_e = \begin{bmatrix} \bar{x} \\ 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix}, \tag{3.3.4}$$

$$C_e = \begin{bmatrix} C & 0 & \ldots & 0 \\ 0 & I & \ddots & \\ \vdots & & \ddots & \vdots \\ 0 & & \ldots & I \end{bmatrix}, \quad G_e = \begin{bmatrix} G \\ 0 \\ \vdots \\ 0 \end{bmatrix}. \tag{3.3.5}$$

Moreover, let us define the generalized νth-degree polynomial observation as the vector $\mathcal{Y} \in \mathbb{R}^\mu$, $\mu = p + p^2 + \cdots + p^\nu$:

$$\mathcal{Y}(k) = \begin{bmatrix} y_e(k) \\ y_e^{[2]}(k) \\ \vdots \\ y_e^{[\nu]}(k) \end{bmatrix}. \tag{3.3.6}$$

Finally let us introduce the extended state $\mathcal{X} \in \mathbb{R}^\chi$, $\chi = q + q^2 + \cdots + q^\nu$:

$$\mathcal{X}(k) = \begin{bmatrix} x_e(k) \\ x_e^{[2]}(k) \\ \vdots \\ x_e^{[\nu]}(k) \end{bmatrix}. \tag{3.3.7}$$

In the following discussion we will denote with $M_i^j(l)$ the binomial matrices (2.2.11), (2.2.12) highlighting the dependence by the dimension l of the vectors, and the symbol $I_{i,j}$ will denote the identity in $\mathbb{R}^{i^j}$. In order to obtain a recursive filter we need to write an evolution equation for the extended state $\mathcal{X}(k)$ and another one that links it to $\mathcal{Y}(k)$. For this purpose we can prove the following important result.

LEMMA 3.3.1. *Let, on the same probability space,* $\{z(k),\ k \geq 0\}$ *and* $\{N(k),\ k \geq 0\}$ *be random sequences in* $\mathbb{R}^\alpha$ *and* $\mathbb{R}^\beta$, *respectively, such that* $\forall k\ N(k)$ *is independent by* $\{z(k), z(j), N(j),\ j < k\}$. *Moreover, let us assume*

$$w(k) = \Gamma z(k) + \Psi N(k), \tag{3.3.8}$$

where $w(k) \in \mathbb{R}^\gamma$ *and* $\Gamma,\ \Psi$ *are subsequently dimensioned deterministic matrices. Consider the Kronecker powers of* $w(k)$ *and* $z(k)$ *up to the* ν*th order aggregated in the vectors*

$$\mathcal{W}(k) = \begin{bmatrix} w(k) \\ w^{[2]}(k) \\ \vdots \\ w^{[\nu]}(k) \end{bmatrix}, \quad \mathcal{Z}(k) = \begin{bmatrix} z(k) \\ z^{[2]}(k) \\ \vdots \\ z^{[\nu]}(k) \end{bmatrix},$$

and

$$\mathcal{O} = \begin{bmatrix} \Gamma & 0 & \dots & 0 \\ O_{2,1} & \Gamma^{[2]} & \dots & 0 \\ \dots & \dots & \dots & \dots \\ O_{\nu,1} & O_{\nu,2} & \dots & \Gamma^{[\nu]} \end{bmatrix}, \quad \mathcal{T} = \begin{bmatrix} \Psi E(N(k)) \\ \Psi^{[2]} E(N^{[2]}(k)) \\ \vdots \\ \Psi^{[\nu]} E(N^{[\nu]}(k)) \end{bmatrix},$$

where

$$O_{i,l} = M_{i-l}^i(\gamma)(\Psi^{[i-l]} \otimes \Gamma^{[l]}) \left(E(N^{[i-l]}(k)) \otimes I_{\alpha,l}\right). \tag{3.3.9}$$

Then there exists the representation

$$\mathcal{W}(k) = \mathcal{O}\mathcal{Z}(k) + \mathcal{T} + \mathcal{N}(k), \tag{3.3.10}$$

where

$$\mathcal{N}(k) = \begin{bmatrix} h_1(k) \\ h_2(k) \\ \vdots \\ h_\nu(k) \end{bmatrix} \tag{3.3.11}$$

and

$$h_i(k) = \sum_{l=0}^{i-1} M_{i-l}^i(\gamma)(\Psi^{[i-l]} \otimes \Gamma^{[l]}) \left(\left(N^{[i-l]}(k) - E(N^{[i-l]}(k))\right) \otimes I_{\alpha,l}\right) z^{[l]}(k).$$

Moreover, $\{\mathcal{N}(k)\}$ *is a zero-mean white sequence such that* $\forall k\ \mathcal{N}(k)$ *is uncorrelated with* $\{\mathcal{Z}(j),\ j \leq k\}$, *with covariance* $\mathcal{S}(k)$ *such that its* (r, s)*-block is given by*

$$\begin{aligned} \mathcal{S}_{r,s} &\triangleq E(h_s(k)h_r(k)^T) \\ &= \sum_{l=0}^{r-1} \sum_{m=0}^{s-1} M_{r-l}^r(\gamma)(\Psi^{[r-l]} \otimes \Gamma^{[l]}) \cdot st^{-1}\left((I_{\beta,s-m} \otimes C_{\beta^{r-l},\alpha^m}^T \otimes I_{\alpha,l})\right. \\ &\quad \cdot \left((E(N^{[s+r-m-l]}(k)) - E(N^{[s-m]}(k)) \otimes E(N^{[r-l]}(k)))\right. \\ &\quad \left.\left. \otimes C_{1,\alpha^m} \otimes I_{\alpha,l}\right) \cdot E(z^{[l+m]}(k))\right)(\Psi^{[s-m]} \otimes \Gamma^{[m]})^T (M_{s-m}^s(\gamma))^T, \end{aligned} \tag{3.3.12}$$

provided that there exist finite all the moments involved.

Proof. Taking the ith Kronecker power of both members in (3.3.8), we have

$$w^{[i]}(k) = (\Gamma z(k) + \Psi N(k))^{[i]}, \tag{3.3.13}$$

which can be exploited by using Theorem 2.2.5 so that

$$\begin{aligned} w^{[i]}(k) &= (\Gamma z(k))^{[i]} + \sum_{j=1}^{i} M_j^i(\gamma)\left((\Psi N(k))^{[j]} \otimes (\Gamma z(k))^{[i-j]}\right) \\ &= \Gamma^{[i]} z^{[i]}(k) + \sum_{j=1}^{i} M_j^i(\gamma)(\Psi^{[j]} \otimes \Gamma^{[i-j]})(N^{[j]}(k) \otimes z^{[i-j]}(k)) \\ &= \Gamma^{[i]} z^{[i]}(k) + \sum_{l=0}^{i-1} M_{i-l}^i(\gamma)(\Psi^{[i-l]} \otimes \Gamma^{[l]})(N^{[i-l]}(k) \otimes I_{\alpha,l}) z^{[l]}(k), \end{aligned} \tag{3.3.14}$$

from which (3.3.10) follows.

Now, let us consider the above-defined "augmented noise" $\mathcal{N}(k)$. From the independence of $z(k)$ and $N(k)$ (and hence, the independence of $N^{[i-l]}(k) - E(N^{[i-l]}(k))$ and $z^{[l]}(k)$ $\forall l = 0, \ldots, i-1$) the zero mean property for $\mathcal{N}(k)$ follows, as can be readily verified. To prove the whiteness property, suppose $k > j$. First of all, observe that because $N(k)$, by the hypotheses, is independent of $\{z(k), z(j), N(j),\ j < k\}$, it follows that

$$N^{[r-l]}(k) - E(N^{[r-l]}(k))$$

is independent of

$$z^{[l]}(k) z^{[m]^T}(j)\left((N^{[s-m]}(j) - E(N^{[s-m]}(j))) \otimes I_{\alpha,m}\right)^T;$$

then for the (r, s)-block of the covariance matrix we have

$$\begin{aligned} &\left(E(\mathcal{N}(k)\mathcal{N}(j)^T)\right)_{r,s} = E(h_r(k) h_s(j)^T) \\ &= \sum_{l=0}^{r-1} \sum_{m=0}^{s-1} M_{r-l}^r(\gamma)\left(\Psi^{[r-l]} \otimes \Gamma^{[l]}\right) \\ &\quad \cdot E\Big(((N^{[r-l]}(k) - E(N^{[r-l]}(k))) \otimes I_{\alpha,l}) z^{[l]}(k) z^{[m]}(j)^T \\ &\qquad \cdot \left(\left(N^{[s-m]}(j) - E(N^{[s-m]}(j))\right) \otimes I_{\alpha,m}\right)^T\Big)(\Psi^{[s-m]} \otimes \Gamma^{[m]})^T (M_{s-m}^s(\gamma))^T \\ &= 0, \end{aligned}$$

because $N^{[r-l]}(k) - E(N^{[r-l]}(k))$ is a zero-mean random variable. Moreover, for $j \leq k$,

$$\begin{aligned} &\left(E(\mathcal{N}(k)\mathcal{Z}(j)^T)\right)_{r,s} = E(h_r(k) z^{[s]}(j)^T) \\ &= \sum_{l=0}^{r-1} M_{r-l}^r(\gamma)\left(\Psi^{[r-l]} \otimes \Gamma^{[l]}\right) \\ &\qquad \cdot E\left(\left((N^{[r-l]}(k) - E(N^{[r-l]}(k))) \otimes I_{\alpha,l}\right) z^{[l]}(k) z^{[s]}(j)^T\right) \\ &= 0, \end{aligned}$$

which follows, as before, by the independence of the random variables involved.

In order to simplify the notation, let us introduce the following symbols for the calculation of the (r, s)-block of the covariance matrix:

$$
\begin{aligned}
M_{u,v} &= M^{u}_{u-v}(\gamma)(\Psi^{[u-v]} \otimes \Gamma^{[v]}),\\
N_{u,v} &= N^{[u-v]}(k) - E\big(N^{[u-v]}(k)\big),\\
z_u &= z^{[u]}(k),
\end{aligned}
\tag{3.3.15}
$$

where $(u, v) \in \{(r, l), (s, m)\}$. Then we have

$$
E\big(h_r(k)h_s(k)^T\big) = \sum_{l=0}^{r-1}\sum_{m=0}^{s-1} M_{r,l} E\left((N_{r,l} \otimes I_{\alpha,l}) z_l z_m^T (N_{s,m} \otimes I_{\alpha,m})^T\right) M_{s,m}^T. \tag{3.3.16}
$$

Let us now consider the argument of the expected value in (3.3.16):

$$
(N_{r,l} \otimes I_{\alpha,l}) z_l z_m^T (N_{s,m} \otimes I_{\alpha,m})^T = st^{-1}\left(st\left((N_{r,l} \otimes I_{\alpha,l}) z_l z_m^T (N_{s,m} \otimes I_{\alpha,m})^T\right)\right). \tag{3.3.17}
$$

Moreover,

(3.3.18)

$$
\begin{aligned}
&st\big((N_{r,l} \otimes I_{\alpha,l}) z_l z_m^T (N_{s,m} \otimes I_{\alpha,m})^T\big)\\
&\quad = \big((N_{s,m} \otimes I_{\alpha,m}) \otimes (N_{r,l} \otimes I_{\alpha,l})\big) \cdot st(z_l z_m^T)\\
&\quad = \big(N_{s,m} \otimes \big(C^T_{\beta^{r-l},\alpha^m}(N_{r,l} \otimes I_{\alpha,m}) C_{1,\alpha^m}\big) \otimes I_{\alpha,l}\big) \cdot (z_m \otimes z_l)\\
&\quad = \big(\big(\big(I_{\beta,s-m} \otimes C^T_{\beta^{r-l},\alpha^m}\big) \cdot \big(N_{s,m} \otimes \big((N_{r,l} \otimes I_{\alpha,m}) C_{1,\alpha^m}\big)\big)\big) \otimes I_{\alpha,l}\big) \cdot z_{l+m}\\
&\quad = \big(\big(\big(I_{\beta,s-m} \otimes C^T_{\beta^{r-l},\alpha^m}\big) \cdot \big(N_{s,m} \otimes N_{r,l} \otimes I_{\alpha,m}\big) \cdot (1 \otimes C_{1,\alpha^m})\big) \otimes I_{\alpha,l}\big) \cdot z_{l+m}\\
&\quad = \big(\big(\big(I_{\beta,s-m} \otimes C^T_{\beta^{r-l},\alpha^m}\big) \cdot \big(\big((N_{s,m} \otimes N_{r,l}) \cdot 1\big) \otimes (I_{\alpha,m} \cdot C_{1,\alpha^m})\big)\big) \otimes I_{\alpha,l}\big) \cdot z_{l+m}\\
&\quad = \big(\big(I_{\beta,s-m} \otimes C^T_{\beta^{r-l},\alpha^m} \otimes I_{\alpha,l}\big) \cdot \big(N_{s,m} \otimes N_{r,l} \otimes C_{1,\alpha^m} \otimes I_{\alpha,l}\big)\big) \cdot z_{l+m};
\end{aligned}
$$

by substituting the previous expression in (3.3.17) and then in (3.3.16), taking into account (3.3.15) we obtain formula (3.3.12). □

Now, we are able to find the "augmented" linear stochastic system that generates the observation powers, as stated in the following theorem.

THEOREM 3.3.2. *The processes* $\{\mathcal{Y}(k)\}$ *and* $\{\mathcal{X}(k)\}$ *defined in* (3.3.6), (3.3.7) *satisfy the following equations:*

$$
\begin{aligned}
\mathcal{X}(k+1) &= \mathcal{A}\mathcal{X}(k) + \mathcal{U} + \mathcal{F}(k), \quad \mathcal{X}(0) = \bar{\mathcal{X}},\\
\mathcal{Y}(k) &= \mathcal{C}\mathcal{X}(k) + \mathcal{V} + \mathcal{G}(k),
\end{aligned}
\tag{3.3.19}
$$

where

$$
\mathcal{A} = \begin{bmatrix} A_e & 0 & \dots & 0\\ H_{2,1} & A_e^{[2]} & \dots & 0\\ \dots & \dots & \dots & \dots\\ H_{\nu,1} & H_{\nu,2} & \dots & A_e^{[\nu]} \end{bmatrix}, \quad \mathcal{U} = \begin{bmatrix} 0\\ F_e^{[2]} E(N^{[2]}(k))\\ \vdots\\ F_e^{[\nu]} E(N^{[\nu]}(k)) \end{bmatrix}, \quad \bar{\mathcal{X}} = \begin{bmatrix} \bar{x}_e\\ \bar{x}_e^{[2]}\\ \vdots\\ \bar{x}_e^{[\nu]} \end{bmatrix},
$$

$$
\mathcal{C} = \begin{bmatrix} C_e & 0 & \dots & 0\\ L_{2,1} & C_e^{[2]} & \dots & 0\\ \dots & \dots & \dots & \dots\\ L_{\nu,1} & L_{\nu,2} & \dots & C_e^{[\nu]} \end{bmatrix}, \quad \mathcal{V} = \begin{bmatrix} 0\\ G_e^{[2]} E(N^{[2]}(k))\\ \vdots\\ G_e^{[\nu]} E(N^{[\nu]}(k)) \end{bmatrix},
$$

$$H_{i,l} = M^i_{i-l}(q)(F_e^{[i-l]} \otimes A_e^{[l]}) \left(E(N^{[i-l]}(k)) \otimes I_{q,l}\right),$$

$$L_{i,l} = M^i_{i-l}(p)(G_e^{[i-l]} \otimes C_e^{[l]}) \left(E(N^{[i-l]}(k)) \otimes I_{q,l}\right),$$

$$\mathcal{F}(k) = \begin{bmatrix} f_1(k) \\ f_2(k) \\ \vdots \\ f_\nu(k) \end{bmatrix}, \quad \mathcal{G}(k) = \begin{bmatrix} g_1(k) \\ g_2(k) \\ \vdots \\ g_\nu(k) \end{bmatrix}, \tag{3.3.20}$$

$$f_i(k) = \sum_{l=0}^{i-1} M^i_{i-l}(q)(F_e^{[i-l]} \otimes A_e^{[l]})\big(\big(N^{[i-l]}(k) - E(N^{[i-l]}(k))\big) \otimes I_{q,l}\big)x_e^{[l]}(k),$$

$$g_i(k) = \sum_{l=0}^{i-1} M^i_{i-l}(p)(G_e^{[i-l]} \otimes C_e^{[l]})\big(\big(N^{[i-l]}(k) - E(N^{[i-l]}(k))\big) \otimes I_{q,l}\big)x_e^{[l]}(k),$$

and $\{\mathcal{F}(k)\}$, $\{\mathcal{G}(k)\}$ *are zero-mean white sequences such that*

$$E(\mathcal{F}(k)\mathcal{G}^T(j)) = 0, \quad k \neq j. \tag{3.3.21}$$

Moreover, defining

$$\begin{aligned} P^{r,s}_{l,m}(k) = st^{-1}\big((I_{u,s-m} \otimes C^T_{u^{r-l},q^m} \otimes I_{q,l}) \\ \cdot\big(\big(E\big(N^{[s+r-m-l]}(k)\big) - E\big(N^{[s-m]}(k)\big) \otimes E\big(N^{[r-l]}(k)\big)\big) \\ \otimes C_{1,q^m} \otimes I_{q,l}\big) \cdot E\big(x_e^{[l+m]}(k)\big)\big), \end{aligned}$$

we have, for the auto-covariances $\mathcal{Q}(k)$, $\mathcal{R}(k)$ *of the noises* $\{\mathcal{F}(k)\}$, $\{\mathcal{G}(k)\}$, *respectively, and for the cross-covariance*

$$\mathcal{J}(k) \triangleq E(\mathcal{F}(k)\mathcal{G}(k)^T),$$

the following formulas:

$$\mathcal{Q}_{r,s}(k) = \sum_{l=0}^{r-1}\sum_{m=0}^{s-1} M^r_{r-l}(q)(F_e^{[r-l]} \otimes A_e^{[l]})P^{r,s}_{l,m}(k)(F_e^{[s-m]} \otimes A_e^{[m]})^T(M^s_{s-m}(q))^T, \tag{3.3.22}$$

$$\mathcal{R}_{r,s}(k) = \sum_{l=0}^{r-1}\sum_{m=0}^{s-1} M^r_{r-l}(p)(G_e^{[r-l]} \otimes C_e^{[l]})P^{r,s}_{l,m}(k)(G_e^{[s-m]} \otimes C_e^{[m]})^T(M^s_{s-m}(p))^T, \tag{3.3.23}$$

$$\mathcal{J}_{r,s}(k) = \sum_{l=0}^{r-1}\sum_{m=0}^{s-1} M^r_{r-l}(q)(F_e^{[r-l]} \otimes A_e^{[l]})P^{r,s}_{l,m}(k)(G_e^{[s-m]} \otimes C_e^{[m]})^T(M^s_{s-m}(p))^T, \tag{3.3.24}$$

where

$$\mathcal{Q}_{r,s}(k) \triangleq E(f_r(k)f_s(k)^T), \quad \mathcal{R}_{r,s}(k) \triangleq E(g_r(k)g_s(k)^T), \quad \mathcal{J}_{r,s}(k) \triangleq E(f_r(k)g_s(k)^T).$$

Proof. Equations (3.3.19) and formulas (3.3.22), (3.3.23) follow immediately by applying Lemma 3.3.1 to (3.3.2) and (3.3.3). Taking into account the structure (3.3.20) of the noises $\mathcal{F}(k)$, $\mathcal{G}(k)$, it follows that $\left(E(\mathcal{F}(k)\mathcal{G}(j)^T)\right)_{r,s}$ is the mean value of a product of terms in the

form (3.3.11) (obtained by means of a suitable substitution of Ψ, Γ, γ, α), so that (3.3.21) is easily shown, and with some manipulations similar to (3.3.18) we obtain (3.3.24). □

Given a stochastic process $\{\xi(k),\ k \geq 0\}$, $\xi(k) \in \mathbb{R}^{\alpha}$, here we say that it is an hth-order asymptotically stationary process if $\forall i,\ 1 \leq i \leq h$, there exists a constant vector $m_i \in \mathbb{R}^{\alpha^i}$ such that

$$\lim_{k \to +\infty} E(\xi^{[i]}(k)) = m_i.$$

For the sequence $\{\mathcal{F}(k)\}$ and $\{\mathcal{G}(k)\}$ in (3.3.20), we can show their second-order asymptotic stationarity, provided that the originary system (3.1.1), (3.1.2) is asymptotically stable, i.e., all the eigenvalues of the matrix A are in the open unit circle of the complex plane. For now, let us prove the following lemma.

LEMMA 3.3.3. *Let us assume the matrix A in* (3.1.1) *to be asymptotically stable. Then the sequence $\{x_e(k)\}$ is a $2v$th-order asymptotically stationary sequence.*

Proof. Let

$$m_i(k) \triangleq E(x_e^{[i]}(k)), \quad i = 1, 2, \ldots, 2v.$$

Taking the ith block in the first equation (3.3.19) we have

$$x_e^{[i]}(k+1) = A_e^{[i]} x_e^{[i]}(k) + \sum_{l=1}^{i-1} H_{i,l} x_e^{[l]}(k) + H_{i,0} + f_i(k),$$

with the $H_{i,l}$'s as in Theorem 3.3.3. Now taking the expected values of the previous equation we obtain

$$m_i(k+1) = A_e^{[i]} m_i(k) + \sum_{l=1}^{i-1} H_{i,e} m_l(k) + H_{i,0},$$

and by defining the vectors $m(k)$ and $\mathcal{U}_{2v}$ as

$$m(k) = \begin{bmatrix} m_1(k) \\ m_2(k) \\ \vdots \\ m_{2v}(k) \end{bmatrix}, \quad \mathcal{U}_{2v} = \begin{bmatrix} 0 \\ H_{2,0} \\ \vdots \\ H_{2v,0} \end{bmatrix},$$

we can write the recursive equation

$$m(k+1) = \mathcal{A}_{2v} m(k) + \mathcal{U}_{2v}, \tag{3.3.25}$$

where $\mathcal{A}_{2v}$ is defined as

$$\mathcal{A}_{2v} = \begin{bmatrix} A_e & 0 & \ldots & 0 \\ H_{2,1} & A_e^{[2]} & \ldots & 0 \\ \ldots & \ldots & \ldots & \ldots \\ H_{2v,1} & H_{2v,2} & \ldots & A_e^{[2v]} \end{bmatrix}.$$

Equation (3.3.25) is a recursive asymptotically stable equation. Actually, the asymptotic stability of A and the block-triangular structure of A_e imply the asymptotic stability of A_e itself and, hence, of all its Kronecker powers [20]. This in turn implies the asymptotic stability of $\mathcal{A}_{2v}$. The lemma is proven by observing that $\mathcal{U}_{2v}$ is a constant input. □

THEOREM 3.3.4. *The stochastic white sequences* $\{\mathcal{F}(k)\}$ *and* $\{\mathcal{G}(k)\}$ *in* (3.3.20) *are second-order asymptotically stationary processes, provided that the matrix* A *in* (3.3.1) *is asymptotically stable.*

Proof. The thesis immediately follows by using Lemma 3.3.3 and recalling that $\{\mathcal{F}(k)\}$ and $\{\mathcal{G}(k)\}$ are zero mean sequences and observing that their covariances, which are given by (3.3.22), (3.3.23), attain to a finite limit if the first 2ν moments of $x_e(k)$ are convergent. □

Note also that, under the hypotheses of Theorem 3.3.4, the cross-covariance matrix between the augmented noises, given by (3.3.24), is convergent for $k \to +\infty$.

Equation (3.3.19) is a linear model with both deterministic and stochastic forcing terms. Note that each noise is white, but they are correlated with each other at the same instant of time. Moreover, for any k, $\mathcal{F}(k)$ and $\mathcal{G}(k)$ are uncorrelated with the initial augmented state $\bar{\mathcal{X}}$, as easily follows by direct calculation. Then for this model it is possible to determine the optimal linear estimate of the extended state $\mathcal{X}(k)$ with respect to the extended observations $\mathcal{Y}(0), \mathcal{Y}(1), \ldots, \mathcal{Y}(k)$, by using the Kalman filter in the form which takes into account the cross-correlation between noises [23]. We can obtain the optimal linear estimate of the original state $x(k)$ with respect to the same set of augmented observations by extracting in $\hat{\mathcal{X}}(k)$ the first n components (as can be readily verified by observing the structure of the vectors x_e and $\mathcal{X}$). Clearly this operation produces an estimate in the generalized recursive form (3.2.5). In the following we will denote this estimate with $\hat{x}^{(\nu,\Delta)}(k)$. Observe that $\hat{x}^{(\nu,\Delta)}(k)$ agrees with the optimal mean square estimate in the (finite-dimensional) Hilbert space $\mathcal{H}_{\nu,\Delta}$ generated by objects as

$$\prod_{l=1}^{s} y(i_l), \qquad 0 \le s \le \nu, \quad 0 \le i \le k - \Delta, \quad i \le i_l \le i + \Delta,$$

which is a subspace of $\mathcal{L}(Y_{k,\nu}, n)$, where

$$Y_{k,\nu} = \begin{bmatrix} 1 \\ Y_k \\ \vdots \\ Y_k^{[\nu]} \end{bmatrix}; \quad Y_k = \begin{bmatrix} y(0) \\ y(1) \\ \vdots \\ y(k) \end{bmatrix}.$$

Roughly speaking we can say that the so-defined estimate approximates the projection of $x(k)$ onto $\mathcal{L}(Y_{k,\nu}, n)$, which is the most general mean square optimal polynomial estimate of fixed degree ν.

Note that the relations

$$\mathcal{H}_{\nu,\Delta} \subset \mathcal{H}_{\nu+1,\Delta},$$
$$\mathcal{H}_{\nu,\Delta} \subset \mathcal{H}_{\nu,\Delta+1}$$

hold $\forall \nu$, Δ and, hence, since $\hat{x}^{(\nu,\Delta)}(k) = \Pi(x(k)/\mathcal{H}_{\nu,\Delta})$, we have that the error variance

$$E(\|\hat{x}^{(\nu,\Delta)}(k) - x(k)\|^2)$$

decreases when ν or δ increases. Moreover, because

$$\hat{x}^{(\nu,\Delta)}(k) = \Pi(x(k)/\mathcal{H}_{\nu,\Delta}) = \Pi(\Pi(x(k)/L^2(Y_k, n))/\mathcal{H}_{\nu,\Delta}) = \Pi(E(x(k)/Y_k)/\mathcal{H}_{\nu,\Delta}),$$

we have also that the expression

$$E(\|\hat{x}^{(\nu,\Delta)}(k) - E(x(k)/Y_k)\|^2)$$

decreases when ν or Δ increases. To conclude, we say that the polynomial filter produces an estimate of the state $x(k)$ which is as "nearer" to the optimal one as the parameters ν or Δ are chosen large.

4. Implementation of the filter. For computation purposes we need to establish the following result.

THEOREM 4.1. *Let $z \in \mathbb{R}^n$. Then, $\forall k$, the ith entry of $z^{[k]}$ is*

$$(z^{[k]})_i = z_{l_1} z_{l_2} \cdot \cdots \cdot z_{l_k}, \tag{4.1}$$

where

$$l_j = \left| \left[\frac{i-1}{n^{k-j}} \right] \right|_n + 1, \quad j = 1, 2, \ldots, k-1, \tag{4.2}$$

$$l_k = |i-1|_n + 1. \tag{4.3}$$

Proof. For $k = 1$ the theorem is true. Proceeding by induction, from (2.2.3) we obtain

$$(z^{[k+1]})_i = (z \otimes z^{[k]})_i = z_{l_1} \cdot (z^{[k]})_{m_1}$$

with

$$\begin{aligned} l_1 &= \left[\tfrac{i-1}{n^k} \right] + 1 = \left| \left[\tfrac{i-1}{n^{k+1-1}} \right] \right|_n + 1, \\ m_1 &= |i-1|_{n^k} + 1 \end{aligned}$$

as in (4.2) for $k+1$. Moreover, by (4.1), (4.2), and (4.3),

$$(z^{[k]})_{m_1} = z_{\hat{l}_1} z_{\hat{l}_2} \cdot \cdots \cdot z_{\hat{l}_k}$$

with

$$\begin{aligned} \hat{l}_j &= \left| \left[\tfrac{m_1-1}{n^{k-j}} \right] \right|_n + 1, \\ \hat{l}_k &= |m_1 - 1|_n + 1 . \end{aligned}$$

Finally by denoting $l_j = \hat{l}_{j-1}$ we have $\forall j = 2, \ldots, k$

$$l_j = \left| \left[\frac{|i-1|_{n^k}}{n^{k-(j-1)}} \right] \right|_n + 1 = \left| \left[\frac{i-1}{n^{k+1-j}} \right] \right|_n + 1,$$

whereas

$$l_{k+1} = ||i-1|_{n^k} + 1 - 1|_n + 1 = |i-1|_n + 1,$$

which proves the theorem. □

Note in (3.3.22), (3.3.23), (3.3.24) that we can evaluate the covariance matrices of the noises $\mathcal{F}(k)$, $\mathcal{G}(k)$ and their cross-covariance from the moments $E(x_e^{[h]}(k))$ and $E(N^{[h']}(k))$, where $h = 1, 2, \ldots, 2(\nu-1)$ and $h' = 1, 2, \ldots, 2\nu$. From Theorem 4.1 it follows for the ith entry of $E(N^{[h']}(k))$ that

$$\left(E(N^{[h']}(k)) \right)_i = E\left(\left(N(k) \right)_{l_1} \left(N(k) \right)_{l_2} \cdot \cdots \cdot \left(N(k) \right)_{l_{h'}} \right) = F(l_1, l_2, \ldots, l_{h'}) .$$

In order to evaluate $E(x_e^{[h]}(k))$, noting that from (3.3.25) it results in

$$m(k) = \mathcal{A}_{2(\nu-1)} m(0) + \left(\sum_{i=0}^{k-1} \mathcal{A}_{2(\nu-1)}^i \right) \mathcal{U}_{2(\nu-1)},$$

we need only evaluate $m(0)$. Taking the hth block $m_h(0)$ of $m(0)$, for $1 \leq h \leq 2(\nu-1)$, we have by definition that $m_h(0) = E(x_e^{[h]}(0))$. Next, for the ith entry of $m_h(0)$, defining the h-tuple $l_1, \ldots, l_h$, which corresponds to i by Theorem 4.1, we have that

$$(m_h(0))_i = E(x_e^{[h]}(0))_i = X_e(l_1, \ldots, l_h), \tag{4.4}$$

where

$$X_e(l_1, \ldots, l_h) = \begin{cases} X(l_1, \ldots, l_h) & \text{if } 1 \leq l_i \leq n \quad \forall i = 1, \ldots, h, \\ 0 & \text{otherwise.} \end{cases} \tag{4.5}$$

Equations (3.3.19) are a state-space model driven by the white noise $\mathcal{F}(k)$ and with white observation noise $\mathcal{G}(k)$. Then we can obtain the optimal mean square linear estimate of the state $\mathcal{X}(k)$ defined in (3.3.7), by using the following Kalman filter equations, which take into account the correlation between noises [21], [22], [23]:

$$\hat{\mathcal{X}}(k) = \hat{\mathcal{X}}(k/k-1) + \mathcal{K}(k)\left(\mathcal{Y}(k) - \mathcal{C}\hat{\mathcal{X}}(k/k-1) - \mathcal{V}\right), \tag{4.6}$$

$$\mathcal{Z}(k) = \mathcal{J}(k)\left(\mathcal{C}\mathcal{P}(k/k-1)\mathcal{C}^T + \mathcal{R}(k)\right)^{-1}, \tag{4.7}$$

$$\begin{aligned} \hat{\mathcal{X}}(k+1/k) = {} & \left(\mathcal{A} - \left(\mathcal{A}\mathcal{K}(k) + \mathcal{Z}(k)\right)\mathcal{C}\right)\hat{\mathcal{X}}(k/k-1) \\ & + \left(\mathcal{A}\mathcal{K}(k) + \mathcal{Z}(k)\right)\left(\mathcal{Y}(k) - \mathcal{V}\right) + \mathcal{U}, \end{aligned} \tag{4.8}$$

$$\begin{aligned} \mathcal{P}(k+1/k) = {} & \mathcal{A}\mathcal{P}(k)\mathcal{A}^T + \mathcal{Q}(k) - \mathcal{Z}(k)\mathcal{J}^T(k) - \mathcal{A}\mathcal{K}(k)\mathcal{J}^T(k) \\ & - \mathcal{J}(k)\mathcal{K}^T(k)\mathcal{A}^T, \end{aligned} \tag{4.9}$$

$$\mathcal{P}(k) = \mathcal{P}(k/k-1) - \mathcal{K}(k)\mathcal{C}\mathcal{P}(k/k-1), \tag{4.10}$$

$$\mathcal{K}(k) = \mathcal{P}(k/k-1)\mathcal{C}^T\left(\mathcal{C}\mathcal{P}(k/k-1)\mathcal{C}^T + \mathcal{R}(k)\right)^{-1}, \tag{4.11}$$

where $\mathcal{K}(k)$ is the filter gain, $\mathcal{P}(k)$, $\mathcal{P}(k/k-1)$ are the filtering and prediction error covariances, respectively, and the other symbols are defined as in Theorem 3.3.2. If the matrix $\mathcal{C}\mathcal{P}(k/k-1)\mathcal{C}^T + \mathcal{R}(k)$ is singular we can use the Moore–Penrose pseudoinverse. The initial condition for (4.6) is

$$\hat{\mathcal{X}}(0/-1) = E(\bar{\mathcal{X}}),$$

and for (4.7) it is

$$\mathcal{P}(0/-1) = E\left((\bar{\mathcal{X}} - E(\bar{\mathcal{X}}))(\bar{\mathcal{X}} - E(\bar{\mathcal{X}}))^T\right),$$

which can be easily calculated by using (4.4), (4.5). By noting that the optimal linear estimate of each entry of the augmented state process $\mathcal{X}(k)$ with respect to the augmented observations $\mathcal{Y}(k)$ agrees with its optimal polynomial estimate with respect to the original observations $y(k)$, in the sense of taking into account all of the powers, up to the νth order, of $y(j)$, $j = 0, \ldots, k$, and all of the cross-products as $y^{[l_1]}(i-\Delta)\, y^{[l_2]}(i-\Delta-1) \cdot \cdots \cdot y^{[l_{\Delta+1}]}(i)$ for $\Delta \leq i \leq k$; $0 \leq l_s \leq \nu$; $\sum_{s=1}^{\Delta+1} l_s \leq \nu$, the method proposed yields the optimal polynomial (as specified before) estimate of the system (3.1.1), (3.1.2), and this estimate can be obtained by extracting the first n entries of the estimated extended state $Xa\hat{\mathcal{X}}(k)$ given by the Kalman filter. Note that in this manner we have obtained a recursive form as (3.2.5).

As we have already observed, if the dynamical matrix of system (3.1.1), (3.1.2) is asymptotically stable, the covariance matrices $\mathcal{Q}(k)$, $\mathcal{R}(k)$, and $\mathcal{J}(k)$ tend to finite limits as time goes to infinity. In this case we certainly can utilize the well-known steady-state form of the Kalman filter, and then much of the heavier calculations (such as the gain computation) can be performed before data processing.

4.1. Reduced-order filter. A considerable reduction of the filter state-space dimension can be obtained by eliminating the redundancy contained in the vector $\hat{\mathcal{X}}(k)$. In fact, the block entries of $\hat{\mathcal{X}}(k)$ are the (polynomial) estimates of monomials in the form: $(x_e)_{l_1} \cdot \cdots \cdot (x_e)_{l_h}$, $1 \le l_1, \ldots, l_h \le q$, $1 \le h \le v$. These terms do not change their values with a permutation of the indices $l_1, \ldots, l_h$, so that the same value can be repeated many times. We can avoid this by using a suitable definition of Kronecker power, instead of the classical one, which eliminates all redundancies, as suggested in [20]. This helps in reducing both memory space and computation time.

Let $X = [x_1 \ldots x_n]^T$. We will call the reduced Kronecker power of hth order the following vector:

$$X_{[h]} = \begin{bmatrix} x_1 \cdot \cdots \cdot x_1 \cdot x_1 \\ \vdots \\ x_1 \cdot \cdots \cdot x_1 \cdot x_n \\ \vdots \\ x_{l_1} \cdot \cdots \cdot x_{l_{h-1}} \cdot x_{l_h} \\ \vdots \\ x_n \cdot \cdots \cdot x_n \cdot x_n \end{bmatrix},$$

where $1 \le l_1 \le \cdots \le l_h \le n$. Note that the entries of $X_{[h]}$, are those of $X^{[h]}$, where all the monomials $x_{i_1} \cdot \cdots \cdot x_{i_h}$ which differ from each other for a permutation of the indices $i_1, \ldots, i_h$ are considered once. Let $X_{[h]}^{(n)}$ denote the hth reduced Kronecker power of X, where we highlight the dimension n of the vector X, and $d(Y)$ is the length of a vector Y. Then it is easy to find the following formulas, both giving the dimension of the vector $X_{[h]}^{(n)}$:

$$d(X_{[h]}^{(n)}) = \sum_{k=1}^{n} d(X_{[h-1]}^{(k)}),$$

$$d(X_{[h]}^{(n)}) = \sum_{i_1=0}^{h} \sum_{i_2=0}^{h-i_1} \cdots \sum_{i_{n-1}=0}^{h-(i_1+\cdots+i_{n-2})} 1.$$

Let $T_h^{(n)} \in \mathbb{R}^{n^h \times d(X_{[h]}^{(n)})}$ and $\tilde{T}_h^{(n)} \in \mathbb{R}^{d(X_{[h]}^{(n)}) \times n^h}$, with the matrices such that

$$X^{[h]} = T_h^{(n)} X_{[h]}; \quad X_{[h]} = \tilde{T}_h^{(n)} X^{[h]}.$$

Note that the following identities hold:

$$T_h^{(n)} \tilde{T}_h^{(n)} X^{[h]} = X^{[h]}; \quad \tilde{T}_h^{(n)} T_h^{(n)} X_{[h]} = X_{[h]}. \tag{4.1.1}$$

In order to obtain an expression for $T_h^{(n)}$ and $\tilde{T}_h^{(n)}$, let us consider the ith and i'th entries in the vectors $X^{[h]}$, $X_{[h]}$, respectively:

$$\{X^{[h]}\}_i = x_{l_1} \cdot \cdots \cdot x_{l_h},$$
$$\{X_{[h]}\}_{i'} = x_{l_1'} \cdot \cdots \cdot x_{l_h'},$$

where $1 \le l_1' \le \cdots \le l_h' \le n$. We shall indicate with ζ, η the functions such that

$$\zeta(i) = (l_1, \ldots, l_h),$$
$$\eta(i') = (l_1', \ldots, l_h').$$

Of course the inverse functions ζ^{-1}, η^{-1} are well defined. Moreover, let $o(l_1, \ldots, l_h)$ be the ordering function acting on a h-tuple $(l_1, \ldots, l_h)$. Then the following expressions hold:

$$\{T_h^{(n)}\}_{i,j} = \begin{cases} 1, & \text{if } j = \eta^{-1}(o(\zeta(i))); \\ 0, & \text{otherwise;} \end{cases}$$

$$\{\tilde{T}_h^{(n)}\}_{i,j} = \begin{cases} 1, & \text{if } j = \zeta^{-1}(\eta(i)); \\ 0, & \text{otherwise.} \end{cases}$$

Note that the function ζ is easily obtained by applying Theorem 4.1. Moreover, it is easy to show that

$$i = \zeta^{-1}(l_1, \ldots, l_h) = \sum_{j=1}^{h-1} (l_j - 1) n^{h-j} + l_h.$$

Now, if we define for a fixed ν

$$\mathcal{X}_r = \begin{bmatrix} X \\ X_{[1]} \\ \vdots \\ X_{[\nu]} \end{bmatrix}; \quad \mathcal{X}_{nr} = \begin{bmatrix} X \\ X^{[1]} \\ \vdots \\ X^{[\nu]} \end{bmatrix},$$

then we have

$$\mathcal{X}_{nr} = T^{(n)} \mathcal{X}_r, \quad \mathcal{X}_r = \tilde{T}^{(n)} \mathcal{X}_{nr},$$

where

$$T^{(n)} = \begin{bmatrix} T_1^{(n)} & 0 & \cdots & \\ 0 & T_2^{(n)} & & \\ \vdots & & \ddots & \\ & & \cdots & T_\nu^{(n)} \end{bmatrix}; \quad \tilde{T}^{(n)} = \begin{bmatrix} \tilde{T}_1^{(n)} & 0 & \cdots & \\ 0 & \tilde{T}_2^{(n)} & & \\ \vdots & & \ddots & \\ & & \cdots & \tilde{T}_\nu^{(n)} \end{bmatrix}.$$

We are now able to write down the reduced-order filter equations.

Let $\mathcal{X}_r(k)$, $\mathcal{Y}_r(k)$ be defined as

$$\mathcal{X}_r(k) = \begin{bmatrix} x_e(k) \\ x_{e[2]}(k) \\ \vdots \\ x_{e[\nu]}(k) \end{bmatrix}, \quad \mathcal{Y}_r(k) = \begin{bmatrix} y_e(k) \\ y_{e[2]}(k) \\ \vdots \\ y_{e[\nu]}(k) \end{bmatrix},$$

where $x_e(k)$, $y_e(k)$ are still given by (3.3.1). Then we have for any k

$$\mathcal{X}(k) = T^{(q)} \mathcal{X}_r(k), \quad \mathcal{X}_r(k) = \tilde{T}^{(q)} \mathcal{X}(k),$$

$$\mathcal{Y}(k) = T^{(p)} \mathcal{Y}_r(k), \quad \mathcal{Y}_r(k) = \tilde{T}^{(p)} \mathcal{Y}(k), \tag{4.1.2}$$

where $\mathcal{Y}(k)$, $\mathcal{X}(k)$ are given by (3.3.6), (3.3.7) and q and p are the same as in (3.3.1). Moreover, we have that the same relations link the vectors $\hat{\mathcal{X}}(k)$, $\hat{\mathcal{X}}(k/k-1)$ in (4.4), (4.5) to their reduced counterparts $\hat{\mathcal{X}}_r(k)$, $\hat{\mathcal{X}}_r(k/k-1)$:

$$\hat{\mathcal{X}}(k) = T^{(q)} \hat{\mathcal{X}}_r(k), \quad \hat{\mathcal{X}}_r(k) = \tilde{T}^{(q)} \hat{\mathcal{X}}(k), \tag{4.1.3}$$

$$\hat{\mathcal{X}}(k/k-1) = T^{(q)}\hat{\mathcal{X}}_r(k/k-1), \quad \hat{\mathcal{X}}_r(k/k-1) = \tilde{T}^{(q)}\hat{\mathcal{X}}(k/k-1). \tag{4.1.4}$$

By using (4.1.2), (4.1.3), (4.1.4) in (4.6), (4.8) and taking into account (4.1.1), we obtain

$$\hat{\mathcal{X}}_r(k) = \hat{\mathcal{X}}_r(k/k-1) - \mathcal{A}_1(k)Xa\hat{\mathcal{X}}_r(k/k-1) + \mathcal{B}_1(k)\mathcal{Y}_r(k) - \mathcal{V}_1(k),$$
$$\hat{\mathcal{X}}_r(k+1/k) = \mathcal{A}_2(k)\hat{\mathcal{X}}_r(k/k-1) + \mathcal{B}_2(k)\mathcal{Y}_r(k) - \mathcal{V}_2(k) + \mathcal{U}_1,$$

where

$$\mathcal{A}_1(k) = \tilde{T}^{(q)}\mathcal{K}(k)\mathcal{C}T^{(q)}, \quad \mathcal{B}_1(k) = \tilde{T}^{(q)}\mathcal{K}(k)T^{(p)}, \quad \mathcal{V}_1(k) = \tilde{T}^{(q)}\mathcal{K}(k)\mathcal{V},$$
$$\mathcal{A}_2(k) = \tilde{T}^{(q)}(\mathcal{A} - (\mathcal{A}\mathcal{K}(k) + \mathcal{Z}(k))\mathcal{C})T^{(q)}, \quad \mathcal{B}_2(k) = \tilde{T}^{(q)}(\mathcal{A}\mathcal{K}(k) + \mathcal{Z}(k))T^{(p)},$$
$$\mathcal{V}_2(k) = \tilde{T}^{(q)}(\mathcal{A}\mathcal{K}(k) + \mathcal{Z}(k))\mathcal{V}, \quad \mathcal{U}_1 = \tilde{T}^{(q)}\mathcal{U},$$

which is the reduced-order filter.

5. Numerical results. Numerical simulations on an IBM Risk 6000 endowed with "Mathematica" have been performed for two examples in order to test the method. In both of them, we consider the problems of signal and state filtering for the following linear discrete time system, where the state and the output noises are non-Gaussian:

$$\begin{aligned} x(k+1) &= Ax(k) + f(k), \qquad x(0) = 0, \\ s(k) &= Cx(k), \\ y(k) &= s(k) + g(k). \end{aligned} \tag{5.1}$$

In the first example it is assumed

$$A = \begin{bmatrix} 0.1 & 0.3 \\ 0.12 & 0.1 \end{bmatrix}, \qquad C = [0.7 \quad 0.3],$$
$$f(k) = \begin{bmatrix} f_1(k) \\ f_2(k) \end{bmatrix} \in \mathbb{R}^2, \qquad g(k) \in \mathbb{R},$$

$\{f(k)\}$ and $\{g(k)\}$ are independent, zero-mean random sequences in $(\Omega, \mathcal{F}, P)$ defined as

$$f_1(k)(\omega) = -0.4\chi_{F_1}(\omega) + 0.1\chi_{F_2}(\omega), \qquad f_2(k)(\omega) = -0.02\chi_{F_3}(\omega) + 0.18\chi_{F_4}(\omega),$$
$$g(k)(\omega) = -0.28\chi_{G_1}(\omega) + 0.62\chi_{G_2}(\omega) + 1.62\chi_{G_3}(\omega),$$

where χ_Q, $Q \in \mathcal{F}$ denotes the characteristic function of Q and the disjoint events (F_1, F_2), (F_3, F_4) and (G_1, G_2, G_3) have probability

$$P(F_1) = 0.2, \quad P(F_2) = 0.8,$$
$$P(F_3) = 0.9, \quad P(F_4) = 0.1,$$
$$P(G_1) = 0.8, \quad P(G_2) = 0.1, \quad P(G_3) = 0.1.$$

The optimal linear, quadratic, and cubic algorithms, without memory ($\Delta = 0$), and the quadratic with $\Delta = 1$ have been implemented. In order to simplify the computations, we have used the steady-state Kalman filter, starting from initial conditions $x(0) = \hat{x}(0) = 0$. The results are displayed in Figs. 5.1–5.5 for 30 iterations with reference to the signal $s(k)$. It can be seen that the quadratic filter follows the true state evolution better than the linear filter, although the quadratic one with $\Delta = 1$ does not give in this case a meaningful improvement. A further remarkable improvement is indeed obtained with the cubic filter. All the mentioned results agree with the steady-state error estimate covariance values obtained by solving the

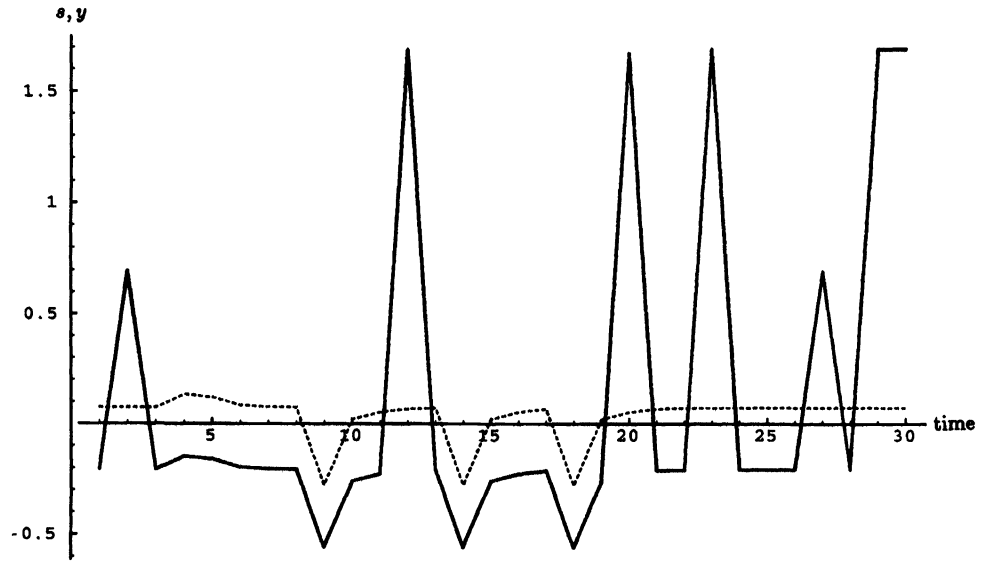

FIG. 5.1. *s=signal (dashed line), y=observation (solid line).*

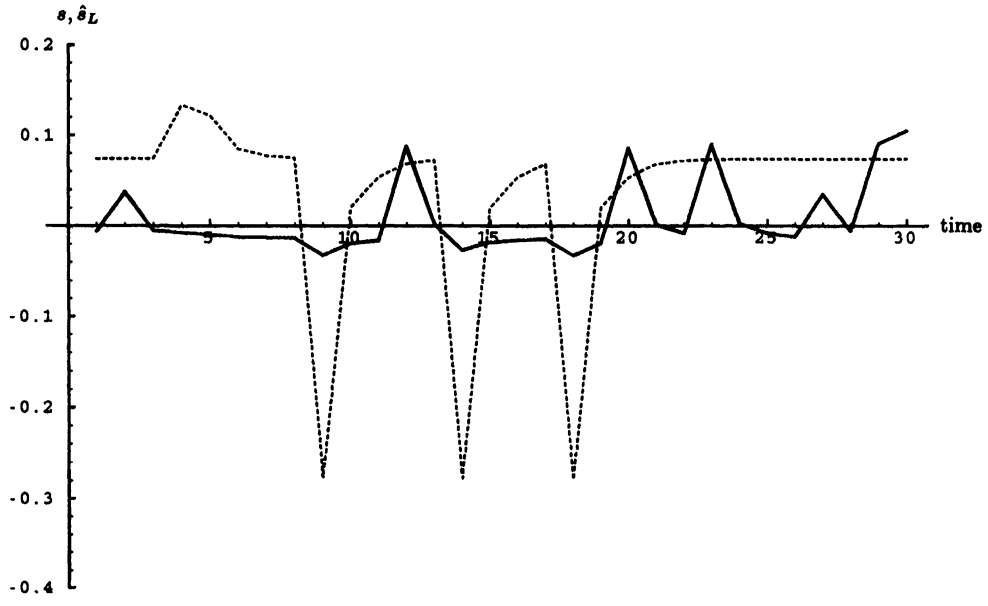

FIG. 5.2. *s=signal (dashed line), $\hat{s}_L$=optimal linear estimate with $\Delta = 0$ (solid line).*

Riccati equation for the linear, quadratic, and cubic cases with $\Delta = 0$, and for the quadratic one with $\Delta = 1$. In particular the above error covariance matrices, namely S_L, S_Q, S_C, and $S_{Q\Delta}$ (which are 2×2, 6×6, 20×20, and 12×12, respectively), have the form

$$S_L = \begin{bmatrix} 0.03864 & 0.00049 \\ 0.00049 & 0.00420 \end{bmatrix}, \qquad S_Q = \begin{bmatrix} 0.02773 & -0.00014 & \cdots \\ -0.00014 & 0.00401 & \cdots \\ \vdots & \vdots & \ddots \end{bmatrix},$$

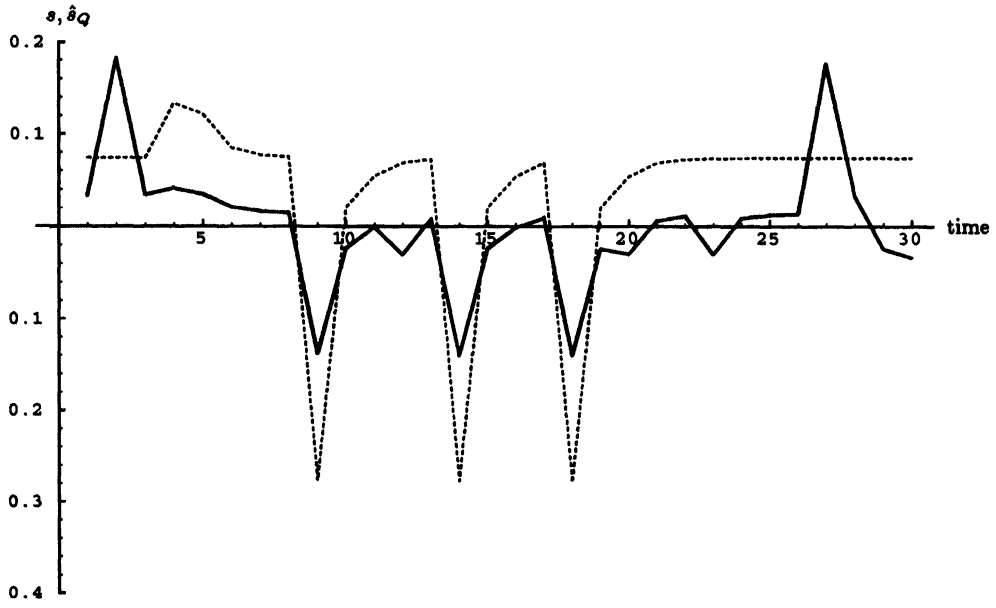

FIG. 5.3. *s=signal (dashed line), $\hat{s}_Q$=optimal quadratic estimate with $\Delta = 0$ (solid line).*

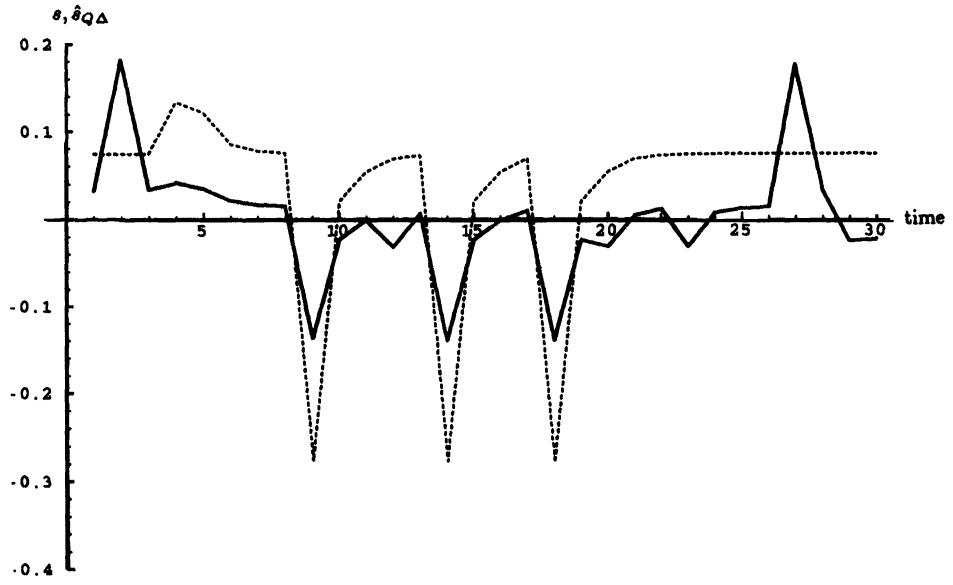

FIG. 5.4. *s=signal (dashed line), $\hat{s}_{Q\Delta}$=optimal quadratic estimate with $\Delta = 1$ (solid line).*

$$S_C = \begin{bmatrix} 0.00898 & -0.00085 & \dots \\ -0.00085 & 0.003711 & \dots \\ \vdots & \vdots & \ddots \end{bmatrix}, \qquad S_{Q\Delta} = \begin{bmatrix} 0.02773 & -0.00014 & \dots \\ -0.00014 & 0.00401 & \dots \\ \vdots & \vdots & \ddots \end{bmatrix},$$

where we have remarked only the 2×2 matrix blocks in the top left side for the matrices S_Q, S_C, and $S_{Q\Delta}$ because they contain in the main diagonal the steady-state estimate error covariance

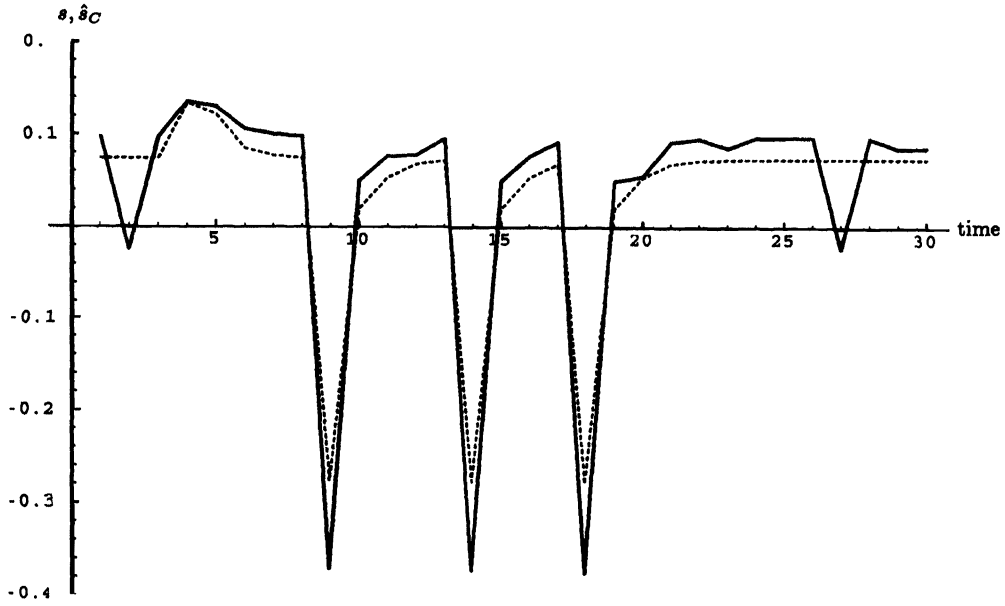

FIG. 5.5. *s=signal (dashed line), $\hat{s}_C$=optimal cubic estimate with $\Delta = 0$ (solid line).*

TABLE 5.1.

	Linear $\Delta = 0$	Quadratic $\Delta = 0$	Quadratic $\Delta = 1$	Cubic $\Delta = 0$
$\sigma^2_{(x-\hat{x})_1}$, $N = 30$	0.02188	0.01377	0.01373	0.00145
$\sigma^2_{(x-\hat{x})_2}$, $N = 30$	0.00181	0.00156	0.00156	0.00145
$\sigma^2_{(s-\hat{s})}$, $N = 30$	0.01084	0.00662	0.00660	0.00060
$\sigma^2_{(x-\hat{x})_1}$, $N = 5000$	0.03809	0.02800	0.02800	0.00913
$\sigma^2_{(x-\hat{x})_2}$, $N = 5000$	0.00429	0.00409	0.00409	0.00378
$\sigma^2_{(s-\hat{s})}$, $N = 5000$	0.01947	0.01422	0.01422	0.00447

of each component of the state. It results in $S_C(1,1) < S_Q(1,1) = S_{Q\Delta}(1,1) < S_L(1,1)$ and $S_C(2,2) < S_Q(2,2) = S_{Q\Delta}(2,2) < S_L(2,2)$. By executing the product CSC^T for all the filters implemented, where S is the block of interest in S_L, S_Q, $S_{Q\Delta}$, S_C, we have the corresponding values v_L, v_Q, $v_{Q\Delta}$, and v_C for the steady-state signal error variances

$$v_L = 0.01952,$$
$$v_Q = 0.01389,$$
$$v_{Q\Delta} = 0.01389,$$
$$v_C = 0.00438.$$

As expected, these values are close to the sampled ones obtained via numerical simulation. In Table 5.1 the sampled variances of the state and signal, obtained with a number of $N = 30$ and $N = 5000$ trials, are reported.

In the second example we will see a case where the quadratic filter with $\Delta = 1$ improves not only the simpler quadratic ($\Delta = 0$) one but also the cubic ($\Delta = 0$) one, showing the

TABLE 5.2.

	Linear $\Delta = 0$	Quadratic $\Delta = 0$	Quadratic $\Delta = 1$	Cubic $\Delta = 0$
$\sigma^2_{(x-\hat{x})}$, $N = 5000$	4.41906	1.88443	1.5012	1.84051
$\sigma^2_{(s-\hat{s})}$, $N = 5000$	2.8282	1.20604	0.96077	1.17793

nonexistence of any relation between ν and Δ. Let us consider a scalar system with

$$A = 0.6, \qquad C = 0.8,$$

and the following noises:

$$f(k)(\omega) = -\chi_{F_1}(\omega) + 3\chi_{F_2}(\omega) + 9\chi_{F_3}(\omega),$$
$$g(k)(\omega) = -9\chi_{G_1}(\omega) - 3\chi_{G_2}(\omega) + \chi_{G_3}(\omega),$$

$$P(F_1) = 15/18, \quad P(F_2) = 2/18, \quad P(F_3) = 1/18,$$
$$P(G_1) = 1/18, \quad P(G_2) = 2/18, \quad P(G_3) = 15/18,$$

where the two systems of disjoint events (F_1, F_2, F_3) and (G_1, G_2, G_3) are independent.

For this system the linear, quadratic, and cubic filters with $\Delta = 0$ and, moreover, the quadratic filter with $\Delta = 1$ have been implemented. Similar to the first example, we report the steady-state error covariance matrices S_L, S_Q, S_C, and $S_{Q\Delta}$ (which are 1×1, 2×2, 3×3, and 6×6, respectively) remarking the entry (1,1):

$$S_L = \begin{bmatrix} 4.39815 & * \\ * & * \end{bmatrix}, \qquad S_Q = \begin{bmatrix} 1.7734 & \dots \\ \vdots & \ddots \end{bmatrix},$$

$$S_C = \begin{bmatrix} 1.75661 & \dots \\ \vdots & \ddots \end{bmatrix}, \qquad S_{Q\Delta} = \begin{bmatrix} 1.53214 & \dots \\ \vdots & \ddots \end{bmatrix}.$$

The corresponding signal error variances are

$$v_L = 2.81482,$$
$$v_Q = 1.13498,$$
$$v_{Q\Delta} = 0.98057,$$
$$v_C = 1.12423.$$

Moreover, in Table 5.2 the error variance results for a numerical simulation with $N = 5000$ trials are reported.

Simulations of higher-order polynomial filters should require a more sophisticated numerical implementation, which is not the aim of this paper.

5.1. An example of polynomial estimate converging to the C.E. It would be of real practical interest (and also add further theoretic insight) to have some idea about the performance of the polynomial approximation, i.e., about the distance between the ideal and approximate estimate (given a particular model). For this purpose, let us consider the following model:

$$x(k) = f(k), \tag{5.1.1}$$
$$y(k) = x(k) + g(k),$$

where $\{f(k)\}, \{g(k)\}$ are scalar white sequences defined on some probability space $(\Omega, \mathcal{F}, P)$, independent of each other, defined as

$$f(k)(\omega) = -2\chi_{F_1}(\omega) + \chi_{F_2}(\omega),$$

$$g(k)(\omega) = -\chi_{G_1}(\omega) + \chi_{G_2}(\omega) + 2\chi_{G_3}(\omega),$$

where (F_1, F_2, F_3) and (G_1, G_2, G_3) are disjoint events having the following probabilities:

$$P(F_1) = 1/4, \quad P(F_2) = 1/2, \quad P(F_3) = 1/4,$$

$$P(G_1) = 4/7, \quad P(G_2) = 2/7, \quad P(G_3) = 1/7.$$

Because (5.1.1) is an instantaneous system it results in

$$\hat{x}(k) = E(x(k)/y(0), y(1), \ldots, y(k)) = E(x(k)/y(k)).$$

Moreover, $x(k)$ and $y(k)$ assume for any k only a finite number of values. Hence we have

$$\hat{x}(k)(\omega) = \sum_{i=1}^{6} \left(\sum_{j=1}^{3} x_j P(x(k)/y = y_i) \right) \chi_{\{y=y_i\}}(\omega). \tag{5.1.2}$$

Moreoever, being

$$y(k)(\omega) = -3\chi_{F_1 \cap G_1}(\omega) - \chi_{(F_1 \cap G_2) \cup (F_3 \cap G_1)}(\omega) + \chi_{F_3 \cap G_2}(\omega) + 2\chi_{(F_3 \cap G_3) \cup (F_2 \cap G_2)}(\omega) + 3\chi_{F_2 \cap G_3}(\omega),$$

by direct calculation and taking into account (5.1.2), we obtain

$$\hat{x}(k)(\omega) = -2\chi_{F_1 \cap G_1}(\omega) - (2/3)\chi_{(F_1 \cap G_2) \cup (F_3 \cap G_1)}(\omega) + (2/3)\chi_{(F_1 \cap G_3) \cup (F_2 \cap G_1)(\omega)} + (4/5)\chi_{(F_3 \cap G_3) \cup (F_2 \cap G_2)}(\omega) + \chi_{F_2 \cap G_3}(\omega),$$

and using this we can calculate the error variance

$$v_o = E((x(k) - \hat{x}(k))^2) = 0.504762.$$

By denoting with v_i, $i = 1, \ldots, 5$, the a priori error variances in the polynomial estimates of degree i, respectively, obtained by applying the polynomial filter to (5.1.1) it results in

$$\begin{aligned} v_1 &= 0.731707, \\ v_2 &= 0.615380, \\ v_3 &= 0.614835, \\ v_4 &= 0.567688, \\ v_5 &= 0.504762. \end{aligned}$$

Observe that $v_o = v_5$. This is not surprising because, from the fact that the observation takes values on a finite set of six numbers, it follows that an at most 5th-degree polynomial is the exact interpolator of $\hat{x}(k)$ versus $y(k)$.

In this example we can see how the polynomial estimates converge (as the polynomial degree increases) to the C.E., even in a finite number of steps.

6. Concluding remark. The method proposed allows us to obtain recursively a νth-order polynomial state estimate of the stochastic linear non-Gaussian system (3.1.1), (3.1.2). For this purpose, we have defined a new linear system in which the state and the observation are obtained in two steps: first of all by augmenting the original ones with the past values of the observations taken over a time window of fixed length Δ, then by aggregating the previous augmented vectors with their powers up to the νth order. The optimal linear estimate of the extended state with respect to the extended observations agrees with the optimal polynomial estimate (of finite memory Δ) with respect to the original observations, so that it can be obtained via the well-known Kalman filter.

It should be noted that denoting by $\sigma^2(\nu, \Delta)$ the signal error covariance (highlighting the dependence from the polynomial order ν and the memory Δ), from the above-developed theory it follows that for any ν,Δ

$$\sigma^2(\nu + 1, \Delta) \leq \sigma^2(\nu, \Delta),$$
$$\sigma^2(\nu, \Delta + 1) \leq \sigma^2(\nu, \Delta).$$

Moreover, $\sigma^2(\nu + 1, \Delta)$ and $\sigma^2(\nu, \Delta + 1)$ are not in any reciprocal relation, and this agrees with the results shown in the numerical simulations where the quadratic filter with $\Delta = 1$ gives, with respect to the cubic one with $\Delta = 0$, a worse and a better result in the first and second case, respectively. Finally, numerical simulations show the heavy inadequacy of optimal linear filtering in a non-Gaussian environment together with the high performance of polynomial filters. Of course this nice behavior is at the expense of growing computational complexity. Nevertheless, it should be stressed that this larger amount of calculations can be performed before the real time data processing, because they are mostly concerned with the computation of the covariance error matrix. Moreover, a further reduction of the filter dimensions can be obtained by using the reduced-order Kronecker powers.

Acknowledgment. The authors thank Prof. S. I. Marcus, the Associate Editor, and the anonymous referees for their critical reading and useful comments.

AN ENTROPY FORMULA FOR TIME-VARYING DISCRETE-TIME CONTROL SYSTEMS*

PABLO A. IGLESIAS†

Abstract. The results of this paper generalize the formula for the entropy of a transfer function to time-varying systems. This is done through the use of some results on spectral factorizations due to Arveson and properties of the $\mathcal{W}$-transform which generalizes the usual $\mathcal{Z}$-transform for time-varying systems. Using the formula defined, it is shown that for linear fractional transformations like those that arise in time-varying $\mathcal{H}_\infty$ control, there exists a unique, bounded contraction which maximizes the entropy. This generalizes known results in the time-invariant case. Possible extensions are discussed, along with state-space formulae.

Key words. time-varying systems, optimal control, spectral factorizations

AMS subject classifications. 93B36, 93C55, 93C50

1. Introduction.

Since the pioneering work of Zames [27], there has been much interest in finding stabilizing controllers which ensure that the $\mathcal{H}_\infty$ norm of a closed-loop transfer function is below a given number $\gamma > 0$. In particular, consider the system depicted in Figure 1.1, and suppose that the open-loop system is given by

$$\begin{bmatrix} z \\ y \end{bmatrix} = G \begin{bmatrix} w \\ u \end{bmatrix} = \begin{bmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{bmatrix} \begin{bmatrix} w \\ u \end{bmatrix},$$

where the signals w, z, y, and u are the external disturbance, output error, measured output, and control input, respectively. The goal of $\mathcal{H}_\infty$ control theory is to find a control law $u = Ky$ such that the closed-loop system, denoted

$$\mathcal{F}_\ell(G, K) = G_{11} + G_{12}K(I - G_{22}K)^{-1}G_{21},$$

has $\mathcal{H}_\infty$ norm less than γ, assuming that such a controller exists.

While early developments relied on transfer function and operator methods, a recent emphasis, based on the work of Glover and co-workers [5, 10], has been to approach the $\mathcal{H}_\infty$ control problem using state-space methods. Glover et al. have shown that the existence of stabilizing controllers achieving the required norm bound is equivalent to the existence of positive semidefinite, stabilizing solutions to two indefinite algebraic Riccati equations. Because of this connection with algebraic Riccati equations, these results are reminiscent of earlier work on linear quadratic Gaussian (LQG) control.

A complete characterization of all controllers achieving the closed-loop $\mathcal{H}_\infty$ norm bound is given in [10]. Assuming that a controller exists such that $\|\mathcal{F}_\ell(G, K)\|_\infty < \gamma$, it can be shown that the set of all such controllers can also be parameterized by a linear fractional transformation of a specific controller K_a and a stable contraction Q:

$$K = \mathcal{F}_\ell(K_a, Q), \qquad \|Q\|_\infty < 1.$$

Given this parameterization, it is easy to see that all possible closed-loop transfer functions satisfying $\|\mathcal{F}_\ell(G, K)\|_\infty < \gamma$ are given by

$$\mathcal{F}_\ell(G, \mathcal{F}_\ell(K_a, Q)) = \mathcal{F}_\ell(J, Q) =: H(Q)$$

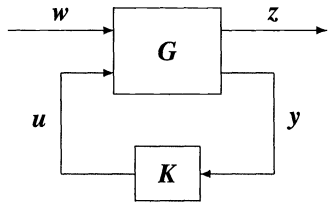

FIG. 1.1. *Closed-loop system.*

for some J. To choose among this "ball" of solutions, it has been proposed that the controller selected be chosen so as to maximize the following "entropy" integral (see [2, 6, 11, 9]):

$$I_d(H(Q),\gamma,\lambda_0) := \frac{\gamma^2}{2\pi}\int_{-\pi}^{\pi} \ln\left|\det\left(I-\gamma^{-2}H^{\sim}(e^{i\omega})H(e^{i\omega})\right)\right| \frac{1-|\lambda_0|^2}{|e^{i\omega}-\lambda_0|^2}d\omega. \tag{1.1}$$

The benefits of using controllers which maximize this entropy integral are outlined in the monograph [21], which treats the continuous-time case, and [16, 15] for the discrete-time case. As shown in [21], these controllers can be thought of as lying between $\mathcal{H}_\infty$ optimal controllers and LQG optimal controllers. Specifically, I_d exhibits some normlike properties; it is monotonically decreasing with respect to γ, and it bounds the LQG cost of the closed-loop system. It has the added property that controllers which maximize the entropy are also optimal with respect to the risk-sensitive control problem of stochastic control theory [25].

Owing to the similarities between $\mathcal{H}_\infty$ control and classical LQG control, which were highlighted in [5], many straightforward extensions have now appeared. In this paper we are particularly interested in controllers for time-varying systems as have been considered in [20, 19, 22]. While the controllers achieving a norm bound can also be written as a linear fractional transformation of an operator K_a and a stable contractive operator Q, it is not clear how to choose among the possible controllers, since the entropy integral (1.1) is given in terms of the transfer functions and is therefore not amenable to time-varying systems. In this paper we give a generalization of the entropy integral for discrete-time, time-varying systems. This generalization will be based on the $\mathcal{W}$-transform, introduced by Alpay, Dewilde, and Dym [1] in the context of interpolation problems for nonstationary processes. As in the stationary case, the entropy defined here for control systems will be related to the entropy used in [12] in the context of interpolants for band extension problems.

In the study of linear time-invariant controllers, the entropy evaluated at $\lambda_0 = 0$ is of particular importance. In this case, it can be shown that the integral (1.1) is an upper bound for the $\mathcal{H}_2$ norm of the transfer function. For our time-varying systems, our entropy definition will deal only with the analogous evaluation at the origin. We will outline the difficulties that arise in generalizing this definition.

The rest of the paper will be organized as follows. We begin by introducing the $\mathcal{W}$-transform in §2 and giving some of its properties. In §3, the definition of the entropy for time-varying systems is given. In §4 we show that for systems that can be expressed as linear fractional transformations of linear, causal, contractive operators, the entropy defined has a maximum. Some possible extensions of the theory are discussed in §5, and, finally, in §6 we give some conclusions.

2. Preliminaries. In this section we introduce the notation and present some preliminary results concerning operators and the $\mathcal{W}$-transform that will be needed in the rest of the paper. Most of these results are taken from [1]. Note that the presentation in [1] assumes that causal

operators are represented as upper triangular matrices. In our presentation, we will use the more common representation of causal operators as lower triangular operators.

2.1. Notation. Let $\boldsymbol{x} = \{x(k) : k \in \mathbb{Z}\}$ denote a sequence of vectors $x(k) \in \mathbb{C}^n$. The set of all such sequences is denoted $\mathcal{S}^n$. The subset of $\mathcal{S}^n$ of square-summable sequences is ℓ_2^n. The space ℓ_2^n is a Hilbert space with inner product

$$\langle \boldsymbol{x}, \boldsymbol{y} \rangle := \sum_{-\infty}^{\infty} x^*(k) y(k)$$

and induced norm $\|\boldsymbol{x}\| := \sqrt{\langle \boldsymbol{x}, \boldsymbol{x} \rangle}$.

Let $\boldsymbol{G}$ represent a linear operator from ℓ_2^m to ℓ_2^p. Then $\boldsymbol{G}$ has a natural representation as a doubly infinite matrix $\{G(i, j)\}$, $i, j \in \mathbb{Z}$, $G(i, j) \in \mathbb{C}^{p \times m}$. We will denote the operation $\boldsymbol{y} = \boldsymbol{G}\boldsymbol{u}$ as follows:

$$\begin{bmatrix} \vdots \\ y(-1) \\ \boxed{y(0)} \\ y(1) \\ \vdots \end{bmatrix} = \begin{bmatrix} \ddots & \vdots & \vdots & \vdots & \\ \cdots & G(-1,-1) & G(-1,0) & G(-1,1) & \cdots \\ \cdots & G(0,-1) & \boxed{G(0,0)} & G(0,1) & \cdots \\ \cdots & G(1,-1) & G(1,0) & G(1,1) & \cdots \\ & \vdots & \vdots & \vdots & \ddots \end{bmatrix} \begin{bmatrix} \vdots \\ u(-1) \\ \boxed{u(0)} \\ u(1) \\ \vdots \end{bmatrix}.$$

The box around the elements in the vectors (resp., matrix) denotes the element with index 0 (resp., 0, 0).

Let $\mathfrak{X}^{p \times m}$ denote the space of bounded linear operators from the space ℓ_2^m to ℓ_2^p. The subspace of $\mathfrak{X}^{p \times m}$ consisting of causal (resp., diagonal) operators is denoted $\mathfrak{L}^{p \times m}$ (resp., $\mathfrak{D}^{p \times m}$).

We will usually drop the superscript on these spaces; the Hilbert spaces on which the operators act should be clear from the context. We write $\mathfrak{X}^{-1}$ to mean the space of operators whose inverses are in $\mathfrak{X}$. Similar expressions are used for $\mathfrak{L}$ and $\mathfrak{D}$.

For operators in $\mathfrak{X}$, the following two facts will be useful. Proofs may be found in [1].

LEMMA 2.1. *For an operator $\boldsymbol{X} \in \mathfrak{X}$, the elements $X(i, j)$ satisfy*

$$\|\boldsymbol{X}(i, j)\| \leq \|\boldsymbol{X}\| \qquad (\forall i, j).$$

LEMMA 2.2. *If $\boldsymbol{D} \in \mathfrak{D}$ is a diagonal operator, then*

$$\|\boldsymbol{D}\| = \sup_i \|D(i)\|.$$

In subsequent discussion, the forward shift operator will play a prominent role. This is the operator $\boldsymbol{Z} \in \mathfrak{X}^{m \times m}$:

$$\boldsymbol{Z} \begin{bmatrix} \vdots \\ y(-1) \\ \boxed{y(0)} \\ y(1) \\ \vdots \end{bmatrix} = \begin{bmatrix} \vdots \\ y(0) \\ \boxed{y(1)} \\ y(2) \\ \vdots \end{bmatrix}.$$

This operator has a matrix representation

$$\boldsymbol{Z} = \{Z(i, j)\} = \begin{cases} I_m, & j - i = 1, \\ 0 & \text{otherwise.} \end{cases}$$

One other useful operator is the projection operator $\boldsymbol{P}_k \in \mathfrak{D}^{m\times m}$, which has a matrix representation $\boldsymbol{P}_k = \{P(i,i)\}$, where

$$P(i,i) = \begin{cases} I_m & \text{if } i < k, \\ 0 & \text{otherwise.} \end{cases}$$

2.2. The $\mathcal{W}$-transform. In order to consider interpolation problems for non-Toeplitz operators, Alpay, Dewilde, and Dym introduced a generalization of the usual Fourier transform on sequences, known as the $\mathcal{W}$-transform. In this section we provide an introduction to this transform as well as some of its properties. Details may be found in [1].

Given an operator $\boldsymbol{G} \in \mathfrak{X}^{p\times m}$, $\boldsymbol{G} = \{G(i,j)\}$, we define the set of diagonal operators $\boldsymbol{G}_{[k]}$ corresponding to the kth subdiagonal shifted up to the diagonal:

$$\boldsymbol{G}_{[k]} = \operatorname{diag}\{\ldots, G(-1,-1-k), \boxed{G(0,-k)}, G(1,1-k), \ldots\}.$$

From Lemmas 2.1 and 2.2,

$$\left\|\boldsymbol{G}_{[k]}\right\| = \sup_i \|G(i,i-k)\| \le \|\boldsymbol{G}\|.$$

An operator $\boldsymbol{G} \in \mathfrak{L}$ has a unique representation as a series in terms of the $\boldsymbol{G}_{[k]}$ as follows:

$$\boldsymbol{G} = \sum_{k=0}^{\infty} \boldsymbol{G}_{[k]} (\boldsymbol{Z}^*)^k,$$

where the sum converges weakly [28].

Let $\boldsymbol{X} \in \mathfrak{X}$. We denote by $\sigma(\boldsymbol{X})$ the spectrum of $\boldsymbol{X}$ and by $\rho(\boldsymbol{X})$ the spectral radius of $\boldsymbol{X}$. It is well known that

$$\begin{aligned} \rho(\boldsymbol{X}) &:= \max\{|\lambda| : \lambda \in \sigma(\boldsymbol{X})\} \\ &= \lim_{n\to\infty} \left\|\boldsymbol{X}^n\right\|^{1/n}. \end{aligned}$$

Finally, for $\boldsymbol{W} \in \mathfrak{D}$, we define

$$\ell(\boldsymbol{W}) := \rho(\boldsymbol{W}\boldsymbol{Z}^*).$$

We are now ready to introduce the $\mathcal{W}$-transform.

DEFINITION 2.3. *Let $\boldsymbol{G} \in \mathfrak{L}$ and $\boldsymbol{W} \in \mathfrak{D}$, with $\ell(\boldsymbol{W}) < 1$. We define*

$$\widehat{\boldsymbol{G}}(\boldsymbol{W}) := \sum_{k=0}^{\infty} \boldsymbol{G}_{[k]} (\boldsymbol{Z}^*)^k (\boldsymbol{Z}\boldsymbol{W})^k. \tag{2.1}$$

This series will converge in norm, provided that $\ell(\boldsymbol{W}) < 1$. The transform (2.1) acts like the λ-transform[1] of a sequence in $\mathbb{C}^n$. Note that in this case, the transform is taken of a sequence $\{\boldsymbol{G}_{[k]}\}$ of operators in $\mathfrak{D}$. In terms of the doubly infinite matrix representation $\boldsymbol{G} = \{G(i,j)\}$ and $\boldsymbol{W} = \operatorname{diag}\{W(i)\}$,

$$(\boldsymbol{Z}^*)^k (\boldsymbol{Z}\boldsymbol{W})^k = \operatorname{diag}\{W(i)W(i+1)\cdots W(i+k-1)\}, \qquad k \ge 1,$$

and hence the $\mathcal{W}$-transform can be written as

$$\widehat{\boldsymbol{G}}(\boldsymbol{W}) = \operatorname{diag}\left\{\sum_{k=0}^{\infty} G(i,i-k)W(i-k+1)W(i-k+2)\cdots W(i-1)W(i)\right\}. \tag{2.2}$$

[1]The λ-transform is just the $\mathcal{Z}$-transform with z^{-1} replaced by λ.

In order to illustrate some of the properties of the $\mathcal{W}$-transform, we provide some examples.

Example 2.4 (time-invariant systems). Suppose that $\boldsymbol{G} \in \mathfrak{L}$ represents a time-invariant operator. Then $\boldsymbol{G}$ has a characterization as a block Toeplitz matrix $\boldsymbol{G} = \{G(i, i-k)\}$ with $G(i, i-k) = g_k$. And thus $\boldsymbol{G}_{[k]} = \operatorname{diag}\{\ldots, g_k, \boxed{g_k}, g_k, \ldots\}$, $k \in \mathbb{Z}_+$. We wish to evaluate this at $W = \lambda \boldsymbol{I}$, where $\lambda \in \mathbb{C}$, $|\lambda| < 1$, and $\boldsymbol{I}$ is the identity operator in $\mathfrak{X}$. Then

$$\widehat{\boldsymbol{G}}(\boldsymbol{W}) = \sum_{k=0}^{\infty} \boldsymbol{G}_{[k]} (\boldsymbol{Z}^*)^k (\lambda \boldsymbol{Z})^k = \sum_{k=0}^{\infty} \lambda^k \boldsymbol{G}_{[k]} = \operatorname{diag}\{G(\lambda)\},$$

where $G(\lambda)$ is the usual λ-transform of the sequence $\{g_k\}$.

Example 2.5 (frozen-time systems). Consider a general causal time-varying operator $\boldsymbol{G}$, but evaluate this as in the previous example at $\boldsymbol{W} = \lambda \boldsymbol{I}$. This gives

$$\widehat{\boldsymbol{G}}(\boldsymbol{W}) = \operatorname{diag}\{\ldots, G_{-1}(\lambda), \boxed{G_0(\lambda)}, G_1(\lambda), \ldots\},$$

where

$$G_i(\lambda) = \sum_{k=0}^{\infty} G(i, i-k) \lambda^k, \qquad i \in \mathbb{Z},$$

is the λ-transform of the frozen-time system at time i. These frozen-time systems have received considerable interest recently in the study of slowly time-varying systems [23, 24, 28].

In what follows we will be interested primarily in the evaluation of $\widehat{\boldsymbol{G}}(\boldsymbol{W})$ at $\boldsymbol{W} = \boldsymbol{0}$. In this case it is easy to see that $\widehat{\boldsymbol{G}}(\boldsymbol{W}) = \boldsymbol{G}_{[0]}$, that is, the diagonal element of the operator $\boldsymbol{G}$.

2.3. $\mathcal{W}$-transform of a state-space system. Consider the system

$$\Sigma_G := \left\{ \begin{array}{rcl} x(k+1) & = & A(k)x(k) + B(k)u(k), \quad k \in \mathbb{Z}^+, \\ y(k) & = & C(k)x(k) + D(k)u(k). \end{array} \right. \tag{2.3}$$

Define the following operator in $\mathfrak{D}$:

$$\boldsymbol{A} := \operatorname{diag}(\ldots, 0, 0, \boxed{A(0)}, A(1), A(2), \ldots),$$

with similar representations for $\boldsymbol{B}$, $\boldsymbol{C}$, and $\boldsymbol{D}$. Let $\boldsymbol{x}$, $\boldsymbol{y}$, and $\boldsymbol{z}$ represent the elements of $\mathcal{S}^n$, $\mathcal{S}^p$, and $\mathcal{S}^m$ corresponding to the $x(k)$, $y(k)$, and $u(k)$. We can express the state-space equations (2.3) as

$$\begin{aligned} \boldsymbol{Z}\boldsymbol{x} &= \boldsymbol{A}\boldsymbol{x} + \boldsymbol{B}\boldsymbol{u}, \\ \boldsymbol{y} &= \boldsymbol{C}\boldsymbol{x} + \boldsymbol{D}\boldsymbol{u}. \end{aligned} \tag{2.4}$$

The operator mapping $\boldsymbol{u}$ to $\boldsymbol{y}$ is the $\mathfrak{L}$ operator:

$$\begin{aligned} \boldsymbol{G} &:= \boldsymbol{C}(\boldsymbol{Z} - \boldsymbol{A})^{-1}\boldsymbol{B} + \boldsymbol{D} \\ &= \boldsymbol{C}\left(\sum_{k=0}^{\infty} (\boldsymbol{Z}^*\boldsymbol{A})^k\right)\boldsymbol{Z}^*\boldsymbol{B} + \boldsymbol{D} \\ &=: \left[\begin{array}{c|c} \boldsymbol{A} & \boldsymbol{B} \\ \hline \boldsymbol{C} & \boldsymbol{D} \end{array}\right]. \end{aligned} \tag{2.5}$$

The series in (2.5) converges, provided that $\rho(\boldsymbol{Z}^*\boldsymbol{A}) < 1$. It can be shown that this condition is equivalent to uniform exponential stability of the autonomous system in (2.3) [18, 13].

For this linear time-varying system, we wish to calculate the $\mathcal{W}$-transform of $\boldsymbol{G}$ for $\boldsymbol{W} = \operatorname{diag}\{W(i)\}$. First of all,

$$\boldsymbol{G}_{[k]} := \begin{cases} \boldsymbol{CZ}^*(\boldsymbol{AZ}^*)^{k-1}\boldsymbol{BZ}^k & \text{for } k > 0, \\ \boldsymbol{D}, & k = 0, \\ \boldsymbol{0}, & k < 0. \end{cases}$$

Thus

$$\begin{aligned} \widehat{\boldsymbol{G}}(\boldsymbol{W}) &= \boldsymbol{D} + \boldsymbol{CZ}^* \sum_{k=1}^{\infty} (\boldsymbol{AZ}^*)^{k-1}\boldsymbol{B}(\boldsymbol{ZW})^k \\ &= \operatorname{diag}\left\{ D(i) + \sum_{k=0}^{\infty} C(i)\Phi_A(i, i-k+1)B(i-k)\Phi_W(i-k, i) \right\}. \end{aligned}$$

Here, Φ represents the transition matrix of the sequences $\boldsymbol{A}$ and $\boldsymbol{W}$, that is,

$$\Phi_A(i, j) = \begin{cases} I & \text{for } i = j, \\ A(i-1)A(i-2)\cdots A(j) & \text{for } i > j, \\ A(i+1)A(i+2)\cdots A(j) & \text{for } i < j. \end{cases}$$

2.4. Properties of the $\mathcal{W}$-transform. In this section we outline some properties of the $\mathcal{W}$-transform.

LEMMA 2.6. *Let $\boldsymbol{G} \in \mathfrak{X}$ and $\boldsymbol{D}, \boldsymbol{W} \in \mathfrak{D}$ with $\ell(\boldsymbol{W}) < 1$; then*

$$\widehat{\boldsymbol{DG}}(\boldsymbol{W}) = \boldsymbol{D}\widehat{\boldsymbol{G}}(\boldsymbol{W}).$$

Proof. Using the identity

$$(\boldsymbol{DG})_{[k]} = \boldsymbol{DG}_{[k]},$$

the proof is straightforward. □

For the next property we need a special operator. Let $\boldsymbol{D} \in \mathfrak{D}$. We define

$$\boldsymbol{D}^{(k)} := (\boldsymbol{Z}^*)^k \boldsymbol{D}(\boldsymbol{Z})^k \in \mathfrak{D}.$$

This operator has the effect of moving the elements of the diagonal $\boldsymbol{D}$ "down" k steps.

LEMMA 2.7. *Let $\boldsymbol{G} \in \mathfrak{X}$, $\boldsymbol{D} \in \mathfrak{D} \cap \mathfrak{D}^{-1}$, and $\boldsymbol{W} \in \mathfrak{D}$ with $\ell(\boldsymbol{W}) < 1$; then*

$$\widehat{\boldsymbol{GD}}(\boldsymbol{W}) = \hat{\boldsymbol{G}}(\boldsymbol{D}^{(1)}\boldsymbol{W}\boldsymbol{D}^{-1})\boldsymbol{D}.$$

Proof. First, note that

$$\boldsymbol{G}_{[k]}(\boldsymbol{Z}^*)^k\boldsymbol{D} = [\boldsymbol{GD}]_{[k]}(\boldsymbol{Z}^*)^k. \tag{2.6}$$

It follows that

$$\begin{aligned} \hat{\boldsymbol{G}}(\boldsymbol{D}^{(1)}\boldsymbol{W}\boldsymbol{D}^{-1})\boldsymbol{D} &= \left(\sum_{k=0}^{\infty} \boldsymbol{G}_{[k]}(\boldsymbol{Z}^*)^k \left(\boldsymbol{Z}\left[\boldsymbol{Z}^*\boldsymbol{DZWD}^{-1}\right]\right)^k \right) \boldsymbol{D} \\ &= \sum_{k=0}^{\infty} \boldsymbol{G}_{[k]}(\boldsymbol{Z}^*)^k \boldsymbol{D}(\boldsymbol{ZW})^k \\ &= \sum_{k=0}^{\infty} [\boldsymbol{GD}]_{[k]}(\boldsymbol{Z}^*)^k(\boldsymbol{ZW})^k \end{aligned}$$

as required. □

The following corollary is straightforward.

COROLLARY 2.8. *Let* $\boldsymbol{G} \in \mathfrak{X}$ *and* $\boldsymbol{D} \in \mathfrak{D}$; *then*

$$\widehat{\boldsymbol{GD}}(\boldsymbol{0}) = \widehat{\boldsymbol{G}}(\boldsymbol{0})\boldsymbol{D}.$$

The following result and, more important, its corollary will be crucial to the results that follow.

LEMMA 2.9. *Let* $\boldsymbol{G}, \boldsymbol{H} \in \mathfrak{X}$, *and* $\boldsymbol{W} \in \mathfrak{D}$ *with* $\ell(\boldsymbol{W}) < 1$; *then*

$$\widehat{\boldsymbol{GH}}(\boldsymbol{W}) = \widehat{\boldsymbol{G}}\widehat{\boldsymbol{H}}(\boldsymbol{W})(\boldsymbol{W}).$$

Proof. See [1, Lem. 3.7]. □

Finally, the following corollary combines the results of Lemma 2.9 and Corollary 2.8.

COROLLARY 2.10. *Let* $\boldsymbol{G}, \boldsymbol{H} \in \mathfrak{X}$; *then*

$$\widehat{\boldsymbol{GH}}(\boldsymbol{0}) = \widehat{\boldsymbol{G}}(\boldsymbol{0})\widehat{\boldsymbol{H}}(\boldsymbol{0}).$$

2.5. Spectral factorizations. For our definition of entropy, we require spectral factorizations of operators. The following lemma, due to Arveson, guarantees the existence of a spectral factor for positive self-adjoint operators.

LEMMA 2.11 (see [3]). *Suppose that* $\boldsymbol{G} \in \mathfrak{X} \cap \mathfrak{X}^{-1}$ *is a positive, self-adjoint operator. There exist operators* $\boldsymbol{A}, \boldsymbol{B} \in \mathfrak{L} \cap \mathfrak{L}^{-1}$ *such that*

$$\boldsymbol{G} = \boldsymbol{A}^*\boldsymbol{A} = \boldsymbol{B}^*\boldsymbol{B}.$$

Moreover, $\boldsymbol{A} = \boldsymbol{DB}$ *where* $\boldsymbol{D} \in \mathfrak{D} \cap \mathfrak{D}^{-1}$ *and* $\boldsymbol{D}^*\boldsymbol{D} = \boldsymbol{I}$.

2.5.1. State-space formulae. We are interested in computing spectral factorizations for operators of the form $\boldsymbol{I} - \boldsymbol{G}^*\boldsymbol{G}$, where $\|\boldsymbol{G}\| < 1$ and $\boldsymbol{G}$ is given by (2.4). The following result provides a state-space equation for a particular spectral factorization.

THEOREM 2.12 (see [17]). *Suppose that* $\boldsymbol{G}$ *is given by* (2.4) *with* $\rho(\boldsymbol{Z}^*\boldsymbol{A}) < 1$. *The following statements are equivalent:*

1. $\boldsymbol{I} - \boldsymbol{G}^*\boldsymbol{G} > 0$.
2. *There exists a uniformly bounded solution* $\boldsymbol{X} = \boldsymbol{X}^* \geq 0$ *to the operator algebraic Riccati equation*

$$\boldsymbol{X} = \boldsymbol{A}^*\boldsymbol{ZXZ}^*\boldsymbol{A} + \boldsymbol{C}^*\boldsymbol{C} + \left(\boldsymbol{A}^*\boldsymbol{ZXZ}^*\boldsymbol{B} + \boldsymbol{C}^*\boldsymbol{D}\right)\boldsymbol{V}^{-1}\left(\boldsymbol{B}^*\boldsymbol{ZXZ}^*\boldsymbol{A} + \boldsymbol{D}^*\boldsymbol{C}\right)$$

with $\boldsymbol{V} := \boldsymbol{I} - \boldsymbol{D}^*\boldsymbol{D} - \boldsymbol{B}^*\boldsymbol{ZXZ}^*\boldsymbol{B} > \boldsymbol{0}$ *and* $\boldsymbol{A} + \boldsymbol{BV}^{-1}\left(\boldsymbol{B}^*\boldsymbol{ZXZ}^*\boldsymbol{A} + \boldsymbol{D}^*\boldsymbol{C}\right)$ *uniformly exponentially stable.*

3. *The operator* $\boldsymbol{I} - \boldsymbol{G}^*\boldsymbol{G}$ *has a spectral factorization, i.e.,*

$$\boldsymbol{I} - \boldsymbol{G}^*\boldsymbol{G} = \boldsymbol{M}^*\boldsymbol{M}$$

with

$$\boldsymbol{M} = \left[\begin{array}{c|c} \boldsymbol{A} & \boldsymbol{B} \\ \hline -\boldsymbol{V}^{-1/2}\left(\boldsymbol{B}^*\boldsymbol{ZXZ}^*\boldsymbol{A} + \boldsymbol{D}^*\boldsymbol{C}\right) & \boldsymbol{V}^{1/2} \end{array}\right].$$

For conciseness we have chosen to write the Riccati equation as an operator algebraic Riccati equation in this theorem. An equivalent representation of this equation is in terms of a recursive Riccati difference equation:

$$\begin{aligned} X_k = {} & A_k^T X_{k+1} A_k + C_k^T C_k \\ & + (A_k^T X_{k+1} B_k + C_k^T D_k) V_k^{-1} (B_k^T X_{k+1} A_k + D_k^T C_k), \end{aligned}$$

where $V_k := I - D_k^T D_k - B_k^T X_{k+1} B_k$. Note that this recursion has no terminal condition.

3. Time-varying entropy.

3.1. Entropy operator. In this section we present our definition of the entropy for a linear time-varying operator $\boldsymbol{G}$.

Suppose that $\boldsymbol{G} \in \mathfrak{X}$ has operator norm $\|\boldsymbol{G}\| < \gamma$. It follows that the self-adjoint operator $\boldsymbol{I} - \gamma^{-2}\boldsymbol{G}^*\boldsymbol{G}$ is positive. By Lemma 2.11, it has a spectral factor $\boldsymbol{M}$. Using this spectral factor we begin by defining an entropy *operator*.

DEFINITION 3.1. *Suppose that* $\boldsymbol{G} \in \mathfrak{X}$ *and* $\|\boldsymbol{G}\| < \gamma$. *Let* $\boldsymbol{M} \in \mathfrak{L} \cap \mathfrak{L}^{-1}$ *be a spectral factor of the positive operator* $\boldsymbol{I} - \gamma^{-2}\boldsymbol{G}^*\boldsymbol{G}$ *and* $\boldsymbol{W} \in \mathfrak{D}$ *be a diagonal operator with* $\ell(\boldsymbol{W}) < 1$. *We define*

$$\boldsymbol{E}(\boldsymbol{G}, \gamma, \boldsymbol{W}) := \widehat{\boldsymbol{M}}^*(\boldsymbol{W})\widehat{\boldsymbol{M}}(\boldsymbol{W}). \tag{3.1}$$

Since spectral factors are not unique, in order for the expression in (3.1) to make sense, we must show that it does not depend on the particular spectral factor chosen. Suppose that

$$\boldsymbol{I} - \gamma^{-2}\boldsymbol{G}^*\boldsymbol{G} = \boldsymbol{M}^*\boldsymbol{M} = \boldsymbol{N}^*\boldsymbol{N},$$

where, from Lemma 2.11, we know that $\boldsymbol{M} = \boldsymbol{D}\boldsymbol{N}$ for some $\boldsymbol{D} \in \mathfrak{D}$ such that $\boldsymbol{D}^*\boldsymbol{D} = \boldsymbol{I}$. Let

$$\boldsymbol{E}_1(\boldsymbol{G}, \gamma, \boldsymbol{W}) := \widehat{\boldsymbol{M}}^*(\boldsymbol{W})\widehat{\boldsymbol{M}}(\boldsymbol{W}), \qquad \boldsymbol{E}_2(\boldsymbol{G}, \gamma, \boldsymbol{W}) := \widehat{\boldsymbol{N}}^*(\boldsymbol{W})\widehat{\boldsymbol{N}}(\boldsymbol{W}).$$

Now, from Lemma 2.6

$$\begin{aligned}\widehat{\boldsymbol{M}}(\boldsymbol{W}) &= \widehat{\boldsymbol{D}\boldsymbol{N}}(\boldsymbol{W}) \\ &= \boldsymbol{D}\widehat{\boldsymbol{N}}(\boldsymbol{W}).\end{aligned}$$

Thus,

$$\begin{aligned}\boldsymbol{E}_1(\boldsymbol{G}, \gamma, \boldsymbol{W}) &= \widehat{\boldsymbol{M}}^*(\boldsymbol{W})\widehat{\boldsymbol{M}}(\boldsymbol{W}) \\ &= \widehat{\boldsymbol{N}}^*(\boldsymbol{W})\boldsymbol{D}^*\boldsymbol{D}\widehat{\boldsymbol{N}}(\boldsymbol{W}) \\ &= \widehat{\boldsymbol{N}}^*(\boldsymbol{W})\widehat{\boldsymbol{N}}(\boldsymbol{W}) \\ &= \boldsymbol{E}_2(\boldsymbol{G}, \gamma, \boldsymbol{W}).\end{aligned}$$

The entropy operator (3.1) has many of the properties that the integral (1.1) exhibits for time-invariant systems. In the next lemma we outline some of these properties. Since we are primarily interested in the $\boldsymbol{W} = \boldsymbol{0}$ case, we abbreviate the notation for this special case: $\boldsymbol{E}(\boldsymbol{G}, \gamma) := \boldsymbol{E}(\boldsymbol{G}, \gamma, \boldsymbol{0})$.

LEMMA 3.2. *With the notation of Definition* 3.1 *we have*

(i) $\boldsymbol{E}(\boldsymbol{G}, \gamma) \geq \boldsymbol{0}$.

(ii) $\boldsymbol{E}(\boldsymbol{G}, \gamma) \leq \boldsymbol{I}$ *with equality iff* $\boldsymbol{G} \equiv \boldsymbol{0}$.

(iii) *If* $\boldsymbol{U} \in \mathfrak{X}$, $\boldsymbol{V} \in \mathfrak{L}$ *with* $\boldsymbol{U}^*\boldsymbol{U} = \boldsymbol{I}$ *and* $\boldsymbol{V}^*\boldsymbol{V} = \boldsymbol{I}$, *then*

$$\boldsymbol{E}(\boldsymbol{U}\boldsymbol{G}\boldsymbol{V}, \gamma) = \widehat{\boldsymbol{V}}^*(\boldsymbol{0})\boldsymbol{E}(\boldsymbol{G}, \gamma)\widehat{\boldsymbol{V}}(\boldsymbol{0}).$$

Proof. Property (i) is straightforward. For property (ii), note from Lemmas 2.1 and 2.2 that since $\widehat{\boldsymbol{M}}(\boldsymbol{0}) = \boldsymbol{M}_{[0]}$,

$$\left\|\widehat{\boldsymbol{M}}(\boldsymbol{0})\right\| = \sup_i \|\boldsymbol{M}(i, i)\| \leq \|\boldsymbol{M}\| \leq 1$$

with equality only when $\boldsymbol{G} \equiv \boldsymbol{0}$. Thus

$$\boldsymbol{I} - \widehat{\boldsymbol{M}}^*(\boldsymbol{0})\widehat{\boldsymbol{M}}(\boldsymbol{0}) \geq \boldsymbol{0}$$

and hence $\boldsymbol{E}(\boldsymbol{G}, \gamma) \leq \boldsymbol{I}$.

To show (iii), first note that

$$\|\boldsymbol{UGV}\| \leq \|\boldsymbol{U}\| \, \|\boldsymbol{G}\| \, \|\boldsymbol{V}\| = \|\boldsymbol{G}\| < \gamma.$$

Thus

$$\begin{aligned} \boldsymbol{I} - \gamma^{-2}(\boldsymbol{UGV})^*(\boldsymbol{UGV}) &= \boldsymbol{V}^* \left(\boldsymbol{I} - \gamma^{-2}\boldsymbol{G}^*\boldsymbol{G}\right) \boldsymbol{V} \\ &= (\boldsymbol{MV})^*(\boldsymbol{MV}). \end{aligned}$$

Since $\boldsymbol{M}$ and $\boldsymbol{V} \in \mathfrak{L}$, the product $\boldsymbol{MV} \in \mathfrak{L}$. Thus $\boldsymbol{MV}$ is a spectral factor for

$$\boldsymbol{I} - \gamma^{-2}(\boldsymbol{UGV})^*(\boldsymbol{UGV}).$$

Using Corollary 2.10, we have

$$\widehat{\boldsymbol{MV}}(\boldsymbol{0}) = \widehat{\boldsymbol{M}}(\boldsymbol{0})\widehat{\boldsymbol{V}}(\boldsymbol{0}),$$

which proves property (iii). □

We now show that this definition of the entropy is a natural generalization of the entropy integral (1.1) by showing that, for time-invariant systems, the two entropies are strongly related.

PROPOSITION 3.3. *Suppose that $\boldsymbol{G} \in \mathfrak{L}$ and that $\boldsymbol{G}$ represents a time-invariant system (that is, $\boldsymbol{G}$ commutes with the shift $\boldsymbol{Z}$). Then $\boldsymbol{E}(\boldsymbol{G}, \gamma, \lambda \boldsymbol{I})$ is a diagonal operator with constant matrix elements along the diagonal, i.e.,*

$$\boldsymbol{E}(\boldsymbol{G}, \gamma, \lambda \boldsymbol{I}) = \operatorname{diag}\{\ldots, E_0, \boxed{E_0}, E_0, \cdots\}. \tag{3.2}$$

Moreover, if $G(\lambda)$ is the transfer function associated with this operator, the entropies $\boldsymbol{E}(\boldsymbol{G}, \gamma, \lambda_0 \boldsymbol{I})$ and $I_d(G, \gamma, \lambda_0)$ are related by

$$I_d(G, \gamma, \lambda_0) = \gamma^2 \ln |\det E_0|. \tag{3.3}$$

Proof. We first evaluate $I_d(G, \gamma, \lambda_0)$. Suppose that

$$I - \gamma^{-2} G^{\sim}(\lambda) G(\lambda) = M^{\sim}(\lambda) M(\lambda)$$

is a spectral factorization. It follows that

$$\begin{aligned} I_d(G, \gamma, \lambda_0) &= \frac{\gamma^2}{\pi} \int_{-\pi}^{\pi} \ln \left|\det \left(M(e^{i\omega})\right)\right| \frac{1 - |\lambda_0|^2}{|e^{i\omega} - \lambda_0|^2} d\omega \\ &= 2\gamma^2 \ln |\det (M(\lambda_0))| \\ &= \gamma^2 \ln \left|\det \left(M^T(\lambda_0) M(\lambda_0)\right)\right|, \end{aligned}$$

where we have used the Poisson integral formula in the second line and the fact that $\det(X) = \det(X^T) = \det(X^T X)$ in the third. Now, let $\boldsymbol{M}$ be the Toeplitz operator with symbol $M(\lambda)$. It follows that this operator is a spectral factor of $\boldsymbol{I} - \gamma^{-2}\boldsymbol{G}^*\boldsymbol{G}$ and

$$\boldsymbol{E}(\boldsymbol{G}, \gamma, \lambda \boldsymbol{I}) = \widehat{\boldsymbol{M}}^*(\lambda_0 \boldsymbol{I}) \widehat{\boldsymbol{M}}(\lambda_0 \boldsymbol{I}).$$

Hence, from Example 2.4 we know that

$$\widehat{\boldsymbol{M}}(\lambda_0 \boldsymbol{I}) = \operatorname{diag}\{M(\lambda_0)\}.$$

Thus (3.2) and (3.3) hold with $E_0 := M^T(\lambda_0) M(\lambda_0)$. □

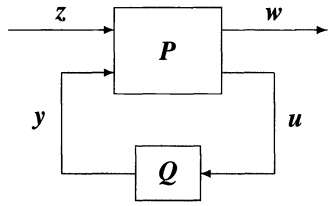

FIG. 4.1. *Closed-loop system.*

3.2. State-space formulae. For systems defined by the state-space representation (2.3), it is possible to give a state-space formula for the entropy. For notational simplicity, we assume that $\gamma = 1$.

It follows from Theorem 2.12 that a spectral factor for $\boldsymbol{M}$ for $\boldsymbol{I} - \boldsymbol{G}^*\boldsymbol{G}$ is given by

$$\boldsymbol{M} = \left[\begin{array}{c|c} \boldsymbol{A} & \boldsymbol{B} \\ \hline -\boldsymbol{V}^{-1/2}(\boldsymbol{B}^*\boldsymbol{Z}\boldsymbol{X}\boldsymbol{Z}^*\boldsymbol{A} + \boldsymbol{D}^*\boldsymbol{C}) & \boldsymbol{V}^{1/2} \end{array}\right].$$

The diagonal component of this spectral factor is $\boldsymbol{V}^{1/2}$, and thus

$$\boldsymbol{E}(\boldsymbol{G}, 1) = \boldsymbol{V} = \boldsymbol{I} - \boldsymbol{D}^*\boldsymbol{D} - \boldsymbol{B}^*\boldsymbol{Z}\boldsymbol{X}\boldsymbol{Z}^*\boldsymbol{B}.$$

In the study of $\mathcal{H}_\infty$ control theory, we find that controllers, and thus closed-loop systems, can often be written as linear fractional transformations of an inner transfer function P and a stable contraction Q. In the next section we show that, as in the case of time-invariant systems, the entropy operator can be used to choose from among a set of controllers.

4. Maximizing the entropy operator. For linear time-invariant systems, the set of closed-loop systems can be characterized in the form of a linear fractional transformations of an inner transfer function P and a stable contraction Q [10, 5, 14]. For time-varying systems, a similar characterization of stabilizing controllers exists [22].

In the time-invariant case, the integral (1.1) can be used to select from among the possible closed-loop systems. Partition the transfer function P as $\left(\begin{smallmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{smallmatrix}\right)$ with respect to the stable contraction Q. It is known that controller which maximizes the entropy integral (1.1) for z_0 is given by the choice $Q_{\max} = [P_{22}(z_0)]^\sim$ [11, 16]. In the time-invariant case this block of the transfer function P is strictly proper, and thus when $z_0 = 0$, the entropy maximizing contraction is $Q = 0$. This is known as the *central* controller of $\mathcal{H}_\infty$ control, which happens to coincide with with the optimal risk-sensitive controller of stochastic control [10].

In this section we will show that the entropy operator $\boldsymbol{E}(\boldsymbol{G}, \gamma)$ plays the corresponding role in time-varying optimization problems. Before doing so, we must show that a linear fractional transformation of the corresponding operators is well posed. In order to do this, we require a time-varying version of Redheffer's lemma.

LEMMA 4.1. *Suppose that, in Figure* 4.1, $\boldsymbol{P} = \left(\begin{smallmatrix} \boldsymbol{P}_{11} & \boldsymbol{P}_{12} \\ \boldsymbol{P}_{21} & \boldsymbol{P}_{22} \end{smallmatrix}\right)$, *with* $\boldsymbol{P}_{11}, \boldsymbol{P}_{12}, \boldsymbol{P}_{22} \in \mathfrak{L}$, $\boldsymbol{P}_{21} \in \mathfrak{L} \cap \mathfrak{L}^{-1}$, *is an isometry that admits a doubly coprime factorization. Furthermore, assume that* $\boldsymbol{Q}$ *is a causal (not necessarily bounded) operator also admitting a doubly coprime factorization. The following two statements are equivalent.*

(i) *The system is internally stable and well posed with* $\|\mathcal{F}_\ell(\boldsymbol{P}, \boldsymbol{Q})\| < 1$.

(ii) $\boldsymbol{Q} \in \mathfrak{L}$ *and* $\|\boldsymbol{Q}\| < 1$.

Proof. See §A.1. □

Suppose that all closed-loop systems $\boldsymbol{H}$ are characterized as a lower linear fractional transformation

$$\boldsymbol{H} = \gamma\mathcal{F}_\ell(\boldsymbol{P}, \boldsymbol{Q}),$$

where P is as in Lemma 4.1 and Q is a causal contraction. By Lemma 4.1, $H \in \mathfrak{L}$ and contractive. Thus, the entropy operator $E(H, \gamma)$ is well defined for all allowable Q. In the following proposition, we show that as Q varies over the set of all causal contractive operators, $E(H, \gamma)$ has a maximum.

PROPOSITION 4.2. *Suppose that* $H = \gamma \mathcal{F}_\ell(P, Q)$ *denotes the set of all closed-loop systems, where* P *is as in Lemma* 4.1 *with* $\|P_{22}(0)\| < 1$ *and* Q *is a causal, bounded contractive operator. Then*

(a) $E(H, \gamma)$ *is maximized by the unique choice*

$$Q = Q_{\max} := \hat{P}_{22}^*(0);$$

(b) *the maximum value of the entropy is given by*

$$E(\mathcal{F}_\ell(P, Q_{\max}), \gamma) = \hat{P}_{21}^*(0)\big(I - \hat{P}_{22}(0)\hat{P}_{22}^*(0)\big)^{-1}\hat{P}_{21}(0).$$

Proof. Since Q is a contractive operator, the bounded, Hermitian operator $I - Q^*Q$ has a spectral factorization. Denote the spectral factor by L. Now,

$$\begin{aligned} I - \gamma^{-2}H^*H &= I - \mathcal{F}_\ell(P, Q)^*\mathcal{F}_\ell(P, Q) \\ &= P_{21}^*\left(I - Q^*P_{22}^*\right)^{-1}\left(I - Q^*Q\right)\left(I - P_{22}Q\right)^{-1}P_{21} \\ &= \left[L\left(I - P_{22}Q\right)^{-1}P_{21}\right]^*\left[L\left(I - P_{22}Q\right)^{-1}P_{21}\right] \\ &=: N^*N. \end{aligned}$$

By assumption, $P_{21} \in \mathfrak{L} \cap \mathfrak{L}^{-1}$. Moreover, $L \in \mathfrak{L} \cap \mathfrak{L}^{-1}$, since L is a spectral factor. Finally, it is shown in the proof of Lemma 4.1 that $(I - P_{22}Q) \in \mathfrak{L} \cap \mathfrak{L}^{-1}$. Thus $N \in \mathfrak{L} \cap \mathfrak{L}^{-1}$, and it is clearly a spectral factor of the operator $I - \gamma^{-2}H^*H$.

Using Corollary 2.10, we can evaluate

$$\left[L\left(I - P_{22}Q\right)^{-1}P_{21}\right]\hat{}(0) = \hat{L}(0)\left(I - P_{22}Q\right)^{-1}\hat{}(0)\hat{P}_{21}(0).$$

Writing $(I - P_{22}Q)^{-1}$ as a series and again using Corollary 2.10 we see that

$$\begin{aligned} \left(I - P_{22}Q\right)^{-1}\hat{}(0) &= \left[\sum_{k=0}^{\infty}(P_{22}Q)^k\right]\hat{}(0) \\ &= \sum_{k=0}^{\infty}\big(\hat{P}_{22}(0)\hat{Q}(0)\big)^k \\ &= \big(I - \hat{P}_{22}(0)\hat{Q}(0)\big)^{-1}. \end{aligned} \tag{4.1}$$

The sum in (4.1) converges, since $\|\hat{P}_{22}(0)\hat{Q}(0)\| \le \|P_{22}Q\| < 1$. It follows that[2]

$$E(H, \gamma) = \hat{P}_{21}^*(0)\big(I - \hat{P}_{22}(0)\hat{Q}(0)\big)^{-*}E(Q, 1)\big(I - \hat{P}_{22}(0)\hat{Q}(0)\big)^{-1}\hat{P}_{21}(0). \tag{4.2}$$

Note that since $\|\hat{P}_{22}(0)\| < 1$, the operators

$$I - \hat{P}_{22}(0)\hat{P}_{22}^*(0), \qquad I - \hat{P}_{22}^*(0)\hat{P}_{22}(0)$$

admit unique positive-definite Hermitian square roots; see [7, p. 88].

[2]We use the notation $A^{-*} = (A^*)^{-1}$.

We proceed now as in [2] and define the following Julia $\mathfrak{D}^{2\times 2}$ operator (see [26, p. 148]) acting on the Hilbert space $\ell_2 \oplus \ell_2$:

$$X := \begin{bmatrix} X_{11} & X_{12} \\ X_{21} & X_{22} \end{bmatrix}$$
$$:= \begin{bmatrix} -\widehat{P}_{22}(0) & \left(I - \widehat{P}_{22}^*(0)\widehat{P}_{22}(0)\right)^{1/2} \\ \left(I - \widehat{P}_{22}(0)\widehat{P}_{22}^*(0)\right)^{1/2} & \widehat{P}_{22}(0) \end{bmatrix}.$$

It is straightforward to check that X is an isometry and thus, by Lemma 4.1, the linear fractional transformation

$$T := \gamma \mathcal{F}_\ell(X, Q)$$

is well defined. Moreover, note that $T = 0 \iff Q = \widehat{P}_{22}^*(0)$.

Since $X_{21} \in \mathfrak{D}$, then $\hat{X}_{21}(0) = X_{21}$. Proceeding as above, we can evaluate

$$E(T, \gamma) = X_{21}^*\left(I - \widehat{P}_{22}(0)\widehat{Q}(0)\right)^{-*} E(Q, 1)\left(I - \widehat{P}_{22}(0)\widehat{Q}(0)\right)^{-1} X_{21}. \tag{4.3}$$

Comparing (4.2) and (4.3), we see that

$$\begin{aligned} E(Q, 1) &= \left(I - \widehat{P}_{22}(0)\widehat{Q}(0)\right)^* \widehat{P}_{21}^{-*}(0) E(H, \gamma) \widehat{P}_{21}^{-1}(0)\left(I - \widehat{P}_{22}(0)\widehat{Q}(0)\right) \\ &= \left(I - \widehat{P}_{22}(0)\widehat{Q}(0)\right)^* X_{21}^{-*} E(T, \gamma) X_{21}^{-1}\left(I - \widehat{P}_{22}(0)\widehat{Q}(0)\right). \end{aligned}$$

Thus

$$E(H, \gamma) = \widehat{P}_{21}^*(0) X_{21}^{-*} E(T, \gamma) X_{21}^{-1} \widehat{P}_{21}(0). \tag{4.4}$$

Since X_{21} and $\widehat{P}_{21}(0)$ are both independent of Q, the maximum in (4.4) is obtained whenever $E(T, \gamma)$ is maximized. By property (ii) of Lemma 3.2, we know that this achieved uniquely for $T \equiv 0 \Rightarrow Q = \widehat{P}_{22}^*(0)$, from which the result of part (a) follows. Part (b) follows immediately upon substitution. □

5. Extensions. In this section we outline some possible extensions of the entropy operator defined here and some difficulties that arise with each.

5.1. Finite-time-horizon systems. The entropy defined in this paper, despite having these many desirable properties, differs significantly from the usual entropy in that the expression in (3.1) defines entropy to be an operator and not a real number as in (1.1). For operators associated with finite-time-horizon systems, we may define an entropy number analogous to that of (3.1); this is now done.

Let $M = \{M(i, j)\}$ represent a bounded, causal operator. Define the operator

$$M_N := P_N M(I - P_0).$$

With respect to the direct sum decomposition $\ell_2 = P_0\ell_2 \oplus (P_N - P_0)\ell_2 \oplus (I - P_N)\ell_2$, this operator has a natural partition as

$$M_N = \begin{bmatrix} 0 & 0 & 0 \\ 0 & H^N & 0 \\ 0 & 0 & 0 \end{bmatrix},$$

where

$$H^N = \begin{cases} \{M(i, j)\}, & 0 \le i, j \le N - 1, \\ 0 & \text{elsewhere.} \end{cases}$$

Note that if $\boldsymbol{M} = \sum_{k=0}^{\infty} \boldsymbol{M}_{[k]}(\boldsymbol{Z}^*)^k$, then

$$\begin{aligned} \boldsymbol{M}_N &= \sum_{k=0}^{\infty} \big(\boldsymbol{P}_N \boldsymbol{M}_{[k]} (\boldsymbol{Z}^*)^k (\boldsymbol{I} - \boldsymbol{P}_0) \boldsymbol{Z}^k\big) (\boldsymbol{Z}^*)^k \\ &= \sum_{k=0}^{N-1} \big(\boldsymbol{P}_N \boldsymbol{M}_{[k]} (\boldsymbol{I} - \boldsymbol{P}_k)\big) (\boldsymbol{Z}^*)^k \qquad (5.1) \\ &=: \sum_{k=0}^{N-1} \boldsymbol{M}^N_{[k]} (\boldsymbol{Z}^*)^k, \end{aligned}$$

where, in (5.1), we have used the identity $(\boldsymbol{Z}^*)^k \boldsymbol{P}_0 \boldsymbol{Z}^k = \boldsymbol{P}_k$. We can evaluate

$$\begin{aligned} \widehat{\boldsymbol{M}}_N(\boldsymbol{0}) = \boldsymbol{M}^N_{[0]} &= \boldsymbol{P}_N \boldsymbol{M}_{[0]} (\boldsymbol{I} - \boldsymbol{P}_0) \\ &=: \begin{bmatrix} \boldsymbol{0} & \boldsymbol{0} & \boldsymbol{0} \\ \boldsymbol{0} & \boldsymbol{H}^N_{[0]} & \boldsymbol{0} \\ \boldsymbol{0} & \boldsymbol{0} & \boldsymbol{0} \end{bmatrix}. \end{aligned}$$

DEFINITION 5.1. *Suppose that $\boldsymbol{G} \in \mathfrak{X}$ and $\|\boldsymbol{G}\| < \gamma$, and let $\boldsymbol{M}$ be a spectral factor of the positive operator $\boldsymbol{I} - \gamma^{-2}\boldsymbol{G}^*\boldsymbol{G}$. Consider the finite rank operator $\boldsymbol{M}_N$ defined as above as well as its nonzero component $\boldsymbol{H}^N$. We define*

$$\mathcal{E}_N(\boldsymbol{G}, \gamma) := \frac{\gamma^2}{N} \ln \left| \det \left((\hat{\boldsymbol{H}}^N_{[0]})^* \hat{\boldsymbol{H}}^N_{[0]} \right) \right|.$$

In the next result we show that, for time-invariant systems, the entropy $\mathcal{E}_N$ coincides with the integral (1.1).

PROPOSITION 5.2. *For time-invariant operators, $\boldsymbol{G} = \{G(i, i-k)\} \in \mathfrak{L}$, with $G(i, i-k) = g_k$ and $\gamma \in \mathbb{R}$ such that $\|\boldsymbol{G}\| < \gamma$, the following holds:*

$$\mathcal{E}_N(\boldsymbol{G}, \gamma) = I_d(G, \gamma, 0),$$

where $G(\lambda)$ is the λ-transform of the sequence $\{g_k\}$.

Proof. The proof of this is very similar to that of Proposition 3.3. Following the notation in that proof, we note that, if

$$G(\lambda) = \sum_{k=0}^{\infty} g_k \lambda^k \qquad \text{and} \qquad M(\lambda) = \sum_{k=0}^{\infty} m_k \lambda^k,$$

then

$$I_d(G, \gamma, 0) = 2\gamma^2 \ln |\det(m_0)|$$

and, recalling from Example 2.2 that for Toeplitz operators, $\boldsymbol{M}_{[k]} = m_k \boldsymbol{I}$,

$$\widehat{\boldsymbol{M}}_N(\boldsymbol{0}) = \boldsymbol{P}_N \boldsymbol{M}_{[0]} (\boldsymbol{I} - \boldsymbol{P}_0) = m_0 \boldsymbol{P}_N (\boldsymbol{I} - \boldsymbol{P}_0)$$

and

$$\hat{\boldsymbol{H}}^N_{[0]} = m_0 I_N,$$

where I_N is a block $N \times N$ identity matrix. Thus

$$\mathcal{E}_N(\boldsymbol{G}, \gamma) = 2\frac{\gamma^2}{N} \ln \left| \det \left(\hat{H}^N_{[0]} \right) \right| = 2\gamma^2 \ln |\det(m_0)|. \qquad \square$$

5.2. General W. While the entropy definition in (1.1) allows one to work with an entropy with respect to any $z_0 \in \{z : |z| < 1\}$, the point of greatest interest is that with $z_0 = 0$. It is to this particular entropy that our operator entropy maximization corresponds. Nevertheless, it would be desirable to generalize Proposition 4.2 to more general "points" corresponding to operators $\boldsymbol{W} \neq \boldsymbol{0}$. Consider the general form of the entropy of Definition 3.1:

$$\boldsymbol{E}(\boldsymbol{G}, \boldsymbol{W}, \gamma) = \widehat{\boldsymbol{M}}(\boldsymbol{W})^* \widehat{\boldsymbol{M}}(\boldsymbol{W}).$$

This formula satisfies properties (i) and (ii) of Lemma 3.2; however, it does not satisfy property (iii). More importantly, it does not seem to satisfy the same maximization property of Proposition 4.2 and for this reason is of limited use. The proof of Proposition 4.2 breaks down since it relies heavily on Corollary 2.10, which does not hold for general $\boldsymbol{W}$.

5.3. Continuous-time systems. In the case of continuous-time, linear time-invariant systems, there exists an entropy integral analogous to that of (1.1); see [21]. For time-varying systems, however, it is well known that the input-output operators which are analogous to $\boldsymbol{G}$ exist in continuous resolution spaces. In general, positive, invertible Hermitian operators in these spaces *do not* have spectral factorizations; see [4, Thm. 14.2]. Since the definition of the entropy for discrete-time systems given here depends crucially on the existence of these factorizations, it is not clear how to generalize this to continuous-time systems.

6. Conclusions. State-space methods have by now become prevalent in the theory of $\mathcal{H}_\infty$ control. Apart from being advantageous in terms of the numerical computations required, they have also allowed straightforward extensions of the theory to other settings, including time-varying systems. Until now, however, it has not been possible to extend the definition of the entropy of a system to this setting, since it relied heavily on the transfer function of the system. This paper has given this extension in terms of non-Toeplitz operators. The entropy defined here, while being an operator rather than a real number, has many of the same properties as that used in the time-invariant case. Moreover, for time-varying systems with state-space realizations, state-space formulae for this entropy have been provided.

Appendix A. In this appendix we prove our time-varying version of Redheffer's lemma.

A.1. Proof of Lemma 4.1. (i)$\Leftarrow$(ii) For our proof, we modify the proof for the time-invariant case found in [5, Lem. 15].

Since $\boldsymbol{P}$ is an isometry, $\|\boldsymbol{P}_{22}\| \leq 1$. This, together with the fact that $\boldsymbol{Q}$ is a contraction, implies that $\|\boldsymbol{P}_{22}\boldsymbol{Q}\| < 1$. Thus, the series

$$\sum_{k=0}^{\infty} (\boldsymbol{P}_{22}\boldsymbol{Q})^k$$

converges in $\mathfrak{L}$ and is equal to $(\boldsymbol{I} - \boldsymbol{P}_{22}\boldsymbol{Q})^{-1}$. This implies that $\boldsymbol{Q}$ stabilizes $\boldsymbol{P}_{22}$. By the coprime assumption on $\boldsymbol{P}$ and a time-varying version of Lemma 4.2.1 in [8], it follows that $\boldsymbol{Q}$ internally stabilizes $\boldsymbol{P}$. Now to show that $\mathcal{F}_\ell(\boldsymbol{P}, \boldsymbol{Q})$ is a contraction, we use the fact that $\boldsymbol{P}$ is an isometry and a little algebra to show that

$$\begin{aligned} \mathcal{F}_\ell(\boldsymbol{P}, \boldsymbol{Q})^* \mathcal{F}_\ell(\boldsymbol{P}, \boldsymbol{Q}) &= \boldsymbol{I} - \boldsymbol{P}_{21}^*(\boldsymbol{I} - \boldsymbol{Q}^*\boldsymbol{P}_{22}^*)^{-1}(\boldsymbol{I} - \boldsymbol{Q}^*\boldsymbol{Q})(\boldsymbol{I} - \boldsymbol{P}_{22}\boldsymbol{Q})^{-1}\boldsymbol{P}_{21} \\ &\leq \boldsymbol{I}, \end{aligned}$$

where we have used the fact that $\boldsymbol{Q}$ is a contraction.

(ii)$\Leftarrow$(i) To show the converse, we first prove that $\boldsymbol{Q}$ is a bounded operator. Recall that $\boldsymbol{Q}$ has a right coprime factorization $\boldsymbol{Q} = \boldsymbol{N}\boldsymbol{D}^{-1}$, where $\boldsymbol{N}, \boldsymbol{D} \in \mathfrak{L}$. Note that $\boldsymbol{Q} \in \mathfrak{L} \iff \boldsymbol{D} \in$

$\mathfrak{L} \cap \mathfrak{L}^{-1}$; see [7, p. 182]. From the internal stability assumption, we know that

$$\boldsymbol{Q}(\boldsymbol{I} - \boldsymbol{P}_{22}\boldsymbol{Q})^{-1} \in \mathfrak{L} \Rightarrow \boldsymbol{N}(\boldsymbol{D} - \boldsymbol{P}_{22}\boldsymbol{N})^{-1} \in \mathfrak{L}.$$

Now, since $\boldsymbol{N}$ and $\boldsymbol{D}$ are right coprime, it follows that $\boldsymbol{N}$ and $\boldsymbol{D} - \boldsymbol{P}_{22}\boldsymbol{N}$ are also right coprime. To see this, suppose that $\tilde{\boldsymbol{X}}, \tilde{\boldsymbol{Y}} \in \mathfrak{L}$ such that $\tilde{\boldsymbol{X}}\boldsymbol{N} + \tilde{\boldsymbol{Y}}\boldsymbol{D} = \boldsymbol{I}$. Then,

$$\boldsymbol{X}\boldsymbol{N} + \boldsymbol{Y}(\boldsymbol{D} - \boldsymbol{P}_{22}\boldsymbol{N}) = \boldsymbol{I}$$

with $\boldsymbol{X} = \tilde{\boldsymbol{X}} + \boldsymbol{Y}\boldsymbol{P}_{22} \in \mathfrak{L}$ and $\boldsymbol{Y} = \hat{\boldsymbol{Y}} \in \mathfrak{L}$, which proves coprimeness. It follows, again from [7, p. 182], that

$$\begin{aligned} \boldsymbol{N}(\boldsymbol{D} - \boldsymbol{P}_{22}\boldsymbol{N})^{-1} \in \mathfrak{L} &\Rightarrow (\boldsymbol{D} - \boldsymbol{P}_{22}\boldsymbol{N})^{-1} \in \mathfrak{L} \\ &\Rightarrow \boldsymbol{D}^{-1}(\boldsymbol{I} - \boldsymbol{P}_{22}\boldsymbol{Q})^{-1} \in \mathfrak{L} \\ &\Rightarrow \boldsymbol{D}^{-1} \in \mathfrak{L}, \end{aligned}$$

where the last line comes from that fact that $(\boldsymbol{I} - \boldsymbol{P}_{22}\boldsymbol{Q})^{-1} \in \mathfrak{L} \cap \mathfrak{L}^{-1}$. Thus, $\boldsymbol{Q} \in \mathfrak{L}$.

We now show that $\boldsymbol{Q}$ is a contraction. Assume otherwise; thus there exists a signal $\boldsymbol{y} \in \ell_2$ such that $\boldsymbol{u} = \boldsymbol{Q}\boldsymbol{y} \in \ell_2$ and $\|\boldsymbol{u}\| \geq \|\boldsymbol{y}\|$. Let $\boldsymbol{w} = \boldsymbol{P}_{21}^{-1}(\boldsymbol{I} - \boldsymbol{P}_{22}\boldsymbol{Q})\boldsymbol{y}$. This is in ℓ_2, since $\boldsymbol{P}_{21} \in \mathfrak{L} \cap \mathfrak{L}^{-1}$. Moreover, from the isometry condition we know that

$$\begin{aligned} \|\boldsymbol{z}\|^2 + \|\boldsymbol{y}\|^2 &= \|\boldsymbol{w}\|^2 + \|\boldsymbol{u}\|^2 \\ &\geq \|\boldsymbol{w}\|^2 + \|\boldsymbol{y}\|^2. \end{aligned}$$

Thus $\|\boldsymbol{z}\|^2 \geq \|\boldsymbol{w}\|^2$, which contradicts the assumption that $\mathcal{F}_\ell(\boldsymbol{P}, \boldsymbol{Q})$ is a contraction.

ON MARKOVIAN FRAGMENTS OF COCOLOG FOR LOGIC CONTROL SYSTEMS*

YUANJUN WEI† AND PETER E. CAINES‡

Abstract. The COCOLOG (Conditional Observer and Controller Logic) system is a partially ordered family of first-order logical theories expressed in the typed first-order languages $\{\mathcal{L}_k; k \geq 0\}$ describing the controlled evolution of the state of a given partially observed finite machine $\mathcal{M}$. The initial theory of the system, denoted Th_0, gives the theory of $\mathcal{M}$ with no data being given on the initial state. Later theories, $\{Th(o_1^k); k \geq 1\}$, depend upon the (partially ordered lists of) observed input-output trajectories $\{o_1^k; k \geq 1\}$, where new data are accepted in the form of the new axioms $AXM^{obs}(\mathcal{L}_k)$, $k \geq 1$. A feedback control input $U(k)$ is determined by the solution of a collection of control problems posed in the form of a set of conditional control rules $CCR(\mathcal{L}_k)$, such a set being paired with the theory $Th(o_1^k)$ for each $k \geq 1$. In this paper, we introduce a restricted version of COCOLOG, called a system of Markovian fragments of COCOLOG, in which a smaller amount of information is communicated from one theory to the next. Such fragment theories are associated with a restricted set of candidate control problems, denoted $CCR(\mathcal{L}_k^m)$, $k \geq 1$. It is shown that a Markovian fragment theory $MTh(o_1^k)$ contains a large subset of $Th(o_1^k)$, which includes, in particular, the state estimation theorems of the corresponding full COCOLOG system and, for the set of control rules $CCR(\mathcal{L}_k^m)$, has what is termed the same control reasoning power. Next, it is shown that proofs of theorems in the fragment systems are necessarily shorter than their proofs in the full COCOLOG systems. Finally some computer-generated examples are given, illustrating this increased theorem-proving efficiency.

1. Introduction.

The COCOLOG system, introduced by P. E. Caines and S. Wang [CW95], [CW91], [W91], is a partially ordered family of first-order logical theories which describe the controlled evolution of the state of a given partially observed finite machine $\mathcal{M}$. Unlike most knowledge-based control systems, reasoning in COCOLOG is based upon the representation of the two fundamental properties of a partially observed dynamical system with inputs, namely, *controllability* (or *reachability*) and *observability*. The predicate symbols Rbl and CSE_k are introduced for this purpose. The initial theory of the system, Th_0, gives the general theory of $\mathcal{M}$ without any data being given on the initial state. Later theories, $\{Th(o_1^k); k \geq 1\}$, depend upon the (partially ordered lists of) observed input-output trajectories $\{o_1^k; k \geq 1\}$, through their axiom sets $\{\Sigma_k; k \geq 1\}$, since new data are accepted sequentially into the subsequent theories in the form of the *new axioms* $AXM^{obs}(\mathcal{L}_k)$. The inputs $U(k)$ are determined by the solution to control problems associated with each theory in the form of the *conditional control rules* $CCR(\mathcal{L}_k)$. An important class of control problems involves the aforementioned reachability predicate $Rbl(x, y, l)$, which is defined axiomatically in each theory and corresponds to the reachability of the state y from the state x in l steps. The solution to one problem of this type would be, say, the first control in a sequence of controls giving a minimal length path to the state y from the current state x.

This paper is concerned with the definition of tractable fragments of the full COCOLOG system which carry enough information to enable significant classes of control problems to be posed (through the conditional control rules) and resolved in a limited subset of the language $\mathcal{L}_k$ at each instant k. Due to the overall dynamical framework of a COCOLOG system, we are able to formulate what we call the Markovian fragments of a general COCOLOG system in such a way that they possess the required tractability properties. These are introduced in

this paper via the definition of a restricted set of languages $\{\mathcal{L}_k^m; k \geq 0\}$ and the associated set of axioms $\{M\Sigma_k(o_1^k); k \geq 0\}$ for the set of theories $\{MTh(o_1^k); k \geq 1\}$. In contrast to the evolution of a full COCOLOG system, the evolution of a system of Markovian fragments consists of a combination of axiom set expansion (adding some previously derived theorems and new axioms into the axiom set) and axiom set contraction (deleting some old axioms) at each time instant. A part of $\{M\Sigma_k(o_1^k); k \geq 0\}$ expresses only the basic dynamical properties of the machine under control plus the most recent observations, while another part expresses the state estimate generated in the most recent COCOLOG theory. In addition, an updated version of a set of control problems is carried in a corresponding set of conditional control rules; these are phrased only in terms of the predicates and axioms available in the restricted theories $MTh(o_1^k)$, $k \geq 1$. In particular, this avoids the unbounded increment in axiomatic theorem proving (ATP) complexity due to the increase in the number of formulas in the successive axiom sets.

The implementation of control reasoning in COCOLOG requires efficient ATP methodologies. The development of function evaluation (FE) resolution [WC92] and the Blitzensturm methodology [CMW93] have been steps in this direction. Both have recently been shown to be efficiently implementable. It may be seen from the analysis in this paper that the sizes of proof trees in Markovian fragment theories are necessarily smaller than or equal to the corresponding proof trees in full COCOLOG theories. At the end of this paper, we present some computer-generated examples to illustrate this comparison. These and other experiments implementing ATP in the full and the Markovian fragment COCOLOG systems result in a corresponding speed-up of the computing time required for certain COCOLOG control problems.

The paper is organized as follows. After a brief review of COCOLOG systems, §3 presents the definition of the fragment languages $\mathcal{L}_k^m$, $k \geq 0$. The axiomatizations of fragment theories and their semantics are given in §§4 and 5, respectively. Section 6 contains the first main result of the paper, stating that, for a large class of control problems, no loss in control reasoning power is incurred by restriction to the fragment theories. Section 7 presents the second main result, which deals with proof complexity. Appendix 1 consists of a complete description of an axiom set of the basic theory, Σ_0. Finally, two pairs of computer-based experiments are presented in Appendix 2 to illustrate the difference between proofs of the same theorems in full COCOLOG and in its Markovian fragment counterpart, respectively.

Earlier versions of the theory developed in this paper were presented in [WeC92] and [CWe94].

2. COCOLOG. The reader is referred to [CW91, CW95, W91, WC92] for a full exposition of all terms and expressions which are not completely explained in the summary of the formulation of a COCOLOG system given below.

2.1. Syntax of COCOLOG.

DEFINITION 2.1. *A (partially observed) finite (input-state-output) machine is a quintuple*

$$\mathcal{M} \underline{\Delta} (\mathbf{U}, \mathbf{X}, \mathbf{Y}, \mathbf{\Phi}, \eta),$$

where $\mathbf{U}$ *is a (finite) set of* inputs, $\mathbf{X}$ *is a (finite) set of* states, $\mathbf{Y}$ *is a (finite) set of* outputs, $\mathbf{\Phi} : X \times U \to X$ *is a* transition function, *and* $\eta : \mathbf{X} \to \mathbf{Y}$ *is an* output function.

In this paper, we set $|\mathbf{U}| = R$, $|\mathbf{X}| = N$, and $|\mathbf{Y}| = M$.

We always use boldface letters to distinguish semantic objects from the symbols in the first-order language that describe them. For the purpose of describing such machines in a first-order language, we define the symbol set $S(\mathcal{L}_0)$ that contains the *constant symbol set*:

$$\begin{aligned}\text{Const}(\mathcal{L}_0) &= U \cup X \cup Y \cup I_{K(N)} \\ &= \{u^1, \ldots, u^R\} \cup \{x^1, \ldots, x^N\} \cup \{y^1, \ldots, y^M\} \cup \{0, 1, \ldots, K(N)+1\};\end{aligned}$$

the *variable symbol set*:

$$\text{Var}(\mathcal{L}_0) = \{u, u', \ldots\} \cup \{x, x', \ldots\} \cup \{y, y', \ldots\} \cup \{i, j, l, \ldots\};$$

the *function symbol set*, $\text{Func}(\mathcal{L}_0)$, that contains the symbols $\{\Phi(\ ,\ ), \eta(), +_{K(N)}, -_{K(N)}\}$; the *atomic predicate symbol set*, $\text{Pre}(\mathcal{L}_0)$, that contains $\{Eq, Rbl\}$; and the *logical symbol set*, $\{\forall, \rightarrow, \bot\}$, where $\bot$ is a logical constant together with the derived symbols $\exists, \neg, \top$. The set of typed terms $\text{Term}(\mathcal{L}_0)$ includes the first two sets of symbols, together with certain finite strings of symbols, whose farthest left symbol is an $n-ary$ functional symbol followed by n terms (see [CW95]).

Any *well-formed formula* of $\mathcal{L}_0$ is given by the standard first-order grammar. The set of such formulas will be denoted $WFF(\mathcal{L}_0)$.

2.2. Axiomatic theory of Th_0. The basic axiom set, which generates the basic theory Th_0, has a set of *logical axioms*, a set of *equality axioms* for an equality predicate, a set of *arithmetic axioms*, and a set of *special axioms* which specify the facts concerning the subject that the logic describes (in at least one of its interpretations).

Finite machine axioms. The special axiom set of Th_0 corresponds exactly to the state transitions and output map relations of the given machine $\mathcal{M}$:

State transition axioms:

$$AXM^{dyn}(\mathcal{L}_0) \underline{\Delta} \{Eq(\Phi(x^i, u^l), x^j);\ x^i, x^j \in X, u^l \in U\},$$

where an entry appears in the braces if and only if, for $\mathcal{M}$, $\mathbf{\Phi(x^i, u^l) = x^j}$.

Output axioms:

$$AXM^{out}(\mathcal{L}_0) \underline{\Delta} \{Eq(\eta(x^i), y^j);\ x^i \in X, y^j \in Y\},$$

where an entry appears in the braces if and only if, for $\mathcal{M}$, $\mathbf{\eta(x^i) = y^j}$.

Example 2.1 (a seven-state machine). Some members of the axiom set AXM^{dyn} for the machine in Figure 1 are

$$\begin{array}{lll} Eq(\Phi(x^1, u^1), x^2) & Eq(\Phi(x^1, u^2), x^3) & Eq(\Phi(x^1, u^3), x^4) \\ Eq(\Phi(x^2, u^1), x^3) & Eq(\Phi(x^2, u^2), x^4) & Eq(\Phi(x^2, u^3), x^5) \\ \cdots & \cdots & \cdots, \end{array}$$

and some members of the axiom set AXM^{out} are

$$\begin{array}{lll} Eq(\eta(x^1), y^1) & Eq(\eta(x^2), y^2) & Eq(\eta(x^3), y^3) \\ \cdots & \cdots & \cdots. \end{array} \quad \square$$

Reachability axioms. Denoted by $AXM^{Rbl}(\mathcal{L}_0)$, these are recursively defined for the *reachability predicate Rbl* by the following:

0. $\forall x \forall x',\ Eq(x, x') \longleftrightarrow Rbl(x, x', 0)$,
1. $\forall x \forall x',\ (\exists u,\ Eq(\Phi(x, u), x')) \longleftrightarrow Rbl(x, x', 1)$,
2. $\forall x \forall x'' \forall l,\ Eq(l, K(N)+1)$
   $\vee [\{\exists x' \exists u,\ Rbl(x', x'', l) \wedge Eq(\Phi(x, u), x')\} \longleftrightarrow Rbl(x, x'', l +_{K(N)} 1)]$. $\square$

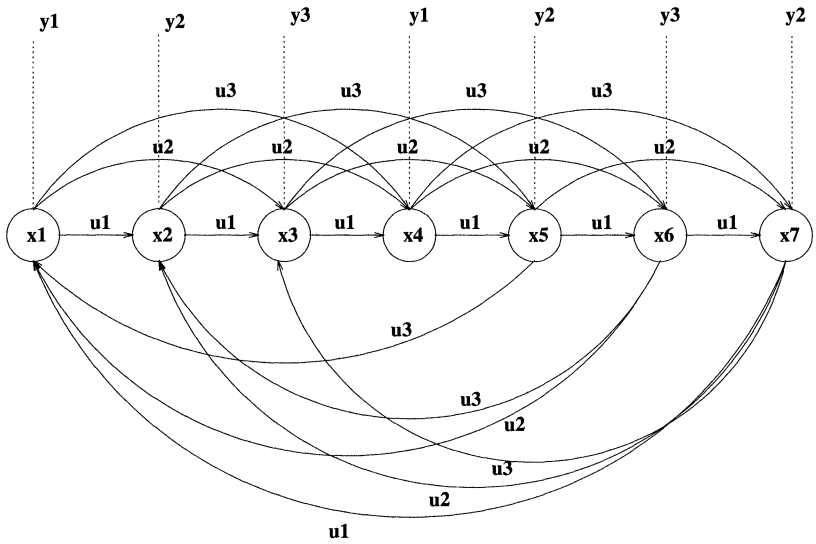

FIG. 1. *A seven-state machine.*

The reachability axioms specify the l-step reachability relation $Rbl(x, x', l)$ among any pair of states x, x'. We note that in these formulas the variables x, x', x'' range over X, the variable u ranges over U, and l ranges over the integers $0, 1, \ldots, K(N)+1$. Axiom 2 excludes consideration of the infinity case in order to characterize reachability on the finite numbers in the arithmetic.

Size axioms (see Appendix 1). Denoted by $AXM^{size}(\mathcal{L}_0)$, these specify the restriction that any model of this axiom set must have a domain that contains exactly N state objects, R input objects, M output objects, and $K(N) + 2$ integers. This restriction is natural since the controlled machine $\mathcal{M}$ is fixed.

Finite arithmetic axioms (see Appendix 1). Denoted by $AXM^{arith}(\mathcal{L}_0)$, these define the arithmetical operations $+_{K(N)}$ and $-_{K(N)}$ on the initial segment of the natural numbers $\{0, \ldots, K(N) + 1\}$.

Equality axioms (see Appendix 1). Denoted by $AXM^{Eq}(\mathcal{L}_0)$, these consist of the basic axioms for equality and the substitution axioms for every functional symbol and predicate symbol in the language.

Logical axioms (see Appendix 1). Denoted by $AXM^{logic}(\mathcal{L}_0)$, this is the standard set of axiom schemata for first-order logic.

Axiom set Σ_0. We write Σ_0 for the union of the above axiom sets of $\mathcal{L}_0$, i.e.,

$$\Sigma_0 \triangleq \{AXM^{arith}(\mathcal{L}_0), AXM^{dyn}(\mathcal{L}_0), AXM^{out}(\mathcal{L}_0), AXM^{Rbl}(\mathcal{L}_0), AXM^{Eq}(\mathcal{L}_0), AXM^{logic}(\mathcal{L}_0)\}.$$

Rules of inference (see Appendix 1). The rules of inference in Th_0 are *Modus Ponens* (MP) and *generalization.*

2.3. Axiomatic Theory of $Th(o_1^k)$. At each instant $k \geq 1$, the controlled machine $\mathcal{M}$ generates a pair of observed data $(\mathbf{u}^p, \mathbf{y}^q)$ for some $\mathbf{u}^p \in \mathbf{U}$, $\mathbf{y}^q \in \mathbf{Y}$. The axiom set is updated to express the acquisition of this new information, and new control rules are added to decide

the subsequent control action $U(k)$. In order to formalize this change the language is extended by introducing new constant symbols.

We will use the notation $\mathbf{o}_1^k$, $k \geq 1$, to denote the observed sequence received on the time interval $[1, k]$, i.e.,

$$\{(\emptyset, \mathbf{y}^{j_1}), (\mathbf{u}^{i_2}, \mathbf{y}^{j_2}), \ldots, (\mathbf{u}^{i_k}, \mathbf{y}^{j_k})\}$$

The typed language $\mathcal{L}_k \triangleq L(o_1^k)$ is an extension of the language $\mathcal{L}_0$ which is obtained by adding new constant symbols and predicates symbols in the following way:

$$S(\mathcal{L}_k) \triangleq S(L(o_1^k)) = S(\mathcal{L}_0) \bigsqcup_{j=1}^{k} \{U(j-1), Y(j)\} \bigsqcup_{j=1}^{k} \{CSE_j\}.$$

Here $U(j-1)$ and $Y(j)$ are new constant symbols, representing the observed control input at the time instant $j-1$ and output at the time instant j generated by the controlled machine $\mathcal{M}$. CSE_j is a new one-place predicate symbol which is called the current state estimation predicate at time j, $j \geq 1$.

The syntax of $\mathcal{L}_k$ is standard, and we remark only that the variables and constants are sorted and the well-formed formulas parse according to the first-order grammar of each $\mathcal{L}_k$.

Observation axioms ($AXM^{obs}(\mathcal{L}_k)$). The observation of the control action $\mathbf{u^p} \in \mathbf{U}$, taken at the instant $k-1$, and the output $\mathbf{y^q} \in \mathbf{Y}$, generated at the instant k, are expressed in the form $Eq(U(k-1), u^p)$ and $Eq(Y(k), y^q)$. These are added to the previous axiom set Σ_{k-1} as axioms to express the fact that these observations have taken place. Let

$$AXM^{obs}(\mathcal{L}_k) \triangleq \{Eq(Y(k), y^q), Eq(U(k-1), u^p)\}, \quad k \geq 1,$$

where this set of formulas is subject to the convention that the second axiom above holds only in case $k > 1$.

State estimation axioms ($AXM^{est}(\mathcal{L}_k)$). These express in axiomatic form the recursive formulas for the current state estimate sets.

In case $k = 1$:

$$Eq(\eta(x^i), Y(k)) \longleftrightarrow CSE_1(x^i), \qquad 1 \leq i \leq N. \tag{1}$$

In case $k > 1$:

$$\exists x, CSE_{k-1}(x) \wedge Eq(\Phi(x, U(k-1)), x^i) \wedge Eq(Y(k), \eta(x^i)) \longleftrightarrow CSE_k(x^i), \qquad 1 \leq i \leq N. \tag{2}$$

This axiom set will also be added to the previous axiom set. Finally we add the following.

Substitution axioms ($AXM^{subs}(\mathcal{L}_k)$ (for CSE_k, $k \geq 1$)).

$$\forall x_1 \forall x_2 (Eq(x_1, x_2) \rightarrow (CSE_k(x_1) \rightarrow CSE_k(x_2))). \tag{3}$$

Henceforth we set

$$\Sigma_k \triangleq \Sigma_k(o_1^k) = \Sigma_0 \bigsqcup_{j=1}^{k} \{AXM^{obs}(\mathcal{L}_j), AXM^{subs}(\mathcal{L}_j), AXM^{est}(\mathcal{L}_j)\}. \tag{4}$$

Rules of inference (see Appendix 1). The rules of inference in $Th(o_1^k)$ are MP and *generalization.*

We formally define the proof mechanics of Σ_k as follows.

DEFINITION 2.2. *For any $k \geq 0$, a proof sequence $\mathcal{P}$ for a formula F with respect to the axiom set Σ_k is a finite indexed list of formulas in which F is the last on the list, and any other formula in the list is either an instance of a logical axiom schemata, a member of Σ_k, or a formula deduced from previous formulas in the list through MP or generalization. We call $\mathcal{P}$ a Σ_k-*proof. *If such a proof sequence exists, we say that F is* deducible from *or* provable from *Σ_k and denote this by $\Sigma_k \vdash F$. F is called a theorem of Σ_k. Finally we use $|\mathcal{P}|$, the length of $\mathcal{P}$, to denote the number of formulas in $\mathcal{P}$.*

$Th(o_1^k)$, called the theory generated from *Σ_k, is the set of all theorems that can be deduced from Σ_k; that is to say, it is the set*

$$\{F : F \in WFF(\mathcal{L}_k), \Sigma_k \vdash F\}. \qquad \square$$

Conditional control rules ($CCR(\mathcal{L}_k)$). The following is the general form of a set of *conditional control rules* at time instant k. Let $C^j(\mathcal{L}_k)$, $1 \leq j \leq R$, be a set of conditional control formulas associated with u^j, $1 \leq j \leq R$, expressed in $WFF(\mathcal{L}_k)$, and let

$$D^p(\mathcal{L}_k) = \bigwedge_{i=1}^{p-1} \neg C^i(\mathcal{L}_k) \wedge C^p(\mathcal{L}_k). \tag{5}$$

Then the associated $CCR(\mathcal{L}_k)$ set is the set of extralogical statements

if	$D^1(\mathcal{L}_k)$,	**then**	$Eq(U(k), u^1)$;
if	$D^2(\mathcal{L}_k)$,	**then**	$Eq(U(k), u^2)$;
if	$\vdots$	**then**	$\vdots$
if	$D^R(\mathcal{L}_k))$,	**then**	$Eq(U(k), u^R)$;
if	$\bigwedge_{j=1}^{R}(\neg C^j(\mathcal{L}_k))$,	**then**	$Eq(U(k), u^*)$. $\square$

We use the notation $CCF(\mathcal{L}_k)$ (standing for the set of *conditional control formulas* in the language $\mathcal{L}_k$) to denote the conditions in the **if** parts of a given set of rules $CCR(\mathcal{L}_k)$, i.e.,

$$CCF(\mathcal{L}_k) \triangleq \left\{ D^1(\mathcal{L}_k), D^2(\mathcal{L}_k), \ldots, D^R(\mathcal{L}_k), \bigwedge_{j=1}^{R} \neg C^j(\mathcal{L}_k) \right\}.$$

The set of rules $CCR(\mathcal{L}_k)$, $k \geq 1$, is central to the construction of a COCOLOG controller. The operation of the members of such a set is as follows.

Extralogical feedback control specification. If the condition $C^1(\mathcal{L}_k)$ is provable from the theory $Th(o_1^k)$, then the first rule gives the value u^1 to the control constant $U(k)$ (i.e., the control action u^1 will take place in the controlled system); if not, but if $C^2(\mathcal{L}_k)$ is provable, then the second rule gives the value u^2 to the control constant $U(k)$, and so on. If none of the conditions $C^1(\mathcal{L}_k), C^2(\mathcal{L}_k), \ldots, C^R(\mathcal{L}_k)$ is provable, then the last rule sets the control action equal to the arbitrary constant control u^*. This procedure uniquely determines the value of $U(k)$. $\square$

When $k \to k+1$, we make the extralogical step of passing to the theory $Th(o_1^{k+1})$ by carrying along all the previous axioms and adding the axioms $AXM^{obs}(\mathcal{L}_{k+1})$ specifying the

observation of the input, e.g., $Eq(U(k), u^i)$ in case u^i was selected, and the observation of the output, e.g., $Eq(Y(k+1), y^q)$ in case y^q was generated. This is formally enforced by the above definition of the axiom set generating $Th(o_1^{k+1})$. Hence, in the new theory $Th(o_1^{k+1})$, the observed control action $U(k)$ is specified so as to be the constant value u^i determined by $Th(o_1^k)$ through $CCR(\mathcal{L}_k)$.

DEFINITION 2.3. *A* COCOLOG controller *for $\mathcal{M}$, together with the observation sequence $\mathbf{o}_1^k$ at time instant $k \geq 0$, is a pair $\langle \Sigma_k, CCR(\mathcal{L}_k) \rangle$, where Σ_k and $CCR(\mathcal{L}_k)$ are defined above.* □

2.4. Semantics of COCOLOG. For the semantics of any theory $Th(o_1^k)$ in a COCOLOG system, we adopt, in Definitions 2.4 and 2.5 below, a conventional set theoretic model interpretation (see, e.g., [RG87]). Since Σ_k contains all symbols of $\mathcal{L}_k$, we will not distinguish the prestructure of the axiom set and that of the language when the context is clear.

DEFINITION 2.4. *For all $k \geq 0$, a* prestructure *of $\mathcal{L}_k$ is a pair $\langle I_k, \mathbf{D} \rangle$, denoted by $\mathcal{I}_k$, where $\mathbf{D}$ is a nonempty set called the domain, which is the union of $\mathbf{U}$, $\mathbf{X}$, $\mathbf{Y}$, and $\mathbf{I}_{K(N)}$, and where I_k is the interpretation mapping which is defined as follows:*

(1) $I_k(c) = \mathbf{c} \in \mathbf{D}$ *for all $c \in \mathcal{L}_k$ such that* $I_k : U \to \mathbf{U}$, $I_k : X \to \mathbf{X}$, $I_k : Y \to \mathbf{Y}$, $I_k : I_{K(N)} \to \mathbf{I}_{K(N)}$.

(2) $I_K(\Phi) = \mathbf{\Phi} : \mathbf{X} \times \mathbf{U} \to \mathbf{X}$.

(3) $I_K(\eta) = \eta : \mathbf{X} \to \mathbf{Y}$.

(4) $I_k(+_{K(N)}) = +_{\mathbf{K(N)}} : \mathbf{I_{K(N)}} \times \mathbf{I_{K(N)}} \to \mathbf{I_{K(N)}}$.

(5) $I_k(-_{K(N)}) = -_{\mathbf{K(N)}} : \mathbf{I_{K(N)}} \times \mathbf{I_{K(N)}} \to \mathbf{I_{K(N)}}$.

(6) *For* $t = f(\vec{t}) \in \mathrm{Term}(\mathcal{L}_k) : I_k(f(\vec{t})) = I_k(f)(I_k(\vec{t}))$.

(7) $I_k(Eq) = \{(\mathbf{d}, \mathbf{d}) : \mathbf{d} \in \mathbf{D}\}$.

(8) $I_k(Rbl) \subset \mathbf{X} \times \mathbf{X} \times \mathbf{I_{K(N)}}$.

(9) $I_k(CSE_j) \subset \mathbf{X}$, $1 \leq j \leq k$.

(10) $I_k(U(j-1)) \in \mathbf{U}$, $1 \leq j \leq k$.

(11) $I_k(Y(j)) \in \mathbf{Y}$, $1 \leq j \leq k$.

(12) *For* $P \in \mathrm{Pre}(\mathcal{L}_k)$, $\vec{t} \in \mathrm{Term}(\mathcal{L}_k)$, $I_k(P(\vec{t})) = I_k(P)(I_k(\vec{t}))$. □

DEFINITION 2.5. *For all $k \geq 0$, a* structure *for Σ_k and an input-output string $\mathbf{o}_1^k$, $k \geq 1$, is a pair $\langle \mathcal{I}_k, V_k \rangle$, denoted by $\mathcal{H}_k$, where $\mathcal{I}_k$ is a prestructure of Σ_k and V_k is a corresponding* evaluation mapping $WFF(\mathcal{L}_k) \to \{0, 1\}$ *with corresponding type. Under this structure, each formula in $WFF(\mathcal{L}_k)$ will be assigned recursively a truth value $V_k(F) \in \{0, 1\}$ as follows:*

(1) $V_k(\perp) = 0$.

(2) *For a ground atomic formula $P(\vec{t})$, $V_k(P(\vec{t})) = 1$ iff $I_k(P(\vec{t})) \in I_k(P)$.*

(3) *For $F = F_1 \vee F_2$, $V_k(F) = 1$ iff either $V_k(F_1) = 1$ or $V_k(F_2) = 1$.*

(4) *For $F = \neg F_1$, $V_k(F) = 1$ iff $V_k(F_1) = 0$.*

(5) *For $F = F_1 \to F_2$, $V_k(F) = 1$ iff either $V_k(F_1) = 0$ or $V_k(F_2) = 1$.*

(6) *For $F = \forall x F_1$, $V_k(F) = 1$ iff $V_k(F_1(x/c)) = 1$ for all $c \in \mathrm{Const}(\mathcal{L}_k)$.*

(7) *For $F = \exists x F_1$, $V_k(F) = 1$ iff $V_k(F_1(x/c)) = 1$ for some $c \in \mathrm{Const}(\mathcal{L}_k)$.*

In cases (6) *and* (7), *the term c is called a* witness *of x.*

When $V_k(F) = 1$, we say that $\mathcal{H}_k$ satisfies *F, or $\mathcal{H}_k$ is a* model *of F, and denote this by $\mathcal{I}_k \models F$. If $\mathcal{I}_k \models F$ holds for every $F \in \Sigma_k$, then we say that this structure is a model of Σ_k and write $\mathcal{H}_k \models \Sigma_k$. If every model of Σ_k is also a model of F, then we call F a* logical consequence *of Σ_k and write $\Sigma_k \models F$.* □

It should be noted that the sets $\mathbf{U}$, $\mathbf{X}$, and $\mathbf{Y}$ in Definition 2.4 are not in general identical to the sets appearing in the definition of the machine $\mathcal{M}$ which defines the language $\mathcal{L}_0$.

Henceforth, for all $k \geq 0$, we assume that any language $\mathcal{L}_k$ and axiom system $\{\Sigma_k, k \geq 0\}$ are defined so that some machine $\mathcal{M}$, together with a given input-output sequence $\mathbf{o}_1^k$, $k \geq 0$, is a model in the sense of Definitions 2.4 and 2.5 for Σ_k. This is expressed by saying that

$\{\Sigma_k; k \geq 0\}$ is an axiom system for $\mathcal{M}$ and the observed sequence $\mathbf{o}_1^k$. Note that for $k \geq 0$ a model $\mathcal{H}_k$ is defined without any reference to an initial state for a given machine $\mathcal{M}$ and that such an entity is not defined in the languages $\{\mathcal{L}_k, k \geq 0\}$.

Some important properties of COCOLOG families of theories are given in the following theorems.

THEOREM 2.1 (see [CW95, W91]). *For all $k \geq 0$, the axiom set Σ_k for $\mathcal{M}$ together with the observed input-output sequence $\mathbf{o}_1^k$ is consistent.* □

THEOREM 2.2 (unique model property [CW95, W91]). *For all $k \geq 0$, the logical theory $Th(o_1^k)$, generated by the axiom system Σ_k for $\mathcal{M}$ together with the observed input-output sequence $\mathbf{o}_1^k$, has a unique model up to isomorphism.* □

THEOREM 2.3 (decidable theoremhood [CW95, W91]). *For all $k \geq 0$, the logical theory $Th(o_1^k)$, generated by the axiom set Σ_k for $\mathcal{M}$ together with the observed input-output sequence $\mathbf{o}_1^k$, is decidable.* □

THEOREM 2.4 (the nesting theorem [CW95, W91]). *For all $k \geq 0$ and $\mathbf{o}_1^k \subset \mathbf{o}_1^{k+1}$, the logical theory $Th(o_1^k)$, generated by the axiom set Σ_k for $\mathcal{M}$ together with the given sequence $\mathbf{o}_1^k$, is a subtheory of $Th(o_1^{k+1})$, generated by the axiom set Σ_{k+1} for $\mathcal{M}$ and the sequence $\mathbf{o}_1^{k+1}$, i.e., $Th(o_1^k) \subset Th(o_1^{k+1})$.* □

Concerning the size of the axiom set at time $k \geq 0$, we have the following lemma.

LEMMA 2.1. *The size of the axiom sets Σ_k for $\mathcal{M}$ together with the generated sequence $\mathbf{o}_1^k$, $k \geq 0$, satisfies*

$$|\Sigma_k| = |\Sigma_0| + k(N+3).$$

Proof.

$$\begin{aligned}
|\Sigma_k| &= \left|\Sigma_0 \bigcup_{j=1}^{j=k} (AXM^{est}(L_j) \cup AXM^{obs}(L_j) \cup AXM^{subs}(L_j))\right| \\
&= |\Sigma_0| + \left|\bigcup_{j=1}^{j=k} AXM^{est}(L_j)\right| + \left|\bigcup_{j=1}^{j=k} AXM^{obs}(L_j)\right| + \left|\bigcup_{j=1}^{j=k} AXM^{subs}(L_j))\right| \\
&= |\Sigma_0| + \sum_{j=1}^{j=k} |AXM^{est}(L_j)| + \sum_{j=1}^{j=k} |AXM^{obs}(L_j)| + \sum_{j=1}^{j=k} |AXM^{subs}(L_j))| \\
&= |\Sigma_0| + k \cdot N + k \cdot 2 + k \cdot 1 \\
&= |\Sigma_0| + k(N+3). \qquad \square
\end{aligned}$$

Since the results in this paper do not depend explicitly on the sequence of values of any given observed sequence $\mathbf{o}_1^k$, we will, from now on, omit the indication of the particular observation sequence, and in particular, we shall write Th_k instead of $Th(o_1^k)$.

Example 2.2. Suppose that the machine in Example 2.1 generates the observation sequence

$$(\emptyset, \mathbf{y}^1) \quad (\mathbf{u}^1, \mathbf{y}^2) \quad (\mathbf{u}^2, \mathbf{y}^1).$$

Then corresponding observation axiom sets are

$$AXM^{obs}(\mathcal{L}_1) = \{Eq(Y(1), y^1)\}, \quad AXM^{obs}(\mathcal{L}_2) = \{Eq(U(1), u^1), Eq(Y(2), y^2)\},$$
$$AXM^{obs}(\mathcal{L}_3) = \{Eq(U(2), u^2), Eq(Y(3), y^1)\}.$$

A proof sequence in Th_3 which gives a deduction of $CSE_3(x^4)$ is as follows:

(1) $Eq(\Phi(x^1, u^1), x^2)$ AXM^{dyn},
(2) $Eq(\Phi(x^2, u^2), x^4)$ AXM^{dyn},
(3) $Eq(\eta(x^1), y^1)$ AXM^{out},
(4) $Eq(\eta(x^2), y^2)$ AXM^{out},
(5) $Eq(\eta(x^4), y^1)$ AXM^{out},
(6) $Eq(Y(1), y^1)$ $AXM^{obs}(\mathcal{L}_1)$,
(7) $Eq(\eta(x^1), Y(1)) \rightarrow CSE_1(x^1)$ $AXM^{est}(\mathcal{L}_1)$,
(8) $CSE_1(x^1)$ (6), (7), MP,
(9) $Eq(U(1), u^1)$ $AXM^{obs}(\mathcal{L}_2)$,
(10) $Eq(Y(2), y^2)$ $AXM^{obs}(\mathcal{L}_2)$,
(11) $\exists x, CSE_1(x) \wedge Eq(\Phi(x, U(1)), x^2) \wedge Eq(\eta(x^2), Y(2)) \rightarrow CSE_2(x^2)$ $AXM^{est}(\mathcal{L}_2)$,
(12) $CSE_1(x^1) \wedge Eq(\Phi(x^1, U(1)), x^2) \wedge Eq(\eta(x^2), Y(2))$ (1), (4), (9), (8), (10), $\wedge$−rule,
(13) $\exists x, CSE_1(x) \wedge Eq(\Phi(x, U(1)), x^2) \wedge Eq(\eta(x^2), Y(2))$ (12), $\exists$−rule,
(14) $CSE_2(x^2)$ (11), (13), MP,
(15) $Eq(U(2), u^2)$ $AXM^{obs}(\mathcal{L}_3)$,
(16) $Eq(Y(3), y^1)$ $AXM^{obs}(\mathcal{L}_3)$,
(17) $\exists x, CSE_2(x) \wedge Eq(\Phi(x, U(2)), x^4) \wedge Eq(\eta(x^4), Y(3)) \rightarrow CSE_3(x^4)$ $AXM^{est}(\mathcal{L}_3)$,
(18) $CSE_2(x^2) \wedge Eq(\Phi(x^2, U(2)), x^4) \wedge Eq(\eta(x^4), Y(3))$ (2), (5), (14), (15), (16), $\wedge$−rule,
(19) $\exists x, CSE_2(x) \wedge Eq(\Phi(x, U(2)), x^4) \wedge Eq(\eta(x^4), Y(3))$ (18), $\exists$−rule,
(20) $CSE_3(x^4)$ (17), (19), MP. □

One may notice that in order to prove (20), $AXM^{obs}(\mathcal{L}_3)$ and (14) are used. Further, the proof of (14) invokes $AXM^{obs}(\mathcal{L}_2)$ and (8), etc. Actually this chain goes back to the first observation pair. It is obvious that the lengths of the proof sequences of theorems in COCOLOG increase with the lengths of the observation sequences. This is an obstacle to the efficiency of a COCOLOG controller. In the rest of this paper, we present a restricted fragment of the COCOLOG system in which the reasoning complexity is independent of the lengths of the observation sequences.

3. Language fragment $\mathcal{L}_k^m$. The full COCOLOG language defined in the previous section has the power to express the whole observation history of the system, and this gives rise to a monotonic evolution of the theories $\{Th_k; k \geq 0\}$(see the nesting theorem above) which, in particular, permits reference to the past. For example, one may write a formula to express the following control law: If the first control has not been invoked since the beginning of the process, then invoke it now. This control rule can be written as

$$\text{(6)} \qquad \textbf{if} \quad \bigwedge_{j=2}^{j=k} \neg Eq(U(j-1), u^1), \quad \textbf{then} \quad Eq(U(k), u^1),$$

and it can be seen to involve the whole collection of languages from $j = 2$ up to $j = k$ whose union is precisely $\mathcal{L}_k$. On the other hand, such expressive power is unnecessary for the purposes of control with respect to control criteria depending on present and future states and outputs, since the controlled dynamical system is, by definition, current state dependent.

There are two motivating ideas for the introduction of the Markovian fragment languages $\mathcal{L}_k^m$ and theories Th_k^m; first, it is well known that the control of partially observed state-space systems, with respect to current and future input-, state-, and output-dependent criteria, need

only be a function of current state estimates; second, the first fact is reflected in the complexity properties of ATP procedures implementing COCOLOG control rules.

Specifically, we notice that the evolution of COCOLOG theories takes place only by acquiring new observation information; there is no other "learning" taking place, and hence all facts which do not simply describe input and output observations must be deduced within each theory Th_k, $k \geq 1$. This will, in many cases, handicap the efficiency of the reasoning process as the length of the observation sequence increases. For instance, in Example 2.4, (14) is necessary to verify the desired theorem (20); but in order to verify (14), (8) is necessary. In a typical ATP implementation, this chaining effect goes back to the state estimation at the time instant $k = 1$. However, if we take (in an extralogical way) the formula in (14) as an axiom when we make the extralogical transition from Σ_2 to Σ_3, the above proof sequence will be shortened considerably. As a result, we introduce the fragment theories $\{MTh_k; k \geq 1\}$. These are propagated from instant to instant and have an exact analogy to the current state estimates which are propagated in classical control theory problems; their use enormously increases the efficiency of the theorem-proving procedures. The first step in defining the fragment theories is to restrict the set of symbols to that sufficient to express the current observation and the immediately previous one at each time instant.

DEFINITION 3.1. *The symbol set of the* Markovian fragment $\mathcal{L}_k^m$ *of* $\mathcal{L}_k$, $k \geq 1$, *is defined via*

$$S(\mathcal{L}_k^m) \triangleq S(\mathcal{L}_0) \bigcup \{CSE_k, CSE_{k-1}\} \bigcup \{U(k-1), Y(k)\},$$

where the constants and variables are sorted accordingly with respect to $\mathcal{L}_k$. □

It is obvious that $\mathcal{L}_k^m$ has a fixed number of symbols, which are fewer in number than those in $\mathcal{L}_k$. Specifically, compared with $\mathcal{L}_k$,

(1) $\text{Const}(\mathcal{L}_k^m) = \text{Const}(\mathcal{L}_0) \bigcup \{U(k-1), Y(k)\} \subset \text{Const}(\mathcal{L}_k)$.

(2) $\text{Pre}(\mathcal{L}_k^m) = \{Rbl, Eq, CSE_{k-1}, CSE_k\} \subset \text{Pre}(\mathcal{L}_k)$.

(3) $\mathcal{L}_k^m$ has the same set of functional symbols as $\mathcal{L}_k$, i.e., $\text{Func}(\mathcal{L}_k^m) = \text{Func}(\mathcal{L}_k)$.

By the above definition, a term in $\mathcal{L}_k^m$ can be formed only through $\text{Func}(\mathcal{L}_k^m)$, $\text{Var}(\mathcal{L}_k^m)$, and $\text{Const}(\mathcal{L}_k^m)$. Hence a term like $\Phi(x^i, U(k-3))$ is not a term of $\mathcal{L}_k^m$. This restriction also holds for the formulas of $\mathcal{L}_k^m$ defined below.

DEFINITION 3.2. *For all* $k \geq 0$, *the set of* well-formed formulas $WFF(\mathcal{L}_k^m)$ *of* $\mathcal{L}_k^m$ *is defined using the same connectives and formation rules as* $\mathcal{L}_k$ *but is subject to the restriction that the only permitted atomic formulas are instances of Rbl,* CSE_k, CSE_{k-1}, *and Eq with respect to terms of* $\mathcal{L}_k^m$. □

Due to the construction of $\mathcal{L}_k^m$,

$$WFF(\mathcal{L}_k^m) \subset WFF(\mathcal{L}_k), \qquad k \geq 1.$$

As a consequence, $\mathcal{L}_k^m$ cannot express the state estimate formulas concerning the state at time $k-2$ or earlier, and so, for example, (6) is no longer a conditional control rule with respect to $WFF(\mathcal{L}_k^m)$. Intuitively, the language fragment $\mathcal{L}_k^m$ can only express information that relates to the most recent change and the current configuration of the controlled machine. Hence $CCR(\mathcal{L}_k^m)$ can be written only with respect to this fraction of the total information concerning $\mathcal{M}$ at the instant k.

4. Construction of $M\Sigma_k$. With the language fragment in hand, we shall give, in this section, the axiom sets for the Markovian fragment system $\{MTh_k; k \geq 0\}$. We shall continue to make the restriction that the admissible control objectives within a fragment $\{MTh_k; k \geq 0\}$, expressed via the control rules $\{CCR(\mathcal{L}_k^m); k \geq 1\}$, shall refer only to the current and future state (estimate) behavior of the controlled system. Correspondingly, we limit the information

to be transferred into MTh_k at any instant k to that necessary to deduce the current state estimate at k or, more precisely, to deduce the set of states satisfying the predicate CSE_k in MTh_k.

We shall be concerned with the temporal structure of the fragment sequences $\ldots, MTh_{k-1}, MTh_k, MTh_{k+1}, \ldots$, each of them nested respectively within $\ldots, Th_{k-1}, Th_k, Th_{k+1}, \ldots$. We observe in passing that this is the logical analogue of the generation of the state estimate in a linear stochastic control problem. Furthermore, since a critical subset of the theorems of MTh_{k-1} forms a part of the axiom set for MTh_k, a certain form of learning may be said to take place, since these theorems do not have to be deduced again from more elementary information given in axiomatic form.

The definitions below specify an axiom set $M\Sigma_k$, expressed within the language $\mathcal{L}_k^m$, to be a certain combination of (i) axioms for the machine dynamics, reachability, and machine size; (ii) a set of axioms carrying the most recent state estimate theorems; (iii) the most recent observation axioms expressed via the equality predicate; and, in addition to the above, (iv) the most recent estimation axioms.

DEFINITION 4.1. *For a given machine $\mathcal{M}$ and the input-output sequence $\mathbf{o}_1^k$, the axiom set $M\Sigma_k$, $k \geq 0$, of a* Markovian fragment *of a COCOLOG system is recursively defined as follows:*

$$M\Sigma_0 = \Sigma_0, \tag{7}$$

$$M\Sigma_1 = \Sigma_1 = \Sigma_0 \cup AXM^{special}(\mathcal{L}_1^m). \tag{8}$$

Suppose that $M\Sigma_{k-1}$ is defined. Then

$$M\Sigma_k = M\Sigma_0 \cup AXM^{special}(\mathcal{L}_k^m) \cup K(M\Sigma_{k-1}), \quad k > 1, \tag{9}$$

where $AXM^{special}(\mathcal{L}_k^m)(\subset WFF(\mathcal{L}_k^m))$ denotes the following union:

$$AXM^{est}(\mathcal{L}_k^m) \cup AXM^{obs}(\mathcal{L}_k^m) \cup AXM^{subs}(CSE_{k-1}) \cup AXM^{subs}(CSE_k), \tag{10}$$

where $AXM^{obs}(\mathcal{L}_k^m) = \{Eq(U(k-1), u^p), Eq(Y(k), y^q)\}$ if and only if $(\mathbf{u}^p, \mathbf{y}^q)$ is the observation pair at time k and where $K(M\Sigma_{k-1})$ is defined as

$$K(M\Sigma_0) = \emptyset, \tag{11}$$

$$K(M\Sigma_{k-1}) \equiv \{?CSE_{k-1}(x^i) : M\Sigma_{k-1} \vdash ?CSE_{k-1}(x^i),\ ? \in \{\neg,\ \},\ x^i \in X\}, \quad k > 1,$$

where the notation $? = \neg$ indicates the negative assertion of CSE_{k-1} and the positive assertion is indicated by the lack of a symbol before CSE_{k-1}. □

The definition of CSE_{k+1} in a Markovian fragment theory is displayed in Figure 2. Those axiom sets that lie on the left of the dotted box will not appear in $M\Sigma_{k+1}$.

It is to be noted that

$$AXM^{est}(\mathcal{L}_k) = AXM^{est}(\mathcal{L}_k^m), \quad AXM^{subs}(CSE_{k-1}), AXM^{subs}(CSE_k) \subset WFF(\mathcal{L}_k^m)$$

by virtue of the definition of the Markovian fragment languages $\mathcal{L}_k^m$, $k \geq 0$. From the definitions of §2.3, we observe that $AXM^{obs}(\mathcal{L}_k) \subset WFF(\mathcal{L}_k^m)$, so the axiom set $M\Sigma_k$ in Definition 4.1 is well defined within $\mathcal{L}_k^m$.

Example 4.1. For the same observation sequence as in Example 2.2 we have

$$\begin{aligned} K(M\Sigma_1) = \{&CSE_1(x^1), CSE_1(x^4), \neg CSE_1(x^2), \neg CSE_1(x^3), \\ &\neg CSE_1(x^5), \neg CSE_1(x^6), \neg CSE_1(x^7)\}, \\ K(M\Sigma_2) = \{&CSE_2(x^2), CSE_2(x^5), \neg CSE_2(x^1), \neg CSE_2(x^4), \\ &\neg CSE_2(x^3), \neg CSE_2(x^6), \neg CSE_2(x^7)\}. \end{aligned}$$

□

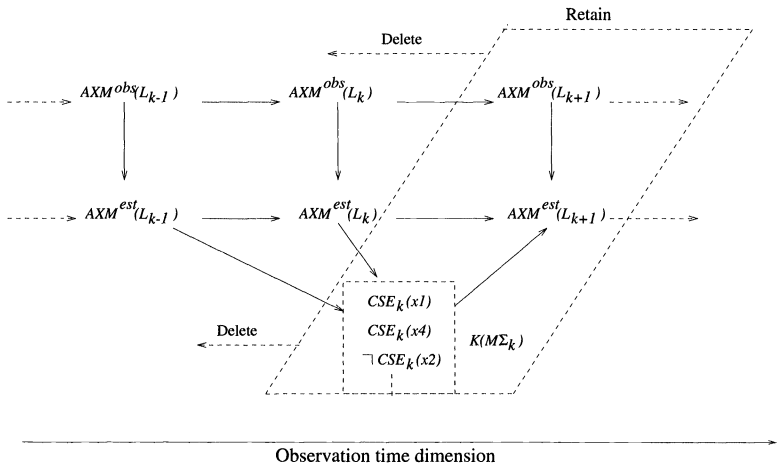

FIG. 2. *Description of definition of* CSE_{k+1}.

Informally speaking, $M\Sigma_k$ drops all the estimation axioms and observation axioms that were added to each Σ_j for $1 \leq j \leq k-1$. The loss of estimation axioms at time instant $k-1$ is compensated for by adding in $K(M\Sigma_{k-1})$, which carries the state estimate theorems from MTh_{k-1} to MTh_k in the form of axioms. Compared to Σ_k, $M\Sigma_k$ contains fewer axioms. But it is not the case that $M\Sigma_k \subset \Sigma_k$ since $K(M\Sigma_{k-1}) \not\subset \Sigma_k$. The axiom evolution for Markovian fragment theories at time instant k can be highlighted by the following equation:

$$\begin{aligned} M\Sigma_k &= M\Sigma_{k-1} \setminus (K(M\Sigma_{k-2}) \cup AXM^{special}(\mathcal{L}_{k-1}^m)) \cup (K(M\Sigma_{k-1}) \cup AXM^{special}(\mathcal{L}_k^m)) \\ &= \Sigma_0 \cup K(M\Sigma_{k-1}) \cup AXM^{special}(\mathcal{L}_k^m). \end{aligned}$$

It should be pointed out that Definition 4.1 itself states that $M\Sigma_k$ and Σ_k use the same state estimation axioms but *does not state that they receive the same observation axioms*; that this is the case requires a proof that the two theories yield the same inputs to the controlled machine $\mathcal{M}$. This is established below in our main result, Theorem 6.1.

The conditional control rules associated with the fragment theories are defined in a way similar to those associated with the full theories.

DEFINITION 4.2 ($CCR(\mathcal{L}_k^m)$). *Let* $\{C^j(\mathcal{L}_k^m), \quad 1 \leq j \leq R\}$ *be a set of formulas in* $WFF(\mathcal{L}_k^m)$, *and let*

$$D^p(\mathcal{L}_k^m) \underline{\Delta} (\neg C^1(\mathcal{L}_k^m) \wedge \cdots \wedge \neg C^{p-1}(\mathcal{L}_k^m)) \wedge C^p(\mathcal{L}_k^m) \quad \textit{for} \quad 1 \leq p \leq R.$$

Then $CCR(\mathcal{L}_k^m)$ *is defined as follows:*

$$\begin{array}{llll} \textbf{if} & D^1(\mathcal{L}_k^m), & \textbf{then} & Eq(U(k), u^1); \\ \textbf{if} & D^2(\mathcal{L}_k^m), & \textbf{then} & Eq(U(k), u^2); \\ \textbf{if} & \vdots & \textbf{then} & \vdots \\ \textbf{if} & D^R(\mathcal{L}_k^m), & \textbf{then} & Eq(U(k), u^R); \\ \textbf{if} & \bigwedge_{i=1}^{R} \neg C^i(\mathcal{L}_k^m), & \textbf{then} & Eq(U(k), u^*). \end{array} \quad \square$$

The *extralogical feedback control specification* and *fragment controller* for the fragment are exactly similar to that for a full COCOLOG system as given in §2.

In exact analogy with Definition 2.2, we define a proof sequence with respect to $M\Sigma_k$ to be a proof sequence which invokes only the members of $M\Sigma_k$. It follows that all formulas of an $M\Sigma_k$-proof sequence fall in $WFF(\mathcal{L}_k^m)$.

We define MTh_k to be the theory generated by $M\Sigma_k$, i.e.,

$$MTh_k \triangleq \{F : M\Sigma_k \vdash F, F \in WFF(\mathcal{L}_k^m)\}.$$

The following assertion concerning the size of the axiom set $M\Sigma_k$ is immediate.

LEMMA 4.1. *With the definition of a Markovian fragment given above, we have*

$$|M\Sigma_k| = |\Sigma_0| + 2N + 4, \qquad k > 1.$$

Proof. It is sufficient to observe that $K(M\Sigma_{k-1})$ contributes N axioms and the bounds are independent of the time index. □

5. Semantics of Markovian fragment theories. The fragment language $\mathcal{L}_k^m$ is a sublanguage of $\mathcal{L}_k$; hence any prestructure of $\mathcal{L}_k^m$ is a substructure of a prestructure of $\mathcal{L}_k$. We observe that the construction of $M\Sigma_k$ is ordained in such a way that a model of $M\Sigma_k$ preserves the essential properties of Σ_k; by this we mean that the properties of an interpretation of $\mathcal{L}_0$ must be preserved in an interpretation of $M\Sigma_k$. These requirements leads to the following definition of a structure for $M\Sigma_k$.

DEFINITION 5.1. *For each $k \geq 0$, the structure $\langle \mathcal{I}_k^m, V_k^m \rangle$ for $M\Sigma_k$ is defined in exactly the same way as that for Σ_k (see Definitions 2.4 and 2.5) except for the following modifications:*

(6′) *for* $t = f(\vec{t}) \in \text{Term}(\mathcal{L}_k^m) : I_k^m(f(\vec{t})) = I_k^m(f)(I_k^m(\vec{t}))$,

(9′) $I_k^m(CSE_j) \subset \mathbf{X}$, $j = k-1, k$,

(10′) $I_k^m(U(k-1)) \in \mathbf{U}$,

(11′) $I_k^m(Y(k)) \in \mathbf{Y}$,

and $V_k^m : WFF(\mathcal{L}_k^m) \longrightarrow \{0, 1\}$. □

In this definition, the model of $M\Sigma_k$ does not depend upon the whole observation sequence but upon the current observation pair and the previous state estimate set characterised by the set of x^i, $1 \leq i \leq N$, such that $CSE_k(x^i)$ holds. We now examine the evolution of full and fragment theories and define the relationship between $\mathcal{H}_{k-1}^m$ and $\mathcal{H}_k^m$.

We give below a well-known lemma for later use.

LEMMA 5.1 (coincidence lemma [EFT84]). *Let $\mathcal{H}' = \langle \mathcal{I}', V' \rangle$ and $\mathcal{H}'' = \langle \mathcal{I}'', V'' \rangle$ be structures for the languages $\mathcal{L}'$ and $\mathcal{L}''$, respectively, both with the same domain* **D**. *Let $\mathcal{L} = \mathcal{L}' \cap \mathcal{L}''$.*

(a) *For any $t \in \text{Term}(\mathcal{L})$, if $\mathcal{H}'$ and $\mathcal{H}''$ agree on the symbols of $S(\mathcal{L})$ occurring in t, then $I'(t) = I''(t)$.*

(b) *For $F \in WFF(\mathcal{L})$, if $\mathcal{H}'$ and $\mathcal{H}''$ agree on the symbols of $S(\mathcal{L})$ occurring in F, and $V'(x) = V''(x)$ for x free in F, then $\mathcal{H}' \models F$ iff $\mathcal{H}'' \models F$.* □

LEMMA 5.2. *Let $\mathcal{H}_{k-1}^m = \langle \mathcal{I}_{k-1}^m, V_{k-1}^m \rangle$ and $\mathcal{H}_k^m = \langle \mathcal{I}_k^m, V_k^m \rangle$ be models of $M\Sigma_{k-1}$ and $M\Sigma_k$, respectively. Then*

(a)

$$I_{k-1}^m|_{\mathcal{L}_{k-1}^m \cap \mathcal{L}_k^m} = I_k^m|_{\mathcal{L}_{k-1}^m \cap \mathcal{L}_k^m}. \tag{12}$$

(b) *V_{k-1}^m and V_k^m agree on the following set:*

$$\Sigma_0 \cup K(M\Sigma_{k-1}). \tag{13}$$

Proof. (a) follows from the definition of $\mathcal{H}_k^m$ and Lemma 5.1. For the proof of (b), it is enough to observe that

$$K(M\Sigma_{k-1}) \subset MTh_{k-1}, \quad K(M\Sigma_{k-1}) \subset M\Sigma_k. \qquad \square$$

DEFINITION 5.2. *Two prestructures $\mathcal{I}$ and $\mathcal{I}'$ of a language L are said to be* isomorphic *if there exists a bijection h between the domains of $\mathcal{I}$ and $\mathcal{I}'$ such that*

(1) *For every $c \in \text{Const}(L)$, $h(I(c)) = I'(c)$.*

(2) *For every $f \in \text{Func}(L)$ and $t_1, \ldots, t_l \in \text{Term}(L)$, $h(I(f(\vec{t}))) = I'(f)(I'(\vec{t}))$.*

(3) *For every $P \in \text{Pre}(L)$ and $t_1, \ldots, t_l \in \text{Term}(L)$, $I(P(\vec{t}))$ iff $I'(P)I'(\vec{t})$.* □

LEMMA 5.3 (isomorphism lemma [EFT84]). *If $\mathcal{I}$ and $\mathcal{I}'$ are isomorphic, then for any $F \in WFF(L)$, we have*

$$\mathcal{H} \models F \Longleftrightarrow \mathcal{H}' \models F. \qquad \square$$

The following theorem is the result of application of Theorem 2.1.

THEOREM 5.1 (see [CW95, W91]). *For $\mathcal{M}$ together with the observation sequence $\mathbf{o}_1^k$, $k \geq 0$, $M\Sigma_k$ is consistent.* □

The proof is via a duplication of that of Theorem 4.2 in [CW95]. Further, we can prove the following theorem.

THEOREM 5.2 (unique model property). *For $k \geq 0$, each logical theory MTh_k^m, generated by the axiom system $M\Sigma_k$ for $\mathcal{M}$ together with the observation sequence $\mathbf{o}_1^k$, has a unique model up to isomorphism.*

Proof. The proof is by induction on k. Let

$$AXM^{obs}(\mathcal{L}_k^m) = \{Eq(U(k-1), u^p), Eq(Y(k), y^q)\},$$

where u^p and y^q shall generically denote the observations at the instant k. We begin with the base case $k = 0$: in this case, $M\Sigma_0 = \Sigma_0$ and the unique model property is given by [CW95, Thm. 4.5].

The inductive step: suppose that theorem holds for $M\Sigma_{k-1}$, $k \geq 1$.

By Lemma 5.2, any two models $\mathcal{H}_k^m = \langle \mathcal{I}_k^m, V_k^m \rangle$ and $\mathcal{H}_k'^m = \langle \mathcal{I}_k'^m, V_k'^m \rangle$ of $M\Sigma_k$ must coincide respectively on a pair of models $\mathcal{H}_{k-1}^m$ and $\mathcal{H}_{k-1}'^m$ of $M\Sigma_{k-1}$ as in Lemma 5.2(b). Further, by the induction hypothesis, there exists an isomorphism $h : \mathbf{D} \longrightarrow \mathbf{D}'$ such that

$$\mathcal{H}_{k-1}^m \overset{h}{\cong} \mathcal{H}_{k-1}'^m.$$

Since both $\mathcal{H}_k^m$ and $\mathcal{H}_k'^m$ satisfy $AXM^{obs}(\mathcal{L}_k^m)$, the following two sets of equations hold:

$$I_k^m(U(k-1)) \overset{U(k-1)=u^p}{=} I_k^m(u^p) \overset{\text{Lemma 5.2}}{=} I_{k-1}^m(u^p) \overset{h}{=} h^{-1}(I'^m_{k-1}(u^p))$$

and

$$I_k^m(Y(k)) \overset{Y(k)=y^q}{=} I_k^m(y^q) \overset{\text{Lemma 5.2}}{=} I_{k-1}^m(y^q) \overset{h}{=} h^{-1}(I_{k-1}^m(y^q)).$$

We define a bijective mapping h^e from $\mathcal{H}_k^m$ to $\mathcal{H}_k'^m$ by extending h as follows:

$$h^e(I_k^m(U(k-1))) = h(I_k^m(u^p)), \qquad h^e(I_k^m(Y(k))) = h(I_k^m(y^q)).$$

It is now straightforward to prove that h^e is a homomorphism from $\mathcal{H}_k^m$ to $\mathcal{H}_k'^m$. Since, first (suppressing subscripts and superscripts on I_k^m for simplicity),

$$\begin{aligned}
h^e(I(\Phi(x^i, U(k-1))) &= h^e(I(\Phi(x^i, u^p))), \qquad \Phi(x^i, U(k-1)) = \Phi(x^i, u^p),\\
&= h(I(\Phi(x^i, u^p))), \qquad h^e|_{\mathcal{L}_0} = h|_{\mathcal{L}_0},\\
&= I'(\Phi)(h(I(x^i)), h(I(u^p))), \qquad h \text{ is a homomorphism},\\
&= I'(\Phi)(h^e(I(x^i)), h^e(I(U(k-1)))),\\
&\quad \text{definition of } h^e,\ h^e(I(U(k-1))) = h^e(I(u^p)).
\end{aligned}$$

Similarly, second, we have $h^e(I(\eta(x^i))) = I'(\eta)(I'(x^i))$. Hence the dynamic axioms have isomorphic interpretations and, hence, so do the reachability axioms. Further, let $E_k(x^i)$ be the abbreviation of the left side of the member of $AXM^{est}(\mathcal{L}_k^m)$ associated with $CSE_k(x^i)$. Then

$$\begin{aligned} V_k^m(CSE_k(x^i)) &= V_k^m(E_k(x^i)), \quad E_k(x^i) \longleftrightarrow CSE_k(x^i), \\ &= V_{k-1}^m(E_k(x^i)), \quad \text{Lemma 5.2}, \\ &= V'^m_{k-1}(E_k(x^i)), \quad \text{inductive hypothesis}, \\ &= V'^m_k(E_k(x^i)), \quad \text{Lemma 5.2}, \\ &= V'^m_k(CSE_k(x^i)), \quad E_k(x^i) \longleftrightarrow CSE_k(x^i). \end{aligned}$$

By the inductive construction of well-formed formulas and by the recursive definitions of V'^m_k and V_k^m, it follows that $V'^m_k(F) = V_k^m(F)$ for all $F \in WFF(\mathcal{L}_k^m)$. Hence

$$\mathcal{H}_k^m \overset{h'}{\cong} \mathcal{H}'^m_k. \qquad \square$$

From the above, we have the following theorem.

THEOREM 5.3 (decidable theoremhood [CW95, W91]). *For all $k \geq 0$, the logical theory MTh_k generated by $M\Sigma_k$ for $\mathcal{M}$ together with the observed input-output pair $(\mathbf{u}^p, \mathbf{y}^q)$ is decidable.* $\square$

We observe that we do not have the nesting property for the Markovian fragment systems since there exist some members of $M\Sigma_{k-1}$ that are not theorems of $M\Sigma_k$. For example, $K(M\Sigma_{k-2}) \not\subset MTh_k$.

6. Control reasoning power of $M\Sigma_k$. In this section, we shall prove that, as long as conditional control formulas are written in $\mathcal{L}_k^m$, there is no difference between the trajectories of identical machines which use a full COCOLOG controller and those that use a Markovian fragment controller to decide which control input shall be applied at each instant of time. In the notation that we have established, we shall prove that if up to any instant k the trajectories of two copies of $\mathcal{M}$ have been identical, then for a formula $F \in WFF(\mathcal{L}_k^m)$, the following holds:

$$M\Sigma_k \vdash F \Longleftrightarrow \Sigma_k \vdash F.$$

Let the formula $D^p(\mathcal{L}_k^m)$ be the conditional formula associated with control action $\mathbf{u}^p$ at time instant k. Assume that one control system carries the axiom set Σ_k, and the other, $M\Sigma_k$. Then the implication of the equivalence above is that the same control decision will be produced by two controllers at the instant k, that is to say,

$$M\Sigma_k \vdash D^p(\mathcal{L}_k^m) \Longleftrightarrow \Sigma_k \vdash D^p(\mathcal{L}_k^m).$$

If we assume that at the instant k both systems are in the same internal state, then the application of the same input takes both systems into the same subsequent state and both emit the same output. Hence the same observation axioms will be entered into the new axiom sets of each control system, and the scenario repeats itself.

To formalize the analysis of this situation we adopt the following hypothesis.

Basic Hypothesis (BH). (1) For all $k \geq 1$, let $\Sigma(o_1^k)$ and $M\Sigma(o'^k_1)$ denote, respectively, the full (COCOLOG) and Markovian fragment axioms systems for two machines, each identical to the given machine $\mathcal{M}$, generating the sequences $\mathbf{o}_1^k$ and $\mathbf{o}'^k_1$ respectively. The two copies of $\mathcal{M}$ are assumed to be in the same state at time $k = 0$.

(2) Furthermore, at each time instant $k \geq 1$, and for all p, $1 \leq p \leq R$, the conditional control formula $D^p(\mathcal{L}_k)$, associated with u^p in the set of formulas $CCR(\mathcal{L}_k)$ attached to $\Sigma_k(o_1^k)$, is identical to $D^p(\mathcal{L}_k^m)$, the conditional control formula associated with u^p in the set of formulas $CCR(\mathcal{L}_k^m)$, attached to $M\Sigma_k(o'^k_1)$, i.e.,

$$D^p(\mathcal{L}_k) = D^p(\mathcal{L}_k^m), \qquad 1 \leq p \leq R. \qquad \square$$

Henceforce, when the context makes the meaning clear, we will write Σ_k (respectively, $M\Sigma_k$) for $\Sigma(o_1^k)$ (respectively, $M\Sigma(o'^k_1)$).

In order to establish our main result, we need the concept of a reduct, which is defined below.

DEFINITION 6.1. *Let $\mathcal{L}$ and $\mathcal{L}'$ be two languages with $S(\mathcal{L}) \subset S(\mathcal{L}')$, and let $\mathcal{H} = \langle \mathcal{I}, V \rangle$ and $\mathcal{H}' = \langle \mathcal{I}', V' \rangle$ be structures for $\mathcal{L}$ and $\mathcal{L}'$, respectively. $\mathcal{H}$ is called a* reduct *of $\mathcal{H}'$ if and only if $\mathbf{D} = \mathbf{D}'$ and V and V' agree on $\mathcal{L}$. In this case, $\mathcal{H}'$ is called an* extension *of $\mathcal{H}$, and we write $\mathcal{H} = \mathcal{H}'|_{\mathcal{L}}$.* $\square$

For a reduct as defined above, the following lemma is well known.

LEMMA 6.1. *For $F \in WFF(\mathcal{L}) \subset WFF(\mathcal{L}')$,*

$$\mathcal{H} \models F \Longleftrightarrow \mathcal{H}' \models F. \qquad \square$$

It is obvious from Lemma 6.1 that $\mathcal{H}_{k-1} = \mathcal{H}_k|_{\mathcal{L}_{k-1}}$.

We now state the main theorem.

THEOREM 6.1. *Let* BH *hold for $\langle \Sigma(o_1^k), CCR(\mathcal{L}_k) \rangle$ and $\langle M\Sigma(o'^k_1), CCR(\mathcal{L}_k^m) \rangle$ with $k \geq 0$. Then for $F \in WFF(\mathcal{L}_k^m)$, we have*

(I) $\Sigma_k \models F \Longleftrightarrow M\Sigma_k \models F$,

(II) $\Sigma_k \vdash F \Longleftrightarrow M\Sigma_k \vdash F$,

(III) $\mathbf{o}_1^k = \mathbf{o}'^k_1$. $\square$

Part (I) states that a formula in $WFF(\mathcal{L}_k^m)$ is a logical consequence of the COCOLOG axiom set if and only if it is a consequence of corresponding fragment axiom set. Part (II) indicates that any formula in $WFF(\mathcal{L}_k^m)$ is provable with respect to the full COCOLOG axiom set if and only if it is provable with respect to the corresponding Markovian fragment axiom set; in other words, $MTh_k = WFF(\mathcal{L}_k^m) \cap Th_k$. Part (III) states that the control input and output sequences generated respectively by the COCOLOG controller and the Markovian fragment controller are identical at each time instant; hence the two closed-loop systems have the same behavior. A schematic representation in terms of both logic controllers is given in Figure 3.

Proof. The proof of the theorem is by induction on k.

Base step: We observe that Theorem 6.1 holds for $k = 0, 1$, since $M\Sigma_0 = \Sigma_0$ and $M\Sigma_1 = \Sigma_1$, and hence the selected input $\mathbf{u}^p$ is the same for both systems. Next, by BH, both copies of the controlled machine are in the same initial state and hence generate the identical observed output $\mathbf{y}^q \in \mathbf{Y}$ at the instant $k = 1$.

Inductive hypothesis: For all $F \in WFF(\mathcal{L}_{k-1}^m)$, $k \geq 1$,

IH1$_{k-1}$ $\Sigma_{k-1} \models F \Longleftrightarrow M\Sigma_{k-1} \models F$,

IH2$_{k-1}$ $\Sigma_{k-1} \vdash F \Longleftrightarrow M\Sigma_{k-1} \vdash F$,

IH3$_{k-1}$ $\mathbf{o}_1^{k-1} = \mathbf{o}'^{k-1}_1$.

Inductive step: Let BH, IH1$_{k-1}$, IH2$_{k-1}$, and IH3$_{k-1}$ hold. Then for $F \in WFF(\mathcal{L}_k^m)$, the following hold:

$$\Sigma_k \models F \Longleftrightarrow M\Sigma_k \models F, \tag{14}$$

$$\Sigma_k \vdash F \Longleftrightarrow M\Sigma_k \vdash F, \tag{15}$$

$$\mathbf{o}_1^k = \mathbf{o}'^k_1. \tag{16}$$

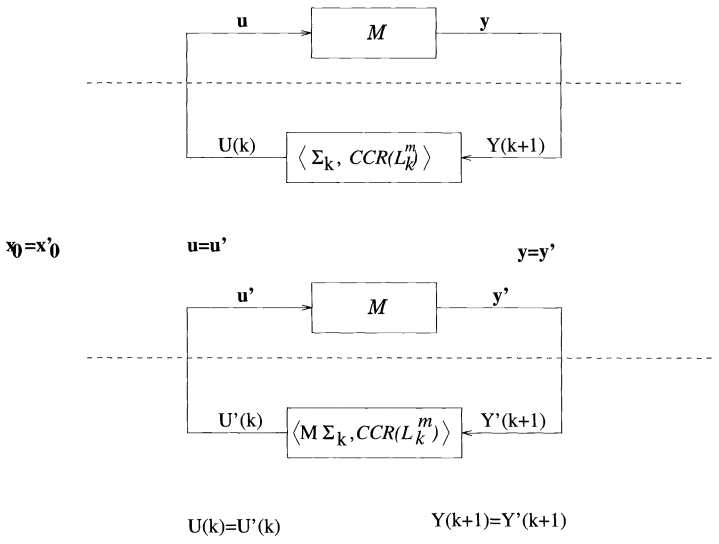

FIG. 3.

The proof of the inductive step is based upon Lemma 6.2, which states that if $\mathcal{H}^m_{k-1}$ is a reduct of $\mathcal{H}_{k-1}$, then $\mathcal{H}^m_k$ is a reduct of $\mathcal{H}_k$.

To establish the inductive step, we observe that statement (14) is an immediate consequence of Lemma 6.2. To prove (15), consider any $F \in WFF(\mathcal{L}^m_k)$. Then

$$\begin{aligned}
& \Sigma_k \vdash F \\
\iff\ & \Sigma_k \models F \quad \text{(completeness of first-order theory } \Sigma_k\text{)} \\
\iff\ & \mathcal{H}_k \models F \quad \text{(unique model property of } \Sigma_k\text{)} \\
\iff\ & \mathcal{H}^m_k \models F \quad \text{(Lemma 6.2)} \\
\iff\ & M\Sigma_k \models F \quad \text{(unique model property of } M\Sigma_k\text{)} \\
\iff\ & M\Sigma_k \vdash F \quad \text{(completeness of first-order theory } M\Sigma_k\text{)}.
\end{aligned}$$

Finally, (16) follows from (15), the identical definitions of the set of control rules $CCR(\mathcal{L}^m_{k-1})$ in each feedback control specification, and the fact that the internal state of each machine is identical at the instant $k-1$. Hence we have established Theorem 6.1 since (14), (15), and (16) of the inductive step have been shown to be the case. □

We now present the lemma.

LEMMA 6.2. *For $k \geq 0$, let $\mathcal{H}^m_k$ be the model defined in Definition* 5.1. *Then* BH, IH1_{k-1}, IH2_{k-1}, IH3_{k-1}, *and $\mathcal{H}^m_{k-1} = \mathcal{H}_{k-1}|_{\mathcal{L}^m_{k-1}}$ imply that $\mathcal{H}^m_k$ is a reduct of $\mathcal{H}_k$, i.e.,*

$$\mathcal{H}^m_k = \mathcal{H}_k|_{\mathcal{L}^m_k}.$$

Proof. We show that the model of the fragment axiom set $M\Sigma_k$ is a reduct of the model of the full-version counterpart Σ_k. First, we note that $AXM^{est}(\mathcal{L}^m_k) = AXM^{est}(\mathcal{L}_k)$. Next, by IH2_{k-1}, for any $F \in WFF(\mathcal{L}^m_{k-1} \cap \mathcal{L}^m_k)$,

$$M\Sigma_{k-1} \vdash F \iff \Sigma_{k-1} \vdash F.$$

Now, by the first part of BH, the (exclusive and exhaustive) conditional control rules attached to Σ_{k-1} and $M\Sigma_{k-1}$ are identical and are both denoted by $CCR(\mathcal{L}^m_{k-1})$. It follows from IH2_{k-1}

that the unique conditional control formula $D^p(\mathcal{L}^m_{k-1})$, $p \in \{1, \ldots, R\}$, which is provable from $M\Sigma_{k-1}$, is also the unique such formula provable from Σ_{k-1}. Hence the same control actions are applied to each system at the instant $k-1$, and by $IH3_{k-1}$, the same holds for the instants j, $1 \leq j \leq k-2$. Further, by BH, the machines controlled by $M\Sigma_{k-1}$ and Σ_{k-1} are identical, and the initial states are same. So the internal state and output sequences must be the same up to the subsequent time instant k. Consequently the same observation axiom sets $AXM^{obs}(\mathcal{L}^m_k)$ and $AXM^{obs}(\mathcal{L}_k)$ are supplied to $M\Sigma_k$ and Σ_k, i.e., $AXM^{obs}(\mathcal{L}_k) = AXM^{obs}(\mathcal{L}^m_k)$, and we have

$$\mathcal{H}_k \models Eq(U(k-1), u^p) \Longleftrightarrow \mathcal{H}^m_k \models Eq(U(k-1), u^p)$$

and

$$\mathcal{H}_k \models Eq(Y(k), y^q) \Longleftrightarrow \mathcal{H}^m_k \models Eq(Y(k), y^q).$$

Further,

$$\begin{aligned}
&\mathcal{H}_k \models CSE_{k-1}(x^i) \\
\Longleftrightarrow &\mathcal{H}_{k-1} \models CSE_{k-1}(x^i) \quad (\mathcal{H}_{k-1} \text{ is a reduct of } \mathcal{H}_k \text{ and Lemma 5.1}) \\
\Longleftrightarrow &\mathcal{H}^m_{k-1} \models CSE_{k-1}(x^i) \quad (\text{inductive hypothesis}) \\
\Longleftrightarrow &\mathcal{H}^m_k \models CSE_{k-1}(x^i) \quad (\text{Theorem 5.2}).
\end{aligned}$$

Since, in addition, $AXM^{est}(\mathcal{L}_k) = AXM^{est}(\mathcal{L}^m_k)$, the result follows from

$$\mathcal{H}^m_k \models CSE_k(x^i) \Longleftrightarrow \mathcal{H}_k \models CSE_k(x^i), \quad 1 \leq i \leq N. \qquad \square$$

As an immediate application of Theorem 6.1, we have the following corollaries.

COROLLARY 6.1. *Let* BH *hold for* $\langle \Sigma_k, CCR(\mathcal{L}_k)\rangle$ *and* $\langle M\Sigma_k, CCR(\mathcal{L}^m_k)\rangle$, $k \geq 1$. *Then*

$$\Sigma_k \vdash CSE_k(x^i) \Longleftrightarrow M\Sigma_k \vdash CSE_k(x^i).$$

Proof. Take $F = CSE_k(x^i)$, and apply Theorem 6.1. $\square$

COROLLARY 6.2. *Let* BH *hold for* $\langle \Sigma_k, CCR(\mathcal{L}_k)\rangle$ *and* $\langle M\Sigma_k, CCR(\mathcal{L}^m_k)\rangle$, $k \geq 0$. *Then for all* $k \geq 0$,

$$Eq(U(k), u^p) \in M\Sigma_{k+1} \Longleftrightarrow Eq(U(k), u^p) \in \Sigma_{k+1}.$$

Proof. Let F be $D^p(\mathcal{L}^m_k)$, and apply Theorem 6.1. $\square$

From Corollary 6.2, we conclude that $AXM^{obs}(\mathcal{L}_{k+1}) = AXM^{obs}(\mathcal{L}^m_{k+1})$, which means that MTh_k and Th_k will be incremented by the same observation axioms.

7. Analysis of MTh_k proof sequences. In this section, we show that shorter proof sequences can be obtained in $M\Sigma_k$ than in Σ_k, $k \geq 1$, for theorems that involve the state estimate predicate. These kinds of formulas are typically used to form conditional control rules. It should be noted that the analysis in this section is proof theoretic and hence does not involve semantic considerations.

Example 7.1. Suppose that Machine 1 generates the observation sequence

$$(\emptyset, \mathbf{y}^1) \quad (\mathbf{u}^1, \mathbf{y}^2) \quad (\mathbf{u}^2, \mathbf{y}^1).$$

Then $M\Sigma_3 \vdash CSE_3(x^4)$ and one of the proof sequences demonstrating $CSE_3(x^4)$ is the following:

(1) $Eq(\Phi(x^1, u^1), x^2)$ AXM^{dyn},
(2) $Eq(\Phi(x^2, u^2), x^4)$ AXM^{dyn},
(3) $Eq(\eta(x^1), y^1)$ AXM^{out},
(4) $Eq(\eta(x^2), y^2)$ AXM^{out},
(5) $Eq(\eta(x^4), y^1)$ AXM^{out},
(6) $CSE_2(x^2)$ $K(M\Sigma_2)$,
(7) $Eq(U(2), u^2)$ $AXM^{obs}(\mathcal{L}_3^m)$,
(8) $Eq(Y(3), y^1)$ $AXM^{obs}(\mathcal{L}_3^m)$,
(9) $\exists x, CSE_2(x) \wedge Eq(\Phi(x, U(2)), x^4) \wedge Eq(\eta(x^4), Y(3)) \rightarrow CSE_3(x^4)$ $AXM^{est}(\mathcal{L}_3^m)$,
(10) $CSE_2(x^2) \wedge Eq(\Phi(x^2, U(2)), x^4) \wedge Eq(\eta(x^4), Y(3))$ (2), (5), (6), (7), (8), $\wedge$–rule,
(11) $\exists x, CSE_2(x) \wedge Eq(\Phi(x, U(2)), x^4) \wedge Eq(\eta(x^4), Y(3))$ (11), $\exists$–rule,
(12) $CSE_3(x^4)$ (9), (11), MP. □

Note that the recursive chain of the Σ_3 proof in Example 2.2 is broken at (6), where $CSE_2(x^2)$ is treated as an axiom and hence needs no verification via proof. By the definition of a proof sequence with respect to Σ_k, formulas in $K(M\Sigma_{k-1})$ (see §2) cannot appear in a Σ_k-proof list $\mathcal{P}$ without being the result of deductions using previous lines in $\mathcal{P}$. This is because the formulas in $K(M\Sigma_{k-1})$ are not logical axioms, nor are they members of Σ_k.

The theorem below formally states how an $M\Sigma_k$-proof can be extended to a Σ_k-proof by extending all $K(M\Sigma_{k-1})$-lines in a $M\Sigma_k$-proof sequence.

THEOREM 7.1. *Suppose that $F \in MTh_k$, and let $\mathcal{P}$ be an $M\Sigma_k$-proof of F. Then there exists a Σ_k-proof $\mathcal{P}'$ of F such that $|\mathcal{P}'| \geq |\mathcal{P}|$.*

Proof. Let $\mathcal{P} \underline{\Delta} \{L_1, L_2, \ldots, L_n\}$ be an $M\Sigma_k$-proof sequence for F. Then the corresponding proof sequence $\mathcal{P}'$ can be constructed as follows. By definition, each of the lines L_i is either a member of $M\Sigma_k$ or a formula deduced from its predecessors in the sequence. Let L_i be the last line in $\mathcal{P}$ such that $L_i \in M\Sigma_k$. Then there are two cases to consider: first, $L_i \notin K(M\Sigma_{k-1})$. In this case,

$$L_i \in \Sigma_0 \cup AXM^{obs}(\mathcal{L}_k^m) \cup AXM^{est}(\mathcal{L}_k^m);$$

hence, by Theorem 6.1,

$$L_i \in \Sigma_0 \cup AXM^{obs}(\mathcal{L}_k) \cup AXM^{est}(\mathcal{L}_k).$$

So L_i itself is a Σ_k-line, and in this case, we leave the line unchanged.

Second, $L_i \in K(M\Sigma_{k-1})$, i.e., $L_i = ?CSE_{k-1}(x^j)$ for some $x^j \in X$; then, by the definition of $K(M\Sigma_{k-1})$,

$$M\Sigma_{k-1} \vdash L_i \in WFF(\mathcal{L}_{k-1}^m),$$

and so there exists an $M\Sigma_{k-1}$-proof sequence of L_i, say, $\mathcal{P}_i^{(1)} \underline{\Delta} \{L_1^i, \ldots, L_{q_i}^i\}$ with $L_{q_i}^i = L_i$. Now replace L_i in $\mathcal{P}$ with $\mathcal{P}_i$ to get the new proof sequence for F:

$$\{L_1, \ldots, L_{i-1}, \{\mathcal{P}_i^{(1)}\}, L_{i+1}, \ldots, L_n\}.$$

Note that L_i appears in the last line of $\mathcal{P}_i$, so if L_i is used to deduce any other formula L_j, $j > i$, it can still be invoked after $\mathcal{P}_i$ has been inserted. This procedure is repeated until all $K(M\Sigma_{k-1})$-lines have been replaced by their corresponding $M\Sigma_{k-1}$-proof sequences. Let the resulting sequence be

$$\mathcal{P}^{(1)} \underline{\Delta} \{\mathcal{P}_1, \mathcal{P}_2, \ldots, \mathcal{P}_n\},$$

where

$$\mathcal{P}_i = \begin{cases} L_i & \text{if } L_i \notin K(M\Sigma_{k-1}), \\ \text{a } M\Sigma_{k-1}\text{-proof of } L_i & \text{otherwise.} \end{cases}$$

If $\mathcal{P}_i$ is an inserted sequence and there exist $K(M\Sigma_{k-2})$-lines in this $M\Sigma_{k-1}$-proof, we apply the same procedure to each of them to get $\mathcal{P}^{(2)}$, in which there are no $K(M\Sigma_{k-1})$- nor $K(M\Sigma_{k-2})$-lines. Repeating this procedure a finite number times eventually yields $\mathcal{P}'$, in which each line is in Σ_k, and hence is such that the whole sequence $\mathcal{P}'$ is in Σ_k. Clearly $|\mathcal{P}'| \geq |\mathcal{P}|$, and this establishes the theorem. □

If the above proof itself is viewed as an expansion method for an $M\Sigma_k$-proof, then the proof in the following lemma can be viewed as a technique for shortening a Σ_k-proof.

LEMMA 7.1. *Suppose that* $\Sigma_k \vdash CSE_k(x^i)$. *Then there exists an* $M\Sigma_k$*-proof of* $CSE_k(x^i)$ *which has a fixed length with respect to* k. □

Proof. First we recall from [CW95] that $Eq(\Phi(x, U(k-1)), y)$ is the abbreviation of $Eq(\Phi(x, u^p), y) \wedge Eq(U(k-1), u^p)$ for some $u^p \in U$, and $Eq(\eta(x^i), Y(k))$ is the abbreviation of $Eq(\eta(x^i), y^q) \wedge Eq(Y(k), y^q)$ for some $y^q \in Y$.

Consider any $k > 1$. Suppose $\Sigma_k \vdash CSE_k(x^i)$. Then from the definition of $AXM^{est}(\mathcal{L}_k^m)$ we have

$$\Sigma_k \vdash \exists x, CSE_{k-1}(x) \wedge Eq(\Phi(x, U(k-1)), x^i) \wedge Eq(\eta(x^i), Y(k)).$$

Then, by the logical axioms,

$$\Sigma_k \vdash CSE_{k-1}(x^j) \wedge Eq(\Phi(x^j, U(k-1)), x^i) \wedge Eq(\eta(x^i), Y(k))$$

for some $x^j \in X$. Hence,

$$\Sigma_k \vdash CSE_{k-1}(x^j),$$

and by Corollary 6.1,

$$M\Sigma_k \vdash CSE_{k-1}(x^j).$$

Hence $CSE_{k-1}(x^j) \in K(M\Sigma_{k-1})$. Similarly we have

$$\Sigma_k \vdash Eq(\Phi(x^j, u^p), x^i) \quad \text{and} \quad \Sigma_k \vdash Eq(\eta(x^i), y^q),$$

which implies

$$Eq(\Phi(x^j, u^p), x^i) \in AXM^{dyn}(\mathcal{L}_0) \quad \text{and} \quad Eq(\eta(x^i), y^q) \in AXM^{out}(\mathcal{L}_0).$$

Now we can construct the following proof sequence for $CSE_k(x^i)$ and hence establish the lemma:

(1) $Eq(Y(k), y^q)$ $AXM^{obs}(\mathcal{L}_k^m)$,
(2) $Eq(U(k-1)), u^p)$ $AXM^{obs}(\mathcal{L}_k^m)$,
(3) $Eq(\Phi(x^j, u^p), x^i)$ $AXM^{dyn}(\mathcal{L}_0)$,
(4) $Eq(\eta(x^i), y^q))$ $AXM^{out}(\mathcal{L}_0)$,
(5) $CSE_{k-1}(x^j)$ $K(M\Sigma_{k-1})$,
(6) $Eq(\Phi(x^j, U(k-1)), x^i)$ (2), (3), AXM^{Eq}, MP,
(7) $Eq(\eta(x^i), Y(k))$ (1), (4) AXM^{Eq}, MP,
(8) $CSE_{k-1}(x^j) \wedge Eq(\Phi(x^j, U(k-1)), x^i)$ (5), (6), $\wedge_1$−rule,
(9) $CSE_{k-1}(x^j) \wedge Eq(\Phi(x^j, U(k-1)), x^i) \wedge Eq(\eta(x^i), Y(k))$ (8), (7), $\wedge_1$−rule,
(10) $\exists x, CSE_{k-1}(x) \wedge Eq(\Phi(x, U(k-1)), x^i) \wedge Eq(\eta(x^i), Y(k))$ (9), logical axiom (4), definition of $\exists$,
(11) $\exists x, CSE_{k-1}(x) \wedge Eq(\Phi(x, U(k-1)), x^i) \wedge Eq(\eta(x^i), Y(k)) \leftrightarrow CSE_k(x^i)$ $AXM^{est}(\mathcal{L}_k^m)$,

(12) $\exists x, CSE_{k-1}(x) \wedge Eq(\Phi(x, U(k-1)), x^i) \wedge Eq(\eta(x^i), Y(k)) \rightarrow CSE_k(x^i)$
(11), $\wedge_1$–rule,
(13) $CSE_k(x^i)$ (10), (12), MP. □

Remark. By use of AXM^{Eq}, we can also find a shorter proof for $CSE_k(t)$ with $t \in \text{Term}(\mathcal{L}_k^m)$ if $\Sigma_k \vdash CSE_k(t)$.

Remark. Although Lemma 7.1 can be generalized to apply to any $F \in WFF(\mathcal{L}_k^m)$, it is not our intention to give a detailed proof in this paper. In general, for a given $F \in WFF(\mathcal{L}_k^m) \cap Th_k$, which does not contain predicates CSE_k or CSE_{k-1}, the shortest Σ_k-proof sequence of such formula is also an $M\Sigma_k$-proof sequence; hence we may not be able to find a shorter proof with respect to $M\Sigma_k$. However, if F contains CSE_k or CSE_{k-1}, then the shortest $M\Sigma_k$-proof of F will be shorter than the shortest Σ_k-proof. Moreover, since the length of proof for the formula $CSE_k(x^i)$ with respect Σ_k depends upon the time index k while that with respect to $M\Sigma_k$ does not, the effect of invoking axioms in $K(M\Sigma_{k-1})$ on the proof of F will become more marked as k increases. In Appendix 2, we present two pairs of examples generated on a computer by theorem-proving software to illustrate such a phenomenon.

Example 7.2. For the seven-state machine presented in Example 2.1, suppose that the target state is x^3. The first line of a $CCR(\mathcal{L}_2)$ associated with u^1 is

$$\textbf{if } \exists x \exists l, CSE_2(x) \wedge Rbl(\Phi(x, u^1), x^3, l), \quad \textbf{then } \quad Eq(U(2), u^1).$$

Given the observation sequence $\{(\emptyset, \mathbf{y}^1), (\mathbf{u}^1, \mathbf{y}^2)\}$ of Example 2.2, we shall obtain the control action u^1 at the instant 2 by proving the antecedent clause of the **if-then** rule $CCR(\mathcal{L}_2)$. The first part of the proof of the conditional control condition is the proof of $CSE_2(x^2)$ in Th_2. For the sake of simplicity, we omit some rudimentary deductions from the two proofs below; these deductions can be carried out as both Σ_k and $M\Sigma_k$ proofs and hence are not relevant in comparisons of the length of Σ_k and $M\Sigma_k$ proofs.

(1) $Eq(Y(1), y^1)$ $AXM^{obs}(\mathcal{L}_1)$,
(2) $Eq(Y(2), y^2)$ $AXM^{obs}(\mathcal{L}_2)$,
(3) $Eq(U(1), u^1)$ $AXM^{obs}(\mathcal{L}_2)$,
(4) $Eq(\eta(x^1), Y(1)) \leftrightarrow CSE_1(x^1)$ $AXM^{est}(\mathcal{L}_1)$,
(5) $Eq(\eta(x^1), y^1)$ AXM^{out},
(6) $Eq(\eta(x^1), y^1) \rightarrow CSE_1(x^1)$ (4), $\wedge_2$–rule,
(7) $CSE_1(x^1)$ (5), (6), MP,
(8) $\exists x CSE_1(x) \wedge Eq(\Phi(x, U(1)), x^2) \wedge Eq(\eta(x^2), Y(2)) \leftrightarrow CSE_2(x^2)$
$AXM^{est}(\mathcal{L}_2)$,
(9) $\exists x CSE_1(x) \wedge Eq(\Phi(x, U(1)), x^2) \wedge Eq(\eta(x^2), Y(2)) \rightarrow CSE_2(x^2)$
(8), $\wedge_2$–rule,
(10) $CSE_1(x^1) \wedge Eq(\Phi(x^1, U(1)), x^2) \wedge Eq(\eta(x^2), Y(2))$ (6), AXM^{dyn},
AXM^{out}, $\wedge_1$–rule,
(11) $\exists x CSE_1(x) \wedge Eq(\Phi(x, U(1)), x^2) \wedge Eq(\eta(x^2), Y(2))$ (10), definition of $\exists$,
(12) $CSE_2(x^2)$ (9), (11), MP. □

The second part is the proof of $Rbl(\Phi(x^2, u^1), x^3, 1)$:

(13) $\forall x \forall y, (\exists u Eq(\Phi(x, u), y) \rightarrow Rbl(x, y, 1))$ AXM^{Rbl},
(14) $Eq(\Phi(x^1, u^2), x^3)$ AXM^{dyn},
(15) $Eq(\Phi(x^1, u^2), x^3) \rightarrow Rbl(x^1, x^3, 1)$ logic axiom (4), (13), MP,
(16) $Rbl(x^1, x^3, 1)$ (14), (15), MP,
(17) $Eq(\Phi(x^2, u^1), x^2)$ AXM^{dyn},
(18) $Eq(\Phi(x^2, u^1), x^1) \rightarrow (Rbl(x^1, x^3, 1) \rightarrow Rbl(\Phi(x^2, u^1), x^3, 1))$
logic axiom (4), AXM^{Eq},
(19) $Rbl(x^1, x^3, 1) \rightarrow Rbl(\Phi(x^2, u^1), x^3, 1)$ (17), (18), MP,
(20) $Rbl(\Phi(x^2, u^1), x^3, 1)$ (16), (19), MP.

Finally,

(21) $CSE_2(x^2) \wedge Rbl(\Phi(x^2, u^1), x^3, 1)$ (11), (20), $\wedge_1$−rule,

(22) $\exists x \exists l, CSE_2(x) \wedge Rbl(\Phi(x, u^i), x^3, l-1)$ definition of $\exists$, (21).

The extralogical control rules $CCR(L_2)$ then give $Eq(U(2), u^1)$. So $Eq(U(2), u^1) \in \Sigma_3$.

The proof of the control condition for $Eq(U(2), u^1)$ with respect to $M\Sigma_2$ can be obtained by appending lines (13) to (22) above to the initial sequence of lines shown below, which constitutes a proof of $CSE_2(x^2)$ in MTh_2. The length of the proof is then 18 steps instead of 22 as in the previous proof with respect to Th_2.

(1) $Eq(Y(2), y^2)$ $AXM^{obs}(\mathcal{L}_2)$,

(2) $Eq(U(1), u^1)$ $AXM^{obs}(\mathcal{L}_2)$,

(3) $CSE_1(x^1)$ $K(M\Sigma_1)$,

(4) $\exists x CSE_1(x) \wedge Eq(\Phi(x, U(1)), x^2) \wedge Eq(\eta(x^2), Y(2)) \rightarrow CSE_2(x^2)$ $AXM^{est}(\mathcal{L}_2)$,

(5) $\exists CSE_1(x^1) \wedge Eq(\Phi(x^1, U(1)), x^2) \wedge Eq(\eta(x^2), Y(2)) \rightarrow CSE_2(x^2)$ $AXM^{est}(\mathcal{L}_2)$,

(6) $\exists CSE_1(x^1) \wedge Eq(\Phi(x^1, U(1)), x^2) \wedge Eq(\eta(x^2), Y(2))$ (1), (2), AXM^{out}, $\wedge_1$−rule,

8. Appendix 1: A complete description of Σ_0. We list all the axioms and other components of Σ_0 except for the particular finite machine axioms, which would be given separately for any specific controlled machine $\mathcal{M}$, and the reachability axioms that appear in §2.

$AXM^{log}(\mathcal{L}_0)$:

(1) $A \rightarrow (B \rightarrow A)$.

(2) $(A \rightarrow (B \rightarrow C)) \rightarrow ((A \rightarrow B) \rightarrow (A \rightarrow C))$.

(3) $(\neg B \rightarrow \neg A) \rightarrow ((\neg B \rightarrow A) \rightarrow B)$.

(4) $\forall x A(x) \rightarrow A(t)$, $t \in \text{Term}(\mathcal{L}_0)$.

(5) $\forall x(A \rightarrow B) \rightarrow (A \rightarrow \forall x B)$, x not free in A.

$AXM^{Eq}(\mathcal{L}_0)$:

(1) $\forall x Eq(x, x)$.

(2) $\forall x \forall y Eq(x, y) \rightarrow Eq(y, x)$.

(3) $\forall x \forall y \forall z Eq(x, y) \wedge Eq(y, z) \rightarrow Eq(x, z)$.

(4) $\forall x \forall y Eq(x, y) \rightarrow Eq(\eta(x), \eta(y))$.

(5) $\forall x \forall y \forall u(Eq(x, y) \rightarrow Eq(\Phi(x, u), \Phi(y, u)))$.

(6) $\forall u \forall v \forall u(Eq(u, v) \rightarrow Eq(\Phi(x, u), \Phi(x, v)))$.

(7) $\forall x \forall y \forall z(Eq(x, y) \rightarrow Eq(+_{K(N)}(x, z), +_{K(N)}(y, z)))$.

(8) $\forall x \forall y \forall z(Eq(x, y) \rightarrow Eq(+_{K(N)}(z, x), +_{K(N)}(z, y)))$.

(9) $\forall x \forall y \forall z(Eq(x, y) \rightarrow Eq(-_{K(N)}(x, z), -_{K(N)}(y, z)))$.

(10) $\forall x \forall y \forall z(Eq(x, y) \rightarrow Eq(-_{K(N)}(z, x), -_{K(N)}(z, y)))$.

(11) $\forall x_1 \forall x_2 \forall x_3 \forall y_1 \forall y_2 \forall y_3(Eq(x_1, y_1) \wedge Eq(x_2, y_2) \wedge Eq(x_3, y_3) \rightarrow (Rbl((x_1, x_2, x_3) \rightarrow Rbl(y_1, y_2, y_3))))$.

(12) $\forall x_1 \forall x_2 \forall y_1 \forall y_2(Eq(x_1, y_1) \wedge Eq(x_2, y_2) \rightarrow (Eq(x_1, x_2) \rightarrow Eq(y_1, y_2)))$.

$AXM^{subs}(\mathcal{L}_k)$:

$\forall x \forall y(Eq(x, y) \rightarrow (CSE_k(x) \rightarrow CSE_k(y)))$.

$AXM^{arith}(\mathcal{L}_0)$: For the arithmetic functions $+_{K(N)}$, $-_{K(N)}$, specified via

$$a +_{K(N)} b = \begin{cases} a + b & \text{if } a + b \leq K(N), \\ K(N) + 1 & \text{if } a + b > K(N) \end{cases}$$

and

$$a -_{K(N)} b = \begin{cases} a - b & \text{if } a + b \geq K(N), \\ 0 & \text{if } a + b < K(N), \end{cases}$$

the axioms are

$$Eq(0 +_{K(N)} 0, 0),\ Eq(0 +_{K(N)} 1, 1), \ldots, Eq(0 +_{K(N)} (N), K(N)),$$

$$Eq(1 +_{K(N)} 1, 2), \ldots, Eq(1 +_{K(N)} K(N), K(N) + 1),$$

$$Eq(2 +_{K(N)} 2, 4), \ldots, Eq(2 +_{K(N)} K(N), K(N) + 1),$$

$$\vdots$$

$$Eq(K(N) +_{K(N)} K(N), K(N) + 1).$$

and

$$Eq(K(N) -_{K(N)} 0, K(N)), \ldots, Eq(K(N) -_{K(N)} K(N), 0),$$

$$Eq((K(N) - 1) -_{K(N)} K(N), 0), \ldots, Eq((K(N) - 1) -_{K(N)} 0, K(N) - 1),$$

$$\vdots$$

$$Eq(0 -_{K(N)} 0, 0).$$

$AXM^{size}(\mathcal{L}_0)$:

(1) For the state space:

$\neg Eq(x^1, x^2) \wedge \neg Eq(x^1, x^3) \wedge \cdots \wedge \neg Eq(x^1, x^N)$
$\wedge \neg Eq(x^2, x^3) \wedge \cdots \wedge \neg Eq(x^2, x^N)$
$\wedge \cdots$
$\wedge \neg Eq(x^{N-1}, x^N).$
$\forall x(\vee_{i=1}^{N} Eq(x, x^i))$

(2) For the input space:

$\neg Eq(u^1, u^2) \wedge \neg Eq(u^1, u^3) \wedge \cdots \wedge \neg Eq(u^1, u^R)$
$\wedge \neg Eq(u^2, u^3) \wedge \cdots \wedge \neg Eq(u^2, u^R)$
$\wedge \cdots$
$\wedge \neg Eq(u^{R-1}, u^R).$
$\forall u(\vee_{i=1}^{R} Eq(u, u^i))$

(3) For the output space:

$\neg Eq(y^1, y^2) \wedge \neg Eq(y^1, y^3) \wedge \cdots \wedge \neg Eq(y^1, y^M)$
$\wedge \neg Eq(y^2, y^3) \wedge \cdots \wedge \neg Eq(y^2, y^M)$
$\wedge \cdots$
$\wedge \neg Eq(y^{M-1}, y^M).$
$\forall y(\vee_{i=1}^{M} Eq(y, y^i))$

(4) For the integers in $\mathcal{L}_0$:

$\neg Eq(0, 1) \wedge \neg Eq(0, 2) \wedge \cdots \wedge \neg Eq(0, K(N) + 1)$
$\wedge \neg Eq(1, 2) \wedge \cdots \wedge \neg Eq(1, K(N) + 1)$
$\wedge \cdots$
$\wedge \neg Eq(K(N), K(N) + 1).$
$\forall l(\vee_{i=0}^{K(N)+1} Eq(l, i))$

Inference rules.

MP. Let A and B be well-formed formulas. Then

$$\frac{A,\ A \rightarrow B}{B}.$$

Generalization. Let A be a well-formed formula. Then

$$\frac{A}{\forall x A}.$$

Invoking the deduction theorem of first-order theory, we add the following rules:

$\bigwedge_1$-*rule.*

$$\frac{A, B}{A \wedge B}.$$

$\bigwedge_2$-*rule.*

$$\frac{A \wedge B}{A}.$$

9. Appendix 2: Two examples of ATP in Σ_k and $M\Sigma_k$. Using the seven-state machine of Example 2.1 and the observation sequences $\mathbf{o}_1^3$ and $\mathbf{o}_1^4$ displayed below, we may present a comparison of the proofs of two COCOLOG theorems in a full COCOLOG theory and its fragmentary counterpart. The first pair of proofs are for the theorem $CSE_3(x^4)$ in, respectively, Σ_3 and $M\Sigma_3$, given the observation sequence $\mathbf{o}_1^3$. The second pair of proofs are for the theorem $CSE_4(x^6)$ in, respectively, Σ_4 and $M\Sigma_4$, given the observation sequence $\mathbf{o}_1^4$. We recall that $CSE_3(x^4)$ (respectively, $CSE_4(x^6)$) means that x^4 (respectively, x^6) lies in the state estimate set at time instant $k = 3$ (respectively, $k = 4$).

The proof methodology used in the examples below is based upon the resolution principle, where the axiom set is written in clausal form. The reader may refer to [CL73] for full description of all terms and concepts from ATP used here. The proofs were generated by use of the general-purpose theorem-proving software GTP that was developed at McGill University by M. Newborn et al. [N89], in conjunction with the so-called function evaluation facility FE, which was proposed by S. Wang and P. E. Caines [WC92] and implemented by Q. X. Yu and S. Wang.

Each proof listing consists of

(1) a modified axiom set, i.e., a modified version of a full COCOLOG axiom set or a Markovian fragment axiom set. In these proof listings, phi7 stands for the transition function Φ. The FE facility of the GTP program (see [WC92]) replaces the axiomatic definition of phi7, and the predicate eta replaces the output function η. For technical reasons concerning the ATP proof procedure, we use the predicate $eta(\cdot, \cdot)$ for the specification of the output function, e.g., eta(x1,y1) replaces the formula $Eq(\eta(x^1), y^1)$. Similarly, output2(y1) (respectively, input1(u1)) replaces the formula $Eq(Y(2), y^1)$ (respectively, $Eq(U(1), u^1)$), and so on. Each axiom line begins with the capital letter A.

(2) the negated theorem $\neg CSE3(x^4)$ (or $\neg CSE4(x^6)$); such a line begins with the capital letter T.

(3) the refutation path, given by a set of lines, each of which begins with two reference indices giving the two parent clauses that generate the current clause by resolution. For example, (12a,22b) means that the current clause is generated by resolving the first literal of clause 12 and the second literal of clause 22.

(4) at the end of each listing, some performance indices.

The most important observation to be made concerning these examples is that the number of resolutions attempted during the proof with respect to $M\Sigma_3$, based upon the observation sequence $\mathbf{o}_1^3$, is only about 1.5% of that with respect to Σ_3. Further, the addition of only one more observation pair results in a dramatic increase in the number of resolutions used in the proof of $CSE_4(x^6)$ with respect to Σ_4, while the complexity of the proof of this theorem with respect to $M\Sigma_4$ is approximately equal to that of $CSE_3(x^4)$ with respect to $M\Sigma_3$.

Observation sequence $\mathbf{o}_1^3$:

$$(\emptyset, \mathbf{y}^1),\ (\mathbf{u}^1, \mathbf{y}^2),\ (\mathbf{u}^2, \mathbf{y}^1).$$

MODEL SIMPLIFICATION AND OPTIMAL CONTROL OF STOCHASTIC SINGULARLY PERTURBED SYSTEMS UNDER EXPONENTIATED QUADRATIC COST*

ZIGANG PAN† AND TAMER BAŞAR†

Abstract. We study the optimal control of a general class of stochastic singularly perturbed linear systems with perfect and noisy state measurements under positively and negatively exponentiated quadratic cost. The (expected) cost function to be minimized is actually taken as the long-term time average of the logarithm of the expected value of an exponentiated quadratic loss. We identify appropriate "slow" and "fast" subproblems, obtain their optimum solutions (compatible with the corresponding measurement structure), and subsequently study the performances they achieve on the full-order system as the singular perturbation parameter ϵ becomes sufficiently small, with the expressions given in all cases being exact to within $O(\sqrt{\epsilon})$. It is shown that the composite controller (obtained by appropriately combining the optimum slow and fast controllers) achieves a performance level close to the optimal one whenever the full-order problem has a solution. The slow controller, on the other hand, achieves (asymptotically, as $\epsilon \to 0$) only a finite performance level (but not necessarily optimal), provided that the fast subsystem is open-loop stable. If the intensity of the noise in the system dynamics decreases to zero, however, the slow controller also achieves a performance level close to the optimal one.

The paper also presents a more direct derivation (than heretofore available) of the solution to the linear exponential quadratic Gaussian (LEQG) problem under noisy state measurements, which allows for a general quadratic cost (with cross terms) in the exponent and correlation between system and measurement noises, and obtains both necessary and sufficient conditions for existence of an optimal solution. Such a general LEQG problem is encountered in the slow-fast decomposition of the full-order problem, even if the original problem does not feature correlated noises. In this general context, the paper also establishes a complete equivalence between the LEQG problem and the H^∞-optimal control problem with measurement feedback, though this equivalence does not extend to the slow and fast subproblems arrived at after time-scale separation.

1. Introduction.

The problem of optimal control of stochastic linear systems under exponentiated quadratic loss (the so-called linear exponential quadratic Gaussian (LEQG) problem) has been studied extensively in the literature, with new interest aroused on the topic due to the recently established relationship with the H^∞-optimal control of similar systems (but with deterministic disturbances) under quadratic loss. Perhaps the first formulation of the LEQG problem was given by Jacobson [8], in both discrete and continuous time, and using perfect state measurements, motivated by the fact that the exponentiated quadratic cost captures risk-seeking or risk-averse behavior, not obtainable using the linear quadratic Gaussian (LQG) formulation (which is risk neutral). Indeed it was discovered in [8] that the LEQG formulation with a positive exponent is equivalent (as far as the optimal solution goes) to a deterministic zero-sum linear quadratic (LQ) differential game, which we now know [2] is equivalent to an H^∞-optimal control problem, thus completing the link. The counterparts of the results of [8] in the imperfect state measurement case for discrete and continuous time were later obtained in [21], [25], and [3], with the relationship with the H^∞-optimal control problem established in a series of subsequent publications, such as [7], [23], [24]; see also the book by Whittle [22]. Similar relationships (between exponentiated-cost stochastic control and worst-case designs) exist also for nonlinear problems, as established for some subclass of such problems in [5]; see also the recent paper [19] for connection with differential games in the

infinite horizon. Another recent paper [9] completely establishes this equivalence in the discrete-time, finite-horizon case.

Our objective in this paper is to study, under both perfect and noisy state measurements, the robustness properties of the optimal solution of the LEQG problem with respect to unmodeled fast dynamics. This study is conducted in the framework of singularly perturbed models, with a small positive parameter ϵ quantifying the extent of coupling between the slow and fast dynamics. We seek ϵ-independent controllers that provide good (in a sense to be made precise later) approximation to the optimal controller of the full-order problem in a neighborhood of $\epsilon = 0$.

As mentioned earlier, at the full-order level there is an equivalence between the positively exponentiated subclass and a class of LQ H^∞-optimal control problems with singularly perturbed dynamics, with this latter class of problems extensively studied recently from the point of view of robustness and model reduction (see [12], [14], [15], [11]). This equivalence, however, does not readily carry over to the "model-reduction" stage, and as will be seen here, the end results in the two cases are considerably different. One of the reasons for this is that (as has been studied earlier in [20]) in stochastic problems the parameter ϵ has to enter the system dynamics and the measurement equation in a certain way for the problem to be well defined as $\epsilon \to 0$. The exact problem formulation provided in §2 shows that indeed in the stochastic case a time-scale separation of the full-order system becomes much more involved. Nevertheless, we still find occasion to use some of our earlier results from [12] and [14] in the present development, to simplify some of the proofs. Furthermore, in the derivation of the optimal solution to the stochastic control problem associated with the slow subsystem, we are faced with the need to obtain a clean and complete solution to the general LEQG problem with general cost structure and correlation between system and measurement noises. This motivates us into the investigation that leads to the results of §4, which generalize the earlier results of [3].

The paper is organized as follows. In the next section (§2) we formulate the LEQG problem with perfect and noisy state measurements for singularly perturbed systems. In §3, we study the singularly perturbed stochastic control problem under perfect state measurements, where we decompose the problem into slow and fast ϵ-free subproblems, obtain optimal controllers for these subproblems, and study the optimality of the composite controller as well as that of the slow controller in terms of the attainable performance for the full-order problem. In §4, we present a clean derivation (under least-stringent conditions) of a complete solution to the general LEQG problem under noisy state measurements with general cost structure and correlation between system and measurement noises, in both finite- and infinite-horizon cases. In §5, we study the singularly perturbed LEQG problem and its decomposition under noisy state measurements, where we identify the slow and fast subproblems to the full-order problem, obtain optimal controllers for these subproblems, construct the composite controller from these controllers, and study the optimality of these suboptimal controllers in terms of the attainable performance for the full-order problem. Three numerical examples are presented in §6 to illustrate the theory, and the paper ends with the concluding remarks of §7. Details of some of the derivations, not included here, can be found in the internal report [13].

2. Problem formulation. The system under consideration, with slow and fast dynamics, is described in the "singularly perturbed" form by

$$\text{(1)} \qquad \begin{cases} dx_1 = (A_{11}x_1 + A_{12}x_2 + B_1u_t)\,dt + G_1\,dw_t, & x_1(0) = x_{10}, \\ \epsilon dx_2 = (\epsilon^\alpha A_{21}x_1 + A_{22}x_2 + B_2u_t)\,dt + \epsilon^{1/2}G_2\,dw_t, & x_2(0) = x_{20}, \end{cases}$$

$$\text{(2)} \qquad \begin{cases} dy_1 = (C_{11}x_1 + C_{12}x_2)\,dt + E_1\,dw_t, & y_1(0) = 0, \\ dy_2 = (\epsilon^{1/2}C_{21}x_1 + C_{22}x_2)\,dt + \epsilon^{1/2}E_2\,dw_t, & y_2(0) = 0, \end{cases}$$

where $x := (x_1', x_2')'$ is the n-dimensional state vector, with x_1 of dimension n_1 and x_2 of dimension $n_2 := n - n_1$; $y := (y_1', y_2')'$ is the m-dimensional measurement process, with y_1 of dimension m_1 and y_2 of dimension $m_2 := m - m_1$; $\{u_t\}$ is the p-dimensional control input, and $\{w_t\}$ is an r-dimensional vector-valued standard Wiener process with $w_0 = 0$ with probability 1, which is independent of the initial condition; ϵ is a small positive scalar, denoting the singular perturbation parameter; the underlying probability space is the triplet $(\Omega, \mathcal{F}, \boldsymbol{P})$; and the parameter α is taken to be equal to $1/2$, except in the perfect state measurements case, when it is taken to be equal to 0. The specific way the parameter ϵ enters equations (1) and (2) is crucial for the system and measurement dynamics to be well defined in the limit as $\epsilon \to 0$, as otherwise (that is, for other powers of ϵ) either the noise dominates in the limit (and hence the optimization problem loses its significance) or the stochastic terms disappear (again making the problem uninteresting)—as extensively discussed in [20] in the context of the singularly perturbed LQG problem, whose arguments equally apply here as the nature of the cost function was irrelevant in that analysis.

Associated with the system (1), we now introduce the infinite-horizon exponentiated quadratic (*risk-sensitive*) cost function

$$J_\theta(\mu) = \lim_{t_f \to \infty} \frac{2}{\theta t_f} \ln \left\{ \boldsymbol{E} \left\{ \exp \left[\frac{\theta}{2} \left(\int_0^{t_f} (x' Q x + u' u)\, dt \right) \right] \right\} \right\}. \tag{3}$$

Here ln denotes the natural logarithm, and the scalar $\theta \neq 0$ is the *risk-sensitivity* parameter, in terms of which we will parametrize the solution.

We will consider two different information structures for the controller: perfect state measurements (where the current and past values of the state are available), and the noisy (imperfect) state measurements, where the measurement equations are as given in (2) above. Thus, in the former case, the control input $u = \{u_t\}$ is generated by a closed-loop control policy μ, according to

$$u_t = \mu(t, x_{[0,t]}), \quad t \geq 0, \tag{4}$$

where $\mu \in \mathcal{M}$ is an admissible controller, satisfying the standard conditions of Lipschitz continuity in x and piecewise continuity in t. Furthermore, as indicated earlier, we take in this case $\alpha = 0$, which makes the system dynamics well defined as $\epsilon \to 0$, as shown in [20]. Our objective is to find an optimal (minimizing) controller with respect to the cost (3), i. e., a $u_t^* = \mu^*(t, x_{[0,t]})$ such that

$$J_\theta(\mu^*) = \min_{\mu \in \mathcal{M}} J_\theta(\mu) := J_\theta^*. \tag{5}$$

Here, the initial state x_0 is taken as a fixed vector in $\mathbf{R}^n$.

In the noisy state measurements case, the initial state is taken to be a Gaussian random vector with mean $\bar{x}_0$ and covariance Σ_0, where Σ_0 is assumed to be positive definite, and it depends on ϵ in a way to be specified shortly. In this case, the control input $u \in \mathcal{H}_u$ is generated by a control policy μ_I, according to[1]

$$u_t = \mu_I(t, y_{[0,t]}), \quad t \geq 0, \tag{6}$$

where $\mu_I : [0, t_f] \times \mathcal{H}_y \to \mathcal{H}_u$ is piecewise continuous in t and Lipschitz continuous in $y := (y_1' \quad y_2')' \in \mathcal{H}_y$, further satisfying the given causality condition. Let us denote the class

[1] $\mathcal{H}_u$ denotes the Hilbert space of p-dimensional square-integrable functions (the controls). Likewise, $\mathcal{H}_y$ denotes the Hilbert space of m-dimensional square-integrable functions (the measurements).

of all admissible controllers in this case by $\mathcal{M}_I$, which is defined in precise mathematical terms in §4 later. For the limiting system and measurement equations to be well defined (as $\epsilon \to 0$), we take $\alpha = 1/2$ in this case. Denoting the cost function (3) for the noisy state measurements case by $J_{I\theta}(\mu_I)$, we again seek an optimal controller with respect to $J_{I\theta}(\mu_I)$, that is, a $u_t^* = \mu_I^*(t, y_{[0,t]})$, $t \geq 0$, such that

$$J_{I\theta}(\mu_I^*) = \min_{\mu_I \in \mathcal{M}_I} J_{I\theta}(\mu_I) := J_{I\theta}^*. \tag{7}$$

To complete the formulation of this risk-sensitive stochastic control problem, we introduce two basic assumptions, which will be required to hold throughout.

A1. Σ_0 and Q in (3) are partitioned as

$$\Sigma_0 = \begin{bmatrix} \Sigma_{011} & \sqrt{\epsilon}\,\Sigma_{012} \\ \sqrt{\epsilon}\,\Sigma_{021} & \Sigma_{022} \end{bmatrix}, \quad Q = \begin{bmatrix} Q_{11} & Q_{12} \\ Q_{21} & Q_{22} \end{bmatrix},$$

where in each case the 11-block is of dimensions $n_1 \times n_1$, and the 22-block of $n_2 \times n_2$.

A2. The matrices A_{22}, Q_{22}, G_2G_2', and $N := EE'$ are invertible, where $E' = [E_1' \; E_2']$.[2] The system noise and the measurement noise are uncorrelated, i.e., $G_1E' = 0$ and $G_2E' = 0$.

3. Model simplification under perfect state measurements. The full-order solution to the (infinite-horizon) LEQG problem with state feedback can be obtained by taking an appropriate limit of the finite-horizon solution first obtained in [8]. Toward presenting this solution, let us first introduce the following useful notation:

$$A_\epsilon := \begin{bmatrix} A_{11} & A_{12} \\ \frac{1}{\epsilon}A_{21} & \frac{1}{\epsilon}A_{22} \end{bmatrix}, \quad B_\epsilon := \begin{bmatrix} B_1 \\ \frac{1}{\epsilon}B_2 \end{bmatrix}, \quad G_\epsilon := \begin{bmatrix} G_1 \\ \frac{1}{\sqrt{\epsilon}}G_2 \end{bmatrix}.$$

Note that in terms of this notation, the n-dimensional system dynamics can be written in the compact form

$$dx = (A_\epsilon x + B_\epsilon u_t)\,dt + G_\epsilon\,dw_t, \quad x(0) = x_0.$$

Introduce the quantity

$$S_\epsilon(\theta) := B_\epsilon B_\epsilon' - \theta G_\epsilon G_\epsilon' \tag{8}$$

and consider the generalized algebraic Riccati equation (GARE)

$$A_\epsilon'\tilde{Z} + \tilde{Z}A_\epsilon - \tilde{Z}S_\epsilon\tilde{Z} + Q = 0. \tag{9}$$

Further introduce the quantity

$$\theta^*(\epsilon) := \sup\{\theta \in \boldsymbol{R} : \text{the GARE (9) admits a positive definite solution } \tilde{Z}(\epsilon)\}. \tag{10}$$

Assume that (A_ϵ, B_ϵ) is controllable and (A_ϵ, Q) is observable for every $\epsilon > 0$. Then it follows by taking an appropriate limit of the finite-horizon result of [8] (see Theorem 7 of

[2]The conditions of invertibility of Q_{22} and G_2G_2' can be further relaxed to the conditions of observability of the pairs (A_{22}, Q_{22}) and (A_{22}, G_2). Results similar to those (to be) presented in this paper can be derived under these relaxed conditions, by perturbing the matrices Q_{22} and G_2G_2' by λI, for some scalar $\lambda > 0$, applying the results of this paper, and then letting $\lambda \to 0$; the limiting quantities are all well defined, as shown in [18].

[13]) that for each $\epsilon > 0$, $\theta^*(\epsilon)$ is positive, and for $\theta < \theta^*(\epsilon)$ the LEQG problem (with perfect state measurements) admits an optimal state-feedback solution

$$u^* = \mu^*(x) = -B_\epsilon' \tilde{Z}(\epsilon)\, x, \quad t \geq 0 \tag{11}$$

with the optimal (minimum) cost being

$$J_\theta^*(\epsilon) = \mathrm{Tr}(G_\epsilon G_\epsilon' \tilde{Z}(\epsilon))\,. \tag{12}$$

Furthermore, the feedback matrix $A_\epsilon - B_\epsilon B_\epsilon' \tilde{Z}(\epsilon)$ is Hurwitz.

Thus completing presentation of the full-order solution (for all $\epsilon > 0$), we now return to the original goal of this paper, which is the derivation of the optimal solution as $\epsilon \to 0$, via model simplification. Toward the end of obtaining ϵ-free solutions, we first decompose the system into slow and fast modes as in [12].

3.1. Time-scale decomposition.

Slow subsystem. The slow subsystem is obtained by letting $\epsilon = 0$ in the system dynamics, and solving for x_2 (to be denoted $\bar{x}_2$) in terms of $x_1 =: x_s$, $u =: u_s$, and under the working assumption A2:

$$\bar{x}_2 = -A_{22}^{-1}(A_{21}x_s + B_2 u_s). \tag{13}$$

Using this in the first equation of (1), we obtain the reduced-order (slow) dynamics

$$dx_{st} = (A_0 x_{st} + B_0 u_{st})\, dt + G_1\, dw_t, \tag{14}$$

where $A_0 := A_{11} - A_{12}A_{22}^{-1}A_{21}$, $B_0 := B_1 - A_{12}A_{22}^{-1}B_2$. Use of (13) also in the cost function (3) leads to the reduced (slow) cost (with $x_1 = x_s$)

$$J_{s\theta}(\mu_s) = \lim_{t_f \to \infty} \frac{2}{\theta t_f} \ln \left\{ \boldsymbol{E} \left\{ \exp \left[\frac{\theta}{2} \left(\int_0^{t_f} (|x_s|^2_{Q_{11}} + x_s' Q_{12} \bar{x}_2 + \bar{x}_2' Q_{21} x_s + |\bar{x}_2|^2_{Q_{22}} + |u_s|^2)\, dt \right) \right] \right\} \right\}. \tag{15}$$

Note that this is another LEQG problem, which this time has a cross term in the cost between the control and the state, but a simple linear state-feedback transformation on the control brings it into the same form as the full-order LEQG problem, and hence the theory described at the beginning of this section (for the full-order problem) applies, with some obvious modifications. Hence, the *slow* LEQG problem admits an optimal solution if the GARE

$$\tilde{A}_0' \tilde{Z}_s + \tilde{Z}_s \tilde{A}_0 - \tilde{Z}_s S_0 \tilde{Z}_s + \tilde{Q} = 0 \tag{16}$$

admits a minimal positive definite solution $Z_{s\theta}$, such that the matrix $\tilde{A}_0 - S_0 Z_{s\theta}$ is Hurwitz, where the coefficient matrices above are explicit functions of the parameter θ, and are written as (see [12] for details)

$$\begin{aligned}
\tilde{A}_0(\theta) &= A_{11} - A_{12}Q_{22}^{-1}Q_{21} - (S_{12} + A_{12}Q_{22}^{-1}A_{22}')(S_{22} + A_{22}Q_{22}^{-1}A_{22}')^{-1} \\
&\quad \cdot (A_{21} - A_{22}Q_{22}^{-1}Q_{21}), \\
\tilde{Q} &= Q_{11} - Q_{12}Q_{22}^{-1}Q_{21} + (A_{21}' - Q_{12}Q_{22}^{-1}A_{22}')(S_{22} + A_{22}Q_{22}^{-1}A_{22}')^{-1} \\
&\quad \cdot (A_{21} - A_{22}Q_{22}^{-1}Q_{21}), \\
S_0(\theta) &= S_{11} + A_{12}Q_{22}^{-1}A_{12}' - (S_{12} + A_{12}Q_{22}^{-1}A_{22}')(S_{22} + A_{22}Q_{22}^{-1}A_{22}')^{-1} \\
&\quad \cdot (S_{21} + A_{22}Q_{22}^{-1}A_{12}'),
\end{aligned}$$

where S_{ij} denotes the ijth block of $S(\theta)$, of dimensions $n_i \times n_j$, $i, j = 1, 2$, where the latter is defined by

$$S(\theta) := BB' - \theta GG', \quad B := \begin{bmatrix} B_1 \\ B_2 \end{bmatrix}, \quad G := \begin{bmatrix} G_1 \\ 0 \end{bmatrix}.$$

In view of this, let us define

$$\theta_s := \sup\{\theta \in \boldsymbol{R} : \text{the GARE (16) admits a positive definite solution}\}. \tag{17}$$

Then, the transformed LEQG problem admits an optimal solution if $\theta < \theta_s$. For $\theta < \theta_s$, let $Z_{s\theta}$ be the unique positive definite solution of (16). Then, the optimal controller (after the inverse transformation) is given by (see [13])

$$\begin{aligned} u^*_{s\theta} = \mu^*_{s\theta}(t, x_s) = (-B_1' Z_{s\theta} + B_2'(S_{22} + A_{22} Q_{22}^{-1} A_{22}')^{-1} \\ \cdot ((S_{21} + A_{22} Q_{22}^{-1} A_{12}') Z_{s\theta} - (A_{21} - A_{22} Q_{22}^{-1} Q_{21}))) x_s \end{aligned} \tag{18}$$

Fast subsystem. To arrive at the fast subproblem, let $x_f := x_2 - \bar{x}_2$, $u_f := u - u_s$, and $\tau = \frac{t'-t}{\epsilon}$, where we take t to be frozen and t' to vary on the same scale as t. We define the fast subsystem and the associated cost (as in the standard regulator problem; see [4]) by

$$\frac{d}{d\tau} x_f^t = A_{22} x_f^t + B_2 u_f^t, \quad x_f^t(0) = x_f, \tag{19a}$$

$$J^t_{f\theta}(\mu^t_f) = \frac{2}{\theta} \ln \left\{ \boldsymbol{E} \left\{ \exp \left[\frac{\theta}{2} \left(\int_0^\infty (|x_f^t|^2_{Q_{22}} + |u_f^t|^2)\, d\tau \right) \right] \right\} \right\}. \tag{19b}$$

This is a deterministic, strictly convex, optimal control problem,[3] which admits a unique optimal controller that does not depend on the parameter θ:

$$\begin{aligned} & u_f^{t*}(\tau) = \mu_f^{t*}(x_f^t(\tau)) = -B_2' Z_f x_f^t(\tau) \\ \Rightarrow \quad & \mu_f^* = \mu_f^{t*}(x_f^t(0)) = -B_2' Z_f x_f = -B_2' Z_f (x_2 - \bar{x}_2), \end{aligned} \tag{20}$$

where Z_f is the positive definite solution to the ARE[4]

$$A_{22}' Z_f + Z_f A_{22} + Q_{22} - Z_f S_{22} Z_f = 0. \tag{21}$$

Substitute (13) and (18) into (20) to obtain

$$\begin{aligned} \mu^*_{f\theta}(t, x) = -B_2' Z_f x_2 - B_2' Z_f Q_{22}^{-1} (A_{12}' Z_{s\theta} + Q_{21} - A_{22}'(S_{22} \\ + A_{22} Q_{22}^{-1} A_{22}')^{-1} ((S_{21} + A_{22} Q_{22}^{-1} A_{12}') Z_{s\theta} - (A_{21} - A_{22} Q_{22}^{-1} Q_{21}))) x_1. \end{aligned} \tag{22}$$

Also, introduce the following Lyapunov equation, when the matrix A_{22} is Hurwitz:

$$A_{22}' Z_{of} + Z_{of} A_{22} + Q_{22} = 0, \tag{23}$$

whose relevance to our problem will be seen shortly.

[3]Recall that by our standard assumption A1, $Q_{22} > 0$.

[4]This ARE admits a unique positive definite solution if the pair (A_{22}, B_2) is controllable.

3.2. Composite controller. We now introduce the composite controller

$$\mu^*_{c\theta}(t,x) = \mu^*_{s\theta}(t,x) + \mu^*_{f\theta}(t,x), \tag{24}$$

where $\mu^*_{s\theta}$ and μ^*_f were defined by (18) and (22), respectively, for $\theta < \theta_s$. After some manipulations, this composite controller can be written as

$$\mu^*_{c\theta}(t,x) = -B' \begin{bmatrix} Z_{s\theta} & 0 \\ Z_c & Z_f \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}, \tag{25}$$

where

$$\begin{aligned} Z_c := {} & Z_f Q_{22}^{-1}(A'_{12}Z_{s\theta} + Q_{21}) - (I + Z_f Q_{22}^{-1}A'_{22})(S_{22} + A_{22}Q_{22}^{-1}A'_{22})^{-1} \\ & \cdot((S_{21} + A_{22}Q_{22}^{-1}A'_{12})Z_{s\theta} - (A_{21} - A_{22}Q_{22}^{-1}Q_{21})) \end{aligned}$$

and

$$B := \begin{pmatrix} B'_1 & B'_2 \end{pmatrix}.$$

3.3. Performances of the suboptimal controllers. The next important set of issues is the derivation of the conditions under which the performances attained by the composite and slow controllers are finite, and study of the limiting behavior of these expected cost values as $\epsilon \to 0$. A complete answer to these questions is given in the following theorem.

THEOREM 1. *For the singularly perturbed system* (1) *with state-feedback information and the cost function* (3), *let the relevant parts of assumptions* A1–A2 *be satisfied, the pairs* (A_0, B_0) *and* (A_{22}, B_2) *be controllable, and the pair* $(A_0, Q_{11} - Q_{12}Q_{22}^{-1}Q_{21})$ *be observable. Then,*

1. $\lim_{\epsilon \to 0^+} \theta^*(\epsilon) = \theta_s$.

2. $\forall \theta < \theta_s$, $\exists \epsilon_\theta > 0$ *such that* $\forall \epsilon \in [0, \epsilon_\theta)$, *the GARE* (9) *admits a positive definite solution, and consequently, the problem has an optimal solution, and the optimal cost for the problem can be approximated by*

$$J^*_{\theta\infty}(\epsilon) = \mathrm{Tr}(G_1 G'_1 Z_{s\theta} + G_2 G'_2 Z_f) + O(\sqrt{\epsilon}). \tag{26}$$

3. $\forall \theta < \theta_s$, *if the composite controller* $\mu^*_{c\theta}$ *is applied to the system, then* $\exists \epsilon'_\theta > 0$ *such that* $\forall \epsilon \in [0, \epsilon'_\theta)$,

$$J^c_\theta := J_\theta(\mu^*_{c\theta}) = J^*_\theta(\epsilon) + O(\sqrt{\epsilon}). \tag{27}$$

4. $\forall \theta < \theta_s$, *if, in addition, the matrix* A_{22} *is Hurwitz, and the slow controller* $\mu^*_{s\theta}$ *is applied to the system, then* $\exists \tilde{\epsilon}_\theta > 0$ *such that* $\forall \epsilon \in [0, \tilde{\epsilon}_\theta)$,

$$J^s_\theta := J_\theta(\mu^*_{s\theta}) = J^*_\theta(\epsilon) + \mathrm{Tr}(G_2 G'_2 (Z_{of} - Z_f)) + O(\sqrt{\epsilon}). \tag{28}$$

Proof. By Theorem 1 in [12], result 1. follows, and there exists an $\epsilon_\theta > 0$, such that the full-order GARE (9) admits a positive definite solution, for $\epsilon \in [0, \epsilon_\theta)$, which can be approximated by

$$\tilde{Z} = \begin{bmatrix} Z_{s\theta} + O(\sqrt{\epsilon}) & \epsilon Z'_c + O(\epsilon^{3/2}) \\ \epsilon Z_c + O(\epsilon^{3/2}) & \epsilon Z_f + O(\epsilon^{3/2}) \end{bmatrix}.$$

By Corollary 2 in [11], we have that the matrix $\tilde{A}_0 - S_0 Z_{s\theta}$ is Hurwitz for $\theta < \theta_{s\infty}$, which leads to 2.

For 3. and 4., we substitute the controllers $\mu^*_{c\theta}$ and $\mu^*_{s\theta}$ into the full-order system to obtain the resulting control-free LEQG problems. We then use the detailed derivations that led to Theorem 1 of [12] to establish 3. and 4. □

3.4. A large-deviation form. Consider now a large-deviation form of the problem considered in this section, which is the case when the system noise intensity asymptotically approaches zero. To formally illustrate this situation, we consider the following setup for the problem.

State dynamics:

$$\begin{cases} dx_1 = (A_{11}x_1 + A_{12}x_2)\,dt + B_1u + \xi G_1\,dw_t, & x_1(0) = x_{10}, \\ \epsilon dx_2 = (A_{21}x_1 + A_{22}x_2 + B_2u)\,dt + \sqrt{\epsilon}\xi G_2\,dw, & x_2(0) = x_{20}, \end{cases} \tag{29}$$

Cost function:

$$J_{\theta\infty}(\mu, \xi) = \lim_{t_f\to\infty} \frac{2\xi^2}{\theta t_f} \ln\left\{\boldsymbol{E}\left\{\exp\left[\frac{\theta}{2\xi^2}\left(\int_0^{t_f}(x'Qx + u'u)\,dt\right)\right]\right\}\right\}, \tag{30}$$

where ξ is a small scalar parameter to be varied. We will study the solution as $\xi \to 0$. Note that this problem is equivalent to the one considered earlier in this section, if we introduce the substitutions

$$\theta \leftarrow \frac{\theta}{\xi^2}, \quad G_\epsilon \leftarrow \xi G_\epsilon. \tag{31}$$

Assume that (A_ϵ, B_ϵ) is controllable, and (A_ϵ, Q) is observable for every $\epsilon > 0$. Under assumptions A1–A2, we know that the optimal solution exists, for each fixed $\epsilon > 0$, if the GARE (9) admits a positive definite solution, in which case the optimal controller is given by (11) independent of the parameter ξ. We define the quantity $\theta^*(\epsilon)$ in the same way as in (10). Thus, $\forall\theta < \theta^*(\epsilon)$, the optimal cost is given by

$$J^*_{\theta\infty}(\epsilon, \xi) = \xi^2 \mathrm{Tr}(G_\epsilon G'_\epsilon \tilde{Z}(t; \epsilon)), \tag{32}$$

where $\tilde{Z}(\epsilon)$ is the minimal positive definite solution to the GARE (9). Hence, $J^*_{\theta\infty}(\epsilon, \xi) \to 0$ as $\xi \to 0$.

To obtain ϵ-free solutions to the problem, we decompose the system into slow and fast subsystems. The slow subsystem is obtained by setting $\epsilon = 0$ in the state dynamics, as well as in the cost function. This slow problem admits an optimal solution if the GARE (16) admits a positive definite solution $Z_{s\theta}$, such that the matrix $\tilde{A}_0 - S_0 Z_{s\theta}$ is Hurwitz. We define θ_s the same way as in (17). Then, for $\theta < \theta_s$, the optimal control for the slow subsystem is again given by (18).

To obtain the fast subsystem, we use the same notation as in §3.1. The fast dynamics are the same as (19a) and the cost function is the same as (19b) under the substitutions (31). Then, the optimal control is given by (20), where Z_f is the unique positive definite solution to ARE (21). Substitution of (13) and (18) into (20) yields the fast controller, which is precisely (22). We also introduce the matrix Z_{of} to be the solution of Lyapunov equation (23).

Then, we form the composite controller as in (24), which leads to (25). We now summarize this result below, as a corollary to Theorem 1.

COROLLARY 1. *For the singularly perturbed system* (29), *with state-feedback information and the cost function* (30), *let assumptions* A1–A2 *be satisfied, the pairs* (A_0, B_0) *and* (A_{22}, B_2) *be controllable, and the pair* $(A_0, Q_{11} - Q_{12}Q_{22}^{-1}Q_{21})$ *be observable. Then,*

1. $\lim_{\epsilon\to 0^+} \theta^*(\epsilon) = \theta_s$.

2. $\forall\theta < \theta_s$, $\exists\epsilon_\theta > 0$ *such that* $\forall\epsilon \in [0, \epsilon_\theta)$, *the GARE* (9) *admits a positive definite solution, and consequently, the problem has an optimal solution, and the optimal cost for the problem can be approximated by*

$$J^*_\theta(\epsilon, \xi) = \xi^2(\mathrm{Tr}(G_1G'_1Z_{s\theta} + G_2G'_2Z_f) + O(\sqrt{\epsilon})). \tag{33}$$

3. $\forall\theta < \theta_s$, *if the composite controller* $\mu^*_{c\theta}$ *is applied to the system, then* $\exists\,\epsilon'_\theta > 0$ *such that* $\forall\epsilon \in [0, \epsilon'_\theta)$,

$$J^c_\theta(\xi) := J_\theta(\mu^*_{c\theta}, \xi) = J^*_\theta(\epsilon, \xi) + O(\xi^2\sqrt{\epsilon}). \tag{34}$$

4. $\forall\theta < \theta_s$, *if, in addition, the matrix* A_{22} *is Hurwitz, and the slow controller* $\mu^*_{s\theta}$ *is applied to the system, then* $\exists\tilde{\epsilon}_\theta > 0$ *such that* $\forall\epsilon \in [0, \tilde{\epsilon}_\theta)$,

$$J^s_\theta(\xi) := J_\theta(\mu^*_{s\theta}, \xi) = J^*_\theta(\epsilon, \xi) + O(\xi^2). \tag{35}$$

4. Imperfect state measurements: Full-order solution. In order to obtain the counterparts of the results of §3 in the noisy state measurements case, we will first need the solution to the full-order case, which is derived in this section. The derivation proceeds in two steps: first the solution to the finite-horizon LEQG problem is obtained, and then an appropriate limit of that solution is taken.

The model we adopt in this section involves, by necessity, a more general version of the problem formulated in §2 (for fixed $\epsilon > 0$), where the system and measurement noises are correlated, and the exponent of the loss function contains an additional cross term between the state and the control. Such a generalized model will be encountered in the next section, when we study the slow subproblem. Hence, the solution derived in this section will serve two purposes: it provides a solution to the full-order problem and also a solution to the slow subproblem which is the counterpart of the one of §3.1 in the noisy measurement case.

Accordingly, we now consider the following system and measurement dynamics:

$$\begin{cases} dx = (Ax + Bu_t)\,dt + G\,dw_t, & x(0) = x_0, \\ dy = Cx\,dt + E\,dw_t, & y(0) = 0, \end{cases} \tag{36}$$

where the correlation between the system and measurement noises is given by $L := GE' \neq 0$, and $x_0 \sim N(\bar{x}_0, \Sigma_0)$, $\Sigma_0 > 0$, $N := EE' > 0$.

4.1. The finite-horizon problem. Along with the system described by (36), consider the cost function

$$J_{I\theta}(\mu_I) = \frac{2}{\theta}\ln\left\{E\left\{\exp\left[\frac{\theta}{2}\left(x'_{t_f}Q_f x_{t_f} + \int_0^{t_f}(x'Qx + 2x'Pu + u'Ru)\,dt\right)\right]\right\}\right\}, \tag{37}$$

where $R > 0$, $Q_f \geq 0$, and $Q - PR^{-1}P \geq 0$.[5]

Introduce the notation

$$\begin{aligned} \bar{A} &:= A - BR^{-1}P', \quad \bar{Q} := Q - PR^{-1}P', \quad \bar{S} := BR^{-1}B' - \theta GG', \\ \tilde{A} &:= A - LN^{-1}C, \quad \tilde{M} := GG' - LN^{-1}L', \quad \tilde{R} := C'N^{-1}C - \theta Q, \end{aligned}$$

and in terms of this the backward generalized (game) Riccati differential equation (GRDE)

$$\dot{\tilde{Z}} + \bar{A}'\tilde{Z} + \tilde{Z}\bar{A} - \tilde{Z}\bar{S}\tilde{Z} + \bar{Q} = 0, \quad \tilde{Z}(t_f) = Q_f\,, \tag{38}$$

and the forward GRDE

$$\dot{\tilde{\Sigma}} = \tilde{\Sigma}\tilde{A}' + \tilde{A}\tilde{\Sigma} - \tilde{\Sigma}\tilde{R}\tilde{\Sigma} + \tilde{M}, \quad \tilde{\Sigma}(0) = \Sigma_0. \tag{39}$$

[5]The analysis and results of this subsection are valid even if the system and cost matrices are time varying, satisfying some natural smoothness conditions, such as continuous differentiability in t; see [13].

Define the quantity

$$\theta_I^* := \sup\{\theta \in \boldsymbol{R} : \text{the GRDEs (38) and (39) admit nonnegative definite solutions } \tilde{Z} \text{ and } \tilde{\Sigma}, \text{ respectively, on } [0, t_f], \text{ and the matrix } I - \theta\tilde{\Sigma}\tilde{Z} \text{ has only positive eigenvalues, for each } t \in [0, t_f]\}, \tag{40}$$

and for $\theta < \theta_I^*$, introduce the filter

$$d\check{x} = (A + \theta\tilde{\Sigma}Q)\check{x}\,dt + (B + \theta\tilde{\Sigma}P)u\,dt + (\tilde{\Sigma}C' + L)N^{-1}(dy - C\check{x}\,dt) \tag{41}$$

with initial state $\check{x}(0) = \bar{x}_0$. Letting $\hat{x} := (I - \theta\tilde{\Sigma}\tilde{Z})^{-1}\check{x}$, it can be shown (see [13]) that $\hat{x}$ is generated by the following dynamics:

$$\begin{aligned} d\hat{x} = {} & (\bar{A} - \bar{S}\tilde{Z})\hat{x}\,dt + (I - \theta\tilde{\Sigma}\tilde{Z})^{-1}(B + \theta\tilde{\Sigma}P)\tilde{u}\,dt + (I - \theta\tilde{\Sigma}\tilde{Z})^{-1} \\ & \cdot (\tilde{\Sigma}C' + L)N^{-1}(dy - (C + \theta L'\tilde{Z})\hat{x}\,dt), \end{aligned} \tag{42}$$

where $\tilde{u} := u + R^{-1}(B'\tilde{Z} + P')\hat{x}$.

Let $\varepsilon := x - \check{x}$ and $e := x - \hat{x}$. We will now restrict our attention to the class of controllers such that the following process ζ defines a martingale on $[0, t_f]$:

$$\begin{aligned} \zeta = \exp\Bigg\{ & \int_0^t (\varepsilon'\tilde{\Sigma}^{-1}G - e'\tilde{\Sigma}^{-1}(\tilde{\Sigma}C' + L)N^{-1}E)dw_t \\ & - \frac{1}{2}\int_0^t |G'\tilde{\Sigma}^{-1}\varepsilon - E'N^{-1}(C\tilde{\Sigma} + L')\tilde{\Sigma}^{-1}e|^2\,dt \Bigg\}. \end{aligned} \tag{43}$$

Hence, we define the set of admissible controllers $\mathcal{M}_I$ to be all mappings $\mu_I : [0, t_f] \times \mathcal{H}_y \to \mathcal{H}_u$ that are piecewise continuous in t and Lipschitz continuous in y, and further satisfying the given causality condition such that ζ is a martingale on $[0, t_f]$.

The above condition will be needed in the application of the Girsanov theorem [6] for a change of probability measures. A sufficient condition for this condition to be satisfied is the existence of positive constants δ and κ such that

$$\boldsymbol{E}\{\exp\{\delta|G'\tilde{\Sigma}^{-1}\varepsilon - E'N^{-1}(C\tilde{\Sigma} + L')\tilde{\Sigma}^{-1}e|^2\}\} \le \kappa \quad \forall t \in [0, t_f].$$

It should be obvious that any linear control law renders this condition valid, and hence the class of admissible controllers is bigger than the class of all linear controllers. We refer the reader to the recent book [6] for a thorough coverage of this topic.

We note at this point that this definition of the admissible controllers involves only one martingale condition, whereas the one of [3] involved two such (separate) conditions. We can do away with the second condition because of fact that in the proof to follow, we pursue a line of reasoning motivated by the "completions of squares" proof for the H^∞-optimal control problem, which avoids recasting of the problem in a new probability space, where the processes $\{w_t\}$ and $\{y_t\}$ are independent Wiener processes. As a result of this alternative approach, the existence of an optimal controller is not restricted by the additional condition of existence of a solution to GRDE (3.5) of [3] which clearly is unnecessary. Hence, the ensuing derivation is much simpler than that of [3], and it is more complete in the sense that it leads to both necessary and sufficient conditions for the existence of an optimal controller.

Now, we prove the following result.

THEOREM 2. *Consider the general finite-horizon LEQG problem described by* (36) *and* (37). *Assume that* $\Sigma_0 > 0$, $R > 0$, $Q - PR^{-1}P' \ge 0$, *and* $N > 0$. *Then, for each* $\theta < \theta_I^*$, *the optimal controller is given by*

$$u_{It}^* = \mu_I^*(t, y_{[0,t]}) = -R^{-1}(B'\tilde{Z} + P')(I - \theta\tilde{\Sigma}\tilde{Z})^{-1}\check{x} \equiv -R^{-1}(B'\tilde{Z} + P')\hat{x}, \tag{44}$$

where $\check{x}$ is generated by the filter (41), *or equivalently, $\hat{x}$ is generated by the filter* (42). *The optimal cost can be written as*

$$J_{I\theta}^* = \inf_{\mu_I \in \mathcal{M}_I} J_{I\theta}(\mu_I) = \bar{x}_0' \tilde{Z}(0)(I - \theta \Sigma_0 \tilde{Z}(0))^{-1} \bar{x}_0 - \frac{1}{\theta} \ln\{\det(I - \theta \tilde{\Sigma}(t_f) Q_f)\} + \int_0^{t_f} \operatorname{Tr}(\tilde{\Sigma} Q + (\tilde{\Sigma} C' + L) N^{-1} (C \tilde{\Sigma} + L') \tilde{Z} (I - \theta \tilde{\Sigma} \tilde{Z})^{-1})\, dt. \tag{45}$$

Furthermore, the above controller is also conditionally optimal.[6]

Proof. The differential equation for ε is easily obtained to be

$$d\varepsilon = (\tilde{A} - \tilde{\Sigma} C' N^{-1} C)\varepsilon\, dt - \theta \tilde{\Sigma} Q \check{x}\, dt - \theta \tilde{\Sigma} P u\, dt + (G - (\tilde{\Sigma} C' + L) N^{-1} E)\, dw_t.$$

Let $\tilde{\Psi} := \tilde{Z}(I - \theta \tilde{\Sigma} \tilde{Z})^{-1}$, and define

$$\Upsilon(t, \varepsilon, \check{x}) := |\varepsilon|^2_{\frac{1}{\theta}\tilde{\Sigma}^{-1}} + |\check{x}|^2_{\tilde{\Psi}} =: \Upsilon_1(t, \varepsilon) + \Upsilon_2(t, \check{x}).$$

Note that the matrix $\tilde{\Psi}$ satisfies the following GRDE:

$$\dot{\tilde{\Psi}} + \tilde{\Psi}(A + \theta \tilde{\Sigma} Q) + (A + \theta \tilde{\Sigma} Q)' \tilde{\Psi} + Q + \theta \tilde{\Psi} (\tilde{\Sigma} C' + L) N^{-1} (C \tilde{\Sigma} + L') \tilde{\Psi} - ((I - \theta \tilde{Z} \tilde{\Sigma})^{-1} P + \tilde{\Psi} B) R^{-1} (P' (I - \theta \tilde{\Sigma} \tilde{Z})^{-1} + B' \tilde{\Psi}) = 0. \tag{46}$$

This, with some additional lengthy but straightforward algebraic manipulations, leads to the following expression of the differential for Υ:

$$\begin{aligned} d\Upsilon = {} & \operatorname{Tr}(E' N^{-1} (C \tilde{\Sigma} + L') \tilde{\Psi} (\tilde{\Sigma} C' + L) N^{-1} E + (G' - E' N^{-1} (C \tilde{\Sigma} + L')) \frac{1}{\theta} \tilde{\Sigma}^{-1} (G \\ & - (\tilde{\Sigma} C' + L) N^{-1} E))\, dt - (x' Q x + 2 x' P u + u' R u)\, dt + |\tilde{u}|^2_R\, dt + \frac{2}{\theta} (\varepsilon' \tilde{\Sigma}^{-1} G \\ & - e' \tilde{\Sigma}^{-1} (\tilde{\Sigma} C' + L) N^{-1} E) dw_t - \frac{1}{\theta} |G' \tilde{\Sigma}^{-1} \varepsilon - E' N^{-1} (C \tilde{\Sigma} + L') \tilde{\Sigma}^{-1} e|^2\, dt. \end{aligned}$$

Adding the identically zero quantity

$$(2/\theta) \int_0^{t_f} d\Upsilon - (2/\theta)(\Upsilon(t_f, \varepsilon(t_f), \check{x}(t_f)) + \Upsilon(0, \varepsilon(0), \bar{x}_0))$$

to the exponent of $J_{I\theta}$ yields, after some rearrangement,

$$J_{I\theta} = \int_0^{t_f} \operatorname{Tr}(\tilde{\Psi}(\tilde{\Sigma} C' + L) N^{-1} (C \tilde{\Sigma} + L') + \frac{1}{\theta} \tilde{\Sigma}^{-1} (\tilde{M} + \tilde{\Sigma} C' N^{-1} C \tilde{\Sigma}))\, dt + \frac{2}{\theta} \ln \left\{ \boldsymbol{E} \left\{ \exp \left\{ \frac{1}{2} |\varepsilon(0)|^2_{\Sigma_0^{-1}} - \frac{1}{2} |e(t_f)|^2_{\tilde{\Sigma}(t_f)^{-1} - \theta Q_f} + \frac{\theta}{2} \int_0^{t_f} |\tilde{u}|^2_R\, dt \right\} \zeta(t_f) \right\} \right\} + |\bar{x}_0|^2_{\tilde{\Psi}}. \tag{47}$$

Introduce the change of probability [6]

$$\frac{d\tilde{\boldsymbol{P}}}{d\boldsymbol{P}} = \zeta(t_f). \tag{48}$$

The measure $\tilde{\boldsymbol{P}}$ is a valid probability measure for all $\mu_I \in \mathcal{M}_I$, since ζ is a martingale on $[0, t_f]$ by our construction of $\mathcal{M}_I$.

[6]For a precise definition, see [3]. This property is also referred to as *strong time consistency* [1].

Under the new probability measure $\tilde{P}$, the process v_t, defined by

$$v_t := w_t - \int_0^{t_f} (G'\tilde{\Sigma}^{-1}\varepsilon - E'N^{-1}(C\tilde{\Sigma} + L')\tilde{\Sigma}^{-1}e)\,dt,$$

is a standard Wiener process starting at 0, and it is independent of x_0.

It is straightforward to derive the following expression for the stochastic differential equation satisfied by y, under the new measure $\tilde{P}$:

$$dy = (C + \theta L'\tilde{Z})\hat{x}\,dt + E\,dv_t.$$

Hence, we conclude the following equivalence of sigma-fields:

$$Y_0^t := \sigma\{y_s : \ 0 \le s \le t\} = \sigma\{Ev_s : \ 0 \le s \le t\},$$

and that Y_0^t is independent of x_0, for each $t \in [0, t_f]$.

Let the expectation with respect to the probability measure $\tilde{P}$ be denoted by $\tilde{E}$. Then,

$$\bar{J}_{I\theta} = \frac{2}{\theta} \ln\left\{\tilde{E}\left\{\exp\left\{\frac{\theta}{2}\int_0^{t_f} |\tilde{u}|_R^2\,dt\right\}\tilde{E}\left\{\exp\left\{\frac{1}{2}|\varepsilon(0)|^2_{\Sigma_0^{-1}} - \frac{1}{2}|e(t_f)|^2_{\tilde{\Sigma}(t_f)^{-1}-\theta Q_f}\right\}|Y_0^{t_f}\right\}\right\}\right\}.$$

We will first obtain an expression for the quantity

$$J_b := \tilde{E}\left\{\exp\left\{\frac{1}{2}|\varepsilon(0)|^2_{\Sigma_0^{-1}} - \frac{1}{2}|e(t_f)|^2_{\tilde{\Sigma}(t_f)^{-1}-\theta Q_f}\right\}|Y_0^{t_f}\right\}.$$

Toward that end, we first derive a differential equation for e in terms of v_t:

$$de = (\tilde{A} + \tilde{M}\tilde{\Sigma}^{-1})e\,dt + (B - (I - \theta\tilde{\Sigma}\tilde{Z})^{-1}(B + \theta\tilde{\Sigma}P))\tilde{u}\,dt$$
$$+ (L - (I - \theta\tilde{\Sigma}\tilde{Z})^{-1}\cdot(\tilde{\Sigma}C' + L))N^{-1}E\,dv_t + (G - LN^{-1}E)\,dv_t.$$

Note that the processes $\{Ev_t\}_{0\le t\le t_f}$ and $\{(G - LN^{-1}E)v_t\}_{0\le t\le t_f}$ are independent, since $(G - LN^{-1}E)E' = 0$. Then, we can decompose e into $e = \hat{e} + \tilde{e}$, where

$$d\hat{e} = (\tilde{A} + \tilde{M}\tilde{\Sigma}^{-1})\hat{e}\,dt + (B - (I - \theta\tilde{\Sigma}\tilde{Z})^{-1}(B + \theta\tilde{\Sigma}P))\tilde{u}\,dt + (L - (I - \theta\tilde{\Sigma}\tilde{Z})^{-1}$$
$$\cdot(\tilde{\Sigma}C' + L))N^{-1}E\,dv_t,$$
$$d\tilde{e} = (\tilde{A} + \tilde{M}\tilde{\Sigma}^{-1})\tilde{e}\,dt + (G - LN^{-1}E)\,dv_t, \quad \tilde{e}(0) = \varepsilon(0).$$

The process $\hat{e}$ belongs to $Y_0^{t_f}$, and the process $\tilde{e}$ is independent of $Y_0^{t_f}$. Therefore, the process $\hat{e}$ is the conditional expectation of the process e given $Y_0^{t_f}$. The conditional distribution of the vector $[\tilde{e}(0)'\ e(t_f)']'$, given the measurement sigma-field $Y_0^{t_f}$, is Gaussian with mean and covariance

$$\begin{bmatrix} 0 \\ \hat{e}(t_f) \end{bmatrix}, \quad \begin{bmatrix} \Sigma_0 & D(t_f)' \\ D(t_f) & \Phi(t_f) \end{bmatrix} =: \Lambda, \quad \text{respectively,}$$

where D satisfies

$$\dot{D} = (\tilde{A} + \tilde{M}\tilde{\Sigma}^{-1})D, \quad D(0) = \Sigma_0,$$

and Φ is the solution to the following Lyapunov differential equation:

$$\dot{\Phi} = (\tilde{A} + \tilde{M}\tilde{\Sigma}^{-1})\Phi + \Phi(\tilde{A} + \tilde{M}\tilde{\Sigma}^{-1})' + \tilde{M}, \quad \Phi(0) = \Sigma_0.$$

Hence, J_b can be evaluated as

$$J_b = \int_{R^{2n}} \frac{1}{(2\pi)^n(\det(\Lambda))^{1/2}} \exp\left\{\frac{1}{2}|\tilde{e}(0)|^2_{\Sigma_0^{-1}} - \frac{1}{2}|\tilde{e}(t_f)+\hat{e}(t_f)|^2_{\tilde{\Sigma}(t_f)^{-1}-\theta Q_f}\right.$$

$$\left. - \frac{1}{2}\left|\left[\begin{array}{c}\tilde{e}(0)\\ \tilde{e}(t_f)\end{array}\right]\right|^2_{\Lambda^{-1}}\right\} d\tilde{e}(0)\,d\tilde{e}(t_f) = \int_{R^{2n}} \frac{1}{(2\pi)^n(\det(\Lambda))^{1/2}} \exp\left\{-\frac{1}{2}\left|\left[\begin{array}{c}\tilde{e}(0)\\ \tilde{e}(t_f)\end{array}\right]\right.\right.$$

$$\left.\left. + \tilde{\Lambda}\left[\begin{array}{c}0\\ (\tilde{\Sigma}^{-1}-\theta Q_f)\hat{e}(t_f)\end{array}\right]\right|^2_{\tilde{\Lambda}^{-1}}\right\} d\tilde{e}(0)\,d\tilde{e}(t_f) = \sqrt{\frac{\det(\tilde{\Lambda})}{\det(\Lambda)}},$$

where

$$\tilde{\Lambda} = \left[\begin{array}{cc}\Sigma_0^{-1}D'\tilde{\Phi}^{-1}D\Sigma_0^{-1} & -\Sigma_0^{-1}D'\tilde{\Phi}^{-1}\\ -\tilde{\Phi}^{-1}D\Sigma_0^{-1} & \tilde{\Phi}^{-1}+\tilde{\Sigma}^{-1}-\theta Q_f\end{array}\right]^{-1}\Bigg|_{t=t_f},$$

$$\tilde{\Phi} = \Phi - D\Sigma_0^{-1}D'.$$

Thus, the cost function can be written as follows:

$$J_{I\theta} = \int_0^{t_f} \mathrm{Tr}(\tilde{\Psi}(\tilde{\Sigma}C'+L)N^{-1}(C\tilde{\Sigma}+L') + \frac{1}{\theta}\tilde{\Sigma}^{-1}(\tilde{M}+\tilde{\Sigma}C'N^{-1}C\tilde{\Sigma}))\,dt$$

$$+ \frac{1}{\theta}\ln(\det(\tilde{\Lambda})) - \frac{1}{\theta}\ln(\det(\Lambda)) + \frac{2}{\theta}\ln\left\{E\left\{\exp\left\{\frac{\theta}{2}\int_0^{t_f}|\tilde{u}|^2_R\,dt\right\}\right\}\right\} + |\bar{x}_0|^2_{\tilde{\Psi}}$$

$$J_{I\theta} \geq \int_0^{t_f} \mathrm{Tr}(\tilde{\Psi}(\tilde{\Sigma}C'+L)N^{-1}(C\tilde{\Sigma}+L') + \frac{1}{\theta}\tilde{\Sigma}^{-1}(\tilde{M}+\tilde{\Sigma}C'N^{-1}C\tilde{\Sigma}))\,dt \tag{49}$$

$$+ \frac{2}{\theta}\ln(J_b) + |\bar{x}_0|^2_{\tilde{\Psi}}.$$

The controller (44) achieves the lower bound above, and hence is optimal. It is easy to see that the controller (44) is also conditionally optimal.

Some straightforward algebraic manipulations lead to the conclusion that the lower bound in (49) is indeed the same as (45).

This completes the proof. □

Remark 1. We observe that the optimal controller obtained for the LEQG problem is precisely the central controller for the H^∞-optimal control problem [2]. The preceding theorem also subsumes the main result of [3] as a special case, and obtains it under less restrictive conditions.

Remark 2. Theorem 2 also holds when $\Sigma_0 \geq 0$, if we restrict the set of admissible controllers to be the set of linear controllers. This generalization can be proved via a standard perturbation analysis, by first replacing Σ_0 by $\Sigma_0 + \rho I$, $\rho > 0$, and then letting $\rho \downarrow 0$.

4.2. The infinite-horizon problem. We now study the infinite-horizon case, where the cost function is taken to be the time-average of (37):

$$J_{I\theta}(\mu_I) = \lim_{t_f\to\infty}\frac{2}{\theta t_f}\ln\left\{E\left\{\exp\left[\frac{\theta}{2}\left(\int_0^{t_f}(x'Qx+2x'Pu+u'Ru)\,dt\right)\right]\right\}\right\}. \tag{50}$$

Introduce two GAREs,

$$\bar{A}'\tilde{Z} + \tilde{Z}\bar{A} - \tilde{Z}\bar{S}\tilde{Z} + \bar{Q} = 0 \tag{51}$$

and

$$\tilde{\Sigma}\tilde{A}' + \tilde{A}\tilde{\Sigma} - \tilde{\Sigma}\tilde{R}\tilde{\Sigma} + \tilde{M} = 0. \tag{52}$$

Define the quantity

$$\theta_I^* := \sup\{\theta \in \boldsymbol{R} : \text{the GAREs (51) and (52) admit minimal positive definite solutions } \tilde{Z} \text{ and } \tilde{\Sigma}, \text{ respectively, and the matrix } I - \theta\tilde{\Sigma}\tilde{Z} \text{ has only positive eigenvalues}\}. \tag{53}$$

For $\theta < \theta_I^*$, we introduce the filter

$$d\check{x} = (A + \theta\tilde{\Sigma}Q)\check{x}\,dt + (B + \theta\tilde{\Sigma}P)u\,dt + (\tilde{\Sigma}C' + L)N^{-1}(dy - C\check{x}\,dt) \tag{54}$$

with the initial state $\check{x}(0) = \bar{x}_0$. Let $\hat{x} := (I - \theta\tilde{\Sigma}\tilde{Z})^{-1}\check{x}$; then it is not difficult to show, as in the finite-horizon case, that $\hat{x}$ is generated by the following differential equation:

$$d\hat{x} = (\bar{A} - \bar{S}\tilde{Z})\hat{x}\,dt + (I - \theta\tilde{\Sigma}\tilde{Z})^{-1}(B + \theta\tilde{\Sigma}P)\tilde{u}\,dt + (I - \theta\tilde{\Sigma}\tilde{Z})^{-1} \cdot(\tilde{\Sigma}C' + L)N^{-1}(dy - (C + \theta L'\tilde{Z})\hat{x}\,dt), \tag{55}$$

where $\tilde{u} = u + R^{-1}(B'\tilde{Z} + P')\hat{x}$.

Suppose $\Sigma_0 > 0$, but $\Sigma_0 \leq \tilde{\Sigma}$; then, the solution of GRDE (39) converges to $\tilde{\Sigma}$ exponentially as $t \to \infty$.

We will define the set of admissible controllers, $\mathcal{M}_I$, to be all mappings $\mu_I : [0, \infty) \times \mathcal{H}_y \to \mathcal{H}_u$ that are admissible for every finite-horizon problem with initial time 0 and final time $t_f > 0$, for all $t_f \in \boldsymbol{R}^+$. Then, we have the following counterpart of Theorem 2.

THEOREM 3. *Consider the general LEQG problem described by* (36) *and* (50). *Let* $\Sigma_0 > 0$, $R > 0$, $Q - PR^{-1}P' \geq 0$, *and* $N > 0$, *and assume that the pairs* (A, B) *and* (A, G) *are controllable, and the pairs* (A, C) *and* (A, Q) *are observable. For each* $\theta < \theta_I^*$, *if* $\Sigma_0 \leq \tilde{\Sigma}$, *then the optimal controller is given by*

$$u_{It}^* = \mu_I^*(t, y_{[0,t]}) \equiv -R^{-1}(B'\tilde{Z} + P')(I - \theta\tilde{\Sigma}\tilde{Z})^{-1}\check{x} = -R^{-1}(B'\tilde{Z} + P')\hat{x}, \tag{56}$$

where $\check{x}$ *is generated by the filter* (54), *or equivalently,* $\hat{x}$ *is generated by filter* (55). *The optimal cost can be written as*

$$J_{I\theta}^* = \inf_{\mu_I \in \mathcal{M}_I} J_{I\theta}(\mu_I) = Tr(\tilde{\Sigma}Q + (\tilde{\Sigma}C' + L)N^{-1}(C\tilde{\Sigma} + L')\tilde{Z}(I - \theta\tilde{\Sigma}\tilde{Z})^{-1}). \tag{57}$$

Proof. By Theorem 2, we have the following relationships, for any admissible controller:

$$\frac{2}{\theta t_f}\ln\left\{\boldsymbol{E}\left\{\exp\left[\frac{\theta}{2}\left(\int_0^{t_f}(x'Qx + u'u)\,dt\right)\right]\right\}\right\}$$

$$\geq \frac{1}{t_f}(\bar{x}_0'\tilde{Z}^{t_f}(0)(I - \theta\Sigma_0\tilde{Z}^{t_f}(0))^{-1}\bar{x}_0 - \frac{1}{\theta}\ln\{\det(I - \theta\tilde{\Sigma}^{t_f}(t_f)Q_f)\}$$

$$+ \int_0^{t_f}\mathrm{Tr}(\tilde{\Sigma}^{t_f}Q + (\tilde{\Sigma}^{t_f}C' + L)N^{-1}(C\tilde{\Sigma}^{t_f} + L')\tilde{Z}^{t_f}(I - \theta\tilde{\Sigma}^{t_f}\tilde{Z}^{t_f})^{-1})\,dt),$$

where $\tilde{Z}^{t_f}$ and $\tilde{\Sigma}^{t_f}$ are the solutions to GRDEs (38) and (39), respectively, on the time interval $[0, t_f]$, in the former case with $Q_f = 0$. Hence,

$$J_{I\theta}(\mu_I) \geq \mathrm{Tr}(\tilde{\Sigma}Q + (\tilde{\Sigma}C' + L)N^{-1}(C\tilde{\Sigma} + L')\tilde{Z}(I - \theta\tilde{\Sigma}\tilde{Z})^{-1}) = J_{I\theta}^*,$$

since $\tilde{Z}^{t_f}$ converges to $\tilde{Z}$ as $t_f \to \infty$ and $\tilde{\Sigma}_f^t$ converges to $\tilde{\Sigma}$ as $t \to \infty$ exponentially.

To prove the theorem, it is sufficient to show that the controller defined by (56) and (54), or equivalently, the one given by (56) and (55), achieves a performance level that is equal to $J^*_{I\theta}$ given by (57).

Let

$$J^{t_f}_{I\theta}(\mu_I) := \frac{2}{\theta}\ln\left\{E\left\{\exp\left[\frac{\theta}{2}\left(\int_0^{t_f}(x'Qx+u'u)\,dt\right)\right]\right\}\right\},$$

$$\bar{J}^{t_f}_{I\theta}(\mu_I) := \frac{2}{\theta}\ln\left\{E\left\{\exp\left[\frac{\theta}{2}\left(\int_0^{t_f}(x'Qx+u'u)\,dt + x(t_f)'\tilde{Z}x(t_f)\right)\right]\right\}\right\}.$$

Then, clearly $\bar{J}^{t_f}_{I\theta}(\mu_I) \geq J^{t_f}_{I\theta}(\mu_I)$, and

$$J_{I\theta}(\mu_I) = \lim_{t_f\to\infty}\frac{1}{t_f}J^{t_f}_{I\theta}(\mu_I).$$

Hence, we have

$$J_{I\theta}(\mu_I) \leq \lim_{t_f\to\infty}\frac{1}{t_f}\bar{J}^{t_f}_{I\theta}(\mu_I).$$

By the proof of Theorem 2, and in particular by (47), we have the identity

$$\bar{J}^{t_f}_{I\theta}(\mu_I) = |\bar{x}_0|^2_{\tilde{\Psi}} + \int_0^{t_f}\mathrm{Tr}(\tilde{\Psi}(\tilde{\Sigma}C'+L)N^{-1}(C\tilde{\Sigma}+L') + \frac{1}{\theta}\tilde{\Sigma}^{-1}(\tilde{M}+\tilde{\Sigma}C'$$
$$\cdot N^{-1}C\tilde{\Sigma}))\,dt + \frac{2}{\theta}\ln\left\{E\left\{\exp\left\{\frac{1}{2}|\varepsilon(0)|^2_{\tilde{\Sigma}^{-1}} - \frac{1}{2}|e(t_f)|^2_{\tilde{\Sigma}^{-1}-\theta\tilde{Z}}\right.\right.\right.$$
$$\left.\left.\left. + \frac{\theta}{2}\int_0^{t_f}|\tilde{u}|^2_R\,dt\right\}\zeta(t_f)\right\}\right\},$$

where $\varepsilon := x-\check{x}$, $e := x-\hat{x}$, $\tilde{u} := u + R^{-1}(B'\tilde{Z}+P')\hat{x}$, $\tilde{\Psi} := \tilde{Z}(I-\theta\tilde{\Sigma}\tilde{Z})^{-1}$, and ζ is defined by

$$\zeta = \exp\left\{\int_0^t(\varepsilon'\tilde{\Sigma}^{-1}G - e'\tilde{\Sigma}^{-1}(\tilde{\Sigma}C'+L)N^{-1}E)dw_t\right.$$
$$\left. - \frac{1}{2}\int_0^t|G'\tilde{\Sigma}^{-1}\varepsilon - E'N^{-1}(C\tilde{\Sigma}+L')\tilde{\Sigma}^{-1}e|^2\,dt\right\}.$$

It is clear that, under the controller μ^*_I, as defined by (56) and (54) (as well as (55)), the process ζ is a martingale on $[0, t_f]$. Introduce a change of probability

$$\frac{d\tilde{P}}{dP} = \zeta(t_f).$$

Then, under the new measure,

$$\bar{J}^{t_f}_{I\theta}(\mu^*_I) = |\bar{x}_0|^2_{\tilde{\Psi}} + \int_0^{t_f}\mathrm{Tr}(\tilde{\Psi}(\tilde{\Sigma}C'+L)N^{-1}(C\tilde{\Sigma}+L') + \frac{1}{\theta}\tilde{\Sigma}^{-1}(\tilde{M}+\tilde{\Sigma}C'$$
$$\cdot N^{-1}C\tilde{\Sigma}))\,dt + \frac{2}{\theta}\ln\left\{\tilde{E}\left\{\exp\left\{\frac{1}{2}|\varepsilon(0)|^2_{\tilde{\Sigma}^{-1}} - \frac{1}{2}|e(t_f)|^2_{\tilde{\Sigma}^{-1}-\theta\tilde{Z}}\right\}\right\}\right\}.$$

This leads to the inequality

$$J_{I\theta}(\mu_I^*) \le \lim_{t_f\to\infty} \frac{1}{t_f} \bar{J}_{I\theta}^{t_f}(\mu_I^*) \le J_{I\theta}^*$$

from which the theorem follows. □

Remark 3. The theorem can be generalized to the case when $\Sigma_0 \ge 0$ if we restrict the set of admissible controllers to linear controllers, in view of Remark 2 and the independence of the solution from the initial condition.

Before concluding this subsection, we write the full-order solution (optimal controller) to the original problem formulated in §2 as a special case of the one given in Theorem 3 above.

First we introduce some additional notation:

$$C_\epsilon := \begin{bmatrix} C_{11} & C_{12} \\ \epsilon^{1/2}C_{21} & C_{22} \end{bmatrix}, \quad E_\epsilon := \begin{bmatrix} E_1 \\ \epsilon^{1/2}E_2 \end{bmatrix}, \quad N_\epsilon := E_\epsilon E_\epsilon',$$

$$R_\epsilon(\theta) := C_\epsilon' N_\epsilon^{-1} C_\epsilon - \theta Q =: \begin{bmatrix} R_{\epsilon 11} & \frac{1}{\sqrt{\epsilon}}R_{\epsilon 12} \\ \frac{1}{\sqrt{\epsilon}}R_{\epsilon 21} & \frac{1}{\epsilon}R_{\epsilon 22} \end{bmatrix}, \quad R_{12}(\theta) = R_{21}(\theta)' := C_1' N^{-1} C_2,$$

$$R_{22}(\theta) := C_2 N^{-1} C_2, \quad R_{11}(\theta) := C_1' N^{-1} C_1 - \theta Q_{11}, \quad R(\theta) := \begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{bmatrix}.$$

Let us assume that the pairs (A_ϵ, B_ϵ) and (A_ϵ, G_ϵ) are controllable, and the pairs (A_ϵ, Q) and (A_ϵ, C_ϵ) are observable for every $\epsilon > 0$. Then the controller is given by

$$u_{I\epsilon}^*(t) = \mu_{I\epsilon}^*(t, y_{[0,t]}) = -B_\epsilon' \tilde{Z}(\epsilon)\hat{x}_t, \tag{58a}$$

$$d\hat{x}_t = (A_\epsilon - S_\epsilon \tilde{Z}(\epsilon))\hat{x}_t\, dt + (I - \theta\tilde{\Sigma}(\epsilon)\tilde{Z}(\epsilon))^{-1}\tilde{\Sigma}(\epsilon)C_\epsilon' N_\epsilon^{-1}(dy_t - C_\epsilon \hat{x}_t\, dt), \tag{58b}$$

where $\hat{x}(0) = (I - \theta\tilde{\Sigma}(\epsilon)\tilde{Z}(\epsilon))^{-1}\bar{x}_0$.[7] Here $\tilde{Z}(\epsilon)$ is the minimal positive definite solution to the GARE (9), and $\tilde{\Sigma}(\epsilon)$ is the minimal positive definite solution to

$$A_\epsilon \tilde{\Sigma} + \tilde{\Sigma} A_\epsilon' - \tilde{\Sigma} R_\epsilon \tilde{\Sigma} + G_\epsilon G_\epsilon' = 0, \tag{59}$$

with

$$R_\epsilon := C_\epsilon' N_\epsilon^{-1} C_\epsilon - \theta Q. \tag{60}$$

This is a valid solution for all $\theta < \theta_I^*(\epsilon)$, provided that $\Sigma_0 \le \tilde{\Sigma}(\epsilon)$, where

$$\begin{aligned} \theta_I^*(\epsilon) := \sup\{\theta \in \boldsymbol{R} :\ & \text{the GAREs (9) and (59) admit minimal} \\ & \text{positive definite solutions, and the matrix} \\ & I - \theta\tilde{\Sigma}(\epsilon)\tilde{Z}(\epsilon) \text{ has only positive eigenvalues}\}. \end{aligned} \tag{61}$$

For all $\theta < \theta_I^*(\epsilon)$ the optimal cost is

$$J_{I\theta}^*(\epsilon) = \mathrm{Tr}(\tilde{\Sigma}(\epsilon)Q + \tilde{\Sigma}(\epsilon)C_\epsilon' N_\epsilon^{-1} C_\epsilon \tilde{\Sigma}(\epsilon)\tilde{Z}(\epsilon)(I - \theta\tilde{\Sigma}(\epsilon)\tilde{Z}(\epsilon))^{-1}). \tag{62}$$

Remark 4. The condition $\Sigma_0 \le \tilde{\Sigma}(\epsilon)$ is essential for the existence of an optimal time-invariant control policy. Accordingly, we will assume henceforth that Σ_0 is less than or equal to (in matrix sense) the solution to GARE (59) at $\theta = 0$ for sufficiently small $\epsilon > 0$.

[7] It follows from a result of [2] that $\hat{r}_t$ of (4.2) in [3] is precisely $(I - \theta\tilde{\Sigma}\tilde{Z})^{-1}\hat{x}_t$, where $\hat{x}_t$ is generated by (58b).

5. Imperfect state measurements: Model simplification. We now turn to model simplification for the noisy state measurements case, with (36) replaced by (1)–(2), with $\alpha = 1/2$, and cost taken as given by (3) (instead of (50)). As in the perfect state measurements case discussed in §3, we first decompose the system into slow and fast subsystems.

5.1. Time-scale decomposition.

Slow subsystem. The slow subsystem is obtained by letting $dx_2 = 0$ and solving for $x_2\,dt$ (to be denoted $\bar{x}_2\,dt$) in terms of x_1, u, dw_t, and under the working assumption A2:

$$\bar{x}_2\,dt = -A_{22}^{-1}(\sqrt{\epsilon}A_{21}x_1\,dt + B_2u\,dt + \sqrt{\epsilon}G_2\,dw_t). \tag{63}$$

Using this in (1)–(2) and denoting $y_s := y$, we obtain

$$dx_1 = ((A_{11} + O(\sqrt{\epsilon}))x_1 + (B_1 - A_{12}A_{22}^{-1}B_2)u)\,dt + (G_1 + O(\sqrt{\epsilon}))\,dw_t, \quad x_1(0) = x_{10}, \tag{64a}$$

$$dy_{s1} = ((C_{11} + O(\sqrt{\epsilon}))x_s - C_{12}A_{22}^{-1}B_2u)\,dt + (E_1 + \sqrt{\epsilon}C_{12}A_{22}^{-1}G_2)\,dw_t, \quad y_1(0) = 0, \tag{64b}$$

$$dy_{s2} = (\sqrt{\epsilon}(C_{21} - C_{22}A_{22}^{-1}A_{21})x_s - C_{22}A_{22}^{-1}B_2u)\,dt + \sqrt{\epsilon}(E_2 - C_{22}A_{22}^{-1}G_2)\,dw_t, \quad y_2(0) = 0. \tag{64c}$$

For each $\epsilon > 0$, measurements (64b) and (64c) are equivalent to the vector measurement $\tilde{y}$, defined by

$$\tilde{y}_s := \begin{bmatrix} y_{s1} \\ \frac{1}{\sqrt{\epsilon}}\,y_{s2} \end{bmatrix} + \begin{bmatrix} C_{12} \\ \frac{1}{\sqrt{\epsilon}}\,C_{22} \end{bmatrix} A_{22}^{-1}B_2u. \tag{65}$$

Now set $\epsilon = 0$ in (64a) and (65) to arrive at the slow subproblem in terms of $x_s := x_1$, w_t, u, and $\tilde{y}_s$, with $\bar{x}_2 = -A_{22}^{-1}B_2u$, reduced (slow) dynamics

$$dx_s = (A_{11}x_s + B_0u)\,dt + G_1\,dw_t, \quad x_s(0) = x_{10}, \tag{66}$$

slow measurements

$$d\tilde{y}_s = C_0x_s\,dt + E^{\square}\,dw_t, \quad \tilde{y}_s(0) = 0, \tag{67}$$

and reduced (slow) cost function

$$J_{Is\theta}(\mu_s) = \lim_{t_f\to\infty} \frac{2}{\theta t_f} \ln\left\{E\left\{\exp\left[\frac{\theta}{2}\int_0^{t_f} (|x_s|^2_{Q_{11}} - 2x_s'Q_{12}A_{22}^{-1}B_2u + |u|^2_{I+B_2'A_{22}^{-1\prime}Q_{22}A_{22}^{-1}B_2})\,dt\right]\right\}\right\}, \tag{68}$$

where

$$B_0 := B_1 - A_{12}A_{22}^{-1}B_2, \quad C_0 := C_1 - C_2A_{22}^{-1}A_{21}, \quad E^{\square} := E - C_2A_{22}^{-1}G_2,$$

$$C_1 := \begin{bmatrix} C_{11}' & C_{21}' \end{bmatrix}', \quad C_2 := \begin{bmatrix} 0 & C_{22}' \end{bmatrix}'.$$

Note that even though we started with independent system and measurement noises, the slow LEQG involves correlated noises and a coupling term between the state and the control in the

exponent of the cost. But, thanks to the general solution presented in the previous section for this class of LEQG problems, we can now solve this slow LEQG problem. By Theorem 3, it admits an optimal solution if

(i) the following GARE admits a (minimal) positive definite solution, $Z_{s\theta}$:

$$\bar{A}_s' Z_{s\theta} + Z_{s\theta}\bar{A}_s - Z_{s\theta}\bar{S}_s Z_{s\theta} + \bar{Q}_s = 0, \tag{69}$$

where

$$\begin{aligned}
\bar{A}_s &:= A_{11} + B_0(I + B_2' A_{22}^{-1\prime} Q_{22} A_{22}^{-1} B_2)^{-1} B_2' A_{22}^{-1\prime} Q_{21},\\
\bar{S}_s(\theta) &:= B_0(I + B_2' A_{22}^{-1\prime} Q_{22} A_{22}^{-1} B_2)^{-1} B_0' - \theta G_1 G_1',\\
\bar{Q}_s &:= Q_{11} - Q_{12} A_{22}^{-1} B_2 (I + B_2' A_{22}^{-1\prime} Q_{22} A_{22}^{-1} B_2)^{-1} B_2' A_{22}^{-1\prime} Q_{21};
\end{aligned}$$

(ii) the following GARE admits a (minimal) positive definite solution, $\Sigma_{s\theta}$:

$$\tilde{A}_s \Sigma_{s\theta} + \Sigma_{s\theta}\tilde{A}_s' - \Sigma_{s\theta}\tilde{R}_s \Sigma_{s\theta} + \tilde{M}_s = 0, \tag{70}$$

where

$$\begin{aligned}
\tilde{A}_s &:= A_{11} - G_1 E^{\square\prime} N^{\square -1} C_0, \quad \tilde{R}_s := C_0' N^{\square -1} C_0 - \theta Q_{11},\\
\tilde{M}_s &:= G_1 G_1' - G_1 E^{\square\prime} N^{\square -1} E^{\square} G_1', \quad N^{\square} := E^{\square} E^{\square\prime};
\end{aligned}$$

and

(iii) the solutions to (69) and (70) satisfy the spectral radius condition

$$I - \theta \Sigma_{s\theta} Z_{s\theta} \quad \text{has only positive eigenvalues.} \tag{71}$$

Hence, let us introduce the quantity

$$\begin{aligned}
\theta_{Is} := \sup\{\theta \in \boldsymbol{R} : &\text{ the GAREs (69) and (70) admit minimal positive}\\
&\text{definite solutions, and further satisfy (71)}\}.
\end{aligned} \tag{72}$$

For $\theta < \theta_{Is}$, the slow LEQG problem admits an optimal controller, given by

$$\tilde{u}_{Is}^* = \tilde{\mu}_{Is}^*(t, \tilde{y}_{s[0,t]}) = -(I + B_2' A_{22}^{-1\prime} Q_{22} A_{22}^{-1} B_2)^{-1}(B_0' Z_{s\theta} - B_2' A_{22}^{-1\prime} Q_{21})\hat{x}_s, \tag{73a}$$

$$\begin{aligned}
d\hat{x}_s = {} & (A_{11} + \theta G_1 G_1' Z_{s\theta})\hat{x}_s\, dt + B_0 \tilde{u}_{Is}^*\, dt + (I - \theta \Sigma_{s\theta} Z_{s\theta})^{-1}(\Sigma_{s\theta} C_0'\\
& + G_1 E^{\square\prime}) N^{\square -1}(d\tilde{y}_s - C_0 \hat{x}_s\, dt - E^{\square}\theta G_1' Z_{s\theta}\hat{x}_s\, dt), \quad \hat{x}_s(0) = (I - \theta\Sigma_{s\theta} Z_{s\theta})^{-1}\bar{x}_{10}.
\end{aligned} \tag{73b}$$

Fast subsystem. To obtain the fast subsystem, we let $x_f := x_2 - \bar{x}_2 = x_2 + A_{22}^{-1} B_2 u_{Is}^*$, $u_f := u - u_s$, $y_f := y - y_s$, and $\tau = \frac{t' - t}{\epsilon}$, where we take t to be frozen, and t' to vary on the same time scale as t. In terms of the equivalent measurements

$$\tilde{y}_f := \begin{bmatrix} \frac{1}{\sqrt{\epsilon}}\, y_{f1}' & \frac{1}{\epsilon}\, y_{f2}' \end{bmatrix}, \tag{74}$$

we define the fast subsystem and the associated cost, respectively, by

$$dx_f^t = (A_{22} x_f^t + B_2 u_f^t)\, d\tau + G_2 dw_\tau, \quad x_f^t(0) = x_f, \tag{75a}$$

$$d\tilde{y}_f^t = C_2 x_f^t\, d\tau + E dw_\tau, \quad y_f^t(0) = 0, \tag{75b}$$

$$J_{If\theta}^t(\mu_f^t) = \boldsymbol{E}\left(\int_0^\infty (|x_f^t|_{Q_{22}}^2 + |u_f^t|^2)\, d\tau\right). \tag{75c}$$

This is a risk-neutral LQG problem, which does not depend on the parameter θ. It admits an optimal controller

$$u_{If}^{t*}(\tau) = \mu_{If}^{t*}(\tau, \tilde{y}_{f(-\infty,\tau]}^{t}) = -B_2' Z_f \hat{x}_f^t(\tau),$$

$$d\hat{x}_f^t = (A_{22} - S_{22}Z_f)\hat{x}_f^t\, d\tau + \Sigma_f C_2' N^{-1}(d\tilde{y}_f^t - C_2\hat{x}_f^t\, d\tau),$$

where Z_f and Σ_f are the unique nonnegative definite solutions to the AREs[8]

$$A_{22}'Z_f + Z_f A_{22} + Q_{22} - Z_f S_{22} Z_f = 0 \tag{76}$$

and

$$A_{22}\Sigma_f + \Sigma_f A_{22}' + G_2 G_2' - \Sigma_f R_{22}\Sigma_f = 0\,, \tag{77}$$

respectively. Transforming the control policy μ_{If}^{t*} back to the t time scale, we obtain the fast controller

$$u_{If}^{*} = \mu_{If}^{*} = \mu_f^{t*}(x_f^t(0)) = -B_2' Z_f \hat{x}_f, \tag{78a}$$

$$\epsilon d\hat{x}_f = (A_{22} - S_{22}Z_f)x_f\, dt + \Sigma_f C_2' N^{-1}\left(\begin{bmatrix} \sqrt{\epsilon}\, y_{f1} \\ y_{f2} \end{bmatrix} - C_2\hat{x}_f\, dt\right), \tag{78b}$$

$$\hat{x}_f(0) = x_f(0).$$

Also, we introduce two Lyapunov equations, for the case when A_{22} is Hurwitz:

$$A_{22}'Z_{of} + Z_{of}A_{22} + Q_{22} = 0, \tag{79}$$

$$A_{22}\Sigma_{of} + \Sigma_{of}A_{22}' + G_2G_2' = 0, \tag{80}$$

which, as we shall see shortly, are relevant to the problem under consideration.

5.2. Performance of suboptimal controllers. We now address the performance evaluation under the slow controller and the composite controller (to be defined), when applied to the full-order system, and the resulting degree of suboptimality with respect to the optimal performance of the full-order system. Toward this end, we first simplify the slow controller (73) using some straightforward algebraic manipulations of the type that can be found in [14] (derived in the context of the corresponding H^∞-optimal control problem):

$$\tilde{u}_{Is}^{*} = \tilde{\mu}_{Is}^{*}(t, \tilde{y}_{s[0,t]}) = -(B_1'Z_{s\theta} + B_2'V)\hat{x}_s, \tag{81a}$$

$$d\hat{x}_s = (\bar{A}_s - \bar{S}_s Z_{s\theta})\hat{x}_s\, dt + (I - \theta\Sigma_{s\theta}Z_{s\theta})^{-1}(\Sigma_{s\theta}C_1' + Y'C_2')N^{-1}(d\tilde{y}_s - (C_1 - C_2A_{22}^{-1}(A_{21} + \theta G_2G_1'Z_{s\theta}))\hat{x}_s\, dt), \tag{81b}$$

$$\hat{x}_s(0) = (I - \theta\Sigma_{s\theta}Z_{s\theta})^{-1}\bar{x}_{10},$$

where

$$Y := Y_1\Sigma_{s\theta} + Y_2, \quad V := V_1 Z_{s\theta} + V_2,$$

$$Y_1 := -(R_{22} + A_{22}'(G_2G_2)^{-1}A_{22})^{-1}(R_{21} + A_{22}'(G_2G_2)^{-1}A_{21}),$$

$$Y_2 := -(R_{22} + A_{22}'(G_2G_2)^{-1}A_{22})^{-1}A_{22}'(G_2G_2')^{-1}G_2G_1,$$

$$V_1 := -(S_{22} + A_{22}Q_{22}^{-1}A_{22}')^{-1}(S_{21} + A_{22}Q_{22}^{-1}A_{12}'),$$

$$V_2 := -(S_{22} + A_{22}Q_{22}^{-1}A_{22}')^{-1}A_{22}Q_{22}^{-1}Q_{21}.$$

[8] As is well known, these AREs admit positive definite solutions if (A_{22}, B_2) is controllable and (A_{22}, C_2) is observable.

Using (65) in (81b), we obtain the following alternative form for the slow controller:

$$u^*_{Is} = \mu^*_{Is}(t, y_{[0,t]}) = -(B_1' Z_{s\theta} + B_2' V)\hat{x}^s_s, \tag{82a}$$

$$\begin{aligned} d\hat{x}^s_s = {} & (\bar{A}_s - \bar{S}_s Z_{s\theta})\hat{x}^s_s\, dt + (I - \theta\Sigma_{s\theta} Z_{s\theta})^{-1}(\Sigma_{s\theta} C_1' + Y' C_2')N^{-1} \\ & \cdot \left(\begin{bmatrix} dy_1' & \frac{1}{\sqrt{\epsilon}} dy_2' \end{bmatrix}' - (C_{2\epsilon} A_{22}^{-1} B_2 (B_1' Z_{s\theta} + B_2' V) + C_1 - C_2 A_{22}^{-1}(A_{21} \right. \\ & \left. + \theta G_2 G_1' Z_{s\theta}))\hat{x}^s_s\, dt \right), \quad \hat{x}^s_s(0) = (I - \theta\Sigma_{s\theta} Z_{s\theta})^{-1}\bar{x}_{10}. \end{aligned} \tag{82b}$$

Before deriving an expression for the composite controller, let us introduce the notation

$$\begin{aligned} X &:= X_1 \Sigma_{s\theta} + X_2, \quad U := U_1 Z_{s\theta} + U_2, \\ X_1 &:= (G_2 G_2)^{-1} A_{21} - (G_2 G_2)^{-1} A_{22}(R_{22} + A_{22}'(G_2 G_2)^{-1} A_{22})^{-1} \\ &\qquad (R_{21} + A_{22}'(G_2 G_2)^{-1} A_{21}), \\ X_2 &:= (G_2 G_2)^{-1} G_2 G_1' - (G_2 G_2)^{-1} A_{22}(R_{22} + A_{22}'(G_2 G_2)^{-1} A_{22})^{-1} \\ &\qquad A_{22}'(G_2 G_2')^{-1} G_2 G_1, \\ U_1 &:= Q_{22}^{-1} A_{12}' - Q_{22}^{-1} A_{22}'(S_{22} + A_{22} Q_{22}^{-1} A_{22}')^{-1}(S_{21} + A_{22} Q_{22}^{-1} A_{12}'), \\ U_2 &:= Q_{22}^{-1} Q_{21} - Q_{22}^{-1} A_{22}'(S_{22} + A_{22} Q_{22}^{-1} A_{22}')^{-1} A_{22} Q_{22}^{-1} Q_{21}. \end{aligned}$$

Then, combining (78a) and (82a), we arrive at the composite controller, expressed as

$$\begin{aligned} u^*_{Ic} &= \mu^*_{Ic}(t, y_{[0,t]}) := \mu^*_{Is}(t, y_{[0,t]}) + \mu^*_{If}(t, y_{[0,t]}) \\ &= -(B_1' Z_{s\theta} + B_2' V)\hat{x}^c_s - B_2' Z_f \hat{x}^c_f, \end{aligned} \tag{83}$$

where a differential equation representation for $\hat{x}^c_s$ can be obtained by using (65) in (81b):

$$\begin{aligned} d\hat{x}^c_s = {} & (\bar{A}_s - \bar{S}_s Z_{s\theta})\hat{x}^c_s\, dt + (I - \theta\Sigma_{s\theta} Z_{s\theta})^{-1}(\Sigma_{s\theta} C_1' + Y' C_2')N^{-1} \\ & \cdot \left(\begin{bmatrix} dy_1' & \frac{1}{\sqrt{\epsilon}} dy_2' \end{bmatrix}' - (C_{2\epsilon} A_{22}^{-1} B_2 (B_1' Z_{s\theta} + B_2' V) + C_1 - C_2 A_{22}^{-1}(A_{21} \right. \\ & \left. + \theta G_2 G_1' Z_{s\theta}))\hat{x}^c_s\, dt - C_{2\epsilon} A_{22}^{-1} B_2 B_2' Z_f \hat{x}^c_f \right), \quad \hat{x}^c_s(0) = (I - \theta\Sigma_{s\theta} Z_{s\theta})^{-1}\bar{x}_{10}. \end{aligned} \tag{84}$$

To obtain the differential equation governing $\hat{x}^c_f$, we let

$$\begin{aligned} \begin{bmatrix} \sqrt{\epsilon} dy_{f1} \\ dy_{f2} \end{bmatrix} = {} & \begin{bmatrix} \sqrt{\epsilon} dy_1 \\ dy_2 \end{bmatrix} - \sqrt{\epsilon}(C_{2\epsilon} A_{22}^{-1} B_2 (B_1' Z_{s\theta} + B_2' V) + C_1 \\ & - C_2 A_{22}^{-1}(A_{21} + \theta G_2 G_1' Z_{s\theta}))\hat{x}^s_s\, dt \end{aligned}$$

and

$$\bar{x}_2 = -A_{22}^{-1} B_2 u^*_{Is} = -U\hat{x}^c_s$$

and substitute the above into (78b), to arrive at

$$\begin{aligned} \epsilon d\hat{x}^c_f = {} & (A_{22} - S_{22} Z_f)\hat{x}^c_f\, dt + \Sigma_f C_2' N^{-1}(\begin{bmatrix} \sqrt{\epsilon} dy_1' & dy_2' \end{bmatrix} - \sqrt{\epsilon}(C_{2\epsilon} A_{22}^{-1} B_2 \\ & \cdot (B_1' Z_{s\theta} + B_2' V) + C_1 - C_2 A_{22}^{-1}(A_{21} + \theta G_2 G_1' Z_{s\theta}))\hat{x}^c_s\, dt - C_2 \hat{x}^c_f\, dt); \\ & \hat{x}^c_f(0) = \bar{x}_{20} + U\hat{x}^c_s(0). \end{aligned} \tag{85}$$

The main results of this section are now given in Theorem 4 below, which provides expressions for the performances of the full-order system under full-order, slow, and composite controllers and establishes their asymptotic optimality (as $\epsilon \to 0$). We note that the condition of Remark 4 is guaranteed in this case by the conditions that $\Sigma_{011} < \Sigma_{s\theta}$ at $\theta = 0$, and $\Sigma_{022} < \Sigma_f$.

THEOREM 4. *For the singularly perturbed system* (1)–(2) *with* $\alpha = 1/2$, *and under cost function* (3):

1. *For each* $\epsilon > 0$, *if* (A_ϵ, B_ϵ) *and* (A_ϵ, G_ϵ) *are controllable,* (A_ϵ, C_ϵ) *and* (A_ϵ, Q) *are observable, and* N_ϵ *is invertible, then* $\forall \theta < \theta^*_{I\infty}(\epsilon)$, *and the optimal cost for the full-order LEQG problem can be written as*

$$J^*_{I\theta}(\epsilon) = \mathrm{Tr}(\tilde{\Sigma} Q + (\tilde{\Pi}^{-1} + \theta(\tilde{Z} - \theta \tilde{Z}\tilde{\Sigma}\tilde{Z}))^{-1}((I - \theta\tilde{Z}\tilde{\Sigma})Q(I - \theta\tilde{\Sigma}\tilde{Z}) + \tilde{Z}B_\epsilon B'_\epsilon \tilde{Z})), \tag{86}$$

where the matrix $\tilde{\Pi}$ *is the unique positive definite solution to the following Lyapunov equation:*

$$(A_\epsilon - S_\epsilon \tilde{Z})\tilde{\Pi} + \tilde{\Pi}(A'_\epsilon - \tilde{Z}S_\epsilon) + (I - \theta\tilde{\Sigma}\tilde{Z})^{-1}\tilde{\Sigma}C'_\epsilon N_\epsilon^{-1} C_\epsilon (I - \theta\tilde{Z}\tilde{\Sigma})^{-1} = 0. \tag{87}$$

2. *Let assumptions* A1 *and* A2 *be satisfied, the pairs* (A_{11}, B_0), $(A_{11}, G_1G'_1 - G_1G'_2(G_2G'_2)^{-1}G_2G'_1)$ *and* (A_{22}, B_2) *be controllable, and the pairs* (A_{11}, C_0), $(A_{11}, Q_{11} - Q_{12}Q_{22}^{-1}Q_{21})$ *and* (A_{22}, C_2) *be observable. Let* $\theta^*_I(\epsilon)$ *be as defined by* (61). *Then,*

(i) $\lim_{\epsilon \to 0^+} \theta^*_I(\epsilon) = \theta_{Is}$.

(ii) $\forall \theta < \theta_{Is}$, *there exists* $\epsilon_\theta > 0$, *such that* $\forall 0 < \epsilon \le \epsilon_\theta$, *the GAREs* (9) *and* (59) *admit minimal positive definite solutions, which can be approximated by*

$$\tilde{Z}(\epsilon) = \begin{bmatrix} Z_{s\theta} + O(\sqrt{\epsilon}) & \epsilon(Z_f U + V)' + O(\epsilon^{3/2}) \\ \epsilon(Z_f U + V) + O(\epsilon^{3/2}) & \epsilon Z_f + O(\epsilon^{3/2}) \end{bmatrix} \tag{88}$$

and

$$\tilde{\Sigma}(\epsilon) = \begin{bmatrix} \Sigma_{s\theta} + O(\sqrt{\epsilon}) & \sqrt{\epsilon}(\Sigma_f X + Y)' + O(\epsilon) \\ \sqrt{\epsilon}(\Sigma_f X + Y) + O(\epsilon) & \Sigma_f + O(\sqrt{\epsilon}) \end{bmatrix}. \tag{89}$$

Furthermore, $I - \theta\tilde{\Sigma}(\epsilon)\tilde{Z}(\epsilon)$ *has only positive eigenvalues.*

(iii) $\forall \theta < \theta_{Is}$, *there exists* $\tilde{\epsilon}_\theta \in (0, \epsilon_\theta]$, *such that* $\forall 0 < \epsilon \le \tilde{\epsilon}_\theta$, *the Lyapunov equation* (87) *admits a positive definite solution, which can be approximated by*

$$\tilde{\Pi}(\epsilon) = \begin{bmatrix} I & 0 \\ -U & I \end{bmatrix} \begin{bmatrix} \Pi_{s\theta} + O(\sqrt{\epsilon}) & O(\sqrt{\epsilon}) \\ O(\sqrt{\epsilon}) & \Pi_f + O(\sqrt{\epsilon}) \end{bmatrix} \begin{bmatrix} I & -U' \\ 0 & I \end{bmatrix}, \tag{90}$$

where $\Pi_{s\theta}$ *is the unique positive definite solution to the Lyapunov equation*

$$(\bar{A}_s - \bar{S}_s Z_{s\theta})\Pi_{s\theta} + \Pi_{s\theta}(\bar{A}'_s - Z_{s\theta}\bar{S}_s) + (I - \theta\Sigma_{s\theta}Z_{s\theta})^{-1}((\Sigma_{s\theta}C'_1 + Y'C'_2) \cdot N^{-1}(C_1\Sigma_{s\theta} + C_2 Y) + X'G_2G'_2X)(I - \theta Z_{s\theta}\Sigma_{s\theta})^{-1} = 0 \tag{91}$$

and Π_f *is the unique positive definite solution to the Lyapunov equation*

$$(A_{22} - B_2B'_2Z_f)\Pi_f + \Pi_f(A'_{22} - Z_fB_2B'_2) + \Sigma_f C'_2 N^{-1} C_2 \Sigma_f = 0. \tag{92}$$

(iv) $\forall \theta < \theta_{Is}$, $\forall 0 < \epsilon \le \tilde{\epsilon}_\theta$, *the optimal cost for the full-order LEQG problem can be approximated by*

$$\begin{aligned} J^*_{I\theta}(\epsilon) = \mathrm{Tr}(&\Sigma_{s\theta}Q_{11} + (\Pi_{s\theta}^{-1} + \theta(Z_{s\theta} - \theta Z_{s\theta}\Sigma_{s\theta}Z_{s\theta}))^{-1}((Z_{s\theta}B_1 + V'B_2) \\ &\cdot (B'_1Z_{s\theta} + B'_2V) + (I - \theta Z_{s\theta}\Sigma_{s\theta})Q_{11}(I - \theta\Sigma_{s\theta}Z_{s\theta}) \\ &- (I - \theta Z_{s\theta}\Sigma_{s\theta})Q_{12}U - U'Q_{21}(I - \theta\Sigma_{s\theta}Z_{s\theta}) + U'Q_{22}U) \\ &+ \Sigma_f Q_{22} + \Pi_f(Q_{22} + Z_fB_2B'_2Z_f)) + O(\sqrt{\epsilon}). \end{aligned} \tag{93}$$

(v) $\forall\theta < \theta_{Is}$, *if the composite controller* $\mu^*_{Ic\theta}$ *is applied to the system, then* $\exists\epsilon'_\theta > 0$ *such that* $\forall\epsilon \in [0, \epsilon'_\theta)$,

$$J^c_{I\theta} := J_{I\theta}(\mu^*_{Ic\theta}) = J^*_{I\theta}(\epsilon) + O(\sqrt{\epsilon}). \tag{94}$$

(vi) $\forall\theta < \theta_{Is}$, *if, in addition, the matrix* A_{22} *is Hurwitz, and the slow controller* $\mu^*_{Is\theta}$ *is applied to the system, then* $\exists\hat{\epsilon}_\theta > 0$ *such that* $\forall\epsilon \in [0, \hat{\epsilon}_\theta)$,

$$\begin{aligned} J^s_{I\theta} := J_{I\theta}(\mu^*_{Is\theta}) = J^*_{I\theta}(\epsilon) + \operatorname{Tr}(&\Sigma_{of} Q_{22} - \Sigma_f Q_{22} \\ &- \Pi_f(Q_{22} + Z_f B_2 B_2' Z_f)) + O(\sqrt{\epsilon}). \end{aligned} \tag{95}$$

Proof. We first substitute the optimal controller (58a)–(58b) into the full-order system, for any $\theta < \theta^*_{Is}(\epsilon)$, to obtain the following control-free LEQG problem in terms of $x^e := [x'\ \hat{x}']'$ and w:

$$\begin{aligned} dx^e &= \begin{bmatrix} A_\epsilon & -B_\epsilon B_\epsilon' \tilde{Z} \\ (I - \theta\tilde{\Sigma}\tilde{Z})^{-1}\tilde{\Sigma}C_\epsilon' N_\epsilon^{-1} C_\epsilon & A_\epsilon - S_\epsilon\tilde{Z} - (I - \theta\tilde{\Sigma}\tilde{Z})^{-1}\tilde{\Sigma}C_\epsilon' N_\epsilon^{-1} C_\epsilon \end{bmatrix} \\ &\quad \cdot x^e\, dt + \begin{bmatrix} G_\epsilon \\ (I - \theta\tilde{\Sigma}\tilde{Z})^{-1}\tilde{\Sigma}C_\epsilon' N_\epsilon^{-1} E_\epsilon \end{bmatrix} dw_t \\ &:= F^e_\epsilon x^e\, dt + G^e_\epsilon\, dw_t, \\ J^*_{I\theta}(\epsilon) &= \lim_{t_f\to\infty} \frac{2}{\theta t_f} \ln\left\{E\left\{\exp\left[\frac{\theta}{2}\int_0^{t_f} x^{e\prime} H^e x^e\, dt\right]\right\}\right\}, \end{aligned}$$

where

$$H^e := \begin{bmatrix} Q & 0 \\ 0 & \tilde{Z}B_\epsilon B_\epsilon'\tilde{Z} \end{bmatrix}$$

and $x^e(0)$ is a Gaussian random variable with mean and variance

$$\boldsymbol{E}x^e(0) = \begin{bmatrix} \bar{x}_0 \\ (I - \theta\tilde{\Sigma}\tilde{Z})^{-1}\bar{x}_0 \end{bmatrix} =: \bar{x}^e_0, \quad \operatorname{Var}(x^e(0)) = \begin{bmatrix} \Sigma_0 & 0 \\ 0 & 0 \end{bmatrix} =: \Theta^e_0.$$

To compute $J^*_{I\theta}(\epsilon)$ explicitly, we associate with the above system a fictitious measurement

$$dy^e = dv_t, \qquad y^e(0) = 0, \tag{96}$$

where v_t, or y^e, is a standard Wiener process independent of the initial condition and w_t.

Then, the two GAREs associated with this problem are (from §4.2)

$$F^{e\prime}_\epsilon\tilde{\Xi} + \tilde{\Xi}F^e_\epsilon + \tilde{\Xi}\theta G^e_\epsilon G^{e\prime}_\epsilon\tilde{\Xi} + H^e = 0 \tag{97}$$

and

$$F^e_\epsilon\tilde{\Theta} + \tilde{\Theta}F^{e\prime}_\epsilon + \tilde{\Theta}\theta H^e\tilde{\Theta} + G^e_\epsilon G^{e\prime}_\epsilon = 0. \tag{98}$$

It is shown in [13] that the minimal solutions to these GAREs are

$$\begin{aligned} \tilde{\Xi} &= \begin{bmatrix} \tilde{Z}^{-1} & \tilde{Z}^{-1} \\ \tilde{Z}^{-1} & (\tilde{Z} - \theta\tilde{Z}\tilde{\Sigma}\tilde{Z})^{-1} + \tilde{\Delta}^{-1} \end{bmatrix}^{-1}, \\ \tilde{\Theta} &= \begin{bmatrix} \tilde{\Sigma}^{-1} & -\tilde{\Sigma}^{-1} + \theta\tilde{Z} \\ -\tilde{\Sigma}^{-1} + \theta\tilde{Z} & \tilde{\Sigma}^{-1} - \theta\tilde{Z} + \tilde{\Pi}^{-1} \end{bmatrix}^{-1}, \end{aligned}$$

where $\tilde{\Delta}$ is the unique positive definite solution to the Lyapunov equation

$$(I-\theta\tilde{Z}\tilde{\Sigma})(A_\epsilon'-R_\epsilon\tilde{\Sigma})(I-\theta\tilde{Z}\tilde{\Sigma})^{-1}\tilde{\Delta}+\tilde{\Delta}(I-\theta\tilde{\Sigma}\tilde{Z})^{-1}(A_\epsilon-\tilde{\Sigma}R_\epsilon)(I-\theta\tilde{\Sigma}\tilde{Z})+\tilde{Z}B_\epsilon B_\epsilon'\tilde{Z}=0.$$

Furthermore, the matrices $F_\epsilon^e+\theta G_\epsilon^e G_\epsilon^{e\prime}\tilde{\Xi}$ and $F_\epsilon^{e\prime}+\theta H^e\tilde{\Theta}$ are Hurwitz.

We note that $\frac{1}{\theta}\tilde{\Theta}^{-1}$ is the maximal solution to the GARE (97), since $F_\epsilon^e+\theta G_\epsilon^e G_\epsilon^{e\prime}\tilde{\Theta}$ is an antistable matrix. Thus, by Theorem 5 of [26], we have $\frac{1}{\theta}\tilde{\Theta}^{-1}>\tilde{\Xi}$. It is easily seen that $\tilde{\Theta}>\Theta_0^e$. Hence, we obtain

$$J_{I\theta}^*=\mathrm{Tr}(\tilde{\Theta}H^e)$$

in view of Theorem 3. Using a matrix inversion identity, we obtain (86), which is an alternative expression to (62). Hence, part (1) is proven.

The GARE (9) also arises in the singularly perturbed H^∞-optimal control problem, whose approximate solution has been studied extensively in [12]. Here, due to the factor $\sqrt{\epsilon}$ multiplying A_{21} and G_2, these two matrices do not enter the slow GARE (69), nor do they enter the zeroth order approximation of the solution. Thus, GARE (9) admits a minimal positive definite solution, which is approximated by (88), for sufficiently small ϵ if $\theta<\theta_{Is}$.

To study the behavior of the solution of GARE (59), we first partition $\tilde{\Sigma}$ as follows (in a way consistent with the given partitioning on Σ_0):

$$\tilde{\Sigma}:=\begin{bmatrix}\tilde{\Sigma}_{11} & \sqrt{\epsilon}\,\tilde{\Sigma}_{12}\\ \sqrt{\epsilon}\,\tilde{\Sigma}_{21} & \tilde{\Sigma}_{22}\end{bmatrix}, \tag{99}$$

where $\tilde{\Sigma}_{12}=\tilde{\Sigma}_{21}'$. Then, by substituting this structure back into GARE (59), we obtain the following coupled matrix Riccati equations for the matrices $\tilde{\Sigma}_{11}$, $\tilde{\Sigma}_{12}$, and $\tilde{\Sigma}_{22}$:

$$\begin{aligned}(100a)\quad & A_{11}\tilde{\Sigma}_{11}+\sqrt{\epsilon}A_{12}\tilde{\Sigma}_{12}'+\tilde{\Sigma}_{11}A_{11}'+\sqrt{\epsilon}\tilde{\Sigma}_{12}A_{12}'+G_1G_1'-\tilde{\Sigma}_{11}R_{\epsilon 11}\tilde{\Sigma}_{11}\\ & -\tilde{\Sigma}_{12}R_{\epsilon 21}\tilde{\Sigma}_{11}-\tilde{\Sigma}_{11}R_{\epsilon 12}\tilde{\Sigma}_{12}'-\tilde{\Sigma}_{12}R_{\epsilon 22}\tilde{\Sigma}_{12}'=0,\\ (100b)\quad & \epsilon A_{11}\tilde{\Sigma}_{12}+\sqrt{\epsilon}A_{12}\tilde{\Sigma}_{22}+\tilde{\Sigma}_{11}A_{21}'+\tilde{\Sigma}_{12}A_{22}'+G_1G_2'-\epsilon\tilde{\Sigma}_{11}R_{\epsilon 11}\tilde{\Sigma}_{12}\\ & -\epsilon\tilde{\Sigma}_{12}R_{\epsilon 21}\tilde{\Sigma}_{12}-\tilde{\Sigma}_{11}R_{\epsilon 12}\tilde{\Sigma}_{22}-\tilde{\Sigma}_{12}R_{\epsilon 22}\tilde{\Sigma}_{22}=0,\\ (100c)\quad & \epsilon A_{21}\tilde{\Sigma}_{12}+A_{22}\tilde{\Sigma}_{22}+\epsilon\tilde{\Sigma}_{12}'A_{21}'+\tilde{\Sigma}_{22}A_{22}'+G_2G_2'-\epsilon^2\tilde{\Sigma}_{12}'R_{\epsilon 11}\tilde{\Sigma}_{12}\\ & -\epsilon\tilde{\Sigma}_{22}R_{\epsilon 21}\tilde{\Sigma}_{12}-\epsilon\tilde{\Sigma}_{12}'R_{\epsilon 12}\tilde{\Sigma}_{22}-\tilde{\Sigma}_{22}R_{\epsilon 22}\tilde{\Sigma}_{22}=0.\end{aligned}$$

The above set of equations are the same as (2.26)–(2.28) of [14] for $\epsilon\to 0$ (except for certain obvious modifications), which permits us to apply the results of [14] to the present case. Hence, for $\theta<\theta_{Is}$, (100) admit solutions for sufficiently small ϵ, which can be approximated by $\tilde{\Sigma}_{11}=\Sigma_{s\theta}+O(\sqrt{\epsilon})$, $\tilde{\Sigma}_{12}=X'\Sigma_f+Y'+O(\sqrt{\epsilon})$, and $\tilde{\Sigma}_{22}=\Sigma_f+O(\sqrt{\epsilon})$. Thus, the solution to (59) can be approximated by (89), for sufficiently small ϵ and for $\theta<\theta_{Is}$.

Furthermore, for $\theta<\theta_{Is}$ and sufficiently small ϵ, the matrix $I-\theta\tilde{\Sigma}(\epsilon)\tilde{Z}(\epsilon)$ can be approximated by

$$\begin{bmatrix}I-\theta\Sigma_{s\theta}Z_{s\theta}+O(\sqrt{\epsilon}) & O(\epsilon)\\ O(\sqrt{\epsilon}) & I+O(\sqrt{\epsilon})\end{bmatrix}.$$

Hence, it can have only positive eigenvalues. Thus, part 2 (ii) is proved.

Fix any $\theta > \theta_{Is}$; then, either one of the GAREs (69) and (70) does not admit any positive definite solution, or the matrix $I - \theta\Sigma_{s\theta}Z_{s\theta}$ has at least one negative eigenvalue. The former implies, in view of a result of [12], that one of the GAREs (9) or (59) does not admit any positive definite solution for sufficiently small ϵ, which further implies that $\theta > \theta_I^*(\epsilon)$. The latter, on the other hand, leads to the conclusion that the matrix $I - \theta\tilde{\Sigma}\tilde{Z}$ has at least one negative eigenvalue for sufficiently small ϵ, which again implies that $\theta > \theta_I^*(\epsilon)$. Hence, $\theta > \theta_I^*(\epsilon)$ for sufficiently small ϵ, $\forall\theta > \theta_{Is}$. Thus, part 2 (i) is also proved.

Let $T = \begin{bmatrix} I & 0 \\ U & I \end{bmatrix}$ and $\Pi = T\tilde{\Pi}T'$. Then, premultiplying (91) by T and postmultiplying it by T' yield the following Lyapunov equation for Π:

$$T(A_\epsilon - S_\epsilon\tilde{Z})T^{-1}\Pi + \Pi T^{-1\prime}(A_\epsilon' - \tilde{Z}S_\epsilon)T' + T(I - \theta\tilde{\Sigma}\tilde{Z})^{-1}\tilde{\Sigma}C_\epsilon' N_\epsilon^{-1}C_\epsilon \cdot (I - \theta\tilde{Z}\tilde{\Sigma})^{-1}T' = 0. \tag{101}$$

Note the following approximations for $\epsilon \in (0, \epsilon_\theta]$, which are easily obtained in view of the given approximations for $\tilde{Z}$ and $\tilde{\Sigma}$:

$$T(A_\epsilon - S_\epsilon\tilde{Z})T^{-1} = \begin{bmatrix} \bar{A}_s - \bar{S}_s Z_{s\theta} & O(1) \\ O(\frac{1}{\sqrt{\epsilon}}) & \frac{1}{\epsilon}(A_{22} - B_2B_2'Z_f) + O(\frac{1}{\sqrt{\epsilon}}) \end{bmatrix},$$

$$T(I - \theta\tilde{\Sigma}\tilde{Z})^{-1}\tilde{\Sigma}C_\epsilon' N_\epsilon^{-1}C_\epsilon(I - \theta\tilde{Z}\tilde{\Sigma})^{-1}T' = \begin{bmatrix} L_s + O(\sqrt{\epsilon}) & O(\frac{1}{\sqrt{\epsilon}}) \\ O(\frac{1}{\sqrt{\epsilon}}) & \frac{1}{\epsilon}\Sigma_f C_2' N^{-1} C_2 \Sigma_f + O(\frac{1}{\sqrt{\epsilon}}) \end{bmatrix},$$

$$L_s = (I - \theta\Sigma_{s\theta}Z_{s\theta})^{-1}((\Sigma_{s\theta}C_1' + Y'C_2')N^{-1}(C_1\Sigma_{s\theta} + C_2Y) + X'G_2G_2'X)(I - \theta Z_{s\theta}\Sigma_{s\theta})^{-1}.$$

Suppose that Π takes the form

$$\begin{bmatrix} \Pi_{11} & \sqrt{\epsilon}\Pi_{12} \\ \sqrt{\epsilon}\Pi_{21} & \Pi_{22} \end{bmatrix},$$

where $\Pi_{21} = \Pi_{12}'$, and substitute it into the Lyapunov equation (101) to arrive at the following equations for Π_{11}, Π_{12}, and Π_{22}:

$$(\bar{A}_s - \bar{S}_s Z_{s\theta})\Pi_{11} + \Pi_{11}(\bar{A}_s - \bar{S}_s Z_{s\theta})' + L_s + O(\sqrt{\epsilon}) = 0, \tag{102a}$$

$$\Pi_{11}O(1) + \Pi_{12}(A_{22} - B_2B_2'Z_f) + O(1) + O(\sqrt{\epsilon}) = 0, \tag{102b}$$

$$(A_{22} - B_2B_2'Z_f)\Pi_{22} + \Pi_{22}(A_{22} - B_2B_2'Z_f)' + \Sigma_f C_2' N^{-1} C_2 \Sigma_f + O(\sqrt{\epsilon}) = 0. \tag{102c}$$

Then, it follows that $\Pi_{11} = \Pi_{s\theta}$, $\Pi_{22} = \Pi_f$, and some Π_{12} (which exists) solve equations (102a)–(102c) at $\epsilon = 0$. By an application of the implicit function theorem [10] as in the proof of Theorem 1 of [12], the solutions to (102a)–(102c) are approximated by $\Pi_{11} = \Pi_{s\theta} + O(\sqrt{\epsilon})$, $\Pi_{22} = \Pi_f + O(\sqrt{\epsilon})$, and $\Pi_{12} = O(1)$, for sufficiently small ϵ. This then completes the proof of part 2 (iii).

A mere substitution of (88), (89), and (90) into (86) yields the desired result (93) (detailed algebraic manipulations can be found in [13]), which proves part 2 (iv).

Now substitute the composite controller μ_{Ic}^* into the full-order system to arrive at an infinite-horizon, control-free LEQG problem. Let

$$x_f^c := x_2 + U\hat{x}_s^c,$$
$$\tilde{x}^{c\prime} := [x_1', \hat{x}_s^{c\prime} + \sqrt{\epsilon}x_f^{c\prime}X(I - \theta Z_{s\theta}\Sigma_{s\theta})^{-1}, x_f^{c\prime}, \hat{x}_f^{c\prime}].$$

In terms of the state variable $\tilde{x}^c$, this LEQG problem can be written as (see [13] for details)

$$d\tilde{x}^c = \begin{bmatrix} F_{11}^c + O(\sqrt{\epsilon}) & O(1) \\ O(\frac{1}{\sqrt{\epsilon}}) & \frac{1}{\epsilon}F_{22}^c + O(\frac{1}{\sqrt{\epsilon}}) \end{bmatrix}\tilde{x}^c\,dt + \begin{bmatrix} G_1^c + O(\sqrt{\epsilon}) \\ \frac{1}{\sqrt{\epsilon}}G_2^c + O(1) \end{bmatrix} dw_t,$$
$$:= F_\epsilon^c\tilde{x}^c\,dt + G_\epsilon^c\,dw_t,$$
$$J_{I\theta}^c := \lim_{t_f\to\infty}\frac{2}{\theta t_f}\ln\left\{E\left\{\exp\left[\frac{\theta}{2}\int_0^{t_f}\tilde{x}^{c\prime}(H^c + O(\sqrt{\epsilon}))\tilde{x}^c\,dt\right]\right\}\right\},$$

where

$$F_{11}^c = \begin{bmatrix} A_{11} \\ (I - \theta\Sigma_{s\theta}Z_{s\theta})^{-1}((\Sigma_{s\theta}C_1' + Y'C_2')N^{-1}C_1 + X'A_{21}) \\ -B_1B_1'Z_{s\theta} - B_1B_2'V - A_{12}U \\ F_{cs} \end{bmatrix}, \tag{103a}$$

$$F_{cs} = \bar{A}_s - \bar{S}_sZ_{s\theta} - (I - \theta\Sigma_{s\theta}Z_{s\theta})^{-1}((\Sigma_{s\theta}C_1' + Y'C_2')N^{-1}C_1 + X'A_{21} + \theta X'G_2G_1'Z_{s\theta}), \tag{103b}$$

$$F_{22}^c = \begin{bmatrix} A_{22} & -B_2B_2'Z_f \\ \Sigma_fC_2'N^{-1}C_2 & A_{22} - B_2B_2'Z_f - \Sigma_fC_2'N^{-1}C_2 \end{bmatrix}, \tag{103c}$$

$$G_1^c = \begin{bmatrix} G_1 \\ (I - \theta\Sigma_{s\theta}Z_{s\theta})^{-1}(X'G_2 + (\Sigma_{s\theta}C_1' + Y'C_2')N^{-1}E) \end{bmatrix}, \tag{103d}$$

$$G_2^c = \begin{bmatrix} G_2 \\ \Sigma_fC_2'N^{-1}E \end{bmatrix}, \tag{103e}$$

$$H^c = \begin{bmatrix} H_{11}^c & O(1) \\ O(1) & H_{22}^c \end{bmatrix}, \tag{103f}$$

$$H_{11}^c = \begin{bmatrix} Q_{11} & -Q_{12}U \\ -U'Q_{21} & (Z_{s\theta}B_1 + V'B_2)(B_1Z_{s\theta} + B_2'V) + U'Q_{22}U \end{bmatrix}, \tag{103g}$$

$$H_{22}^c = \begin{bmatrix} Q_{22} & 0 \\ 0 & Z_fB_2B_2'Z_f \end{bmatrix}. \tag{103h}$$

The initial state $\tilde{x}^c(0)$ is a Gaussian random vector with mean $\bar{x}_0^c$ and covariance Σ_0^c, given by

$$\bar{x}_0^c := \begin{bmatrix} \bar{x}_{10} \\ (I - \theta\Sigma_{s\theta}Z_{s\theta})^{-1}\bar{x}_{10} + O(\sqrt{\epsilon}) \\ \bar{x}_{20} + U(I - \theta\Sigma_{s\theta}Z_{s\theta})^{-1}\bar{x}_{10} \\ \bar{x}_{20} + U(I - \theta\Sigma_{s\theta}Z_{s\theta})^{-1}\bar{x}_{10} \end{bmatrix},$$

$$\Sigma_0^c := \begin{bmatrix} \begin{bmatrix} \Sigma_{011} & 0 \\ 0 & 0 \end{bmatrix} + O(\epsilon) & O(\sqrt{\epsilon}) \\ O(\sqrt{\epsilon}) & \begin{bmatrix} \Sigma_{022} & 0 \\ 0 & 0 \end{bmatrix} \end{bmatrix}.$$

To evaluate the cost $J_{I\theta\infty}^c$, we associate a fictitious measurement (96) with this LEQG problem (as in the proof of part 1), where v_t, or y^e, is a standard Wiener process independent of the initial state and w_t.

Then, the two GAREs associated with this problem are

$$F_\epsilon^{c\prime}\tilde{\Xi}^c + \tilde{\Xi}^c F_\epsilon^c + \tilde{\Xi}^c \theta G_\epsilon^c G_\epsilon^{c\prime} \tilde{\Xi}^c + H^c = 0$$

and

$$F_\epsilon^c \tilde{\Theta}^c + \tilde{\Theta}^c F_\epsilon^{c\prime} + \tilde{\Theta}^c \theta H^c \tilde{\Theta}^c + G_\epsilon^c G_\epsilon^{c\prime} = 0.$$

It is shown in [13] that the minimal solutions to these GAREs exist for $\theta < \theta_{Is}$ and sufficiently small ϵ, and can be approximated by

$$\tilde{\Xi}^c = \begin{bmatrix} \tilde{\Xi}_{11}^c + O(\sqrt{\epsilon}) & O(\epsilon) \\ O(\epsilon) & \epsilon\tilde{\Xi}_{22}^c + O(\epsilon^{3/2}) \end{bmatrix}, \tag{104a}$$

$$\tilde{\Xi}_{11}^c = \begin{bmatrix} Z_{s\theta}^{-1} & Z_{s\theta}^{-1} \\ Z_{s\theta}^{-1} & (Z_{s\theta} - \theta Z_{s\theta}\Sigma_{s\theta}Z_{s\theta})^{-1} + \Delta_{s\theta}^{-1} \end{bmatrix}^{-1}, \tag{104b}$$

$$\tilde{\Xi}_{22}^c = \begin{bmatrix} Z_f + \Delta_f & -\Delta_f \\ -\Delta_f & \Delta_f \end{bmatrix}, \tag{104c}$$

$$\Delta_{s\theta}(I - \theta\Sigma_{s\theta}Z_{s\theta})^{-1}(\tilde{A}_s - \Sigma_{s\theta}\tilde{R}_s)(I - \theta\Sigma_{s\theta}Z_{s\theta}) + (I - \theta Z_{s\theta}\Sigma_{s\theta})(\tilde{A}_s' \tag{104d}$$

$$- \tilde{R}_s\Sigma_{s\theta})(I - \theta Z_{s\theta}\Sigma_{s\theta})^{-1}\Delta_{s\theta} + (Z_{s\theta}B_1 + V'B_2)(B_1 Z_{s\theta} + B_2'V) + U'Q_{22}U = 0,$$

$$\Delta_f(A_{22} - \Sigma_f R_{22}) + \Delta_f(A_{22}' - R_{22}\Sigma_f) + Z_f B_2 B_2' Z_f = 0, \tag{104e}$$

$$\tilde{\Theta}^c = \begin{bmatrix} \tilde{\Theta}_{11}^c + O(\sqrt{\epsilon}) & O(\sqrt{\epsilon}) \\ O(\sqrt{\epsilon}) & \tilde{\Theta}_{22}^c + O(\sqrt{\epsilon}) \end{bmatrix}, \tag{104f}$$

$$\tilde{\Theta}_{11}^c = \begin{bmatrix} \Sigma_{s\theta}^{-1} & \theta Z_{s\theta} - \Sigma_{s\theta}^{-1} \\ \theta Z_{s\theta} - \Sigma_{s\theta}^{-1} & \Sigma_{s\theta}^{-1} - \theta Z_{s\theta} + \Pi_{s\theta}^{-1} \end{bmatrix}^{-1}, \tag{104g}$$

$$\tilde{\Theta}_{22}^c = \begin{bmatrix} \Sigma_f + \Pi & \Pi_f \\ \Pi_f & \Pi_f \end{bmatrix}. \tag{104h}$$

Furthermore, the matrices $F_\epsilon^c + \theta G_\epsilon^c G_\epsilon^{c\prime}\tilde{\Xi}^c$ and $F_\epsilon^{c\prime} + \theta H^c\tilde{\Theta}^c$ are Hurwitz. By Theorem 5 of [26], the matrix $I - \theta\tilde{\Theta}^c\tilde{\Xi}^c$ has only positive eigenvalues.

Obviously $\tilde{\Theta}^c > \Theta_0^c$. Hence, by Theorem 3, $J_{I\theta}^c = \mathrm{Tr}(\tilde{\Theta}^c H^c)$. Some straightforward algebraic manipulations lead to part 2 (v).

Now substitute the slow controller μ_{Is}^* into the full-order system to arrive at another control-free LEQG problem. Let

$$x_f^s := x_2 + U\hat{x}_s^s,$$

$$\tilde{x}^{s\prime} := [x_1',\ \hat{x}_s^{s\prime} + \sqrt{\epsilon}x_f^{s\prime}X(I - \theta Z_{s\theta}\Sigma_{s\theta})^{-1},\ x_f^{s\prime}].$$

In terms of the state variable $\tilde{x}^s$, this LEQG problem can be written as (see again [13] for details)

$$d\tilde{x}^s = \begin{bmatrix} F_{11}^c + O(\sqrt{\epsilon}) & O(1) \\ O(\frac{1}{\sqrt{\epsilon}}) + & \frac{1}{\epsilon}A_{22} + O(\frac{1}{\sqrt{\epsilon}}) \end{bmatrix} \tilde{x}^s\, dt + \begin{bmatrix} G_1^c + O(\sqrt{\epsilon}) \\ \frac{1}{\sqrt{\epsilon}}G_2 + O(1) \end{bmatrix} dw_t$$

$$:= F_\epsilon^s \tilde{x}^s\, dt + G_\epsilon^s\, dw_t,$$

$$J_{I\theta}^s := \lim_{t_f \to \infty} \frac{2}{\theta t_f} \ln \left\{ E \left\{ \exp \left[\frac{\theta}{2} \int_0^{t_f} \tilde{x}^{c\prime}(H^s + O(\sqrt{\epsilon}))\tilde{x}^c\, dt \right] \right\} \right\},$$

where

$$H^s = \begin{bmatrix} H_{11}^c & O(1) \\ O(1) & Q_{22} \end{bmatrix}$$

and F_{11}^c, G_1^c, and H_{11}^c are as defined in (103a), (103d), and (103g).

The initial state $\tilde{x}^s(0)$ is a Gaussian random vector with mean $\bar{x}_0^s$ and covariance Σ_0^s, given by

$$\bar{x}_0^s := \begin{bmatrix} \bar{x}_{10} \\ (I - \theta\Sigma_\theta Z_{s\theta})^{-1}\bar{x}_{10} + O(\sqrt{\epsilon}) \\ \bar{x}_{20} + U(I - \theta\Sigma_\theta Z_{s\theta})^{-1}\bar{x}_{10} \end{bmatrix},$$

$$\Sigma_0^s := \begin{bmatrix} \begin{bmatrix} \Sigma_{011} & 0 \\ 0 & 0 \end{bmatrix} + O(\sqrt{\epsilon}) & O(\sqrt{\epsilon}) \\ O(\sqrt{\epsilon}) & \Sigma_{022} + O(\sqrt{\epsilon}) \end{bmatrix}.$$

To evaluate the cost $J_{I\theta\infty}^s$, we associate (as in the composite controller case) a fictitious measurement (96) with this LEQG problem, where v_t, or y^e, is a standard Wiener process independent of the initial state and w_t.

Then, the two GAREs associated with this problem are

$$F_\epsilon^{s\prime}\tilde{\Xi}^s + \tilde{\Xi}^s F_\epsilon^s + \tilde{\Xi}^s\theta G_\epsilon^s G_\epsilon^{s\prime}\tilde{\Xi}^s + H^s = 0$$

and

$$F_\epsilon^s\tilde{\Theta}^s + \tilde{\Theta}^s F_\epsilon^{s\prime} + \tilde{\Theta}^s\theta H^s\tilde{\Theta}^s + G_\epsilon^s G_\epsilon^{s\prime} = 0.$$

It is shown in [13] that, if A_{22} is Hurwitz, the minimal solutions to these GAREs exist for $\theta < \theta_{Is}$ and sufficiently small ϵ, and can be approximated by

$$\tilde{\Xi}^s = \begin{bmatrix} \tilde{\Xi}_{11}^c + O(\sqrt{\epsilon}) & O(\epsilon) \\ O(\epsilon) & \epsilon Z_{of} + O(\epsilon^{3/2}) \end{bmatrix},$$

$$\tilde{\Theta}^s = \begin{bmatrix} \tilde{\Theta}_{11}^c + O(\sqrt{\epsilon}) & O(\sqrt{\epsilon}) \\ O(\sqrt{\epsilon}) & \Sigma_{of} + O(\sqrt{\epsilon}) \end{bmatrix},$$

where $\tilde{\Xi}_{11}^c$ and $\tilde{\Theta}_{11}^c$ are as defined in (104b) and (104g). Furthermore, the matrices $F_\epsilon^s + \theta G_\epsilon^s G_\epsilon^{s\prime}\tilde{\Xi}^s$ and $F_\epsilon^{s\prime} + \theta H^s\tilde{\Theta}^s$ are Hurwitz. By Theorem 5 of [26], the matrix $I - \theta\tilde{\Theta}^s\tilde{\Xi}^s$ has only positive eigenvalues.

Hence, by Theorem 3, $J_{I\theta}^s = \mathrm{Tr}(\tilde{\Theta}^s H^s)$. Some straightforward algebraic manipulations lead to (95). This completes the proof of the theorem. □

5.3. A large-deviation form. As the counterpart of the analysis of §3.4, we again consider a large-deviation form of the problem. The system under consideration is described by

$$\text{(105)}\qquad \begin{cases} dx_1 = (A_{11}x_1 + A_{12}x_2 + B_1u_t)\,dt + \xi G_1\,dw_t; \quad x_1(0) = x_{10}, \\ \epsilon dx_2 = (\epsilon^{1/2}A_{21}x_1 + A_{22}x_2 + B_2u_t)\,dt + \epsilon^{1/2}\xi G_2\,dw_t; \quad x_2(0) = x_{20}, \\ dy_1 = (C_{11}x_1 + C_{12}x_2)\,dt + \xi E_1\,dv_t; \quad y_1(0) = 0, \\ dy_2 = (\epsilon^{1/2}C_{21}x_1 + C_{22}x_2)\,dt + \epsilon^{1/2}\xi E_2\,dv_t; \quad y_2(0) = 0, \end{cases}$$

and the cost function is given as

$$\text{(106)}\qquad J_{I\theta}(\mu_I, \xi) = \lim_{t_f\to\infty} \frac{2\xi^2}{\theta t_f} \ln\left\{E\left\{\exp\left[\frac{\theta}{2\xi^2}\int_0^{t_f}(x'Qx + u'u)\,dt\right]\right\}\right\},$$

where the initial state x_0 is a Gaussian random variable with mean $\bar{x}_0$ and variance $\xi^2\Sigma_0$, and ξ is a small scalar parameter to be varied. We will again study the solution as the parameter $\xi \to 0$. This problem is equivalent to the one considered in §4, if we introduce the following substitutions:

$$\text{(107)}\qquad \theta \leftarrow \frac{\theta}{\xi^2}; \quad G_\epsilon \leftarrow \xi G_\epsilon; \quad E_\epsilon \leftarrow \xi E_\epsilon; \quad \Sigma_0 \leftarrow \xi^2\Sigma_0.$$

Define the quantity $\theta_I^*(\epsilon)$ exactly as in (61). Then, for any $\theta < \theta_I^*(\epsilon)$, the problem admits an optimal controller, given by (58a) and (58b).

The optimal solution to the full-order problem again depends on the value of ϵ explicitly. To obtain ϵ-free solutions, we decompose the system into slow and fast subsystems. The slow subsystem can be obtained in the same way as before. Under the substitution law (107), the slow LEQG problem is again described by (66), (67), and (68). This leads to a definition of θ_{Is} exactly as in (72). For any $\theta < \theta_{Is}$, the optimal controller for the slow subproblem is as in (73). The fast subsystem is again (75), under the substitution law (107). Thus, the fast controller is exactly the same as (78a)–(78b). Hence, we can form the slow and composite controllers μ_{Is}^* and μ_{Ic}^* as before. The slow controller μ_{Is}^* is as in (82a) and (82b), and the composite controller μ_{Ic}^* is as in (83), (84), and (85), of course now parametrized also by ξ.

Then, all this leads to the following corollary to Theorem 4.

COROLLARY 2. *For the ξ-parametrized singularly perturbed system* (105) *under the cost function* (106):

1. *For each $\epsilon > 0$, if the pairs (A_ϵ, B_ϵ) and (A_ϵ, G_ϵ) are controllable, the pairs (A_ϵ, C_ϵ) and (A_ϵ, Q) are observable, and the matrix N_ϵ is invertible, then, $\forall\theta < \theta_I^*(\epsilon)$, the optimal cost for the full-order LEQG problem can be written as*

$$\text{(108)}\qquad J_{I\theta}^*(\epsilon; \xi) = O(\xi^2).$$

2. *Let assumption* A2 *hold, the pairs (A_{11}, B_0), $(A_{11}, G_1G_1' - G_1G_2'(G_2G_2')^{-1}G_2G_1')$, and (A_{22}, B_2) be controllable, and the pairs (A_{11}, C_0), $(A_{11}, Q_{11} - Q_{12}Q_{22}^{-1}Q_{21})$, and (A_{22}, C_2) be observable. Then,*

(i) $\lim_{\epsilon\to 0^+}\theta_I^*(\epsilon) = \theta_{Is}$.

(ii) *$\forall\theta < \theta_{Is}$, if the composite controller $\mu_{Ic\theta}^*$ is applied to the system, then $\exists\epsilon_\theta' > 0$ such that $\forall\epsilon \in [0, \epsilon_\theta')$,*

$$\text{(109)}\qquad J_{I\theta}^c := J_{I\theta}(\mu_{Ic\theta}^*) = J_{I\theta}^*(\epsilon; \xi) + O(\xi^2\sqrt{\epsilon}).$$

(iii) *$\forall\theta < \theta_{Is}$, if, in addition, the matrix A_{22} is Hurwitz, and the slow controller $\mu_{Is\theta}^*$ is applied to the system, then $\exists\hat{\epsilon}_\theta > 0$ such that $\forall\epsilon \in [0, \hat{\epsilon}_\theta)$,*

$$\text{(110)}\qquad J_{I\theta}^s := J_{I\theta}(\mu_{Is\theta}^*) = O(\xi^2).$$

6. Examples. We present here three sets of numerical results, one for perfect state measurements and two for noisy state measurements. As stressed earlier, the quantities θ_s and θ_{Is} play important roles in the computation of approximate values for $\theta^*(\epsilon)$ and $\theta_I^*(\epsilon)$.

Example 1. Consider the system and cost function

$$\text{(111a)} \quad \begin{bmatrix} dx_1 \\ \epsilon dx_2 \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} dt + \begin{bmatrix} 1 \\ 2 \end{bmatrix} u\, dt + \begin{bmatrix} 1 \\ \sqrt{\epsilon} \end{bmatrix} dw_t,$$

$$\text{(111b)} \quad J_\theta = \lim_{t_f \to \infty} \frac{2}{\theta t_f} \ln \left\{ \boldsymbol{E} \left\{ \exp \left[\frac{\theta}{2} \left(\int_0^{t_f} (2x_1^2 + 2x_1 x_2 + x_2^2 + u'u)\, dt \right) \right] \right\} \right\}.$$

By using a particular search algorithm, we can compute the quantity

$$\theta_s = 1.8892.$$

We next compute the maximum allowable θ-levels for the full-order system (111) for different fixed values of ϵ.

$\theta^*(\epsilon)$	1.5616	1.9842	1.9274	1.9019	1.8930	1.8903
ϵ	1	0.1	0.01	0.001	0.0001	0.00001

Note that as $\epsilon \to 0$, $\theta^*(\epsilon) \to \theta_s$.

Now, we choose $\theta = 1.6 < \theta_s$ and design the suboptimal controllers for the system based on this value of θ:

$$\mu_s^*(x_1) = -1.7633x_1, \quad \mu_c^*(x_1, x_2) = -3.3249x_1 - 0.61803x_2.$$

Then, we apply these controllers, μ_s^* and μ_c^*, to system (111) and obtain the corresponding performance levels J_s and J_c, respectively. These values are tabulated below along with the optimal cost levels, for different values of ϵ:

ϵ	1	0.1	0.01	0.001	0.0001	0.00001
$J^*(\epsilon)$	∞	3.0434	2.1560	1.9818	1.9350	1.9209
$J_c(\epsilon)$	∞	∞	2.1638	1.9828	1.9351	1.9209
$J_s(\epsilon)$	∞	∞	∞	2.2150	2.1366	2.1151

We also compute the cost level at $\epsilon = 0$,

$$J^*(0) = J_c(0) = 1.9146, \quad J_s(0) = 2.1056,$$

and observe that the composite controller asymptotically achieves the optimal performance level as $\epsilon \to 0$; however, the slow controller achieves only a suboptimal, but finite performance level asymptotically—all this being consistent with the result of Theorem 1. Also, the composite controller appears to be more robust than the slow one with respect to changes in the value of ϵ.

Example 2. Consider the setup

$$\text{(112a)} \quad \begin{bmatrix} dx_1 \\ \epsilon dx_2 \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ \sqrt{\epsilon} & -1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} dt + \begin{bmatrix} 1 \\ 2 \end{bmatrix} u\, dt + \begin{bmatrix} 1 \\ \sqrt{\epsilon} \end{bmatrix} dw_t,$$

$$\text{(112b)}\quad \begin{bmatrix} dy_1 \\ dy_2 \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ \sqrt{\epsilon} & 2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} dt + \begin{bmatrix} 1 & 0 \\ 0 & \sqrt{\epsilon} \end{bmatrix} dv_t,$$

$$\text{(112c)}\quad J_{I\theta} = \lim_{t_f \to \infty} \frac{2}{\theta t_f} \ln \left\{ \boldsymbol{E} \left\{ \exp \left[\frac{\theta}{2} \int_0^{t_f} (2x_1^2 + 2x_1 x_2 + x_2^2 + u'u)\, dt \right] \right\} \right\}.$$

The maximum allowable θ-level for the slow subsystem is

$$\theta_{Is} = 1.4212.$$

We can also compute the maximum allowable θ-level, $\theta_I^*(\epsilon)$, for this system for different values of ϵ:

$\theta_I^*(\epsilon)$	1.4133	1.4189	1.4204	1.4209	1.4211
ϵ	0.001	10^{-4}	10^{-5}	10^{-6}	10^{-7}

Note again that as $\epsilon \to 0$, $\theta_I^*(\epsilon) \to \theta_{Is}$.

Now, we choose $\theta = 1 < \theta_{Is}$, and design the slow and composite controllers under the corresponding cost functions

$$\mu_{Is}^* = -\hat{x}_s^s, \quad \mu_{Ic}^* = -\hat{x}_s^c - 0.61803\hat{x}_f^c,$$

where

$$d\hat{x}_s^s = -5.6833\hat{x}_s^s\, dt + \begin{bmatrix} 0.44721 & 0.84721/\sqrt{\epsilon} \end{bmatrix} \begin{bmatrix} dy_1 + 2\hat{x}_s^s\, dt \\ dy_2 + 4\hat{x}_s^s\, dt \end{bmatrix},$$

$$\begin{bmatrix} d\hat{x}_s^c \\ \epsilon d\hat{x}_f^c \end{bmatrix} = \begin{bmatrix} -5.6833 & 2.0944/\sqrt{\epsilon} \\ -3.0902\sqrt{\epsilon} & -3.4721 \end{bmatrix} \begin{bmatrix} \hat{x}_s^c \\ \hat{x}_f^c \end{bmatrix} dt + \begin{bmatrix} 0.44721 & 0.84721/\sqrt{\epsilon} \\ 0 & 0.61803 \end{bmatrix} \begin{bmatrix} dy_1 + 2\hat{x}_s^c\, dt \\ dy_2 + 4\hat{x}_s^c\, dt \end{bmatrix}.$$

Then, we apply μ_{Is}^* and μ_{Ic}^* to system (112) and obtain the corresponding performance levels J_{Is} and J_{Ic}. They are tabulated below for different values of ϵ, along with the corresponding optimal cost levels.

ϵ	0.001	10^{-4}	10^{-5}	10^{-6}	10^{-7}
$J_I^*(\epsilon)$	3.9236	3.7409	3.6873	3.6707	3.6655
$J_{Ic}(\epsilon)$	∞	∞	3.6921	3.6710	3.6655
$J_{Is}(\epsilon)$	∞	3.9147	3.7691	3.7361	3.7390

We can also compute the optimal cost level at $\epsilon = 0$,

$$J_I^*(0) = J_{Ic}(0) = 3.6631, \quad J_{Is}(0) = 3.7361.$$

We see that the composite controller asymptotically achieves the optimal performance level as $\epsilon \to 0$. The slow controller, on the other hand, achieves a suboptimal but finite performance level asymptotically, which is again consistent with the statement of Theorem 4. We also note that in this case the composite controller is more sensitive than the slow one to changes in the value of ϵ. A possible explanation for this behavior is the following: since the quantity $J_{Is}(0)$ is very close to $J_{Ic}(0)$, this means there is little for the fast controller to do to improve the performance of the overall system. Furthermore, since the fast controller is an LQG design for the fast subsystem, the closed-loop fast subsystem under such a controller may not exhibit better H^∞ performance than the open-loop fast subsystem.

Example 3. Consider the following system and cost function:

$$\begin{bmatrix} dx_1 \\ \epsilon dx_2 \end{bmatrix} = \begin{bmatrix} -2 & 1 \\ \sqrt{\epsilon} & -1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} dt + \begin{bmatrix} 2 \\ 1 \end{bmatrix} u\, dt + \begin{bmatrix} 1 \\ 2\sqrt{\epsilon} \end{bmatrix} dw_t, \tag{113a}$$

$$\begin{bmatrix} dy_1 \\ dy_2 \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 2\sqrt{\epsilon} & 2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} dt + \begin{bmatrix} 1 & 0 \\ 0 & \sqrt{\epsilon} \end{bmatrix} dv_t, \tag{113b}$$

$$J_{I\theta} = \lim_{t_f \to \infty} \frac{2}{\theta t_f} \ln \left\{ E \left\{ \exp \left[\frac{\theta}{2} \int_0^{t_f} (3x_1^2 + 2x_1x_2 + 2x_2^2 + u'u)\, dt \right] \right\} \right\}. \tag{113c}$$

The maximum allowable θ-level for the slow subsystem is

$$\theta_{Is} = 6.3756.$$

We can also compute the maximum allowable θ-level, $\theta_I^*(\epsilon)$, for this system, for different values of ϵ:

$\theta_I^*(\epsilon)$	6.8401	6.8836	6.5390	6.4289	6.3923
ϵ	0.01	0.0015	10^{-4}	10^{-5}	10^{-6}

Note again that as $\epsilon \to 0$, $\theta_I^*(\epsilon) \to \theta_{Is}$.

Now, we choose $\theta = 5 < \theta_{Is}$, and design the slow and composite controllers under the corresponding cost functions

$$\mu_{Is}^* = -0.87591\hat{x}_s^s, \quad \mu_{Ic}^* = -0.87591\hat{x}_s^c - 0.73205\hat{x}_f^c,$$

where

$$d\hat{x}_s^s = -5.5564\hat{x}_s^s\, dt + \begin{bmatrix} 0.010525 & 0.24449/\sqrt{\epsilon} \end{bmatrix} \begin{bmatrix} dy_1 + 0.87591\hat{x}_s^s\, dt, \\ dy_2 + 1.7518\hat{x}_s^s\, dt \end{bmatrix},$$

$$\begin{bmatrix} d\hat{x}_s^c \\ \epsilon d\hat{x}_f^c \end{bmatrix} = \begin{bmatrix} -5.5564 & 0.35796/\sqrt{\epsilon} \\ -23.191\sqrt{\epsilon} & -4.8552 \end{bmatrix} \begin{bmatrix} \hat{x}_s^c \\ \hat{x}_f^c \end{bmatrix} dt + \begin{bmatrix} 0.010525 & 0.24449/\sqrt{\epsilon} \\ 0 & 1.5616 \end{bmatrix} \begin{bmatrix} dy_1 + 0.87591\hat{x}_s^c\, dt \\ dy_2 + 1.7518\hat{x}_s^c\, dt \end{bmatrix}.$$

Then, we apply μ_{Is}^* and μ_{Ic}^* to system (113) and obtain the corresponding performance levels J_{Is} and J_{Ic}. They are tabulated below for different values of ϵ, along with the corresponding optimal cost levels.

ϵ	0.01	0.0015	10^{-4}	10^{-5}	10^{-6}
$J_I^*(\epsilon)$	4.6326	4.0662	3.9404	3.9210	3.9157
$J_{Ic}(\epsilon)$	∞	4.1528	3.9408	3.9210	3.9157
$J_{Is}(\epsilon)$	∞	∞	4.6194	4.5808	4.5710

We can also compute the cost level at $\epsilon = 0$,

$$J_I^*(0) = J_{Ic}(0) = 3.9134, \quad J_{Is}(0) = 4.5668.$$

Again the composite controller asymptotically achieves the optimal performance level as $\epsilon \to 0$, and the slow controller achieves a suboptimal but finite performance level asymptotically. In contradistinction with what was observed in Example 2, however, here the composite controller is less sensitive to changes in the value of ϵ than the slow one.

7. Conclusion. In this paper, we have presented a model reduction technique for the LEQG problem for linear singularly perturbed systems under perfect and imperfect state measurements. We have developed a time-scale decomposition procedure that breaks the full-order problem into appropriate slow and fast lower-order subproblems, the optimal solutions of which yield slow and fast controllers. When combined in an appropriate way, these lead to a composite controller under which the optimal performance level for the full-order system is achieved asymptotically as the singular perturbation parameter $\epsilon \to 0$. It has also been shown that when the fast subsystem is open-loop stable, the slow controller can achieve asymptotically some finite (but not optimal) performance level whenever the full-order problem admits a solution. In this case there is a clear positive gap between the asymptotic performance level a slow controller can achieve and the asymptotic performance level achieved by a full-order optimal controller, and the paper has provided a clear characterization of this performance loss. This indicates that there is a definite tradeoff between controller simplicity (due to model reduction) and loss of performance. In a large-deviations context, i.e., when the intensity of the noise in the system dynamics goes to zero, however, the slow controller can achieve asymptotically the performance level for the full-order system, provided that the fast subsystem is open-loop stable. Counterparts of these results in the finite-horizon case exist, and can be found in the internal report [13].

To obtain the optimal solution to the slow subsystem arrived at as a result of model reduction, it has turned out that one needs to develop a theory for the general LEQG problem with general cost structure (with cross terms between the state and control) and correlation between system and measurement noises. Since the LEQG problem has not been solved in the literature in such a full generality, we have also provided in the paper (§4) a clean and complete solution to this problem in both finite and infinite horizons via a different line from that of [3], which had addressed the finite-horizon case only, and under some restrictive assumptions. The solution obtained in §4 is precisely the central solution of the corresponding H^∞-optimal control problem [2], and the line of proof there would be useful even for the standard LEQG problem (i.e., without the cross term and with uncorrelated system and measurement noises) since it requires the least restrictive assumptions (leading to both necessary and sufficient conditions).

One possible nontrivial extension of the results of this paper would be the derivation of higher-order correction terms. The composite controller constructed in the paper achieves a performance level that is $O(\sqrt{\epsilon})$ close to the optimal one. This, however, may not be sufficient in some applications. Hence, high-order correction terms for the composite controller are of some interest. Another extension would be to the multiple time-scale problems, so as to obtain the counterparts of [16], which deals with the H^∞-optimal control problem. One other challenging extension would be to the nonlinear case, under both regular [17] and singular [18] perturbations.

ANALYSIS AND OPTIMIZATION OF FEEDBACK CONTROL ALGORITHMS FOR DATA TRANSFERS IN HIGH-SPEED NETWORKS*

RAUF IZMAILOV†

Abstract. Two linear feedback control algorithms for handling and preventing congestion in high-speed networks are proposed and analyzed. The fluid approximation model is described with a continuous-time system of delay-differential equations. The algorithms are asymptotically stable, and the transient processes are nonoscillatory. The control parameters are locally optimal (optimality is based on the asymptotic rate of convergence). The results of numerical experiments suggest that these parameters are globally optimal as well. The dependence of the quality of service on the duration of the control intervals is analyzed, and the performance of algorithms in a nonstationary environment is addressed.

Key words. delay-differential equations, stability, feedback, transient process

AMS subject classifications. 93C30, 93D20

1. Introduction.

Asynchronous transfer mode (ATM) transport technology [7] is generally considered as a basis for future integrated telecommunications service. Since there would be an inevitable interaction and interference among users in the communication network, an increasing amount of research has been devoted to different control issues (see [1], [18], [19], [22], [23], [26] and their references). One of the basic problems arising here is the presence of propagation delays which pose a challenge for stability, since speed of data transmission in modern high-speed networks keeps increasing.

In most of the proposed algorithms and models (see [4], [5], [6], [11], [17], [25], and [27] and their references) control decisions are based on a single number (the deviation of the state of the system from the target value) or a single bit (the sign of such deviation). Analysis and numerical simulations [4], [10], [12], [9], [24] demonstrated that the stability of such algorithms in the presence of propagation delays has the form of bounded oscillations (occurring even in the deterministic setting).

The single number limitation on the number of control parameters appears to be the key obstacle to the elimination of these undesirable oscillations. As proved in [10], a large class of feedback algorithms based on a single number always has an unstable equilibrium. Thus it seems natural to address the question of what additional parameters should be considered and how to translate them into control algorithms. However, this question has begun to be addressed only recently [3], [8], [15], [16].

We start this paper with a description of a simple fluid flow model describing a single ATM connection. For this model we consider two feedback control algorithms proposed in the previous report [15]: the first algorithm uses two control parameters, whereas the second one uses three control parameters. The control decision is based on the system states separated with constant control time intervals. The closed-loop system is described by differential-difference equations (see [2] and [20] and their references). We formulate results about stability and local optimality of the algorithms (all proofs are in the appendix). In the next section we analyze the performance of the algorithms: global optimality, asymptotic rates of convergence, optimal duration of the control intervals, transient regimes, and performance in nonstationary conditions. In particular, we demonstrate that faster asymptotic convergence (which could be obtained by decreasing the duration of the control intervals) may lead to worse transient processes and, in the nonstationary case, to worse frequency response. In the

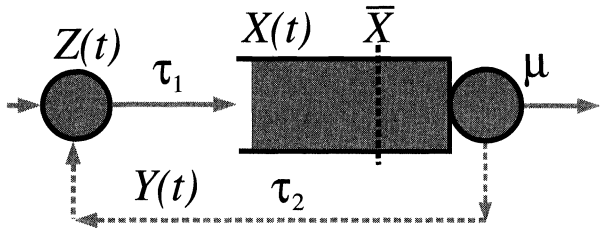

FIG. 1. *Single connection.*

conclusion we present a brief summary of results, recommendations on a proper choice of algorithm, and an outline of future directions of research.

2. Basic model. Consider a single connection (Figure 1) between a source controlled by an access regulator and a distant node served with a constant transmission capacity μ. The traffic source is monitored and regulated by the access regulator, and the distant bottleneck node sends back the information on its congestion status, defined as the difference between the current buffer contents and the target value (a fixed threshold) $\overline{X}$.

In order to describe large data transfers and isolate the issue of control mechanism from other considerations, assume (as in [10]) that there is an infinite amount of traffic to be sent to the remote node. In order to capture the small size of ATM packets as well as high rates of the network, we approximate the traffic by fluid flows. This assumption is not restrictive, and the basic results of our analysis could be extended to the discrete version of the model. The access regulator controls the current input rate $Z(t)$, basing its decisions on the buffer contents $X(t)$ of the distant node, which is continually monitored by the source. A target value $\overline{X}$ of the remote buffer contents is fixed: if $X(t) > \overline{X}$, the node is considered congested. The propagation delays from the source to the bottleneck and back are τ_1 and τ_2, which add up to the round-trip delay $\tau = \tau_1 + \tau_2$. The control objective is to adapt $Z(t)$ to μ dynamically while keeping $X(t)$ at an acceptable level.

In the next section we present two linear feedback algorithms. Each algorithm controls the source rate $Z(t)$ and varies it in proportion (determined by two or three gain parameters) to the differences between the buffer contents $X(t)$ and the target value $\overline{X}$.

3. Control algorithms. The first algorithm takes into account the deviations of $X(t)$ from the target value $\overline{X}$ during two consecutive time slots, separated by the control time interval r. (In [15] the control interval r was equal to the round-trip delay τ.) These deviations are weighted with linear gain parameters a and b, so in a neighborhood of the threshold $\overline{X}$ the system evolution is described by

$$\begin{cases} X'(t) &= Z(t-\tau_1) - \mu, \\ Z'(t) &= -a(X(t-\tau_2) - \overline{X}) - b(X(t-\tau_2 - r) - \overline{X}). \end{cases}$$

We take the derivative of the first equation here and substitute $Y(t) = X(t) - \overline{X}$ to obtain the delay-differential equation in the normalized time scale $T = t/\tau$ (where $A = a\tau^2$, $B = b\tau^2$, $R = r/\tau$):

$$Y''(T) + AY(T-1) + BY(T-1-R) = 0.$$

Its characteristic equation is

$$f(z) = z^2 e^{(R+1)z} + Ae^{Rz} + B = 0,$$

which has an infinite number of roots λ_i. The location of these roots on the complex plane determines [2, Thm. 6.7] the asymptotic behavior of $Y(T)$. In particular, the degree of stability

$\lambda = \sup_i\{\Re\lambda_i\}$ guarantees the asymptotic convergence of $Y(T)$ with the exponential rate λ: $|Y(T)| \le Ke^{-\lambda T}$ for some K [20, Chap. 3, Thm. 2.1]. The location of these roots on the complex plane determines [2] the behavior of $Y(t)$ around the equilibrium point 0.

THEOREM 1. *Denote*

$$\begin{cases} V &= \dfrac{\sqrt{R^2+2R+2}-R-2}{1+R}, \\ A^* &= -2\exp(V)\dfrac{1+R-\sqrt{2+2R+R^2}}{R}, \\ B^* &= 2\exp(V(1+R))\dfrac{1-1\sqrt{2+2R+R^2}}{R(1+R)^2}. \end{cases}$$

Then V is the degree of stability of $f(z)$, and any small deviation of A and B from A^* and B^* decreases the degree of stability of $f(z)$.

It may seem surprising that $B^*(R) < 0$ since it increases the rate $Z(t)$ when the buffer contents $X(t-\tau_2-r)$ exceeds $\overline{X}$ and vice versa. One may view this effect as a counterbalance dampening the oscillations generated by the regular feedback with the positive coefficient $A^*(R)$.

The second algorithm takes into account the deviations of $X(t)$ from the target value $\overline{X}$ during two consecutive time slots, separated by the time interval $r/2$. These deviations are weighted with linear gain parameters a, b, and c, so in a neighborhood of the threshold $\overline{X}$ the system evolution is described by

$$\begin{cases} X'(t) &= Z(t-\tau_1)-\mu, \\ Z'(t) &= -a(X(t-\tau_2)-\overline{X})-b(X(t-\tau_2-r/2)-\overline{X})-c(X(t-\tau_2-r)-\overline{X}). \end{cases}$$

We take the derivative of the first equation here and substitute $Y(t) = X(t) - \overline{X}$ to obtain the delay-differential equation in the normalized time scale $T = t/\tau$ (where $A = a\tau^2$, $B = b\tau^2$, $C = c\tau^2$, $R = r/\tau$):

$$Y''(T) + AY(T-1) + BY(T-1-R/2) + CY(T-1-R) = 0.$$

Its characteristic equation is

$$f(z) = z^2e^{(R+1)z} + Ae^{Rz} + Be^{\frac{Rz}{2}} + C = 0,$$

which has an infinite number of roots (eigenvalues). The location of these roots on the complex plane determines [2] the behavior of $Y(t)$ around the equilibrium point 0.

THEOREM 2. *Denote*

$$\begin{cases} W = \dfrac{-6-6R-R^2+\sqrt{12+24R+18R^2+6R^3+R^4}}{2+3R+R^2}, \\ A^* = \dfrac{2e^W\left(-2-3R-R^2+\sqrt{12+24R+18R^2+6R^3+R^4}\right)}{R^2}, \\ B^* = \dfrac{16e^{\frac{W(2+R)}{2}}\left(2+2R-\sqrt{12+24R+18R^2+6R^3+R^4}\right)}{(2+R)^2R^2}, \\ C^* = \dfrac{2e^{W(1+R)}\left(-2-R+\sqrt{12+24R+18R^2+6R^3+R^4}\right)}{R^2(1+R)^2}. \end{cases}$$

Then W is the degree of stability of $f(z)$, and any small deviation of A, B, and C from A^*, B^*, and C^* decreases the degree of stability of $f(z)$.

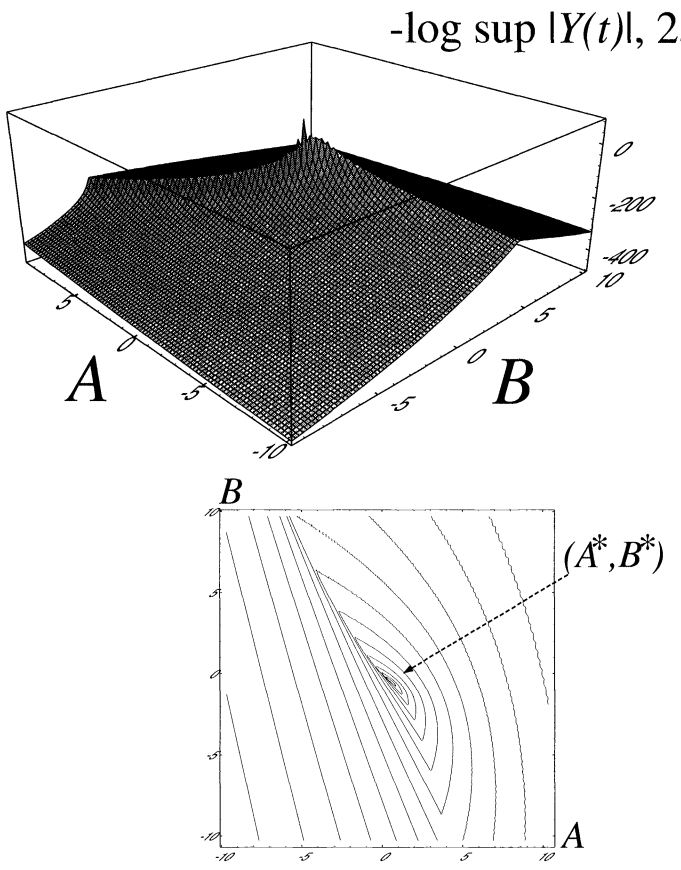

FIG. 2. *Numerical optimization.*

4. Performance analysis. Since the principal roots V and W for both algorithms are negative and real, the choice of damping parameters $A = A^*$, $B = B^*$, and $C = C^*$ suggested in the theorems of the previous section guarantees the exponential and nonoscillatory convergence of algorithms.

The structure of the proof also demonstrates the robustness of algorithms to small uncertainties in the knowledge of the round-trip delay. In other words, if the algorithms are constructed on the assumption that the round-trip delay is τ that whereas the actual round-trip delay is $\tau^* \neq \tau$, then the first algorithm has the degree of stability V^* (the second algorithm the has degree of stability W^*), where $V^* \to V$ as $\tau^* \to \tau$ (for the second algorithm, $W^* \to W$ as $\tau^* \to \tau$). The exponential stability of the control algorithms means the discrete versions of the algorithms are also stable.

The theorems also state the control coefficients are locally optimal. Extensive numerical calculations have been carried out, and the results obtained so far suggest the gain parameters described in Theorems 1 and 2 are globally optimal as well. In particular, to analyze the global optimality of $A = A^*$ and $B = B^*$ in Theorem 1, the number $S = \sup_{250<T<300} |Y(T)|$ has been calculated for each pair A and B in the square lattices $A^* - 6/R \leq A \leq A^* + 6/R$, $B^* - 6/R \leq B \leq B^* + 6/R$ of 300×300 points with the initial condition $Y(T) = T$ for $0 \leq T \leq 1$. The data were used to plot $d = -\log S$ as a function of A and B for $R = 1,\ 0.1,\ 0.01$. For all R considered, the function d has the single maximum (a typical picture for $R = 1$ is shown in Figure 2) corresponding to the single optimal point $A = A^*$, $B = B^*$. According

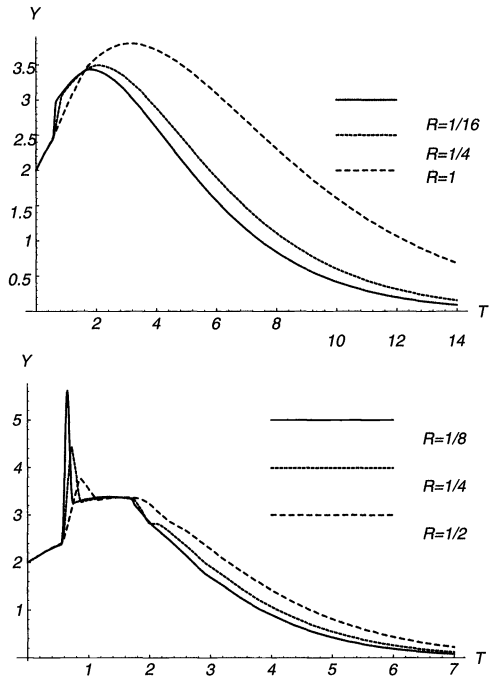

FIG. 3. *Transient processes for the first algorithm (upper graph) and for the second algorithm (lower graph) under impulse initial disturbance.*

to the definition of d, the pair (A^*, B^*) minimizes the sum S, which translates into the fastest convergence of $Y(T)$ to zero. Similar results were obtained for other target values S with different initial conditions and different time boundaries T. All this suggests that the pair (A^*, B^*) is indeed the global optimum for all R. Similar numerical calculations suggest that the triple (A^*, B^*, C^*) is the global optimum for any R.

The formulas of theorems show that the shorter the control time interval R, the better the asymptotic performance (degree of stability). If $R \to 0$, the asymptotic rate of convergence V of the first algorithm tends to $\sqrt{2} - 2 = -0.5857\ldots$ and the asymptotic rate of convergence W of the second algorithm tends to $\sqrt{3} - 3 = -1.26795\ldots$. Small control time intervals R require large gain parameters. As the control interval R decreases, the absolute values of gain parameters increase as R^{-1} for the first algorithm and as R^{-2} for the second one. The different behavior of gain parameters for the control algorithms leads to different transient performance. To illustrate it, consider the transient reaction of two algorithms on a unit jump (delta-function) disturbance. As shown in Figure 3, the first algorithm "absorbs" the jump for all values of control time intervals R uniformly, whereas the second algorithm exhibits sharp deterioration of the transient behavior (short and large peaks) for small R.

Suppose now the server rate μ is not constant: $\mu = \mu(t)$. Then [2] the function $Y(T)$ tends (as $T \to \infty$) to the stabilized solution

$$y(T) = \int_0^T h(T - z)\mu(z)\, dz, \tag{1}$$

where

$$h(s) = \frac{s}{s^2 + Ae^{-s} + Be^{-s(1+R)}}.$$

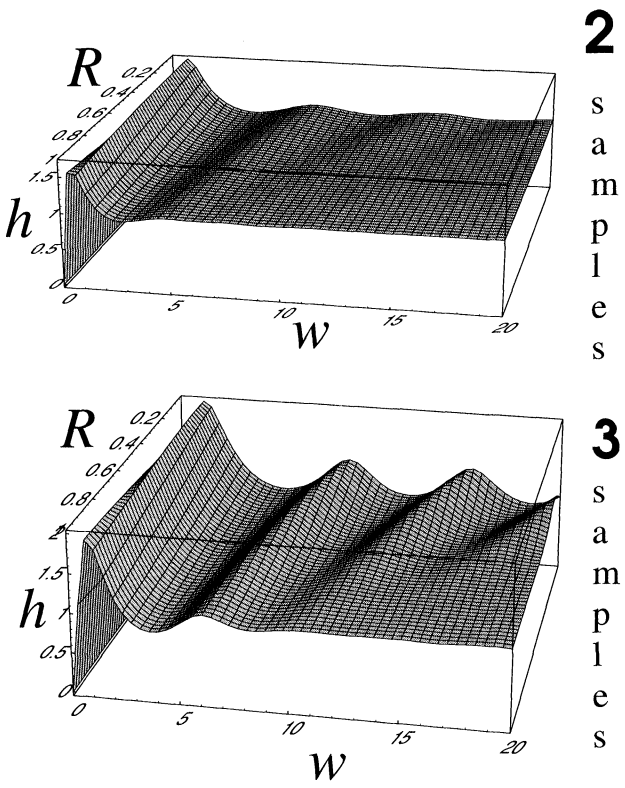

FIG. 4. *Frequency responses.*

Similarly, the stabilized reaction for the second algorithm has the form (1) with the function

$$h(s) = \frac{s}{s^2 + Ae^{-s} + Be^{\frac{-s(1+R)}{2}} + Ce^{-s(1+R)}}.$$

These integral representations give an opportunity to analyze the stabilized reaction of the proposed algorithms on variable (deterministic or random) server rate $\mu(t)$.

Since the server rate $\mu(T)$ is bounded and the model is linear, it is helpful to analyze the reaction on the harmonically changing server rate. If $\mu(T) = e^{iwT}$, then the reaction $Y(T)$ tends to $h(iw)e^{iwT}$. The absolute value $|h(iw)|$ describes the ratio of the oscillations of the buffer occupancy versus the server rate oscillations. Figure 4 displays $|h(iw)|$ for $0 \leq w \leq 20$ and $0 < R < 1$ for both algorithms.

All these observations indicate that the first algorithm has certain advantages over the second one. Although in the case of the fixed server rate, three control parameters lead to a better asymptotic convergence (the more control information is available, the better asymptotic properties could be achieved), the two-parameter scheme gives more robust transient performance as well as better performance in a nonstationary environment: since the second algorithm has large gain coefficients of order R^{-2}, it underperforms the first algorithm with smaller gain coefficients of order R^{-1} when the conditions change (transients and/or changing server rate). Similar effects (where large gain parameters, while being beneficial for the asymptotic behavior, lead to unsatisfactory transient regimes) have been observed in other control systems as well (see, for example, [14], [28], and their references).

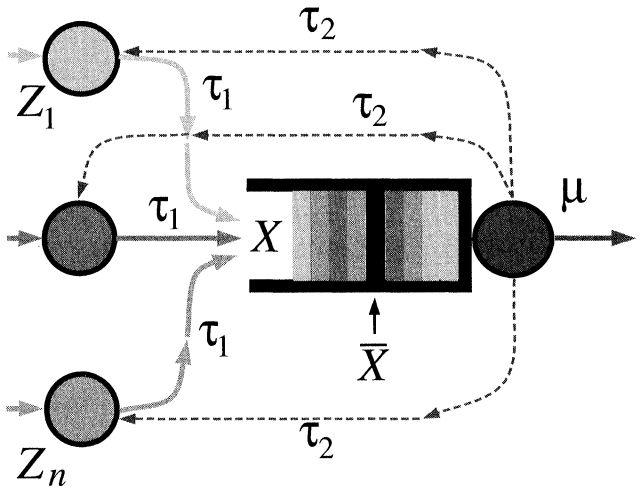

FIG. 5. *Dynamic access node.*

We conclude our analysis by noting that both control algorithms are applicable to the case where multiple connections share the bottleneck node (Figure 5) and the propagation delays are the same for each connection. For example, the first algorithm could be modified to

$$
(2)\qquad \begin{cases} X'(t) = \sum_i Z(t-\tau_1) - \mu, \\ Z_1'(t) = -(a/n)(X(t-\tau_2) - \overline{X}) - (b/n)(X(t-\tau_2-r) - \overline{X}), \\ \vdots \\ Z_n'(t) = -(a/n)(X(t-\tau_2) - \overline{X}) - (b/n)(X(t-\tau_2-r) - \overline{X}). \end{cases}
$$

Denoting $Z(t) = \sum_i Z_i(t)$, we can describe the behavior of algorithm (2) by the same formulas as in the single connection case. The stability properties of the new algorithm (2) are identical to those obtained for single connection case. The common asymptotic rate of convergence for all connections is determined by the principal root of the characteristic equation associated with the global system. The same generalization is applicable to the second algorithm.

5. Conclusion. We analyzed two linear feedback control algorithms and their convergence and optimality. The problems of the optimal choice of control intervals were addressed. We also analyzed the robustness of the algorithms for nonstationary server rate and performance of transient regimes. The results obtained suggest that the two-control parameter scheme is probably better than the three-parameter one: although it has slightly worse asymptotic properties, it has much better transient response as well as a better rate of convergence to changing server rate. It would be important to continue the analysis of these issues. In particular, the next challenging question to be addressed is to extend these algorithms to control of traffic mixture with different propagation delays.

6. Appendix.

6.1. Proof of Theorem 1. Since $f(V) = f'(V) = f''(V) = 0$ for $A = A^*$ and $B = B^*$, then V is a triple root of $f(z)$. To prove that all other roots have lesser real parts than V, the following three steps are accomplished. First we prove that there are exactly three roots in the domain $Q = \{z : |\Im z| \le 2\pi/(1+R)\}$. Next we prove that there are no roots of $f(z)$ in the domain $P = \{z : \Re z \ge -0.6,\ |z| \ge 2\pi/(1+R)\}$. Since the triple root V belongs to Q, that

would mean the absence of other roots of $f(z)$ in Q. The final step is to combine two previous steps and to conclude that there are no zeros (but V) in the domain $R = \{z : |\Re z| \geq -0.6\}$.

The first step uses theory of rotation of planar vector fields [21]. Consider the rotation of the vector field $(\Re f(z), \Im f(z))$ on the boundaries of rectangular domains

$$Q_N = \{z : |\Im z| \leq 2\pi/(1+R),\ |\Re z| \leq N\}, \qquad N \to \infty.$$

As $N \to \infty$, $e^{(1+R)z}z^2$ becomes the dominant member in $f(z)$ on the right vertical boundary of Q_N and, as such, determines the rotation of $(\Re f(z), \Im f(z))$ on the segment $(x = N,\ y \in [-2\pi/(1+R), 2\pi/(1+R)])$. The rotation of $e^{(1+R)z}z^2$ on this segment tends (as $N \to \infty$) to the rotation of $e^{(1+R)z}$, which is 4π. On the left vertical boundary, $-B$ is the dominant member, so the rotation tends to zero as $N \to \infty$. On the upper boundary (where $y \equiv 2\pi/(1+R)$) the function $g(x) = f(x+iy)$ is equal to

$$\left(e^{(1+R)x}\left(x^2 - \frac{4\pi^2}{(1+R)^2}\right) + Ae^{Rx}\cos\left(\frac{2\pi R}{1+R}\right) + B\right)$$
$$+ i\left(\frac{4\pi x}{1+R}e^{(1+R)x} + A\sin\left(\frac{2\pi R}{1+R}\right)e^{Rx}\right).$$

The rotation on the upper boundary of Q_N tends to π as $N \to \infty$: in order to prove it, it is sufficient to show that $\Re g(x) < 0$ for $x \leq 0$ (since $\Im g(x) > 0$ for $x \geq 0$ and the quarter $\{\Re g(x), \Im g(x)\}$ is not visited by the point $g(x)$, which would imply that the rotation is defined correctly $(g(x) \neq 0)$ and is equal to π).

To prove that $\Re g(x) < 0$ for $x \leq 0$, we consider two cases: case α, $1/3 \leq R \leq 1$; case β, $0 \leq R < 1/3$.

Consider case α. If $-2\pi/(1+R) \leq x \leq 0$, then all three components of $\Re g(x)$ are negative. Let $-\infty \leq x \leq -2\pi/(1+R)$. Then $\exp((1+R)x)(x^2 - 4\pi^2/(1+R)^2) < \exp((1+R)x)x^2$, and the latter function has its maximum at $x = -2/(1+R)$ at the considered interval. The first member of $\Re g(x)$ is less than $e^{-2\pi}4\pi^2/(1+R)^2 < 0.042$ (since $R \geq 1/3$). The second member of $\Re g(x)$ is negative, and the third member is less than -0.28 (since $R \leq 1$). Hence $\Re g(x)$ is negative.

Consider case β and its three subcases: case (i), $-2\pi/(1+R) < x < -\pi/(1+R)$; case (ii), $-\infty < x \leq -2\pi/(1+R)$; case (iii), $-\pi/R \leq x \leq 0$.

In case (i) the first member in $\Re g(x)$ is negative, whereas the sum of other two members is less than $A\exp(-\pi R/(1+R))\cos(2\pi R/(1+R)) + B$, which is less than -0.98 on $1/3 \leq R \leq 1$. In case (ii) the first member in $\Re g(x)$ is less than 0.041, whereas the sum of other two members is less than $A\exp(-2\pi R/(1+R))\cos(2\pi R/(1+R)) + B$, which is less than -0.919 on $1/3 \leq R \leq 1$. In case (iii) the sum of the second and third members is less than $A\cos(2\pi R/(1+R)) + B$, which is less than -0.919 on $1/3 \leq R \leq 1$, whereas the first member is less than $e^{-\pi}(3\pi^2/(1+R)^2) < -0.72$.

The same analysis is applicable for the lower boundary ($y \equiv \pi$): the rotation there tends to π.

Therefore, the rotation of $(\Re f(z), \Im f(z))$ on the boundaries of Q_N is 6π for sufficiently large N. Hence $f(z)$ has three zeros (counted with their multiplicity) inside Q.

The second step is proven as follows. For $1/3 \leq R \leq 1$ and $x \geq -0.6$, $y \geq 2\pi/(1+R)$ we have

$$|e^{(1+R)z}z^2| = |e^{Rz}||e^z||z^2| \geq 5.416|e^{Rz}|, \quad |Ae^{Rz}| \leq 1.213|e^{Rz}|.$$

Hence $|e^{(1+R)z}z^2 + Ae^{Rz}| \geq (5.41 - 1.22)|e^{Rz}| \geq 4.19|e^{Rz}| > 3 > |B|$. Assume further that $0 < R < 1/3$. Since $|AR| < 1/2$ and $|BR| < 1/2$ for $0 < R \leq 1/3$, then

$$|Ae^{Rz} + B| \leq |Ae^{Rz}| + B \leq |e^{Rz}|\frac{0.7}{R} + \frac{0.7}{R} < |e^{Rz}|\frac{0.7}{R} + |e^{Rz}|\frac{0.7}{R}e^{0.6} \leq 2\frac{|e^{Rz}|}{R}$$

on the domain $\{x \geq -0.6,\ y \geq \pi/R\}$. (The last relations follow from the inequality $|e^{Rz}| \geq e^{-0.6}$.) On the other hand, $|e^{(R+1)z}z^2| = |e^{Rz}||z^2||e^z| \geq e^{-0.6}|e^{Rz}|\pi^2/R^2 \geq |e^{Rz}|5.5/R^2$, which exceeds the previous expression for $R \leq 1$. This means there are no roots in the domain $\{x \geq -0.6,\ y \geq \pi/R\}$.

Consider now the domain $D = \{N \geq x \geq -0.6,\ 2\pi/(1+R) \leq y \geq \pi/R\}$. It is sufficient to prove that the rotation of f on the boundaries is the same as the rotation of the function $e^{(R+1)z}z^2$ (which has no zeros inside D).

Consider all four boundaries of D separately. On the upper boundary $|e^{(R+1)z}z^2| > |Ae^{Rz} + B|$ since the right part is more than $|e^{Rz}|0.44\pi^2/R^2$, whereas the left part is less than $|e^{Rz}|$. On the right boundary $|e^{(R+1)z}z^2| \gg |Ae^{Rz} + B|$ for sufficiently large N. On the left boundary $|e^{(R+1)z}z^2| \geq |y|^2$, which is larger than

$$\begin{aligned} |Ae^{Rz} + B| &\leq 1.5\max\{B + A\cos Ry,\ A\sin Ry\} \\ &\leq 1.5\max\{0.3 + 0.2Ry^2,\ 0.5y\} \leq 0.45 + 0.3y^2 \end{aligned}$$

for $|y| \geq 2\pi/(1+R)$ and $R < 1/3$. (Since $(B+A)R \to 0$ as $R \to 0$, then $h(R, y) = B + Ae^{Rx}\cos(Ry)$ is less than $0.242 + 0.2y^2$ (for $R \leq 1/3$ and $y < \pi/R$).) Finally, on the lower boundary for $x = -0.6$ the same analysis as for the left boundary shows that $|e^{(R+1)z}z^2| > |Ae^{Rz} + B|$; for $x = N$ this follows from the analysis of the right boundary. Since (see the first step of the proof) both $(\Re f, \Im f)$ and $(\Re g, \Im g)$, where

$$g(x) = \left(e^{(1+R)x}\left(x^2 - \frac{4\pi^2}{(1+R)^2}\right)\right) + i\left(\frac{4\pi x}{1+R}e^{(1+R)x}\right),$$

do not belong to the quarter $\{\Re Z > 0, \Im Z < 0\}$, a linear homotopy exists between f and g. Therefore, the final step is completed, and V is the degree of stability of $f(z)$.

To prove the local optimality of A^* and B^*, denote $A = A^* + \alpha$, $B = B^* + \beta$, and consider the Taylor series $f(z) = \sum_i f_i(z - V)^i$:

$$\begin{aligned} f_0 &= \beta + \alpha e^{RV},\ f_1 = \alpha R e^{RV},\ f_2 = \frac{\alpha R^2 e^{RV}}{2}, \\ f_3 &= \frac{\alpha R^3 e^{RV}}{6} + \frac{\sqrt{2+2R+R^2}e^{(R+1)V}}{3}, \\ f_4 &= \frac{\alpha R^4 e^{RV}}{24} + \frac{(1+R+(2+3R)\sqrt{2+2R+R^2})e^{(R+1)V}}{12}. \end{aligned}$$

Then the function $g(s) + \delta(s)s^4 = (g_0 + \delta(s))s^4 + g_1 s^3 + g_2 s^2 + g_3 s + g_4$ has the same roots as $f(z - V)$, where $g_i = f_{4-i}$ $(i = 0, \ldots, 4)$ and $\delta(s) = o(1)$.

Let $\varepsilon < 0.001$. If $\alpha = \beta = 0$, then $\max_U |\delta(s)| < \varepsilon/2$, $\min_{\partial U} |g(s)/s^4| > 2\varepsilon$, $\min_U(g_0 + \delta(s)) > g_0/2$ for sufficiently small ε_0, where ∂U is the boundary of $U = \{z : |z| \leq \varepsilon_0\}$. Then for sufficiently small $\varepsilon_1 < \varepsilon$ (i) $\max_U |\delta(s)| = \varepsilon_2 < \varepsilon$, (ii) $\min_{\partial U} |g(s)/s^4| > \varepsilon$, (iii) $\min_U(g_0 + \delta(s)) > 0$ for any $|\alpha|, |\beta| < \varepsilon_1$. Parts (i) and (ii) imply that $g(s)$ and $g(s) + \delta(s)s^4$ have the same rotation on δU and the same number of roots inside U for any $|\alpha|, |\beta| < \varepsilon_1$. Part (ii) implies that any polynomial $G_\delta(s) = g(s) + \delta s^4$ (where $|\delta| < \varepsilon_2$) has three roots in U and a negative root outside of U for any $|\alpha|, |\beta| < \varepsilon_1$. Part (iii) implies $G_\delta(s)$ has no roots in the right half-plane (RHP) iff all its Hurwitz determinants $\Delta_1 = g_1$, $\Delta_2 = g_1 g_2 - (g_0 + \delta)g_3$, $\Delta_3 = g_1 g_2 g_3 - (g_0 + \delta)g_3^2 - g_4 g_1^2$, $\Delta_4 = g_4\Delta_3$ are positive (Routh–Hurwitz criterion, [13, Chap. XV, Thm. 4]).

If $g_4 = 0$, then one of the roots of $G_\delta(s)$ is zero and one of the Hurwitz determinants $\Delta_2 = g_1 g_2 - (g_0 + \delta)g_3$, $\Delta_3 = \Delta_2 g_3$ of the polynomial $G_\delta(s)/s$ is negative for $|\delta|, |\alpha|, |\beta| < \varepsilon$,

which means that $G_\delta(s)$ has a root in the RHP. If $g_4 \neq 0$, then $G_\delta(s)$ has a root in the RHP both for $g_4 < 0$ (since $\Delta_4 = g_4\Delta_3$) and for $g_4 > 0$ (since

$$\Delta_3 = -g_4 g_1^2 + \frac{\alpha^2 R^2 e^{2RV}}{24} \times \left(-24\delta + \alpha R^4 e^{RV} - 2e^{(1+R)V}(1 + R + (2+R)\sqrt{2+2R+R^2})\right) < 0$$

for $|\delta|, |\alpha|, |\beta| < \varepsilon < 0.001$).

Fix α and β. Since the sign of any of the Hurwitz determinants of the functions $G_\delta(s)$ does not depend on δ for all $|\delta| < \varepsilon$ (Δ_1 does not depend on δ, the sign of

$$\Delta_2 = \frac{\alpha R e^{RV}}{24}\left(-24\delta + \alpha R^4 e^{RV} - 2e^{(1+R)V}(1 + R + (2+R)\sqrt{2+2R+R^2})\right)$$

does not depend on δ for $|\delta| < \varepsilon$, $\Delta_3 < 0$ for $|\delta|, |\alpha|, |\beta| < \varepsilon$, and the sign of $\Delta_4 = g_4\Delta_3$ does not depend on δ since g_4 does not depend on δ), then [13, Chap. XV, Thm. 5] $G_\delta(s)$ has the same number of roots in the RHP for any $|\delta| < \varepsilon$. As δ changes from $-\varepsilon$ to ε, the roots of $G_\delta(s)$ in the RHP form the set R (separated from the imaginary axis), and the rest of the roots form the set L. The continuous homotopy $g(s) + \gamma\delta(s)s^4$ (for $\gamma \in [0, 1]$) preserves the rotation on ∂U and continuously moves the roots of $g(s) + \delta(s)s^4$ to the roots of $g(s)$. For any $\gamma \in [0, 1]$ the roots of $g(s)$ in U belong to the set $R \cup L$ (if $r \in U$ is a root of $g(s) + \gamma\delta(s)s^4$, then it is also a root of $G_{\gamma\delta(r)}(s)$: since $\delta(s)$ is a regular function, $|\delta(r)| < \varepsilon$). Since $g(s)$ has a root $r \in R$ for $\gamma = 0$, then the homotopic prototype of r for $\gamma = 1$ also belongs to R. This completes the proof of Theorem 1.

6.2. Proof of Theorem 2. The proof of Theorem 2 closely follows the proof of Theorem 1.

Since $f(W) = f'(W) = f''(W) = f'''(W) = 0$ for $A = A^*$, $B = B^*$ and $C = C^*$, then W is a quadruple root of $f(z)$. To prove that all other roots have lesser real parts than V, the following three steps are accomplished. First, we prove that there are exactly four roots in the domain $Q = \{z : |\Im z| \leq 2\pi/(1 + R)\}$. Next, we prove that there are no roots of $f(z)$ in the domain $P = \{z : \Re z \geq -1.268,\ |z| \geq 2\pi/(1 + R)\}$. Since the quadruple root W belongs to Q, that would mean the absence of other zeros in Q. The final step is to combine two previous steps and to conclude that there are no zeros (but W) in the domain $R = \{z : |\Re z| \geq -1.268\}$.

The first step uses theory of rotation of planar vector fields [21]. We will analyze the rotation of the vector field $(\Re f(z), \Im f(z))$ on the boundaries of rectangular domains

$$Q_N = \{z : |\Im z| \leq 2\pi/(1 + R),\ |\Re z| \leq N\}, \qquad N \to \infty.$$

Consider the right vertical boundary of Q_N. For $N \to \infty$ the member $e^{(1+R)z}z^2$ becomes the dominant member in $f(z)$ and, as such, determines the rotation of $(\Re f(z), \Im f(z))$ on the segment $(x = N,\ y \in [-2\pi/(1+R), 2\pi/(1+R)])$. The rotation of $e^{(1+R)z}z^2$ on this segment tends (as $N \to \infty$) to the rotation of $e^{(1+R)z}$, which is 4π. On the left vertical boundary, $-B$ is the dominant member, so the rotation tends to zero as $N \to \infty$. On the upper boundary (where $y \equiv 2\pi/(1 + R)$) the function $f(x + iy) = g_1(x) + ig_2(x)$ has the form

$$g_1(x) = C + e^{(1+R)x}\left(\frac{-4\pi^2}{(1+R)^2} + x^2\right) + Be^{\frac{Rx}{2}}\cos\left(\frac{\pi R}{1+R}\right) + Ae^{Rx}\cos\left(\frac{2\pi R}{1+R}\right),$$

$$g_2(x) = \frac{4e^{(1+R)x}\pi x}{1+R} + Be^{\frac{Rx}{2}}\sin\left(\frac{\pi R}{1+R}\right) + Ae^{Rx}\sin\left(\frac{2\pi R}{1+R}\right).$$

The rotation tends to 2π as $N \to \infty$: to prove it, it is sufficient to show that (i) $\Im g(x) < 0$ for $x \le -1$; (ii) $\Im g(x) > 0$ for $x > 1$; (iii) $\Re g(x) < 0$ for $-1 \le x \le 1$. That will imply that $g(x) \neq 0$ for all x (and the rotation is defined correctly) and the rotation is indeed equal to 2π (given the behavior of $g_1(x) + ig_2(x)$ on infinity).

The case (i) is verified by direct analysis.

Consider case (ii). If $R < 1/3$, then the statement is verified by direct analysis. Otherwise, since $|A|, |B| \le 7$ for $R > 1/3$, we then have that the first member is larger than $17e^{Rx}$ and the third member is positive, whereas the second member is less than $15e^{Rx}$.

In case (iii) $e^{(1+R)x}(x^2 - 4\pi^2/(1+R)^2) \le -1.2$ for $-1 \le x \le 1$. If $R > 1/3$, then the last member in

$$q = C + Be^{\frac{Rx}{2}} \cos\left(\frac{\pi R}{1+R}\right) + Ae^{Rx} \cos\left(\frac{2\pi R}{1+R}\right)$$

is negative, and it is sufficient to prove that $Q = C + Be^{Rx/2}\cos(\pi R/(1+R)) \le 1$, which is verified directly. In the same way we verify that q is negative for $R < 1/3$.

The same analysis is applicable for the lower boundary ($y \equiv \pi$): the rotation there tends to π.

Therefore, the rotation of $(\Re f(z), \Im f(z))$ on the boundaries of Q_N is 8π for sufficiently large N. Hence $f(z)$ has four zeros (counted with their multiplicity) inside Q. This completes the first step.

The second step is proven as follows. For $0 < R \le 1$ the analysis shows that $AR^2 < 1.61$, $BR^2 < -1.8$, $CR^2 < 0.82$. Hence

$$|Ae^{Rz} + Be^{\frac{Rz}{2}} + C| \le |Ae^{Rz}| + |Be^{\frac{Rz}{2}}| + |C| \le |e^{Rz}|\frac{1.61}{R^2} + |e^{\frac{Rz}{2}}|\frac{1.8}{R^2} + \frac{0.82}{R^2}$$

on the domain $\{x \ge -1.268,\ y \ge 2\pi/R\}$. This expression is less than $|e^{Rz}|8/R^2$ (since $|e^{Rz}| \ge e^{-1.3}$). On the other hand, $|e^{(R+1)z}z^2| \ge e^{-1.3}(4\pi^2/R^2)|e^{Rz}| \ge |e^{Rz}|(10/R^2)$, which exceeds the previous expression for $R \le 1$. This means there are no roots in the domain $\{x \ge -1.268,\ y \ge 2\pi/R\}$.

Now consider the domain $D_1 = \{0 \le x \le N,\ 2\pi/(1+R) \le y \le 2\pi/R\}$. It is sufficient to prove the rotation of f on the boundaries of D is the same as the rotation of $e^{(R+1)z}z^2$ (which has no zeros inside D_1).

Consider all four boundaries of D_1 separately. On the upper boundary $|e^{(R+1)z}z^2| > |Ae^{Rz} + Be^{Rz/2} + C|$ as has been proven already, and the same is true for the right boundary for sufficiently large N. On the left boundary the direct analysis of both $Ae^{Rx}\cos(Ry) + Be^{Rx/2}\cos(Ry/2) + C$ and $Ae^{Rx}\sin(Ry) + Be^{Rx/2}\sin(Ry/2) + C$ shows that these functions are least 1.5 times less than the main member $|e^{(R+1)z}z^2| = |y|^2$. On the lower boundary we use the already established (in the first step) existence of a homotopy between $(\Re f, \Im f)$ and $(\Re g, \Im g)$ on this boundary.

Consider now the domain $D_2 = \{-1.268 \le x \le 0,\ 2\pi/(1+R) \le y \le 2\pi/R\}$. It is sufficient to prove the rotation of f on the boundaries of D is the same as the rotation of $e^{(R+1)z}z^2$ (which has no zeros inside D_1).

Consider all four boundaries of D_2 separately. The upper boundary and the right boundary are analyzed in the same way as for D_1. On the left boundary the function $|Ae^{Rz} + Be^{Rz/2} + C|^2 - |e^{(R+1)z}z^2|^2$ is negative for $R < 1/2$, which is verified directly. Let $R > 1/2$. Then for $2\pi/(1+R) \le y \le (8/3)\pi/(1+R)$ the imaginary parts of both $Ae^{Rz} + Be^{Rz/2} + C$ and $e^{(R+1)z}z^2$ are negative, which permits a linear homotopy between them. For $4\pi/(1+R)y > (8/3)\pi/(1+R)$ we prove directly that $|Ae^{Rz} + Be^{Rz/2} + C|^2 - |e^{(R+1)z}z^2|^2$ is negative, and for $y > 4\pi/(1+R)$ we prove it by proving that the upper estimate of this difference, which is

$|Ae^x - Be^R x/2 + C - e^{(R+1)x}(x^2+y^2)$, is negative for $0 < R \le 1$. On the lower boundary we use the already established (in the first step) existence of a homotopy between $(\Re f, \Im f)$ and $(\Re g, \Im g)$ on this boundary. This proves the second statement of the theorem.

To prove the third statement of the theorem, denote $A = A^* + a$, $B = B^* + b$, $C = C^* + c$, where $|a| < \varepsilon$, $|b| < \varepsilon$, $|c| < \varepsilon$, $\varepsilon \ll 1$. Consider the Taylor series of $f(z)$ in the neighborhood of W:

$$f(z) = f_0 + f_1(z-W) + f_2(z-W)^2 + f_3(z-W)^3 + f_4(z-W)^4 + f_5(z-W)^5 + O(z-W)^6.$$

Then the function

$$g(s) = g_0 s^5 + g_1 s^4 + g_2 s^3 + g_3 s^2 + g_4 s + g_5$$

has the same roots as $f(z-W)$, where

$$g_0 = \alpha + \beta + \gamma + \varepsilon_1 + o(\varepsilon),\ g_1 = (5/R)\alpha + (10/R)\beta + \varepsilon_2,\ g_2 = (20/R^2)\alpha + (80/R^2)\beta,$$
$$g_3 = (60/R^3)\alpha + (480/R^3)\beta,$$
$$g_4 = (120/R^4)\alpha + (1920/R^4)\beta,\quad g_5 = (120/R^5)\alpha + (3840/R^5)\beta + \gamma,$$

and

$$\alpha = e^{WR}(R^5/120)a,\quad \beta = e^{WR/2}(R^5/3840)b,\quad \gamma = c,$$

$$\varepsilon_1 = \frac{e^{W(1+R)}\left(4 + 6R + 2R^2 + (4+7R)\sqrt{12 + 24R + 18R^2 + 6R^3 + R^4}\right)}{240},$$

$$\varepsilon_2 = \frac{e^{W(1+R)}\sqrt{12 + 24R + 18R^2 + 6R^3 + R^4}}{24}.$$

The technique used in the proof of Theorem 1 is applicable here as well, and we have to prove only that all the Routh–Hurwitz determinants $\Delta_1, \ldots, \Delta_5$ of the polynomial $G_\delta(s) = g(s) + \delta s^5$ cannot be positive for small $|\alpha|, |\beta|, |\gamma| < \varepsilon$.

Let $g_5 = 0$. Then one of the Hurwitz polynomials of $G_\delta(s)/s$ (if $g_4 \ne 0$) and $G_\delta(s)/s^2$ (if $g_4 = 0$) is negative. Let $g_5 \ne 0$. Since $\Delta_5 = g_5 \Delta_4$, it is sufficient to prove that both $g_5 > 0$ and $\Delta_4 > 0$ cannot hold simultaneously for small $\alpha, \beta, \gamma, \delta$.

Consider the Hessian of Δ_4. It has one negative eigenvalue, tending to $-e^{W(1+R)}h \times (28800R^{10})^{-1}$, where h is equal to

$$3070080000 + 9203328000R + 11381760000R^2 + 7430400000R^3 + 2772720000R^4$$
$$+ 590256000R^5 + 59112000R^6 + 208R^{10} + 1104R^{11} + 2272R^{12} + 2304R^{13} + 1238R^{14}$$
$$+ 350R^{15} + 49R^{16}$$
$$+ (472320000 + 944064000R + 589536000R^2 + 117792000R^3 + 32R^{10}$$
$$+ 104R^{11} + 100R^{12} + 28R^{13}) \times \sqrt{12 + 24R + 18R^2 + 6R^3 + R^4}.$$

The other two zero eigenvalues define the two-dimensional invariant subspace M for the kernel of the Hessian. Since $g_5 > 0$ and

$$g_5 = \frac{10\sqrt{12 + 24R + 18R^2 + 6R^3 + R^4}\left(1920\beta + \gamma R^5\right)}{R^4\left(-4 - 6R - 2R^2 + (3R-4)\sqrt{12 + 24R + 18R^2 + 6R^3 + R^4}\right)}$$

on M, then $1920\beta + \gamma R^5 < 0$ on M. Since the restriction of Δ_4 on M has the form $\Delta_4 = (1920\beta + \gamma R^5)g$, where g is analytical on M, then it is sufficient to prove that g is

positive on M. The Hessian of g has one positive eigenvalue, equal to $e^{W(1+R)}g_1/g_2$, where

$$\begin{aligned}
g_1 &= 4146934579200 + 29659181875200R + 97501976985600R^2 + 194586181632000R^3 \\
&\quad + 262598757580800R^4 + 252803933798400R^5 + 178538876928000R^6 \\
&\quad + 93651451084800R^7 + 36470878617600R^8 + 10381801881600R^9 \\
&\quad + 2074990272768R^{10} + 265720094208R^{11} + 17063053824R^{12} \\
&\quad + 39632640R^{13} + 60500352R^{14} + 64471296R^{15} + 49433920R^{16} \\
&\quad + 27682752R^{17} + 11348884R^{18} + 3362664R^{19} + 693152R^{20} + 90860R^{21} + 5929R^{22} \\
&\quad + (993735475200 + 5950734336000R + 15851814912000R^2 + 24608489472000R^3 \\
&\quad + 24505461964800R^4 + 16245389721600R^5 + 7204036608000R^6 \\
&\quad + 2086060032000R^7 + 366206976000R^8 + 30582374400R^9 \\
&\quad + 1198808R^{10} + 883200R^{11} + 2803200R^{12} + 5034240R^{13} + 5649792R^{14} \\
&\quad + 4125504R^{15} + 1976000R^{16} + 608480R^{17} + 112480R^{18} + 9856R^{19}) \\
&\quad \times\sqrt{12 + 24R + 18R^2 + 6R^3 + R^4}, \\
g_2 &= 4320R^{10}(2368 + 4896R + 1248R^2 - 3600R^3 - 2568R^4 + 324R^5 + 860R^6 \\
&\quad + 342R^7 + 54R^8 + (960 + 240R - 816R^2 - 120R^3 + 328R^4 - 18R^5 - 54R^6 - 27R^7) \\
&\quad \times\sqrt{12 + 24R + 18R^2 + 6R^3 + R^4},
\end{aligned}$$

while the second eigenvalue is zero. Restricting the function g on the one-dimensional subspace L, corresponding to the zero eigenvalue, we see that g is equal to $\overline{g} = \gamma^3 R^5 p_1/p_2$, where

$$\begin{aligned}
p_1 &= -(2 + R)(1 + R + \sqrt{12 + 24R + 18R^2 + 6R^3 + R^4}) \\
&\quad \times(4 + 6R + 2R^2 + (4 + 7R)\sqrt{12 + 24R + 18R^2 + 6R^3 + R^4})^2 \\
&\quad \times(936 + 4224R + 7614R^2 + 7008R^3 + 3516R^4 + 952R^5 + 127R^6 \\
&\quad + (144 + 406R + 357R^2 + 95R^3)\sqrt{12 + 24R + 18R^2 + 6R^3 + R^4})^2, \\
p_2 &= 3072(4 + 6R + 2R^2 + (4 - 3R)\sqrt{12 + 24R + 18R^2 + 6R^3 + R^4}) \\
&\quad \times(936 + 3408R + 5274R^2 + 4368R^3 + 2046R^4 \\
&\quad + 530R^5 + 68R^6 + (144 + 338R + 255R^2 + 61R^3)\sqrt{12 + 24R + 18R^2 + 6R^3 + R^4})^3.
\end{aligned}$$

This expression is positive if $\gamma < 0$. The latter relation follows from the fact that $(1920\beta + \gamma R^5) < 0$ on M (and on L as well) and from the representation of $(1920\beta + \gamma R^5)$ on L in the form

$$\begin{aligned}
z_1 &= 3\gamma R^5(2 + R)\left(52 + 70R + 8R^2 - 28R^3 - 14R^4 - 3R^5\right. \\
&\quad \left. + (8 + 7R + R^2)\sqrt{12 + 24R + 18R^2 + 6R^3 + R^4}\right), \\
z_2 &= 936 + 3408R + 5274R^2 + 4368R^3 + 2046R^4 + 530R^5 + 68R^6 \\
&\quad + (144 + 338R + 255R^2 + 61R^3)\sqrt{12 + 24R + 18R^2 + 6R^3 + R^4}.
\end{aligned}$$

This proves the third statement of the theorem.

Acknowledgments. I am grateful to the anonymous reviewers for their helpful comments.

HEAVY TRAFFIC ANALYSIS OF A CONTROLLED MULTICLASS QUEUEING NETWORK VIA WEAK CONVERGENCE METHODS*

HAROLD J. KUSHNER† AND L. FELIPE MARTINS‡

Abstract. The workload formulation due to Harrison and coworkers of multiclass queueing networks has been fundamental to its analysis. Until recently, there was no actual theory which started with the physical queue and showed that under heavy traffic conditions, the optimal costs could be approximated by those for an optimization problem using the "limit" workload equations. Recently, this was done via viscosity solution methods by Martins, Shreve, and Soner for one important class. For this same class of problems (and including the cases not treated there), we use weak convergence methods to show that the sequence of optimal costs for the original network converges to the optimal cost for the workload limit problem. The proof is simpler and allows weaker (and non-Markovian) conditions. It uses current techniques in weak convergence analysis. It seems to be the first analysis of such multiclass "workload" problems by weak convergence methods. The general structure of the development seems applicable to the analysis of more complex systems.

Key words. controlled queues, weak convergence, heavy traffic analysis, multiclass queues

AMS subject classifications. 90B15, 90B22, 93E20, 93E25, 60F17

1. Introduction.

Multiclass queueing network problems where some processor is required to serve more than one class of customers have been the subject of much recent interest. The choice of which customer to serve at any time (or whether the processor should remain idle, even if customers are present in its queue) has not been easy. The basic papers [2, 3, 10, 11] cast the problem in the "heavy traffic/workload" formulation, and various rules were derived for the control policies in the limit. These papers developed key ideas and intuition, but did not actually present a proof of the validity of the "approximating" workload equations for getting the controls. In [8], a proof was provided in a heavy traffic context for one important case.

The problem in [8], in what has been named the "criss-cross" system, has two processors. Processor 1 receives customers of two classes (named 1 and 2) from outside the system. Each class has its own interarrival time distribution and service time requirements. When service is completed on a class 1 customer, that customer leaves the system. When service is completed on a class 2 customer, that customer goes on to processor 2 and is renamed a class 3 customer.

In [8], the interarrival and service times were exponentially distributed and mutually independent so that a Markovian framework could be used. The analysis was of a heavy traffic type, in that one studied the limit of a sequence of problems (indexed by N), for which the difference between the mean rate of offered traffic and the service capacity went to zero as $N \to \infty$. The paper used viscosity solution methods for the convergence analysis for the Bellman equation. They established the important fact that the sequence of optimal value functions for the physical processes (indexed by N) converged to a function which solved the Bellman equation in the viscosity solution sense, and in certain cases they exhibited the control form which was optimal for the limit problem and nearly optimal for the physical process for large N. A key technique was the conversion of the physical problem into the so-called workload formulation of [2, 3, 10, 11]. The limit problem was actually a stochastic singular control problem.

Our approach is also of a heavy traffic type, but we use simple adaptations of the weak convergence methods of the type used in [4, 6, 7, 9] for various control problems with a single customer class. We work with the basic system of [8], also with the workload formulation, and show that the limit of the optimal cost functions for the physical system is the optimal cost for an appropriately defined limit of the workload equations for the physical systems. A crucial innovation in the analysis here is that we introduce the workload formulation *before* we pass to the limit.

The weak convergence methods are capable of treating a more general problem than that in [8]. Markovian assumptions are not needed, and we treat all of the cases discussed in [8], even the cases not solved there. We do not obtain the actual controls. However, the methods of proof can be adapted to work on variations of the problem for the type of queue structure at hand: for example, with correlated service or interarrival times, batch arrivals or services, state dependencies in the service and arrival data, and appropriate nonlinear cost functions. We believe that the proofs used here point the way toward possible proofs for more general queues with more complex flow and class structure, and some specific remarks to that end are at the end of the paper. Numerical methods of the Markov chain approximation type exist for singular control problems more general than the limit workload problem obtained for our cases [5, 6]. These can be of use on those problems where the actual solution cannot be obtained analytically, and the proof technique shows how to adapt these for use on the actual physical problem.

Heretofore, it was not clear how to use weak convergence methods on such multiclass problems, particularly with the workload formulation. Even when one could write the equations for the "physical" workload processes, it was not clear how to show that this sequence was tight, so that limits of weakly convergent subsequences could be chosen and worked with. It had appeared that for such problems, where one could not easily get convergent subsequences (in the weak convergence sense), that viscosity solutions were more natural. The relatively simple technique used here shows a direction for using the powerful weak convergence methods in many such problems. Basically, we just use ideas that are well understood from other problems in heavy traffic limits, and the proofs are relatively simple. An advantage of our approach is that it does not require knowledge of the solution of the limit problem. Obtaining this solution was the difficult part of the work in [8].

The problem is formulated, assumptions stated, and useful representations of the input and output processes are given in §2. The dynamical equations for the queues and workloads are developed in §3. Section 4 discusses the so-called workload cost transformation and states the workload limit equations. The convergence theorem and proof are in §5.

2. Assumptions and problem formulation. The set of all interarrival and service intervals are mutually independent, and the members of each class of arrival and service times are identically distributed. This assumption is made to simplify the notation. (As is common with weak convergence-type analyses, various forms of correlations can be introduced without affecting the end result, except for the variances of the Wiener processes.) We consider a sequence of problems indexed by N, which is a measure of the traffic intensity, and assume that the intensity approaches unity as $N \to \infty$. The interarrival intervals for classes $i = 1, 2$ are denoted by $\alpha_{i,j}^N$, $j = 1, 2, \ldots$, and have mean values $\overline{\alpha}_i^N$. The service times for classes $i = 1, 2, 3$ are denoted by $\Delta_{i,j}^N$, $j = 1, 2, \ldots$, and have mean values $\overline{\Delta}_i^N$. Let the arrival rate for class $i = 1, 2$ be denoted by $\lambda_i^N = [\overline{\alpha}_i^N]^{-1}$, and the mean service rates by $\mu_i^N = [\overline{\Delta}_i^N]^{-1}$.

Suppose that there are positive λ_i, μ_i such that $\lambda_i^N \to \lambda_i$ and $\mu_i^N \to \mu_i$. The basic heavy traffic assumption is that for $\lambda_i/\mu_i = p_i$, $i = 1, 2$, $p_1 + p_2 = 1$, and there are $b_i > 0$ such that

$$\lim_N \sqrt{N}\left(\frac{\lambda_1^N}{\mu_1^N} + \frac{\lambda_2^N}{\mu_2^N} - 1\right) = -b_1, \tag{2.1}$$

$$\lim_N \sqrt{N}\left(\frac{\lambda_2^N}{\mu_3^N} - 1\right) = -b_2. \tag{2.2}$$

From (2.1) and (2.2) it follows that the difference between service capacity and mean total input rate is positive for large N and is of order $O(1/\sqrt{N})$ for each processor. We suppose that the third absolute moments of the interarrival and service intervals are bounded uniformly in N, j, i, and that for finite $\sigma_{i,A}$, $\sigma_{i,D}$

$$E\left[(\alpha_{i,j}^N - \overline{\alpha}_i^N)/\overline{\alpha}_i^N\right]^2 \to [\sigma_{i,A}]^2,$$

$$E\left[(\Delta_{i,j}^N - \overline{\Delta}_i^N)/\overline{\Delta}_i^N\right]^2 \to [\sigma_{i,D}]^2.$$

We refer to the queue of customers of class i as queue i. Define $Z_i^N(t)$ to be the number of customers in queue i at time Nt divided by $\sqrt{N}$. Define $A_i^N(t)$ ($D_i^N(t)$, resp.) to be the number of arrivals (and completed services, resp.) at queue i by time Nt, divided by $\sqrt{N}$. Finally, define

$$S_i^{N,A}(t) = A_i^N(t)/\sqrt{N}$$

and

$$S_i^{N,D}(t) = D_i^N(t)/\sqrt{N}.$$

In this "$1/N$" time scale, the input-output equation for queue i is[1]

$$Z_i^N(t) = Z_i^N(0) + A_i^N(t) - D_i^N(t). \tag{2.3}$$

By the definition, $NS_i^{N,A}(t)$ is the number of arrivals of class i by time Nt. It can be written as $\max\{n : \sum_{j=1}^n \alpha_{i,j}^N \le Nt\}$. For use below, define $\bar{S}_i^{N,A}(t)$ by

$$N\bar{S}_i^{N,A}(t) = \min\left\{n : \sum_{j=1}^n \alpha_{i,j}^N \ge Nt\right\}.$$

Define $\bar{S}_i^{N,D}(t)$ analogously. Then $\bar{S}_i^{N,A}(t) - S_i^{N,A}(t)$ is either zero or $1/N$, and similarly for D replacing A.

Controls. Let $c_i > 0$, $\beta > 0$. The cost function of interest in this paper is

$$E\int_0^\infty e^{-\beta t}\sum_{i=1}^3 c_i Z_i^N(t)dt.$$

For the physical system, the only control problem concerns what to do at processor 1. There, at any time we must choose between serving class 1 or 2 or to not serve either. In the physical

[1]Notice that, contrary to frequent practice in heavy traffic analysis, $D_i^N(t)$ represents the *actual* number of class i customers on which service was completed by time t, not the number that would have been served if the processor kept processing and turning out "fictitious" outputs during its idle times.

system, it is obvious that processor 2 should always work when there is work for it to do, and processor 1 should always work when $Z_1^N(t) > 0$. However, to facilitate the analysis below, it will be convenient to allow somewhat more general controls by adding the possibility of shutting processor 2 off when there is work for it to do or of shutting processor 1 off when $Z_1^N(t) > 0$. Obviously, use of the extended controls will not reduce the cost.

We now define a model for the allocation of time (or for planned idling) which will be convenient for the weak convergence analysis. The basic control is the amount of time allocated for work on each class, and for idling. These will be simply nondecreasing and nonanticipative processes which do not violate the physical feasibility constraint that we can use only the time that is available.

We define the controls by starting with a particular prior allocation of service time and then modifying that to get whatever policy is actually desired. The prior allocation is $p_i Nt$ to the physical queue, $i = 1, 2$, and Nt to queue 3, in the real time interval $[0, Nt]$. This allocation is equivalent to an allocation of $p_i t$, $i = 1, 2$, in the rescaled time used in (2.3). The control for processor 1 then involves the reallocation of time between queues 1 and 2, as well as the choice of whether or not to actually use the finally allocated time or to let the processor idle (even if customers are present). We define the reallocation of service time between queues 1 and 2 by introducing a function $G_i^N(\cdot)$ such that $\sqrt{N}G_i^N(t)$ is the service time in the real time interval $[0, Nt]$ allocated originally to queue i but which is reallocated to queue j, $j \neq i$, in that interval. All the allocations and reallocations are assumed to be nonanticipative. Analogously, let $\sqrt{N}L_i^N(t)$, $i = 1, 2, 3$, denote the total service time finally allocated to queue i in the real time interval $[0, Nt]$ but not used because either queue i was empty or because the control required that there be no service. In the latter case, the allocated time cannot be allocated to another queue but remains unused.

Useful representations of the arrival and departure processes. Define the processes

$$\hat{A}_i^N(n) = \frac{1}{\sqrt{N}} \sum_{j=1}^{n} \left(1 - \frac{\alpha_{i,j}^N}{\bar{\alpha}_i^N}\right),$$

$$\hat{D}_i^N(n) = \frac{1}{\sqrt{N}} \sum_{j=1}^{n} \left(1 - \frac{\Delta_{i,j}^N}{\bar{\Delta}_i^N}\right),$$

and let $\hat{\mathcal{B}}_i^{N,A}(n)$ (resp., $\hat{\mathcal{B}}_i^{N,D}(n)$) be the minimal σ-algebra which measures the family $\{\hat{A}_i^N(j), j \leq n\}$ (resp., $\{\hat{D}_i^N(j), j \leq n\}$). For future use, we note that $\hat{A}_i^N(n)$ is a $\hat{\mathcal{B}}_i^{N,A}(n)$-martingale, and for each t, $N\bar{S}^{N,A}(t)$ is a $\hat{\mathcal{B}}_i^{N,A}(n)$-stopping time, with analogous assertions holding for $\hat{D}_i^N(n)$ and $N\bar{S}^{N,D}(t)$.

For $i = 1, 2$, the definitions of the terms involved allow us to write

$$A_i^N(t) = \frac{1}{\sqrt{N}} \sum_{j=1}^{NS_i^{N,A}(t)} 1 = W_i^{N,A}(t) + \frac{1}{\sqrt{N}} \sum_{j=1}^{NS_i^{N,A}(t)} \frac{\alpha_{i,j}^N}{\bar{\alpha}_i^N}, \tag{2.4}$$

where we define

$$W_i^{N,A}(t) = \frac{1}{\sqrt{N}} \sum_{j=1}^{NS_i^{N,A}(t)} \left[1 - \frac{\alpha_{i,j}^N}{\bar{\alpha}_i^N}\right].$$

By the definitions of $\bar{S}_i^{N,A}(t)$ and $\hat{A}_i^N(n)$, we have (note that the upper limit of the sum is $N\bar{S}_i^{N,A}(t)$ here)

$$W_i^{N,A}(t) = \frac{1}{\sqrt{N}} \sum_{j=1}^{N\bar{S}_i^{N,A}(t)} \left[1 - \frac{\alpha_{i,j}^N}{\bar{\alpha}_i^N}\right] - r_i^{N,A}(t) \tag{2.4a}$$

$$= \hat{A}_i^N(N\bar{S}_i^{N,A}(t)) - r_i^{N,A}(t),$$

where $r_i^{N,A}(t)$ is either zero or $1/\sqrt{N}$ times the last term in the sum in (2.4a).

By the definition of λ_i^N and the fact that

$$\sum_{j=1}^{NS_i^{N,A}(t)} \alpha_{i,j}^N = Nt - \rho_i^N(t),$$

where $\rho_i^N(t)$ is Nt minus the time of the last arrival of a class i input before time Nt, we can write

$$A_i^N(t) = W_i^{N,A}(t) + \frac{1}{\sqrt{N}}\lambda_i^N[Nt - \rho_i^N(t)].$$

All the terms called ρ^N which are used below are either of similar origin (i.e., residual times) to the $\rho_i^N(t)$ above or are bounded by a constant times the sum of such expressions. *We will omit the subscripts and use the same symbol for all of them.*

We can similarly write, for $i = 1, 2$,

$$D_i^N(t) = \frac{1}{\sqrt{N}} \sum_{j=1}^{NS_i^{N,D}(t)} 1 = W_i^{N,D}(t) + \frac{1}{\sqrt{N}} \sum_{j=1}^{NS_i^{N,D}(t)} \frac{\Delta_{i,j}^N}{\bar{\Delta}_i^N}, \tag{2.5}$$

where we define

$$W_i^{N,D}(t) = \frac{1}{\sqrt{N}} \sum_{j=1}^{NS_i^{N,D}(t)} \left[1 - \frac{\Delta_{i,j}^N}{\bar{\Delta}_i^N}\right].$$

Recall that we defined $[\bar{\Delta}_i^N]^{-1} = \mu_i^N$. We can write (for $j \neq i, i = 1, 2$)

$$D_i^N(t) = W_i^{N,D}(t) + \frac{1}{\sqrt{N}}\mu_i^N\left[p_i Nt + \sqrt{N}G_j^N(t) - \sqrt{N}G_i^N(t) - \sqrt{N}L_i^N(t) - \rho^N(t)\right].$$

In getting this expression, we use the fact that the term in the square bracket in the above equation is $\sum_{j=1}^{NS_i^{N,D}(t)} \Delta_{i,j}^N$, the total time allocated to processing completed customers of class i by time Nt: the prior allocation plus the *net* reallocation minus the unused allocation of time minus the time ($\rho^N(t)$) spent on the current incompleted customer (if any).

Analogously to the "arrival" case, the definitions of $\bar{S}_i^{N,D}(t)$ and $\hat{D}_i^N(n)$ imply that (note that the upper limit of the sum is $N\bar{S}_i^{N,D}(t)$ here)

$$W_i^{N,D}(t) = \frac{1}{\sqrt{N}} \sum_{j=1}^{N\bar{S}_i^{N,D}(t)} \left[1 - \frac{\Delta_{i,j}^N}{\bar{\Delta}_i^N}\right] - r_i^{N,D}(t) \tag{2.5a}$$

$$= \hat{D}_i^N(N\bar{S}_i^{N,D}(t)) - r_i^{N,D}(t),$$

where $r_i^{N,D}(t)$ is either zero or $1/\sqrt{N}$ times the last term in the sum in (2.5a).

3. Dynamical equations and workload formulation. We now put the representations of the last section together. Define $\tilde{W}_i^N(t) = W_i^{N,A}(t) - W_i^{N,D}(t)$, $i = 1, 2$. Then we can write

$$\begin{aligned} Z_1^N(t) &= Z_1^N(0) + \tilde{W}_1^N(t) + \sqrt{N}t[\lambda_1^N - \mu_1^N p_1] \\ &\quad + \mu_1^N[G_1^N(t) - G_2^N(t) + L_1^N(t)] + \rho^N(t)/\sqrt{N}. \end{aligned} \tag{3.1a}$$

Analogously,

$$\begin{aligned} Z_2^N(t) &= Z_2^N(0) + \tilde{W}_2^N(t) + \sqrt{N}t[\lambda_2^N - \mu_2^N p_2] \\ &\quad + \mu_2^N[G_2^N(t) - G_1^N(t) + L_2^N(t)] + \rho^N(t)/\sqrt{N}. \end{aligned} \tag{3.1b}$$

The term $D_3^N(\cdot)$ can be treated analogously to what was done for the $D_1^N(\cdot)$, except that there is no reallocation now. Using such a representation, defining $\tilde{W}_3^N(t) = W_2^{N,D}(t) - W_3^{N,D}(t)$, and using the fact that $A_3^N(t) = D_2^N(t)$, we can write

$$\begin{aligned} Z_3^N(t) &= Z_3^N(0) + \tilde{W}_3^N + \sqrt{N}t[\mu_2^N p_2 - \mu_3^N] \\ &\quad + \mu_2^N[G_1^N(t) - G_2^N(t) - L_2^N(t)] + \mu_3^N L_3^N(t) + \rho^N(t)/\sqrt{N}. \end{aligned} \tag{3.1c}$$

The workload formulation. Define the workloads[2] for the Nth queueing system by

$$WL_1^N(t) = \frac{Z_1^N(t)}{\mu_1^N} + \frac{Z_2^N(t)}{\mu_2^N}, \quad WL_2^N(t) = \frac{Z_2^N(t) + Z_3^N(t)}{\mu_3^N}.$$

It was shown in [3, 2, 10, 11] that the workload concept is fundamental to the formulation of multiclass queueing problems and to the derivation of heavy traffic approximations to them. Define

$$W_1^N(t) = \frac{\tilde{W}_1^N(t)}{\mu_1^N} + \frac{\tilde{W}_2^N(t)}{\mu_2^N}, \quad W_2^N(t) = \frac{\tilde{W}_2^N(t) + \tilde{W}_3^N(t)}{\mu_3^N}.$$

The workload satisfies the equations

$$\begin{aligned} WL_1^N(t) &= WL_1^N(0) + W_1^N(t) + [L_1^N(t) + L_2^N(t)] \\ &\quad + \sqrt{N}t\left[\frac{\lambda_1^N}{\mu_1^N} - p_1\right] + \sqrt{N}t\left[\frac{\lambda_2^N}{\mu_2^N} - p_2\right] + \rho^N(t)/\sqrt{N}, \end{aligned} \tag{3.2}$$

$$\begin{aligned} WL_2^N(t) &= WL_2^N(0) + W_2^N(t) + L_3^N(t) \\ &\quad + \sqrt{N}t\left[\frac{\lambda_2^N}{\mu_3^N} - 1\right] + \rho^N(t)/\sqrt{N}. \end{aligned} \tag{3.3}$$

Representing the idle time terms in the above equations in terms of reflection terms and control functions. The idle time terms $L_1^N(\cdot) + L_2^N(\cdot)$ and $L_3^N(\cdot)$ in (3.2) and (3.3), respectively, might increase at times t at which the corresponding workloads (1 and 2, resp.)

[2]There is a problem in the literature with the use of W for different things. W is often used for both a Wiener and a workload process. Partially compromising with these traditions leads to our use of WL for the workload, and W for either a Wiener or an "almost" Wiener process.

are positive. Let $Y_i^N(\cdot), i = 1, 2$, denote the part of these terms which increases only when the corresponding workload (1 or 2, resp.) is zero. Define $F_i^N(\cdot)$ by

$$L_1^N(t) + L_2^N(t) = Y_1^N(t) + F_1^N(t), \quad L_3^N(t) = Y_2^N(t) + F_2^N(t). \tag{3.4}$$

To get some intuitive feeling for the formulation, it is worthwhile to discuss the physical meaning of the F^N-terms. The discussion which follows, however, is not used subsequently. We do not require any detailed knowledge of the optimal controls to do the proof.

Under an optimal control, $L_2^N(\cdot)$ would not increase at t unless $Z_1^N(t) = 0$, since we would not allocate service time to queue 2 when it is empty and queue 1 is not empty. However, it is conceivable that under an optimal control, service time will be allocated to queue 1 when it is empty but queue 2 is not. This would happen, for example, if the cost of waiting at queue 3 is relatively large and $Z_3^N(t) > 0$. In this case, we might prefer not to add new customers to queue 3 until it drops below a certain level. Thus, under an optimal control, the term $F_1^N(\cdot)$ represents the part of $L_1^N(\cdot)$ which increases when queue 2 is not empty. Of course, if we are not using an optimal control, then $F_1^N(\cdot)$ represents the increase in $L_1^N(\cdot) + L_2^N(\cdot)$ at those times that either $Z_1^N(t)$ or $Z_2^N(t)$ are positive. Under an optimal control, $F_2^N(\cdot)$ represents the part of $L_3^N(\cdot)$ which increases when $Z_2^N(t) \neq 0$ and $Z_3^N(t) = 0$, and we expect that it would be close to zero for large N. If we shut processor 2 off when $Z_3^N(t) > 0$, then $F_2^N(\cdot)$ would also increase at those times, although this is not an optimal procedure.

The cost function of interest. The $G^N(\cdot) = (G_i^N(\cdot), i = 1, 2)$ and $L^N(\cdot)$ determine the $F^N(\cdot) = (F_i^N(\cdot), i = 1, 2)$ and $(G^N(\cdot), F^N(\cdot))$ determines $L^N(\cdot)$. It will be convenient to consider the pair $(G^N(\cdot), F^N(\cdot))$ as the control, although the (G, L)-terms will not show up in the limit workload equations, and only the F-terms remain. For $c_i > 0, \beta > 0$, and $Z^N(0) = z$, define the cost

$$V^N(z, G^N, F^N) = E \int_0^\infty e^{-\beta t} \sum_{i=1}^3 c_i Z_i^N(t) dt,$$

$$\bar{V}^N(z) = \inf_{F,G} V^N(z, G, F).$$

Now, using (2.1), (2.2), and the definitions of the $F^N(\cdot), Y^N(\cdot)$, rewrite the workload equations as

$$\begin{aligned} WL_1^N(t) &= WL_1^N(0) + W_1^N(t) + Y_1^N(t) + F_1^N(t) - b_1 t + \rho^N(t)/\sqrt{N} + \delta_1^N(t), \\ WL_2^N(t) &= WL_2^N(0) + W_2^N(t) + Y_2^N(t) + F_2^N(t) - b_2 t + \rho^N(t)/\sqrt{N} + \delta_2^N(t), \end{aligned} \tag{3.5}$$

where the $\delta_i^N \to 0$ and are due to the use of (2.1), (2.2) and are ignored henceforth. Note that the only explicit influence of $G^N(\cdot)$ on the workload process is via the $F^N(\cdot)$-terms.

4. The workload cost transformation and limit problem. The full exploitation of the workload concept occurs via the following transformation of the cost function which allows one to view the workload equations as the primary system equations, at least in the heavy traffic limit [2, 3, 8, 10, 11]. Define $g(z) = \sum c_i z_i$, $w_1^N(z) = z_1/\mu_1^N + z_2/\mu_2^N$, $w_2^N(z) = (z_2 + z_3)/\mu_3^N$. For each $w = (w_1, w_2)$ with $w_i \geq 0$, define

$$\bar{g}^N(w) = \min\{g(z) : w_1^N(z) = w_1, w_2^N(z) = w_2, z_i \geq 0\}. \tag{4.1}$$

We can thus write

$$g(z) = \bar{g}^N(w^N(z)) + \tilde{g}^N(z), \ \tilde{g}^N(z) \geq 0. \tag{4.2}$$

Let $\bar{z}^N(w)$ denote the minimizing value of z in (4.1). We also define the "limit quantities" analogously: $w_1(z) = z_1/\mu_1 + z_2/\mu_2$, $w_2(z) = (z_2 + z_3)/\mu_3$, and

$$\bar{g}(w) = \min\{g(z) : w_1(z) = w_1, w_2(z) = w_2, z_i \geq 0\}.$$

We note that there are $\epsilon_i^N \to 0$ as $N \to \infty$ such that

$$|w^N(z) - w(z)| \leq \epsilon_1^N |z|, \quad |\bar{g}^N(w) - \bar{g}(w)| \leq \epsilon_2^N |w|,$$

and $\bar{g}(w)$, $\bar{g}^N(w)$, $\tilde{g}(z)$, $\tilde{g}^N(z)$ have at most (uniform) linear growth.

From the reformulation in terms of workload, it is suggested that the individual classes have essentially disappeared, and that there is now one equation in (3.5) for each processor. Suppose that, given the current values $WL^N(t) = w(Z^N(t)) = w$, $Z^N(t) = z$, we are able to "instantaneously and freely" rearrange the queues in such a way that the workload is conserved but the minimal cost point $\bar{g}^N(w)$ is attained. Then, ignoring the small terms $\rho^N(\cdot)/\sqrt{N}$ and the possible policy dependence of the $W_i^N(\cdot)$, the only control appears to be the $F^N(\cdot)$. This formal point of view will be validated in the limit as $N \to \infty$. (It will also be shown in the proof that the $W_i^N(\cdot)$ are asymptotically independent of the policy, for reasonable policies.)

The limit problem. The correct equations for the limit workload problem will turn out to be

$$\begin{aligned} WL_1(t) &= WL_1(0) + W_1(t) + Y_1(t) + F_1(t) - b_1 t, \\ WL_2(t) &= WL_2(0) + W_2(t) + Y_2(t) + F_2(t) - b_2 t, \end{aligned} \tag{4.3}$$

where the $W_i(\cdot)$ are Wiener processes with variances

$$E[W_1(1)]^2 = \frac{\lambda_1}{\mu_1^2}(\sigma_{1,A}^2 + \sigma_{1,D}^2) + \frac{\lambda_2}{\mu_2^2}(\sigma_{2,A}^2 + \sigma_{2,D}^2), \tag{4.4a}$$

$$E[W_2(1)]^2 = \frac{\lambda_2}{\mu_3^2}(\sigma_{2,A}^2 + \sigma_{3,D}^2), \tag{4.4b}$$

$$EW_1(1)W_2(1) = \frac{\lambda_2}{\mu_2\mu_3}\sigma_{2,A}^2. \tag{4.4c}$$

In (4.3), the $Y_j(\cdot)$ are the minimal nondecreasing processes such that the $WL_i(\cdot)$ are nonnegative and the $F_i(\cdot)$, $i = 1, 2$ are arbitrary, nonanticipative, nondecreasing controls (singular controls). For $WL(0) = w$, the associated cost is

$$V(w, F) = E\int_0^\infty e^{-\beta t}\bar{g}(WL(t))dt, \tag{4.5}$$

and we define

$$\bar{V}(w) = \inf_F V(w, F).$$

The problem can be broken into the two following fundamental cases, according to the value of the minimizer in (4.1) [8].

Case 1. $c_1\mu_1^N + c_3\mu_2^N \leq c_2\mu_2^N$. Then the optimizing value in (4.1) is $\bar{z}_2(w) = 0$, and

$$\bar{g}^N(w) = c_1\mu_1^N w_1 + c_3\mu_3^N w_2.$$

To approximate this value as closely as possible requires that queue 2 have priority over queue 1 and $F^N(t) = 0$. There is no control problem (see [8]).

Case 2. $c_1\mu_1^N + c_3\mu_2^N > c_2\mu_2^N$. In this case, the minimizer of the linear program (4.1) depends on the region of the nonnegative quadrant to which (w_1, w_2) belongs:

(4.6a) If $\mu_3^N w_2 > \mu_2^N w_1$ or, equivalently, $z_3 > \mu_2^N z_1/\mu_1^N$,

then the optimizing value $\bar{z}(w)$ is

(4.7a) $$\bar{z}_1(w) = 0,\ \bar{z}_2(w) = \mu_2^N w_1,\ \bar{z}_3(w) = \mu_3^N w_2 - \mu_2^N w_1,$$

and we have

(4.8a) $$\bar{g}^N(w) = [c_2\mu_2^N - c_3\mu_2^N]w_1 + c_3\mu_2^N w_2.$$

(4.6b) If $\mu_3^N w_2 \le \mu_2^N w_1$ or, equivalently, $z_3 \le \mu_2^N z_1/\mu_1^N$,

then the optimizing values are given by

(4.7b) $$\bar{z}_3(w) = 0, \quad \bar{z}_1(w) = \frac{\mu_1^N}{\mu_2^N}[\mu_2^N w_1 - \mu_3^N w_2], \quad \bar{z}_2(w) = \mu_3^N w_2,$$

and we have

(4.8b) $$\bar{g}^N(w) = c_1\mu_1^N w_1 + \frac{\mu_3^N}{\mu_2^N}[c_2\mu_2^N - c_1\mu_1^N]w_2.$$

Since the μ_i^N depend on N, it is conceivable that one could switch infinitely often between Cases 1 and 2 as $N \to \infty$. In order to avoid this minor annoyance, we suppose that only one of the cases holds for all N.

Note that Case 2 is equivalent to $\bar{z}_1(w)\bar{z}_3(w) = 0$. Under (4.6a), $\bar{z}_1(w) = 0$ and $\bar{z}_3(w) > 0$. To approximate this for the physical system, queue 1 has priority, and we continue to give queue 1 priority until queue 3 is zero, when (4.6b) takes over. To attain the minimizer in (4.7b) requires that queue 1 again have priority, but (loosely speaking) we must avoid "starving" queue 3. Thus, when queue 3 is zero, "briefly" serve queue 2. This rough description ignores some details, such as the possible introduction of idleness in processor 1. Full details are in the proof in the next section, and we see that the main purpose of the $G^N(\cdot)$ is to bring us close to this strategy for large N.

5. The main theorem: Uniqueness of the solution to (4.3). We use $D^k[0, \infty)$, the space of CADLAG functions, for appropriate integers k, with the Skorohod topology as the canonical sample space. Given the distribution of $(F(\cdot), W(\cdot), WL(0))$, with $(F(\cdot), WL(0))$ nonanticipative with respect to $W(\cdot)$, the distribution of the process $(WL(\cdot), F(\cdot), W(\cdot), Y(\cdot))$ is determined uniquely.

The following lemmas will be useful in the proof of the main theorem.

LEMMA 5.1. *Given any* ϵ, *for each* $w = WL(0)$ *there are a* $T(\epsilon) > 0$ *and an* ϵ*-optimal control* $F^\epsilon(\cdot)$ *for* (4.3), (4.5) *such that* $F^\epsilon(\cdot)$ *is constant after time* $T(\epsilon)$.

Proof. It is easily verified that the policy with the "zero control" $F(t) \equiv 0$ has finite cost. In general, we have

$$F_j(t) + Y_j(t) = WL_j(t) - WL_j(0) + b_j t - W_j(t).$$

For any policy with finite cost this implies that

(5.1) $$E\int_0^\infty e^{-\beta t}(F_j(t) + Y_j(t))\,dt < \infty.$$

Now fix T and define the policy $F^T(\cdot)$ by

$$F^T(t) = F(t) \text{ if } t \le T$$

and

$$F^T(t) = F(T) \text{ if } t \ge T.$$

We can suppose without loss of generality that we have processes $WL^T(\cdot)$, $WL(\cdot)$ defined on the same sample space and driven by the *same* Wiener process $W(\cdot)$ and with controls $F^T(\cdot)$, $F(\cdot)$, respectively. Denote the corresponding reflection terms by $Y^T(\cdot)$, $Y(\cdot)$. We clearly have

$$E\int_0^\infty e^{-\beta t}(F_j^T(t) + Y_j^T(t))\,dt < \infty. \tag{5.2}$$

Then, for $t > T$,

$$WL_j(t) - WL_j^T(t) = F_j(t) - F_j(T) + Y_j(t) - Y_j^T(t) \ge 0,$$

and (5.1) and the Lipschitz continuity of $\bar g(\cdot)$ imply that

$$|\bar g(WL(t)) - \bar g(WL^T(t))| \le \gamma \sum_j [F_j(t) - F_j(T) + Y_j(t) - Y_j^T(t)], \quad t > T,$$

where γ is the Lipschitz constant. This gives

$$\begin{aligned}
&E\int_0^\infty e^{-\beta t}|\bar g(WL(t)) - \bar g(WL^T(t))|\,dt \\
&= E\int_T^\infty e^{-\beta t}|\bar g(WL(t)) - \bar g(WL^T(t))|\,dt \\
&\le \gamma E\int_T^\infty e^{-\beta t}\sum_j [F_j(t) - F_j(T) + Y_j(t) - Y_j^T(t)]\,dt \\
&\le \gamma E\int_T^\infty e^{-\beta t}\sum_j (F_j(t) + Y_j(t))\,dt,
\end{aligned}$$

but, by (5.1) and the monotone convergence theorem, the right-hand term above goes to zero as $T \to \infty$. This proves that the cost of the control $F^T(\cdot)$ converges to the cost of the control $F(\cdot)$ as T goes to infinity. The lemma follows if we take $F^\epsilon(\cdot)$ to be a $\epsilon/2$-optimal policy, and $T = T(\epsilon)$ suitably large. □

LEMMA 5.2. *Fix $\epsilon > 0$ and $WL(0) = w$. For each w, there are $T(\epsilon) > 0$, an integer K, $\Delta > 0$, $0 < \Delta_1 < \Delta$, $\rho > 0$, and an ϵ-optimal control $F^\epsilon(\cdot)$ for* (4.3), (4.5) *satisfying the following properties:*

(a) *$F^\epsilon(\cdot)$ is constant in each of the intervals $[k\Delta, (k+1)\Delta)$ and on $[T(\epsilon), \infty)$, and only one of the two components can increase at each $k\Delta$.*

(b) *$F^\epsilon(n\Delta + \Delta) - F^\epsilon(n\Delta) \equiv \delta F^\epsilon(n\Delta)$ takes values in the discrete set $\{j\rho : j = 0, 1, \dots, K\}$.*

(c) *For $n = 0, \dots$, $j = 0, \dots, K$, $i = 1, 2$, there are functions $q_{nji}(\cdot)$ such that the choice of $F^\epsilon(\cdot)$ according to the probability law* (5.3) *gives a (possibly randomized) ϵ-optimal control whose sample paths satisfy* (a) *and* (b)*:*

$$\begin{aligned}
&q_{nji}(\delta F^\epsilon(m\Delta), m < n, W(l\Delta_1), l\Delta_1 \le n\Delta) \\
&= P\{\delta F_i^\epsilon(n\Delta) = j\rho | \delta F^\epsilon(m\Delta), m < n, W(l\Delta_1), l\Delta_1 \le n\Delta\},
\end{aligned} \tag{5.3}$$

and $q_{nji}(\cdot)$ is continuous in the W-variables for each choice of the other variables.

Comment on the proof. Given the previous lemma and the weak sense uniqueness of the solution to (4.3), the proof is identical to the proof of the analogous result in [9, Thms. 15, 16], and is omitted. (The solution is also pathwise unique, but that fact is not needed in the proof.)

THEOREM 5.3. *Let* $Z^N(0) = z^N \to z$ *as* $N \to \infty$. *Then, under the conditions of* §2, *as* $N \to \infty$,

$$\bar{V}^N(z^N) \to \bar{V}(w(z)). \tag{5.4}$$

Proof. Part 1. In all of the weak convergence analysis, we use the Skorohod topology on $D^k[0, \infty)$ [1] for appropriate integers k.

In this part of the proof we prove, for a class of "good" policies, certain bounds and the weak convergence of the processes associated with the limit Wiener processes. These will be used to prove both the lower bound (5.7) and the upper bound (5.12).

Let $T < \infty$ and $\epsilon > 0$. Owing to the fact that the interarrival and service intervals have uniformly bounded third absolute moments, the $\rho^N(\cdot)$ processes are tight and $\lim_N E|\rho^N(t)|/\sqrt{N} = 0$ in all cases. Also, $\{\rho^N(t)/\sqrt{N}, N, t\}$ is uniformly integrable. Let $\bar{G}^N(\cdot)$, $\bar{F}^N(\cdot)$ be a sequence of controls for which $\liminf_{N\to\infty} V^N(z^N, \bar{G}^N, \bar{F}^N) < \infty$. Let us abuse terminology and let N index an "infimizing sequence in the "liminf" above.

Recall from formulas (2.4a) and (2.5a) that

$$W_i^{N,A}(t) = \hat{A}_i^N(N\bar{S}_i^{N,A}(t)) - r_i^{N,A}(t),$$
$$W_i^{N,D}(t) = \hat{D}_i^N(N\bar{S}_i^{N,D}(t)) - r_i^{N,D}(t),$$

where the arrival/departure r-terms are bounded by

$$\frac{1}{\sqrt{N}}(1 + \text{ time between last arrival/departure before } Nt \text{ and first after } Nt).$$

The r-terms are of the same type as, and will be absorbed into, the ρ-terms.

By the comments in §2 concerning the martingale properties of the $\hat{A}_i^N(n)$ and $\hat{D}_i^N(n)$ and stopping time properties of the $N\bar{S}_i^{N,A}(t)$ and $N\bar{S}_i^{N,D}(t)$, the processes $\hat{A}_i^N(N\bar{S}_i^{N,A}(t))$ and $\hat{D}_i^N(N\bar{S}_i^{N,D}(t))$ are continuous-parameter martingales (with respect to the "natural σ-algebras).

The above comments and representations in terms of the martingales (modulo small errors) imply that the mean square value of $W_i^{N,A}(t)$ is bounded above (modulo $O(1/N)$) by a constant times $ES_i^{N,A}(t)$.

We have $\limsup_N [ES_i^{N,A}(t)/\lambda_i^N t] \le 1$. Also, no matter what policy is being used, we have $S_i^{N,D}(t) \le S_i^{N,A}(t)$ for all t. This then implies a similar bound for $E[W_i^{N,D}(t)]^2$. Thus, for some constant C_1 independent of N,

$$\limsup_N EW_i^{N,A}(t)^2 \le C_1 t, \quad \limsup_N EW_i^{N,D}(t)^2 \le C_1 t. \tag{5.5a}$$

A similar argument and Doob's inequality yields

$$\limsup_n E \sup_{s\le t} W_i^{N,A}(s)^2 \le 4C_1 t, \quad \limsup_N E \sup_{s\le t} W_i^{N,D}(s)^2 \le 4C_1 t. \tag{5.5b}$$

We claim that

$$\limsup_{N\to\infty} E\bar{F}_i^N(t) < \infty, \text{ each } t < \infty. \tag{5.6}$$

To prove this, we note first that $EY_i^N(t) \leq \text{constant(t)} + E\max_{s\leq t}|W_i^N(s)|$ which, together with (5.5), yields $\sup_N EY_i^N(t) < \infty$ for each t. Thus, failure of the assertion (5.6) yields that $EWL^N(s)$ (and hence $EZ^N(s)$) becomes arbitrarity large on some interval after t, as $N \to \infty$. This implies that the costs go to infinity as $N \to \infty$, a contradiction.

These arguments also imply that $\limsup_N E\sup_{s\leq t}|Z^N(s)| < \infty$. Equivalently, by the definition of $Z_i^N(t)$,

$$E\sup_{s\leq t}\frac{\text{number of class } i \text{ arrivals by } Nt \text{ not served by } Nt}{\sqrt{N}} < \infty.$$

This can be written as (using $S_3^{N,A}(\cdot) = S_2^{N,D}(\cdot)$)

$$\limsup_{N\to\infty} E\sup_{s\leq t}\sqrt{N}(S_i^{N,A}(s) - S_i^{N,D}(s)) < \infty,\ i = 1, 2, 3.$$

A functional law of large numbers implies that $S_i^{N,A}(\cdot)$ converges weakly to the constant process with values $\lambda_i t$. Thus, for $i = 1, 2$, $S_i^{N,D}(\cdot)$ converges weakly to the process with values $\lambda_i t$, and $S_3^{N,D}(\cdot)$ converges weakly to the process with values $\lambda_2 t$.

Using the cited convergences of the $S_i^{N,A}(\cdot)$, $S_i^{N,D}(\cdot)$ and the martingale properties of the $\hat{A}_i^N(N\bar{S}_i^{N,A}(\cdot))$ and $\hat{D}_i^N(N\bar{S}_i^{N,D}(\cdot))$ and standard arguments such as those associated with equation (2.6) of [9] or with the B^ϵ-terms in (3.10) of [7, Lem. 5.2], it follows that the $W_i^{N,A}(\cdot)$, $W_i^{N,D}(\cdot)$ are tight, with all weak limits being Wiener processes. Using the definitions of the $W_i^N(\cdot)$, it now follows that these latter sequences are tight and all limits are Wiener processes. The calculation of the variance parameters (4.4) follow from the corresponding values for the prelimit processes.

Part 2. We next prove the lower bound

$$\liminf_N \bar{V}^N(z_N) \geq \bar{V}(w(z)). \tag{5.7}$$

We will use a weak convergence argument. This will be a little indirect, since in general it is not possible to prove tightness of $\bar{F}^N(\cdot)$. In [5, Chap. 11.1.2] and [6, §4] a very useful time rescaling idea was introduced which greatly simplified the treatment of weak convergence issues for "singular" or "reflected" cases. That method will be used here.

Define $T^N(t) = t + \bar{F}_1^N(t) + \bar{F}_2^N(t)$, and its inverse $\hat{T}^N(t) = \inf\{s : T^N(s) > t\}$. Define the "hat" processes by the time transformation: $\hat{Z}^N(t) = Z^N(\hat{T}^N(t))$, $\hat{F}^N(t) = \bar{F}^N(\hat{T}^N(t))$, etc. Note that the transformation "stretches out" time and that $\hat{F}_i^N(\cdot)$ are Lipschitz continuous with constant ≤ 1. (In the references, the Y^N-processes were included in the $T^N(t)$, but that is not needed here.) Then

$$\hat{WL}_i^N(t) = WL_i^N(0) + \hat{W}_i^N(t) + \hat{Y}_i^N(t) + \hat{F}_i^N(t) - b_i\hat{T}^N(t) + \hat{\rho}^N(t)/\sqrt{N},$$

where $\hat{Y}_i^N(\cdot)$ is the reflection process at the boundary segment $w_i = 0$.

The set

$$\{\hat{WL}^N(\cdot), \hat{F}^N(\cdot), \hat{W}^N(\cdot), \hat{T}^N(\cdot), \hat{Y}^N(\cdot), W^N(\cdot)\}$$

is tight, all weak limits are continuous, and $\hat{\rho}^N(\cdot)/\sqrt{N}$ converges to the zero process. Let $\hat{WL}(\cdot)$, $\hat{F}(\cdot)$, $\hat{W}(\cdot)$, $\hat{T}(\cdot)$, $\hat{Y}(\cdot)$, $W(\cdot)$ denote the limit of an arbitrary weakly convergent subsequence. We have $\hat{W}(t) = W(\hat{T}(t))$. The limit processes satisfy

$$\hat{WL}_i(t) = WL_i(0) + \hat{W}_i(t) + \hat{Y}_i(t) + \hat{F}_i(t) - b_i\hat{T}(t). \tag{5.8}$$

By standard weak convergence and martingale arguments it can be shown that the other processes in (5.8) are nonanticipative with respect to the (stretched out) Wiener process $\hat{W}(\cdot)$.

Using the fact that $w(\hat{Z}^N(t)) = \hat{WL}^N(t)$ and $g(z) \geq \bar{g}^N(w^N(z))$ and changing the time scale yield

$$
\begin{aligned}
V^N(z^N, \bar{G}^N, \bar{F}^N) &= E\int_0^\infty e^{-\beta t} g(Z^N(t))dt \\
&= E\int_0^\infty e^{-\beta \hat{T}^N(t)} g(\hat{Z}^N(t))d\hat{T}^N(t) \\
&\geq E\int_0^\infty e^{-\beta \hat{T}^N(t)} \bar{g}^N(\hat{WL}^N(t))d\hat{T}^N(t) \\
&= E\int_0^\infty e^{-\beta \hat{T}^N(t)} \bar{g}(\hat{WL}^N(t))\, d\hat{T}^N(t) \\
&\quad + E\int_0^\infty e^{-\beta \hat{T}^N(t)} [\bar{g}^N(\hat{WL}^N(t)) - \bar{g}(\hat{WL}^N(t))]\, d\hat{T}^N(t).
\end{aligned} \tag{5.9}
$$

There is $\epsilon_N \to 0$ and a constant K such that the last term is bounded above by

$$
\epsilon_N E\int_0^\infty e^{-\beta \hat{T}^N(t)} |\hat{WL}^N(t)| d\hat{T}^N(t) \leq K\epsilon_N V^N(z^N, \bar{G}^N, \bar{F}^N),
$$

which goes to zero. Also, by the weak convergence and Fatou's lemma,

$$
\liminf_N E\int_0^\infty e^{-\beta \hat{T}^N(t))} \bar{g}(\hat{WL}^N(t))d\hat{T}^N(t) \geq E\int_0^\infty e^{-\beta \hat{T}(t))} \bar{g}(\hat{WL}(t))d\hat{T}(t). \tag{5.10}
$$

Now define the inverse $T(t) = \inf\{s : \hat{T}(s) > t\}$. (See [5, p. 312] or [6, Thm. 5.3] for a similar transformation and application.) Since $\hat{T}^N(t) \leq t, \hat{T}(t) \leq t$. Since $\limsup_N E\bar{F}_i^N(t) < \infty$ for each t, $\hat{T}(t)$ goes to infinity with probability one as $t \to \infty$. Hence, $T(t) \to \infty$ as $t \to \infty$ with probability one. It is also right continuous. Define the rescaled processes by $WL(t) = \hat{WL}(T(t))$, $F(t) = \hat{F}(T(t))$, etc. The rescaled processes satisfy (4.3), the other rescaled processes are nonanticipative with respect to the Wiener process $W(\cdot)$, and $Y(\cdot)$ is the reflection process. We now see that the right side of (5.10) equals

$$
E\int_0^\infty e^{-\beta t} \bar{g}(WL(t))dt = V(w(z), F).
$$

By the minimality of $\bar{V}(w(z))$,

$$
V(w(z), F) \geq \bar{V}(w(z)). \tag{5.11}
$$

Now (5.9)–(5.11) and the fact that $\bar{G}^N(\cdot)$, $\bar{F}^N(\cdot)$ are arbitrary controls with finite cost yields (5.7).

Part 3. Now we need to get the reverse inequality to (5.7), namely,

$$
\limsup_N \bar{V}^N(z^N) \leq \bar{V}(w(z)). \tag{5.12}
$$

This will be done via a standard "comparison control" method (see [5, 6]) and using the time transformation idea of Part 2. Fix $\epsilon > 0$ and let $F^\epsilon(\cdot)$ be an ϵ-optimal policy for (4.3), (4.5) defined by the $q_{nji}(\cdot)$ conditional probability functions in Lemma 5.2, and with the properties

given in Lemma 5.2. Recall that the conditional distribution of the jumps of $F^\epsilon(\cdot)$ at time $n\Delta$ is given by the functions q_{nij} of (5.3). We write

$$WL(t) = w(z) + W(t) + F^\epsilon(t) + Y(t) - bt. \tag{5.13}$$

We will adapt the $F^\epsilon(\cdot)$ strategy to the physical process by appropriately adapting the $q_{nji}(\cdot)$ rules, and then use the optimality of $\bar{V}^N(z^N)$ to get the desired result.

Denote the *desired* adaptation of $F^\epsilon(\cdot)$ to the physical system by $F^N_\epsilon(\cdot)$. The subscript ϵ will be used to denote the various processes ($WL^N_\epsilon(\cdot)$, $W^N_\epsilon(\cdot)$, etc.) associated with the adaptation of the $F^\epsilon(\cdot)$ to the physical system. Define a set of random variables $\delta\bar{F}^N_\epsilon(n\Delta) = (\delta\bar{F}^N_{\epsilon,1}(n\Delta), \delta\bar{F}^N_{\epsilon,2}(n\Delta))$ in such a way that

$$\begin{aligned} &q_{nji}(\delta\bar{F}^N_\epsilon(m\Delta), m < n, W^N_\epsilon(l\Delta_1), l\Delta_1 \le n\Delta) \\ &\quad = P\{\delta\bar{F}^N_{\epsilon,i}(n\Delta) = j\rho | \delta\bar{F}^N_\epsilon(m\Delta), m < n, W^N_\epsilon(l\Delta_1), l\Delta_1 \le n\Delta\}. \end{aligned} \tag{5.14}$$

We would like the conditional distribution of the jumps of $F^N_\epsilon(\cdot)$ at time $n\Delta$ to be exactly equal to $\delta\bar{F}^N_\epsilon(n\Delta)$. However, the $F^N_\epsilon(\cdot)$ cannot be realized as a "pure jump" process, as can the $F^\epsilon(\cdot)$, since the only physical influence that we have over the $F^N_\epsilon(\cdot)$ is via manipulation of the idle times and sequencing of the customer classes at processor 1. But there will be $\delta'_N \to 0$ such that for each n, the $\delta\bar{F}^N_\epsilon(n\Delta)$ are realized by $F^N_\epsilon(\cdot)$ on $[n\Delta, n\Delta + \delta'_N]$, with probability close to one as $N \to \infty$. By "realizing" $\delta\bar{F}^N_{\epsilon,i}(n\Delta)$ on an interval $[n\Delta, t]$, $t \le n\Delta + \Delta$, we mean that $F^N_{\epsilon,i}(t) - F^N_{\epsilon,i}(n\Delta) = \delta\bar{F}^N_{\epsilon,i}(n\Delta)$.

The $F^N_\epsilon(\cdot)$ which will be constructed below will be bounded by the bound on the $F^\epsilon(\cdot)$ and will not increase after time $T(\epsilon)$. Thus, for each $T_1 < \infty$,

$$\sup_N E \sup_{t \le T_1} |Z^N(t)|^2 < \infty. \tag{5.15a}$$

It is easy to verify by a direct calcualation that there are real numbers k_i such that for all $t < \infty$

$$\sup_N E|WL^N(t)| \le k_1 + k_2 t. \tag{5.15b}$$

Equations (5.15a) and (5.15b) imply that as long as $F^N_\epsilon(\cdot)$ is uniformly bounded, nonanticipative, and constant after some $T(\epsilon)$ (no matter how the terms are realized), we have that

$$\lim_T \limsup_N E \int_T^\infty e^{-\beta t} |WL^N_\epsilon(t)| dt = 0, \tag{5.15c}$$

and then it follows that

$$\lim_T \limsup_N E \int_T^\infty e^{-\beta t} |Z^N_\epsilon(t)| dt = 0. \tag{5.15d}$$

Keep in mind that the control constructed below is used only to prove (5.12), and is not a practical control.

In the first two cases (0a, 0b) and (1a, 1b) below, we modify the problem as follows. If $Z^N_{\epsilon,3} = 1/\sqrt{N}$ and $Z^N_{\epsilon,2}(t) > 0$ and we are serving queue 2, then if the current service at queue 3 is completed before the current service at queue 2, extend the service at queue 3 until the next customer arrives there so that queue 3 is not empty in this event. This does not affect the truth of (5.15a)–(5.15d). Also, if (5.12) holds with this modification it holds without it, since the modification does not decrease the costs. The modification serves to assure that $F^N_{\epsilon,2}(\cdot)$

will not increase in this interval due to queue 3 waiting for a customer when a nonempty queue 2 is being served. Recall that (Lemma 5.2) at most one component of $\bar{F}^{\epsilon}(\cdot)$ can increase at a time, hence at most one component of $\delta\bar{F}^N_{\epsilon}(n\Delta)$ can be positive for each n. Let ϵ_N be a sequence of positive numbers going to zero and satisfying $\epsilon_N\sqrt{N} \to \infty$.

First, suppose that at $t = n\Delta$, the sample that (5.14) tells us to realize is $\delta\bar{F}^N_{\epsilon}(n\Delta) = 0$. Then follow the steps (0a, 0b) below until time $(n\Delta + \Delta)$. Processor 2 continues to work when there is work to do.

(0a) Serve queue 1 until either $\{Z^N_{\epsilon,1}(t) = 0$ *and* $Z^N_{\epsilon,2}(t) > 0\}$ or $\{Z^N_{\epsilon,3}(t) \le \epsilon_N$ *and* $Z^N_{\epsilon,2}(t) > 0\}$ and then go to (0b).

(0b) Serve queue 2 until either $Z^N_{\epsilon,2}(t) = 0$ or $\{Z^N_{\epsilon,1}(t) \ge \epsilon_N$ *and* $Z^N_{\epsilon,3}(t) > \epsilon_N\}$. Then go to (0a).

By (5.15a) and the above rules, for any $\epsilon' > 0$

$$\lim_N P\{Z^N_{\epsilon,1}(t)Z^N_{\epsilon,3}(t) \ge \epsilon'\} = 0, \quad t \in (n\Delta, n\Delta + \Delta]. \tag{5.16}$$

By (5.16), the fact that $|\tilde{g}^N(z)| \le k_0 + k_1|z|$ for some real k_i, the fact that $\tilde{g}^N(z) \to 0$ uniformly on any compact set as $z_1 z_3 \to 0$, and the uniform integrability (5.15d), we have

$$\begin{gathered} \lim_N E\tilde{g}^N(Z^N_{\epsilon}(t)) = 0, \quad t \in (n\Delta, n\Delta + \Delta], \\ \sup_{t,N} E\tilde{g}^N(z^N(t)) < \infty. \end{gathered} \tag{5.17}$$

Note that the procedure (0a, 0b) does not increase the F^N_{ϵ}-term. While the $G^N_{\epsilon}(\cdot)$-terms do not appear explicitly above, they represent the part of the given rule which guarantees (5.16).

Now suppose that the realization that we aim for at time $n\Delta$ is $\delta\bar{F}^N_{\epsilon,1}(n\Delta) > 0$. Then follow the steps (1a, 1b) below until time $(n\Delta + \Delta)$ is reached. Processor 2 continues to work when there is work to do.

(1a) Processor 1 serves queue 1 only (or idles when $Z^N_{\epsilon,1}(t) = 0$) until either $Z^N_{\epsilon,3}(t) \le \epsilon_N$ or $\delta\bar{F}^N_{\epsilon,1}(n\Delta)$ is realized. In the second case, go to (0a). In the first case, if $Z^N_{\epsilon,2}(t) > 0$ go to (1b). Otherwise serve queue 1 or idle (if $Z^N_{\epsilon,1}(t) = 0$) until $Z^N_{\epsilon,2}(t) > 0$, and then go to (1b).

(1b) Processor 1 serves queue 2 or idles (if $Z^N_{\epsilon,2}(t) = 0$) until either $Z^N_{\epsilon,3}(t) \ge \epsilon_N$ or $\delta\bar{F}^N_{\epsilon,1}(n\Delta)$ is realized, whichever comes first. In the first case, go to (1a), and in the second go to (0a).

The increase in $F^N_{\epsilon,1}(\cdot)$ is due to the idling of processor 1 when either queue 1 or 2 is nonzero. There are $\delta'_N \to 0$ such that the probability that the desired magnitude $\delta\bar{F}^N_{\epsilon,1}(n\Delta)$ is realized on $[n\Delta, n\Delta + \delta'_N]$ goes to unity as $N \to \infty$. Note that (5.16), (5.17) continue to hold, and that $F^N_{\epsilon,2}(\cdot)$ does not change on the interval.

Next, suppose that our aim is to realize $\delta\bar{F}^N_{\epsilon,2}(n\Delta) > 0$. Then follow (2a) below until time $(n\Delta + \Delta)$ is reached.

(2a) Shut down processor 2 and serve both queues 1 and 2, with queue 1 given priority. If $\delta\bar{F}_{\epsilon,2}(n\Delta)$ is realized then go to (0a).

Note that $F^N_{\epsilon,1}(\cdot)$ doesn't increase during this last procedure, and that (5.16), (5.17) hold. The increase in $F^N_{\epsilon,2}(\cdot)$ is due to the idling of processor 2 and the fact that queue 2 continues to be served when queue 1 is empty.

We now use the time transformation $\hat{T}^N(t)$ of Part 2 (to be called $\hat{T}^N_{\epsilon}(t)$ here). Abusing notation, let us henceforth use N to index a weakly convergent subsequence of the

$$\{\hat{WL}^N_{\epsilon}(\cdot), \hat{F}^N_{\epsilon}(\cdot), \hat{W}^N_{\epsilon}(\cdot), \hat{T}^N_{\epsilon}(\cdot), \hat{Y}^N_{\epsilon}(\cdot), W^N_{\epsilon}(\cdot)\}.$$

Denote the limit by $(\hat{WL}_{\epsilon}(\cdot), \hat{F}_{\epsilon}(\cdot), \hat{W}_{\epsilon}(\cdot), , \hat{T}_{\epsilon}(\cdot), \hat{Y}_{\epsilon}(\cdot), W_{\epsilon}(\cdot)$. As in Part 2 of the proof,

$$WL_{\epsilon}(t) = w(z) + \hat{W}_{\epsilon}(\cdot) + \hat{F}_{\epsilon}(\cdot) - b\hat{T}_{\epsilon}(t) + \hat{Y}_{\epsilon}(\cdot). \tag{5.18}$$

We have

$$V^N(z^N, G_\epsilon^N, F_\epsilon^N) = E\int_0^\infty e^{-\beta t} g(Z_\epsilon^N(t))dt$$
$$= E\int_0^\infty e^{-\beta t}\bar{g}^N(WL_\epsilon^N(t))dt + E\int_0^\infty e^{-\beta t}\tilde{g}^N(Z_\epsilon^N(t))dt.$$

By (5.17) the term with $\tilde{g}^N$ goes to zero as $N \to \infty$. We can write

$$E\int_0^\infty e^{-\beta t}\bar{g}^N(WL_\epsilon^N(t))dt = E\int_0^\infty e^{-\beta \hat{T}_\epsilon^N(t)}\bar{g}^N(\hat{WL}_\epsilon^N(t))d\hat{T}_\epsilon^N(t). \tag{5.19}$$

Now (5.15a), (5.15b), and the fact $F_\epsilon^N(\cdot)$ stops increasing after $T(\epsilon)$ can be used to show that

$$\lim_T \limsup_N E\int_T^\infty e^{-\beta \hat{T}_\epsilon^N(t)}|\hat{WL}_\epsilon^N(t)|dt = 0. \tag{5.20}$$

Now using (5.15a), (5.20), the weak convergence, the linear growth of $\bar{g}(\cdot)$ and $\bar{g}^N(\cdot)$ (uniformly in N), the convergence $\bar{g}^N(\cdot)$ to $\bar{g}(\cdot)$ (uniformly on compacta), and the fact that for large t, $d\hat{T}_\epsilon^N(t) = dt$, we see that the right side of (5.19) converges to

$$E\int_0^\infty e^{-\beta \hat{T}_\epsilon(t)}\bar{g}(\hat{WL}_\epsilon(t))d\hat{T}_\epsilon(t). \tag{5.21}$$

Define $T_\epsilon(t) = \inf\{s : \hat{T}_\epsilon(s) > t\}$. Then defining the inverses $WL_\epsilon(t) = \hat{WL}(T_\epsilon(t))$, etc., analogous to what was done in Part 2, yields

$$WL_\epsilon(t) = w(z) + W_\epsilon(t) + F_\epsilon(t) - bt + Y_\epsilon(t),$$

where $Y_\epsilon(\cdot)$ is the reflection term and the processes are nonanticipative with respect to the Wiener process $W_\epsilon(\cdot)$. By the inverse transformation, the right side of (5.21) equals

$$E\int_0^\infty e^{-\beta t}\bar{g}(WL_\epsilon(t))dt. \tag{5.22}$$

By the minimality of $\bar{V}^N(z^N)$, we have

$$\limsup_N \bar{V}^N(z^N) \le \lim_N V^N(z^N, F_\epsilon^N, G_\epsilon^N) = (5.22). \tag{5.23}$$

By the method of construction of the $\delta\bar{F}_\epsilon^N(\cdot)$ in terms of the $W_\epsilon^N(\cdot)$ via (5.14) and the rules (0a, 0b), (1a, 1b) and (2a), we see that the distribution of $(F_\epsilon(\cdot), W_\epsilon(\cdot))$ is the same as that of $(F^\epsilon(\cdot), W(\cdot))$ of (5.13). Using this and the weak sense uniqueness of the solution to (4.3), (5.22) equals $V(w(z), F^\epsilon)$. By the ϵ-optimality of $F^\epsilon(\cdot)$, $V(w(z), F^\epsilon) \le \bar{V}(w(z)) + \epsilon$. Since ϵ is arbitrary, (5.11) follows. □

Comments on extensions. The scheme used in the paper follows a simple pattern which should be applicable to more general problems. First, $g^N(\cdot)$ is minimized subject to the "workload" constraints with minimum denoted by $\bar{g}^N(\cdot)$. Then the dynamical equation for the workload process is obtained in terms of a control (the F^N-term) and a reflection (the Y^N-term). A weak convergence analysis is applied to the workload formulation, under heavy traffic conditions and cost rate $\bar{g}^N(\cdot)$. This yields (5.7). To get (5.12), use the workload

equations to get uniform integrability, and obtain appropriate estimates for the "errors" $\tilde{g}^N(\cdot)$ and $\bar{g}^N(\cdot) - \bar{g}(\cdot)$. The appropriate form of the ϵ-optimal comparison control $F^\epsilon(\cdot)$ will exist under quite broad conditions, as shown in the references. The main problem is getting the right rule for the realization of the $F^\epsilon(\cdot)$ on the physical process, something akin to our (0a, 0b), (1a, 1b), (2a). A more general method for doing this without having to compute the minimizing $z(w)$ explicitly in each case is needed.

STABILIZABILITY DOES NOT IMPLY HOMOGENEOUS STABILIZABILITY FOR CONTROLLABLE HOMOGENEOUS SYSTEMS*

RODOLPHE SEPULCHRE† AND DIRK AEYELS‡

Abstract. This paper presents an example of a homogeneous planar controllable system which is stabilizable while not stabilizable by homogeneous feedback. Addition of an integrator to the system provides a three-dimensional *affine* system with the same properties.

Key words. continuous feedback stabilization, homogeneous systems, homogeneous feedbacks

AMS subject classifications. 34D20, 93D15, 93D20

1. Introduction.

This paper deals with the local stabilization problem for nonlinear systems that are small-time locally controllable (STLC, [9]) and homogeneous with respect to some dilation [8]. By stabilization, we mean that there exists a continuous feedback $u(x, y) \in C^1(\mathbb{R}^2\backslash\{0\}, \mathbb{R})$ that renders the null solution of the closed-loop system (locally) asymptotically stable. This particular class of systems has recently been considered by several authors (e.g., [12], [8], [7], [2]). These systems appear naturally as local approximations of general controllable systems where the higher-order terms have been neglected. The associated homogeneous approximation might exhibit important control properties of the original system: for instance, local controllability of the homogeneous approximation implies local controllability of the original system. (See, for instance, [8]. Note that the converse is not true in general [10].) It seems then an attractive idea—in order to construct a stabilizing feedback for a nonlinear system—to consider a homogeneous approximation and to try to design a *homogeneous* stabilizing feedback for this approximation. First of all this would be a simpler problem to solve—in particular for small-dimensional systems—as one may take full profit of the symmetry properties of the homogeneous vectorfield [12]. But more important, for the closed-loop *homogeneous* system there exists a *homogeneous* Liapunov function [15]. This in turn implies robustness of the stabilization law with respect to higher-order terms (see also [8] for an independent proof). In summary, the stabilizing homogeneous control law of the homogeneous approximation would serve as a stabilizing feedback for the original system.

It is well known that with respect to the linearization of a nonlinear system this procedure works perfectly well. Also for the special class of *planar affine* controllable systems Kawski [11] has shown that every *planar affine* controllable system admits a homogeneous approximation which is stabilizable by homogeneous feedback. It has, however, been shown that the restriction to homogeneous feedback introduces extra necessary conditions for the stabilization problem [12], [7]. This leads us to the fundamental question of whether the approach sketched above works in general or—if not—for systems that are affine in the control (see also [7]).

The goal of this paper is to show that for general controllable homogeneous systems, the existence of a stabilizing feedback does not necessarily imply the existence of a *homogeneous*

stabilizing feedback. More precisely we will show that the system

$$(\Sigma_1) \qquad \begin{cases} \dot{x} &= x + u, \\ \dot{y} &= 3y + xu^2, \end{cases} \qquad (x, y) \in \mathbb{R}^2,\ u \in \mathbb{R},$$

is stabilizable while not stabilizable by homogeneous feedback.

The restriction to homogeneous stabilization is also a limitation for *affine* controllable systems of dimension larger than two. Indeed we will prove that the addition of an integrator to (Σ_1) results in a three-dimensional affine controllable system

$$(\Sigma_1') \qquad \begin{cases} \dot{x} &= x + z, \\ \dot{y} &= 3y + xz^2, \\ \dot{z} &= u, \end{cases} \qquad (x, y, z) \in \mathbb{R}^3,\ u \in \mathbb{R},$$

which also is stabilizable while not stabilizable by homogeneous feedback.

In §2, we review some definitions and provide basic properties for (Σ_1) and (Σ_1'). Section 3 is devoted to the explicit construction of a stabilizing feedback for (Σ_1). We also analyze the regularity of the proposed feedback. In §4, we combine the result of §3 and a recent result of Rosier [14] in order to establish the stabilizability of (Σ_1'). Conclusions are given in §5.

2. Preliminaries. We first recall the general definition of a homogeneous (control) system as given in [6]: the control system

$$\dot{x} = f(x, u) \tag{1}$$

with $f = (f_i)_{i=1,n} : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^n$ a map of class C^1 satisfying

$$\forall i \in \{1, \dots, n\},\ \forall x = (x_1, \dots, x_n)^T \in \mathbb{R}^n,\ \forall \epsilon \geq 0,\ \forall u \in \mathbb{R},$$
$$f_i(\epsilon^{r_1} x_1, \dots, \epsilon^{r_n} x_n, \epsilon^{r_{n+1}} u) = \epsilon^{\tau + r_i} f_i(x_1, \dots, x_n, u)$$

for some $r_i > 0$ and some $\tau \in (-\min_j\{r_j\}, +\infty)$ is said to be *homogeneous of degree* τ *with respect to the dilation* $\delta_\epsilon^r(x, u) = (\epsilon^{r_1} x_1, \dots, \epsilon^{r_n} x_n, \epsilon^{r_{n+1}} u)$. The system (1) is *stabilizable by homogeneous feedback* if there exists a continuous feedback law $u(x) \in C^1(\mathbb{R}^n \setminus \{0\}, \mathbb{R})$ such that

1. $u(\epsilon^{r_1} x_1, \dots, \epsilon^{r_n} x_n) = \epsilon^{r_{n+1}} u(x_1, \dots, x_n)\ \forall x \in \mathbb{R}^n,\ \forall \epsilon \geq 0$;
2. the point $x = 0$ is a globally asymptotically stable equilibrium of the closed-loop system $\dot{x} = f(x, u(x))$.

The following proposition collects some basic properties of the system (Σ_1) and of its dynamic extension (Σ_1').

PROPOSITION 1. (i) (Σ_1) *(resp.,* (Σ_1')*) is homogeneous of degree* 0 *with respect to the dilation* $\delta_\epsilon^r(x, y, u) = (\epsilon x, \epsilon^3 y, \epsilon u)$ *(resp.,* $\delta_\epsilon^r(x, y, z, u) = (\epsilon x, \epsilon^3 y, \epsilon z, \epsilon u)$*);*

(ii) (Σ_1) *and* (Σ_1') *are locally controllable (i.e., STLC);*

(iii) (Σ_1) *and* (Σ_1') *are not stabilizable by homogeneous feedback.*

Proof. (i) The proof follows from the definition.

(ii)(Σ_1') is locally controllable: using the standard notation

$$f(x, y, z) := (x + z, 3y + xz^2, 0)^T,\ g(x, y, z) := (0, 0, 1)^T,$$

we compute that the nonvanishing brackets at the origin are $g(0) = (0, 0, 1)^T$, $[f, g](0) = (-1, 0, 0)^T$, and $[[[f, [f, g]], g], g](0) = (0, -2, 0)^T$. They are independent and satisfy the so-called Hermes condition. Using a result of Coron (see §5 of [5]), this also implies that (Σ_1) is locally controllable.

(iii) Suppose that $u(x, y)$ is a homogeneous stabilizing feedback for (Σ_1). Then there exists a homogeneous Liapunov function $V(x, y)$ such that [15]

$$\nabla V(x, y).h(x, y) < 0 \quad \forall (x, y) \neq (0, 0),$$

where $h(x, y) := (x + u(x, y), 3y + xu^2(x, y))^T$ and with the additional property (due to homogeneity of V, say, of degree k) that

$$\nabla V(x, y).\lambda(x, y) = kV(x, y) > 0 \quad \forall (x, y) \neq (0, 0),$$

where $\lambda(x, y) = (x, 3y)^T$ is the Euler vector field associated with the dilation $\delta_\epsilon^r(x, y) = (\epsilon x, \epsilon^3 y)$. As a consequence, we have that

$$\nabla V(x, y).(h(x, y) - \lambda(x, y)) < 0 \quad \forall (x, y) \neq (0, 0),$$

which means that $u(x, y)$ also stabilizes the system $f(x, u) := (u, xu^2)^T$. But this is a contradiction since the latter system does not satisfy Brockett's necessary condition for continuous stabilization [3]. A similar argument proves that (Σ_1') also is not stabilizable by homogeneous feedback. □

3. Main result. This section is devoted to an explicit construction of a stabilizing feedback for (Σ_1) and to an analysis of its properties.

THEOREM 1. *There exists a stabilizing feedback $u(x, y) \in C(\mathbb{R}^2, \mathbb{R})$ such that the origin of (Σ_1) is locally asymptotically stable.*

Proof. The proof is constructive. For each $\epsilon > 0$ sufficiently small, we construct in the plane a simple closed curve ∂V_ϵ surrounding the origin. The family of curves $\{\partial V_\epsilon\}_{0<\epsilon\leq\bar{\epsilon}}$ implicitly defines the ϵ-level sets of a continuous positive definite function $V(x, y)$. We design a continuous function $u(x, y)$ such that

$$D^+V(x, y) \leq 0 \quad \forall (x, y) \in U, \tag{2}$$

where $D^+(.)$ denotes the right derivative (also called the Dini derivative; see [13]) of V along the trajectories of the closed-loop system.

Our construction is illustrated in Figure 1. We divide the plane in sectors delimited by the following curves:

1. $\mathcal{A} \equiv \{(x, y) \mid y + \alpha x^3 = 0\}$,
2. $\mathcal{B} \equiv \{(x, y) \mid y + \beta x^{3+\nu} = 0\}$,
3. $\mathcal{C} \equiv \{(x, y) \mid y + \gamma x^{3+\nu} = 0\}$,
4. $\mathcal{D} \equiv \{(x, y) \mid y + \delta x^{3+\nu} = 0\}$,
5. $\mathcal{E} \equiv \{(x, y) \mid y - 3x^3 = 0\}$,

where the positive constants $0 < \nu < 1$ and $\alpha > \beta > \gamma > \delta > 0$ will be suitably chosen in the following. (The value of α and the ratios β/γ and γ/δ will be fixed in the course of the proof.)

Let $\epsilon > 0$ sufficiently small. In each sector we will define ∂V_ϵ as a smooth curve in x and y and design the control function in such a way that (2) is satisfied in the considered region. Each sector being symmetric with respect to the origin, the construction is given in a half-sector and can be extended to the full sector by means of a symmetry argument. (As a consequence, the stabilizing control function will be odd.) The construction holds for arbitrary small ϵ, and therefore (2) ensures stability of the origin. In addition, we will show that the largest invariant set contained in the set $\{(x, y) \mid D^+V(x, y) = 0\}$ is the origin. Asymptotic stability of the origin follows by LaSalle's theorem.

I. Let S_1 be the connected region of the right-half plane delimited by $\mathcal{D}$ and $\mathcal{E}$. Let $D \in \mathcal{D}$, with $x_D = d\epsilon$, $d > 1$, and $E \in \mathcal{E}$, with $x_E = \epsilon$. Define ∂V_ϵ in S_1 by connecting D

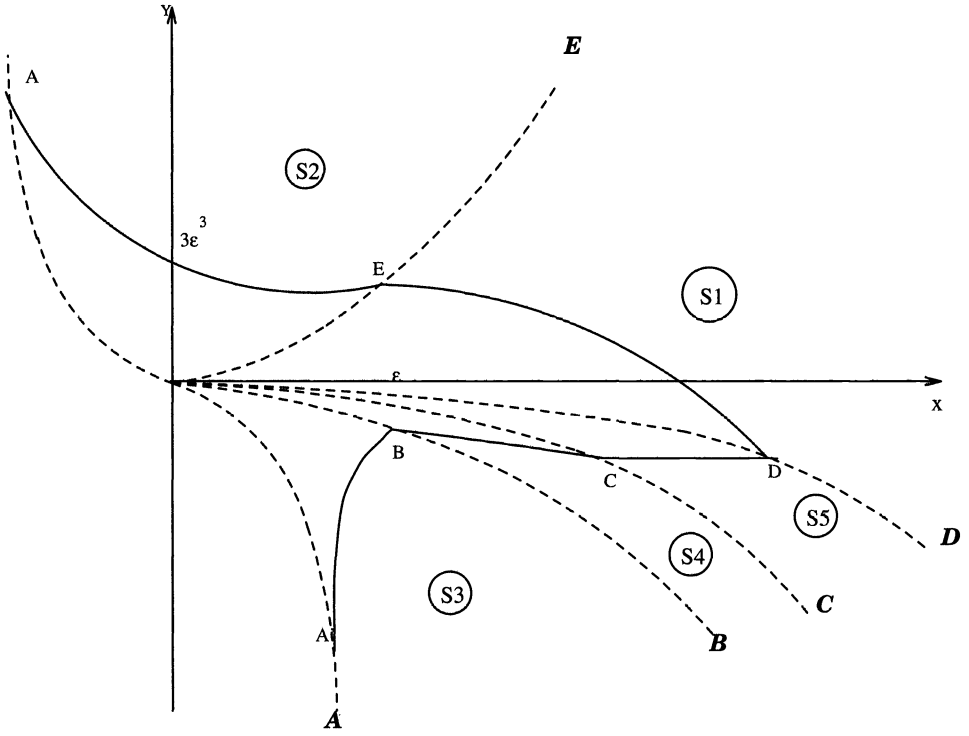

FIG. 1. *Half ϵ-level set of $V(x, y)$ for small $\epsilon > 0$.*

and E along the smooth curve

$$\Gamma_1 \equiv \{(x, y) \mid y + nx^3 - (n+3)\epsilon^3 = 0,\ x \in [\epsilon, d\epsilon]\}, \tag{3}$$

with n chosen such that D belongs to $\mathcal{D}$, i.e.,

$$n = n(\epsilon) = \frac{3 + \delta d^{3+\nu}\epsilon^{\nu}}{d^3 - 1}. \tag{4}$$

On Γ_1, the constraint (2) can be rewritten as follows:

$$\dot{\Gamma}_1 = 3(n+3)\epsilon^3 + ux(u + 3nx) \leq 0, \quad \epsilon \leq x \leq d\epsilon. \tag{5}$$

Since $x > 0$ on Γ_1, the quantity $ux(u+3nx)$ is minimized with the choice $u(x, y) = -3nx/2$. For simplicity, we design a control independent of ϵ and we choose $u(x, y) = -3\bar{n}x/2$ with

$$\bar{n} := n(0) = \frac{3}{d^3 - 1}.$$

Choosing for instance $\bar{n} = 10/3$ (which fixes the value of $d = (19/10)^{1/3}$), we obtain a smooth control function $u(x, y)$ in S_1:

$$u(x, y) := f_1(x, \epsilon) = -5x. \tag{6}$$

Substituting (6) in (5) we obtain on Γ_1

$$\dot{\Gamma}_1 \leq -6\epsilon^3 - 12(n - \bar{n})\epsilon^3. \tag{7}$$

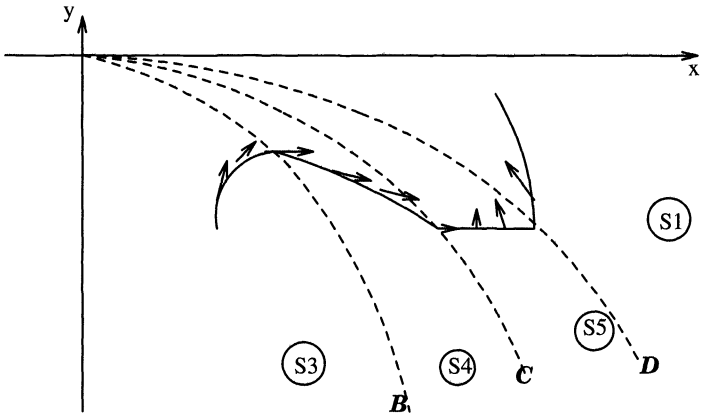

FIG. 2. *Change of sign in* $u(x, y)$.

Since $(n - \bar{n})$ is positive for each $\epsilon \geq 0$, the right-hand side of the above inequality is negative and (2) is satisfied in S_1.

II. Next let S_2 be the connected region of the upper half-plane delimited by $\mathcal{E}$ and $\mathcal{A}$. Let $A \in \mathcal{A}$, with $x_A = -\epsilon/2$. Define ∂V_ϵ in S_2 by connecting E and A along the smooth curve

$$\Gamma_2 \equiv \{(x, y) \mid y + 3(x - 2\epsilon)^3 = 0\}, \qquad x \in [x_A, x_E]. \tag{8}$$

Note that this determines the value of α ($\alpha = 375$). On Γ_2, the constraint (2) can be rewritten as follows:

$$xu^2 + 9(x - 2\epsilon)^2(u + 2\epsilon) \leq 0, \qquad x_A \leq x \leq x_E. \tag{9}$$

Define for $(x, y) \in \Gamma_2$ the control function

$$\begin{aligned} u(x, y) &= -5\epsilon, && 0 \leq x \leq x_E, \\ &= Kx - 5\epsilon, && x_A \leq x \leq 0, \end{aligned} \tag{10}$$

where K is a positive constant still to be chosen. It is readily checked that this choice satisfies the constraint (9) on Γ_2 and is compatible with (6) in $E = \Gamma_1 \cap \Gamma_2$. On the other hand, by choosing K sufficiently large, it is possible to obtain in A

$$u(x_A, y_A) = -a\epsilon, \tag{11}$$

with $a > 0$ as large as desired. By smoothing the control (10) around $x = 0$ and by repeating the construction for each $\epsilon > 0$, we design a continuous function

$$u(x, y) := f_2(x, \epsilon)$$

in S_2 such that f_2 is continuously differentiable as a function of x and ϵ, and such that (2) is fulfilled in this region.

III. Consider the lower right half-plane, i.e., the fourth quadrant. By construction, the control is positive along $\mathcal{A}$ (using (11) and oddness of the control) and negative along $\mathcal{D}$ (by (6)). By continuity, the control must change sign in the fourth quadrant. Since $\dot{y} = 3y + xu^2$, the change of sign of $u(x, y)$ leads to a region in the fourth quadrant where $\dot{y}$ is nonpositive (indeed $\dot{y} < 0$ in the neighborhood of $u = 0$). This is illustrated in Figure 2.

We will design the control in such a way that this region is precisely S_4, i.e., the connected region of the fourth quadrant delimited by $\mathcal{B}$ and $\mathcal{C}$. In particular, the constraint $\dot{y} = 0$ determines the control value on $\mathcal{B}$ and $\mathcal{C}$ according to

$$u(x, y) = \sqrt{3\beta x^{2+\nu}} \quad \forall (x, y) \in \mathcal{B},\ x \geq 0 \tag{12}$$

and

$$u(x, y) = -\sqrt{3\gamma x^{2+\nu}} \quad \forall (x, y) \in \mathcal{C},\ x \geq 0. \tag{13}$$

IV. Consider S_3, the connected region of the fourth quadrant delimited by $\mathcal{A}$ and $\mathcal{B}$. Let $A' \in \mathcal{A}$, with $x_{A'} = \epsilon/2$, and $B \in \mathcal{B}$, with $x_B = \epsilon$. Define ∂V_ϵ in sector$(\mathcal{A}, \mathcal{B})$ by connecting A' and B along the smooth curve

$$\Gamma_3 \equiv \{(x, y) \mid y - m(x - \epsilon)^3 + \beta\epsilon^{3+\nu} = 0\}, \qquad x \in [x_{A'}, x_B], \tag{14}$$

where m is chosen in such a way that $A' \in \Gamma_3$, i.e.,

$$m = \alpha - 8\beta\epsilon^{\nu}.$$

Note that m is positive for small ϵ. On Γ_3, the constraint (2) can be rewritten as follows:

$$xu^2 - 3m(x - \epsilon)^2(\epsilon + u) - 3\beta\epsilon^{3+\nu} \geq 0, \qquad x_{A'} < x < x_B. \tag{15}$$

The left-hand side of (15) is a quadratic function in u. For x positive, the expression has two real roots and is positive, provided that

$$u \geq \frac{3m(x - \epsilon)^2 + \sqrt{\rho}}{2x} \tag{16}$$

with $\rho := ((3m(x - \epsilon)^2)^2 + 4x(3m\epsilon(x - \epsilon)^2 + 3\beta\epsilon^{3+\nu})$ being positive in the considered interval $[x_{A'}, x_B] = [\epsilon/2, \epsilon]$. Note that (16) is satisfied in A', provided that a is sufficiently large. On the other hand, (16) or equivalently (15) reduces in B to the constraint $\dot{y} \geq 0$, which is satisfied by construction with the choice (12). As a consequence, we can design a continuous control function along Γ_3, which interpolates between the value $a\epsilon$ in A' and the value at B specified by (12) and satisfies (16). Repeating the argument for each $\epsilon > 0$, we design a continuous function

$$u(x, y) := f_3(x, \epsilon)$$

in $S_3 \cap U$ such that f_3 is continuously differentiable as a function of x and ϵ and such that (2) is satisfied.

V. Consider S_5, the connected region of the fourth quadrant delimited by $\mathcal{C}$ and $\mathcal{D}$. Let $C \in \mathcal{C}$, with $x_C = c\epsilon, c \in (1, d)$. Define ∂V_ϵ in S_5 by connecting C and D along the horizontal line

$$\Gamma_5 \equiv \{(x, y) \mid y = y_C,\ x \in [c\epsilon, d\epsilon]\}. \tag{17}$$

This specifies the ratio γ/δ:

$$\frac{\gamma}{\delta} = \left(\frac{d}{c}\right)^{3+\nu}. \tag{18}$$

The constraint (2) is therefore satisfied in S_5 if $\dot{y} \geq 0$. We thus design a continuous function

$$u(x, y) := f_5(x, \epsilon) \tag{19}$$

in S_5, monotonically decreasing along Γ_5 from $u(x_C, y_C) = -\sqrt{3\gamma x_C^{2+\nu}}$ until $u(x_D, y_D) = -5d\epsilon$, such that (2) is satisfied and such that f_5 is continuously differentiable as a function of x and ϵ.

VI. Finally consider S_4, the connected region of the fourth quadrant delimited by $\mathcal{B}$ and $\mathcal{C}$. Let the control function be a continuous function

$$u(x, y) := f_4(x, \epsilon)$$

in S_4 such that f_4 is continuously differentiable as a function of x and ϵ and monotonically decreases as a function of x from $u(x, y) = \sqrt{3\beta x^{2+\nu}}$ in B to $u(x, y) = -\sqrt{3\gamma x^{2+\nu}}$ in C. It must be shown that B and C can be connected along a curve segment in such a way that (2) is satisfied for some $\beta > \gamma > 0$ and $c \in (1, d)$. For this we note that in S_4 and for x positive, we have

$$u(x, y) \geq -\sqrt{3\gamma x^{2+\nu}}$$

and therefore

$$\dot{x} \geq (1 - \sqrt{3\gamma x^{\nu}})x, \tag{20}$$

$$\dot{y} \geq 3y. \tag{21}$$

Define a constant $\mu \in (0, 1)$. Then (20) can be rewritten as

$$\dot{x} \geq (1 - \sqrt{3\gamma x^{\nu}})x > \mu x, \tag{22}$$

provided that

$$x \in [0, ((1 - \mu)/\sqrt{3\gamma})^{2/\nu}),$$

which is satisfied for $x \in [x_B, x_C]$ when ϵ is small. Consider the following curve in S_4:

$$\Gamma_4 \equiv \{(x, y) \mid x = x_B e^{\mu t},\ y = y_B e^{3t},\ t \geq 0,\ x \leq x_C\}. \tag{23}$$

Since for small ϵ the trajectories of the closed-loop system satisfy (21), (22) in S_4, we obtain

$$\dot{\Gamma}_4(p) < 0 \quad \forall p \in \Gamma_4. \tag{24}$$

It is therefore sufficient to impose that C belongs to Γ_4 in order to obtain a closed curve ∂V_ϵ in such a way that (2) holds in S_4. This leads to the following requirement:

$$\left(\frac{y_C}{y_B}\right)^{\mu} = \left(\frac{x_C}{x_B}\right)^{3} \tag{25}$$

$$\Leftrightarrow \left(\frac{\gamma}{\beta} c^{3+\nu}\right)^{\mu} = c^3 \tag{26}$$

$$\Leftrightarrow c = \left(\frac{\gamma}{\beta}\right)^{\frac{\mu}{3-(3+\nu)\mu}}. \tag{27}$$

This fixes the ratio γ/β and shows that by choosing μ such that

$$\frac{3}{3+\nu} < \mu < 1,$$

we obtain the desired connection between B and C with c as close to 1 as desired. (Note that this flexibility allows to satisfy $c < d$.) The connection between B and C closes the boundary of V_ϵ. Moreover we have shown that the constraint (2) can be satisfied with a strict inequality in any point of ∂V_ϵ except in B and C. Note that by construction $x\dot{x} > 0$ and $\dot{y} = 0$ at any point (except the origin) of the curves $\mathcal{B}$ and $\mathcal{C}$ (see Figure 2). As a consequence these curves do not contain any invariant set outside the origin.

To prove asymptotic stability of the null solution, it remains to show that the different level sets ∂V_ϵ do not intersect and continuously cover a neighborhood of the origin. An argument for this part of the proof is postponed in Lemma 2. □

The next corollary shows that the above construction can be extended to an arbitrarily large bounded set containing the origin (semiglobal stabilization).

COROLLARY 1. *The stabilization of* Σ_1 *is semiglobal.*

Proof. We denote the open ball centered at the origin and of radius r by $B(0, r)$. Let K be the compact to be contained in the region of attraction of the origin, and choose $\bar{r}$ such that $K \subset B(0, \bar{r})$. Note that for each ϵ, the ball $B(0, r(\epsilon))$ is included in V_ϵ with $r(\epsilon)$ defined by

$$r(\epsilon) := \min\left\{\frac{\epsilon}{2}, \frac{3\epsilon^3}{2}, \frac{\beta\epsilon^{3+\nu}}{2}\right\}.$$

As a consequence, it is always possible to choose $\bar{\epsilon}$ large enough such that $B(0, \bar{r}) \subset V_{\bar{\epsilon}}$. The construction of Theorem 1 holds only locally around the origin, i.e., for sufficiently small ϵ. However, note that the constants d and c define the ratios β/γ and γ/δ according to (27) and (18). The remaining freedom can be used in order that the construction of Theorem 1 holds for $\epsilon \leq \bar{\epsilon}$.

First remark that the parameter m defined in (14) must be a positive value in order that the construction hold. This leads to the constraint

$$\beta < \frac{375}{8\bar{\epsilon}^\nu}, \tag{28}$$

which provides a maximum admissible value for the constant β.

Inequality (22) also imposes a maximum value for the constant γ with the constraint

$$\sqrt{3\gamma(c\bar{\epsilon})^\nu} \leq 1 - \mu. \tag{29}$$

Note that inequalities (28) and (29) can be satisfied by choosing δ sufficiently small. □

The remainder of the section is devoted to a regularity analysis of the control function constructed in Theorem 1. Note that for each $i \in \{1, \ldots, 5\}$, the curve Γ_i is defined in S_i by an implicit equation in (x, y, ϵ), which we denote by $G_i(x, y, \epsilon) = 0$. The following lemma shows that this equation implicitly defines a function $\epsilon_i(x, y)$ with some regularity properties. The proof of this technical lemma is given in the appendix.

LEMMA 1. *In each sector* S_i, $i \in \{1, \ldots, 5\}$, *there exists a continuous function* $\epsilon_i(x, y) \in C^1(S_i \backslash \{0\}, \mathbb{R})$ *such that*

(i)

$$\epsilon_i(0, 0) = 0 \; \forall (x, y) \in S_i \backslash \{0\} : G_i(x, y, \epsilon_i(x, y)) = 0, \tag{30}$$

(ii)

$$\forall (x, y) \in S_i \backslash \{0\} \cap U : \left| \frac{\partial \epsilon_i}{\partial x} \right| \leq C, \quad \left| \frac{\partial \epsilon_i}{\partial y} \right| \leq C \mid y \mid^{\frac{1}{3+\nu}-1}, \tag{31}$$

(iii)

$$\forall (x, y) \in S_i \backslash \{0\} : \frac{\partial \epsilon_i}{\partial y}(x, y) \neq 0, \tag{32}$$

with U some neighborhood of $(0, 0)$ and C some positive constant.

The proof of Lemma 1 can be used to complete the proof of Theorem 1, i.e., to show that the level sets ∂V_ϵ, $0 \leq \epsilon \leq \bar{\epsilon}$, do not intersect and cover an arbitrary large neighborhood of the origin. The proof of the following lemma is given in the appendix.

LEMMA 2. *Define the function*

$$V(x, y) := \epsilon_i(x, y), \qquad (x, y) \in S_i.$$

Then there exists a neighborhood U of the origin such that $V \in C^0(U, \mathbb{R})$, $V(0, 0) = 0$, and V is "radially" increasing in U. Moreover, the constants β, γ, and δ of Theorem 1 can be chosen such that U contains an arbitrary large compact set.

The existence of a continuous stabilizing feedback which is continuously differentiable outside the origin is asserted from Theorem 1 by a result of Coron [4]. The next corollary specifies the regularity that we can obtain with our particular construction. This regularity will be used in the next section.

COROLLARY 2. *The continuous stabilizing feedback of Theorem 1 can be chosen in $C^1(\mathbb{R}^2 \backslash \{0\}, \mathbb{R})$. Moreover we have for some constant C*

$$\forall (x, y) \in U \backslash \{(0, 0)\} : \left| \frac{\partial u}{\partial x} \right| \leq C, \quad \left| \frac{\partial u}{\partial y} \right| \leq C \mid y \mid^{\frac{1}{3+\nu}-1}. \tag{33}$$

Proof. First consider a point p in the interior of some sector S_i. The result is then a consequence of the chain rule and of the regularity of f_i and ϵ_i for each $i \in \{1, \ldots, 5\}$:

$$\frac{\partial u}{\partial x}(x, y) = \frac{\partial f_i}{\partial x}(x, \epsilon) + \frac{\partial f_i}{\partial \epsilon}(x, \epsilon) \frac{\partial \epsilon_i}{\partial x}(x, y), \tag{34}$$

$$\frac{\partial u}{\partial y}(x, y) = \frac{\partial f_i}{\partial \epsilon}(x, \epsilon) \frac{\partial \epsilon_i}{\partial y}(x, y), \tag{35}$$

with $G_i(x, y, \epsilon_i(x, y)) = 0$. The right-hand members of (34) and (35) are continuous and bounded in a neighborhood of the origin. As a consequence, $u(x, y)$ is C^1 in the interior of each sector S_i. Define for each i the constant

$$C_i := \sup_{S_i \cap U} \left\{ \left| \frac{\partial f_i}{\partial x} \right|, \left| \frac{\partial f_i}{\partial \epsilon} \right| \right\} < +\infty. \tag{36}$$

It follows from (34) and (35) that

$$\left| \frac{\partial u}{\partial x}(x, y) \right| \leq \max_i C_i \left(1 + \left| \frac{\partial \epsilon}{\partial x}(x, y) \right| \right), \tag{37}$$

$$\left| \frac{\partial u}{\partial y}(x, y) \right| \leq \max_i C_i \left| \frac{\partial \epsilon}{\partial y}(x, y) \right|. \tag{38}$$

Using Lemma 1(ii), we obtain the estimate (33) for any point in the interior of $S_i \cap U$, $i \in \{1, \ldots, 5\}$.

Next consider a point $(x, y) \in S_i \cap S_j$ different from the origin. We will further specify the choice of the control in the neighborhood of the curves $\mathcal{A}$, $\mathcal{B}$, $\mathcal{C}$, and $\mathcal{D}$ in order to achieve differentiability outside the origin. (The control is already smooth in the neighborhood of $\mathcal{E}$.) Since the procedure is relatively straightforward, we give a complete argument only around $\mathcal{A}$ and omit the details for the other curves.

Define the local coordinate $\theta = y^{1/3}/x$, $x > 0$. We claim that for a sufficiently small constant $\xi > 0$, we can choose the control law around $\mathcal{A}\backslash\{0\}$ according to the particular form

$$u(x, y) = (g_1(\theta) + C_1)x, \qquad \theta \in [\bar{\theta} - \xi, \bar{\theta} + \xi], \tag{39}$$

with $\bar{\theta} := -\alpha^{1/3}$, C_1 a constant, and $g_1(\theta)$ smooth. For $-\infty < \theta \leq \bar{\theta}$, there is no restriction to impose on $f_2(x, \epsilon)$ to be of the form (39), provided that $g_1(\theta)$ is sufficiently large. We can choose g_1 smooth, strictly increasing for $\theta < \bar{\theta}$, and maximum for $\bar{\theta}$. For $\bar{\theta} \leq \theta \leq \bar{\theta} + \xi$, the only constraint imposed by the construction of Theorem 1 is again that $g_1(\theta)$ be sufficiently large in the considered interval. In particular, (11) imposes $g_1(\bar{\theta}) + C \geq 2a$. We can choose g_1 smooth and strictly decreasing for $\theta > \bar{\theta}$.

Note that the definition (39) is not in contradiction with the continuous differentiability of $f_2(x, \epsilon)$ (resp., $f_3(x, \epsilon)$) as a function of ϵ and x in S_2 (resp., S_3). For f_2, this is immediate since the expression (53) gives

$$\epsilon_2(x, y) = \frac{1}{2}(3^{-1/3}\theta + 1)x$$

and therefore

$$\frac{\partial \theta}{\partial \epsilon} = \frac{2\epsilon}{3^{-1/3}x}.$$

It follows that the expression

$$\frac{\partial f_2}{\partial \epsilon}(x, y) = x g_1'(\theta)\frac{\partial \theta}{\partial \epsilon}$$

is well defined and smooth. For f_3, using the chain rule and (56), we obtain

$$\frac{\partial f_3}{\partial \epsilon}(x, y) = g_1'(\theta)\frac{1}{3x^2\theta^2}(K_1(x)\epsilon^2 + K_2(x)\epsilon^{\nu+2}),$$

where θ stands for $y^{1/3}/x$. The above expression is bounded for θ in a neighborhood of $\bar{\theta}$.

A similar procedure can be used to express the control law in the neighborhood of the curves $\mathcal{B}$ and $\mathcal{C}$. Define the local coordinate $\eta := y/x^{3+\nu}$, $x > 0$. Then it is sufficient to choose (locally) the functions f_3, f_4, and f_5 of the particular form

$$u(x, y) = (g_2(\eta))x^{\frac{2+\nu}{2}}, \qquad \eta \in [-\beta - \xi, -\gamma + \xi], \tag{40}$$

with g_2 smooth. We can be in accordance with the construction of Theorem 1 by choosing g_2 smooth, strictly decreasing, and satisfying $g_2(\beta) = \sqrt{3\beta}$ and $g_2(\gamma) = -\sqrt{3\gamma}$.

Finally it is clear that f_5 can be chosen in such a way that the control is smooth along $\mathcal{D}$: this follows from the fact that the partial derivatives of f_1 satisfy

$$\frac{\partial f_1}{\partial \epsilon} = 0, \qquad \frac{\partial f_1}{\partial x} = -5$$

and that the function f_5 is only constrained to be decreasing in x.

From the particular form of the expressions (39) and (40), it is clear that the estimate (33) also holds at the intersection of the different sectors. □

4. Adding an integrator. In this section, we show that the stabilizability properties of Σ_1 are basically unchanged under the addition of an integrator. Proposition 1 states that (Σ_1') is controllable and not stabilizable by homogeneous feedback. To prove that (Σ_1') is stabilizable by (nonhomogeneous) continuous feedback, we apply to (Σ_1) the following result of Rosier.

PROPOSITION 2 (see [14]). *Let $F \in C^0(\mathbb{R}^{n+1}, \mathbb{R}^n)$ with $F(0,0) = 0$. Assume that there exists a function $u \in C^1(U \setminus \{0\}, \mathbb{R}) \cap C^0(U, \mathbb{R})$ (U is some neighborhood of 0 in $\mathbb{R}^n$) with $u(0) = 0$ such that the system*

$$\dot{x} = F(x, u(x))$$

is locally asymptotically stable and such that the following holds:

$$\sup_{y \in [[0, u(x)]]} |\nabla u(x) \cdot F(x, y)| \to 0 \text{ as } x \to 0$$

([[0, $u(x)$]] denoting the set $[\min(0, u(x)), \max(0, u(x))]$*). Then the system*

$$\begin{cases} \dot{x} = F(x, y), \\ \dot{y} = v \end{cases}$$

is locally asymptotically stabilizable around $(0, 0)$.

THEOREM 2. *There exists a control function $u(x, y, z) \in C^1(U \setminus \{0\}, \mathbb{R}) \cap C^0(U, \mathbb{R})$ (U is some neighborhood of 0 in $\mathbb{R}^3$) such that the origin of (Σ_1') is locally asymptotically stable.*

Proof. Let $u(x, y)$ be the stabilizing feedback designed in Theorem 1 with the regularity properties characterized by (33). Throughout the proof, the notation $z(x, y)$ stands for any (scalar) value in $[[0, u(x, y)]]$. Using the above criterion, it is sufficient to prove that

$$\left| \frac{\partial u}{\partial x}(x + z(x, y)) + \frac{\partial u}{\partial y}(3y + xz^2(x, y)) \right| \to 0, \quad |(x, y)| \to 0. \tag{41}$$

Note that by (33), $|\partial u / \partial x|$ is bounded in U. Since $u(x, y)$ is continuous at the origin and $u(0, 0) = 0$, we conclude that

$$\left| \frac{\partial u}{\partial x}(x + z(x, y)) \right| \to 0, \qquad |(x, y)| \to 0. \tag{42}$$

Now we will prove that

$$\left| \frac{\partial u}{\partial y}(3y + xz^2(x, y)) \right| \to 0, \qquad |(x, y)| \to 0. \tag{43}$$

For a point (x, y) in $U \cap S_1$, (43) is immediate because in this region

$$\frac{\partial u}{\partial y} \equiv 0.$$

On the other hand, we have by (33)

$$\left| \frac{\partial u}{\partial y} \right| \leq C |y|^{\frac{1}{3+\nu} - 1}. \tag{44}$$

It is therefore sufficient to prove that in $U \cap S_i$, $i \neq 1$,

$$|3y + xz^2(x, y)| < K_3 |y|^{\frac{3}{3+\nu}}. \tag{45}$$

Inequalities (44) and (45) show that near the origin,

$$\left|\frac{\partial u}{\partial y}(3y + xz^2(x, y))\right| < K_2 K_3 \mid y \mid^{\frac{4}{3+\nu}-1},$$

which establishes (43) provided that $0 < \nu < 1$.

It remains to verify that (45) holds in each sector S_i, $i \neq 1$. First consider $S_2 \cup S_3$. We have in this region that $\mid x \mid \leq \mid \epsilon(x, y) \mid$, and we can also assume

$$\mid u(x, y) \mid \leq a \mid \epsilon(x, y) \mid .$$

Therefore we obtain

$$\mid xz^2(x, y) \mid \leq \mid xu^2(x, y) \mid < a^2 \mid \epsilon^3(x, y) \mid,$$

with a defined by (11). Now we easily check that in S_2

$$\mid y \mid = \mid 3(x - 2\epsilon)^3 \mid \geq 3 \mid \epsilon^3(x, y) \mid$$

and that in S_3

$$\mid y \mid = \mid m(x - \epsilon)^3 - \beta\epsilon^{3+\nu} \mid \geq (\beta\epsilon^{\nu} + m/8) \mid \epsilon^3(x, y) \mid .$$

We conclude that in $S_2 \cup S_3$

$$\mid 3y + xz^2(x, y) \mid < 3 \mid y \mid + a^2 \mid \epsilon^3(x, y) \mid < K_4 \mid y \mid$$

for some constant K_4. For small $\mid y \mid$, this establishes (45) in the considered region.
Next consider S_4. In this region, we have by construction

$$\mid 3y + xu^2(x, y) \mid \leq \mid 3y \mid,$$

and therefore (45) immediately follows. Finally consider S_5. We have in this region that $\mid x \mid \leq d \mid \epsilon(x, y) \mid$ and also

$$\mid u(x, y) \mid < 3n/2 \mid x \mid .$$

Therefore we get for some constant K_5 that

$$\mid xz^2(x, y) \mid \leq \mid xu^2(x, y) \mid < K_5 \mid \epsilon^3(x, y) \mid .$$

Now since in S_5

$$\mid y \mid = K_6 \mid \epsilon^{3+\nu} \mid$$

holds for some constant K_6, we conclude that (45) also holds in this region. This ends the proof of (43), and (41) follows from (42) and (43). □

5. Conclusions. It has been shown that the existence of a continuous stabilizing feedback for a homogeneous system does not imply the existence of a continuous stabilizing feedback that preserves the homogeneity of the system in the closed loop. Our example is an analytic planar controllable system. The stabilizing feedback that we have exhibited is semiglobal and has continuous partial derivatives outside the origin. The addition of an integrator to the original system provides an affine three-dimensional homogeneous system that is controllable, not stabilizable by homogeneous feedback, and stabilizable by continuous feedback. The paper extends partial results presented in [1].

Remark. Independently, Rosier [14] has recently provided an example of planar system which is stabilizable by continuous feedback while not stabilizable by continuous *homogeneous* feedback. Contrary to our result, this example is not analytic, and addition of an integrator results in a nonstabilizable system.

6. Appendix.

6.1. Proof of Lemma 1. We prove that Lemma 1 holds in each sector S_i, $i \in \{1, \ldots, 5\}$. Consider S_1. We compute successively

$$G_1(x, y, \epsilon) = y + nx^3 - (n+3)\epsilon^3, \tag{46}$$

$$\frac{\partial G_1}{\partial x} = 3nx^2, \quad \frac{\partial G_1}{\partial y} = 1, \tag{47}$$

$$\frac{\partial G_1}{\partial \epsilon} = \frac{\partial n}{\partial \epsilon}(x^3 - \epsilon^3) - 3(n+3)\epsilon^2$$

$$= -K_1\epsilon^2 - K_2(x)\epsilon^{\nu+2}, \tag{48}$$

with K_1 some positive constant and $K_2(x) \leq d^3 - 4 < 0$ for $\epsilon \leq x \leq d\epsilon$. Since $\partial G_1/\partial \epsilon$ does not vanish for $\epsilon \neq 0$, the implicit function theorem asserts that $\epsilon_1(x, y)$ exists and has continuous partial derivatives in $S_1 \backslash \{0\}$. On the other hand we have in $S_1 \backslash \{0\}$

$$\left|\frac{\partial \epsilon}{\partial x}\right| = \left|\frac{\partial G_1}{\partial x}\left(\frac{\partial G_1}{\partial \epsilon}\right)^{-1}\right|$$

$$= \left|\frac{3nx^2}{K_1\epsilon^2 + K_2(x)\epsilon^{2+\nu}}\right|$$

$$< \left|\frac{3nd}{K_1 + K_2(x)\epsilon^{\nu}}\right|, \tag{49}$$

which shows that $\partial \epsilon/\partial x$ is bounded in a neighborhood the origin. Analogously, we compute

$$\left|\frac{\partial \epsilon}{\partial y}\right| = \left|\frac{\partial G_1}{\partial y}\left(\frac{\partial G_1}{\partial \epsilon}\right)^{-1}\right|$$

$$= \left|\frac{1}{K_1\epsilon^2 + K_2(x)\epsilon^{2+\nu}}\right| \tag{50}$$

$$< \left|\frac{1}{K_1\epsilon^2}\right|. \tag{51}$$

For $y \in S_1$ and ϵ small, we have by construction

$$| y | < 3\epsilon^3$$

and therefore

$$\left|\frac{1}{K_1\epsilon^2}\right| < C_1 |y^{-2/3}| \tag{52}$$

for some constant C. Equations (51) and (52) end the proof of Lemma 1(ii). Lemma 1(iii) follows from (50).

In S_2 we can obtain the following explicit expression for $\epsilon_2(x, y)$:

$$\epsilon_2(x, y) = 1/2\left(x + \left(\frac{y}{3}\right)^{1/3}\right). \tag{53}$$

Lemma 1 is therefore readily checked.

In S_3 the proof follows the same lines as in S_1. We compute successively

$$G_3(x, y, \epsilon) = y - m(x - \epsilon)^3 + \beta\epsilon^{3+\nu}, \tag{54}$$

$$\frac{\partial G_3}{\partial x} = -3m(x - \epsilon)^2, \quad \frac{\partial G_3}{\partial y} = 1, \tag{55}$$

$$\frac{\partial G_3}{\partial \epsilon} = -\frac{\partial m}{\partial \epsilon}(x - \epsilon)^3 + 3m(x - \epsilon)^2 + (3 + \nu)\beta\epsilon^{2+\nu} \tag{56}$$

$$= K_1(x)\epsilon^2 + K_2(x)\epsilon^{\nu+2}, \tag{57}$$

with $K_1(x) \geq 0$ and $K_2(x) \geq 3$ for $\epsilon/2 \leq x \leq \epsilon$. Since $\partial G_3/\partial\epsilon$ does not vanish for $\epsilon \neq 0$, the implicit function theorem asserts that $\epsilon_3(x, y)$ exists and has continuous partial derivatives in $S_3\backslash\{0\}$.

As in S_1, we compute

$$\left|\frac{\partial \epsilon}{\partial x}\right| = \left|\frac{3m(x - \epsilon)^2}{3m(x - \epsilon)^2 + K_2(x)\epsilon^{\nu+2}}\right| \tag{58}$$

$$< \left|\frac{3m/4}{3m/4 + K_2(x)\epsilon^{\nu}}\right|, \tag{59}$$

which shows that $\partial\epsilon/\partial x$ is bounded in a neighborhood the origin and

$$\left|\frac{\partial \epsilon}{\partial y}\right| = \left|\frac{1}{3m(x - \epsilon)^2 + K_2(x)\epsilon^{\nu+2}}\right|. \tag{60}$$

Using (54) and (60), Lemma 1(ii) is proven if the inequality

$$\frac{|\, m(x - \epsilon)^3 + \beta\epsilon^{3+\nu}\,|^{\frac{2+\nu}{3+\nu}}}{|\, 3m(x - \epsilon)^2 + K_2(x)\epsilon^{nu+2}\,|} < C_3 \tag{61}$$

holds in S_3 for some constant C_3. The left-hand side can be unbounded only when ϵ tends to zero. For $x = \epsilon$, the left-hand side is a constant, while for $x \neq \epsilon$, the left-hand side tends to $0(\epsilon^{\nu})$ for ϵ sufficiently small. Finally Lemma 1(iii) follows from (60).

In S_4 we can also obtain an explicit expression for $\epsilon_4(x, y)$:

$$\epsilon_4(x, y) = \left(\frac{-y^{\mu}}{\beta^{\mu}x^3}\right)^{\xi}, \tag{62}$$

with $\xi := 1/((3 + \nu)\mu - 3) > 0$. We easily verify that

$$\left|\frac{\partial \epsilon}{\partial x}\right| = K_4\left|\frac{y}{x^{3+\nu}}\right|^{\mu\xi} \leq K_4\,|\gamma|^{\mu\xi},$$

$$\left|\frac{\partial \epsilon}{\partial y}\right| = K_4'\left|\frac{y^{3+\nu}}{x^3}\right|^{\mu\xi}\left|y^{\frac{1}{3+\nu}-1}\right| \leq K_4''\left|y^{\frac{1}{3+\nu}-1}\right|$$

for some constants K_4, K_4', and K_4''.

Finally Lemma 1 is readily checked in S_5 with the following explicit expression for $\epsilon_5(x, y)$:

$$\epsilon_5(x, y) = \frac{1}{c}\left(\frac{-y}{\gamma}\right)^{\frac{1}{3+\nu}}. \tag{63}$$

Lemma 1 is proven in each sector. □

6.2. Proof of Lemma 2. It has already been proven that for a fixed $\epsilon > 0$ the level set ∂V_ϵ defines a simple closed curve surrounding the origin. Morevover, any compact set K can be included in ∂V_ϵ by a suitable choice of the constants ϵ, β, γ, and δ (see the proof of Corollary 1).

Here we will prove that the function V is "radially" increasing in the following sense: in each sector S_i, we will consider a set of local "polar" coordinates (ρ, θ) such that, for a fixed θ, ϵ_i is strictly increasing as a function of ρ.

The argument is straightforward in the sectors where we have an explicit expression for $V(x, y)$. In S_2, the natural coordinates are $\theta = x/y^{1/3}$ and $\rho = y^{1/3}$. Then the expression (53) gives

$$V(x, y) = \frac{1}{2}(\theta + 3^{-1/3})\rho.$$

Noting that $\theta \in [-\alpha^{-1/3}, 3^{-1/3}]$ and that $\alpha > 3$, we obtain $\partial V/\partial\rho > 0$ in $S_2\backslash\{0\}$. In S_4 and S_5, natural coordinates are given by $\theta = -y/x^{3+\nu}$ and $\rho = x$, since the expressions (62) and (63) respectively give

$$\epsilon_4(x, y) = \left(\frac{\theta}{\beta}\right)^{\mu\xi} \rho$$

and

$$\epsilon_5(x, y) = \frac{1}{c}\left(\frac{\theta}{\gamma}\right)^{\frac{1}{3+\nu}} \rho,$$

from which it directly follows that $\partial V/\partial\rho > 0$ in $S_4 \cup S_5\backslash\{0\}$.

Now consider S_1. Natural polar coordinates are given by $\theta = y/x^3$ and $\rho = x$. Then we have

$$\tilde{G}_1(\rho, \theta, \epsilon) := \frac{G_1(x, y, \epsilon)}{x^3} = \theta + n - (n+3)\left(\frac{\epsilon}{\rho}\right)^3,$$

$$\frac{\partial \tilde{G}_1}{\partial \rho} = 3(n+3)\epsilon^3\rho^{-4} > 0,$$

$$\frac{\partial \tilde{G}_1}{\partial \epsilon} = \rho^{-3}\frac{\partial G_1}{\partial \epsilon} < 0,$$

where the inequalities hold for any (x, y) in $S_1\backslash\{0\}$. By the implicit function theorem, we conclude that $\partial V/\partial\rho > 0$ in $S_1\backslash\{0\}$.

Finally consider S_3. We can cover the sector with the following definition of "radial" curves: pick any (x_1, y_1) in S_3. If (x_1, y_1) is such that $-\alpha \le y_1/x_1^3 \le -\beta$, we define a radial curve through (x_1, y_1) by $\theta = \{(x, y) \in S_3 \mid y/x^3 = y_1/x_1^3\}$. If (x_1, y_1) is such that $y_1/x_1^3 \ge -\beta$, then we choose $s \in [0, \nu]$ such that $y_1/x_1^{3+s} = -\beta$ and define a radial curve through (x_1, y_1) by $\theta = \{(x, y) \in S_3 \mid y/x^{3+s} = y_1/x_1^{3+s}\}$. It is clear that with this definition, each point of $S_3\backslash\{0\}$ belongs to one (and only one) "radial" curve. We will show that V is strictly increasing as a function of $\rho := x$ on each "radial" curve.

Pick any "radial" curve in S_3. Then we have for some constant $s \in [0, \nu]$ and $C = y/x^{3+s} < 0$

$$\tilde{G}_3(\rho, \epsilon) := \frac{G_3(x, y, \epsilon)}{x^{3+s}} = C + \frac{1}{\rho^{3+s}}(-m(\rho - \epsilon)^3 + \beta\epsilon^{3+\nu}),$$

$$\frac{\partial \tilde{G}_3}{\partial \rho} = (3+s)C\frac{1}{\rho} + \frac{1}{\rho^{3+s}}\frac{\partial G_3}{\partial x} < 0,$$

$$\frac{\partial \tilde{G}_3}{\partial \epsilon} = \frac{1}{\rho^{3+s}}\frac{\partial G_3}{\partial \epsilon} > 0,$$

where the inequalities hold in $S_3 \setminus \{0\}$. By the implicit function theorem, we conclude that $\partial V / \partial \rho > 0$ in S_3, which ends the proof of the lemma. □

MODIFIED PROJECTION-TYPE METHODS FOR MONOTONE VARIATIONAL INEQUALITIES*

MICHAEL V. SOLODOV† AND PAUL TSENG‡

Abstract. We propose new methods for solving the variational inequality problem where the underlying function F is monotone. These methods may be viewed as projection-type methods in which the projection direction is modified by a strongly monotone mapping of the form $I-\alpha F$ or, if F is affine with underlying matrix M, of the form $I+\alpha M^T$, with $\alpha \in (0, \infty)$. We show that these methods are globally convergent, and if in addition a certain error bound based on the natural residual holds locally, the convergence is linear. Computational experience with the new methods is also reported.

Key words. monotone variational inequalities, projection-type methods, error bound, linear convergence

AMS subject classifications. 49M45, 90C25, 90C33

1. Introduction.

We consider the monotone variational inequality problem of finding an $x^* \in X$ satisfying

$$F(x^*)^T(x-x^*) \geq 0 \ \ \forall x \in X, \tag{1.1}$$

where X is a closed convex set in $\Re^n$ and F is a monotone and continuous function from $\Re^n$ to $\Re^n$. This problem, which we abbreviate as VI(X, F), is well known in optimization (see [1, 6, 15]) and, in the special case where F is affine and X is the nonnegative orthant, reduces to the classical monotone linear complementarity problem (LCP) (see [7, 36]).

Many methods have been proposed to solve VI(X, F). The simplest of these is the projection method [46] (also see [1, 2, 3, 8, 27]) which, starting with any $x \in \Re^n$, iteratively updates x according to the formula

$$x^{\text{new}} := [x-\alpha F(x)]^+,$$

where $[\cdot]^+$ denotes the orthogonal projection map onto X and α is a judiciously chosen positive stepsize. However, the projection method requires the restrictive assumption that F or F^{-1} be strongly monotone for convergence. The extragradient method [22] (also see [47, 20, 21, 31] for extensions) overcomes this difficulty by the ingenious technique of updating x according to the double projection formula:

$$x^{\text{new}} := \left[x-\alpha F\left([x-\alpha F(x)]^+\right)\right]^+.$$

This method, by virtue of its using only function evaluations and projection onto X, is easy to implement, uses little storage, and can readily exploit any sparsity or separable structure in F or in X, such as those arising in the applications considered in [3, 9, 38, 45]. Moreover, its convergence requires only that a solution exists [20], while its only drawback is its, at best, linear convergence. In contrast, the methods in [4, 8, 12, 27, 32, 33, 34, 38, 40, 50, 54] require restrictive assumptions on the problem (such as F or F^{-1} being strongly monotone or F being affine; for some of the methods, it is further required that F be continuously differentiable with nonsingular Jacobian or X be bounded and polyhedral), while the matrix-splitting methods in

[10, 34, 49, 51] are applicable only when F is affine (and these methods also have, at best, linear convergence). And all these methods require more computation per iteration than the extragradient method. For the special case where X is the nonnegative orthant (the monotone nonlinear complementarity problem) or a box, many other solution methods exist, but these methods tend to be ill suited for large sparse problems and are not practically extendable to more general X. Thus, it can be said that, unless F has a special structure (F or F^{-1} is strongly monotone or F is affine) and X has a special structure (X is polyhedral or, better still, just a box), the extragradient method is a very practical method (and sometimes the only practical method) for solving VI(X, F). And, even when F is affine, there are situations where the extragradient method may be practical. As a case in point, suppose X is the Cartesian product of simplices and ellipsoids and F is affine with an underlying matrix M that is asymmetric, positive semidefinite, sparse, and having no particular structure (so M^{-1} may be dense and impractical to compute). The extragradient method can be practically implemented to solve this special case of VI(X, F) since it requires only projection onto the simplices and ellipsoids (for which many efficient methods exist [42, 53]) and multiplication of x by the sparse matrix M. In contrast, the matrix-splitting methods in [10, 34, 49, 51] require solving a nontrivial strongly monotone variational inequality problem over X at each iteration. And even on structured problems such as the discrete-time deterministic optimal control problem [45], the extragradient method may yet be practical since it is linearly convergent like the methods in [5, 10, 49, 55], while its iterations are simpler.

In this paper, we propose a new class of methods for solving VI(X, F) that are as versatile and capable of exploiting problem structure as the extragradient method and, yet, are even simpler than the latter and have a scaling feature absent in the latter. And our preliminary computational experience suggests that the new methods are practical alternatives to the extragradient method. The idea of the new methods is to choose an $n \times n$ symmetric positive definite matrix P and, starting with any $x \in \Re^n$, to iteratively update x according to the formula

$$x^{\text{new}} := x - \gamma P^{-1}\left(T_\alpha(x) - T_\alpha\left([x - \alpha F(x)]^+\right)\right), \tag{1.2}$$

where γ is a positive stepsize and either $T_\alpha \equiv I - \alpha F$ or, if F is affine with underlying matrix M, $T_\alpha \equiv I + \alpha M^T$, with $\alpha \in (0, \infty)$ chosen so T_α is strongly monotone. These methods are like the projection method except the projection direction $[x - \alpha F(x)]^+ - x$ is modified by T_α and P^{-1}. Like the extragradient method, these methods use two function evaluations per iteration and, as we shall show (see Theorems 2.1 and 3.2), their convergence requires only that a solution exists. Unlike the extragradient method, these methods require only one projection per iteration, rather than two, and they have an additional parameter, the scaling matrix P, that can be chosen to help accelerate the convergence (see §2 and §4 for examples and further discussions). Thus, the new methods require less work per iteration than does the extragradient method (assuming P is chosen so P^{-1} is easily computed and stored), with the savings being the greatest when the projection is expensive. Our computational experience (§4) suggests that the new methods are practical alternatives to the extragradient method, especially when F is affine or when projection onto X is expensive.

Although we will also present computational results to illustrate the practical behavior of the new methods, the focus of our paper is on laying the theoretical foundations for these methods. In particular, we will present various convergence and rate of convergence results for the new methods. Central to our rate of convergence analysis is the following growth condition on the 2-norm of the projection residual function $r : \Re^n \mapsto \Re^n$, given by

$$r(x) = x - [x - F(x)]^+,$$

near the solution set S of VI(X, F) (i.e., S comprises all $x^* \in X$ satisfying (1.1)): There exist positive constants μ and δ (depending on F, X only) such that

$$d(x, S) \leq \mu \|r(x)\| \quad \forall x \text{ with } \|r(x)\| \leq \delta, \tag{1.3}$$

where $\|\cdot\|$ denotes the 2-norm and $d(\cdot, S)$ denotes the 2-norm distance to S. (It is well known that an $x^* \in \Re^n$ solves VI(X, F) if and only if $r(x^*) = 0$.) This growth condition on $\|r(\cdot)\|$ (also called error bound) has been used in the rate of convergence analysis of various methods [25, 26, 51] and is known to hold whenever X is polyhedral and either F is affine (see [26, 43]) or F has certain strong monotonicity structure (see [51, Thm. 2]). Moreover, under additional assumptions on F, this condition holds with $\delta = \infty$ (see [23, 24, 28, 39]). Our rate of convergence analysis, similar to that in [51], entails (roughly) showing that $d(x, S)^2$ decreases by an amount in the order of $\|r(x)\|^2$ per iteration, so $\|r(x)\|$ must eventually decrease below δ, at which time (1.3) yields that $d(x, S)^2$ decreases at a linear rate. The analysis is also similar in spirit to those for feasible descent methods (see [25, 26, 28]) but uses $d(\cdot, S)^2$, rather than the objective function, as the merit function.

Our main results are as follows: In §2, we consider the special case of VI(X, F) where F is affine. We show that, for suitable choices of the stepsize γ, the iterates generated by (1.2) with $T_\alpha \equiv I + \alpha M^T$ and $\alpha = 1$ converge to a solution of VI(X, F) and, under the assumption of (1.3) for some μ and δ, the convergence is linear (see Algorithm 2.1 and Theorem 2.1). We then extend this method by replacing the projection direction with a more general matrix-splitting direction (see Algorithm 2.2 and Theorem 2.2). Also, we consider a modification of this method whereby one of the "$[x - F(x)]^+$" terms is replaced with $x - F(x)$ and an extra projection step is taken (see Algorithm 2.3 and Theorem 2.3). In §3, we consider the general case of VI(X, F) and we analogously analyze the convergence of iterates generated by (1.2) with $T_\alpha \equiv I - \alpha F$ (see Algorithms 3.1, 3.2 and Theorems 3.1, 3.2). In §4, we report our preliminary computational experience with the new methods on sparse linear programs (LPs), dense monotone LCPs, and linearly constrained variational inequality problems. In §5, we give some concluding remarks.

Subsequent to the writing of this paper, we learned of the recently proposed methods of He [18, 19] which may be viewed as special cases of Algorithm 2.1 in §2, with specific choices of the scaling matrix P. He's convergence and rate of convergence results for his methods are similar to ours for Algorithm 2.1 (Theorem 2.1), although He's rate of convergence results further require X to be an orthant. In an earlier work [17], He proposed a related method which may be viewed as a version of Algorithm 2.3 in §2 with $P = I$ and X an orthant, but using a different choice of the stepsize γ_i. During the finalization of this paper, we learned of a very recently proposed method of Sun [48] which may be viewed as a version of Algorithm 3.2 in §3 with $P = I$, but using a different choice of the stepsize γ_i (see Remark 4.3 therein). The convergence analysis in [48] applies to the more general problem where F is pseudomonotone and continuous, though no convergence rate result was given.

A few words about our notation. We denote by $\Re^n$ the space of n-dimensional real column-vectors and by superscript T the transpose (of vectors and matrices). We denote by $\|\cdot\|$ the 2-norm (i.e., $\|x\| = (x^T x)^{\frac{1}{2}}$ for all vectors x) and, for any $n \times n$ symmetric positive definite matrix P, by $\|\cdot\|_P$ the 2-norm in $\Re^n$ scaled by P (i.e., $\|x\|_P = (x^T P x)^{\frac{1}{2}}$ for all $x \in \Re$) and by $P^{-1/2}$ the (unique) $n \times n$ symmetric positive definite matrix whose product with itself is P^{-1}. We denote by I either the identity matrix or the identity map and, by R-linear convergence and Q-linear convergence, we mean linear convergence in the root sense and in the quotient sense, respectively, as defined in [37].

2. Algorithms for F affine. In this section we consider the case of VI(X, F) where F is monotone and affine, i.e.,

$$F(x) = Mx + q$$

for some $n \times n$ positive semidefinite (not necessarily symmetric) matrix M and some $q \in \Re^n$. We present and analyze three methods for solving this special case of VI(X, F). The first method is our basic method (1.2) with $T_\alpha \equiv I + \alpha M^T$ and, for simplicity, $\alpha = 1$. The second method is an extension of the first method in which the projection direction is replaced with a matrix-splitting direction. The third method is a modification of the first method in which the projection operation is removed from one part and added to another part of the method.

We describe the first method formally below.

ALGORITHM 2.1. *Choose any $n \times n$ symmetric positive definite matrix P and any $x^0 \in \Re^n$. Also choose a $\theta \in (0, 2)$. For $i = 0, 1, \ldots$, compute x^{i+1} from x^i according to*

$$x^{i+1} = x^i - \gamma_i P^{-1}(I + M^T)r(x^i), \tag{2.1}$$

where

$$\gamma_i = \theta \| P^{-1/2}(I + M^T)r(x^i)\|^{-2} \|r(x^i)\|^2. \tag{2.2}$$

The parameters P and θ are key to the performance of Algorithm 2.1. We can choose P so that P^{-1} is easily computed and stored (e.g., $P = I$) or so that $\|P^{-1/2}(I + M^T)\|$ is small (e.g., $P = (I + M^T)(I + M)$) so γ_i is large. Below we show that this simple method is convergent and, when the error bound (1.3) holds, is linearly convergent. The proof is based on showing that $(I + M^T)r(x)$ makes an acute angle with $x - x^*$ for any solution x^*, so the distance from x to the solution set S, measured in the scaled 2-norm $\| \cdot \|_P$, decreases when x is moved opposite the direction $P^{-1}(I + M^T)r(x)$.

THEOREM 2.1. *Assume that $F(x) = Mx + q$ for some $n \times n$ positive semidefinite matrix M and some $q \in \Re^n$, and that the solution set S of* VI(X, F) *is nonempty. Then any sequence $\{x^i\}$ generated by Algorithm* 2.1 *converges to an element of S and, if* (1.3) *holds for some μ and δ, the convergence is R-linear.*

Proof. Let x^* be any element of S. For each $i \in \{0, 1, \ldots\}$, we have from (2.1) that

$$\begin{aligned} &\|x^{i+1} - x^*\|_P^2 \\ &= \|x^i - x^* - \gamma_i P^{-1}(I + M^T)r(x^i)\|_P^2 \\ &= \|x^i - x^*\|_P^2 - 2\gamma_i (x^i - x^*)^T (I + M^T)r(x^i) + \gamma_i^2 \|P^{-1/2}(I + M^T)r(x^i)\|^2. \end{aligned} \tag{2.3}$$

We bound below the next-to-last term in (2.3). Let $z^i = [x^i - Mx^i - q]^+$ (so $r(x^i) = x^i - z^i$). By properties of the projection operator, we have

$$0 \le (y - z^i)^T (Mx^i + q + z^i - x^i) \ \ \forall y \in X.$$

Similarly, since x^* is a solution of VI(X, F), we have

$$0 \le (y - x^*)^T (Mx^* + q) \ \ \forall y \in X.$$

Taking $y = x^*$ in the first inequality and taking $y = z^i$ in the second inequality and then adding the two resulting inequalities yields

$$\begin{aligned} 0 &\le (x^* - z^i)^T (M(x^i - x^*) + z^i - x^i) \\ &= (x^* - x^i)^T M(x^i - x^*) + (x^i - x^*)^T (I + M^T)(x^i - z^i) - \|x^i - z^i\|^2 \\ &\le (x^i - x^*)^T (I + M^T)(x^i - z^i) - \|x^i - z^i\|^2 \\ &= (x^i - x^*)^T (I + M^T)r(x^i) - \|r(x^i)\|^2, \end{aligned}$$

where the second inequality follows from the positive semidefinite property of M. Using this to bound the next-to-last term in (2.3) yields the key relation

$$\|x^{i+1}-x^*\|_P^2 \le \|x^i-x^*\|_P^2 - 2\gamma_i\|r(x^i)\|^2 + \gamma_i^2\|P^{-1/2}(I+M^T)r(x^i)\|^2$$

$$= \|x^i-x^*\|_P^2 - \theta(2-\theta)\|P^{-1/2}(I+M^T)r(x^i)\|^{-2}\|r(x^i)\|^4 \tag{2.4}$$

$$\le \|x^i-x^*\|_P^2 - \theta(2-\theta)\|P^{-1/2}(I+M^T)\|^{-2}\|r(x^i)\|^2, \tag{2.5}$$

where the equality follows from (2.2). The remaining argument is patterned after the proof of [44, Thm. 1] and of [51, Thm. 1].

Since (2.5) holds for all i, it follows that $\|x^i-x^*\|_P$ is nonincreasing with i and that $\|r(x^i)\| \to 0$ as $i \to \infty$. This shows that $\{x^i\}$ is bounded and, by continuity of $r(\cdot)$, each cluster point x^∞ satisfies $r(x^\infty)=0$ and hence is in S. Then, we can choose x^* in (2.5) to be x^∞ and conclude that $\|x^i-x^\infty\|_P \to 0$ as $i \to \infty$, i.e., $\{x^i\}$ converges to x^∞.

Assume that (1.3) holds for some μ and δ. Let $\psi(x) = \min_{x^* \in S}\|x-x^*\|_P^2$ (so $\psi(x) \le \|P\|d(x,S)^2$). Since (2.4) holds for all i and all $x^* \in S$, by choosing (for each i) x^* to be the element of S closest to x^i in the norm $\|\cdot\|_P$, we obtain for all i

$$\psi(x^{i+1}) \le \|x^{i+1}-x^*\|_P^2$$

$$\le \|x^i-x^*\|_P^2 - \theta(2-\theta)\|P^{-1/2}(I+M^T)r(x^i)\|^{-2}\|r(x^i)\|^4$$

$$= \psi(x^i) - \theta(2-\theta)\|P^{-1/2}(I+M^T)r(x^i)\|^{-2}\|r(x^i)\|^4 \tag{2.6}$$

$$\le \psi(x^i) - \eta\|r(x^i)\|^2, \tag{2.7}$$

where we let $\eta = \theta(2-\theta)\|P^{-1/2}(I+M^T)\|^{-2}$. Since $\|r(x^i)\| \to 0$, we have $\|r(x^i)\| \le \delta$ for all i greater than some $\bar{i}$, in which case (1.3) yields $d(x^i,S) \le \mu\|r(x^i)\|$. Using this to bound the right-hand side of the above inequality yields

$$\psi(x^{i+1}) \le \psi(x^i) - \frac{\eta}{\mu^2}d(x^i,S)^2 \le \psi(x^i) - \frac{\eta}{\mu^2\|P\|}\psi(x^i)$$

for all $i > \bar{i}$, so $\{\psi(x^i)\}$ converges Q-linearly to zero and, by (2.7), $\{r(x^i)\}$ converges R-linearly to zero. Since by (2.1), (2.2), and (2.6) we have

$$\|x^{i+1}-x^i\|_P = \theta\|P^{-1/2}(I+M^T)r(x^i)\|^{-1}\|r(x^i)\|^2 \le \theta^{1/2}(2-\theta)^{-1/2}(\psi(x^i)-\psi(x^{i+1}))^{1/2}$$

for all i, it follows from $\{\psi(x^i)\}$ converging Q-linearly to zero that $\{\|x^{i+1}-x^i\|_P\}$ converges R-linearly to zero and hence $\{x^i\}$ converges R-linearly. □

The above proof shows that we can alternatively choose $\gamma_i = \bar{\gamma}$ for all i in Algorithm 2.1, where $\bar{\gamma}$ is any scalar satisfying

$$0 < \bar{\gamma} < 2\|P^{-1/2}(I+M^T)\|^{-2}.$$

However, this constant stepsize choice is impractical since it is conservative and difficult to compute.

Algorithm 2.1 can be further extended by replacing the projection term $[x-(Mx+q)]^+$ in the definition of $r(x)$ with a more general matrix-splitting term. In particular, consider the following method.

ALGORITHM 2.2. *Choose any $n \times n$ symmetric positive definite matrix P and any $x^0 \in \Re^n$. Also choose an $n \times n$ positive definite matrix B and a $\theta \in (0,2)$. For $i=0,1,\ldots$, compute x^{i+1} from x^i according to*

$$x^{i+1} = x^i - \gamma_i P^{-1}(B+M^T)(x^i-z^i) \tag{2.8}$$

where z^i is the unique solution of the nonlinear equations

$$z^i = [z^i - (B(z^i - x^i) + Mx^i + q)]^+ \tag{2.9}$$

and γ_i is given by

$$\gamma_i = \theta \| P^{-1/2}(B + M^T)(x^i - z^i)\|^{-2}(x^i - z^i)^T B(x^i - z^i). \tag{2.10}$$

Notice that if we choose $B = I$, then Algorithm 2.2 reduces to Algorithm 2.1. In general, we should choose B to be close to M (so that z^i is close to S for fast convergence) and yet to have enough structure (e.g., lower/upper triangular or tridiagonal or block diagonal) so that z^i is easily computable. We have the following result whose proof is similar to that of Theorem 2.1 and thus is omitted.

THEOREM 2.2. *Assume that $F(x) = Mx + q$ for some $n \times n$ positive semidefinite matrix M and some $q \in \Re^n$, and that the solution set S of* VI(X, F) *is nonempty. Then any sequence $\{x^i\}$ generated by Algorithm* 2.2 *converges to an element of S and, if* (1.3) *holds for some μ and δ, the convergence is R-linear.*

We note that Algorithm 2.2 is closely related to the following iterative method proposed in [11]:

$$x^{i+1} = \arg\min_{x \in X} \left\{ \psi_i(x) := (x - x^i)^T(Mx + q) + \frac{\nu}{2}\|x - x^i\|^2 \right\}, \tag{2.11}$$

where ν is a positive scalar. For the specific choice of $B = M + M^T + \nu I$, we have from (2.9) that

$$\begin{aligned} z^i &= [z^i - (B(z^i - x^i) + Mx^i + q)]^+ \\ &= [z^i - \big((M + M^T + \nu I)(z^i - x^i) + Mx^i + q\big)]^+ \\ &= [z^i - \big((M + M^T)z^i - M^T x^i + q + \nu(z^i - x^i)\big)]^+ \\ &= [z^i - \nabla\psi_i(z^i)]^+, \end{aligned}$$

so that

$$z^i = \arg\min_{x \in X} \psi_i(x).$$

Thus (2.9) generalizes (2.11). We note that in [11] no convergence result is given for (2.11). Theorem 2.2 shows that if the step (2.8) is added, the resulting method (2.8)–(2.10) converges to a solution of VI(X, F) and, if (1.3) holds (as in the case where X is also polyhedral), the convergence is R-linear.

Additional modifications of the preceding methods are possible. For example, we can pass each iterate through a nearest-point projection (with respect to the norm $\|\cdot\|_P$) on to X. For Algorithm 2.1, this modification would entail replacing (2.1) with

$$x^{i+1} = [x^i - \gamma_i P^{-1}(I + M^T)r(x^i)]_P^+,$$

where $[y]_P^+$ denotes the point in X whose distance to y (measured in the norm $\|\cdot\|_P$) is minimal. To see that this does not affect the convergence (and, in fact, accelerates convergence) of the methods, we use the following fact about nearest-point projection:

$$\|[y]_P^+ - x^*\|_P^2 \le \|y - x^*\|_P^2 - \|y - [y]_P^+\|_P^2 \tag{2.12}$$

for all $y \in \Re^n$ and all $x^* \in X$ (see, e.g., [31, Appendix]).

We next present a modification, rather than an extension, of Algorithm 2.1, in which we expand out $(I + M^T)r(x^i) = x^i - [x^i - (Mx^i + q)]^+ + M^T r(x^i)$ and replace the "$[x^i - (Mx^i + q)]^+$" term with $x^i - (Mx^i + q)$. In contrast to Algorithm 2.1, an extra projection onto X is needed.

ALGORITHM 2.3. *Choose any $n \times n$ symmetric positive definite matrix P and any $x^0 \in X$. Also choose a $\theta \in (0, 2)$. For $i = 0, 1, \ldots$, compute x^{i+1} from x^i according to*

$$x^{i+1} = \left[x^i - \gamma_i P^{-1}(Mx^i + q + M^T r(x^i))\right]_P^+, \tag{2.13}$$

where γ_i is given by

$$\gamma_i = \theta \| P^{-1/2}(Mx^i + q + M^T r(x^i))\|^{-2} \|r(x^i)\|^2. \tag{2.14}$$

The convergence properties of Algorithm 2.3 are stated in the following theorem, whose proof is similar to that of Theorem 2.1.

THEOREM 2.3. *Assume that $F(x) = Mx + q$ for some $n \times n$ positive semidefinite matrix M and some $q \in \Re^n$, and that the solution set S of* VI(X, F) *is nonempty. Then any sequence $\{x^i\}$ generated by Algorithm* 2.3 *converges to an element of S.*

Proof. Let x^* be any element of S. For each $i \in \{0, 1, \ldots\}$, we have from (2.13) and (2.12) (with $y = x^i - \gamma_i P^{-1}(Mx^i + q + M^T r(x^i))$) that

$$\begin{aligned} \|x^{i+1} - x^*\|_P^2 &\le \|x^i - x^* - \gamma_i P^{-1}(Mx^i + q + M^T r(x^i))\|_P^2 \\ &= \|x^i - x^*\|_P^2 - 2\gamma_i (x^i - x^*)^T (Mx^i + q + M^T r(x^i)) \\ &\quad + \gamma_i^2 \| P^{-1/2}(Mx^i + q + M^T r(x^i))\|^2. \end{aligned} \tag{2.15}$$

We bound below the next-to-last term in (2.15). Let $z^i = [x^i - Mx^i - q]^+$ (so $r(x^i) = x^i - z^i$). By properties of the projection operator, we have

$$0 \le (y - z^i)^T (Mx^i + q + z^i - x^i) \quad \forall y \in X.$$

Similarly, since x^* is a solution of VI(X, F), we have

$$0 \le (y - x^*)^T (Mx^* + q) \quad \forall y \in X.$$

Taking $y = x^i$ in the first inequality and taking $y = z^i$ in the second inequality and then adding the two resulting inequalities yield

$$\begin{aligned} 0 &\le (x^i - z^i)^T (Mx^i + q + z^i - x^i) + (z^i - x^*)^T (Mx^* + q) \\ &= (x^i - x^*)^T (Mx^i + q + M^T (x^i - z^i)) + (x^i - x^*)^T M (x^* - x^i) - \|x^i - z^i\|^2 \\ &\le (x^i - x^*)^T (Mx^i + q + M^T (x^i - z^i)) - \|x^i - z^i\|^2 \\ &= (x^i - x^*)^T (Mx^i + q + M^T r(x^i)) - \|r(x^i)\|^2, \end{aligned}$$

where the second inequality follows from the positive semidefinite property of M. Using this to bound the next-to-last term in (2.3) yields

$$\begin{aligned} \|x^{i+1} - x^*\|_P^2 &\le \|x^i - x^*\|_P^2 - 2\gamma_i \|r(x^i)\|^2 + \gamma_i^2 \| P^{-1/2}(Mx^i + q + M^T r(x^i))\|^2 \\ &= \|x^i - x^*\|_P^2 - \theta(2 - \theta) \| P^{-1/2}(Mx^i + q + M^T r(x^i))\|^{-2} \|r(x^i)\|^4, \end{aligned}$$

where the equality follows from (2.14). The remainder of the proof is similar to that of Theorem 2.1, but using the above relation instead of (2.5). □

Notice that Algorithm 2.3 requires two projections per iteration, the same as the extragradient method. However, unlike the extragradient method, Algorithm 2.3 does not appear to have linear convergence, even if (1.3) holds for some μ and δ.[1]

3. Algorithms for F nonaffine. In this section we consider the general case of VI(X, F) where F is monotone and continuous. We present and analyze two versions of our basic method (1.2) with $T_\alpha \equiv I - \alpha F$ and with α chosen so T_α is strongly monotone. The first version, which uses a fixed α, is simpler but requires F furthermore to be Lipschitz continuous. The second version, which chooses α dynamically, is more intricate but is more practical and solves the general problem.

We describe the first method formally below. For this method to be applicable, we require F furthermore to be Lipschitz continuous.

ALGORITHM 3.1. *Choose any $n \times n$ symmetric positive definite matrix P and any $x^0 \in \Re^n$. Also choose any $\theta \in (0, 2)$ and any $\alpha \in (0, 1/\lambda)$, where λ is a constant satisfying*

$$(x - z)^T(F(x) - F(z)) \leq \lambda \|x - z\|^2 \quad \forall x, z \in \Re^n. \tag{3.1}$$

(We can, for example, take λ to be the Lipschitz constant of F.) For $i = 0, 1, \ldots$, compute x^{i+1} from x^i according to

$$x^{i+1} = x^i - \gamma_i P^{-1}(x^i - z^i - \alpha F(x^i) + \alpha F(z^i)), \tag{3.2}$$

where z^i and γ_i are given by, respectively,

$$z^i = [x^i - \alpha F(x^i)]^+, \tag{3.3}$$

$$\gamma_i = \theta(1 - \alpha\lambda)\|P^{-1/2}(x^i - z^i - \alpha F(x^i) + \alpha F(z^i))\|^{-2}\|x^i - z^i\|^2. \tag{3.4}$$

Algorithm 3.1 requires less computation per iteration than the extragradient method (in particular, it avoids performing an extra projection step). Also, unlike the extragradient method, Algorithm 3.1 allows scaling of direction by P^{-1} without having to accordingly scale the norm with respect to which projection is taken. In the case where F is affine, i.e., $F(x) = Mx + q$ for some $n \times n$ positive semidefinite matrix M and some $q \in \Re^n$, the formula (3.2) reduces to

$$x^{i+1} = x^i - \gamma_i P^{-1}(I - \alpha M)(x^i - z^i),$$

which is reminiscent of (2.1). If in addition M is skew symmetric (i.e., $M^T = -M$) so that (3.1) holds with $\lambda = 0$, we can choose α arbitrarily large and can reasonably choose P to be $P = (I - \alpha M)(I - \alpha M^T)$. In fact, for the choice of $\alpha = 1$ (and using $M^T = -M$), the formula (3.2) reduces precisely to (2.1).

We show in the following theorem that Algorithm 3.1 has convergence properties similar to that of Algorithm 2.1. The proof of this theorem is patterned after that of Theorem 2.1.

THEOREM 3.1. *Assume that F is monotone and Lipschitz continuous and that the solution set S of* VI(X, F) *is nonempty. Then any sequence $\{x^i\}$ generated by Algorithm* 3.1 *converges to an element of S and, if* (1.3) *holds for some μ and δ, the convergence is R-linear.*

Proof. Let x^* be any element of S. For each $i \in \{0, 1, \ldots\}$, we have from (3.2) that

$$\begin{aligned} \|x^{i+1} - x^*\|_P^2 &= \|x^i - x^* - \gamma_i P^{-1}(x^i - z^i - \alpha F(x^i) + \alpha F(z^i))\|_P^2 \\ &= \|x^i - x^*\|_P^2 - 2\gamma_i(x^i - x^*)^T(x^i - z^i - \alpha F(x^i) + \alpha F(z^i)) \\ &\quad + \gamma_i^2\|P^{-1/2}(x^i - z^i - \alpha F(x^i) + \alpha F(z^i))\|^2. \end{aligned} \tag{3.5}$$

[1] Subsequent to the writing of the original paper, we were informed by B. He that, for the method he proposed in [17] (which may be viewed as Algorithm 2.3 with $P = I$ and X an orthant, but using a different choice of γ_i), he could show a linear convergence result analogous to that shown in [18] (see [19, eq. (8)]).

We bound below the next-to-last term in (3.5). By (3.3) and properties of the projection operator, we have

$$0 \le (y - z^i)^T(\alpha F(x^i) + z^i - x^i) \quad \forall y \in X.$$

Similarly, since x^* is a solution of VI(X, F), we have

$$0 \le (y - x^*)^T F(x^*) \quad \forall y \in X.$$

Taking $y = x^*$ in the first inequality and taking $y = z^i$ in the second inequality and then adding the two resulting inequalities yield

$$\begin{aligned}
0 &\le (x^* - z^i)^T(\alpha F(x^i) + z^i - x^i) + \alpha(z^i - x^*)^T F(x^*) \\
&= \alpha(x^* - z^i)^T(F(z^i) - F(x^*)) + (x^* - x^i)^T(\alpha F(x^i) - \alpha F(z^i) + z^i - x^i) \\
&\quad + \alpha(x^i - z^i)^T(F(x^i) - F(z^i)) - \|x^i - z^i\|^2 \\
&\le (x^* - x^i)^T(\alpha F(x^i) - \alpha F(z^i) + z^i - x^i) + \alpha(x^i - z^i)^T(F(x^i) - F(z^i)) - \|x^i - z^i\|^2 \\
&\le (x^* - x^i)^T(\alpha F(x^i) - \alpha F(z^i) + z^i - x^i) - (1 - \alpha\lambda)\|x^i - z^i\|^2,
\end{aligned}$$

where the second inequality follows from the monotone property of F and the last inequality follows from (3.1). Using this to bound the next-to-last term in (3.5) yields

$$\begin{aligned}
&\|x^{i+1} - x^*\|_P^2 \\
&\le \|x^i - x^*\|_P^2 - 2\gamma_i(1 - \alpha\lambda)\|x^i - z^i\|^2 + \gamma_i^2\|P^{-1/2}(x^i - z^i - \alpha F(x^i) + \alpha F(z^i))\|^2 \\
&= \|x^i - x^*\|_P^2 - \theta(2 - \theta)(1 - \alpha\lambda)^2\|P^{-1/2}(x^i - z^i - \alpha F(x^i) + \alpha F(z^i))\|^{-2}\|x^i - z^i\|^4,
\end{aligned} \tag{3.6}$$

where the equality follows from (3.4).

The remainder of the proof is similar to that of Theorem 2.1, but using (3.6) instead of (2.5). For the R-linear convergence result, we also use the observations (see (3.3) and (3.4)) that

$$\begin{aligned}
\|x^{i+1} - x^i\|_P &= \theta(1 - \alpha\lambda)\|P^{-1/2}(x^i - z^i - \alpha F(x^i) + \alpha F(z^i))\|^{-1}\|x^i - z^i\|^2 \\
&\ge \theta(1 - \alpha\lambda)\|P^{-1/2}\|^{-1}(1 + \alpha L)^{-1}\|x^i - z^i\| \\
&\ge \theta(1 - \alpha\lambda)\|P^{-1/2}\|^{-1}(1 + \alpha L)^{-1}\min\{1, \alpha\}\|r(x^i)\|
\end{aligned}$$

for all i, where L denotes the Lipschitz constant of F and the last inequality follows from [13, Lem. 1]. Thus, the rightmost term in (3.6) is bounded above by a positive constant times $-\|r(x^i)\|^2$ and, whenever this term converges R-linearly to zero as $i \to \infty$, so does $\|x^{i+1} - x^i\|_P^2$; hence $\{x^i\}$ converges R-linearly. □

Algorithm 3.1 is a conceptual method since in practice F need not be Lipschitz continuous or the constant λ may be difficult to estimate or a stepsize of less than $1/\lambda$ may be too conservative. Below we present a practical version of Algorithm 3.1 that chooses α dynamically according to a novel Armijo–Goldstein-type rule. This practical version has all the convergence properties of Algorithm 3.1 and requires F to be only monotone and continuous for convergence (see Theorem 3.2).

ALGORITHM 3.2. *Choose any $n \times n$ symmetric positive definite matrix P and any $x^0 \in \Re^n$ and $\alpha_{-1} \in (0, \infty)$. Also choose any $\theta \in (0, 2)$, $\rho \in (0, 1)$, and $\beta \in (0, 1)$. For $i = 0, 1, \ldots$, compute (x^{i+1}, α_i) from (x^i, α_{i-1}) according to: Choose α_i to be the largest $\alpha \in \{\alpha_{i-1}, \alpha_{i-1}\beta, \alpha_{i-1}\beta^2, \ldots\}$ satisfying*

$$\alpha(x^i - z^i(\alpha))^T(F(x^i) - F(z^i(\alpha))) \le (1 - \rho)\|x^i - z^i(\alpha)\|^2, \tag{3.7}$$

and let

$$x^{i+1} = x^i - \gamma_i P^{-1}(x^i - z^i(\alpha_i) - \alpha_i F(x^i) + \alpha_i F(z^i(\alpha_i))), \tag{3.8}$$

where $z^i(\alpha)$ *and* γ_i *are given by, respectively,*

$$z^i(\alpha) = [x^i - \alpha F(x^i)]^+ \quad \forall \alpha \in (0, \infty), \tag{3.9}$$

$$\gamma_i = \theta\rho \| P^{-1/2}(x^i - z^i(\alpha_i) - \alpha_i F(x^i) + \alpha_i F(z^i(\alpha_i)))\|^{-2} \|x^i - z^i(\alpha_i)\|^2. \tag{3.10}$$

The motivation for taking trial values of α starting at α_{i-1} comes from our empirical experience that, for $i > 0$, $\alpha = \alpha_{i-1}$ either satisfies or comes close to satisfying (3.7), so in general only a few trial values of α are needed to find α_i. The condition (3.7) may be viewed as a local approximation to the condition $\alpha < 1/\lambda$ used in Algorithm 3.1. (If we let $\lambda_i = (x^i - z^i(\alpha))^T(F(x^i) - F(z^i(\alpha)))/\|x^i - z^i(\alpha)\|^2$, then (3.7) reduces to $\alpha \leq (1-\rho)/\lambda_i$.) We had also considered choosing α_i to be the largest $\alpha \in \{\sigma, \sigma\beta, \sigma\beta^2, \ldots\}$ satisfying (3.7), where $\sigma \in (0, \infty)$. It can be checked that the convergence results below still hold for this alternative stepsize rule, but this rule is not as practical since it typically needs many more trial values of α to find α_i. Lastly, as with Algorithm 2.1 for the affine case, we can pass each iterate generated by Algorithm 3.2 through a nearest-point projection (with respect to the norm $\|\cdot\|_P$) onto X and the convergence results below would still hold.

Below we present the convergence results for Algorithm 3.2. The proof is patterned after that for Theorem 3.1 and, for simplicity, we supply only the key steps.

THEOREM 3.2. *Assume that* F *is monotone and continuous and that the solution set* S *of* VI(X, F) *is nonempty. Then any sequence* $\{x^i\}$ *generated by Algorithm* 3.2 *converges to an element of* S *and, if* (1.3) *holds for some* μ *and* δ *and* F *is Lipschitz continuous on* $S + \epsilon B$ *for some* $\epsilon > 0$ *(where* $B = \{x \mid \|x\| \leq 1\}$*), the convergence is R-linear.*

Proof. First, we claim that, for each i, (3.7) holds for all α sufficiently small, so α_i is well defined. To see this, note that $z^i(\alpha) \to [x^i]^+$ as $\alpha \to 0$, so if $x^i \notin X$, then the right-hand side of (3.7) would tend to a positive limit while the left-hand side of (3.7) would tend to zero as $\alpha \to 0$, implying the claim. If $x^i \in X$ (so $x^i = [x^i]^+$), then since F is continuous and $z^i(\alpha) \to [x^i]^+ = x^i$ as $\alpha \to 0$, we have

$$\|F(x^i)\| \|F(x^i) - F(z^i(\alpha))\| \leq (1-\rho)\|r(x^i)\|^2$$

for all $\alpha \in (0, 1]$ sufficiently small. For any such α, we have

$$\begin{aligned}
\alpha(x^i - z^i(\alpha))^T(F(x^i) - F(z^i(\alpha))) &= \alpha([x^i]^+ - [x^i - \alpha F(x^i)]^+)^T(F(x^i) - F(z^i(\alpha))) \\
&\leq \alpha^2 \|F(x^i)\| \|F(x^i) - F(z^i(\alpha))\| \\
&\leq \alpha^2(1-\rho)\|r(x^i)\|^2 \\
&\leq (1-\rho)\|x^i - z^i(\alpha)\|^2,
\end{aligned}$$

where the first inequality uses the Cauchy–Schwartz inequality and the nonexpansive property of $[\cdot]^+$; the last inequality uses $\alpha \in (0, 1]$ and [13, Lem. 1]. Thus, the claim holds.

To show that $\{x^i\}$ converges to an element of S, let x^* be any element of S. For each $i \in \{0, 1, \ldots\}$, we have by an argument analogous to the proof of Theorem 3.1, but with (3.1)–(3.4) replaced by (3.7)–(3.10) (and taking $\alpha = \alpha_i$ in (3.7)), that (cf. (3.6))

$$\begin{aligned}
\|x^{i+1} - x^*\|_P^2 \leq \|x^i - x^*\|_P^2 &- \theta(2-\theta)\rho^2 \|x^i - z^i(\alpha_i)\|^4 \\
&\cdot \|P^{-1/2}(x^i - z^i(\alpha_i) - \alpha_i F(x^i) + \alpha_i F(z^i(\alpha_i)))\|^{-2}.
\end{aligned} \tag{3.11}$$

Thus $\{x^i\}$ is bounded and $\{\|x^i - z^i(\alpha_i)\|\} \to 0$. Also, $\{\alpha_i\}$ is nonincreasing, so it has a limit α_∞. We claim that $\{x^i\}$ has at least one cluster point in S. In the case where $\alpha_\infty > 0$, this

follows from $\{\|x^i - z^i(\alpha_i)\|\} \to 0$ and the the continuity of F and the projection operator, which imply that every cluster point x^∞ of $\{x^i\}$ satisfies

$$x^\infty = [x^\infty - \alpha_\infty F(x^\infty)]^+,$$

and hence is in S. In the case where $\alpha_\infty = 0$, we argue by contradiction by supposing that every cluster point of $\{x^i\}$ is not in S. Since $\alpha_\infty = 0$, there must exist a subsequence K of $\{0, 1, \ldots, \}$ satisfying $\alpha_i < \alpha_{i-1}$ for all $i \in K$, and, by passing to a subsequence if necessary, we can assume that $\{x^i\}_{i\in K}$ converges to some $x^\infty \notin S$. Since $x^\infty \notin S$, it follows from the continuity of F and our earlier argument showing that (3.7) holds for all α sufficiently small that, for all $i \in K$ sufficiently large (so that x^i is near x^∞ and α_{i-1} is sufficiently small), $\alpha = \alpha_{i-1}$ satisfies (3.7). This implies we would choose $\alpha_i = \alpha_{i-1}$ for all $i \in K$ sufficient large, contradicting our hypothesis on K. Thus, $\{x^i\}$ has at least one cluster point, say x^∞, that is in S. Letting $x^* = x^\infty$ in (3.11), we obtain that the sequence $\{\|x^i - x^\infty\|\}$ is nonincreasing. Since this sequence has a subsequence converging to zero, the entire sequence must converge to zero.

In the case where (1.3) holds for some μ and δ and F is Lipschitz continuous (with constant L) on $S + \epsilon B$ for some $\epsilon > 0$, we note that since $\{x^i\}$ converges to an element of S, we have x^i and $z^i(\alpha)$ inside $S+\epsilon B$ for all $\alpha \in (0, \alpha_{-1}]$ and all i exceeding some $\bar{i}$. For all such i, (3.7) holds for all $\alpha \in (0, (1-\rho)/L)$, so our choice of α_i implies $\alpha_i \geq \min\{\alpha_{\bar{i}}, \beta(1-\rho)/L\}$. Thus, $\{\alpha_i\}$ is bounded away from zero. The R-linear convergence of $\{x^i\}$ then follows from an argument analogous to the the proof of Theorem 3.1. □

4. Computational experience. To better understand the behavior of the new methods in practice, we implemented Algorithm 2.1 in Fortran to solve sparse LPs and dense monotone LCPs and implemented Algorithms 2.1 and 3.2 in Matlab to solve linearly constrained variational inequality problems (using the quadratic-program solver qp.m from the Matlab optimization toolbox to perform the projection). For a benchmark, we compared the performance of these implementations with analogous implementations of the extragradient method as described in [31]. (We have included LPs and dense monotone LCPs in our tests not because they are problems which the new methods are designed to solve but because these problems are well-known special cases of VI(X, F) and tests on them give us a better overall understanding of the new methods.) Though our results are preliminary, they suggest that the new methods are practical alternatives to the extragradient method, especially when F is affine or when projection onto X is expensive. We describe the test details below.

All Fortran codes were compiled by the DEC Fortran-77 compiler Version 4.2 using the default optimization option and were run on a Decstation 5000 under the operating system Ultrix Version 4.2A. All Matlab codes were run on the same Decstation 5000 under Matlab Version 4.2a.

Our first set of tests was conducted on sparse LP of the form $\min\{\, c^T y \mid Ay = b,\ y \geq 0\,\}$, where A is an $m \times l$ matrix, $b \in \Re^m$, and $c \in \Re^l$. We reformulated the LP as a VI(X, F) with

$$X = \Re^l_+ \times \{0\}^m, \quad F(x) = Mx + q, \quad M = \begin{bmatrix} 0 & -A^T \\ A & 0 \end{bmatrix}, \quad q = \begin{bmatrix} c \\ -b \end{bmatrix}.$$

Then we applied Algorithm 2.1 and the extragradient method to this VI(X, F). The first six test problems were randomly generated, with the entries of c uniformly generated from [1, 100], with the number of nonzeros per column of A fixed at 5% and the nonzeros uniformly generated from [−5, 5], and with $b = A\bar{x}$, where $\bar{x} = (10/l, \ldots, 10/l)$. The seventh to ninth test problems were taken from the Netlib library (see [14]). The performance of Algorithm 2.1 is sensitive to the choice of P and θ, and in our implementation of Algorithm 2.1, we chose P to be the diagonal part of $(I + M^T)(I + M)$ (which made P^{-1} easy to compute and

still yielded fast convergence) and chose $\theta = .7$ (which yielded much faster convergence than with $\theta = 1$). The parameters in the extragradient method were similarly tuned to optimize the method's performance. The test results are summarized in Table 1. In general, Algorithm 2.1 required fewer iterations and less time than the extragradient method, with the improvement most pronounced when $l \leq 2m$. However, both methods did very poorly on the Netlib problems, which suggests that these methods are not well suited for solving small to medium-sized LP. For large-sized LP, these methods may yet be practical since they have low storage requirements and can exploit sparsity structure in the problem.

Our second set of tests was conducted on dense monotone LCP, corresponding to VI(X, F) with

$$X = \Re^n_+, \qquad F(x) = Mx + q$$

for some $n \times n$ positive semidefinite matrix M and some $q \in \Re^n$. The first three (respectively, fourth to sixth) test problems were randomly generated with

$$M = \omega E E^T + E - E^T,$$

where $\omega = 0$ (respectively, $\omega = 1$) and every entry of the $n \times n$ matrix E was uniformly generated from $[-5, 5]$, and with $q = -M\bar{x} + \bar{y}$, where each entry of $\bar{x}$ has equal probability of being 0 or being uniformly generated from [5, 10] and each entry of $\bar{y}$ is 0 if the corresponding entry of $\bar{x}$ is 0 and otherwise has equal probability of being 0 or being uniformly generated from [5, 10] (so $\bar{x}$ is a solution). The seventh to ninth test problems were deterministically generated with

$$M = EE^T,$$

where the (i, j)th entry of the $n \times n$ matrix E is $5(i-j)/n$ for all i and j, and with $q = -M\bar{x} + \bar{y}$, where the first $n/2$ entries of $\bar{x}$ are 0 and the rest are 7.5 and the first $n/4$ entries of $\bar{y}$ are 5 and

[2]Algorithm 2.1 with P being the diagonal part of $(I + M^T)(I + M)$ and $\theta = .7$.

[3]The extragradient method as described in [31], with $\beta = .7$ and initial $\alpha = 1$.

[4]For all methods, $x^0 = 0$ and the termination criterion is $\|r(x)\| \leq \epsilon$.

Lemke	100	1057	21.3	1107	22.0	1508	27.5	2261	44.3

the rest are 0 (so $\bar{x}$ is a solution). The remaining test problems were borrowed from [16, §5]. In particular, the tenth (respectively, eleventh) test problem was randomly generated with

$$M = AA^T + B + D,$$

where every entry of the $n \times n$ matrix A and of the $n \times n$ skew-symmetric matrix B is uniformly generated from $(-5, 5)$ and every diagonal entry of the $n \times n$ diagonal B is uniformly generated from $(0, 0.3)$ (so M is positive definite), and with every entry of q uniformly generated from $(-500, 500)$ (respectively, $(-500, 0)$). The twelfth test problem is one for which Lemke's method is known to run in exponential time, with the (i, j)th entry of M equal to 2 (respectively, 1 and 0) if $j > i$ (respectively, $j = i$ and $j < i$) for all i and j (so M is positive semidefinite), and with every entry of q equal to -1. In our implementation of Algorithm 2.1, we chose P to be $(I + M^T)(I + M)$ and chose $\theta = 1$ (so $\gamma_i = 1$ for all i). The performance of Algorithm 2.1 also benefited substantially from a priori scaling of M and q and, in our test, we scaled M and q by multiplying both with $10 \cdot (\text{maximum magnitude of entries of } M \text{ and } q)^{-1}$. (We did not need to scale M and q for the extragradient method since the scaling is done automatically via its stepsize parameter α.) The test results are summarized in Table 2. In general, Algorithm 2.1 required fewer iterations and less time than the extragradient method, though both had difficulty on skew-symmetric problems (the first three test problems). On the other hand, we caution that the performance of Algorithm 2.1 strongly depends on the scaling of M and q and finding a suitable choice of scaling can be difficult in general.

Our third set of tests was conducted on VI(X, F), where X is not an orthant or a box. The first test problem, used first by Mathiesen [35], and later in [41, 54], has

$$F(x_1, x_2, x_3) = \begin{bmatrix} .9(5x_2 + 3x_3)/x_1 \\ .1(5x_2 + 3x_3)/x_2 - 5 \\ -3 \end{bmatrix},$$

$$X = \left\{(x_1, x_2, x_3) \in \Re^3_+ \mid x_1 + x_2 + x_3 = 1, x_1 - x_2 - x_3 \leq 0\right\}.$$

[7]Algorithm 2.1 with $P = (I + M^T)(I + M)$ and $\theta = 1$.

[8]The extragradient method as described in [31], with $\beta = .7$ and initial $\alpha = 1$.

[9]For all methods, $x^0 = 0$ and the termination criterion is $\|r(x)\| \leq \epsilon$.

[10]Time (in seconds) obtained using the intrinsic function SECNDS and with the codes compiled by the DEC Fortran-77 compiler and run on a Decstation 5000; does not include time to read problem data.

We had trouble finding more test problems from the literature, so we created five additional test problems of our own, in which $X = \{x \in \Re^n_+ \mid x_1 + \cdots + x_n = n\}$ and F and n are specified as follows: For the first three problems, F is the function from, respectively, the Kojima–Shindo nonlinear complementarity problem (NCP) (with $n = 4$) and the Nash–Cournot NCP (with $n = 5$ and $n = 10$) [41, pp. 321–322]; for the fourth problem, F is affine and is generated as in the problem HPHard of Table 2, but with $n = 20$; for the fifth problem, we took the F from the fourth problem and added to its ith component the linear/quadratic term $\max\{0, x_i\}^2$ for $i = 1, \ldots, \lfloor n/2 \rfloor$. In our implementation of Algorithm 3.2, we chose $P = I$, $\alpha_{-1} = 1$, $\theta = 1.5$, $\rho = .1$, and $\beta = .3$. On the Mathiesen problem, we used the same x^0 as in [54]; on the other problems, we used $x^0 = (1, \ldots, 1)$. (The F from the Mathiesen problem and from the Nash–Cournot NCP are defined on the positive orthant only.) The test results are summarized in Table 3. In general, Algorithm 3.2 requires more iterations and function evaluations, but fewer projections, than the extragradient method. (The performance of Algorithm 3.2 is also less sensitive to the starting point than the extragradient method. Surprisingly, both methods solved problems, such as the Kojima–Shindo problem, for which F is not monotone.) Thus, on problems where projection onto X is expensive, Algorithm 3.2 may be more practical than the extragradient method, as is reflected in its lower CPU times on all problems except Nash5. But if F is affine, Algorithm 2.1 may be more practical than either method (compare their CPU times on HPHard). In general, the performance of Algorithm 3.2 is insensitive to x^0 or ρ or α_{-1}, as long these parameters are reasonably chosen. We had also tried alternative choices for P and more conservative choices for θ and β (e.g., $\theta = 1$ and $\beta = .7$), but the results were typically worse.

5. Concluding remarks. We have presented new iterative methods for solving monotone variational inequality problems and have established their convergence and rate of convergence under mild assumptions on the problem. Preliminary computational experience with the new methods suggests the new methods are practical alternatives to the extragradient method.

[11] Algorithm 2.1 with $P = (I + M^T)(I + M)$ and $\theta = 1.5$.

[12] Algorithm 3.2 with $P = I$, $\alpha_{-1} = 1$, $\theta = 1.5$, $\rho = .1$ and $\beta = .3$.

[13] The extragradient method as described in [31], with $\beta = .7$ and initial $\alpha = 1$.

[14] For all methods, the termination criterion is $\|r(x)\| \leq 10^{-4}$. (nf denotes the total number of times F is evaluated, and np denotes the total number of times a projection onto X is performed.) On the Mathiesen problem, we ran each method twice with $x^0 = (.1, .8, .1)$ and $x^0 = (.4, .3, .3)$, respectively; on the other problems, we used $x^0 = (1, \ldots, 1)$.

[15] Time (in seconds) obtained using the intrinsic Matlab function etime and with the codes run on a Decstation 5000; does not include time to read problem data.

We mention in passing that Algorithms 2.1 and 3.1 may be generated by the following general approach: We set y in the inequality

$$0 \leq (y - z)^T(\alpha F(x) + z - x) \ \ \forall y \in X,$$

where $z = [x - \alpha F(x)]^+$, to x^*; and we set y in the inequality

$$0 \leq \alpha(y - x^*)F(x^*) \ \ \forall y \in X,$$

where $x^* \in S$, to z. Then we add the two inequalities and, by using the monotone property of F and, if necessary, the affine property of F, we reduce the resulting inequality to the form

$$0 \leq (x - x^*)^T T(x) + (\text{an expression involving } \alpha, F, x, \text{ and } z \text{ only})$$

for some mapping T (depending on F and α) from $\Re^n$ to $\Re^n$. Provided that the rightmost term is negative, the method then updates x according to the formula

$$x^{\text{new}} := x - \gamma T(x).$$

Algorithm 2.3, as well as the extragradient method, may be similarly generated except we set y in the first inequality to x instead. Then, we need x to be in X which is why an extra projection onto X is needed. (We can also set y in the second inequality to x, but this does not appear to yield anything useful.)

INFINITE-DIMENSIONAL HAMILTON–JACOBI EQUATIONS AND DIRICHLET BOUNDARY CONTROL PROBLEMS OF PARABOLIC TYPE*

PIERMARCO CANNARSA† AND MARIA ELISABETTA TESSITORE‡

Abstract. The paper is concerned with an infinite-dimensional Hamilton–Jacobi equation. This equation is related to boundary control problems of Dirichlet type for semilinear parabolic systems.

The viscosity solution approach is adapted to the equation under consideration, using the properties of fractional powers of generators of analytic semigroups. An existence-and-uniqueness result for such problem is obtained.

Key words. boundary control, viscosity solutions, Hamilton–Jacobi equation, parabolic equations, Dirichlet boundary conditions

AMS subject classifications. 49C20, 35K22, 35K55

1. Introduction.

In this paper we study the existence and uniqueness of viscosity solutions to the infinite-dimensional Hamilton–Jacobi equation

$$\lambda v(x) + \langle Ax + \Phi(x), Dv(x)\rangle + H(A^\beta x, Dv(x)) = 0, \quad x \in X, \tag{1.1}$$

where X is a real Hilbert space, $\lambda > 0$, and $H : X \times X \to \mathbb{R}$ is continuous. Moreover, $A : D(A) \subset X \to X$ is a closed linear operator with a compact and dense inclusion $D(A) \subset X$. Also, we assume A to be positive and self-adjoint. We denote by A^β the fractional power of A. Finally $\Phi : D(A^\beta) \to D(A^{-\beta})$ is Lipschitz continuous.

There is an increasing interest and a growing literature on Hamilton–Jacobi equations in infinite dimensions. These equations were first studied by V. Barbu and G. Da Prato (see, e.g., [2]), setting the problem in classes of convex functions and using semigroup and perturbation methods.

The viscosity solution approach was then adapted to infinite-dimensional equations by M. G. Crandall and P. L. Lions in a sequence of papers [9]. This approach was introduced in [8] (see also [7]) for finite-dimensional problems. It allows one to obtain uniqueness and comparison results for weak solutions of nonlinear first-order PDEs. Additional contributions to the viscosity solution method were obtained by M. Soner [18], H. Ishii [14], and D. Tataru [19], [20]. The latter two authors treated equations with a maximal monotone operator A, possibly multivalued. On the other hand, due to the presence of the unbounded term A^β inside the Hamiltonian H, the results proved in these papers do not apply to (1.1) except for the case of $\beta = 0$.

In this paper we study the above equation for $\beta \in (0, 1)$. We are interested in this problem because it is related to boundary control of parabolic equations under Dirichlet boundary conditions. We now briefly describe such a problem, and more details are given in §2.

It is well known that a possible abstract formulation for modelling parabolic systems controlled at the boundary is given by

$$\begin{cases} x'(t) + Ax(t) + F(x(t)) = A^\beta B\gamma(t), \\ x(0) = x_0, \end{cases} \tag{1.2}$$

where $x_0 \in X$ and $\gamma : [0, +\infty) \to U$ is measurable, U being another Hilbert space. Moreover, $B : U \to X$ is a bounded operator, $F : X \to X$ is Lipschitz, and A is maximal accretive. In

our setup, Neumann-type boundary conditions correspond to values of β in the interval $\left(\frac{1}{4}, 1\right)$, whereas Dirichlet data restrict the range of β to $\left(\frac{3}{4}, 1\right)$. Therefore, all the results that can be obtained for (1.1) with $\beta \in \left(\frac{3}{4}, 1\right)$ apply to both Dirichlet and Neumann boundary control problems.

Denoting by $x(\cdot; x_0, \gamma)$ the mild solution of (1.2), one then seeks to minimize a suitable cost functional over all controls γ. In this paper, we consider the functional

$$J(x_0; \gamma) = \int_0^\infty e^{-\lambda t} L(x(t; x_0, \gamma), \gamma(t))dt, \tag{1.3}$$

where $\lambda > 0$ and $L : X \times U \to \mathbb{R}$ is a given running cost.

Boundary control plays a central role in the theory of distributed parameter systems. There is a vast literature dealing with linear quadratic problems; see, for instance, [1], [11], [15], [3]. In this theory, the main tool for constructing optimal boundary controls is represented by the Riccati equation. The technique used to study this equation for Neumann boundary conditions differs substantially from the one used for Dirichlet conditions. In particular, the way to solve Riccati equations for Neumann data does not apply to Dirichlet data; see, for instance, [12], [13], [10], [15]. In fact, the latter problem requires a much more careful choice of weighted norms and function spaces; see, e.g., [3].

For boundary control problems that are not linear quadratic, the role of the Riccati equation is played by the dynamic programming equation

$$\lambda u(x) + \langle Ax + F(x), Du(x)\rangle + H(x, A^\beta Du(x)) = 0, \quad x \in X, \tag{1.4}$$

where $H : X \times X \to \mathbb{R}$ is defined as

$$H(x, p) = \sup_{\gamma \in U} \left[-\langle B\gamma, p\rangle - L(x, \gamma)\right]. \tag{1.5}$$

The value function of problem (1.3), defined as

$$u(x_0) = \inf \left\{ \int_0^\infty e^{-\lambda t} L(x(t; x_0, \gamma), \gamma(t))dt \mid \gamma : [0, +\infty) \to U \right\}, \tag{1.6}$$

is characterized as the unique solution of (1.4).

In [5], the viscosity solution approach has been adapted to (1.4) for $\beta \in \left(\frac{1}{4}, \frac{1}{2}\right)$. Therefore the results of [5] yield an existence-and-uniqueness theorem for the dynamic programming equation of boundary control problems of Neumann type. On the other hand, similarly to the linear quadratic case, the method of [5] does not apply to (1.4) if $\beta \geq \frac{1}{2}$ and, in particular, to boundary conditions of Dirichlet type.

In this paper we transform the state equation (1.2) by the change of variable $y = A^{-\beta}x$. Accordingly, the dynamic programming equation (1.4) is tranformed into (1.1) with H defined as in (1.5) and

$$\Phi(x) = A^{-\beta}F(A^\beta x).$$

Following the approach of [14], in §3 we give a definition of solution to (1.1) which requires that the equation be satisfied in a suitable viscosity sense only on $D(A)$. Using this definition, we obtain a comparison result for Hölder continuous viscosity solutions of (1.1); see Theorem 3.2. In §4 we prove a Hölder continuity result for the function $v(x) = u(A^\beta x)$. Moreover, we show that v is the unique viscosity solution of (1.1); see Corollary 4.3. In particular, our results characterize the value function u in (1.6) as well.

We conclude this introduction with some comments on possible extensions and applications of our approach. The assumption that $A = A^*$ has been made just to simplify the exposition. Using similar ideas one can treat systems governed by operators that are not necessarily self-adjoint. On the other hand, to prove that the function v is a viscosity solution of (1.1), we need to assume that $-A$ generates an analytic semigroup of compact operators. Therefore, the results of this paper concerning existence typically apply to parabolic boundary control problems in bounded space domains.

Finally, the techniques of this paper can also be used to study boundary control problems of Dirichlet type with finite horizon. In this case, the dynamic programming equation is an evolution equation. For the corresponding Cauchy problem one can prove existence and uniqueness results. The analogous equation for Neumann boundary control is treated in [6].

2. Preliminaries. Let X and U be two real Hilbert spaces and let $\tilde{U} \subset U$ be closed and bounded. We set $R = \sup_{\gamma \in \tilde{U}} |\gamma|$.

Let $x_0 \in X$ and consider the problem of minimizing the functional

$$J(x_0; \gamma) = \int_0^\infty e^{-\lambda t} L(x(t; x_0, \gamma), \gamma(t)) dt \tag{2.1}$$

over all measurable functions $\gamma : [0, \infty) \to \tilde{U}$ (usually called controls). Here $x(\cdot; x_0, \gamma)$ is the mild solution of

$$\begin{cases} x'(t) + Ax(t) + F(x(t)) = A^\beta B\gamma(t), \\ x(0) = x_0 \end{cases} \tag{2.2}$$

that is the solution of the integral equation

$$x(t) = e^{-tA}x_0 - \int_0^t e^{-(t-s)A} F(x(s)) ds + A^\beta \int_0^t e^{-(t-s)A} B\gamma(s) ds. \tag{2.3}$$

In (2.2), A^β denotes the fractional powers of the operator A; see [17]. The discount factor λ is positive, and L satisfies the following assumptions:

$$\begin{aligned} &\text{(i)} \quad L \in C(X \times \tilde{U}), \quad |L(x, \gamma)| \le C_L \quad \forall (x, \gamma) \in X \times \tilde{U}, \\ &\text{(ii)} \quad |L(x, \gamma) - L(y, \gamma)| \le K_L |x - y| \quad \forall \gamma \in \tilde{U}, \ x, y \in X, \end{aligned} \tag{2.4}$$

for some $C_L > 0$ and $K_L > 0$. Moreover we assume

$$\begin{aligned} &\text{(i)} \quad A : D(A) \subset X \to X \text{ is a closed linear operator} \\ &\qquad \text{such that } A = A^* \text{ and } \langle Ax, x \rangle \ge \omega |x|^2 \text{ for some } \omega > 0 \text{ and all } x \in D(A); \\ &\text{(ii)} \quad \text{the inclusion } D(A) \subset X \text{ is dense and compact;} \\ &\text{(iii)} \quad F : X \to X, \ |F(x) - F(y)| \le K_F |x - y|, \ |F(x)| \le C_F \\ &\qquad \forall x, y \in X; \\ &\text{(iv)} \quad \beta \in (0, 1); \\ &\text{(v)} \quad \text{there exists } \rho > 0 \text{ such that } B \in \mathcal{L}(U, D(A^\rho)) \end{aligned} \tag{2.5}$$

for some constants $K_F, C_F > 0$.

We note that (i) and (ii) imply that $-A$ is the infinitesimal generator of an analytic semigroup satisfying $||e^{-tA}|| \le e^{-\omega t}$ for some $\omega > 0$ and all $t \ge 0$. In assumption (v)

above, we have denoted by $\mathcal{L}(U, D(A^\rho))$ the Banach space of all bounded linear operators $B : U \to D(A^\rho)$, where $D(A^\rho)$ is equipped with the graph norm.

It is well known that, under the above assumptions, problem (2.3) has a unique solution in $L^2(0, T; X)$ for any $T > 0$. We define the value function of problem (2.1), (2.2) as

$$u(x_0) = \inf \left\{ \int_0^\infty e^{-\lambda t} L(x(t; x_0, \gamma), \gamma(t)) dt \;\middle|\; \gamma : [0, +\infty) \to \tilde{U} \text{ measurable} \right\}. \tag{2.6}$$

Control processes as above are very important for applications. In fact, (2.2) describes the evolution of a system which is governed by a parabolic PDE and controlled by Dirichlet-type boundary data. We explain this fact below. Let $\Omega \subset \mathbb{R}^n$ be open and bounded with smooth boundary. Consider the following problem:

$$\begin{cases} \dfrac{\partial x}{\partial t}(t, \xi) = \Delta_\xi x(t, \xi) + f(x(t, \xi)) & \text{in } (0, \infty) \times \Omega, \\ x(0, \xi) = x_0(\xi) & \text{on } \Omega, \\ x(t, \xi) = \gamma(t, \xi) & \text{on } (0, \infty) \times \partial\Omega, \end{cases} \tag{2.7}$$

where $x_0 \in L^2(\Omega)$, $\gamma \in L^2(0, \infty; L^2(\partial\Omega))$, and $f : \mathbb{R} \to \mathbb{R}$.

Problem (2.7) may be rewritten in abstract form as follows. Let $X = L^2(\Omega)$ and $U = L^2(\partial\Omega)$, and define an unbounded operator A in X by

$$\begin{aligned} D(A) &= H^2(\Omega) \cap H_0^1(\Omega), \\ Ax &= -\Delta x. \end{aligned}$$

Next, we define the Dirichlet map $\mathbf{D} : U \to X$ as

$$\mathbf{D}\gamma = x \quad \Leftrightarrow \quad \begin{cases} \Delta x = 0 & \text{in } \Omega, \\ x = \gamma & \text{on } \partial\Omega. \end{cases}$$

Formally, (2.7) may be written as

$$\begin{cases} x'(t) + Ax(t) + F(x(t)) = A\mathbf{D}\gamma(t), \\ x(t_0) = x_0, \end{cases} \tag{2.8}$$

where

$$F(x)(\xi) = -f(x(\xi)) \quad \forall x \in X.$$

The right-hand side of (2.8) is not well defined because the range of $\mathbf{D}$ is not contained in $D(A)$. However, we note that $\mathbf{D}$ has some regularizing effect. Indeed, by classical results (see, e.g., [16]), $\mathbf{D} : L^2(\partial\Omega) \to H^{\frac{1}{2}}(\Omega)$, which may be expressed in abstract form using the fractional powers of A. In fact,

$$D(A^\theta) = \begin{cases} H^{2\theta}(\Omega) & \text{if } 0 \le \theta < \frac{1}{4}, \\ \left\{ x \in H^{2\theta}(\Omega) \;:\; x = 0 \text{ on } \partial\Omega \right\} & \text{if } \frac{1}{4} < \theta \le 1. \end{cases}$$

Hence $\mathbf{D} : U \to D(A^\alpha)$ for all $\alpha \in \left[0, \frac{1}{4}\right)$. Consequently, having fixed $\beta \in \left(\frac{3}{4}, 1\right]$, (2.8) can be written as

$$\begin{cases} x'(t) + Ax(t) + F(x(t)) = A^\beta \mathbf{D}_\beta \gamma(t), \\ x(t_0) = x_0, \end{cases} \tag{2.9}$$

where $\mathbf{D}_\beta = A^{1-\beta}\mathbf{D} \in \mathcal{L}(U, X)$. Moreover $\mathbf{D}_\beta$ satisfies (2.5)(v) for any $\rho < \beta - \frac{3}{4}$.

Using the same technique described above, one can show that Neumann-type boundary control problems may be formulated in the same abstract form (2.2). In this case β may be taken in the interval $\left(\frac{1}{4}, 1\right]$. Note that if $\beta \in \left(\frac{3}{4}, 1\right)$ we are modelling the Neumann and the Dirichlet boundary conditions at the same time.

We now return to the analysis of problem (2.6). We transform (2.2) by the change of variable

$$y(t) = A^{-\beta}x(t). \tag{2.10}$$

More precisely, let $y_0 \in X$, and denote by $y(\cdot; y_0, \gamma)$ the solution of

$$\begin{cases} y'(t) + Ay(t) + A^{-\beta}F(A^{\beta}y(t)) = B\gamma(t), \\ y(0) = y_0 \in X. \end{cases} \tag{2.11}$$

Again the above equation has to be understood in mild form

$$y(t) = e^{-tA}y_0 - A^{-\beta}\int_0^t e^{-(t-s)A}F(A^{\beta}y(s))ds + \int_0^t e^{-(t-s)A}B\gamma(s)ds. \tag{2.12}$$

The solution of (2.12) turns out to be continuous, as we show below.

We recall that, since operator $-A$ is the generator of an analytic semigroup in X, for every $\theta \in [0, 1]$ there exists a constant $M_\theta > 0$ such that

$$|A^{\theta}e^{-tA}x| \le \frac{M_\theta}{t^{\theta}}|x| \quad \forall t > 0, \forall x \in X. \tag{2.13}$$

Moreover let $\gamma \in (0, 1]$ and $\alpha \in (0, \gamma)$. Then, a well-known interpolation inequality (see, e.g., [17]) states that for every $\sigma > 0$ there exists $C_\sigma > 0$ such that

$$|A^{\alpha}x| \le \sigma|A^{\gamma}x| + C_\sigma|x| \quad \forall x \in D(A^{\gamma}), \tag{2.14}$$

and there exists $C_{\alpha\gamma} > 0$ such that

$$|A^{\alpha}x| \le C_{\alpha\gamma}|A^{\gamma}x|^{\frac{\alpha}{\gamma}}|x|^{1-\frac{\alpha}{\gamma}} \quad \forall x \in D(A^{\gamma}). \tag{2.15}$$

PROPOSITION 2.1. *Assume that* (2.5) *holds. Let* $\gamma : [0, \infty) \to U$ *be a bounded measurable control, and fix* $T > 0$. *Then for any* $y_0 \in X$ *there exists a unique solution of* (2.12) *and*

$$y \in C([0, T]; X) \cap L^1(0, T; D(A^{\beta})). \tag{2.16}$$

Moreover, if $y_0 \in D(A^{\frac{1}{2}})$, *then*

$$y \in C([0, T]; D(A^{\frac{1}{2}})) \cap L^2(0, T; D(A)) \cap W^{1,2}(0, T; X). \tag{2.17}$$

Finally, if $y_0 \in D(A)$, *then*

$$y \in C([0, T]; D(A)). \tag{2.18}$$

Proof. The argument is well known. We sketch the proof for the reader's convenience. First we show that (2.12) has a unique solution $y \in L^1(0, T; D(A^{\beta}))$. Fix $y_0 \in X$, and let $T_1 = \frac{1}{2K_F}$. Define the map Φ on $L^1(0, T_1; D(A^{\beta}))$ by

$$\Phi y(t) = e^{-tA}y_0 - A^{-\beta}\int_0^t e^{-(t-s)A}F(A^{\beta}y(s))ds + \int_0^t e^{-(t-s)A}B\gamma(s)ds$$

for any $0 \le t \le T_1$. Let us prove that

$$\Phi : L^1(0, T_1; D(A^\beta)) \to L^1(0, T_1; D(A^\beta)).$$

Indeed, recalling (2.13), we have

$$\int_0^{T_1} |A^\beta \Phi y(t)| dt \le \int_0^{T_1} |A^\beta e^{-tA} y_0| dt$$

$$+ \int_0^{T_1} \left| \int_0^t e^{-(t-s)A} F(A^\beta y(s)) ds \right| dt + \int_0^{T_1} \left| A^\beta \int_0^t e^{-(t-s)A} B\gamma(s) ds \right| dt$$

$$\le M_\beta \int_0^{T_1} \frac{|y_0|}{t^\beta} dt + C_F \int_0^{T_1} \int_0^t \left(|A^\beta y(s)| + 1\right) ds dt + M_\beta \int_0^{T_1} \int_0^t \frac{|B\gamma(s)|}{(t-s)^\beta} ds dt$$

$$\le M_\beta |y_0| T_1^{1-\beta} + C_F T_1 ||y||_{L^1(0,T_1;D(A^\beta))} + C_F T_1^2 + M_\beta R ||B|| T_1^{1-\beta},$$

recalling that $|\gamma(s)| \le R$. Hence $\Phi y \in L^1(0, T_1; D(A^\beta))$.

Next we prove that Φ is a contraction. For any $y, z \in L^1(0, T_1; D(A^\beta))$ we have

$$\int_0^{T_1} \left| A^\beta (\Phi y(s) - \Phi z(s)) \right| ds$$

$$\le K_F \int_0^{T_1} \int_0^t \left| A^\beta (y(s) - z(s)) \right| ds dt = K_F T_1 ||y(s) - z(s)||_{L^1(0,T_1;D(A^\beta))}.$$

By the contraction map theorem it follows that (2.12) has a unique solution $y \in L^1(0, T_1; D(A^\beta))$. Then by classical results (see, e.g., [17]), $y(t) \in C([0, T_1]; X)$. Therefore, iterating this procedure, we can cover the interval $[0, T]$ with a finite number of steps.

As for (2.17), the maximal regularity result $y \in L^2(0, T; D(A)) \cap W^{1,2}(0, T; X)$ is well known; see, e.g., [3]. The fact that $y \in C([0, T]; D(A^{\frac{1}{2}}))$ is also a well-known consequence of the maximal regularity result.

Finally, if $y_0 \in D(A)$, then recalling assumption (2.5)(v) and writing Ay as

$$Ay(t) = Ae^{-tA} y_0 - A^{1-\beta} \int_0^t e^{-(t-s)A} F(A^\beta y(s)) ds + A^{1-\rho} \int_0^t A^\rho e^{-(t-s)A} B\gamma(s) ds$$

$$= Ay_1(t) + A^{1-\beta} y_2(t) + A^{1-\rho} y_3(t)$$

we easily see that, since e^{-tA} is a strongly continuous semigroup, then Ay_1 is continuous. In addition $A^{1-\beta} y_2$ is continuous since we know that $y_2 \in C([0, T]; D(A^{\frac{1}{2}}))$ and $1 - \beta < \frac{1}{2}$. Moreover since

$$|A^{1-\rho}(y_3(t_1) - y_3(t_2))| \le \left| A^{1-\rho} \int_0^{t_2} e^{-(t_2-s)A} [e^{-(t_1-t_2)A} - I] A^\rho B\gamma(s) ds \right|$$

$$+ \left| A^{1-\rho} \int_{t_2}^{t_1} e^{-(t_1-s)A} A^\rho B\gamma(s) ds \right|$$

if $t_1 \ge t_2$, exploiting inequality (2.13) and the boundedness of γ, we derive that $A^{1-\rho} y_3(t)$ is continuous. □

By inserting the change of variable (2.10) in the cost functional (2.1), we obtain a new optimal control problem whose value function v is given by

$$v(y_0) = \inf_{\gamma(t)\in\tilde{U}} \int_0^\infty e^{-\lambda t} L(A^\beta y(t; y_0, \gamma), \gamma(t))dt. \tag{2.19}$$

It is easy to realize that value functions v and u are related by the formula

$$u(x) = v(A^{-\beta}x) \quad \forall x \in X. \tag{2.20}$$

In particular, u is uniquely determined once v has been characterized. Therefore, we will study problem (2.11)–(2.19) instead of (2.2)–(2.6).

We will show that v is the unique solution of the following Hamilton–Jacobi–Bellman equation:

$$\lambda v(x) + H(A^\beta x, Dv(x)) + \langle Ax + A^{-\beta}F(A^\beta x), Dv(x)\rangle = 0, \tag{2.21}$$

where

$$H(x, p) = \sup_{\gamma\in\tilde{U}} \left[-\langle B\gamma, p\rangle - L(x, \gamma)\right]. \tag{2.22}$$

Clearly, one needs a suitable notion of weak solution of problem (2.21), since v is not everywhere differentiable and the coefficients of the equation are discontinuous. In the subsequent discussion, we use viscosity solutions to overcome these difficulties.

3. Definition of viscosity solution and comparison result. In this section we study the Hamilton–Jacobi equation

$$\lambda u(x) + H(A^\beta x, Du(x)) + \langle Ax + A^{-\beta}F(A^\beta x), Du(x)\rangle = 0. \tag{3.1}$$

We assume that (2.5) holds and that $H : X \times X \to \mathbb{R}$ is a function, not necessarily given by (2.22), satisfying

$$|H(A^\beta x, p) - H(A^\beta y, q)| \le K_H \left(|A^\beta(x - y)| + |p - q|\right) \text{ for some } K_H > 0. \tag{3.2}$$

Let $w, \varphi : D(A^{\frac{1}{2}}) \to \mathbb{R}$ be given. For any $\delta > 0$ we define $M_\delta^+(w, \varphi)$ to be the set of all points $x \in D(A^{\frac{1}{2}})$ such that

$$w(x) - \varphi(x) - \frac{\delta}{2}|A^{\frac{1}{2}}x|^2 \ge w(y) - \varphi(y) - \frac{\delta}{2}|A^{\frac{1}{2}}y|^2 \tag{3.3}$$

for all $y \in D(A^{\frac{1}{2}})$. Similarly, we denote by $M_\delta^-(w, \varphi)$ the set of all points $x \in D(A^{\frac{1}{2}})$ such that

$$w(x) - \varphi(x) + \frac{\delta}{2}|A^{\frac{1}{2}}x|^2 \le w(y) - \varphi(y) + \frac{\delta}{2}|A^{\frac{1}{2}}y|^2 \tag{3.4}$$

for all $y \in D(A^{\frac{1}{2}})$.

DEFINITION 3.1. *We say that a bounded continuous function $w : X \to \mathbb{R}$ is a viscosity subsolution of* (3.1) *if w is sequentially weakly upper semicontinuous, and, for every test function $\varphi \in C^1(D(A^{\frac{1}{2}}))$ and $\delta > 0$,*

(i) $M_\delta^+(w, \varphi) \subset D(A)$;

(ii) $$\lambda w(x) + H(A^\beta x, D\varphi(x) + \delta Ax) + \langle Ax + A^{-\beta}F(A^\beta x), D\varphi(x)\rangle$$
$$+\delta|Ax|^2 + \delta\langle Ax, A^{-\beta}F(A^\beta x)\rangle \le 0 \quad \forall x \in M_\delta^+(w, \varphi). \tag{3.5}$$

We say that w is a viscosity supersolution of (3.1) *if w is sequentially weakly lower semicontinuous, and, for every test function $\varphi \in C^1(D(A^{\frac{1}{2}}))$ and $\delta > 0$,*

$$\text{(i)} \quad M_\delta^-(w,\varphi) \subset D(A);$$

$$\text{(ii)} \quad \lambda w(x) + H(A^\beta x, D\varphi(x) - \delta Ax) + \left\langle Ax + A^{-\beta}F(A^\beta x), D\varphi(x)\right\rangle \tag{3.6}$$
$$-\delta|Ax|^2 - \delta\left\langle Ax, A^{-\beta}F(A^\beta x)\right\rangle \geq 0 \quad \forall x \in M_\delta^-(w,\varphi).$$

We say that w is a viscosity solution of (3.1) *if it is both a viscosity subsolution and a supersolution of* (3.1).

Now we give a comparison result between viscosity subsolutions and supersolutions of (3.1).

THEOREM 3.2. *Assume that* (2.5) *and* (3.2) *hold true and suppose $\beta \in \left(\frac{3}{4}, 1\right)$. Define $\alpha_\beta \in (0,1)$ as*

$$\alpha_\beta = \frac{4\beta - 3}{2\beta - 1}. \tag{3.7}$$

Let u and v be, respectively, a viscosity subsolution and supersolution of the Hamilton–Jacobi equation (3.1). *If u and v are Hölder continuous of exponent $\alpha > \alpha_\beta$, then*

$$u(x) \leq v(x) \quad \forall x \in X. \tag{3.8}$$

Proof. For simplicity we take $\lambda = 1$. For ε and δ positive, we define a function $\phi : D(A^{\frac{1}{2}}) \times D(A^{\frac{1}{2}}) \to \mathbb{R}$ as

$$\phi(x,y) = u(x) - v(y) - \frac{1}{2\varepsilon}\left\langle A^{\frac{1}{2}}(x-y), x-y\right\rangle - \frac{\delta}{2}\left[\langle Ax, x\rangle + \langle Ay, y\rangle\right]. \tag{3.9}$$

Note that ϕ is weakly upper semicontinuous. Let $(x_{\varepsilon,\delta}, y_{\varepsilon,\delta}) \in D(A^{\frac{1}{2}}) \times D(A^{\frac{1}{2}})$ be such that

$$\phi(x_{\varepsilon,\delta}, y_{\varepsilon,\delta}) = \max_{D(A^{\frac{1}{2}})\times D(A^{\frac{1}{2}})} \phi(x,y).$$

First of all we prove that

$$|x_{\varepsilon,\delta} - y_{\varepsilon,\delta}| \leq C_1 \varepsilon^{\frac{1}{2-\alpha}}, \tag{3.10}$$

where $C_1 > 0$ and α is the Hölder exponent of u and v. Since

$$\phi(x_{\varepsilon,\delta}, x_{\varepsilon,\delta}) + \phi(y_{\varepsilon,\delta}, y_{\varepsilon,\delta}) \leq 2\phi(x_{\varepsilon,\delta}, y_{\varepsilon,\delta}),$$

from the Hölder continuity of u and v we derive

$$\frac{1}{\varepsilon}|x_{\varepsilon,\delta} - y_{\varepsilon,\delta}|^2 \leq C|x_{\varepsilon,\delta} - y_{\varepsilon,\delta}|^\alpha \tag{3.11}$$

for some positive constant C. Therefore (3.10) holds.

Now let us consider

$$\varphi(x) = v(y_{\varepsilon,\delta}) + \frac{1}{2\varepsilon}\left\langle A^{\frac{1}{2}}(x - y_{\varepsilon,\delta}), x - y_{\varepsilon,\delta}\right\rangle + \frac{\delta}{2}\left\langle Ay_{\varepsilon,\delta}, y_{\varepsilon,\delta}\right\rangle,$$
$$\psi(y) = u(x_{\varepsilon,\delta}) - \frac{1}{2\varepsilon}\left\langle A^{\frac{1}{2}}(x_{\varepsilon,\delta} - y), x_{\varepsilon,\delta} - y\right\rangle - \frac{\delta}{2}\left\langle Ax_{\varepsilon,\delta}, x_{\varepsilon,\delta}\right\rangle.$$

Note that $\varphi, \psi \in C^1(D(A^{\frac{1}{2}}))$. Also, $x_{\varepsilon,\delta} \in M_\delta^+(u,\varphi)$ and $y_{\varepsilon,\delta} \in M_\delta^-(v,\psi)$ by construction. Since u is a viscosity subsolution, using φ as a test function, we have

$$\begin{aligned} &u(x_{\varepsilon,\delta}) + H\left(A^\beta x_{\varepsilon,\delta}, \frac{A^{\frac{1}{2}}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})}{\varepsilon} + \delta A x_{\varepsilon,\delta}\right) + \delta |A x_{\varepsilon,\delta}|^2 \\ &+\delta \left\langle A x_{\varepsilon,\delta}, A^{-\beta} F(A^\beta x_{\varepsilon,\delta})\right\rangle + \left\langle A x_{\varepsilon,\delta} + A^{-\beta} F(A^\beta x_{\varepsilon,\delta}), \frac{A^{\frac{1}{2}}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})}{\varepsilon}\right\rangle \le 0. \end{aligned} \tag{3.12}$$

Since v is a viscosity supersolution, using ψ as a test function, we have

$$\begin{aligned} &v(y_{\varepsilon,\delta}) + H\left(A^\beta y_{\varepsilon,\delta}, \frac{A^{\frac{1}{2}}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})}{\varepsilon} - \delta A y_{\varepsilon,\delta}\right) - \delta |A y_{\varepsilon,\delta}|^2 \\ &-\delta \left\langle A y_{\varepsilon,\delta}, A^{-\beta} F(A^\beta y_{\varepsilon,\delta})\right\rangle + \left\langle A y_{\varepsilon,\delta} + A^{-\beta} F(A^\beta y_{\varepsilon,\delta}), \frac{A^{\frac{1}{2}}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})}{\varepsilon}\right\rangle \ge 0. \end{aligned} \tag{3.13}$$

Subtracting (3.13) from (3.12), we obtain

$$\begin{aligned} &u(x_{\varepsilon,\delta}) - v(y_{\varepsilon,\delta}) + \delta\left[|A x_{\varepsilon,\delta}|^2 + |A y_{\varepsilon,\delta}|^2\right] + \frac{1}{\varepsilon}|A^{\frac{3}{4}}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|^2 \\ &\le H\left(A^\beta y_{\varepsilon,\delta}, \frac{A^{\frac{1}{2}}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})}{\varepsilon} - \delta A y_{\varepsilon,\delta}\right) - H\left(A^\beta x_{\varepsilon,\delta}, \frac{A^{\frac{1}{2}}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})}{\varepsilon} + \delta A x_{\varepsilon,\delta}\right) \\ &-\delta\left[\left\langle A x_{\varepsilon,\delta}, A^{-\beta} F(A^\beta x_{\varepsilon,\delta})\right\rangle + \left\langle A y_{\varepsilon,\delta}, A^{-\beta}[F(A^\beta y_{\varepsilon,\delta})]\right\rangle\right] \\ &+\left\langle A^{-\beta}\left[F(A^\beta y_{\varepsilon,\delta}) - F(A^\beta x_{\varepsilon,\delta})\right], \frac{A^{\frac{1}{2}}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})}{\varepsilon}\right\rangle. \end{aligned} \tag{3.14}$$

Recalling assumption (3.2) on H and assumption (2.5) on F, the above inequality yields

$$\begin{aligned} &u(x_{\varepsilon,\delta}) - v(y_{\varepsilon,\delta}) + \delta\left[|A x_{\varepsilon,\delta}|^2 + |A y_{\varepsilon,\delta}|^2\right] + \frac{1}{\varepsilon}|A^{\frac{3}{4}}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|^2 \\ &\le K_H \delta\left[|A x_{\varepsilon,\delta}| + |A y_{\varepsilon,\delta}|\right] + K_H |A^\beta(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})| \\ &+\delta C_F ||A^{-\beta}||[|A x_{\varepsilon,\delta}| + |A y_{\varepsilon,\delta}|] + K_F |A^\beta(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})| \frac{|A^{\frac{1}{2}-\beta}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|}{\varepsilon}. \end{aligned} \tag{3.15}$$

Now we estimate the right-hand side of (3.15). Recalling the interpolation inequality (2.15), we get

$$K_H |A^\beta(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})| \le C_2 |A(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|^{4\beta-3} |A^{\frac{3}{4}}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|^{4-4\beta} \tag{3.16}$$

for some $C_2 > 0$. Moreover recall the well-known inequality

$$ab \le \frac{\sigma^p}{p} a^p + \frac{1}{\sigma^q q} b^q \tag{3.17}$$

for every $a, b \in \mathbb{R}^+$, $p > 1$, $\frac{1}{p} + \frac{1}{q} = 1$, and $\sigma > 0$. Choosing $\sigma = (\frac{\delta}{16})^{(4\beta-3)/2}$ and $p = \frac{2}{4\beta-3}$ in (3.17) and applying it to (3.16) we derive

$$
\begin{aligned}
&C_2|A(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|^{4\beta-3}|A^{\frac{3}{4}}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|^{4-4\beta} \\
&\leq \frac{\delta}{16}|A(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|^2 + \frac{C_3}{\delta^{\frac{4\beta-3}{5-4\beta}}}\left|A^{\frac{3}{4}}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})\right|^{\frac{8-8\beta}{5-4\beta}},
\end{aligned} \tag{3.18}
$$

where C_3 is some positive constant. On the other hand, again applying (3.17) with $p = \frac{5-4\beta}{4-4\beta}$ and $\sigma = \left(\frac{1}{4\varepsilon}\right)^{(4-4\beta)/(5-4\beta)}$, we find

$$
\frac{C_3}{\delta^{\frac{4\beta-3}{5-4\beta}}}\left|A^{\frac{3}{4}}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})\right|^{\frac{8-8\beta}{5-4\beta}} \leq \frac{1}{4\varepsilon}|A^{\frac{3}{4}}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|^2 + \frac{C_4\varepsilon^{4-4\beta}}{\delta^{4\beta-3}} \tag{3.19}
$$

for $C_4 > 0$. From estimates (3.18) and (3.19), inequality (3.16) can be rewritten as

$$
K_H|A^\beta(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})| \leq \frac{\delta}{8}\left[|Ax_{\varepsilon,\delta}|^2 + |Ay_{\varepsilon,\delta}|^2\right] + \frac{1}{4\varepsilon}|A^{\frac{3}{4}}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|^2 + \frac{C_4\varepsilon^{4-4\beta}}{\delta^{4\beta-3}}. \tag{3.20}
$$

Moreover

$$
K_H\delta\left[|Ax_{\varepsilon,\delta}| + |Ay_{\varepsilon,\delta}|\right] \leq \frac{\delta}{8}\left[|Ax_{\varepsilon,\delta}|^2 + |Ay_{\varepsilon,\delta}|^2\right] + C_5\delta, \tag{3.21}
$$

where C_5 is a positive constant. On the other hand we get

$$
\delta C_F||A^{-\beta}||[|Ax_{\varepsilon,\delta}| + |Ay_{\varepsilon,\delta}|] \leq \frac{\delta}{8}\left[|Ax_{\varepsilon,\delta}|^2 + |Ay_{\varepsilon,\delta}|^2\right] + C_6\delta \tag{3.22}
$$

for $C_6 > 0$. Finally from estimate (3.11), it follows that

$$
K_F|A^\beta(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|\frac{|A^{\frac{1}{2}-\beta}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|}{\varepsilon} \leq \frac{C_7|A^\beta(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|}{\varepsilon^{\frac{1-\alpha}{2-\alpha}}}, \tag{3.23}
$$

where $C_7 > 0$. Applying the interpolation inequality (2.15) and inequality (3.17) to (3.23) as we did in (3.16) we find

$$
\frac{C_7|A^\beta(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|}{\varepsilon^{\frac{1-\alpha}{2-\alpha}}} \leq \frac{\delta}{16}|A(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|^2 + \frac{C_8|A^{\frac{3}{4}}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|^{\frac{8-8\beta}{5-4\beta}}}{\delta^{\frac{4\beta-3}{5-4\beta}}\varepsilon^{\frac{2-2\alpha}{(2-\alpha)(5-4\beta)}}}
$$

for some positive constant C_8. Again, using (3.17) in the last term of the above inequality we rewrite (3.23) as

$$
\begin{aligned}
&K_F|A^\beta(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|\frac{|A^{\frac{1}{2}-\beta}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|}{\varepsilon} \\
&\leq \frac{\delta}{16}|A(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|^2 + \frac{1}{4\varepsilon}|A^{\frac{3}{4}}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|^2 + \frac{C_9\varepsilon^{4-4\beta}}{\delta^{4\beta-3}\varepsilon^{\frac{2-2\alpha}{2-\alpha}}},
\end{aligned} \tag{3.24}
$$

with C_9 positive constant. Substituting estimates (3.20)–(3.22) and (3.24) in inequality (3.15) we get

$$
u(x_{\varepsilon,\delta}) - v(y_{\varepsilon,\delta}) + \frac{\delta}{2}\left[|Ax_{\varepsilon,\delta}|^2 + |Ay_{\varepsilon,\delta}|^2\right] + \frac{1}{2\varepsilon}|A^{\frac{3}{4}}(x_{\varepsilon,\delta} - y_{\varepsilon,\delta})|^2 \leq C_{10}\delta + \frac{C_9\varepsilon^\gamma}{\delta^{4\beta-3}}, \tag{3.25}
$$

where $C_{10} > 0$ and $\gamma = 4 - 4\beta - \frac{2-2\alpha}{2-\alpha}$ is positive as $\alpha > \alpha_\beta$. Therefore, if $x \in D(A^{\frac{1}{2}})$ we have

$$u(x) - v(x) = \phi(x, x) + \delta\langle Ax, x\rangle \leq \phi(x_{\varepsilon,\delta}, y_{\varepsilon,\delta}) + \delta\langle Ax, x\rangle$$

$$\leq u(x_{\varepsilon,\delta}) - v(y_{\varepsilon,\delta}) + \delta\langle Ax, x\rangle \leq C_{10}\delta + \frac{C_9\varepsilon^\gamma}{\delta^{4\beta-3}} + \delta\langle Ax, x\rangle.$$

Letting $\varepsilon \to 0$ and then $\delta \to 0$ we conclude that

$$u(x) \leq v(x) \quad \forall x \in D(A^{\frac{1}{2}}).$$

Since $D(A^{\frac{1}{2}})$ is dense in X, we have $u(x) \leq v(x)$ for every $x \in X$. □

4. Properties of the value function and existence results. In this section we prove that the value function v of problem (2.11)–(2.19) is the unique viscosity solution of

$$\lambda v(x) + H(A^\beta x, Dv(x)) + \left\langle Ax + A^{-\beta}F(A^\beta x), Dv(x)\right\rangle = 0, \tag{4.1}$$

where

$$H(x, p) = \sup_{\gamma \in \tilde{U}} \left[-\langle B\gamma, p\rangle - L(x, \gamma)\right].$$

We first show a Hölder continuity result for v. We will exploit the technique of [5].

PROPOSITION 4.1. *Assume* (2.5), (2.4). *Then the value function v defined in* (2.19) *is Hölder continuous in X with any exponent $\alpha \in (0, 1]$ satisfying $\alpha < \frac{\lambda}{K_F}$. Moreover for any $\theta \in [0, 1 - \beta)$ there exists a constant $C_{\alpha\theta} > 0$ such that*

$$|v(x) - v(y)| \leq C_{\alpha\theta}|A^{-\theta}(x - y)|^\alpha \tag{4.2}$$

for all $x, y \in X$.

Proof. Let $x_0, y_0 \in X$ and $\gamma(t) \in \tilde{U}$ be given. Let us set $x(\cdot) = x(\cdot; x_0, \gamma)$ and $y(\cdot) = y(\cdot; y_0, \gamma)$. Then

$$x(t) = e^{-tA}x_0 - A^{-\beta}\int_0^t e^{-(t-s)A}F(A^\beta x(s))ds + \int_0^t e^{-(t-s)A}B\gamma(s)ds$$

and

$$y(t) = e^{-tA}y_0 - A^{-\beta}\int_0^t e^{-(t-s)A}F(A^\beta y(s))ds + \int_0^t e^{-(t-s)A}B\gamma(s)ds$$

for any $t \geq 0$. Now we estimate $|A^\beta(x(t) - y(t))|^\alpha$. From assumption (2.5) and from inequality (2.13) we have

$$|A^\beta(x(t) - y(t))| \leq \frac{M_\theta}{t^{\beta+\theta}}|A^{-\theta}(x_0 - y_0)| + K_F\int_0^t |A^\beta(x(s) - y(s))|ds \tag{4.3}$$

for any $\theta \in [0, 1 - \beta)$. Now set $\eta(t) = \int_0^t |A^\beta(x(s) - y(s))|ds$. Integrating the above inequality we get

$$\eta(t) \leq \frac{M_\theta}{1 - (\beta + \theta)}|A^{-\theta}(x_0 - y_0)|t^{1-\beta-\theta} + K_F\int_0^t \eta(s)ds.$$

By Gronwall's lemma we obtain an estimate on $\eta(t)$. Applying this estimate to the right-hand side of (4.3) we derive

$$|A^\beta(x(t)-y(t))| \le \left(\frac{C}{t^{\beta+\theta}} + Ce^{K_F t} t^{1-\beta-\theta}\right) |A^{-\theta}(x_0-y_0)|. \tag{4.4}$$

Then, for every $\alpha \in (0, \frac{\lambda}{K_F})$, $\alpha \le 1$, we have

$$|A^\beta(x(t)-y(t))|^\alpha \le 2^\alpha \left(\frac{C}{t^{\alpha(\beta+\theta)}} + Ce^{K_F \alpha t} t^{(1-\beta-\theta)\alpha}\right) |A^{-\theta}(x_0-y_0)|^\alpha. \tag{4.5}$$

Moreover, by (2.4),

$$\begin{aligned} &\left|L(A^\beta x(t), \gamma(t)) - L(A^\beta y(t), \gamma(t))\right| \\ &\le (2C_L)^{1-\alpha} \left|L(A^\beta x(t), \gamma(t)) - L(A^\beta y(t), \gamma(t))\right|^\alpha \le \tilde{L}|A^\beta(x(t)-y(t))|^\alpha, \end{aligned} \tag{4.6}$$

where $\tilde{L} = (2C_L)^{1-\alpha} K_L^\alpha$. Now choose T such that

$$\frac{2e^{-\lambda T} C_L}{\lambda} \le |A^{-\theta}(x_0-y_0)|^\alpha.$$

From the definition of value function and from the dynamic programming principle it follows that there exists a control $\gamma(\cdot)$ such that

$$v(y_0) > \int_0^T e^{-\lambda t} L(A^\beta y(t), \gamma(t))dt + e^{-\lambda T} v(y(T)) - |A^{-\theta}(x_0-y_0)|^\alpha.$$

Here, we may suppose that $|A^{-\theta}(x_0-y_0)|^\alpha > 0$, since (4.2) is trivial if $|A^{-\theta}(x_0-y_0)|^\alpha = 0$.

From the dynamic programming principle and from the above estimate it follows that

$$\begin{aligned} &v(x_0) - v(y_0) \le |A^{-\theta}(x_0-y_0)|^\alpha \\ &+ \int_0^T e^{-\lambda t} \left|L(A^\beta x(t), \gamma(t)) - L(A^\beta y(t), \gamma(t))\right| dt + e^{-\lambda T}[v(x(T)) - v(y(T))] \\ &\le 2|A^{-\theta}(x_0-y_0)|^\alpha + \tilde{L} \int_0^T e^{-\lambda t} |A^\beta(x(t)-y(t))|^\alpha dt. \end{aligned} \tag{4.7}$$

Substituting (4.5) in (4.7), we get

$$\begin{aligned} &v(x_0) - v(y_0) \le 2|A^{-\theta}(x_0-y_0)|^\alpha \\ &+\tilde{L}2^\alpha |A^{-\theta}(x_0-y_0)|^\alpha \int_0^T \left(\frac{Ce^{-\lambda t}}{t^{\alpha(\beta+\theta)}} + Ce^{(K_F\alpha-\lambda)t} t^{(1-\beta-\theta)\alpha}\right) dt. \end{aligned}$$

The result follows since $\alpha < \frac{\lambda}{K_F}$ and $\theta \in [0, 1-\beta)$. □

We now give an existence result for (4.1).

THEOREM 4.2. *Assume that* (2.5) *and* (2.4) *hold true. Then the value function* v *is a viscosity solution of* (2.21) *in the sense of Definition* 3.1.

Proof. Recalling the compactness assumption (2.5)(ii), from (4.2) we conclude that v is sequentially weakly continuous in X. It remains to prove that v satisfies (3.5) and (3.6). We show this fact in the next two steps.

Step I: Proof of (3.5). Let $\gamma \in \tilde{U}$ be a constant control, $\varphi \in C^1(D(A^{\frac{1}{2}}))$, and $x \in M_\delta^+(v, \varphi)$. Moreover let $y(\cdot) = y(\cdot; x, \gamma)$. Then, recalling Proposition 2.1, we obtain

$$v(x) - \varphi(x) - \frac{\delta}{2}\langle Ax, x\rangle \geq v(y(t)) - \varphi(y(t)) - \frac{\delta}{2}\langle Ay(t), y(t)\rangle \tag{4.8}$$

for every $t \geq 0$. From (4.8) and from the dynamic programming principle it follows that

$$\begin{aligned} &\frac{\varphi(x) - \varphi(y(t))}{t} + \frac{\delta}{2}\frac{\langle Ax, x\rangle - \langle Ay(t), y(t)\rangle}{t} \\ &\leq \frac{v(x) - v(y(t))}{t} \leq \frac{1}{t}\int_0^t e^{-\lambda s} L(A^\beta y(s), \gamma) ds + \frac{e^{-\lambda t} - 1}{t} v(y(t)). \end{aligned} \tag{4.9}$$

Note that, since by Proposition 2.1 $y \in L^2(0, T; D(A))$, we get

$$\varphi(x) - \varphi(y(t)) = -\int_0^t \big\langle D\varphi(y(s)), -Ay(s) - A^{-\beta} F(A^\beta y(s)) + B\gamma \big\rangle ds \tag{4.10}$$

and

$$\begin{aligned} \frac{1}{2}(\langle Ax, x\rangle - \langle Ay(t), y(t)\rangle) &= -\int_0^t \big\langle Ay(s), -Ay(s) - A^{-\beta} F(A^\beta y(s)) + B\gamma \big\rangle ds \\ &= \int_0^t \big[|Ay(s)|^2 + \big\langle Ay(s), A^{-\beta} F(A^\beta y(s)) - B\gamma \big\rangle\big] ds. \end{aligned} \tag{4.11}$$

Therefore, exploiting (4.10) and (4.11), (4.9) can be rewritten as

$$\begin{aligned} &\frac{1}{t}\int_0^t \big\langle D\varphi(y(s)), Ay(s) + A^{-\beta} F(A^\beta y(s)) - B\gamma \big\rangle ds \\ &+ \frac{\delta}{t}\int_0^t \big[|Ay(s)|^2 + \big\langle Ay(s), A^{-\beta} F(A^\beta y(s)) - B\gamma \big\rangle\big] ds \\ &\leq \frac{1}{t}\int_0^t e^{-\lambda s} L(A^\beta y(s), \gamma) ds + \frac{e^{-\lambda t} - 1}{t} v(y(t)). \end{aligned} \tag{4.12}$$

By Proposition 2.1 $y \in L^2(0, T; D(A))$ and so

$$\frac{1}{t}\int_0^t \big\langle D\varphi(y(s)), Ay(s) + A^{-\beta} F(A^\beta y(s)) - B\gamma \big\rangle ds \leq \frac{\delta}{4t}\int_0^t |Ay(s)|^2 ds + C_\delta \tag{4.13}$$

and

$$\begin{aligned} &\frac{\delta}{t}\int_0^t \big\langle Ay(s), A^{-\beta} F(A^\beta y(s)) - B\gamma \big\rangle ds \\ &\leq \frac{\delta}{t}\int_0^t ||A^{-\beta}|| C_F |Ay(s)| ds + \frac{\delta}{t}\int_0^t |Ay(s)|||B||R ds \leq \frac{\delta}{4t}\int_0^t |Ay(s)|^2 ds + C_\delta \end{aligned} \tag{4.14}$$

for some positive C_δ.

From (4.12)–(4.14), since v and L are bounded it follows that

$$\frac{1}{t}\int_0^t |Ay(s)|^2 ds \leq C_\delta$$

for C_δ positive. Hence, there exists a sequence $\{t_n\}$, $t_n \downarrow 0$ such that

$$|Ay(t_n)| \le C_\delta.$$

Taking a subsequence we have that $Ay(t_n) \rightharpoonup z$ and $y(t_n) \to x$. Therefore we get $y(t_n) = A^{-1}Ay(t_n) \rightharpoonup A^{-1}z = x$, and so $x \in D(A)$. This proves (3.5)(i).

In order to show that (ii) holds, we recall that if $x \in D(A)$ and $\gamma(\cdot) = \gamma$, then $y \in C([0,T]; D(A))$; see Proposition 2.1. Then, passing to the limit as $t \downarrow 0$ in (4.12), we derive

$$\begin{aligned}&\langle D\varphi(x), Ax + A^{-\beta}F(A^\beta x)\rangle + \left[-\langle D\varphi(x) + \delta Ax, B\gamma\rangle - L(A^\beta x, \gamma)\right]\\ &+\delta|Ax|^2 + \delta\langle Ax, A^{-\beta}F(A^\beta x)\rangle + \lambda v(x) \le 0.\end{aligned}$$

Taking the supremum over $\gamma \in \tilde{U}$ we obtain (3.5)(ii).

Step II: Proof of (3.6). Let $\varphi \in C^1(D(A^{\frac{1}{2}}))$ and $x \in M_\delta^-(v,\varphi)$. For every $n \in \mathbb{N}$ there exists a control $\gamma_n(\cdot)$ such that

$$v(x) + \frac{1}{n^2} \ge \int_0^{\frac{1}{n}} e^{-\lambda s} L(A^\beta y_n(s), \gamma_n(s))ds + e^{-\frac{\lambda}{n}} v\left(y_n\left(\frac{1}{n}\right)\right), \tag{4.15}$$

where $y_n(\cdot) = y_n(\cdot; x, \gamma_n)$. Moreover we get

$$v(x) - \varphi(x) + \frac{\delta}{2}\langle Ax, x\rangle \le v\left(y_n\left(\frac{1}{n}\right)\right) - \varphi\left(y_n\left(\frac{1}{n}\right)\right) + \frac{\delta}{2}\left\langle Ay_n\left(\frac{1}{n}\right), y_n\left(\frac{1}{n}\right)\right\rangle.$$

From (4.15) and from the above inequality we obtain

$$\begin{aligned}&n\left[\varphi(x) - \varphi\left(y_n\left(\frac{1}{n}\right)\right)\right] + \frac{\delta n}{2}\left[\left\langle Ay_n\left(\frac{1}{n}\right), y_n\left(\frac{1}{n}\right)\right\rangle - \langle Ax, x\rangle\right]\\ &\ge n\int_0^{\frac{1}{n}} e^{-\lambda s} L(A^\beta y_n(s), \gamma_n(s))ds + n(e^{-\frac{\lambda}{n}} - 1)v\left(y_n\left(\frac{1}{n}\right)\right) + \omega\left(\frac{1}{n}\right).\end{aligned} \tag{4.16}$$

Here and in the rest of the proof we denote by $\omega(t)$ a function such that $\omega(t) \downarrow 0$ as $t \downarrow 0$. Similarly to Step I we have

$$\varphi(x) - \varphi\left(y_n\left(\frac{1}{n}\right)\right) = \int_0^{\frac{1}{n}} \langle D\varphi(y_n(s)), Ay_n(s) + A^{-\beta}F(A^\beta y_n(s)) - B\gamma_n(s)\rangle ds \tag{4.17}$$

and

$$\begin{aligned}&\frac{1}{2}\left[\left\langle Ay_n\left(\frac{1}{n}\right), y_n\left(\frac{1}{n}\right)\right\rangle - \langle Ax, x\rangle\right]\\ &= \int_0^{\frac{1}{n}} \langle Ay_n(s), -Ay_n(s) - A^{-\beta}F(A^\beta y_n(s)) + B\gamma_n(s)\rangle ds\\ &= \int_0^{\frac{1}{n}} \left[-|Ay_n(s)|^2 - \langle Ay_n(s), A^{-\beta}F(A^\beta y_n(s))\rangle + \langle Ay_n(s), B\gamma_n(s)\rangle\right] ds.\end{aligned} \tag{4.18}$$

Therefore inequality (4.16) can be rewritten as

$$
\begin{aligned}
&n\int_0^{\frac{1}{n}} \left\langle D\varphi(y_n(s)),\, Ay_n(s) + A^{-\beta}F(A^{\beta}y_n(s)) - B\gamma_n(s)\right\rangle ds \\
&+n\delta\int_0^{\frac{1}{n}} \left[-|Ay_n(s)|^2 - \left\langle Ay_n(s),\, A^{-\beta}F(A^{\beta}y_n(s))\right\rangle + \langle Ay_n(s),\, B\gamma_n(s)\rangle\right] ds \qquad (4.19)\\
&\geq n\int_0^{\frac{1}{n}} e^{-\lambda s}L(A^{\beta}y_n(s),\gamma_n(s))ds + n(e^{-\frac{\lambda}{n}}-1)v\left(y_n\left(\frac{1}{n}\right)\right) + \omega\left(\frac{1}{n}\right).
\end{aligned}
$$

Again, reasoning as in Step I, from the above estimate we derive

$$
n\int_0^{\frac{1}{n}} |Ay_n(s)|^2 ds \leq C_{\delta};
$$

hence, there exists a sequence $\{s_n\}$, $s_n \downarrow 0$, such that

$$
|Ay_n(s_n)| \leq C, \quad y_n(s_n) \to x \quad \text{and} \quad Ay_n(s_n) \rightharpoonup z. \qquad (4.20)
$$

As in Step I we conclude that $x \in D(A)$. Therefore (3.6)(i) holds.

In order to show that (ii) is verified, we have to estimate the terms contained in (4.19). First we note that, by easy computations exploiting estimate (2.13), as $x \in D(A)$

$$
\lim_{n\to\infty} \sup_{0\leq t\leq \frac{1}{n}} |A^{\alpha}(y_n(t) - x)| = 0, \qquad (4.21)
$$

where $\alpha \in [0, 1)$. Since $\varphi \in C^1(D(A^{\frac{1}{2}}))$ and $x \in D(A)$, by (4.21) we obtain

$$
-n\int_0^{\frac{1}{n}} \langle D\varphi(y_n(s)), B\gamma_n(s)\rangle\, ds = -n\int_0^{\frac{1}{n}} \langle D\varphi(x), B\gamma_n(s)\rangle ds + \omega\left(\frac{1}{n}\right). \qquad (4.22)
$$

Moreover, by (4.21)

$$
n\int_0^{\frac{1}{n}} \langle D\varphi(y_n(s)), A^{-\beta}F(A^{\beta}y_n(s))\rangle ds = \langle D\varphi(x), A^{-\beta}F(A^{\beta}x)\rangle + \omega\left(\frac{1}{n}\right). \qquad (4.23)
$$

On the other hand we recall that by assumption (2.5)(v), there exists ρ such that $A^{\rho}B$, is bounded. Hence, (4.21) yields

$$
\begin{aligned}
n\int_0^{\frac{1}{n}} \langle Ay_n(s), B\gamma_n(s)\rangle\, ds &= n\int_0^{\frac{1}{n}} \left\langle A^{1-\rho}x,\, A^{\rho}B\gamma_n(s)\right\rangle ds + \omega\left(\frac{1}{n}\right) \\
&= n\int_0^{\frac{1}{n}} \langle Ax, B\gamma_n(s)\rangle\, ds + \omega\left(\frac{1}{n}\right).
\end{aligned} \qquad (4.24)
$$

In addition, from (4.21) we have

$$
-n\int_0^{\frac{1}{n}} \left\langle Ay_n(s),\, A^{-\beta}F(A^{\beta}y_n(s))\right\rangle ds = -\left\langle Ax,\, A^{-\beta}F(A^{\beta}x)\right\rangle + \omega\left(\frac{1}{n}\right). \qquad (4.25)
$$

Finally, again from (4.21)

$$
n\int_0^{\frac{1}{n}} e^{-\lambda s}L(A^{\beta}y_n(s),\gamma_n(s))ds = n\int_0^{\frac{1}{n}} L(A^{\beta}x,\gamma_n(s))ds + \omega\left(\frac{1}{n}\right). \qquad (4.26)
$$

Since v is continuous, substituting estimates (4.22)–(4.26) into (4.19), we derive

$$\lambda v(x) + n\int_0^{\frac{1}{n}} \left[-\langle D\varphi(x) - \delta Ax, B\gamma_n(s)\rangle - L(A^\beta x, \gamma_n(s))\right] ds + \left\langle A^{-\beta}F(A^\beta x), D\varphi(x)\right\rangle$$

$$+n\int_0^{\frac{1}{n}} \left[\langle D\varphi(y_n(s)), Ay_n(s)\rangle - \delta|Ay_n(s)|^2\right] ds - \delta\left\langle Ax, A^{-\beta}F(A^\beta x)\right\rangle \geq \omega\left(\frac{1}{n}\right).$$

On the other hand, recalling the definition of the Hamiltonian (2.22),

$$n\int_0^{\frac{1}{n}} \left[-\langle D\varphi(x) - \delta Ax, B\gamma_n(s)\rangle - L(A^\beta x, \gamma_n(s))\right] ds \leq H(A^\beta x, D\varphi(x) - \delta Ax).$$

Therefore, for some sequence $\{s_n\}$, $0 \leq s_n \leq \frac{1}{n}$, as in (4.20) it follows that

$$\lambda v(x) + H(A^\beta x, D\varphi(x) - \delta Ax) + \left\langle A^{-\beta}F(A^\beta x), D\varphi(x)\right\rangle - \delta\left\langle Ax, A^{-\beta}F(A^\beta x)\right\rangle$$

$$\geq -\langle D\varphi(y_n(s_n)), Ay_n(s_n)\rangle + \delta|Ay_n(s_n)|^2 + \omega\left(\frac{1}{n}\right).$$

By (4.20), taking the $\liminf_{n\to\infty}$ of the right-hand side of the above inequality, we derive that (3.6)(ii) holds. □

Combining Theorem 4.2 with Theorem 3.2 we obtain the following existence and uniqueness result for the Hamilton–Jacobi equation (4.1).

COROLLARY 4.3. *Assume that* (2.5) *and* (2.4) *hold true and let* $\lambda_F = \min\{1, \frac{\lambda}{K_F}\}$. *Fix*

$$\beta \in \left(\frac{3}{4}, \frac{3-\lambda_F}{4-2\lambda_F}\right). \tag{4.27}$$

Then the value function v *defined in* (2.19) *is the unique viscosity solution of the Hamilton–Jacobi equation* (4.1) *satisfying a Hölder condition with exponent* $\alpha \in (\alpha_\beta, 1)$, *where* α_β *is defined in* (3.7).

Proof. Applying Theorem 4.2, we obtain that v is a viscosity solution of equation (4.1). From Proposition 4.1 it follows that v is Hölder continuous of exponent α for any $0 < \alpha < \lambda_F$. From (4.27) it is easily seen that $\lambda_F > \alpha_\beta$. The proof of existence is thus complete. As for uniqueness we note that assumption (2.4) implies that the Hamiltonian (2.22) satisfies hypothesis (3.2). Therefore uniqueness follows from Theorem 3.2. □

VALUE ITERATION IN A CLASS OF COMMUNICATING MARKOV DECISION CHAINS WITH THE AVERAGE COST CRITERION*

ROLANDO CAVAZOS-CADENA†

Abstract. Markov decision processes with denumerable state space and discrete time parameter are considered. The performance index of a control policy is the (lim sup expected) *average cost criterion*, and the the main structural restrictions on the model are the following: (i) under the action of any stationary policy, the state space is a communicating class; (ii) the cost function has an almost monotone—or penalized—structure [V. S. Borkar, *SIAM J. Control Optim.*, 21 (1983), pp. 652–666; 22 (1984), pp. 965–978]; and (iii) some stationary policy induces an ergodic chain with finite average cost. In this context it is shown that the *value iteration* scheme can be used to construct convergent approximations of a solution to the optimality equation, as well as a sequence of stationary policies whose limit points are optimal.

Key words. Markov decision chains, average cost criterion, almost monotone cost function, value iteration scheme, pointwise convergence

AMS subject classifications. Primary, 90C40, 93E20; Secondary, 60J05

1. Introduction.

This paper concerns Markov decision processes with denumerable state space and discrete time parameter. The performance of a control strategy is measured by the (lim sup expected) *average cost criterion*, and in addition to standard continuity–compactness conditions, the class of models under consideration is essentially determined by the following restrictions: (i) under the action of each stationary policy, the state space is a communicating class; (ii) some stationary policy induces an ergodic chain with finite average cost; and (iii) the cost function is "almost monotone" in the following sense: outside a finite set of states, the cost is sufficiently large. These restrictions are basically those used by Borkar in [1, 2] to establish the existence of optimal stationary policies and a solution to the *average cost optimality equation* (ACOE) (see also [3, 4, 29]). However, in contrast to the context in [1, 2], the cost function is allowed to depend on the actions. Within this framework *the main objective of this paper* is to show that the *value iteration* (VI) scheme can be used to produce

(1) convergent approximations of a solution to the ACOE,

(2) a sequence of stationary policies whose limit points are *average optimal.*

The main result in this note, stated in Theorem 3.1 below, provides a solution to these problems. Since the VI method has been studied extensively in the literature, it is convenient to begin by pointing out the main differences between the results in this note and other theorems already available. First, the VI scheme has been widely studied under strong stability assumptions on the transition structure of the model—such as the diverse variants of the simultaneous Doeblin condition (SDC) [28]—under which the relative value functions and differential costs produced by the VI scheme are shown to converge, at a geometric rate, to a solution of the ACOE whenever the cost function is *bounded.* However, SDC is quite restrictive and is seldom satisfied, except for models with *finite state space* [12, 14, 20, 26, 30], so the results obtained within such a framework cannot be used in many important applications. On the other hand, Hordjik, Schweitzer, and Tijms obtained convergence results for the VI method in [17] under the so-called *Lyapunov function condition* (LFC) [16, 28], a stability assumption that is substantially weaker than SDC and allows unbounded costs but implies that the Markov chain induced by each stationary policy is ergodic, a feature that is frequently absent in simple

†Departamento de Estadística y Cálculo, Universidad Autónoma Agraria Antonio Narro, Buenavista, Saltillo, COAH, 25315, México.

but interesting applications, as in Example 9.1. The present paper is more on the line of the work by Sennott [24], where the assumptions on the recurrence structure of the model are quite general. The approach used in [24] is, essentially, based on the results in [17]. In the latter paper it was postulated that "the first error function" produced by the VI scheme is bounded—an assumption that is very strong and is closely related to SDC [7]—and such a restriction was translated to the context in [24] as Assumption 5, which, generally, is very difficult to verify; the techniques in [24] were extended to more general contexts in [19]. On the other hand, this note extends ideas recently used in [7, 10], where LFC was assumed but the condition on the boundedness of the first error function was avoided. Roughly, the usual way to study the VI scheme consists of analyzing the differences $V_n(\cdot) - (n+1)g$, where V_n is the nth VI function and g is the optimal average cost. Here, following [7, 10], the analysis relies on a direct study of the differential cost function $V_n - V_{n-1}$, and this allows one to develop an approach to solve problems (1) and (2) under, essentially, *nothing more* but the conditions in [1, 2]; however, it should be mentioned that, unfortunately, the required argumentation becomes substantially more complicated within this framework.

The remainder of the paper is organized as follows: in §2 the decision model is introduced, whereas the VI scheme is presented in §3, with the main result being stated in the form of Theorem 3.1. The necessary technical preliminaries to establish this theorem have been divided into four parts presented in §§4–7, whereas the proof of Theorem 3.1 is given in §8, with an example presented in §9. Finally, the paper concludes with some brief comments in §10.

Notation. $\mathbb{R}$ denotes the set of real numbers, and $\mathbb{N}$ stands for the set of nonnegative integers. If $a, b \in \mathbb{R}$, set $a \wedge b := \min\{a, b\}$ and $a \vee b := \max\{a, b\}$. On the other hand, a Cartesian product of topological spaces is always endowed with the corresponding product topology, and for topological spaces A and $\mathbb{K}$, the set of all transition kernels on A given $\mathbb{K}$ is denoted by $\mathbb{P}(A|\mathbb{K})$, i.e., $\pi(\cdot|\cdot) \in \mathbb{P}(A|\mathbb{K})$, if, for each $k \in \mathbb{K}$, $\pi(\cdot|k)$ is a probability measure on the Borel subsets of A, and for each Borel subset B of A, the mapping $k \mapsto \pi(B|k)$, $k \in \mathbb{K}$, is measurable. Finally, for an event W, the corresponding indicator function is denoted by $I[W]$.

2. Decision model. Let (S, A, C, p) be a Markov decision process (MDP) where the *state space* S is a denumerable set endowed with the discrete topology and the *action set* A is a compact metric space. On the other hand, C is the cost function and p is the transition law. This model represents a dynamical system evolving as follows: at each time $t \in \mathbb{N}$ the state of the system is observed—say, $X_t = x \in S$—and an action $A_t = a \in A$ is chosen. As a consequence, (i) a cost $C(x, a)$ is incurred, and (ii) regardless of the states observed and actions applied before t, the state of the system at time $t+1$ will be $X_{t+1} = y \in S$ with probability $p_{xy}(a)$; this is the Markov property of the process. Note that it is assumed that all actions in A are available at each state x; as noted by Borkar in [2], this assumption does not imply any loss of generality.

Assumption 2.1. (i) (Continuity.) For each $x, y \in S$, the mappings $a \mapsto C(x, a)$ and $a \mapsto p_{xy}(a)$ are continuous on A.

(ii) The cost function is nonnegative: $C(x, a) \geq 0$, $x \in S$, $a \in A$.

Policies. Let $t \in \mathbb{N}$ be arbitrary. The space of state–action histories up to time t is denoted by H_t and is given by $H_0 := S$ and $H_t := H_{t-1} \times (A \times S)$, $t \geq 1$, whereas $h_t := (x_0, a_0, \ldots, x_{t-1}, a_{t-1}, x_t)$ stands for a generic element of H_t. Define the information vector up to time t as follows:

$$I_0 := X_0 \quad \text{and} \quad I_t := (X_0, A_0, \ldots, X_{t-1}, A_{t-1}, X_t), \quad t \geq 1. \tag{2.1}$$

A *policy* is a sequence $\pi = \{\pi_t \in \mathbb{P}(A|H_t) | t \in \mathbb{N}\}$; when the system is in progress under π and $I_t = h_t$ has been observed, $\pi_t(B|h_t)$ is the probability of choosing action A_t within (the

Borel subset) $B \subset A$. The space of all policies is denoted by $\mathbb{P}$. Now set $\mathbb{F} := \Pi_{x \in S} A$—i.e., $\mathbb{F}$ consists of all functions $f : S \to A$—and note that $\mathbb{F}$ is a compact metric space in the product topology [11]. A policy π is stationary if there exists $f \in \mathbb{F}$ such that $\pi_t(\{f(x_t)\}|h_t) = 1$ for all $t \in \mathbb{N}$ and $h_t \in H_t$. Next, define $\mathbb{M} := \Pi_{t \in \mathbb{N}} \mathbb{F}$, which is also a compact metric space and consists of all sequences $\{f_t | t \in \mathbb{N}\}$ of members of $\mathbb{F}$. A policy π is Markovian if there exists $\{f_t\} \in \mathbb{M}$ such that $\pi_t(\{f_t(x_t)\}|h_t) = 1$ is always valid. The class of stationary (resp., Markovian) policies is naturally identified with $\mathbb{F}$ (resp., $\mathbb{M}$) and, with these conventions, $\mathbb{F} \subset \mathbb{M} \subset \mathbb{P}$.

On the other hand, given the initial state $X_0 = x$ and the policy $\pi \in \mathbb{P}$ being used, the distribution of the state–action process $\{(X_t, A_t)\}$ is uniquely determined via the Ionescu–Tulcea theorem; see [14, 15, 20] for details. This distribution is denoted by P_x^π, whereas E_x^π stands for the corresponding expectation operator. It is known that under the action of any policy $f \in \mathbb{F}$ the state process $\{X_t\}$ is a Markov chain with stationary transition mechanism [14, 20, 22].

Assumption 2.2 (communication). Under the action of any policy $f \in \mathbb{F}$ the state space is a communicating class. More explicitly, given $x, y \in S$ and $f \in \mathbb{F}$, there exists a positive integer $m = m(x, y, f)$ such that $P_x^f[X_m = y] > 0$.

Optimality criterion. The (lim sup expected) *average cost* at state $x \in S$ under policy $\pi \in \mathbb{P}$ is defined by

$$J(x, \pi) := \limsup_{n \to \infty} \frac{1}{n+1} E_x^\pi \left[\sum_{t=0}^{n} C(X_n, A_n) \right], \tag{2.2}$$

while

$$J(x) := \inf_{\pi \in \mathbb{P}} J(x, \pi) \tag{2.3}$$

is the *optimal average cost* at state x. A policy π is *average optimal* (AO) if $J(x, \pi) = J(x)$ for all $x \in S$.

Since $C \geq 0$, the expectation in (2.2) is well defined, but under Assumptions 2.1 and 2.2 alone, $J(\cdot)$ may be identically infinite. Assumption 2.3 below avoids this situation and, in addition, allows one to establish the existence of a solution to the ACOE yielding AO stationary policies. This restriction is a version of a condition introduced by Borkar in [1, 2] for cost functions depending only on the state; see also [3, 4], where the latter restriction is avoided.

Assumption 2.3. (i) (Almost monotone (penalized) costs.) For each $b > 0$ there exists a *finite* set $G(b) \subset S$ such that

$$C(x, a) > b \quad \text{for all} \quad (x, a) \in (S \setminus G(b)) \times A.$$

(ii) (Finite average cost.) There exists a policy $f \in \mathbb{F}$ such that $J(x, f) < \infty$ for all $x \in S$.

The following basic result is the most important consequence of Assumptions 2.1–2.3. Throughout the remainder of the paper, $z \in S$ is a *fixed state*.

LEMMA 2.1. *There exist* $g \in \mathbb{R}$ *and* $h : S \to \mathbb{R}$ *satisfying* (i)–(iv) *below.*

(i) $J(x) = g$ *for all* $x \in S$.

(ii) h *is bounded below and* $h(z) = 0$.

(iii) *The ACOE holds:*

$$g + h(x) = \inf_{a \in A} \left[C(x, a) + \sum_y p_{xy}(a) h(y) \right], \quad x \in S. \tag{2.4}$$

(iv) *An optimal stationary policy exists. Indeed, for each* $x \in S$, *the term in brackets in* (2.4) *has a minimizer* $f^*(x) \in A$ *and the corresponding policy* f^* *is optimal.*

This lemma was essentially obtained in [1–4]. A short proof is given, since it plays a basic role in this note.

Proof of Lemma 4.1. From Assumptions 2.1–2.3 it can be shown that conditions 1–3 and 3* in [23] hold true; see [6] or Remark 6.3ii in [5]. Thus, the conclusion follows from Sennott's results in [23]. □

Note that g in Lemma 2.1 is *the optimal average* cost at each state, so it is uniquely determined. As will be shown in §4, a function h satisfying (2.4) is also unique if it is bounded below and is normalized by the condition $h(z) = 0$.

As already mentioned, the main objective of the paper is to show that the value iteration scheme can be used to produce convergent approximations of the pair $(g, h(\cdot))$ in (2.4). The result in this direction is stated in the next section as Theorem 3.1 and requires the next additional condition.

Assumption 2.4. For all $x \in S$ and $a \in A$, $p_{xx}(a) > 0$.

Throughout the remainder of this paper, Assumptions 2.1–2.4 are supposed to hold true, even without explicit reference. On the other hand, it is interesting to observe that Assumption 2.4 will be used only in one place, namely, in the proof of Theorem 7.1(i) in §7.

Remark 2.1. The restriction imposed in Assumption 2.4 does not imply any loss of generality. In fact, assume that $M = (S, A, C, p)$ satisfies Assumptions 2.1–2.3, and define a new transition law p^* as follows: for all $x, y \in S$ and $a \in A$,

$$p^*_{xy}(a) := \alpha\delta_{xy} + (1-\alpha)p_{xy}(a),$$

where $\alpha \in (0, 1)$ is a given number and $\delta_{xy} := 0$ (resp., 1) if $x \neq y$ (resp., $x = y$); the transformation $p \mapsto p^*$ was introduced by Schweitzer in [27]. Now set $M^* = (S, A, C, p^*)$, which clearly satisfies Assumptions 2.1 and 2.4; note that $p^*_{xx}(a)$ is always $\geq \alpha$. Now let $P^{*\pi}_x$ and $J^*(x, \pi)$ be associated with model M^* in the same way as P^π_x and $J(x, \pi)$ are related to M. In this case it is not difficult to verify that for all $x, y \in S$, $f \in \mathbb{F}$, and $m \in \mathbb{N}$, $P^{*f}_x[X_m = y] \geq (1-\alpha)^m P^f_x[X_m = y]$ and $J^*(x, f) = J(x, f)$, and these facts immediately yield that M^* also satisfies Assumptions 2.2 and 2.3. In short, if M satisfies Assumptions 2.1–2.3, then the modified model M^* satisfies Assumptions 2.1–2.4. Furthermore, M and M^* are *equivalent* MDPs in the following sense: let (g^*, h^*) be the pair given in Lemma 2.1 applied to M^*. Then (i) $g^* = g$; (ii) $h^* = h/\alpha$; and (iii) a policy $f^* \in \mathbb{F}$ is obtained as in Lemma 2.1(iv) applied to model M if and only if f^* satisfies Lemma 2.1(iv) applied to model M^*; see [20, pp. 371–372].

This section concludes with some remarks about Markov chains that will be used later; details can be found, for instance, in [18, Chap. 1]. First, recall that a function $\mu_f : S \to \mathbb{R}$ is an *invariant* distribution of the Markov chain induced by a stationary policy $f \in \mathbb{F}$ or, simply, of the transition matrix $P_f \equiv [P_f(x, y)] := [p_{xy}(f(x))]$ if

$$\text{(2.5)} \qquad \mu_f(y) \geq 0, \quad \sum_x \mu_f(x) = 1, \quad \text{and} \quad \mu_f(y) = \sum_x \mu_f(x) p_{xy}(f(x)), \quad y \in S.$$

Also, by Assumption 2.2, if the Markov chain induced by f has an invariant distribution, then it is *unique* [18, pp. 39–42] and it follows that

$$\text{(2.6)} \qquad \begin{aligned} J(x, f) &= \lim_{n\to\infty} \frac{1}{n+1} E^f_x \left[\sum_{t=0}^{n} C(X_t, A_t) \right] \\ &= \sum_y \mu_f(y) C(y, f(y)), \quad x \in S. \end{aligned}$$

Next, for each $x \in S$ define the first passage time T_x by

$$T_x := \min\{n > 0 | X_n = x\}, \tag{2.7}$$

where, as usual, the minimum of the empty set is ∞. By notational convenience, the time of the first arrival to the distinguished state z in a positive time is simply written as T, i.e.,

$$T_z \equiv T. \tag{2.8}$$

Remark 2.2. Let $f \in \mathbb{F}$ be fixed.

(i) P_f has an invariant distribution if and only if $E_y^f[T_y] < \infty$ for some state y; in this case Assumption 2.2 yields [18] that

(2.9)

$$E_x^f[T_x] < \infty \quad \text{and} \quad \frac{1}{E_x^f[T_x]} = \lim_{n\to\infty} \frac{1}{n+1} \sum_{t=0}^{n} P_y^f[X_t = x] = \mu_f(x) > 0 \quad \text{for all } x, y \in S.$$

(ii) If the Markov chain induced by f has an invariant distribution, then successive visits to a fixed state y determine a (possibly delayed) renewal process. In this case, if $J(x, f) < \infty$,

$$\begin{aligned} \infty > J(x, f) &= \lim_{n\to\infty} \frac{1}{n+1} E_x^f \left[\sum_{t=0}^{n} C(X_t, A_t) \right] \\ &= \frac{E_y^f[\sum_{n=0}^{T_y - 1} C(X_t, A_t)]}{E_y^f[T_y]} \\ &= \frac{E_z^f[\sum_{n=0}^{T-1} C(X_t, A_t)]}{E_z^f[T]}; \end{aligned} \tag{2.10}$$

see (2.7) and (2.8). These equalities follow from the theory of (delayed) renewal reward processes as presented in [22].

(iii) Suppose that P_f has an invariant distribution and that $J(\cdot, f)$ is finite. In this case (2.6) holds and, by Assumption 2.2, there is a positive probability of reaching a given state $y \in S$ between successive visits to state z, and it follows that

$$S = \bigcup_{k=0}^{\infty} S_k,$$

where

$$S_0 := \{z\} \quad \text{and} \quad S_k := \{y \in S | P_z^f[X_k = y, T > k] > 0\}.$$

The following fact, whose proof can be seen in [23, Prop. 4], will be useful:

$$E_y^f \left[\sum_{t=0}^{T-1} C(X_t, A_t) \right] < \infty, \quad y \in S; \tag{2.11}$$

see (2.7) and (2.8). This is true for arbitrary (nonnegative) cost function, and setting $C(\cdot, \cdot) \equiv 1$ it follows that

$$E_y^f[T] < \infty, \quad y \in S. \tag{2.12}$$

3. Main result. In this section the main result of this note is stated as Theorem 3.1 below. First, the necessary notions are introduced.

DEFINITION 3.1 (the VI scheme). *The sequence* $\{V_k : S \to \mathbb{R} | k = -1, 0, 1, 2, \ldots\}$ *of VI functions is recursively defined as follows:* $V_{-1} \equiv 0$ *and, for* $k \geq 0$,

$$V_k(x) := \inf_{a \in A} \left[C(x, a) + \sum_y p_{xy}(a) V_{k-1}(y) \right], \quad x \in S.$$

It is known that, for each $k \in \mathbb{N}$, there exists a policy π^k such that [14, 20, 22, $\cdots$] for all $x \in S$,

$$\begin{aligned} V_k(x) &= E_x^{\pi^k} \left[\sum_{t=0}^{k} C(X_t, A_t) \right] \\ &= \min_{\pi \in \mathbb{P}} E_\pi \left[\sum_{t=0}^{k} C(X_t, A_t) \right]. \end{aligned} \tag{3.1}$$

Also, since the cost function is nonnegative,

$$0 \leq V_n(x) \leq V_{n+k}(x), \quad x \in S, \ n, k \in \mathbb{N}. \tag{3.2}$$

On the other hand, observe that if $f \in \mathbb{F}$ is as in Assumption 2.3(ii), then $J(x, f) < \infty$ immediately implies that $\infty > E_x^f[\sum_{t=0}^n C(X_t, A_t)] \geq V_n(x)$ for all state x and $n \in \mathbb{N}$, so the VI functions are always finite.

DEFINITION 3.2. (i) *The relative value functions* $\{R_n : S \to \mathbb{R}\}$ *are defined by*

$$R_n(x) := V_n(x) - V_n(z), \quad x \in S, \quad n = -1, 0, 1, \ldots.$$

(ii) *The nth differential cost at state* $x \in S$ *is given by* $g_n(x) := V_n(x) - V_{n-1}(x)$, $n \in \mathbb{N}$.

The main result in this note is the following.

THEOREM 3.1. *Suppose that Assumptions* 2.1–2.4 *hold true, and let* g *and* $h(\cdot)$ *be as in Lemma* 4.1. *Then*

(i) *for all* $x \in S$, $\lim_{n \to \infty} g_n(x) = g$;

(ii) *for each* $x \in S$, $\lim_{n \to \infty} R_n(x) = h(x)$.

Furthermore,

(iii) *for each* $n \in \mathbb{N}$, *there exists a policy* $f_n \in \mathbb{F}$ *such that, for each* $x \in S$, $f_n(x)$ *is a minimizer of the mapping* $a \mapsto C(x, a) + \sum_y R_n(y) p_{xy}(f_n(a))$, $a \in A$. *Moreover, every limit point of* $\{f_n\}$ *is AO.*

We have not been able to find a simple and direct proof of this result. Indeed, the method used below to establish Theorem 3.1 is somewhat technical and consists of four steps, which are presented in §§4–7.

Remark 3.1. Theorem 3.1 is an extension of results in [8, 9, 25]. In these papers it was shown that, as $n \to \infty$, the sequence $\{(g_n(z), R_n(\cdot)\}$ converges to $(g, h(\cdot))$ in the Cesàro sense, i.e.,

$$\lim_{n \to \infty} \frac{1}{n+1} \sum_{k=0}^{n} g_n(z) = g \tag{3.3}$$

and

$$\lim_{n \to \infty} \frac{1}{n+1} \sum_{k=0}^{n} R_n(x) = h(x), \quad x \in S.$$

These convergences were obtained in [8] under the Lyapunov function condition, in [9] under conditions slightly stronger than Assumptions 2.1–2.3, and in [25] under conditions involving the behavior of the optimal *discounted* value function as the discount factor increases to 1. The assumptions in [25] are satisfied within the framework described in §2; see, for instance, [6]. On the other hand, (3.3) was obtained by Gosh and Marcus in [13] as a tool to establish the existence of strong average optimal stationary policies under Assumptions 2.1–2.3.

4. Preliminaries: First part. The starting point on the way to the proof of Theorem 3.1 is the following result, which establishes uniqueness of the function $h(\cdot)$ in Lemma 2.1.

THEOREM 4.1. *Let* $h_1, h_2 : S \to \mathbb{R}$ *satisfy* (a)–(c) *below.*

(a) h_1 *and* h_2 *are* bounded below.

(b) $h_1(z) = h_2(z) = 0$.

(c) h_1 *and* h_2 *satisfy the ACOE, i.e.,*

$$g + h_i(x) = \min_{a \in A}\left[C(x,a) + \sum_y p_{xy}(a)h_i(y)\right], \quad x \in S, \quad i = 1, 2. \tag{4.1}$$

Then $h_1(\cdot) = h_2(\cdot)$.

The proof of this theorem is based on the following lemma, which is the most important technical tool in this note.

LEMMA 4.1. *Let* $W : S \to \mathbb{R}$ *be a* bounded below *function satisfying* $W(z) = 0$, *and suppose that the stationary policy* $f \in \mathbb{F}$ *is such that*

$$g + W(x) \geq C(x, f(x)) + \sum_y p_{xy}(f(x))W(y), \quad x \in S. \tag{4.2}$$

Then assertions (i)–(vi) *below occur.*

(i) $g = J(x, f)$, $x \in S$, *i.e., f is AO.*

(ii) *Every state x is positive recurrent* [18] *with respect to* P_f. *Hence* P_f *has an invariant distribution* μ_f; *see* (2.5).

(iii) *For all* $x \in S$,

$$\frac{1}{n+1}E_x^f\left[\sum_{t=0}^{n} W(X_{n+1})\right] \to 0 \quad as \quad n \to \infty.$$

(iv) *For all* $a \in A$ *and* $x \in S$,

$$g + W(x) \leq C(x,a) + \sum_y p_{xy}(a)W(y); \tag{4.3}$$

in particular, equality holds in (4.2) *and the pair* $(g, W(\cdot))$ *satisfies the ACOE:*

$$g + W(x) = \min_{a \in A}\left[C(x,a) + \sum_y p_{xy}(a)W(y)\right], \quad x \in S.$$

(v) *Let* $D : S \to [0, \infty)$ *be such that* (a) $D(z) = 0$ *and* (b) $D(x) = E_x^f[D(X_1)]$, $x \in S$. *Then*

$$D(x) = 0 \quad \textit{for all state } x.$$

(vi) $W(x) = E_x^f[\sum_{t=0}^{T-1}(C(X_t, A_t) - g)]$ *for all* $x \in S$ (*see* (2.7) *and* (2.8)).

Proof. To begin, note that, since $W(\cdot)$ is bounded below,

$$\liminf_{n\to\infty} \frac{E_x^f[W(X_{n+1})]}{n+1} \geq 0. \tag{4.4}$$

(i) A simple induction argument using (4.2) shows that for all $x \in S$ and $n \in \mathbb{N}$,

$$g + \frac{1}{n+1}W(x) \geq \frac{1}{n+1}E_x^f\left[\sum_{t=0}^{n} C(X_t, A_t)\right] + \frac{1}{n+1}E_x^f[W(X_{n+1})], \tag{4.5}$$

and taking limit superior in both sides of this inequality, it follows, via (4.4), that for all $x \in S$

$$g \geq \limsup_{n\to\infty} \frac{1}{n+1}E_x^f\left[\sum_{t=0}^{n} C(X_t, A_t)\right] = J(x, f),$$

which yields that $g = J(x, f)$, $x \in S$, since g is the optimal average cost at every state; see (2.2), (2.3), and Lemma 2.1(i).

(ii) By Assumption 2.2, it is sufficient to prove that *some* state is positive recurrent [18] with respect to P_f. This fact will be established by contradiction. Thus, *suppose that*

every state is transient or null recurrent with respect to P_f. (4.6)

Under this assumption, for each *finite* set $G \subset S$ [18],

$$\lim_{n\to\infty} \frac{1}{n+1}E_x^f\left[\sum_{t=0}^{n} I[X_t \in G]\right] = 0 \quad \text{and} \quad \lim_{n\to\infty} \frac{1}{n+1}E_x^f\left[\sum_{t=0}^{n} I[X_t \in S \setminus G]\right] = 1. \tag{4.7}$$

Combining these relations with (2.2) it follows immediately that

$$J(x, f) = \limsup_{n\to\infty} \frac{1}{n+1}E_x^f\left[\sum_{t=0}^{n} C(X_t, A_t) I[X_t \in S \setminus G]\right]. \tag{4.8}$$

To conclude, choose $G = G(g+1)$, the finite set in Assumption 2.3(i) with $b = g + 1$. In this case $C(X_t, A_t)I[X_t \in S \setminus G] \geq (g+1)I[X_t \in S \setminus G]$, and (4.7) and (4.8) together yield that $J(x, f) \geq g + 1$, which contradicts part (i). In short, (4.6) leads to a contradiction, and this establishes part (ii).

(iii) Since the Markov chain induced by f has an invariant distribution, it follows that

$$g = J(x, f) = \lim_{n\to\infty} \frac{1}{n+1}E_x^f\left[\sum_{t=0}^{n} C(X_t, A_t)\right];$$

see (2.6). This immediately yields, in combination with (4.5), that

$$\begin{aligned} g &\geq \limsup_{n\to\infty} \left\{\frac{1}{n+1}E_x^f\left[\sum_{t=0}^{n} C(X_t, A_t)\right] + \frac{1}{n+1}E_x^f[W(X_{n+1})]\right\} \\ &= g + \limsup_{n\to\infty} \frac{1}{n+1}E_x^f[W(X_{n+1})], \end{aligned}$$

so

$$\limsup_{n} \frac{1}{n+1}E_x^f[W(X_{n+1})] \leq 0,$$

and the desired conclusion follows from combining this inequality with (4.4).

(iv) The proof is by contradiction. Let $(\tilde{x}, \tilde{a}) \in S \times A$ be arbitrary but fixed, and *suppose* that

$$\Delta := g + W(\tilde{x}) - C(\tilde{x}, \tilde{a}) - \sum_y p_{\tilde{x}y}(\tilde{a})W(y) > 0. \tag{4.9}$$

Define a new policy $\tilde{f} \in \mathbb{F}$ and a function $\psi : S \to \mathbb{R}$ by

$$\tilde{f}(x) = \begin{cases} f(x) & \text{if } x \neq \tilde{x}, \\ \tilde{a} & \text{if } x = \tilde{x} \end{cases}$$

and

$$\psi(x) = \begin{cases} \Delta & \text{if } x = \tilde{x}, \\ 0 & \text{if } x \neq \tilde{x}. \end{cases} \tag{4.10}$$

Combining these definitions with (4.2) and (4.9) it follows that for all $x \in S$,

$$\begin{aligned} g + W(x) &\geq C(x, \tilde{f}(x)) + \psi(x) + \sum_y P_{\tilde{x}y}(\tilde{f}(x))W(y) \\ &\geq C(x, \tilde{f}(x)) + \sum_y P_{\tilde{x}y}(\tilde{f}(x))W(y) \end{aligned}$$

so that, by parts (i) and (ii), $\tilde{f}$ is AO and the Markov chain induced by $\tilde{f}$ has an invariant distribution $\mu_{\tilde{f}}$. Next observe that for all $x \in S$ and $n \in \mathbb{N}$ (see the proof of part (i)),

$$g + \frac{1}{n+1}W(x) \geq \frac{1}{n+1}E_x^{\tilde{f}}\left[\sum_{t=0}^{n}(C(X_t, A_t) + \psi(X_t))\right] + \frac{1}{n+1}E_x^{\tilde{f}}[W(X_{n+1})]. \tag{4.11}$$

By (2.6) with $f = \tilde{f}$, as $n \to \infty$,

$$\frac{1}{n+1}E_x^{\tilde{f}}\left[\sum_{t=0}^{n} C(X_t, A_t)\right] \to \sum_y \mu_{\tilde{f}}(y)C(y, \tilde{f}(y)) = J(x, \tilde{f})$$

and similarly (see (2.9) and (4.10))

$$\frac{1}{n+1}E_x^{\tilde{f}}\left[\sum_{t=0}^{n} \psi(X_t)\right] \to \sum_y \mu_{\tilde{f}}(y)\psi(y) = \mu_{\tilde{f}}(\tilde{x})\Delta.$$

Using these convergences and part (iii) with $\tilde{f}$ instead of f, it follows, after letting n increase to ∞ in (4.11), that

$$g \geq J(x, \tilde{f}) + \mu_{\tilde{f}}(\tilde{x})\Delta > J(x, \tilde{f}),$$

where the strict inequality follows from (2.9) and (4.9). However, this contradicts the equality $g = J(x, \tilde{f})$, and it follows that Δ in (4.9) is ≤ 0, establishing (4.3), since the pair $(\tilde{x}, \tilde{a}) \in S \times A$ was arbitrary. Clearly, (4.3) implies that equality holds in (4.2), and, finally, (4.2) and (4.3) together yield that the pair $(g, W(\cdot))$ satisfies the ACOE.

(v) It is sufficient to prove that $D(y) \leq 0$ for $y \neq z$ since, by assumption, D is a nonnegative function and $D(z) = 0$. Note that $D(x) = E_x^f[D(X_1)]$ is equivalent to $D(x) = E_x^f[D(X_1)I[T > 1]]$; this is due to the condition $D(z) = 0$ and the definition of T (see (2.7) and (2.8)). Then, from a simple induction argument using the Markov property, it follows that

$$D(x) = E_x^f[D(X_n)I[T > n]], \quad x \in S, \ n \in \mathbb{N}.$$

Next, set $x = z$ to obtain

$$0 = D(z) = E_z^f[D(X_n)I[T > n]] \geq D(y)P_z^f[X_n = y, T > n], \quad n \in \mathbb{N}, \tag{4.12}$$

where $y \neq z$ is an arbitrary state and the nonnegativity of $D(\cdot)$ was used to obtain the inequality. Since there exists a positive integer n with $P_z^f[X_n = y, T > n] > 0$ (see Remark 2.2(iii)), (4.12) yields that $0 \geq D(y)$, and as already mentioned, this establishes part (v), since $y \in S \setminus \{z\}$ was arbitrary.

(vi) Recalling that equality holds in (4.2) and using that $W(z) = 0$, it follows that for each $x \in S$

$$\begin{aligned} W(x) &= C(x, f(x)) - g + \sum_{y \neq z} p_{xy}(f(x))W(y) \\ &= E_x^f[(C(X_0, A_0) - g)I[T > 0] + W(X_1)I[T > 1]]; \end{aligned} \tag{4.13}$$

note that $T = T_z$ is always ≥ 1 by (2.7) and (2.8). This implies, via an induction argument, that

$$W(x) = E_x^f\left[\sum_{t=0}^{n}(C(X_t, A_t) - g)I[T > t] + W(X_{n+1})I[T > n+1]\right], \quad x \in S,\ n \in \mathbb{N}. \tag{4.14}$$

Next observe that, since P_f has an invariant distribution and $J(\cdot, f) \equiv g(< \infty)$ (by parts (i) and (ii)),

(a) (2.11), (2.12), and the dominated converge theorem together imply that

$$\begin{aligned} \lim_{n\to\infty} E_x^f\left[\sum_{t=0}^{n}(CX_t, A_t) - g)I[T > t]\right] &= E_x^f\left[\sum_{t=0}^{\infty}(C_t, A_t) - g)I[T > t]\right] \\ &= E_x^f\left[\sum_{t=0}^{T-1}(C_t, A_t) - g)\right]; \end{aligned}$$

(b) $E_x^f[W(X_n)I[T > n]] \geq E_x^f[bI[T > n]] = bP_x^f[T > n] \to bP_x^f[T = \infty] = 0$ as $n \to \infty$, where b is a lower bound of $W(\cdot)$, and the last equality is a consequence of (2.12). Then, letting n increase to ∞ in (4.14) and using (a) and (b) it follows that

$$W(x) \geq E_x^f\left[\sum_{t=0}^{\infty}(C(X_t, A_t) - g)I[T > t]\right] = E_x^f\left[\sum_{t=0}^{T-1}(C(X_t, A_t) - g)\right] =: M(x). \tag{4.15}$$

On the other hand, the Markov property and the definition of $M(\cdot)$ together yield that

$$\begin{aligned} M(x) &= C(x, f(x)) - g + \sum_{y \neq z} p_{xy}(f(x))M(y) \\ &= E_x^f[(C(X_0, A_0) - g)I[T > 0] + M(X_1)I[T > 1]], \end{aligned}$$

which combined with (4.13) implies that

$$W(x) - M(x) = E_x^f[(W(X_1) - M(X_1))I[T_z > 1]], \quad x \in S. \tag{4.16}$$

To conclude set $D(x) := W(x) - M(x)$, $x \in S$, and observe that $D(\cdot) \geq 0$ by (4.15). Now recall that $J(\cdot, f) = g$, so (4.15) and the third equality in (2.10) together yield that $M(z) = 0$. Since $W(z) = 0$ (by assumption), it follows that $D(z) = W(z) - M(z) = 0$. Then (4.16) can be written as

$$D(x) = E_x^f[D(X_1)], \quad x \in S,$$

and from an application of part (v) it follows that $W(x) - M(x) = D(x) = 0$ for all $x \in S$, and the conclusion follows from combining this with the definition of $M(\cdot)$ in (4.15). □

This lemma will be now used to establish Theorem 4.1.

Proof of Theorem 4.1. Let $x \in S$ be arbitrary. Since h_i is bounded below, Assumption 2.1 yields that the mapping $a \mapsto C(x, a) + \sum_y p_{xy}(a)h_i(y)$ is lower semicontinuous and then has a minimizer $f_i(x)$, since A is compact [11], so

$$g + h_i(x) = C(x, f_i(x)) + \sum_y p_{xy}(f_i(x))h_i(y), \quad i = 1, 2 \quad x \in S. \tag{4.17}$$

Then, for $i = 1, 2$, f_i is AO and has an invariant distribution μ_{f_i}, by parts (i) and (ii) of Lemma 4.1. Now define $\hat{h} : S \to \mathbb{R}$ by

$$\hat{h}(x) := h_1(x) \wedge h_2(x), \quad x \in S; \tag{4.18}$$

note that $\hat{h}(\cdot)$ is bounded below and that (4.17) implies that for all $x \in S$,

$$g + h_i(x) \geq C(x, a) + \sum_y p_{xy}(f_i(x))\hat{h}(y), \quad i = 1, 2.$$

Then

$$g + \hat{h}(x) \geq C(x, \hat{f}(x)) + \sum_y p_{xy}(\hat{f}(x))\hat{h}(y), \tag{4.19}$$

where the policy $\hat{f} \in \mathbb{F}$ is given by

$$\hat{f} := \begin{cases} f_1(x) & \text{if } h_1(x) \leq h_2(x), \\ f_2(x) & \text{if } h_2(x) < h_1(x). \end{cases}$$

Using Lemma 4.1(iv) with $W = \hat{h}$ and $\hat{f}$ instead of f, (4.19) implies that

$$g + \hat{h}(x) \leq C(x, f_i(x)) + \sum_y p_{xy}(f_i(x))\hat{h}(y), \quad x \in S, \ i = 1, 2, \tag{4.20}$$

and it will be proven below that the equality holds, i.e.,

$$g + \hat{h}(x) = C(x, f_i(x)) + \sum_y p_{xy}(f_i(x))\hat{h}(y). \tag{4.21}$$

The conclusion follows from this assertion, since by Lemma 4.1(vi), (4.17) and (4.21) together yield that

$$h_i(x) = E_x^{f_i}\left[\sum_{t=0}^{T-1}(C(X_t, A_t) - g)\right] = \hat{h}(x), \quad x \in S, \ i = 1, 2;$$

recall that $h_1(z) = h_2(z) = 0$ and then $\hat{h}(z) = 0$ by (4.18). Thus, to complete the proof it is sufficient to establish (4.21). With this in mind let $\tilde{x} \in S$ and $i \in \{1, 2\}$ be fixed, and note that $\sum_y p_{xy}(f_i(x))\hat{h}(y) \leq \sum_y p_{xy}(f_i(x))h_i(y) < \infty$ by (4.17) and (4.18). Now define $\psi : S \to \mathbb{R}$ by

$$\psi(x) := \begin{cases} g + \hat{h}(x) - C(x, f_i(x)) - \sum_y p_{xy}(f_i(x))\hat{h}(y) & \text{if } x = \tilde{x}, \\ 0 & \text{if } x \neq \tilde{x}, \end{cases} \tag{4.22}$$

so (4.20) implies that for all state x

$$g + \hat{h}(x) \le C(x, f_i(x)) + \psi(x) + \sum_y p_{xy}(f_i(x))\hat{h}(y),$$

with equality for $x = \tilde{x}$. An induction argument yields that

(4.23)

$$g + \frac{1}{n+1}\hat{h}(x) \le \frac{1}{n+1}E_x^{f_i}\left[\sum_{t=0}^{n} C(X_t, f_i(X_t)) + \psi(X_t)\right] + \frac{1}{n+1}E_x^{f_i}[\hat{h}(X_{n+1})], \quad x \in S.$$

Next observe that, by (4.17) and Lemma 4.1(iii) with $W(\cdot) = h_i(\cdot)$ and $f = f_i$, $E_x^{f_i}[h_i(X_{n+1})]/(n+1) \to 0$ as $n \to \infty$. Since $\hat{h} \le h_i$ this implies (recall that $\hat{h}$ is bounded below) that $\lim_{n\to\infty} E_x^{f_i}[\hat{h}(X_{n+1})]/(n+1) = 0$. With this in mind, take limit as $n \to \infty$ in both sides of (4.23) to obtain, via (2.6), (2.9), and (4.22), that

$$g \le \lim_{n\to\infty} \frac{1}{n+1}E_x^{f_i}\left[\sum_{t=0}^{n} C(X_t, f_i(X_t)) + \psi(X_t)\right] = \sum_y \mu_{f_i}(y)C(y, f_i(y)) + \mu_{f_i}(\tilde{x})\psi(\tilde{x}).$$

Since $\sum_y \mu_{f_i}(y)C(y, f_i(y)) = g$ (f_i is AO) and $\mu_{f_i}(\tilde{x}) > 0$ (by (2.9)), the last displayed inequality renders that $\psi(\tilde{x}) \ge 0$ and then $\psi(\tilde{x}) = 0$, since by (4.20) and (4.22), $\psi(\cdot) \le 0$. Therefore, (4.21) holds for $x = \tilde{x}$, and the conclusion follows, since $\tilde{x}$ and i were arbitrary. □

5. Preliminaries: Second part. This section is the second step in the journey to the proof of Theorem 3.1. The present objective is to establish Theorem 5.1, which concerns the asymptotic behavior of the differential costs introduced in Definition 3.2. First, it is convenient to introduce some useful notation.

DEFINITION 5.1. *The functions $U, L : S \to \mathbb{R}$ are defined as follows: for each $x \in S$,*

$$U(x) := \limsup_{n\to\infty} g_n(x) \quad \textit{and} \quad L(x) := \liminf_{n\to\infty} g_n(x).$$

Note that (3.2) and Definition 3.2 together imply that U and L are nonnegative functions. The next theorem is the main result of this section.

THEOREM 5.1. *Let $g \in \mathbb{R}$ and $f^* \in \mathbb{F}$ be as in Lemma* 2.1. *Then*

$$\frac{U(x) - L(x)}{E_x^{f^*}[T_x]} + L(x) \le g \quad \textit{for all } x \in S. \tag{5.1}$$

In particular, U and L are finite *functions.*

Proof. For each $k \in \mathbb{N}$ let policy π^k be as in (3.1). Now let the state x and the nonnegative integer n be arbitrary but fixed, and define a new policy π^{*n} as follows: for $t \in \mathbb{N}$ and $h_t = (x_0, a_0, \ldots, x_{t-1}, a_{t-1}, x_t) \in H_t$,

(a) suppose that $x_s \ne x$ for $1 \le s \le t$. In this case

$$\pi_t^{*n}(\{f^*(x_t)\}|h_t) := 1.$$

(b) if $x_s \ne x$ for $1 \le s < k$ and $x_k = x$ for some integer $k \le t$, set

$$\pi_t^{*n}(\cdot|\cdot) := \pi_{t-k}^{n-k}(\cdot|\cdot) \quad \text{if} \quad k \le n$$

and

$$\pi_t^{*n}(\{f^*(x_t)\}|h_t) := 1 \quad \text{if} \quad k > n.$$

In words, a controller using π^{*n} operates as follows: actions are chosen according to f^* until state x is reached in a positive time; if it occurs after time n, policy f^* continues in use, whereas if $T_x = k \leq n$ the controller switches to policy π^{n-k} as if the process had started again. Then it is clear that for all $x \in S$,

$$E_x^{\pi^{*n}}\left[\sum_{t=0}^{n} C(X_t, A_t)I[T_x > n]\right] = E_x^{f^*}\left[\sum_{t=0}^{n} C(X_t, A_t)I[T_x > n]\right] \tag{5.2}$$

and

$$E_x^{\pi^{*n}}\left[\sum_{t=0}^{T_x-1} C(X_t, A_t)I[T_x \leq n]\right] = E_x^{f^*}\left[\sum_{t=0}^{T_x-1} C(X_t, A_t)I[T_x \leq n]\right]. \tag{5.3}$$

Now let $k \leq n$ and recall that $X_k = x$ on $[T_x = k]$ and that T_x is I_k-measurable. Since on $[T_x = k]$ policy π^{*n} coincides with π^{n-k} from time k onward, the Markov property yields that

$$\begin{aligned} E_x^{\pi^{*n}}\left[\sum_{t=T_x}^{n} C(X_t, A_t)I[T_x = k]|I_k\right] &= I[T_x = k]E_{X_k}^{\pi^{*n}}\left[\sum_{t=T_x}^{n} C(X_t, A_t)\right] \\ &= I[T_x = k]E_x^{\pi^{n-k}}\left[\sum_{t=0}^{n-k} C(X_t, A_t)\right] \\ &= I[T_x = k]V_{n-k}(x) \qquad \text{(see (3.1))}. \end{aligned}$$

Therefore, $E_x^{\pi^{*n}}[\sum_{t=T_x}^{n} C(X_t, A_t)I[T_x = k]] = P_x^{\pi^{*n}}[T_x = k]V_{n-k}(x) = P_x^{f^*}[T_x = k]V_{n-k}(x)$ for all $k \leq n$, where the second equality follows from the definition of π^{*n}; this implies that

$$E_x^{\pi^{*n}}\left[\sum_{t=T_x}^{n} C(X_t, A_t)I[T_x \leq n]\right] = E_x^{f^*}[V_{n-T_x}(x)I[T_x \leq n]].$$

Combining this equality with (3.1), (5.2), and (5.3) it follows that

$$\begin{aligned} V_n(x) &\leq E_x^{\pi^{*n}}\left[\sum_{t=0}^{n} C(X_t, A_t)\right] \\ &= E_x^{\pi^{*n}}\left[\sum_{t=0}^{T_x-1} C(X_t, A_t)I[T_x \leq n]\right] + E_x^{\pi^{*n}}\left[\sum_{t=T_x}^{n} C(X_t, A_t)I[T_x \leq n]\right] \\ &\quad + E_x^{\pi^{*n}}\left[\sum_{t=0}^{n} C(X_t, A_t)I[T_x > n]\right] \\ &= E_x^{f^*}\left[\sum_{t=0}^{T_x-1} C(X_t, A_t)I[T_x \leq n]\right] + E_x^{f^*}[V_{n-T_x}(X_{T_x})I[T_x \leq n]] \\ &\quad + E_x^{f^*}\left[\sum_{t=0}^{n} C(X_t, A_t)I[T_x > n]\right] \\ &\leq E_x^{f^*}\left[\sum_{t=0}^{T_x-1} C(X_t, A_t)\right] + E_x^{f^*}[V_{n-T_x}(x)I[T_x \leq n]], \end{aligned}$$

where the nonnegativity of the cost function was used to obtain the second inequality. Thus,

$$V_n(x) - E_x^{f^*}[V_{n-T_x}(x)I[T_x \le n]] \le E_x^{f^*}\left[\sum_{t=0}^{T_x-1} C(X_t, A_t)\right]. \tag{5.4}$$

Now observe that

$$\begin{aligned} V_n(x) - E_x^{f^*}[V_{n-T_x}(x)I[T_x \le n]] &= V_n(x)P_x^{f^*}[T_x > n] \\ &\quad + \sum_{k=1}^{n}(V_n(x) - V_{n-k}(x))P_x^{f^*}[T_x = k]. \end{aligned} \tag{5.5}$$

On the other hand, (2.9) and the dominated convergence together imply that $E_x^{f^*}[T_x I[T_x > n]] \to 0$, whereas $\lim_{n\to\infty} V_n(x)/n = g$ (see [13]). Therefore, it follows that

$$\begin{aligned} 0 \le V_n(x)P_x^{f^*}[T_x > n] &= \frac{V_n(x)}{n} nP_x^{f^*}[T_x > n] \\ &\le \frac{V_n(x)}{n} E_x^{f^*}[T_x I[T_x > n]] \to g \cdot 0 = 0 \text{ as } n \to \infty. \end{aligned} \tag{5.6}$$

Now let $\{n(r)\}$ be a sequence increasing to ∞ such that

$$\lim_{r\to\infty} g_{n(r)}(x) = U(x), \tag{5.7}$$

and note that

$$\liminf_{r\to\infty} g_{n(r)-t}(x) \ge L(x), \quad t = 1, 2, 3, \ldots, \tag{5.8}$$

where the inequality is due to the definition of $L(x)$ as the limit inferior of the *whole* sequence $\{g_n(x)\}$. Hence, for all $s \ge 1$, (5.7) and (5.8) together yield that

$$\begin{aligned} \liminf_{r\to\infty}[V_{n(r)}(X) - V_{n(r)-s}(x)] &= \liminf_{r\to\infty} \sum_{t=0}^{s-1} g_{n(r)-t}(x) \\ &= \liminf_{r\to\infty}\left[g_{n(r)}(x) + \sum_{t=1}^{s-1} g_{n(r)-t}(x)\right] \\ &\ge U(x) + (s-1)L(x), \end{aligned}$$

so an application of Fatou's lemma [21] leads to

$$\begin{aligned} \liminf_{r\to\infty} \sum_{k=1}^{n(r)}(V_{n(r)}(x) - V_{n(r)-k}(x))P_x^{f^*}[T_x = k] &\ge \sum_{k=1}^{\infty}(U(x) + (k-1)L(x))P_x^{f^*}[T_x = k] \\ &= U(x) + E_x^{f^*}[T_x - 1]L(x). \end{aligned} \tag{5.9}$$

Replacing n with $n(r)$ in (5.4) and taking limit inferior as $r \to \infty$ in both sides of the resulting inequality it follows, via (5.5), (5.6), and (5.9), that

$$U(x) + E_x^{f^*}[T_x - 1]L(x) \le E_x^{f^*}\left[\sum_{t=0}^{T_x-1} C(X_t, A_t)\right]. \tag{5.10}$$

This immediately implies that $U(x)$ is finite, and then so is $L(x)$, since $0 \le L(\cdot) \le U(\cdot)$, by Definition 5.1. Next observe that, by Lemma 2.1(iv), $g + h(x) = C(x, f^*(x)) + \sum_y p_{xy}(f^*(x))h(y)$, $x \in S$, so that P_{f^*} has an invariant distribution, by Lemma 4.1(ii). Since f^* is AO, (5.1) follows from (5.10) after simple rearrangements using that $g = E_x^{f^*}[\sum_{t=0}^{T_x-1} C(X_t, A_t)]/E_x^{f^*}[T_x]$; see Remark 2.2, especially (2.10). □

6. Preliminaries: Third part. The objective of this section is to show that the relative value functions in Definition 3.2 are appropriately bounded and that the function L in Definition 5.1 has a minimizer.

THEOREM 6.1. (i) *There exists* $N > 0$ *and a function* $B : S \to [0, \infty)$ *such that* $-N \le R_n(x) \le B(x)$ *for all* $x \in S$ *and* $n \in \mathbb{N}$.

(ii) *There exists* $z^* \in S$ *such that* $L(z^*) \le L(x)$, $x \in S$.

The proof of this result relies on Lemmas 6.1 and 6.2 below.

LEMMA 6.1. *Let* $G \subset S$ *be a finite set. There exists a finite constant* $K(G) > 0$ *such that*

$$|V_n(x) - V_n(y)| \le K(G) \quad \text{for all } x, y \in G,\ n \in \mathbb{N}.$$

Proof. Let $x \in S$ and $n \in \mathbb{N}$ be fixed, and define the policy π^{*n} as in the proof of Theorem 5.1. Recalling that π^{*n} coincides with f^* before time T_x, it follows that for all $y \in S$, $E_y^{\pi^{*n}}[\sum_{t=0}^{n} C(X_t, A_t)I[T_x > n]] = E_y^{f^*}[\sum_{t=0}^{n} C(X_t, A_t)I[T_x > n]]$ and $E_y^{\pi^{*n}}[\sum_{t=0}^{T_x-1} C(X_t, A_t)I[T_x \le n]] = E_y^{f^*}[\sum_{t=0}^{T_x-1} C(X_t, A_t)I[T_x \le n]]$. Also, using that for each $k \le n$, π^{*n} coincides with π^{n-k} from time k onward in the event $[T_x = k]$, it follows that

$$\begin{aligned} E_y^{\pi^{*n}}\left[\sum_{t=T_x}^{n} C(X_t, A_t)I[T_x \le n]\right] &= E_y^{\pi^{*n}}[V_{n-T_x}(x)I[T_x \le n]] \\ &= E_y^{f^*}[V_{n-T_x}(x)I[T_x \le n]], \end{aligned}$$

since policy π^{*n} coincides with f^* before T_x; see the arguments in the paragraph following (5.3). Then (3.1) yields

$$\begin{aligned} V_n(y) &\le E_y^{\pi^{*n}}\left[\sum_{t=0}^{n} C(X_t, A_t)\right] \\ &= E_y^{\pi^{*n}}\left[\sum_{t=0}^{n} C(X_t, A_t)I[T_x > n]\right] + E_y^{\pi^{*n}}\left[\sum_{t=0}^{T_x-1} C(X_t, A_t)I[T_x \le n]\right] \\ &\quad + E_y^{\pi^{*n}}\left[\sum_{t=T_x}^{n} C(X_t, A_t)I[T_x \le n]\right] \\ &= E_y^{f^*}\left[\sum_{t=0}^{n} C(X_t, A_t)I[T_x > n]\right] + E_y^{f^*}\left[\sum_{t=0}^{T_x-1} C(X_t, A_t)I[T_x \le n]\right] \\ &\quad + E_y^{f^*}[V_{n-T_x}(x)I[T_x \le n]] \\ &\le E_y^{f^*}\left[\sum_{t=0}^{T_x-1} C(X_t, A_t)\right] + E_y^{f^*}[V_{n-T_x}(x)I[T_x \le n]]. \end{aligned}$$

Combining this inequality with (3.2) it follows immediately that

$$V_n(y) - V_n(x) \le E_y^{f^*}\left[\sum_{t=0}^{T_x-1} C(X_t, A_t)\right], \tag{6.1}$$

and the conclusion follows setting $K(G) := \max_{x,y\in G}\{E_y^{f^*}[\sum_{t=0}^{T_x-1} C(X_t, A_t)]\}$. □

This lemma will be used to prove part (i) of Theorem 6.1. First notice that, by Theorem 5.1, $U(z) = \limsup_{n\to\infty} g_n(z)$ is finite. Since $g_n(\cdot) \ge 0$, this yields that $\{g_n(z)\}$ is a bounded sequence. Throughout the remainder $b > 0$ is fixed and satisfies

$$b \ge g_n(z), \quad n \in \mathbb{N}. \tag{6.2}$$

In this case

$$kb \ge \sum_{s=0}^{k-1} g_{n-s} = \sum_{s=0}^{k-1}(V_{n-s} - V_{n-s-1}) = V_n(z) - V_{n-k}(z), \quad n-k \ge -1,\ n,k \in \mathbb{N}, \tag{6.3}$$

and since $V_{-1} \equiv 0$,

$$b \ge \frac{1}{n+1} V_n(z). \tag{6.4}$$

On the other hand, $G = G(b+1)$ is the *finite* set guaranteed by Assumption 2.3(i), i.e.,

$$C(x,a) \ge b+1, \quad (x,a) \in (S \setminus G) \times A. \tag{6.5}$$

Finally, set

$$T_G := \min\{n > 0 |\, X_n \in G\} = \min_{x\in G} T_x. \tag{6.6}$$

Proof of Theorem 6.1(i). Let $\pi^n \in \mathbb{M}$ be as in (3.1), and note that

$$\begin{aligned} V_n(x) &= E_x^{\pi^n}\left[\sum_{t=0}^{n} C(X_t, A_t)\right] \\ &= E_x^{\pi^n}\left[\sum_{t=0}^{n} C(X_t, A_t) I[T_G > n]\right] + E_x^{\pi^n}\left[\sum_{t=0}^{T_G-1} C(X_t, A_t) I[T_G \le n]\right] \\ &\quad + E_x^{\pi^n}\left[\sum_{t=T_G}^{n} C(X_t, A_t) I[T_G \le n]\right] \\ &= E_x^{\pi^n}\left[\sum_{t=0}^{n} C(X_t, A_t) I[T_G > n]\right] + E_x^{\pi^n}\left[\sum_{t=0}^{T_G-1} C(X_t, A_t) I[T_G \le n]\right] \\ &\quad + E_x^{\pi^n}[V_{n-T_G}(X_{T_G}) I[T_G \le n]], \end{aligned} \tag{6.7}$$

where Bellman's optimality principle was used to obtain the last equality. Next observe that $M := \max\{|V_n(z) - V_n(y)| \,|\, y \in G,\ n \in \mathbb{N}\}$ is finite, by Lemma 6.1, so (6.7) leads to

$$\begin{aligned} V_n(x) &\ge E_x^{\pi^n}\left[\sum_{t=0}^{n} C(X_t, A_t) I[T_G > n]\right] + E_x^{\pi^n}\left[\sum_{t=0}^{T_G-1} C(X_t, A_t) I[T_G \le n]\right] \\ &\quad + E_x^{\pi^n}[V_{n-T_G}(z) I[T_G \le n]] - M, \end{aligned}$$

and using (6.3) and (6.4),

$$\begin{aligned}
V_n(x) - V_n(z) &\geq E_x^{\pi^n}\left[\sum_{t=0}^{n}(C(X_t, A_t) - \frac{1}{n+1}V_n(z))I[T_G > n]\right] \\
&\quad + E_x^{\pi^n}\left[\sum_{t=0}^{T_G-1} C(X_t, A_t)I[T_G \leq n]\right] \\
&\quad + E_x^{\pi^n}[(V_{n-T_G}(z) - V_n(z))I[T_G \leq n]] - M \\
&\geq E_x^{\pi^n}\left[\sum_{t=0}^{n}(C(X_t, A_t) - b)I[T_G > n]\right] + E_x^{\pi^n}\left[\sum_{t=0}^{T_G-1} C(X_t, A_t)I[T_G \leq n]\right] \\
&\quad - E_x^{\pi^n}[bT_G I[T_G \leq n]] - M \\
&= E_x^{\pi^n}\left[\sum_{t=0}^{n}(C(X_t, A_t) - b)I[T_G > n]\right] \\
&\quad + E_x^{\pi^n}\left[\sum_{t=0}^{T_G-1}(C(X_t, A_t) - b)I[T_G \leq n]\right] - M.
\end{aligned}$$

Now observe that $X_t \notin G$ for $1 \leq t < T_G$, which yields $C(X_t, A_t) - b > 1$ (see (6.5) and (6.6)), so from the last displayed relation

$$\begin{aligned}
V_n(x) - V_n(z) &\geq E_x^{\pi^n}[(C(X_0, A_0) - b + n)I[T_G > n]] \\
&\quad + E_x^{\pi^n}[(C(X_0, A_0) - b + T_G - 1)I[T_G \leq n]] - M \\
&\geq -b + E_x^{\pi^n}[T_G \wedge n - 1] - M \quad \text{(since } C(\cdot,\cdot) \geq 0\text{)} \\
&\geq -b - M - 1,
\end{aligned} \tag{6.8}$$

and then $R_n(x) = V_n(x) - V_n(z) \geq -N$ for all state x and $n \in \mathbb{N}$, where $N := M + b + 1$. To conclude set $B(y) := E_y^{f^*}[\sum_{t=0}^{T-1} C(X_t, A_t)]$ and note that (6.1) with $x = z$ yields that $R_n(y) \leq B(y)$ for all state y; by (2.11) with f^* instead of f, $B(\cdot)$ is finite. □

The arguments used above will be used to prove the following lemma, which plays an important role in the proof of the second part of Theorem 6.1.

LEMMA 6.2. *Let $\pi^k \in \mathbb{M}$ be as in* (3.1)*, and suppose that for some sequence $\{n(r)\}$ increasing to infinity, $\pi^{n(r)} \to \pi \in \mathbb{M}$ as $r \to \infty$. Then, for all $x \in S$,*

$$P_x^{\pi}[T_G < \infty] = 1.$$

Proof. Recall that G is a finite set. A simple induction argument combining Assumption 2.1 with Proposition 18 in [21, p. 232] shows that for all $x \in S$, $n \in \mathbb{N}$, and $y \in G$, the mapping

(6.9)

$$\pi \mapsto P_x^{\pi}[X_s \notin G, 1 \leq s < n, X_n = y] = P_x^{\pi}[X_n = y, T_G = n], \quad \pi \in \mathbb{M}, \quad \text{is continuous,}$$

and since $P_x[T_G = n] = \sum_{y \in G} P_x^{\pi}[X_n = y, T_G = n]$,

$$\pi \mapsto P_x^{\pi}[T_G = n], \quad \pi \in \mathbb{M}, \quad \text{is also continuous.} \tag{6.10}$$

Now let $x \in S$ be arbitrary but fixed, and let $B(x)$ be the upper bound for $\{R_n(x)\}$ given in Theorem 6.1(i). Using (6.8) it follows that

$$M + b + 1 + B(x) \geq E_x^{\pi^n}[T_G \wedge n], \quad n \in \mathbb{N}.$$

Thus, if $q_n(\cdot)$ is the distribution of $T_G \wedge n$ with respect to $P_x^{\pi^n}$, the above relation and Markov's inequality together imply that

$$\sum_{k \geq K} q_n(k) \leq \frac{M + 1 + b + B(x)}{K}, \quad K > 0,$$

so that $\{q_n(\cdot)\}$ is a tight family of probability distributions on the subsets of $\mathbb{N} \setminus \{0\}$. Now suppose that $\pi^{n(r)} \to \pi$ as $r \to \infty$. In this case,

$$\begin{aligned} \lim_{r \to \infty} q_{n(r)}(k) &= \lim_{r \to \infty} P_x^{\pi^{n(r)}}[T_G \wedge n(r) = k] \\ &= \lim_{r \to \infty} P_x^{\pi^{n(r)}}[T_G = k] \quad (T_G \wedge n(r) = T_G \quad \text{when} \quad n(r) > k) \\ &= P_x^{\pi}[T_G = k], \end{aligned}$$

where the third equality follows from (6.10). Since $\{q_{n(r)}\}$ is a tight family, this convergence implies that $1 = \sum_k P_x^{\pi}[T_G = k] = P_x^{\pi}[T_G < \infty]$. □

Using this lemma the proof of Theorem 6.1 can be completed as follows.

Proof of Theorem 6.1(ii). Let n be a positive integer, and select π^n as in (3.1). For each $x \in S$ and $0 < k < n$,

$$\begin{aligned} V_n(x) &= E_x^{\pi^n}\left[\sum_{t=0}^{T_G \wedge k-1} C(X_t, A_t) + \sum_{t=T_G \wedge k}^{n} C(X_t, A_t)\right] \\ &= E_x^{\pi^n}\left[\sum_{t=0}^{T_G \wedge k-1} C(X_t, A_t) + V_{n-T_G \wedge k}(X_{T_G \wedge k})\right], \end{aligned} \tag{6.11}$$

where the last equality follows from Bellman's optimality principle. Now define a new policy $\pi^{n;k}$ as follows:

(a) $\pi_0^{n;k}(\cdot|x_0) = \pi_0^n(\cdot|x_0), \quad x_0 \in S.$

Suppose now that t is a positive integer, and pick $h_t = (x_0, a_0, \ldots, x_{t-1}, a_{t-1}, x_t) \in H_t$.

(b) If $x_s \notin G$ for all $s \in \{1, 2, \ldots, t\}$,

$$\pi_t^{n;k}(\cdot|h_t) = \begin{cases} \pi_t^n(\cdot|h_t) & \text{if } t < k, \\ \pi_{t-k}^{n-1-k}(\cdot|x_k, a_k, \ldots, x_t) & \text{if } t \geq k. \end{cases}$$

(c) Suppose that $x_s \notin G$ for $1 \leq s < r \leq t$ and $x_r \in G$. In this case,

$$\pi_t^{n;k}(\cdot|h_t) = \pi_{t-(r \wedge k)}^{n-1-(r \wedge k)}(\cdot|x_{r \wedge k}, a_{r \wedge k}, \ldots, x_t).$$

In words, a controller using $\pi^{n;k}$ operates as follows: the controller starts choosing actions according to π^n (see (a)) and keeps on using π^n until a state in G is reached or time gets value k, whatever occurs first. Then, at time $T_G \wedge k = s$, the controller switches to policy π^{n-1-s} as if the process had started again. According to this interpretation,

$$E_x^{\pi^{n;k}}\left[\sum_{t=0}^{T_G \wedge k-1} C(X_t, A_t)\right] = E_x^{\pi^n}\left[\sum_{t=0}^{T_G \wedge k-1} C(X_t, A_t)\right]$$

and

$$E_x^{\pi^{n;k}}\left[\sum_{t=T_G \wedge k}^{n-1} C(X_t, A_t)\right] = E_x^{\pi^n}[V_{n-1-T_G \wedge k}(X_{T_G \wedge k})].$$

Combining (3.1) with these equalities it follows that

$$V_{n-1}(x) \le E_x^{\pi^{n;k}}\left[\sum_{t=0}^{T_G\wedge k-1} C(X_t, A_t) + \sum_{T_G\wedge k}^{n-1} C(X_t, A_t)\right]$$
$$= E_x^{\pi^n}\left[\sum_{t=0}^{T_G\wedge k-1} C(X_t, A_t) + V_{n-1-T_G\wedge k}(X_{T_G\wedge k})\right],$$

which together with (6.11) and Definition 3.2(ii) yields

$$\begin{aligned} g_n(x) &\ge E_x^{\pi^n}[g_{n-T_G\wedge k}(X_{T_G\wedge k})] \\ &\ge E_x^{\pi^n}[g_{n-T_G}(X_{T_G})I[T_G \le k]] \quad (\text{since } g_t(\cdot) \ge 0) \\ &= \sum_{s=1}^{k}\sum_{y\in G} P_x^{\pi^n}[T_G = s, X_s = y]g_{n-s}(y). \end{aligned} \tag{6.12}$$

Now pick a subsequence $\{n(r)\}$ such that $\lim_{r\to\infty} g_{n(r)}(x) = L(x)$. After taking a subsequence, if necessary, there is no loss of generality in assuming that $\pi^{n(r)} \to \pi \in \mathbb{M}$ as $r \to \infty$, since $\mathbb{M}$ is compact metric. Replacing n with $n(r)$ in (6.12) and taking limit as $r \to \infty$ in the resulting inequality, it follows, via (6.9), that

$$\begin{aligned} L(x) &= \lim_{r\to\infty} g_{n(r)}(x) \\ &\ge \liminf_{r\to\infty} \sum_{s=1}^{k}\sum_{y\in G} P_x^{\pi^{n(r)}}[T_G = s, X_s = y]g_{n(r)-s}(y) \\ &\ge \sum_{s=1}^{k}\sum_{y\in G} \liminf_{r\to\infty} P_x^{\pi^{n(r)}}[T_G = s, X_s = y]g_{n(r)-s}(y) \\ &= \sum_{s=1}^{k}\sum_{y\in G} P_x^{\pi}[T_G = s, X_s = y] \liminf_{r\to\infty} g_{n(r)-s}(y) \\ &\ge \sum_{s=1}^{k}\sum_{y\in G} P_x^{\pi}[T_G = s, X_s = y]L(y) \\ &= E_x^{\pi}[L(X_{T_G})I[T_G \le k]], \end{aligned}$$

where (5.8) was used to obtain the third inequality, and letting k increase to ∞, this implies that

$$L(x) \ge E_x^{\pi}[L(X_{T_G})I[T_G < \infty]].$$

Finally, let $z^* \in G$ be such that $L(z^*) = \min\{L(y)|y \in G\}$; such a point exists, since G is finite. In this case the last displayed relation yields that

$$L(x) \ge E_x^{\pi}[L(z^*)I[T_G < \infty]] = L(z^*)P_x^{\pi}[T_G < \infty] = L(z^*),$$

where Lemma 6.2 was used to obtain the second equality. This completes the proof of Theorem 6.1, since $x \in S$ was arbitrary. □

7. Preliminaries: Fourth part. This is the last step before the proof of Theorem 3.1, and the main objective is to establish the following result.

THEOREM 7.1. (i) *Let z^* be as in Theorem* 6.1(ii), *and suppose that $\{n(r)\}$ is a sequence of positive integers converging to ∞ satisfying*

$$\lim_{r\to\infty} g_{n(r)}(z^*) = L(z^*). \tag{7.1}$$

Then

$$\lim_{r\to\infty} g_{n(r)-1}(z^*) = L(z^*). \tag{7.2}$$

(ii) *There exists a sequence $\{R_k^* : S \to \mathbb{R} \mid k \in \mathbb{N}\}$ and a sequence of stationary policies $\{f_k^*\} \subset \mathbb{F}$ satisfying the following: for some $N' \in (0, \infty)$ and $B' : S \to [0, \infty)$,*

(a) $R_k^* \in \Pi_{x\in S}[-N', B'(x)]$ *for all* $k \in \mathbb{N}$.

(b) $L(z^*) + R_k^*(x) \geq C(x, f_k^*(x)) + \sum_y p_{xy}(f_k^*(x))R_{k+1}^*(y)$, $x \in S$, $k \in \mathbb{N}$.

Proof. For each positive integer n select $f_n \in \mathbb{F}$ such that

$$V_n(x) = C(x, f_n(x)) + \sum_y p_{xy}(f_n(x))V_{n-1}(y), \quad x \in S. \tag{7.3}$$

(i) By (3.1), $V_{n-1}(x) \leq C(x, f_n(x)) + \sum_y p_{xy}(f_n(x))V_{n-2}(y)$, so

$$g_n(x) = V_n(x) - V_{n-1}(x) \geq \sum_y p_{xy}(f_n(x))(V_{n-1}(y) - V_{n-2}(y)) = \sum_y p_{xy}(f_n(x))g_{n-1}(y). \tag{7.4}$$

Now let $\{n(r)\}$ be as in (7.1), let L' be an *arbitrary* limit point of $\{g_{n(r)-1}(z^*)\}$, and note that (7.2) will be proven if it can be shown that

$$L' = L(z^*). \tag{7.5}$$

With this in mind, note that by taking a subsequence if necessary, it can be assumed that

$$g_{n(r)-1}(z^*) \to L' \quad \text{and} \quad f_{n(r)} \to f \in \mathbb{F} \text{ as } r \to \infty; \tag{7.6}$$

recall that $\mathbb{F}$ is compact metric. Next replace n by $n(r)$ and set $x = z^*$ in (7.4). Taking limit inferior as $r \to \infty$ in the resulting inequality it follows, via (7.1), Assumption 2.1, and Fatou's lemma, that

$$\begin{aligned} L(z^*) = \liminf_{r\to\infty} g_{n(r)}(z^*) &\geq \liminf_{r\to\infty} \sum_y p_{z^*y}(f_{n(r)}(z^*))g_{n(r)-1}(y) \\ &\geq \sum_y p_{z^*y}(f(z^*)) \liminf_{r\to\infty} g_{n(r)-1}(y) \\ &\geq \sum_y p_{z^*y}(f(z^*))L(y) \quad \text{(see (5.8))} \\ &\geq L(z^*), \end{aligned} \tag{7.7}$$

where the last inequality is due to Theorem 6.1(ii). Therefore, all inequalities in (7.7) are equalities, and then

$$\sum_y p_{z^*y}(f(z^*)) \liminf_{r\to\infty} g_{n(r)-1}(y) = \sum_y p_{z^*y}(f(z^*))L(y).$$

Combining this with (5.8) it follows that

$$\liminf_{r\to\infty} g_{n(r)-1}(y) = L(y) \quad \text{if } p_{z^*y}(f(z^*)) > 0,$$

but, by Assumption 2.4, this implies that $\liminf_{r\to\infty} g_{n(r)-1}(z^*) = L(z^*)$, which combined with the first convergence in (7.6) yields (7.5), and as already mentioned, this completes the proof of part (i).

(ii) Pick a sequence $\{n(r)\}$ such that $g_{n(r)}(z^*) \to L(z^*)$ as $r \to \infty$. By repeated application of part (i),

$$\lim_{r\to\infty} g_{n(r)-s}(z^*) = L(z^*) \quad \text{for all } s \in \mathbb{N}. \tag{7.8}$$

Replacing n with $n(r) - s$ in (7.3), simple rearrangements using Definition 3.2(ii) yield that

$$g_{n(r)-s}(z^*) + \tilde{R}_{n(r)-s}(x) = C(x, f_{n(r)-s}(x)) + \sum_y p_{xy}(f_{n(r)-s})(x)\tilde{R}_{n(r)-s-1}(x), \tag{7.9}$$
$$x \in S, \quad n(r) > s,$$

where, $\tilde{R}_{n(r)-s}(x) := V_{n(r)-s}(x) - V_{n(r)-s}(z^*) = R_{n(r)-s}(x) + [V_{n(r)-s}(z) - V_{n(r)-s}(z^*)]$. By Lemma 6.1, $\max\{|V_{n(r)-s}(z) - V_{n(r)-s}(z^*)| \mid r, s \in \mathbb{N},\ n(r) \geq s\} =: K < \infty$, and combining this with Theorem 6.1(i) it follows that

$$\tilde{R}_{n(r)-s} \in \mathbb{D} := \Pi_{x\in S}[-N - K, B(x) + K]. \tag{7.10}$$

Now set $\tilde{R}_t \equiv 0$ and $f_t \equiv f_1$ for $t < 0$, and note that

$$\rho_{n(r)} := (\tilde{R}_{n(r)-s} | s \in \mathbb{N}) \in \mathbb{D}^\infty =: \mathbb{E},$$
$$\phi_{n(r)} := (f_{n(r)-s} | s \in \mathbb{N}) \in \mathbb{F}^\infty = \mathbb{M}.$$

Since $\mathbb{E}$ and $\mathbb{M}$ are compact metric, taking a subsequence if necessary, it can be assumed that in addition to (7.8), as $r \to \infty$, $\rho_{n(r)} \to \rho^* := (R_s^* | s \in \mathbb{N}) \in \mathbb{E}$ and $\phi_{n(r)} \to \phi^* := (f_s^* | s \in \mathbb{N}) \in \mathbb{M}$. These convergences are equivalent to the following: for each $s \in \mathbb{N}$

$$\lim_{r\to\infty} \tilde{R}_{n(r)-s}(x) = R_s^*(x) \in [-N - K, B(x) + K], \quad x \in S. \tag{7.11}$$

$$\lim_{r\to\infty} f_{n(r)-s}(x) = f_s^*(x), \quad x \in S. \tag{7.12}$$

Setting $N' := N + K$ and $B'(x) = B(x) + K$, (7.11) shows that the sequence $\{R_s^*\}$ satisfies part (a). To conclude, take limit as $r \to \infty$ in both sides of (7.9). In this situation, using (7.8), (7.11), (7.12), and Assumption 2.1, it follows that for all $s \in \mathbb{N}$ and $x \in S$

$$\begin{aligned} L(z^*) + R_s^*(x) &= C(x, f_s^*(x)) + \lim_{r\to\infty} \sum_y p_{xy}(f_{n(r)-s}^*(x))\tilde{R}_{n(r)-s-1}(y) \\ &\geq C(x, f_s^*(x)) + \sum_y \liminf_{r\to\infty} p_{xy}(f_{n(r)-s}^*(x))\tilde{R}_{n(r)-s-1}(y) \\ &= C(x, f_s^*(x)) + \sum_y p_{xy}(f_s^*(x))R_{s+1}^*(y), \end{aligned}$$

where Fatou's lemma was used to obtain the inequality. Then $\{R_s^*\}$ and $\{f_s^*\}$ satisfy condition (b), and the proof is complete. □

8. Proof of the main result. The preliminaries in the previous sections will be now used to establish Theorem 3.1.

Proof of Theorem 3.1. (i) Let $\{R_k^* : S \to \mathbb{R}\}$ and $\{f_k^*\} \subset \mathbb{F}$ be as in Theorem 7.1. Set $\pi^* := \{f_s^*\} \in \mathbb{M}$. An induction argument using part (ii(b)) of Theorem 7.1 yields that for all $x \in S$ and $n \in \mathbb{N}$,

$$L(z^*) + \frac{1}{n+1}R_0^*(x) \geq \frac{1}{n+1}E_x^{\pi^*}\left[\sum_{t=0}^{n} C(X_t, A_t)\right] + \frac{1}{n+1}E_x^{\pi^*}[R_{n+1}^*(X_{n+1})]. \tag{8.1}$$

On the other hand, note that $R^*_{n+1}(\cdot) \geq -N' \in (-\infty, 0]$, so

$$\liminf_{n\to\infty} \frac{E_x^{\pi^*}[R^*_{n+1}(X_{n+1})]}{(n+1)} \geq 0.$$

Therefore, taking limit superior as $n \to \infty$ in both sides of (8.1), it follows that

$$L(z^*) \geq \limsup_{n\to\infty} \frac{1}{n+1} E_x^{\pi^*}\left[\sum_{t=0}^{n} C(X_t, A_t)\right] = J(x, \pi^*),$$

and then

$$L(z^*) \geq g,$$

since g is the optimal average cost; see Lemma 2.1(i). Combining this inequality with Theorem 5.1 and Theorem 6.1(ii) it follows that

$$g \leq L(z^*) \leq L(x) \leq \frac{U(x) - L(x)}{E_x^{f^*}[T_x]} + L(x) \leq g, \quad x \in S,$$

which immediately yields that

$$L(x) = g \quad \text{and} \quad \frac{U(x) - L(x)}{E_x^{f^*}[T_x]} = 0, \quad x \in S. \tag{8.2}$$

To conclude, recall that policy f^* is obtained as in Lemma 2.1(iv) and that, as already noted in the proof of Theorem 5.1, the corresponding transition matrix P_{f^*} has an invariant distribution. Thus, $E_x^{f^*}[T_x]$ is finite for all state x (see Remark 2.2(i)), and it follows that (8.2) is equivalent to

$$U(x) = L(x) = g, \quad x \in S,$$

i.e., $\lim_{n\to\infty} g_n(x) = g$ for all state x; see Definition 3.2(ii).

(ii) By Theorem 6.1(i),

$$R_n \in \Pi_{x\in S}[-N, B(x)] =: \mathbb{K}, \quad n \in \mathbb{N}, \tag{8.3}$$

for some positive constant N and a certain function $B : S \to [0, \infty)$. Since $\mathbb{K}$ is a compact metric space, it is sufficient to show that any limit point—say, $Q \in \mathbb{K}$—of $\{R_n\}$ coincides with the function $h(\cdot)$ in Lemma 2.1. Thus, pick a sequence $\{n(r)\}$ increasing to ∞ such that

$$\lim_{r\to\infty} R_{n(r)}(x) = Q(x) \in [-N, B(x)], \quad x \in S. \tag{8.4}$$

From Definition 3.2 it follows that $R_n(x) - R_{n-1}(x) = g_n(x) - g_n(z)$ and then $R_n(x) - R_{n-1}(x) \to 0$ as $n \to \infty$, by part (i). Therefore, (8.4) implies that

$$\lim_{r\to\infty} R_{n(r)-1}(x) = Q(x) \in [-N, B(x)], \quad x \in S. \tag{8.5}$$

Now pick a policy $f_{n(r)} \in \mathbb{F}$ such that

$$V_{n(r)}(x) = C(x, f_{n(r)}(x)) + \sum_y p_{xy}(f_{n(r)}(x)) V_{n(r)-1}(y)$$

for all state x, which after simple rearrangements using Definition 3.2 can be written as

$$g_{n(r)}(z) + R_{n(r)}(x) = C(x, f_{n(r)}(x)) + \sum_y p_{xy}(f_{n(r)}(x))R_{n(r)-1}(y), \quad x \in S. \tag{8.6}$$

Recalling that $\mathbb{F}$ is a compact metric, after taking a subsequence if necessary, it can be assumed that in addition to (8.4) and (8.5), $f_{n(r)} \to f \in \mathbb{F}$ as $r \to \infty$. In this case, letting r increase to ∞ in both sides of (8.6), it follows, via part (i), Assumption 2.1, (8.4), and (8.5), that

$$\begin{aligned} g + Q(x) &= \lim_{r\to\infty} \{g_{n(r)}(z) + R_{n(r)}(x)\} \\ &= \lim_{r\to\infty} \left\{ C(x, f_{n(r)}(x)) + \sum_y p_{xy}(f_{n(r)}(x))R_{n(r)-1}(y) \right\} \\ &= C(x, f(x)) + \lim_{r\to\infty} \sum_y p_{xy}(f_{n(r)}(x))R_{n(r)-1}(y) \\ &\geq C(x, f(x)) + \sum_y \liminf_{r\to\infty} p_{xy}(f_{n(r)}(x))R_{n(r)-1}(y) \\ &= C(x, f(x)) + \sum_y p_{xy}(f(x))Q(y), \end{aligned} \tag{8.7}$$

where Fatou's lemma was used to obtain the inequality; this is possible, since $R_n(\cdot) \geq -N$. Next observe that

$$Q(z) = 0 \quad \text{and} \quad Q(\cdot) \geq -N \in (-\infty, 0]; \tag{8.8}$$

see (8.4) and recall that $R_n(z) = 0$ for all n by Definition 3.2. Note now that (8.7) and (8.8) allow to use Lemma 4.1(iv) with W replaced by Q to obtain

$$g + Q(x) = \min_{a\in A} \left[C(x, a) + \sum_y p_{xy}(a)Q(y) \right], \quad x \in S;$$

i.e., Q satisfies the ACOE. To conclude observe that the assumptions in Theorem 4.1 are satisfied with $h_1 := Q$ and $h_2 = h$; see (8.8) and parts (ii) and (iii) of Lemma 2.1. Therefore, Theorem 4.1 implies that $Q = h$, and as already noted, this shows that $\{R_n(\cdot)\}$ converges pointwise to $h(\cdot)$.

(iii) Since $R_n(\cdot)$ is bounded below, by Theorem 6.1(i), Assumption 2.1 implies that for each $x \in S$ the mapping $a \mapsto C(x, a) + \sum_y p_{xy}(a)R_n(y)$, $a \in A$, is lower semicontinuous and then has a minimizer $f_n(x)$. In this case,

$$\begin{aligned} C(x, f_n(x)) + \sum_y p_{xy}(f_n(x))R_n(y) &= \min_{a\in A} \left[C(x, a) + \sum_y p_{xy}(a)R_n(y) \right] \\ &= \min_{a\in A} \left[C(x, a) + \sum_y p_{xy}(a)V_n(y) \right] - V_n(z) \\ &= V_{n+1}(x) - V_n(z), \end{aligned}$$

and then (see Definition 3.2)

$$C(x, f_n(x)) + \sum_y p_{xy}(f_n(x))R_n(y) = R_{n+1}(x) + g_{n+1}(z). \tag{8.9}$$

To conclude let $f \in \mathbb{F}$ be a limit point of $\{f_n\}$, and select a sequence $\{n(r)\}$ increasing to ∞ such that for all $x \in S$, $f_{n(r)}(x) \to f(x)$ as $r \to \infty$. In this case, replacing n by $n(r)$ in (8.9) and taking limit as $r \to \infty$ in both sides of the resulting equality, it follows, using Assumption 2.1, Fatou's lemma, and parts (i) and (ii), that for all $x \in S$

$$\begin{aligned} g + h(x) &= \lim_{r\to\infty} [g_{n(r)+1}(z) + R_{n(r)+1}(x)] \\ &= \lim_{r\to\infty} \left[C(x, f_{n(r)}(x)) + \sum_y p_{xy}(f_{n(r)}(x)) R_{n(r)}(y) \right] \\ &= C(x, f(x)) + \lim_{r\to\infty} \sum_y p_{xy}(f_{n(r)}(x)) R_{n(r)}(y) \\ &\geq C(x, f(x)) + \sum_y \liminf_{r\to\infty} p_{xy}(f_{n(r)}(x)) R_{n(r)}(y) \\ &= C(x, f(x)) + \sum_y p_{xy}(f(x)) h(x), \end{aligned}$$

and from the ACOE (see (2.4)), it follows that $f(x)$ is a minimizer of the mapping $a \mapsto C(x, a) + \sum_y p_{xy}(a)h(y)$, $a \in A$, so that $f \in \mathbb{F}$ is AO, by Lemma 2.1(iv). □

9. An example. This section contains an example illustrating the application of Theorem 3.1 to a single-server queueing system.

Example 9.1. Let A be a finite set endowed with the discrete topology and suppose that $\{U_{na}, D_{na} \mid a \in A, n \in \mathbb{N}\}$ is a collection of independent $\mathbb{N}$-valued random variables satisfying (i)–(iii) below.

(i) For each $a \in A$, the random variables $\{U_{na} \mid n \in \mathbb{N}\}$ are identically distributed with common distribution $\{q_a(\cdot)\}$: $P[U_{na} = k] = q_a(k)$, $n, k \in \mathbb{N}$, where

$$q_a(0) \in (0, 1). \tag{9.1}$$

(ii) For each $a \in A$ and $n \in \mathbb{N}$,

$$P[D_{na} = 1] = 1 - P[D_{na} = 0] = \delta_a \in (0, 1). \tag{9.2}$$

These random variables will be interpreted as the arriving and service streams in a single-server queueing model with state space $S = \mathbb{N}$ and action space A. For each time $n \in \mathbb{N}$, let $X_n = x \in S$ be the number of customers waiting for service at the beginning of the period $[n, n+1)$. If action $A_n = a$ is applied, then the number of customers arriving between times n and $n+1$ is U_{na}, whereas if $X_n > 0$, the server can provide a complete service in that period with probability δ_a; $D_{na} (= 0, 1)$ is interpreted as the number of customers leaving the system after service completion in $[n, n+1)$. Formally, this can be summarized in the following evolution equation:

$$X_{n+1} = \begin{cases} X_n + U_{na} - D_{na} & \text{if } X_n > 0 \text{ and } A_n = a, \\ U_{na} & \text{if } X_n = 0 \text{ and } A_n = a. \end{cases} \tag{9.3}$$

Note that this equation immediately determines the transition law $p_{xy}(a) = P[X_{n+1} = y | X_n = x, A_n = a]$.

(iii) For some $a^* \in A$, $E[U_{na^*}^2] =: \lambda_{a^*}^{(2)} < \infty$ and $E[U_{na^*}] =: \lambda_{a^*} < \delta_{a^*}$.

Finally, define the cost function by $C(x, a) := x$, $(x, a) \in S \times A$.

PROPOSITION 9.1. *Assumptions* 2.1–2.4 *are satisfied in Example* 9.1. *Therefore, the conclusions in Theorem* 3.1 *occur.*

Proof. (1) Since A is finite and $C(x,a) = x$, Assumption 2.1 clearly holds.

(2) Let f be an arbitrary stationary policy, and note that (9.1)–(9.3) together imply that for all $x, y \in S$ and $n \in \mathbb{N}$, $P_y^f[X_{n+1} \geq x+1 | X_n = x] \geq P[U_{n\,f(x)} > 0, D_{n\,f(x)} = 0] = (1-q_{f(x)}(0))(1-\delta_{f(x)}) > 0$, and that if $x > 0$, $P_x^f[X_{n+1} = x-1 | X_n = x] = q_{f(x)}(0)\delta_{f(x)} > 0$. Using these inequalities, a simple induction argument yields that

$$P_y^f[X_n \geq y+n] > 0, \quad y \in S,\ n \in \mathbb{N}, \tag{9.4}$$

and

$$P_y^f[X_n = y-n] > 0, \quad y, n \in S,\ y > n. \tag{9.5}$$

Assumption 2.2 follows immediately from these facts. Indeed, let $x, y \in S$. By (9.4), there exists a positive integer n such that $P_x^f[X_n = w] > 0$ for some $w > x \vee y$, and then (9.5) yields, for $m = w - y$, that $P_w^f[X_m = y] > 0$. Therefore, $P_x^f[X_{n+m} = y] \geq P_x^f[X_n = w] P_w^f[X_m = y] > 0$, showing that Assumption 2.2 holds, since $f \in \mathbb{F}$ was arbitrary.

(3) Note that part (i) of Assumption 2.3 clearly holds, since $C(x,a) = x$ for all $(x,a) \in S \times A$. To verify part (ii) define real constants l_i, $i = 0, 1, 2$, by

$$l_2 := \frac{1}{\delta_{a^*} - \lambda_{a^*}}, \quad l_1 := \frac{E[(U_{n,a^*} - D_{n\,a^*})^2] - (\delta_{a^*} - \lambda_{a^*})}{\delta_{a^*} - \lambda_{a^*}},$$

and

$$l_0 := \frac{1 + l_1\lambda_{a^*} + l_2\lambda_{a^*}^{(2)}}{q_{a^*}(0)}.$$

Now set $l(x) := l_0 + l_1 x + l_2 x^2$, $x \in S$, and define the stationary policy f by $f(x) := a^*$, $x \in S$. In this case, straightforward calculations using (9.3) show that

$$1 + C(x, f(x)) + \sum_{y \neq 0} p_{x\,y}(f(x)) l(y) \leq l(x), \quad x \in S,$$

so $l(\cdot)$ is a Lyapunov function of the Markov chain induced by f, and this yields that $J(\cdot, f)$ is finite [16, 28]; alternatively, the finiteness of $J(\cdot, f)$ can be obtained from Proposition 4 in [23]. This completes the verification of Assumption 2.3.

(4) Note that $p_{x\,x}(a) = P[X_{n+1} = x | X_n = x, A_n = a] \geq P[U_{n\,a} = 0] P[D_{n\,a} = 0] = q_a(0)(1 - \delta_a) > 0$ by (9.1) and (9.2), so Assumption 2.4 occurs. □

In the above example notice that, if $E[U_{n\,a}] > \delta_a$ for some $a \in A$, then it is not difficult to see that the policy $f_a \in \mathbb{F}$ given by $f_a(\cdot) \equiv a$ induces a transient Markov chain.

10. Conclusion. The value iteration procedure has been studied in the class of communicating MDPs characterized by Assumptions 2.1–2.4, and it was shown in Theorem 3.1 that, within this framework, the differential costs and relative value functions produced by the VI scheme converge to the (unique) solution of the ACOE given in Lemma 2.1. The approach used in this work—following the ideas in [7, 10]—is not based on an analysis of the differences $V_n(\cdot) - (n+1)g$ but relies on a direct study of the differential costs; see Theorems 5.1, 6.1(ii), and 7.1. This allows one to avoid other (somewhat restrictive) conditions imposed in other works, such as Assumption 5 in [24] and the boundedness of the first error function [17].

Acknowledgment. The author is grateful to the unknown reviewers for their careful reading of the original manuscript, constructive criticism and helpful suggestions.

CAUSAL FEEDBACK OPTIMAL CONTROL FOR VOLTERRA INTEGRAL EQUATIONS*

A. J. PRITCHARD† AND YUNCHENG YOU‡

Abstract. The optimal control problem for Volterra integral equations with respect to quadratic criteria is studied by a projection causality approach. The work features a synthesis result where the optimal control is implemented via a linear causal feedback in which the feedback operator is determined by solving an independent Fredholm integral operator equation.

Key words. Volterra integral equations, linear quadratic control, causal state feedback, Fredholm integral operator equation

AMS subject classifications. 93C22, 45D05

1. Introduction.

The state-space approach in modern control theory provides a mathematical framework in which many control problems for ordinary differential equations, partial differential equations, and functional differential equations can be formulated and treated in a unified manner via abstract operators on Banach spaces and semigroup theory; cf. [2], [9], [3], [12], [14], [15]. On the other hand, engineering control designs often feature direct input-output relations in either time or frequency domain. Some difficulties in this approach arise in handling control problems governed by partial differential equations, due to the fact that functions of several complex variables are involved. But it also has merit since the transfer functions are theoretically independent of whether the outputs are related to the inputs via the solution of an initial value problem. A very general class of input-output relations, which includes all initial value problems for linear evolutionary equations in Banach spaces as a proper subset, is described by Volterra integral equations. These are what we study in this paper.

We shall consider quadratic optimal control problems for general linear Volterra equations in Hilbert spaces. The open-loop control is easily obtained, but since we do not assume that there exists a realization in terms of a differential equation on the Hilbert space, we cannot apply standard theory to obtain a state feedback via the solution of a Riccati equation. Thus the principal objective of the paper will be to derive a closed-loop synthesis which provides a feedback optimal control in a causal sense. We establish the results for the single-variable case, but they are easily generalized to the bivariate and multivariate cases, which have some direct applications to multidimensional signal processing and data analysis; cf. [8].

To introduce the model equation and optimal control problem, consider the following input-output relation given by a Volterra integral operator:

$$y(t) = f(t) + \int_0^t K(t,\tau)u(\tau)\,d\tau, \qquad 0 \le t \le T, \tag{1}$$

where $T > 0$ is finite and fixed. We let $\Delta = \{(t,\tau) \in [0,T]^2;\ 0 \le \tau \le t \le T\}$, where $[0,T]^2 = [0,T] \times [0,T]$.

Let Y and U be real Hilbert spaces. We assume that

$$f \in C([0,T]; Y), \tag{A1}$$

$$K \in C(\Delta; \mathcal{L}(U;Y)), \tag{A2}$$

where the continuity is in the strong sense; i.e., for each $u \in U$, the function $K(t, \tau)u : \Delta \to Y$ is strongly continuous. Thus by the Banach–Steinhaus theorem, one has $\sup_{(t,\tau)\in\Delta} \|K(t, \tau)\|_{\mathcal{L}(U;Y)} < \infty$. For convenience, we make a convention that $K(t, \tau) = 0$ whenever $(t, \tau) \in [0, T]^2 \backslash \Delta$.

We denote $\mathcal{Y} = L^2(0, T; Y)$ and $\mathcal{U} = L^2(0, T; U)$. The quadratic cost functional is

$$J(u, f) = \langle Gy(T), y(T)\rangle + \int_0^T [\langle Q(t)y(t), y(t)\rangle + \langle R(t)u(t), u(t)\rangle]\, dt, \tag{2}$$

where the inner products $\langle \cdot, \cdot \rangle$ are related to the spaces Y or U according to the context. We assume furthermore that

(A3)

$$G \in \mathcal{L}(Y),\ Q(\cdot) \in C(0, T; \mathcal{L}(Y)),\ R(\cdot) \in C(0, T; \mathcal{L}(U)), \quad \text{where } G, Q(t), R(t)$$

are self-adjoint and there exists a constant $\delta > 0$ such that $R(t) \geq \delta I_U, t \in [0, T]$.

The problem is to find an optimal control $u^* \in \mathcal{U}$ which minimizes $J(u, f)$ over $\mathcal{U}$ for any given f satisfying (A1). We shall refer to this optimal control problem as (OCP).

Before getting into the mathematical theory, let us remark that more general controlled linear Volterra integral equations can be reduced to the form (1). For instance consider the integral equation

$$y(t) = f(t) + \int_0^t \Lambda(t, \tau)y(\tau)\, d\tau + \int_0^t N(t, \tau)u(\tau)\, d\tau, \qquad 0 \leq t \leq T, \tag{3}$$

with appropriate assumptions similar to those above. Then it is easy to prove the following lemma, which reduces (3) to (1).

LEMMA 1.1. *Define an operator* $\mathcal{T} \in \mathcal{L}(C([0, T]; Y))$ *by*

$$(\mathcal{T}y)(t) = \int_0^t \Lambda(t, \tau)y(\tau)\, d\tau, \qquad t \in [0, T],$$

where $\Lambda \in C(\Delta; \mathcal{L}(Y))$. *Then the following statements hold.*

(i) $\mathcal{T}$ *is a quasi-nilpotent operator so that* $\sigma(\mathcal{T}) = \{0\}$.

(ii) *There exists a unique solution* y *of* (3), *which can be expressed by*

$$y(t) = g(t) + \int_0^t K(t, \tau)u(\tau)\, d\tau, \qquad 0 \leq t \leq T, \tag{4}$$

where

$$g(t) = f(t) + \int_0^t R(t, \tau)f(\tau)\, d\tau, \qquad 0 \leq t \leq T,$$

$$K(t, \tau)u = N(t, \tau)u + \int_\tau^t R(t, s)N(s, \tau)u\, ds, \qquad (t, \tau) \in \Delta,$$

and the resolvent kernel $R(t, s)$ *is given by*

$$R(t, s) = \sum_{j=1}^{\infty} \Lambda_j(t, s) \tag{5}$$

with

$$\Lambda_1(t,s) = \Lambda(t,s), \quad \Lambda_{j+1}(t,s)y = \int_s^t \Lambda(t,\rho)\Lambda_j(\rho,s)y\,d\rho, \quad j = 1,2,\ldots.$$

Here the series in (5) *converges in the operator norm.*

As we mentioned earlier, the difficulty in this work lies in the determination of a feedback optimal control in the causal sense. Namely, the optimal control $u^*(t)$ at any time t should not involve future information of the corresponding trajectory $y^*(\cdot)$. But it would be naive to seek an optimal control whose real-time value depends only on the past information of the function $f(\cdot)$, since the whole input $f(t)$, $t \in [0,T]$, determines the optimality conditions.

2. Existence and open-loop result. We now define various linear operators on the function spaces $\mathcal{Y}$ and $\mathcal{U}$: $\Gamma \in \mathcal{L}(\mathcal{U},\mathcal{Y})$, $\Gamma_T \in \mathcal{L}(\mathcal{U},\mathcal{Y})$, $\mathcal{Q} \in \mathcal{L}(\mathcal{Y})$, $\mathcal{R} \in \mathcal{L}(\mathcal{U})$,

$$(\Gamma u)(t) = \int_0^t K(t,\tau)u(\tau)\,d\tau, \quad t \in [0,T], \quad u \in \mathcal{U};$$

$$\Gamma_T u = \int_0^T K(T,\tau)u(\tau)\,d\tau = (\Gamma u)(T), \qquad u \in \mathcal{U};$$

$$(\mathcal{Q}y)(t) = Q(t)y(t), \quad t \in [0,T], \quad y \in \mathcal{Y};$$

$$(\mathcal{R}u)(t) = R(t)u(t), \quad t \in [0,T], \quad u \in \mathcal{U}.$$

It is easy to see that $\mathcal{Q}$ and $\mathcal{R}$ are self-adjoint and the adjoints of Γ and Γ_T are given by

$$(\Gamma^* y)(t) = \int_t^T K^*(\tau,t)y(\tau)\,d\tau, \quad t \in [0,T], \quad y \in \mathcal{Y};$$

$$(\Gamma_T^* \varphi)(t) = K^*(T,t)\varphi, \quad t \in [0,T], \quad \varphi \in Y.$$

An important role will be played by an operator $\Phi \in \mathcal{L}(\mathcal{U})$, where

$$\Phi = \mathcal{R}I + \Gamma^*\mathcal{Q}\Gamma + \Gamma_T^* G T_T. \tag{6}$$

Our final assumption is that

$$\text{there exists } \epsilon > 0 \text{ such that } \quad \Phi \geq \epsilon I_{\mathcal{U}}. \tag{A4}$$

A preliminary characterization of the optimal control is given in the following theorem.

THEOREM 2.1. *Suppose that* (A1)–(A4) *hold. Then for any given* $f \in C([0,T],Y)$ *there exists a unique optimal control* u (*we drop the* * *notation where there is no confusion*) *for (OCP). The pair* $\{u,y\}$ *is optimal if and only if the following relation is satisfied:*

$$u(t) = -R(t)^{-1}\left[K^*(T,t)Gy(T) + \int_t^T K^*(s,t)Q(s)y(s)\,ds\right], \qquad t \in [0,T]. \tag{7}$$

Proof. Substituting the expressions

$$y = f + \Gamma u \quad \text{and} \quad y(T) = f(T) + \Gamma_T u \tag{8}$$

into the cost functional (2), we obtain

$$J(u,f) = \langle \Phi u, u\rangle_{\mathcal{U}} + 2\langle \Gamma^*\mathcal{Q}f + \Gamma_T^* G f(T), u\rangle_{\mathcal{U}} + \text{ const}(f).$$

By assumption (A4), $\Phi^{-1} \in \mathcal{L}(\mathcal{U})$; therefore, the unique optimal control function $u \in \mathcal{U}$ is given by

$$u = -\Phi^{-1}(\Gamma^* \mathcal{Q} f + \Gamma_T^* G f(T)) \tag{9}$$

or equivalently

$$\begin{aligned} \mathcal{R}u &= -[\Gamma^* \mathcal{Q}(\Gamma u + f) + \Gamma_T^* G(\Gamma_T u + f(T))] \\ &= -[\Gamma^* \mathcal{Q} y + \Gamma_T^* G y(T)]. \end{aligned} \tag{10}$$

Replacing Γ^*, Γ_T^*, $\mathcal{Q}$, and $\mathcal{R}$ by their explicit forms yields (7). □

Another equivalent and useful expression for the open-loop optimal control u is given by the following corollary.

COROLLARY 2.2. *Under the same assumptions, the optimal control u is the unique solution of the following equation in $\mathcal{U}$:*

$$\begin{aligned} R(t)u(t) + \int_0^T L(t,\tau)u(\tau)\,d\tau \\ = -\left[K^*(T,t)Gf(T) + \int_t^T K^*(s,t)Q(s)f(s)\,ds\right], \qquad t \in [0,T], \end{aligned} \tag{11}$$

where

(12)

$$L(t,\tau)u = K^*(T,t)GK(T,\tau)u + \int_{\max(t,\tau)}^T K^*(\rho,t)Q(\rho)K(\rho,\tau)u\,d\rho, \qquad (t,\tau) \in \Delta.$$

Proof. This is simply a consequence of the variational equation

$$\Phi u = -(\Gamma^* \mathcal{Q} f + \Gamma_T^* G f(T))$$

and the concrete integral expression of the operator

$$[(\Gamma^* \mathcal{Q} \Gamma + \Gamma_T^* G \Gamma_T)u](t) = \int_0^T L(t,\tau)u(\tau)\,d\tau. \qquad \square$$

It follows that the minimum of $J(u, f)$ over $\mathcal{U}$ is given by

$$J_*(f) := \min_{u \in \mathcal{U}} J(u, f) = \left\langle \Psi \begin{pmatrix} f \\ f(T) \end{pmatrix}, \begin{pmatrix} f \\ f(T) \end{pmatrix} \right\rangle_{\mathcal{Y} \times Y}, \tag{13}$$

with

$$\Psi = \begin{bmatrix} \mathcal{Q} - \mathcal{Q}\Gamma\Phi^{-1}\Gamma^*\mathcal{Q} & -\mathcal{Q}\Gamma\Phi^{-1}\Gamma_T^* G \\ -G\Gamma_T\Phi^{-1}\Gamma^*\mathcal{Q} & G - G\Gamma_T\Phi^{-1}\Gamma_T^* G \end{bmatrix}.$$

The next task is to explore the possibility of producing a causal feedback optimal control.

3. Causal projections. In the open-loop relation (7) the real-time value of the optimal control $u(t)$, $t \in [0, T]$, is given in terms of the future-time values of the corresponding state trajectory $y = y(s; u, f)$, $t \leq s \leq T$. The key issue here is to convert such a noncausal dependence into a causal one. And as noted earlier, we are not able to proceed via a differential Riccati equation because the Volterra integral equation (1) may not have a state-space realization. We need, therefore, a different approach in order to treat the causality problem and a new way to accomplish the synthesis.

DEFINITION 3.1. *We define a truncation operator* π_ξ *by*

$$(\pi_\xi u)(t) = \left\{ \begin{array}{ll} u(t) & \text{for } t \in [0, \xi] \\ 0 & \text{for } t \in (\xi, T] \end{array} \right\}, \tag{14}$$

where $0 \leq \xi \leq T$ *is a parameter which can be chosen arbitrarily.*

Obviously, both π_ξ and $I - \pi_\xi$ are projection operators on the function space $\mathcal{U}$. They are idempotent and commute with the operators $\mathcal{R}$ and $\mathcal{R}^{-1}$. We shall call these projections *causal projections*. Similar truncations were introduced in the literature by Miller and Sell [11]; see also the books by Gripenberg, Londen, and Staffans [4] and Bensoussan et al. [1]. In the control literature they have been used by Ichikawa [7], Vinter and Kwong [13], and Delfour [5], [6]. We denote

$$\mathcal{U}_\xi^+ = \text{range } (I - \pi_\xi) = (I - \pi_\xi)\mathcal{U},$$

which is a closed subspace of $\mathcal{U}$, and define a parametrized operator Φ_ξ^+ by

$$\Phi_\xi^+ = (I - \pi_\xi)\Phi \,|\, \mathcal{U}_\xi^+. \tag{15}$$

It has the following properties.

LEMMA 3.2. *For any given* $\xi \in [0, T)$, *the operator* $\Phi_\xi^+ \in \mathcal{L}(\mathcal{U}_\xi^+)$ *is positive definite and self-adjoint. Moreover.*

$$\|(\Phi_\xi^+)^{-1}\|_{\mathcal{L}(\mathcal{U}_\xi^+)} \leq \text{ const } (\textit{uniform in } \xi \in [0, T)). \tag{16}$$

Proof. For any u and v in $\mathcal{U}_\xi^+$, we have

$$\begin{aligned} \langle \Phi_\xi^+ u, v\rangle_{\mathcal{U}_\xi^+} &= \langle \Phi_\xi^+ u, v\rangle_{\mathcal{U}} = \langle \Phi u, (I - \pi_\xi)v\rangle_{\mathcal{U}} = \langle \Phi u, v\rangle_{\mathcal{U}} = \langle u, \Phi v\rangle_{\mathcal{U}} \\ &= (\text{by tracing back in a similar way})\langle u, \Phi_\xi^+ v\rangle_{\mathcal{U}_\xi^+}. \end{aligned}$$

Moreover for any $u \in \mathcal{U}_\xi^+$,

$$\langle \Phi_\xi^+ u, u\rangle_{\mathcal{U}_\xi^+} = \langle \Phi_\xi^+ u, u\rangle_{\mathcal{U}} \geq \epsilon \|u\|_{\mathcal{U}}^2 = \epsilon \|u\|_{\mathcal{U}_\xi^+}^2.$$

Thus Φ_ξ^+ is boundedly invertible and $\|(\Phi_\xi^+)^{-1}\|_{\mathcal{L}(\mathcal{U}_\xi^+)} \leq 1/\epsilon$ for all $\xi \in [0, T)$. □

Note that Φ_T^+ is the zero operator, but $\mathcal{U}_T^+ = \{0\}$, and so we may also take the inverse $(\Phi_T^+)^{-1}$ as the zero operator. Hence, the above lemma can be extended to the case $\xi = T$.

DEFINITION 3.3. *For any state trajectory* $y(\cdot)$ *corresponding to an admissible control* $u(\cdot)$, *we define the* ξ*-causal trajectory* $y_\xi(\cdot)$ *by*

$$y_\xi(t) = f(t) + \int_0^t K(t, \tau)(\pi_\xi u)(\tau)\, d\tau, \qquad t \in [0, T]. \tag{17}$$

One can call a ξ-causal trajectory $y_\xi(\cdot)$ a semicausal trajectory because the control function is truncated, but not the function f. Note that (17) can be written as $y_\xi = f + \Gamma\pi_\xi u$, and it is obvious that

$$y = y_\xi + \Gamma(I - \pi_\xi)u, \qquad y(T) = y_\xi(T) + \Gamma_T(I - \pi_\xi)u. \tag{18}$$

DEFINITION 3.4. *For any $\xi \in [0, T]$, we define a ξ-evolutionary operator $N_\xi \in \mathcal{L}(\mathcal{Y} \times Y)$ by*

$$N_\xi = I_{\mathcal{Y}\times Y} - \begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}(\Phi_\xi^+)^{-1}(I - \pi_\xi)(\Gamma^*\mathcal{Q}, \Gamma_T^* G). \tag{19}$$

Now we prove two important identities which will be used later in establishing the synthesis equations.

LEMMA 3.5. *The following hold:*

$$(\Phi_\xi^+)^{-1}(I - \pi_\xi)(\Gamma^*\mathcal{Q}, \Gamma_T^* G) = (I - \pi_\xi)\mathcal{R}^{-1}(\Gamma^*\mathcal{Q}, \Gamma_T^* G)N_\xi : \mathcal{Y} \times Y \to \mathcal{U}_\xi^+, \tag{20}$$

$$\begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}(\Phi_\xi^+)^{-1}(I - \pi_\xi) = N_\xi\begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}(I - \pi_\xi)\mathcal{R}^{-1} : \mathcal{U} \to \mathcal{Y} \times Y. \tag{21}$$

Proof. The verification of the two identities is straightforward, using the idempotent property of $(I - \pi_\xi)$ and the commutative property $(I - \pi_\xi)\mathcal{R}^{-1} = \mathcal{R}^{-1}(I - \pi_\xi)$. In detail, (20) follows from

$$\begin{aligned}
(I - \pi_\xi)\mathcal{R}^{-1}(\Gamma^*\mathcal{Q}, \Gamma_T^* G)N_\xi &= (I - \pi_\xi)\mathcal{R}^{-1}(\Gamma^*\mathcal{Q}, \Gamma_T^* G)\\
&\quad - (I - \pi_\xi)\mathcal{R}^{-1}(\Gamma^*\mathcal{Q}, \Gamma_T^* G)\begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}(\Phi_\xi^+)^{-1}(I - \pi_\xi)(\Gamma^*\mathcal{Q}, \Gamma_T^* G)\\
&= [\mathcal{R}^{-1} - \mathcal{R}^{-1}(I - \pi_\xi)(\Gamma^*\mathcal{Q}\Gamma + \Gamma_T^* G\Gamma_T)(\Phi_\xi^+)^{-1}](I - \pi_\xi)(\Gamma^*\mathcal{Q}, \Gamma_T^* G)\\
&= [\mathcal{R}^{-1} - \mathcal{R}^{-1}(I - \pi_\xi)(\Phi - \mathcal{R})(\Phi_\xi^+)^{-1}](I - \pi_\xi)(\Gamma^*\mathcal{Q}, \Gamma_T^* G)\\
&= [\mathcal{R}^{-1} - \mathcal{R}^{-1}\Phi_\xi^+(\Phi_\xi^+)^{-1} + (I - \pi_\xi)(\Phi_\xi^+)^{-1}](I - \pi_\xi)(\Gamma^*\mathcal{Q}, \Gamma_T^* G)\\
&= (\Phi_\xi^+)^{-1}(I - \pi_\xi)(\Gamma^*\mathcal{Q}, \Gamma_T^* G).
\end{aligned}$$

Equation (21) follows from

$$\begin{aligned}
N_\xi\begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}(I - \pi_\xi)\mathcal{R}^{-1} &= \begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}(I - \pi_\xi)\mathcal{R}^{-1}\\
&\quad - \begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}(\Phi_\xi^+)^{-1}(I - \pi_\xi)(\Gamma^*\mathcal{Q}, \Gamma_T^* G)\begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}(I - \pi_\xi)\mathcal{R}^{-1}\\
&= \begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}[\mathcal{R}^{-1} - (\Phi_\xi^+)^{-1}(I - \pi_\xi)(\Gamma^*\mathcal{Q}\Gamma + \Gamma_T^* G\Gamma_T)\mathcal{R}^{-1}](I - \pi_\xi)\\
&= \begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}[\mathcal{R}^{-1} - (\Phi_\xi^+)^{-1}(I - \pi_\xi)(\Phi - \mathcal{R})\mathcal{R}^{-1}](I - \pi_\xi)\\
&= \begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}(\Phi_\xi^+)^{-1}(I - \pi_\xi). \qquad \square
\end{aligned}$$

4. Semicausal optimality principle. In the previous section, we defined several new concepts: π_ξ, Φ_ξ^+, N_ξ, and semicausal trajectories $y_\xi(\cdot)$. We will now study their interrelations, and it will turn out that the result can be regarded as a generalization of the well-known optimality principle. We call such a new result the *semicausal optimality principle*.

THEOREM 4.1. *Let $\xi \in [0, T]$ and $f \in \mathcal{Y}$ be given. The optimal state trajectory $y(\cdot)$ and the corresponding semicausal trajectory $y_\xi(\cdot)$ are related by*

$$\begin{pmatrix} y \\ y(T) \end{pmatrix} = N_\xi \begin{pmatrix} y_\xi \\ y_\xi(T) \end{pmatrix}. \tag{22}$$

Proof. Note that (22) is an equality in the space $\mathcal{Y} \times Y$. To show it, we substitute (18) into (10) to obtain

$$\mathcal{R}u + (\Gamma^* \mathcal{Q} \Gamma + \Gamma_T^* G \Gamma_T)(I - \pi_\xi)u = -(\Gamma^* \mathcal{Q} y_\xi + \Gamma_T^* G y_\xi(T)).$$

Premultiplying the above equality by $(I - \pi_\xi)$ yields

$$\Phi_\xi^+ (I - \pi_\xi)u = -(I - \pi_\xi)(\Gamma^* \mathcal{Q}, \Gamma_T^* G) \begin{pmatrix} y_\xi \\ y_\xi(T) \end{pmatrix}.$$

By Lemma 3.2, it follows that

$$(I - \pi_\xi)u = -(\Phi_\xi^+)^{-1}(I - \pi_\xi)(\Gamma^* \mathcal{Q}, \Gamma_T^* G) \begin{pmatrix} y_\xi \\ y_\xi(T) \end{pmatrix}. \tag{23}$$

Then, substituting (23) into (18), we see that (22) holds. □

This theorem shows that the entire optimal state trajectory $y(\cdot)$ is determined by the semicausal trajectory $y_\xi(\cdot)$. The latter depends *only* on the optimal control $u(t)$, $0 \le t \le \xi$, and the real-time information of the function $f(\cdot)$. Furthermore, we get an immediate synthesis result.

THEOREM 4.2. *$u(\cdot)$ is the optimal control if and only if*

$$u(t) = -R^{-1}(t)[(\Gamma^* \mathcal{Q})(t), (\Gamma_T^* G)(t)] N_t \begin{pmatrix} y_t \\ y_t(T) \end{pmatrix}, \qquad t \in [0, T], \tag{24}$$

where $y_t(\cdot)$ is the semicausal trajectory with parameter ξ equal to t and

$$(\Gamma^* \mathcal{Q} y)(t) = \int_t^T K^*(\tau, t) Q(\tau) y(\tau)\, d\tau, \quad y \in \mathcal{Y}, \quad (\Gamma_T^* G)(t)\phi = K^*(T, t) G \phi, \quad \phi \in Y. \tag{25}$$

Proof. From (10), (22), and the expressions for Γ^* and Γ_T^*, we see that

$$u(t) = -R^{-1}(t)[(\Gamma^* \mathcal{Q})(t), (\Gamma_T^* G)(t)] N_\xi \begin{pmatrix} y_\xi \\ y_\xi(T) \end{pmatrix}, \qquad t \in [0, T], \tag{26}$$

where u is the optimal control and $\xi \in [0, T]$ is arbitrary. The choice $\xi = t$ yields (24).

Conversely, in order to show that if $u(\cdot)$ satisfies (24), then it is optimal, we need only show that the pair $\{u(\cdot), y(\cdot, u, f)\}$ satisfying (24) is unique. Since both (1) and (24) are linear, it suffices to show that when $f = 0$, the unique solution of (24) is $u(t) = 0$, $t \in [0, T]$. Below we prove this. Since $f = 0$, we have $y_t = \Gamma \pi_t u$. If this pair satisfies (24), then

$$\|u(t)\|_U \le \|R^{-1}(t)\|_{\mathcal{L}(U)} \|(\Gamma^* \mathcal{Q})(t), (\Gamma_T^* G)(t)\|_{\mathcal{L}(\mathcal{Y} \times Y, U)} \|N_t\|_{\mathcal{L}(\mathcal{Y} \times Y)} \left\| \begin{pmatrix} y_t \\ y_t(T) \end{pmatrix} \right\|_{\mathcal{Y} \times Y}.$$

By (25), (19), and Lemma 3.2, we have

$$\|(\Gamma^*\mathcal{Q})(t), (\Gamma_T^*G)(t)\|_{\mathcal{L}(\mathcal{Y}\times Y,U)}\|N_t\|_{\mathcal{L}(\mathcal{Y}\times Y)} \leq \text{const (uniform in } t)$$

and

$$\left\|\begin{pmatrix} y_t \\ y_t(T)\end{pmatrix}\right\|_{\mathcal{Y}\times Y} = \left\|\begin{pmatrix}\Gamma \\ \Gamma_T\end{pmatrix}\pi_t u\right\|_{\mathcal{Y}\times Y} \leq (\text{const})\,\|\pi_t u\|_{\mathcal{U}},$$

where again the constant is uniform in t. Therefore

$$\|u(t)\|_U^2 \leq (\text{const})\,\|\pi_t u\|_{\mathcal{U}}^2 = (\text{const})\int_0^T \|\pi_t u(s)\|_U^2\,ds = (\text{const})\int_0^t \|u(s)\|_U^2\,ds.$$

Applying Gronwall's inequality it follows that $u(t) = 0$, $t \in [0, T]$, and this completes the proof. □

Although the expression (24) looks like a causal feedback, it involves the abstract operators N_t and $(\Phi_t^+)^{-1}$, and we really need more effort to reach a computable implementation. This will be the subject of the next section.

5. Feedback optimal control. Based on the result given in Theorem 4.2, we will now focus on the further manipulation of the abstract operator N_t. We want to convert it into another feedback gain operator which can be accessed in a computational manner. For this purpose we define, for $\xi \in [0, T]$, the operator $B_\xi(t, \tau) \in \mathcal{L}(U)$ by

$$B_\xi(t,\tau) = -R^{-1}(t)[(\Gamma^*\mathcal{Q})(t), (\Gamma_T^*G)(t)]N_\xi\begin{pmatrix}K(\cdot,\tau)\\ K(T,\tau)\end{pmatrix}, \qquad (t,\tau)\in\Omega. \tag{27}$$

Here $\Omega = [0, T]\times[0, T]$. In the following we will write operator equations without specifying their action on various functions. This is really an abuse of notation since the integrands will in general not be uniformly measurable. However, we feel that the proper interpretation is always clear.

LEMMA 5.1. *For any given $\xi \in [0, T]$, there exists a unique strongly continuous solution $B_\xi(t, \tau)$ of the following integral equation:*

$$B_\xi(t,\tau) + \int_\xi^T R^{-1}(t)L(t,s)B_\xi(s,\tau)\,ds = -R^{-1}(t)L(t,\tau), \qquad (t,\tau)\in\Omega, \tag{28}$$

where $L(t, \tau)$ is given by (12). *This solution is given by the expression in* (27) *and is such that*

$$\sup_{(\xi,t,\tau)\in[0,T]^3}\|B_\xi(t,\tau)\| < \infty. \tag{29}$$

Proof. First we show that the expression on the right-hand side of (27) really is a solution of (28), and then it is easy to see that the solution is strongly continuous and satisfies the equiboundedness condition (29). We have

$$\begin{aligned} B_\xi(t,\tau) &= -R^{-1}[(\Gamma^*\mathcal{Q})(t), (\Gamma_T^*G)(t)]N_\xi\begin{pmatrix}K(\cdot,\tau)\\ K(T,\tau)\end{pmatrix}\\ &= -R^{-1}(t)[(\Gamma^*\mathcal{Q})(t), (\Gamma_T^*G)(t)](I_{\mathcal{Y}\times Y}\\ &\quad -\begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}(\Phi_\xi^+)^{-1}(I-\pi_\xi)(\Gamma^*\mathcal{Q},\Gamma_T^*G)\begin{pmatrix}K(\cdot,\tau)\\ K(T,\tau)\end{pmatrix}\end{aligned}$$

$$= - R^{-1}(t)[(\Gamma^*\mathcal{Q})(t)K(\cdot,\tau) + (\Gamma_T^*G)(t)K(T,\tau)]$$

$$+ R^{-1}(t)[(\Gamma^*\mathcal{Q})(t)\Gamma + (\Gamma_T^*G)(t)\Gamma_T](\Phi_\xi^+)^{-1}(I-\pi_\xi)(\Gamma^*\mathcal{Q}, \Gamma_T^*G)\begin{pmatrix} K(\cdot,\tau) \\ K(T,\tau)\end{pmatrix}$$

$$= - R^{-1}(t)[(\Gamma^*\mathcal{Q})(t)K(\cdot,\tau) + (\Gamma_T^*G)(t)K(T,\tau)]$$

$$+ R^{-1}(t)[(\Gamma^*\mathcal{Q}(t)\Gamma + \Gamma_T^*G)(t)\Gamma_T](I-\pi_\xi)\mathcal{R}^{-1}(\Gamma^*\mathcal{Q}, \Gamma_T^*G)N_\xi\begin{pmatrix} K(\cdot,\tau) \\ K(T,\tau)\end{pmatrix}$$

(in this step (20) is used)

$$= - R^{-1}(t)L(t,\tau) - R^{-1}(t)[(\Gamma^*\mathcal{Q})(t)\Gamma + (\Gamma_T^*G)(t)\Gamma_T](I-\pi_\xi)B_\xi(\cdot,\tau)$$

$$= - R^{-1}(t)L(t,\tau) - \int_0^T R^{-1}(t)L(t,s)((I-\pi_\xi)B_\xi)(s,\tau)\,ds$$

$$= - R^{-1}(t)L(t,\tau) - \int_\xi^T R^{-1}(t)L(t,s)B_\xi(s,\tau)\,ds, \qquad (t,\tau)\in\Omega.$$

Next we prove the uniqueness. It is enough to show that the homogeneous operator equation

$$\tilde{B}_\xi(t,\tau) + \int_\xi^T R^{-1}(t)L(t,s)\tilde{B}_\xi(s,\tau)\,ds = 0, \qquad (t,\tau)\in\Omega, \tag{30}$$

admits only the null solution. Applying the operator $(I-\pi_\xi)\mathcal{R}$ to (30), we obtain

$$(I-\pi_\xi)(\mathcal{R}I + \Gamma^*\mathcal{Q}\Gamma + \Gamma_T^*G\Gamma_T)[(I-\pi_\xi)\tilde{B}_\xi(\cdot,\tau)] = 0 \quad \text{in} \quad \mathcal{U}_\xi^+,$$

i.e.,

$$\Phi_\xi^+(I-\pi_\xi)\tilde{B}_\xi(\cdot,\tau) = 0 \quad \text{in} \quad \mathcal{U}_\xi^+.$$

By Lemma 3.2, this reduces to

$$(I-\pi_\xi)\tilde{B}_\xi(\cdot,\tau) = 0, \qquad \tau\in[0,T].$$

So $\tilde{B}_\xi(t,\tau) = 0$ for $(t,\tau)\in(\xi,T]\times[0,T]$. Substituting this in (30) yields $\tilde{B}_\xi(t,\tau) = 0$ for $(t,\tau)\in\Omega$, and this completes the proof. □

Now we present the main results on feedback optimal control.

THEOREM 5.2. *Suppose that* (A1)–(A4) *hold. Then* $u(\cdot)$ *is the optimal control if and only if*

$$\begin{aligned} u(t) = &-R^{-1}(t)[(\Gamma^*\mathcal{Q})(t)y_t + (\Gamma_T^*G)(t)y_t(T)] \\ &- \int_t^T B_t(t,s)R^{-1}(s)[(\Gamma^*\mathcal{Q})(s)y_t + (\Gamma_T^*G)(s)y_t(T)]\,ds, \qquad t\in[0,T], \end{aligned} \tag{31}$$

where $B_\xi(t,\tau)$ *is the unique solution of the integral operator equation* (28) *of Fredholm type and* $y_t(\cdot)$ *is the corresponding real-time semicausal trajectory which depends only on the past information* $\{u(\tau): 0\le\tau<t\}$.

Proof. Suppose that $u(\cdot)$ is the optimal control. Then by (24), the definition (19) of N_t, and the identity (21), we have

$$
\begin{aligned}
u(t) &= -R^{-1}(t)[(\Gamma^*\mathcal{Q})(t), (\Gamma_T^*G)(t)]N_t\begin{pmatrix} y_t \\ y_t(T)\end{pmatrix} \\
&= -R^{-1}(t)[(\Gamma^*\mathcal{Q})(t), (\Gamma_T^*G)(t)]\begin{pmatrix} y_t \\ y_t(T)\end{pmatrix} \\
&\quad + R^{-1}(t)[(\Gamma^*\mathcal{Q})(t), (\Gamma_T^*G)(t)]\begin{pmatrix}\Gamma \\ \Gamma_T\end{pmatrix}(\Phi_t^+)^{-1}(I-\pi_t)(\Gamma^*\mathcal{Q}, \Gamma_T^*G)\begin{pmatrix} y_t \\ y_t(T)\end{pmatrix} \\
&= -R^{-1}(t)[(\Gamma^*\mathcal{Q})(t), (\Gamma_T^*G)(t)]\begin{pmatrix} y_t \\ y_t(T)\end{pmatrix} \\
&\quad + R^{-1}(t)[(\Gamma^*\mathcal{Q})(t), (\Gamma_T^*G)(t)]N_t\begin{pmatrix}\Gamma \\ \Gamma_T\end{pmatrix}(I-\pi_t)\mathcal{R}^{-1}(\Gamma^*\mathcal{Q}, \Gamma_T^*G)\begin{pmatrix} y_t \\ y_t(T)\end{pmatrix} \\
&= -R^{-1}(t)[(\Gamma^*\mathcal{Q})(t)y_t + (\Gamma_T^*G)(t)y_t(T)] \\
&\quad + R^{-1}(t)[(\Gamma^*\mathcal{Q})(t), (\Gamma_T^*G)(t)]N_t\int_t^T \begin{pmatrix} K(\cdot, s) \\ K(T, s)\end{pmatrix} \\
&\quad \times R(s)^{-1}[(\Gamma^*\mathcal{Q})(s)y_t + (\Gamma_T^*G)(s)y_t(T)]\,ds \\
&= -R^{-1}(t)[(\Gamma^*\mathcal{Q})(t)y_t + (\Gamma_T^*G)(t)y_t(T)] \\
&\quad - \int_t^T B_t(t, s)R(s)^{-1}[(\Gamma^*\mathcal{Q})(s)y_t + (\Gamma_T^*G)(s)y_t(T)]\,ds,
\end{aligned}
$$

where in the last step we used Lemma 5.1 and (27). Therefore, (31) is satisfied by the optimal control $u(\cdot)$ and its corresponding semicausal trajectory $y_{(\cdot)}$.

Conversely, for any given f, there is only one pair $\{u, y\}$ which satisfies the relation (31). This can be proven in a way similar to the proof of Theorem 4.2 by using Gronwall's inequality. The proof is omitted. □

Finally we replace the operators Γ^* and Γ_T^* with their explicit expressions and obtain the following synthesis result.

THEOREM 5.3. *Suppose that* (A1)–(A4) *hold. Then* $u(\cdot)$ *is the optimal control if and only if*

$$
u(t) = -H(T, t)Gy_t(T) - \int_0^T H(\tau, t)Q(\tau)y_t(\tau)\,d\tau, \qquad t \in [0, T], \tag{32}
$$

where y_t *is the corresponding semicausal trajectory, the feedback operator* $H(\cdot, \cdot)$ *is* independently *determined by*

$$
H(\tau, t) = R(t)^{-1}K^*(\tau, t) + \int_t^T B_t(t, s)R(s)^{-1}K^*(\tau, s)\,ds, \tag{33}
$$

and $B_t(t, s)$ *is the unique solution of the Fredholm integral equation* (28).

Proof. Substituting (25) into (31), we obtain

$$
\begin{aligned}
u(t) &= -R^{-1}(t)\left[K^*(T, t)Gy_t(T) + \int_t^T K^*(\tau, t)Q(\tau)y_t(\tau)\,d\tau\right] \\
&\quad - \int_t^T B_t(t, s)R^{-1}(s)\left[K^*(T, s)Gy_t(T) + \int_s^T K^*(\tau, s)Q(\tau)y_t(\tau)\,d\tau\right]ds.
\end{aligned} \tag{34}
$$

Note that we have a convention that $K(\tau, s) = K^*(\tau, s)$ for $(\tau, s) \in \Omega\backslash\Delta$. Interchanging the order of integration in the last term of (34) gives

$$\begin{aligned} u(t) &= -H(T,t)Gy_t(T) - \int_0^T R^{-1}(t)K^*(\tau,t)Q(\tau)y_t(\tau)\,d\tau \\ &\quad - \int_t^T B_t(t,s)R^{-1}(s)\int_0^T K^*(\tau,s)Q(\tau)y_t(\tau)\,d\tau\,ds \\ &= -H(T,t)Gy_t(T) - \int_0^T H(\tau,t)Q(\tau)y_t(\tau)\,d\tau. \end{aligned}$$

Conversely, since we can deduce (31) from (32), the control process satisfying (32) must be optimal by Theorem 5.2. □

COROLLARY 5.4. *$u(\cdot)$ is the optimal control if and only if it satisfies the following linear integral equation:*

(35)
$$u(t) = -H(T,t)Gf(T) - \int_0^T H(\tau,t)Q(\tau)f(\tau)\,d\tau - \int_0^t \Pi(t,s)u(s)\,ds, \qquad t \in [0,T],$$

where $H(\cdot\,,\cdot)$ is defined by (33) *and the operator $\Pi(\cdot\,,\cdot)$ is given by*

$$\Pi(t,\tau) = H(T,t)GK(T,\tau) + \int_0^T H(s,t)Q(s)K(s,\tau)\,ds. \tag{36}$$

Proof. By the definition (17) and the convention on K, we have

$$y_t(\tau) = f(\tau) + \int_0^t K(\tau,s)u(s)\,ds, \qquad \tau \in [0,T]. \tag{37}$$

Substituting (37) in (32) gives (35). □

Remark 5.5. We have achieved a feedback optimal control given by (32). In this closed-loop formula, there are two ingredients. One is the semicausal trajectory $y_t(\cdot)$ and its terminal value at time T but with the parameter at the real time t. The other is the feedback operator $H(\tau, t)$, given by (33), and essentially relies on another operator $B_\xi(\tau, t)$, which is obtained by solving the linear integral equation (28). This latter equation is totally independent of the function f. For this reason we call the Fredholm integral equation (28) the *synthesis equation*. It plays a role similar to that of the operator Riccati equation.

Since the general Volterra equation does not have a semigroup evolutionary property, the direct feedback implementation of the optimal control in terms of the actual trajectory $\{y(\tau) : 0 \le \tau \le t\}$ is not possible, because the future information of the function f is not counted. In view of this, the semicausal trajectory feedback is the best that can be hoped for. However, when the Volterra integral actually represents a mild solution of a linear evolution equation, our results incorporate both the regulator and the tracking problems. Indeed we are able to obtain

- the usual feedback via Riccati equations for the regulator problem,
- the additional input which solves the tracking problem.

The approach is similar to that carried out in [10], and the first is illustrated in the next section.

6. The reduction for controlled evolution equations. In this section we show that when the Volterra integral equation is given by the mild solution of a time-invariant evolution equation, our results reduce to the well-known ones in terms of Riccati equations. Specifically we assume that

$$\dot{y}(t) = Ay(t) + Bu(t), \quad 0 \le t \le T, \quad y(0) = y_0 \in Y,$$

where A generates a strongly continuous semigroup $S(t)$, $t \ge 0$, on Y and $B \in \mathcal{L}(U, Y)$ so that

$$f(t) = S(t)y_0, \qquad K(t, \tau) = S(t - \tau)B. \tag{38}$$

Consider the differential Riccati equation

$$\langle \dot{\mathbb{P}}(t)x, y\rangle + \langle \mathbb{P}(t)x, Ay\rangle + \langle Ax, \mathbb{P}(t)y\rangle + \langle Qx, y\rangle - \langle \mathbb{P}(t)BR^{-1}B^*\mathbb{P}(t)x, y\rangle = 0, \quad \mathbb{P}(T) = G,$$

where $t \in [0, T]$, $x, y \in D(A)$, and we have assumed for simplicity that Q and R are time invariant. We will prove that the optimal control as given in Theorem 5.3 is $u(t) = -R^{-1}B^*\mathbb{P}(t)y(t)$, $t \in [0, T]$. The proof of this reduction will be given in detail so that one can see the correspondence between the standard approach and the one presented here. In this way more insight is obtained into the operator method and causality argument that we have used for Volterra integral equations.

LEMMA 6.1. *If* (38) *holds for* (1), *then the optimal control* $u(\cdot)$ *is given by*

$$u(t) = -E(t, t)y(t), \qquad t \in [0, T], \tag{39}$$

where $y(\cdot)$ *is the corresponding trajectory*

$$E(t, \tau) = H(T, t)GS(T - \tau) + \int_t^T H(s, t)QS(s - \tau)\, ds, \qquad (t, \tau) \in [0, T]^2, \tag{40}$$

$H(\cdot, \cdot)$ *is defined by* (33), *and we have the convention* $S(t) = 0$ *whenever* $t < 0$.

Proof. By (17),

$$\begin{aligned} y_\xi(t) &= S(t)y_0 + \int_0^t S(t - \tau)B\pi_\xi u(\tau)\, d\tau, \qquad t \ge 0, \\ &= y(t), \qquad t \le \xi, \\ &= S(t - \xi)S(\xi)y_0 + S(t - \xi)\int_0^\xi S(\xi - \tau)Bu(\tau)\, d\tau, \qquad t > \xi, \\ &= S(t - \xi)y(\xi), \qquad t > \xi. \end{aligned}$$

Hence

$$y_\xi(t) = \begin{cases} y(t), & t \le \xi, \\ S(t - \xi)y(\xi), & t > \xi, \end{cases} \tag{41}$$

and the result follows by substitution of (41) in (32). □

Using (38), the expressions (12) and (33) for $L(\cdot, \cdot)$ and $H(\cdot, \cdot)$ take the form

$$\begin{aligned} L(t, \tau) &= B^*S^*(T - t)GS(T - \tau)B + B^*\int_{\max(t,\tau)}^T S^*(s - t)QS(s - \tau)B\, ds \\ &= B^*S^*(T - t)GS(T - \tau)B + B^*\int_t^T S^*(s - t)QS(s - \tau)B\, ds \end{aligned}$$

and

$$\begin{aligned} H(\tau, t) &= R^{-1}B^*S^*(\tau - t) + \int_t^T B_t(t, s)R^{-1}B^*S^*(\tau - s)\, ds \\ &= R^{-1}B^*S^*(\tau - t) + \int_t^\tau B_t(t, s)R^{-1}B^*S^*(\tau - s)\, ds. \end{aligned} \tag{42}$$

We define an operator $W(\cdot, \cdot)$ by

(43)
$$W(t,\xi) = S(t-\xi) - \Gamma(t)(\Phi_\xi^+)^{-1}(I-\pi_\xi)(\Gamma^*Q, \Gamma_T^*G)\begin{pmatrix} S(\cdot-\xi) \\ S(T-\xi)\end{pmatrix}, \qquad 0 \le \xi \le t \le T,$$

where $W(T,T) = I$. We have the convention that $W(t,\xi) = 0$ for $t < \xi$ and with slight abuse $\Gamma(t)u = (\Gamma u)(t)$, $u \in \mathcal{U}$.

LEMMA 6.2. *The operator W has the following properties:*

(i) *for any initial data, the optimal trajectory $y(\cdot)$ satisfies*

(44)
$$y(t) = W(t,\xi)y(\xi), \qquad 0 < \xi \le t \le T.$$

(ii) $\sup_{0\le\xi\le t\le T} \|W(t,\xi)\|_{\mathcal{L}(Y)} < \infty$.

(iii) $W(t,\eta)W(\eta,\xi) = W(t,\xi), \qquad 0 < \xi \le \eta \le t \le T.$

(iv) *$W(t,\xi)$ is strongly continuous in $t \in [\xi, T]$ and in $\xi \in (0,t]$, respectively.*

Proof. To prove (i) we note the following facts:

$$\begin{aligned} y &= y_\xi + \Gamma(I-\pi_\xi)u, \\ (I-\pi_\xi)u &= -(\Phi_\xi^+)^{-1}(I-\pi_\xi)(\Gamma^*Qy_\xi + \Gamma_T^*Gy_\xi(T)), \\ y_\xi(t) &= S(t-\xi)y(\xi), \qquad 0 < \xi \le t \le T. \end{aligned}$$

Hence

$$\begin{aligned} y(t) &= S(t-\xi)y(\xi) - \Gamma(t)(\Phi_\xi^+)^{-1}(I-\pi_\xi)(\Gamma^*Q, \Gamma_T^*G)\begin{pmatrix} S(\cdot-\xi) \\ S(T-\xi)\end{pmatrix}y(\xi) \\ &= W(t,\xi)y(\xi), \qquad (t,\xi) \in \{0 < \xi \le t \le T : \xi \ne T\}. \end{aligned}$$

For $\xi = t = T$, (44) holds since $W(T,T) = I$.

The proof of (ii) follows from Lemma 3.2.

For (iii), let $0 < \xi \le \eta \le t \le T$. By using (43) and (19), we find

$$\begin{aligned} W(t,\eta)W(\eta,\xi) &= S(t-\xi) - S(t-\eta)\Gamma(\eta)(\Phi_\xi^+)^{-1}(I-\pi_\xi)(\Gamma^*Q, \Gamma_T^*G)\begin{pmatrix} S(\cdot-\xi) \\ S(T-\xi)\end{pmatrix} \\ &\quad - \Gamma(t)(\Phi_\eta^+)^{-1}(I-\pi_\eta)(\Gamma^*Q, \Gamma_T^*G)\begin{pmatrix} S(\cdot-\eta) \\ S(T-\eta)\end{pmatrix}S(\eta-\xi) \\ &\quad + \Gamma(t)(\Phi_\eta^+)^{-1}(I-\pi_\eta)(\Gamma^*Q, \Gamma_T^*G)\begin{pmatrix} S(\cdot-\eta) \\ S(T-\eta)\end{pmatrix} \\ &\quad \times \Gamma(\eta)(\Phi_\xi^+)^{-1}(I-\pi_\xi)(\Gamma^*Q, \Gamma_T^*G)\begin{pmatrix} S(\cdot-\xi) \\ S(T-\xi)\end{pmatrix} \\ &= S(t-\xi) - S(t-\eta)\Gamma(\eta)(I-\pi_\xi)R^{-1}(\Gamma^*Q, \Gamma_T^*G)N_\xi\begin{pmatrix} S(\cdot-\xi) \\ S(T-\xi)\end{pmatrix} \\ &\quad - \Gamma(t)(I-\pi_\eta)R^{-1}(\Gamma^*Q, \Gamma_T^*G)N_\eta \\ &\quad \times \left\{I - \begin{pmatrix} S(\cdot-\eta) \\ S(T-\eta)\end{pmatrix}\Gamma(\eta)(I-\pi_\xi)R^{-1}(\Gamma^*Q, \Gamma_T^*G)N_\xi\right\}\begin{pmatrix} S(\cdot-\xi) \\ S(T-\xi)\end{pmatrix}. \end{aligned}$$

By (19), (20), and (21), we have

$$\begin{aligned}
N_\eta - N_\xi &= N_\eta(I - N_\xi) - (I - N_\eta)N_\xi \\
&= N_\eta\begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}(I - \pi_\xi)R^{-1}(\Gamma^*Q, \Gamma_T^*G)N_\xi - N_\eta\begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}(I - \pi_\eta)R^{-1}(\Gamma^*Q, \Gamma_T^*G)N_\xi \\
&= N_\eta\begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}(\pi_\eta - \pi_\xi)R^{-1}(\Gamma^*Q, \Gamma_T^*G)N_\xi \\
&= N_\eta\begin{pmatrix}S(\cdot - \xi)\\ S(T - \xi)\end{pmatrix}\Gamma(\eta)(I - \pi_\xi)R^{-1}(\Gamma^*Q, \Gamma_T^*G)N_\xi.
\end{aligned}$$

Substituting this into the parenthesis $\{\ldots\}$ of the last term in the above expression, we have

$$\begin{aligned}
W(t,\eta)W(\eta,\xi) &= S(t - \xi) - S(t - \eta)\Gamma(\eta)(I - \pi_\xi)R^{-1}(\Gamma^*Q, \Gamma_T^*G)N_\xi\begin{pmatrix}S(\cdot - \xi)\\ S(T - \xi)\end{pmatrix} \\
&\quad - \Gamma(t)(I - \pi_\eta)R^{-1}(\Gamma^*Q, \Gamma_T^*G)N_\xi\begin{pmatrix}S(\cdot - \xi)\\ S(T - \xi)\end{pmatrix} \\
&= S(t - \xi) - \int_\xi^\eta S(t - \sigma)BR^{-1}((\Gamma^*Q)(\sigma), (\Gamma_T^*G)(\sigma))N_\xi\begin{pmatrix}S(\cdot - \xi)\\ S(T - \xi)\end{pmatrix}d\sigma \\
&\quad - \int_\eta^t S(t - \sigma)BR^{-1}((\Gamma^*Q)(\sigma), (\Gamma_T^*G)(\sigma))N_\xi\begin{pmatrix}S(\cdot - \xi)\\ S(T - \xi)\end{pmatrix}d\sigma \\
&= S(t - \xi) - \Gamma(t)(I - \pi_\xi)R^{-1}(\Gamma^*Q, \Gamma_T^*G)N_\xi\begin{pmatrix}S(\cdot - \xi)\\ S(T - \xi)\end{pmatrix} \\
&= S(t - \xi) - \Gamma(t)(\Phi_\xi^+)^{-1}(I - \pi_\xi)(\Gamma^*Q, \Gamma_T^*G)\begin{pmatrix}S(\cdot - \xi)\\ S(T - \xi)\end{pmatrix} \\
&= W(t,\xi)
\end{aligned}$$

for any $0 < \xi \le \eta \le t \le T$ with $\xi < T, \eta < T$, but if $\xi < T$ and $\eta = t = T$, then the equality remains valid, viz. $W(T,T)W(T,\xi) = W(T,\xi)$. Clearly it is true for $\xi = \eta = t = T$, and hence (iii) is proven.

For (iv), by the definition of W it is clear that $W(t,\xi)$ is strongly continuous in $t \in [\xi, T]$. Using this continuity and properties (ii) and (iii), it is easy to prove the strong continuity in $\xi \in (0, t]$. The detail is omitted. □

LEMMA 6.3. *Let $P : [0,T] \to \mathcal{L}(Y)$ be defined by*

$$\begin{aligned}
P(t) &= S^*(T - t)GS(T - t) + \int_t^T S^*(s - t)QS(s - t)\,ds \\
&= -((\tilde{\Gamma}^*Q)(t), (\tilde{\Gamma}_T G)(t))N_t\begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}(I - \pi_t)R^{-1}(\Gamma^*Q, \Gamma_T^*G)\begin{pmatrix}S(\cdot - t)\\ S(T - t)\end{pmatrix},
\end{aligned} \tag{45}$$

where the new operators $\tilde{\Gamma}^* \in \mathcal{L}(\mathcal{Y})$ and $\tilde{\Gamma}_T^* \in \mathcal{L}(Y, \mathcal{Y})$ are defined by

$$(\tilde{\Gamma}^*\phi)(t) = \int_t^T S^*(\sigma - t)\phi(\sigma)d\sigma, \quad (\tilde{\Gamma}_T^*)(t)\phi_0 = S^*(T - t)\phi_0, \quad t \in [0,T].$$

Then if E is given by (40), *we have*

$$E(t,t) = R^{-1}B^*P(t), \qquad t \in [0,T]. \tag{46}$$

Proof. From (27), (40), and (42), we have

$$
\begin{aligned}
E(t,t) &= H(T,t)GS(T-t) + \int_t^T H(s,t)QS(s-t)\,ds \\
&= R^{-1}B^*\left[S^*(T-t)GS(T-t) + \int_t^T S^*(s-t)QS(s-t)\,ds\right] \\
&\quad - R^{-1}B^*\int_t^T ((\tilde{\Gamma}^*\mathcal{Q})(t), (\tilde{\Gamma}_T^*G)(t))N_t\begin{pmatrix} S(\cdot-\sigma) \\ S(T-\sigma)\end{pmatrix} \\
&\quad \times BR^{-1}B^*S^*(T-\sigma)GS(T-t)\,d\sigma \\
&\quad - R^{-1}B^*\int_t^T\int_t^s ((\tilde{\Gamma}^*\mathcal{Q})(t), (\tilde{\Gamma}_T^*G)(t))N_t\begin{pmatrix} S(\cdot-\sigma) \\ S(T-\sigma)\end{pmatrix} \\
&\quad \times BR^{-1}B^*S^*(s-\sigma)QS(s-t)d\sigma\,ds \\
&= R^{-1}B^*\left[S^*(T-t)GS(T-t) + \int_t^T S^*(s-t)QS(s-t)\,ds\right] \\
&\quad - R^{-1}B^*((\tilde{\Gamma}\mathcal{Q})(t), (\tilde{\Gamma}_T^*G)(t))N_t\int_t^T \begin{pmatrix} S(\cdot-\sigma) \\ S(T-\sigma)\end{pmatrix} \\
&\quad \times BR^{-1}B^*\left[S^*(T-\sigma)GS(T-t) + \int_\sigma^T S^*(s-\sigma)QS(s-t)\,ds\right]d\sigma \\
&= R^{-1}B^*\left[S^*(T-t)GS(T-t) + \int_t^T S^*(s-t)QS(s-t)\,ds\right] \\
&\quad - R^{-1}B^*((\tilde{\Gamma}^*Q)(t), (\tilde{\Gamma}_T^*G)(t))N_t\begin{pmatrix}\Gamma \\ \Gamma_T\end{pmatrix}(I-\pi_t)R^{-1}(\Gamma^*Q, \Gamma_T^*G)\begin{pmatrix} s(\cdot-t) \\ S(T-t)\end{pmatrix},
\end{aligned}
$$

which completes the proof. □

LEMMA 6.4. *Let P and W be defined by* (45) *and* (43), *respectively. Then*

$$
P(t)y = S^*(T-t)GW(T,t) + \int_t^T S^*(s-t)QW(s,t)\,ds, \qquad t\in[0,T]. \tag{47}
$$

Proof. From (43) and (20), it follows that

$$
\begin{aligned}
&S^*(T-t)GW(T,t) + \int_t^T S^*(s-t)QW(s,t)\,ds \\
&\quad = S^*(T-t)GS(T-t) + \int_t^T S^*(s-t)QS(s-t)\,ds \\
&\qquad - S^*(T-t)G\Gamma(T)(\Phi_t^+)^{-1}(I-\pi_t)(\Gamma^*Q, \Gamma_T^*G)\begin{pmatrix} S(\cdot-t) \\ S(T-t)\end{pmatrix} \\
&\qquad - \int_t^T S^*(s-t)Q\Gamma(s)(\Phi_t^+)^{-1}(I-\pi_t)(\Gamma^*Q, \Gamma_T^*G)\begin{pmatrix} S(\cdot-t) \\ S(T-t)\end{pmatrix}ds \\
&\quad = S^*(T-t)GS(T-t) + \int_t^T S^*(s-t)QS(s-t)\,ds
\end{aligned}
$$

$$
\begin{aligned}
&- ((\tilde{\Gamma}^* Q)(t), (\tilde{\Gamma}_T^* G)(t))\begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}(\Phi_t^+)^{-1}(I-\pi_t)(\Gamma^* Q, \Gamma_T^* G)\begin{pmatrix}S(\cdot - t)\\ S(T-t)\end{pmatrix}\\
&= S^*(T-t)GS(T-t) + \int_t^T S^*(s-t)QS(s-t)\,ds\\
&\quad - ((\tilde{\Gamma}^* Q)(t), (\tilde{\Gamma}_T^* G)(t))N_t\begin{pmatrix}\Gamma\\ \Gamma_T\end{pmatrix}(I-\pi_t)R^{-1}(\Gamma^* Q, \Gamma_T^* G)\begin{pmatrix}S(\cdot - t)\\ S(T-t)\end{pmatrix}\\
&= P(t), \qquad t \in [0, T]. \qquad \square
\end{aligned}
$$

LEMMA 6.5. *The relation*

$$
W(t,\xi) = S(t-\xi) - \int_\xi^t W(t,\sigma)BR^{-1}B^*P(\sigma)S(\sigma-\xi)\,d\sigma \tag{48}
$$

holds, and P is the unique strongly continuous and self-adjoint solution of the integral Riccati equation

(49)

$$
P(t) = S^*(T-t)GS(T-t) + \int_t^T S^*(s-t)[Q - P(s)BR^{-1}B^*P(s)]S(s-t)\,ds, \qquad t \in [0, T].
$$

Proof. First we prove (48). Let the function on the right of (48) be denoted by $\theta(t,\xi)$. Then it can be verified that both

$$
g_1(t) = W(t,\xi) \quad \text{and} \quad g_2(t) = \theta(t,\xi), \quad t \in (\xi, T],
$$

are continuous solutions of the Volterra integral equation

$$
g(t) = S(t-\xi) - \int_\xi^t S(t-\sigma)BR^{-1}B^*P(\sigma)g(\sigma)\,d\sigma, \qquad t \in [\xi, t].
$$

Then by the uniqueness of the solution, (48) is valid.

Now we prove (49). By (47) and (48), for $t \in [0, T]$, we have

$$
\begin{aligned}
P(t) &= S^*(T-t)GW(T,t) + \int_t^T S^*(s-t)QW(s,t)\,ds\\
&= S^*(T-t)GS(T-t) + \int_t^T S^*(s-t)QS(s-t)\,ds\\
&\quad - S^*(T-t)G\int_t^T W(T,s)BR^{-1}B^*P(s)S(s-t)\,ds\\
&\quad - \int_t^T S^*(\eta-t)Q\int_t^\eta W(\eta,s)P(s)BR^{-1}B^*P(s)S(s-t)\,ds\,d\eta\\
&= S^*(T-t)GS(T-t) + \int_t^T S^*(s-t)QS(s-t)\,ds\\
&\quad - \int_t^T S^*(s-t)BR^{-1}B^*P(s)S(s-t)\,ds\\
&= S^*(T-t)GS(T-t) + \int_t^T S^*(s-t)[Q - P(s)BR^{-1}B^*P(s)]S(s-t)\,ds.
\end{aligned}
$$

By (47) and Lemma 6.2(iv), we see that $P(\cdot)$ is strongly continuous. In [2], it is proven that the strongly continuous solution of (49) is unique. By transposition, it can be seen that $P^*(\cdot)$ is also a strongly continuous solution of (49). Hence, by uniqueness, $P^*(t) = P(t)$, $t \in [0, T]$, and the proof is complete. □

We have finally reached our goal in the reduction. This is stated in the following theorem.

THEOREM 6.6. *Suppose that* (A3) *and* (A4) *hold for the data given by* (38). *Then the optimal control is given by*

$$u(t) = -R^{-1}B^*\mathbb{P}(t)y(t), \qquad t \in [0, T], \tag{50}$$

where $\mathbb{P}$ *is the unique strongly continuous and self-adjoint solution of the differential Riccati equation and* $y(\cdot)$ *is the corresponding trajectory.*

Proof. This follows from Lemmas 6.1, 6.3, and 6.5 and the known fact that the integral Riccati equation (49) is equivalent to the aforementioned differential Riccati equation and hence $P = \mathbb{P}$. □

ON THE USE OF CONSISTENT APPROXIMATIONS FOR THE OPTIMAL DESIGN OF BEAMS*

C. KIRJNER NETO† AND E. POLAK†

Abstract. This paper presents a discretization strategy, based on the concept of consistent approximations, for certain optimal beam design problems, where the beam is modeled using Euler–Bernoulli beam theory. It is shown that any accumulation point of the sequence of the stationary points of the family of resulting approximating problems is a stationary point of the original, infinite-dimensional problem. The construction of approximating problems requires the development of a relaxation of constraints to ensure existence of solutions. The numerical solution of the approximating problems, by means of nonlinear programming algorithms that are not scale invariant, must be preceded by a change of variables to guard against deterioration of performance. The use of such approximating problems, in conjunction with a diagonalization strategy, is illustrated by a numerical example.

1. Introduction.

Over the past 15 years, there has been a great deal of activity in the development of numerical methods for the solution of optimal design problems (see, e.g., [4, 5, 9, 10, 12, 16] and references therein). A major class of these methods is based on the construction of an infinite sequence of finite-dimensional approximating problems by means of numerical integration techniques. To be of any value, such approximating problems must be consistent in the sense that their solutions converge to those of the original problem. Now, in the context of optimization problems, the concept of a solution is not unique; one may mean a *global* minimizer, a *local* minimizer, or, quite commonly, simply a *stationary point*.

A scan through the optimal design literature (see, e.g., [6, 9, 13, 16]) shows that only the question of convergence of global minimizers of approximating problems to a global minimizer of the original problem is usually addressed. However, it has been observed empirically (see [7]) that some numerical methods used to solve boundary value problems result in approximating problems with local minimizers that converge to nonstationary points of the original problem. A simple example of how such a pathology can occur is given in §2.

The impact of the multiplicity of solution concepts in optimization on the issue of consistency of approximation is only now beginning to be recognized. In [18] we find an abstract theory of consistent approximations for optimization problems. This theory provides guidance to the construction of approximating finite-dimensional optimization problems and to the use of efficient diagonalization techniques for constructing sequences of finite-dimensional approximating problems in the approximate solution of an infinite-dimensional optimization problem.[1] Within this theory, optimization problems are not endowed with a specific structure, and hence optimality conditions are expressed in terms of zeros of *optimality functions*.[2] Approximating problems are judged to be consistent if the constrained epigraphs of their cost functions and the hypographs of their optimality functions converge, in the Kuratowski sense, to those of the original problem. Consistency in the sense of [18] ensures the convergence of the global

[1]Referring to [11], we see that using a diagonalization strategy in getting an approximation at specified precision to a solution of an infinite-dimensional optimization problem is always more efficient than simply solving an approximating problem of the given precision.

[2]Optimality functions are usually the value functions of quadratic optimization problems that arise when one attempts to verify whether a classical optimality condition is satisfied or not.

minimizers, local minimizers, and stationary points of approximating problems to corresponding points of the original problem.

To apply the results in [18] to optimal design, one must carry out three tasks. The first, and often the easiest, is the selection of bases for finite-dimensional subspaces of the original infinite-dimensional design space. Next, one must show that the selected numerical integration method converges with the same rate *on all* the finite-dimensional subspaces used, uniformly in the decision variables. This fact shows that there is an important interaction between the selection of the subspaces and the selection of the method of integration (see, e.g. [22]). The literature on numerical integration usually does not include such results, and their development can be a serious source of difficulty. Finally, to ensure that the approximating problems have solutions, one often has to invent a satisfactory relaxation of the constraints.

To date, the applicability of the theory of consistent approximations in [18] has been established for discrete optimal control problems [19, 22] resulting from the use of Euler and Runge–Kutta methods of integration on ordinary differential equations.

This paper uses the theory of consistent approximations in developing an approach to the solution of a class of optimal Euler–Bernoulli beam design problems with continuum constraints, such as constraints on vertical deflection, shear stress, and normal stress at the extreme fiber. The continuum constraints make these problems nondifferentiable and hence quite difficult to solve.

In the process of developing consistent approximations for the beam problems, we have addressed two important issues that are usually ignored. The first is that of finding a rational method for relaxing constraints so as to ensure that the approximating problems have solutions. The second issue is that of preserving problem conditioning. It is well known in nonlinear programming that changing norms can have a profoundly adverse effect on the behavior of algorithms, such as the phase I–phase II method of centers in [20], that are not scale invariant. When the basis functions used for the finite-dimensional subspaces on which the approximating problems are defined are not orthonormal, the corresponding Euclidean coefficient spaces are not isometric with the function subspaces. Hence, if one compares the behavior of a nonscale invariant algorithm in solving an approximating problem formulated in a finite-dimensional subspace of the original function space using the original norm, with its behavior in solving the same approximating problem formulated in the space of coefficients using the Euclidean norm, one often finds that in the Euclidean space this algorithm performs much worse. To correct for this possibility, one must develop appropriate transformations in Euclidean space, as we have done in this paper.

For ease of exposition we will restrict ourselves to beams with rectangular cross section, fixed width, and distributed loads. Although beams with nonuniform cross sections are more difficult to manufacture when weight is at a premium, as in aerospace applications, the construction of minimum weight beams may be quite realistic. Moreover, the problem of determining the optimal dimensions of a uniform beam subject to continuum constraints is a particular case of the problems with which we will deal. It is straightforward to generalize our results to beams whose cross sections are not necessarily rectangular, provided that the cross sections have horizontal and vertical axes of symmetry and the plane containing the vertical axis of symmetry also contains the loads. For instance, one can extend our results to the design of rectangular beams with varying depth and width or the design of a cylindrical beam with varying radius.

The paper is organized as follows. In §2 we summarize the basic definitions and results on consistent approximations in [18]. In §3 we develop a mathematical formulation of the optimal design problem together with an optimality function. Then we construct a sequence of

approximating problems, together with their optimality functions, which we show to be consistent in the sense of [18]. In §4 we develop transformations of variables that compensate for the fact that our coefficient spaces are not isometric with the corresponding finite-dimensional function subspaces. Also, we present a diagonalization strategy for the numerical solution of the optimal design problems under consideration. In §5 we present the results of a numerical experiment. Finally, in §6 we present our conclusions.

2. Consistent approximations. We begin by presenting a summary of the main definitions and results related to the concept of consistent approximations introduced in [18].

Let B be a topological vector space, and consider the problem

$$\mathbf{P} \qquad \min_{z \in Z} f(z) \tag{2.1a}$$

where $f : \mathsf{B} \to \mathbb{R}$ is continuous and $Z \subset \mathsf{B}$ is the constraint set. Let $\{\mathsf{B}_N\}_{N=1}^{\infty}$ be a family of finite-dimensional subspaces of B such that $\mathsf{B}_N = \mathsf{B}$ if B is finite dimensional ($\mathbb{R}^n$) and $\mathsf{B}_N \subset \mathsf{B}_{N+1}$ for all N otherwise. Consider the family of approximating problems

$$\mathbf{P}_N \qquad \min_{z \in Z_N} f_N(z), \qquad N \in \mathbb{N}, \tag{2.1b}$$

where $f_N : \mathsf{B}_N \to \mathbb{R}$ is continuous and $Z_N \subset \mathsf{B}_N$. To be of any use to us at all, the problems $\mathbf{P}_N$ must, at least, converge epigraphically to $\mathbf{P}$; i.e., the epigraphs $E_N \triangleq \{(z^0, z) \in \mathbb{R} \times Z_N | z^0 \geq f_N(z)\}$ of the problems $\mathbf{P}_N$ must converge in the sense of Kuratowski to the epigraph $E \triangleq \{(z^0, z) \in \mathbb{R} \times Z | z^0 \geq f(z)\}$ of the problem $\mathbf{P}$. Equivalently, we have the following definition.

DEFINITION 2.1 (see [1, 8]). *The problems in the family* $\{\mathbf{P}_N\}_{N=1}^{\infty}$ converge epigraphically *to* $\mathbf{P}$, ($\mathbf{P}_N \to^{\text{Epi}} \mathbf{P}$) *if* (a) *for every* $z \in Z$ *there exists a sequence* $\{z_N\}_{N=1}^{\infty}$ *with* $z_N \in Z_N$ *such that* $z_N \to z$ *and* $\lim f_N(z_N) \leq f(z)$ *and* (b) *for every sequence* $\{z_{N_k}\}_{k=1}^{\infty}$ *with* $z_{N_k} \in Z_{N_k}$ *such that* $z_{N_k} \to z$ *as* $k \to \infty$, $z \in Z$, *and* $\lim f_{N_k}(z_{N_k}) \geq f(z)$.

Epigraphic convergence, or epiconvergence for short, can be viewed as a "zeroth-order" consistency property. In particular, it ensures the following result.

THEOREM 2.2. *Suppose that* $\mathbf{P}_N \to^{\text{Epi}} \mathbf{P}$ *and that* $\{\hat{z}_N\}_{N=1}^{\infty}$ *is a sequence such that* $\hat{z}_N \in Z_N$ *for all* N *and* $\hat{z}_N \to \hat{z}$.

(a) *If the* $\hat{z}_N$ *are global minimizers for the* $\mathbf{P}_N$, *then* $\hat{z}$ *is a global minimizer of* $\mathbf{P}$.

(b) *If* $\hat{z}_N$ *are strict local minimizers for the* $\mathbf{P}_N$ *whose radii of attraction do not converge to zero as* $N \to \infty$, *then* $\hat{z}$ *is a local minimizer of* $\mathbf{P}$.

The reader is referred to [1, 8] for the proof of Theorem 2.2(a) and to [18] for the proof of Theorem 2.2(b).

Optimization algorithms, applied to the finite-dimensional problems $\mathbf{P}_N$, are known only to compute stationary points. As the following example shows, epiconvergence alone does not rule out the possibility that stationary points of the $\mathbf{P}_N$ converge to a nonstationary point of $\mathbf{P}$. Let $\mathsf{B} = \mathbb{R}^2$ so that $z = (x, y)$, and let $f(z) = f_N(z) = (x-2)^2$, $N \in \mathbb{N}$. Let

$$Z \triangleq \{(x, y) \in \mathbb{R}^2 | x^2 + y^2 \leq 2\}, \tag{2.2a}$$

and, for all $N \in \mathbb{N}$ let

$$Z_N \triangleq \left\{(x, y) \in \mathbb{R}^2 | (x-y)^2(x^2+y^2-2) \leq 0, x^2 + y^2 \leq 2 + \frac{1}{N}\right\}. \tag{2.2b}$$

Then we see that $\mathbf{P}_N \to^{\text{Epi}} \mathbf{P}$. Nevertheless, the point (1, 1) is feasible and satisfies the F. John

optimality condition for all $\mathbf{P}_N$, but it is not a stationary point for the problem $\mathbf{P}$. The reason for this is an incompatibility of the constraint sets Z_N with the constraint set Z that shows up only at the level of optimality conditions.

To eliminate the possibility of pathologies such as in the above example, as well as some others (e.g., failure of derivatives to converge), [18] imposed a second condition on the approximating problems in terms of optimality conditions that can be viewed as a "first-order" consistency requirement. For the purpose of this condition, it is convenient to characterize stationary points as the zeros of optimality functions $\theta : \mathsf{D} \to \mathbb{R}$ for $\mathbf{P}$ and $\theta_N : \mathsf{D}_N \to \mathbb{R}$ for $\mathbf{P}_N$, $N \in \mathbb{N}$, where $\mathsf{D} \subset \mathsf{B}$ and $\mathsf{D}_N \subset \mathsf{B}_N$; i.e., the optimality functions may not be defined on the entire space. We will assume that $\mathsf{D}_N \subset \mathsf{D} \cap \mathsf{B}_N$ for all $N \in \mathbb{N}$.

DEFINITION 2.3. *A function* $\theta : \mathsf{D} \to \mathbb{R}$ *is an* optimality function *for* $\mathbf{P}$ *if* (i) $Z \subset \mathsf{D}$, (ii) $\theta(\cdot)$ *is sequentially upper semicontinuous,* (iii) $\theta(z) \leq 0$ *for all* $z \in \mathsf{D}$, *and* (iv) $\theta(\hat{z}) = 0$ *for any* $\hat{z} \in Z$ *that is a local minimizer for* $\mathbf{P}$. *Similarly, a function* $\theta_N : \mathsf{D}_N \to \mathbb{R}$ *is an* optimality function *for* $\mathbf{P}_N$ *if* (i) $Z_N \subset \mathsf{D}_N$, (ii) $\theta_N(\cdot)$ *is sequentially upper semicontinuous,* (iii) $\theta_N(z) \leq 0$ *for all* $z \in \mathsf{D}_N$, *and* (iv) $\theta_N(\hat{z}_N) = 0$ *for any* $\hat{z}_N \in Z_N$ *that is a local minimizer for* $\mathbf{P}_N$.

DEFINITION 2.4. *Let* $\theta(\cdot), \theta_N(\cdot), N \in \mathbb{N}$, *be optimality functions for* $\mathbf{P}$, $\mathbf{P}_N$, *respectively. The pairs* $(\mathbf{P}_N, \theta_N)$, *in the sequence* $\{(\mathbf{P}_N, \theta_N)\}_{N=1}^{\infty}$ *are* weakly consistent approximations *to the pair* $(\mathbf{P}, \theta)$ *if* (i) $\mathbf{P}_N \xrightarrow{\text{Epi}} \mathbf{P}$ *and* (ii) *for any sequence* $\{z_N\}_{N \in K}$, $K \subset \mathbb{N}$, *with* $z_N \in \mathsf{D}_N$ *for all* $N \in K$ *such that* $z_N \to z$, $\limsup \theta_N(z_N) \leq \theta(z)$.

As a result of this definition, we immediately get the following result, which subsumes Theorem 2.2.

THEOREM 2.5. *Suppose that the pairs* $(\mathbf{P}_N, \theta_N)$ *in the sequence* $\{(\mathbf{P}_N, \theta_N)\}_{N=1}^{\infty}$ *are weakly consistent approximations to the pair* $(\mathbf{P}, \theta)$ *and that* $\{\hat{z}_N\}_{N=1}^{\infty}$ *is a sequence such that* $\hat{z}_N \in Z_N$ *for all* N *and* $\hat{z}_N \to \hat{z}$.

(a) *If the* $\hat{z}_N$ *are global minimizers for the* $\mathbf{P}_N$, *then* $\hat{z}$ *is a global minimizer of* $\mathbf{P}$.

(b) *If* $\hat{z}_N$ *are strict local minimizers whose radii of attraction do not converge to zero, as* $N \to \infty$, *then* $\hat{z}$ *is a local minimizer of* $\mathbf{P}$.

(c) *If* $\overline{\lim} \theta_N(\hat{z}_N) = 0$, *then* $\theta(\hat{z}) = 0$.

If we define a point $\hat{z}$ to be stationary for $\mathbf{P}$ if $\theta(\hat{z}) = 0$, then we see that Definition 2.3 permits nonfeasible points to be stationary (e.g., they can be stationary points for a problem with relaxed or modified constraints). This phenomenon can be removed by imposing an additional condition, as is done in the following definition.

DEFINITION 2.6. *Let* $\theta(\cdot), \theta_N(\cdot), N \in \mathbb{N}$, *be optimality functions for* $\mathbf{P}$, $\mathbf{P}_N$, *respectively. The pairs* $(\mathbf{P}_N, \theta_N)$, *in the sequence* $\{(\mathbf{P}_N, \theta_N)\}_{N=1}^{\infty}$ *are* consistent approximations *to* $(\mathbf{P}, \theta)$, *if they are weakly consistent approximations, and in addition* $\theta(z) < 0$ *for all* $z \notin Z$ *and* $\theta_N(z) < 0$ *for all* $z \notin Z_N$, $N \in \mathbb{N}$.

3. Consistent approximations for the optimal design of a fixed beam. In this section we formulate the optimal fixed beam design problem and decompose it into a family of consistent approximations. First, we present the equations for modeling a fixed beam from which the bending moment, the shear, and the displacement of the beam can be computed, as can the corresponding sensitivity equations. Second, we formulate the optimal design problem and define an optimality function for it. Third, we choose a dense family of finite-dimensional subsets of the design space and obtain discrete counterparts of the equations modeling the beam as well as the corresponding sensitivity equations. Fourth, we formulate the finite-dimensional, approximating optimal design problems and define optimality functions for them. Fifth, we prove that the approximating problems, with their respective optimality functions, constitute a family of consistent approximations for the original problem and its optimality function.

3.1. Mathematical model of the beam. Consider a fixed beam of length $L > 0$ and rectangular cross section with constant width $b > 0$ and variable depth defined by a positive, Lipschitz continuous function $h : [0, L] \to \mathbb{R}$. The material of the beam has modulus of elasticity $E > 0$, and the beam is subjected to a vertical load with density $l(h, \cdot)$ of the form

$$l(h, x) = m(x) - Kh(x), \qquad x \in [0, L], \tag{3.1}$$

where $K \geq 0$ is a given constant and $m(\cdot)$ is the density of an external load applied to the beam. We assume that $m(\cdot)$ is piecewise Lipschitz continuous with finitely many points of discontinuity in $[0, L]$. We model the beam using Euler–Bernoulli beam theory.

We will obtain an expression for the bending moment in a fixed beam by using the bending moment in a similarly loaded cantilever beam and duality theory. For a cantilever beam of length L, depth determined by the function $h(\cdot)$, and subject to the load density $l(h, \cdot)$, the bending moment $M_c(h, \cdot)$ is the unique solution of the final value problem

$$M_c''(h, x) = l(h, x), \quad x \in [0, L]; \quad M_c(h, L) = 0; \quad M_c'(h, L) = 0, \tag{3.2a}$$

where the prime denotes differentiation with respect to x. It is convenient to rewrite (3.2a) as follows:

$$\frac{d}{dx}\begin{bmatrix} M_c(h, x) \\ M_c'(h, x) \end{bmatrix} = \begin{bmatrix} M_c'(h, x) \\ l(h, x) \end{bmatrix}, \quad x \in [0, L]; \quad M_c(h, L) = M_c'(h, L) = 0. \tag{3.2b}$$

The bending moment $M(h, \cdot)$ in a fixed beam of length L, depth determined by the function $h(\cdot)$, and subject to the load density $l(h, \cdot)$ differs from $M_c(h, \cdot)$ only by an affine term in x that is due to the reactions at the support points. Hence we have that

$$M(h, x) = M_c(h, x) + g_1(h)x + g_2(h), \qquad x \in [0, L], \tag{3.2c}$$

where $g_1(h)$ and $g_2(h)$ are reals, depending on h, that can be computed by using a variational formulation. Let

$$S \triangleq \{p \in L_2[0, L] | p(x) = M_c(h, x) + ax + b, a, b \in \mathbb{R}, x \in [0, L]\}.$$

It follows from the dual formulation of the variational problem associated with the bending of the fixed beam (see [13, 21]) that $M(h, \cdot)$ is the minimizer of the convex functional $W(h, \cdot) : S \to \mathbb{R}$ defined by

$$W(h, p) \triangleq \frac{12}{Eb} \int_0^L \frac{p(x)^2}{h(x)^3}\, dx.$$

From (3.2c) and the first-order optimality condition for $W(h, \cdot)$ we conclude that the vector $g(h) \triangleq [g_1(h) g_2(h)]^T$ satisfies

$$\begin{bmatrix} \int_0^L \frac{x^2}{h(x)^3}\, dx & \int_0^L \frac{x}{h(x)^3}\, dx \\ \int_0^L \frac{x}{h(x)^3}\, dx & \int_0^L \frac{1}{h(x)^3}\, dx \end{bmatrix} \begin{bmatrix} g_1(h) \\ g_2(h) \end{bmatrix} = \begin{pmatrix} -\int_0^L \frac{M_c(h, x)x}{h(x)^3}\, dx \\ -\int_0^L \frac{M_c(h, x)}{h(x)^3}\, dx \end{pmatrix}. \tag{3.2d}$$

The shear force at $x \in [0, L]$ is given by

$$V(h, x) = -M'(h, x) = -M_c'(h, x) - g_1(h), \qquad x \in [0, L], \tag{3.2e}$$

and the deflection of the beam $y(h, \cdot)$ is the solution of the initial value problem

$$\frac{d}{dx}\begin{bmatrix} y(h,x) \\ y'(h,x) \end{bmatrix} = \begin{bmatrix} y'(h,x) \\ 12M(h,x)/Ebh(x)^3 \end{bmatrix}, x \in [0, L], y(h,0) = y'(h,0) = 0. \tag{3.2f}$$

For design purposes we assume that the depth function is an element of the set

$$H_{\text{ad}} \triangleq \{h \in C[0, L] | 0 < \alpha \leq h(x) \leq \beta, |dh(x)/dx| \leq \gamma, \text{ for a.e. } x \in [0, L]\}, \tag{3.3}$$

where $0 < \alpha < \beta < \infty$ and $\gamma \geq 0$ are given constants and $C[0, L]$ is the space of continuous real-valued functions defined on $[0, L]$.

The "natural" norm on $C[0, L]$ for establishing continuity and differentiability of solutions of (3.2b)–(3.2f) with respect to depth functions $h(\cdot)$ is the sup-norm $\|\cdot\|_\infty$. However, when we define optimality functions for our design problems, by extension of optimality functions for problems defined on $\mathbb{R}^n$, which is a Hilbert space, it is much more natural to use the $L_2[0, L]$ norm $\|\cdot\|_2$. Hence, we will work in the inner product space $(C[0, L], \|\cdot\|_2, \langle\cdot, \cdot\rangle_2)$, where $\langle\cdot, \cdot\rangle_2$ denotes the usual inner product on $L_2[0, L]$.

DEFINITION 3.1. *Let $(V, \|\cdot\|_V)$ be a normed space, and let $\zeta : H_{\text{ad}} \subset (C[0, L], \|\cdot\|_2, \langle\cdot, \cdot\rangle_2) \to (V, \|\cdot\|_V)$. We will say that*

(a) *$\zeta(\cdot)$ is Lipschitz continuous relative to H_{ad} if there exists a $C \in (0, \infty)$ such that for all $h, h' \in H_{\text{ad}}$*

$$\|\zeta(h) - \zeta(h')\|_V \leq C\|h - h'\|_2; \tag{3.4a}$$

(b) *$\zeta(\cdot)$ is differentiable relative to H_{ad} if for any $h \in H_{\text{ad}}$ there exists a map $D\zeta(h; \cdot) \in \mathsf{L}(C[0, L], V)$ (the space of continuous linear maps from $(C[0, L], \|\cdot\|_2, \langle\cdot, \cdot\rangle_2)$ into $(V, \|\cdot\|_V)$), called the H_{ad}-derivative of $\zeta(\cdot)$ at h, such that*

$$\lim_{\substack{h' \in H_{\text{ad}} \\ \|h'-h\|_2 \to 0}} \frac{\|\zeta(h') - \zeta(h) - D\zeta(h; h' - h)\|_V}{\|h' - h\|_2}; \tag{3.4b}$$

(c) *$\zeta(\cdot)$ is Lipschitz continuously differentiable relative to H_{ad} if it is differentiable relative to H_{ad}, and the mapping $h \in H_{\text{ad}} \mapsto D\zeta(h, \cdot) \in \mathsf{L}(C[0, L], V)$ is Lipschitz continuous relative to H_{ad}.*

It can be deduced from the results in [3] that the mappings $h \mapsto M_c(h, \cdot)$, and $h \mapsto M_c'(h, \cdot)$ from $H_{\text{ad}} \subset (C[0, L], \|\cdot\|_2, \langle\cdot, \cdot\rangle_2)$ into $(C[0, L], \|\cdot\|_\infty)$ are Lipschitz continuously differentiable relative to H_{ad}. Their H_{ad}-derivatives are denoted by $D_1M_c'(h, \cdot; \cdot)$ and $D_1M_c(h, \cdot; \cdot)$, respectively.

Let $A(h)$ denote the matrix on the left-hand side of (3.2d), and let $b(h)$ denote the vector on the right-hand side of (3.2d) so that, abstractly, (3.2d) becomes $A(h)g(h) = b(h)$. To establish differentiability of the mapping $h \mapsto g(h)$ we need the following result.

LEMMA 3.2. *There exist constants $c, C \in (0, \infty)$ such that for all $h \in H_{\text{ad}}$ and $w \in \mathbb{R}^2$ we have*

$$c\|w\|^2 \leq w^T A(h)w \leq C\|w\|^2. \tag{3.5a}$$

The proof of Lemma 3.2 can be found in the appendix.

It can be easily seen that each entry of $A(h)$ and $b(h)$ is Lipschitz continuously differentiable relative to H_{ad}. We denote their H_{ad}-derivatives by $DA(h; \cdot)$ and $Db(h; \cdot)$. It follows from (3.2d) and Lemma 3.2 that the mapping $h \in H_{\text{ad}} \mapsto g(h) \in \mathbb{R}^2$ is also Lipschitz continuously differentiable relative to H_{ad}. Hence, (3.2c), (3.2e), and (3.2f) imply

$h \mapsto M(h, \cdot)$, $h \mapsto V(h, \cdot)$, and $h \mapsto y(h, \cdot)$, all mapping $H_{\text{ad}} \subset (C[0, L], \|\cdot\|_2, \langle \cdot, \cdot \rangle_2)$ into $(C[0, L], \|\cdot\|_\infty)$, are Lipschitz continuously differentiable relative to H_{ad}. We denote their H_{ad}-derivatives at h by $Dg(h; \cdot)$, $D_1 M(h, \cdot; \cdot)$, $D_1 V(h, \cdot; \cdot)$, and $D_1 y(h, \cdot; \cdot)$, respectively.

Given $h, h' \in H_{\text{ad}}$, let $\delta h \triangleq h' - h$. It can be shown, using (3.1) and (3.2b)–(3.2f), that the following relations hold:

$$\text{(3.5b)} \qquad \frac{d}{dx}\begin{bmatrix} D_1 M_c(h, x; \delta h) \\ D_1 M_c'(h, x; \delta h) \end{bmatrix} = \begin{bmatrix} D_1 M_c'(h, x; \delta h) \\ -K \delta h(x) \end{bmatrix}, \quad x \in [0, L],$$

$$\begin{bmatrix} D_1 M_c(h, L; \delta h) \\ D_1 M_c'(h, L; \delta h) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix};$$

$$\text{(3.5c)} \qquad DA(h; \delta h) = -3 \begin{bmatrix} \int_0^L \frac{x^2 \delta h(x)}{h(x)^4}\, dx & \int_0^L \frac{x \delta h(x)}{h(x)^4}\, dx \\ \int_0^L \frac{x \delta h(x)}{h(x)^4}\, dx & \int_0^L \frac{\delta h(x)}{h(x)^4}\, dx \end{bmatrix};$$

$$\text{(3.5d)} \qquad Db(h; \delta h) = \begin{pmatrix} \int_0^L \frac{3M_c(h, x)\delta h(x) - DM_c(h, x; \delta h)h(x)}{h(x)^4} x\, dx \\ \int_0^L \frac{3M_c(h, x)\delta h(x) - DM_c(h, x; \delta h)h(x)}{h(x)^4}\, dx \end{pmatrix};$$

$$\text{(3.5e)} \qquad A(h) Dg(h; \delta h) = Db(h; \delta h) - DA(h; \delta h) g(h);$$

$$\text{(3.5f)} \qquad D_1 M(h, x; \delta h) = D_1 M_c(h, x; \delta h) + Dg_1(h; \delta h)x + Dg_2(h; \delta h), \qquad x \in [0, L];$$

$$\text{(3.5g)} \qquad D_1 V(h, x; \delta h) = -D_1 M_c'(h, x; \delta h) - Dg_1(h; \delta h), \qquad x \in [0, L];$$

$$\frac{d}{dx}\begin{bmatrix} D_1 y(h, x; \delta h) \\ D_1 y'(h, x; \delta h) \end{bmatrix} = \begin{bmatrix} D_1 y'(h, x; \delta h) \\ \frac{12}{Ebh(x)^3}\left(D_1 M(h, x; \delta h) - 3M(h, x)\frac{\delta h(x)}{h(x)} \right) \end{bmatrix}, x \in [0, L];$$

$$\text{(3.5h)} \qquad D_1 y(h, 0; \delta h) = D_1 y'(h, 0; \delta h) = 0.$$

3.2. Formulation of the optimal design problem. We will consider optimal beam design problems with continuum constraints on the shear force, the bending moment, and the deflection. For example, suppose that we wish to minimize the weight or volume of a fixed beam of constant width subject to constraints on the maximum normal stress at the extreme fiber $\sigma_{\max}(h, \cdot)$, on the maximum shear stress $\tau_{\max}(h, \cdot)$, and on the deflection $y(h, \cdot)$ of the form

$$\text{(3.6a)} \qquad |\sigma_{\max}(h, x)| \le a^1, \quad |\tau_{\max}(h, x)| \le a^2, \quad |\sigma_{\max}(h, x)| \le a^3 \quad \forall x \in [0, L],$$

where the a^j's are given positive constants. To obtain a convenient mathematical formulation for this problem we define the cost function as

$$\text{(3.6b)} \qquad f(h) \triangleq \int_0^L h(\tau)\, d\tau;$$

the bounds as $r^1 = r^2 = a^1$, $r^3 = r^4 = a^2$, $r^5 = r^6 = a^3$; and the constraint functions as

$$\text{(3.6c)} \qquad \phi^1(h, x) \triangleq \sigma_{\max}(h, x) = \frac{6}{b}\frac{M(h, x)}{h(x)^2}, \quad \phi^2(h, x) \triangleq -\phi^1(h, x), \qquad x \in [0, L],$$

$$\text{(3.6d)} \qquad \phi^3(h, x) \triangleq \tau_{\max}(h, x) = \frac{3}{2}\frac{V(h, x)}{bh(x)}, \quad \phi^4(h, x) \triangleq -\phi^3(h, x), \qquad x \in [0, L],$$

(3.6e) $$\phi^5(h,x) \triangleq y(h,x), \phi^6(h,x) \triangleq -\phi^5(h,x), \qquad x \in [0,L].$$

In terms of these functions and bounds, the above-described problem becomes

(3.6f) $$\min_{h\in H_{ad}} \left\{ f(h) | \max_{1\le j\le 6} \max_{x\in[0,L]} \phi^j(h,x) - r^j \le 0 \right\}.$$

The above example is a particular case of optimal design problems of the form

(3.7a) $$\mathbf{P} \qquad \min_{h\in H_{ad}} \left\{ f(h) | \max_{j\in\mathbf{q}} \max_{x\in[0,L]} \phi^j(h,x) - r^j(x) \le 0 \right\},$$

where for any integer $q > 0$, $\mathbf{q} \triangleq \{1, 2, \ldots, q\}$ and the functions $f(\cdot)$ and $\phi^j(\cdot,\cdot)$, $j \in \mathbf{q}$, are of the form

(3.7b) $$f(h) = \int_0^L \phi^0(h,x)\,dx,$$

(3.7c) $$\phi^j(h,x) = \tilde{\phi}^j(h(x), M(h,x), V(h,x), y(h,x), x), \qquad j \in \bar{\mathbf{q}},$$

with $M(h,\cdot)$, $V(h,\cdot)$, and $y(h,\cdot)$ determined by (3.2b)–(3.2f) and, for $j \in \bar{\mathbf{q}} \triangleq \{0, 1, \ldots, q\}$, $\tilde{\phi}^j : [\alpha,\beta] \times \mathbb{R} \times \mathbb{R} \times \mathbb{R} \times [0,L] \to \mathbb{R}$.

Assumption 3.3. (a) The functions $r^j(\cdot)$, $j \in \mathbf{q}$, are Lipschitz continuously differentiable on $[0, L]$ and satisfy

(3.8) $$\min_{j\in\mathbf{q}} \min_{x\in[0,L]} r^j(x) = \hat{r} > 0.$$

(b) The functions $\tilde{\phi}^j(\cdot,\cdot,\cdot,\cdot,\cdot)$, $j \in \bar{\mathbf{q}}$, are Lipschitz continuously differentiable.

(c) The feasible set for **P** is nonempty.

Existence of a solution to **P** follows from the Ascoli–Arzelà theorem, which implies that the set H_{ad} is compact in $(C[0,L], \|\cdot\|_2, \langle\cdot,\cdot\rangle_2)$. The proofs of existence of solutions for similar problems can be found in [6, 9, 15].

It follows from (3.7b), (3.7c), and the Lipschitz continuous differentiability of $\tilde{\phi}^j(\cdot,\cdot,\cdot,\cdot,\cdot)$, $j \in \bar{\mathbf{q}}$, with respect to all their arguments and of $M(h,\cdot)$, $V(h,\cdot)$, and $y(h,\cdot)$ with respect to h that $h \mapsto \phi^j(h,\cdot)$, $j \in \bar{\mathbf{q}}$, and $h \mapsto f(h)$ are Lipschitz continuously differentiable functions relative to H_{ad}. We will denote by $D_1\phi^j(h,\cdot;\cdot)$, $j \in \bar{\mathbf{q}}$, and $Df(h;\cdot)$ their H_{ad}-derivatives.

LEMMA 3.4. *There exists a constant* $C \in (0,\infty)$ *such that for any* $h, \tilde{h}, h', h'' \in H_{ad}$,

(3.9a) $$|Df(h;h'-h) - Df(\tilde{h};h''-\tilde{h})| \le C[\|h-\tilde{h}\|_2 + \|h'-h''\|_2]$$

and for all $j \in \bar{\mathbf{q}}$,

(3.9b) $$\|D_1\phi^j(h,\cdot;h'-h) - D_1\phi^j(\tilde{h},\cdot;h''-\tilde{h})\|_\infty \le C[\|h-\tilde{h}\|_2 + \|h'-h''\|_2].$$

Proof. Both inequalities are direct consequences of the Lipschitz continuity relative to H_{ad} of the H_{ad}-derivatives of $h \mapsto M(h,\cdot)$, $h \mapsto V(h,\cdot)$, and $h \mapsto y(h,\cdot)$ and the Lipschitz continuous differentiability of the functions $\tilde{\phi}^j(\cdot,\cdot,\cdot,\cdot,\cdot)$, $j \in \bar{\mathbf{q}}$, in (3.7c). □

We define the constraint violation function $\psi : H_{ad} \to \mathbb{R}$ for **P** by

(3.10a) $$\psi(h) \triangleq \max_{j\in\mathbf{q}} \max_{x\in[0,L]} \phi^j(h,x) - r^j(x)$$

and the surrogate cost function $F : H_{ad} \times H_{ad} \to \mathbb{R}$, suggested by method of centers-type algorithms, by

$$F(h, h') \triangleq \max\{f(h') - f(h) - \omega\psi(h)_+, \max_{j\in\mathbf{q}} \max_{x\in[0,1]} \phi^j(h', x) - r^j(x) - \psi(h)_+\}, \tag{3.10b}$$

where $\psi(h)_+ \triangleq \max\{\psi(h), 0\}$ and $\omega > 0$ is a parameter. Note that (i) for all $h \in H_{ad}$, $F(h, h) = 0$, and (ii) if $\hat{h} \in H_{ad}$ is a local minimizer for **P**, then since $\psi(h) > 0$ when h is infeasible and $f(h) \geq f(\hat{h})$ for all feasible h in a ball about $\hat{h}$, $\hat{h}$ must also be a local minimizer for the surrogate problem

$$\min_{h\in H_{ad}} F(\hat{h}, h). \tag{3.10c}$$

This fact is used in [2] to obtain the following first-order optimality condition for **P**.

PROPOSITION 3.5. *If $\hat{h}$ is a local minimizer for* **P**, *then*

$$\hat{h} \in H_{ad} \text{ and } d_2F(\hat{h}, \hat{h}; h' - \hat{h}) \geq 0 \quad \forall h' \in H_{ad} \tag{3.10d}$$

where $d_2F(\hat{h}, \hat{h}; h' - \hat{h})$ denotes the (one-sided) directional derivative of $F(\cdot, \cdot)$ at $(\hat{h}, \hat{h})$ with respect to the second argument in the direction $h' - \hat{h}$.

Referring to [17], we see that one way to verify whether (3.10d) holds at a given $h \in H_{ad}$ is to define an optimality function $\theta : H_{ad} \to \mathbb{R}$ for **P** based on a *convex*, first-order approximation $\tilde{F}(h, h')$ to $F(h, h')$. Thus we define

$$\begin{aligned}\tilde{F}(h, h') \triangleq \max \Big\{ & Df(h; h' - h) - \omega\psi(h)_+, \\ & \max_{j\in\mathbf{q}} \max_{x\in[0,L]} \phi^j(h, x) + D_1\phi^j(h, x; h' - h) - \psi(h)_+ \Big\} \\ & + \frac{1}{2}\|h' - h\|_2^2\end{aligned} \tag{3.10e}$$

and

$$\theta(h) \triangleq \min_{h'\in H_{ad}} \tilde{F}(h, h'). \tag{3.11}$$

THEOREM 3.6. (a) *The function $\theta(\cdot)$ is well defined and takes values in $(-\infty, 0]$.*

(b) *$\theta : H_{ad} \to \mathbb{R}$ is upper semicontinuous.*

(c) *For any $\hat{h} \in H_{ad}$, $\theta(\hat{h}) = 0$ if and only if* either *$\psi(\hat{h}) \leq 0$ and* (3.10d) *holds* or *$\psi(\hat{h}) > 0$ and $0 \in \partial\psi(\hat{h})$, where $\psi(\hat{h})$ denotes the Clarke generalized gradient* [2] *of $\psi(\cdot)$ at $\hat{h}$ (i.e., $\hat{h}$ satisfies the first-order optimality condition for the problem $\min_{h\in H_{ad}} \psi(h)$).*

Proof. We start by showing that $\theta(\cdot)$ is well defined. In view of (3.7b), (3.7c), and Assumption 3.3(b), it should be clear that for all $j \in \bar{\mathbf{q}}$ and $x \in [0, L]$ the mappings $h \mapsto \phi^j(h, x)$ and $h \mapsto \psi(h)$ are continuous on H_{ad}. Hence, as a consequence of the definition of $\tilde{F}(\cdot, \cdot)$, (3.9a), and (3.9b) we have that $\tilde{F} : H_{ad} \times H_{ad} \to \mathbb{R}$ is continuous. Since $H_{ad} \subset (C[0, L], \|\cdot\|_2, \langle\cdot, \cdot\rangle)$ is compact (by the Ascoli–Arzelà theorem), it follows from (3.11) that $\theta(\cdot)$ is well defined.

The fact that $\theta(\cdot)$ takes values in $(-\infty, 0]$, and part (c) can be deduced from Propositions 5.4 and 5.5 in [17]. We now prove part (b).

Suppose $\{h_j\}_{j=0}^{\infty} \subset H_{ad}$ is such that $h_j \to h \in H_{ad}$ as $j \to \infty$. Let $h' \in H_{ad}$ be such that $\theta(h) = \tilde{F}(h, h')$. Then

$$\theta(h_j) \leq \tilde{F}(h_j, h') \quad \forall j \in \mathbb{N}. \tag{3.12a}$$

Hence, taking $\overline{\lim}$ on both sides and using the continuity of $\tilde{F}(\cdot, \cdot)$, we get

$$\overline{\lim_{j\to\infty}}\ \theta(h_j) \leq \overline{\lim_{j\to\infty}}\ \tilde{F}(h_j, h') = \tilde{F}(h, h') = \theta(h). \tag{3.12b}$$

COROLLARY 3.7. *$\theta(\cdot)$ is an optimality function for* $\mathbf{P}$.

3.3. Choice of finite-dimensional subsets of H_{ad} and discretization of the beam equations. According to the theory in §2, to define approximating problems $\mathbf{P}_N$ we must begin by selecting a family of finite-dimensional subspaces of $C[0, L]$. We specify these subspaces by constructing basis sets for them.

For every integer $N > 0$ we let $\Delta_N \triangleq L/N$ and define the mesh $T_N \triangleq \{0, \Delta_N, 2\Delta_N, \ldots, L\}$ with nodes $x_{N,k} = (k-1)\Delta_N$, $k \in \mathbf{N+1}$.

Let

$$P_{N,k}(x) \triangleq \begin{cases} \dfrac{x - x_{N,k-1}}{\Delta_N} & \forall x \in [x_{N,k-1}, x_{N,k}],\ k \in \{2, \cdots, N+1\}; \\ \dfrac{x_{N,k+1} - x}{\Delta_N} & \forall x \in [x_{N,k}, x_{N,k+1}],\ k \in \mathbf{N}; \\ 0 & \text{otherwise.} \end{cases} \tag{3.13a}$$

We denote by H_N the span of the basis set $\{P_{N,k}\}_{k=1}^{N+1}$. Clearly, H_N is a subspace of $C[0, L]$, and for each $h \in H_{\text{ad},N}$ there exists a unique $(\eta_1, \eta_2, \ldots, \eta_{N+1})^T \in \mathbb{R}^{N+1}$ such that

$$h(x) = \sum_{k=1}^{N+1} \eta_k P_{N,k}(x), \qquad x \in [0, L]. \tag{3.13b}$$

We let $H_{\text{ad},N} \triangleq H_N \cap H_{\text{ad}}$.

Next, we discretize the equations describing the behavior of the beam. We will use Euler's method to discretize the initial value problem (3.2f) and the final value problem (3.2b) and the rectangle rule to approximate the integrals in (3.2d). The choice of this simple discretization scheme is motivated by the fact that, in the context of optimal design problems, it is not clear whether using higher order integration schemes is more efficient. To see this consider an unconstrained optimal design problem $\mathbf{P}_u$ defined over H_{ad} and a sequence of approximating problems $\mathbf{P}_{u,N}$ defined over $H_{\text{ad},N}$ and obtained by discretizing $\mathbf{P}_u$. We assume that to define the $\mathbf{P}_{u,N}$ one uses an integration scheme of order $r \geq 1$ to discretize the differential equations and the integrals defining $\mathbf{P}_u$. Let $f^0(\cdot)$ and $f_N^0(\cdot)$ be the cost functions for $\mathbf{P}_u$ and $\mathbf{P}_{u,N}$, respectively. Then one can show, under appropriate assumptions, that there exists a $K \in (0, \infty)$ such that for all N

$$-K[\Delta_N + \Delta_N^r] \leq f^0(\hat{h}) - f_N^0(\hat{h}_N) \leq K\Delta_N, \tag{3.13c}$$

where $\hat{h}$ is the minimizer of $\mathbf{P}_u$ and $\hat{h}_N$ is the minimizer of $\mathbf{P}_{u,N}$. The term $-K\Delta_N$ in the left-hand side of (3.13c) is due to the replacement of H_{ad} by $H_{\text{ad},N}$, while the term $-K\Delta_N^r$ is due to the replacement of the differential equations and integrals by discrete counterparts arising from the use of an rth-order integration method. Hence, if we use a first-order method (i.e., $r = 1$) according to (3.13c) the uncertainty interval in the computation of the optimal value is of length $3K\Delta_N$. As $r \to \infty$, the length of the interval of uncertainty decreases to $K\Delta_N$. Hence we see that the difference between the optimal cost of the approximating problem and that of the original problem is of order $O(\Delta_N)$ regardless of the accuracy of the integration method used. Therefore, it is not clear that much is gained by using the

more computationally intensive higher order integration methods to solve optimal design methods.

Let $M_N(h, x_{N,k})$, $V_N(h, x_{N,k})$, and $y_N(h, x_{N,k})$, $k \in \mathbf{N+1}$, denote the discrete bending moment, the discrete shear force, and the discrete deflection, respectively, defined by the recursions

$$\begin{aligned} \begin{bmatrix} M_{c,N}(h, x_{N,k}) \\ M'_{c,N}(h, x_{N,k}) \end{bmatrix} &= \begin{bmatrix} M_{c,N}(h, x_{N,k+1}) - \Delta_N M'_{c,N}(h, x_{N,k+1}) \\ M_{c,N}(h, x_{N,k+1}) - \Delta_N l(h, x_{N,k+1}) \end{bmatrix}, \qquad k \in \mathbf{N}, \\ \begin{bmatrix} M_{c,N}(h, x_{N,N+1}) \\ M'_{c,N}(h, x_{N,N+1}) \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix}; \end{aligned} \tag{3.14a}$$

$$\begin{bmatrix} \sum_{j=1}^{N} \frac{(j-1)^2 \Delta_N^3}{h(x_{N,j})^3} & \sum_{j=1}^{N} \frac{(j-1)\Delta_N^2}{h(x_{N,j})^3} \\ \sum_{j=1}^{N} \frac{(j-1)\Delta_N^2}{h(x_{N,j})^3} & \sum_{j=1}^{N} \frac{\Delta_N}{h(x_{N,j})^3} \end{bmatrix} \begin{bmatrix} g_{1,N}(h) \\ g_{2,N}(h) \end{bmatrix} = \begin{pmatrix} -\sum_{j=1}^{N} \frac{(j-1)\Delta_N^2}{h(x_{N,j})^3} M_{c,N}(h, x_{N,j}) \\ -\sum_{j=1}^{N} \frac{\Delta_N}{h(x_{N,j})^3} M_{c,N}(h, x_{N,j}) \end{pmatrix}; \tag{3.14b}$$

$$M_N(h, x_{N,k}) = M_{c,N}(h, x_{N,k}) + g_{1,N}(h) x_{N,k} + g_{2,N}(h), \qquad k \in \mathbf{N+1}; \tag{3.14c}$$

$$V_N(h, x_{N,k}) = -M'_{c,N}(h, x_{N,k}) - g_{1,N}(h), \qquad k \in \mathbf{N+1}; \tag{3.14d}$$

and, for $k \in \mathbf{N}$,

$$\begin{aligned} \begin{bmatrix} y_N(h, x_{N,k+1}) \\ y'_N(h, x_{N,k+1}) \end{bmatrix} &= \begin{bmatrix} y_N(h, x_{N,k}) + \Delta_N y'_N(h, x_{N,k}) \\ y'_N(h, x_{N,k}) + \Delta_N \frac{12 M_N(h, x_{N,k})}{E b h(x_{N,k})^3} \end{bmatrix}, \\ \begin{bmatrix} y_N(h, x_{N,1}) \\ y'_N(h, x_{N,1}) \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix}. \end{aligned} \tag{3.14e}$$

Let $A_N(h)$ denote the matrix on the left-hand side of (3.14b), and let $b_N(h)$ denote the vector on the right-hand side of (3.14b) so that, abstractly, (3.14b) becomes $A_N(h) g_N(h) = b_N(h)$.

LEMMA 3.8. *There exist constants* $c, C \in (0, \infty)$ *such that for all* $N \geq 1$, $h \in H_{ad,N}$, *and* $w \in \mathbb{R}^2$, *we have*

$$c\|w\|^2 \leq w^T A_N(h) w \leq C\|w\|^2. \tag{3.15}$$

The proof of Lemma 3.8 is similar to that of Lemma 3.2 and hence we omit it.

It follows from the implicit function theorem (see, e.g., [14]) that the maps $h \mapsto M_{c,N}(h, \cdot)$, $h \mapsto M'_{c,N}(h, \cdot)$ from $H_{ad,N}$ into $\mathbb{R}^{N+1}$ are Lipschitz continuously differentiable. Lipschitz continuous differentiablity of the map $h \mapsto g_N(h)$ from $H_{ad,N}$ into $\mathbb{R}^2$ and the maps $h \mapsto M_N(h, \cdot)$, $h \mapsto V_N(h, \cdot)$, and $h \mapsto y_N(h, \cdot)$ from $H_{ad,N}$ into $\mathbb{R}^{N+1}$ follows from the Implicit Function Theorem, (3.14b)–(3.14e), and from Lemma 3.8.

Given $h, h' \in H_{ad,N}$, let $\delta h \triangleq h' - h$. One can show, by differentiating (3.14a)–(3.14e), that

$$\begin{bmatrix} D_1 M_{c,N}(h, x_{N,k}; \delta h) \\ D_1 M'_{c,N}(h, x_{N,k}; \delta h) \end{bmatrix} = \begin{bmatrix} D_1 M_{c,N}(h, x_{N,k+1}; \delta h) - \Delta_N D_1 M'_{c,N}(h, x_{N,k+1}; \delta h) \\ D_1 M_{c,N}(h, x_{N,k+1}; \delta h) - \Delta_N K \delta h(x_{N,k+1}) \end{bmatrix}, \qquad k \in \mathbf{N},$$

$$D_1 M'_{c,N}(h, x_{N,N+1}; \delta h) = D_1 M_{c,N}(h, x_{N,N+1}; \delta h) = 0; \tag{3.16a}$$

(3.16b) $$DA_N(h_N;\delta h) = -3\begin{bmatrix} \sum_{j=1}^{N}\frac{(j-1)^2\Delta_N^3\delta h(x_{N,j})}{h_N(x_{N,j})^4} & \sum_{j=1}^{N}\frac{(j-1)\Delta_N^2\delta h(x_{N,j})}{h_N(x_{N,j})^4} \\ \sum_{j=1}^{N}\frac{(j-1)\Delta_N^2\delta h(x_{N,j})}{h_N(x_{N,j})^4} & \sum_{j=1}^{N}\frac{\Delta_N\delta h(x_{N,j})}{h_N(x_{N,j})^4} \end{bmatrix};$$

(3.16c)
$$Db_N(h_N;\delta h) = \begin{pmatrix} -\sum_{j=1}^{N}(j-1)\Delta_N^2\left[\frac{DM_{c,N}(h_N,x_{N,j};\delta h)}{h_N(x_{N,j})^3} - \frac{3M_{c,N}(h_N,x_{N,j})}{h_N(x_{N,j})^4}\delta h(x_{N,j})\right] \\ -\sum_{j=1}^{N}\Delta_N\left[\frac{DM_{c,N}(h_N,x_{N,j};\delta h)}{h_N(x_{N,j})^3} - \frac{3M_{c,N}(h_N,x_{N,j})}{h_N(x_{N,j})^4}\delta h(x_{N,j})\right] \end{pmatrix};$$

(3.16d) $$A_N(h_N)Dg_N(h_N;\delta h) = Db_N(h_N;\delta h) - DA_N(h_N;\delta h)g_N(h_N);$$

(3.16e)
$$D_1M_N(h,x_{N,k};\delta h) = D_1M_{c,N}(h,x_{N,k};\delta h)+Dg_{1,N}(h;\delta h)x_{N,k}+Dg_{2,N}(h;\delta h), \quad k\in\mathbf{N+1};$$

(3.16f) $$D_1V_N(h,x_{N,k};\delta h) = -D_1M'_N(h,x_{N,k};\delta h) - Dg_{1,N}(h;\delta h), \qquad k\in\mathbf{N+1};$$

and $D_1y_N(h,x_{N,k};\delta h) = \delta y_N(h,x_{N,k})$, $k\in\mathbf{N+1}$, where $\delta y_N(h,x_{N,k})$ is the solution of

$$\begin{bmatrix}\delta y_{k+1}\\ \delta y'_{k+1}\end{bmatrix} = \begin{bmatrix} \delta y_k + \Delta_N\delta y'_k \\ \delta y'_k + \frac{12\Delta_N}{Ebh(x_{N,k})^3}\left(D_1M_N(h,x_{N,k};\delta h) - \frac{3M_N(h,x_{N,k})}{h(x_{N,k})}\delta h(x_{N,k})\right)\end{bmatrix}, \quad k\in\mathbf{N},$$

(3.16g) $$\delta y_1 = \delta y'_1 = 0.$$

3.4. Formulation of the approximating problems. We now define the family of approximating problems $\mathbf{P}_N$, $N = 1, 2, \ldots$, as

(3.17a) $\mathbf{P}_N$
$$\min_{h\in H_{ad,N}}\left\{f_N(h)\,|\,\max_{j\in\mathbf{q}}\max_{k\in\mathbf{N+1}}\phi_N^j(h,x_{N,k}) - (1+\Delta_N^{1/2})r^j(x_{N,k})\le 0\right\},$$

where

(3.17b) $$f_N(h)\triangleq\sum_{k=1}^{N}\phi_N^0(h,x_{N,k})\Delta_N,$$

(3.17c) $$\phi_N^j(h,x_{N,k}) = \tilde{\phi}^j(h(x_{N,k}),M_N(h,x_{N,k}),V_N(h,x_{N,k}),y_N(h,x_{N,k}),x_{N,k}), \quad j\in\bar{\mathbf{q}}.$$

Equation (3.17c) defines the functions $\phi_N^j(h,\cdot)$, $j\in\bar{\mathbf{q}}$, only on the mesh points $x_{N,k}$, $k\in\mathbf{N+1}$. We define the functions $\phi_N^j(h,\cdot):[0,L]\to\mathbb{R}$ as the piecewise affine interpolation of the values $\phi_N^j(h,x_{N,k})$, $k\in\mathbf{N+1}$.

The term $\Delta_N^{1/2}$ in (3.17a) is added to guarantee that for N large enough the feasible set for $\mathbf{P}_N$ is nonempty. This relaxation of the constraints will be needed in the proof of Theorem 3.10(a).

It follows from (3.17c) and Assumption 3.3(b) that the functions $\phi_N^j(\cdot,\cdot)$, $j\in\bar{\mathbf{q}}$, are Lipschitz continuously differentiable on $H_{ad,N}$. The derivatives of the mappings $h\mapsto\phi_N^j(h,\cdot)$, $j\in\bar{\mathbf{q}}$, and $h\mapsto f(h)$, which we denote by $D_1\phi_N^j(h,\cdot;\cdot)$ and $Df_N(h;\cdot)$, are easily obtained from (3.17b), (3.17c) and (3.16a)–(3.16g) by applying the chain rule.

Next, we define the constraint violation function $\psi_N : H_{ad,N}\to\mathbb{R}$ for $\mathbf{P}_N$ and the surrogate cost $F_N : H_{ad,N}\times H_{ad,N}\to\mathbb{R}$ by

$$\psi_N(h) \triangleq \max_{j\in\mathbf{q}} \max_{k\in\mathbf{N+1}} \phi_N^j(h, x_{N,k}) - (1 + \Delta_N^{1/2}) r^j(x_{N,k}), \tag{3.18a}$$

(3.18b)

$$F_N(h, h') \triangleq \max \left\{ f_N(h') - f_N(h) - \omega\psi_N(h)_+, \max_{j\in\mathbf{q}} \max_{k\in\mathbf{N+1}} \phi_N^j(h', x_{N,k}) - \psi_N(h)_+ \right\}.$$

Any local minimizer $\hat{h} \in H_{\mathrm{ad},N}$ of $\mathbf{P}_N$ is also a local minimizer of $F_N(\hat{h}, \cdot)$ on $H_{\mathrm{ad},N}$, and hence it satisfies the optimality condition

$$\hat{h} \in H_{\mathrm{ad},N} \text{ and } d_2 F_N'(\hat{h}, \hat{h}; h' - \hat{h}) \geq 0 \quad \forall h' \in H_{\mathrm{ad},N}. \tag{3.19}$$

Following the pattern set in §3.2 we define an optimality function $\theta_N : H_{\mathrm{ad},N} \to \mathbb{R}$ based on a *convex*, first-order approximation $\tilde{F}_N(h, h')$ of $F_N(h, h')$ defined by

$$\tilde{F}_N(h, h') \triangleq \max \left\{ Df_N(h; h' - h) - \omega\psi_N(h)_+, \right.$$

$$\left. \max_{j\in\mathbf{q}} \max_{k\in\mathbf{N+1}} \phi_N^j(h, x_{N,k}) - \psi_N(h)_+ + D_1\phi_N^j(h, x_{N,k}; h' - h) \right\} \tag{3.20a}$$

$$+ \frac{1}{2}\|h' - h\|_2^2,$$

$$\theta_N(h) \triangleq \min_{h'\in H_{\mathrm{ad},N}} \tilde{F}_N(h, h'). \tag{3.20b}$$

It is not difficult to show, using (3.20a), that $\theta_N(h)$ can be computed by solving a positive definite quadratic program. An evaluation of $\theta_N(h)$ provides a computational method for checking whether $h \in H_{\mathrm{ad},N}$ satisfies the basic optimality condition (3.19).

Results analogous to Theorem 3.6 and Corollary 3.7 hold for $\theta_N(\cdot)$.

3.5. Epiconvergence and consistency of approximations. We start by establishing some results relating the functions defining $\mathbf{P}$ with those defining $\mathbf{P}_N$. The proof of the following lemma is given in the appendix.

LEMMA 3.9. (a) *For every $h \in H_{\mathrm{ad}}$, and every integer $N \geq 1$, there exists an $h_N \in H_{\mathrm{ad},N}$ such that*

$$\max_{x\in[0,L]} |h(x) - h_N(x)| \leq \gamma\Delta_N. \tag{3.21a}$$

(b) *There exists a constant $C \in (0, \infty)$ such that for all $j \in \bar{\mathbf{q}}$, $N \geq 1$, $h \in H_{\mathrm{ad}}$, and $h_N \in H_{\mathrm{ad},N}$,*

$$\max_{x\in[0,L]} |\phi^j(h, x) - \phi_N^j(h_N, x)| \leq C[\Delta_N + \|h - h_N\|_2], \tag{3.21b}$$

$$|\psi(h) - \psi_N(h_N)| \leq C[\Delta_N^{1/2} + \|h - h_N\|_2], \tag{3.21c}$$

$$|f(h) - f_N(h_N)| \leq C[\Delta_N + \|h - h_N\|_2]. \tag{3.21d}$$

In view of the definitions of $\psi(h)$ and $\psi_N(h)$, it is clear that the feasible sets $\mathbf{Z}$ and $\mathbf{Z}_N$ for $\mathbf{P}$ and $\mathbf{P}_N$ are given by

$$\mathbf{Z} = \{h \in H_{\mathrm{ad}} | \psi(h) \leq 0\}, \qquad \mathbf{Z}_N = \{h \in H_{\mathrm{ad},N} | \psi_N(h) \leq 0\}. \tag{3.21e}$$

THEOREM 3.10 (epiconvergence). (a) *For every $h \in \mathbf{Z}$, there exists a sequence $\{h_N\}_{N=N_0}^{\infty}$, with $h_N \in \mathbf{Z}_N$, such that $f_N(h_N) \to f(h)$ as $N \to \infty$.* (b) *Let $\{h_N\}_{N=N_0}^{\infty}$ be a sequence such that $h_N \in \mathbf{Z}_N$ and $h_N \to \hat{h}$ as $N \to \infty$; then $\hat{h} \in \mathbf{Z}$, and $f_N(h_N) \to f(\hat{h})$.*

Proof. Suppose $h \in \mathbf{Z}$ is given. Then, by Lemma 3.9(a), for each integer N there exists an $h_N \in H_{\text{ad},N}$ such that (3.21a) holds. Clearly, $h_N \to h$ as $N \to \infty$. It follows from (3.21d) that $f_N(h_N) \to f(h)$ as $N \to \infty$. To complete the proof of part (a) it remains to show that there exists an N_0 such that $h_N \in \mathbf{Z}_N$ for all $N \geq N_0$. Indeed, since $h \in \mathbf{Z}$ by assumption we have $\psi(h) \leq 0$. Hence, using (3.21b) and (3.21a) we obtain

$$
\begin{aligned}
\psi_N(h_N) &\leq \psi_N(h_N) - \psi(h) \\
&= \max_{j \in \mathbf{q}} \max_{x \in [0,L]} [\phi_N^j(h_N, x) - r^j(x)(1 + \Delta_N^{1/2})] - \max_{j \in \mathbf{q}} \max_{x \in [0,L]} [\phi^j(h, x) - r^j(x)] \\
&\leq \max_{j \in \mathbf{q}} \max_{x \in [0,L]} [|\phi_N^j(h_N, x) - \phi^j(h, x)| - r^j(x)\Delta_N^{1/2}] \qquad (3.22) \\
&\leq C[\Delta_N + \|h - h_N\|_2] - \hat{r}\Delta_N^{1/2} \leq C[\Delta_N + \|h - h_N\|_\infty] - \hat{r}\Delta_N^{1/2} \\
&\leq C(1 + \gamma)\Delta_N - \hat{r}\Delta_N^{1/2},
\end{aligned}
$$

where $\hat{r} > 0$ is as in (3.8). It follows from (3.22) that there exists an N_0 such that for all $N \geq N_0$, $\psi_N(h_N) \leq 0$, which proves (a).

Let $\{h_N\}_{N=N_0}^\infty$ be a sequence as in (b). Since H_{ad} is closed and $\mathbf{Z}_N \subset H_{\text{ad},N} \subset H_{\text{ad}}$ for all $N \in \mathbb{N}$, it follows that $\hat{h} \in H_{\text{ad}}$. The facts that $\hat{h} \in \mathbf{Z}$, that is, that $\psi(\hat{h}) \leq 0$, and that $f_N(h_N) \to f(\hat{h})$ follow directly from (3.21c) and (3.21d), respectively. □

Next, we establish approximation results relating the derivatives of the functions defining $\mathbf{P}$ and $\mathbf{P}_N$.

LEMMA 3.11. *There exists a constant $C < \infty$ such that for all positive integers N and h, $h' \in H_{\text{ad},N}$,*

$$
|Df(h; h' - h) - Df_N(h; h' - h)| \leq C\Delta_N \|h' - h\|_2, \qquad (3.23a)
$$

$$
\max_{k \in \mathbf{N+1}} |D_1\phi^j(h, x_{N,k}; h' - h) - D_1\phi_N^j(h, x_{N,k}; h' - h)| \leq C\Delta_N \|h' - h\|_2. \qquad (3.23b)
$$

Lemma 3.11 is proved in the appendix.

LEMMA 3.12. *There exists a constant $C \in (0, \infty)$ such that for all positive integers N and h, $h' \in H_{\text{ad},N}$,*

$$
|\tilde{F}(h, h') - \tilde{F}_N(h, h')| \leq C\Delta_N^{1/2}. \qquad (3.24)
$$

Lemma 3.12 follows from the boundedness of $H_{\text{ad},N}$, (3.21c), and (3.21d), the definitions of $\tilde{F}(\cdot, \cdot)$ and $\tilde{F}_N(\cdot, \cdot)$ in (3.10e) and (3.20a), respectively, and Lemma 3.11.

THEOREM 3.13. *Suppose that $\{h_N\}_{N=N_0}^\infty$, with $h_N \in H_{\text{ad},N}$, is such that $h_N \to h$ as $N \to \infty$. Then $h \in H_{\text{ad}}$ and $\overline{\lim}_{N \to \infty} \theta_N(h_N) \leq \theta(h)$.*

Proof. Let $h' \in H_{\text{ad}}$ be such that $\theta(h) = \tilde{F}(h, h')$. Let $\{h'_N\}_{N=N_0}^\infty$ be such that $h'_N \in H_{\text{ad},N}$ and $h'_N \to h'$ as $N \to \infty$. Then we have

$$
\theta_N(h_N) \leq \tilde{F}_N(h_N, h'_N) \leq \tilde{F}(h_N, h'_N) + C\Delta_N^{1/2}, \qquad (3.25a)
$$

where we made use of Lemma 3.12 to obtain the last inequality. Hence, taking $\overline{\lim}$ on both sides and using the fact that $\tilde{F}(\cdot, \cdot)$ is continuous, we obtain

$$
\overline{\lim_{N \to \infty}}\, \theta_N(h_N) \leq \overline{\lim_{N \to \infty}}\, \tilde{F}(h_N, h'_N) = \tilde{F}(h, h') = \theta(h). \qquad (3.25b)
$$

COROLLARY 3.14. *The sequence $\{(\mathbf{P}_N, \theta_N)\}_{N=1}^\infty$ is a family of weakly consistent approximations to the pair $(\mathbf{P}, \theta)$. Furthermore, if for all $h \in H_{\text{ad}}$ such that $\psi(h) > 0$, $0 \notin \partial\psi(h)$, then $\{(\mathbf{P}_N, \theta_N)\}_{N=1}^\infty$ is a family of consistent approximations to $(\mathbf{P}, \theta)$.*

4. Transcription of $\mathbf{P}_N$ into a nonlinear programming problem. We will now establish a transcription of the problem $\mathbf{P}_N$, which is defined on the finite-dimensional subspace $H_N \subset C[0, L]$, into an equivalent nonlinear programming problem, $\bar{\mathbf{P}}_N$, defined on $\mathbb{R}^{N+1}$. Given any $h \in H_N$ there exists a unique vector $\eta = (\eta_1, \ldots, \eta_{N+1})^T \in \mathbb{R}^{N+1}$ satisfying (3.13b). In fact, in view of (3.13a), we have that $\eta_k = h(x_{N,k})$, $k \in \mathbf{N+1}$. Let the mapping $W_N : H_N \to \mathbb{R}^{N+1}$ be defined by

$$W_N(h) \triangleq (\eta_1, \eta_2, \ldots, \eta_{N+1})^T. \tag{4.1a}$$

Clearly, W_N is a bijection and the components of $\eta \in \mathbb{R}^{N+1}$ are the coordinates of $h \in H_N$ with respect to the basis set $\{P_{N,k}(\cdot)\}_{k=1}^{N+1}$. Since the basis set $\{P_{N,i}(\cdot)\}_{i=1}^{N+1}$ is not orthonormal, given a vector $h(\cdot) = \sum_{i=1}^{N+1} \eta_i P_{N,i}(\cdot) \in H_N$, it is *not true* that $\|h\|_2^2 = \sum_{i=1}^{N+1} \eta_i^2 \triangleq \|W_N(h)\|^2$; i.e., $W_N(\cdot)$ is not an isometry. Now suppose that we define the problem $\bar{\mathbf{P}}_N$ using the map $W_N(\cdot)$ and try to solve P_N by solving $\bar{\mathbf{P}}_N$, using a nonlinear programming algorithm, without taking into account the fact that W_N is not an isometry. Then it turns out that we are trying to solve the problem $\mathbf{P}_N$ using a nonlinear programming algorithm with a modified metric. As is well known, changing the metric can cause the performance of nonscale invariant algorithms to deteriorate considerably.

To compute in $\mathbb{R}^{N+1}$, using a metric that is equivalent to the one on H_N one can either modify existing nonlinear programming software, something not easily undertaken when using a standard library of programs, or define the $\bar{\mathbf{P}}_N$ in terms of coordinates corresponding to an orthonormal basis. Problems $\bar{\mathbf{P}}_N$ thus defined can be solved by standard nonlinear programming algorithms, in the space of coordinates corresponding to this basis, without incurring penalties due to induced ill-conditioning.

We will now show how to define $\bar{\mathbf{P}}_N$ in terms of coordinates corresponding to an orthonormal basis for H_N.

Let $Q_N \in \mathbb{R}^{(N+1)\times(N+1)}$ be such that

$$(Q_N)_{ij} \triangleq \int_0^L P_{N,i}(x) P_{N,j}(x)\, dx, \tag{4.1b}$$

where for any matrix $A \in \mathbb{R}^{(N+1)\times(N+1)}$, A_{ij} denotes the i,jth entry of A. One can verify that

$$Q_N = \frac{\Delta_N}{6} \begin{bmatrix} 2 & 1 & 0 & \cdot & \cdot & \cdot & 0 \\ 1 & 4 & 1 & 0 & \cdot & \cdot & 0 \\ 0 & 1 & 4 & 1 & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & \cdot & \cdot & \cdot & 1 & 4 & 1 \\ 0 & \cdot & \cdot & \cdot & \cdot & 1 & 2 \end{bmatrix}. \tag{4.1c}$$

Let $T_N : H_N \to \mathbb{R}^{N+1}$ be defined by

$$T_N(h) \triangleq Q_N^{1/2} W_N(h) \tag{4.2a}$$

so that, for any $h \in H_N$ and $\bar{h} = T_N(h)$, we have

$$\begin{aligned} \|h\|_2^2 &= \int_0^L \sum_{i,j=1}^{N+1} (W_N(h))_j P_{N,j}(x) (W_N(h))_i P_{N,i}(x)\, dx \\ &= (Q_N^{1/2} W_N(h))^T (Q_N^{1/2} W_N(h)) = \|\bar{h}\|^2. \end{aligned} \tag{4.2b}$$

Equation (4.2b) implies that the distance between two elements h and h' of $H_N \subset (C[0, L], \|\cdot\|_2, \langle\cdot,\cdot\rangle)$ is equal to the Euclidean distance between $T_N(h)$ and $T_N(h')$. It is not difficult to see that for each $h \in H_N$, $T_N(h)$ is the $(N+1)$-tuple made up of the coordinates of h with

respect to the basis set $\{B_{N,k}(\cdot)\}_{k=1}^{N+1}$ for H_N, defined by

$$B_{N,k}(\cdot) \triangleq W_N^{-1}(Q_N^{-1/2}e_k) = \sum_{i=1}^{N+1}(Q_N^{-1/2})_{ik}P_{N,i}(\cdot), \qquad k \in \mathbf{N+1}, \tag{4.2c}$$

where e_k denotes the kth canonical basis vector in $\mathbb{R}^{N+1}$. $\{B_{N,k}(\cdot)\}_{k=1}^{N+1}$ is an orthonormal basis set for H_N. Indeed,

$$\begin{aligned}\langle B_{N,k}(\cdot), B_{N,l}(\cdot)\rangle_2 &= \sum_{i,j=1}^{N+1}(Q_N^{-1/2})_{ik}(Q_N^{-1/2})_{jl}\langle P_{N,i}, P_{N,i}\rangle_2 \\ &= \sum_{i,j=1}^{N+1}(Q_N^{-1/2})_{ik}(Q_N^{-1/2})_{jl}(Q_N)_{ij} = e_k e_l^T.\end{aligned} \tag{4.2d}$$

Next, let $\bar{H}_N \triangleq T_N(H_N)$ and $\bar{H}_{\mathrm{ad},N} \triangleq T_N(H_{\mathrm{ad},N}) \subset \mathbb{R}^{N+1}$ so that

$$\begin{aligned}\bar{H}_{\mathrm{ad},N} = \{\bar{h} \in \mathbb{R}^{N+1} | &\alpha \le Q_N^{-1/2}\bar{h}_k \le \beta, k \in \mathbf{N+1}, |(Q_N^{-1/2}\bar{h})_{k+1} - (Q_N^{-1/2}\bar{h})_k| \\ &\le \gamma\Delta_N, k \in \mathbf{N}\}.\end{aligned} \tag{4.2e}$$

We define the mappings $\bar{\phi}_N^j(\cdot, x_{N,k}) : \bar{H}_{\mathrm{ad},N} \to \mathbb{R}$, $j \in \bar{\mathbf{q}}$, $k \in \mathbf{N+1}$, and $\bar{f}_N : \bar{H}_{\mathrm{ad},N} \to \mathbb{R}$ by

$$\bar{\phi}_N^j(\bar{h}, x_{N,k}) \triangleq \phi_N^j(T_N^{-1}(\bar{h}), x_{N,k}), \tag{4.3a}$$

$$\bar{f}_N(\bar{h}) \triangleq \sum_{k=1}^{N}\bar{\phi}_N^0(\bar{h}, x_{N,k})\Delta_N, \tag{4.3b}$$

which can be computed using (3.14a)–(3.14e), (3.17b), and (3.17c).

Finally, we define a family the problems $\bar{\mathbf{P}}_N$, $N = 1, 2, \ldots$, by

$$\bar{\mathbf{P}}_N \qquad \min_{\bar{h}\in\bar{H}_{\mathrm{ad},N}}\left\{\bar{f}_N(\bar{h}) | \max_{j\in\mathbf{q}}\max_{k\in\mathbf{N+1}}\bar{\phi}_N^j(\bar{h}, x_{N,k}) - (1+\Delta_N^{1/2})r^j(x_{N,k}) \le 0\right\}. \tag{4.4}$$

The following result, which establishes a correspondence between $\mathbf{P}_N$ and $\bar{\mathbf{P}}_N$, $N = 1, 2, \ldots$, follows directly from (3.17a)–(3.17c), (4.3a), (4.3b), and (4.4).

PROPOSITION 4.1. *Problems $\mathbf{P}_N$ and $\bar{\mathbf{P}}_N$ are equivalent in the following sense.* (a) *$h \in H_N$ is feasible for $\mathbf{P}_N$ if and only if $\bar{h} = T_N(h) \in \mathbb{R}^{N+1}$ is feasible for $\bar{\mathbf{P}}_N$; and* (b) *$h \in H_N$ is a global/local minimizer for $\mathbf{P}_N$ if and only if $\bar{h} = T_N(h) \in \mathbb{R}^{N+1}$ is a global/local minimizer for $\bar{\mathbf{P}}_N$.*

We define the constraint violation function $\bar{\psi}_N : \bar{H}_{\mathrm{ad},N} \to \mathbb{R}$; the surrogate cost $\bar{F}_N : \bar{H}_{\mathrm{ad},N} \times \bar{H}_{\mathrm{ad},N} \to \mathbb{R}$; the convex first-order approximation to $\bar{F}_N(\bar{h}, \bar{h}')$, denoted by $\tilde{\bar{F}}_N : \bar{H}_{\mathrm{ad},N} \times \bar{H}_{\mathrm{ad},N} \to \mathbb{R}$; and the optimality function $\bar{\theta}_N : \bar{H}_{\mathrm{ad},N} \to \mathbb{R}$ by

$$\bar{\psi}_N(\bar{h}) \triangleq \max_{j\in\mathbf{q}}\max_{k\in\mathbf{N+1}}\bar{\phi}_N^j(\bar{h}, x_{N,k}) - (1+\Delta_N^{1/2})r^j(x_{N,k}), \tag{4.5a}$$

$$\begin{aligned}\bar{F}_N(\bar{h}, \bar{h}') \triangleq \max\Big\{&\bar{f}_N(\bar{h}') - \bar{f}_N(\bar{h}) - \omega\bar{\psi}_N(\bar{h})_+, \\ &\max_{j\in\mathbf{q}}\max_{k\in\mathbf{N+1}}\bar{\phi}_N^j(\bar{h}', x_{N,k}) - \bar{\psi}_N(\bar{h})_+\Big\},\end{aligned} \tag{4.5b}$$

$$\begin{aligned}\tilde{\bar{F}}_N(\bar{h}, \bar{h}') \triangleq \max\Big\{&\langle\nabla\bar{f}_N(\bar{h}), \bar{h}' - \bar{h}\rangle - \omega\bar{\psi}_N(\bar{h})_+, \\ &\max_{j\in\mathbf{q}}\max_{k\in\mathbf{N+1}}\bar{\phi}_N^j(\bar{h}, x_k) - \bar{\psi}_N(\bar{h})_+ + \langle\nabla_1\bar{\phi}_N^j(\bar{h}, x_{N,k}), \bar{h}' - \bar{h}\rangle\Big\} \\ &+ \frac{1}{2}\|\bar{h}' - \bar{h}\|^2,\end{aligned} \tag{4.5c}$$

$$\bar{\theta}_N(\bar{h}) \triangleq \min_{\bar{h}'\in\bar{H}_{\mathrm{ad},N}}\tilde{\bar{F}}_N(\bar{h}, \bar{h}'). \tag{4.5d}$$

PROPOSITION 4.2. (a) $\bar{\theta}_N : \bar{H}_{\mathrm{ad},N} \to \mathbb{R}$ *is an optimality function for* $\bar{\mathbf{P}}_N$.

(b) *For any* $h, h' \in H_{\mathrm{ad},N}$, $\bar{h} = T_N(h)$, *and* $\bar{h}' = T_N(h')$ *we have*

$$F_N(h, h') = \bar{F}_N(\bar{h}, \bar{h}'), \tag{4.6a}$$

$$\theta_N(h) = \bar{\theta}_N(\bar{h}). \tag{4.6b}$$

Proof. A proof of part (a) can be found in [17]. Next we prove (b). First, in view of (3.17b), (3.18a), (4.3a), (4.3b), and (4.5a) it is clear that $\psi(h) = \bar{\psi}(\bar{h})$ and $f(h) = \bar{f}(\bar{h})$. Hence, it follows from (3.18b) and (4.5b) that $F_N(h, h') = \bar{F}_N(\bar{h}, \bar{h}')$.

Second, given $\delta h \in H_N$ let $\overline{\delta h} \triangleq T_N(\delta h)$. Then for all $j \in \bar{\mathbf{q}}$ and $k \in \mathbf{N+1}$ we have, using (4.3a) and the chain rule, that

$$\begin{aligned} \langle \nabla_1 \bar{\phi}_N^j(\bar{h}, x_{N,k}), \overline{\delta h} \rangle &= D_1 \bar{\phi}_N^j(\bar{h}, x_{N,k}; \overline{\delta h}) = D_1 \phi_N^j(T_N^{-1}(\bar{h}), x_{N,k}; T_N^{-1}(\overline{\delta h})) \\ &= D_1 \phi_N^j(h, x_{N,k}; \delta h), \end{aligned} \tag{4.7a}$$

which, together with (3.17b) and (4.4b), implies

$$\langle \nabla \bar{f}_N(\bar{h}), \bar{h}' - \bar{h} \rangle = Df_N(h; h' - h). \tag{4.7b}$$

It follows from (3.20a), (4.2b), (4.3a), (4.3b), (4.5c), (4.7a), and (4.7b) that for all $h, h' \in H_{\mathrm{ad},N}$,

$$\tilde{F}_N(h, h') = \bar{\tilde{F}}_N(\bar{h}, \bar{h}'), \tag{4.7c}$$

where $\bar{h} = T_N(h)$ and $\bar{h}' = T_N(h')$. Equality (4.6b) follows directly from the definition of $\bar{H}_{\mathrm{ad},N}$, (3.20b), (4.5d), and (4.7c). □

We now show how the gradients $\nabla_1 \bar{\phi}_N^j(\bar{h}, x_{N,k})$, $j \in \bar{\mathbf{q}}$, $k \in \mathbf{N+1}$, can be computed. Let e_i denote the ith canonical basis vector in $\mathbb{R}^{N+1}$. Then, for $\bar{h} \in \bar{H}_{\mathrm{ad},N}$, $j \in \bar{\mathbf{q}}$, and $k \in \mathbf{N+1}$, we have from (4.7a) that

$$\langle \nabla_1 \bar{\phi}_N^j(\bar{h}, x_{N,k}), e_i \rangle = D_1 \phi_N^j(T_N^{-1}(\bar{h}), x_{N,k}; T_N^{-1}(e_i)), \qquad i \in \mathbf{N+1}, \tag{4.8a}$$

which can be computed using (3.17c), (3.16a)–(3.16g), and the chain rule.

We will apply the algorithm described in [20] to solve problem **P** using the framework of consistent approximations, as suggested in [18].

ALGORITHM 4.3.

Parameters: $a, b, s \in (0, 1)$, $w, \epsilon > 0$ and $N_0 \in \mathbb{N}$.

Data. $h_0 \in H_{\mathrm{ad},N_0}$.

Step 0. Set $i = 0$.

Step 1.

Inner-Step 0. Set $N = N_i$, $\bar{h}_i = T_N(h_i)$.

Inner-Step 1. Compute

$$\bar{\theta}_N(\bar{h}_i) = \min_{\bar{h}' \in H_{\mathrm{ad},N}} \bar{\tilde{F}}_N(\bar{h}_i, \bar{h}'), \tag{4.9a}$$

$$d_i = \arg \min_{\bar{h}' \in \bar{H}_{\mathrm{ad},N}} \bar{\tilde{F}}_N(\bar{h}_i, \bar{h}'). \tag{4.9b}$$

Inner-Step 2. If $\bar{\theta}_N(\bar{h}_i) = 0$, set $\bar{h}_* = \bar{h}_i$ and go to Step 3. Else, compute the *step size*

$$\lambda_i \triangleq \arg \max_{k \in \mathbb{N}} \{b^k \mid \bar{F}_N(\bar{h}_i + b^k d_i, \bar{h}_i) \le b^k a \bar{\theta}_N(\bar{h}_i)\}. \tag{4.9c}$$

Inner-Step 3. Set

$$\bar{h}_* = \bar{h}_i + \lambda_i d_i. \tag{4.9d}$$

Step 2. If

$$\bar{F}_N(\bar{h}_i, \bar{h}_*) \le -\epsilon \Delta_N^s, \tag{4.9e}$$

go to Step 3. Else, set $h_i = T_N^{-1}(\bar{h}_i)$, replace N_i by $2N_i$ and go to Inner-Step 0.

Step 3. Set $h_{i+1} = T_{N_i}^{-1}(\bar{h}_*)$, $N_{i+1} = N_i$, replace i by $i + 1$, and go to Step 1.

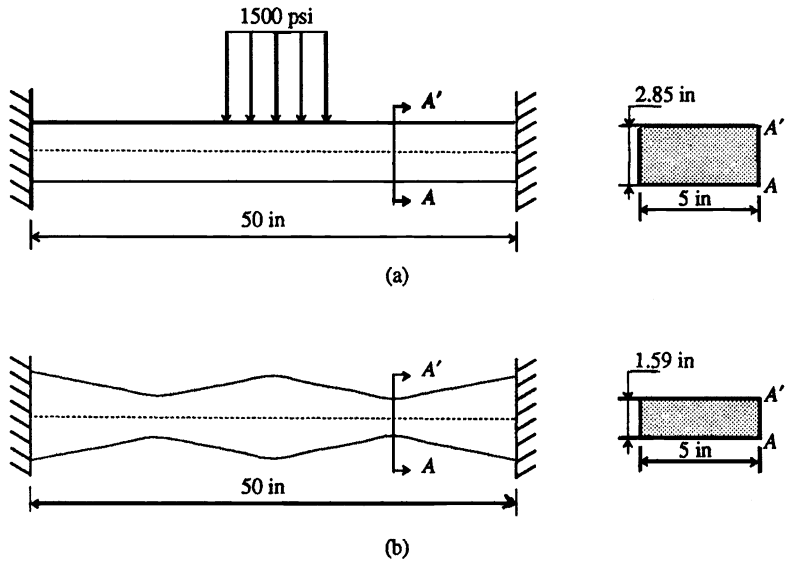

FIG. 5.1. (a) *Initial design*; (b) *final design.*

The following theorem on the convergence properties of Algorithm 4.3 can be deduced from Theorem 5.15 in [18].

THEOREM 4.4. *Suppose that Algorithm* 4.3 *has constructed an infinite sequence* $\{h_i\}_{i=0}^{\infty}$ *that has an accumulation point* $\hat{h}$. *Then* $\theta(\hat{h}) = 0$.

5. Numerical results. We will illustrate the use of consistent approximations and Algorithm 4.3 in solving a particular problem of the kind **P**. In our example, we assumed that $E = 10^7$ psi, $L = 50$ in, $b = 5$ in, $K = 0$ (we neglected the weight of the beam), $\alpha = 1.0$ in, $\beta = 5.0$ in, and $\gamma = 0.15$. We imposed continuum constraints on the maximum normal stress, on the maximum shear, and on the deflection, as follows:

$$|\sigma_{\max}(h, x)| \leq 30{,}000 \text{ psi} \quad \forall x \in [0, L], \tag{5.1a}$$

$$|\tau_{\max}(h, x)| \leq 15{,}000 \text{ psi} \quad \forall x \in [0, L], \tag{5.1b}$$

$$|y(h, x)| \leq 0.1 \text{ in} \quad \forall x \in [0, L]. \tag{5.1c}$$

The cost function was proportional to the total mass of the beam,

$$f(h) = \int_0^L h(x)\, dx. \tag{5.1d}$$

The load applied to the beam was

$$l(x) = \begin{cases} -1500 \text{ psi} & \text{if } x \in [20, 30], \\ 0 & \text{otherwise.} \end{cases} \tag{5.1e}$$

The initial discretization was set to $N = 8$ points; and the initial $h(\cdot)$ was constant, with value 2.85 in (see Fig. 5.1(a)). This initial design, whose cost is 142.5, corresponds to the uniform beam of least mass that satisfies the constraints (for this $h(\cdot)$ the constraint on the displacement is active and the other two are slack).

In Fig. 5.1(b), we find the beam obtained after 16 inner-steps of Algorithm 4.1. The discretization level at the end of the 16th inner-step was $N = 128$. The corresponding cost

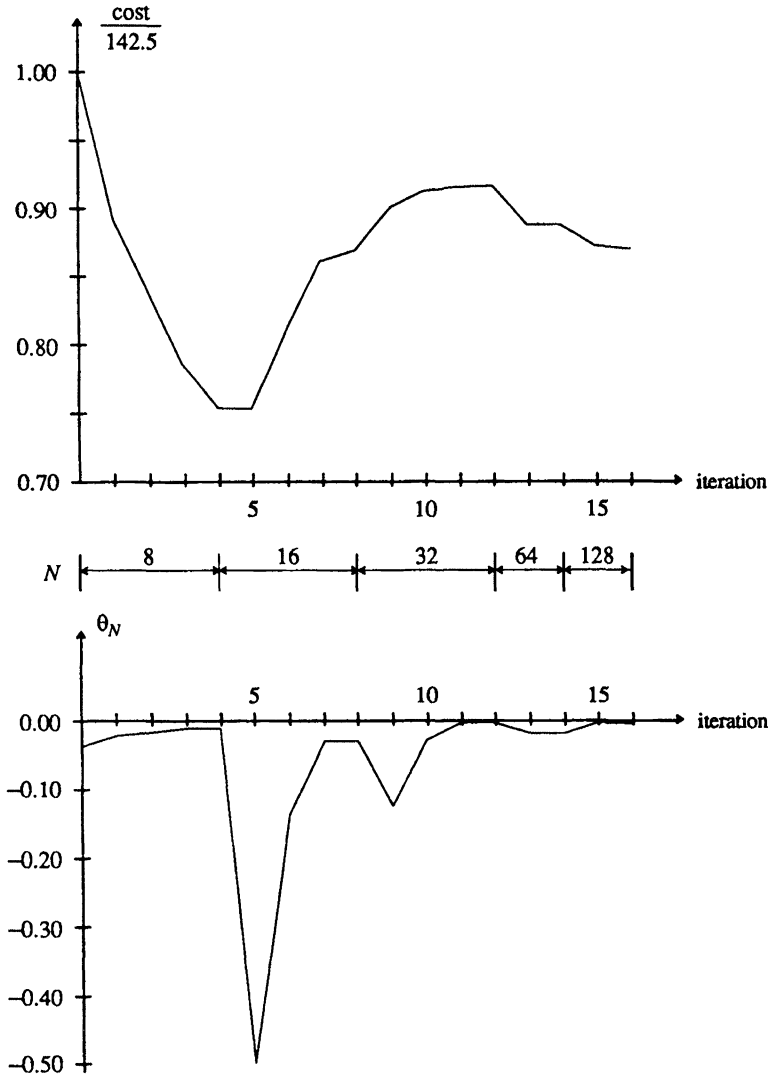

FIG. 5.2. *Computed cost and computed optimality function.*

was 124.05, about 87% of the initial cost. For the final design, the constraint on the deflection of the beam was active and the constraints on the maximum normal stress and on the maximum shear stress were slack.

In Fig. 5.2 we present the computed cost at each iteration as a percentage of the initial cost, 142.5, and the computed value of the optimality function θ_N, at each iteration. The number of discretization points used at each iteration is also shown in Fig. 5.2. As our analysis indicates, for each given discretization the optimality function is driven to zero, but when the discretization is refined (at iterations 4, 8, 12, and 14) the value of the optimality function may decrease. However, as the algorithm progresses, the optimality function is eventually driven to zero and, therefore, the computed depth functions $h_i(\cdot)$ approach a stationary point.

6. Conclusion. We have shown that one can obtain consistent approximations, satisfying the axioms formulated in [18], for certain classes of optimal beam design problems involving Euler–Bernoulli beams subject to continuum constraints, which include displacement,

maximum shear stress, and maximum normal stress constraints. We have also demonstrated numerically how an algorithm first described in [20] and proposed for use with consistent approximations in [18] can be used to obtain an arbitrarily good approximation to a stationary point of these design problems.

Appendix A.

Proof of Lemma 3.2. First we show that for all $h \in H_{\text{ad}}$ the determinants of the two principal minors of $A(h) \in \mathbb{R}^{2\times 2}$ are positive, which implies that $A(h)$ is positive definite. Clearly, $\int_0^L x^2/h(x)^3\,dx \geq L^3/3\beta^3 > 0$. Next, because all $h \in H_{\text{ad}}$ take values in $[\alpha, \beta]$, we have that for all $p_1, p_2, \epsilon \in (0, \infty)$

$$\int_0^1 \frac{(p_1x - p_2)^2}{h(x)^3}\,dx \geq \int_0^1 \frac{(p_1x - p_2)^2}{\beta^3}\,dx = \frac{p_1^2}{3\beta^3} + \frac{p_2^2}{\beta^3} - \frac{p_1p_2}{\beta^3} \geq \frac{p_1^2}{3\beta^3} + \frac{p_2^2}{\beta^3} - \frac{\epsilon p_1^2}{\beta^3} - \frac{p_2^2}{4\epsilon\beta^3}. \tag{A.1a}$$

If we set $\epsilon = 1/4$ and choose

$$p_1^2 = \int_0^1 \frac{1}{h(x)^3}\,dx \quad \text{and} \quad p_2 = \frac{1}{p_1}\int_0^1 \frac{x}{h(x)^3}\,dx, \tag{A.1b}$$

we get from (A.1a) that

$$\begin{aligned} \det A(h) &= \int_0^1 \frac{x^2}{h(x)^3}\,dx \int_0^1 \frac{1}{h(x)^3}\,dx - \left(\int_0^1 \frac{x}{h(x)^3}\,dx\right)^2 \\ &= \int_0^1 \frac{(p_1x - p_2)^2}{h(x)^3}\,dx \geq \frac{p_1^2}{12\beta^3} \geq \frac{1}{12\beta^6}, \end{aligned} \tag{A.1c}$$

which implies that $A(h) \in \mathbb{R}^{2\times 2}$ is positive definite.

Next, we observe that all entries of $A(h)$ are bounded by $(L^3 + 1)/\alpha^3$. Hence there exists an $M \in (0, \infty)$ such that for all $w \in \mathbb{R}^2$

$$w^T A(h) w \leq M\|w\|^2. \tag{A.1d}$$

Since the strictly positive lower bounds on the principal determinants are independent of $h \in H_{\text{ad}}$, it follows that the smallest eigenvalue of $A(h)$ is bounded away from 0 for all $h \in H_{\text{ad}}$, which implies the desired result. □

Proof of Lemma 3.8(a). Given $h \in H_{\text{ad}}$, let h_N be the linear interpolate of h on the mesh T_N. Clearly, $h_N \in H_{\text{ad},N}$. From (3.3), we have that h is Lipschitz continuous with Lipschitz constant γ, and hence $\|h - h_N\|_\infty \leq \gamma\Delta_N$, which proves (3.21a). □

PROPOSITION A1. *There exists a constant $C \in (0, \infty)$ such that for all $N \geq 1$, $h \in H_{\text{ad}}$, and $h_N \in H_{\text{ad},N}$,*

$$\max_{k\in\mathbf{N+1}} |M_c'(h, x_{N,k}) - M_{c,N}'(h_N, x_{N,k})| \leq C[\Delta_N + \|h - h_N\|_2], \tag{A.2a}$$

$$\max_{k\in\mathbf{N+1}} |M_c(h, x_{N,k}) - M_{c,N}(h_N, x_{N,k})| \leq C[\Delta_N + \|h - h_N\|_2], \tag{A.2b}$$

$$\|A(h) - A_N(h_N)\| \leq C[\|h - h_N\|_2 + \Delta_N], \tag{A.2c}$$

$$\|b(h) - b_N(h_N)\| \leq C[\|h - h_N\|_2 + \Delta_N], \tag{A.2d}$$

$$\|g(h) - g_N(h_N)\| \leq C[\|h - h_N\|_2 + \Delta_N], \tag{A.2e}$$

$$\max_{k\in\mathbf{N+1}} |M(h, x_{N,k}) - M_N(h_N, x_{N,k})| \leq C[\Delta_N + \|h - h_N\|_2], \tag{A.2f}$$

$$\max_{k\in\mathbf{N+1}} |V(h, x_{N,k}) - V_N(h_N, x_{N,k})| \leq C[\Delta_N + \|h - h_N\|_2], \tag{A.2g}$$

$$\max_{k\in\mathbf{N+1}} |y(h, x_{N,k}) - y_N(h_N, x_{N,k})| \leq C[\Delta_N + \|h - h_N\|_2]. \tag{A.2h}$$

Proof. Let $h \in H_{\text{ad}}$ and $h_N \in H_{\text{ad},N}$ be given. First, from (3.2a) it follows that

$$M_{\text{c}}''(h, x) - M_{\text{c}}''(h_N, x) = -K(h(x) - h_N(x)), \qquad x \in [0, L];$$

$$\text{(A.3a)} \qquad M_{\text{c}}'(h, L) - M_{\text{c}}'(h_N, L) = 0, \qquad M_{\text{c}}(h, L) - M_{\text{c}}(h_N, L) = 0.$$

Hence, integrating both sides of (A.3a) and using Holder's inequality, we get that

$$\text{(A.3b)} \qquad |M_{\text{c}}'(h, x) - M_{\text{c}}'(h_N, x)| \le K\sqrt{L}\|h - h_N\|_2, \qquad x \in [0, L].$$

If we integrate (A.3a) twice and use (A.3b) we get

$$\text{(A.3c)} \qquad |M_{\text{c}}(h, x) - M_{\text{c}}(h_N, x)| \le KL^{3/2}\|h - h_N\|_2, \qquad x \in [0, L].$$

Next, we show that there exists a $C \ge \max\{K\sqrt{L}, KL^{3/2}\}$ such that for all $N \in \mathbb{N}$ and $h_N \in H_{\text{ad},N}$,

$$\text{(A.3d)} \qquad \max_{k \in \mathbf{N+1}} |M_{\text{c},N}'(h_N, x_{N,k}) - M_{\text{c}}'(h_N, x_{N,k})| \le C\Delta_N,$$

$$\text{(A.3e)} \qquad \max_{k \in \mathbf{N+1}} |M_{\text{c},N}(h_N, x_{N,k}) - M_{\text{c}}(h_N, x_{N,k})| \le C\Delta_N,$$

where $M_{\text{c},N}'(h_N, x_{N,k})$ and $M_{\text{c},N}(h_N, x_{N,k})$ are determined by (3.14a). Equations (A.3d), (A.3e), (A.3b), and (A.3c) and the triangle inequality imply (A.2a) and (A.2b).

First we prove (A.3d). Recall that $m(\cdot)$ is assumed to be piecewise Lipschitz continuous (see (3.1)). From (3.1) and (3.3), it follows that for any $h_N \in H_{\text{ad},N} \subset H_{\text{ad}}$, $l(h_N, \cdot)$ is also piecewise Lipschitz continuous and has finitely many points of discontinuity in $[0, L]$. Hence, there exists a constant C', independent of $N \in \mathbb{N}$ and of $h_N \in H_{\text{ad},N}$, such that C' is a Lipschitz constant for $l(h_N, \cdot)$ on any subinterval of $[0, L]$ in which $l(h_N, \cdot)$ is continuous. Consider the mesh T_N. In each mesh interval $[x_{N,k}, x_{N,k+1}]$, $k \in \mathbf{N}$, $l(h_N, \cdot)$ is either Lipschitz continuous or has at least one point of discontinuity. There are at most finitely many mesh intervals, say $p \ge 0$, in which $l(h_N, \cdot)$ is discontinuous. Clearly, p is no larger than the number of discontinuities of $m(\cdot)$ and, hence, is independent of $N \in \mathbb{N}$. If we apply Euler's method to integrate the second equation in (3.2d), obtaining the second equation in (3.14a), the local truncation error, on each mesh interval where $l(h_N, \cdot)$ has at least one discontinuity, is bounded by $2\Delta_N \max_{x \in [0,L]} |l(h_N, x)|$. In the intervals where $l(h_N, \cdot)$ is Lipschitz continuous, and there are at most $N - p$ of these, the local truncation error of Euler's method is bounded by $C'\Delta_N^2$ such that

$$\text{(A.3f)} \qquad |M_{\text{c},N}'(h_N, x_{N,k}) - M_{\text{c}}'(h_N, x_{N,k})| \le C'\Delta_N^2(N - p) + 2p \max_{x \in [0,L]} |l(h_N, x)|\Delta_N,$$

which implies (A.3d). To prove (A.3e) we first note that if we set

$$\text{(A.3g)} \qquad K' \triangleq \max_{x \in [0,L]} |m(x)| + K\beta,$$

where K is as in (3.1), then K' is Lipschitz constant for $M_{\text{c}}'(h, x)$ for all $h \in H_{\text{ad}}$; that is,

$$\text{(A.3h)} \qquad |M_{\text{c}}'(h, x) - M_{\text{c}}'(h, y)| \le K'|x - y| \quad \forall\, h \in H_{\text{ad}}\ \forall\, x, y \in [0, L].$$

Now consider the first differential equation in (3.2b) and its discrete counterpart in (3.14a). Their solutions satisfy

$$\text{(A.3i)} \qquad M_{\text{c}}(h, x_{N,k}) = M_{\text{c}}(h, x_{N,k+1}) + \int_{x_{N,k+1}}^{x_{N,k}} M_{\text{c}}'(h, x)\, dx, \qquad k \in \mathbf{N},$$

$$\text{(A.3j)} \qquad M_{\text{c},N}(h, x_{N,k}) = M_{\text{c},N}(h, x_{N,k+1}) + \int_{x_{N,k+1}}^{x_{N,k}} M_{\text{c},N}'(h, x_{N,k+1})\, dx, \qquad k \in \mathbf{N}.$$

Defining $e_k \triangleq |M_c(h, x_{N,k}) - M_{c,N}(h, x_{N,k})|$, $k \in \mathbf{N+1}$, and subtracting (A.3j) from (A.3i), we obtain, after taking absolute values on both sides,

$$e_k \leq e_{k+1} + \int_{x_{N,k+1}}^{x_{N,k}} |M_c'(h, x) - M_{c,N}'(h, x_{N,k+1})|\, dx, \qquad k \in \mathbf{N}, e_{N+1} = 0. \tag{A.3k}$$

Adding and subtracting $M_c'(h, x_{N,k+1})$ to the integrand in (A.3k) and using the triangle inequality we get

$$\begin{aligned} e_k \leq e_{k+1} &+ \int_{x_{N,k+1}}^{x_{N,k}} |M_c'(h, x) - M_c'(h, x_{N,k+1})|\, dx + \int_{x_{N,k+1}}^{x_{N,k}} |M_c'(h, x_{N,k+1}) \\ &- M_{c,N}'(h, x_{N,k+1})|\, dx, \end{aligned} \tag{A.3l}$$

which, in view of (A.3d) and (A.3h) implies that there exists a constant $C < \infty$ such that

$$e_k \leq e_{k+1} + C\Delta_N^2, \qquad k \in \mathbf{N}, e_{N+1} = 0, \tag{A.3m}$$

which in turn implies $|e_k| \leq C\Delta_N$ for all $k \in \mathbf{N+1}$ and hence proves (A.3e).

Inequalities (A.2c) and (A.2d) follow from the fact that $h(x)$ and $h_N(x)$ take values in $[\alpha, \beta]$, Holder's inequality, the fact that the rectangle rule is $O(\Delta_N)$, and from the definitions of $A(h)$ and $b(h)$ and of $A_N(h_N)$ and $b_N(h_N)$ (see (3.2d) and (3.14d)). To prove (A.2e), we first note that $A(h)g(h) = b(h)$ and $A_N(h_N)g_N(h_N) = b_N(h_N)$ imply

$$g(h) - g_N(h_N) = A(h)^{-1}[(A_N(h_N) - A(h))g_N(h_N) + (b(h) - b_N(h_N))], \tag{A.3n}$$

which in view of Lemmas 3.2 and 3.8 and (A.2c,d) implies (A.2e).

Inequalities (A.2f)–(A.2h) follow directly from (3.2c), (3.2e), and (3.2f) and (A.2a), (A.2b), (A.2e), and (A.2f). □

Proof of Lemma 3.8(b). In view of Assumption 3.3(b), (3.21b) is a direct consequence of (A.2f)–(A.2h), and the definitions of $\phi^j(\cdot, \cdot)$ and $\phi_N^j(\cdot, \cdot)$ in (3.7c) and (3.6b), respectively. Next, if we let $R \triangleq \max_{j \in \mathbf{q}} \max_{x \in [0,L]} r^j(x)$ and make use of (3.21b), it follows from (3.10a) and (3.18a) that

$$\begin{aligned} \psi(h) - \psi_N(h_N) &\leq \max_{j \in \mathbf{q}} \max_{x \in [0,L]} \{\phi^j(h, x) - r^j(x) - \phi_N^j(h_N, x) + (1 - \Delta_N^{1/2}) r^j(x)\} \\ &\leq C[\Delta_N + \|h - h_N\|_2] + R\Delta_N^{1/2} \leq C[\Delta_N^{1/2} + \|h - h_N\|_2]. \end{aligned} \tag{A.4a}$$

In a similar way, an upper bound for $\psi_N(h_N) - \psi(h)$ can be obtained, namely,

$$\psi_N(h_N) - \psi(h) \leq C[\Delta_N^{1/2} + \|h - h_N\|_2], \tag{A.4b}$$

which together with (A.4a) implies (3.21c).

Finally, we prove (3.21d). First we note that because all $h \in H_{ad}$ take values between $[\alpha, \beta]$ and $l(\cdot, \cdot)$ is bounded, $V(h, \cdot)$, $M(h, \cdot)$, and $y(h, \cdot)$ are Lipschitz continuous on $[0, L]$, with a common Lipschitz constant independent of $h \in H_{ad}$. In view of Assumption 3.3(b) we get that there exists a constant C such that for all $x, y \in [0, L]$

$$|\phi^0(h, x) - \phi^0(h, y)| \leq C|x - y|. \tag{A.4c}$$

Hence,

$$|f(h) - f_N(h_N)| \leq \sum_{j=1}^{N} \int_{x_{N,j}}^{x_{N,j+1}} \{|\phi^0(h, x) - \phi^0(h, x_{N,j})| + |\phi^0(h, x_{N,j}) - \phi_N^0(h_N, x_{N,j})|\}\, dx, \tag{A.4d}$$

which in view of (A.4c) and (3.21c) implies that there exists a constant C such that

$$|f(h) - f_N(h_N)| \leq C[\Delta_N + \|h - h_N\|_2]. \tag{A.4e}$$

□

The proof of the following result is similar to that of Proposition A.1 and hence is omitted.

PROPOSITION A.2. *There exists a constant* $C \in (0, \infty)$ *such that for all integers* $N > 0$, $h, h' \in H_{\mathrm{ad},N}$, *we have*

$$\max_{k\in\mathbf{N+1}} |D_1 M_{\mathrm{c}}(h, x_{N,k}; h' - h) - D_1 M_{\mathrm{c},N}(h, x_{N,k}; h' - h)| \le C\|h' - h\|_2 \Delta_N, \tag{A.5a}$$

$$\max_{k\in\mathbf{N+1}} |D_1 M'_{\mathrm{c}}(h, x_{N,k}; h' - h) - D_1 M'_{\mathrm{c},N}(h, x_{N,k}; h' - h)| \le C\|h' - h\|_2 \Delta_N, \tag{A.5b}$$

$$\|DA(h; h' - h) - DA_N(h; h' - h)\| \le C\Delta_N \|h' - h\|_2, \tag{A.5c}$$

$$\|Db(h; h' - h) - Db_N(h; h' - h)\| \le C\Delta_N \|h' - h\|_2, \tag{A.5d}$$

$$\|Dg(h; h' - h) - Dg_N(h; h' - h)\| \le C\Delta_N \|h' - h\|_2. \tag{A.5e}$$

$$\max_{k\in\mathbf{N+1}} |D_1 M(h, x_{N,k}; h' - h) - D_1 M_N(h, x_{N,k}; h' - h)| \le C\|h' - h\|_2 \Delta_N, \tag{A.5f}$$

$$\max_{k\in\mathbf{N+1}} |D_1 V(h, x_{N,k}; h' - h) - D_1 V_N(h, x_{N,k}; h' - h)| \le C\|h' - h\|_2 \Delta_N, \tag{A.5g}$$

$$\max_{k\in\mathbf{N+1}} |D_1 y(h, x_{N,k}; h' - h) - D_1 y_N(h, x_{N,k}; h' - h)| \le C\|h' - h\|_2 \Delta_N. \tag{A.5h}$$

Proof of Lemma 3.11. The result follows directly from (A.5f)–(A.5h) and Assumption 3.3. □

CLASSIFICATION OF GENERIC SINGULARITIES FOR THE PLANAR TIME-OPTIMAL SYNTHESIS*

B. PICCOLI†

Abstract. This paper is concerned with control systems on the plane with control appearing linearly. It is known that under generic conditions the problem of reaching points from the origin in minimum time admits a regular synthesis. The minimum time function is piecewise smooth, possibly nondifferentiable on a set that is a finite union of embedded submanifolds of dimension 1 or 0, called singularities. The purpose of the present paper is to provide a classification of all types of singularities arising under generic conditions.

Key words. time-optimal control, two-dimensional system, regular synthesis

AMS subject classifications. 93C10, 93B20

1. Introduction.

This paper is concerned with the control system on the plane

$$\dot{x} = F(x) + u\,G(x), \qquad |u| \le 1, \tag{1.1}$$

with $F(0) = 0$.

Let $R(\tau)$ be the reachable set for (1.1) at a given time τ. Under generic conditions on the vector fields F and G, it is known that the problem of reaching points $x \in R(\tau)$ from the origin in minimum time admits a regular synthesis [8]–[11]. Indeed, one can partition the set $R(\tau)$ into finitely many embedded submanifolds $\mathcal{M}_i$ such that, on each $\mathcal{M}_i$, the corresponding optimal control is either $u \equiv \pm 1$ or singular, i.e., $u = \varphi_S(x) \notin \{-1, +1\}$, where

$$\varphi_S(x) = -\frac{\nabla \Delta_B(x) \cdot F(x)}{\nabla \Delta_B(x) \cdot G(x)}.$$

See (2.11) for the definition of Δ_B.

In particular, the minimum time function is piecewise smooth on $R(\tau)$, possibly nondifferentiable on the boundaries of the submanifolds $\mathcal{M}_i$. These boundaries, of dimension 1 or 0, were called, in [8], frame curves (FCs) and frame points, respectively.

The purpose of the present paper is to provide a classification of all types of FCs and frame points, arising under generic conditions on F and G. In §§3 and 4 we classify all generic types of singularities, up to a relation of topological equivalence, and construct explicit examples of each one of them. We refer to the examples as representations of the various equivalence classes.

This paper is a first part of a research aimed at the generic classification of feedbacks, analogous to the work of Peixoto; for ordinary differential equations see [7]. The research will be completed in a subsequent paper.

2. Basic definitions.

We consider the Banach space $\mathcal{V}$ of $\mathcal{C}^3$ vector fields on $\mathbb{R}^2$, having all derivatives, up to order three, continuous and bounded on the plane. We endow the space $\mathcal{V}$ with the norm

$$F = (F_1, F_2), \qquad \| F \|_{\mathcal{C}^3} = \sup \{ |D^\alpha F_i(x)| : x \in \mathbb{R}^2;\ |\alpha| \le 3;\ i = 1, 2 \}.$$

We denote by $\Xi \subset \mathcal{V} \times \mathcal{V}$ the Banach subspace of couples (F, G) such that $F(0) = 0$, endowed with the restriction of the product norm. With every couple $(F, G) \in \Xi$ we associate the control system (1.1), called Σ, and write $\Sigma \in \Xi$.

We recall that the *Lie bracket* of two vector fields F and G is the vector field

$$[F, G] \doteq \nabla G \cdot F - \nabla F \cdot G. \tag{2.1}$$

A *control* is a measurable function $u : [a, b] \mapsto [-1, 1]$, where $-\infty < a \leq b < +\infty$. A *trajectory of* Σ corresponding to u is an absolutely continuous curve $\gamma : [a, b] \mapsto \mathbb{R}^2$ which satisfies the equation

$$\dot{\gamma}(t) = F(\gamma(t)) + u(t)G(\gamma(t)) \tag{2.2}$$

for almost every t in the domain of u. We write $\mathrm{Dom}(u)$ (resp., $\mathrm{Dom}(\gamma)$) to indicate the domain of u (resp., γ) and $\gamma \restriction [c, d]$ to denote the restriction of γ to $[c, d] \subset \mathrm{Dom}(\gamma)$. The initial point of γ is denoted by $\mathrm{In}(\gamma) = \gamma(a)$, and its terminal point by $\mathrm{Term}(\gamma) = \gamma(b)$. The time along γ is defined as

$$T(\gamma) = b - a. \tag{2.3}$$

A trajectory $\gamma \in \mathrm{Traj}(\Sigma)$ (the set of trajectories of Σ) is *time optimal* if, for every trajectory γ' having the same initial and terminal points, one has $T(\gamma') \geq T(\gamma)$.

If $u_1 : [a, b] \mapsto [-1, 1]$ and $u_2 : [b, c] \mapsto [-1, 1]$ are controls, their *concatenation* $u_2 * u_1$ is the control

$$(u_2 * u_1)(t) \doteq \begin{cases} u_1(t) & \text{for } t \in [a, b], \\ u_2(t) & \text{for } t \in (b, c]. \end{cases}$$

If $\gamma_1 : [a, b] \mapsto \mathbb{R}^2$, $\gamma_2 : [b, c] \mapsto \mathbb{R}^2$ are trajectories of Σ for u_1 and u_2 such that $\gamma_1(b) = \gamma_2(b)$, then the *concatenation* $\gamma_2 * \gamma_1$ is the trajectory

$$(\gamma_2 * \gamma_1)(t) = \begin{cases} \gamma_1(t) & \text{for } t \in [a, b], \\ \gamma_2(t) & \text{for } t \in [b, c]. \end{cases}$$

For convenience, we also define the vector fields

$$X = F - G, \qquad Y = F + G.$$

We say that γ is an X-trajectory and write $\gamma \in \mathrm{Traj}(X)$ if it corresponds to the constant control -1. Similarly we define Y-trajectories.

If a trajectory γ is concatenation of an X-trajectory and a Y-trajectory, then we say that γ is a $Y * X$-trajectory. (The X-trajectory comes first.) Similarly we define trajectories of type $X * Y$, $X * Y * X$, and so on. For a complete description of notations see [9].

If $\tau \geq 0$, we denote by $R(\tau)$ the *reachable set* within time τ:

$$R(\tau) = \{x : \exists \gamma \in \mathrm{Traj}(\Sigma) \quad \text{s.t. } \gamma(0) = 0 \in \mathbb{R}^2, \ \gamma(t) = x, \ \text{for some } t \leq \tau\}. \tag{2.4}$$

The *minimum time function*, $T : \mathbb{R}^2 \mapsto [0, +\infty]$, is defined by

$$T(x) \doteq \inf\{\tau : x \in R(\tau)\}. \tag{2.5}$$

The control system Σ is *locally controllable* if, for each $\tau > 0$, the set $R(\tau)$ contains a neighborhood of the origin. The following lemma is well known (see [6]).

LEMMA 2.1. *If $F(0) = 0$ and the vector fields G, $[F, G]$ are linearly independent at the origin, then the system $\Sigma = (F, G)$ in (1.1) is locally controllable.*

A *synthesis* for the control system Σ at time τ is a family $\Gamma = \{\gamma_x : [0, b_x] \mapsto \mathbb{R}^2 | x \in R(\tau)\}$ of trajectories satisfying the following conditions:

(a) For each $x \in R(\tau)$ one has $\gamma_x(0) = 0$, $\gamma_x(b_x) = x$.

(b) If $y = \gamma_x(t)$, where $t \in \text{Dom}(\gamma)$, then $\gamma_y = \gamma_x \restriction [0, t]$.

A synthesis for the system Σ is *time optimal* if, for each $x \in R(\tau)$, one has $\gamma_x(T(x)) = x$, where T is the minimum time function defined at (2.5).

An *admissible pair* for the system Σ is a couple (u, γ) such that u is a control and γ is a trajectory corresponding to u. We use the symbol $\text{Adm}(\Sigma)$ to denote the set of admissible pairs and say that $(u, \gamma) \in \text{Adm}(\Sigma)$ is optimal if γ is optimal.

A *variational vector field along* $(u, \gamma) \in \text{Adm}(\Sigma)$ is the vector-valued absolutely continuous function $v : \text{Dom}(\gamma) \mapsto \mathbb{R}^2$ that satisfies the equation

$$\dot{v}(t) = ((\nabla F)(\gamma(t)) + u(t)(\nabla G)(\gamma(t))) \cdot v(t) \tag{2.6}$$

for almost all $t \in \text{Dom}(\gamma)$.

A *variational covector field along* $(u, \gamma) \in \text{Adm}(\Sigma)$ is an absolutely continuous function $\lambda : \text{Dom}(\gamma) \mapsto \mathbb{R}^2_*$ that satisfies the equation

$$\dot{\lambda}(t) = -\lambda(t) \cdot ((\nabla F)(\gamma(t)) + u(t)(\nabla G)(\gamma(t))) \tag{2.7}$$

for almost all $t \in \text{Dom}(\gamma)$. Here $\mathbb{R}^2_*$ denotes a space of row vectors.

The Hamiltonian $\mathcal{H} : \mathbb{R}^2_* \times \mathbb{R}^2 \times \mathbb{R} \mapsto \mathbb{R}$ is defined as

$$\mathcal{H}(\lambda, x, u) = \lambda \cdot (F(x) + uG(x)). \tag{2.8}$$

If λ is a variational covector field along $(u, \gamma) \in \text{Adm}(\Sigma)$, we say that λ is *maximizing* if

$$\mathcal{H}(\lambda(t), \gamma(t), u(t)) = \max \{\mathcal{H}(\lambda(t), \gamma(t), w) : |w| \leq 1\} \tag{2.9}$$

for almost all $t \in \text{Dom}(\gamma)$.

The *Pontryagin maximum principle* (PMP) states that if $(u, \gamma) \in \text{Adm}(\Sigma)$ is time optimal, then there exists

(PMP1) a nontrivial maximizing variational covector field λ along (u, γ);

(PMP2) a constant $\lambda_0 \leq 0$ such that $\mathcal{H}(\lambda(t), \gamma(t), u(t)) + \lambda_0 = 0$ for almost all $t \in \text{Dom}(\gamma)$.

In this case λ is called an *adjoint covector field along* (u, γ) or simply an *adjoint variable*, and we say that (γ, λ) satisfies the PMP or that γ is an *extremal trajectory*. Moreover, the function $\phi_\lambda(t) \doteq \lambda(t) \cdot G(\gamma(t))$ is called the switching function along (u, γ, λ).

Consider $(u, \gamma) \in \text{Adm}(\Sigma)$, $t_0 \in \text{Dom}(\gamma)$, and $v_0 \in \mathbb{R}^2$. We write $v(v_0, t_0; t)$ to denote the value at time t of the variational vector field along (u, γ) satisfying (2.6) together with the boundary condition $v(t_0) = v_0$. If $t_0, t_1 \in \text{Dom}(\gamma)$, we say that t_0 and t_1 are *conjugate* along γ if the vectors $v(G(\gamma(t_1)), t_1; t_0)$ and $G(\gamma(t_0))$ are linearly dependent. Let D and D' be two $\mathcal{C}^3$ connected one-dimensional embedded submanifolds of $\mathbb{R}^2$. We say that D' is a *conjugate curve* to D along the X-trajectories if there is a bijective function $\psi : D \mapsto D'$ with the following properties. If γ_x is the X-trajectory satisfying $\gamma_x(0) = x$, then $\psi(x) = \gamma_x(t(x))$ for some time t depending continuously on x, and the times 0, $t(x)$ are conjugate along γ_x. Conjugate curves along the Y-trajectories are defined similarly.

For each $x \in \mathbb{R}^2$, one can form the 2×2 matrices whose columns are the vectors F, G, or $[F, G]$. As in [9], we shall use the following scalar functions on $\mathbb{R}^2$:

$$\Delta_A(x) \doteq \det\big(F(x), G(x)\big), \tag{2.10}$$

$$\Delta_B(x) \doteq \det\big(G(x), [F, G](x)\big), \tag{2.11}$$

where det stands for determinant. A point $x \in \mathbb{R}^2$ is called an *ordinary point* if

$$\Delta_A(x) \cdot \Delta_B(x) \neq 0. \tag{2.12}$$

On the set of ordinary points we define the scalar functions f and g as the coefficients of the linear combination

$$[F, G](x) = f(x)F(x) + g(x)G(x). \tag{2.13}$$

In [9, p. 447] it was shown that

$$f(x) = -\frac{\Delta_B(x)}{\Delta_A(x)}. \tag{2.14}$$

These functions play a key role in the study of the structure of time-optimal trajectories. Of particular interest are the curves formed by zeros of the function Δ_B called turnpikes. These are the only curves that can be run by optimal trajectories corresponding to controls different from ± 1.

A point x at which $\Delta_A(x)\Delta_B(x) = 0$ is called a *nonordinary point*. A C^2 one-dimensional connected embedded submanifold S of $\mathbb{R}^2$, with the property that every $x \in S$ is a nonordinary point, is a *nonordinary arc* and it is *isolated* (or it is an INOA) if there exists a set U satisfying the following conditions:

(C1) U is an open connected subset of $\mathbb{R}^2$.

(C2) S is a relatively closed subset of U.

(C3) If $x \in U \setminus S$, then x is an ordinary point.

(C4) The set $U \setminus S$ has exactly two connected components.

A *turnpike* is an isolated nonordinary arc that satisfies the following conditions:

(S1) For each $x \in S$ the vectors $X(x)$ and $Y(x)$ are not tangent to S and point to opposite sides of S.

(S2) For each $x \in S$ one has $\Delta_B(x) = 0$ and $\Delta_A(x) \neq 0$.

(S3) Let U be an open set which satisfies (C1)–(C4) above. If U_X and U_Y are the connected components of $U \setminus S$ labelled in such a way that $X(x)$ points into U_X and $Y(x)$ points into U_Y, then the function f in (2.14) satisfies

$$f(x) > 0 \quad \text{on} \quad U_Y, \qquad\qquad f(x) < 0 \quad \text{on} \quad U_X.$$

Next, consider a turnpike S and a point $x_0 \in S$. We wish to construct a trajectory $\gamma \in \text{Traj}(\Sigma)$ such that $\gamma(t_0) = x_0$ and $\gamma(t) \in S$ for each $t \in \text{Dom}(\gamma) \doteq [t_0, t_1]$. After straightforward calculations we have that γ must correspond to the feedback control

$$\varphi_S(x) \doteq -\frac{\nabla\Delta_B \cdot F(x)}{\nabla\Delta_B \cdot G(x)}. \tag{2.15}$$

The turnpike S is said to be *regular* if the function φ_S in (2.15) satisfies

$$|\varphi_S(x)| < 1, \qquad x \in S. \tag{2.16}$$

A trajectory γ is said to be a *Z- or S-trajectory* or *singular trajectory* if there exists a regular turnpike S such that $\{\gamma(t) : t \in \text{Dom}(\gamma)\} \subset S$; in this case we write $\gamma \in \text{Traj}(Z)$.

Given a trajectory γ we denote by $n(\gamma)$ the smallest integer such that there exist $\gamma_i \in \text{Traj}(X) \cup \text{Traj}(Y) \cup \text{Traj}(Z)$, $i = 1, \ldots, n(\gamma)$, verifying

$$\gamma = \gamma_{n(\gamma)} * \cdots * \gamma_1.$$

We call $n(\gamma)$ the number of arcs of γ.

Given $\tau > 0$, define Π_τ to be the class of systems having an a priori bound on the number of arcs of optimal trajectories:

$$\Pi_\tau = \{\Sigma \in \Xi : \exists N(\Sigma) \text{ s.t. } \forall \gamma : [0, \tau] \to \mathbb{R}^2, \text{ optimal, } n(\gamma) \leq N(\Sigma)\}.$$

A subset of Ξ is said to be *generic* if it contains an open and dense subset of Ξ. In [8] the following theorem was proven.

THEOREM 2.2. *For every $\tau > 0$ the set Π_τ is a generic subset of Ξ.*

Given a system $\Sigma \in \Pi_\tau$ it is possible to construct a synthesis Γ for Σ. We can follow the classical idea of constructing extremal trajectories and deleting those trajectories which are not globally optimal. At the end we obtain a set of trajectories from which we can extract a synthesis. By construction, this synthesis is optimal. For synthesis theory see [2]–[4] and [14].

We describe an algorithm $\mathcal{A}$ by induction. At step N, we construct precisely those trajectories which are concatenation of N bang- or singular arcs and satisfy the PMP. The endpoints of the arcs forming these trajectories, corresponding to the switching times of the control, are determined by certain nonlinear equations. Under generic conditions, such equations can be solved by the implicit function theorem, thus determining a smooth switching locus. Eventually the algorithm will partition the reachable set $R(\tau)$ into finitely many open regions (where the optimal feedback control is either $u = 1$ or $u = -1$), separated by boundary curves and points, called *frame curves* and *frame points*, respectively.

At each step, it may happen that distinct extremal trajectories reach the same point x_0 at different times. It is therefore necessary to delete from the synthesis those trajectories which are not globally optimal. This procedure will usually produce new "overlap curves," consisting of points reached in minimum time by two distinct trajectories, one ending with the control value $u = 1$, the other with $u = -1$.

If at step N the algorithm $\mathcal{A}$ does not construct any new trajectory, then we say that $\mathcal{A}$ *stops at step N (for Σ at time τ)* or that $\mathcal{A}$ *succeeds for* Σ. From Theorem 2.2, it is clear that under generic assumptions there exists $N(\Sigma)$ such that $\mathcal{A}$ stops before step $N(\Sigma)$ and every γ constructed by $\mathcal{A}$ is optimal. By definition, $\mathrm{Fr}(R(\tau))$ is a frame curve, and its intersections with other frame curves are frame points.

If $\mathcal{A}$ stops, then for each $x \in R(\tau)$ there exists a set of constructed trajectories that reach x. Define $\Gamma_x \doteq \{\gamma : \gamma \text{ is constructed by } \mathcal{A}, \mathrm{Term}(\gamma) = x\}$.

We want to select, for each $x \in R(\tau)$, a trajectory from Γ_x to form a synthesis. Define K_k to be the set of points $x \in R(\tau)$ reached by at least one constructed trajectory γ satisfying $n(\gamma) \leq k$. Note that K_k is compact for each k and $K_{N(\Sigma)} = R(\tau)$. We proceed by induction on k. Given $x \in K_k \setminus K_{k-1}$, we consider the optimal trajectories $\gamma \in \Gamma_x$ formed by k arcs, for which the following holds. If $y = \gamma(t)$ is the initial point of the last arc of γ, then $\gamma \restriction [0, t]$ has been selected from Γ_y by induction. Finally, if there is more than one such trajectory, then we select one, say, according to the preference order X, Y, Z on the type of the last arc.

In this way, at step $N(\Sigma)$, we have constructed a synthesis for Σ at time τ. We use the symbol $\Gamma_{\mathcal{A}}(\Sigma, \tau)$ to denote this synthesis and call it *the synthesis generated by the algorithm $\mathcal{A}$.*

THEOREM 2.3. *Consider $\Sigma \in \Xi$ and $\tau > 0$. If $\mathcal{A}$ stops for Σ at time τ, then $\Gamma_{\mathcal{A}}(\Sigma, \tau)$ is an optimal synthesis.*

Remark 2.1. The points of overlap curves are reached by two different optimal trajectories. Moreover, if a trajectory $\gamma \neq \gamma^{\pm}$ (see (F1) and (F2) below) goes through an endpoint of an overlap curve, say, at time t_0, then all points $\gamma(t)$, $t \geq t_0$, are reached in two different optimal way. See Example 13 in §4. These are the only cases in which a point can be reached by two different optimal trajectories. Now, if a trajectory γ as above enters a turnpike, then

there is an open region on which the synthesis is not unique. But this situation is not generic. Therefore, for systems in a generic set the trajectories γ of the above type do not reach turnpikes, and the synthesis is unique, excluding a finite set of one-dimensional manifolds. Hence we have that the synthesis $\Gamma_{\mathcal{A}}(\Sigma, \tau)$ depends on the algorithm $\mathcal{A}$, but generically the optimal synthesis is *essentially* unique.

Given $x \in R(\tau)$ we denote by γ_x, u_x the trajectory of $\Gamma_{\mathcal{A}}(\Sigma, \tau)$ and the corresponding control such that $\gamma_x(t_x) = x$. If x does not belong to any frame curve, then we denote by $u_{\mathcal{A}}(x)$ the control $u_x(t_x)$. We have $|u_{\mathcal{A}}| = 1$.

The algorithm constructs only six types of frame curves:

(F1) the trajectory γ^-, starting from 0 and corresponding to the control $u^- \equiv -1$.

(F2) the trajectory γ^+, starting from 0 and corresponding to the control $u^+ \equiv 1$.

(F3) the topological frontier of the reachable set: $\mathrm{Fr}(R(\tau))$.

(F4) conjugate curves to other frame curves, also called switching curves.

(F5) regular turnpikes.

(F6) overlap curves.

To denote these types of curves we use, respectively, the symbols: X, Y, F, C, S, and K. Therefore we say that an FC D is an X-curve if $D \subset \gamma^-(\mathrm{Dom}(\gamma^-))$ and similarly for the other types of curves. We write $D \in \Gamma_{\mathcal{A}}(\Sigma, \tau)$ to denote the fact that D is an FC constructed by $\mathcal{A}$.

Now consider two systems Σ_1 and Σ_2, a time $\tau \geq 0$, and two open sets $U_1 \subset R_1(\tau)$ and $U_2 \subset R_2(\tau)$; here R_1 and R_2 denote the reachable sets of Σ_1 and Σ_2, respectively. Assume that $\mathcal{A}$ succeeds for Σ_1 and Σ_2 at time τ. We will say that $\Gamma_1 = \Gamma_{\mathcal{A}}(\Sigma_1, \tau) \restriction U_1$ and $\Gamma_2 = \Gamma_{\mathcal{A}}(\Sigma_2, \tau) \restriction U_2$ are *equivalent* if there exists an homeomorphism $\varphi : U_1 \mapsto U_2$ such that

(EC1) φ induces a bijection on Γ_i: $\{\varphi(\gamma_x(t)) : t \in \mathrm{Dom}(\gamma_x)\} \cap U_1 = \{\gamma_{\varphi(x)}(t) : t \in \mathrm{Dom}(\gamma_{\varphi(x)})\} \cap U_2$ for each $x \in U_1$; if the two sets are oriented for increasing t, then φ preserves the orientation.

(EC2) φ induces a bijection on FCs; i.e., for each FC D_1 of Γ_1 we have that $\varphi(D_1)$ is an FC of Γ_2 of the same type and vice versa, assuming that the types X- and Y- are equivalent. In this case we write $\Gamma_1 \restriction U_1 \equiv \Gamma_2 \restriction U_2$.

Remark 2.2. Note that in the definition of equivalence there are no requests about the time along γ_x; in fact there are no conditions of the type $\varphi(\gamma_x(t)) = \gamma_{\varphi(x)}(t)$. It is necessary to give a not-too-strict definition of equivalence to have a discrete set of equivalence classes. The same problem occurs in the definition of equivalence for a singular point of a dynamical system. In this case the orbital equivalence was introduced (see [1]).

Given x_1 and x_2 we say that $\Gamma_1 \restriction x_1$ and $\Gamma_2 \restriction x_2$ are equivalent, or we write $\Gamma_1 \restriction x_1 \equiv \Gamma_2 \restriction x_2$, if there exist U_1 and U_2 neighborhoods of x_1 and x_2, respectively, such that $\Gamma_1 \restriction U_1 \equiv \Gamma_2 \restriction U_2$. We say that two FCs D_i of Γ_i, $i = 1, 2$, are *equivalent* if for each $y_1 \in D_1 \setminus \partial D_1$, $y_2 \in D_2 \setminus \partial D_2$ we have that $\Gamma_1 \restriction y_1 \equiv \Gamma_2 \restriction y_2$. Similarly two frame points x_i of Γ_i, $i = 1, 2$, are *equivalent* if $\Gamma_1 \restriction x_1 \equiv \Gamma_2 \restriction x_2$.

If $\mathcal{A}$ succeeds for Σ at time τ, then under generic conditions, all frame points are intersections of two FCs. Using the same notation used for FCs, we will say that the origin is an (X, Y)-point; in fact, $0 \in \gamma^+ \cap \gamma^-$. Similarly if a frame point x is the intersection of two FCs D_1 and D_2 of respective type V_1 and V_2, then we say that x is a (V_1, V_2)-point. As for FCs we write $x \in \Gamma_{\mathcal{A}}(\Sigma, \tau)$ to denote the fact that x is a frame point constructed by $\mathcal{A}$.

Given $\varepsilon > 0$ we say that two systems $\Sigma_1 = (F_1, G_1)$, $\Sigma_2 = (F_2, G_2)$ are *ε-near* if

$$\max \{\| F_1 - F_2 \|_{C^3}, \| G_1 - G_2 \|_{C^3}\} \leq \varepsilon. \tag{2.17}$$

Consider a system Σ for which $\mathcal{A}$ succeeds at a time τ and a frame point x of $\Gamma_{\mathcal{A}}(\Sigma, \tau)$. We say that x is *structurally stable* if there exist $\varepsilon > 0$, $\delta > 0$ such that for each system Σ', ε-near

to Σ, there exists a unique frame point x' of the same type verifying

$$\| x - x' \| \leq \delta, \tag{2.18}$$

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma', \tau) \restriction x'. \tag{2.19}$$

We are interested only in structurally stable frame points: from conditions (2.18) and (2.19) we know that these are the only points that are *observable*; i.e., a small perturbation of the system does not change the structure of the synthesis near these points.

3. Frame curves. In this section we give a complete description of the FCs generated by the algorithm $\mathcal{A}$. We use the notation introduced in §2 for the six types (F1)–(F6) of FCs. From now on we consider a fixed $\tau \geq 0$ and a fixed system Σ for which $\mathcal{A}$ succeeds at time τ.

An FC D is *simple* if $D \setminus \partial D$ does not contain any frame point. Every FC can be divided into a finite number of simple FCs. The classification of simple FCs in connection with the classification of frame points, described in the following section, gives a complete classification of FCs. In fact two FCs D_1 and D_2 are equivalent if we can divide them into two families of simple FCs $D_1^1, \ldots, D_1^n$ and $D_2^1, \ldots, D_2^n$ such that

$$D_1^i \equiv D_2^i, \qquad D_1^i \cap D_1^j \equiv D_2^i \cap D_2^j \quad \forall\, i, j \in \{1, \ldots, n\},$$

where we assume, by definition, that $\emptyset \equiv \emptyset$. Therefore, throughout this section we consider only simple FCs.

***X*-curve.** Consider an X-curve D and $x \in D \setminus \partial D$. There exists a neighborhood U of x such that the control $u_{\mathcal{A}}$ is constant in each one of the two connected components U_1 and U_2 of $U \setminus D$. If, for example, $u_{\mathcal{A}} = 1$ on U_1, then Y-trajectories leave from D entering U_1. It is clear that there are only two possibilities:

(X1) $u_{\mathcal{A}} = 1$ on U_1 and $u_{\mathcal{A}} = -1$ on U_2, or vice versa;

(X2) $u_{\mathcal{A}} = -1$ on $U_1 \cup U_2$.

Example 1. Let $\tau > 2$, and consider the control system

$$\begin{cases} \dot{x}_1 = u, \\ \dot{x}_2 = x_1 + \dfrac{1}{2} x_1^2. \end{cases} \tag{3.1}$$

The X- and Y-trajectories can be described, giving x_2 as a function of x_1, and are, respectively, cubic polynomials of the following type:

$$x_2 = -\frac{x_1^3}{6} - \frac{x_1^2}{2} + \alpha, \qquad \alpha \in \mathbb{R}, \tag{3.2}$$

$$x_2 = \frac{x_1^3}{6} + \frac{x_1^2}{2} + \alpha, \qquad \alpha \in \mathbb{R}. \tag{3.3}$$

With a straightforward computation we obtain

$$[F, G] = \begin{pmatrix} 0 \\ -1 - x_1 \end{pmatrix}.$$

Then

$$\Delta_B(x) = \det \begin{pmatrix} 0 & 1 \\ -1 - x_1 & 0 \end{pmatrix} = 1 + x_1. \tag{3.4}$$

From (3.4) it follows that every turnpike is a subset of $\{(x_1, x_2) \in \mathbb{R}^2 : x_1 = -1\}$. Indeed, at the second step the algorithm $\mathcal{A}$ constructs the turnpike

$$S = \left\{(x_1, x_2) : x_1 = -1, x_2 \leq -\frac{1}{3}\right\}. \tag{3.5}$$

Given b, consider the trajectories $\gamma_1 : [0, b] \mapsto \mathbb{R}^2$ for which there exists $t_0 \in [0, b]$ such that $\gamma_1 \restriction [0, t_0]$ is a Y-trajectory and $\gamma_1 \restriction [t_0, b]$ is an X-trajectory, and the trajectories $\gamma_2 : [0, b] \mapsto \mathbb{R}^2$, $b > 2$, for which there exists $t_1 \in [2, b]$ such that $\gamma_2 \restriction [0, t_1]$ is an X-trajectory and $\gamma_2 \restriction [t_1, b]$ is a Y-trajectory. For every $b > 2$, these trajectories cross each other in the region of the plane above the cubic (3.3) with $\alpha = 0$ and determine an overlap curve K that originates from the point $(-2, -\frac{2}{3})$. We use the symbols $x^{+-}(b, t_0)$ and $x^{-+}(b, t_1)$ to indicate, respectively, the terminal points of γ_1 and γ_2 above. Explicitly we have

$$x_1^{+-} = 2t_0 - b, \qquad x_2^{+-} = -\frac{(2t_0 - b)^3}{6} - \frac{(2t_0 - b)^2}{2} + t_0^2 + \frac{t_0^3}{3}, \tag{3.6}$$

$$x_1^{-+} = b - 2t_1, \qquad x_2^{-+} = \frac{(b - 2t_1)^3}{6} + \frac{(b - 2t_1)^2}{2} - t_1^2 + \frac{t_1^3}{3}. \tag{3.7}$$

Now the equation

$$x^{+-}(b, t_0) = x^{-+}(b, t_1), \tag{3.8}$$

as b varies in $[2, +\infty[$, describes the set K. From (3.6), (3.7), and (3.8) it follows that

$$t_0 = b - t_1, \qquad t_1\Big(-2t_1^2 + (2 + 3b)t_1 + (-b^2 - 2b)\Big) = 0.$$

Solving for t_1 we obtain three solutions:

$$t_1 = 0, \qquad t_1 = b, \qquad t_1 = 1 + \frac{b}{2}. \tag{3.9}$$

The first two equations of (3.9) are trivial, while the third determines a point of K so that

$$K = \left\{(x_1, x_2) : x_1 = -2, x_2 \geq -\frac{2}{3}\right\}.$$

The set $R(\tau)$ is portrayed in Fig. 1.

Consider the system Σ_1 of Example 1 at time $\tau_1 > 2$. If (X1) holds true, then

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_1, \tau_1) \restriction \gamma^-(t_0), \tag{EC1a}$$

where

$$0 < t_0 < 1. \tag{EC1b}$$

Hence D is equivalent to $\gamma^- \restriction [0, 1]$. In this case we say that D is of type X_1 or that D is an X_1-curve.

If (X2) holds true, then

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_1, \tau_1) \restriction \gamma^-(t_0), \tag{EC2a}$$

where

$$1 < t_0 < 2. \tag{EC2b}$$

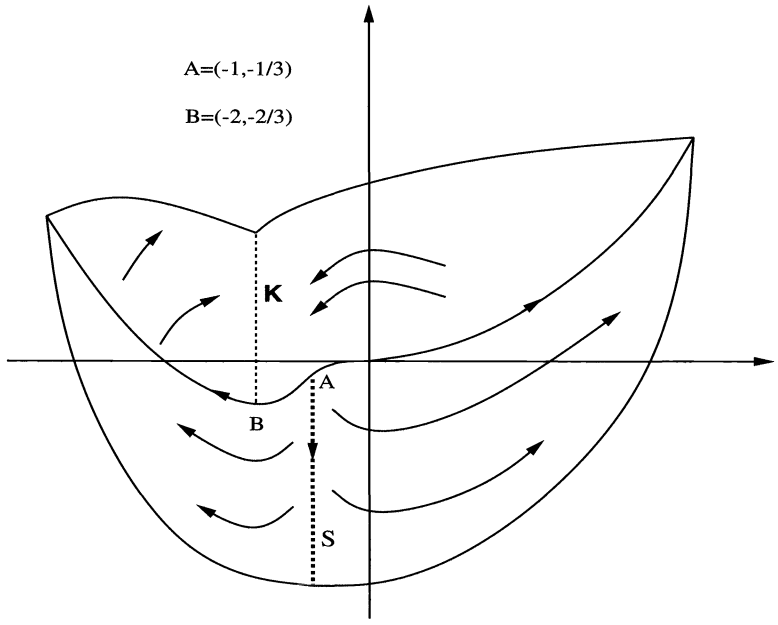

FIG. 1.

Then D is equivalent to $\gamma^- \restriction [1, 2]$. As before, we say that D is of type X_2 or that D is an X_2-curve.

***Y*-curve.** This case can be treated as the previous one, and we have the same equivalences. Now, the only difference is the sign of $u_{\mathcal{A}}$.

***F*-curve.** Consider an F-curve D and $x \in D \setminus \partial D$. There exists a neighborhood U of x in $R(\tau)$ such that $u_{\mathcal{A}}$ is constant on $U \setminus Fr(R(\tau))$. Consider the system Σ_1 at time τ_1 of Example 1. Choose $0 < \varepsilon < 1$, and let x_1 be the point reached by the trajectory corresponding to the control

$$u_1 = -1 \text{ on } [0, \varepsilon], \qquad u_1 = 1 \text{ on } [\varepsilon, \tau].$$

We have

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_1, \tau_1) \restriction x_1. \tag{EC3}$$

***C*-curve.** Let D be a C-curve, and consider a point x of $D \setminus \partial D$. There exists a neighborhood U of x such that the control $u_{\mathcal{A}}$ is constant in each one of the two connected components of $U \setminus D$. From the description of the switching curves it is clear that $u_{\mathcal{A}}$ is equal to 1 on one component and equal to -1 on the other.

Example 2. Consider $\tau > \pi$ and the control system

$$\begin{cases} \dot{x}_1 = x_2, \\ \dot{x}_2 = -x_1 + u. \end{cases} \tag{3.10}$$

This example is accurately described in [6, pp. 11–14] and [5, p. 80].

The X- and Y-trajectories are circles centered at $(-1, 0)$ and at $(1, 0)$, respectively. The algorithm $\mathcal{A}$ constructs $\gamma^{\pm}$ only up to time π; indeed after this time they are not extremal.

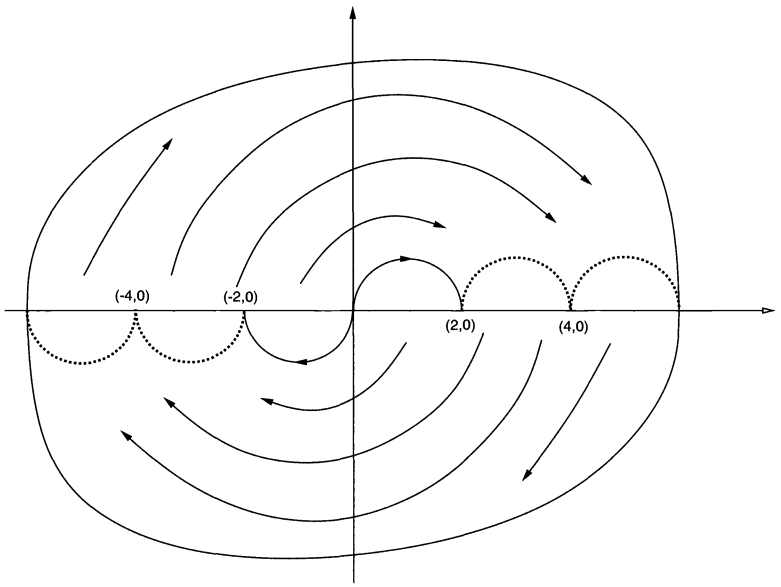

FIG. 2.

At step $n+1$ the following switching curves originate:

(a) all the semicircles of radius 1 centered at $(2n+1, 0)$ and contained in the half plane $\{(x_1, x_2) : x_2 \geq 0\}$.

(b) all the semicircles of radius 1 centered at $(-2n-1, 0)$ and contained in the half plane $\{(x_1, x_2) : x_2 \leq 0\}$.

Along the switching curves described in (a) the constructed trajectories arrive as Y-trajectories and leave as X-trajectories; i.e., the controls switch from $+1$ to -1. The opposite happens along the switching curves described in (b).

The set $R(\tau)$ is represented in Fig. 2.

Consider the system Σ_2 of Example 2 at time $\tau_2 > \frac{3}{2}\pi$. We have

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_2, \tau_2) \restriction (-3, -1). \tag{EC4}$$

***S*-curve.** Let x be a point of the relative interior of an S-curve D. As for the previous case, there exists a neighborhood U of x such that $u_{\mathcal{A}}$ is constant in each connected component of $U \setminus D$. From the definition of turnpike we have that $u_{\mathcal{A}}$ has different signs on the two components.

Consider the system Σ_1 at time τ_1 of Example 1. The following equivalence holds:

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_1, \tau_1) \restriction \left(-1, -\frac{1}{2}\right). \tag{EC5}$$

***K*-curve.** Consider a K-curve D and $x \in D \setminus \partial D$. If U is a suitably small neighborhood of x, then the control $u_{\mathcal{A}}$ is constant in each connected component of $U \setminus D$. As before, $u_{\mathcal{A}}$ has different signs on the two components. Consider the system Σ_1 of Example 1 at time $\tau_1 > 4$. We have the equivalence

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_1, \tau_1) \restriction (-2, 0). \tag{EC6}$$

Thanks to this analysis we have the following theorem.

THEOREM 3.1. *Consider $\Sigma \in \Xi$ and $\tau > 0$. If $\mathcal{A}$ succeeds for Σ at time τ and D is a simple FC of $\Gamma_{\mathcal{A}}(\Sigma, \tau)$, then D is of one of the following six types:*

$$X_1, \quad X_2, \quad F, \quad C, \quad S, \quad K,$$

and we have, respectively, one of the equivalences (EC1)–(EC6).

4. Frame points. In this section we give a complete description of the local structure of $\Gamma_{\mathcal{A}}$ in a neighborhood of a frame point. More precisely, only structurally stable frame points are considered. Therefore, all frame points will be intersections of no more than two FCs. Indeed, an intersection of three or more FCs can be destroyed by an arbitrary small perturbation (see (2.17)) of the system.

From now on we consider a fixed $\tau > 0$ and a fixed system Σ for which $\mathcal{A}$ succeeds at time τ. In particular Σ is locally controllable. For each type of frame point there are only a finite number of equivalence classes.

Before starting to examine frame points, case by case, we make a general observation. Consider a frame point x and two FCs D_1 and D_2 such that $\{x\} = D_1 \cap D_2$. There are four possible cases:

(FP0) $x \in D_1 \setminus \partial D_1, x \in D_2 \setminus \partial D_2$,
(FP1) $x \in D_1 \setminus \partial D_1, x \in \partial D_2$,
(FP2) $x \in \partial D_1, x \in D_2 \setminus \partial D_2$,
(FP3) $x \in \partial D_1, x \in \partial D_2$.

It is easy to check that, by construction, (FP0) can never occur. The case in which one frame curve is of type X, Y, F, S, or K is immediate. The case in which D_1 and D_2 are both C FCs is a consequence of the following observation. If we assume that D_1 and D_2 are not tangent and this is a generic situation, then there are some curves of zeros of either Δ_A or Δ_B to which x belongs. Indeed, near x, there are trajectories switching from control $+1$ to -1 and vice versa. Moreover, from Theorem 3.9 of [9] it follows that the possibility of switching from control $+1$ to -1 and vice versa depends on the sign of the function f of (2.14). In all possible cases, we obtain the existence of trajectories having two switchings near such curves. But this is prohibited by Lemma 7.1 of [9].

However, for each point we have to examine the other three possibilities.

The classification of frame points will be based on the types of the two intersecting curves D_1 and D_2. We will use the notation, introduced in §2, for frame points and the symbols $\gamma^{\pm}$, F, C, S, and K to indicate the curve of types (F1)–(F6), respectively.

(X, Y)-point. Consider an (X, Y)-point x of $\Gamma_{\mathcal{A}}(\Sigma, \tau)$. If $x = (0, 0)$, then it is a structurally stable (X, Y)-frame point. Indeed if Σ' is ε-near to Σ and ε is sufficiently small, then Σ' is locally controllable and $\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction (0, 0) \equiv \Gamma_{\mathcal{A}}(\Sigma', \tau) \restriction (0, 0)$. Let Σ_1 be the system of Example 1 at time $\tau_1 > 0$, then

$$\text{(EP1)} \qquad \Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction (0, 0) \equiv \Gamma_{\mathcal{A}}(\Sigma_1, \tau_1) \restriction (0, 0).$$

Now suppose that $x \neq (0, 0)$. It follows that $x = \gamma^-(t^-) = \gamma^+(t^+)$, $t^- > 0$, $t^+ > 0$. We have that $t^- = t^+$; otherwise one of the two trajectories would have been deleted from the synthesis. Since the condition $t^- = t^+$ can be destroyed by a small perturbation, x is not structurally stable. In fact in this case x belongs to an overlap curve; hence it is the intersection of at least three FCs.

(X, F)-point. Let x be an (X, F)-frame point. The cases (FP1) and (FP3) cannot occur because $\partial\big(\mathrm{Fr}(R(\tau))\big) = \emptyset$. Therefore we are in the case (FP2). There exists a neighborhood U of x (in $R(\tau)$) such that $u_{\mathcal{A}}$ is constant in each one of the two connected components U_1 and U_2 of $U \setminus (\gamma^- \cup F)$. One of the two following cases holds:

(XF1) $u_{\mathcal{A}} = -1$ on $U_1 \cup U_2$,

(XF2) $u_{\mathcal{A}} = 1$ on U_1 and $u_{\mathcal{A}} = -1$ on U_2, or vice versa.

Consider the system Σ_1 of Example 1 (§3) at time τ_1, and let $x_1 = \gamma^-(\tau_1)$. If (XF1) holds true and

$$1 < \tau_1 < 2, \tag{EP2a}$$

then

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_1, \tau_1) \restriction x_1. \tag{EP2b}$$

In this case we say that x is a frame point of type $(X, F)_1$.

If (XF2) holds true, then some Y-trajectories arise from γ^- and reach F. Let

$$\tau_1 > 2. \tag{EP3a}$$

Then

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_1, \tau_1) \restriction x_1, \tag{EP3b}$$

and x is a frame point of type $(X, F)_2$.

(X, C)-point. Assume that (FP1) holds true. There exists a neighborhood U of the (X, C)-frame point x such that $u_{\mathcal{A}}$ is constant in each one of the three connected components U_1, U_2, and U_3 of $U \setminus (\gamma^- \cup C)$. We label U_1, U_2, and U_3 in such a way that U_3 is the connected component of $U \setminus \gamma^-$ that does not contain $C \cap U$; U_1 comes before U_2 along γ^- for the orientation of increasing time. Because of the definition of C-curve we have one of the following:

(XC1) $u_{\mathcal{A}} = 1$ on U_1,

(XC2) $u_{\mathcal{A}} = 1$ on U_2.

Example 3. Consider $\tau > \frac{1}{3}\ln(4)$ and the system Σ:

$$\begin{cases} \dot{x}_1 = 3x_1 + u, \\ \dot{x}_2 = x_1^2 + x_1. \end{cases} \tag{4.1}$$

Since $\Sigma \in \Xi$ and

$$[F, G] = \begin{pmatrix} -3 \\ -2x_1 - 1 \end{pmatrix},$$

the system is locally controllable. The X-trajectory passing through the point (x_1^0, x_2^0) at time 0 is

$$x_1(t) = \left(x_1^0 - \frac{1}{3}\right) e^{3t} + \frac{1}{3}, \tag{4.2}$$

$$\begin{aligned} x_2(t) = {} & \frac{1}{6}\left(x_1^0 - \frac{1}{3}\right)^2 e^{6t} + \frac{5}{9}\left(x_1^0 - \frac{1}{3}\right) e^{3t} \\ & + \frac{4}{9}t + x_2^0 - \frac{1}{6}\left(x_1^0 - \frac{1}{3}\right)^2 - \frac{5}{9}\left(x_1^0 - \frac{1}{3}\right). \end{aligned} \tag{4.3}$$

While the Y-trajectory passing through the point (x_1^0, x_2^0) at time 0 is

$$x_1(t) = \left(x_1^0 + \frac{1}{3}\right) e^{3t} - \frac{1}{3}, \tag{4.4}$$

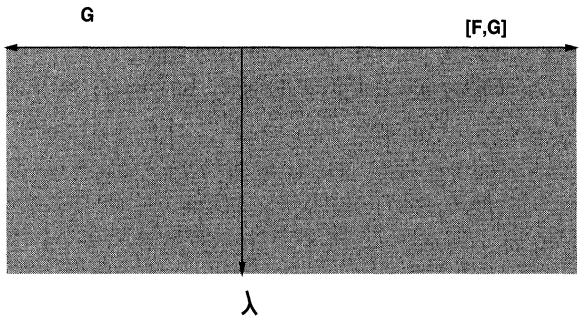

FIG. 3.

$$x_2(t) = \frac{1}{6}\left(x_1^0 + \frac{1}{3}\right)^2 e^{6t} + \frac{1}{9}\left(x_1^0 + \frac{1}{3}\right) e^{3t} - \frac{2}{9}t + x_2^0 - \frac{1}{6}\left(x_1^0 + \frac{1}{3}\right)^2 - \frac{1}{9}\left(x_1^0 + \frac{1}{3}\right). \tag{4.5}$$

The equation for turnpikes is

$$0 = \Delta_B(x_1, x_2) = -(2x_1 + 1).$$

Hence every turnpike is a subset of $S = \{(x_1, x_2) : x_1 = -\frac{1}{2}\}$. We have that the control φ_S to stay on S (cf. (2.15)) is

$$\varphi_S(x_1, x_2) = \frac{3}{2}.$$

Then there is no regular turnpike.

Now consider the pairs $(\gamma_s, u_s) \in \mathrm{Adm}(\Sigma)$, $\mathrm{In}(\gamma_s) = 0$, $\mathrm{Dom}(\gamma_s) = [0, s + \varepsilon_s]$ $(\varepsilon_s \geq 0)$ such that γ_s originates as an X-trajectory and switches at time s, going on as a Y-trajectory up to the time $s + \varepsilon_s$. Let $(\gamma^*, u^*) = (\gamma_{s^*}, u_{s^*})$ be the pair that verifies

$$\gamma^*(s^*) = \left(-\frac{1}{2}, -\frac{13}{72} + \frac{4}{9}\ln\left(\sqrt[3]{\frac{5}{2}}\right)\right). \tag{4.6}$$

Define $\varepsilon^* = \varepsilon_{s^*}$, and assume that γ^* satisfies the PMP with adjoint variable λ^*. We know that

$$\lambda^*(s^*) \cdot G(\gamma^*(s^*)) = 0, \qquad \Delta_B(\gamma^*(s^*)) = 0. \tag{4.7a}$$

Then

$$\frac{d}{dt}(\lambda^*(t) \cdot G(\gamma^*(t)))\Big|_{t=s^*} = \lambda^*(s^*) \cdot [F, G](\gamma^*(s^*)) = 0. \tag{4.7b}$$

From (4.7a), (4.7b), and straightforward calculations we have at $\gamma^*(s^*)$ the situation of Fig. 3.

Now it is easy to verify that

$$\forall t \in [s^*, s^* + \varepsilon^*] \qquad \Delta_B\big(\gamma^*(t)\big) > 0. \tag{4.8}$$

Thus, for each $t \in [s^*, s^* + \varepsilon^*]$, the pair of vectors $(G(t), [F, G](t))$ forms a positive-oriented base of $\mathbb{R}^2$. Since $u^*(t) \restriction [s^*, s^* + \varepsilon^*] \equiv 1$, it follows that the two functions $\lambda^*(t) \cdot G(\gamma^*(t))$ and $\lambda^*(t) \cdot [F, G](\gamma^*(t))$ are positive in a right neighborhood of s^*. Therefore G and $[F, G]$

lie in the darkened region of Fig. 3. But this is prohibited by (4.8), as observed above; hence it follows that $\varepsilon^* = 0$.

Similarly, if the trajectories γ_s, $s \in [\ln(\sqrt[3]{2}), s^*]$, satisfy the PMP, then ε_s is small. More precisely the algorithm $\mathcal{A}$ constructs trajectories that have a second switching point, and these switching points form a switching curve C_1 originating at (4.6).

The above geometric reasoning is very general; however, in this case we can compute explicit calculations. Suppose that γ_s satisfies the PMP with adjoint variable λ^s. The equation for λ^s is

$$\dot{\lambda}^s(t) = -\lambda^s(t) \cdot \big(\nabla F\big(\gamma_s(t)\big) + u_s(t)\, \nabla G\big(\gamma_s(t)\big)\big) = -\lambda^s(t) \cdot \big(\nabla F\big(\gamma_s(t)\big)\big). \tag{4.9}$$

Let x_1^s be the first component of γ_s. For time $t \geq s$, the explicit form of (4.9) is

$$(\dot{\lambda}_1^s, \dot{\lambda}_2^s)(t) = \left(-3\lambda_1^s(t) - \lambda_2^s(t)\left[2\left(x_1^s(s) + \frac{1}{3}\right) e^{3(t-s)} + \frac{1}{3}\right], 0\right). \tag{4.10}$$

Denote by ϕ_s the switching function along $(\gamma_s, u_s, \lambda^s)$. The solution to (4.10) with initial condition

$$\lambda^s(s) \cdot G\big(\gamma_s(s)\big) = 0$$

is

$$\lambda_2^s(t) \equiv \lambda_2^s(0),$$

$$\phi_s(t) = \lambda_1^s(t) = \lambda_2^s(t)\left[\frac{1}{3}\left(x_1^s(s) + \frac{2}{3}\right) e^{-3(t-s)} - \frac{1}{3}\left(x_1^s(s) + \frac{1}{3}\right) e^{3(t-s)} - \frac{1}{9}\right].$$

Now, the equation $\phi_s(t) = 0$ has two solutions:

$$t_1^s = s, \qquad t_2^s = s + \ln\left(\sqrt[3]{\frac{-3x_1^s(s) - 2}{3x_1^s(s) + 1}}\right).$$

Thus

$$x_1^s(t_2^s) = -x_1^s(s) - 1$$

gives the first component of switching points belonging to C_1.

Let γ^- be, as before, the X-trajectory verifying $\mathrm{In}(\gamma^-) = \gamma^-(0) = 0$. The point $\gamma^-(\ln \sqrt[3]{4})$ is conjugate to the origin along γ^-. Consider the trajectories γ_r, $\mathrm{In}(\gamma_r) = 0$, $\mathrm{Dom}(\gamma_r) = [0, b_r]$ $(b_r \geq r)$ that originate as Y-trajectories and have a switching at time r, going on as X-trajectories. Again we can make direct calculations and obtain the existence of a second switching time (if $r < \ln \sqrt[3]{2}$):

$$t_r = r + \ln\left(\sqrt[3]{-1 - \frac{10}{6\, a_r}}\right), \tag{4.11}$$

where $a_r = \big(\gamma_r(r) - \frac{1}{3}\big)$. These switching points form another switching curve C_2 that intersects γ^- at $\gamma^-(\ln \sqrt[3]{4})$. If we denote by x_1^r the first component of γ_r, then from (4.11) it follows that

$$x_1^r(t_r) = -x_1^r(r) - 1.$$

In Fig. 4, the reachable set $R(\tau)$ is represented.

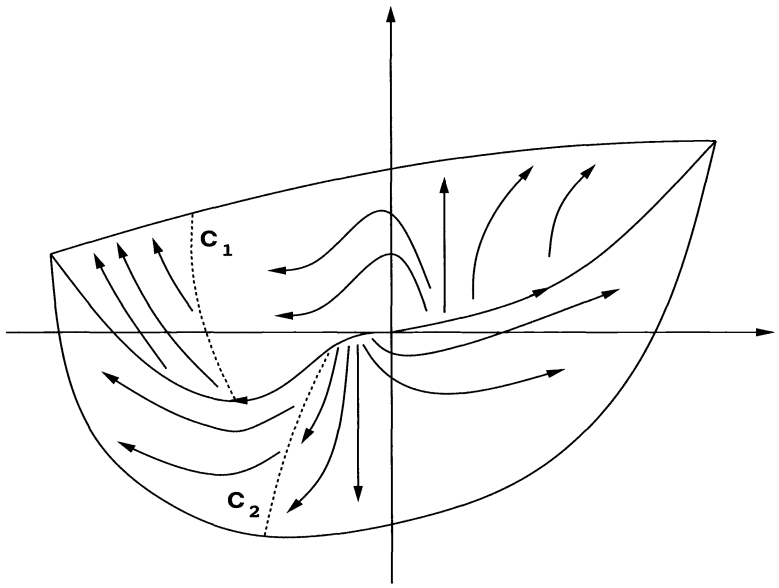

FIG. 4.

Consider the system Σ_3 at time τ_3 of Example 3. If (XC1) holds true, then $u_{\mathcal{A}} = -1$ on $U_2 \cup U_3$ and the Y-trajectories leaving γ^- reach C. We have

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_3, \tau_3) \restriction \gamma^-\left(\frac{1}{3} \ln \frac{5}{2}\right). \tag{EP4}$$

In this case we say that x is of type $(X, C)_1$.

If (XC2) holds true, then $u_{\mathcal{A}} = -1$ on $U_1 \cup U_3$. Hence

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_3, \tau_3) \restriction \gamma^-\left(\frac{1}{3} \ln 4\right), \tag{EP5}$$

and we say that x is of type $(X, C)_2$.

Remark 4.1. Consider the equivalence (EP4). In Example 3, $\gamma^-(\frac{1}{3} \ln \frac{5}{2})$ belongs to a nonordinary arc that is not a turnpike. This happens for every frame point x of type $(X, C)_1$. Indeed, assume $x = \gamma^-(t_x)$ and let (γ_r, u_r), $r \in [t_x - \varepsilon, t_x + \varepsilon]$ $(\varepsilon > 0)$, be the pair such that $\gamma_r(0) = \gamma^-(r)$ and $u_r \equiv 1$. Let λ_r be the covector field along (γ_r, u_r) satisfying

$$\lambda_r(0) \cdot G\big(\gamma_r(0)\big) = 0, \qquad \det\big[\lambda_r(0), G\big(\gamma_r(0)\big)\big] > 0, \qquad \| \lambda_r(0) \| = 1,$$

and consider the function

$$\psi(r, s) = \lambda_r(s) \cdot G\big(\gamma_r(s)\big).$$

The equation $\psi(r, s) = 0$ has two branches of solutions in $(t_x, 0)$. Then we have

$$0 = \left.\frac{\partial \psi}{\partial s}\right|_{(t_x, 0)} = \lambda_{t_x}(0) \cdot [F, G](\gamma^-(t_x)).$$

Now $0 = \lambda_{t_x}(0) \cdot G(x) = \lambda_{t_x}(0) \cdot [F, G](x)$ and $\lambda_{t_x}(0) \neq 0$. Then

$$\Delta_B(x) = \det\Big(G(x), [F, G](x)\Big) = 0.$$

It follows that if $\nabla(\Delta_B(x)) \neq 0$, then x belongs to an INOA (see §2 and [9]). This INOA cannot be a regular turnpike; otherwise it would have been constructed by the algorithm $\mathcal{A}$.

The case (FP2) is not generic. Indeed if (FP2) holds, then there exists a neighborhood U of x in C such that for each $y \in U$ there exists a trajectory γ_y that switches at $y = \gamma_y(t_y)$. One side of C with respect to x is reached by trajectories γ_y that arise from an FC D_1. The other side is reached by trajectories that originate from a different FC, say, D_2. Then at x, two different switching curves meet each other and x is not stable.

Suppose that (FP3) holds true. If C lies on the left (right) of γ^-, then $u_{\mathcal{A}} \equiv -1$ to the left (right) of γ^-. Consider the system Σ_2 of Example 2 at time $\tau_2 > \pi$. Then we have that

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_2, \tau_2) \restriction (2, 0). \tag{EP6}$$

In this case x is of type $(X, C)_3$.

(X, S)-point. Let x be an (X, S)-point x, and assume that (FP1) holds true. There exists a neighborhood U of x such that $u_{\mathcal{A}}$ is constant on each one of the three connected components U_1, U_2, and U_3 of $U \setminus (\gamma^- \cup S)$. We suppose that U_1, U_2, and U_3 are labelled in such a way that U_3 is the connected component of $U \setminus \gamma^-$ that does not contain $S \cap U$; U_1 comes before U_2 along γ^- for the orientation of increasing time. From the definition of a turnpike it follows that $u_{\mathcal{A}} = 1$ on U_1 and $u_{\mathcal{A}} = -1$ on $U_2 \cup U_3$. Consider the system Σ_1 at time τ_1 of the first example (§3). The following equivalence holds:

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_1, \tau_1) \restriction \left(-1, -\frac{1}{3}\right). \tag{EP7}$$

The cases (FP2) and (FP3) cannot occur because, from the description of turnpikes, it follows that γ^- cannot terminate at x.

(X, K)-point. Assume that (FP1) holds true. As before, there exists a neighborhood U of x such that $u_{\mathcal{A}}$ is constant in each one of the three connected components U_1, U_2, U_3 of $U \setminus (\gamma^- \cup K)$. We label U_1, U_2, and U_3 in such a way that U_3 is the connected component of $U \setminus \gamma^-$ that does not contain $K \cap U$; U_1 comes before U_2 along γ^- for increasing time. We have that $u_{\mathcal{A}} = 1$ on U_2 and $u_{\mathcal{A}} = -1$ on $U_1 \cup U_3$. Under generic assumptions, the Y-trajectories arising from γ^- reach K. In fact, if the opposite happens, then $X(x)$ and $Y(x)$ are parallel and have the same versus, but this is not generic. Consider again the system Σ_1 at time τ_1 of the first example (§3). In this case we have

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_1, \tau_1) \restriction \left(-2, -\frac{2}{3}\right), \tag{EP8}$$

and we say that x is of type $(X, K)_1$.

Now let (FP2) hold. For every sufficiently small neighborhood U of x, we have that $u_{\mathcal{A}}$ is constant in each one of the two connected components U_1 and U_2 of $U \setminus K$. If, for example, U_1 contains $\gamma^- \cap U$, then $u_{\mathcal{A}} = -1$ on U_1 and $u_{\mathcal{A}} = 1$ on U_2.

Example 4. Consider ε, $0 < \varepsilon < 1$, $\tau > \frac{\pi}{\sqrt{1-\varepsilon}}$, and the system Σ:

$$\begin{cases} \dot{x}_1 = \varepsilon x_2 + u x_2, \\ \dot{x}_2 = u(1 - x_1). \end{cases} \tag{4.12}$$

It is easy to check that

$$[F, G] = \begin{pmatrix} -\varepsilon(1 - x_1) \\ -\varepsilon x_2 \end{pmatrix}. \tag{4.13}$$

From (4.13) and Lemma 2.1 we have that the system is locally controllable.

The X-trajectory passing through the point (x_1^0, x_2^0) at time 0 is

$$x_1(t) = (x_1^0 - 1)\cos(\sqrt{1-\varepsilon}\,t) + x_2^0\sqrt{1-\varepsilon}\,\sin(\sqrt{1-\varepsilon}\,t) + 1, \tag{4.14}$$

$$x_2(t) = \frac{(x_1^0 - 1)}{\sqrt{1-\varepsilon}}\sin(\sqrt{1-\varepsilon}\,t) - x_2^0\cos(\sqrt{1-\varepsilon}\,t). \tag{4.15}$$

The Y-trajectory passing through the point (x_1^0, x_2^0) at time 0 is

$$x_1(t) = (x_1^0 - 1)\cos(\sqrt{1+\varepsilon}\,t) + x_2^0\sqrt{1+\varepsilon}\,\sin(\sqrt{1+\varepsilon}\,t) + 1, \tag{4.16}$$

$$x_2(t) = -\frac{(x_1^0 - 1)}{\sqrt{1+\varepsilon}}\sin(\sqrt{1+\varepsilon}\,t) + x_2^0\cos(\sqrt{1+\varepsilon}\,t). \tag{4.17}$$

The equation for turnpikes is

$$0 = \Delta_B(x_1, x_2) = -\varepsilon x_2^2 + \varepsilon(1 - x_1)^2. \tag{4.18}$$

Hence every turnpike is a subset of $S = \{(x_1, x_2) : x_2 = \pm(1 - x_1)\}$. Using (4.16)–(4.18) it is easy to verify that the trajectory γ^+ intersects the set S in a point (x_1^+, x_2^+) of the first quadrant. The algorithm $\mathcal{A}$ constructs the turnpike $S_1 = \{(x_1, x_2) : x_2 = 1 - x_1, x_1^+ \le x_1 < 1\}$. The singular control φ_S^1 along the turnpike S_1 (cf. (2.15)) is

$$\varphi_S^1(x_1, x_2) = -\frac{\varepsilon x_2}{1 - x_1 + x_2} > -1. \tag{4.19}$$

From (4.19) we have

$$\dot{x}_1(\varphi_S^1) = \frac{\varepsilon}{2}(1 - x_1). \tag{4.20}$$

Hence the point $(1, 0)$ is not reached in finite time by a singular trajectory.

Similarly, using (4.14), (4.15) it is easy to verify that the trajectory γ^- intersects the set S in a point of the fourth quadrant:

$$(x_1^-, x_2^-) \doteq \gamma^-\left(\frac{1}{\sqrt{1-\varepsilon}}\arccos\left(\sqrt{\frac{1}{2-\varepsilon}}\right)\right). \tag{4.21}$$

Hence the algorithm $\mathcal{A}$ constructs the turnpike $S_2 = \{(x_1, x_2) : x_2 = x_1 - 1, x_1 \le x_1^-\}$. Indeed, the control φ_S^2 (cf. (2.15)) is

$$\varphi_S^2(x_1, x_2) = \frac{\varepsilon x_2}{1 - x_1 - x_2}.$$

The trajectories $\gamma^\pm$ are very close to the circle A of center $(1, 0)$ and radius 1; γ^+ runs clockwise, and γ^- counterclockwise. From (4.14)–(4.17) we have that γ^+ lies inside A, γ^- outside, and

$$\gamma^+ \cap \gamma^- \cap A = \{(0, 0), (2, 0)\}.$$

However, the two trajectories $\gamma^\pm$ do not meet each other at $(2, 0)$; indeed,

$$(2, 0) = \gamma^+\left(\frac{\pi}{\sqrt{1+\varepsilon}}\right) = \gamma^-\left(\frac{\pi}{\sqrt{1-\varepsilon}}\right).$$

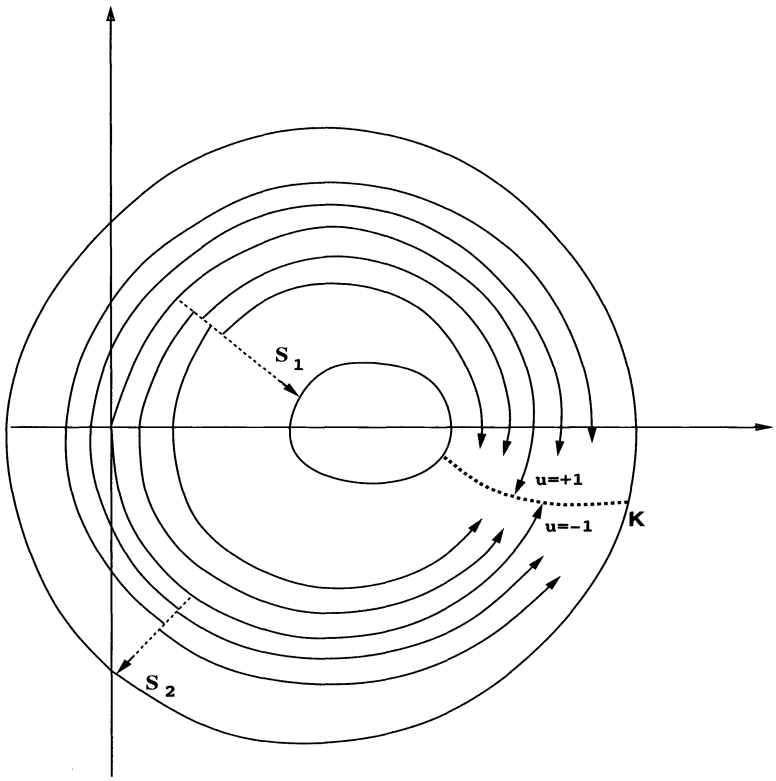

FIG. 5.

But the $X * Y$ and $Y * X$ trajectories constructed by the algorithm give rise to an overlap curve K, and $\gamma^{\pm}$ end on it. In Fig. 5, $R(\tau)$ is represented.

Consider the system Σ_4 at time τ_4 of Example 4, and let $\bar{x}$ be the point in which γ^- intersects the overlap curve. We have

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_4, \tau_4) \restriction \bar{x}, \tag{EP9}$$

and we say that x is of type $(X, K)_2$.

Assume that (FP3) holds true and that X and K are not tangent. There exists a neighborhood U of x such that $u_{\mathcal{A}}$ is constant in each one of the two connected components U_1 and U_2 of $U \setminus (\gamma^- \cup K)$. Suppose that U_1 and U_2 are labelled in such a way that the vector $X(x)$ points into U_2. It is clear that $u_{\mathcal{A}} = -1$ on U_1 and $u_{\mathcal{A}} = 1$ on U_2. The Y-trajectories leaving from γ^- do not reach K.

Example 5. Consider the system (cf. Example 1)

$$\begin{cases} \dot{x}_1 = u, \\ \dot{x}_2 = \dfrac{1}{2}x_1^2 + x_1 \end{cases} \tag{4.22}$$

and the two embedded submanifolds

$$M_1 = \left\{(x_1, x_2) : x_1 = 0, -\frac{2}{3} \le x_2 \le 0\right\},$$

$$M_2 = \left\{(x_1, x_2) : x_1 = \sqrt{2}, -\frac{2}{3} \le x_2 \le \frac{2}{3}\right\}.$$

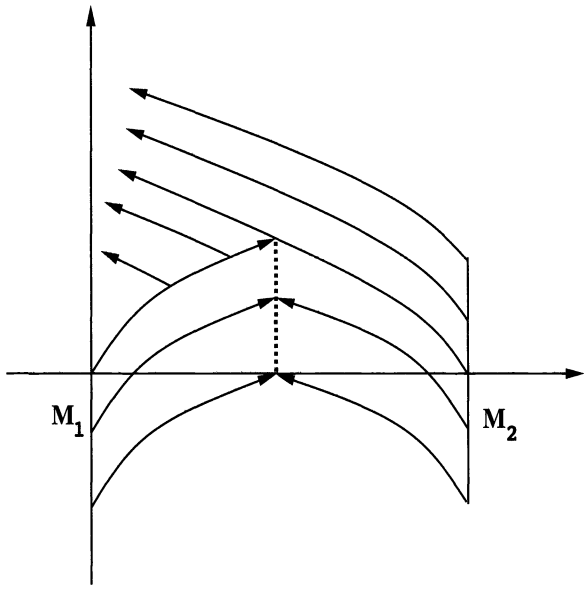

FIG. 6.

We assume that for each $y \in M_1$ there exists a Y-trajectory $\gamma_1(y)$ that verifies $\gamma_1(y)(0) = y$. Moreover, for each $x \in M_2$ there exists an X-trajectory $\gamma_2(x)$ that arises from x at time 0. Finally, an X-trajectory originates from each point of the Y-trajectory $\gamma_1(0)$, i.e., $\gamma_1(0)$ is the trajectory γ^+ of a given system.

At the point $(1, \frac{2}{3})$ the trajectories $\gamma_1(0)$, $\gamma_2\big((\sqrt{2}, 0)\big)$ meet each other. After this point $\gamma_1(0)$ is not constructed by $\mathcal{A}$ because the trajectories $\gamma_2\big((\sqrt{2}, c)\big)$, $c \geq 0$, achieve a better performance. The trajectories $\gamma_1\big((0, -c)\big)$ and $\gamma_2\big((\sqrt{2}, -c)\big)$, meeting each other, give rise to an overlap curve:

$$K = \left\{(x_1, x_2) : x_1 = -1, 0 \leq x_2 \leq \frac{2}{3}\right\}.$$

In Fig. 6, this local example is portrayed.

Consider the synthesis Γ_5 of Example 5. We have that

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_5 \restriction \left(1, \frac{2}{3}\right), \tag{EP10}$$

and we say that x is of type $(X, K)_3$.

(Y, F)-, (Y, C)-, (Y, S)-, (Y, K)-points. These points can be treated as the corresponding points with Y replaced by X, and we have the same equivalences. In this case the only difference is the sign of $u_{\mathcal{A}}$.

(X, X)-, (Y, Y)-, (F, F)-points. It is easy to verify that points of these types cannot exist.

(F, C)-point. Consider an (F, C)-point x. Since $\partial\big(\mathrm{Fr}(R(\tau))\big) = \emptyset$, the cases (FP2) and (FP3) cannot occur. Then (FP1) holds true. There exists a neighborhood U of x in $R(\tau)$ such that $u_{\mathcal{A}}$ is constant in each one of the two connected components of $U \setminus (F \cup C)$. It is clear that $u_{\mathcal{A}} = 1$ on one connected component and $u_{\mathcal{A}} = -1$ on the other. The trajectories leaving from C reach F. Consider the system Σ_2 of Example 2 at time π. We have

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_2, \pi) \restriction (-3, -1). \tag{EP11}$$

(F, S)-point. As for the previous type, only the case (FP1) can hold. There exists a neighborhood U of x in $R(\tau)$ such that $u_{\mathcal{A}}$ is constant in each one of the two connected components of $U \setminus (F \cup S)$. Again $u_{\mathcal{A}} = 1$ on one connected component and $u_{\mathcal{A}} = -1$ on the other. Under generic assumptions the trajectories leaving from S reach F. Consider the system Σ_1 at time τ_1 of Example 1. Let x_1 be the point in which the turnpike intersects the frontier of the reachable set, namely,

$$x_1 = \left(-1, -\frac{1}{3} - \frac{1}{2}(\tau_1 - 1)\right).$$

It follows that

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_1, \tau_1) \restriction x_1. \tag{EP12}$$

(F, K)-point. Consider an (F, K)-point x. The case (FP1) is the only possible one. There exists a neighborhood U of x in $R(\tau)$ such that $u_{\mathcal{A}}$ is constant in each one of the two connected components of $U \setminus (F \cup K)$. It is clear that $u_{\mathcal{A}} = 1$ on one connected component and $u_{\mathcal{A}} = -1$ on the other. Consider again the system Σ_1 at time τ_1 of Example 1. Let x_1 be the point in which the overlap curve intersects the frontier of the reachable set, namely,

$$x_1 = \left(-2, \frac{2}{3} + \frac{1}{3}\left(1 + \frac{\tau}{2}\right)^3 - \left(1 + \frac{\tau}{2}\right)^2\right).$$

We have the following:

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_1, \tau_1) \restriction x_1. \tag{EP13}$$

(C, C)-point. Let x be a (C, C)-point. From the definition of switching curve we have that the cases (FP1) and (FP2) cannot occur. Therefore (FP3) holds.

There exist two switching curves C_1 and C_2 verifying $x = C_1 \cap C_2$ and a neighborhood U of x such that $u_{\mathcal{A}}$ is constant in each connected component of $U \setminus (C_1 \cup C_2)$. We have that $u_{\mathcal{A}}$ has different signs on the two connected components. Consider the following cases:

(CCa) The curves leaving from C_1 reach C_2.

(CCb) The curves leaving from C_2 reach C_1.

It is easy to show that (CCa) and (CCb) cannot hold at the same time; otherwise there is no trajectory reaching x. Hence we have two cases:

(CC1) (CCa) holds and (CCb) does not, or vice versa.

(CC2) (CCa) and (CCb) do not hold.

Example 6. Consider the system (4.1) of Example 3 and the manifold

$$M = \{(x_1, x_2) : x_1 = 0, |x_2| \leq 1\}.$$

We assume that from every point $(0, x_2) \in M$ an X-trajectory $\gamma(x_2)$ arises, with initial time 0 and with adjoint variable satisfying

$$[\lambda_1(x_2)](0) = -\frac{9}{36} - \frac{1}{36}\operatorname{sgn}(x_2)\, x_2, \qquad [\lambda_2(x_2)](0) = -1.$$

With simple calculations we obtain the solutions to the equation $[\phi(x_2)](t) = 0$, where $\phi(x_2)$ is the switching function along $(\gamma(x_2), -1, \lambda(x_2))$:

$$t^{\pm}(x_2) = \ln\left(\sqrt[3]{\frac{5}{2} \pm \frac{1}{2}\sqrt{9 + 36\,[\lambda_1(x_2)](0)}}\right).$$

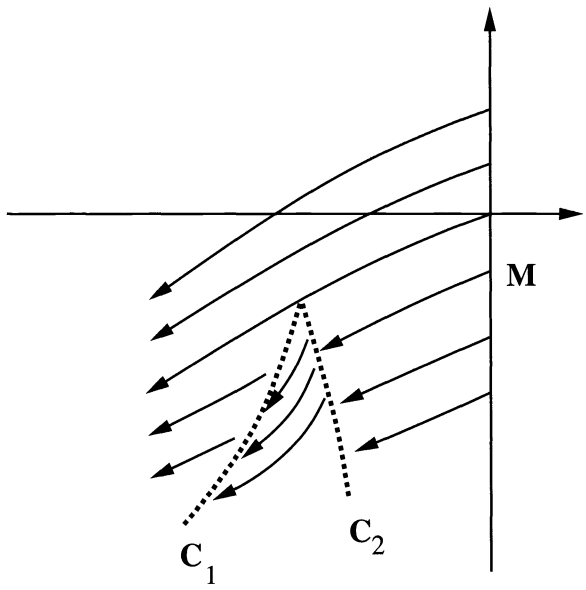

FIG. 7.

Hence, the trajectories $\gamma(x_2)$, $x_2 \leq 0$, has a switching at time $t^-(x_2)$, while the trajectories $\gamma(x_2)$, $x_2 > 0$, do not switch. These switching points form a switching curve C_1 having the point (4.6) as endpoint.

Now the equation $\phi(x_2) = 0$ has another solution after the time $t^-(x_2)$, namely,

$$t'(x_2) = t^-(x_2) + \ln\left(\sqrt[3]{\frac{-3\ p_1(x_2) - 2}{3\ p_1(x_2) + 1}}\right),$$

where $p_1(x_2)$ is the first coordinate of the first switching point of $\gamma(x_2)$. These switching points form another switching curve C_2 that meets C_1 at the point (4.6). This local example is portrayed in Fig. 7.

Consider the synthesis Γ_6 of Example 6. If (CC1) holds true, then

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_6 \restriction \left(-\frac{1}{3}, -\frac{13}{72} + \frac{4}{9}\ln\left(\sqrt[3]{\frac{5}{2}}\right)\right), \tag{EP14}$$

and we say that x is of type $(C, C)_1$.

Consider the system Σ_2 at time $\tau_2 > 3\pi$ of Example 2. If (CC2) holds true, then

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_2, \tau_2) \restriction (4, 0), \tag{EP15}$$

and we say that x is of type $(C, C)_2$.

Remark 4.2. Reasoning as in Remark 4.1 one can prove that if x is a frame point of type $(C, C)_1$, then $\Delta_B(x) = 0$.

The frame points of type $(C, C)_2$ are not *effective* singular points. Indeed, the optimal synthesis near these points is equivalent to the synthesis near a point x of a simple FC of type C, verifying $x \in C \setminus \partial C$.

(C, S)-point. Consider a (C, S)-point x. There exists a neighborhood U of x such that $u_{\mathcal{A}}$ is constant in each connected component of $U \setminus (C \cup S)$.

The cases (FP1) and (FP2) cannot occur because the control $u_{\mathcal{A}}$ changes sign crossing S (or C); moreover it has to be constant along each side of C (or S).

Therefore (FP3) holds true. There exists a C^1 diffeomorphism $\alpha : [0, \varepsilon] \mapsto \mathbb{R}^2$, $\varepsilon > 0$, such that $\alpha(t) \in C$, $\alpha(0) = x$. Consider the vectors

$$C(x) = \lim_{t \to 0} \dot{\alpha}(t), \qquad S(x) = F(x) + \varphi_S(x)G(x),$$

where φ_S is the control to stay on S (cf. (2.15)). Assume that $C(x)$ and $S(x)$ are not parallel. Let U_X and U_Y be the connected component of $U \setminus \{x + tS(x) : t \in \mathbb{R}\}$ labelled in such a way that $X(x)$ and $Y(x)$ point into U_X and U_Y, respectively. Moreover, let U_1 and U_2 be the connected component of $U \setminus (C \cup S)$ labelled in such a way that the angle with vertex x and sides $C(x)$ and $S(x)$ contained in U_1 is smaller than that one contained in U_2. Now, if U_1 is contained in U_Y, then $u_{\mathcal{A}} = 1$ on U_1; otherwise $u_{\mathcal{A}} = -1$ on U_1.

There exists $\gamma_S \in \mathrm{Traj}(\Sigma)$ such that $\gamma_S(\mathrm{Dom}(\gamma_S)) = S \cap U$. We have two cases:

(CS1) $\mathrm{In}(\gamma_S) = x$.

(CS2) $\mathrm{Term}(\gamma_S) = x$.

Assume that (CS1) holds. There are two subcases:

(CSa) Some constructed trajectories reach C from U_2.

(CSb) Some constructed trajectories reach C from U_1.

If (CSb) holds, then no nontrivial trajectory reaches x, but this is not possible. Hence (CSa) holds true. For the same reason the trajectories originating from S and entering U_2 cannot reach C.

Example 7. Consider the system (4.22) of Example 5 and the manifold

$$M = \left\{(x_1, x_2) : x_1 = 0, -\frac{1}{3} \le x_2 \le \frac{1}{3}\right\}.$$

We assume that from each $(x_1, x_2) \in M$ there arises, with initial time 0, an X-trajectory $\gamma(x_1, x_2) = \gamma(x_2)$ with adjoint variable $\lambda(x_2)$ that satisfies

$$[\lambda_1(x_2)](0) = \frac{-1 - 4\,\mathrm{sgn}(x_2)\,x_2^2}{2}, \qquad [\lambda_2(x_2)](0) = -1,$$

where $\mathrm{sgn}(x) = x \mid x \mid^{-1}$ if $x \neq 0$ and $\mathrm{sgn}(0) = 0$. Now, the switching function along $(\gamma(x_2), -1, \lambda(x_2))$ is

$$[\phi(x_2)](t) = \lambda_1(t) = -\frac{t^2}{2} + t - \frac{1 + 4\,\mathrm{sgn}(x_2)\,x_2^2}{2}.$$

If $x_2 \le 0$, the equation $[\phi(x_2)](t) = 0$ has the following solutions:

$$t_1(x_2) = 1 + 2|x_2|, \qquad t_2(x_2) = 1 - 2|x_2|;$$

otherwise there is no solution. Then every trajectory $\gamma(x_2)$, $x_2 \le 0$, switches at the point

$$[\gamma(x_2)](t_2) = \left(2|x_2| - 1, -\frac{(2|x_2| - 1)^3}{6} - \frac{(2|x_2| - 1)^2}{2} + x_2\right).$$

These switching points form a switching curve C.

The trajectory $\gamma(0)$ crosses the set $\{(x_1, x_2) : \Delta_B(x_1, x_2) = 0\} = \{(x_1, x_2) : x_1 = -1\}$ at a switching point; hence the algorithm $\mathcal{A}$ constructs the turnpike

$$S = \left\{(x_1, x_2) : x_1 = -1, x_2 \le -\frac{1}{3}\right\}.$$

This local example is represented in Fig. 8.

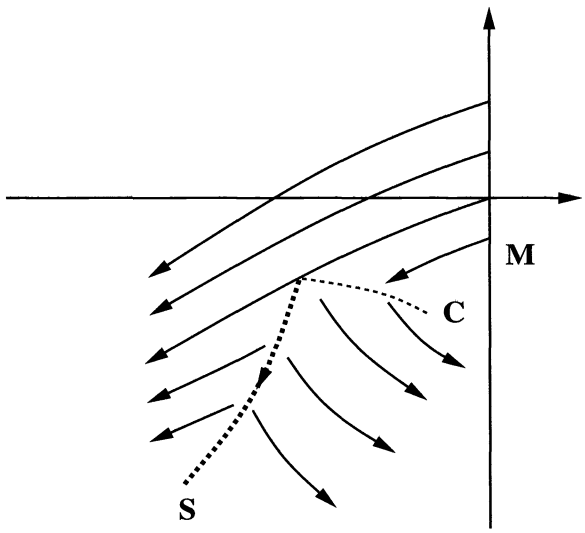

FIG. 8.

Consider the synthesis Γ_7 of Example 7. We have

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_7 \restriction \left(-1, -\frac{1}{3}\right), \tag{EP16}$$

and we say that x is of type $(C, C)_1$.

Suppose that (CS2) holds. We again have the subcases (CSa) and (CSb). The case (CSa) cannot hold. Indeed, the trajectories arising from S and entering U_2 cannot reach C, and then, from the direction of $X(x)$, $Y(x)$, we have that $\mathrm{In}(\gamma_S) = x$, contradicting (CS2).

Suppose that (CSb) holds. We have that the trajectories leaving from S and entering U_1 reach C. From Theorem 3.9 of [9] it follows that Δ_B cannot have constant sign on $V \cap U_1$ for any neighborhood V of x. Hence we have the nongeneric condition $\nabla\Delta_B(x) = 0$.

Consider again the case (CS2), and assume that $C(x)$ and $S(x)$ are parallel. The trajectories arriving onto C come from S.

Example 8. Let $\tau > \frac{7}{3} + \sqrt[3]{4}$, and consider the system

$$\begin{cases} \dot{x}_1 = u, \\ \dot{x}_2 = (x_1 + \psi(x_2)) + \dfrac{1}{2}(x_1 + \psi(x_2))^2, \end{cases} \tag{4.23}$$

where

$$\psi(x_2) = \begin{cases} 0, & x_2 > -1, \\ (x_2 + 1)^4, & x_2 \leq -1. \end{cases} \tag{4.24}$$

Observe that for $x_2 > -1$ the system is the same as in Example 1. There is a turnpike S that lies on the line $x_1 = -1$ between the points $(-1, -\frac{1}{3})$ and $(-1, -1)$. Moreover, for $x_2 \leq -1$, S is represented by the equations

$$x_1 + (x_2 + 1)^4 + 1 = 0, \qquad x_2 \leq -1. \tag{4.25}$$

Recalling (2.15), from (4.23)–(4.25) we have that the control φ_S is

$$\varphi_S(x_1, x_2) = 0 \quad \text{if } x_2 \geq -1, \qquad \varphi_S(x_1, x_2) = 2(x_2 + 1)^3 \quad \text{if } x_2 \leq -1. \tag{4.26}$$

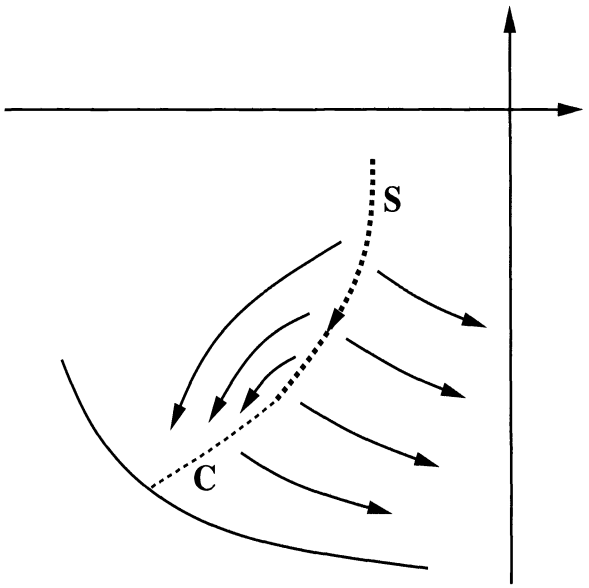

FIG. 9.

By (4.26), the turnpike S is regular up to the point

$$(\bar{x}_1, \bar{x}_2) = \left(-1 - \frac{1}{2\sqrt[3]{2}}, -1 - \frac{1}{\sqrt[3]{2}}\right). \tag{4.27}$$

Indeed

$$\varphi_S(\bar{x}_1, \bar{x}_2) = -1.$$

Hence, the algorithm $\mathcal{A}$ constructs a turnpike that ends at the the point (4.27). The set $R(\tau)$ near the point (4.27) is represented in Fig. 9.

Consider the system Σ_8 at time τ of Example 8. We have

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_8, \tau) \restriction \left(-1 - \frac{1}{2\sqrt[3]{2}}, -1 - \frac{1}{\sqrt[3]{2}}\right), \tag{EP17}$$

and we say that x is of type $(C, S)_2$.

(C, K)-point. There exists a neighborhood U of the (C, K)-point x such that $u_{\mathcal{A}}$ is constant in each connected component of $U \setminus (C \cup K)$.

The cases (FP1) and (FP2) cannot occur because the control $u_{\mathcal{A}}$ changes sign when we cross K (or C), but it also has to be constant along each side of C (or K).

Therefore (FP3) holds true. There exist two C^1 diffeomorphisms $\alpha_{1,2} : [0, \varepsilon] \mapsto \mathbb{R}^2$, $\varepsilon > 0$, such that $\alpha_1(t) \in C$, $\alpha_2(t) \in K$, $\alpha_{1,2}(0) = x$. Consider the vectors

$$C(x) = \lim_{t \to 0} \dot{\alpha}_1(t), \qquad K(x) = \lim_{t \to 0} \dot{\alpha}_2(t).$$

Suppose that $C(x)$ and $K(x)$ are not parallel. Let U_X and U_Y be the connected components of $U \setminus \{x + tK(x) : t \in \mathbb{R}\}$ labelled in such a way that $X(x)$, $Y(x)$ point into U_X and U_Y, respectively. Let U_1 and U_2 be the connected components of $U \setminus (C \cup K)$ labelled in such a way that the angle with vertex x and sides $C(x)$ and $K(x)$ contained in U_1 is smaller than that one contained in U_2. If U_1 is contained in U_X, then $u_{\mathcal{A}} = 1$ on U_1; otherwise $u_{\mathcal{A}} = -1$ on U_1.

We have two cases:

(CK1) Some constructed trajectories reach C from U_1.

(CK2) Some constructed trajectories reach C from U_2.

Assume that (CK1) holds. The trajectories originating from C cannot reach K; otherwise we have one of the not generic conditions $Y(x) = 0$, $X(x) = 0$.

Example 9. Consider the system (cf. Example 2)

$$\begin{cases} \dot{x}_1 = x_2, \\ \dot{x}_2 = -x_1 + u \end{cases} \tag{4.28}$$

and the two manifolds

$$M_1 = \{(x_1, x_2) : x_1 = 0,\ 1 \le x_2 \le 2\},$$

$$M_2 = \{(x_1, x_2) : 1 \le x_1 \le 2,\ x_2 = 3\}.$$

The algorithm $\mathcal{A}$ succeeds for the system (4.28) at time 4. A Y-trajectory $\gamma'(x) \in \Gamma_{\mathcal{A}}(\Sigma, 4)$, with an associate adjoint variable $\lambda'(x)$, passes through each point $x \in M_1$. We suppose that from each $x \in M_1$ a Y-trajectory $\gamma(x)$ with adjoint variable $\lambda(x)$ arises at time 0. Moreover, $(\gamma(x), \lambda(x))$ is obtained from $(\gamma'(x), \lambda'(x))$ shifting the time.

Consider the line given by the equation

$$x_2 = (\sqrt{2} - 3)\, x_1 + 8 - \sqrt{8}. \tag{4.29}$$

For each $s \in [1, \frac{2}{3}\sqrt{6}]$ the trajectory $\gamma^s = \gamma\big((0, s)\big)$ intersects the line (4.29) in a point, say, (x_1^s, x_2^s).

Let $r(s) \in [1, 2]$ be such that the X-trajectory passing through $(r(s), 3)$ intersects the line (4.29) in (x_1^s, x_2^s). We assume that an X-trajectory γ_r with initial time $t(r)$ originates from each $(r, 3) \in M_2$. If $r = r(s)$ for some s, define, denoting by d the Euclidean distance,

$$t_s \doteq t\big(r(s)\big) = 2 \arcsin\left(\frac{d\big((0, s), (x_1^s, x_2^s)\big)}{2\sqrt{1 + s^2}}\right) - 2 \arcsin\left(\frac{d\big((r(s), 3), (x_1^s, x_2^s)\big)}{2\sqrt{(r(s) + 1)^2 + 9}}\right). \tag{4.30}$$

Otherwise

$$t(r) \doteq \max\{t_s : s \in [1, 2]\}.$$

We associate with every γ_r an adjoint variable λ_r verifying

$$\lambda_1^r\big(t(r)\big) = -1, \qquad \lambda_2^r\big(t(r)\big) = 0. \tag{4.31}$$

The equation (4.31) implies that $\lambda^r\big(t(r)\big) \cdot G\big((r, 3)\big) = 0$. Then to satisfy the PMP the trajectory γ_r is an X-trajectory for a time interval of length π.

The trajectories γ^s, $s \in [1, \frac{2}{3}\sqrt{6}]$, form a switching curve:

$$C = \left\{(x_1, x_2) : x_2 = \sqrt{1 - (x_1 - 3)^2},\ 2 \le x_1 \le \frac{8}{3}\right\}.$$

By direct calculations, one can verify that (4.30) ensures that the trajectories γ^s and $\gamma_{r(s)}$, $s \in [\frac{2}{3}\sqrt{6}, 2]$, meet each other, giving rise to an overlap curve:

$$K = \left\{(x_1, x_2) : (x_1, x_2) \text{ satisfies (4.29)},\ 2 \le x_1 \le \frac{8}{3}\right\}.$$

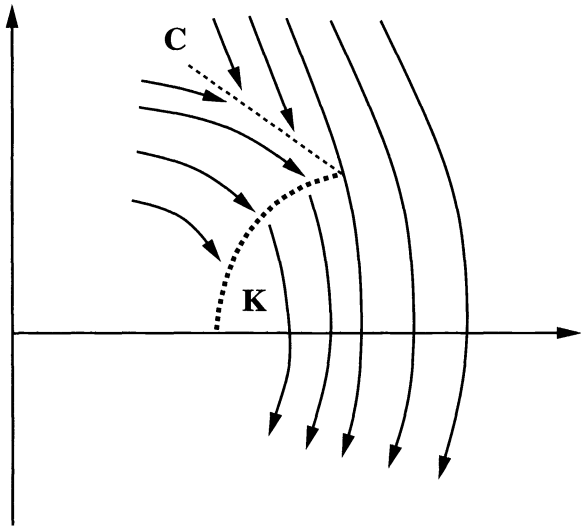

FIG. 10.

The curves K and C meet each other at the point

$$\left(\frac{8}{3}, \frac{\sqrt{8}}{3}\right).$$

In Fig. 10, this local example is portrayed.

Consider the synthesis Γ_9 of Example 9. We have

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_9 \restriction \left(\frac{8}{3}, \frac{\sqrt{8}}{3}\right), \tag{EP18}$$

and we say that x is of type $(C, K)_1$.

Example 10. Consider the system

$$\begin{cases} \dot{x}_1 = 3\, x_1 - u, \\ \dot{x}_2 = x_1^2 + x_1 \end{cases} \tag{4.32}$$

that is obtained from the system (4.1), replacing G with $-G$, and the manifold

$$M = \{(x_1, x_2) : x_1 = 0, |x_2| < \varepsilon\}.$$

We assume that from every point $(0, x_2) \in M$ a Y-trajectory $\gamma(x_2)$ with initial time $t_0(x_2)$ arises. Moreover, $\gamma(x_2)$ admits an adjoint variable satisfying

$$[\lambda_1(x_2)](0) = -\frac{9}{36} + 25\ \mathrm{sgn}(x_2)\ x_2, \qquad [\lambda_2(x_2)](0) = -1.$$

With simple calculations we obtain the solutions to the equation $[\phi(x_2)](t) = 0$, where $\phi(x_2)$ is the switching function along $(\gamma(x_2), +1, \lambda(x_2))$:

$$t^{\pm}(x_2) = t_0(x_2) + \ln\left(\sqrt[3]{\frac{5}{2} \pm \frac{1}{2}\sqrt{9 + 36\ [\lambda_1(x_2)](0)}}\right). \tag{4.33}$$

Hence the trajectories $\gamma(x_2)$, $x_2 \geq 0$, have a switching at time $t^-(x_2)$, while the trajectories $\gamma(x_2)$, $x_2 < 0$, do not switch. Let $x^-(x_2) \doteq [\gamma(x_2)](t^-(x_2))$, $x_2 \geq 0$. From (4.33) we have

$$x_1^- = -\frac{1}{2} + 5\, x_2^2, \tag{4.34}$$

and these switching points form a switching curve C_1 originating from (4.6).

Now the equation $\phi(x_2) = 0$, where $\phi(x_2)$ denotes again the switching function along $\gamma(x_2)$, after the time $t^-(x_2)$ has another solution:

$$t'(x_2) = t^-(x_2) + \ln\left(\sqrt[3]{\frac{-3\, x_1^-(x_2) - 2}{3\, x_1^-(x_2) + 1}}\right). \tag{4.35}$$

These switching points give rise to another switching curve C_2 that meets C_1 at the point (4.6).

It is easy to verify that the X-trajectories leaving from C_1 cross the trajectory $\gamma_0 \doteq \gamma(0)$ before reaching the switching curve C_2. Hence, we can define $P(x_2)$, $x_2 \geq 0$, to be the point at which $\gamma(x_2)$ meets γ_0.

Let $r(x_2)$, $x_2 \geq 0$, be such that the trajectory $\gamma(r(x_2))$ meets $\gamma(x_2)$ at the point $Q(x_2) \doteq [\gamma(x_2)](t'(x_2))$; i.e., they meet each other on C_2.

Now let $t_1(x_2)$, $t_2(x_2)$ be the time in which, respectively, $\gamma(x_2)$, γ_0 reaches $P(x_2)$ and $t_3(x_2)$, $t_4(x_2)$ be the time in which, respectively, $\gamma(x_2)$, $\gamma(r(x_2))$ reaches $Q(x_2)$. If x_2 is sufficiently small, from (4.34), (4.35) we have that

$$t_4 - t_3 < t_2 - t_1.$$

Then, taking ε sufficiently small, we can define

$$t_0(x_2) = 0 \qquad \text{if } x_2 < 0,$$

$$t_0(x_2) = \frac{(t_2 - t_1) + (t_4 - t_3)}{2} \qquad \text{if } x_2 \geq 0.$$

With this choice, the trajectories $\gamma(x_2)$, $x_2 \geq 0$, and $\gamma(x_2)$, $x_2 < 0$, meet each other, forming an overlap curve K that meets C_1 at (4.6). The curve C_2 is deleted by the algorithm. In Fig. 11, this local example is portrayed.

Assume that (CK2) holds. Consider the synthesis Γ_{10} of Example 10. We have

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{10} \restriction \left(-\frac{1}{3}, -\frac{13}{72} + \frac{4}{9}\, \ln\left(\sqrt[3]{\frac{5}{2}}\right)\right), \tag{EP19}$$

and we say that x is of type $(C, K)_2$.

Now suppose that $C(x)$ and $K(x)$ are parallel. If the trajectories leaving from C do not reach K, then the equivalence (EP18) holds and an unstable tangency between C and K is verified. If the opposite happens, then we have a stable tangency between C and K.

Example 11. Consider the system

$$\begin{cases} \dot{x}_1 = \dfrac{x_1 + 1}{2} + u\, \dfrac{x_1 - 1}{2}, \\ \dot{x}_2 = \dfrac{x_2}{2} + u\, \dfrac{x_2}{2} \end{cases} \tag{4.36}$$

and the manifold

$$M = \{(x_1, x_2) : x_1 = 0, 0 < x_2 < 1\}.$$

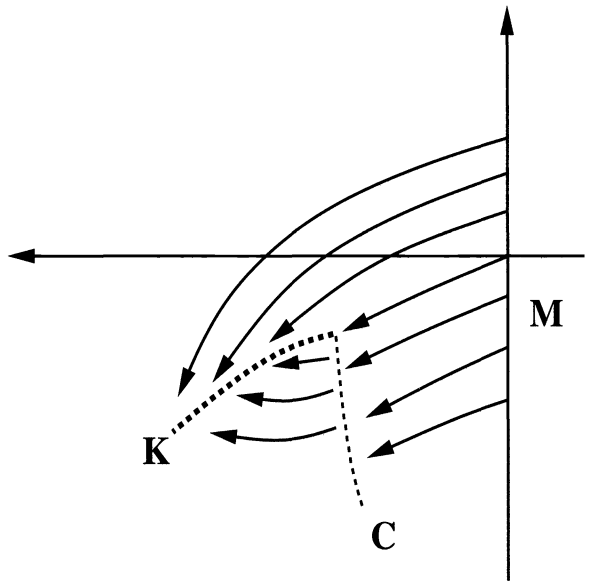

FIG. 11.

Assume that from every point $(0, x_2) \in M$, with initial time 0, an X-trajectory $\gamma(x_2)$ originates with adjoint variable satisfying

$$[\lambda_1(x_2)](0) = \frac{x_2}{1 - \sqrt{1 - x_2^2}}, \qquad [\lambda_2(x_2)](0) = -1. \tag{4.37}$$

It is easy to verify, from (4.36), (4.37), that every $\gamma(x_2)$ switches at time

$$t(x_2) = 2 - \sqrt{1 - x_2^2}$$

and the corresponding switching points form a switching curve

$$C = \{(x_1, \psi(x_1)) : 1 < x_1 < 2\}, \qquad \psi(x_1) \doteq \sqrt{1 - (2 - x_1)^2},$$

that is an arc of circle.

Observe that for ε small, $Y(\varepsilon, \psi(\varepsilon))$ points to the right of C and $Y(2 - \varepsilon, \psi(2 - \varepsilon))$ points to the left of C. Then there exists $(\bar{x}_1, \bar{x}_2) \in C$ such that $Y(\bar{x}_1, \bar{x}_2)$ is tangent to C. Define $C' \doteq \{(x_1, \psi(x_1)) \in C : x_1 \geq \bar{x}_1\}$. The trajectories $\gamma(x_2)$ that reach C' meet other trajectories $\gamma(x_2)$, giving rise to an overlap curve K. It is possible to move along C' with a trajectory of the system. Hence we can construct an envelope for the curves $\gamma(x_2) \restriction [0, t(x_2)]$ that reach C'; see [12], [13] for envelope theory. Hence the subset C' of C is removed by the algorithm. In Fig. 12 this local example is represented.

Consider the synthesis Γ_{11} of Example 11, and define $(\bar{x}_1, \bar{x}_2)$ in the same way. The following equivalences hold:

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{11} \restriction (\bar{x}_1, \bar{x}_2)$$

$$\equiv \Gamma_{10} \restriction \left(-\frac{1}{3}, -\frac{13}{72} + \frac{4}{9} \ln\left(\sqrt[3]{\frac{5}{2}} \right) \right).$$

Remark 4.3. The point $(\bar{x}_1, \bar{x}_2)$ of Example 11 and (4.6) of Example 10 are equivalent, but they are in some sense different. In fact, proceeding as in Remark 4.1 one can prove that

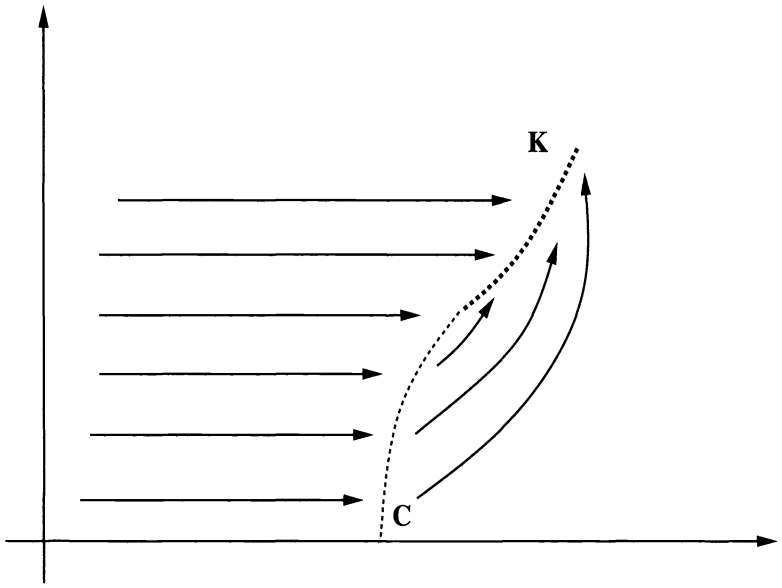

FIG. 12.

if $K(x)$ and $C(x)$ are linearly independent and (CK2) holds, then $\Delta_B(x) = 0$. If, instead, $K(x)$ and $C(x)$ are parallel, we can have that $\Delta_B(x) \neq 0$ as in Example 10.

(S, S)-point. It is easy to verify that these points cannot exist.

(S, K)-point. Consider an (S, K)-point x. The control $u_{\mathcal{A}}$ is constant in each connected component of $U \setminus (S \cup K)$ for every sufficiently small neighborhood U of x.

The cases (FP1) and (FP2) cannot occur because the control $u_{\mathcal{A}}$ changes sign when we cross K (or S) and is constant along each side of S (or K).

Therefore (FP3) holds true. The cases in which every trajectory arising from S reaches K or no trajectory leaving from S reaches K are not generic. Indeed, we have that $X(x)$ and $Y(x)$ are linearly dependent. Therefore the trajectories leaving from one side of S reach K, and those leaving from the other side do not. There exists $\gamma_S \in \mathrm{Traj}(\Sigma)$ such that $\gamma_S(\mathrm{Dom}(\gamma_S)) = S \cap U$. There are two cases:

(SK1) $\mathrm{In}(\gamma_S) = x$.

(SK2) $\mathrm{Term}(\gamma_S) = x$.

Example 12. Consider the same system and the same manifold of Example 7, and define S in the same way. We assume that from each $(0, x_2) \in M$ an X-trajectory $\gamma(x_2)$ arises with initial time

$$t_0(x_2) = -\frac{2}{3}\, x_2$$

and with adjoint variable satisfying

$$[\lambda_1(x_2)](0) = \frac{-1 - \alpha\ \mathrm{sgn}(x_2)\ x_2^2}{2}, \qquad [\lambda_2(x_2)](0) = -1,$$

where $\alpha > 0$ and sgn is defined as in Example 7. There is again a switching curve C. The X-trajectories starting from $(0, x_2)$, $x_2 \leq 0$, reach $(-1, -\frac{1}{3} - x_2) \in S$ at time

$$1 + \frac{2}{3}\, |x_2|.$$

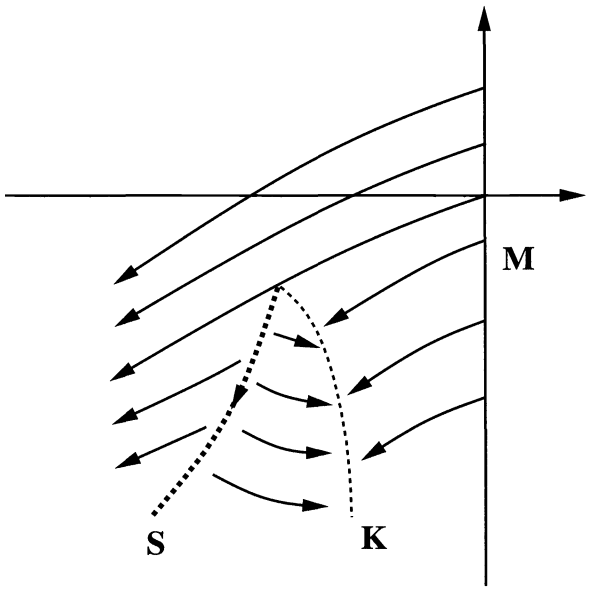

FIG. 13.

On the other hand the $Z * X$-trajectories, concatenations of an X- and a Z- trajectory, starting from 0 reach the same point at time

$$1 + \frac{|x_2|}{2}.$$

Therefore the $Y * Z * X$-trajectories, concatenations of an X-, a Z-, and a Y-trajectory, starting from the origin, and the X-trajectories starting from $(0, x_2)$, $x_2 \leq 0$, give rise to an overlap curve K having $(-1, -\frac{1}{3})$ as its endpoint.

Let $(s, k(s))$ be a parametrization of K in a neighborhood of $(-1, -\frac{1}{3})$, and define

$$\beta \doteq \left.\frac{dk(s)}{ds}\right|_{s=-1^+}.$$

Now let $(c_1(x_2), c_2(x_2))$ be a parametrization of the switching curve C. After straightforward calculations we have

$$\left.\frac{dc_2}{dc_1}\right|_{c_1=-1^+} = -\frac{3}{2} - \frac{1}{\alpha}.$$

Thus if α is sufficiently small,

$$\beta \geq -\frac{3}{2} - \frac{1}{\alpha},$$

and the overlap curve K arises. Therefore the curve C is deleted by the algorithm. This local example is portrayed in Fig. 13.

If (SK1) holds true, then consider the synthesis Γ_{12} of Example 12. We have

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \upharpoonright x \equiv \Gamma_{12} \upharpoonright \left(-1, -\frac{1}{3}\right), \tag{EP20}$$

and we say that x is of type $(S, K)_1$.

Example 13. Consider $0 < \varepsilon << 1$, $\tau > 1$, and the system Σ:

$$\begin{cases} \dot{x}_1 = u, \\ \dot{x}_2 = x_1^3 - \varepsilon x_1. \end{cases} \tag{4.38}$$

We have that

$$[F, G] = \begin{pmatrix} 0 \\ \varepsilon - 3x_1^2 \end{pmatrix};$$

hence the system is locally controllable. The X- and Y-trajectories are quartic polynomials of the following types, respectively:

$$x_2 = -\frac{x_1^4}{4} + \varepsilon \frac{x_1^2}{2} + \alpha, \qquad \alpha \in \mathbb{R},$$

$$x_2 = \frac{x_1^4}{4} - \varepsilon \frac{x_1^2}{2} + \alpha, \qquad \alpha \in \mathbb{R}.$$

The equation for turnpikes is

$$0 = \Delta_B(x_1, x_2) = \varepsilon - 3x_1^2,$$

whose set of solutions is

$$\left\{(x_1, x_2) : x_1 = \pm\sqrt{\frac{\varepsilon}{3}}\right\}. \tag{4.39}$$

Every turnpike is a subset of (4.39). The algorithm constructs the turnpikes

$$S_1' = \left\{(x_1, x_2) : x_1 = \sqrt{\frac{\varepsilon}{3}}, x_2 \leq -\frac{5}{36}\varepsilon^2\right\} \cap R(\tau),$$

$$S_2' = \left\{(x_1, x_2) : x_1 = -\sqrt{\frac{\varepsilon}{3}}, x_2 \geq \frac{5}{36}\varepsilon^2\right\} \cap R(\tau).$$

The points $(\pm\sqrt{\varepsilon}, \mp\frac{\varepsilon^2}{4})$ are conjugate to the origin along $\gamma^{\pm}$. Two overlap curves K_2 and K_1, respectively, originate at these points. The algorithm partially deletes the turnpikes S_1' and S_2', determining two new turnpikes $S_1 \subset S_1'$ and $S_2 \subset S_2'$. The new turnpikes S_1 and S_2 end on K_1 and K_2, respectively. In Fig. 14, $R(\tau)$ is represented.

Remark 4.4. Let Σ'' be the system $(\dot{x}_1, \dot{x}_2) = (u, x_1^3 - \psi(x_1)\varepsilon x_1)$, where ψ is a smooth function, $\{x : \psi(x) \neq 0\} \subset B(0, 1)$, and $\psi \restriction B(0, \frac{1}{2}) \equiv 1$. Note that this system is obtained by a small perturbation of the system Σ': $(\dot{x}_1, \dot{x}_2) = (u, x_1^3)$. The synthesis $\Gamma_{\mathcal{A}}(\Sigma', \tau)$ is formed by bang-bang trajectories with at most one switching. It is clear that Σ' is not structurally stable (in a sense that will be stated more precisely in a following paper). In fact we have that for ε small the system Σ'' is ε-near (cf. (2.17)) to Σ', but $\Gamma_{\mathcal{A}}(\Sigma'', \tau)$ has a structure completely different from $\Gamma_{\mathcal{A}}(\Sigma', \tau)$.

If (SK2) holds, consider the system Σ_{13} at time τ and the curves S_1 and K_1 of Example 13. Let $x_1 = S_1 \cap K_1$. We have

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_{13}, \tau) \restriction x_1, \tag{EP21}$$

and we say that x is of type $(S, K)_2$.

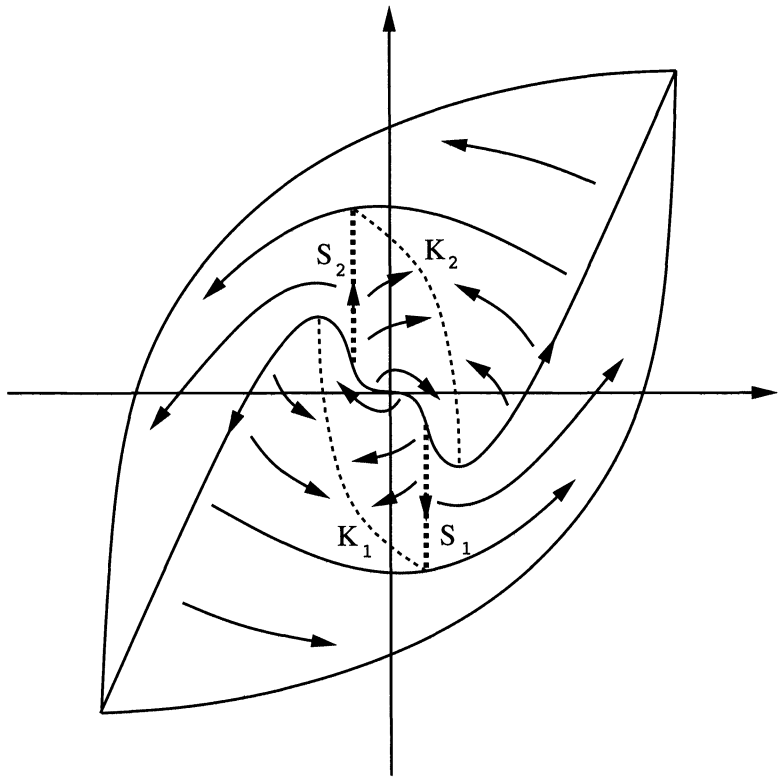

FIG. 14.

(K, K)-point. Consider a (K, K)-point x. From the definition of overlap curve we have that the cases (FP1) and (FP2) cannot occur; then (FP3) holds. Consider the system Σ_{13} at time τ of Example 13. The overlap curve K_1 is union of two overlap curves K_1' and K_1''. The set K_1' is formed by intersections of $Y * X$- and $X * Y$-trajectories, while K_1'' is formed by intersections of $Y * X$- and $X * S * Y$-trajectories. Let $x_1 = K_1' \cap K_1''$. We have

$$\Gamma_{\mathcal{A}}(\Sigma, \tau) \restriction x \equiv \Gamma_{\mathcal{A}}(\Sigma_{13}, \tau) \restriction x_1. \tag{EP22}$$

Remark 4.5. As observed for $(C, C)_2$ points (see Remark 4.2), the frame points of type (K, K) are not *effective* singular points.

From the present analysis we immediately have the following theorem.

THEOREM 5.2. *Consider $\Sigma \in \Xi$ and $\tau > 0$. If $\mathcal{A}$ succeeds at time τ for Σ and x is a frame point, then x is of one of the following 22 types:*

$$(X, Y),\ (X, F)_{1,2},\ (X, C)_{1,2,3},\ (X, S),\ (X, K)_{1,2,3},\ (F, C),$$

$$(F, S),\ (F, K),\ (C, C)_{1,2},\ (C, S)_{1,2},\ (C, K)_{1,2},\ (S, K)_{1,2},\ (K, K),$$

and we have, respectively, one of the equivalences (EP1)–(EP22).

Acknowledgments. We wish to thank Prof. A. Bressan for suggesting the problem and for much useful advice.

BIFURCATION PROBLEMS FOR SOME PARAMETRIC NONLINEAR PROGRAMS IN BANACH SPACES*

AUBREY B. POORE†

Abstract. Singularities in a class of parametric nonlinear programming problems in Banach spaces are investigated using bifurcation theory. Motivated by the Fritz John first-order necessary conditions and a nonstandard normalization of the multipliers, this problem is first formulated as a system of nonlinear equations. Conditions for this system to be Fredholm are then derived, and singularities are shown to arise from a violation of one or more of the following conditions: strict complementarity, surjectivity of the Fréchet derivative of the active constraints, and a second-order condition. A branching analysis is developed for each of these singularities under a second-order nondegeneracy assumption. Examples from the calculus of variations are then used to illustrate these singularities.

Key words. bifurcation, singularity, parametric nonlinear programming, Banach spaces

AMS subject classifications. 90C31, 90C48

1. Introduction. The parametric constrained optimization problem considered in this work is that of determining the behavior of solution(s) as a parameter or vector of parameters $\alpha \in \mathbf{R}^r$ varies over a region of interest for the problem

$$\begin{aligned} &\text{minimize} && f_0(x,\alpha) \\ &\text{subject to} && F(x,\alpha) = 0, \\ &&& f_i(x,\alpha) \le 0 \text{ for } i = 1,\dots,m, \end{aligned} \tag{1.1}$$

where $f_i \in C^2(U \times V; \mathbf{R})$, $F \in C^2(U \times V; Y)$, U and V are open subsets of the Banach space X and $\mathbf{R}^r$, respectively, and Y is a second Banach space that contains the range of $F(x,\alpha)$. This formulation is sufficiently general to cover classes of parametric problem in the calculus of variations and nonlinear optimal control [1, 9, 16, 23, 56]. Physical problems leading to (1.1) contain parameters. Some are fixed and are known either precisely or imprecisely; others (sometimes called control parameters) may be varied to enhance the system. For imprecisely known parameters, the sensitivity and persistence of the solution to variations in these parameters can be of paramount importance. For control parameters that are varied over a wide range to enhance the system, persistence of minima, exchanges in the type of solutions of (1.1), differentiability, and sensitivity of the solution with respect to variations in the natural parameters are equally important. Indeed, varying system parameters can often assist in obtaining a "global" view of the solution set of (1.1).

For finite-dimensional versions of problem (1.1), local behavior of regular and singular points has been investigated extensively (see, e.g., [4, 6, 20, 25–27, 32, 41, 42, 55] and the references therein). Reviews with extensive bibliographies can be found in the works of Jongen and Weber [28]; Bonnans, Ioffe, and Shapiro [7]; and Fiacco and Ishizuka [15] and the books of Fiacco [13, 14] and Levitin [36]. Numerical continuation procedures for investigating the global behavior of the finite-dimensional versions of (1.1) have also been developed [19, 37]. Following the work of Robinson [46–48], the sensitivity analysis of generalized equations was investigated by several authors [11, 30, 35, 44, 48]. The case of infinite-dimensional space and general cone and set constraints are discussed in a number of recent papers [2, 12, 24, 38, 53, 54]. The questions of parametric dependence for these problems are indeed more difficult than for (1.1). Thus, and as reviewed by Ioffe [22], these investigations have generally made three basic assumptions: (a) local uniqueness of the unperturbed solution, (b) constraint

qualifications, and (c) a second-order sufficient condition. In a different direction, Ioffe [22] has relaxed the first two assumptions and to an extent the third assumption by reducing a problem of the form (1.1) to a composite unconstrained problem and developing a sensitivity theory for the latter. In this work, we also investigate the problem (1.1) in those cases where (a), (b), and (c) are relaxed, but our methods are those of bifurcation (and singularity) theory. In particular, this work extends some of our previous bifurcation work on the finite-dimensional problem [41, 55] to the infinite-dimensional problem (1.1).

Since the general setting for bifurcation theory is that of Fredholm operators, the first task is to convert the optimization problem to a system of nonlinear equations and to determine conditions under which the system is Fredholm. The formulated system is motivated by the Fritz John first-order necessary conditions, uses a nonstandard normalization of the multipliers similar to that used in our earlier work [41], and contains minimizers, maximizers, and saddle points as well as nonfeasible solutions of the problem (1.1). Given a solution of this system (see (2.4)), the classical implicit function theorem is generally applicable when the following three conditions are valid: (1) strict complementarity, (2) surjectivity of the Fréchet derivative of the active constraints (a constraint qualification), and (3) the bijectivity of the Hessian of the Lagrangian on the null space (kernel) of the Fréchet derivative of the active constraints to an appropriate subspace of the (topological) dual of X (a second-order condition). (Theorem 2.2 gives the precise conditions.) When these conditions are valid, the implicit function theorem guarantees the existence of a locally unique and smooth solution, and one can compute derivatives of the solution and multipliers with respect to the system parameters and thus perform a first-order sensitivity analysis. As a system parameter(s) is varied, one invariably encounters situations where one or more of these three conditions fail. Many of the interesting phenomena, e.g., changes in the active set, loss of the minima, exchanges in critical point type, multiple solutions, and loss of differentiability of the solution in the natural parameters of the system, occur at these singularities. Thus, neighborhoods of these singularities are regions of "extreme sensitivity."

Bifurcation theory is now quite a large subject as evidenced by books on the subject (e.g., [10, 17, 18]), and the various singularities are far too numerous to delineate in this work. In particular, we do not exploit symmetry in the problem. Instead, the objectives are to derive sufficient and almost necessary conditions for the applicability of this theory to the parametric problem (1.1) and to demonstrate a branching analysis for some of the simplest but generic singularities. Associated with the bifurcation or branching of multiple solutions is the question of the persistence of minima or changes in critical point type as the parameter or parameters are varied about the singularity. Although we treat this stability topic to some extent in the examples, a systematic study under more restrictive assumptions will be undertaken in future work.

The paper is organized as follows. Section 2 contains a summary of much of the notation used in the paper, the formulation of a system of nonlinear equations that must be satisfied by a minimizer of (1.1), the development of necessary and sufficient conditions for the solution of this system to be regular, and conditions under which this system is Fredholm. The bifurcation theory framework for the investigation of the singularities is presented in §3. A bifurcation analysis for some of the more commonly occurring singularities is presented in §§4–6 with some illustrative examples. Further research problems are discussed in §7.

2. Systems formulation and the bifurcation problems. The first objective is to convert the parametric constrained optimization problem (1.1) to a closed system of nonlinear equations; this is accomplished through the use of the Fritz John first-order necessary conditions and a nonstandard normalization of the Lagrange multipliers. Having developed this system, we next establish sufficient and almost necessary conditions (Theorem 2.2) for the Fréchet

derivative of this system to be bijective so that with sufficient smoothness the hypotheses of the implicit function theorem are satisfied. (If one adds a strong monotonicity condition (Theorem 2.3), then a minimizer exists and persists locally.) The primary interest in this work is the investigation of the local solution structure when this Fréchet derivative is no longer bijective, but is Fredholm in which case bifurcation theory is applicable. Thus the final Theorem 2.4 in this section gives conditions sufficient to ensure that the Fréchet derivative of this system is Fredholm. We first explain the notation used in subsequent discussion and review some of the needed facts from functional analysis [50].

2.1. Notation. X and Y with appropriate norms will be assumed to be Banach spaces throughout without further comment. If $F : X \times \mathbf{R}^r \to Y$, the Fréchet derivative with respect to $x \in X$ will be denoted by $D_x F(x, \alpha)$, with respect to $\alpha \in \mathbf{R}^r$ by $D_\alpha F(x, \alpha)$, and similarly for higher derivatives. X^* denotes the topological (normed) dual of the normed linear space X, i.e., the space of bounded linear functionals on X, and $\langle x, x^* \rangle_X$ represents the action of a bounded linear functional $x^* \in X^*$ on an element $x \in X$. The subscript X on $\langle x, x^* \rangle_X$ will be omitted if the context is clear. If $L : X \to Y$ is a linear transformation, $\mathcal{N}(L)$ will denote the null space (kernel) of L and $\mathcal{R}(L)$, the range (image) of L. The adjoint of a bounded linear transformation $L : X \to Y$ is that unique bounded linear transformation $L^* : Y^* \to X^*$ satisfying $\langle Lx, y^* \rangle = \langle x, L^* y^* \rangle$ for all $x \in X$ and $y^* \in Y^*$. The following closed-range theorem will be used: assuming X and Y are Banach spaces, the range of L is norm closed if and only if the range of L^* is norm (or wk*-) closed.

Let M be a subspace of the Banach space X, and N, a subspace of X^*. Then define the annihilators $M^\perp$ and ${}^\perp N$ by $M^\perp = \{x^* \in X^* : \langle x, x^* \rangle = 0 \text{ for all } x \in M\}$ and ${}^\perp N = \{x \in X : \langle x, x^* \rangle = 0 \text{ for all } x^* \in N\}$, respectively. If $L : X \to Y$ is a bounded linear transformation, then $\mathcal{N}(L) = {}^\perp \mathcal{R}(L^*)$ and $\mathcal{N}(L^*) = \mathcal{R}(L)^\perp$; and if, in addition, the range of L is closed, $\mathcal{R}(L) = {}^\perp \mathcal{N}(L^*)$ and $\mathcal{R}(L^*) = \mathcal{N}(L)^\perp$.

A bounded linear transformation $L : X \to Y$ is called a Fredholm operator if the range is closed, the codimension of the range is finite (i.e., the dimension of the quotient space $Y/\mathcal{R}(L)$ is finite), and the dimension of the null space is finite. In this case, the index of L is defined by $\text{index}\,(L) = \dim \mathcal{N}(L) - \dim Y/\mathcal{R}(L)$. (To compute this index, we make use of $\dim Y/\mathcal{R}(L) = \dim \mathcal{N}(L^*)$ for a closed $\mathcal{R}(L)$.) A bounded linear transformation $L : X \to Y$ is called a semi-Fredholm operator if it has closed range and either the codimension of the range is finite or the dimension of the null space is finite. Properties of Fredholm and semi-Fredholm operators can be found in the books by Kato [29] and Schechter [51].

Two basic assumptions in the theorems to follow are that the Fréchet derivative $D_x F(\hat{x}, \hat{\alpha})$ has closed range and $\mathcal{N}(D_x F(\hat{x}, \hat{\alpha}))$ is complemented in X (or splits the space X). A closed subspace X_1 of a Banach space is complemented in X if there exists a closed subspace X_2 of X such that $X_1 + X_2 = X$ and $X_1 \cap X_2 = \{0\}$. In this case we write $X = X_1 \oplus X_2$ and say that X is the topological (internal) direct sum of X_1 and X_2 and that X_1 splits the space. This assumption is needed since infinite-dimensional closed subspaces of Banach spaces need not be complemented. Here are some valid examples. If X is a Hilbert space, then closed subspaces are complemented. If M is a closed subspace of a Banach space X and either M or X/M is finite-dimensional, then M is complemented in X [50, p. 106]. A fact that will be used in some of the examples from the calculus of variations is that if $L : X \to Y$ is a bounded linear transformation with a finite-dimensional range, i.e., L is compact [50, p. 104], then the null space of L has finite codimension and is thus complemented in X. In nonlinear optimal control, the space $X = X_1 \oplus X_2$ is split into state and control variables. One can often use this along with the above facts to show that $\mathcal{N}(L)$ is complemented even when it and $X/\mathcal{N}(L)$ are infinite dimensional.

The Cartesian product of two Banach spaces Y and Z, denoted by $Y \times Z$, is a Banach space under the norm $\|(y, z)\|_{Y\times Z} = (\|y\|_Y^2 + \|z\|_Z^2)^{1/2}$. (There are several such equivalent norms.) Next, if $L : X \to Y$ and $K : X \to Z$ are bounded linear transformations, then $J : X \to Y \times Z$ by $Jx = (Lx, Kx)$ is also a bounded linear transformation. We shall make use of the following lemma on the closed image (range) [1, p. 80]: If the subspace $\mathcal{R}(L)$ is closed in Y and $\mathcal{R}(K|_{\mathcal{N}(L)})$ is closed in Z, then the subspace $\mathcal{R}(J)$ is closed in $Y \times Z$.

Next, define two index sets $\mathcal{A}$ and $\mathcal{A}_s$ by

$$\begin{aligned} \mathcal{A}(\hat{x}, \hat{\alpha}) &= \{i \geq 1 : f_i(\hat{x}, \hat{\alpha}) = 0\}, \\ \mathcal{A}_s(\hat{x}, \hat{\alpha}) &= \{i \in \mathcal{A} : \lambda_i \neq 0\}, \end{aligned} \tag{2.1}$$

where the subscript s on $\mathcal{A}$ is for "strongly active" and the λ_i is the multiplier corresponding to the ith constraint f_i used in the Lagrangian $\mathcal{L}$ in (2.3). By permuting the inequality constraints, we may assume $\mathcal{A}_s(\hat{x}, \hat{\alpha}) = \{1, 2, \ldots, l\}$ and $\mathcal{A}(\hat{x}, \hat{\alpha}) = \{1, 2, \ldots, k\}$ with $l \leq k$ and define

$$\begin{aligned} D_x f_A &= \begin{bmatrix} D_x f_1(\hat{x}, \hat{\alpha}) \\ \vdots \\ D_x f_l(\hat{x}, \hat{\alpha}) \end{bmatrix}, \quad D_x f_B = \begin{bmatrix} D_x f_{l+1}(\hat{x}, \hat{\alpha}) \\ \vdots \\ D_x f_k(\hat{x}, \hat{\alpha}) \end{bmatrix}, \quad \text{and} \\ D_x f_C &= \begin{bmatrix} D_x f_{k+1}(\hat{x}, \hat{\alpha}) \\ \vdots \\ D_x f_m(\hat{x}, \hat{\alpha}) \end{bmatrix}. \end{aligned} \tag{2.2}$$

Since the codimension of $\mathcal{N}(D_x f_A)$ is finite, which follows from $\mathcal{R}(D_x f_A)$ being finite dimensional, $\mathcal{N}(D_x f_A)$ is complemented in X. Let $L = D_x F(\hat{x}, \hat{\alpha})$, and suppose that the null space of L is complemented in X and the range is closed in Y. If $\tilde{L} = \begin{bmatrix} L \\ D_x f_A \end{bmatrix}$, the lemma on the closed image [1, p. 80] implies that the range of $\tilde{L}$ is closed. Also, one can show that $\mathcal{N}(\tilde{L})$ is complemented in X so that $X = X_1 \oplus X_2$, where $X_1 = \mathcal{N}(\tilde{L})$. This decomposition defines two continuous projections P_1 and P_2 ($P_i : X \to X_i$). The adjoints P_1^* and P_2^* are also continuous projections and induce a topological direct sum of the dual space $X^* = X_1^* \oplus X_2^*$, where $X_1^* = P_1^* X^* = X_2^\perp$ and $X_2^* = P_2^* X^* = X_1^\perp = \mathcal{N}(\tilde{L})^\perp = \mathcal{R}(\tilde{L}^*)$. The notation is consistent with the fact that X_i^* is the topological dual of X_i. Similarly, the adjoint P_i^{**} of P_i^* is a continuous projection of the second dual X^{**} onto $P_i^{**} X^{**} \equiv X_i^{**}$ ($P_i^{**} : X^{**} \to X_i^{**}$) with the corresponding decomposition $X^{**} = X_1^{**} \oplus X_2^{**}$, where $X_1^{**} = \mathcal{R}(\tilde{L}^*)^\perp = \mathcal{N}(\tilde{L}^{**})$.

The (weak) Lagrangian for the problem (1.1) is

$$\mathcal{L} = \langle f_0(x, \alpha), \lambda_0 \rangle_{\mathbf{R}} + \langle f(x, \alpha), \lambda \rangle_{\mathbf{R}^m} + \langle F(x, \alpha), y^* \rangle_Y, \tag{2.3}$$

where $\lambda_0 \in \mathbf{R}^*$ ($= \mathbf{R}$), $\lambda \in \mathbf{R}^{m*}$ ($= \mathbf{R}^m$), and $y^* \in Y^*$ are Lagrange multipliers. Here we have used the notation λ without a subscript to refer to the vector $(\lambda_1, \lambda_2, \ldots, \lambda_m)$ that does not include, in particular, the component λ_0. The same applies to the vector f with a range in $\mathbf{R}^m$. Finally, define $D_x^2 \mathcal{L}_{ij} = P_i^* D_x^2 \mathcal{L} P_j$, and note that $D_x^2 \mathcal{L}_{ij}^* = P_j^* D_x^2 \mathcal{L}^* P_i^{**}$.

2.2. The nonlinear system. Having completed a discussion of some of the notation, the next task is to convert the parametric optimization problem (1.1) to a system of nonlinear equations using the Fritz John first-order necessary conditions. This is the content of the following theorem.

THEOREM 2.1 (see [1]). *Let $f_i \in C^2(U \times V; \mathbf{R})$, $F \in C^2(U \times V; Y)$, U and V be open subsets of the Banach space X and $\mathbf{R}^r$, respectively, and Y be a second Banach space containing the range of $F(x, \alpha)$. Let $\hat{x} \in U$ be a local minimizer of the optimization problem*

(1.1) *at* $\hat{\alpha} \in V$, *and assume that the Fréchet derivative* $D_x F(\hat{x}, \hat{\alpha})$ *has closed range. Then there exist Lagrange multipliers* $\hat{\lambda}_i$ $(i = 0, 1, \ldots, m)$ *and* $\hat{y}^* \in Y^*$, *not all zero, such that* $\chi \equiv (x, y^*, \lambda, \lambda_0) = (\hat{x}, \hat{y}^*, \hat{\lambda}, \hat{\lambda}_0)$ *solves the system of equations*

$$G(x, y^*, \lambda, \lambda_0; \alpha) = \begin{bmatrix} D_x \mathcal{L}(x, y^*, \lambda, \lambda_0; \alpha) \\ F(x, \alpha) \\ \Lambda f(x, \alpha) \\ N(\lambda_0, \lambda, y^*) \end{bmatrix} = 0 \tag{2.4}$$

and inequalities $\lambda_0 \geq 0$ *and* $\lambda_i \geq 0$ *and* $f_i(x, \alpha) \leq 0$ *for* $i = 1, \ldots, m$. *Here,* $\Lambda = \operatorname{diag}(\lambda_1, \ldots, \lambda_m)$ *is a diagonal matrix and the equation* $N(\lambda_0, \lambda, y^*) = 0$ *represents a normalization of the multipliers that ensures that not all multipliers are zero.*

Choices for the normalization N include

$$N_1(\lambda_0, \lambda, y^*) = \lambda_0 - 1, \tag{2.5a}$$

$$N_2(\lambda_0, \lambda, y^*) = \sum_{i=0}^{m} \lambda_i^2 + \|y^*\|^2 - 1, \tag{2.5b}$$

$$N_3(\lambda_0, \lambda, y^*) = \sum_{i=0}^{m} \lambda_i^2 + |\langle y_0, y^* \rangle|^2 - 1, \tag{2.5c}$$

where $y_0 \in Y$ is chosen so that $|\langle y_0, y^* \rangle| \geq \frac{1}{2}\|y^*\|$. The usual choice is $N_1 = 0$, which is guaranteed by a variety of constraint qualifications such as the following. If the active inequality constraints at $(\hat{x}, \hat{\alpha})$ are $\{f_i\}_{i=1}^k$, then $\lambda_0 \neq 0$ if either of the following two constraint qualifications is satisfied:

LICQ: The map $(D_x F(\hat{x}, \hat{\alpha}), D_x f_1(\hat{x}, \hat{\alpha}), \ldots, D_x f_k(\hat{x}, \hat{\alpha})) : X \to Y \times \mathbf{R}^k$ is surjective.

MFCQ: The map $D_x F(\hat{x}, \hat{\alpha}) : X \to Y$ is surjective and $\{h \in X : D_x f_i(\hat{x}, \hat{\alpha})h < 0$ for $i = 1, \ldots, k;\ D_x F(\hat{x}, \hat{\alpha})h = 0\}$ is nonempty.

LICQ is the infinite-dimensional analogue of the linear independence constraint qualification and MFCQ, the Mangasarian–Fromovitz constraint qualification. The latter is weaker than the first in that it is implied by the first. Thus, not LICQ is implied by not MFCQ, so a violation of LICQ is a weaker condition than a violation of MFCQ. Since a violation of the LICQ may lead to bifurcations, we do not use the normalization $N_1 = 0$ when $\lambda_0 = 0$. Instead, we use either the normalization N_2 or N_3, which allows for the smooth transition of λ_0 away from zero. (Such normalizations were introduced in our earlier work [41] on finite-dimensional problems.) With the exception of a Hilbert space in which case $\|y^*\|^2 = \langle y^*, y^* \rangle$, N_2 is generally not differentiable with respect to y^*. Thus the normalization N_3 will be used in those cases where $\lambda_0 = 0$.

2.3. The regular case. The next objective is to establish sufficient and almost sufficient conditions for the Fréchet derivative of the system (2.4) to be bijective at a solution of the system, in which case the conclusion of the implicit function theorem is valid.

THEOREM 2.2. *Let* $f_i \in C^2(U \times V; \mathbf{R})$ *for* $i = 0, 1, \ldots, m$, $F \in C^2(U \times V; Y)$, U *and* V *be open sets in the Banach space* X *and* $\mathbf{R}^r$, *respectively, and* Y *be a second Banach space containing the range of* $F(x, \alpha)$. *Let* $\mathcal{X} \equiv X \times Y^* \times \mathbf{R}^m \times \mathbf{R}$, *and suppose that* $(\hat{\chi}; \hat{\alpha}) = (\hat{x}, \hat{y}^*, \hat{\lambda}, \hat{\lambda}_0; \hat{\alpha}) \in \mathcal{X} \times \mathbf{R}^r$ *is a solution of* $G(\chi; \alpha) = 0$. *Suppose that the Fréchet derivative* $D_x F(\hat{x}, \hat{\alpha})$ *has closed range and its null space is complemented in* X. *Under these assumptions, a set of necessary and sufficient conditions for* $D_\chi G(\hat{\chi}, \hat{\alpha})$ *to be bijective is that*

(a) *strict complementarity holds, i.e.,* $\mathcal{A} = \mathcal{A}_s$ *and* $k = l$ *in* (2.2);

(b) *the bounded linear transformation* $D_x^2 \mathcal{L}_{11} : X_1 \to X_1^*$ *is bijective;*

(c) *the bounded linear transformation* $\tilde{L} \equiv (D_x F(\hat{x}, \hat{\alpha}), D_x f_1(\hat{x}, \hat{\alpha}), \ldots, D_x f_l(\hat{x}, \hat{\alpha})) : X \to Y \times \mathbf{R}^l$ *is surjective.*

If the bounded linear transformation $D_\chi G(\hat{\chi}, \hat{\alpha})$ *is bijective, then there exist neighborhoods* $\mathcal{B}_1$ *of* $\alpha = \hat{\alpha}$ *and* $\mathcal{B}_2$ *of* $\hat{\chi} = (\hat{x}, \hat{y}^*, \hat{\lambda}, \hat{\lambda}_0)$ *such that the following is true: there exists a function* $\phi \in C^1(\mathcal{B}_1, \mathcal{X})$ *such that* $\phi(\hat{\alpha}) = \hat{\chi}$, $G(\phi(\alpha), \alpha) = 0$ *for all* $\alpha \in \mathcal{B}_1$, *and this solution is locally unique in that if* $(\chi, \alpha) \in \mathcal{B}_1 \times \mathcal{B}_2$ *and* $G(\chi, \alpha) = 0$, *then* (χ, α) *belongs to the manifold defined by* ϕ, *i.e.,* $\chi = \phi(\alpha)$ *for some* $\alpha \in \mathcal{B}_1$. *Finally, if* f_i *and* F *are* $C^k (k \geq 2)$ (C^∞ *or real analytic*), *then* ϕ *is* C^{k-1} (C^∞ *or real analytic, respectively*) *on* $\mathcal{B}_1$.

Several remarks are in order. The term *critical point* will refer to any solution of system (2.4), *regular point* will describe any solution of (2.4) for which conditions (a), (b), and (c) of Theorem 2.2 are valid, and *singular point* is reserved for any solution of (2.4) at which $D_\chi G$ is not bijective, i.e., at which one or more of (a), (b), and (c) is violated. The importance of the three conditions (a), (b), and (c) in this theorem is that they provide a set of necessary and sufficient conditions for a violation of the bijectivity of $D_\chi G$ and thus an initial classification for the singularities and bifurcation problems. Next, note that condition (c) is just the surjectivity (linear independence) constraint qualification. Certainly, weaker constraint qualifications such as those of the MFCQ guarantee $\lambda_0 \neq 0$. In the bifurcation analysis to follow we treat the case $\lambda_0 \neq 0$ or $\lambda_0 = 0$ by the *weakest possible set of conditions*, i.e., whether or not $D_x f_0(\hat{x}, \hat{\alpha}) \in \mathcal{R}(\tilde{L})$.

In the finite-dimensional case, we [41, 55] have characterized the type (i.e., maximum, minimum, or saddle point) of a regular point of (2.4) by three sets of numbers: (1) the sign of $f_i(x, \alpha)$ for $i \notin \{1, \ldots, k\}$, (2) the sign of λ_i for $i \in \{0, 1, \ldots, k\}$, and (3) signs of the eigenvalues of $D_x^2 \mathcal{L}_{11}$. The index, i.e., dimension of the largest space on which $D_x^2 \mathcal{L}_{11}$ is negative definite, and the nullity, i.e., the dimension of the null space of $D_x^2 \mathcal{L}_{11}$, are sufficient to characterize the numbers in (3). Definitions for the index and nullity of a bounded bilinear form $B : X \times X \to \mathbf{R}$ on a Banach space X can be similarly defined [57, pp. 86–87].

Finally and for completeness, we remark that a modification of this theorem guarantees the local persistence of a minimizer as stated in the following theorem.

THEOREM 2.3. *Suppose that in addition to the hypotheses of Theorem* 2.2 *that*

$$D_x^2 \mathcal{L}(\hat{\chi}, \hat{\alpha})[h, h] \geq C \|h\|_X^2 \tag{2.6}$$

for all $h \in \mathcal{N}(\tilde{L}(\hat{x}, \hat{\alpha}))$. *Then* $\hat{x}$ *is a local minimizer of* (1.1) *at* $\alpha = \hat{\alpha}$, *and there exists a constant* $\bar{C}$ *and neighborhood* $\tilde{\mathcal{B}}_1$ *of* $\alpha = \hat{\alpha}$ *such that for each* $\alpha \in \tilde{\mathcal{B}}_1$, $D_x^2 \mathcal{L}(\chi(\alpha), \alpha)[h, h] \geq \bar{C} \|h\|_X^2$ *for all* $h \in \mathcal{N}(\tilde{L}(x(\alpha), \alpha))$ *and* $\lambda_i(\alpha) > 0$ *for each* $i = 1, \ldots, l = k$. *In particular, the local minimizer persists locally about* $\alpha = \hat{\alpha}$.

This theorem is established under weaker assumptions by Alt [3] and Shapiro [52], and thus we omit the proof. As noted by Alekseev, Tikhomirov, and Fomin [1, p. 157], the strong monotonicity condition (2.6) places severe restrictions on the space $\mathcal{N}(\tilde{L}(\hat{x}, \hat{\alpha}))$. To explain, first note that the closed subspace $\mathcal{N}(\tilde{L}(\hat{x}, \hat{\alpha}))$ of X along with the norm of X is a Banach space. Next, $\langle u, v \rangle = D_x^2 \mathcal{L}(\hat{\chi}, \hat{\alpha})[u, v]$ defines an inner product on $\mathcal{N}(\tilde{L}(\hat{x}, \hat{\alpha}))$, and due to the assumptions of Theorem 2.2 we have

$$C \|h\|_X^2 \leq \langle h, h \rangle \leq \|D_x^2 \mathcal{L}(\hat{\chi}, \hat{\alpha})\| \, \|h\|_X^2.$$

Thus the norm induced on $\mathcal{N}(\tilde{L}(\hat{x}, \hat{\alpha}))$ by the inner product $\langle \cdot, \cdot \rangle$ is equivalent to that of $\| \cdot \|_X$, so the Banach space $(\mathcal{N}(\tilde{L}(\hat{x}, \hat{\alpha})), \| \cdot \|_X)$ is linearly homeomorphic to the Hilbert space $(\mathcal{N}(\tilde{L}(\hat{x}, \hat{\alpha})), \langle \cdot, \cdot \rangle)$. Interestingly, we now have that $X_1^* = \mathcal{N}(\tilde{L}(\hat{x}, \hat{\alpha}))^*$ is identified with this Hilbert space via the Riesz representation theorem. Given these remarks, note that the strong monotonicity condition (2.6) then implies condition (b) in Theorem 2.2.

To circumvent this restrictive strong monotonicity condition (2.6), Ioffe [21] and Maurer [39] replace it with a coercivity condition in a weaker norm and use this *two-norm discrepancy* along with some compatibility conditions to establish a locally isolated minimum [21, 39]. This technique is now commonly used in the literature, particularly for the integral-type objective functions. Indeed, it is used in §4.2 to establish a minimum in an example from the calculus of variations. From the implicit function point of view, this same problem manifests itself in condition (b) in Theorem 2.2 in that the topological duals X^* and X_1^* are too large to obtain surjectivity of the bounded linear transformation $D_x^2\mathcal{L}_{11} : X_1 \to X_1^*$ for integral-type objective functions.

2.4. The Fredholm operator and bifurcation problems. Since the general framework for bifurcation problems is that of Fredholm operators, conditions must be imposed to ensure that the Fréchet derivative $D_\chi G$ is Fredholm. This is the content of the next theorem.

THEOREM 2.4. *Let $f_i \in C^2(U \times V; \mathbf{R})$ for $i = 0, 1, \ldots, m$, $F \in C^2(U \times V; Y)$, U and V be open sets in the Banach space X and $\mathbf{R}^r$, respectively, and Y be a second Banach space containing the range of $F(x, \alpha)$. Let $(\hat{\chi}; \hat{\alpha}) = (\hat{x}, \hat{y}^*, \hat{\lambda}, \hat{\lambda}_0; \hat{\alpha}) \in U \times V$ be a solution of $G(\chi; \alpha) = 0$. Suppose that $\mathcal{N}(D_x F(\hat{x}, \hat{\alpha}))$ is complemented in X. Then the Fréchet derivative $D_\chi G(\hat{\chi}, \hat{\alpha})$ is Fredholm if*

(a) *$D_x^2\mathcal{L}_{11} : X_1 \to X_1^*$ is Fredholm;*

(b) *the range of $D_x F(\hat{x}, \hat{\alpha})$ is closed and has finite codimension in Y.*

Also, if $D_x^2\mathcal{L}_{11}$ and $D_x F(\hat{x}, \hat{\alpha})$ have closed ranges and $D_\chi G(\hat{\chi}, \hat{\alpha})$ is Fredholm, then (a) *and* (b) *are valid.*

The proof of this theorem is included in the appendix. Just as we have discussed the surjectivity of $D_x^2\mathcal{L}_{11} : X_1 \to X_1^*$ in Theorem 2.2 as being too strong for integral-type objective functions, we also note that condition $D_x^2\mathcal{L}_{11} : X_1 \to X_1^*$ being Fredholm is too strong for certain applications. Such problems arise for unconstrained problem in the calculus of variations and have been resolved by two methods. The first approach is described by Zeidler [59, §29.18], wherein one introduces a generalized inner product on a Banach space. The second method is to embed the function spaces continuously and densely in a Hilbert space and then use the structure of the Hilbert space to perform the bifurcation analysis as in the work of Bobylev and Krasnosel'skii [5]. These same approaches will be investigated in future work for the constrained problem with applications to the calculus of variations and control systems.

3. A brief review of the bifurcation setting. The objective in this section is to give two bifurcation theorems (3.2 and 3.4) that will be used in the subsequent three sections. The singularities in these theorems are generic [17]. To explain these theorems within the context of a general problem $G(x, y) = 0$, we briefly describe the Lyapunov–Schmidt procedure for a reduction to a finite number of equations in a finite number of unknowns and then delineate some of the cases to which Theorems 3.2 and 3.4 apply. The setting described here is based on the books by Nirenberg [40] and Rabier [45] as well as our earlier work [55]. We start with the implicit function theorem, which is also used in §6.

THEOREM 3.1 (implicit function theorem [40]). *Let $\mathcal{X}$, $\mathcal{Y}$, and $\mathcal{Z}$ be Banach spaces, let $U_0 \times V_0 \subset \mathcal{X} \times \mathcal{Y}$ be an open neighborhood of a point (x_0, y_0) that solves $G(x, y) = 0$, and suppose that*

(a) *$G \in C^p(U_0 \times V_0, \mathcal{Z})$ for some $p \geq 1$;*

(b) *$\mathcal{R}(D_x G(x_0, y_0)) = \mathcal{Z}$;*

(c) *$\mathcal{N}(D_x G(x_0, y_0)) = \mathcal{X}_1$ has a closed complementing subspace $\mathcal{X}_2$ in $\mathcal{X}$; i.e., $\mathcal{X}$ is a topological direct sum $\mathcal{X} = \mathcal{X}_1 \oplus \mathcal{X}_2$.*

Then there exist open neighborhoods U of x_0 and V of y_0 and a solution $x_2 = u(x_1, y) \in C^p(PU \times V, \mathcal{X}_2)$ of $G(x_1 + x_2, y) = 0$, where $P : \mathcal{X} \to \mathcal{X}_1$ is a projection of $\mathcal{X}$ onto $\mathcal{X}_1$,

$u(x_{01}, y_0) = x_{02}$, $x_{01} = Px_0$, and $x_{02} = (I - P)(x_0)$. Furthermore, U and V can be chosen so that this solution is locally unique in that if $(x, y) \in U \times V$ is a solution of $G(x, y) = 0$, then $x = x_1 + u(x_1, y)$ for some $x_1 \in PU$.

The problem of the previous section was that of determining the local structure of the solutions of the equation $G(\chi, \alpha) = 0$, where $\chi \in \mathcal{X} \equiv X \times Y^* \times \mathbf{R}^m \times \mathbf{R}$, the range of G is in $\mathcal{Z} \equiv X^* \times Y \times \mathbf{R}^m \times \mathbf{R}$, and $\alpha \in \mathbf{R}^r$. The Lyapunov–Schmidt method for reducing this problem to one of a finite number of equations in a finite number of unknowns is perhaps best described by putting $\tilde{\chi} = (\chi, \alpha)$ and explaining the procedure for the generic problem $G(\tilde{\chi}) = 0$, where $G : \tilde{\mathcal{X}} \to \mathcal{Z}$. For smoothness, we require $G \in C^p(U_0, \mathcal{Z})$ for some fixed $p \geq 1$, where U_0 is an open neighborhood of a solution $\tilde{\chi}_0$ of $G = 0$. Next, assume that $D_{\tilde{\chi}} G(\tilde{\chi}_0)$ is Fredholm operator in that $\mathcal{R}(D_{\tilde{\chi}} G(\tilde{\chi}_0)) = \mathcal{Z}_1$ is a closed linear subspace of $\mathcal{Z}$ of finite codimension and $\mathcal{N}(D_{\tilde{\chi}} G(\tilde{\chi}_0)) = \tilde{\mathcal{X}}_1$ is finite dimensional. By this assumption, $\tilde{\mathcal{X}}$ and $\mathcal{Z}$ can be decomposed into topological direct sums $\tilde{\mathcal{X}} = \tilde{\mathcal{X}}_1 \oplus \tilde{\mathcal{X}}_2$ and $\mathcal{Z} = \mathcal{Z}_1 \oplus \mathcal{Z}_2$, where $\dim \mathcal{Z}_2$ and $\dim \tilde{\mathcal{X}}_1$ are finite. Let Q be an associated (continuous) projection of $\mathcal{Z}$ onto $\mathcal{Z}_1$. Applying Q and $(I - Q)$ to the equation $G(\tilde{\chi}) = 0$ yields an equivalent system

$$\begin{aligned} QG(\tilde{\chi}) &= 0, \\ (I - Q)G(\tilde{\chi}) &= 0. \end{aligned} \tag{3.1}$$

Theorem 3.1 can be applied to the problem

$$0 = g(\tilde{\chi}_2, \tilde{\chi}_1) \equiv QG(\tilde{\chi}_1 + \tilde{\chi}_2) \; : \; \tilde{\mathcal{X}}_2 \times \tilde{\mathcal{X}}_1 \to \mathcal{Z}_1 \tag{3.2}$$

to obtain the existence of a C^p locally unique solution $\tilde{\chi}_2 = u(\tilde{\chi}_1)$ (locally about χ_{01}). Hence $\tilde{\chi}_1 + u(\tilde{\chi}_1)$ is a solution of $G(\tilde{\chi}) = 0$ if and only if

$$(I - Q)G(\tilde{\chi}_1 + u(\tilde{\chi}_1)) = 0. \tag{3.3}$$

Since the range of $I - Q$ is finite dimensional, the problem $G(x, y) = 0$ has been reduced to one of a finite number of equations in a finite number of unknowns. We now consider the simplest but generic cases of the bifurcation equations (3.3).

The first case is that in which $\mathcal{Z}_1 = \mathcal{Z}$ and the index of the Fredholm operator $D_{\tilde{\chi}} G(\tilde{\chi}_0)$ is one. Then the dimension of the null space of $D_{\tilde{\chi}} G(\tilde{\chi}_0)$ is one. For the parametric problem $G(\chi, \alpha) = 0$, where $G(\chi, \alpha) : \mathcal{X} \times \mathbf{R} \to \mathcal{Z}$ (α is now a single parameter), the problem breaks into two cases:

(i) $D_\chi G(\chi_0, \alpha_0)$ is surjective.

(ii) Codimension of $\mathcal{R}(D_\chi G(\chi_0, \alpha_0))$ is one and $D_\alpha G(\chi_0, \alpha_0) \notin \mathcal{R}(D_\chi G(\chi_0, \alpha_0))$.

In case (i), $D_\chi G(\chi_0, \alpha_0)$ is bijective and the implicit function theorem (Theorem 3.1) is applicable with $y = \alpha$ and $\mathcal{X}_1 = \{0\}$ so that $\mathcal{X} = \mathcal{X}_2$. This is the content of Theorem 2.2 for a one-dimensional parameter $\alpha \in \mathbf{R}$. The second case (ii) is addressed in the following theorem.

THEOREM 3.2. *Let $\mathcal{X}$ and $\mathcal{Z}$ be Banach spaces and $\mathcal{B}_1$ and $\mathcal{B}_2$ be open neighborhoods of $\chi_0 \in \mathcal{X}$ and $\alpha_0 \in \mathbf{R}$, respectively, and assume that $G(\chi_0, \alpha_0) = 0$, $G \in C^p(\mathcal{B}_1 \times \mathcal{B}_2; \mathcal{Z})$ for some fixed $p \geq 1$, $D_{(\chi,\alpha)} G(\chi_0, \alpha_0)$ is a Fredholm operator of index one, the codimension of $\mathcal{R}(D_\chi G(\chi_0, \alpha_0))$ is one, and $D_\alpha G(\chi_0, \alpha_0) \notin \mathcal{R}(D_\chi G(\chi_0, \alpha_0))$ so that the dimension $\mathcal{N}(D_\chi G(\chi_0, \alpha_0))$ is one. Let $\phi \in \mathcal{X}$, $\phi^* \in \mathcal{X}^*$, and $\psi^* \in \mathcal{Z}^*$ span the null space of $D_\chi G(\chi_0, \alpha_0)$, the one-dimensional space complement of the range of $D_\chi G(\chi_0, \alpha_0)^*$, and the null space of $D_\chi G(\chi_0, \alpha_0)^*$, respectively. Then there exist open neighborhoods $U \subset \mathcal{B}_1 \times \mathcal{B}_2$ of (χ_0, α_0) and $I \subset \mathbf{R}$ of 0 and a function $(\chi(\epsilon), \alpha(\epsilon)) \in C^p(I; U)$ such that $(\chi(0), \alpha(0)) = (\chi_0, \alpha_0)$, $\frac{d\alpha(0)}{d\epsilon} = 0$, and $G(\chi(\epsilon), \alpha(\epsilon)) = 0$ for all $\epsilon \in I$. Furthermore, any solution $(\chi, \alpha) \in U$ of $G = 0$ is given by $(\chi, \alpha) = (\chi(\epsilon), \alpha(\epsilon))$ for some $\epsilon \in I$; and the parameterization can be chosen so that $P(\chi(\epsilon) - \chi_0) = \epsilon\phi$ and $(I - P)(\chi(\epsilon) - \chi_0) = v(\epsilon)$,*

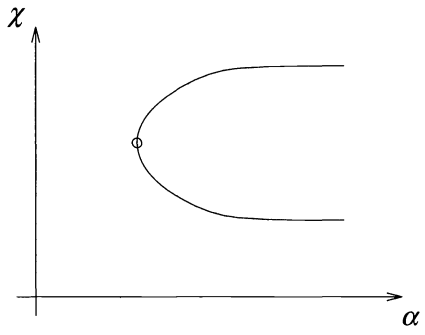

FIG. 1. *Quadratic fold point.*

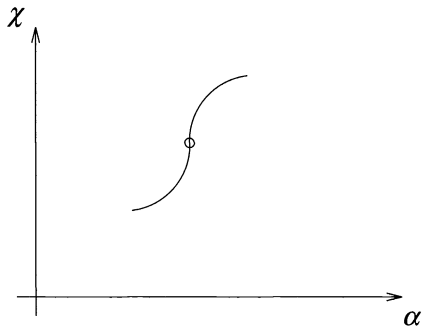

FIG. 2. *Hysteresis point.*

where $v(0) = 0$, $\frac{dv(0)}{d\epsilon} = 0$, *and the projection* P *is defined by* $Pu = \langle u, \phi^* \rangle \phi / \langle \phi, \phi^* \rangle$. *Finally, if* G *is an analytic function of* (χ, α) *near* (χ_0, α_0), *then* $(\chi(\epsilon), \alpha(\epsilon))$ *is analytic in* ϵ *near zero.*

Proof of Theorem 3.2. Let $[\phi] = \mathcal{N}(D_\chi G(\chi_0, \alpha_0))$ and $[\psi^*] = \mathcal{N}(D_\chi G(\chi_0, \alpha_0)^*)$. Make the transformation $\chi = \chi_0 + \epsilon\phi + v$, where $v \in \mathcal{N}(P) = \mathcal{R}(I - P)$, and consider the problem

$$\hat{G}(v, \alpha, \epsilon) = G(\chi_0 + \epsilon\phi + v, \alpha).$$

Then $\hat{G} : (I - P)\mathcal{X} \times \mathbf{R} \times \mathbf{R} \to \mathcal{Z}$. Now $\hat{G}(0, \alpha_0, 0) = 0$, $\hat{G}(v, \alpha, \epsilon) \in C^p(\hat{U} \times \hat{V} \times \hat{I}; \mathcal{Y})$ for some open sets $\hat{U} \subset (I - P)\mathcal{X}$ of $(I - P)\chi_0$ and $\hat{V} \subset \mathbf{R}$ and $\hat{I} \subset \mathbf{R}$ about zero. The Fréchet derivative $D_{(v,\alpha)}\hat{G}(0, \alpha, 0)$ is a bijective, bounded operator from $(I - P)\mathcal{X} \times \mathbf{R}$ onto $\mathcal{Z}$. Thus the implicit function theorem (Theorem 3.1) yields the result. □

If $p \geq 2$ and

$$\frac{d^2\alpha(0)}{d\epsilon^2} \equiv -\frac{\langle D_\chi^2 G(\chi_0, \alpha_0)[\phi, \phi], \psi^* \rangle}{\langle D_\alpha G(\chi_0, \alpha_0)[1], \psi^* \rangle} \neq 0, \tag{3.4}$$

the singularity in this theorem is called a *quadratic fold point*. Figure 1 illustrates the case $\frac{d^2\alpha(0)}{d\epsilon^2} > 0$. Likewise, if $\frac{d^2\alpha(0)}{d\epsilon^2} = 0$ but $\frac{d^3\alpha(0)}{d\epsilon^3} \neq 0$, then the singularity is called a hysteresis point, which is illustrated in Figure 2.

The second case is that in which $D_{\tilde{\chi}} G$ *is a Fredholm operator of index one and* $\mathcal{Z}_1 \equiv \mathcal{R}(D_{\tilde{\chi}} G)$ *has codimension one in* $\mathcal{Z}$, so the dimension of $\tilde{\mathcal{X}}_1 \equiv \mathcal{N}(D_{\tilde{\chi}} G(\tilde{\chi}_0))$ is two and there exists a continuous linear functional $\psi^* \in \mathcal{N}(D_\chi G^*)$ so that $\mathcal{Z}_1 = \{z \in \mathcal{Z} | \langle z, \psi^* \rangle = 0\}$. The study of the local solutions of $G(\tilde{\chi}) = 0$ about $\tilde{\chi}_0$ is thereby reduced to the investigation of the single equation

$$g(\tilde{\chi}_1) \equiv \langle G(\tilde{\chi}_1 + u(\tilde{\chi}_1)), \psi^* \rangle = 0 \text{ for } \tilde{\chi}_1 \in \tilde{\mathcal{X}}_1,$$

where $\tilde{\mathcal{X}} = \tilde{\mathcal{X}}_1 \oplus \tilde{\mathcal{X}}_2$ and $u(\tilde{\chi}_1) \in C^p((I - P)U, \tilde{\mathcal{X}}_2)$ for some open neighborhood $U \subset \tilde{\mathcal{X}}$ of $\tilde{\chi}_0$. Here $P : \tilde{\mathcal{X}} \to \tilde{\mathcal{X}}_1$ is a continuous projection. This situation breaks into three cases:

(i) $g(\tilde{\chi}_{01}) = 0$ and $D_{\tilde{\chi}_1} g(\tilde{\chi}_{01}) \neq 0$;

(ii) $g(\tilde{\chi}_{01}) = 0$, $D_{\tilde{\chi}_1} g(\tilde{\chi}_{01}) = 0$, and $D_{\tilde{\chi}_1}^2 g(\tilde{\chi}_{01})$ is nonsingular;

(iii) $g(\tilde{\chi}_{01}) = 0$, $D_{\tilde{\chi}_1} g(\tilde{\chi}_{01}) = 0$, and $D_{\tilde{\chi}_1}^2 g(\tilde{\chi}_{01})$ is singular, including the case when it vanishes identically.

For case (i) we obtain a C^p curve locally about $\tilde{\chi}_0$. We do not consider case (iii), which leads to higher-order singularities, since such singularities can be treated efficiently via singularity theory [17, 18]. For case (ii) we use the following theorem.

THEOREM 3.3 (see [40, 45]). *Let $\tilde{\mathcal{X}}$ and $\mathcal{Z}$ be Banach spaces, let $U_0 \subset \tilde{\mathcal{X}}$ be an open neighborhood of a point $\tilde{\chi}_0$ that solves $G(\tilde{\chi}) = 0$, and suppose that*

(a) *$G \in C^p(U_0, \mathcal{Z})$ for $p \geq 2$;*

(b) *$\mathcal{R}(D_{\tilde{\chi}} G(\tilde{\chi}_0)) = \mathcal{Z}_1$ has codimension one so that there exists a bounded linear functional $\psi^* \in \mathcal{Z}^*$ such that $\mathcal{Z}_1 = \{z \in \mathcal{Z} : \langle z, \psi^* \rangle = 0\}$;*

(c) *$\mathcal{N}(D_{\tilde{\chi}} G(\tilde{\chi}_0) = \tilde{\mathcal{X}}_1$ has dimension two (2), and $\tilde{\mathcal{X}}_2$ is a closed complementing subspace in $\tilde{\mathcal{X}}$.*

Then, if the 2×2 symmetric matrix associated with the quadratic form $D^2_{\tilde{\chi}_1} g(\tilde{\chi}_{01})[v, v]$, where $v \in \mathcal{N}(D_{\tilde{\chi}} G(\tilde{\chi}_0))$, is indefinite, there is an open neighborhood U of $\tilde{\chi}_0$ such that the solution set of $G(\tilde{\chi}) = 0$ consists of two C^{p-1} curves crossing transversally at the $\tilde{\chi}_0$. In a sufficiently small deleted neighborhood of $\tilde{\chi}_0$, these two curves are C^p. If the 2×2 symmetric matrix associated with $D^2_{\tilde{\chi}_1} g(\tilde{\chi}_{01})[v, v]$ is definite, then $\tilde{\chi}_0$ is the only local solution of $G(\tilde{\chi}) = 0$.

We note in passing that this statement of the theorem requires only that $p \geq 2$, whereas that stated in Nirenberg [40] requires $p \geq 3$. The improved version is due to Kuiper [33]. The application of this theorem to the situation in which $\tilde{\mathcal{X}} = \mathcal{X} \times \mathbf{R}$ yields the following theorem.

THEOREM 3.4. *Let $\mathcal{X}$ and $\mathcal{Z}$ be Banach spaces, $\mathcal{B}_1$ and $\mathcal{B}_2$ be open neighborhoods of $\chi_0 \in \mathcal{X}$ and $\alpha_0 \in \mathbf{R}$, respectively, and assume that $G(\chi_0, \alpha_0) = 0$, $G \in \mathcal{C}^p(\mathcal{B}_1 \times \mathcal{B}_2; \mathcal{Z})$ for some fixed $p \geq 2$. Assume that the Fréchet derivative $D_{(\chi,\alpha)} G(\chi_0, \alpha_0)$ is a Fredholm operator of index one with a two-dimensional null space, the dimension of $\mathcal{N}(D_\chi G(\chi_0, \alpha_0))$ is one, and $D_\alpha G(\chi_0, \alpha_0) \in \mathcal{R}(D_\chi G(\chi_0, \alpha_0))$. Let $\phi \in \mathcal{X}$, $\phi^* \in \mathcal{X}^*$, and $\psi^* \in \mathcal{Z}^*$ span $\mathcal{N}(D_\chi G(\chi_0, \alpha_0))$, the one-dimensional space complement of $\mathcal{R}(D_\chi G(\chi_0, \alpha_0)^*)$, and $\mathcal{N}(D_\chi G(\chi_0, \alpha_0)^*)$, respectively, and define*

$$
\begin{aligned}
a &= \langle D^2_\alpha G[1, 1] + 2 D_\alpha D_\chi G[W, 1] + D^2_\chi G[W, W], \psi^* \rangle, \\
b &= \langle D^2_\chi G[\phi, W] + D_\alpha D_\chi G[\phi, 1], \psi^* \rangle, \\
c &= \langle D^2_\chi G[\phi, \phi], \psi^* \rangle, \\
\mathcal{D} &= b^2 - ac,
\end{aligned} \tag{3.5}
$$

where derivatives of G are evaluated at (χ_0, α_0), W is the unique solution of $PW = 0$ and $D_\chi G(\chi_0, \alpha_0) W = -D_\alpha G(\chi_0, \alpha_0)$, and the projection P is defined by $Pu = \frac{\langle u, \phi^* \rangle}{\langle \phi, \phi^* \rangle} \phi$. If $\mathcal{D} > 0$, then there exist open neighborhoods $U \subset \mathcal{B}_1 \times \mathcal{B}_2$ of (χ_0, α_0) and $I \subset \mathbf{R}$ of 0, and two distinct functions $(\chi^\pm, \alpha^\pm) \in \mathcal{C}^{p-1}(I; U)$ such that $(\chi^\pm(0), \alpha^\pm(0)) = (\chi_0, \alpha_0)$ and $G(\chi^\pm(\epsilon), \alpha^\pm(\epsilon)) = 0$ for all $\epsilon \in I$. These two solution manifolds represent the totality of solutions of $G = 0$ in U. Also, if G is an analytic function of (χ, α) in a neighborhood of (χ_0, α_0), then $(\chi^\pm(\epsilon), \alpha^\pm(\epsilon))$ are also analytic on I.

Parameterizations of these manifolds are given as follows:

(i) *If $c \neq 0$ and $\mathcal{D} > 0$, then $\alpha = \alpha^\pm(\epsilon) \equiv \alpha_0 + \epsilon$ so that the two curves can be parameterized by the natural parameter α. These two curves have the structure $\chi = \chi^\pm(\alpha) \equiv \chi_0 + \gamma^\pm(\alpha)\phi + w^\pm(\alpha)$, where $\gamma^\pm(0) = 0$, $\frac{d\gamma^\pm(\alpha_0)}{d\alpha} = \frac{-b \pm \sqrt{\mathcal{D}}}{c}$, $Pw^\pm(\alpha) = 0$, $w^\pm(\alpha_0) = 0$, and $\frac{dw^\pm(\alpha_0)}{d\alpha} \equiv W$ is the unique solution of $PW = 0$ and $D_\chi G(\chi_0, \alpha_0) W = -D_\alpha G(\chi_0, \alpha_0)$.*

(ii) *If $c = 0$ and $\mathcal{D} > 0$, then the two solutions are parameterized as follows:*

(a) *$\alpha = \alpha^-(\epsilon) \equiv \alpha_0 + \epsilon$ so that the natural parameter α can be used and $\chi = \chi^-(\alpha) \equiv \chi_0 + \gamma^-(\alpha)\phi + w^-(\alpha)$, where $\gamma^-(\alpha_0) = 0$, $\frac{d\gamma^-(\alpha_0)}{d\alpha} = \frac{-a}{2b}$, $Pw(\alpha) = 0$, $w(\alpha_0) = 0$, and $\frac{dw^-(\alpha_0)}{d\alpha} \equiv W$ is the unique solution of $PW = 0$ and $D_\chi G(\chi_0, \alpha_0) W = -D_\alpha G(\chi_0, \alpha_0)$;*

(b) *$\alpha = \alpha^+(\epsilon)$ and $\chi = \chi^+(\epsilon) \equiv \chi_0 + \epsilon\phi + w^+(\epsilon)$, where $\alpha^+(0) = \alpha_0$, $\frac{d\alpha^+(0)}{d\epsilon} = 0$, $Pw^+(\epsilon) \equiv 0$, $w^+(0) = 0$, and $\frac{dw^+(0)}{d\epsilon} = 0$.*

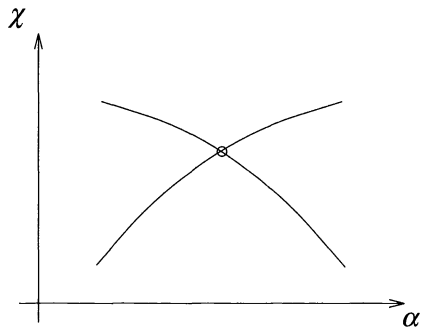

FIG. 3. *Simple bifurcation.*

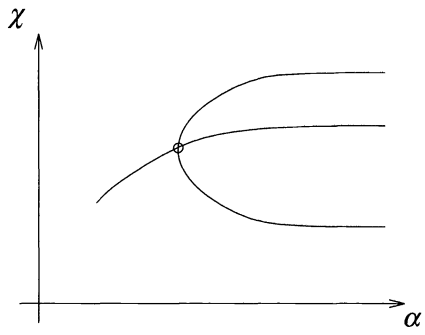

FIG. 4. *Pitchfork bifurcation.*

The simple bifurcation for case (i) in this theorem is illustrated in Figure 3, and case (ii), which is frequently called *pitchfork bifurcation*, in Figure 4. The bifurcation condition $\mathcal{D} > 0$ in this theorem is the same as the condition in Theorem 3.3 that the 2×2 symmetric matrix associated with the quadratic form $D^2_{\tilde{\chi}_1} g(\tilde{\chi}_{01})[v, v]$, where $v \in \mathcal{N}(D_{\tilde{\chi}} G(\tilde{\chi}_0))$, is indefinite.

The quantities a, b, and c in this theorem are significant in that they define a quadratic

$$a\alpha_1^2 + 2b\alpha_1\gamma_1 + c\gamma_1^2 = 0, \tag{3.6}$$

whose solutions indirectly determine the tangents to the two paths at the singularity (χ_0, α_0). For case (i) in which $\mathcal{D} > 0$ and $c \neq 0$, tangents bifurcating curves are

$$T = \begin{pmatrix} W \\ 1 \end{pmatrix} + \frac{-b \pm \sqrt{\mathcal{D}}}{c} \begin{pmatrix} \phi \\ 0 \end{pmatrix}, \tag{3.7}$$

where W is the unique solution of $PW = 0$ and $D_\chi G(\chi_0, \alpha_0)W = -D_\alpha G(\chi_0, \alpha_0)$.

For case (ii) in which $c = 0$ the two tangents for subcases (a) and (b) are, respectively,

$$T = \begin{pmatrix} W \\ 1 \end{pmatrix} - \frac{a}{2b} \begin{pmatrix} \phi \\ 0 \end{pmatrix} \text{ and } T = \begin{pmatrix} \phi \\ 0 \end{pmatrix}, \tag{3.8}$$

where W is as defined in the previous paragraph.

4. Bifurcations for loss of strict complementarity. In this section we relax the strict complementarity condition in Theorem 2.2 but maintain the remaining assumptions. Specifically, we assume that

(a′) strict complementarity is violated by one inequality constraint—say, $\mathcal{A} - \mathcal{A}_s = \{k\}$—so that $f_k(\hat{x}, \hat{\alpha}) = 0$, $\hat{\lambda}_k = 0$, and $l = k - 1$;

(b) the bounded linear transformation $D_x^2 \mathcal{L}_{11} : X_1 \to X_1^*$ is bijective;

(c) The bounded linear transformation $\tilde{L} \equiv (D_x F(\hat{x}, \hat{\alpha}), D_x f_1(\hat{x}, \hat{\alpha}), \ldots, D_x f_l(\hat{x}, \hat{\alpha})) : X \to Y \times \mathbf{R}^l$ is surjective.

If (a′) is replaced by $\mathcal{A} - \mathcal{A}_s = \{l + 1, \ldots, k\}$ for any $l + 1 \leq k$, one can proceed along the lines developed in our earlier work on the finite-dimensional problem [41] to deduce multiple bifurcating branches under conditions similar to those developed there. Although we shall content ourselves with the case (a′), we do note that if (a′) and (b) hold and if in (c) l is replaced by k, Robinson [46] established (in the finite-dimensional case) the existence of a locally unique minimum of (1.1) under a coercivity assumption on $D_x^2 \mathcal{L}_{11}$. Similar results have been obtained by Ito and Kunisch [24] for the Hilbert space setting. The bifurcation analysis below shows that the condition for bifurcation in Theorem 3.4 implies surjectivity of $D_x f_k(\hat{x}, \hat{\alpha})$; however, higher-order bifurcations can occur when there is a loss of this surjectivity.

4.1. Branching for loss of strict complementarity. In the current case the bifurcation Theorem 3.4 applies but Theorem 3.2 does not. As the following theorem shows, the conclusions can be characterized nicely in terms of the problem for which the constraint $f_k \leq 0$ is removed.

THEOREM 4.1. *Let $f_i \in C^2(U \times V; \mathbf{R})$ for $i = 0, 1, \ldots, m$, $F \in C^2(U \times V; Y)$, U and V be open sets in the Banach space X and $\mathbf{R}$, respectively, and Y be a second Banach space containing the range of $F(x, \alpha)$. Let $\mathcal{X} \equiv X \times Y^* \times \mathbf{R}^m \times \mathbf{R}$, and suppose $(\hat{\chi}; \hat{\alpha}) = (\hat{x}, \hat{y}^*, \hat{\lambda}, \hat{\lambda}_0; \hat{\alpha}) \in \mathcal{X} \times \mathbf{R}$ is a solution of $G(\chi; \alpha) = 0$. Suppose that the Fréchet derivative $D_x F(\hat{x}, \hat{\alpha})$ has closed range, its null space is complemented in X, and the aforementioned conditions* (a′), (b), *and* (c) *are valid.*

Then $D_\chi G(\hat{\chi}, \hat{\alpha})$ is a Fredholm operator of index zero with a one-dimensional null space and $D_\alpha G(\hat{\chi}, \hat{\alpha}) \in \mathcal{R}(D_\chi G(\hat{\chi}, \hat{\alpha}))$. If the constraint $f_k \leq 0$ is removed from (1.1), *then conditions* (a)–(c) *in Theorem* 2.2 *are satisfied for the resulting problem. Let $(\bar{x}(\alpha), \alpha)$ be the locally unique solution of* (1.1) *with the constraint $f_k \leq 0$ removed. Then there is a bifurcation provided that $\frac{d}{d\alpha} f_k(\bar{x}(\alpha), \alpha) \neq 0$ at $(\hat{x}, \hat{\alpha})$; i.e., the path $(\bar{x}(\alpha), \alpha)$ is transversal to $f_k(x, \alpha)$ at $(\hat{x}, \hat{\alpha})$.*

Several observations are in order before proceeding to a discussion of the proof. First, if assumption (a) in Theorem 2.2 is relaxed to $\mathcal{A} - \mathcal{A}_s = \{l + 1, \ldots, k\}$ for any $l + 1 \leq k$, assumption (c) implies that the dimension of the null space of the operator $\tilde{L}^*$ is zero so that $\lambda_0 \neq 0$. (Otherwise, all multipliers must be zero.) Also in this case, $D_\alpha G(\hat{\chi}, \hat{\alpha}) \in \mathcal{R}(D_\chi G(\hat{\chi}, \hat{\alpha}))$ so that in the special case of assumption (a′) above, Theorem 3.4 but not Theorem 3.2 is applicable when $\dim \mathcal{N}(D_\chi G(\hat{\chi}, \hat{\alpha})) = 1$. Next, the bifurcation that arises in this "loss of strict complementarity" case is due to the loss surjectivity in the nonlinear system of equations. The relevant part is $\lambda_k f_k(x, \alpha) = 0$. Differentiation of the expression $\lambda_k f_k(x, \alpha)$ shows that it cannot be surjective when both $\lambda_k = 0$ and $f_k(x, \alpha) = 0$; i.e., there is a loss of strict complementarity. Furthermore, since all parametric perturbations occur through the function $f_k(x, \alpha)$, the form of the equation (one of the dependent variables times the constraint) rules out the simple quadratic fold point. Although this is true for the parametric programming problem, the quadratic fold point does arise in numerical methods such as augmented Lagrangian, penalty, and interior point methods because the entire term $\lambda_k f_k(x, \alpha)$ is perturbed (e.g., by the penalty parameter).

We now proceed to the algebraic expressions in Theorem 3.4 for the current problem. Given the assumptions (a′), (b), and (c), $D_\chi G(\hat{\chi}, \hat{\alpha})$ is a Fredholm operator of index zero with a one-dimensional null space. Vectors $\phi \in X \times Y^* \times \mathbf{R}^{k-1} \times \mathbf{R} \times \mathbf{R}^{m-k} \times \mathbf{R}$ and $\psi^* \in X^{**} \times Y^* \times \mathbf{R}^{k-1} \times \mathbf{R} \times \mathbf{R}^{m-k} \times \mathbf{R}$ that span the null spaces of $D_\chi G(\hat{\chi}, \hat{\alpha})$ and $D_\chi G(\hat{\chi}, \hat{\alpha})^*$, respectively, are given by

$$\phi = \begin{bmatrix} \phi_1 \\ \phi_2 \\ \phi_3 \\ \phi_4 \\ \phi_5 \\ \phi_6 \end{bmatrix} = \begin{bmatrix} \Delta\bar{x}_1 \\ \nu\hat{y}^* + y_p^* \\ \nu\hat{\lambda}_A^* + \lambda_{Ap}^* \\ 1 \\ 0 \\ \nu\lambda_0 \end{bmatrix} \text{ and } \psi^* = \begin{bmatrix} \psi_1^* \\ \psi_2^* \\ \psi_3^* \\ \psi_4^* \\ \psi_5^* \\ \psi_6^* \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \\ 0 \\ 0 \end{bmatrix},$$

where $\Delta\bar{x}_1 \in X_1$ solves $D_x^2 \mathcal{L}_{11} \Delta\bar{x}_1 + P_1^* D_x f_k = 0$, $(\hat{y}^*, \hat{\lambda}_A) \in Y^* \times \mathbf{R}^{k-1}$ solves $L^* y^* + D_x f_A^* \lambda_A + \lambda_0 D_x f_0 = 0$, $(y_p^*, \lambda_{Ap}) \in Y^* \times \mathbf{R}^{k-1}$ solves $L^* y^* + D_x f_A^* \lambda_A + D_x^2 \mathcal{L}_{21} \Delta\bar{x}_1 + P_2^* D_x f_k = 0$, and $\nu = -\langle y_0, \hat{y}^* \rangle \langle y_0, y_p^* \rangle - \langle \hat{\lambda}_A, \lambda_{Ap} \rangle$.

To define the projection used in Theorem 3.4, i.e., $P\chi = \frac{\langle \chi, \phi^* \rangle}{\langle \phi, \phi^* \rangle} \phi$, one needs the element ϕ^*. Now $D_\chi G^* : X^{**} \times Y^* \times \mathbf{R}^m \times \mathbf{R} \to X^* \times Y^{**} \times \mathbf{R}^m \times \mathbf{R} = \mathcal{R}(D_\chi G^*) \oplus [\phi^*]$ and

$D_\chi G : X \times Y^* \times \mathbf{R}^m \times \mathbf{R} \to X^* \times Y \times \mathbf{R}^m \times \mathbf{R} = \mathcal{R}(D_\chi G) \oplus [\psi]$. Thus the required ϕ^* and ψ are given by

$$\phi^* = \begin{bmatrix} \phi_1^* \\ \phi_2^* \\ \phi_3^* \\ \phi_4^* \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ e_k \\ 0 \end{bmatrix} \text{ and } \psi = \begin{bmatrix} 0 \\ 0 \\ e_k \\ 0 \end{bmatrix},$$

where $e_k \in \mathbf{R}^m$ is the standard basis vector with a one in the kth position and zeros elsewhere.

To evaluate the algebraic expressions for a, b, c, and $\mathcal{D}$ in Theorem 3.4 one needs, in addition to the above expressions, the solution $\frac{dw(\alpha_0)}{d\alpha} \equiv W = (W_1, W_2, W_3, W_4, W_5, W_6) \in X \times Y^* \times \mathbf{R}^{k-1} \times \mathbf{R} \times \mathbf{R}^{m-k} \times \mathbf{R}$ to the problem $D_\chi G W = -D_\alpha G$ and $PW = 0$, where $P\chi \equiv \frac{\langle \chi, \phi^* \rangle}{\langle \phi, \phi^* \rangle}\phi$. The requirement $PW = 0$ forces $W_4 = 0$. To explain the remaining parts of W, note that if the constraint $f_k \leq 0$ and the corresponding multiplier λ_k are deleted from the problem (1.1), then due to the assumptions (a′), (b), and (c) the resulting system is nonsingular at the corresponding critical point $(\hat{x}, \hat{\alpha})$ and $\bar{W} = (W_1, W_2, W_3, W_5, W_6) \in X \times Y^* \times \mathbf{R}^{k-1} \times \mathbf{R}^{m-k} \times \mathbf{R}$ is the solution of the modified system $D_{\bar{\chi}} \bar{G} \frac{d\bar{\chi}}{d\alpha} = -D_\alpha \bar{G}$, where $\bar{\chi}$ is χ with λ_k and the constraint f_k removed. In particular, $W_1 \equiv \frac{d\bar{x}}{d\alpha}$.

The substitution of these into the algebraic expressions for a, b, c, and $\mathcal{D} > 0$ yields $a = 0$, $b = D_\alpha f_k + D_x f_k W_1$, $c = D_x f_k \phi_1$, $\mathcal{D} = b^2$. The bifurcation condition $\mathcal{D} > 0$ in Theorem 3.4 is that $b = \frac{d}{d\alpha} f_k(\bar{x}(\alpha), \alpha) \neq 0$ at $(\hat{x}, \hat{\alpha})$, which says the path $(\bar{x}(\alpha), \alpha)$ is transversal to $f_k(x, \alpha)$ at $(\hat{x}, \hat{\alpha})$.

Returning to Theorem 3.4, we consider the first of two cases presented in that theorem. First, if $c \neq 0$, the two curves can be parameterized by the natural parameter α and have the structure and $x = x^{\pm}(\alpha) \equiv x_0 + \gamma^{\pm}(\alpha)\phi + w^{\pm}(\alpha)$, where $\gamma^{\pm}(\alpha_0) = 0$, and $\frac{d\gamma^{\pm}(\alpha_0)}{d\alpha} = \frac{-b \pm |b|}{c}$, $Pw^{\pm}(\alpha) = 0$, $w^{\pm}(\alpha_0) = 0$, and $\frac{dw^{\pm}(\alpha_0)}{d\alpha} \equiv W$ as defined above. From the definition of the projection P, $\lambda_k = \gamma^{\pm}(\alpha)$. Now one of $\frac{d\gamma^{\pm}(\alpha_0)}{d\alpha} = \frac{-b \pm |b|}{c}$ is zero and one is not. That which is zero corresponds to the aforementioned path $(\bar{x}(\alpha), \alpha)$ about $\alpha = \alpha_0$ in which $\lambda_k \equiv 0$. This path is feasible for α on one side of α_0 and is infeasible on the other side. The second path has $\lambda_k \neq 0$, so the constraint $f_k(x, \alpha) \leq 0$ must be active along this path locally about α_0 since $\lambda_k f_k(x, \alpha) = 0$.

For the second case, if $c = 0$ and $\mathcal{D} > 0$, then the two solutions are parameterized as follows: the first path is parameterized by the natural parameter α as $x = x^-(\alpha) \equiv x_0 + \gamma^-(\alpha)\phi + w^-(\alpha)$, where $\lambda_k = \gamma^-(\alpha)$, $\gamma^-(\alpha_0) = 0$, $\frac{d\gamma^-(\alpha_0)}{d\alpha} = \frac{-a}{2b} = 0$, $Pw^-(\alpha) \equiv 0$, $w^-(\alpha_0) = 0$, and $\frac{dw^-(\alpha_0)}{d\alpha} = W$, where W is as defined above. It is this solution that is transversal to the constraint $f_k = 0$ with $\lambda_k = \gamma^-(\alpha) \equiv 0$. The second path has the parameterization $\alpha = \alpha^+(\epsilon)$ and $x = x^+(\epsilon) \equiv x_0 + \epsilon\phi + w^+(\epsilon)$, where $\alpha^+(0) = \alpha_0$, $\frac{d\alpha^+(0)}{d\epsilon} = 0$, $Pw^+(\epsilon) \equiv 0$, $w^+(0) = 0$, and $\frac{dw^+(0)}{d\alpha} = 0$. In fact, from the definition of the projection P, we conclude that $\epsilon \equiv \lambda_k$ is the parameterization parameter and the constraint $f_k \leq 0$ is active.

In summary, the bifurcation diagram is as in Figure 3. One of the solution branches corresponds to the constraint $f_k \leq 0$ being active, i.e., $f_k = 0$, and the other solution branch crosses this constraint transversally as the parameter α crosses α_0, going from the interior feasible region of the constraint $f_k \leq 0$ to the exterior or vice versa. For a stability result, we have a result similar to the finite-dimensional case.

THEOREM 4.2. *Let $f_i \in C^2(U \times V; \mathbf{R})$ for $i = 0, 1, \ldots, m$, $F \in C^2(U \times V; Y)$, U and V be open sets in the Banach space X and $\mathbf{R}$, respectively, and Y be a second Banach space containing the range of $F(x, \alpha)$. Let $\mathcal{X} \equiv X \times Y^* \times \mathbf{R}^m \times \mathbf{R}$, and suppose that*

$(\hat{\chi};\hat{\alpha}) = (\hat{x}, \hat{y}^*, \hat{\lambda}, \hat{\lambda}_0; \hat{\alpha}) \in \mathcal{X} \times \mathbf{R}^m$ is a solution of $G(\chi;\alpha) = 0$. Suppose the Fréchet derivative $D_x F(\hat{x},\hat{\alpha})$ has closed range, its null space is complemented in X, and the following are valid.

(a′) *Strict complementarity is violated by one inequality constraint—say, $\mathcal{A} - \mathcal{A}_s = \{k\}$—so that $f_k(\hat{x},\hat{\alpha}) = 0$, $\hat{\lambda}_k = 0$, and $l = k - 1$.*

(b′) *$D_x^2\mathcal{L}(\hat{\chi},\hat{\alpha})[h,h] \geq C\|h\|_X^2$ for all $h \in \mathcal{N}(\tilde{L})$.*

(c) *The bounded linear transformation $\tilde{L} \equiv (D_x F(\hat{x},\hat{\alpha}), D_x f_1(\hat{x},\hat{\alpha}), \ldots, D_x f_l(\hat{x},\hat{\alpha})) : X \to Y \times \mathbf{R}^l$ is surjective.*

(d) *The multipliers $\lambda_i > 0$ for $i = 1, \ldots, l$ at $(x,\alpha) = (\hat{x},\hat{\alpha})$.*

On that branch emanating from $(\hat{x},\hat{\alpha})$ that is interior to the constraint $f_k \leq 0$, there exists an interval $[\alpha_0,\hat{\alpha}]$ on which $D_x^2\mathcal{L}(\hat{\chi},\hat{\alpha})[h,h] \geq \bar{C}\|h\|_X^2$ for all $h \in \mathcal{N}(\tilde{L}(\alpha))$. On that branch emanating from $(\hat{x},\hat{\alpha})$, where the constraint $f_k \leq 0$ is active and $\lambda_k > 0$, a similar result holds. Thus and in particular, there is a local persistence of the unique minimizer along these two solution branches.

4.2. An isoperimetric example. A simple example that illustrates the foregoing bifurcation phenomena is

$$\begin{aligned} &\text{minimize} && J(x) = \int_0^1 \left(\frac{dx}{dt}\right)^2 dt \\ &\text{subject to} && x(0) = 0, x(1) = \alpha, \\ &&& \int_0^1 x\,dt \leq l, \qquad x \in C^1([0,1],\mathbf{R}). \end{aligned}$$

For this problem the constraints are affine, so we use the Lagrangian

$$\mathcal{L} = \int_0^1 \left(\frac{dx}{dt}\right)^2 dt + \lambda\left(\int_0^1 x\,dx - l\right) + \mu_1 x(0) + \mu_2\big(x(1) - \alpha\big).$$

If the constraint $\int_0^1 x\,dx \leq l$ is not active, then the solution is given by $\hat{x}(t) = \alpha t$. Furthermore,

$$J(\hat{x}+h) = J(\hat{x}) + J(h) \geq J(x) + \frac{1}{2}\|h\|_{W^{1,2}}^2$$

for all $h \in C^1([0,1],\mathbf{R})$ such that $h(0) = h(1) = 0$. Here, $W^{m,p}[a,b] = \{v \in C^{m-1}[a,b] : v^{(m-1)}$ is absolutely continuous on $[a,b]$, $v^{(m)} \in L^p[a,b]\}$ for $1 \leq p < \infty$ and $\|v\|_{W^{m,p}} = \big(\sum_{k=0}^m \|v^{(k)}\|_{L^p}^p\big)^{1/p}$. (This technique of using two different norms in establishing a minimizer was mentioned at the end of §2.3 and is presented in the work of Ioffe [21] and Maurer [39].) Thus, this solution is a global minimizer as long as the inequality constraint is satisfied and is not active, i.e., $\int_0^1 \hat{x}(t)\,dt = \frac{\alpha}{2} < l$. At $\alpha = 2l$, the inequality constraint becomes active, and as α increases beyond $2l$, the inequality constraint is violated. As discussed in the previous subsection, this path represents one branch in the bifurcation diagram in Figure 3.

The second solution branch emanates from $\alpha = 2l$ and satisfies the active inequality constraint, i.e., $\int_0^1 x\,dt = l$. The solution is $\hat{x}(t) = (\frac{\lambda}{4})t^2 + (\alpha - \frac{\lambda}{4})t$, where α is related to the Lagrange multiplier λ by $\lambda = 12(\alpha - 2l)$, which is zero when $\alpha = 2l$. This solution exists for both α less than and greater than $2l$; however, only for $\alpha > 2l$ is the multiplier positive. In this case, the same inequality $J(\hat{x}+h) = J(\hat{x}) + J(h) \geq J(x) + \frac{1}{2}\|h\|_{W^{1,2}}^2$ holds for all $h \in C^1([0,1],\mathbf{R})$, $h(0) = h(1) = 0$, and $\int_0^1 h(t)\,dt = 0$. Thus for $\alpha > 2l$, which implies that $\lambda > 0$, we have a global minimizer with the inequality constraint being active. The bifurcation diagram is as in Figure 3.

5. Bifurcations for loss of surjectivity. In this section we investigate the problem (2.4) under the same assumptions as in Theorem 2.2, except that the surjectivity assumption is relaxed. In particular, we assume that

(a) strict complementarity holds, i.e., $\mathcal{A}_s = \mathcal{A}$ and $k = l$;

(b) the bounded linear transformation $D_x^2\mathcal{L}_{11} : X_1 \to X_1^*$ is bijective;

(c′) the range of $\tilde{L} = (D_xF(\hat{x}, \hat{\alpha}), D_xf_1(\hat{x}, \hat{\alpha}), \ldots, D_xf_k(\hat{x}, \hat{\alpha})) : X \to Y \times \mathbf{R}^k$ has codimension one in $Y \times \mathbf{R}^k$.

When we use these hypotheses, it is easily verified that the Fréchet derivative $D_\chi G(\hat{x}, \hat{y}^*, \hat{\lambda}, \lambda_0; \hat{\alpha})$ is a Fredholm operator of index zero with a one-dimensional null space. As in the appendix we partition $\lambda \in \mathbf{R}^m$ into $\lambda_A \in \mathbf{R}^k$ and $\lambda_C \in \mathbf{R}^{m-k}$ by $\lambda = \begin{bmatrix} \lambda_A \\ \lambda_C \end{bmatrix}$. ($\lambda_B$ is vacuous since $k = l$.) Likewise, D_xf is to be partitioned into D_xf_A and D_xf_C by

$$D_xf_A = \begin{bmatrix} D_xf_1 \\ \vdots \\ D_xf_k \end{bmatrix} \text{ and } D_xf_C = \begin{bmatrix} D_xf_{k+1} \\ \vdots \\ D_xf_m \end{bmatrix}.$$

The analysis of this situation breaks into two cases: (1) $D_xf_0(\hat{x}, \hat{\alpha}) \notin \mathcal{R}(\tilde{L}^*)$ and (2) $D_xf_0(\hat{x}, \hat{\alpha}) \in \mathcal{R}(\tilde{L}^*)$, as given in §§5.1 and 5.3, respectively. We refer to these two cases as the abnormal and normal cases, respectively. Rather than restating Theorems 3.2 and 3.4 as they relate to the current cases, we adopt an informal style.

5.1. Loss of surjectivity: The abnormal case. In this case, $D_xf_0(\hat{x}, \hat{\alpha}) \notin \mathcal{R}(\tilde{L}^*)$, so $\mathcal{N}(\tilde{L}^*) = \mathcal{R}(\tilde{L})^\perp$ and $\dim \mathcal{N}(\tilde{L}^*) = 1$ imply that the only choice of λ_0 in (2.4) is $\lambda_0 = 0$. Thus, there exists a nonzero multiplier $(y_1^*, \lambda_{A1}) \in \mathcal{N}(\tilde{L}^*)$, where $y_1^* \in Y^*$ and $\lambda_{A1} \in (\mathbf{R}^k)^*$, that spans $\mathcal{N}(\tilde{L}^*)$. We normalize these multipliers by first choosing a $y_0 \in Y$ such that $|\langle y_0, y_1^*\rangle| \geq \frac{1}{2}\|y_1^*\|$ and scaling y_1^* and λ_{A1} so that $|\langle y_0, y_1^*\rangle|^2 + \langle \lambda_{A1}, \lambda_{A1}\rangle = 1$. Then the system of nonlinear equations (2.4) has the following solution $(x, y^*, \lambda_A, \lambda_C, \lambda_0; \alpha) = (\hat{x}, \hat{y}^*, \hat{\lambda}_A, 0, 0; \hat{\alpha})$, where $\hat{y}^* = \tau y_1^*$, $\hat{\lambda}_A = \tau\lambda_{A1}$ and $\tau = \pm 1$.

From the expressions for $D_\chi G(\hat{x}, \hat{y}^*, \hat{\lambda}, \hat{\lambda}_0; \hat{\alpha})$ and its adjoint in the appendix, spanning vectors for the one-dimensional null spaces can be defined as follows. Under the assumed hypotheses, $\Delta x_2 = 0$, $\lambda_0 = 0$, $\hat{\lambda}_C = 0$, and Λ_A is invertible. Let $\Delta\bar{x}_1$ be the unique solution of $D_x^2\mathcal{L}_{11}\Delta\bar{x}_1 + P_1^*(D_xf_0) = 0$. The general solution $(\Delta y^*, \Delta\lambda)$ of $L^*\Delta y^* + D_xf_A^*\Delta\lambda_A = -\Delta\lambda_0 D_x^2\mathcal{L}_{21}\bar{\Delta}x_1 - \Delta\lambda_0 P_2^*(D_xf_0)$ is

$$\begin{bmatrix} \Delta y^* \\ \Delta\lambda_A \end{bmatrix} = \Delta\lambda_0\nu \begin{bmatrix} \hat{y}^* \\ \hat{\lambda}_A \end{bmatrix} + \Delta\lambda_0 \begin{bmatrix} y_p^* \\ \lambda_{Ap} \end{bmatrix},$$

where $\begin{bmatrix} y_p^* \\ \lambda_{Ap} \end{bmatrix}$ is a particular solution with $\Delta\lambda_0 = 1$ and is chosen to be in the space complement of $\mathcal{N}(\tilde{L}^*)$. Also, $\nu = -\langle y_0, \hat{y}^*\rangle\langle y_0, y_p^*\rangle - \langle\hat{\lambda}_A, \hat{\lambda}_{Ap}\rangle$. Thus $\phi \in X \times Y^* \times \mathbf{R}^k \times \mathbf{R}^{m-k} \times \mathbf{R}$ and $\psi^* \in X^{**} \times Y^* \times \mathbf{R}^{k*} \times \mathbf{R}^{(m-k)*} \times \mathbf{R}^*$, given by

$$\phi = \begin{bmatrix} \phi_1 \\ \phi_2 \\ \phi_3 \\ \phi_4 \\ \phi_5 \end{bmatrix} = \begin{bmatrix} \Delta\bar{x}_1 \\ \nu\hat{y}^* + y_p^* \\ \nu\hat{\lambda}_A + \lambda_{Ap} \\ 0 \\ 1 \end{bmatrix} \text{ and } \psi^* = \begin{bmatrix} \psi_1^* \\ \psi_2^* \\ \psi_3^* \\ \psi_4^* \\ \psi_5^* \end{bmatrix} = \begin{bmatrix} 0 \\ \hat{y}^* \\ \Lambda_A^{*-1}\hat{\lambda}_A \\ 0 \\ 0 \end{bmatrix},$$

span the null spaces of $D_\chi G(\hat{\chi}, \hat{\alpha})$ and $D_\chi G(\hat{\chi}, \hat{\alpha})^*$, respectively.

For evaluation of the expressions in Theorems 3.2 and 3.4, note that $\langle D_\chi^2 G(\hat\chi,\hat\alpha)[u,v],\psi^*\rangle = D_x^2\mathcal{L}(\hat\chi,\hat\alpha)[u_1,v_1]$, $\langle D_\alpha G(\hat x,\hat\alpha)[1],\psi^*\rangle = D_\alpha\mathcal{L}(\hat\chi,\hat\alpha)$, and $D_\alpha D_\chi G(\hat\chi,\hat\alpha)[u],\psi^*\rangle = D_\alpha D_x\mathcal{L}(\hat\chi,\hat\alpha)[u_1]$, where u and $v \in \mathcal{X} = X \times Y^* \times \mathbf{R}^m \times \mathbf{R}$ and u_1 represents the first component of u, i.e., the projection of u onto X.

Theorem 3.2 is applicable when $D_\alpha G \notin \mathcal{R}(D_\chi G)$ or equivalently $D_\alpha\mathcal{L} \neq 0$. Note in particular that $\lambda_0 \equiv \epsilon$ crosses zero with ϵ in Theorem 3.2. If $D_x^2\mathcal{L}(\hat\chi,\hat\alpha)[\phi_1,\phi_1] \neq 0$, then

$$\frac{d^2\alpha(0)}{d\epsilon^2} \equiv -\frac{\langle D_\chi^2 G(\hat\chi,\hat\alpha)[\phi,\phi],\psi^*\rangle}{\langle D_\alpha G(\hat\chi,\hat\alpha)[1],\psi^*\rangle} = -\frac{D_x^2\mathcal{L}(\hat\chi,\hat\alpha)[\phi_1,\phi_1]}{D_\alpha\mathcal{L}(\hat\chi,\hat\alpha)[1]} \neq 0.$$

(Note that the signs of $D_x^2\mathcal{L}(\hat\chi,\hat\alpha)[\phi_1,\phi_1]$ and $D_\alpha\mathcal{L}$ change with τ, but the sign of $\frac{d^2\alpha(0)}{d\epsilon^2}$ does not.)

Theorem 3.4 is applicable when $D_\alpha G \in \mathcal{R}(D_\chi G)$ or equivalently $D_\alpha\mathcal{L}(\hat\chi,\hat\alpha)[1] = 0$. In this case the algebraic expressions for a, b, and c in this theorem reduce to

$$\begin{aligned} a &= D_\alpha^2\mathcal{L}[1,1] + 2D_\alpha D_x\mathcal{L}[W_1,1] + D_x^2\mathcal{L}[W_1,W_1],\\ b &= D_x^2\mathcal{L}[\phi_1,W_1] + D_\alpha D_x\mathcal{L}[\phi_1,1],\\ c &= D_x^2\mathcal{L}[\phi_1,\phi_1] \end{aligned}$$

and depend on τ; however, the sign of $\mathcal{D} = b^2 - ac$, which is crucial for bifurcation, is invariant with respect to τ.

5.2. A fold point example. An example that illustrates the fold point phenomena for this case is Queen Dido's problem of maximizing the area under a curve of fixed length [1]:

$$\begin{aligned} \text{maximize} \quad & \int_{-a}^{a} y(x)\,dx\\ \text{subject to} \quad & \int_{-a}^{a} \sqrt{1+\left(\frac{dy}{dx}\right)^2}\,dx = l,\\ & y(-a) = 0, \qquad y(a) = 0,\\ & y \in C^1([-a,a],\mathbf{R}). \end{aligned}$$

The solution $y \equiv 0$ at $l = 2a$ is a quadratic fold point for the above problem and is an *abnormal case*. To see this, first note that at these values $D_y\big(\int_{-a}^{a}(1+\big(\frac{dy}{dx}\big)^2)^{1/2}\,dx - l\big)[h] = \int_{-a}^{a} 0\cdot h + 0\cdot\frac{dh}{dx}\,dx = 0$ for all $h \in C^1$, so the Fréchet derivative of this constraint is not surjective at $l = 2a$. Since $D_l\big(\int_{-a}^{a}(1+\big(\frac{dy}{dx}\big)^2)^{1/2}\,dx - l\big) = -1$, which is not in the range of the Fréchet derivative of this constraint with respect to y, we are in the abnormal case and the situation is much like that in Theorem 3.2 for the parameter $\alpha = \frac{2a}{l}$. The global solution structure is as follows.

For $\frac{2a}{l} > 1$, there is no feasible solution to the constraints and thus no solution to the problem. For $\frac{2a}{l} = 1$, the unique solution to the constraints (and thus to the problem) is $y \equiv 0$. (This is the fold point.)

For $\frac{2}{\pi} < \frac{2a}{l} < 1$, there are two solutions to the first-order necessary conditions and each is defined implicitly by the circle $x^2 + (y-\kappa)^2 = R^2$, where the center $(0,\kappa)$ and radius R are defined as follows. From the center $(0,\kappa)$ draw two straight lines, one to the origin (0,0) and one to $(a,0)$, and let θ denote the angle between these two lines at $(0,\kappa)$. Then, the relations $2R\theta = l$, $R\cos\theta = |\kappa|$, and $R\sin\theta = a$ yield the equation $\sin\theta = \big(\frac{2a}{l}\big)\theta$ which has a solution in $(0,\pi/2)$, say θ_0, for $\frac{2}{\pi} < \frac{2a}{l} < 1$. The corresponding radius and center are $R = \frac{l}{2\theta_0}$ and

$\kappa = -\frac{l\cos(\theta_0)}{2\theta_0}$, respectively. The solution y is given by $y(x;\kappa,R) = \kappa + \sqrt{R^2 - x^2}$; the second solution is a minimum and is given by the negative of this one. Note also that as $\alpha \equiv \frac{2a}{l} \to 1^-$ the solutions $y \to 0$ and as $\alpha \equiv \frac{2a}{l} \to \frac{2}{\pi}^+$, the solutions $y \to \pm\sqrt{a^2 - x^2}$, either of which has an infinite C^1 norm.

For $\frac{2a}{l} \leq \frac{2}{\pi}$, there are no C^1 solutions in nonparametric form for the above problem. (One can continue the solution in parametric form.) Finally, there is a complete exchange of the stability in the solution as λ_0 crosses the origin. The bifurcation diagram is qualitatively like that in Figure 1.

5.3. Loss of surjectivity: The normal case. In the normal case $D_x f_0(\hat{x},\hat{\alpha}) \in \mathcal{R}(\tilde{L}^*)$, so $\lambda_0 \neq 0$. We modify the normalization in problem (2.4) and replace it with $\lambda_0 = 1$; otherwise, the assumptions are as follows:

(a) strict complementarity holds, i.e., $\mathcal{A}_s = \mathcal{A}$ and $k = l$;

(b) $D_x^2\mathcal{L}_{11} : X_1 \to X_1^*$ is bijective;

(c) the range of $(D_x F(\hat{x},\hat{\alpha}), D_x f_1(\hat{x},\hat{\alpha}), \ldots, D_x f_l(\hat{x},\hat{\alpha})) : X \to Y \times \mathbf{R}^l$ has codimension one in $Y \times \mathbf{R}^l$;

(d′) $D_x f_0(\hat{x},\hat{\alpha}) \in \mathcal{R}(\tilde{L}^*)$.

The situation (d′) occurs for the case (a)–(c) when, for example, the active constraints are affine and consistent (i.e., have a feasible solution).

Since the codimension of the range of the operator $\tilde{L} = \begin{bmatrix} L \\ D_x f_A \end{bmatrix}$ is one, the dimension of the null space of $\tilde{L}^*$ is also one, so there exist nonzero multipliers $(y_1^*, \lambda_1^*) \in \mathcal{N}(\tilde{L}^*)$, where $y_1^* \in Y^*$ and $\lambda_1^* \in (\mathbf{R}^l)^*$ such that $L^* y_1^* + D_x f_A^* \lambda_1^* = 0$ and any solution of this problem is a constant multiple of (y_1^*, λ_1^*). Thus the solution of the (2.4) with the normalization N_3 replaced by N_1 (see equation (2.5)) can be written as

$$\begin{bmatrix} \hat{y}^* \\ \hat{\lambda}_A^* \end{bmatrix} = \gamma \begin{bmatrix} y_1^* \\ \lambda_1^* \end{bmatrix} + \lambda_0 \begin{bmatrix} y_p^* \\ \lambda_{Ap}^* \end{bmatrix}$$

where $\begin{bmatrix} y_p^* \\ \lambda_{Ap}^* \end{bmatrix}$ is a particular solution of (2.4) corresponding to $\lambda_0 = 1$ and is in the space complement of $\mathcal{N}(\tilde{L}^*)$. One can show that the null spaces of $D_\chi G(\hat{\chi},\hat{\alpha})$ and $D_\chi G(\hat{\chi},\hat{\alpha})^*$ are spanned by

$$\phi = \begin{bmatrix} \phi_1 \\ \phi_2 \\ \phi_3 \\ \phi_4 \\ \phi_5 \end{bmatrix} = \begin{bmatrix} 0 \\ y_1^* \\ \lambda_1^* \\ 0 \\ 0 \end{bmatrix} \text{ and } \psi^* = \begin{bmatrix} \psi_1^* \\ \psi_2^* \\ \psi_3^* \\ \psi_4^* \\ \psi_5^* \end{bmatrix} = \begin{bmatrix} 0 \\ y_1^* \\ \Lambda_1^{*-1}\lambda_1^* \\ 0 \\ 0 \end{bmatrix},$$

respectively.

The bifurcation Theorem 3.2 is applicable when $D_\alpha G(\hat{x},\hat{\alpha}) \notin \mathcal{R}(D_x G(\hat{x},\hat{\alpha}))$, i.e., when $\langle D_\alpha F(\hat{x},\hat{\alpha}), y_1^*\rangle + \langle D_\alpha f_A(\hat{x},\hat{\alpha}), \lambda_1^*\rangle \neq 0$. In this case there is a locally unique solution according to Theorem 3.2 given by

$$\begin{bmatrix} \hat{y}^* \\ \hat{\lambda}_A^* \end{bmatrix} = \gamma \begin{bmatrix} y_1^* \\ \lambda_1^* \end{bmatrix} + \lambda_0 \begin{bmatrix} y_p^* \\ \lambda_{Ap}^* \end{bmatrix}$$

for each γ. Thus, this solution represents the entirety of solutions to the modified (2.4) at $(\hat{x},\hat{\alpha})$.

The bifurcation Theorem 3.4 is applicable when $D_\alpha G(\hat{x}, \hat{\alpha}) \in \mathcal{R}(D_x G(\hat{x}, \hat{\alpha}))$, i.e., when $\langle D_\alpha F(\hat{x}, \hat{\alpha}), y_1^* \rangle + \langle D_\alpha f_A(\hat{x}, \hat{\alpha}), \lambda_1^* \rangle = 0$. However, in this case the algebraic expressions for (a), (b), and (c) now take the values $b = 0$ and $c = 0$, so Theorem 3.4 gives no information about branching.

6. $D_x^2 \mathcal{L}_{11}$ is singular. Finally in this section we relax the condition in Theorem 2.2 that $D_x^2 \mathcal{L}_{11}$ is bijective, but we maintain the remaining assumptions. Specifically, we assume that

(a) strict complementarity holds, i.e., $\mathcal{A} = \mathcal{A}_s$ and $k = l$;

(b′) the bounded linear transformation $D_x^2 \mathcal{L}_{11} : X_1 \to X_1^*$ ($X_1 = \mathcal{N}(\tilde{L})$) is a Fredholm operator of index 0 with a one-dimensional null space;

(c) $\tilde{L} \equiv (D_x F(\hat{x}, \hat{\alpha}), D_x f_1(\hat{x}, \hat{\alpha}), \ldots, D_x f_l(\hat{x}, \hat{\alpha})) : X \to Y \times \mathbf{R}^l$ is surjective.

Before proceeding, it is worth noting that, under the assumptions of $\mathcal{N}(L)$ splitting the space X (Theorem 2.4) and (a), $\mathcal{N}(\tilde{L})$ also splits the space [1, lemma on the closed image]. Thus, there exists a closed linear subspace X_2 such that $X = X_1 \oplus X_2$ with $X_1 = \mathcal{N}(\tilde{L})$. Then by assumption (c), the implicit function Theorem 3.1 implies the existence of a locally unique C^p solution $x_2 = u(x_1, \alpha)$ of $\tilde{F}(x, \alpha) = 0$, where $\tilde{F} = (F, f_1(x, \alpha), \ldots, f_l(x, \alpha)) = 0$. Since $k = l$ by assumption (a), all active constraints in the problem can be removed and one can, for the purposes of local phenomena, consider the equivalent unconstrained optimization problem: minimize $\widetilde{f_0}(x_1, \alpha) \equiv f_0(x_1 + u(x_1, \alpha), \alpha)$. Such unconstrained problems are most efficiently treated by using catastrophe theory as in the book by Poston and Stewart [43], and the examples in this section are for this reduced unconstrained problem. However, we first present the theory within the current framework.

6.1. Branching analysis for a singular $D_x^2 \mathcal{L}_{11}$. Let $\hat{y}^*, \hat{\lambda}_A, \hat{\lambda}_C = 0$ and $\hat{\lambda}_0$ represent the solution of (2.4) at $(x, \alpha) = (\hat{x}, \hat{\alpha})$, and suppose that $\mathcal{N}(D_x^2 \mathcal{L}_{11})$ is spanned by ϕ_1. Finally, let y_p^* and λ_{Ap}^* be the unique solution of $L^* y_p^* + (D_x f_A)^* \lambda_{Ap}^* = -D_x^2 \mathcal{L}_{21} \phi_1$. Then the general solutions of $D_\chi G \phi = 0$ and $D_\chi G^* \psi^* = 0$ are spanned by

$$\phi = \begin{bmatrix} \phi_1 \\ \phi_2 \\ \phi_3 \\ \phi_4 \\ \phi_5 \end{bmatrix} = \begin{bmatrix} \phi_1 \\ \nu \hat{y}^* + y_p^* \\ \nu \hat{\lambda}_A^* + \lambda_{Ap}^* \\ 0 \\ \nu \hat{\lambda}_0 \end{bmatrix} \quad \text{and} \quad \psi^* = \begin{bmatrix} \psi_1^* \\ \psi_2^* \\ \psi_3^* \\ \psi_4^* \\ \psi_5^* \end{bmatrix} = \begin{bmatrix} \psi_1^* \\ y_a^* \\ \Lambda_A^{*-1} \lambda_{Aa}^* \\ \lambda_{Ca}^* \\ 0 \end{bmatrix}, \tag{6.1}$$

respectively, where the parameter ν is determined from the normalization equation in (2.5c), i.e., $\nu = -\langle y_0, \hat{y}^* \rangle \langle y_0, y_p^* \rangle - \langle \hat{\lambda}_A^*, \lambda_{Ap}^* \rangle$, $\mathcal{N}(D_x^2 \mathcal{L}_{11}^*)$ is spanned by ψ_1^*, y_a^* and λ_{Aa}^* solve $L^* y_a^* + D_x f_A^* \lambda_{Aa}^* = -D_x^2 \mathcal{L}_{12}^* \psi_1^*$, and λ_{Ca}^* solves $\operatorname{diag}(f_{k+1}, \ldots, f_m) \lambda_{Ca}^* = -D_x f_C^{**} P_1^{**} \psi_1^*$. Since the algebraic expressions in Theorems 3.2 and 3.4 do not simplify any further except for the obvious substitutions, we omit a restatement of these theorems incorporating these expressions.

Finally, we remark that the assumptions (a) and (b) imply that $\lambda_0 \neq 0$. Thus, if the normalization $\sum_{i=0}^m \lambda_i^2 + \|y^*\|^2 = 1$ in (2.4) is replaced by $\lambda_0 = 1$, then the eigenvectors are determined as follows: let $y_p^*, \lambda_{Ap}^*, \lambda_{Cp}^* = 0$ solve $L^* y_p^* + D_x f_A^* \lambda_{Ap}^* = -D_x^2 \mathcal{L}_{12} \phi_1$. Then the null spaces of $D_\chi G$ and G_χ^* are spanned by

$$\phi = \begin{bmatrix} \phi_1 \\ \phi_2 \\ \phi_3 \\ \phi_4 \end{bmatrix} = \begin{bmatrix} \phi_1 \\ y_p^* \\ \lambda_{Ap}^* \\ 0 \end{bmatrix} \quad \text{and} \quad \psi^* = \begin{bmatrix} \psi_1^* \\ \psi_2^* \\ \psi_3^* \\ \psi_4^* \end{bmatrix} = \begin{bmatrix} \psi_1^* \\ y_a^* \\ \Lambda_A^{*-1} \lambda_{Aa}^* \\ \lambda_{Ca}^* \end{bmatrix}, \tag{6.2}$$

respectively, where $\mathcal{N}(D_x^2\mathcal{L}_{11}^*)$ is spanned by ψ_1^*, y_a^* and λ_{Aa}^* solve $L^*y_a^* + D_x f_A^*\lambda_{Aa}^* = -D_x^2\mathcal{L}_{12}^*\psi_1^*$, and λ_{Ca}^* solves $\operatorname{diag}(f_{k+1}, \ldots, f_m)\lambda_{Ca}^* = -D_x f_C^{**}\psi_1^*$.

6.2. Examples for loss of bijectivity. As remarked above, it suffices to consider the unconstrained problem of minimizing $f(x, \alpha)$, where $f(x, \alpha) : X \times \mathbf{R} \to \mathbf{R}$ and X is a Banach space. The first example illustrates the quadratic fold point phenomena, and the second, pitchfork bifurcation; however, the local bifurcation analysis rests on the extended approach of Zeidler [59, §29.18] and Bobylev and Krasnosel'skii [5].

The problem of finding the minimum surface of revolution connecting two coaxial circular loops each of radius R separated by a distance of $2l$ can be formulated as [16]

$$\begin{aligned} \text{minimize} \quad & 2\pi \int_{-l}^{l} r\sqrt{1 + \left(\frac{dr}{dx}\right)^2}\, dx \\ \text{subject to} \quad & r(-l) = a, \qquad r(l) = a, \\ & r \in C^1([0, 1], \mathbf{R}). \end{aligned}$$

The answer to this problem is as follows. For $0 < \frac{l}{R} < 0.6627$, there are two zeros $\frac{l}{C}$ to the equation $\frac{R}{l}\frac{l}{C} - \cosh\left(\frac{l}{C}\right) = 0$. For either of these two zeros the curve defined by

$$r(x) = C \cosh\left(\frac{x}{C}\right)$$

is an extremal of the above problem: the smaller zero yields a minimum and the larger, a local maximum. In either case the area is given by

$$A_{min} = \begin{cases} 2\pi R^2 \left(\tanh\left(\frac{l}{C}\right) + \frac{l}{C}\operatorname{sech}^2\left(\frac{l}{C}\right)\right) & \text{for } 0 < \frac{l}{C} \le 0.6627, \\ 2\pi R^2 & \text{for } \frac{l}{C} > 0.6627, \end{cases}$$

where the constant C is determined from the above equation.

For $\frac{l}{R} = 0.6627$, there is exactly one zero $\frac{l}{C} = 1.1996786$ to the above equation; the corresponding solution is a quadratic fold point. For $\frac{l}{R} > 0.6627$, there is no C^1 solution. The bifurcation diagram is qualitatively like that in Figure 1.

The next example is that of the equilibrium-deflected shape of an Euler beam as determined from the variational principle [60]:

$$\begin{aligned} \text{minimize} \quad & \int_0^l \frac{EI}{2}u^2 - P(1 - \cos\theta)\, ds \\ \text{subject to} \quad & \frac{d\theta}{ds} = u, \\ & \theta(0) = 0, \qquad \theta(l) = 0, \\ & \theta \in C^1([0, l], \mathbf{R}),\ u \in C([0, l], \mathbf{R}), \end{aligned}$$

where P is the load on the column, E is the modulus of elasticity, I is the second moment of cross-sectional area about the neutral axis, $\tan\theta$ is the slope of the neutral axis, l is the length of the column, s is the arc-length along the neutral axis of the column, and $\frac{d\theta}{ds} = u$ is the curvature. Euler's equation for this problem is

$$\begin{aligned} \frac{d^2\theta}{dx^2} + \omega^2 \sin\theta = 0, \\ \theta(0) = 0, \qquad \theta(1) = 0, \end{aligned}$$

where $\omega^2 = \frac{Pl^2}{EI}$ and $lx = s$. This well-known example in bifurcation theory illustrates the pitchfork bifurcation in Figure 4. Since it is analyzed rather completely in the book by Zeidler [59], we forego any further discussion.

7. Conclusions. The primary objective in this work has been the derivation of conditions under which bifurcation theory is applicable to the parametric optimization problem (1.1) posed in Banach spaces. By using the Fritz John first-order necessary conditions and a nonstandard normalization of the multipliers, this problem has been formulated as a set of equations on Banach spaces. By relaxing the bijectivity assumptions of the implicit function theorem but maintaining the Fredholm property of the Fréchet derivative of the nonlinear system of equations, a rather general framework for the analysis of bifurcation problems has been developed. Singularities generally arise when the strict complementarity fails, the Fréchet derivative of the active constraints fails to be surjective, or a second-order condition fails (see Theorem 2.2). A branching analysis has been provided for each of the generic cases.

With respect to further developments, one can analyze higher-codimension problems as in the books by Golubitsky, Stewart and Schaeffer [17, 18] and by Poston and Stewart [43]. Exploitation of symmetry in the bifurcation analysis has been an active area of research, and the use of this work should prove to be equally productive for the nonlinear program (1.1). Another fundamentally important aspect is the exchange in the stability (i.e., persistence of minima) at the singularities. Similar problems have been investigated for unconstrained problems using monotone operators and spectral theory, as presented in the books of Zeidler [58–60] and references therein. The Hilbert space setting developed by Bobylev and Krasnosel'skii [5] for the unconstrained problem appears to provide a correct framework. These approaches should play a central part in the development of the stability theory for the abstract constrained optimization problem (1.1) and will be investigated in future work.

Finally, we discussed the difficulty of treating problems with general cone constraints in the introduction. To investigate the applicability of bifurcation theory to these problems, one might consider, for example,

$$\begin{aligned} &\text{minimize} && f_0(x, \alpha) \\ &\text{subject to} && F(x, \alpha) = 0, \qquad G(x, \alpha) \in K, \end{aligned}$$

where $f_0 \in C^2(U \times V; \mathbf{R})$, $F \in C^2(U \times V; Y)$, $G \in C^2(U \times V; Z)$, U and V are open subsets of the Banach space X and $\mathbf{R}^r$, respectively, Y and Z are Banach spaces, and $K \subset Z$ is a closed convex cone with a nonempty interior. Under appropriate conditions [34, Thm. 4.5], one has a Fritz John condition in which a constraint qualification is relaxed, and a system of equations somewhat similar to (2.4) can be derived. (The interiority assumption on K again places restrictions on the Banach space Z.) This problem will also be investigated in future work.

Appendix. Proof of Theorems 2.2 and 2.4. Central to the proofs of Theorems 2.2 and 2.4 are expressions for both $D_\chi G$ and $D_\chi G^*$ since we need to investigate solutions of $D_\chi G(\Delta\chi) = b$ and $D_\chi G^* \Delta\chi^* = b^*$, respectively. First, note that $D_\chi G : X \times Y^* \times \mathbf{R}^m \times \mathbf{R} \to X^* \times Y \times \mathbf{R}^m \times \mathbf{R}$ and that the problem $D_\chi G \Delta\chi = b$ can be written as

$$\begin{aligned} D_x^2 \mathcal{L} \Delta x + L^* \Delta y^* + (D_x f)^* \Delta\lambda + (D_x f_0)^* \Delta\lambda_0 &= b_1, \\ L \Delta x &= b_2, \\ \Lambda D_x f \Delta x + \operatorname{diag}(f) \Delta\lambda &= b_3, \\ 2\langle y_0, y^* \rangle \langle y_0, \Delta y^* \rangle + 2\langle \lambda, \Delta\lambda \rangle + 2\lambda_0 \Delta\lambda_0 &= b_4, \end{aligned} \tag{A.1}$$

where $(b_1, b_2, b_3, b_4) \in X^* \times Y \times \mathbf{R}^m \times \mathbf{R}$. The projections P_i and P_j^* defined in §2.1, the definitions $\Lambda_A = \operatorname{diag}(\lambda_1, \ldots, \lambda_l)$, $\Lambda_B = \operatorname{diag}(\lambda_{l+1}, \ldots, \lambda_k)$, $\Lambda_C = \operatorname{diag}(\lambda_{k+1}, \ldots, \lambda_m)$,

$\lambda_A = (\lambda_1, \ldots, \lambda_l)$, $\lambda_B = (\lambda_{l+1}, \ldots, \lambda_k)$, $\lambda_C = (\lambda_{k+1}, \ldots, \lambda_m)$, and similar definitions for f_A, f_B, and f_C allow one to rewrite the system (A.1) as

$$D_x^2\mathcal{L}_{11}\Delta x_1 + D_x^2\mathcal{L}_{12}\Delta x_2 + P_1^*L^*\Delta y^* + P_1^*(D_xf)^*\Delta\lambda + P_1^*(D_xf_0)^*\Delta\lambda_0 = P_1^*b_1, \tag{A.2}$$

$$D_x^2\mathcal{L}_{21}\Delta x_1 + D_x^2\mathcal{L}_{22}\Delta x_2 + P_2^*L^*\Delta y^* + P_2^*(D_xf)^*\Delta\lambda + P_2^*(D_xf_0)^*\Delta\lambda_0 = P_2^*b_1, \tag{A.3}$$

$$L\Delta x_1 + L\Delta x_2 = b_2, \tag{A.4}$$

$$\Lambda_A D_x f_A\Delta x_1 + \Lambda_A D_x f_A\Delta x_2 = b_{31}, \tag{A.5}$$

$$0\Delta\lambda_B = b_{32}, \tag{A.6}$$

$$\operatorname{diag} f_C\Delta\lambda_C = b_{33}, \tag{A.7}$$

$$2\langle y_0, y^*\rangle\langle y_0, \Delta y^*\rangle + 2\langle\lambda_A, \Delta\lambda_A\rangle + 2\lambda_0\Delta\lambda_0 = b_4. \tag{A.8}$$

An important observation about equation (A.3) is that, due to the definition of the projection P_2^* as projecting X^* onto the range of the transformation $\tilde{L}^* = (D_xF^*, D_xf_A^*)$, (A.3) is *always* solvable for $(\Delta y^*, \Delta\lambda_A^*)$.

The problem $D_\chi G^*\Delta\chi^* = b^*$ for the linear transformation $D_\chi G^* : X^{**} \times Y^* \times \mathbf{R}^{m*} \times \mathbf{R}^* \to X^* \times Y^{**} \times \mathbf{R}^{m*} \times \mathbf{R}^*$ can be written as

$$\begin{aligned} D_x^2\mathcal{L}^*\Delta x^{**} + L^*\Delta y^* + (D_xf)^*\Lambda^*\Delta\lambda^* &= b_1^*, \\ L^{**}\Delta x^{**} + 2\langle y_0, y^*\rangle J(y_0)\Delta\lambda_0^* &= b_2^*, \\ D_xf^{**}\Delta x^{**} + \operatorname{diag}(f)\Delta\lambda^* + 2\lambda\Delta\lambda_0^* &= b_3^*, \\ D_xf_0^{**}\Delta x^{**} + 2\lambda_0\Delta\lambda_0^* &= b_4^* \end{aligned} \tag{A.9}$$

and decomposed as

$$D_x^2\mathcal{L}_{11}^*\Delta x_1^{**} + D_x^2\mathcal{L}_{21}^*\Delta x_2^{**} + P_1^*L^*\Delta y^* + P_1^*D_xf_A^*\Lambda_A^*\Delta\lambda_A^* = P_1^*b_1^*, \tag{A.10}$$

$$D_x^2\mathcal{L}_{12}^*\Delta x_1^{**} + D_x^2\mathcal{L}_{22}^*\Delta x_2^{**} + P_2^*L^*\Delta y^* + P_2^*D_xf_A^*\Lambda_A^*\Delta\lambda_A^* = P_2^*b_1^*, \tag{A.11}$$

$$L^{**}P_1^{**}\Delta x_1^{**} + L^{**}P_2^{**}\Delta x_2^{**} + 2\langle y_0, y^*\rangle J(y_0)\Delta\lambda_0^* = b_2^*, \tag{A.12}$$

$$D_xf_A^{**}P_1^{**}\Delta x_1^{**} + D_xf_A^{**}P_2^{**}\Delta x_2^{**} + 2\lambda_A\Delta\lambda_0^* = b_{31}^*, \tag{A.13}$$

$$D_xf_B^{**}P_1^{**}\Delta x_1^{**} + D_xf_B^{**}P_2^{**}\Delta x_2^{**} = b_{32}^*, \tag{A.14}$$

$$D_xf_C^{**}P_1^{**}\Delta x_1^{**} + D_xf_C^{**}P_2^{**}\Delta x_2^{**} + \operatorname{diag}(f_C)\Delta\lambda_C^* = b_{33}^*, \tag{A.15}$$

$$(D_xf_0)^{**}P_1^{**}\Delta x_1^{**} + (D_xf_0)^{**}P_2^{**}\Delta x_2^{**} + 2\lambda_0\Delta\lambda_0^* = b_4^*, \tag{A.16}$$

where $J : Y \to Y^{**}$ is *the* isometric isomorphism of Y onto a closed subspace of Y^{**} defined by $\langle y, y^*\rangle = \langle y^*, J(y)\rangle$ for all $y \in Y$ and $y^* \in Y^*$ [50, p. 95]. As above, note that equation (A.11) is *always* solvable for $(\Delta y^*, \Delta\lambda_A^*)$.

Proof of Theorem 2.2. First assume that (a), (b), and (c) are valid. Assumption (a) implies $k = l$, so equation (A.6) is vacuous. Note that Λ_A and $\operatorname{diag} f_C$ are nonsingular and that $\tilde{L}$ being surjective implies $\tilde{L}^*$ is injective. The latter, along with the first equation in (2.4) and (2.5c), implies that $\lambda_0 \neq 0$ and $D_xf_0(x) \in \mathcal{R}(\tilde{L}^*)$. The proof that $D_\chi G$ is *bijective* is broken into two parts: $D_\chi G$ is injective and then $D_\chi G$ is surjective.

To show that $D_\chi G$ is *injective*, set $b = 0$. Equations (A.4) and (A.5) imply $\Delta x_2 = 0$. Equation (A.7) implies $\Delta\lambda_C = 0$. Equation (A.2) now reduces to $D_x^2\mathcal{L}_{11}\Delta x_1 = 0$, which forces $\Delta x_1 = 0$ by assumption (b). Equation (A.3) with $\Delta x_1 = 0$, $\Delta x_2 = 0$, and $\Delta\lambda_C = 0$

and $(\tilde{L}^*)$ being injective on $Y^* \times \mathbf{R}^l$ implies $\Delta y^* = \gamma y^*$, $\Delta\lambda = \gamma\lambda$, and $\Delta\lambda_0 = \gamma\lambda_0$ for some scalar γ. Equation (A.8) then requires $\gamma = 0$, so $\Delta\chi = 0$.

To show that $D_\chi G$ is *surjective*, let b be an arbitrary member of $X^* \times Y \times \mathbf{R}^m \times \mathbf{R}^1$. Assumption (a) ($k = l$) shows that (A.6) is vacuous. Equation (A.7) is uniquely solvable for $\Delta\lambda_C$. Equations (A.4) and (A.5) are uniquely solvable for Δx_2 since $\tilde{L}$ is surjective and Λ_A is nonsingular. Equation (A.2) is uniquely solvable for Δx_1 since $D_x^2\mathcal{L}_{11} : X_1 \to X_1^*$ is bijective. Since $\tilde{L}^* = (L^*, D_x f_A^*)$ is injective, P_2^* is a projection onto the range of $\tilde{L}^*$, and Δx_1, Δx_2, and Λ_C are now determined, (A.3) is solvable with a solution having the structure $\Delta y^* = \gamma y^* + y_p^*$, $\Delta\lambda_A = \gamma\lambda_A + \hat{\lambda}_{Ap}$, and $\Delta\lambda_0 = \gamma\lambda_0$, where y_p^* and $\hat{\lambda}_{1p}$ are particular solutions. Substitution into the last equation, (A.8), shows that it is now uniquely solvable for γ.

Assume now that $D_\chi G$ is bijective. The objective is to establish (a), (b), and (c). That $D_\chi G$ is surjective implies that (A.6) must be vacuous so that assumption (a) must hold. Condition (c), i.e., surjectivity of $\tilde{L}$, follows from (A.4) and (A.5) and the fact that Λ_A is nonsingular. In particular, $D_x f_0(x) \in \mathcal{R}(\tilde{L}^*)$ and $\lambda_0 \neq 0$ for the same reason as above. Finally, we must show that $D_x^2\mathcal{L}_{11}$ is bijective. Consider the system (A.2)–(A.8) with $b_2 = 0$, $b_{31} = 0$, $b_{32} = 0$, $b_{33} = 0$, and $b_4 = 0$ and with (a) and (c) being valid. Note that $\Delta x_2 = 0$ and $\Delta\lambda_C = 0$. Now (A.2) reduces to $D_x^2\mathcal{L}_{11}\Delta x_1 = P_1^* b_1$, which must be solvable for some Δx_1 since the entire system is uniquely solvable. Thus $D_x^2\mathcal{L}_{11}$ is surjective. We need to show that it is injective. Let Δx_1 be any solution to this equation. Now (A.3) reduces to $L^*\Delta y^* + D_x f_A^*\Delta\lambda_A + (D_x f_0)\Delta\lambda_0 = P_2^* b_1 - D_x^2\mathcal{L}_{21}\Delta x_1$. Thus given b_1 and Δx_1, this equation and (A.8) are uniquely solvable for Δy^*, $\Delta\lambda_A$, and $\Delta\lambda_0$. Hence, if there are two solutions of $D_x^2\mathcal{L}_{11}\Delta x_1 = P_1^* b_1$, there are two distinct solutions of the system (A.2)–(A.8), a contradiction. Thus $D_x^2\mathcal{L}_{11}$ is bijective and (b) must hold. □

Proof of Theorem 2.4. Assuming first that (a) and (b) are valid, we need to demonstrate that the dimension of the null spaces of $D_\chi G(\hat{\chi}, \hat{\alpha})$ and $D_\chi G(\hat{\chi}, \hat{\alpha})^*$ are finite and the range of $D_\chi G(\hat{\chi}, \hat{\alpha}))$ is closed. To determine $\mathcal{N}(D_\chi G(\hat{\chi}, \hat{\alpha}))$, consider equations (A.2)–(A.8) with $b_i = 0$ for $i = 1, \ldots, 4$. Equations (A.4)–(A.6) imply $\Delta x_2 = 0$ and $\Delta\lambda_C = 0$. Equation (A.6) leaves $\Delta\lambda_B$ as a vector of arbitrary constants. Equation (A.2) now reduces to $D_x^2\mathcal{L}_{11}\Delta x_1 = -P_1^*(D_x f_0)\Delta\lambda_0 - P_1^* \sum_{i=l+1}^{k}(D_x f_i)\Delta\lambda_i$. By the Fredholm alternative theorem, this equation has a solution if and only if $\langle P_1^*(D_x f_0)\Delta\lambda_0 + P_1^* \sum_{i=l+1}^{k}(D_x f_i)\Delta\lambda_i, x^{**}\rangle = 0$ for each $x^{**} \in \mathcal{N}(D_x^2\mathcal{L}_{11}^*)$, which is finite dimensional since $D_x^2\mathcal{L}_{11}$ is assumed to be Fredholm. These finite number of conditions are imposed on the quantities $\Delta\lambda_i$ for $i = 0$ and $l+1, \ldots, k$. Thus the solution Δx_1 is in the span of at most a finite number of elements from X. Next, to address (A.11), recall that $\dim\mathcal{N}(L^*) = \dim Y/\mathcal{R}(L)$ [50, p. 112], which is finite since $\mathcal{R}(L)$ has finite codimension. Thus the solution $(\Delta y^*, \Delta\lambda_A)$ to (A.3), which is always solvable, is the linear span of a finite number of elements from $(Y^*, \mathbf{R}^l)$. Finally, (A.8) places one more restriction on these finite number of elements from their respective spaces. This shows that the dimension of the null space of $D_\chi G(\hat{\chi}, \hat{\alpha})$ is finite.

Continuing to assume (a) and (b), we turn to the linear transformation $D_\chi G^* : X^{**} \times Y^* \times \mathbf{R}^m \times \mathbf{R} \to X^* \times Y^{**} \times \mathbf{R}^m \times \mathbf{R}$ and show that it has a finite-dimensional null space. First (a) implies that $D_x^2\mathcal{L}_{11}^*$ is Fredholm; that $\mathcal{R}(L)$ is closed and has finite codimension implies [50, p. 112] that $\mathcal{R}(L^{**})$ is closed and has the same finite codimension in Y^{**}. Furthermore, by our earlier remarks $X^{**} = X_1^{**} \oplus X_2^{**}$, where $X_1^{**} = \mathcal{N}(\tilde{L}^{**})$. Before proceeding, we need to compute $D_x\mathcal{L}$ and its adjoint. Given $\mathcal{L} = \mathcal{L}(x, y^*, \lambda, \lambda_0; \alpha)$ from (2.3), the linear functional $D_x\mathcal{L} : X \to \mathbf{R}$ is bounded so that $D_x\mathcal{L} \in X^*$. Now

$$\begin{aligned} D_x\mathcal{L}\bar{x} &= \langle D_x f_0(x, \alpha)\bar{x}, \lambda_0\rangle + \langle D_x f(x, \alpha)\bar{x}, \lambda\rangle + \langle D_x F(x, \alpha)\bar{x}, y^*\rangle \\ &= \langle \bar{x}, D_x f_0(x, \alpha)^*\lambda_0\rangle + \langle \bar{x}, D_x F(x, \alpha)^* y^*\rangle + \langle \bar{x}, D_x f(x, \alpha)^*\lambda\rangle. \end{aligned}$$

Thus $\langle D_x\mathcal{L}\bar{x}, \gamma\rangle = \langle \bar{x}, D_x\mathcal{L}^*\gamma\rangle$, where $D_x\mathcal{L}^* : \mathbf{R}^* \to X^*$ and

$$D_x\mathcal{L}^* = D_x f_0(x,\alpha)^*\lambda_0 + D_x F(x,\alpha)^* y^* + D_x f(x,\alpha)^*\lambda.$$

Next, we can compute $D_x\mathcal{L}^{**}$ from the requirement $\langle D_x\mathcal{L}^*\gamma, \bar{x}^{**}\rangle = \langle \gamma, D_x\mathcal{L}^{**}\bar{x}^{**}\rangle$ for all $\bar{x}^{**} \in X^{**}$ and $\gamma \in \mathbf{R}^* = \mathbf{R}$. The result is

$$D_x\mathcal{L}^{**}\bar{x}^{**} = \langle \lambda_0, D_x f_0(x,\alpha)^{**}\bar{x}^{**}\rangle + \langle y^*, D_x F(x,\alpha)^{**}\bar{x}^{**}\rangle + \langle \lambda, D_x f(x,\alpha)^{**}\bar{x}^{**}\rangle.$$

Since $D_x\mathcal{L}(\chi,\alpha) = 0$ at $(\chi,\alpha) = (\hat{\chi},\hat{\alpha})$, the same is true of $D_x\mathcal{L}^*(\hat{\chi},\hat{\alpha})$ and $D_x\mathcal{L}^{**}(\hat{\chi},\hat{\alpha})$. Thus, in view of the above, an appropriate combination of (A.12), (A.13), and (A.16) yields $D_x\mathcal{L}^{**}\Delta x^{**} + (|\langle y_0, y^*\rangle|^2 + \langle\lambda_A, \lambda_A\rangle + \lambda_0^2)\Delta\lambda_0^* = 0$; however, $D_x\mathcal{L}^{**}\Delta x^{**} = 0$ and the coefficient of $\Delta\lambda_0^*$ is one, so $\Delta\lambda_0^* = 0$ and thus $\Delta x_2^{**} = 0$. Then (A.10) reduces to $D_x^2\mathcal{L}^*\Delta x_1^{**} = 0$ so that Δx_1^{**} is a linear combination of a finite number of specific elements in X^{**}. Equations (A.14) ($D_x f_B^{**}\Delta x_1^{**} = 0$) and (A.16) ($D_x f_0^{**}\Delta x_1^{**} = 0$) can only further restrict this finite number. Equation (A.15) is solvable for $\Delta\lambda_C^*$ given this Δx_1^{**}. Finally, we come to (A.11), which is always solvable for $(\Delta y^*, \Delta\lambda_A)$. Since the dimension of $\mathcal{N}(L^*)$ is finite, the entire system (A.10)–(A.16) is now solvable for $(\Delta x^{**}, \Delta y^*, \Delta\lambda, \Delta\lambda_0)$ in terms of linear combination of a finite number of elements in $X^{**} \times Y^* \times \mathbf{R}^m \times \mathbf{R}^*$, so the null space of $D_\chi G^*$ is finite dimensional.

It remains to show that $D_\chi G$ has closed range. For this, we make repeated use of the closed-range theorem [50] and the lemma on the closed image [1, p. 80]. Consider first (A.4) and (A.5)–(A.7), i.e., $L\Delta x = b_2$ and $\Lambda D_x f\Delta x + \operatorname{diag}(f)\Delta\lambda = b_3$. Now L as a mapping from $\mathcal{X} = X \times Y^* \times \mathbf{R}^m \times \mathbf{R}$ to Y has closed range since L does as a mapping from X to Y. Then the range of $\Lambda D_x f\Delta x + \operatorname{diag}(f)\Delta\lambda$, where Δx is restricted to $\mathcal{N}(L)$, is a subspace of a finite-dimensional space. Hence the range of the linear transformation defined by (A.5)–(A.7) is a closed subspace of $Y \times \mathbf{R}^m$. Next, as another application of the lemma on the closed image [1, p. 80] consider (A.2) restricted to the kernel of the linear transformation defined by (A.4)–(A.7). This equation reduces to $D_x^2\mathcal{L}_{11}\Delta x_1 + P_1^*(D_x f_B)^*\Delta\lambda_B + P_1^*(D_x f_0)^*\Delta\lambda_0 = 0$. Now by assumption (a), the range of $D_x^2\mathcal{L}_{11}$ is closed and the range of $P_1^*(D_x f_B)^*$ and $P_1^*(D_x f_0)^*$ are finite dimensional. Thus, the range of the algebraic sum is closed [50, p. 32]. Next we turn to (A.3) and apply the same lemma to this equation restricted to the null space of the linear transformation defined by equations (A.2) and (A.4)–(A.7). Now the range of $\tilde{L}$ is all of $P_2^*X^*$, so we have that the range of (A.2)–(A.7) is closed in $X^* \times Y \times \mathbf{R}^m$. Finally, the range of (A.8) restricted to the kernel of (A.2)–(A.7) is either $\mathbf{R}$ or $\{0\}$, both of which are closed. Thus, $D_\chi G$ has closed range. This completes the first half of the theorem.

Next, assume $D_\chi G(\hat{\chi},\hat{\alpha})$ is a Fredholm operator and $D_x^2\mathcal{L}_{11}$ and $D_x F(\hat{x},\hat{\alpha})$ have closed ranges. The objective is to show that (a) and (b) are valid. Thus we start with $\dim\mathcal{N}(D_\chi G(\hat{\chi},\hat{\alpha})) < \infty$ and examine equations (A.2)–(A.8). Equations (A.4) and (A.5) imply $\Delta x_2 = 0$, and equation (A.6) leaves $\Delta\lambda_i$ for $i = l+1, \ldots, k$ as arbitrary constants. Equation (A.6) implies $\Delta\lambda_i = 0$ for $i = k+1, \ldots, m$. Equation (A.2) now takes the form $D_x^2\mathcal{L}_{11}\Delta x_1 = -P_1^*(D_x f_0)\Delta\lambda_0 - P_1^*\sum_{i=l+1}^{k}(D_x f_i)\Delta\lambda_i$, whose solution Δx_1 must belong to a finite-dimensional space. Thus, the dimension of the null space of $D_x^2\mathcal{L}_{11}$ can be at most finite dimensional. Also, (A.3) implies that the dimension of the null space of L^* is at most finite since Δy^* is further constrained only by (A.8). Since $\mathcal{N}(L^*) = \mathcal{R}(L)^\perp$, $Y/\mathcal{R}(L)$ has same finite dimension as $\mathcal{N}(L^*)$, i.e., $\mathcal{R}(L)$ has finite codimension.

Finally, to show the range of $D_x^2\mathcal{L}_{11}$ has finite codimension, we show that $D_x^2\mathcal{L}_{11}^*$ has a finite-dimensional null space by considering the null space of $D_\chi G(\hat{\chi},\hat{\alpha})^*$, which must be finite dimensional since it is Fredholm. Once again considering equations (A.10)–(A.16) with $b^* = 0$, the same argument as above shows that $\Delta\lambda_0^* = 0$ and $\Delta x_2^{**} = 0$. Regardless of Δx_1^{**}, (A.11) is always solvable for $(\Delta y^*, \Delta\lambda_A)$, and (A.15) for $\Delta\lambda_C$. Now Δx_1^{**} by

its definition already satisfies (A.12) and (A.13). Thus we are left with (A.10), (A.14), and (A.16), which reduce to $D_x^2\mathcal{L}_{11}^*\Delta x_1^{**} = 0$, $D_x f_B^{**}\Delta x_1^{**} = 0$, and $D_x f_0^{**}\Delta x_1^{**} = 0$. Since the ranges of $D_x f_B^{**}$ and $D_x f_0^{**}$ are finite dimensional, so is the codimension of the null spaces. Thus $\mathcal{N}(D_x^2\mathcal{L}_{11}^*) \cap \mathcal{N}(D_x f_B^{**}) \cap \mathcal{N}(D_x f_0^{**})$ is finite dimensional if and only if $\mathcal{N}(D_x^2\mathcal{L}_{11}^*)$ is finite dimensional. □

STABILITY RADII OF SYSTEMS WITH STOCHASTIC UNCERTAINTY AND THEIR OPTIMIZATION BY OUTPUT FEEDBACK*

D. HINRICHSEN† AND A. J. PRITCHARD‡

Abstract. We consider linear plants controlled by dynamic output feedback which are subjected to blockdiagonal stochastic parameter perturbations. The stability radii of these systems are characterized, and it is shown that, for real data, the real and the complex stability radii coincide. A corresponding result does not hold in the deterministic case, even for perturbations of single-output feedback type. In a second part of the paper we study the problem of optimizing the stability radius by dynamic linear output feedback. Necessary and sufficient conditions are derived for the existence of a compensator which achieves a suboptimal stability radius. These conditions consist of a parametrized Riccati equation, a parametrized Liapunov inequality, a coupling inequality, and a number of linear matrix inequalities (one for each disturbance term). The corresponding problem in the deterministic case, the optimal μ-synthesis problem, is still unsolved.

Key words. stability radius, stochastic systems, multiperturbations, state-dependent noise, dynamic output feedback, Riccati inequalities, linear matrix inequalities, scaling

1. Introduction.

One of the main purposes of feedback control is to ensure satisfactory behaviour of a dynamical system in the presence of unforeseen disturbances. This classical problem, which was central to the work of Bode and Nyquist, has seen a vigorous renaissance over the past decade, and recent developments in control theory have been strongly influenced by it. The focus has been on deterministic disturbances: *either* unstructured (additive or multiplicative) perturbations of the plant's transfer function *or* structured perturbations of the parameters of a given nominal state-space model. As examples, we mention two approaches, H^∞ and stability radii. H^∞ theory (see [6], [20]) deals with the problem of minimizing (by feedback compensation) the effect of deterministic disturbances on the variables to be controlled. The results can be applied to maximize robustness of stability with respect to unstructured perturbations of the transfer matrix. On the other hand, the theory of stability radii determines precise robustness measures for stable linear state-space systems subject to different classes of structured parameter perturbations [14]. Surprisingly there is a close relationship between the two theories for the special case where stability radii with respect to *complex* perturbations of single-output feedback type are considered. In fact, in this case the problem of optimizing the stability radius by feedback control is equivalent to a singular H^∞ control problem [13].

In this paper we use the framework of stability radii to study robust stability and robust stabilization problems for systems with *stochastic* uncertainty. Because of the close relationship between the theories of stability radii and H^∞ control, our results can be regarded as an extension of H^∞ control theory to systems with stochastic uncertainty.

We consider the system

$$(1) \qquad dx(t) = Ax(t)\,dt + \sum_{i=1}^{N} D_i \Delta_i(E_i x(t))dw_i(t) + Bu(t)\,dt, \qquad y(t) = Cx(t),$$

where the matrices A, B, C, D_i, and E_i are given and the processes w_i are independent scalar Wiener processes, $i = 1, \ldots, N$. We view the above equations as describing a linear deterministic differentiable system (A, B, C) perturbed by stochastic multiperturbations

*Received by the editors November 11, 1994; accepted for publication (in revised form) August 8, 1995.

$\sum_{i=1}^{N} D_i \Delta_i(E_i x(t))dw_i(t)$. The family $(D_i, E_i)_{i\in\underline{N}}$ of matrix pairs describes the structure of these perturbations, while Δ_i, $i = 1, \ldots, N$, are unknown Lipschitzian nonlinearities. We assume that *all the Wiener processes w_i have zero mean.* In other words, the nominal model (A, B, C) is assumed to be *exact in the mean.* If the system matrix A is also subject to *deterministic* parameter perturbations, the problems of robust stability and robust stabilization are more involved, and so far only estimates are available for the corresponding stability radii; see [15].

Many authors have studied stability and stabilization problems for systems with state-dependent noise; see, for example, [17]. The quadratic optimal control problem was solved in [19], and a collection of papers concerning Liapunov exponents for such systems can be found in [1]. However, there are few papers dealing with robustness issues for this class of systems. An important reference is [18], which, in our terminology, derives necessary and sufficient conditions under which infinite or arbitrarily large stability radii can be achieved by state feedback. Some results on stochastic stability radii defined via Liapunov exponents can be found in [4, §7]. A characterization of the stability radius in the special case where all the E_i are equal was given in [7]. (The mathematical development is essentially the same as in the single-perturbation case $N = 1$.)

Here we study the robust stability and robust stabilization problems under multiperturbations. For deterministic systems the development of such stability radii requires the use of μ-analysis [14], and it is well known that in the presence of more than three perturbation terms ($N > 3$) scaling techniques yield only lower estimates for the complex stability radius. In contrast, we will derive a precise characterization via scaling techniques in this stochastic case. This is based on the analysis of an associated minimax problem for quadratic forms. Moreover we will show that the *real* and the *complex* stability radii coincide for stochastic multiperturbations of the above kind.

The second main contribution of this paper concerns the problem of optimizing the stability radius of systems of the form (1) by dynamic output feedback. We characterize the supremal stability radius by combining a Riccati inequality with a Liapunov inequality, a coupling condition, and a number of additional linear matrix inequalities. Moreover we give explicit formulae for suboptimal controllers. These results are obtained by using an inequality approach to deterministic H^∞ control theory developed by Gahinet and his co-workers; see [10], [11]. Whereas in the deterministic case the suboptimal controllers can be characterized by a pair of Riccati equations and a coupling condition, it is not possible in the stochastic case to replace both the Riccati and the Liapunov inequalities by equalities. This will be illustrated by an example.

We proceed as follows. In the next section we give some results on a minimax problem for quadratic forms. (The proofs are in an appendix.) These results will be instrumental for our characterization of the stability radius relative to stochastic multiperturbations in §3. In §4 the problem of optimizing the stability radius by (linear) feedback is studied, and it is shown that the supremal stability radius can be determined via matrix inequalities. Finally, in §5 we show that in this characterization the Riccati inequality may be replaced by a Riccati equation, whereas the Liapunov inequality *cannot* be transformed into an equality. Moreover the corresponding results for state feedback are derived as corollaries of the previous results on dynamic output feedback.

2. A minimax problem for quadratic forms. Throughout the paper we use the following notation. $\mathbb{K}$ is either the field $\mathbb{R}$ of real numbers or the field $\mathbb{C}$ of complex numbers. For any integer $\ell \geq 1$, $\mathcal{H}_\ell(\mathbb{K})$ is the real vector space of Hermitian matrices in $\mathbb{K}^{\ell\times\ell}$ and $\mathcal{H}_\ell^+(\mathbb{K}) = \{H \in \mathcal{H}_\ell(\mathbb{K});\ H \succeq 0\}$ is the convex cone of positive semidefinite matrices in $\mathcal{H}_\ell(\mathbb{K})$. By $\langle\cdot,\cdot\rangle$ we denote the usual inner product on $\mathbb{K}^\ell$, $\ell \in \mathbb{N}$, and by $\|H\|$, the associated

operator norm or spectral norm of $H \in \mathcal{H}_\ell(\mathbb{K})$:

$$\|H\| = \max_{v \in \mathbb{K}^\ell, \|v\|=1} \langle v, Hv \rangle, \qquad \|v\| = \langle v, v \rangle^{1/2}.$$

We suppose that $N \in \mathbb{N}$ is given and

$$H_{ij} \in \mathcal{H}^+_{\ell_j}(\mathbb{K}), \qquad i, j \in \underline{N} := \{1, \ldots, N\}, \tag{2}$$

is a given family of nonnegative $\ell_j \times \ell_j$ Hermitian matrices. For any set C, we denote by $(0, \infty)^C$ the set of all mappings from C to $(0, \infty)$, the set of all positive real numbers. If C is finite, the elements of $(0, \infty)^C$ are represented by finite families $\alpha = (\alpha_c)_{c \in C}$. In particular the set $(0, \infty)^{\underline{N}}$ consists of all N-tuples $\alpha = (\alpha_1, \ldots, \alpha_N)$, with $\alpha_i > 0$ for all $i \in \underline{N}$. In our later analysis the H_{ij} will be given by

$$H_{ij} = \lambda_j \int_0^\infty D_j^* e^{A^* \tau} E_i^* E_i e^{A\tau} D_j d\tau \succeq 0, \qquad i, j \in \underline{N},$$

and the α_i's are free scaling parameters which are used to improve a lower bound for the stability radius. In fact we will see that the scaling technique applied to multiperturbations leads to the following optimization problem:

$$\text{minimize} \quad \max_{j \in \underline{N}} \left\| \sum_{i=1}^N \left(\frac{\alpha_i}{\alpha_j} \right)^2 H_{ij} \right\| \quad \text{with respect to} \quad \alpha = (\alpha_1, \ldots, \alpha_N) \in (0, \infty)^{\underline{N}}. \tag{3}$$

Let

$$f(\alpha) = \max_{j \in \underline{N}} f_j(\alpha), \quad f_j(\alpha) = \left\| \sum_{i=1}^N \left(\frac{\alpha_i}{\alpha_j} \right)^2 H_{ij} \right\|, \quad \alpha \in (0, \infty)^{\underline{N}}. \tag{4}$$

Then the optimization problem (3) is equivalent to minimizing the function $f(\cdot)$ on the positive orthant $(0, \infty)^{\underline{N}}$. The optimal value of (3) is denoted by

$$\hat{\mu} = \inf_{\alpha \in (0,\infty)^{\underline{N}}} f(\alpha). \tag{5}$$

In this section, in order to maintain the flow of the paper, we give only the pertinent results. The proofs are relegated to the appendix. Nevertheless we would like to stress that these proofs are an important part of the overall proof of our main results in §§3–5.

The solution of (3) depends strongly on the zero block pattern of the compound matrix $H = (H_{ij})_{i,j=1}^N$. To capture this pattern we denote by $\mathcal{G}$ the directed graph [3] with *node set* $\underline{N} = \{1, \ldots, N\}$ and *set of directed arcs*

$$\mathcal{A} = \{(i, j) \in \underline{N}^2; H_{ij} \neq 0\}.$$

$\mathcal{G}$ is said to be *strongly connected* if every node of $\mathcal{G}$ is connected to every distinct node of $\mathcal{G}$ by a directed path in $\mathcal{G}$.

THEOREM 2.1. *Suppose that $\mathcal{G}$ is strongly connected. Then there exists a subset $J \subset \underline{N}$ and a vector $\hat{\alpha} \in (0, \infty)^{\underline{N}}$ satisfying $f(\hat{\alpha}) = \hat{\mu}$, and*

$$\left\| \sum_{i=1}^N \left(\frac{\hat{\alpha}_i}{\hat{\alpha}_j} \right)^2 H_{ij} \right\| = \left\| \sum_{i \in J} \left(\frac{\hat{\alpha}_i}{\hat{\alpha}_j} \right)^2 H_{ij} \right\| = \hat{\mu} \quad \text{if } j \in J,$$

$$\left\| \sum_{i=1}^N \left(\frac{\hat{\alpha}_i}{\hat{\alpha}_j} \right)^2 H_{ij} \right\| < \hat{\mu} \quad \text{if } j \in \underline{N} \backslash J. \tag{6}$$

The theorem shows that in the strongly connected case the optimal value of the minimization problem (3) is equal to the optimal value of the subproblem

$$\text{(7)} \qquad \text{minimize} \quad \max_{j\in J} \left\| \sum_{i\in J} \left(\frac{\alpha_i}{\alpha_j}\right)^2 H_{ij} \right\| \quad \text{subject to } \alpha \in (0,\infty)^J,$$

for which only the data H_{ij}, $i, j \in J$, play a role. According to (6) the reduced scaling vector $\hat{\alpha}_J = (\hat{\alpha}_i)_{i\in J}$ is a minimizer for (7), and each of the norms $\| \sum_{i\in J} (\frac{\hat{\alpha}_i}{\hat{\alpha}_j})^2 H_{ij} \|$, $j \in J$, is equal to $\hat{\mu}$. A natural question is, under which conditions is the subset $J = \underline{N}$? The following proposition gives a sufficient condition.

PROPOSITION 2.2. *Suppose that $\mathcal{G}$ is strongly connected and for every nonempty subset $J \subset \underline{N}$, $J \neq \underline{N}$ there exists $j \in \underline{N}\backslash J$ such that*

$$\text{(8)} \qquad \bigcap_{i\in \underline{N}\backslash J} \ker H_{ij} \cap \left(\bigcap_{i\in J} \ker H_{ij} \right)^{\perp} = \{0\}.$$

Then

$$\text{(9)} \qquad f_1(\hat{\alpha}) = \cdots = f_N(\hat{\alpha}) = \hat{\mu}$$

for all $\hat{\alpha} \in (0,\infty)^{\underline{N}}$ satisfying $f(\hat{\alpha}) = \hat{\mu}$.

Remark 2.3. Suppose that each Hermitian matrix H_{ij}, $i, j \in \underline{N}$, is either invertible or zero. Then assumption (8) is satisfied if $\mathcal{G}$ is strongly connected. In particular, (9) always holds in the scalar case ($\ell_j = 1$, $j \in \underline{N}$) if $\mathcal{G}$ is strongly connected. □

If $\mathcal{G}$ is not strongly connected, there will not, in general, exist a minimum of f. To deal with this case we introduce the following notation. Let C_k, $k = 1, \ldots, K$, be the node sets of the strongly connected components [3] of $\mathcal{G}$ ordered in such a way that for $1 \le h < k \le K$ there is no directed arc $(i, j) \in \mathcal{A}$ such that $i \in C_k$, $j \in C_h$. Then, for all $h, k \in \underline{K}$,

$$\text{(10)} \qquad h < k \implies (i \in C_k \text{ and } j \in C_h \Rightarrow H_{ij} = 0).$$

Since $\underline{N} = \cup_{k\in\underline{K}} C_k$, it follows from (10) that

$$\text{(11)} \qquad f(\alpha) = \max_{h\in\underline{K}} \max_{j\in C_h} \left\| \sum_{i=1}^{N} \left(\frac{\alpha_i}{\alpha_j}\right)^2 H_{ij} \right\| = \max_{h\in\underline{K}} \max_{j\in C_h} \left\| \sum_{k=1}^{K} \sum_{i\in C_k} \left(\frac{\alpha_i}{\alpha_j}\right)^2 H_{ij} \right\|, \qquad \alpha \in (0,\infty)^{\underline{N}}.$$

The next theorem shows that problem (3) can be solved by restricting our considerations to the strongly connected components of $\mathcal{G}$.

THEOREM 2.4. *Let*

$$\text{(12)} \qquad \mu_k = \min_{\alpha\in(0,\infty)^{C_k}} \max_{j\in C_k} \left\| \sum_{i\in C_k} \left(\frac{\alpha_i}{\alpha_j}\right)^2 H_{ij} \right\|, \qquad k \in \underline{K}.$$

Then

$$\hat{\mu} = \max_{k\in\underline{K}} \mu_k.$$

Moreover, if $\hat{k}$ satisfies $\mu_{\hat{k}} = \max_{k \in \underline{K}} \mu_k$ there exist a subset $J \subset C_{\hat{k}}$ and, for every $\delta > 0$, a vector $\alpha \in (0, \infty)^{\underline{N}}$ such that

$$\left\| \sum_{i=1}^{N} \left(\frac{\alpha_i}{\alpha_j} \right)^2 H_{ij} \right\| \leq \hat{\mu} + \delta, \qquad j \in \underline{N},$$

(13)

$$\left\| \sum_{i \in C_{\hat{k}}} \left(\frac{\alpha_i}{\alpha_j} \right)^2 H_{ij} \right\| = \left\| \sum_{i \in J} \left(\frac{\alpha_i}{\alpha_j} \right)^2 H_{ij} \right\| = \hat{\mu}, \qquad j \in J.$$

We see that the solution of problem (3) can always be reduced to the solution of a subproblem corresponding to a strongly connected component of $\mathcal{G}$.

3. Characterization of stability radii. Suppose that $A \in \mathbb{K}^{n \times n}$ is a given matrix with spectrum $\sigma(A)$ in the open left half-plane $\mathbb{C}_- = \{s \in \mathbb{C};\ \mathrm{Re}\, s < 0\}$. Let $N \in \mathbb{N}$, and let $((D_i, E_i))_{i \in \underline{N}}$ be a given family of matrices $D_i \in \mathbb{K}^{n \times \ell_i}$, $E_i \in \mathbb{K}^{q_i \times n}$, $i = 1, \ldots, N$. We will consider uncertain systems described by Ito stochastic differential equations of the form

$$dx(t) = Ax(t)\,dt + \sum_{i=1}^{N} D_i \Delta_i(E_i x(t)) dw_i(t), \tag{14}$$

where $\Delta_1, \ldots, \Delta_N$ are unknown Lipschitzian nonlinearities satisfying

$$\|\Delta_i\|_L < \sigma, \qquad i = 1, \ldots, N. \tag{15}$$

$(w_i(t))_{t \in \mathbb{R}_+}, i = 1, \ldots, N$, are independent zero-mean Wiener processes on a probability space $(\Omega, \mathcal{F}, \mu)$ relative to an increasing family $(\mathcal{F}_t)_{t \in \mathbb{R}_+}$ of σ-algebras $\mathcal{F}_t \subset \mathcal{F}$. Thus, if λ_i denotes the variance of $(w_i(t))_{t \in \mathbb{R}_+}$, we have

$$\mathcal{E}(w_i(t)) = 0, \quad \mathcal{E}((w_i(t) - w_i(s))(w_j(t) - w_j(s))) = \delta_{ij} \lambda_i (t - s), \quad t, s \in \mathbb{R}_+, t > s, i, j \in \underline{N},$$

where δ_{ij} is the Kronecker symbol. For each $i = 1, \ldots, N$, the Euclidean norm is taken on $\mathbb{K}^{q_i}, \mathbb{K}^{\ell_i}$. The disturbances Δ_i vary in

$$\mathrm{Lip}\,(\mathbb{K}^{q_i}, \mathbb{K}^{l_i}) = \{\Delta : \mathbb{K}^{q_i} \longmapsto \mathbb{K}^{\ell_i};\ \Delta(0) = 0 \text{ and } \Delta \text{ is Lipschitzian}\},$$

and the size of each $\Delta_i \in \mathrm{Lip}\,(\mathbb{K}^{q_i}, \mathbb{K}^{l_i})$ is measured by the *Lipschitz norm*

$$\|\Delta_i\|_L = \inf\{\gamma_i > 0;\ \forall y, \hat{y} \in \mathbb{K}^{q_i} : \|\Delta_i(y) - \Delta_i(\hat{y})\|_{\mathbb{K}^{\ell_i}} \leq \gamma_i \|y - \hat{y}\|_{\mathbb{K}^{q_i}}\}.$$

The unknown Δ_i represent uncertainty in the state-dependent gains through which the stationary white noise processes $dw_i(t)$ affect the evolution of the system. The matrix family $((D_i, E_i))_{i \in \underline{N}}$ determines the structure of the perturbations, and $\sigma > 0$ indicates the overall level of the stochastic disturbances. Altogether (14) with constraints (15) describes a *set* of stochastic systems parametrized by $\Delta_i \in \mathrm{Lip}\,(\mathbb{K}^{q_i}, \mathbb{K}^{l_i})$, $\|\Delta_i\|_L < \sigma$ for $i \in \underline{N}$.

Let $L^2(\Omega, \mathbb{K}^m)$ denote the space of square-integrable $\mathbb{K}^m$-valued functions (modulo equivalence) on the probability space $(\Omega, \mathcal{F}, \mu)$. We denote by $L^2_w(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^m))$ the space of nonanticipative stochastic processes $z(\cdot) = (z(t))_{t \in \mathbb{R}_+}$ with respect to $(\mathcal{F}_t)_{t \in \mathbb{R}_+}$ (see, e.g., [9]) satisfying

$$\|z(\cdot)\|^2_{L^2_w} = \mathcal{E}\left(\int_0^\infty \|z(t)\|^2\,dt \right) = \int_0^\infty \mathcal{E}(\|z(t)\|^2)\,dt < \infty, \tag{16}$$

where $\mathcal{E}$ denotes the expectation. For arbitrary $\Delta_i \in \text{Lip}(\mathbb{K}^{q_i}, \mathbb{K}^{l_i})$, $i \in \underline{N}$, and any initial state $x^0 \in \mathbb{K}^n$ there exists a unique solution $x(\cdot) = (x(t))_{t\in\mathbb{R}_+}$ of (14) on $\mathbb{R}_+ = [0, \infty)$ such that $x(0) = x^0$ (see, e.g., [9]). $x(\cdot)$ is a continuous nonanticipative stochastic process with L^2 second moments on every finite interval $[0, T]$:

$$\int_0^T \mathcal{E}(\|x(t)\|^2)\, dt < \infty, \qquad T \geq 0.$$

Many concepts of stability have been studied for stochastic systems. In this paper we consider L^2-stability.

DEFINITION 3.1. *The system* (14) *is said to be* L^2*-stable if, for every* $x^0 \in \mathbb{K}^n$*, the unique solution* $x(\cdot)$ *of* (14) *on* $\mathbb{R}_+ = [0, \infty)$ *with initial value* $x(0) = x^0$ *satisfies*

$$\int_0^\infty \mathcal{E}(\|x(t)\|^2)\, dt < \infty.$$

Our aim is to determine which bounds σ on the perturbations Δ_i ensure that the stability of the deterministic system $\dot{x}(t) = Ax(t)$ is preserved under additive stochastic perturbations of the form $\sum_{i=1}^N D_i \Delta_i(E_i x(t))dw_i(t)$. Let Δ denote the combined perturbation operator

$$\Delta = \bigoplus_1^N \Delta_i \in \text{Lip}(\mathbb{K}^q, \mathbb{K}^\ell), \qquad q = q_1 + \cdots + q_N, \ell = \ell_1 + \cdots + \ell_N. \tag{17}$$

The Lipschitz norm of Δ is given by

$$\|\Delta\|_L = \max_{i\in\underline{N}} \|\Delta_i\|_L.$$

Note that because $\Delta_i(0) = 0$, we have

$$\|\Delta(y)\|^2_{\mathbb{K}^\ell} = \sum_1^N \|\Delta_i(y_i)\|^2_{\mathbb{K}^{\ell_i}} \leq \sum_1^N \|\Delta_i\|_L^2 \|y_i\|^2_{\mathbb{K}^{q_i}} \leq \|\Delta\|_L^2 \|y\|^2_{\mathbb{K}^q}, \qquad y = (y_i)_{i\in\underline{N}} \in \mathbb{K}^q. \tag{18}$$

The maximum $\sigma > 0$ for which all the systems in (14) are L^2-stable is called the stability radius of (14).

DEFINITION 3.2. *The* stochastic stability radius *of* $A \in \mathbb{K}^{n\times n}$ *with respect to the perturbation structure* $((D_i, E_i))_{i\in\underline{N}}$ *and the Wiener processes* $(w_i)_{i\in\underline{N}}$ *is*

$$r^w_{\mathbb{K}}(A; (D_i, E_i)_{i\in\underline{N}}) = \inf\left\{ \left\| \bigoplus_1^N \Delta_i \right\|_L ; \Delta_i \in \text{Lip}(\mathbb{K}^{q_i}, \mathbb{K}^{\ell_i}) \text{ such that (14) is not } L^2\text{-stable} \right\}. \tag{19}$$

Remark 3.3. (i) We have chosen $x^0 \in \mathbb{K}^n$ since we regard (14) as a stochastic perturbation of a deterministic system. However, it is straightforward to extend the theory to any $\mathcal{F}_0$-measurable initial state $x^0 \in L^2(\Omega, \mathbb{K}^n)$.

(ii) A stability radius with respect to *linear* perturbations can be defined analogously by restricting the perturbations Δ_i in (19) to be linear, i.e., $\Delta_i \in \mathcal{L}(\mathbb{K}^{q_i}, \mathbb{K}^{\ell_i})$. It is an open question whether this restriction leads to a different stability radius.

(iii) If the data A, D_i, E_i are real, two stability radii are obtained according to whether one chooses $\mathbb{K} = \mathbb{C}$ (complex perturbations) or $\mathbb{K} = \mathbb{R}$ (only real perturbations) in (19). In a deterministic framework the real and the complex stability radii are, in general, distinct; see [14]. We will show later that they are equal in the present stochastic framework. □

In order to characterize the stochastic stability radius we need the following lemmas.

LEMMA 3.4. *Suppose that* $E \in \mathbb{K}^{q\times n}$ *and*

$$y(t) = Ee^{At}x^0 + \sum_{i=1}^{N} \int_0^t Ee^{A(t-s)} D_i v_i(s) dw_i(s),$$

where $v_i \in L_w^2(\mathbb{R}_+; L_2(\Omega, \mathbb{K}^{\ell_i}))$, $i \in \underline{N}$, *and* $x^0 \in \mathbb{K}^n$. *Then*

$$\mathcal{E}(\|y(t)\|^2) = \|Ee^{At}x^0\|^2 + \sum_{i=1}^{N} \lambda_i \int_0^t \mathcal{E}(\|Ee^{A(t-s)} D_i v_i(s)\|^2)\, ds, \qquad t \in \mathbb{R}_+. \tag{20}$$

Moreover, $y(\cdot) \in L_w^2(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^q))$ *and*

$$\begin{aligned} \|y(\cdot)\|_{L_w^2}^2 &= \int_0^\infty \mathcal{E}(\|y(t)\|^2)\, dt \\ &= \int_0^\infty \|Ee^{At}x^0\|^2\, dt + \sum_{i=1}^{N} \lambda_i \int_0^\infty \mathcal{E}(\langle D_i v_i(s), P D_i v_i(s)\rangle)\, ds, \end{aligned} \tag{21}$$

where

$$PA + A^*P + E^*E = 0. \tag{22}$$

Proof. The first part is a standard result for stochastic integrals [9]. Now since $\sigma(A) \subset \mathbb{C}_-$, the following integrals are well defined, and we have

$$\int_0^\infty \mathcal{E}(\|y(t)\|^2)\, dt = \int_0^\infty \|Ee^{At}x^0\|^2\, dt + \sum_{i=1}^{N} \lambda_i \int_0^\infty \int_0^t \mathcal{E}(\|Ee^{A(t-s)} D_i v_i(s)\|^2)\, ds dt.$$

By Fubini's theorem

$$\begin{aligned} &\int_0^\infty \int_0^t \mathcal{E}(\|Ee^{A(t-s)} D_i v_i(s)\|^2)\, ds dt \\ &\quad = \int_0^\infty \int_s^\infty \mathcal{E}(\|Ee^{A(t-s)} D_i v_i(s)\|^2)\, dt ds \\ &\quad = \int_0^\infty \mathcal{E}\left(\left\langle D_i v_i(s), \int_s^\infty e^{A^*(t-s)} E^* E e^{A(t-s)}\, dt\, D_i v_i(s)\right\rangle\right) ds. \end{aligned}$$

The result follows since the unique solution $P = P^*$ of (22) is given by

$$P = \int_0^\infty e^{A^*\tau} E^* E e^{A\tau}\, d\tau. \qquad \square \tag{23}$$

Consider the map $\mathbb{L} : L_w^2(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^\ell)) \to L_w^2(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^q))$ defined by

$$(\mathbb{L}v(\cdot))(t) = \left(\mathbb{L}\begin{bmatrix} v_1(\cdot) \\ \vdots \\ v_N(\cdot) \end{bmatrix}\right)(t) = \sum_{i=1}^{N} \int_0^t Ee^{A(t-s)} D_i v_i(s) dw_i(s). \tag{24}$$

$\mathbb{L}v(\cdot) \in L_w^2(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^q))$ for all $v(\cdot) \in L_w^2(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^\ell))$ by the previous lemma.

LEMMA 3.5. *The linear map* $\mathbb{L} : L_w^2(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^\ell)) \to L_w^2(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^q))$ *defined by* (24) *has the operator norm*

$$\|\mathbb{L}\| = \max_{i \in \underline{N}} \left(\lambda_i \|D_i^* \left[\int_0^\infty e^{A^*\tau} E^* E e^{A\tau} \, d\tau \right] D_i \| \right)^{1/2} = \max_{i \in \underline{N}} (\lambda_i \|D_i^* P D_i\|)^{1/2} \tag{25}$$

where P *satisfies* (22).

Proof. If $v(\cdot) \in L_w^2(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^\ell))$ and $y = \mathbb{L}v$, we have by Lemma 3.4

$$\|\mathbb{L}v\|_{L_w^2}^2 = \int_0^\infty \mathcal{E}(\|y(t)\|^2) \, dt = \sum_{i=1}^N \lambda_i \int_0^\infty \mathcal{E}(\langle D_i v_i(s), P D_i v_i(s) \rangle) \, ds,$$

where P satisfies (22). Hence

$$\|\mathbb{L}v\|_{L_w^2}^2 \le \max_{i \in \underline{N}} (\lambda_i \|D_i^* P D_i\|) \sum_{i=1}^N \int_0^\infty \mathcal{E}(\|v_i(s)\|^2) \, ds = \max_{i \in \underline{N}} (\lambda_i \|D_i^* P D_i\|) \|v\|_{L_w^2}^2.$$

So $\|\mathbb{L}\| \le \max_{i \in \underline{N}} (\lambda_i \|D_i^* P D_i\|)^{1/2}$. Now suppose that $\max_{i \in \underline{N}} (\lambda_i \|D_i^* P D_i\|)^{1/2}$ is achieved for $i = j$ and $v_j \in \mathbb{K}^{\ell_j}$ satisfies $\|v_j\|_{\mathbb{K}^{\ell_j}} = 1$ and $\langle v_j, D_j^* P D_j v_j \rangle = \|D_j^* P D_j\|$. Let $v_i(t) = 0$, $t \in \mathbb{R}_+$, $i \ne j$, and $v_j(\cdot) = \beta(\cdot) v_j$, where $\beta(\cdot) \in L^2(\mathbb{R}_+; \mathbb{R})$, $\|\beta(\cdot)\|_{L^2} = 1$ is chosen arbitrarily. Then $v(\cdot) = (v_i(\cdot))_{i \in \underline{N}} \in L_w^2(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^\ell))$, $\|v(\cdot)\|_{L_w^2} = 1$, and

$$\begin{aligned} \|\mathbb{L}v\|_{L_w^2}^2 &= \lambda_j \int_0^\infty \mathcal{E}(\langle D_j v_j \beta(s), P D_j v_j \beta(s) \rangle) \, ds \\ &= \lambda_j \|D_j^* P D_j\| \int_0^\infty |\beta(s)|^2 \, ds = \max_{i \in \underline{N}} (\lambda_i \|D_i^* P D_i\|). \end{aligned}$$

This completes the proof. □

THEOREM 3.6. *Suppose that* A *is stable and there exist* $\alpha = (\alpha_i)_{i \in \underline{N}} \in (0, \infty)^{\underline{N}}$, $P \in \mathcal{H}_n^+(\mathbb{K})$ *satisfying*

$$A^* P + P A + \sum_{i=1}^N \alpha_i^2 E_i^* E_i = 0, \tag{26}$$

$$I_{\ell_j} - (\sigma/\alpha_j)^2 \lambda_j D_j^* P D_j \succeq 0, \qquad j \in \underline{N}. \tag{27}$$

Then $r_{\mathbb{K}}^w(A; (D_i, E_i)_{i \in \underline{N}}) \ge \sigma$.

Proof. Let $x^0 \in \mathbb{K}^n$, $\Delta_i \in \text{Lip}(\mathbb{K}^{q_i}, \mathbb{K}^{l_i})$, $i \in \underline{N}$, $\Delta = \oplus_1^N \Delta_i$, and $\|\Delta\|_L < \sigma$, and suppose that $\alpha \in (0, \infty)^{\underline{N}}$, $P \in \mathcal{H}_n^+(\mathbb{K})$ are such that (26), (27) hold. The unique solution $x(\cdot)$ of (14) with initial condition $x(0) = x^0$ satisfies the scaled integral equation

$$x(t) = e^{At} x^0 + \sum_{i=1}^N \int_0^t e^{A(t-s)} D_i^{\alpha_i} \Delta_i^{\alpha_i} (E_i^{\alpha_i} x(s)) dw_i(s), \qquad t \in \mathbb{R}_+, \tag{28}$$

where

$$D_i^{\alpha_i} = \alpha_i^{-1} D_i, \quad E_i^{\alpha_i} = \alpha_i E_i, \quad \Delta_i^{\alpha_i}(\cdot) = \alpha_i \Delta_i(\alpha_i^{-1} \cdot), \quad i \in \underline{N}. \tag{29}$$

The input-output operator $\mathbb{L}^\alpha : L_w^2(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^\ell)) \to L_w^2(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^q))$ of the scaled system $(A, (D_i^{\alpha_i}, E_i^{\alpha_i})_{i \in \underline{N}})$ is given by

$$(\mathbb{L}^\alpha v(\cdot))(t) = \left(\mathbb{L}^\alpha \begin{bmatrix} v_1(\cdot) \\ \vdots \\ v_N(\cdot) \end{bmatrix} \right)(t) = \sum_{i=1}^N \int_0^t \begin{bmatrix} E_1^{\alpha_1} \\ \vdots \\ E_N^{\alpha_N} \end{bmatrix} e^{A(t-s)} D_i^{\alpha_i} v_i(s) dw_i(s), \qquad t \in \mathbb{R}_+.$$

Let $u_i^{\alpha_i}(t) = \Delta_i^{\alpha_i}(E_i^{\alpha_i}x(t))$, $y_i^{\alpha_i}(t) = E_i^{\alpha_i}x(t)$, $t \in \mathbb{R}_+$, and

$$
\begin{aligned}
E(\alpha) &= \begin{bmatrix} E_1^{\alpha_1} \\ \vdots \\ E_N^{\alpha_N} \end{bmatrix}, \quad \Delta^\alpha = \bigoplus_1^N \Delta_i^{\alpha_i}; \\
y^\alpha(t) &= \begin{bmatrix} y_1^{\alpha_1}(t) \\ \vdots \\ y_N^{\alpha_N}(t) \end{bmatrix}, \quad u^\alpha(t) = \begin{bmatrix} u_1^{\alpha_1}(t) \\ \vdots \\ u_N^{\alpha_N}(t) \end{bmatrix}, \quad t \in \mathbb{R}_+.
\end{aligned} \tag{30}
$$

Then (28) implies

$$
y^\alpha(t) = E(\alpha)e^{At}x^0 + \sum_{i=1}^N \int_0^t E(\alpha)e^{A(t-s)}D_i^{\alpha_i}u_i^{\alpha_i}(s)dw_i(s), \qquad t \in \mathbb{R}_+. \tag{31}
$$

For every $T > 0$, define the truncations $u_{i,T}^{\alpha_i} \in L_w^2(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^{\ell_i}))$, $i \in \underline{N}$, and $u_T^\alpha \in L_w^2(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^\ell))$ by

$$
u_{i,T}^{\alpha_i}(t) = \begin{cases} u_i^{\alpha_i}(t) = \Delta_i^{\alpha_i}(y_i^{\alpha_i}(t)) & \text{if } t \in [0, T], \\ 0 \quad \text{if } t > T, \end{cases} \qquad u_T^\alpha(t) = \begin{bmatrix} u_{1,T}^{\alpha_1}(t) \\ \vdots \\ u_{N,T}^{\alpha_N}(t) \end{bmatrix}.
$$

Then

$$
\begin{aligned}
\|u_T^\alpha\|_{L_w^2}^2 &= \int_0^T \left(\sum_{i=1}^N \int_\Omega \|u_i^{\alpha_i}(t,\omega)\|_{\mathbb{K}^{\ell_i}}^2 \mu(d\omega) \right) dt \\
&\le \int_0^T \left(\sum_{i=1}^N \int_\Omega \|\Delta_i^{\alpha_i}\|_L^2 \|y_i^{\alpha_i}(t,\omega)\|_{\mathbb{K}^{q_i}}^2 \mu(d\omega) \right) dt \\
&\le \|\Delta^\alpha\|_L^2 \int_0^T \mathcal{E}(\|y^\alpha(t)\|^2)\, dt.
\end{aligned} \tag{32}
$$

Let y_T^α denote the output of the scaled system $(A, (D_i^\alpha, E_i^\alpha)_{i \in \underline{N}})$ generated by the input u_T^α with initial condition $x(0) = x^0$:

$$
\begin{aligned}
y_T^\alpha(t) &= E(\alpha)e^{At}x^0 + \sum_{i=1}^N E(\alpha) \int_0^t e^{A(t-s)}D_i^{\alpha_i}u_{i,T}^{\alpha_i}(s)dw_i(s) \\
&= E(\alpha)e^{At}x^0 + (\mathbb{L}^\alpha u_T^\alpha(\cdot))(t), \qquad t \in \mathbb{R}_+.
\end{aligned} \tag{33}
$$

It follows from (31)–(33) that

$$
\begin{aligned}
\left(\int_0^T \mathcal{E}(\|y^\alpha(t)\|^2)\, dt \right)^{1/2} &\le \|y_T^\alpha(\cdot)\|_{L_w^2} \le \|E(\alpha)e^{A(\cdot)}x^0\|_{L_w^2} + \|\mathbb{L}^\alpha\| \|u_T^\alpha(\cdot)\|_{L_w^2} \\
&\le \|E(\alpha)e^{A(\cdot)}x^0\|_{L_w^2} + \|\mathbb{L}^\alpha\|\, \|\Delta^\alpha\|_L \left(\int_0^T \mathcal{E}(\|y^\alpha(t)\|^2)\, dt \right)^{1/2}.
\end{aligned} \tag{34}
$$

By Lemma 3.5

$$\|\mathbb{L}^\alpha\| = \max_{i\in\underline{N}} (\lambda_i \|(D_i^{\alpha_i})^* P D_i^{\alpha_i}\|)^{1/2},$$

where P satisfies (26). Thus from (27) we have $\|\mathbb{L}^\alpha\| \le \sigma^{-1}$, and since $\|\Delta^\alpha\|_L = \|\Delta\|_L < \sigma$, the operator $\mathbb{L}^\alpha\Delta^\alpha$ is a contraction on $L_w^2(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^q))$ with $\gamma := \|\mathbb{L}^\alpha\|\,\|\Delta^\alpha\|_L < 1$. Hence from (34) for all $T > 0$,

$$\left(\int_0^T \mathcal{E}(\|y^\alpha(t)\|^2)\,dt\right)^{1/2} \le (1-\gamma)^{-1}\|E(\alpha)e^{A(\cdot)}x^0\|_{L_w^2}.$$

Therefore $y^\alpha(\cdot) \in L_w^2(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^q))$ and $u^\alpha(\cdot) = \Delta^\alpha(y^\alpha(\cdot)) \in L_w^2(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^\ell))$. Applying Lemma 3.4 (with $E = I_n$, D_i^α instead of D_i and $u^\alpha(\cdot)$ instead of $v(\cdot)$) it follows from (28) that $x(\cdot) \in L_w^2(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^n))$, and this completes the proof. □

Remark 3.7. Suppose the $\Delta_i(t, y)$ are *time-varying* Lipschitzian nonlinearities, measurable in $(t, y) \in \mathbb{R}_+ \times \mathbb{K}^{q_i}$, satisfying $\Delta_i(t, 0) = 0$, $t \ge 0$, and

$$\|\Delta_i\|_L = \inf\{\gamma_i > 0;\ \forall y, \hat{y} \in \mathbb{K}^{q_i} \forall t \in \mathbb{R}_+ : \|\Delta_i(t, y) - \Delta_i(t, \hat{y})\|_{\mathbb{K}^{\ell_i}} \le \gamma_i \|y - \hat{y}\|_{\mathbb{K}^{q_i}}\} < \sigma.$$

Then the previous proof carries through, showing that no time-varying Lipschitzian perturbations $\Delta_i(t, y)$ of Lipschitz norm smaller than σ can destabilize the system. □

If in the previous theorem condition (27) is satisfied with $\succ$ instead of $\succeq$, then clearly $r_{\mathbb{K}}^w(A; (D_i, E_i)_{i\in\underline{N}}) > \sigma$ follows. Similarly, the equality in (26) may be replaced by an inequality $\preceq$.

COROLLARY 3.8. *Suppose that A is stable and there exist $\alpha \in (0, \infty)^{\underline{N}}$, $P \in \mathcal{H}_n^+(\mathbb{K})$ satisfying*

$$A^*P + PA + \sum_{i=1}^N \alpha_i^2 E_i^* E_i \preceq 0, \tag{35}$$

$$I_{\ell_j} - (\sigma/\alpha_j)^2 \lambda_j D_j^* P D_j \succeq 0 \quad (\textit{resp.}, I_{\ell_j} - (\sigma/\alpha_j)^2\lambda_j D_j^* P D_j \succ 0), \qquad j \in \underline{N}. \tag{36}$$

Then $r_{\mathbb{K}}^w(A; (D_i, E_i)_{i\in\underline{N}}) \ge \sigma$ (resp., $r_{\mathbb{K}}^w(A; (D_i, E_i)_{i\in\underline{N}}) > \sigma$).

Proof. Let $P(\alpha)$ denote the solution of the Liapunov equation (26). Then $0 \preceq P(\alpha) \preceq P$. Hence $P(\alpha)$ satisfies (26) and (27) and $r_{\mathbb{K}}^w(A; (D_i, E_i)_{i\in\underline{N}}) \ge \sigma$ follows from Theorem 3.6. □

For any $J \subset \underline{N}$ and any scaling vector $\alpha^J \in (0, \infty)^J$, define

$$P(\alpha^J) = \int_0^\infty e^{A^*\tau}\left(\sum_{i\in J} \alpha_i^2 E_i^* E_i\right) e^{A\tau}\,d\tau; \tag{37}$$

i.e., $P(\alpha^J) \in \mathcal{H}_n^+(\mathbb{K})$ is the unique solution of

$$A^*P + PA + \sum_{i\in J} \alpha_i^2 E_i^* E_i = 0. \tag{38}$$

Then

$$\begin{aligned}(\lambda_j/\alpha_j^2) D_j^* P(\alpha^J) D_j &= \sum_{i\in J} (\alpha_i/\alpha_j)^2 \lambda_j \int_0^\infty D_j^* e^{A^*\tau} E_i^* E_i e^{A\tau} D_j\,d\tau \\ &= \sum_{i\in J} (\alpha_i/\alpha_j)^2 H_{ij}, \qquad j \in J,\end{aligned} \tag{39}$$

where

$$H_{ij} = \lambda_j \int_0^\infty D_j^* e^{A^*\tau} E_i^* E_i e^{A\tau} D_j d\tau \geq 0, \qquad i, j \in \underline{N}. \tag{40}$$

We are now in a position to prove our main theorem by applying the results of §2 to the family of positive semidefinite matrices (40).

THEOREM 3.9. *Given* $(A, (D_i, E_i)_{i\in\underline{N}})$, $\sigma(A) \subset \mathbb{C}_-$, *and* $(w_i)_{i\in\underline{N}}$ *as in* (14), *the associated stability radius is determined by*

$$r_{\mathbb{K}}^w(A; (D_i, E_i)_{i\in\underline{N}}) = \sup_{\alpha\in(0,\infty)^{\underline{N}}} \left(\max_{j\in\underline{N}} \|(\lambda_j/\alpha_j^2) D_j^* P(\alpha) D_j\|\right)^{-1/2}, \tag{41}$$

where $P(\alpha)$ *is the unique solution of* (26). *If* $r_{\mathbb{K}}^w(A; (D_i, E_i)_{i\in\underline{N}}) < \infty$, *there exists a minimum norm destabilizing perturbation* $\Delta = \oplus_1^N \Delta_i \in \text{Lip}\,(\mathbb{K}^q, \mathbb{K}^l)$, $\|\Delta\|_L = r_{\mathbb{K}}^w$. *Moreover, there exist a subset* $J \subset \underline{N}$ *and a scaling vector* $\alpha^J \in (0, \infty)^J$ *such that*

$$r_{\mathbb{K}}^w(A; (D_i, E_i)_{i\in\underline{N}}) = \left(\max_{j\in J} \|(\lambda_j/\alpha_j^2) D_j^* P(\alpha^J) D_j\|\right)^{-1/2} = r_{\mathbb{K}}^w(A; (D_i, E_i)_{i\in J}), \tag{42}$$

where $P(\alpha^J) \in \mathcal{H}_n^+(\mathbb{K})$ *is the unique solution of* (38).

Proof. By (39)

$$\begin{aligned} \hat{\mu} &:= \inf_{\alpha\in(0,\infty)^{\underline{N}}} \max_{j\in\underline{N}} \|(\lambda_j/\alpha_j^2) D_j^* P(\alpha) D_j\| \\ &= \inf_{\alpha\in(0,\infty)^{\underline{N}}} \max_{j\in\underline{N}} \left\| \sum_{i=1}^N (\alpha_i/\alpha_j)^2 H_{ij} \right\| \geq 0. \end{aligned} \tag{43}$$

If $\hat{\mu} = 0$, then $r_{\mathbb{K}}^w(A; (D_i, E_i)_{i\in\underline{N}}) = \infty$ by Theorem 3.6; hence (41) is satisfied. Moreover, in this trivial case,

$$E_j e^{A\tau} D_j = 0, \qquad \tau \in R_+, j \in \underline{N},$$

so that (42) is satisfied for every singleton $J = \{j\} \subset \underline{N}$ and all $\alpha^J \in (0, \infty)$.

Now assume that $\hat{\mu} > 0$. For every $\alpha \in (0, \infty)^{\underline{N}}$ let $\sigma(\alpha)$ be the largest σ for which (26) and (27) have a joint solution $P \in \mathcal{H}_n(\mathbb{K})$, i.e.,

$$\sigma(\alpha)^2 = \left(\max_{j\in\underline{N}} \|(\lambda_j/\alpha_j^2) D_j^* P(\alpha) D_j\|\right)^{-1} = \left(\max_{j\in\underline{N}} \left\| \sum_{i=1}^N (\alpha_i/\alpha_j)^2 H_{ij} \right\|\right)^{-1} \tag{44}$$

(see (39)), whence $\sup_{\alpha\in(0,\infty)^{\underline{N}}} \sigma(\alpha)^2 = \hat{\mu}^{-1}$. By Theorem 2.4 there exist $J \subset \underline{N}$ and a vector $\alpha^J = (\alpha_j)_{j\in J} \in (0, \infty)^J$ satisfying

$$\hat{\mu} = \left\| \sum_{i\in J} (\alpha_i/\alpha_j)^2 H_{ij} \right\| = \|(\lambda_j/\alpha_j^2) D_j^* P(\alpha^J) D_j\|, \qquad j \in J, \tag{45}$$

where $P(\alpha^J) \in \mathcal{H}_n^+(\mathbb{K})$ is the unique solution of (38). Hence there are $v_j \in \mathbb{K}^{\ell_j}$, $j \in J$, $\|v_j\|_{\mathbb{K}^{\ell_j}} = 1$ such that

$$\left\langle v^j, \left(\sum_{i\in J} (\alpha_i/\alpha_j)^2 H_{ij} \right) v^j \right\rangle = \langle v^j, (\lambda_j/\alpha_j^2) D_j^* P(\alpha^J) D_j v^j \rangle = \hat{\mu}, \qquad j \in J.$$

Setting $\hat{\sigma}^2 = \hat{\mu}^{-1}$ we obtain

$$\langle v_j, (\lambda_j/\alpha_j^2)\hat{\sigma}^2 D_j^* P(\alpha^J) D_j v_j\rangle = 1, \qquad j \in J. \tag{46}$$

Define $\Delta_j(\cdot) \in \text{Lip}\,(\mathbb{K}^{q_j}, \mathbb{K}^{l_j})$ for $j \in \underline{N}$ by

$$\begin{aligned} \Delta_j(y_j) &= \hat{\sigma}\|y_j\| v_j, \qquad y_j \in \mathbb{K}^{q_j}, j \in J, \\ \Delta_i &= 0, \qquad i \in \underline{N}\backslash J. \end{aligned} \tag{47}$$

Then $\|\Delta_j\|_L = \hat{\sigma}$, $j \in J$, and hence $\|\Delta\|_L = \hat{\sigma}$ for $\Delta = \oplus_1^N \Delta_i$. We will show that for this Δ (14) cannot be stable. Assume the contrary; then, for all $x^0 \in \mathbb{K}^n$, the solution $x(\cdot)$ of (14) with $x(0) = x^0$ must satisfy $\int_0^\infty \mathcal{E}(\|x(t)\|^2)\,dt < \infty$. $x(\cdot)$ satisfies the reduced scaled integral equation

$$x(t) = e^{At}x^0 + \sum_{j\in J} \int_0^t e^{A(t-s)} D_j^{\alpha_j} \Delta_j^{\alpha_j}(E_j^{\alpha_j} x(s)) dw_j(s), \tag{48}$$

where $D_j^{\alpha_j}$, $E_j^{\alpha_j}$, and $\Delta_j^{\alpha_j}(\cdot)$ are defined by (29). By assumption $y_j^{\alpha_j}(\cdot) = E_j^{\alpha_j} x(\cdot) \in L_w^2(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^{q_j}))$, $j \in J$. Now

$$\Delta_j^{\alpha_j}(y_j) = \alpha_j \Delta_j(\alpha_j^{-1} y_j) = \hat{\sigma}\|y_j\| v_j, \qquad y_j \in \mathbb{K}^{q_j}, j \in J.$$

Defining $y^{\alpha^J}(\cdot)$ and E^{α^J} by

$$\begin{aligned} y^{\alpha^J}(\cdot) &= (y_j^{\alpha_j}(\cdot))_{j\in J}, \\ E^{\alpha^J} x &= (E_j^{\alpha_j} x)_{j\in J} \in \bigoplus_{j\in J} \mathbb{K}^{q_j}, \qquad x \in \mathbb{K}^n, \end{aligned}$$

we get

$$y^{\alpha^J}(t) = E^{\alpha^J} e^{At} x^0 + \hat{\sigma} \sum_{j\in J} E^{\alpha^J} \int_0^t e^{A(t-s)} D_j^{\alpha_j} v_j \|y_j^{\alpha_j}(s)\| dw_j(s). \tag{49}$$

Application of Lemma 3.4 to (49) yields

$$\begin{aligned} \int_0^\infty \mathcal{E}(\|y^{\alpha^J}(t)\|^2)\,dt &= \int_0^\infty \|E^{\alpha^J} e^{At} x^0\|^2\,dt \\ &\quad + \hat{\sigma}^2 \sum_{j\in J} \lambda_j \langle D_j^{\alpha_j} v_j, P(\alpha^J) D_j^{\alpha_j} v_j\rangle \int_0^\infty \mathcal{E}(\|y_j^{\alpha_j}(s)\|^2)\,ds, \end{aligned}$$

where $P(\alpha^J) \in \mathcal{H}_n^+(\mathbb{K})$ is the unique solution of (38). But then by (46), we have

$$\begin{aligned} \int_0^\infty \mathcal{E}(\|y^{\alpha^J}(t)\|^2)\,dt &= \int_0^\infty \|E^{\alpha^J} e^{At} x^0\|^2\,dt + \sum_{j\in J} \int_0^\infty \mathcal{E}(\|y_j^{\alpha_j}(s)\|^2)\,ds \\ &= \int_0^\infty \|E^{\alpha^J} e^{At} x^0\|^2\,dt + \int_0^\infty \mathcal{E}(\|y^{\alpha^J}(s)\|^2)\,ds \end{aligned}$$

for all $x^0 \in \mathbb{K}^n$. This would imply that $E_j = 0$ for every $j \in J$; hence $P(\alpha^J) = 0$ and $\hat{\mu} = 0$, contrary to our assumption. Therefore, there exists $x^0 \in \mathbb{K}^n$ such that $\int_0^\infty \mathcal{E}(\|x(t)\|^2)\,dt = \infty$ and neither of the two stochastic systems (14) and (48) is L^2-stable. It follows that

$$r_{\mathbb{K}}^w(A; (D_i, E_i)_{i\in\underline{N}}) \le r_{\mathbb{K}}^w(A; (D_i, E_i)_{i\in J}) \le \left(\max_{j\in J} \|\lambda_j D_j^* P(\alpha^J) D_j/\alpha_j^2\|\right)^{-1/2} = \hat{\mu}^{-1/2}.$$

On the other hand, for every $\sigma < \hat{\sigma} = \hat{\mu}^{-1/2}$, i.e., $\sigma^{-2} > \hat{\mu}$, there exists $\alpha \in (0, \infty)^{\underline{N}}$ such that

$$\max_{j \in \underline{N}} \|(\lambda_j/\alpha_j^2) D_j^* P(\alpha) D_j\| = \max_{j \in \underline{N}} \left\| \sum_{i=1}^{N} (\alpha_i/\alpha_j)^2 H_{ij} \right\| < \sigma^{-2}.$$

But this implies $\sigma \leq r_{\mathbb{K}}^w(A; (D_i, E_i)_{i \in \underline{N}})$ by Theorem 3.6 and concludes the proof. □

Note that the destabilizing disturbance Δ defined by (47) is real when the data $(A, (D_i, E_i)_{i \in \underline{N}})$ are real. In this case we can choose $\mathbb{K} = \mathbb{R}$ in (41) and obtain a formula for the real stability radius. However, we may also choose $\mathbb{K} = \mathbb{C}$ so that we obtain the same formula for the complex stability radius since the right-hand side of (41) does not depend on the choice of the field $\mathbb{K}$. Thus we obtain the following corollary.

COROLLARY 3.10. *Under the conditions of Theorem* 3.9, *if the data* $(A, (D_i, E_i)_{i \in \underline{N}})$ *are real, then the complex and the real stability radii coincide:*

$$r_{\mathbb{R}}^w(A; (D_i, E_i)_{i \in \underline{N}}) = r_{\mathbb{C}}^w(A; (D_i, E_i)_{i \in \underline{N}}).$$

Remark 3.11. In the deterministic case, stability radii for *complex* and *real* multiperturbations are, in general, not the same, not even in the single-perturbation case ($N = 1$); see [14]. Moreover, the scaling technique does not provide a characterization of the complex stability radius but yields only a lower bound; see [16]. In the stochastic case, however, the scaling technique works and we have, as a consequence of (41),

$$r_{\mathbb{K}}^w(A; (D_i, E_i)_{i \in \underline{N}}) = \sup_{\alpha \in (0,\infty)^{\underline{N}}} \|\mathbb{L}^\alpha\|^{-1} = \sup_{\alpha \in (0,\infty)^{\underline{N}}} r_{\mathbb{K}}^w(A; D^\alpha, E^\alpha)$$

for $\mathbb{K} = \mathbb{R}$ and $\mathbb{K} = \mathbb{C}$. The application of the theorems of §2 to obtain this result is based on the simple formula (25) for the norm of $\mathbb{L}$. The corresponding characterization in the deterministic case is much more complicated and involves a parametrized Riccati equation (see [14]) instead of the single Liapunov equation (22) without parameters.

One reason for the basic difference between the deterministic and the stochastic case lies in the fact that there is no deterministic counterpart to the fundamental equation (20) (on which all our results are built). □

For later use we note the following characterization of the stability radius in terms of strict inequalities.

COROLLARY 3.12. *Given* $(A, (D_i, E_i)_{i \in \underline{N}})$ *and* $(w_i)_{i \in \underline{N}}$ *as in* (14), *the following statements are equivalent for* $\sigma \geq 0$:

(i) $\sigma(A) \subset \mathbb{C}_-$ *and* $r_{\mathbb{K}}^w(A; (D_i, E_i)_{i \in \underline{N}}) > \sigma$;

(ii) *there exists* $\alpha_i > 0$, $i \in \underline{N}$, *and* $X \in \mathcal{H}_n^+(\mathbb{K})$ *satisfying*

$$XA + A^*X + E(\alpha)^*E(\alpha) \prec 0, \tag{50}$$

$$I_{\ell_i} - \lambda_i(\sigma/\alpha_i)^2 D_i^* X D_i \succ 0, \qquad i = 1, \ldots, N. \tag{51}$$

Proof. Suppose (i) and choose $\sigma' \in (\sigma, r_{\mathbb{K}}^w(A; (D_i, E_i)_{i \in \underline{N}}))$. By Theorem 3.9 there exists $\alpha \in (0, \infty)^{\underline{N}}$ such that

$$(\sigma'/\alpha_i)^2 \lambda_i D_i^* \left[\int_0^\infty e^{A^*\tau} E(\alpha)^* E(\alpha) e^{A\tau} d\tau \right] D_i \preceq I_{\ell_i}, \qquad i \in \underline{N}.$$

But then

$$(\sigma/\alpha_i)^2 \lambda_i D_i^* \left[\int_0^\infty e^{A^*\tau} E(\alpha)^* E(\alpha) e^{A\tau} d\tau \right] D_i \prec I_{\ell_i}, \qquad i \in \underline{N},$$

and hence there exists $\varepsilon > 0$ such that

$$(\sigma/\alpha_i)^2 \lambda_i D_i^* \left[\int_0^\infty e^{A^*\tau}(E(\alpha)^* E(\alpha) + \varepsilon I_n) e^{A\tau} d\tau \right] D_i \prec I_{\ell_i}, \qquad i \in \underline{N}.$$

Setting $X = \int_0^\infty e^{A^*\tau}(E(\alpha)^* E(\alpha) + \varepsilon I_n) e^{A\tau} d\tau$ it follows that

$$XA + A^* X + E(\alpha)^* E(\alpha) + \varepsilon I_n = 0.$$

Hence $X \succ 0$ satisfies (ii).

Conversely, (ii) $\Rightarrow$ (i) follows first from the fact that (50) implies $\sigma(A) \subset \mathbb{C}_-$ and then from application of Corollary 3.8. □

Remark 3.13. Let $\mathcal{G}$ denote the directed graph with node set $\underline{N}$ and set of directed arcs $\mathcal{A} = \{(i, j) \in \underline{N}^2;\ H_{ij} \neq 0\}$, where the Hermitian matrices $H_{ij} \in \mathcal{H}_n^+(\mathbb{K})$ are defined by (40). By Theorem 2.4

$$\hat{\mu} = \max_{k \in \underline{K}} \mu_k \quad \mu_k = \min_{\alpha \in (0,\infty)^{C_k}} \max_{j \in C_k} \left\| \sum_{i \in C_k} \left(\frac{\alpha_i}{\alpha_j} \right)^2 H_{ij} \right\|, \quad k \in \underline{K},$$

where $\hat{\mu}$ is defined by (43) and C_k, $k \in \underline{K}$, are the strongly connected components of $\mathcal{G}$. Since $\mu_k^{-1/2} = r_{\mathbb{K}}^w(A; (D_i, E_i)_{i \in C_k})$ we have

$$r_{\mathbb{K}}^w(A; (D_i, E_i)_{i \in \underline{N}}) = \max_{k \in \underline{K}} r_{\mathbb{K}}^w(A; (D_i, E_i)_{i \in C_k}).$$

Thus the L^2-stability of the uncertain stochastic system (14) is equivalent to the L^2-stability of each uncertain stochastic system corresponding to the connected components of $\mathcal{G}$:

$$dx(t) = Ax(t)\,dt + \sum_{i \in C_k} D_i \Delta_i(E_i x(t)) dw_i(t), \qquad \|\Delta_i\|_L < \sigma, i \in C_k, k = 1, \ldots, K.$$

This reduces our original problem to the separate investigation of K uncertain stochastic systems with strongly connected perturbation structures. In particular, the subset J in Theorem 3.9 can be chosen in a strongly connected component C_k with $\mu_k = \hat{\mu}$. The question of determining conditions under which no further reduction beyond the connected components is possible, i.e., $J = C_k$, has been dealt with in Proposition 2.2. □

4. Maximizing the stability radius by dynamic output feedback. In this section we investigate how the stability radius of a stochastically perturbed system can be improved by dynamic output feedback. For this we introduce a control term into the system equation (14) and add a measurement equation. We consider controlled stochastic systems described by Ito equations of the form

$$(52)\quad dx(t) = Ax(t)dt + \sum_{i=1}^{N} D_i \Delta_i(E_i x(t)) dw_i(t) + Bu(t)dt, \quad y(t) = Cx(t), \quad t \in \mathbb{R}_+,$$

where $B \in \mathbb{K}^{n \times m}$ and $C \in \mathbb{K}^{p \times n}$ are the input and output matrices, respectively, and the other variables and matrices are of the form specified in the previous section.

Remark 4.1. Extensions of this problem, including control-dependent noise and noise corrupting the output, should be considered in the framework of a general stochastic H^∞ control. While the development of a comprehensive H^∞ control theory for stochastic systems requires substantial new work, it can be built on the results presented here. This will be the subject of future work. □

The compensator takes the form

$$d\hat{x}(t) = H\hat{x}(t)dt + Gy(t)dt, \qquad u(t) = F\hat{x}(t) + Ky(t), \tag{53}$$

where $(H, G, F, K) \in \mathbb{K}^{\hat{n}\times\hat{n}} \times \mathbb{K}^{\hat{n}\times p} \times \mathbb{K}^{m\times\hat{n}} \times \mathbb{K}^{m\times p}$ and the dimension $\hat{n} \geq 0$ is arbitrary. The resulting overall system is

$$\begin{bmatrix} dx(t) \\ d\hat{x}(t) \end{bmatrix} = \begin{bmatrix} A + BKC & BF \\ GC & H \end{bmatrix} \begin{bmatrix} x(t) \\ \hat{x}(t) \end{bmatrix} dt + \sum_{i=1}^{N} \begin{bmatrix} D_i \\ 0 \end{bmatrix} \Delta_i \left([E_i \;\; 0] \begin{bmatrix} x(t) \\ \hat{x}(t) \end{bmatrix} \right) dw_i(t).$$

We will use the notation

$$\mathcal{A} = \begin{bmatrix} A + BKC & BF \\ GC & H \end{bmatrix} \in \mathbb{K}^{(n+\hat{n})\times(n+\hat{n})}, \mathcal{D}_i = \begin{bmatrix} D_i \\ 0 \end{bmatrix} \in \mathbb{K}^{(n+\hat{n})\times\ell_i},$$

$$\mathcal{E}_i = [E_i \;\; 0] \in \mathbb{K}^{q_i\times(n+\hat{n})},$$

and $\overline{x} = \left[\begin{smallmatrix} x \\ \hat{x} \end{smallmatrix}\right] \in \mathbb{K}^{n+\hat{n}}$. Then the above system can be written

$$d\overline{x}(t) = \mathcal{A}\overline{x}(t)dt + \sum_{i=1}^{N} \mathcal{D}_i \Delta_i(\mathcal{E}_i\overline{x}(t))dw_i(t). \tag{54}$$

For all compensators (53), arbitrary $\Delta_i \in \text{Lip}\,(\mathbb{K}^{q_i}, \mathbb{K}^{l_i})$, $i \in \underline{N}$, and any $\overline{x}^0 \in \mathbb{K}^{n+\hat{n}}$ there exists a unique solution $\overline{x}(\cdot) = (\overline{x}(t))_{t\in\mathbb{R}_+}$ of (54) on $\mathbb{R}_+$ such that $\overline{x}(0) = \overline{x}_0$ [9].

Our aim is to determine conditions for the existence of dynamic compensators of the form (53) that stabilize the system and achieve a stability radius $r^w_{\mathbb{K}}(\mathcal{A}; (\mathcal{D}_i, \mathcal{E}_i)_{i\in\underline{N}}) > \sigma$ for a given $\sigma > 0$. We follow an approach based on inequalities similar to that which Gahinet developed in his approach to the H^∞ control problem; see [10], [11]. We proceed in two steps. First we derive some necessary conditions, and then we show that these conditions are also sufficient for building a stabilizing compensator of dimension n which achieves the required stability radius. We will make use of the following criterion for the positive definiteness of Hermitian block matrices.

LEMMA 4.2. *Let* $\mathcal{X} = \left[\begin{smallmatrix} S & N \\ N^* & Q \end{smallmatrix}\right]$, *where* $S \in \mathcal{H}_k(\mathbb{K})$, $Q \in \mathcal{H}_\ell(\mathbb{K})$, $N \in \mathbb{K}^{k\times\ell}$. *Then*

$$\mathcal{X} \succ 0 \quad \Leftrightarrow \quad Q \succ 0 \;\; \text{and} \;\; S - NQ^{-1}N^* \succ 0.$$

THEOREM 4.3. *Given* $\sigma > 0$ *and a compensator* (53) *such that* $\sigma(\mathcal{A}) \subset \mathbb{C}_-$ *and* $r^w_{\mathbb{K}}(\mathcal{A}; (\mathcal{D}_i, \mathcal{E}_i)_{i\in\underline{N}}) > \sigma$. *Then there exist* $\alpha \in (0, \infty)^{\underline{N}}$, $\gamma, \delta > 0$, $R, S \in \mathcal{H}^+_n(\mathbb{K})$ *such that*

$$AR + RA^* + RE(\alpha)^*E(\alpha)R - BB^*/\gamma^2 \prec 0, \tag{55}$$

$$SA + A^*S + E(\alpha)^*E(\alpha) - C^*C/\delta^2 \prec 0, \tag{56}$$

$$R \succ 0 \;\; \text{and} \;\; S \succ R^{-1}, \tag{57}$$

$$I_{\ell_i} - \lambda_i(\sigma/\alpha_i)^2 D_i^* S D_i \succ 0, \qquad i = 1, \ldots, N, \tag{58}$$

where (*see* (30)) $E(\alpha)^*E(\alpha) = \sum_{i=1}^N \alpha_i^2 E_i^* E_i$.

Proof. By Corollary 3.12 there exists $\alpha \in (0, \infty)^{\underline{N}}$, $\mathcal{X} \in \mathcal{H}^+_{n+\hat{n}}(\mathbb{K})$, $\mathcal{X} \succ 0$, such that

$$\mathcal{X}\mathcal{A} + \mathcal{A}^*\mathcal{X} + \mathcal{E}(\alpha)^*\mathcal{E}(\alpha) \prec 0, \tag{59}$$

$$I_{\ell_i} - \lambda_i(\sigma/\alpha_i)^2 \mathcal{D}_i^* \mathcal{X} \mathcal{D}_i \succ 0, \qquad i = 1, \ldots, N. \tag{60}$$

Writing

$$\mathcal{X} = \begin{bmatrix} S & N \\ N^* & Q \end{bmatrix}, \qquad \mathcal{X}^{-1} = \begin{bmatrix} R & M \\ M^* & P \end{bmatrix}$$

with $R, S \in \mathcal{H}^+_n(\mathbb{K})$, we obtain

$$SR + NM^* = I_n, \qquad N^*R + QM^* = 0.$$

Since $\mathcal{X} \succ 0$, we have

$$S \succ 0, \quad Q \succ 0, \quad S - NQ^{-1}N^* \succ 0,$$
$$R \succ 0, \quad P \succ 0, \quad R - MP^{-1}M^* \succ 0.$$

Now $SR - NQ^{-1}N^*R = I_n$ and $\mathcal{D}_i^* = [D_i^* \ \ 0]$. Hence

$$\begin{aligned} &0 \prec R^{-1} = S - NQ^{-1}N^* \preceq S, \\ &I_{\ell_i} - \lambda_i(\sigma/\alpha_i)^2 D_i^* S D_i \succ 0, \qquad i = 1, \ldots, N, \end{aligned} \tag{61}$$

because of (60). Moreover,

$$\mathcal{X} \begin{bmatrix} I_n & R \\ 0 & M^* \end{bmatrix} = \begin{bmatrix} S & I_n \\ N^* & 0 \end{bmatrix}. \tag{62}$$

Multiplying (59) on the left by $\left[\begin{smallmatrix} I_n & 0 \\ R & M \end{smallmatrix}\right]$ and on the right by $\left[\begin{smallmatrix} I_n & R \\ 0 & M^* \end{smallmatrix}\right]$ yields

$$\begin{aligned} &\begin{bmatrix} S & N \\ I_n & 0 \end{bmatrix} \begin{bmatrix} A + BKC & BF \\ GC & H \end{bmatrix} \begin{bmatrix} I_n & R \\ 0 & M^* \end{bmatrix} \\ &\quad + \begin{bmatrix} I_n & 0 \\ R & M \end{bmatrix} \begin{bmatrix} (A + BKC)^* & C^*G^* \\ F^*B^* & H^* \end{bmatrix} \begin{bmatrix} S & I_n \\ N^* & 0 \end{bmatrix} \\ &\quad + \begin{bmatrix} I_n & 0 \\ R & M \end{bmatrix} \begin{bmatrix} E(\alpha)^*E(\alpha) & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} I_n & R \\ 0 & M^* \end{bmatrix} \\ &\quad + \begin{bmatrix} I_n & 0 \\ R & M \end{bmatrix} \begin{bmatrix} \Pi_{11} & \Pi_{12} \\ \Pi_{21} & \Pi_{22} \end{bmatrix} \begin{bmatrix} I_n & R \\ 0 & M^* \end{bmatrix} = 0 \end{aligned} \tag{63}$$

for some

$$\Pi = \begin{bmatrix} \Pi_{11} & \Pi_{12} \\ \Pi_{21} & \Pi_{22} \end{bmatrix} \succ 0.$$

Writing out these equations, we obtain

$$(A + BKC)^*S + C^*G^*N^* + S(A + BKC) + NGC + E(\alpha)^*E(\alpha) + \Pi_{11} = 0, \tag{64}$$

(65)
$$R(A+BKC)^*+MF^*B^*+(A+BKC)R+BFM^*+RE(\alpha)^*E(\alpha)R+[R\ M]\Pi\begin{bmatrix} R \\ M^* \end{bmatrix}=0,$$

(66)
$$(A+BKC)^*+SAR+NGCR+SBFM^*+NHM^*+E(\alpha)^*E(\alpha)R+\Pi_{11}R+\Pi_{12}M^*=0.$$

Equation (64) is equivalent to

$$A^*S+SA+E(\alpha)^*E(\alpha)-C^*C/\delta^2+(C^*/\delta+\delta(NG+SBK))(C^*/\delta+\delta(NG+SBK))^*$$
$$-\delta^2(NG+SBK)(NG+SBK)^*=-\Pi_{11},$$

and (65) is equivalent to

$$AR+RA^*+RE(\alpha)^*E(\alpha)R$$
$$-BB^*/\gamma^2+(B^*/\gamma+\gamma(FM^*+KCR))^*(B^*/\gamma+\gamma(FM^*+KCR))$$
$$-\gamma^2(FM^*+KCR)^*(FM^*+KCR)=-[R\ M]\Pi\begin{bmatrix} R \\ M^* \end{bmatrix}.$$

Note that $[R\ \ M]$ has full row rank so that $[R\ \ M]\Pi\left[\begin{smallmatrix} R \\ M^* \end{smallmatrix}\right]\succ 0$. Therefore, choosing γ and δ sufficiently small we obtain (55) and (56). These inequalities and (61) are still satisfied if for $\varepsilon>0$ sufficiently small we replace S with $S+\varepsilon I_n$. Denoting the modified S by the same symbol we get $0\prec R^{-1}\prec S$, and thus (55)–(58) are satisfied. □

Remark 4.4. Equations (55) and (56) hold for some $\gamma,\delta>0$ if and only if

$$AR+RA^*+RE(\alpha)^*E(\alpha)R\prec 0 \quad \text{on } \ker B^*,$$
$$SA+A^*S+E(\alpha)^*E(\alpha)\prec 0 \quad \text{on } \ker C,$$

so it is possible to state an equivalent theorem which does not involve γ and δ. □

THEOREM 4.5. *Suppose that* (55)–(58) *hold for some* $\alpha\in(0,\infty)^{\underline{N}}$, $\sigma>0$, $\gamma>0$, $\delta>0$, $R,S\in\mathcal{H}_n^+(\mathbb{K})$. *Then there exists an n-dimensional compensator* $(H,G,F,K)\in\mathbb{K}^{n\times n}\times\mathbb{K}^{n\times p}\times\mathbb{K}^{m\times n}\times\mathbb{K}^{m\times p}$ *such that* $\sigma(\mathcal{A})\subset\mathbb{C}_-$ *and* $r_{\mathbb{K}}^w(\mathcal{A};(\mathcal{D}_i,\mathcal{E}_i)_{i\in\underline{N}})>\sigma$.

Proof. Choose

(67) $$K=0,\quad F=-B^*R^{-1}/\gamma^2,\quad G=-N^{-1}C^*/\delta^2,\quad N=R^{-1}-S,$$

(68) $$M=R,\quad \Pi_{11}=-(A^*S+SA+E(\alpha)^*E(\alpha)-2C^*C/\delta^2),\quad \Pi_{12}=-\Pi_{11},$$

(69) $$\Pi_{22}=\Pi_{11}-R^{-1}[AR+RA^*+RE(\alpha)^*E(\alpha)R-2BB^*/\gamma^2]R^{-1}.$$

An easy calculation shows that (64) and (65) hold. Moreover, it follows from (55) and (56) that $0\prec\Pi_{11}\prec\Pi_{22}$ and $\Pi_{11}-\Pi_{12}\Pi_{22}^{-1}\Pi_{12}=\Pi_{11}-\Pi_{11}\Pi_{22}^{-1}\Pi_{11}\succ 0$; hence

$$\Pi=\begin{bmatrix} \Pi_{11} & \Pi_{12} \\ \Pi_{12} & \Pi_{22} \end{bmatrix}\succ 0.$$

Finally, we have by assumption $0\prec R^{-1}\prec S$ so that $N=(I-SR)R^{-1}$ and $M=R$ are invertible. Therefore,

(70) $$H=-N^{-1}[A^*R^{-1}+SA+NGC+SBF+E(\alpha)^*E(\alpha)]$$

is the unique $H \in \mathbb{K}^{n\times n}$ satisfying (66) (with specifications (67)–(69)). Altogether we see that, with the above choices, (63) holds with $\Pi \succ 0$. Now $\left[\begin{smallmatrix} I_n & R \\ 0 & M^* \end{smallmatrix}\right] = \left[\begin{smallmatrix} I_n & R \\ 0 & R \end{smallmatrix}\right]$ is invertible. Multiplication of (63) on the left by $\left[\begin{smallmatrix} I_n & 0 \\ R & M \end{smallmatrix}\right]^{-1}$ and on the right by $\left[\begin{smallmatrix} I_n & R \\ 0 & M^* \end{smallmatrix}\right]^{-1}$ yields equation (59) with

$$\mathcal{X} = \begin{bmatrix} S & I_n \\ N^* & 0 \end{bmatrix} \begin{bmatrix} I_n & R \\ 0 & M^* \end{bmatrix}^{-1} = \begin{bmatrix} S & N \\ N & -N \end{bmatrix}. \tag{71}$$

□

Remark 4.6. (i) The above theorems show that if a compensator of any order $\hat{n}$ stabilizes the system with a stability radius greater than σ, then this can always be achieved by a compensator of order n. Moreover, for this compensator the feedthrough matrix K may be taken to be zero. We do not address the problem of reduced-order observers but expect that a development similar to [11] (in the deterministic case) is possible.

(ii) For $\sigma \geq 0$, let $\mathcal{A}_\sigma$ denote the set of all pairs $(R, S) \in \mathcal{H}_n(\mathbb{K}) \times \mathcal{H}_n(\mathbb{K})$ such that (55)–(58) hold for some $\gamma > 0$, $\delta > 0$, $\alpha \in (0, \infty)^{\underline{N}}$. By the construction in the proof of Theorem 4.3, for any stabilizing compensator (H, G, F, K) which achieves a stability radius $r^w_{\mathbb{K}}(\mathcal{A}; (\mathcal{D}_i, \mathcal{E}_i)_{i\in\underline{N}}) > \sigma$, there exists an $(R, S) \in \mathcal{A}_\sigma$ obtained from the solutions $\mathcal{X}$ of the matrix inequalities (59) and (60). Conversely, by the construction in the proof of Theorem 4.5, for every given $(R, S) \in \mathcal{A}_\sigma$ there is an associated stabilizing compensator (H, G, F, K) which achieves a stability radius greater than σ. □

For later use we add another remark in which an alternative formula for the system matrix H of the observer is derived; cf. (70).

Remark 4.7. The gap between the Riccati inequality (55) and the corresponding Riccati equation is measured by the operator

$$\Pi_R = -[AR + RA^* + RE(\alpha)^*E(\alpha)R - BB^*/\gamma^2] \succ 0. \tag{72}$$

Using specifications (67)–(69) we get

$$SA + SBF = S(A - BB^*R^{-1}/\gamma^2) = -S[RA^*R^{-1} + RE(\alpha)^*E(\alpha) + \Pi_R R^{-1}],$$

and so

$$\begin{aligned} &A^*R^{-1} + SA + SBF + E(\alpha)^*E(\alpha) \\ &\quad = (I_n - SR)A^*R^{-1} + (I_n - SR)E(\alpha)^*E(\alpha) - S\Pi_R R^{-1}. \end{aligned}$$

Using this equation and $N^{-1} = R(I - SR)^{-1}$ to transform (70) we get

$$-H = RA^*R^{-1} + RE(\alpha)^*E(\alpha) - R(I_n - SR)^{-1}S\Pi_R R^{-1} + GC.$$

It follows from (72) and $F = -B^*R^{-1}/\gamma^2$ that

$$\begin{aligned} H &= [AR - BB^*/\gamma^2 + \Pi_R]R^{-1} - GC + R(I_n - SR)^{-1}S\Pi_R R^{-1} \\ &= [A - BB^*R^{-1}/\gamma^2] - GC + [I_n + R(I_n - SR)^{-1}S]\Pi_R R^{-1} \\ &= A + BF - GC + (R^{-1} - S)^{-1}R^{-1}\Pi_R R^{-1}. \end{aligned} \tag{73}$$

Thus H is the sum of the usual matrix of the observer-based compensator system $A+BF-GC$ and a correction term $(R^{-1} - S)^{-1}R^{-1}\Pi_R R^{-1}$ depending on the gap between the Riccati inequality (55) and the corresponding equality. □

Theorems 4.3 and 4.5 together yield a complete characterization of the stability radii which can be achieved by dynamic output feedback applied to the system (52). We conclude this section by discussing this point.

For any $\alpha \in (0, \infty)^{\underline{N}}$, $\sigma \geq 0$, $\gamma > 0$, $\delta > 0$, define

$$\mathcal{A}_{\sigma,\gamma,\delta,\alpha} = \{(R, S) \in \mathcal{H}_n(\mathbb{K}) \times \mathcal{H}_n(\mathbb{K});\ (55)\text{–}(58) \text{ hold}\},$$

$$\mathcal{A}_{\sigma,\gamma,\delta} = \bigcup_{\alpha \in (0,\infty)^{\underline{N}}} \mathcal{A}_{\sigma,\gamma,\delta,\alpha},$$

$$\sigma(\gamma, \delta) = \sup\{\sigma : \mathcal{A}_{\sigma,\gamma,\delta} \neq \emptyset\}.$$

In the following remark we collect some properties of $\mathcal{A}_{\sigma,\gamma,\delta,\alpha}$ and $\sigma(\gamma, \delta)$.

Remark 4.8. $\mathcal{A}_{\sigma,\gamma,\delta,\alpha}$ is an open subset of $\mathcal{H}_n(\mathbb{K}) \times \mathcal{H}_n(\mathbb{K})$ for all $\sigma \geq 0$, $\gamma > 0$, $\delta > 0$, $\alpha \in (0, \infty)^{\underline{N}}$. If $\alpha \in (0, \infty)^{\underline{N}}$ is fixed, the set $\mathcal{A}_{\sigma,\gamma,\delta,\alpha}$ increases as the parameters $\sigma, \gamma, \delta > 0$ decrease:

$$\sigma_2 \geq \sigma_1 \geq 0, \quad \gamma_2 \geq \gamma_1 > 0, \quad \text{and } \delta_2 \geq \delta_1 > 0 \quad \Rightarrow \quad \mathcal{A}_{\sigma_2,\gamma_2,\delta_2,\alpha} \subseteq \mathcal{A}_{\sigma_1,\gamma_1,\delta_1,\alpha}.$$

As a consequence we have

$$0 < \gamma_1 \leq \gamma_2 \quad \text{and} \quad 0 < \delta_1 \leq \delta_2 \quad \Rightarrow \quad \sigma(\gamma_1, \delta_1) \geq \sigma(\gamma_2, \delta_2). \qquad \square$$

DEFINITION 4.9. $\bar{r}(A; (D_i, E_i)_{i \in \underline{N}}; B, C) = \sup\{r^w_{\mathbb{K}}(\mathcal{A}; (\mathcal{D}_i, \mathcal{E}_i)_{i \in \underline{N}});$ the compensator (H, G, F, K) is stabilizing$\}$ *is said to be the* supreme stability radius *for the uncertain stochastic system* (52).

As a consequence of the previous two theorems we obtain the following characterization of the supreme stability radius.

COROLLARY 4.10.

$$\bar{r}(A; (D_i, E_i)_{i \in \underline{N}}; B, C) = \lim_{(\gamma,\delta) \downarrow (0,0)} \sigma(\gamma, \delta) = \sup\{\sigma(\gamma, \delta);\ \gamma > 0, \delta > 0\}.$$

For the computation of $\sigma(\gamma, \delta)$ the following description of the sets $\mathcal{A}_{\sigma,\gamma,\delta,\alpha}$ in terms of linear matrix inequalities is useful.

LEMMA 4.11. *Given* $\alpha \in (0, \infty)^{\underline{N}}$, $\sigma \geq 0$, $\gamma > 0$, $\delta > 0$, *the set* $\mathcal{A}_{\sigma,\gamma,\delta,\alpha}$ *consists of all Hermitian matrix pairs* $(R, S) \in \mathcal{H}_n(\mathbb{K}) \times \mathcal{H}_n(\mathbb{K})$ *which satisfy the following linear matrix inequalities:*

$$\begin{bmatrix} AR + RA^* - BB^*/\gamma^2 & RE(\alpha)^* \\ E(\alpha)R & -I_q \end{bmatrix} \prec 0, \tag{74}$$

$$SA + A^*S + E(\alpha)^*E(\alpha) - C^*C/\delta^2 \prec 0, \tag{75}$$

$$R \succ 0, \quad S \succ 0, \quad \begin{bmatrix} R & I_n \\ I_n & S \end{bmatrix} \succ 0, \tag{76}$$

$$I_{\ell_i} - \lambda_i(\sigma/\alpha_i)^2 D_i^* S D_i \succ 0 \qquad i = 1, \ldots, N. \tag{77}$$

In particular, $\mathcal{A}_{\sigma,\gamma,\delta,\alpha}$ *is convex.*

Proof. The equivalence of (55)–(58) and (74)–(77) is obtained by application of Lemma 4.2. The convexity of $\mathcal{A}_{\sigma,\gamma,\delta,\alpha}$ then follows. $\square$

For a discussion of linear matrix inequalities and their numerical solution, see [2].

Remark 4.12. In the case of *single complex* perturbations ($N = 1$) the deterministic counterpart of the problem considered in this section leads to a singular H^∞-optimal control problem which can be solved via Riccati equations (see [13]) or linear matrix inequalities (see [11]). The maximization of the *real* stability radius by dynamic output feedback is still an unsolved problem, even for $N = 1$. In the (complex) multiperturbation case, the deterministic version of our problem leads to an optimal μ-synthesis problem since the stability radius with respect to multiperturbations can be characterized via the μ-function [14]. To our knowledge this problem is still unsolved. Our solution of the stochastic problem is based on the fact that the scaling technique works and yields a characterization of the stochastic stability radius in terms of matrix inequalities; see Theorem 3.9. A similar result is not available for deterministic multiperturbations; see Remark 3.11. □

5. Replacing Riccati inequalities with Riccati equations. In this section we explore the possibility of replacing the Riccati inequality (55) with a Riccati equation. *Throughout the section we will assume that* (A, B) *is stabilizable and* (A, C) *is detectable.*

As a starting point we take the Riccati inequality

$$PA + A^*P + E(\alpha)^*E(\alpha) - PBB^*P/\gamma^2 \prec 0. \tag{78}$$

Since (A, B) is assumed to be stabilizable, this inequality always has positive definite solutions. Moreover, every such solution $P \in \mathcal{H}_n(\mathbb{K})$ is invertible and solves (78) if and only if $R = P^{-1}$ solves (55). We will also consider the usual linear-quadratic control Riccati equation,

$$XA + A^*X + E(\alpha)^*E(\alpha) - XBB^*X/\gamma^2 = 0, \tag{$\mathrm{ARE}_{\alpha,\gamma}$}$$

and its ε-approximations,

$$XA + A^*X + E(\alpha)^*E(\alpha) - XBB^*X/\gamma^2 + \varepsilon^2 I_n = 0. \tag{79}$$

The following lemma summarizes some useful and well-known properties of these equations; see, e.g., [12], [5].

LEMMA 5.1. *Suppose that* (A, B) *is stabilizable and* $\gamma > 0$, $\alpha \in (0, \infty)^{\underline{N}}$. *Then*

(i) *for each* $\varepsilon > 0$ (79) *has a unique solution* $X_{\alpha,\gamma}(\varepsilon)$ *in* $\mathcal{H}_n^+(\mathbb{K})$, *and* $X_{\alpha,\gamma}(\varepsilon) \succ 0$. *For every solution* $P \succ 0$ *of* (78) *there exists* ε *such that* $X_{\alpha,\gamma}(\varepsilon) \prec P$.

(ii) $(\mathrm{ARE}_{\alpha,\gamma})$ *has a unique maximal solution* $X_{\alpha,\gamma} \in \mathcal{H}_n^+(\mathbb{K})$, *and this solution is characterized among all other Hermitian solutions of* $(\mathrm{ARE}_{\alpha,\gamma})$ *by the property*

$$\sigma(A - BB^*X_{\alpha\gamma}/\gamma^2) \subset \overline{\mathbb{C}_-}.$$

Moreover, $X_{\alpha,\gamma} \prec X_{\alpha,\gamma}(\varepsilon)$, *for all* $\varepsilon > 0$.

(iii) *If* $\varepsilon \downarrow 0$, *then* $X_{\alpha,\gamma}(\varepsilon) \downarrow X_{\alpha,\gamma}$.

Remark 5.2. It can be shown that the maximal solution $X_{\alpha,\gamma}$ of $(\mathrm{ARE}_{\alpha,\gamma})$ is stabilizing if and only if

$$\ker(\iota\omega I_n - A) \cap \ker E_1 \cap \cdots \cap \ker E_N = \{0\}, \qquad \omega \in \mathbb{R}. \tag{80}$$

□

Consider the following set of conditions for $S \in \mathcal{H}_n(\mathbb{K})$:

$$SA + A^*S + E(\alpha)^*E(\alpha) - C^*C/\delta^2 \prec 0, \tag{81}$$

$$S \succ X_{\alpha,\gamma}, \tag{82}$$

$$I_{\ell_i} - \lambda_i(\sigma/\alpha_i)^2 D_i^* S D_i \succ 0, \qquad i = 1, \ldots, N, \tag{83}$$

where $X_{\alpha,\gamma}$ denotes the maximal solution of $(\mathrm{ARE}_{\alpha,\gamma})$. For $\sigma \geq 0$, $\gamma > 0$, $\delta > 0$, let

$$\mathcal{A}^R_{\sigma,\gamma,\delta,\alpha} = \{S \in \mathcal{H}_n(\mathbb{K}); \quad (81)\text{–}(83) \text{ hold}\},$$

$$\mathcal{A}^R_{\sigma,\gamma,\delta} = \bigcup_{\alpha \in (0,\infty)^{\underline{N}}} \mathcal{A}^R_{\sigma,\gamma,\delta,\alpha},$$

$$\sigma^R(\gamma,\delta) = \sup\{\sigma : \mathcal{A}^R_{\sigma,\gamma,\delta} \neq \emptyset\}.$$

The following proposition is derived by means of Lemma 5.1.

PROPOSITION 5.3. *Suppose that* (A, B) *is stabilizable and* $\gamma > 0$, $\delta > 0$. *Then*

$$\sigma^R(\gamma,\delta) = \sigma(\gamma,\delta).$$

Proof. Let $\sigma < \sigma(\gamma,\delta)$. Then there exist $\alpha \in (0,\infty)^{\underline{N}}$, $(R, S) \in \mathcal{H}_n(\mathbb{K}) \times \mathcal{H}_n(\mathbb{K})$ such that (55)–(58) hold. By Lemma 5.1 $R^{-1} \succ X_{\alpha,\gamma}$ since R^{-1} solves (78). But $S \succ R^{-1}$ and hence $S \succ X_{\alpha,\gamma}$. So $S \in \mathcal{A}^R_{\sigma,\gamma,\delta}$ and thus $\sigma \leq \sigma^R(\gamma,\delta)$. This shows that $\sigma^R(\gamma,\delta) \geq \sigma(\gamma,\delta)$.

Conversely, suppose that $\sigma < \sigma^R(\gamma,\delta)$. Then there exist $\alpha \in (0,\infty)^{\underline{N}}$, $S \in \mathcal{H}_n(\mathbb{K})$ such that (81)–(83) hold. By Lemma 5.1 and (82) there exists $\varepsilon > 0$ such that $X = X_{\alpha,\gamma}(\varepsilon) \prec S$. Hence $(X^{-1}, S) \in \mathcal{A}_{\sigma,\gamma,\delta}$ and thus $\sigma \leq \sigma(\gamma,\delta)$. This shows that $\sigma(\gamma,\delta) \geq \sigma^R(\gamma,\delta)$ and concludes the proof. □

For any $\sigma < \sigma^R(\gamma,\delta)$ we now construct, *via the Riccati equation* $(\mathrm{ARE}_{\alpha,\gamma})$, a compensator of order n so that the stability radius of the overall system is greater than σ. For this, the maximal solution of $(\mathrm{ARE}_{\alpha,\gamma})$ must be stabilizing; i.e., condition (80) must be satisfied.

PROPOSITION 5.4. *Suppose that* (80), (81)–(83) *hold for some* $S \in \mathcal{H}_n(\mathbb{K})$ *and given* $\sigma \geq 0$, $\gamma > 0$, $\delta > 0$, $\alpha \in (0,\infty)^{\underline{N}}$. *Then the compensator* (53) *defined by*

$$(84)\quad H = A + BF - GC, \quad K = 0, \quad F = -B^*X_{\alpha,\gamma}/\gamma^2, \quad G = -(X_{\alpha,\gamma} - S)^{-1}C^*/\delta^2$$

achieves a stability radius $r^w_{\mathbb{K}}(\mathcal{A}; (\mathcal{D}_i, \mathcal{E}_i)_{i\in\underline{N}}) > \sigma$.

Proof. Replacing R^{-1} with $X_{\alpha,\gamma}$ in the formulas (67) and (73), then using equation (72) for Π_R, we see that the compensator (H, G, F, K) in (84) coincides with the compensator defined in the proof of Theorem 4.5 by (67) and (70). Let

$$\mathcal{X} = \begin{bmatrix} S & N \\ N & -N \end{bmatrix}.$$

Then the same calculation as in the proof of Theorem 4.5 yields

$$(85)\qquad \mathcal{X}\mathcal{A} + \mathcal{A}^*\mathcal{X} + \mathcal{E}(\alpha)^*\mathcal{E}(\alpha) = -\Pi,$$

where now

$$\Pi = \begin{bmatrix} \Pi_{11} & -\Pi_{11} \\ -\Pi_{11} & \Pi_{11} + X_{\alpha,\gamma}BB^*X_{\alpha,\gamma}/\gamma^2 \end{bmatrix}, \quad \Pi_{11} = -(SA + A^*S + E(\alpha)^*E(\alpha) - 2C^*C/\delta^2).$$

$\Pi_{11} \succ 0$, but note that in contrast to the development in the proof of Theorem 4.5 we only have $\mathcal{X} \succeq 0$ and $\Pi \succeq 0$. Now $\overline{x} \in \ker \Pi$ if and only if $\overline{x} = \begin{bmatrix} x_1 \\ x_1 \end{bmatrix}$ with $x_1 \in \ker B^*X_{\alpha,\gamma}$. We will now show that $\sigma(\mathcal{A}) \subset \mathbb{C}_-$. Suppose there exist $\overline{x} \in \mathbb{C}^{2n}$, $\overline{x} \neq 0$, and $\lambda \in \mathbb{C}$ with $\operatorname{Re}\lambda \geq 0$ such that $\mathcal{A}\overline{x} = \lambda\overline{x}$. Multiplying (85) on the right by $\overline{x}$ and on the left by $\overline{x}^*$, we obtain

$$2(\operatorname{Re}\lambda)\langle\overline{x}, \mathcal{X}\overline{x}\rangle + \langle\overline{x}, \Pi\overline{x}\rangle \leq 0.$$

This can only be the case if $\overline{x} \in \ker \Pi$, i.e., $\overline{x} = \left[\begin{smallmatrix} x_1 \\ x_1 \end{smallmatrix}\right]$ with $x_1 \in \ker B^* X_{\alpha,\gamma}$. But then the first component of the equation $\mathcal{A}\overline{x} = \lambda \overline{x}$ reads $(A - BB^* X_{\alpha,\gamma}/\gamma^2)x_1 = \lambda x_1$, and this contradicts assumption (80), which implies that $(A - BB^* X_{\alpha,\gamma}/\gamma^2) \subset \mathbb{C}_-$. So $\sigma(\mathcal{A}) \subset \mathbb{C}_-$, and we conclude from Corollary 3.8 and

$$\mathcal{X}\mathcal{A} + \mathcal{A}^*\mathcal{X} + \mathcal{E}(\alpha)^*\mathcal{E}(\alpha) \preceq 0,$$

$$I_{\ell_i} - \lambda_i(\sigma/\alpha_i)^2 \mathcal{D}_i^* \mathcal{X} \mathcal{D}_i = I_{\ell_i} - \lambda_i(\sigma/\alpha_i)^2 D_i^* S D_i \succ 0, \qquad i = 1, \ldots, N,$$

that $r_{\mathbb{K}}^w(\mathcal{A}; (\mathcal{D}_i, \mathcal{E}_i)_{i \in \underline{N}}) > \sigma$. □

In the deterministic case the Liapunov inequality (81) takes the form of a Riccati inequality, and it is possible to replace this by a Riccati equation. Here this is not possible, in general, since the requirements $S \succ R^{-1}$ and $I_{\ell_i} - \lambda_i(\sigma/\alpha_i)^2 D_i^* S D_i \succ 0$, $i = 1, \ldots, N$, work against each other as S increases or decreases. This is an essential difference between the deterministic and stochastic cases. We illustrate it in the following example.

Example 5.5. Consider the perturbed stochastic system

$$\begin{aligned} dx_1(t) &= (-x_1(t) + x_2(t))dt + \Delta_1(x_1(t))dw_1(t), \\ dx_2(t) &= (x_2(t) + u(t))dt + \Delta_2(x_1(t))dw_2(t), \\ y(t) &= x_2(t), \end{aligned}$$

i.e.,

$$A = \begin{bmatrix} -1 & 1 \\ 0 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \quad C = [0 \;\; 1], \quad E_1 = E_2 = [1 \;\; 0],$$

$$D_1 = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \quad D_2 = \begin{bmatrix} 0 \\ 1 \end{bmatrix}.$$

Note that (A, B) is controllable, (A, C) is detectable, and $\ker(\iota\omega I_2 - A) \cap \ker E_1 = \{0\}$ for all $\omega \in \mathbb{R}$. We write

$$R = \begin{bmatrix} r_{11} & r_{12} \\ r_{12}^* & r_{22} \end{bmatrix}, \qquad S = \begin{bmatrix} s_{11} & s_{12} \\ s_{12}^* & s_{22} \end{bmatrix}.$$

Equality in (56) or (81) takes the form

$$-2s_{11} + (\alpha_1^2 + \alpha_2^2) = 0, \tag{86}$$

$$s_{11} = 0, \tag{87}$$

$$s_{12} + s_{12}^* + 2s_{22} - 1/\delta^2 = 0. \tag{88}$$

We see that, for arbitrary parameters $\alpha_1 > 0$, $\alpha_2 > 0$, $\delta > 0$, there does not exist any solution $S \in \mathcal{H}_2(\mathbb{K})$ of (86)–(88). Therefore, we cannot replace the inequalities in (56) or (81) with equalities.

We will now determine $\overline{r} = \overline{r}(A; (D_i, E_i)_{i=1,2}; B, C)$ for the present example and do so via inequalities rather than the Riccati equation ($\mathrm{ARE}_{\alpha,\gamma}$) and (81)–(83). Suppose $\sigma < \overline{r}$. Since $\left[\begin{smallmatrix} 1 \\ 0 \end{smallmatrix}\right]$ is a basis for both $\ker B^*$ and $\ker C$, by Theorem 4.3 and Remark 4.4, there exist $R, S \in \mathcal{H}_2(\mathbb{K})$ and $\alpha_1 > 0$, $\alpha_2 > 0$ such that

$$-2s_{11} + (\alpha_1^2 + \alpha_2^2) < 0, \qquad -2r_{11} + r_{12}^* + r_{12} + (\alpha_1^2 + \alpha_2^2)(r_{11}^2 + |r_{12}|^2) < 0, \tag{89}$$

(90) $$1 - \lambda_1\sigma^2 s_{11}/\alpha_1^2 > 0, \qquad 1 - \lambda_2\sigma^2 s_{22}/\alpha_2^2 > 0.$$

Therefore, $\sigma^2 < \alpha_1^2/(\lambda_1 s_{11}) < 2\alpha_1^2/[\lambda_1(\alpha_1^2 + \alpha_2^2)] < 2/\lambda_1$ and hence $\bar{r} \leq [2/\lambda_1]^{1/2}$.

We will now demonstrate that equality holds. For this let $\lambda_1\sigma^2 = 2(1-\varepsilon) < 2, 1 > \varepsilon > 0$. We must show that there exist $\alpha_1 > 0, \alpha_2 > 0$ such that (89) and (90) hold and $S \succ R^{-1} \succ 0$. Normalizing $\alpha_1^2 + \alpha_2^2 = 1$, (89) becomes

(91) $$s_{11} > 1/2, \qquad (r_{11} - 1)^2 + |r_{12} + 1|^2 - 2 < 0.$$

Choose

$$\alpha_2 = \varepsilon, \quad s_{11} = (1 + \varepsilon/2)/2, \quad r_{12} = s_{12} = 0,$$
$$r_{11} = 2(1 + \varepsilon/3)^{-1}, \quad s_{22} = \varepsilon^2/(2\lambda_2\sigma^2), \quad r_{22} = 3/(2s_{22}).$$

Then it is easy to see that (91) is satisfied. Since

$$1 - \lambda_1\sigma^2 s_{11}/\alpha_1^2 = 1 - (1 + \varepsilon/2)(1 + \varepsilon)^{-1}, \qquad 1 - \lambda_2\sigma^2 s_{22}/\alpha_2^2 = 1 - 1/2,$$

(90) also holds. So all we need to show is $S \succ R^{-1} \succ 0$. But

$$S - R^{-1} = \begin{bmatrix} (1+\varepsilon/2)/2 & 0 \\ 0 & \varepsilon^2/(2\lambda_2\sigma^2) \end{bmatrix} - \begin{bmatrix} (1+\varepsilon/3)/2 & 0 \\ 0 & \varepsilon^2/(3\lambda_2\sigma^2) \end{bmatrix} \succ 0. \qquad \square$$

We conclude the paper with a proposition concerning the *state feedback case*.

PROPOSITION 5.6. *Suppose $p = n$ and C is invertible. Then the following conditions are equivalent for $\sigma \geq 0$:*

(i) *There exists a static feedback matrix $K \in \mathbb{K}^{m\times n}$ such that $\sigma(A + BKC) \subset \mathbb{C}_-$ and $r_{\mathbb{K}}^w(A + BKC; (D_i, E_i)_{i\in\underline{N}}) > \sigma$.*

(ii) *There exists a dynamic output feedback of the form* (53) *such that $\sigma(\mathcal{A}) \subset \mathbb{C}_-$ and $r_{\mathbb{K}}^w(\mathcal{A}; (\mathcal{D}_i, \mathcal{E}_i)_{i\in\underline{N}}) > \sigma$.*

(iii) *There exist $\alpha \in (0,\infty)^{\underline{N}}$, $\gamma > 0$, $R \in \mathcal{H}_n^+(\mathbb{K})$, $R \succ 0$, such that*

$$AR + RA^* + RE(\alpha)^*E(\alpha)R - BB^*/\gamma^2 \prec 0,$$
$$I_{\ell_i} - \lambda_i(\sigma/\alpha_i)^2 D_i^* R^{-1} D_i \succ 0, \qquad i = 1, \ldots, N.$$

(iv) *There exist $\alpha \in (0,\infty)^{\underline{N}}$, $\gamma > 0$ such that the maximal solution $X_{\alpha,\gamma}$ of* ($\mathrm{ARE}_{\alpha,\gamma}$) *satisfies*

$$I_{\ell_i} - \lambda_i(\sigma/\alpha_i)^2 D_i^* X_{\alpha,\gamma} D_i \succ 0, \qquad i = 1, \ldots, N.$$

Proof. Clearly (i) $\Rightarrow$ (ii). (ii) $\Rightarrow$ (iii) follows from Theorem 4.3, and (iii) $\Rightarrow$ (iv) follows from Lemma 5.1. Now suppose (iv). Select an $S \in \mathcal{H}_n(\mathbb{K})$ such that $S \succ X_{\alpha,\gamma}$ and (83) are satisfied. Then choose $\delta > 0$ sufficiently small so that (81) holds. Then (81)–(83) hold, and (ii) follows from Proposition 5.3 and Theorem 4.3. Hence (ii), (iii), and (iv) are equivalent.

It remains to prove, e.g., (iii) $\Rightarrow$ (i). Suppose (iii). Then there exist $\alpha \in (0,\infty)^{\underline{N}}$, $\gamma > 0$, $P \in \mathcal{H}_n^+(\mathbb{K})$, $P \succ 0$, such that

$$PA + A^*P + E(\alpha)^*E(\alpha) - PBB^*P/\gamma^2 \prec 0,$$
$$I_{\ell_i} - \lambda_i(\sigma/\alpha_i)^2 D_i^* P D_i \succ 0, \qquad i = 1, \ldots, N.$$

From the first inequality it follows that

$$P(A - BB^*P/\gamma^2) + (A - BB^*P/\gamma^2)^*P + E(\alpha)^*E(\alpha) \prec 0.$$

Applying Corollary 3.12 we get $r_{\mathbb{K}}^w(A - BB^*P/\gamma^2; (D_i, E_i)_{i\in\underline{N}}) > \sigma$. Thus is suffices to choose $K = -B^*PC^{-1}/\gamma^2$ in order to obtain (i). $\square$

In particular, the proposition shows that it is not possible to obtain a larger stability radius by *dynamic state feedback* than that which can be achieved by *static state feedback*.

In [8] the equivalence (i) $\Leftrightarrow$ (iv) was proven for the special case $E_i = E, i \in \underline{N}$.

6. Appendix. We use the notation introduced in §2. In order to prove Theorem 2.1 we need the following lemmas. First note that the functions f_j, $j \in \underline{N}$, and f in (4) are constant on rays in $(0, \infty)^{\underline{N}}$:

$$f(r\alpha) = f(\alpha), \qquad \alpha \in (0, \infty)^{\underline{N}}, r > 0.$$

LEMMA 6.1. *Suppose that $(\alpha^k)_{k\in N}$ is a sequence in $S_+^N = \{\alpha \in (0, \infty)^{\underline{N}}; \|\alpha\| = 1\}$ and $(f(\alpha^k))_{k\in\mathbb{N}}$ is bounded. If $j \in \underline{N}$ can be reached from $i \in \underline{N}$ via a directed path in $\mathcal{G}$, then*

$$\lim_{k\to\infty} \alpha_j^k = 0 \quad \Rightarrow \quad \lim_{k\to\infty} \alpha_i^k = 0. \tag{92}$$

Proof. By induction it suffices to prove (92) for the case where $(i, j) \in \mathcal{A}$. But in this case $H_{ij} \neq 0$, and thus (92) follows from the boundedness of $(f(\alpha^k))_{k\in\mathbb{N}}$, because

$$f(\alpha^k) \geq f_j(\alpha^k) \geq \left(\frac{\alpha_i^k}{\alpha_j^k}\right)^2 \|H_{ij}\|. \qquad \square$$

Applying this lemma we obtain the following existence result.

PROPOSITION 6.2. *Suppose that $\mathcal{G}$ is strongly connected. Then there exists $\hat{\alpha} \in S_+^N$ such that*

$$f(\hat{\alpha}) = \hat{\mu}. \tag{93}$$

Proof. Since f is constant on rays, it suffices to consider f on S_+^N. Let (α^k) be a minimizing sequence for f on S_+^N which converges toward some limit $\hat{\alpha}$ in the closure of S_+^N. We have only to prove that $\hat{\alpha} \in S_+^N$, i.e., $\hat{\alpha}_i > 0$ for all $i \in \underline{N}$. But if $\hat{\alpha}_j = 0$ for some $j \in \underline{N}$, then since $(f(\alpha^k))$ is bounded and j can be reached from every $i \in \underline{N}$ via a directed path in $\mathcal{G}$, we must have $\hat{\alpha} = 0$ by the previous lemma. On the other hand $\hat{\alpha} \neq 0$ because (α^k) is a sequence in S_+^N. The contradiction shows that $\hat{\alpha}_i > 0$ for all $i \in \underline{N}$. $\square$

LEMMA 6.3. *Suppose H_0, $H \in \mathcal{H}_\ell^+(\mathbb{K})$, and $r_1 < r_2$ are such that*

$$\|H_0 + r_1 H\| = \|H_0 + r_2 H\|.$$

Then

$$\|H_0 + rH\| = \|H_0\|, \qquad 0 \leq r \leq r_2.$$

Proof. Let $v \in \mathbb{K}^\ell$, $\|v\| = 1$, be such that $\langle v, (H_0 + r_1 H)v\rangle = \|H_0 + r_1 H\|$. Then

$$\langle v, (H_0 + r_1 H)v\rangle \leq \langle v, (H_0 + r_2 H)v\rangle \leq \|H_0 + r_2 H\| = \langle v, (H_0 + r_1 H)v\rangle.$$

Hence $Hv = 0$. So $\|H_0 + r_2 H\| = \langle v, H_0 v\rangle \leq \|H_0\|$. But $r \mapsto \|H_0 + rH\|$ is increasing, and hence the result follows. $\square$

Proof of Theorem 2.1. By Proposition 6.2 there is a vector $z \in (0, \infty)^{\underline{N}}$ such that

$$\max_{j\in\underline{N}} \left\| \sum_{i\in\underline{N}} \left(\frac{z_i}{z_j}\right)^2 H_{ij} \right\| = \hat{\mu}.$$

Among all these minimizing vectors we choose one, denoted by $\hat{z}$, for which the number of $j \in \underline{N}$ satisfying

$$\left\| \sum_{i\in\underline{N}} \left(\frac{\hat{z}_i}{\hat{z}_j}\right)^2 H_{ij} \right\| = \hat{\mu} \tag{94}$$

is minimal. Let J be the set of these $j \in \underline{N}$. Then

$$\left\| \sum_{i \in \underline{N}} \left(\frac{\hat{z}_i}{\hat{z}_j} \right)^2 H_{ij} \right\| < \hat{\mu}, \qquad j \in \underline{N} \backslash J. \tag{95}$$

For $r \in [0, 1]$, define $\hat{z}(r) \in (0, \infty)^{\underline{N}}$ by setting $\hat{z}_j(r) = \hat{z}_j$ if $j \in J$ and $\hat{z}_j(r) = r\hat{z}_j$ if $j \in \underline{N} \backslash J$. For r sufficiently close to 1, say $r \in [\hat{r}, 1]$ with $\hat{r} < r$, the inequalities (95) still hold when $\hat{z}$ is replaced by $\hat{z}(r)$. For these r,

$$\left\| \sum_{i \in \underline{N}} \left(\frac{\hat{z}_i(r)}{\hat{z}_j(r)} \right)^2 H_{ij} \right\| = \left\| \sum_{i \in J} \left(\frac{\hat{z}_i}{\hat{z}_j} \right)^2 H_{ij} + r^2 \sum_{i \in \underline{N} \backslash J} \left(\frac{\hat{z}_i}{\hat{z}_j} \right)^2 H_{ij} \right\| \leq \hat{\mu}, \qquad j \in J.$$

But by the minimality assumption on J, none of the above inequalities can be strict for $r \in [\hat{r}, 1]$. Applying Lemma 6.3 with $H_0 = \sum_{i \in J} \left(\frac{\hat{z}_i}{\hat{z}_j} \right)^2 H_{ij}$ and $H = \sum_{i \in \underline{N} \backslash J} \left(\frac{\hat{z}_i}{\hat{z}_j} \right)^2 H_{ij}$ we conclude that

$$\left\| \sum_{i \in \underline{N}} \left(\frac{\hat{z}_i(r)}{\hat{z}_j(r)} \right)^2 H_{ij} \right\| = \left\| \sum_{i \in J} \left(\frac{\hat{z}_i}{\hat{z}_j} \right)^2 H_{ij} \right\| = \hat{\mu}, \qquad r \in [0, 1], \qquad j \in J. \tag{96}$$

Setting $\hat{\alpha}_i = \hat{z}_i(\hat{r})$, $i \in \underline{N}$ it follows from (96), (95) that (6) is satisfied. □

Proof of Proposition 2.2. Let $\hat{\alpha}$ be a minimum such that $J = \{j \in \underline{N};\ f_j(\hat{\alpha}) = \hat{\mu}\}$ has a minimum number of elements, and suppose $J \neq \underline{N}$. Arguing as in the proof of Theorem 2.1 we obtain (see (96))

$$\left\| \sum_{i \in \underline{N}} \left(\frac{\hat{\alpha}_i}{\hat{\alpha}_j} \right)^2 H_{ij} \right\| = \left\| \sum_{i \in J} \left(\frac{\hat{\alpha}_i}{\hat{\alpha}_j} \right)^2 H_{ij} \right\| = \hat{\mu}, \qquad j \in J. \tag{97}$$

If $\hat{\mu} = 0$, (9) is trivially satisfied. Therefore we may assume $\hat{\mu} \neq 0$. Choose $v^j \in \mathbb{K}^{\ell_j}$, $\|v^j\| = 1$, such that

$$\left\| \sum_{i \in J} \left(\frac{\hat{\alpha}_i}{\hat{\alpha}_j} \right)^2 H_{ij} \right\| = \left\langle v^j, \left(\sum_{i \in J} \left(\frac{\hat{\alpha}_i}{\hat{\alpha}_j} \right)^2 H_{ij} \right) v^j \right\rangle.$$

Then

$$v^j \in \left(\ker \left(\sum_{i \in J} \left(\frac{\hat{\alpha}_i}{\hat{\alpha}_j} \right)^2 H_{ij} \right) \right)^{\perp} = \left(\bigcap_{i \in J} \ker H_{ij} \right)^{\perp}, \qquad j \in J,$$

$$\left\langle v^j, \left(\sum_{i \in \underline{N} \backslash J} \left(\frac{\hat{\alpha}_i}{\hat{\alpha}_j} \right)^2 H_{ij} \right) v^j \right\rangle = 0.$$

It follows that $v^j \in \bigcap_{i \in \underline{N} \backslash J} \ker H_{ij} \cap (\bigcap_{i \in J} \ker H_{ij})^{\perp}$ for all $j \in J$, and this contradicts assumption (8). Thus $J = \underline{N}$, and the proposition is proven. □

In the case where $\mathcal{G}$ is not strongly connected, for every $\varepsilon > 0$ we define the set

$$X(\varepsilon) = \left\{ \alpha \in (0, \infty)^{\underline{N}};\ \forall k \in \underline{K-1} : i \in C_k \wedge j \in C_{k+1} \Rightarrow \frac{\alpha_i}{\alpha_j} < \varepsilon \right\}. \tag{98}$$

The proof of the following statement is straightforward.

LEMMA 6.4. *Suppose that, for each* $k \in \underline{K}$, *a positive vector* $z^k \in (0, \infty)^{C_k}$ *is given. Choose* $r_k > 0$ *for all* $k \in \underline{K}$ *such that*

$$\max_{i \in C_k} r_k (z^k)_i < \min_{j \in C_{k+1}} r_{k+1} (z^{k+1})_j, \qquad k = 1, \ldots, K-1,$$

and define $\alpha \in (0, \infty)^{\underline{N}}$ *by*

$$\alpha_i = r_k \varepsilon^{K-k} (z^k)_i, \qquad k \in \underline{K}, i \in C_k.$$

Then

$$\alpha \in X(\varepsilon) \quad \textit{and} \quad \forall i, j \in C_k : \frac{\alpha_i}{\alpha_j} = \frac{(z^k)_i}{(z^k)_j}. \tag{99}$$

LEMMA 6.5. *Given a family of vectors* $z^k \in (0, \infty)^{C_k}$, $k \in \underline{K}$, *satisfying*

$$\max_{j \in C_k} \left\| \sum_{i \in C_k} \left(\frac{(z^k)_i}{(z^k)_j} \right)^2 H_{ij} \right\| = \mu_k, \qquad k \in \underline{K}, \tag{100}$$

(*where* μ_k *is defined by* (12)), *there exists, for every* $\delta > 0$, *a vector* $\alpha \in (0, \infty)^{\underline{N}}$ *such that*

$$f(\alpha) \leq \max_{k \in \underline{K}} \mu_k + \delta \quad \textit{and} \quad \forall k \in \underline{K} \ \forall i, j \in C_k : \frac{\alpha_i}{\alpha_j} = \frac{(z^k)_i}{(z^k)_j}. \tag{101}$$

Proof. Suppose that $z^k \in (0, \infty)^{C_k}$, $k \in \underline{K}$, satisfy (100), and let $\delta > 0$. Then

$$\max_{k \in \underline{K}} \max_{j \in C_k} \left\| \sum_{i \in C_k} \left(\frac{(z^k)_i}{(z^k)_j} \right)^2 H_{ij} \right\| = \max_{k \in \underline{K}} \mu_k.$$

For every $\varepsilon > 0$, there exists, by Lemma 6.4, a vector $\alpha = \alpha(\varepsilon) \in (0, \infty)^{\underline{N}}$ such that (99) is satisfied. It follows that

$$\begin{aligned} f(\alpha(\varepsilon)) &= \max_{k \in \underline{K}} \max_{j \in C_k} \left\| \sum_{h=1}^{k} \sum_{i \in C_h} \left(\frac{\alpha(\varepsilon)_i}{\alpha(\varepsilon)_j} \right)^2 H_{ij} \right\| \\ &\leq \max_{k \in \underline{K}} \max_{j \in C_k} \left\| \sum_{h=1}^{k-1} \sum_{i \in C_h} \left(\frac{\alpha(\varepsilon)_i}{\alpha(\varepsilon)_j} \right)^2 H_{ij} \right\| + \max_{k \in \underline{K}} \mu_k. \end{aligned}$$

But for all $\varepsilon \in (0, 1)$ we have

$$i \in C_h, \quad j \in C_k, \quad \text{and} \quad h < k \quad \Rightarrow \quad \frac{\alpha(\varepsilon)_i}{\alpha(\varepsilon)_j} \leq \varepsilon.$$

Choosing $\varepsilon \in (0, 1)$ such that

$$\max_{k \in \underline{K}} \max_{j \in C_k} \left\| \sum_{h=1}^{k-1} \sum_{i \in C_h} \varepsilon^2 H_{ij} \right\| \leq \delta$$

we obtain

$$f(\alpha(\varepsilon)) \leq \max_{k \in \underline{K}} \mu_k + \delta.$$

This concludes the proof. □

Proof of Theorem 2.4. By Proposition 6.2 there always exists a family of vectors z^k, $k \in \underline{K}$, satisfying (100). Hence by Lemma 6.5 for $\delta > 0$ there exists $\alpha \in (0, \infty)^{\underline{N}}$ such that

$$f(\alpha) \leq \max_{k \in \underline{K}} \mu_k + \delta.$$

But for every $\alpha \in (0, \infty)^{\underline{N}}$,

$$f(\alpha) = \max_{k \in \underline{K}} \max_{j \in C_k} \left\| \sum_{h=1}^{k} \sum_{i \in C_h} \left(\frac{\alpha_i}{\alpha_j} \right)^2 H_{ij} \right\| \geq \max_{k \in \underline{K}} \max_{j \in C_k} \left\| \sum_{i \in C_k} \left(\frac{\alpha_i}{\alpha_j} \right)^2 H_{ij} \right\| \geq \max_{k \in \underline{K}} \mu_k.$$

Since $\hat{\mu} = \inf_{\alpha \in (0,\infty)^{\underline{N}}} f(\alpha)$, we conclude that $\hat{\mu} = \max_{k \in \underline{K}} \mu_k$. The second part of Theorem 2.4 follows from this and Theorem 2.1. □

LINEARIZATION OF DISCRETE-TIME SYSTEMS*

E. ARANDA-BRICAIRE†, Ü. KOTTA‡, AND C. H. MOOG§

Abstract. The algebraic formalism developed in this paper unifies the study of the accessibility problem and various notions of feedback linearizability for discrete-time nonlinear systems. The accessibility problem for nonlinear discrete-time systems is shown to be easy to tackle by means of standard linear algebraic tools, whereas this is not the case for nonlinear continuous-time systems, in which case the most suitable approach is provided by differential geometry. The feedback linearization problem for discrete-time systems is recasted through the language of differential forms. In the event that a system is not feedback linearizable, the largest feedback linearizable subsystem is characterized within the same formalism using the notion of derived flag of a Pfaffian system. A discrete-time system may be linearizable by dynamic state feedback, though it is not linearizable by static state feedback. Necessary and sufficient conditions are given for the existence of a so-called linearizing output, which in turn is a sufficient condition for dynamic state feedback linearizability.

Key words. nonlinear discrete-time systems, algebraic methods, accessibility, feedback linearization, differential forms, Pfaffian systems

1. Introduction.

Suppose one is given a discrete-time nonlinear (analytic) system Σ. The goal of this paper is to develop a formalism that provides answers to the following four questions.

Question 1. Is there a neighborhood from which the system Σ is (forward) accessible?

Question 2. Does there exist a regular static state feedback and a state diffeomorphism such that in new coordinates the system Σ reads as a linear controllable system in Brunovsky canonical form?

Question 3. If the answer to Question 2 is negative, then which is the largest feedback linearizable subsystem contained in Σ?

Question 4. If the answer to Question 2 is negative, then does there exist a dynamic state feedback such that the extended system becomes linearizable by static state feedback and state diffeomorphism?

Question 1 has originated a great amount of work; cf. [2, 29, 30] and the references therein. Current literature characterizes pointwise accessibility, whereas we will consider accessibility in a generic sense. Another difference from our work is that we replaced the assumption of invertibility of the discrete-time dynamics by the weaker assumption of submersivity, which is, by the way, invariant under regular static state feedback. On the other hand, our algebraic formalism seems to be a natural tool for the analysis of discrete-time systems.

Question 2 has also received a lot of attention; cf. [21, 27, 31, 34, 35, 45, 46]. The problem consists of finding candidates for output functions whose feedback linearization (as done in [36, 37, 40, 41, 42, 43]) fully linearizes the state equation. The interest of recasting the problem of static state feedback linearization is that it fits nicely in our formalism. For example, it can be viewed as a special case of the answer to Questions 3 and 4.

For nonlinear continuous-time systems, Question 3 was solved in [38]. However, this problem has never been studied for discrete-time systems. The solution that we provide to this problem can be seen as a dual version of the differential geometric approach used in [38].

The dynamic feedback linearization problem is a challenging research problem. Although in the continuous-time case it has been tackled by several authors (cf. [5, 8, 9, 17, 18, 19, 28, 47, 48, 49]), a complete answer is still missing. To our best knowledge, this problem has never been addressed for discrete-time systems. It should be acknowledged, however, that the idea of using a dynamic compensator in order to linearize fully a discrete-time system with outputs was outlined in [44]. We give necessary and sufficient conditions for a nonlinear discrete-time system to admit a so-called linearizing output [17]. This is a sufficient condition for dynamic feedback linearizability.

Preliminary results of this work have been presented in [3, 4].

The contributions of this paper are organized around the classification of one-forms (not necessarily exact) with respect to their relative degree. Our mathematical formalism employs several results both from difference algebra and from exterior differential systems. For the reader's convenience, these results are briefly summarized in §2.

The paper is organized in the following manner. In §3 we develop the algebraic formalism that will allow us to tackle the problems stated above. In §4 we give three equivalent conditions for a discrete-time system to be (forward) accessible. The feedback linearization problem is addressed in §5. Necessary and sufficient conditions are derived under which a discrete-time system is fully linearizable by regular static state feedback and coordinates transformation. When these conditions are not met, it is interesting to characterize the largest feedback linearizable subsystem. This is done in §6. In §7 we define the notion of linearizing output and show its relation with the dynamic feedback linearization problem. Finally, concluding remarks are offered in §8.

2. Mathematical preliminaries.

2.1. Difference algebra. J. F. Ritt founded the branch of mathematics known as difference algebra in the late thirties. His aim was to provide difference equations with a formalism as powerful as commutative algebra is for algebraic equations. Fifty years later, M. Fliess used this formalism for the analysis of discrete-time nonlinear systems [14]. Some basic definitions of difference algebra are recalled in this section. For an introductory exposition of difference algebra we refer the reader to [14], and for a complete panorama of the subject to [11].

A difference ring $\mathcal{B}$ is a pair consisting of a commutative ring $\mathcal{U}$—called the underlying ring—and a monomorphism τ of $\mathcal{U}$ onto a subring $\mathcal{U}'$—called the transforming operator. If $a \in \mathcal{U}$ and $\tau^{-1}a$ is defined, it is unique and is called the inverse transform of a. If $\tau^{-1}a$ is defined for all $a \in \mathcal{U}$, then $\mathcal{B}$ is said to be inversive. $\mathcal{B}$ is inversive if and only if $\mathcal{U}' = \mathcal{U}$.

A difference ring $\mathcal{D} = (\mathcal{S}, \sigma)$ is called a difference overring of the difference ring $\mathcal{B} = (\mathcal{U}, \tau)$ if $\mathcal{S}$ is an overring of $\mathcal{U}$ in the sense of ring theory and if $\tau : \mathcal{U} \to \mathcal{U}$ is a contraction of $\sigma : \mathcal{S} \to \mathcal{S}$. A pair such as $(\mathcal{D}, \mathcal{B})$ is called a difference ring extension and is denoted by the symbol $\mathcal{D}/\mathcal{B}$. An isomorphism of the difference extension $\mathcal{D}/\mathcal{B}$ into the difference extension $\mathcal{D}'/\mathcal{B}$ is an isomorphism of difference rings that leaves fixed every element of the difference ring $\mathcal{B}$.

If rings are replaced by fields in the preceding discussion, one obtains the definitions of difference field, inversive difference field, difference overfield, and difference field extension.

It is often helpful to work with difference rings that are inversive. The inversive closure of a difference ring $\mathcal{B}$ is defined to be a difference overring $\mathcal{D}$ that is inversive and is such that, for every $a \in \mathcal{D}$, there exists an integer $r \geq 0$ such that $\tau^r a \in \mathcal{B}$.

It is proved [11] that every difference ring admits an inversive closure. The inversive closure is not unique, but any two inversive closures of a given difference ring are isomorphic. Finally notice that the inversive closure of a difference field is a difference field as well.

In §3 we define a difference field associated to a discrete-time nonlinear system. A practical procedure for the construction of the inversive closure of this difference field is given in Appendix A.

2.2. Exterior differential systems. The material of this section has been borrowed from [6, 10]. Henceforth, it is assumed that the reader is comfortable with the notions of analytic manifold, vector fields, differential forms, Lie derivative, and Lie bracket [1, 50].

Given an analytic manifold M, which in general will be $\mathbb{R}^N$ for some positive integer N, we adopt the following notation. TM denotes the tangent bundle, T^*M the cotangent bundle, $C^\omega(M)$ the ring of analytic functions defined over M, $V(M)$ the set of analytic vector fields defined over M, and $\Omega^p(M)$ the set of differential p-forms. In particular, $\Omega^0(M) = C^\omega(M)$ and $\Omega^1(M) = T^*M$. $V(M)$ and $\Omega^p(M)$ are $C^\omega(M)$-modules.

Let $\{x_i\}$ be a system of local coordinates of M. Thus $\{\mathrm{d}x_i\}$ is a system of local coordinates of the cotangent bundle. In this frame, every p-form $\alpha \in \Omega^p(M)$ has a unique representation of the form

$$\alpha = \sum_{i_1<\cdots<i_p} a_{i_1,\ldots,i_p}\mathrm{d}x_{i_1} \wedge \cdots \wedge \mathrm{d}x_{i_p}, \qquad a_{i_1,\ldots,i_p} \in C^\omega(M).$$

The exterior product of a p-form α and a q-form β is a mapping

$$\wedge : \Omega^p(M) \times \Omega^q(M) \to \Omega^{(p+q)}(M),$$

which is bilinear and associative. In general, the exterior product is not commutative. Instead, it satisfies the relation $\alpha \wedge \beta = (-1)^{pq}\beta \wedge \alpha$. This relation implies that

1. if α is an odd form, then $\alpha \wedge \alpha \equiv 0$.
2. the exterior product of a p-form α and a q-form β commutes if pq is even.

The exterior differential d is an $\mathbb{R}$-linear operator

$$\mathrm{d} : \Omega^p(M) \to \Omega^{p+1}(M),$$

which satisfies the following properties.

1. $\mathrm{d}(\alpha \wedge \beta) = \mathrm{d}\alpha \wedge \beta + (-1)^p\alpha \wedge \mathrm{d}\beta$, where p is the degree of α.
2. If $f \in C^\omega(M)$ f, then $\mathrm{d}f$ coincides with ordinary differential.
3. $\mathrm{d}^2 = 0$.

These properties uniquely define the operator d.

A differential p-form $\alpha \in \Omega^p(M)$ is said to be closed if $\mathrm{d}\alpha = 0$. It is said to be exact if there exists a differential $(p-1)$-form $\beta \in \Omega^{(p-1)}(M)$ such that $\alpha = \mathrm{d}\beta$. An exact differential form is closed. Poincaré's lemma states that the converse holds locally.

A Pfaffian system I is a $C^\omega(M)$-submodule of the cotangent bundle. The rank of a Pfaffian system I at point x is the dimension of the submodule $I_x \subset T_x^*M$. The rank depends in general on the point x, but if it is maximal at point x, then it is constant in a neighborhood of x.

An algebraic ideal $\mathcal{I}$ is a $C^\omega(M)$-module of differential forms that is also an ideal with respect to the exterior product. An exterior differential system is an algebraic ideal $\mathcal{I}$ that is stable with respect to exterior differentiation.

Frobenius's theorem states that in the event that the algebraic ideal and the exterior differential system generated by a Pfaffian system I coincide, then there exists a collection of exact forms that generates I.

THEOREM 2.1 (Frobenius). *Let I be a Pfaffian system generated by the one-forms $\{\omega_1 \dots, \omega_s\}$. Suppose that the condition*

$$d\omega_k \wedge \omega_1 \wedge \cdots \wedge \omega_s = 0, \qquad k = 1, \dots, s,$$

is satisfied. Then, there exists locally a system of coordinates $\{x_i\}$ such that I is generated by $\{dx_1, \dots, dx_s\}$. In this case, the Pfaffian system I is said to be completely integrable.

The interior product by a vector field $X \in V(M)$ is an $\mathbb{R}$-linear operator

$$X\lrcorner : \Omega^p(M) \to \Omega^{p-1}(M),$$

which satisfies the following properties.

1. $X \lrcorner (\alpha \wedge \beta) = (X \lrcorner \alpha) \wedge \beta + (-1)^p \alpha \wedge (X \lrcorner \beta)$, where p is the degree of α.
2. $\forall f \in \Omega^0(M),\ X \lrcorner f = 0$.
3. $X \lrcorner dx_i = X_i$, where X_i is the i-th component of X.

The characteristic vector fields associated with an exterior differential system $\mathcal{I}$ are the elements of the set

$$A(\mathcal{I}) = \{X \in V(M) \mid X \lrcorner \mathcal{I} \subset \mathcal{I}\}.$$

The annihilator $C(\mathcal{I})$ of $A(\mathcal{I})$ is the characteristic system of $\mathcal{I}$. The characteristic system is completely integrable.

The first derived system of a Pfaffian system $\mathcal{I}$ is defined by

$$I^{(1)} = \{\omega \in I \mid d\omega \equiv 0 \bmod I\},$$

where mod I means modulo the algebraic ideal generated by I. The first derived system is again a Pfaffian system. Higher order derived systems are defined by $I^{(k+1)} = (I^{(k)})^{(1)}$ and yield the filtration $I \supset I^{(1)} \supset \cdots \supset I^{(k)}$, which is called the derived flag. Let K be the smallest integer such that $I^{(K+1)} = I^{(K)}$. It is proved that such an integer exists. $I^{(K)}$ is called the bottom derived system, and K the derived length. The bottom derived system is the largest completely integrable subsystem contained in I.

3. Algebraic formalism. The material that we shall develop in this section is related to the linear algebraic approach introduced by Grizzle [22] and with the difference algebraic approach introduced by Fliess [13, 14] for the analysis of discrete-time systems. The ground field $\mathcal{K}^*$ that we consider below can be viewed as a field extension of the field $\mathcal{K}$ of meromorphic functions that was already defined in [22]. As a matter of fact, $\mathcal{K}^*$ is the inversive closure of $\mathcal{K}$ that is unique up to an isomorphism.

Working with $\mathcal{K}$ instead of $\mathcal{K}^*$ leads to sets of one-forms whose dimension or whose integrability properties are not the appropriate tool for characterizing accessibility or for solving the various feedback linearization problems.

Consider the discrete-time nonlinear system

$$\Sigma : x(t+1) = f(x(t), u(t)), \qquad t = 0, 1, \dots, \tag{1}$$

where $x(t) \in \mathbb{R}^n$, $u(t) \in \mathbb{R}^m$, and the map

$$f : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$$

is supposed to be analytic and generically to define a submersion, i.e.,

$$\operatorname{rank} \frac{\partial f}{\partial (x, u)} = n.$$

The assumption that the discrete-time system Σ admits the (global) analytic representation (1) may be a disadvantage in some cases. This may be circumvented by stating our results locally. As in [2], equations (1) are assumed to hold only for positive time, which is not the case in [15]. Throughout the paper it is also assumed that

$$\operatorname{rank} \frac{\partial f}{\partial u} = m.$$

Except in §6, where dynamic state feedbacks will be considered, through the paper we shall consider regular static state feedbacks, which are defined as follows.

DEFINITION 3.1. *A regular static state feedback is a mapping*

$$\begin{aligned} u : \mathbb{R}^n \times \mathbb{R}^m &\to \mathbb{R}^m, \\ (x(t), v(t)) &\mapsto u(t) = \varphi(x(t), v(t)) \end{aligned} \tag{2}$$

such that

$$\operatorname{rank} \frac{\partial \varphi}{\partial v} = m.$$

Let $\mathcal{R}$ denote the ring of analytic functions in a finite number of the variables $\{x(0), u(t), t \geq 0\}$; and let $\mathcal{K}$ be its associated quotient field, i.e., the field of meromorphic functions in a finite number of the variables $\{x(0), u(t), t \geq 0\}$. The forward-shift operator $\delta : \mathcal{R} \to \mathcal{R}$ is defined by

$$\delta \varphi(x(0), u(0), \ldots, u(N)) = \varphi(f(x(0), u(0)), u(1), \ldots, u(N+1)).$$

The mapping $\delta : \mathcal{R} \to \mathcal{R}$ is injective, thanks to the following technical lemma [22].

LEMMA 3.2. *Assume that the system Σ is submersive. Hence the kernel of the endomorphism $\delta : \mathcal{R} \to \mathcal{R}$ is trivial.*

Thus, the pair $(\mathcal{R}, \delta)$ is a difference ring [11, 14]. Moreover, Lemma 3.2 also implies that the mapping $\delta : \mathcal{K} \to \mathcal{K}$ is well defined. Hence the pair $(\mathcal{K}, \delta)$ is a difference field [11, 14]. $(\mathcal{K}, \delta)$ is not inversive in general. Nevertheless, it is always possible to embed $\mathcal{K}$ into an inversive difference overfield $\mathcal{K}^*$, called the *inversive closure* [11, 14] of $\mathcal{K}$. With a slight abuse of notation, we denote by $\delta : \mathcal{K}^* \to \mathcal{K}^*$ the forward-shift operator that extends $\delta : \mathcal{K} \to \mathcal{K}$. Sometimes the abridged notation $\varphi^+(\cdot) = \delta\varphi(\cdot)$ and $\varphi^-(\cdot) = \delta^{-1}\varphi(\cdot)$ are used.

The inversive closure of $\mathcal{K}$ is unique up to an isomorphism [11]. From now, we assume that the inversive closure $\mathcal{K}^*$ is given. A practical procedure for the construction of $\mathcal{K}^*$ is given in Appendix A.

Let $\mathcal{F} = \operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}\varphi \mid \varphi \in \mathcal{K}^*\}$. The operators δ and δ^{-1} induce, respectively, the operators $\Delta : \mathcal{F} \to \mathcal{F}$ and $\Delta^{-1} : \mathcal{F} \to \mathcal{F}$ by

$$\begin{aligned} \Delta(\textstyle\sum_i a_i \mathrm{d}\varphi_i) &\mapsto \textstyle\sum_i a_i^+ \mathrm{d}\varphi_i^+, \\ \Delta^{-1}(\textstyle\sum_i a_i \mathrm{d}\varphi_i) &\mapsto \textstyle\sum_i a_i^- \mathrm{d}\varphi_i^-. \end{aligned}$$

With some abuse of notation, sometimes we write $\omega^+ = \Delta\,\omega$ and $\omega^- = \Delta^{-1}\omega$. The elements of $\mathcal{F}$ are called one-forms. Hereafter, for any set $\mathcal{W}$ of one-forms, the notation $\mathcal{W}^+$ should be understood elementwise.

Let us investigate the following introductory example.

Example 3.3. Consider the nonlinear control system

$$\begin{aligned} x_1(t+1) &= u_1(t), \\ x_2(t+1) &= x_3(t)u_1(t), \\ x_3(t+1) &= u_2(t). \end{aligned} \tag{3}$$

For system (3), one can readily check that

$$\begin{aligned}\operatorname{span}_{\mathcal{K}}\{\mathrm{d}x(1)\} \cap \operatorname{span}_{\mathcal{K}}\{\mathrm{d}x(0)\} &= \operatorname{span}_{\mathcal{K}}\{\mathrm{d}x_2(1) - x_3(0)\mathrm{d}x_1(1)\} \\ &= \operatorname{span}_{\mathcal{K}}\{\mathrm{d}x_3(0)\}.\end{aligned}$$

More precisely, $x_3(0) = x_2(1)/x_1(1)$. Thus, a pre-image in $\mathcal{K}$ (through δ) of $x_3(0)$ is $x_2(0)/x_1(0)$. Whereas $x_3(0)$ has a pre-image in $\mathcal{K}$, $x_1(0)$ and $x_2(0)$ have none. According to the procedure given in Appendix A (see also the Proof of Theorem II in pp. 66–67 of [11]), the construction of the inversive closure of $\mathcal{K}$ amounts to embed $\mathcal{K}$ into an overfield $\mathcal{K}^*$ and extend δ in such a way that $\delta : \mathcal{K}^* \to \mathcal{K}^*$ becomes an automorphism. For our example, $\mathcal{K}^*$ is nothing but the field of meromorphic functions in a finite number of the variables $\{x(0), u(t), u(-k), z(-k)\ t \geq 0,\ k \geq 1\}$, where $z(-k) = [z_1(-k), z_2(-k)]$, subject to $\delta(z_1(-1)) = x_1(0)$ and $\delta(z_2(-1)) = x_2(0)$.

We now continue with the analysis of the general case. The relative degree r of a one-form $\omega(0) \in \operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x(0), \mathrm{d}u(0)\}$ is defined to be

$$r = \min\{k \geq 0 \mid w(k) = \Delta^k \omega(0) \notin \operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x(0)\}\}.$$

If such an integer does not exist, set $r = \infty$. The relative degree of a meromorphic function $\varphi(x(0), u(0))$ is defined to be the relative degree of the one-form $\mathrm{d}\varphi(x(0), u(0))$.

Introduce the sequence of subspaces $\mathcal{H}_0 \supset \mathcal{H}_1 \supset \cdots \supset \mathcal{H}_k$ of $\mathcal{F}$ defined by

$$\begin{aligned}\mathcal{H}_0 &= \operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x(0), \mathrm{d}u(0)\}, \\ \mathcal{H}_k &= \Delta^{-k}\left(\mathcal{H}_0 \cap \Delta\mathcal{H}_0 \cap \cdots \cap \Delta^k \mathcal{H}_0\right),\end{aligned} \tag{4}$$

where $\Delta\mathcal{H}_0 = \operatorname{span}_{\mathcal{K}^*}\{\omega^+ \mid \omega \in \mathcal{H}_0\}$ and $\Delta^k\mathcal{H}_0 = \operatorname{span}_{\mathcal{K}^*}\{\omega^+ \mid \omega \in \Delta^{k-1}\mathcal{H}_0\}$, $k \geq 1$.

PROPOSITION 3.4. 1. *For $k \geq 0$, $\mathcal{H}_k$ is the space of one-forms whose relative degree is greater than or equal to k.*

2. *There exists an integer $k^* \leq n$ such that, for $0 \leq k \leq k^*$, $\mathcal{H}_{k+1} \subset \mathcal{H}_k$ but $\mathcal{H}_{k+1} \neq \mathcal{H}_k$ and $\mathcal{H}_{k^*+1} = \mathcal{H}_{k^*+2} = \cdots = \mathcal{H}_\infty$.*

3. *The subspaces $\mathcal{H}_k$ are invariant under regular static state feedback and under state diffeomorphism.*

Proof. Point 1 is clear because the $\mathcal{H}_k$'s can alternatively be defined by

$$\mathcal{H}_k = \operatorname{span}_{\mathcal{K}^*}\{\omega \in \mathcal{H}_{k-1} \mid \omega^+ \in \mathcal{H}_{k-1}\}, \qquad k \geq 1.$$

In particular, $\mathcal{H}_1 = \operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x(0)\}$. Existence of the integer k^* comes from the fact that each $\mathcal{H}_k$ is a finite-dimensional $\mathcal{K}^*$-vector space so that, at each step, either its dimension decreases or $\mathcal{H}_{k+1} = \mathcal{H}_k$. Moreover, $k^* \leq n = \dim_{\mathcal{K}^*} \mathcal{H}_1$. Feedback invariance comes from the fact that the relative degree is obviously invariant under regular static state feedback. □

THEOREM 3.5. *Suppose $\mathcal{H}_\infty = 0$. Then there exists a list of integers $r_1, \ldots, r_m$, invariant under regular static state feedback, and m one-forms $\omega_1(0), \ldots, \omega_m(0) \in \operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x(0)\}$ whose relative degrees are, respectively, $r_1, \ldots, r_m$ such that*

1. $\operatorname{span}_{\mathcal{K}^*}\{\omega_i(k), 1 \leq i \leq m, 0 \leq k \leq r_i - 1\} = \operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x(0)\}$.
2. $\operatorname{span}_{\mathcal{K}^*}\{\omega_i(k), 1 \leq i \leq m, 0 \leq k \leq r_i\} = \operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x(0), \mathrm{d}u(0)\}$.
3. *The one-forms $\{\omega_i(k), 1 \leq i \leq m, k \geq 0\}$ are linearly independent; in particular, $\sum_i r_i = n$.*

Proof. Let $\mathcal{W}_{k^*}$ be a basis for $\mathcal{H}_{k^*}$. By definition, $\mathcal{W}_{k^*}$ and $\mathcal{W}_{k^*}^+$ are in $\mathcal{H}_{k^*-1}$. We next prove that $\mathcal{W}_{k^*}$ and $\mathcal{W}_{k^*}^+$ are linearly independent. Let $\mathcal{W}_{k^*} = \{\eta_1, \ldots, \eta_{\rho_{k^*}}\}$; then $\mathcal{W}_{k^*}^+ = \{\eta_1^+, \ldots, \eta_{\rho_{k^*}}^+\}$. Suppose, contrary to our claim, that $\mathcal{W}_{k^*}$ and $\mathcal{W}_{k^*}^+$ are linearly dependent. This means that there exist some coefficients λ_i, μ_i, $1 \leq i \leq \rho_{k^*}$, which are not all zero, such that

$$\sum_{i=1}^{\rho_{k^*}} (\lambda_i \eta_i + \mu_i \eta_i^+) = 0. \tag{5}$$

The linear independence of the η_i's implies that not all the μ_i's vanish. Now, consider the one-form $\omega = \sum_i \mu_i^- \eta_i \in \mathcal{H}_{k^*}$ whose forward-time shift is, by (5),

$$\omega^+ = \sum_i \mu_i \eta_i^+ = -\sum_i \lambda_i \eta_i \in \mathcal{H}_{k^*}.$$

So, equality (5) implies that $\omega \in \mathcal{H}_{k^*+1} = \mathcal{H}_\infty$, which contradicts our assumption $\mathcal{H}_\infty = 0$. Hence, it is always possible to choose a set (possibly empty) $\mathcal{W}_{k^*-1}$ such that $\mathcal{W}_{k^*} \cup \mathcal{W}_{k^*}^+ \cup \mathcal{W}_{k^*-1}$ is a basis for $\mathcal{H}_{k^*-1}$. Repeating this procedure $k^* - 1$ times we obtain

$$\mathcal{H}_k = \operatorname{span}_{\mathcal{K}^*}\{\mathcal{W}_i(j),\ k \le i \le k^*,\ 0 \le j \le i-k\}, \qquad 0 \le k \le k^*.$$

The assumption $\operatorname{rank} \frac{\partial f}{\partial u} = m$ implies $\mathcal{W}_0 = \emptyset$. Finally, set

$$\{\omega_1(0), \ldots, \omega_m(0)\} = \mathcal{W}_{k^*} \cup \cdots \cup \mathcal{W}_1.$$

Since the subspaces $\mathcal{H}_k$ are invariant under regular static state feedback, the invariance of the integers $\{r_i\}$ is obvious from the construction. □

COROLLARY 3.6. *Suppose $\mathcal{H}_\infty = 0$. Then there exists a basis*

$$\{\omega_{i,j}(0),\ 1 \le i \le m,\ 1 \le j \le r_i\}$$

of $\operatorname{span}_{\mathcal{K}^*}\{dx(0)\}$ *such that the first-order approximation of* Σ *yields the infinitesimal Brunovsky form*

$$\begin{aligned}
\omega_{i,1}(t+1) &= w_{i,2}(t),\\
\omega_{i,2}(t+1) &= w_{i,3}(t),\\
&\vdots\\
\omega_{i,r_i-1}(t+1) &= w_{i,r_i}(t),\\
\omega_{i,r_i}(t+1) &= \textstyle\sum_{s=1}^m \sum_{j=1}^{r_s} a_{s,j}^i w_{s,j}(t) + \sum_{j=1}^m b_j^i du_j(t), \qquad 1 \le i \le m,
\end{aligned} \tag{6}$$

where $a_{s,j}^i$, $b_j^i \in \mathcal{K}^*$ and $[b_j^i]$ has an inverse in the ring of $m \times m$ matrices with entries in $\mathcal{K}^*$.

Proof. For $1 \le i \le m$ and $1 \le j \le r_i$, take $\omega_{i,j}(0) = \omega_i(j-1)$. □

Example 3.7. Consider the nonlinear discrete-time system

$$\begin{aligned}
x_1(t+1) &= u_1(t), & x_4(t+1) &= x_5(t)u_1(t),\\
x_2(t+1) &= x_3(t)u_1(t), & x_5(t+1) &= x_6(t)u_1(t),\\
x_3(t+1) &= x_4(t)u_1(t), & x_6(t+1) &= u_2(t).
\end{aligned} \tag{7}$$

For system (7), one has

$$\begin{aligned}
\operatorname{span}_{\mathcal{K}^*}\{dx(0)\} \cap \operatorname{span}_{\mathcal{K}^*}\{dx(1)\} &= \operatorname{span}_{\mathcal{K}^*}\{dx_i(1) - x_{i+1}(0)dx_1(1),\ i = 2, \ldots, 5\}\\
&= \operatorname{span}_{\mathcal{K}^*}\{u_1(0)dx_i(0),\ i = 3, \ldots, 6\}.
\end{aligned}$$

In fact, it is straightforward to check that

$$x_i(0) = \frac{x_{i-1}(1)}{x_1(1)} = \delta\left(\frac{x_{i-1}(0)}{x_1(0)}\right), \qquad i = 3, \ldots, 6. \tag{8}$$

This shows that $x_i(-1)$, for $i = 3, \ldots, 6$, must not be considered as independent variables in the sense that they can be expressed as functions of $x(0)$. This is not the case for $x_1(-1)$ and $x_2(-1)$, which cannot be expressed as functions of $x(0)$. Thus we can choose, according to the procedure given in Appendix A, $z(0) = (x_1(0), x_2(0))$.

We carry out the computations necessary to bring forward the infinitesimal Brunovsky form associated with the system described by (7). We know that $\mathcal{H}_1 = \operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x(0)\}$ and we already computed

$$\operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x(0)\} \cap \operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x(1)\} = \operatorname{span}_{\mathcal{K}}\{\mathrm{d}x_i(1) - x_{i+1}(0)\mathrm{d}x_1(1),\ i = 2, \ldots, 5\}.$$

Thus, using (8), one obtains

$$\mathcal{H}_2 = \Delta^{-1}(\mathcal{H}_1 \cap \Delta\,\mathcal{H}_1) = \operatorname{span}_{\mathcal{K}^*}\{x_1(0)\mathrm{d}x_i(0) - x_i(0)\mathrm{d}x_1(0),\ i = 2, \ldots, 5\}.$$

In a similar vein, one may check that

$$\begin{aligned}
\mathcal{H}_3 &= \operatorname{span}_{\mathcal{K}^*}\{x_2(0)\mathrm{d}x_3(0) - x_3(0)\mathrm{d}x_2(0),\ x_2(0)\mathrm{d}x_4(0) - x_4(0)\mathrm{d}x_2(0)\},\\
\mathcal{H}_4 &= \operatorname{span}_{\mathcal{K}^*}\{x_2(0)\mathrm{d}x_3(0) - x_3(0)\mathrm{d}x_2(0)\},\\
\mathcal{H}_5 &= 0.
\end{aligned}$$

Up to multiplication by a nonzero function, the choice of ω_1 is unique. Namely

$$\omega_1 = x_2(0)\mathrm{d}x_3(0) - x_3(0)\mathrm{d}x_2(0),$$

whose relative degree is $r_1 = 4$. For ω_2 it suffices to pick any one-form $\omega_2 \in \mathcal{H}_2$ independent of $\omega_1(0)$, $\omega_1(1)$, $\omega_1(2)$. Let

$$\omega_2 = x_1(0)\mathrm{d}x_2(0) - x_2(0)\mathrm{d}x_1(0),$$

whose relative degree is $r_2 = 2$. Finally set $\omega_{i,j} = \omega_i(j-1)$, for $i = 1, 2$, $j = 1, \ldots, r_i$. In coordinates $\omega_{i,j}$, the first-order approximation of (7) takes the infinitesimal Brunovsky form (6).

4. Accessibility. Following the notation in [30] we shall denote by $A_k(x)$ the set of points reachable from x in k forward steps using arbitrary sequences of controls

$$\mathbf{u} = (u(0), \ldots, u(k-1)) \in (\mathbb{R}^m)^k.$$

Denote by $A(x)$ the set of points reachable from x in any number of forward steps using arbitrary sequences of controls. That is, $A(x) = \bigcup_{k\geq 0} A_k(x)$. The system Σ is forward accessible from x if its reachable set $A(x)$ has nonempty interior. A generic notion of accessibility can be derived from this pointwise definition as in [2, §5].

DEFINITION 4.1 (see [2]). *System Σ is said to be (forward) accessible if its reachable set $A(x)$ has a nonempty interior in $\mathbb{R}^n$ for almost all $x \in \mathbb{R}^n$.*

Associated with Σ there is a family of maps

$$f_u = f(\cdot, u) : \mathbb{R}^n \to \mathbb{R}^n, \qquad u \in \mathbb{R}^m.$$

If we apply a sequence of controls $\mathbf{u}$, then we obtain the composition of such maps, which is denoted by

$$f_{\mathbf{u}} = f_{u(k-1)} \circ \cdots \circ f_{u(0)} : \mathbb{R}^n \to \mathbb{R}^n.$$

Conversely, for each fixed state x define the transition map

$$\begin{aligned}
\Gamma(k, x)(\mathbf{u}) : (\mathbb{R}^m)^k &\to \mathbb{R}^n,\\
\mathbf{u} &\mapsto f_{\mathbf{u}}(x).
\end{aligned}$$

By definition, $A_k(x) = \operatorname{Im}\Gamma(k, x)(\mathbf{u})$.

PROPOSITION 4.2 (see [30]). *The interior of the reachable set $A_k(x)$ is nonempty if and only if*

$$\sup\left\{\operatorname{rank}\frac{\partial}{\partial \mathbf{u}}\Gamma(k,x)(\mathbf{u}),\ \mathbf{u}\in(\mathbb{R}^m)^k\right\}=n.$$

Thus, system Σ is (forward) accessible if and only if

$$\sup_{x\in\mathbb{R}^n}\left\{\operatorname{rank}\frac{\partial}{\partial \mathbf{u}}\Gamma(k,x)(\mathbf{u}),\ \mathbf{u}\in(\mathbb{R}^m)^k,\ k\geq 1\right\}=n.$$

It was pointed out in [30] that Proposition 4.2 does not provide a practical test of accessibility mainly because from a computational point of view the composition of functions is a difficult task. In the rest of this section we develop alternative accessibility criteria that require only a reduced number of algebraic operations.

From this point, we make extensive use of the results on exterior differential systems presented in §1. However, we need to state some facts in order to employ such results. Notice that the elements of $\mathcal{K}^*$ are defined over a space that is isomorphic to $\mathbb{R}^\infty$ and hence is not a Banach space. It turns out that the results of §1 do not apply to general subspaces of $\mathcal{F}$, viewed as Pfaffian systems. Nevertheless, the filtration

$$\operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x(0)\}=\mathcal{H}_1\supset\mathcal{H}_2\supset\cdots\supset\mathcal{H}_{k^*}\supset\mathcal{H}_{k^*+1}=\mathcal{H}_\infty \tag{9}$$

has some nice properties that we examine next.

LEMMA 4.3. *For $1\leq k\leq k^*+1$, there exist ρ_k one-forms $\omega_1,\ldots,\omega_{\rho_k}$ that depend only on the variables $\{x(0),u(-j),z(-j),\ j\leq k-1\}$ and constitute a basis for $\mathcal{H}_k$.*

Proof. We proceed by induction. Lemma 4.3 is evidently true for $k=1$. Suppose it is also true for some integer $k\geq 1$. Let $\{\eta_1,\ldots,\eta_{\rho_k},\mu_1,\ldots,\mu_{\rho_{k-1}-\rho_k}\}$ and $\{\eta_1,\ldots,\eta_{\rho_k}\}$ be, respectively, bases of $\mathcal{H}_{k-1}$ and $\mathcal{H}_k$. An arbitrary element $\omega=\sum_i a_i\eta_i\in\mathcal{H}_k$ belongs to $\mathcal{H}_{k+1}$ if and only if $\omega^+=\sum_i a_i^+\eta_i^+\in\mathcal{H}_k$. Notice, since $\eta_i\in\mathcal{H}_k$, it follows that $\eta_i,\ \eta_i^+\in\mathcal{H}_{k-1}$. Hence,

$$\omega^+=\sum_i a_i^+\left(\sum_j b_{ij}\eta_j+\sum_\ell c_{i\ell}\mu_\ell\right).$$

Thus, $\omega\in\mathcal{H}_{k+1}$ if and only if the a_i^+'s satisfy the system of linear equations

$$\sum_i a_i^+c_{i\ell}=0,\qquad 1\leq\ell\leq\rho_{k-1}-\rho_k. \tag{10}$$

To each nontrivial solution a_i^+ of (10) corresponds a form $\omega=\sum_i a_i\eta_i$ that belongs to $\mathcal{H}_{k+1}$. More precisely, $\dim_{\mathcal{K}^*}\mathcal{H}_{k+1}=\rho_k-\operatorname{rank}_{\mathcal{K}^*}[c_{ij}]$. Now, notice that from the induction assumption the a_i^+'s may be chosen to depend only on the variables $\{x(0),u(-j),z(-j),\ j\leq k-1\}$. Finally notice that, since $a_i=\delta^{-1}a_i^+$, the a_i's depend only on the variables $\{x(0),u(-j),z(-j),\ j\leq k\}$. □

Lemma 4.3 is crucial because it allows consideration of the filtration (9) as a nested sequence of Pfaffian systems defined over $\mathbb{R}^N$, for some integer N large enough. Moreover, the proof of Lemma 4.3 provides a systematic procedure to compute bases of the subspaces $\mathcal{H}_k$.

PROPOSITION 4.4. *Let $\{\alpha_1,\ldots,\alpha_{\rho_\infty}\}$ be a basis for $\mathcal{H}_\infty$. Then the Frobenius condition*

$$\mathrm{d}\alpha_i\wedge\alpha_1\wedge\cdots\wedge\alpha_{\rho_\infty}=0,\qquad i=1,\ldots,\rho_\infty,$$

is satisfied. In other words, there exists (locally) a basis for $\mathcal{H}_\infty$ composed of exact one-forms.

Proof. The proof is largely technical and is given in Appendix B. □

Theorem 4.5 is our main result concerning the accessibility property. It should be strengthened that the characterization of this property through condition 2 is very natural. In plain words, it means that every nonconstant function of the state is eventually influenced by the input of the system and hence cannot satisfy any autonomous difference equation. On the other hand, from a computational point of view, condition 3 can be checked rather easily.

THEOREM 4.5 (Accessibility criteria). *The following statements are equivalent.*

1. *System* Σ *is (forward) accessible.*
2. *Any nonconstant function* $\varphi(x(0))$ *has finite relative degree.*
3. $\mathcal{H}_\infty = 0$.
4. *Define* $\mathcal{X}_k = \text{span}_{\mathcal{K}^*}\{\text{d}x(k)\}$. *Then, there exists an integer* $k \geq 0$ *such that*

$$\dim_{\mathcal{K}^*} \frac{\mathcal{X}_0 + \mathcal{X}_k}{\mathcal{X}_0} = n.$$

Proof. We show (1) $\Leftrightarrow$ (4) $\Rightarrow$ (2) $\Rightarrow$ (3) $\Rightarrow$ (1).

(1) $\Leftrightarrow$ (4) By definition, $x(k) = \Gamma(k, x)(\mathbf{u})$. Hence

$$\text{d}x(k) = \frac{\partial \Gamma(k, x)}{\partial x(0)} \text{d}x(0) + \frac{\partial \Gamma(k, x)}{\partial \mathbf{u}} \text{d}\mathbf{u}$$

and thus

$$\frac{\mathcal{X}_0 + \mathcal{X}_k}{\mathcal{X}_0} \sim \text{span}_{\mathcal{K}^*} \left\{ \frac{\partial \Gamma(k, x)}{\partial \mathbf{u}} \text{d}\mathbf{u} \right\}.$$

The equivalence follows from Proposition 4.2.

(4) $\Rightarrow$ (2) Suppose that there exists a function $\varphi(x(0))$ whose relative degree is infinite. $\varphi(x(0))$ can always be completed to define a diffeomorphism $z(k) = \phi(x(k))$. Define $\mathcal{Z}_k = \text{span}_{\mathcal{K}^*}\{\text{d}z(k)\}$. The fact that $\varphi(x(0))$ has infinite relative degree implies that, for $k \geq 0$, $\dim_{\mathcal{K}^*} (\mathcal{Z}_0 + \mathcal{Z}_k)/\mathcal{Z}_0 = \dim_{\mathcal{K}^*} \mathcal{Z}_k - \dim_{\mathcal{K}^*} (\mathcal{Z}_0 \cap \mathcal{Z}_k) < n$. The implication follows because, for $k \geq 0$, $\mathcal{X}_k \sim \mathcal{Z}_k$.

(2) $\Rightarrow$ (3) Suppose $\mathcal{H}_\infty \neq 0$. By Proposition 4.4, this implies the existence of ρ_∞ functions whose relative degrees are infinite.

(3) $\Rightarrow$ (1) Suppose that system Σ is not accessible. Since (1) $\Leftrightarrow$ (4), this implies that $\dim_{\mathcal{K}^*} (\mathcal{X}_0 + \mathcal{X}_k)/\mathcal{X}_0 = \dim_{\mathcal{K}^*} \mathcal{X}_0 - \dim_{\mathcal{K}^*} (\mathcal{X}_0 \cap \mathcal{X}_k) < n$, for $k > 0$. Thus $\mathcal{X}_0 \cap \mathcal{X}_k \neq 0$ and hence there exists a nonzero one-form $\omega \in \mathcal{X}_0$ whose relative degree is infinite, i.e., $\mathcal{H}_\infty \neq 0$. □

Remark 4.6. For linear time-invariant systems, condition 4 of Theorem 4.5 coincides with the celebrated *Kalman controllability criterion,* i.e.,

$$\dim_{\mathcal{K}^*} \frac{\mathcal{X}_0 + \mathcal{X}_k}{\mathcal{X}_0} = \text{rank}\left[B \mid AB \mid \cdots \mid A^{k-1}B\right].$$

Example 4.7 shows the application of the results of this section. It has been borrowed from [30].

Example 4.7 (see [30]). Consider the discrete-time polynomial system

$$\begin{aligned} x_1(t+1) &= x_1(t)(x_3^2(t)+1)^2, \\ x_2(t+1) &= x_2(t)(x_3^2(t)+1)^3, \\ x_3(t+1) &= x_3(t) + u(t). \end{aligned} \tag{11}$$

Clearly, for system (11) one has $\mathcal{H}_2 = \text{span}_{\mathcal{K}^*}\{dx_1(0), dx_2(0)\}$. Straightforward computations also show that $\mathcal{H}_3 = \text{span}_{\mathcal{K}^*}\{\eta\}$, where

$$\eta = 3x_2(0)dx_1(0) - 2x_1(0)dx_2(0).$$

Moreover, $\mathcal{H}_3$ is closed under forward-shifting. In fact, $\eta^+ = (x_3^2(0) + 1)^5\eta$. Thus system (11) is not accessible.

Note that although η is not an exact one-form, Proposition 4.4 guarantees the existence of an integrating factor, i.e., a nonzero function $a \in \mathcal{K}^*$ such that $a\,\eta$ becomes integrable. Taking $a = x_1^2(0)/x_2^3(0)$ one obtains

$$a\,\eta = 3\frac{x_1^2(0)}{x_2^2(0)}dx_1(0) - 2\frac{x_1^3(0)}{x_2^3(0)}dx_1(0) = d\left(\frac{x_1^3(0)}{x_2^2(0)}\right).$$

The relative degree of the function $\varphi(x(t)) = x_1^3(t)/x_2^2(t)$ is infinite.

5. Static state feedback linearization. The static state feedback linearization problem has already been considered by several authors; cf. [21, 27, 31, 34, 35, 45, 46]. The problem can be thought of as consisting of finding suitable output functions (without zero dynamics and with vector relative degree) and of applying standard input-output feedback linearization techniques [41, 40, 42, 43]. The interest of recasting this problem is that our solution naturally fits in the more general frame of dynamic feedback linearization. In the rest of this paper, the results on the various feedback linearization problems are local results.

DEFINITION 5.1. *System Σ is said to be linearizable by static state feedback if there exist a state diffeomorphism*

$$\tilde{x}(t) = \phi(x(t)) \tag{12}$$

and a regular static state feedback (2) *such that, in new coordinates, the compensated system reads*

$$\tilde{x}(t+1) = A\tilde{x}(t) + Bv(t), \tag{13}$$

where the pair (A, B) is in Brunovsky canonical form.

THEOREM 5.2. *System Σ is linearizable by regular static state feedback if and only if*

1. $\mathcal{H}_\infty = 0$.
2. *For $1 \le k \le k^*$, $\mathcal{H}_k$ is completely integrable.*

Proof. Sufficiency. If $\mathcal{H}_\infty = 0$, then by Corollary 3.6 there exists a basis

$$\{\omega_{i,j}(0), 1 \le i \le m, 1 \le j \le r_i\} \tag{14}$$

of $\text{span}_{\mathcal{K}^*}\{dx(0)\}$ such that in this basis the first-order approximation of system Σ, i.e.,

$$dx(t+1) = \frac{\partial f}{\partial x}(x(t), u(t))dx(t) + \frac{\partial f}{\partial u}(x(t), u(t))du(t),$$

takes the infinitesimal Brunovsky form (6). By Frobenius's Theorem, there is no loss of generality if we assume that the basis (14) is composed of exact one-forms. Thus, every $\omega_{i,j}(0)$, $1 \le i \le m$, $1 \le j \le r_i$, can be integrated; i.e., there exist $\phi_{i,j}(x(0))$ such that $\omega_{i,j}(0) = d\phi_{i,j}(x(0))$. In coordinates $\tilde{x}_{i,j} = \phi_{i,j}(x)$, $1 \le i \le m$, $1 \le j \le r_i$, system Σ reads

$$\begin{aligned}
\tilde{x}_{i,1}(t+1) &= \tilde{x}_{i,2}(t),\\
\tilde{x}_{i,2}(t+1) &= \tilde{x}_{i,3}(t),\\
&\vdots\\
\tilde{x}_{i,r_i-1}(t+1) &= \tilde{x}_{i,r_i}(t),\\
\tilde{x}_{i,r_i}(t+1) &= \tilde{f}_i(\tilde{x}(t), u(t)), \quad 1 \le i \le m,
\end{aligned}$$

with $\frac{\partial \tilde{f}_i}{\partial \tilde{x}_{s,j}} = a^i_{s,j}$, $\frac{\partial \tilde{f}_i}{\partial u_j} = b^i_j$. The proof is completed by showing that under the feedback $u(t) = \varphi(\tilde{x}(t), v(t))$ where

$$\tilde{f}_i(\tilde{x}(t), \varphi(\tilde{x}(t), v(t))) = v_i(t), \ 1 \leq i \leq m, \tag{15}$$

the system Σ takes the Brunovsky canonical form (13) with controllability indices $r_1, \ldots, r_m$. Note that by the implicit function theorem (15) has a local solution with respect to $u(t) = \varphi(\tilde{x}(t), v(t))$ since the matrix with elements b^i_j is invertible by Corollary 3.6.

Necessity. This is clear because for a linear system the $\mathcal{H}_k$'s are completely integrable and this property is invariant under regular static state feedback and state diffeomorphism. □

Remark 5.3. Theorem 5.2 gives an alternative solution to the static linearization problem, considered earlier in [21, 27, 31, 34, 35, 45, 46]. One can see a particular close connection with Lemma 5 of [35]. The proof of our theorem indicates how actually to find the functions $h_1, \ldots, h_m$ in terms of which Lemma 5 is formulated.

Example 5.4 (Example 3.7 continued). We have computed, for the system (7), the one-forms

$$\omega_1 = x_2(0)\mathrm{d}x_3(0) - x_3(0)\mathrm{d}x_2(0),$$
$$\omega_2 = x_1(0)\mathrm{d}x_2(0) - x_2(0)\mathrm{d}x_1(0)$$

that generate the infinitesimal Brunovsky form (6). The one-forms ω_1, ω_2 are not exact. However, one can readily verify that

$$\mathrm{d}\omega_1 \wedge \omega_1 = \mathrm{d}\omega_2 \wedge \omega_2 = 0,$$

so that there exist integrating factors a_i such that $\tilde{\omega}_i = a_i\omega_i$ are exact one-forms for $i = 1, 2$. This implies that the conditions of Theorem 5.2 are satisfied and hence system (7) is linearizable by regular static state feedback. Taking $a_1 = 1/x_2^2(0)$ and $a_2 = 1/x_1^2(0)$ one obtains

$$\tilde{\omega}_1 = \mathrm{d}\left(\frac{x_3(0)}{x_2(0)}\right), \qquad \tilde{\omega}_2 = \mathrm{d}\left(\frac{x_2(0)}{x_1(0)}\right).$$

Define now the diffeomorphism

$$\tilde{x}(t) = \left(\frac{x_3(t)}{x_2(t)}, \frac{x_4(t)}{x_3(t)}, \frac{x_5(t)}{x_4(t)}, \frac{x_6(t)}{x_5(t)}, \frac{x_2(t)}{x_1(t)}, x_3(t)\right).$$

In coordinates $\tilde{x}(t)$, the system (7) reads

$$\begin{aligned}
\tilde{x}_1(t+1) &= \tilde{x}_2(t), & \tilde{x}_4(t+1) &= u_2(t)/(\tilde{x}_2(t)\tilde{x}_3(t)\tilde{x}_4(t)\tilde{x}_6(t)u_1(t)),\\
\tilde{x}_2(t+1) &= \tilde{x}_3(t), & \tilde{x}_5(t+1) &= \tilde{x}_6(t),\\
\tilde{x}_3(t+1) &= \tilde{x}_4(t), & \tilde{x}_6(t+1) &= \tilde{x}_2(t)\tilde{x}_6(t)u_1(t).
\end{aligned}$$

Finally, the state feedback

$$u_1(t) = \frac{v_1(t)}{\tilde{x}_2(t)\tilde{x}_6(t)}, \qquad u_2(t) = \tilde{x}_3(t)\tilde{x}_4(t)v_1(t)v_2(t)$$

yields the Brunovsky form (13) with controllability indices $\{4, 2\}$.

6. The largest feedback linearizable subsystem. When system Σ cannot be fully linearized using static state feedback, it is interesting to characterize the largest feedback linearizable subsystem. This is done in this section. Throughout this section, we assume that system Σ is accessible, i.e., $\mathcal{H}_\infty = 0$.

DEFINITION 6.1. *System Σ is said to be partially linearizable with controllability indices $n_1 \geq \cdots \geq n_m$ if there exists a state diffeomorphism* (12) *and a regular static state feedback* (2) *such that, in new coordinates, the compensated system reads*

$$\begin{aligned} \tilde{x}^1(t+1) &= A^1\tilde{x}^1(t) + B^1 v(t), \\ \tilde{x}^2(t+1) &= f^2(\tilde{x}^1(t), \tilde{x}^2(t), v(t)), \end{aligned} \tag{16}$$

where the pair (A^1, B^1) is in Brunovsky canonical form with controllability indices $n_1 \geq \cdots \geq n_m$.

The sequence of subspaces $\mathcal{H}_0 \supset \mathcal{H}_1 \supset \cdots \supset \mathcal{H}_{k^*}$ can be viewed as a nested sequence of Pfaffian systems. For $k = 1, \ldots, k^*$, the bottom derived system of $\mathcal{H}_k$ is denoted $\bar{\mathcal{H}}_k$. Also, introduce the list of integers $\{p'_k\}$, defined by

$$p'_k = \dim_{\mathcal{K}^*} \frac{\bar{\mathcal{H}}_k + \mathcal{H}_{k+1}}{\mathcal{H}_{k+1}},$$

and its dual list $\{n^*_j\}$, defined by $n^*_j = \operatorname{card}\{p'_k \mid p'_k \geq j\}$.

Our claim is that $\{n^*_j\}$ is the list of controllability indices of the largest feedback linearizable subsystem.

THEOREM 6.2. *System Σ is partially feedback linearizable with controllability indices $n^*_1 \geq \cdots \geq n^*_m$.*

Proof. Let $\bar{\mathcal{W}}_{k^*}$ be a basis for $\bar{\mathcal{H}}_{k^*}$, and choose a set $\hat{\mathcal{W}}_{k^*}$ such that $\bar{\mathcal{W}}_{k^*} \cup \hat{\mathcal{W}}_{k^*}$ is a basis for $\mathcal{H}_{k^*}$. Let $\bar{\mathcal{W}}_{k^*-1}$ be a set such that

$$\bar{\mathcal{W}}_{k^*} \cup \bar{\mathcal{W}}^+_{k^*} \cup \hat{\mathcal{W}}_{k^*} \cup \bar{\mathcal{W}}_{k^*-1}$$

is a basis for $\bar{\mathcal{H}}_{k^*-1} + \mathcal{H}_{k^*}$, and choose a set $\hat{\mathcal{W}}_{k^*-1}$ such that

$$\bar{\mathcal{W}}_{k^*} \cup \bar{\mathcal{W}}^+_{k^*} \cup \bar{\mathcal{W}}_{k^*-1} \cup \hat{\mathcal{W}}_{k^*-1}$$

is a basis for $\mathcal{H}_{k^*-1}$. This procedure can be repeated $k^* - 1$ times in such a way that

$$\left\{ \bigcup_{k+1 \leq i \leq k^*} \bigcup_{0 \leq j \leq i-k} \bar{\mathcal{W}}_i(j) \right\} \cup \hat{\mathcal{W}}_{k+1} \cup \bar{\mathcal{W}}_k$$

is a basis for $\bar{\mathcal{H}}_k + \mathcal{H}_{k+1}$ and

$$\left\{ \bigcup_{k \leq i \leq k^*} \bigcup_{0 \leq j \leq i-k} \bar{\mathcal{W}}_i(j) \right\} \cup \hat{\mathcal{W}}_k$$

is a basis for $\mathcal{H}_k$. For $k = 1, \ldots, k^*$, denote $p_k = \operatorname{card} \bar{\mathcal{W}}_k$. Thus, the k^* sets we have constructed (some of them possibly empty) satisfy

$$p'_k = \dim_{\mathcal{K}^*} \frac{\bar{\mathcal{H}}_k + \mathcal{H}_{k+1}}{\mathcal{H}_{k+1}} = \sum_{i \geq k} p_i. \tag{17}$$

Clearly, the $\bar{\mathcal{W}}_k$'s can be chosen to be composed by exact one-forms. Say, for $k = 1, \ldots, k^*$, $\bar{\mathcal{W}}_k = \{\mathrm{d}\theta_{k,1}, \ldots, \mathrm{d}\theta_{k,p_k}\}$. Moreover, the fact that each $\bar{\mathcal{W}}_k$ can be completed into a basis for $\mathcal{H}_k$ implies that the $\mathrm{d}\theta_{k,j}$'s and their corresponding forward shifts are linearly independent.

Introduce the set of indices $\mathcal{I}$ such that $\forall k \in \mathcal{I}$, $\bar{\mathcal{W}}_k \neq \emptyset$. For $k \in \mathcal{I}$ and $1 \leq j \leq k$, define $\phi_{k,j} = (\theta_{k,1}(j-1), \ldots, \theta_{k,p_k}(j-1))$. Let $\bar{n} = \sum_{k\in\mathcal{I}} k\, p_k$. Complete the $\phi_{k,j}$'s by a set of arbitrary functions $\psi = (\psi_{\bar{n}+1}, \ldots, \psi_n)$ such that $(\tilde{x}^1_{k,j}, \tilde{x}^2) = (\phi_{k,j}, \psi)$ defines a diffeomorphism. In new coordinates, system Σ reads

$$
\begin{aligned}
\tilde{x}^1_{k,1}(t+1) &= \tilde{x}^1_{k,2}(t),\\
\tilde{x}^1_{k,2}(t+1) &= \tilde{x}^1_{k,3}(t),\\
&\vdots\\
\tilde{x}^1_{k,k-1}(t+1) &= \tilde{x}^1_{k,k}(t),\\
\tilde{x}^1_{k,k}(t+1) &= \tilde{f}^1_k(\tilde{x}^1(t), \tilde{x}^2(t), u(t)), \qquad k \in \mathcal{I};\\
\tilde{x}^2(t+1) &= \tilde{f}^2(\tilde{x}^1(t), \tilde{x}^2(t), u(t)).
\end{aligned} \tag{18}
$$

Under the state feedback $u = \varphi(\tilde{x}^1(t), \tilde{x}^2(t), v(t))$ where

$$
\tilde{f}^1_k(\tilde{x}^1(t), \tilde{x}^2(t), u(t)) = v_k(t), \qquad \dim v_k(t) = p_k, \qquad k \in \mathcal{I}, \tag{19}
$$

system Σ takes the form (16). Next we prove that (19) has a local solution. The fact that the $\mathrm{d}\theta_{k,j}$'s are linearly independent implies

$$
\operatorname{rank} \frac{\partial \tilde{f}^1}{\partial u} = \sum_{k\in\mathcal{I}} \dim\, \tilde{x}^1_{k,k} = \sum_{k\in\mathcal{I}} p_k,
$$

where $\tilde{f}^1 = [(\tilde{f}^1_k)^T,\ k \in \mathcal{I}]^T$. On the other hand, by (17), one has

$$
\sum_{k\in\mathcal{I}} p_k = p'_1 = \dim_{\mathcal{K}^*} \frac{\bar{\mathcal{H}}_1 + \mathcal{H}_2}{\mathcal{H}_2} = m.
$$

Then, our assertion holds by the Implicit Function Theorem.

The proof is completed by showing that the linear part of (18) under the state feedback (19) has $n^*_1 \geq \cdots \geq n^*_m$ as controllability indices.

The controllability indices of (18) are $\{k_i \mid k_i \in \mathcal{I}\}$ with multiplicities p_{k_i}, i.e., $\{n^j_k = k \mid k \in \mathcal{I},\ 1 \leq j \leq p_k\}$. Up to reordering one has, by (17), $p'_k = \sum_{i\geq k} p_i = \operatorname{card}\{n^j_i \geq k\}$. The result follows because both lists $\{n^*_i\}$, $\{n^j_i\}$ are dual to the list $\{p'_k\}$ and then they are the same. □

We state the following theorem without proof. It can be easily demonstrated by contradiction.

THEOREM 6.3. *If system Σ is feedback linearizable with controllability indices $n_1 \geq \cdots \geq n_m$, then $n_i \leq n^*_i$, $i = 1, \ldots, m$.*

Example 6.4. Consider the nonlinear discrete-time system

$$
\begin{aligned}
x_1(t+1) &= x_2(t) + u_1(t),\\
x_2(t+1) &= x_3(t)u_1(t),\\
x_3(t+1) &= x_3(t)u_2(t),\\
x_4(t+1) &= x_4(t) + u_1(t).
\end{aligned} \tag{20}
$$

For system (20) one can readily check that

$$\frac{\operatorname{span}_{\mathcal{K}}\{\mathrm{d}x(0)\}}{\operatorname{span}_{\mathcal{K}}\{\mathrm{d}x(0)\} \cap \operatorname{span}_{\mathcal{K}}\{\mathrm{d}x(1)\}} \sim \operatorname{span}_{\mathcal{K}}\{\mathrm{d}x_1(0), \mathrm{d}x_3(0)\}.$$

Thus one can set $z(0) = (x_1(0), x_3(0))$. This allows us to compute

$$\mathcal{H}_2 = \operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x_4(0) - \mathrm{d}x_1(0),\ \mathrm{d}x_2(0) - z_2(-1)\mathrm{d}x_1(0)\},$$
$$\mathcal{H}_3 = 0.$$

Clearly, $\bar{\mathcal{H}}_2 = \operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x_4(0) - \mathrm{d}x_1(0)\}$; thus set $\bar{\mathcal{W}}_2 = \{\mathrm{d}(x_4(0) - x_1(0))\}$ and $\hat{\mathcal{W}}_2 = \{\mathrm{d}x_2(0) - z_2(-1)\mathrm{d}x_1(0)\}$. According to the proof of Theorem 6.2, $\bar{\mathcal{W}}_1$ has to be chosen in such a way that $\bar{\mathcal{W}}_2 \cup \bar{\mathcal{W}}_2^+ \cup \hat{\mathcal{W}}_2 \cup \bar{\mathcal{W}}_1$ is a basis for $\bar{\mathcal{H}}_1 + \mathcal{H}_2$; set $\bar{\mathcal{W}}_1 = \{\mathrm{d}x_3\}$. One concludes that system (20) is partially feedback linearizable with controllability indices $\{2, 1\}$. Consider the diffeomorphism

$$\tilde{x}(t) = (x_4(t) - x_1(t), x_4(t) - x_2(t), x_3(t), x_4(t))\,.$$

In new coordinates, system (20) reads

$$\tilde{x}_1(t+1) = \tilde{x}_2(t), \qquad \tilde{x}_3(t+1) = \tilde{x}_3(t)u_2(t),$$
$$\tilde{x}_2(t+1) = \tilde{x}_4(t) - \tilde{x}_3(t)u_1(t), \qquad \tilde{x}_4(t+1) = \tilde{x}_4(t) + u_1(t).$$

Under the state feedback

$$u_1(t) = \frac{\tilde{x}_4(t) - v_1(t)}{\tilde{x}_3(t)}, \qquad u_2(t) = \frac{v_2(t)}{\tilde{x}_3(t)},$$

system (20) takes form (16) with controllability indices $\{2, 1\}$.

7. Dynamic state feedback linearization. For continuous-time systems it is well known [7, 24, 25] that a sufficient condition for a nonlinear system with outputs to be linearizable by dynamic state feedback is that

1. the system be right-invertible; and
2. the system has no zero dynamics, in the sense of the dynamics of the reduced inverse system [26].

In [44] it was pointed out that a similar property can be deduced for discrete-time systems. However, if a system without outputs is given (or if the outputs of the system do not satisfy the properties above), then it is interesting to decide whether these outputs exist or not. This question is addressed in this section. To be more precise, the existence of outputs satisfying properties 1 and 2 is shown to be equivalent to the existence of a transformal operator that maps a certain Pfaffian system into another one that is completely integrable.

Consider system Σ and suppose that the output function $y(t) = h(x(t))$, $y(t) \in \mathbb{R}^m$, has been specified. Then one has the following definitions and results.

Define a chain of subspaces $\mathcal{E}_0 \subset \mathcal{E}_1 \subset \cdots \subset \mathcal{E}_n$ of $\mathcal{F}$ by

$$\mathcal{E}_k = \operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x(0), \mathrm{d}y(0), \ldots, \mathrm{d}y(k)\} \tag{21}$$

and the associated list of dimensions $\rho_k = \dim_{\mathcal{K}^*} \mathcal{E}_k$ [22].

DEFINITION 7.1. 1. *For $k = 0, \ldots, n$, $\sigma_k = \rho_k - \rho_{k-1}$ is the number of zeros at infinity of order less than or equal to k, with the convention that $\rho_{-1} = n$.*

2. *The rank ρ^* of the system is the total number of zeros at infinity, i.e., $\rho^* = \sigma_n = \rho_n - \rho_{n-1}$.*

3. *The system is said to be invertible if $\rho^* = m$.*

Definition 7.1 gives an abstract characterization of the rank [12, 14, 22] and the structure at infinity [22] for discrete-time nonlinear systems. These notions have, however, a meaningful interpretation in terms of the inversion algorithm [22, 32]. The integer σ_k represents the number of independent scalar inputs that can be recovered at the k-th step of the inversion algorithm. In a similar vein, invertibility of the system means that it is possible to recover the complete input $u(t)$ as a function of the output $y(t)$ and its forward-shifts.

The structure at infinity can be expressed in different manners, which are of course equivalent and suitable for different tasks. For instance, the list $\{n'_1, \ldots, n'_{\rho^*}\}$ of the orders of the zeros at infinity is the list of integers k such that $\sigma_k - \sigma_{k-1} \neq 0$, each one repeated $\sigma_k - \sigma_{k-1}$ times.

In the rest of this section we are concerned with dynamic compensators of the type

$$\mathcal{C} : \begin{cases} \xi(t+1) = a(x(t), \xi(t), v(t)), \\ u(t) = b(x(t), \xi(t), v(t)), \end{cases} \tag{22}$$

where $\xi(t) \in \mathbb{R}^q$ and $v(t) \in \mathbb{R}^m$. Like in the continuous-time case [20, 23], a dynamic compensator $\mathcal{C}$ is said to be regular if it is invertible when $v(t)$ is viewed as input and $u(t)$ is viewed as output. This leads to the characterization of the regularity of the compensator $\mathcal{C}$ as

$$\dim_{\mathcal{K}^*} \frac{\operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x(0), \ldots, \mathrm{d}x(q), \mathrm{d}\xi(0), \mathrm{d}u(0), \ldots, \mathrm{d}u(q)\}}{\operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x(0), \ldots, \mathrm{d}x(q), \mathrm{d}\xi(0), \mathrm{d}u(0), \ldots, \mathrm{d}u(q-1)\}} = m.$$

For invertible systems it is always possible to construct a dynamic compensator $\mathcal{C}$ in such a way that

1. noninteracting control is achieved; i.e., for the compensated system $\Sigma \circ \mathcal{C}$ one has $y_i(t + \delta_i) = v_i(t)$, for some integers δ_i.
2. the dimension of the compensated system $\Sigma \circ \mathcal{C}$ is $n + \sum_i (\delta_i - n'_i)$ [46].

Set $n_1 = \sum_i \delta_i$, $n_2 = n - \sum_i n'_i$. The n_1 functions

$$\{y_i(t+j),\ 1 \leq i \leq m,\ 0 \leq j \leq \delta_i - 1\}$$

can be completed by n_2 functions φ_k such that $(\tilde{x}_1, \tilde{x}_2) = (y_i(t+j), \varphi_k)$ defines a diffeomorphism on $\mathbb{R}^{n_1+n_2}$. In new coordinates $\tilde{x}$ the compensated system $\Sigma \circ \mathcal{C}$ reads

$$\Sigma \circ \mathcal{C} : \begin{cases} \tilde{x}^1(t+1) = A^1 \tilde{x}^1(t) + B^1 v(t), \\ \tilde{x}^2(t+1) = f^2(\tilde{x}^1(t), \tilde{x}^2(t), v(t)), \\ y(t) = C^1 \tilde{x}^1(t), \end{cases}$$

where $\dim \tilde{x}^1 = \sum_i \delta_i$, $\dim \tilde{x}^2 = n - \sum_i n'_i$, and the pair (A^1, B^1) is in Brunovsky canonical form with controllability indices $\{\delta_i\}$. The dynamics

$$\tilde{x}^2(t+1) = f^2(\tilde{x}^1(t), \tilde{x}^2(t), v(t))$$

is the zero dynamics in the sense of the reduced inverse system.

DEFINITION 7.2. *System Σ is said to be linearizable by dynamic state feedback if there exist a regular dynamic compensator* (22) *and an extended coordinates transformation $\tilde{x}(t) = \phi(x(t), \xi(t))$ such that, in new coordinates, the compensated system reads*

$$\tilde{x}(t+1) = A\tilde{x}(t) + Bv(t), \qquad t = 0, 1, \ldots, \tag{23}$$

where $\tilde{x} \in \mathbb{R}^{n+q}$ and the pair (A, B) is in Brunovsky canonical form.

From our previous analysis, one concludes that the existence of an output $y(t) = h(x(t))$, $y(t) \in \mathbb{R}^m$, which defines an invertible system without zero dynamics, is a sufficient condition for dynamic feedback linearizability. This property was already recognized in [44, §4]. One can also see that the sum of the orders of the zeros at infinity will play an important role. Lemma 7.3 gives a characterization of this quantity. Define the subspaces

$$\mathcal{X} = \operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x(0)\},\ \mathcal{Y} = \operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}y(k),\ k \geq 0\}.$$

LEMMA 7.3. *Suppose that the output $y(t) = h(x(t))$, $y(t) \in \mathbb{R}^m$, defines an invertible system. Then*

$$\dim_{\mathcal{K}^*}(\mathcal{X} \cap \mathcal{Y}) = \sum_i p_i' = \sum_i n_i',$$

where $p_i' = m - \sigma_i$ is the number of zeros at infinity of order greater than or equal to $i + 1$.

Proof. The proof is a direct consequence of the inversion algorithm [22]; see also [32]. An application of the algorithm for invertible systems gives, for each $0 \leq k \leq n$,

$$\dim_{\mathcal{K}^*}\left(\mathcal{X} \cap \operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}y(\ell),\ 0 \leq \ell \leq k\}\right) = \sum_{i=0}^{k}(m - \sigma_i) = \sum_{i=0}^{k}(p_1' - \sigma_i) = \sum_{i=0}^{k} p_i'.$$

On the other hand, one has $\sum_i n_i' = \sum_i i(p_i' - p_{i+1}') = \sum_i p_i'$. □

For continuous-time systems, Fliess et al. [17] have shown that a more general formulation consists of allowing the output function to depend explicitly on the input and a finite number of its time-derivatives. Accordingly, for discrete-time systems, a more general problem statement consists of allowing the output $y(t)$ to depend explicitly on $u(t)$ and a finite number $\nu - 1$ of its forward shifts. Within our framework, this implies the statement of a more general definition of the structure at infinity, which includes possibly nonproper discrete-time systems. This can be done by applying the usual definition to an extended system for which the forward-shifts of the input that explicitly appear in the output equation are considered as states. See for example [39] for the continuous-time case. We do not pursue this line further because, as we explain next, it is possible to state the problem without making explicit reference to the extended system. More precisely, we seek an output $y(t) = h(x(t), u(t), \ldots, u(t + \nu - 1))$, $y(t) \in \mathbb{R}^m$, such that

$$\dim_{\mathcal{K}^*}(\mathcal{X}_\nu \cap \mathcal{Y}) = n + m\nu,$$

where $\mathcal{X}_\nu = \operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x(0), \mathrm{d}u(0), \ldots, \mathrm{d}u(\nu - 1)\}$. For square invertible systems one has

$$\mathcal{X}_\nu + \mathcal{Y} = \mathcal{X} + \mathcal{Y}$$

and hence

$$\dim_{\mathcal{K}^*}(\mathcal{X}_\nu \cap \mathcal{Y}) = \dim_{\mathcal{K}^*}(\mathcal{X} \cap \mathcal{Y}) + m\nu.$$

The term *linearizing output* in Definition 7.4 below is borrowed from [17].

DEFINITION 7.4. *A linearizing output is an output function*

$$y(t) = h(x(t), u(t), \ldots, u(t + \nu - 1)), \qquad y(t) \in \mathbb{R}^m,$$

that satisfies the following properties.

1. *$y(t) = h(x(t), u(t), \ldots, u(t + \nu - 1))$ defines an invertible system.*
2. *$\dim_{\mathcal{K}^*}(\mathcal{X} \cap \mathcal{Y}) = n$.*

Remark 7.5. For continuous-time systems [17, 19, 39], a linearizing output has the important property that any variable of the system can be expressed as a function of the linearizing output and a finite number of its time-derivatives, i.e., without integrating any differential equation. The corresponding property for the discrete-time case should be that any variable of the system can be expressed as a function of the linearizing output and a finite number of its forward-shifts, i.e., without solving any difference equation. As a matter of fact, this property can be deduced from Definition 7.4. First, recall that invertibility of the system means that one is able to recover the complete input of the system as a function of the output, a finite number of its forward-shifts, and the state. Second, notice that the second property of Definition 7.4 implies that each state variable can also be expressed as a function of the linearizing output and its forward-shifts.

It is also possible to show that the conditions of Definition 7.4 are independent of the system of coordinates.

Let $\mathcal{K}^*[\Delta]$ denote the set of polynomials in the operator Δ with coefficients in $\mathcal{K}^*$. One can give $\mathcal{K}^*[\Delta]$ the structure of a noncommutative ring with the addition defined in the usual manner and the multiplication defined by the noncommutative operation

$$\Delta\, p = p^{+}\Delta, \qquad \text{for all } p \in \mathcal{K}^*,$$

which corresponds to operators composition. Let $\mathcal{K}^{*m\times m}[\Delta]$ denote the set of $m \times m$ matrices whose entries belong to $\mathcal{K}^*[\Delta]$. The set $\mathcal{K}^{*m\times m}[\Delta]$ is also a noncommutative ring. The elements of $\mathcal{K}^{*m\times m}[\Delta]$ are called transformal operators.

Let $\mathcal{F}^m$ denote the $\mathcal{K}^*$-vector space spanned by m-tuples of one-forms. Every transformal operator $P \in \mathcal{K}^{*m\times m}[\Delta]$ defines a mapping from $\mathcal{F}^m$ to $\mathcal{F}^m$ in the following way. Let $P = \sum_i P_i\,(\Delta)^i \in \mathcal{K}^{*m\times m}[\Delta]$, and let $\Omega(0) = (\omega_1(0), \ldots, \omega_m(0)) \in \mathcal{F}^m$. Then define

$$\begin{aligned} P \;:\; & \mathcal{F}^m \to \mathcal{F}^m, \\ & \Omega \mapsto P\,\Omega = \textstyle\sum_i P_i \Omega(i), \end{aligned}$$

where $\Omega(i) = (\omega_1(i), \ldots, \omega_m(i))$. A transformal operator $P \in \mathcal{K}^{*m\times m}[\Delta]$ is said to be invertible if there exists another transformal operator $Q \in \mathcal{K}^{*m\times m}[\Delta]$ such that

$$\text{for all } \Omega \in \mathcal{F}^m, \qquad P \circ Q\,(\Omega) = Q \circ P\,(\Omega) = \Omega,$$

or, equivalently, $P \circ Q = Q \circ P = I_m$, the identity matrix in $\mathbb{R}^{m\times m}$. The only invertible elements of $\mathcal{K}^*[\Delta]$ are the nonzero polynomials of degree zero.

The concept of infinite zero structure can be generalized in a natural way to arbitrary m-tuples of one-forms $\Omega(t) = (\omega_1(t), \ldots, \omega_m(t)) \in \mathcal{F}^m$, which are not necessarily exact. The m-tuple $\Omega(t)$ is said to have

$$\sigma_k = \dim_{\mathcal{K}^*}\left(\frac{\operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x(0), \Omega(0), \ldots, \Omega(k)\}}{\operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x(0), \Omega(0), \ldots, \Omega(k-1)\}}\right) \tag{24}$$

zeros at infinity of order less than or equal to k. If $\Omega(t)$ is a set of exact one-forms ($\omega_i(t) = \mathrm{d}h_i(t)$), then (24) coincides with the definition of structure at infinity given above. In particular, Lemma 7.3 is also valid for m-tuples of one-forms, provided that one defines invertibility of a set of one-forms $\Omega(t)$ by condition $\sigma_n = m$.

Proposition 7.6 below states that the sum of the orders of the zeros at infinity of a system of one-forms cannot increase under the action of a transformal operator $P \in \mathcal{K}^{*m\times m}[\Delta]$.

PROPOSITION 7.6. *Consider the m-tuple of one-forms $\Omega(t) = (\omega_1(t), \ldots \omega_m(t))$ and the polynomial matrix operator $P \in \mathcal{K}^{*m\times m}[\Delta]$. Define $\tilde{\Omega}(t) = P\Omega(t)$. Then*

$$\dim_{\mathcal{K}^*}\left(\mathcal{X} \cap \operatorname{span}_{\mathcal{K}^*}\{\tilde{\Omega}(k), k \geq 0\}\right) \leq \dim_{\mathcal{K}^*}\left(\mathcal{X} \cap \operatorname{span}_{\mathcal{K}^*}\{\Omega(k), k \geq 0\}\right).$$

The proof is straightforward and is left to the reader. Note that Proposition 7.6 establishes that the sum of the orders of the zeros at infinity of an m-tuple of one-forms remains constant under the action of invertible transformal operators $P \in \mathcal{K}^{*m\times m}[\Delta]$.

Let $\Omega(t) = (\omega_1(t), \ldots \omega_m(t))$ be a system of one-forms satisfying the conditions of Theorem 3.5. Then $\Omega(t)$ satisfies the properties

1. $\sigma_n = m$.
2. $\dim_{\mathcal{K}^*}\left(\mathcal{X} \cap \operatorname{span}_{\mathcal{K}}\{\Omega(k),\ k \geq 0\}\right) = n$.

In the case when $\Omega(t)$ is composed of exact one-forms ($\omega_i(t) = \mathrm{d}h_i(t)$), these properties coincide with the conditions in Definition 7.4. Therefore, an m-tuple of one-forms that satisfies the conditions of Theorem 3.5 is called a *system of linearizing one-forms.*

THEOREM 7.7. *Suppose $\mathcal{H}_\infty = 0$, and let $\Omega(t)$ be a system of linearizing one-forms. Then, there locally exists a system of linearizing outputs if and only if there exists an invertible transformal operator $P \in \mathcal{K}^{*m\times m}[\Delta]$ such that*

$$\mathrm{d}(P\Omega) = 0. \tag{25}$$

Hence (25) *is a sufficient condition for system Σ to be dynamic feedback linearizable.*

Proof. Necessity. Suppose $y(t) = h(x(t), u(t), \ldots, u(t+\nu-1))$ is a linearizing output. Definition 7.4 implies that $\mathcal{F} = \mathcal{Y}$. Theorem 3.5 implies that $\mathcal{F} = \operatorname{span}_{\mathcal{K}^*}\{\Omega(k), k \geq 0\}$. Thus there exist transformal operators P, Q such that $\mathrm{d}y(t) = P\,\Omega(t)$ and $\Omega(t) = Q\,\mathrm{d}y(t)$. Clearly $PQ = QP = I_m$, and hence P is invertible. Moreover $\mathrm{d}(P\Omega(t)) = \mathrm{d}(\mathrm{d}y(t)) = 0$.

Sufficiency. Let

$$N = \dim_{\mathcal{K}^*}\left(\mathcal{X} \cap \operatorname{span}_{\mathcal{K}^*}\{\Omega(k),\ k \geq 0\}\right),$$
$$\tilde{N} = \dim_{\mathcal{K}^*}\left(\mathcal{X} \cap \operatorname{span}_{\mathcal{K}^*}\{\tilde{\Omega}(k),\ k \geq 0\}\right),$$

where $\tilde{\Omega}(t) = P\Omega(t)$. Theorem 3.5 implies that $N = n$. Existence of the operator P implies $\tilde{N} \leq N$. Invertibility of P implies the existence of an operator Q such that $\Omega(t) = Q\,\tilde{\Omega}(t)$; i.e., $N \leq \tilde{N}$ and hence $\tilde{N} = N$. The result follows because one can assume, without loss of generality, that $\tilde{\Omega}(t) = \mathrm{d}\psi(x(t), u(t), \ldots, u(t+\nu-1))$. $\psi(x(t), u(t), \ldots, u(t+\nu-1))$ is a linearizing output. □

COROLLARY 7.8. *Suppose $\mathcal{H}_\infty = 0$, and let $\Omega(t) = (\omega_1(t), \ldots, \omega_m(t))$ be a system of linearizing one-forms. Further, suppose that the Frobenius condition*

$$\mathrm{d}\omega_k(t) \wedge \omega_1(t) \wedge \cdots \wedge \omega_m(t) = 0, \qquad k = 1, \ldots, m,$$

is satisfied. Then there exists a linearizing output. The relative degrees of the $\omega_k(t)$'s coincide with the orders of the zeros at infinity of the linearizing output.

Proof. The Frobenius condition implies that the Pfaffian system generated by $\Omega(t) = (\omega_1(t), \ldots, \omega_m(t))$ admits a basis composed of exact one-forms. Therefore there exists an invertible matrix (with entries in $\mathcal{K}^*$) relating this basis to $\{\omega_1(t), \ldots, \omega_m(t)\}$. □

Example 7.9. We already showed that system (20) cannot be fully linearized using regular static state feedback. However, we shall show that system (20) is linearizable by dynamic state feedback. For system (20) we have already computed

$$\mathcal{H}_2 = \operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x_4(0) - \mathrm{d}x_1(0),\ \mathrm{d}x_2(0) - z_2(-1)\mathrm{d}x_1(0)\},$$
$$\mathcal{H}_3 = 0;$$

hence

$$\Omega(t) = \begin{pmatrix} \omega_1(t) \\ \omega_2(t) \end{pmatrix} = \begin{pmatrix} \mathrm{d}x_2(t) - z_2(-1)\mathrm{d}x_1(t) \\ \mathrm{d}x_4(t) - \mathrm{d}x_1(t) \end{pmatrix}$$

is a system of linearizing one-forms. Consider now the transformal operators

$$P(\Delta) = \begin{pmatrix} \frac{1}{1-z_2(-1)} & \frac{z_2(-1)\Delta - z_2(-1)}{1-z_2(-1)} \\ 0 & 1 \end{pmatrix},$$

$$Q(\Delta) = \begin{pmatrix} 1 - z_2(-1) & z_2(-1) - z_2(-1)\Delta \\ 0 & 1 \end{pmatrix}.$$

Straightforward computations show that $P \circ Q = Q \circ P = I_2$ and that

$$\begin{pmatrix} \mathrm{d}x_2(t) \\ \mathrm{d}(x_4(t) - x_1(t)) \end{pmatrix} = P(\Delta) \begin{pmatrix} \omega_1(t) \\ \omega_2(t) \end{pmatrix}.$$

Therefore,

$$y(t) = \begin{pmatrix} x_2(t) \\ x_4(t) - x_1(t) \end{pmatrix} \tag{26}$$

is a linearizing output.

Consider the dynamic state feedback

$$\begin{aligned} \xi(t+1) &= \tilde{u}_1(t), \\ u_1(t) &= \xi(t), \\ u_2(t) &= \tilde{u}_2(t) \end{aligned} \tag{27}$$

and the extended diffeomorphism

$$\tilde{x}(t) = (x_2(t), x_3(t)\xi(t), x_4(t) - x_1(t), x_4(t) - x_2(t), x_4(t) - \xi(t) - x_3(t)\xi(t)).$$

In new coordinates, the extended system (20)–(27) reads

$$\begin{aligned} \tilde{x}_1(t+1) &= \tilde{x}_2(t), \\ \tilde{x}_2(t+1) &= \frac{\tilde{x}_2(t)\tilde{u}_1(t)\tilde{u}_2(t)}{\tilde{x}_2(t) + \tilde{x}_5(t) - \tilde{x}_1(t) - \tilde{x}_4(t)}, \\ \tilde{x}_3(t+1) &= \tilde{x}_4(t), \\ \tilde{x}_4(t+1) &= \tilde{x}_5(t), \\ \tilde{x}_5(t+1) &= \tilde{x}_2(t) + \tilde{x}_5(t) + \tilde{u}_1(t) - \frac{\tilde{x}_2(t)\tilde{u}_1(t)\tilde{u}_2(t)}{\tilde{x}_2(t) + \tilde{x}_5(t) - \tilde{x}_1(t) - \tilde{x}_4(t)}, \end{aligned} \tag{28}$$

and under the state feedback

$$\begin{aligned} \tilde{u}_1(t) &= v_1(t) + v_2(t) - \tilde{x}_2(t) - \tilde{x}_5(t), \\ \tilde{u}_2(t) &= \frac{v_2(t)(\tilde{x}_2(t) + \tilde{x}_5(t) - \tilde{x}_1(t) - \tilde{x}_4(t))}{\tilde{x}_2(t)(v_1(t) + v_2(t) - \tilde{x}_2(t) - \tilde{x}_5(t))} \end{aligned}$$

the extended system (28) reads as a linear system in Brunovsky canonical form with controllability indices $\{3, 2\}$.

The linearizing output (26) is not unique. For instance, the output function

$$\tilde{y}(t) = \begin{pmatrix} x_2(t) \\ x_3(t)u_1(t) + x_4(t) - x_1(t) \end{pmatrix} \tag{29}$$

(which depends on the input) is a linearizing output as well in the sense of Definition 7.4. Both linearizing outputs are related by the invertible transformal operator

$$\tilde{P} = \begin{pmatrix} 1 & 0 \\ \Delta & 1 \end{pmatrix}. \tag{30}$$

Remark 7.10. For continuous-time systems, it has been shown in [8] that any single-input system is dynamic feedback linearizable if and only if it is linearizable by static state feedback. We can state an analogous result for discrete-time systems. Let Σ be a single-input system, and suppose $\mathcal{H}_\infty = 0$. Then a system of linearizing one-forms reduces to any single one-form $\omega_1(t)$ such that $\mathcal{H}_n = \operatorname{span}_{\mathcal{K}^*}\{\omega_1(0)\}$.

THEOREM 7.11. *Let Σ be a single-input system, and suppose $\mathcal{H}_\infty = 0$. Then, the following statements are equivalent.*

1. *Σ admits a linearizing output.*
2. *Σ is linearizable by static state feedback.*
3. *$\mathrm{d}\omega_1(t) \wedge \omega_1(t) = 0$, where $\omega_1(t)$ is such that $\mathcal{H}_n = \operatorname{span}_{\mathcal{K}^*}\{\omega_1(0)\}$.*

The proof of Theorem 7.11 is an immediate consequence of Theorems 5.2 and 7.7 and is left to the reader.

8. Conclusion. The accessibility problem and three different notions of feedback linearizability for discrete-time analytic systems have been addressed in this paper. Our main contribution has been to show that these issues can be organized around the classification of differential forms with respect to their relative degree. The solutions that we have stated along the paper fit within a single linear algebraic framework.

The notion of dynamic feedback linearizability defined in §7 relies on the use of a discrete-time version of a so-called *Singh compensator* [23]. An open problem for further research is to determine to what extent the existence of a linearizing output is necessary for dynamic feedback linearizability using a more general class of dynamic compensators.

A. Construction of $\mathcal{K}^*$. As pointed out in §2, every difference field $\mathcal{K}$ can be embedded into an inversive difference overfield $\mathcal{K}^*$, which is called the inversive closure of $\mathcal{K}$. The inversive closure is unique up to an isomorphism. A precise statement of these properties can be found on pp. 66–67 of Cohn's monograph [11].

We next give an explicit construction of $\mathcal{K}^*$. This construction allows us to carry out the practical computations.

Assume that system Σ is given and is submersive. Hence $(\mathcal{K}, \delta)$ is a difference field. Denote by $\mathcal{E}$ the $\mathcal{K}$-vector space spanned by $\{\mathrm{d}\varphi \mid \varphi \in \mathcal{K}\}$. The operator δ induces a forward-shift operator $\Delta : \mathcal{E} \to \mathcal{E}$ by

$$\Delta\left(\sum_i a_i \mathrm{d}\varphi_i\right) \mapsto \sum_i a_i^+ \mathrm{d}\varphi_i^+,$$

where $a_i, \varphi_i \in \mathcal{K}$. With some abuse of notation, sometimes we write $\omega^+ = \Delta\,\omega$. The pair $(\mathcal{E}, \Delta)$ is a difference vector space [14]. Introduce a (nonunique) vector-valued function $z(0) = \varphi(x(0))$ such that $\mathrm{d}\varphi \in \operatorname{span}_{\mathcal{K}}\{\mathrm{d}x(0)\}$ and

$$\operatorname{span}_{\mathcal{K}}\{\mathrm{d}\bar{z}(0)\} \sim \frac{\operatorname{span}_{\mathcal{K}}\{\mathrm{d}x(0)\}}{\operatorname{span}_{\mathcal{K}}\{\mathrm{d}x(0)\} \cap \operatorname{span}_{\mathcal{K}}\{\mathrm{d}x(1)\}},$$

where $\mathrm{d}\bar{z}(0)$ denotes the coset associated to the element $\mathrm{d}z(0)$. Consequently,

$$\operatorname{span}_{\mathcal{K}}\{\mathrm{d}x(0)\} \subset \operatorname{span}_{\mathcal{K}}\{\mathrm{d}x(1)\} + \operatorname{span}_{\mathcal{K}}\{\mathrm{d}z(0)\}.$$

This implies that (locally) there exist a vector-valued function $\psi(x(1), z(0))$ such that $x(0) = \psi(x(1), z(0))$. Finally, let $\mathcal{K}^*/\mathcal{K}$ be the field extension of meromorphic functions in a finite number of the independent variables

$$\{x(0), u(t), u(-k), z(-k),\ t \geq 0\ k \geq 1\}.$$

Notice that although the choice of a variable $z(0) = \varphi(x(0))$ is not unique, each possible choice brings up a field extension that is isomorphic to $\mathcal{K}^*/\mathcal{K}$.

The pair $(\mathcal{K}^*, \delta)$ can be given the structure of an inversive difference field using the usual rules and noting that

$$\delta^{-1}x(0) = \delta^{-1}\psi(x(1), z(0)) = \psi(x(0), z(-1)).$$

B. Integrability of $\mathcal{H}_\infty$. Let $\mathcal{F}^*$ be the algebraic dual of $\mathcal{F}$. More precisely, $\mathcal{F}^*$ is the space of linear mappings from $\mathcal{F}$ to $\mathcal{K}^*$. As pointed out in §4 (see Lemma 4.3), the filtration

$$\operatorname{span}_{\mathcal{K}^*}\{\mathrm{d}x(0)\} = \mathcal{H}_1 \supset \cdots \supset \mathcal{H}_{k^*} \supset \mathcal{H}_\infty$$

can be viewed as a nested sequence of Pfaffian systems defined over $\mathbb{R}^N$, for some integer N large enough. Therefore, the elements of $\mathcal{F}^*$ can be viewed as sections or vector fields of the tangent bundle $T\mathbb{R}^N$. These vector fields can be written in the manner

$$X = \sum_{i,j} a_i \frac{\partial}{\partial x_i(0)} + \sum_{i,j} b_{i,j} \frac{\partial}{\partial u_i(j)} + \sum_{i,j} c_{i,j} \frac{\partial}{\partial u_i(-j)} + \sum_{i,j} d_{i,j} \frac{\partial}{\partial z_i(-j)},$$

where $a_i, b_{i,j}, c_{i,j}, d_{i,j} \in \mathcal{K}^*$, all sums are finite, and the set

$$\left\{ \frac{\partial}{\partial x_i(0)}, \frac{\partial}{\partial u_i(j)}, \frac{\partial}{\partial u_i(-j)}, \frac{\partial}{\partial z_i(-j)} \right\}$$

is defined to be a dual basis of the canonical basis $\{\mathrm{d}x_i(0), \mathrm{d}u_i(j), \mathrm{d}u_i(-j), \mathrm{d}z_i(-j)\}$ of $\mathcal{F}$. Given a vector field $X \in \mathcal{F}^*$, its forward-shift X^+ is defined by

$$\langle X, \omega\rangle^+ = \langle X^+, \omega^+\rangle \quad \text{for all } \omega \in \mathcal{F}. \tag{31}$$

Formula (31) has to be interpreted in the following manner. First notice that $\langle X, \omega\rangle \in \mathcal{K}^*$, so that $\langle X, \omega\rangle^+ = \delta\langle X, \omega\rangle$ is well defined. Therefore, evaluating (31) with different choices of ω, we obtain a system of equations that uniquely defines X^+. Let us investigate this by an example.

Example B.1 (Example 4.7 continued). Consider the nonlinear system described by (11), and let $X = \frac{\partial}{\partial x_3(0)}$ be an element of $\mathcal{F}^*$. Assume that X^+ has the form

$$X^+ = \sum_{i=1}^{3} a_i \frac{\partial}{\partial x_i(0)} + \sum_{j=0}^{N} b_j \frac{\partial}{\partial u(j)},$$

where $a_i, b_j \in \mathcal{K}^*$. Evaluating (31) with different choices of ω yields the system of equations

$$\begin{aligned}
&\langle X, \mathrm{d}x_1(0)\rangle^+ = 0 = \langle X^+, \mathrm{d}x_1(1)\rangle = (x_3^2(0)+1)^2 a_1 + 4x_1(0)x_3(0)(x_3^2(0)+1)a_3,\\
&\langle X, \mathrm{d}x_2(0)\rangle^+ = 0 = \langle X^+, \mathrm{d}x_2(1)\rangle = (x_3^2(0)+1)^3 a_2 + 6x_2(0)x_3(0)(x_3^2(0)+1)^2 a_3,\\
&\langle X, \mathrm{d}x_3(0)\rangle^+ = 1 = \langle X^+, \mathrm{d}x_3(1)\rangle = a_3 + b_0,\\
&\langle X, \mathrm{d}u(j)\rangle^+ = 0 = \langle X^+, \mathrm{d}u(j+1)\rangle = b_{j+1}, \qquad j \geq -1.
\end{aligned} \tag{32}$$

Equations (32) have the unique solution $b_j = 0$, $a_3 = 1$, $a_2 = -6x_2(0)x_3(0)/(x_3^2(0)+1)$, $a_1 = -4x_1(0)x_3(0)/(x_3^2(0)+1)$. Therefore, one concludes that

$$X^+ = -4\left[\frac{x_1(0)x_3(0)}{(x_3^2(0)+1)}\right]\frac{\partial}{\partial x_1(0)} - 6\left[\frac{x_2(0)x_3(0)}{(x_3^2(0)+1)}\right]\frac{\partial}{\partial x_2(0)} + \frac{\partial}{\partial x_3(0)}.$$

We now prove that $\mathcal{H}_\infty$, when viewed as a Pfaffian system defined on $T^*\mathbb{R}^N$, is completely integrable.

Let $\{\alpha_1, \ldots, \alpha_{\rho_\infty}\}$ be a basis for $\mathcal{H}_\infty$. The characteristic vector fields $\mathcal{H}_\infty$ are the elements of the set

$$\mathcal{G}_\infty = \{X \in \mathcal{F}^* \mid \langle X, \omega\rangle = 0,\ \alpha_1 \wedge \cdots \wedge \alpha_{\rho_\infty} \wedge X \lrcorner d\omega = 0\ \forall\, \omega \in \mathcal{H}_\infty\}.$$

The characteristic system of $\mathcal{H}_\infty$ is defined to be $C(\mathcal{H}_\infty) = \mathcal{G}_\infty^\perp$. It is clear that $\mathcal{H}_\infty \subset C(\mathcal{H}_\infty)$. The rest of the proof consists of showing the converse inclusion.

First we show that $\mathcal{G}_\infty$ is invariant under forward-shifting. Let $X \in \mathcal{G}_\infty$, and $\omega \in \mathcal{H}_\infty$. Therefore one has

$$\begin{aligned} \langle X, \omega\rangle^+ &= \langle X^+, \omega^+\rangle = 0, \\ (\alpha_1 \wedge \cdots \wedge \alpha_{\rho_\infty} \wedge X \lrcorner d\omega)^+ &= \alpha_1^+ \wedge \cdots \wedge \alpha_{\rho_\infty}^+ \wedge X^+ \lrcorner d\omega^+ = 0. \end{aligned} \tag{33}$$

The fact that $\mathcal{H}_\infty$ is closed under forward-shifting implies that $\alpha_i^+, \omega^+ \in \mathcal{H}_\infty$. Hence, $\mathcal{G}_\infty$ is closed under forward-shifting because (33) hold for any $\omega \in \mathcal{H}_\infty$.

Next we show that $C(\mathcal{H}_\infty)$ is also closed under forward-shifting. Let $\eta \in C(\mathcal{H}_\infty)$ and $X \in \mathcal{G}_\infty$. Then one has

$$\langle X, \eta\rangle^+ = \langle X^+, \eta^+\rangle = 0. \tag{34}$$

The fact that $\mathcal{G}_\infty$ is closed under forward-shifting implies that $X^+ \in \mathcal{G}_\infty$. Hence $C(\mathcal{H}_\infty)$ is closed under forward-shifting because (34) holds for any $X \in \mathcal{G}_\infty$.

Finally note that $\mathcal{H}_\infty$ is the largest subspace of $\mathcal{H}_1$ that is closed under forward-shifting so that $C(\mathcal{H}_\infty) \subset \mathcal{H}_\infty$. We have shown that $\mathcal{H}_\infty = C(\mathcal{H}_\infty)$, and the result follows.

Acknowledgments. The authors are greatly indebted to the anonymous referees for their insightful comments. The first and the third authors would also like to thank Professor J. W. Grizzle for his valuable comments on the subject of this paper.

This work was performed in part with the auspices of the GR Automatique of CNRS, France. The work of E. Aranda-Bricaire was done while he was with Laboratoire d'Automatique de Nantes with the support of CONACYT and CINVESTAV-IPN, Mexico. The work of Ü. Kotta was done during her visit at Laboratoire d'Automatique de Nantes with the support of the European Union.

NUMERICAL STABILIZATION OF BILINEAR CONTROL SYSTEMS*

LARS GRÜNE†

Abstract. Extremal Lyapunov exponents for bilinear control systems with constrained control values are computed numerically by solving discounted optimal control problems. Based on this computation a numerical algorithm to calculate stabilizing control functions is developed.

Key words. stabilization, bilinear control systems, Lyapunov exponents, discounted optimal control problems, Hamilton–Jacobi–Bellman equation

1. Introduction.

In this paper we present numerical algorithms for the calculation of extremal Lyapunov exponents and stabilization of bilinear control systems in $\mathbb{R}^d$, i.e., systems of the form

$$\dot{x}(t) = \Big(A_0 + \sum_{i=1}^{m} u_i(t) A_i\Big) x(t), \quad x(0) = x_0 \in \mathbb{R}^d \setminus \{0\} \tag{1.1}$$

with $A_j \in \mathbb{R}^{d\times d}$, $j = 0, \dots, m$, $u(\cdot) \in \mathcal{U} := \{u : \mathbb{R} \to U,\ u \text{ measurable}\}$ with a compact and convex set of control values $U \subset \mathbb{R}^m$ with nonvoid interior. The Lyapunov exponent of (1.1) with respect to an initial value $x_0 \in \mathbb{R}^d$ and a control function $u(\cdot) \in \mathcal{U}$ is given by

$$\lambda(x_0, u(\cdot)) := \limsup_{t\to\infty} \frac{1}{t} \ln \|x(t, x_0, u(\cdot))\|,$$

where $x(t, x_0, u(\cdot))$ denotes the trajectory of (1.1).

Bilinear control systems arise, e.g., by linearization of a nonlinear control system with a common fixed point x^* for all control values $u \in U$ with respect to x. They were first studied systematically by Mohler [18] in 1973. Lyapunov exponents were introduced by A.V. Lyapunov in 1892 (under the name of order numbers) as a tool to study nonlinear differential equations via their linearizations along trajectories. Recent results about the Lyapunov spectrum of families of time-varying matrices (cf. Colonius and Kliemann [11]) made it possible to characterize the domain of null controllability of bilinear systems using Lyapunov exponents (cf. Colonius and Kliemann [10]). A basic property of the Lyapunov exponents is that $\lambda(x, u(\cdot)) < 0$ iff $x(t, x_0, u(t))$ converges to zero faster than any exponential e^{at} with $\lambda(x_0, u(\cdot)) < a < 0$. As an easy consequence $\inf_{u(\cdot)\in\mathcal{U}} \lambda(x_0, u(\cdot)) < 0$ implies that there exists a control function such that the corresponding trajectory converges to zero. The domain of null controllability—the set of all points x_0 with negative minimal Lyapunov exponent—may be only a part of $\mathbb{R}^d$ and as a consequence stabilization may only be possible for subsets of $\mathbb{R}^d$. Null controllability in this context always means asymptotical null controllability since the origin is not reachable in finite time from any other point of the state space. This implies that an approach via the minimum time function (cf. e.g., Bardi and Falcone [1]) does not apply here.

In contrast to the direct approach to this stabilization problem via Lyapunov functions (cf., e.g., Chabour, Sallet, and Vivalda [5]) the method developed here is in some sense an indirect approach:

*Received by the editors August 3, 1994; accepted for publication (in revised form) September 8, 1995.

†Institut für Mathematik, Universität Augsburg, Universitätsstr. 8, 86135 Augsburg, Germany (Lars.Gruene@Math.Uni-Augsburg.de).

First a numerical approximation of the extremal Lyapunov exponents of (1.1) is calculated. This enables us to characterize the stability properties of (1.1). Once this approximation is known we stabilize the system (i.e., we find control functions such that the corresponding trajectories converge to zero) by searching for control functions such that the corresponding Lyapunov exponent is close to the minimal exponent or at least negative. In §2 these problems are discussed in terms of optimal control theory. We show that the problem of calculating extremal Lyapunov exponents—which can be expressed as an average yield optimal control problem—can be approximated by discounted optimal control problems.

If we look at the uncontrolled system with $U = \{0\}$ it turns out that the Lyapunov exponents are just the real parts of the eigenvalues of A_0. Together with the corresponding eigenspaces they determine the stability properties of the system. For the controlled system we need suitable generalizations of eigenspaces associated with the Lyapunov exponents. The basic ideas of this concept are presented in §3, followed by an interpretation of the results of §2 in terms of calculating extremal Lyapunov exponents.

Section 4 presents algorithms to solve discounted optimal control problems numerically based on a discretization scheme by Capuzzo Dolcetta [2], Capuzzo Dolcetta and Ishii [4], and Falcone [12], [13] connected to the framework of dynamic programming (cf. [3]). Section 5 contains several numerical examples calculated with these algorithms.

2. Discounted and average cost optimal control problem. In this section we will show that average yield optimal control problems can be approximated by discounted optimal control problems.

Consider a control system on a *connected n-dimensional C^∞-manifold M* given by

$$\dot{x}(t) = X(x(t), u(t)) \quad \text{for all } t \in \mathbb{R}, \tag{2.1}$$

$$x(0) = x_0 \in M, \tag{2.2}$$

$$u(\cdot) \in \mathcal{U} := \{u : \mathbb{R} \to U \mid u \text{ measurable}\}, \tag{2.3}$$

with

$$U \subseteq \mathbb{R}^m \text{ compact}, \tag{2.4}$$

$$X(\cdot, u) \text{ is a } C^\infty\text{−vector field on } M, \text{ continuous on } M \times U, \tag{2.5}$$

$$\text{for all } x \in M,\ u(\cdot) \in \mathcal{U} \text{ the trajectory } \varphi(t, x, u(\cdot)) \text{ exists for all } t \in \mathbb{R}. \tag{2.6}$$

We now consider the following two optimal control problems given by the control system (2.1)–(2.6) and a cost function g satisfying

$$g : M \times U \to \mathbb{R} \text{ continuous on } M \times U, \tag{2.7}$$

$$|g(x, u)| \le M_g \quad \text{for all } (x, u) \in M \times U. \tag{2.8}$$

The δ-discounted cost for $\delta > 0$ and the average cost are defined by

$$J_\delta(x, u(\cdot)) := \int_0^\infty e^{-\delta t} g(\varphi(t, x, u(\cdot)), u(t))dt, \tag{2.9}$$

$$J_0(x, u(\cdot)) := \limsup_{T\to\infty} \frac{1}{T} \int_0^T g(\varphi(t, x, u(\cdot)), u(t))dt. \tag{2.10}$$

The associated optimal value functions are

$$v_\delta(x) := \inf_{u(\cdot)\in\mathcal{U}} J_\delta(x, u(\cdot)), \tag{2.11}$$

$$v_0(x) := \inf_{u(\cdot)\in\mathcal{U}} J_0(x, u(\cdot)). \tag{2.12}$$

A basic property of the discounted optimal value function is Bellman's optimality principle: for any $t > 0$ we have

$$v_\delta(x) = \inf_{u(\cdot)\in\mathcal{U}} \left\{ \int_0^t e^{-\delta s} g(\varphi(s, x, u(\cdot)), u(s))ds \;+\; e^{-\delta t} v_\delta(\varphi(t, x, u(\cdot))) \right\}. \tag{2.13}$$

For the average cost a similar estimate is valid: for any $t > 0$ we have

$$v_0(x) = \inf_{u(\cdot)\in\mathcal{U}} \{v_0(\varphi(t, x, u(\cdot)))\}. \tag{2.14}$$

Results about the relation between discounted and average cost optimal control problems as the discount rate tends to zero have been developed by Colonius [6] and Wirth [20]. Here we will first show the relation between the values of δJ_δ and J_0 along certain trajectories. Then we will use similar techniques as in [6] and [20] to obtain convergence results for the optimal value functions. The first theorem shows that J_0 is bounded if δJ_δ is bounded. Since J_0 has an infinite time horizon it is not sufficient that δJ_δ is bounded for the initial value. It has to be bounded for all $\varphi(t, x, u(\cdot))$, $t > 0$, and the corresponding shifted control function.

THEOREM 2.1 (approximation theorem I). *Consider optimal control systems on M given by* (2.1)–(2.6) *and* (2.7)–(2.10)*, a discount rate $\delta > 0$, $x \in M$, $u(\cdot) \in \mathcal{U}$, $C \in \mathbb{R}$, and $\alpha > 0$ such that $\delta J_\delta(\varphi(t, x, u(\cdot)), u(t + \cdot)) \le C - \alpha$ for all $t \ge 0$. Then*

$$J_0(x, u(\cdot)) < C.$$

Proof. We may assume $C = 0$ by using $g - C$ instead of g. In the first step we show that for every $t > 0$ there exists a $\tilde\tau(t)$ such that

$$\int_t^{\tilde\tau(t)} g(\varphi(s, x, u(\cdot)), u(s))ds \le -\frac{\alpha}{2\delta}. \tag{2.15}$$

Abbreviate $f(s) := e^{-\delta(s-t)} g(\varphi(s, x, u(\cdot)), u(s))$. Obviously there exists a $\tilde\tau(t)$ such that (2.15) is true for the shifted discounted functional $\int_t^{\tilde\tau(t)} f(s)ds \le -\frac{\alpha}{2\delta}$. Choose $\tilde\tau(t)$ minimal with this property. Since g is bounded there exist constants $a, b > 0$ such that $\tilde\tau(t) - t \in [a, b]$ for all $t > 0$, $a = \frac{\alpha}{2\delta M_g}$. In the case of $\int_t^{\tilde\tau(t)} f^+(s)ds = 0$, (2.15) is immediately implied. In the case of $\int_t^{\tilde\tau(t)} f^+(s)ds > 0$ it follows that $\int_t^{\tilde\tau(t)} f^-(s)ds < -\frac{\alpha}{2\delta}$, and we can choose $\gamma > 0$ maximal such that $\int_t^{t+\gamma} f^-(s)ds = -\frac{\alpha}{2\delta}$. Hence we have

$$\int_t^\tau f^+(s)ds - \int_{t+\gamma}^\tau f^-(s)ds > 0 \quad \text{for all } \tau \in [t + \gamma, \tau(\tilde t))$$

and

$$\int_t^{\tilde\tau(t)} f^+(s)ds - \int_{t+\gamma}^{\tilde\tau(t)} f^-(s)ds = 0.$$

Fixing $\varepsilon > 0$ we can define a monotone increasing sequence (τ_i), $i \in \mathbb{N}$ by $\tau_1 := t$, $\tau_2 := t + \gamma$,

$$\tau_{i+1} := \max \left\{ \tau \in [\tau_i, \tilde\tau(t) \mid \int_{\tau_{i-1}}^{\tau_i} f^+(s)ds = \int_{\tau_i}^{\tau_{i+1}} f^-(s)ds \right\}.$$

From the construction of this sequence it follows that τ_i converges to $\tilde{\tau}(t)$, and we may truncate the sequence by choosing $k \in \mathbb{N}$ such that $|\tau_{k-1} - \tilde{\tau}(t)| < \varepsilon$ and set $\tau_k := \tilde{\tau}(t)$. Now we can estimate

$$\begin{aligned}
\int_t^{\tilde{\tau}(t)} g(\varphi(s,x,u(\cdot)),u(s))ds &= \int_t^{\tilde{\tau}(t)} e^{\delta(s-t)} f(s)ds \\
&\leq \sum_{i=2}^{n-1} \left(\int_{\tau_{i-1}}^{\tau_i} e^{\delta(s-t)} f^+(s)ds - \int_{\tau_i}^{\tau_{i+1}} e^{\delta(s-t)} f^-(s)ds \right) + M_g\varepsilon - \frac{\alpha}{2\delta} \\
&\leq \sum_{i=2}^{n-1} \left(\underbrace{\int_{\tau_{i-1}}^{\tau_i} e^{\delta(\tau_i-t)} f^+(s)ds - \int_{\tau_i}^{\tau_{i+1}} e^{\delta(\tau_i-t)} f^-(s)ds}_{=0} \right) + M_g\varepsilon - \frac{\alpha}{2\delta} \\
&= M_g\varepsilon - \frac{\alpha}{2\delta},
\end{aligned}$$

which proves (2.15) since $\varepsilon > 0$ was arbitrary.

To prove the theorem we first fix $T > 0$ and define a sequence $(\tilde{\tau}_i)$, $1 \leq i \leq k$ by $\tilde{\tau}_0 := 0$, $\tilde{\tau}_{i+1} := \tilde{\tau}(\tilde{\tau}_i)$, as long as $\tilde{\tau}(\tilde{\tau}_i) \leq T$, $\tilde{\tau}_k := T$. Then we have $a \leq \tilde{\tau}_{i+1} - \tilde{\tau}_i \leq b$ for all $i = 0, \ldots, k-1$ and hence $\frac{T}{b} \leq k \leq \frac{T}{a}$. By definition of $\tilde{\tau}(t)$ it follows that $\int_{\tilde{\tau}_i}^{\tilde{\tau}_{i+1}} g(\varphi(t,x,u(\cdot)),u(t))dt < -\frac{\alpha}{2\delta}$ for all $i = 0, \ldots, k-2$. This yields

$$\begin{aligned}
&\int_0^T g(\varphi(t,x,u(\cdot)),u(t))dt \\
&= \sum_{i=0}^{k-2} \int_{\tilde{\tau}_i}^{\tilde{\tau}_{i+1}} g(\varphi(t,x,u(\cdot)),u(t))dt + \int_{\tilde{\tau}_{k-1}}^{\tilde{\tau}_k} g(\varphi(t,x,u(\cdot)),u(t))dt \\
&\leq -\frac{k\alpha}{2\delta} + (\tilde{\tau}_k - \tilde{\tau}_{k-1})M_g \leq -\frac{T\alpha}{2b\delta} + bM_g \qquad (2.16)
\end{aligned}$$

and as a conclusion

$$\limsup_{T\to\infty} \frac{1}{T} \int_0^T g(\varphi(t,x,u(\cdot)),u(t))dt \leq \limsup_{T\to\infty} -\frac{\alpha}{2b\delta} + \frac{bM_g}{T} = -\frac{\alpha}{2b\delta} < 0,$$

which finishes the proof. □

Note that it is possible just to replace $\leq$ by $\geq$ and $-\alpha$ by $+\alpha$ to obtain the analogous result for a lower bound of J_0.

THEOREM 2.2 (approximation theorem II). *Consider optimal control systems on M given by* (2.1)–(2.6) *and* (2.7)–(2.10).

Assume there exists a control function $u(\cdot) \in \mathcal{U}$ such that $J_0(x,u(\cdot)) \leq C - \alpha$ for constants $C \in \mathbb{R}$, $\alpha > 0$. Then there exists a constant $R = R(x,u(\cdot),\alpha) > 0$ such that

$$\delta J_\delta(x,u(\cdot)) < C \quad \text{for all } \delta < R.$$

Proof. We may again assume $C = 0$. Hence it follows that there exists $T_0 \geq 0$ such that

$$\int_0^T g(\varphi(t,x,u(\cdot)),u(t))dt \leq T\left(-\frac{\alpha}{2}\right) \quad \text{for all } T \geq T_0. \qquad (2.17)$$

Now assume that $\delta J_\delta(x, u(\cdot)) \geq 0$ for arbitrarily small $\delta > 0$. The first step of the proof of Theorem 2.1 for the opposite inequality with $t = 0$ applied to $g + \frac{\alpha}{2}$ then yields that there exist arbitrarily large times $\tilde{T} > 0$ such that

$$\int_0^{\tilde{T}} g(\varphi(t, x, u(\cdot)), u(t))dt + \tilde{T}\frac{\alpha}{2} > 0,$$

which contradicts (2.17). Hence the assertion follows. □

In contrast to the first approximation theorem here it is not possible simply to replace $\leq$ by $\geq$ and $-\alpha$ by $+\alpha$ to obtain an analogous result for the lower bound. Estimate (2.17) does only hold for the reverse inequality if in (2.10) the lim sup is replaced by the lim inf.

We will now combine these two theorems with controllability properties to obtain results about the relation between δv_δ and v_0 as δ tends to zero. To do this we first introduce some definitions.

DEFINITION 2.3. *The* positive orbit *of $x \in M$ up to the time T is defined by*

$$O_T^+(x) := \{y \in M \mid \text{there is } 0 \leq t \leq T \text{ and } u(\cdot) \in \mathcal{U}, \text{ such that } \varphi(t, x, u(\cdot)) = y\}.$$

The positive orbit *of $x \in M$ is defined by*

$$O^+(x) := \bigcup_{T \geq 0} O_T^+(x).$$

The negative orbits $O_T^-(x)$ and $O^-(x)$ are defined similarly by using the time-reversed system.

For a subset $D \subset M$ we define $O_T^+(D) := \bigcup_{x \in D} O_T^+(x)$ and $O^+(D)$, $O_T^-(D)$, $O^-(D)$ analogously.

DEFINITION 2.4. *A subset $D \subseteq M$ is called a* control set *if*

(i) $D \subseteq \overline{O^+(x)}$ *for all $x \in D$,*

(ii) *for every $x \in D$ there is $u(\cdot) \in \mathcal{U}$ such that the corresponding trajectory $\varphi(t, x, u(\cdot))$ stays in D for all $t \geq 0$,*

(iii) *D is maximal with the properties* (i) *and* (ii).

A control set C is called invariant *if*

$$\overline{C} = \overline{O^+(x)} \text{ for all } x \in C.$$

A noninvariant control set is called variant.

In order to avoid degenerate situations we need the following setup: Let $L = \mathcal{LA}\{X(\cdot, u), u \in U\}$ denote the Lie algebra generated by the vector fields $X(\cdot, u)$. Let Δ_L denote the distribution generated by L in TM, the tangent space of M. Assume that

$$\dim \Delta_L(x) = \dim M \text{ for all } x \in M. \tag{2.18}$$

This assumption guarantees that the positive and negative orbits of any point $x \in M$ up to any time $T \neq 0$ have nonvoid interior. Note that the definition of control sets demands only approximate reachability (i.e., existence of controls steering into any neighborhood of a given point); as a consequence of assumption (2.18) we have exact controllability in the interior of control sets, more precisely $\text{int}D \subset O^+(x)$ for all $x \in D$.

The following proposition shows—as an extension of [7, Prop. 2.3]—that we have exact controllability in *finite time* on certain compact subsets.

PROPOSITION 2.5. *Consider a control system on M given by* (2.1)–(2.6) *and satisfying* (2.18). *Let $D \subset M$ be a control set and consider compact sets $K_1 \subset O^-(D)$, $K_2 \subset \text{int}D$.*

Then there exists a constant $r > 0$ such that for every $x \in K_1$, $y \in K_2$ there exists a control function $u(\cdot) \in \mathcal{U}$ with $\varphi(t_0, x, u(\cdot)) = y$ for some $t_0 \leq r$.

Proof. (i) We first show that for every $x \in K_1$, $z \in K_2$ there is an open neighborhood $U(x)$ such that all $y \in U(x)$ can be steered to z in bounded time t_0. By (2.18) there is $T < \infty$ and $z_1 \in \text{int}D \cap O^-_{\leq T}(z)$ and an open neighborhood $U(z_1) \subset \text{int}D \cap O^-_{\leq T}(z)$. For $x \in K$ there exists a control $u(\cdot) \in \mathcal{U}$ and a time $t_1 < \infty$ such that $\varphi(t_1, x, u(\cdot)) = z_1$ (as a consequence of exact controllability in the interior of control sets). Since the solutions of the system depend continuously on the initial value, there is an open neighborhood $U(x)$ with $\varphi(t_1, x_1, u(\cdot)) \in U(z_1)$ for all $x_1 \in U(x)$. Putting this together yields $U(x) \subset O^-_{\leq t_1+T}(y)$, which proves the assertion with $t_0 \leq t_1 + T$.

(ii) For $x \in K_1$, $y \in K_2$ we now show that there exists a time $t_y < \infty$ such that all z in some open neighborhood of y can be reached from x in time t_y. Let $x_1 \in \text{int}D$ and $u_1(\cdot) \in \mathcal{U}$, $t_1 < \infty$ such that $\varphi(t_1, x, u(\cdot)) = x_1$ (the existence of x_1, $u_1(\cdot)$, t_1 follows from (2.18)). Again by (2.18) there exists $T < \infty$ and $y_1 \in \text{int}D \cap \mathcal{O}^-_{\leq T}(x_1)$; let $U(y_1)$ be an open neighborhood of y_1 contained in $\text{int}D \cap \mathcal{O}^-_{\leq T}(x_1)$. Now because of the exact controllability there exists $u_2(\cdot) \in \mathcal{U}$, $t_2 < \infty$ with $\varphi(t_2, y_1, u_2) = y$. Since the solution of the control system using the control $u_2(\cdot)$ defines a semigroup of homeomorphisms on M, the open neighborhood $U(y_1)$ is mapped onto some open neighborhood $U(y)$ and $U(y) \subset \mathcal{O}^+_{\leq t_1+T+t_2}(x)$. This means that all $z \in U(y)$ can be reached from x in time $t_y = t_1 + T + t_2$.

(iii) Because of the compactness of K_1 and K_2 now the proof of the proposition follows. □

The following proposition summarizes the consequences of these controllability properties for the optimal value functions.

PROPOSITION 2.6. *Consider optimal control systems on M given by* (2.1)–(2.6) *and* (2.7)–(2.10) *and satisfying* (2.18). *Let $D \subset M$ be a control set and consider compact sets $K_1 \subset O^-(D)$, $K_2 \subset \text{int}D$. Then the following estimates hold:*

(i) $v_0(x) = v_0(y)$ *for all* $x, y \in \text{int}D$.

(ii) $v_0(x) \leq v_0(y)$ *for all* $x \in O^-(D)$, $y \in \text{int}D$.

(iii) $|\delta v_\delta(x) - \delta v_\delta(y)| \leq \varepsilon(\delta)$ *for all* $x, y \in K_2$.

(iv) $\delta v_\delta(x) \leq \delta v_\delta(y) + \varepsilon(\delta)$ *for all* $x \in K_1$, $y \in K_2$

and $\varepsilon(\delta) \to 0$ as δ tends to zero.

Proof. Just combine (2.13) and (2.14) with the controllability properties stated above. □

Now we can formulate the results about the relation between the optimal value functions.

PROPOSITION 2.7. *Consider optimal control systems on M given by* (2.1)–(2.6) *and* (2.7)–(2.10) *and satisfying* (2.18). *Then*

$$\limsup_{\delta \to 0} \delta v_\delta(x) \leq v_0(x) \quad \textit{for all } x \in M.$$

Proof. Fix $\varepsilon > 0$. Choose a control function $u(\cdot)$ such that $|v_0(x) - J_0(x, u(\cdot))| \leq \frac{\varepsilon}{2}$. Using Theorem 2.2 with $\alpha = \frac{\varepsilon}{2}$ yields a $R_1 > 0$ such that for all $\delta \in (0, R_1]$: $\delta v_\delta(x) \leq \delta J_\delta(x, u(\cdot)) \leq J_0(x, u(\cdot)) + \frac{\varepsilon}{2} \leq v_0(x) + \varepsilon$. It follows that $\limsup_{\delta \to 0} \delta v_\delta(x) \leq v_0(x)$ since $\varepsilon > 0$ was arbitrary. □

PROPOSITION 2.8. *Consider optimal control systems on M given by* (2.1)–(2.6) *and* (2.7)–(2.10) *and satisfying* (2.18). *Let $D \subseteq M$ be a control set. Then for every compact $Q \subset \text{int}D$ and every $\varepsilon > 0$ there exists a $R_0 > 0$ such that*

$$\delta v_\delta(x) \leq v_0(x) + \varepsilon \quad \textit{for all } \delta \in (0, R_0], \quad x \in Q.$$

Proof. Fix $x_0 \in Q$. Using Proposition 2.7 we know that there exists a constant $R_1 > 0$ such that $\delta v_\delta(x_0) \leq v_0(x_0) + \frac{\varepsilon}{2}$ for all $\delta \in (0, R_1]$. Now choose $R_2 > 0$ such that

Proposition 2.6 (iii) holds with $\varepsilon(\delta) < \frac{\varepsilon}{2}$ for $\delta < R_2$. Since v_0 is constant on Q now the assertion holds for all $x \in Q$ with $R_0 := \min\{R_1, R_2\}$. □

LEMMA 2.9 (pointwise convergence). *Consider optimal control systems on M given by* (2.1)–(2.6) *and* (2.7)–(2.10). *Assume there exists $x \in M$, $R \in \mathbb{R}$, and a set $B \subset M$ such that $\delta v_\delta(y) \le \delta v_\delta(x) + \alpha(\delta)$ for all $y \in B$, $\delta \in (0, R]$, and constants $\alpha(\delta) \ge 0$. Assume there exist optimal controls $u_\delta(\cdot) \in \mathcal{U}$ for all $\delta \in (0, R]$ such that $\varphi(t, x, u_\delta(\cdot)) \in B$ for all $t \ge 0$. Then for every $\varepsilon > 0$ there exists $R_0 > 0$ such that*

$$|\delta v_\delta(x) - v_0(x)| \le \max\{\varepsilon, \alpha(\delta)\} \text{ for all } \delta \in (0, R_0].$$

In particular if $\alpha(\delta) \to 0$ as $\delta \to 0$ the convergence $\delta v_\delta(x) \to v_0(x)$ is implied.

Proof. From Theorem 2.1 it is clear that $v_0(x) \le \delta v_\delta(x) + \alpha(\delta)$ for all $\delta < R$. Now choose a control function $u(\cdot)$ such that $|v_0(x) - J_0(x, u(\cdot))| \le \frac{\varepsilon}{2}$. Using Theorem 2.2 with $\alpha = \frac{\varepsilon}{2}$ yields $R_0 > 0$ such that for all $\delta < R_0$: $\delta v_\delta(x) \le \delta J_\delta(x, u(\cdot)) \le J_0(x, u(\cdot)) + \frac{\varepsilon}{2} \le v_0(x) + \varepsilon$. Combining these inequalities finishes the proof. □

By using the estimate of Proposition 2.6, two results on uniform convergence can be obtained.

THEOREM 2.10 (uniform convergence). *Consider optimal control systems on M given by* (2.1)–(2.6) *and* (2.7)–(2.10) *and satisfying* (2.18). *Let $D \subseteq M$ be a control set and assume there exist $x_0 \in \mathrm{int}D$, a compact subset $K \subseteq D$, and optimal controls $u_\delta(\cdot)$ such that*

$$\varphi(t, x_0, u_\delta(\cdot)) \in K \text{ for all } t \ge 0 \text{ for all } \delta \in (0, R]$$

for some constant $R > 0$. Then

$$\delta v_\delta \to v_0 \text{ uniformly on compact subsets of } \mathrm{int}D.$$

Proof. By Proposition 2.6 (iii), on any compact subset Q of $\mathrm{int}D$ we have $|\delta v_\delta(x) - \delta v_\delta(y)| \le \varepsilon(\delta) \to 0$ uniformly for all $x, y \in Q$ as δ tends to zero. By Proposition 2.6 (iv), x_0 and K fulfill the conditions of Lemma 2.9 with $\alpha(\delta) = \varepsilon(\delta)$ since $K \subseteq D \subseteq O^-(D)$. Hence pointwise convergence follows. Since v_0 is constant on $\mathrm{int}D$, uniform convergence on Q follows. □

THEOREM 2.11 (uniform convergence in compact invariant control sets). *Consider optimal control systems on M given by* (2.1)–(2.6) *and* (2.7)–(2.10) *and satisfying* (2.18). *Let $C \subseteq M$ be a compact invariant control set. Then for $\delta \to 0$*

(i) $\delta v_\delta(x) \to v_0(x)$ *for all* $x \in \mathrm{int}C$,

(ii) $\delta v_\delta \to v_0$ *uniformly on compact subsets of* $\mathrm{int}C$,

(iii) *if M is compact and C is the unique invariant control set we have* $\sup_{x \in M} \delta v_\delta(x) \to \sup_{x \in M} v_0(x)$.

Proof. Since C is a compact subset of C and no trajectory can leave C, the conditions of Theorem 2 (with $K = C$) are fulfilled. Hence the assertions (i) and (ii) follow.

If M is compact and C is the unique invariant control set it follows that $O^-(C) = M$ [16, proof of Lem. 2.2 (i)].

From Proposition 2.6 (ii) and (iv) and the compactness of $M = O^-(C)$, it follows for any compact subset $Q \subset \mathrm{int}C$ that $v_0(x) \le v_0(y)$ and $\delta v_\delta(x) \le \delta v_\delta(y) + \varepsilon(\delta)$ for all $x \in M$, $y \in Q$. Since we have uniform convergence on Q assertion (iii) of Theorem 2.11 is proved. □

Remark 2.12. Note that these results are not valid in general for the corresponding maximization problems, since the second approximation theorem is not valid for the reverse inequality. However some of the results remain valid and others are valid under additional conditions.

(i) The application of the results to the maximization problems is possible if the lim sup in (2.10) can be replaced by a lim inf without changing the value of v_0. This is possible if there exist approximately optimal trajectories and controls—with respect to the maximization problem—such that the lim sup is a limit. From [20, proof of Prop. 1.4 (a)] it is clear that this is the fact if there exist approximately optimal trajectories and controls which are periodic. A sufficient condition for this is that there exists an optimal trajectory that stays inside some compact subset $K \subset \operatorname{int} D$ (cf. [20, Prop. 2.7]).

(ii) Adding this condition to the assumptions of Theorem 2.10 we obtain Theorem 2.10 from Wirth [20] under the weaker condition that the optimal trajectories with respect to the discounted problems stay inside a compact subset of a control set instead of a compact subset of the *interior* of a control set.

(iii) For invariant control sets C we can use [7, Cor. 4.3] to conclude that for any initial value $x_0 \in \operatorname{int} C$ there exist approximately optimal periodic control functions and trajectories. Hence Theorem 3 remains valid for the maximization problem without any additional assumptions.

3. Lyapunov exponents of bilinear control systems. We will now return to the *bilinear control systems* in $\mathbb{R}^d$, i.e., systems of the form

$$\dot{x}(t) = \Big(A_0 + \sum_{i=1}^{m} u_i(t) A_i\Big) x(t), \quad x(0) = x_0 \in \mathbb{R}^d \setminus \{0\} \tag{3.1}$$

with $A_j \in \mathbb{R}^{d\times d}$, $j = 0, \dots, m$, $u(\cdot) \in \mathcal{U} := \{u : \mathbb{R} \to U,\ u \text{ measurable}\}$ with a compact and convex set of control values $U \subset \mathbb{R}^m$ with nonvoid interior.

We denote the unique trajectory for any initial value $x_0 \in \mathbb{R}^d$ and any control function $u(\cdot) \in \mathcal{U}$ by $x(t, x_0, u(\cdot))$.

In order to characterize the exponential growth rate of the solutions of (3.1) we define the Lyapunov exponent of a solution by

$$\lambda(x_0, u(\cdot)) := \limsup_{t\to\infty} \frac{1}{t} \ln \|x(t, x_0, u(\cdot))\|. \tag{3.2}$$

The minimal Lyapunov exponent with respect to $x_0 \in \mathbb{R}^n \setminus \{0\}$ is defined by

$$\lambda^*(x_0) := \inf_{u(\cdot)\in\mathcal{U}} \lambda(x_0, u(\cdot)), \tag{3.3}$$

and the extremal Lyapunov exponents of the control system are defined by

$$\kappa^* := \inf_{x_0\neq 0} \inf_{u(\cdot)\in\mathcal{U}} \lambda(x_0, u(\cdot)), \tag{3.4}$$

$$\kappa := \sup_{x_0\neq 0} \sup_{u(\cdot)\in\mathcal{U}} \lambda(x_0, u(\cdot)), \tag{3.5}$$

$$\tilde{\kappa} := \sup_{x_0\neq 0} \inf_{u(\cdot)\in\mathcal{U}} \lambda(x_0, u(\cdot)). \tag{3.6}$$

The Lyapunov exponent can be interpreted as a measure for the exponential growth of trajectories. Our aim is to calculate numerical approximations of the minimal and maximal Lyapunov exponents with respect to the initial values. If $\lambda^*(x_0) < 0$ the system can be steered asymptotically to the origin from x_0. Using the approximation of the Lyapunov exponents we then are able to calculate controls that stabilize the system.

For a bilinear control system (3.1) the following identity is obvious:

$$\lambda(x_0, u(\cdot)) = \lambda(\alpha x_0, u(\cdot)) \text{ for all } x_0 \in \mathbb{R}^d \setminus \{0\},\ \alpha \in \mathbb{R} \setminus \{0\},\ u \in \mathcal{U}.$$

Due to this observation we can identify all $x \neq 0$ lying on a straight line through the origin. Hence it is sufficient to consider initial values s_0 in $\mathbb{P}^{d-1}$, the real projective space. To calculate the Lyapunov exponents we can project the system onto the unit sphere $\mathbb{S}^{d-1}$ via $s_0 := x_0/\|x_0\|$. This yields the projection onto $\mathbb{P}^{d-1}$ by identifying opposite points. A simple application of the chain rule shows that the projected system can be written as

$$\dot{s}(t) = h_0(s(t)) + \sum_{i=1}^{m} u_i(t) h_i(s(t)) \tag{3.7}$$

where

$$h_i(s) = [A_i - s^t A_i s \cdot \mathrm{Id}]s \quad \text{for all } i = 0, \ldots, m.$$

The Lyapunov exponent (3.2) with respect to $s_0 = x_0/\|x_0\|$ can be written as

$$\lambda(x_0, u(\cdot)) = \lambda(s_0, u(\cdot)) = \limsup_{t\to\infty} \frac{1}{t} \int_0^t q(s(\tau, s_0, u(\cdot)), u(\tau)) d\tau \tag{3.8}$$

where

$$q(s, u) = s^t \Big(A_0 + \sum_{i=0}^{m} u_i A_i \Big) s. \tag{3.9}$$

We recall some facts about projected bilinear control systems and their Lyapunov exponents.

For the projected bilinear system assumption (2.18) reads

$$\dim \Delta_L(p) = d - 1 \text{ for all } p \in \mathbb{P}^{d-1}, \quad L = \mathcal{LA}\{h(\cdot, u), u \in U\}$$

where $h(\cdot, u) := h_0(\cdot) + \sum_{i=1}^{m} u_i h_i(\cdot)$. Under this assumption the following facts hold (cf. [9, Cor. 4.4], [8, Thm. 3.10]):

If κ_1 denotes the maximal Lyapunov exponent of the original system and κ_2^* the minimal exponent of the time-reversed system the identity $\kappa_1 = -\kappa_2^*$ holds.

For the projected system there exist k control sets with nonvoid interior where $1 \leq k \leq d$. These are called the main control sets. They are linearly ordered by $D_i < D_j \Leftrightarrow$ there exists $p_i \in D_i$, $p_j \in D_j$, $t > 0$, and $u(\cdot) \in \mathcal{U}$ such that $\varphi(t, p_i, u) = p_j$.

The control set D_1 is open; the control set $C := D_k$ is closed and invariant. All other control sets are neither open nor closed. Furthermore we have $O^-(p) = \mathbb{P}^{d-1}$ for all $p \in \mathrm{int}C$.

The linear order of the control sets implies a linear order on the minimal Lyapunov exponents (which can easily be proved using Proposition 2.6): $\lambda^*(p_i) \leq \lambda^*(p_j)$ for $p_i \in D_i$, $p_j \in D_j$, and $i < j$. Furthermore, $\lambda^*(p)$ is constant on the interior of control sets.

Under the following condition there is a stronger relation between the control sets of the projected and the Lyapunov exponents of the bilinear system. Considering the set of control values $\rho U := \{\rho u \mid u \in U\}$ for $\rho \geq 0$ and the corresponding set of control functions $\mathcal{U}^\rho$ we assume the following ρ–ρ' inner pair condition:

> For all $0 \leq \rho \leq \rho'$ and all $(u(\cdot), p) \in \mathcal{U}^\rho \times \mathbb{P}^{d-1}$ there exist $T > 0$ and $S > 0$ such that $\varphi(T, p, u(\cdot)) \in \mathrm{int} O_{S+T}^{\rho'+}(p)$ (the positive orbit corresponding to $\mathcal{U}^{\rho'}$).

Let D^ρ be a main control set corresponding to $\mathcal{U}^\rho$. We define the *Lyapunov spectrum of* (3.1) *over* $\overline{D^\rho}$ by

$$\Sigma_{Ly}^\rho(\overline{D^\rho}) := \{\lambda(p, u(\cdot)) \mid \varphi(t, p, u) \in \overline{D^\rho} \text{ for all } t \geq T \text{ for some } T \geq 0\}$$

and the *Lyapunov spectrum of* (3.1) by

$$\Sigma_{Ly}^{\rho} := \{\lambda(p, u(\cdot)) \mid u(\cdot) \in \mathcal{U},\ p \in \mathbb{P}^{d-1}\}.$$

Under the ρ–ρ' inner pair condition we know that

$$\Sigma_{Ly} = \bigcup_{i=1}^{k(\rho)} \Sigma_{Ly}(\overline{D_i^{\rho}}) \tag{3.10}$$

for all except at most countably many $\rho < \rho'$, where $k(\rho)$ is the number of main control sets D_i^{ρ} corresponding to $\mathcal{U}^{\rho}$ [11, Cor. 5.6].

Furthermore $\Sigma_{Ly}^{\rho}(\overline{D_i^{\rho}})$ are closed intervals and thus it is sufficient to calculate the minima and the maxima of $\Sigma_{Ly}(\overline{D_i^{\rho}})$ to obtain the whole Lyapunov spectrum of the system. These maxima and minima can be approximated by periodic trajectories with initial values in $\operatorname{int} D_i^{\rho}$.

In the case $d = 2$ these results hold for all $\rho > 0$ without assuming the ρ–ρ' inner pair condition [11, Cor. 4.9].

We will now give an interpretation of the results of §2 in terms of calculating Lyapunov exponents and stabilization. Since we are going to solve the discounted optimal control problem numerically we cannot expect to calculate optimal control functions but only ε-optimal control functions. We call a control function $u_x(\cdot) \in \mathcal{U}$ *uniformly ε-optimal* with respect to $x \in M$ iff $|\delta J_\delta(\varphi(t, x, u_x(\cdot)), u_x(t + \cdot)) - \delta v_\delta(\varphi(t, x, u_x(\cdot)))| < \varepsilon$ for all $t \geq 0$.

THEOREM 3.1. *Consider a bilinear control system* (3.1) *and the related optimal control system on* $\mathbb{P}^{d-1}$ *given by* (3.7) *and* (3.8) *with cost function q from* (3.9). *Assume* (2.18) *is satisfied. Let*

$$v_\delta(x) := \inf_{u(\cdot)\in\mathcal{U}} J_\delta(x, u(\cdot)) \quad \text{and} \quad \bar{v}_\delta(x) := \sup_{u(\cdot)\in\mathcal{U}} J_\delta(x, u(\cdot)).$$

Then the following estimates hold with $\varepsilon \to 0$ as δ tends to zero.

(i) $\delta v_\delta(x) \leq \lambda^*(x) + \varepsilon$ *for all* $x \in M$.

(ii) $\delta v_\delta(x) \leq \lambda^*(x) + \varepsilon$ *uniformly on compact subsets Q of the interior of control sets.*

(iii) $|\delta v_\delta(x) - \lambda^*(x)| \leq \varepsilon$ *uniformly on compact subsets Q of the interior of control sets under the conditions of Theorem* 2.10.

(iv) $|\delta v_\delta(x) - \lambda^*(x)| \leq \varepsilon$ *uniformly on compact subsets Q of the interior of the invariant control set.*

(v) $\sup_{x\in M} \delta v_\delta(x) \to \tilde{\kappa}$ *as δ tends to zero.*

(vi) $\inf_{x\in M} \delta \bar{v}_\delta(x) \to \kappa$ *as δ tends to zero.*

(vii) *If $\tilde{\kappa} < 0$ and $u_s(\cdot)$ is uniformly ε-optimal with respect to s then $\varphi(t, x, u_s(\cdot))$ is asymptotically stable for all $x \in \mathbb{R}^d$ with $s = x/\|x\|$ provided δ and ε are sufficiently small.*

(viii) *If $\lambda^* < 0$ in the interior of some control set D and $u_s(\cdot)$ is uniformly ε-optimal with respect to s and $\varphi(t, s, u_s(\cdot))$ stays inside a compact subset of $O^-(D)$ for all times, then $\varphi(t, x, u_s(\cdot))$ is asymptotically stable for all $x \in \mathbb{R}^d$ with $s = x/\|x\|$ provided δ and ε are sufficiently small.*

Proof. All assertions follow directly from the results in §2. Assertion (iv) is true since the invariant control set of the projected system is compact. Assertions (v) and (vi) are proved using the fact that the projective space is compact and that there exists a unique invariant control set for the projected system. □

Remark 3.2. Knowing the facts cited in this section we can see that even more can be calculated.

(i) Property (vi) can be used to calculate κ^* by calculating κ of the time reversed system. Hence it is possible to approximate κ, κ^*, and $\tilde{\kappa}$ for any bilinear control system satisfying (2.18) by solving discounted optimal control problems.

(ii) For all main control sets D_i we can approximate the minimal Lyapunov exponent over $\operatorname{int} D_i$ as follows: Proposition 2.8 yields that $\delta v_\delta < \lambda^* + \varepsilon$ uniformly on compact subsets of $\operatorname{int} D_i$. If we find control functions as described in Theorem 3.1 (viii) for $\varepsilon > 0$ we know that there exists a Lyapunov exponent $\lambda^* < \delta v_\delta + \varepsilon$; hence $\lambda^* \in [\delta v_\delta - \varepsilon, \delta v_\delta + \varepsilon]$. However, the existence of such control functions is not guaranteed; nevertheless for all examples discussed in §5 it was possible to find them.

(iii) For systems with $d = 2$ or systems with $d > 2$ satisfying the ρ–ρ' inner pair condition we are also able to compute $\Sigma_{Ly}^{\rho}(\overline{D})$ for $D = C$ and $D = D_1$ at least for all but countably many $\rho > 0$, since in this case the upper and lower bounds of this interval coincide with κ and $\tilde{\kappa}$ of the original or of the time-reversed system, respectively. For all other main control sets we can apply the technique from (ii) to both the original and the time-reversed system to calculate $\Sigma_{Ly}^{\rho}(\overline{D_i})$.

(iv) In the case that $d > 2$ and $\rho > 0$ is one of the (at most countably many) exceptional points of the spectrum (3.10) we can use the monotonicity of v_δ and Σ_{Ly}^{ρ} in ρ. This implies that there exist values $\rho_1 < \rho < \rho_2$ arbitrarily close to ρ such that the approximated spectrum contains $\Sigma_{Ly}^{\rho_1}$ and is contained in $\Sigma_{Ly}^{\rho_2}$.

4. Numerical solution of the discounted optimal control problem. A discretization scheme to solve discounted optimal control problems in $\mathbb{R}^n$ has been developed by Capuzzo Dolcetta [2], Capuzzo Dolcetta and Falcone [3], Capuzzo Dolcetta and Ishii [4], and Falcone [12], [13]. The algorithm used here to solve these problems is based on this discretization. We will first describe this discretization scheme and then present the modifications for our case, where the system is given on $\mathbb{P}^{d-1}$ instead of $\mathbb{R}^n$.

Hence we first assume that we have a discounted optimal control problem defined by (2.1)–(2.6) and (2.8) with $M = \mathbb{R}^n$. In addition we need the following conditions on X and g:

$$\|X(x,u) - X(y,u)\| \le L_X \|x - y\| \quad \text{for all } x, y \in \mathbb{R}^n \text{ for all } u \in U \text{ for an } L_X \in \mathbb{R}, \tag{4.1}$$

$$\|X(x,u)\| \le M_X \quad \text{for all } (x,u) \in \mathbb{R}^n \times U \text{ for an } M_X \in \mathbb{R}, \tag{4.2}$$

$$|g(x,u) - g(y,u)| \le L_g \|x - y\| \quad \text{for all } x, y \in \mathbb{R}^n \text{ for all } u \in U \text{ for an } L_g \in \mathbb{R}. \tag{4.3}$$

The δ discounted cost functional J_δ and the optimal value function v_δ are defined as in (2.9) and (2.11).

Under the assumptions made above the value function v_δ satisfies

$$|v_\delta(x)| \le \frac{M_g}{\delta} \quad \text{and} \quad |v_\delta(x) - v_\delta(y)| \le C|x - y|^\gamma \tag{4.4}$$

for all $x, y \in \mathbb{R}^n$ (cf. [4]; the second estimate can be proved by using [4, Lem. 4.1]). For small $\delta > 0$ we have $C = \frac{M}{\delta}$ for a constant M independent on δ, and γ is a constant satisfying $\gamma = 1$ for $\delta > L_X$, $\gamma = \frac{\delta}{L_X}$ for $\delta < L_X$, and $\gamma \in (0,1)$ arbitrary for $\delta = L_X$.

Furthermore (cf. [17]) v_δ is the unique bounded and uniformly continuous viscosity solution of the Hamilton–Jacobi–Bellman equation

$$\sup_{u \in U} \{\delta v_\delta(x_0) - g(x_0,u) - Dv_\delta(x_0) X(x_0,u)\} = 0. \tag{4.5}$$

The first discretization step is a discretization in time. By replacing Dv_δ by the difference quotient with time step h one obtains

$$\sup_{u \in U} \{v_h(x) - \beta v_h(x + hX(x,u)) - hg(x,u)\} = 0 \tag{4.6}$$

with $\beta := 1 - \delta h$.

It turns out that the unique bounded solution of this equation is the optimal value function v_h of the *discretized optimal control system* with respect to the space $\mathcal{U}_h$ of all controls constant on each interval $[jh, (j+1)h)$, $j \in \mathbb{N}$:

$$x_0 := x, \quad x_{j+1} := x_j + hX(x_j, u_j), \quad j = 0, 1, 2, \ldots, \tag{4.7}$$

with running cost

$$J_h(x, u(\cdot)) := h \sum_{j=0}^{\infty} \beta^j g(x_j, u_j).$$

Furthermore for all $p \in \mathbb{N}$, v_h satisfies

$$v_h(x) = \inf_{u(\cdot) \in \mathcal{U}_h} \left\{ h \sum_{j=0}^{p-1} \beta^j g(x_j, u_j) + \beta^p v_h(x_p) \right\} \tag{4.8}$$

and the estimates (4.4) also apply to v_h.

The discretization error can be estimated as follows [4, Thm. 3.1]:

$$\sup_{x \in \mathbb{R}^n} |(v_\delta - v_h)(x)| \le C h^{\frac{\gamma}{2}} \tag{4.9}$$

for all $h \in (0, \frac{1}{\delta})$. Here we have $C = \frac{M}{\delta^2}$ for small $\delta > 0$ and γ is the constant from (4.4).

The discretization error of the functionals for any $u(\cdot) \in \mathcal{U}_h$ can be estimated as

$$\sup_{x \in \mathbb{R}^n,\, u(\cdot) \in \mathcal{U}_h} |J_h(x, u(\cdot)) - J_\delta(x, u(\cdot))| \le C h^\gamma \tag{4.10}$$

where $C = \frac{M}{\delta}$ for small $\delta > 0$ and γ as above [4, Lem. 4.1].

In order to reduce (4.6) to a finite-dimensional problem we apply a finite difference technique. To do this we assume the existence of an open, bounded, and convex subset Ω of the state space $\mathbb{R}^n$ which is invariant for (2.1). Thus a triangulation of Ω into a finite number P of simplices S_j with N nodes x_i can be constructed (cf. [13, Prop. 2.5]) such that $\Omega^k := \cup_{j=1,\ldots,P} S_j$ is invariant with respect to the discretized trajectories (4.7). Here $k := \sup\{\|x - y\| \mid x \text{ and } y \text{ are nodes of } S_j,\ j = 1, \ldots, P\}$. We are now looking for a solution of (4.6) in the space of piecewise affine functions $\mathcal{W} := \{w \in C(\Omega^k) \mid Dw(x) = c_j \text{ in } S_j\}$.

Every point $x_i + hf(x_i, u)$ can be written as a convex combination of the nodes of the simplex containing it with coefficients $\lambda_{ij}(u)$. Let $\Lambda(u) := [\lambda_{ij}(u)]_{i,j=1,\ldots,N}$ be the matrix containing the coefficients and $G(u) := [g(x_i, u)]_{i=1,\ldots,N}$ an N-dimensional vector containing the values of g with control value u at the nodes of the triangulation. Now we can rewrite (4.6) as a fixed point equation

$$V = T_h^k(V), \quad T_h^k(V) := \inf_{u \in U} (\beta \Lambda(u) V + hG(u)). \tag{4.11}$$

It follows that T_h^k is a contraction in $\mathbb{R}^N$ with contraction factor $\beta := 1 - \delta h$ and therefore has a unique fixed point V^*. If v_h^k denotes the function obtained by $v_h^k(x_i) := [V^*]_i$ and linear interpolation between the nodes, the discretization error can be estimated by

$$\sup_{x \in \Omega^k} |(v_h^k - v_h)(x)| \le C \frac{k^\gamma}{h} \tag{4.12}$$

with γ as in (4.4) and $C = \frac{M}{\delta^2}$ for small $\delta > 0$ (cf. [13, corrigenda]).

For the whole discretization error we obtain the following estimate:

$$\sup_{x\in\Omega^k} |(v_h^k - v_\delta)(x)| \le C\left(h^{\frac{\gamma}{2}} + \frac{k^\gamma}{h}\right) \tag{4.13}$$

with the constants from (4.9) and (4.12).

Remark 4.1. These results have been improved by Gonzales and Tidball [14]. From [14, Lem. 3.4] in connection with [4, Lem. 4.1] it follows that

$$\sup_{x\in\Omega^k} |(v_h^k - v_h)(x)| \le C\left(\frac{k}{\sqrt{h}}\right)^\gamma; \tag{4.14}$$

[14, Thm. 3.1] yields

$$\sup_{x\in\Omega^k} |(v_h^k - v_\delta)(x)| \le C\left(\sqrt{h} + \frac{k}{\sqrt{h}}\right)^\gamma \tag{4.15}$$

with similar constants C and γ.

Remark 4.2. Note that the convergence becomes slow if the discount rate δ becomes small. For the approximation of the average cost functional as described in §2 it is nevertheless necessary to calculate v_δ for small $\delta > 0$. This means that for this purpose we need a fine discretization in time and space to get reliable results.

If one uses estimate (4.13) we obtain as an additional condition that k should be smaller than h, using (4.15) convergence for the case $k = h$ is guaranteed.

To handle the optimal control problem on $\mathbb{P}^{d-1}$ we use the following modifications on this scheme.

We first consider the optimal control problem on $\mathbb{S}^{d-1}$ defined by the projected system (3.7). The optimal value function v_δ then again satisfies (4.4) and is the unique bounded and uniformly continuous viscosity solution of (4.5). This can be proved exactly the same way as in the $\mathbb{R}^n$ case by using the metric on $\mathbb{S}^{d-1}$ induced by the norm on $\mathbb{R}^d$.

We have seen that the discretization in time of (4.5) corresponds to the Euler discretization of the control system. Hence here we use the following Euler method on $\mathbb{S}^{d-1}$. For $h > 0$ and any $s \in \mathbb{S}^{d-1}$ we define

$$\Phi_h(s,u) := \frac{s + hX(s,u)}{\|s + hX(s,u)\|}; \tag{4.16}$$

i.e., we perform an Euler step in $\mathbb{R}^d$ and project the solution back to $\mathbb{S}^{d-1}$. With this (4.6) reads

$$\sup_{u\in U}\{v_h(s) - \beta v_h(\Phi_h(s,u)) - hg(s,u)\} = 0 \tag{4.17}$$

and (4.7) translates to

$$s_0 := s, \quad s_{j+1} := \Phi_h(s_j, u), \quad j = 0, 1, 2, \ldots. \tag{4.18}$$

The estimates (4.8)–(4.10) remain valid; again all proofs from the $\mathbb{R}^n$ case apply by using the metric on $\mathbb{S}^{d-1}$ induced by the norm on $\mathbb{R}^d$.

We will now use the fact that this discrete time control system on $\mathbb{S}^{d-1}$ defines a (well-defined) control system on $\mathbb{P}^{d-1}$ by identifying s and $-s$ on $\mathbb{S}^{d-1}$. Let $W \subset \mathbb{S}^{d-1}$ be an open set in $\mathbb{S}^{d-1}$ such that it contains the upper half of the sphere. Any discrete time trajectory

$(s_i)_{i\in\mathbb{N}_0} \subset \mathbb{S}^{d-1}$ as defined in (4.18) can be mapped on a trajectory $(\tilde{s}_i)_{i\in\mathbb{N}_0} \subset W$ by $\tilde{s}_i := s_i$ if $s_i \in W$, $\tilde{s}_i := -s_i$ if $s_i \notin W$. Since $X(s,u) = -X(-s,u)$ this mapping is well defined and $g(s,u) = g(-s,u)$ implies that v_h does not change if we only consider trajectories in W. Hence we can define a discrete time optimal control problem on W via

$$\tilde{\Phi}_h(s) = \begin{cases} \Phi_h(s), & \Phi_h(s) \in W, \\ -\Phi_h(s), & \Phi_h(s) \notin W \end{cases}$$

without changing v_h.

To obtain a region $\Omega \subset \mathbb{R}^{d-1}$ suitable for the space discretization we use a parametrization Ψ of $\mathbb{S}^{d-1}$ which is invertible on W such that Ψ^{-1} maps W to an open and bounded set $\Omega \subset \mathbb{R}^{d-1}$. (The parametrizations used in our examples are given in §5.) Now we can project the system on W to a system on Ω and compute v_h on Ω. The system on Ω is then given by

$$\Phi_{h,\Omega}(x,u) := \Psi^{-1}(\tilde{\Phi}_h(\Psi(x),u)), \quad g_\Omega(x,u) := g(\Psi(x),u),$$

and by definition of $\tilde{\Phi}_h$ the set Ω is invariant for this discrete time system. We can rewrite (4.17) by using $\Phi_{h,\Omega}$ and g_Ω and denoting the solution by $v_{h,\Omega}$. This solution satisfies $v_h(\Psi(x)) = v_{h,\Omega}(x)$ and, since Ψ is Lipschitz continuous, estimate (4.4) remains valid for $v_{h,\Omega}$.

Thus we can proceed as in the $\mathbb{R}^n$ case described above. Keeping in mind that there exists a one-to-one relation between the system on W and the system on Ω we can simplify the notation by writing Φ_h, g, and v_h instead of $\Phi_{h,\Omega}$, g_Ω, and $v_{h,\Omega}$.

We will now turn to the problem of how the fixed point equation (4.11) can be solved numerically. In order to do this it is possible to use the contraction T_h^k to construct an iteration scheme, but since the contraction factor $\beta = 1-\delta h$ is close to one this iteration converges rather slowly. An acceleration method for this iteration scheme has been proposed by Falcone [12]. Falcone uses the set $\mathcal{V}$ of monotone convergence of T_h^k given by $\mathcal{V} := \{V \in \mathbb{R}^N \mid T_h^k(V) \geq V\}$ where "$\geq$" denotes the componentwise order. A simple computation shows that $\mathcal{V}$ is a convex closed subset of $\mathbb{R}^N$. Given a $V_0 \in \mathcal{V}$ the operator T_h^k is used to determine an initial direction. The algorithm follows this direction until it crosses the boundary of $\mathcal{V}$; then it determines a new direction using T_h^k and continues the same way.

A different algorithm to calculate V^* can be developed by observing that V^* is the componentwise maximum of $\mathcal{V}$ and that $\mathcal{V}$ can be written as

$$\mathcal{V} = \left\{ V \in \mathbb{R}^N \;\middle|\; [V]_i \leq \min_{u\in U} \left\{ \frac{\beta \sum_{\substack{j=1,\dots,N \\ j\neq i}} \lambda_{ij}(u)[V]_j + hG_i(u)}{1-\beta\lambda_{ii}(u)} \right\} \text{ for all } i \in \{1,\dots,N\} \right\}. \tag{4.19}$$

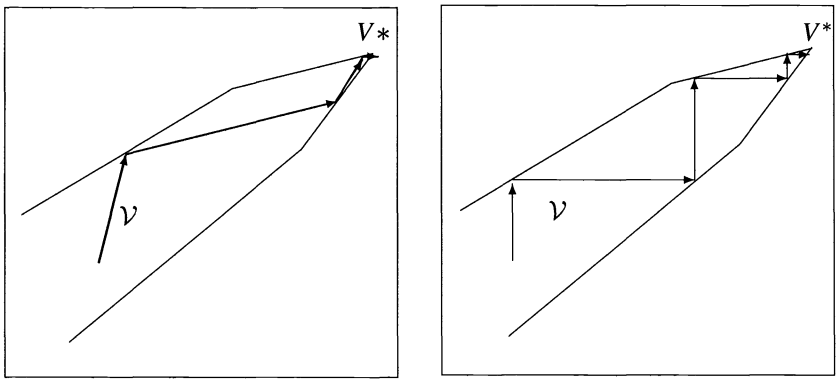
Note that the fraction on the right side does not depend on $[V]_i$. Thus we can construct the *increasing coordinate algorithm*:

Step 1: take $V \in \mathcal{V}$ (e.g., $V = (-\frac{M_g}{\delta}, \dots, -\frac{M_g}{\delta})^T$)
Step 2: compute sequentially

$$[V]_i = \min_{u\in U} \left\{ \frac{\beta \sum_{\substack{j=1,\dots,N \\ j\neq i}} \lambda_{ij}(u)[V]_j + hG_i(u)}{1-\beta\lambda_{ii}(u)} \right\} \quad \text{for all } i \in \{1,\dots,N\}.$$

Step 3: continue with Step 2 and the new vector V.

Figure 4.1 shows an illustration of the algorithms for $N = 2$.



Falcone's accelerated method Increasing coordinate algorithm

FIG. 4.1. *Algorithms.*

Note that for every arrow in the left picture the intersection between the initial direction and the boundary of $\mathcal{V}$ has to be determined. To do this, e.g., by bisection as in the implementation used here, the operator T_h^k has to be evaluated several times to decide if a point is inside or outside $\mathcal{V}$. In the increasing coordinate algorithm N arrows (i.e., two arrows in Figure 4.1) are calculated by N evaluations of the fraction in Step 2. These N evaluations are about as expensive as one evaluation of T_h^k. This means that one iteration in the increasing coordinate algorithm corresponds to one evaluation of T_h^k in the acceleration method.

The convergence of this algorithm is guaranteed by the following lemma.

LEMMA 4.3. *Let V_1 be the vector obtained by applying Step 2 for $i = 1, \dots, N$ to a vector $V_0 \in \mathcal{V}$. Then*

$$[V_1]_i - [V_0]_i \;\geq\; [T_h^k(V_0)]_i - [V_0]_i.$$

Proof. Because of $V_0 \in \mathcal{V}$ and (4.19) it follows that $[V_1]_i \geq [V_0]_i$ for all $i = 1, \dots, N$. Hence

$$\begin{aligned}
[V_1]_i - [V_0]_i &= \min_{u\in U} \left\{ \frac{\beta \sum_{\substack{j=1,\dots,N \\ j\neq i}} \lambda_{ij}(u)[V_1]_j + hG_i(u) - (1-\beta\lambda_{ii}(u))[V_0]_i}{1-\beta\lambda_{ii}(u)} \right\} \\
&\geq \min_{u\in U} \left\{ \beta \sum_{\substack{j=1,\dots,N \\ j\neq i}} \lambda_{ij}(u)[V_0]_j + hG_i(u) - (1-\beta\lambda_{ii}(u))[V_0]_i \right\} \\
&= \min_{u\in U} \left\{ \beta \sum_{j=1}^{N} \lambda_{ij}(u)[V_0]_j + hG_i(u) - [V_0]_i \right\} \;=\; [T_h^k(V_0)]_i - [V_0]_i. \qquad \square
\end{aligned}$$

The convergence of the increasing coordinate algorithm therefore is a consequence of the monotone convergence of the iteration scheme using the contraction T_h^k.

All iteration methods described here have in common that during the iteration a minimum over all $u \in U$ has to be calculated. The following lemma shows that this can be done by minimizing over a finite set $U_\varepsilon \subset U$.

LEMMA 4.4. *Assume that X and g are uniformly Lipschitz continuous in the control $u \in U$ with Lipschitz constant L_u. Let $U_\varepsilon \subset U$ such that for all $u \in U$ there exists $\bar{u} \in U_\varepsilon$ with $\|u - \bar{u}\| < \varepsilon$. Let $\mathcal{U}_\varepsilon$ denote the corresponding set of control functions. Then for all $s \in \mathbb{S}^{d-1}$*

it holds that

$$\| \inf_{u(\cdot)\in\mathcal{U}} J_\delta(s,u(\cdot)) - \inf_{\bar u(\cdot)\in\mathcal{U}_\varepsilon} J_\delta(s,\bar u(\cdot))\| < C\varepsilon^\eta$$

where for $\delta < L_X + 1$ *we have* $\eta = \frac{L_X+1}{\delta}$.

Proof. For all $u(\cdot) \in \mathcal{U}$ there exists $\bar u(\cdot) \in \mathcal{U}_\varepsilon$ such that $\|u(t) - \bar u(t)\| < \varepsilon$ for almost all $t \in \mathbb{R}$. Hence we have

$$\|\varphi(t,s,u(\cdot)) - \varphi(t,s,\bar u(\cdot))\| < L_u\varepsilon t + \int_0^t L_X\|\varphi(\tau,s,u(\cdot)) - \varphi(\tau,s,\bar u(\cdot))\|d\tau$$

where $\|\cdot\|$ denotes the norm on $\mathbb{R}^d$. Now the Gronwall lemma and [4, Lem. 4.1] can be used to estimate this integral equation and the assertion follows. □

For the projected bilinear control system with cost function $g = q$ the assumptions of Lemma 4.4 are fulfilled and hence we may use a finite set of control values to calculate v_h^k.

Once v_h^k is calculated it can be used to construct ε-optimal control functions:

Step 1: Let $x_0 = x$, $n = 0$.

Step 2: Choose a control value $\tilde u^k_{x_n,h} \in U$ such that $\beta v_h^k(\Phi_h(x_n, \tilde u^k_{x_n,h})) + hg(x_n, \tilde u^k_{x_n,h})$ becomes minimal.

Step 3: Let $u^k_{x,h}(t) = \tilde u^k_{x_n,h}$ for all $t \in [nh, (n+1)h]$.

Step 4: Let $x_{n+1} = \Phi_h(x_n, \tilde u^k_{x_n,h})$, $n = n + 1$ and continue with Step 2.

In Step 2 a unique $\tilde u^k_{x_n,h} \in U$ may be found, e.g., by using a lexicographic order on U.

THEOREM 4.5. *Let* $u^k_{x,h}$ *denote the control function defined above. Then for every* $\varepsilon > 0$ *there exist* $H > 0$, $K(h) > 0$, *such that for all* $h < H$, $k \le K(h)$:

$$|J_\delta(x, u^k_{x,h}(\cdot)) - v_\delta(x)| \le \varepsilon \quad \textit{for all } x \in \Omega.$$

Proof. Using (4.12) or (4.14) and the definition of $u^{k,i}_{x,h} := u^k_{x,h}|_{[ih,(i+1)h)}$ we have the following for sufficiently small k and x_i from (4.7):

$$\begin{aligned} hg(x_i, u^{k,i}_{x,h}) + \beta v_h^k(\Phi_h(x_i, u^{k,i}_{x,h})) &\ge hg(x_i, u^{k,i}_{x,h}) + \beta v_h(\Phi_h(x_i, u^{k,i}_{x,h})) - \frac{\varepsilon}{2} \\ &\ge v_h(x_i) - \frac{\varepsilon}{2} \ \ge\ v_h^k(x_i) - \varepsilon \end{aligned}$$

and with $u^{0,i}_{x,h} \in U$ denoting the value, where $hg(x_i,u) + \beta v_h(\Phi_h(x_i,u))$, $u \in U$ attains its minimum:

$$\begin{aligned} hg(x_i, u^{k,i}_{x,h}) + \beta v_h^k(\Phi_h(x_i, u^{k,i}_{x,h})) &\le hg(x_i, u^{0,i}_{x,h}) + \beta v_h^k(\Phi_h(x_i, u^{0,i}_{x,h})) \\ &\le hg(x_i, u^{0,i}_{x,h}) + \beta v_h(\Phi_h(x_i, u^{0,i}_{x,h})) + \frac{\varepsilon}{2} \\ &= v_h(x_i) + \frac{\varepsilon}{2} \ \le\ v_h^k(x_i) + \varepsilon. \end{aligned}$$

Putting this together yields

$$|hg(x_i, u^{k,i}_{x,h}) + \beta v_h^k(\Phi_h(x_i, u^{k,i}_{x,h})) - v_h^k(x_i)| \le \varepsilon \quad \text{for all } x \in \overline{\Omega^k}. \tag{4.20}$$

By induction we can conclude that for every $\varepsilon > 0$, $p \in \mathbb{N}$, $h > 0$ there exists $k > 0$ such that

$$\left| h\sum_{j=0}^{p} \beta^j g(x_j, u^{k,j}_{x,h}) + \beta^{p+1} v_k^h(x_{p+1}) - v_h^k(x) \right| \le \frac{\varepsilon}{2} \quad \text{for all } x \in \overline{\Omega^k}. \tag{4.21}$$

Since $\beta < 1$ for all $h > 0$ and g and v_h^k are bounded on $\overline{\Omega^k}$, for every $\varepsilon > 0$ we may find a $p_h \in \mathbb{N}$ such that

$$\left| h \sum_{j=0}^{\infty} \beta^j g(x, u_{x,h}^{k,j}) - h \sum_{j=0}^{p_h} \beta^j g(x, u_{x,h}^{k,j}) - \beta^{p_h+1} v_h^k(x) \right| < \frac{\varepsilon}{2} \quad \text{for all } x \in \overline{\Omega^k},\ u \in \mathcal{U}_h. \tag{4.22}$$

Combining (4.12) or (4.14), (4.21), and (4.22) yields

$$|J_h(x, u_{x,h}^k(\cdot)) - v_h(x)| \le \varepsilon \quad \text{for all } x \in \Omega.$$

Using estimates (4.10) and (4.9) the assertion follows. □

Remark 4.6. The proof also shows how k and h have to be chosen: first choose h such that (4.10) and (4.9) hold for the desired accuracy; then choose k dependent on p_h from (4.22) such that (4.21) is fulfilled.

To construct a control function that is uniformly ε-optimal we can put together the ε-optimal control functions according to the following definition and lemma.

DEFINITION 4.7. *Let $u_x(\cdot) \in \mathcal{U}$ be control functions for every $x \in \overline{\Omega^k}$. Let $(\tau_i)_{i\in\mathbb{N}}$ be a real sequence of* switching times *satisfying $\tau_1 = 0$, $\tau_{i+1} > \tau_i$ and $a \le \tau_{i+1} - \tau_i \le b$ for all $i \in \mathbb{N}$ for positive constants a, $b \in \mathbb{R}$, $a \le b$. Then we define control functions $\bar{u}_x(\cdot) \in \mathcal{U}$ by*

$$\bar{u}_x|_{[\tau_i,\tau_{i+1})} \equiv u_{\varphi(x,\tau_i,\bar{u}_x(\cdot))}|_{[0,\tau_{i+1}-\tau_i)} \quad \text{for all } i \in \mathbb{N}.$$

LEMMA 4.8. *Assume for every $x \in \overline{\Omega^k}$ there exists a control function $u_x(\cdot) \in \mathcal{U}$ such that $|J_\delta(x, u_x(\cdot)) - v_\delta(x)| < \varepsilon$. Then for $\bar{u}_x(\cdot) \in \mathcal{U}$ from Definition* 4 *the following estimate holds:*

$$J_\delta(\varphi(\sigma, x, \bar{u}_x(\cdot)), \bar{u}_x(\sigma + \cdot)) \le v_\delta(\varphi(\sigma, x, \bar{u}_x(\cdot))) + \frac{e^{\delta b}}{\delta a}\varepsilon \quad \text{for all } \sigma \ge 0.$$

Proof. For all $t > 0$ it holds that

$$\begin{aligned} v_\delta(x) &\ge J_\delta(x, u_x(\cdot)) - \varepsilon \\ &\ge \int_0^t e^{-\delta\tau} g(\varphi(x, \tau, u_x(\cdot)), u_x(\tau)) d\tau + e^{-\delta t} v_\delta(\varphi(x, t, u_x(\cdot)) - \varepsilon. \end{aligned} \tag{4.23}$$

By induction with $t = \tau_i$ it follows that

$$J_\delta(x, \bar{u}_x(\cdot)) \le v_\delta(x) + \sum_{i=0}^{\infty} e^{-\delta\tau_i}\varepsilon$$

and for $0 < 1 - \delta a < 1$ this sum can be estimated by

$$\sum_{i=0}^{\infty} e^{-\delta\tau_i} \le \sum_{i=0}^{\infty} e^{-\delta a i} \le \sum_{i=0}^{\infty} (1 - \delta a)^i \le \frac{1}{\delta a}.$$

Together with the definition of the $\bar{u}_x(\cdot)$ this implies

$$J_\delta(\varphi(\tau_i, x, \bar{u}_x(\cdot)), \bar{u}_x(\tau_i + \cdot)) \le v_\delta(\varphi(\tau_i, x, \bar{u}_x(\cdot))) + \frac{\varepsilon}{\delta a}$$

for all $i \in \mathbb{N}$.

For the times between τ_i let $\sigma > 0, \tilde{\varepsilon} > 0$ and consider $u_{x_0}(\cdot) \in \mathcal{U}$ such that $|J_\delta(x_0, u_{x_0}(\cdot)) - v_\delta(x_0)| \leq \tilde{\varepsilon}$:

$$\begin{aligned} v_\delta(x_0) + \tilde{\varepsilon} &\geq \int_0^\infty e^{-\delta t} g(\varphi(t, x_0, u_{x_0}(\cdot)), u_{x_0}(t)) dt \\ &= \int_0^\sigma e^{-\delta t} g(\varphi(t, x_0, u_{x_0}(\cdot)), u_{x_0}(t)) dt \\ &\quad + e^{-\delta\sigma} \int_0^\infty e^{-\delta t} g(\varphi(t, \varphi(\sigma, x_0, u_{x_0}(\cdot)), u_{x_0}(\sigma + \cdot)), u_{x_0}(\sigma + t)) dt \\ &= \int_0^\sigma e^{-\delta t} g(\varphi(t, x_0, u_{x_0}(\cdot)), u_{x_0}(t)) dt \\ &\quad + e^{-\delta\sigma} J_\delta(\varphi(\sigma, x_0, u_{x_0}(\cdot)), u_{x_0}(\sigma + \cdot)) \\ &\geq \int_0^\sigma e^{-\delta t} g(\varphi(t, x_0, u_{x_0}), u_{x_0}(t)) dt \quad + \quad e^{-\delta\sigma} v_\delta(\varphi(\sigma, x_0, u_{x_0})) \\ &\geq v_\delta(x_0). \end{aligned}$$

From this inequality it follows that

$$|v_\delta(\varphi(\sigma, x_0, u_{x_0}(\cdot))) - J_\delta(\varphi(\sigma, x_0, u_{x_0}(\cdot)), u_{x_0}(\sigma + \cdot))| \quad \leq \quad e^{\delta\sigma} \tilde{\varepsilon}.$$

Choosing $i \in \mathbb{N}$ maximal with $\tau_i \leq \sigma$ and $x_0 := \varphi(\tau_i, x, \bar{u}_x(\cdot))$ it follows that

$$|v_\delta(\varphi(\sigma, x, \bar{u}_x(\cdot))) - J_\delta(\varphi(\sigma, x, \bar{u}_x(\cdot)), \bar{u}_x(\sigma + \cdot))| \leq e^{\delta(\sigma - \tau_i)} \frac{1}{\delta a} \varepsilon \leq e^{\delta b} \frac{1}{\delta a} \varepsilon = \frac{e^{\delta b}}{\delta a} \varepsilon$$

which finishes the proof. □

Remark 4.9. This lemma does not answer the question of which switching times τ_i are optimal. In estimate (4.23) we have to assume the worst case, i.e., that the error up to the time t

$$\varepsilon(t) := \left| v_\delta(x) - \int_0^t e^{-\delta\tau} g(\varphi(x, \tau, u_x(\cdot)), u_x(\tau)) d\tau - e^{-\delta t} v_\delta(\varphi(x, t, u_x(\cdot)) \right|$$

may be equal to ε for all $t > 0$ and hence the error becomes large if $a = \min(\tau_{i+1} - \tau_i)$ becomes small. The numerical examples discussed in the next section show that good results can be obtained for small a.

Using the results from Theorem 3.1 we can use the control functions constructed here to develop an *algorithm to stabilize bilinear control systems*:

Step 1: Calculate v_h^k, the approximation of the optimal value function for small discount rate $\delta > 0$ to approximate the minimal Lyapunov exponents of the systems (under the assumptions of Theorem 3.1).

Step 2: Given an initial value $x \in \mathbb{R}^d$ with $\lambda^*(x) < 0$ compute the control function that is ε-optimal along its trajectory according to Definition 4 (using the projected system). The trajectory of the bilinear system using this control is asymptotically stable under the assumptions of Theorem 3.1 provided h and k are small enough.

Note that the main numerical expense lies in the calculation of the approximated optimal value function v_h^k. Once this function is known the algorithm to calculate the control functions is numerically simple and quite fast.

For this algorithm only the information $x(t, x_0, u(\cdot))/\|x(t, x_0, u(\cdot))\|$ of the bilinear system is needed. In particular the calculated control functions are exactly the same for all x_1, $x_2 \in \mathbb{R}^d$ with $x_1/\|x_1\| = x_2/\|x_2\|$ and hence the algorithm works for arbitrarily large or small $\|x\|$. It is not necessary to discretize the trajectory of the bilinear system or to lift the discretized solution from $\mathbb{S}^{d-1}$ to $\mathbb{R}^d$ which then would imply that small discretization errors on $\mathbb{S}^{d-1}$ could become large in $\mathbb{R}^d$.

The value function and the corresponding optimal control values for each point can also be used to "verify" the assumptions of Theorem 3.1 (viii) numerically: if there exists a set such that $v_h^k < 0$ and this set is invariant with respect to the numerically computed optimal controls, the corresponding trajectory will tend to zero for any initial value from this set, provided the discretization is fine enough (see also Remark 3.2).

Remark 4.10. The way the stabilizing control functions are constructed leads to the question of whether v_h^k can be used to construct a stabilizing feedback for the bilinear control system. This question is closely related to the optimal switching times τ_i. If it is possible to choose $(\tau_{i+1} - \tau_i)$ arbitrarily small it could also be possible to obtain an ε-optimal feedback, e.g., by linear interpolation or averaging of the feedback for the discrete time system.

The main problem in proving this property of the switching times lies in the fact that the Euler method yields only linear convergence in h, hence quadratic convergence for one time step. Thus the difference between $v_h(\varphi(h, x, u))$ (the value that can be reached after the first time step) and $v_h(\Phi_h(x, u))$ (the value that is supposed to be reached) is of the order $h^{2\gamma}$. For $\gamma < \frac{1}{2}$ this error will accumulate and convergence is no longer guaranteed. However, there is hope to overcome this difficulty by using a higher-order method to calculate $\Phi_h(x, u)$ which then will require a different proof of the convergence of v_h.

5. Numerical examples. In this section we will present some numerical examples calculated with the algorithm developed in the previous sections. All examples were computed on an IBM6000 Workstation.

The first example is a bilinear control system in $\mathbb{R}^2$, the two-dimensional linear oscillator given by

$$\ddot{x} + 2b\dot{x} + (1 + u)x = 0$$

or written as a two-dimensional system by $x_1 = x$, $x_2 = \dot{x}$:

$$\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix} = \underbrace{\begin{pmatrix} 0 & 1 \\ -1-u & -2b \end{pmatrix}}_{=:A(u)} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}. \tag{5.1}$$

The projection of the system to $\mathbb{S}^1$ by $s = \frac{x}{\|x\|}$ reads

$$\dot{s} = \begin{pmatrix} s_2(1 + us_1^2 + 2bs_1s_2) \\ -(1+u)s_1 - 2bs_2 + s_2^2(us_1 + 2bs_2) \end{pmatrix}. \tag{5.2}$$

For the one-dimensional sphere we may use the parametrization via polar coordinates $\Psi(\varphi) = (\cos\varphi, \sin\varphi)$ where $\Psi^{-1}(s) = \arcsin(s_2)$, $s_2 \in [-\frac{\pi}{2}, \frac{\pi}{2}]$, $\Psi^{-1}(s) = \arcsin(\pi - s_2)$, $s_2 \in [\frac{\pi}{2}, \frac{3\pi}{2}]$. In polar coordinates the cost function reads $g(\varphi, u) = -\sin\varphi(u\cos\varphi + 2b\sin\varphi)$, and we can choose $\Omega = (0 - \varepsilon, \pi + \varepsilon)$ to cover the whole projective space (identified with one half of the sphere).

Tables 5.1–5.3 show the number of iterations in the increasing coordinate algorithm (ops_1) and the number of evaluations of the operator T_h^k in the accelerated algorithm (ops_2) depending

on certain parameters with damping parameter $b = 1.5$. Remember that one iteration in the increasing coordinate algorithm corresponds to one evaluation of T_h^k. The used set of control values was ρU with $U = \{-1, 1\}$ and $\rho = 0.5$.

Using the techniques described in Remark 3.2 the whole Lyapunov spectrum for this system was computed for $\rho = \{0.1, 0.2, \ldots, 1.3\}$ with parameters $h = 0.01$, $k = 0.006$, and $\delta = 0.01$ and locally refined grid with $k = 0.0016$ around the variant control set for $\rho \leq 0.5$. (For $\rho = 0.0$ the exponents are just the eigenvalues of A.) The calculated intervals are shown in Table 5.4 and Figure 5.1. For $\rho \leq 1.2$ there exist two control sets D_1 and D_2 and therefore two intervals of Lyapunov exponents. For $\rho = 1.3$ there is only one control set and thus only

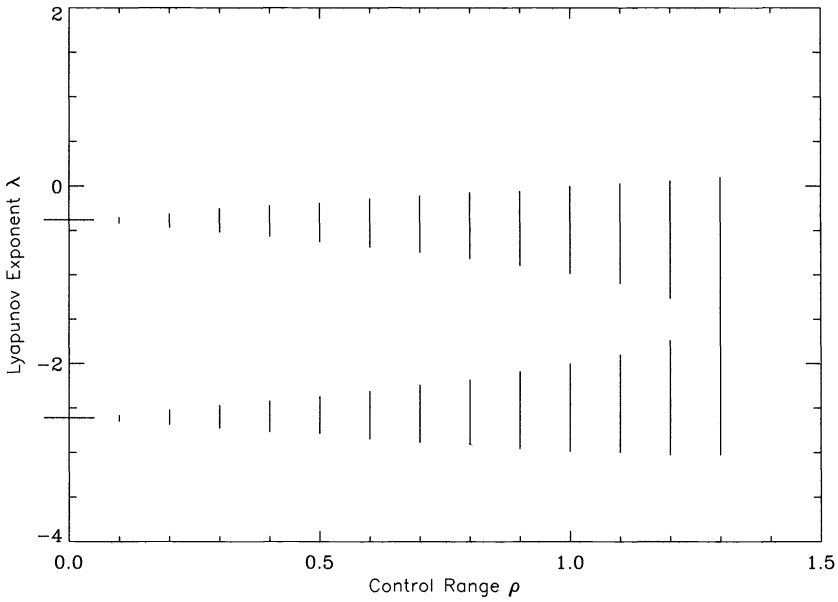

FIG. 5.1. *Lyapunov spectrum of system* (5.1) *with* $b = 1.5$.

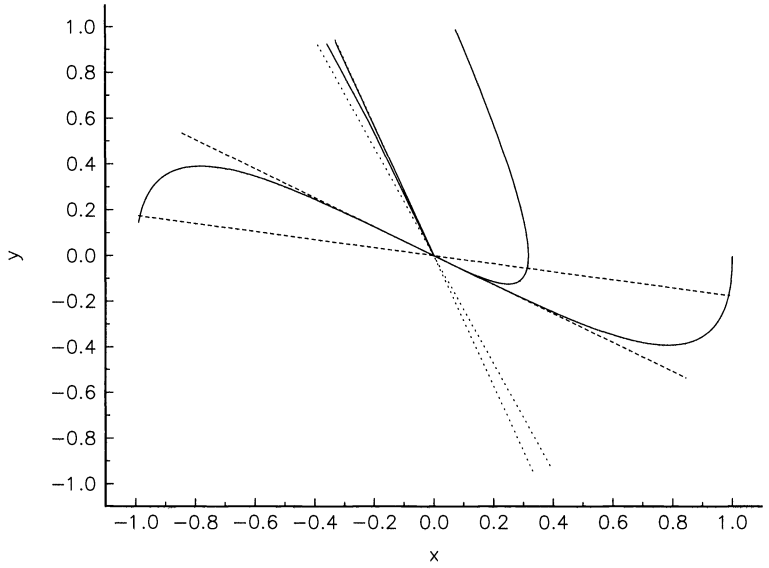

FIG. 5.2. *Trajectories for* $b = 1.5$, $\rho = 0.5$.

one interval. For this system a finer discretization of U does not yield different values for v_h^k; it is sufficient to minimize over the extremal control values.

For $\rho = 0.5$ the system is asymptotically stable for all control functions since the maximal Lyapunov exponent is negative. But as the Lyapunov exponents corresponding to D_1 are much smaller than those of the control set D_2 it can be expected that the optimal trajectories with initial value inside D_1 tend to zero much faster.

Figure 5.2 shows that this is exactly what happens. In this figure the dotted lines correspond to the boundaries of D_1, the dashed lines to the boundary of D_2.

All trajectories in this section were computed using the extrapolation method for ordinary differential equations by Stoer and Bulirsch [19, §7.2.14]. The parameter a from Definition 4 was chosen as $a = h$ (see Remark 4.9).

The second example is the three-dimensional linear oscillator given by

$$\dddot{y} + a\ddot{y} + b\dot{y} + (c + u)y = 0 \tag{5.3}$$

or written as a three-dimensional system by

$$\begin{pmatrix} \dot{y}_1 \\ \dot{y}_2 \\ \dot{y}_3 \end{pmatrix} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -(c+u) & -b & -a \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \\ y_3 \end{pmatrix} \tag{5.4}$$

with $a, b, c \in \mathbb{R}$, and $u \in U$. The projected system on $\mathbb{S}^2$ reads

$$\dot{s} = \begin{pmatrix} s_2 - s_1(-\tilde{u}s_1s_3 + s_1s_2 + (1-b)s_2s_3 - as_3^2) \\ s_3 - s_2(-\tilde{u}s_1s_3 + s_1s_2 + (1-b)s_2s_3 - as_3^2) \\ -\tilde{u}s_1 - bs_2 - as_3 - s_3(-\tilde{u}s_1s_3 + s_1s_2 + (1-b)s_2s_3 - as_3^2) \end{pmatrix} \tag{5.5}$$

with $\tilde{u} := c + u$.

For $\mathbb{S}^2$ the parametrization by spherical coordinates is not suitable since this parametrization maps two opposite points to a line and hence it is not invertible on one half of the sphere. Thus the stereographic projection is used instead; it is given by

$$\Psi(x) = \left(\frac{2x_1}{1 + \|x\|^2}, \frac{2x_2}{1 + \|x\|^2}, \frac{2}{1 + \|x\|^2} - 1 \right)$$

and

$$\Psi^{-1}(s) = \left(\frac{1}{1+s_3} s_1, \frac{1}{1+s_3} s_2 \right).$$

The cost function reads

$$g(x, u) = -(c+u)\Psi_1(x)\Psi_3(x) + \Psi_1(x)\Psi_2(x) + (1-b)\Psi_2(x)\Psi_3(x) - a\Psi_3(x)^2$$

with $\Psi = (\Psi_1, \Psi_2, \Psi_3)$. The set Ω was chosen as $\Omega = (-1-\varepsilon, 1+\varepsilon) \times (-1-\varepsilon, 1+\varepsilon)$ to cover the whole $\mathbb{P}^2$ (identified with the upper half of $\mathbb{S}^2$).

All values given have been checked according to Remark 3.2 (ii); in all cases it was possible to find trajectories that realized the values as Lyapunov exponents. Hence the calculated values at least give an approximation of the minimal Lyapunov exponents over the interior of the control sets. To apply the results of Remark 3.2 (iii), i.e., to make sure that this is indeed the Lyapunov spectrum, we have to check the $\rho - \rho'$ inner pair condition described in §3. Unfortunately as of now it is not known how to check this condition analytically. However, the program CS2DIM from Häckl [15] has been used to calculate reachable sets for the system for different ρ-parameters numerically. Since they turned out to be strictly increasing in this example there is strong evidence that the condition is fulfilled.

For Figures 5.3–5.8 spherical coordinates ($s_1 = \sin\theta\cos\varphi$, $s_2 = \sin\theta\sin\varphi$, $s_3 = \cos\theta$)$x = \theta$, $y = \varphi$ were used and the system was transformed by $z(t) := e^{\frac{1}{3}at}y(t)$.

The first parameters considered for this system were $a = 1$, $b = 0$, $c = 0.5$, and $U = \{-0.3, -0.25, \ldots, 0.25, 0.3\}$. Figure 5.3 shows the two control sets of this system. The control sets were computed again using the program CS2DIM [15].

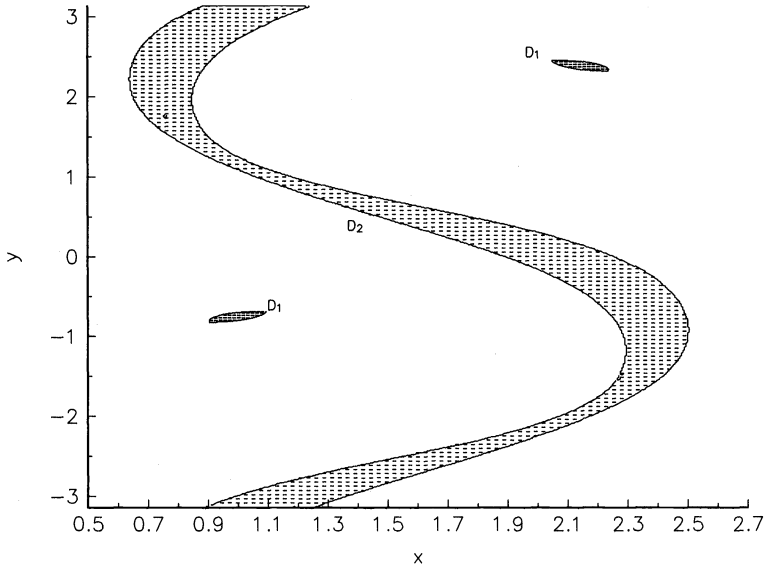

FIG. 5.3. *Control sets of system* (5.5) *with* $a = 1$, $b = 0$, $c = 0.5$.

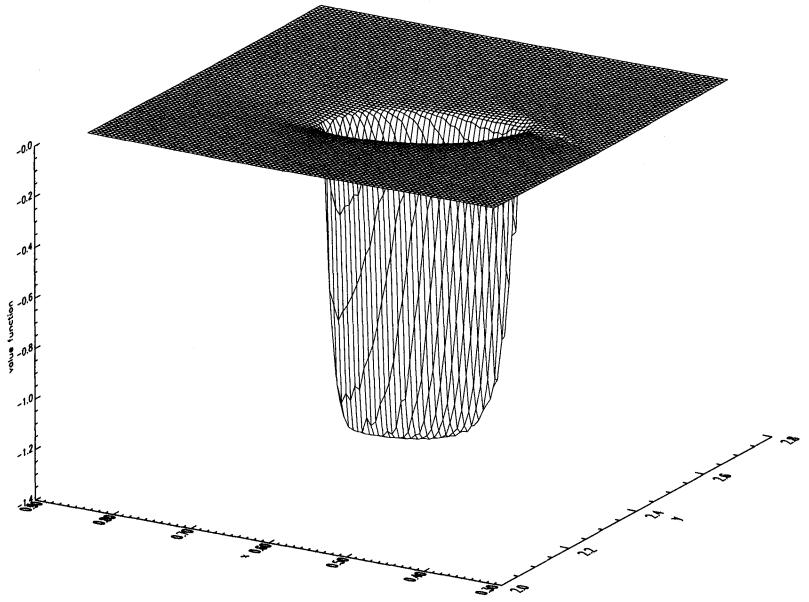

FIG. 5.4. *Value function around* D_1.

The numerical parameters used for this example are $k = 0.003$ around D_1, $k = 0.09$ elsewhere, $h = 0.05$, and $\delta = 0.01$. The discounted value function of this system around D_1 is shown in Figure 5.4. The calculated minimal Lyapunov exponent over D_1 is -1.25, the maximal exponent is -1.15. The calculated minimal and maximal exponents over D_2 are 0.019 and 0.24 and the value function is constant outside D_1. Figure 5.5 shows two

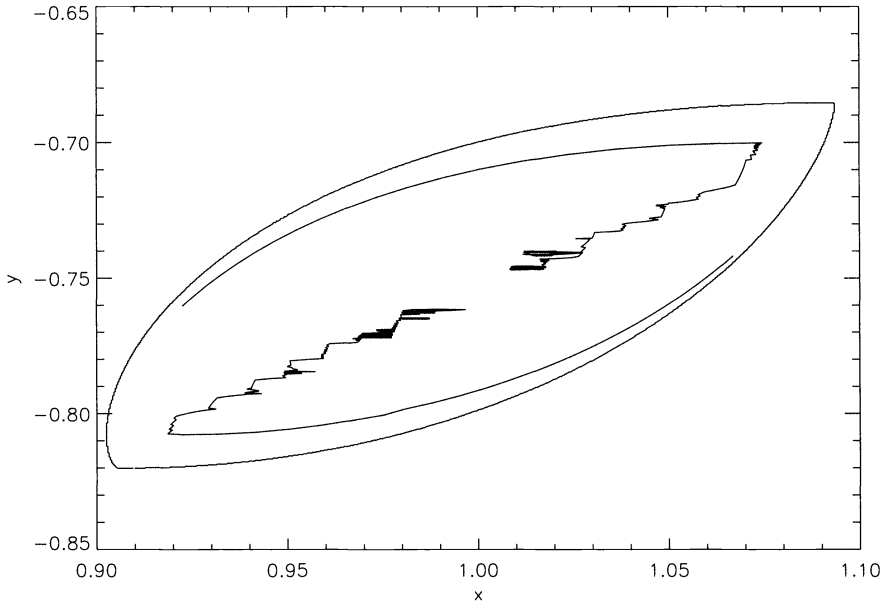

FIG. 5.5. *Optimal trajectories in* D_1.

trajectories of the projected system with initial values inside D_1. Table 5.5 shows the values of one corresponding trajectory in $\mathbb{R}^3$.

The second set of parameters considered for this system is $a = -1$, $b = -3$, $c = 0.5$, and $U = \{-1.0, -0.9, \ldots, 0.9, 1.0\}$. Figure 5.6 shows the three control sets of the projected system, the domain of attraction of D_2 (denoted by $A^-(D_2)$), and the domain of attraction of D_2 of the time-reversed system (denoted by $A^+(D_2)$).

Here the numerical parameters were $k = 0.002$ around D_1, $k = 0.045$ elsewhere, $h = 0.05$, and $\delta = 0.01$. Figure 5.7 shows the discounted optimal value function around D_1.

The calculated spectrum for this example is $\lambda(D_1) = [-1.47, -1.17]$, $\lambda(D_2) = [-0.10, 0.43]$, and $\lambda(D_3) = [2.07, 2.36]$.

Figure 5.8 shows an optimal trajectory in $\mathbb{P}^2$, starting in the domain of attraction of D_2. Table 5.6 shows the corresponding trajectory (x_1, x_2, x_3) in $\mathbb{R}^3$ and another trajectory

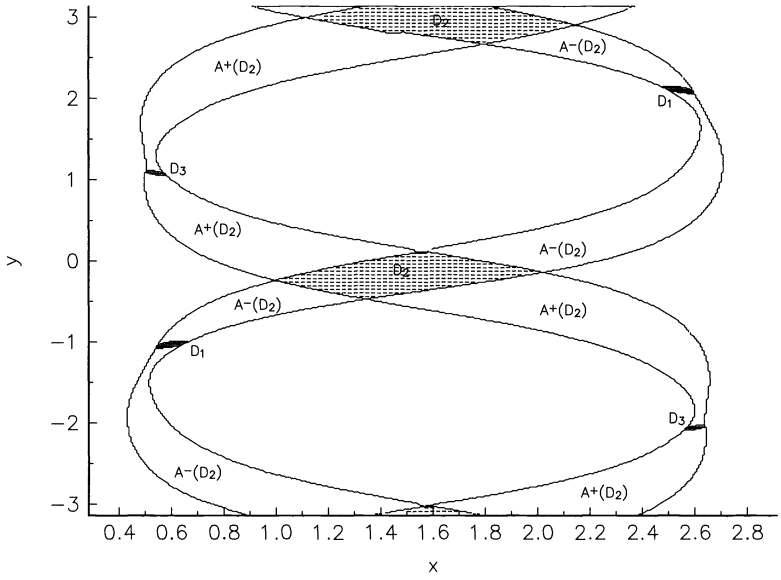

FIG. 5.6. *Control sets of system* (5.5) *with* $a = -1.0$, $b = -3.0$, $c = 0.5$.

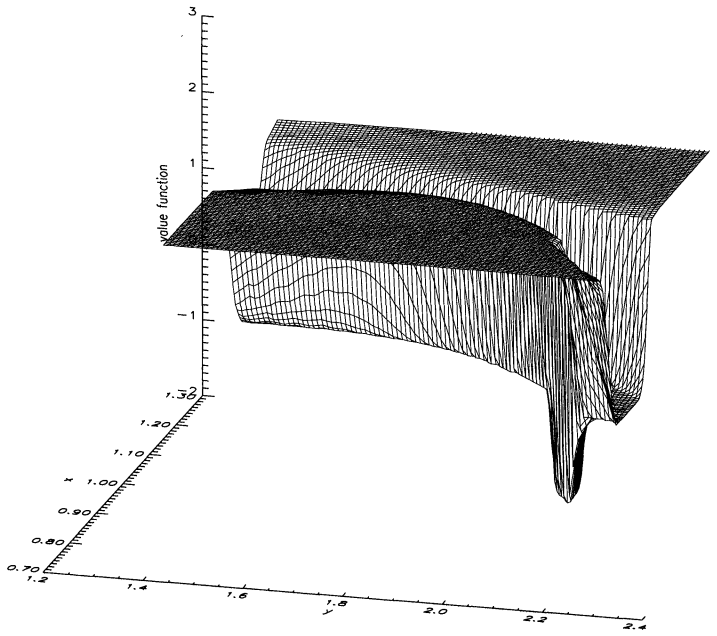

FIG. 5.7. *Value function of the system.*

(y_1, y_2, y_3) in $\mathbb{R}^3$ with projected initial value in D_1. This trajectory tends to zero much faster, which is exactly what one would expect since the minimal Lyapunov exponent inside D_1 is much smaller.

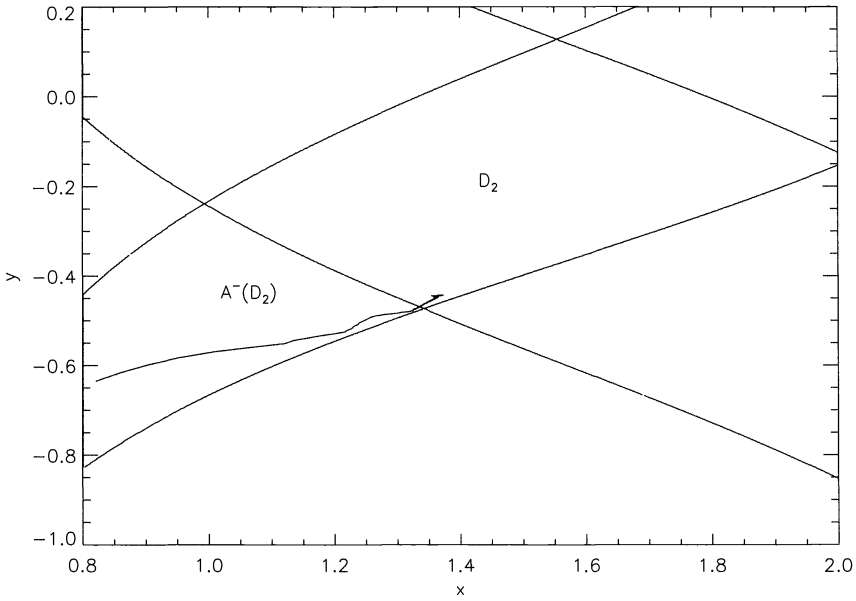

FIG. 5.8. *Optimal trajectory starting in* $A^-(D_2)$.

CONVERGENCE OF THE BFGS METHOD FOR LC^1 CONVEX CONSTRAINED OPTIMIZATION*

XIAOJUN CHEN†

Abstract. This paper proposes a BFGS-SQP method for linearly constrained optimization where the objective function f is required only to have a Lipschitz gradient. The Karush–Kuhn–Tucker system of the problem is equivalent to a system of nonsmooth equations $F(v) = 0$. At every step a quasi-Newton matrix is updated if $\|F(v_k)\|$ satisfies a rule. This method converges globally, and the rate of convergence is superlinear when f is twice strongly differentiable at a solution of the optimization problem. No assumptions on the constraints are required. This generalizes the classical convergence theory of the BFGS method, which requires a twice continuous differentiability assumption on the objective function. Applications to stochastic programs with recourse on a CM5 parallel computer are discussed.

Key words. quasi-Newton methods, convex programming, nonsmooth equations

AMS subject classifications. 90C30, 90C25

1. Introduction. The Broyden–Fletcher–Goldfarb–Shanno (BFGS) method is the most successful quasi-Newton method for solving convex minimization problems [11], [14]. In this paper we consider the BFGS method for solving the following constrained minimization problem:

$$\begin{aligned} &\min \ f(x) \\ &\text{subject to (s.t.)} \ Ax \le b, \end{aligned} \tag{1.1}$$

where $A \in R^{m\times n}$, $b \in R^m$, and $f : R^n \to R$ is a convex LC^1 function.

The LC^1 property of f means that f is Fréchet differentiable at all points in an open convex set $\Omega \subseteq R^n$ containing $X = \{x \in R^n : Ax \le b\}$, and the gradient function $g := \nabla f : \Omega \to R^n$ is locally Lipschitz in Ω. If f is LC^1 and X is nonempty, then (1.1) is called an LC^1 minimization problem. LC^1 optimization problems arise from nonlinear minimax problems, stochastic programs, augmented Lagrangians, semi-infinite programs, and some differentiable penalty function methods for constrained optimization problems. See [2], [7], [8], [13], [27], [28], [31], [32], [33], [37].

The Karush–Kuhn–Tucker (KKT) system for (1.1) is

$$\nabla f(x) + A^T u = 0,$$

$$u \ge 0, \ b - Ax \ge 0, \ u^T(b - Ax) = 0,$$

where $x \in R^n$ and $u \in R^m$. Let $N = n + m$ and $v = (x^T, u^T)^T$. Then the KKT system is equivalent to a system of nonsmooth equations [25]:

$$F(v) := \begin{pmatrix} \nabla f(x) + A^T u, \\ \min(u, b - Ax) \end{pmatrix} = 0, \tag{1.2}$$

where the "min" operator denotes the componentwise minimum of two vectors.

The local convergence theory of quasi-Newton methods for smooth equations and smooth unconstrained minimization problems is well developed. See [3], [4], [11], [12], [14], [22]. Quasi-Newton methods have been applied to nonsmooth equations in [5], [6], [9], [16], [17],

[19], [21], [23], but local superlinear convergence properties have not been obtained without the differentiability of the function F at a solution of the system of nonsmooth equations. Recently, Bonnans, Gilbert, Lemaréchal, and Sagastizábal [2] presented a conceptual method for LC^1 unconstrained minimization combining the BFGS method with the Moreau–Yosida regularization. Their local superlinear convergence requires that f be twice strongly differentiable at the solution.

Several authors [7], [8], [27], [28], [31], [32] studied the generalized Newton method for solving problem (1.1). Local superlinear convergence properties were established under a "semismoothness" assumption on the gradient function g at a solution [28], [31]. The generalized Newton method utilizes the generalized Hessian instead of $\nabla^2 f$ in a Newton method or a sequential quadratic programming (SQP) method. In many cases, however, calculating the generalized Hessian is very difficult.

Motivated by the fact that the BFGS method combines global convergence, a rate of superlinear convergence, and simple updates for smooth unconstrained minimization problems [4], we present a BFGS-SQP method for solving the LC^1 minimization problem (1.1). This method replaces the Hessian in the SQP method by the updated BFGS matrix and uses an Armijo line search to reduce the objective value. Moreover, this method uses the BFGS formula to update the quasi-Newton matrix if $\|F(v_k)\|$ satisfies a rule at every step.

The goal of this paper is to establish global and superlinear convergence of the BFGS-SQP method for the LC^1 convex optimization problem (1.1). Global convergence of this method only requires Lipschitz continuity of the gradient function and boundedness of the level sets of f in X. Superlinear convergence of this method requires twice strong differentiability of f at the solution of (1.1), but it does not require differentiability of F at the solution of (1.2). Furthermore no assumptions on the constraints are required, for example, the linear independence condition [31]. Note that an LC^1 function f can be twice strongly differentiable at a single point but can fail to be twice differentiable at arbitrarily close neighboring points (cf. [25]). Our results extend the classical convergence theory of the BFGS method for convex, smooth minimization problems which typically requires a twice continuous differentiability assumption on the objective function.

The remainder of the paper is organized as follows. In §2 we review the key analytic properties of the BFGS method. In §3 we give the BFGS-SQP method and study global convergence of this method. In §4 we study superlinear convergence of the BFGS-SQP method. In §5 we discuss applications to stochastic programs with recourse on a CM5 parallel computer.

2. The BFGS method. Quasi-Newton versions of SQP methods for solving linearly constrained minimization problems are iterative methods of the form [14]

$$x_{k+1} = x_k + \alpha_k d_k,$$

where α_k is a steplength and d_k is a solution of the quadratic subproblem

$$\begin{aligned} &\min g_k^T d + \frac{1}{2} d^T B_k d \\ &\text{s.t. } A(x_k + d) \le b. \end{aligned}$$

The matrix B_k is updated at every step by means of a quasi-Newton update formula, and g_k is the gradient of f at x_k. In particular, the BFGS update formula is given by

$$B_{k+1} = B_k - \frac{B_k s_k s_k^T B_k}{s_k^T B_k s_k} + \frac{y_k y_k^T}{y_k^T s_k}, \tag{2.1}$$

where $y_k = g_{k+1} - g_k$ and $s_k = x_{k+1} - x_k$.

The BFGS formula has an important property that B_{k+1} is positive definite if B_k is positive definite and $y_k^T s_k > 0$.

Powell [29] first proved the global convergence of the BFGS method for unconstrained optimization by measuring the trace

$$\operatorname{tr}(B_{k+1}) = \operatorname{tr}(B_k) - \frac{\|B_k s_k\|^2}{s_k^T B_k s_k} + \frac{\|y_k\|^2}{y_k^T s_k} \tag{2.2}$$

and the determinant

$$\det(B_{k+1}) = \det(B_k)\frac{y_k^T s_k}{s_k^T B_k s_k}.$$

Byrd and Nocedal [4] simplified the proof by using a function

$$\psi(B_k) = \operatorname{tr}(B_k) - \ln(\det(B_k)).$$

Let x_0 be the starting point for the BFGS method. We define the level set

$$\hat{D}_0 = \{x \in R^n : \ f(x) \le f(x_0)\}.$$

Byrd and Nocedal [4] proved the global convergence of the BFGS method under the conditions that f is twice continuously differentiable and there exist positive constants μ and ν such that

$$\mu\|z\|^2 \le z^T \nabla^2 f(x) z \le \nu\|z\|^2 \tag{2.3}$$

for all $z \in R^n$ and all $x \in \hat{D}_0$. Note that (2.3) implies that f has a unique minimizer $x^* \in \hat{D}_0$. They proved the local superlinear convergence under assumption (2.3) and that $\nabla^2 f$ is Lipschitz continuous at the minimizer x^*.

Bonnans, Gilbert, Lemaréchal, and Sagastizábal [2] presented a BFGS proximal method for LC^1 unconstrained optimization problems which combines the Moreau–Yosida regularization and the BFGS method. The BFGS proximal method is an iterative method of the form

$$x_{k+1} = x_k + \alpha_k(x_k^p - x_k),$$

where α_k is a steplength and

$$x_k^p = \arg\min\left\{ f(x) + \frac{1}{2}(x - x_k)^T B_k (x - x_k), \ x \in R^n \right\}. \tag{2.4}$$

The matrix B_k is updated at every step by the BFGS formula (2.1).

Paper [2] gave preliminary results to combine methods for nonsmooth optimization and classical quasi-Newton methods. However, the BFGS proximal method is only a conceptual algorithm because we do not specify how $\{x_k^p\}$ can be calculated from (2.4). The superlinear convergence theorem for the BFGS proximal method requires that f be twice strongly differentiable at the solution. This assumption has been required in superlinear convergence analysis of the Broyden method. See [5] and [19].

3. Global convergence. We will now use ideas from both smooth and nonsmooth optimization [2], [4], [29] to study a new BFGS-SQP method for LC^1 convex constrained optimization (1.1). We show global convergence of this method in this section.

BFGS-SQP method

Given constants $\tau, \sigma, \rho, \eta \in (0, 1)$, $\epsilon_0 > 0$ and an integer $r > 0$, choose $x_0 \in X$, $u_0 \geq 0$, and an $n \times n$ symmetric positive definite matrix B_0. Let $v_0 = (x_0^T, u_0^T)^T$ and let $\delta = \|F(v_0)\|$. For $k \geq 0$

1. Solve the quadratic program

$$\begin{aligned} &\min g_k^T d + \tfrac{1}{2} d^T (B_k + \epsilon_k I) d \\ &\text{s.t. } A(x_k + d) \leq b. \end{aligned} \tag{3.1}$$

Let d_k be the solution of (3.1) and u_{k+1} be the Lagrange multipliers at d_k corresponding to $A(x_k + d) \leq b$.

2. Let t_k be the minimum integer $t \geq 0$ such that

$$f(x_k + \rho^t d_k) - f(x_k) \leq \frac{\sigma}{2} \rho^t g_k^T d_k. \tag{3.2}$$

Let $\alpha_k = \rho^{t_k}$ and let $x_{k+1} = x_k + \alpha_k d_k$.

3. Let $v_{k+1} = (x_{k+1}^T, u_{k+1}^T)^T$.

If $\|F(v_{k+1})\|/\delta \leq \eta$,

let $\delta = \|F(v_{k+1})\|$, $\epsilon_{k+1} = \tau \epsilon_k$.

Otherwise let $\epsilon_{k+1} = \epsilon_k$.

4. If $y_k^T d_k \geq \rho^{r+1} \epsilon_k d_k^T d_k$, update B_k by the BFGS formula (2.1). Otherwise, set $B_{k+1} = B_k$.

5. If x_{k+1} satisfies a prescribed stopping criterion, terminate; otherwise, return to Step 1 with k replaced by $k + 1$.

Without loss of generality, we assume that x_k is feasible but nonoptimal to (1.1). Suppose that B_k is symmetric positive definite. Since $d = 0$ is feasible to (3.1), the optimal objective value of (3.1) must be nonpositive. Moreover, the nonoptimality of x_k to (1.1) implies that (3.1) has a unique optimal solution d_k which satisfies

$$g_k^T d_k + \frac{1}{2} d_k^T (B_k + \epsilon_k I) d_k < 0. \tag{3.3}$$

This implies

$$g_k^T d_k < 0.$$

A standard result in nonlinear programming [1] establishes that the integer t_k is well defined and finite. Therefore, we have

$$y_k^T s_k = \alpha_k y_k^T d_k > 0 \qquad \text{if } y_k^T d_k \geq \rho^{r+1} \epsilon_k d_k^T d_k.$$

By construction, the matrix B_{k+1} is symmetric positive definite. By the convexity of X, the point x_{k+1} is feasible. Hence the BFGS-SQP method is well defined and generates an infinite sequence $\{x_k\} \subseteq X$.

We define the level set $D_0 = \{x \in X : f(x) \leq f(x_0)\}$, where x_0 is the starting point for the BFGS-SQP method.

Assumption 3.1. Assume that the level set D_0 is bounded and there is a positive constant L such that

$$\|g(x) - g(y)\| \leq L\|x - y\| \qquad \text{if } x, y \in D_0.$$

THEOREM 3.1. *Under Assumption* 3.1, *every accumulation point* $\bar{x}$ *of the sequence* $\{x_k\}$ *produced by the BFGS-SQP method is an optimal solution of* (1.1).

Proof. Let $K = \{0, 1, 2, \ldots\}$ and $K_0 = \{k \in K : \epsilon_{k+1} = \tau\epsilon_k \text{ at iteration } k\}$.

If K_0 is infinite, then every accumulation point $\bar{v}$ of the sequence $\{v_k : k \in K_0\}$ is a solution of $F(v) = 0$. By Theorem 9.4.2 in [14], $\bar{x}$ is a global minimum point of (1.1).

The remainder of this proof is for the case where K_0 is finite.

Since D_0 is bounded, the sequence $\{x_k\}$ is bounded. Since K_0 is finite, there is a large $\hat{k}$ such that $\epsilon_k = \epsilon_{\hat{k}}$ for all $k \geq \hat{k}$, and thus $\epsilon_k \geq \epsilon_{\hat{k}}$ for all $k \geq 0$. Let $\hat{\epsilon} = \epsilon_{\hat{k}}$. Since B_k is symmetric positive definite, we have

$$d^T(B_k + \epsilon_k I)d \geq \hat{\epsilon}\|d\|^2 \quad \text{for all } d \in R^n \text{ and all } k \geq 0\,. \tag{3.4}$$

By the variational principle of the quadratic program (3.1), the unique optimal solution d_k satisfies

$$g_k^T d_k + d_k^T(B_k + \epsilon_k I)d_k \leq 0. \tag{3.5}$$

Let $K_1 = \{k \in K, y_k^T d_k \geq \rho^{r+1}\epsilon_k d_k^T d_k\}$. If K_1 is finite, then there is a large $\bar{k}$ such that $B_{k+1} = B_{\bar{k}}$ for $k \geq \bar{k}$. Using the inequality [29]

$$\|y_k\|^2 \leq L y_k^T s_k$$

and the trace relation (2.2), we obtain

$$\operatorname{tr}(B_{k+1}) \leq \operatorname{tr}(B_k) + L \qquad \text{if } k \in K_1.$$

Noticing $B_{k+1} = B_k$ if $k \notin K_1$ we have

$$\operatorname{tr}(B_k) \leq \operatorname{tr}(B_0) + \bar{k}L \qquad \text{for all } k \geq 0.$$

Since the largest eigenvalue λ_{k_n} of B_k is less than the trace, we get

$$d^T(B_k + \epsilon_k I)d \leq (\lambda_{k_n} + \epsilon_k)\|d\|^2 \leq (\operatorname{tr}(B_0) + \bar{k}L + \epsilon_0)\|d\|^2$$

for all $d \in R^n$ and all $k \in K$. Hence we can show that every accumulation point $\bar{x}$ is an optimal solution of (1.1) by a standard proof (see, e.g., [26]). We omit the details.

Now we consider the case where K_1 is infinite. From (3.2), (3.4), and (3.5) and that D_0 is bounded, we have

$$\hat{\epsilon}\sum_{k=0}^{\infty}\alpha_k\|d_k\|^2 \leq \sum_{k=0}^{\infty}\alpha_k d_k^T(B_k+\epsilon_k I)d_k \leq \sum_{k=0}^{\infty} -\alpha_k g_k^T d_k \leq \frac{2}{\sigma}(f(x_0)-f(\bar{x})) < \infty. \tag{3.6}$$

Furthermore, if $k \in K_1$, we have

$$d_k^T d_k \leq y_k^T d_k/(\rho^{r+1}\epsilon_k) \leq L\|s_k\|\|d_k\|/(\rho^{r+1}\hat{\epsilon}) = \alpha_k L d_k^T d_k/(\rho^{r+1}\hat{\epsilon}).$$

This implies

$$\alpha_k \geq \frac{\rho^{r+1}\hat{\epsilon}}{L} \qquad \text{for } k \in K_1.$$

Since K_1 is infinite and $\rho^{r+1}\hat{\epsilon}/L$ is a constant, we obtain

$$\sum_{k=0}^{\infty}\alpha_k \geq \sum_{k\in K_1}\alpha_k \geq \sum_{k\in K_1}\frac{\rho^{r+1}\hat{\epsilon}}{L} = \infty. \tag{3.7}$$

From (3.6) and (3.7), the sequence $\{\|d_k\|\}$ cannot be bounded away from 0. There exists a subset $K_2 \subset K_1$ such that $\lim_{k\in K_2} \|d_k\| = 0$.

Let $\bar{f}$ denote the optimal value of f. Extract from K_2 a further subset, say $K_3 \subset K_2$, such that $\{x_k, k \in K_3\}$ tends to some limit $\bar{x}$ and $\|B_k s_k\| \le \beta \|s_k\|$ for $k \in K_3$, where β is a constant (cf. Theorem 2.1 in [4]). By construction, the point $\bar{x}$ must necessarily belong to X. Let $\{d_k, k \in K_3\}$ be a corresponding sequence of directions. Since $\lim_{k\in K_3} d_k = 0$, $\bar{x}$ is an optimal solution of (1.1) and $f(\bar{x}) = \bar{f}$.

Since $\{f(x_k)\}$ is nonincreasing and has a limit f^*,

$$\begin{aligned} f^* - f(x_k) \le f(x_{k+1}) - f(x_k) &\le \frac{\sigma}{2}\alpha_k g_k^T d_k \\ &\le -\frac{\sigma}{2}\alpha_k d_k^T (B_k + \epsilon_k I) d_k \\ &\le -\frac{\sigma}{2}\hat{\epsilon}\alpha_k \|d_k\|^2. \end{aligned} \tag{3.8}$$

From (3.6), $\alpha_k \|d_k\|^2 \to 0$. Pass to the limit in (3.8), written for $k \in K_3$; we obtain $f^* = \bar{f}$. Then any accumulation point of $\{x_k\}$ is also optimal. □

Analysis in [4] covered a large class of line search strategies. We can generalize the results to LC^1 problems easily. In particular, the Armijo line search in the BFGS-SQP method has the following relationship with two other line search strategies.

LEMMA 3.1. *Under Assumption* 3.1, *there exist positive constants* η_1 *and* η_2 *such that the steplength* α_k *produced by the BFGS-SQP method will satisfy either*

$$f(x_k + \alpha_k d_k) - f(x_k) \le -\eta_1 \frac{(g_k^T d_k)^2}{\|d_k\|^2}$$

or

$$f(x_k + \alpha_k d_k) - f(x_k) \le \eta_2 g_k^T d_k. \qquad \square$$

We can prove Lemma 3.1 by the same technique in [4, Lem. 4.1], since g is Lipschitz continuous and construction of the BFGS-SQP method implies $g_k^T d_k < 0$ and

$$f(x_k + \rho^{t_k - 1} d_k) - f(x_k) > \frac{\sigma}{2}\rho^{t_k-1} g_k^T d_k \qquad \text{if } t_k > 0. \tag{3.9}$$

Lemma 3.1 will be applied to superlinear convergence analysis of the BFGS-SQP method.

4. Superlinear convergence. In this section we first prove superlinear convergence of the BFGS-SQP method under a Dennis–Moré–type condition [10]. Next we show that the condition is satisfied when f is twice strongly differentiable at a solution of (1.1).

Assumption 4.1. The objective function f is twice differentiable at a solution x^*, and $\nabla^2 f(x^*)$ is nonsingular.

Assumption 4.1 and the convexity of f imply that x^* is a unique minimizer of (1.1) [33]. Clearly, if a sequence $\{x_k\}$ generated by the BFGS-SQP method converges to x^*, then $\epsilon_k \to 0$ as $k \to \infty$.

Assumption 4.1 implies that the following limit holds:

$$\lim_{\|d\|\to 0} \frac{\|g(x^* + d) - g(x^*) - \nabla^2 f(x^*) d\|}{\|d\|} = 0. \tag{4.1}$$

THEOREM 4.1. *Under Assumptions* 3.1 *and* 4.1, *the BFGS-SQP method generates a sequence* $\{x_k\}$ *that converges to the unique minimum point* x^* *of* (1.1). *Moreover, if*

$$\lim_{k\to\infty} \frac{\|(\nabla^2 f(x^*) - B_k) d_k\|}{\|d_k\|} = 0 \tag{4.2}$$

and the sequence $\{\|B_k^{-1}\|\}$ *is bounded, then there exists an integer* k_0 *such that* $\alpha_k = 1$ *for all* $k \geq k_0$ *and the sequence* $\{x_k\}$ *converges to* x^* *at least Q-superlinearly; i.e.,*

$$\lim_{k\to\infty} \frac{\|x_{k+1} - x^*\|}{\|x_k - x^*\|} = 0.$$

Proof. From Theorem 3.1, the BFGS-SQP method generates a sequence $\{x_k\}$ that converges to x^*.

Now we show that $\{x_k\}$ converges to x^* at least Q-superlinearly. First we show

$$\|x_k + d_k - x^*\| = o(\|x_k - x^*\|). \tag{4.3}$$

Combining (4.1) and (4.2), we have

$$\begin{aligned} &g_k - g(x^*) - \nabla^2 f(x^*)(x_k - x^*) - (\nabla^2 f(x^*) - B_k)d_k \\ &= g_k - g(x^*) - B_k(x_k - x^*) - (\nabla^2 f(x^*) - B_k)(x_k + d_k - x^*) \\ &= o(\|x_k - x^*\|) + o(\|d_k\|). \end{aligned}$$

Hence we may write

$$\begin{aligned} g(x^*) = g_k + B_k(x^* - x_k) - (\nabla^2 f(x^*) - B_k)(x_k + d_k - x^*) \\ + o(\|x^* - x_k\|) + o(\|d_k\|). \end{aligned}$$

By the variational principle of (1.1), we have

$$\begin{aligned} 0 &\leq (x_k + d_k - x^*)^T g(x^*) \\ &= (x_k + d_k - x^*)^T (g_k + B_k(x^* - x_k) - (\nabla^2 f(x^*) - B_k)(x_k + d_k - x^*) \\ &\quad + o(\|x^* - x_k\|) + o(\|d_k\|)). \end{aligned} \tag{4.4}$$

Since d_k is the solution of (3.1), by the variational principle of (3.1) we have

$$0 \leq (x^* - x_k - d_k)^T (g_k + (B_k + \epsilon_k I)d_k),$$

which implies

$$\begin{aligned} &(x^* - x_k - d_k)^T (B_k + \epsilon_k I)(x^* - x_k - d_k) \\ &\leq (x^* - x_k - d_k)^T (g_k + (B_k + \epsilon_k I)(x^* - x_k)). \end{aligned} \tag{4.5}$$

Adding (4.4) to (4.5), we have

$$\begin{aligned} &(x^* - x_k - d_k)^T (B_k + \epsilon_k I)(x^* - x_k - d_k) \\ &\leq (x^* - x_k - d_k)^T (\epsilon_k (x^* - x_k) + o(\|x^* - x_k\|) + o(\|d_k\|)) \\ &\quad -(x_k + d_k - x^*)^T (\nabla^2 f(x^*) - B_k)(x_k + d_k - x^*). \end{aligned} \tag{4.6}$$

Since f is convex, the nonsingularity of $\nabla^2 f(x^*)$ implies that the matrix $\nabla^2 f(x^*)$ is symmetric positive definite [20]. Hence there exists a constant $\mu > 0$ such that

$$\mu\|z\|^2 \leq z^T \nabla^2 f(x^*) z \qquad \text{for all } z \in R^n.$$

Therefore from (4.6) and that $\epsilon_k \to 0$ as $k \to \infty$ we have

$$\begin{aligned} \mu\|x_k + d_k - x^*\|^2 &\leq (x^* - x_k - d_k)^T (\nabla^2 f(x^*) + \epsilon_k I)(x^* - x_k - d_k) \\ &\leq \|x_k + d_k - x^*\|(o(\|x_k - x^*\|) + o(\|d_k\|)). \end{aligned}$$

This implies

$$\|d_k\| = O(\|x_k - x^*\|) \tag{4.7}$$

and (4.3).

Now we show that there exists an integer $k_0 \geq 0$ such that $\alpha_k = 1$ for all $k \geq k_0$.

From (4.1), we have for all large k,

$$f(x_k) = f(x^*) + g(x^*)^T(x_k - x^*) + \frac{1}{2}(x_k - x^*)^T \nabla^2 f(x^*)(x_k - x^*) + o(\|x_k - x^*\|^2) \tag{4.8}$$

and

$$f(x_k + d_k) = f(x^*) + g(x^*)^T(x_k + d_k - x^*) + \frac{1}{2}(x_k + d_k - x^*)^T \nabla^2 f(x^*)(x_k + d_k - x^*)$$

$$+ o(\|x_k + d_k - x^*\|^2). \tag{4.9}$$

By subtracting (4.8) from (4.9), we obtain

$$f(x_k + d_k) - f(x_k) = \frac{1}{2} g_k^T d_k + (g(x^*) - g_k + \nabla^2 f(x^*)(x_k - x^*))^T d_k$$

$$+ \frac{1}{2} d_k^T (g_k + B_k d_k) + \frac{1}{2} d_k^T (\nabla^2 f(x^*) - B_k) d_k + o(\|x_k - x^*\|^2).$$

Using the relation $d_k^T(g_k + B_k d_k) \leq 0$ and (4.1), (4.2), and (4.7), we have

$$f(x_k + d_k) - f(x_k) - \frac{1}{2} g_k^T d_k \leq o(\|x_k - x^*\|^2). \tag{4.10}$$

Since the sequence $\{\|B_k^{-1}\|\}$ is bounded, there exists a constant $\tilde{c} > 0$ such that for all large k

$$-g_k^T d_k \geq d_k^T (B_k + \epsilon_k I) d_k \geq \tilde{c} \|d_k\|^2.$$

Thus from (4.7) there exists a constant $c > 0$ such that

$$c\|x_k - x^*\|^2 \leq -g_k^T d_k \qquad \text{for all large } k. \tag{4.11}$$

Combining (4.10) and (4.11), we have the existence of k_0 such that for all $k \geq k_0$ there is a positive scalar $\delta < \min\{\frac{1}{2}, \frac{c}{2}(1 - \sigma)\}$ such that

$$f(x_k + d_k) - f(x_k) - \frac{\sigma}{2} g_k^T d_k \leq \frac{1 - \sigma}{2} g_k^T d_k + \delta \|x_k - x^*\|^2$$

$$\leq \left(\frac{1 - \sigma}{2} - \frac{\delta}{c} \right) g_k^T d_k \leq 0.$$

Hence for all $k \geq k_0$ we have $\alpha_k = 1$ and $x_{k+1} = x_k + d_k$. From (4.3) we obtain that $\{x_k\}$ superlinearly converges to x^*. □

The condition (4.2) is a Dennis–Moré–type condition [10] which plays a key role in the superlinear convergence analysis. We give the following sufficient conditions for (4.2) by using Theorem 3.2 in [4].

LEMMA 4.1. *Suppose that f satisfies Assumption* 4.1 *and $y_k^T d_k \geq \rho^{r+1} \epsilon_k d_k^T d_k$ for all large k. Assume that $\{s_k\}$ and $\{y_k\}$ are such that*

$$\frac{\|y_k - \nabla^2 f(x^*) s_k\|}{\|s_k\|} \leq w_k$$

for some sequence $\{w_k\}$ *with the property* $\sum_{k=0}^{\infty} w_k < \infty$. *Then* (4.2) *holds and the sequences* $\{\|B_k\|\}$, $\{\|B_k^{-1}\|\}$ *are bounded.*

The assumption that $y_k^T d_k \geq \rho^{r+1}\epsilon_k d_k^T d_k$ for all large k implies that $s_k^T y_k > 0$ and B_k is updated for all large k in the BFGS-SQP method. See Theorem 3.2 in [4] for a proof of Lemma 4.1.

To prove $y_k^T d_k \geq \rho^{r+1}\epsilon_k d_k^T d_k$ for all large k, we require the strong convexity of f.

Assumption 4.2. f is strongly convex on D_0 with modulus $\frac{\mu}{2} > 0$; i.e., for any $\lambda \in (0, 1)$ there holds

$$\lambda f(x) + (1-\lambda) f(y) - f(\lambda x + (1-\lambda)y) \geq \frac{1}{2}\mu\lambda(1-\lambda)\|x-y\|^2$$

for all $x, y \in D_0$.

There are two equivalent properties to Assumption 4.2 (see Theorems 3.4.4 and 3.4.5 in [24]):

$$f(x) - f(y) \geq g(y)^T(x-y) + \frac{\mu}{2}\|x-y\|^2 \qquad \text{for all } x, y \in D_0 \tag{4.12}$$

and

$$(g(x) - g(y))^T(x-y) \geq \mu\|x-y\|^2 \qquad \text{for all } x, y \in D_0. \tag{4.13}$$

THEOREM 4.2. *Under Assumptions* 3.1, 4.1, *and* 4.2, *if*

$$L \leq \frac{\mu(1+\rho^r)}{2\rho^r}, \tag{4.14}$$

then the following statements hold:

(i) *there exists an integer* $k_0 \geq 0$ *such that for all* $k \geq k_0$ *the sequences* $\{y_k\}$, $\{d_k\}$, $\{\epsilon_k\}$ *generated by the BFGS-SQP method satisfy*

$$y_k^T d_k \geq \rho^{r+1}\epsilon_k d_k^T d_k;$$

(ii) *the sequence* $\{x_k\}$ *converges to* x^* *at least r-linearly; this implies*

$$\sum_{k=0}^{\infty} \|x_k - x^*\| < \infty.$$

Proof. (i) Since

$$y_k^T d_k = y_k^T s_k/\alpha_k \geq \mu\|s_k\|^2/\alpha_k = \mu\alpha_k\|d_k\|^2,$$

it suffices to show that there is a $k_0 \geq 0$ such that

$$\mu\alpha_k \geq \rho^{r+1}\epsilon_k \qquad \text{for } k \geq k_0. \tag{4.15}$$

From (4.12) for any $\alpha \in (0, 1]$ there holds

$$f(x_k) - f(x_k + \alpha d_k) \geq -\alpha g(x_k + \alpha d_k)^T d_k + \frac{\mu}{2}\alpha^2\|d_k\|^2. \tag{4.16}$$

From (4.14), we have

$$\alpha(g(x_k + \alpha d_k) - g_k)^T d_k \leq \alpha\|g(x_k + \alpha d_k) - g_k\|\|d_k\| \leq L\alpha^2\|d_k\|^2 \leq \frac{1+\rho^r}{2\rho^r}\mu\alpha^2\|d_k\|^2. \tag{4.17}$$

Combining (4.16) and (4.17), we have

$$\begin{aligned}
&f(x_k) - f(x_k + \alpha d_k) \geq -\alpha g(x_k + \alpha d_k)^T d_k + \frac{\mu}{2}\alpha^2 \|d_k\|^2 \\
&\geq -\alpha g_k^T d_k - \frac{1+\rho^r}{2\rho^r}\mu\alpha^2\|d_k\|^2 + \frac{\mu}{2}\alpha^2\|d_k\|^2 \\
&= -\frac{\sigma}{2}\alpha g_k^T d_k - \frac{2-\sigma}{2}\alpha g_k^T d_k - \frac{1}{2\rho^r}\mu\alpha^2\|d_k\|^2 \\
&\geq -\frac{\sigma}{2}\alpha g_k^T d_k + \frac{2-\sigma}{2} d_k^T (B_k + \epsilon_k I) d_k - \frac{1}{2\rho^r}\mu\alpha^2\|d_k\|^2 \\
&\geq -\frac{\sigma}{2}\alpha g_k^T d_k + \frac{1}{2}\left((2-\sigma)\epsilon_k - \frac{\mu}{\rho^r}\alpha\right)\alpha\|d_k\|^2 \\
&\geq -\frac{\sigma}{2}\alpha g_k^T d_k + \frac{1}{2}\left(\epsilon_k - \frac{\mu}{\rho^r}\alpha\right)\alpha\|d_k\|^2.
\end{aligned}$$

Hence

$$f(x_k + \alpha d_k) - f(x_k) \leq \frac{\sigma}{2}\alpha g_k^T d_k \qquad \text{if } \alpha \leq \min\left(1, \frac{\rho^r \epsilon_k}{\mu}\right).$$

Since $\epsilon_k \to 0$ as $k \to \infty$, there exists $k_0 \geq 0$ such that $\rho^r \epsilon_k / \mu < 1$ for $k \geq k_0$. Therefore, for $k \geq k_0$ there is an integer $l_k \geq 0$ such that

$$\rho^{l_k+1} \leq \rho^r \frac{\epsilon_k}{\mu} \leq \rho^{l_k}.$$

Consequently, we have

$$f(x_k + \rho^{l_k+1} d_k) - f(x_k) \leq \frac{\sigma}{2}\rho^{l_k+1} g_k^T d_k.$$

By construction of the BFGS-SQP method, we have

$$\alpha_k = \rho^{t_k} \geq \rho^{l_k+1} \geq \frac{\epsilon_k}{\mu}\rho^{r+1};$$

thus (4.15) holds.

(ii) The Lipschitz property of g ensures [29]

$$L y_k^T s_k \geq \|y_k\|^2 \qquad \text{for } k \geq k_0. \tag{4.18}$$

From (4.13), we have

$$y_k^T s_k \geq \mu \|s_k\|^2 \qquad \text{for } k \geq 0. \tag{4.19}$$

From Theorem 2.1 in [4] and Lemma 3.1, (4.18) and (4.19) imply that there is a constant $\beta > 0$ such that

$$f(x_j) - f(x_j + \alpha_j d_j) \geq \beta \|g_j\|^2 \tag{4.20}$$

holds for at least $[p(k - k_0 + 1)](p \in (0, 1))$ values of $j \in [k_0, k]$ where k_0 is defined in (i) of this theorem.

Now we show

$$\frac{1}{2}\mu\|x_k - x^*\|^2 \leq f(x_k) - f(x^*) \leq \frac{1}{\mu}\|g_k\|^2. \tag{4.21}$$

The lower bound follows from (4.12) and

$$(x_k - x^*)^T g(x^*) \geq 0. \tag{4.22}$$

The upper bound follows from

$$f(x_k) - f(x^*) \le g_k^T(x_k - x^*) \le \|g_k\|\|x_k - x^*\|$$

and

$$\|g_k\| \ge \frac{g_k^T(x_k - x^*)}{\|x_k - x^*\|} \ge \frac{(g_k - g(x^*))^T(x_k - x^*)}{\|x_k - x^*\|} \ge \mu\|x_k - x^*\|, \tag{4.23}$$

where (4.23) is derived by (4.13) and (4.22).

From (4.20) and (4.21), the r-linear convergence of $\{x_k\}$ can be obtained by a simple manipulation (see, e.g., [4, p. 733]). We omit the details. □

We are now ready to give the superlinear convergence result.

THEOREM 4.3. *Under the assumptions of Theorem* 4.2, *if there exist a positive constant* $\tilde{L}$ *and a neighborhood* $\mathcal{N}_*$ *of* x^* *such that for any* $x, y \in \mathcal{N}_*$,

$$\frac{\|g(x) - g(y) - \nabla^2 f(x^*)(x - y)\|}{\|x - y\|} \le \tilde{L}\max(\|x - x^*\|, \|y - x^*\|), \tag{4.24}$$

then the sequence $\{x_k\}$ *generated by the BFGS-SQP method converges to the unique solution* x^* *of* (1.1) *Q-superlinearly.*

From Theorems 4.1 and 4.2, there exists $k_0 > 0$ such that for $k \ge k_0$, $x_k, x_{k+1} \in \mathcal{N}_*$, and $y_k^T d_k \ge \rho^{r+1}\epsilon_k d_k^T d_k$. Hence for $k \ge k_0$,

$$\frac{\|y_k - \nabla^2 f(x^*)s_k\|}{\|s_k\|} \le \tilde{L}\max(\|x_k - x^*\|, \|x_{k+1} - x^*\|) =: w_k$$

where $\sum_{k=k_0}^{\infty} w_k < \infty$. Let $w_k = \|y_k - \nabla^2 f(x^*)s_k\|/\|s_k\|$ for $k < k_0$. Since $\|s_k\| > 0$ and the sequences $\|y_k\|$ and $\|s_k\|$ are bounded, $\sum_{k=0}^{k_0-1} w_k < \infty$. Hence from Theorem 4.1 and Lemma 4.1, we conclude the rate of convergence is superlinear.

5. Applications. Some source problems for LC^1 convex optimization have been discussed in [2], [7], [8], [13], [27], [28], [31], [32], [33], [37]. In this section we use the BFGS-SQP method to solve quadratic stochastic programming problems on a 16-node partition of a CM5 parallel computer using data parallel constructs expressed by Fortran 90 style matrix operations.

The quadratic stochastic programming model was introduced by Rockafellar and Wets [34], [35], [36]. A version of a 2-stage quadratic stochastic program with fixed recourse is

$$\begin{aligned} \min \quad & \frac{1}{2}x^T Px + c^T x + \sum_{i=0}^{\gamma} \psi(x, \omega_i)\xi_i \\ \text{s.t.} \quad & Ax \le b \end{aligned} \tag{5.1}$$

where

$$\begin{aligned} \psi(x, \omega) = \max \quad & -\frac{1}{2}z^T Hz + z^T(\omega - Tx) \\ \text{s.t.} \quad & Wz \le q. \end{aligned}$$

Here $P \in R^{n\times n}$ and $H \in R^{n_1\times n_1}$ are symmetric positive definite; $c \in R^n$, $T \in R^{n_1\times n}$, $W \in R^{m_1\times n_1}$, $q \in R^{m_1}$, $\omega_i \in R^{n_1}$, $i = 0, 1, \ldots, \gamma$, and $\xi_i \ge 0$, $i = 0, 1, \ldots, \gamma$ are scalars satisfying $\sum_{i=0}^{\gamma} \xi_i = 1$.

The objective function of (5.1) is strongly convex and has a Lipschitz continuous gradient at all points in X but it is not twice differentiable in X. Hence this problem is an LC^1 convex constrained optimization problem. The gradient of the objective function is

$$Px + c - T^T H^{-\frac{1}{2}} \sum_{i=0}^{\gamma} z_i^*(x)\xi_i,$$

TABLE 1

γ	$k(t_{k-2}, t_{k-1}, t_k)$	$\|x^* - x_k\|$	$\|F(v_k)\|$	CPU(sec)
2^5	6 (6, 6, 1)	3.6×10^{-11}	6.7×10^{-12}	236.3
5^5	5 (6, 6, 1)	2.1×10^{-11}	2.1×10^{-12}	246.0
8^5	4 (1, 4, 2)	1.1×10^{-10}	9.3×10^{-12}	1062.8

where

$$z_i^*(x) = \operatorname{argmax}\left\{-\frac{1}{2}z^T Hz + z^T(\omega_i - Tx),\ Wz \le q\right\} = \Pi_S(H^{-\frac{1}{2}}(\omega_i - Tx)).$$

Here $\Pi_S(u)$ is the projection of $u \in R^{n_1}$ into the set $S = \{s \in R^{n_1}, WH^{-\frac{1}{2}}s \le q\}$. Since the projection operator is nonexpansive, we have a Lipschitz constant $L = \|P\| + \|T^T H^{-\frac{1}{2}}\|\|H^{-\frac{1}{2}}T\|$ for Assumption 3.1. Furthermore, we can choose a positive integer r and positive scalars $\rho < 1$, $\mu \le \lambda_{\min}(P)$ (the smallest eigenvalue of P) such that condition (4.14) holds.

Calculating the objective and its gradient involves a large number of quadratic programs. We tested the BFGS-SQP method for solving (5.1) on a CM5 parallel computer. At each step, $f(x_k)$ and g_k are calculated in parallel. The test problems are randomly generated but with known solution characteristics so different features of the algorithm can be tested.

We chose $n = 100, m = 60, n_1 = 5, m_1 = 3, \kappa(P) = \kappa(H) = 10^2, \kappa(A) = \kappa(W) = 2.5^2, \mu_0 = 30, \nu_0 = 15$. Here $\kappa(G) = \tau^2$ is the condition number of a matrix G whose nonzero eigenvalues are distributed on $[1/\tau, \tau]$, μ_0 is the number of active constraints at the solution x^* with positive multipliers, and ν_0 is the number of active constraints at the solution x^* with zero multipliers. We generate $\omega_i = (\omega_{i,1}, \omega_{i,2}, \omega_{i,3}, \omega_{i,4}, \omega_{i,5}) \in [0, 1]^5$, $i = 1, 2, \ldots, \gamma$ with $\omega_{i,j} \in \{0, \frac{1}{l-1}, \ldots, 1\}$, $\gamma = l^5$. In the BFGS-SQP method, we chose $B_0 = P, \tau = \sigma = \rho = \eta = \epsilon_0 = 0.75$, and $r = 20$. We choose the starting point $x_0 = \Pi_X(\tilde{x}), u_0 = 0$, where $\tilde{x} \in R^n$ was randomly generated. The algorithm terminated when $v_k = (x_k^T, u_k^T)^T$ satisfied $\|F(v_k)\| \le 10^{-11}$. Numerical results are reported in Table 1, where t_k is the number of iterations on the Armijo line search at the kth iteration.

Acknowledgments. The author is grateful to Liqun Qi, Robert S. Womersley, and Tetsuro Yamamoto for their valuable comments.

EXISTENCE RESULTS FOR NONCOERCIVE VARIATIONAL PROBLEMS*

GRAZIANO CRASTA† AND ANNALISA MALUSA‡

Abstract. The aim of this paper is to give an existence result for a class of one-dimensional, nonconvex, noncoercive problems in the calculus of variations. The main tools for the proof are an existence theorem in the convex case and the closure of the convex hull of the epigraph of functions strictly convex at infinity.

Key words. existence theory, nonconvex problems, noncoercive problems

AMS subject classification. 49J05

1. Introduction. It is well known that if L is a continuous function, such that $\xi \mapsto L(t, x, \xi)$ is convex and superlinear, then the variational problem

$$\min\left\{\int_0^T L(t, u, u')dt \;\Big|\; u \in W^{1,1}([0, T], \mathbb{R}^m),\ u(0) = a,\ u(T) = b\right\} \tag{1.1}$$

has a solution (see, for instance, [7]).

In recent years, the possibility of avoiding the convexity or the superlinearity assumption was investigated by many authors.

Some existence results for nonconvex coercive problems were obtained in the case $L(t, x, \xi) = g(t, x) + f(t, \xi)$ (see, for instance, [5], [14], [16], and the references therein). In particular, in [5] it was proved that the convexity assumption on $f(t, \cdot)$ can be replaced by the condition of concavity of $g(t, \cdot)$.

More recently, some techniques were developed in order to treat convex but noncoercive problems. In this case, even if the functionals considered are lower semicontinuous in the weak topology of $W^{1,1}([0, T], \mathbb{R}^m)$, the direct method of the calculus of variations cannot be applied due to the lack of compactness of the minimizing sequences.

In [10] problem (1.1) was studied with L continuous, bounded from below and convex with respect to ξ, the superlinearity being replaced by a weaker condition which permits construction of a relatively compact minimizing sequence, obtained by considering the minima of suitable coercive approximating problems. The main step in the proof of the existence result in [10] was to show that every minimum point of the approximating problems solves a generalized DuBois–Reymond condition, which implies that the minimizing sequence is bounded in the space $W^{1,\infty}([0, T], \mathbb{R}^m)$.

A similar approach was used in [6] for the autonomous problem $L(t, x, \xi) = g(x) + f(\xi)$, where g is a nonnegative continuous function and $f \in C^1(\mathbb{R}^m, \mathbb{R})$ is a strictly convex function bounded from below, such that

$$\lim_{|\xi| \to +\infty} [f(\xi) - \langle \nabla f(\xi),\ \xi \rangle] = -\infty. \tag{1.2}$$

In that paper, it was proved that for every rectifiable curve C in $\mathbb{R}^m$ joining a to b there exists a unique solution to the problem (1.1) restricted to the class of all absolutely continuous parameterizations $u: I \to \mathbb{R}^m$ of C. Thus, every element u_n of a minimizing sequence can be replaced by the minimum corresponding to the curve parameterized by u_n. It can be shown, still using a DuBois–Reymond condition satisfied by those minima and by (1.2), that this new

sequence is bounded in $W^{1,\infty}([0, T], \mathbb{R}^m)$, so that there exists a minimum point for (1.1) in this space.

In [12] both the superlinearity and the convexity assumptions were dropped for Lagrangians of the form $L(t, x, \xi) = \langle a(t), x\rangle + f(\xi)$ where f is a lower semicontinuous function whose convexification f^{**} satisfies (1.2) for every diverging sequence of points of differentiability of the Lipschitz continuous function f^{**}. The existence of a minimum is proved by a technique relying only on a Lyapunov-type theorem due to Olech (see [15]).

For other results concerning noncoercive problems we mention [1], [2], and [3].

In this paper we consider nonautonomous problems of the form

$$\min\left\{\int_0^T \left[g(t, u) + f(t, u')\right] dt \;\middle|\; u \in W^{1,1}([0, T], \mathbb{R}^m),\ u(0) = a,\ u(T) = b\right\} \tag{1.3}$$

with neither coercivity nor convexity assumptions. More precisely, we introduce the class $\mathcal{E}$ of all functions $\psi : [0, T] \times \mathbb{R}^m \to \mathbb{R}$, bounded from below, such that $\psi(\cdot, \xi)$ is Lipschitz continuous for every fixed $\xi \in \mathbb{R}^m$ and $\psi(t, \cdot)$ is lower semicontinuous and satisfies

$$\lim_{n\to+\infty} \left[\psi^{**}(t^n, \xi^n) - \langle \nabla\psi^{**}(t^n, \xi^n), \xi^n\rangle\right] = -\infty$$

for every sequence $\{t^n\} \in [0, T]$ and for every choice of points ξ^n of differentiability of $\psi^{**}(t^n, \cdot)$ such that $\lim_n |\xi^n| = +\infty$. We show that if $f \in \mathcal{E}$ and there exist two constants A and B, $B > 0$ such that $f(t, \xi) \geq -A + B|\xi|$ for every $(t, \xi) \in [0, T] \times \mathbb{R}^m$ and $g(t, x)$ is a continuous function, Lipschitz continuous with respect to t, concave with respect to x, satisfying $g(t, x) \geq -\alpha - \beta|x|$ for every $(t, x) \in [0, T] \times \mathbb{R}^m$ and for suitable constants α and $0 \leq \beta \leq B/T$, then the problem (1.3) has a solution in the space $W^{1,\infty}([0, T], \mathbb{R}^m)$. This result is the analogue for a class of noncoercive functionals of the one in [5], but it is not a generalization of that result due to the additional requirement of the Lipschitz continuity of the Lagrangian with respect to the variable t. However this extra regularity allows us to obtain the necessary conditions that, used at an intermediate step, also give a regularity result, which is interesting.

As a first step we prove an existence result for (1.3) requiring that f be convex with respect to ξ and dropping the concavity assumption on g. This can be done following [10] and making suitable changes due to the the fact that the Lagrangian is not bounded from below. The second step, linking the convex to the nonconvex case, is based on a result concerning the closure of the convex hull of the epigraph of functions whose convexification is strictly convex at infinity (that is, the graph of the convexification contains no rays). This result is an extension of the classical theorem that holds for superlinear functions (see [13]). We want to remark that the notion of strict convexity at infinity was still used in [11] in order to study noncoercive problems of the type (1.1) with the additional state constraint $\|u\|_{L^\infty} < R$. We shall prove that every function in the class $\mathcal{E}$ is strictly convex at infinity for every fixed t, so that by using the previous results and the Lyapunov theorem on the range of nonatomic measures the existence result for the nonconvex problems follows. The regularity of the solution of (1.3) is a consequence of the regularity of the solution to the relaxed problem.

2. Preliminaries. We shall denote by $\langle x, y\rangle$ the standard scalar product of two vectors $x, y \in \mathbb{R}^m$. For every $1 \leq p \leq +\infty$ we shall denote by $L^p(I, \mathbb{R}^m)$ and $W^{1,p}(I, \mathbb{R}^m)$, respectively, the usual Lebesgue and Sobolev spaces of functions from the interval $I \doteq [0, T]$ into $\mathbb{R}^m$. We shall use the symbol $\|\cdot\|_{L^p}$ to denote the norm in $L^p(I, \mathbb{R}^m)$.

If $A \subset \mathbb{R}^m$, we shall denote by $\operatorname{int} A$ the interior of A and by $\operatorname{co} A$ the convex hull of a A, that is, the smallest convex set which contains A. It is well known that, by Carathéodory's

theorem, the convex hull of A can be characterized by

$$\text{(2.1)}\qquad \operatorname{co} A = \left\{ x \in \mathbb{R}^m \;\middle|\; x = \sum_{i=1}^{m+1} \lambda_i x_i\,,\ \tilde{\lambda} \in E_{m+1}\,,\ x_i \in A,\ i = 1, \dots, m+1 \right\},$$

where $\tilde{\lambda} \doteq (\lambda_1, \dots, \lambda_{m+1})$ and E_{m+1} denotes the standard simplex

$$E_{m+1} \doteq \left\{ (\lambda_1, \dots, \lambda_{m+1}) \in \mathbb{R}^{m+1} \;\middle|\; \lambda_i \geq 0\ \forall i = 1, \dots, m+1,\ \sum_{i=1}^{m+1} \lambda_i = 1 \right\}.$$

Given a function $\psi : \mathbb{R}^m \to \overline{\mathbb{R}}$, we shall denote by $\operatorname{dom}(\psi)$ its effective domain, defined as the subset of $\mathbb{R}^m$ $\{\xi \mid \psi(\xi) < +\infty\}$, and by $\operatorname{epi} \psi$ its epigraph, that is, the set

$$\operatorname{epi} \psi \doteq \{(x, a) \in \mathbb{R}^m \times \mathbb{R} \mid \psi(x) \leq a\}.$$

If $\psi : \mathbb{R}^m \to \overline{\mathbb{R}}$ is Lipschitz continuous in a neighborhood of a point ξ, we shall denote by $\partial\psi(\xi)$ the generalized gradient of ψ at ξ, defined by

$$\text{(2.2)}\qquad \partial\psi(\xi) \doteq \operatorname{co} \left\{ \lim_{i \to +\infty} \nabla\psi(\xi_i) \;\middle|\; \xi_i \to \xi,\ \xi_i \in \mathcal{D}(\psi) \right\},$$

where $\mathcal{D}(\psi)$ denotes the set of points of differentiability of ψ. We recall that a Lipschitz continuous function ψ is almost everywhere differentiable in $\operatorname{int}(\operatorname{dom}(\psi))$.

A function $\psi : \mathbb{R}^m \to (-\infty, +\infty]$ is convex if for every $\xi, \eta \in \mathbb{R}^m$ and for every $\lambda \in [0, 1]$, we have $\psi(\lambda\xi + (1-\lambda)\eta) \leq \lambda\psi(\xi) + (1-\lambda)\psi(\eta)$. We say that ψ is concave if $-\psi$ is convex.

Given a function $\psi : \mathbb{R}^m \to (-\infty, +\infty]$, we shall denote by ψ^* its dual function, defined for every $p \in \mathbb{R}^m$ by

$$\psi^*(p) \doteq \sup_{\xi \in \mathbb{R}^m} \{\langle p\,,\, \xi\rangle - \psi(\xi)\}.$$

It is well known that the bipolar function ψ^{**} coincides with the convexification of ψ, which is the largest convex function φ satisfying $\varphi \leq \psi$.

If $\psi : \mathbb{R}^m \to (-\infty, +\infty]$ is convex, then the generalized gradient of ψ coincides in $\operatorname{int}(\operatorname{dom}(\psi))$ with the subgradient of ψ in the sense of convex analysis, defined at every point $\xi \in \operatorname{dom}(\psi)$ by

$$\text{(2.3)}\qquad \partial\psi(\xi) \doteq \left\{ p \in \mathbb{R}^m \;\middle|\; \psi(\eta) \geq \psi(\xi) + \langle p\,,\, \eta - \xi\rangle \text{ for every } \eta \in \mathbb{R}^m \right\}$$

(see [8, Prop. 2.2.7]). By definition, we set $\partial\psi(\xi) \doteq \emptyset$ for every $\xi \notin \operatorname{dom}(\psi)$. We recall that, if ψ is differentiable at ξ, then $\partial\psi(\xi) = \{\nabla\psi(\xi)\}$.

In the following proposition we collect some well-known properties of the subgradient (see [8] and [13]).

PROPOSITION 2.1. *Let $\psi : \mathbb{R}^m \to (-\infty, +\infty]$ be a convex function. Then the following properties hold:*

(i) *if ψ is bounded from above in a nonempty open set A, then ψ is locally Lipschitz continuous in A;*

(ii) *for every $\xi \in \mathbb{R}^m$ the set $\partial\psi(\xi)$ (possibly empty) is convex and closed in $\mathbb{R}^m$;*

(iii) *if $\xi \in \operatorname{int}(\operatorname{dom}(\psi))$, then $\partial\psi(\xi)$ is a nonempty compact set.*

3. The closure result. In this section we shall prove a result concerning the closure of the convex hull of the epigraph of functions possibly without superlinear growth.

We recall the notion of strict convexity at infinity introduced by Clarke and Loewen in [11].

DEFINITION 3.1. *A convex function $\psi:\mathbb{R}^m \to \mathbb{R}$ is said to be strictly convex at infinity if its graph contains no rays; that is, for every $\nu \in \mathbb{R}^m$, $\nu \neq 0$, and for every $\xi \in \mathbb{R}^m$, the function $\psi_{\nu,\xi}(s) \doteq \psi(s\nu+\xi)$ has the following property: for every $s_0 \in \mathcal{D}(\psi_{\nu,\xi})$ there exists $s_1 \in \mathcal{D}(\psi_{\nu,\xi})$, $s_1 > s_0$, such that $\psi'_{\nu,\xi}(s_1) > \psi'_{\nu,\xi}(s_0)$.*

Remark 3.2. It is easy to see that if $\psi:\mathbb{R}^m \to \mathbb{R}$ is convex then ψ is strictly convex at infinity if and only if $\partial\psi^*(p)$ is either empty or bounded for every $p \in \mathbb{R}^m$.

DEFINITION 3.3. *We shall denote by $\mathcal{G}$ the family of all lower semicontinuous functions $\psi : \mathbb{R}^m \to \mathbb{R}$ such that $\psi^{**} \not\equiv -\infty$ and ψ^{**} is strictly convex at infinity.*

Remark 3.4. Clearly every strictly convex function is strictly convex at infinity. Moreover, every lower semicontinuous superlinear function $\psi:\mathbb{R}^m \to \mathbb{R}$ belongs to $\mathcal{G}$. Indeed, denoting by φ the convexification ψ^{**}, for every fixed $\nu, \xi \in \mathbb{R}^m$, $\nu \neq 0$, by (2.3) it follows that the inequality $\langle \nabla\varphi(s\nu+\xi)\,,\, s\nu\rangle \geq \varphi(s\nu+\xi) - \varphi(\xi)$ holds for every $s \in \mathcal{D}(\varphi_{\nu,\xi})$. This implies that

$$\varphi'_{\nu,\xi}(s) = \langle \nabla\varphi(s\nu+\xi)\,,\, \nu\rangle \geq \frac{\varphi(s\nu+\xi)-\varphi(\xi)}{s} \quad \text{for every } s \in \mathcal{D}(\varphi_{\nu,\xi}),\ s > 0.$$

Since ψ is superlinear, the last term tends to $+\infty$ as s goes to $+\infty$.

LEMMA 3.5. *For every function $\psi \in \mathcal{G}$ satisfying $\psi \geq 0$ and $\psi(0) = 0$ there exist two positive constants C, ρ such that $\psi(\xi) \geq C|\xi|$ for every $|\xi| > \rho$.*

Proof. We can certainly assume that ψ is convex; if not, we replace ψ by ψ^{**}. We start by proving that ψ is coercive; that is, $\psi(\xi) \to +\infty$ as $|\xi| \to +\infty$. Since ψ is convex, the sets $\psi^a \doteq \{\xi \in \mathbb{R}^m \mid \psi(\xi) < a\}$ are convex subsets of $\mathbb{R}^m$ for every $a \geq 0$. By contradiction, suppose that there exists $a > 0$ such that ψ^a is unbounded. Since ψ^a is convex, it contains at least one half-line $\{s\nu \mid s \geq 0\}$ for some $\nu \in \mathbb{R}^m$, $\nu \neq 0$. This means that $\psi_{\nu,0}(s) < a$ for every $s \geq 0$. Since $\psi_{\nu,0}$ is an absolutely continuous function, then for every $\tau > 0$ we have

$$0 \leq \psi_{\nu,0}(\tau) - \psi_{\nu,0}(0) = \int_0^\tau \psi'_{\nu,0}(\sigma)\, d\sigma.$$

Hence there exists $s_0 \in \mathcal{D}(\psi_{\nu,0}) \cap [0,\tau]$ such that $\psi'_{\nu,0}(s_0) \geq 0$. Since ψ is strictly convex at infinity, there exists $s_1 \in \mathcal{D}(\psi_{\nu,0})$, $s_1 > s_0$ such that $\psi'_{\nu,0}(s_1) > 0$. By the convexity of $\psi_{\nu,0}$ it follows that

$$\psi_{\nu,0}(s) \geq \psi_{\nu,0}(s_1) + (s-s_1)\psi'_{\nu,0}(s_1) \quad \text{for every } s \geq 0,$$

and this implies that $\lim_{s\to+\infty} \psi_{\nu,0}(s) = +\infty$ in contradiction with $\psi_{\nu,0} < a$.

Since ψ is coercive, there exist two positive constants ρ, δ such that

$$\psi(\eta) \geq \delta \quad \text{for all } |\eta| = \rho.$$

If $|\xi| > \rho$, let us define $\lambda \doteq \rho/|\xi|$ and $\eta \doteq \lambda\xi$. By the convexity of ψ, and recalling that $\psi(0) = 0$, we get

$$\psi(\xi) \geq \frac{1}{\lambda}\psi(\eta) = \frac{\psi(\eta)}{\rho}|\xi| \geq \frac{\delta}{\rho}|\xi|,$$

so that we conclude by choosing $C = \delta/\rho$. □

We are now in a position to prove the closure result. The proof is based on the fact that if f belongs to the class $\mathcal{G}$ then for every support hyperplane r of f^{**} the function $f - r$ belongs to $\mathcal{G}$. Applying the estimate of Lemma 3.5 to this function, we can follow the lines of the proof of Lemma IX.3.3 in [13].

THEOREM 3.6. *For every $f \in \mathcal{G}$ the set* co epi f *is closed.*

Proof. Let $(\xi, a) \in \partial(\text{co epi } f)$, where ∂S denotes the boundary of the set S, and let $r(\eta) \doteq \langle c\,,\ \eta\rangle + d$ be an affine function such that the hyperplane $H \doteq \{(\eta, r(\eta))\}$ weakly separates co epi f and the point (ξ, a). Let us define the function

$$\phi(\eta) \doteq f(\eta + \xi) - r(\eta + \xi).$$

We have $\phi^{**}(\eta) = f^{**}(\eta + \xi) - r(\eta + \xi)$, $\phi^{**} \geq 0$, $\phi^{**}(0) = 0$. Moreover, for every $\nu \in \mathbb{R}^m$, $\nu \neq 0$, for every $\eta \in \mathbb{R}^m$, and for every $s \in \mathcal{D}(f^{**}_{\nu,\xi+\eta})$ we have $(\phi^{**}_{\nu,\eta})'(s) = (f^{**}_{\nu,\xi+\eta})'(s) - \langle c\,,\ \nu\rangle$. Since f^{**} is strictly convex at infinity, then so is ϕ^{**}. By Lemma 3.5, there exist two positive constants C, ρ such that

$$\phi^{**}(\eta) \geq C|\eta| \quad \text{for every } |\eta| \geq \rho. \tag{3.1}$$

Notice that $(\xi, a) \in \text{co epi } f$ if and only if $(0, 0) \in \text{co epi } \phi$. Moreover, $(\xi, a) \in \partial(\text{co epi } f)$ if and only if $(0, 0) \in \partial(\text{co epi } \phi)$. Hence, to prove the proposition, it suffices to show that $(0, 0) \in \text{co epi } \phi$.

Let $(\xi^n, a^n) \in \text{co epi } \phi$ be such that $\lim_n (\xi^n, a^n) = (0, 0)$. By the characterization (2.1) of the convex hull, for every n there exist $\tilde{\lambda}^n \in E_{m+2}$ and $(\xi^n_j, a^n_j) \in \text{epi } \phi$, $j = 1, \ldots, m+2$, such that

$$\sum_{j=1}^{m+2} \lambda^n_j (\xi^n_j, a^n_j) = (\xi^n, a^n).$$

By the very definition of epigraph it follows that

$$a^n = \sum_{j=1}^{m+2} \lambda^n_j a^n_j \geq \sum_{j=1}^{m+2} \lambda^n_j \phi(\xi^n_j). \tag{3.2}$$

Moreover, (3.2) and the fact that $\phi \geq \phi^{**}$ imply that $a^n \geq \sum_{j=1}^{m+2} \lambda^n_j \phi^{**}(\xi^n_j)$. Since $\phi^{**} \geq 0$, the inequality

$$a^n \geq \lambda^n_j \phi^{**}(\xi^n_j) \tag{3.3}$$

holds for every $j = 1, \ldots, m+2$. Let $J \subset \{1, \ldots, m+2\}$ be the set of all j such that $\{|\xi^n_j|\}_n$ is unbounded, and let $I \doteq \{1, \ldots, m+2\} \backslash J$. By passing to a subsequence, we can assume that there exist $\bar{\xi}_j$, $j \in I$, and $\tilde{\lambda} \in E_{m+2}$, such that

$$\begin{aligned}
&\lim_{n\to+\infty} |\xi^n_j| = +\infty, \quad j \in J,\\
&\lim_{n\to+\infty} \xi^n_j = \bar{\xi}_j, \quad j \in I,\\
&\lim_{n\to+\infty} \lambda^n_j = \lambda_j, \quad j \in \{1, \ldots, m+2\}.
\end{aligned}$$

For every $j \in J$ we have $|\xi^n_j| > \rho$ for n large enough, and then from (3.1) and (3.3) it follows that $a^n \geq C\lambda^n_j |\xi^n_j|$. Since $\lim_n a^n = 0$, we get

$$\lim_{n\to+\infty} \lambda^n_j |\xi^n_j| = 0, \quad j \in J. \tag{3.4}$$

From (3.4) and recalling that $\lim_n \xi^n = 0$, we deduce that

$$\begin{aligned}\sum_{j\in I}\lambda_j\bar{\xi}_j &= \lim_{n\to+\infty}\sum_{j\in I}\lambda_j^n\xi_j^n \\ &= \lim_{n\to+\infty}\left(\sum_{j=1}^{m+2}\lambda_j^n\xi_j^n - \sum_{j\in J}\lambda_j^n\xi_j^n\right) = \lim_{n\to+\infty}\left(\xi^n - \sum_{j\in J}\lambda_j^n\xi_j^n\right) = 0.\end{aligned} \tag{3.5}$$

Moreover, since $\lim_n \lambda_j^n = 0$ for every $j \in J$, we obtain

$$\sum_{j\in I}\lambda_j = \lim_{n\to+\infty}\sum_{j\in I}\lambda_j^n = 1. \tag{3.6}$$

Since ϕ is a nonnegative lower semicontinuous function, we get

$$0 \le \sum_{j\in I}\lambda_j\phi(\bar{\xi}_j) \le \liminf_{n\to+\infty}\sum_{j\in I}\lambda_j^n\phi(\xi_j^n) \le \liminf_{n\to+\infty} a^n = 0. \tag{3.7}$$

There is no loss of generality in assuming that $\lambda_j > 0$ for every $j \in I$; hence (3.7) implies that $\phi(\bar{\xi}_j) = 0$ for every $j \in I$; that is, $(\bar{\xi}_j, 0) \in \operatorname{epi}\phi$ for every $j \in I$. Thus by (3.5) and (3.6) we can conclude that $(0, 0)$ belongs to $\operatorname{co}\operatorname{epi}\phi$. □

Now we state two direct consequences of Theorem 3.6.

COROLLARY 3.7. *If $f \in \mathcal{G}$, then*

$$f^{**}(\xi) = \min\left\{\sum_{j=1}^{m+1}\lambda_j f(\xi_j) \;\Big|\; \sum_{j=1}^{m+1}\lambda_j\xi_j = \xi,\ \tilde{\lambda} \in E_{m+1}\right\}$$

for every $\xi \in \mathbb{R}^m$.

Proof. See [13, Lem. IX.3.3]. □

We recall that a function $f: I \times \mathbb{R}^m \to \mathbb{R}$ is said to be a normal integrand (see [13]) if $f(t, \cdot)$ is lower semicontinuous for almost every (a.e.) $t \in I$ and there exists a Borel function $\tilde{f}: I \times \mathbb{R}^m \to \mathbb{R}$ such that $\tilde{f}(t, \cdot) = f(t, \cdot)$ for a.e. $t \in I$.

COROLLARY 3.8. *Let $f: I \times \mathbb{R}^m \to \mathbb{R}$ be a normal integrand and suppose that $f(t, \cdot) \in \mathcal{G}$ for every $t \in I$. Then for any measurable mapping $p: [0, T] \to \mathbb{R}^m$, there exist a measurable mapping $\tilde{\lambda}: [0, T] \to E_{m+1}$ and $m + 1$ measurable mappings $q_j: [0, T] \to \mathbb{R}^m$ such that*

$$\sum_{j=1}^{m+1}\lambda_j(t)q_j(t) = p(t), \quad \sum_{j=1}^{m+1}\lambda_j(t)f(t, q_j(t)) = f^{**}(t, p(t))$$

for almost all $t \in [0, T]$.

Proof. See [13, Prop. IX.3.1]. □

4. Existence results for variational problems. In this section we shall show that the existence result proved by Cellina and Colombo in [5] holds even for functions of the class $\mathcal{E}$ defined below. In the following, the convexification and the gradient of a function $\psi(t, \xi)$ are understood with respect to ξ.

DEFINITION 4.1. *We shall denote by $\mathcal{E}$ the family of all functions $\psi: I \times \mathbb{R}^m \to \mathbb{R}$, bounded from below, such that $\psi(\cdot, \xi)$ is Lipschitz continuous for every fixed $\xi \in \mathbb{R}^m$, $\psi(t, \cdot)$ is lower semicontinuous for every fixed $t \in I$, and*

$$\lim_{R\to+\infty}\sup_{\substack{t\in I\\ |\xi|>R}}\sup\left\{\psi^{**}(t, \xi) - \langle p\,,\,\xi\rangle \;\middle|\; p \in \partial_\xi\psi^{**}(t, \xi)\right\} = -\infty. \tag{4.1}$$

The following proposition gives a characterization of the family $\mathcal{E}$. The proof is similar to the one of Proposition 3.2 in [12].

PROPOSITION 4.2. *The condition* (4.1) *in Definition* 4.1 *is equivalent to*

$$\lim_{n\to+\infty}\left[\psi^{**}(t^n,\xi^n)-\langle\nabla\psi^{**}(t^n,\xi^n)\,,\,\xi^n\rangle\right]=-\infty \tag{4.2}$$

for every sequence $(t^n,\xi^n)\in I\times\mathbb{R}^m$ *such that* $\xi^n\in\mathcal{D}(\psi^{**}(t^n,\cdot))$, $\lim_n|\xi^n|=+\infty$.

Proof. We have to prove that (4.2) implies (4.1), the other implication being trivial. Let us denote by $\chi(R)$ the argument of the limit in (4.1), and let $\{R_n\}$ be a diverging sequence. For every fixed $n\in\mathbb{N}$, by definition of supremum, there exists $(t^n,\xi^n,p^n)\in I\times\mathbb{R}^m\times\mathbb{R}^m$, with $p^n\in\partial_\xi\psi^{**}(t^n,\xi^n)$ and $|\xi^n|>R_n$, such that

$$\chi(R_n)\le\psi^{**}(t^n,\xi^n)-\langle p^n\,,\,\xi^n\rangle+1. \tag{4.3}$$

From (2.2) and (2.1) there exist $p_j^n\in\partial_\xi\psi^{**}(t^n,\xi^n)$, $\xi_j^n\in\mathcal{D}(\psi^{**}(t^n,\cdot))$ with $|\xi_j^n-\xi^n|<1$, $j\in J\doteq\{1,\dots,m+1\}$, and $\tilde\lambda^n\in E_{m+1}$ such that

$$p^n=\sum_{j=1}^{m+1}\lambda_j^n p_j^n,\qquad\left|\nabla\psi^{**}(t^n,\xi_j^n)-p_j^n\right|<\frac{1}{|\xi^n|+1}\quad\text{for every } j\in J.$$

For every $j\in J$ the last inequality and the fact that $|\xi_j^n-\xi^n|<1$ imply that

$$\left|\langle\nabla\psi^{**}(t^n,\xi_j^n)-p_j^n\,,\,\xi_j^n\rangle\right|<\frac{|\xi_j^n|}{|\xi^n|+1}<1\,. \tag{4.4}$$

By the convexity of $\psi^{**}(t^n,\cdot)$ we have

$$\psi^{**}(t^n,\xi^n)-\psi^{**}(t^n,\xi_j^n)\le\langle p_j^n\,,\,\xi^n-\xi_j^n\rangle\quad\text{for every } j\in J. \tag{4.5}$$

Using (4.4) and (4.5) we obtain

$$\psi^{**}(t^n,\xi^n)-\langle p_j^n\,,\,\xi^n\rangle\le\psi^{**}(t^n,\xi_j^n)-\langle\nabla\psi^{**}(t^n,\xi_j^n)\,,\,\xi_j^n\rangle+1\,. \tag{4.6}$$

Multiplying (4.6) by λ_j^n and summing over j it follows that $\psi^{**}(t^n,\xi^n)-\langle p^n\,,\,\xi^n\rangle\le\mu^n$, where $\mu^n\doteq 1+\max_j\{\psi^{**}(t^n,\xi_j^n)-\langle\nabla\psi^{**}(t^n,\xi_j^n)\,,\,\xi_j^n\rangle\}$.

Since $\lim_n|\xi_j^n|=+\infty$ for every $j\in J$, (4.2) implies that $\lim_n\mu^n=-\infty$. Hence by (4.3) it follows that

$$\lim_{n\to+\infty}\chi(R_n)\le\lim_{n\to+\infty}(\mu^n+1)=-\infty\,.$$

Since χ is a monotone nonincreasing function, (4.1) holds. □

Remark 4.3. Definition 4.1 agrees with the one given in [6] and [12], respectively, in the case of convex time-independent smooth functions and nonconvex time-independent functions.

LEMMA 4.4. *If* $\psi\in\mathcal{E}$, *then* $\psi(t,\cdot)\in\mathcal{G}$ *for every* $t\in I$.

Proof. Let us fix $t\in I$ and denote by φ the convexification with respect to ξ of $\psi(t,\xi)$. By Lemma 3.3 in [12], the effective domain $\mathrm{dom}(\varphi^*)$ of φ^* is an open subset of $\mathbb{R}^m$. Hence by Proposition 2.1(iii), $\partial\varphi^*(p)$ is either bounded, if $p\in\mathrm{dom}(\varphi^*)$, or empty, if $p\notin\mathrm{dom}(\varphi^*)$. By Remark 3.2, the result is thus proved. □

LEMMA 4.5. *Let* $\varphi\colon I\times\mathbb{R}^m\times\mathbb{R}^m\to\mathbb{R}$ *be a lower semicontinuous function, Lipschitz continuous with respect to the first variable. Assume that* $\varphi(t,x,\cdot)$ *is convex for a.e.* $t\in I$ *and for every* $x\in\mathbb{R}^m$ *and that there exist three constants* C_i, $i=0,1,2$, *such that*

$$|v|\le C_0|\varphi(t,x,\xi)|+C_1|x|+C_2 \tag{4.7}$$

for every $(t, x, \xi) \in I \times \mathbb{R}^m \times \mathbb{R}^m$ *and for every* $v \in \partial_t \varphi(t, x, \xi)$, *where* $\partial_t \varphi$ *denotes the generalized gradient of* φ *with respect to* t.

Let $u \in W^{1,1}(I, \mathbb{R}^m)$ *and assume that the function* $t \mapsto \varphi(t, u(t), u'(t))$ *belongs to* $L^1(I)$. *Then there exists* $k_0 \in L^1(I)$ *such that*

$$\left|\varphi(s_2, u(t), u'(t)) - \varphi(s_1, u(t), u'(t))\right| \leq k_0(t)|s_2 - s_1|$$

for every $t, s_1, s_2 \in I$.

Proof. For every fixed $t_1, t_2 \in I$, let us define the function

$$g(s) \doteq |\varphi(t_1 + sd, x, \xi) - \varphi(t_1, x, \xi)|, \quad s \in [0, 1],$$

where $d \doteq t_2 - t_1$. By (4.7), it follows that for a.e. $s \in [0, 1]$

$$g'(s) \leq |d||\partial_t \varphi(t_1 + sd, x, \xi)| \leq |d|\,(C_0 g(s) + C_0|\varphi(t_1, x, \xi)| + C_1|x| + C_2)\,.$$

We can apply Gronwall's inequality to the nonnegative absolutely continuous function g, obtaining

$$|\varphi(t_2, x, \xi) - \varphi(t_1, x, \xi)| = g(1) \leq |t_2 - t_1| e^{C_0 T}\,(C_0|\varphi(t_1, x, \xi)| + C_1|x| + C_2)\,. \tag{4.8}$$

This inequality, with $t_1 = t$ and $t_2 = s_1$, implies that

$$|\varphi(s_1, x, \xi)| \leq |\varphi(t, x, \xi)| + T e^{C_0 T}\,(C_0|\varphi(t, x, \xi)| + C_1|x| + C_2)\,. \tag{4.9}$$

Again by (4.8), with $t_1 = s_1$, $t_2 = s_2$, and by (4.9), it follows that

$$|\varphi(s_2, x, \xi) - \varphi(s_1, x, \xi)| \leq |s_2 - s_1|(\tilde{C}_0|\varphi(t, x, \xi)| + \tilde{C}_1|x| + \tilde{C}_2),$$

where $\tilde{C}_i \doteq C_i e^{C_0 T}(1 + T C_0 e^{C_0 T})$, $i = 0, 1, 2$. Finally, by hypothesis, the function

$$k_0(t) \doteq \tilde{C}_0|\varphi(t, u(t), u'(t))| + \tilde{C}_1|u(t)| + \tilde{C}_2$$

belongs to $L^1(I)$, completing the proof. □

DEFINITION 4.6. *We shall say that* $\theta \in C^1((0, +\infty), \mathbb{R})$ *is a Nagumo function if* θ *is convex and increasing and it satisfies* $\lim_{r \to +\infty} \theta(r)/r = +\infty$.

We begin the study of minimization problems, starting with an existence result for convex functionals. We collect here the basic hypotheses on the integrand.

(H_0) $f \in \mathcal{E}$ and $f(t, \cdot)$ is a convex function for every $t \in I$.

(H_1) There exist two constants A and B, with $B > 0$, such that $f(t, \xi) \geq -A + B|\xi|$ for every $(t, \xi) \in I \times \mathbb{R}^m$.

(H_2) $g: I \times \mathbb{R}^m \to \mathbb{R}$ is Lipschitz continuous with respect to the first variable and continuous with respect to the second, and there exist two constants α and β, with $0 \leq \beta < B/T$, such that $g(t, x) \geq -\alpha - \beta|x|$ for every $(t, x) \in I \times \mathbb{R}^m$.

(H_3) There exist three constants C_i, $i = 0, 1, 2$, such that the condition (4.7) holds with $\varphi(t, x, \xi) \doteq g(t, x) + f(t, \xi)$.

Remark 4.7. If $f \in \mathcal{E}$ is independent of t, then it is easily seen that Lemmas 3.5 and 4.4 imply that condition (H_1) is always satisfied for suitable constants A and B, with $B > 0$.

THEOREM 4.8. *Let* f *and* g *satisfy the hypotheses* (H_0), (H_1), (H_2), (H_3). *Then there exists a solution to the problem*

$$\min\left\{F(u) \;\middle|\; u \in W^{1,1}(I, \mathbb{R}^m),\ u(0) = a,\ u(T) = b\right\}, \tag{4.10}$$

where

$$F(u) \doteq \int_I [f(t, u'(t)) + g(t, u(t))]\, dt\,.$$

Moreover every solution $\tilde{u}$ belongs to $W^{1,\infty}(I, \mathbb{R}^m)$ and satisfies for a.e. $t \in I$

$$f(t, \tilde{u}'(t)) - \langle p(t)\,,\, \tilde{u}'(t)\rangle + g(t, \tilde{u}(t)) = c + \int_0^t v(\tau)\, d\tau\,, \tag{4.11}$$

where c is a constant and $(v(t),\, p(t)) \in (\partial_t f(t, \tilde{u}'(t)) + \partial_t g(t, \tilde{u}(t)),\, \partial_\xi f(t, \tilde{u}'(t)))$ for almost every $t \in I$.

Proof. The proof follows the lines of the proof of Theorem 3 in [10], with some changes due to the fact that in this case the Lagrangian is not bounded from below. As in [10] one can prove, using the De Giorgi semicontinuity result (see [4]) and the Dunford–Pettis criterion of weak compactness in $L^1(I, \mathbb{R}^m)$, that for every Nagumo function θ and for every $l > 0$ there exists a solution u_l to the problem

$$\min\left\{F(u) \;\middle|\; u \in AC^l_\theta(I, \mathbb{R}^m),\ u(0) = a,\ u(T) = b\right\}\,,$$

where $AC^l_\theta(I, \mathbb{R}^m)$ denotes the class of all function $u \in W^{1,1}(I, \mathbb{R}^m)$ such that $\Theta(u) \le l$, with $\Theta(u) \doteq \int_I \theta(|u'(t)|)\, dt$. Let us set $V_\theta(l) \doteq F(u_l)$.

One can easily check that if $V_\theta(l) = V_\theta(l_0)$ for every $l \ge l_0$ then u_{l_0} is a solution to the problem

$$\min\left\{F(u) \;\middle|\; u \in W^{1,1}(I, \mathbb{R}^m),\ \Theta(u) < +\infty,\ u(0) = a,\ u(T) = b\right\}\,. \tag{4.12}$$

Finally, as in [10], if we are able to prove that u_{l_0} belongs to $W^{1,\infty}(I, \mathbb{R}^m)$ then we can conclude that such a function is a solution to (4.10). Furthermore, any other solution $\tilde{u}$ of (4.10) would solve (4.12) for some Nagumo function θ and hence would belong to $W^{1,\infty}(I, \mathbb{R}^m)$ and satisfy (4.11).

Thus it remains to prove that V_θ is eventually constant and that, for l large enough, u_l belongs to $W^{1,\infty}(I, \mathbb{R}^m)$ and satisfies (4.11). Since V_θ is lower semicontinuous, for every $l > 0$ there exists a proximal subgradient (see [9]) of V_θ at l and, since V_θ is nonincreasing, it is nonpositive. If V_θ is not eventually constant, by Proposition 6.1 in [10], there exists a diverging sequence $\{l_k\}$ such that the proximal subgradient of V_θ at l_k takes the form $-r_k$, with $r_k > 0$. Moreover, it is easy to check that, if we set $u_k \equiv u_{l_k}$, then $\Theta(u_k) = l_k$, so that

$$\lim_{k\to+\infty} \|u_k'\|_{L^\infty} \ge \lim_{k\to+\infty} \theta^{-1}(l_k/T) = +\infty\,. \tag{4.13}$$

By definition of r_k and the fact that $\Theta(u_k) = l_k$, it follows that for every $k \in \mathbb{N}$ there exists a positive constant σ_k such that, if we define

$$G(u) \doteq F(u) + r_k\Theta(u) + \sigma_k|\Theta(u) - \Theta(u_k)|^2\,,$$

then we get that $G(u_k) \le G(u)$ for every u admissible for (4.12) and such that $\Theta(u)$ is sufficiently near to $\Theta(u_k)$ (see [10]). By (H_3) and Lemma 4.5, it follows that there exists $k_0 \in L^1(I)$ such that for every $s_1, s_2, t \in I$

$$|f(s_1, u_k'(t)) + g(s_1, u_k(t)) - f(s_2, u_k'(t)) - g(s_2, u_k(t))| \le k_0(t)|s_1 - s_2|\,,$$

so that we can apply Theorem 5 of [10]. Thus we obtain that u_k satisfies

$$E_f(t, u_k'(t)) + g(t, u_k(t)) + r_k E_\theta(|u_k'(t)|) = c_k + \int_0^t v_k(\tau)\, d\tau\,, \tag{4.14}$$

where c_k is a constant, $E_f(t, u_k'(t)) \doteq f(t, u_k'(t)) - \langle p_k(t)\,,\, u_k'(t)\rangle$, with $(v_k(t),\, p_k(t)) \in (\partial_t f(t, u_k'(t)) + \partial_t g(t, u_k(t)),\, \partial_\xi f(t, u_k'(t)))$ for a.e. $t \in I$, and $E_\theta(s) \doteq \theta(s) - s\theta'(s)$.

Moreover there exists $M_1 > 0$ such that $\|u_k\|_{L^\infty} \le M_1$ for every $k \in \mathbb{N}$. Actually, if there exists $t_k \in I$ such that $\limsup_k |u_k(t_k)| = +\infty$, then

$$\limsup_{k\to+\infty} \int_I |u_k'(t)|\,dt \ge \limsup_{k\to+\infty} \left| \int_0^{t_k} u_k'(t)\,dt \right| = \limsup_{k\to+\infty} |u_k(t_k) - a| = +\infty\,,$$

whereas, if we define $u_0(t) \doteq a + \xi t$, with $\xi \doteq (b-a)/T$, then u_0 is admissible for (4.12), $F(u_0) < +\infty$, and

$$F(u_0) \ge F(u_k) \ge (-A-\alpha)T + B\|u_k'\|_{L^1} - \beta\|u_k\|_{L^1} \ge \tilde{A} + (B - \beta T)\|u_k'\|_{L^1}\,, \tag{4.15}$$

so that, by (H_2), $\{u_k'\}$ must be bounded in $L^1(I, \mathbb{R}^m)$.

The boundedness of $\{u_k\}$ in $L^\infty(I, \mathbb{R}^m)$ and the continuity of g guarantee that there exists M_2 such that

$$|g(t, u_k(t)| \le M_2 \tag{4.16}$$

for a.e. $t \in I$ and for every k. Moreover, by (H_3) we obtain

$$\begin{aligned} \left| \int_0^t v_k(s)\,ds \right| &\le \int_I \left[C_0 \left| f(s, u_k'(s)) + g(s, u_k(s)) \right| + C_1 |u_k(s)| + C_2 \right] ds \\ &\le \int_I \left[C_0 \left| \alpha + \beta |u_k(s)| + f(s, u_k'(s)) + g(s, u_k(s)) \right| + \tilde{C}_1 |u_k(s)| + \tilde{C}_2 \right] ds\,, \end{aligned} \tag{4.17}$$

where $\tilde{C}_1 \doteq C_0\beta + C_1$ and $\tilde{C}_2 \doteq C_0|\alpha| + C_2$. Without loss of generality we can assume that f is positive, so that, thanks to (H_2), it follows that for every $k \in \mathbb{N}$

$$f(s, u_k'(s)) + g(s, u_k(s)) + \alpha + \beta|u_k(s)| \ge 0 \quad \text{a.e. } s \in I\,. \tag{4.18}$$

By (4.15), (4.17), and (4.18) there exist $M_3 > 0$ and two constants $\hat{C}_1$, $\hat{C}_2$ such that

$$\left| \int_0^t v_k(s)\,ds \right| \le C_0 F(u_k) + \hat{C}_1 \|u_k\|_{L^1} + \hat{C}_2 \le M_3 \quad \text{for every } t \in I. \tag{4.19}$$

By (4.14), (4.16), and (4.19) we obtain

$$E_f(t, u_k'(t)) + r_k E_\theta(|u_k'(t)|) \le c_k + M_2 + M_3$$

for every $t \in I$ and for every $k \in \mathbb{N}$.

We claim that it is not possible that there exists a subsequence of $\{c_k\}$, still denoted by $\{c_k\}$, such that $\lim_k c_k = -\infty$. Indeed, if this is the case, then for every $t \in I$ we should have

$$\lim_{k\to+\infty} E_f(t, u_k'(t)) + r_k E_\theta(|u_k'(t)|) = -\infty\,. \tag{4.20}$$

Since $f \in \mathcal{E}$ and θ is superlinear, (4.20) implies that $\lim_k |u_k'(t)| = +\infty$ for every $t \in I$, which by Fatou's lemma contradicts the boundedness of u_k' in $L^1(I, \mathbb{R}^m)$.

Thus there exists c^* such that $c_k \ge c^*$ for every k. From (4.14) we obtain, for every $t \in I$,

$$E_f(t, u_k'(t)) + r_k E_\theta(|u_k'(t)|) \ge c^* - M_2 - M_3\,. \tag{4.21}$$

Now let us suppose that for every k there exists $t_k \in I$ such that $\limsup_k |\xi_k| = +\infty$, where $\xi_k \doteq u_k'(t_k)$. Since f and θ belong to $\mathcal{E}$, we have

$$\liminf_{k\to+\infty} \left[E_f(t_k, \xi_k) + r_k E_\theta(|\xi_k|)\right] \le \liminf_{k\to+\infty} \sup_{t\in I} \left\{E_f(t, \xi_k) + r_k E_\theta(|\xi_k|)\right\} = -\infty\,,$$

in contradiction with (4.21). This implies that $\|u_k'\|_{L^\infty}$ is bounded, which contradicts (4.13).

So we can conclude that V_θ is eventually constant. Hence for k sufficiently large $u_k \in W^{1,\infty}(I, \mathbb{R}^m)$ is a solution of (4.12). Moreover $r_k = 0$, so that u_k satisfies (4.11). Then the proof is complete. □

The last part of this section is devoted to the study of the nonconvex case. The hypotheses (H_0) and (H_3) will be replaced, respectively, by

(H_0') $f \in \mathcal{E}$;

(H_3') there exist three constants C_i, $i = 0, 1, 2$, such that the condition (4.7) holds with $\varphi(t, x, \xi) \doteq g(t, x) + f^{**}(t, \xi)$.

Notice that (H_3') requires the Lipschitz continuity of f^{**} with respect to t. The following two lemmas show that this conclusion follows from (H_0') and

(H_4) for every $R > 0$ there exists a constant L such that

$$|f(t, \xi) - f(s, \xi)| \le L|t - s| \quad \text{for every } t, s \in I, \text{ and } \xi \in \overline{B}_R,$$

where $\overline{B}_R$ denotes the closed ball centered at the origin and with radius R.

LEMMA 4.9. *Let $\psi \in \mathcal{E}$ and let us define, for every $(t, p) \in I \times \mathbb{R}^m$, the set*

$$W(t, p) \doteq \{\xi \in \mathbb{R}^m \mid p \in \partial_\xi \psi^{**}(t, \xi)\}\,.$$

Then for every $r > 0$ there exists $R > 0$ such that for every $(t, p) \in I \times \mathbb{R}^m$ the condition $W(t, p) \cap \overline{B}_r \neq \emptyset$ implies $W(t, p) \subset \overline{B}_R$.

Proof. Suppose, by contradiction, that there exist sequences $(t_n, p_n) \subset I \times \mathbb{R}^m$, $(\eta_n) \subset \overline{B}_r$, $(\xi_n) \subset \mathbb{R}^m$, with $\lim_n |\xi_n| = +\infty$, such that for every $n \in \mathbb{N}$

$$p_n \in \partial_\xi \psi^{**}(t_n, \eta_n), \quad p_n \in \partial_\xi \psi^{**}(t_n, \xi_n)\,. \tag{4.22}$$

From (4.22) it follows that for every $n \in \mathbb{N}$

$$\psi^{**}(t_n, \eta_n) - \langle p_n\,,\, \eta_n\rangle = \psi^{**}(t_n, \xi_n) - \langle p_n\,,\, \xi_n\rangle\,. \tag{4.23}$$

Since (η_n) is a bounded sequence, there exists a constant C such that the left-hand side of (4.23) is bounded from below by C. Thus

$$C \le \psi^{**}(t_n, \xi_n) - \langle p_n\,,\, \xi_n\rangle \le \chi(|\xi_n|) \quad \text{for every } n \in \mathbb{N}, \tag{4.24}$$

where $\chi(R)$ is the argument of the limit in (4.1). Since $\lim_n |\xi_n| = +\infty$, from (4.1) we have that $\lim_n \chi(|\xi_n|) = -\infty$, which contradicts (4.24). □

Remark 4.10. Let us fix $\xi \in \mathbb{R}^m$. Let $t \in I$, $\tilde{\lambda} \in E_{m+1}$, $\xi_j \in \mathbb{R}^m$, $j = 1, \dots, m+1$ satisfy

$$f^{**}(t, \xi) = \sum_{j=1}^{m+1} \lambda_j f(t, \xi_j), \quad \xi = \sum_{j=1}^{m+1} \lambda_j \xi_j.$$

Since for every j there exists $p_j \in \partial_\xi f^{**}(t, \xi)$ such that $\xi_j \in W(t, p_j)$, by Lemma 4.9 we obtain that there exists $R > 0$, depending only on $|\xi|$, such that $\xi_j \in \overline{B}_R$ for every $j = 1, \dots, m+1$.

LEMMA 4.11. *If $f \in \mathcal{E}$ satisfies (H_4), then $f^{**}(\cdot, \xi)$ is Lipschitz continuous for every $\xi \in \mathbb{R}^m$.*

Proof. Let us fix $\xi \in \mathbb{R}^m$ and consider $t, s \in I$. By Corollary 3.7, there exist $\tilde{\lambda}, \tilde{\mu} \in E_{m+1}$, $\xi_j, \eta_j \in \mathbb{R}^m$, $j = 1, \dots, m+1$ such that

$$f^{**}(t, \xi) = \sum_{j=1}^{m+1} \lambda_j f(t, \xi_j), \quad f^{**}(s, \xi) = \sum_{j=1}^{m+1} \mu_j f(s, \eta_j),$$

and $\xi = \sum_j \lambda_j \xi_j = \sum_j \mu_j \eta_j$. Moreover, one has

$$f^{**}(t, \xi) \le \sum_{j=1}^{m+1} \mu_j f(t, \eta_j), \quad f^{**}(s, \xi) \le \sum_{j=1}^{m+1} \lambda_j f(s, \xi_j).$$

Then, by Remark 4.10 and (H_4), there exists $L > 0$, depending only on $|\xi|$, such that

$$f^{**}(s, \xi) - f^{**}(t, \xi) \le \sum_{j=1}^{m+1} \lambda_j [f(s, \xi_j) - f(t, \xi_j)] \le \sum_{j=1}^{m+1} \lambda_j L|t - s| = L|t - s|.$$

In the same way one obtains

$$f^{**}(t, \xi) - f^{**}(s, \xi) \le \sum_{j=1}^{m+1} \mu_j [f(t, \eta_j) - f(s, \eta_j)] \le L|t - s|,$$

completing the proof. □

We are now in a position to prove the existence result for the nonconvex case.

THEOREM 4.12. *Let g and f satisfy the basic hypotheses (H_0'), (H_1), (H_2), (H_3'), (H_4) and assume that $g(t, \cdot)$ is concave for every $t \in I$. Then the problem* (4.10) *has a solution $u \in W^{1,\infty}([0, T], \mathbb{R}^m)$.*

Proof. The proof follows the same lines of the one of Theorem 1 in [5]. It is enough to use Theorem 4.8 to obtain a solution $\tilde{u} \in W^{1,\infty}([0, T], \mathbb{R}^m)$ of the relaxed problem and to replace Lemma IX.3.3 and Proposition IX.3.1 of [13] with Corollaries 3.7 and 3.8. Since $\tilde{u}' \in L^\infty([0, T], \mathbb{R}^m)$, it is easily seen, using Lemma 4.9, that we obtain a solution $u \in W^{1,\infty}([0, T], \mathbb{R}^m)$. □

Acknowledgments. The authors wish to thank Arrigo Cellina for kindly suggesting the problem.

RELAXATION OF CONSTRAINED CONTROL PROBLEMS*

E. N. BARRON† AND R. JENSEN†

Abstract. The problem of relaxation of optimal control problems with state and control constraints is formulated in this paper. We determine that if the original problem consists of minimizing, over control functions $\zeta(\cdot)$, $g(\xi(T))$ subject to $d\xi/ds = f(s,\xi,\zeta)$, $t < s \leq T$, and $h(s,\xi(s),\zeta(s)) \leq 0$ for a.e. $t \leq s \leq T$, then the relaxed problem consists of minimizing, over measure-valued control functions $\mu(\cdot)$, $g(\hat{\xi}(T))$, subject to $d\hat{\xi}/ds = \int_Z f(s,\hat{\xi}(s),z)\mu(s,dz)$ and $\mu(s) - \operatorname{ess\,sup}_z h(s,\hat{\xi}(s),z) \leq 0$ for a.e. $t \leq s \leq T$. For each s this is the essential supremum of h in z with respect to the measure $\mu(s)$.

Key words. relaxed controls, state and control constraints

1. Introduction.

In this paper we will determine the relaxed formulation of the following constrained optimal control problem of Mayer type:

$$\text{minimize } P_{t,x}(\zeta) = g(\xi(T)) \text{ over controls } \zeta(\cdot)$$

subject to $d\xi(\tau)/d\tau = f(\tau,\xi(\tau),\zeta(\tau)), 0 \leq t < \tau \leq T$, $\xi(t) = x \in R^n$, and the state and control constraints $h(\tau,\xi(\tau),\zeta(\tau)) \leq 0$ for a.e. $t \leq \tau \leq T$. The control functions $\zeta(\cdot)$ typically take values in a compact control set Z. Relaxing this problem consists of enlarging the space of control functions to include control functions $\mu(\cdot)$ which, for each fixed $\tau \in [0,T]$ is a probability measure on the control set Z. Then we have the problem of how to define $f(\cdot,\cdot,\mu)$ as well as $h(\cdot,\cdot,\mu)$.

The reason for relaxing a control problem is twofold. First, it is always pleasant to have an optimal control, but this optimal control is usually found only in the class of relaxed controls, which is compact in the weak topology. We do not, in general nonconvex problems, expect an optimal control to exist outside of the class of measure-valued controls. Of course, optimal controls can be found for special problems with additional hypotheses. For example, even in nonconvex problems, an optimal control will exist in the class of uniformly bounded and uniformly Lipschitz continuous control functions with a fixed Lipschitz constant. Many of these results can be found in books by Cesari [10], Berkovitz [7] and Ekeland and Temam [13]. Second, numerical approximations of a control problem are known (for example, [8]) to converge to the relaxed version of the original problem. For these reasons, when one speaks of relaxing an optimal control problem, the relaxation chosen, since there is often more than one way to do this, must satisfy the following properties:

(i) an optimal relaxed control must exist for all problems with reasonable hypotheses;

(ii) the relaxation should have the same minimum as the infimum of the original problem.

A relaxation satisfying these two properties can be said to be correct.

Relaxation theory has been important ever since the origin of optimal control theory, especially when L. C. Young emphasized the important role of convexity. The standard reference for relaxation theory is [22]. For some more recent results see [21], and for relaxation applied to some state contrained problems (but without mixed control and state constraints) see [20].

The theory has led to a major tool in variational problems, appropriately named Young measures = relaxed controls. It is known that the straightforward idea of defining $f(t,x,\mu)$ by $\int_Z f(t,x,z)\mu(dz)$ and $h(t,x,\mu)$ by $\int_Z h(t,x,z)\mu(dz)$ will *not* work since simple examples

show that (ii) will not be satisfied. That is, enlarging to relaxed control functions with this definition of f and h may decrease the minimum. We will prove that the way to relax this problem is to define $f(t, x, \mu)$ in the usual way by $\int_Z f(t, x, z)\mu(dz)$, *but* $h(t, x, \mu)$ should be defined by $\mu - \operatorname{ess\,sup}_{z\in Z} h(t, x, z)$, the essential supremum in z of h, with respect to the measure μ. We will prove that this relaxation is the correct relaxation. In particular, (ii) will be proven by using the uniqueness results of viscosity solutions to first-order PDEs, initiated in the seminal papers of Crandall and Lions [11] and Crandall, Evans, and Lions [12].

A major role in this paper is played by the constraint condition (for one constraint function) that when $h(t, x, z) = 0$, $D_z h(t, x, z) \neq 0$. This condition is very stringent and should be weakened. Nevertheless, it is consistent with the assumption for necessary conditions in [15] and is intuitive as well. That is, in practical problems one expects to be able to control the system back into the desired region when one reaches the boundary. The condition says that the control variable can still be used when the constraint is about to be violated. Helene Frankowska has informed us that under this constraint assumption, the theory of differential inclusions already proves the relaxation theorem in this paper. The specific formulation of the relaxed problem and the proof of the relaxation theorem using viscosity solutions appears to be new. In any case, our goal in this paper is not to find the most general result regarding the state constraint problem but to determine the correct formulation of the relaxed state constrained problem in an explicit form.

The problem of this paper was brought to our attention by an anonymous referee of [3], where we determined the relaxation of optimal control problems with L^∞ cost functionals. The referee pointed out that the result obtained there was a special case of the problem considered in the present paper.

2. Statement of the problem. Consider the controlled system of ordinary differential equations

$$d\xi(\tau)/d\tau = f(\tau, \xi(\tau), \zeta(\tau)), \qquad 0 \leq t < \tau \leq T, \tag{2.1}$$

$$\xi(t) = x \in R^n. \tag{2.2}$$

In this section we will begin by imposing only one constraint on the control functions ζ. Consequently, the controls will be allowed to take values in R^q. Specifically, the control functions $\zeta(\cdot)$ are chosen from the class of functions

$$\mathcal{Z}[t, T] = \{\zeta : [t, T] \to R^q : \zeta \text{ is Lebesgue measurable}\}, \qquad q \geq 1.$$

Throughout this paper we will assume that the following condition holds. The letter K will be a symbol perhaps denoting a different constant at different times.

(A) $f : [0, T] \times R^n \times R^q \to R^n$ is jointly continuous and is Lipschitz in x and z. That is, there is a constant K such that

$$|f(t, x, z) - f(t, x', z')| \leq K(|x - x'| + |z - z'|) \quad \forall x, x' \in R^n,\ z, z' \in R^q. \tag{2.3}$$

In addition, $|f(t, x, z)| \leq K(1 + |x|)$. The given function $g : R^n \to R^1$ is Lipschitz and uniformly bounded below.

We turn now to the single constraint function $h : [0, T] \times R^n \times R^q \to R^1$. Later we will indicate the hypotheses needed when we have more than one constraint. In particular, we will need more than one constraint function in order to incorporate constraints such as $|\zeta| \leq M$, which gives us a compact control set.

(B) $h(t, x, z)$ is continuously differentiable and Lipschitz in all variables and satisfies the two conditions

$$D_z h(t, x, z) \neq 0 \text{ if } h(t, x, z) = 0, \tag{2.4}$$

and

$$\{z \in R^q : h(t,x,z) \le r\} \text{ is compact } \forall\, r \in R^1. \tag{2.5}$$

The goal is to choose a control function $\zeta \in \mathcal{Z}$ which minimizes the cost functional

$$P_{t,x}(\zeta) = g(\xi(T))$$

subject to the constraints that

$$h(\tau, \xi(\tau), \zeta(\tau)) \le 0 \quad \text{for a.e. } t \le \tau \le T.$$

Define the set of feasible control functions

$$\mathcal{Z}_h[t,T] = \{\zeta \in \mathcal{Z}[t,T] : h(\tau, \xi(\tau), \zeta(\tau)) \le 0 \text{ a.e. } t \le \tau \le T\}.$$

The constrained value function $V : [0,T] \times R^n \to R^1$ is defined by

$$V(t,x) = \inf_{\zeta \in \mathcal{Z}_h[t,T]} P_{t,x}(\zeta) \tag{2.6}$$

By the usual convention, $V(t,x) = +\infty$ if $\mathcal{Z}_h[t,T] = \emptyset$. We shall have use of the domain

$$\Omega = \left\{(t,x) \in [0,T] \times R^n : \min_{z \in R^q} h(t,x,z) < 0\right\}$$

and the function

$$\gamma(t,x) = \min_{z \in R^q} h(t,x,z).$$

LEMMA 2.1. *When* (B) *holds, the minimum in the definition of* γ *is achieved for each* (t,x). *Also,* $\Omega = [0,T] \times R^n$.

Proof. Let z_k satisfy $\gamma(t,x) \ge h(t,x,z_k) - 1/k$, $k = 1, 2, \ldots$. Then $z_k \in \{z : h(t,x,z) \le \gamma + 1\}$, which is assumed compact. So we may assume $z_k \to z^*$, and then it is easy to see that z^* provides the minimum.

Under the assumption (2.5) when $\gamma(t,x) = 0$—say, $h(t,x,z_0) = 0$—the fact that $D_z h(t,x,z_0) \ne 0$ implies that $\gamma(t,x) < 0$. Thus, $\{\gamma < 0\}$ everywhere, which says that $\Omega = [0,T] \times R^n$. □

We assume throughout this paper that

$$V : \Omega \to R^1 \text{ is finite for each } (t,x) \in \Omega. \tag{2.7}$$

This is equivalent to assuming that $\mathcal{Z}_h[t,T] \ne \emptyset$ for $(t,x) \in \Omega$.

Remark 2.1. If we assume that there is a constant $C > 0$ such that $\min_z h(t,x,z) \le -C$, it will follow that $V < +\infty$ for all (t,x). Indeed, we set

$$u(t,x) = \inf_{\zeta \in \mathcal{Z}[t,T]} \operatorname{ess\,sup} h(s, \xi(s), \zeta(s)),$$

which is the value function for the L^∞ control problem with cost function h (see [2]–[4]). Then u is the unique viscosity solution of

$$\max\left\{u_t + \min_{\{z : h(t,x,z) \le u\}} D_x u \cdot f(t,x,z),\ \min_z h(t,x,z) - u\right\} = 0$$

in Ω, with $u(T,x) = \min_z h(T,x,z)$. The assumption (2.5) replaces the need for a compact control set used in [4]. Under the assumption $\min_z h(t,x,z) \le -C$, we verify that $u_0(t,x) \equiv -C$ is a viscosity supersolution of the L^∞ problem and therefore $u \le u_0 = -C$ everywhere. But then one can always find a control $\zeta \in \mathcal{Z}[t,T]$ so that $h(s,\xi(s),\zeta(s)) \le -C/2 \le 0$, i.e., $\zeta \in \mathcal{Z}_h$.

Define the Hamiltonian function

$$H(t,x,r,p) = \min_{\{z \in R^q : h(t,x,z) \le r\}} p \cdot f(t,x,z) \tag{2.8}$$

for $r \in R^1$ and $p \in R^n$.

Observe that the minimum is over the r-level set $\{z \in R^q : h(t,x,z) \le r\}$, which is assumed to be compact in R^q $\forall r \in R^1$ by (2.5). If this set is empty, H is defined as $+\infty$. It is known that $H(\cdot,\cdot,r,\cdot)$ is, in general, discontinuous, in which case we must calculate the upper and lower semicontinuous envelopes of H. This was done in [4] for H given in (2.8):

$$H^*(t,x,r,p) \equiv \limsup_{(s,y,\rho,q)\to(t,x,r,p)} H(s,y,\rho,q) = H(t,x,r-0,p)$$

and

$$H_*(t,x,r,p) \equiv \liminf_{(s,y,\rho,q)\to(t,x,r,p)} H(s,y,\rho,q) = H(t,x,r+0,p).$$

In general, upper (lower) * denotes the upper (lower) semicontinuous envelope. Using the continuity of h we see quickly that

$$H_*(t,x,r,p) = H(t,x,r+0,p) = \min_{\{z \in R^q : h(t,x,z) \le 0\}} p \cdot f(t,x,z). \tag{2.9}$$

Using condition (B) we can say more.

LEMMA 2.2. *Assuming* (A) *and* (B), $H^*(t,x,0,p) = H_*(t,x,0,p) = H(t,x,0,p)$.

Proof. We know that

$$H^*(t,x,0,p) = H(t,x,0-0,p) \ge H(t,x,0,p) = H(t,x,0+0,p) = H_*(t,x,0,p),$$

and so it is sufficient to prove that $H(t,x,0,p) \ge H(t,x,0-0,p)$. Fix $(t,x) \in \Omega$ and let z_0 satisfy $h(t,x,z_0) \le 0$ and $\min_{\{z \in R^q : h(t,x,z) \le 0\}} p \cdot f(t,x,z) = p \cdot f(t,x,z_0)$. If $h(t,x,z_0) < 0$, we are done. If $h(t,x,z_0) = 0$, then (B) says that for each $\varepsilon > 0$, we can find $\delta(\varepsilon) > 0$ and $\widehat{z}$ so that $|z_0 - \widehat{z}| < \delta$ and $h(t,x,\widehat{z}) \le -\varepsilon$. Using (A) we get, with K_f the Lipschitz constant for f,

$$\begin{aligned} H(t,x,0,p) = p \cdot f(t,x,z_0) &\ge p \cdot f(t,x,\widehat{z}) - K_f |z_0 - \widehat{z}| \\ &\ge \min_{\{z \in R^q : h(t,x,z) \le -\varepsilon\}} p \cdot f(t,x,z) - K\delta \\ &= H(t,x,-\varepsilon,p) - K\delta. \end{aligned}$$

Since $\varepsilon > 0$ was arbitrary, we reach the result. □

Now we will characterize the constrained value function.

THEOREM 2.3. *Assume* (A), (B), *and* (2.7). *The value function* $V : \Omega \to R^1$ *is the unique continuous viscosity solution of the problem*

$$V_t + \min_{\{z \in R^q : h(t,x,z) \le 0\}} D_x V \cdot f(t,x,z) = 0, \quad (t,x) \in \Omega, \tag{2.10}$$

satisfying the terminal condition

$$V(T, x) = g(x), \qquad x \in R^n. \tag{2.11}$$

We recall here the definition due to Ishii (see [16] and [1]) of a viscosity solution for problems with discontinuous Hamiltonians. Even though we have proved the continuity of H, the formulation of the definition using upper and lower semicontinuous envelopes is convenient for use in some of the proofs below.

DEFINITION 2.1. *A locally bounded function u is a viscosity solution of $u_t + H(t, x, 0, D_x u) = 0$ if*

(i) *u is a viscosity subsolution on Ω, i.e., for any $(t_0, x_0) \in \Omega$ for which $u^* - \varphi$ has a maximum, for a smooth function φ, it follows that*

$$\varphi_t + H^*(t_0, x_0, 0, D_x\varphi(t_0, x_0)) \geq 0;$$

and

(ii) *u is a viscosity supersolution on Ω, i.e., for any $(t_0, x_0) \in \Omega$ for which $u_* - \varphi$ has a minimum, for a smooth function φ, it follows that*

$$\varphi_t + H_*(t_0, x_0, 0, D_x\varphi(t_0, x_0)) \leq 0.$$

Since Ω is all of $[0, T] \times R^n$ we do not have to work with *constrained viscosity solutions* (see [9], [17]–[19]) in this paper. These are functions which are subsolutions in the interior of a constraint set and supersolutions on the entire constraint set, including the boundary. In order to relax assumption (B) constrained viscosity solutions will have to be used.

Proof of Theorem 2.3. The fact that V is locally bounded on Ω follows from the classical results of Hestenes [15, Chap. 7, §5] and is a consequence of the implicit function theorem using assumption (B). In fact, it is proven in [15] that if there is a control $\zeta \in \mathcal{Z}_h$ for a starting point $(s, y) \in \Omega$, then the same is true in a neighborhood of (s, y). Let $\varepsilon > 0$ and $(s, y) \in \Omega$. Let $\zeta_\varepsilon \in \mathcal{Z}_h[s, T]$ be near optimal, i.e., $V(s, y) + \varepsilon \geq g(\xi_\varepsilon(T; s, y)) - \varepsilon$, where $\xi_\varepsilon(\cdot\,; s, y)$ is the trajectory associated with ζ_ε. Then, using assumption (A) and standard results in ODEs, it is easy to verify that $V(t, x) \leq V(s, y) + K\delta + \varepsilon$ for all $(t, x) \in B_\delta(s, y)$. It follows that V is locally bounded above. V is bounded below also by assumption (A).

The fact that V satisfies (2.10) follows in a standard way (see [19]) from the dynamic programming principle:

$$V(t, x) = \inf_{\zeta \in \mathcal{Z}_h[t,s]} V(s, \xi(s)), \tag{2.12}$$

where $\mathcal{Z}_h[t, s] = \{\zeta \in \mathcal{Z}[t, s] : h(\tau, \xi(\tau), \zeta(\tau)) \leq 0, \text{ a.e. } t \leq \tau \leq s\}$.

We will only prove that V is a subsolution, the proof that V is a supersolution is similar. Suppose that $V^* - \varphi$ achieves a strict zero maximum at $(s, y) \in \Omega$. If V is not a subsolution, then there is $\delta > 0$ such that

$$\varphi_t + H(s, y, -\delta, D_x\varphi) \leq -\delta$$

at (s, y). By the definition of H and (2.5), there is a $z_\delta \in R^q$ so that $h(s, y, z_\delta) \leq -\delta$ and

$$\varphi_t + D_x\varphi \cdot f(s, y, z_\delta) \leq -\delta. \tag{2.13}$$

Set $\zeta(\tau) \equiv z_\delta$, and let $\xi(\cdot; t, x)$ be the trajectory associated with ζ on $[s, T]$ with $\xi(t) = x$. Set

$$\mathcal{A}(z, \rho) = \{(t, x) : h(t, x, z) \leq \rho\}.$$

There is an $r > 0$ such that $(\tau, \xi(\tau; t, x)) \in \mathcal{A}(\zeta(\tau), -\delta/2)$ for all $(t, x) \in B_r(s, y)$ and for all $s \le t \le \tau \le s + r$. Let $\varepsilon > 0$ such that $\varepsilon < r$ and select $(s_\varepsilon, y_\varepsilon) \in B_r(s, y) \cap \mathcal{A}(z_\delta, -\delta/2)$ such that

$$V(s_\varepsilon, y_\varepsilon) > \varphi(s_\varepsilon, y_\varepsilon) - \varepsilon^2.$$

Using the dynamic programming principle (2.12) we have

$$\varphi(s_\varepsilon, y_\varepsilon) - \varepsilon^2 < V(s_\varepsilon, y_\varepsilon) \le V(s_\varepsilon + \varepsilon, \xi(s_\varepsilon + \varepsilon; s_\varepsilon, y_\varepsilon)) \le \varphi(s_\varepsilon + \varepsilon, \xi(s_\varepsilon + \varepsilon; s_\varepsilon, y_\varepsilon)).$$

From this and (2.13) we get, for small $\varepsilon > 0$, that

$$\begin{aligned} -\varepsilon^2 &< \varphi(s_\varepsilon + \varepsilon, \xi(s_\varepsilon + \varepsilon; s_\varepsilon, y_\varepsilon)) - \varphi(s_\varepsilon, y_\varepsilon) \\ &= \int_{s_\varepsilon}^{s_\varepsilon + \varepsilon} \varphi_t(\tau, \xi(\tau)) + D_x\varphi(\tau, \xi(\tau)) \cdot f(\tau, \xi(\tau), \zeta(\tau))\, d\tau \\ &\le -\delta/2\, \varepsilon. \end{aligned}$$

This leads to a contradiction if we let $\varepsilon \to 0$ and so we conclude that V is indeed a subsolution.

To prove uniqueness and continuity we will use the following comparison principle.

PROPOSITION 2.4. *If $u : \Omega \to R^1$ is an upper semicontinuous subsolution and $v : \Omega \to R^1$ is a lower semicontinuous supersolution of* (2.10), *both of which satisfy the terminal condition* (2.11), *then $u \le v$ on Ω.*

Proof. We only sketch the proof since it is similar to the proof of uniqueness in [4] until we get near the end.

By assumption, in the viscosity sense, u solves

$$u_t + H^*(t, x, 0, D_x u) \ge 0, \qquad (t, x) \in \Omega,$$

and v solves

$$v_t + H_*(t, x, 0, D_x v) \le 0, \qquad (t, x) \in \Omega.$$

If $\beta > 0, M > 0$ and we set $v'(t, x) = v(t, x) + \frac{\beta}{t} + M\beta(T - t) + \beta g_R(|x|)$, where $g_R \in C^1(R^1)$ satisfies $0 \le dg_R(r)/dr \le 1$, $g_R(r) = 0$ if $r \le R$, and $g_R(r) \to +\infty$ as $r \to \infty$. Then $v' \ge v$ and it is easy to check that v' is a solution of

$$v'_t + H_*(t, x, 0, D_x v') + \frac{\beta}{t^2} \le 0, \qquad (t, x) \in \Omega.$$

We refer to [4, Thm. 4.2, p. 1086] for similar details. Set $w(t, x, y) = u(t, x) - v'(t, y)$. Since u is a subsolution and v' is a supersolution, w is a viscosity solution of

$$w_t + H^*(t, x, 0, D_x w) - H_*(t, y, 0, -D_y w) - \frac{\beta}{t^2} \ge 0. \tag{2.14}$$

We want to prove that $u \le v'$ on Ω. For the sake of contradiction, suppose that

$$u(t', x') - v'(t', x') = \sup_{(t,x)\in\Omega} (u - v') > 0.$$

The presence of g_R in v' guarantees that the supremum is achieved even though $\Omega = [0, T] \times R^n$ is unbounded. In addition the terms $M\beta(T - t)$ and β/t allow us to assume that $0 < t' < T$. Consider

$$M_\alpha = \sup_{(t,x,y)} \left(w(t, x, y) - \frac{\alpha}{2}|x - y|^2 \right)$$

for $\alpha > 0$. Then $M_\alpha < +\infty$ for large α, and if $(t_\alpha, x_\alpha, y_\alpha)$ satisfies

$$\lim_{\alpha\to\infty}\left(M_\alpha - w(t_\alpha, x_\alpha, y_\alpha) + \frac{\alpha}{2}|x_\alpha - y_\alpha|^2\right) = 0,$$

then (i) $\alpha|x_\alpha - y_\alpha|^2 \to 0$ and (ii) $M_\alpha \to u(t', x') - v'(t', x')$. Using the definition of subsolution with the test function $\frac{\alpha}{2}|x - y|^2$, at $(t, x, y) = (t_\alpha, x_\alpha, y_\alpha)$ we have from (2.14) that

$$H^*(t, x, 0, \alpha(x - y)) - H_*(t, y, 0, \alpha(x - y)) - \frac{\beta}{t^2} \geq 0.$$

Using the fact that

$$H^*(t, x, 0, \alpha(x - y)) = H(t, x, 0 - 0, \alpha(x - y)) = H(t, x, 0, \alpha(x - y)),$$
$$H_*(t, y, 0, \alpha(x - y)) = H(t, y, 0 + 0, \alpha(x - y)) = H(t, y, 0, \alpha(x - y)),$$

we obtain

$$\begin{aligned} 0 &\leq H(t, x, 0, \alpha(x - y)) - H(t, y, 0, \alpha(x - y)) - \frac{\beta}{t^2} \\ &\leq H(t, x, 0, \alpha(x - y)) - \alpha(x - y) \cdot f(t, y, \overline{z}) - \frac{\beta}{t^2} \\ &\leq H(t, x, 0, \alpha(x - y)) - \alpha(x - y) \cdot f(t, x, \overline{z}) + K_f\alpha|x - y|^2 - \frac{\beta}{t^2}, \end{aligned}$$

where $\overline{z} \in \{z : h(t, y, z) \leq 0\}$ achieves the minimum in $H(t, y, 0, \alpha(x - y))$. We have used the Lipschitz continuity of f in the last line.

Now suppose that $h(t, y, \overline{z}) = 0$; the case when $h(t, y, \overline{z}) < 0$ is similar but easier. Using assumption (B), there exists $\widehat{z}$ so that

$$|\widehat{z} - \overline{z}| \leq K_f|x - y| \text{ and } h(t, y, \widehat{z}) \leq -2K_h|x - y|. \tag{2.15}$$

Then

$$h(t, x, \widehat{z}) = h(t, y, \widehat{z}) + h(t, x, \widehat{z}) - h(t, y, \widehat{z}) \leq -2K_h|x-y| + K_h|x-y| = -K_h|x-y| < 0.$$

Consequently, $\widehat{z}$ is a member of the set over which the minimum is taken in the Hamiltonian $H(t, x, 0, \alpha(x - y))$. Therefore, using (2.15),

$$\begin{aligned} 0 &\leq H(t, x, 0, \alpha(x - y)) - \alpha(x - y) \cdot f(t, x, \overline{z}) + K_f\alpha|x - y|^2 - \frac{\beta}{t^2} \\ &\leq \alpha(x - y) \cdot f(t, x, \widehat{z}) - \alpha(x - y) \cdot f(t, x, \overline{z}) + K_f\alpha|x - y|^2 - \frac{\beta}{t^2} \\ &\leq K_f\alpha|x - y|\,|\widehat{z} - \overline{z}| + K_f\alpha|x - y|^2 - \frac{\beta}{t^2} \\ &\leq K\alpha|x - y|^2 - \frac{\beta}{t^2}. \end{aligned}$$

Since $\alpha|x - y|^2 \to 0$, we have reached a contradiction. This contradiction tells us that $u \leq v' = v + o_\beta(1)$, and since $\beta > 0$ was arbitrary, $u \leq v$. □

Completing the proof of the theorem, we have shown that V^* is an upper semicontinuous subsolution and V_* is a lower semicontinuous supersolution, both satisfying the terminal

condition (2.11). By the proposition, we conclude that $V^* \leq V_*$ and therefore that V is continuous. Uniqueness is also an immediate consequence of the proposition. □

Remark 2.2. If we have $m > 1$ constraint functions—say, $h_1(t, x, z), \ldots, h_m(t, x, z)$—then we generalize assumption (B) to the condition that

(B′) The matrix

$$\left(\frac{\partial h_i}{\partial z_j}\right), \qquad i = i_1, \ldots, i_r, \ j = 1, 2, \ldots, q, \tag{2.16}$$

has rank r, where $i_1, \ldots, i_r$ are the indices i from $1, 2, \ldots, m$ such that $h_i(t, x, z) = 0$.

In the remainder of this paper we will assume that we have $m + 1$ constraint functions with $h_i = h_i(z)$ for $i = 1, 2, \ldots, m$ and $h_{m+1} = h(t, x, z)$. We will set

$$Z = \{z \in R^q : h_i(z) \leq 0, \ i = 1, 2, \ldots, m\}, \tag{2.17}$$

which is assumed to be compact in R^q. The set Z is the usual compact control set of control theory, often taking the form $Z = \{z \in R^q : |z| \leq M\}$. A set of this form is easily expressed using smooth functions $h_1, \ldots, h_m$.

Assuming the rank condition (2.16) for the continuously differentiable functions $h_1(z)$, $\ldots, h_m(z)$, $h(t, x, z)$, we prove, using the method of this section, that the value function with these constraints on the controls is the unique continuous viscosity solution of

$$V_t + H(t, x, 0, D_x V) = 0, \qquad (t, x) \in \Omega, \tag{2.18}$$

and terminal condition (2.11), but now since

$$\{z \in R^q : h_1(z) \leq 0, \ldots, h_m(z) \leq 0, h(t, x, z) \leq 0\} = \{z \in Z : h(t, x, z) \leq 0\},$$

$$H(t, x, r, p) = \min_{\{z \in Z : h(t,x,z) \leq r\}} p \cdot f(t, x, z).$$

The value function is given by $V(t, x) = \inf_{\zeta \in \mathcal{Z}_h[t,T]} g(\xi(T))$, but now we take

$$\mathcal{Z}_h[t, T] = \{\zeta : [t, T] \to Z : h(\tau, \xi(\tau), \zeta(\tau)) \leq 0, \text{ a.e. } t \leq \tau \leq T\}.$$

In other words, we have the admissible controls taking values in the compact set $Z \subset R^q$. We no longer need to assume that the level sets of $h(t, x, z)$ in the z variable, i.e., $\{z \in Z : h(t, x, z) \leq r\}$, are compact because this will follow from the assumption that Z is compact.

3. The relaxed problem. Since our aim in this paper is to determine the relaxed version of the problem just formulated, we need to introduce the space of relaxed controls and the relaxed dynamics.

We assume throughout the remainder of this paper that condition (A) and the assumption (B′) on the constraint functions given in Remark 2.2 hold, as does (2.7).

Let $M(Z)$ denote the space of bounded measures on the compact control set $Z = \{z \in R^q : h_1(z) \leq 0, \ldots, h_m(z) \leq 0\}$ and $\mathcal{PM}(Z)$ be the set of probability measures on Z. Viewing $M(Z)$ as the dual space of $C(Z) =$ continuous functions on Z, we endow $M(Z)$ and $\mathcal{PM}(Z)$ with the weak star topology of $C(Z)^*$. For any $\mu \in \mathcal{PM}(Z)$ define the functions

$$\widehat{f}(t, x, \mu) = \int_Z f(t, x, z) \, \mu(dz), \tag{3.1}$$

and

$$\widehat{h}(t, x, \mu) = \mu - \operatorname*{ess\,sup}_{z \in Z} h(t, x, z). \tag{3.2}$$

This means that we take the essential supremum in $z \in Z$ of $h(\cdot, \cdot, z)$ with respect to the measure μ.

Let $\widehat{\mathcal{Z}}[t, T] = L^\infty([t, T]; \mathcal{PM}(Z))$, and define the space of feasible relaxed controls by

$$\widehat{\mathcal{Z}}_h[t, T] = \{\mu \in \widehat{\mathcal{Z}}[t, T] : \widehat{h}(s, \widehat{\xi}(s), \mu(s)) \leq 0, \text{ a.e. } t \leq s \leq T\},$$

where $\widehat{\xi}(\cdot)$, for any control $\mu \in \widehat{\mathcal{Z}}[t, T]$, is the unique relaxed trajectory given by

$$\widehat{\xi}(\tau) = x + \int_t^\tau \int_Z f(s, \widehat{\xi}(s), z)\, \mu(s, dz)ds. \tag{3.3}$$

Remark 3.1. We proved in [3] that, for each (t, x) fixed, the mapping

$$\mu \in \mathcal{PM}(Z) \mapsto \widehat{h}(t, x, \mu)$$

is weakly sequentially lower semicontinuous. The continuity properties of $\widehat{h}$ in the (t, x) variables are the same as those of h. In general, however, $\widehat{h}$ is not continuously differentiable.

DEFINITION 3.1. *The relaxed value function associated with the constrained problem is*

$$\widehat{V}(t, x) = \inf_{\mu(\cdot) \in \widehat{\mathcal{Z}}_h[t,T]} g(\widehat{\xi}(T)). \tag{3.4}$$

Consider the set

$$\widehat{\Omega} = \left\{(t, x) \in [0, T] \times R^n : \min_{\mu \in \mathcal{PM}(Z)} \widehat{h}(t, x, \mu) < 0\right\}, \tag{3.5}$$

and set

$$\widehat{\gamma}(t, x) = \min_{\mu \in \mathcal{PM}(Z)} \widehat{h}(t, x, \mu). \tag{3.6}$$

PROPOSITION 3.1. $\Omega = \widehat{\Omega} = [0, T] \times R^n$.

Proof. The proof follows from the fact that

$$\widehat{\gamma}(t, x) = \gamma(t, x) = \min_{z \in Z} h(t, x, z) \qquad \forall (t, x) \in [0, T] \times R^n. \tag{3.7}$$

To see that this is true, we have that, for any $\mu \in \mathcal{PM}(Z)$,

$$\widehat{h}(t, x, \mu) = \mu - \operatorname{ess\,sup}_{z \in Z} h(t, x, z) \geq \min_{z \in Z} h(t, x, z),$$

and so $\widehat{\gamma}(t, x) \geq \gamma(t, x)$. If z_0 satisfies $\gamma(t, x) = h(t, x, z_0)$, let $\mu_0 \in \mathcal{PM}(Z)$ be the Dirac measure on Z concentrated at z_0, $\mu_0 = \delta_{z_0}$. Then

$$\widehat{\gamma}(t, x) \leq \widehat{h}(t, x, \mu_0) = h(t, x, z_0) = \gamma(t, x),$$

and (3.7) is proven. □

THEOREM 3.2. *Assume* (A), *the conditions of Remark* 2.2, *and* (2.7). $\widehat{V}$ *is a continuous viscosity solution of the Bellman equation* (2.18) *satisfying the terminal condition* (2.11).

Proof. Since any ordinary control $\zeta \in \mathcal{Z}_h[t, T]$ can be viewed as a relaxed control (by taking the relaxed control to be the Dirac measure concentrated on ζ, $\mu(\tau) = \delta_{\zeta(\tau)}$), it is immediate that $\widehat{V}(t, x) \leq V(t, x)$ $\forall (t, x) \in \Omega$. Assumption (A) implies that $\widehat{V}$ is bounded below. Thus, $\widehat{V}$ is locally bounded. Also, it is clear that $\widehat{V}(T, x) = g(x)$.

Define the relaxed Hamiltonian

$$\widehat{H}(t,x,r,p) = \min_{\{\mu\in\mathcal{PM}(Z):\widehat{h}(t,x,\mu)\le r\}} p\cdot\widehat{f}(t,x,\mu). \tag{3.8}$$

Then, just as in the unrelaxed case,

$$\widehat{H}^*(t,x,r,p) = \widehat{H}(t,x,r-0,p) \text{ and } \widehat{H}_*(t,x,r,p) = \widehat{H}(t,x,r+0,p).$$

We may not yet conclude continuity of the Hamiltonians because we have not imposed condition (B′) on $\widehat{h}$. To obtain continuity we will need the following lemma relating the relaxed Hamiltonian with the ordinary Hamiltonian.

LEMMA 3.3. *$\widehat{H}(t,x,r,p) = H(t,x,r,p)$, i.e.,*

$$\min_{\{\mu\in\mathcal{PM}(Z):\widehat{h}(t,x,\mu)\le r\}} p\cdot\widehat{f}(t,x,\mu) \;=\; \min_{\{z\in Z:h(t,x,z)\le r\}} p\cdot f(t,x,z). \tag{3.9}$$

Proof of Lemma 3.3. First, if the set $\{\mu\in\mathcal{PM}(Z) : \widehat{h}(t,x,\mu)\le r\}$ is nonempty, then it contains a measure μ such that for μ a.e. $z\in Z$, $h(t,x,z)\le r$. Therefore, the set $\{z\in Z : h(t,x,z)\le r\}$ also is nonempty. The converse statement is also clearly true by using Dirac measures. Without loss of generality we may therefore assume the sets are nonempty since otherwise the Hamiltonians are both $+\infty$. Now $\widehat{H}(t,x,r,p)\le H(t,x,r,p)$ since, for each z_0 such that $h(t,x,z_0)\le r$, we can let $\mu=\delta_{z_0}$. To see the opposite inequality, let $\varepsilon>0$ be given and $\mu^*\in\mathcal{PM}(Z)$ satisfy

$$\widehat{H}(t,x,r,p)\ge p\cdot\widehat{f}(t,x,\mu^*)-\varepsilon = \int_Z p\cdot f(t,x,z)\mu^*(dz)-\varepsilon$$

and $\mu^*-\operatorname{ess\,sup}_z h(t,x,z)\le r$. Let $B=\{z\in Z : h(t,x,z)\le r\}$. Then $\mu^*(B)=1$, and

$$\begin{aligned}\widehat{H}(t,x,r,p) &\ge \int_Z p\cdot f(t,x,z)\mu^*(dz)-\varepsilon\\ &= \int_B p\cdot f(t,x,z)\mu^*(dz)-\varepsilon\\ &\ge \min_{z\in B} p\cdot f(t,x,z)-\varepsilon = H(t,x,r,p)-\varepsilon.\end{aligned}$$

Therefore, (3.9) is true. □

One consequence of the lemma is that even though $\widehat{h}(t,x,\mu)$ is not a continuously differentiable function, at least for the purpose of calculating the Hamiltonian we may use the continuously differentiable function h from which $\widehat{h}$ is defined.

Returning to the proof of the theorem, we begin the proof that $\widehat{V}$ is a subsolution of (2.18). Assume that $\widehat{V}^*-\varphi$ achieves a zero maximum at $(s,y)\in\Omega=\widehat{\Omega}$. If $\widehat{V}$ is not a subsolution, then there is $\delta>0$ so that

$$\varphi_t(s,y)+H(s,y,-\delta,D_x\varphi(s,y)) = \varphi_t(s,y)+\widehat{H}(s,y,-\delta,D_x\varphi(s,y))\le -\delta.$$

Observe that we have used the fact that H and $\widehat{H}$ are identical. Now we may use the dynamic programming principle for the relaxed value, i.e.,

$$\widehat{V}(s,y) = \inf_{\{\mu\in\widehat{\mathcal{Z}}[s,\sigma]\}} \widehat{V}(\sigma,\widehat{\xi}(\sigma;s,y)), \qquad s\le\sigma\le T,$$

and we complete the proof that $\widehat{V}$ is a subsolution of (2.18) in a manner entirely similar to that of Theorem 2.3. In this proof we use a control $\zeta(\tau)=z_\delta$ and the relaxed control $\mu(\tau)=\delta_{\zeta(\tau)}$.

The assumption (B′) is used exactly as in the proof of Theorem 2.3 to achieve a contradiction. The continuity of $\widehat{V}$ also follows from the comparison principle once we know that $\widehat{V}$ is a viscosity solution. □

Once we know that $\widehat{V}$ is a viscosity solution of (2.18) and satisfies the terminal condition (2.11), the uniqueness of viscosity solutions is used to yield the following relaxation theorem.

COROLLARY 3.4. *The relaxed value function $\widehat{V}$ and the ordinary value function V are identical on Ω.*

The reader may well ask whence comes our definition of the relaxed problem and, in particular, the use of the function $\widehat{h}$. The following theorem provides the answer to that question.

Denote by $a^+ = \max\{a, 0\}$.

THEOREM 3.5. *Assume* (A), *the conditions of Remark* 2.2, *and* (2.7). *Define, for each* $n = 1, 2, \ldots$, *the value function for the unconstrained problem*

$$V_n(t,x) = \inf_{\zeta \in \mathcal{Z}[t,T]} \left\{ g(\xi(T)) + n \cdot \int_t^T h^+(s, \xi(s), \zeta(s))\, ds \right\},$$

where ξ is the trajectory starting from $x \in R^n$ at time t. Here $\mathcal{Z}[t,T] = \{\zeta : [t,T] \to Z\}$, and recall that $Z = \{z \in R^q : h_i(z) \le 0, 1 \le i \le m\}$. Let $\widehat{V}_n(t,x)$ be the classical unconstrained relaxed value:

$$\widehat{V}_n(t,x) = \inf_{\mu \in \widehat{\mathcal{Z}}[t,T]} \left\{ g(\widehat{\xi}(T)) + n \cdot \int_Z \int_t^T h^+(s, \widehat{\xi}(s), z)\, \mu(s, dz)\, ds \right\}.$$

Then, for $(t,x) \in [0,T] \times R^n$,

$$\lim_{n \to \infty} V_n(t,x) = V(t,x) \tag{3.10}$$

and

$$\lim_{n \to \infty} \widehat{V}_n(t,x) = \widehat{V}(t,x). \tag{3.11}$$

Proof. To prove (3.10), we know (see [19]) that V_n is the unique continuous viscosity solution of

$$\frac{\partial V_n}{\partial t} + \min_{z \in Z} \left(D_x V_n \cdot f(t,x,z) + n \cdot h^+(t,x,z) \right) = 0, \qquad (t,x) \in [0,T) \times R^n,$$

with terminal condition $V_n(T,x) = g(x)$. Set

$$H_n(t,x,p) = \min_{z \in Z} \left(p \cdot f(t,x,z) + n \cdot h^+(t,x,z) \right).$$

Then, by classical penalization arguments (cf. [4] and [6]), assuming that all of the Hamiltonians are finite,

$$\limsup_{(n,s,y,q) \to (\infty,t,x,p)} H_n(s,y,q) = H(t,x,0-0,p)$$

and

$$\liminf_{(n,s,y,q) \to (\infty,t,x,p)} H_n(s,y,q) = H(t,x,0+0,p).$$

Recall that under our assumptions, V is locally uniformly bounded. The stability result of Barles and Perthame (see Fleming and Soner [19, p. 288]) then gives us (3.10).

To prove (3.11), we know that $\widehat{V}_n$ is the continuous viscosity solution of

$$\frac{\partial V_n}{\partial t} + \min_{\mu \in \mathcal{PM}(Z)} \left(D_x \widehat{V}_n \cdot \widehat{f}(t, x, \mu) + n \cdot \int_Z h^+(t, x, z) \mu(dz) \right) = 0, \ (t, x) \in [0, T) \times R^n,$$

with $\widehat{V}_n(T, x) = g(x)$. Now, setting

$$\widehat{H}_n(t, x, r, p) = \min_{\mu \in \mathcal{PM}(Z)} p.\widehat{f}(t, x, \mu) + n \cdot \int_Z (h(t, x, z) - r)^+ \mu(dz),$$

we verify easily that

$$\limsup_{(n,s,y,b,q) \to (\infty,t,x,r,p)} \widehat{H}_n(s, y, b, q) = \min_{\{\mu \in \mathcal{PM}(Z): \int_Z (h(t,x,z)-r+0)^+ \mu(dz) \le 0\}} p.\widehat{f}(t, x, \mu)$$

and

$$\liminf_{(n,s,y,b,q) \to (\infty,t,x,r,p)} \widehat{H}_n(s, y, b, q) = \min_{\{\mu \in \mathcal{PM}(Z): \int_Z (h(t,x,z)-r-0)^+ \mu(dz) \le 0\}} p.\widehat{f}(t, x, \mu).$$

Indeed to verify the first claim, we have, for all $(s, y, b, q) \in B_\varepsilon(t, x, r, p)$,

$$\min_{\{\mu \in \mathcal{PM}(Z): \int_Z (h(s,y,z)-b)^+ \mu(dz) \le 0\}} q \cdot \widehat{f}(s, y, \mu)$$

$$= \lim_{n \to \infty} \min_{\mu \in \mathcal{PM}(Z)} \left(q.\widehat{f}(s, y, \mu) + n \cdot \int_Z (h(s, y, z) - b)^+ \mu(dz) \right)$$

$$\le \lim_{n \to \infty} \min_{\mu \in \mathcal{PM}(Z)} \left(p.\widehat{f}(t, x, \mu) + n \cdot \int_Z (h(t, x, z) - r + (K_h + 1)\varepsilon)^+ \mu(dz) + K_f \varepsilon + |p|\varepsilon \right)$$

$$= \min_{\{\mu \in \mathcal{PM}(Z): \int_Z (h(t,x,z)-r+(K_h+1)\varepsilon)^+ \mu(dz) \le 0\}} \left(p \cdot \widehat{f}(t, x, \mu) + K_f \varepsilon + |p|\varepsilon \right).$$

Since $\varepsilon > 0$ was arbitrary we have shown that

$$\limsup_{(n,s,y,b,q) \to (\infty,t,x,r,p)} \widehat{H}_n(s, y, b, q) \le \min_{\{\mu \in \mathcal{PM}(Z): \int_Z (h(t,x,z)-r+0)^+ \mu(dz) \le 0\}} p.\widehat{f}(t, x, \mu).$$

The reverse inequality is immediate, so the claim is verified.

Now $\int_Z (h(t, x, z) - r + 0)^+ \mu(dz) \le 0$, if and only if $\mu - \operatorname{ess\,sup}_z h(t, x, z) < r$ and so

$$\limsup_{(n,s,y,b,q) \to (\infty,t,x,r,p)} \widehat{H}_n(s, y, b, q)$$

$$= \min_{\{\mu \in \mathcal{PM}(Z) \,:\, \mu - \operatorname{ess\,sup}_z h(t,x,z) \le r-0\}} p.\widehat{f}(t, x, \mu)$$

$$= \widehat{H}^*(t, x, r, p).$$

Similarly,

$$\liminf_{(n,s,y,b,q)\to(\infty,t,x,r,p)} \widehat{H}_n(s, y, b, q)$$

$$= \min_{\{\mu\in\mathcal{PM}(Z)\,:\,\mu-\operatorname{ess\,sup}_z h(t,x,z)\le r+0\}} p.\widehat{f}(t, x, \mu)$$

$$= \widehat{H}_*(t, x, r, p).$$

Once again the Hamiltonian for $\widehat{V}_n$ converges correctly to the Hamiltonian for $\widehat{V}$ and the theorem of Barles and Perthame allows us to conclude. Without loss of generality we are assuming that all of the Hamiltonians in the proof are finite to avoid trivial cases. □

Remark 3.2. It is apparent from Theorem 3.5 that the natural approach to relaxing the constrained problem, i.e., convexifying h by taking $\int_Z h(t, x, z)\mu(dz)$, is *not* correct. The theorem shows that we must relax h^+, not h. The distinction comes from the fact that $(\int_Z h(t, x, z)\mu(dz))^+ \neq \int_Z h^+(t, x, z)\mu(dz)$.

We have proved so far that the relaxed value defined in this paper and the original value function will coincide. Thus, even though the class of controls is enlarged to guarantee the existence of an optimal control, this enlargement will not decrease the value. Furthermore, the fact that the values are the same means that it will be possible to approximate the relaxed value function with ordinary controls and trajectories. This is the first part of establishing that the formulation of the relaxed problem in this paper is the correct one.

The second part now consists of showing that an optimal relaxed control will always exist in our formulation. If we do that, then our formulation will satisfy the properties required in enlarging the class of controls to give us existence of an optimal control.

We recall here the definition of a quasi-convex function. A quasi-convex function—say, $g : X \to R^1$, X a convex set—satisfies

$$g(\lambda x + (1-\lambda)y) \le \max\{g(x), g(y)\}, \qquad 0 < \lambda < 1, \quad x, y \in X.$$

Equivalently, g is quasi-convex if the r-level set of g, $\{x \in X : g(x) \le r\}$ is convex for all $r \in R^1$.

It was proven in [3] that $\mu \mapsto \widehat{h}(t, x, \mu)$ is a quasi-convex function. In fact,

$$\widehat{h}(t, x, \lambda\mu_1 + (1-\lambda)\mu_2) = \max\{\widehat{h}(t, x, \mu_1), \widehat{h}(t, x, \mu_2)\} \tag{3.12}$$

for $0 < \lambda < 1$. Furthermore, it is obvious that $\mu \mapsto \widehat{f}(t, x, \mu)$ is linear and weakly continuous. The continuity properties of $\widehat{f}$ and $\widehat{h}$ in the (t, x) variables are inherited from f and h.

THEOREM 3.6. *For each fixed* $(t, x) \in \Omega$, *there exists an optimal relaxed constrained control* $\mu^*(\cdot) \in \widehat{\mathcal{Z}}_h[t, T]$.

Proof. Let $\{\mu_n\} \subset \widehat{\mathcal{Z}}_h[t, T]$ be a minimizing sequence and $\widehat{\xi}_n$ the associated relaxed trajectory for each $n = 1, 2, \ldots$, starting from $x \in R^n$ at time $t \ge 0$. Then, we know that on a subsequence $\mu_n \rightharpoonup \mu^*$, weak-* for some $\mu^* \in \widehat{\mathcal{Z}}[t, T]$, as well as $\widehat{\xi}_n \to \widehat{\xi}^*$, uniformly on $[t, T]$, with $\widehat{\xi}^*$ the trajectory associated with μ^*. We first need to show that $\mu^* \in \widehat{\mathcal{Z}}_h[t, T]$, i.e., that the constraint $\widehat{h}(s, \widehat{\xi}^*(s), \mu^*(s)) \le 0$ for a.e. $t \le s \le T$, is satisfied. This constraint is equivalently expressed as

$$\lambda - \operatorname*{ess\,sup}_{t\le s\le T} \widehat{h}(s, \widehat{\xi}^*(s), \mu^*(s)) \le 0, \tag{3.13}$$

where λ denotes Lebesgue measure on $[0, T]$. It was proved in [3] and [5] (see Remark 3.3) that the functional $F : \widehat{\mathcal{Z}}[t, T] \to R^1$ defined by

$$F(\mu) = \lambda - \operatorname*{ess\,sup}_{t\le s\le T} \widehat{h}(s, \widehat{\xi}(s), \mu(s))$$

is weakly lower semicontinuous if $\widehat{h}(\cdot, \cdot, \mu)$ is quasi-convex. Since (3.12) shows that this function is indeed quasi-convex, and since $\mu_n \in \widehat{\mathcal{Z}}_h[t, T]$, we have that

$$F(\mu^*) \leq \liminf_{n\to\infty} F(\mu_n) \leq 0,$$

and (3.13) is proven.

Finally, since $\widehat{\xi}_n(T) \to \widehat{\xi}^*(T)$,

$$\widehat{V}(t, x) = \lim_{n\to\infty} g(\widehat{\xi}_n(T)) = g(\widehat{\xi}^*(T)) \geq \widehat{V}(t, x),$$

which says that (μ^*, ξ^*) is optimal. □

Remark 3.3. We will sketch a proof of the fact that $u \in L^\infty([0, T]; R^n) \mapsto \operatorname{ess\,sup} h(u(\tau))$ is weakly lower semicontinuous when h is quasi-convex. The proof here is modeled after a similar statement for integrals of convex functions in [14]. The proof given in [3] is based on Mazur's lemma. Set $G(u) = \operatorname{ess\,sup}_{0\leq\tau\leq T} h(u(\tau))$. Suppose that $u_k \to u$ weak-* in $L^\infty([0, T], R^n)$. We assume that h is represented as

$$h(p) = \max_{1\leq j\leq m} (q_j \cdot p + d_j) \wedge c_j, \qquad q_j \in R^n,\ c_j \in R^1,\ 1 \leq j \leq m < \infty.$$

Indeed, it is proven in [5] that any quasi-convex function can be represented as $h(q) = \sup_{p,c} ((q \cdot p - h^*(p, c)) \wedge c)$, where $h^*(p, c) = \left(\sup_q (p \cdot q - h(q)) \wedge c\right)$. Set $E_j = \{\tau \in [0, T] : h(u(\tau)) = (q_j \cdot u(\tau) + d_j) \wedge c_j\}$. Then $[0, T] = \cup_j E_j$, and we assume that the sets are disjoint. Then, since $u_k \to u$ weak-*,

$$\begin{aligned} G(u) = \operatorname*{ess\,sup}_{0\leq\tau\leq T} h(u(\tau)) &= \max_j \operatorname*{ess\,sup}_{\tau\in E_j} h(u(\tau)) \\ &= \max_j \operatorname*{ess\,sup}_{\tau\in E_j} (q_j \cdot u(\tau) + d_j) \wedge c_j \\ &\leq \liminf_{k\to\infty} \max_j \operatorname*{ess\,sup}_{\tau\in E_j} (q_j \cdot u_k(\tau) + d_j) \wedge c_j \\ &= \liminf_{k\to\infty} G(u_k). \end{aligned}$$

A limiting argument on $m \to \infty$ then completes the proof.

Remark 3.4. Recall that $Z = \{z \in R^q : h_1(z) \leq 0, \ldots, h_m(z) \leq 0\}$. The class $\mathcal{PM}(Z)$ convexifies Z. Also,

$$\{\mu \in \mathcal{PM}(R^q) : \widehat{h}_1(\mu) \leq 0, \ldots, \widehat{h}_m(\mu) \leq 0\} = \{\mu \in \mathcal{PM}(Z)\}.$$

An equivalent formulation of the relaxed problem can be stated, using the greatest quasi-convex minorant of h. It was shown in [5] that the greatest quasi-convex minorant of a function h can be written

$$h^{**}(z) = \min \left\{ \max_{1\leq i\leq q+1} h(z_i) : z = \sum_{i=1}^{q+1} \lambda_i z_i, \lambda_i \geq 0, \sum_i \lambda_i = 1 \right\}.$$

Once we have $h^{**}(t, x, z)$, we may state the relaxed optimal control problem using chattering controls as in [7].

Acknowledgment. We are grateful to the referees for pointing out several simplifications in the use of the set Ω.

SOLVABILITY AND RIGHT-INVERSION OF IMPLICIT NONLINEAR DISCRETE-TIME SYSTEMS*

T. FLIEGNER†, Ü. KOTTA‡, AND H. NIJMEIJER§

Abstract. In this paper the problems of solvability and right-invertibility for implicit nonlinear discrete-time control systems are investigated. The concept "solvability" is defined in such a way that consistency of the implicit system equations is locally guaranteed for all input sequences, and an algorithm is introduced to verify the solvability of an implicit system in that sense. It is demonstrated how this mechanism may be used to decide on the right-invertibility or functional reproducibility of a given system. In contrast to previous work on right-invertibility for special classes of implicit nonlinear systems, the approach is not restricted to the characterization of right-invertibility, but it is shown in addition how an inverse system can actually be obtained. The theory is illustrated by a realistic economic example in which the inversion procedure is applied using formula manipulation.

Key words. implicit nonlinear systems, solvability, right-invertibility

AMS subject classifications. 93C10, 93C55, 93B40

1. Introduction.

Controllability questions play a prominent role in the study of dynamical control systems. Among them the problem of right-inversion has, starting with the paper [4], received a lot of attention. Roughly speaking, a control system is right-invertible (also referred to as functionally reproducible or dynamic path controllable) if for all time paths in the output space, one can find an input sequence and an initial state $x(0)$ such that, applied to the system, the system generates precisely the given time path as its output. Practically, the problem consists of two parts: the decision whether or not a given system is right-invertible and, if the answer is affirmative, construction of a feedback/feedforward mechanism producing the desired inputs.

Concerning linear standard state-space systems, the problem of system inversion is satisfactorily solved. Some of the major references are [4], [18], and [19]. There also exist a number of articles dealing with the inversion of standard explicit nonlinear systems in continuous time, such as [16], [17], and [20], and similar work in discrete time (see, e.g., [11], [15]).

In this paper we are concerned with the right-inversion of implicit nonlinear discrete-time systems, a problem which, to the best of our knowledge, has not been considered before in this form. However, note that in [6], [7] left- and right-invertibility are characterized for (implicit) rational systems in a differential/difference algebraic language.

We formulate necessary and sufficient conditions for right-invertibility, and an inversion algorithm is introduced which can be used to obtain a right-inverse system in case such a system exists.

The results of this paper are inspired by a series of articles [12]–[14] by Luenberger in which he studied problems of the existence and uniqueness of solutions for both linear and nonlinear implicit discrete-time systems. As suggested by Luenberger (but not further pursued), we tackle the inversion problem as the solvability problem of the system with respect to the state variables and control variables; that is, we ask whether there exists for every given output sequence a sequence of states and inputs, respectively, such that the system equations are satisfied. For this purpose we generalize the shuffle algorithm given in [14] for linear

systems to the nonlinear setting. The outcome of this algorithm decides upon local solvability of the given implicit system and rearranges the system equations in a way that solutions can be obtained easily if they exist.

Note that the inversion algorithm introduced in this paper applies to implicit systems as well as to standard state-space systems. In the latter case it just reduces to the traditional inversion algorithm suggested in [11]. The order of the obtained inverse system is the same as the order of the original system.

To our knowledge, the approach suggested by Luenberger and used in this paper for constructing a right-inverse system has not been used before, even for linear systems. All the papers [2], [8], [21] seem to follow the traditional semiimplicit case where the dynamic part and the algebraic part are treated separately. This either causes a lot of trouble or leads to a very complicated inversion procedure. In [2], for instance, the author conjectures that his inversion procedure finds an inverse system whenever one exists, but a formal proof is not available. The procedure in [8] consists of three steps. At a first step, the consistency of the system equations with respect to states and control variables is checked. The second step deals with the construction of a so-called "candidate inverse system" whose order is in general greater than that of the original system. Finally, a finite iterative method is applied to the "candidate inverse" to reduce its dimension, either yielding an inverse system or providing evidence that there is no such system.

In our approach, we try to circumvent some of these disadvantages by directly attacking the problem of obtaining a right-inverse system without a preliminary test of the invertibility conditions. The shuffle algorithm provides both a simple criterion for checking invertibility and a systematic procedure for constructing a right-inverse system. Moreover, our method—in contrast to, for example, [8]—does not require state transformations.

A main part of the paper is dedicated to show that, in spite of the fact that the shuffle algorithm extensively uses the theorem on the functional dependence of functions, which, in turn, is based on the implicit function theorem, the procedure lends itself to a numerical treatment and may even be performed using formula manipulation in case the nonlinearities are not too serious.

The organization of this paper is as follows. In §2 we consider the solvability of nonlinear implicit systems over a finite time interval. Section 3 is concerned with the extension of the shuffle algorithm to nonlinear systems, and §4 connects the results of the previous sections. The problem of right-invertibility is addressed in §5. The purpose of §6 is to show in some detail how the methods introduced so far can be used to treat problems arising in economic policy making. Final remarks conclude the paper.

2. Preliminaries. In the following discussion we consider implicit nonlinear discrete-time systems described by equations of the form

$$\Sigma : \begin{cases} f(x(k+1), x(k), u(k)) &= 0, \\ h(x(k), u(k), y(k)) &= 0, \end{cases} \tag{1}$$

where, for all k, $x(k)$ belongs to some open part $\mathcal{X}$ of $\mathbb{R}^n$, the inputs $u(k)$ are in an open part $\mathcal{U}$ of $\mathbb{R}^m$, and the outputs $y(k)$ belong to some open set $\mathcal{Y}$ of $\mathbb{R}^p$. With regard to right-inversion we moreover assume $p \leq m$.

The mappings $f : \mathcal{X} \times \mathcal{X} \times \mathcal{U} \longrightarrow \mathbb{R}^s$, $s \leq n$, and $h : \mathcal{X} \times \mathcal{U} \times \mathcal{Y} \longrightarrow \mathbb{R}^p$ are supposed to be smooth; that is, all partial derivatives of the functions f and h exist and are continuous.

Remark 2.1. In the terminology of [23], systems of this type are state-space systems. Therefore, we do not hesitate to call the x variables states. In [12] and many other papers they are referred to as *descriptor variables* (or *generalized states* or *semi-states*), expressing their role in the modelling process. In order to differentiate among systems given in implicit

(respectively, explicit) state-space form, we call the latter systems in standard state-space form. Implicit systems may not be necessarily input-output systems; that is, u and y may not possess additional properties which qualify them as inputs and outputs, respectively. Despite of this we often refer to the u and y variables as inputs and outputs even if there is no justification to do so.

We work on a finite time interval $k = 0, 1, \ldots, k_F < \infty$, where k_F is supposed to be greater than n. Furthermore, we adopt a local point of view by assuming the existence of an equilibrium point for the system Σ; that means a point $(x_e, u_e, y_e) \in \mathcal{X} \times \mathcal{U} \times \mathcal{Y}$ satisfying $f(x_e, x_e, u_e) = 0$ and $h(x_e, u_e, y_e) = 0$. Throughout the paper, we work in a neighbourhood $\mathcal{X}^0 \times \mathcal{U}^0 \times \mathcal{Y}^0$ of this equilibrium point not further specified, although everything works in the same way in case Σ is given in a neighbourhood of a reference trajectory of the system (cf. §6).

Denote by $\mathcal{X}^0_{k_F}, \mathcal{U}^0_{k_F}$, and $\mathcal{Y}^0_{k_F}$ the sets of state variable sequences

$$\mathcal{X}^0_{k_F} := \{\{x(k)\}_{k=0}^{k=k_F} | x(k) \in \mathcal{X}^0, 0 \le k \le k_F\},$$

control sequences

$$\mathcal{U}^0_{k_F} := \{\{u(k)\}_{k=0}^{k=k_F-1} | u(k) \in \mathcal{U}^0, 0 \le k \le k_F - 1\},$$

and output sequences

$$\mathcal{Y}^0_{k_F} := \{\{y(k)\}_{k=0}^{k=k_F-1} | y(k) \in \mathcal{Y}^0, 0 \le k \le k_F - 1\}.$$

Individual members of these sets will be denoted $\mathbf{x}$, $\mathbf{u}$, and $\mathbf{y}$, respectively.

DEFINITION 2.2. *A triple* $(\mathbf{x}, \mathbf{u}, \mathbf{y}) \in \mathcal{X}^0_{k_F} \times \mathcal{U}^0_{k_F} \times \mathcal{Y}^0_{k_F}$ *is said to be admissible for* Σ *if it satisfies equations* (1) *on the time horizon considered.*

Remark 2.3. Since we are working on a finite time horizon, Σ may equivalently be considered, for a fixed $\mathbf{u}$, as a set of $k_F \times (s + p)$ nonlinear equations in the variables $x(0), y(0), x(1), \ldots, y(k_F - 1), x(k_F)$ (abbreviated $(\mathbf{x}, \mathbf{y})$).

Observe that in case of implicit system equations, the initial state $x(0)$ cannot be arbitrarily selected in general. This peculiarity arises because implicit system equations usually consist of a dynamic and an algebraic part of implicit equations. In the most general case, this algebraic part constitutes implicit relations which, at $k = 0$, relate the components of $x(0)$ and those of $u(0)$, including special cases such as relations between the components of $x(0)$ and $u(0)$, respectively, only. A free choice of $x(0)$ can therefore lead to inconsistencies in the system equations or impose constraints on the inputs. The latter is not desirable because the inputs are then not what is called "free" in system-theoretic terms. This unwanted situation especially occurs when there exist algebraic implicit equations relating only components of u. At any rate, performing the shuffle algorithm propagates these relations between $x(0)$ and $u(0)$, leading to equations of the form

$$L(x(0), u(0), u(1), \ldots, u(l)) = 0 \tag{2}$$

for some $l \le n$ (see Remark 3.1), and if these relations fail to hold for $x(0)$, the system equations are not satisfied. We call the initial variable $x(0)$ admissible if all the implicit algebraic relations which can be derived from Σ and which relate the components of $x(0)$ and $u(k)$, $0 \le k \le l$, hold for $x(0)$. We specify these implicit equations in §4 after extending the shuffle algorithm to nonlinear systems in §3. At the moment, we do not fix $x(0)$.

Moreover, again in contrast to systems in standard state-space form, in general neither existence nor uniqueness of solutions $(\mathbf{x},\mathbf{y})$ for Σ can be guaranteed for arbitrary control sequences $\mathbf{u} \in \mathcal{U}^0_{k_F}$ without further assumptions.

Luenberger [13] introduced the notion of local solvability for systems of the form

$$F_k(x(k+1), x(k)) = 0, \tag{3}$$

where the number $s = n$ of scalar equations of (3) equals dim x. If we interpret both x and y as descriptor variables, Σ may be considered, for a given input sequence $\mathbf{u}$, as a special case of (3), and the notion of solvability may be easily specified to our case. An input sequence $\mathbf{u}$ then merely specifies a certain set of functions F_k. Note, however, that we allow the number of scalar equations in (3) to be less than dim x.

Denote for $\alpha \in \mathbb{Z}$ the time shift operator by σ^α, that is, for instance $\sigma^\alpha x(k) = x(k+\alpha)$. In order to economize notations, we frequently drop time dependence if there is no danger of confusion.

For a given input sequence $\mathbf{u} \in \mathcal{U}^0_{k_F}$, let $\mathcal{M}_\mathbf{u}$ denote the set of pairs $(\mathbf{x}, \mathbf{y}) \in \mathcal{X}^0_{k_F} \times \mathcal{Y}^0_{k_F}$ such that (**x**,**u**,**y**) becomes an admissible triple of system Σ. Following Luenberger [13], we define the matrices

$$\begin{aligned}
A^i_{(x,u,y)} &= \frac{\partial f(\sigma x, x, u)}{\partial x}|_{x(i+1),x(i),u(i)}, \qquad 0 \le i \le k_F - 1,\\
E^i_{(x,u,y)} &= \frac{\partial f(\sigma x, x, u)}{\partial \sigma x}|_{x(i),x(i-1),u(i-1)}, \qquad 1 \le i \le k_F,\\
C^i_{(x,u,y)} &= \frac{\partial h(x, u, y)}{\partial x}|_{x(i),u(i),y(i)}, \qquad 0 \le i \le k_F - 1,\\
G^i_{(x,u,y)} &= \frac{\partial h(x, u, y)}{\partial y}|_{x(i),u(i),y(i)}, \qquad 0 \le i \le k_F - 1,
\end{aligned}$$

which are computed for every admissible (**x**,**u**,**y**). These matrices usually differ for different admissible triples. The same holds for the matrix $F_{(\mathbf{x},\mathbf{u},\mathbf{y})}(0, k_F)$ defined by

$$F_{(\mathbf{x},\mathbf{u},\mathbf{y})}(0, k_F) = \begin{pmatrix}
A^0 & 0 & E^1 & & & & & & \\
C^0 & G^0 & 0 & & & & & & \\
 & & A^1 & 0 & E^2 & & 0 & & \\
 & & C^1 & G^1 & 0 & & & & \\
 & & & & & \ddots & & & \\
 & & 0 & & & & A^{k_F-1} & 0 & E^{k_F} \\
 & & & & & & C^{k_F-1} & G^{k_F-1} & 0
\end{pmatrix}.$$

$F_{(\mathbf{x},\mathbf{u},\mathbf{y})}(0, k_F)$ is of size $k_F(s+p) \times [(k_F+1)n + k_F p]$ and is referred to as *solvability matrix*. Essentially, it represents the collection of coefficient matrices of the linearization of Σ along the admissible path (**x**,**u**,**y**).

DEFINITION 2.4 (see [13]). *The system Σ is said to be locally solvable about the equilibrium point (x_e, u_e, y_e) if there exist neighbourhoods $\mathcal{X}^0$, $\mathcal{U}^0$, and $\mathcal{Y}^0$ of x_e, u_e, and y_e, respectively, such that for every control sequence $\mathbf{u} \in \mathcal{U}^0_{k_F}$ the solvability matrix $F_{(\mathbf{x},\mathbf{u},\mathbf{y})}(0, k_F)$ has full row rank for every admissible triple.*

Remark 2.5. This definition essentially entails that if the conditions are satisfied, the solution set $\mathcal{M}_\mathbf{u}$ forms a manifold of dimension $(n-s)k_F + n$ for every $\mathbf{u} \in \mathcal{U}^0_{k_F}$ and thus displays a nice structure.

Remark 2.6. In connection with the question under which conditions nonlinear implicit state-space systems can be converted to standard state-space form, some sufficient conditions for the existence of solutions for nonlinear implicit systems that are considered over an infinite time horizon are derived in [9].

If system Σ is solvable on $0 \leq k \leq k_F - 1$, its solution is not unique. This follows from the fact that one has $(k_F+1)n+k_F p$ unknowns but only $k_F(s+p)$ equations. Thus in order to define a unique solution, $k_F(n-s)+n$ additional conditions have to be imposed to make the sequences of state vectors $\mathbf{x}$ and outputs $\mathbf{y}$ corresponding to a prescribed sequence of control vectors unique. Special cases of such additional conditions are initial ($x_{cond} = x(0)$) and final conditions ($x_{cond} = x(k_F)$) (both together also termed end-point conditions) or combinations of them. Evidently, in case of an explicitly given system in standard state-space form, where especially $n = s$, the necessary n additional conditions can always be obtained by fixing the initial value $x(0)$. For an arbitrary system Σ, an end-point conditioning is not always possible, and the degrees of freedom in the solution require one to restrict certain components of the x-vector also at intermediate points of time. Again, we specify these additional conditions in §4 after having extended the shuffle algorithm.

3. The shuffle algorithm. Strictly speaking, Definition 2.4 throws light upon two aspects of the solutions of Σ. If satisfied, it guarantees the existence of admissible triples for arbitrary $\mathbf{u} \in \mathcal{U}^0_{k_F}$, and it excludes pathological solution sets $\mathcal{M}_{\mathbf{u}}$. But it does not provide a computational means to obtain solutions.

In this section we generalize the shuffle algorithm given in [14] for linear systems to nonlinear implicit systems. We maintain the name "shuffle algorithm," although it does not become clear in the nonlinear setting where the name originates. In the linear case this name is derived from the fact that certain matrix blocks are "shuffled" from the right side to the left while performing the algorithm. As already mentioned, the result of this algorithm indicates whether or not Σ is solvable in the sense of Definition 2.4. Moreover it converts the system to a form which allows an easy—which here should be understood as recursive—computation of the solutions. The main operations of the shuffle algorithm are

1. separation of the functionally independent components in the system equations;
2. expression of the functionally dependent components by the independent ones;
3. restriction of the considered time horizon in order to avoid variables at time instants greater than k_F when time-shifting the arguments of the dependent components.

3.1. The shuffle algorithm. Before presenting the shuffle algorithm we want to draw attention to a part of the algorithm which may be difficult to grasp at first sight. It concerns the part immediately after expressing functionally dependent components by the independent ones in each step $l \geq 1$ of the algorithm. Having permuted independent and dependent components to obtain the system

$$[\Phi^{l^T}(x(k), u(k), \ldots, \sigma^{l-1}u(k)), \tilde{F}^{l^T}(\sigma x(k), x(k), u(k), \ldots, \sigma^{l-1}u(k), y(k))]^T = 0,$$

which is considered for $0 \leq k \leq k_F - l$, one temporarily interprets the system as collection of simultaneous equations in the variables $x(0), y(0), x(1), \ldots$ (cf. Remark 2.3). Then the system $F^{l+1} = 0$ is formed by deleting the equations

$$\Phi^l(x(0), u(0), \ldots, u(l-1)) = 0,$$

$$\tilde{F}^l(x(k_F - l + 1), x(k_F - l), u(k_F - l), \ldots, u(k_F - 1), y(k_F - l)) = 0.$$

This comes down to applying the time-shift operator σ to the dependent components Φ^l in the unpermuted system but avoids the occurrence of variables at time instants greater than k_F. The new system is considered on the restricted time horizon $0 \leq k \leq k_F - (l+1)$.

We now present the shuffle algorithm. In performing the algorithm one should keep in mind that most of the derived equations hold only along trajectories of Σ.

Let $F^1 := (f^T, h^T)^T$.

STEP 1

Define

$$\rho_1 := \operatorname{rank} \frac{\partial}{\partial(\sigma x, y)} F^1(\sigma x, x, u, y) \quad \left(= \operatorname{rank} \frac{\partial}{\partial(\sigma x, y)} \begin{bmatrix} f(\sigma x, x, u) \\ h(x, u, y) \end{bmatrix} \right),$$

and assume that $\rho_1 =$ constant in a neighbourhood of (x_e, u_e, y_e). If $\rho_1 < s + p$, then the components of the functions f and h are not independent but functionally related. Choose ρ_1 components of $(f^T, h^T)^T$, denoted by $(\tilde{f}^T, \tilde{h}^T)^T$, which are functionally independent, and define

$$\tilde{F}^1 := (\tilde{f}^T, \tilde{h}^T)^T.$$

The remaining $s + p - \rho_1$ components, denoted by $\hat{F}^1$, are functionally dependent and can therefore be expressed as a function of $\tilde{F}^1$, x, and u, that is,

$$\hat{F}^1(\sigma x, x, u, y) = \xi^1(\tilde{F}^1(\sigma x, x, u, y), x, u).$$

Since $\tilde{F}^1 = 0$, we have

$$\hat{F}^1(\sigma x, x, u, y) = \Phi^1(x, u) \tag{4}$$

for some function Φ^1. Write the system in the form $[\Phi^{1^T}(x, u), \tilde{F}^{1^T}(\sigma x, x, u, y)]^T = 0$, and define

$$F^2(\sigma x, x, u, \sigma u, y) := \begin{pmatrix} \tilde{F}^1(\sigma x, x, u, y) \\ \Phi^1(\sigma x, \sigma u) \end{pmatrix},$$

considered on the time horizon $0 \le k \le k_F - 2$.

Go to the next step.

If $\rho_1 = s + p$, then define

$$\tilde{F}^1 := F^1, \quad \Phi^1 := \hat{F}^1 = 0,$$

and the equation

$$\tilde{F}^1(\sigma x, x, u, y) = 0$$

can be solved locally for $s + p$ components of σx and y. In this case the algorithm stops.

STEP (l+1)

Suppose that in steps 1 through l the functions $F^{l+1} := (\tilde{F}^{l^T}, \Phi^{l^T})^T$, where $\tilde{F}^l$ and Φ^l are ρ_l- and $(s+p-\rho_l)$-dimensional, respectively, considered on the time interval $0 \le k \le k_F - (l+1)$, have been defined in such a way that

$$\tilde{F}^l(\sigma x, x, u, \sigma u, \ldots, \sigma^{l-1} u, y) = 0,$$

$$\Phi^l(\sigma x, \sigma u, \ldots, \sigma^l u) = 0,$$

and $\partial \tilde{F}^l(\cdot)/\partial(\sigma x, y)$ has full row rank equal to ρ_l in some neighbourhood of (x_e, u_e, y_e). Next define

$$\rho_{l+1} := \operatorname{rank} \frac{\partial}{\partial(\sigma x, y)} F^{l+1}(\sigma x, x, u, \ldots, \sigma^l u, y),$$

and assume that $\rho_{l+1} =$ constant in a neighbourhood of (x_e, u_e, y_e). If $\rho_{l+1} < s + p$, then the components of the functions $\tilde{F}^l$ and Φ^l are functionally dependent about (x_e, u_e, y_e). Choose $\rho_{l+1} - \rho_l$ components of Φ^l, denoted by $\tilde{\Phi}^l$, which together with $\tilde{F}^l$ are functionally independent, and define

$$\tilde{F}^{l+1} := (\tilde{F}^{l^T}, \tilde{\Phi}^{l^T})^T.$$

If $\rho_{l+1} = \rho_l$, then

$$\tilde{F}^{l+1} := \tilde{F}^l \text{ and } \hat{\Phi}^l := \Phi^l.$$

The remaining $s + p - \rho_{l+1}$ components, denoted by $\hat{\Phi}^l$, can be expressed as

$$\hat{\Phi}^l(\sigma x, \sigma u, \ldots, \sigma^l u) = \Phi^{l+1}(x, u, \ldots, \sigma^l u). \tag{5}$$

Write the system in the form $[\Phi^{(l+1)^T}(x, u, \ldots, \sigma^l u), \tilde{F}^{(l+1)^T}(\sigma x, x, u, \ldots, \sigma^l u, y)]^T = 0$, and define

$$F^{l+2}(\sigma x, x, u, \ldots, \sigma^{l+1} u, y) := \begin{pmatrix} \tilde{F}^{l+1}(\sigma x, x, u, \ldots, \sigma^l u, y) \\ \Phi^{l+1}(\sigma x, \sigma u, \ldots, \sigma^{l+1} u) \end{pmatrix},$$

considered on the time horizon $0 \le k \le k_F - (l + 2)$.

Go to the next step.

If $\rho_{l+1} = s + p$, define

$$\tilde{F}^{l+1} := F^{l+1}, \quad \Phi^{l+1} := \hat{\Phi}^l = 0,$$

and the equation

$$\tilde{F}^{l+1}(\sigma x, x, y, u, \ldots, \sigma^l u) = 0$$

can be solved locally for $s + p$ components of σx and y. Then the algorithm stops.

Remark 3.1. Before introducing the shuffle algorithm we have explained how the functions F^{l+1} in each step l of the algorithm are obtained by deleting certain equations. Some of these deleted equations, namely,

$$\Phi^1(x(0), u(0)) = 0, \quad \Phi^2(x(0), u(0), u(1)) = 0, \ldots, \quad \Phi^{l+1}(x(0), u(0), \ldots, u(l)) = 0,$$

are just the algebraic restrictions connecting $x(0)$ and successive inputs and which have already been mentioned in the preliminaries. They are indispensable for a consistent initialization of the system. The other part consists of such equations of system Σ in the interpretation of Remark 2.3 which already exhibit a maximal possible rank with respect to $x(k + 1)$ and $y(k)$ for k sufficiently large.

Remark 3.2. The algebraic constraints occur in the first step of the shuffle algorithm in form of the equation $\Phi^1(x, u) = 0$. It can happen that parts of these constraints involve only components of the inputs u. A consequence of this situation is that the inputs cannot be chosen

freely. Moreover it turns out that in this case the system is never solvable in the sense that we have defined above. If these particular constraints can be solved for a number of input components, we can take remedial measures by eliminating them. In case these constraints are inconsistent, the system is not solvable in any sense whatever. In the subsequent discussion we therefore exclude systems which exhibit constraints that only involve input components.

Remark 3.3. The following linear example is intended to show that $\rho_{l+1} = \rho_l$ is not sufficient for the termination of the algorithm, and hence a separate stopping criterion has to be introduced. Consider the system

$$\begin{aligned} x_1(k+1) + x_2(k) + x_3(k) &= 0, & x_2(k+1) + u(k) &= 0, \\ x_1(k) + x_2(k) &= 0, & y(k) + x_1(k) &= 0. \end{aligned}$$

Evidently, $\rho_1 = 3$ for this system, with $x_1(k) + x_2(k) = 0$ the functionally dependent component. Time-shifting this component does not increase the rank of the Jacobian with respect to $x(k+1)$ and $y(k)$, which results in $\rho_2 = 3$. It is not hard to see that in the third step we obtain $\rho_3 = 4$.

3.2. The stopping criterion. We now give the stopping criterion for the shuffle algorithm.

Denote $W^0 = 0$ and

$$W^l(x, u, \sigma u, \dots, \sigma^{l-1}u) = \begin{bmatrix} W^{l-1}(x, u, \sigma u, \dots, \sigma^{l-2}u) \\ \Phi^l(x, u, \sigma u, \dots, \sigma^{l-1}u) \end{bmatrix}, \qquad l \geq 1.$$

Define

$$r_l := \operatorname{rank} \frac{\partial}{\partial x} W^l(x, u, \sigma u, \dots, \sigma^{l-1}u),$$

and assume that for all $l \geq 1$, $r_l =$ constant in a neighbourhood of (x_e, u_e, y_e). Stop if

$$r_l = r_{l-1}. \tag{6}$$

LEMMA 3.1. *The stopping criterion* (6) *of the shuffle algorithm is always reached for some* $l \leq n$.

Proof. Note that the sequence $\{r_l : l \geq 1\}$ is nondecreasing by its definition. Hence, by the finite dimensionality of x, (6) must be reached for some $l \leq n$. □

Remark 3.4. Observe that the functions W^l are just the collection of the functionally dependent components up to step l and, for $k = 0$, contain all information about the algebraic restrictions on $x(0)$.

The next lemma shows that when condition (6) is satisfied, the sequence $\{\rho_l : l \geq 1\}$ defined by the shuffle algorithm has converged so that it can indeed be concluded that the algorithm has terminated.

LEMMA 3.2. *Denote by* α *the first integer* l *such that* (6) *is satisfied. Then* ρ_l *does not increase by further iterations of the algorithm, that is,* $\rho_l = \rho_\alpha$ *for all* $l > \alpha$.

Proof. The stopping criterion (6) or equivalently

$$\operatorname{rank} \frac{\partial}{\partial x} \begin{bmatrix} \Phi^1(\cdot) \\ \vdots \\ \Phi^{\alpha-1}(\cdot) \\ \Phi^\alpha(\cdot) \end{bmatrix} = \operatorname{rank} \frac{\partial}{\partial x} \begin{bmatrix} \Phi^1(\cdot) \\ \vdots \\ \Phi^{\alpha-1}(\cdot) \end{bmatrix}$$

implies that about the point (x_e, u_e)

$$\Phi^\alpha(x, u, \sigma u, \dots, \sigma^{\alpha-1}u) = \mu(\Phi^l, \dots, \Phi^{\alpha-1}, u, \sigma u, \dots, \sigma^{\alpha-1}u).$$

Since $\Phi^l(\cdot) = 0$ for $1 \leq l \leq \alpha - 1$, we have

$$\Phi^\alpha(x, u, \sigma u, \ldots, \sigma^{\alpha-1}u) = \lambda(u, \sigma u, \ldots, \sigma^{\alpha-1}u). \tag{7}$$

According to the shuffle algorithm define

$$\rho_{\alpha+1} := \operatorname{rank} \frac{\partial}{\partial(\sigma x, y)} \begin{bmatrix} \tilde{F}^\alpha(\sigma x, x, y, u, \sigma u, \ldots, \sigma^{\alpha-1}u) \\ \lambda(\sigma u, \ldots, \sigma^\alpha u) \end{bmatrix} = \operatorname{rank} \frac{\partial}{\partial(\sigma x, y)} \tilde{F}^\alpha(\cdot) = \rho_\alpha.$$

This means $\tilde{F}^{\alpha+1} = \tilde{F}^\alpha$ and $\hat{\Phi}^\alpha = \Phi^\alpha$, which by (7) is equal to λ.

Thus, it is clear that for every $l \geq 1$, $\Phi^{\alpha+l}$ does not depend on σx and y anymore, which completes the proof. □

Note that the application of the shuffle algorithm is not unique. In general there exist different selections of $\tilde{\Phi}^l$ in each step $l + 1$, $l \geq 1$, so that the matrix

$$\frac{\partial}{\partial(\sigma x, y)} \tilde{F}^{l+1}(\cdot) = \frac{\partial}{\partial(\sigma x, y)} \begin{bmatrix} \tilde{F}^l(\cdot) \\ \tilde{\Phi}^l(\cdot) \end{bmatrix}$$

has full row rank equal to ρ_{l+1} in a neighbourhood of (x_e, u_e, y_e). Note moreover that different choices of $\tilde{\Phi}^l$ result in different functions $\tilde{F}^{l+1}$ and Φ^{l+1}.

In the shuffle algorithm certain constant rank conditions have been imposed to ensure that the algorithm can be applied about a given equilibrium point. We summarize these conditions in the definition of regularity of an equilibrium point associated with the shuffle algorithm.

DEFINITION 3.5. *We call the equilibrium point (x_e, u_e, y_e) of the implicit system Σ regular with respect to the shuffle algorithm if for some specific application of the shuffle algorithm, the constant rank assumptions of the algorithm with respect to the sequence $\{\rho_l\}$ are satisfied. We call (x_e, u_e, y_e) strongly regular if this holds for each application of the algorithm.*

Although the result of the application of the shuffle algorithm apparently depends on the actual choice of $\tilde{\Phi}^l$ at each step of the algorithm, the sequences of quantities ρ_l and r_l are unique. We especially have the following lemma.

LEMMA 3.3. *About a strongly regular equilibrium point, the integers ρ_l, $l \geq 1$, do not depend on the specific application of the algorithm; that is, for any two applications of the algorithm we have*

$$\rho_l^1 = \rho_l^2, \qquad l \geq 1,$$

where superscripts refer to the application under consideration.

Proof. The proof is given in the appendix. □

From the proof of Lemma 3.3 one concludes that any "successful" application of the algorithm leads to the same sequence $\{\rho_l\}$ and thus to the same α. In particular, applying the shuffle algorithm about a strongly regular equilibrium point, one obtains a uniquely defined sequence of integers $\rho_1 \leq \rho_2 \leq \cdots \leq \rho_l \leq \cdots \leq s + p$. Define $\rho^* := \max\{\rho_l : l \geq 1\}$, and let α be defined as the smallest $l \in \mathbb{N}$ such that $\rho_\alpha = \rho^*$.

4. Necessary and sufficient conditions for local solvability.

4.1. Local solvability. It is clear that about a strongly regular equilibrium point the shuffle algorithm can terminate in either of the following ways:

(i) The rank of $\partial \tilde{F}^\alpha(\cdot)/\partial(\sigma x, y)$ is equal to $s + p$.

(ii) At least one function appears in Φ^α which does not depend on σx.

It will turn out that there exists a close connection between the solvability of the given implicit system and the outcome of the shuffle algorithm. In order to prove this relation, we have to provide an additional result.

In each step of the shuffle algorithm, functionally dependent components of certain functions are expressed as a function of the independent components and parameters. The purpose of the next lemma is to show that these manipulations have no influence on the row ranks of the row blocks of the solvability matrix $F_{(\mathbf{x},\mathbf{u},\mathbf{y})}(0, k_F)$.

To this end, consider the equation

$$F(z, x) = (F_1(z, x), \ldots, F_s(z, x))^T = 0,$$

where $\dim x = \dim z = n \geq s$. Suppose that in a neighbourhood of a point (z_0, x_0) with $F(z_0, x_0) = 0$ we have

$$\operatorname{rank} \frac{\partial F(z, x)}{\partial z} = \rho < s,$$

and assume moreover without loss of generality that

$$\operatorname{rank} \frac{\partial (F_1(z, x), \ldots, F_\rho(z, x))}{\partial z} = \rho. \tag{8}$$

Denote $\tilde{F} = (F_1, \ldots, F_\rho)^T$, $\hat{F} = (F_{\rho+1}, \ldots, F_s)^T$. Then we know that we can write

$$\hat{F}(z, x) = \xi(\tilde{F}, x),$$

which becomes for $\tilde{F}(z, x) = 0$ a function $\Phi(x)$ of x only. Now consider the matrices

$$A(z, x) = \begin{pmatrix} \frac{\partial \tilde{F}(z,x)}{\partial x} & \frac{\partial \tilde{F}(z,x)}{\partial z} \\ \frac{\partial \hat{F}(z,x)}{\partial x} & \frac{\partial \hat{F}(z,x)}{\partial z} \end{pmatrix} \text{ and } \overline{A}(z, x) = \begin{pmatrix} \frac{\partial \tilde{F}(z,x)}{\partial x} & \frac{\partial \tilde{F}(z,x)}{\partial z} \\ \frac{\partial \Phi(x)}{\partial x} & 0 \end{pmatrix}.$$

We then have the following lemma.

LEMMA 4.1. $\operatorname{rank} A(z, x) = \operatorname{rank} \overline{A}(z, x)$.

Proof. We show the existence of an invertible matrix,

$$M(z, x) = \begin{pmatrix} M_1(z, x) & M_2(z, x) \\ M_3(z, x) & M_4(z, x) \end{pmatrix},$$

such that $A(z, x) = M(z, x)\overline{A}(z, x)$. Set $M_1(z, x) = I_{\rho\times\rho}$, $M_2(z, x) = 0_{\rho\times(s-\rho)}$, and $M_4(z, x) = I_{(s-\rho)\times(s-\rho)}$. It remains to show the existence of a $((s - \rho) \times \rho)$ matrix $M_3(z, x)$ satisfying

$$M_3(z, x)\frac{\partial \tilde{F}(z, x)}{\partial x} + \frac{\partial \Phi(x)}{\partial x} = \frac{\partial \hat{F}(z, x)}{\partial x} \tag{9}$$

and

$$M_3(z, x)\frac{\partial \tilde{F}(z, x)}{\partial z} = \frac{\partial \hat{F}(z, x)}{\partial z}. \tag{10}$$

From $\hat{F}(z, x) = \xi(\tilde{F}, x)$ it follows that

$$\frac{\partial \hat{F}(z, x)}{\partial z} = \frac{\partial \xi(\tilde{F}, x)}{\partial \tilde{F}}\frac{\partial \tilde{F}(z, x)}{\partial z} \quad \text{and} \quad \frac{\partial \hat{F}(z, x)}{\partial x} = \frac{\partial \xi(\tilde{F}, x)}{\partial \tilde{F}}\frac{\partial \tilde{F}(z, x)}{\partial x} + \left.\frac{\partial \xi(\tilde{F}, x)}{\partial x}\right|_{(\tilde{F},x)}.$$

Observing that about solutions $\xi(0, x) = \Phi(x)$, it immediately follows that $M_3 = \frac{\partial \xi}{\partial F}$ satisfies (9) and (10). This means

$$A(z, x) = M(z, x)\overline{A}(z, x)$$

with a nonsingular matrix $M(z, x)$, and therefore rank $A(z, x) = \text{rank } \overline{A}(z, x)$. □

The main result of this subsection consists of the following theorem.

THEOREM 4.1. *About a strongly regular equilibrium point, the following statements are equivalent:*

1. $F_{(\mathbf{x},\mathbf{u},\mathbf{y})}(0, k_F)$ *has full row rank for every* $(\mathbf{x},\mathbf{y},\mathbf{u}) \in \mathcal{M}_{\mathbf{u}} \times \mathbf{u},\ \mathbf{u} \in \mathcal{U}^0_{k_F}$.
2. *The application of the shuffle algorithm with respect to* σx *and* y *terminates with* $\rho^* = s + p$.

Proof. Consider the solvability matrix $F_{(\mathbf{x},\mathbf{u},\mathbf{y})}(0, k_F)$ of the original system. According to Lemma 4.1, the solvability matrix $F^1_{(\mathbf{x},\mathbf{u},\mathbf{y})}(0, k_F)$ of the system obtained after the first step of the shuffle algorithm can be computed by multiplying the original one from the left by a permutation matrix Π^1 representing the permutations of the components of $F^1(\sigma x, x, u, y)$ performed in the first step and a nonsingular block diagonal matrix, the blocks of which consist of the inverses of matrices as obtained in Lemma 4.1, that is,

$$F^1_{(\mathbf{x},\mathbf{u},\mathbf{y})}(0, k_F) = \begin{bmatrix} M^1(x(1), x(0), u(0), y(0)) & & \\ & \ddots & \\ & & M^1(x(k_F), x(k_F-1), u(k_F-1), y(k_F-1)) \end{bmatrix} \Pi^1 F_{(\mathbf{x},\mathbf{u},\mathbf{y})}(0, k_F).$$

Now suppose that the solvability matrix $F^l_{(\mathbf{x},\mathbf{u},\mathbf{y})}(0, k_F)$ of the system obtained after the lth step of the shuffle algorithm (including the deleted parts) has been obtained by left-multiplying $F^{l-1}_{(\mathbf{x},\mathbf{u},\mathbf{y})}(0, k_F)$ by a nonsingular matrix. After the lth step, we are left with the modified system

$$\begin{aligned} \Phi^1(x(0), u(0)) &= 0, \\ &\vdots \\ \Phi^l(x(0), u(0), \ldots, u(l-1)) &= 0, \\ F^{l+1}(\sigma x, x, u, \sigma u, \ldots, \sigma^l u, y) &= 0, \\ \tilde{F}^l(\sigma x(k_F-l), x(k_F-l), u(k_F-l), \ldots, u(k_F-1), y(k_F-l)) &= 0, \\ &\vdots \\ \tilde{F}^1(x(k_F), x(k_F-1), u(k_F-1), y(k_F-1)) &= 0. \end{aligned}$$

The $(l+1)$th step modifies F^{l+1} only. If the solvability matrix of this restricted system is denoted by $F^l_{r_{(\mathbf{x},\mathbf{u},\mathbf{y})}}$ and that for the system after performing the $(l+1)$th step is denoted by $F^{l+1}_{r_{(\mathbf{x},\mathbf{u},\mathbf{y})}}$, we know that

$$F^{l+1}_{r_{(\mathbf{x},\mathbf{u},\mathbf{y})}} = \Gamma F^l_{r_{(\mathbf{x},\mathbf{u},\mathbf{y})}},$$

where Γ is some invertible matrix computed as described above. It is then clear that

$$F^{l+1}_{(\mathbf{x},\mathbf{u},\mathbf{y})}(0, k_F) = \text{diag}\,[I, \Gamma, I] F^l_{(\mathbf{x},\mathbf{u},\mathbf{y})}(0, k_F), \tag{11}$$

where the identity matrices in (11) represent the unaltered equations of the system above. Thus, applying the shuffle algorithm does not change the rank of the solvability matrices connected with the systems obtained in each step of the algorithm. Now consider the function

$$F^{(\alpha+1)}(\sigma x, x, u, \ldots, \sigma^\alpha u, y) := \begin{pmatrix} \tilde{F}^\alpha(\sigma x, x, u, \ldots, \sigma^{(\alpha-1)} u, y) \\ \Phi^\alpha(\sigma x, \sigma u, \ldots, \sigma^\alpha u) \end{pmatrix}$$

obtained in the final step of the shuffle algorithm. From the proof up to now and the special structure of $F^{(\alpha+1)}$ (Φ^α does not depend on x!), it immediately follows that $F_{(\mathbf{x},\mathbf{u},\mathbf{y})}(0, k_F)$ has full row rank if and only if $\rho^* = s + p$. □

From now on we assume that the shuffle algorithm terminates with $\rho_\alpha = s + p$. In this case, the implicit system Σ may be expressed locally in the equivalent form

$$\left.\begin{aligned} \tilde{f}(x(k+1), x(k), u(k)) &= 0, && 0 \le k \le k_F - 1, \\ \tilde{h}(x(k), u(k), y(k)) &= 0, && 0 \le k \le k_F - 1, \\ \tilde{\Phi}^1(x(k+1), u(k+1)) &= 0, && 0 \le k \le k_F - 2, \\ &\vdots \\ \tilde{\Phi}^{\alpha-1}(x(k+1), u(k+1), \ldots, u(k+\alpha-1)) &= 0, && 0 \le k \le k_F - \alpha, \end{aligned}\right\} \tag{12}$$

$$W^{\alpha-1}(x(0), u(0), \ldots, u(\alpha-2)) = 0, \tag{13}$$

where, according to the shuffle algorithm, (12) can be solved for $s + p$ components of $(x(k+1), y(k))$. Assume furthermore that these components contain all components of $y(k)$.

Remark 4.2. This full rank assumption with respect to the output components is very natural in view of right-inversion. In case it is not satisfied, there exist functional relations between the output components, making right-invertibility impossible. Those situations are often a result of overparameterization in the modelling process. A consequence of this assumption is $\tilde{h} = h$ in the first step of the shuffle algorithm.

Hence, possibly after reordering the components of x, (12) is solvable for

$$x^1(k+1) := [x_1(k+1), \ldots, x_s(k+1)] \quad \text{and} \quad y(k)$$

in terms of

$$x(k), u(k), \ldots, u(k+\alpha-1) \quad \text{and} \quad x^2(k+1) := [x_{s+1}(k+1), \ldots, x_n(k+1)],$$

that is,

$$\begin{aligned} x^1(k+1) &= \psi(x(k), u(k), \ldots, u(k+\alpha-1), x^2(k+1)), \\ y(k) &= \phi(x(k), u(k), \ldots, u(k+\alpha-1), x^2(k+1)), \end{aligned} \tag{14}$$

where these equations hold for $0 \le k \le k_F - \alpha$. For the role of (13) see Remark 3.4.

4.2. Uniqueness of solutions. The rest of this section is concerned with the question of how to impose further restrictions in order to make the solution of (12), (13) unique. Introduce the following notation:

$$\tilde{\Phi}^{(1,\alpha-1)} := [\tilde{\Phi}^{1^T}, \ldots, \tilde{\Phi}^{\alpha-1^T}]^T.$$

Consider (12), (13), and specify unique initial and final conditions via equations of the form

$$f^{init}(x^1(0)) = 0, \; f_1^{fin}(x^1(k_F - \alpha + 2)) = 0, \ldots, f_{\alpha-1}^{fin}(x^1(k_F)) = 0. \tag{15}$$

Here, $f^{init}, f_1^{fin}, \ldots, f_{\alpha-1}^{fin}$ are arbitrary functions with dimensions $s - r_{\alpha-1}$, $s + p - \rho_{\alpha-1}, \ldots, s + p - \rho_1$, respectively, such that

$$\operatorname{rank} \frac{\partial}{\partial x^1(0)} \begin{bmatrix} f^{init}(x^1(0)) \\ W^{\alpha-1}(x(0), u(0), \ldots, u(\alpha-2)) \end{bmatrix} = s, \tag{16}$$

$$\operatorname{rank} \frac{\partial}{\partial x^1(k_F-\alpha+2)} \begin{bmatrix} \tilde{f}(x(k_F-\alpha+2), x(k_F-\alpha+1), u(k_F-\alpha+1)) \\ \tilde{\Phi}^{(1,\alpha-2)}(x(k_F-\alpha+2), u(k_F-\alpha+2), \ldots, u(k_F-1)) \\ f_1^{fin}(x^1(k_F-\alpha+2)) \end{bmatrix} = s, \tag{17}$$

$$\vdots$$

$$\operatorname{rank} \frac{\partial}{\partial x^1(k_F-1)} \begin{bmatrix} \tilde{f}(x(k_F-1), x(k_F-2), u(k_F-2)) \\ \tilde{\Phi}^{(1,1)}(x(k_F-1), u(k_F-1)) \\ f_{\alpha-2}^{fin}(x^1(k_F-1)) \end{bmatrix} = s, \tag{18}$$

$$\operatorname{rank} \frac{\partial}{\partial x^1(k_F)} \begin{bmatrix} \tilde{f}(x(k_F), x(k_F-1), u(k_F-1)) \\ f_{\alpha-1}^{fin}(x^1(k_F)) \end{bmatrix} = s. \tag{19}$$

In order to make the solution unique, one has to specify x^2 for the whole time interval as well:

$$x^2(k) = x^{20}(k), \quad 0 \le k \le k_F. \tag{20}$$

After determining initial and final conditions and specifying $x^2(k)$ over the whole time interval, the number of equations and unknowns in equations (12), (13), (15), (20) is the same, and the system is still solvable.

A feature of the system equations as obtained after applying the shuffle algorithm is that they can be solved recursively if they are solvable at all.

1. From

$$f^{init}(x^1(0)) = 0,$$
$$W^{\alpha-1}(x^1(0), u(0), \ldots, u(\alpha-2)) = 0,$$

we compute $x^1(0)$.

2. Then, using $x^1(0)$ and the given control sequence $\mathbf{u} \in \mathcal{U}_{k_F}^0$, we obtain $x^1(k)$, $1 \le k \le k_F - \alpha + 1$, and $y(k)$, $0 \le k \le k_F - \alpha$, from (14).

3. Finally, by means of the set of equations

$$\begin{aligned}
\tilde{f}(x(k_F-\alpha+2), x(k_F-\alpha+1), u(k_F-\alpha+1)) &= 0, \\
h(x(k_F-\alpha+1), u(k_F-\alpha+1), y(k_F-\alpha+1)) &= 0, \\
\tilde{\Phi}^{(1,\alpha-2)}(x(k_F-\alpha+2), u(k_F-\alpha+2), \ldots, u(k_F-1)) &= 0, \\
f_1^{fin}(x^1(k_F-\alpha+2)) &= 0, \\
\vdots \qquad\qquad & \qquad \vdots \\
\tilde{f}(x(k_F-1), x(k_F-2), u(k_F-2)) &= 0, \\
h(x(k_F-2), u(k_F-2), y(k_F-2)) &= 0, \\
\tilde{\Phi}^{(1,1)}(x(k_F-1), u(k_F-1)) &= 0, \\
f_{\alpha-2}^{fin}(x^1(k_F-1)) &= 0, \\
\tilde{f}(x(k_F), x(k_F-1), u(k_F-1)) &= 0, \\
h(x(k_F-1), u(k_F-1), y(k_F-1)) &= 0, \\
f_{\alpha-1}^{fin}(x^1(k_F)) &= 0,
\end{aligned}$$

we obtain $x^1(k_F-\alpha+2)$, $y(k_F-\alpha+1), \ldots, x^1(k_F-1)$, $y(k_F-2)$ and $x^1(k_F)$,$y(k_F-1)$, respectively.

5. Right-invertibility. If the solvability conditions stated in Theorem 4.1 are satisfied, we know that there is for every locally given input sequence $\mathbf{u} \in \mathcal{U}^0_{k_F}$ at least one pair $(\mathbf{x},\mathbf{y})$ satisfying the system equations for $0 \le k \le k_F - 1$ or, stated equivalently, for every such $\mathbf{u}$ there exists $(\mathbf{x},\mathbf{y})$ such that $(\mathbf{x},\mathbf{u},\mathbf{y})$ is an admissible triple. Of course, one can ask as well whether or not the same holds true if, instead of $\mathbf{u}$, a sequence of outputs $\mathbf{y} \in \mathcal{Y}^0_{k_F}$ is considered to be given; that is, does there exist for arbitrary $\mathbf{y}$ a pair $(\mathbf{x},\mathbf{u})$ such that the system equations are satisfied? Obviously, this question can be decided by performing the shuffle algorithm with respect to σx and u. But this is basically what right-invertibility means: given a desired output trajectory, one wishes to determine a control sequence (not necessarily unique) that enforces the prespecified output trajectory. Thus, the problem of right-invertibility appears as the solvability problem of the system with respect to σx and u. To make things precise we use the following definition.

DEFINITION 5.1. *System Σ is said to be locally right-invertible in a neighbourhood of its equilibrium point (x_e, u_e, y_e) if for any sequence $\mathbf{y}^{ref} \in \mathcal{Y}^0_{k_F}$, it is possible to find $\mathbf{x}^{ref} \in \mathcal{X}^0_{k_F}$ and a control sequence $\mathbf{u}^{ref} \in \mathcal{U}^0_{k_F}$ such that $(\mathbf{x}^{ref}, \mathbf{u}^{ref}, \mathbf{y}^{ref})$ is admissible.*

As already mentioned, the right-inversion problem can be solved quite routinely via the shuffle algorithm. The algorithm can also be used to determine explicit recursive equations for the inverse system.

In order to differentiate between the two versions of the shuffle algorithm, that is, between the cases where we check the solvability with respect to σx and y or σx and u, we will refer to the second case as the inversion algorithm.

Introduce in addition to the matrices defined in §2 the following matrices:

$$B^i_{(x,u,y)} = \frac{\partial f(\sigma x, x, u)}{\partial u}|_{x(i+1),x(i),u(i)}, \qquad 0 \le i \le k_F - 1,$$
$$D^i_{(x,u,y)} = \frac{\partial h(x, u, y)}{\partial u}|_{x(i),u(i),y(i)}, \qquad 0 \le i \le k_F - 1,$$

and

$$G_{(\mathbf{x},\mathbf{u},\mathbf{y})}(0, k_F) = \begin{pmatrix} A^0 & B^0 & E^1 & & & & \\ C^0 & D^0 & 0 & & & & \\ & & A^1 & B^1 & E^2 & & \\ & & C^1 & D^1 & 0 & & \\ & & & & & \ddots & \\ & & 0 & & & A^{k_F-1} & B^{k_F-1} & E^{k_F} \\ & & & & & C^{k_F-1} & D^{k_F-1} & 0 \end{pmatrix},$$

where $G_{(\mathbf{x},\mathbf{u},\mathbf{y})}(0, k_F)$ is of size $k_F(s + p) \times [(k_F + 1)n + k_F m]$. Again, these matrices are defined along every admissible path $(\mathbf{x},\mathbf{u},\mathbf{y})$ of system Σ .

Similarly to Theorem 4.1 one now proves the following theorem.

THEOREM 5.2. *Consider system Σ about—with respect to the inversion algorithm—the strongly regular equilibrium point (x_e, u_e, y_e). Then the following statements are equivalent:*

1. *System Σ is locally right-invertible about (x_e, u_e, y_e).*
2. *$G_{(\mathbf{x},\mathbf{u},\mathbf{y})}(0, k_F)$ has full row rank for every $(\mathbf{x},\mathbf{u},\mathbf{y}) \in \mathcal{M}_{\mathbf{y}} \times \mathbf{y}$, $\mathbf{y} \in \mathcal{Y}^0_{k_F}$.*
3. *The application of the inversion algorithm terminates with $\rho^* = s + p$.*

6. Example: Economic policy making by right-inversion. The inversion algorithm (and the shuffle algorithm) essentially uses the implicit function theorem, which is frequently considered a restriction on the applicability of an algorithm. The aim of this section is to show by means of a realistic model that for many problems a numerical treatment is still possible.

Moreover if the nonlinearities are such that they include only, for instance, rational expressions (as is the case in most macroeconomic models), then an inverse system can even be obtained by symbolic computations.

The model we want to use for our considerations was created by Klein and Goldberger (cf. [10]) and adapted by a number of economists over the course of the years. It aimed at modelling the U.S. economy of the years 1929–1952 and is probably the first macroeconomic model used for economic forecasting (cf. [3]). This was done in a way still in use nowadays. The approach simply consists of predetermining a policy scenario and investigating the corresponding behaviour of the state variables by solving the system equations.

In this section we are going to demonstrate how the right-inversion approach of §5 can be employed to actively enforce a desired evolution of a number of (important) state variables depending on the number of control variables available to a policy maker.

6.1. The Klein–Goldberger model. In the sequel we use the Klein–Goldberger model as adapted by Adelman and Adelman [1]. The model consists of 22 state and 10 exogenous variables, the latter containing 4 control variables, which have the following meaning.

Exogenous control variables:

u_1 = government employee compensation,
u_2 = government expenditures for goods and services,
u_3 = government payment to farmers,
u_4 = number of government employees.

Exogenous variables with no interpretation as control variables:

z_1 = index of agricultural exports,
z_2 = number of persons in the United States,
z_3 = number of persons in the labour force,
z_4 = number of nonfarm entrepreneurs,
z_5 = number of farm operators,
z_6 = time in years; $z_6(0) = 0$ corresponds to the year 1929.

State variables:

x_1 = consumer expenditures in 1939 dollars,
x_2 = gross private domestic capital formation in 1939 dollars,
x_3 = corporate savings,
x_4 = corporate profits,
x_5 = capital consumption charges,
x_6 = private employee compensation,
x_7 = number of wage-and-salary earners,
x_8 = index of hourly wages,
x_9 = farm income,
x_{10} = index of agricultural prices,
x_{11} = end-of-year liquid assets held by persons,
x_{12} = end-of-year liquid assets held by businesses,
x_{13} = gross national product,

x_{14} = nonwage nonfarm income,
x_{15} = price index of gross national product,
x_{16} = end-of-year stock of private capital,
x_{17} = end-of-year corporate surplus,
x_{18} = indirect taxes less subsidies,
x_{19} = personal and payroll taxes less transfers,
x_{20} = corporate income tax,
x_{21} = personal and corporate taxes less transfers,
x_{22} = taxes less transfers associated with farm income,

where states and exogenous variables are combined by the following set of simultaneous implicit nonlinear equations:

$$x_1(k) = 0.55[x_6(k) + u_1(k) - x_{19}(k)] + 0.41[x_{14}(k) - x_{21}(k) - x_3(k)] + 0.34[x_9(k) + u_3(k) - x_{22}(k)] + 0.26x_1(k-1) + 0.072x_{11}(k-1) + 0.26z_2(k) - 22.26, \tag{21}$$

$$x_2(k) = 0.78[x_{14}(k-1) - x_{21}(k-1) + x_9(k-1) + u_3(k-1) - x_{22}(k-1) + x_5(k-1)] - 0.073x_{16}(k-1) + 0.14x_{12}(k-1) - 16.71, \tag{22}$$

$$x_3(k) = -3.53 + 0.72[x_4(k) - x_{20}(k)] - 0.027x_{17}(k-1), \tag{23}$$

$$x_4(k) = -7.60 + 0.68x_{14}(k), \tag{24}$$

$$x_5(k) = 7.25 + 0.05[x_{16}(k) + x_{16}(k-1)] + 0.044[x_{13}(k) - u_1(k)], \tag{25}$$

$$x_6(k) = -1.40 + 0.24[x_{13}(k) - u_1(k)] + 0.24[x_{13}(k-1) - u_1(k-1)] + z_6(k), \tag{26}$$

$$x_7(k) = \frac{[26.08 + x_{13}(k) - u_1(k) - 0.08x_{16}(k) - 0.08x_{16}(k-1) - 2.05z_6(k)]}{2.17 \times 1.062} + u_4(k) - [z_4(k) + z_5(k)]/1.062, \tag{27}$$

$$x_8(k) = x_8(k-1) + 4.11 - 0.74[z_3(k) - x_7(k) - z_4(k) - z_5(k)] + 0.52[x_{15}(k-1) - x_{23}(k-1)] + 0.54z_6(k), \tag{28}$$

$$x_9(k) = 0.054[x_6(k) + u_1(k) - x_{19}(k) + x_{14}(k) - x_{21}(k) - x_3(k)] + \frac{0.012z_1(k)x_{10}(k)}{x_{15}(k)}, \tag{29}$$

$$x_{10}(k) = 1.39x_{15}(k) + 32.0, \tag{30}$$

$$x_{11}(k) = 0.14[x_6(k) + u_1(k) - x_{19}(k) + x_{14}(k) - x_{21}(k) - x_3(k) + x_9(k) + u_3(k) - x_{22}(k)] + 76.03(1.5)^{-0.84}, \tag{31}$$

$$x_{12}(k) = 0.26x_6(k) - 2.55 - 0.26[x_{15}(k) - x_{15}(k-1)] + 0.61x_{12}(k-1), \tag{32}$$

$$x_{13}(k) = x_1(k) + x_2(k) + u_2(k), \tag{33}$$

$$x_{14}(k) = x_{13}(k) - x_{18}(k) - x_5(k) - x_6(k) - u_1(k) - x_9(k) - u_3(k), \tag{34}$$

$$x_{15}(k) = \frac{1.062x_7(k)x_8(k)}{(x_6(k) + u_1(k))}, \tag{35}$$

$$x_{16}(k) = x_{16}(k-1) + x_2(k) - x_5(k), \tag{36}$$

$$x_{17}(k) = x_{17}(k-1) + x_3(k), \tag{37}$$

$$x_{18}(k) = 0.0924x_{13}(k) - 1.3607, \tag{38}$$

$$x_{19}(k) = 0.1549x_6(k) + 0.131u_1(k) - 6.9076, \tag{39}$$

$$x_{20}(k) = 0.4497x_4(k) + 2.7085, \tag{40}$$

$$x_{21}(k) = \frac{0.2695x_{15}(k-1)}{x_{15}(k)}[x_{14}(k-1) - x_{20}(k-1) - x_3(k-1)] + 0.248[x_{14}(k) - x_{20}(k) - x_3(k)] + 0.4497x_4(k) - 5.7416, \tag{41}$$

$$x_{22}(k) = 0.0512[x_9(k) + u_3(k)], \tag{42}$$

$$x_{23}(k) = x_{15}(k-1) \tag{43}$$

with $x = (x_1, \ldots, x_{22})^T$ the vector of state variables, $u = (u_1, \ldots, u_4)$ the vector of exogenous control variables, and $z = (z_1, \ldots, z_6)$ the vector of exogenous variables without control interpretation. Considering the system equations above, one recognizes a number of deviations from the model form as given by (1). This mainly concerns the occurrence of lagged exogenous variables such as for instance $u_1(k)$ and $u_1(k-1)$ in (26). A second point is the explicit time dependence of the system via the variable z_6. We are therefore left with structural equations of the form

$$x(k) - f[x(k), x(k-1), u(k), u(k-1), z(k)] = 0, \tag{44}$$

where (43) is introduced only to avoid lag-2 variables.

The flexibility of the algorithm appears among other things in its robustness with respect to the model form. This is due to the fact that all variables which do not enter into the computation of Jacobians are treated on an equal footing by simply regarding them as parameters. Hence, even though it is possible to bring (44) to the form (1) by redefining variables if required, there is actually no need to do so. On the contrary, it would unnecessarily complicate the model!

The incorporation of time-varying exogenous variables without an interpretation as control variables in the model equations leads to the nonexistence of equilibrium points. The role of the equilibrium point is now taken over by the points of a reference trajectory about which the inversion algorithm may be performed. Eventually, the results can be patched together, provided that the applications of the inversion algorithm about each single reference point led to the same number of independent functions in each step of the algorithm, and moreover independent components could be chosen to be the same.

In the next subsection we demonstrate the right-invertibility of the considered model along the lines of §5. As it is common practice in economics, the goal will be the guidance of selected state variables as to enforce a desired behaviour.

6.2. Right-invertibility of the Klein–Goldberger model. The first part of the following investigations is dedicated to the generation of a reference trajectory for the considered model beyond the year 1952. This trajectory should reflect a reasonable—meaning economically possible—behaviour of the underlying system. Such a trajectory can be generated by determining the evolution of the state variables under the influence of exogenous variables obtained by extrapolating their historical trends and with initial conditions as actually observed. Information about initial values and extrapolations for the exogenous variables are taken from [1].

In order to perform the inversion algorithm we have to fix output equations. In view of the fact that we have only four control variables at our disposal, their number will naturally be bounded above by four if one wants to have an outlook for a positive result with respect to right-invertibility. This follows from well-known necessary right-invertibility conditions which generalize Tinbergen's counting rule for the inversion of static systems (cf. [22]).

As already mentioned, the most common objective in economics is the control of selected state variables rather than the control of certain combinations of them. The output equations are therefore chosen in the following form:

$$y_i(k) - x_{j_i}(k) = 0, \qquad i = 1, \ldots, 4; \qquad j_i \neq j_l \text{ for } i \neq l;$$

that is, the outputs consist of mutually different components of the vector of state variables. We now perform the inversion algorithm with an arbitrary selection of four outputs of the form above.

The Jacobian (with respect to $x(k)$ and $u(k)$) obtained in the first step of the algorithm is a simply structured rational matrix with only six nonconstant elements resulting from the nonlinearities in equations (29), (35), and (41). According to the occurrence of x_{15} and $(x_6 + u_1)$ as divisors in matrix elements, it can be computed for all combinations of variables where these terms do not vanish.

To determine its rank, one has to distinguish two cases. In the first case the selection of outputs is such that $x_{j_i} \neq x_2$, $i = 1, \ldots, 4$. Then the rank is maximal—that is, 27—independent (with exception of the restriction made above) of the chosen values of $x(k)$, $u(k)$, $y(k)$, and $z(k)$ and thus also along the considered reference trajectory resulting in a termination of the inversion algorithm. By Theorem 5.2 (global) right-invertibility of the system is ensured.

The remaining case is concerned with the situation in which $x_{j_i} = x_2$ for some i. Obviously, the rank of the Jacobian matrix obtained now is one less than maximal. Bearing in mind that the rank is computed with respect to $x(k)$ and $u(k)$, this is easily seen by comparing equations (22) and $y_i(k) - x_2(k) = 0$. Since (22) does not contain variables at time instant k others than $x_2(k)$, the corresponding rows of the Jacobian matrix will be dependent. The observed rank defect indicates the functional dependence of this output component which makes a representation

$$\begin{aligned} y_i(k) - x_2(k) = &- 0.78[x_{14}(k-1) - x_{21}(k-1) + x_9(k-1) + u_3(k-1) \\ &- x_{22}(k-1) + x_5(k-1)] + 0.073x_{16}(k-1) \\ &- 0.14x_{12}(k-1) + 16.71 + y_i(k) = 0 \end{aligned} \tag{45}$$

independent of $x(k)$ and $u(k)$ possible. Applying the shift operator σ to (45) we get a new equation in the variables $x(k)$ and $u(k)$. Adding this equation to the system of equations already recognized as functionally independent (seen as functions of $x(k)$ and $u(k)$) and computing the rank of the resulting Jacobian give full rank. Again the system is right-invertible. Hence, the inversion algorithm terminates after at most two steps irrespective of the selection of output functions.

In the next subsection we consider both cases with the help of concrete examples.

6.3. Some simulation results. As a first example we want to retrace results obtained by Chow in [5]. In this article similar objectives—namely, the guidance of certain state variables along desired paths—are pursued. However, the employed methods differ essentially from ours. Chow formulates the intended goal as an optimal control problem which is solved with the method of dynamic programming minimizing a quadratic loss function with respect to the control variables. The remarkable point is that dynamic programming is not applied directly to the nonlinear problem but instead relies on the linearized system. This involves an iterative computation of the control variables until convergence occurs.

As an illustration of his method, Chow used the Klein–Goldberger model. In a first control experiment he considered the number of wage-and-salary earners x_7, the gross national product x_{13}, the nonwage income x_{14}, and the price index of the gross national product x_{15} as targets and tried to steer them to grow at 2%, 5%, 5%, and 1% per year, respectively, from their initial values at 1952. This will also be the objective in our first simulation.

We have already seen in the previous subsection that with this choice of targets, the inversion algorithm terminates in the first step with a favourable outcome. Stated differently, the unmodified system can be solved for the controls and the state variables, which enables the computation of control values enforcing the intended growth of the targets. For the considered

example this leads for instance to the following time-varying nonlinear feedback generating the unique control sequence which achieves our goal. In the equations below most of the coefficients occur rounded off to four-digit accuracy.

$$
\begin{aligned}
u_1(k) = [&5.743y_1(k) + 1.034y_1^2(k) + 1.842y_4(k) + 0.316u_1(k-1)y_4(k)\\
&- 0.316y_2(k)y_4(k) - 1.034y_1(k)z_3(k) + 1.034y_1(k)z_4(k) + 1.034y_1(k)z_5(k)\\

&+ 0.064y_4(k)x_{16}(k-1) - 0.026y_4(k)x_{21}(k-1) - 0.026y_4(k)x_{22}(k-1)\\
&- 0.316y_1(k)x_{23}(k-1)]/y_4(k).
\end{aligned}
$$

This feedback has been obtained by means of formula manipulation packages and leads to the controls depicted in Figure 1 (computed with the exact coefficients). Incidentally, they coincide with those computed in [5] as far as they are available. The resulting closed-loop system generates the desired target paths (Figure 2). As an example for the second case we are going to steer the gross private domestic capital formation x_2 by means of the control variable u_2 to grow at a rate of, say, 5% per year, with extrapolations used for the other controls. It should be noticed that since x_2 is exclusively dependent on lagged variables and in view of fixed initial conditions for all involved quantities, we have no access to x_2 in the first year of the planning period. Afterwards, exact tracking can be achieved as above.

FIG. 1. *Time paths of the control variables.*

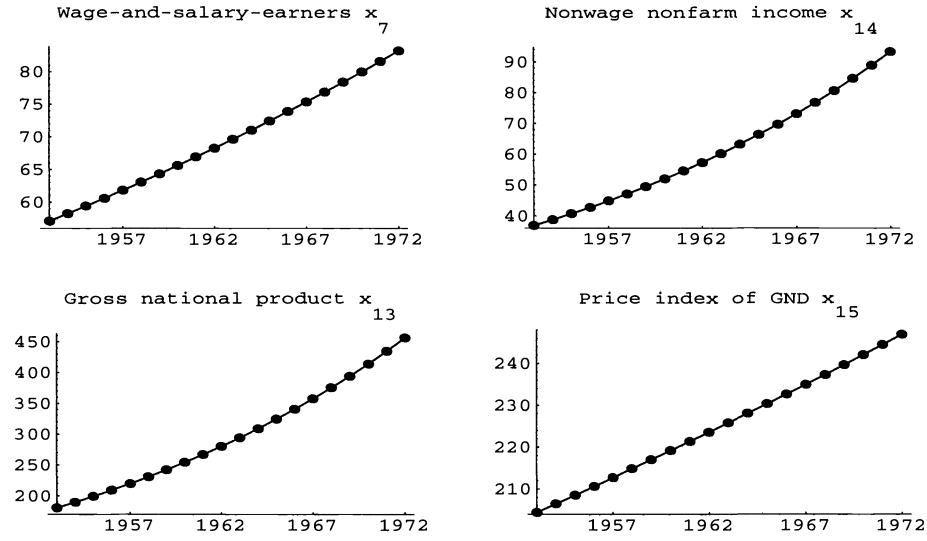

FIG. 2. *Computed target values.*

The results of the simulations can be seen in Figure 3. Clockwise, this figure shows the evolution of the gross private domestic capital formation x_2 as obtained by using extrapolated values for all exogenous variables, the desired time path of x_2, the computed sequence of controls attaining the control objective, and, finally, the resulting evolution of x_2. Again, exact matching is achieved starting with the year 1954.

7. Final remarks. In this article we focused on the problems of solvability and right-invertibility of implicit nonlinear discrete-time systems. The concept "solvability" has been defined for this class of systems in such a way that the existence of solutions for any locally given input sequence is ensured. Moreover we showed how this property can be checked algorithmically and how the algorithmically modified system can be equipped with additional conditions in order to obtain unique solutions which can be calculated recursively.

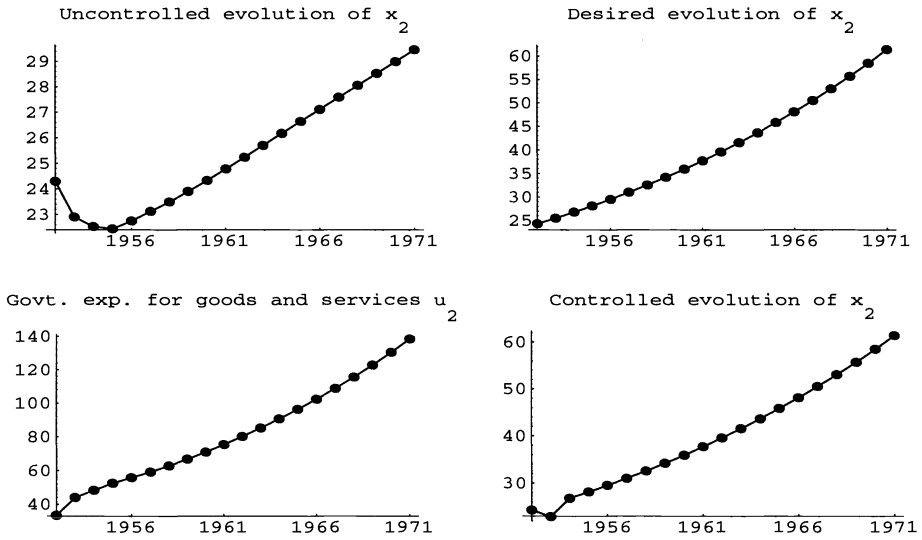

FIG. 3. *Time paths of the second control experiment.*

A second question was that of right-inversion of implicit systems. It turned out that the problem of right-inversion appears as a special solvability problem which can be solved quite routinely with the methods developed so far, lending itself to a numerical treatment.

We would like to mention that the approach used here to investigate the solvability of a difference-algebraic equation shows at least some similarity with the procedure which is used to determine what is called the *index* of a differential-algebraic equation, a natural number which is considered an indicator for the numerical complexity of such an equation. This similarity opens a wide field of research on the mutual connections between the solvability theories of constraint systems in discrete and continuous time.

Apart from a theoretical characterization of solvability and right-invertibility for implicit nonlinear discrete-time systems, a main objective was to demonstrate that important classes of such systems may be conveniently approached within the developed framework also from a computational point of view. One should not forget, however, that right-invertibility merely reflects an ideal with respect to a complete access to the outputs and does not say anything whatever about the possibility of a practical realization of the inputs required to enforce a desired output behaviour. Moreover, even if the necessary inputs can be generated, their values may not be acceptable from a practical point of view. A way out of this situation could consist in fixing an acceptance region for the inputs and finding, within this region, those inputs generating the output which is "nearest" to the desired one. We believe that the right-inversion approach as introduced above could be helpful in this direction.

Appendix.

Proof of Lemma 3.3. Consider the system of equations

$$f(z, x, u) = 0,$$
$$h(x, u, y) = 0,$$

and define $F := (f^T, h^T)^T$. Observe that we use slightly different notations to keep notations compact. In the first step of the shuffle algorithm let

$$\operatorname{rank} \partial F(z, x, u, y)/\partial(z, y) = \rho_1.$$

We show that ρ_2 does not depend on the selection of ρ_1 functionally independent (with respect to (z, y)) components of F in the first step. For the other steps, the proof is analogous. Now let $(\tilde{F}_1, \dots, \tilde{F}_{\rho_1}, \hat{F}_1, \dots, \hat{F}_{s+p-\rho_1})^T$ and $(\tilde{F}_1^*, \dots, \tilde{F}_{\rho_1}^*, \hat{F}_1^*, \dots, \hat{F}_{s+p-\rho_1}^*)^T$ denote two arbitrary permutations of components of F such that

$$\operatorname{rank} \frac{\partial F}{\partial(z, y)} = \operatorname{rank} \frac{\partial(\tilde{F}_1, \dots, \tilde{F}_{\rho_1})}{\partial(z, y)} = \operatorname{rank} \frac{\partial(\tilde{F}_1^*, \dots, \tilde{F}_{\rho_1}^*)}{\partial(z, y)} = \rho_1.$$

It then follows that

$$\hat{F}_k(z, x, u, y) = \xi_k(\tilde{F}_1, \dots, \tilde{F}_{\rho_1}, x, u), \qquad 1 \le k \le s + p - \rho_1,$$

and along trajectories of the system

$$\hat{F}_k(z, x, u, y) = \Phi_k(x, u).$$

Analogous equations hold for the starred functions. If $\{\tilde{F}_1, \dots, \tilde{F}_{\rho_1}\} = \{\tilde{F}_1^*, \dots, \tilde{F}_{\rho_1}^*\}$, nothing has to be shown. Assume therefore that this is not the case. Then there exists a number d with $1 \le d \le \rho_1 \le s + p$ such that the following hold:

$$\operatorname{card}(\{\tilde{F}_1^*, \dots, \tilde{F}_{\rho_1}^*\} \cap \{\hat{F}_1, \dots, \hat{F}_{s+p-\rho_1}\}) = d,$$

$$\operatorname{card}(\{\tilde{F}_1^*, \dots, \tilde{F}_{\rho_1}^*\} \cap \{\tilde{F}_1, \dots, \tilde{F}_{\rho_1}\}) = \rho_1 - d,$$

$$\operatorname{card}(\{\hat{F}_1^*, \dots, \hat{F}_{s+p-\rho_1}^*\} \cap \{\tilde{F}_1, \dots, \tilde{F}_{\rho_1}\}) = d,$$

$$\operatorname{card}(\{\hat{F}_1^*, \dots, \hat{F}_{s+p-\rho_1}^*\} \cap \{\hat{F}_1, \dots, \hat{F}_{s+p-\rho_1}\}) = s + p - \rho_1 - d.$$

Rename the components $(\tilde{F}_1, \dots, \tilde{F}_{\rho_1})$ and $(\hat{F}_1, \dots, \hat{F}_{s+p-\rho_1})$ on the one hand and the components $(\tilde{F}_1^*, \dots, \tilde{F}_{\rho_1}^*)$ and $(\hat{F}_1^*, \dots, \hat{F}_{s+p-\rho_1}^*)$ on the other hand to obtain

$$\begin{aligned}&(\tilde{F}_1^*, \dots, \tilde{F}_d^*, \tilde{F}_{d+1}^*, \dots, \tilde{F}_{\rho_1}^*, \hat{F}_1^*, \dots, \hat{F}_d^*, \hat{F}_{d+1}^*, \dots, \hat{F}_{s+p-\rho_1}^*)^T \\ &\quad = (\hat{F}_1, \dots, \hat{F}_d, \tilde{F}_1, \dots, \tilde{F}_{\rho_1-d}, \tilde{F}_{\rho_1-d+1}, \dots, \tilde{F}_{\rho_1}, \hat{F}_{d+1}, \dots, \hat{F}_{s+p-\rho_1})^T\end{aligned}$$

Observe that we only renamed components rather than altering groups of components that had been selected to be independent and dependent, respectively.

(i) For components $\hat{F}_1^*, \dots, \hat{F}_d^*$ we obtain

$$\begin{aligned}\hat{F}_k^* &= \xi_k^*(\tilde{F}_1^*, \dots, \tilde{F}_d^*, \tilde{F}_{d+1}^*, \dots, \tilde{F}_{\rho_1}^*, x, u) \\ &= \xi_k^*(\xi_1(\tilde{F}_1, \dots, \tilde{F}_{\rho_1}, x, u), \dots, \xi_d(\tilde{F}_1, \dots, \tilde{F}_{\rho_1}, x, u), \tilde{F}_{d+1}^*, \dots, \tilde{F}_{\rho_1}^*, x, u).\end{aligned}$$

Restricting ourselves to $\tilde{F}_1 = \cdots = \tilde{F}_{\rho_1} = 0$ we get, after applying the shift operator σ,

$$\xi_k^*(\Phi_1(z, u), \dots, \Phi_d(z, u), 0, \dots, 0, z, u) \equiv 0$$

$$\Longrightarrow \frac{\partial \xi_k^*}{\partial(z, y)} = \frac{\partial \xi_k^*}{\partial \tilde{F}_1^*} \frac{\partial \Phi_1}{\partial(z, y)} + \cdots + \frac{\partial \xi_k^*}{\partial \tilde{F}_d^*} \frac{\partial \Phi_d}{\partial(z, y)} + \frac{\partial \Phi_k^*}{\partial(z, y)} \equiv 0$$

$$\Longrightarrow \frac{\partial \Phi_k^*}{\partial(z, y)} = -\left(\frac{\partial \xi_k^*}{\partial \tilde{F}_1^*} \frac{\partial \Phi_1}{\partial(z, y)} + \cdots + \frac{\partial \xi_k^*}{\partial \tilde{F}_d^*} \frac{\partial \Phi_d}{\partial(z, y)} \right).$$

(ii) For components $\hat{F}^*_{d+1}, \ldots, \hat{F}^*_{s+p-\rho_1}$ we get by similar computations

$$\frac{\partial \Phi^*_k}{\partial(z, y)} = \frac{\partial \Phi_k}{\partial(z, y)} - \left(\frac{\partial \xi^*_k}{\partial \tilde{F}^*_1} \frac{\partial \Phi_1}{\partial(z, y)} + \cdots + \frac{\partial \xi^*_k}{\partial \tilde{F}^*_d} \frac{\partial \Phi_d}{\partial(z, y)} \right).$$

Partial derivatives with respect to y occurring in (i) and (ii) are of course equal to zero and appear only for formal reasons. $\partial \Phi^*/\partial(z, y)$ and $\partial \Phi/\partial(z, y)$ are therefore connected via

$$\text{(46)} \quad \left(\begin{array}{c} \frac{\partial \Phi^*_1}{\partial(z,y)} \\ \vdots \\ \frac{\partial \Phi^*_d}{\partial(z,y)} \\ \hline \frac{\partial \Phi^*_{d+1}}{\partial(z,y)} \\ \vdots \\ \frac{\partial \Phi^*_{s+p-\rho_1}}{\partial(z,y)} \end{array} \right) = \left(\begin{array}{ccc|ccc} -\frac{\partial \xi^*_1}{\partial \tilde{F}^*_1} & \cdots & -\frac{\partial \xi^*_1}{\partial \tilde{F}^*_d} & 0 & \cdots & 0 \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ -\frac{\partial \xi^*_d}{\partial \tilde{F}^*_1} & \cdots & -\frac{\partial \xi^*_d}{\partial \tilde{F}^*_d} & 0 & \cdots & 0 \\ \hline -\frac{\partial \xi^*_{d+1}}{\partial \tilde{F}^*_1} & \cdots & -\frac{\partial \xi^*_{d+1}}{\partial \tilde{F}^*_d} & 1 & \cdots & 0 \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ -\frac{\partial \xi^*_{s+p-\rho_1}}{\partial \tilde{F}^*_1} & \cdots & -\frac{\partial \xi^*_{s+p-\rho_1}}{\partial \tilde{F}^*_d} & 0 & \cdots & 1 \end{array} \right) \left(\begin{array}{c} \frac{\partial \Phi_1}{\partial(z,y)} \\ \vdots \\ \frac{\partial \Phi_d}{\partial(z,y)} \\ \hline \frac{\partial \Phi_{d+1}}{\partial(z,y)} \\ \vdots \\ \frac{\partial \Phi_{s+p-\rho_1}}{\partial(z,y)} \end{array} \right).$$

Denote the coefficient matrix of (46) by A. A is invertible if and only if the upper left corner is nonsingular. It will turn out later that this is indeed the case. Now consider the set of components

$$\begin{aligned} (\tilde{F}_1, \ldots, \tilde{F}_{\rho_1}) &= (\tilde{F}^*_{d+1}, \ldots, \tilde{F}^*_{\rho_1}, \hat{F}^*_1, \ldots, \hat{F}^*_d) \\ &= (\tilde{F}^*_{d+1}, \ldots, \tilde{F}^*_{\rho_1}, \xi^*_1(\tilde{F}^*_1, \ldots, \tilde{F}^*_{\rho_1}, x, u), \ldots, \xi^*_d(\tilde{F}^*_1, \ldots, \tilde{F}^*_{\rho_1}, x, u)). \end{aligned}$$

This provides the following relation between

$$\frac{\partial(\tilde{F}_1, \ldots, \tilde{F}_{\rho_1})}{\partial(z, y)} \quad \text{and} \quad \frac{\partial(\tilde{F}^*_1, \ldots, \tilde{F}^*_{\rho_1})}{\partial(z, y)}:$$

$$\text{(47)} \quad \left(\begin{array}{c} \frac{\partial \tilde{F}_1}{\partial(z,y)} \\ \vdots \\ \frac{\partial \tilde{F}_{\rho_1-d}}{\partial(z,y)} \\ \hline \frac{\partial \tilde{F}_{\rho_1-d+1}}{\partial(z,y)} \\ \vdots \\ \frac{\partial \tilde{F}_{\rho_1}}{\partial(z,y)} \end{array} \right) = \left(\begin{array}{ccc|ccc} 0 & \cdots & 0 & 1 & \cdots & 0 \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ 0 & \cdots & 0 & 0 & \cdots & 1 \\ \hline \frac{\partial \xi^*_1}{\partial \tilde{F}^*_1} & \cdots & \frac{\partial \xi^*_1}{\partial \tilde{F}^*_d} & \frac{\partial \xi^*_1}{\partial \tilde{F}^*_{d+1}} & \cdots & \frac{\partial \xi^*_1}{\partial \tilde{F}^*_{\rho_1}} \\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ \frac{\partial \xi^*_d}{\partial \tilde{F}^*_1} & \cdots & \frac{\partial \xi^*_d}{\partial \tilde{F}^*_d} & \frac{\partial \xi^*_d}{\partial \tilde{F}^*_{d+1}} & \cdots & \frac{\partial \xi^*_d}{\partial \tilde{F}^*_{\rho_1}} \end{array} \right) \left(\begin{array}{c} \frac{\partial \tilde{F}^*_1}{\partial(z,y)} \\ \vdots \\ \frac{\partial \tilde{F}^*_d}{\partial(z,y)} \\ \hline \frac{\partial \tilde{F}^*_{d+1}}{\partial(z,y)} \\ \vdots \\ \frac{\partial \tilde{F}^*_{\rho_1}}{\partial(z,y)} \end{array} \right).$$

Denote the coefficient matrix of (47) by B. Observe that the lower left corner of B is, up to the sign, equal to the upper left corner of A. Since

$$\frac{\partial(\tilde{F}_1, \ldots, \tilde{F}_{\rho_1})}{\partial(z, y)} \quad \text{and} \quad \frac{\partial(\tilde{F}^*_1, \ldots, \tilde{F}^*_{\rho_1})}{\partial(z, y)}$$

have full row rank by assumption, B and consequently its lower left corner must be invertible in a neighbourhood of $(x_e, u_e, y_e) \implies A$ is invertible.

It finally follows that

$$\begin{pmatrix} \frac{\partial \tilde{F}_1^*}{\partial(z,y)} \\ \vdots \\ \frac{\partial \tilde{F}_{\rho_1}^*}{\partial(z,y)} \\ \frac{\partial \Phi_1^*}{\partial(z,y)} \\ \vdots \\ \frac{\partial \Phi_{s+p-\rho_1}^*}{\partial(z,y)} \end{pmatrix} = \begin{pmatrix} B^{-1} & 0 \\ 0 & A \end{pmatrix} \begin{pmatrix} \frac{\partial \tilde{F}_1}{\partial(z,y)} \\ \vdots \\ \frac{\partial \tilde{F}_{\rho_1}}{\partial(z,y)} \\ \frac{\partial \Phi_1}{\partial(z,y)} \\ \vdots \\ \frac{\partial \Phi_{s+p-\rho_1}}{\partial(z,y)} \end{pmatrix},$$

which proves that ρ_2 will not depend on the choice of independent components in Step 1.

A TARGET RECOGNITION PROBLEM: SEQUENTIAL ANALYSIS AND OPTIMAL CONTROL*

MARK H. A. DAVIS† AND MOHAMMAD FARID‡

Abstract. An iterative computational method for determining the value function of an optimal control problem, related to target tracking, is presented. The target is assumed to be located in a fixed known position in space, but its identity (hostile or friendly) is known only with a prior probability. An observation of the target can be made at any location, and its error has position-dependent probability. The objective is finding the optimal navigation and observation strategy which leads to a final decision (i.e., the target is friendly or hostile). The value function is shown to be the unique viscosity solution of a variational inequality. Furthermore it is the unique fixed point of a nondecreasing concave operator.

Key words. optimal control, viscosity solutions, variational inequality, dynamic programming, Hamilton–Jacobi–Bellman equation, target tracking, hypothesis testing

1. Introduction.

An aircraft locates a target and seeks to classify it as one of a finite number of possible objects. This is done by taking a sequence of observations, each observation (consisting, say, of emission of a radar pulse) being processed to produce a classification which is subject to errors occurring with distance and relative orientation-dependent probabilities. After a certain number of observations a final classification decision is made. There are known penalties for misclassification and costs associated with taking observations. The latter might be actual costs of physically taking an observation, or more indirect penalties associated with, for example, the risk of giving one's own position away by emitting a radar pulse. The problem is to decide how to navigate, when to take the observations, and at what point to make a final classification, in such a way as to minimize overall costs.

This problem incorporates features of several traditional statistical and control-theoretic paradigms. It is *sequential analysis* in that a data-dependent number of observations is taken. There is an element of *experimental design* in that the distribution of the observations is not fixed in advance but depends on some design parameters. It is *optimal control* in that these design parameters are actually the control inputs to a dynamical system. This combination of features does not appear to have been studied before, and our objective is to outline how the problem is solved in a fairly simple setting, described in more detail below.

The problem arose in connection with a study of Bayes-optimal tracking and interception strategies. It has of course been widely appreciated since the pioneering work of Fel'dbaum [F] on "dual control" that control problems in which the control is used with a view to acquiring information as well as steering along a low-cost trajectory are typically extremely hard. Considerable insight into the form of optimal strategies in the case of a binary (friend/foe) classification with penalties for missing a foe or hitting a friend has been gained by exact solution of very simple discrete-time models [H]. It turns out that, typically, an optimal strategy avoids "commitment" as long as possible, steering to a point as close to the target as possible but from which both hitting the target and avoiding it are still feasible. Up to arrival at this point the main function of the control action is information gathering. At the "commitment point"

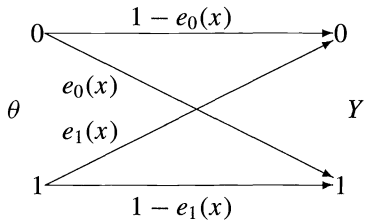
a classification decision must be made and the appropriate subsequent action taken. To study tracking in a more general setting it seems worthwhile to isolate the "information-gathering" phase as a separate problem in its own right, and this is what we do in the present paper. Of course, various applications of the problem formulation, other than the one outlined above, are easily envisaged.

The paper is laid out as follows. In §2 below a precise formulation of the problem is given. As will be seen, the target is assumed to be stationary and the "own vehicle" dynamics are deterministic, so the only sources of uncertainty in the problem arise from the classification mechanism. For simplicity we assume a binary (friend/foe) classification, but the theory would be the same for any finite classification. In §3 Bayes' formula is used to make an information-updating procedure after each observation. A dynamic programming formulation of the problem is described, and the variational inequality formally satisfied by the value function is obtained. Later in §4 the value function is proven to be the unique viscosity solution of this variational inequality. We also present a computational algorithm for the value function and prove its convergence. Finally, some simulation results are presented in §5.

2. Problem formulation. A target is located in a certain fixed known position in space but may be hostile or friendly. Let $\theta = \mathbf{1}_{(\text{target is hostile})}$, and suppose that the event $(\theta = 1)$ has prior probability p_0. An observation of the target can be made at any point x in space (or, more generally, at any point in the state space of the vehicle; see below), and the observation device produces an output Y which takes the values 0, 1 and misclassifies the target with position-dependent probabilities $e_0(x)$, $e_1(x)$, i.e., $P[Y = 1|\theta = 0] = e_0(x)$ and $P[Y = 0|\theta = 1] = e_1(x)$ (see below).



For definiteness, we assume that

$$0 < r \leq e_0(x), e_1(x) \leq \frac{1}{2}. \tag{1}$$

The observations are taken from a vehicle whose state $x(s)$ satisfies the dynamical equation

$$\dot{x}(s) = g(x(s), u(s)). \tag{2}$$

Here $x(s) \in \mathbb{R}^n$ and $u(s)$ is a control, taking values in U, a subset of $\mathbb{R}^m$. We make the following assumptions:

(3) U is compact,

(4) $g \in C(\mathbb{R}^n \times U)$,

(5) $\exists K > 0$: $|g(x, u) - g(x', u)| \leq K|x - x'| \quad \forall x, x' \in \mathbb{R}^n$ and $\forall u \in U$,

(6) g is bounded.

Equation (2) then has a global solution for any measurable control function $u(\cdot)$ and starting point $x(0)$.

An *observation strategy* is a collection $S = \{k, \tau_1, \dots, \tau_k, u, d\}$, where k is a nonnegative integer, $\tau_1 \le \tau_2 \le \cdots \le \tau_k$ are observation times (there are none of these if $k = 0$), $u = \{u(t), 0 \le t \le \tau_k\}$ is a control, and d is a final classification of the target. Observations Y_j are taken at each time τ_j, $j = 1, \dots, k$ (when the vehicle's state is $x(\tau_j)$).

Admissible strategies are nonanticipative in the sense that either $k = 0$ and $d \in \{0, 1\}$ is fixed decision or $\tau_1 \ge 0$ and $u_1 = \{u(t), 0 \le t \le \tau_1\}$ are fixed and τ_j and $u_j = \{u(t), \tau_{j-1} < t \le \tau_j\}$ are functions of $(Y_1, \dots, Y_{j-1})$ only, for $j = 2, \dots, k$. It may be the case that $\tau_{j-1} = \tau_j$ with positive probability. The number k is a stopping time of the filtration $\mathcal{Y}_j = \sigma\{Y_1, \dots, Y_j\}$, and the decision d is $\mathcal{Y}_k$-measurable. A penalty or cost $\ell_1 > 0$ is incurred if a hostile target is identified as friendly, and a cost $\ell_2 > 0$ is incurred for the converse error. In addition, a cost of $c(x(\tau_j))$ is paid each time that an observation is taken, and a cost $\ell(x, u)$ per unit time is paid when the vehicle is in state x, control action u is applied, and $t < \tau_k$. We assume $c(x)$, $\ell(x, u) \ge \delta > 0$, and that c, ℓ are uniformly continuous on $\mathbb{R}^n$ and $\mathbb{R}^n \times U$, respectively. The problem is now to choose a strategy S to minimize

$$J(S) = \mathbb{E}\left\{\int_0^{\tau_k} \ell(x(s), u(s))\, ds + \sum_{j=1}^{k} c(x(\tau_j)) + \ell_1(1-d)\theta + \ell_2\, d(1-\theta)\right\}. \tag{7}$$

One possible strategy is to make an immediate decision at time zero without taking any observations, and for this strategy clearly $J(S) \le L = \max(\ell_1, \ell_2)$. We can therefore restrict attention to strategies such that $\mathbb{E}[k]$, $\mathbb{E}[\tau_k] \le L/\delta$, so that in particular k and τ_k are finite with probability 1.

Let $\pi_{\tau_k} = P[\theta = 1 | \mathcal{Y}_k]$. Temporarily writing $\pi = \pi_{\tau_k}$, we have

$$\begin{aligned}\mathbb{E}[\ell_1(1-d)\theta + \ell_2\, d(1-\theta)] &= \mathbb{E}[\ell_1(1-d)\pi + \ell_2\, d(1-\pi)] \\ &= \mathbb{E}[\ell_1\pi + (\ell_2 - (\ell_1+\ell_2)\pi)d].\end{aligned}$$

The minimum cost decision is therefore $d = \mathbf{1}_{(\pi \ge \ell_2/(\ell_1+\ell_2))}$. Thus d can be taken out of the problem and the cost written as

$$J(S) = \mathbb{E}\left\{\int_0^{\tau_k} \ell(x(s), u(s))\, ds + \sum_{j=1}^{k} c(x(\tau_j)) + h(\pi_{\tau_k})\right\}, \tag{8}$$

where

$$h(\pi) := \min\{\pi\ell_1,\ (1-\pi)\ell_2\}. \tag{9}$$

3. Dynamic programming. For a strategy S, define the filtration $\mathcal{F}_t$ as follows:

$$\mathcal{F}_t := \sigma\{Y_j\, \mathbf{1}_{(\tau_j \le t)},\quad j = 1, 2, \dots\}.$$

Clearly $\mathcal{F}_t \bigcap(\tau_j \le t < \tau_{j+1}) = \mathcal{F}_{\tau_j} \bigcap(\tau_j \le t < \tau_{j+1})$. We denote $\pi(t) = P[\theta = 1 | \mathcal{F}_t]$. At time τ_j, random variable Y_j is observed. Denote temporarily $\pi = \pi(\tau_j^-)$ $(= \pi(\tau_{j-1})$ if $\tau_j > \tau_{j-1})$ and $x = x(\tau_j)$. By Bayes' formula, π is updated to π_0' or π_1' when Y_j takes the values 0 or 1, respectively, where π_0' and π_1' are given by

$$\begin{aligned}\pi_0' &= P_\pi[\theta = 1 | Y = 0] \\ &= \frac{P[Y = 0|\theta = 1]\, P_\pi[\theta = 1]}{P[Y = 0|\theta = 1]\, P_\pi[\theta = 1] + P[Y = 0|\theta = 0]\, P_\pi[\theta = 0]} \\ &= \frac{e_1(x)\pi}{e_1(x)\pi + (1 - e_0(x))(1-\pi)}, \qquad (10)\end{aligned}$$

and similarly

$$\pi_1' = \frac{(1 - e_1(x))\pi}{(1 - e_1(x))\pi + e_0(x)(1 - \pi)}. \tag{11}$$

If $V: \mathbb{R}^n \times [0, 1] \longmapsto \mathbb{R}$ is a given bounded measurable function, we therefore have

$$\begin{aligned}\mathbb{E}[V(x(\tau_j), \pi(\tau_j))|\mathcal{F}_{\tau_j^-}] &= V(x, \pi_0')\ P_\pi[Y_{\tau_j} = 0] + V(x, \pi_1')\ P_\pi[Y_{\tau_j} = 1] \\ &= V(x, \pi_0') + (V(x, \pi_1') - V(x, \pi_0'))((1 - e_1(x))\pi \\ &\qquad + e_0(x)(1 - \pi)),\end{aligned}$$

since

$$\begin{aligned}P_\pi[Y_{\tau_j} = 1] &= P_\pi[Y_{\tau_j} = 1|\theta = 1]\ P_\pi[\theta = 1] + P_\pi[Y_{\tau_j} = 1|\theta = 0]\ P_\pi[\theta = 0] \\ &= (1 - e_1(x))\pi + e_0(x)(1 - \pi),\end{aligned} \tag{12}$$

and $P_\pi[Y_{\tau_j} = 0] = 1 - P_\pi[Y_{\tau_j} = 1]$. We define an operator M acting on the space of bounded measurable functions as follows:

$$MV(x, \pi) := c(x) + V(x, \pi_0') + (V(x, \pi_1') - V(x, \pi_0'))((1 - e_1(x))\pi + e_0(x)(1 - \pi)), \tag{13}$$

where π_0', π_1' are defined by (10) and (11). $MV(x, \pi)$ represents the average cost paid if one observation Y is taken, updating the original π to $\pi^+ = \pi_0'\ \mathbf{1}_{(Y=0)} + \pi_1'\ \mathbf{1}_{(Y=1)}$, and then a cost $V(x, \pi^+)$ is paid. For example, let S' be the strategy such that $k = 1$ and $\tau_k = 0$; i.e., one observation is taken at time zero and then a decision is made. Then $J(S') = M\upsilon_0(x, p_0)$, where $\upsilon_0(x, \pi) = h(\pi)$, h is given by (9), and p_0 is the prior probability that $\theta = 1$.

Define the *value function* $W(x, \pi)$ as

$$W(x, \pi) = \inf_{S \in \mathbb{S}_{ad}} \mathbb{E}\left\{\int_0^{\tau_k} \ell(x(s), u(s))\, ds\ + \sum_{j=1}^{k} c(x(\tau_j)) + h(\pi(\tau_k))\right\}, \tag{14}$$

where x and π are, respectively, the starting point and the prior classification probability and $\mathbb{S}_{ad}$ is the set of all admissible strategies as defined in §2. At time zero, there are three possible courses of action:

(i) Take no observations and make an immediate decision; expected cost $= h(\pi)$.

(ii) Take an observation immediately and then continue "optimally"; expected cost $= MW(x, \pi)$.

(iii) Maneuver for a short time t before continuing optimally. In this case we have

$$W(x, \pi) \leq \inf_{u \in U} \left\{\int_0^t \ell(x(s), u(s))\, ds\ + W(x(t), \pi)\right\},$$

where $x(s)$ is the solution of the dynamical equation (2). Assuming that W is C^1 in x, this leads in the standard way to the inequality

$$\sup_{u \in U}[-g(x, u) \cdot D_x W(x, \pi) - \ell(x, u)] \leq 0.$$

Combining this with the inequalities $W \leq h$ and $W \leq MW$ obtained from (i) and (ii) we obtain the basic *variational inequality*

$$\max\left\{\sup_{u \in U}[-g(x, u) \cdot D_x W(x, \pi) - \ell(x, u)],\ W - h,\ W - MW\right\} = 0. \tag{15}$$

The (x, π) space splits into three regions $\mathcal{C}, \mathcal{S}$, and $\mathcal{O}$ in which each of the three expressions in (15) is equal to zero (in the respective order). The conjectured form of the optimal strategy is this: starting at $(x, \pi) \in \mathcal{C}$ (the *continuation region*) the process evolves, with π constant, until region $\mathcal{O}$ (for *observation*) is hit at, say, (x', π). (It cannot be the case that $\mathcal{S}$ is hit first.) An observation is now taken, and the process jumps to (x', π^+), where $\pi^+ = \pi_0'$ or π_1' (see (10) and (11)). If $(x', \pi^+) \in \mathcal{C}$, this process is repeated; if $(x', \pi^+) \in \mathcal{S}$ (*stopping region*), one stops, paying $h(\pi^+)$, while if $(x', \pi^+) \in \mathcal{O}$, one takes another observation. It is thus possible in principle to take a sequence of observations at the same place and time, but as argued above, both k and τ_k are a.s. finite. The variational inequality in (15) may be written as follows:

$$\max\left\{\sup_{u\in U}[-g(x,u)\cdot D_x W(x,\pi) - \ell(x,u)],\ W(x,\pi) - NW(x,\pi)\right\} = 0, \tag{16}$$

where $NW(x, \pi) := h(\pi) \wedge MW(x, \pi)$. The variational inequality given in (16) will be used throughout the following section.

4. Viscosity solution. Since we cannot guarantee in advance that (16) has a C^1 solution, a rigorous theory should be sought in the framework of viscosity solutions [CL] and [FS]. An approach to this is as follows. Let $B(E)_+$ denote the set of all positive bounded measurable functions on E. Define

$$NV(x, \pi) := h(\pi) \wedge MV(x, \pi), \tag{17}$$

and for a given function $\psi \in B(\mathbb{R}^n \times [0, 1])_+$ define an operator $\mathcal{G}$ by

$$\mathcal{G}\psi(x, \pi) := \inf_{(u,t_f)} \int_0^{t_f} \ell(x(s), u(s))\, ds + N\psi(x(t_f), \pi), \tag{18}$$

where the infimum is taken over pairs $t_f \geq 0$ and $u \in L^\infty([0, t_f]; U)$. Thus the $\mathcal{G}$-operator defines a free end-time deterministic optimal control problem.

Let us give the definition of viscosity solutions for a variational inequality [B].

DEFINITION 4.1. *Let* $S_0 = \mathbb{R}^n \times (0, 1)$, $\psi \in BUC(\bar{S}_0)$, *and consider the following variational inequality for all* $(x, \pi) \in S_0$:

$$\max\left\{\sup_{u\in U}[-g(x,u)\cdot D_x V(x,\pi) - \ell(x,u)],\ V(x,\pi) - \psi(x,\pi)\right\} = 0. \tag{19}$$

Assume $V \in BUC(\bar{S}_0)$; *then viscosity solutions are defined as follows.*

(a) *V is a viscosity subsolution of* (19) *in* S_0 *if for each* $w \in C^1(S_0)$,

$$\max\left\{\sup_{u\in U}[-g(\bar{x},u)\cdot D_x w(\bar{x},\bar{\pi}) - \ell(\bar{x},u)],\ V(\bar{x},\bar{\pi}) - \psi(\bar{x},\bar{\pi})\right\} \leq 0$$

at every $(\bar{x}, \bar{\pi}) \in S_0$ *which is a local maximum of* $V - w$ *on* S_0.

(b) *V is a viscosity supersolution of* (19) *in* S_0 *if for each* $w \in C^1(S_0)$,

$$\max\left\{\sup_{u\in U}[-g(\bar{x},u)\cdot D_x w(\bar{x},\bar{\pi}) - \ell(\bar{x},u)],\ V(\bar{x},\bar{\pi}) - \psi(\bar{x},\bar{\pi})\right\} \geq 0$$

at every $(\bar{x}, \bar{\pi}) \in S_0$ *which is a local minimum of* $V - w$ *on* S_0.

(c) *V is a viscosity solution of* (19) *in* S_0 *if it is both a viscosity subsolution and a viscosity supersolution of* (19) *in* S_0. □

THEOREM 4.2. *Assume* (1)–(6). *Moreover assume that* c, ℓ, *and* ψ *are bounded and uniformly continuous on* $\mathbb{R}^n$, $\mathbb{R}^n \times U$, *and* $\bar{S_0}$, *respectively. We also assume that* e_0 *and* e_1 *are uniformly continuous on* $\mathbb{R}^n$ *and* ψ *is positive. Then* $V(x,\pi) = \mathcal{G}\psi(x,\pi)$ *is bounded uniformly continuous in* $\bar{S_0}$ *and is a viscosity solution of the equation*

$$F_\psi(x,\pi,V,D_xV) = 0, \tag{20}$$

where

$$F_\psi(x,\pi,r,p) = \max\left\{\sup_{u\in U}[-g(x,u)\cdot p - \ell(x,u)],\ r - N\psi(x,\pi)\right\}.$$

The following three lemmas prove that $V \in BUC(\bar{S_0})$.

LEMMA 4.3. $\psi \in BUC(\bar{S_0})$ *implies that* $N\psi \in BUC(\bar{S_0})$.

Proof. The following is an outline of the proof. Given the above assumptions, π_0' and π_1' ((10) and (11)) are bounded uniformly continuous functions in $\bar{S_0}$. So $\psi \in BUC(\bar{S_0})$ implies that $M\psi \in BUC(\bar{S_0})$. It is easily verified that h (refer to (9)) is bounded uniformly continuous in $[0,1]$. Finally, $N\psi(x,\pi) = \min\{h(\pi),\ M\psi(x,\pi)\}$, so $N\psi \in BUC(\bar{S_0})$. □

LEMMA 4.4. *For* $\rho \geq 0$ *define*

$$m_\ell(\rho) = \sup\{|\ell(x,u) - \ell(y,u)|\colon\ |x-y| \leq \rho,\ u \in U\},$$

$$m_\psi(\rho) = \sup\{|N\psi(x,\pi) - N\psi(y,\pi')|\colon\ |x-y| + |\pi - \pi'| \leq \rho\}.$$

Then the uniform continuity of ℓ *and* $N\psi$ *implies that* $m_\ell, m_\psi \in C([0,\infty])$ *and* $m_\ell(0) = 0$, $m_\psi(0) = 0$.

Proof. It can easily be verified. For a similar argument refer to the proof of theorem II(10.1), pp. 95–97 in [FS]. □

LEMMA 4.5. $V \leq h(\ell_2/(\ell_1+\ell_2))$ *and*

$$|V(x,\pi) - V(y,\pi')| \leq \tau_{\max} m_\ell(|x-y|e^{K\tau_{\max}}) + m_\psi(|x-y|e^{K\tau_{\max}}) + m_\psi(|\pi-\pi'|),$$

where $\tau_{\max} = h(\ell_2/(\ell_1+\ell_2))/\delta$ *and* K *is the Lipschitz constant. Hence* $V \in BUC(\bar{S_0})$.

Proof. Since h achieves its maximum at $\ell_2/(\ell_1+\ell_2)$ and $V \leq h$ (take $t_f = 0$ in (18)), one can write

$$V(x,\pi) \leq h(\ell_2/(\ell_1+\ell_2)),$$

$$V(x,\pi) = \inf_{\tau\in[0,\tau_{\max}],\ u(\cdot)\in L^\infty([0,\tau_{\max}];U)} \int_0^\tau \ell(x(s),u(s))\,ds + N\psi(x(\tau),\pi).$$

Using $\inf\ldots - \inf\ldots \leq \sup\ldots$ and Gronwall's inequality [PSV], one can obtain the required result. □

Proof of Theorem 4.2. The above lemmas imply that $V \in BUC(\bar{S_0})$. Now let us prove that V is a viscosity solution of (20). The argument is very similar to that in [B]. Let $\varphi \in C^1(\mathbb{R}^n \times (0,1))$, and assume that $(\bar{x},\bar{\pi}) \in \mathbb{R}^n \times (0,1)$ is a local maximum point of $V - \varphi$. Then for a fixed control $\bar{u} \in U$ and all $T > 0$ we have

$$V(\bar{x},\bar{\pi}) \leq \int_0^T \ell(x(s),\bar{u})\,ds + V(x(T),\bar{\pi}).$$

But for small values of T one can write

$$V(x(T),\bar{\pi}) - \varphi(x(T),\bar{\pi}) \leq V(\bar{x},\bar{\pi}) - \varphi(\bar{x},\bar{\pi}),$$

so replacing for $V(x(T), \bar{\pi})$ from the above inequality gives

$$\int_0^T \ell(x(s), \bar{u})\, ds + (\varphi(x(T), \bar{\pi}) - \varphi(\bar{x}, \bar{\pi})) \geq 0.$$

Then dividing both sides of the above inequality by T and taking the limit when $T \downarrow 0$, one finally gets

$$-g(\bar{x}, \bar{u}) \cdot D_x \varphi(\bar{x}, \bar{\pi}) - \ell(\bar{x}, \bar{u}) \leq 0 \quad \forall\, \bar{u} \in U.$$

According to the definition of $V(x, \pi)$ one can immediately say that $V(\bar{x}, \bar{\pi}) \leq N\psi(\bar{x}, \bar{\pi})$, so

$$\max\left\{\sup_{u \in U}[-g(\bar{x}, u) \cdot D_x \varphi(\bar{x}, \bar{\pi}) - \ell(\bar{x}, u)],\ V(\bar{x}, \bar{\pi}) - N\psi(\bar{x}, \bar{\pi})\right\} \leq 0; \tag{21}$$

in other words, V is a viscosity subsolution of (20).

Now let $\varphi \in C^1(\mathbb{R}^n \times (0, 1))$, and assume that $(\bar{x}, \bar{\pi}) \in \mathbb{R}^n \times (0, 1)$ is a local minimum point of $V - \varphi$. We have two cases.

Case 1. If $V(\bar{x}, \bar{\pi}) = N\psi(\bar{x}, \bar{\pi})$, then there is nothing to prove.

Case 2. $V(\bar{x}, \bar{\pi}) < N\psi(\bar{x}, \bar{\pi})$, which means $(\bar{x}, \bar{\pi}) \in \mathcal{C}$ (continuation region). So $\exists \epsilon > 0$ such that $\forall\, T \in (0, \epsilon)$ we have

$$V(\bar{x}, \bar{\pi}) = \inf_{u \in U}\left\{\int_0^T \ell(x(s), u(s))\, ds + V(x(T), \bar{\pi})\right\},$$

but if we choose T small enough, one can write

$$V(x(T), \bar{\pi}) - \varphi(x(T), \bar{\pi}) \geq V(\bar{x}, \bar{\pi}) - \varphi(\bar{x}, \bar{\pi}).$$

Again replacing for $V(x(T), \bar{\pi})$ from the above inequality gives

$$\inf_{u \in U}\left\{\int_0^T \ell(x(s), u(s))\, ds + (\varphi(x(T), \bar{\pi}) - \varphi(\bar{x}, \bar{\pi}))\right\} \leq 0.$$

Then dividing both sides by T and taking the limit when $T \downarrow 0$, one finally obtains

$$\sup_{u \in U}[-g(\bar{x}, u) \cdot D_x \varphi(\bar{x}, \bar{\pi}) - \ell(\bar{x}, u)] \geq 0,$$

which immediately implies

$$\max\left\{\sup_{u \in U}[-g(\bar{x}, u) \cdot D_x \varphi(\bar{x}, \bar{\pi}) - \ell(\bar{x}, u)],\ V(\bar{x}, \bar{\pi}) - N\psi(\bar{x}, \bar{\pi})\right\} \geq 0, \tag{22}$$

so V is a viscosity supersolution of (20). If we use the definition of viscosity solutions and inequalities in (21) and (22), it is easy to see that V is a viscosity solution of (20). □

Now we prove that $V(x, \pi) = \mathcal{G}\psi(x, \pi)$ is the unique viscosity solution of (20).

THEOREM 4.6. *Consider the variational inequality for all* $(x, \pi) \in \mathbb{R}^n \times (0, 1)$,

$$\max\left\{\sup_{u \in U}[-\ell(x, u) - g(x, u) \cdot D_x V(x, \pi)],\ V(x, \pi) - \psi(x, \pi)\right\} = 0, \tag{23}$$

and make all the assumptions of Theorem 4.2; *then if* $\psi(x, \pi) > 0\ \forall\, (x, \pi) \in \mathbb{R}^n \times (0, 1)$, *there is at most one viscosity solution of* (23).

We will need the following lemmas.

LEMMA 4.7. *Define* $H(x, p) := \sup_{u \in U}[-\ell(x, u) - g(x, u) \cdot p]$; *then* $H(x, p)$ *is a convex function with respect to* p.

Proof. This is easily verified. □

LEMMA 4.8. *Define*

$$\tilde{H}(x, r, p) := \max\{H(x, p),\ r - \psi(x)\},$$

where

$$\ell(x, u) \geq \delta > 0 \quad \forall\, (x, u) \in R^n \times U,$$
$$\psi(x) > 0 \quad \forall\, x \in R^n.$$

Then $\tilde{H}(x, V, DV)$ *has a strict subsolution, i.e.,*

$$\exists w \in C^1(\mathbb{R}^n) \cap BUC(\mathbb{R}^n) \text{ s.t. } \tilde{H}(x, w, Dw) < 0 \text{ in } \mathbb{R}^n.$$

Proof. It is easily seen that $w(x) \equiv 0$ is a strict subsolution. □

LEMMA 4.9. *Assume that* $u(x)$ *is a viscosity subsolution of* $\tilde{H}(x, V, DV) = 0$. *Then* $\eta u(x) + (1 - \eta)w(x)$ *is a strict viscosity subsolution of* $\tilde{H}$, *where* $w(x)$ *is a strict subsolution and* $\eta \in (0, 1)$.

Proof. u is a viscosity subsolution of $\tilde{H}(x, V, DV) = 0$, so for all $\varphi \in C^1(\mathbb{R}^n)$, if $u - \varphi$ attains a local maximum at $x_0 \in \mathbb{R}^n$, then

$$\tilde{H}(x_0, u(x_0), D\varphi(x_0)) \leq 0.$$

When $u - \varphi$ attains a local maximum at x_0, so does $\eta u + (1 - \eta)w - (\eta\varphi + (1 - \eta)w)$ for $\eta \in (0, 1)$. Here $w \in C^1(\mathbb{R}^n)$ is a strict subsolution of $\tilde{H}$. Now we show $\eta u + (1 - \eta)w$ is a strict viscosity subsolution of $\tilde{H}$:

$$\begin{aligned}
&\tilde{H}(x_0,\ \eta u(x_0) + (1 - \eta)w(x_0),\ \eta D\varphi(x_0) + (1 - \eta)Dw(x_0)) \\
&\quad = \max\{H(x_0, \eta D\varphi(x_0) + (1 - \eta)Dw(x_0)),\ \eta u(x_0) + (1 - \eta)w(x_0) - \psi(x_0)\} \\
&\quad \leq \max\{\eta H(x_0, D\varphi(x_0)) + (1 - \eta)H(x_0, Dw(x_0)),\ \eta u(x_0) + (1 - \eta)w(x_0) - \psi(x_0)\} \\
&\quad \leq \eta \max\{H(x_0, D\varphi(x_0)),\ u(x_0) - \psi(x_0)\} \\
&\qquad + (1 - \eta)\max\{H(x_0, Dw(x_0)),\ w(x_0) - \psi(x_0)\} \\
&\quad < 0,
\end{aligned}$$

because u is a viscosity subsolution and w is a strict subsolution. □

Proof of Theorem 4.6. Without loss of generality we drop π in all arguments. Consider the following auxiliary test function:

$$\Phi(x, y) = v_1(x) - v_2(y) - \frac{(x - y)^2}{2\epsilon}, \qquad \epsilon > 0,$$

where v_1 and v_2 are a viscosity subsolution and a viscosity supersolution of (23), respectively. In our problem any viscosity subsolution or supersolution must be bounded and uniformly continuous, so $\Phi(x, y)$ has a maximiser over $\mathbb{R}^n \times \mathbb{R}^n$ at $(\bar{x}_\epsilon, \bar{y}_\epsilon) \in \bar{Q} \times \bar{Q}$, where Q is a bounded subset of $\mathbb{R}^n$. Obviously

$$\Phi(x, y) \leq \Phi(\bar{x}_\epsilon, \bar{y}_\epsilon) \quad \forall (x, y) \in \mathbb{R}^n \times \mathbb{R}^n. \tag{24}$$

For $\rho \geq 0$ define

$$D_\rho = \{(x, y) \in \bar{Q} \times \bar{Q} : |x - y|^2 \leq \rho\},$$
$$m_{v_1}(\rho) = 2\sup\{|v_1(x) - v_1(y)| : (x, y) \in D_\rho\},$$
$$K_1 = \sup\{m_{v_1}(\rho) : \rho \geq 0\}.$$

$\bar{Q}$ is compact and v_1 is uniformly continuous on $\bar{Q}$. Thus $m_{v_1} \in C([0,\infty))$ with $m_{v_1}(0) = 0$. We have

$$\Phi(\bar{y}_\epsilon, \bar{y}_\epsilon) \le \Phi(\bar{x}_\epsilon, \bar{y}_\epsilon),$$

so

$$\frac{(\bar{x}_\epsilon - \bar{y}_\epsilon)^2}{\epsilon} \le 2(v_1(\bar{x}_\epsilon) - v_1(\bar{y}_\epsilon)) \le K_1, \tag{25}$$

which gives

$$|\bar{x}_\epsilon - \bar{y}_\epsilon| \le \sqrt{K_1 \epsilon}. \tag{26}$$

One can observe that $|\bar{x}_\epsilon - \bar{y}_\epsilon| \to 0$ as $\epsilon \downarrow 0$. Using (25) and (26) it is easily verified that $(\bar{x}_\epsilon - \bar{y}_\epsilon)^2/\epsilon \downarrow 0$ as $\epsilon \downarrow 0$. Now let us define $p_\epsilon := (\bar{x}_\epsilon - \bar{y}_\epsilon)/\epsilon$. Then

$$\begin{aligned} |H(\bar{x}_\epsilon, p_\epsilon) - H(\bar{y}_\epsilon, p_\epsilon)| &\le \sup_{u\in U} |(g(\bar{y}_\epsilon, u) - g(\bar{x}_\epsilon, u)) \cdot p_\epsilon + \ell(\bar{y}_\epsilon, u) - \ell(\bar{x}_\epsilon, u)| \\ &\le \sup_{u\in U} |\ell(\bar{x}_\epsilon, u) - \ell(\bar{y}_\epsilon, u)| + \sup_{u\in U} |g(\bar{x}_\epsilon, u) - g(\bar{y}_\epsilon, u)|\, |p_\epsilon| \\ &\le m_\ell(|\bar{x}_\epsilon - \bar{y}_\epsilon|) + K|\bar{x}_\epsilon - \bar{y}_\epsilon||p_\epsilon|, \end{aligned} \tag{27}$$

where K is the Lipschitz constant of g and $m_\ell \in C([0,\infty))$ with $m_\ell(0) = 0$. Using (27) one can show that $|H(\bar{x}_\epsilon, p_\epsilon) - H(\bar{y}_\epsilon, p_\epsilon)| \to 0$ as $\epsilon \downarrow 0$.

Define

$$w_1(x) = v_2(\bar{y}_\epsilon) + \frac{(x - \bar{y}_\epsilon)^2}{2\epsilon}.$$

Obviously $w_1 \in C^\infty(\mathbb{R}^n)$ and $v_1 - w_1$ attains its local maximum at $\bar{x}_\epsilon$. By Lemma 4.8 we know that (23) has a strict subsolution, which is $w(x) \equiv 0$. So according to Lemma 4.9 we have

$$\max\{H(\bar{x}_\epsilon, \eta p_\epsilon),\ \eta v_1(\bar{x}_\epsilon) + (1-\eta)w(\bar{x}_\epsilon) - \psi(\bar{x}_\epsilon)\} < 0. \tag{28}$$

Now define

$$w_2(y) = v_1(\bar{x}_\epsilon) - \frac{(\bar{x}_\epsilon - y)^2}{2\epsilon},$$

where $w_2 \in C^\infty(\mathbb{R}^n)$ and $v_2 - w_2$ attains its local minimum at $\bar{y}_\epsilon$, so

$$\max\{H(\bar{y}_\epsilon, p_\epsilon),\ v_2(\bar{y}_\epsilon) - \psi(\bar{y}_\epsilon)\} \ge 0. \tag{29}$$

The inequality in (28) implies

$$\begin{aligned} &H(\bar{x}_\epsilon, \eta p_\epsilon) < 0 \quad \forall\, \epsilon > 0 \text{ and } \eta \in (0,1), \\ &\eta v_1(\bar{x}_\epsilon) + (1-\eta)w(\bar{x}_\epsilon) - \psi(\bar{x}_\epsilon) < 0. \end{aligned}$$

Now we show that the inequality in (29) implies only that

$$v_2(\bar{y}_\epsilon) \ge \psi(\bar{y}_\epsilon) \quad \forall\, \epsilon < \epsilon_0 \text{ for some } \epsilon_0 > 0. \tag{30}$$

An argument similar to (27) verifies that $H(x, p)$ is uniformly continuous in x and p, so we have

$$\lim_{\epsilon \downarrow 0,\ \eta \uparrow 1} |H(\bar{x}_\epsilon, \eta p_\epsilon) - H(\bar{y}_\epsilon, p_\epsilon)| = 0,$$

but we know that $H(\bar{x}_\epsilon, \eta p_\epsilon) < 0\ \forall\, \epsilon > 0$ and $\eta \in (0, 1)$, so $\exists\, \epsilon_0 > 0$ such that $H(\bar{y}_\epsilon, p_\epsilon) < 0\ \forall\, \epsilon < \epsilon_0$. Together with (29) this implies (30). We also have

$$v_1(\bar{x}_\epsilon) \le \psi(\bar{x}_\epsilon), \tag{31}$$

because v_1 is a viscosity subsolution of (23). Using (24), (30), and (31) we have

$$\begin{aligned} v_1(x) - v_2(x) &\le v_1(\bar{x}_\epsilon) - v_2(\bar{y}_\epsilon) - \frac{(\bar{x}_\epsilon - \bar{y}_\epsilon)^2}{2\epsilon} \quad \forall\, x \in \mathbb{R}^n \\ &= (v_1(\bar{x}_\epsilon) - \psi(\bar{x}_\epsilon)) - (v_2(\bar{y}_\epsilon) - \psi(\bar{y}_\epsilon)) + (\psi(\bar{x}_\epsilon) - \psi(\bar{y}_\epsilon)) - \frac{(\bar{x}_\epsilon - \bar{y}_\epsilon)^2}{2\epsilon} \\ &\le (\psi(\bar{x}_\epsilon) - \psi(\bar{y}_\epsilon)) - (\bar{x}_\epsilon - \bar{y}_\epsilon)^2/2\epsilon, \end{aligned}$$

so when $\epsilon \downarrow 0$ one gets $v_1(x) - v_2(x) \le 0$ or

$$v_1(x) \le v_2(x). \tag{32}$$

The inequality in (32) simply says that any viscosity subsolution is less than or equal to any viscosity supersolution. A viscosity solution is both a viscosity subsolution and a viscosity supersolution, so if V_1 and V_2 are two different viscosity solutions for (23), then by (32) we must have $V_1 \le V_2$ and $V_1 \ge V_2$, which implies that $V_1 = V_2$. So there is at most one viscosity solution of (23). □

COROLLARY 4.10. *$V(x, \pi) = \mathcal{G}\psi(x, \pi)$ is the unique viscosity solution of* (20). This is easily verified by replacing ψ with $N\psi$ in Theorem 4.6 and using Theorem 4.2.

LEMMA 4.11. *Define $v_0(x, \pi) = h(\pi)$ and $v_n(x, \pi) = \mathcal{G}v_{n-1}(x, \pi)$ for $n = 1, 2, \ldots$, where h and $\mathcal{G}$ are defined in* (9) *and* (18), *respectively. Then $v_n(x, \pi)$ is the minimal cost with at most n observations.*

Proof. In view of the definition of N and the fact that $t_f = 0$ is admissible in (18), it is clear that $v_1(x, \pi) = \mathcal{G}v_0(x, \pi)$ is the minimal cost if *at most one* observation is taken. The result follows by induction. □

THEOREM 4.12. *Consider an operator $\mathcal{G}$, defined by* (18). *Then*

$$W(x, \pi) = \inf_{S \in \mathbb{S}_{ad}} \mathbb{E}\left\{ \int_0^{\tau_k} \ell(x(s), u(s))\, ds + \sum_{j=1}^{k} c(x(\tau_j)) + h(\pi(\tau_k)) \right\}$$

is the unique fixed point of $\mathcal{G}$, where $\mathbb{S}_{ad}$ is the set of all admissible strategies as defined in §2.

We will need the following lemmas.

LEMMA 4.13. *W is a fixed point of $\mathcal{G}$, i.e., $W = \mathcal{G}W$.*

Proof. Define

$$\mathbb{S}_{ad}^{ob} = \{S \in \mathbb{S}_{ad}\colon\ \tau_1 \ge 0\},$$

$$\mathbb{S}_{ad}^{st} = \{S = \text{immediate stopping}\},$$

$$\mathbb{S}_{ad}(\tilde{u}, \tilde{\tau}) = \{S \in \mathbb{S}_{ad}^{ob}\colon\ u(t) = \tilde{u}(t), \quad 0 \le t \le \tilde{\tau} \text{ and } \tau_1 = \tilde{\tau}\},$$

where $\mathbb{S}_{ad}^{ob}$ is the set of all admissible strategies with at least one observation. Obviously $\mathbb{S}_{ad} = \mathbb{S}_{ad}^{ob} \cup \mathbb{S}_{ad}^{st}$, so

$$\inf_{S\in\mathbb{S}_{ad}} J(S) = \inf_{S\in\mathbb{S}_{ad}^{ob}\cup\mathbb{S}_{ad}^{st}} J(S)$$

$$= \min\left\{h(\pi),\ \inf_{S\in\mathbb{S}_{ad}^{ob}} J(S)\right\}. \tag{33}$$

We also have

$$\inf_{S\in\mathbb{S}_{ad}^{ob}} J(S) = \inf_{(\tilde{u},\tilde{\tau})} \inf_{S\in\mathbb{S}_{ad}(\tilde{u},\tilde{\tau})} \mathbb{E}_{x,\pi}\left\{\int_0^{\tilde{\tau}} \ell(x(s),\tilde{u}(s))\,ds + c(x(\tilde{\tau}))\right.$$

$$\left. + \int_{\tilde{\tau}}^{\tau_k} \ell(x(s),u(s))\,ds + \sum_{j=2}^{k} c(x(\tau_j)) + h(\pi_{\tau_k})\right\}$$

$$= \inf_{(\tilde{u},\tilde{\tau})}\left\{\int_0^{\tilde{\tau}} \ell(x(s),\tilde{u}(s))\,ds + c(x(\tilde{\tau}))\right.$$

$$\left. + \inf_{S\in\mathbb{S}_{ad}(\tilde{u},\tilde{\tau})} \mathbb{E}_{x(\tilde{\tau}),\pi}\left[\int_{\tilde{\tau}}^{\tau_k} \ell(x(s),u(s))\,ds + \sum_{j=2}^{k} c(x(\tau_j)) + h(\pi_{\tau_k})\right]\right\},$$

and it is easy to observe that

$$\inf_{S\in\mathbb{S}_{ad}^{ob}} J(S) = \inf_{(\tilde{u},\tilde{\tau})}\left\{\int_0^{\tilde{\tau}} \ell(x(s),\tilde{u}(s))\,ds + MW(x(\tilde{\tau}),\pi)\right\}. \tag{34}$$

Combining (33) and (34) yields

$$W(x,\pi) = \inf_{(\tilde{u},\tilde{\tau})}\left\{\int_0^{\tilde{\tau}} \ell(x(s),\tilde{u}(s))\,ds + NW(x(\tilde{\tau}),\pi)\right\},$$

and the result follows. □

LEMMA 4.14. *N, acting on the space of bounded measurable functions, is nondecreasing and concave.*

Proof. Assume that for all $(x,\pi) \in \mathbb{R}^n \times [0,1]$, we have $V_1(x,\pi) \le V_2(x,\pi)$. Then it is easy to show that

$$NV_1(x,\pi) \le NV_2(x,\pi),$$

because $MV_1(x,\pi) \le MV_2(x,\pi)$, so N is nondecreasing. Now assume that $\mu \in [0,1]$. Then

$$\begin{aligned} N(\mu V_1 + (1-\mu)V_2) &= \min\{\mu h + (1-\mu)h,\ M(\mu V_1 + (1-\mu)V_2)\} \\ &= \min\{\mu h + (1-\mu)h,\ \mu MV_1 + (1-\mu)MV_2\} \\ &\ge \min\{\mu h + (1-\mu)h,\ \mu h + (1-\mu)MV_2,\ \mu MV_1 + (1-\mu)h, \\ &\qquad \mu MV_1 + (1-\mu)MV_2\} \\ &= \mu\min\{h,\ MV_1\} + (1-\mu)\min\{h,\ MV_2\}, \end{aligned}$$

so $N(\mu V_1 + (1-\mu)V_2) \ge \mu NV_1 + (1-\mu)NV_2$ and N is concave. □

LEMMA 4.15. *$\mathcal{G}$ is nondecreasing and concave.*

Proof. Let us assume that $V_1 \le V_2\ \forall (x,\pi) \in \mathbb{R}^n \times [0,1]$. Then

$$\begin{aligned}\mathcal{G}V_2(x,\pi) &= \inf_{(u,\tau)} \left\{ \int_0^\tau \ell(x(s),u(s))\,ds + NV_2(x(\tau),\pi) - NV_1(x(\tau),\pi) + NV_1(x(\tau),\pi) \right\} \\ &= \inf_{(u,\tau)} \left\{ \int_0^\tau \ell(x(s),u(s))\,ds + NV_1(x(\tau),\pi) + [NV_2(x(\tau),\pi) - NV_1(x(\tau),\pi)] \right\} \\ &\ge \mathcal{G}V_1(x,\pi) + \inf_{(u,\tau)} [NV_2(x(\tau),\pi) - NV_1(x(\tau),\pi)],\end{aligned}$$

but

$$\inf_{(u,\tau)} [NV_2(x(\tau),\pi) - NV_1(x(\tau),\pi)] \ge 0,$$

because $NV_2(x(\tau),\pi) \ge NV_1(x(\tau),\pi)$, so

$$\mathcal{G}V_2(x,\pi) \ge \mathcal{G}V_1(x,\pi)$$

and $\mathcal{G}$ is nondecreasing. Now assume that $\mu \in [0,1]$. Then

$$\begin{aligned}\mathcal{G}(\mu V_1 + (1-\mu)V_2) &= \inf_{(u,\tau)} \left\{ \mu \int_0^\tau \ell(x(s),u(s))\,ds + (1-\mu)\int_0^\tau \ell(x(s),u(s))\,ds \right. \\ &\qquad \left. + N(\mu V_1 + (1-\mu)V_2) \right\} \\ &\ge \inf_{(u,\tau)} \left\{ \mu \int_0^\tau \ell(x(s),u(s))\,ds + \mu N V_1 \right. \\ &\qquad \left. + (1-\mu)\int_0^\tau \ell(x(s),u(s))\,ds + (1-\mu)NV_2 \right\} \\ &\ge \mu \inf_{(u,\tau)} \left\{ \int_0^\tau \ell(x(s),u(s))\,ds + NV_1 \right\} \\ &\quad + (1-\mu) \inf_{(u,\tau)} \left\{ \int_0^\tau \ell(x(s),u(s))\,ds + NV_2 \right\} \\ &= \mu\mathcal{G}V_1 + (1-\mu)\mathcal{G}V_2,\end{aligned}$$

so

$$\mathcal{G}(\mu V_1 + (1-\mu)V_2) \ge \mu\mathcal{G}V_1 + (1-\mu)\mathcal{G}V_2. \qquad \square$$

LEMMA 4.16. *Let $V = \mathcal{G}\psi$ for some $\psi \in B(\mathbb{R}^n \times [0,1])_+$. Then there exists $\kappa \in \mathbb{R}_+$ such that $V \le \kappa\mathcal{G}0$.*

Proof. For all $\psi \in B(\mathbb{R}^n \times [0,1])_+$ we have

$$V(x,\pi) \le h(\pi). \tag{35}$$

Let $\max_{\pi\in[0,1]} h(\pi) = h_{\max}$. (The maximum is actually achieved at $\pi = \ell_2/(\ell_1+\ell_2)$.) One can verify that $\mathcal{G}0 \ge h(\pi) \wedge \delta$, because $c \ge \delta > 0$. Now two cases can happen.

Case 1. If $h_{\max} > \delta$, then

$$h(\pi) \le \frac{h_{\max}}{\delta}\,(h(\pi) \wedge \delta)$$

$$\le \frac{h_{\max}}{\delta}\,\mathcal{G}0.$$

Case 2. If $h_{\max} \le \delta$, then $\mathcal{G}0 = h(\pi)$.

Finally, using (35) one can write $V \le (1 \vee h_{\max}/\delta)\,\mathcal{G}0$, i.e., $\kappa = (1 \vee h_{\max}/\delta)$. □

LEMMA 4.17. *Let* $\mathcal{P}_{\mathcal{G}} = \{V \in B(\mathbb{R}^n \times [0,1])_+ : V \le \kappa \mathcal{G}0 \text{ for some } \kappa \in \mathbb{R}_+\}$. *Then* $\mathcal{G}$ *has at most one fixed point in* $\mathcal{P}_{\mathcal{G}}$.

Proof. The following proof is very similar to the one on p. 250 of [D]. Let $V_1, V_2 \in \mathcal{P}_{\mathcal{G}}$, and assume that $\mathcal{G}V_1 = V_1$ and $\mathcal{G}V_2 = V_2$. Without loss of generality we can consider

$$V_1 - V_2 \notin B(\mathbb{R}^n \times [0,1])_+.$$

So let $t_0 = \sup\{t \in \mathbb{R}^+ : V_1 \ge tV_2\}$, $t_0 \in [0,1)$ since $V_1 \ge 0$ and $V_1 \not\ge V_2$. We have $V_1 \ge t_0 V_2$, so

$$\begin{aligned} V_1 = \mathcal{G}V_1 &\ge \mathcal{G}(t_0 V_2) \\ &= \mathcal{G}(t_0 V_2 + (1-t_0)0) \\ &\ge t_0 \mathcal{G}V_2 + (1-t_0)\mathcal{G}0 \\ &= t_0 V_2 + (1-t_0)\mathcal{G}0 \\ &\ge t_0 V_2 + \frac{(1-t_0)}{\kappa} V_2 \quad \text{for some } \kappa \in \mathbb{R}_+ \\ &= \left(t_0 + \frac{1-t_0}{\kappa}\right) V_2, \end{aligned} \tag{36}$$

since $V_2 \in \mathcal{P}_{\mathcal{G}}$. Inequality (36) gives $V_1 \ge (t_0 + (1-t_0)/k)V_2$, which contradicts the definition of t_0, so we must have $V_1 \ge V_2$. Now assume that $V_2 - V_1 \notin B(\mathbb{R}^n \times [0,1])_+$ and conclude that $V_2 \ge V_1$, so $V_1 = V_2$. □

Proof of Theorem 4.12. According to Lemma 4.13 $W(x,\pi)$ is a fixed point of $\mathcal{G}$. Then Lemma 4.17 proves that $W(x,\pi)$ is the unique fixed point of $\mathcal{G}$. □

Before proceeding to the following theorem let us remark that the definition of viscosity solutions for $F_V(x,\pi,V,D_xV) = 0$ can be stated exactly in the same way as Definition 4.1, but ψ must be replaced by NV throughout the definition.

THEOREM 4.18. *W is the unique viscosity solution of the equation*

$$F_V(x,\pi,V,D_xV) = 0, \tag{37}$$

where $W(x,\pi)$ *is given by* (14).

The following lemmas are needed.

LEMMA 4.19. *W is a viscosity solution of* (37).

Proof. This is due to the fact that if $V = \mathcal{G}V$, then $V \le NV$, and one can follow the proof of Theorem 4.2. □

LEMMA 4.20. *Any viscosity solution of* (37) *is a fixed point of* $\mathcal{G}$.

Proof. If V is a viscosity solution of (37), then by Corollary 4.10 V is the unique viscosity solution of the equation $F_V(x,\pi,\tilde{V},D_x\tilde{V}) = 0$ (regarded as an equation for unknown $\tilde{V}$ with V "frozen"), and this solution is given by $V = \mathcal{G}V$; i.e., V is a fixed point of $\mathcal{G}$. □

Proof of Theorem 4.18. According to Theorem 4.12, W is the unique fixed point of $\mathcal{G}$. Using the above lemmas it is clear that W is the unique viscosity solution of (37). □

The following theorem describes a computational algorithm for the value function and gives the necessary convergence result.

THEOREM 4.21. *Let* $v_0 = h$ *and* $v_n = \mathcal{G}v_{n-1}$ *for* $n = 1, 2, \ldots$. *Then* $\lim_{n\to\infty} v_n = W$, *where* W *is the value function given by* (14).

Proof. It is obvious that $0 \le v_n \le h$ for $n = 0, 1, \ldots$. Since $v_1 \le v_0$, a simple induction argument proves that $v_n \le v_{n-1}$ for all $n = 1, 2, \ldots$, because $\mathcal{G}$ is a nondecreasing operator (Lemma 4.15). So the limit $V(x, \pi) = \lim_{n\to\infty} v_n(x, \pi)$ certainly exists and $V = \mathcal{G}V$, which implies $V = W$ since W is the unique fixed point of $\mathcal{G}$ (Theorem 4.12). □

5. Simulation results. As an example, consider the following scalar system:

$$\begin{aligned} &\dot{x}(s) = u(s); \quad x(0) = x_0, \\ &U = [-K, K], \\ &\ell(x(s), u(s)) = \ell, \\ &c(x) = 1. \end{aligned}$$

We also assume that the target is located at $x = 0$. This simple one-dimensional example is obviously a minimum-time optimal control problem, so we expect to get bang-bang control. This problem may be solved by the following iterative computational scheme ((18) and (17)):

$$\begin{aligned} &v_n(x, \pi) = \mathcal{G}v_{n-1}(x, \pi), \\ &\mathcal{G}v_{n-1}(x, \pi) = \inf_{(u,t_f)} \int_0^{t_f} \ell \, ds + Nv_{n-1}(x(t_f), \pi), \\ &Nv_{n-1}(x, \pi) = h(\pi) \wedge Mv_{n-1}(x, \pi), \end{aligned} \tag{38}$$

with $v_0(x, \pi) = h(\pi)$. Let $\gamma > 0$ as the time step. Then Σ_0^γ would be the state-space set, where

$$\Sigma_0^\gamma = \{x_j = x_0 + j\gamma K, \ j = 0, \pm 1, \pm 2, \ldots\}.$$

Then (38) can be written as

$$v_n(x_0, \pi) = \inf_{j=0,\pm1,\pm2,\ldots} [|j|\gamma\ell + Nv_{n-1}(x_j, \pi)]. \tag{39}$$

After obtaining $W(x, \pi)$ one can find the optimal observation strategy. In (39), replacing $v_{n-1}(x_j, \pi)$ and $v_n(x_0, \pi)$ with $W(x_j, \pi)$ and $W(x_0, \pi)$, respectively, gives the necessary formula:

$$W(x_0, \pi) = \inf_{j=0,\pm1,\pm2,\ldots} [|j|\gamma\ell + NW(x_j, \pi)].$$

So starting from any initial condition (x_0, π), one can obtain τ_1. Then choosing $(x(\tau_1), \pi(\tau_1))$ as the new starting point, τ_2 can be calculated and one can continue until $(x(\tau_k), \pi(\tau_k)) \in \mathcal{S}$. The following forms are assumed for $e_0(x)$ and $e_1(x)$ throughout the simulation:

$$e_0(x) = \frac{1}{2}(1 - \exp(-b_1 x)), \qquad b_1 > 0,$$

$$e_1(x) = \frac{1}{2}(1 - \exp(-b_2 x)), \qquad b_2 > 0.$$

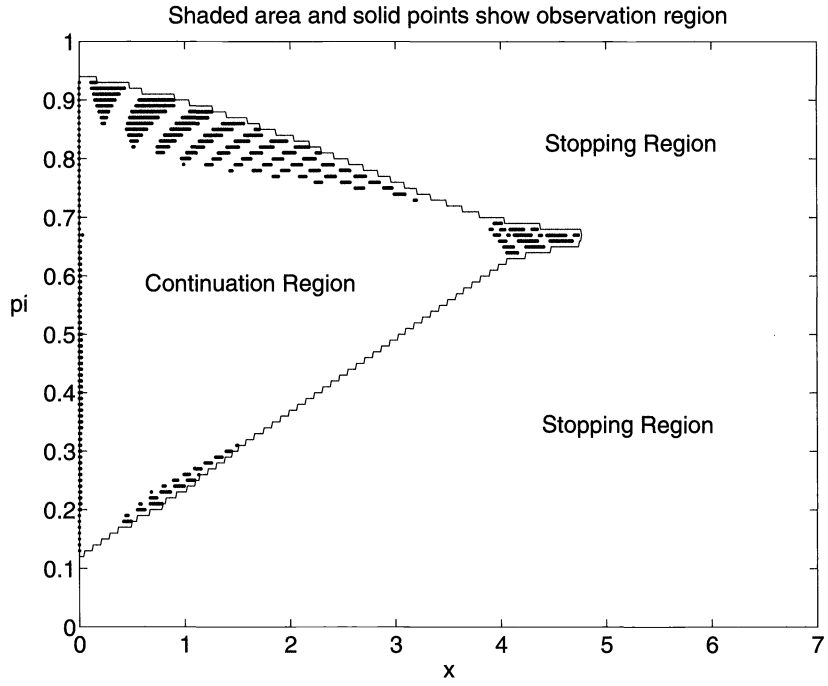


FIG. 1. *Stopping, observation, and continuation regions.*

Although assumption (1) is not satisfied here, one can show that all the results hold when $0 \leq e_0(x), e_1(x) \leq \frac{1}{2}$, $e_0(0) = 0$, $e_1(0) = 0$, and $\forall x \in \mathbb{R}^n \setminus \{0\}$ $e_0(x), e_1(x) \neq 0$. Figures 1–3 show the simulation results for $\gamma = 0.01$, $b_1 = 0.25$, $b_2 = 0.5$, $\ell_1 = 8$, $\ell_2 = 16$, and $\ell = 1$. The discretization step along the π-axis is equal to 0.01. Stopping, observation, and continuation regions are shown in Figure 1. $\ell_2 > \ell_1$, so there are more observation points for $\pi \geq 0.5$. Some continuation points are scattered in the observation region. This arises either due to numerical inaccuracy (discretization) or as a result of position-dependent probabilities ($e_0(x)$ and $e_1(x)$). So at some starting points the optimal strategy is as follows: go a bit forward and then make an observation, because otherwise the cost is slightly more. When $\ell_1 = \ell_2$ and $b_1 = b_2$, the regions are symmetric with respect to $\pi = 0.5$. Figure 2 shows the maximum difference, i.e., $\max |\upsilon_n - \upsilon_{n-1}|$, at each iteration. At the third iteration, υ_n is approximately equal to υ_{n-1}. Thus one can claim that most optimal strategies will have at most two observations. The value function is also depicted in Figure 3. The observation strategy was determined for a friendly target ($\theta = 0$) and starting point ($x_0 = 1, \pi = 0.25$) $\in C$. The results were as follows:

$$\begin{aligned}
&\tau_1 = 0.07, \qquad \tau_2 = 1,\\
&k = 2,\\
&x(\tau_1) = 0.93, \qquad x(\tau_2) = 0,\\
&\pi(\tau_1) = 0.72, \qquad \pi(\tau_2) = 0,\\
&d = 0.
\end{aligned}$$

The sequence of two observations, which was produced by a random generator with the associated distributions, was $Y_1 = 1$ and $Y_2 = 0$.

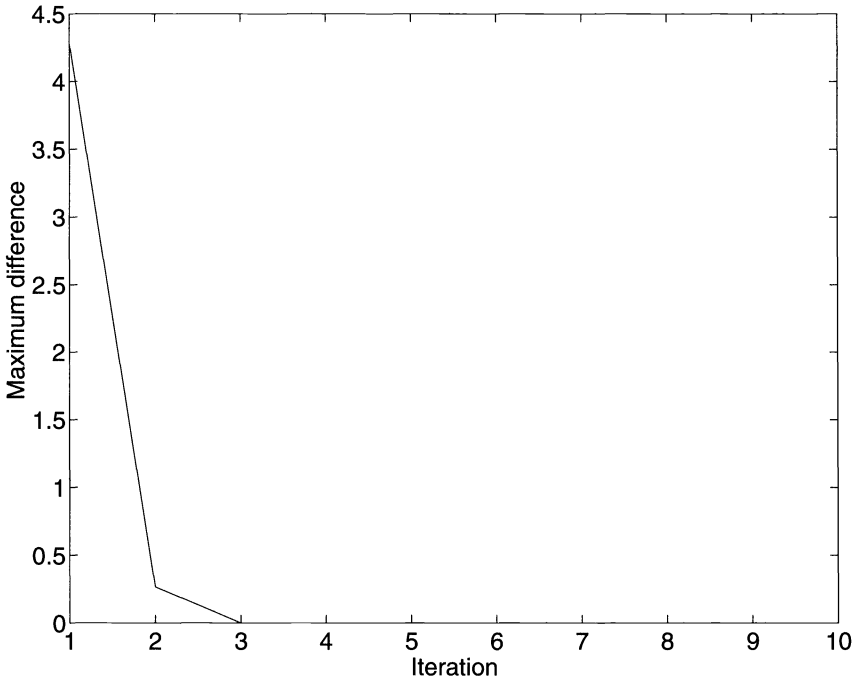

FIG. 2. $\max |v_n - v_{n-1}|$ *versus iteration.*

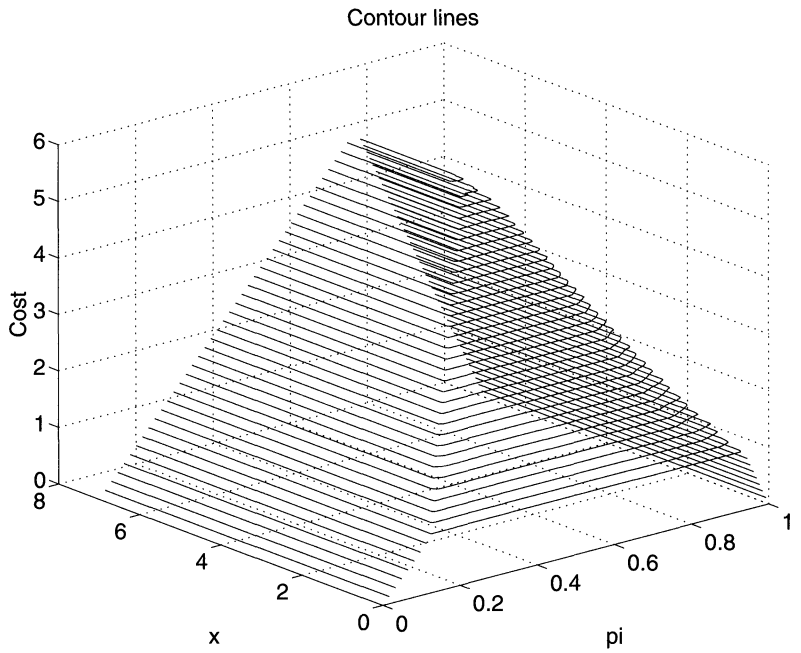

FIG. 3. *Value function.*

As one may expect, any observation error within the vicinity of target can cause a wrong decision. Due to discretization inaccuracies, finding the accurate boundaries between stopping,

observation, and continuation regions is very difficult. Nevertheless, the resulting difference in the value function is very small.

Acknowledgment. We would like to thank Guy Barles, Martin Clark, Jeremy Hodgson, David Salmond, Mete Soner, Gwen Tanner, Mihail Zervos, and the referees of this paper for their help, comments and suggestions. Thanks are due to Dimitris Sarris for doing the simulations.

HEAVY TRAFFIC CONVERGENCE OF A CONTROLLED, MULTICLASS QUEUEING SYSTEM*

L. F. MARTINS†, S. E. SHREVE‡, AND H. M. SONER‡

Abstract. This paper provides a rigorous proof of the connection between the optimal sequencing problem for a two-station, two-customer-class queueing network and the problem of control of a multidimensional diffusion process, obtained as a heavy traffic limit of the queueing problem. In particular, the diffusion problem, which is one of "singular control" of a Brownian motion, is used to develop policies which are shown to be asymptotically nearly optimal as the traffic intensity approaches one in the queueing network. The results are proved by a viscosity solution analysis of the related Hamilton–Jacobi–Bellman equations.

Key words. Brownian networks, queueing, heavy traffic, viscosity solutions, stochastic control

1. Introduction.

This paper provides a rigorous proof of the connection between the optimal sequencing problem for a two-station, two-customer-class queueing network and the problem of control of a multidimensional diffusion process, obtained as a heavy traffic limit of the queueing problem. In particular, the diffusion problem, which is one of "singular control" of a Brownian motion (also called "regulated Brownian motion" by Harrison (1985)), is used to develop policies which are shown to be asymptotically optimal as the traffic intensity approaches one in the queueing network.

The diffusion we wish to control here has been given the name *Brownian network* by Harrison (1988), who proposed such models as approximations to multiclass queueing networks. The idea of using diffusion approximations for single-class queueing systems dates back to Inglehart and Whitt (1970), Reiman (1984), and Johnson (1983). More recently, Reiman (1988), Peterson (1990), and Dai and Kurtz (1995) have obtained diffusion approximations for multiclass queues.

The control of Brownian networks for the purpose of obtaining control policies for queueing networks was initiated by Wein (1990a, 1990b, 1992) and Harrison and Wein (1989, 1990). These papers derive rules for sequencing customer services and for controlling input to queueing networks. Laws and Louth (1990) and Laws (1992) use Brownian networks to derive queueing network routing policies as well. All these papers are based on a heuristic understanding, amply supported by simulations, of the connection between the Brownian network control problem and the original queueing problem. Such a connection has been rigorously established in models with a single customer class by Kushner and Ramachandran (1988, 1989), Kushner and Martins (1990, 1991), and Krichagina et al. (1993, 1994). These papers use weak convergence methods. After the completion of this paper, Kushner and Martins (1994) used these methods to obtain the convergence of the value function considered in this paper. For weak convergence methods, the exogenous processes (e.g., arrival and service processes) can be quite general, provided that they have finite first and second moments.

In this paper, we assume that the arrival processes are Poisson and the service times are exponentially distributed. We base our analysis on the Hamilton–Jacobi–Bellman (HJB) equation, which, in turn, is based on the Markov property. In contrast to most other rigorous treatments of convergence, we treat a network with multiple customer classes. Our analysis

uses the theory of viscosity solutions of HJB equations. Viscosity solutions were first introduced by Crandall and Lions (1984), and equivalent definitions were given by Crandall, Evans, and Lions (1984). For recent developments, we refer the reader to Crandall, Ishii, and Lions (1992) and Fleming and Soner (1993).

The particular example chosen for our study has also been examined by Harrison and Wein (1989) and Chen, Yang, and Yao (1991). The former work derives a plausible asymptotically nearly optimal sequencing policy for the queueing network in one of the parameter cases that we study; we confirm the asymptotic near-optimality of this policy. The latter work, which does not introduce the Brownian network, solves the original queueing problem in some parameter cases; we obtain consistent results in the case where comparison of results is appropriate, and we obtain an asymptotically nearly optimal policy in a parameter case not solved by Chen, Yang, and Yao (1991).

This paper is organized as follows. In §2 we describe enough of the queueing system problem, including the heavy traffic assumptions, to enable us to summarize our results. We complete the problem formulation in §3. Sections 4 and 5 establish elementary results concerning the value function for the queueing system problem. In §6 we define the limit of the value functions for a sequence of queueing systems. Of course, our goals are to represent this limit as the value function for a diffusion control problem and to use this representation to construct asymptotically optimal policies for the queueing systems. In §7 we introduce the associated controlled Brownian network, and in §8 we reduce the Brownian network problem to one of workload control. Section 9 dispatches the easy Case I. Section 10 provides an overview of the harder Case II. The remaining sections are devoted to the technical analysis of a subcase of Case II, which we call Case IIA.

We choose only Case IIA for full treatment because

(i) it includes the common situation of seeking to minimize the sum of the queue lengths when the service time at station one is independent of customer class;

(ii) a closed-form solution to the queueing system problem in this subcase is unknown;

(iii) the convergence result in this subcase requires new methodology; and

(iv) the workload control problem in this subcase has a simple solution.

We believe that the techniques developed here can be extended to the other cases, but this would first require the solution of nontrivial singular stochastic control problems to prove existence of the functions Ψ_1 and Ψ_2, which appear in the discussion of cases IIB, IIC, and IID in §2.

2. Summary of results. We study a family of two-station queueing networks with Poisson arrivals and exponential service times. In the nth network, customers of class 1 and 2 arrive at station 1 with arrival rates $\lambda_1^{(n)}$ and $\lambda_2^{(n)}$, respectively, and are served at respective rates $\mu_1^{(n)}$ and $\mu_2^{(n)}$. Class 1 customers then exit the system, whereas class 2 customers proceed to station 2, where they are redesignated as class 3 customers and served at rate $\mu_3^{(n)}$. See Figure 1.

The cost per unit time of holding a class i customer is $c_i > 0$. The objective is to minimize

$$E \int_0^\infty e^{-\alpha t/n} \sum_{i=1}^{3} c_i Q_i^{(n)}(t) dt, \tag{2.1}$$

where $Q_i^{(n)}$ is the number of class i customers queued or undergoing service at time t, and α is a positive constant.

In order to minimize this objective, we may decide at each time t whether to serve a class 1 or a class 2 customer. Service can be switched away from one class to the other and subsequently switched back, resuming where it left off. We may also decide to idle station 1,

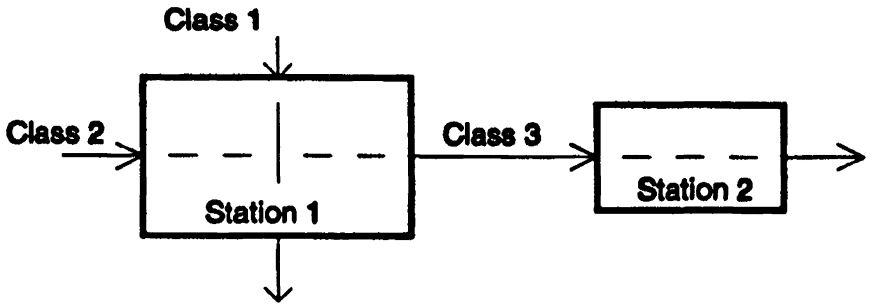

FIG. 1. *Criss-cross network.*

even though there are customers who could be served. This may be desirable if there are no class 1 customers and the cost c_3 is high relative to c_2 so that we prefer not to serve any class 2 customers until a backlog of class 3 customers has been reduced.

We want these networks to approach heavy traffic conditions as $n \to \infty$. Therefore, we define numbers $b_1^{(n)}$ and $b_2^{(n)}$ by the formulas

$$\frac{\lambda_1^{(n)}}{\mu_1^{(n)}} + \frac{\lambda_2^{(n)}}{\mu_2^{(n)}} = 1 - \frac{b_1^{(n)}}{\sqrt{n}}, \qquad \frac{\lambda_2^{(n)}}{\mu_3^{(n)}} = 1 - \frac{b_2^{(n)}}{\sqrt{n}} \tag{2.2}$$

so that $1 - \frac{b_1^{(n)}}{\sqrt{n}}$ is the traffic intensity at station 1 and $1 - \frac{b_2^{(n)}}{\sqrt{n}}$ is the traffic intensity at station 2. The *heavy traffic assumption* is that for $i = 1, 2, 3$ and $j = 1, 2$ the limits

$$\lambda_j = \lim_{n\to\infty} \lambda_j^{(n)}, \quad \mu_i = \lim_{n\to\infty} \mu_i^{(n)}, \quad b_j = \lim_{n\to\infty} b_j^{(n)}$$

are defined and positive and satisfy

$$\sup_n \left[\sqrt{n} \sum_{j=1}^{2} |\lambda_j^{(n)} - \lambda_j| + \sqrt{n} \sum_{i=1}^{3} |\mu_i^{(n)} - \mu_i| + \sum_{j=1}^{2} |b_j^{(n)} - b_j| \right] < \infty. \tag{2.3}$$

Our analysis divides naturally into two main cases, and the second case divides into four subcases. We describe our results in each case.

Case I ($c_1\mu_1 - c_2\mu_2 + c_3\mu_2 \le 0$). As long as customer class 2 is present, it should be served. If all class 2 customers have been served, then class 1 customers should be served.

This result agrees with Theorem 5.2 of Chen, Yang, and Yao (1991). The expected cost reduction per unit of service effort devoted to a class 2 customer is $(c_2 - c_3)\mu_2$, since service turns a class 2 customer into a class 3 customer. In Case I, $(c_2 - c_3)\mu_2$ dominates $c_1\mu_1$, the expected cost reduction per unit of service effort to a class 1 customer. This results in the simple fixed priority rule of serving class 2 customers whenever they are present.

Case II ($c_1\mu_1 - c_2\mu_2 + c_3\mu_2 > 0$). We further divide this case into four subcases. Reasoning behind this subdivision is given in §10 below.

Case IIA ($c_1\mu_1 - c_2\mu_2 + c_3\mu_2 > 0$, $c_2\mu_2 - c_3\mu_2 \ge 0$, $c_2\mu_2 - c_1\mu_1 \ge 0$). Now a unit of service applied to class 1 results in a greater expected cost reduction than a unit of service to class 2. In §12 we prove the asymptotic near-optimality (see the last paragraph of §6 for this concept) of the policy of serving class 1 unless the number of class 3 customers falls below a positive threshold, in which case priority is switched to class 2 so that station 2 is not starved. The switching threshold depends on the queue lengths in the following way. Let

$a, b : [0, \infty) \to [0, \infty)$ be bounded, concave, increasing functions satisfying

$$a(0) = b(0) = 0, \qquad \eta \triangleq b(\infty) < (a(\infty))^2.$$

Define $\gamma(z_1, z_2, z_3) \triangleq a(z_1)a(z_3) - b(z_2)$. The nearly asymptotically optimal policy is given by

$$\text{serve class 1 if} \quad \gamma(Q_1^{(n)}(t)/\sqrt{n}, Q_2^{(n)}(t)/\sqrt{n}, Q_3^{(n)}(t)/\sqrt{n}) \geq 0,$$

$$\text{serve class 2 if} \quad \gamma(Q_1^{(n)}(t)/\sqrt{n}, Q_2^{(n)}(t)/\sqrt{n}, Q_3^{(n)}(t)/\sqrt{n}) < 0,$$

where $Q_i^{(n)}(t)$ denotes the number of class i customers present at time i. As $\eta \downarrow 0$, this policy approaches asymptotic optimality.

Harrison and Wein's (1989) model with $c_1 = c_2 = c_3 = 1$, $\mu_1 = \mu_2 = 2$, $\mu_3 = 1$ falls into this subcase, and their proposed policy is to serve class 1 if and only if $Q_3^{(n)}(t)/\sqrt{n}$ exceeds a positive constant which is independent of n and the other queue lengths. They showed by simulation that with a properly chosen constant, this policy outperforms the rules "first-in, first-out," "longest expected remaining processing time," and "shortest expected remaining processing time." They also found that its performance was within about 5% of a lower bound that they obtained for the optimal cost. We have not done simulation testing of our policy.

The heuristic justification of the policy in Case IIA suggests that the same policy is asymptotically optimal under only the Case II condition $c_1\mu_1 - c_2\mu_2 + c_3\mu_2 > 0$. Our proof of the result stated in Case IIA suggests otherwise. Although we have not worked out a full proof for the other three subcases, the proof for Case IIA strongly suggests the following conjectures. A brief motivation of the following conjectures is given in §10 below. Chen, Yang, and Yao (1991) offer a heuristic policy, based only on the length of the queue at the second station, for all subcases of Case II. (Note that one must set $r = 0$ in Chen, Yang, and Yao in order to compare to our result.)

Case IIB ($c_1\mu_1 - c_2\mu_2 + c_3\mu_2 > 0, c_2\mu_2 - c_3\mu_2 < 0, c_2\mu_2 - c_1\mu_1 \geq 0$). There is a continuous, increasing function $\Psi_2 : [0, \infty) \to [0, \infty)$ satisfying

$$0 \leq \Psi_2(\omega_2) < \mu_3\omega_2/\mu_2 \quad \forall \omega_2 \geq 0, \qquad \lim_{\omega_2 \to \infty} \Psi_2(\omega_2) = \infty.$$

Class 1 should be given priority unless either the queue length $Q_1^{(n)}$ of class 1 customers falls to zero or the queue length $Q_3^{(n)}$ of class 3 customers falls below some positive threshold. While either of these conditions is satisfied, priority should be switched to class 2, except that whenever $Q_1^{(n)} = 0$ and

$$\frac{Q_2^{(n)}}{\sqrt{n}\,\mu_2} < \Psi_2\left(\frac{Q_2^{(n)} + Q_3^{(n)}}{\sqrt{n}\,\mu_3}\right),$$

station 1 should be idled. This idleness can be explained by the fact that it is cheaper to hold class 2 customers at station 1 than to send them on to be held as class 3 customers at station 2; note that in this subcase, $c_2 < c_3$. Also observe that when $Q_1^{(n)} = 0$, the pair $(Q_2^{(n)}/\mu_2, (Q_2^{(n)} + Q_3^{(n)})/\mu_3)$ is equal to the expected impending service time for the two stations embodied in customers anywhere in the network; see §8 below for details. The term $1/\sqrt{n}$ that appears in the above formulas is related to time scaling that will be introduced in the next section.

Case IIC ($c_1\mu_1 - c_2\mu_2 + c_3\mu_2 > 0, c_2\mu_2 - c_3\mu_2 \geq 0, c_2\mu_2 - c_1\mu_1 < 0$). There exists a continuous, increasing function $\Psi_1 : [0, \infty) \to [0, \infty)$ satisfying

$$0 \leq \Psi_1(\omega_1) < \mu_2\omega_1/\mu_3 \quad \forall \omega_1 \geq 0, \qquad \lim_{\omega_1 \to \infty} \Psi_1(\omega_1) = \infty.$$

Class 1 should be given priority unless either $Q_1^{(n)} = 0$ or $Q_3^{(n)}$ is less than a positive threshold. While either of these conditions is satisfied, priority should be switched to class 2, except that when $Q_1^{(n)} > 0$ and

$$\frac{Q_2^{(n)}}{\sqrt{n}\,\mu_3} < \Psi_1\left(\frac{Q_1^{(n)}}{\sqrt{n}\,\mu_1} + \frac{Q_2^{(n)}}{\sqrt{n}\,\mu_2}\right),$$

priority should be given to class 1, even though this may cause station 2 to starve. Idling station 2 can be explained by the fact that the cost of operating the network can be reduced more quickly by serving class 1 than by serving class 2; note that $c_1\mu_1 > c_2\mu_2$. As in the previous case, the term $1/\sqrt{n}$ is related to time scaling, and when $Q_3^{(n)} = 0$, the pair

$$\left(\frac{Q_1^{(n)}}{\mu_1} + \frac{Q_2^{(n)}}{\mu_2}, \frac{Q_2^{(n)}}{\mu_3}\right)$$

is equal to the expected impending service time for the two stations embodied in customers anywhere in the network.

Case IID ($c_1\mu_1 - c_2\mu_2 + c_3\mu_2 > 0, c_2\mu_2 - c_3\mu_2 < 0, c_2\mu_2 - c_1\mu_1 < 0$). This case is a combination of Case IIB and Case IIC. We conjecture the existence of functions Ψ_1 and Ψ_2 as described above. Idling can occur at either station 1 or station 2, as described in Case IIB and Case IIC, respectively.

3. The queueing network problem. For the queueing network of the previous section, for $i = 1, 2$, let $\{A_i^{(n)}(t); 0 \le t < \infty)$ be the class i customer *arrival process*, assumed to be Poisson with intensity $\lambda_i^{(n)}$. For $i = 1, 2, 3$, let $\{S_i^{(n)}(t); 0 \le t < \infty\}$ be the class i customer *service process*, assumed to be Poisson with intensity $\mu_i^{(n)}$. We take all these processes to be left-continuous, and we denote by $\{\mathcal{F}^{(n)}(t); 0 \le t < \infty\}$ the filtration generated by these five processes.

A *control law* $\{Y(t), U(t); 0 \le t < \infty\}$ is a pair of left-continuous, $\{\mathcal{F}^{(n)}(t); 0 \le t < \infty\}$-adapted, $\{0, 1\}$-valued processes. The process $Y(t)$ indicates whether station 1 is active ($Y(t) = 1$) or idle ($Y(t) = 0$), and $U(t)$ indicates whether station 1 is serving customer class 1 ($U(t) = 1$) or customer class 2 ($U(t) = 0$). Given nonnegative initial queue lengths $Q_1^{(n)}(0)$, $Q_2^{(n)}(0)$, and $Q_3^{(n)}(0)$ for the three customer classes, and given a control law (Y, U), there is a unique triple of *queue length processes* satisfying

$$Q_1^{(n)}(t) = Q_1^{(n)}(0) + A_1^{(n)}(t) - \int_0^t Y(s)U(s)1_{\{Q_1^{(n)}(s)\ge 1\}} dS_1^{(n)}(s),$$

$$Q_2^{(n)}(t) = Q_2^{(n)}(0) + A_2^{(n)}(t) - \int_0^t Y(s)(1 - U(s))1_{\{Q_2^{(n)}(s)\ge 1\}} dS_2^{(n)}(s),$$

$$Q_3^{(n)}(t) = Q_3^{(n)}(0) + \int_0^t Y(s)(1 - U(s))1_{\{Q_2^{(n)}(s)\ge 1\}} dS_2^{(n)}(s) - \int_0^t 1_{\{Q_3^{(n)}(s)\ge 1\}} dS_3^{(n)}(s),$$

where 1_A is the indicator of the set A. We denote the vector of queue length processes by

$$Q^{(n)}(t) = (Q_1^{(n)}(t), Q_2^{(n)}(t)Q_3^{(n)}(t)).$$

(Note: Because the interservice times are exponentially distributed, the processes

$$\int_0^t Y(s)U(s)1_{\{Q_1^{(n)}(s)\ge 1\}} dS_1^{(n)}(s) \quad \text{and} \quad S_1^{(n)}\left(\int_0^t Y(s)U(s)1_{\{Q_1^{(n)}(s)\ge 1\}} ds\right)$$

have the same law. This permits us to write $Q_1^{(n)}(t)$ in terms of the former, although the latter more nearly reflects the way we interpret the system. If service of a customer is preempted and later resumed, we assume that service begins where it was left off. After resumption of service, the time to completion has the same exponential distribution as the original distribution of the service time. Similar comments apply to $Q_2^{(n)}(t)$ and $Q_3^{(n)}(t)$.)

The vector of *scaled queue length processes* is

$$Z^{(n)}(t) \triangleq \frac{1}{\sqrt{n}} Q^{(n)}(nt).$$

For fixed controls $(y, u) \in \{0, 1\}^2$, this is a Markov chain with lattice state space $L^{(n)} \triangleq \{\frac{k}{\sqrt{n}}; k = 0, 1, \ldots\}^3$, and its infinitesimal generator is (see Chung (1960))

$$\begin{aligned}(\mathcal{L}^{n,y,u}\varphi)(z) \triangleq\ & n\lambda_1^{(n)}\left[\varphi\left(z + \frac{1}{\sqrt{n}}e_1\right) - \varphi(z)\right] + n\lambda_2^{(n)}\left[\varphi\left(z + \frac{1}{\sqrt{n}}e_2\right) - \varphi(z)\right] \\ & + n\mu_1^{(n)} yu\left[\varphi\left(z - \frac{1}{\sqrt{n}}e_1\right) - \varphi(z)\right] 1_{\{z_1>0\}} \\ & + n\mu_2^{(n)} y(1-u)\left[\varphi\left(z - \frac{1}{\sqrt{n}}e_2 + \frac{1}{\sqrt{n}}e_3\right) - \varphi(z)\right] 1_{\{z_2>0\}} \\ & + n\mu_3^{(n)}\left[\varphi\left(z - \frac{1}{\sqrt{n}}e_3\right) - \varphi(z)\right] 1_{\{z_3>0\}},\end{aligned} \tag{3.1}$$

where $z = (z_1, z_2, z_3)$, $e_1 = (1, 0, 0)$, $e_2 = (0, 1, 0)$, and $e_3 = (0, 0, 1)$. In particular, given any control law $(Y(\cdot), U(\cdot))$, for any real-valued function φ on $L^{(n)}$, the process

$$e^{-\alpha t}\varphi(Z^{(n)}(t)) + \int_0^t e^{-\alpha s}[\alpha\varphi(Z^{(n)}(s)) - \mathcal{L}^{n,Y(s),U(s)}\varphi(Z^{(n)}(s))]ds \tag{3.2}$$

is a local martingale.

Using the positive holding costs c_1, c_2, c_3, we define the *holding cost function* $h(z) = \sum_{i=1}^3 c_i z_i$. Given an initial condition $Z^{(n)}(0) = z \in L^{(n)}$ and a control law $(Y(\cdot), U(\cdot))$, we define the associated *cost function* at z by

$$J_{Y,U}^{(n)}(z) \triangleq E\int_0^\infty e^{-\alpha t}h(Z^{(n)}(t))dt. \tag{3.3}$$

In terms of the original queue length process, this cost can be written as (cf. (2.1))

$$n^{-\frac{3}{2}}E\int_0^\infty e^{-(\alpha t)/n}h(Q^{(n)}(t))dt.$$

The *value function* at z is

$$J_*^{(n)}(z) \triangleq \inf\{J_{Y,U}^{(n)}(z);\ (Y, U) \text{ is a control law}\}. \tag{3.4}$$

4. Stationary control laws for the queueing network. A *stationary control law* for the nth queueing network is a pair of functions $Y : L^{(n)} \to \{0, 1\}$, $U : L^{(n)} \to \{0, 1\}$. The value of the control at time t is given in feedback form as $(Y(Z^{(n)}(t)), U(Z^{(n)}(t)))$. Because the

queueing network is driven by time-homogeneous Markov arrival and service processes, we have

$$J_*^{(n)}(z) = \inf\{J_{Y,U}^{(n)}(z);\ (Y, U) \text{ is a } \textit{stationary} \text{ control law}\}. \tag{4.1}$$

Let $\mathcal{L}^{n,Y,U}$ denote the infinitesimal generator of the controlled process with stationary controls Y, U. Then $\mathcal{L}^{n,Y,U}$ is given as in (3.1) with the pair (y, u) replaced by $(Y(z), U(z))$.

PROPOSITION 4.1. *For any stationary control law (Y, U), the function $J_{Y,U}^{(n)}$ is the unique, linearly growing solution of the equation*

$$\alpha\varphi - \mathcal{L}^{n,Y,U}\varphi - h = 0 \quad \textit{on} \quad L^{(n)}. \tag{4.2}$$

If φ is a linearly growing subsolution of this equation, i.e.,

$$\alpha\varphi - \mathcal{L}^{n,Y,U}\varphi - h \le 0 \quad \textit{on} \quad L^{(n)},$$

or if φ is a linearly growing supersolution, *i.e.,*

$$\alpha\varphi - \mathcal{L}^{n,Y,U}\varphi - h \ge 0 \quad \textit{on} \quad L^{(n)},$$

then $\varphi \le J_{Y,U}^{(n)}$ or $\varphi \ge J_{Y,U}^{(n)}$, respectively.

Proof. Under any control law, we have

$$EZ_1^{(n)}(t) \le Z_1^{(n)}(0) + \frac{1}{\sqrt{n}} EA_1^{(n)}(nt) = Z_1^{(n)}(0) + \sqrt{n}\,\lambda_1^{(n)} t, \tag{4.3}$$

$$EZ_2^{(n)}(t) \le Z_2^{(n)}(0) + \frac{1}{\sqrt{n}} EA_2^{(n)}(nt) = Z_2^{(n)}(0) + \sqrt{n}\,\lambda_2^{(n)} t, \tag{4.4}$$

$$EZ_3^{(n)}(t) \le Z_3^{(n)}(0) + \frac{1}{\sqrt{n}} ES_2^{(n)}(nt) = Z_3^{(n)}(0) + \sqrt{n}\,\mu_2^{(n)} t, \tag{4.5}$$

so

$$J_{Y,U}^{(n)}(z) \le h(z) + \frac{\sqrt{n}}{\alpha} h(\lambda_1^{(n)}, \lambda_2^{(n)}, \mu_2^{(n)}), \tag{4.6}$$

and $J_*^{(n)}$ has the same upper bound. Using the bounds (4.3)–(4.5) and the dominated convergence theorem, one can show that for any linearly growing φ, the local martingale (3.2) is in fact a martingale. In particular, if (Y, U) is a stationary control law, then

$$\begin{aligned} J_{Y,U}^{(n)}(Z^{(n)}(0)) &= Ee^{-\alpha t} J_{Y,U}^{(n)}(Z^{(n)}(t)) \\ &\quad + E\int_0^t e^{-\alpha s}[\alpha J_{Y,U}^{(n)}(Z^{(n)}(s)) - (\mathcal{L}^{n,Y(Z^{(n)}(s)),U(Z^{(n)}(s))} J_{Y,U}^{(n)})(Z^{(n)}(s))]ds. \end{aligned}$$

But for a stationary control law, the Markov property implies

$$J_{Y,U}^{(n)}(Z^{(n)}(0)) = Ee^{-\alpha t} J_{Y,U}^{(n)}(Z^{(n)}(t)) + E\int_0^t e^{-\alpha s} h(Z^{(n)}(s))ds.$$

Comparing these two equations, we see that

$$\begin{aligned} E\int_0^t e^{-\alpha s}[\alpha J_{Y,U}^{(n)}(Z^{(n)}(s)) - (\mathcal{L}^{n,Y(Z^{(n)}(s)),U(Z^{(n)}(s))} J_{Y,U}^{(n)})(X^{(n)}(s))]ds \\ = E\int_0^t e^{-\alpha s} h(Z^{(n)}(s))ds. \end{aligned}$$

Dividing by t and letting $t \downarrow 0$, we see that $J^{(n)}_{Y,U}$ satisfies (4.2). Uniqueness of this solution will follow from the second part of the proposition.

If φ is a linearly growing subsolution of (4.2), then the martingale property for (3.2) implies

$$\varphi(Z^{(n)}(0)) \leq E\left[e^{-\alpha t}\varphi(Z^{(n)}(t)) + \int_0^t e^{-\alpha s}h(Z^{(n)}(s))ds\right].$$

Letting $t \to \infty$, using (4.3)–(4.5) and the linear growth of φ, we obtain $\varphi \leq J^{(n)}_{Y,U}$. The supersolution claim is proved similarly. □

5. The HJB equation for the queueing network. For $\varphi : L^{(n)} \to \mathcal{R}$, we define the nonlinear operator $\mathcal{L}^{n,*}$ acting on φ by

$$\mathcal{L}^{n,*}\varphi(z) \triangleq \min\{\mathcal{L}^{n,y,u}\varphi(z);\ (y,u) \in \{0,1\}^2\} \quad \forall z \in L^{(n)}. \tag{5.1}$$

The HJB equation for the nth queueing network is

$$\alpha\varphi - \mathcal{L}^{n,*}\varphi - h = 0 \quad \text{on} \quad L^{(n)}. \tag{5.2}$$

PROPOSITION 5.1. *The value function $J^{(n)}_*$ is the unique, linearly growing solution of the HJB equation* (5.2). *If φ is a linearly growing subsolution (respectively, supersolution) of this equation, then $\varphi \leq J^{(n)}_*$ (respectively, $\varphi \geq J^{(n)}_*$). Furthermore, any stationary control law (Y^*, U^*) satisfying*

$$\mathcal{L}^{n,Y^*,U^*}J^{(n)}_* = \mathcal{L}^{n,*}J^{(n)}_* \tag{5.3}$$

is optimal.

Proof. We first prove the comparisons. Let φ be a linearly growing subsolution of (5.2). Then, for any stationary control (Y, U), we have

$$\alpha\varphi - \mathcal{L}^{n,Y,U} - h \leq \alpha\varphi - \mathcal{L}^{n,*}\varphi - h \leq 0.$$

Proposition 4.1 implies $\varphi \leq J^{(n)}_{Y,U}$, and minimization over (Y, U) yields $\varphi \leq J^{(n)}_*$.

Now let φ be a linearly growing supersolution of (5.2), and choose a stationary control (Y, U) satisfying

$$\alpha\varphi - \mathcal{L}^{n,Y,U}\varphi - h = \alpha\varphi - \mathcal{L}^{n,*}\varphi - h \geq 0.$$

Proposition 4.1 implies $\varphi \geq J^{(n)}_{Y,U}$, which dominates $J^{(n)}_*$.

A linearly growing solution of (5.2) can be constructed by the policy iteration algorithm. Let (Y_0, U_0) be any stationary control, and choose (Y_{k+1}, U_{k+1}) recursively so that

$$\mathcal{L}^{n,Y_{k+1},U_{k+1}}J^{(n)}_{Y_k,U_k} = \mathcal{L}^{n,*}J^{(n)}_{Y_k,U_k}.$$

Then $J^{(n)}_\infty \triangleq \lim_{k\to\infty} J^{(n)}_{Y_k,U_k}$ can be shown to be a linearly growing solution of (5.2); we omit the details. By the comparisons already proved, any linearly growing solution of (5.2) must agree with $J^{(n)}_*$, and since (5.2) has a linearly growing solution, $J^{(n)}_*$ is a solution. □

Remark 5.2. In certain situations, we will need to extend the definition of the operator $\mathcal{L}^{n,y,u}$ to allow (y, u) to take values in the square $[0, 1]^2$, rather than just at the corners. Fractional values of u correspond to processor sharing at the first station, and fractional values

of y correspond to partial utilization of this station. The only property that will be needed, however, is that (5.1) can be rewritten as

$$\mathcal{L}^{n,*}\varphi(z) = \min\{\mathcal{L}^{n,y,u}\varphi(z);\ \ (y,u) \in [0,1]^2\}, \tag{5.4}$$

a fact easily verified by noting from (3.1) that the minimum in (5.4) will be obtained at some corner of $[0,1]^2$.

6. The heavy traffic limit of the value function. In order to let $n \to \infty$, we need an upper bound, independent of n, for the nonnegative functions $\{J_*^{(n)}\}_{n=1}^{\infty}$.

PROPOSITION 6.1. *There are constants K_1 and K_2, independent of n, such that*

$$J_*^{(n)}(z) \le K_1 + K_2(z_1 + z_2 + z_3) \quad \forall z \in L^{(n)}.$$

Proof. Define $\varphi(z) = \sum_{i=1}^{3}(z_i + e^{-z_i})$ for all $z \in L^{(n)}$. Set $u = \lambda_1/\mu_1$. We begin by verifying that $(\mathcal{L}^{n,1,u}\varphi)(z)$ is bounded above by a constant independent of n and $z \in L^{(n)}$.

From (2.2) and (2.3) we have $\frac{\lambda_1}{\mu_1} + \frac{\lambda_2}{\mu_2} = 1$, $\lambda_2 = \mu_3$, $\lambda_i^{(n)} = \lambda_i + O(\frac{1}{\sqrt{n}})$, and $\mu_i^{(n)} = \mu_i + O(\frac{1}{\sqrt{n}})$, where $O(n^p)$ denotes a term whose absolute value is bounded by Kn^p and K is a constant independent of n and $z \in L^{(n)}$. We may thus rewrite (3.1) as

$$\begin{aligned}
(\mathcal{L}^{n,l,u}\varphi)(z) &= n\lambda_1\left[\varphi\left(z + \frac{1}{\sqrt{n}}e_1\right) + \varphi\left(z - \frac{1}{\sqrt{n}}e_1\right) - 2\varphi(z)\right] \\
&\quad + n\lambda_2\left[\varphi\left(z + \frac{1}{\sqrt{n}}e_2\right) + \varphi\left(z - \frac{1}{\sqrt{n}}e_2 + \frac{1}{\sqrt{n}}e_3\right) + \varphi\left(z - \frac{1}{\sqrt{n}}e_3\right) - 3\varphi(z)\right] \\
&\quad - n\lambda_1\left[\varphi\left(z - \frac{1}{\sqrt{n}}e_1\right) - \varphi(z)\right]1_{\{z_1=0\}} \\
&\quad - n\lambda_2\left[\varphi\left(z - \frac{1}{\sqrt{n}}e_2 + \frac{1}{\sqrt{n}}e_3\right) - \varphi(z)\right]1_{\{z_2=0\}} \\
&\quad - n\lambda_2\left[\varphi\left(z - \frac{1}{\sqrt{n}}e_3\right) - \varphi(z)\right]1_{\{z_3=0\}} \\
&\quad + O(\sqrt{n})\left[\sum_{i=1}^{3}\left|\varphi\left(z \pm \frac{1}{\sqrt{n}}e_i\right) - \varphi(z)\right| + \left|\varphi\left(z - \frac{1}{\sqrt{n}}e_2 + \frac{1}{\sqrt{n}}e_3\right) - \varphi(z)\right|\right].
\end{aligned}$$

Since $\varphi(z \pm \frac{1}{\sqrt{n}}e_i) - \varphi(z) = \pm\frac{1}{\sqrt{n}}(1 - e^{-z_i}) + O(\frac{1}{n})$ and $\varphi(z - \frac{1}{\sqrt{n}}e_2 + \frac{1}{\sqrt{n}}e_3) - \varphi(z) = \frac{1}{\sqrt{n}}(e^{-z_2} - e^{-z_3}) + O(\frac{1}{n})$, we have

$$(\mathcal{L}^{n,1,u}\varphi)(z) = -\sqrt{n}\ \lambda_2(1 - e^{-z_3}) + O(1).$$

This implies that $\mathcal{L}^{n,1,u}\varphi$ is bounded above by a constant K_0.

Let $K_2 = \frac{1}{\alpha}\max\{c_1, c_2, c_3\}$, so $\alpha K_2\varphi - h \ge 0$. Put $\Psi = \frac{1}{\alpha}K_2K_0 + K_2\varphi$. Then

$$\alpha\Psi - \mathcal{L}^{n,1,u}\Psi - h = \alpha K_2\varphi - h + K_2(K_0 - \mathcal{L}^{n,1,u}\varphi) \ge 0,$$

which shows that $\alpha\Psi - \mathcal{L}^{n,*}\Psi - h \ge 0$. (Recall Remark 5.2.) The supersolution part of Proposition 5.1 implies

$$J_*^{(n)}(z) \le \Psi(z) \le \frac{1}{\alpha}K_2K_0 + 3K_2 + K_2(z_1 + z_2 + z_3). \qquad \square$$

We wish to consider $\lim_{n\to\infty} J_*^{(n)}$, but since each $J_*^{(n)}$ is defined on a different set $L^{(n)}$, the definition of this limit is not straightforward. Borrowing the technique developed by Barles and Perthame (1988) (see also Fleming and Soner (1993, §7.3)), we define the *upper semicontinuous limit* $J^\#$ of $\{J_*^{(n)}\}_{n=1}^\infty$ by

$$J^\#(z) \triangleq \lim_{\epsilon\downarrow 0} \lim_{n\to\infty} \sup_{\substack{\zeta\in L^{(n)} \\ \|\zeta - z\|<\epsilon}} J_*^{(n)}(\zeta) \quad \forall z \in [0,\infty)^3 \tag{6.1}$$

and the *lower semicontinuous limit* $J_\#$ by

$$J_\#(z) \triangleq \lim_{\epsilon\downarrow 0} \lim_{n\to\infty} \inf_{\substack{\zeta\in L^{(n)} \\ \|\zeta - z\|<\epsilon}} J_*^{(n)}(\zeta) \quad \forall z \in [0,\infty)^3. \tag{6.2}$$

Then $J^\#$ is upper semicontinuous, $J_\#$ is lower semicontinuous, and

$$0 \le J_\#(z) \le J^\#(z) \le K_1 + K_2(z_1 + z_2 + z_3) \quad \forall z \in [0,\infty)^3. \tag{6.3}$$

We shall eventually show that $J_\# = J^\#$, and we shall use a Brownian network problem to suggest, for each $\eta > 0$, a sequence of stationary policies $\{(Y^n, U^n)\}_{n=1}^\infty$ such that

$$\lim_{\epsilon\downarrow 0} \lim_{n\to\infty} \sup_{\substack{\zeta\in L^n \\ \|\zeta - z\|<\epsilon}} |J^{(n)}_{Y^n,U^n}(\zeta) - J_\#(\zeta)| \le \eta \quad \forall z \in [0,\infty)^3. \tag{6.4}$$

We call such a family (parametrized by η) of sequences of policies *asymptotically nearly optimal*.

7. The controlled Brownian network. We first introduce the controlled Brownian network and then explain by an analysis of the infinitesimal generator $\mathcal{L}^{n,y,u}$ why it is relevant. Let M_1, M_2, and M_3 be continuous martingales relative to a filtration $\{\mathcal{F}(t)\}$ satisfying the usual conditions that each $\mathcal{F}(t)$ contains all null sets of $\mathcal{F}(\infty)$ and that $\mathcal{F}(t) = \cap_{s>t}\mathcal{F}(s)$ for all t. Assume that for all t,

$$\langle M_1\rangle(t) = 2\lambda_1 t, \qquad \langle M_2\rangle(t) = \langle M_3\rangle(t) = 2\lambda_2 t, \tag{7.1}$$

$$\langle M_1, M_2\rangle(t) = \langle M_1, M_3\rangle(t) = 0, \qquad \langle M_2, M_3\rangle(t) = -\lambda_2 t. \tag{7.2}$$

Given $z \in [0,\infty)^3$, we will say that the quadruple $(\ell_0, \ell_1, \ell_2, \ell_3)$ of $\{\mathcal{F}(t)\}$-adapted processes is *admissible for initial condition* z, provided that

(i) $(\ell_0, \ell_1, \ell_2, \ell_3)$ are right-continuous with left-hand limits, with the convention that $\ell_i(0^-) = 0$, $i = 1, 2, 3$;

(ii) ℓ_0 is of finite variation on bounded intervals;

(iii) ℓ_1, ℓ_2, and ℓ_3 are nondecreasing,

(iv) the *state process* $Z(t) = (Z_1(t), Z_2(t), Z_3(t))$ is in $[0,\infty)^3$ for all $t \ge 0$, where

$$Z_1(t) \triangleq z_1 + M_1(t) + \mu_1\ell_0(t) + \ell_1(t), \tag{7.3}$$

$$Z_2(t) \triangleq z_2 - b_1\mu_2 t + M_2(t) - \mu_2\ell_0(t) + \ell_2(t), \tag{7.4}$$

$$Z_3(t) \triangleq z_3 + (b_1\mu_2 - b_2\mu_3)t + M_3(t) + \mu_2\ell_0(t) - \ell_2(t) + \ell_3(t). \tag{7.5}$$

The *cost function* associated with $(\ell_0, \ell_1, \ell_2, \ell_3)$, admissible at $z \in [0,\infty)^3$, is

$$V_{\ell_0,\ell_1,\ell_2,\ell_3}(z) \triangleq E\int_0^\infty e^{-\alpha t} h(Z(t))dt.$$

The *value function* for the controlled Brownian network is

$$V(z) \triangleq \inf\{V_{\ell_0,\ell_1,\ell_2,\ell_3}(z);\ (\ell_0, \ell_1, \ell_2, \ell_3) \text{ is admissible at } z\}, \qquad z \in [0, \infty)^3. \tag{7.6}$$

The cross variation formulas (7.1), (7.2) imply that the vector of martingales (M_1, M_2, M_3) is nothing more than a three-dimensional standard Brownian motion multiplied by a nonsingular matrix, so this vector of martingales is also a Markov process. If we set the control processes $\ell_0, \ell_1, \ell_2, \ell_3$ equal to zero, the state process $Z(t)$ given by (7.3)–(7.5) is Markov with infinitesimal generator

$$\mathcal{L}\varphi = -b_1\mu_2\varphi_2 + (b_1\mu_2 - b_2\mu_3)\varphi_3 + \lambda_1\varphi_{11} + \lambda_2\varphi_{22} - \lambda_2\varphi_{23} + \lambda_2\varphi_{33}, \tag{7.7}$$

where φ is any C^2 function from $[0, \infty)^3$ to $\mathbf{R}$ with φ_i denoting partial derivative with respect to the ith variable.

The controlled Brownian network is an intermediate problem between the queueing networks studied thus far and the workload control problem of the next section. Although the value function is well defined by (7.6), the problem does not have an optimal solution. We shall see in the next section that one would like to keep the state $Z(t)$ on a face of the orthant $[0, \infty)^3$, but this is not possible with the bounded variation control processes $\ell_0, \ell_1, \ell_2, \ell_3$. Fortunately, when we pass to the workload formulation, we will obtain a well-posed control problem.

We conclude this section with an asymptotic expansion of the infinitesimal generator $\mathcal{L}^{n,y,u}$ of (3.1) for the controlled queueing network. This expansion is needed for the proofs in the following sections and also explains the origin of the Brownian network problem introduced in this section.

Suppose that $\varphi : [0, \infty)^3 \to \mathcal{R}$ is thrice continuously differentiable, and all derivatives of φ up to order three are bounded uniformly on $[0, \infty)^3$. Fix $(y, u) \in \{0, 1\}^2$, and define

$$\theta^{(n)} = \sqrt{n}\left[\frac{\lambda_1^{(n)}}{\mu_1^{(n)}} - u\right], \quad \sigma_1 = \sqrt{n}\mu_1^{(n)}(1-y)u, \quad \sigma_2 = \sqrt{n}\mu_2^{(n)}(1-y)(1-u). \tag{7.8}$$

Recalling (2.2), we may write

$$u = -\frac{\theta^{(n)}}{\sqrt{n}} + \frac{\lambda_1^{(n)}}{\mu_1^{(n)}}, \qquad (1-u) = \frac{\theta^{(n)}}{\sqrt{n}} + \frac{\lambda_2^{(n)}}{\mu_2^{(n)}} + \frac{b_1^{(n)}}{\sqrt{n}}. \tag{7.9}$$

For $z \in [0, \infty)^3$, we set

$$\mathcal{B}_1^{n,y,u}\varphi(z) \triangleq \sqrt{n}\,\mu_1^{(n)} yu\left[\varphi_1(z) - \frac{1}{2\sqrt{n}}\varphi_{11}(z)\right] 1_{\{z_1=0\}}, \tag{7.10}$$

$$\begin{aligned}\mathcal{B}_2^{n,y,u}\varphi(z) \triangleq \sqrt{n}\,\mu_2^{(n)} y(1-u)\Bigg(&\varphi_2(z) - \varphi_3(z) - \frac{1}{2\sqrt{n}}\varphi_{22}(z) \\ &+ \frac{1}{\sqrt{n}}\varphi_{23}(z) - \frac{1}{2\sqrt{n}}\varphi_{33}(z)\Bigg) 1_{\{z_2=0\}},\end{aligned} \tag{7.11}$$

$$\mathcal{B}_3^{n,y,u}\varphi(z) \triangleq \sqrt{n}\,\mu_3^{(n)}\left[\varphi_3(z) - \frac{1}{2\sqrt{n}}\varphi_{33}(z)\right] 1_{\{z_3=0\}} \tag{7.12}$$

so that (3.1) becomes, by use of a Taylor expansion,

$$\begin{aligned}\mathcal{L}^{n,y,u}\varphi(z) &= \sqrt{n}\,\lambda_1^{(n)}\left[\varphi_1(z)+\frac{1}{2\sqrt{n}}\varphi_{11}(z)\right]+\sqrt{n}\,\lambda_2^{(n)}\left[\varphi_2(z)+\frac{1}{2\sqrt{n}}\varphi_{22}(z)\right]\\ &+(\sqrt{n}\,\mu_1^{(n)}u-\sigma_1)\left[-\varphi_1(z)+\frac{1}{2\sqrt{n}}\varphi_{11}(z)\right]+\mathcal{B}_1^{n,y,u}\varphi(z)\\ &+(\sqrt{n}\,\mu_2^{(n)}(1-u)-\sigma_2)\left[-\varphi_2(z)+\varphi_3(z)+\frac{1}{2\sqrt{n}}\varphi_{22}(z)-\frac{1}{\sqrt{n}}\varphi_{23}(z)+\frac{1}{2\sqrt{n}}\varphi_{33}(z)\right]\\ &+\mathcal{B}_2^{n,y,u}\varphi(z)\\ &+\sqrt{n}\,\mu_3^{(n)}\left[-\varphi_3(z)+\frac{1}{2\sqrt{n}}\varphi_{33}(z)\right]+\mathcal{B}_3^{n,y,u}\varphi(z)+O\left(\frac{1}{\sqrt{n}}\right).\end{aligned}$$

Because the derivatives of φ are bounded, we can conclude from (2.3) and (7.9) that

$$\begin{aligned}\mathcal{L}^{n,y,u}\varphi(z) &= \mathcal{L}\varphi(z)+\theta^{(n)}\left[\nabla\varphi(z)\cdot\xi^{(n)}+\frac{1}{\sqrt{n}}\mathcal{A}^{(n)}\varphi(z)\right]\\ &+\sigma_1\left[\varphi_1(z)-\frac{1}{\sqrt{n}}\varphi_{11}(z)\right]\\ &+\sigma_2\left[\varphi_2(z)-\varphi_3(z)-\frac{1}{2\sqrt{n}}(\varphi_{22}(z)-2\varphi_{23}(z)+\varphi_{33}(z))\right]\\ &+\sum_{i=1}^{3}\mathcal{B}_i^{n,y,u}\varphi(z)+O\left(\frac{1}{\sqrt{n}}\right),\end{aligned}\tag{7.13}$$

where $\mathcal{L}\varphi$ is given by (7.7) and

$$\xi^{(n)} \triangleq (\mu_1^{(n)}, -\mu_2^{(n)}, \mu_2^{(n)}),\tag{7.14}$$

$$\mathcal{A}^{(n)}\varphi \triangleq -\frac{1}{2}\mu_1^{(n)}\varphi_{11}+\frac{1}{2}\mu_2^{(n)}(\varphi_{22}-2\varphi_{23}+\varphi_{33}).\tag{7.15}$$

The expressions in (7.14), (7.15) are bounded uniformly in n. However, $\theta^{(n)}$, σ_1, and σ_2 are of order $\sqrt{n}$, as are the terms $\mathcal{B}_i^{n,y,u}\varphi$. The term $\nabla\varphi\cdot\xi^{(n)}+\frac{1}{\sqrt{n}}\mathcal{A}^{(n)}\varphi$ in (7.13) agrees with $\nabla\varphi\cdot\xi$ up to an error of order $\frac{1}{\sqrt{n}}$, but this term cannot immediately be replaced by $\nabla\varphi\cdot\xi$ because $\theta^{(n)}$ multiplying it is of order $\sqrt{n}$. In §11 we treat this term by adding a corrector to the function which is the argument of $\mathcal{L}^{n,y,u}$. The corrector causes the offending term to vanish.

Equation (7.13) suggests that the controlled Brownian motion $Z(t)$ given by (7.3)–(7.5) approximates the scaled queue length process $Z^{(n)}(t)=\frac{1}{\sqrt{n}}Q^{(n)}(nt)$. The control variable $\theta^{(n)}$ in (7.13), which can be either positive or negative, corresponds to pushing in approximately the direction $\xi \triangleq (\mu_1, -\mu_2, \mu_2)$ or the direction $-\xi$. In (7.3)–(7.5), this pushing is accomplished by the locally finite variation process ℓ_0. The processes ℓ_1, ℓ_2, and ℓ_3 appearing in (7.3)–(7.5) allow us to enforce the condition $Z(t)\in[0,\infty)^3$ for all $t\geq 0$. We have set up the controlled Brownian network to allow ℓ_i to grow even when $Z_i(t)>0$; this corresponds to idling the serving stations.

Remark 7.1. When all derivatives of φ up to order three are bounded uniformly on $[0,\infty)^3$, then $O(\frac{1}{\sqrt{n}})$ in (7.13) is a term whose absolute value is bounded by $K/\sqrt{n}$, where

K is a constant independent of n and $z \in [0, \infty)^3$. If φ is of class C^3, but only with locally bounded derivatives, then the term $O(\frac{1}{\sqrt{n}})$ is bounded by $k(z)/\sqrt{n}$, where $k(\cdot)$ is a locally bounded function of $z \in [0, \infty)^3$. We need the uniform bound in (11.24) when we are obtaining a lower bound on the limit of the queueing system value functions so that we can proceed to (11.25). The nonuniform bound is sufficient for (12.66) when the upper bound is sought.

8. The workload formulation. Following Harrison and Wein (1989), we introduce the *workload transformation*

$$\omega(z_1, z_2, z_3) \triangleq \left(\frac{z_1}{\mu_1} + \frac{z_2}{\mu_2}, \frac{z_2 + z_3}{\mu_3} \right), \tag{8.1}$$

which maps the state space $[0, \infty)^3$ of the controlled Brownian network onto the state space $[0, \infty)^2$ of the *workload control problem* formulated in this section. If (z_1, z_2, z_3) represents the three queue lengths, then $(w_1, w_2) = \omega(z_1, z_2, z_3)$ is the expected impending service time for the two stations embodied in customers anywhere in the network. The workload formulation reduces the dimensionality of the control problem from three (the number of customer classes) to two (the number of stations).

Because we can use the control process ℓ_0 in (7.3)–(7.5) to instantaneously change the state $Z(t)$ in the directions $\pm\xi = \pm(\mu_1, -\mu_2, \mu_2)$ at no cost, the Brownian network value function V of (7.6) will be constant along the direction ξ. This means that $V(z)$ can be written as a function of $\omega(z)$, because $\omega(z)$ does not change along the ξ-direction. It also means that one would want to keep the process $Z(t)$ on the locus of points in $[0, \infty)^3$ which minimize h along line segments parallel to ξ. To find this locus, one considers for each $(w_1, w_2) \in [0, \infty)^2$ the linear program

$$\begin{aligned} \text{minimize} \quad & c_1 z_1 + c_2 z_2 + c_3 z_3 \\ \text{subject to} \quad & \frac{z_1}{\mu_1} + \frac{z_2}{\mu_2} = w_1, \\ & \frac{z_2}{\mu_3} + \frac{z_3}{\mu_3} = w_2, \\ & z_1 \geq 0, \quad z_2 \geq 0, \quad z_3 \geq 0. \end{aligned}$$

Denote by $\hat{h}(w_1, w_2)$ the value of this linear program. We have two major cases.

Case I ($c_1\mu_1 - c_2\mu_2 + c_3\mu_2 \leq 0$). In this case,

$$\hat{h}(w_1, w_2) = c_1\mu_1 w_1 + c_3\mu_3 w_2, \tag{8.2}$$

and the minimizer in the linear program is

$$z_1^* = \mu_1 w_1, \quad z_2^* = 0, \quad z_3^* = \mu_3 w_2. \tag{8.3}$$

Case II ($c_1\mu_1 - c_2\mu_2 + c_3\mu_2 > 0$). Now

$$\hat{h}(w_1, w_2) = \begin{cases} (c_2\mu_2 - c_3\mu_2)w_1 + c_3\mu_3 w_2 & \text{if} \quad \mu_3 w_2 \geq \mu_2 w_1, \\ c_1\mu_1 w_1 + \dfrac{\mu_3}{\mu_2}(c_2\mu_2 - c_1\mu_1)w_2 & \text{if} \quad \mu_3 w_2 \leq \mu_2 w_1. \end{cases} \tag{8.4}$$

The minimizing values are

$$z_1^* = 0, \quad z_2^* = \mu_2 w_1, \quad z_3^* = \mu_3 w_2 - \mu_2 w_1 \quad \text{if} \quad \mu_3 w_2 \geq \mu_2 w_1, \tag{8.5a}$$

$$z_1^* = \frac{\mu_1}{\mu_2}(\mu_2 w_1 - \mu_3 w_2), \quad z_2^* = \mu_3 w_2, \quad z_3^* = 0 \quad \text{if} \quad \mu_3 w_2 \leq \mu_2 w_1. \tag{8.5b}$$

The *workload control problem* has state equations

$$W_1(t) = w_1 - b_1 t + \frac{1}{\mu_1} M_1(t) + \frac{1}{\mu_2} M_2(t) + m_1(t), \tag{8.6}$$

$$W_2(t) = w_2 - b_2 t + \frac{1}{\mu_3} M_2(t) + \frac{1}{\mu_3} M_3(t) + m_2(t), \tag{8.7}$$

where the pair (m_1, m_2) of $\{\mathcal{F}(t)\}$-adapted control processes is *admissible for initial condition* $w = (w_1, w_2) \in [0, \infty)^2$, provided that

(i) m_1 and m_2 are right-continuous with left-hand limits, with the convention that

$$m_i(0^-) = 0, \qquad i = 1, 2;$$

(ii) m_1 and m_2 are nondecreasing;

(iii) the state process $W(t) = (W_1(t), W_2(t))$ is in $[0, \infty)^2$ for all $t \geq 0$.

(We have in mind, of course, that $m_1(t) = \frac{\ell_1(t)}{\mu_1} + \frac{\ell_2(t)}{\mu_2}$, $m_2(t) = \frac{\ell_3(t)}{\mu_3}$, where ℓ_1 and ℓ_3 are part of an admissible quadruple $(\ell_0, \ell_1, \ell_2, \ell_3)$ for the controlled Brownian network.) The *cost function* associated with (m_1, m_2) at $w \in [0, \infty)^2$ is

$$\hat{V}_{m_1, m_2}(w) \triangleq E \int_0^\infty e^{-\alpha t} \hat{h}(W(t)) dt,$$

and the *value function* at w is

$$\hat{V}(w) = \inf\{\hat{V}_{m_1, m_2}(w); \quad (m_1, m_2) \text{ is admissible at } w\}. \tag{8.8}$$

Although we do not need this fact for our analysis, one can show that V of (7.6) and $\hat{V}$ of (8.8) are related by the equation

$$V(z_1, z_2, z_3) = \hat{V}\left(\frac{z_1}{\mu_1} + \frac{z_2}{\mu_2}, \frac{z_2 + z_3}{\mu_3}\right) \quad \forall\, z \in [0, \infty)^3. \tag{8.9}$$

If one had an optimal (m_1^*, m_2^*) for the workload control problem, then as an optimal policy for the Brownian network problem, one would want to take $\ell_1^*(t) = \mu_1 m_1^*(t)$, $\ell_2^*(t) \equiv 0$, $\ell_3^*(t) = \mu_3 m_2^*(t)$ and choose ℓ_0 to ensure that $Z^*(t)$ is always given by (8.3) or (8.5) with $w_i = W_i^*(t)$, $i = 1, 2$, depending on the sign of $c_1\mu_1 - c_2\mu_2 + c_3\mu_2$. However, such an ℓ_0 does not exist, so the Brownian network control problem is ill posed.

9. Solution of Case I. This is the case $c_1\mu_1 - c_2\mu_2 + c_3\mu_2 \leq 0$. Since $\hat{h}$ given by (8.2) is increasing in each variable separately, the optimal control processes m_1 and m_2 act only when $W_1 = 0$ or $W_2 = 0$, respectively. More precisely,

$$m_1(t) \triangleq \max_{0 \leq s \leq t} \left[-w_1 + b_1 s - \frac{1}{\mu_1} M_1(s) - \frac{1}{\mu_2} M_2(s)\right]^+, \tag{9.1}$$

$$m_2(t) \triangleq \max_{0 \leq s \leq t} \left[-w_2 + b_2 s - \frac{1}{\mu_3} M_2(s) - \frac{1}{\mu_3} M_3(s)\right]^+ \tag{9.2}$$

(see, e.g., Harrison (1985)) are the minimal nondecreasing processes which ensure that the associated state processes remain nonnegative almost surely. In particular,

$$m_i(t) = \int_0^t 1_{\{W_1(s) = 0\}} dm_i(s), \qquad 0 \leq t < \infty. \tag{9.3}$$

One can actually compute the value function

$$\begin{aligned}\hat{V}(w_1, w_2) &= \hat{V}_{m_1,m_2}(w_1, w_2) \\ &= A + \gamma_1 B_1 w_1 + \gamma_2 B_2 w_2 + B_1 e^{-\gamma_1 w_1} + B_2 e^{-\gamma_2 w_2},\end{aligned} \tag{9.4}$$

where $\gamma_1 > 0$, $\gamma_2 > 0$ solve the quadratic equations

$$\left(\frac{\lambda_1}{\mu_1^2} + \frac{\lambda_2}{\mu_2^2}\right)\gamma_1^2 + b_1\gamma_1 - 1 = 0, \qquad \frac{\lambda_2}{\mu_3^2}\gamma_2^2 + b_2\gamma_2 - 1 = 0,$$

and $B_1 = c_1\mu_1/\gamma_1$, $B_2 = c_3\mu_3/\gamma_2$, $A = -\gamma_1 b_1 B_1 - \gamma_2 b_2 B_2$.

The formula $z_2^* = 0$ in (8.3) suggests that customer class 2 should always have priority, a fact already established by Chen, Yang, and Yao (1991). Thus, for the queueing networks, we define the stationary control law (independent of n in this case)

$$Y(z) \triangleq \begin{cases} 1 & \text{if} \quad z_1 > 0 \quad \text{or} \quad z_2 > 0, \\ 0 & \text{if} \quad z_1 = z_2 = 0, \end{cases}$$

$$U(z) \triangleq \begin{cases} 0 & \text{if} \quad z_2 > 0, \\ 1 & \text{if} \quad z_2 = 0. \end{cases}$$

One can show that (Y, U) is asymptotically optimal in the sense of (6.4) with $\eta = 0$. We omit the proof, focusing instead on the more complicated Case IIA below.

10. Discussion of Case II. This is the case $c_1\mu_1 - c_2\mu_2 + c_3\mu_2 > 0$. We shall complete the analysis only for Case IIA.

Case IIA ($c_1\mu_1 - c_2\mu_2 + c_3\mu_2 > 0, c_2\mu_2 - c_3\mu_2 \geq 0, c_2\mu_2 - c_1\mu_1 \geq 0$). In this case, the function $\hat{h}$ given by (8.4) is nondecreasing in each variable separately. The optimal control processes for the workload problem are still given by (9.1), (9.2) and satisfy (9.3), but $\hat{V}$ no longer has the simple closed form (9.4). Because

$$\hat{V}(w) = E\int_0^\infty e^{-\alpha t}\hat{h}(W(t))dt \quad \forall\, w \in [0, \infty)^2, \tag{10.1}$$

the Feynman–Kac formula and elliptic regularity imply that $\hat{V}$ is C^2 on the open quadrant $(0, \infty)^2$, $\hat{V}$ is C^1 on the closed quadrant $[0, \infty)^2$, and

$$\hat{V}_1(0, w_2) = \hat{V}_2(w_1, 0) = 0 \quad \forall (w_1, w_2) \in [0, \infty)^2, \tag{10.2}$$

$$\alpha\hat{V} - \hat{\mathcal{L}}\hat{V} - \hat{h} = 0 \quad \text{on} \quad (0, \infty)^2, \tag{10.3}$$

where

$$\hat{\mathcal{L}}\hat{\varphi} \triangleq -b_1\hat{\varphi}_1 - b_2\hat{\varphi}_2 + \left(\frac{\lambda_1}{\mu_1^2} + \frac{\lambda_1}{\mu_2^2}\right)\hat{\varphi}_{11} + \frac{\lambda_2}{\mu_2\mu_3}\hat{\varphi}_{12} + \frac{\lambda_2}{\mu_3^2}\hat{\varphi}_{22} \tag{10.4}$$

for any C^2 function $\hat{\varphi} : (0, \infty)^2 \to \mathbf{R}$. To verify that $\hat{V}$ is of class C^2 on $(0, \infty)^2$, we can let Ω be an arbitrary domain in $(0, \infty)^2$ satisfying an exterior sphere condition and then solve the Dirichlet problem

$$\alpha u - \hat{\mathcal{L}}u - \hat{h} = 0 \quad \text{in} \quad \Omega, \quad u = \hat{V} \quad \text{on} \quad \partial\Omega.$$

This problem has a solution u which is C^2 in Ω (Gilbarg and Trudinger (1977, Thm. 11.5)), and it is an easy exercise using Itô's formula to verify that $u = \hat{V}$. To prove the claimed boundary behavior along the w_1-axis, we can choose a domain Ω in $(0, \infty) \times \mathbf{R}$ which is symmetric about the w_1-axis, and we can extend $\hat{\mathcal{L}}$, $\hat{h}$, and $\hat{V}$ across the w_1-axis by even symmetry so that the extended functions are continuous and piecewise differentiable. The above Dirichlet problem still has a solution u which is C^1 in Ω (Gilbarg and Trudinger (1977, Thm. 8.9)), and because of the even symmetry, $w_2 = 0$ on the intersection of Ω with the w_1-axis. Again, Itô's formula can be used to verify that u and $\hat{V}$ agree in the intersection of Ω with the upper half-plane. The same argument applies to the w_2-axis, and the condition $\hat{V}_1(0, 0) = \hat{V}_2(0, 0) = 0$ is obtained by letting Ω be symmetric with respect to the origin. Note that with $\hat{\varphi}$ as in (10.4) we have

$$(\hat{\mathcal{L}}\hat{\varphi})(\omega(z)) = \mathcal{L}(\hat{\varphi} \circ \omega)(z) \quad \forall\, z \in [0, \infty)^3. \tag{10.5}$$

The principal result of this paper is the following theorem.

THEOREM 10.1. *Assume Case* IIA. *Then*

$$J_\#(z) = J^\#(z) = \hat{V}(\omega(z)) \quad \forall\, z \in [0, \infty)^3,$$

where $J_\#$ and $J^\#$ are the lower and upper semicontinuous limits of the queueing network value functions, defined by (6.1) *and* (6.2), *respectively.*

The proof of Theorem 10.1 is the subject of the next two sections. Since $J_\# \leq J^\#$, it suffices to prove the two inequalities

$$\hat{V}(\omega(z)) \leq J_\#(z), \quad J^\#(z) \leq \hat{V}(\omega(z)) \quad \forall\, z \in [0, \infty)^3.$$

In §11, we prove the first of these inequalities, and in §12, we prove the second. The proof of the second inequality requires the construction of a sequence of asymptotically nearly optimal stationary policies (defined by (12.5a), (12.5b)) which satisfy (6.4). We establish additional properties of $\hat{V}$ in the next section.

Case IIB ($c_1\mu_1 - c_2\mu_2 + c_3\mu_2 > 0$, $c_2\mu_2 - c_3\mu_2 < 0$, $c_2\mu_2 - c_1\mu_1 \geq 0$). Now $\hat{h}$ is strictly decreasing in w_1 for $w_1 \in [0, \frac{\mu_3}{\mu_2} w_2]$, which suggests that w_1 should not be allowed to fall too far below $\frac{\mu_3}{\mu_2} w_2$. Numerical experimentation supports the conjecture that there is a continuous, increasing function $\Psi_2 : [0, \infty) \longrightarrow [0, \infty)$ such that the optimal control process m_1 in the workload control problem acts whenever $W_1(t) = \Psi_2(W_2(t))$ to ensure that the inequality $W_1(t) \geq \Psi_2(W_2(t))$ is always satisfied. The rest of the conjecture was set out in §2.

Cases IIC, IID. The functions Ψ_1 and Ψ_2 appearing in the conjectures in §2 about these cases are the free boundaries on which reflection should occur in the optimal control of the workload processes.

11. The lower bound. Throughout the remainder of the paper, we assume Case IIA. In particular, $\hat{V}$ is given by (10.1), where W is determined by (8.6), (8.7), (9.1), and (9.2), and $\hat{h}$ is given by (8.4). The purpose of this section is to prove the following proposition.

PROPOSITION 11.1. *Assume Case* IIA. *Then*

$$\hat{V}(\omega(z)) \leq J_\#(z) \quad \forall\, z \in [0, \infty)^3, \tag{11.1}$$

where $J_\#$, defined by (6.2), *is the lower semicontinuous limit of the queueing network value functions and ω is given by* (8.1).

The proof of Proposition 11.1 proceeds through several steps.

LEMMA 11.2. *The workload value function* $\hat{V} : [0, \infty)^2 \longrightarrow [0, \infty)$ *is strictly increasing in each variable and is convex. There are positive constants* K_0, K_1, *and* K_2 *such that*

$$K_0\hat{h}(w) \leq \hat{V}(w) \leq K_1 + K_2\hat{h}(w) \quad \forall\, w \in [0, \infty). \tag{11.2}$$

Furthermore, the partial derivatives $\hat{V}_1$ *and* $\hat{V}_2$ *are uniformly bounded on* $[0, \infty)^2$.

Proof. We may rewrite (8.4) as

$$\hat{h}(w) = \max\left\{(c_2\mu_2 - c_3\mu_2)w_1 + c_3\mu_3 w_2,\, c_1\mu_1 w_1 + \frac{\mu_3}{\mu_2}(c_2\mu_2 - c_1\mu_1)w_2\right\} \quad \forall\, w \in [0, \infty)^2,$$

which shows that $\hat{h}$ is convex, and $\hat{V}$, being the value function for a control problem with linear dynamics and a convex state space, inherits the convexity of $\hat{h}$. The representation (10.1) of $\hat{V}$ shows that $\hat{V}$ is strictly increasing in each variable and grows at most linearly. Such a function must also grow at least linearly, and we have (11.2) for suitable positive constants K_0, K_1, and K_2. A linearly growing convex function must have bounded partial derivatives. □

The idea behind the proof of Proposition 11.1 is to alter the function

$$v(z) \triangleq \hat{V}(\omega(z)), \qquad z \in [0, \infty)^3, \tag{11.3}$$

in order to obtain a subsolution of the HJB equation (5.2). Proposition 5.1 will then imply that $J_*^{(n)}$ of (10.4) dominates the altered function. We then let $n \to \infty$ to obtain (11.1).

The construction of the altered version of v requires three steps. First, we mollify v to obtain a smoother function. Next, we compose v with a truncation function so as to restrict attention to a compact subset of the domain of v. Finally, we add a "corrector" to cancel the order $\frac{1}{\sqrt{n}}$ error incurred when $\nabla v(z) \cdot \xi^{(n)} + \frac{1}{\sqrt{n}}\mathcal{A}^{(n)}v(z)$ is replaced by $\nabla v \cdot \xi$ in the expansion of $\mathcal{L}^{n,y,u}v$ (see (7.13)). This error must be cancelled because $\theta^{(n)}$ multiplying the error is of order $\sqrt{n}$.

Step 1. *Mollification.* Let ρ_ϵ be a nonnegative C^∞ function with support contained in the open ball $B_\epsilon(0)$ of radius $\epsilon > 0$ centered at the origin in $\mathbf{R}^2$ and such that $\int_{B_\epsilon(0)} \rho_\epsilon = 1$. We define

$$\hat{V}_0^\epsilon(w) = \int_{B_\epsilon(0)} \hat{V}(x + w)\rho_\epsilon(x)dx = \int_{\mathbf{R}^2} \hat{V}(x)\rho_\epsilon(x - w)dx.$$

(To make this definition possible, we first extend $\hat{V}$ to $\mathbf{R}^2$ so that it remains continuous.) We likewise define

$$\hat{h}^\epsilon(w) = \int_{B_\epsilon(0)} \hat{h}(x + w)\rho_\epsilon(x)dx = \int_{\mathbf{R}^2} \hat{h}(x)\rho_\epsilon(x - w)dx.$$

On the set $(\epsilon, \infty)^2$, (10.3) implies $\alpha\hat{V}_0^\epsilon - \hat{\mathcal{L}}\hat{V}_0^\epsilon - \hat{h}^\epsilon = 0$.

Let us set $\hat{V}^\epsilon(w_1, w_2) = \hat{V}_0^\epsilon(w_1 + 2\epsilon, w_2 + 2\epsilon)$. The Lipschitz continuity of $\hat{h}$ (and hence $\hat{h}^\epsilon$) implies

$$|\alpha\hat{V}^\epsilon - \hat{\mathcal{L}}\hat{V}^\epsilon - \hat{h}^\epsilon| \leq L_0\epsilon \quad \text{on} \quad (-\epsilon, \infty)^2, \tag{11.4}$$

where L_0 is a Lipschitz constant for $\hat{h}$. Like $\hat{V}$, each $\hat{V}^\epsilon$ is strictly increasing in each variable and satisfies (11.2). Furthermore,

$$\frac{\partial}{\partial w_i}\hat{V}_0^\epsilon(w) = \int_{B_\epsilon(0)} \hat{V}_i(x + w)\rho_\epsilon(x)dx = \int_{\mathbf{R}^2} \hat{V}_i(x)\rho_\epsilon(x - w)dx.$$

Computing all higher-order derivatives by differentiating under the second integral, we see that for each N, there is a constant $C_{N,\epsilon}$ such that all partial derivatives up to order N of $\hat{V}^\epsilon$ are bounded in absolute value by $C_{N,\epsilon}$ uniformly on $(-\epsilon, \infty)^2$.

We next define

$$v^\epsilon(z) = \hat{V}^\epsilon(\omega(z)), \qquad z \in (-\delta, \infty)^3, \tag{11.5}$$

where $\delta \triangleq \frac{\epsilon}{2} \min\{\mu_1, \mu_2, \mu_3\}$, and note that v^ϵ converges to v of (11.3) uniformly on $[0, \infty)^3$, i.e.,

$$\lim_{\epsilon \downarrow 0} \sup_{z \in [0,\infty)^3} |v^\epsilon(z) - v(z)| = 0. \tag{11.6}$$

From its definition, we see that v^ϵ satisfies

$$\nabla v^\epsilon(z) \cdot \xi = 0 \quad \forall\, z \in (-\delta, \infty)^3, \tag{11.7}$$

where $\xi = (\mu_1, -\mu_2, \mu_2)$. Inequality (11.4) and the fact that $\hat{h}$ solves the linear program in §8 imply

$$\begin{aligned} \alpha v^\epsilon(z) - \mathcal{L} v^\epsilon(z) &\le \hat{h}^\epsilon\left(\frac{z_1}{\mu_1} + \frac{z_2}{\mu_2}, \frac{z_2}{\mu_3} + \frac{z_3}{\mu_3}\right) + L_0\epsilon \\ &\le c \cdot z + 2L_0\epsilon, \end{aligned} \tag{11.8}$$

where $c \triangleq (c_1, c_2, c_3)$. There is a constant $C_{1,\epsilon}$ such that

$$\|v_i^\epsilon\|_\infty + \|v_{ij}^\epsilon\|_\infty + \|v_{ijk}^\epsilon\|_\infty + \|v_{ijkl}^\epsilon\|_\infty + \|v_{ijklm}^\epsilon\|_\infty \le C_{1,\epsilon} \quad \forall\, i, j, k, l, m \in \{1, 2, 3\}, \tag{11.9}$$

where $\|\cdot\|_\infty$ is the supremum norm on $(-\delta, \infty)^3$.

Finally, because $\hat{v}$ is increasing in each variable separately, we have

$$v_1^\epsilon \ge 0, \quad v_2^\epsilon - v_3^\epsilon \ge 0, \quad v_3^\epsilon \ge 0 \quad \text{on} \quad (-\delta, \infty)^3, \tag{11.10}$$

and there is a constant K_1^ϵ satisfying

$$v^\epsilon(z) \le K_1^\epsilon + \frac{1}{\alpha} c \cdot z \quad \forall\, z \in [0, \infty)^3, \tag{11.11}$$

the last inequality following from (11.8) and the uniform boundedness of $\mathcal{L} v^\epsilon$.

Step 2. *Truncation.* Fix $\beta > 0$, and let $\varphi_\beta : \mathcal{R} \to \mathcal{R}$ be a C^∞ function with the following properties:

(i) $\varphi_\beta(x) = x$ if $x \le \frac{1}{\beta}$;
(ii) $\varphi_\beta'(x) = 0$ if $x \ge \frac{4}{\beta}$;
(iii) $-\beta \le \varphi_\beta''(x) \le 0 \ \forall\, x \ge 0$.

One could, for example, take the C^1 function

$$f(x) = \begin{cases} x & \text{if} \quad x \le \dfrac{2}{\beta}, \\ -\dfrac{1}{2}\beta x^2 + 3x - \dfrac{2}{\beta} & \text{if} \quad \dfrac{2}{\beta} \le x \le \dfrac{3}{\beta}, \\ \dfrac{5}{2\beta} & \text{if} \quad x \ge \dfrac{3}{\beta} \end{cases}$$

and mollify it.

We truncate v^ϵ by defining $u^{\beta,\epsilon}(z) = \varphi_\beta(v^\epsilon(z))$ for $z \in (-\delta, \infty)^3$. Then

$$\alpha u^{\beta,\epsilon}(z) - \mathcal{L}u^{\beta,\epsilon}(z) = \alpha\varphi_\beta(v^\epsilon(z)) - \varphi'_\beta(v^\epsilon(z))\mathcal{L}v^\epsilon(z) + O(\beta),$$

where $|O(\beta)|$ is bounded by β times a constant depending on $C_{1,\epsilon}$ in (11.9). Because $\varphi_\beta(x) = x$ for $0 \le x \le \frac{1}{\beta}$, we have from (11.8) that

$$v^\epsilon(z) \le \frac{1}{\beta} \Rightarrow \alpha u^{\beta,\epsilon}(z) - \mathcal{L}u^{\beta,\epsilon}(z) = \alpha v^\epsilon(z) - \mathcal{L}v^\epsilon(z) \le c \cdot z + 2L_0\epsilon.$$

Conditions (i)–(iii) above imply

(iv) $0 \le \varphi'_\beta(x) \le 1 \; \forall x \ge 0$.

This fact, (11.8), and (11.11) allow us to argue that

$$\begin{aligned}
\alpha u^{\beta,\epsilon}(z) - \mathcal{L}u^{\beta,\epsilon}(z) &\le \alpha\varphi_\beta(v^\epsilon(z)) - \varphi'_\beta(v^\epsilon(z))[\alpha v^\epsilon(z) - c \cdot z - 2L_0\epsilon] + O(\beta) \\
&\le \alpha[\varphi_\beta(v^\epsilon(z)) - \varphi'_\beta(v^\epsilon(z))v^\epsilon(z)] \\
&\quad - [1 - \varphi'_\beta(v^\epsilon(z))]c \cdot z + c \cdot z + 2L_0\epsilon + O(\beta) \\
&\le \alpha[\varphi_\beta(v^\epsilon(z)) - \varphi'_\beta(v^\epsilon(z))v^\epsilon(z) \\
&\qquad - (1 - \varphi'_\beta(v^\epsilon(z))(v^\epsilon(z) - K_1^\epsilon))] \\
&\quad + c \cdot z + 2L_0\epsilon + O(\beta) \\
&= \alpha[\varphi_\beta(v^\epsilon(z)) - v^\epsilon(z) + K_1^\epsilon(1 - \varphi'_\beta(v^\epsilon(z)))] \\
&\quad + c \cdot z + 2L_0\epsilon + O(\beta).
\end{aligned}$$

Since $\varphi_\beta(x) \le x$ for all x,

$$\varphi_\beta(v^\epsilon(z) - K_1^\epsilon) \le v^\epsilon(z) - K_1^\epsilon,$$

from which we conclude that

$$\begin{aligned}
\varphi_\beta(v^\epsilon(z)) - v^\epsilon(z) + K_1^\epsilon(1 - \varphi'_\beta(v^\epsilon(z))) &\le \varphi_\beta(v^\epsilon(z)) - \varphi_\beta(v^\epsilon(z) - K_1^\epsilon) - K_1^\epsilon\varphi'_\beta(v^\epsilon(z)) \\
&\le \int_{v^\epsilon(z)-K_1^\epsilon}^{v^\epsilon(z)} [\varphi'_\beta(r) - \varphi'_\beta(v^\epsilon(z))]dr \\
&= -\int_{v^\epsilon(z)-K_1^\epsilon}^{v^\epsilon(z)} \int_r^{v^\epsilon(z)} \varphi''_\beta(\rho)d\rho\, dr \\
&\le \frac{1}{2}(K_1^\epsilon)^2\beta = O(\beta).
\end{aligned}$$

Thus, regardless of whether $v^\epsilon(z) \le \frac{1}{\beta}$ or $v^\epsilon(z) \ge \frac{1}{\beta}$, we have

$$\alpha u^{\beta,\epsilon}(z) - \mathcal{L}u^{\beta,\epsilon}(z) \le c \cdot z + 2L_0\epsilon + O(\beta), \qquad z \in (-\delta, \infty)^3. \tag{11.12}$$

Also, from (11.7), (11.9), and (11.10), we have

$$\nabla u^{\beta,\epsilon}(z) \cdot \xi = 0 \quad \forall\, z \in (-\delta, \infty)^3, \tag{11.13}$$

$$\begin{aligned}
&\|u_i^{\beta,\epsilon}\|_\infty + \|u_{ij}^{\beta,\epsilon}\|_\infty + \|u_{i,j,k}^{\beta,\epsilon}\|_\infty + \|u_{i,j,k,l}^{\beta,\epsilon}\|_\infty + \|u_{i,j,k,l,m}^{\beta,\epsilon}\|_\infty \le C_{2,\epsilon} \\
&\quad \forall\ \in i, j, k, \ell, m \in \{1, 2, 3\},
\end{aligned} \tag{11.14}$$

$$u_1^{\beta,\epsilon} \ge 0, \quad u_2^{\beta,\epsilon} - u_3^{\beta,\epsilon} \ge 0, u_3^{\beta,\epsilon} \ge 0 \quad \text{on} \quad (-\delta, \infty)^3, \tag{11.15}$$

where $C_{2,\epsilon}$ is a constant depending on ϵ. In place of (11.11), we have now the existence of a constant $R_1^{\beta,\epsilon}$ such that

$$u_i^{\beta,\epsilon}(z_1, z_2, z_3) = 0 \quad \text{if} \quad z_1 \vee z_2 \vee z_3 \geq R_1^{\beta,\epsilon}, \quad i = 1, 2, 3. \tag{11.16}$$

Step 3. *Construction of the corrector.* For each n, define

$$\begin{aligned} \Psi^{n,\beta,\epsilon}(z) &\triangleq -\sqrt{n}\nabla u^{\beta,\epsilon}(z) \cdot \xi^{(n)} - \mathcal{A}^n u^{\beta,\epsilon}(z) \\ &= \sqrt{n}\nabla u^{\beta,\epsilon}(z) \cdot (\xi - \xi^{(n)}) - \mathcal{A}^n u^{\beta,\epsilon}(z), \qquad z \in (-\delta, \infty)^3 \end{aligned} \tag{11.17}$$

($\mathcal{A}^n$ is defined by (7.15)), and note that $\Psi^{n,\beta,\epsilon}$ and its first, second, and third partial derivatives are bounded uniformly in z, n, and β and

$$\Psi^{u,\beta,\epsilon}(z) = 0 \quad \text{if} \quad z_1 \vee z_2 \vee z_3 \geq R_1^{\beta,\epsilon}. \tag{11.18}$$

Define $t(z) \triangleq \min\{\frac{z_1}{\mu_1}, \frac{z_3}{\mu_2}\}$, and let $T : [-\delta, \infty)^3 \to \mathbf{R}$ be a mollification of t which does not depend on the variable z_2 and which satisfies the following:

(v) T is thrice continuously differentiable;
(vi) the derivatives of T, up to second order, are uniformly bounded;
(vii) $\mu_1 T_1 + \mu_2 T_3 = 1$ on $[0, \infty)^3$;
(viii) $t(z) \leq T(z) \leq t(z) + \nu_2 \; \forall\, z \in [-\nu_1, \infty]^3$,

where $\nu_1 > 0$ and $\nu_2 > 0$ are chosen so that

$$z - t(z)\xi^{(n)} \in (-\delta, \infty)^3, \quad z - (t(z) + \nu_2)\xi^{(n)} \in (-\delta, \infty)^3 \quad \forall\, z \in [-\nu_1, \infty)^3, \forall n.$$

We may now define the corrector

$$f^{n,\beta,\epsilon}(z) \triangleq C_{3,\epsilon,\beta}(w_1^{(n)} + w_2^{(n)}) + \int_0^{T(z)} \Psi^{n,\beta,\epsilon}(z - \rho\xi^{(n)})d\rho, \qquad z \in [-\nu_1, \infty)^3, \tag{11.19}$$

where

$$w_1^{(n)} \triangleq \frac{z_1}{\mu_1^{(n)}} + \frac{z_2}{\mu_2^{(n)}}, \qquad w_2^{(n)} = \frac{z_2}{\mu_3^{(n)}} + \frac{z_3}{\mu_3^{(n)}},$$

and the constant $C_{3,\epsilon,\beta}$ is chosen below, independently of n.

Direct computation reveals that

$$\nabla f^{n,\beta,\epsilon} \cdot \xi^{(n)} = \Psi^{n,\beta,\epsilon} + O\left(\frac{1}{\sqrt{n}}\right) \quad \text{on} \quad [-\nu_1, \infty)^3. \tag{11.20}$$

Also, (11.18) shows that the term $\int_0^{T(z)} \Psi^{n,\beta,\epsilon}(z - \rho\xi^{(n)})d\rho$ and its first, second, and third partial derivatives are bounded uniformly in z and n. Consequently, we may choose the constant $C_{3,\epsilon,\beta}$ independently of n so that

$$f_1^{n,\beta,\epsilon} \geq 0, \; f_2^{n,\beta,\epsilon} - f_3^{n,\beta,\epsilon} \geq 0, \; f_3^{n,\beta,\epsilon} \geq 0 \quad \text{on} \quad [-\nu_1, \infty)^3. \tag{11.21}$$

Similarly, we may choose a constant $K_{\epsilon,\beta}$ independently of n so that

$$-K_{\epsilon,\beta} \leq f^{n,\beta,\epsilon}(z) \leq K_{\epsilon,\beta}(1 + c \cdot z) \quad \forall\, z \in [-\nu_1, \infty)^3. \tag{11.22}$$

Finally, we have

$$\|f_i^{n,\beta,\epsilon}\|_\infty + \|f_{i,j}^{n,\beta,\epsilon}\|_\infty + \|f_{i,j,k}^{n,\beta,\epsilon}\|_\infty \leq C_{4,\epsilon,\beta} \quad \forall i, j, k \in \{1, 2, 3\}, \tag{11.23}$$

where $C_{4,\epsilon,\beta}$ is independent of n and we mean $\|\cdot\|_\infty$ to be the supremum norm on $[0, \infty)^3$.

Step 4. *Subsolution confirmation.* We set

$$g^{n,\beta,\epsilon}(z) = u^{\beta,\epsilon}(z) + \frac{1}{\sqrt{n}} f^{n,\beta,\epsilon}(z) \quad \forall z \in [-\nu_1, \infty)^3$$

and check that for $\frac{1}{\sqrt{n}} < \nu_1$, $g^{n,\beta,\epsilon}$ is *nearly* a subsolution of (5.2). Using (7.13), we compute for $z \in [0, \infty)^3$:

$$\begin{aligned}
\alpha g^{n,\beta,\epsilon} - \mathcal{L}^{n,y,u} g^{n,\beta,\epsilon} &= \alpha u^{\beta,\epsilon} - \mathcal{L}^{n,y,u} u^{\beta,\epsilon} + \frac{1}{\sqrt{n}} [\alpha f^{n,\beta,\epsilon} - \mathcal{L}^{n,y,u} f^{n,\beta,\epsilon}] \\
&\quad - \theta^{(n)} \left[\nabla u^{\beta,\epsilon} \cdot \xi^{(n)} + \frac{1}{\sqrt{n}} \mathcal{A}^n u^{\beta,\epsilon} \right] \\
&\quad - \frac{\theta^{(n)}}{\sqrt{n}} \left[\nabla f^{n,\beta,\epsilon} \cdot \xi^{(n)} + \frac{1}{\sqrt{n}} \mathcal{A}^n f^{n,\beta,\epsilon} \right] + \sigma_1 \left[-g_1^{n,\beta,\epsilon} + \frac{1}{2\sqrt{n}} g_{11}^{n,\beta,\epsilon} \right] \\
&\quad + \sigma_2 \left[-g_2^{n,\beta,\epsilon} + g_3^{n,\beta,\epsilon} + \frac{1}{2\sqrt{n}} (g_{22}^{n,\beta,\epsilon} - 2g_{23}^{n,\beta,\epsilon} + g_{33}^{n,\beta,\epsilon}) \right] \\
&\quad - \sum_{i=1}^{3} \mathcal{B}_i^{n,y,u} g^{n,\beta,\epsilon} + O\left(\frac{1}{\sqrt{n}}\right).
\end{aligned} \tag{11.24}$$

The term $O(\frac{1}{\sqrt{n}})$ is independent of z (see Remark 7.1). The terms multiplying σ_1 and σ_2 are respective Taylor series approximations of the nonpositive (see (11.15), (11.21)) differences

$$g^{n,\beta,\epsilon}\left(z - \frac{1}{\sqrt{n}} e_1\right) - g^{n,\beta,\epsilon}(z), \qquad g^{n,\beta,\epsilon}\left(z - \frac{1}{\sqrt{n}} e_2 + \frac{1}{\sqrt{n}} e_3\right) - g^{n,\beta,\epsilon}(z),$$

and the error in these approximations is of order $\frac{1}{n}$. Thus

$$\sigma_1 \left[-g_1^{n,\beta,\epsilon}(z) + \frac{1}{2\sqrt{n}} g_{11}^{n,\beta,\epsilon}(z) \right] \le O\left(\frac{1}{\sqrt{n}}\right),$$

and the term involving σ_2 has the same upper bound. A similar argument shows that

$$\mathcal{B}_i^{n,y,u} g^{n,\beta,\epsilon}(z) \le O\left(\frac{1}{\sqrt{n}}\right), \qquad i \in \{1, 2, 3\}.$$

Dropping these five terms and using (11.12), (11.22), (11.23), (11.17), and (11.20), we see that

$$\alpha g^{n,\beta,\epsilon}(z) - \mathcal{L}^{n,y,u} g^{n,\beta,\epsilon}(z) \le c \cdot z + 2L_0\epsilon + O(\beta) + \frac{\alpha K_{\epsilon,\beta}}{\sqrt{n}} (1 + c \cdot z) + O\left(\frac{1}{\sqrt{n}}\right),$$

where as before $|O(\frac{1}{\sqrt{n}})|$ is bounded by a constant, $K = K(\epsilon, \beta)$ times $\frac{1}{\sqrt{n}}$, and $|O(\beta)|$ is bounded by a constant, $K = K(\epsilon)$ times β. Minimization of $\mathcal{L}^{n,y,u} g^{n,\beta,\epsilon}(z)$ over $(y, u) \in \{0, 1\}^2$ results in the inequality

$$\alpha g^{n,\beta,\epsilon}(z) - \mathcal{L}^{n,*} g^{n,\beta,\epsilon}(z) \le \left(1 + \frac{\alpha K_{\epsilon,\beta}}{\sqrt{n}}\right) c \cdot z + 2L_0\epsilon + O(\beta) + O\left(\frac{1}{\sqrt{n}}\right) \quad \forall z \in [0, \infty)^3.$$

This shows that

$$\left[g^{n,\beta,\epsilon} - \frac{1}{\alpha} \left(2L_0\epsilon + O(\beta) + O\left(\frac{1}{\sqrt{n}}\right) \right) \right] \left[1 + \frac{\alpha K_{\epsilon,\beta}}{\sqrt{n}} \right]^{-1}$$

is a subsolution of (5.2), and Proposition 5.1 implies

$$g^{n,\beta,\epsilon}(z) \le \left(1 + \frac{\alpha K_{\epsilon,\beta}}{\sqrt{n}}\right) J_*^{(n)}(z) + \frac{1}{\alpha}\left(2L_0\epsilon + O(\beta) + O\left(\frac{1}{\sqrt{n}}\right)\right) \quad \forall z \in L^{(n)}. \tag{11.25}$$

Step 5. *Passage to the limit.* As a final step, we let $n \to \infty$, then $\beta \downarrow 0$, and then $\epsilon \downarrow 0$ in (11.25). From the bound (11.22), we see that $\lim_{n\to\infty} g^{n,\beta,\epsilon}(z) = u^{\beta,\epsilon}(z)$ and the convergence is uniform on compact sets. Therefore,

$$u^{\beta,\epsilon}(z) \le J_\#(z) + \frac{1}{\alpha}(2L_0\epsilon + O(\beta)) \quad \forall z \in [0,\infty)^3,$$

where $J_\#$ is given by (6.2). As $\beta \downarrow 0$, φ_β approaches the identity function and $u^{\beta,\epsilon}(z) \to v^\epsilon(z)$. Finally, (11.6) implies $\lim_{\epsilon\downarrow 0} v^\epsilon(z) = v(z)$, given by (11.3). This concludes the proof of Proposition 11.1. □

12. The upper bound. In this section we prove the following proposition.

PROPOSITION 12.1. *Assume Case* IIA. *Then*

$$J^\#(z) \le \hat{V}(\omega(z)) \quad \forall z \in [0,\infty)^3, \tag{12.1}$$

where $J^\#$, *defined in* (6.1), *is the upper semicontinuous limit of the queueing network value functions and* ω *is given by* (8.1).

The proof of Proposition 12.1 depends on the construction of a sequence of asymptotically nearly optimal policies for the queueing networks. We now describe this sequence of policies.

Let a and b be functions in $C_b^4([0,\infty))$ which are strictly increasing, concave, and such that $a(0) = b(0) = 0$ and

$$\delta_1 \triangleq \lim_{x\to\infty} a(x), \qquad \delta_2 \triangleq \lim_{x\to\infty} b(x) \tag{12.2}$$

are finite. We also require

$$\delta_2 < \delta_1^2. \tag{12.3}$$

We define a function $\gamma : [0,\infty)^3 \to \mathcal{R}$ by

$$\gamma(z) = a(z_1)a(z_3) - b(z_2) \tag{12.4}$$

and use γ to define a stationary control law (Y, U) for the nth queueing network by setting

$$Y(z) = 1; \tag{12.5a}$$

$$U(z) = \begin{cases} 1 & \text{if} \quad \gamma(z) \ge 0, \\ 0 & \text{if} \quad \gamma(z) < 0 \end{cases} \tag{12.5b}$$

for $z \in L^{(n)}$.

The control used at $z \in L^{(n)}$ thus depends on which "side" of the surface $\gamma = 0$ the scaled queue length vector z is located. Note that if δ_1 and δ_2 are small, the surface $\gamma = 0$ is "close" to the set $\{z \in [0,\infty)^3 : z_1 z_3 = 0\}$, which, by the discussion in §8, is the set toward which we would like to push our system. The meaning of "close" above is better explained in Lemma 12.2(d) and (e) below.

The policy (12.5a), (12.5b) is also chosen in such a way as to simplify the boundary terms in expansion (7.13). Suppose that $z_2 = 0$. Then $\gamma(z) \ge 0$, so that $U(z) = 1$, and

$\mathcal{B}_2^{n,Y(z),U(z)}\varphi(z) = 0$ for any φ. In the same way, if $z_1 = 0$ and $z_2 > 0$, then $\gamma(z) < 0$ and the $\mathcal{B}_1$ term vanishes. We finally note that (12.5b) and (7.8) imply, for $z \in L^{(n)}$,

$$\theta^n(z)\gamma(z) \le 0, \tag{12.6}$$

with strict inequality if $\gamma(z) \neq 0$.

The next lemma collects the relevant properties of γ.

LEMMA 12.2. (a) *For* $z \in [0,\infty)^3$,

$$\nabla\gamma(z)\cdot\xi > 0 \quad \text{and} \quad \nabla\gamma(z)\cdot\xi^{(n)} > 0, \tag{12.7}$$

where $\xi = (\mu_1, -\mu_2, \mu_3)$ *and* $\xi^{(n)} = (\mu_1^{(n)}, -\mu_2^{(n)}, \mu_3^{(n)})$. *Furthermore, there is a* $\delta_3 > 0$ *such that*

$$\nabla\gamma(z)\cdot\xi \ge \delta_3 \quad \text{if} \quad \gamma(z) = 0. \tag{12.8}$$

(b) *For all* $z \in [0,\infty)^3$, *there is a unique* $r \in \mathcal{R}$ *such that* $\gamma(z+r\xi) = 0$, ($\gamma(z+r\xi^{(n)}) = 0$, *respectively*). *We denote this* r *by* $\rho(z)$ ($\rho^{(n)}(z)$, *respectively*).

(c) *The functions* $\rho : [0,\infty)^3 \to \mathcal{R}$ *and* $\rho^{(n)} : [0,\infty)^3 \to \mathcal{R}$ *defined in* (b) *are four times differentiable and linearly growing, and their derivatives of order up to four are bounded on* $[0,\infty)^3$ *uniformly in* n. *We also have*

$$\gamma(z)\rho(z) \le 0; \quad \gamma(z)\rho^{(n)}(z) \le 0 \quad \forall z \in [0,\infty)^3, \tag{12.9}$$

with strict inequality if $\gamma(z) \neq 0$.

(d) *Set*

$$\delta_4 \triangleq \frac{1}{\mu_1 \wedge \mu_2} a^{-1}(\sqrt{\delta_2}), \qquad \delta_4^{(n)} \triangleq \frac{1}{\mu_1^{(n)} \wedge \mu_2^{(n)}} a^{-1}(\sqrt{\delta_2}).$$

Then for all $z \in [0,\infty)^3$ *we have*

$$|\rho(z)| \le \delta_4; \quad |\rho^{(n)}(z)| \le \delta_4^{(n)} \quad \text{if} \quad z_1 z_3 = 0. \tag{12.10}$$

(e) *The constant* $C_0 \triangleq c_1\mu_1 - c_2\mu_2 + c_3\mu_3$, *which is positive under the Case* II *assumption, satisfies*

$$|c\cdot z - \hat{h}(\omega(z))| \le C_0\delta_4 \tag{12.11}$$

for all $z \in [0,\infty)^3$ *such that* $\gamma(z) = 0$.

Proof. We will give the proof for the vector ξ. The proof for $\xi^{(n)}$ is identical.

(a) We have

$$\nabla\gamma(z)\cdot\xi = \mu_1 a'(z_1)a(z_3) + \mu_3[a(z_1)a'(z_3) + b'(z_2)], \tag{12.12}$$

which is obviously positive for all $z \in [0,\infty)^3$. Now suppose that $\gamma(z) = 0$. Since by (12.3)

$$\left(\frac{\delta_2}{\delta_1}\right)^2 < \delta_2,$$

by (12.2) there is an x_0 such that $b(x_0) > (\frac{\delta_2}{\delta_1})^2$. Therefore x_0 satisfies, $\frac{\delta_2}{\sqrt{b(x_0)}} < \delta_1$. If $z_2 \le x_0$, we then have

$$\nabla\gamma(z)\cdot\xi \ge \mu_2 b'(x_0).$$

Next, assume $z_2 \geq x_0$. Then $a(z_1)a(z_3) = b(z_2) \geq b(x_0)$, so either

$$a(z_1) \geq \sqrt{b(x_0)} \tag{12.13}$$

or

$$a(z_3) \geq \sqrt{b(x_0)}. \tag{12.14}$$

We also have that $a(z_1)a(z_3) < \delta_2$, so (12.13) implies

$$z_3 \leq a^{-1}\left(\frac{\delta_2}{\sqrt{b(x_0)}}\right),$$

and we get

$$\nabla\gamma(z)\cdot\xi \geq \mu_2 a(z_1)a'(z_3) \geq \mu_2\sqrt{b(x_0)}a'\left(a^{-1}\left(\frac{\delta_2}{\sqrt{b(x_0)}}\right)\right).$$

By repeating the same argument following from (12.14), we conclude that we can take

$$\delta_3 = \min\left\{\mu_2 b'(x_0), (\mu_1 \wedge \mu_2)\sqrt{b(x_0)}a'\left(a^{-1}\left(\frac{\delta_2}{\sqrt{b(x_0)}}\right)\right)\right\}.$$

(b) Suppose that $z \in [0,\infty)^3$. Denote by I the internal $[-(\frac{z_1}{\mu_1} \wedge \frac{z_3}{\mu_2}), \frac{z_2}{\mu_2}]$. Note that $z + r\xi \in [0,+\infty)^3$ if and only if $r \in I$. Let $h(r) = \gamma(z + r\xi)$ for $r \in I$. From (12.7), h is strictly increasing in I. Also, $h(-(\frac{z_1}{\mu_1} \wedge \frac{z_3}{\mu_2})) \leq 0$ and $h(\frac{z_2}{\mu_2}) \geq 0$. The conclusion follows.

(c) Since $\gamma \in C^4([0,\infty)^3)$, we have $\rho \in C^4([0,\infty)^3)$, by the implicit function theorem. Also,

$$\rho_i(z) = \frac{-\gamma_i(z + \rho(z)\xi)}{\nabla\gamma(z + \rho(z)\xi)\cdot\xi}, \tag{12.15}$$

which is bounded by (12.8) and boundedness of γ_i. Boundedness of higher-order derivatives is obtained by repeatedly differentiating (12.15). Relation (12.9) follows from (12.7) and the definition of ρ.

(d) Assume that $z_3 = 0$. Then

$$\begin{aligned}\delta_2 &\geq b(z_2 - \mu_2\rho(z)) = a(z_1 + \mu_1\rho(z))a(\mu_2\rho(z))\\ &\geq a((\mu_1 \wedge \mu_2)\rho(z))^2,\end{aligned}$$

so

$$\rho(z) \leq \frac{1}{\mu_1 \wedge \mu_2}a^{-1}(\sqrt{\delta_2}),$$

where the term on the right is well defined by (12.2) and (12.3). We have a symmetrical argument if $z_1 = 0$, and thus we can take

$$\delta_4 = \frac{1}{\mu_1 \wedge \mu_2}a^{-1}(\sqrt{\delta_2}).$$

We note that if we hold the function $a(\cdot)$ fixed and vary $b(\cdot)$ so that $\delta_2 \downarrow 0$, then $\delta_4 \downarrow 0$ also.

(e) Let $z \in [0, \infty)^3$ be such that $\gamma(z) = 0$. There is a unique $\bar{z}$ such that $\bar{z}_1 \bar{z}_3 = 0$ and $z = \bar{z} + \rho(\bar{z})\xi$. Furthermore, by (8.5), $\hat{h}(\omega(z))\hat{h}(\omega(\bar{z})) = c \cdot \bar{z}$. It follows that

$$\begin{aligned} |c \cdot z - \hat{h}(\omega(z)) &= |c \cdot (\bar{z} + \rho(\bar{z})\xi) - \hat{h}(\omega(\bar{z}))| \\ &= (c \cdot \xi)\rho(\bar{z}) \leq (c \cdot \xi)\delta_4. \qquad \square \end{aligned}$$

Let $J^{(n)} = J^{(n)}_{Y,U}$ be the cost associated with policy (12.5a), (12.5b). The next proposition shows that the sequence of costs $J^{(n)}$ grows linearly in z, uniformly in n. In particular, it shows that the sequence $\{J^{(n)}(z)\}_{n=1}^{\infty}$ is bounded for each z.

PROPOSITION 12.3. *There are constants K_1 and K_2 independent of n such that*

$$J^{(n)}(z) \leq K_1|z| + K_2 \quad \forall z \in L^{(n)}, \forall n. \tag{12.16}$$

Proof. We will construct a function $\varphi : [0, \infty)^3 \to \mathcal{R}$ such that

$$k_1|z| - k_2 \leq \varphi(z) \leq k_3|z| + k_4 \quad \forall z \in [0, +\infty)^3 \tag{12.17}$$

and

$$\mathcal{L}^{n,Y(z),U(z)}\varphi(z) \leq k_5 \quad \forall z \in L^{(n)}, \tag{12.18}$$

where $\mathcal{L}^{n,y,u}$ is given by (3.1) and $k_1, \ldots, k_5$ are positive constants independent of n. Once φ has been constructed, we proceed as follows. Let $L_1 = \frac{3}{\alpha k_1} \max\{c_1, c_2, c_3\}$. Then $\alpha L_1 \varphi \geq h - \alpha L_1 k_2$. Put $\Psi = L_1\varphi + \frac{L_1 k_5}{\alpha} + L_1 k_2$. Then

$$\alpha\Psi - \mathcal{L}^{n,Y,U}\Psi - h = \alpha L_1\varphi - (h - \alpha L_1 k_2) + L_1(k_5 - \mathcal{L}^{n,Y,U}\varphi) \geq 0,$$

and, by Proposition 4.1,

$$J^{(n)}(z) \leq \Psi(z) \leq L_1 k_3|z| + L_1 k_4 + \frac{L_1 k_5}{\alpha} + L_1 k_2.$$

It remains to construct φ. We fix a real number $\Delta > \sup_n\{\delta_4^{(n)}\mu_2^{(n)}\}$, and define

$$\zeta \stackrel{\Delta}{=} \Delta - \sup_n\{\delta_4^{(n)}\mu_2^{(n)}\} \tag{12.19}$$

and

$$K = \inf_m \left\{\frac{1}{\mu_2^{(m)}}\right\} a^{-1}\left(\frac{b(\zeta)}{\delta_1}\right) > 0. \tag{12.20}$$

Inequality (12.3) guarantees that K can be defined this way. In order to construct φ, we will need to define a number of auxiliary functions. We let $G \in C^4(\mathcal{R})$ be an even convex function such that

$$G(x) = |x| \quad \text{if} \quad |x| \geq 1. \tag{12.21}$$

We note that $G'(0) = 0$ and

$$xG'(x) \geq 0 \quad \forall x \in \mathcal{R}. \tag{12.22}$$

Let $H \in C^4(\mathcal{R})$ be a nondecreasing convex function such that

$$H'(x) = \begin{cases} 0 & \text{if} \quad x \le \Delta, \\ 1 & \text{if} \quad x \ge 2\Delta, \end{cases} \tag{12.23}$$

and let $\lambda \in C_b^4(\mathcal{R})$ be a bounded nonincreasing function such that

$$\lambda(x) = 0 \quad \text{if} \quad x \le 0, \quad \lambda(x) \le 0 \quad \text{if} \quad x > 0, \quad \lambda(K) \le -\sup_n\{\mu_2^{(n)}\}. \tag{12.24}$$

We then define

$$f(z) = G(\mu_1^{(n)} z_3 - \mu_2^{(n)} z_1) + H(z_2), \quad z \in [0,\infty)^3, \tag{12.25}$$

and, finally, we set

$$\varphi(z) = f(z + \rho^{(n)}(z)\xi^{(n)}) - \int_0^{\rho^{(n)}(z)} \lambda(s)ds, \qquad z \in [0,\infty)^3. \tag{12.26}$$

We first verify (12.18). Because the derivatives of φ up to order four are bounded, we may use the expansion (7.13) to write for any $z \in L^{(n)}$

$$\begin{aligned} \mathcal{L}^{n,Y(z),U(z)}\varphi(z) = \mathcal{L}\varphi(z) + \theta^{(n)}(z)\left[\nabla\varphi(z)\cdot\xi^{(n)} + \frac{1}{\sqrt{n}}\mathcal{A}^n\varphi(z)\right] \\ + \mathcal{B}_1^{n,Y(z),U(z)}\varphi(z) + \mathcal{B}_3^{n,Y(z),U(z)}\varphi(z) + O\left(\frac{1}{\sqrt{n}}\right). \end{aligned} \tag{12.27}$$

Note that, as remarked earlier, there is no $\mathcal{B}_2$ term above. Also, the $\mathcal{B}_1$ term above is nonzero only if $z_1 = z_2 = 0$.

The terms $\mathcal{L}\varphi(z)$, $\frac{g^{(n)}(z)}{\sqrt{n}}\mathcal{A}^n(z)$, and $O(\frac{1}{\sqrt{n}})$ in (12.27) are bounded. Furthermore, $\nabla\varphi(z)\cdot\xi^{(n)} = \lambda(\rho^{(n)}(z))$, so from (12.24) we get $\rho^{(n)}(z)\nabla\varphi(z)\cdot\xi^{(n)} \le 0$, and from (12.6) and Lemma 12.2(c), it follows that

$$\theta^{(n)}(z)\nabla\varphi(z)\cdot\xi^{(n)} \le 0. \tag{12.28}$$

From (7.10) we have

$$\mathcal{B}_1^{n,Y(z),U(z)}\varphi(z) = \sqrt{n}\mu_1^{(n)}\varphi_1(z)1_{\{z_1=z_2=0\}} + O(1),$$

where $O(1)$ is uniformly bounded in n. If $z_1 = z_2 = 0$, then $\gamma(z) = \rho^{(n)}(z) = 0$. Also a simple computation from (12.25) and (12.26) shows that, if $z_1 = z_2 = 0$, then $\varphi_1(z) = -\mu_2^{(n)}G'(\mu_1^{(n)}z_3) \le 0$, which shows that $\mathcal{B}_1^{n,Y(z),U(z)}\varphi(z)$ is uniformly bounded from above in n.

By an analogous reasoning, to show that $\mathcal{B}_3^{n,Y^{(n)}(z),U^{(n)}(z)}\varphi(z)$ is bounded from above, it is enough to show that $\varphi_3(z) \le 0$ if $z_3 = 0$. A direct computation gives, for $z_3 = 0$,

$$\varphi_3(z) = \mu_1^{(n)}G'(-\mu_2^{(n)}z_1) - \rho_3^{(n)}(z)[\mu_2^{(n)}H'(z_2 - \mu_2^{(n)}\rho^{(n)}(z)) + \lambda(\rho^{(n)}(z))].$$

Note first that, from (12.15), $\rho_3^{(n)}(z) \le 0$. Also, from (12.22), $G'(-\mu_2^{(n)}z_1) \le 0$. To show that $\varphi_3(z)$ is nonpositive, it is then enough to show that

$$A = \mu_2^{(n)}H'(z_2 - \mu_2\rho^{(n)}(z)) + \lambda(\rho^{(n)}(z))$$

is nonpositive. Suppose first that $z_2 \le \Delta$. Then (12.23) implies $A = \lambda(\rho^{(n)}(z)) \le 0$. Next assume that $z_2 \ge \Delta$. Then by (12.10) and (12.19) we have $z_2 - \mu_2^{(n)}\rho^{(n)}(z) \ge \zeta$. It follows that

$$b(\zeta) \le b(z_2 - \mu_2^{(n)}\rho^{(n)}(z)) = a(z_1 + \mu_1^{(n)}\rho^{(n)}(z))a(\mu_2^{(n)}\rho^{(n)}(z)) \le \delta_1 a(\mu_2^{(n)}\rho^{(n)}(z))$$

so that

$$\rho^{(n)}(z) \ge \frac{1}{\mu_2^{(n)}} a^{-1}\left(\frac{b(\zeta)}{\delta_1}\right) \ge K$$

by (12.20). Using (12.23) and (12.24), we now get

$$A \le \mu_2^{(n)} + \lambda(\rho^{(n)}(z)) \le \mu_2^{(n)} - \sup_m |\mu_2^{(m)}| \le 0$$

as desired. This concludes the proof of (12.18). We continue with the proof of (12.17). First note that it is clear that φ grows at most linearly, since its derivatives are bounded. To exhibit a linearly growing lower bound for φ, we start by showing that φ grows linearly on the surface $\gamma(z) = 0$. It is obvious that there is a constant m_1 such that

$$H(z_2) \ge z_2 - m_1. \tag{12.29}$$

Now suppose that $\gamma(z) = 0$ and $\mu_1^{(n)}z_3 - \mu_2^{(n)}z_1 \ge 1$. This implies

$$\delta_2 > b(z_2) = a(z_1)a(z_3) \ge a(z_1)a\left(\frac{\mu_2^{(n)}}{\mu_1^{(n)}}z_1\right) \ge a\left(\left(1 \wedge \frac{\mu_2^{(n)}}{\mu_1^{(n)}}\right)z_1\right)^2$$

so that

$$z_1 \le k_1 \triangleq \sup_n \left\{1 \vee \frac{\mu_1^{(n)}}{\mu_2^{(n)}}\right\} a^{-1}(\sqrt{\delta_2})$$

and it follows that, in this case,

$$G(\mu_1^{(n)}z_3 - \mu_2^{(n)}z_1) = \mu_1^{(n)}z_3 - \mu_2^{(n)}z_1 \ge \mu_1^{(n)}z_3 - \mu_2^{(n)}k_1 \ge \mu_1^{(n)}z_3 + z_1 - (1 + \mu_2^{(n)})k_1.$$

Thus, there are constants m_2, m_3, and m_4 such that for all n

$$G(\mu_1^{(n)}z_3 - \mu_2^{(n)}z_1) \ge m_2z_1 + m_3z_3 - m_4 \quad \text{if} \quad \gamma(z) = 0, \mu_1^{(n)}z_3 - \mu_2^{(n)}z_1 \ge 1. \tag{12.30}$$

By analogous reasoning, there are m_5, m_6, and m_7 such that for all n

$$G(\mu_1^{(n)}z_3 - \mu_2^{(n)}z_1) \ge m_5z_1 + m_6z_3 - m_7 \quad \text{if} \quad \gamma(z) = 0, \mu_1^{(n)}z_3 - \mu_2^{(n)}z_1 \le -1. \tag{12.31}$$

Now suppose that $\gamma(z) = 0$ and $|\mu_1^{(n)}z_3 - \mu_2^{(n)}z_1| \le 1$. Then (z_1, z_3) is contained in the set

$$A_n \triangleq \{(x, y) : x \ge 0, y \ge 0, |\mu_1^{(n)}y - \mu_2^{(n)}x| \le 1, \quad a(x) \wedge a(y) \le \sqrt{\delta_2}\}.$$

The set $A = \cup_{n\ge1}A_n$ is clearly bounded. Let k_2 be such that $A \subseteq [0, k_2]^2$. We then have

$$G(\mu_1^{(n)}z_3 - \mu_2^{(n)}z_1) \ge z_1 + z_3 - 2k_2 \quad \text{if} \quad \gamma(z) = 0, |\mu_1^{(n)}z_3 - \mu_2^{(n)}z_1| \le 1. \tag{12.32}$$

Putting (12.29)–(12.32) together, we see that there are constants K_0, K_1 such that

$$f(z) \geq K_0|z| - K_1 \quad \text{if} \quad z \in [0,\infty)^3, \gamma(z) = 0,$$

so

$$f(z + \rho^{(n)}(z)\xi^{(n)}) \geq K_0|z + \rho^{(n)}(z)\xi^{(n)}| - K_1.$$

To prove the lower bound (12.17), it is then enough to show that there is a K_2 such that

$$|z + \rho^{(n)}(z)\xi^{(n)}| \geq K_2|z| \quad \forall z \in [0,\infty)^3.$$

Since all norms on $\mathcal{R}^3$ are equivalent, we may rewrite this as

$$\sum_{i=1}^{3}(z_i + \rho_i^{(n)}(z)\xi_i^{(n)}) \geq K_2 \sum_{i=1}^{3} z_i \quad \forall z \in [0,\infty)^3. \tag{12.33}$$

For $z \in [0,\infty)^3$,

$$\begin{aligned}\sum_{i=1}^{3}(z_i + \rho_i^{(n)}(z)\xi_i^{(n)}) &\geq A \\ &\triangleq \min\left\{\sum_{i=1}^{3} z_i + r\xi_i^{(n)}; -\left(\frac{z_1}{\mu_1^{(n)}} \wedge \frac{z_3}{\mu_2^{(n)}}\right) \leq r \leq \frac{z_2}{\mu_2^{(n)}}\right\} \\ &= z_1 + z_2 + z_3 - \mu_1^{(n)}\left(\frac{z_1}{\mu_1^{(n)}} \wedge \frac{z_3}{\mu_2^{(n)}}\right).\end{aligned}$$

Suppose that

$$\frac{z_1}{\mu_1^{(n)}} \leq 2\frac{z_3}{\mu_2^{(n)}}.$$

Then

$$A \geq z_2 + z_3 \geq \frac{\mu_2^{(n)}}{4\mu_1^{(n)}} z_1 + z_2 + \frac{1}{2} z_3.$$

If, however,

$$\frac{z_1}{\mu_1^{(n)}} > 2\frac{z_3}{\mu_2^{(n)}},$$

then

$$A \geq \frac{1}{2} z_1 + z_2 + z_3.$$

We can therefore take $K_2 = \frac{1}{2} \wedge \inf_n \frac{\mu_1^{(n)}}{4\mu_2^{(n)}}$ in (12.33). □

In view of Proposition 12.3 we can define

$$J^{\infty}(z) = \lim_{\delta \downarrow 0} \overline{\lim_{n\to\infty}} \max_{\substack{\zeta \in L^{(n)} \\ |\zeta - z| \leq \delta}} J^{(n)}(\zeta).$$

We obviously have $J^{\#}(z) \leq J^{\infty}(z)$, so to prove Proposition 12.1 it is enough to show that

$$J^{\infty}(z) \leq \hat{V}(\omega(z)) \quad \forall z \in [0,\infty)^3. \tag{12.34}$$

The remainder of this section is devoted to the proof of (12.34). First observe that because of the special structure of the control process U, the scaled queue length process $Z^{(n)}$ moves very rapidly towards the surface $\gamma = 0$. Therefore in the limit we expect the value of $J^\infty(z)$ to be equal to $J^\infty(z + \rho(z)\xi)$. Indeed we have the following result.

LEMMA 12.4. *Let $z \in [0, \infty)^3$ be such that $z_3 > 0$. Then*

$$J^\infty(z) \le J^\infty(z + \rho(z)\xi). \tag{12.35}$$

Since the proof of this lemma is rather technical, we will first give a brief outline of the proof. Let z^0 be a point in $(0, \infty)^3$, and suppose that there is a smooth function φ such that $J^\infty - \varphi$ has a strict maximum at z_0. Then by an elementary argument, we can construct a sequence z^n converging to z^0 such that z^n maximizes the difference $J^{(n)} - \varphi$. Setting $u = U(z)$, we have from the definition (3.1) of $\mathcal{L}^{n,1,u}$ and from Proposition 4.1 that

$$\mathcal{L}^{n,1,u}\varphi(z^n) \ge \mathcal{L}^{n,1,u}J^{(n)}(z^n) = \alpha J^{(n)}(z^n) - h(z^n). \tag{12.36}$$

For $z \in (0, \infty)^3$, the only unbounded term in the expansion (7.13) of $\mathcal{L}^{n,1,u}\varphi(z)$ is

$$\sqrt{n}\left[\frac{\lambda_1^{(n)}}{\mu_1^{(n)}} - U(z)\right]\nabla\varphi(z) - \xi^{(n)}.$$

By the definition (12.5b) of U, the term in the brackets has the same sign as $-\gamma$. By letting n go to infinity and using the fact that the right-hand side of (12.36) remains bounded, we conclude that

$$\gamma(z^0)\nabla\varphi(z^0) \cdot \xi \le 0.$$

Now if J^∞ is differentiable, then $\nabla J^\infty(z^0) = \nabla\varphi(z^0)$, and we would have

$$\gamma(z^0)\nabla J^\infty(z^0) \cdot \xi \le 0 \quad \forall z^0 \in (0, \infty)^3.$$

This inequality tells us that $\frac{d}{dt}J^\infty(z + t\xi)$ has the sign as $-\gamma(z + t\xi)$, so $J^\infty(z + t\xi)$ is maximized at $t = \rho(z)$.

Proof. Fix $\bar{z} \in [0, \infty)^3$ such that $\bar{z}_3 > 0$. If $\bar{z}_1 = \bar{z}_2 = 0$, then $\rho(\bar{z}) = 0$ and (12.35) holds at $z = \bar{z}$. We thus assume, without loss of generality, that

$$\bar{z}_1 \vee \bar{z}_2 > 0. \tag{12.37}$$

The idea of the proof is to construct, for each sufficiently small positive ϵ, a point z^ϵ satisfying $\gamma(z^\epsilon) = 0$ such that

$$\lim_{\epsilon \downarrow 0} z^\epsilon = \bar{z} + \rho(\bar{z})\xi, \qquad J^\infty(\bar{z}) \le \overline{\lim_{\epsilon \downarrow 0}} J^\infty(z^\epsilon). \tag{12.38}$$

The upper semicontinuity of J^∞, which follows from its definition, will then yield the desired result, (12.35).

Step 1. *Choice of constants.* From Proposition 12.3 it follows that there are positive constants k_1 and k_2 such that

$$J^{(n)}(z) \le k_1|\omega(z)| + k_2 \quad \forall z \in L^{(n)}, \forall n \ge 1. \tag{12.39}$$

We put $k_3 \triangleq 2(1 + k_1 + k_2 + |\omega(\bar{z})|)$, $k_4 \triangleq 2(k_1k_3 + k_2 + 1)$. For $\epsilon > 0$, set

$$\beta(\epsilon) \triangleq \min\{\rho(z);\, z \in [0, \infty)^3, |\omega(z) - \omega(\bar{z})|^2 \le k_4\epsilon, z_3 = 0\}, \tag{12.40}$$

where we use the convention $\min \phi = \infty$. Since $\bar{z}_3 > 0$, there is an $\epsilon_0 > 0$ such that

$$\rho(\bar{z}) < \beta(\epsilon) \quad \forall \epsilon \in (0, \epsilon_0). \tag{12.41}$$

Henceforth, we consider only $\epsilon \in (0, 1 \wedge \epsilon_0)$.

Step 2. *Definition of* φ_ϵ. Let $\psi_\epsilon \in C^4(\mathcal{R})$ be such that

$$\psi_\epsilon(0) = 0 \quad \text{and} \quad \psi_\epsilon(x) \geq 0 \quad \forall x \in \mathcal{R},$$

$$x\psi_\epsilon'(x) > 0 \quad \forall x \in \mathcal{R}, x \neq 0, \tag{12.42}$$

$$\psi_\epsilon(\beta(\epsilon)) = k_1 k_3 + k_2 + 1, \tag{12.43}$$

$$\psi_\epsilon(\rho(\bar{z})) \leq \epsilon. \tag{12.44}$$

Inequality (12.41) guarantees the existence of such a ψ_ϵ. We put

$$\varphi_\epsilon(z) \triangleq \psi_\epsilon(\rho(z)) + \frac{1}{2\epsilon}|\omega(z) - \omega(\bar{z})|^2, \qquad z \in [0, \infty)^3. \tag{12.45}$$

Step 3. *Definition of* z^ϵ. Because φ_ϵ grows quadratically and $J^{(n)}$ grows linearly (Proposition 12.3), the difference $J^{(n)} - \varphi_\epsilon$ attains its maximum at some point $z^n \in L^{(n)}$. Indeed, the linear growth of $J^{(n)}$ is uniform in n, so the sequence $\{z^n\}$ is bounded. We can thus select a convergent subsequence $\{z^{n_k}\}$ such that

$$\begin{aligned} \lim_{k\to\infty} [J^{(n_k)}(z^{n_k}) - \varphi_\epsilon(z^{n_k})] &= \overline{\lim_{n\to\infty}} [J^{(n)}(z^n) - \varphi_\epsilon(z^n)] \\ &\geq J^\infty(z) - \varphi_\epsilon(z) \quad \forall z \in [0, \infty)^3. \end{aligned} \tag{12.46}$$

Let z^ϵ denote the limit of $\{z^n\}$. From (12.46) we see that

$$J^\infty(z^\epsilon) - \varphi_\epsilon(z^\epsilon) \geq J^\infty(z) - \varphi_\epsilon(z) \quad \forall z \in [0, \infty)^3. \tag{12.47}$$

Step 4. *Bounds on* $\{z^n\}$ *and* z^ϵ. Because z^n maximizes $J^{(n)} - \varphi_\epsilon$, we have

$$J^{(n)}(z^n) - \varphi_\epsilon(z^n) \geq J^{(n)}(\bar{z}) - \varphi_\epsilon(\bar{z}) \geq -\epsilon > -1, \tag{12.48}$$

where we have used (12.44). It follows then from (12.39) that

$$\frac{1}{2\epsilon}|\omega(z^n) - \omega(\bar{z})|^2 \leq \varphi_\epsilon(z^n) \leq J^{(n)}(z^n) + 1 \leq k_1|\omega(z^n)| + k_2 + 1. \tag{12.49}$$

This inequality implies

$$\frac{1}{2\epsilon}|\omega(z^n)|^2 \leq k_1|\omega(z^n)| + k_2 + 1 + \frac{1}{\epsilon}|\omega(z^n)|\,|\omega(\bar{z})|,$$

so if $|\omega(z^n)| \geq \epsilon$, we have

$$\frac{1}{2\epsilon}|\omega(z^n)| \leq k_1 + \frac{1}{\epsilon}[k_2 + 1 + |\omega(\bar{z})|] \leq \frac{k_3}{2\epsilon}.$$

Regardless of the value of $|\omega(z^n)|$, we have

$$|\omega(z^n)| \leq \min\{\epsilon, k_3\} \leq k_3. \tag{12.50}$$

Substitution of (12.50) into (12.49) yields

$$|\omega(z^n) - \omega(\bar{z})|^2 \leq k_4\epsilon. \tag{12.51}$$

Taking the limit along the sequence $\{n_k\}$, we obtain from (12.48), (12.50), and (12.51)

$$J^\infty(z^\epsilon) - \varphi_\epsilon(z^\epsilon) \geq -\epsilon > -1, \tag{12.52}$$

$$|\omega(z^\epsilon)| \leq k_3, \tag{12.53}$$

$$|\omega(z^\epsilon) - \omega(\bar{z})|^2 \leq k_4\epsilon. \tag{12.54}$$

Finally, we show that $z_3^\epsilon > 0$. If z_3^ϵ were zero, then (12.40) and (12.54) would imply $\beta(\epsilon) \leq \rho(z^\epsilon)$. But (12.52) implies

$$\psi_\epsilon(\rho(z^\epsilon)) \leq \varphi_\epsilon(z^\epsilon) < J^\infty(z^\epsilon) + 1 \leq k_1|\omega(z^\epsilon)| + k_2 + 1 \leq k_1k_3 + k_2 + 1,$$

where we have used (12.53) and the limit form of (12.39). From (12.42) and (12.43), we conclude that $\rho(z^\epsilon) < \beta(\epsilon)$ and hence $z_3^\epsilon > 0$.

For sufficiently small ϵ, (12.37) and (12.54) imply $z_1^\epsilon \vee z_2^\epsilon > 0$. Thus, we may choose $\epsilon_1 \in (0, 1 \wedge \epsilon_0)$ such that, for each $\epsilon \in (0, \epsilon_1)$, there is a positive integer k^ϵ satisfying

$$z_3^{n_k} > 0, \quad z_1^{n_k} \vee z_2^{n_k} > 0 \quad \forall k \geq k^\epsilon. \tag{12.55}$$

Step 5. $\gamma(z^\epsilon) = 0$. Given $\epsilon \in (0, \epsilon_1)$, let k^ϵ be as in (12.55), and let $k \geq k^\epsilon$ be given. Because z^{n_k} maximizes $J^{(n_k)} - \varphi_\epsilon$, we have $\mathcal{L}^{n_k,y,u}(J^{(n_k)} - \varphi_\epsilon)(z^{n_k}) \leq 0$ (see (3.1)). Setting $y = 1$ and $u = U^{n_k}(z^{n_k})$, we have from Proposition 4.1 that

$$\mathcal{L}^{n_k,1,u}\varphi_\epsilon(z^{n_k}) \geq \mathcal{L}^{n_k,1,u}J^{(n_k)}(z^{n_k}) = \alpha J^{(n_k)}(z^{n_k}) - h(z^{n_k}),$$

which is bounded below uniformly in k because $\{z^{n_k}\}$ is bounded. But with $\theta^{(n_k)} \triangleq \sqrt{n_k}[\frac{\lambda_1^{(n_k)}}{\mu_1^{(n_k)}} - U^{n_k}(z^{n_k})]$, we have from (7.13) that

$$\mathcal{L}^{n_k,1,u}\varphi_\epsilon(z^{n_k}) = \mathcal{L}\varphi(z^{n_k}) + \theta^{(n_k)}\left[\nabla\varphi(z^{n_k})\cdot\xi^{(n_k)} + \frac{1}{\sqrt{n_k}}\mathcal{A}^n\varphi(z^{n_k})\right] + O\left(\frac{1}{\sqrt{n_k}}\right). \tag{12.56}$$

The terms σ_1 and σ_2 in (7.13) vanish because $y = 1$. The terms $\mathcal{B}_i^{n_k,1,u}$, $i = 1, 2, 3$, vanish because $z_1^{n_k} \wedge z_2^{n_k} > 0$, $z_3^{n_k} > 0$, and

1. $z_1^{n_k} = 0 \Rightarrow z_2^{n_k} > 0, \gamma(z_2^{n_k}) < 0, u = 0$;
2. $z_2^{n_k} = 0 \Rightarrow \gamma(z^{n_k}) \geq 0, u = 1$.

All the terms on the right-hand side of (12.56) are bounded uniformly in k, except possibly $\theta^{(n_k)}\nabla\varphi(z^{n_k})\cdot\xi^{(n_k)}$. Therefore, this term must be bounded from below, uniformly in k, i.e.,

$$\inf_{k\geq k^\epsilon}\left\{\sqrt{n_k}\left[\frac{\lambda_1^{(n_k)}}{\mu_1^{(n_k)}} - U^{n_k}(z^{n_k})\right]\nabla\varphi(z^{n_k})\cdot\xi^{(n_k)}\right\} > -\infty. \tag{12.57}$$

We use (12.57) to prove that $\gamma(z^\epsilon) = 0$. If $\gamma(z^\epsilon) > 0$, then $\gamma(z^{n_k}) > 0$ and $U^{n_k}(z^{n_k}) = 1$ for sufficiently large k. Since

$$\lim_{k\to\infty}\left[\frac{\lambda_1^{(n_k)}}{\mu_1^{(n_k)}} - 1\right] = \frac{\lambda_1}{\mu_1} - 1 = -\frac{\lambda_2}{\mu_2} < 0,$$

(12.57) implies that

$$\nabla\varphi(z^\epsilon)\cdot\xi = \lim_{k\to\infty}\nabla\varphi(z^{n_k})\cdot\xi^{(n_k)} \leq 0. \tag{12.58}$$

But

$$\nabla\varphi(z^\epsilon)\cdot\xi = \psi_\epsilon'(\rho(z^\epsilon))\nabla\rho(z^\epsilon)\cdot\xi = -\psi_\epsilon'(\rho(z^\epsilon)), \tag{12.59}$$

where we have used (12.15). From (12.58), (12.59), and (12.42), we conclude that $\rho(z^\epsilon) \geq 0$. Lemma 12.2(c) implies that $\gamma(z^\epsilon) \leq 0$, which contradicts our initial assumption $\gamma(z^\epsilon) > 0$. A similar argument rules out the possibility $\gamma(z^\epsilon) < 0$, and we are left with the conclusion $\gamma(z^\epsilon) = 0$.

Step 6. *Conclusion.* Because $\lim_{\epsilon\downarrow 0}\omega(z^\epsilon) = \omega(\bar z)$ (see (12.54)) and $\gamma(z^\epsilon) = 0$, and we have $\lim_{\epsilon\downarrow 0} z^\epsilon = \bar z + \rho(\bar z)\xi$. We may now take the limit as $\epsilon \downarrow 0$ in (12.47), using (12.44), to conclude

$$J^\infty(\bar z + \rho(\bar z)\xi) \geq \overline{\lim_{\epsilon\downarrow 0}} J^\infty(z^\epsilon) \geq \lim_{\epsilon\downarrow 0}[J^\infty(\bar z) - \varphi_\epsilon(\bar z)] = J^\infty(\bar z).$$

This completes the proof of (12.38). □

The next few lemmas allow us to remove the condition $z_3 > 0$ in Lemma 12.4.

LEMMA 12.5. *Suppose that $\varphi \in C^3([0,\infty)^3)$ is such that $J^\infty - \varphi$ has a local maximum at $\bar z$. Assume that $\bar z_1 \vee \bar z_2 > 0$ and either $\bar z_3 > 0$ or $\bar z_3 = 0$ and $\varphi_3(\bar z) < 0$. Then $\gamma(\bar z)\nabla\varphi(\bar z)\cdot\xi \leq 0$, where $\xi = (\mu_1, -\mu_2, \mu_3)$.*

Proof. Assume for the moment that $J^\infty - \varphi$ has a *strict* local maximum at $\bar z$. Let $\tilde K \subset \mathcal{R}^3$ be a compact set whose interior contains $\bar z$ and is such that $\bar z$ strictly maximizes $J^\infty - \varphi$ over $[0,\infty)^3 \cap \operatorname{int}(\tilde K)$. Define $K = [0,\infty)^3 \cap \tilde K$, and let z^n maximize $J^{(n)} - \varphi$ over the finite set $K \cap L^{(n)}$. Choose a convergent subsequence $\{z^{n_k}\}$ with limit z^∞ such that

$$\lim_{k\to\infty}[J^{(n_k)}(z^{n_k}) - \varphi(z^{n_k})] = \overline{\lim_{n\to\infty}}[J^{(n)}(z^n) - \varphi(z^n)].$$

Then

$$\begin{aligned} J^\infty(z^\infty) - \varphi(z^\infty) &\geq \overline{\lim_{n\to\infty}}[J^{(n)}(z^n) - \varphi(z^n)] \\ &\geq J^\infty(z) - \varphi(z) \quad \forall z \in [0,\infty)^3 \cap \operatorname{int}(\tilde K). \end{aligned}$$

It follows that $z^\infty = \bar z$.

There exists a positive integer k_0 such that $z_1^{n_k} \vee z_2^{n_k} > 0$ for all $k \geq k_0$, and either $z_3^{n_k} > 0$ for all $k \geq k_0$ or else $z_3^{n_k} = 0$ and $\varphi_3(z^{n_k}) < 0$ for all $k \geq k_0$. Consequently, $\mathcal{B}_3^{n,1,U^{n_k}(z^{n_k})}\varphi(z^{n_k})$ given by (7.12) is either zero or else is bounded from above, uniformly in $k \geq k_0$. This observation allows us to use the argument in Step 5 of the proof of Lemma 12.4 to conclude that $\gamma(\bar z)\nabla\varphi(\bar z)\cdot\xi \leq 0$.

If the maximum attained by $J^\infty - \varphi$ at $\bar z$ is not strict, we introduce the function $\varphi_\delta(z) \triangleq \varphi(z) + \delta e^{-|z-\bar z|^2}$. For all $\delta > 0$, the function $J^\infty - \varphi_\delta$ attains a strict maximum at $\bar z$. Furthermore, $\nabla\varphi_\delta(\bar z) = \nabla\varphi(\bar z)$. The preceding argument shows that $\gamma(z)\nabla\varphi(\bar z)\cdot\xi = \gamma(z)\cdot\nabla\varphi_\delta(\bar z)\cdot\xi \leq 0$. □

LEMMA 12.6. *Suppose that $\varphi \in C^3([0,\infty)^3)$ is such that $J^\infty - \varphi$ has a local maximum at $\bar z$. Assume that $\bar z_3 = 0$. Then $J^\infty(\bar z) \leq J^\infty(\bar z + \rho(\bar z)\xi)$.*

Proof. We assume without loss of generality that $\bar z_2 > 0$, since if $\bar z_2 = 0$, then $\rho(\bar z) = 0$ and the result follows. The assumption $\bar z_2 > 0$ is equivalent to $\gamma(\bar z) < 0$.

Suppose the desired result is false, i.e., there is an $\epsilon > 0$ such that $J^\infty(\bar z) \geq J^\infty(\bar z + \rho(\bar z)\xi) + \epsilon$. Continuity of ρ and upper semicontinuity of J^∞ imply the existence of $\delta > 0$ such that

$$\begin{aligned} |z - \bar z| < \delta \Rightarrow J^\infty(z + \rho(z)\xi) &\leq J^\infty(\bar z + \rho(\bar z)\xi) + \frac{\epsilon}{2} \\ &\leq J^\infty(\bar z) - \frac{\epsilon}{2}. \end{aligned}$$

From Lemma 12.4, we have then that

$$|z - \bar{z}| < \delta, z_3 > 0 \Rightarrow J^\infty(z) \leq J^\infty(\bar{z}) - \frac{\epsilon}{2};$$

i.e., J^∞ jumps up at $\bar{z}$ as the boundary $z_3 = 0$ is approached. Consequently, with $K > 0$ and $\tilde{\varphi}(z) \triangleq \varphi(z) - Kz_3$, the function $J^\infty - \tilde{\varphi}$ has a local maximum at $\bar{z}$. For K large enough, we also have $\bar{\varphi}_3(\bar{z}) < 0$. Applying Lemma 12.5 to $\tilde{\varphi}$ and recalling our assumption $\gamma(\bar{z}) < 0$, we see that

$$0 \leq \nabla\tilde{\varphi}(\bar{z}) \cdot \xi = \frac{1}{\mu_1}\varphi_1(\bar{z}) - \frac{1}{\mu_2}\varphi_2(\bar{z}) + \frac{1}{\mu_2}\varphi_3(\bar{z}) - \frac{K}{\mu_2}.$$

This inequality is violated for sufficiently large K. □

PROPOSITION 12.7. *$J^\infty(z) \leq J^\infty(z+\rho(z)\xi)$ for all $z \in [0,\infty)^3$, where $\xi = (\mu_1, -\mu_2, \mu_3)$.*

Proof. In light of Lemma 12.5, it is enough to consider the case $z_3 = 0$. As in that lemma, we assume without loss of generality that $z_1 \vee z_2 > 0$. Consider the so-called *sup-convolution* (Crandall, Ishii, and Lions (1992), Fleming and Soner (1993))

$$J^\epsilon(z) = \sup_{y \in [0,\infty)^3} \left\{ J^\infty(y) - \frac{1}{\epsilon}|y - z|^2 \right\}.$$

By the linear growth of J^∞, there is, for each ϵ, a point $y(\epsilon)$ at which the supremum is attained. We then have

$$J^\infty(y(\epsilon)) - \frac{1}{\epsilon}|y(\epsilon) - z|^2 \geq J^\infty(z) \geq 0,$$

and this implies that $\{y(\epsilon) : \epsilon > 0\}$ is bounded and $y(\epsilon) \to z$ as $\epsilon \to 0$. Since $J^\infty(y(\epsilon)) \geq J^\infty(z)$, upper semicontinuity of J^∞ implies $J^\infty(y(\epsilon)) \to J^\infty(z)$. Now note that $J^\infty(y(\epsilon)) \leq J^\infty(y(\epsilon) + \rho(y(\epsilon))\xi)$. This follows either from Lemma 12.4 if the third coordinate of $y(\epsilon)$ is positive or from Lemma 12.6 (taking $\varphi(y) = \frac{1}{\epsilon}|y - z|^2$) if the third coordinate is zero. We have then

$$J^\infty(z) = \lim_{\epsilon \downarrow 0} J^\infty(y(\epsilon)) \leq \overline{\lim_{\epsilon \downarrow 0}} J^\infty(y(\epsilon) + \rho(y(\epsilon))\xi) \leq J^\infty(z + \rho(z)\xi). \qquad \square$$

For $w \in [0,\infty)^2$, we denote by $\zeta(w)$ the unique $z \in [0,\infty)^3$ for which $\omega(z) = w$ and $\gamma(z) = 0$. In terms of the function ρ constructed in Lemma 12.2, we have the formula

$$\zeta(\omega(z)) = z + \rho(z)\xi \quad \forall z \in [0,\infty)^3. \tag{12.60}$$

We set

$$\hat{J}(w) \triangleq J^\infty(\zeta(w)), \qquad w \in [0,\infty)^2. \tag{12.61}$$

It will be shown that $\hat{J}$ is a viscosity subsolution (defined below) of the partial differential equation

$$\alpha J - \hat{\mathcal{L}}J - h = C_0\delta_4 \quad \text{on} \quad (0,\infty)^2 \tag{12.62a}$$

and the Neumann boundary conditions

$$-J_1(0, w_2) = 0 \quad \forall w_2 \geq 0, \tag{12.62b}$$

$$-J_2(w_1, 0) = 0 \quad \forall w_1 \geq 0. \tag{12.62c}$$

Here, δ_4 and C_0 are the constants defined in Lemma 12.2(d), (e), $\hat{\mathcal{L}}$ is defined by (10.4), and $\hat{h}$ by (8.4). The value function $\hat{V}$ for the workload control problem is a classical solution of the related equations (10.2), (10.3). These facts will allow us to obtain an upper bound on $\hat{J}$ in terms of $\hat{V}$, and Proposition 12.1 will follow.

DEFINITION 12.8 (Crandall, Evans, and Lions (1984), Crandall and Lions (1984), Crandall, Ishii, and Lions (1992)). *We say that an upper semicontinuous function* $J : [0,\infty)^2 \to \mathcal{R}$ *is a* viscosity subsolution *of* (12.62a)–(12.62c) *if, whenever* $\bar{w} \in \arg\max_{[0,\infty)^2}(J-\varphi)$ *for some* $\varphi \in C^\infty(\mathcal{R}^2)$, *we have*

(a) *if* $\bar{w}_1 > 0$ *and* $\bar{w}_2 > 0$, *then*

$$\alpha J(\bar{w}) - \hat{\mathcal{L}}\varphi(\bar{w}) - \hat{h}(\bar{w}) \le C_0\delta_4;$$

(b) *if* $\bar{w}_1 = 0$ *and* $\bar{w}_2 > 0$, *then*

$$\min\{\alpha J(\bar{w}) - \hat{\mathcal{L}}\varphi(\bar{w}) - \hat{h}(\bar{w}) - C_0\delta_4, -\varphi_1(\bar{w})\} \le 0;$$

(c) *if* $\bar{w}_1 > 0$ *and* $\bar{w}_2 = 0$, *then*

$$\min\{\alpha J(\bar{w}) - \hat{\mathcal{L}}\varphi(\bar{w}) - \hat{h}(\bar{w}) - C_0\delta_4, -\varphi_2(\bar{w})\} \le 0;$$

(d) *if* $\bar{w}_1 = 0$ *and* $\bar{w}_2 = 0$, *then*

$$\min\{\alpha J(\bar{w}) - \hat{\mathcal{L}}\varphi(\bar{w}) - \hat{h}(\bar{w}) - C_0\delta_4, -\varphi_1(\bar{w}), -\varphi_2(\bar{w})\} \le 0.$$

Remark 12.9. A function J is a viscosity subsolution of (12.62a)–(12.62c) if and only if, for every C^∞ function $\varphi : \mathcal{R}^2 \to \mathcal{R}$ and every $\bar{w}$ which is a *strict maximum* of $J-\varphi$ over $[0,\infty)^2$, conditions (a)–(d) of Definition 12.8 hold. Indeed, if we have these conditions at strict maxima and if $\bar{w}$ maximizes $J-\varphi$, but perhaps not strictly, then $\bar{w}$ is a strict maximum of $J-\varphi_\delta$, where $\delta > 0$ and $\varphi_\delta(w) \triangleq \varphi(w) + \delta e^{-|w-w|^2}$. Writing conditions (a)–(d) for φ_δ and letting $\delta \downarrow 0$, we obtain these conditions for φ.

PROPOSITION 12.10. $\hat{J}$ *defined by* (12.61) *is a viscosity subsolution of* (12.62a)–(12.62c).

Let $\varphi : \mathcal{R}^2 \to \mathcal{R}$ be of class C^∞, and let $\bar{w}$ maximize $\hat{J}-\varphi$ over $[0,\infty)^2$. In light of Remark 12.9, we may assume that $\hat{J}-\varphi$ has a *strict* maximum over $[0,\infty)^2$ at $\bar{w}$.

For $\epsilon > 0$, put

$$\varphi^\epsilon(z) = \varphi(\omega(z)) + \frac{\epsilon}{2}(\gamma(z))^2, \qquad z \in (-1,\infty)^3.$$

We claim that $\bar{z} \triangleq \zeta(\bar{w})$ is a strict maximizer of $J^\infty - \varphi^\epsilon$ over $[0,\infty)^3$, i.e.,

$$J^\infty(z) - \varphi(\omega(z)) - \frac{\epsilon}{2}(\gamma(z))^2 < \hat{J}(\bar{w}) - \varphi(\bar{w}) \ \forall z \in [0,\infty)^3\backslash\{\bar{z}\}. \tag{12.63}$$

Consider $z \in [0,\infty)^3$, $z \neq \bar{z}$. If $\omega(z) = \bar{w}$, then $\gamma(z) \neq 0$ and Proposition 12.7 implies

$$J^\infty(z) - \varphi(\omega(z)) \le J^\infty(z + \rho(z)\xi) - \varphi(\omega(z)) = \hat{J}(\bar{w}) - \varphi(\bar{w});$$

inequality (12.63) follows. On the other hand, if $w(z) \neq \bar{w}$, then Proposition 12.7 implies

$$\begin{aligned} J^\infty(z) - \varphi(\omega(z)) &\le J^\infty(z + \rho(z)\xi) - \varphi(\omega(z)) \\ &= \hat{J}(\omega(z)) - \varphi(\omega(z)) \\ &< \hat{J}(\bar{w}) - \varphi(\bar{w}). \end{aligned}$$

Set

$$\Psi^{n,\epsilon}(z) \triangleq \sqrt{n}\nabla\varphi^\epsilon(z)\cdot(\xi - \xi^{(n)}) - \mathcal{A}^{(n)}\varphi^\epsilon(z), \qquad z \in (-1,\infty)^3,$$

where $\xi^{(n)}$ and $\mathcal{A}^{(n)}$ are given by (7.14) and (7.15). Let T be as in Step 3 of the proof of Proposition 11.1. For $z \in [0,\infty)^3$, set

$$f^{n,\epsilon}(z) \triangleq \int_0^{T(z)} \psi^{n,\epsilon}(z - r\xi^{(n)})dr, \qquad g^{n,\epsilon}(z) \triangleq \varphi^\epsilon(z) + \frac{1}{\sqrt{n}} f^{n,\epsilon}(z).$$

Note that

$$\nabla f^{n,\epsilon}(z)\cdot\xi^{(n)} = \psi^{n,\epsilon}(z) + O\left(\frac{1}{\sqrt{n}}\right), \qquad g^{n,\epsilon}(z) = \varphi^{\epsilon}(z) + O\left(\frac{1}{\sqrt{n}}\right),$$

where $O(\frac{1}{\sqrt{n}})$ is bounded in absolute value by $K(z)/\sqrt{n}$ and $K : [0,\infty)^3 \to [0,\infty)$ is locally bounded. Indeed, we may choose a linearly growing K because $f^{n,\epsilon}$ grows at most linearly.

Because $\bar{z}$ is a strict maximizer of $J^{\infty} - \varphi^{\epsilon}$ over $[0,\infty)^3$, we can find a compact set $G \subset \mathcal{R}^3$ containing $\bar{z}$ in its interior, a strictly increasing sequence of positive integers $\{k_n\}_{n=1}^{\infty}$, and a sequence $\{z^{k_n}\}_{n=1}^{\infty}$ such that $J^{(k_n)}(z^{k_n}) \to J^{\infty}(\bar{z})$ and each z^{k_n} maximizes $J^{(k_n)} - g^{k_n,\epsilon}$ over $G \wedge L^{(k_n)}$. To simplify typography, we assume that $k_n = n$, i.e.,

$$\lim_{n\to\infty} J^{(n)}(z^n) = J^{\infty}(\bar{z}), \tag{12.64}$$

$$J^{(n)}(z^n) - g^{n,\epsilon}(z^n) \geq J^{(n)}(z) - g^{n,\epsilon}(z) \quad \forall z \in G \cap L^{(n)}. \tag{12.65}$$

Directly from (3.1), this implies $\mathcal{L}^{n,1,U^n(z^n)}(J^{(n)} - g^{n,\epsilon})(z^n) \leq 0$, and Proposition 4.1 yields

$$\alpha J^{(n)}(z^n) - \mathcal{L}^{n,1,U^n(z^n)} g^{n,\epsilon}(z^n) \leq c\cdot z^n. \tag{12.66}$$

We now use expansion (7.13) to obtain

$$\begin{aligned}\mathcal{L}^{n,1,U^n(z^n)} g^{n,\epsilon}(z^n) &= \mathcal{L}g^{n,\epsilon}(z^n) + \theta^{(n)}\left[\nabla g^{n,\epsilon}(z^n)\cdot\xi^{(n)} + \frac{1}{\sqrt{n}}\mathcal{A}^{(n)} g^{n,\epsilon}(z^n)\right] \\ &\quad + \sum_{i=1}^{3} \mathcal{B}_i^{n,1,U^n(z^n)} g^{n,\epsilon}(z) + O\left(\frac{1}{\sqrt{n}}\right),\end{aligned} \tag{12.67}$$

where $\theta^{(n)} = \sqrt{n}[\frac{\lambda_1^{(n)}}{\mu_1^{(n)}} - U^n(z^n)]$ and $O(\frac{1}{\sqrt{n}})$ is bounded in absolute value by $K(z)/\sqrt{n}$ for some locally bounded function K (see Remark 7.1). Simplifying the right-hand side of (12.67) and using the inequalities $\theta^{(n)}\gamma(z^n) \leq 0$, $\nabla\gamma(z^n)\cdot\xi \geq 0$, we obtain

$$\begin{aligned}\mathcal{L}^{n,1,U^n(z^n)} g^{n,\epsilon}(z^n) &= \mathcal{L}\varphi^{\epsilon}(z^n) + \frac{\epsilon}{\sqrt{n}}\theta^{(n)}\gamma(z^n)\nabla\gamma(z^n)\cdot\xi \\ &\quad + \sum_{i=1}^{3} \mathcal{B}_1^{n,1,U^n(z^n)} g^{n,\epsilon}(z^n) + O\left(\frac{1}{\sqrt{n}}\right) \\ &\leq \mathcal{L}\varphi^{\epsilon}(z^n) + \sum_{i=1}^{3} \mathcal{B}_1^{n,1,U^n(z^n)} g^{n,\epsilon}(z^n) + O\left(\frac{1}{\sqrt{n}}\right)\end{aligned} \tag{12.68}$$

and

$$\mathcal{B}_1^{n,1,U^n(z^n)} g^{n,\epsilon}(z^n) = \sqrt{n}\mu_1^{(n)} U^n(z^n)\left[\varphi_1(\omega(z^n)) + \epsilon\gamma(z^n)\gamma_1(z^n) + O\left(\frac{1}{\sqrt{n}}\right)\right] 1_{\{z_1^n=0\}},$$

$$\mathcal{B}_2^{n,1,U^n(z^n)} g^{n,\epsilon}(z^n) = \sqrt{n}\mu_2^{(n)}(1 - U^n(z^n))\left[\varphi_2(\omega(z^n)) + \epsilon\gamma(z^n)\gamma_2(z^n) + O\left(\frac{1}{\sqrt{n}}\right)\right] 1_{\{z_2^n=0\}},$$

$$\mathcal{B}_3^{n,1,U^n(z^n)} g^{n,\epsilon}(z^n) = \sqrt{n}\mu_3^{(n)}\left[\varphi_2(\omega(z^n)) + \epsilon\gamma(z^n)\gamma_3(z^n) + O\left(\frac{1}{\sqrt{n}}\right)\right] 1_{\{z_3^n=0\}}.$$

Note that $\gamma(z^n) \geq 0$ whenever $z_2^n = 0$, which implies $(1 - U^{(n)}(z^n))1_{\{z_2^n=0\}} = 0$; hence $\mathcal{B}_2^{n,1,U^n(z^n)} g^{n,\epsilon}(z^n) = 0$.

Let us consider now the four cases (a)–(d) of Definition 12.8.

Case (a) ($\bar{w}_1 > 0, \bar{w}_2 > 0$). Because $\gamma(\bar{z}) = a(\bar{z}_1)a(\bar{z}_3) - b(\bar{z}_2) = 0$, we must have $\bar{z}_1 > 0, \bar{z}_2 > 0, \bar{z}_3 > 0$. Thus, for sufficiently large n,

$$\mathcal{B}_1^{n,1,U^n(z_n)} g^{n,\epsilon}(z^n) = \mathcal{B}_3^{n,1,U^n(z_n)} g^{n,\epsilon}(z^n) = 0,$$

and (12.68) implies

$$\mathcal{L}^{n,1,U^{(n)}(z^n)} g^{n,\epsilon}(z^n) \le \mathcal{L}\varphi^\epsilon(z^n) + O\left(\frac{1}{\sqrt{n}}\right). \tag{12.69}$$

From (12.66), we see that

$$\alpha J^{(n)}(z^n) - \mathcal{L}\varphi^\epsilon(z^n) \le c \cdot z^n + O\left(\frac{1}{\sqrt{n}}\right),$$

and letting first $n \to \infty$ and then $\epsilon \downarrow 0$, we obtain

$$\alpha J^\infty(\bar{z}) - \mathcal{L}\varphi(\omega(\bar{z})) \le c \cdot \bar{z}.$$

But $J^\infty(\bar{z}) = \hat{J}(\bar{w})$ and $\mathcal{L}\varphi(\omega(\bar{z})) = \hat{\mathcal{L}}\varphi(\bar{w})$, so (12.11) yields

$$\alpha \hat{J}(\bar{w}) - \hat{\mathcal{L}}\varphi(\bar{w}) \le \hat{h}(\bar{w}) + C_0\delta_4, \tag{12.70}$$

as required by Definition 12.8(a).

Case (b) ($\bar{w}_1 = 0, \bar{w}_2 > 0$). We have $\bar{z}_1 = \bar{z}_2 = 0, \bar{z}_3 > 0$. If $\varphi_1(\bar{w}) \ge 0$, the inequality in Definition 12.8(b) is satisfied and we are done, so we assume that $\varphi_1(\bar{w}) < 0$. But in this case

$$\lim_{n\to\infty}\left[\varphi_1(\omega(z^n)) + \epsilon\gamma(z^n)\gamma_1(z^n) + O\left(\frac{1}{\sqrt{n}}\right)\right] = \varphi_1(\bar{w}),$$

so we have $\mathcal{B}_1^{n,1,U^n(z^n)} g^{n,\epsilon}(z^n) \le 0$ for sufficiently large n. Since $\bar{z}_3 > 0$, we have $\mathcal{B}_3^{n,1,U^n(z^n)} g^{n,\epsilon}(z^n) = 0$ for sufficiently large n; (12.69) follows and leads to (12.70) as before.

Cases (c) and (d) are similar. □

PROPOSITION 12.11. *We have*

$$\hat{J}(w) \le \hat{V}(w) + \frac{C_0\delta_4}{\alpha} \quad \forall w \in [0,\infty)^2,$$

where δ_4 and C_0 are the constants defined in Lemma 12.2(d), (e).

Proof. For each $\epsilon > 0$, let $\hat{V}^\epsilon$ be the C^∞ function constructed in Step 1 of the proof of Proposition 11.1. For $\delta > 0$, define

$$\varphi^{\epsilon,\delta}(w) \triangleq \hat{V}^\epsilon(w) + \delta\eta(w), \qquad w \in [0,\infty)^2,$$

where $\eta(w) \triangleq w_1^2 + w_2^2 - w_1 - w_2$. Since $\hat{J}$ and $\hat{V}$ grow at most linearly, $\hat{J} - \varphi^{\epsilon,\delta}$ attains its maximum over $[0,\infty)^2$ at some point $\bar{w}^{\epsilon,\delta}$. Furthermore, the set $\{\bar{w}^{\epsilon,\delta}; 0 < \epsilon < 1\}$ is bounded for each fixed $\delta > 0$.

With $\delta > 0$ fixed, let $k^\delta > 0$ be such that $\bar{w}^{\epsilon,\delta} \in [0, k^\delta]^2$ for all $\epsilon \in (0,1)$. On the compact set $[0, k^\delta + 3]^2$, $\hat{V}_1$ and $\hat{V}_2$ are uniformly continuous. Consequently, there exists $\epsilon^\delta \in (0,1)$ such that for all $w, w' \in [0, k^\delta + 3]^2$, we have

$$|\hat{V}_i(w) - \hat{V}_i(w')| \le \frac{\delta}{2}, \qquad i = 1, 2,$$

whenever $|w - w'| < 4\epsilon^\delta$. In particular, if $\epsilon \le \epsilon^\delta$ and $\bar{w}_1^{\epsilon,\delta} = 0$, then because $\hat{V}_1(\bar{w}^{\epsilon,\delta}) = 0$ (see (10.2)), we have

$$\begin{aligned}\varphi_1^{\epsilon,\delta}(\bar{w}^{\epsilon,\delta}) &= \hat{V}_1^{\epsilon}(\bar{w}^{\epsilon,\delta}) - \delta \\ &= \int_{B_\epsilon(0)} \hat{V}_1(x + \bar{w}^{\epsilon,\delta} + 2\epsilon(1,1))\rho_\epsilon(x)dx - \delta \\ &\le -\frac{\delta}{2}.\end{aligned} \tag{12.71}$$

Similarly, if $\epsilon \le \epsilon^\delta$ and $\bar{w}_2^{\epsilon,\delta} = 0$, then $\varphi_2^{\epsilon,\delta}(\bar{w}^{\epsilon,\delta}) \le -\frac{\delta}{2}$.

We next show that

$$\alpha\hat{J}(\bar{w}^{\epsilon,\delta}) - \hat{\mathcal{L}}\varphi^{\epsilon,\delta}(\bar{w}^{\epsilon,\delta}) - \hat{h}(\bar{w}^{\epsilon,\delta}) \le C_0\delta_4 \quad \forall\delta > 0, \forall\epsilon \in (0, \epsilon^\delta). \tag{12.72}$$

For $\delta > 0$ and $0 < \epsilon < \epsilon^\delta$, if $\bar{w}_1^{\epsilon,\delta} > 0$ and $\bar{w}_2^{\epsilon,\delta} > 0$, inequality (12.72) follows immediately from Proposition 12.10 and (a) of Definition 12.8. If $\bar{w}_1^{\epsilon,\delta} = 0$ and $\bar{w}_2^{\epsilon,\delta} > 0$, then we use (12.71) and (b) of Definition 12.8. The case $\bar{w}_1^{\epsilon,\delta} > 0$, $\bar{w}_2^{\epsilon,\delta} = 0$ and the case $\bar{w}_1^{\epsilon,\delta} = 0$, $\bar{w}_2^{\epsilon,\delta} = 0$ are handled similarly.

From (11.4) we have

$$\begin{aligned}\alpha\varphi^{\epsilon,\delta}(\bar{w}^{\epsilon,\delta}) &= \alpha\hat{V}^{\epsilon}(\bar{w}^{\epsilon,\delta}) + \alpha\delta\eta(\bar{w}^{\epsilon,\delta}) \\ &\ge \hat{\mathcal{L}}\hat{V}^{\epsilon}(\bar{w}^{\epsilon,\delta}) + \hat{h}^{\epsilon}(\bar{w}^{\epsilon,\delta}) + \alpha\delta\eta(\bar{w}^{\epsilon,\delta}) - L_0\epsilon \\ &= \hat{\mathcal{L}}\varphi^{\epsilon,\delta}(\bar{w}^{\epsilon,\delta}) + \hat{h}^{\epsilon}(\bar{w}^{\epsilon,\delta}) + \delta[\alpha\eta(\bar{w}^{\epsilon,\delta}) - \hat{\mathcal{L}}\eta(\bar{w}^{\epsilon,\delta})] - L_0\epsilon.\end{aligned} \tag{12.73}$$

Combining this inequality with (12.72), and using the fact that $\bar{w}^{\epsilon,\delta}$ maximizes $\hat{J} - \varphi^{\epsilon,\delta}$, we see that

$$\begin{aligned}\alpha[\hat{J}(w) - \varphi^{\epsilon,\delta}(w)] &\le \alpha[\hat{J}(\bar{w}^{\epsilon,\delta}) - \varphi^{\epsilon,\delta}(\bar{w}^{\epsilon,\delta})] \\ &\le \alpha\bar{J}(\bar{w}^{\epsilon,\delta}) - \hat{\mathcal{L}}\varphi^{\epsilon,\delta}(\bar{w}^{\epsilon,\delta}) - \hat{h}^{\epsilon}(\bar{w}^{\epsilon,\delta}) \\ &\quad - \delta[\alpha\eta(\bar{w}^{\epsilon,\delta}) - \hat{\mathcal{L}}\eta(\bar{w}^{\epsilon,\delta})] + L_0\epsilon \\ &\le C_0\delta_4 + \hat{h}(\bar{w}^{\epsilon,\delta}) - \hat{h}^{\epsilon}(\bar{w}^{\epsilon,\delta}) \\ &\quad - \delta[\alpha\eta(\bar{w}^{\epsilon,\delta}) - \hat{\mathcal{L}}\eta(\bar{w}^{\epsilon,\delta})] + L_0\epsilon \\ &\le C_0\delta_4 + \hat{h}(\bar{w}^{\epsilon,\delta}) - \hat{h}^{\epsilon}(\bar{w}^{\epsilon,\delta}) + K\delta + L_0\epsilon \quad \forall\omega \in [0,\infty)^2,\end{aligned} \tag{12.74}$$

where

$$K \triangleq \max_{w\in[0,\infty)^2}\{-\alpha\eta(w) + \hat{\mathcal{L}}\eta(w)\} < \infty.$$

Letting first $\epsilon \downarrow 0$ and then $\delta \downarrow 0$ in (12.73), we conclude that

$$\alpha[\hat{J}(w) - \hat{V}(w)] \le C_0\delta_4,$$

which establishes the proposition. □

Proof of Proposition 12.1. Propositions 12.7 and 12.11 and (12.59), (12.60) imply that for any $z \in [0,\infty)^3$

$$J^{\#}(z) \le J^{\infty}(z) \le J^{\infty}(z + \rho(z)\xi) = \hat{J}(\omega(z)) \le \hat{V}(\omega(z)) + \frac{C_0\delta_4}{\alpha}. \tag{12.75}$$

But $C_0 = c_1\mu_1 - c_2\mu_2 + c_3\mu_3$ is constant, and $\delta_4 = \frac{1}{\mu_1 \wedge \mu_2} a^{-1}(\sqrt{\delta_2})$ can be made as small as we like by choice of the functions a and b introduced at the beginning of this section. □

COROLLARY 12.12. *Recalling that $J^{(n)} = J^{(n)}_{Y^n, U^n}$ denotes the cost of using the control law* (12.5a), (12.5b) *in the* nth *queueing network, and $J^{(n)}_*$ denotes the optimal cost in this network, we have*

$$\lim_{\delta \downarrow 0} \lim_{n \to \infty} \max_{\substack{\zeta \in L^{(n)} \\ |\zeta - z| \le \delta}} J^{(n)}(\delta) \le \lim_{\delta \downarrow 0} \lim_{n \to \infty} \min_{\substack{\zeta \in L^{(n)} \\ |\zeta - z| \le \delta}} J^{(n)}_*(\zeta) + \frac{C_0 \delta_4}{\alpha} \quad \forall z \in [0, \infty)^3. \tag{12.76}$$

Proof. Inequality (12.75) is simply

$$J^\infty(z) \le J_\#(z) + \frac{C_0 \delta_4}{\alpha}.$$

But Proposition 11.1 and 12.1 imply $J_\#(z) = J^\#(z) = \hat{V}(\omega(z))$ for all $z \in [0, \infty)^3$, and (12.76) follows from (12.74). □

ON THE LAVRENTIEV PHENOMENON FOR OPTIMAL CONTROL PROBLEMS WITH SECOND-ORDER DYNAMICS*

CHIH-WEN CHENG† AND VICTOR J. MIZEL‡

Abstract. The present article examines control problems in one dimension for which there is an autonomous running cost and a specified terminal state. In this case, when the running cost involves only the control and the state, it is known that the infimal cost corresponding to any initial state is unaffected by the precise choice of L^p space ($1 \leq p < \infty$) which is specified for controls to be admissible. Here we show that the situation is different in the case of an autonomous running cost involving, in addition to the control, the state *and* its derivative. That is, despite the density of each space with higher exponent in those with lower exponent, the infimal cost will generally depend on the choice of p if sign constraints are present.

Key words. Lavrentiev gap, free zone, fully coercive running cost

AMS subject classifications. 49J05, 49J45

1. Introduction.

We are concerned with control problems of the autonomous form

$$\text{(P)} \qquad C[u] = \int_{-1}^{0} f(x, x', u)\, dt \quad \text{with } x'' = u,$$

over $A^p_{a,b} = \{u \in L^p(-1,0) | \, x(-1) = a, x'(-1) = b, x(0) = x'(0) = 0\}$, $1 \leq p < \infty$, where $f \geq 0$ is smooth and is convex in its third argument. Intuitively, one is evaluating the cost of parking a moving railroad car at the origin in unit time, but the availability of less artificial applications is not clear. (One possible exception is the control of second-order nonlinear materials with negative capillarity [CMM].) The question to be raised is whether—despite the density of L^{p_2} in L^{p_1} for each $p_1 < p_2$—the minimal cost $m_p := \inf_{A^p_{a,b}} C$ varies with the choice of exponent $p \in [1, \infty)$. If such an effect occurs, one says that Lavrentiev's phenomenon is present (cf., e.g., [La], [Ma], [Ce], [BM], [M1], [M2], [M3], [HM1], [HM2], [HM3], [L], [Da], [BuM]). It is known that in analogous autonomous control problems with *first-order* dynamics, namely,

$$C[u] = \int_{-1}^{0} f(x, u)\, dt, \quad \text{with} \quad x' = u, \quad \text{over}$$
$$A^p_a = \{u \in L^p(-1,0) \,|\, x(-1) = a, x(0) = 0\},$$

the minimizing u in A^p_a actually lies in L^∞, so such an outcome is impossible [CV1], [Da], [AAB]. In contrast, we present a class of examples in the second-order context for which such a phenomenon does take place on suitable subsets of $A^p_{a,b}$. This sheds light on a conjecture raised in [CV2] concerning higher-order integrands. It also provides an incentive for further study of the troubling issue raised in [BK], [NM], and [Li]: the invalidity in such examples of standard numerical methods for dealing with optimization problems.

To illustrate the phenomenon, consider the following example:

$$C[u] = \int_{-1}^{0} (x')^6 (u)^8 \, dt, \quad \text{with } x'' = u,$$

over $A^p_{a,b} = \{u \in L^p(-1,0) \mid x(-1) = a > 0, x'(-1) = b < 0, x(0) = x'(0) = 0\}$. Now by Jensen's inequality and the chain rule for absolutely continuous functions (cf., e.g., [MM])

$$\begin{aligned} \int_s^0 (x'(t))^6 (u(t))^8 dt &= \int_s^0 (|x'(t)|^{3/4} x''(t))^8 dt \\ &= (4/7)^8 \int_s^0 (d/dt(|x'(t)|^{7/4}))^8 dt \\ &\geq (4/7)^8 |x'(s)|^{14}/|s|^7, \qquad -1 \leq s \leq 0. \end{aligned} \tag{1}$$

In particular, it follows that for all $u \in A^p_{a,b}$

$$C[u] \geq (4/7)^8 |b|^{14}. \tag{2}$$

Now consider the curve Γ given by $\Gamma = \{(x, y) | y = -x^{1/3}, x \geq 0\}$, and multiply the integrand by a weight factor $\theta(x, y)$, which vanishes along Γ and is positive everywhere else. Denoting the modified integrand by $f^\#$, we have

$$f^\#(x, x', u) = \theta(x, x')(x')^6 (u)^8 =: d(x, x')(u)^8.$$

Consider first the extreme case

$$\begin{aligned} \theta(x, y) &= 0 \quad \text{if } (x, y) \in \Gamma \\ &= 1 \quad \text{if } (x, y) \in [0, \infty) \times (-\infty, 0] \backslash \Gamma \\ &= \infty \quad \text{otherwise.} \end{aligned}$$

It is not hard to see why there is a Lavrentiev phenomenon for the cost function $C^\#$ corresponding to $f^\#$. Indeed consider the trajectory $x^\star$ given by

$$x_\star(t) = (-2t/3)^{3/2}, \qquad x'_\star(t) = -(-2t/3)^{1/2},$$

with corresponding boundary data $a = x_\star(-1)$, $b = x'_\star(-1)$. For this trajectory, $u_\star = x''_\star \in L^p(-1,0)$ for all $p \in [1,2)$, and $C^\#[u_\star] = 0$ ($d(x_\star(t), x'_\star(t)) = 0$ for all $t \in [-1,0]$). However, if we restrict attention to the smaller class $L^2(-1,0)$, then the optimizing control $u_\star$ is no longer admissible. It then follows from the previous estimate (1) that, in particular, we have the gap $(4/7)^8(2/3)^7$ for those controls $u \in L^2(-1,0)$ that coincide with $u_\star$ on an interval $[-1, s]$ for some $s < 0$ but are such that $\theta(x_\star(t), x'_\star(t)) \neq 0$ for all $t \in (s, 0)$. The full demonstration that there is a Lavrentiev gap for *all* L^2 controls for these and other a, b values will follow from the proof of Theorem A below.

Now the phenomenon is not restricted to cases in which the weight function d is non-smooth. Indeed, as follows from Theorem A stated below, the same basic result applies, for example, even to the polynomial weight function $d(x, y) = (x + y^3)^2$. More precisely, if we restrict attention to the state constrained subclasses

$$A^{p,+}_{a,b} = \{u \in L^p(-1,0) \mid x(-1) = a > 0, x'(-1) = b < 0, x(0) = x'(0) = 0 \text{ with } x(\cdot) \geq 0\},$$

then there will again exist for appropriate data a, b the relation

$$m_2^+ := \inf_{A_{a,b}^{2,+}} C^\# > 0 = m_1^+ = \min_{A_{a,b}^{1,+}} C^\#.$$

However, if one relaxes the sign constraint on x, then the *Lavrentiev gap* disappears:

$$m_p = \inf_{A_{a,b}^{p}} C^\# = 0 = m_1 = \min_{A_{a,b}^{1}} C^\# \quad \text{for all } p \in (1, \infty).$$

The initial class of problems that we discuss here retains the following features of the example analyzed above:

- There are zero-cost curves ("turnpikes") in the fourth quadrant of the (x, y) plane that correspond to trajectories arising from controls in $L^p(-1, 0)$ only for $1 \leq p < p_0$ for some $p_0 > 1$. The optimal trajectories for exponents $p < p_0$ follow these zero-cost curves, but such trajectories are not admissible when controls are restricted to $L^{p_0}(-1, 0)$.
- The weight function $d = d(x, y)$ has the following *homogeneity* property: for some $\gamma \in (1, 2)$ and $\alpha \geq 0$

$$d(x\lambda^\gamma, y\lambda^{\gamma-1}) = \lambda^\alpha d(x, y) \quad \text{for all } \lambda > 0.$$

This article is organized as follows. In §2 two propositions are presented that demonstrate that there is a certain region in the fourth quadrant of the (x, y) plane over which every trajectory in the subclass $A_{a,b}^{p_0,+}$ must cross, while such crossing can be avoided by trajectories in the classes $A_{a,b}^{p,+}$, $1 \leq p < p_0$. Then our main results for cost functions as above are presented. Finally, in §3, it is pointed out how perturbation of this special class of cost functions leads to *fully coercive* cost integrands that still exhibit the Lavrentiev phenomenon. Related results are presented in [CM].

2. Basic results. Our first result is a simple consequence of Hölder's inequality.

PROPOSITION 2.1. *Given $\gamma \in (1, 2)$, set $p_0 = 1/(2-\gamma)$. Suppose that $x \in W^{2,p_0}(-1, 0)$ satisfies $x(t_0) = 0$, $x'(t_0) = 0$. Then the functions $Y_0, Y_1 : [-1, t_0] \to \mathbb{R}$ defined by*

$$Y_0(t) = x(t)|t - t_0|^{-\gamma}, \qquad Y_1(t) = x'(t)|t - t_0|^{1-\gamma}$$

satisfy

$$Y_0(t) = o(1), \quad Y_1(t) = o(1) \quad \text{as } t \to t_{0^-}.$$

Our next result shows that with γ and p_0 as above, the phase vector $(x(t), x'(t))$ associated with any function in $A_{a,b}^{p_0^+}$ must occupy a plane sector $-c_2 \leq x^{(1-\gamma)/\gamma} y \leq -c_1$ for some nondegenerate time interval $[t_0, t_1]$. Note that Y_0, Y_1 above satisfy $Y_0'(t) = [Y_1(t) + \gamma Y_0(t)]/(t_0 - t)$.

PROPOSITION 2.2. *With γ and p_0 as above, suppose that $x \in A_{a,b}^{p_0,+}$. Put $t_0 = \min\{t \in [-1, 0] \mid x(t) = x'(t) = 0\}$, $Y_0(t) = x(t)|t - t_0|^{-\gamma}$, $Y_1(t) = x'(t)|t - t_0|^{1-\gamma}$, $Z(t) = x'(t)|x(t)|^{(1-\gamma)/\gamma}$.*

For any constants c and D satisfying $0 < c < D\gamma < a\gamma$ and any choice of c_1 and c_2 satisfying $0 < c_1 < c_2 < cD^{(1-\gamma)/\gamma}$ there exist t_2, $t_1 \in (-1, t_0)$ such that the following conditions hold: $Z(t_2) = -c_2$, $Z(t_1) = -c_1$, $0 \leq Y_0(t) \leq D$, $-c \leq Y_1(t)$, $-c_2 \leq Z(t) \leq -c_1$ for all $t \in [t_2, t_1]$.

Proof. Since $Y_0(-1) \geq a$ and, by Proposition 2.1, $Y_0(t) = o(1)$ near t_0, it follows by continuity that there is a $t \in [-1, t_0)$ such that $Y_0(t) = D$. Define $t_4 = \max\{t \in [-1, t_0) \mid Y_0(t) = D\}$, so $0 \leq Y_0(t) \leq D$ for all $t \in [t_4, t_0)$. Consequently

$Y_0'(t_4) \le 0$, which implies that $Y_1(t_4) \le -D\gamma$. Since by Proposition 2.1 $Y_1(t) = o(1)$ near t_0, it follows by continuity that there is a $t \in (t_4, t_0)$ such that $Y_1(t) = -c$. Defining $t_3 = \max\{t \in (t_4, t_0) \mid Y_1(t) = -c\}$, we obtain $-c \le Y_1(t)$ for all $t \in [t_3, t_0]$. Examine $G_2(t) = Y_1(t) + c_2|Y_0(t)|^{(\gamma-1)/\gamma} = [c_2 + Z(t)]x(t)^{(\gamma-1)/\gamma}(t_0 - t)^{1-\gamma}$. Note that $G_2(t_3) \le D^{(\gamma-1)/\gamma}[c_2 - cD^{(1-\gamma)/\gamma}] < 0$ by choice of c and c_2. If, for some $t \in [t_3, t_0)$, $Y_1(t) \ge 0$ or $Y_0(t) = 0$, then it follows by continuity that $G_2(s) = 0$ for some $s \in [t_3, t_0)$. ($x(t) \ge 0$ implies that also $Y_1(t) = 0$ in the latter case.) Otherwise, $Y_0(t) > 0$, $Y_1(t) < 0$ for all $t \in [t_3, t_0)$. We now show that in this case $\sup\{Z(t) \mid t \in [t_3, t_0)\} = 0$, so again $G_2(s) = 0$ for some $s \in [t_3, t_0)$. Otherwise, for some $k > 0$, $x'(t)|x(t)|^{(1-\gamma)/\gamma} \le -k$ for all $t \in [t_3, t_0)$.

Integrating both sides of this inequality over (t, t_0) gives $x(t) \ge (k/\gamma)^\gamma |t - t_0|^\gamma$, i.e., $Y_0(t) \ge (k/\gamma)^\gamma > 0$ for all $t \in [t_3, t_0)$, contradicting Proposition 2.1. A similar argument establishes that $G_1(t) = Y_1(t) + c_1|Y_0(t)|^{(\gamma-1)/\gamma}$ satisfies $G_1(s) = 0$ for some $s \in [t_3, t_0)$. On setting $t_2 = \max\{t \in [t_3, t_0) \mid G_2(t) = 0\}$, $t_1 = \min\{t \in [t_2, t_0) \mid G_1(t) = 0\}$, we obtain the desired conclusion.

We now state our main results.

THEOREM A. *Consider problem* (P) *with a cost integrand of the form*

$$f(x, y, u) = d(x, y)|u|^k,$$

where $k > 1$ *and* $d \in \mathrm{Cont}(\mathbb{R}^2)$ *satisfies the homogeneity condition*

(Hom) $\quad d(x\lambda^\gamma, y\lambda^{\gamma-1}) = \lambda^\alpha d(x, y)$ *for all* $\lambda > 0$ *for some* $\gamma \in (1, 2)$ *and* $\alpha \ge 0$.

Put $F = \{\beta > 0 \mid d(1, -\beta) = 0\}$, *and define the "free zone"* $\mathbb{F}$ *by*

$$\mathbb{F} = \{(x, y) \mid y = -\beta x^{(\gamma-1)/\gamma} \text{ with } \beta \in F\}.$$

Suppose that F *is nonempty with empty interior and that*

$(\star)$ $$\alpha - k(2 - \gamma) \le -1.$$

Then if the boundary data $a > 0$ *and* $b < 0$ *satisfy*

(#) $$(|b|/\beta)^{\gamma/(\gamma-1)} \le a \le |b| - (\gamma - 1)(|b|/\beta)^{\gamma/(\gamma-1)} \quad \text{for some } \beta \in F,$$

the Lavrentiev phenomenon holds for $A_{a,b}^{p_0,+}$, *where* $p_0 = 1/(2 - \gamma)$.

Remark. Note that (#) is nondegenerate, i.e., allows real values for a, if and only if $|b| \le \beta^\gamma/\gamma^{\gamma-1}$.

Proof. We begin by estimating $C[u]$ for controls $u \in L^{p_0}(-1, 0)$. By setting $\lambda = |y|^{1/(1-\gamma)}$ in (Hom) we can express f as follows:

$$f(x, y, u) = d(x|y|^{\gamma/(1-\gamma)}, -1)|y|^{\alpha/(\gamma-1)}|u|^k \quad \text{for } y < 0.$$

Now choose scalars c, D, c_1, and c_2 satisfying $0 < c < D\gamma < a\gamma$, $0 < c_1 < c_2 < cD^{(1-\gamma)/\gamma}$ such that $[-c_2, -c_1]$ contains no point of F. By Proposition 2.2, for the above choice of constants there exists $[t_2, t_1] \subset (-1, 0)$ such that

$$x'(t_2) = -c_2|x(t_2)|^{(\gamma-1)/\gamma}, \qquad x'(t_1) = -c_1|x(t_1)|^{(\gamma-1)/\gamma}$$

with $0 \le x(t) \le D$, $-c_2 \le x'(t)|x(t)|^{(1-\gamma)/\gamma} \le -c_1$ for all $t \in [t_2, t_1]$. Hence by continuity of d we conclude that there is a constant $\delta_1 = \delta_1(c_2, c_1) > 0$ such that

$$d(x(t)|x'(t))^{\gamma/(\gamma-1)}, -1) \ge \delta_1 > 0 \quad \text{for all } t \in [t_2, t_1].$$

Consequently, setting $\alpha/(\gamma-1)=\ell$ we have the following appraisal:

$$\begin{aligned} C[u] \geq \delta_1 \int_{t_2}^{t_1} |x'(t)|^{\ell}|u(t)|^k dt &= \delta_1 \int_{t_2}^{t_1} |x'(t)|^{\ell}|x''(t)|^k dt \\ &= \delta_1 \int_{x_1}^{x_2} |x'(t)|^{\ell+k-1}|dx'/dx|^k(t)dx \\ &= \Delta \int_{x_1}^{x_2} |d/dx|x'(t)|^{(\ell+2k-1)/k}|^k dx, \end{aligned}$$

where $\Delta=\delta_1(k/(\ell+2k-1))^k$, $x_1:=x(t_1)$, $x_2:=x(t_2)$, and we have employed the chain rule as well as the substitution rule for integrals [F, Thm. 3.2.6]. Putting $(\ell+2k-1)/k=r$ and applying Jensen's inequality and the chain rule we now obtain

$$\begin{aligned} C[u] &\geq \Delta \int_{x_1}^{x_2} |d/dx|x'(t)|^r|^k dx \\ &\geq \Delta \left|[|x'(t_2)|^r - |x'(t_1)|^r]/(x_2-x_1)\right|^k (x_2-x_1) \\ &= \Delta \left|[c_2^r x_2^{(\gamma-1)r/\gamma} - c_1^r x_1^{(\gamma-1)r/\gamma}]/(x_2-x_1)\right|^k (x_2-x_1) \\ &= \Delta c_2^{kr} x_2^{k(\gamma-1)r/\gamma+(1-k)} \left|1-(c_1/c_2)^r (x_1/x_2)^{(\gamma-1)r/\gamma}\right| A^{k-1}, \end{aligned}$$

where $A=[1-(c_1/c_2)^r(x_1/x_2)^{(\gamma-1)r/\gamma}]/(1-x_1/x_2) \geq 1-(c_1/c_2)^r$. Since $x_2 \in [0, D]$ and its exponent is nonpositive, we obtain

$$\begin{aligned} C[u] &\geq \Delta c_2^{rk} x_2^{(\alpha-k(2-\gamma)+1)/\gamma}|1-(c_1/c_2)^r|^k \\ &\geq \Delta c_2^{rk} D^{(\alpha-k(2-\gamma)+1)/\gamma}|1-(c_1/c_2)^r|^k =: \delta(D, c_1, c_2) > 0. \end{aligned}$$

Next we appraise $C[u]$ for controls $u \in L^1(-1,0)$. To do so we take β to be a point of F chosen to satisfy (#) and consider the specific control function $u^\star \notin L^{p_0}(-1,0)$ defined by

$$\begin{aligned} u^\star(t) &= 0 \quad \text{for all } t \in [-1, t^\star], \text{ where } t^\star+1=[a-(|b|/\beta)^{\gamma/(\gamma-1)}]/|b| \\ &= \omega\beta^\gamma(t_0-t)^{\gamma-2} \quad \text{for all } t \in [t^\star, t_0] \\ &= 0 \quad \text{for all } t \in [t_0, 0], \end{aligned}$$

where $\omega=(\gamma-1)\gamma^{1-\gamma}$ and $1+t_0=[a+(\gamma-1)(|b|/\beta)^{\gamma/(\gamma-1)}]/|b|$.

Simple integration gives

$$\begin{aligned} x^{\star\prime}(t) &= b \quad \text{for } t \in (-1, t^\star) \\ &= b+[\omega\beta^\gamma/(\gamma-1)][(t_0-t^\star)^{\gamma-1}-(t_0-t)^{\gamma-1}] \quad \text{for } t \in (t^\star, t_0) \\ &= b+[\omega\beta^\gamma/(\gamma-1)][(t_0-t^\star)^{\gamma-1}] \quad \text{for } t \in (t_0, 0). \end{aligned}$$

Our choice of t_0 and $t^\star$ ensures that $x^{\star\prime}(0-)=0$, which simplifies the expressions above and implies via a second integration that

$$\begin{aligned} x^\star(t) &= a+b(t+1) \quad \text{for } t \in [-1, t^\star] \\ &= (\beta/\gamma)^\gamma(t_0-t)^\gamma \quad \text{for } t \in (t^\star, t_0] \\ &= 0 \quad \text{for } t \in (t_0, 0]. \end{aligned}$$

Hence $C[u^\star] = 0$, since on the subset of $[-1, 0]$ where $u^\star \neq 0$, $x'(t) = -\beta(x(t))^{(\gamma-1)/\gamma}$ for all $t \in [t^\star, t_0]$, so $d(x^\star(t), x^{\star\prime}(t)) = 0$.

By the preceding calculations we conclude that, as claimed,

$$m_{p_0}^+ \geq \delta(D, c_1, c_2) > 0 = m_1^+.$$

Some analogue of the positivity restriction on trajectories in the above result is essential, as is shown below; cf., e.g., [J, Chap. 10].

THEOREM B. *Consider problem* (P) *with the same cost integrand as in the preceding result and with boundary data subject to* (#) *as before. Then the Lavrentiev phenomenon fails to take place over the spaces* $A_{a,b}^p$, $1 \leq p < \infty$. *That is,*

$$m_p = \inf_{A_{a,b}^p} C = 0 = m_1 = \inf_{A_{a,b}^1} C \quad \textit{for all } p \in (1, \infty).$$

Proof. We define the control $u^\star \in L^1(-1, 0) \backslash L^{p_0}(-1, 0)$ as before. Thus since $C[u^\star] = 0$, it remains to prove that $m_p = 0$ for $p \geq p_0$ as well. Recall that in the definition of $u^\star$ the time $t_0 \leq 0$ following which $u^\star$ is identically zero was determined by the boundary data according to $1 + t_0 = [a + (\gamma - 1)(|b|/\beta)^{\gamma/(\gamma-1)}]/|b|$. We separate our analysis into two cases, according to whether $t_0 < 0$ or $t_0 = 0$.

Case 1 ($t_0 < 0$). In this case, given any $\varepsilon > 0$, we construct a control $u_\varepsilon \in A_{a,b}^{p_0}$, which bifurcates from $u^\star$ and satisfies $C[u_\varepsilon] < \varepsilon$. Necessarily, this requires that the corresponding trajectory $(x_\varepsilon(t), x_\varepsilon'(t))$ avoid crossing the zone of the (x, y) plane defined by $-c_2 \leq y|x|^{(1-\gamma)/\gamma} \leq -c_1$, since otherwise by our previous calculations $C[u_\varepsilon] \geq \delta(D, c_1, c_2) > 0$.

Let $\rho > 0$ be taken sufficiently small. (Its value will be specified later.) On the interval $[t^\star, t_0]$ where $u^\star$ is nonzero, we select a point $(s_4, -\rho)$ on the graph $(t, x^{\star\prime}(t))$, $t \in [t^\star, t_0]$ such that $\sigma := t_0 - s_4 \in (0, |t_0|/4)$. (By a straightforward computation it is seen that $x^{\star\prime}(t) = -\beta[(\beta/\gamma)(t_0 - t)]^{\gamma-1}$ on this interval.) Subdivide the interval $[s_4, 0]$ into four subintervals $[s_4, s_3]$, $[s_3, s_2]$, $[s_2, -\sigma]$, $[-\sigma, 0]$ of lengths $|t_0|/2$, $|t_0|/4$, $|t_0|/4$, σ, respectively. Now we define u_ε by the requirement

$$\begin{aligned} u_\varepsilon(t) &= u^\star(t), \qquad t \in [-1, s_4] \\ &= 2\rho/|t_0|, \qquad t \in [s_4, s_3] \\ &= 4\tau/|t_0|, \qquad t \in [s_3, s_2] \\ &= -4\tau/|t_0|, \qquad t \in [s_2, -\sigma] \\ &= 0, \qquad t \in [-\sigma, 0], \end{aligned}$$

with $\tau \in (0, \rho)$ chosen so that $x_\varepsilon(s_4) = x^\star(s_4)$ and $x_\varepsilon(-\sigma) = x^\star(t_0) = 0$, i.e., so that $(\rho - \tau)t_0/4 = \int_{s_4}^{t_0} |x^{\star\prime}(t)|\, dt = x^\star(s_4)$. It is easily verified that $|u_\varepsilon(t)| \leq 4\rho/|t_0|$, $|x_\varepsilon'(t)| \leq \rho$, $|x_\varepsilon(t)| \leq \rho|t_0|/2$ for $t \in [s_4, 0]$. Thus by the continuity of d at $(0, 0)$, for ρ sufficiently small we obtain $d(x_\varepsilon(t), x_\varepsilon'(t)) < 1$ over $[s_4, 0]$, whereby

$$\begin{aligned} C[u_\varepsilon] &= \int_{s_4}^{-\sigma} d(x_\varepsilon(t), x_\varepsilon'(t))|u_\varepsilon(t)|^k dt \\ &\leq \int_{s_4}^{-\sigma} |u_\varepsilon(t)|^k dt \leq |4\rho/t_0|^k |t_0|. \end{aligned}$$

This value is $< \varepsilon$ for $\rho < (\varepsilon/4)^{1/k}(t_0/4)^{(k-1)/k}$, so the gap phenomenon does not occur. (Note that $u_\varepsilon \in L^\infty(-1, 0)$.)

Case 2 ($t_0 = 0$). In this case the preceding construction for u_ε as a direct perturbation of $u^\star$ is clearly no longer available. We still apply the above construction, but this time for each $\varepsilon > 0$ it is performed as a perturbation of a control $u^{\star\star} \in L^1(-1, 0)\backslash L^{p_0}(-1, 0)$ satisfying both $C[u^{\star\star}] < \varepsilon$ and the requirement that there be a $t_0' \in [-1, 0)$ such that $u^{\star\star}(t) = 0$ for all $t \in [t_0', 0]$. Examine the fourth quadrant of the (x, y) plane. The control $u^\star$ led to a curve proceeding from the initial point (a, b) in this quadrant to the origin by a path consisting of a horizontal segment which intersected the locus $\Gamma = \{(x, y) \mid y = -\beta x^{(\gamma-1)/\gamma}\}$ at a point $P^\star$, followed by that portion of Γ extending from the point of intersection to the origin. By the convexity of Γ, each tangent to this locus lies below the locus. Let $P \in \Gamma$ be a point to the left of $P^\star$, and let Q be the point of intersection of the tangent line at P with the horizontal segment $y = b$. It can be verified that the locus consisting of those points of the horizontal segment $y = b$ between (a, b) and Q, together with the points of the tangent line at P lying between Q and P and that portion of Γ lying between P and the origin, corresponds to a control $u^{\star\star}(t) = x^{\star\star\prime\prime}(t)$ for which the associated trajectory satisfies $x^{\star\star}(t_0') = 0$, $x^{\star\star\prime}(t_0') = 0$, with $t_0' < 0$ but arbitrarily near 0 as P approaches $P^\star$. Indeed $u^{\star\star}(t) = 0$ for all $t \in [t^{\star\prime}, 0]$, where $t^{\star\prime} - t^\star > 0$; $u^{\star\star}(t) = \rho e^{\theta(t-t^{\star\prime})}$ for all $t \in [t^{\star\prime}, t^{\star\star}]$ for appropriate $\rho > 0$, $\theta < 0$, and $t^{\star\star} > t^{\star\prime}$; $u^{\star\star}(t) = \text{ const } (t_0' - t)^{(\gamma-2)}$ for all $t \in [t^{\star\star}, t_0']$; and $u^{\star\star}(t) = 0$ for all $t \in [t_0', 0]$. Furthermore since $C[u^{\star\star}]$ achieves a positive contribution only for those t values associated with points of the tangent line between P and Q, it is clear that $C[u^{\star\star}]$ is smaller than any preassigned $\varepsilon > 0$, once P is chosen sufficiently near to $P^\star$. Therefore, by forming a control $u_\varepsilon \in L^\infty(-1, 0)$ bifurcating from $u^{\star\star}$ in the same manner as was done in Case 1 in relation to $u^\star$, we obtain $C[u^{\star\star}] < 2\varepsilon$. Hence the gap phenomenon does not occur.

3. Perturbations of f. In this section we point out how an additive perturbation of the type of running cost integrand appearing in §2 can lead to the Lavrentiev phenomenon, even for running cost integrands $f^\#$ satisfying the following "Tonelli-type" regularity and growth conditions:

$$f^\#_{uu}(x, y, u) > 0, \quad f^\#(x, y, u) \geq \varphi(u), \quad \text{with } \liminf_{|u|\to\infty} \varphi(u)/|u| = \infty.$$

COROLLARY. *Let $f = f(x, y, u)$ be an integrand satisfying the hypotheses of Theorem* A, *and let $x(-1) = a, x'(-1) = b$ denote boundary data satisfying the conditions of that theorem. Suppose that $e = e(x, y, u)$ is a nonnegative function satisfying $e_{uu} > 0$, $e(x, y, u) > \varphi(u)$, with φ as above. Let $u^\star$ denote the minimizer for C obtained in Theorem* A *for the given boundary data. Then if $e(x^\star(t), x^{\star\prime}(t), u^\star(t))$ is a function in $L^1(-1, 0)$, the Lavrentiev phenomenon $m^+_{p_0} > m^+_1$ also occurs for the cost C_ε associated with the integrand*

$$f_\varepsilon(x, y, u) = f(x, y, u) + \varepsilon e(x, y, u)$$

for $\varepsilon > 0$ taken sufficiently small.

This result is clear if ε is taken sufficiently small so that $C_\varepsilon[u^\star] < \delta(D, c_1, c_2)$ in the notation of Theorem A.

Example. Consider problem (P) with

$$C_\varepsilon[u] = \int_{-1}^{0} [(|x(t)|^{4/9} + x'(t))^{18}|u(t)|^k + \varepsilon|u(t)|^2]\,dt \quad \text{with } x'' = u$$

for data $x(0) = x'(0) = 0, x(-1) = a > 0, x'(-1) = b < 0$. By the corollary this can be treated as an additive perturbation for the cost functional

$$C[u] = \int_{-1}^{0} [(|x(t)|^{4/9} + x'(t))^{18}|u(t)|^k]\,dt.$$

The latter problem fits into Theorem A with $\gamma = 9/5$, $\alpha = 72/5$, $F = \{-1\}$, $k \geq 77$, and $p_0 = 5$, provided that a and b satisfy (#). The function $e(x^\star(t), x^{\star\prime}(t), u^\star(t)) \sim |t|^{-2/5}$ at $t = 0$ is integrable on $[-1, 0]$, so by the corollary for $\varepsilon > 0$ sufficiently small $C_\varepsilon[u]$ does exhibit the Lavrentiev phenomenon $m_5^+ = \inf_{A_{a,b}^{5,+}} > m_1^+ = \inf_{A_{a,b}^{1,+}}$.

Acknowledgments. We wish to thank an anonymous referee for several helpful suggestions improving the clarity of the presentation.
