Extending [Shc92], we now describe an *orthogonal surrogate projection* (OSP) version of Procedure 5.4 that sets $\tilde{y}^n = P_{\tilde{\mathcal{P}}_n}(\tilde{x}^n)$ for $\tilde{\mathcal{P}}_n = \{x : \langle q^j, x\rangle \leq c_j, j \in \check{J}^n\}$, where each inequality is a surrogate of $A^Tx \leq b$ (so that $\mathcal{P} \subset \tilde{\mathcal{P}}_n$), the system $\mathcal{Q}_{\check{J}^n} = \{q^j\}_{j\in\check{J}^n}$ is orthonormal, and $\check{J}^n \subset \{1\!:\!n\}$. Here $A^T_{\tilde{I}^{n-1}}x \leq b_{\tilde{I}^{n-1}}$ is replaced by the *accumulated* surrogates $\langle q^j, x\rangle \leq c_j$, $j \in \check{J}^{n-1}$, at step 3 in constructing the new surrogate $\langle q^n, x\rangle \leq c_n$ via orthogonalization as in Lemma 5.2. Specifically, at step 0 set $\check{J}^0 = \emptyset$. At step 3 set $\tilde{J}^{n-1} = \{j \in \check{J}^{n-1} : \langle a^{i_n}, q^j\rangle \leq 0\}$ and $\check{J}^n = \tilde{J}^{n-1} \cup \{n\}$. At step 4 set

$$\text{(5.6a)}\qquad \tilde{q}^n = a^{i_n} - \sum_{j\in\tilde{J}^{n-1}} \langle a^{i_n}, q^j\rangle q^j = 0 \quad\text{and}\quad q^n = \tilde{q}^n/|\tilde{q}^n| \quad\text{if}\quad \tilde{q}^n \neq 0,$$

print "$\mathcal{P} = \emptyset$," and terminate if $\tilde{q}^n = 0$; otherwise set $\sigma^n_{\tilde{J}^{n-1}} = (1-\tilde{t}_{n-1})\sigma^{n-1}_{\tilde{J}^{n-1}}$,

$$\text{(5.6b)}\qquad (c_n, \sigma_n^n) = \left[(b_{i_n}, s^n_{i_n}) - \sum_{j\in\tilde{J}^{n-1}} \langle a^{i_n}, q^j\rangle (c_j, \sigma_j^n)\right]/|\tilde{q}^n|,$$

$\tilde{d}^n = -Q_{\check{J}^n}\sigma^n_{\check{J}^n}$, and $\tilde{y}^n = \tilde{x}^n + \tilde{d}^n$, and choose $\tilde{t}_n \leq 1$. Here $Q_{\check{J}^n} = [Q_{\tilde{J}^{n-1}}, q^n]$, where $Q_{\tilde{J}^{n-1}}$ is the $N \times |\tilde{J}^{n-1}|$ orthonormal matrix corresponding to $\mathcal{Q}_{\tilde{J}^{n-1}}$.

To validate this modification, suppose $\mathcal{P} \neq \emptyset$, $Q_{\tilde{J}^{n-1}}$ is orthonormal, $\sigma^n_{\tilde{J}^{n-1}} = Q^T_{\tilde{J}^{n-1}}\tilde{x}^n - c_{\tilde{J}^{n-1}} \geq 0$, and $Q^T_{\tilde{J}^{n-1}}x \leq c_{\tilde{J}^{n-1}}$ is a surrogate of $A^Tx \leq b$, so that $\mathcal{P} \subset \mathcal{P}_n = \tilde{x}^n + \mathcal{D}_n$, where $\mathcal{D}_n = \{d : Q^T_{\tilde{J}^{n-1}}d \leq -\sigma^n_{\tilde{J}^{n-1}}, \langle a^{i_n}, d\rangle \leq -s^n_{i_n}\}$. Also $s^n_{i_n} > 0$ and $Q^T_{\tilde{J}^{n-1}}a^{i_n} \leq 0$ by construction. Hence, replacing $\mathcal{D}_{\mathcal{I}}$ by $\mathcal{D}_n \neq \emptyset$ in Lemma

5.3, we deduce that $\operatorname{rank}[Q_{\check{J}^{n-1}}, a^{i_n}] = \hat{m} := |\check{J}^n|$, so $\tilde{q}^n \neq 0$ and by construction $[Q_{\check{J}^{n-1}}, a^{i_n}] = Q_{\check{J}^n} R$, where $Q_{\check{J}^n}$ is orthonormal, $r_{jj} = 1$ and $r_{j\hat{m}} = \langle a^{i_n}, q^j \rangle \leq 0$, $j = 1{:}\hat{m}-1$, $r_{\hat{m}\hat{m}} = |\tilde{q}^n|$, and the remaining $r_{ij} = 0$. Then by (5.6), $\langle q^n, x \rangle \leq c_n$ is a surrogate of $Q_{\check{J}^{n-1}}^T x \leq c_{\check{J}^{n-1}}$, $\langle a^{i_n}, x \rangle \leq b_{i_n}$ (and hence of $A^T x \leq b$) with $\sigma_n^n = \langle q^n, \tilde{x}^n \rangle - c_n > 0$, and $R^{-T}[(\sigma^n_{\check{J}^{n-1}})^T, s^n_{i_n}]^T = \sigma^n_{\check{J}^n}$. Therefore, since $\tilde{d}^n = -Q_{\check{J}^n}\sigma^n_{\check{J}^n}$, we deduce from Lemma 5.3(v) applied to $\mathcal{D}_n$ that $Q^T_{\check{J}^n}\tilde{d}^n = -\sigma^n_{\check{J}^n}$,

$$\mathcal{D}_n \subset \tilde{\mathcal{D}}_n := \{\, d : Q^T_{\check{J}^n} d \leq -\sigma^n_{\check{J}^n} \,\} \quad \text{and} \quad \tilde{d}^n = P_{\mathcal{D}_n}(\tilde{x}^n) = P_{\tilde{\mathcal{D}}_n}(\tilde{x}^n). \tag{5.7}$$

Thus $\tilde{y}^n = P_{\mathcal{P}_n}(\tilde{x}^n) = P_{\tilde{\mathcal{P}}_n}(\tilde{x}^n)$, where $\mathcal{P}_n \subset \{x : \langle a^{i_n}, x \rangle \leq b_{i_n}\}$ and $\tilde{\mathcal{P}}_n = \tilde{x}^n + \tilde{\mathcal{D}}_n$. Using $Q^T_{\check{J}^n}\tilde{d}^n = -\sigma^n_{\check{J}^n}$, $\tilde{x}^{n+1} = \tilde{x}^n + \tilde{t}_n\tilde{d}^n$, and $\tilde{t}_n \leq 1$ gives $\sigma^{n+1}_{\check{J}^n} = Q^T_{\check{J}^n}\tilde{x}^{n+1} - c_{\check{J}^n} = \sigma^n_{\check{J}^n} + \tilde{t}_n Q^T_{\check{J}^n}\tilde{d}^n = (1-\tilde{t}_n)\sigma^n_{\check{J}^n} \geq 0$. Also $Q^T_{\check{J}^n} x \leq c_{\check{J}^n}$ is a surrogate of $A^T x \leq b$. Hence one may use induction to show that this OSP version shares the convergence properties of the original one.

Note that if $\tilde{t}_{n-1} = 1$, then $\sigma^n_{\check{J}^{n-1}} = 0$ and $\tilde{d}^n = -\sigma^n_n q^n = -s^n_{i_n} q^n/|\tilde{q}^n|$ as in Remark 5.8. Thus $\tilde{y}^n$ is the projection of $\tilde{x}^n$ on the "orthogonalized" surrogate $\langle q^n, x \rangle \leq c_n$. Also the preceding validation would go through if, to save work, we increased $c_{\check{J}^{n-1}}$ by $\sigma^n_{\check{J}^{n-1}} \neq 0$, i.e., enlarged $\mathcal{P}_n$ to get $\sigma^n_{\check{J}^{n-1}} = 0$ and $\tilde{d}^n = -s^n_{i_n} q^n/|\tilde{q}^n|$ as in Remark 5.7.

Step 3 could construct more than one surrogate. Specifically, if $s^n_i > 0$ and $Q^T_{\check{J}^n} a^i \leq 0$ for some i, then step 3 could append to $Q^T_{\check{J}^n} x \leq c_{\check{J}^n}$ another surrogate derived from $\langle a^i, x \rangle \leq b_i$ and $Q^T_{\check{J}^n} x \leq c_{\check{J}^n}$ as in (5.6), and this may be repeated for other violated constraints. Again, Lemma 5.3 validates this extension.

To improve accuracy, *iterative refinement* of the form $\tilde{y}^n \leftarrow \tilde{y}^n + Q_{\check{J}^n}(c_{\check{J}^n} - Q^T_{\check{J}^n}\tilde{y}^n)$ or $\tilde{d}^n \leftarrow \tilde{d}^n + Q_{\check{J}^n}(\sigma^n_{\check{J}^n} - Q^T_{\check{J}^n}\tilde{d}^n)$ may be used at some iterations, and q^n should be *reorthogonalized* with respect to $Q_{\check{J}^{n-1}}$; see, e.g., [Bjö90, DGKS76].

When the OSP procedure is called repeatedly with $\mathcal{P} = \mathcal{L}(\hat{f}^k, f^k_{\text{lev}})$, we may generate a vector $\check{c}_{\check{J}^n} > 0$ recursively via $\check{c}_n = (1 - \sum_{j \in \check{J}^{n-1}} \langle a^{i_n}, q^j \rangle \check{c}_j)/|\tilde{q}^n|$. Then, by induction on the surrogate construction (5.6), there exist $\nu_j \geq 0$ such that

$$(q^n, c_n) = \sum_{j=1}^n \nu_j (a^{i_j}, b_{i_j}) \quad \text{and} \quad \check{c}_n = \sum_{j=1}^n \nu_j \geq \nu_n = 1/|\tilde{q}^n| > 0, \tag{5.8}$$

so dividing by $\check{c}_n$ yields $(\langle q^n, \cdot \rangle - c_n)/\check{c}_n \in \operatorname{co}\{\langle a^i, \cdot \rangle - b_i\}_{i=1}^m \in \operatorname{co}\{f^j\}_{j \in J^k} - f^k_{\text{lev}}$, and hence $\operatorname{co}\{(q^j, c_j)/\check{c}_j\}_{j \in \check{J}^n} \in \operatorname{co}\{(a^i, b_i)\}_{i=1}^m$. Thus, when f^k_{lev} changes to f^{k+1}_{lev} on the next call then $(f^{k+1}_{\text{lev}} - f^k_{\text{lev}})\check{c}_{\check{J}^n}$ should be added to $c_{\check{J}^n}$ and $\sigma^n_{\check{J}^n}$. If $x^{k+1} \neq \tilde{x}^n$ (e.g., due to $x^{k+1} = P_S(\tilde{x}^n)$), then $\sigma^n_{\check{J}^n} = Q^T_{\check{J}^n}\tilde{x}^1 - c_{\check{J}^n}$ must be recomputed for $\tilde{x}^1 = x^{k+1}$. Alternatively, using $Q^T_{\check{J}^n} x - c_{\check{J}^n} = Q^T_{\check{J}^n}(x - \tilde{x}^n) + \sigma_{\check{J}^n}$, we may update $\sigma^n_{\check{J}^n} \leftarrow \sigma^n_{\check{J}^n} + Q^T_{\check{J}^n}(x^{k+1} - \tilde{x}^n)$ (then $c_{\check{J}^n}$ is not required). Next, dropping j with $\sigma^n_j < 0$ from $\check{J}^n$, if any, a hot start can proceed as if $\check{J}^0$ were $\check{J}^n$. Note that Remark 5.10 holds for the OSP version with A_{I^n} replaced by $[Q_{\check{J}^{n-1}}, a^{i_n}]$ (since $A^T x^* < b \Rightarrow Q^T_{\check{J}^{n-1}} x^* - c_{\check{J}^{n-1}} < 0 \leq \sigma^n_{\check{J}^{n-1}} = Q^T_{\check{J}^{n-1}}\tilde{x}^n - c_{\check{J}^{n-1}}$ by (5.8)).

Remark 5.11. By the preceding argument, the *surrogate linearizations*

$$\tilde{f}^j(\cdot) = (\langle q^j, \cdot \rangle - c_j)/\check{c}_j + f^k_{\text{lev}} = (\langle q^j, \cdot - \tilde{x}^n \rangle + \sigma^n_j)/\check{c}_j + f^k_{\text{lev}}, \quad j \in \check{J}^n, \tag{5.9}$$

satisfy $\tilde{f}^j \in \operatorname{co}\{f^j\}_{j \in J^k} \subset \Phi$. Hence they may be used as any other linearizations of f. For instance, no additional storage is required if, at step 6, $\tilde{f}^n$ replaces the

f^j corresponding to $\langle a^{i_n}, \cdot \rangle - b_{i_n}$. Also $\lambda_j^n = \check{c}_j \sigma_j^n$ are Lagrange multipliers for $\tilde{f}^j$, $j \in \check{J}^n$, since $\tilde{d}^n = P_{\check{\mathcal{D}}_n}(\tilde{x}^n)$ with $\check{\mathcal{D}}_n = \{d : \langle q^j/\check{c}_j, d \rangle \le -\sigma_j^n/\check{c}_j, j \in \check{J}^n\}$, whereas σ_j^n are Lagrange multipliers for $\tilde{d}^n = P_{\tilde{\mathcal{D}}_n}(\tilde{x}^n)$ in (5.7). Thus $\lambda_{\check{J}^{\bar{n}}}^{\bar{n}}$ can be used for selective aggregation as in Remark 5.9, and normalization of the aggregated column ensures orthonormality of the new $Q_{\check{J}^{\bar{n}}}$.

Remark 5.12. Consider the simplest case where step 6 always exits, so that we may let $n = k$ and $\tilde{x}^n = x^k$. Suppose $\mathcal{P} = \mathcal{L}(\phi^k, f_{\text{lev}}^k)$ with $\phi = \max\{f^k, \psi^{k-1}\}$ as for (4.2), where ψ^{k-1} is the previous aggregate satisfying $\psi^{k-1}(\tilde{x}^n) = f_{\text{lev}}^k$, so that a hot start occurs from $\check{J}^{n-1} = \{n-1\}$ using $\tilde{q}^{n-1} = g_\psi^{k-1}$, $q^{n-1} = \tilde{q}^{n-1}/|\tilde{q}^{n-1}|$, $c_{n-1} = 1/|\tilde{q}^{n-1}|$ and $\sigma_{n-1}^n = 0$. Assume $\langle g^k, g_\psi^{k-1} \rangle < 0$. By simple calculation, either infeasibility is detected at steps 4 or 5, or step 6 terminates with $\tilde{d}^n = -(f(x^k) - f_{\text{lev}}^k)\tilde{q}^n/|\tilde{q}^n|^2$, where $\tilde{q}^n = g^k - \langle g^k, g_\psi^{k-1} \rangle g_\psi^{k-1}/|g_\psi^{k-1}|^2$ has $|\tilde{q}^n|^2 = |g^k|^2 - \langle g^k, g_\psi^{k-1} \rangle^2/|g_\psi^{k-1}|^2$ (use $\tilde{d}^n = -\sigma_n^n q^n$, $\sigma_n^n = s_{i_n}^n/|\tilde{q}^n|$ and $s_{i_n}^n = f(x^k) - f_{\text{lev}}^k$). Also, since $\sigma_{n-1}^n = 0$, the aggregate ψ^k of f^k and ψ^{k-1} coincides with $\tilde{f}^n$. Note that for $\langle g^k, g_\psi^{k-1} \rangle \ge 0$ we would get $\tilde{q}^n = g^k$ (as if $\phi^k = f^k$), and that if we had $\psi^{k-1}(\tilde{x}^n) > f_{\text{lev}}^k$, then the same formulae would hold if we set $c_{n-1}^n = 0$. It is not surprising that *the same* $\tilde{d}^n$ and ψ^k would be produced via the original version of Procedure 5.4 restarted from $A_{I^{n-1}} \cdot - b_{I^{n-1}} \equiv \psi^{k-1} - f_{\text{lev}}^k$. (Use $\alpha_\psi^k = 0$ in (4.3)–(4.4) to get $\lambda_k^k = (f(x^k) - f_{\text{lev}}^k)/|\tilde{q}^n|^2$ and $d^k = -\lambda_k^k \tilde{q}^n = \tilde{d}^n$.) We add that $\psi^k(x^{k+1}) \ge f_{\text{lev}}^{k+1}$ if $t_k \le 1$ (cf. Lemma 6.1(v)).

We may add that the method of [Shc79, Shc92] corresponds to a version of Algorithm 2.1 that attempts to solve the inequality $f(x) \le 0$. It sets $f_{\text{lev}}^k = f_{\text{low}}^k = 0$ and finds $x^{k+1} = \tilde{x}^2$ via one iteration of a simplified OSP version of Procedure 5.4 that starts with $\tilde{x}^1 = x^k$ and $f^k(x) \le 0$ appended to the accumulated surrogates and exits at step 6 unless infeasibility is detected earlier, in which case it terminates. First, it sets $\tilde{t}_n = 1$ for all n, whereas our OSP version allows smaller stepsizes that may be useful at initial iterations. Second, it expresses $\tilde{d}^n$ as $\tilde{d}^n = -|\tilde{a}^n|^2 q^n/\langle \tilde{a}^n, q^n \rangle$, where $\tilde{a}^n = s_{i_n}^n a^{i_n}/|a^{i_n}|^2$, so $\tilde{d}^n = -s_{i_n}^n q^n/|\tilde{q}^n|$ from $\langle a^{i_n}, \tilde{q}^n \rangle = |\tilde{q}^n|^2$ by orthogonality. (In fact it replaces a^{i_n} by $\tilde{a}^n$ in calculating q^n, but this does not affect $Q_{\check{J}^n}$.) Third, it does not compute $c_{\check{J}^n}$ and $\check{c}_{\check{J}^n}$, thus preventing iterative refinement and hot starts that would be necessary for handling the additional constraint $x \in S$ (except when S is a flat [Shc87]). Fourth, both methods should cope with the instability of the Gram–Schmidt process. Periodic resets to $\check{J}^n = \{n\}$ recommended in [Shc87, Shc92] slow down convergence. It seems better to employ iterative refinement and reorthogonalization in computing q^n. To sum up, our method appears competitive with that of [Shc92]. Finally, note that such methods project on sets $\mathcal{P}_n$ that may or may not be larger than $\mathcal{P}_{I^n}$ with $I^n = \{i_j\}_{j \in \check{J}^n}$. Thus it is not clear whether our OSP version could compete with, e.g., a Cholesky-based implementation of Procedure 5.4. We note that encouraging numerical results were obtained in [Ceg92] by a method that combines greatly simplified versions of Algorithm 2.1 and Procedure 5.4 for solving a consistent inequality $f(x) \le 0$.

6. Conjugate subgradient techniques. In this section we use the dual framework of [Kiw96, §9] for extending some CS techniques; see, e.g., [Brä93, CFM75, KiA90, SaK87, SKR87, ShU89, Sho79].

First, we identify surrogate linearizations of f that may be generated via CS methods.

LEMMA 6.1. *Let* $0 < \mu \le 1$. *Suppose iteration* $k-1$ *provides an affine model* ψ^{k-1} *of* f_S *of the form* $\psi^{k-1}(\cdot) = \psi^{k-1}(x^k) + \langle g_\psi^{k-1}, \cdot - x^k \rangle$ *with* $\psi^{k-1}(x^k) \ge f_{\text{lev}}^k$ *such that*

$\psi^{k-1} \in \Phi$ *if* $f^k_{\text{lev}} \geq f^*$. *Let* $\check{\psi}^{k-1} = \psi^{k-1} + f^k_{\text{lev}} - \psi^{k-1}(x^k)$ *denote a shifted version of* ψ^{k-1} *such that* $\check{\psi}^{k-1}(x^k) = f^k_{\text{lev}}$. *The corresponding current models of* f_S *are given by* $\hat{\phi}^k = \max\{f^k, \psi^{k-1}\}$ *and* $\check{\phi}^k = \max\{f^k, \check{\psi}^{k-1}\}$. *Next, let* $\check{\phi}^k = f(x^k) + \langle \check{g}^k_\phi, \cdot - x^k \rangle = f^k + \beta_k \langle g^{k-1}_\psi, \cdot - x^k \rangle$ *be the current CS model of* f_S, *where* $\check{g}^k_\phi = g^k + \beta_k g^{k-1}_\psi$ *for* $\beta_k \geq 0$ *such that* $|\check{g}^k_\phi| \leq |g^k|/\mu$, *and let* $\tilde{\phi}^k = (f^k + \beta_k \psi^{k-1})/(1+\beta_k)$ *denote another CS-like model of* f_S *that is a convex combination of* f^k *and* ψ^{k-1}. *Finally, let* $\check{\beta}_k = \arg\min_{\beta \geq 0} |g^k + \beta g^{k-1}_\psi|$. *If* $f^k_{\text{lev}} \geq f^*$, *then*

(i) $\psi^{k-1}, \check{\psi}^{k-1} \in \Phi$, $\hat{\phi}^k, \check{\phi}^k \in \Phi^k_1$ *and* $\check{\phi}^k, \tilde{\phi}^k \in \Phi^k_\mu$ (*cf.* (2.3)). *In particular,*

$$d_{\mathcal{L}(\hat{\phi}^k, f^k_{\text{lev}})}(x^k) \geq d_{\mathcal{L}(\tilde{\phi}^k, f^k_{\text{lev}})}(x^k) = [f(x^k) - f^k_{\text{lev}} + \beta_k(\psi^{k-1}(x^k) - f^k_{\text{lev}})]/|\check{g}^k_\phi|$$
$$\geq d_{\mathcal{L}(\check{\phi}^k, f^k_{\text{lev}})}(x^k) = (f(x^k) - f^k_{\text{lev}})/|\check{g}^k_\phi| \geq \mu\kappa\Delta^k/L_f$$

and $d_{\mathcal{L}(\hat{\phi}^k, f^k_{\text{lev}})}(x^k) \geq d_{\mathcal{L}(\check{\phi}^k, f^k_{\text{lev}})}(x^k) \geq d_{\mathcal{L}(f^k, f^k_{\text{lev}})}(x^k)$.

(ii) $\check{\beta}_k = \langle g^k, -g^{k-1}_\psi \rangle_+ / |g^{k-1}_\psi|^2$. *Moreover,* $|\check{g}^k_\phi|^2 = |g^k|^2 - \langle g^k, g^{k-1}_\psi \rangle^2 / |g^{k-1}_\psi|^2$ *if* $\beta_k = \check{\beta}_k$ *and* $\langle g^k, g^{k-1}_\psi \rangle < 0$, $|\check{g}^k_\phi| \leq |g^k|$ *if* $\beta_k \leq 2\check{\beta}_k$, *and* $|\check{g}^k_\phi| \leq 2|g^k|$ *if* $\beta_k = |g^k|/|g^{k-1}_\psi|$.

(iii) $\beta_k \leq 2\check{\beta}_k \Rightarrow d_{\mathcal{L}(\check{\phi}^k, f^k_{\text{lev}})}(x^k) \geq d_{\mathcal{L}(f^k, f^k_{\text{lev}})}(x^k)$; $\beta_k < 2\check{\beta}_k \Rightarrow d_{\mathcal{L}(\check{\phi}^k, f^k_{\text{lev}})}(x^k) > d_{\mathcal{L}(f^k, f^k_{\text{lev}})}(x^k)$.

(iv) *If* $\langle g^k, g^{k-1}_\psi \rangle < 0$ *and* $\beta_k = \check{\beta}_k$, *then* $P_{\mathcal{L}(\check{\phi}^k, f^k_{\text{lev}})}(x^k) = P_{\mathcal{L}(\tilde{\phi}^k, f^k_{\text{lev}})}(x^k)$.

(v) $\phi^k(x^{k+1}) \geq f^k_{\text{lev}}$ *if* $t_k \leq 1$ *and* $\phi^k(x^k) > f^k_{\text{lev}}$; *e.g.,* $\phi^k = \check{\phi}^k$, $\tilde{\phi}^k$, $\hat{\phi}^k$, *or* $\check{\phi}^k$ *at step* 4.

Conversely, if $\phi^k = \check{\phi}^k$, $\tilde{\phi}^k$, $\hat{\phi}^k$, *or* $\check{\phi}^k$ *and* $\mathcal{L}(\phi^k, f^k_{\text{lev}}) = \emptyset$, *then* $f^k_{\text{lev}} < f^*$.

Proof. (i) Let $x^* \in S^*$. Since $\psi^{k-1}(x^k) + \langle g^{k-1}_\psi, x^* - x^k \rangle = \psi^{k-1}(x^*) \leq f^*$ and $f^k(x^*) \leq f^*$, we have $\langle g^{k-1}_\psi, x^* - x^k \rangle \leq f^* - \psi^{k-1}(x^k) \leq 0$ and $\check{\phi}^k(x^*) = f^k(x^*) + \beta_k \langle g^{k-1}_\psi, x^* - x^k \rangle \leq f^*$. Next, $d_{\mathcal{L}(\check{\phi}^k, f^k_{\text{lev}})}(x^k) = (f(x^k) - f^k_{\text{lev}})/|\check{g}^k_\phi| \geq \kappa\Delta^k/(|g^k|/\mu) \geq \mu\kappa\Delta^k/L_f$, while $\tilde{\phi}^k(x) = \tilde{\phi}^k(x^k) + \langle \tilde{g}^k_\phi, x - x^k \rangle$ with $\tilde{\phi}^k(x^k) - f^k_{\text{lev}} = [f^k(x^k) - f^k_{\text{lev}} + \beta_k(\psi^{k-1}(x^k) - f^k_{\text{lev}})/(1+\beta_k)$ and $\tilde{g}^k_\phi = (g^k + \beta_k g^{k-1}_\psi)/(1+\beta_k)$ yield $d_{\mathcal{L}(\tilde{\phi}^k, f^k_{\text{lev}})}(x^k) = [f(x^k) - f^k_{\text{lev}} + \beta_k(f(x^k) - f^k_{\text{lev}})]/|\check{g}^k_\phi|$, so the conclusion follows from $\check{\psi}^{k-1} \leq \psi^{k-1}$, $f^k \leq \check{\phi}^k \leq \hat{\phi}^k$, and $\tilde{\phi}^k \leq \check{\phi}^k$.

(ii) Solve $\min_{\beta \geq 0} |g^k + \beta g^{k-1}_\psi|^2$, and use $|\check{g}^k| \leq |g^k| + \beta_k |g^{k-1}_\psi|$.

(iii) Invoke (i) with $|\check{g}^k| \leq |g^k|$ and $d_{\mathcal{L}(f^k, f^k_{\text{lev}})}(x^k) = (f(x^k) - f^k_{\text{lev}})/|g^k|$.

(iv) Use $|\check{g}^k_\phi|^2 = |g^k|^2 - \langle g^k, g^{k-1}_\psi \rangle^2 / |g^{k-1}_\psi|^2$ and $\alpha^k_\psi = 0$ in (4.3)–(4.4) to get $\lambda^k_k = (f(x^k) - f^k_{\text{lev}})/|\check{g}^k_\phi|^2$ and $d^k = -\lambda^k_k \check{g}^k_\phi = P_{\mathcal{L}(\check{\phi}^k, f^k_{\text{lev}})}(x^k) - x^k$ with $J^k = \{k\}$ in (4.2).

(v) Using (1.4), $x^{k+1} = P_S(z^k)$, $x^k \in S$ and $t_k \leq 1$, we get $|x^{k+1} - x^k| \leq |z^k - x^k| = t_k |y^k - x^k| \leq |y^k - x^k|$. But $y^k = P_{\mathcal{L}(\phi^k, f^k_{\text{lev}})}(x^k)$ with $\phi^k(x^k) > f^k_{\text{lev}}$, so $f^k_{\text{lev}} = \phi^k(y^k) \leq \phi^k(x^{k+1})$. □

Lemma 6.1 suggests the following *CS implementation* of Algorithm 2.1. Let $0 < \mu \leq 1$ and $\phi^1 = f^1$. At iteration $k \geq 2$, let $\psi^{k-1} = \phi^{k-1}$ and $\phi^k = \check{\phi}^k$ with $\beta_k \geq 0$ such that $|\check{g}^k_\phi| \leq |g^k|/\mu$ if $\psi^{k-1}(x^k) \geq f^k_{\text{lev}}$, and $\beta_k = 0$ ($\phi^k = f^k$) otherwise. Then by induction, as in [Kiw96, §9], we see that only the first terms of the constants in all the efficiency estimates and the right side of (7.3) in [Kiw96] need be divided by μ^2, with $\mu = 1$ if $\beta_k \leq 2\check{\beta}_k$ $\forall k$; of course, Δ^k_{lev} replaces $\kappa\Delta^k$ in Lemma 6.1 for the frozen level gaps of [Kiw96, §7].

Note that by construction, $d^k = -(f(x^k) - f^k_{\rm lev})\breve{g}^k_\phi/|\breve{g}^k_\phi|^2$, and if $d^{k-1} \neq 0$, then $d^{k-1}/|d^{k-1}| = -g^{k-1}_\psi/|g^{k-1}_\psi|$, so if $\beta_k = \breve{\beta}_k$ and $\langle g^k, d^{k-1}\rangle > 0$, then $\breve{g}^k_\phi = g^k - \langle g^k, d^{k-1}\rangle d^{k-1}/|d^{k-1}|^2$ and $\langle d^k, d^{k-1}\rangle = 0$. These CS relations correspond to those of the methods in [Brä93, CFM75, KiA90, ShU89, Sho79], which set $f^k_{\rm lev} = f^*$ and $t_k \leq 1$. Incidentally, when $t_k \leq 1$ and $f^{k+1}_{\rm lev} \leq f^k_{\rm lev}$, then $\phi^k(x^{k+1}) \geq f^{k+1}_{\rm lev}$ by Lemma 6.1(v), so such methods can skip computing $\psi^{k-1}(x^k)$ $(\geq f^*)$; this is the main reason for choosing $t_k \leq 1$. Usually $\beta_k \leq 2\breve{\beta}_k$ is advocated; with the choice of $\beta_k = |g^k|/|g^{k-1}_\psi|$ from [ShU89], the direction d^k simply bisects the angle between $-g^k$ and d^{k-1} and in this sense is an *average direction*. Since $|y - y^k|^2 \leq |y - x^k|^2 - d^2_{\mathcal{L}(\phi^k, f^k_{\rm lev})}(x^k)$ if $y \in S^*$, $y^k = P_{\mathcal{L}(\phi^k, f^k_{\rm lev})}(x^k)$, and $f^k_{\rm lev} \geq f^*$, Lemma 6.1(iii) augments the usual angle-based motivation for using $\breve{\phi}^k$ instead of f^k, while Lemma 6.1(iv) complements results in [KiA90]. In particular, the CS implementation with $\beta_k = \breve{\beta}_k$ corresponds to the simplest OSP implementation of Remark 5.12 with ψ^{k-1} replaced by $\breve{\psi}^{k-1}$ to zero its σ^n_{n-1} and $\breve{g}^k_\phi = \tilde{q}^n$ obtained by orthogonalizing g^k and g^{k-1}_ψ.

Lemma 6.1 says that we may easily improve classical CS techniques by taking $\phi^k = \breve{\phi}^k$, $\tilde{\phi}^k$, or $\hat{\phi}^k$ instead of $\phi^k = \breve{\phi}^k$ to increase $d_{\mathcal{L}(\phi^k, f^k_{\rm lev})}(x^k)$; cf. [Kiw96, Rem. 3.9]. In particular, $\tilde{\phi}^k$ is a convex combination of f^k and ψ^{k-1}, and other such combinations could be developed as in [Kiw96, §9]. It seems, however, that $\hat{\phi}^k = \max\{f^k, \psi^{k-1}\}$ is preferable anyway. First, Lemma 6.1 and [Kiw96, Lem. 9.4] show that $\hat{\phi}^k$ is best in terms of efficiency estimates. Second, the resulting choice of $\psi^{k-1} = \phi^{k-1}$ and $\hat{\phi}^k = \max\{f^k, \phi^{k-1}\}$ corresponds to the aggregate subgradient implementation of §4, which, in contrast to the other CS choices, does not require $t_k \leq 1$ and does not need to resort to the poorest model $\phi^k = f^k$ when $\phi^{k-1}(x^k) < f^k_{\rm lev}$ or $\langle g^k, g^{k-1}_\psi\rangle \geq 0$. Third, it involves little additional work (cf. (4.3)). Last, but not least, it is simpler conceptually. Incidentally, the choices of $\phi^k = \breve{\phi}^k$ and $\phi^k = \hat{\phi}^k$ may be compared in dual terms by noting that $\breve{\beta}_k = \arg\max_{\beta \geq 0}(f(x^k) - f^k_{\rm lev})/|g^k + \beta g^{k-1}_\psi|$ and $(\lambda^k_k, \lambda^k_\psi) \in \operatorname{Arg\,max}\{[\lambda_k(f(x^k) - f^k_{\rm lev}) + \lambda_\psi(\psi^{k-1}(x^k) - f^k_{\rm lev})]/|\lambda_k g^k + \lambda_\psi g^{k-1}_\psi| : \lambda_k \geq 0, \lambda_\psi \geq 0, \lambda_k + \lambda_\psi = 1\}$, where the second maximum $(= d_{\mathcal{L}(\hat{\phi}^k, f^k_{\rm lev})}(x^k))$ can be much greater.

An obvious extension of the CS techniques is to take $\phi^k = \max\{\hat{f}^k, \breve{\phi}^k\}$ or $\max\{\hat{f}^k, \tilde{\phi}^k\}$ to increase $d_{\mathcal{L}(\phi^k, f^k_{\rm lev})}(x^k)$. Further, more than one CS step can be made as in Remark 4.2.

7. Constraint modelling. Since Algorithm 2.1 minimizes f on S, ϕ^k should be chosen to model the extended objective $f_S = f + \delta_S$ and not just f alone, where $\delta_S(x) = 0$ if $x \in S$, $\delta_S(x) = \infty$ if $x \notin S$. Failure to do so may result in severe deficiencies, as shown in the following simple example.

Example 7.1. Let $N = 2$, $S = [0,1] \times [0,1]$, and $f(x) = \epsilon x_1 + x_2$, where $0 < \epsilon < 1$ is a small parameter. Then $S^* = \{(0,0)\}$, $f^* = 0$, $\operatorname{diam}(S) = \sqrt{2}$, and $L_f = \sqrt{1+\epsilon^2}$. Let $x^1 = (1,0)$ and $t_{\min} = t_{\max} = 1$. The following facts are easy to verify by induction. The SPA (1.2) generates $x^k = ((1+\epsilon^2)^{1-k}, 0)$ and $f(x^k) = \epsilon(1+\epsilon^2)^{1-k}$ $\forall k$; i.e., its convergence is linear but very slow for small ϵ. The situation is even slightly worse for the SPLA (2.2) with $f^1_{\rm low} = f^*$, which yields $x^k = ([1 - \kappa\epsilon^2]/(1+\epsilon^2)^{k-1}, 0)$ $\forall k$. In contrast, Algorithm 2.1 with $f^1_{\rm low} = f^*$, $\bar{D} \geq \sqrt{2}$ and $\phi^k \equiv f^k + \delta_S$ gives $x^k = ((1-\kappa)^{k-1}, 0)$ $\forall k$; i.e., it is much faster for typical κ, independent of ϵ. In fact for $\kappa = 1$ (cf. [Kiw96, Thm 6.1]) it terminates with $x^2 \in S^*$, being equivalent to the iteration (1.3).

Example 7.1 and [Kiw96, Rem. 3.9] suggest that the following modification of

(2.2),

$$x^{k+1} = \arg\min\{\,|x - x^k|^2/2 : f(x^k) + \langle g_f(x^k), x - x^k\rangle \le f^k_{\text{lev}}, x \in S\,\}, \tag{7.1}$$

should be more efficient in practice. Supposing S is a box of the form $[x^{\text{low}}, x^{\text{up}}]$, let $x(\nu) = \arg\min_{x\in S}\{|x - x^k|^2/2 + \nu\langle g^k, x\rangle\}\ \forall \nu \ge 0$. Then $x^{k+1} = x(\hat\nu)$, where $\hat\nu \ge 0$ solves the equation $h(\nu) \equiv f(x^k) + \langle g^k, x(\nu) - x^k\rangle - f^k_{\text{lev}} = 0$. Since $x_i(\nu) = \max\{\min[x_i^{\text{low}}, x_i^k - \nu g_i^k], x_i^{\text{up}}\}$, $i = 1{:}N$, and h is nonincreasing and piecewise linear, $\hat\nu$ is easy to compute.

Of course, projecting on S is easy only if S is simple enough, e.g., a Cartesian product of boxes, simplices, balls, ellipsoids, cylinders, etc. Additional linear constraints may complicate the projections; e.g., for $\phi^k = \hat f^k + \delta_S$ we must find

$$y^k = \arg\min\{\,|x - x^k|^2/2 : f^j(x) \le f^k_{\text{lev}}, j \in J^k, x \in S\,\}. \tag{7.2}$$

Fortunately, accurate projections are not really necessary. For instance, (7.2) can be implemented approximately by projecting *cyclically* on $\mathcal{L}(\hat f^k, f^k_{\text{lev}})$ and S as in Remark 4.2, possibly with inexact projections on $\mathcal{L}(\hat f^k, f^k_{\text{lev}})$ being performed via the methods of §§4, 5 and 6. Also if S is polyhedral then (7.2) is just (4.1) augmented with the inequalities of S, so it can be solved approximately by several steps of these methods.

It is crucial to observe that even if S is not polyhedral, it may still be *linearized* via inequalities generated in the course of calculations. First, such inequalities may be recovered *geometrically* by noting that $S \subset \mathcal{H}^k := \{x : \langle z^{k-1} - x^k, x - x^k\rangle \le 0\}$ from $x^k = P_S(z^{k-1})$. Hence we may replace S in (7.2) by $S^k = \cap_{j\in J^k_S}\mathcal{H}^j$ with $J^k_S \subset \{2{:}k\}$. Second, similar inequalities may be generated *analytically* if $S = \{x : F(x) \le 0\}$ say, where $F : \mathbb{R}^N \to \mathbb{R}$ is convex, and we can find its linearization $\bar F(\cdot; x) = F(x) + \langle g_F(x), \cdot - x\rangle$ with $g_F(x) \in \partial F(x)$ for any x. Then we may use $\mathcal{H}^k = \{x : \bar F(x; x^k) \le 0\}$ as above. In other words, we may accumulate $\mathcal{H}^j$ for the model δ_{S^k} of δ_S in the same way as we use f^j in the model $\hat f^k$ of f, so that $f + \delta_S$ is approximated by $\phi^k = \hat f^k + \delta_{S^k}$, with $\delta_{S_k} \le \delta_S$ from $S \subset S^k$. To save storage, some of the inequalities defining S^k may be aggregated as in §4.

The following observation is useful for the dual models of §2. If we take $\hat\phi^k = \hat f^k + \delta_S$ for a polyhedral $S = \{x : \langle a^i, x\rangle \le b_i, i = 1{:}m\}$, say, then $\partial_{\epsilon_k}\hat\phi^k(x^k) = \{\partial_{\epsilon'}\hat f^k(x^k) + \partial_{\epsilon''}\delta_S(x^k) : \epsilon' + \epsilon'' \le \epsilon_k, \epsilon', \epsilon'' \ge 0\}$ with

$$\partial_\epsilon\delta_S(x^k) = \left\{\sum_{i=1}^m \nu_i a^i : \sum_{i=1}^m \nu_i(b_i - \langle a^i, x^k\rangle) \le \epsilon, \nu_i \ge 0, i = 1{:}m\right\},$$

so $p^k = \arg\min\{|p|^2/2 : p \in \partial_{\epsilon_k}\hat\phi^k(x^k)\}$ of (2.4) can again be found via QP using (2.5). Next, letting $I^k = \{i : \langle a^i, x^k\rangle = b_i\}$ and $\hat S^k = \{x : \langle a^i, x\rangle \le b_i, i \in I^k\}$, consider the simpler model $\hat\phi^k = f^k + \delta_{\hat S^k}$. Clearly, $\hat\phi^k \le f_S$, $\hat\phi^k(x^k) = f(x^k)$ and $\partial_{\epsilon_k}\hat\phi^k(x^k) = g^k + \partial\delta_{\hat S^k}(x^k)$ for *any* $\epsilon_k \ge 0$; i.e., p^k does not depend on ϵ_k. Hence by [Kiw96, Lem. 9.4], $\epsilon_k = 0$ gives the "optimal" dual method with $d^k = y^k - x^k = -(f(x^k) - f^k_{\text{lev}})p^k/|p^k|^2 = P_{\mathcal{L}(\hat\phi^k, f^k_{\text{lev}})}(x^k) - x^k$ if $p^k \ne 0$; otherwise $f^k_{\text{lev}} < f^*$ by [Kiw96, Lem. 9.2]. (Thus it is not suprising that this dual method behaves like the primal one in Example 7.1.) Additional insight may be gained as follows. The cones $C = \text{cone}\{a^i\}_{i\in I^k}$ and $C^- = \{x : \langle a^i, x\rangle \le 0, i \in I^k\}$ provide the classical orthogonal decomposition

$$g = P_C(g) + P_{C^-}(g), \quad P_C(g) \perp P_{C^-}(g) \quad \forall g \in \mathbb{R}^N,$$

since $P_{C^-}(g) = \arg\min\{|x-g|^2/2 : A_{I^k}^T x \le 0\}$ has multipliers

$$\lambda_{I^k} \in \operatorname{Arg\,min}\{|A_{I^k}\lambda_{I^k} - g|^2/2 : \lambda_{I^k} \ge 0\}$$

satisfying $P_C(g) = A_{I^k}\lambda_{I^k}$ and $\lambda_{I^k}^T A_{I^k}^T P_{C^-}(g) = 0$ by the KKT conditions, so for $g = -g^k$,

$$-p^k = -g^k - P_{\mathcal{N}_S(x^k)}(-g^k) = P_{\mathcal{T}_S(x^k)}(-g^k), \tag{7.3}$$

where $\mathcal{N}_S(x^k) = \partial\delta_S(x^k) = C$ and $\mathcal{T}_S(x^k) = C^-$ are the normal and tangent cones to S at x^k, respectively. Hence $-p^k$ and d^k are feasible directions for S at x^k. Thus if t_k is sufficiently small, then $z^k = x^k + t_k d^k \in S$, so that one may take $x^{k+1} = z^k$, skipping its projection on S. This motivates a similar technique in [KiU89] (with $f_{\text{lev}}^k = f^*$), but small stepsizes may yield slow convergence.

Of course, if S is not polyhedral, then the preceding construction may employ its accumulated approximation S^k. A simple but useful example is given in the following lemma.

LEMMA 7.2. *Suppose $\mathcal{H}^k = \{x : \langle a^k, x - x^k\rangle \le 0\}$ is a nontrivial outer approximation to S at x^k; e.g., $a^k = z^{k-1} - x^k \ne 0$. Let $\hat\gamma_k = \arg\min_{\gamma\ge 0}|g^k + \gamma a^k|$, choose $0 \le \gamma_k \le 2\hat\gamma_k$, and let $g_S^k = g^k + \gamma_k a^k$. Then $f_S^k(\cdot) = f^k(\cdot) + \gamma_k\langle a^k, \cdot - x^k\rangle = f(x^k) + \langle g_S^k, \cdot - x^k\rangle$ is a valid linearization of f_S, i.e., $f_S^k \in \Phi_1^k$, satisfying $f_S^k(x^*) \le f^* \ \forall x^* \in S^*$, and $d_{\mathcal{L}(f_S^k, f_{\text{lev}}^k)}(x^k) \ge d_{\mathcal{L}(f^k, f_{\text{lev}}^k)}(x^k)$, with strict inequality if $0 < \gamma_k < 2\hat\gamma_k$. In particular, if $\langle g^k, a^k\rangle < 0$ and $\gamma_k = \hat\gamma_k = -\langle g^k, a^k\rangle/|a^k|^2$, then $g_S^k = g^k - \langle g^k, a^k\rangle a^k/|a^k|^2 = -P_{\mathcal{H}^k}(-g^k)$.*

Proof. Clearly, $f_S^k(x^k) = f(x^k)$ and $f^k(x) \ge f_S^k(x)\ \forall x \in S \subset \mathcal{H}^k$, so $f_S^k(x^*) \le f^*$ if $x^* \in S^*$. As for the rest, solve $\min_{\gamma\ge 0}|g^k + \gamma a^k|^2$ and use $d_{\mathcal{L}(f_S^k, f_{\text{lev}}^k)}(x^k) = (f(x^k) - f_{\text{lev}}^k)/|g_S^k|$. □

In view of Lemma 7.2, we may replace g^k with $g_S^k \in \partial f_S(x^k)$, a conditional subgradient of f on S. In general, f_S^k is a worse model of f_S than $f^k + \delta_{\mathcal{H}^k}$, but it may be easier to handle.

We now extend the *average direction strategy* (ADS) of [ShU89].

LEMMA 7.3. *Suppose $t_k \le 1$ and $\phi^k = \breve\phi^k \in \Phi_\mu^k$, where $\breve\phi^k = f(x^k) + \langle \breve g_\phi^k, \cdot - x^k\rangle$ is the CS model of Lemma 6.1. Let $\psi^k = \breve\phi^k(x^{k+1}) + \langle g_\psi^k, \cdot - x^{k+1}\rangle$, where $g_\psi^k = \breve g_\phi^k + \gamma_k(z^k - x^{k+1})$ for some $\gamma_k \ge 0$. Then $\psi^k(x^{k+1}) \ge f_{\text{lev}}^k$ and $\psi^k \in \Phi$ if $f_{\text{lev}}^k \ge f^*$. Moreover, if $\gamma_k = \breve\gamma_k := |\breve g_\phi^k|^2/(\breve\phi^k(x^k) - f_{\text{lev}}^k)t_k$, then $\breve d^k = -g_\psi^k/\gamma_k$, where $\breve d^k = x^{k+1} - x^k$ is the actual direction of motion which includes the effect of the projection operation. In particular, if $\breve d^k \ne 0$ and ψ^k is used to define the next $\phi^{k+1} = \breve\phi^{k+1}$ with $\beta_{k+1} = |g^{k+1}|/|g_\psi^{k+1}|$, then $\breve g_\phi^{k+1} = g^{k+1} - |g^{k+1}|\breve d^k/|\breve d^k|$; i.e., the move $y^{k+1} = x^{k+1} - (f(x^{k+1}) - f_{\text{lev}}^{k+1})\breve g_\phi^{k+1}/|\breve g_\phi^{k+1}|^2$ occurs along the average direction of $-g^{k+1}$ and $\breve d^k$.*

Proof. If $f_{\text{lev}}^k \ge f^*$ and $x^* \in S^*$, then $\breve\phi^k(x^{k+1}) + \langle \breve g_\phi^k, x^* - x^{k+1}\rangle = \breve\phi^k(x^*) \le f^*$ by (2.3) and $\langle z^k - x^{k+1}, x^* - x^{k+1}\rangle \le 0$ because $x^{k+1} = P_S(z^k)$ and $x^* \in S$, so $\psi^k(x^*) \le f^*$, while $\psi^k(x^{k+1}) = \phi^k(x^{k+1}) \ge f_{\text{lev}}^k$ by Lemma 6.1(v). Next, suppose $\gamma_k = \breve\gamma_k$. Then $z^k - x^k = -t_k(\breve\phi^k(x^k) - f_{\text{lev}}^k)\breve g_\phi^k/|\breve g_\phi^k|^2$ yields $-g_\psi^k/\gamma_k = z^k - x^k - (z^k - x^{k+1}) = \breve d^k$. The rest follows by construction. □

Lemma 7.3 suggests the following *ADS version* of the CS implementation from §6. Let $0 < \mu \le 1$. At iteration k, let $\phi^1 = f^1$ if $k = 1$, otherwise use ψ^{k-1} to find $\phi^k = \breve\phi^k$ with $\beta_k \ge 0$ such that $|\breve g_\phi^k| \le |g^k|/\mu$ if $\psi^{k-1}(x^k) \ge f_{\text{lev}}^k$, and $\beta_k = 0$

otherwise; in both cases choose $\gamma_k \geq 0$ to construct ψ^k as in Lemma 7.3. In other words, instead of using $\psi^{k-1} = \phi^{k-1}$, the ADS version modifies ψ^{k-1} to include the effect of the projection operation. Clearly, the ADS version shares the efficiency estimates of the CS one's. On the other hand, the ADS version of a similar method in [ShU89] (with $\gamma_k \equiv \check{\gamma}_k$) performed better than the standard CS version of [CFM75] (corresponding to $\beta_k = \check{\beta}_k$ in Lemma 6.1). (By the way, the ADS version was not validated theoretically in [ShU89].) We note, however, that the arguments of §6 that favor $\hat{\phi}^k = \max\{f^k, \psi^{k-1}\}$ versus $\check{\phi}^k$ hold also for this modified form of ψ^{k-1}.

8. Conclusions. We have extended various acceleration techniques for subgradient methods, such as surrogate constraints, deepest surrogate cuts, simultaneous projections, orthogonal surrogate projections, CSs, and projected (conditional) subgradients. We have also proposed to use subgradient aggregation and parallel projection methods for implementing our methods in the large-scale case.

Of course, some of our ideas have been inspired by other popular approaches [AHKS87, BaS81, HWC74, KKA87, SeS86, ShM88, ShU89] and may in turn be used to modify the methods given in these papers. For example, the concept of relying on subgradient aggregation to provide some "conjugacy" (cf. §§4, 6, and 7) would enable the method of [ShU89] to use "deeper cuts," thus enabling faster convergence. We hope, therefore, that this paper will contribute to the development of other subgradient methods.

Acknowledgments. This work was started during my six-month stay at INRIA, Rocquencourt, in 1992, owing to the kind invitation by C. Lemaréchal and the French Ministry for Research and Technology, whose financial support is gratefully acknowledged. I would also like to thank the two anonymous referees for their valuable comments.

GENERAL OPTIMALITY CONDITIONS FOR CONSTRAINED CONVEX CONTROL PROBLEMS*

MAÏTINE BERGOUNIOUX† AND DAN TIBA‡

Abstract. In this paper we investigate some optimal convex control problems, with mixed constraints on the state and the control. We give a general condition which allows us to set optimality conditions for nonqualified problems (in the Slater sense). Then we give some applications and examples involving generalized bang-bang results.

Key words. optimal control with mixed constraints, qualification condition, optimality conditions

AMS subject classification. 49B22

1. Formulation of the problem. Let $V \subset H \subset V'$ compactly and densely be Hilbert spaces; $A(t) : V \to V'$, $B : U \to V'$ be linear bounded operators (U is another nontrivial Hilbert space); and $L : L^2(0,T;H \times U) \to \mathbb{R}$, $l : H \to \mathbb{R}$ be convex, continuous mappings.

We consider the following optimal control problem:

$$\text{(P)} \qquad \text{Min } \{ L(x,u) + l(x(T)) \}$$

subject to

$$x'(t) + A(t)x(t) = Bu(t) + f(t) \qquad \text{a.e. in }]0,T[, \tag{1.1}$$

$$[x,u] \in D \subset \mathcal{X} \times L^2(0,T;U), \text{ closed convex subset}, \tag{1.2}$$

where

- $\mathcal{X} = L^2(0,T;V) \cap W^{1,2}(0,T;V')$,
- $f \in L^2(0,T;V')$,
- L is coercive in the sense

$$\begin{gathered} \exists c \text{ (a generic constant)} > 0 \text{ such that} \\ \forall [y,u] \in L^2(0,T;H \times U) \qquad L(y,u) > c\, \|u\|^2_{L^2(0,T;U)} - c, \end{gathered} \tag{1.3}$$

- $\forall z \in V \quad t \mapsto A(t)z$ is V'-measurable on]0,T[, and

$$\forall z \in V \quad \|A(t)z\|_{V'} \leq c\|z\|_V, \tag{1.4}$$

$$\exists \alpha\ ,\ \exists \beta > 0\ ,\ \forall z \in V \quad \langle A(t)z, z\rangle_{V \times V'} + \alpha\|z\|^2_H \geq \beta\|z\|^2_V\ . \tag{1.5}$$

We assume the initial condition $x(0) = x^o \in H$, and the possible final restrictions are included in the definition of D. The evolution equation (1.1) has a unique solution $x \in \mathcal{X}$ for any $u \in L^2(0,T;U)$ by theorem 4.5 in Barbu and Precupanu [3, Chap. 1].

Moreover, by condition (1.3), it is a standard argument to show that (P) has at least one optimal pair (denoted $[x^*, u^*]$) in D if some admissibility assumption is fulfilled:

$$\exists\, [x,u] \in D \text{ such that } T(x,u) = 0 \tag{1.6}$$

with

$$\forall [x,u] \in \mathcal{X} \times L^2(0,T;U) \qquad T(x,u) = x' + A(t)x - Bu - f.$$

The problem (P) is a generalization of the Bolza optimal control problem studied by Barbu and Precupanu [3, Chap. 4] both with respect to the cost functional and with respect to the form of the mixed constraints. The continuity hypothesis on L and l is quite restrictive, but as we keep the constraints separate (i.e., we do not include them into the cost via the indicator function of D), then the class of examples is very large.

For state-constrained control problems, one usually assumes a Slater-type interiority condition. In the general setting of (1.2), it takes the form

$$(\mathcal{S}) \quad \exists\, [\bar{x}, \bar{u}] \text{ feasible for (P) such that } \bar{x} \in \operatorname{int} \{\, y \in \mathcal{X} \mid [y, \bar{u}] \in D\} \text{ in } \mathcal{C}(0,T;H),$$

and it has very severe implications for the set of possible applications.

It is our main concern to weaken this classical qualification constraint. Namely, instead of $(\mathcal{S})$, we shall suppose that

$$(\mathcal{H}) \qquad \begin{array}{c} \exists \mathcal{M} \subset D \text{ bounded in } \mathcal{C}(0,T;H) \times L^2(0,T;U) \\ \text{such that } 0 \in \operatorname{int} T(\mathcal{M}) \text{ in } L^2(0,T;V'). \end{array}$$

Let us first notice that 0 appears naturally in $(\mathcal{H})$ since the problem constraint is expressed as $T(x,u) = 0$. Moreover, the elements (pairs) of the set $\mathcal{M}$ need not be feasible for (P).

We first compare the two conditions $(\mathcal{S})$ and $(\mathcal{H})$; the following proposition proves that $(\mathcal{S})$ is always stronger than $(\mathcal{H})$.

PROPOSITION 1.1. $(\mathcal{S}) \Rightarrow (\mathcal{H})$.

Proof. Thanks to $(\mathcal{S})$, (1.1), and (1.2) we have

$$\bar{x}' + A(t)\bar{x} = B\bar{u} + f, \ \bar{x}(0) = x^o \ \text{ a.e. in }]0,T[. \tag{1.7}$$

Let $\rho > 0$ and $\xi \in L^2(0,T;V')$ such that $\|\xi\|_{L^2(0,T;V')} = 1$. We denote by x_ξ the solution of

$$x_\xi' + A(t)x_\xi = B\bar{u} + f + \rho\xi, \ x_\xi(0) = x^o \ \text{ a.e. in }]0,T[. \tag{1.8}$$

Taking the difference between (1.7) and (1.8), we get that

$$\|\bar{x} - x_\xi\|_{\mathcal{X}} \le k\rho$$

with k independent of ξ. Then, if ρ is small enough, $(\mathcal{S})$ gives $[x_\xi, \bar{u}] \in D$ for all $\xi \in L^2(0,T;V')$ such that $\|\xi\|_{L^2(0,T;V')} = 1$. Here we set

$$\mathcal{M} = \operatorname{conv}(\{\, [x_\xi, \bar{u}] \mid \xi \in L^2(0,T;V'),\ \|\xi\|_{L^2(0,T;V')} = 1 \,\}),$$

where conv(E) is the convex hull of the set E, and the proof is complete. □

Remark 1.1. Assume that $U \subset V'$ continuously and $B : U \to V'$ is the canonical injection. Then one makes an interiority assumption with respect to the control of the type

$$(\mathcal{I}) \qquad \begin{array}{c} \exists\ [\tilde{x}, \tilde{u}] \text{ feasible for (P) such that} \\ \text{Int } \{\ u \in U \mid [\tilde{x}, u] \in D\ \} \text{ is nonempty in } L^2(0,T;V'). \end{array}$$

This again implies $(\mathcal{H})$ by an argument as above. In this case the Slater condition need not be fulfilled; that is to say, the condition $(\mathcal{H})$ is strictly weaker than $(\mathcal{S})$.

Condition $(\mathcal{H})$ or its weaker variant $(\mathcal{H}')$ from §3 may be mainly compared with Zowe and Kurcyusz's [18] condition in the mathematical programming theory. This was previously used in abstract control problems by Tröltzsch [16], [17], combined with interiority-type assumptions at the level of applications. In the examples of §3, we show that the interior of the constraint set may be empty even in the uniform topology, but the argument still applies.

In the recent work of Barbu and Pavel [2] another case of empty interior constraints is discussed for optimal control problems governed by periodic evolution equations and by a different method. Our approach is based on the penalization of the only state system rather than of both the state system and the constraints (as in Bonnans and Casas [8]); the constraints are kept explicit throughout the proof. This is quite a classical philosophy in connection to Lagrange multipliers techniques (see, for instance, the monograph of Tikhomirov [15]). In the setting of partial differential equations, it has been extensively exploited in books by Lions [12] and Tiba [14, Chap. 2] in connection to nonlinear singular control problems. Recently Bergounioux [5, 6] has applied this method to control problems with state constraints governed by elliptic systems, and Bergounioux, Männikkö, and Tiba [7] have studied some examples of parabolic control problems. Applications of the obtained optimality system to augmented Lagrangian algorithms were also indicated.

Finally, we point out that the technique used in the next section makes evident with full accuracy the relationship between the operator T and the set D of constraints.

2. The optimality system. We define the penalized problem as follows:

$$(\mathrm{P}_\varepsilon) \qquad \begin{aligned} \text{Min} \Big\{ & L_\varepsilon(x,u) + l_\varepsilon(x(T)) + \frac{1}{2}\int_0^T \|u - u^*\|_U^2\ dt \\ & + \frac{1}{2\varepsilon}\int_0^T \|x' + Ax - Bu - f\|_{V'}^2\ dt \Big\} \end{aligned}$$

over all $[x,u] \in D$. It should be noted that the first integral is an "adapted" penalization term according to Barbu [1], while L_ε and l_ε are the Moreau–Yosida regularization of the convex mappings L and l.

Remark 2.1. Let us briefly recall the Moreau–Yosida regularization. Let f be a proper, convex mapping on a Banach space X. For any $\varepsilon > 0$, the Moreau–Yosida regularization of f is

$$\forall x \in X \qquad f_\varepsilon(x) = \inf \left\{ \frac{1}{2\varepsilon}\|x - y\|_X^2 + f(y) \mid y \in X \right\}.$$

A thorough study of the properties of L_ε and l_ε may be found in Barbu and Precupanu [3, Chap. 2]. We shall recall some of them when needed in the text.

The existence of a unique optimal pair $[x_\varepsilon, u_\varepsilon]$ is obvious. We also denote

$$r_\varepsilon = \frac{1}{\varepsilon} J^{-1}(x'_\varepsilon + Ax_\varepsilon - Bu_\varepsilon - f) \in L^2(0,T;V),$$

where $J : V \to V'$ is the canonical isomorphism.

PROPOSITION 2.1. *We have*

$$x_\varepsilon \to x^* \quad \textit{strongly in } \mathcal{X}, \tag{2.1}$$

$$u_\varepsilon \to u^* \quad \textit{strongly in } L^2(0,T;U), \tag{2.2}$$

$$\varepsilon^{\frac{1}{2}} r_\varepsilon \quad \textit{is bounded in } L^2(0,T;V). \tag{2.3}$$

Proof. The optimality of the pair $[x^*, u^*]$ and the properties of the convex regularized mappings give

$$\begin{aligned} L_\varepsilon(x_\varepsilon, u_\varepsilon) + l_\varepsilon(x_\varepsilon(T)) + \frac{1}{2}\int_0^T \|u_\varepsilon - u^*\|_U^2 \, dt + \frac{1}{2\varepsilon}\int_0^T \|x'_\varepsilon + A(t)x_\varepsilon - Bu_\varepsilon - f\|_{V'}^2 dt \\ \leq L_\varepsilon(x^*, u^*) + l_\varepsilon(x^*(T)) \leq L(x^*, u^*) + l(x^*(T)). \end{aligned} \tag{2.4}$$

With the coercivity assumption (1.3), the relation (2.4) gives

$$l_\varepsilon(x_\varepsilon(T)) + \frac{1}{2}\int_0^T \|u_\varepsilon - u^*\|_U^2 \, dt + \frac{1}{2\varepsilon}\int_0^T \|x'_\varepsilon + A(t)x_\varepsilon - Bu_\varepsilon - f\|_{V'}^2 dt \leq c.$$

Moreover l_ε is lower bounded by an affine mapping uniformly with respect to $\varepsilon > 0$ so that

$$\frac{1}{2}\int_0^T \|u_\varepsilon - u^*\|_U^2 \, dt + \frac{1}{2\varepsilon}\int_0^T \|x'_\varepsilon + A(t)x_\varepsilon - Bu_\varepsilon - f\|_{V'}^2 dt \leq c + c\,\|x_\varepsilon(T)\|_H.$$

As the initial condition is contained in D and the dependence from the right-hand side as defined by (1.1) is sublinear, then we see that (u_ε) is bounded in $L^2(0,T;U)$, x_ε is bounded in $\mathcal{X}$, and $\varepsilon^{\frac{1}{2}} r_\varepsilon$ is bounded in $L^2(0,T;V)$.

We denote by $[\hat{x}, \hat{u}]$ their weak limit on a subsequence. Since

$$x'_\varepsilon + A(t)x_\varepsilon = Bu_\varepsilon + f + \varepsilon J(r_\varepsilon)\ ,$$

we can pass to the limit and $[\hat{x}, \hat{u}]$ is an feasible pair for (P). We have

$$L_\varepsilon(x_\varepsilon, u_\varepsilon) = L((I + \varepsilon\partial L)^{-1}(x_\varepsilon, u_\varepsilon)) + \frac{1}{2\varepsilon}\|[x_\varepsilon, u_\varepsilon] - (I + \varepsilon\partial L)^{-1}(x_\varepsilon, u_\varepsilon)\|_{H\times U}^2,$$

where I is the identity in $H \times U$. Coming back to (2.4), we get easily that $L_\varepsilon(x_\varepsilon, u_\varepsilon)$ is bounded, so $(I + \varepsilon\partial L)^{-1}(x_\varepsilon, u_\varepsilon) \rightharpoonup [\hat{x}, \hat{u}]$ weakly in $L^2(0,T;H \times U)$ by the above formula. Taking into account the weak lower semicontinuity of L and l we can pass to the limit in (2.4):

$$L(\hat{x}, \hat{u}) + l(\hat{x}(T)) + \frac{1}{2}\int_0^T \|\hat{u} - u^*\|_U^2 \, dt \leq L(x^*, u^*) + l(x^*(T)).$$

Then $\hat{u} = u^*$, $\hat{x} = x^*$, and we have (2.2) and (2.1) by a strong convergence criterion in Hilbert spaces. □

PROPOSITION 2.2. *We have the following first-order optimality condition:*

$$\begin{aligned}(2.5)\qquad &\langle \nabla L_\varepsilon(x_\varepsilon, u_\varepsilon), [x_\varepsilon, u_\varepsilon] - [x, u]\rangle_{L^2(0,T;H\times U)} + \langle \nabla l_\varepsilon(x_\varepsilon(T)), x_\varepsilon(T) - x(T)\rangle_H \\ &+ \int_0^T \langle u_\varepsilon - u, u_\varepsilon - u^*\rangle_U \, dt - \int_0^T \langle x' + Ax - Bu - f, J(r_\varepsilon)\rangle_{V'} \, dt \le 0\end{aligned}$$

for any $[x, u]$ in D. (Here ∇ denotes the Gâteaux derivative.)

This is a standard result in the optimization of convex differentiable functionals (see, for instance, Lions [11, Chap. 1]) and $J(r_\varepsilon)$ plays the role of a Lagrange multiplier.

Proof. We make feasible variations in x and u:

$$\begin{aligned}&L_\varepsilon(x_\varepsilon, u_\varepsilon) + l_\varepsilon(x_\varepsilon(T)) + \frac{1}{2}\int_0^T \|u_\varepsilon - u^*\|_U^2 \, dt + \frac{1}{2\varepsilon}\int_0^T \|x'_\varepsilon + Ax_\varepsilon - Bu_\varepsilon - f\|_{V'}^2 \, dt \\ &\le L_\varepsilon(x_s, u_s) + l_\varepsilon(x_s(T)) + \frac{1}{2}\int_0^T \|u_s - u^*\|_U^2 \, dt + \frac{1}{2\varepsilon}\int_0^T \|x'_s + Ax_s - Bu_s - f\|_{V'}^2 \, dt,\end{aligned}$$

where $x_s = x_\varepsilon + s(x - x_\varepsilon)$, $u_s = u_\varepsilon + s(u - u_\varepsilon)$, $s \in]0, 1]$, and $[x, u] \in D$ arbitrary.

Moving all the terms to the left-hand side, dividing by $s > 0$, and letting s tend to 0, we obtain

$$\begin{aligned}(2.6)\qquad &\langle \nabla L_\varepsilon(x_\varepsilon, u_\varepsilon), [x_\varepsilon, u_\varepsilon] - [x, u]\rangle_{L^2(0,T;H\times U)} + \langle \nabla l_\varepsilon(x_\varepsilon(T)), x_\varepsilon(T) - x(T)\rangle_H \\ &+ \int_0^T \langle u_\varepsilon - u, u_\varepsilon - u^*\rangle_U \, dt - \int_0^T \langle x' + Ax - Bu - f - \varepsilon J(r_\varepsilon), J(r_\varepsilon)\rangle_{V'} \, dt \le 0\end{aligned}$$

for any $[x, u]$ in D. Then (2.5) follows from (2.6) since $\varepsilon\|J(r_\varepsilon)\|^2_{L^2(0,T;V')} \ge 0$. (We have also used the properties of $J(r_\varepsilon)$.) □

Remark 2.2. The condition (2.6) is also sufficient for optimality in (P). We can reexpress (2.5) as

$$\begin{aligned}(2.7)\qquad &\langle \nabla L_\varepsilon(x_\varepsilon, u_\varepsilon), [x_\varepsilon, u_\varepsilon] - [x, u]\rangle_{L^2(0,T;H\times U)} + \langle \nabla l_\varepsilon(x_\varepsilon(T)), x_\varepsilon(T) - x(T)\rangle_H \\ &+ \int_0^T \langle u_\varepsilon - u, u_\varepsilon - u^*\rangle_U \, dt - \int_0^T \langle x' + Ax - Bu - f, r_\varepsilon\rangle_{V'\times V} \, dt \le 0\end{aligned}$$

for any $[x, u]$ in D.

Now we define the simplified adjoint system

$$(2.8)\qquad -p'_\varepsilon + A^*(t)p_\varepsilon = \nabla_x L_\varepsilon(x_\varepsilon, u_\varepsilon),$$

$$(2.9)\qquad p_\varepsilon(T) = \nabla l_\varepsilon(x_\varepsilon(T)),$$

where A^* denotes the adjoint operator of A.

Multiply (2.8) by $x_\varepsilon - x$ for any x in $\mathcal{X}$ such that $x(0) = x^o$, and integrating by parts we get

$$\begin{aligned}(2.10)\qquad \langle \nabla_x L_\varepsilon(x_\varepsilon, u_\varepsilon), x_\varepsilon - x\rangle_{L^2(0,T;H)} &= \int_0^T \langle -p'_\varepsilon + A^*p_\varepsilon, x_\varepsilon - x\rangle_H \, dt \\ &= \int_0^T \langle x'_\varepsilon - x' + A(x_\varepsilon - x), p_\varepsilon\rangle_{V'\times V} \, dt \\ &\quad - \langle \nabla l_\varepsilon(x_\varepsilon(T)), x_\varepsilon(T) - x(T)\rangle_H .\end{aligned}$$

Replacing (2.10) in (2.6), we obtain the equivalent form

$$\begin{aligned}(2.11)\qquad &\langle \nabla_u L_\varepsilon(x_\varepsilon,u_\varepsilon),u_\varepsilon-u\rangle_{L^2(0,T;U)}+\int_0^T \langle x_\varepsilon'-x'+A(x_\varepsilon-x),p_\varepsilon\rangle_{V'\times V}\,dt\\ &+\int_0^T \langle u_\varepsilon-u,u_\varepsilon-u^*\rangle_U\,dt-\int_0^T \langle x'+Ax-Bu-f,J(r_\varepsilon)\rangle_{V'}\,dt\\ &\qquad\le -\varepsilon\|J(r_\varepsilon)\|^2_{L^2(0,T;V')}\le 0\end{aligned}$$

for any $[x,u]$ in D.

Taking in turn $u=u_\varepsilon$, $x=x_\varepsilon$, a short computation provides the following decoupled system:

$$(2.12)\qquad \int_0^T \langle x_\varepsilon'-x'+Ax_\varepsilon-Ax,p_\varepsilon+r_\varepsilon\rangle_{V'\times V}\,dt\le 0,$$

$$\begin{aligned}(2.13)\qquad &\int_0^T \langle u_\varepsilon-u,u_\varepsilon-u^*\rangle_U\,dt+\langle \nabla_u L_\varepsilon(x_\varepsilon,u_\varepsilon),u_\varepsilon-u\rangle_{L^2(0,T;U)}\\ &\qquad-\int_0^T \langle u_\varepsilon-u,B^*J(r_\varepsilon)\rangle_U\,dt\le 0\end{aligned}$$

for any $[x,u]$ such that $[x,u_\varepsilon]\in D$ and $[x_\varepsilon,u]\in D$.

Remark 2.3. The relations (2.8)–(2.9) and (2.12)–(2.13) give the optimality conditions for the problem (P_ε) in a more usual form. In particular, if $D=K\times U_{\mathrm{ad}}$ (i.e., the constraints are separate) and if $\mathcal{N}(u_\varepsilon)$ denotes the normal cone to the control constraints set at u_ε, that is,

$$\mathcal{N}(u_\varepsilon)=\{\,z\in L^2(0,T;U)\mid \langle z,u_\varepsilon-u\rangle_{L^2(0,T;U)}\ge 0\ \forall u\in U_{\mathrm{ad}}\,\},$$

then (2.13) becomes

$$\nabla_u L_\varepsilon(x_\varepsilon,u_\varepsilon)+u_\varepsilon-u^*+\mathcal{N}(u_\varepsilon)\ni B^*J(r_\varepsilon),$$

which is a standard form of the Pontryagin maximum principle (Barbu and Precupanu [3, Chap. IV] and Tiba [14, Chap. II]).

PROPOSITION 2.3. *On a subsequence, we have*

$$(2.14)\qquad \nabla l_\varepsilon(x_\varepsilon(T))\rightharpoonup w\in\partial l(x^*(T))\ \textit{weakly in } H,$$

$$(2.15)\qquad \nabla L_\varepsilon(x_\varepsilon,u_\varepsilon)\rightharpoonup (w_1,w_2)\in\partial L(x^*,u^*)\ \textit{weakly in } L^2(0,T;H\times U),$$

$$(2.16)\qquad p_\varepsilon\to p^*\ \textit{strongly in } C(0,T;H),$$

where p^* is the solution of the simplified adjoint system

$$(2.17)\qquad -\frac{dp^*}{dt}+A^*p^*=w_1,$$

$$(2.18)\qquad p^*(T)=w.$$

Proof. We have $\nabla L_\varepsilon(x_\varepsilon, u_\varepsilon) \in \partial L((I+\varepsilon\partial L)^{-1})(x_\varepsilon, u_\varepsilon)$. With an argument similar to the one in the proof of Proposition 2.1, it yields that $(I+\varepsilon\partial L)^{-1})(x_\varepsilon, u_\varepsilon)$ strongly converges to $[x^*, u^*]$ in $L^2(0,T; H \times U)$. As L is continuous, it is everywhere subdifferentiable and ∂L is locally bounded. Then $\nabla L_\varepsilon(x_\varepsilon, u_\varepsilon)$ is bounded in $L^2(0,T; H \times U)$ and (2.15) is a consequence of the demiclosedness of maximal monotone operators.

The argument is the same for relation (2.14), and (2.16)–(2.18) may be obtained by taking the limit in (2.8)–(2.9). □

PROPOSITION 2.4. *Under hypothesis* $(\mathcal{H})$, (r_ε) *is bounded in* $L^2(0,T;V)$ *and* $r_\varepsilon \rightharpoonup r^*$ *on a subsequence weakly in* $L^2(0,T;V)$.

Proof. We use the relation (2.7) and take test functions $[x_\xi, u_\xi] \in \mathcal{M} \subset D$ such that

$$T(x_\xi, u_\xi) = \rho\, \xi$$

for any $\xi \in L^2(0,T;V')$ such that $\|\xi\|_{L^2(0,T;V')} = 1$ and for some $\rho > 0$. The boundedness of $\mathcal{M}$ and Propositions 2.1 and 2.3 allow us to infer

$$\rho \int_0^T \langle \xi, r_\varepsilon \rangle_{V' \times V}\, dt \;\leq\; c,$$

where c is an absolute constant independent of $\varepsilon > 0$ and ξ. □

We finally have the following theorem.

THEOREM 2.1. *If the pair* $[x^*, u^*]$ *is optimal for the problem* (P), *then*

$$\int_0^T \langle x^{*\prime} - x' + Ax^* - Ax, p^* + r^* \rangle_{V' \times V}\; dt \;\leq 0, \tag{2.19}$$

$$\langle w_2, u^* - u \rangle_{L^2(0,T;U)} - \int_0^T \langle u^* - u, B^* J^{-1}(r^*) \rangle_U\; dt \;\leq 0 \tag{2.20}$$

for any $[x,u]$ *such that* $[x,u^*] \in D$ *and* $[x^*,u] \in D$.

Moreover the inequality summing (2.19) *and* (2.20) *is valid for any* $[x,u] \in D$; *it is also sufficient for the optimality of* $[x^*,u^*]$.

Proof. The necessity has been established with the previous sequence of propositions. Let us prove the sufficiency of the condition. Let $[x,u]$ be any feasible pair for (P) and add (2.19) and (2.20):

$$\int_0^T \langle x^{*\prime} - x' + Ax^* - Ax, p^* + r^* \rangle_{V' \times V}\, dt + \langle w_2, u^* - u \rangle_{L^2(0,T;U)} - \int_0^T \langle Bu^* - Bu, r^* \rangle_{V' \times V}\, dt \leq 0.$$

As $[x,u]$ is feasible, we get

$$\langle w_2, u^* - u \rangle_{L^2(0,T;U)} + \int_0^T \langle x^{*\prime} - x' + Ax^* - Ax, p^* \rangle_{V' \times V}\; dt \;\leq 0\,.$$

Integrating by parts and taking in account the adjoint equation, we obtain

$$\langle w_2, u^* - u \rangle_{L^2(0,T;U)} + \langle w_1, x^* - x \rangle_{L^2(0,T;H)} + \langle w, x^*(T) - x(T) \rangle_H \leq 0\,.$$

The definition of the subdifferential achieves the proof. □

Remark 2.4. To get a better insight into the relation (2.19), let us assume that $D = K \times U_{ad}$ (closed convex subsets in appropriate spaces). Let r^* be in $\mathcal{X}$ (regularity). Then (2.19) can be written as follows:

$$\int_0^T \langle \partial_x L(x^*, u^*) - r^{*\prime} + A^* r^*, x^* - x \rangle_{V \times V'} \, dt + \langle \partial l(x^*(T)) + r^*(T), x^*(T) - x(T) \rangle_H \leq 0 \tag{2.21}$$

by partial integration and for any x in K. If we consider the evolution system, which gives the adjoint equation of Barbu and Precupanu [3],

$$-\frac{dr^*}{dt} + A^*(t) r^* + \partial 1_K(x^*) \ni -\partial_x L(x^*, u^*) \quad \text{a.e. in }]0, T[, \tag{2.22}$$

$$r^*(T) \in -\partial l(x^*(T)), \tag{2.23}$$

(where 1_K is the indicatrix function of K), then (2.21) is as a weak variant of (2.22)–(2.23). In particular, when no state constraints are imposed, one may easily infer that $p^* = -r^*$. We see that condition $(\mathcal{H})$ yields the existence of a Lagrange multiplier, while $(\mathcal{S})$ ensures better regularity properties for it (Barbu and Precupanu [3]).

Remark 2.5. The form of the optimality conditions may also be compared with the works of Bonnans and Casas [8, 9]. Basically, we decouple the influence of the state constraints from the adjoint equation and put it as an independent inequality (2.19). The remaining simplified adjoint system (2.17)–(2.18) just performs the necessary integrations by parts in order to reexpress the gradient of the cost functional, and it is identical to the case without any state constraints (Lions [11]). This also avoids the delicate analysis of adjoint systems with measures as data, which is necessary when the classical approach is used (Casas [10]).

3. Some applications. Let $W \subset L^2(0, T; V')$ continuously, densely be a Banach space. We replace $(\mathcal{H})$ with the weaker variant

$$\begin{aligned} &\exists \mathcal{M} \subset D \text{ bounded in } \mathcal{C}(0, T; H) \times L^2(0, T; U) \text{ such that} \\ &0 \in \text{Int } T(\mathcal{M}) \text{ in the } W \text{ topology.} \end{aligned} \tag{$\mathcal{H}'$}$$

Since condition $(\mathcal{H})$ is used only in the proof of Proposition 2.4, then Propositions 2.1–2.3 remain valid. We also ask the following pairing compatibility condition, which is automatically fulfilled in many examples:

$$\langle v, w \rangle_{W \times W'} = \int_0^T \langle v, w \rangle_{V \times V'} \tag{3.1}$$

when both terms have sense. We keep the notations of the proof of Proposition 2.4. Condition $(\mathcal{H}')$ yields that

$$\rho \ \langle \xi, r_\varepsilon \rangle_{W \times W'} < \ c; \tag{3.2}$$

that is, (r_ε) is bounded in the "larger" space W' instead of $L^2(0, T; V)$. Let r^* denote a weak * cluster point for this set.

THEOREM 3.1. *The pair* $[x^*, u^*]$ *is an optimal pair for* (P) *if and only if*

$$\langle w_2, u^* - u \rangle_{L^2(0,T;U)} + \int_0^T \langle x^{*\prime} - x' + Ax^* - Ax, p^* \rangle_{V' \times V} \, dt - \langle x' + Ax - Bu - f, r^* \rangle_{W \times W'} \leq 0 \tag{3.3}$$

for any $[x,u]$ *such that* $T(x,u) \in W$.

Proof. Necessity is a direct consequence of (2.7) and (3.2) since one may pass to the limit in all the terms if $T(x,u) \in W$.

For the sufficiency we notice that any feasible pair for (P) satisfies $T(x,u) = 0 \in W$. Then (3.3) may be used, and only the first two terms will remain. The proof is completed as in Theorem 2.1. □

Remark 3.1. In applications, $T(x,u) \in W$ may be valid for any pair $[x,u] \in D$, or this may be equivalent to a regularity condition which is possible to include in the definition of the state and control spaces. See [9] for the details of this technique in a different setting.

3.1. A first example: Empty interior constraints. We analyse in some detail the following example of optimal control problem governed by a parabolic partial differential equation

$$\text{(PP)} \qquad \text{Min} \left\{ \frac{1}{2} \int_Q (y - z_d)^2 \, dx \, dt + \frac{N}{2} \int_Q u^2 \, dx \, dt \right\}$$

subject to

$$\frac{\partial y}{\partial t} - \Delta y = f + u \quad \text{in } Q = \Omega \times]0,T[, \tag{3.4}$$

$$y(x,t) = 0 \quad \text{on } \Sigma = \partial\Omega \times]0,T[, \tag{3.5}$$

$$y(x,0) = y_o(x) \quad \text{in } \Omega \tag{3.6}$$

and the constraints

$$e(x,t) \le y(x,t) \le g(x,t) \quad \text{a.e. in } Q, \tag{3.7}$$

$$a(x,t) \le u(x,t) \le b(x,t) \quad \text{a.e. in } Q. \tag{3.8}$$

Here Ω is a smooth, open, and bounded domain of $\mathbb{R}^n$; $z_d \in L^2(Q)$; $N \ge 0$; $y_o \in L^2(\Omega)$; f, a, and b are in $L^\infty(Q)$; and e and g in $C(\bar{Q})$. We denote

$$K = \{ \, y \in L^2(0,T; H_o^1(\Omega)) \cap W^{1,2}(0,T; H^{-1}(\Omega)) \mid e \le y \le g, \; y(.,0) = y_o \, \},$$

$$U_{\text{ad}} = \{ \, u \in L^2(Q) \mid a \le u \le b \;\; \text{a.e. in } Q \, \},$$

$$D = K \times U_{\text{ad}},$$

which are closed convex sets. One has to assume the compatibility condition

$$e \le y^o \le g \qquad \text{in } \Omega$$

and some admissibility hypothesis. We ask

$$(\mathcal{E}) \qquad \exists \alpha > 0, \; \exists \tilde{u} \in U_{\text{ad}} \quad \text{such that} \quad e \le Y(\tilde{u} - \alpha) \le Y(\tilde{u} + \alpha) \le g \qquad \text{in } Q,$$

where Y is the solution operator $u \mapsto y$ defined by (3.4)–(3.6). By comparison, $(\mathcal{E})$ implies that the pair $[\tilde{u}, Y(\tilde{u})]$ is feasible for (PP). However, this is not an interiority assumption since e may be equal to g in some points. For instance, we may allow $e(x,t) = g(x,t) = 0$ on the border of the domain. Moreover, the mappings $\tilde{u} + \alpha, \tilde{u} - \alpha$ need not belong to U_{ad}, which may also have a void interior, i.e., $a = b$ on some subset.

Remark 3.2. A stronger variant of $(\mathcal{E})$ is that there exist two controls $\tilde{u}, \hat{u}$ feasible for (PP), which can be "strictly separated." It means that $(\mathcal{E})$ is stronger than the standard admissibility assumption but weaker than the hypothesis of existence of two feasible pairs (with this separation property). As $(\mathcal{E})$, in turn, yields $(\mathcal{H}')$, this gives a hint on the generality of the hypothesis $(\mathcal{H}')$. Moreover $(\mathcal{H}')$ requires that the problem (P) is nontrivial; that is, the set of admissible pairs is "rich."

In order to apply the abstract theory, we take the spaces $V = H_o^1(\Omega)$, $H = U = L^2(\Omega)$; the operators $A(t) : V \to V'$, $A(t)z = -\Delta z$, $B : H \to V'$, $B = i$, the canonical injection; and the mappings $l = 0$ and

$$L(y,u) = \frac{1}{2}\int_Q (y - z_d)^2 \, dx \, dt + \frac{N}{2}\int_Q u^2 \, dx \, dt.$$

The hypothesis $(\mathcal{H}')$ is a clear consequence of $(\mathcal{E})$ with $W = L^\infty(Q)$ by fixing

$$y_\xi = Y(u_\xi) = Y(\tilde{u} + \alpha\xi), \quad \xi \in W, \ \|\xi\|_W = 1.$$

Again a comparison argument shows that $[y_\xi, u_\xi] \in D$ for any ξ as above, and we can choose in $(\mathcal{H}')$ the bounded set

$$\mathcal{M} = \text{ conv } \{ \, [y_\xi, u_\xi] \mid \xi \in W, \ \|\xi\|_W = 1 \, \}.$$

Then relation (3.3) may be rewritten as

$$\begin{aligned} \int_Q Nu^*(u^* - u) \, dx \, dt + \int_Q (y^{*\prime} - y' - \Delta(y^* - y))p^* \, dx \, dt \\ - \langle y' - \Delta y - u - f, r^* \rangle_{W \times W'} \leq 0 \end{aligned} \tag{3.9}$$

for any y in K, u in U_{ad} such that $T(y,u) \in W = L^\infty(Q)$.

Note also that, since $f \in W, U_{\text{ad}} \subset W$, the last condition $(T(y,u) \in W = L^\infty(Q))$ is equivalent to a regularity condition on y : $y' - \Delta y \in L^\infty(Q)$, which is satisfied by y^*.

Here $[y^*, u^*]$ is the optimal pair of (PP), and p^* satisfies

$$\begin{aligned} -p^{*\prime} - \Delta p^* &= y^* - z_d \quad \text{in } Q, \\ p^* &= 0 \quad \text{on } \Sigma, \\ p^*(T) &= 0 \quad \text{in } \Omega. \end{aligned}$$

Choosing in turn $u = u^*$ and $y = y^*$ in (3.9), we get

(3.10)
$$\forall y \in K \text{ such that } y' - \Delta y \in L^\infty(Q) \qquad \langle y^{*\prime} - y' - \Delta(y^* - y), p^* + r^* \rangle_{W \times W'} \leq 0,$$

$$\forall u \in U_{\text{ad}} \qquad \langle Nu^* - r^*, u^* - u \rangle_{W \times W'} \leq 0. \tag{3.11}$$

The relations (3.10) and (3.11) represent the decoupled form of the optimality condition (3.9) and may be compared with (2.19) and (2.20).

Now we are going to use these above relations to get some more precise information about the optimal pair. Let us define the sets

$$Q_e = \{ \, (x,t) \in \bar{Q} \mid y^*(x,t) = e(x,t) \, \}, \qquad Q_g = \{ \, (x,t) \in \bar{Q} \mid y^*(x,t) = g(x,t) \, \},$$

$$Q^o = Q - (Q_e \cup Q_g) \ .$$

Thanks to (3.4)–(3.6) and the Sobolev embedding theorem, we infer that $y^* \in C(\bar{Q})$ if y_o is regular. Then Q_e and Q_g are closed sets and Q^o is an open subset of Q. Let $d \in \mathcal{D}(Q)$ be a test function with compact support supp $d \subset Q^o$. By the continuity of y^*, e, g and the compactness of supp d, one can find $\rho > 0$ such that $y^* + \rho d$ and $y^* - \rho d$ remain in K. Obviously, they are also regular, and we can use them in (3.10) as test functions to infer

$$\left\langle p^* + r^*, \frac{\partial d}{\partial t} - \Delta d \right\rangle_{W \times W'} = 0$$

for any $d \in \mathcal{D}(Q)$ with compact support in Q^o. Taking in account this relation and the equation satisfied by p^*, we see that there exists a distribution $j \in \mathcal{D}'(Q)$ with support included in $Q - Q^o$ such that

$$\frac{\partial r^*}{\partial t} - \Delta r^* + j = y^* - z_d \qquad \text{in } \mathcal{D}'(Q). \tag{3.12}$$

The previous equation is another familiar form of the adjoint system for state constrained control problems. In particular, it shows that $r^* \in W^{2,1,p}_{loc}(Q^o)$ for $p > 1$ if z_d belongs to $L^p(Q)$. Then $r^* \in C(Q^o)$ by the Sobolev theorem if p is big enough.

We are now prepared to give a result on the structure of the optimal pair of (PP), which may be termed a generalized bang-bang result (Tröltzsch [16]). We suppose from here that $N = 0$.

COROLLARY 3.1. *We have*

$$\begin{aligned} Q^o \subseteq & \{ \ (x,t) \mid y^*(x,t) = z_d(x,t) \ \} \\ & \cup \{ \ (x,t) \mid u^*(x,t) = a(x,t) \ \} \cup \{ \ (x,t) \mid u^*(x,t) = b(x,t) \ \}. \end{aligned}$$

Proof. Choose $u = u^*$ in $Q - Q^o$ so that (3.11) yields

$$\forall u \in U_{\text{ad}} \qquad \int_{Q^o} r^*(u^* - u) \, dx \, dt \ \geq 0. \tag{3.13}$$

Since $r^* \in C(Q^o)$, obviously

$$\begin{aligned} Q^o = & \{ \ (x,t) \in Q^o \mid r^*(x,t) > 0 \ \} \\ & \cup \{ \ (x,t) \in Q^o \mid r^*(x,t) < 0 \ \} \cup \{ \ (x,t) \in Q^o \mid r^*(x,t) = 0 \ \} \end{aligned}$$

and (3.13) shows that $u^* = b$ on the first set and $u^* = a$ on the second set. If the last set has positive measure, then (3.12) and the maximal regularity of r^* on Q^o give that $y^* = z_d$ on this subset. □

Remark 3.3. Taking into account the definition of Q^o, we see that at least one from y^* and u^* equals the extremal values e, g, a, b, or z_d in any point of Q. A similar analysis may be pursued when $N > 0$, but the structure of the optimal pair will be more complicated.

3.2. A second example: "Bottleneck" problems. We examine "bottleneck"-type problems, which were introduced by Bellman [4] in connection with some models for industrial production processes. They were discussed by a different approach in the work of Miricà [13].

We assume that the state equation and the cost functional are the same as in the previous example, with $f \in L^\infty(Q)$, $y_o \in W_o^{1,\infty}(\Omega) \cap W^{2,\infty}(\Omega)$, $y_o \geq 0$ a.e. in Ω, but the constraint has the form

$$|y| \leq u \quad \text{a.e. in } Q. \tag{3.14}$$

This is equivalent to $-u \leq y \leq u$, so the set D defined by (3.14) is convex.

Remark 3.4. If $f \geq 0$, the maximum principle gives $y \geq 0$ (with (3.4)) and the constraint (3.14) is equivalent to

$$0 \leq y \leq u \quad \text{a.e. in } Q, \tag{3.14$'$}$$

which is the original form considered by Bellman [4]. We also emphasize that the boundary condition (3.5) shows that the feasible pairs *are not* in the interior of D even in the $L^\infty(Q)$-topology; that is, Slater-type conditions cannot be valid in (3.14′).

Now take $\tilde{u} = \alpha e^t$, $\alpha > 0$, and $\tilde{y}$, the solution of (3.4)–(3.6) associated with $\tilde{u}$. If α is great enough, then $f + \tilde{u} \geq 0$ a.e. in Q and $\tilde{y} \geq 0$ a.e. in Q by the maximum principle. Let $w = \alpha e^t - \alpha \geq 0$ a.e. in Q. We notice that w satisfies

$$\begin{array}{rcll} \dfrac{\partial w}{\partial t} - \Delta w & = & \alpha e^t & \text{in } Q, \\ w & = & (\alpha e^t - \alpha)_{|\Sigma} \quad \geq 0 & \text{on } \Sigma, \\ w(0) & = & 0 & \text{in } \Omega. \end{array} \tag{3.15}$$

Let us denote by y^v the solution of (3.4)–(3.6) associated with v (so that y^o is associated with $v = 0$). By comparison, it yields that $w \geq \tilde{y} - y^o$; that is, $\tilde{u} - \alpha + y^o \geq \tilde{y} \geq 0$. There is some constant m such that $-m \leq y^o \leq m$ a.e. in Q. Then if $\alpha > 2m$ is large enough, we have

$$0 \leq \tilde{y} \leq \tilde{u} - m \qquad \text{a.e. in } Q. \tag{3.16}$$

The pair $[\tilde{y}, \tilde{u}]$ is feasible and (3.16) shows that hypothesis $(\mathcal{H}')$ is satisfied. Indeed we take

$$\mathcal{M} = \{\ [y^v, \tilde{u}] \mid v \in B_{L^p(Q)}(\tilde{u}, \lambda)\ \}, \qquad p > \frac{n+2}{2},$$

where $B_{L^p(Q)}(\tilde{u}, \lambda)$ is the L^p-ball centered in $\tilde{u}$ with radius λ and $\lambda > 0$ is small. By the continuity with respect of the right-hand side and the Sobolev embedding theorem, we can choose λ such that

$$\|\tilde{y} - y_v\|_{C(\bar{Q})} \leq m,$$

that is, $\mathcal{M} \subset D$. Moreover $T(\mathcal{M}) = B_{L^p(Q)}(0, \lambda)$ and $(\mathcal{H}')$ is fulfilled in $L^p(Q)$. If $n = 1$, we may take $p = 2$ and even condition $(\mathcal{H})$ is fulfilled.

Remark 3.5. We also notice that for the "linear" constraint (3.14′), a simpler argument may be used. For instance, we may define the new control function

$$\varphi = y - u,$$

and D may be reexpressed in the "decoupled" form

$$y \geq 0, \quad \varphi \leq 0 \text{ a.e. in } Q.$$

The same substitution may be performed in (3.4)–(3.6) and in the cost functional so that the penalization method from §2 may be used directly.

Finally, we prove that a generalized bang-bang result also remains valid in this case under some regularity assumptions.

COROLLARY 3.2. *Let N be equal to 0, and assume that y^*, u^* exist and are continuous functions on $\bar{Q}$. Then*

$$(3.17)\quad Q = \{\ (x,t) \in Q \mid |y^*(x,t)| = u^*(x,t)\ \} \cup \{\ (x,t) \in Q \mid y^*(x,t) = z_d(x,t)\ \}.$$

(The two sets above need not be disjoint. The first one corresponds to the case where the constraint is active.)

Proof. As hypothesis $(\mathcal{H}')$ is fulfilled, Theorem (3.1) gives the existence of $r^* \in L^q(Q)$ where $\frac{1}{p} + \frac{1}{q} = 1$ and

$$(3.18)\quad \int_Q (y^{*\prime} - y' - \Delta(y^* - y))p^*\ dx\ dt - \int_Q (y' - \Delta y - u - f)r^*\ dx\ dt \le 0$$

for any $[y,u] \in D$ such that $T(y,u) \in L^p(Q)$.

Here we used that $N = 0$ and p^* is given by

$$(3.19)\quad \begin{array}{rcll} -p^{*\prime} - \Delta p^* & = & y^* - z_d & \text{in } Q, \\ p^* & = & 0 & \text{on } \Sigma, \\ p^*(T) & = & 0 & \text{in } \Omega. \end{array}$$

Let $Q^* \subset Q$ be the open set defined as follows:

$$Q^* = \{(x,t) \in Q \mid |y^*(x,t)| < u^*(x,t)\},$$

where the constraint is inactive. First we take test pairs of the type

$$[y,u] = [y^* \pm \lambda_d d, u^*] \in D,$$

where $d \in \mathcal{D}(Q)$, supp $d \subset Q^*$, and $\lambda_d > 0$ is a small constant given by the Weierstrass theorem applied to the continuous functions $|y^*|$, u^* on the compact set supp d such that

$$|y^*(x,t) \pm \lambda_d d(x,t)| \le |y^*(x,t)| + \lambda_d |d(x,t)| \le u^*(x,t).$$

Thanks to (3.18), we obtain after a short calculation that

$$(3.20)\quad \int_Q (d' - \Delta d)(p^* + r^*)\ dx\ dt = 0$$

for every $d \in \mathcal{D}(Q)$ with compact support in Q^*. Then, we may find a distribution $j \in \mathcal{D}'(Q)$ with support in $Q - Q^*$ (active constraints set) such that

$$(3.21)\quad \frac{\partial r^*}{\partial t} + \Delta r^* + j = y^* - z_d \quad \text{in } \mathcal{D}'(Q).$$

This follows from (3.19) and (3.20) and implies a local regularity property for the Lagrange multiplier r^* : $r^* \in W^{2,1,2}_{\text{loc}}(Q^*)$ since $z_d \in L^2(Q)$.

Now let us take the test pairs

$$[y,u] = [y^*, u^* \pm \lambda_d d\ ] \in D,$$

where d, λ_d are as above. Again, by (3.18) we get

$$\int_Q d \quad r^* \, dx \, dt = 0.$$

Multiplying (3.21) by d, we infer

$$\int_Q d(y^* - z_d) \, dx \, dt = \langle r^{*\prime} + \Delta r^*, d \rangle_{\mathcal{D}'(Q) \times \mathcal{D}(Q)} = - \int_Q r^*(d' - \Delta d) \, dx \, dt = 0$$

for any $d \in \mathcal{D}(Q)$ with support in Q^*. This proves that $y^* = z_d$ in Q^*, and the proof is complete. □

STOCHASTIC APPROXIMATION METHODS FOR SYSTEMS OVER AN INFINITE HORIZON*

HAROLD J. KUSHNER† AND FELISA J. VÁZQUEZ-ABAD‡

Abstract. The paper develops efficient and general stochastic approximation (SA) methods for improving the operation of parametrized systems of either the continuous- or discrete-event dynamical systems types and which are of interest over a long time period. For example, one might wish to optimize or improve the stationary (or average cost per unit time) performance by adjusting the systems parameters. The number of applications and the associated literature are increasing at a rapid rate. This is partly due to the increasing activity in computing pathwise derivatives and adapting them to the average-cost problem. Although the original motivation and the examples come from an interest in the infinite-horizon problem, the techniques and results are of general applicability in SA. We present an updating and review of powerful ordinary differential equation–type methods, in a fairly general context, and based on weak convergence ideas. The results and proof techniques are applicable to a wide variety of applications. Exploiting the full potential of these ideas can greatly simplify and extend much current work. Their breadth as well as the relative ease of using the basic ideas are illustrated in detail via typical examples drawn from discrete-event dynamical systems, piecewise deterministic dynamical systems, and a stochastic differential equations model. In these particular illustrations, we use either infinitesimal perturbation analysis–type estimators, mean square derivative-type estimators, or finite-difference type estimators. Markov and non-Markov models are discussed. The algorithms for distributed/asynchronous updating as well as the fully synchronous schemes are developed.

Key words. stochastic approximation, ordinary differential equation method, weak convergence, recursive optimization, Monte Carlo optimization, discrete-event dynamical systems, piecewise deterministic dynamical systems, stationary cost problems

1. Introduction.

The paper is concerned with efficient and general stochastic approximation (SA) methods for parametrized systems of either continuous or discrete event dynamical systems that are of interest over a long time period. For example, one might wish to optimize or improve the stationary (or average cost per unit time) performance by adjusting the systems parameters. The number of applications and the associated literature are increasing at a rapid rate. Although the motivation and examples come from an interest in this infinite-horizon problem, the techniques and results are of general applicability in SA. Basic techniques for such problems have appeared in [2, 22, 27]. These techniques are still fundamental for applications to to the general problems of current interest. Exploiting their full potential can greatly simplify and extend much current work. We present a full development of the basic ideas in [22, 27] and related works in a more general context, with the particular goal of illustrating their breadth as well as the relative ease of using them in particular applications.

To fix ideas, let θ denote an adjustable parameter of a dynamical system and $x(\cdot,\theta)$ the associated system state process. For a cost rate $c(\theta,x)$, define $C_T(\theta,x(0)) = E\int_0^T c(\theta,x(t,\theta))dt/T$ and $C(\theta,x(0)) = \lim C_T(\theta,x(0))$. We wish to minimize $C(\theta,x(0))$

by the dynamic adjustment of the parameter θ, using estimates of the derivatives made from measurements of the sample path. Indeed, much of the recent interest in SA methods has been motivated by the increasing availability of good estimators of the derivatives of objects such as $C_T(\theta, x(0))$, say, of the infinitesimal perturbation analysis (IPA) or related types [13, 14, 18, 34, 42, 45] or of the mean square derivative type [5]. With ϵ_n a step-size parameter and θ_n the nth estimate of the parameter, the basic SA algorithm is $\theta_{n+1} = \theta_n + \epsilon_n Y_n$, where Y_n is the measurement used for the current update. One is concerned with the asymptotic properties of the sequence θ_n. The ordinary differential equations (ODE) method shows that the asymptotic properties can be characterized in terms of the limit properties of the solution to an ODE $\dot{\theta} = g(\theta)$, where, loosely speaking, $g(\theta)$ is the stationary mean value of Y_n given that the parameter value is always fixed at θ. Thus the individual Y_n themselves need not be (asymptotically) unbiased estimators of the gradient at the current parameter values. The fact that the estimators are taken over a finite time interval but one actually wishes to use them effectively for the infinite-time problem has led to various ad hoc approaches, often driven by the proof technique. One technique was to let the successive estimation intervals go to infinity. It will appear from the results in §§3–5 (a direct consequence of the results in [22, 27]) that to get the desired limit result one generally need not reinitialize the estimator periodically nor let the intervals go to infinity. One basically does what is more natural: keep the successive updating time intervals bounded and appropriately update the estimator without "reinitializing" it. The proofs of such results are the essence of the "local averaging" intuition in the ODE method, initiated by Ljung [33], although the techniques used here are quite different.

The paper is not concerned with optimization per se but rather with getting the appropriate ODE for the SA algorithm of interest and in showing the great flexibility in the algorithms that one can use and analyze. For the optimization problem, one generally needs to show that the solution of the ODE converges to the desired point, and this requires a closer look at the right-hand side of the ODE. In some cases, this involves showing that the right side of the ODE is the negative of the gradient of a desired cost function with a particular structure. Indeed, in §§7 and 8, we show that the right side is indeed the negative of the gradient of the desired ergodic cost. But in any application, one needs first to characterize the correct ODE and then to analyze the limits of its solutions. The latter job is highly problem dependent.

One can try to prove that the convergence either is with probability one (w.p.1) or is in a weak (or generalized distributional) sense. Our framework for getting the asymptotic properties is that of weak convergence. This allows the use of what might be the simplest mathematical techniques and conditions. For example, for the SA with decreasing step sizes $0 < \epsilon_n \to 0$ satisfying $\sum \epsilon_n = \infty$, no additional conditions need be imposed on the ϵ_n. Conditions of the often used type [2] $\sum \epsilon_n^{1+\alpha} < \infty$ for some $\alpha > 0$ are not needed. The sequence of estimators need only be uniformly integrable, and no additional moment conditions are needed. The weak convergence technique correctly identifies the places where the process spends either almost all or all of its (asymptotic) time, and gives us a fairly complete stability structure of the algorithm.

For the decreasing step-size algorithms, the difference between the probability-one and the weak convergence results is not as great as what one might at first suppose. Indeed, known results show that under quite weak additional conditions, probability one convergence follows directly from the weak convergence results, and we

now comment loosely on this. Suppose that the ODE is locally asymptotically stable about a point θ^* with open domain of attraction Γ. The ODE method associated with the weak convergence approach quite generally allows us to show that some such set Γ is entered infinitely often. Then, under very weak conditions, one can appeal to existing applications of large deviations methods to SA's to get probability one convergence. This idea is fully developed in [9]. Among other things, it is shown in this reference that one gets probability one convergence with the only additional requirement on the step-size sequence ϵ_n is that it satisfy

$$\sum_n e^{-\delta/\epsilon_n} < \infty$$

for each $\delta > 0$. That is, we need only that $\epsilon_n < c_n/\log n$, where $c_n \to 0$. The conditions on the noise process in [9] are satisfied by the usual processes that are not too "heavily tailed," and for such processes these probability one convergence results might be about the best now available. The main point is that once the weak convergence results are available, probability one results follow directly from existing works under broad conditions, and the basic weak convergence techniques are very much simpler than those required for probability-one convergence.

It is worth noting that in applications, probability-one results might be of illusory advantage over weak convergence results. The algorithms generally have stopping rules and, when these are applied, one generally has only probabilistic or distributional information about the last iterate.

We are also concerned with constant step size cases where one can only use weak (and not w.p.1) convergence ideas. Indeed, in problems of tracking time-varying systems one must use constant step sizes. In adaptive problems in communication theory and signal processing, constant step sizes are the common practice. Even if the problem is such that decreasing step sizes can be used, one often lets them be constant due to robustness considerations. Indeed, in practice one often prefers algorithms which get to a neighborhood of the desired point quickly, and this argues for a constant step size.

The development in the paper requires only some of the elementary concepts from the theory of weak convergence. These are reviewed in §2. Perhaps the only required nonelementary fact concerns the use in Theorem 3.1 of random variables which are measure valued. Our application of this concept is straightforward, since for our purposes the important facts concerning such random variables are determined by their mean values and will be implied by the conditions imposed on the "noise" terms. The concept of measure-valued random variables allows us to deal more easily than in the past with unbounded noise.

The basic result of the paper is Theorem 3.1. It is basic in that it lays out the fundamental ideas of the averaging method, and most subsequent results can be derived by mild modifications of the technique of that theorem. The theorem is for the constant-step-size case. But, as seen in §4, the case where $\epsilon_n \to 0$ differs only in the way certain terms are grouped in the proof. In Theorem 3.1, we have tried to use conditions that are fairly general. Since one's imagination in constructing algorithms is endless, no set of conditions is "completely general." But it will be seen that the conditions used are quite minimal, and allow the few basic ideas to be exposed. The first basic idea is to repose the problem as a "martingale problem," which allows us to replace the noise terms by appropriate conditional expectations given the past, and greatly facilitates the averaging. Then we are confronted by the fact that the

noise at step n can depend on the values of the state at that time as well as at previous times. In Theorem 3.1, this is handled in a convenient way (coming originally from [27]) by the use of a Markov model for the joint (noise, state) process, and imposing appropriate weak continuity conditions on the transition function. (Non-Markov models are treated in Appendix 1, but the Markov assumption in Theorem 3.1 is quite powerful, since the state space can be a complete separable metric space, thus allowing convenient "Markovianizations.") In doing the local averaging to get the appropriate ODE, these weak continuity assumptions allow us to average as though the state did not change. They facilitate the use of the appropriate (mean) ergodic theorems for the noise processes which, for the purposes of averaging, can be assumed to evolve as though the state did not change. These few basic and powerful ideas underlie all the results and are widely adaptable. The averaging idea of Theorem 3.1 is like that in [27] but is somewhat more general, particularly in the treatment of unbounded noise.

Section 3.2 concerns the asymptotic points of the algorithm, and in Theorem 3.2 they are identified with the two-sided invariant set (in the sense of dynamical systems theory) of the ODE. The other parts of §3 concern the simplifications when the basic observation has an "additive" character or the problem has a regenerative structure and one wishes to update at the regeneration times. This "additivity" property is common to numerous applications, as seen in §§6–9. In general, updating at regenerative intervals, even if the process has a regenerative structure, is not needed and might not even be a good idea. More will be said about this later. It is certainly inadvisable when the regenerative periods are very long. In §4, we make the few necessary changes when the step sizes ϵ_n go to zero.

Section 5 gives the simple alterations when the iterate is to be confined to some constraint set. It was noted in [25] and elsewhere subsequently that the ODE for the constrained problem follows directly from that for the unconstrained problem by use of a simple decomposition of the iterate into the sum of the unprojected value plus an "error." The "error" is easy to treat since it is what brings an infeasible point back to the constraint set. The unprojected values are treated as for the unconstrained algorithm. So, under appropriate conditions on the constraint set, the constrained problems are easy extensions of the unconstrained problem.

Section 6 formally introduces the application of Theorem 3.1 and its extensions for use on systems whose performance function involves a stationary average. The basic heuristic illustration is for a system where an IPA- or mean square derivative–type estimator might be used and we wish to minimize a stationary cost. The right side of the limit ODE is the negative of the derivative of the stationary cost with respect to the adjustable parameter. All of this is a consequence of the basic theorem. Many authors [6, 7, 16, 32, 34, 45] consider finite-horizon gradient estimators. They reset the estimation (reset the accumulator, to use current jargon) at the start of each observation interval, whose length becomes large as $n \to \infty$. It will be seen that quite often one does not need to let the observation intervals become large nor to reset the estimator. Indeed, these latter techniques are frequently adopted just because it is under those conditions that the authors have proved their convergence results.

To illustrate the basic simplicity and power of the approach, in §§7 and 8 we have chosen examples of current importance and on which much work has been done. Each example is typical of a large class of great current interest and illustrates the application of the methods to that class. The problem of §7 concerns the optimization of a single queue with respect to a service time parameter. This problem has been well

studied and is typical of the use of IPA in many discrete event dynamical systems. The problem in §8 concerns the optimization of an "unreliable" manufacturing system via the choice of suitable production rates and thresholds and is typical of many applications to piecewise deterministic systems. In both cases, the general techniques discussed here are relatively quick to apply and yield good results for many forms of the algorithms and under conditions which are weaker than those generally used. The power of the approach allows much flexibility in the SA algorithm.

In §9 we apply the ideas of §3 to a stochastic differential equation (SDE) model, where the sample derivative is obtained from the equation for the adjoint or mean square derivative. This is just the SDE analogue of the IPA-type estimator and has been in use for a long time. In such examples one often has the problem of proving stability of the derivative estimators, and there is no regenerative structure to help. When stability can be proved, the results are exactly as for the discrete-event and piecewise deterministic dynamical systems cases; one need not restart the estimator nor let the estimation periods increase with time, each of which might not be good practice. In the limit one gets the basic ODE, whose right side is the negative of the gradient of the stationary cost with respect to the parameter. When stability of the mean square derivative process cannot be proved, one can use various forms of finite differences. For example, one might use one continuous run either with the parameter being perturbed over successive intervals of, say, fixed length, or with the use of independent samples for the positive and negative perturbations. In the former (one sample) case, it is noteworthy that we can often get something close to the desired limit ODE. Either finite difference method can be employed when the functions in the cost or dynamical equation are not smooth (say, the cost involves the indicator function of some event) or when we do not know the model well enough to even try to compute a pathwise derivative.

The appendices contain various extensions. Appendix 1 uses a perturbed test function type method (of the type used in [23]) to avoid the Markov assumption. In Appendix 2, we illustrate the use of a method with which one can sometimes avoid the use of occupation measures in the argument of Theorem 3.1 and which is adaptable to many uses. Appendix 3 contains the few additional details when one wishes to work within a regenerative context but possibly update at rather arbitrary random times during the interval as well as at its end. Appendix 4 contains the essential ideas for dealing with a decentralized algorithm, where the different processors update on their own (asynchronous) schedule, with possible delays in communication. Using simple time-change arguments (extensions of the type first used in [30]), we show that the proof and the end results are essentially as for the basic synchronized case, except for some notational changes. This approach generalizes the results in [40]. Thus, the described approach efficiently encompasses a very diverse group of algorithms and applications.

Although the essential ideas are all in Theorem 3.1, the paper is long because we wish to show the great flexibility of the ideas and how to extend them effectively in the many possible (not entirely obvious) directions which are of increasing current interest and to properly illustrate their practical use via concrete applications to important problems.

We note that the convergence can generally be accelerated using the iterate averaging methods initiated by Polyak and discussed in [29, 36, 46, 47].

2. Some background on weak convergence. The methods of the theory of weak convergence are powerful and widely used tools for problems concerning approx-

imations and limit theorems for random processes [3, 10, 22]. They do for random processes what the central limit theorem and the law of large numbers do for sequences of vector-valued random variables. Because they are averaging methods for random processes evolving on different time scales, they are natural methods for SA and have been widely used. Only the basic definitions will be given, since the ideas will be used in a simple way. Further information for those interested can be found in the references.

Let $\{X_n, n < \infty\}$ be a sequence of random variables with values in a complete and separable metric space (CSMS) S. In this paper, S will generally be either some Euclidean space R^k, a space of functions representing the paths of the SA process, or a set of probability measures, as specified below. We say that $\{X_n, n < \infty\}$ *converges weakly* to a random variable X and write $X_n \Rightarrow X$, if for each continuous and bounded real-valued function $f(\cdot)$ on S we have $Ef(X_n) \to Ef(X)$. Thus, weak convergence is an extension of the concept of convergence in distribution of a sequence of real valued random variables to more general spaces. If P_n and P, resp., are the measures of X_n and X, resp., we also say that $P_n \Rightarrow P$. The sequence $\{X_n, n < \infty\}$ is said to be *tight* if for each $\delta > 0$ there is a compact set $K_\delta \subset S$ such that $P\{X_n \notin K_\delta\} \leq \delta$ for all n. Equivalently, a set of measures $\{P_n, n < \infty\}$ on the Borel sets of S is said to be tight if $P_n\{S - K_\delta\} \leq \delta$ for all n. Tightness implies the existence of a weakly convergent subsequence [10, p. 104].

The Skorohod representation. Since weak convergence is a generalized distributional convergence, it does not depend on the actual probability space that is used. It is often more convenient in the analysis to work with w.p.1 convergence rather than with weak convergence directly. The *Skorohod representation* [10] guarantees that we can choose the probability space so that w.p.1 convergence holds if weak convergence does, as follows. Suppose that $X_n \Rightarrow X$ weakly. Then we can find a probability space with random variables $\{\tilde{X}_n, n < \infty\}, \tilde{X}$ defined on it, where $\tilde{X}_n$ (resp., $\tilde{X}$) has the same measure as X_n (resp., X) and on which $\tilde{X}_n \to \tilde{X}$ w.p.1 in the topology of S [10, p. 102]. We will use the Skorohod representation where convenient.

The path spaces. Define $D^r[0, \infty)$ or $D^r(-\infty, \infty)$, where $D^r(I)$ is the space of R^r-valued functions on the interval I which are right continuous and have left-hand limits (and are continuous at $t = 0$ in the case of $D^r[0, \infty)$). The topology will be that of uniform convergence on finite intervals, making both spaces into CSMSs.

Notation on interpolated processes. In the SA algorithms that we study, we will have recursions of the form $X^\epsilon_{n+1} = X^\epsilon_n + \epsilon\chi^\epsilon_n$, where χ^ϵ_n is a sequence of R^r-valued random variables. We are interested in studying the limit behavior as $\epsilon \to 0$ and $n \to \infty$. The piecewise constant interpolation of X^ϵ_n on $(-\infty, \infty)$ is defined as $X^\epsilon(t) = X^\epsilon_n$ for $t \in [\epsilon n, \epsilon(n+1))$ and $X^\epsilon(t) = X^\epsilon_0$ for $t < 0$. For $t \geq 0$, let $[t]$ denote the integer part of t. Then,

$$X^\epsilon(t) = X(0) + \epsilon \sum_{i=0}^{[t/\epsilon]-1} \chi^\epsilon_i, \qquad t \geq 0. \tag{2.1}$$

$X^\epsilon(\cdot)$ is a random process with paths in $D^r(-\infty, \infty)$. We also view it as a random variable with values in $D^r(-\infty, \infty)$. We will also use shifted processes, as follows. Let q_ϵ be a sequence of integers such that $\epsilon q_\epsilon \to \infty$ as $\epsilon \to 0$. Then $X^\epsilon(\epsilon q_\epsilon + \cdot)$ will also be of interest, since the "tail" of the original process is now in the "vicinity of the origin" for large ϵq_ϵ. We will be interested in the limits of the $X^\epsilon(\cdot)$ as $\epsilon \to 0$. For notational simplicity, we henceforth write $[t/\epsilon]$ simply as t/ϵ in the limits of the sums.

Next, let ϵ_j be a sequence of positive numbers which goes to zero and such that $\sum_j \epsilon_j = \infty$. Let χ_i be a sequence of R^r-valued random variables. Define $t_n = \sum_{i=0}^{n-1} \epsilon_i$, $m(t) = \max\{i : t_i \leq t\}$. With $X(0)$ given, define the interpolation $X^0(\cdot)$ by $X^0(t) = X(0)$ for $t \leq 0$, and for $t \geq 0$,

$$X^0(t) = X(0) + \sum_{i=0}^{m(t)-1} \epsilon_i \chi_i. \tag{2.2}$$

The shifted processes $X^n(t) = X^0(t+t_n)$ will play an important role since they bring the tail of $X^0(\cdot)$ to the forefront. The following result will be used. It is not hard to prove directly and follows from [3, Thm. 15.2].

LEMMA 2.1. *Suppose that* $\{\chi_n^\epsilon, \epsilon > 0, n < \infty\}$ *and* $\{\chi_n, n < \infty\}$ *are uniformly integrable and* $\{X_n\}$, $\{X_n^\epsilon\}$ *are tight. Then* $\{X^\epsilon(\cdot), \epsilon > 0\}$, $\{X^\epsilon(\epsilon q_\epsilon + \cdot), \epsilon > 0\}$, *and* $\{X^n(\cdot), n < \infty\}$ *are tight and any weak limit has Lipschitz continuous paths w.p.1.*

Random measures. The treatment of the unbounded noise case (which is generally the situation in the problems of interest here) will be simplified and extended (over that in [22, 27]) by the use of random variables which are measure valued. The concept will be used in a rather simple way and all that we need to know will now be stated.

Let $\mathcal{P}(S)$ denote the set of probability measures over the Borel subsets of S. The Prohorov metric [10] will be used on this space. An important point is that under this metric $\mathcal{P}(S)$ is a CSMS, since S is [10, p. 101]. Convergence $P_n \to P$ in this topology is equivalent to weak convergence of $\{P_n, n < \infty\}$ to P [10, p. 108].

Now let $\{R_n, n < \infty\}$ be a sequence of *random variables* whose values are points in $\mathcal{P}(S)$. By definition, $\{R_n, n < \infty\}$ converges weakly (as a sequence of random variables) to the measure-valued random variable R if $EF(R_n) \to EF(R)$ for each bounded and continuous real-valued function $F(\cdot)$ on $\mathcal{P}(S)$. The function $\bar{R}_n$ defined by $\bar{R}_n = ER_n$ is a measure in $\mathcal{P}(S)$. We will need the following important fact

LEMMA 2.2 (see [24, pp. 14–15]). *The set* $\{R_n, n < \infty\}$ *has a weakly convergent subsequence if* $\{\bar{R}_n, n < \infty\}$ *is tight.*

This characterization in terms of the mean values is of great help, since the mean values $\{\bar{R}_n, n < \infty\}$ are much easier to deal with. Recall that the sequence $\{\bar{R}_n, n < \infty\}$ is tight if the associated sequence of random variables is tight. Let $f(\cdot)$ be a bounded, continuous, and real-valued function on S. The function defined by $F_f(P) = \int f(x)P(dx)$ is real valued, bounded, and continuous on $\mathcal{P}(S)$. Thus, if $R_n \Rightarrow R$ then $F_f(R_n) \to F_f(R)$ in distribution for each $f(\cdot)$. If the Skorohod representation is used, then we can say that w.p.1 for each such $f(\cdot)$

$$F_f(R_n) \to F_f(R). \tag{2.3}$$

3. The basic SA algorithms. The section contains several parts. Section 3.1 gives the main convergence theorem from which all others will be derived. Section 3.2 concerns the limit points of the ODEs which characterize the asymptotics of the SA. In many cases, the observation has a certain decomposition property which simplifies the verification of the assumptions, and this is exploited in §3.3. A simplified result for regenerative type processes, where we update at the end of the regeneration intervals, is in §3.4.

3.1. The canonical algorithm. Let $\epsilon > 0$. We will develop the basic ideas for the algorithm

$$\theta_{n+1}^{\epsilon} = \theta_n^{\epsilon} + \epsilon Y_n^{\epsilon}, \qquad n \geq 0,\ \theta_n^{\epsilon} \in R^r, \tag{3.1}$$

where Y_n^{ϵ} is a sequence of R^r-valued random variables. The proofs of subsequent results for other SA forms will be more or less simple variations of the proof for (3.1). We next state the conditions which will be needed. The conditions seem to be nearly minimal and will be illustrated in the examples in §§7–9.

Let $\mathcal{B}_n^{\epsilon}$ be a sequence of nondecreasing sequence of sigma-algebras where $\mathcal{B}_n^{\epsilon}$ measures at least $\{\theta_0^{\epsilon}, Y_i^{\epsilon}, i < n\}$ and E_n^{ϵ} be the expectation conditioned on $\mathcal{B}_n^{\epsilon}$. Write $E_n^{\epsilon} Y_n^{\epsilon} = \bar{Y}_n^{\epsilon}$. Then the δY_n^{ϵ} defined by $Y_n^{\epsilon} = \bar{Y}_n^{\epsilon} + \delta Y_n^{\epsilon}$ are $\mathcal{B}_n^{\epsilon}$-martingale differences. Generally, $\mathcal{B}_n^{\epsilon}$ will measure "all the information" which is used to get the $\{Y_i^{\epsilon}, i < n\}$. Suppose that

$$\{Y_n^{\epsilon}, n < \infty, \epsilon > 0\} \text{ is uniformly integrable.} \tag{3.2}$$

Suppose that there is a process $\{\xi_n^{\epsilon}, n < \infty\}$ which takes values in some CSMS and measurable functions $G_n^{\epsilon}(\cdot)$ such that we can write

$$\bar{Y}_n^{\epsilon} = G_n^{\epsilon}(\theta_n^{\epsilon}, \xi_n^{\epsilon}). \tag{3.3}$$

Assume that

$$\text{the set } \{\xi_n^{\epsilon}, \theta_n^{\epsilon}, \epsilon > 0, n < \infty\} \text{ is tight.} \tag{3.4}$$

Tightness of $\{\theta_n^{\epsilon}, \epsilon > 0, n < \infty\}$ holds if a projection algorithm is used (§5). Otherwise a stability argument might need to be used. Suppose that for each ϵ, θ, n there is a transition function $P_n^{\epsilon}(\cdot, \cdot|\theta)$ such that $P_n^{\epsilon}(\cdot, A|\cdot)$ is measurable for each Borel set A in the range space of ξ and

$$P\{\xi_{n+1}^{\epsilon} \in \cdot | \xi_i^{\epsilon}, \theta_i^{\epsilon}, i \leq n\} = P_n^{\epsilon}(\xi_n^{\epsilon}, \cdot | \theta_n^{\epsilon}). \tag{3.5}$$

By this Markov assumption, E_n^{ϵ} is the expectation conditioned on $(\theta_n^{\epsilon}, \xi_n^{\epsilon})$. For each fixed θ, let there be a transition function $P(\xi, \cdot|\theta)$ such that

$$P_n^{\epsilon}(\xi, \cdot|\theta) \Rightarrow P(\xi, \cdot|\theta) \text{ as } n \to \infty, \epsilon \to 0, \tag{3.6}$$

where the limit is uniform on each compact (θ, ξ) set; i.e., for each bounded and continuous real-valued function $f(\cdot)$,

$$\int f(\tilde{\xi}) P_n^{\epsilon}(\xi, d\tilde{\xi}|\theta) \to \int f(\tilde{\xi}) P(\xi, d\tilde{\xi}|\theta)$$

uniformly on each compact (θ, ξ) set. Assume

$$P(\xi, \cdot|\theta) \text{ is weakly continuous in } (\theta, \xi). \tag{3.7}$$

For each fixed θ the transition function $P(\cdot, \cdot|\theta)$ determines a Markov chain and we let $\{\xi_n(\theta)\}$ denote the associated random variables. Let $\mu(\cdot|\theta)$ denote the invariant measures under the transition function $P(\xi, \cdot|\theta)$. Suppose that

$$\{\mu(\cdot|\theta), \theta \in \Theta\} \text{ is tight for each compact } \Theta. \tag{3.8}$$

Henceforth, let q_ϵ be a sequence of integers such that

$$\text{either} \quad q_\epsilon \equiv 0 \qquad \text{or} \quad \epsilon q_\epsilon \to \infty. \tag{3.8'}$$

Suppose that there is a continuous function $G(\cdot)$ such that for each $\delta > 0$

$$\lim_{\epsilon} \limsup_{n} P\{|G_n^\epsilon(\theta_n^\epsilon, \xi_n^\epsilon) - G(\theta_n^\epsilon, \xi_n^\epsilon)| \geq \delta\} = 0 \tag{3.9}$$

and that for each compact θ-set Θ there is $K_0(\Theta) < \infty$ such that for all stationary processes $\{\xi_n(\theta)\}$

$$\sup_{\theta \in \Theta} E|G(\theta, \xi_j(\theta))| < K_0(\Theta). \tag{3.10}$$

Finally, we assume either (3.11a) or (3.11b):

$$\text{For each } \theta, \mu(\cdot|\theta) \text{ is unique.} \tag{3.11a}$$

There is a continuous $g(\cdot)$ such that for each θ and initial condition $\xi_0(\theta)$

$$\lim_N \frac{1}{N} \sum_{n=0}^{N-1} EG(\theta, \xi_n(\theta)) = g(\theta). \tag{3.11b}$$

Under (3.11a), define

$$g(\theta) = \int G(\theta, \xi)\mu(d\xi|\theta).$$

Define the continuous parameter interpolation $\theta^\epsilon(\cdot)$ by $\theta^\epsilon(t) = \theta_n^\epsilon$ for $t \in [n\epsilon, n\epsilon + \epsilon), n \geq 0$. For $t < 0$, set $\theta^\epsilon(t) = \theta_0^\epsilon$.

THEOREM 3.1. *Assume the conditions* (3.2)–(3.11). *Each subsequence of* $\{\theta^\epsilon(q_\epsilon\epsilon + \cdot), \epsilon > 0\}$ *has a further subsequence which converges weakly to a bounded solution* $\theta(\cdot)$ *of*

$$\dot{\theta} = g(\theta) \tag{3.12}$$

on $[0, \infty)$ *if* $q_\epsilon = 0$ *and on* $(-\infty, \infty)$ *if* $\epsilon q_\epsilon \to \infty$. *Also,* $g(\cdot)$ *is a continuous function of* θ.

Remark. We note that in current applications it is often the case that the P_n^ϵ and the G_n^ϵ do not depend on either ϵ or n. See the examples in §§6–8. A way of avoiding the Markovianization is described in Appendix 1. Condition (3.11b) is often much easier to check than is uniqueness of the invariant measure. In typical examples where one uses some sort of weak sense derivative or an IPA-type estimator, it is equivalent to the asymptotic consistency of the estimator under fixed θ, as will be seen in the examples in §§6–8. This is a minimal condition. The ability to use such a condition is basically a consequence of the "martingale problem" formulation used in the proof. It is exploited in the use of conditional expectations in the expressions from (3.17) on.

The basic idea in the proof is to first replace the Y_n^ϵ by its conditional expectation, given the past. Then use a piecewise constant approximation to the state process, and finally exploit this last approximation via an ergodic condition. The type of continuity

and uniform integrability conditions required seem rather weak and have their roots in the basic references [22, 27].

Remark. If Y_n^ϵ can be represented as $g(\theta_n^\epsilon)$ plus a "martingale difference" plus a term which goes to zero in mean[1] as $\epsilon \to \infty$ and/or $n \to \infty$, then the proof becomes nearly trivial since no averaging needs to be done. The difficulties arise when the conditional expectation (given past data) of Y_n^ϵ depends on the past, and this holds true in many important cases. The basic structure and motivation of the proof are analogous to those of [22, 27], but many of the details are different. Here there is a smoother development of the unbounded noise case under weaker conditions. The proof also provides a simpler way of characterizing the limit points (see Theorem 3.2) and dealing with the other extensions. In order to simplify the notation, we use $q_\epsilon = 0$ in the proof. The details are exactly the same for the general case.

Proof. Part 1. *A continuity result.* Until the last part of the proof, assume (3.11a). Let $f(\cdot)$ be bounded, continuous, and real valued. Given $\theta_0 \in R^r$, let θ_n be a deterministic sequence tending to θ_0. We have

$$\int f(\xi)\mu(d\xi|\theta_n) = \int \left[\int f(\tilde{\xi})P(\xi, d\tilde{\xi}|\theta_n)\right] \mu(d\xi|\theta_n).$$

Now as $n \to \infty$ $P(\xi, \cdot|\theta_n)$ converges weakly to $P(\xi, \cdot|\theta_0)$ uniformly on each compact (θ, ξ) set by (3.7). Using (3.8), extract a weakly convergent subsequence of $\{\mu(\cdot|\theta_n), n < \infty\}$ and denote the limit by $\tilde{\mu}(\cdot)$. Then

$$\int f(\xi)\tilde{\mu}(d\xi) = \int \left[\int f(\tilde{\xi})P(\xi, d\tilde{\xi}|\theta_0)\right] \tilde{\mu}(d\xi),$$

which implies, via uniqueness, that $\tilde{\mu}(\cdot) = \mu(\cdot|\theta_0)$. This argument yields the continuity of $\int f(\xi)\mu(d\xi|\theta)$.

Part 2. *A martingale problem representation.* By (3.1) and (3.3)

$$\theta^\epsilon(t) = \theta_0^\epsilon + \epsilon \sum_{i=0}^{t/\epsilon-1} G_i^\epsilon(\theta_i^\epsilon, \xi_i^\epsilon) + \epsilon \sum_{i=0}^{t/\epsilon-1} \delta Y_i^\epsilon. \tag{3.13}$$

First, we show that the martingale term (the one on the right) goes to zero as $\epsilon \to 0$. This would be easy if the uniform integrability in (3.2) were replaced by square integrability, since then the martingale would be square integrable and its variance at t would be bounded by $\epsilon^2(t/\epsilon)\sup_{\epsilon,n} \operatorname{var}(\delta Y_n^\epsilon) = O(\epsilon t)$. Hence the term would have the zero process as a weak limit. We get the same result by a truncation argument, as follows. For large positive B, let $I_{n,B}^\epsilon$ be the indicator function of the event that Y_n^ϵ does not exceed B in absolute magnitude. Then use $Y_n^\epsilon I_{n,B}^\epsilon$ in lieu of Y_n^ϵ, as follows. Define $\delta Y_{n,B}^\epsilon$ and $\beta_{n,B}^\epsilon$ by

$$Y_n^\epsilon I_{n,B}^\epsilon = E_n^\epsilon Y_n^\epsilon I_{n,B}^\epsilon + \delta Y_{n,B}^\epsilon, \qquad Y_n^\epsilon = Y_n^\epsilon I_{n,B}^\epsilon + \beta_{n,B}^\epsilon.$$

We have $\sup_{\epsilon,n} E|\beta_{n,B}^\epsilon| \to 0$ as $B \to \infty$ by the uniform integrability. Since $\{\delta Y_{n,B}^\epsilon\}$ are bounded, for each $B < \infty$ the martingale term $\epsilon \sum_{i=0}^{t/\epsilon-1} \delta Y_{i,B}^\epsilon$ contributes nothing to the limit by the "square integrability" theory. Now the uniform integrability (3.2) yields

$$\limsup_B \sup_{n,\epsilon} E|E_n^\epsilon Y_n^\epsilon I_{n,B}^\epsilon - G_n^\epsilon(\theta_n^\epsilon, \xi_n^\epsilon)| = 0.$$

[1] If, for a sequence $Z_n, E|Z_n| \to 0$, we say that it converges in mean to zero.

These results imply that (3.13) can be written as

$$\theta^\epsilon(t) = \theta^\epsilon(0) + \epsilon \sum_{j=0}^{t/\epsilon-1} G_j^\epsilon(\theta_j^\epsilon, \xi_j^\epsilon) + \rho^\epsilon(t), \tag{3.14}$$

where $|\rho^\epsilon(t)| \to 0$ in the mean uniformly on each bounded t-interval. Now the uniform integrability (3.2) and the form (3.1) imply that $\{\theta^\epsilon(\cdot), \epsilon > 0\}$ is tight and that any weak limit has Lipschitz-continuous paths w.p.1 (see Lemma 2.1).

The conditions seem to be weakest if we work with a "martingale problem" formulation, and we proceed to do so. Now, with a slight abuse of notation, let ϵ index a weakly convergent subsequence of $\{\theta^\epsilon(\cdot), \epsilon > 0\}$ with limit process denoted by $\theta(\cdot)$. Let t, τ be arbitrary positive numbers; q be an integer; $s_i, i \le q$, be nonnegative numbers no larger than t; and $h(\cdot)$ be a bounded, continuous, and real-valued function of its arguments. As is common in weak convergence–type arguments, we will show that

$$Eh(\theta(s_i), i \le q)\left[\theta(t+\tau) - \theta(t) - \int_t^{t+\tau} g(\theta(u))du\right] = 0. \tag{3.15}$$

By the arbitrariness of the $h(\cdot), q, t, \tau, s_i$, (3.15) implies that $\theta(t) - \theta(0) - \int_0^t g(\theta(u))du$ is a martingale (with respect to the filtration which it generates). Since $E|\rho^\epsilon(\cdot)| \to 0$ and $\{G_n^\epsilon(\theta_n^\epsilon, \xi_n^\epsilon), \epsilon > 0, n < \infty\}$ is uniformly integrable, the form (3.14) implies that the martingale has zero quadratic variation; hence it is constant. Since it takes the value zero at $t = 0$, it is identically zero w.p.1. Thus, the theorem will be proved once (3.15) is proved.

Part 3. *Approximating the* $G_j^\epsilon(\cdot)$. By the properties of $\rho^\epsilon(\cdot)$, we can write

$$Eh(\theta^\epsilon(s_i), i \le q)\left[\theta^\epsilon(t+\tau) - \theta^\epsilon(t) - \epsilon \sum_{j=t/\epsilon}^{(t+\tau)/\epsilon-1} G_j^\epsilon(\theta_j^\epsilon, \xi_j^\epsilon)\right] \to 0 \tag{3.16}$$

as $\epsilon \to 0$. We proceed to rearrange the terms in (3.16) so that efficient averaging methods can be used. Let $n_\epsilon \to \infty$ be a sequence of integers such that $\delta_\epsilon = \epsilon n_\epsilon \to 0$ and τ is an integral multiple of δ_ϵ. Without loss of generality and for notational simplicity, suppose that t is also an integral multiple of δ_ϵ. By collecting terms in groups of size n_ϵ and using the freedom that we have with taking the conditional expectations given "past data" inside the brackets in (3.16), we can write the left side of (3.16) as

$$Eh(\theta^\epsilon(s_i), i \le q)\left\{\theta^\epsilon(t+\tau) - \theta^\epsilon(t) - \sum_{l:l\delta_\epsilon=t}^{t+\tau-\delta_\epsilon} \delta_\epsilon\left[\frac{1}{n_\epsilon}\sum_{j=ln_\epsilon}^{ln_\epsilon+n_\epsilon-1} E_{ln_\epsilon}^\epsilon G_j^\epsilon(\theta_j^\epsilon, \xi_j^\epsilon)\right]\right\}. \tag{3.17}$$

For a real-valued function $f(\cdot)$ and $\infty > B > 0$, define $f_B(\cdot)$ by $f_B(x) = \min[f(x), B]$ for $f(x) \ge 0$ and by $f(x) = \max[f(x), -B]$ otherwise.

By the uniform integrability (3.2), given any $\rho > 0$ there is $B < \infty$ such that we can use $G_{n,B}^\epsilon(\cdot)$ while changing the expectations of the absolute values of the summands in the brackets of (3.17) by at most ρ. Continuing in the bracketed term, first replace $G_j^\epsilon(\theta_j^\epsilon, \xi_j^\epsilon)$ with $G_{j,B}^\epsilon(\theta_j^\epsilon, \xi_j^\epsilon)$ plus a small error term. Then use (3.9) (which also holds for the B-truncated functions) to replace $G_{j,B}^\epsilon(\theta_j^\epsilon, \xi_j^\epsilon)$ with $G_B(\theta_j^\epsilon, \xi_j^\epsilon)$ plus

a small error. Finally, use the (uniform in compact (θ, ξ) sets) continuity of $G_B(\cdot, \xi)$, (3.4) and the fact that (in probability, uniformly in l)

$$\sup_{j \le n_\epsilon} |\theta^\epsilon_{ln_\epsilon + j} - \theta^\epsilon_{ln_\epsilon}| \to 0 \quad \text{as } \epsilon \to 0 \tag{3.18}$$

to justify replacing θ^ϵ_j by $\theta^\epsilon_{ln_\epsilon}$ (plus a small error term), yielding that (3.17) equals (3.19)

$$Eh(\theta^\epsilon(s_i), i \le q) \left\{ \theta^\epsilon(t+\tau) - \theta^\epsilon(t) - \sum_{l: l\delta_\epsilon = t}^{t+\tau-\delta_\epsilon} \delta_\epsilon \left[\frac{1}{n_\epsilon} \sum_{j=ln_\epsilon}^{ln_\epsilon + n_\epsilon - 1} E^\epsilon_{ln_\epsilon} G_B(\theta^\epsilon_{ln_\epsilon}, \xi^\epsilon_j) \right] \right\}$$

modulo an error ρ' which can be made as small as desired in mean value by choosing B large enough and then ϵ small enough. The sum in (3.19) can be written as $\int_t^{t+\tau} \tilde{G}^\epsilon_B(s)ds$, with the obvious definition of $\tilde{G}^\epsilon_B(\cdot)$ as the process which is constant on intervals $[l\delta_\epsilon, (l+1)\delta_\epsilon)$, as defined[2] by the bracketed term.

The weak convergence arguments in the next parts will show that

$$Eh(\theta^\epsilon(s_i), i \le q)\tilde{G}^\epsilon_B(s) \to Eh(\theta(s_i), i \le q) g_B(\theta(s)), \tag{3.20}$$

where $g_B(\theta) = \int G_B(\theta, \xi)\mu(d\xi|\theta)$. This will imply that the outer sum in (3.19) can be replaced by $\int_t^{t+\tau} g_B(\theta(s))ds$ in the limit as $\epsilon \to 0$. These results will yield that

$$\dot{\theta} = g_B(\theta) + \rho_B, \tag{3.21}$$

where $E\int_0^t |\rho_B(s)|ds \to 0$ as $B \to \infty$. The proof under (3.11a) will then be completed in part 5 by showing that we can let $B = \infty$. Part 6 will deal with (3.11b).

Part 4. *Averaging out the* ξ^ϵ_j. To complete our program, we need to average out the ξ^ϵ_j terms in (3.19). Define the measure-valued random variable (an average of conditional probabilities)

$$R(l, \epsilon, \cdot) = \frac{1}{n_\epsilon} \sum_{j=ln_\epsilon}^{ln_\epsilon + n_\epsilon - 1} P\{\xi^\epsilon_j \in \cdot | \theta^\epsilon_{ln_\epsilon}, \xi^\epsilon_{ln_\epsilon}\}, \tag{3.22}$$

and recall that the $E^\epsilon_{ln_\epsilon}$ is the expectation conditioned on $(\theta^\epsilon_{ln_\epsilon}, \xi^\epsilon_{ln_\epsilon})$ by the Markov assumption. The inner square bracketed term in (3.19) can now be written

$$\int R(l, \epsilon, d\xi) G_B(\theta^\epsilon_{ln_\epsilon}, \xi). \tag{3.23}$$

The set of measure-valued random variables $\{R(l, \epsilon, \cdot), l < \infty, \epsilon > 0\}$ is tight, since the mean values are just

$$\bar{R}(l, \epsilon, \cdot) = \frac{1}{n_\epsilon} \sum_{j=ln_\epsilon}^{ln_\epsilon + n_\epsilon - 1} P\{\xi^\epsilon_j \in \cdot\}$$

[2] We note here that the major problem in averaging the inner square bracket is in showing that the ξ^ϵ_j in the inner sum in (3.19) can be replaced by $\xi_j(\theta^\epsilon_{ln_\epsilon})$, all of which have the same value of θ as an argument, so that some sort of ergodic theorem or averaging principle can be used to get the ultimate averaged limit. Recall that $\xi_i(\theta)$ is the Markov chain with fixed parameter θ. This idea is basic to all of the averaging methods. The continuity (3.7) of the transition function is the basic property that is used. Various alternatives will appear in the appendices.

and the tightness of $\{\bar{R}(l,\epsilon,\cdot), l \geq 0, \epsilon > 0\}$ is just the tightness of $\{\xi_n^\epsilon, \epsilon > 0, n < \infty\}$, and this latter sequence is tight by assumption (3.4) (see Lemma 2.2). We will characterize the limits of weakly convergent subsequences of $\{R(l,\epsilon,\cdot), l < \infty, \epsilon > 0\}$ as measures whose values are (w.p.1) just the invariant measure $\mu(\cdot|\theta)$ with appropriate values of θ. Now we follow the ideas in the development in [22, p. 110], except for the use of the random measures in place of their pointwise values. (We note that the use of random measures here greatly simplifies the treatment of the unbounded noise case over that in the references.)

Fix $s > 0$, and let l_ϵ be such that $s \in [l_\epsilon\delta_\epsilon, l_\epsilon\delta_\epsilon + \delta_\epsilon)$ for all ϵ. Let $f(\cdot)$ be a bounded and continuous real-valued function of ξ. Using (3.8), extract a weakly convergent subsequence of $\{R(l_\epsilon,\epsilon,\cdot), \theta^\epsilon(\cdot), \epsilon > 0\}$, and index it by $\epsilon(p), p \to \infty$. The proof will show that this further subsequence is irrelevant, due to the uniqueness of the $\mu(\cdot|\theta)$, and that we can let $\epsilon(p) = \epsilon$. We also suppose that the Skorohod representation is used so that the convergences are w.p.1 in the appropriate topologies. Denote the limit by $(\tilde{R}(\cdot), \theta(\cdot))$.[3] Define $m_{\epsilon(p)} = l_{\epsilon(p)} n_{\epsilon(p)}$. Note that $m_\epsilon(p) \to \infty$ as $p \to \infty$. We can write

$$\begin{aligned}\int \tilde{R}(d\xi) f(\xi) &= \lim_{p\to\infty} \int R(l_{\epsilon(p)}, \epsilon(p), d\xi) f(\xi) \\ &= \lim_{p\to\infty} \frac{1}{n_{\epsilon(p)}} \sum_{j=m_{\epsilon(p)}}^{m_{\epsilon(p)}+n_{\epsilon(p)}-1} \int P\{\xi_j^{\epsilon(p)} \in d\xi | \theta^{\epsilon(p)}_{m_{\epsilon(p)}}, \xi^{\epsilon(p)}_{m_{\epsilon(p)}}\} f(\xi).\end{aligned} \tag{3.24}$$

The first equality follows from the definition of the weak limit. The second follows from definition of $R(l_\epsilon,\epsilon,\cdot)$. Continuing, we use the one-step transition function $P_j^{\epsilon(p)}(\cdot)$ to rewrite the right side of (3.24) as (minus the first term of the sum)

(3.25)

$$\lim_p \frac{1}{n_{\epsilon(p)}} \sum_{j=m_{\epsilon(p)}+1}^{m_{\epsilon(p)}+n_{\epsilon(p)}-1} \int\int P\{\theta_{j-1}^{\epsilon(p)} \in d\tilde{\theta}, \xi_{j-1}^{\epsilon(p)} \in d\tilde{\xi} | \theta^{\epsilon(p)}_{m_{\epsilon(p)}}, \xi^{\epsilon(p)}_{m_{\epsilon(p)}}\} P_{j-1}^{\epsilon(p)}(\tilde{\xi}, d\xi|\tilde{\theta}) f(\xi).$$

Condition (3.6) yields

$$\lim_{p,n} \int P_n^{\epsilon(p)}(\tilde{\xi}, d\xi|\tilde{\theta}) f(\xi) = \int P(\tilde{\xi}, d\xi|\tilde{\theta}) f(\xi) \equiv \bar{f}(\tilde{\theta}, \tilde{\xi}),$$

and the limit is uniform on each compact $(\tilde{\theta}, \tilde{\xi})$ set. By (3.7), the right-hand side is continuous. By using these facts and the fact that the limit $\theta(\cdot)$ is continuous, we can concentrate the measure of $\tilde{\theta}$ in (3.25) at $\theta^{\epsilon(p)}_{m_{\epsilon(p)}}$ without affecting the limit. With this replacement, (3.25) can be written as

$$\lim_p \int R(l_{\epsilon(p)}, \epsilon(p), d\xi) \bar{f}(\theta^{\epsilon(p)}_{m_{\epsilon(p)}}, \xi),$$

which by the use of the weak convergence of $\{R^{\epsilon(p)}(l_{\epsilon(p)}, \epsilon(p), \cdot), \theta^{\epsilon(p)}_{m_{\epsilon(p)}}\}$ to $(\tilde{R}(\cdot), \theta(s))$ as $p \to \infty$ equals

$$\int \tilde{R}(d\xi) \bar{f}(\theta(s), \xi) = \int\int \tilde{R}(d\tilde{\xi}) P(\tilde{\xi}, d\xi|\theta(s)) f(\xi). \tag{3.26}$$

[3] Strictly speaking, when taking limits of $\{\tilde{R}(l_{\epsilon(p)}, \epsilon(p), \cdot), \theta^{\epsilon(p)}(\cdot), p < \infty\}$ and using Skorohod representation, the probability space might be different from what was used when we got the original weakly convergent subsequence with limit $\theta(\cdot)$ in part 2. But since $\{\theta^{\epsilon(p)}(\cdot), p < \infty\}$ is a subsequence of $\{\theta^\epsilon(\cdot), \epsilon > 0\}$ and all that matters are the distributions of the resulting limits anyway, we write $\theta(\cdot)$ for the limit as $p \to \infty$ for notational simplicity and without loss of generality.

Let ω denote the canonical probability space variable. Equating the right side of (3.26) with the left-hand side of (3.24) yields that (w.p.1) each sample value $\tilde{R}(\cdot,\omega)$ must be an invariant measure for the transition probability $P(\xi,\cdot|\theta(s,\omega))$. By the uniqueness of the invariant measure, $\tilde{R}(\cdot)=\mu(\cdot|\theta(s))$ w.p.1, and the subsequence of $\{R(l_\epsilon,\epsilon,\cdot),\epsilon>0\}$ which is used is irrelevant. This implies that the limit in (3.23) is $g_B(\theta(s))$ w.p.1, which yields (3.20).

Part 5. *Replacing* $g_B(\cdot)$ *by* $g(\cdot)$. The results of the previous parts imply that we can replace the square bracketed term of (3.20) by (3.19) by $g_B(\theta(s))$ and that (3.20), (3.21) hold. We need only show that we can let $B\to\infty$ in (3.21). We can let $B\to\infty$ and replace $g_B(\cdot)$ by $g(\cdot)$ if $G(\theta,\cdot)$ is $\mu(\cdot|\theta)$ integrable for each θ, the integral is bounded on each compact θ set, and

$$\int G_B(\theta,\xi)\mu(d\xi|\theta)\to\int G(\theta,\xi)\mu(d\xi|\theta) \tag{3.27}$$

uniformly on each compact θ set. But this follows from (3.10) and the monotone convergence theorem.

Part 6. *Using* (3.11b). If we drop the uniqueness condition, then the subsequence $\epsilon(p)$ might be important. However, note that the above proof established that, whether or not there is uniqueness,

$$\dot{\theta}(s)=\int G(\theta(s),\xi)\mu(d\xi|\theta(s))$$

for some invariant measure, which might depend on (ω,s). But (3.11b) implies that the right-hand side equals $g(\theta(s))$ for the function $g(\cdot)$ defined there. □

3.2. Limit points and nonunique invariant measures: Limit points of (3.12). We use some elementary facts from the theory of differential equations. Given an ODE $\dot{x}=f(x)$, $x\in R^r$, with continuous $f(\cdot)$ and a bounded solution $x(\cdot)$ on $[0,\infty)$, let L denote the set of limit points of the path $x(\cdot)$. Define an *invariant set* M for the ODE as follows. For each $y\in M$, there is a solution $y(\cdot)$ to the ODE on $(-\infty,\infty)$ such that $y(t)\in M$ for all t and $y(0)=y$. Then [15] L is a compact invariant set. We can now state the following result.

THEOREM 3.2. *Assume the conditions of Theorem* 3.1. *The limit points of* (3.12) *are contained in the largest bounded invariant set* M *of* $\dot{x}=g(x)$. *Now let* $\epsilon q_\epsilon\to\infty$ *and* $\theta^\epsilon(\epsilon q_\epsilon+\cdot)\Rightarrow\theta(\cdot)$ *as* $\epsilon\to 0$. *Then, w.p.1 for each* $t\in(-\infty,\infty)$, $\theta(t)\in M$.

Remark. The last assertion holds since the solution is defined on the doubly infinite time interval. If the ODE has a unique stationary point $\hat{\theta}$, then the last assertion implies that $\theta(t)=\hat{\theta}$ for all t. Appropriate perturbation schemes will guarantee that the iterate won't get stuck at a maximum or at a saddle point. Reference [1] shows that the set of limit points are confined to the set of chain recurrent points, which might be smaller than the largest bounded invariant set, but the conditions are stronger.

Nonunique invariant measure. Suppose that $\mu(\cdot|\theta)$ is not unique and (3.11b) cannot be verified. We might still be able to get a useful result. Let $V(\theta)$ denote the (convex) set of invariant measures under θ. The proof of Theorem 3.1 can be easily modified to get the following theorem.

THEOREM 3.3. *Assume the conditions of Theorem* 3.1 *except for* (3.11). *Then w.p.1 and for almost all* t, *the theorem holds with* (3.12) *replaced by*

$$\dot{\theta}(t)\in\left\{\int G(\theta(t),\xi)\mu(d\xi|\theta(t)),\ \mu(\cdot|\theta(t))\in V(\theta(t))\right\}. \tag{3.28}$$

3.3. "Atomic" increments. Return to the basic algorithm (3.1). In many applications the Y-variables have an additivity property which can simplify the verification of the conditions and which we now explain and exploit. Define $q_0^\epsilon = 0$ and suppose that we update at the increasing random times $q_n^\epsilon, n = 1, \ldots$. Let $k^\epsilon(n)$ be the last time of updating before and including time n. By additivity, we mean that the observations can be divided up such that the algorithm can be written

$$\theta_{n+1}^\epsilon = \theta_n^\epsilon + \epsilon \sum_{i=q_n^\epsilon}^{q_{n+1}^\epsilon - 1} Y_i^\epsilon, \tag{3.29}$$

where the Y_n^ϵ obey the conditions of Theorem 3.1. At each instant i in the interval $[q_n^\epsilon, q_{n+1}^\epsilon)$ the value θ_n^ϵ is used to get Y_i^ϵ. From the point of view of the convergence theory, one can just as well update in "real time" and use the modified algorithm

$$\theta_{n+1}^\epsilon = \theta_n^\epsilon + \epsilon Y_n^\epsilon, \tag{3.30}$$

where $\theta_{k^\epsilon(n)}^\epsilon$ is used to get Y_n^ϵ. Suppose that $q_{n+1}^\epsilon - q_n^\epsilon$ is bounded by some constant independently of ϵ, n. Then the conditions of Theorem 3.1 guarantee that its conclusions hold for the SA (3.30) and similarly for its extensions. If the intervals $q_{n+1}^\epsilon - q_n^\epsilon$ are unbounded, then in order for the two time scales of (3.29) and (3.30) to be compatible, we need in addition that the conditions of Theorem 3.1 hold for the original algorithm, in particular that $[\theta_{n+1}^\epsilon - \theta_n^\epsilon]/\epsilon$ be uniformly (in n, ϵ) integrable.

The advantage of this "atomic" decomposition is that it makes it easier to verify the conditions on the Markov chain ξ_n^ϵ for (3.30) than for (3.39), since the transitions are viewed "more locally."

3.4. Updating at regeneration times. Suppose that the problem has a structure that allows $g(\theta)$ to be estimated regeneratively. When $g(\theta)$ is the derivative of $C(\theta)$, a continuously differentiable, "stationary cost" function of a regenerative process, an excellent treatment of the regenerative estimation of the derivative is in [14]. We might wish to use SA to minimize $C(\theta)$. In particular, suppose that θ_n^ϵ will be updated at the end of each new k regeneration intervals and that there are Y_n^ϵ which are "nearly" unbiased estimators of $g(\theta_n^\epsilon)$ and which depend on data in regeneration intervals $[nk+1, nk+k]$ only. Let (3.1) be used. Define

$$G_n^\epsilon(\theta) = E[Y_n^\epsilon | \theta_n^\epsilon = \theta, \theta_i^\epsilon, i < n] = E[Y_n^\epsilon | \theta_n^\epsilon = \theta].$$

Assume that $\{\theta_n^\epsilon, \epsilon > 0, n < \infty\}$ is tight, $\{Y_n^\epsilon, \epsilon > 0, n < \infty\}$ is uniformly integrable, and, for each $\delta > 0$,

$$\lim_\epsilon \limsup_n P\{|G_n^\epsilon(\theta_n^\epsilon) - g(\theta_n^\epsilon)| \geq \delta\} = 0. \tag{3.31}$$

Then a simpler proof than that of Theorem 3.1 says that the conclusions of Theorem 3.1 hold (and similarly for the other theorems). The proof is simpler since there is no need to introduce ξ_n^ϵ or the averaging measures. We note that sometimes the minimization of an average cost per unit time can be reduced to an SA iteration where we update at the end of each k intervals for some integer k. See, for example, §2.2 of [32]. The results of Theorem 3.1, as expanded in Appendices 3 and 4, show that it is not necessary to use regeneration intervals as the basis for updating. Indeed, updating only at the ends of these intervals might be a poor idea in practice in general, despite the fact that the proofs are simplified. For network problems, a regeneration

interval-based approach would be a handicap, since the intervals would generally be very long. The situation is even worse if the processing is distributed (Appendix 4). The same point was made by [35].

4. Time-varying gains $\epsilon_n \to 0$. Suppose that the positive real numbers ϵ_n go to zero such that

$$\sum_{n=0}^{\infty} \epsilon_n = \infty \tag{4.1a}$$

and

$$\text{either } \sum_n |\epsilon_{n+1} - \epsilon_n| < \infty \text{ or } \epsilon_n/\epsilon_{n+1} \to 1. \tag{4.1b}$$

These ϵ_j could actually be random if they are nonanticipative and satisfy (4.1). The SA algorithm is

$$\theta_{n+1} = \theta_n + \epsilon_n Y_n. \tag{4.2}$$

Let $\mathcal{B}_n$ be a sequence of nondecreasing sigma-algebras measuring at least $\{\theta_0, Y_i, i < n\}$. Write E_n for the conditional expectation given $\mathcal{B}_n$. The δY_n defined by $Y_n = E_n Y_n + \delta Y_n$ are $\mathcal{B}_n$-martingale differences. As for Theorem 3.1, suppose that there is a process $\{\xi_n, n < \infty\}$ taking values in a CSMS and functions $G_n(\cdot)$ such that $E_n Y_n = G_n(\theta_n, \xi_n)$. Define $t_n = \sum_{i=0}^{n-1} \epsilon_i$. Following the definition (2.2) for $t \geq 0$, define $\theta^0(t) = \theta_n$ on $[t_n, t_{n+1})$ and set $\theta^0(t) = \theta_0$ on $(-\infty, 0]$. Define $\theta^n(t) = \theta^0(t_n + t)$. Thus $\theta^n(0) = \theta_n$.

Theorems 3.1–3.3 readily lead to the following theorem.

THEOREM 4.1. *Assume the conditions of Theorem* 3.1 *with* (4.1), (4.2), *and the following replacements. Equations* (3.2)–(3.6) *and* (3.10) *hold with the superscript* ϵ *dropped. Use* $\limsup_n$ *in* (3.9). *Then* $\{\theta^n(\cdot), n < \infty\}$ *is tight and the limit of any weakly convergent subsequence satisfies* (3.12) *on* $(-\infty, \infty)$ *w.p.*1. *Also, w.p.*1., *for all* t, $\theta(t) \in M$, *the largest bounded invariant set of* (3.12). *If* (3.11) *is dropped, the the conclusions of Theorem* 3.3 *still hold. The obvious analogue of the results for the "atomic" increments formulation also hold.*

Remarks on the proof. Again, the general structure is similar to that used in [28] but with differing details. The proof is essentially the same as those of Theorems 3.1 and 3.3. The only difference concerns the way the terms are grouped, i.e., the analogy to the arrangement in (3.17). For simplicity, let $t \geq 0, \tau > 0$. Define $m_n(t) = \max\{j \geq n : t_j - t_n \leq t\}$. The following expression replaces (3.16):

$$Eh(\theta^n(s_i), i \leq q)\left[\theta^n(t+\tau) - \theta^n(t) - \sum_{j=m_n(t)}^{m_n(t+\tau)-1} \epsilon_j (G_j(\theta_j, \xi_j) + \delta Y_j)\right] = 0. \tag{4.3}$$

The martingale term

$$\sum_{j=m_n(t)}^{m_n(t+\tau)-1} \epsilon_j \delta Y_j$$

goes to zero as $n \to \infty$ by a bounding argument of the type used in Theorem 3.1 and the fact that $\epsilon_n \to 0$. Note in particular that no condition of the form $\sum \epsilon_j^{1+\delta} < \infty$

for $\delta > 0$ is needed. It is only required that $\epsilon_n \to 0$. Indeed, if the $\{Y_n, n < \infty\}$ were uniformly square integrable, then the variance of the martingale term would be $O(1)\sum_{m_n(t)}^{m_n(t+\tau)-1} \epsilon_j^2$ and this goes to zero if $\epsilon_j \to 0$, since $\sum_{j=m_n(t)}^{m_n(t+\tau)-1} \epsilon_j \approx \tau$. In general, one uses uniform integrability to the same end as in part 2 of the proof of Theorem 3.1.

We now comment briefly on the appropriate grouping of the terms. The δ_ϵ used for the grouping in (3.17) is replaced with a sequence of positive numbers $\delta_n \to 0$ which satisfy $\lim_n \sup\{\epsilon_j/\delta_n : j \geq n\} = 0$. Define $m(n,0) = n$. For each n, define an increasing sequence of integers $m(n,l), l = 1, \ldots,$ by

$$m(n,l) = \min\left\{j : \sum_{i=n}^{j-1} \epsilon_i \geq l\delta_n\right\}.$$

Thus

$$\sum_{j=m(n,l)}^{m(n,l+1)-1} \epsilon_j \approx \delta_n.$$

For each n, we will arrange the terms in groups of successive sizes $m(n,l+1) - m(n,l)$ as follows. Suppose, for notational simplicity, that both t and $t+\tau$ are integral multiples of δ_n. The changes for the general case should be obvious. Now, analogously to what was done in part 3 of the proof of Theorem 3.1, replace the sum of the $\epsilon_j G_j$ in (4.3) with

$$\sum_{l:l\delta_n=t}^{(t+\tau)-\delta_n} \delta_n \left[\frac{1}{\delta_n} E_{m(n,l)} \sum_{j=m(n,l)}^{m(n,l+1)-1} \epsilon_j G_j(\theta_j, \xi_j)\right]. \tag{4.4}$$

Then argue that the $G_j(\theta_j, \xi_j)$ in the sum on the right can be replaced by $G_B(\theta_{m(n,l)}, \xi_j)$ plus an arbirarily small (in the mean) error for large B, n. Define the measure-valued random variables $R(l,n,\cdot)$ by

$$R(l,n,\cdot) = \frac{1}{\delta_n} \sum_{j=m(n,l)}^{m(n,l+1)-1} \epsilon_j P\{\xi_j \in \cdot | \theta_{m(n,l)}, \xi_{m(n,l)}\}. \tag{4.5}$$

Thus, as in part 4 of the proof of Theorem 3.1, we approximate the bracketed term in (4.4) by

$$\int G_B(\theta_{m(n,l)}, \xi) R(l,n,d\xi).$$

Next consider the analogue of the factorization taking the sum on the right side of (3.24) to that in (3.25). The analogue of (3.25) (before extracting the convergent subsequence and without the limit) is

$$\frac{1}{\delta_n} \sum_{j=m(n,l)+1}^{m(n,l+1)-1} \int\int \epsilon_j P\{\theta_{j-1} \in d\tilde{\theta}, \xi_{j-1} \in d\tilde{\xi} | \theta_{m(n,l)}, \xi_{m(n,l)}\} P_{j-1}(\tilde{\xi}, d\xi | \tilde{\theta}) f(\xi).$$

Analogously to part 4 of the proof of Theorem 3.1, we can fix $\tilde{\theta}$ at $\theta_{m(n,l)}$ and replace $P_j(\cdot)$ with $P(\cdot)$ to get the representation

$$\int R(l,n,d\tilde{\xi}) \int f(\xi) P(\tilde{\xi}, d\xi | \theta_{m(n,l)}),$$

where ϵ_{j-1} replaces ϵ_j in the definition of $R(\cdot)$. By either option in (4.1b), this replacement does not affect the limit.

5. A constrained algorithm. Let H be a closed set in R^r. Let $\Pi_H(x)$ denote the closest point in H to x. The following development is a slight extension of [22, pp. 111–114]. Define the projected form of (3.1) as

$$\theta_{n+1}^{\epsilon} = \Pi_H(\theta_n^{\epsilon} + \epsilon Y_n^{\epsilon}). \tag{5.1}$$

Rewrite (5.1) as

$$\theta_{n+1}^{\epsilon} = \theta_n^{\epsilon} + \epsilon Y_n^{\epsilon} + \epsilon z_n^{\epsilon},$$

where z_n^{ϵ} is the "correction term." The decomposition (5.1) is the key to the analysis and first appeared in [25]. Under (3.2), the sequence $\{z_n^{\epsilon}, \epsilon > 0, n < \infty\}$ is uniformly integrable. Let q_ϵ be a sequence of integers satisfying (3.8′). The proof of Theorem 3.1 yields immediately that the limit of any convergent subsequence of $\{\theta^{\epsilon}(q_\epsilon \epsilon + \cdot), \epsilon > 0\}$ as $\epsilon \to 0$ has the form

$$\dot{\theta} = g(\theta) + z, \tag{5.2}$$

where $\int_0^t z(s)ds$ is the limit of the process with values $\epsilon \sum_{n=q_\epsilon}^{q_\epsilon + t/\epsilon - 1} z_n^{\epsilon}$ for $t \geq 0$, and with the obvious change for $t < 0$. Thus the only problem concerns the characterization of $z(\cdot)$. By the uniform integrability, $(z(\cdot), \theta(\cdot))$ are Lipschitz continuous w.p.1 (Lemma 2.1). Clearly, $z(u) = 0$ on any interval $(t, t+\tau)$ in which $\theta(u) \in H^0$, the interior of H. To proceed, we need to specify H more fully, and we assume either of I or II below.

I. Let $q_i(\cdot), i = 1, \cdots, p$, be continuously differentiable real-valued functions on R^r, with gradients $q_{i,x}(\cdot)$. Without loss of generality, let $q_{i,x}(x) \neq 0$ if $q_i(x) = 0$. Define $H = \{x : q_i(x) \leq 0, i = 1, \ldots, p\}$ and assume that it is nonempty. Define $A(x)$, the set of active constraints at x, by $A(x) = \{i : q_i(x) = 0\}$. Define $C(x)$ to be the closed convex cone generated by $\{y : y = q_{i,x}(x), i \in A(x)\}$. Suppose that for each x with nonempty $A(x)$, the set $\{q_{i,x}(x), i \in A(x)\}$ is linearly independent.

II. H is an R^{r-1}-dimensional connected surface with a continuously differentiable outer normal. In this case, define $C(x), x \in H$, to be just the linear span of the outer normal at x.

THEOREM 5.1. *Assume the conditions above and the conditions of Theorem* 3.1. *Then the conclusions of Theorem* 3.1 *and Theorem* 3.2 *hold with* (5.2) *replacing* (3.12) *and* $z \in -C(\theta(t))$, *where the limit points of* (5.2) *replace* M. *If* (3.11) *is dropped, then the the conclusions of Theorem* 3.3 *still hold. The same conclusions hold for the constrained form of Theorem* 4.1.

Proof. The basic proof is a straightforward extension of that of Theorem 3.1. To characterize $z(t)$ we use the fact that if for any (t, x), $\theta^{\epsilon}(t) = x$, then $z_{t/\epsilon}^{\epsilon}$ is in a small neighborhood of $-C(y)$ for some y near x when ϵ is small. Then use the fact that $C(x)$ is upper semicontinuous in the sense that if $N_\delta(x)$ is a $\delta-$neighborhood of x, then

$$\cap_{\delta > 0} \cup_{y \in N_\delta(x)} C(y) \subset C(x);$$

i.e., the set of active constraints at x contains that for points very close to it. □

Note. If, under I, there is only one active constraint (say, i) at t, and $g(\theta(t))$ points out of H, then the right-hand side of (5.2) is just the projection of $g(\theta(t))$ onto the boundary surface.

6. Applications of Theorem 3.1: Introduction. As they are stated, the results in §§3–5 do not explicitly deal with the optimization of an average cost over an infinite interval. In the examples in the remaining sections, we show that they are very powerful tools for proving convergence for just such problems. Three canonical examples of optimization will be described in detail. All use some approximation to a gradient search procedure. We will use constant step sizes as in Theorem 3.1, but the extensions to the decreasing step-size case will follow immediately from Theorem 4.1. Note that the constant step-size case $\epsilon_n = \epsilon$ has applications in tracking and adaptive control also. The examples concern the minimization of a stationary average cost associated with the path of a dynamical system. This section deals with a general discussion of the issues. Section 7 concerns a discrete event dynamical system example and an IPA-type estimator [13, 18]. Section 8 concerns a "piecewise deterministic" example, also using an IPA-type estimator and involving a problem in manufacturing. The third example involves a stochastic differential equations model. The examples are illustrative of many others using various methods of estimating derivatives.

Let us consider a canonical continuous time model in a rather informal way, since we wish only to illustrate the basic ideas in an unincumbered way. The general considerations hold also for discrete-time models, as will be seen in the next two sections. Among the points to be clarified is the so-called resetting of the IPA "accumulator." It will be seen that it is often neither necessary nor desirable. The basic ideas are in [22, 27], but their full potential has not been realized in the literature.

Suppose that for fixed parameter θ, $x(\cdot,\theta)$ represents the dynamical state process of the system. In order to fix ideas, let $x(\cdot,\theta)$ be defined by the SDE

$$dx(t,\theta) = b(x(t,\theta),\theta))dt + dw.$$

For the sake of simple notation, let both x and θ be real valued and the function $b(\cdot)$ be smooth enough so that the following calculations make sense. We return to this example in a more thorough way in §9. For initial condition $x(0,\theta) = x(0)$, fixed parameter θ, and cost rate $c(\theta, x(s,\theta))$, define the average cost per unit time on $[0,T]$ by

$$C_T(\theta, x(0)) = E\frac{1}{T}\int_0^T c(\theta, x(s,\theta))ds.$$

Suppose that $C_T(\theta, x(0))$ is continuously differentiable with respect to θ with gradient $C_{T,\theta}(\theta, x(0))$. Suppose that for each θ the limit $C(\theta) = \lim_T C_T(\theta, x(0))$ exists and does not depend on $x(0)$. Suppose that the pointwise limit of $C_{T,\theta}(\theta, x(0))$ exists and is denoted by $\hat{C}_\theta(\theta)$. Then $\hat{C}_\theta(\theta) = C_\theta(\theta)$.

We wish to use SA to minimize $C(\theta)$. A common procedure for updating θ via gradient seach is based on the consistency of $C_{T,\theta}(\theta, x(0))$; i.e., it is a good estimator of $C_\theta(\theta)$ if T is large. Pursuing this idea, let us update the parameter at times $nT, n = 1, 2, \ldots$, as follows. Letting θ_n^ϵ denote the nth choice of the parameter, use it on $[nT, nT+T)$ to get an estimator $\hat{Y}_n^\epsilon$ of $-C_{T,\theta}(\theta_n^\epsilon, x(\theta_n^\epsilon, nT))$. Then use

$$\theta_{n+1}^\epsilon = \theta_n^\epsilon + \epsilon\hat{Y}_n^\epsilon. \tag{6.1}$$

Let $x^\epsilon(\cdot)$ (with $x^\epsilon(0) = x(0)$) denote the actual physical state process with the time varying θ_n^ϵ used, i.e., on $[nT, nT+T)$ $x^\epsilon(t) = x(t, \theta_n^\epsilon)$ with the "initial condition" of $x(\cdot, \theta_n^\epsilon)$ at time nT being

$$x(nT, \theta_n^\epsilon) = x^\epsilon(nT). \tag{6.2}$$

Continuing, suppose that $\hat{Y}_n^\epsilon$ is an unbiased estimator of $-C_{T,\theta}(\theta_n^\epsilon, x^\epsilon(nT))$. This is equivalent to "restarting" the estimation procedure anew at each nT with initial condition $x^\epsilon(nT)$. To see what the limit ODE for (6.1) might be, proceed purely formally, let $\xi_n^\epsilon = x^\epsilon(nT)$ and apply Theorem 3.1 to get

$$\dot{\theta} = -\int C_{T,\theta}(\theta, \xi)\mu(d\xi|\theta). \tag{6.3}$$

The right side of (6.3) would not be close to $-C_\theta(\theta)$ unless (at least) T is large. For this reason, it is often suggested that T depend on either or both ϵ, n and go to infinity as one or both of these quantities goes to its limit. In [41], there are conditions for the convergence of the right side of (6.3) to $-C_\theta(\theta)$ for Markov chain models.

Before showing how to improve (6.3), let us look at a typical procedure more closely. In order to get a (pathwise) gradient estimator one generally introduces an auxiliary process $y(\cdot, \theta)$. For IPA estimators [13, 18, 32], this would be the pathwise derivative of $x(\cdot, \theta)$ with respect to θ; for likelihood ratio estimators [32, 37, 38] this would be the score function which keeps the information on the derivative of the measure. Other methods such as smoothed perturbation analysis and rare perturbation analysis [4] use auxiliary information that represents the difference between the path $x(\cdot, \theta)$ and a perturbed one. See also the discussion of mean square derivatives and finite differences in §9.

For the model used in our illustrative example, the appropriate $y(\cdot, \theta)$ process is the mean square derivative defined by $x_\theta(t, \theta) = y(t, \theta)$:

$$\dot{y}(t, \theta) = b_x(x(t, \theta), \theta) + b_\theta(x(t, \theta), \theta)$$

with initial condition $y(0, \theta) = 0$. Define $z(\cdot, \theta) = (x(\cdot, \theta), y(\cdot, \theta))$ The estimator of $C_{T,\theta}(\theta, x(0))$ has the form

$$\frac{1}{T}\int_0^T \lambda(\theta, z(s, \theta))ds,$$

where

$$\lambda(\theta, z(s, \theta)) = c_x(\theta, x(s, \theta))y(s, \theta) + c_\theta(\theta, x(s, \theta)).$$

Let $z^\epsilon(\cdot) = (x^\epsilon(\cdot), y^\epsilon(\cdot))$ be the actual process with the time-varying parameter used. Then the formal procedure leading to (6.3) would use

$$\hat{Y}_n^\epsilon = -\frac{1}{T}\int_{nT}^{nT+T} \lambda(\theta, z^\epsilon(s))ds, \tag{6.4}$$

where on $[nT, nT + T)$ we have $y^\epsilon(t) = y(t, \theta_n^\epsilon)$ with initial condition $y^\epsilon(nT) = 0$.

Now consider an alternative where $x^\epsilon(\cdot)$ is as above but $y^\epsilon(\cdot)$ is not reset to zero at times nT. Use $y^\epsilon(0) = 0$ and on $[nT, nT + T)$ use $y^\epsilon(\cdot) = y(\cdot, \theta_n^\epsilon)$ with initial condition at nT defined recursively by

$$y^\epsilon(nT) = y(nT, \theta_n^\epsilon). \tag{6.5}$$

Then with the new definition of $z^\epsilon(\cdot)$, use the estimator

$$Y_n^\epsilon = -\frac{1}{T}\int_{nT}^{nT+T} \lambda(\theta_n^\epsilon, z^\epsilon(s))ds. \tag{6.6}$$

Note that in general (6.6) would not be an unbiased estimator of $-C_{T,\theta}(\theta_n^\epsilon, x^\epsilon(nT))$ due to the "memory " in its "initial conditions."

Now define the process $\xi_n^\epsilon = z^\epsilon(nT)$, and assume the conditions of Theorem 3.1. Then the ODE which characterizes the limit behavior is (3.12), where

$$G(\theta, \xi) = -E[Y_n^\epsilon | \xi_n^\epsilon = \xi, \theta_n^\epsilon = \theta].$$

By the definition of the invariant measure, we then have

$$g(\theta) \equiv \int G(\theta, \xi)\mu(d\xi|\theta) = \lim_n \frac{1}{n}\sum_{i=1}^{n} EG(\theta, \xi_i(\theta)), \tag{6.7}$$

where $\xi_i(\theta)$ is the stationary process under θ. Under either (3.11a) or (3.11b), the limit on the right side is the same if we used the process $\xi_n(\theta)$ with initial condition $\xi_0(\theta) = (x(0), 0)$. Thus, with this new initial condition (6.7) equals

$$-\lim \frac{1}{nT} E \int_0^{nT} \lambda(\theta, z(s, \theta))ds = -\lim_T C_{T,\theta}(\theta, x(0)) = -C_\theta(\theta). \tag{6.8}$$

This is what we want since it yields the gradient descent ODE

$$\dot{\theta} = -C_\theta(\theta) \tag{6.9}$$

in lieu of the "biased" (6.3). In the parlance of the literature (e.g., [32]), (6.9) results when we do not reset the "accumulator." While there has been some discussion of this preferable alternative, proofs and a clear understanding were lacking. In the next three sections, the details are filled in for three classes of applications.

7. A discrete example: A GI/G/1 queue. We consider the problem treated in [7, 11, 31, 32]. The model is a single-server queue with a renewal arrival process and general service time distribution, which is parametrized by $\theta > 0$. For notational simplicity, we suppose that θ is real valued, but the development and results are the same in general. For fixed θ let $X_i(\theta)$ denote the sojourn time of the ith customer and $K(\theta)$ be a bounded real-valued function with a continuous and bounded gradient. The cost of interest is

$$C(\theta) = \lim_N \frac{1}{N}\sum_{i=1}^{N} EX_i(\theta) + K(\theta) \equiv \hat{C}(\theta) + K(\theta), \tag{7.1}$$

and we wish to use SA to get the minimizing θ. Again, we suppose that the parameter θ is bounded. Indeed, the parameter might have to be restrained to some particular interval $[\theta_-, \theta_+]$ in order for the assumptions below to hold, and we assume that this is done. The example is widely studied, but the conditions used here are about as simple as one can expect. The structure of the problem is similar (from the point of view of SA) to those arising in other applications to single queues (and even for some network problems). For example, consider the multiclass problem [34], admission control [42], flow control in a closed network [43], routing in an open network [40], and routing in a closed network [17]. Appendix 4 discusses the decentralized case that is of interest in network models.

Fixed θ-process: Application of IPA. We proceed to make the usual assumptions to assure that $dX_i(\theta)/d\theta$ exists and can be estimated via IPA. Define the

parametrized service time distribution $F(\cdot|\theta)$, and suppose that it is weakly continuous in θ. Define the inverse function $F^{-1}(\cdot|\theta)$ by

$$F^{-1}(\chi|\theta) = \min\{\zeta : F(\zeta|\theta) \geq \chi\}, \qquad \chi \in [0,1],$$

and assume that it is differentiable in θ for each χ, with a bounded and continuous (uniformly in χ) derivative denoted by $F_\theta^{-1}(\chi|\theta)$. For fixed θ, let $\{\zeta_i(\theta), i < \infty\}$ denote the sequence of service times and define $\chi_n(\theta) = F(\zeta_n(\theta)|\theta)$ and the derivative $Z_n(\theta) = F_\theta^{-1}(\chi_n(\theta)|\theta)$. Let $Q_i(\theta)$ denote the queue length and $\tau_i(\theta)$ the (residual) time until the next arrival, all taken just after the departure of the ith customer. Then $x_n(\theta) = (Q_n(\theta), \tau_n(\theta))$ is a Markov process. Define the cost for the first N customers, initialized at an arbitrary initial condition, as

$$C_N(\theta, x_0) = \hat{C}_N(\theta, x_0) + K(\theta) = \frac{1}{N}\sum_{i=1}^{N} EX_i(\theta) + K(\theta). \tag{7.2}$$

Suppose that the busy periods have finite mean length for each fixed θ. Let $\bar{Z}_n(\theta)$ denote the sum of the $|Z_j(\theta)|$ in the nth busy period. Suppose that

$$\sup_\theta E|\bar{Z}_n(\theta)| < \infty. \tag{7.3}$$

Remark on (7.3). In many cases where IPA can be applied, the θ is a scale parameter of the service distribution. Then we have the form $F(\zeta|\theta) = F(\theta\zeta|1)$, $\zeta_n(\theta) = \theta F^{-1}(\chi_n(\theta)|1)$, and $Z_n(\theta) = \zeta_n(\theta)/\theta$, where the $\chi_n(\theta)$. Letting $N(\theta)$ denote the number of services in a busy period, Wald's identity yields $E|\bar{Z}_n(\theta)| = E\bar{Z}_n(\theta) = EN(\theta)EZ_j(\theta)$. If the system is stable, then $EN(\theta) < \infty$ and (7.3) holds.

Continuing, consider the estimator

$$\hat{Z}_m(\theta) = \frac{1}{m}\sum_{i=1}^{m}\sum_{j=v_i(\theta)}^{i} Z_j(\theta), \tag{7.4}$$

where $v_i(\theta)$ is the index of the first arrival in the busy period in which customer i arrives. If $Q_0 = 0$, then (7.4) is an unbiased estimator of the derivative of $\hat{C}_m(\theta, x_0)$, where x_0 is the state at time zero. It is an asymptotically consistent estimator in that [13] for each initial condition

$$E\hat{Z}_m(\theta) \to \hat{C}_\theta(\theta). \tag{7.5}$$

Henceforth, just to simplify notation and not have to worry about the possibly separate indices for arrivals and departures, we suppose that the queue starts empty. The conditions and results are the same in general.

The estimator for the SA. We wish to use SA to minimize the cost (7.1) via use of the IPA estimator. Suppose that the parameter is updated after the departure of each successive group of N customers. We use the "customer number" instead of real time. For fixed θ, the estimator used on the nth interval (the departures $[nN+1, nN+N]$) is to be

$$\hat{Y}_n(\theta) = \frac{1}{N}\sum_{i=nN+1}^{nN+N}\sum_{j=v_i(\theta)}^{i} Z_j(\theta).$$

Recall that $v_{nN}(\theta)$ is the index of the first arrival in the busy period in which arrival (equivalently, departure) nN occurs. Let $D_n(\theta)$ denote the number of departures from the $(nN+1)$st to the end of the busy period in which departure nN occurs. It is zero if the nNth departure ends a busy period. Now, to separate the "past" from the contributions over $[nN+1, nN+N)$, we split $\hat{Y}_n(\theta)$ by defining

$$\psi_n(\theta) = \sum_{j=v_{nN}(\theta)}^{nN} Z_j(\theta), \text{ "past"}$$

$$A_n(\theta) = \frac{1}{N} \sum_{i=nN+1}^{nN+N} \sum_{j=v_i(\theta)\vee(nN+1)-1}^{i} Z_j(\ t), \text{ "future,"}$$

$$B_n(\theta) = \frac{1}{N} \sum_{i=nN+1}^{nN+N} \sum_{j=v_i(\theta)}^{v_i(\theta)\vee(nN+1)-1} Z_j(\theta),$$

Then

$$\hat{Y}_n(\theta) = A_n(\theta) + B_n(\theta).$$

We can write

$$B_n(\theta) = D_n(\theta)\psi_n(\theta)/N.$$

Following the basic framework of §3, define the Markov chain $\xi_n(\theta) = (Q_n(\theta), \tau_{nN}(\theta), \psi_n(\theta))$. Define $G_i(\cdot)$ by

$$G_0(\theta, \xi_n(\theta)) = E_n A_n(\theta), \qquad G_1(\theta, \xi_n(\theta)) = E_n D_n(\theta)/N,$$

where E_n denotes the expectation conditioned on all the systems data up to and including the time of the nNth departure. It is equivalent to conditioning on $\xi_n(\theta)$.

The functions $G_i(\cdot, \xi)$ are continuous in θ, uniformly in each compact (θ, ξ) set by the continuity assumptions made on the distribution of the service interval and the derivative of its inverse. In preparation for the conclusion of the SA argument, note that (and define $G(\cdot)$ by)

$$E_n \hat{Y}_n(\theta) = G_0(\theta, \xi_n(\theta)) + G_1(\theta, \xi_n(\theta))\psi_n(\theta) \equiv G(\theta, \xi_n(\theta))$$

and that

$$\lim_n \frac{1}{n} \sum_{i=1}^{n} EG(\theta, \xi_n(\theta)) = \lim_n \frac{1}{nN} E \sum_{i=1}^{nN} \sum_{j=v_i(\theta)}^{i} Z_j(\theta) = \hat{C}_\theta(\theta) \tag{7.6}$$

for each initial condition.

The SA problem. For the actual physical system with the time-varying parameter, let ζ_n^ϵ denote the actual service time of the nth customer and Z_n^ϵ the derivative of the inverse function, using the parameter θ_n^ϵ for $nN+1 \le j \le nN+N$. Let v_i^ϵ be the index of the first arrival in the busy period in which customer i departs. Let

τ_i^ϵ be the residual time to the next arrival and Q_i^ϵ the queue length, all taken at the time of the ith departure. To update θ_n^ϵ we use the estimator

$$\hat{Y}_n^\epsilon = \frac{1}{N} \sum_{i=nN+1}^{nN+N} \sum_{j=v_i^\epsilon}^{i} Z_j^\epsilon. \tag{7.7}$$

The SA algorithm is

$$\theta_{n+1}^\epsilon = \left[\theta_n^\epsilon - \epsilon \hat{Y}_n^\epsilon - \epsilon K_\theta(\theta_n^\epsilon)\right]_{\theta_-}^{\theta_+}. \tag{7.8}$$

Now define

$$\psi_n^\epsilon = \sum_{j=v_{nN}^\epsilon}^{nN} Z_j^\epsilon,$$

and define $A_n^\epsilon, B_n^\epsilon$ analogously to what was done for the fixed θ case. Then $\hat{Y}_n^\epsilon = A_n^\epsilon + B_n^\epsilon \psi_n^\epsilon$ and $\xi_n^\epsilon = (Q_{nN}^\epsilon, \tau_{nN}^\epsilon, \psi_n^\epsilon)$ is a Markov chain. We can write

$$E_n^\epsilon \hat{Y}_n^\epsilon = G_0(\theta_n^\epsilon, \xi_n^\epsilon) + G_1(\theta_n^\epsilon, \xi_n^\epsilon)\psi_n^\epsilon = G(\theta_n^\epsilon, \xi_n^\epsilon). \tag{7.9}$$

In this example, the P_n^ϵ in (3.5) does not depend on ϵ, n. Thus, (3.6) holds. Assumption (3.7) follows from the assumptions on the service time distribution. Also, the G_n^ϵ in (3.9) does not depend on ϵ, n. Assumption (3.11b) follows from (7.6).

We need conditions which guarantee (3.2), (3.4), and (3.8). Define $\bar{Z}_n^\epsilon$ to be the sums of $|Z_j^\epsilon|$ over the nth busy period. Suppose that

$$\{\bar{Z}_n^\epsilon, \epsilon > 0, n < \infty\} \text{ is uniformly integrable,} \tag{7.10}$$

$$\sup_\theta E\zeta(\theta) < E[\text{ interarrival time}]. \tag{7.11}$$

By (7.10), (3.2) holds for $\hat{Y}_n^\epsilon$. The θ_n^ϵ are bounded and tightness of $\{\xi_n^\epsilon, \epsilon > 0, n < \infty\}$ follows from (7.3) and (7.11). Condition (3.8) follows from (7.3) and (7.11), and (3.10) is a consequence of (7.3). Now the convergence to the ODE

$$\dot{\theta} = -C_\theta(\theta) - K_\theta(\theta) \tag{7.12}$$

projected onto $[\theta_-, \theta_+]$ follows from Theorem 3.1. The case $\epsilon_n \to 0$ follows from Theorem 4.1.

Remark. We note that the updates need not be at regular intervals. If the interupdate times are bounded, then the end result is the same. Unbounded interupdate times might conceivably be of future interest, but at the moment it is hard to imagine an application in which it would be allowed, but with suitable conditions on the increments between updates we get the same result. If the estimator were reset at each nN, then the $\hat{Y}_n^\epsilon$ in (7.8) is replaced by A_n^ϵ and the $C_\theta(\theta)$ in (7.12) would be replaced by the biased quantity $\int \hat{C}_{N,\theta}(\theta, x)\mu_0(dx|\theta)$, where $\mu_0(\cdot|\theta)$ is the invariant measure of the $x_n(\theta)$ process defined above (7.2).

8. An example from manufacturing: A piecewise deterministic problem. We now consider an interesting example from [44]. The reference considers a manufacturing system with two unreliable tandem machines and is typical of many applications to production rate scheduling problems. Let $\alpha_i(t)$ denote the indicator function that machine i is working, and assume that these processes are independent renewal processes. The production rates $u_i(\cdot), i = 1, 2$, of the machines can be controlled, subject to the machines' working and to upper bounds $\bar{u}_i$ on the rates. Machine 1 feeds into machine 2 via a buffer for surplus inventory, and the demand rate for the output of machine 2 is fixed at d. The dynamical state is the current inventory level $x(\cdot) = (x_1(\cdot), x_2(\cdot))$. The inventory of machine 2 can be negative (backlog). The reference assumes that the inventory process defined below satisfies a Harris recurrence condition, but we will not need to suppose that. The dynamical state equation is $x(0) = 0$ and

$$\dot{x}_1(t) = u_1(t) - u_2(t), \qquad \dot{x}_2(t) = u_2(t) - d.$$

The control problem is actually more conveniently formulated in terms of the surplus variables, defined by

$$s_1(t) = x_1(t) + x_2(t) = \int_0^t u_1(s)ds, \qquad s_2(t) = x_2(t).$$

They consider control strategies of a threshold type on the $s_i(\cdot)$. (Their thresholds B_1, B_2 are the θ_1, θ_2 here.) In order to illustrate our method, we shall focus on one of their strategies, called the surplus control. Loosely speaking, for this control the production rate is held at the maximum value if the surplus is less than the threshold and tries to stay at the threshold if it ever reaches it. If (during the transient initial period) the surplus on some machine is higher than the threshold, then production on that machine is zero. For notational simplicity, we suppose that the initial surpluses do not exceed the thresholds. The surplus process $s_i(\cdot)$ evolves with deterministic slopes ($\bar{u}_i$, 0, or $-d$) which correspond to maximum production rate minus demand, production rate equals demand, and no production, and these change at random times which depend on the values of the renewal $\alpha(\cdot)$ and state processes $s(\cdot)$. With minor exceptions, the assumptions used here are implied by those in [44]. The $\alpha_i(\cdot)$ processes do not depend on the thresholds. It is assumed that the maximum production rates satisfy $\bar{u}_1 > \bar{u}_2 > d$. Also, it is supposed that $\theta_1 > \theta_2 \geq 0$, with each threshold subject to an upper bound, and that the SA algorithm is constructed to guarantee this.

DEFINITIONS (the fixed θ processes). Henceforth, for the fixed θ processes, we write the state and surplus variables as $x(\cdot, \theta), s(\cdot, \theta)$, resp. For fixed thresholds θ, the control is such that the surplus processes are defined by

$$\dot{s}_1(t,\theta) = \begin{cases} (\bar{u}_1 - d)I_{\{s_1(t,\theta) < \theta_1\}} - dI_{\{s_1(t,\theta) > \theta_1\}} & \text{if } \alpha_1(t) = 1, \\ -d & \text{otherwise,} \end{cases} \tag{8.1}$$

$$\begin{aligned} \dot{s}_2(t,\theta) &= (\bar{u}_2 - d)I_{\{s_2(t,\theta) < \theta_2\}} - dI_{\{s_2(t,\theta) > \theta_2\}} \\ &\qquad \text{if } \alpha_2(t) = 1 \text{ and } (s_1(t,\theta) \geq s_2(t,\theta) \text{ or } \alpha_1(t) = 1), \\ \dot{s}_2(t,\theta) &= -d \quad \text{otherwise.} \end{aligned} \tag{8.2}$$

The dynamics are such that $s_1(t,\theta) - s_2(t,\theta) \geq 0$ if this condition holds at time zero, which we suppose. (The condition will eventually hold in any case.)

The system just described is an example of a piecewise deterministic control system [8, 16], where $x(\cdot,\theta)$ is piecewise linear, with the intervals being random. In [44], the interval distributions are exponential so that the state process is Markovian. For $c_1 > 0, c_2^{\pm} > 0$, the cost rate of concern is

$$c(s) = c_1 s_1 + c_2^+ s_2^+ + c_2^- s_2^-.$$

Actually, the reference starts with $\tilde{c}(x) = c_1 x_1 + c_2^+ x_2^+ + c_2^- x_2^-$, but in the derivative calculations switches to $c(\cdot)$. The two cost rates are equivalent, with appropriate definitions of the coefficients.

The thresholds are adjusted via an SA algorithm using IPA-type derivatives of the cost with respect to the θ_i, with the aim of minimizing the cost function

$$C(\theta) = \lim_M \frac{1}{M} \int_0^M c(s(t,\theta))dt, \tag{8.3}$$

where we suppose that the limit exists for each θ in the desired range. The reference [44] derives auxiliary processes $y_j^{(i)}(t,\theta)$, which is the pathwise derivative of $s_j(t,\theta)$ with respect to θ_i. We now describe these derivative processes.

The (IPA) derivative processes. The following results are taken from the reference, with only the terminology changed to bring it into line with our own. Define the random time $\tau(\theta) = \inf\{t > 0 : s_1(t,\theta) = \theta_1\}$. Then

$$y_1^{(1)}(t,\theta) = I_{\{t \geq \tau(\theta)\}}.$$

Define the random times $\tau_i^k(\theta)$ recursively by $\tau_2^0(\theta) = \tau(\theta)$ and

$$\tau_1^k(\theta) = \min\{t \geq \tau_2^{k-1}(\theta) \colon s_1(t,\theta) = s_2(t,\theta)\},$$

$$\tau_2^k(\theta) = \min\{t \geq \tau_1^k(\theta) \colon s_2(t,\theta) = \theta_2\}.$$

Then the pathwise derivative of the surplus process at machine 2 with respect to θ_1 is

$$y_2^{(1)}(t,\theta) = \sum_{k=1}^{\infty} I_{\{\tau_1^k(\theta) \leq t \leq \tau_2^k(\theta)\}}.$$

Note that at most one of the indicator functions in the sum can be positive at a time. Clearly, the expression for $\dot{s}_1(t,\theta)$ implies that $y_1^{(2)}(t) = 0$. Define the additional random times $\gamma_i^k(\theta)$ recursively by $\gamma_2^0(\theta) = 0$ and

$$\gamma_1^k(\theta) = \min\{t \geq \gamma_2^{k-1}(\theta) \colon s_2(t,\theta) = \theta_2\},$$

$$\gamma_2^k(\theta) = \min\{t \geq \gamma_1^k(\theta) \colon s_1(t,\theta) = s_2(t,\theta)\}.$$

Then the pathwise derivative with respect to θ_2 of the surplus process at machine 2 is

$$y_2^{(2)}(t,\theta) = \sum_{k=1}^{\infty} I_{\{\gamma_1^k(\theta) \leq t \leq \gamma_2^k(\theta)\}}.$$

Again, at most one of the indicator functions can be positive at a time.

Let $z(\cdot,\theta) = (x(\cdot,\theta), y(\cdot,\theta))$. Define $Y_n(\theta) = (Y_n^1(\theta), Y_n^2(\theta))$, where

$$Y_n^i(\theta) = -\frac{1}{T}\int_{nT}^{nT+T} \lambda_i(\theta, z(t,\theta))dt, \tag{8.4}$$

where

$$\lambda_1(\theta, z(s,\theta)) = c_1 y_1^{(1)}(t,\theta) + c_2^+ y_2^{(1)}(t,\theta) I_{\{s_2(t,\theta)\geq 0\}} - c_2^- y_2^{(1)}(t,\theta) I_{\{s_2(t,\theta)<0\}}, \tag{8.5a}$$

$$\lambda_2(\theta, z(s,\theta)) = c_2^+ y_2^{(2)}(t,\theta) I_{\{s_2(t,\theta)\geq 0\}} - c_2^- y_2^{(2)}(t,\theta) I_{\{s_2(t,\theta)<0\}}. \tag{8.5b}$$

Then $Y_n^i(\theta)$ is an unbiased estimator for $-C_{T,\theta_i}(\theta, x(0))$.

The SA updates will be at times $nT, n = 1, \ldots$, for some $T > 0$. Below, we will be concerned with the set $(s(nT,\theta), y(nT,\theta), \alpha(nT))$. For a general renewal process, this set is not a Markov process. To Markovianize, we augment it by adding the residual times until the next change of values of the $\alpha_1(\cdot), \alpha_2(\cdot)$ after nT. Let $\xi_n(\theta)$ denote the consequent quadruple.

To minimize work, we suppose that for each initial condition the limit

$$-\lim_M \frac{1}{M}\int_0^M E\lambda(\theta, z(\theta,t))dt \tag{8.6}$$

exists for each θ value of interest and is continuous in θ. Define it as $g(\theta)$. These conditions are weaker than those in the reference. Then $C_\theta(\theta) = -g(\theta)$. In any case, these conditions amount to nothing more than asymptotic consistency, and are a minimal condition for the convergence. Define $G(\xi,\theta) = E[Y_n(\theta)|\xi_n(\theta) = \xi]$. Then $G(\cdot)$ is continuous and bounded. The limit (8.6) is the same as

$$\lim_n \frac{1}{n}\sum_{i=1}^n EG(\xi_n(\theta),\theta).$$

In order to prove the tightness of $\{s^\epsilon(t)\}$, we need the following conditions. Let p_i be the stationary probability that machine i is working. We suppose that

$$\bar{u}_2 p_2 > \bar{u}_1 p_1 > d; \tag{8.7}$$

i.e., the average maximum possible production rate for machine 2 is greater than that of machine 1, which is greater than the demand rate. Also, suppose that, where E_t is the expectation given $\{\alpha_i(v), v \leq t, i = 1,2\}$,

$$\int_t^\infty E_t[\alpha_i(v) - p_i]dv = O(1), \tag{8.8}$$

where $O(1)$ means that the term is bounded uniformly in all variables. Loosely speaking, (8.8) is equivalent to the expectation of the time to the next change in the $\alpha_i(\cdot)$ being uniformly bounded, conditioned on the current data. This is certainly not a strong condition.

THE SA ALGORITHM. Fix $T > 0$, the time interval between parameter updates. Let $s^\epsilon(\cdot)$ denote the actual surplus process with the time-varying parameter. Define $y^\epsilon(\cdot)$ as the derivative process with the random times determined by the actual time of

the associated events in the true physical process. It is not reset at each nT. Then set $z^\epsilon(\cdot) = (x^\epsilon(\cdot), z^\epsilon(\cdot))$. Let Y_n^ϵ be (8.4) with $z^\epsilon(\cdot)$ used in lieu of $z(\cdot, \theta)$. The algorithm is now (3.1).

Convergence of the SA. Condition (3.2) holds since the Y_n^ϵ are uniformly bounded. Tightness of all the components of the Markov chain (as needed for (3.4)) follows once tightness of $\{s^\epsilon(nT), \epsilon > 0, n < \infty\}$ is shown. This will be discussed at the end of the section. The $P(\cdot)$ and $G(\cdot)$ do not depend on n or ϵ. The weak continuity of the transition probability is a consequence of the basic structure of the problem. In particular, of the continuous effects of the threshold variations and the monotone nature of the evolution of the residual times. Finally, (3.11b) holds by assumption (8.6). Thus, the conclusions of Theorem 3.1 hold, and the extensions of Theorem 3.1 can also be readily handled. Theorem 3.1 asserts that the limit ODE is $\dot{\theta} = g(\theta)$ for the function $g(\theta)$ defined above. The reference [44] presents numerical data which implies that the cost function has a unique minimum and that their SA converges nicely.

The requirements are generally much weaker than those in the reference, and we do not need to restart the estimator periodically or let $T \to \infty$ as $\epsilon \to 0$. Some other references concerned with the use of SA in related manufacturing problems are [6, 39, 16, 45]. In [16], another interesting work on the same subject, they use an SA with gains $\epsilon_n \to 0$ and an IPA-type estimator where the estimation intervals go to infinity as $n \to \infty$. They do not "reset the accumulator." The conditions used here are simpler whether or not the step size is constant. The paper [19] was one of the early works which attempted to improve the operation of a production line subject to random breakdowns using IPA-type estimates, and dealt with a production line in an automobile factory. Some of the background analytical work is in [20].

Tightness of $\{s^\epsilon(t)$, small $\epsilon > 0, t < \infty\}$. Let $\mathcal{B}_t$ denote the minimal sigma-algebra measuring $\{\alpha_i(v), v \le t, i = 1, 2\}$ and E_t the associated conditional expectation. We define a differential operator $\tilde{A}$ and its domain.

The real-valued functions $f(\cdot), g(\cdot)$ of (t, ω) will be measurable with $f(t), g(t)$ being $\mathcal{B}_t$-measurable. Suppose that for each $T < \infty$,

$$\sup_{t \le T} E|g(t)| < \infty, \ \limsup_{\delta \downarrow 0} \sup_{t \le T} E\left|\frac{E_t f(t+\delta) - f(t)}{\delta}\right| < \infty,$$

$$\lim_{\delta \downarrow 0} E\left|\frac{E_t f(t+\delta) - f(t)}{\delta} - g(t)\right| = 0.$$

Then we say that $\tilde{A}f(\cdot) = g(\cdot)$. The process $f(t) - \int_0^t g(v)dv$ is a martingale [21], [22, §3.2.2].

The $s_i^\epsilon(t)$ are bounded above by the upper bounds to the thresholds. Thus the tightness problem concerns the probability of large negative excursions. We will work with altered processes, which provide the appropriate bounds from below. First we work with $s_1^\epsilon(t)$. To get a lower bound, we can suppose that $\theta_{i,n}^\epsilon = 0$. Let $q_1(t)$ be the process (8.1) with $\theta_1 = 0$. Then $\tilde{A}q_1^2(t)^2/2 = q_1(t)\dot{q}_1(t)$, which is $q_1(t)[\bar{u}_1\alpha_1(t) - d]$. To help in averaging the term with the $\alpha_1(t)$, define

$$\tilde{q}_1(t) = q_1(t)\bar{u}_1 \int_t^\infty E_t[\alpha_1(v) - p_1]dv.$$

We have

$$\tilde{A}\tilde{q}_1(t) = -q_1(t)\bar{u}_1[\alpha_1(t) - p_1] + O(1).$$

Define $Q_1(t) = q_1^2(t)/2 + \tilde{q}_1(t)$. Then

$$\tilde{A}\tilde{Q}_1(t) = q_1(t)[\bar{u}_1 p_1 - d] + O(1). \tag{8.9}$$

By (8.7), $\bar{u}_1 p_1 - d > 0$. Thus there are $k_i > 0$ such that for $q_1 \leq -k_1$, we have the right side of (8.9) less than $-k_2$. This implies that when $q_1 \leq -k_1$, $Q_1(\cdot)$ has the supermartingale property (until it hits the interval $[-k_1, 0]$). These considerations and the quadratic dependence of $Q_1(t)$ on $q_1(t)$ imply the tightness of $\{Q_1(t), t < \infty\}$. The tightness of $\{q_1(t), t < \infty\}$ (hence of $\{s_1^\epsilon(t), \text{small } \epsilon > 0, t < \infty\}$ follows from this tightness and the quadratic dependence of $Q_1(t)$ on $q_1(t)$.

The tightness of the $\{s_2^\epsilon(t)\}$ is proved in the same way. By the above results, it is sufficient to prove tightness for $s_1^\epsilon(t) - s_2^\epsilon(t)$ instead. Again, this can be done by a bounding argument. We have $s_1^\epsilon(t) - s_2^\epsilon(t) \geq 0$. Thus, we need to be concerned with large positive excursions of this difference. We start by fixing the thresholds at the upper bound for s_1^ϵ and the lower bound for s_2^ϵ. Once these thresholds are fixed, their actual values do not affect the result, so we can set them equal to zero without loss of generality. Let $q_i(\cdot)$ denote the new processes with the thresholds fixed at zero. One starts the argument by using a tentative Liapunov function (for the variables with the thresholds fixed at zero): $(q_1(t) - q_2(t))^2/2$. One bounds the derivative from above. Then introduces a function $\tilde{q}_2(\cdot)$ whose purpose is analogous to that of $\tilde{q}_1(\cdot)$ above. We omit the rest of the details due to lack of space. But by an argument similar to what was done for $q_1(\cdot)$ above, we get the tightness under the conditions (8.7), (8.8).

9. A continuous time SDE example: The system. We continue the discussion of the SDE model of §6 but with more detail and a more general system. We start by using the mean square derivatives and then discuss finite-difference forms. The finite-difference forms can be advantageous. One can use them without knowing the exact model and for more general cost functions. They can also be used for discrete-event systems in the same way. Let θ be real valued (for notational simplicity only) and $x \in R^k$. Let $b(\cdot)$ be a R^k-valued and continuously differentiable function of (x, θ) with bounded x and θ first derivatives, $\sigma(\cdot)$ a continuously differentiable matrix-valued function of x with bounded first derivatives, and let the fixed θ state process satisfy the SDE

$$dx(t,\theta) = b(x(t,\theta),\theta)dt + \sigma(x(t,\theta))dw(t), \tag{9.1}$$

where $w(t)$ is a standard vector valued Wiener process. Define the auxiliary process $y(t,\theta)$ by

$$dy(t,\theta) = b_x(x(t,\theta),\theta)y(t,\theta)dt + b_\theta(x(t,\theta),\theta)dt + (\sigma, y)(t,\theta)dw(t), \tag{9.2}$$

where the vector $(\sigma, y)(t,\theta)dw(t)$ is defined by its components

$$\sum_{j,p} \frac{\partial \sigma_{ij}(x(t,\theta))}{\partial x_p} y_p(t,\theta)dw_j(t), \qquad i = 1, \ldots, k,$$

The $y(t,\theta)$ is the pathwise (mean square) derivative of $x(t,\theta)$ with respect to θ. This "pathwise derivative" for the SDE was in use [12] long before its analogue for the

discrete case was developed. Define $z(\cdot,\theta) = (x(\cdot,\theta), y(\cdot,\theta))$. Let $c(\cdot,\cdot)$ be a bounded, real-valued, continuously differentiable function of (θ, x) with bounded derivatives, and define $C_T(\theta) = \int_0^T c(\theta, x(s,\theta))ds/T$ as in §6.

The SA procedure. Use the method of §6, where we update at intervals $nT, n = 1, \ldots,$ with θ_n^ϵ being the parameter value used on $[nT, nT+T)$. Use (3.1) with $x^\epsilon(\cdot)$ again defined as the state process with the time-varying parameter used. Define $y^\epsilon(\cdot)$ as above (6.5) (i.e., it is never reset), and define $z^\epsilon(\cdot) = (x^\epsilon(\cdot), y(\cdot))$. Define

$$Y_n^\epsilon = -\frac{1}{T}\int_{nT}^{nT+T}\left[\sum_j c_{x_j}(\theta_n^\epsilon, x^\epsilon(s))y_j^\epsilon(s) + c_\theta(\theta_n^\epsilon, x^\epsilon(s))\right]ds. \tag{9.3}$$

We assume the following conditions.

(9.4) The process $\{z(nT,\theta)\}$ has a unique invariant measure for each θ.

$$\{z^\epsilon(nT), \theta_n^\epsilon, \epsilon > 0, n < \infty\} \text{ is tight} \tag{9.5}$$

$$\{Y_n^\epsilon, \epsilon > 0, n < \infty\} \text{ is uniformly integrable.} \tag{9.6}$$

$$\{z(0,\theta) : \theta \in \Theta \text{ compact }, z(\cdot,\theta) \text{ stationary }\} \text{ is tight.} \tag{9.7}$$

Condition (9.4) implies that the limit $C(\theta)$ of $C_T(\theta, x(0)))$ exists and does not depend on $x(0)$. Under these conditions, Theorem 3.1 and its extensions hold. Thus (6.9) holds for algorithm (3.1). An SA procedure using mean square derivatives was used to good practical effect in [5, 26]. There is an analagous result under (3.11b).

Finite-difference methods. The main difficulties in applications concern the verification of the various conditions on the y processes. This was an unresolved issue in [5]. These difficulties can be alleviated by using a finite-difference method rather than the derivative $y^\epsilon(\cdot)$ process. We will discuss two forms of the finite-difference method. The first is the more traditional, using separate runs for the different components of the difference. The second combines these runs into one "concatenated difference" and provides a useful alternative since it can be used on line. There is an obvious analogue for discrete-event systems.

A finite-difference alternative: Simultaneous runs. Tightness and uniqueness of the appropriate invariant measure are often much easier to prove if a finite-difference method is used in lieu of the estimator (9.3), since then the troublesome $y^\epsilon(\cdot)$ process does not appear. We retain the conditions of the last part, with the exception of those concerning the y process. We also let $c(\cdot)$ be simply bounded and continuous. Given a finite-difference interval $\delta\theta$, replace the integrand in (9.3) with

$$\frac{c(\theta_n^\epsilon + \delta\theta, x(s, \theta_n^\epsilon + \delta\theta)) - c(\theta_n^\epsilon - \delta\theta, x(s, \theta_n^\epsilon - \delta\ t))}{2(\delta\theta)}. \tag{9.8}$$

Here we use two separate simulations, one for $\{\theta_n^\epsilon + \delta\theta\}$ and one for $\{\theta_n^\epsilon - \delta\theta\}$. We thus run two processes $x^{\epsilon,\pm}(\cdot)$ defined by $x^{\epsilon,\pm}(0) = x(0)$, and on $[nT, nT+T)$ set $x^{\epsilon,\pm}(\cdot) = x(\cdot, \theta_n^\epsilon \pm \delta\theta)$ with initial condition at nT defined recursively by $x(nT, \theta_n^\epsilon \pm \delta\theta) = x^{\epsilon,\pm}(nT)$. Generally, one would want to use the same Wiener process to drive

the two processes. This (common random variables) form often yields essentially the same path properties as does the use of the derivative process.

Under the given conditions, Theorem 3.1 yields that the limit ODE is

$$\dot{\theta} = -\frac{1}{2\delta\theta}\int [c(\theta+\delta\theta,\xi)\mu(d\xi|\theta+\delta\theta) - c(\theta-\delta\theta,\xi)\mu(d\xi|\theta-\delta\theta)]\,, \tag{9.9}$$

where $\mu(\cdot|\theta)$ is the invariant measure of $\{x(nT,\theta)\}$, and with the analogous formula for the multidimensional θ case. Due to the additive way that the two terms appear in (9.8), we do not need to have a unique invariant measure of the pair $\{x(nT,\theta+\delta\theta), x(nT,\theta-\delta\theta)\}$ for each θ but only of $\{x(nT,\theta)\}$ for each θ.

The finite-difference approach can be either easier or harder than the pathwise derivative approach. The order of the SDEs to be solved in each case is the same. If $\sigma(x)$ actually depended on x, then the pathwise derivative procedure cannot be conducted "on line," since we need to know the Wiener process to get $y(\cdot,\theta)$. If $\sigma(x)$ does not depend on x, then the equation for $y(\cdot,\theta)$ or $y^\epsilon(\cdot)$ is linear in the y variable (but with time varying coefficients) and it is simpler to solve. The procedure can then be done "on line," at least in principle. An additional point to be kept in mind is that any simulation can only approximate the solution to (9.1) and (9.2). Thus, there is the additional question concerning the relations between the estimators for the approximations and those of the original model. See [26] for some results on this important problem. Finally, the finite-difference method can be used for cases where the $c(\cdot), b(\cdot)$ are not smooth, e.g., where $c(\cdot)$ is an indicator function of a event of interest.

Finite differences with only one run. Alternatively to the traditional simultaneous run method discussed above, a single run can be used to get a good estimate of the desired quantity and will be useful when the optimization must be done "on line," where simultaneous runs might not be possible. Let $T > 0$ and $\delta\theta > 0$ be given. For the "one run" method, we use $\theta_n^\epsilon + \delta\theta$ on the interval $[2nT, 2nT+T)$ and then $\theta_n^\epsilon - \delta\theta$ on $[2nT+T, 2nT+2T)$. Let $x^\epsilon(\cdot)$ denote the actual process with the $\theta_n^\epsilon \pm \delta\theta$ being used on the appropriate alternating time intervals. The appropriate fixed θ process, which we call $\hat{x}(\cdot,\theta)$, uses parameter value $\theta+\delta\theta$ on $[0,T)$ and then alternates between $\theta-\delta\theta$ and $\theta+\delta\theta$ on successive intervals of width T. We use

$$Y_n^\epsilon = -\frac{1}{2T\delta\theta}\int_0^T [c(\theta_n^\epsilon+\delta\theta, x^\epsilon(nT+s)) - c(\theta_n^\epsilon-\delta\theta, x^\epsilon(nT+T+s))]\,ds.$$

The analysis follows the lines of Theorem 3.1, but the limit form will be slightly different from that above. It is worth commenting on the differences between the simultaneous and single run cases since they are of practical importance and of interest in related algorithms. The main additional problem is due to the fact that the transition function for the fixed θ process depends periodically on time.

Let $\xi_n^+(\theta) = \hat{x}(2nT,\theta)$ and $\xi_n^-(\theta) = \hat{x}(2nT+T,\theta)$. Suppose that the stationary processes exist and are unique, with invariant measures $\mu^+(\cdot|\theta)$ and $\mu^-(\cdot|\theta)$, resp. Define

$$G^+(\theta,\xi) = \frac{1}{2T\delta\theta}\int_0^T E\,[c(\theta+\delta\theta, x(s,\theta+\delta\theta))|x(0)=\xi]\,ds,$$

$$G^-(\theta,\xi) = \frac{1}{2T\delta\theta}\int_0^T E\,[c(\theta-\delta\theta, x(s,\theta-\delta\theta))|x(0)=\xi]\,ds.$$

The right side of the limit ODE is

$$g(\theta) = -\int \left[G^+(\theta,\xi)\mu^+(d\xi|\theta) - G^-(\theta,\xi)\mu^-(d\xi|\theta)\right]. \tag{9.10}$$

Let $P_T(\xi,\cdot|\theta+\delta\theta)$ denote the transition function for the process $x(nT,\theta+\delta\theta)$. Note that

$$\mu^-(d\xi|\theta) = \int \mu^+(d\tilde{\xi}|\theta)P_T(\tilde{\xi},d\xi|\theta+\delta\theta). \tag{9.11}$$

Thus, as $\delta\theta \to 0$, the $\mu^{\pm}(\cdot|\theta)$ converge weakly to $\mu(\cdot|\theta)$, and so do the $\mu(\cdot|\theta\pm\delta\theta)$. Thus the $\mu^{\pm}(\cdot|\theta)$ become closer to the $\mu(\cdot|\theta\pm\delta\theta)$, which are the measures in the right side of (9.9). This line of reasoning suggests that the one sample procedure might be quite reasonable. The obvious form of (3.11b) can replace the assumption of uniqueness of the invariant measures.

To better understand the above "one-run" procedure, one needs to compare it to an alternative one-run procedure, say where we restart the process each T units of time at some fixed initial value, still using the $\theta \pm \delta\theta$ on the alternate intervals (assuming that such restarts were possible in the application). This would yield a right side of the form (9.10), where the $\mu^{\pm}$ are replaced by the measures concentrated on the fixed initial values. We expect that this "restarted method" would be much inferior to the original procedure, since the $\mu^{\pm}(\cdot|\theta)$ defined above would be much closer to the desired values $\mu(\cdot|\theta\pm\delta\theta)$, particularly for large T. The situation would be a little more complicated if θ were vector valued, but the general idea is the same. Analogous remarks can be made on the use of finite differences for discrete-event systems.

Appendix 1. Non-Markov models. Consider the algorithm (3.1). Suppose that due to the nature of the correlations, there is no convenient Markov chain $\{\xi_n^\epsilon, n < \infty\}$ for each ϵ. For example, the service or interarrival intervals in a queue might be correlated in a "non-Markovian way." The first-order perturbed test function methods of [22] are often very helpful in such circumstances, and we will outline the general idea in the context of Theorem 3.1.

For each $\epsilon > 0$, $\{Y_n^\epsilon, n < \infty\}$ denotes the observation sequence, and the uniform integrability (3.2) is assumed. The θ_n will be assumed to be in a compact set to make the development simpler. For fixed parameter θ and each integer m we define the fixed θ process $\{Y_j^m(\theta), j \geq m\}$, and define $Y_j^m(\theta) = Y_j^\epsilon$ for $j \leq m$ by supposing that after time m the sequence evolves as though the parameter were held fixed at θ. This process is the analogue of the fixed θ Markov chain of §3. The key to the development is to work with an appropriately chosen "perturbed" θ_n^ϵ, which differs only slightly from θ_n^ϵ and for which the theorem can be proved. Suppose that there is a continuous function $g(\cdot)$ such that for each large $T_1 < T_2 < \infty$ and $m < T_1/\epsilon$, the sum defined by

$$\delta f_m^\epsilon(\theta) = \sum_{j=m}^{T_2/\epsilon} \epsilon E_m^\epsilon \left[Y_j^m(\theta) - g(\theta)\right] \tag{A1.1}$$

goes to zero in mean, uniformly in $m \leq T_1/\epsilon$ as $\epsilon \to 0$. The convergence of (A1.1) is a condition on the "mixing rate" of the noise process.

Define $\delta f_n^\epsilon = \delta f_n^\epsilon(\theta_n^\epsilon)$. In the analysis, $\tilde{\theta}_n^\epsilon = \theta_n^\epsilon + \delta f_n^\epsilon(\theta_n^\epsilon)$ replaces θ_n^ϵ. We also need the continuity condition that

$$\text{(A1.2)} \qquad \sum_{j=m}^{T_2/\epsilon} E_m^\epsilon \left[Y_j^m(\theta+\delta\theta) - g(\theta+\delta\theta)\right] - \sum_{j=m}^{T_2/\epsilon} E_m^\epsilon \left[Y_j^m(\theta) - g(\theta)\right] \to 0$$

in the mean, uniformly in $m \le T_1/\epsilon$ as $\delta\theta \to 0$.

We have the following theorem.

THEOREM A1.1. *Let q_ϵ satisfy* (3.8′). *Then, assuming* (3.2) *and the conditions concerning* (A1.1) *and* (A1.2), $\{\theta^\epsilon(\epsilon q_\epsilon + \cdot), \epsilon > 0\}$ *is tight, and the limit of any weakly convergent subsequence satisfies* (3.12). *If $\epsilon q_\epsilon \to \infty$, then the conclusions of Theorem* 3.2 *hold.*

Proof. The proof is much simpler than that of Theorem 3.1. Again, for simplicity, we let $q_\epsilon = 0$. Let $\tilde{\theta}^\epsilon(\cdot)$ denote the continuous parameter interpolation (interval ϵ) of the $\tilde{\theta}_n^\epsilon$ sequence defined above (A1.2). $\{\theta^\epsilon(\cdot)\}$ is tight. For notational simplicity, let ϵ index a weakly convergent subsequence. Let $h(\cdot), s_i, t, \tau$ be as in Theorem 3.1 with $t+\tau \le T_1$, and suppose for notational simplicity that ϵ indexes a weakly convergent subsequence. By the definition of conditional expectation,

$$\text{(A1.3)} \qquad Eh(\tilde{\theta}^\epsilon(s_i), i \le q)\left[\tilde{\theta}^\epsilon(t+\tau) - \tilde{\theta}^\epsilon(t) - \sum_{m=t/\epsilon}^{(t+\tau)/\epsilon-1} E_m^\epsilon(\tilde{\theta}_{m+1}^\epsilon - \tilde{\theta}_m^\epsilon)\right] = 0.$$

We have

$$\text{(A1.4)} \qquad E_m^\epsilon\left(\tilde{\theta}_{m+1}^\epsilon - \tilde{\theta}_m^\epsilon\right) = \epsilon E_m^\epsilon Y_m^\epsilon + E_m^\epsilon\left[\delta f_{m+1}^\epsilon - \delta f_m^\epsilon\right].$$

The last term on the right equals

$$\epsilon\left[g(\theta_m^\epsilon) - E_m^\epsilon Y_m^m(\theta_m^\epsilon)\right] + \epsilon W_m^\epsilon,$$

where

$$W_m^\epsilon = \sum_{j=m+1}^{T_2/\epsilon} E_m^\epsilon\left[Y_j^{m+1}(\theta_{m+1}^\epsilon) - g(\theta_{m+1}^\epsilon)\right] - \sum_{j=m+1}^{T_2/\epsilon} E_m^\epsilon\left[Y_j^m(\theta_m^\epsilon) - g(\theta_m^\epsilon)\right].$$

Hence, we can write (A1.4) as $\epsilon g(\theta_m^\epsilon) + \epsilon W_m^\epsilon$. By definition,

$$Y_j^{m+1}(\theta_{m+1}^\epsilon) = Y_j^m(\theta_{m+1}^\epsilon), \qquad j \ge m+1.$$

Therefore, if the Y_n^ϵ were bounded (so that $|\theta_{m+1}^\epsilon - \theta_m^\epsilon| \to 0$ as $\epsilon \to 0$ uniformly in (m,ω)), we could use (A1.2) to get that $E|W_m^\epsilon| \to 0$ uniformly in $m : m\epsilon \le T_1$ as $\epsilon \to 0$. Then, (A1.3) would imply that

$$\text{(A1.5)} \qquad \lim_\epsilon Eh(\theta^\epsilon(s_i), i \le q)\left[\theta^\epsilon(t+\tau) - \theta^\epsilon(t) - \epsilon \sum_{m=t/\epsilon}^{(t+\tau)/\epsilon-1} g(\theta_m^\epsilon)\right] = 0.$$

The theorem would follow from this last equality, analogously to the situation in Theorem 3.1. If the Y_n^ϵ are not bounded, use the uniform integrability (3.2) to bound them for the purposes of the proof. For $B > 0$ define $Y_{n,,B}^\epsilon$ to be Y_n^ϵ but with

the components truncated at $\pm B$. Define $\hat{\theta}^\epsilon_m$ as follows. Let $\hat{\theta}^\epsilon_{t/\epsilon} = \theta^\epsilon_{t/\epsilon}$. Then, for $(t+\tau)/\epsilon \geq m \geq t/\epsilon$, set $\hat{\theta}^\epsilon_{m+1} = \hat{\theta}^\epsilon_m + \epsilon Y^\epsilon_{m,B}$. Now proceed with $\hat{\theta}^\epsilon_n$ replacing θ^ϵ_n, but continuing to use the original definition of W^ϵ_n. The result is (A1.5) plus an error which goes to zero as $B \to \infty$. □

An interpretation. Refer to the example in §7. Fix the parameter at θ. Suppose that $Y_n(\theta)$ is the IPA estimator on the interval $[nN, nN+N)$ without "resetting the accumulator." Then

$$Y_0(\theta) + \cdots + Y_{n-1}(\theta)$$

is an unbiased estimator of the derivative of the cost on $[0, nN]$. Suppose that for each fixed θ, the system is stationary. The condition (A1.1) is close to the assumption that

$$\frac{1}{n}\sum_{i=0}^{n-1} EY_i(\theta) \to g(\theta) \tag{A1.6}$$

for each initial condition, the only difference being in the conditioning data. Suppose that the mean cost per unit time on $[0,T]$ converges as time goes to infinity. This convergence and the convergence of the mean value of the left side of (A1.6) to $g(\theta)$ imply (the closed graph theorem) that $g(\theta)$ is the derivative of the mean ergodic cost at θ. Analogous comments apply to the example of §8.

The extensions of Theorem A1.1 are handled analogously to the way that the extensions of Theorem 3.1 were handled; e.g., for the analog of Theorem 3.3, replace the T_2/ϵ in (A1.1) by $m_n(T_2)$ and ϵ by ϵ_m. The general scheme is very flexible and allows many variations. More background and examples satisfying the conditions is in [22].

Appendix 2. An alternative averaging method. Return to (3.17) and the problem of replacing $(\xi^\epsilon_j, \theta^\epsilon_j)$ by $(\xi_j(\theta^\epsilon_{ln_\epsilon}), \theta^\epsilon_{ln_\epsilon})$ in

$$\frac{1}{n_\epsilon}\sum_{j=ln_\epsilon}^{ln_\epsilon+n_\epsilon-1} E^\epsilon_{ln_\epsilon} G^\epsilon_j(\theta^\epsilon_j, \xi^\epsilon_j) = \frac{1}{n_\epsilon}\sum_{j=0}^{n_\epsilon-1} E^\epsilon_{ln_\epsilon} G^\epsilon_{ln_\epsilon+j}(\theta^\epsilon_{ln_\epsilon+j}, \xi^\epsilon_{ln_\epsilon+j}). \tag{A2.1}$$

We present an alternative approach which avoids the use of the occupation measure $R(l,\epsilon,\cdot)$ but involves some other conditions. The method relies more heavily on continuity properties. Only a brief outline will be given, but the main idea should be clear. The sequence of integers n_ϵ might be different here than in Theorem 3.1. Continue to assume (3.2)–(3.5), (3.8), and (3.10). Suppose that $P^\epsilon_n(\xi, \cdot|\theta)$ is weakly continuous in (θ,ξ), uniformly in (ϵ, n) and in each compact (θ,ξ) set. Let $G^\epsilon_n(\theta,\xi)$ be continuous in (θ,ξ), uniformly in (ϵ,n) and in each compact (θ,ξ) set.

Due to the tightness (3.4), the uniform integrability (3.2) and the assumed uniform θ continuity of the $G^\epsilon_j(\cdot)$, we can suppose (as in Theorem 3.1) that the Y^ϵ_n are truncated and that in the interval $[t, t+\tau]$ of concern (see proof of Theorem 3.1) the θ^ϵ_n take values in some compact set. Thus we can suppose that $|\theta^\epsilon_{j+1} - \theta^\epsilon_j| = O(\epsilon)$ for all j of interest. For notational simplicity, we will not use the truncation notation.

Define

$$P^\epsilon_n\{d\xi, d\theta|\xi^\epsilon_n, \theta^\epsilon_n\} = P^\epsilon_n\{\xi^\epsilon_{n+1} \in d\xi, \theta^\epsilon_{n+1} \in d\theta|\xi^\epsilon_n, \theta^\epsilon_n\}.$$

Writing out the conditional expectation $E^\epsilon_{ln_\epsilon} G^\epsilon_{ln_\epsilon+j}(\theta^\epsilon_{ln_\epsilon+j}, \xi^\epsilon_{ln_\epsilon+j})$ in (A2.1), we have

$$\begin{aligned}\int \cdots \quad & \int P^\epsilon_{ln_\epsilon}\{d\xi_1, d\theta_1 | \xi^\epsilon_{ln_\epsilon}, \theta^\epsilon_{ln_\epsilon}\} \cdots \\ & P^\epsilon_{ln_\epsilon+j-1}\{d\xi_j, d\theta_j | \xi_{j-1}, \theta_{j-1}\} G^\epsilon_{ln_\epsilon+j}(\theta_j, \xi_j).\end{aligned}$$

Let $\epsilon n_\epsilon \to 0$. Now, using the uniform weak continuity of the P^ϵ_k, the uniform continuity of the G^ϵ_k, the tightness (3.4), and the fact that

$$\sup_{0 \le j \le n_\epsilon} |\theta^\epsilon_{ln_\epsilon+j} - \theta^\epsilon_{ln_\epsilon}| \to 0,$$

we can work backwards in the above equation, successively concentrating the measure of $\theta^\epsilon_{ln_\epsilon+j}$ at $\theta^\epsilon_{ln_\epsilon}$ and ultimately yielding the representation

$$\begin{aligned}\int \cdots \quad & \int P^\epsilon_{ln_\epsilon}(\xi^\epsilon_{ln_\epsilon}, d\xi_1 | \theta^\epsilon_{ln_\epsilon}) \cdots \\ & P^\epsilon_{ln_\epsilon+j-1}(\xi_{j-1}, d\xi_j | \theta^\epsilon_{ln_\epsilon}) G^\epsilon_{ln_\epsilon+j}(\theta^\epsilon_{ln_\epsilon}, \xi_j) + \rho^\epsilon_{ln_\epsilon}(\epsilon, j).\end{aligned}$$

The error term satisfies $|\rho^\epsilon_{ln_\epsilon}(\epsilon, j)| \le \rho(\epsilon, n_\epsilon)$, where $\rho(\epsilon, n_\epsilon)$ depends on the moduli of continuity and

$$\rho(\epsilon, n_\epsilon) \to 0 \tag{A2.2}$$

as $\epsilon \to 0$ for each constant $n_\epsilon = m$. Consequently, there are $n_\epsilon \to \infty$ such that (A2.2) holds for this sequence. The above discussion and the proof of Theorem 3.1 imply that the conclusions of Theorem 3.1 will hold under the additional condition that there is a function $g(\cdot)$ (which must be continuous by the above arguments) such that

$$\frac{1}{n_\epsilon} \sum_{j=ln_\epsilon}^{ln_\epsilon+n_\epsilon-1} E^\epsilon_{ln_\epsilon} G^\epsilon_j(\theta, \xi_j(\theta)) \to g(\theta) \tag{A2.3}$$

in mean for each θ, as $l \to \infty$, $\epsilon \to 0$, and $n_\epsilon \to \infty$.

An advantage of this averaging approach is that it can be used for grouping terms when the dependence of G^ϵ_j on ϵ, j does not vanish for large j and small ϵ.

Appendix 3. Arbitrary updatings within a regeneration period. This appendix illustrates the possibilities when updates are made after "partial" observations. It is intended to be suggestive and is a little vague. To ensure that the "partial" observations fit together properly, additional conditions are needed. Recall the example of §7, where we updated after each N departures. Owing to the regeneration stucture of the problem, one could have updated at the end of each regeneration period if the conditions of §3.4 held. These two approaches yield two different time scales in which to get the limit results. The $g(\cdot)$ functions would be different in the two cases but are related by the constant, which is the mean length of the renewal period. The results are equivalent since the two ODEs have the same asymptotic behavior. As seen in §3 and in the examples, there is no need in general to update at the end of regeneration periods. Indeed, even if the problem admits of a regeneration model, for general problems the intervals might be excessively long. If the problem has the "atomic increment" property of §3.3, then the regenerative structure does allow a rather arbitrary method of updating, within the intervals. By a regeneration process, we mean that for each fixed θ the process is regenerative and that for the physical process with the varying θ the conditional distribution of functionals of the

intervals $n, n+1, \ldots$ given the past depends only on the parameter value at the start of the nth interval. We will work within the regeneration setup but wish to update at arbitrary intervals (random times). This falls easily and naturally into our framework, as will now be shown. Only a brief outline will be given.

The basic algorithm is still (3.1). The updating times within the regeneration intervals can be chosen rather arbitrarily, subject to the mild conditions below. But we always update at the end of each regeneration interval. This last condition is not necessary but does simplify the discussion. Otherwise the groupings of the terms would be more involved. Let N_n^ϵ denote the number of updatings in the nth regeneration interval, $n = 1, 2, \ldots$. Define $M_0^\epsilon = 0$ and $M_n^\epsilon = \sum_{i=1}^{n-1} N_i^\epsilon$, $n \geq 1$. We now state the basic redefinitions and assumptions. They are essentially copies of those of Theorem 3.1. But since the estimation process begins anew at the start of each regeneration interval, the assumptions concern what happens within the intervals.

Let $N_n^\epsilon < \infty$ w.p.1 for all $\epsilon > 0, n < \infty$. Let $Y_{n,j}^\epsilon, j = 0, \ldots, N_n^\epsilon - 1$ denote the observations in the nth regeneration interval. We update after each observation. Hence there will be N_n^ϵ updates in the nth interval. Due to the assumption of a regenerative structure, the $\{Y_{m,i}^\epsilon, m \geq n, i \geq 0\}$ are conditionally independent of $\{Y_{m,i}^\epsilon, m < n, i \geq 0\}$ given $\theta_{M_n^\epsilon}^\epsilon$, the parameter value at the start of the nth interval. For $j \geq N_n^\epsilon$, set $Y_{n,j}^\epsilon = 0$. For each $\epsilon > 0, n \geq 1$, let $\mathcal{B}_{n,j}^\epsilon$ be a nondecreasing sequence of sigma-algebras measuring at least $\{\theta_{M_n^\epsilon}^\epsilon, Y_{n,i}^\epsilon, i < j\}$, with $E_{n,j}^\epsilon$ denoting the associated conditional expectation. Assume

(A3.1a) $$\left\{ \sum_{j=0}^{K} |Y_{n,j}^\epsilon|; n, \epsilon \right\} \text{ is uniformly integrable for each } K,$$

(A3.1b) $$E \sum_{N_n^\epsilon \wedge K}^{N_n^\epsilon} |Y_{n,j}^\epsilon| \to 0 \text{ as } K \to \infty.$$

Remark on (A3.1) *for the example of* §7. Return to the physical problem of §7. Suppose that there is an integer M such that we update at least after each new M departures but otherwise use the updating model of this section. Let R_n^ϵ denote the number of customers in the nth regeneration interval, and set $Q_n^\epsilon = \sum_{i=1}^{n-1} R_i^\epsilon$. We have

$$\sum_{i=0}^{N_n^\epsilon - 1} |Y_{n,i}^\epsilon| \leq \sum_{i=1}^{R_n^\epsilon} \sum_{l=1}^{i} |Z_{Q_n^\epsilon + l}^\epsilon|.$$

Condition (A3.1a) holds if $\{Z_l^\epsilon, \epsilon, l\}$ is uniformly integrable. Condition (A3.1b) holds if

$$\lim_{K \to \infty} E \sum_{i=K \wedge R_n^\epsilon}^{R_n^\epsilon} \sum_{l=1}^{i} |Z_{Q_n^\epsilon + l}^\epsilon| = 0,$$

where the limit is taken on uniformly in (n, ϵ).

The SA algorithm and interpolation. Now define $\theta_{n,j}^\epsilon = \theta_{M_n^\epsilon + j}^\epsilon$. The algorithm within the nth interval is

(A3.2) $$\theta_{n,j+1}^\epsilon = \theta_{n,j}^\epsilon + \epsilon Y_{n,j}^\epsilon, \qquad j < N_n^\epsilon.$$

Define the interpolated process $\theta^\epsilon(\cdot)$ by $\theta^\epsilon(\cdot) = \theta^\epsilon_{M^\epsilon_n}$ on the interval $[\epsilon n, \epsilon n + \epsilon)$, $\theta^\epsilon(t) = \theta^\epsilon_0, t \leq 0$. Thus, we update the parameter at arbitrary times but define the interpolation $\theta^\epsilon(\cdot)$ by the values of the parameter at the end of the regeneration intervals only. This makes the scaling easier, allows a nicer representation of the limit ODE, and yields the desired limit points of the algorithm. Assume that

$$\{\theta^\epsilon_{M^\epsilon_n}; \epsilon > 0, n < \infty\} \text{ is tight.} \tag{A3.3}$$

Analogous to the situation in Theorem 3.1, suppose that there are random variables $\{\xi^\epsilon_{n,j}; \epsilon > 0, j < \infty\}$ and measurable $G^\epsilon_{n,j}(\cdot)$ such that for $j < N^\epsilon_n$

$$E^\epsilon_{n,j} Y^\epsilon_{n,j} = G^\epsilon_{n,j}(\theta^\epsilon_{n,j}, \xi^\epsilon_{n,j}).$$

The values of $\xi^\epsilon_{n,j}$ for $j \geq N^\epsilon_n$ are irrelevant, and one can use any convenient one. Let $G^\epsilon_{n,j}(\cdot)$ be continuous, uniformly in ϵ, n, j and on each compact (θ, ξ) set. Assume

$$\{\xi^\epsilon_{n,j}; \epsilon > 0, n < \infty, j < \infty\} \text{ is tight.} \tag{A3.4}$$

Suppose that there are transition functions $P^\epsilon_{n,j}(\cdot)$ such that $P^\epsilon_{n,j}(\cdot, A|\cdot)$ is measurable for each Borel set A and that

$$P^\epsilon_{n,j}(\xi^\epsilon_{n,j}, \xi^\epsilon_{n,j+1} \in \cdot|\theta^\epsilon_{n,j}) = P\{\xi^\epsilon_{n,j+1} \in \cdot|\theta^\epsilon_{M^\epsilon_n}, Y^\epsilon_{n,k}, k \leq j\}. \tag{A3.5}$$

Let $P^\epsilon_{n,j}(\xi, d\tilde{\xi}|\theta)$ be weakly continuous in (θ, ξ), uniformly in ϵ, n, j and in each compact (θ, ξ) set. Now for each n, ϵ and θ, $P^\epsilon_{n,j}(\cdot|\theta), j \geq 0$, defines a nonhomogeneous "fixed θ" Markov chain. Let $\{\xi^\epsilon_{n,j}(\theta), j = 0, 1, \ldots\}$ denote the random variables of this chain.

Assume that there are continuous functions $g^\epsilon_n(\cdot)$ such that

$$g^\epsilon_n(\theta) = E \sum_{j=0}^{N^\epsilon_n - 1} G^\epsilon_{n,j}(\theta, \xi^\epsilon_{n,j}(\theta)). \tag{A3.6}$$

Define $\hat{\theta}^\epsilon_n = \theta^\epsilon_{M^\epsilon_n}$. Let there be a continuous function $g(\cdot)$ such that for each $\delta > 0$

$$\lim_\epsilon \limsup_n P\{|g^\epsilon_{n+1}(\hat{\theta}^\epsilon_n) - g(\hat{\theta}^\epsilon_n)| \geq \delta\} = 0. \tag{A3.7}$$

THEOREM A3.1. *Assume the conditions of this section. Then the conclusions of Theorem* 3.1 *continue to hold for* $\hat{\theta}^\epsilon(\cdot)$ *and* $\hat{\theta}^\epsilon(\epsilon q_\epsilon + \cdot)$ *and similarly for Theorems* 3.2, 3.3, 4.1, *and* 5.1.

Proof. Only a few basic remarks will be made. The assumption (A3.1) allows the set of observations in an interval to be truncated to and well approximated by some finite number K and guarantees uniform integrability of the set of those truncations. By (A3.1) and following the scheme in Theorem 3.1, for $n > 0$ we can write

$$\hat{\theta}^\epsilon_n = \theta^\epsilon_0 + \epsilon \sum_{i=1}^{n} E^\epsilon_{i,0} \sum_{j=0}^{N^\epsilon_i - 1} G^\epsilon_{i,j}(\theta^\epsilon_{i,j}, \xi^\epsilon_{i,j}) + \rho^\epsilon_n, \tag{A3.8}$$

where, for each t, $\sup_{\epsilon, n:\epsilon n \leq t} E|\rho^\epsilon_n| \to 0$ as $\epsilon \to 0$. Indeed, (A3.1) implies the tightness of $\{\hat{\theta}^\epsilon(\cdot), \hat{\theta}^\epsilon(\epsilon q_\epsilon + \cdot), \epsilon > 0\}$ and the fact that any weak limit will have Lipschitz

continuous paths w.p.1. The assumed uniform θ continuity of $G^\epsilon_{n,j}(\cdot)$, (A3.1), and the fact that

$$\sup_{j<N^\epsilon_i} |\theta^\epsilon_{i,j} - \hat{\theta}^\epsilon_{i-1}| \to 0$$

(in probability, uniform in i) as $\epsilon \to 0$ imply that we can replace the $\theta^\epsilon_{i,j}$ in (A3.8) with $\hat{\theta}^\epsilon_{i-1}$ without affecting the limit.

The only remaining problem concerns the fact that the distribution of the $\xi^\epsilon_{i,j}$ in (A3.8) depends on all the $\theta^\epsilon_{i,k}, k < j$. But the representation (A3.5), condition (A3.1), and the asserted uniform continuity of the $P^\epsilon_{i,j}, G^\epsilon_{i,j}$ can be used to show that $\xi^\epsilon_{i,j}$ can be replaced with $\xi^\epsilon_{i,j}(\hat{\theta}^\epsilon_{i-1})$ without changing the limits. Finally, (A3.6) and (A3.7) are used to complete the proof of the analogue of Theorem 3.1. The analogues of the other theorems will then follow. □

Appendix 4. Distributed/asynchronous updating: A network example. We will discuss a useful canonical form for a SA procedure that operates in a decentralized way and where different components of the iterate might be updated at different (random) times. Some components might be updated much more frequently than others. This is typical of a growing number of applications. One example is given below. Owing to this asynchronous behavior between the components, one needs to work with interpolated processes in an appropriate *real time* scale. Heretofore, the interpolations were based on the iterate number. But now, due to the possibly different times and frequencies of updating of the different components, one needs to use a common time scale for all the components, and this will be an appropriate "real" time scale. The general idea of the proof is just that of Theorem 3.1. The main added feature concerns the difference in the time scaling of the interpolations. Working directly with the iterates can lead to a notational nightmare. We avoid the need to deal directly with the possibly different and random interpolation intervals by using appropriate rescaling. This puts the problem into a framework where the previous results can be directly applied. The result is a simplification and extension of the results in [30, 40], where the ideas of time scaling first appeared. The central idea of the rescaling is easier to see if we start with a centralized and synchronized updating and interpolate in real time. This will be done in the subsection below. The general result for the decentralized problem is in §A4.2.

A4.1. A synchronized updating: Real time scale. Assume the conditions of Theorem 3.1. The algorithm is

$$\theta^\epsilon_{n+1} = \theta^\epsilon_n + \epsilon Y^\epsilon_n.$$

Then Theorem 3.1 holds for the interpolations $\{\theta^\epsilon(\cdot), \theta^\epsilon(\epsilon q_\epsilon + \cdot)\}$.

Now let us rewrite the interpolation in real time. Let $\delta\tau^\epsilon_n$ denote the time interval between the nth and $(n+1)$st updating. Let $\mathcal{B}^\epsilon_n$ be a nondecreasing sequence of sigma-algebras such that $\mathcal{B}^\epsilon_n$ measures at least $\{\theta^\epsilon_0, Y^\epsilon_i, \delta\tau^\epsilon_i, i < n\}$. Let E^ϵ_n denote the associated conditional expectation. We keep the same framework as in §3. Suppose that there is a Markov chain ξ^ϵ_n and a continuous and strictly positive function $u(\cdot)$ such that $E^\epsilon_n \delta\tau^\epsilon_n = u(\theta^\epsilon_n, \xi^\epsilon_n)$. Assume the tightness condition (3.4), the uniform integrability condition (3.2), and

(A4.1) $\{\delta\tau^\epsilon_n, n < \infty\}$ is uniformly integrable.

Also suppose that there is a continuous and bounded function $\hat{u}(\cdot)$ such that

$$\frac{1}{n}\sum_{i=0}^{n-1} Eu(\theta, \xi_i(\theta)) \to \hat{u}(\theta) \tag{A4.2}$$

for each θ and initial condition.

Define

$$\tau_n^\epsilon = \epsilon \sum_{i=0}^{n-1} \delta\tau_i^\epsilon,$$

$$N^\epsilon(t) = \epsilon[\text{ number of updatings by time } t/\epsilon].$$

Let $\tau^\epsilon(\cdot)$ be the interpolation of $\{\tau_n^\epsilon, n < \infty\}$ defined by $\tau^\epsilon(t) = \tau_n^\epsilon$ on $[\epsilon n, \epsilon(n+1))$. Note that $\tau^\epsilon(\cdot)$ is the inverse of $N^\epsilon(\cdot)$ in the sense that $N^\epsilon(\tau^\epsilon(t)) = n\epsilon$ for $t \in [n\epsilon, n\epsilon + \epsilon)$ and

$$\tau^\epsilon(t) = \inf\{s : N^\epsilon(s) \geq t\}. \tag{A4.3}$$

Define $\hat{\theta}^\epsilon(t) = \theta^\epsilon(N^\epsilon(t))$. This is the interpolation in the real time scale, not the iterate time scale. The weak convergence and characterization of the ODE for the $\hat{\theta}^\epsilon(\cdot)$ are now easily done. In all cases we suppose that the original sequence indexed by ϵ converges weakly. Otherwise take appropriate subsequences. By the above conditions and the proof of Theorem 3.1, $(\tau^\epsilon(\cdot), \hat{\theta}^\epsilon(\cdot), N^\epsilon(\cdot), \theta^\epsilon(\cdot)) \Rightarrow (\tau(\cdot), \hat{\theta}(\cdot), N(\cdot), \theta(\cdot))$, where

$$\hat{\theta}(t) = \theta(N(t)) \quad \text{and} \quad \tau(t) = \int_0^t \hat{u}(\theta(s))ds. \tag{A4.4}$$

From the positivity of $\hat{u}(\theta)$ and the "inverse" definitions of $N^\epsilon(\cdot)$ and $\tau^\epsilon(\cdot)$, it follows that $N^\epsilon(\cdot) \Rightarrow N(\cdot)$, where $N(\tau(t)) = t$. Taking derivatives, we get $\dot{N}(\tau(t))\dot{\tau}(t) = 1$. Call $s = \tau(t)$. Then using (A4.4), the slope of $N(s)$ is $\dot{N}(s) = 1/\hat{u}(\theta(\tau^{-1}(s))) = 1/\hat{u}(\hat{\theta}(s))$. Therefore

$$N(t) = \int_0^t \frac{ds}{\hat{u}(\hat{\theta}(s))}. \tag{A4.5}$$

By Theorem 3.1, $\theta(\cdot)$ satisfies $\dot{\theta} = g(\theta)$. Recall that

$$\hat{\theta}^\epsilon(\cdot) = \theta^\epsilon(N^\epsilon(\cdot)) \Rightarrow \theta(N(\cdot)) \equiv \hat{\theta}(\cdot). \tag{A4.6}$$

Thus, using the fact that $N(\tau(t)) = t$, we can write

$$\dot{\hat{\theta}}(t) = [\dot{\theta}(N(t))]\dot{N}(t) = g(\theta(N(t)))/\hat{u}(\hat{\theta}(t)) = g(\hat{\theta}(t))/\hat{u}(\hat{\theta}(t)). \tag{A4.7}$$

Thus, the proof is just Theorem 3.1 plus a time change argument. The purpose of the time change argument is to avoid dealing with random interpolation intervals and the interaction of the Y_n^ϵ and the $\delta\tau_n^\epsilon$. It exploits the convergence of both the "time" processes and of the original interpolation $\theta^\epsilon(\cdot)$.

Remark. The above argument is for processes that start at time zero with limits defined on the interval $[0, \infty)$. Suppose that we wish to get the limit on $(-\infty, \infty)$ of

$\hat{\theta}^\epsilon(T^\epsilon + \cdot)$, where T^ϵ is a sequence of real numbers tending to infinity. The T^ϵ is simply the replacement for the ϵq_ϵ in Theorem 3.1. Then the analysis is the same as above, except that the initial condition of the interpolation is

$$\hat{\theta}^\epsilon(T^\epsilon) = \theta^\epsilon(N^\epsilon(T^\epsilon)) = \theta^\epsilon_{N^\epsilon(T^\epsilon)/\epsilon},$$

the values of the parameter at increasingly large iterate numbers, and the uniform integrability and tightness conditions must reflect this change. In particular, we need tightness of

$$\{\xi^\epsilon_{N^\epsilon(t)/\epsilon+n}, \theta^\epsilon_{N^\epsilon(t)/\epsilon+n}; \epsilon, n, t\} \tag{A4.8}$$

and uniform integrability of

$$\{Y^\epsilon_{N^\epsilon(t)/\epsilon+n}, \delta\tau^\epsilon_{N^\epsilon(t)/\epsilon+n}; \epsilon, n, t\}. \tag{A4.9}$$

Since all sorts of dependencies among the two sequences Y^ϵ_n and $\delta\tau^\epsilon_n$ can be constructed, little can be said without further assumptions. But a casual examination of some simple cases suggests that (A4.8) and (A4.9) are not very restrictive.

A distributed and decentralized network model. We work with one canonical model in order to illustrate some of the possibilities and minimize notation. To simplify the notation, some of the conditions will be less general than can be handled by the introduced technique. The basic work is in setting up the notation for the various time scales. Basically the general method uses the idea of the above subsection separately on different parts of the problem, as will now be seen.

Let $\theta = (\theta_1, \ldots, \theta_K)$, where the θ_α are the scalar components of θ. Consider a system with K controllers, each of which is responsible for the updating of one component. We wish to minimize a function $F(\cdot)$ which takes the form $F(\theta) = \sum_{\beta=1}^K F^\beta(\theta)$ for real-valued and continuously differentiable $F^\beta(\cdot)$. Let $F^\beta_\alpha(\theta) = \partial F^\beta(\theta)/\partial\theta_\alpha$. In our model, for each α subsystem β produces a sequence of estimates $Y^{\beta,\epsilon}_{\alpha,n}, n = 0, \ldots,$ which it sends to node α for help in estimating F^β_α at whatever the current value of θ is. It also sends the current values of its own component θ_β.

Example. An important class of examples that provides a guide to the development are the problems of optimal routing in queueing networks. Let the network have K nodes, with θ the K vector of routing parameters, where θ_α is the component associated with the αth node. Let $F^\beta(\theta)$ denote the stationary average queue length at node β under parameter value θ. We wish to minimize the stationary average number of customers in the network $F(\theta) = \sum F^\beta(\theta)$. The problem arises in control of telecommunication networks and has been treated in [42, 40]. The controller at node α updates the component θ_α of θ, and it does so based on both its own observations and relevant data sent from other nodes. In one useful approach, called the *surrogate estimation method* in the above references, each node β estimates the sensitivity of the mean length of its own queue to variations in *external* inputs to that node. Then one uses the mean systems flow equations to get acceptable estimates of the $F^\beta_\alpha(\theta)$. These estimates are transmitted to node α for use in estimating the derivative of $F(\theta)$ with respect to θ_α at the current value of θ and then updating the value of θ_α. After each transmission, new estimates are taken and the process is repeated. The method gave good results in simulations.

The times required for the estimation intervals can depend heavily and randomly on the node. They might be functions of the number of service completions or simply

deterministic time intervals. The nodes would transmit their estimates in an asynchronous way. Thus the SA is both decentralized and unsynchronized. In general, θ_α would be a vector of routing probabilities. For simplicity of notation, we shall consider only scalar components. The extensions to the vector case are straightforward. In a typical application of SA, each time a new estimate of $F_\alpha^\beta(\theta)$ (at the current value of θ) is received at node α, that estimate is multiplied by a step-size parameter and subtracted from the current value of state component θ_α. This "additive" structure allows us to represent the algorithm in a useful decomposed way by writing the current value of the component θ_α as the sum of the initial value plus K terms. The βth such term is the product of an appropriate step-size times the sum of the past transmissions from node β to node α of the estimates of $F_\alpha^\beta(\theta)$ at whatever the operating values of the parameter were when the estimates were made. In the development below, this decomposition is formalized and provides a useful simplification.

We shall now return to our general model. The time for transmission of information can have bounded delays, and these delays cause no problems in the analysis. But only to simplify notation, we work under the assumption that there are no delays and that the parameters are updated as soon as new information is available. The reader can fill in the few additional details for the delayed case. We are reluctant to try a very general development since the entire field of decentralized/asynchronous optimization is in its infancy, and one expects many new models and methods for estimation to appear in the next few years. But the methods employed would be fundamental to any extensions.

Notation. Let $\delta\tau_{\alpha,n}^{\beta,\epsilon}$ denote the interval between the nth and $(n+1)$st transmissions from β to α. Define

$$\tau_{\alpha,n}^{\beta,\epsilon} = \epsilon \sum_{i=0}^{n-1} \delta\tau_{\alpha,i}^{\beta,\epsilon},$$

ϵ times the real time required by the first n transmissions from β to α. Define

$$N_\alpha^{\beta,\epsilon}(t) = \epsilon \text{ [number of transmissions from } \beta \text{ to } \alpha \text{ to reach real time } t/\epsilon].$$

Let $\tau_\alpha^{\beta,\epsilon}(t)$ be the interpolation of the $\tau_{\alpha,n}^{\beta,\epsilon}$ with interpolation intervals ϵ and initial condition zero. Analogously to the situation in the last subsection, $N_\alpha^{\beta,\epsilon}(\cdot)$ and $\tau_\alpha^{\beta,\epsilon}(\cdot)$ are inverses of one another.

The SA algorithm. The notation is a little complex but very natural. It enables us to carry over the results of Theorem 3.1 to a much more complex situation via several time-change arguments and thus saves a great deal of work over a direct analysis. Let $\hat{\theta}^\epsilon(\cdot) = \{\hat{\theta}_i^\epsilon(\cdot), i \le K\}$ denote the interpolation in the real time (times ϵ) scale. As mentioned in the discussion of the example, it is convenient to separate $\hat{\theta}_\alpha^\epsilon(\cdot)$ into components which come from the same node. This suggests the following decomposed representation for the SA algorithm. For each α, β, let $c_\alpha^\beta(\cdot)$ be a continuous and bounded real-valued function and define the sequence $\theta_{\alpha,n}^{\beta,\epsilon}$ by

$$\theta_{\alpha,n+1}^{\beta,\epsilon} = \theta_{\alpha,n}^{\beta,\epsilon} + \epsilon c_a^\beta(\hat{\theta}^\epsilon(\tau_{\alpha,n}^{\beta,\epsilon}))Y_{\alpha,n}^{\beta,\epsilon}. \tag{A4.10}$$

The role of the $c_\alpha^\beta(\cdot)$ functions is to partially compensate for the fact that the frequency of the intervals between updates might depend on θ, α, β, and will be further commented upon at the end of the section. In many cases, we would use $c_\alpha^\beta(\theta) \equiv 1$. Note

that by the definitions $\hat{\theta}^{\epsilon}(\tau_{\alpha,n}^{\beta,\epsilon})$ is the state value at the time of the nth transmission from node β to node α. Indeed, we can write

$$\begin{aligned} &\hat{\theta}_{\alpha}^{\beta,\epsilon}(t) = \theta_{\alpha,N_{\alpha}^{\beta,\epsilon}(t)/\epsilon}^{\beta,\epsilon} = \theta_{\alpha}^{\beta,\epsilon}(N_{\alpha}^{\beta,\epsilon}(t)), \\ &\hat{\theta}_{\alpha}^{\beta,\epsilon}(\tau_{\alpha}^{\beta,\epsilon}(t)) = \theta_{\alpha}^{\beta,\epsilon}(t), \text{ where } \theta_{\alpha}^{\beta,\epsilon}(t) = \theta_{\alpha,n}^{\beta,\epsilon} \text{ for } t \in [n\epsilon, (n+1)\epsilon). \end{aligned} \tag{A4.11}$$

We can now define the actual interpolated iterate in the appropriate real time scale in terms of the components as

$$\hat{\theta}_{\alpha}^{\epsilon}(t) = \hat{\theta}_{\alpha}^{\epsilon}(0) + \sum_{\beta=1}^{K} \hat{\theta}_{\alpha}^{\beta,\epsilon}(t), \ \hat{\theta}_{\alpha}^{\beta,\epsilon}(0) = 0. \tag{A4.12}$$

It will be shown that the proofs are just adaptations of the argument in the last subsection to the vector case. It will be seen from the argument that all sorts of groupings and variations can be added to the format.

Assumptions. Let $\mathcal{B}_t^{\epsilon}$ be a nondecreasing sequence of sigma-algebras which measure at least the initial conditions and all the data transmitted by all the nodes up to real time t. Let $E_{\alpha,n}^{\beta,\epsilon}$ equal the expectation conditioned on $\mathcal{B}_{\tau_{\alpha,n}^{\beta,\epsilon}/\epsilon}^{\epsilon}$. Thus, $E_{\alpha,n}^{\beta,\epsilon}$ can be interpreted as the expectation conditioned on the information which is available at the time $\tau_{\alpha,n}^{\beta,\epsilon}$ of the nth transmission from β to α. We next give the conditions on the interupdate intervals. We suppose that for each α, β, ϵ there is a Markov chain $\{\xi_{\alpha,n}^{\beta,\epsilon}, n < \infty\}$ whose transition functions satisfy the obvious analogue of (3.5) and continuous functions $u_{\alpha}^{\beta}(\cdot)$ such that

$$\{\delta\tau_{\alpha,n}^{\beta,\epsilon}; \alpha, \beta, \epsilon, n\} \text{ is uniformly integrable,} \tag{A4.13}$$

$$E_{\alpha,n}^{\beta,\epsilon}\delta\tau_{\alpha,n}^{\beta,\epsilon} = u_{\alpha}^{\beta}(\hat{\theta}^{\epsilon}(\tau_{\alpha,n}^{\beta,\epsilon}), \xi_{\alpha,n}^{\beta,\epsilon}). \tag{A4.14}$$

Let there be fixed θ Markov chains $\{\xi_{\alpha,n}^{\beta}(\theta)\}$ with transition probabilities satisfying the analogues of (3.6)–(3.8). Let there be continuous functions $\hat{u}_{\alpha}^{\beta}(\cdot)$ such that for each initial condition and each θ

$$\lim_{N} \frac{1}{N} \sum_{i=0}^{N-1} E u_{\alpha}^{\beta}(\theta, \xi_{\alpha,n}^{\beta}(\theta)) = \hat{u}_{\alpha}^{\beta}(\theta). \tag{A4.15}$$

We also need that

$$\inf_{\theta,\xi} u_{\alpha}^{\beta}(\theta, \xi) > 0. \tag{A4.16}$$

Let there be uniform integrability of

$$\{Y_{\alpha,n}^{\beta,\epsilon}; \alpha, \beta, \epsilon, n\} \tag{A4.17}$$

and tightness of

$$\{\xi_{\alpha,n}^{\beta,\epsilon}, \theta_{\alpha,n}^{\beta,\epsilon}; \alpha, \beta, \epsilon, n\}. \tag{A4.18}$$

Define $G_{\alpha}^{\beta}(\cdot)$ in the usual way:

$$E_{\alpha,n}^{\beta,\epsilon} Y_{\alpha,n}^{\beta,\epsilon} = G_{\alpha}^{\beta}(\hat{\theta}(\tau_{\alpha,n}^{\beta,\epsilon}), \xi_{\alpha,n}^{\beta,\epsilon}) + \text{ small error,}$$

where the small error goes to zero in the mean as $\epsilon \to 0$ and $n \to \infty$. Suppose that there are continuous functions $g_\alpha^\beta(\theta)$ such that for each initial condition and each θ

$$\lim_N \frac{1}{N} \sum_{n=1}^{N} EG_\alpha^\beta(\theta, \xi_{\alpha,n}^\beta(\theta)) = g_\alpha^\beta(\theta). \tag{A4.19}$$

The above conditions are for starting at time zero. If we wish to work with $\hat{\theta}^\epsilon(T^\epsilon + \cdot)$ as in the first subsection, then we need to shift the indices analogously to what was done there.

Remark. In the case of the example mentioned above, the assumptions on the interupdate intervals are obviously satisfied if the nodes compute the estimators at constant intervals but also in many cases where (for example) either a fixed number of service completions or perhaps a "local" regenerative approach is used for the local estimation. Note that the chains are "local" in the sense that they can depend on the pair α, β. Thus, we work with each pair separately, which can give a simpler chain than what would appear if we treated all the pairs simultaneously. Equation (A4.16) is used to guarantee that $\{N_\alpha^{\beta,\epsilon}(\cdot), \epsilon > 0\}$ is tight and has continuous limits.

THEOREM A4.1. *Every subsequence of $\hat{\theta}(\cdot)$ has a further subsequence that converges weakly to a solution of the ODE:*

$$\dot{\hat{\theta}}_\alpha = \sum_{\beta=1}^{K} \frac{c_\alpha^\beta(\hat{\theta})}{\hat{u}_\alpha^\beta(\hat{\theta})} g_\alpha^\beta(\hat{\theta}).$$

Comments. Now we see the use of the $c_\alpha^\beta(\cdot)$ functions as a way of dealing with the variable $\hat{u}_\alpha^\beta(\theta)$. For the example, the $g_\alpha^\beta(\theta)$ are supposed to be approximations to the $F_\alpha^\beta(\theta)$. The proof of the theorem uses the ideas of the previous subsection. The $\{\theta_\alpha^{\beta,\epsilon}(\cdot), \tau_\alpha^{\beta,\epsilon}(\cdot)\}$ is tight, and all weak limits have Lipschitz-continuous paths w.p.1. Also, $\{N_\alpha^{\beta,\epsilon}(\cdot)\}$ is tight, and all limits have Lipschitz-continuous paths. Thus, $\{\hat{\theta}_\alpha^{\beta,\epsilon}(\cdot), \hat{\theta}^\epsilon(\cdot)\}$ is tight and has Lipschitz-continuous limits. Let $(\theta_\alpha^\beta(\cdot), \theta(\cdot), \hat{\theta}(\cdot), \tau_\alpha^\beta(\cdot), N_\alpha^\beta(\cdot))$ denote the limit processes. We have $\tau_\alpha^{\beta,\epsilon}(\cdot) \Rightarrow \tau_\alpha^\beta(\cdot)$, where

$$\tau_\alpha^\beta(t) = \int_0^t \hat{u}_\alpha^\beta(\hat{\theta}(\tau_\alpha^\beta(s)))ds.$$

In the centralized case of the previous subsection, the argument of the $\hat{u}$ reduces to just $\theta(s)$. Also $N_\alpha^{\beta,\epsilon}(\cdot) \Rightarrow N_\alpha^\beta(\cdot)$, where

$$N_\alpha^\beta(t) = \int_0^t \frac{ds}{\hat{u}_\alpha^\beta(\hat{\theta}(s))}.$$

The form of the algorithm (A4.10), the weak convergence of $(\hat{\theta}^\epsilon(\cdot), \tau_\alpha^{\beta,\epsilon}(\cdot))$ to $(\hat{\theta}(\cdot), \tau_\alpha^\beta(\cdot))$, and Theorem 3.1 yield that

$$\dot{\theta}_\alpha^\beta(t) = c_\alpha^\beta(\hat{\theta}(\tau_\alpha^\beta(t)))g_\alpha^\beta(\hat{\theta}(\tau_\alpha^\beta(t))).$$

The theorem follows by writing the expression for $\dot{\hat{\theta}}_\alpha^\beta(t)$ and using the fact that $N_\alpha^\beta(\tau_\alpha^\beta(t)) = t$.

Remark. Note the great advantage in using the rescaling idea. It allows us to separate the intervals form the values of the updates in the analysis and permits a result under quite weak conditions with minimal new work. It is a technique of considerable utility. The analogues of Theorems 3.2, 4.1, and 5.1 also hold.

INFINITE-DIMENSIONAL CONTINUOUS-TIME LINEAR SYSTEMS: STABILITY AND STRUCTURE ANALYSIS*

RAIMUND J. OBER† AND YUANYIN WU†

Abstract. The question of exponential and asymptotic stability of infinite-dimensional continuous-time state-space systems is investigated. It is shown that every (par)balanced realization is asymptotically stable. Conditions are given for (par)balanced, input-normal, or output-normal realizations to be asymptotically and/or exponentially stable. The boundedness of the system operators is also studied. Examples of delay systems are given to illustrate the theory.

Key words. linear infinite-dimensional systems, balanced realizations, stability, Hankel operators, semigroups of operators

AMS subject classifications. 93B15, 93B20, 93B28, 93D20

1. Introduction.

For a finite-dimensional linear system with transfer function G, there are standard ways to obtain a minimal, i.e., reachable and observable, state-space realization:

$$\begin{cases} \dot{x}(t) &= Ax(t) + Bu(t), \\ y(t) &= Cx(t) + Du(t). \end{cases}$$

This realization is unique in the sense that every other minimal realization is equivalent to it. The spectrum of the state propagation operator A is precisely the set of poles of the transfer function $G(s) = C(sI - A)^{-1}B + D$, which is proper rational. Hence the realization is exponentially stable if and only if the poles of G are all in the open left half plane. Furthermore, exponential stability of the system is equivalent to asymptotic stability.

This paper is concerned with the question of stability for infinite-dimensional systems. If the transfer function G is not rational, then we have an infinite-dimensional system of the above form, where the system operators A, B, and C are usually unbounded operators. In general, it is no longer true that all observable and reachable realizations are equivalent. The correspondence between the spectrum of the realization and the singularities of the transfer function does not necessarily hold. In general the exponential stability of a system cannot be determined by the location of the singularities of the transfer function (see, e.g., [18]). Also asymptotically stable systems are typically not exponentially stable.

There have been attempts to extend the results for finite-dimensional systems mentioned above to the infinite-dimensional case by restricting the transfer functions to a certain class. For example, Curtain [4], Yamamoto [29], and several other authors considered the equivalence between input/output stability and internal stability. We refer to [4] and [29] and the reference therein for the work in this direction. Inevitably, the stronger the results are, the smaller the class of transfer functions is.

Here we present another approach. Instead of putting too stringent restrictions on the class of transfer functions to be studied, we restrict the class of realizations to (par)balanced realizations and the closely related input-normal and output-normal realizations. These types of realizations have been advocated by several authors [20], [13], [14], [30]. They were introduced in the finite-dimensional case as a means to perform model reduction in an easy fashion

[20]. Glover, Curtain, and Partington [14] derived infinite-dimensional continuous-time balanced realizations for a class of transfer functions with nuclear Hankel operators. Young [30] developed a general realization theory of balanced realizations of infinite-dimensional discrete-time systems. The results were generalized to the continuous-time case by Ober and Montgomery-Smith [23]. The results by Young were also used by the authors to conduct an analysis of the stability and structural properties for infinite-dimensional discrete-time systems in [24].

In this paper we extend our analysis in [24] to the continuous-time case. The exponential and asymptotic stability properties of parbalanced, input-normal, and output-normal realizations are studied in detail. It is shown that all parbalanced realizations are asymptotically stable. For a subclass of transfer functions—namely, strictly noncyclic functions—results that are reminiscent of the finite-dimensional case are obtained. For this class of transfer functions the location of the singularities of the transfer function determines the exponential stability properties of parbalanced systems. The stability properties of parbalanced realizations are studied without the explicit presentation of the realizations. Structural properties of the realizations are also analyzed. In particular the boundedness of the system operators of the input- and output-normal realizations is investigated.

Most of the results presented in this paper are in terms of the properties of the transfer functions and the Hankel operators with the transfer functions as symbols. This may therefore be regarded as expressing the internal properties of a system in terms of input/output properties. Related topics can be found in Dewilde [7], where systems with strictly noncyclic transfer functions are studied from an input/output point of view. We also refer to Baras, Brockett, and Fuhrmann [2], [3], [11]. For realization theory of nonrational transfer functions, Fuhrmann [11] and Helton [16] reference for transfer provide general references.

Our main tool is a bilinear map that maps discrete-time systems to continuous-time systems. This bilinear map is routinely used for finite-dimensional systems to translate discrete-time results to continuous-time results and vice versa. In [23] properties of this bilinear map were studied for infinite-dimensional systems (see also [11]). Some continuous-time questions, however, such as exponential stability, cannot be directly answered by simply applying the bilinear transform to a discrete-time result. In such cases a more detailed study of the problem is necessary.

The contents of the paper can be summarized as follows. In §2 we review the settings of infinite-dimensional continuous-time systems we will deal with. We restrict ourselves to so-called admissible systems. We relate continuous-time systems to discrete-time systems in §3, using the above-mentioned bilinear map. As Hankel operators play an important role in our approach, we discuss Hankel operators in §4 in both the discrete- and the continuous-time case. Concrete constructions of the continuous time restricted and *-restricted shift realizations are given in §5. They respectively represent the classes of input-normal and output-normal realizations and are intimately related to Hankel operators and translation semigroups. In §6 we establish the asymptotic stability of all parbalanced continuous-time realizations. Conditions for input-normal or output-normal realizations to be asymptotically stable are also given in terms of the cyclicity of the transfer functions. The topic of §7 is exponential stability. Necessary and sufficient conditions are given for the input- and output-normal realizations to be exponentially stable. These conditions are based on the spectral properties of the transfer functions. They also hold for parbalanced realizations as long as the transfer functions are strictly noncyclic. In §8 we investigate when the system operators are bounded, and finally some examples are given in §9.

The following symbols are used:

$\mathbb{D}$	the open unit disk,
$\partial\mathbb{D}$	the unit circle,
$\mathbb{D}_e$	the complement of $(\partial\mathbb{D}) \cup \mathbb{D}$,
$D_X^{U,Y}$	admissible discrete-time systems (§3),
$C_X^{U,Y}$	admissible continuous-time systems (§3),
$D(A) \subseteq X$	the domain of an operator A on X,
$(D(A), \|\cdot\|_A)$	the space $D(A)$ equipped with norm $\|x\|_A^2 = \|x\|^2 + \|Ax\|^2$,
$(D(A)^{(\prime)}, \|\cdot\|')$	$\{f \mid f : (D(A), \|\cdot\|_A) \to \mathbb{C}$, antilinear, bounded$\}$,
$G_d^{\perp}(z)$	$\frac{1}{z}[G_d(\frac{1}{z}) - G_d(\infty)]$, $z \in \mathbb{D}$, for $G_d \in TLD^{U,Y}$,
$G_c(+\infty)$	$\lim_{\substack{r\in\mathbb{R} \\ r\to+\infty}} G_c(r)$,
H_K	the Hankel operator with symbol K,
$H^{\infty}_{L(U,Y)}(W)$	$\{F \mid F : W \to L(U,Y)$ analytic, $\sup_{z\in W} \|F(z)\| < \infty\}$; $W = \mathbb{D}$ or RHP,
$H_Y^2(\mathbb{D})$	$\{f \mid f : \mathbb{D} \to Y$ analytic on $\mathbb{D}$ and $\sup_{0<r<1} \int_0^{2\pi} \|f(re^{it})\|^2 dt < \infty\}$,
$H_Y^2(RHP)$	$\{f \mid f : RHP \to Y$ analytic on RHP and $\sup_{x>0} \int_{-\infty}^{\infty} \|f(x+iy)\|^2 dy < \infty\}$,
$\tilde{K}(z)$	$(K(\bar{z}))^*$,
$\mathcal{L}$	the Laplace transform (§3),
$L(U,Y)$	$\{A \mid A : U \to Y$ a bounded operator$\}$,
$L_Y^2(\Delta)$	$\{f \mid f : L \to Y$ square integrable on $\Delta\}$, $\Delta = \partial\mathbb{D}$ or $i\mathbb{R}$,
LHP	the open left half plane: $\{s \in \mathbb{C} : Re(s) < 0\}$,
P_+	The orthogonal projection of $L_Y^2(\Delta)$ onto $H_Y^2(W)$; $\Delta = \partial\mathbb{D}$, $W = \mathbb{D}$, or $\Delta = i\mathbb{R}$, $W = RHP$,
P_X	the orthogonal projection of $H_Y^2(W)$ onto $X \subseteq H_Y^2(W)$; $W = \mathbb{D}$ or RHP,
RHP	the open right half plane: $\{s \in \mathbb{C} : Re(s) > 0\}$,
S	the forward shift: $(Sf)(z) = zf(z)$ for $f \in H_Y^2(\mathbb{D})$,
S^*	the backward shift: $(S^*f)(z) = z^{-1}[f(z) - f(0)]$ for $f \in H_Y^2(\mathbb{D})$,
$S(Q)$	$P_X S\|_X$, the compression of S to X, where $X = H_Y^2(\mathbb{D}) \ominus (QH_Y^2(\mathbb{D}))$,
$S(Q)^*$	$S^*\|_{H_Y^2(\mathbb{D})\ominus(QH_Y^2(\mathbb{D}))}$, the restriction of S^* to $H_Y^2(\mathbb{D}) \ominus (QH_Y^2(\mathbb{D}))$,
$\sigma(A)$	the spectrum of an operator A,
$\sigma_p(A)$	the point spectrum of an operator A,
$\sigma(Q)$	the spectrum of an inner function $Q \in H_Y^{\infty}(W)$ (Lemma 7.3),
$\sigma_s(G)$	the set of points in $\mathbb{C}$ where G has no analytic continuation (§7),
$TLD^{U,Y}$	$\{G_d \mid G_d : \mathbb{D}_e \to L(U,Y)$ has a reachable and observable admissible realization$\}$,
$TLC^{U,Y}$	$\{G_c \mid G_c : RHP \to L(U,Y)$ has a reachable and observable admissible realization$\}$,
$X \vee Y$	closed linear span of subsets X and Y of a Hilbert space,
$(F,G)_L = I_Y$	F and G are weakly left coprime (§3),
$(F,G)_R = I_U$	F and G are weakly right coprime (§3).

2. Admissible continuous-time state-space systems. The main aim of this section is to briefly set out the notation and introduce the most important system theoretic concepts for this paper. More details can be found in [11], [23], [27], and [6]. In the first subsection, admissible continuous-time systems are discussed. Input-normal, output-normal, and parbalanced

realizations are defined in the second subsection. It is these classes of systems that are being analyzed in detail in later sections. What is meant by system equivalence for infinite-dimensional systems is defined in the third subsection.

2.1. Admissible continuous-time systems. It is well known that if A is the generator of a strongly continuous semigroup of operators $(e^{tA})_{t\geq 0}$ with domain of definition $D(A)$, then $D(A)$ is a Hilbert space with inner product induced by the graph norm

$$\|x\|_A^2 := \|x\|_X^2 + \|Ax\|_X^2, \quad x \in D(A).$$

Since $\|x\|_A \geq \|x\|$ for $x \in D(A)$, we can embed X in $D(A)^{(\prime)}$, the set of antilinear continuous functionals on $(D(A), \|\cdot\|_A)$, by

$$\begin{aligned} E: \quad & X \to D(A)^{(\prime)}, \\ & x \longmapsto (y \longmapsto \langle x, y\rangle). \end{aligned}$$

Note that $D(A)^{(\prime)}$ is a Hilbert space with norm $\|f\|' := \sup_{\|x\|_A\leq 1} |f(x)|$. Since $\langle\cdot,\cdot\rangle$ is linear in the first component, the embedding E is linear. By the above, we have the rigged structure

$$D(A) \subseteq X \subseteq D(A)^{(\prime)}.$$

If $(A, D(A))$ is the generator of a strongly continuous semigroup of contractions $(e^{tA})_{t\geq 0}$ on a Hilbert space, then the adjoint $(A^*, D(A^*))$ of $(A, D(A))$ is the generator of the adjoint semigroup $(e^{tA})_{t\geq 0}^*$ (see [26]). Hence, we have similarly that

$$D(A^*) \subseteq X \subseteq D(A^*)^{(\prime)}.$$

We are now in a position to define admissible continuous-time systems.

DEFINITION 2.1. *A quadruple of operators (A_c, B_c, C_c, D_c) is called an* admissible continuous-time system *with state space X, input space U, and output space Y, where X, U, and Y are separable Hilbert spaces, if*

1. *$(A_c, D(A_c))$ is the generator of a strongly continuous semigroup of contractions on X;*
2. *$B_c : U \to (D(A_c^*)^{(\prime)}, \|\cdot\|')$ is a bounded linear operator;*
3. *$C_c : D(C_c) \to Y$ is linear with $D(C_c) = D(A_c) + (I - A_c)^{-1}B_cU$ and $C_{c|D(A_c)} : (D(A_c), \|\cdot\|_{A_c}) \to Y$ is bounded;*
4. *$C_c(I - A_c)^{-1}B_c \in L(U, Y)$;*
5. *A_c, B_c, and C_c are such that $\lim_{\substack{s\in\mathbb{R}\\ s\to+\infty}} C_c(sI - A_c)^{-1}B_c = 0$ in the norm topology;*
6. *$D_c \in L(U, Y)$.*

We write $C_X^{U,Y}$ for the set of admissible continuous-time systems with input space U, output space Y, and state space X. □

By the resolvent identity, part 4 of the definition implies that $G_c(s) := C_c(sI - A_c)^{-1}B_c \in L(U, Y)$ for all $s \in RHP$ and G_c is analytic on the RHP. The function G_c is called the transfer function of the system, and (A_c, B_c, C_c, D_c) is called a realization of G_c.

2.2. Duality, observability, reachability, and parbalanced realizations. In order to define observability and reachability for continuous-time systems we need to introduce the notion of the dual system of an admissible continuous-time system.

DEFINITION 2.2. *Let $(A_c, B_c, C_c, D_c) \in C_X^{U,Y}$. Then the* dual system $(\tilde{A_c}, \tilde{B_c}, \tilde{C_c}, \tilde{D_c})$ *of (A_c, B_c, C_c, D_c) is given by*

1. *$(\tilde{A_c}, D(\tilde{A_c})) = (A_c^*, D(A_c^*))$, the adjoint operator of $(A_c, D(A_c))$;*
2. *$\tilde{B_c} : Y \to D(A_c)^{(\prime)}; y \longmapsto \tilde{B_c}(y)[\cdot] := \langle y, C_c(\cdot)\rangle$;*

3. $\tilde{C}_c : D(\tilde{C}_c) \to U$, $D(\tilde{C}_c) = D(\tilde{A}_c) + (I - \tilde{A}_c)^{-1}\tilde{B}_c Y$, *where* $\tilde{C}_c x_0$ *is defined by*

$$\begin{cases} \langle u, \tilde{C}_c x_0\rangle = B_c(u)[x_0], & x_0 \in D(A_c^*), u \in U, \\ \langle \tilde{C}_c x_0, u\rangle = \langle y_0, C_c(I - A_c)^{-1}B_c u\rangle, & x_0 = (I - \tilde{A}_c)^{-1}\tilde{B}_c y_0,\ y_0 \in Y, u \in U; \end{cases}$$

4. $\tilde{D}_c := D_c^* : Y \to U$. □

It can be directly verified that the dual system $(\tilde{A}_c, \tilde{B}_c, \tilde{C}_c, \tilde{D}_c)$ of an admissible continuous-time system (A_c, B_c, C_c, D_c) is admissible. If the continuous-time transfer function $G(s) : RHP \to L(U, Y)$ has an admissible realization (A_c, B_c, C_c, D_c), then the dual system $(\tilde{A}_c, \tilde{B}_c, \tilde{C}_c, \tilde{D}_c)$ is a realization of the transfer function $\tilde{G}(s) := (G(\bar{s}))^*$, $s \in RHP$, i.e., for all $s \in RHP$,

$$\tilde{G}(s) = (G(\bar{s}))^* = \tilde{C}_c(sI - \tilde{A}_c)^{-1}\tilde{B}_c + \tilde{D}_c.$$

The definition of observability and reachability of admissible continuous-time systems is now given.

DEFINITION 2.3. *Let* $(A_c, B_c, C_c, D_c) \in C_X^{U,Y}$; *then the operator*

$$\begin{aligned} \mathcal{O}_c : D(\mathcal{O}_c) &\to L_Y^2([0, \infty)), \\ x &\longmapsto (C_c e^{tA_c} x)_{t \geq 0} \end{aligned}$$

is called the observability operator *of the system* (A_c, B_c, C_c, D_c), *where*

$$D(\mathcal{O}_c) = \{x \in X \mid C_c e^{tA_c} x \text{ exists for almost all } t \in [0, \infty), \text{ and } C_c e^{tA_c} x \in L_Y^2([0, \infty))\}.$$

We say that (A_c, B_c, C_c, D_c) *has a bounded observability operator if* $D(A_c) \subseteq D(\mathcal{O}_c)$ *and* $\mathcal{O}_c$ *extends to a bounded operator on* X. *This extension will also be denoted by* $\mathcal{O}_c$.

If (A_c, B_c, C_c, D_c) *has a bounded observability operator* $\mathcal{O}_c$ *such that* $\operatorname{Ker}(\mathcal{O}_c) = \{0\}$, *then the system* (A_c, B_c, C_c, D_c) *is called* observable.

Let $(\tilde{A}_c, \tilde{B}_c, \tilde{C}_c, \tilde{D}_c)$ *be the dual system of* (A_c, B_c, C_c, D_c). *If the observability operator* $\tilde{\mathcal{O}}_c$ *of* $(\tilde{A}_c, \tilde{B}_c, \tilde{C}_c, \tilde{D}_c)$ *is a bounded operator on* X, *the adjoint of* $\tilde{\mathcal{O}}_c$ *is called the* reachability operator, *denoted by* $\mathcal{R}_c$, *of* (A_c, B_c, C_c, D_c), *i.e.,*

$$\mathcal{R}_c := \tilde{\mathcal{O}}_c^*.$$

If $\mathcal{R}_c$ *exists and* range$(\mathcal{R}_c)$ *is dense in* X, *the system* (A_c, B_c, C_c, D_c) *is said to be* reachable. □

The set of all reachable and observable continuous-time systems with input space U, output space Y, and state space X is denoted by $LC_X^{U,Y}$. We mainly deal with this set of systems.

The *reachability Gramian* $\mathcal{W}_c$ and the *observability Gramian* $\mathcal{M}_c$ of a continuous-time system with bounded reachability operator $\mathcal{R}_c$ and bounded observability operator $\mathcal{O}_c$ are defined to be

$$\begin{aligned} \mathcal{W}_c &:= \mathcal{R}_c\mathcal{R}_c^* : X \to X, \\ \mathcal{M}_c &:= \mathcal{O}_c^*\mathcal{O}_c : X \to X. \end{aligned}$$

When $\mathcal{W}_c = \mathcal{M}_c$ and the admissible system is observable and reachable, we say that the system is *parbalanced.* A reachable and observable admissible system is said to be *balanced* if $\mathcal{W}_c = \mathcal{M}_c$ and $\mathcal{W}_c$ has a diagonal representation with respect to an orthonormal basis of the state space. If $\mathcal{W}_c = I$, then a reachable and observable admissible system is called *input-normal.* If $\mathcal{M}_c = I$, then a reachable and observable admissible system is called *output-normal.*

2.3. System equivalence. The concept of an equivalent state-space transformation of an admissible continuous-time system is slightly more complicated than in the discrete time case as the system operators are in general unbounded.

Two systems $(A_c^i, B_c^i, C_c^i, D_c^i) \in C_{X_i}^{U,Y}$, $i = 1, 2$, are called *equivalent* if there exists a boundedly invertible operator $V \in L(X_1, X_2)$ such that

$$\begin{aligned}&\left((A_c^2, D(A_c^2)), B_c^2, (C_c^2, D(C_c^2)), D_c^2\right) =\\ &\left((VA_c^1V^{-1}, VD(A_c^1)), VB_c^1, (C_c^1V^{-1}, VD(C_c^1)), D_c^1\right),\end{aligned}$$

where

$$B_c^2 = (VB_c^1) : U \to \left(\left(D(A_c^{2*})\right)^{(\prime)}, \|\cdot\|'\right)$$

is given by

$$[B_c^2(u)](x) = (VB_c^1)(u)[x] := B_c^1(u)[V^*x], \quad u \in U, \ x \in D(A_c^{2*}) = (V^*)^{-1}D(A_c^{1*}).$$

If V is a unitary operator, then the two systems are said to be *unitarily equivalent.*

We have the following results concerning equivalent systems.

PROPOSITION 2.4. *Let* $(A_c^i, B_c^i, C_c^i, D_c^i) \in C_{X_i}^{U,Y}$, $i = 1, 2$, *be two equivalent systems such that*

$$\begin{aligned}&\left((A_c^2, D(A_c^2)), B_c^2, (C_c^2, D(C_c^2)), D_c^2\right) =\\ &\left((VA_c^1V^{-1}, VD(A_c^1)), VB_c^1, (C_c^1V^{-1}, VD(C_c^1)), D_c^1\right)\end{aligned}$$

with $V \in L(X_1, X_2)$ *a boundedly invertible operator. Then*

1. *both* $(A_c^1, B_c^1, C_c^1, D_c^1)$ *and* $(A_c^2, B_c^2, C_c^2, D_c^2)$ *realize the same transfer function.*
2. *if* $(A_c^1, B_c^1, C_c^1, D_c^1) \in C_{X_1}^{U,Y}$ *has observability operator* $\mathcal{O}$ *and reachability operator* $\mathcal{R}$, *then the observability and reachability operators of* $(A_c^2, B_c^2, C_c^2, D_c^2) \in C_{X_2}^{U,Y}$ *are respectively*

$$\mathcal{O}V^{-1} \quad \text{and} \quad V\mathcal{R}.$$

Proof. The proof is straightforward. □

Thus equivalent systems have the same transfer function as well as the same observability and reachability properties. Moreover, it can be seen that unitary equivalent systems have the same Gramians. Hence unitary equivalence preserves parbalancing.

We point out that for an admissible system $((A_c^1, D(A_c^1)), B_c^1, C_c^1, D_c^1) \in C_{X_1}^{U,Y}$ and a unitary operator $V : X_1 \to X_2$, the system

$$\begin{aligned}&\left((A_c^2, D(A_c^2)), B_c^2, (C_c^2, D(C_c^2)), D_c^2\right) =\\ &\left((VA_c^1V^{-1}, VD(A_c^1)), VB_c^1, (C_c^1V^{-1}, VD(C_c^1)), D_c^1\right)\end{aligned}$$

is also admissible, where VB_c^1 is defined as above. Therefore $((A_c^1, D(A_c^1)), B_c^1, C_c^1, D_c^1)$ and $(A_c^2, B_c^2, C_c^2, D_c^2)$ are unitarily equivalent.

The class of continuous-time transfer functions that we are interested in are those that have reachable and observable continuous time realizations on some state space X, where X is a separable Hilbert space. This class will be denoted by $TLC^{U,Y}$, where U and Y are the input and output spaces, respectively. We characterize those transfer functions in terms of their Hankel operators in §4.

3. Connection between continuous- and discrete-time systems. What is essential in our development is to relate discrete-time systems to continuous-time systems using a generalization of the well-known bilinear transformation for finite-dimensional systems. Thereby it is possible to carry some of the results in [24] for discrete-time systems over to continuous-time systems. It should be noted, however, that not all results of discrete-time systems can be translated to the continuous-time case in this way. For example, under this bilinear map an exponentially stable continuous-time system does not necessarily correspond to a power stable discrete-time system.

3.1. Admissible discrete-time systems. We recall [24] that an *admissible discrete-time system* with input space U, output space Y, and state space X, with U, X, and Y being separable Hilbert spaces, is a quadruple of operators (A_d, B_d, C_d, D_d) that satisfy the following:

1. $A_d \in L(X)$ is a contraction and $-1 \notin \sigma_p(A_d)$;
2. $B_d \in L(U, X)$, $C_d \in L(X, Y)$ and $D_d \in L(U, Y)$;
3. the limit $\lim_{r>1, r\to 1} C_d(rI + A_d)^{-1}B_d$ exists in the norm topology.

The set of all such systems is denoted by $D_X^{U,Y}$. For $(A_d, B_d, C_d, D_d) \in D_X^{U,Y}$, the function

$$G_d(z) = C_d(zI - A_d)^{-1}B_d + D_d : \mathbb{D}_e \to L(U, Y)$$

is called the *transfer function* of (A_d, B_d, C_d, D_d) and (A_d, B_d, C_d, D_d) is called a *realization* of G_d. Evidently, the transfer function G_d is analytic on $\mathbb{D}_e$ and at infinity.

For $(A_d, B_d, C_d, D_d) \in D_X^{U,Y}$, its *observability operator* $\mathcal{O}_d : D(\mathcal{O}_d) \to H_Y^2$ is defined as

$$(\mathcal{O}_d x)(z) = \sum_{n\geq 0}(C_d A_d^n x)z^n, \qquad x \in D(\mathcal{O}_d) := \left\{ x \mid \sum_{n\geq 0}(C_d A_d^n x)z^n \in H_Y^2 \right\}.$$

If $D(\mathcal{O}_d) = X$, $\mathcal{O}_d$ is bounded and $\operatorname{Ker}(\mathcal{O}_d) = \{0\}$, then the system (A_d, B_d, C_d, D_d) is said to be *observable*. The system (A_d, B_d, C_d, D_d) is said to be *reachable* if its *reachability operator* $\mathcal{R}_d : D(\mathcal{R}_d) \to X$ defined by

$$\mathcal{R}_d\left(\sum_{n\geq 0} u_n z^n\right) = \sum_{n\geq 0} A_d^n B_d u_n \quad \left(\sum_{n\geq 0} u_n z^n \in D(\mathcal{R}_d)\right),$$

where $D(\mathcal{R}_d) = \{\sum_{n=0}^{N} u_n z^n \mid N = 0, 1, \ldots, u_n \in U\}$ can be extended to a bounded operator with range dense in X. The set of all reachable and observable discrete-time admissible systems with input space U, output space Y, and state space X is denoted by $LD_X^{U,Y}$. The set of all discrete-time transfer functions that have realizations $(A_d, B_d, C_d, D_d) \in LD_X^{U,Y}$ for some state space X is denoted by $TLD^{U,Y}$. A characterization will be given of this class of transfer functions in the next section.

For $(A_d, B_d, C_d, D_d) \in LD_X^{U,Y}$, we define its *reachability Gramian* $\mathcal{W}_d : X \to X$ as

$$\mathcal{W}_d x = \mathcal{R}_d \mathcal{R}_d^* x, \quad x \in X,$$

and its *observability Gramian* $\mathcal{M}_d : X \to X$ as

$$\mathcal{M}_d x = \mathcal{O}_d^* \mathcal{O}_d x, \quad x \in X.$$

If $\mathcal{W}_d = \mathcal{M}_d$ and (A_d, B_d, C_d, D_d) is reachable and observable, then (A_d, B_d, C_d, D_d) is said to be a *parbalanced* realization. If the Gramian of a parbalanced realization has a diagonal representation with respect to an orthonormal basis, the realization is said to be *balanced*. If $\mathcal{W}_d = I$, then the reachable and observable admissible system is called *input-normal*. If $\mathcal{M}_d = I$, then the reachable and observable admissible system is called *output-normal*.

3.2. Bilinear transform. In the following theorems (see [23]) we introduce the map $T : D_X^{U,Y} \to C_X^{U,Y}$, which transforms discrete-time systems to continuous-time systems. Throughout the rest of this paper T will denote this map.

THEOREM 3.1. *Let* $(A_d, B_d, C_d, D_d) \in D_X^{U,Y}$; *then* $T((A_d, B_d, C_d, D_d)) := (A_c, B_c, C_c, D_c) \in C_X^{U,Y}$, *where the operators* A_c, B_c, C_c, *and* D_c *are defined as follows:*

1. $A_c := (I + A_d)^{-1}(A_d - I) = (A_d - I)(I + A_d)^{-1}$, $D(A_c) := D((I + A_d)^{-1})$. *It generates a strongly continuous semigroup of contractions on* X *given by* $\varphi_t(A_d)$, $t \geq 0$, *with* $\varphi_t(z) = e^{t\frac{z-1}{z+1}}$.

2. *The operator B_c is given by*

$$\begin{aligned} B_c := \sqrt{2}(I + A_d)^{-1}B_d : U &\to D(A_c^*)^{(\prime)}, \\ u &\longmapsto \sqrt{2}(I + A_d)^{-1}B_d(u)[x] \\ &:= \sqrt{2} < B_d(u), (I + A_d^*)^{-1}(x) >_X . \end{aligned}$$

3. *The operator C_c is given by*

$$\begin{aligned} C_c : D(C_c) &\to Y, \\ x &\longmapsto \lim_{\substack{\lambda \to 1 \\ \lambda > 1}} \sqrt{2}C_d(\lambda I + A_d)^{-1}x, \end{aligned}$$

where $D(C_c) = D(A_c) + (I - A_c)^{-1}B_cU$. On $D(A_c)$ we have

$$C_{c|D(A_c)} = \sqrt{2}C_d(I + A_d)^{-1}.$$

4. $D_c := D_d - \lim_{\substack{\lambda \to 1 \\ \lambda > 1}} C_d(\lambda I + A_d)^{-1}B_d$.

Moreover, let the admissible discrete-time system (A_d, B_d, C_d, D_d) be a realization of the transfer function

$$G_d : \mathbb{D}_e \to L(U, Y) ,$$

i.e., $G_d(z) = C_d(zI - A_d)^{-1}B_d + D_d$ for $z \in \mathbb{D}_e$. Then

$$(A_c, B_c, C_c, D_c) = T((A_d, B_d, C_d, D_d))$$

is an admissible continuous-time realization of the transfer function

$$G_c(s) := G_d\left(\frac{1+s}{1-s}\right) : RHP \to L(U, Y). \qquad \square$$

The inverse map is considered in the next theorem [23].

THEOREM 3.2. *Let $(A_c, B_c, C_c, D_c) \in C_X^{U,Y}$; then $T^{-1}((A_c, B_c, C_c, D_c)) := (A_d, B_d, C_d, D_d) \in D_X^{U,Y}$, where the operators A_d, B_d, C_d, and D_d are defined as follows:*

1. $A_d := (I+A_c)(I-A_c)^{-1}$, *and for $x \in D(A_c)$ we have $A_dx = (I-A_c)^{-1}(I+A_c)x$.*
2. $B_d := \sqrt{2}(I - A_c)^{-1}B_c$.
3. $C_d := \sqrt{2}C_c(I - A_c)^{-1}$.
4. $D_d := C_c(I - A_c)^{-1}B_c + D_c$.

Moreover, let the admissible continuous time system (A_c, B_c, C_c, D_c) be a realization of the transfer function

$$G_c : RHP \to L(U, Y) ,$$

i.e., $G_c(s) = C_c(sI - A_c)^{-1}B_c + D_c$ for $s \in RHP$. Then

$$(A_d, B_d, C_d, D_d) = T^{-1}((A_c, B_c, C_c, D_c))$$

is an admissible discrete-time realization of the transfer function

$$G_d(z) := G_c\left(\frac{z-1}{z+1}\right) : \mathbb{D}_e \to L(U, Y). \qquad \square$$

We recall that two discrete-time systems $(A_{di}, B_{di}, C_{di}, D_{di}) \in D_{X_i}^{U,Y}$ $(i = 1, 2)$ are equivalent (unitarily equivalent) if there is a bounded operator (a unitary operator) V from X_1 onto X_2 such that

$$(A_{d1}, B_{d1}, C_{d1}, D_{d1}) = (VA_{d2}V^{-1}, VB_{d2}, C_{d2}V^{-1}, D_{d2}).$$

In [23] it was shown that T preserves (unitary) equivalence of systems and respects duality of systems.

Note that in the previous two theorems the state spaces for the continuous- and discrete-time realizations are the same. As will be seen in later sections for continuous-time systems it is more natural to work on a different yet unitarily equivalent state space that is a subspace of $H_Y^2(RHP)$. Here we point out the equivalence of the Hilbert spaces $H_Y^2(\mathbb{D})$ and $H_Y^2(RHP)$, where Y is a separable Hilbert space (see [25, Thm. 4.6]).

PROPOSITION 3.3. *The spaces $H_Y^2(\mathbb{D})$ and $H_Y^2(RHP)$ are unitarily equivalent by the map*

$$\begin{aligned} V_Y : \quad H_Y^2(\mathbb{D}) &\to H_Y^2(RHP), \\ f_d &\mapsto (V_Y f_d)(\bullet) := f_c(\bullet) := \frac{1}{\sqrt{\pi}(1+\bullet)} f_d\left(\frac{1-\bullet}{1+\bullet}\right). \end{aligned}$$

The inverse of V is given by

$$\begin{aligned} V_Y^{-1} : \quad H_Y^2(RHP) &\to H_Y^2(\mathbb{D}) \\ f_c &\mapsto (V_Y^{-1} f_c)(\bullet) := f_d(\bullet) := \frac{2\sqrt{\pi}}{(1+\bullet)} f_c\left(\frac{1-\bullet}{1+\bullet}\right). \end{aligned}$$

□

The next result shows that observability and reachability properties as well as the Gramians are preserved under T. This implies that the transformation preserves parbalancing of systems. This result is the translation of a result in [23] to the frequency domain.

THEOREM 3.4. *Let $(A_c, B_c, C_c, D_c) \in C_X^{U,Y}$ and $(A_d, B_d, C_d, D_d) \in D_X^{U,Y}$ be such that*

$$(A_c, B_c, C_c, D_c) = T((A_d, B_d, C_d, D_d)).$$

Then

1. *(A_c, B_c, C_c, D_c) is observable (reachable) if and only if (A_d, B_d, C_d, D_d) is observable (reachable). In fact, if $\mathcal{O}_c$ ($\mathcal{R}_c$) and $\mathcal{O}_d$ ($\mathcal{R}_d$) are the observability (reachability) operators of (A_c, B_c, C_c, D_c) and (A_d, B_d, C_d, D_d), respectively, and if either (A_c, B_c, C_c, D_c) or (A_d, B_d, C_d, D_d) has a bounded observability (reachability) operator, then the following relations hold:*

$$V_1 \mathcal{O}_d x = \mathcal{L}\mathcal{O}_c x, \quad x \in X \quad (\mathcal{R}_d V_2^{-1} u = \mathcal{R}_c \mathcal{L}^{-1} u, \quad u \in H_U^2(RHP))$$

where $V_1 : H_Y^2(\mathbb{D}) \to H_Y^2(RHP)$ and $V_2 : H_U^2(\mathbb{D}) \to H_U^2(RHP)$ are unitary transformations as defined in Proposition 3.3:

$$V_i f_i = \frac{1}{\sqrt{\pi}(1+s)} f_i\left(\frac{1-s}{1+s}\right), \quad f_1 \in H_Y^2(\mathbb{D}), \text{ and } f_2 \in H_U^2(\mathbb{D}), \quad i = 1, 2,$$

and $\mathcal{L}$ is the Laplace transform.

2. *If the reachability Gramians $\mathcal{W}_c$ and $\mathcal{W}_d$ (observability Gramians $\mathcal{M}_c$ and $\mathcal{M}_d$) of (A_d, B_d, C_d, D_d) and (A_c, B_c, C_c, D_c) are defined, then*

$$\mathcal{W}_c = \mathcal{W}_d \qquad (\mathcal{M}_c = \mathcal{M}_d).$$

Proof. In [23] a "time domain" version of this result was proven. The present result follows from the result in [23] by applying the z-transform (respectively, Laplace transform) and using the unitary transformation of Proposition 3.3. □

Therefore if $G_d(z) = G_c(\frac{z-1}{z+1})$, then $G_d \in TLD^{U,Y}$, i.e., G_d has a reachable and observable discrete-time admissible realization, if and only if $G_c \in TLC^{U,Y}$, i.e., if and only if G_c has a reachable and observable continuous-time admissible realization.

The combination of Theorems 3.1, 3.2, and 3.4 gives us an effective machinery to transform discrete-time results to the continuous-time case. Before doing this, we need to study Hankel operators which will be important in the analysis of parbalanced, input-normal, or output-normal realizations treated in the sequel.

4. Linear systems and Hankel operators. In the study of discrete-time systems Hankel operators on $H^2(\mathbb{D})$ play an important role [11]. Given a discrete-time transfer function, a Hankel operator can be associated with it in a natural way. The so-called *restricted shift realization* of the transfer function is constructed by using the range of the Hankel operator as its state space (see [11], [30], [24], and §5 below). When the Hankel operator is compact, a balanced realization can be obtained whose Gramians have diagonal representations with diagonal entries equal to the singular values of the Hankel operator [30]. In the continuous-time situation Hankel operators on $H^2(RHP)$ will be of equal importance. We therefore examine the relationship between discrete-time Hankel operators and their continuous-time counterparts.

4.1. Hankel operators and realizability. Let G_d be analytic on $\mathbb{D}_e$ and at infinity so that $G_d^\perp(z) = z^{-1}[G_d(z^{-1}) - G_d(\infty)]$ is analytic on $\mathbb{D}$. We define the operator $H_{G_d^\perp,\mathbb{D}} : D(H_{G_d^\perp,\mathbb{D}}) \to H_Y^2(\mathbb{D})$ by

$$(H_{G_d^\perp,\mathbb{D}} f)(z) = P_+ G_d^\perp J f \quad (f \in D(H_{G_d^\perp})),$$

where $D(H_{G_d^\perp,\mathbb{D}}) = \{f \in H_U^2(\mathbb{D}) : f \text{ polynomial, } G_d^\perp Jf \text{ has nontangential limit in } \mathbb{D} \text{ almost everywhere (a.e.) at } \partial\mathbb{D} \text{ with limit in } L_Y^2(\partial\mathbb{D})\}$ and $(Jf)(z) = f(1/z)$. The operator $H_{G_d^\perp}$ is called the Hankel operator with symbol $G_d^\perp$. If $D(H_{G_d^\perp,\mathbb{D}})$ is dense in $H_U^2(\mathbb{D})$ and $H_{G_d^\perp,\mathbb{D}}$ extends to a bounded operator on $H_U^2(\mathbb{D})$, this extension is also called the Hankel operator with symbol $G_d^\perp$ and is denoted by $H_{G_d^\perp,\mathbb{D}}$.

The following lemma [24] relates the existence of a reachable and observable realization of a discrete-time transfer function G_d to the boundedness of the Hankel operator $H_{G_d^\perp,\mathbb{D}}$.

LEMMA 4.1. *The transfer function G_d is in $TLD^{U,Y}$; i.e., G_d has an admissible reachable and observable realization if and only if* (i) *G_d is analytic on $\mathbb{D}_e$ and at infinity,* (ii) *the limit $\lim_{r<-1,\ r\to-1,\ r\in\mathbb{R}} G_d(r)$ exists in the norm topology, and* (iii) *the Hankel operator $H_{G_d^\perp,\mathbb{D}}$ is bounded.* □

We analogously define Hankel operators for continuous-time transfer functions.

DEFINITION 4.2. *If G_c is an $L(U,Y)$-valued function analytic on RHP, then the operator*

$$\begin{aligned} H_{G_c,RHP} : \quad D(H_{G_c,RHP}) &\to H_Y^2(RHP), \\ f &\mapsto P_+ M_{G_c} R f, \end{aligned}$$

where

$$Rf(s) = f(-s),$$

M_{G_c} *is the multiplication operator by* G_c,

P_+ *is the projection on* $H_Y^2(RHP)$,

with $D(H_{G_c,RHP}) = \{f \in H_U^2(RHP) : f$ *rational,* $G_c Rf$ *has a nontangential limit in* RHP *on a.e. on* $i\mathbb{R}$ *that is in* $L_Y^2(i\mathbb{R})\}$, *is called the* Hankel operator $H_{G_c,RHP}$ with symbol G_c. □

If $D(H_{G_c,RHP})$ is dense in $H_U^2(RHP)$ and $H_{G_c,RHP}$ extends to a bounded operator on $H_U^2(RHP)$, this extension is also called the Hankel operator with symbol G_c and is denoted by $H_{G_c,RHP}$.

If it is clear from the context that the Hankel operator is defined on RHP, we will drop the subscript RHP and write H_G instead of $H_{G,RHP}$.

It is important in our context that Hankel operators defined on the disk are unitarily equivalent to Hankel operators in the right half plane in the following way (see, e.g., [25, Thm. 4.6]).

PROPOSITION 4.3. *Let* V_U *and* V_Y *be the unitary operators defined in Proposition* 3.3.

1. *Let* $G_d \in TLD^{U,Y}$ *and* $G_c \in TLC^{U,Y}$. *If*

$$G_d(z) = G_c\left(\frac{z-1}{z+1}\right) \quad \text{for } z \in \mathbb{D}_e,$$

or equivalently

$$G_c(s) = G_d\left(\frac{1+s}{1-s}\right) \quad \text{for } s \in RHP,$$

then the Hankel operators $H_{G_d^\perp,\mathbb{D}}$ *and* $H_{G_c,RHP}$ *are unitarily equivalent, i.e.,*

$$H_{G_c,RHP} = V_Y H_{G_d^\perp,\mathbb{D}} V_U^{-1},$$

where $G_d^\perp(z) = z^{-1}[G_d(z^{-1}) - G_d(\infty)]$ $(z \in \mathbb{D})$.

2. *Let* $K_d \in H_{L(U,Y)}^\infty(\mathbb{D})$ *and* $K_c \in H_{L(U,Y)}^\infty(RHP)$ *be such that*

$$K_d(z) = K_c\left(\frac{1-z}{1+z}\right), \qquad z \in \mathbb{D},$$

or equivalently

$$K_c(s) = K_d\left(\frac{1-s}{1+s}\right), \qquad s \in RHP.$$

Then

$$V_Y(K_d H_U^2(\mathbb{D})) = K_c H_U^2(RHP), \quad V_Y\left((K_d H_U^2(\mathbb{D}))^\perp\right) = (K_c H_U^2(RHP))^\perp$$

and

$$V_Y^{-1}(K_c H_U^2(RHP)) = K_d H_U^2(\mathbb{D}), \quad V_Y^{-1}\left((K_c H_U^2(RHP))^\perp\right) = (K_d H_U^2(\mathbb{D}))^\perp.$$

Proof. The proposition follows from direct verification. □

Using this proposition we can give a characterization for a continuous-time transfer function G_c to be in $TLC^{U,Y}$, i.e., to have an observable, reachable, and admissible continuous-time realization.

COROLLARY 4.4. *The following two statements are equivalent.*

1. $G_c \in TLC^{U,Y}$, *that is,* G_c *has a reachable, observable, and admissible realization on some Hilbert space.*

2. $G_c(s)$ *is analytic on* RHP, *the limit* $\lim_{r\in\mathbb{R},r\to+\infty} G_c(r)$ *exists in the norm topology, and the Hankel operator* $H_{G_c} : H_U^2(RHP) \to H_Y^2(RHP)$ *is bounded.*

Proof. This follows from Theorem 3.4, Proposition 4.3, and Lemma 4.1. □

4.2. Range spaces of Hankel operators and factorizations of transfer functions. It is known that the orthogonal complement,

$$(\text{range}H_{G_c})^{\perp} = H_Y^2(RHP) \ominus \overline{\text{range}}H_{G_c},$$

of the range of the Hankel operator H_{G_c} is invariant under any multiplication operator with symbol in H_Y^∞. Hence by Beurling's theorem, the subspace $(\text{range}H_{G_c})^{\perp}$ is either $\{0\}$ or $QH_Y^2(RHP)$, where $Q \in H_Y^\infty(RHP)$ is a rigid function. A rigid function is a function $Q \neq 0$ such that $Q(iy)$ is for a.e. $y \in \mathbb{R}$ a partial isometry with a fixed initial space (see, e.g., [11, p. 186], and [15]). In particular, inner functions are rigid functions.

Using the above-defined notions, we introduce the concept of cyclicity of continuous-time transfer functions, which relates Hankel operators with their symbols. The discrete-time case was studied in, e.g., Fuhrmann [11]. A general study of strictly noncyclic transfer functions can also be found in Dewilde [7].

DEFINITION 4.5. *Let $G_c \in H^\infty_{L(U,Y)}(RHP)$. Then G_c is called*

1. cyclic *if* $(\text{range}H_{G_c,RHP})^{\perp} = \{0\}$;
2. noncyclic *if* $(\text{range}H_{G_c,RHP})^{\perp} = QH_Y^2(RHP)$, *where* $Q \in H_Y^\infty(RHP)$ *is a rigid function*;
3. strictly noncyclic *if* $(\text{range}H_{G_c,RHP})^{\perp} = QH_Y^2(RHP)$, *where* $Q \in H_Y^\infty(RHP)$ *is an inner function.* □

Evidently in the scalar case G_c is strictly noncyclic if and only if it is noncyclic.

In the sequel it will be seen that the cyclicity of the transfer functions has much to do with the stability and other properties of their realizations. Here we present more information on cyclicity of H^∞ transfer functions.

DEFINITION 4.6. *Let G be in $H^\infty_{L(U,Y)}(RHP)$. Then the $L(U, Y)$-valued function $\hat{G}$ defined on LHP is called a* meromorphic pseudocontinuation of bounded type *of G if*

1. *$\hat{G}$ is of bounded type, i.e.,*

$$\hat{G} = \frac{F}{h},$$

where F is a $L(U, Y)$-valued function and h is a scalar-valued function and both functions are bounded and analytic in LHP.

2. *G and $\hat{G}$ have the same strong radial limits on $i\mathbb{R}$, i.e., for a.e. $y \in \mathbb{R}$*

$$\lim_{x<0,x\to 0} \hat{G}(x+iy) = \lim_{x>0,x\to 0} G(x+iy). \qquad \square$$

The following proposition summarizes the connection between discrete- and continuous-time transfer functions in terms of cyclicity, meromorphic pseudocontinuation of bounded type, and factorizations. We refer to [11] for a discussion of these concepts for discrete-time transfer functions, which are analogous to those that have been defined here for continuous-time transfer functions.

PROPOSITION 4.7. *Let $G_c \in TLC^{U,Y}$, $G_d \in TLD^{U,Y}$, and set $G_d^{\perp}(z) = z^{-1}[G_d(z^{-1}) - G_d(\infty)]$. Assume that*

$$G_d(z) = G_c\left(\frac{z-1}{z+1}\right) \quad (z \in \mathbb{D}_e),$$

or equivalently

$$G_c(s) = G_d\left(\frac{1+s}{1-s}\right) \quad (s \in RHP).$$

Then

1. *$G_d^{\perp}$ is strictly noncyclic (cyclic, noncyclic) if and only if G_c is strictly noncyclic (cyclic, noncyclic).*

2. *Let $Q_{d,1} \in H^{\infty}_{L(Y)}(\mathbb{D})$, $Q_{d,2} \in H^{\infty}_{L(U)}(\mathbb{D})$, $Q_{c,1} \in H^{\infty}_{L(Y)}(RHP)$, and $Q_{c,2} \in H^{\infty}_{L(U)}(RHP)$ be inner functions. Let $F_{d,1} \in H^{\infty}_{L(Y,U)}(\mathbb{D})$, $F_{d,2} \in H^{\infty}_{L(U,Y)}(\mathbb{D})$, $F_{c,1} \in H^{\infty}_{L(Y,Y)}(RHP)$, and $F_{c,2} \in H^{\infty}_{L(U,Y)}(RHP)$. Assume*

$$F_{d,1}(z) = F_{c,1}\left(\frac{1-z}{1+z}\right) - G_c(1)^* Q_{c,1}\left(\frac{1-z}{1+z}\right), \quad z \in \mathbb{D},$$

$$F_{d,2}(z) = F_{c,2}\left(\frac{1-z}{1+z}\right) - Q_{c,2}\left(\frac{1-z}{1+z}\right) G_c(1)^*, \quad z \in \mathbb{D},$$

$$Q_{d,i}(z) = Q_{c,i}\left(\frac{1-z}{1+z}\right), \quad z \in \mathbb{D}, \quad i = 1, 2,$$

or equivalently

$$F_{c,1}(s) = F_{d,1}\left(\frac{1-s}{1+s}\right) + G_d(\infty)^* Q_{d,1}\left(\frac{1-s}{1+s}\right), \quad s \in RHP,$$

$$F_{c,2}(s) = F_{d,2}\left(\frac{1-s}{1+s}\right) + Q_{d,2}\left(\frac{1-s}{1+s}\right) G_d(\infty)^*, \quad s \in RHP,$$

$$Q_{c,i}(s) = Q_{d,i}\left(\frac{1-s}{1+s}\right), \quad s \in RHP, \quad i = 1, 2.$$

Then G_c can be factored on $i\mathbb{R}$ as

$$G_c = Q_{c,1} F_{c,1}^* = F_{c,2}^* Q_{c,2}$$

if and only if $G_d^{\perp}$ can be factored on $\partial\mathbb{D}$ as

$$G_d^{\perp}(z) = Q_{d,1}(z)(zF_{d,1}(z))^* = (zF_{d,2}(z))^* Q_{d,2}(z) \quad (z \in \partial\mathbb{D}).$$

3. *Assume that $G_c \in H^{\infty}_{L(U,Y)}(RHP)$ and $G_d^{\perp} \in H^{\infty}_{L(U,Y)}(\mathbb{D})$. Let F_d (F_c) be a $L(U, Y)$-valued analytic function in $\mathbb{D}_e$ (LHP) and h_d (h_c) be a scalar-valued analytic function in $\mathbb{D}_e$ (LHP), both bounded, such that*

$$F_d(z) = \frac{1}{z}\left[F_c\left(\frac{1-z}{1+z}\right) - G_c(1) h_c\left(\frac{1-z}{1+z}\right)\right], \quad z \in \mathbb{D}_e,$$

$$h_d(z) = h_c\left(\frac{1-z}{1+z}\right), \quad z \in \mathbb{D}_e,$$

or equivalently

$$F_c(s) = \frac{1-s}{1+s} F_d\left(\frac{1-s}{1+s}\right) + G_d(\infty) h_d\left(\frac{1-s}{1+s}\right), \quad s \in LHP,$$

$$h_c(s) = h_d\left(\frac{1-s}{1+s}\right), \quad s \in LHP.$$

Then $G_d^{\perp}$ has a meromorphic pseudocontinuation $\hat{G}_d^{\perp}$ of bounded type in $\mathbb{D}_e$, which is given by

$$\hat{G_d^{\perp}} = \frac{F_d}{h_d}$$

if and only if G_c has a meromorphic pseudocontinuation $\hat{G}_c$ of bounded type in LHP, which is given by

$$\hat{G}_c = \frac{F_c}{h_c}.$$

Proof. The results can be directly verified. □

The next theorem provides some convenient ways to determine whether a transfer function is cyclic, noncyclic, or strictly noncyclic. Note that $Q \in H^\infty_{L(Z,Y)}(RHP)$ and $F \in H^\infty_{L(U,Y)}(RHP)$ are said to be *weakly left coprime* if $QH^2_Z(RHP) \vee FH^2_U(RHP) = H^2_Y(RHP)$, where $\vee$ denotes the closed linear span. In this case we write $(Q, F)_L = I_Y$. If two functions $Q_1 \in H^\infty_{L(U,Y)}(RHP)$ and $F_1 \in H^\infty_{L(U,Z)}(RHP)$ are such that $\tilde{Q}_1$ and $\tilde{F}_1$ are weakly left coprime, where $\tilde{Q}_1(s) = (Q_1(\bar{s}))^*$ and $\tilde{F}_1(s) = (F_1(\bar{s}))^*$ ($s \in RHP$), they are said to be weakly right coprime, and we denote this by $(Q_1, F_1)_R = I_U$ (see Fuhrmann [11]).

THEOREM 4.8. *Let $G_c \in H^\infty_{L(U,Y)}(RHP)$ with finite-dimensional U and Y. Then the following statements are equivalent:*

1. *G_c is strictly noncyclic.*
2. *G_c has a meromorphic pseudocontinuation of bounded type on LHP.*
3. *On $i\mathbb{R}$ the function G_c can be factored as*

$$G_c = Q_1 F_1^* = F_2^* Q_2,$$

where Q_1 and Q_2 are inner functions in $H^\infty_{L(Y)}(RHP)$ and $H^\infty_{L(U)}(RHP)$, respectively. The functions F_1 and F_2 are in $H^\infty_{L(Y,U)}(RHP)$ and $H^\infty_{L(U,Y)}(RHP)$, respectively, and the coprimeness conditions

$$(Q_1, F_1)_R = I_Y, \qquad (Q_2, F_2)_L = I_U$$

hold. If part 3 holds, then $Q_1 H^2_U(RHP) = (\text{range} H_{G_c})^\perp$ and $\tilde{Q}_2 H^2_U(RHP) = (\text{range} H_{\tilde{G}_c})^\perp$, where $\tilde{Q}_2(s) = (Q_2(\bar{s}))^*$ and $\tilde{G}_c(s) = (G_c(\bar{s}))^*$.

Proof. Analogous results are shown in [11] for discrete-time transfer functions. Thus the theorem follows from Proposition 4.7. □

The factorization in the theorem is Fuhrmann's generalization of the Douglas, Shapiro, and Shields factorization [8] to matrix-valued functions. For a given function, part 2 of the theorem may be easy to check. For example, the function $e^{-\alpha s} R(s)$ is strictly noncyclic, where $\alpha > 0$ and $R(s)$ is any rational function in $H^\infty_{L(U,Y)}(RHP)$. This is because $e^{-\alpha s} R(s)$ has a meromorphic pseudocontinuation of bounded type on LHP of the form $F(s)/e^{\alpha s} h(s)$, where if $a_1, \ldots, a_n$ denote the poles of $R(s)$, then,

$$h(s) = \frac{(s - a_1) \cdots (s - a_n)}{(s + a_1) \cdots (s + a_n)},$$

and $F(s) = h(s)R(s)$. Part 2 of the theorem also gives the following corollary.

COROLLARY 4.9. *Under the assumption of the theorem, $G \in H^\infty_{L(U,Y)}(RHP)$ is strictly noncyclic if and only if $\tilde{G} \in H^\infty_{L(Y,U)}(RHP)$ is strictly noncyclic.* □

4.3. Hankel operators with closed range. Similarly to Theorem 4.8, the following theorem (see [11]) gives necessary and sufficient conditions for the Hankel operator to have closed range.

THEOREM 4.10. *Let $G_c \in H_{L(U,Y)^\infty}(RHP)$ with U and Y finite dimensional. Then the Hankel operator H_{G_c} has closed range if and only if on $i\mathbb{R}$ the function G_c has the factorization*

$$G_c(s) = Q(s) F(s)^*,$$

where $Q \in H^\infty_{L(Y)}(RHP)$, $F \in H^\infty_{L(Y,U)}(RHP)$, *and the equality*

$$WQ + VF = I_Y$$

holds for some $W \in H^\infty_{L(Y)}(RHP)$ *and* $V \in H^\infty_{L(U,Y)}(RHP)$; *that is,* Q *and* F *are* strongly right coprime. *In this case*

$$H_{G_c}\left(H^2_{L(U)}(RHP)\right) = H^2_{L(Y)}(RHP) \ominus QH^2_{L(Y)}(RHP). \qquad \square$$

This section essentially established that the unitary equivalence of the spaces $H^2(\mathbb{D})$ and $H^2(RHP)$ implies the unitary equivalence of the Hankel operators $H_{G_d^\perp}$ and H_{G_c}, where $G_d(z) = G_c(\frac{z-1}{z+1})$, $z \in \mathbb{D}$. Therefore the spaces $\overline{\text{range}}H_{G_d^\perp}$ and $\overline{\text{range}}H_{G_c}$ are unitarily equivalent. As a consequence, the discrete-time transfer function G_d and the continuous-time transfer function G_c have the same cyclicity properties.

These results will be repeatedly used in the next section when we obtain the restricted shift realization of a continuous-time system by applying the bilinear map in §3 to the corresponding discrete-time system.

5. Continuous-time shift realizations via a bilinear transformation. As a direct application of the bilinear transformation T given in §3 the continuous-time restricted and *-restricted shift realizations can be obtained from the corresponding discrete realizations. These realizations can be further analyzed via the connection between continuous and discrete-time transfer functions shown in §§3 and 4.

Restricted and *-restricted shift realizations are central to the development here since they serve as prototypes of output-normal (respectively, input-normal) realizations. It will be shown in Proposition 6.2 that each output-(input-)normal realization of an admissible transfer function G is unitarily equivalent to the restricted (*-restricted) shift realization. The concrete representations of the continuous-time shift realizations obtained in this section will allow us to analyze input- and output-normal realizations in some detail in later sections.

Another important result of this section is Proposition 5.11, in which the state spaces of the restricted shift realizations for strictly noncyclic transfer functions are characterized through the inner factors in the Douglas–Shapiro–Shields factorizations of the transfer function.

5.1. Discrete-time shift realizations. We first recall the discrete-time restricted and *-restricted shift realizations of a discrete-time transfer function (see [11], [30], and [24]).

THEOREM 5.1. *Let* $G_d \in TLD^{U,Y}$. *Then* G_d *has two state-space realizations:* (A_d, B_d, C_d, D_d) *with state space* X_d *and* $(A_{d,*}, B_{d,*}, C_{d,*}, D_{d,*})$ *with state space* $X_{d,*}$, *i.e., for* $z \in \mathbb{D}_e$

$$G_d(z) = C_d(zI - A_d)^{-1}B_d + D_d = C_{d,*}(zI - A_{d,*})^{-1}B_{d,*} + D_{d,*}.$$

They are given in the following way:

1. *The state space* X_d *is given by* $X_d = \overline{\text{range}}H_{G^\perp} \subseteq H^2_Y(\mathbb{D})$, *where*

$$G_d^\perp(z) = \frac{1}{z}\left[G_d\left(\frac{1}{z}\right) - G_d(\infty)\right]$$

and $H_{G_d^\perp}$ *is the Hankel operator with symbol* $G_d^\perp$. *The operators* A_d, B_d, C_d, *and* D_d *are given as follows:*

$$(A_d f)(z) := (S^* f)(z) = \frac{f(z) - f(0)}{z}, \quad f \in X, \quad z \in \mathbb{D},$$

$$(B_d u)(z) := G_d^{\perp}(z)u, \quad u \in U, \quad z \in \mathbb{D},$$

$$C_d f := f(0), \quad f \in X,$$

$$D_d u := G_d(+\infty)u, \quad u \in U,$$

where S is the (forward) shift operator $(Sf)(z) = zf(z)$, $f \in H_Y^2(\mathbb{D})$, $z \in \mathbb{D}$.

The realization (A_d, B_d, C_d, D_d) is called the restricted shift realization *of the transfer function G_d. It is admissible, observable, and reachable, and the observability and reachability operators $\mathcal{R}_d$ and $\mathcal{O}_d$ are, respectively,*

$$\mathcal{O}_d = I_{X_d}, \quad \mathcal{R} = H_{G_d^{\perp}}.$$

2. *The realization $(A_{d,*}, B_{d,*}, C_{d,*}, D_{d,*})$ is given as follows: The state space $X_{d,*}$ is given by $X_{d,*} = \overline{\text{range}} H_{\tilde{G}_d^{\perp}}$ with*

$$\tilde{G}_d(z) = (G_d(\bar{z}))^* \text{ and } \tilde{G}_d^{\perp}(z) = \frac{1}{z}\left(\tilde{G}_d\left(\frac{1}{z}\right) - \tilde{G}_d(\infty)\right), \qquad z \in \mathbb{D}.$$

The operators $A_{d,*}$, $B_{d,*}$, $C_{d,*}$, and $C_{d,*}$ are defined as

$$\begin{aligned} A_{d,*} &= P_{X_{d,*}} S|_{X_{d,*}}, \\ B_{d,*} &: U \to X_{d,*}; u \mapsto P_{X_{d,*}} u, \\ C_{d,*} &: X_{d,*} \to Y; x \mapsto \tfrac{1}{2\pi i} \int_{\partial \mathbb{D}} (z\tilde{G}_d^{\perp}(z))^* x(z) dz = P_Y H_{G_d^{\perp}} x = (H_{G_d^{\perp}} x)(0), \\ D_{d,*} &= G_d(+\infty), \end{aligned}$$

where Y is considered a subspace embedded in $H_Y^2(\mathbb{D})$: $Y = \{y_0 + 0z + 0z^2 + \cdots \mid y_0 \in Y\} \subseteq H_Y^2(\mathbb{D})$, and $P_{X_{d,*}}$ and P_Y are orthogonal projections from $H_Y^2(\mathbb{D})$ onto $X_{d,*}$ and Y, respectively.

The realization $(A_{d,*}, B_{d,*}, C_{d,*}, D_{d,*})$ is called the *-restricted shift realization *of the transfer function G_d. It is admissible, observable, and reachable, and the observability and reachability operators $\mathcal{O}_{d,*}$ and $\mathcal{R}_{d,*}$ are, respectively,*

$$\mathcal{R}_{d,*} = P_{X_{d,*}} : H_U^2(\mathbb{D}) \to X_* \text{ and } \mathcal{O}_{d,*} = H_{\tilde{G}_d^{\perp}}^*|_{X_{d,*}} = H_{G_d^{\perp}}|_{X_{d,*}}. \qquad \square$$

5.2. Continuous-time restricted shift realization. Now we apply T to the realizations given in the theorem to get the continuous-time realizations. We need some simple lemmas.

LEMMA 5.2. *For any $x \in H_Y^2(\mathbb{D})$, $\lim_{r \in \mathbb{R},\, r>-1,\, r \to -1}(1+r)x(r) = 0$ in the norm of Y. For any $f \in H_Y^2(RHP)$, $\lim_{r \in \mathbb{R},\, r \to +\infty} f(r) = 0$ in the norm of Y.*

Proof. For $x \in H_Y^2(\mathbb{D})$ and $z \in \mathbb{D}$ we have $x(z) = \sum_{n \geq 0} z^n \hat{x}_n$, where $\hat{x}_n \in Y$ and $\sum_{n \geq 0} \|\hat{x}_n\|^2 = \|x\|_{H_Y^2(\mathbb{D})}^2$. Thus

$$\begin{aligned} \|x(z)\|_Y &\leq \sum_{n \geq 0} |z^n| \, \|\hat{x}_n\| \leq \left(\sum_{n \geq 0} |z^n|^2\right)^{1/2} \left(\sum_{n \geq 0} \|\hat{x}_n\|^2\right)^{1/2} \\ &= (1 - |z|)^{-1/2}(1 + |z|)^{-1/2}\|x\|. \end{aligned}$$

Hence $\lim_{r>-1,\, r \to -1}(1+r)x(r) = 0$.

Now for $f \in H_Y^2(RHP)$ and any $s \in RHP$, it is shown in [22, p. 254] that

$$\|f(s)\| \leq \delta(Re(s))^{-1/2},$$

where δ is a constant depending on f. Thus the lemma is proven. □

LEMMA 5.3. *With the notation of Theorem* 5.1 *we have*

1. $$\text{range}(I + A_d) = \left\{ x \mid x(z) = \frac{(1+z)h(z) - h(0)}{z},\ (z \in \mathbb{D}),\ h \in X_d \right\},$$

and for $x \in \text{range}(I + A_d)$ *the limit* $\lim_{r \in \mathbb{R},\ r>-1,\ r \to -1} x(r)$ *exists*;

2. $$[(\lambda I + A_d)^{-1}x](z) = \frac{z}{1+\lambda z}x(z) + \frac{1}{\lambda(1+\lambda z)}x\left(-\frac{1}{\lambda}\right),$$

where $x \in X_d$, $\lambda \in \mathbb{D}_e$, $z \in \mathbb{D}$;

3. $$C_d(\lambda I + A_d)^{-1}x = \frac{1}{\lambda}x\left(-\frac{1}{\lambda}\right),\ \lambda \in \mathbb{D}_e,\ x \in X_d;$$

4. $$[(I + A_d)^{-1}x](z) = \frac{z}{1+z}\left[x(z) + \frac{1}{z}x(-1)\right],\ x \in \text{range}(I + A_d),$$

where $x(-1) = \lim_{r \in \mathbb{R},\ r>-1, r \to -1} x(r)$.

Proof. 1. Since $\text{range}(I + A_d) = \{x + A_d x \mid x \in X_d\} = \{\frac{x(z)-x(0)}{z} + x(z) \mid x \in X_d\}$, we have the equality in 1. If $x \in \text{range}(I + A_d)$, then $x(z) = \frac{(1+z)h(z)-h(0)}{z}$ for some $h \in X_d$. By Lemma 5.2,

$$\lim_{r \in \mathbb{R},\ r>-1,\ r \to -1} x(r) = \lim_{r \in \mathbb{R},\ r>-1,\ r \to -1} \frac{(1+r)h(r) - h(0)}{r} = h(0).$$

2. First we show that for $x \in X_d$ and $\lambda \in \mathbb{D}_e$, the element

$$\frac{z}{1+\lambda z}x(z) + \frac{1}{\lambda(1+\lambda z)}x\left(-\frac{1}{\lambda}\right) = P_+\left(\frac{z}{1+\lambda z}x(z)\right)$$

is in X_d. Take any y in the invariant space $H_Y^2(\mathbb{D}) \ominus X_d$. Since $\frac{1}{z+\bar{\lambda}} \in H^\infty$ for $\lambda \in \mathbb{D}_e$, we have $\frac{1}{z+\bar{\lambda}}y \in H_Y^2(\mathbb{D}) \ominus X_d$. Therefore,

$$\left\langle P_+\left(\frac{z}{1+\lambda z}x(z)\right),\ y\right\rangle_{H_Y^2(\mathbb{D})} = \left\langle x,\ \frac{1}{z+\bar{\lambda}}y\right\rangle = 0.$$

This shows that $P_+\left(\frac{z}{1+\lambda z}x(z)\right) \in X_d$. Since A_d is a contraction, $(\lambda I + A_d)^{-1}$ is a bounded operator on X_d for $\lambda \in \mathbb{D}_e$. Then the equality in 2. follows from the equality

$$(\lambda I + A_d)\left[\frac{z}{1+\lambda z}x(z) + \frac{1}{\lambda(1+\lambda z)}x\left(-\frac{1}{\lambda}\right)\right] = x(z).$$

3. Using 2. and the definition of C_d we get 3.

4. If $x \in \text{range}(I + A_d)$, then by 1. and its proof there exists $h \in X_d$ such that $x(z) = \frac{(1+z)h(z)-h(0)}{z}$ and $\lim_{r \in \mathbb{R},\ r>-1,\ r \to -1} x(r) = h(0)$. Set

$$x(-1) = \lim_{r \in \mathbb{R},\ r>-1,\ r \to -1} x(r) = h(0).$$

We have

$$\frac{z}{1+z}\left[x(z) + \frac{1}{z}x(-1)\right] = h(z),$$

which is in X_d. Note that $-1 \notin \sigma_p(A_d)$. Thus $(I + A_d)^{-1}$ is defined on range$(I + A_d)$. The equality in 4. then follows from

$$(I + A_d)\left(\frac{z}{1+z}\left[x(z) + \frac{x(-1)}{z}\right]\right) = [(I + A_d)h](z) = \frac{(1+z)h(z) - h(0)}{z} = x(z). \qquad \square$$

LEMMA 5.4. *Let $f \in L^2_Y(i\mathbb{R})$. Then in $L^2_Y(i\mathbb{R})$ norm,*

$$\lim_{n\to\infty} \frac{s}{n+s} f = \lim_{n\to\infty} \frac{s}{n-s} f = 0.$$

Proof. Since $\|\frac{s}{n+s} f(s)\|^2_Y \le \|f(s)\|^2_Y$ for any $s \in i\mathbb{R}$ and $n > 0$ and

$$\lim_{n\to\infty} \left\| \frac{s}{n+s} f(s) \right\|^2_Y = 0$$

for a.e. $s \in i\mathbb{R}$, the lemma follows from the Lebesgue dominated convergence theorem. $\square$

LEMMA 5.5. *Let $G_c \in TLC^{U,Y}$. Set $X = \overline{\text{range}} H_{G_c}$ and $\mathcal{D} = P_X\{\frac{u}{1+s} : u \in U\}$. Then the map*

$$\begin{aligned} M_1 : \mathcal{D} &\to Y, \\ P_X \tfrac{u}{1+s} &\mapsto [\tilde{G}_c(1) - \tilde{G}(\infty)]u \end{aligned}$$

is well defined and the map

$$\begin{aligned} M_2 : X &\to X, \\ f &\mapsto P_X \tfrac{f}{1+s} \end{aligned}$$

is injective.

Proof. Assume $P_X \frac{u_1}{1+s} = P_X \frac{u_2}{1+s}$. Then $P_X \frac{u_1-u_2}{1+s} = 0$. This shows that $\frac{u_1-u_2}{1+s} \in H^2_Y(RHP) \ominus X$. Therefore, for any $f \in H^2_Y(RHP)$,

$$\begin{aligned} 0 &= \left\langle \frac{u_1 - u_2}{1+s},\ H_{G_c} f \right\rangle_{H^2_U(RHP)} = \left\langle \frac{u_1 - u_2}{1+s},\ P_+ G_c f(-s) \right\rangle_{H^2_U(RHP)} \\ &= \left\langle \frac{u_1 - u_2}{1+s},\ P_+[G_c - G_c(+\infty)] f(-s) \right\rangle \\ &= \left\langle \frac{u_1 - u_2}{1+s},\ [G_c(s) - G_c(+\infty)] f(-s) \right\rangle \\ &= \left\langle [G_c(s) - G_c(+\infty)]^* \frac{u_1 - u_2}{1+s},\ f(-s) \right\rangle \\ &= \left\langle [\tilde{G}_c(s) - \tilde{G}_c(\infty)] \frac{u_1 - u_2}{1-s},\ f(s) \right\rangle. \end{aligned}$$

Hence $[\tilde{G}(s) - \tilde{G}(1)]\frac{u_1-u_2}{1-s} = 0$. So we have $[\tilde{G}(s) - \tilde{G}(1)](u_1 - u_2) = 0$. Taking the limit on the real line, we get

$$[\tilde{G}_c(1) - \tilde{G}_c(+\infty)](u_1 - u_2) = 0.$$

This shows that indeed M_1 is well defined.

To show that M_2 is injective, assume $P_X \frac{h_1(s)}{1+s} = P_X \frac{h_2(s)}{1+s}$, $h_1, h_2 \in X$. Then $P_X \frac{h_1(s)-h_2(s)}{1+s} = 0$. Hence

$$\frac{h_1(s) - h_2(s)}{1+s} \in H_Y^2 \ominus X.$$

By Lemma 5.4, we have

$$\lim_{n\to\infty} \left\| \frac{1+s}{1+s/n} \frac{h_1(s) - h_2(s)}{1+s} - (h_1 - h_2) \right\|_{H_Y^2(RHP)} = \lim_{n\to\infty} \left\| \frac{-s}{n+s}(h_1 - h_2) \right\| = 0.$$

Hence $\lim_{n\to+\infty} \frac{1+s}{1+s/n} \frac{h_1(s)-h_2(s)}{1+s} = h_1 - h_2$ in H_Y^2. Note that $H_Y^2 \ominus X$ is an invariant space and $\frac{1+s}{1+s/n} \in H^\infty$ for $n > 0$. So $\frac{1+s}{1+s/n} \frac{h_1(s)-h_2(s)}{1+s} \in H_Y^2 \ominus X$, and hence $h_1 - h_2 \in H_Y^2 \ominus X$. Since $h_1 - h_2 \in X$, we therefore have $h_1 - h_2 = 0$. This shows that M_2 is injective. □

We will need the following result on the reproducing kernel in $H^2(RHP)$ (see, e.g., [10]).

LEMMA 5.6. *For $f \in H_U^2(RHP)$, $u \in U$, and $\alpha \in RHP$ the following hold:*

$$\left\langle f, \frac{u}{s+\bar{\alpha}} \right\rangle_{H_U^2(RHP)} = 2\pi \langle f(\alpha), u \rangle_U,$$

$$\left\langle \frac{u}{s+\bar{\alpha}}, f \right\rangle_{H_U^2(RHP)} = 2\pi \langle u, f(\alpha) \rangle_U.$$

We are ready to present the continuous-time restricted shift realization using the bilinear transform T. For a continuous-time transfer function G_c we first realize the discrete-time transfer function G_d defined by

$$G_d(z) = G_c\left(\frac{z-1}{z+1}\right)$$

in terms of the restricted shift realization. Applying T to this discrete-time realization we obtain a realization of G_c with the same state space. Then we use a unitary transformation to get the continuous-time restricted shift realization with state space $\overline{\text{range}} H_{G_c}$.

THEOREM 5.7. *Let $G_c \in TLC^{U,Y}$. Then G_c has a state-space realization $(A_c, B_c, D_c, C_c) \in C_X^{U,Y}$, which is given in the following way:*

1. *The state space is given by*

$$X = \overline{\text{range}} H_{G_c,RHP} \subseteq H_Y^2(RHP).$$

2. *The semigroup $(e^{tA_c})_{t\geq 0}$ corresponding to the realization is given by*

$$\begin{aligned} e^{tA_c}: \quad X &\to X, \\ f &\mapsto (e^{tA_c} f)(s) = P_+ e^{ts} f(s). \end{aligned}$$

The infinitesimal generator $(A_c, D(A_c))$ of the semigroup $(e^{tA_c})_{t\geq 0}$ is given by

$$\begin{aligned} A_c: \quad D(A_c) &\to X, \\ f &\mapsto (A_c f)(s) = sf(s) - \lim_{\substack{r\in\mathbb{R} \\ r\to\infty}} rf(r). \end{aligned}$$

The domain $D(A_c)$ is dense in X, and we have

$$D(A_c) = \left\{ f \mid f(s) = \frac{1}{1-s}[h(s) - h(1)] : (s \in RHP),\ h \in X \right\}.$$

The domain of the adjoint A_c^* of the operator A_c is

$$D(A_c^*) = \left\{ f \mid f(s) = P_X \frac{h(s)}{1+s} : (s \in RHP),\ h \in X \right\}$$

and

$$A_c^* f = f - h \text{ for } f(s) = P_X \frac{h(s)}{1+s} \in D(A_c^*).$$

On $\mathcal{L}^{-1}(X) \subseteq L^2_U([0,+\infty))$ the semigroup is given by

$$\begin{aligned} e^{tA_c} :\ \mathcal{L}^{-1}(X) &\to \mathcal{L}^{-1}(X), \\ f &\mapsto (e^{tA_c} f)(\tau) = P_{L^2_U([0,+\infty))}(f(\tau+t))_{\tau \geq 0}. \end{aligned}$$

3. *The input operator is given by*

$$\begin{aligned} B_c :\ U &\to D(A_c^*)^{(\prime)}, \\ u &\mapsto B_c(u), \end{aligned}$$

where for $u \in U$ and $x(s) = P_X \frac{h(s)}{1+s} \in D(A_c^*)$,

$$\begin{aligned} [B_c(u)](x) &= \frac{1}{\sqrt{2\pi}} \left\langle \frac{1}{1-s}[G_c(s) - G_c(1)]u,\ (1 - A_c^*)x \right\rangle \\ &= \frac{1}{\sqrt{2\pi}} \left\langle H_{G_c} \frac{u}{1+s},\ (1 - A_c^*)x \right\rangle \\ &= \frac{1}{\sqrt{2\pi}} \left\langle H_{G_c} \frac{u}{1+s},\ h \right\rangle \\ &= \sqrt{2\pi} \left\langle u, (H_{\tilde{G}_c} h)(1) \right\rangle_U. \end{aligned}$$

4. *The output operator is given by*

$$\begin{aligned} C_c : D(C) = D(A_c) + (I - A_c)^{-1} B_c U &\to Y, \\ x &\mapsto \sqrt{2\pi} \lim_{\substack{r \in \mathbb{R} \\ r \to \infty}} rx(r). \end{aligned}$$

5. *The feedthrough operator is given by*

$$\begin{aligned} D_c :\ U &\to Y, \\ u &\mapsto G_c(+\infty)u := \lim_{\substack{r \in \mathbb{R} \\ r \to +\infty}} G_c(r)u. \end{aligned}$$

The realization (A_c, B_c, C_c, D_c) of G_c is called the restricted shift realization.

Proof. These results are obtained by applying the map T of Theorem 3.1 to the restricted shift realization (A_d, B_d, C_d, D_d) of $G_d(z) = G_c(\frac{z-1}{z+1})$, $(z \in \mathbb{D}_e)$, with the state space then transformed by the unitary operator $V = V_Y$ defined in Proposition 3.3.

1. Let $(A_{c1}, B_{c1}, C_{c1}, D_{c1}) = T((A_d, B_d, C_d, D_d))$ and

$$(A_c, B_c, C_c, D_c) = (VA_{c1}V^{-1}, VB_{c1}, CV^{-1}, D_{c1}).$$

We use the following notation: $G_d^{\perp}(z) = \frac{1}{z}[G_d(\frac{1}{z}) - G_d(\infty)] = \frac{1}{z}[G_c(\frac{1-z}{1+z}) - G_c(1)]$ $(z \in \mathbb{D})$, $X_d = \overline{\text{range}} H_{G_d^{\perp}}$, and $\phi_t(z) = e^{t\frac{z-1}{z+1}}$, $t \geq 0$. Then by Proposition 4.3 $X = VX_d$, and $\phi_t(A_d)$ is

the semigroup of contractions on X_d with infinitesimal generator $(A_d - I)(A_d + I)^{-1} = A_{c1}$ (see [28, p. 141]). Specifically, for $x \in X_d$ we have

$$\phi_t(A_d)x = P_+\phi_t\left(\frac{1}{z}\right)x = P_+e^{t\frac{\frac{1}{z}-1}{\frac{1}{z}+1}}x = P_+e^{t\frac{1-z}{1+z}}x.$$

Then it is easy to see that $A_c = VA_{c1}V^{-1}$ generates the semigroup of contractions $V\phi_t(A_d)V^{-1}$ on X. If we extend the unitary transformation $V : H^2(\mathbb{D}) \to H^2(RHP)$ naturally to

$$\begin{aligned} V : L^2(\partial\mathbb{D}) &\to L^2(i\mathbb{R}), \\ x_d &\mapsto (Vx_d)(\bullet) = \frac{1}{\sqrt{\pi}(1+\bullet)}x_d\left(\frac{1-\bullet}{1+\bullet}\right), \end{aligned}$$

we still have a unitary transformation. Moreover, by considering $z^n y$ for $n \in \mathbb{Z}$ and $y \in Y$ we can show that

$$VP_+^{\mathbb{D}} = P_+^{RHP}V,$$

where $P_+^{\mathbb{D}} : L^2(\partial\mathbb{D}) \to H^2(\mathbb{D})$ and $P_+^{RHP} : L^2(i\mathbb{R}) \to H^2(RHP)$ are the orthogonal projections. From this it follows that for $f \in X$,

$$e^{tA_c}f = V\phi_t(A_d)V^{-1}f = VP_+^{\mathbb{D}}e^{t\frac{1-z}{1+z}}V^{-1}f = P_+^{RHP}Ve^{t\frac{1-z}{1+z}}V^{-1}f = P_+e^{ts}f.$$

Clearly, $D(A_{c1}) = \text{range}(A_d+I)$, and by Lemma 5.3 $\text{range}(A_d+I) = \{\frac{(1+z)x(z)-x(0)}{z} \mid x \in X_d\}$. Since $D(A_c) = VD(A_{c1})$ and $x(0) = 2\sqrt{\pi}(Vx)(1)$ for $x \in X_d$, we have

$$D(A_c) = V\text{range}(A_d + I) = V\left\{\frac{(1+z)x(z) - x(0)}{z} \mid x \in X_d\right\}$$

$$= \left\{V\left(\frac{(1+z)x(z) - x(0)}{z}\right) \mid x \in X_d\right\} = \left\{\frac{(1+\frac{1-s}{1+s})f(s) - \frac{2f(1)}{1+s}}{\frac{1-s}{1+s}} \mid f \in X\right\}$$

$$= \left\{\frac{f(s) - f(1)}{1-s} \mid f \in X\right\}.$$

For $x \in D(A_{c1}) = \text{range}(A_d + I)$ the limit $\lim_{r\in\mathbb{R},\, r>-1,\, r\to-1} x(r)$ exists by Lemma 5.3. Denoting it by $x(-1)$ and using Lemma 5.3, part 4, we have

$$(A_{c1}x)(z) = [(A_d - I)(A_d + I)^{-1}x](z)$$

$$= (A_d - I)\left(\frac{z}{1+z}\left[x(z) + \frac{1}{z}x(-1)\right]\right) = \frac{(1-z)x(z) - 2x(-1)}{1+z}.$$

From this we obtain, for $f \in D(A_c) = VD(A_{c1})$,

$$(A_cf)(s) = (VA_{c1}V^{-1}f)(s) = V\left(\frac{(1-z)(V^{-1}f)(z) - 2(V^{-1}f)(-1)}{1+z}\right)$$
$$= sf(s) - \lim_{r\in\mathbb{R},\, r\to+\infty} rf(r),$$

where we have used the fact that for $f \in D(A_c)$

$$(V^{-1}f)(-1) = \sqrt{\pi}\lim_{\substack{r\in\mathbb{R} \\ r\to+\infty}}(1+r)f(r) = \sqrt{\pi}\lim_{\substack{r\in\mathbb{R} \\ r\to+\infty}} rf(r).$$

Now we show the form of A_c^*. Recall that A_c^* is the generator of the strongly continuous semigroup $(e^{tA_c})^*$. Let

$$D(\hat{A}) = \left\{ f \mid f(s) = P_X \frac{h(s)}{1+s} \text{ for some } h \in X \right\}$$

and

$$\begin{aligned} \hat{A} : D(\hat{A}) &\to X, \\ \hat{A}f &= f - h \quad \left(f = P_X \frac{h(s)}{1+s} \in D(\hat{A}) \right). \end{aligned}$$

By Lemma 5.5, the operator $\hat{A}$ is well defined.

For $f \in D(\hat{A})$ and $g \in D(A_c)$ there are v and w in X such that $f = P_X \frac{v}{1+s}$ and $g = \frac{w-w(1)}{1-s}$. By the definition of A_c and $\hat{A}$, we have $A_c g = w$ and $\hat{A}f = v$. It then follows that

$$\langle A_c g,\ f \rangle = \left\langle w,\ P_X \frac{v}{1+s} \right\rangle = \left\langle \frac{w}{1-s},\ v \right\rangle = \left\langle \frac{w-w(1)}{1-s}, v \right\rangle = \langle g,\ \hat{A}f \rangle.$$

This shows that $D(\hat{A}) \subseteq D(A_c^*)$ and $\hat{A} = A_c^*|_{D(\hat{A})}$. On the other hand, we clearly have $(I - \hat{A})D(\hat{A}) = X$ and hence

$$(I - A_c^*)D(\hat{A}) = X.$$

Let $x \in D(A_c^*)$. Then there exists $x_1 \in D(\hat{A})$ such that

$$(I - A_c^*)x_1 = (I - A_c^*)x.$$

Since A_c^* is the infinitesimal generator of a semigroup of contractions, the number 1 is not in the spectrum of A_c^*. Thus we must have $x_1 = x$. This shows that

$$D(A_c^*) \subseteq D(\hat{A}).$$

Therefore $D(A_c^*) = D(\hat{A})$ and hence $A_c^* = \hat{A}$.

2. For the operator B_c we first compute B_{c1}, following the definition of T:

$$\begin{aligned} B_{c1} := \sqrt{2}(I + A_d)^{-1} B_d : U &\to D(A_c^*)^{(\prime)}, \\ u &\longmapsto \sqrt{2}(I + A_d)^{-1} B_d(u)[\cdot], \\ &:= \sqrt{2} < B_d(u), (I + A_d^*)^{-1}(\cdot) >_{X_d}. \end{aligned}$$

Note that $V^* = V^{-1}$, $(I + A_d^*)^{-1} = \frac{1}{2}(I - A_{c1}^*)$, and

$$(VB_d u)(s) = \frac{1}{\sqrt{\pi}} \frac{G_c(s) - G_c(1)}{1-s} u \quad (s \in RHP).$$

Thus for $x = P_X \frac{h(s)}{1+s} \in D(A_c^*) \subseteq X$, we have $(I - A_c^*)x = h$ and

$$\begin{aligned} (B_c u)(x) &= (VB_{c1})(x) = (B_{c1}u)(V^*x) = \sqrt{2}\langle B_d u,\ (I + A_d^*)^{-1} V^{-1} x \rangle_{X_d} \\ &= \sqrt{2}\langle VB_d u,\ V(I + A_d^*)^{-1} V^{-1} x \rangle_X = \sqrt{2} \left\langle VB_d u,\ \frac{1}{2} V(I - A_{c1}^*) V^{-1} x \right\rangle_X \\ &= \frac{1}{\sqrt{2}} \langle VB_d u,\ (I - A_c^*)x \rangle_X \end{aligned}$$

$$= \frac{1}{\sqrt{2\pi}} \left\langle \frac{G_c(s) - G_c(1)}{1-s} u,\ (I - A_c^*)x \right\rangle_X$$

$$= \frac{1}{\sqrt{2\pi}} \left\langle \frac{G_c(s) - G_c(1)}{1-s} u,\ h \right\rangle_X$$

$$= \frac{1}{\sqrt{2\pi}} \left\langle H_{G_c} \frac{u}{1+s},\ h \right\rangle_X .$$

Since $(H_{G_c})^* = H_{\tilde{G}_c}$, we have

$$(B_c u)(x) = \frac{1}{\sqrt{2\pi}} \left\langle \frac{u}{1+s},\ H_{\tilde{G}_c} h \right\rangle .$$

By Lemma 5.6 the right-hand side is $\sqrt{2\pi}\langle u,\ (H_{\tilde{G}_c} h)(1)\rangle_U$.

3. To compute C_c we use Lemma 5.3, part 3, to get

$$C_d(\lambda I + A_d)^{-1} x = \frac{1}{\lambda} x\left(-\frac{1}{\lambda}\right), \quad \lambda \in \mathbb{D}_e .$$

So for $x \in D(C_{c1}) = D(A_{c1}) + (I - A_{c1})^{-1} B_{c1} U$ we have

$$C_{c1} x = \sqrt{2} \lim_{\substack{\lambda > 1 \\ \lambda \to 1}} C_d(\lambda I + A_d)^{-1} x$$

$$= \sqrt{2} \lim_{\substack{\lambda > 1 \\ \lambda \to 1}} \frac{1}{\lambda} x\left(-\frac{1}{\lambda}\right) = \sqrt{2} \lim_{\substack{\lambda > -1 \\ \lambda \to -1}} x(\lambda).$$

The existence of the limit for $x \in D(A_{c1})$ follows from Lemma 5.3, part 1, because $D(A_{c1}) = \text{range}(A_d + I)$. For $x \in (I - A_{c1})^{-1} B_{c1} U$ we have that the limit

$$\sqrt{2} \lim_{\substack{\lambda > 1 \\ \lambda \to 1}} C_d(\lambda I + A_d)^{-1} x$$

also exists by the admissibility of G_d, since $(I - A_{c1}) B_{c1} u = \frac{1}{\sqrt{2}} B_d u = \frac{1}{\sqrt{2}} G_d^{\perp} u$ (see [23]). Now it can be verified that $V D(C_{c1}) = D(A_c) + (I - A_c)^{-1} B_c U$, i.e., $V D(C_{c1}) = D(C_c)$. Hence we get, for $f \in D(C_c)$,

$$C_c f = C_{c1} V^{-1} f = \sqrt{2} \lim_{\substack{\lambda > -1 \\ \lambda \to -1}} \frac{2\sqrt{\pi}}{1+\lambda} f\left(\frac{1-\lambda}{1+\lambda}\right)$$

$$= \sqrt{2\pi} \lim_{\substack{r \in \mathbb{R} \\ r \to +\infty}} (1+r) f(r) = \sqrt{2\pi} \lim_{\substack{r \in \mathbb{R} \\ r \to +\infty}} r f(r).$$

Finally, the obvious expression $D_c = G_c(\infty)$ can also be verified as follows:

$$D_c u = D_{c1} u = D_d u - \lim_{\substack{\lambda > 1 \\ \lambda \to 1}} C_d(\lambda I + A_d)^{-1} B_d u$$

$$= G_d(\infty) u - \lim_{\substack{\lambda > 1 \\ \lambda \to 1}} C_d(\lambda I + A_d)^{-1} G_d^{\perp} u = G_c(1) u - \lim_{\substack{\lambda > 1 \\ \lambda \to 1}} \frac{1}{\lambda} G_d^{\perp}\left(-\frac{1}{\lambda}\right) u$$

$$= G_c(1) u - \lim_{\substack{\lambda > 1 \\ \lambda \to 1}} (-1)\left[G_c\left(\frac{\lambda+1}{\lambda-1}\right) - G_c(1) \right] u = \lim_{\substack{\lambda > 1 \\ \lambda \to 1}} G_c\left(\frac{\lambda+1}{\lambda-1}\right)$$

$$= G_c(+\infty). \qquad \square$$

Regarding the expressions for the operator B_c in the theorem we have the following corollary.

COROLLARY 5.8. *$B_c u \in X$, $(u \in U)$ if and only if $[G_c - G_c(+\infty)]u \in X$ $(u \in U)$. In this case*

$$(B_c u)(s) = \frac{1}{\sqrt{2\pi}}[G_c(s) - G_c(+\infty)]u \quad (u \in U).$$

In particular, if G_c satisfies

$$\sup_{x>0} \int_{-\infty}^{+\infty} \|G_c(x+iy) - G_c(+\infty)\|^2 dy < \infty,$$

where for $s \in RHP$ the expression $\|G_c(s) - G_c(+\infty)\|$ denotes the operator norm of the operator $G_c(s) - G_c(+\infty) \in L(U, Y)$, then $B_c u \in X$ and

$$(B_c u)(s) = \frac{1}{\sqrt{2\pi}}[G_c(s) - G_c(+\infty)]u$$

for any $u \in U$.

Proof. First we assume that $[G_c - G_c(+\infty)]u \in X$ $(u \in U)$. Define $F(s) = G_c(s) - G_c(+\infty)$. Then $Fu \in X$. It follows from the formula for $D(A_c)$ that

$$\frac{1}{1-s}[G_c(s) - G_c(1)]u = \frac{1}{1-s}[F(s)u - F(1)u] \in D(A_c)$$

and hence for $x \in D(A_c^*)$,

$$[B_c(u)](x) = \frac{1}{\sqrt{2\pi}}\left\langle \frac{1}{1-s}[G_c(s) - G_c(1)]u,\ (I - A_c^*)x \right\rangle_{H_Y^2(RHP)}$$

$$= \frac{1}{\sqrt{2\pi}}\left\langle (I - A_c)\frac{1}{1-s}[G_c(s) - G_c(1)]u,\ x \right\rangle$$

$$= \frac{1}{\sqrt{2\pi}}\left\langle \left(\frac{1}{1-s} - \frac{s}{1-s}\right)[G_c(s) - G_c(1)]u + \lim_{\substack{r\in\mathbb{R} \\ r\to+\infty}} \frac{r}{1-r}[G_c(r) - G_c(1)]u,\ x \right\rangle$$

$$= \frac{1}{\sqrt{2\pi}}\langle [G_c(s) - G_c(+\infty)]u,\ x\rangle = \frac{1}{\sqrt{2\pi}}\langle Fu,\ x\rangle.$$

Here we have used the definition of A_c and the fact that the limit $\lim_{\substack{r\in\mathbb{R} \\ r\to+\infty}} G_c(r)u$ exists, which follows from the admissibility of G_c. Thus we have shown that $B_c(u) \in X$ and $B_c(u) = \frac{1}{\sqrt{2\pi}}Fu$ for any $u \in U$.

On the other hand, if $B_c(u) \in X$, $(u \in U)$, then there is $f_u \in X$ such that $[B_c(u)](x) = \langle f_u,\ x\rangle$ for any $x \in X$. Therefore

$$\frac{1}{\sqrt{2\pi}}\left\langle \frac{1}{1-s}[G_c(s) - G_c(1)]u,\ (I - A_c^*)x \right\rangle = \langle f_u,\ x\rangle \ (x \in X).$$

This shows that $\frac{1}{1-s}[G_c(s) - G_c(1)]u \in D((I - A_c^*)^*) = D(I - A_c) = D(A_c)$. So there is $h \in X$ such that

$$\frac{1}{1-s}[G_c(s) - G_c(1)]u = \frac{h(s) - h(1)}{1-s}.$$

Hence $G_c(s) - G_c(1) = h(s) - h(1)$. Since $\lim_{\substack{s\in\mathbb{R}\\ s\to\infty}} h(s) = 0$ (see Lemma 5.2), we have $G_c - G_c(+\infty) = h \in X$.

To complete the proof of the corollary, it suffices to show that the condition that G_c is analytic for $Re(s) > 0$ and satisfies

$$\sup_{x>0} \int_{-\infty}^{+\infty} \|G_c(x+iy) - G_c(+\infty)\|^2 dy < \infty$$

implies that $[G_c - G_c(+\infty)]u \in X$ for any $u \in U$.

Again let $F(s) = G_c(s) - G_c(+\infty)$. We have the equality of Hankel operators:

$$H_{G_c} = H_F.$$

The assumption on G_c implies that $Fu \in L^2_Y(i\mathbb{R})$ for any $u \in U$. Now we show that in $L^2_Y(i\mathbb{R})$ norm

$$Fu = \lim_{n\to\infty} H_F \frac{n}{n+s} u$$

and hence $Fu \in X = \overline{\text{range}} H_F$. The proof will then be complete.

Consider

$$\left\| Fu - H_F \frac{n}{n+s} u \right\|_{L^2_Y(i\mathbb{R})} = \left\| P_+ F \frac{-s}{n-s} u \right\| = \left\| P_+ \frac{-s}{n-s} Fu \right\|.$$

By Lemma 5.4, we have $\lim_{n\to\infty} \| \frac{-s}{n-s} Fu \|_{L^2_Y(i\mathbb{R})} = 0$. Therefore

$$\lim_{n\to\infty} \| P_+ \frac{-s}{n-s} Fu \| = 0.$$

So we indeed have $Fu = \lim_{n\to\infty} H_F \frac{n}{n+s} u$, converging in $L^2_Y(i\mathbb{R})$ norm. □

5.3. Continuous-time $*$-restricted shift realization. If we apply the map T in Theorem 3.1 to the *-restricted shift realization of $G_d(z) = G_c(\frac{z-1}{z+1})$ and then transform the state space by the unitary operator of Proposition 3.3, we obtain the *-restricted shift realization of G_c. Alternatively, we can find the restricted shift realization of the transfer function $\tilde{G}_c \in TLC^{Y,U}$ first, and then the dual system of this restricted shift realization will be the *-restricted shift realization of G_c.

THEOREM 5.9. *Let $G_c \in TLC^{U,Y}$. Then G_c has a state-space realization $(A_{c,*}, B_{c,*}, C_{c,*}, D_{c,*}) \in C_X^{U,Y}$, which is given in the following way:*

1. *The state space is given by*

$$X_* = \overline{\text{range}} H_{\tilde{G}_c, RHP} \subseteq H^2_U(RHP),$$

where $\tilde{G}_c(s) = (G(\bar{s}))^*$ for $s \in RHP$.

2. *The semigroup $(e^{tA_{c,*}})_{t\geq 0}$ corresponding to the realization is given by*

$$\begin{aligned} e^{tA_{c,*}} : \quad X_* &\to X_*, \\ f &\mapsto (e^{tA_{c,*}} f)(s) = P_{X_*} e^{-ts} f(s), \end{aligned}$$

where the operator $A_{c,*}$ has domain

$$D(A_{c,*}) = P_{X_*} \left\{ \frac{1}{1+s} h(s) : h \in X_* \right\}$$

and for $f(s) = P_{X_*}\frac{1}{1+s}h(s) \in D(A_{c,*})$,

$$A_{c,*}f = f - h.$$

On $\mathcal{L}^{-1}(X_*) \subseteq L^2_U([0,\infty))$ *the semigroup is given by*

$$\begin{aligned} e^{tA_{c,*}}: \quad \mathcal{L}^{-1}(X_*) &\to \quad \mathcal{L}^{-1}(X_*), \\ f &\mapsto \quad (e^{tA_{c,*}}f)(s) = P_{\mathcal{L}^{-1}(X)_*}f(s-t). \end{aligned}$$

3. *The input operator* $B_{c,*}: U \to D(A^*_{c,*})^{(\prime)}$ *is given by*

$$u \mapsto B_c(u)$$

with

$$\begin{aligned} \left[B_{c,*}(u)\right](x) &= \frac{1}{\sqrt{2\pi}}\left\langle \frac{1}{1+s}u,\ (1-A^*_{c,*})x\right\rangle \\ &= \frac{1}{\sqrt{2\pi}}\left\langle \frac{1}{1+s}u,\ h\right\rangle \\ &= \sqrt{2\pi}\langle u, h(1)\rangle_U, \quad x = \frac{h(s)-h(1)}{1-s} \in D(A^*_{c,*}),\ h \in X^*. \end{aligned}$$

4. *The output operator has the following form:*

$$\begin{aligned} D(C_{c,*}) &= D(A_{*,c}) + (I - A_{*,c})^{-1}B_{c,*}U \\ &= P_{X_*}\left\{\frac{h(s)}{1+s} \mid h \in X_*\right\} + P_{X_*}\left\{\frac{u}{1+s} \mid u \in U\right\}. \end{aligned}$$

If $x = P_{X_*}\frac{h(s)}{1+s}$, *then*

$$C_{c,*}x = \sqrt{2\pi}(H_{G_c}h)(1),$$

and if $x = P_{X_*}\frac{u}{1+s}$, *then*

$$C_{c,*}x = \sqrt{2\pi}[G_c(1) - G(+\infty)]u.$$

5. *The feedthrough operator is given by*

$$\begin{aligned} D_{c,*}: \quad U &\to \quad Y, \\ u &\mapsto \quad G_c(+\infty)u := \lim_{\substack{r\in\mathbb{R}\\ r\to\infty}} G_c(r)u. \end{aligned}$$

The realization $(A_{c,*}, B_{c,*}, C_{c,*}, D_{c,*})$ *of* G_c *is called the* *- restricted shift realization.

Proof. Let (A, B, C, D) be the restricted shift realization of the transfer function $\tilde{G}_c(s) = (G(\bar{s}))^*$. Take $(A_{c,*}, B_{c,*}, C_{c,*}, D_{c,*})$ to be the dual system $(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D})$ of (A, B, C, D). Then $(A_{c,*}, B_{c,*}, C_{c,*}, D_{c,*})$ is a realization of G (see Definition 2.2). We show that $(A_{c,*}, B_{c,*}, C_{c,*}, D_{c,*})$ obtained this way has the expressions as given in the theorem. Notice that $\tilde{A} = A^*$, i.e., $A_{c,*} = A^*$.

1. By Theorem 5.1 the state space of the realization (A, B, C, D) is $\overline{\text{range}}H_{\tilde{G}_c}$. Thus the dual system $(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D})$ has the same state space. That is,

$$X_* = \overline{\text{range}}H_{\tilde{G}_c}.$$

2. The semigroup generated by A is defined as

$$e^{tA}f = P_+ e^{ts} f \quad (f \in X_*).$$

It is easy to verify

$$e^{tA^*}f = (e^{tA})^* f = P_{X_*} e^{-ts} f \quad (f \in X_*).$$

That is,

$$e^{tA_{c,*}} f = P_{X_*} e^{-ts} f \quad (f \in X_*).$$

By Theorem 5.1,

$$D(A_{c,*}) = D(A^*) = \left\{ P_{X_*} \frac{1}{1+s} h(s) \mid h \in X_* \right\},$$

$$A_{c,*} f = f - h \text{ for } f(s) = P_{X_*} \frac{1}{1+s} h(s) \in D(A_{c,*}),$$

and $A_{c,*}$ is well defined.

3. By the definition of the dual system (Definition 2.2), we have

$$\tilde{B} : U \to D(A)^{(\prime)}; \qquad u \longmapsto \tilde{B}(u)[\cdot] := \langle u,\ C(\cdot)\rangle.$$

For $x(s) = \frac{1}{1-s}[h(s) - h(1)] \in D(A)$ $(h \in X_*)$, we have

$$\tilde{B}(u)[x] = \langle u,\ Cx\rangle = \left\langle u, \sqrt{2\pi} \lim_{\substack{r\in\mathbb{R}\\ r\to\infty}} rx(r) \right\rangle = \sqrt{2\pi}\langle u, h(1)\rangle.$$

By Lemma 5.6, $\sqrt{2\pi}\langle u, h(1)\rangle_U = \frac{1}{\sqrt{2\pi}}\langle \frac{1}{1+s} u,\ h\rangle_{H_U^2(RHP)}$.

4. Now we compute $C_{c,*} = \tilde{C}$. Again use Definition 2.2:

$$D(\tilde{C}) = D(\tilde{A}) + (I - \tilde{A})^{-1}\tilde{B}U = D(A_{c,*}) + (I - A_{c,*})^{-1} B_{c,*} U,$$

and $\tilde{C}x_0$ is defined by

$$\begin{cases} \langle y, \tilde{C}x_0\rangle = B(y)[x_0], & x_0 \in D(A_{c,*}) \\ \langle \tilde{C}x_0, y\rangle = \langle u_0, C(I - A)^{-1} By\rangle, & x_0 = (I - A_{c,*})^{-1} B_{c,*} u_0,\ u_0 \in U,\ y \in Y. \end{cases}$$

Since by Theorem 5.7

$$B(y)[x] = \sqrt{2\pi}\langle y,\ (H_{G_c} h)(1)\rangle_Y \quad \left(x = P_X \frac{h(s)}{1+s} \in D(A_{c,*}) \right),$$

we have

$$\tilde{C}x = \sqrt{2\pi}(H_{G_c} h)(1) \text{ for } x = P_X \frac{h(s)}{1+s} \in D(A_{c,*}).$$

From Lemma 5.5 it follows that $\tilde{C}$ is well defined for $x \in D(A_{c,*})$.

Note that $C(I - A)^{-1}By = [\tilde{G}_c(1) - \tilde{G}_c(+\infty)]y$. Thus

$$\tilde{C}x_0 = [G_c(1) - G_c(+\infty)]u_0 \text{ for } x_0 = (I - A_{c,*})^{-1} B_{c,*} u_0.$$

Now we show that $(I - A_{c,*})^{-1}B_{c,*}u_0 = \frac{1}{\sqrt{2\pi}}P_{X_*}\frac{u_0}{1+s}$. Let $x \in D(A_{c,*}^*)$. Since by Theorem 5.7 $(I - A_{c,*}^*)^{-1}x = \frac{x-x(1)}{1-s}$, we have

$$\begin{aligned}
&\langle (I - A_{c,*})^{-1}B_{c,*}u_0,\ x\rangle = [(I - A_{c,*})^{-1}B_{c,*}u_0](x)\\
&= [B_{c,*}u_0]((I - A_{c,*}^*)^{-1}x)\\
&= [B_{c,*}u_0]\left(\frac{x - x(1)}{1-s}\right)\\
&= \frac{1}{\sqrt{2\pi}}\left\langle \frac{u_0}{1+s},\ x\right\rangle = \frac{1}{\sqrt{2\pi}}\left\langle P_{X_*}\frac{u_0}{1+s},\ x\right\rangle.
\end{aligned}$$

This shows that $(I - A_{c,*})^{-1}B_{c,*}u_0 = \frac{1}{\sqrt{2\pi}}P_{X_*}\frac{u_0}{1+s}$. Hence, to sum up, the operator $C_{c,*} = \tilde{C}$ is defined in the following way:

$$D(C_{c,*}) = P_{X_*}\left\{\frac{h(s)}{1+s} \mid h \in X_*\right\} + P_{X_*}\left\{\frac{u}{1+s} \mid u \in U\right\}.$$

If $x = P_{X_*}\frac{h(s)}{1+s}$, then

$$C_{c,*}x = \sqrt{2\pi}(H_{G_c}h)(1),$$

and if $x = P_{X_*}\frac{u}{1+s}$, then

$$C_{c,*}x = \sqrt{2\pi}[G_c(1) - G_c(+\infty)]u.$$

Note that by Lemma 5.5 $C_{c,*}x$ is also well defined for $x \in P_{X_*}\{\frac{u}{1+s} \mid u \in U\}$.

4. It is straightforward to get

$$D_{c,*} = \tilde{D}^* = ((G_c(+\infty))^*)^* = G_c(+\infty). \qquad \square$$

Note that the restricted and *-restricted shift realizations of admissible transfer functions in H^∞ are well posed in the sense of Curtain and Weiss [5] and Salamon [27]. Indeed we have the following corollary concerning the reachability and observability of the restricted and *-restricted shift realizations.

COROLLARY 5.10. 1. *The reachability operator of the restricted shift realization is given by*

$$\mathcal{R}_c : L_U^2[0, +\infty) \to X,\quad f \mapsto H_{G_c,RHP}\mathcal{L}f.$$

The observability operator of the restricted shift realization is given by

$$\mathcal{O}_c|_X : X \to L_Y^2[0, +\infty),\quad x \mapsto \mathcal{L}^{-1}x.$$

2. *The reachability operator of the *-restricted shift realization is given by*

$$\mathcal{R}_{c,*} : L_U^2[0, +\infty) \to X_*,\quad f \mapsto P_{X_*}\mathcal{L}f.$$

*The observability operator of the *-restricted shift realization is given by*

$$\mathcal{O}_{c,*} : X_* \to L_Y^2[0, +\infty),\quad x \mapsto \mathcal{L}^{-1}H_{G_c,RHP}x.$$

Here $\mathcal{L}$ denotes the Laplace transform.

Proof. This follows from Theorem 3.4 and Theorem 5.7 □

We categorize the state spaces of the restricted and *-restricted shift realizations here for later use.

PROPOSITION 5.11. *Let X and X_* be, respectively, the state spaces of restricted and *-restricted shift realizations of $G_c \in TLC^{U,Y}$. Then*

1. *if G_c is cyclic, then $X = H^2_Y(RHP)$ and $X_* = H^2_U(RHP)$;*
2. *if G_c is noncyclic, then $X = H^2_Y(RHP) \ominus Q_1 H^2_Y(RHP)$ and $X_* = H^2_U(RHP) \ominus Q_2 H^2_U(RHP)$, where $Q_1 \in H^\infty_{L(Y)}(RHP)$ and $Q_2 \in H^\infty_{L(U)}(RHP)$ are rigid functions;*
3. *if G_c is in $H^\infty_{L(U,Y)}(RHP)$, is strictly noncyclic, and has factorization $G_c = Q_1 F_1^* = \tilde{F}_2^* \tilde{Q}_2$, where $Q_1 \in H^\infty_{L(Y)}(RHP)$ and $Q_2 \in H^\infty_{L(U)}(RHP)$ are inner, Q_1 and F_1 are left coprime, and Q_2 and F_2 are also left coprime, then $X = H^2_Y(RHP) \ominus Q_1 H^2_Y(RHP)$ and $X_* = H^2_U(RHP) \ominus Q_2 H^2_U(RHP)$.*

Proof. This follows from Definition 4.5 and Theorems 4.8, 5.7, and 5.9.

6. Continuous-time input-normal, output-normal, parbalanced realizations and their asymptotic stability. Recall that a reachable and observable admissible system (A_c, B_c, C_c, D_c) is said to be input-normal if $\mathcal{W}_c = I$. It is output-normal if $\mathcal{M}_c = I$. The reachable and observable admissible systems are said to be parbalanced if

$$\mathcal{W}_c = \mathcal{M}_c.$$

Here $\mathcal{W}_c$ and $\mathcal{M}_c$ are, respectively, the reachability and observability Gramians of the system. Given a transfer function $G_c \in TLC^{U,Y}$, by Corollary 5.10 the restricted and *-restricted shift realizations are examples of, respectively, output-normal and input-normal realizations of G_c. Proposition 6.2 shows that up to unitary equivalence all observable input-normal and reachable output-normal realizations of an admissible transfer function G are up to unitary equivalence *-restricted and restricted shift realizations, respectively.

In this section we establish the existence of a parbalanced realization for any $G_c \in TLC^{U,Y}$ and study the stability properties of input-normal, output-normal, and parbalanced realizations.

A parbalanced realization of a continuous-time transfer function $G_c \in TLC^{U,Y}$ can be obtained from the map T in Theorem 3.1 applied to a discrete-time parbalanced realization of the corresponding discrete-time transfer function G_d. The existence of parbalanced realizations was shown by Young [30]. In [23] Young's results are cast into the continuous-time situation and the following theorem is proven.

THEOREM 6.1. 1. *For $G_c \in TLC^{U,Y}$, there exists a parbalanced realization $(A_c, B_c, C_c, D_c) \in C_X^{U,Y}$ of G_c. The state space of this realization is given by the closure of the range of the Hankel operator with symbol G_c, i.e., $X = \overline{\text{range}} H_{G_c}$. If $(\bar{A}_c, \bar{B}_c, \bar{C}_c, \bar{D}_c)$ is another parbalanced realization of G_c with state space $\bar{X}$, then (A_c, B_c, C_c, D_c) and $(\bar{A}_c, \bar{B}_c, \bar{C}_c, \bar{D}_c)$ are unitarily equivalent.*

2. *If in addition $G_c(s)$ is continuous on the extended $i\mathbb{R}$ (i.e. on $i\mathbb{R} \cup \{i\infty\}$) and is a compact operator for each $s \in i\mathbb{R}$, then there is a basis of $X = \overline{\text{range}} H_{G_c}$ on which the Gramians of the above realization have a diagonal matrix representation with its diagonal consisting of the Hankel singular values of G_c. We will call this realization a balanced realization of G_c.* □

6.1. Characterization of the realizations. Concerning the equivalence of different realizations, we have the following proposition.

PROPOSITION 6.2. 1. *Any two input-normal (output-normal) realizations of $G_c \in TLC^{U,Y}$ are unitarily equivalent. Hence every input-normal (output-normal) realization of G_c is unitarily equivalent to the *-restricted (restricted) shift realization of G_c.*

2. *An input-normal realization and an output-normal realization of* $G_c \in TLC^{U,Y}$ *are equivalent if and only if the Hankel operator* H_{G_c} *has closed range.*

3. *All reachable and observable admissible realizations of* G_c *are equivalent if and only if the Hankel operator* H_{G_c} *has closed range.*

Proof. Analogous results in the discrete-time case are shown in [24] (see Theorem 3.1, Corollary 3.1, and Proposition 4.1 therein). Applying Theorem 3.1, Theorem 3.4, and Proposition 4.3 to these results we have the proposition. □

A consequence of the proposition is that the study of input-normal (output-normal) realizations reduces to the study of the *-restricted (restricted) shift realizations. This point will be used repeatedly.

Part 2 of the proposition shows when the state-space isomorphism theorem holds. Note that the Hankel operator H_{G_c} to have closed range is a very strong condition. This condition can be stated in terms of the Douglas–Shapiro–Shields factorization of the transfer function G_c (see Theorem 4.10 and [11]).

6.2. Asymptotic stability. Now we turn to the study of stability properties of continuous-time systems and use the classes $C_{i,j}$ to describe different asymptotic stability properties of systems [28].

DEFINITION 6.3. *Let* $(e^{tA_c})_{t\geq 0}$ *be a semigroup of contractions on the Hilbert space* H. *Then*

1. $(e^{tA_c})_{t\geq 0} \in C_{0\cdot}$ *if* $\lim_{t\to\infty} e^{tA_c}h = 0$ *for all* $h \in H$,
2. $(e^{tA_c})_{t\geq 0} \in C_{\cdot 0}$ *if* $\lim_{t\to\infty} e^{tA_c^*}h = 0$ *for all* $h \in H$,
3. $(e^{tA_c})_{t\geq 0} \in C_{1\cdot}$ *if* $\lim_{t\to\infty} e^{tA_c}h \neq 0$ *for all* $h \in H$,
4. $(e^{tA_c})_{t\geq 0} \in C_{\cdot 1}$ *if* $\lim_{t\to\infty} e^{tA_c^*}h \neq 0$ *for all* $h \in H$.

We further set

$$C_{ij} = C_{i\cdot} \cap C_{\cdot j}, \qquad i, j = 0, 1. \qquad \square$$

The notions of stability that we consider are the following.

DEFINITION 6.4. *A continuous-time system* $(A_c, B_c, C_c, D_c) \in C_X^{U,Y}$ *is*

1. asymptotically stable *if for all* $x \in X$,

$$e^{tA_c}x \to 0$$

as $t \to \infty$, *i.e.,* $(e^{tA_c})_{t\geq 0} \in C_0$;

2. exponentially stable *if*

$$\omega := \inf\{\alpha \in \mathbb{R} \mid \text{there exists } M_\alpha \geq 0 \text{ such that } \|e^{tA_c}\| \leq M_\alpha e^{\alpha t} \ (t \geq 0)\} < 0.$$

The number ω *is called the* growth bound *of the semigroup.* □

We comment that the asymptotic and exponential stability of a system is preserved by system equivalence. Moreover, if two systems are unitarily equivalent, they will have the same growth bound.

An important result in [28, Prop. 9.1, p. 148] implies that a continuous-time system is asymptotically stable if and only if the corresponding discrete-time system is asymptotically stable.

PROPOSITION 6.5. *Let* $(A_d, B_d, C_d, D_d) \in D_X^{U,Y}$ *and* $(A_c, B_c, C_c, D_c) \in C_X^{U,Y}$ *such that*

$$(A_c, B_c, C_c, D_c) = T((A_d, B_d, C_d, D_d)).$$

Then for all $x \in X$,

$$\lim_{n\to\infty} \|A_d^n x\| = \lim_{t\to\infty} \|e^{tA_c}x\|$$

and

$$\lim_{n\to\infty} \|(A_d^*)^n x\| = \lim_{t\to\infty} \|e^{tA_c^*} x\|. \qquad \square$$

Therefore, the study of asymptotic stability of a continuous-time system reduces to the study of the asymptotic stability of the corresponding discrete-time system.

Now we state the main result of this section, which asserts that any admissible parbalanced realization of an admissible continuous-time transfer function is asymptotically stable.

THEOREM 6.6. *Let* $G_c \in TC^{U,Y}$. *Let* (A_b, B_b, C_b, D_b), (A_i, B_i, C_i, D_i), *and* (A_o, B_o, C_o, D_o) *be, respectively, a parbalanced, an input-normal, and an output-normal observable and reachable realization of* G_c. *Then*

1. (a) $(e^{tA_i})_{t\geq 0} \in C_{\cdot 0}$,
   (b) $(e^{tA_i})_{t\geq 0} \in C_{00}$ *if* $G_c^{\perp}$ *is strictly noncyclic,*
   (c) $(e^{tA_i})_{t\geq 0} \in C_{10}$ *if* $G_c^{\perp}$ *is cyclic,*
2. (a) $(e^{tA_o})_{t\geq 0} \in C_{0\cdot}$, *i.e., asymptotically stable,*
   (b) $(e^{tA_o})_{t\geq 0} \in C_{00}$ *if* G_c *is strictly noncyclic,*
   (c) $(e^{tA_o})_{t\geq 0} \in C_{01}$ *if* G_c *is cyclic,*
3. $(e^{tA_b})_{t\geq 0} \in C_{00}$.

Proof. The corresponding asymptotic stability results for discrete-time systems were obtained in Theorem 3.2 and Theorem 4.2 of [24]. Hence, combining those theorems with Proposition 6.5 and part 1 of Proposition 4.7, we have the theorem. $\square$

Since by Proposition 6.2 all reachable and observable realizations of G_c are equivalent when the Hankel operator H_{G_c} has closed range, and equivalent realizations have the same asymptotic stability properties, the theorem has the following corollary.

COROLLARY 6.7. *If the Hankel operator* H_{G_c} *has closed range, then all reachable, observable, and admissible realizations of* G_c *are asymptotically stable.* $\square$

7. Spectral minimality and exponential stability of input-normal, output-normal, and parbalanced realizations. This section aims to examine the exponential stability of continuous-time input-normal, output-normal, and parbalanced realizations of certain classes of transfer functions. The results are mainly based upon a detailed spectral analysis of input-normal and output-normal realizations. While the asymptotic stability properties of continuous-time systems can be obtained directly from the discrete-time case as we did in the previous section, exponential stability properties of continuous-time systems do not follow in the same way. However, we can relate the spectrum of the discrete-time system to that of the continuous-time system and thus establish the exponential stability results.

Recall that a continuous-time system (A_c, B_c, C_c, D_c) is exponentially stable if

$$\inf\{\alpha \in \mathbb{R} | \text{ there exists } M_\alpha \geq 0 \text{ such that } \|e^{tA_c}\| \leq M_\alpha e^{\alpha t} \text{ for } t \geq 0\} < 0.$$

The following proposition gives an interpretation of the growth bound of a semigroup in terms of the spectral radius of the semigroup (see, e.g., [21, p. 60]).

PROPOSITION 7.1. *Let* ω *be the growth bound of the semigroup* $(e^{tA_c})_{t\geq 0}$ *and* $r(e^{tA_c})$ *the spectral radius of* e^{tA_c}; *then*

$$r(e^{tA_c}) = e^{\omega t}$$

for $t \geq 0$. $\square$

Note that it follows from this proposition that equivalent systems have the same growth bound.

7.1. Spectral analysis. Thus we have to investigate the spectral properties of a continuous-time linear system (A_c, B_c, C_c, D_c) in order to study its exponential stability.

The way we do this is to relate the spectral properties of (A_c, B_c, C_c, D_c) to those of the corresponding discrete-time system (A_d, B_d, C_d, D_d). First we have the following relation between $\sigma(A_d)$ and $\sigma(A_c)$.

PROPOSITION 7.2. *Let A_c be the infinitesimal generator of a semigroup of contractions and A_d the co-generator such that $A_c = (A_d - I)(A_d + I)^{-1}$. Then*

$$\sigma_p(A_c) = \left\{ \frac{z-1}{z+1} : \ z \in \sigma_p(A_d) \right\} \text{ and } \sigma_p(A_d) = \left\{ \frac{1+s}{1-s} : \ s \in \sigma_p(A_c) \right\},$$

$$\sigma(A_c) = \left\{ \frac{z-1}{z+1} : \ z \in \sigma(A_d),\ z \neq -1 \right\} \text{ and } \sigma(A_d) \setminus \{-1\} = \left\{ \frac{1+s}{1-s} : \ s \in \sigma(A_c) \right\}.$$

Proof. First note that $1 \notin \sigma(A_c)$ since e^{tA_c} is a semigroup of contractions and that by Theorem 3.1,

$$A_c x = (A_d - I)(A_d + I)^{-1}x = (A_d + I)^{-1}(A_d - I)x \text{ for } x \in D(A_c),$$

where $D(A_c) = \text{range}(A_d + I)$. Hence the following relations hold:

$$\begin{aligned} (7.1) \quad (sI - A_c)(A_d + I)x &= [sI - (A_d - I)(A_d + I)^{-1}](A_d + I)x \\ &= [s(A_d + I) - (A_d - I)]x \\ &= (1-s)\left(\frac{1+s}{1-s}I - A_d\right)x, \qquad x \in X_d,\ s \neq 1; \end{aligned}$$

$$\begin{aligned} (7.2) \quad (A_d + I)(sI - A_c)x &= (A_d + I)[sI - (A_d - I)(A_d + I)^{-1}]x \\ &= (1-s)\left(\frac{1+s}{1-s}I - A_d\right)x, \qquad x \in D(A_c),\ s \neq 1. \end{aligned}$$

The equations (7.1) and (7.2) show that

$$\sigma_p(A_d) = \left\{ \frac{1+s}{1-s} : \ s \in \sigma_p(A_c) \right\}.$$

Now if $\frac{1+s}{1-s} \notin \sigma(A_d)$, i.e., if $(\frac{1+s}{1-s}I - A_d)^{-1}$ exists and is bounded, then

$$(A_d + I)\left(\frac{1+s}{1-s}I - A_d\right)^{-1} = \left(\frac{1+s}{1-s}I - A_d\right)^{-1}(A_d + I).$$

Thus by (7.1) and (7.2)

$$\begin{aligned} (7.3) \quad (sI - A_c)^{-1}x &= (1-s)^{-1}(A_d + I)\left(\frac{1+s}{1-s}I - A_d\right)^{-1}x \\ &= (1-s)^{-1}\left(\frac{1+s}{1-s}I - A_d\right)^{-1}(A_d + I)x, \ x \in D(A_c). \end{aligned}$$

So $(sI - A_c)^{-1}$ is bounded and densely defined, i.e., $s \notin \sigma(A_c)$. Hence

$$(7.4) \qquad \left\{ \frac{1+s}{1-s} : \ s \in \sigma(A_c) \right\} \subseteq \sigma(A_d).$$

On the other hand, if $s \neq 1$ and $s \notin \sigma(A_c)$, then $(sI - A_c)^{-1}$ is a bounded operator. It is easy to verify in this case that

$$\left(\frac{1+s}{1-s}I - A_d\right)^{-1} x = \frac{(1-s)^2}{2}(sI - A_c)^{-1} + \frac{1-s}{2}x, \qquad x \in D(A_c).$$

In fact from (7.3) we have

$$\left(\frac{1+s}{1-s}I - A_d\right)\left[\frac{(1-s)^2}{2}(sI - A_c)^{-1} + \frac{1-s}{2}I\right]x$$

$$= \frac{(1-s)^2}{2}\left(\frac{1+s}{1-s}I - A_d\right)(sI - A_c)^{-1}x + \frac{1-s}{2}\left(\frac{1+s}{1-s}I - A_d\right)x$$

$$= \frac{(1-s)^2}{2}(1-s)^{-1}(A_d + I)x + \frac{1-s}{2}\left(\frac{1+s}{1-s}I - A_d\right)x$$

$$= x, \quad x \in D(A_c).$$

Similarly,

$$\left[\frac{(1-s)^2}{2}(sI - A_c)^{-1} + \frac{1-s}{2}x\right]\left(\frac{1+s}{1-s}I - A_d\right)x = x, \qquad x \in D(A_c).$$

Thus $\frac{1+s}{1-s} \notin \sigma(A_d)$. So we have

$$\left\{s : \frac{1+s}{1-s} \in \sigma(A_d)\right\} \subseteq \sigma(A_c). \tag{7.5}$$

Combining (7.4) and (7.5) we have that

$$\sigma(A_c) = \left\{s : \frac{1+s}{1-s} \in \sigma(A_d)\right\} = \left\{\frac{z-1}{z+1} : z \in \sigma(A_d), z \neq -1\right\},$$

which implies

$$\sigma(A_d) \setminus \{-1\} = \left\{\frac{1+s}{1-s} : s \in \sigma(A_c)\right\}. \qquad \square$$

In our application of the proposition, A_c is the state propagation operator of a continuous-time system $(A_c, B_c, C_c, D_c) \in C_X^{U,Y}$ and A_d is the state propagation operator of the corresponding discrete-time system $(A_d, B_d, C_d, D_d) \in D_X^{U,Y}$, which is related to (A_c, B_c, C_c, D_c) by

$$(A_c, B_c, C_c, D_c) = T((A_d, B_d, C_d, D_d)),$$

where T is the bilinear mapping in Theorem 3.1.

A powerful tool in spectral analysis is the spectral mapping theorem for C_0 operators (see, e.g., [22, p. 74]). A contraction $W \in L(M)$, where M is a separable Hilbert space, is called a C_0 operator, denoted $W \in C_0$, if there exists no subspace $V \in M$ such that $W|_V : V \to V$ is unitary and if there exists an inner function $m \in H^\infty(\mathbb{D})$ such that $m(W) = 0$. The least common divisor of all such inner functions is called the minimal function of W, denoted

m_W, which is still an inner function such that $m_W(W) = 0$. Note that if W is a C_0 operator, W is unitarily equivalent to a left shift S^* restricted to a left invariant space of the form $H_Y^2(\mathbb{D}) \ominus QH_Y^2(\mathbb{D})$, where Q is inner (see, [22, p. 72]). It can be seen that minimal functions are the generalizations of minimal polynomials of matrices. As in the matrix case, the spectrum of a C_0 operator is given by the "zeros" of its minimal function in the following sense (see [22, p. 72]).

LEMMA 7.3. *If $W \in C_0$, then $\sigma(W) = \sigma(m_W)$ and $\sigma_p(W) = \sigma(m_W) \cap \mathbb{D}$, where for an inner function $Q \in H^\infty_{L(Y)}(\mathbb{D})$, Y is a Hilbert space, and the spectrum of Q is defined as*

$$\sigma(Q) = \left\{ \lambda \in \overline{\mathbb{D}} \mid \lim_{\delta \to 0} \inf_{\substack{|\xi - \lambda| < \delta \\ \xi \in \mathbb{D}}} \inf_{\substack{\|y\| = 1 \\ y \in Y}} \|Q(\xi) y\| = 0 \right\}. \qquad \square$$

Given a C_0 operator W and a function $\phi \in H^\infty(\mathbb{D})$, the operator

$$\phi(W) := \lim_{r<1,\ r \to 1} \phi(rW)$$

is well-defined. The following theorem relates the spectra of these two operators (see [22, p. 74]).

THEOREM 7.4 (the spectral mapping theorem). *Let $\phi \in H^\infty(\mathbb{D})$ and $W \in C_0$. Then*

$$\sigma(\phi(W)) \subseteq \left\{ \xi \in \mathbb{C} \mid \inf_{z \in \mathbb{D}} (|\phi(z) - \xi| + |m_W(z)|) = 0 \right\},$$

where m_W is the minimal function of W. $\square$

7.2. Spectral minimality. We are going to use these results to transpose the spectral properties of the discrete-time input- and output-normal realizations to those of the continuous-time case. First we recall the discrete-time results. Assume that the input and output spaces are of finite dimension. If the transfer function G_d is such that $G_d^\perp$ is strictly noncyclic, then G_d has a pseudomorphic continuation of bounded type to the unit disk $\mathbb{D}$ (see [11]). Take this continuation as the definition of G_d on $\mathbb{D}$, wherever defined. Consider the analytic continuation of the extended G_d. Let $\sigma_s(G_d)$ be the set of points at which G_d has no analytic continuation. We are interested in the relationship between $\sigma_s(G_d)$ and $\sigma(A_d)$. The following theorem shows $\sigma_s(G_d) = \sigma(A_d)$ for input-normal or output-normal realizations. If G_d is not strictly noncyclic, the spectrum of A_d can also be characterized (see [24] and [11]).

THEOREM 7.5. *Let $G_d \in TLD^{U,Y}$ with U and Y finite dimensional and let $(A_{d,o}, B_{d,o}, C_{d,o}, D_{d,o})$, $(A_{d,i}, B_{d,i}, C_{d,i}, D_{d,i})$, and $(A_{d,b}, B_{d,b}, C_{d,b}, D_{d,b})$ be, respectively, an output-normal, an input-normal, and a parbalanced realization of G_d.*

1. *If $G_d^\perp$ is in $H^\infty_{L(Y)}(\mathbb{D})$ and strictly noncyclic, then $(A_{d,o}, B_{d,o}, C_{d,o}, D_{d,o})$, $(A_{d,i}, B_{d,i}, C_{d,i}, D_{d,i})$, and $(A_{d,b}, B_{d,b}, C_{d,b}, D_{d,b})$ are* spectrally minimal, *i.e.,*

$$\sigma(A_{d,o}) = \sigma(A_{d,i}) = \sigma(A_{d,b}) = \sigma_s(G_d).$$

In this case $A_{d,o}$, $A_{d,i}$, and $A_{d,b}$ are all C_0 operators and have the same minimal function—say, m. Moreover, if $G_c(e^{it}) = Q_1(e^{it})(e^{it}F_1(e^{it}))^*$ is the Douglas–Shapiro–Shields factorization of G_d (see Theorem 4.8) and $\tilde{G}_d(e^{it}) = Q_2(e^{it})(e^{it}F_2(e^{it}))^*$ is the factorization of $\tilde{G}_d$, then the following equalities hold:

$$\sigma(m) = \sigma_s(G_d) = (\sigma(Q_1))^* = \sigma(Q_2),$$

$$\sigma_p(A_{d,o}) = \{\overline{\lambda} \in \mathbb{D} \mid \operatorname{Ker} Q_1(\lambda)^* \neq \{0\}\},$$

and

$$\sigma_p(A_{d,i}) = \{\lambda \in \mathbb{D} | \operatorname{Ker} Q_2(\lambda) \neq \{0\}\},$$

where $(\sigma(Q_1))^* = \{\bar{\lambda} | \lambda \in \sigma(Q_1)\}$ *and*

$$\sigma(Q_i) = \{\lambda \in \overline{\mathbb{D}} \mid \liminf_{\substack{\xi \to \lambda \\ \xi \in \mathbb{D}}} \inf_{\substack{\|y\|=1 \\ y \in Y}} \|Q_i(\xi) y\| = 0\} \quad (i = 1, 2).$$

2. *If* $G_d^{\perp}$ *is noncyclic but not strictly noncyclic, then*

$$\sigma(A_o) = \sigma(A_i) = \overline{\mathbb{D}}.$$

3. *If* $G_d^{\perp}$ *is cyclic, then*

$$\sigma_p(A_o) = \mathbb{D}, \quad \sigma_p(A_i) = \emptyset, \quad \sigma(A_o) = \sigma(A_i) = \overline{\mathbb{D}} \ . \qquad \square$$

Corresponding to this theorem we have the following continuous-time analogue. For a strictly noncyclic continuous-time transfer function G_c, we define $\sigma_s(G_c)$ similarly as in the discrete-time situation. Specifically, G_c has a pseudomorphic continuation of bounded type to LHP (see Theorem 4.8), which is taken to be the definition of G_c on LHP. We consider the analytic continuation of the redefined G_c and denote by $\sigma_s(G_c)$ the set of points in the complex plane at which G_c has no analytic continuation.

We note that results in part 1 of the following theorem can be found in the thesis by Gearheart [12] and a paper by Moeller [19].

THEOREM 7.6. *Let* $G_c \in TLC^{U,Y}$ *and let* $(A_{c,o}, B_{c,o}, C_{c,o}, D_{c,o}) \in C_X^{U,Y}$ *be an output-normal realization with* U *and* Y *finite dimensional. Then*

1. *if* G_c *is in* $H^{\infty}_{L(U,Y)}(RHP)$ *and is strictly noncyclic with factorization* $G_c = Q_1 F_1^*$, *where* $Q_1 \in H^{\infty}_{L(Y)}(RHP)$ *is inner and* Q_1 *and* $F_1 \in H^{\infty}_{L(Y,U)}(RHP)$ *are weakly coprime, then* $\lambda \notin \sigma(e^{A_{c,o}})$, $|\lambda| < 1$, *if and only if for*

$$w_n = -\log \bar{\lambda} + 2\pi n i, \qquad n \in \mathbb{Z},$$

$Q_1(w_n)$ *is invertible for all* $n \in \mathbb{Z}$ *and*

$$\sup_{-\infty < n < \infty} \|Q_1(w_n)^{-1}\| < \infty.$$

For $|\lambda| = 1$, $\lambda \notin \sigma(e^{A_{c,o}})$ *if and only if there exists a* $\delta > 0$ *and* $M > 0$ *such that* $Q_1(w_n)^{-1}$ *exists for all* $n \in \mathbb{Z}$ *and* $Q_1(s)^{-1}$ *is bounded by* M *in the* δ *neighborhood of each point* w_n.

For the point spectrum, we have

$$\sigma_p(e^{A_{c,o}}) \setminus \{0\} = \{e^{-\bar{s}} : s \in RHP \text{ and } \operatorname{Ker} Q_1(s)^* \neq \{0\}\}.$$

2. *under the same assumptions on* G_c *as in* 1., *we have*

$$\sigma(A_{c,o}) = \{-\bar{s} : s \in \sigma(Q_1)\} = \sigma_s(G_c)$$
$$\sigma_p(A_{c,o}) = \{-\bar{s} : s \in RHP \text{ and } \operatorname{Ker} Q_1(s)^* \neq \{0\}\}.$$

3. *if* G_c *is noncyclic but not strictly noncyclic, then*

$$\sigma(A_{c,o}) = \text{the closed left half plane.}$$

4. *if G_c is cyclic, then*

$$\sigma(e^{A_{c,o}}) = \bar{\mathbb{D}}, \qquad \sigma_p(e^{A_{c,o}}) \setminus \{0\} = \mathbb{D} \setminus \{0\},$$
$$\sigma(A_{c,o}) = \textit{the closed left half plane}, \quad \sigma_p(A_{c,o}) = LHP.$$

Proof. Without loss of generality we may assume that $(A_{c,o}, B_{c,o}, C_{c,o}, D_{c,o})$ is the restricted shift realization. We write (A_c, B_c, C_c, D_c) for $(A_{c,o}, B_{c,o}, C_{c,o}, D_{c,o})$. Let $G_d(z) = G_c(\frac{z-1}{z+1})$ for $z \in \mathbb{D}_e$ and let

$$G_d^{\perp}(z) = z^{-1}[G_d(z^{-1}) - G_d(\infty)] = z^{-1}\left[G_c\left(\frac{1-z}{1+z}\right) - G_c(1)\right], \quad z \in \mathbb{D}.$$

Suppose (A_d, B_d, C_d, D_d) is the restricted shift realization of the discrete-time transfer function G_d. We use the mapping T defined in Theorem 3.1.

1. The formula for $\sigma(e^{A_c})$ can be found in [19] in the case $0 < |\lambda| < 1$. If $|\lambda| = 1$ or $\lambda = 0$, see [12].

For the formula of $\sigma_p(e^{A_c})$ see the proof of 2. below.

2. Note that by Proposition 4.7 $G_d^{\perp}$ is also strictly noncyclic and has a factorization $G_d = Q_{d,1}F_{d,1}^*$, where $Q_{d,1}(z) = Q_1(\frac{1-z}{1+z})$ and $F_{d,1}(z) = F_1(\frac{1-z}{1+z})$. The spectra of $Q_{d,1}$ and Q_1 are related as

$$\sigma(Q_{d,1}) = \left\{\frac{1-s}{1+s} \mid s \in \sigma(Q_1)\right\},$$

and the sets $\sigma_s(G_d)$ and $\sigma_s(G_c)$ are related as

$$\sigma_s(G_c) = \left\{s : \frac{1+s}{1-s} \in \sigma_s(G_d)\right\}.$$

Then the equalities about $\sigma(A_c)$ and $\sigma_s(G_c)$ follow from Proposition 7.2 and Theorem 7.5. Similarly the expression for $\sigma_p(A_c)$ also follows from Proposition 7.2 and Theorem 7.5.

The point spectrum $\sigma_p(e^{A_c})$ can be obtained by the general formula (see [26, Thm. 2.4, p. 46])

$$\sigma_p(e^{tA_c}) \setminus \{0\} = e^{\sigma_p(tA_c)}.$$

3. This also follows from Proposition 7.2 and Theorem 7.5.

4. We offer a direct proof here, although the result again follows from Proposition 7.2 and Theorem 7.5.

If G_c is cyclic, then the state space is $X_c = H_Y^2(RHP)$. It is easy to see that for any $\mu \in LHP, t \geq 0$, and $y \in Y$ we have $\frac{y}{s-\mu} \in X_c = H_Y^2(RHP)$ and

$$\frac{e^{ts} - e^{t\mu}}{s-\mu} y \in H_Y^2(LHP) = (H_Y^2(RHP))^{\perp},$$

where the orthogonal complement is taken in $L_Y^2(i\mathbb{R})$. Therefore,

$$e^{tA_c}\frac{1}{s-\mu}y = P_+\frac{e^{ts}}{s-\mu}y = P_+\left[\frac{e^{t\mu}}{s-\mu}y + \frac{e^{ts}-e^{t\mu}}{s-\mu}y\right] = \frac{e^{t\mu}}{s-\mu}y.$$

Hence $e^{t\mu} \in \sigma_p(e^{tA_c})$. This shows that $\sigma_p(e^{tA_c}) \setminus \{0\} = \mathbb{D} \setminus \{0\}$ and hence $\sigma(e^{tA_c}) = \bar{\mathbb{D}}$.

Also for any $\mu \in LHP$ and $y \in Y$ we have $h = \frac{1-\mu}{s-\mu} y \in H_Y^2(RHP)$ and

$$\frac{y}{s-\mu} = \frac{h(s)-h(1)}{1-s}.$$

Hence $\frac{y}{s-\mu} \in D(A_c)$. Using the definition of A_c we have

$$A_c \frac{y}{s-\mu} = \frac{sy}{s-\mu} - \lim_{\substack{r \in \mathbb{R} \\ r \to \infty}} \frac{ry}{r-\mu} = \mu \frac{y}{s-\mu}.$$

Therefore $\mu \in \sigma_p(A_c)$. This shows that $\sigma_p(A_c) = LHP$ and hence $\sigma(A_c) = \overline{LHP}$. □

For input-normal realizations we have results analogous to the results above. The proof is similar to the proof of the previous results.

THEOREM 7.7. *Let $G_c \in TLC^{U,Y}$ and let $(A_{c,i}, B_{c,i}, C_{c,i}, D_{c,i}) \in C_X^{U,Y}$ be an observable input-normal realization with U and Y finite dimensional. Then*

1. *if G_c is in $H^\infty_{L(U,Y)}(RHP)$ and is strictly noncyclic with $\tilde{G}_c = Q_2 F_2^*$, where $Q_2 \in H^\infty_{L(U)}(RHP)$ is inner and Q_2 and $F_2 \in H^\infty_{L(U,Y)}(RHP)$ are weakly coprime, then $\lambda \notin \sigma(e^{A_{c,i}})$, $|\lambda| < 1$, if and only if for*

$$w_n = -\log \lambda + 2\pi n i, \qquad n \in \mathbb{Z},$$

$Q_2(w_n)$ is invertible for all $n \in \mathbb{Z}$ and

$$\sup_{-\infty < n < \infty} \|Q_2(w_n)^{-1}\| < \infty.$$

For $|\lambda| = 1$, $\lambda \notin \sigma(e^{A_{c,i}})$ if and only if there exists a $\delta > 0$ and $M > 0$ such that $Q_2(w_n)^{-1}$ exists for all $n \in \mathbb{Z}$ and $Q_2(s)^{-1}$ is bounded by M in a δ neighborhood of each point w_n. As to the point spectrum, we have

$$\sigma_p(e^{A_{c,i}}) \setminus \{0\} = \{e^{-s} : s \in RHP, \ \mathrm{Ker} Q_2(s) \neq \{0\}\}.$$

2. *Under the same assumption as in 1., for the generator $A_{c,i}$ we have*

$$\sigma(A_{c,i}) = \{-\lambda : \lambda \in \sigma(Q_2)\} = \sigma_s(G_c),$$
$$\sigma_p(A_{c,i}) = \{-s : s \in RHP, \ \mathrm{Ker} Q_2(s) \neq \{0\}\}.$$

3. *If $\tilde{G}_c$ is noncyclic and $\overline{\mathrm{range}}(H_{\tilde{G}_c}) = (Q_2 H_U^2(RHP))^\perp$, where Q_2 is a non-inner rigid function, then*

$$\sigma(A_{c,i}) = \text{the closed left half plane.}$$

4. *If G_c is cyclic, then*

$$\sigma(e^{A_{c,i}}) = \bar{\mathbb{D}}, \qquad \sigma_p(e^{A_{c,i}}) \setminus \{0\} = \emptyset,$$
$$\sigma(A_{c,i}) = \text{the closed left half plane.}$$ □

The following proposition gives the spectral properties of parbalanced realizations in the case of strictly noncyclic transfer functions.

PROPOSITION 7.8. *If $G_c \in H^\infty_{L(U,Y)}(RHP)$ is strictly noncyclic with finite dimensional U and Y, then*

$$\sigma(A_{c,o}) = \sigma(A_{c,i}) = \sigma(A_{c,b}) = \sigma_s(G_c),$$

where $(A_{c,b}, B_{c,b}, C_{c,b}, D_{c,b})$ is a parbalanced realization of G_c.

Proof. The analogous results in the discrete-time case are proven in [24, Cor. 4.3]. Since $\sigma_s(G_c) = \{\frac{z-1}{z+1} | \ z \in \sigma_s(G_d), \ z \neq -1\}$, where $G_d(z) = G_c(\frac{z-1}{z+1})$, $(z \in \mathbb{D}_e)$, the statement follows from Propositions 4.7 and 7.2 and Theorem 7.5. □

7.3. Exponential stability. Before we can give a criterion for the exponential stability of input- and output-normal realizations, we need some results concerning the relation between the spectrum of a semigroup and the spectrum of its generator. The following lemma can be deduced from [9, p. 622] (see also [21, p. 84]).

LEMMA 7.9. *Let e^{tA} be a strongly continuous semigroup of operators on a Hilbert space X with infinitesimal generator A. If $\sigma(e^{tA}) \subseteq \{\lambda : |\lambda| \leq e^{\alpha t}\}$ $(t > 0)$, then $\sigma(A) \subseteq \{s : Re(s) \leq \alpha\}$.* □

Note that in particular if $\|e^{tA}\| \leq Me^{\alpha t}$ for some $M > 0$, then $r(e^{tA}) \leq e^{\alpha t}$ and hence $\sigma(A) \subseteq \{s : Re(s) \leq \alpha\}$, where $r(e^{tA})$ is the spectral radius.

It is well known that in general the converse of the lemma is not true (see [21, Chap. A-III]). However, the converse can be proven in some particular cases.

PROPOSITION 7.10. *Let e^{tA} be a strongly continuous semigroup of contractions on a Hilbert space X with infinitesimal generator A. Let A_d be its co-generator; that is, A_d is a contraction with $-1 \notin \sigma(A_d)$ and*

$$Ax = (A_d - I)(I + A_d)^{-1}x \quad (x \in D(A) = \text{range}(I + A_d)).$$

Assume that A_d is a C_0 operator with minimal function m. Then $\sigma(e^{tA}) \subseteq \{\lambda : |\lambda| \leq e^{\alpha t}\}$ $(t > 0)$, if and only if $\sigma(A) \subseteq \{s : Re(s) \leq \alpha\}$. Here α is a real number.

Proof. The necessity part follows from Lemma 7.9.

Now assume $\sigma(A) \subseteq \{s : Re(s) \leq \alpha\}$. Since $\sigma(e^{tA}) \subseteq \{\lambda : |\lambda| \leq 1\}$, we may assume $\alpha < 0$.

By Lemma 7.3, we have $\sigma(A_d) = \sigma(m)$. On the other hand Proposition 7.2 shows that

$$\sigma(A_d) \setminus \{-1\} = \left\{\frac{1+s}{1-s} : \ s \in \sigma(A)\right\}.$$

Since $\sigma(A) \subseteq \{s : Re(s) \leq \alpha\}$, we have

$$\sigma(A_d) \setminus \{-1\} \subseteq \left\{\frac{1+s}{1-s} : \ Re(s) \leq \alpha\right\}.$$

Thus

$$\sigma(m) \setminus \{-1\} \subseteq \left\{\frac{1+s}{1-s} : \ Re(s) \leq \alpha\right\}.$$

Let $\xi = \frac{1+s}{1-s}$. Then $Re(s) \leq \alpha$ if and only if $|\xi - \frac{\alpha}{2-\alpha}| \leq 1 + \frac{\alpha}{2-\alpha}$. This shows that

$$\sigma(m) \subseteq \left\{\xi : \ |\xi - \frac{\alpha}{2-\alpha}| \leq 1 + \frac{\alpha}{2-\alpha}\right\}.$$

Therefore if $\xi \in \bar{\mathbb{D}}$ and $|\xi - \frac{\alpha}{2-\alpha}| > 1 + \frac{\alpha}{2-\alpha}$, then $\xi \notin \sigma(m)$. Hence there exist $\delta_1 > 0$ and $\delta_2 > 0$ such that

$$|m(z)| \geq \delta_1 \text{ for any } z \in \mathbb{D} \text{ satisfying } |z - \xi| \leq \delta_2.$$

Now for each $t > 0$, let $u(z) = e^{t\frac{z-1}{z+1}}$. Then $u \in H^\infty(\mathbb{D})$ and $e^{tA} = u(A_d)$. Using the spectral mapping theorem (Theorem 7.4) we have (note again that if $\xi = \frac{1+s}{1-s}$, then $Re(s) \leq \alpha$ if and only if $|\xi - \frac{\alpha}{2-\alpha}| \leq 1 + \frac{\alpha}{2-\alpha}$)

$$\sigma(e^{tA}) = \sigma(u(A_d))$$

$$\subseteq \left\{\lambda : \inf_{\xi\in\mathbb{D}}\{|u(\xi) - \lambda| + |m(\xi)|\} = 0\right\}$$

$$= \left\{\lambda : \inf_{|\xi - \frac{\alpha}{2-\alpha}|\le 1+\frac{\alpha}{2-\alpha}}\{|u(\xi) - \lambda| + |m(\xi)|\} = 0\right\}$$

$$\subseteq \left\{\lambda : \inf_{|\xi - \frac{\alpha}{2-\alpha}|\le 1+\frac{\alpha}{2-\alpha}}\{|u(\xi) - \lambda|\} = 0\right\}$$

$$= \left\{\lambda : \inf_{|\xi - \frac{\alpha}{2-\alpha}|\le 1+\frac{\alpha}{2-\alpha}}\{|e^{t\frac{\xi-1}{\xi+1}} - \lambda|\} = 0\right\}$$

$$= \text{closure}\left\{e^{t\frac{\xi-1}{\xi+1}} : \ |\xi - \frac{\alpha}{2-\alpha}| \le 1 + \frac{\alpha}{2-\alpha}\right\}$$

$$= \text{closure}\{e^{st} : \ Re(s) \le \alpha\}$$

$$= \{\lambda : \ |\lambda| \le e^{\alpha t}\}, \quad (t > 0).$$

This completes the proof. □

We are ready to show when an input- or output-normal realization is exponentially stable. For exponentially stable realizations we also characterize the growth bound in terms of the analyticity of the transfer function. The results remarkably resemble the related results for finite dimensional systems.

THEOREM 7.11. *Let G_c be in $H^\infty_{L(U,Y)}(RHP)$ with finite dimensional U and Y. Then an input-normal or output-normal realization of G_c is exponentially stable if and only if G_c is strictly noncyclic and there is $\alpha < 0$ such that G_c has analytic continuation on $Re(s) > \alpha$.*

In this case the growth bound is given by

$$\omega = \inf\{\alpha : \ G_c \text{ has analytic continuation on } Re(s) > \alpha\}.$$

Proof. We prove the theorem for output-normal realizations. The proof in the input-normal case is exactly the same. For output-normal realizations, it suffices to prove the result for the restricted shift realization.

Thus we assume that the restricted shift realization (A, B, C, D) of G_c is exponentially stable. Hence there are $\alpha < 0$ and $M > 0$ such that

$$\|e^{tA}\| \le Me^{\alpha t} \text{ for } t \ge 0.$$

Then by the remark after Lemma 7.9 $\sigma(A) \subseteq \{s|\ Re(s) \le \alpha\}$. As $\alpha < 0$, from Theorem 7.6 it follows that G_c has to be strictly noncyclic since otherwise $\sigma(A) = \overline{LHP}$. Now applying Proposition 7.8 we have

$$\sigma_s(G_c) = \sigma(A) \subseteq \{s : \ Re(s) \le \alpha\}.$$

Hence G_c has analytic continuation on $Re(s) > \alpha$. This also shows that

$$\inf\{\alpha' : \ G_c \text{ has analytic continuation on } Re(s) > \alpha'\}$$

is not greater than the growth bound of (A, B, C, D).

Conversely, assume that G_c is strictly noncyclic and there is $\alpha < 0$ such that G_c has an analytic continuation on $Re(s) > \alpha$. Let (A, B, C, D) be the restricted shift realization of G_c and (A_d, B_d, C_d, D_d) be the discrete-time restricted shift realization of $G_d(z) = G_c(\frac{z-1}{z+1})$. Note that $(A, B, C, D) = T((A_d, B_d, C_d, D_d))$.

Again by Proposition 7.8 we have

$$\sigma(A) = \sigma_s(G_c).$$

Therefore $\sigma(A) \subseteq \{s : Re(s) \leq \alpha\}$. Note that G_d is also strictly noncyclic. It follows from Theorem 7.5 that A_d is a C_0 operator. Now we can apply Proposition 7.10 to get

$$\sigma(e^{tA}) \subseteq \{\lambda : |\lambda| \leq e^{\alpha t}\}.$$

This shows that $r(e^{tA}) \leq e^{\alpha t}$. Thus by Proposition 7.1, (A, B, C, D) is exponentially stable. This also implies that the growth bound of (A, B, C, D) is not greater than

$$\inf\{\alpha' : G_c \text{ has analytic continuation on } Re(s) > \alpha'\}.$$

The proof is now complete. □

The following proposition shows that for strictly noncyclic transfer functions parbalanced realizations have the same exponential stability properties as input- and output-normal realizations.

PROPOSITION 7.12. *Let $G_c \in H^\infty_{L(U,Y)}(RHP)$ be strictly noncyclic with U and Y finite dimensional and let $(A_{c,o}, B_{c,o}, C_{c,o}, D_{c,o})$, $(A_{c,i}, B_{c,i}, C_{c,i}, D_{c,i})$, and $(A_{c,b}, B_{c,b}, C_{c,b}, D_{c,b})$ be, respectively, an output-normal, an input-normal, and a parbalanced realization of G_c. Then the following are equivalent:*

1. *$(A_{c,o}, B_{c,o}, C_{c,o}, D_{c,o})$ is exponentially stable with growth bound α;*
2. *$(A_{c,i}, B_{c,i}, C_{c,i}, D_{c,i})$ is exponentially stable with growth bound α;*
3. *$(A_{c,b}, B_{c,b}, C_{c,b}, D_{c,b})$ is exponentially stable with growth bound α.*

Proof. By Theorem 7.11, 1. and 2. are equivalent. Hence we need only to prove the equivalence of 1. and 3. Assume that 1. is true. Then there exist $M > 0$ and $\alpha < 0$ such that

$$\|e^{tA_{c,o}}\| \leq Me^{t\alpha} \quad (t > 0).$$

From the remark after Lemma 7.9 it follows that $\sigma(A_{c,o}) \subseteq \{s | \ Re(s) \leq \alpha\}$. Since now by Proposition 7.8 $\sigma(A_{c,b}) = \sigma(A_{c,o})$ we have

$$\sigma(A_{c,b}) \subseteq \{s \mid \ Re(s) \leq \alpha\}.$$

Let $A_{d,b} = (I + A_{c,b})(I - A_{c,b})^{-1}$ be the propagation operator of the corresponding discrete-time parbalanced realization of $G_d(z) = G_c(\frac{z-1}{z+1})$ $(z \in \mathbb{D}_e)$. That is, $A_{d,b}$ is the co-generator of the semigroup $e^{tA_{c,b}}$. Note that $G_d^\perp$ is strictly noncyclic. By Theorem 7.5 $A_{d,b}$ is a C_0 operator. Therefore it follows from Proposition 7.10 that

$$\sigma(e^{tA_{c,b}}) \subseteq \{\lambda : |\lambda| \leq e^{\alpha t}\}.$$

This, by Proposition 7.1, shows that $(A_{c,b}, B_{c,b}, C_{c,b}, D_{c,b})$ is exponentially stable with growth bound no greater than α and hence no greater than the growth bound of $(A_{c,o}, B_{c,o}, C_{c,o}, D_{c,o})$.

If we assume 3., a similar argument will lead to 1. □

If the Hankel operator H_{G_c} has closed range, then by Proposition 6.2 all reachable, observable, and admissible realizations of G_c are equivalent. Hence we have the following corollary.

COROLLARY 7.13. *Assume that the spaces U and Y are finite dimensional and the Hankel operator H_{G_c} has closed range. Then a reachable, observable, and admissible realization of G_c is exponentially stable if and only if there is a number $\alpha < 0$ such that G_c is strictly noncyclic and can be analytically continued to the half plane $\{s|\ Re(s) > \alpha\}$. The growth bound of these systems is* $\inf \alpha$. □

8. Boundedness of the system operators. We have seen that for an admissible continuous-time transfer function $G_c(s)$ there are always output-normal, input-normal, and parbalanced realizations with well-defined bounded observability and reachability operators. In this sense those realization are well posed. As expected for all infinite-dimensional continuous-time realizations, the propagation, input, and output operators of those realizations are in general unbounded. The input operators are defined in such a way that the range may not be contained in the state space. In this section we are going to investigate when those operators are bounded. We will use the specific form of the restricted and *-restricted shift realizations obtained in §5.

8.1. Boundedness of A_c. First we have the following lemma which shows that the input and output operators are bounded when the propagation operators are.

LEMMA 8.1. *Let (A_c, B_c, C_c, D_c) be an admissible system in $C_X^{U,Y}$. If $A_c : X \to X$ is bounded, then $C_c \in L(X, Y)$ and B_c can be considered as an operator in $L(U, X)$.*

Proof. By definition $C_c|_{D(A_c)} : \big(D(A_c), \|\cdot\|_{A_c}\big) \to Y$ is bounded. Now that A_c is bounded, $D(A_c) = X$. Hence for any $x \in X = D(A_c)$,

$$\begin{aligned}\|C_c x\| &\le \|C_c|_{D(A_c)}\|\,(\|x\|^2 + \|A_c x\|^2)^{1/2}\\ &\le \|C_c|_{D(A_c)}\|\,(\|x\|^2 + \|A_c\|^2\,\|x\|^2)^{1/2}\\ &= \|C_c|_{D(A_c)}\|(1 + \|A_c\|^2)^{1/2}\|x\|.\end{aligned}$$

So $C_c \in L(X, Y)$.

For B we know that $B_c u \in D(A_c^*)^{(')}$ and by definition $\|B_c u\|^{(')} \le b\|u\|$ for any $u \in U$ and some fixed number $b > 0$. By the Riesz representation theorem, there exists $x_u \in D(A_c^*) = X$ such that

$$\|B_c u\|^{(')} = \|x_u\|_{A_c^*}$$

and for $x \in D(A_c^*) = X$,

$$(B_c u)(x) = \langle x_u, x\rangle_{A_c^*} = \langle x_u, x\rangle + \langle A_c^* x_u, A_c^* x\rangle = \langle (1 + A_c A_c^*)x_u, x\rangle.$$

Therefore $B_c u = (1 + A_c A_c^*)x_u \in X$ and

$$\begin{aligned}\|B_c u\| &= \|(1 + A_c A_c^*)x_u\|\\ &\le \|1 + A_c A_c^*\|\,\|x_u\| \le \|1 + A_c A_c^*\|\,\|x_u\|_{A_c^*}\\ &= \|1 + A_c A_c^*\|\,\|B_c u\|^{(')} \le \|1 + A_c A_c^*\|\,b\,\|u\|.\end{aligned}$$

Hence $B_c \in L(U, X)$. □

Now we give a necessary and sufficient condition for the propagation operators in the input-normal and output-normal realizations to be bounded.

THEOREM 8.2. *Let G_c be in $H^\infty_{L(U,Y)}(RHP)$ with U and Y finite dimensional and let (A_c, B_c, C_c, D_c) be an input-normal (or output-normal) realization of G_c. Then A_c is bounded*

if and only if $G_c(s)$ is strictly noncyclic and analytic at infinity. Here analyticity at infinity means that $G_c(\frac{1}{s})$ is analytic at the origin.

Proof. Since all output-normal (input-normal) realizations are unitarily equivalent to the restricted (*-restricted) shift realizations, we prove the theorem for the restricted shift realization and *-restricted shift realization. Let $G_d(z) = G_c(\frac{z-1}{z+1})$ $(z \in \mathbb{D}_e)$ and (A_d, B_d, C_d, D_d) be the restricted realization of G_d on $X_d = \overline{\text{range}}(H_{G_d^\perp})$. Then $A_c = V(A_d - I)(A_d + I)^{-1}V^{-1}$, where V is the unitary operator defined in Proposition 3.3.

If $G_c(s)$ is strictly noncyclic and analytic at infinity, then $G_d(z)$ is strictly noncyclic and analytic at -1. Hence by the spectral minimality of the discrete-time restricted shift realization (see [11]) $-1 \notin \sigma(A_d)$; i.e., $(A_d + I)^{-1}$ is bounded and so $A_c = V(A_d - I)(A_d + I)^{-1}V^{-1}$ is bounded.

Conversely, if A_c is bounded, then $(A_d+I)^{-1} = \frac{1}{2}(I - V^{-1}A_cV)$ is also bounded and thus $-1 \notin \sigma(A_d)$. By Theorem 7.5 G_d has to be strictly noncyclic since otherwise $\sigma(A_d) = \bar{\mathbb{D}}$. Also $G_d(z) = C_d(zI - A_d)^{-1}B_d + D_d$ is analytic at -1. Therefore $G_c(s)$ is strictly noncyclic and analytic at infinity.

Exactly the same argument can also be applied to the *-restricted case. □

Regarding the boundedness of a parbalanced realization, we have the following.

COROLLARY 8.3. *Let $G_c \in H^\infty_{L(U,Y)}(RHP)$ be strictly noncyclic with finite dimensional U and Y and let $(A_{c,o}, B_{c,o}, C_{c,o}, D_{c,o})$, $(A_{c,i}, B_{c,i}, C_{c,i}, D_{c,i})$, and $(A_{c,b}, B_{c,b}, C_{c,b}, D_{c,b})$ be, respectively, an output-normal, an input-normal, and a parbalanced realization of G_c. Then the boundedness of one of $A_{c,o}$, $A_{c,i}$, and $A_{c,b}$ implies the boundedness of the other two.*

Proof. By Theorem 8.2, it suffices to prove that the boundedness of $A_{c,o}$ implies and is implied by that of $A_{c,b}$. We do this by connecting the continuous-time and discrete-time systems as in Theorem 3.1.

Assume that $A_{c,o}$ is bounded. Then, as in the proof of Theorem 8.2, $-1 \notin \sigma(A_{d,o})$. Since G_c and hence $G_d^\perp$ are strictly noncyclic, $\sigma(A_{d,o}) = \sigma(A_{d,b})$. Thus $-1 \notin \sigma(A_{d,b})$ and hence $A_{c,b} = (A_{d,b} - I)(A_{d,b} + I)^{-1}$ is bounded. The same argument can also go the other direction, and the result is proven. □

8.2. Boundedness of B_c in output-normal realizations. We now consider the boundedness of the input and output operators. First we recall that for the input operator B_c of the restricted shift realization with state space X, we have that $B_cu \in X$ $(u \in U)$ if and only if

$$[G_c(s) - G_c(+\infty)]u \in X \quad (u \in U),$$

and in this case

$$(B_cu)(s) = \frac{1}{\sqrt{2\pi}}[G_c(s) - G_c(+\infty)]u$$

(see Theorem 5.7 and Corollary 5.8).

PROPOSITION 8.4. *Let $G_c \in TLC^{U,Y}$.*

1. *The input operator of an output-normal realization of G_c is bounded if and only if there is $M > 0$ such that*

$$\sup_{x>0} \int_{-\infty}^{+\infty} \|[G_c(x + iy) - G_c(+\infty)]u\|^2 dy \le (M\|u\|)^2 \text{ for any } u \in U,$$

where $M > 0$ is a constant.

2. *The output operator of an input-normal realization of G_c is bounded if and only if there is $M > 0$ such that*

$$\sup_{x>0} \int_{-\infty}^{+\infty} \|[\tilde{G}_c(x + iy) - \tilde{G}_c(+\infty)]v\|^2 dy \le (M\|v\|)^2 \text{ for any } v \in Y.$$

3. *If*

$$\sup_{x>0}\int_{-\infty}^{+\infty}\|[G_c(x+iy)-G_c(+\infty)]\|^2dy<\infty,$$

then the input operator of any output-normal realization and the output operator of any input-normal realization are bounded. If in addition the Hankel operator H_{G_c} has closed range, then both the input and the output operators of any output-normal, input-normal, and parbalanced realizations are bounded.

Proof. 1. It suffices to prove the result for the restricted shift realization of G_c. Let B_c be the input operator of the restricted shift realization (see Theorem 5.7).

Assume

$$\sup_{x>0}\int_{-\infty}^{+\infty}\|[G_c(x+iy)-G_c(+\infty)]u\|^2dy\le(M\|u\|)^2 \text{ for any } u\in U.$$

This condition implies that $[G_c-G_c(+\infty)]u\in X$ for any $u\in U$ because as in the proof of Corollary 5.8 we have in $L^2(i\mathbb{R})$ norm

$$[G_c-G_c(+\infty)]u=\lim_{n\to\infty}\frac{G_c(s)-G_c(n)}{1-s/n}u=\lim_{n\to\infty}H_{G_c}\frac{n}{n+s}u.$$

Hence $(B_cu)(s)=\frac{1}{\sqrt{2\pi}}[G_c(s)-G_c(+\infty)]u$ $(u\in U)$ and $\|B_cu\|\le\frac{1}{\sqrt{2\pi}}M\|u\|$.

Conversely, if B_c is bounded, then there is $M>0$ such that $\|B_cu\|\le M\|u\|$. Also $B_cu\in X$ for any $u\in U$. By Corollary 5.8

$$(B_cu)(s)=\frac{1}{\sqrt{2\pi}}[G_c(s)-G_c(+\infty)]u\ \ (u\in U).$$

Thus we have

$$\sup_{x>0}\int_{-\infty}^{+\infty}\|[G_c(x+iy)-G_c(+\infty)]u\|^2dy=\frac{1}{2\pi}\|B_cu\|^2\le\frac{1}{2\pi}M^2\|u\|^2.$$

2. Similarly we only need to prove the result for the *-restricted shift realization. Since the *-restricted shift realization of G_c is the dual of the restricted shift realization of $\tilde{G}_c$, the result follows from 1.

3. First note that

$$\sup_{x>0}\int_{-\infty}^{+\infty}\|[G_c(x+iy)-G_c(+\infty)]\|^2dy<\infty$$

if and only if

$$\sup_{x>0}\int_{-\infty}^{+\infty}\|\tilde{G}_c(x+iy)-\tilde{G}_c(+\infty)\|^2dy<\infty.$$

Clearly these conditions imply

$$\sup_{x>0}\int_{-\infty}^{+\infty}\|[G_c(x+iy)-G_c(+\infty)]u\|^2dy\le(M\|u\|)^2 \text{ for any } u\in U$$

and

$$\sup_{x>0}\int_{-\infty}^{+\infty}\|[\tilde{G}_c(x+iy)-\tilde{G}c(+\infty)]u\|^2dy\le(\tilde{M}\|u\|)^2 \text{ for any } u\in U$$

for some constants $M < \infty$ and $\tilde{M} < \infty$. Hence by 1. and 2. the input operator of any output-normal realization and the output operator of any input-normal realization are bounded. If in addition H_{G_c} has closed range, then by Proposition 6.2 all reachable and observable admissible realizations of G_c are equivalent. Thus all have bounded input and output operators. □

The following corollary gives a simple condition for the input operator of an output-normal realization and the output operator of an input-normal realization to be bounded.

COROLLARY 8.5. *Let $G_c \in H^\infty_{L(U,Y)}(RHP)$ be analytic at ∞. Then the input operator of the output-normal realizations and the output operator of the input-normal realizations are bounded.*

Proof. Let $F_d(z) = G_c(\frac{1-z}{1+z}) - G_c(\infty)$. The analyticity of G_c at ∞ means that F_d and $\frac{F_d(z)}{1+z}$ are both analytic at -1. Hence $\frac{F_d(z)}{1+z} \in H^\infty_{L(U,Y)}(\mathbb{D})$ and for any $u \in U$,

$$\left\| \frac{F_d(z)}{1+z} u \right\|_{H^2_Y(\mathbb{D})} \leq M \|u\|_U,$$

where $M = \sup_{z\in\mathbb{D}} \| \frac{F_d(z)}{1+z} \|_{L(U,Y)}$. Applying the unitary transformation V in Proposition 3.3, we have

$$\|(G_c - G_c(\infty))u\|_{H^2_Y(RHP)} = 2\sqrt{\pi} \| V \frac{F_d(z)}{1+z} u \|_{H^2_Y(\mathbb{D})} \leq 2\sqrt{\pi} M \|u\|_U \quad (u \in U).$$

Since the analyticity of G_c at ∞ implies the analyticity of $\tilde{G}_c$ at ∞, we have similarly

$$\|(\tilde{G}_c - \tilde{G}_c(\infty))y\|_{H^2_U(RHP)} \leq 2\sqrt{\pi} M \|y\|_Y \quad (y \in Y).$$

By Proposition 8.4 it follows that the input operator of the restricted shift realization and the output operator of the *-restricted shift realization are bounded. This proves the corollary. □

8.3. Boundedness of C_c in output-normal realization. Now we consider the boundedness of the input operator of the *-restricted shift realization and the output operator of the restricted shift realization. We present here results for noncyclic scalar transfer functions.

It is well known that a scalar inner function $q_d \in H^\infty(\mathbb{D})$ admits a factorization of the form $q_d(z) = \lambda \mathcal{B}_d(z) \mathcal{S}_d(z)$, where λ is a complex number, $|\lambda| = 1$;

$$\mathcal{B}_d(z) = \prod_{n=1}^{\infty} \frac{\bar{\alpha}_n}{|\alpha_n|} \frac{\alpha_n - z}{1 - \bar{\alpha}_n z}$$

is a Blaschke product, and

$$\mathcal{S}_d(z) = \exp\left[- \int_0^{2\pi} \frac{e^{i\theta} + z}{e^{i\theta} - z} d\mu_d(\theta) \right]$$

is a singular inner function with μ_d a finite singular positive measure on the unit circle $\partial\mathbb{D}$ (see [17]). Here we take $\frac{\bar{\alpha}_n}{|\alpha_n|}$ to be 1 when $\alpha_n = 0$. Ahern and Clark [1] have proved the following theorem.

THEOREM 8.6. *Set $X = H^2(\mathbb{D}) \ominus q_d H^2(\mathbb{D})$ and denote the compressed shift operator on X by $S(q_d) := P_{X_d} z|_{X_d}$. Then the following statements are equivalent.*

1. *For every $x \in X$ the nontangential limit of $x(z)$ exists at -1.*
2. $P_X 1 \in \text{range}(I + S(q_d))$.
3. *For the function q_d*

$$\sum_{n=1}^{\infty} \frac{1 - |\alpha_n|^2}{|1 + \alpha_n|^2} < \infty \quad \text{and} \quad \int_0^{2\pi} \frac{d\mu_d(\theta)}{|1 + e^{i\theta}|} < \infty.$$

Furthermore, if one of these conditions hold, then there exists a function $k \in X$ such that the nontangential limit of any $x \in X$ at -1 is

$$x(-1) := \lim_{\substack{z \to -1,\ z \in \mathbb{D} \\ \text{nontangential}}} x(z) = \langle x, k \rangle. \qquad \square$$

This theorem can be cast into left invariant spaces on the right half plane. Let q_c be an inner function in $H^\infty(RHP)$. Then q_c has the form $q_c(s) = \lambda \mathcal{B}_c(s)\mathcal{S}_c(s)$, where $\mathcal{B}_c$ is a Blaschke product on the right half plane,

$$\mathcal{B}_c(s) = \prod_{n=1}^{\infty} \frac{|1-\beta_n^2|}{1-\beta_n^2} \frac{s-\beta_n}{s+\bar{\beta}_n},$$

and

$$\mathcal{S}_c(s) = e^{-as} \exp\left[-\int_{-\infty}^{\infty} \frac{ys+i}{y+is} d\mu_c(y) \right]$$

is a singular inner function with μ_c a finite singular positive measure on $i\mathbb{R}$ and $a \geq 0$ (see [17]). Here $\frac{|1-\beta_n^2|}{1-\beta_n^2}$ is taken to be 1 if $\beta_n = 1$. Let V be the transformation defined in Proposition 3.3. Applying V to X_d in Theorem 8.6, we obtain the following theorem.

THEOREM 8.7. *Set $X = H^2(RHP) \ominus q_c H^2(RHP)$ and $\mathcal{D} = \{P_X \frac{h}{1+s} : h \in X\}$. Then the following statements are equivalent.*

1. *For every $f \in X$, the limit*

$$\lim_{\substack{s \to \infty,\ Re(s) > 0 \\ Re(s) > \epsilon |s|}} sf(s)$$

exists for any $\epsilon > 0$.

2. $P_X \frac{1}{1+s} \in \mathcal{D}$.

3. *For the inner function q_c,*

$$a = 0, \quad \sum_{n=1}^{\infty} Re\beta_n < \infty, \quad \text{and} \quad \int_{-\infty}^{\infty} \sqrt{1+y^2} d\mu_c(y) < \infty.$$

Moreover, if one of the statements holds, then there exists $k \in X$ such that

$$\lim_{\substack{s \to \infty, Re(s) > 0 \\ Re(s) > \epsilon |s|}} sf(s) = \langle f, k \rangle \quad (f \in X).$$

Proof. Let $q_d(z) = q_c(\frac{1-z}{1+z})$ $(z \in \mathbb{D})$. Then q_d admits factorization as in Theorem 8.6: $q_d(z) = \lambda \mathcal{B}_d(z)\mathcal{S}_d(z)$. It can be easily seen that the Blaschke products $\mathcal{B}_d(z)$ and $\mathcal{B}_c(z)$ can be related by $\beta_n = \frac{1-\alpha_n}{1+\alpha_n}$; that the functions $\mathcal{S}_c(s)$ and $\mathcal{S}_d(z)$ are related by

$$\mathcal{S}_c(s) = \mathcal{S}_d\left(\frac{1-s}{1+s}\right) \quad (s \in RHP),$$

with $a = \mu_d(\{-1\})$; and that the measure μ_c is the measure μ_d transformed by the bilinear transformation

$$s = \frac{1-z}{1+z} : \partial\mathbb{D} \backslash \{-1\} \to i\mathbb{R}.$$

Hence the condition $\sum_{n=1}^{\infty} \frac{1-|\alpha_n|^2}{|1+\alpha_n|^2} < \infty$ is equivalent to

$$\sum_{n=1}^{\infty} Re\beta_n < \infty,$$

and the condition $\int_0^{2\pi} \frac{d\mu_d(\theta)}{|1+e^{i\theta}|} < \infty$ is equivalent to

$$a = 0, \quad \int_{-\infty}^{\infty} \sqrt{1+y^2}\, d\mu_c(y) < \infty.$$

This shows that condition 3 of Theorem 8.6 and condition 3 of Theorem 8.7 are equivalent.

Let V be the unitary transformation defined in Proposition 3.3. Then $V(H^2(\mathbb{D}) \ominus q_d H^2(\mathbb{D})) = H^2(RHP) \ominus q_c H^2(RHP)$, $V(\text{range}(I + S(q_d))) = \{P_X \frac{h}{1+s} : h \in H^2(RHP) \ominus q_c H^2(RHP)\} = \mathcal{D}$, and

$$P_{H^2(RHP)\ominus q_c H^2(RHP)} \frac{1}{1+s} = \sqrt{\pi} V P_{H^2(\mathbb{D})\ominus q_d H^2(\mathbb{D})} 1.$$

Therefore condition 2 of Theorem 8.6 and condition 2 of Theorem 8.7 are equivalent.

Finally, for $x \in H^2(\mathbb{D}) \ominus q_d H^2(\mathbb{D})$, we have $f := Vx \in H^2(RHP) \ominus q_c H^2(RHP)$ and

$$\lim_{\substack{z\in\mathbb{D}, z\to -1 \\ \text{nontangential}}} x(z) := \lim_{\substack{z\in\mathbb{D}, z\to -1 \\ (1-|z|)>\epsilon|z+1|}} x(z) = \sqrt{\pi} \lim_{\substack{s\to\infty,\ Re(s)>0 \\ Re(s)>\epsilon|s|}} sf(s)$$

for any $\epsilon > 0$. This completes the proof. □

If in the theorem we replace q_c by $\tilde{q}_c(s) = \overline{q_c(\bar{s})}$ and $H^2(RHP) \ominus q_c H^2(RHP)$ by $H^2(RHP) \ominus \tilde{q}_c H^2(RHP)$, then we have the results to be true for the space $H^2(RHP) \ominus \tilde{q}_c H^2(RHP)$ while condition 3 of Theorem 8.7 remains unchanged in terms of a, β_n's and the singular measure μ_c.

These results can be immediately used to show the boundedness of the output operators of output-normal realizations and the input operators of input-normal realizations.

COROLLARY 8.8. *Let $G_c \in H^\infty(RHP)$ be a scalar noncyclic transfer function admitting the factorization $G_c = q_c f^*$, where $q_c \in H^\infty(RHP)$ is inner and q_c and $f \in H^\infty(RHP)$ are weakly coprime. Assume q_c has decomposition as in Theorem* 8.7, *and set $X = H^2(RHP) \ominus q_c H^2(RHP)$. Then the following statements are equivalent:*

1. *The output operator C_c of the restricted shift realization of G_c is bounded.*
2. *The input operator $B_{c,*}$ of the *-restricted shift realization of G_c is bounded.*
3. *One of the statements in Theorem* 8.7 *is true.*

Hence the output operator of every output-normal realization and the input operator of every input-normal realization are bounded if and only if one of the statements in Theorem 8.7 *is true.*

If in addition the Hankel operator H_{G_c} has closed range, then both the input operator and the output operator of every reachable and observable admissible realization of G_c are bounded.

Proof. First assume one and hence all of the statements in Theorem 8.7 to be true. We prove 1. and 2.

By Theorem 5.7, the output operator of the shift realization of G_c is given by

$$\begin{aligned} C_c : D(C) = D(A_c) + (I - A)^{-1} B_c U \subseteq X_c &\to Y, \\ x &\mapsto \sqrt{2\pi} \lim_{\substack{r\in\mathbb{R} \\ r\to\infty}} rx(r), \end{aligned}$$

where $X_c = H^2(RHP) \ominus q_c H^2(RHP)$. Now by Theorem 8.7 there exists $k \in X_c$ such that

$$\lim_{\substack{r\in\mathbb{R} \\ r\to\infty}} rx(r) = \langle x, k\rangle \quad (x \in X_c).$$

Hence

$$C_c x = \sqrt{2\pi} \lim_{\substack{r\in\mathbb{R} \\ r\to\infty}} rx(r) = \sqrt{2\pi}\langle x, k\rangle$$

for any $x \in D(C_c)$, and it follows that C_c is bounded: $\|C_c\| \le \sqrt{2\pi}\|k\|$.

To show the boundedness of the input operator $B_{c,*}$ of the *-restricted shift realization we use the expression of $B_{c,*}$ as given in Theorem 5.9: The state space is $X_{c,*} = H^2(RHP) \ominus \tilde{q}_c H^2(RHP)$ and

$$\begin{aligned} B_{c,*}: \qquad U &\to D(A_{c,*}^*)', \\ u &\mapsto B_c(u), \\ [B_{c,*}(u)](x) &= \frac{1}{\sqrt{2\pi}} \left\langle \frac{1}{1+s} u,\ (1 - A_{c,*}^*)x \right\rangle,\ x \in D(A_{c,*}^*), \end{aligned}$$

where the operator $A_{c,*}$ has domain $D(A_{c,*}) = \{P_{X_{c,*}} \frac{h}{1+s} : h \in X_{c,*}\}$. Here $U = \mathbb{C}$. Since by Theorem 8.7 we have $P_{X_{c,*}} \frac{1}{1+s} \in D(A_{c,*})$, it follows that

$$\begin{aligned} [B_{c,*}(u)](x) &= \frac{1}{\sqrt{2\pi}} \left\langle \frac{1}{1+s} u,\ (1 - A_{c,*}^*)x \right\rangle \\ &= \frac{1}{\sqrt{2\pi}} \left\langle P_{X_{c,*}} \frac{1}{1+s} u,\ (1 - A_{c,*}^*)x \right\rangle \\ &= \frac{1}{\sqrt{2\pi}} \left\langle (1 - A_{c,*}) P_{X_{c,*}} \frac{1}{1+s} u,\ x \right\rangle. \end{aligned}$$

This shows that $B_{c,*}(u) \in X_c$ and $B_{c,*}(u) = \frac{1}{\sqrt{2\pi}}(I - A_{c,*}) P_{X_{c,*}} \frac{1}{1+s} u$ for $u \in \mathbb{C}$. Hence B_c is bounded: $\|B_c\| \le \frac{1}{\sqrt{2\pi}} \|(I - A_{c,*}) P_{X_{c,*}} \frac{1}{1+s}\|_{H^2(RHP)}$.

Now we assume 2. and prove that this implies 3. As in the above, $X_{c,*} = H^2(RHP) \ominus \tilde{q}_c H^2(RHP)$ and

$$[B_{c,*}(u)](x) = \frac{1}{\sqrt{2\pi}} \left\langle P_{X_{c,*}} \frac{1}{1+s} u,\ (1 - A_{c,*}^*)x \right\rangle \quad (x \in D(A_{c,*}^*))$$

where $D(A_{c,*}) = \{P_{X_{c,*}} \frac{h}{1+s} : h \in X_{c,*}\}$. As $B_{c,*}$ is assumed to be bounded, for any $u \in \mathbb{C}$ there exists $k(u) \in X_{c,*}$ such that

$$[B_{c,*}(u)](x) = \langle k(u),\ x \rangle \ (x \in D(A_{c,*}^*)).$$

Hence $\langle k(u),\ x \rangle = \frac{1}{\sqrt{2\pi}} \langle P_{X_{c,*}} \frac{1}{1+s} u,\ (1 - A_{c,*}^*)x \rangle$ for any $x \in D(A_{c,*}^*)$. This shows that

$$P_{X_{c,*}} \frac{u}{1+s} \in D((1 - A_{c,*}^*)^*) = D(1 - A_{c,*}) = D(A_{c,*}) = \left\{ P_{X_{c,*}} \frac{h}{1+s} : h \in X_{c,*} \right\}.$$

Thus statement 2 in Theorem 8.7 is true if the space X is replaced by $X_{c,*}$ and the inner function q_c is replaced by $\tilde{q}_c$. By the remark following Theorem 8.7, we know that the statements in Theorem 8.7 are true for X and q_c.

Finally, we show that 1. implies 3. Let (A_c, B_c, C_c, D_c) be the restricted shift realization of $G_c = q_c f^*$ and assume that C_c is bounded. Denote by $(\tilde{A}_c, \tilde{B}_c, \tilde{C}_c, \tilde{D}_c)$ the dual system of (A_c, B_c, C_c, D_c). Then $(\tilde{A}_c, \tilde{B}_c, \tilde{C}_c, \tilde{D}_c)$ is the *-restricted shift realization of $\tilde{G}_c = \tilde{q}_c \tilde{f}^*$ with state space $X = H^2(RHP) \ominus q_c H^2(RHP)$, and

$$\tilde{B}_c = C_c^*.$$

Hence $\tilde{B}_c$ is bounded. By the preceding proof, statement 2 in Theorem 8.7 is true for the space X and the inner function q_c. This completes the proof. □

8.4. Boundedness of B_c, C_c for parbalanced realizations. To conclude this section we show some results on the boundedness of the input and output operators of parbalanced realizations.

PROPOSITION 8.9. *If the output operator of an output-normal realization of $G_c \in TLC^{U,Y}$ is bounded, then the output operator of a parbalanced realization of G_c is bounded.*

Proof. Consider the discrete-time transfer function $G_d(z) = G_c(\frac{z-1}{z+1})$. Let $(A_{do}, B_{do}, C_{do}, D_{do})$ be the discrete-time restricted shift realization of G_d with state space X and $(A_{co}, B_{co}, C_{co}, D_{co}) = T((A_{do}, B_{do}, C_{do}, D_{do}))$ be the continuous-time restricted shift realization of G_c with the same state space X. Denote their observability operators by $\mathcal{O}_{do}$ and $\mathcal{O}_{co}$, respectively. By Theorem 3.4 we have

$$V\mathcal{O}_{do}x = \mathcal{L}\mathcal{O}_{co}x, \quad x \in X,$$

where $V : H_Y^2(\mathbb{D}) \to H_Y^2(RHP)$ is the unitary transformation as defined in Proposition 3.3, and $\mathcal{L}$ is the Laplace transform.

In [30] (see also [24]) it has been shown that there is a parbalanced realization $(A_{db}, B_{db}, C_{db}, D_{db})$ of G_d with state space X that satisfies the following:

$$\mathcal{W}^{1/4}A_{db} = A_{do}\mathcal{W}^{1/4}$$

and

$$\mathcal{O}_{db} = \mathcal{W}^{1/4},$$

where $\mathcal{W} = H_{G^\perp}H_{G^\perp}^*|_X$, and $\mathcal{O}_{db}$ is the observability operator of $(A_{db}, B_{db}, C_{db}, D_{db})$.

Let $(A_{cb}, B_{cb}, C_{cb}, D_{cb}) = T((A_{db}, B_{db}, C_{db}, D_{db}))$, where T is the transformation defined in Theorem 3.1. Since $D(A_{cb}) = \text{range}(A_{db} + I)$ and $D(A_{co}) = \text{range}(A_{do} + I)$, we have, by the equality $\mathcal{W}^{1/4}A_{db} = A_{do}\mathcal{W}^{1/4}$, that $\mathcal{W}^{1/4}D(A_{cb}) \subseteq D(A_{co})$. By Theorem 3.4, $(A_{cb}, B_{cb}, C_{cb}, D_{cb})$ is a parbalanced realization of G_c and for the observability operator $\mathcal{O}_{cb}$ of $(A_{cb}, B_{cb}, C_{cb}, D_{cb})$ we have

$$\mathcal{L}\mathcal{O}_{cb}x = V\mathcal{O}_{db}x = V\mathcal{W}^{1/4}x, \quad x \in X.$$

Notice that in fact by Theorem 5.1 we have $\mathcal{O}_{do} = I_X$. Thus

$$\mathcal{L}\mathcal{O}_{cb}x = V\mathcal{O}_{do}\mathcal{W}^{1/4}x = \mathcal{L}\mathcal{O}_{co}\mathcal{W}^{1/4}x, \quad x \in X.$$

Since $\mathcal{L}$ is unitary, this shows that $\mathcal{O}_{cb}x = \mathcal{O}_{co}\mathcal{W}^{1/4}x$ for $x \in X$. By the definition of $\mathcal{O}_{co}$ and $\mathcal{O}_{cb}$ we have

$$C_{cb}e^{tA_{cb}}x = C_{co}e^{tA_{co}}\mathcal{W}^{1/4}x, \quad x \in D(A_{cb}).$$

Note that C_{cb} is a bounded operator from $(D(A_{cb}), \|\cdot\|_{A_{cb}})$ to Y (see Definition 2.1) and C_{co} has the analogous property. For $x \in D(A_{cb})$ the function $e^{tA_{cb}}x$ is continuous in t in the graph norm $\|\cdot\|_{A_{cb}}$. Similarly, since $\mathcal{W}^{1/4}x \in D(A_{co})$ for $x \in D(A_{cb})$, $e^{tA_{co}}\mathcal{W}^{1/4}x$ is continuous in t in the graph norm $\|\cdot\|_{A_{co}}$. Therefore both $C_{cb}e^{tA_{cb}}x$ and $C_{co}e^{tA_{co}}\mathcal{W}^{1/4}x$ are continuous in t in the norm of Y. Taking $t = 0$, we have

$$C_{cb}x = C_{co}\mathcal{W}^{1/4}x, \quad x \in D(A_{cb}).$$

Since by assumption C_{co} and hence $C_{co}\mathcal{W}^{1/4}$ are bounded, the operator

$$C_{cb}|_{A_{cb}} : D(A_{cb}) \to Y$$

is bounded, where $D(A_{cb})$ is equipped with the norm of X. As $D(A_{cb})$ is dense in X, C_{cb} can be boundedly extended to X.

To complete the proof we just note that the restricted shift realization is unitarily equivalent to any output-normal realization of G_c and that all parbalanced realizations of G_c are equivalent. □

COROLLARY 8.10. *If the input operator of an input-normal realization of* $G_c \in TLC^{U,Y}$ *is bounded, then the input operator of a parbalanced realization of* G_c *is bounded.*

Proof. Let (A_*, B_*, C_*, D_*) be the *-restricted shift realization of G_c and let (A_o, B_o, C_o, D_o) be its dual realization. Then (A_o, B_o, C_o, D_o) is the restricted shift realization of $\tilde{G}_c$. By the assumption, the operator B_* is bounded. Hence so is the operator C_o. By Proposition 8.9 the output operator of a parbalanced realization of $\tilde{G}_c$ is bounded. Consider the dual system (A, B, C, D) of this parbalanced realization of $\tilde{G}_c$. We have B to be bounded. Notice that the dual system of a parbalanced realization of $\tilde{G}_c$ is a parbalanced realization of G_c. Therefore the input operator of any parbalanced realization of G_c is bounded. □

COROLLARY 8.11. *Let* G_c *be in* $TLC^{U,Y}$. *Assume that the Hankel operator* H_{G_c} *has closed range. Then the input (output) operator of a parbalanced realization of* G_c *is bounded if and only if there is a constant* $M > 0$ *such that*

$$\sup_{x>0} \int_{-\infty}^{+\infty} \|[G_c(x+iy) - G_c(+\infty)]u\|^2 dy \le (M\|u\|)^2 \text{ for any } u \in U,$$

$$\left(\sup_{x>0} \int_{-\infty}^{+\infty} \|[\tilde{G}_c(x+iy) - \tilde{G}c(+\infty)]v\|^2 dy \le (M\|v\|)^2 \text{ for any } v \in Y\right).$$

Proof. Since the Hankel operator H_{G_c} has closed range, by Proposition 6.2 all input-normal, output-normal, and parbalanced realizations of G_c are equivalent. The corollary then follows from Proposition 8.4. □

9. Examples.

Example 1: Rational transfer function. Let $g(s)$ be a scalar-valued rational proper transfer function in $H^\infty(RHP)$, i.e., $g(s)$ has all its poles in the open left half plane.

Note that $g(s)$ has, up to a unitary scalar, a unique factorization as

$$g(s) = q(s)f(-s),$$

where $q(s)$ is an inner function, i.e., a Blaschke product with poles in LHP, and $f(s)$ is a rational function in $H^\infty(RHP)$, i.e., a proper rational function with poles in LHP. The functions $q(s)$ and $f(s)$ are strongly coprime, which is for rational functions equivalent to both functions not having common zeros in the extended RHP, i.e., $\{s \in \mathbb{C} \mid Re(s) \ge 0\} \cup \{\infty\}$.

The Blaschke product q is determined by the poles of g. For example if

$$g(s) = \frac{(s-1)(s+2)}{(s+3)(s+4)(s+5)},$$

then the Blaschke product is given by

$$q(s) = \frac{(s-3)(s-4)(s-5)}{(s+3)(s+4)(s+5)}$$

and

$$f(s) = \frac{(s+1)(s-2)}{(s+3)(s+4)(s+5)}.$$

It follows from the results in §6 that the state space of the restricted and *-restricted shift realization of the transfer function g is given by

$$X = (qH^2(RHP))^\perp.$$

Note that by Kronecker's theorem (see, e.g., [22]) X is a finite-dimensional space with dimension equal to the number of zeros or poles (counted with multiplicities) of the Blaschke product. From the construction it is clear that the Blaschke product is completely determined by the poles of the transfer function. Hence we have recovered the well-known result that the dimension of a minimal state-space realization equals the number of poles of the transfer function.

Example 2: Delay system with strictly proper rational part. In this example we consider single-input single-output delay systems. We continue with the notation in the above example and let the transfer function have the form $g_1(s) = e^{-\alpha s}g(s)$ with $\alpha > 0$. Let $p(s) = e^{-\alpha s}q(s)$. Clearly p is in $H^\infty(RHP)$ and inner. Later we will show that in fact p and f are weakly coprime. For now assume that this is true. Thus by Theorem 4.8 g_1 is strictly noncyclic, and by Proposition 5.11 the state space X of the restricted shift realization (A_c, B_c, C_c, D_c) has the form

$$X = H^2(RHP) \ominus pH^2(RHP).$$

The domain of A_c is $D(A_c) = \{\frac{x(s)-x(1)}{1-s} \mid x \in X\}$. Hence for $h \in D(A_c)$ we will have $h(s) = \frac{x(s)-x(1)}{1-s}$ for some $x \in X$, $\lim_{r\in\mathbb{R}, r\to+\infty} rh(r) = x(1)$ and

$$(A_c h)(s) = sh(s) - \lim_{r\in\mathbb{R}, r\to+\infty} rh(r) = sh(s) - x(1).$$

Note that g_1 satisfies the condition in Proposition 8.4. So the operator B_c is defined as

$$(B_c u)(s) = \frac{1}{\sqrt{2\pi}}[g_1(s) - g_1(+\infty)]u = \frac{1}{\sqrt{2\pi}}g_1(s)u, \qquad u \in \mathbb{C},$$

and B_c is bounded. Hence $(I - A_c)^{-1}B\mathbb{C} \subseteq D(A_c)$ and

$$D(C_c) = D(A_c) + (I - A_c)^{-1}BU = D(A_c).$$

We have, for $h \in D(A_c)$,

$$C_c h = \sqrt{2\pi} \lim_{r\in\mathbb{R}, r\to+\infty} rh(r).$$

Note that because $\alpha \neq 0$, by Corollary 8.8 C_c is unbounded.

The operator D_c is $D_c = g_1(+\infty) = 0$.

We can directly verify that this is a realization of g_1. Let $\xi \in RHP$. An easy calculation will show that for $h \in D(A_c)$

$$((\xi I - A_c)^{-1}h)(s) = \frac{h(s) - h(\xi)}{\xi - s}.$$

(We remark here that this formula is true in general, not just for this particular example.) Then

$$((\xi I - A_c)^{-1}B_c u)(s) = \frac{1}{\sqrt{2\pi}}(\xi I - A_c)^{-1}g_1(s)u = \frac{1}{\sqrt{2\pi}}\frac{g_1(s) - g_1(\xi)}{\xi - s}.$$

Hence

$$C_c(\xi I - A_c)^{-1}B_c u = \lim_{r\in\mathbb{R},\ r\to+\infty} r\frac{g_1(r) - g_1(\xi)}{\xi - r} = g_1(\xi).$$

This realization is exponentially stable by Theorem 7.11 since g_1 is clearly analytic on $Re(s) > -3$. It also follows from Theorem 7.11 that the degree of stability is $-3 = \max\{s : s \text{ is a pole of } g\}$. Consequently the parbalanced realization will also be exponentially stable

with the same degree of stability. Notice that g_1 is continuous in the extended $i\mathbb{R}$. Hence the Hankel operator H_{g_1} is compact. Therefore by Theorem 6.1 there exists a balanced realization.

To show that p and f are weakly coprime, consider the closed linear span $S := pH^2(RHP) \vee fH^2(RHP)$. We need to show that $S = H^2(RHP)$. The space S is obviously a (right) invariant subspace of $H^2(RHP)$. Hence by Beurling's theorem [22] there is an inner function $\Theta \in H^\infty(RHP)$ such that

$$S = \Theta H^2(RHP).$$

Hence $pH^2(RHP) \subseteq \Theta H^2(RHP)$ and $\overline{fH^2(RHP)} \subseteq \Theta H^2(RHP)$. Let $q_1(s) = \frac{s-2}{s+2}$ (which is the inner part of the inner-outer factorization of f; see [22, p. 11]). Then

$$q_1 H^2(RHP) = \overline{fH^2(RHP)}.$$

So by [22, Cor. 5, p. 13] we must have that p/Θ and q_1/Θ are both inner functions. Note that $\Theta(2) \neq 0$ since otherwise $h(2) = 0$ for any $h \in pH^2(RHP) \subseteq \Theta H^2(RHP)$, and this is certainly not true. Thus the inner function $q_1(s)/\Theta(s)$ has a zero at 2. Hence the function $\frac{s+2}{s-2}\frac{q_1(s)}{\Theta(s)}$ will still be in $H^\infty(RHP)$. That is, $1/\Theta \in H^\infty(RHP)$. Hence $H^2(RHP) = \Theta(1/\Theta)H^2(RHP) \subseteq \Theta H^2(RHP) = S$.

Note that exactly the same argument in this example will apply for any transfer function $g_1 = e^{-\alpha s}g(s)$, where g is a stable and strictly proper rational function and $\alpha > 0$. Also, in a similar manner we can obtain the *-restricted shift realization which will have bounded output operator and has the same stability properties as the restricted shift realization.

We summarize these as follows.

PROPOSITION 9.1. *If a scalar transfer function G has the form $G(s) = e^{-\alpha s}g(s)$, $\alpha > 0$, where g is a stable and strictly proper rational function, then*

1. *G has a balanced realization;*

2. *all reachable output-normal realizations of G have bounded input operator and unbounded output operator, whereas all observable input-normal realizations have bounded output operator and unbounded input operator;*

3. *all reachable and observable input- and output-normal realizations and all parbalanced realizations are exponentially stable with growth bound equal to* $\max\{Re(s) : s$ *is a pole of* $G\}$. □

Example 3: Delay system with not strictly proper rational part. When the rational transfer function g in the previous example is not strictly proper, the resulting realizations will be different: the input operator of the restricted shift realization is not necessarily bounded, and it is not clear whether there is a balanced realization of g_1 because the Hankel operator H_{g_1} is not compact. A parbalanced realization, however, exists by Theorem 6.1. We first consider the simplest case with $g(s) = 1$. This is a simple delay $g_1(s) = e^{-\alpha s}$ ($\alpha > 0$). The state space of the restricted shift realization is $X = H^2 \ominus e^{-\alpha s}H^2$, which is the image of the Laplace transform $\mathcal{L}$ on $L^2([0, \alpha])$. Let (A_c, B_c, C_c, D_c) be the restricted shift realization and let

$$(A, B, C, D) = (\mathcal{L}^{-1}A_c\mathcal{L}, \mathcal{L}^{-1}B_c, C_c\mathcal{L}, D_c).$$

We know that (see Theorem 5.7)

$$(e^{tA_c}f)(x) = f(x + t)|_{[0,\alpha]}, \qquad f \in L^2([0, \alpha]),\ x \in [0, \alpha], t \geq 0,$$

where $f(x + t)|_{[0,\alpha]} = f(t + x)$ if $t + x \in [0, \alpha]$ and 0 otherwise. Thus

$$Af = f', \qquad f \in D(A),$$

with $D(A) = \{x \in L^2([0,\alpha]) : x \text{ is absolutely continuous}, x' \in L^2([0,\alpha]),\ x(\alpha) = 0\}$. By Theorem 5.7, for $x \in D(A_c^*)$ and $u \in \mathbb{C}$,

$$\begin{aligned}
[B_c(u)](x) &= \frac{1}{\sqrt{2\pi}}\left\langle \frac{1}{1-s}[G_c(s) - G_c(1)]u,\ (1 - A_c^*)x \right\rangle \\
&= \frac{1}{\sqrt{2\pi}}\left\langle \frac{1}{1-s}(e^{-\alpha s} - e^{-\alpha})u, (1 - A_c^*)x \right\rangle \\
&= \frac{1}{\sqrt{2\pi}}\left\langle \mathcal{L}^{-1}\frac{e^{-\alpha s} - e^{-\alpha}}{1-s}u, \mathcal{L}^{-1}(1 - A_c^*)\mathcal{L}\mathcal{L}^{-1}x \right\rangle \\
&= \langle e^{t-\alpha}u|_{[0,\alpha]}, \mathcal{L}^{-1}(1 - A_c^*)\mathcal{L}\mathcal{L}^{-1}x\rangle_{L^2([0,\alpha])} \\
&= \langle e^{t-\alpha}u, (1 - A^*)\mathcal{L}^{-1}x\rangle_{L^2([0,\alpha])},
\end{aligned}$$

where $e^{t-\alpha}u|_{[0,\alpha]} = \left(\frac{1}{\sqrt{2\pi}}\mathcal{L}^{-1}\frac{e^{-\alpha s} - e^{-\alpha}}{1-s}u\right)(t)$ is $e^{t-\alpha}u$ for $t \in [0,\alpha]$ and 0 otherwise. This shows that for $x \in D(A^*) \subseteq L^2([0,\alpha])$,

$$[B(u)](x) = [\mathcal{L}^{-1}B_c u](x) = [\mathcal{L}^* B_c u](x) = [B_c u](\mathcal{L}x) = \langle e^{t-\alpha}u, (1 - A^*)x\rangle_{L^2([0,\alpha])}.$$

It can be shown that

$$D(A^*) = \{x \in L^2([0,\alpha]) : x \text{ is absolutely continuous}, x' \in L^2([0,\alpha]),\ x(0) = 0\},$$

and $A^*x = -x'$ for $x \in D(A^*)$. Hence

$$[B(u)](x) = \langle e^{t-\alpha}u, (1 - A^*)x\rangle_{L^2([0,\alpha])} = \langle e^{t-\alpha}u, x + x'\rangle_{L^2([0,\alpha])} = ux(\alpha).$$

Since for $x \in D(C_c)$,

$$C_c x = \sqrt{2\pi}\lim_{\substack{r\in\mathbb{R}\\ r\to\infty}} rx(r),$$

we have for $x \in D(C) \subseteq L^2([0,\alpha])$,

$$Cx = C_c\mathcal{L}x = \sqrt{2\pi}\lim_{\substack{r\in\mathbb{R}\\ r\to\infty}} r(\mathcal{L}x)(r) = \lim_{\substack{\lambda\to 0\\ \lambda>0}} x(\lambda) = x(0).$$

Finally, $D_c = g(+\infty) = 0$.

This realization is, by Theorem 7.11, exponentially stable. In fact, the spectrum of e^{tA} is $\{0\}$ $(t > 0)$. The operators B and C are both unbounded.

Now consider the factorization $e^{-\alpha s} = qf^*$, where $q(s) = e^{-\alpha s}$ and $f(s) = 1$. Clearly this is a strongly coprime factorization. Therefore by Proposition 6.2 all reachable and observable realizations of $e^{-\alpha s}$ are equivalent. This shows that all reachable and observable realizations are exponentially stable and have unbounded input, output, and state propagation operators.

As in the previous example, we can generalize this result.

PROPOSITION 9.2. *If a scalar transfer function G has the form $G(s) = e^{-\alpha s}g(s)$, where g is a stable proper rational function and $g(\infty) \neq 0$, $\alpha > 0$, then*

1. *all reachable and observable admissible realizations of G are equivalent;*

2. *if (A, B, C, D) is a reachable and observable admissible realization of G, then the operators A, B, and C are all unbounded;*

3. *every reachable and observable admissible realization of G is exponentially stable with growth bound equal to* $\max\{Re(s) : s \text{ is a pole of } G\}$.

Proof. Since g is a stable proper rational function, g has a factorization $g = qf^*$ such that q and f are stable proper rational and strongly coprime (see Theorem 4.10 for the definition of strong coprimeness). Hence

$$\inf_{s\in RHP}[|q(s)| + |f(s)|] > 0.$$

Since $g(\infty) \neq 0$, we must have that $f(\infty) \neq 0$. Therefore

$$\inf_{s\in RHP}[|q(s)e^{-\alpha s}| + |f(s)|] > 0.$$

This, by the Corona theorem (see [22, p. 66]), shows that $qe^{-\alpha s}$ and f are strongly coprime. So by Theorem 4.10 the Hankel operator H_G has closed range and by Proposition 6.2 all reachable and observable realizations of G are equivalent. Thus 1. is proven.

Since G is not analytic at infinity, by Theorem 8.2 the state propagation operator of any reachable output-normal realization is unbounded. Note that in the factorization $G = (qe^{-\alpha s})f^*$ the inner function does not satisfy condition 3 in Theorem 8.6 because now $\alpha \neq 0$. Therefore by Corollary 8.8 the output operator of the restricted shift realization and the input operator of the *-restricted shift realization are unbounded. Thus 2. follows from 1.

Since G is strictly noncyclic and

$$\begin{aligned}&\inf\{\alpha : G(s) \text{ has analytic continuation on } Re(s) > \alpha\}\\ &\quad = \max\{Re(s) : s \text{ is a pole of } g\}\\ &\quad < 0,\end{aligned}$$

by Theorem 7.11 all reachable output-normal realizations of G are exponentially stable with growth bound $\max\{Re(s) : s \text{ is a pole of } g\}$. As equivalent systems have the same exponential stability property and growth bound, 3. also follows from 1. □

Example 4: Systems with infinite Blaschke product. In this example we consider transfer functions of the form $g(s) = R(s)B(s)$, where $R(s)$ is a proper rational function in $H^\infty(RHP)$ and $B(s)$ is an infinite Blaschke product also in $H^\infty(RHP)$. We assume that there is no pole-zero cancellation. That is, the zeros of $R(s)$ ($B(s)$) do not coincide with any of the poles of $B(s)$ (respectively, $R(s)$). We point out that B has the form

$$B(s) = \prod_{n=1}^{\infty} \frac{|1-\beta_n^2|}{1-\beta_n^2}\,\frac{s-\beta_n}{s+\bar{\beta}_n},$$

where $\frac{|1-\beta_n^2|}{1-\beta_n^2}$ is assumed to be 1 if $\beta_n = 1$. The zeros $\beta_n (n = 1, 2, \ldots)$ of B satisfy the condition (see [17])

$$\sum_{n=1}^{\infty} \frac{Re(\beta_n)}{1+|\beta_n|^2} < \infty.$$

Note that either infinity is an accumulation point of the zeros (and the poles) of B, or else, the zeros (and the poles) of B are bounded and have accumulation points which are on the imaginary line.

First we consider the case that $R(s)$ is not strictly proper and the zeros of $R(s)$ do not coincide with any of the accumulation points of the poles of $B(s)$.

Write $R(s) = n(s)/d(s)$, where $n(s)$ and $d(s)$ are coprime polynomials. Then we have

$$g(s) = \frac{d^*(s)}{d(s)}B(s)\frac{n(s)}{d^*(s)},$$

where $d^*(s) = \overline{d(-\bar{s})}$. Set $q(s) = \frac{d^*(s)}{d(s)} B(s)$ and $f(s) = \frac{n^*(s)}{d(s)}$. We have $g = qf^*$. The inner function $q(s)$ is again a Blaschke product and $f(s)$ is in $H^\infty(RHP)$ and rational. Furthermore, from the assumption on $R(s)$ and $B(s)$ it follows that the zeros of $f(s)$ do not coincide with any of the zeros or accumulation points of the zeros of $q(s)$. Thus we must have

$$\inf_{s \in RHP} |f(s)| + |q(s)| > 0.$$

This shows that g has a strongly coprime Douglas–Shapiro–Shields factorization. Hence the Hankel operator H_g has closed range. Thus by Proposition 6.2 all reachable and observable admissible realizations of g are equivalent. Therefore all these realizations are asymptotically stable. They are exponentially stable if and only if there exists $\alpha > 0$ such that g is analytic on $Re(s) > -\alpha$. Since $R(s)$ is rational and in $H^\infty(RHP)$, we know that g is analytic on $Re(s) > -\alpha$ for some $\alpha > 0$ if and only if there is $\lambda > 0$ such that $B(s)$ is analytic on $Re(s) > -\lambda$. Note that the last condition on $B(s)$ is equivalent to that there is $\lambda > 0$ such that $Re(\beta_n) > \lambda$, $n = 1, 2, \ldots$.

By Corollary 8.8 we know that the input and output operators of any reachable and observable admissible realization of g are bounded if and only if $\sum Re(\beta_n) < \infty$.

The second case is that $R(s)$ is strictly proper, no zero of $R(s)$ coincides with any accumulation point of the poles of $B(s)$, and infinity is not an accumulation point of the poles of $B(s)$. In this case B is analytic at infinity and the poles of B have accumulation points on the imaginary line. As in the first case, g has a strongly coprime factorization and hence H_g has closed range. Thus all reachable and observable admissible realizations of g are equivalent and asymptotically stable. However, no reachable and observable realization of g is exponentially stable, since the poles of B have accumulation points on the imaginary line and hence g is not analytic on $Re(s) > -\alpha$ for any $\alpha > 0$.

Since in this case we have $g \in H^2(RHP)$ by Proposition 8.4, the input and output operators of any reachable and observable realization of g are bounded.

The third case is that $R(s)$ is strictly proper, no zero of $R(s)$ coincides with any accumulation point of the poles of $B(s)$, and infinity is an accumulation point of the poles of $B(s)$. In this case we can show as was done in Example 2 that the factorization of g in the first case is a weakly coprime factorization. Hence g is strictly noncyclic. Thus all input-normal, output-normal, and parbalanced realizations of g are asymptotically stable. As in the first case, an input-normal, an output-normal, or a parbalanced realization of g is exponentially stable if and only if there exists $\lambda > 0$ such that $Re(\beta_n) > \lambda$, $(n = 1, 2, \ldots)$.

From Corollary 8.8 it follows that the input operator of an input-normal realization or the output operator of an output-normal realization is bounded if and only if $\sum Re(\beta_n) < \infty$. Thus by Proposition 8.9 and Corollary 8.10 the input operator and output operator of any parbalanced realization of g are bounded if $\sum Re(\beta_n) < \infty$.

Since clearly $g \in H^2(RHP)$, by Proposition 8.4 the input operator of an output-normal realization and the output operator of an input-normal realization of g are bounded. If in addition no accumulation point of the poles of $B(s)$ is on the imaginary line, then g is continuous in the extended imaginary line and therefore g has a balanced realization.

We observe that in this case an output-normal realization cannot have a bounded output operator and still be exponentially stable. An analogous fact holds for an input-normal realization and its input operator.

The fourth and final case is that at least one of the zeros of $R(s)$ coincides with an accumulation point of the poles of $B(s)$. Note that this accumulation point must be on the imaginary line.

As in the previous case, the factorization of g in the first case is a weakly coprime factorization. Hence g is strictly noncyclic. Thus all input-normal, output-normal, and parbalanced realizations of g are asymptotically stable. They are not exponentially stable because g is not analytic on $Re(s) > -\alpha$ for any $\alpha > 0$.

Again by Corollary 8.8 the input operator of an input-normal realization or the output operator of an output-normal realization is bounded if and only if $\sum Re(\beta_n) < \infty$. Thus by Proposition 8.9 and Corollary 8.10 the input operator and output operator of any parbalanced realization of g are bounded if $\sum Re(\beta_n) < \infty$.

If every accumulation point of the poles of B is a zero of R, then g is continuous on the extended imaginary line. Hence g has a balanced realization.

We now summarize the results as follows.

PROPOSITION 9.3. *Consider $g(s) = R(s)B(s)$, where $R(s)$ is a proper rational function and $B(s)$ is an infinite Blaschke product, both in $H^\infty(RHP)$, and B and R have no pole-zero cancellation.*

DYNAMIC POLE ASSIGNMENT AND SCHUBERT CALCULUS*

M. S. RAVI†, JOACHIM ROSENTHAL‡, AND XIAOCHANG WANG§

Abstract. The output feedback pole assignment problem is a classical problem in linear systems theory. In this paper we calculate the number of complex dynamic compensators of order q assigning a given set of poles for a q-nondegenerate m-input, p-output system of McMillan degree $n = q(m + p - 1) + mp$. As a corollary it follows that when this number is odd, the generic system can be arbitrarily pole assigned by output feedback with a real dynamic compensator of order at most q if and only if $q(m + p - 1) + mp \geq n$.

Key words. output feedback pole assignment, dynamic compensator, holomorphic curves in Grassmannian, degree of variety

AMS subject classifications. 93B55, 93B27, 14M15

1. Introduction.

The output feedback pole assignment of linear systems with static or dynamic compensators is a classical problem in control theory and many theoretical and numerical research papers have been devoted to this problem.

Although the systems involved are linear, the problem is in fact not linear. It was Brockett and Byrnes [4] who first explained the pole assignment problem with static compensators as an intersection problem in a compactified set of static compensators, the Grassmann manifold $\text{Grass}(m, m + p)$. In making the connection to the classical Schubert calculus they were able to show that there are

$$d(m, p) = \deg \text{Grass}(m, m + p) = \frac{1!2! \cdots (p-1)!(mp)!}{m!(m+1)! \cdots (m+p-1)!} \tag{1.1}$$

complex static output feedback laws which assign a set of poles for a nondegenerate m-input, p-output linear system of McMillan degree $n = mp$. In particular if the number $d(m, p)$ is odd, pole assignment by real static feedback is possible, because the set of complex solutions has to be invariant under complex conjugation. Moreover even if $d(m, p)$ is even, Wang, using algebrogeometric techniques, showed in [25] that a real solution exists for the generic system as soon as $mp > n$.

People have been looking for similar results for the dynamic pole assignment problem for a long time. A first attempt was made by Byrnes in [5]. Recently Rosenthal interpreted in [16, 17] the pole assignment problem with dynamic compensators, again as an intersection problem in a compactified space of dynamic compensators which we denote by $K^q_{m,p}$. It was also proven in [17] that if a plant has McMillan degree $n = q(m + p - 1) + mp$ and is q-nondegenerate, then there exist

$$d(m, p, q) = \deg K^q_{m,p} \tag{1.2}$$

complex dynamic feedback compensators of order q which assign a set of $n + q$ closed-loop poles. At this point we want to mention that all major results derived in [4, 17, 25] are based on a careful study of the associated pole assignment map. (See §2 for more details.) Indeed the number $d(m, p, q)$ can also be viewed as the mapping degree of the associated pole assignment map and this map has geometrically the format of a central projection.

One goal of our paper is to derive a formula for $d(m, p, q)$. Historically the formula (1.1) for $d(m, p) = d(m, p, 0)$ was first discovered in 1886 by Hannibal Schubert [18], a German high school teacher, using a symbolic formalism known as Schubert calculus. Using modern language the number $d(m, p)$ is equal to σ_1^{mp}, where σ_1 denotes the first Chern class of the classifying bundle over the Grassmann manifold Grass$(m, m+p)$. By applying Pieri's formula (see §3 for more details)

$$(i_1, i_2, \ldots, i_m) \cdot \sigma_1 = \sum_{i_l - 1 > i_{l-1}} (i_1, \ldots, i_l - 1, \ldots, i_m) \tag{1.3}$$

repeatedly to $(p, p+2, p+3, \ldots, p+m) = \sigma_1$, we can compute the number $d(m, p) = \deg \text{Grass}(m, m+p)$.

In [15] we defined a set of subvarieties of $K_{m,p}^q$ similar to the Schubert varieties of Grass$(m, m+p)$ and proved a geometric formula similar to Pieri's formula (1.3). This enables us to express $d(m, p, q) = \deg K_{m,p}^q$ as the solution of a partial difference equation with boundary condition. In this paper (§3) we will solve this difference equation and derive a closed formula for $d(m, p, q)$ which is valid for all positive integers m, p, and q. From this formula we finally will derive several new results which predict real and complex solutions assigning a specific set of closed-loop poles. One of the main results of this paper is Theorem 1.1.

THEOREM 1.1. *The poles of an m-input, p-output, q-nondegenerate, linear system of McMillan degree*

$$n = q(m + p - 1) + mp \tag{1.4}$$

can be assigned arbitrarily by using output feedback with complex dynamic compensators of order at most q, and there are

$$d(m, p, q) = (-1)^{q(m+1)}(mp + q(m+p))! \sum_{n_1 + \cdots + n_m = q} \frac{\prod_{k<j} (j - k + (n_j - n_k)(m+p))}{\prod_{j=1}^{m} (p + j + n_j(m+p) - 1)!} \tag{1.5}$$

complex solutions for each set of poles. In particular, if $d(m, p, q)$ is odd, a real solution always exists. Moreover when $d(m, p, q)$ is odd, the generic system can be arbitrarily pole assigned by output feedback with real dynamic compensators of order at most q if and only if

$$n \leq q(m + p - 1) + mp. \tag{1.6}$$

The variety $K_{m,p}^q$ which parameterizes the set of m-input, p-output compensators of McMillan degree q can also be viewed as a parameterization of the space of rational curves of degree q on the Grassmann variety Grass$(m, m+p)$. This geometric link originates from the well-known Hermann-Martin identification [12]. (Compare also with [6, 17].)

We were surprised to learn that there has recently been a tremendous interest in the intersection theory of parameterized curves (of arbitrary genus) on Grassmann varieties and other homogeneous spaces [2, 8, 24, 31]. Researchers working in conformal quantum field theory conjectured several new intersection numbers and an interesting formula for all numbers $d(m, p, q)$, different from (1.5), was part of this conjecture. Readers interested in the physics behind this conjecture are referred to Vafa [24]. The conjecture itself is formulated by Intriligator in [8] as well as in [2]. In [15] we were able to verify this conjecture for all numbers $d(m, p, q)$. More recently Siebert and Tian [22] presented a proof covering the conjecture for all spaces of parameterized curves on a Grassmann variety. For readers interested in these connections we will give some more details at the end of §3.

The paper is organized as follows. In the next section we review the notion of an autoregressive system. This class of systems generalizes the class of transfer functions and it allows us to define the pole placement map by using the behavioral approach to systems modeling as proposed by Willems [28, 29]. In this framework the points of the variety $K^q_{m,p}$ naturally parameterize all autoregressive compensators of a fixed number of inputs, outputs, and a bounded McMillan degree. We also restate the main results derived in [17], which were in part the motivation of this paper. We conclude this section with two new theorems (Theorems 2.14 and 2.15) which sharpen the main results derived in [17].

The main theorem (Theorem 1.1) is proven in §3. The proof involves the review of the generalized Pieri formula which was derived in [15]. To derive the new formula (1.5) describing the degree of the pole placement map in the critical dimension, we solve the partial recurrence relation mentioned earlier. This leads not only to a closed formula for the degree of the pole placement map in the critical dimension but also to a formula of the degree of some generalized Schubert varieties (Theorem 3.5). The section is concluded with several simplified formulas covering particular situations.

In §4 we concentrate on the question of for which triples m, p, q the degree $d(m, p, q)$ is odd, respectively, even. In Theorem 4.2 and Corollary 4.4 we present a relatively simple combinatorial procedure which computes the mod 2 degree of the variety $K^q_{m,p}$ for arbitrary m, p, q. Using this procedure we prove the existence of odd degrees even if $\min(m, p) \geq 3$, covering in this way many multi-input, multi-output feedback situations. (If $\min(m, p) \geq 3$ the degree of all Grassmann varieties is even. In part because of this there do not exist any positive pole placement results over $\mathbb{R}$ in the critical dimension, i.e., when $n = mp$.) We conclude the section with a complete description of all odd numbers $d(m, p, q)$ for $q = 0, 1, 2$.

Finally in the last section we merge the derived results and provide a collection of corollaries and consequences. In this section we also cover situations when the plant is represented by a "traditional" strictly proper transfer function or when the compensator is supposed to be a proper transfer function only.

2. The set of autoregressive systems $A^q_{m,p}$, the projective variety $K^q_{m,p}$, and the pole placement map. In this section we collect some mathematical preliminaries and simultaneously establish our notation. We develop the theory by using the behavioral approach of Willems [28] because we believe that the problem formulation in this setting is very natural. For the relation of this formulation to the traditional transfer function formulation we refer to [17, 28, 29].

First we review the notion of signal space, behavior, and autoregressive system. For this let $\mathbb{K}$ denote either the set of real numbers or the set of complex numbers, i.e., $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$. Let $\mathbb{K}^{\mathbb{R}}$ denote the set of all functions $\psi : \mathbb{R} \to \mathbb{K}$. With respect to the usual addition and scalar multiplication of functions, $\mathbb{K}^{\mathbb{R}}$ is a real vector space. A linear subspace $\mathcal{H} \subset \mathbb{K}^{\mathbb{R}}$ which consists of functions that are arbitrarily many times differentiable will be called a signal space (see [3, 27]). In other words, $\mathcal{H}$ is a linear subspace which is invariant under the linear transformation $\frac{d}{dt}$. Usually we will assume that $\mathcal{H} = C^\infty(\mathbb{R}, \mathbb{K})$, though other function spaces are well possible. (Compare with [3, p. 76] and [28].)

Let $p(s)$ be a polynomial with coefficients in $\mathbb{K}$, i.e., $p(s) \in \mathbb{K}[s]$. Such a polynomial induces a linear transformation $\hat{p} : \mathcal{H} \to \mathcal{H}$, $w(t) \mapsto p(\frac{d}{dt})w(t)$. More generally consider a $p \times k$ polynomial matrix $P(s)$ with entries in $\mathbb{K}[s]$. $P(s)$ induces a linear transformation

$$\begin{aligned} (2.1) \qquad \hat{P} : \mathcal{H}^k &\longrightarrow \mathcal{H}^p, \\ *w(t) &\longmapsto P\left(\frac{d}{dt}\right) w(t). \end{aligned}$$

Using the language of Willems [28], we call the kernel of the linear transformation $\hat{P}$ the behavior and will denote this subset of the signal set $\mathcal{H}^k$ by $\mathcal{B}$.

In general the behavior $\mathcal{B} = \ker(P(\frac{d}{dt}))$ is an infinite-dimensional $\mathbb{R}$-vector space of the signal space $\mathcal{H}^k$. In the case where $P(s)$ is square and invertible it is, however, well known that the behavior $\mathcal{B}$ has real dimension $n = \deg \det P(s)$. Moreover the dynamics of this autonomous system are described by the roots of the characteristic polynomial $\det P(s) = 0$.

Recall that two $p \times k$ polynomial matrices $P(s)$ and $\tilde{P}(s)$ are called (row) equivalent if there is a unimodular matrix $U(s)$ with $\tilde{P}(s) = U(s)P(s)$. Clearly row equivalent matrices define the same behavior. On the other hand if the signal space is sufficiently rich, e.g., if $C^\infty(\mathbb{R}, \mathbb{R}) \subset \mathcal{H}$, we have the following result. (Compare with [3, §6.2] and [10, Thm. 3.9].)

LEMMA 2.1 (cf. [19, Cor. 2.5]). *If $C^\infty(\mathbb{R}, \mathbb{R}) \subset \mathcal{H}$, then $P(s)$ and $\tilde{P}(s)$ define the same behavior if and only if they are row equivalent.*

Based on this result we have the following definition.

DEFINITION 2.2. *An equivalence class of full rank $p \times k$ polynomial matrices is called an* autoregressive system.

The class of autoregressive systems generalizes the class of transfer functions in the following way. Consider a proper or improper $p \times m$ transfer function $G(s)$. Assume $G(s)$ has a left (polynomial) coprime factorization $D^{-1}(s)N(s) = G(s)$. If $\tilde{D}^{-1}(s)\tilde{N}(s) = G(s)$ is a second left coprime factorization, then it is well known that the $p \times (m + p)$ polynomial matrices $(N(s)\ D(s))$ and $(\tilde{N}(s)\ \tilde{D}(s))$ are row equivalent. In other words $(N(s)\ D(s))$ defines an autoregressive system.

The following definition extends the notion of McMillan degree to the class of autoregressive systems.

DEFINITION 2.3 (see [17, 26, 28]). *The degree of an autoregressive system $P(s)$ is given by the maximal degree of the full-size minors of $P(s)$.*

Next we would like to introduce feedback. For this consider a $p \times (m + p)$ autoregressive system $P(s)$ (the plant) and an $m \times (m + p)$ autoregressive system $C(s)$ (the compensator). The closed-loop system is then the dynamical system described through the system of autoregressive equations

$$\begin{pmatrix} P(\frac{d}{dt}) \\ C(\frac{d}{dt}) \end{pmatrix} \cdot w(t) = 0. \tag{2.2}$$

Note that the square polynomial matrix $\binom{P(s)}{C(s)}$ is in general not of full rank, i.e., (2.2) does not describe an autoregressive system as defined in Definition 2.2. To single out the compensators which give rise to a closed-loop autoregressive system we need the following definition (compare with [20]).

DEFINITION 2.4. *A compensator $C(s)$ is called* admissible *if the closed-loop characteristic polynomial*

$$\phi(s) := \det \begin{pmatrix} P(s) \\ C(s) \end{pmatrix} \neq 0. \tag{2.3}$$

We are now in a position to define the pole placement map. Let $P(s)$ be a $p \times (m + p)$ autoregressive system of McMillan degree n and denote by $A^q_{m,p}$ the set of all $m \times (m + p)$ autoregressive systems of McMillan degree at most q. Let $B_p \subset A^q_{m,p}$ be the set of autoregressive systems which are not admissible compensators. Finally identify the set of nonzero polynomials of degree at most d with the projective space $\mathbb{P}^d$. Then define the pole placement map as follows.

DEFINITION 2.5. *The pole placement map for a plant $P(s)$ is defined as the rational map given by*

$$\rho_P : A^q_{m,p} - B_P \longrightarrow \mathbb{P}^{n+q}, \tag{2.4}$$
$$C(s) \longmapsto \phi(s) = \det \begin{pmatrix} P(s) \\ C(s) \end{pmatrix}.$$

We want to note at this point that the roots of $\phi(s)$ do not depend on the particular representation of the plant $P(s)$ or the compensator $C(s)$. Indeed if $\tilde{P}(s) = U_1(s)P(s)$ and $\tilde{C}(s) = U_2(s)C(s)$, then $\tilde{\phi}(s) = \det U_1(s) \cdot \det U_2(s) \cdot \phi(s)$. Finally the roots of $\phi(s)$ correspond to the poles of the closed-loop system in the transfer function formulation. (See [17] for details.)

For a given plant $P(s)$ we usually say that $P(s)$ is pole assignable (almost pole assignable) in the class of feedback compensators of degree at most q if the map ρ_P is onto (almost onto). Though many results are known when a system is pole assignable in the class of feedback compensators of order at most q over the complex numbers $\mathbb{C}$ [17], the question is still far from being solved over the reals and in the ungeneric situation. (Compare with [28].) Clearly the following property is a necessary condition for pole assignability.

DEFINITION 2.6 (see [26, 28]). *An autoregressive system $P(s)$ is called* controllable *or* irreducible *if the matrix $P(s)$ is of full row rank for all $s \in \mathbb{C}$.*

Indeed if the system $P(s)$ is not controllable, the full-size minors of $P(s)$ have a common factor which is necessarily a factor of the closed-loop characteristic polynomial $\phi(s)$. Clearly, even if $P(s)$ is controllable we cannot expect that $P(s)$ is pole assignable in the set of feedback compensators of degree at most q. The following definition singles out an interesting class of systems which has the pole assignability property in the critical dimension (i.e., when $\dim A^q_{m,p} = \dim \mathbb{P}^{n+q}$) over the complex numbers.

DEFINITION 2.7 (see [17]). *A plant $P(s)$ is called* q-nondegenerate *if all compensators $C(s)$ of order at most q are admissible. To put it in other words, $P(s)$ is q-nondegenerate if the set B_p introduced in* (2.4) *is empty.*

In the last part of this section we establish the connection to our earlier work in [17, 26]. First we would like to point out the following observation. The pole placement map ρ_P as introduced in (2.4) actually depends only on the full-size minors of $P(s)$ and $C(s)$. In other words if $C(s)$ and $\tilde{C}(s)$ have the same full-size minors, then the resulting closed-loop characteristic polynomial $\rho_P(C(s))$ and $\rho_P(\tilde{C}(s))$ have the same roots. Based on this fact we assign to each autoregressive system $C(s) \in A^q_{m,p}$ its full-size minors, i.e., we consider the following Plücker map:

$$\pi : A^q_{m,p} \longrightarrow \mathbb{P}(\mathbb{K}^{q+1} \otimes \wedge^m \mathbb{K}^{m+p}) \tag{2.5}$$
$$C(s) \longmapsto c_1(s) \wedge \cdots \wedge c_m(s).$$

Here $c_l(s)$ denotes the lth row vector of the $m \times (m+p)$ matrix $C(s)$. Of course when describing the map π with respect to the standard basis

$$\{e_{i_1} \wedge \cdots \wedge e_{i_m} \mid 1 \le i_1 < \cdots < i_m \le m+p\}, \tag{2.6}$$

it is well known that the coordinates are exactly the full-size minors of the matrix $C(s)$. In particular the map π is well defined.

In the following, whenever we work with coordinates, we will assume the standard basis (2.6). More specifically, if

$$\pi(C(s)) = \sum_{i \in I(m)} f_i(s) \cdot e_{i_1} \wedge \cdots \wedge e_{i_m}, \tag{2.7}$$

we will use the coordinates

$$f_i(s) = z_{(i;q)}s^q + z_{(i;q-1)}s^{q-1} + \cdots + z_{(i;0)}. \tag{2.8}$$

The map π is in general not an embedding as it is for the classical Plücker embedding (the case $q = 0$). Indeed as shown in [17], $\pi(C(s)) = \pi(\tilde{C}(s))$ if and only if the matrices $C(s)$ and $\tilde{C}(s)$ are H-equivalent. (See [17] for details.) On the other hand if $C(s)$ and $\tilde{C}(s)$ are both controllable (see Definition 2.6), then $C(s)$ and $\tilde{C}(s)$ are H-equivalent if and only if they are row equivalent. The following lemma summarizes these statements.

LEMMA 2.8. *π restricted to the set of controllable autoregressive systems is an embedding, in particular π is generically one-to-one.*

From the earlier remarks it is clear that the pole placement map ρ_p factors over the image of π. We introduce therefore the following notation.

DEFINITION 2.9. *$K^q_{m,p}$ denotes the image of $A^q_{m,p}$ under the map π.*

By definition the set $K^q_{m,p}$ is a subset of the projective space

$$\mathbb{P}^N := \mathbb{P}(\mathbb{K}^{q+1} \otimes \wedge^m \mathbb{K}^{m+p}).$$

Note that the Plücker coordinates $\{f_i(s)\}$ introduced in (2.8) satisfy a set of quadratic relations coming from the description of Grass$(m, m+p)$ in $\mathbb{P}^{\binom{m+p}{m}-1}$ [7, p. 65]. Those relations must hold for all $s \in \mathbb{K}$. Equating coefficients we get a necessary set of quadratic relations for the coordinates $z_{(i;d)}$ as well. The following theorem states that those relations define $K^q_{m,p}$.

THEOREM 2.10 (see [17]). *$K^q_{m,p}$ is a projective (sub)variety of $\mathbb{P}^N$. The defining relations are given by a set of homogeneous quadratic polynomials obtained from equating the coefficients in the Plücker relations. The variety $K^q_{m,p}$ is in general singular and has dimension $q(m+p)+mp$.*

The following example explains the situation.

Example 2.11 (see [16]). The only Plücker relation of Grass(2, 4) in $\mathbb{P}^5$ is given by

$$x_{12}x_{34} - x_{13}x_{24} + x_{14}x_{23} = 0. \tag{2.9}$$

Let $f_{ij}(s) = z_{(ij;1)}s + z_{(ij;0)}$ and

$$f_{12}(s)f_{34}(s) - f_{13}(s)f_{24}(s) + f_{14}(s)f_{23}(s) = 0; \tag{2.10}$$

we then have three quadratic equations

$$z_{(12;1)}z_{(34;1)} - z_{(13;1)}z_{(24;1)} + z_{(14;1)}z_{(23;1)} = 0,$$

$$z_{(12;1)}z_{(34;0)} - z_{(13;1)}z_{(24;0)} + z_{(14;1)}z_{(23;0)} + z_{(12;0)}z_{(34;1)} - z_{(13;0)}z_{(24;1)} + z_{(14;0)}z_{(23;1)} = 0,$$

$$z_{(12;0)}z_{(34;0)} - z_{(13;0)}z_{(24;0)} + z_{(14;0)}z_{(23;0)} = 0,$$

which define the projective variety $K^1_{2,2}$ in $\mathbb{P}^{11}$. Because $\dim K^1_{2,2} = 8$, it follows that $K^1_{2,2}$ is a complete intersection and by Bézout's theorem [7], the degree is equal to $2^3 = 8$.

As we can describe the compensator $C(s)$ through the vector

$$c(s) = c_1(s) \wedge \cdots \wedge c_m(s), \tag{2.11}$$

we can describe the plant $P(s)$ through the vector

$$p(s) = p_1(s) \wedge \cdots \wedge p_p(s). \tag{2.12}$$

Finally the closed-loop characteristic polynomial is given through the linear pairing

$$\langle p(s), c(s)\rangle := c_1(s) \wedge \cdots \wedge c_m(s) \wedge p_1(s) \wedge \cdots \wedge p_p(s) = \phi(s). \tag{2.13}$$

Note that the linear pairing $\langle , \rangle$ originally defined on $K^n_{p,m} \times K^q_{m,p}$ extends linearly to the product space $\mathbb{P}(\mathbb{K}^{n+1} \otimes \wedge^p \mathbb{K}^{m+p}) \times \mathbb{P}(\mathbb{K}^{q+1} \otimes \wedge^m \mathbb{K}^{m+p})$.

Next we show that the pole placement map ρ_p induces a central projection in the projective space $\mathbb{P}^N = \mathbb{P}(\mathbb{K}^{q+1} \otimes \wedge^m \mathbb{K}^{m+p})$. For this consider a fixed plant $P(s)$ represented through the vector $p(s) = p_1(s) \wedge \cdots \wedge p_p(s)$. Consider the subspace

$$E_P := \{c(s) | \langle p(s), c(s)\rangle \equiv 0\} \subset \mathbb{P}^N. \tag{2.14}$$

Then we have a central projection (compare with [17, 25]):

$$\begin{aligned} L_P \; : \; \mathbb{P}^N - E_P &\longrightarrow \mathbb{P}^{n+q}, \\ f(s) &\longmapsto \langle\, g(s)\,,\, f(s)\,\rangle. \end{aligned} \tag{2.15}$$

Let χ_P be the restriction map $L_P \mid_{(K^q_{m,p} - E_P)}$, i.e.,

$$\chi_P \; : \; K^q_{m,p} - E_P \longrightarrow \mathbb{P}^{n+q}. \tag{2.16}$$

The next lemma explains the relation between the maps χ_P, L_P and the pole placement map ρ_P.

LEMMA 2.12. *The pole placement map ρ_P introduced in* (2.4) *factors over the variety $K^q_{m,p}$ through*

$$\rho_P = L_P \circ \pi. \tag{2.17}$$

The map ρ_P is onto (almost onto) if and only if χ_P is. Finally a plant $P(s)$ is q-nondegenerate if and only if $K^q_{m,p} \cap E_P = \emptyset$.

Proof. From the definition of the linear pairing $\langle , \rangle$ it is clear that $\rho_P = L_P \circ \pi$. Moreover because

$$\pi \; : \; A^q_{m,p} \to K^q_{m,p} \tag{2.18}$$

is onto, the second statement follows. Finally if $P(s)$ is q-degenerate there is a compensator $C(s) \in A^q_{m,p}$ which is not admissible. But this is equivalent to the statement

$$c_1(s) \wedge \cdots \wedge c_m(s) \in K^q_{m,p} \cap E_P. \tag{2.19}$$

□

This lemma will allow us to study the pole assignment problem completely in the projective space $\mathbb{P}^N$. In the geometric picture the set $K^q_{m,p} \cap E_P$ will be of crucial importance. Note that

$$\pi(B_P) = K^q_{m,p} \cap E_P.$$

By abuse of notation we will denote $K^q_{m,p} \cap E_P$ by B_P as well; Lemma 2.12 justifies this choice. The set B_P is sometimes called the base locus of the central projection χ_P and by Lemma 2.12 this set is empty if and only if the plant $P(s)$ is q-nondegenerate. The following theorem gives the result which mainly motivated this paper.

THEOREM 2.13 (see [17]). *For a q-nondegenerate system of McMillan degree $n = q(m + p - 1) + mp$, the pole assignment map χ_P is onto over $\mathbb{C}$ and there are* $\deg K^q_{m,p}$ *(counted with multiplicity) complex dynamic compensators assigning each set of poles. In particular, a real solution always exists if* $\deg K^q_{m,p}$ *is odd.*

Proof. Since $B_P = \emptyset$, the pole placement map $\chi_P : K^q_{m,p} \to \mathbb{P}^{n+q}$ is a finite morphism [21, Chap. I, §5, Thm. 7]. Therefore χ_P is onto over $\mathbb{C}$ [21, Chap. I, §5, Thm. 4] and $\deg \chi_P = \deg K^q_{m,p}$ [13, Cor. (5.6)]. □

Actually we can strengthen this result with the following theorem.

THEOREM 2.14. *Let P be a system of degree $n < q(m + p - 1) + mp$. If*

$$\dim B_P = \dim E_P \cap K^q_{m,p} = q(m + p) + mp - n - q - 1, \tag{2.20}$$

then χ_P is onto over $\mathbb{C}$ (and over $\mathbb{R}$ if $\deg K^q_{m,p}$ is also odd).

Proof. Let H be the $q(m + p) + mp - n - q$ codimensional projective subspace in $\mathbb{P}^N$ such that

$$B_P \cap H = \emptyset \tag{2.21}$$

(such H exists by [13, Cor. (2.29)]), $\pi_1 : K^q_{m,p} \to \mathbb{P}^{q(m+p)+mp}$ is the central projection with center $E_P \cap H$, and $\pi_2 : \mathbb{P}^{q(m+p)+mp} - \pi_1(B_P) \to \mathbb{P}^{n+q}$ is the central projection with center $\pi_1(E_P)$. Then π_1 is onto over $\mathbb{C}$ and is onto over $\mathbb{R}$ if $\deg K^q_{m,p}$ is also odd, and

$$\chi_P = \pi_2 \circ \pi_1. \qquad \square$$

THEOREM 2.15. *The pole assignment map χ_P is onto over $\mathbb{C}$ for the generic system if and only if*

$$n \leq q(m + p - 1) + mp. \tag{2.22}$$

This condition is also sufficient over $\mathbb{R}$ if $\deg K^q_{m,p}$ is odd.

Proof. The necessity was proven by Willems and Hesselink in [30]. On the other hand if $n = q(m + p - 1) + mp$, the generic system is q-nondegenerate by [17, Cor. 5.6] and the sufficiency follows from Theorem 2.13. If $n < q(m + p - 1) + mp$, then it follows for the generic system from [17, Thm. 5.5] that

$$\dim B_P = q(m + p) + mp - n - q - 1. \tag{2.23}$$

By Theorem 2.14 the sufficiency follows. □

3. The subvarieties Z_α of the variety $K^q_{m,p}$ and a closed formula of their degrees. In this section we derive a closed formula for the degree of a set of generalized Schubert subvarieties of the variety $K^q_{m,p}$. As a corollary we will obtain a formula for the mapping degree of the pole placement map in the critical dimension. For the convenience of the reader we quickly review some geometric aspects of the classical Pieri formula (1.3). For this consider the index set

$$I = \{i = (i_1, \ldots, i_m) | 1 \leq i_1 < \cdots < i_m\}$$

equipped with the partial order

$$(i_1, \ldots, i_m) \leq (j_1, \ldots, j_m) \quad \Leftrightarrow \quad i_l \leq j_l \forall l. \tag{3.1}$$

If an m-dimensional plane $P \in \mathrm{Grass}(m, m + p) \subset \mathbb{P}(\wedge^m \mathbb{K}^{m+p})$ is expanded in terms of the standard basis (2.6), i.e., if P is represented by the vector

$$x := \sum_{i \in I} x_i \cdot e_{i_1} \wedge \cdots \wedge e_{i_m}, \tag{3.2}$$

we will call the coordinates x_i the Plücker coordinates (see [7, p. 64]) of the plane P. The set

$$S_i := \{x \in \mathrm{Grass}(m, m+p) | x_j = 0 \text{ for all } j \not\leq i\} \tag{3.3}$$

is called a Schubert variety. Let H_i be the hyperplane defined by setting $x_i = 0$ and let $|i| := \sum_{l=1}^{m}(i_l - l)$. Then the geometric version of Pieri's formula states that

$$S_i \cap H_i = \bigcup_{\substack{j \in I \\ j<i,\ |j|=|i|-1}} S_j \tag{3.4}$$

and that the intersection multiplicity along each S_j is 1. In terms of the intersection ring, S_i represents a Schubert cycle $(i_1, i_2, \ldots, i_m)$, H_i represents the Schubert cycle $\sigma_1 := (p, p+2, p+3, \ldots, p+m)$, and the geometric intersection is expressed through a formal multiplication as given in (1.3). Readers who want to learn more about Schubert calculus are referred to the excellent survey article of Kleiman and Laksov [9].

In [15] we proved a similar formula as given in (3.4) for subvarieties of $K^q_{m,p}$. To explain this generalized Pieri formula we first re-index the coordinates $z_{(i;d)}$ of $K^q_{m,p}$.

DEFINITION 3.1. *For each* $(i; d)$, $i = (i_1, \ldots, i_m)$, $1 \leq i_1 < \cdots < i_m \leq m+p$, *let* $\alpha := (\alpha_1, \ldots, \alpha_m)$ *be defined as*

$$\alpha_l = \begin{cases} [d/m](m+p) + i_{l+d-m[d/m]} & \text{for } l = 1, 2, \ldots, m[d/m] + m - d, \\ ([d/m]+1)(m+p) + i_{l+d-m[d/m]-m} & \text{for } l = m[d/m] + m - d + 1, \ldots, m. \end{cases}$$

Using this re-indexing we can associate to every coordinate $z_{(i;d)}$ of $K^q_{m,p}$ a new coordinate z_α. The following example shows the relation between the indices $(i; d)$ and α:

$$\begin{aligned} z_{(i;0)} &= z_i, \\ z_{(i;1)} &= z_{(i_2,\ldots,i_m,i_1+m+p)}, \\ z_{(i;2)} &= z_{(i_3,\ldots,i_m,i_1+m+p,i_2+m+p)}, \\ &\vdots \\ z_{(i;m)} &= z_{(i_1+m+p,\ldots,i_m+m+p)}, \\ z_{(i;m+1)} &= z_{(i_2+m+p,\ldots,i_m+m+p,i_1+2(m+p))}, \\ &\vdots \end{aligned}$$

Note that the indices α belong to the index set

$$\tilde{I} := \{\alpha \in I | \alpha_m - \alpha_1 < m + p\}, \tag{3.5}$$

which is by definition a subset of the index set I. In particular $\tilde{I}$ is also equipped with a partial order. Using this partial order we can now define an interesting set of subvarieties of $K^q_{m,p}$.

DEFINITION 3.2.

$$Z_\alpha := \{z \in K^q_{m,p} | z_\beta = 0 \textit{ for all } \beta \not\leq \alpha\}. \tag{3.6}$$

The main results of [15] are summarized in the following proposition and corollary.

PROPOSITION 3.3 (see [15]). *For each index* α, Z_α *is a subvariety of dimension* $|\alpha|$. *If* H_α *is the hyperplane of* $\mathbb{P}^N$ *defined by* $z_\alpha = 0$, *then*

$$Z_\alpha \cap H_\alpha = \bigcup_{\substack{\beta \in \tilde{I} \\ \beta<\alpha,\ |\beta|=|\alpha|-1}} Z_\beta \tag{3.7}$$

and the intersection multiplicity along each Z_β *is* 1.

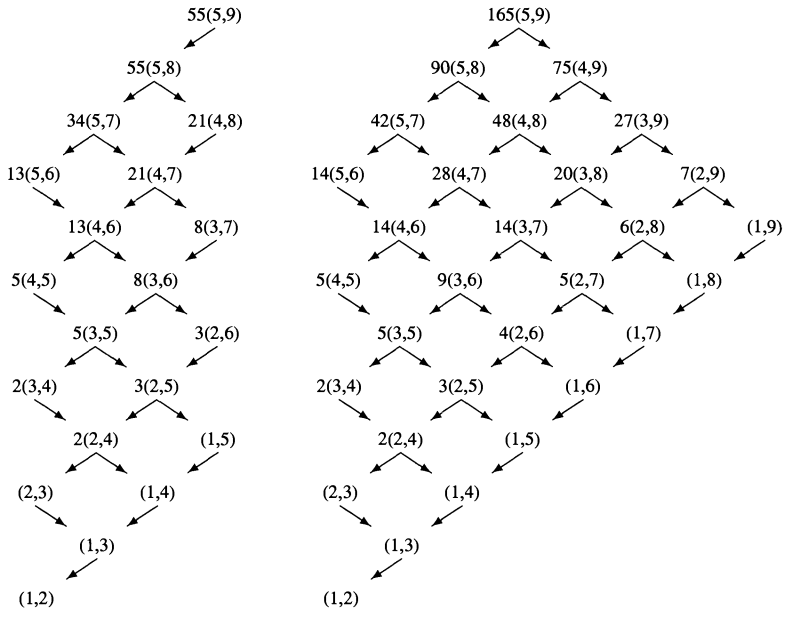

FIG. 1. (a) *Hasse Diagram of* $Z_{(5,9)}$. (b) *Hasse Diagram of* $S_{(5,9)}$.

Using Bézout's theorem [7, Thm. 18.3] the expression (3.7) translates into a partial recurrence relation, which the degrees of the varieties Z_α have to satisfy.

COROLLARY 3.4 (see [15]).

$$\deg Z_\alpha = \sum_{\substack{\beta \in \tilde{I} \\ \beta < \alpha,\ |\beta| = |\alpha| - 1}} \deg Z_\beta. \tag{3.8}$$

The partial recurrence relation (3.8) has to be satisfied for the whole index set $\tilde{I}$. It is possible to depict this relation with the help of a Hasse diagram. A Hasse diagram corresponding to the variety Z_α is a directed graph, whose vertices are all $\beta \in \tilde{I}$, $\beta \leq \alpha$. The directed edges $\beta \to \gamma$ are precisely those ordered pairs such that β covers γ (i.e., $\beta > \gamma$ and $|\beta| = |\gamma| + 1$). Then according to Corollary 3.4, the degree of Z_α can be computed graphically in the following way: If we label the vertices in such a way that the number on $(1, 2, \ldots, m)$ is 1 and the number on β is the sum of the numbers on the vertices covered by β, then the number on α is $\deg Z_\alpha$. Figure 1 provides an example of $Z_{(5,9)} = K^1_{2,3}$. Note that Rosenthal obtained $\deg K^1_{m,p} = 55$ by computing the coefficients of the Hilbert polynomial using the computer program CoCoA in [16]. For comparison we also include the Hasse diagram of the Schubert variety $S_{(5,9)}$, whose underlying diagram corresponds to all indices $i \in I, i \leq (5, 9)$.

From Fig. 1 we can see that the Hasse diagram of Z_α an be obtained by "cutting off" all the vertices of I that are not in $\tilde{I}$ in the Hasse diagram of S_α. If we use $d(\alpha_1, \ldots, \alpha_m)$ for the degree, then both $\deg Z_\alpha$ and $\deg S_\alpha$ satisfy the partial difference equation

$$d(\alpha_1, \ldots, \alpha_m) = \sum_{l=1}^{m} d(\alpha_1, \ldots, \alpha_l - 1, \ldots, \alpha_m) \tag{3.9}$$

subject to the initial condition

$$d(1, 2, \ldots, m) = 1 \tag{3.10}$$

and subject to the boundary conditions

$$d(0, \ldots, \alpha_m) = 0, \tag{3.11}$$

$$d(\ldots, k, k, \ldots) = 0. \tag{3.12}$$

$\deg Z_\alpha$ is subject to one more boundary condition, namely,

$$d(k, \ldots, k + m + p) = 0. \tag{3.13}$$

The computation of the degrees of the varieties Z_α is therefore reduced to the solution of a partial difference equation with boundary conditions. The next theorem provides a closed formula for this problem.

THEOREM 3.5.

$$\deg Z_\alpha = |\alpha|! \sum_{n_1+\cdots+n_m=0} \frac{\prod_{k<j}(\alpha_j - \alpha_k + (n_j - n_k)(m+p))}{\prod_j (\alpha_j + n_j(m+p) - 1)!} \tag{3.14}$$

with the convention that $1/k! = 0$ *if* $k < 0$.

Proof. Let $g(\alpha) = \deg S_\alpha$. Then (see [11, p. 103] and [23])

$$g(\alpha) = |\alpha|! \frac{\prod_{k<j}(\alpha_j - \alpha_k)}{\prod_{j=1}^{m}(\alpha_j - 1)!} = |\alpha|! \det \begin{bmatrix} \frac{1}{(\alpha_1-1)!} & \frac{1}{(\alpha_1-2)!} & \cdots & \frac{1}{(\alpha_1-m)!} \\ \frac{1}{(\alpha_2-1)!} & \frac{1}{(\alpha_2-2)!} & \cdots & \frac{1}{(\alpha_2-m)!} \\ \vdots & \vdots & & \vdots \\ \frac{1}{(\alpha_m-1)!} & \frac{1}{(\alpha_m-2)!} & \cdots & \frac{1}{(\alpha_m-m)!} \end{bmatrix} \tag{3.15}$$

and (3.14) becomes

$$\deg Z_\alpha = \sum_{n_1+\cdots+n_m=0} g(\alpha_1 + n_1(m+p), \ldots, \alpha_m + n_m(m+p)). \tag{3.16}$$

Let

$$d(\alpha) = \sum_{n_1+\cdots+n_m=0} g(\alpha_1 + n_1(m+p), \ldots, \alpha_m + n_m(m+p)).$$

Then $d(\alpha)$ satisfies the equation (3.9) because $g(\alpha)$ does. Moreover since

$$d(\alpha_1, \ldots, \alpha_m) = g(\alpha_1, \ldots, \alpha_m)$$

for $\alpha_1 < \cdots < \alpha_m < m + p$, $d(\alpha)$ satisfies the conditions (3.10) and (3.11) for $\alpha_m < m + p$. We only need to verify (3.12) and (3.13).

Notice that by (3.15)

$$g(\ldots, \alpha_j, \ldots, \alpha_k, \ldots) = -g(\ldots, \alpha_k, \ldots, \alpha_j \ldots). \tag{3.17}$$

If $\alpha_j = \alpha_{j+1}$, then

$$\begin{aligned} &g(\ldots, \alpha_j + k_j(m+p), \alpha_{j+1} + k_{j+1}(m+p), \ldots) \\ &= -g(\ldots, \alpha_j + k_{j+1}(m+p), \alpha_{j+1} + k_j(m+p), \ldots). \end{aligned}$$

On the other hand if $\alpha_1 + m + p = \alpha_m$, then

$$\begin{aligned} &g(\alpha_1 + k_1(m+p), \ldots, \alpha_m + k_m(m+p)) \\ &= g(\alpha_m + (k_1 - 1)(m+p), \ldots, \alpha_1 + (k_m + 1)(m+p)) \\ &= -g(\alpha_1 + (k_m + 1)(m+p), \ldots, \alpha_m + (k_1 - 1)(m+p)). \end{aligned}$$

In either case $d(\alpha) = -d(\alpha)$; i.e., $d(\alpha) = 0$. □

Applying the formula (3.14) to $K^q_{m,p}$ we then have a formula for $\deg K^q_{m,p}$.

THEOREM 3.6.

$$\deg K^q_{m,p} = (-1)^{q(m+1)}(mp+q(m+p))! \sum_{n_1+\cdots+n_m=q} \frac{\prod_{k<j}(j-k+(n_j-n_k)(m+p))}{\prod_{j=1}^{m}(p+j+n_j(m+p)-1)!}. \tag{3.18}$$

Proof. Let $k = [q/m]$ and $r = q - km$. Then

$$K^q_{m,p} = Z_{(p+r+1+k(m+p),\ldots,p+m+k(m+p),p+1+(k+1)(m+p),\ldots,p+r+(k+1)(m+p))}.$$

So

$$\deg K^q_{m,p} = (\operatorname{sgn}\sigma) \sum_{n_1+\cdots+n_m=q} g(p+1+n_1(m+p),\ldots,p+m+n_m(m+p)),$$

where σ is the permutation

$$(r+1, r+2, \ldots, m, 1, 2, \ldots, r) \to (1, 2, \ldots, m),$$

and the sign of this permutation is given by

$$\begin{aligned}\operatorname{sgn}\sigma &= (-1)^{r(m-r)} = (-1)^{(q-km)((k+1)m-q)} = (-1)^{2qkm+mq-q^2-k(k+1)m^2} \\ &= (-1)^{mq}(-1)^{q^2} = (-1)^{mq}(-1)^q.\end{aligned}$$

Therefore

$$\deg K^q_{m,p} = (-1)^{q(m+1)} \sum_{n_1+\cdots+n_m=q} g(p+1+n_1(m+p),\ldots,p+m+n_m(m+p)),$$

which is the formula (3.18). □

Combining Theorems 2.13, 2.15, and 3.6, we then have Theorem 1.1.

We conclude this section with several simplified formulas. First recall the definition of the Fibonacci numbers given by the recurrence relation $f_1 = 1$, $f_2 = 1$, and $f_{n+1} = f_n + f_{n-1}$ for $n > 1$. From Corollary 3.4 it follows immediately that

$$\deg K^q_{2,3} = f_{5q+5}. \tag{3.19}$$

Using a well-known expression for the Fibonacci sequence we therefore get

$$\deg K^q_{2,3} = \frac{1}{\sqrt{5}}\left(\left(\frac{1+\sqrt{5}}{2}\right)^{5(q+1)} - \left(\frac{1-\sqrt{5}}{2}\right)^{5(q+1)}\right). \tag{3.20}$$

Note that formula (3.20) has also been given by Intriligator [8, p. 3554] as an illustration of the conjectured intersection numbers arising from some computation in conformal quantum field theory. For $q = 1$, we again get $\deg K^1_{2,3} = 55$ (compare with the Hasse diagram of $Z_{(5,9)}$) and for $q = 2$, we get $\deg K^2_{2,3} = 610$.

In general, for $m = 2$, formula (3.18) can be simplified to

$$\deg K^q_{2,p} = (-1)^q(q(p+2)+2p)! \sum_{j=0}^{q} \frac{(q-2j)(p+2)+1}{(p+j(p+2))!(p+1+(q-j)(p+2))!}.$$

To illustrate "the nonlinear character" of the pole placement map we derive a table that shows all degrees of the variety $K^q_{2,p}$ for $p = 1, \ldots, 9$ and $q = 0, \ldots, 5$; see Table 1.

TABLE 1.

$p\backslash q$	0	1	2	3	4	5

4. Odd or even degrees. In this section we introduce some methods that can be used to determine whether the deg $K^q_{m,p}$ is odd or even without computing the degree itself.

For Grass$(m, m+p) = K^0_{m,p}$, it is a well-known fact that deg Grass$(m, p+m)$ is even whenever $\min(m, p) \geq 3$ [1]. This is not the case for general $K^q_{m,p}$, i.e., in a certain sense there are many more odd numbers for a fixed $q > 0$ than there are for $q = 0$.

The main result of this section is Theorem 4.2, which provides a short combinatorial description of all triples m, p, q which result in an odd degree. Using this theorem we derive several corollaries classifying the odd- and even-degree varieties.

To prepare for the main theorem we first rewrite formula (3.18):

$$\deg K^q_{m,p} = (-1)^{q(m+1)}(mp+q(m+p))! \sum_{n_1+\cdots+n_m=q} (-1)^{\frac{m(m-1)}{2}}$$

$$\cdot \det \begin{bmatrix} \frac{1}{(p-m+1+n_1(m+p))!} & \frac{1}{(p-m+2+n_1(m+p))!} & \cdots & \frac{1}{(p+n_1(m+p))!} \\ \frac{1}{(p-m+2+n_2(m+p))!} & \frac{1}{(p-m+3+n_2(m+p))!} & \cdots & \frac{1}{(p+1+n_2(m+p))!} \\ \vdots & \vdots & & \vdots \\ \frac{1}{(p+n_m(m+p))!} & \frac{1}{(p+1+n_m(m+p))!} & \cdots & \frac{1}{(p+m-1+n_m(m+p))!} \end{bmatrix} \tag{4.1}$$

$$= (-1)^{q(m+1)}(-1)^{\frac{m(m-1)}{2}} \sum_{n_1+\cdots+n_m=q} \sum_{\sigma} \operatorname{sgn}\sigma$$

$$\cdot \frac{(mp+q(m+p))!}{(p-m+\sigma(1)+n_1(m+p))!\cdots(p-1+\sigma(m)+n_m(m+p))!}. \tag{4.2}$$

Note that $\sum_{i=1}^m((p-m-1)+i+\sigma(i)+n_i(m+p)) = mp+q(m+p)$. It therefore follows that every summand in the expression (4.2) is a multinomial coefficient

$$\binom{k}{k_1,\ldots,k_m} := \frac{(k_1+k_2+\cdots+k_m)!}{k_1!k_2!\cdots k_m!}. \tag{4.3}$$

For multinomial coefficients there is a well-known criterion frequently used by topologists which guarantees that such a coefficient is odd. We formulate this criterion as a lemma.

LEMMA 4.1. *The multinomial coefficient* $\binom{k}{k_1,\ldots,k_m}$ *is odd if and only if there are no "carry overs" in the summation* $k_1+\cdots+k_m$ *when calculated using binary representation.*

Proof. Let

$$k = 2^{n_1}+\cdots+2^{n_l},\ 0 \leq n_1 < \cdots < n_l.$$

Then

$$(x_1+\cdots+x_m)^k = \prod_{i=1}^{l}(x_1^{2^{n_i}}+\cdots+x_m^{2^{n_i}}) \bmod 2. \qquad \square$$

In particular it follows from this lemma that $\binom{k}{k_1,\ldots,k_m}$ is even as soon as two numbers among $\{k_1, \ldots, k_m\}$ are equal or two numbers are odd.

We will call a set $\{k_1, k_2, \ldots, k_m\}$ of positive integers *a disjoint binary partition of* k if the multinomial coefficient $\binom{k}{k_1,\ldots,k_m}$ is odd. To put it in other words, $\{k_1, k_2, \ldots, k_m\}$ is a disjoint binary partition of k if $k_1 + k_2 + \cdots + k_m = k$ and if their binary representations

$$k_i = 2^{n_{i1}} + 2^{n_{i2}} + \cdots + 2^{n_{ir_i}},\ 0 \le n_{i1} < n_{i2} < \cdots < n_{ir_i},\quad i = 1, 2, \ldots, m,$$

have disjoint exponents; i.e., $n_{ij} \neq n_{rs}$ for all i, j, r, s.

THEOREM 4.2. *Let* $a = \min(m, p)$. *Then* $\deg K^q_{m,p}$ *is odd if and only if the number of disjoint binary partitions* $\{k_1, \ldots, k_a\}$ *of* $q(m + p) + mp$ *having the property that*

$$\{k_1, \ldots, k_a\} = \{m + p - 1, m + p - 3, \ldots, m + p - 2a + 1\} \bmod m + p$$

is odd.

Before we give the proof we will illustrate Theorem 4.2 with several examples.

Example 4.3. a. $m = 2, p = 9, q = 4, q(m + p) + mp = 62 = 2 + 2^2 + 2^3 + 2^4 + 2^5$. The disjoint binary partitions equal to $\{10, 8\}$ mod 11 are

$$\{2^5, 2 + 2^2 + 2^3 + 2^4\} = \{32, 30\},$$
$$\{2 + 2^2 + 2^4 + 2^5, 2^3\} = \{54, 8\},$$
$$\{2 + 2^3, 2^2 + 2^4 + 2^5\} = \{10, 52\}.$$

So $\deg K^4_{2,9} = \deg K^4_{9,2}$ is odd.

b. $m = 3, p = 4, q = 5, q(m + p) + mp = 47 = 1 + 2 + 2^2 + 2^3 + 2^5$. The disjoint binary partitions equal to $\{6, 4, 2\}$ mod 7 are

$$\{2 + 2^2, 2^5, 1 + 2^3\} = \{6, 32, 9\},$$
$$\{2 + 2^5, 2^2, 1 + 2^3\} = \{34, 4, 9\},$$
$$\{1 + 2^2 + 2^3, 2^5, 2\} = \{13, 32, 2\},$$
$$\{1 + 2^3 + 2^5, 2^2, 2\} = \{41, 4, 2\}.$$

So $\deg K^5_{3,4} = \deg K^5_{4,3}$ is even.

c. $m = 3, p = 6, q = 3, q(m + p) + mp = 45 = 1 + 2^2 + 2^3 + 2^5$. There is only one disjoint binary partition equal to $\{8, 6, 4\}$ mod 9:

$$\{2^3, 1 + 2^5, 2^2\} = \{8, 33, 4\}.$$

So $\deg K^3_{3,6} = \deg K^3_{6,3}$ is odd.

d. $m = 5, p = 6, q = 3, q(m + p) + mp = 63 = 1 + 2 + 2^2 + 2^3 + 2^4 + 2^5$. There is only one disjoint binary partition equal to $\{10, 8, 6, 4, 2\}$ mod 11:

$$\{2^5, 2^3, 1 + 2^4, 2^2, 2\} = \{32, 8, 17, 4, 2\}.$$

So $\deg K^3_{5,6} = \deg K^3_{6,5}$ is odd.

Proof. Without loss of generality, assume $m \le p$. Consider again the description of the degree of the variety $K^q_{m,p}$ as it was provided in formula (4.2). It is our goal to show that in the summation mod 2 the only relevant permutation is $\sigma = id$. In other words, we will show by clever "book keeping" that all other multinomial coefficients are either 0 or cancel each other.

First assume σ is not an idempotent, i.e., $\sigma^2 \neq id$ or $\sigma \neq \sigma^{-1}$. In this case we immediately verify that the sets

$$\{((p-m-1)+i+\sigma(i)+n_i(m+p)) \mid i=1,\ldots,m\}$$

and

$$\{((p-m-1)+i+\sigma^{-1}(i)+n_{\sigma^{-1}(i)}(m+p)) \mid i=1,\ldots,m\}$$

are equal as unordered sets. But this just means that the corresponding multinomial coefficients in the summation (4.2) cancel each other mod 2. So it follows that we only have to sum over idempotent permutations.

Assume therefore that $\sigma^2 = id$. If $\sigma \neq id$ then σ contains a pure transposition, i.e., there are two distinct integers a, b having the property that $\sigma(a) = b$ and $\sigma(b) = a$. Consider the ordered set

$$(((p-m-1)+i+\sigma(i)+n_i(m+p)) \mid i=1,\ldots,m).$$

If $n_a = n_b$, then the corresponding multinomial coefficient is zero since two numbers in the binary partition (namely the numbers at positions a and b) are equal. On the other hand if $n_a \neq n_b$, then the corresponding multinomial coefficient cancels with the multinomial coefficient obtained by interchanging n_a and n_b.

It therefore follows that the only relevant summand in (4.2) is $\sigma = id$. The mod 2 degree of $K^q_{m,p}$ reduces, therefore, to the evaluation of the mod 2 sum of

(4.4)

$$\sum_{n_1+\cdots+n_m=q} \binom{(mp+q(m+p))}{p-m+1+n_1(m+p),\ p-m+3+n_2(m+p),\ \ldots,\ p+m-1+n_m(m+p)}.$$

Since a summand

$$\binom{(mp+q(m+p))}{p-m+1+n_1(m+p),\ p-m+3+n_2(m+p),\ \ldots,\ p+m-1+n_m(m+p)}$$

is odd if and only if $\{p-m+1+n_1(m+p), \ldots, p+m-1+n_m(m+p)\}$ is a disjoint binary partition of $mp+q(m+p)$, the deg $K^q_{m,p}$ is odd if and only if the number of disjoint binary partitions equal to $\{p-m+1, p-m+3, \ldots, p+m-1\}$ mod $m+p$ of $q(m+p)+mp$ is odd. □

For the Grassmann variety it is possible to identify the first Chern class c_1 (respectively, the first Stiefel-Whitney class w_1) of the classifying bundle with the first elementary symmetric function

$$x_1+\cdots+x_m \in \mathcal{Z}[x_1,\ldots,x_m].$$

The degree (respectively, the mod 2 degree) of the Grassmann variety is then represented through the coefficient of a certain monom (see [23] for details) in the expansion of

$$(x_1+\cdots+x_m)^{\dim \mathrm{Grass}(m,m+p)}.$$

For the mod 2 degree of the variety $K^q_{m,p}$, Theorem 4.2 gives a way to do a similar computation. For this consider the polynomial ring $\mathcal{Z}_2[x_1,\ldots,x_m]$, the ideal

$$I := \left\langle x_1^{m+p}-1, \ldots, x_m^{m+p}-1 \right\rangle,$$

and the factor ring $R := \mathcal{Z}_2[x_1,\ldots,x_m]/I$. Then we have the following corollary.

COROLLARY 4.4. *If $m \leq p$ the* mod 2 *degree of the variety $K^q_{m,p}$ is equal to the coefficient of the monom $x_1^{m+p-1}x_2^{m+p-3}\cdots x_m^{p-m+1}$ in the expansion of*

$$(x_1 + \cdots + x_m)^{\dim K^q_{m,p}} \in R.$$

Proof. From the proof of Theorem 4.2 it follows that the mod 2 degree of $K^q_{m,p}$ is equal to the sum of certain multinomial coefficients of the form

$$\binom{\dim K^q_{m,p}}{k_1, \ldots, k_m} = \binom{q(m+p)+mp}{k_1, \ldots, k_m}.$$

Since the mod $(m+p)$ identification of disjoint binary partitions in Theorem 4.2 corresponds to the ideal theoretic identification of monoms in the factor ring R, the total mod 2 number of identified monoms is exactly the mod 2 degree of $K^q_{m,p}$. □

In practice we can often use the "freshman's dream"

$$(x_1 + \cdots + x_m)^{2^k} = x_1^{2^k} + \cdots + x_m^{2^k} \mod 2.$$

The following examples illustrate the corollary.

Example 4.5. a. $m = 2$, $p = 3$, $q = 3$. In this case $\dim K^3_{2,3} = 21$ and we know from the table at the end of §3 that $\deg K^3_{2,3} = 6765$. Using the corollary we compute

$$(x+y+z)^{21} = (x^{16}+y^{16}+z^{16})(x+y+z)^5 = (x^2+y^2+z^2)^3.$$

Since the coefficient in front of the monom x^4y^2 is indeed 1, we conclude once more that $K^3_{2,3}$ is of odd degree.

b. $m = 3, p = 4, q = 69, q(m+p)+mp = 495 = 1+2+2^2+2^3+2^5+2^6+2^7+2^8$. Since the dimension is quite large we reduce mod 7 in the first step:

$$(1, 2, 2^2, 2^3, 2^5, 2^6, 2^7, 2^8) = (1, 2, 4, 1, 4, 1, 2, 4) \mod 7.$$

Using this reduction we have

$$\begin{aligned}(x+y+z)^{495} &= (x+y+z)^3(x^2+y^2+z^2)^2(x^4+y^4+z^4)^3\\ &= (x+y+z)(x^4+y^4+z^4).\end{aligned}$$

Since there is no monom $x^6y^4z^2$ in this expansion, we conclude that $K^{69}_{3,4}$ and $K^{69}_{4,3}$ both have an even degree.

COROLLARY 4.6. *Let* $\min(m, p) > 1$. *Then any of the following conditions implies that* $\deg K^q_{m,p}$ *is even:*

a) $m + p$ *is even.*
b) $mp + 3 > (m+p)(q+2)$.
c) $\min(m, p) \geq q + 2 + \sqrt{q^2+4q+1}$.
d) *The binary number of* $q(m+p)+mp$ *has less than* m 1*'s other than the digit on the* 2^0 *position.*
e) $2^{\min(m,p)+1} > q(m+p)+mp+2$.
f) $\sum_{i=1}^{l} r_i < mp$, *where* $r_i \in [0, m+p)$ *is the number, equals the* $2^{n_i} \bmod m+p$ *in the binary representation* $q(m+p)+mp = 2^{n_1}+\cdots+2^{n_l}$.
g) $m + p = 2^k - 1$.

Proof. Without loss of generality assume that $m \leq p$.

a) When $m+p$ is even, all the integers $p-m+1+n_1(m+p), \ldots, p+m-1+n_m(m+p)$ are odd. By the remark after Lemma 4.1, all multinomial coefficients appearing in (4.4) are even.

b) Let $2^r \le q(m+p)+mp < 2^{r+1}$. Then a necessary condition for $\{p-m+1+n_1(m+p), \dots, p+m-1+n_m(m+p)\}$ to be a disjoint binary partition is

$$p-m+2i-1+n_i(m+p) \ge 2^r$$

for some i. In particular

$$p+m-1+q(m+p) \ge 2^r \ge (1/2)(q(m+p)+mp+1),$$

which implies

$$(m+p)(q+2) \ge mp+3.$$

c) Consider $-(m^2-2(q+2)m+3)$. It has two roots: $q+2 \pm \sqrt{q^2+4q+1}$. So when $m \ge q+2+\sqrt{q^2+4q+1}$,

$$-(m^2-2(q+2)m+3) \le 0.$$

The degree is even if $m=p$ by a). If $m<p$ (note that $q+2-m<0$),

$$\begin{aligned}(m+p)(q+2)-mp-3 &= -(m^2-2(q+2)m+3)+(q+2-m)(p-m)\\ &< -(m^2-2(q+2)m+3)\\ &\le 0.\end{aligned}$$

So c) implies b).

d) Under the condition, $q(m+p)+mp$ cannot have a disjoint binary partition $\{k_1, \dots, k_m\}$ such that none of the k_i is 1.

e) The smallest number such that d) is not satisfied is $2^{m+1}-2$. So e) implies d).

f) A necessary condition for

$$(k_1, \dots, k_m) = (p-m+1, \dots, p+m-1) \mod m+p, \quad k_i > 0,$$

is $\sum_{i=1}^m k_i \ge mp$.

g) Notice that $m+p$ is odd. So $2 \le m < p$. For any $n \ge k$, let $n = ak+r$, $0 \le r < k$. Then

$$2^n = 2^r(1+2^k+\cdots+2^{k(a-1)})(2^k-1)+2^r.$$

So $2^n = 2^r \mod m+p$. Let the binary representation of $q(m+p)+mp$ be $2^{n_1}+2^{n_2}+\cdots+2^{n_l}$ and consider

$$\prod_{i=1}^{l}(x_1^{2^{n_i}}+\cdots+x_m^{2^{n_i}}).$$

By replacing 2^{n_i} with 2^{r_i} for $r_i = n_i \mod k$, $r_i \in [0,k)$, and using the property

$$(x_1^{2^r}+\cdots+x_m^{2^r})^2 = (x_1^{2^{r+1}}+\cdots+x_m^{2^{r+1}}) \mod 2$$

repeatedly, we get

$$\prod_{i=1}^{j}(x_1^{2^{r_i}}+\cdots+x_m^{2^{r_i}}), \tag{4.5}$$

with $\{r_1, \dots, r_j\} \subset [0,k)$ distinct. The polynomial (4.5) has degree at most $1+2+\cdots+2^{k-1} = m+p$, which is always less than mp under the condition $2 \le m < p$. By the same argument as in the proof of (f), the degree is even. □

An immediate corollary of Theorem 4.2 is the result of [1]: deg Grass$(m, m+p)$ is odd if and only if

1. $\min(m, p) = 1$ or
2. $\min(m, p) = 2$, $\max(m, p) = 2^k - 1$.

We say this corollary is immediate because when $m = 2 \leq p$, $\{p+1, p-1\}$ is a disjoint binary partition if and only if $p = 2^k - 1$, and when $\min(m, p) \geq 3$, all the degrees are even by Corollary 4.6 (c).

COROLLARY 4.7. deg $K^1_{m,p}$ *is odd if and only if either*

1. $\min(m, p) = 1$ *or*
2. $\min(m, p) = 2$, $\max(m, p) = 2^{n_1} + 2^{n_2} + \cdots + 2^{n_l} - 1$ *with* $n_{i+1} > n_i + 1$, $i = 1, \ldots, l-1$.

Proof. By letting $m + p = 1 + 2^{n_1} + \cdots + 2^{n_l}$ we can easily show that neither of the sets

$$\{m+p-1, m+p-3, m+p-5\},\ \{2(m+p)-1, m+p-3, m+p-5\},$$

$$\{m+p-1, 2(m+p)-3, m+p-5\},\ \{m+p-1, m+p-3, 2(m+p)-5\}$$

can have disjoint exponents in the binary representations of the elements. So the degree is even if $\min(m, p) \geq 3$. Now let $m = 2$, $p > m$, be odd and

$$p + 1 = 2^{n_1} + \cdots + 2^{n_l}.$$

Then 2^{n_1} appears in both $p + 1 = m + p - 1$ and $2p + 1 = 2(m + p) - 3$. So deg $K^1_{2,p}$ is odd if and only if

$$\{p-1, 2p+3\} = \{2 + 2^2 + \cdots + 2^{n_1 - 1} + 2^{n_2} + \cdots + 2^{n_l},\ 1 + 2^{n_1+1} + \cdots + 2^{n_l+1}\}$$

is a disjoint binary partition, i.e., if and only if $n_{i+1} > n_i + 1$ for $i = 1, \ldots, l-1$. □

Similar results can also be proven for $q > 1$. The combinatorics however becomes very involved. We provide without proof the result for $q = 2$.

COROLLARY 4.8. deg $K^2_{m,p}$ *is odd if and only if either*

1. $\min(m, p) = 1$,
2. $\min(m, p) = 2$, $\max(m, p) = 8(\frac{4^k - 1}{3}) + 1$, *or*
3. $\min(m, p) = 3$, $\max(m, p) = 8$.

5. Corollaries and additional new positive pole placement results. In this section we establish the connection to the classical state space and transfer function formulation of the pole placement problem. We also derive several results which combine the results derived in §3 with some results derived in [17].

Consider a controllable observable linear system

$$\dot{x} = Ax + Bu, \quad y = Cx, \tag{5.1}$$

where $x \in \mathbb{R}^n$, $u \in \mathbb{R}^m$, and $y \in \mathbb{R}^p$, respectively. If a controllable observable dynamic compensator of order q,

$$\dot{u} = Fu + Ey, \quad u = Hu + Ky, \tag{5.2}$$

is applied to the system, the closed-loop system becomes

$$\begin{pmatrix} \dot{x} \\ \dot{u} \end{pmatrix} = \begin{pmatrix} A + BKC & BH \\ EC & F \end{pmatrix} \begin{pmatrix} x \\ u \end{pmatrix}, \quad y = Cx. \tag{5.3}$$

So the closed-loop characteristic polynomial is

$$\phi(s) = \det \begin{pmatrix} sI - A - BKC & -BH \\ -EC & sI - F \end{pmatrix}. \tag{5.4}$$

If $G(s) = C(sI - A)^{-1}B$ and $T(s) = K + H(sI - F)^{-1}E$ are the transfer functions of the system (5.1) and compensator (5.2), respectively, and if $G(s) = D(s)^{-1}N(s)$ and $T(s) = T_d^{-1}(s)T_n(s)$ are left coprime fractions such that $\det(sI - A) = \det D(s)$ and $\det(sI - F) = \det T_d(s)$, then $\phi(s)$ can also be written as

$$\phi(s) = \det(sI - A)\det(I - G(s)T(s))\det(sI - F) = \det \begin{pmatrix} D(s) & N(s) \\ T_n(s) & T_d(s) \end{pmatrix}. \tag{5.5}$$

Let $P(s) = (D(s)\ N(s))$ and $C(s) = (T_n(s)\ T_d(s))$. Then $P(s)$ and $C(s)$ can be viewed as autoregressive systems describing the behavior of the plant and the compensator, respectively. The combined dynamics are then described by

$$\begin{pmatrix} D(\frac{d}{dt}) & N(\frac{d}{dt}) \\ T_n(\frac{d}{dt}) & T_d(\frac{d}{dt}) \end{pmatrix} \cdot \begin{pmatrix} y \\ -u \end{pmatrix}(t) = 0. \tag{5.6}$$

The following result combines Theorem 2.15 with [17, Cor. 5.8].

THEOREM 5.1. *Consider a generic set of matrices* $(A, B, C) \in \mathbb{R}^{n(n+m+p)}$ *describing a plant as in* (5.1) *and consider an arbitrary monic polynomial* $\phi(s) \in \mathbb{R}[s]$ *of degree* $n + q$. *If*

$$n \leq q(m + p - 1) + mp, \tag{5.7}$$

then there exists a complex dynamic compensator of the form (5.2) *resulting in the closed-loop characteristic polynomial* $\phi(s)$. *If in addition the number* $d(m, p, q)$ *introduced in* (1.5) *is odd, then there even exists a real compensator assigning the closed-loop characteristic polynomial* $\phi(s)$.

Proof. We only outline the main steps. Using the same argument as in Theorem 2.15, we verify that $\dim B_p = q(m + p) + mp - n - q - 1$ for the generic and strictly proper plant. Theorem 2.14 therefore still applies and the pole placement map is onto if we allow all autoregressive systems. Since the plant is strictly proper a closed-loop characteristic polynomial of degree $n + q$ can only be achieved if the compensator is proper. □

The following example illustrates how this theorem can be applied.

Example 5.2. Assume the matrices (A, B, C) describe the plant parameters of a generic real 2-input, 9-output plant of McMillan degree n. From Table 1 it follows immediately that there exists a real compensator of degree 1 as long as $n \leq 28$. If, e.g., $n \leq 58$, then it follows that there is a real compensator of degree 4 assigning an arbitrary set of self-conjugate closed-loop poles.

Combining Theorem 2.15 with [17, Cor. 5.9] one can finally prove the following result.

THEOREM 5.3. *Let* $G(s)$ *be a generic* m*-input,* p*-output proper transfer function of McMillan degree* n *and let* $\phi(s) \in \mathbb{K}[s]$ *be a generic polynomial of degree* $n + q$. *If*

$$n \leq q(m + p - 1) + mp, \tag{5.8}$$

then there exists a proper complex compensator $T(s)$ *of McMillan degree* q *such that the closed-loop transfer function*

$$G_T(s) := (I - G(s)T(s))^{-1}G(s)$$

has characteristic polynomial $\phi(s)$. *If in addition the number* $d(m, p, q)$ *introduced in* (1.5) *is odd, then there even exists a real transfer function* $T(s)$.

ON THE GENERICITY OF STABILIZABILITY FOR TIME-DELAY SYSTEMS*

LUC C. G. J. M. HABETS†

Abstract. Conditions for the stabilizability of time-delay systems with incommensurable point delays by dynamic state feedback are known in the literature. In this paper it is shown that these conditions are satisfied generically.

Although an algebraic approach is used to describe the class of all time-delay systems with point delays, the concept of genericity is formulated in a topological framework. In the metric space consisting of all parametrizations of time-delay systems, the subset of all stabilizable systems is an open and dense subset.

The proof is given for the commensurable delay case first. It is shown that the incommensurable delay case is not significantly more difficult and that the same arguments prove also that systems with incommensurable time-delays are generically stabilizable.

Key words. time-delay systems with point delays, stabilizability, genericity

AMS subject classifications. 93B25, 93D15, 15A54

1. Introduction.

Time-delay systems with point delays can be seen as rather straightforward generalizations of ordinary linear time-invariant systems. In the delay case, $\dot{x}(t)$, the derivative of the evolution variable x at time t, and $y(t)$, the output y at time t, do not depend only on the evolution variable x and the input u at time t but also on the evolution variable and input from specific time instants in the past. Let $\sigma_1, \ldots, \sigma_k$ denote k delay operators with incommensurable time-delays $\tau_1, \ldots, \tau_k$, acting on the trajectories of the evolution variable and the input:

$$\sigma_i x(t) = x(t - \tau_i), \qquad \sigma_i u(t) = u(t - \tau_i), \qquad (i = 1, \ldots, k). \tag{1}$$

Then a system with k *incommensurable* time-delays $\tau_1, \ldots, \tau_k$ can be written as

$$\begin{cases} \dot{x}(t) = A(\sigma_1, \ldots, \sigma_k)x(t) + B(\sigma_1, \ldots, \sigma_k)u(t), \\ y(t) = C(\sigma_1, \ldots, \sigma_k)x(t) + D(\sigma_1, \ldots, \sigma_k)u(t), \end{cases} \tag{2}$$

where $A(\sigma_1, \ldots, \sigma_k)$, $B(\sigma_1, \ldots, \sigma_k)$, $C(\sigma_1, \ldots, \sigma_k)$, and $D(\sigma_1, \ldots, \sigma_k)$ are polynomial matrices in the delay operators $\sigma_1, \ldots, \sigma_k$ of appropriate dimensions. Note that the state of this system at time t is not the evolution variable $x(t)$ but the time-trajectory $\{x(\xi) \mid \xi \in [t-T, t]\}$ of this evolution variable. Here T denotes the length of the largest time-delay occurring in (2).

After substitution of indeterminates $s_1, \ldots, s_k$ for the delay operators $\sigma_1, \ldots, \sigma_k$ in (2), the system $\Sigma = (A(s_1, \ldots, s_k), B(s_1, \ldots, s_k), C(s_1, \ldots, s_k), D(s_1, \ldots, s_k))$ over the polynomial ring $\mathbb{R}[s_1, \ldots, s_k]$ is obtained. Together with the delays $\tau_1, \ldots, \tau_k$, this quadruple of matrices is a complete description of the delay system (2); since the time-delays $\tau_1, \ldots, \tau_k$ are incommensurable, there is a 1-1 correspondence between time-delay systems of the form (2) and systems $\Sigma = (A(s_1, \ldots, s_k), B(s_1, \ldots, s_k), C(s_1, \ldots, s_k), D(s_1, \ldots, s_k))$ over the ring $\mathbb{R}[s_1, \ldots, s_k]$.

To study the concept of internal stability for time-delay systems, consider the differential-difference equation for the evolution variable x, and assume that no input is applied. Then the system is called *internally stable* if, independent of the given initial conditions, the evolution

*Received by the editors April 23, 1993; accepted for publication (in revised form) December 23, 1994. This research was supported by the Netherlands Organization for Scientific Research (NWO) and carried out while the author was with the Department of Mathematics and Computing Science, Eindhoven University of Technology, Eindhoven, the Netherlands.

†Institut für Dynamische Systeme, Department of Mathematics, University of Bremen, P.O. Box 330 440, D-28334 Bremen, Germany (luc@mathematik.uni-Bremen.de).

variable $x(t)$ tends to zero for $t \to \infty$. According to [7, Cor. 4.1, p. 182], this notion of stability is equivalent to the following condition on the matrix $A(s_1, \ldots, s_k)$:

$$\forall \lambda \in \overline{\mathbb{C}^+} : \det(\lambda I - A(e^{-\tau_1 \lambda}, \ldots, e^{-\tau_k \lambda})) \neq 0.$$

Here $\tau_1, \ldots, \tau_k$ are the time-delays of the delay operators $\sigma_1, \ldots, \sigma_k$ corresponding to the indeterminates $s_1, \ldots, s_k$, and $\mathbb{C}^+$ denotes the open complex right half plane.

If a system is not internally stable, this property may be achieved by a proper choice of a static or dynamic feedback compensator. Completely analogous to the case of systems without delays, this so-called stabilizability problem can be split into two dual parts: the problem of stabilization by (static or dynamic) *state* feedback and the detectability problem. In the rest of this paper we confine ourselves to the problem of stabilizability by state feedback and therefore assume that $C = I$ and $D = 0$.

In the literature, the problem of stabilizability of time-delay systems has been solved in at least two different ways. Surprisingly, both the infinite-dimensional systems approach and the systems over rings approach yield the same conditions for the solvability of this problem. However, there are also important differences between these results. In the infinite-dimensional systems approach, a static state feedback (possibly containing distributed time-delays) suffices to achieve internal stability, whereas in the algebraic approach a dynamic feedback compensator (containing only point delays) is required for this.

THEOREM 1.1 (see [12], [3], [14], [4]). *Consider a time-delay system* Σ*:*

$$\dot{x}(t) = A(\sigma_1, \ldots, \sigma_k)x(t) + B(\sigma_1, \ldots, \sigma_k)u(t), \tag{3}$$

where σ_i $(i = 1, \ldots, k)$ *denotes the delay operator with time-delay* τ_i *and where* $A(\sigma_1, \ldots, \sigma_k)$ *and* $B(\sigma_1, \ldots, \sigma_k)$ *are matrices of polynomials in the delay operators* $\sigma_1, \ldots, \sigma_k$*, of size* $n \times n$ *and* $n \times m$*, respectively. Substitute indeterminates* $s_1, \ldots, s_k$ *for* $\sigma_1, \ldots, \sigma_k$ *and regard* $\Sigma = (A(s_1, \ldots, s_k), B(s_1, \ldots, s_k))$ *as a linear system over the polynomial ring* $\mathcal{R} = \mathbb{R}[s_1, \ldots, s_k]$*. Then the following three conditions are equivalent:*

(i) Σ *is internally stabilizable by a dynamic state feedback compensator only containing point delays,*

(ii) Σ *is internally stabilizable by a static state feedback, possibly containing distributed time-delays,*

(iii) $\forall z \in \overline{\mathbb{C}^+} : \operatorname{rank}(zI - A(e^{-\tau_1 z}, \ldots, e^{-\tau_k z}) \mid B(e^{-\tau_1 z}, \ldots, e^{-\tau_k z})) = n.$ (4)

Rank condition (iii), which can be seen as a generalization of the well-known Hautus test (see [8]) to the case of time-delay systems with point delays, is the starting point of this paper. We shall prove that this condition is generically satisfied on the parameter-space describing all time-delay systems with point delays of the form (3). This means that condition (iii) is very weak; it is satisfied for most time-delay systems.

The condition of reachability for systems over polynomial rings (see, e.g., [9], [16]) can be stated as a rank condition in almost the same way as the stabilizability condition (for a short proof see, for example, [5]). In [11], Lee and Olbrot prove that this condition is generically satisfied if and only if the number of inputs to the system is larger than the number of indeterminates of the polynomial ring (i.e., the number of incommensurable time-delays). Their approach is completely algebraic; they compare the number of polynomial equations that have to be satisfied with the number of unknowns and apply some results from algebraic geometry to prove their result (except on some hypersurfaces in the parameter-space of all time-delay systems, the reachability condition is always satisfied).

At first sight, this approach also looks very promising for solving the genericity problem of stabilizability for time-delay systems. In this case, however, each indeterminate s_i in the polynomial ring corresponds to a delay operator σ_i of length τ_i, and in the Laplace domain

σ_i and τ_i are interrelated via an exponential function. In this way some extra (exponential) equations are obtained that are probably enough to remove the condition on the number of inputs. Unfortunately, this method fails because we are now dealing with both polynomial and exponential equations, which do not fit into the algebraic-geometric framework any more.

In this paper we choose a completely different approach; we describe the concept of genericity in a topological way. In this setting, a certain property is called *generic* if it holds on an open and dense subset of the parameter-space describing all time-delay systems. However, before we can speak of open or dense subsets, we first have to introduce a topology on this space. This topology formalizes our intuitive ideas on the following question: when are the parametrizations of two time-delay systems said to be close to each other? In §2 this topological framework is treated in more detail.

Then all tools are available to prove that the set of stabilizable time-delay systems is open, which is described in our §3. The proof of denseness is more involved. In §4 we start with some preliminary results on matrices over the ring of analytic functions. These are used in §5 to show that the set of stabilizable time-delay systems is indeed a dense subset of the parameter-space describing all time-delay systems.

Remark 1.2. In the rest of this paper it is always tacitly assumed that we are dealing with time-delay systems with commensurable delays. This implies that there is only one delay operator σ required to describe the system equations (2). In general, this situation is much simpler than the incommensurable delay case. Fortunately this distinction does not make any difference for the approach we take to the problem. All results are easily generalized to the incommensurable delay case because the assumption of the presence of only one time-delay operator is never used explicitly. This assumption is only made to simplify notation to highlight the really important ideas more clearly. In §6 we return to this subject briefly and explain why the methods developed in this paper are also applicable in the incommensurable delay case.

2. A topological framework for time-delay systems. This section is devoted to the introduction of a topology on the parameter-space describing all time-delay systems with commensurable time-delays. This topology reflects our intuitive notion of the concept of genericity. Also the space of all 2-dimensional polynomials is equipped with a suitable norm. These polynomials, and especially characteristic polynomials, play a vital role in the characterization of stability. Some of the topological aspects of this relationship are discussed in more detail.

Consider a triple $\Sigma = (A(s), B(s), \tau)$, with $A(s) \in \mathbb{R}[s]^{n\times n}$, $B(s) \in \mathbb{R}[s]^{n\times m}$, and $\tau \in \mathbb{R}^+$. After substitution of the delay operator σ with time-delay τ for the indeterminate s, such a triple is a complete description of the time-delay system:

$$\begin{cases} \dot{x}(t) = A(\sigma)x(t) + B(\sigma)u(t), \\ \sigma x(t) = x(t-\tau), \qquad \sigma u(t) = u(t-\tau). \end{cases} \tag{5}$$

On the other hand, the triple $\Sigma = (A(s), B(s), \tau)$ can be seen as a point in the parameter-space

$$\mathcal{V} = \{(A(s), B(s), \tau) \mid A(s) \in \mathbb{R}[s]^{n\times n}, B(s) \in \mathbb{R}[s]^{n\times m}, \tau \in \mathbb{R}^+\}. \tag{6}$$

Clearly, to each element of $\mathcal{V}$ there corresponds a time-delay system as defined in (5). By imposing a metric on each of the three components of $\mathcal{V}$, the parameter-space $\mathcal{V}$ is turned into a metric space, and thereby its topology is fixed. We start with the introduction of a norm on polynomial matrices in $\mathbb{R}[s]^{p\times q}$.

Let $P(s)$ be a $p \times q$ polynomial matrix over $\mathbb{R}[s]$. Then there exists an $\ell \in \mathbb{N} \cup \{0\}$ and real matrices $P_0, P_1, \ldots, P_\ell$, with $P_\ell \neq 0$, such that

$$P(s) = \sum_{i=0}^{\ell} P_i s^i.$$

This ℓ is called the *degree* of the polynomial matrix $P(s)$ and is denoted by $\ell = \deg(P(s))$. Defining $P_i := 0$ for $i > \ell$, we can map the polynomial matrix $P(s)$ to the sequence $(P_i)_{i=0}^{\infty}$ of real matrices. In this way we obtain an explicit description of $P(s)$ in terms of its parameters. In fact, there is a 1-1 correspondence between polynomial matrices and the space $\ell_0(\mathbb{R}^{p\times q})$ consisting of all real matrix sequences with only a finite number of nonzero elements (i.e., matrices with at least one nonzero entry), via the bijection

$$\psi : \ell_0(\mathbb{R}^{p\times q}) \to \mathbb{R}[s]^{p\times q} : \psi((P_i)_{i=0}^{\infty}) = \sum_{i=0}^{\infty} P_i s^i.$$

The space $\ell_0(\mathbb{R}^{p\times q})$ is easily turned into a normed space by defining the norm of $(P_i)_{i=0}^{\infty}$ by

$$\|(P_i)_{i=0}^{\infty}\| = \sum_{i=0}^{\infty} \|P_i\|,$$

where $\|P_i\|$ is the operator induced norm of the real matrix P_i. It is evident that the same norm can also be used for polynomial matrices.

DEFINITION 2.1. *Let $P(s)$ be a $p \times q$ matrix over $\mathbb{R}[s]$. Let $(P_i)_{i=0}^{\infty} \in \ell_0(\mathbb{R}^{p\times q})$ be such that*

$$P(s) = \sum_{i=0}^{\infty} P_i s^i. \tag{7}$$

Then the norm *of $P(s)$ is defined as*

$$\|P(s)\|_{pm} := \sum_{i=0}^{\infty} \|P_i\|, \tag{8}$$

where $\|P_i\|$ is the operator induced matrix norm of P_i for all $i \in \mathbb{N} \cup \{0\}$.

The norm $\|\cdot\|_{pm}$ for polynomial matrices has a very important property. In the Introduction we have seen that for the investigation of the stability properties of a time-delay system, the exponential function $e^{-\tau z}$ has to be substituted for the indeterminate s in a polynomial matrix $A(s)$. Since for all $z \in \overline{\mathbb{C}^+}$, the norm $|e^{-\tau z}|$ is bounded above by 1, the norm $\|P(s)\|_{pm}$ of the polynomial matrix $P(s)$ is a uniform upper bound for the norm of $P(e^{-\tau z})$ in the closed right half plane.

LEMMA 2.2. *Let $P(s) \in \mathbb{R}[s]^{p\times q}$. Then for all $\tau > 0$ and for all $z \in \overline{\mathbb{C}^+}$, we have*

$$\|P(e^{-\tau z})\| \leq \|P(s)\|_{pm}.$$

With condition (iii) of Theorem 1.1 in mind, we see that Lemma 2.2 has a very interesting consequence for square polynomial matrices.

COROLLARY 2.3. *Let $A(s) \in \mathbb{R}[s]^{n\times n}$. Then for all $\tau > 0$ and $z \in \overline{\mathbb{C}^+}$, and for all $w \in \mathbb{C}$ satisfying $|w| > \|A(s)\|_{pm}$, we have*

$$\operatorname{rank}(wI - A(e^{-\tau z})) = n.$$

Using Definition 2.1, the parameter-space $\mathcal{V}$ may be equipped with a suitable metric.

DEFINITION 2.4. *Let* $\Sigma_1 = (A_1(s), B_1(s), \tau_1)$ *and* $\Sigma_2 = (A_2(s), B_2(s), \tau_2)$ *be two elements of the parameter-space* $\mathcal{V}$. *Then the* distance *between* Σ_1 *and* Σ_2 *is defined as*

$$d_{\mathcal{V}}(\Sigma_1, \Sigma_2) := \|A_1(s) - A_2(s)\|_{pm} + \|B_1(s) - B_2(s)\|_{pm} + |\tau_1 - \tau_2|. \tag{9}$$

With this distance function $d_{\mathcal{V}}(\cdot, \cdot)$, *the parameter-space* $\mathcal{V}$ *becomes a* metric space.

Once the topology on the parameter-space $\mathcal{V}$ has been fixed, the concept of genericity is easily defined. For each triple $\Sigma = (A(s), B(s), \tau)$ in $\mathcal{V}$, it is possible to check the stabilizability of the corresponding time-delay system using Theorem 1.1. Let

$$S := \{(A(s), B(s), \tau) \in \mathcal{V} \mid \forall z \in \overline{\mathbb{C}^+} : \operatorname{rank}(zI - A(e^{-\tau z}) | B(e^{-\tau z})) = n\}$$

be the set of all stabilizable delay systems. Then the property of stabilizability is called *generic* if the set S is an open and dense subset of the parameter-space $\mathcal{V}$. In the topology on $\mathcal{V}$ generated by the metric $d_{\mathcal{V}}(\cdot, \cdot)$, this implies that the set S covers almost the whole space $\mathcal{V}$:

(i) *S is open.* A stabilizable time-delay system remains stabilizable after a small perturbation of the parameters describing the system (i.e., the property of stabilizability is a robust property).

(ii) *S is a dense subset of $\mathcal{V}$.* Every element $\Sigma \in \mathcal{V}$ can be approximated arbitrarily close by a sequence of stabilizable systems (i.e., a sequence in S).

We see that the topology generated by the metric of Definition 2.4 leads to a formal definition of genericity that looks very natural and that is completely in accordance with our intuitive notion of this concept.

In almost the same way as for polynomial matrices, it is possible to regard the polynomial ring $\mathbb{R}[s, z]$ as a linear space and to define a norm on this space.

DEFINITION 2.5. *Let* $p(s, z) \in \mathbb{R}[s, z]$, *and write* $p(s, z)$ *as*

$$p(s, z) = \sum_{i=0}^{\ell} \sum_{j=0}^{k} p_{ij} s^j z^i. \tag{10}$$

Then the norm of $p(s, z)$ *is defined as*

$$\|p(s, z)\|_p := \sum_{i=0}^{\ell} \sum_{j=0}^{k} |p_{ij}|. \tag{11}$$

With this norm, $\mathbb{R}[s, z]$ *becomes a normed ring.*

Analogously to the polynomial matrix case, there exists a 1-1 correspondence between polynomials $p(s, z)$ in two variables and exponential polynomials of the form $p(e^{-\tau z}, z)$. Characteristic polynomials of this form determine the stabilizability of a time-delay system. From this point of view, the norm of Definition 2.5 has several interesting properties. For example, the norm $\|p(s, z)\|_p$ is a good measure for the magnitude of $|p(e^{-\tau z}, z)|$ in a bounded part of the closed right half plane.

LEMMA 2.6. *Let* $p(s, z) \in \mathbb{R}[s, z]$, *and assume that the degree of* p *in* z *is* n, *i.e.,*

$$p(s, z) = \sum_{i=0}^{n} \sum_{j=0}^{k} p_{ij} s^j z^i,$$

and there exists a $j \in \{0, \ldots, k\}$ *such that* $p_{nj} \neq 0$. *Let* $M > 1$ *and* $\varepsilon > 0$. *If*

$$\|p(s, z)\|_p < \varepsilon \cdot \frac{M - 1}{M^{n+1} - 1}, \tag{12}$$

then

$$\forall \tau > 0 \, \forall z \in \overline{\mathbb{C}^+} \text{ s.t. } |z| \leq M : |p(e^{-\tau z}, z)| < \varepsilon. \tag{13}$$

Finally there is a clear relationship between polynomial matrices in one indeterminate on the one hand and 2-dimensional polynomials on the other. In this relationship the characteristic polynomial plays the leading role. In the rest of this paper we need only the following result.

PROPOSITION 2.7. *Let* $A(s) \in \mathbb{R}[s]^{n \times n}$. *Then*

$$\forall \varepsilon > 0 \, \exists \delta > 0 \, \forall B(s) \in \mathbb{R}[s]^{n \times n} :$$
$$\|A(s) - B(s)\|_{pm} < \delta \Longrightarrow \|\det(zI - A(s)) - \det(zI - B(s))\|_p < \varepsilon.$$

According to Proposition 2.7, the map χ,

$$\chi : \mathbb{R}[s]^{n \times n} \longrightarrow \mathbb{R}[s, z] : \chi(A(s)) = \det(zI - A(s)), \tag{14}$$

is continuous with respect to the norms on $\mathbb{R}[s]^{n \times n}$ and $\mathbb{R}[s, z]$ as defined in (8) and (11), respectively. The validity of this result follows from the fact that the determinant of a matrix is a sum of products of its entries. Since both addition and multiplication are continuous operations, a proof of Proposition 2.7 follows straightforwardly.

Remark 2.8. With the norms and metrics defined in this section, none of the spaces $\mathcal{V}$, $\mathbb{R}[s]^{p \times q}$, or $\mathbb{R}[s, z]$ becomes a complete metric space. All these spaces basically consist of sequences (of scalars or matrices) with a finite number of nonzero elements. However, we imposed a sort of ℓ_1-norm on these spaces that does not distinguish between sequences with a finite and an infinite number of nonzero elements. Therefore it is easy to construct a Cauchy sequence that does not converge.

Fortunately, this somewhat unsatisfactory situation is not troublesome because completeness is never used in the proofs of our genericity result. Moreover, this problem may be solved by introducing so-called *inductive limit topologies* (see, e.g., [1, Chap. IV, §5]). For the study of genericity of more general concepts of stabilizability, this topology is indispensable (see [6, §3.3]), but in our case, inductive limit topologies would make things unnecessarily complicated.

3. On the robustness of the property of stabilizability. In this section the first part of our genericity result is proved. Based on the topological framework introduced in the previous section, it is shown that the subset S of $\mathcal{V}$, consisting of all parametrizations of stabilizable time-delay systems, is an open subset of $\mathcal{V}$. In practice this means that stabilizability of a time-delay system is a robust property: it is preserved after small perturbations of the parameters. In this section an upper bound is derived for the distance between a nominal stabilizable system and all the perturbed systems that are allowed. If the distance between a perturbed system and the nominal system is smaller than this upper bound, the perturbed system is still stabilizable. Since this upper bound is always larger than zero, this immediately implies that S is open.

From Theorem 1.1 we know that the stabilizability condition for time-delay systems is a full rank condition on a matrix in the variable z, which has to be satisfied for all $z \in \overline{\mathbb{C}^+}$. Now the proof of the main theorem of this section is based on the fact that in $\mathbb{C}^{n \times (n+m)}$ the set of all matrices of full row rank is open, i.e., a full row rank matrix in $\mathbb{C}^{n \times (n+m)}$ remains of full row rank after small perturbations of its entries.

THEOREM 3.1. *Let* $\Sigma_0 = (A_0(s), B_0(s), \tau_0)$ *be a point in* $\mathcal{V}$, *and assume that the time-delay system* (5) *corresponding to* Σ_0 *is stabilizable, i.e.,*

$$\forall z \in \overline{\mathbb{C}^+} : \operatorname{rank}(zI - A_0(e^{-\tau_0 z}) | B_0(e^{-\tau_0 z})) = n.$$

Then there exists a $\rho > 0$ such that all systems Σ in the ball around Σ_0 with radius ρ,

$$\mathcal{B}(\Sigma_0, \rho) := \{\Sigma \in \mathcal{V} \mid d_{\mathcal{V}}(\Sigma, \Sigma_0) < \rho\},$$

are stabilizable.

Proof. First of all there exists an $\ell \in \mathbb{N}$ such that $A_0(s)$ and $B_0(s)$ can be written as

$$A_0(s) = \sum_{i=0}^{\ell} A_i s^i, \qquad B_0(s) = \sum_{i=0}^{\ell} B_i s^i.$$

Next define G as

$$G := \{z \in \mathbb{C} \mid \operatorname{Re} z \geq 0 \text{ and } |z| \leq \|A_0(s)\|_{pm} + 1\}. \tag{15}$$

Since the delay system corresponding to $\Sigma_0 = (A_0(s), B_0(s), \tau_0)$ is stabilizable, it follows from [3] or [14] that the matrix $(zI - A_0(e^{-\tau_0 z})|B_0(e^{-\tau_0 z}))$ has a right-inverse $T(z)$ that is analytic on $\overline{\mathbb{C}^+}$. Now G is a compact subset of $\overline{\mathbb{C}^+}$, so $T(z)$ is bounded on G, and thus

$$K := \max\{\|T(z)\| \mid z \in G\} \tag{16}$$

is well defined.

Choose

$$\rho := \min\left(1, \frac{1}{4K}, \frac{1}{\|A_0(s)\|_{pm} + 1} \cdot \frac{1}{4K\ell} \cdot \min\left(\frac{1}{\|A_0(s)\|_{pm}}, \frac{1}{\|B_0(s)\|_{pm}}\right)\right), \tag{17}$$

then clearly $\rho > 0$. We show that all systems in $\mathcal{B}(\Sigma_0, \rho)$ are stabilizable.

Let $\Sigma = (A(s), B(s), \tau) \in \mathcal{V}$ be such that $d_{\mathcal{V}}(\Sigma, \Sigma_0) < \rho$. The proof that Σ is stabilizable, i.e., that

$$\forall z \in \overline{\mathbb{C}^+} : \operatorname{rank}(zI - A(e^{-\tau z}) \mid B(e^{-\tau z})) = n,$$

is divided into two parts: the case $|z| > \|A_0(s)\|_{pm} + 1$ and the case $|z| \leq \|A_0(s)\|_{pm} + 1$.

Let $z \in \overline{\mathbb{C}^+}$, and assume that $|z| > \|A_0(s)\|_{pm} + 1$. Because $d_{\mathcal{V}}(\Sigma, \Sigma_0) < \rho$, we have

$$\|A(s)\|_{pm} \leq \|A_0(s)\|_{pm} + \|A(s) - A_0(s)\|_{pm} < \|A_0(s)\|_{pm} + \rho.$$

Using (17) it follows that $|z| > \|A_0(s)\|_{pm} + 1 \geq \|A_0(s)\|_{pm} + \rho > \|A(s)\|_{pm}$ and, according to Corollary 2.3 (with $w = z$), this implies that

$$\operatorname{rank}(zI - A(e^{-\tau z})) = n.$$

But then certainly $\operatorname{rank}(zI - A(e^{-\tau z}) \mid B(e^{-\tau z})) = n$.

The second part of the proof is more complicated. Let $z \in \overline{\mathbb{C}^+}$, $|z| \leq \|A_0(s)\|_{pm} + 1$. We start by proving that

$$\|(zI - A(e^{-\tau z}) \mid B(e^{-\tau z})) - (zI - A_0(e^{-\tau_0 z}) \mid B_0(e^{-\tau_0 z}))\| < \frac{1}{K}. \tag{18}$$

First note that

$$\|(zI - A(e^{-\tau z}) \mid B(e^{-\tau z})) - (zI - A_0(e^{-\tau_0 z}) \mid B_0(e^{-\tau_0 z}))\|$$

$$\leq \|A_0(e^{-\tau_0 z}) - A(e^{-\tau z})\| + \|B(e^{-\tau z}) - B_0(e^{-\tau_0 z})\|. \tag{19}$$

Now clearly

$$\|A_0(e^{-\tau_0 z}) - A(e^{-\tau z})\| \leq \|A_0(e^{-\tau_0 z}) - A_0(e^{-\tau z})\| + \|A_0(e^{-\tau z}) - A(e^{-\tau z})\|. \tag{20}$$

With Lemma 2.2 it is easy to see that the second term in (20) is bounded from above. Since $\|A(s) - A_0(s)\|_{pm} \leq d_{\mathcal{V}}(\Sigma, \Sigma_0) < \rho$ and $\rho \leq \frac{1}{4K}$, we obtain

$$\|A_0(e^{-\tau z}) - A(e^{-\tau z})\| \leq \|A_0(s) - A(s)\|_{pm} < \rho \leq \frac{1}{4K}. \tag{21}$$

To estimate the other term, we apply the mean value theorem:

$$\|A_0(e^{-\tau_0 z}) - A_0(e^{-\tau z})\| = \left\| \sum_{i=0}^{\ell} A_i \cdot (e^{-i\tau_0 z} - e^{-i\tau z}) \right\| \leq \sum_{i=0}^{\ell} \|A_i\| \cdot i|z| \int_{\tau_0}^{\tau} |e^{-i\xi z}| d\xi$$

$$\leq \|A_0(s)\|_{pm} \cdot \ell \cdot (\|A_0(s)\|_{pm} + 1) \cdot \rho < \frac{1}{4K}, \tag{22}$$

where in the last inequality (17) was used.

Completely analogously we can prove that

$$\|B(e^{-\tau z}) - B_0(e^{-\tau_0 z})\| \leq \|B(e^{-\tau z}) - B_0(e^{-\tau z})\| + \|B_0(e^{-\tau z}) - B_0(e^{-\tau_0 z})\| < \frac{1}{2K}. \tag{23}$$

Combining the previous inequality with (19)–(22), we get (18).

Now recall that $(zI - A_0(e^{-\tau_0 z}) \mid B_0(e^{-\tau_0 z}))$ is right-invertible, with right-inverse $T(z)$. Moreover $\|T(z)\| \leq K$. So

$$\|(zI - A(e^{-\tau z}) \mid B(e^{-\tau z})) - (zI - A_0(e^{-\tau_0 z}) \mid B_0(e^{-\tau_0 z}))\| < \frac{1}{K} \leq \frac{1}{\|T(z)\|}. \tag{24}$$

Finally, according to [10, p. 399], (24) implies that the matrix $(zI - A(e^{-\tau z}) \mid B(e^{-\tau z}))$ is right-invertible. This completes the proof. □

Remark 3.2. Although Theorem 3.1 seems to have much in common with the result of Pandolfi in [13, §5], there are several differences. First of all, Pandolfi's result is obtained within the more general framework of distributed parameter systems, of which the class of time-delay systems considered in this paper is only a small subclass. Moreover, in the setting of Pandolfi, perturbations of systems are perturbations of the linear operators describing the system, and robustness of stabilizability is studied in this context. In our approach, perturbations are described within the metric space $\mathcal{V}$ of all parametrizations. Although Pandolfi's result holds in a much more general setting, our result is more specialized to capture the concept of genericity for the class of time-delay systems with point delays.

Remark 3.3. For robustness of stabilizability it is crucial that the rank condition for stabilizability, $\operatorname{rank}(zI - A(e^{-\tau z}) \mid B(e^{-\tau z})) = n$, has to be satisfied only on the half plane $\overline{\mathbb{C}^+}$. In [13, §4] it is shown that modal controllability, i.e., the property that the same rank condition is satisfied on the whole complex plane, is not robust. In that situation, the division of the proof into two parts (the cases $|z| > \|A_0(s)\|_{pm} + 1$ and $|z| \leq \|A_0(s)\|_{pm} + 1$) is of no use because the norm of $A(e^{-\tau z})$ may become arbitrarily large when $\operatorname{Re} z \to -\infty$.

4. Some results on matrices over the ring of analytic functions. In the second part of the proof of our genericity result, matrices of analytic functions play an important role. The relationship between the rank of these matrices and their determinants is of special interest. This section can be seen as an intermezzo in which this relationship between rank and determinant is studied using projection matrices.

The first lemma describes how projections can be helpful for the computation of the determinant of a matrix.

LEMMA 4.1. *Let A_1 and A_2 be two arbitrary square matrices, and let E be a projection. Define $\rho(E) := \operatorname{rank}(E)$. Let α be an indeterminate. Then*

$$\det(\alpha E A_1 + (I - E)A_2) = \alpha^{\rho(E)} \cdot \det(E A_1 + (I - E)A_2). \tag{25}$$

Proof. Choose a basis $\{x_1, \ldots, x_n\}$ such that $\operatorname{range}(E) = \langle x_1, \ldots, x_{\rho(E)}\rangle$ and $\operatorname{range}(I - E) = \langle x_{\rho(E)+1}, \ldots, x_n\rangle$. Let $B = \left(\frac{B_1}{B_2}\right)$ denote the matrix of $EA_1 + (I - E)A_2$ with respect to this new basis, where B_1 consists of the first $\rho(E)$ rows of B and B_2 consists of the last $n - \rho(E)$ rows. Then $\left(\frac{\alpha B_1}{B_2}\right)$ is the matrix of $\alpha E A_1 + (I - E)A_2$ with respect to this basis. Hence

$$\begin{aligned}\det(\alpha E A_1 + (I - E)A_2) &= \det\left(\frac{\alpha B_1}{B_2}\right) = \alpha^{\rho(E)} \cdot \det\left(\frac{B_1}{B_2}\right) \\ &= \alpha^{\rho(E)} \cdot \det(E A_1 + (I - E)A_2). \qquad \square\end{aligned}$$

Let $Q(z)$ be an $n \times n$ matrix over the ring of analytic functions on $\mathbb{C}$, i.e., all entries of $Q(z)$ are analytic functions in z. Define

$$p(z) := \det(Q(z)). \tag{26}$$

It is clear that in a point $\lambda \in \mathbb{C}$, the matrix $Q(\lambda)$ is of full rank if and only if $p(\lambda) \neq 0$. Also, when $p(\lambda) = 0$, it is possible to obtain more precise information on the rank of $Q(\lambda)$ from the determinant function $p(z)$, by using a suitable projection E.

PROPOSITION 4.2. *Let $Q(z)$ be an $n \times n$ matrix of analytic functions and $p(z) = \det(Q(z))$. Assume that for a certain $\lambda \in \mathbb{C}$, $p(\lambda) = 0$. Define the matrix of analytic functions $Q_1(z)$ as*

$$Q_1(z) := \frac{Q(z) - Q(\lambda)}{z - \lambda} = \sum_{j=1}^{\infty} \frac{1}{j!} Q^{(j)}(\lambda)(z - \lambda)^{j-1}.$$

Let E be a projection such that $EQ(\lambda) = 0$. Then

$$p(z) = (z - \lambda)^{\rho(E)} \cdot \det(E Q_1(z) + (I - E)Q(z)). \tag{27}$$

Moreover, if $\rho(E) = k$, then

$$\begin{cases} p^{(j)}(\lambda) = 0 \quad \text{for } j = 1, \ldots, k - 1, \\ p^{(k)}(\lambda) = k! \cdot \det(E Q'(\lambda) + (I - E)Q(\lambda)). \end{cases} \tag{28}$$

Proof. $Q(z)$ can be written as $Q(z) = Q(\lambda) + (z - \lambda)Q_1(z)$. Therefore

$$\begin{aligned}p(z) &= \det(EQ(z) + (I - E)Q(z)) = \det((z - \lambda)EQ_1(z) + (I - E)Q(z)) \\ &= (z - \lambda)^{\rho(E)} \cdot \det(EQ_1(z) + (I - E)Q(z)),\end{aligned}$$

where in the last step Lemma 4.1 is used. The result on the derivatives of $p(z)$ in λ when $\rho(E) = k$ is an easy consequence of (27) and the definition of $Q_1(z)$. $\square$

COROLLARY 4.3. *Let $Q(z)$ be an $n \times n$ matrix of analytic functions and $p(z) = \det(Q(z))$. Then*

$$\forall \lambda \in \mathbb{C} : \left[\begin{matrix} p(\lambda) = 0 \\ p'(\lambda) \neq 0 \end{matrix} \right\} \Longrightarrow \operatorname{rank}(Q(\lambda)) = n - 1 \Bigg]. \tag{29}$$

Proof. Let $\lambda \in \mathbb{C}$ be such that $p(\lambda) = 0$ and $p'(\lambda) \neq 0$. Choose a projection E with $\text{range}(Q(\lambda)) = \ker(E)$. Since $Q(\lambda)$ is singular, $\rho(E) = \text{rank}(E) \geq 1$. According to Proposition 4.2 we have

$$p(z) = (z - \lambda)^{\rho(E)} \cdot \det(EQ_1(z) + (I - E)Q(z)).$$

Suppose that $\rho(E) > 1$. Then $p'(\lambda) = 0$. This contradicts our assumption, and therefore, $\rho(E) = 1$. This implies that $\dim(\text{range}(Q(\lambda))) = n - 1$. □

Remark 4.4. From Proposition 4.2 it is clear that ($p(\lambda) = 0$ and $p'(\lambda) \neq 0$) is a sufficient condition for $Q(\lambda)$ to have rank $n - 1$, but it is not a necessary one. It is also possible that $\text{rank}(Q(\lambda)) = n - 1$ while $p'(\lambda) = 0$. In that case the matrix $EQ'(\lambda) + (I - E)Q(\lambda)$ is singular.

In §5 we are especially interested in matrices $Q(z)$ of analytic functions for which the determinant $p(z)$ has only simple zeros. According to Corollary 4.3 this implies that

$$\text{if } p(\lambda) = 0, \text{ then } \text{rank}(Q(\lambda)) = n - 1.$$

Let $Q(z)$ be given, and assume that $\lambda \in \mathbb{C}$ is such that $p(\lambda) = \det(Q(\lambda)) = 0$ and also $p'(\lambda) = 0$. Then it is possible to perturb $Q(z)$ in such a way that λ becomes a simple zero of $p(z)$. However, to prove this result, we first need a lemma that describes how a constant matrix can be perturbed to increase its rank.

LEMMA 4.5. *Let A be an $n \times n$ matrix over $\mathbb{C}$, and assume that* $\text{rank}(A) = \ell$. *For each $j \in \{1, \ldots, n - \ell\}$, there exists a matrix $B \in \mathbb{R}^{n \times n}$ satisfying the following properties:*

(i) $\|B\| = 1$ *and* $\text{rank}(B) = j$,

(ii) $\forall \alpha, \beta \neq 0 :$ $\text{range}(\alpha A + \beta B) = \text{range}(A) \oplus \text{range}(B)$.

Proof. Let $e_1, \ldots, e_n$ denote the standard basis in $\mathbb{C}^n$. Then there exists a permutation $\pi : \{1, \ldots, n\} \to \{1, \ldots, n\}$ such that

$$\text{range}(A) = \langle Ae_{\pi(1)}, \ldots, Ae_{\pi(\ell)} \rangle. \tag{30}$$

Choose vectors $e_{i_1}, \ldots, e_{i_{n-\ell}}$ from the standard basis satisfying

$$\langle e_{i_1}, \ldots, e_{i_{n-\ell}} \rangle \oplus \text{range}(A) = \mathbb{C}^n. \tag{31}$$

Let $j \in \{1, \ldots, n - \ell\}$, and define B as

$$\begin{cases} Be_{\pi(k)} = 0 & \text{for } k = 1, \ldots, \ell, \ell + j + 1, \ldots, n, \\ Be_{\pi(k)} = e_{i_{k-\ell}} & \text{for } k = \ell + 1, \ldots, \ell + j. \end{cases}$$

With this choice of B, it is obvious that (i) is satisfied.

From the construction of B it is immediately clear that $\text{range}(A) \cap \text{range}(B) = \{0\}$. Moreover, the inclusion $\text{range}(\alpha A + \beta B) \subset \text{range}(A) + \text{range}(B)$ is trivial. So, to prove (ii), we only have to show the correctness of the other inclusion.

Let $x_1 \in \text{range}(A)$. Then there exists a $y_1 \in \langle e_{\pi(1)}, \ldots, e_{\pi(\ell)} \rangle$ such that $x_1 = Ay_1$. But clearly $By_1 = 0$. Hence

$$(\alpha A + \beta B)\left(\frac{1}{\alpha} y_1\right) = Ay_1 + \frac{\beta}{\alpha} By_1 = x_1,$$

and $x_1 \in \text{range}(\alpha A + \beta B)$.

Let $x_2 \in \text{range}(B)$. Then there exists a $y_2 \in \langle e_{\pi(\ell+1)}, \ldots, e_{\pi(\ell+j)} \rangle$ such that $By_2 = x_2$. Since $Ay_2 \in \text{range}(A)$, there exists a $y_3 \in \langle e_{\pi(1)}, \ldots, e_{\pi(\ell)} \rangle$ such that $Ay_2 = Ay_3$. Now

$$(\alpha A + \beta B) \cdot \frac{1}{\beta}(y_2 - y_3) = \frac{\alpha}{\beta}(Ay_2 - Ay_3) + By_2 - By_3 = By_2 = x_2,$$

and $x_2 \in \text{range}(\alpha A + \beta B)$. This completes the proof of (ii). □

At this stage all ingredients to prove the main result of this section are available. This result describes how a matrix of analytic functions may be perturbed to reduce the multiplicity of one of the zeros of its determinant to 1.

PROPOSITION 4.6. *Let $Q(z)$ be an $n \times n$ matrix of analytic functions, and define $p(z) = \det(Q(z))$. Assume that $\lambda \in \mathbb{C}$ satisfies $p(\lambda) = 0$. Let $g(z)$ be an analytic function such that $g'(\lambda) \neq 0$.*

Then for each $\varepsilon > 0$ there exists an $n \times n$ polynomial matrix $\Delta(s)$ over $\mathbb{R}[s]$ that satisfies the following properties (where $\tilde{Q}(z) := Q(z) + \Delta(g(z))$ and $\tilde{p}(z) := \det(\tilde{Q}(z))$):

(i) $\|\Delta(s)\|_{pm} < \varepsilon$,

(ii) $\deg(\Delta(s)) \leq 1$ *if $g(\lambda)$ is real, and* $\deg(\Delta(s)) \leq 2$ *if $g(\lambda)$ is complex,*

(iii) $\tilde{p}(\lambda) = 0$ *and* $\tilde{p}'(\lambda) \neq 0$.

Proof. If $p'(\lambda) \neq 0$, the proof is trivial: take $\Delta(s) = 0$.

Assume $p'(\lambda) = 0$. Let $\varepsilon > 0$. If $\text{rank}(Q(\lambda)) = n-1$, define $B_1 := 0$. Otherwise, choose a matrix B_1 according to Lemma 4.5, with $\|B_1\| = 1$ and $\text{rank}(B_1) = n - 1 - \text{rank}(Q(\lambda))$ in such a way that

$$\forall \alpha \neq 0 : \ \text{range}(Q(\lambda) + \alpha B_1) = \text{range}(Q(\lambda)) \oplus \text{range}(B_1).$$

This implies that for all $\alpha \neq 0$, $\text{rank}(Q(\lambda) + \alpha B_1) = n - 1$.

Fix $\alpha := \frac{1}{3}\varepsilon$ and apply Lemma 4.5 again, but now to the matrix $Q(\lambda) + \alpha B_1$. In this way we find a matrix B_2 (possibly depending on α), satisfying $\|B_2\| = 1$, $\text{rank}(B_2) = 1$, and

$$\forall \beta \neq 0 : \ \text{range}(Q(\lambda) + \alpha B_1 + \beta B_2) = \text{range}(Q(\lambda)) \oplus \text{range}(B_1) \oplus \text{range}(B_2).$$

So for every $\beta \neq 0$, the matrix $(Q(\lambda) + \alpha B_1 + \beta B_2)$ has rank n.

Let E denote the projection on $\text{range}(B_2)$ along $\text{range}(Q(\lambda) + \alpha B_1)$, so that $E(Q(\lambda) + \alpha B_1) = 0$ and $EB_2 = B_2$. Then $\rho(E) = \text{rank}(E) = 1$. Define $Q_\alpha(z) := Q(z) + \alpha B_1$ and $p_\alpha(z) := \det(Q_\alpha(z))$. So $p_\alpha(\lambda) = \det(Q(\lambda) + \alpha B_1) = 0$ and using formula (28) from Proposition 4.2 we obtain

$$p'_\alpha(\lambda) = \det(EQ'_\alpha(\lambda) + (I - E)Q_\alpha(\lambda)) = \det(EQ'(\lambda) + (I - E)Q_\alpha(\lambda)).$$

First note that $\ker(EQ'(\lambda) + (I - E)Q_\alpha(\lambda)) \subset \ker(Q_\alpha(\lambda))$. Moreover, we know that $\dim(\ker(Q_\alpha(\lambda))) = 1$. Therefore the problem can be divided into two different cases.

Case 1. $\ker(EQ'(\lambda) + (I - E)Q_\alpha(\lambda)) = \{0\}$. Then $p'_\alpha(\lambda) = \det(EQ'(\lambda) + (I - E)Q_\alpha(\lambda)) \neq 0$, and $\Delta(s) := \alpha B_1$ satisfies (ii), (iii), and also (i) because $\|\Delta(s)\|_{pm} = \|\alpha B_1\| \leq \frac{1}{3}\varepsilon$.

Case 2. $\ker(EQ'(\lambda) + (I - E)Q_\alpha(\lambda)) = \ker(Q_\alpha(\lambda))$. If $g(\lambda)$ is real, define for all $\beta \in \mathbb{R}\backslash\{0\}$

$$\Delta_\beta(s) := \alpha B_1 + \beta(s - g(\lambda))B_2;$$

if $g(\lambda)$ is complex, define for all $\beta \in \mathbb{R}\backslash\{0\}$

$$\Delta_\beta(s) := \alpha B_1 + \beta(s - g(\lambda))(s - \overline{g(\lambda)})B_2.$$

Then in each case $\Delta_\beta(s) \in \mathbb{R}[s]^{n \times n}$, and moreover (ii) is satisfied.

Let $\beta \in \mathbb{R}\backslash\{0\}$ and define $\tilde{Q}(z) := Q(z) + \Delta_\beta(g(z))$. Then $\tilde{Q}(\lambda) = Q(\lambda) + \alpha B_1$, and in both the real and the complex cases there exists a $\gamma \neq 0$ such that $\tilde{Q}'(\lambda) = Q'(\lambda) + \gamma B_2$. Since $\tilde{Q}(\lambda) = Q(\lambda) + \alpha B_1$ is singular, we still have that $\tilde{p}(\lambda) = 0$, and according to Proposition 4.2,

$$\tilde{p}'(\lambda) = \det(E\tilde{Q}'(\lambda) + (I - E)\tilde{Q}(\lambda)) = \det(E(Q'(\lambda) + \gamma B_2) + (I - E)Q_\alpha(\lambda)).$$

Assume that $x \in \ker(E(Q'(\lambda) + \gamma B_2) + (I - E)Q_\alpha(\lambda))$. Then $x \in \ker(Q_\alpha(\lambda))$. So by assumption, $x \in \ker(EQ'(\lambda) + (I - E)Q_\alpha(\lambda))$. Moreover we have that $EB_2 = B_2$, and thus we obtain

$$\gamma B_2 x = (E(Q'(\lambda) + \gamma B_2) + (I - E)Q_\alpha(\lambda))x - (EQ'(\lambda) + (I - E)Q_\alpha(\lambda))x = 0.$$

So $(Q_\alpha(\lambda) + \gamma B_2)x = 0$. By construction $Q_\alpha(\lambda) + \gamma B_2 = Q(\lambda) + \alpha B_1 + \gamma B_2$ has full rank, and thus $x = 0$. This implies that $\operatorname{rank}(E(Q'(\lambda) + \gamma B_2) + (I - E)Q_\alpha(\lambda)) = n$. Therefore $\tilde{p}'(\lambda) \neq 0$, and $\tilde{Q}(z)$ satisfies condition (iii) for all $\beta \neq 0$.

To satisfy (i), we choose

$$\beta := \frac{1}{4}\varepsilon \cdot \min\left(\frac{1}{|g(\lambda)|}, 1\right),$$

when $g(\lambda)$ is real, and

$$\beta := \frac{1}{8}\varepsilon \cdot \min\left(\frac{1}{|g(\lambda) + \overline{g(\lambda)}|}, \frac{1}{g(\lambda) \cdot \overline{g(\lambda)}}, 1\right),$$

when $g(\lambda)$ is complex. Then it is easily verified that $\|\Delta_\beta(s)\|_{pm} < \varepsilon$. This completes the proof. □

Remark 4.7. When the matrix $Q(z)$ of analytic functions has the property that $\overline{Q(\overline{z})} = Q(z)$, its determinant $p(z)$ also has that property. This implies that λ is a zero of $p(z)$ of multiplicity k if and only if $\overline{\lambda}$ is a zero of $p(z)$ of the same multiplicity. Note also that if $\overline{g(\overline{z})} = g(z)$ and $g(\lambda)$ is complex, the reduction process described in the proof of Proposition 4.6 reduces the multiplicity of both the zeros λ and $\overline{\lambda}$ to 1 in only one step. Although in general a perturbation matrix $\Delta(s)$ of degree 2 is needed to fix this problem, this matrix handles both zeros λ and $\overline{\lambda}$ at the same time.

Remark 4.8. Corollary 4.3 and Proposition 4.6 are formulated in a very general context of matrices over analytic functions, but in the next section they are only used for a very specific case. It is clear that for the time-delay system corresponding to the point $\Sigma = (A(s), B(s), \tau) \in \mathcal{V}$, the matrix $(zI - A(e^{-\tau z}))$ is very important for its stabilizability properties. Therefore the results of this section are applied to the case $Q(z) = (zI - A(e^{-\tau z}))$ and $g(z) = e^{-\tau z}$. Then clearly $g'(\lambda) = -\tau e^{-\tau\lambda} \neq 0$ for all $\lambda \in \mathbb{C}$. In this perspective, Proposition 4.6 describes how the matrix $A(s)$ has to be perturbed within the normed ring $\mathbb{R}[s]^{n\times n}$ in such a way that $(zI - (A(e^{-\tau z}) + \Delta(e^{-\tau z})))$ satisfies the condition of Corollary 4.3.

5. Approximation by stabilizable time-delay systems. In this section, the second and final part of our genericity result is proven. We show that the subset S of $\mathcal{V}$, consisting of all parametrizations of stabilizable time-delay systems, is a dense subset of $\mathcal{V}$. This means that in any arbitrary small neighborhood of a point $\Sigma \in \mathcal{V}$, corresponding to a nonstabilizable time-delay system, there is a point $\tilde{\Sigma} \in S \subset \mathcal{V}$ that describes a stabilizable time-delay system. In this section such an approximation by stabilizable time-delay systems is constructed explicitly.

The main idea of the proof is as follows. Let a point $\Sigma = (A(s), B(s), \tau) \in \mathcal{V}$ be given such that the corresponding time-delay system is not stabilizable. First of all it may be shown (use, e.g., Corollary 2.3) that for all matrices $\tilde{A}(s) \in \mathbb{R}[s]^{n\times n}$, the analytic function $\tilde{p}(z) = \det(zI - \tilde{A}(e^{-\tau z}))$ has only a finite number of zeros in $\overline{\mathbb{C}^+}$. Using Rouché's theorem,

Corollary 4.3, and Proposition 4.6, it is possible to prove that for every $\varepsilon > 0$, there exists a matrix $A_\varepsilon(s) \in \mathbb{R}[s]^{n\times n}$ such that $\|A(s) - A_\varepsilon(s)\|_{pm} < \frac{1}{2}\varepsilon$ and

$$(32) \qquad \forall z \in \overline{\mathbb{C}^+} : \left[\operatorname{rank}(zI - A_\varepsilon(e^{-\tau z})) < n \Longrightarrow \operatorname{rank}(zI - A_\varepsilon(e^{-\tau z})) = n - 1 \right].$$

So, in all points $z \in \overline{\mathbb{C}^+}$ where the matrix $(zI - A_\varepsilon(e^{-\tau z}))$ loses rank, it loses only rank 1. This loss of rank has to be compensated by the matrix $B(s)$. Therefore this matrix has to be perturbed in such a way that the perturbed version $B_\varepsilon(s)$ satisfies the inequality $\|B_\varepsilon(s) - B(s)\|_{pm} < \frac{1}{2}\varepsilon$ and is such that

$$(33) \quad \forall z \in \overline{\mathbb{C}^+} : \left[\operatorname{rank}(zI - A_\varepsilon(e^{-\tau z})) < n \Longrightarrow \operatorname{rank}(zI - A_\varepsilon(e^{-\tau z}) \mid B_\varepsilon(e^{-\tau z})) = n \right].$$

Since the analytic function $p_\varepsilon(z) = \det(zI - A_\varepsilon(e^{-\tau z}))$ has only a finite number of zeros in the closed right half plane, it is possible to satisfy this condition. In this way we find a stabilizable time-delay system $\Sigma_\varepsilon = (A_\varepsilon(s), B_\varepsilon(s), \tau)$ such that $d_\nu(\Sigma, \Sigma_\varepsilon) < \varepsilon$, and the proof is complete.

The rest of this section is devoted to a detailed elaboration of the scheme of the proof given above. The first lemma (which can be seen as a direct consequence of Corollary 2.3) describes the location of the zeros of the analytic function $p(z) = \det(zI - A(e^{-\tau z}))$ corresponding to the square polynomial matrix $A(s)$.

LEMMA 5.1 (see [7, p. 18]). *Let $A(s) \in \mathbb{R}[s]^{n\times n}$ and $\tau > 0$ be given. Then the analytic function $p(z) = \det(zI - A(e^{-\tau z}))$ has only a finite number of zeros in the closed right half plane $\overline{\mathbb{C}^+}$. Moreover, all the zeros of $p(z)$ in $\overline{\mathbb{C}^+}$ are located within the semi-disc*

$$(34) \qquad D := \{z \in \mathbb{C} \mid \operatorname{Re} z \geq 0 \text{ and } |z| \leq \|A(s)\|_{pm}\}.$$

In Lemma 5.1, the role of the right half plane $\overline{\mathbb{C}^+}$ is not crucial. By shifting to the left and to the right it is possible to show that $p(z) = \det(zI - A(e^{-\tau z}))$ has a finite number of zeros in any arbitrary right half plane.

In the proof of the main results of this section, we often assume that the function $p(z) = \det(zI - A(e^{-\tau z}))$ has no zeros on the boundary of $\mathbb{C}^+$, i.e., $p(z)$ has no zeros on the imaginary axis. Fortunately, this is not really a restriction. By an arbitrarily small perturbation of the matrix $A(s)$ corresponding to $p(z) = \det(zI - A(e^{-\tau z}))$, it is possible to shift the zeros of $p(z)$ in the horizontal direction. In this way we can prove the following result.

PROPOSITION 5.2. *Let $A(s) \in \mathbb{R}[s]^{n\times n}$ and $\tau > 0$ be given. Let $\varepsilon > 0$. Then there exists a polynomial matrix $A_1(s) \in \mathbb{R}[s]^{n\times n}$ satisfying the following properties:*

(i) $\|A(s) - A_1(s)\|_{pm} < \varepsilon$,

(ii) $\deg(A_1(s)) = \deg(A(s))$,

(iii) *the characteristic function $p_1(z) := \det(zI - A_1(e^{-\tau z}))$ has no zeros on the imaginary axis.*

The next theorem is a restatement of a well-known result from complex analysis. It plays a crucial role in the rest of this section because it describes how small perturbations of an analytic function influence the location of its zeros.

THEOREM 5.3 (Rouché's theorem (see, e.g., [15, Thm. 10.43])). *Let f and g be two functions that are analytic inside and on a Jordan curve $\mathcal{J}$. Suppose that f and g have no zeros on $\mathcal{J}$. Denote by N_f and N_g the total number of zeros of f and g inside $\mathcal{J}$, also counting multiplicities. Then*

$$(35) \qquad [\, \forall z \in \mathcal{J} : |f(z) - g(z)| < |f(z)| \,] \Longrightarrow N_g = N_f.$$

Let $\mathcal{J}$ be a Jordan curve, and let f and g be two functions satisfying the conditions of Theorem 5.3. Define $\delta := \min\{|f(z)| \mid z \in \mathcal{J}\}$. Then the condition $|f(z) - g(z)| < \delta$ implies

that f and g have the same number of zeros inside $\mathcal{J}$. This observation is exploited in the next lemma.

LEMMA 5.4. *Let $A(s) \in \mathbb{R}[s]^{n\times n}$ and $\tau > 0$ be given. Let $\mathcal{J}$ be a Jordan curve in $\overline{\mathbb{C}^+}$ such that $p(z) = \det(zI - A(e^{-\tau z}))$ has no zeros on $\mathcal{J}$. Then there exists an $\bar{\varepsilon} > 0$ such that for all polynomial matrices $\tilde{A}(s) \in \mathbb{R}[s]^{n\times n}$ satisfying $\|A(s) - \tilde{A}(s)\|_{pm} < \bar{\varepsilon}$, the characteristic function $\tilde{p}(z) := \det(zI - \tilde{A}(e^{-\tau z}))$ corresponding to $\tilde{A}(s)$ has the same number of zeros within $\mathcal{J}$ as $p(z)$ (counting multiplicities) and no zeros on $\mathcal{J}$.*

Proof. Define $p_c(s, z) := \det(zI - A(s))$. Then $p_c(s, z) \in \mathbb{R}[s, z]$, and the degree of $p_c(s, z)$ in z is n. Define

$$\delta := \min\{|p(z)| \mid z \in \mathcal{J}\}, \tag{36}$$

and $M := 1 + \max\{|z| \mid z \in \mathcal{J}\}$. Now apply Proposition 2.7. Choose an $\bar{\varepsilon} > 0$ in such a way that for all matrices $\tilde{A}(s) \in \mathbb{R}[s]^{n\times n}$ satisfying $\|A(s) - \tilde{A}(s)\|_{pm} < \bar{\varepsilon}$, the following inequality holds:

$$\|p_c(s, z) - \tilde{p}_c(s, z)\|_p < \delta \frac{M - 1}{M^{n+1} - 1}. \tag{37}$$

Here $\tilde{p}_c(s, z)$ denotes the characteristic polynomial $\det(zI - \tilde{A}(s))$ of $\tilde{A}(s)$, which is also of degree n in z. We show that for $\bar{\varepsilon}$ the claim of Lemma 5.4 holds.

Let $\tilde{A}(s) \in \mathbb{R}[s]^{n\times n}$ be such that $\|A(s) - \tilde{A}(s)\|_{pm} < \bar{\varepsilon}$. First apply Lemma 2.6 to $r(s, z) := p_c(s, z) - \tilde{p}_c(s, z)$ and use inequality (37). In this way we obtain

$$\forall z \in \overline{\mathbb{C}^+}, |z| \le M : \ |p(z) - \tilde{p}(z)| < \delta. \tag{38}$$

So in particular $|p(z) - \tilde{p}(z)| < \delta$ for all $z \in \mathcal{J}$. Apparently $\tilde{p}(z)$ has no zeros on $\mathcal{J}$. (Otherwise there would be a $\lambda \in \mathcal{J}$ such that $|p(\lambda)| < \delta$, which contradicts definition (36).) Finally, since both $p(z)$ and $\tilde{p}(z)$ are analytic functions without zeros on $\mathcal{J}$, Rouché's theorem and formulae (36) and (38) imply that $p(z)$ and $\tilde{p}(z)$ have the same number of zeros inside the Jordan curve $\mathcal{J}$ (counting multiplicities). □

Lemma 5.4 indicates that small perturbations of the matrix $A(s)$ affect the zeros of $p(z)$ only slightly: they cannot cross the Jordan curve $\mathcal{J}$. The idea is now to perturb $A(s)$ in such a way that the multiple zeros of $p(z)$ inside $\mathcal{J}$ become simple without changing the total number of zeros inside $\mathcal{J}$. In this approach, Rouché's theorem (in the disguised form of Lemma 5.4) again plays an important role.

PROPOSITION 5.5. *Let $A(s) \in \mathbb{R}[s]^{n\times n}$ and $\tau > 0$ be given. Let $\mathcal{J}$ be a Jordan curve in $\overline{\mathbb{C}^+}$, and assume that $p(z) = \det(zI - A(e^{-\tau z}))$ has no zeros on $\mathcal{J}$. Choose $\bar{\varepsilon} > 0$ such that Lemma 5.4 is satisfied. Let N_p denote the total number of zeros of $p(z)$ within $\mathcal{J}$, counting multiplicities. Then for all $\varepsilon \in (0, \bar{\varepsilon})$ there exists a matrix $\tilde{A}(s) \in \mathbb{R}[s]^{n\times n}$ such that*

(i) $\|A(s) - \tilde{A}(s)\|_{pm} < \varepsilon$,

(ii) $\deg(\tilde{A}(s)) \le \max(\deg(A(s)), 2)$,

(iii) *the analytic function $\tilde{p}(z) := \det(zI - \tilde{A}(e^{-\tau z}))$ has N_p zeros within $\mathcal{J}$ and all these zeros are simple.*

Proof. Let $\varepsilon \in (0, \bar{\varepsilon})$. Then it follows from Lemma 5.4 that for all $\tilde{A}(s) \in \mathbb{R}[s]^{n\times n}$ satisfying $\|A(s) - \tilde{A}(s)\|_{pm} < \varepsilon < \bar{\varepsilon}$, the number of zeros of $\tilde{p}(z) = \det(zI - \tilde{A}(e^{-\tau z}))$ inside $\mathcal{J}$ is equal to N_p. Let L_p denote the number of simple zeros of $p(z)$ within $\mathcal{J}$. The proposition is proved with the following induction argument:

$$\forall i \in \{0, 1, \ldots, N_p - L_p\} \ \exists A_i(s) \in \mathbb{R}[s]^{n\times n} \text{ such that}$$

(1) $\|A(s) - A_i(s)\|_{pm} \le \frac{2^i - 1}{2^i} \cdot \varepsilon$,

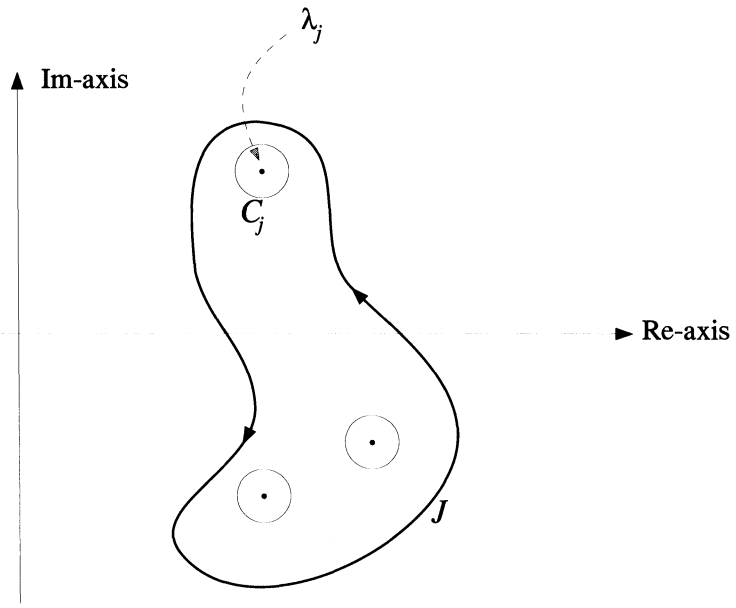

FIG. 5.1. *Location of the zeros inside a Jordan curve* $\mathcal{J}$.

(2) $\deg(A_i(s)) \leq \max(\deg(A(s)), 2)$,

(3) the analytic function $p_i(z) = \det(zI - A_i(e^{-\tau z}))$ has at least $L_p + i$ simple zeros within $\mathcal{J}$, i.e., $L_{p_i} \geq L_p + i$, where L_{p_i} denotes the number of simple zeros of $p_i(z)$ enclosed by $\mathcal{J}$.

When $i = 0$, this is trivial. Choose $A_0(s) = A(s)$.

Induction step. Suppose that for certain $i \in \{0, 1, \ldots, N_p - L_p - 1\}$ we have found a matrix $A_i(s)$ satisfying (1)-(3). If $L_{p_i} \geq L_p + i + 1$, choose $A_{i+1}(s) = A_i(s)$, and we are ready.

Next assume that $L_{p_i} = L_p + i$. Since $i < N_p - L_p$, we know that at least one of the N_p zeros of $p_i(z)$ inside $\mathcal{J}$ is a multiple zero. Let λ_j, $j \in \{1, \ldots, \ell\}$, denote all distinct zeros of $p_i(z)$ in $\mathcal{J}$. Then there exists a $\rho > 0$ such that the circles C_j defined by

$$C_j = \{z \in \mathbb{C} \mid |z - \lambda_j| = \rho\} \tag{39}$$

neither intersect one another nor the Jordan curve $\mathcal{J}$ (see Figure 5.1). Apply Lemma 5.4 to each of these circles C_j. Then for all $j = 1, \ldots, \ell$, we find an $\bar{\varepsilon}_j > 0$ such that for all $\hat{A}(s) \in \mathbb{R}[s]^{n \times n}$, the inequality $\|A(s) - \hat{A}(s)\|_{pm} < \bar{\varepsilon}_j$ implies that $p_i(z)$ and $\hat{p}(z) = \det(zI - \hat{A}(e^{-\tau z}))$ have the same number of zeros within C_j and no zeros on C_j. Define $\hat{\varepsilon} := \min\{\bar{\varepsilon}_j \mid j = 1, \ldots, \ell\}$.

Assume, without loss of generality, that λ_1 is a multiple zero of $p_i(z)$. Apply Proposition 4.6 to $Q(z) = (zI - A_i(e^{-\tau z}))$ with $g(z) = e^{-\tau z}$ and $\lambda = \lambda_1$. Clearly $g'(\lambda_1) = -\tau e^{-\tau \lambda_1} \neq 0$, so there exists a polynomial matrix $\Delta(s) \in \mathbb{R}[s]^{n \times n}$, with $\deg(\Delta(s)) \leq 2$, in norm bounded by

$$\|\Delta(s)\|_{pm} < \min\left(\hat{\varepsilon}, \frac{1}{2^{i+1}} \cdot \varepsilon\right)$$

and such that $\tilde{p}(z) = \det(Q(z) + \Delta(e^{-\tau z}))$ has only a simple zero in $z = \lambda_1$. We show that $A_{i+1}(s) := A_i(s) + \Delta(s)$ meets the requirements (1)-(3), with i replaced by $i + 1$.

(1) and (2) are very straightforward:

$$\begin{aligned}\|A(s) - A_{i+1}(s)\|_{pm} &\leq \|A(s) - A_i(s)\|_{pm} + \|A_i(s) - A_{i+1}(s)\|_{pm} \\ &\leq \frac{2^i - 1}{2^i} \cdot \varepsilon + \frac{1}{2^{i+1}} \cdot \varepsilon = \frac{2^{i+1} - 1}{2^{i+1}} \cdot \varepsilon,\end{aligned}$$

and $\deg(A_{i+1}(s)) \leq \max(\deg(A_i(s)), 2) \leq \max(\deg(A(s)), 2)$.

(3) Since $\|A_{i+1}(s) - A_i(s)\|_{pm} < \hat{\varepsilon}$, we can apply Lemma 5.4 to each of the circles $\mathcal{C}_j$ defined in (39) separately. In this way we determine that for all $j \in \{1, \ldots, \ell\}$, the number of zeros of $p_{i+1}(z)$ within $\mathcal{C}_j$ is equal to the number of zeros of $p_i(z)$ within $\mathcal{C}_j$ (counting multiplicities). This implies that the L_{p_i} circles containing a simple zero of $p_i(z)$ also contain exactly one (simple) zero of $p_{i+1}(z)$. Moreover, the multiple zero λ_1 has become simple by construction, and thus

$$L_{p_{i+1}} \geq L_{p_i} + 1 = L_p + i + 1.$$

This completes the proof of the induction argument. The correctness of Proposition 5.5 follows immediately by taking $\tilde{A}(s) = A_{N_p - L_p}(s)$. □

Proposition 5.5 shows that the matrix perturbations introduced in Proposition 4.6 can be used successively to reduce the multiplicity of zeros to 1. Rouché's theorem guarantees not only that the total number of zeros within the Jordan curve $\mathcal{J}$ remains constant but also that simple zeros remain simple. Combining Propositions 5.2 and 5.5, we can finish the first part of the proof as indicated in the introduction of this section by an appropriate choice of the Jordan curve $\mathcal{J}$.

THEOREM 5.6. *Let $A(s) \in \mathbb{R}[s]^{n \times n}$ and $\tau > 0$ be given. Then for all $\varepsilon > 0$ there exists a matrix $A_\varepsilon(s) \in \mathbb{R}[s]^{n \times n}$ such that*

(i) $\|A(s) - A_\varepsilon(s)\|_{pm} < \varepsilon$,

(ii) $\deg(A_\varepsilon(s)) \leq \max(\deg(A(s)), 2)$,

(iii) $\forall \lambda \in \overline{\mathbb{C}^+} : \operatorname{rank}(\lambda I - A_\varepsilon(e^{-\tau\lambda})) \geq n - 1$.

Proof. Let $\varepsilon > 0$. Choose according to Proposition 5.2 a matrix $A_1(s) \in \mathbb{R}[s]^{n \times n}$, of the same degree as $A(s)$, satisfying $\|A(s) - A_1(s)\|_{pm} < \frac{1}{2}\varepsilon$ and such that $p_1(z) = \det(zI - A_1(e^{-\tau z}))$ has no zeros on the imaginary axis.

Define $R := \|A_1(s)\|_{pm} + 1$ and the Jordan curve $\mathcal{J}$, as depicted in Figure 5.2, by

$$\mathcal{J} := \{z \in \mathbb{C} \mid (\operatorname{Re} z = 0 \text{ and } |z| < R) \text{ or } (\operatorname{Re} z \geq 0 \text{ and } |z| = R)\}. \tag{40}$$

So, according to Lemma 5.1, all zeros of $p_1(z) = \det(zI - A_1(e^{-\tau z}))$ in $\overline{\mathbb{C}^+}$ are located inside the Jordan curve $\mathcal{J}$. Let N_{p_1} denote this number of zeros of $p_1(z)$ within $\mathcal{J}$ (counting multiplicities). We choose $\bar{\varepsilon} > 0$ such that Lemma 5.4 is satisfied and apply Proposition 5.5 with $\tilde{\varepsilon} := \frac{1}{2} \cdot \min(1, \varepsilon, \bar{\varepsilon})$. Then we find a matrix $A_\varepsilon(s) \in \mathbb{R}[s]^{n \times n}$ such that

(1) $\|A_1(s) - A_\varepsilon(s)\|_{pm} \leq \frac{1}{2} \cdot \min(1, \varepsilon, \bar{\varepsilon}) \leq \frac{1}{2}\varepsilon$,

(2) $\deg(A_\varepsilon(s)) \leq \max(\deg(A_1(s)), 2)$,

(3) $p_\varepsilon(z) = \det(zI - A_\varepsilon(e^{-\tau z}))$ has N_{p_1} zeros within $\mathcal{J}$ that are all simple.

Clearly, the matrix $A_\varepsilon(s)$ satisfies both (i) and (ii), so we have to prove only (iii). Since $\|A_\varepsilon(s)\|_{pm} < \|A_1(s)\|_{pm} + \frac{1}{2}$, Lemma 5.1 implies that $p_\varepsilon(z)$ has no zeros in $\overline{\mathbb{C}^+}$ outside $\mathcal{J}$. Moreover, since $\|A_1(s) - A_\varepsilon(s)\|_{pm} < \bar{\varepsilon}$, we know from Lemma 5.4 that $p_\varepsilon(z)$ has no zeros on $\mathcal{J}$. Therefore all zeros of $p_\varepsilon(z)$ in $\overline{\mathbb{C}^+}$ are located within $\mathcal{J}$. According to (3), all these zeros are simple and thus we have

$$\forall z \in \overline{\mathbb{C}^+} : \left[p_\varepsilon(z) = 0 \Longrightarrow p_\varepsilon'(z) \neq 0\right]. \tag{41}$$

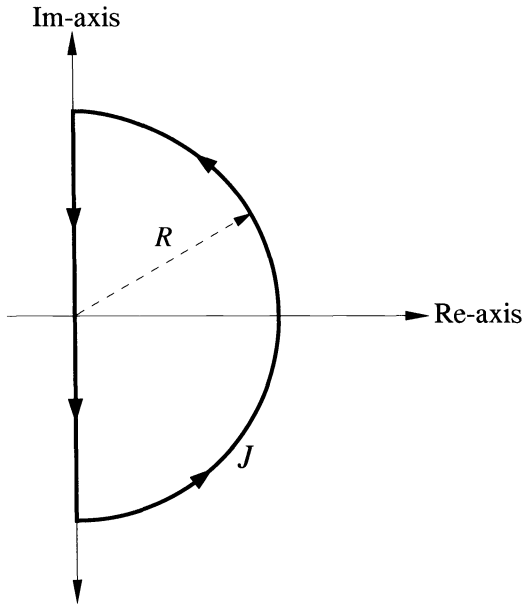

FIG. 5.2. *The Jordan curve* $\mathcal{J}$.

Now, let $\lambda \in \overline{\mathbb{C}^+}$, and assume that $\operatorname{rank}(\lambda I - A_\varepsilon(e^{-\tau\lambda})) < n$. Then $p_\varepsilon(\lambda) = \det(\lambda I - A_\varepsilon(e^{-\tau\lambda})) = 0$, and thus according to (41), $p'_\varepsilon(\lambda) \neq 0$. Applying Corollary 4.3 to the matrix $(zI - A_\varepsilon(e^{-\tau z}))$, we obtain

$$\operatorname{rank}(\lambda I - A_\varepsilon(e^{-\tau\lambda})) = n - 1.$$

This completes the proof. □

In the second part of this section we are concerned with perturbations of the matrix $B(s)$. Suppose that a point $\Sigma = (A(s), B(s), \tau) \in \mathcal{V}$ is given. First perturb $A(s)$ in such a way that for $A_\varepsilon(s)$ conditions (i)-(iii) of Theorem 5.6 are satisfied. From Lemma 5.1 it follows that the analytic function $p_\varepsilon(z) = \det(zI - A_\varepsilon(e^{-\tau z}))$ has only a finite number of zeros in $\overline{\mathbb{C}^+}$, say $\lambda_1, \ldots, \lambda_k$. We know that for each $i \in \{1, \ldots, k\}$, $\operatorname{rank}(\lambda_i I - A_\varepsilon(e^{-\tau\lambda_i})) = n - 1$, and therefore the left-kernel of the matrix $(\lambda_i I - A_\varepsilon(e^{-\tau\lambda_i}))$, i.e., the linear subspace of $\mathbb{C}^n$ consisting of all row vectors x^T such that $x^T \cdot (\lambda_i I - A_\varepsilon(e^{-\tau\lambda_i})) = 0$, is 1-dimensional. So for each $i \in \{1, \ldots, k\}$, this left-kernel is spanned by one row vector $v_i^T \in \mathbb{C}^n$. Now $(\lambda_i I - A_\varepsilon(e^{-\tau\lambda_i}) \mid B(e^{-\tau\lambda_i}))$ has rank n if and only if

$$v_i^T \cdot B(e^{-\tau\lambda_i}) \neq 0. \tag{42}$$

So, to achieve stabilizability, we have to perturb $B(s)$ in such a way that for the perturbed version $B_\varepsilon(s)$ the following holds:

$$\forall i \in \{1, \ldots, k\} : \; v_i^T \cdot B_\varepsilon(e^{-\tau\lambda_i}) \neq 0. \tag{43}$$

To find such a perturbation of $B(s)$, we first look for a vector b that is not perpendicular to a given finite set of vectors.

LEMMA 5.7. *Let the column vectors* $v_1, \ldots, v_k \in \mathbb{C}^n$ *be given, and assume that they are all nonzero. Then there exists a vector* $b \in \mathbb{R}^n$ *such that*

$$\forall i \in \{1, \ldots, k\} : v_i^T \cdot b \neq 0.$$

Proof. First define for all $i = 1, \ldots, k$ the linear spaces

$$V_i := \{x \in \mathbb{R}^n \mid v_i^{\mathrm{T}} \cdot x = 0\}.$$

Since all vectors v_i are nonzero, the sets V_i are linear subspaces of $\mathbb{R}^n$, with dimension smaller than or equal to $n-1$. This implies that each V_i is a nowhere dense subset of $\mathbb{R}^n$. Application of Baire's category theorem (see, for example, [15, Thm. 5.6 and Rem. 5.7]) yields

$$\mathbb{R}^n \neq \bigcup_{i=1}^{k} V_i. \qquad \square$$

Intuitively, the result of Lemma 5.7 is clear. The vectors $v_1, \ldots, v_k$ correspond to linear subspaces $V_1, \ldots, V_k$ in $\mathbb{R}^n$ of dimension smaller than or equal to $n-1$. Now we simply have to pick a vector $b \in \mathbb{R}^n$ that is not an element of one of these subspaces $V_1, \ldots, V_k$. Since we only consider a finite number of subspaces, this is a rather easy task.

Lemma 5.7 makes it possible to find a perturbation of the matrix $B(s)$ that is suitable for our purpose. This result is stated in the next lemma.

LEMMA 5.8. *Let the vectors $v_1, \ldots, v_k \in \mathbb{C}^n$ and $b_1, \ldots, b_k \in \mathbb{C}^n$ be given. Assume that for all $i \in \{1, \ldots, k\} : \|v_i\| = 1$. Then for all $\varepsilon > 0$ there exists a vector $\beta \in \mathbb{R}^n$ such that*

(i) $\|\beta\| < \varepsilon$,

(ii) $\forall i \in \{1, \ldots, k\} : \; v_i^{\mathrm{T}} \cdot (b_i + \beta) \neq 0$.

Proof. Let $\varepsilon > 0$. Choose, according to Lemma 5.7, a vector $\gamma \in \mathbb{R}^n$ such that $v_i^{\mathrm{T}} \cdot \gamma \neq 0$ for all $i \in \{1, \ldots, k\}$. If for all $i \in \{1, \ldots, k\}$ we have $v_i^{\mathrm{T}} \cdot b_i = 0$, then $\beta = \frac{1}{2}\varepsilon \cdot \frac{\gamma}{\|\gamma\|}$ satisfies the claim. Otherwise, choose a $\rho \in (0, \min\{|v_i^{\mathrm{T}} \cdot b_i| \mid v_i^{\mathrm{T}} \cdot b_i \neq 0, \; i = 1, \ldots, k\})$, and define

$$\beta := \frac{1}{2} \cdot \min(\varepsilon, \rho) \cdot \frac{1}{\|\gamma\|} \cdot \gamma.$$

Then (i) is clear: $\|\beta\| \leq \frac{1}{2} \cdot \varepsilon \cdot 1 < \varepsilon$. To prove (ii), let $i \in \{1, \ldots, k\}$. If $v_i^{\mathrm{T}} \cdot b_i = 0$, then

$$v_i^{\mathrm{T}} \cdot (b_i + \beta) = v_i^{\mathrm{T}} \cdot \beta = \frac{1}{2} \cdot (v_i^{\mathrm{T}} \gamma) \cdot \frac{1}{\|\gamma\|} \cdot \min(\varepsilon, \rho) \neq 0.$$

On the other hand, if $v_i^{\mathrm{T}} \cdot b_i \neq 0$, then

$$|v_i^{\mathrm{T}} \cdot (b_i + \beta)| = |v_i^{\mathrm{T}} b_i + v_i^{\mathrm{T}} \beta| \geq |v_i^{\mathrm{T}} b_i| - |v_i^{\mathrm{T}} \beta| \geq \rho - \|v_i\| \cdot \|\beta\| \geq \rho - \frac{1}{2}\rho > 0.$$

So, in either case, $v_i^{\mathrm{T}} \cdot (b_i + \beta) \neq 0$. $\square$

At this point, the proof outlined in the introduction of this section is almost complete. We have only to state and prove the main result.

THEOREM 5.9. *Let $\Sigma = (A(s), B(s), \tau) \in \mathcal{V}$ be given. For all $\varepsilon > 0$ there exists a point $\tilde{\Sigma} = (\tilde{A}(s), \tilde{B}(s), \tilde{\tau}) \in \mathcal{V}$ such that*

(i) $d_{\mathcal{V}}(\Sigma, \tilde{\Sigma}) < \varepsilon$,

(ii) $\deg(\tilde{A}(s)) \leq \max(\deg(A(s)), 2)$ *and* $\deg(\tilde{B}(s)) = \deg(B(s))$,

(iii) *the time-delay system corresponding to $\tilde{\Sigma}$ is stabilizable, i.e.,*

$$\forall z \in \overline{\mathbb{C}^+} : \; \operatorname{rank}(zI - \tilde{A}(e^{-\tilde{\tau}z}) \mid \tilde{B}(e^{-\tilde{\tau}z})) = n.$$

Proof. Let $\varepsilon > 0$. First apply Theorem 5.6 to $A(s)$, and choose a matrix $\tilde{A}(s) \in \mathbb{R}[s]^{n \times n}$ such that

(1) $\|A(s) - \tilde{A}(s)\|_{pm} < \frac{1}{2}\varepsilon$,

(2) $\deg(\tilde{A}(s)) \leq \max(\deg(A(s)), 2)$,

(3) $\forall z \in \overline{\mathbb{C}^+} : \; \operatorname{rank}(zI - \tilde{A}(e^{-\tau z})) \geq n - 1$.

According to Lemma 5.1, the function $\tilde{p}(z) = \det(zI - \tilde{A}(e^{-\tau z}))$ has only a finite number of zeros in $\overline{\mathbb{C}^+}$, say $\lambda_1, \ldots, \lambda_k$. Only in these points, $(zI - \tilde{A}(e^{-\tau z}))$ loses rank, but still $\operatorname{rank}(zI - \tilde{A}(e^{-\tau z})) = n - 1$. So the left-kernel of $(zI - \tilde{A}(e^{-\tau z}))$ is one-dimensional for all $z \in \{\lambda_1, \ldots, \lambda_k\}$. Choose vectors $v_1, \ldots, v_k$ of norm 1 in $\mathbb{C}^n$, spanning these left-kernels:

$$\forall i \in \{1, \ldots, k\} : \operatorname{span}(v_i) = \{x \in \mathbb{C}^n \mid x^{\mathrm{T}} \cdot (\lambda_i I - \tilde{A}(e^{-\tau\lambda_i})) = 0\}.$$

Denote for all $i \in \{1, \ldots, k\}$ the first column of $B(e^{-\tau\lambda_i})$ by b_i. According to Lemma 5.8, there exists a $\beta \in \mathbb{R}^n$ such that $\|\beta\| < \frac{1}{2}\varepsilon$ and $v_i^{\mathrm{T}} \cdot (b_i + \beta) \neq 0$ for all $i = 1, \ldots, k$.

Define $\tilde{B}(s)$ as the sum of $B(s)$ and the $n \times m$ matrix $(\beta \mid 0)$ consisting of the column β, completed with zeros:

$$\tilde{B}(s) := B(s) + (\beta \mid 0).$$

Then (i) and (ii) obviously hold, and we need to show only that $\tilde{\Sigma} = (\tilde{A}(s), \tilde{B}(s), \tau)$ satisfies (iii).

For this, let $z \in \overline{\mathbb{C}^+}$. If $z \notin \{\lambda_1, \ldots, \lambda_k\}$, then $\operatorname{rank}(zI - \tilde{A}(e^{-\tau z})) = n$, so certainly $\operatorname{rank}(zI - \tilde{A}(e^{-\tau z}) \mid \tilde{B}(e^{-\tau z})) = n$.

Otherwise, suppose that $z = \lambda_i$ for certain $i \in \{1, \ldots, k\}$. Let $x \in \mathbb{C}^n$ be such that

$$x^{\mathrm{T}} \cdot (\lambda_i I - \tilde{A}(e^{-\tau\lambda_i}) \mid \tilde{B}(e^{-\tau\lambda_i})) = 0. \tag{44}$$

Hence, x^{T} is an element of the left-kernel of $(\lambda_i I - \tilde{A}(e^{-\tau\lambda_i}))$, and there exists an $\alpha \in \mathbb{C}$ such that $x = \alpha \cdot v_i$. Now the first column of $\tilde{B}(e^{-\tau\lambda_i})$ is $b_i + \beta$, and

$$0 = x^{\mathrm{T}} \cdot (b_i + \beta) = \alpha v_i^{\mathrm{T}} \cdot (b_i + \beta) = \alpha \cdot [v_i^{\mathrm{T}} \cdot (b_i + \beta)].$$

We conclude that $\alpha = 0$. This completes the proof. □

From Theorem 5.9 it follows directly that the subset S of $\mathcal{V}$, consisting of all parametrizations of stabilizable time-delay systems, is a dense subset of $\mathcal{V}$. Note that the conditions on the degrees of $\tilde{A}(s)$ and $\tilde{B}(s)$ are essential. According to Theorem 5.9, it is possible to construct a sequence of time-delay systems $(\Sigma_i)_{i=1}^{\infty} = (A_i(s), B_i(s), \tau_i)_{i=1}^{\infty}$ converging to $\Sigma = (A(s), B(s), \tau)$ (in the sense of §2) with the property that

$$\forall i \in \mathbb{N} : \deg(A_i(s)) \leq \max(\deg(A(s)), 2) \text{ and } \deg(B_i(s)) = \deg(B(s)).$$

This means that to achieve stabilizability, we have to perturb only a finite number of all parameters describing the original system Σ. Construction of a sequence of stabilizable systems converging to Σ, but with an increasing degree in s, is of no use for our genericity result because this requires systems with time-delays of constantly increasing length. Since we can always obtain a stabilizable system using perturbations of an a priori given degree, the result of Theorem 5.9 also holds within the framework of so-called inductive limit topologies, mentioned at the end of §2.

At this stage, our conjecture on the genericity of stabilizability for time-delay systems is reduced to a simple corollary from Theorems 3.1 and 5.9.

THEOREM 5.10. *Time-delay systems of the form* (5) *are generically stabilizable in the following sense: the subset S of the parameter-space $\mathcal{V}$, consisting of all parametrizations $\Sigma = (A(s), B(s), \tau)$ of time-delay systems satisfying*

$$\forall z \in \overline{\mathbb{C}^+} : \operatorname{rank}(zI - A(e^{-\tau z}) \mid B(e^{-\tau z})) = n,$$

is an open and dense subset of the metric space $\mathcal{V}$.

6. Generalization to the case of incommensurable time-delays. In §§2-5, a derivation of our genericity result is given for systems with commensurable time-delays. This restriction was made only for notational convenience; the incommensurable delay case is not significantly more difficult. In this section we point out that with exactly the same arguments as before, the genericity result can also be proved for the more general class of systems with incommensurable time-delays.

In the algebraic terminology, systems with k incommensurable time-delays, given by $\tau_1, \ldots, \tau_k$, are modeled as systems over the ring $\mathbb{R}[s_1, \ldots, s_k]$, where the indeterminate s_i corresponds to the delay operator σ_i with time-delay τ_i. To apply a topological approach to our genericity problem, first a parameter-space $\mathcal{W}$ (the incommensurable version of $\mathcal{V}$) has to be introduced. Denoting $\mathbb{R}[s_1, \ldots, s_k]$ by $\mathcal{R}$, $\mathcal{W}$ is defined as

$$\mathcal{W} := \{\Sigma = (A, B, (\tau_1, \ldots, \tau_k)) \mid A \in \mathcal{R}^{n\times n},\ B \in \mathcal{R}^{n\times m},\ \tau_i \in \mathbb{R}^+ (i = 1, \ldots, k)\}.$$

In the same way as in the commensurable delay case, a matrix over $\mathbb{R}[s_1, \ldots, s_k]^{p\times q}$ can be seen as a k-dimensional sequence of $p \times q$ matrices over $\mathbb{R}$, with only a finite number of nonzero elements. So, application of an ℓ_1-norm is possible, and in this way Definition 2.1 may be generalized. In the same way, polynomials in more than two indeterminates can be treated.

With these generalized definitions of the norms, the results of §2 remain valid. Most of these results rely on the fact that for all $z \in \overline{\mathbb{C}^+}$: $|e^{-\tau z}| \leq 1$. Since all time-delays τ_i are strictly larger than zero, we still have

$$\forall i \in \{1, \ldots, k\}\ \forall \tau_i > 0\ \forall z \in \overline{\mathbb{C}^+} :\ |e^{-\tau_i z}| \leq 1, \tag{45}$$

and the same proofs may be applied. The only difficulty left is the result on the continuity of the map χ from a polynomial matrix to its characteristic polynomial. Here exponentials do not play a role, but for this result the number of indeterminates is not significant at all, and therefore it also holds in the incommensurable delay case.

The results of §3 are easily generalized, as far as perturbations of the matrices $A(s_1, \ldots, s_k)$ and $B(s_1, \ldots, s_k)$ are concerned. Perturbations of the lengths of the time-delays are more complicated. However, because of (45), all perturbations of time-delays can be treated successively. In each step $i (i = 1, \ldots, k)$, the exponentials $e^{-\tau_1 z}, \ldots, e^{-\tau_{i-1} z}$ and $e^{-\tau_{i+1} z}, \ldots, e^{-\tau_k z}$, corresponding to all the other time-delays except τ_i, are bounded above by 1 in absolute value because we assume that $z \in \overline{\mathbb{C}^+}$. Therefore exactly the same techniques as in formula (22) may be applied successively for each τ_i separately to arrive at the desired result.

Section 4 is already put in a general context, so here nothing has to be done. Note however that in Proposition 4.6 only one time-delay is required to achieve an appropriate perturbation of the matrix $Q(z)$.

In the first part of §5 we are now dealing with analytic functions of the form

$$p(z) = \det(zI - A(e^{-\tau_1 z}, \ldots, e^{-\tau_k z})).$$

The assumption on the absence of zeros on the imaginary axis can be removed in almost the same way as stated in Proposition 5.2. Trivially, Rouché's theorem is still valid, and it is also easily seen that all zeros of $p(z) = \det(zI - A(e^{-\tau_1 z}, \ldots, e^{-\tau_k z}))$ in $\overline{\mathbb{C}^+}$ are contained in a compact subset of $\overline{\mathbb{C}^+}$. Therefore, Lemma 5.4 still holds and the same process of successively reducing the order of the zeros to 1 can be used. Again, Rouché's theorem guarantees that the total number of zeros in $\overline{\mathbb{C}^+}$ remains constant and that simple zeros remain simple. Moreover, the results of §4 imply that the condition on the degree of $A(s_1, \ldots, s_k)$ is satisfied. Perturbations of the matrix $B(s)$ can be obtained in exactly the same way as described for the

commensurable delay case. Therefore Theorem 5.9 may also be generalized to delay systems with incommensurable time-delays.

Summarizing, we conclude that our genericity result for the stabilizability of time-delay systems with commensurable time-delays also holds in the incommensurable delay case. This final conclusion is stated in the last theorem.

THEOREM 6.1. *Time-delay systems with incommensurable time-delays of the form*

$$\dot{x}(t) = A(\sigma_1, \ldots, \sigma_k)x(t) + B(\sigma_1, \ldots, \sigma_k)u(t),$$

where σ_i $(i = 1, \ldots, k)$ *denotes the delay operator corresponding to a time-delay* τ_i, *are generically stabilizable in the following sense: the subset of the parameter-space*

$$\mathcal{W} = \{(A(s_1, \ldots, s_k), B(s_1, \ldots, s_k), (\tau_1, \ldots, \tau_k)) \mid A(s_1, \ldots, s_k) \in \mathbb{R}[s_1, \ldots, s_k]^{n\times n},$$
$$B(s_1, \ldots, s_k) \in \mathbb{R}[s_1, \ldots, s_k]^{n\times m} \text{ and } \forall i \in \{1, \ldots, k\} : \tau_i > 0\},$$

consisting of all parametrizations $\Sigma = (A(s_1, \ldots, s_k), B(s_1, \ldots, s_k), (\tau_1, \ldots, \tau_k))$ *of time-delay systems satisfying*

$$\forall z \in \overline{\mathbb{C}^+} : \operatorname{rank}(zI - A(e^{-\tau_1 z}, \ldots, e^{-\tau_k z}) \mid B(e^{-\tau_1 z}, \ldots, e^{-\tau_k z})) = n,$$

is an open and dense subset of the metric space $\mathcal{W}$.

7. Conclusions. In this paper it was shown that time-delay systems with commensurable or incommensurable time-delays are generically stabilizable. First, an algebraic approach was used to model time-delay systems with point delays. For this class of systems, a topological framework was introduced to formalize the concept of genericity. In this setting it was shown that the set of stabilizable time-delay systems is an open and dense subset of the parameter-space describing all time-delay systems. This means that stabilizability is a robust property; it is preserved after small perturbations of the parameters. Moreover, a nonstabilizable time-delay system can be approximated arbitrarily close by a sequence of stabilizable time-delay systems. Therefore the property of stabilizability is very weak; it is generic in the sense described above.

Acknowledgments. I am indebted to Malo Hautus, Henri Huijberts, and Anton Stoorvogel for all their valuable suggestions and help during the writing of this paper. I would especially like to thank Stef van Eijndhoven for his guidance and his enthusiasm for my work. His ideas had a great influence on the contents of this paper.

OPTIMAL POSITIONING OF ANODES FOR CATHODIC PROTECTION*

L. STEVEN HOU† AND WEIWEI SUN‡

Abstract. We consider an optimal control problem that arises in cathodic protection. The control is the position of a finite number of anodes, each with a prescribed current density. The goal is to obtain a desired potential distribution on the cathode that will prevent or reduce cathodic corrosion. The existence of an optimal solution is proven. The differentiability of the functional minimized is justified, and the equations satisfied by the derivative are established. Then a numerical algorithm is proposed for computing the optimal position of the anodes. Finally, we present some numerical results obtained by implementing the proposed numerical algorithm with a boundary element method.

Key words. optimal control, cathodic protection, nonlinear boundary value problem, gradient method

1. Introduction.

This article is motivated by the desire to reduce corrosion (caused by chemical reactions) of ship propellers surrounded by sea water or of metal containers filled with an electrolyte. The corrosion process can be significantly slowed by maintaining a critical electrical potential on the portion of the structure surface to be protected. This portion of the surface to be protected usually acts as cathodes. The rest part of the surface is either insulated or anodes. The placement of a number of anodes on the structure surface could effectively change the potential distribution on the surface. Thus one could attempt to adjust the current density on the anodes and/or the location of the anodes to best match a desired potential distribution on the cathode. In light of this, mathematicians, scientists, and engineers have been trying to use optimal control theory and techniques to design cathodic protection systems. For instance, [13] contained a survey on this subject. Zamani and Chuang [12] studied a potential matching problem by controlling the electrical current density on the anode. The models used in [12], however, are essentially linear. Hou and Sun [7] discussed, mainly from an algorithmic point of view, several control problems, including adjusting the positions of anodes, in order to achieve a desired potential on the structure; nonlinear models as well as linear ones were employed. Amaya and Aoki [2] used discrete optimization techniques to handle optimal control problems with hybrid controls; i.e., several controls are applied simultaneously. The controls being used in the design of cathodic systems can be loosely divided into two categories. The first is "value controls," i.e., the current density on the anodes or the density of point charges. The second is "location controls," i.e., the location of anodes and/or location of point charges. In this article, we will attempt to mathematically analyze optimal control problems with "location controls" and devise some numerical algorithms that can aid the design of a cathodic control system. The theories presented in this paper can be applied to a variety of cathodic protection problems. Propeller and container protection serves as two concrete examples.

We assume the "corrosive fluid" occupies a physical domain Ω with a boundary Γ. The domain can be finite as in the case of a metal tank containing an electrolyte (see Figure 1) or infinite (but with a bounded boundary) as in the case of a ship body surrounded by sea water (see Figure 2). The "corrosive fluid" in the former case is the electrolyte and in the latter is the sea water. The electrical potential ϕ in Ω is governed by the differential equation

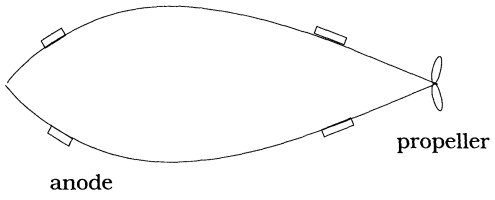

FIG. 2. *An exterior domain example: a ship surrounded by sea water.*

$$-\operatorname{div}(\sigma \operatorname{grad}\phi) = 0 \quad \text{in } \Omega,$$

where the conductivity σ has a positive lower bound.

For simplicity of exposition, we will deal only with interior problems. Since we will use boundary element methods for computations, the treatments for infinite domains and finite domains are essentially the same (see [7], [11] for details). For general theories and applications of boundary element methods, see [4].

The boundary of the domain Ω is divided into three parts: namely, the cathode Γ_C (the surface to be protected), the anode $\cup_{i=1}^{N}\Gamma_i$ (on which electrical current or potential is given), and Γ_0 (the insulated part).

On Γ_C, ϕ satisfies the relation

$$\sigma\frac{\partial\phi}{\partial n} = -f(\phi) \quad \text{on } \Gamma_C,$$

where f is an empirical function that depends on the "corrosive fluid" and the cathode materials (see [3]).

We assume that we have at our disposal a number of given electrical current sources (anodes) that are to be connected to the boundary of Ω, but the location of the anodes can be adjusted, i.e., the location of Γ_i's, acts as control variables. Our task is to determine the optimal location for Γ_i's such that the resulting potential distribution on Γ_C best matches some desired one. On each Γ_i, we have the boundary condition

$$\sigma\frac{\partial\phi}{\partial n} = u_i \quad \text{on } \Gamma_i,$$

which corresponds to the specification of the current density. This is the case for impressed cathodic controls [7], [12] and is the case we will treat in this paper. In some other cases, other types of boundary conditions may be specified instead of the current density, e.g., in the case of a nonpolarizable electrode [13].

A mathematical description proceeds as follows. Let Ω be a bounded open domain in $\mathbb{R}^2$ and Γ be the boundary of Ω. Assume $\Gamma = [\cup_{i=1}^N \Gamma_i] \cup \Gamma_C \cup \Gamma_0$. We assume that all boundary segments are closed and they may intersect with each other only at the end points. We assume that the boundary Γ is parameterized by the arc length coordinate $s \in [0, L]$ and each Γ_i has a fixed arc length $d_i > 0$. Since each point on Γ is uniquely determined by its arc length coordinate s, we will use s to denote, without confusion from the context, both the arc length coordinate for the point and the point itself. Thus each Γ_i is determined by the arc length coordinate t_i of its center point. The location of all the Γ_i's is the control variable, i.e., the center position t_i's constitute the control variable. Each t_i is constrained to range on a finite interval $[a_i, b_i]$. Since the partition of Γ depends on $\mathbf{t} = (t_1, t_2, \ldots, t_N)$, we rewrite $\Gamma = [\cup_{i=1}^N \Gamma_i(\mathbf{t})] \cup \Gamma_C \cup \Gamma_0(\mathbf{t})$. Each segment $\Gamma_i(\mathbf{t})$ is centered at t_i with a fixed arc length d_i. Γ_C is fixed (independent of $\mathbf{t}$) with a positive measure. We assume that each $\Gamma_i(\mathbf{t})$ is parameterized by $s \in [t_i - \frac{d_i}{2}, t_i + \frac{d_i}{2}]$. $\Gamma_0(\mathbf{t}) = \Gamma \setminus \left[\Gamma_C \cup (\cup_{i=1}^N \Gamma_i(\mathbf{t}))\right]$. We assume that $\frac{d_1}{2} \le a_1 < b_1 < a_2 < b_2 < \cdots < a_N < b_N < (L - \frac{d_N}{2})$ and $b_i \le a_{i+1} - \frac{d_i}{2} - \frac{d_{i+1}}{2}$ for $i = 1, \ldots, N-1$ and that $a_{i+1} - b_i \ge \frac{d_i + d_{i+1}}{2}$ for $i = 1, \ldots, N-1$. Recall that each t_i is the center point of the ith anode and the width of the ith anode $d_i > 0$; thus under these assumptions, the situation of two anodes joining together is permitted, but overlapping of two anodes is disallowed. We assume that each u_i is a given function in $C(\mathbb{R})$ with a compact support on the interval $(-\frac{d_i}{2}, \frac{d_i}{2})$. Thus the function $s \mapsto u_i(s - t_i)$ for $s \in [t_i - \frac{d_i}{2}, t_i + \frac{d_i}{2}]$ has a compact support on $\Gamma_i(\mathbf{t})$.

We are concerned with the following optimal control problem: seek a state ϕ and a $\mathbf{t} \in \mathbb{R}^N$ with components $t_i \in [a_i, b_i]$, $i = 1, \ldots, N$, such that the functional

$$\mathcal{J}(\phi, \mathbf{t}) = \frac{1}{2} \int_{\Gamma_C} (\phi - \phi_0)^2 \, d\Gamma \tag{1.1}$$

is minimized subject to the the constraint equations

$$-\operatorname{div}(\sigma \operatorname{grad} \phi) = 0 \quad \text{in } \Omega, \tag{1.2}$$

$$\sigma \frac{\partial \phi}{\partial n} = u_i(s - t_i) \quad \forall\, s \in \left[t_i - \frac{d_i}{2}, t_i + \frac{d_i}{2}\right] \text{ on } \Gamma_i(\mathbf{t}), \quad i = 1, \ldots, N, \tag{1.3}$$

$$\sigma \frac{\partial \phi}{\partial n} = 0 \quad \text{on } \Gamma_0(\mathbf{t}), \tag{1.4}$$

and

$$\sigma \frac{\partial \phi}{\partial n} = -f(\phi) \quad \text{on } \Gamma_C. \tag{1.5}$$

Here ϕ_0 is a desired potential distribution on Γ_C under which the corrosion rate is minimized. The function $f \in C^1(\mathbb{R})$ is given by either

$$f(\phi) = k\phi + l\phi^3, \tag{1.6}$$

where k and l are constants and $k > 0$, $l \ge 0$ (see [7]), or

$$f(\phi) = C_3[e^{C_1\phi} - e^{-C_2\phi}], \tag{1.7}$$

where C_1, C_2, and C_3 are positive constants (see [3]). If $l = 0$ in (1.6), the problem reduces to a linear one. For f given by either (1.6) or (1.7), one can easily verify that there exists an $\alpha > 0$ such that

$$f'(\phi) \geq \alpha \quad \forall\, \phi \qquad \text{and} \qquad f(0) = 0. \tag{1.8}$$

Note that the boundary conditions (1.3)-(1.5) can be written into a unified form

$$\sigma \frac{\partial \phi}{\partial n} = -\tilde{f}(\phi) + \tilde{u}(\cdot, \mathbf{t})$$

with appropriately defined $\tilde{f}$ and $\tilde{u}$.

We will use a variational weak formulation (1.9) of the nonlinear boundary value problem (1.2)-(1.5). We will utilize Sobolev spaces $H^m(\Omega)$, $H^s(\Gamma_i)$, $H^s(\Gamma_C)$, $H^s(\Gamma_0)$, and $H^s(\Gamma)$. The norms on these spaces are denoted by, e.g., $\|\cdot\|_m$, $\|\cdot\|_{s,\Gamma_i}$, and so on. For details, see [1] and [5]. We restate the minimization problem as follows: seek a state $\phi \in H^1(\Omega)$ and a $\mathbf{t} \in \Pi_{i=1}^N [a_i, b_i]$ such that the functional (1.1) is minimized subject to the the constraint equation

$$\begin{aligned} &\int_\Omega \sigma \operatorname{grad}\phi \cdot \operatorname{grad}\psi \, d\Omega + \int_{\Gamma_C} f(\phi)\psi \, d\Gamma \\ &\qquad = \sum_{i=1}^N \int_{\Gamma_i(\mathbf{t})} u_i(s - t_i)\psi \, ds \quad \forall\, \psi \in H^1(\Omega). \end{aligned} \tag{1.9}$$

The nonlinear boundary value problem (1.2)-(1.5) is understood in the sense of (1.9). Of course when the solution is smooth enough, (1.2)-(1.5) can hold in the classical sense.

Now we state a useful fact whose proof can be found in, e.g., [9]. The norm on $H^1(\Omega)$ defined by

$$|||\phi|||_1 = \left\{ \int_\Omega \sigma |\operatorname{grad}\phi|^2 \, d\Omega + \alpha \int_{\Gamma_C} \phi^2 \, d\Gamma \right\}^{1/2} \quad \forall\, \phi \in H^1(\Omega)$$

is equivalent to the usual $H^1(\Omega)$-norm $\|\cdot\|_1$; i.e., there exist constants $\rho > 0$ and $\gamma > 0$ such that

$$\rho \|\phi\|_1^2 \geq \int_\Omega \sigma |\operatorname{grad}\phi|^2 \, d\Omega + \alpha \int_{\Gamma_C} \phi^2 \, d\Gamma \geq \gamma \|\phi\|_1^2 \quad \forall\, \phi \in H^1(\Omega). \tag{1.10}$$

The rest of the paper is organized as follows. In §2 we prove the existence and uniqueness of solutions to (1.9) so that the constraint equation is well posed. In §3 we show the existence of an optimal pair $(\hat{\mathbf{t}}, \hat{\phi})$ that minimizes (1.1) subject to (1.9). In §4 we establish the differentiability of the constraint minimization problem so that a first-order optimality condition is derived. In §5 we propose an algorithm for computing optimal solutions using gradient methods. Finally in §6 we report some numerical results that demonstrate the effectiveness of our theory and algorithm.

2. Existence and uniqueness of solutions to the constraint equations. We first examine the existence of a solution to (1.9), which is a partial differential equation with nonlinear boundary conditions. In this section we assume that $\mathbf{t}$ is given; thus the boundary components Γ_i, $i = 1, \ldots, N$, are fixed. We will show that for f given by either (1.6) or (1.7), equation (1.9) possesses a unique solution $\phi \in H^1(\Omega)$. We point out that [10] studied general nonlinear boundary value problems using a boundary integral method. It is possible to generalize the

ideas of boundary integral methods in [10] to study (1.2)-(1.5) (then, equivalently, (1.9)). For the case in which f is given by (1.7), existence and uniqueness results for (1.9) were established in [8] by a variational method for an energy functional. For completeness we still give a proof of existence and uniqueness, but the approach is different from that of [8] and [10]. Also, although we will restrict our attention to the physical boundary conditions (1.6) and (1.7), it is possible to deal with more general nonlinear boundary conditions with our methods.

LEMMA 2.1. *X is a finite-dimensional Hilbert space whose scalar product is denoted by $(\cdot,\cdot)$ and the corresponding norm by $|\cdot|$. Let F be a continuous mapping form X into X with the following property: there exists an $r > 0$ such that*

$$(F(\phi),\phi) \geq 0 \quad \forall\, \phi \in X \text{ with } |\phi| = r\,.$$

Then there exists a $\phi \in X$ such that

$$F(\phi) = 0 \quad \text{and} \quad |\phi| \leq r\,.$$

Proof. See [5, p. 279]. □

LEMMA 2.2. *Assume $\phi \in H^1(\Omega)$ and $s > 0$. Then $e^{s|\phi|} \in L^1(\Gamma)$. Moreover, there exists a constant κ, independent of ϕ, such that*

$$\int_\Gamma e^{s|\phi|}\,d\Gamma \leq 1 + |\Gamma| + e^{s^2\kappa^2\|\phi\|_1^2}\,|\Gamma| < \infty\,,$$

where $|\Gamma|$ is the measure of Γ.

Proof. The proof is based on an imbedding theorem for Sobolev-Orlicz spaces [1]. See [8] for details. □

LEMMA 2.3. *Assume $\{\phi_n\} \subset L^2(\Gamma_C)$ is a sequence such that $\phi_n \to \phi$ almost everywhere on Γ_C and*

$$\int_{\Gamma_C} f(\phi_n)\phi_n\,d\Gamma \leq B \quad \forall\, n, \tag{2.1}$$

where f is defined by (1.1) and $B > 0$ is a constant independent of n. Then

$$\int_{\Gamma_C} f(\phi)\phi\,d\Gamma \leq \liminf_{n\to\infty} \int_{\Gamma_C} f(\phi_n)\phi_n\,d\Gamma$$

and

$$\lim_{n\to\infty} \int_{\Gamma_C} |f(\phi_n) - f(\phi)|\,d\Gamma = 0\,.$$

Proof. See [8] or [6]. □

THEOREM 2.4. *Assume each $u_i \in C(\Gamma_i)$, $i = 1,\ldots,N$. Then there exists a unique $\phi \in H^1(\Omega)$ that satisfies (1.9). Furthermore, $\phi \in C^2(\Omega) \cap C(\overline{\Omega})$.*

Proof. We first show the existence of a $\phi \in H^1(\Omega)$ that satisfies (1.9). Using (1.8) and the mean value theorem we have

$$\int_{\Gamma_C} f(\phi)\phi\,d\Gamma = \int_{\Gamma_C} [f(\phi) - f(0)]\phi\,d\Gamma = \int_{\Gamma_C} [f'(\tilde{\phi})]\phi^2\,d\Gamma \geq \alpha \int_{\Gamma_C} \phi^2\,d\Gamma,$$

where $\tilde{\phi}$ is between 0 and ϕ. It follows from the last relation and (1.10) that

$$\int_\Omega \sigma\,\operatorname{grad}\phi \cdot \operatorname{grad}\phi\,d\Omega + \int_{\Gamma_C} f(\phi)\phi\,d\Gamma \geq \gamma\|\phi\|_1^2 \quad \forall\, \phi \in H^1(\Omega)\,.$$

Using the Cauchy-Schwarz inequality and trace theorems we obtain the estimate

$$\left|\sum_{i=1}^{N}\int_{\Gamma_i} u_i(s-t_i)\phi\,ds\right| \le \beta\|\phi\|_1 \sum_{i=1}^{N}\|u_i(\cdot-t_i)\|_{0,\Gamma_i} \quad \forall\,\phi\in H^1(\Omega),$$

where β is a positive constant. By combining the last two estimates we deduce that for $r=\frac{\beta}{\gamma}\left\{\sum_{i=1}^{N}\|u_i(\cdot-t_i)\|_{0,\Gamma_i}+1\right\}>0$ we have

$$\int_\Omega \sigma\,\operatorname{grad}\phi\cdot\operatorname{grad}\phi\,d\Omega+\int_{\Gamma_C} f(\phi)\phi\,d\Gamma-\sum_{i=1}^{N}\int_{\Gamma_i} u_i(s-t_i)\phi\,ds \ge 0 \quad \forall\,\phi\in H^1(\Omega) \text{ with } \|\phi\|_1=r. \tag{2.2}$$

Since $H^1(\Omega)$ is separable, we choose a countable basis of $H^1(\Omega)$: $\{\psi_i\}_{i=1}^{\infty}$. We set $X_n=\operatorname{span}\{\psi_1,\dots,\psi_n\}$. The inner product and norm on each X_n are defined by that of $H^1(\Omega)$ restricted to X_n. We introduce the mapping $F_n: X_n\to X_n$ defined by

$$(F_n(\phi),\psi_j)=\int_\Omega \sigma\,\operatorname{grad}\phi\cdot\operatorname{grad}\psi_j\,d\Omega+\int_{\Gamma_C} f(\phi)\psi_j\,d\Gamma - \sum_{i=1}^{N}\int_{\Gamma_i} u_i(s-t_i)\psi_j\,ds, \quad 1\le j\le n.$$

It follows from (2.2) and Lemma 2.1 that the finite-dimensional problem

$$\int_\Omega \operatorname{grad}\phi_n\cdot\operatorname{grad}\psi\,d\Omega+\int_{\Gamma_C} f(\phi_n)\psi\,d\Gamma=\sum_{i=1}^{N}\int_{\Gamma_i} u_i(s-t_i)\psi\,ds \quad \forall\,\psi\in X_n \tag{2.3}$$

has a solution $\phi_n\in X_n$ with a bound

$$\|\phi_n\|_1\le\frac{\beta}{\gamma}\left\{\sum_{i=1}^{N}\|u_i(\cdot-t_i)\|_{0,\Gamma_i}+1\right\}.$$

We can extract a subsequence of $\{\phi_n\}$, still denoted by $\{\phi_n\}$, that converges weakly to some $\phi\in H^1(\Omega)$ as $n\to 0$. Then $\{\phi_n\}$ also converges weakly in $H^{1/2}(\Gamma)$, using a trace theorem. By compact imbedding results, $\{\phi_n\}$ converges strongly in $L^3(\Gamma)$, and by extracting a further subsequence, $\{\phi_n\}$ converges pointwise almost everywhere. Now we examine the two cases (1.6) and (1.7) separately. For f given by (1.6), using the strong convergence of $\{\phi_n\}$ in $L^3(\Gamma)$, the obvious growth condition

$$|f(\phi)|\le C(1+|\phi|^3) \quad \forall\,\phi$$

and the well-known continuity properties of the Němyckiĭ operator on Carathéodory functions, we may pass to the limit in (2.3) to show that

$$\int_\Omega \sigma\,\operatorname{grad}\phi\cdot\operatorname{grad}\psi\,d\Omega+\int_{\Gamma_C} f(\phi)\psi\,d\Gamma=\sum_{i=1}^{N}\int_{\Gamma_i} u_i(s-t_i)\psi\,ds \quad \forall\,\psi\in C^1(\overline{\Omega}).$$

Then, using the denseness of $C^1(\overline{\Omega})$ in $H^1(\Omega)$ and the fact that $\phi|_{\Gamma_C}\in L^4(\Gamma_C)$, we conclude ϕ satisfies (1.9). For f given by (1.7) we see that by setting $\psi=\phi_n$ in (2.3) we obtain

$$\begin{aligned}\int_{\Gamma_C} f(\phi_n)\phi_n\,d\Gamma &\le \|u\|_{0,\Gamma_A}\|\phi_n\|_{0,\Gamma_A}\\ &\le C\|u\|_{0,\Gamma_A}\|\phi_n\|_1\le C\,\|u\|_{0,\Gamma_A}\frac{\beta}{\gamma}\left\{\|u\|_{0,\Gamma_A}+1\right\}.\end{aligned}$$

By Lemma 2.3 we have

$$\int_{\Gamma_C} f(\phi)\phi \, d\Gamma \leq \liminf_{n\to\infty} \int_{\Gamma_C} f(\phi_n)\phi_n \, d\Gamma$$

and

$$\lim_{n\to\infty} \int_{\Gamma_C} |f(\phi_n) - f(\phi)| \, d\Gamma = 0 .$$

Thus for each $\psi \in C^1(\overline{\Omega})$ we may pass to the limit in (2.3) and obtain

$$\int_\Omega \sigma \operatorname{grad}\phi \cdot \operatorname{grad}\psi \, d\Omega + \int_{\Gamma_C} f(\phi)\psi \, d\Gamma = \int_{\Gamma_A} u\psi \, d\Gamma \quad \forall\, \psi \in C^1(\overline{\Omega}) .$$

Using the denseness of $C^1(\overline{\Omega})$ in $H^1(\Omega)$ and the fact that $f(\phi) \in L^2(\Gamma_C)$ (which follows from Lemma 2.2), we conclude ϕ satisfies (1.9).

We briefly examine the regularity of the solution $\phi \in H^1(\Omega)$. If f is given by (1.6), then trace theorems on $\Omega \subset \mathbb{R}^2$ imply that $f(\phi) \in L^r(\Gamma)$ for all $r > 1$. If f is given by (1.7), then Lemma 2.2 implies that $f(\phi) \in L^r(\Gamma)$ for all $r > 1$. Employing elliptic regularity theories, we see that $\phi \in W^{3/2,r}(\Omega)$ for all $r > 1$, which in turn implies $\phi|_\Gamma \in W^{1,r}(\Gamma)$ so that $\phi \in C(\overline{\Omega})$. Interior regularity results for the Laplacian equation implies $\phi \in C^2(\Omega)$. Thus we have shown that there exists a solution $\phi \in H^1(\Omega) \cap C^2(\Omega) \cap C(\overline{\Omega})$.

To answer the question of uniqueness, we assume that ϕ and $\bar{\phi}$ are two solutions to (1.9). Then we have

$$\int_\Omega \sigma \operatorname{grad}(\phi - \bar{\phi}) \cdot \operatorname{grad}\psi \, d\Omega + \int_{\Gamma_C} [f(\phi) - f(\bar{\phi})]\psi \, d\Gamma = 0 \quad \forall\, \psi \in H^1(\Omega) .$$

Setting $\psi = \phi - \bar{\phi}$, we see that

$$\int_\Omega \sigma |\operatorname{grad}(\phi - \bar{\phi})|^2 \, d\Omega + \int_{\Gamma_C} [f(\phi) - f(\bar{\phi})](\phi - \bar{\phi}) \, d\Gamma = 0 .$$

Using the mean value theorem,

$$\int_\Omega \sigma |\operatorname{grad}(\phi - \bar{\phi})|^2 \, d\Omega + \int_{\Gamma_C} f'(\tilde{\phi})(\phi - \bar{\phi})^2 \, d\Gamma = 0$$

for some $\tilde{\phi}$ between ϕ and $\bar{\phi}$. Using (1.8), we see that

$$\int_\Omega \sigma |\operatorname{grad}(\phi - \bar{\phi})|^2 \, d\Omega + \alpha \int_{\Gamma_C} (\phi - \bar{\phi})^2 \, d\Gamma \leq 0 .$$

Hence we deduce that $\operatorname{grad}(\phi - \bar{\phi}) = 0$ in Ω and $(\phi - \bar{\phi}) = 0$ on Γ_C. This in turn implies $(\phi - \bar{\phi}) = 0$ in Ω; i.e., uniqueness holds. □

3. Existence of an optimal solution. We have shown that for each fixed $\mathbf{t}$, (1.9) has a unique solution, which will be denoted by $\phi = \phi(\mathbf{t})$ in subsequent discussion. We are now prepared to study the existence of an optimal $\mathbf{t}$ that minimizes the functional (1.1) subject to (1.9).

THEOREM 3.1. *Assume $u_i \in C^1(\mathbb{R})$ with a compact support on Γ_i, $i = 1, \ldots, N$. Then there exists a $(\hat{\mathbf{t}}, \hat{\phi}) \in \left(\prod_{i=1}^N [a_i, b_i]\right) \times H^1(\Omega)$ that minimizes* (1.1) *subject to* (1.9).

Proof. We first prove that the mapping $\mathbf{t} \mapsto \phi(\mathbf{t})$, where $\phi(\mathbf{t})$ is the solution of (1.9), is continuous from $\prod_{i=1}^{N}[a_i, b_i]$ into $H^1(\Omega)$. Let $\mathbf{t} \in \prod_{i=1}^{N}[a_i, b_i]$ be given. For each $\delta\mathbf{t} \in \mathbb{R}^N$ we introduce

$$\phi_{\delta\mathbf{t}} = \phi(\mathbf{t} + \delta\mathbf{t}) - \phi(\mathbf{t}).$$

Then $\phi_{\delta\mathbf{t}} \in H^1(\Omega)$ satisfies

$$\int_\Omega \operatorname{grad}\phi_{\delta\mathbf{t}} \cdot \operatorname{grad} v \, d\Omega + \int_{\Gamma_C} [f(\phi(\mathbf{t}+\delta\mathbf{t})) - f(\phi(\mathbf{t}))]\, v \, d\Gamma$$
$$= \sum_{i=1}^{N} \int_{\Gamma_i(\mathbf{t})} [u_i(s - t_i - \delta t_i) - u_i(s - t_i)]\, v \, ds \quad \forall\, v \in H^1(\Omega).$$

Here we have used the fact that $u_i(\cdot)$ has a compact support on $\left(-\frac{d_i}{2}, \frac{d_i}{2}\right)$, and thus for $|\delta\mathbf{t}|$ small enough, the support of $u_i(s - t_i - \delta t_i)$ for $s \in \left(t_i + \delta t_i - \frac{d_i}{2}, t_i + \delta t_i + \frac{d_i}{2}\right)$ lies on $\Gamma_i(\mathbf{t})$. Using the mean value theorem we have

$$\int_\Omega \operatorname{grad}\phi_{\delta\mathbf{t}} \cdot \operatorname{grad} v \, d\Omega + \int_{\Gamma_C} f'(\tilde{\phi})\phi_{\delta\mathbf{t}} v \, d\Gamma$$
$$= \sum_{i=1}^{N} \int_{\Gamma_i(\mathbf{t})} [u_i(s - t_i - \delta t_i) - u_i(s - t_i)]\, v \, ds \quad \forall\, v \in H^1(\Omega).$$

By setting $v = \phi_{\delta\mathbf{t}}$ and using (1.8), (1.10), and a trace theorem, we see that

$$\gamma \|\phi_{\delta\mathbf{t}}\|_1^2 \le \|\phi_{\delta\mathbf{t}}\|_{0,\Gamma_C} \sum_{i=1}^{N} \|u_i(\cdot - t_i - \delta t_i) - u_i(\cdot - t_i)\|_{0,\Gamma_i(\mathbf{t})}$$
$$\le C\, \|\phi_{\delta\mathbf{t}}\|_1 \sum_{i=1}^{N} \|u_i(\cdot - t_i - \delta t_i) - u_i(\cdot - t_i)\|_{0,\Gamma_i(\mathbf{t})},$$

so

$$\|\phi_{\delta\mathbf{t}}\|_1 \le C \sum_{i=1}^{N} \|u_i(\cdot - t_i - \delta t_i) - u_i(\cdot - t_i)\|_{0,\Gamma_i(\mathbf{t})}.$$

Since each u_i is continuous, the right-hand side clearly goes to zero as $|\delta\mathbf{t}| \to 0$. Hence,

$$\|\phi_{\delta\mathbf{t}}\|_1 \to 0 \quad \text{as } |\delta\mathbf{t}| \to 0;$$

i.e., we have shown that the mapping $\mathbf{t} \mapsto \phi(\mathbf{t})$ is continuous from $\prod_{i=1}^{N}[a_i, b_i] \to H^1(\Omega)$. This in turn shows that $\mathcal{J}(\phi(\mathbf{t}), \mathbf{t})$ is continuous on the bounded, closed set $\prod_{i=1}^{N}[a_i, b_i]$ so that $\mathcal{J}(\phi(\mathbf{t}), \mathbf{t})$ has a minimum, attained at, say, $\hat{\mathbf{t}}$. Of course $(\hat{\mathbf{t}}, \phi(\hat{\mathbf{t}}))$ minimizes (1.1) subject to (1.9). The proof is completed by setting $\hat{\phi} = \phi(\hat{\mathbf{t}})$. □

4. Differentiability and first-order optimality conditions. In this section, we will attempt to characterize the optimal solution. The main result can be simply stated as follows: the minimum is attained when each $\hat{t}_i$ is either on the boundary of $[a_i, b_i]$ or in the interior of (a_i, b_i) with a vanishing ith partial derivative.

THEOREM 4.1. *Assume $u_i \in C^1(\mathbb{R})$ with a compact support in $\Gamma_i(\mathbf{t})$, $i = 1, \ldots, N$. Then the mapping $\mathbf{t} \mapsto \phi(\mathbf{t})$ is differentiable for $\mathbf{t} \in \prod_{i=1}^{N}(a_i, b_i)$. Furthermore, let $\lambda_i \in H^1(\Omega)$ be*

the solution of the following equation:

$$\int_\Omega \sigma \operatorname{grad}\lambda_i \cdot \operatorname{grad}\psi \, d\Omega + \int_{\Gamma_C} f'(\phi)\lambda_i \psi \, d\Gamma = -\int_{\Gamma_i(\mathbf{t})} u_i'(s - t_i)\psi \, ds \quad \forall\, \psi \in H^1(\Omega)\,. \tag{4.1}$$

Then $\lambda_i = \frac{\partial \phi(\mathbf{t})}{\partial t_i}$.

Proof. Let a $\mathbf{t} \in \prod_{i=1}^N (a_i, b_i)$ be given. Since $\phi(\cdot)$ is continuous on $\prod_{i=1}^N [a_i, b_i]$ and f is C^1, $f'(\phi(\mathbf{t}))$ is continuous on Γ_C. Equations (1.8) and (1.10) imply that (4.1) is a well-posed mixed Neumann–Robin-type boundary value problem, and there exists a unique $\lambda_i = \lambda_i(\mathbf{t}) \in H^1(\Omega)$ satisfying (4.1) and

$$\|\lambda_i\|_1 \le C(\phi, u_1, \ldots, u_N)\,, \tag{4.2}$$

where $C(\phi, u_1, \ldots, u_N)$ is a constant depending on $(\phi, u_1, \ldots, u_N)$.

For each nonzero $\epsilon \in \mathbb{R}$, we introduce

$$\psi_\epsilon = \frac{\phi(\mathbf{t} + \epsilon \mathbf{e}_i) - \phi(\mathbf{t})}{\epsilon} - \lambda_i\,,$$

where $\mathbf{e}_i$ is the ith standard basis vector in $\mathbb{R}^N$. Using the fact that $u_i(\cdot)$ has a compact support on $\left(-\frac{d_i}{2}, \frac{d_i}{2}\right)$ we see that for ϵ small enough, the support of $u_i(s - t_i - \epsilon)$ for $s \in \left(t_i + \epsilon - \frac{d_i}{2}, t_i + \epsilon + \frac{d_i}{2}\right)$ lies on $\Gamma_i(\mathbf{t})$. Thus the defining equations for $\phi(\mathbf{t} + \epsilon \mathbf{e}_i)$ and $\phi(\mathbf{t})$ are given by, respectively,

$$\int_\Omega \sigma \operatorname{grad}\phi(\mathbf{t} + \epsilon \mathbf{e}_i) \cdot \operatorname{grad} v \, d\Omega + \int_{\Gamma_C} f(\phi(\mathbf{t} + \epsilon \mathbf{e}_i)) v \, d\Gamma = \sum_{j=1}^N \int_{\Gamma_j(\mathbf{t})} u_j(s - t_j - \epsilon \delta_j^i)\, v \, ds \quad \forall\, v \in H^1(\Omega)$$

and

$$\int_\Omega \sigma \operatorname{grad}\phi(\mathbf{t}) \cdot \operatorname{grad} v \, d\Omega + \int_{\Gamma_C} f(\phi(\mathbf{t})) v \, d\Gamma = \sum_{j=1}^N \int_{\Gamma_j(\mathbf{t})} u_j(s - t_j)\, v \, ds \quad \forall\, v \in H^1(\Omega)\,.$$

(δ_j^i is the Kronecker delta.) Now we subtract the last two equations, divide by ϵ, and then subtract (4.1). The resulting equation reads as follows:

$$\int_\Omega \sigma \operatorname{grad}\psi_\epsilon \cdot \operatorname{grad} v \, d\Omega + \int_{\Gamma_C} \left[\frac{f(\phi(\mathbf{t}+\epsilon\mathbf{e}_i)) - f(\phi(\mathbf{t}))}{\epsilon} - f'(\phi(\mathbf{t}))\lambda_i\right] v \, d\Gamma = \int_{\Gamma_i(\mathbf{t})} \left[u_i'(s - t_i) - \frac{u_i(s - t_i - \epsilon) - u_i(s - t_i)}{-\epsilon}\right] v \, ds\,. \tag{4.3}$$

Note that

$$\frac{f(\phi(\mathbf{t}+\epsilon\mathbf{e}_i)) - f(\phi(\mathbf{t}))}{\epsilon} = \int_0^1 f'\big((1-s)\phi(\mathbf{t}) + s\phi(\mathbf{t}+\epsilon\mathbf{e}_i)\big)\, ds \, \frac{\phi(\mathbf{t} + \epsilon \mathbf{e}_i) - \phi(\mathbf{t})}{\epsilon}$$

and

$$f'(\phi(\mathbf{t})) - \int_0^1 f'\big((1-s)\phi(\mathbf{t}) + s\phi(\mathbf{t}+\epsilon\mathbf{e}_i)\big)\,ds$$

$$= \int_0^1 \int_0^1 f''\big(\phi(\mathbf{t}) + s(1-r)(\phi(\mathbf{t}+\epsilon\mathbf{e}_i) - \phi(\mathbf{t}))\big)\,ds\,dr\,[\phi(\mathbf{t}+\epsilon\mathbf{e}_i) - \phi(\mathbf{t})];$$

thus by adding and subtracting terms in (4.3) we have

$$\begin{aligned}
&\int_\Omega \sigma\,\mathrm{grad}\,\psi_\epsilon \cdot \mathrm{grad}\,v\,d\Omega + \int_{\Gamma_C}\int_0^1 f'\big((1-s)\phi(\mathbf{t}) + s\phi(\mathbf{t}+\epsilon\mathbf{e}_i)\big)\,ds\,\psi_\epsilon v\,d\Gamma \\
&= \int_{\Gamma_i(\mathbf{t})}\left[u_i'(s-t_i) - \frac{u_i(s-t_i-\epsilon) - u_i(s-t_i)}{-\epsilon}\right] v\,ds \\
&\quad + \int_{\Gamma_C}\int_0^1\int_0^1 f''\big(\phi(\mathbf{t}) + s(1-r)(\phi(\mathbf{t}+\epsilon\mathbf{e}_i) - \phi(\mathbf{t}))\big)\,ds\,dr\,[\phi(\mathbf{t}+\epsilon\mathbf{e}_i) - \phi(\mathbf{t})]\,\lambda_i\,v\,d\Gamma.
\end{aligned} \tag{4.4}$$

If f is given by (1.6), then $f''(\phi) = 6\phi$ so that

$$\begin{aligned}
&\left\{\int_{\Gamma_C}\int_0^1\int_0^1 s\left|f''\big(\phi(\mathbf{t}) + s(1-r)(\phi(\mathbf{t}+\epsilon\mathbf{e}_i) - \phi(\mathbf{t}))\big)\,ds\,dr\right|^4 d\Gamma\right\}^{1/4} \\
&\qquad \le C\,\|\phi(\mathbf{t}) + s(1-r)(\phi(\mathbf{t}+\epsilon\mathbf{e}_i) - \phi(\mathbf{t}))\|_1 \\
&\qquad \le C\,\{\|\phi(\mathbf{t})\|_1 + \|\phi(\mathbf{t}+\epsilon\mathbf{e}_i)\|_1\}.
\end{aligned}$$

If f is given by (1.7), then $f''(\phi) = C_3\big[C_1^2 e^{C_1\phi} - C_2^2 e^{-C_2\phi}\big]$ so that from Lemma 2.2 we infer that

$$\begin{aligned}
&\left\{\int_{\Gamma_C}\int_0^1\int_0^1 s\left|f''\big(\phi(\mathbf{t}) + s(1-r)(\phi(\mathbf{t}+\epsilon\mathbf{e}_i) - \phi(\mathbf{t}))\big)\,ds\,dr\right|^4 d\Gamma\right\}^{1/4} \\
&\qquad \le C\big[1 + |\Gamma| + e^{C\,\|\phi(\mathbf{t}) + s(1-r)(\phi(\mathbf{t}+\epsilon\mathbf{e}_i) - \phi(\mathbf{t}))\|_1^2)}\big]^{1/4} \\
&\qquad \le C\left[1 + |\Gamma| + e^{C\,\{\|\phi(\mathbf{t})\|_1^2 + \|\phi(\mathbf{t}+\epsilon\mathbf{e}_i)\|_1^2\}}\right]^{1/4}.
\end{aligned}$$

Thus by setting $v = \psi_\epsilon$ in (4.4) and using (1.8) and (2.1) we obtain

$$\begin{aligned}
\gamma\,\|\psi_\epsilon\|_1^2 \le C &\left\|u_i'(\cdot - t_i) - \frac{u_i(\cdot - t_i - \epsilon) - u_i(\cdot - t_i)}{-\epsilon}\right\|_{0,\Gamma_i(\mathbf{t})} \|\psi_\epsilon\|_{0,\Gamma_i(\mathbf{t})} \\
&+ K(\|\phi(\mathbf{t})\|_1, \|\phi(\mathbf{t}+\epsilon\mathbf{e}_i)\|_1)\,\|\phi(\mathbf{t}+\epsilon\mathbf{e}_i) - \phi(\mathbf{t})\|_{L^4(\Gamma_C)}\,\|\lambda_i\|_{L^4(\Gamma_C)}\,\|\psi_\epsilon\|_{L^4(\Gamma_C)},
\end{aligned}$$

where

$$\begin{aligned}
&K(\|\phi(\mathbf{t})\|_1, \|\phi(\mathbf{t}+\epsilon\mathbf{e}_i)\|_1) \\
&= \max\left\{C\left[1 + |\Gamma| + e^{C\,(\|\phi(\mathbf{t})\|_1^2 + \|\phi(\mathbf{t}+\epsilon\mathbf{e}_i)\|_1^2)}\right]^{1/4},\ C\,(\|\phi(\mathbf{t})\|_1 + \|\phi(\mathbf{t}+\epsilon\mathbf{e}_i)\|_1)\right\}.
\end{aligned}$$

Trace theorems imply that

$$\|\psi_\epsilon\|_{0,\Gamma_i(\mathbf{t})} \le \|\psi_\epsilon\|_{0,\Gamma} \le C\|\psi_\epsilon\|_1\,,$$

$$\|\phi(\mathbf{t}+\epsilon\mathbf{e}_i) - \phi(\mathbf{t})\|_{L^4(\Gamma_C)} \le \|\phi(\mathbf{t}+\epsilon\mathbf{e}_i) - \phi(\mathbf{t})\|_{L^4(\Gamma)} \le C\|\phi(\mathbf{t}+\epsilon\mathbf{e}_i) - \phi(\mathbf{t})\|_1\,,$$

$$\|\lambda_i\|_{L^4(\Gamma_C)} \le \|\lambda_i\|_{L^4(\Gamma)} \le C\|\lambda_i\|_1 \quad \text{and} \quad \|\psi_\epsilon\|_{L^4(\Gamma_C)} \le \|\psi_\epsilon\|_{L^4(\Gamma)} \le C\|\psi_\epsilon\|_1$$

so that

$$\|\psi_\epsilon\|_1 \le C\left\|u_i'(\cdot - t_i) - \frac{u_i(\cdot - t_i - \epsilon) - u_i(\cdot - t_i)}{-\epsilon}\right\|_{0,\Gamma_i(\mathbf{t})} + C\,K(\|\phi(\mathbf{t})\|_1, \|\phi(\mathbf{t}+\epsilon\mathbf{e}_i)\|_1)\,\|\phi(\mathbf{t}+\epsilon\mathbf{e}_i) - \phi(\mathbf{t})\|_1\,\|\lambda_i\|_1\,. \tag{4.5}$$

Since each $u_i \in C^1(\mathbb{R})$, the first term on the right-hand side of (4.5) clearly goes to zero as $\epsilon \to 0$. Since the mapping $\mathbf{t} \mapsto \phi(\mathbf{t})$ is continuous from $\prod_{i=1}^N [a_i, b_i] \to H^1(\Omega)$, we see that the quantity $K(\|\phi(\mathbf{t})\|_1, \|\phi(\mathbf{t}+\epsilon\mathbf{e}_i)\|_1)$ is bounded as $\epsilon \to 0$ and $\|\phi(\mathbf{t}+\epsilon\mathbf{e}_i) - \phi(\mathbf{t})\|_1 \to 0$ as $\epsilon \to 0$. We recall (4.2) that $\|\lambda_i\|_1$ is bounded. Hence we conclude that the right-hand side of (4.5) goes to zero as $\epsilon \to 0$, i.e.,

$$\|\psi_\epsilon\|_1 \to 0 \quad \text{as } \epsilon \to 0\,.$$

Thus we have shown that the mapping $\mathbf{t} \mapsto \phi(\mathbf{t})$ is differentiable from $\prod_{i=1}^N (a_i, b_i) \to H^1(\Omega)$ and $\frac{\partial\phi(\mathbf{t})}{\partial t_i} = \lambda_i$. □

Integration by parts yields that λ_i is the solution of the following linearized boundary value problem:

$$-\operatorname{div}(\sigma \operatorname{grad}\lambda_i) = 0 \quad \text{in } \Omega\,,$$

$$\sigma\frac{\partial\lambda_i}{\partial n} = -u_i'(s - t_i) \quad \forall\, s \in \left[t_i - \frac{d_i}{2}, t_i + \frac{d_i}{2}\right] \text{ on } \Gamma_i(\mathbf{t})\,,$$

$$\sigma\frac{\partial\lambda_i}{\partial n} = 0 \quad \forall\, s \in \left[t_j - \frac{d_j}{2}, t_j + \frac{d_j}{2}\right] \text{ on } \Gamma_j(\mathbf{t})\,, \quad j \ne i\,, \quad j = 1, \ldots, N,$$

$$\sigma\frac{\partial\lambda_i}{\partial n} = 0 \quad \text{on } \Gamma_0(\mathbf{t}),$$

and

$$\sigma\frac{\partial\lambda_i}{\partial n} = -f'(\phi(\mathbf{t}))\lambda_i \quad \text{on } \Gamma_C\,.$$

THEOREM 4.2. *Assume that* $(\hat\phi, \hat{\mathbf{t}})$ *minimizes* (1.1) *subject to* (1.9). *Then for each* i, $\hat t_i$ *either is on the boundary of* $[a_i, b_i]$ *or satisfies the equation*

$$\int_{\Gamma_C} (\phi(\hat{\mathbf{t}}) - \phi_0)\hat\lambda_i\, d\Gamma = 0,$$

where $\hat\lambda_i$ *is the solution of* (4.1) *with* $\mathbf{t} = \hat{\mathbf{t}}$.

Proof. Since $(\hat\phi, \hat{\mathbf{t}})$ satisfies (1.9), we have $\hat\phi = \phi(\hat{\mathbf{t}})$. Define $\mathcal{K}(\mathbf{t}) = \mathcal{J}(\phi(\mathbf{t}), \mathbf{t})$. We have shown in previous lemmas that $\phi(\cdot)$ is continuous in $\prod_{i=1}^N [a_i, b_i]$ and differentiable in $\prod_{i=1}^N (a_i, b_i)$. Minimizing (1.1) subject to (1.9) is obviously equivalent to minimizing $\mathcal{K}$ over

$\prod_{i=1}^{N}[a_i, b_i]$. Thus $\hat{\mathbf{t}}$ is a minimum of $\mathcal{K}$. Hence, we have that for each i, $\hat{t}_i$ is either on the boundary of $[a_i, b_i]$ or in the interior of (a_i, b_i) with

$$\frac{\partial \mathcal{K}(\hat{\mathbf{t}})}{\partial t_i} = 0.$$

Differentiating $\mathcal{K}(\cdot)$ by the chain rule yields

$$\frac{\partial \mathcal{K}(\hat{\mathbf{t}})}{\partial t_i} = \int_{\Gamma_C} (\phi(\hat{\mathbf{t}}) - \phi_0)\hat{\lambda}_i \, d\Gamma,$$

where $\hat{\lambda}_i$ satisfies (4.1) with $\mathbf{t} = \hat{\mathbf{t}}$. Thus if $\hat{t}_i$ is in the interior of (a_i, b_i), then

$$\int_{\Gamma_C} (\phi(\hat{\mathbf{t}}) - \phi_0)\hat{\lambda}_i \, d\Gamma = 0. \qquad \square$$

Remark (three-dimensional formulation). The analysis we have done for the two-dimensional case can be generalized to the three-dimensional case in a straightforward manner by replacing the function space $H^1(\Omega)$ with $W^{1,p}(\Omega)$ for some $p \geq 3$. (Then Lemma 2.2 holds.) In the three-dimensional case, each center point on the ith anode Γ_i is parameterized by (x_i, y_i). Let $\mathbf{t} = (x_1, y_1, x_2, y_2, \ldots, x_N, y_N)$. Then we obtain essentially the same results as in the two-dimensional case. $\square$

Remark (exterior problems). For infinite-domain problems, we assume the following condition at infinity:

$$\phi(\mathbf{x}) \to \phi_\infty \quad \text{as } |\mathbf{x}| \to \infty,$$

where ϕ_∞ is a constant. Then the results of this paper hold equally well. $\square$

5. Gradient methods. Grandient methods for minimizing $\mathcal{K}(\mathbf{t})$ with variable step lengths are given as follows:

$$\mathbf{t}^{n+1} = \mathbf{t}^n - \rho_n \nabla \mathcal{K}(\mathbf{t}^n).$$

This algorithm applied to the problem (1.1)-(1.5) takes on the following form:

a) Choose a $\mathbf{t}^{(0)} \in \prod_{i-1}^{N}(a_i, b_i)$.

b) For $n \geq 0$, solve for $\phi^{(n)} = \phi^{(n)}(\mathbf{t}^{(n)})$ from

$$-\operatorname{div}(\sigma \operatorname{grad} \phi^{(n)}) = 0 \quad \text{in } \Omega, \tag{5.1}$$

$$\sigma \frac{\partial \phi^{(n)}}{\partial n} = u_i(s - t_i^{(n)}) \quad \forall\, s \in \left[t_i^{(n)} - \frac{d_i}{2}, t_i^{(n)} + \frac{d_i}{2}\right] \text{ on } \Gamma_i(\mathbf{t}^{(n)}), \ \forall\, i, \tag{5.2}$$

$$\sigma \frac{\partial \phi^{(n)}}{\partial n} = 0 \quad \text{on } \Gamma_0(\mathbf{t}^{(n)}), \tag{5.3}$$

and

$$\sigma \frac{\partial \phi^{(n)}}{\partial n} = -f(\phi^{(n)}) \quad \text{on } \Gamma_C. \tag{5.4}$$

c) Solve for $\lambda_i^{(n)}$ for each $i = 1, \ldots, N$ from

$$-\operatorname{div}(\sigma \operatorname{grad} \lambda_i^{(n)}) = 0 \quad \text{in } \Omega, \tag{5.5}$$

$$\sigma \frac{\partial \lambda_i^{(n)}}{\partial n} = -u_i'(s - t_i^{(n)}) \quad \forall\, s \in \left[t_i^{(n)} - \frac{d_i}{2}, t_i^{(n)} + \frac{d_i}{2}\right] \quad \text{on } \Gamma_i(\mathbf{t}^{(n)}), \tag{5.6}$$

$$\sigma \frac{\partial \lambda_i^{(n)}}{\partial n} = 0 \quad \forall\, s \in \left[t_j^{(n)} - \frac{d_j}{2}, t_j^{(n)} + \frac{d_j}{2}\right] \text{ on } \Gamma_j(\mathbf{t}^{(n)}), \ \forall\, j \neq i, \tag{5.7}$$

$$\sigma \frac{\partial \lambda_i^{(n)}}{\partial n} = 0 \quad \text{on } \Gamma_0(\mathbf{t}^{(n)}), \tag{5.8}$$

and

$$\sigma \frac{\partial \lambda_i^{(n)}}{\partial n} = -f'(\phi^{(n)})\lambda_i^{(n)} \quad \text{on } \Gamma_C. \tag{5.9}$$

d) Update $\mathbf{t}$ by

$$t_i^{(n+1)} = t_i^{(n)} - \rho_n \int_{\Gamma_C} (\phi^{(n)} - \phi_0)\, \lambda_i^{(n)}\, d\Gamma,$$
$$\text{if } t_i^{(n+1)} > b_i, \quad \text{set } t_i^{(n+1)} = b_i,$$
$$\text{if } t_i^{(n+1)} < a_i, \quad \text{set } t_i^{(n+1)} = a_i.$$

e) $n + 1 \to n$; go to b).

Remark. A stopping criterion has to be used in actual implementation.

Remark. Standard convergence results for the constrained gradient method requires that the step length ρ_n be sufficiently small. However, the convergence will be very slow if the step length is chosen to be too small. In our implementation, we use the test-and-trial strategy to ensure the locations will improve by at least a fixed tolerant distance per iteration so that the number of iterations needed to obtain an optimal solution is typically small. Effective choices of ρ_n also depend on the dimensions of all the variables involved. Boundary element methods are employed to implement the above algorithm, and if necessary, the mesh is adjusted at each iteration so that each set of new locations form part of the set of all grid points.

Remark. In step d) in the algorithm, $t^{(n+1)}$ is calculated and then projected into the admissible set. In our experience with several examples, such a projection is not needed when the step size and initial guesses are chosen properly so that our constrained optimization problem can often be treated as an unconstrained optimization problem.

6. Computational examples. We tested our algorithm with an electrolyte container problem. The metal container is assumed to occupy a rectangular domain $\Omega : 0 \leq x \leq 3,\ 0 \leq y \leq 2$ (see Figures 3, 6, and 9), and the container is filled with an electrolyte. The cathode Γ_C is on the bottom boundary described by the coordinates $1 \leq x \leq 2$ and $y = 0$. We investigated several cases: single-anode control (Example 1), double-anode control with different densities on the top and right segments (Examples 2a and 2b), and double-anode control on the top segment (Example 3).

Example 1 (single-anode control on the top segment). We want to place an anode of width 0.4 on the top boundary. The center point $(x_c, 2)$ of the anode segment is constrained to the interval $0.2 \leq x_c \leq 2.8$. The current density on the anode is chosen to be $u = -20\cos^2(2.5(x - x_c))$ for $x \in (x_c - 0.2, x_c + 0.2)$. We use the empirical function $f(\phi) = 4\phi + 0.4\phi^3$. The desired potential distribution on Γ_C is $\phi_0 = -1$.

Our initial guess of x_c is $x_c^{(0)} = 2.6$ (Figure 3). After four iterations using the gradient algorithm, we arrive at $x_c^{(4)} = 1.5$, which corresponds to the center point on the top boundary

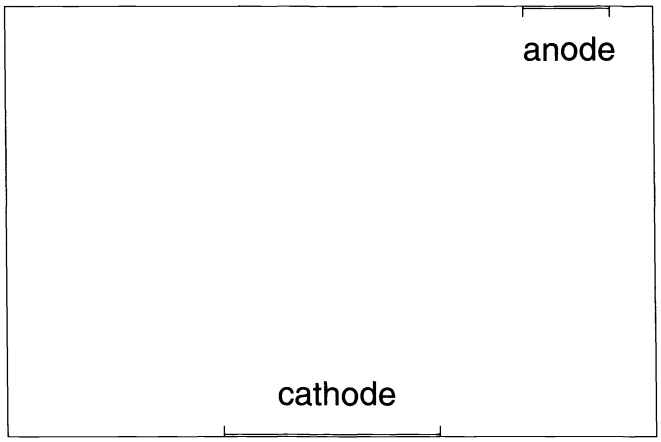

FIG. 3. *Initial guess of the anode position on the container* (*Example* 1).

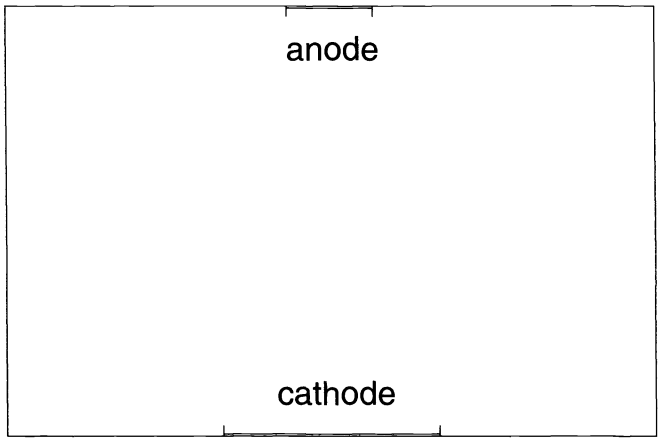

FIG. 4. *Optimal anode position* (*Example* 1).

(Figure 4). The step lengths in the gradient method had to be adjusted properly to ensure fast convergence. In Figure 5 we plotted the initial and final potential distributions on Γ_C. We could verify that $x_c = 1.5$ is indeed the minimum. This result is also consistent with intuitive explanations by chemists.

Example 2a (double-anode control on the top and right segments). We want to place two anodes of width 0.4 on the boundary, one on the top boundary with a center point $(x_c, 2)$, where $0.2 \leq x_c \leq 2.8$, and another on the right boundary with a center point $(3, y_c)$, where $0.2 \leq y_c \leq 1.8$. The current densities on the two anodes are chosen to be $u_1 = -16\cos^2(2.5(x-x_c))$ for $x \in (x_c - 0.2, x_c + 0.2)$ and $u_2 = -4\cos^2(2.5(y - y_c))$ for $y \in (y_c - 0.2, y_c + 0.2)$. The function f and desired ϕ_0 are chosen to be the same as in Example 1.

Our initial guesses for the two anodes are $x_c^{(0)} = 2.6$ on top boundary and $y_c^{(0)} = 0.4$ on the right boundary (Figure 6). After four iterations using the gradient algorithm, we arrive at $x_c^{(4)} = 1.1$ on the top boundary and $y_c^{(4)} = 0.6$ on the right boundary (Figure 7). Again, the step lengths in the gradient method had to be adjusted properly to ensure fast convergence. In Figure 8 we plotted the initial and final potential distributions on Γ_C. We verified by small perturbations of the anode locations that we indeed obtained a minimum with $x_c = 1.1$ on

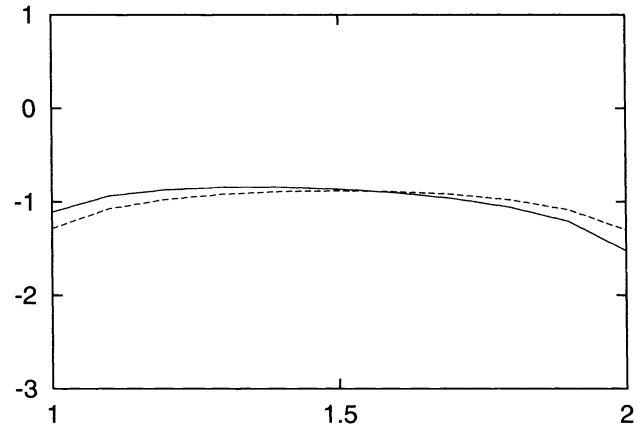

FIG. 5. *Initial and optimal potential distribution on the cathode* Γ_C (*Example* 1) (*initial:* ——, *optimal:* ·····).

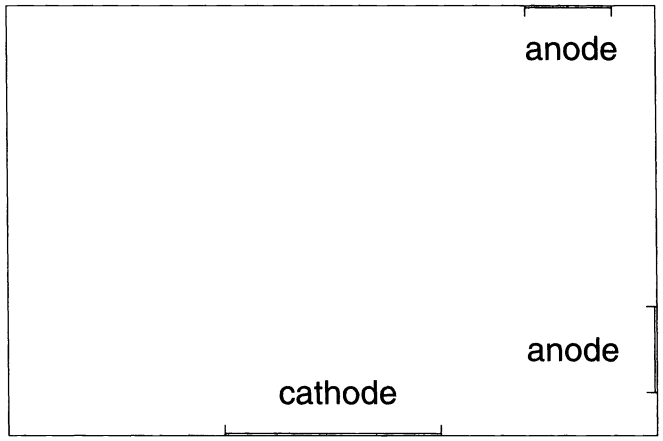

FIG. 6. *Initial guess of the anode positions on the container* (*Examples* 2a *and* 2b).

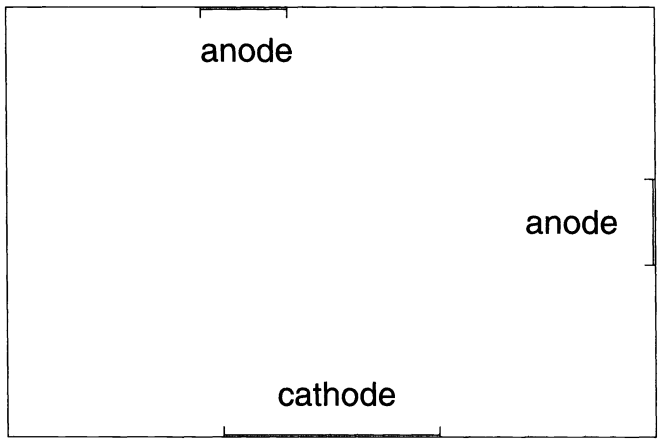

FIG. 7. *Optimal anode positions on the top and right boundary* (*Example* 2a).

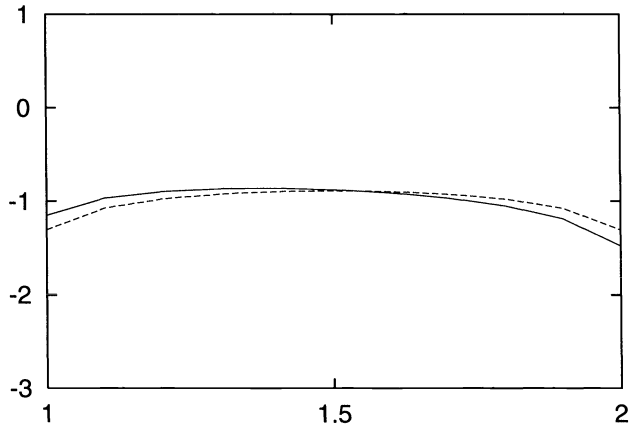

FIG. 8. *Initial and optimal potential distribution on the cathode* Γ_C (*Example* 2a) (*initial:* ——, *optimal:* ·····).

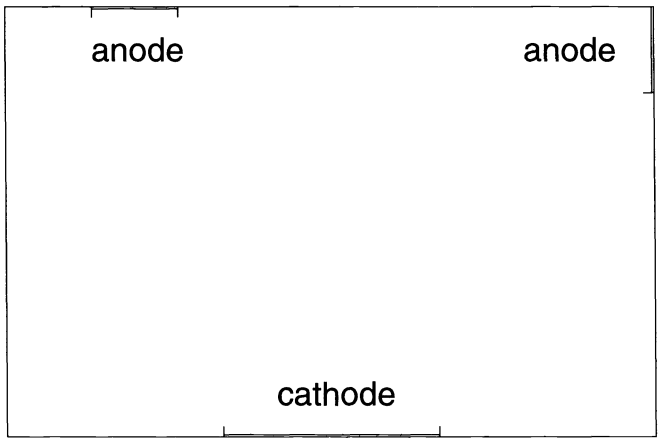

FIG. 9. *Optimal anode positions on the top and right boundary* (*Example* 2b).

the top boundary and $y_c = 0.6$ on the right boundary. This result is not an obvious fact. Our algorithm and calculation proved to be useful in providing the optimal locations for the placement of the double anodes.

Example 2b (double-anode control on the top and right segments—densities interchanged). All the data are the same as in Example 2a, except that the two density functions are interchanged, i.e., $u_1 = -4\cos^2(2.5(x-x_c))$ for $x \in (x_c-0.2, x_c+0.2)$ and $u_2 = -16\cos^2(2.5(y-y_c))$ for $y \in (y_c - 0.2, y_c + 0.2)$.

We use the same initial guess as in Example 2a (Figure 6). After nine iterations using the gradient algorithm, we arrive at $x_c^{(9)} = 2.6$ on the top boundary and $y_c^{(9)} = 1.8$ on the right boundary (Figure 9), which are different from the optimal positions that we obtained in Example 2a. In Figure 10 we plotted the initial and final potential distributions on Γ_C.

Remark. The results of Examples 2a and 2b indicate that after we have found the optimal locations for each anode, it is still important not to misplace the anodes with different current density. □

Example 3 (double-anode control on the top segment). We want to place two anodes of the width 0.4 on the top boundary, one with a center point $(x_{1c}, 2)$, where $0.2 \le x_{1c} \le 1.3$,

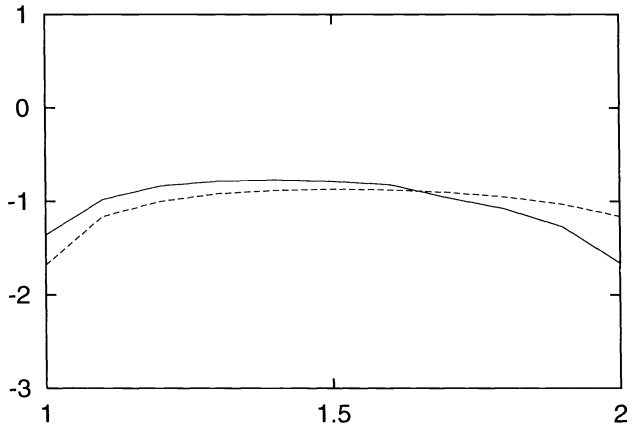

FIG. 10. *Initial and optimal potential distribution on the cathode* Γ_C (*Example* 2b) (*initial:* ——, *optimal:* ·····).

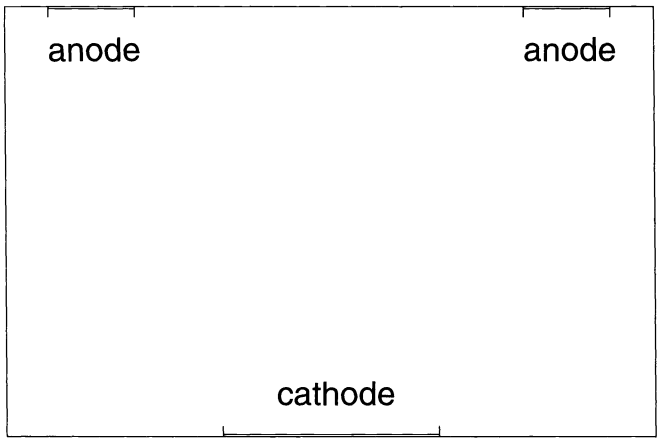

FIG. 11. *Initial guess of the anode positions on the container* (*Example* 3).

and another with a center point $(x_{2c}, 2)$, where $1.7 \leq x_{2c} \leq 2.8$. The current densities on the two anodes are chosen to be $u_1 = -16\cos^2(2.5(x - x_{1c}))$ for $x \in (x_{1c} - 0.2, x_{1c} + 0.2)$ and $u_2 = -4\cos^2(2.5(x - x_{2c}))$ for $x \in (x_{2c} - 0.2, x_{2c} + 0.2)$. The function f and desired ϕ_0 are chosen to be the same as in Example 1.

Our initial guesses for the two anodes are $x_{1c}^{(0)} = 0.4$ and $x_{2c}^{(0)} = 2.6$ (Figure 11). After seven iterations using the gradient algorithm, we arrive at $x_{1c}^{(7)} = 1.2$ and $x_{2c}^{(7)} = 1.6$ (Figure 12). Again, the step lengths in the gradient method had to be adjusted properly to ensure fast convergence. In Figure 13 we plotted the initial and final potential distributions on Γ_C. Clearly, the two anodes at their optimal positions join together at the common end point (1.4, 2) on the top boundary. The common end point of the two anodes has to be insulated in order to maintain the two anode system.

Remark. In Examples 2a and 3 we allow the anodes on different target segments to join together. In the case of Example 2a the optimal solution yields two disjoint anodes. In the case of Example 3 the optimal solution yields two anodes that join together at a point on the top boundary. When this happens, we can simply combine the two anodes to form a larger anode with different density profiles on the two sections of the combined anode. However, to

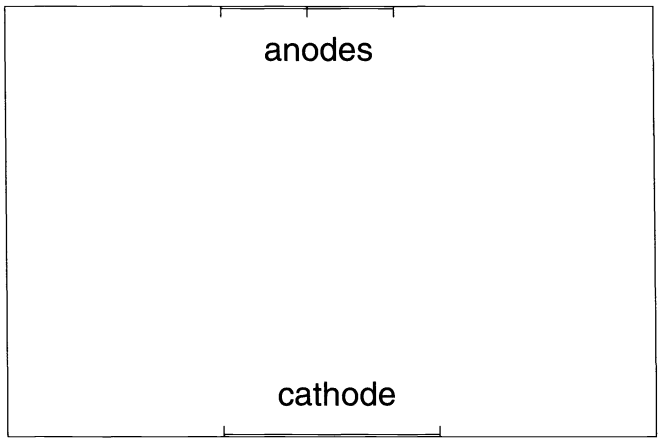

FIG. 12. *Optimal anode positions on the top and right boundary (Example 3).*

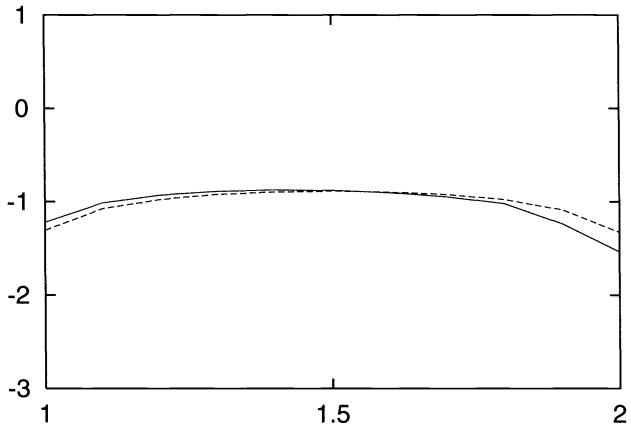

FIG. 13. *Initial and optimal potential distribution on the cathode Γ_C (Example 3) (initial: ——, optimal: ·····).*

maintain the combined (piecewise) density function, one will still need two separate electric sources. Inserting a thin insulator makes it easier to generate the required electric density profile on each anode. In most practical applications, one usually looks for optimal locations for anodes in isolated segments and thus will not encounter the situation of joining anodes. For instance, in the case of ship propeller protection, one wishes to place one anode near the front and two near the rear end; thus the target segments for these anodes are far apart from each other. Returning to Example 3, we may restrict the first anode to near the top left corner (say, $x_{1c} \leq 0.4$) and restrict the second anode to the right half of the top boundary. With such restrictions, the two anodes will never join each other. □

In all examples we have used boundary element methods (see [4], [7], [10]) to carry out the algorithm proposed in §5, i.e., to solve the systems (5.1)-(5.4) and (5.5)-(5.9) repeatedly. The calculations were performed on a SUN Sparc 2. Details for the boundary element method and numerical examples for propeller protection and/or for hybrid controls can be found in [7].

Acknowledgments. The authors thank the anonymous referees for many useful comments that have helped improve the results of this paper.

AUGMENTED LAGRANGIAN-SQP METHODS FOR NONLINEAR OPTIMAL CONTROL PROBLEMS OF TRACKING TYPE*

KAZUFUMI ITO† AND KARL KUNISCH‡

Abstract. An augmented Lagrangian method with second-order update is developed and its relationship to the sequential quadratic programming method is described. The rate of convergence proof depends on a second-order sufficient optimality condition, which is shown to be satisfied for a class of nonlinear optimal control problems of tracking type. Numerical examples are included which demonstrate the globalizing effect of the augmented Lagrangian method.

Key words. Lagrangian methods, SQP methods, nonlinear optimal programming

AMS subject classifications. 49D, 65K

1. Introduction.

The mathematical and, more specifically, the numerical treatment of optimal control problems for nonlinear partial differential equations arising in diverse areas of science has received an increasing amount of attention in the recent past. We mention optimal control problems in phase field modeling [CH, H], in superconductivity [GHS], in combustion, and, of course, in fluid dynamics. The numerical treatment of such problems offers a multitude of open problems and the present paper addresses one such problem.

We study a class of optimal control problems for nonlinear partial differential equations where the cost is of tracking type. The technique that we propose and analyze is the augmented Lagrangian-SQP (sequential quadratic programming) algorithm as developed in [IK]. In this method the differential equation is treated as a constraint which is realized by a Lagrangian term together with a penalty functional. The resulting augmented Lagrangian functional allows a rather straightforward characterization of the second derivative. We prove second-order convergence rate of the algorithm and we also demonstrate this rate with numerical examples. The second-order convergence rate depends upon a second-order sufficient optimality condition. We verify this second-order condition under variants of assumptions on the smallness of the cost functional at the solution. While this analysis is to a certain degree specific for the class of problems under consideration, the general principle becomes apparent: For optimal control problems with cost functional of tracking type, smallness of the cost or the residue helps (guarantees for the problems in this paper) the second-order sufficient optimality condition to hold.

Another important aspect of this research is the global behavior of the algorithm in numerical experiments. We did not implement any globalization strategy and yet convergence was observed even for very unfavorable start-up values. The cost functional for the augmented Lagrangian-SQP algorithm involves a penalty term. We point out that the specific size of the penalty parameter is not too significant (details are given in §5) unless it is chosen to be zero, in which case convergence generally fails. Let us also mention that the approach of this paper is quite different from that chosen in [CH, GHS, H], for example, which is based on iterative techniques for solving the necessary optimality system.

This paper is organized in the following manner. In §2 relevant results on the augmented Lagrangian-SQP technique are summarized. The optimal control problems and the associated

Lagrangian framework are developed in §3. The second-order sufficient optimality condition is analyzed in §4 and numerical test examples are given in §5.

2. Review of augmented Lagrangian–SQP methods. In this section results on augmented Lagrangian–SQP methods which are relevant in the following sections are summarized. We refer to [Be] for further details concerning such methods for finite-dimensional problems and to [IK] for infinite-dimensional problems.

We consider

$$(\mathcal{P}) \qquad \min F(x) \text{ subject to } e(x) = 0,$$

where $F : X \to \mathbb{R}$, $e : X \to Y$, with X and Y Hilbert spaces. We make the following three assumptions.

(H1) There exists a (local) solution x^* of $(\mathcal{P})$, F and e are twice continuously Fréchet differentiable, and the second Fréchet derivatives are Lipschitz continuous in a neighborhood $\tilde{V}(x^*)$ of x^*. The Fréchet derivative of any function with respect to x is denoted by a prime. The Lagrangian $\mathcal{L} : X \times Y \to \mathbb{R}$ associated with $(\mathcal{P})$ is defined by

$$\mathcal{L}(x, \lambda) = F(x) + \langle \lambda, e(x) \rangle_Y,$$

where $\langle \cdot, \cdot \rangle_Y$ stands for the inner product in Y. An element $\lambda^* \in Y$ is called Lagrange multiplier for $(\mathcal{P})$ if

$$\mathcal{L}'(x^*, \lambda^*) = F'(x^*) + e'(x^*)^* \lambda^* = 0. \tag{2.1}$$

Here $e'(x^*)^*$ denotes the adjoint operator of $e'(x^*)$. In (2.1) and also below, we frequently do not distinguish between $F'(x^*) \in \mathcal{L}(X; \mathbb{R})$ and its Riesz representation in X.

(H2) $e'(x^*)$ is surjective.

(H3) There exists $\kappa > 0$ such that

$$\mathcal{L}''(x^*, \lambda^*)(h, h) \geq \kappa |h|_X^2 \quad \text{for all } h \in \ker e'(x^*).$$

Under these assumptions there exists a neighborhood $V(x^*)$ of x^* and constants $\bar{\sigma} > 0$ and $\bar{c} > 0$ such that

$$\mathcal{L}_c(x, \lambda^*) \geq \mathcal{L}_c(x^*, \lambda^*) + \sigma |x - x^*|_X^2 \quad \text{for all } x \in V(x^*) \text{ and } c \geq \bar{c},$$

where $\mathcal{L}_c$ is the augmented Lagrangian defined by

$$\mathcal{L}_c(x, \lambda) = \mathcal{L}(x, \lambda) + \frac{c}{2} |e(x)|_Y^2.$$

We shall describe two algorithms and introduce

$$M(x, \lambda) = \begin{pmatrix} \mathcal{L}''(x, \lambda) & e'(x)^* \\ e'(x) & 0 \end{pmatrix}.$$

ALGORITHM 1.

(i) Choose $\lambda_0 \in Y$, $c \in (\bar{c}, \infty)$, and set $\sigma = c - \bar{c}$, $n = 0$.

(ii) Determine $\tilde{x}$ as solution of

$$(P_{aux}) \qquad \min \mathcal{L}_c(x, \lambda_n) \text{ subject to } x \in \overline{V(x^*)}.$$

(iii) Set $\tilde{\lambda} = \lambda_n + \sigma e(\tilde{x})$.

(iv) Solve for $(\hat{x}, \hat{\lambda})$

$$M(\tilde{x}, \tilde{\lambda}) \begin{pmatrix} \hat{x} - \tilde{x} \\ \hat{\lambda} - \tilde{\lambda} \end{pmatrix} = - \begin{pmatrix} \mathcal{L}'(\tilde{x}, \tilde{\lambda}) \\ e(\tilde{x}) \end{pmatrix}.$$

(v) Set $\lambda_{n+1} = \hat{\lambda}$, $n = n + 1$ goto (ii).

Existence of a solution to (P_{aux}) is guaranteed if $f : X \to \mathbb{R}$ is weakly lower semicontinuous and $e : X \to Y$ maps weakly convergent sequences to weakly convergent sequences. The following algorithm differs from the first one in that (P_{aux}) is eliminated.

ALGORITHM 2.

(i) Choose $(x_0, \lambda_0) \in X \times Y$, $c \geq 0$, and set $n = 0$.

(ii) Set $\tilde{\lambda} = \lambda_n + ce(x_n)$.

(iii) Solve for $(\hat{x}, \hat{\lambda})$

$$M(x_n, \tilde{\lambda}) \begin{pmatrix} \hat{x} - x_n \\ \hat{\lambda} - \tilde{\lambda} \end{pmatrix} = - \begin{pmatrix} \mathcal{L}'(x_n, \tilde{\lambda}) \\ e(x_n) \end{pmatrix}.$$

(iv) Set $(x_{n+1}, \lambda_{n+1}) = (\hat{x}, \hat{\lambda})$, $n = n + 1$ and goto (ii).

PROPOSITION 2.1. *Let* (H1) *and* (H2) *hold, and in the case of Algorithm* 1 *assume that* (P_{aux}) *admits a solution for all* n.

(i) *If* $\frac{1}{c - \bar{c}} |\lambda_0 - \lambda^*|^2$ *is sufficiently small, then Algorithm* 1 *is well defined and its iterates satisfy*

$$|(x_{n+1}, \lambda_{n+1}) - (x^*, \lambda^*)|_{X \times Y} \leq \frac{\hat{K}}{c - \bar{c}} |\lambda_n - \lambda^*|_Y^2,$$

for a constant $\hat{K}$ *independent of* c *and* $n = 0, 1, \ldots$.

(ii) *If* $c|(x_0, \lambda_0) - (x^*, \lambda^*)|_{X \times Y}$ *is sufficiently small, then Algorithm* 2 *is well defined and its iterates satisfy*

$$|(x_{n+1}, \lambda_{n+1}) - (x^*, \lambda^*)|_{X \times Y} \leq \tilde{K} |(x_n, \lambda_n) - (x^*, \lambda^*)|_{X \times Y}^2,$$

for a constant $\tilde{K}$ *independent of* $n = 0, 1, \ldots$.

For a proof we refer to [IK].

3. A class of nonlinear optimal control problems. The general framework of the previous section will be applied to optimal control problems governed by partial differential equations of the type

$$\text{(3.1)} \qquad \begin{cases} -\Delta y + f(y) = \tilde{h} & \text{in} \quad \Omega, \\ \dfrac{\partial y}{\partial n} = g & \text{on} \quad \Gamma_1, \\ \dfrac{\partial y}{\partial n} = g_2 & \text{on} \quad \Gamma_2, \end{cases}$$

where $\tilde{h} \in L^2(\Omega)$ and $g_2 \in L^2(\Gamma_2)$ are fixed and $g \in L^2(\Gamma_1)$ is the control variable. Here Ω is a bounded domain in $\mathbb{R}^n$ with $C^{1,1}$ boundary or Ω is convex. The boundary Γ is assumed to consist of two disjoint sets Γ_1, Γ_2, each of which is connected (or possibly consisting of finitely many connected components), with $\Gamma = \Gamma_1 \cup \Gamma_2$ and Γ_2 possibly empty. Further it is assumed

that $f \in C^2(\mathbb{R})$, $f(H^1(\Omega)) \subset L^{1+\varepsilon}(\Omega)$ for some $\varepsilon > 0$ if $n = 2$, and $f(H^1(\Omega)) \subset L^{\frac{2n}{n+2}}(\Omega)$ if $n \geq 3$. Equation (3.1) is understood in the variational sense, i.e.,

$$\langle \nabla y, \nabla \varphi \rangle_\Omega + \langle f(y), \varphi \rangle_\Omega = \langle \tilde{h}, \varphi \rangle_\Omega + \langle \tilde{g}, \varphi \rangle_\Gamma \quad \text{for all } \varphi \in H^1(\Omega), \tag{3.2}$$

where

$$\tilde{g} = \begin{cases} g & \text{on } \Gamma_1, \\ g_2 & \text{on } \Gamma_2, \end{cases}$$

$\langle \cdot, \cdot \rangle_\Gamma$ denotes the L^2-inner product on Γ, and $\langle \cdot, \cdot \rangle_\Omega$ stands for duality pairing between functions in $L^p(\Omega)$ and $L^q(\Omega)$ with $p^{-1} + q^{-1} = 1$. In (3.2) we should more precisely write $\langle \tilde{g}, \tau_\Gamma \varphi \rangle_\Gamma$ instead of $\langle \tilde{g}, \varphi \rangle_\Gamma$, with τ_Γ the zero-order trace operator on Γ. However, we shall frequently suppress this notation. We refer to (y, g) as a solution of (3.1) if (3.2) holds. The optimal control problem is given by

$$(P) \qquad \begin{cases} \min \dfrac{1}{2}|Cy - y_d|_Z^2 + \dfrac{\alpha}{2}|g|^2_{L^2(\Gamma_1)}, \\ \text{subject to } (y, g) \in H^1(\Omega) \times L^2(\Gamma_1) \text{ a solution of (3.1).} \end{cases}$$

Here C is a bounded linear (observation) operator from $H^1(\Omega)$ to a Hilbert space Z, and $y_d \in Z$ and $\alpha > 0$ are fixed.

To express (P) in the form $(\mathcal{P})$ of §2 we introduce

$$\tilde{e} : H^1(\Omega) \times L^2(\Gamma_1) \to H^1(\Omega)^*$$

with

$$\langle \tilde{e}(y, g), \varphi \rangle_{(H^1)^*, H^1} = \langle \nabla y, \nabla \varphi \rangle_\Omega + \langle f(y) - \tilde{h}, \varphi \rangle_\Omega - \langle \tilde{g}, \varphi \rangle_\Gamma,$$

and

$$e : H^1(\Omega) \times L^2(\Gamma) \to H^1(\Omega)$$

by

$$e = \mathcal{N} \tilde{e},$$

where $\mathcal{N} : H^1(\Omega)^* \to H^1(\Omega)$ is the Neumann solution operator associated with

$$\langle \nabla v, \nabla \varphi \rangle_\Omega + \langle v, \varphi \rangle = \langle h, \varphi \rangle_\Omega \quad \text{for all } \varphi \in H^1(\Omega),$$

where $h \in H^1(\Omega)^*$. In the context of §2 we set

$$X = H^1(\Omega) \times L^2(\Gamma_1), \qquad Y = H^1(\Omega),$$

with $x = (y, g) \in X$, and

$$F(x) = F(y, g) = \frac{1}{2}|Cy - y_d|_Z^2 + \frac{\alpha}{2}|g|^2_{L^2(\Gamma_1)}.$$

We assume that (H1) holds, i.e., that (P) has a solution $x^* = (y^*, g^*)$. The regularity requirements of §2 are clearly met by the mapping F. Those for e are implied by

$$\text{(h0)} \qquad \begin{cases} y \to f(y) & \text{is continuous from } H^1(\Omega) \text{ to } L^{1+\varepsilon}(\Omega) \text{ for some } \varepsilon > 0 \text{ if } n = 2, \\ & \qquad\qquad H^1(\Omega) \text{ to } L^{\frac{2n}{n+2}}(\Omega) \text{ if } n \geq 3, \\ y \to f'(y) & \text{is continuous from } H^1(\Omega) \text{ to } L^{1+\varepsilon}(\Omega) \text{ for some } \varepsilon > 0 \text{ if } n = 2, \\ & \qquad\qquad H^1(\Omega) \text{ to } L^{\frac{n}{2}}(\Omega) \text{ if } n \geq 3, \\ y \to f''(y) & \text{is Lipschitz continuous in a neighborhood of } y^* \\ & \qquad\qquad \text{from } H^1(\Omega) \text{ to } L^{1+\varepsilon}(\Omega) \text{ for some } \varepsilon > 0 \text{ if } n = 2, \\ & \qquad\qquad \text{from } H^1(\Omega) \text{ to } L^{\frac{2n}{6-n}}(\Omega) \text{ if } 3 \leq n \leq 6. \end{cases}$$

Here we used the fact that due to Sobolev's embedding theorem $H^1(\Omega)$ is continuously embedded into $L^p(\Omega)$ for $p \leq \frac{2n}{n-2}$ if $n \geq 3$, and into L^p for every $p \geq 1$ if $n = 2$. We note that (h0) is satisfied by $f(y) = y^k$ for $k \leq 5$, for example.

In the remainder of this section we focus on the Lagrangian functional and on properties of the Lagrange multiplier associated with (P). We require the following hypothesis:

$$\text{(h1)} \qquad \begin{cases} f'(y^*) \in L^{2+\varepsilon}(\Omega) \text{ for some } \varepsilon > 0 \text{ if } n = 2, \\ f'(y^*) \in L^n(\Omega) \text{ if } n \geq 3. \end{cases}$$

With (h1) holding, $f'(y^*)\varphi \in L^2(\Omega)$ for every $\varphi \in H^1(\Omega)$. It is simple to argue that

$$\ker e'(x^*) = \{(v, h) : \langle \nabla v, \nabla \varphi \rangle_\Omega + \langle f'(y^*)v, \varphi \rangle_\Omega = \langle h, \varphi \rangle_{\Gamma_1} \text{ for all } \varphi \in H^1(\Omega)\},$$

i.e., $(v, h) \in \ker e'(x^*)$ if and only if (v, h) is a variational solution of

$$\text{(3.3)} \qquad \begin{cases} -\Delta v + f'(y^*)v = 0 & \text{in} \quad \Omega, \\ \dfrac{\partial v}{\partial n} = h & \text{on} \quad \Gamma_1, \\ \dfrac{\partial v}{\partial n} = 0 & \text{on} \quad \Gamma_2. \end{cases}$$

We also require (H2), assuring existence of a unique Lagrange multiplier $\lambda^* \in H^1(\Omega)$ satisfying

$$\text{(3.4)} \qquad e'(x^*)^*\lambda^* + (\mathcal{N}C^*(Cy^* - y_d), \alpha g^*) = 0 \quad \text{in } H^1(\Omega) \times L^2(\Gamma_1),$$

where $e'(x^*)^* : H^1(\Omega) \to H^1(\Omega) \times L^2(\Gamma_1)$ denotes the adjoint of $e'(x^*)$ and $C^* : Z \to H^1(\Omega)^*$ stands for the adjoint of $C : H^1(\Omega) \to Z$ with Z its pivot space. The Lagrange multiplier satisfies the following proposition.

PROPOSITION 3.1 (Necessary condition). *Let* (H1), (H2), *and* (h1) *hold. Then* λ^* *is a variational solution of*

$$\text{(3.5)} \qquad \begin{cases} -\Delta\lambda^* + f'(y^*)\lambda^* = -C^*(Cy^* - y_d) & \textit{in} \quad \Omega, \\ \dfrac{\partial \lambda^*}{\partial n} = 0 & \textit{on} \quad \Gamma, \end{cases}$$

i.e., $(\nabla\lambda^*, \nabla\varphi) + (f'(y^*)\lambda^*, \varphi) + (Cy^* - y_d, C\varphi)_Z = 0$ *for all* $\varphi \in H^1(\Omega)$ *and*

$$\text{(3.6)} \qquad \tau_{\Gamma_1}\lambda^* = \alpha g^* \quad \textit{on } \Gamma_1.$$

Proof. The Lagrangian associated with (P) can be expressed by

$$\mathcal{L}(y, g, \lambda) = \frac{1}{2}|Cy - y_d|_Z^2 + \frac{\alpha}{2}|g|_{L^2(\Gamma_1)}^2 + \langle \nabla\lambda, \nabla y \rangle_\Omega + \langle \lambda, f(y) - \tilde{h} \rangle_\Omega - \langle \lambda, \tilde{g} \rangle_\Gamma.$$

For every $(v, h) \in H^1(\Omega) \times L^2(\Gamma_1)$ we find

$$\mathcal{L}_y(y^*, g^*, \lambda^*)(v) = \langle Cy^* - y_d, Cv \rangle_Z + \langle \nabla\lambda^*, \nabla v \rangle_\Omega + \langle \lambda^*, f'(y^*)v \rangle_\Omega$$

and

$$\mathcal{L}_g(y^*, g^*, \lambda^*)(h) = \alpha\langle g^*, h \rangle_{\Gamma_1} - \langle \lambda^*, h \rangle_{\Gamma_1}.$$

Thus the claim follows.

In the following regularity result we let $\tilde{g}^*$ denote the function

$$\tilde{g}^* = \begin{cases} g^* & \text{on} \quad \Gamma_1, \\ g_2 & \text{on} \quad \Gamma_2. \end{cases}$$

COROLLARY 3.2. *Under the assumptions of Proposition* 3.1 *and if* $C^*(Cy^* - y_d) \in L^2(\Omega)$, *then* $\lambda^* \in H^2(\Omega)$ *and* $g^* \in H^{3/2}(\Gamma_1)$. *If* $n = 2$ *and* Ω *is a convex curvilinear polygon of class* C^1, $g_2 \in H^{3/2}(\Gamma_2)$, $g^* \in H^{3/2}(\Gamma_1)$, *and* $\tilde{g}^*$ *is "sufficiently smooth" at the endpoints of* Γ_1, *then* $y^* \in H^2(\Omega)$.

These regularity properties follow from well-known results on elliptic boundary value problems [G, pp. 44, 126, 149].

Let $B : H^1(\Omega) \to H^1(\Omega)^*$ be the differential operator given by the left-hand side of (3.5), i.e., $Bv = \varphi$ is characterized as the solution to

$$\langle \nabla v, \nabla \psi \rangle_\Omega + \langle f'(y^*)v, \psi \rangle_\Omega = \langle \varphi, \psi \rangle_{(H^1)^*, H^1} \quad \text{for all } \psi \in H^1(\Omega).$$

We shall use the following hypothesis:

(h2) 0 is not an eigenvalue of B.

Note that (h2) holds, for example, if

$$f'(y^*) \geq \underline{\beta} \quad \text{a.e. on } \Omega,$$

for some $\underline{\beta} > 0$. With (h2) holding, B is an isomorphism from $H^1(\Omega)$ onto $H^1(\Omega)^*$. Moreover, (h2) implies (H2).

COROLLARY 3.3. *Let* (H1), (H2), *and* (h1) *hold.*

(i) *There exists a constant* $K(x^*)$ *such that*

$$|\lambda^*|_{H^1} \leq K(x^*)|(\mathcal{N}C^*(Cy^* - y_d), \alpha g^*)|_X.$$

(ii) *If moreover* (h2) *is satisfied and* $C^*(Cy^* - y_d) \in L^2(\Omega)$, *then there exists a constant* $K(y^*)$ *such that*

$$|\lambda^*|_{H^2} \leq K(y^*)|C^*(Cy^* - y_d)|_{L^2(\Omega)}.$$

Proof. Due to (H2) we have $(e'(x^*)e'(x^*)^*)^{-1} \in \mathcal{L}(H^1(\Omega))$ and thus (i) follows from (3.4). Let us turn to (ii). Due to (h2) and (3.5) there exists a constant K_{y^*} such that

$$|\lambda^*|_{H^1} \leq K_{y^*}|C^*(Cy^* - y_d)|_{(H^1)^*}. \tag{3.7}$$

To obtain the desired $H^2(\Omega)$-estimate for λ^* we apply the well-known H^2 a priori estimate for Neumann problems to

$$\begin{aligned} -\Delta\lambda^* + \lambda^* &= \tilde{f}, \\ \frac{\partial \lambda^*}{\partial n} &= 0, \end{aligned}$$

with $\tilde{f} = \lambda^* - f'(y^*)\lambda^* - C^*(Cy^* - y_d)$. This gives

$$|\lambda^*|_{H^2} \leq K\left(|\lambda^*|_{L^2} + |f'(y^*)\lambda^*|_{L^2} + |C^*(Cy^* - y_d)|_{L^2}\right)$$

for a constant K (depending on Ω but independent of y^*). Since

$$|f'(y^*)\lambda^*|_{L^2} \leq |f'(y^*)|_{L^s}|\lambda^*|_{H^1},$$

where

$$s = \begin{cases} 2+\varepsilon & \text{if } n = 2, \\ n & \text{if } n \geq 3, \end{cases}$$

the desired result follows from (3.7).

To calculate the second Fréchet derivative we shall use

$$\text{(h3)} \qquad \begin{cases} f''(y^*) \in L^{1+\varepsilon}(\Omega) & \text{for some } \varepsilon > 0 \text{ if } n = 2, \\ f''(y^*) \in L^{\frac{2n}{6-n}}(\Omega) & \text{for } 3 \leq n \leq 6. \end{cases}$$

PROPOSITION 3.4. *Let* (H1), (H2) *and* (h1), (h3) *hold. Then*

$$\mathcal{L}''(y^*, g^*, \lambda^*)((v,h),(v,h)) = |Cv|_Z^2 + \alpha |h|_{L^2(\Gamma_1)}^2 + \langle \lambda^*, f''(y^*)v^2 \rangle_\Omega, \tag{3.8}$$

for all $(v,h) \in X$.

Proof. By Sobolev's embedding theorem there exists a constant K_e such that

$$|\langle \lambda^*, f''(y^*)v^2 \rangle_\Omega| \leq K_e |\lambda^*|_{H^1} |f''(y^*)|_{L^q} |v|_{H^1}^2 \tag{3.9}$$

for all $v \in H^1(\Omega)$, where

$$q = \begin{cases} 1+\varepsilon, & \varepsilon > 0, \text{ if } n = 2, \\ \dfrac{2n}{6-n} & \text{if } 3 \leq n \leq 6. \end{cases} \tag{3.10}$$

Referring back to the proof of Proposition 3.1 we see that the claim easily follows.

4. The second-order sufficient optimality condition. We turn now to an analysis of the second-order sufficient optimality condition (H3) for the optimal control problem (P). In view of (3.8) the crucial term is given by $\langle \lambda^*, f''(y^*)v^2 \rangle_\Omega$. Two types of results will be given. The first class of results will guarantee that $|\langle \lambda^*, f''(y^*)v^2 \rangle_\Omega|$ is small. This can be achieved by guaranteeing that λ^*, or, in view of (2.1), that $F'(x^*)$ is small. We may refer to this type of assumption as a small residual problem. The second class of assumptions rests on guaranteeing that $\lambda^* f''(y^*) \geq 0$ on Ω.

In the statement of Theorems 4.1 and 4.2 we use K_e and q which are defined in (3.9), (3.10). Further $\|B^{-1}\|$ denotes the norm of B^{-1} as operator from $H^1(\Omega)^*$ to $H^1(\Omega)$.

THEOREM 4.1. *Let* (H1), (H2), (h1), (h3) *hold.*

(i) *If* $Z = H^1(\Omega)$, $C = \mathrm{id}$, *and*

$$K_e K(x^*) |(y^* - y_d, \alpha g^*)|_X |f''(y^*)|_{L^q} < 1, \tag{4.1}$$

then the second-order sufficient optimality condition (H3) *holds.*

(ii) *If* $Z = L^2(\Omega)$, C *is the injection of* $H^1(\Omega)$ *into* $L^2(\Omega)$, $n \leq 3$, *and if in addition* (h2) *holds and*

$$\tilde{k}_e K(y^*) |y^* - y_d|_{L^2(\Omega)} |f''(y^*)|_{L^\infty(\Omega)} \leq 1, \tag{4.2}$$

where $\tilde{k}_e$ *is the embedding constant of* $H^2(\Omega)$ *into* $L^\infty(\Omega)$, *then* (H3) *is satisfied.*

Proof. (i) By (3.8) and (3.9) we have for every $(v,h) \in X$

$$\begin{aligned} &\mathcal{L}''(y^*, g^*, \lambda^*)((v,h),(v,h)) \\ &\quad \geq |v|_{H^1(\Omega)}^2 + \alpha |h|_{L^2(\Gamma_1)}^2 - K_e |\lambda^*|_{H^1(\Omega)} |f''(y^*)|_{L^q(\Omega)} |v|_{H^1(\Omega)}^2 \\ &\quad \geq \left(1 - K_e K(x^*) |(y^* - y_d, \alpha g^*)|_X |f''(y^*)|_{L^q(\Omega)}\right) |v|_{H^1}^2 + \alpha |h|_{L^2(\Gamma_1)}^2, \end{aligned}$$

where in the last estimate we used Corollary 3.3(i). The claim now follows from (4.1). We observe that in this case $\mathcal{L}''(y^*, g^*, \lambda^*)$ is positive definite on all X, not only on $\ker e'(x^*)$.

(ii) By (3.3) and (h2) we obtain

$$|v|_{H^1(\Omega)} \le \|B^{-1}\| \|\tau_{\Gamma_1}\| |h|_{L^2(\Gamma_1)} \quad \text{for all } (v, h) \in \ker e'(x^*). \tag{4.3}$$

Here $\|\tau_{\Gamma_1}\|$ denotes the norm of the trace operator from $H^1(\Omega)$ onto $L^2(\Gamma_1)$. Hence by Corollary 3.3(ii) and (4.3), we find for every $(v, h) \in \ker e'(x^*)$

$$\begin{aligned}
\mathcal{L}''(v^*, g^*, \lambda^*)((v, h), (v, h)) &= |v|^2_{L^2(\Omega)} + \alpha |h|^2_{L^2(\Gamma_1)} - \langle \lambda^*, f''(y^*)v^2 \rangle_\Omega \\
&\ge |v|^2_{L^2(\Omega)} + \alpha |h|^2_{L^2(\Gamma_1)} - |\lambda^*|_{L^\infty(\Omega)} |f''(y^*)|_{L^\infty(\Omega)} |v|^2_{L^2(\Omega)} \\
&\ge \left[1 - \tilde{k}_e K(y^*) |f''(y^*)|_{L^\infty(\Omega)} |y^* - y_d|_{L^2(\Omega)}\right] |v|^2_{L^2(\Omega)} \\
&\quad + \frac{\alpha}{2} \left(|h|^2_{L^2(\Gamma_1)} + \frac{1}{\|B^{-1}\|^2 \|\tau_{\Gamma_1}\|^2} |v|^2_{H^1(\Omega)} \right).
\end{aligned}$$

Due to (4.2) the expression in brackets is nonnegative and the result follows.

In the following result, C can be a boundary observation operator, for example.

THEOREM 4.2. *Let* (H1), (h1)–(h3) *hold, and let* $\|\tau_{\Gamma_1}\|$ *be the norm of the trace operator from* $H^1(\Omega)$ *onto* $L^2(\Gamma_1)$. *Then*

$$2\|B^{-1}\| \|\tau_{\Gamma_1}\| K_{y^*} |C^*(Cy^* - y_d)|_{(H^1)^*} < \alpha \tag{4.4}$$

implies that the second-order sufficient optimality condition (H3) *is satisfied, where* K_{y^*} *is the constant appearing in* (3.7).

Proof. As in the proof of Theorem 4.1(i) we find

$$\begin{aligned}
\mathcal{L}''(y^*, g^*, \lambda^*)((v, h), (v, h)) &\ge |Cv|^2_Z + \alpha |h|^2_{L^2(\Gamma_1)} - K_e |\lambda^*|_{H^1(\Omega)} |f''|_{L^q(\Omega)} |v|^2_{H^1(\Omega)} \\
&\ge |Cv|^2_Z + \alpha |h|^2_{L^2(\Gamma_1)} - K_{y^*} |C^*(Cy^* - y_d)|_{(H^1)^*} |f''|_{L^q(\Omega)} |v|^2_{H^1(\Omega)},
\end{aligned}$$

where (3.7) was used. For $(v, h) \in \ker e'(x^*)$ this implies by (4.3)

$$\begin{aligned}
\mathcal{L}''(y^*, g^*, \lambda^*)((v, h), (v, h)) &\ge |Cv|^2_Z + \frac{\alpha}{2} |h|^2_{L^2(\Gamma_1)} \\
&\quad + \left[\frac{\alpha}{2\|B^{-1}\| \|\tau_{\Gamma_1}\|} - K_{y^*} |C^*(Cy^* - y_d)|_{(H^1)^*} |f''|_{L^q(\Omega)} \right] |v|^2_{H^1(\Omega)}.
\end{aligned}$$

The desired result follows from (4.4).

In view of (4.1), (4.2), (4.4), and the fact that $|y^* - y_d|$ is decreasing with $\alpha \to 0^+$, the question arises as to whether by decreasing α we can always verify that the second-order sufficient optimality condition holds. The answer to this question is not obvious since the term $|y^* - y_d|$ in (4.1), (4.2), (4.4) is multiplied by factors which depend on x^* and hence on α themselves.

We next analyze one specific situation for which the second-order sufficient optimality condition holds for all α which are sufficiently small. In continuation of Theorem 4.1(i) we consider the specific situation where

$$Z = L^2(\Omega), \ C \text{ is the embedding of } H^1(\Omega) \text{ into } L^2(\Omega), \text{ and } n = 2. \tag{4.5}$$

In the following Lemma 4.3 and Theorem 4.4 we shall write (P_α) instead of (P) and denote by $x^\alpha = (y^\alpha, g^\alpha)$ a solution to

$$(P_\alpha) \qquad \begin{cases} \min \dfrac{1}{2} |y - y_d|^2_{L^2(\Omega)} + \dfrac{\alpha}{2} |g|^2_{L^2(\Gamma_1)}, \\ \text{subject to } (y, g) \in H^1(\Omega) \times L^2(\Gamma_1) \text{ a solution of (3.1).} \end{cases}$$

We assume

$$\text{(h4)} \quad \begin{cases} \text{(i) there exists } a \in \mathbb{R} \text{ such that } f(t)t \geq at^2 \text{ for all } t \in \mathbb{R} \text{ and} \\ \quad y_n \rightharpoonup y \text{ in } H^1(\Omega) \text{ implies } f(y_n) \rightharpoonup f(y) \text{ in } L^2(\Omega); \\ \text{(ii) } f \text{ maps bounded set in } H^1(\Omega) \text{ into bounded sets in } L^{4/3}(\Omega). \end{cases}$$

LEMMA 4.3. *If* (3.1) *has a solution* $(\bar{y}, \bar{g})$ *and if* (h4(i)) *holds, then there exists a solution* $x^\alpha = (y^\alpha, g^\alpha)$ *of* (P_α) *for every* $\alpha > 0$.

Proof. Let $\alpha > 0$ and let (y_n, g_n) be a minimizing sequence of (P_α). Then

$$\lim_{n\to\infty} \left(|y_n - y_\alpha|^2_{L^2(\Omega)} + \alpha |g_n|^2_{L^2(\Gamma_1)} \right) \leq |\bar{y} - y_d|^2_{L^2(\Omega)} + \alpha |\bar{g}|^2_{L^2(\Gamma_1)},$$

and hence $\{(y_n, g_n)\}_{n=1}^\infty$ is bounded in $L^2(\Omega) \times L^2(\Gamma_1)$. By (3.2) and (h4(i)) we find that $\{(y_n, g_n)\}_{n=1}^\infty$ is bounded in $H^1(\Omega) \times L^2(\Gamma_1)$. Consequently there exists a subsequence of $\{(y_n, g_n)\}_{n=1}^\infty$, denoted by the same symbol, and (y^α, g^α) with $(y_n, g_n) \to (y^\alpha, g^\alpha)$ weakly in $H^1(\Omega) \times L^2(\Gamma_1)$. Due to (h4(i)) and weak lower semicontinuity of norms, (y^α, g^α) is a solution of (P_α).

For the next theorem we require additional hypotheses.

$$\text{(h5)} \quad \begin{cases} \text{There exists a solution } (y^0, g^0) \text{ of (3.1) with the property that} \\ |y^0 - y_d|_{L^2(\Omega)} \leq |y - y_d|_{L^2(\Omega)}, \\ \text{where } y \text{ is the first coordinate of any solution } (y, g) \text{ of (3.1).} \end{cases}$$

Under the conditions of Lemma 4.3 let $B_\alpha : H^1(\Omega) \to H^1(\Omega)^*$ denote the differential operators characterzied by $B_\alpha v = \varphi$ where

$$\langle \nabla v, \nabla \psi \rangle_\Omega + \langle f'(y^\alpha)v, \psi \rangle_\Omega = \langle \varphi, \psi \rangle_{(H^1)^*, H^1} \quad \text{for all } \psi \in H^1(\Omega).$$

$$\text{(h6)} \quad \begin{cases} \text{There exists } \bar{\alpha} > 0 \text{ and } \bar{b} \text{ such that } B_\alpha \text{ is surjective} \\ \text{and } \|B_\alpha^{-1}\| \leq \bar{b} \text{ for every } \alpha \in [0, \bar{\alpha}]. \end{cases}$$

A sufficient condition that implies (h6) is given in Remark 4.5 below.

THEOREM 4.4. *Let* (4.5), (h4), (h5), *and* (h6) *hold, and assume that* $n = 2$ *and* Γ *is* $C^{1,1}$ *smooth. Then there exists* $\hat{\alpha} \in (0, \bar{\alpha}]$ *such that the second-order sufficient optimality condition holds for* (P_α) *for all* $\alpha \in (0, \hat{\alpha}]$.

Proof. Due to Lemma 4.3 and (h5) there exists a solution $x^\alpha = (y^\alpha, g^\alpha)$ of (P_α) for every $\alpha > 0$. By (h5)

$$\begin{aligned} |y^0 - y_d|^2_{L^2(\Omega)} + \alpha |g^\alpha|^2_{L^2(\Gamma_1)} &\leq |y^\alpha - y_d|^2_{L^2(\Omega)} + \alpha |g^\alpha|^2_{L^2(\Gamma_1)} \\ &\leq |y^0 - y_d|^2_{L^2(\Omega)} + \alpha |g^0|^2_{L^2(\Gamma_1)}, \end{aligned}$$

which implies

$$|g^\alpha|_{L^2(\Gamma_1)} \leq |g^0|_{L^2(\Gamma_1)}$$

and

$$|y^\alpha - y_d|^2_{L^2(\Omega)} \leq |y^0 - y_d|^2_{L^2(\Omega)} + \alpha \left(|g^0|^2_{L^2(\Gamma_1)} - |g^\alpha|^2_{L^2(\Gamma_1)} \right).$$

Hence $\{(y^\alpha, g^\alpha)\}_{\alpha>0}$ is bounded in $L^2(\Omega) \times L^2(\Gamma_1)$. From (h4(i)) and (3.2) it follows that $\{(y^\alpha, g^\alpha)\}_{\alpha>0}$ is also bounded in $H^1(\Omega) \times L^2(\Gamma_1)$.

Next we argue that there exists a constant K_1 such that

$$|y^\alpha|_{W^{1,4}(\Omega)} \leq K_1 \quad \text{for all } \alpha \in [0, \bar{\alpha}]. \tag{4.6}$$

In fact, since $n = 2$, the functionals $\varphi \to \tilde{G}_\alpha(\varphi) = \int_\Gamma \tilde{g}_\alpha \varphi ds$, with

$$\tilde{g}_\alpha = \begin{cases} g_\alpha & \text{on } \Gamma_1, \\ g_2 & \text{on } \Gamma_2, \end{cases}$$

are elements of $W^{1,4/3}(\Omega)^*$ [Tr, p. 72], and there exist constants K_2 and K_3 such that

$$\|G_\alpha\|_{(W^{1,4/3})^*} \leq K_2 |\tilde{g}_\alpha|_{L^2(\Gamma)} \leq K_3 \quad \text{for all } \alpha \in [0, \bar{\alpha}]. \tag{4.7}$$

The functions y^α satisfy

$$\langle \nabla y^\alpha, \nabla \varphi \rangle_\Omega + \langle y^\alpha, \varphi \rangle_\Omega = \langle \tilde{h}, \varphi \rangle_\Omega + \langle \tilde{g}_\alpha, \varphi \rangle_\Gamma + \langle y_\alpha, \varphi \rangle_\Omega + \langle f(y_\alpha), \varphi \rangle_\Omega. \tag{4.8}$$

Due to (h4(ii)) and (4.7) the right-hand side in (4.8) describes a family (in α) of bounded linear functionals on $W^{1,4/3}(\Omega)$. Hence there exists K_1 such that (4.6) holds [Tr, p. 179]. From continuity of f' from $\mathbb{R}$ to $\mathbb{R}$ and the fact that $W^{1,4}(\Omega)$ is continuously embedded in $C(\Omega)$ for $n = 2$, it follows that

$$|f'(y^\alpha)\lambda|_{L^2(\Omega)} \leq M |\lambda|_{L^2(\Omega)}$$

for a constant M independent of $\alpha \in [0, \bar{\alpha}]$ and $\lambda \in L^2(\Omega)$. Therefore $B_\alpha \in \mathcal{L}(H^1(\Omega), (H^1(\Omega))^*)$ and (h6) is applicable.

Due to (h6) there exists a Lagrange multiplier λ_α satisfying the variational form of

$$\begin{aligned} -\Delta \lambda^\alpha + f'(y^\alpha)\lambda^\alpha &= -(y^\alpha - y_d) \quad \text{in } \Omega, \\ \frac{\partial \lambda^\alpha}{\partial n} &= 0 \quad \text{on } \Gamma \end{aligned}$$

and

$$|\lambda^\alpha|_{H^1(\Omega)} \leq \bar{b} |y^\alpha - y_d|_{(H^1)^*} \tag{4.9}$$

for every $\alpha \in [0, \bar{\alpha}]$. As in the proof of Corollary 3.3 we show that

$$|\lambda^\alpha|_{H^2(\Omega)} \leq K_4 |y^\alpha - y^d|_{L^2(\Omega)}$$

for a constant K_4 independent of $\alpha \in [0, \bar{\alpha}]$.

With these preliminaries we find for the Hessian

$$\begin{aligned} \mathcal{L}''(y^\alpha, g^\alpha, \lambda^\alpha)((v, h), (v, h)) &= |v|^2_{L^2(\Omega)} + \alpha |h|^2_{L^2(\Gamma_1)} + \langle \lambda^\alpha, f''(y^\alpha) v^2 \rangle_\Omega \\ &\geq |v|^2_{L^2(\Omega)} + \alpha |h|^2_{L^2(\Gamma_1)} - |\lambda^\alpha|_{L^\infty(\Omega)} |f''(y^\alpha)|_{L^\infty(\Omega)} |v|^2_{L^2(\Omega)} \\ &\geq (1 - \tilde{k}_e K_4 |y^\alpha - y_d|_{L^2(\Omega)} |f''(y^\alpha)|_{L^\infty(\Omega)}) |v|^2_{L^2(\Omega)} + \alpha |h|^2_{L^2(\Gamma_1)}, \end{aligned}$$

where $\tilde{k}_e$ denotes the embedding constant of $H^2(\Omega)$ into $L^\infty(\Omega)$. Since $f \in C^2(\mathbb{R})$ by assumption, (4.6) implies the existence of K_5 such that $|f''(y^\alpha)|_{L^\infty(\Omega)} \leq K_5$. Combining these estimates with (h6) we find

$$\begin{aligned} \mathcal{L}''(y^\alpha, g^\alpha, \lambda^\alpha)((v, h), (v, h)) \geq (1 - \tilde{k}_e K_4 K_5 |y^\alpha - y_d|_{L^2(\Omega)}) |v|^2_{L^2(\Omega)} \\ + \frac{\alpha}{2} \left(|h|^2_{L^2(\Gamma_1)} + \frac{1}{\bar{b}^2 \|\tau_{\Gamma_1}\|^2} |v|^2_{H^1(\Omega)} \right) \end{aligned}$$

for all $(v, h) \in \ker e'(x^\alpha)$. Finally

$$|y^\alpha - y_d|^2_{L^2(\Omega)} \leq |y^0 - y_d|^2_{L^2(\Omega)} + \alpha(|g^0|^2_{L^2(\Gamma_1)} - |g^\alpha|^2_{L^2(\Gamma_1)})$$

and $|g^\alpha|_{L^2(\Gamma_1)} \leq |g^0|_{L^2(\Gamma_1)}$, and therefore

$$\mathcal{L}''(y^\alpha, g^\alpha, \lambda^\alpha)((v, h), (v, h)) \geq \frac{\alpha}{2}\left(|h|^2_{L^2(\Gamma_1)} + \frac{1}{\tilde{b}^2\|\tau_{\Gamma_1}\|^2}|v|^2_{H^1(\Omega)}\right)$$

$$+\left[1 - \tilde{k}_e K_4 K_5\left(|y^0 - y_d|_{L^2(\Omega)} + \sqrt{\alpha}\sqrt{|g^0|^2_{L^2(\Gamma_1)} - |g^\alpha|^2_{L^2(\Gamma_1)}}\right)\right]|v|^2_{L^2(\Omega)}$$

for all $(v, h) \in \ker e'(x^\alpha)$. The conclusion follows from this estimate.

Remark 4.5. Let the assumptions of Theorem 4.4 except possibly (h6) hold, and assume that (y^0, g^0) in (h5) is unique. Then, using (4.6) we can argue that $(y^\alpha, g^\alpha) \to (y^0, g^0)$ weakly in $W^{1,4}(\Omega) \times L^2(\Gamma_1)$ as $\alpha \to 0^+$. If moreover $f'(y^0) \geq 2\beta > 0$ on Ω, then there exists $\bar{\alpha} > 0$ such that $f'(y^\alpha) \geq \beta$ on Ω for all $\alpha \in [0, \bar{\alpha}]$. By the Lax–Milgram lemma, (h6) follows.

In Theorems 4.1, 4.2, and 4.4 the second-order optimality condition was guaranteed by assuring that the term $\langle \lambda^*, f''(y^*)v^2\rangle_\Omega$ is small when compared to $|Cv|^2_Z + \alpha|h|^2_{L^2(\Gamma_1)}$. Alternatively we can proceed by assuming that

(h7) $$\lambda^* f''(y^*) \geq 0 \quad \text{a.e. on } \Omega.$$

THEOREM 4.6. *Assume that* (H1), (H2), (h1), (h3), *and* (h7) *hold and that*

(a) $Z = H^1(\Omega)$, *and* $C = \mathrm{id}$, *or*

(b) (h2) *is satisfied.*

Then (H3) *holds.*

Proof. By Proposition 3.4 and (h7) we find for all $(v, h) \in X$

$$\mathcal{L}''(y^*, g^*, \lambda^*)((v, h), (v, h)) \geq |Cv|^2_Z + \alpha|h|^2_{L^2(\Gamma_1)}.$$

In the case where (a) holds, the conclusion is obvious and $\mathcal{L}''(v^*, g^*, \lambda^*)$ is positive not only on $\ker e'(x^*)$ but also on all of X. In case (b) we use (4.3) to conclude that

$$\mathcal{L}''(y^*, g^*, \lambda^*)((v, h), (v, h)) \geq |Cv|^2_Z + \frac{\alpha}{2}\left(|h|^2_{L^2(\Gamma_1)} + \frac{1}{\|B^{-1}\|^2\|\tau_{\Gamma_1}\|^2}|v|^2_{H^1(\Omega)}\right)$$

for all $(v, h) \in \ker e'(x^*)$.

Next we give a sufficient condition for (h7).

THEOREM 4.7. *Let* (H1), (H2), (h1) *hold and assume that*

(i) $\langle C^*(y_d - Cy^*), \psi\rangle_{(H^1)^*, H^1} \geq 0$ *for all* $\psi \in H^1(\Omega)$ *with* $\psi \geq 0$, *a.e.*,

(ii) $f'(y^*) \geq 0$ *a.e. on* Ω,

(iii) $f''(y^*) \geq 0$ *a.e. on* Ω.

Then (h7) *holds. The conclusion remains correct if the inequalities in* (i) *and* (iii) *are reversed.*

Proof. Set $\varphi = \inf(0, \lambda^*) \in H^1(\Omega)$ in (3.5). Then we have

$$\int_\Omega |\nabla\varphi|^2 dx + (f'(y^*)\varphi, \varphi) + \langle c^*(Cy^* - y_d), \varphi\rangle_{(H^1)^* \times H^1} = 0.$$

Since $f'(y^*) \geq 0$ it follows from (i) that $|\nabla\varphi|^2_{L^2(\Omega)} = 0$ and $\lambda^* \geq 0$. Together with (iii) we find $\lambda^* f''(y^*) \geq 0$ a.e. on Ω. If the inequalities in (i) and (iii) are reversed, we take $\varphi = \sup(0, \lambda^*)$.

Example 4.8. We consider

$$\begin{aligned} -\Delta y + y^3 - y &= \tilde{h} \quad \text{in } \Omega, \\ \frac{\partial y}{\partial n} &= g \quad \text{on } \Gamma, \end{aligned} \tag{4.10}$$

and the associated optimal control problem

$$\begin{cases} \min \dfrac{1}{2}\displaystyle\int_\Omega |y - y_d|^2 dx + \frac{\alpha}{2}\int_\Gamma g^2 dx, \\ \text{subject to } (y, g) \in H^1(\Omega) \times L^2(\Gamma) \text{ a solution of (4.10).} \end{cases} \tag{4.11}$$

Here Ω is a bounded domain in $\mathbb{R}^n$, $n \leq 3$, satisfying the general requirements specified at the beginning of this section. In the present example $\Gamma_1 = \Gamma = \partial\Omega$, $\Gamma_2 = \emptyset$, and consequently $\tilde{g} = g$. In the context of the general theory we put

$$Z = L^2(\Omega), \quad C : H^1(\Omega) \to L^2(\Omega) \text{ canonical injection}, \qquad f(t) = t^3 - t.$$

Equation (4.10) represents a simplified Ginzburg-Landau model for superconductivity with y denoting the wave function, which is valid in the absence of internal magnetic fields [T, Chaps. 1, 4]. Both (4.10) and

$$-\Delta y + y^3 + y = \tilde{h} \tag{4.12}$$

are of interest for superconductivity, but we prefer to concentrate on (4.10) here rather than on (4.12), since the former has three equilibria while the latter has only one equilibrium.

The optimal control problem (4.11) with a slightly more general version of (4.10) (i.e., (4.12)) was studied in [GHS]. The numerical approach in that paper is based on solving the optimality system associated with (4.11), which involves solving (4.10) and the costate equation.

Let us discuss the validity of some of the conditions (hi) and (Hi) for the present problem. Existence of a minimum $x^* = (y^*, g^*)$ is proved in [GHS] for any $\alpha > 0$. It is also proved there (using $n \leq 3$) that $e'(x^*)$ is surjective and thus (H1) and (H2) hold. Sobolev's embedding theorem and

$$f'(t) = 3t^2 - 1 \quad \text{and} \quad f''(t) = 6t$$

imply that (h1), (h3), and (h4) hold. Let us note that f has the three equilibria ± 1 and 0, of which ± 1 are stable and 0 is unstable. It is therefore quite reasonable to conjecture that in general for $\tilde{h} = 0$, $y_d \geq 1$ implies $1 \leq y^* \leq y_d$ and, similarly, that $y_d \leq -1$ implies $y_d \leq y^* \leq -1$. This was confirmed numerically. In these cases $f'(y^*) \geq \underline{\beta} > 0$ and (i)-(iii) of Theorem 4.7 hold. The situation is more delicate if $-1 \leq y_d \leq 1$ and the (numerical) solution y^* depends qualitatively more significantly on the cost α of the control. We shall elaborate further on this point when discussing numerical examples below.

Example 4.9. Here we investigate

$$\begin{aligned} -\Delta y + y^3 - y &= \tilde{h} \quad \text{in } \Omega, \\ \frac{\partial y}{\partial n} &= g \quad \text{on } \Gamma_1, \\ \frac{\partial y}{\partial n} &= 0 \quad \text{on } \Gamma_2, \end{aligned} \tag{4.13}$$

and the associated optimal control problem is given by

$$\text{(4.14)} \qquad \begin{cases} \min \dfrac{1}{2}\displaystyle\int_{\Gamma_3} |y - y_d|^2 ds + \dfrac{\alpha}{2}\int_{\Gamma_1} g^2 ds, \\ \text{subject to } (y, g) \in H^1(\Omega) \times L^2(\Gamma_1) \text{ a solution of (4.13),} \end{cases}$$

where Γ_3 is a nontrivial measurable subset of Γ_2 and Ω satisfies the properties specified at the beginning of this section. Moreover

$$Z = L^2(\Gamma_3), \qquad C \text{ is the trace operator from } H^1(\Omega) \text{ onto } L^2(\Gamma_3),$$

and f is as in Example 4.8. To argue existence of a solution to (4.14), first note that (4.13) is satisfied for at least one pair $(y, g) \in H^1(\Omega) \times L^2(\Gamma_1)$, which renders the cost functional in (4.14) finite. Hence there exists a minimizing sequence (y_n, g_n) in $H^1(\Omega) \times L^2(\Gamma_1)$. Using (4.13) it is simple to deduce that (y_n, g_n) is bounded in $H^1(\Omega) \times L^2(\Gamma_1)$ and every weak subsequential limit is a solution to (4.14). Thus (H1) holds. Concerning the remaining hypotheses, the same remarks apply to (4.14) as to (4.11).

Example 4.10. This is the singular system

$$\text{(4.15)} \qquad \begin{aligned} -\Delta y - y^3 &= \tilde{h} \quad \text{in } \Omega \\ \frac{\partial y}{\partial n} &= g \quad \text{on } \Gamma, \end{aligned}$$

and the associated optimal control problem

$$\text{(4.16)} \qquad \begin{cases} \min \dfrac{1}{2}|y - y_d|^2_{H^1(\Omega)} + \dfrac{\alpha}{2}\displaystyle\int_{\Gamma} g^2 ds, \\ \text{subject to } (y, g) \in H^1(\Omega) \times L^2(\Gamma_1) \text{ a solution of (4.15),} \end{cases}$$

where $y_d \in H^1(\Omega)$. If (4.15) admits at least one feasible pair (y, g), then it is simple to argue that (4.16) has a solution $x^* = (y^*, g^*)$. (We refer to [L, Chap. 3] for existence results in the case where the cost functional is of the form $|y - y_d|^r_{L^r(\Omega)} + \alpha|g|^2_{L^2(\Gamma)}$ for appropriately chosen $r > 2$.) The existence of a Lagrange multiplier is assured in the same manner as in Example 4.8. Clearly (h1) and (h3) are satisfied. For $y_d = \text{ const } \geq \frac{1}{2}$, we observed that $0 \leq y^* \leq y_d$, $\lambda^* < 0$, which in view of (h7) and Theorem 4.6 explains the second-order convergence rate that is observed numerically.

5. Numerical tests. We carried out numerous tests for Examples 4.8–4.10 and focused our interest on the following aspects:

- convergence for wide ranges of initial values and values for the penalty parameter c (no globalization, e.g., by line search),
- rate of convergence,
- how well the desired state y_d can be reached and how strongly this depends on α,
- influence of equilibria.

All of the tests were carried out with $\Omega = [0, 1] \times [0, 2]$ with a five-point central finite difference discretization of the state equation (appropriately modified at the boundary so that the discretized system equation for (4.10) is symmetric) on the grid $\{(\frac{i}{N}, \frac{j}{N})\}_{i=0,\ldots,N}^{j=0,\ldots,2N}$. The programs were written in MATLAB. Convergence was achieved for all test examples for a wide range of values for c. For $c \in [10, 1000]$ and $\alpha \in [10^{-7}, 10^{-1}]$, the algorithm was quite insensitive with respect to the specific value of c. For $c \in [10^{-7}, 10]$ the number of iterations increased as c was decreased. For $c = 0$ divergence was observed in all runs. The case $c = 0$

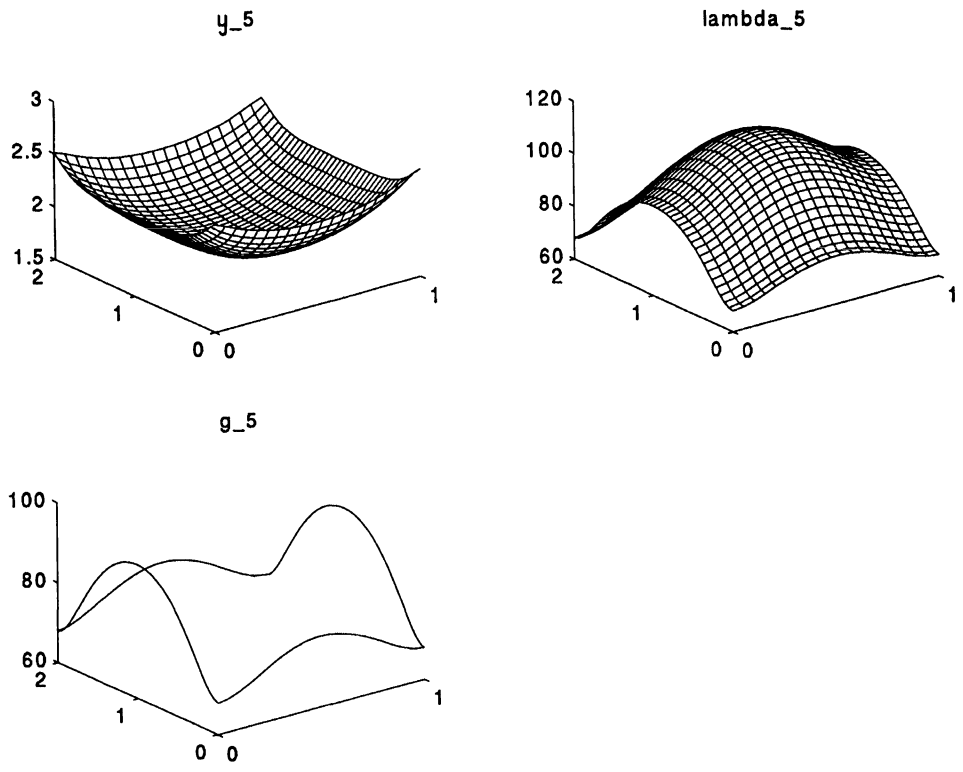

FIG. 5.1.

in Algorithm 2 corresponds to the SQP method without globalization strategy or, equivalently, to the Newton method applied to the first-order necessary optimality condition. Second-order rate of convergence was the typical behavior for all three examples with reasonable choices for α and c.

In all examples below we chose Algorithm 2, and $N = 20$, $\tilde{h} = 0$, $\lambda_0 = 0$ (start-up value for λ^*), $y_0 = y_d$ (start-up value for y^*), $g_0 = 0$ (start-up value for g^*), unless otherwise specified. We denote the converged numerical solution by (y^*, g^*, λ^*).

RUN 1. This is Example 4.8 with

$$c = 1,\ \alpha = 10^{-3},\ y_d = 3.$$

In Figure 5.1 we give the graph of the converged solution after five iterations. The values for

$$e_n = \frac{|y_{n+1} - y_n|_{H^1} + |g_{n+1} - g_n|_{L^2}}{|y_n - y_{n-1}|^2_{H^1} + |g_n - g_{n-1}|^2_{L^2}}$$

are given in Table 5.1. We observe that $1 \leq y^*(= y^5) \leq y_d$, i.e., the solution is attracted by the stable equilibrium. As a consequence, Theorem 3.4 applies. Moreover $\tau_\Gamma \lambda^5 = g^5$, which confirms (3.6) of Proposition 3.1.

Let us make some additional comments on further runs. If the desired state was chosen between the two equilibria 0 and 1 so that $0 \leq y_d \leq 1$, then the numerical solution satisfied $0 \leq y^* \leq 1$, as well. In these cases $\lambda^* < 0$ and Theorem 4.6 is not applicable. Nevertheless

TABLE 5.1.

n	1	2	3	4
e_n	.0080	.0019	.0001	.0181

TABLE 5.2.

n	1	2	3	4	5	6	7	8	9
$\hat{e}_n$	13.4	.023	.023	.023	.040	.029	.080	.020	4.25

very good convergence could always be achieved. For $y_d(x) = x, c = 10, \alpha = 1$, for example, we found $\{e_n\}_{n=1}^4 = (.0032, .015, 0.04, 6 * 10^{14})$. While typically convergence was achieved within the first ten iterations, we should also mention our worst result with

$$\tilde{h} = 100^3 - 100, \quad c = 1, \quad \alpha = 10^{-3}, \quad y_0 = 0, \quad g_0 = 1, \quad \lambda_0 = 0, \quad N = 10.$$

The exact solution is $(y^*, g^*, \lambda^*) = (100, 0, 0)$. Convergence was achieved after 294 iterations, and for

$$\tilde{e}_n = \frac{|y_n - y^*|_{H^1}}{|y_{n-1} - y^*|_{H^1}^2},$$

we found $(\tilde{e}_{291}, \ldots, \tilde{e}_{294}) = (.028, .011, .011, .10)$.

RUN 2. This is Example 4.9 with

$$c = 100, \ \alpha = 10^{-5}, \ y_d = 1, \ g_0 = 1, \ \Gamma_1 = (0, 1) \times \{0\}, \ \Gamma_3 = (0, 1) \times \{2\}. \tag{5.1}$$

The rates for

$$\hat{e}_n = \frac{|y_n - y^*|_{H^1} + |g_n - g^*|_{L^2}}{|y_{n-1} - y^*|_{H^1}^2 + |g_{n-1} - g^*|_{L^2}^2}$$

are given in Table 5.2. The exact solution is $(y^*, g^*) = (1, 0)$. We also give graphs for the evolution of y_i. Convergence is a little slower for small c and thus the graphs are more interesting. Figure 5.2 gives, therefore, the results for $c = 1$, with the remaining specifications being those of (5.1).

RUN 3. This is Example 4.9 with (5.1). Here, unlike in the previous run, we chose the value $y_0 = -2$ as the initial guess for y^*. In the course of the iteration y_i has to "pass through" the equilibria -1 and 0 to reach $y^* = y_d = 1$. Selected graphs of the sequence y_i are shown in Figure 5.3. Between iterations 9 and 10 the step over the unstable equilibrium occurs. This step was too large and due to the weak influence of the control which was applied at the ordinate value $y = 0$ on the state at ordinate value $y = 2$, it took about 16 additional iterations until the desired state y_d was reached ($|y_{36} - y^*|_{H^1(\Omega)} = 7 * 10^{-5}$). In Figure 5.4 we give a plot for the evolution of $|g_i|_{L^2(\Gamma_1)}$. We observe that recovery after passing through the unstable equilibrium is only possible with large values of the cost (for $i = 11, \ldots, 14$).

RUN 4. This is Example 4.9 with

$$c = 100, \quad \alpha = 10^{-5} (\alpha = 10^{-7}), \quad y_d = \frac{1}{2} + x, \quad y_0 = 1, \quad \Gamma_1, \Gamma_3 \text{ as in (5.1)}. \tag{5.2}$$

In Figure 5.5 we give the plots for y^6 with $\alpha = 10^{-5}$ and $\alpha = 10^{-7}$, respectively. Clearly the cheaper cost allows us to reach the desired state y_d better than the more expensive cost.

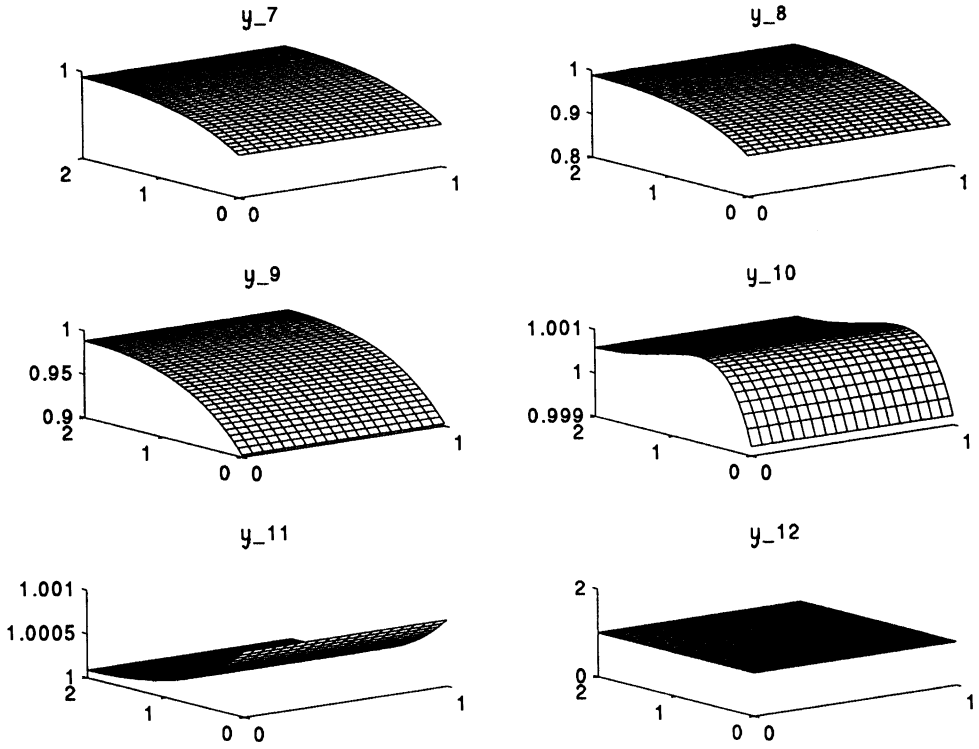

FIG. 5.2.

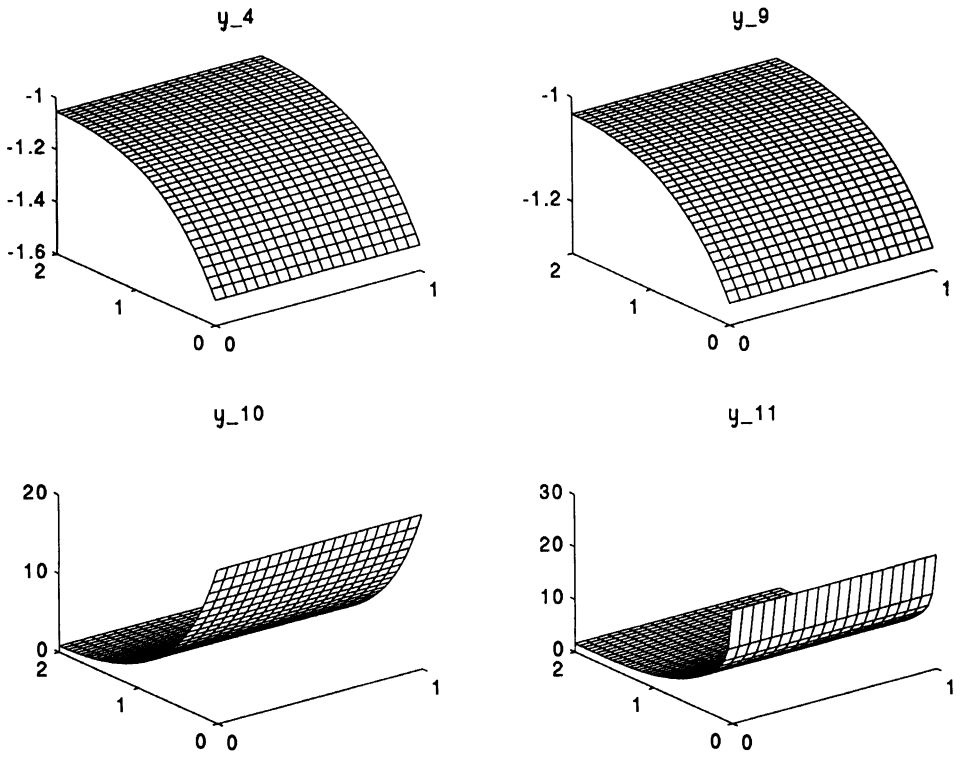

FIG. 5.3.

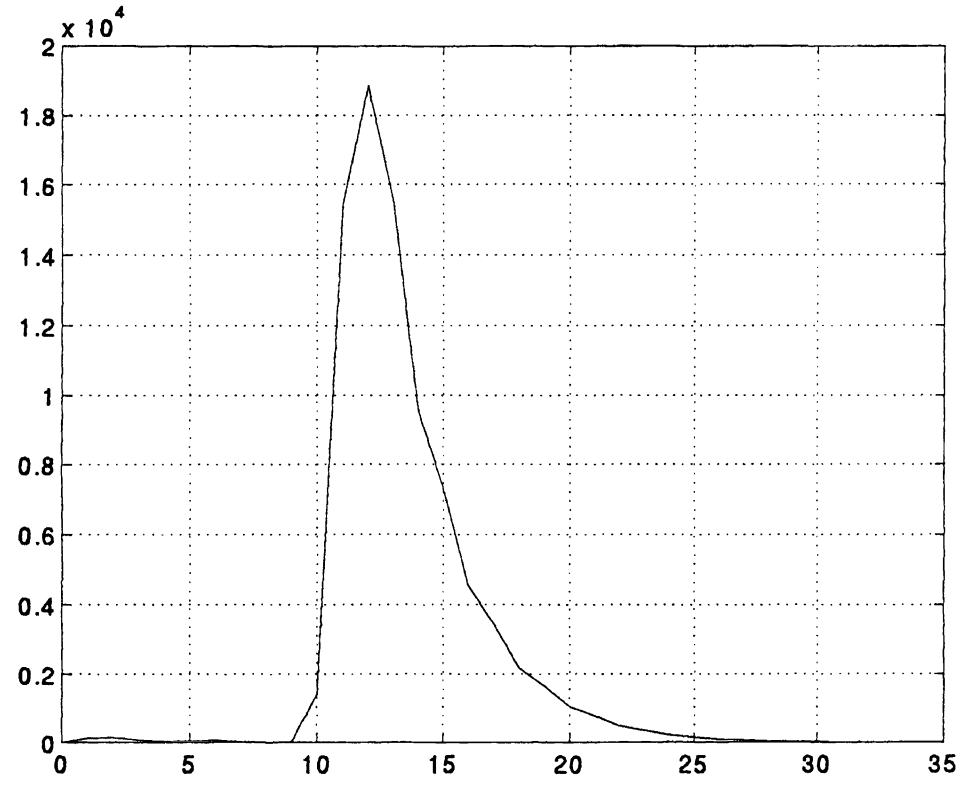

FIG. 5.4.

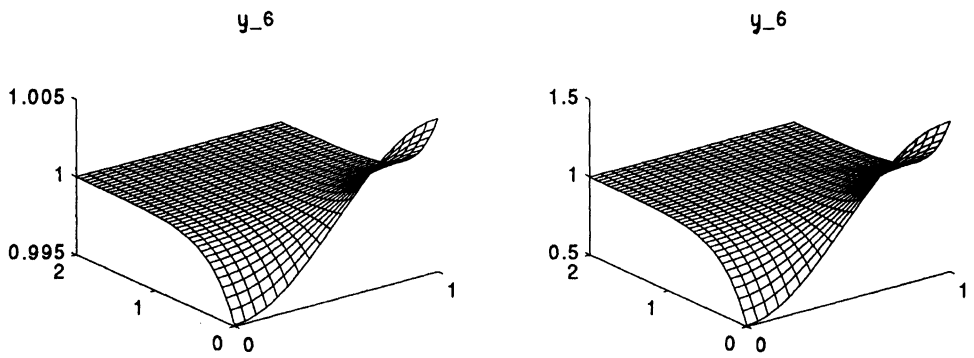

FIG. 5.5.

RUN 5. Here we consider Example 4.9 with a more challenging desired state:

$$N = 40,\ c = 20,\ \alpha = 10^{-7},\ y_d = \frac{1}{2}\sin\left(\frac{3\pi}{2}x\right). \tag{5.3}$$

For the convergence rate we found the results of Table 5.3.

RUN 6. This is the singular control system of Example 4.10 with

$$c = 10,\ \alpha = 10^{-2},\ y_d = 1 + xy,\ y_0 = 0. \tag{5.4}$$

The results after 10 iterations are given in Figure 5.6. We ran other tests with $y_d = \text{const}$ (and, e.g., $c = 10$, $\alpha = .1$) and observed that for const $> 0 (< 0)$ the resulting Lagrange parameter

satisfies $\lambda^* < 0 (> 0)$. If $y_d \geq .5 (\leq .5)$, then $0 \leq y^* \leq y_d$, $(y_d \leq y^* \leq 0)$, so Theorem 4.6 is applicable.

THE KORTEWEG-DE VRIES EQUATION ON A PERIODIC DOMAIN WITH SINGULAR-POINT DISSIPATION*

S. M. SUN†

Abstract. This paper considers the Korteweg-de Vries (KdV) equation

$$u_t + uu_x + u_{xxx} = 0, \quad 0 < x < 1, \ t > 0, \quad u(0, x) = u_0(x),$$

and the periodic boundary conditions $u(t, 1) = u(t, 0), u_{xx}(t, 0) = u_{xx}(t, 1)$ with an L^2-stabilizing control input implemented by a feedback mechanism $u_x(t, 1) = \alpha u_x(t, 0)$ and $|\alpha| < 1$. It can be shown that the solutions conserve the volume $[u] = \int_0^1 u(t, x)dx$ and the constant state $[u_0]$ possesses the smallest energy among solutions with same volume. It has been proved that the solution of the system exists and approaches $[u_0]$ as $t \to +\infty$ when $\alpha \neq -1/2$. This paper studies the case for $\alpha = -1/2$ and gives a proof of the existence and exponential decay of the solutions by deriving estimates of the corresponding Green's function and using semigroup theory. The method used here also works for the other cases with $|\alpha| < 1$.

1. Introduction.

Recently the Korteweg-de Vries (KdV) equation

$$u_t + \gamma uu_x + u_{xxx} = 0, \tag{1.1}$$

has been studied intensively in many papers. For $\gamma = 0$, this is a third-order linear dispersion equation and has been studied in [12]. The cases with $\gamma \neq 0$ are essentially equivalent and can be covered by letting $\gamma = 1$.

The literature for (1.1) both for x on a periodic domain and for a domain $-\infty < x < \infty$ is enormous, and the reader may be referred to [1, 2, 4, 5, 9, 15] for more details and to [7, 8, 12-14] for related control problems. Here we are considering the following initial boundary value problem:

$$\begin{aligned} &u_t + uu_x + u_{xxx} = 0, \quad 0 < x < 1, \quad t > 0, \\ &u(0, x) = \phi(x), \\ &u(t, 1) = u(t, 0), \quad u_x(t, 1) = \alpha u_x(t, 0), \quad u_{xx}(t, 1) = u_{xx}(t, 0), \end{aligned} \tag{1.2}$$

where $|\alpha| < 1$. By integrating the equation in (1.2) from zero to one and using the boundary conditions, it can be easily obtained that the volume $[u] = \int_0^1 u(t, x)dx$ of the solution $u(t, x)$ is conserved for $t \geq 0$, which is physically reasonable.

It is well known that the KdV equation (1.1) is a model equation for water waves in a channel using long-wave approximations. The equation is usually considered for $x \in (-\infty, +\infty)$. However, the fluid regions are always finite in physical applications and fluid-dynamical experiments as well as numerical computations. Therefore, it is more realistic to consider the KdV equation in a bounded region. The KdV equations with periodic boundary conditions are relevant to wave motions in a circular channel with a great radius. Also, the periodic boundary conditions are mostly used in experiments and numerical computations to find the properties of long waves on the free surfaces of channel flows, which are governed by the KdV equation. Furthermore, it is much easier to control the boundary conditions of the flows, such as by using wave-makers at boundaries, so that certain states of the flows can

†Department of Mathematics, Virginia Polytechnic Institute and State University, Blacksburg, VA 24061.

be reached. The boundary conditions in (1.2) can be viewed as a control mechanism of the vertical velocity of the fluid at boundary, which is intended to stabilize the flow.

In control theory, the system (1.2) is described as a closed-loop point dissipation process. Closed-loop control generally refers to control synthesis via state feedback of some sort and is predominantly concerned with achieving asymptotic stability of an equilibrium or invariant set. From an identity

$$\int_0^1 |u(t,x)|^2 dx = \int_0^1 |u(t,x) - [u]|^2 dx + \int_0^1 |[u]|^2 dx,$$

it shows that among all functions $u \in L^2(0,1)$ for which $[u]$ is a fixed constant, $\|u\|_{L^2(0,1)}$ is uniquely minimized by the constant function $u \equiv c = [u]$, which is an equilibrium state of (1.2). Therefore, a solution of (1.2) may be caused to approach the constant state $[u] = [\phi]$ as $t \to +\infty$ through use of a control process designed to make $\|u(t,\cdot)\|_{L^2(0,1)}$ nonincreasing. By multiplying the equation in (1.2) by $u(t,x)$, integrating it from zero to one, and using the boundary conditions again, we can obtain an identity for the solution of (1.2),

$$\frac{d}{dt}\left(\int_0^1 |u(t,x)|^2 dx\right) = (1/2)(\alpha^2 - 1)|u_x(t,0)|^2. \tag{1.3}$$

When $|\alpha| < 1$, the energy is decreasing unless $u_x(t,0) = u_x(t,1) \equiv 0$. Therefore, the boundary condition $u_x(t,1) = \alpha u_x(t,0)$ for $|\alpha| < 1$ can be viewed as a dissipation mechanism for the system (1.2). This condition was obtained by Russell and Zhang [13] using an L^2-stabilizing control input, implemented by a feedback mechanism. Because of the dissipation mechanism at the boundaries, it is reasonable to expect that the solution $u(t,x)$ of (1.2) approaches $[\phi(x)]$ as $t \to +\infty$.

The system (1.2) was first derived in [13] to study the smoothing properties of the solution of (1.2) with asymptotic decay properties in $L^2(0,1)$. Their results can be summarized as follows. Let

$$(A_\alpha u)(x) = -u'''(x) \tag{1.4}$$

with

$$\mathcal{D}(A_\alpha) = \left\{w \in H^3(0,1) \mid w(1) = w(0),\ w'(1) = \alpha w'(0),\ w''(1) = w''(0)\right\},$$

and let A_α^* be its adjoint operator in $L^2 = L^2(0,1)$. If $\alpha \neq -1/2$, then A_α and A_α^* have complete sets of eigenvectors—respectively, $\{\phi_k \mid -\infty < k < \infty\}$ and $\{\psi_k \mid -\infty < k < \infty\}$—which are normalized so that $\psi_j^* \phi_k = \delta_{kj}$ and form dual Riesz bases for L^2. Define

$$H_\alpha^{s,p} = \left\{ w = \sum_{k=-\infty}^{\infty} c_k \phi_k ; \quad \sum_{k=-\infty}^{\infty} (1 + |k|^{ps})|c_k|^p < \infty \right\}$$

with the norm

$$\|w\|_{H_\alpha^{s,p}}^p = \sum_{k=-\infty}^{\infty} |c_k|^p (1 + |k|^{ps}).$$

If we denote $H_\alpha^{s,2}$ by H_α^s, then the main results in [13] can be stated as follows.

THEOREM 1.1. *Assume $|\alpha| < 1$ and $\alpha \neq -1/2$. Then there exists a $\beta > 0$ such that for any $\phi \in H_\alpha^1$ with $\|\phi\|_{H_\alpha^1} \leq \beta$, (1.2) has a unique solution $u \in C([0,\infty); H_\alpha^1)$ and*

$$\|u(t,\cdot) - [\phi]\|_{L^2} \leq K e^{-\rho t} \|\phi - [\phi]\|$$

for $t \geq 0$, where $K > 0$ and $\rho > 0$ are independent of ϕ and $[\phi] = \int_0^1 \phi dx$.

The existence of solutions in Theorem 1.1 was proven by using an integral equation based on the "variation of parameters" formula and explicit representation of the semigroup associated with the operator A_α obtained from the dual Riesz bases $\{\phi_k\}$ and $\{\psi_k\}$. Then the asymptotic decay of the solutions was obtained by use of Lyapounov techniques based on properties of a linear equation $u_t + u_{xxx} = 0$. However, when $\alpha = -1/2$, the eigenvectors of A_α and A_α^* do not form dual Riesz bases for L^2 and the proof in [13] cannot be carried over. Therefore, a new method must be introduced for the proof when $\alpha = -1/2$.

The objective of this paper is to give a proof of Theorem 1.1 for $\alpha = -1/2$. We consider this singular case in Theorem 1.1 with $\alpha = -1/2$ and construct the semigroup corresponding to A_α using the Green's function to study the existence of solutions for (1.2) when $\alpha = -1/2$. After we derive the estimates for the linear operator, we can invert (1.2) into an integral equation and show that the corresponding integral operator is a contraction. Therefore, the contraction mapping theorem implies the existence of the solutions of (1.2). Finally we use an inequality similar to the Gronwall inequality to prove the exponential decay of the solutions. We note that the method developed here can also be used to prove Theorem 1.1. It is interesting to note that all the large eigenvalues of $A_{-1/2}$ are on the negative real axis. However, Komornik showed that $A_{-1/2}$ does not generate an analytic semigroup [6], which will be given in Appendix 3.

The paper is organized as follows. In §2, the exact form of the semigroup $S(t)$ corresponding to $A_{-1/2}$ is constructed by using Green's function, and some properties of the Green's function are given. In §3, various properties and estimates for $S(t)$ applying to functions in $L^2(0, 1)$ and $H^1(0, 1)$ are derived. In §4, the local and global existence of solutions of (1.2) is proven and the exponential decay of the solutions to their mean values is obtained.

2. Representation of the semigroup for $A_{-1/2}$. Let A_α be an operator defined in (1.4). If $|\alpha| \leq 1$, it is easy to check that A_α is dissipative in $L^2 = L^2(0, 1)$. By using elementary theory of ordinary differential equations, we can show that the range $\mathcal{R}(\lambda_0 I - A)$ is the whole space L^2 if $\lambda_0 > 0$ is large enough. Thus by Lumer-Phillip's theorem [10], A_α is the infinitesimal generator of a C_0-semigroup $S_\alpha(t)$ of contractions in L^2; that is, for $f \in L^2$ and $|\alpha| \leq 1$,

$$\|S_\alpha(t) f\|_{L^2} \leq \|f\|_{L^2}. \tag{2.1}$$

Since $\alpha \neq -1/2$ was studied in [13], here we assume that $\alpha = -1/2$ and let $A = A_{-1/2}$. Now we determine the discrete spectrum of A. Assume that μ_1, μ_2, and μ_3 are the three complex cubic roots of $-\lambda$. Then after some tedious computation, we can see that the eigenvalue λ of $Au = \lambda u$ satisfies either $\lambda = 0$ or

$$3 - (e^{-\mu_1} + e^{-\mu_2} + e^{-\mu_3}) = 0. \tag{2.2}$$

Since A is dissipative, $\operatorname{Re} \lambda \leq 0$ if λ is an eigenvalue. Also, every eigenvalue has multiplicity one. Next we obtain the asymptotic forms of the eigenvalues λ.

LEMMA 2.1. *If λ is an eigenvalue and $|\lambda|$ is large, then λ is real and $\lambda \sim -(2k + 1)\pi/2$ as $k \to +\infty$. Also, there is no eigenvalue on the imaginary axis except $\lambda = 0$.*

Proof. If $\lambda = ir$ with r real, then there exists one cubic root of $-ir$—say, μ_1—such that $\mu_1 = ir^{1/3}$. Therefore, by (2.2),

$$3 - (e^{-ir^{1/3}} + e^{(\sqrt{3}+i)r^{1/3}/2} + e^{(-\sqrt{3}+i)r^{1/3}/2}) = 0.$$

By separating the real part and the imaginary part, it is straightforward to show that the only root is $r = 0$. Thus, no eigenvalues are on the imaginary axis except zero. Next we show that λ is real for large eigenvalues λ. Since all eigenvalues have negative real parts except zero, $\operatorname{Re}(-\lambda) > 0$. Let μ_1 be the cubic root of $-\lambda$ with $|\arg \mu_1| \leq \pi/6$. Then $\mu_1 = \mu_r + i\mu_i$

with $\mu_r > 0$ and $|\mu_i| \le \mu_r/\sqrt{3}$. Substitution of $\mu_1 = \mu_r + i\mu_i$, $\mu_2 = \omega\mu_1$, $\mu_3 = \omega^2\mu_1$ with $\omega = (-1 + i\sqrt{3})/2$ into (2.2) and separating the real and imaginary parts yield

$$\begin{aligned} 3 - e^{-\mu_r}\cos\mu_i - e^{(\mu_r+\sqrt{3}\mu_i)/2}\cos((\sqrt{3}\mu_r - \mu_i)/2) \\ -e^{(\mu_r-\sqrt{3}\mu_i)/2}\cos((\sqrt{3}\mu_r + \mu_i)/2) = 0, \\ e^{-\mu_r}\sin\mu_i + e^{(\mu_r+\sqrt{3}\mu_i)/2}\sin((\sqrt{3}\mu_r - \mu_i)/2) \\ -e^{(\mu_r-\sqrt{3}\mu_i)/2}\sin((\sqrt{3}\mu_r + \mu_i)/2) = 0. \end{aligned}$$

Rewrite these two equations as

$$\begin{aligned} 2\cosh(\sqrt{3}\mu_i/2)\cos(\sqrt{3}\mu_r/2)\cos(\mu_i/2) + 2\sinh(\sqrt{3}\mu_i/2)\sin(\sqrt{3}\mu_r/2)\sin(\mu_i/2) \\ = 3e^{-\mu_r/2} - e^{-(\sqrt{3}\mu_r/2)}\cos\mu_i\,, \\ 2\sinh(\sqrt{3}\mu_i/2)\sin(\sqrt{3}\mu_r/2)\cos(\mu_i/2) - 2\cosh(\sqrt{3}\mu_i/2)\cos(\sqrt{3}\mu_r/2)\sin(\mu_i/2) \\ = e^{-(\sqrt{3}\mu_r/2)}\sin\mu_i\,. \end{aligned}$$

Multiply the first equation by $\cos(\mu_i/2)$ and the second by $\sin(\mu_i/2)$, and subtract the resulting equations to get

$$2\cosh(\sqrt{3}\mu_i/2)\cos(\sqrt{3}\mu_r/2) = \cos(\mu_i/2)(3e^{-\mu_r/2} - e^{-\sqrt{3}\mu_r/2}). \tag{2.3}$$

Then multiply the first by $\sin(\mu_i/2)$ and the second by $\cos(\mu_i/2)$, and add them together to obtain

$$2\sinh(\sqrt{3}\mu_i/2)\sin(\sqrt{3}\mu_r/2) = \sin(\mu_i/2)(3e^{-\mu_r/2} + e^{-\sqrt{3}\mu_r/2}). \tag{2.4}$$

Since $|\mu_i| \le \mu_r/\sqrt{3}$, $\mu_r \to +\infty$ if $\lambda \to \infty$. But $\cosh(\sqrt{3}\mu_i/2) \ge 1$. Thus as $\lambda \to \infty$, by (2.3) $|\cos(\sqrt{3}\mu_r/2)| \le K\exp(-\mu_r/2)$, where K is a fixed constant, which implies

$$\mu_r = (2k+1)\pi/\sqrt{3} + O(e^{-k\pi/\sqrt{3}}) \qquad \text{for } k \text{ large}.$$

Therefore, $|\sin(\sqrt{3}\mu_r/2)| \to 1$, and from (2.4) we have that $\mu_i = o(\exp(-k\pi/\sqrt{3}))$, which yields that for λ large, the cubic root μ_1 of $-\lambda$ must be

$$\mu_1 = (2k+1)\pi/\sqrt{3} + O(e^{-k\pi/\sqrt{3}}). \tag{2.5}$$

However, $2\cos(\sqrt{3}\mu/2) = 3e^{-\mu/2} - e^{-\sqrt{3}\mu/2}$ has infinitely many real roots $\tilde{\mu}_k = (2k+1)\pi/\sqrt{3} + O(\exp(-k\pi/\sqrt{3}))$, which satisfy (2.3) and (2.4) with $\mu_i = 0$. Thus $-\tilde{\mu}_k^3$, $k = 1, 2, \ldots$, are also the eigenvalues of A. Now let us consider the analytic function

$$f(z) = e^{-z/2}(3 - e^{-z} - e^{-\omega z} - e^{-\omega^2 z}).$$

If $\operatorname{Re} z \ge 0$ and $|\operatorname{Im} z| \le 1$, then $|f(z)| + |f'(z)| + |f''(z)| \le K$, where K is a fixed constant. $f(z)$ has infinitely many real zeros $\tilde{\mu}_k$, and at $\tilde{\mu}_k$, $|f'(\tilde{\mu}_k)| = \sqrt{3} + O(\exp(-k\pi/\sqrt{3}))$. For z in a disk centered at $\tilde{\mu}_k$ with radius $1/2$, we have

$$f(z) = f(\tilde{\mu}_k) + f'(\tilde{\mu}_k)(z - \tilde{\mu}_k) + (1/2)f''(\tilde{z})(z - \tilde{\mu}_k)^2,$$

where $\tilde{z}$ is in the disk. Thus

$$|f(z)| \ge |z - \tilde{\mu}_k|\left(|f'(\tilde{\mu}_k)| - K|z - \tilde{\mu}_k|\right),$$

where K is independent of z and k. Therefore, there is a $\tilde{\delta} > 0$ such that for $|z - \tilde{\mu}_k| \leq \tilde{\delta}$ and $z \neq \tilde{\mu}_k$, $f(z) \neq 0$. Thus μ_1 in (2.5) must be real also, which implies that the large eigenvalues are real, completing the proof of Lemma 2.1.

We note here that A does not generate an analytic semigroup, which will be shown in Appendix 3. In the following, we shall give a representation of the semigroup $S(t) = S_{-1/2}(t)$, where $S_\alpha(t)$ is the corresponding C_0-semigroup of A_α. Let λ be in either the upper half or the lower half plane. Without loss of generality, we assume that λ is in the upper half plane since the discussion is similar for λ in the lower half plane. Let $\mu_1^3 = -\lambda$, $\mu_2 = \omega\mu_1$, $\mu_3 = \omega^2\mu_1$ with $\omega = (-1 + i\sqrt{3})/2$. Since $\operatorname{Im}\lambda \geq 0$, $\operatorname{Re}(-i\lambda) \geq 0$. There is a μ^* such that $(\mu^*)^3 = -i\lambda$ with $|\arg\mu^*| \leq (\pi/6)$ and $(i\mu^*)^3 = -\lambda$. Let $\mu_1 = i\mu^*$, which implies $|(\pi/2) - \arg\mu_1| \leq (\pi/6)$. Now let $G(\lambda, x, \xi)$ be the Green's function of $(\lambda I - A)^{-1}$ in L^2. Then for $f \in L^2$,

$$(\lambda I - A)^{-1} f = \int_0^1 G(\lambda, x, \xi) f(\xi) d\xi \in \mathcal{D}(A)\,, \tag{2.6}$$

where $G(\lambda, x, \xi)$ is given in Appendix 1. Since A is an infinitesimal generator of a C_0-semigroup of contractions, by a formula in [10, Cor. 7.5, p. 28], we have

$$S(t) f = (1/2\pi i) \int_{\gamma - i\infty}^{\gamma + i\infty} e^{\lambda t} (\lambda I - A)^{-1} f d\lambda \tag{2.7}$$

for $t > 0, \gamma > 0$ and $f \in \mathcal{D}(A^2)$. It is well known that $(\lambda I - A)^{-1} f$ is analytic in the complex λ-plane except poles, which are the eigenvalues of A. However, by Lemma 2.1 all the eigenvalues except zero are in the left side of the complex plane. By using the spectral decomposition theorem and the residue theorem [3] for the pole of $(\lambda I - A)^{-1}$ at zero, we have

$$S(t) f = (1/2\pi i) \int_{\Gamma^*} e^{\lambda t} (\lambda I - A)^{-1} f d\lambda + c_0 \int_0^1 f(x) dx,$$

where c_0 is a fixed constant and the last term is the projection of $f(x)$ onto 1 in L^2, since 1 is the eigenvector for the eigenvalue zero. Here Γ^* is a contour with only the eigenvalue zero of A on its right side and asymptotic to $\gamma \pm i\infty$ as $|\lambda| \to +\infty$. Next we deform the contour Γ^* further into $\tilde{\Gamma} = \tilde{\Gamma}_+ \cup \tilde{\Gamma}_-$, where, for $\lambda = \lambda_r + i\lambda_i$,

$$\begin{aligned} \tilde{\Gamma}_+ = \Big\{ & F(\lambda_i) + i\lambda_i, 0 \leq \lambda_i \to +\infty \text{ and } F(\lambda_i) \\ & \text{is a smooth function of } \lambda_i \text{ with } |F(\lambda_i)|^{3/2}/\lambda_i \to \delta > 0 \text{ and } F(\lambda_i) < 0 \Big\}, \\ \tilde{\Gamma}_- = \Big\{ & F(-\lambda_i) + i\lambda_i, 0 \geq \lambda_i \to -\infty \Big\}, \end{aligned} \tag{2.8}$$

$F(0) = \Gamma^* \cap \{\operatorname{Im}\lambda = 0\} < 0$, and all the eigenvalues of A except zero are on the left side of $\tilde{\Gamma}$. Using Cauchy's theorem, we have

$$\begin{aligned} S(t) f &= (1/2\pi i) \left(\int_{\Gamma^* \cap \{\operatorname{Im}\lambda \geq 0\}} + \int_{\Gamma^* \cap \{\operatorname{Im}\lambda \leq 0\}} \right) e^{\lambda t} (\lambda I - A)^{-1} f d\lambda + c_0 \int_0^1 f(x) dx \\ &= (1/2\pi i) \left(\int_{\tilde{\Gamma}_+} + \int_{\tilde{\Gamma}_-} \right) e^{\lambda t} (\lambda I - A)^{-1} f d\lambda + c_0 \int_0^1 f(x) dx \end{aligned} \tag{2.9}$$

for $t > 0$ and $f \in \mathcal{D}(A^2)$ since the integrals over contours at infinity are seen to be zero by using the exponential decay of $e^{\lambda t}$ and the explicit form of $G(\lambda, x, \xi)$ for $(\lambda I - A)^{-1}$.

However, for $t > 0$, $\operatorname{Re}(\lambda t) \to -\infty$ with order of $-|\lambda t|^{2/3}$ if $\lambda \in \tilde{\Gamma}$. Thus the right-hand side of (2.9) is well defined for all $f \in L^2$ if $t > 0$. Since $S(t)$ is equal to the right-hand side of (2.9) for $f \in \mathcal{D}(A^2)$ and $\mathcal{D}(A^2)$ is dense in L^2,

$$S(t)f = \frac{1}{2\pi i}\int_{\tilde{\Gamma}_+} e^{\lambda t}(\lambda I - A)^{-1} f\, d\lambda + \frac{1}{2\pi i}\int_{\tilde{\Gamma}_-} e^{\lambda t}(\lambda I - A)^{-1} f\, d\lambda + c_0 \int_0^1 f(x)dx \tag{2.10}$$

for $f \in L^2$ and $t > 0$. Now we rewrite (2.10) in terms of $\mu_1 = \mu$

$$S(t) = \frac{1}{2\pi i}\left(\int_{\Gamma_+} + \int_{\Gamma_-}\right)(3\mu^2)e^{-\mu^3 t}(\mu^3 I + A)^{-1} f\, d\mu + c_0 \int_0^1 f(x)dx, \tag{2.11}$$

where Γ_+ is in $\{\mu : |\arg \mu - (\pi/2)| \le (\pi/6),\ \operatorname{Im} \mu > 0\}$ and is from $\mu_i = b > 0$ to $\mu_i = +\infty$, and Γ_- is in $\{\mu : |\arg \mu - (3\pi/2)| \le (\pi/6),\ \operatorname{Im} \mu < 0\}$ and is from $\mu_i = -b < 0$ to $\mu_i = -\infty$. Also, Γ_+ and Γ_- are disconnected. For $\mu = \mu_r + i\mu_i$ and $\lambda = \lambda_r + i\lambda_i$ with $\mu^3 = -\lambda$, we have $\lambda_r = 3\mu_r\mu_i^2 - \mu_r^3$ and $\lambda_i = \mu_i^3 - 3\mu_r^2\mu_i$. Therefore, on $\Gamma_\pm$, $\mu_r \le c_1 < 0$, $3\mu_r\mu_i^2 - \mu_r^3 \le c_1 < 0$ for a small fixed negative number c_1, and $\mu_r \to -\delta^{2/3}/3$ as $\mu \to \infty$ (i.e., $\mu_i \to \pm\infty$). From the formula of the Green's function in Appendix 1, we have

$$G(-\mu^3, x, \xi) = \begin{cases} -(1/3\mu^2)e^{\mu(x-\xi)} + R(\mu, x, \xi), & 0 < x < \xi < 1, \\ R(\mu, x, \xi), & 0 < \xi < x < 1. \end{cases} \tag{2.12}$$

Since $G(-\mu^3, x, \xi)$ is analytic in μ when μ is in the upper or lower μ-plane, we assume that for μ_i large—say, $|\mu_i| \ge r$—$\mu_r = -\delta^{2/3}/3 = \delta_0$ and $3\mu_r\mu_i^2 - \mu_r^3 \le -2\beta_1 < 0$ on $\Gamma_\pm$ for two small fixed positive numbers δ and β_1. Also, by checking the terms in $G(-\mu^3, x, \xi)$, we can see that

$$\sup_{0\le x,\xi\le 1} |G(-\mu^3, x, \xi)| \le K/|\mu|^2 \tag{2.13}$$

if $|\mu_r| \le \epsilon_0$ for large μ_i and a fixed small constant $\epsilon_0 > 0$, where μ is on $\Gamma_\pm$ and K is independent of μ. Let δ_0 be fixed with $|\delta_0| \le \epsilon_0$. We then have the following properties of the C_0-semigroup $S(t)$.

3. Properties of the C_0-semigroup $S(t)$. Since we use the contraction mapping theorem to obtain the existence of solutions, we first need the following estimates.

PROPOSITION 3.1. *Let $T > 0$ be given. Then for $f \in L^\infty(0, T; L^2)$,*

$$\sup_{0\le t\le T}\left\|\int_0^t S(\tau)f(t-\tau, \cdot)d\tau\right\|_{H^1} \le K\left(T^{1/4}\sup_{0\le t\le T}\|f(t,\cdot)\|_{L^2} + T\sup_{0\le t\le T}\left|\int_0^1 f(t,x)dx\right|\right),$$

where $H^1 = H^1(0, 1)$ and K is independent of T.

Proof. By the form of $S(t)$ in (2.11), we have

$$\left\|\int_0^t S(\tau)f(t-\tau, \cdot)d\tau\right\|_{L^2} \le I_1 + I_2 + K\int_0^t \left|\int_0^1 f(\tau, x)dx\right| d\tau,$$

where

$$I_{1,2} = \left\|\int_0^t \frac{1}{2\pi i}\int_{\Gamma_\pm} 3\mu^2 e^{-\mu^3\tau}\int_0^1 G(-\tau^3, x, \xi)f(t-\tau, \xi)d\xi\, d\mu\, d\tau\right\|_{L^2}. \tag{3.1}$$

By (2.13), $0 < \delta_0 \le \epsilon_0$, and Hölder's inequality, we have

$$
\begin{aligned}
I_1^2 &\le K \int_0^1 \left(\int_0^t \int_b^{+\infty} e^{-\mu_i^2 \tau \delta^{2/3}} d\mu_i d\tau \right)^2 dx \sup_{0<\tau\le t} \|f(\tau,\cdot)\|_{L^2}^2 \\
&\le K t^{1/2} \sup_{0<\tau\le t} \|f(\tau,\cdot)\|_{L^2}^2.
\end{aligned} \tag{3.2}
$$

By a similar calculation, we have $I_2^2 \le K t^{1/2} \sup_{0<\tau\le t} \|f(\tau,\cdot)\|_{L^2}^2$ and

$$
\left\| \int_0^t S(\tau) f(t-\tau,\cdot) d\tau \right\|_{L^2} \le K \left(T^{1/4} \sup_{0\le t\le T} \|f(t,\cdot)\|_{L^2} + T \sup_{0\le t\le T} \left| \int_0^1 f(t,x) dx \right| \right).
$$

In order to estimate the first-order derivative, from (2.12) we first consider

$$
\begin{aligned}
\|II(x)\|_{L^2} &\overset{\text{def}}{=} \left\| (1/2\pi i) \int_0^1 \int_0^t \int_{\Gamma_+} 3\mu^2 e^{-\mu^3\tau} G_x(-\mu^3, x, \xi) f(t-\tau,\xi) d\mu d\tau d\xi \right\|_{L^2} \\
&= (1/2\pi) \Bigg(\int_0^1 \Bigg| \int_x^1 \int_0^t \int_{\Gamma_+} 3\mu^2 e^{-\mu^3\tau} (-1/3\mu) e^{\mu(x-\xi)} f(t-\tau,\xi) d\mu d\tau d\xi \\
&\qquad + \int_0^1 \int_0^t \int_{\Gamma_+} 3\mu^2 e^{-\mu^3\tau} R_x(\mu,x,\xi) f(t-\tau,\xi) d\mu d\tau d\xi \Bigg|^2 dx \Bigg)^{1/2} \\
&\le (1/2\pi) \left(\int_0^1 \left| \int_x^1 \int_0^t \int_{\Gamma_+} 3\mu^2 e^{-\mu^3\tau} (-1/3\mu) e^{\mu(x-\xi)} f(t-\tau,\xi) d\mu d\tau d\xi \right|^2 dx \right)^{1/2} \\
&\qquad + (1/2\pi) \left(\int_0^1 \left| \int_0^1 \int_0^t \int_{\Gamma_+} 3\mu^2 e^{-\mu^3\tau} R_x(\mu,x,\xi) f(t-\tau,\xi) d\mu d\tau d\xi \right|^2 dx \right)^{1/2} \\
&\overset{\text{def}}{=} II_1 + II_2.
\end{aligned}
$$

By using Fubini's theorem and Minkowski's inequality in integral form,

$$
\begin{aligned}
II_2 &\le (1/2\pi) \left(\int_0^1 \left(\int_0^t \int_{\Gamma_+} \int_0^1 \left| 3\mu^2 e^{-\mu^3\tau} R_x(\mu,x,\xi) f(t-\tau,\xi) \right| d\xi |d\mu| d\tau \right)^2 dx \right)^{1/2} \\
&\le (1/2\pi) \int_0^t \int_{\Gamma_+} \left(\int_0^1 \left(\int_0^1 \left| 3\mu^2 e^{-\mu^3\tau} R_x(\mu,x,\xi) f(t-\tau,\xi) \right| d\xi \right)^2 dx \right)^{1/2} |d\mu| d\tau \\
&\le K \sup_{0<\tau\le t} \|f(\tau,\cdot)\|_{L^2} \int_0^t \int_{\Gamma_+} \left(\int_0^1 \int_0^1 \left| 3\mu^2 e^{-\mu^3\tau} R_x(\mu,x,\xi) \right|^2 d\xi dx \right)^{1/2} |d\mu| d\tau.
\end{aligned}
$$

In Appendix 1, we shall show that

$$
\left(\int_0^1 \int_0^1 \left| R_x(\mu,x,\xi) \right|^2 d\xi dx \right)^{1/2} \le K/|\mu|^{3/2}.
$$

Therefore,

$$
\begin{aligned}
II_2 &\le K \sup_{0<\tau\le t} \|f(\tau,\cdot)\|_{L^2} \int_0^t \int_b^{+\infty} |\mu_i|^{1/2} e^{-\mu_i^2 \delta^{2/3} \tau} d\mu_i d\tau \\
&\le K t^{1/4} \sup_{0<\tau\le t} \|f(\tau,\cdot)\|_{L^2}.
\end{aligned}
$$

For II_1 and $x-\xi<0$,

$$\int_{\Gamma_+}\mu e^{-\mu^3\tau+\mu(x-\xi)}d\mu=\left(\int_{\Gamma_+^*}+\int_{ir}^{+\infty i}\right)\mu e^{-\mu^3\tau+(x-\xi)\mu}d\mu,$$

where Γ_+^* is a finite smooth curve on Γ_+ with $b\le\mu_i\le r$. Then

$$\left|\int_{\Gamma_+^*}\mu e^{-\mu^3\tau+(x-\xi)\mu}d\mu\right|\le K<+\infty,$$

and

$$\int_{ir}^{+\infty i}\mu e^{-\mu^3\tau+(x-\xi)\mu}d\mu=-\int_r^{+\infty}\mu e^{i(\mu^3\tau+(x-\xi)\mu)}d\mu.$$

In Appendix 2, we show that if $x-\xi$ is bounded, then

$$\left|\int_r^{+\infty}\mu e^{i(\mu^3\tau+\mu(x-\xi))}d\mu\right|\le K\tau^{-3/4}.$$

Therefore,

$$\begin{aligned}II_1&\le K\left(\int_0^1\left(\int_x^1\int_0^t|f(t-\tau,\xi)|\tau^{-3/4}d\xi d\tau\right)^2dx\right)^{1/2}\\&\le K\left(\int_0^1\left(\int_0^t\tau^{-3/4}\sup_{0<\tau\le t}\|f(\tau,\cdot)\|_{L^2}d\tau\right)^2dx\right)^{1/2}\\&\le Kt^{1/4}\sup_{0<\tau\le t}\|f(\tau,\cdot)\|_{L^2}.\end{aligned}$$

Thus $\|II(x)\|_{L^2}\le Kt^{1/4}\sup_{0<\tau\le t}\|f(\tau,\cdot)\|_{L^2}$. However, by (3.1) and (3.2) we know that the multiple integrals in $\int_0^t S(\tau)f(t-\tau,\cdot)d\tau$ are absolutely integrable and the order of the integration can be interchanged by Fubini's theorem. Also, since $G(-\mu^3,x,\xi)$ is continuous at $x=\xi$ and each term in $G(-\mu^3,x,\xi)$ has a form $X(x)Y(\xi)$, then

$$\begin{aligned}III(x)&\overset{\text{def}}{=}\frac{\partial}{\partial x}\int_0^t\frac{1}{2\pi i}\int_{\Gamma_+}3\mu^2e^{-\mu^3\tau}\left(\int_0^x+\int_x^1\right)G(-\mu^3,x,\xi)f(t-\tau,\xi)d\xi d\mu d\tau\\&=\frac{\partial}{\partial x}\left(\int_0^x+\int_x^1\right)\int_0^t\frac{1}{2\pi i}\int_{\Gamma_+}3\mu^2e^{-\mu^3\tau}G(-\mu^3,x,\xi)f(t-\tau,\xi)d\mu d\tau d\xi\\&=\int_0^1\int_0^t\frac{1}{2\pi i}\int_{\Gamma_+}3\mu^2e^{-\mu^3\tau}G_x(-\mu^3,x,\xi)f(t-\tau,\xi)d\mu d\tau d\xi=II(x).\end{aligned}$$

Therefore

$$\|III(x)\|_{L^2}\le Kt^{1/4}\sup_{0<\tau\le t}\|f(\tau,\cdot)\|_{L^2}.$$

By a similar proof, we have

$$\begin{aligned}&\left\|\frac{\partial}{\partial x}\int_0^t\frac{1}{2\pi i}\int_{\Gamma_-}3\mu^2e^{-\mu^3\tau}\left(\int_0^x+\int_x^1\right)G(-\mu^3,x,\xi)f(t-\tau,\xi)d\xi d\mu d\tau\right\|_{L^2}\\&\qquad\le Kt^{1/4}\sup_{0<\tau\le t}\|f(\tau,\cdot)\|_{L^2}.\end{aligned}$$

Combining the above estimates, we have

$$\left\| \frac{\partial}{\partial x} \int_0^t S(\tau) f(t-\tau, \cdot) d\tau \right\|_{L^2} \leq K t^{1/4} \sup_{0<\tau\leq t} \|f(\tau, \cdot)\|_{L^2}.$$

Finally we have

$$\sup_{0<t\leq T} \left\| \int_0^t S(\tau) f(t-\tau, \cdot) d\tau \right\|_{H^1} \leq K \left(T^{1/4} \sup_{0<t\leq T} \|f(\tau, \cdot)\|_{L^2} + T \sup_{0<\tau\leq T} \left| \int_0^1 f(\tau, x) dx \right| \right).$$

Proposition 3.1 is a local estimate. Next we give a global estimate under some condition on $f(t, x)$.

PROPOSITION 3.2. *If $f(t, x) \in L^\infty([0, \infty); L^2)$ and $\int_0^1 f(t, x) dx \equiv 0$ for all $t \geq 0$, then there exists a K such that*

$$\sup_{0<\tau<+\infty} \left\| \int_0^t S(\tau) f(t-\tau, \cdot) d\tau \right\|_{H^1} \leq K \sup_{0<\tau<+\infty} \|f(\tau, \cdot)\|_{L^2}.$$

Proof. By Proposition 3.1, we need only to prove the inequality for $t \geq 1$. If $t \geq 1$, then

$$\begin{aligned} \|I\|_{H^1} &\overset{\text{def}}{=} \left\| \int_0^t S(\tau) f(t-\tau, \cdot) d\tau \right\|_{H^1} \\ &\leq \left\| \int_0^1 S(\tau) f(t-\tau, \cdot) d\tau \right\|_{H^1} + \left\| \int_1^t S(\tau) f(t-\tau, \cdot) d\tau \right\|_{H^1} \\ &\overset{\text{def}}{=} II_1 + II_2. \end{aligned}$$

But $II_1 = \| \int_0^1 S(\tau) g_t(1-\tau, \cdot) d\tau \|_{H^1}$, where $g_t(s, x) = f(s+t-1, x)$ for $s \geq 0$. By Proposition 3.1,

$$\begin{aligned} II_1 &\leq K \sup_{0<\tau\leq 1} \|g_t(\tau, \cdot)\|_{L^2} \leq K \sup_{0<\tau\leq 1} \|f(\tau+t-1, \cdot)\|_{L^2} \\ &\leq K \sup_{0<\tau<+\infty} \|f(\tau, \cdot)\|_{L^2}. \end{aligned}$$

By using (2.11), (2.13), and the uniform convergence of the integral and its derivatives for $\tau \geq 1$, we have

$$\begin{aligned} II_2 &\leq K \left\| \int_1^t \left(\int_{\Gamma_+} + \int_{\Gamma_-} \right) |\mu|^2 |e^{-\mu^3 \tau}| \left[\left(\int_0^1 |G(-\mu^3, x, \xi)|^2 d\xi \right)^{1/2} \right. \right. \\ &\qquad \left. \left. + \left(\int_0^1 |G_x(-\mu^3, x, \xi)|^2 d\xi \right)^{1/2} \right] \left(\int_0^1 |f(t-\tau, \xi)|^2 d\xi \right)^{1/2} |d\mu| d\tau \right\|_{L^2} \\ &\leq K \sup_{0<\tau<\infty} \|f(\tau, \cdot)\|_{L^2} \int_1^t \left(\int_{\Gamma_+} + \int_{\Gamma_-} \right) |\mu^2| |e^{-\mu^3 \tau}| (|\mu^{-2}| + |\mu^{-1}|) |d\mu| d\tau \\ &\leq K \sup_{0<\tau<\infty} \|f(\tau, \cdot)\|_{L^2} \int_1^t \left(\int_b^{+\infty} + \int_{-\infty}^{-b} \right) |\mu_i^2| |e^{-\mu_i^2 \tau \delta^{2/3}} (|\mu_i|^{-2} + |\mu_i|^{-1}) d\mu_i d\tau \\ &\leq K \sup_{0<\tau<\infty} \|f(\tau, \cdot)\|_{L^2} \left(\int_b^{+\infty} + \int_{-\infty}^{-b} \right) e^{-\mu_i^2 \delta^{2/3}} (|\mu_i|^{-2} + |\mu_i|^{-1}) d\mu_i \\ &\leq K \sup_{0<\tau<\infty} \|f(\tau, \cdot)\|_{L^2}, \end{aligned}$$

where K is independent of t. Thus $\sup_{t\geq 1} II_2 \leq K \sup_{0<\tau<\infty} \|f(\tau,\cdot)\|_{L^2}$. Combining the estimate for $0 \leq t \leq 1$, we obtain

$$\sup_{0<t<+\infty} \left\| \int_0^t S(\tau) f(t-\tau,\cdot) d\tau \right\|_{H^1} \leq K \sup_{0<\tau<\infty} \|f(\tau,\cdot)\|_{L^2}.$$

Finally we derive the estimates for the C_0-semigroup $S(t)$ applying to an H^1-function.

PROPOSITION 3.3. *For $w_0(x) \in H^1 = H^1(0,1)$, $S(t)w_0 \in H^1$ and $\|S(t)w_0\|_{H^1} \leq K\|w_0\|_{H^1}$ for all $t \in [0,\infty)$, where K is independent of t.*

Proof. Since $S(t)$ is a C_0-semigroup of contraction in L^2,

$$\|S(t)w_0\|_{L^2} \leq \|w_0\|_{L^2}, \quad \|S(t)w_{0x}\|_{L^2} \leq \|w_{0x}\|_{L^2},$$

and $S(0)w_0 = w_0$. For $t > 0$,

$$\begin{aligned} \frac{\partial}{\partial x} S(t)w_0 &= \frac{1}{2\pi i}\left(\int_{\Gamma_+} + \int_{\Gamma_-}\right) \frac{\partial}{\partial x} \int_0^1 3\mu^2 e^{-\mu^3 t} G(-\mu^3, x, \xi) w_0(\xi) d\xi d\mu \\ &= \frac{1}{2\pi i}\left(\int_{\Gamma_+} + \int_{\Gamma_-}\right) \int_0^1 3\mu^2 e^{-\mu^3 t} G_x(-\mu^3, x, \xi) w_0(\xi) d\xi d\mu \,, \end{aligned} \tag{3.3}$$

since the integrals are uniformly convergent for $t > 0$ and $G(-\mu^3, x, \xi)$ is continuous at $x = \xi$. By the form of $G(-\mu^3, x, \xi)$ and integration by parts, we obtain

(3.4)

$$\begin{aligned} &\int_0^1 G_x(-\mu^3, x, \xi) w_0(\xi) d\xi = \int_0^1 G(-\mu^3, x, \xi) w_{0\xi}(\xi) d\xi \\ &+ \int_0^1 [3(-\mu_1^3)(3 - e^{-\mu_1} - e^{-\mu_2} - e^{-\mu_3})]^{-1} \Big[(e^{\mu_2} - e^{-\mu_1}) \mu_3 \mu_2^{-1} (\mu_1 - \mu_2) e^{\mu_1 x - \mu_2 \xi} \\ &+ (e^{\mu_3} - e^{-\mu_1}) \mu_2 \mu_3^{-1} (\mu_1 - \mu_3) e^{\mu_1 x - \mu_3 \xi} + (e^{\mu_3} - e^{-\mu_2}) \mu_1 \mu_3^{-1} (\mu_2 - \mu_3) e^{\mu_2 x - \mu_3 \xi} \\ &+ (e^{\mu_1} - e^{-\mu_2}) \mu_3 \mu_1^{-1} (\mu_2 - \mu_1) e^{\mu_2 x - \mu_1 \xi} + (e^{\mu_1} - e^{-\mu_3}) \mu_2 \mu_1^{-1} (\mu_3 - \mu_1) e^{\mu_3 x - \mu_1 \xi} \\ &+ (e^{\mu_2} - e^{-\mu_3}) \mu_1 \mu_2^{-1} (\mu_3 - \mu_2) e^{\mu_3 x - \mu_2 \xi} \Big] w_{0\xi}(\xi) d\xi \\ &\stackrel{\text{def}}{=} I(\mu, x) + II(\mu, x), \end{aligned}$$

where $\mu_1 = \mu$, $\mu_2 = \omega\mu$, $\mu_3 = \omega^3\mu$ with $\omega = (-1 + i\sqrt{3})/2$. Therefore, for $t > 0$,

$$\left\| \frac{1}{2\pi i} \int_{\Gamma_\pm} 3\mu^2 e^{-\mu^3 t} I(\mu, x) d\mu \right\|_{L^2} \leq \|S(t)w_{0x}\|_{L^2} + |c_0| \int_0^1 |w_{0\xi}| d\xi \leq K\|w_{0x}\|_{L^2}.$$

In order to estimate $II(\mu, x)$, we need the following lemma.

LEMMA 3.1. *If $f(y) \in L^2[0,\infty)$ and $\operatorname{Re}\alpha \leq 0$ with $\alpha \neq 0$, then $\int_0^\infty \exp(\alpha x y) f(y) dy \in L^2[0,\infty)$ and*

$$\left\| \int_0^{+\infty} e^{\alpha x y} f(y) dy \right\|^2_{L^2[0,,\infty)} \leq K \|f(y)\|^2_{L^2[0,,\infty)}.$$

The proof of the lemma can be easily obtained by generalizing a lemma in [3, p. 2332]. Now we rewrite $II(\mu, x)$ as

$$II(\mu, x) = II_1(\mu, x) + II_2(\mu, x) + \cdots + II_6(\mu, x). \tag{3.5}$$

Then

$$III \overset{\text{def}}{=} \left\| \frac{1}{2\pi i} \int_{\Gamma_+} 3\mu^2 e^{-\mu^3 t} II_1(\mu, x) d\mu \right\|_{L^2}^2$$

$$= (1/4\pi^2) \int_0^1 \left| \int_{\Gamma_+} \mu^2 e^{-\mu^3 t + \mu_1 x} (\mu^3 (3 - e^{-\mu_1} - e^{-\mu_2} - e^{-\mu_3}))^{-1} \right.$$

$$\left. \times (e^{\mu_2} - e^{-\mu_1})(\mu_3/\mu_2)(\mu_1 - \mu_2) \int_0^1 e^{-\mu_2 \xi} w_{0\xi} d\xi d\mu \right|^2 dx.$$

Since $\mu = \mu_r + i\mu_i$ and μ_r is a function of μ_i for μ on Γ_+, i.e., $\mu_r = s(\mu_i)$ with $s(\mu_i) = -\delta^{2/3}/3 = \delta_0$ for $\mu_i \geq r$,

$$III = \frac{|1-\omega|}{4\pi^2} \int_0^1 \left| \int_b^{+\infty} e^{-(s(\mu_i)+i\mu_i)^3 t + (s(\mu_i)+i\mu_i)x} \right.$$

$$\times (3 - e^{-(s(\mu_i)+i\mu_i)} - e^{-\omega(s(\mu_i)+i\mu_i)} - e^{-\omega^2(s(\mu_i)+i\mu_i)})^{-1}$$

$$\left. \times (e^{\omega(s(\mu_i)+i\mu_i)} - e^{-(s(\mu_i)+i\mu_i)})(s'(\mu_i) + i) \int_0^1 e^{-\omega(s(\mu_i)+i\mu_i)\xi} w_{0\xi}(\xi) d\xi d\mu_i \right|^2 dx$$

$$= \frac{|1-\omega|}{4\pi^2} \int_0^1 \left| \left(\int_b^r + \int_r^\infty \right) (\cdots) d\mu_i \right|^2 dx$$

$$\overset{\text{def}}{=} III_1 + III_2.$$

Since $-s(\mu_i)^3 + 3s(\mu_i)\mu_i^2 < 0$ for $\mu_i \in [b, r]$ and every term inside the integral of III_1 is bounded, we have

$$III_1 = \frac{|1-\omega|}{4\pi^2} \int_0^1 \left| \int_b^r (\cdots) d\mu_i \right| dx \leq K \left(\int_0^1 |w_{0\xi}(\xi)| d\xi \right)^2 \leq K \|w_{0x}\|_{L^2}^2.$$

However, by Lemma 3.1, we have

$$III_2 = \frac{|1-\omega|}{4\pi^2} \int_0^1 e^{\delta_0 x} \left| \int_r^{+\infty} e^{-(\delta_0 + i\mu_i)^3 t + i\mu_i x} \right.$$

$$\times (3 - e^{-(\delta_0+i\mu_i)} - e^{-\omega(\delta_0+i\mu_i)} - e^{-\omega^2(\delta_0+i\mu_i)})^{-1} (e^{\omega(\delta_0+i\mu_i)} - e^{-(\delta_0+i\mu_i)})$$

$$\left. \times \int_0^1 e^{-\omega(\delta_0+i\mu_i)\xi} w_{0\xi}(\xi) d\xi d\mu_i \right|^2 dx$$

$$\leq K \int_r^{+\infty} \left| e^{-(\delta_0+i\mu_i)^3 t} (3 - e^{-(\delta_0+i\mu_i)} - e^{-\omega(\delta_0+i\mu_i)} - e^{-\omega^2(\delta_0+i\mu_i)})^{-1} \right.$$

$$\left. \times (e^{\omega(\delta_0+i\mu_i)} - e^{-(\delta_0+i\mu_i)}) \int_0^1 e^{-\omega(\delta_0+i\mu_i)\xi} w_{0\xi}(\xi) d\xi \right|^2 d\mu_i$$

$$\leq K \int_r^{+\infty} \left| \int_0^1 e^{i\omega\mu_i - \omega(\delta_0+i\mu_i)\xi} w_{0\xi}(\xi) d\xi \right|^2 d\mu_i$$

$$\leq K \int_r^{+\infty} \left| \int_0^1 e^{i\omega\mu_i(1-\xi)} e^{-\omega\delta_0\xi} w_{0\xi}(\xi) d\xi \right|^2 d\mu_i$$

$$\leq K \int_r^{+\infty} \left| \int_0^1 e^{i\omega\mu_i\zeta} (e^{-\omega\delta_0(1-\zeta)} w_{0\xi}(1-\zeta)) d\zeta \right|^2 d\mu_i.$$

Since $\operatorname{Re}(i\omega) < 0$, by Lemma 3.1 again, we obtain

$$III_2 \le K \int_0^1 |e^{-\omega\delta_0(1-\zeta)} w_{0\zeta}(1-\zeta)|^2 d\zeta \le K\|w_{0x}\|_{L^2}^2.$$

By a similar proof, we have

$$\left\| \int_{\Gamma_-} \frac{3\mu^2}{2\pi i} e^{-\mu^3 t} II_1(\mu, x) d\mu \right\|_{L^2}^2 \le K\|w_{0x}\|_{L^2}^2,$$

and therefore

$$\left\| \left(\int_{\Gamma_+} + \int_{\Gamma_-} \right) \frac{3\mu^2}{2\pi i} e^{-\mu^3 t} II_1(\mu, x) d\mu \right\|_{L^2}^2 \le K\|w_{0x}\|_{L^2}^2.$$

Then by applying the same procedure to $II_i(\mu, x)$, $i = 2, 3, \ldots, 6$, we have

$$\left\| \left(\int_{\Gamma_+} + \int_{\Gamma_-} \right) \frac{3\mu^2}{2\pi i} e^{-\mu^3 t} II_i(\mu, x) d\mu \right\|_{L^2}^2 \le K\|w_{0x}\|_{L^2}^2$$

for $i = 2, 3, \ldots, 6$. By (3.3)-(3.5), we have

$$\left\| \left(\int_{\Gamma_+} + \int_{\Gamma_-} \right) \frac{3\mu^2}{2\pi i} e^{-\mu^3 t} II(\mu, x) d\mu \right\|_{L^2}^2 \le K\|w_{0x}\|_{L^2}^2.$$

By the estimate of $I(\mu, x)$, we have

$$\left\| \frac{\partial}{\partial x} S(t) w_0 \right\|_{L^2}^2 \le K\|w_{0x}\|_{L^2}^2.$$

Thus $\|S(t)w_0\|_{H^1} \le K\|w_0\|_{H^1}$. The proof is completed.

Now we are ready to obtain the existence and exponential decay of the solutions.

4. Existence and exponential decay of solutions with small amplitude. We now study the initial value problem for the KdV equation

$$w_t + ww_x + w_{xxx} = 0 \quad \text{for} \quad 0 < x < 1,\ t > 0, \tag{4.1}$$

$$w(0, x) = w_0(x), \tag{4.2}$$

with boundary conditions

$$w(t, 1) = w(t, 0), \quad w_x(t, 1) = (-1/2)w_x(t, 0), \quad w_{xx}(t, 1) = w_{xx}(t, 0). \tag{4.3}$$

If the nonlinear term ww_x is moved to the right-hand side of (4.1), then variation of parameters yields an equivalent integral equation:

$$w(t, \cdot) = S(t)w_0 - \int_0^t S(\tau)(ww_x)(t-\tau, \cdot) d\tau. \tag{4.4}$$

Let

$$Fu \overset{\text{def}}{=} S(t)w_0 - \int_0^t S(\tau)(uu_x)(t-\tau, \cdot) d\tau. \tag{4.5}$$

Then the solution of (4.4) is a fixed point of Fu in $L^2 = L^2(0, 1)$. First we prove the well-posedness of (4.1)-(4.3) in $H^1 = H^1(0, 1)$.

THEOREM 4.1. *For any $w_0 \in H^1$, there exists a $T = T(\|w_0\|_{H^1}) > 0$ such that (4.1)-(4.3) has a unique solution $u \in C(0, T; H^1)$, where $T \to +\infty$ as $\|w_0\|_{H^1} \to 0$. For any $T' < T(\|\phi(x)\|_{H^1})$, there exists a neighborhood U of $\phi(x)$ in H^1 such that the map $\mathcal{G} : w_0 \to u(t, \cdot)$ from U to $C(0, T; H^1)$ is Lipschitz continuous.*

Proof. Let

$$\mathcal{S}_{T,b} = \left\{ v \in C(0, T; H^1) \;\middle|\; \sup_{0\le t\le T} \|v(t, \cdot)\|_{H^1} \le b \right\}$$

for some $b > 0$ and $T > 0$ to be determined. From Propositions 3.1 and 3.3, we have

$$\begin{aligned} \sup_{0\le t\le T} \|Fv\|_{H^1} &\le K_3\|w_0\|_{H^1} + K_1(T^{1/4} + T) \sup_{0\le t\le T} \|(vv_x)(t, \cdot)\|_{L^2} \\ &\le K_3\|w_0\|_{H^1} + K_1(T^{1/4} + T) \left(\sup_{0\le t\le T} \|v(t, \cdot)\|_{H^1} \right)^2, \end{aligned}$$

where K_1 and K_3 are the constants in Propositions 3.1 and 3.3, respectively, and are independent of T and v. If we let $b = 2K_3\|w_0\|_{H^1}$ and $K_1(T^{1/4}+T)b = 2K_1K_3\|w_0\|_{H^1}(T^{1/4}+T) < 1/2$, then $\sup_{0\le t\le T} \|Fv\|_{H^1} \le b$ and F maps $\mathcal{S}_{T,b}$ into itself. For $v_1, v_2 \in \mathcal{S}_{T,b}$, we have

$$Fv_1 - Fv_2 = -\int_0^t S(\tau)(v_1w_x + wv_{2x})(t - \tau, \cdot)d\tau,$$

where $w = v_1 - v_2$. Thus by Proposition 3.1 we have

$$\begin{aligned} \sup_{0\le t\le T} \|Fv_1 - Fv_2\|_{H^1} &\le K_1(T^{1/4} + T) \sup_{0\le t\le T} \|v_1w_x + wv_{2x}\|_{L^2} \\ &\le K_1(T^{1/4} + T) \left(\sup_{0\le t\le T} \|v_1\|_{H^1} + \sup_{0\le t\le T} \|v_2\|_{H^1} \right) \sup_{0\le t\le T} \|w\|_{H^1} \\ &\le 2K_1b(T^{1/4} + T) \sup_{0\le t\le T} \|w\|_{H^1}. \end{aligned}$$

Since $2K_1b(T^{1/4}+T) < 1$ by the choice of b and T, F is a contraction, and by the contraction mapping theorem F has a unique fixed point in $\mathcal{S}_{T,b}$. If we choose $K_1(T^{1/4} + T)b = 1/4 = 2K_1K_3(T^{1/4} + T)\|w_0\|_{H^1}$, then $T \to +\infty$ as $\|w_0\|_{H^1} \to 0$. Finally it is obvious that for any $T' < T(\|\phi(x)\|_{H^1})$, there is a neighborhood U of ϕ in H^1 such that $\mathcal{G}$ is well defined from U to $C(0, T'; H^1)$. For any $w_1, w_2 \in U$, let $u_1 = \mathcal{G}w_1$, $u_2 = \mathcal{G}w_2$, and $w = u_1 - u_2$. Thus

$$w = S(t)(w_1 - w_2) - \int_0^t S(\tau)(u_1w_x + wu_{2x})(t - \tau, \cdot)d\tau.$$

By Propositions 3.1 and 3.3, we have

$$\begin{aligned} \sup_{0\le t\le T} \|w\|_{H^1} &\le K_3\|w_1 - w_2\|_{H^1} + K_1(T^{1/4} + T) \left(\sup_{0\le t\le T} \|u_1\|_{H^1} \right. \\ &\qquad \left. + \sup_{0\le t\le T} \|u_2\|_{H^1} \right) \sup_{0\le t\le T} \|w\|_{H^1} \\ &\le K_3\|w_1 - w_2\|_{H^1} + 2K_1(T^{1/4} + T)b \sup_{0\le t\le T} \|w\|_{H^1}. \end{aligned}$$

Thus $\sup_{0\le t\le T}\|w\|_{H^1}\le K_3(1-2K_1(T^{1/4}+T)b)^{-1}\|w_1-w_2\|_{H^1}$, which implies $\mathcal{G}$ is Lipschitz continuous from U to $C(0,T;H^1)$.

After we have the local existence, we prove the global existence of the solutions of (4.1)-(4.3) with small initial data.

THEOREM 4.2. *There exists a $\beta>0$ such that for any $w_0\in H^1$ with $\|w_0\|_{H^1}\le\beta$, (4.1)-(4.3) have a unique solution $u\in C(\mathbf{R}^+,H^1)$ with $\mathbf{R}^+=[0,+\infty)$.*

Proof. Let

$$\mathcal{S}_b=\left\{v\in C(\mathbf{R}^+;H^1)\;\middle|\;\sup_{0\le t<+\infty}\|v(t,\cdot)\|_{H^1}\le b \text{ and } v(t,0)=v(t,1)\right\}$$

with $b>0$ to be determined. Let

$$Fv=S(t)w_0-\int_0^t S(\tau)(vv_x)(\tau)d\tau.$$

Using Propositions 3.2 and 3.3, we have

$$\begin{aligned}\sup_{0\le t<+\infty}\|Fv\|_{H^1}&\le K_3\|w_0\|_{H^1}+K_2\sup_{0\le t<+\infty}\|vv_x\|_{L^2}\\&\le K_3\|w_0\|_{H^1}+K_2\left(\sup_{0\le t<+\infty}\|v\|_{H^1}\right)^2,\end{aligned}$$

since $\int_0^1 vv_x dx=0$, where K_2 and K_3 are the constants in Propositions 3.2 and 3.3, respectively. Choose $b>0$ and $\beta>0$ such that $K_2b<(1/2)$ and $K_3\beta<(b/2)$. Then F maps $\mathcal{S}_b$ into itself since $\int_0^t S(\tau)(vv_x)(t-\tau)d\tau\in\mathcal{D}(A)$ and $S(t)w_0\in H^1$ with $(S(t)w_0)(0)=(S(t)w_0)(1)$ by the construction of $S(t)$. The contraction property of F can be obtained similarly in Theorem 4.1. Thus F has a unique fixed point in $\mathcal{S}_b$, which is a solution of (4.1)-(4.3).

Finally we show the exponential decay of the global solutions of (4.1)-(4.3) as $t\to+\infty$.

THEOREM 4.3. *There exists δ_1 with $\beta\ge\delta_1>0$ such that for any $w_0\in H^1$ with $\|w_0\|_{H^1}<\delta_1$, the solution $u(t,x)$ of (4.1)-(4.3) satisfies*

$$\|u(t,\cdot)-[w_0]\|_{L^2}\le Ke^{-\rho t}\|w_0-[w_0]\|_{L^2}$$

for all $t\ge0$, where β is defined in Theorem 4.2, $K>0$ and $\rho>0$ are independent of w_0 and t, and $[w_0]=\int_0^1 w_0(x)dx$.

Proof. Since $[u]=[w_0]$ for all $t\ge0$ and the solution is periodic in L^2, i.e., $u(t,0)=u(t,1)$, by substituting $u-[u]$ into the equation and changing the variable, we can assume that $[w_0]=[u]=0$. For $\delta_1<\beta$, (4.1)-(4.3) has a unique global solution u satisfying

$$u(x,t)=S(t)w_0+\int_0^t S(\tau)(uu_x)(t-\tau,\cdot)d\tau.$$

First let us estimate $\|S(t)w_0\|_{L^2}$ for $t\ge1$. In (2.11), we note that if $\mu_r+i\mu_i\in\Gamma_\pm$, then $3\mu_r\mu_i^2-\mu_r^3<0$. However, since $\mu_r\to-\delta^{2/3}/3=\delta_0$ as $\mu_i\to+\infty$, then $3\mu_r\mu_i^2-\mu_r^3\le-2\beta_1$ for some $\beta_1>0$ whenever $\mu_r+i\mu_i\in\Gamma_\pm$. Since $[w_0]=0$, by

(2.11) and (2.13) we have

$$\begin{aligned}\|S(t)w_0\|_{L^2}^2 &= e^{-2\beta_1 t}(2\pi)^{-2}\int_0^1 \left|\left(\int_{\Gamma_+}+\int_{\Gamma_-}\right)3\mu^2 e^{-(\mu^3-\beta_1)t}\right.\\ &\qquad\left.\times\int_0^1 G(-\mu^3,x,\xi)w_0(\xi)d\xi d\mu\right|^2 dx\\ &\le Ke^{-2\beta_1 t}\left[\left(\int_{\Gamma_+}+\int_{\Gamma_-}\right)|e^{-(\mu^3-\beta_1)t}||d\mu|\right]^2\|w_0\|_{L^2}^2\\ &\le Ke^{-2\beta_1 t}\left(\int_{-\infty}^{+\infty}\exp(-\max(\beta_1,\delta^{2/3}\mu_i^2-\beta_1)t)d\mu_i\right)^2\|w_0\|_{L^2}^2\\ &\le Ke^{-2\beta_1 t}\|w_0\|_{L^2}^2.\end{aligned}$$

Thus for $t \ge 1$, $\|S(t)w_0\|_{L^2} \le Ke^{-\beta_1 t}\|w_0\|_{L^2}$. By the semigroup property of $S(t)$, we have $\|S(t)w_0\|_{L^2} \le Ke^{-\beta_1 t}\|w_0\|_{L^2}$ for all $t \ge 0$. Since $u(0) = u(1)$, $\int_0^1 uu_x dx = 0$, and $G(-\mu^3, x, \xi)$ is continuous at $x = \xi$, the integration by parts yields

$$\begin{aligned}S(t-\tau)((u^2/2)_x)(\tau,x) &= \frac{-1}{2\pi i}\int_{\Gamma_+\cup\Gamma_-}3\mu^2 e^{-\mu^3(t-\tau)}\int_0^1 G(-\mu^3,x,\xi)(u^2(\tau,\xi)/2)_\xi d\xi d\mu\\ &= \frac{1}{2\pi i}\int_{\Gamma_+\cup\Gamma_-}3\mu^2 e^{-\mu^3(t-\tau)}\int_0^1 G_\xi(-\mu^3,x,\xi)(u^2(\tau,\xi)/2)d\xi d\mu\\ &= \frac{e^{-\beta_1(t-\tau)}}{2\pi i}\int_{\Gamma_+\cup\Gamma_-}3\mu^2 e^{-(\mu^3-\beta_1)(t-\tau)}\int_0^1 G(-\mu^3,x,\xi)_\xi(u^2(\tau,\xi)/2)d\xi d\mu.\end{aligned}$$

By using the same derivation of the estimate for $(\partial S(t-\tau)f(\tau,\cdot)/\partial x)$ in Proposition 3.1, we can obtain

$$\begin{aligned}\left\|\int_0^t S(\tau)(u^2(t-\tau,\cdot)/2)_x d\tau\right\|_{L^2} &\le K\int_0^t \tau^{-3/4}e^{-\beta_1\tau}\|u^2(t-\tau,\cdot)\|_{L^2}d\tau\\ &\le K\int_0^t (t-\tau)^{-3/4}e^{-\beta_1(t-\tau)}\|u^2(\tau,\cdot)\|_{L^2}d\tau\\ &\le K\sup_{0\le\tau<+\infty}\|u(\tau,\cdot)\|_{H^1}\int_0^t (t-\tau)^{-3/4}e^{-\beta_1(t-\tau)}\|u(\tau,\cdot)\|_{L^2}d\tau.\end{aligned}$$

Thus the solution $u(t,x)$ satisfies

$$\begin{aligned}&\|u(t,\cdot)\|_{L^2}\\ &\le K\left(e^{-\beta_1 t}\|w_0\|_{L^2}+\sup_{0\le\tau<+\infty}\|u(\tau,\cdot)\|_{H^1}\int_0^t (t-\tau)^{-3/4}e^{-\beta_1(t-\tau)}\|u(\tau,\cdot)\|_{L^2}d\tau\right),\end{aligned}$$

where K is independent of t, u and w_0. Let $K\|w_0\|_{L^2} = c_1$, $K\sup_{0\le\tau<+\infty}\|u(\tau,\cdot)\|_{H^1} = c_2$, and $w(t) = e^{\beta_1 t}\|u(t,\cdot)\|_{L^2}$. Then $w(t)$ satisfies

$$w(t) \le c_1 + c_2\int_0^t (t-\tau)^{-3/4}w(\tau)d\tau.$$

Define $g(t) = \sup_{[t]\le\tau<[t]+1} w(\tau)$, where $[t]$ is the largest integer less than or equal to t. Then

$$w(t) \le c_1 + c_2 \sum_{k=0}^{[t]-1} \int_k^{k+1} (t-\tau)^{-3/4} w(\tau)\,d\tau + c_2 \int_{[t]}^{t} (t-\tau)^{-3/4} w(\tau)\,d\tau$$

$$\le c_1 + c_2 \sum_{k=0}^{[t]-1} g(k) 4((t-k)^{1/4} - (t-k-1)^{1/4}) + c_2 g([t]) 4(t-[t])^{1/4}.$$

But

$$(t-k)^{1/4} - (t-k-1)^{1/4} = \left(\sum_{i=0}^{3} (t-k)^{i/4} (t-k-1)^{(3-i)/4} \right)^{-1} \le (t-k)^{-3/4} \le 1$$

for $k \le [t]-1$. Thus

$$w(t) \le c_1 + 4c_2 \sum_{k=0}^{[t]-1} g(k) + 4c_2 g([t])$$

$$= c_1 + 4c_2 \sum_{k=1}^{[t]} g(k),$$

which implies

$$\sup_{[t]\le\tau<[t]+1} w(\tau) \le c_1 + 4c_2 \sum_{k=1}^{[t]} g(k)$$

and

$$g(t) \le c_1 + 4c_2 \int_0^{[t]+1} g(\tau)\,d\tau$$

$$= c_1 + 4c_2 \int_0^t g(\tau)\,d\tau + 4c_2 \int_t^{[t]+1} g(\tau)\,d\tau$$

$$\le c_1 + 4c_2 g(t) + 4c_2 \int_0^t g(\tau)\,d\tau.$$

If $4c_2 \le 1/2$, then

$$g(t) \le \frac{c_1}{1-4c_2} + \frac{4c_1}{1-4c_2} \int_0^t g(\tau)\,d\tau,$$

which yields

$$g(t) \le \frac{c_1}{1-4c_2} \exp\left(\frac{4c_1 t}{1-4c_2} \right) \le 2c_1 e^{8c_2 t}$$

by the Gronwall inequality. Therefore, from the definition of $g(t)$, $w(t)$, c_1, and c_2, we have

$$\|u(t,\cdot)\|_{L^2} \le 2K\|w_0\|_{L^2} \exp\Big(-(\beta_1 - 8K \sup_{0\le\tau<+\infty} \|u(\tau,\cdot)\|_{H^1})t \Big).$$

By the proof of Theorem 4.2, we choose $\|w_0\|_{H^1}$ so small that

$$\beta_1 - 8K \sup_{0\le\tau<+\infty} \|u(\tau,\cdot)\|_{H^1} \ge \beta_2 > 0$$

and $K \sup_{0\le\tau<+\infty} \|u(\tau,\cdot)\|_{H^1} \le (1/8)$. Then $\|u(t,\cdot)\|_{L^2} \le 2K\|w_0\|_{L^2} e^{-\beta_2 t}$, which implies Theorem 4.3.

Appendix 1. The Green's function $G(\lambda, x, \xi)$ is the following: for $0 < x < \xi < 1$,

$$\begin{aligned} G(\lambda, x, \xi) &= (3\lambda)^{-1}\mu_1 e^{\mu_1(x-\xi)} + (3\lambda(3-B))^{-1}\Big[(e^{-\mu_1}-1)\mu_1 e^{\mu_1(x-\xi)} \\ &\quad +(2-e^{-\mu_1}-e^{-\mu_3})\mu_2 e^{\mu_2(x-\xi)} + (2-e^{-\mu_1}-e^{-\mu_2})\mu_3 e^{\mu_3(x-\xi)} \\ &\quad +(e^{\mu_2}-e^{-\mu_1})\mu_3 e^{\mu_1 x-\mu_2\xi} + (e^{\mu_3}-e^{-\mu_1})\mu_2 e^{\mu_1 x-\mu_3\xi} \\ &\quad +(e^{\mu_3}-e^{-\mu_2})\mu_1 e^{\mu_2 x-\mu_3\xi} + (e^{\mu_1}-e^{-\mu_2})\mu_3 e^{\mu_2 x-\mu_1\xi} \\ &\quad +(e^{\mu_1}-e^{-\mu_3})\mu_2 e^{\mu_3 x-\mu_1\xi} + (e^{\mu_2}-e^{-\mu_3})\mu_1 e^{\mu_3 x-\mu_2\xi}\Big] \\ &= (3\lambda)^{-1}\mu_1 e^{\mu_1(x-\xi)} + R(\mu, x, \xi); \end{aligned}$$

for $0 < \xi < x < 1$,

$$\begin{aligned} G(\lambda, x, \xi) &= (3\lambda(3-B))^{-1}\Big[(e^{-\mu_1}-1)\mu_1 e^{\mu_1(x-\xi)} \\ &\quad +(e^{-\mu_2}-1)\mu_2 e^{\mu_2(x-\xi)} + (e^{-\mu_3}-1)\mu_3 e^{\mu_3(x-\xi)} \\ &\quad +(e^{\mu_2}-e^{-\mu_1})\mu_3 e^{\mu_1 x-\mu_2\xi} + (e^{\mu_3}-e^{-\mu_1})\mu_2 e^{\mu_1 x-\mu_3\xi} \\ &\quad +(e^{\mu_3}-e^{-\mu_2})\mu_1 e^{\mu_2 x-\mu_3\xi} + (e^{\mu_1}-e^{-\mu_2})\mu_3 e^{\mu_2 x-\mu_1\xi} \\ &\quad +(e^{\mu_1}-e^{-\mu_3})\mu_2 e^{\mu_3 x-\mu_1\xi} + (e^{\mu_2}-e^{-\mu_3})\mu_1 e^{\mu_3 x-\mu_2\xi}\Big] \\ &= R(\mu, x, \xi), \end{aligned}$$

where $B = e^{-\mu_1} + e^{-\mu_2} + e^{-\mu_3}$. Here $\mu_1^3 = -\lambda$, $\mu_2 = \omega\mu_1$, and $\mu_3 = \omega^2\mu_1$ with $\omega = (-1 + i\sqrt{3})/2$. Next we show that

$$\int_0^1\int_0^1 \left|\frac{\partial}{\partial x}R(\mu, x, \xi)\right|^2 d\xi dx \le K/|\mu|^3,$$

where $\mu \in \Gamma_\pm$ with $|\mu| > 0$. Note that on $\Gamma_\pm$, $\mu_i \to \pm\infty$ and μ_r is negative and bounded with $\mu_r \to -\delta^{2/3}/3$ as $\mu_i \to \pm\infty$. Write $R(\mu, x, \xi)$ as

$$R(\mu, x, \xi) = A_0 + B_1 + B_2 + A_1 + A_2 + \cdots + A_6.$$

Then we derive the following estimates:

$$\int_0^1\int_0^1 \left|\frac{\partial A_i}{\partial x}\right|^2 d\xi dx \le K|\mu|^{-4} \quad \text{for} \quad i = 0, 3, 6,$$

$$\int_0^1\int_0^1 \left|\frac{\partial A_i}{\partial x}\right|^2 d\xi dx \le K|\mu|^{-3} \quad \text{for} \quad i = 1, 2, 4, 5,$$

$$\int_0^1\int_0^1 \left|\frac{\partial B_i}{\partial x}\right|^2 d\xi dx \le K|\mu|^{-3} \quad \text{for} \quad i = 1, 2.$$

Here we check only a few of them for $\mu \in \Gamma_+$. The others and the case for $\mu \in \Gamma_-$ are similar and left to the reader. By noting that $|3 - B| \ge K > 0$ for $\mu \in \Gamma_+$, μ_r is bounded and small, and $|3 - B|^{-1} \le Ke^{-\sqrt{3}\mu_i/2}$ if $\mu \in \Gamma_+$ and $\mu_i \to +\infty$, we have

$$\int_0^1\int_0^1 \left|\frac{\partial A_0}{\partial x}\right|^2 dxd\xi = \int_0^1\int_0^1 |3\lambda(3-B)|^{-2}|e^{-\mu_1}-1|^2|\mu_1|^4|e^{\mu_1(x-\xi)}|^2 d\xi dx$$
$$\le K|\mu|^{-2}e^{-\sqrt{3}|\mu_i|}\int_0^1\int_0^1 |e^{\mu_1(x-\xi)}|^2 d\xi dx \le K|\mu|^{-4},$$
$$\int_0^1\int_0^1 \left|\frac{\partial A_3}{\partial x}\right|^2 dxd\xi = \int_0^1\int_0^1 |3\lambda(3-B)|^{-2}|e^{\mu_3}-e^{-\mu_2}|^2|\mu_1\mu_2|^2|e^{2\mu_2 x-2\mu_3\xi}|dxd\xi$$
$$\le K|\mu|^{-2}e^{-\sqrt{3}|\mu_i|}\int_0^1\int_0^1 |e^{\mu_3}-e^{-\mu_2}|^2|e^{\mu_2 x-\mu_3\xi}|^2 dxd\xi$$
$$\le K|\mu|^{-2}\int_0^1\int_0^1 e^{-\sqrt{3}|\mu_i|x-\sqrt{3}|\mu_i|\xi}dxd\xi \le K|\mu|^{-4},$$
$$\int_0^1\int_0^1 \left|\frac{\partial A_1}{\partial x}\right|^2 dxd\xi = \int_0^1\int_0^1 |3\lambda(3-B)|^{-2}|e^{\mu_2}-e^{-\mu_1}|^2|\mu_1\mu_3|^2|e^{2\mu_1 x-2\mu_2\xi}|dxd\xi$$
$$\le K|\mu|^{-2}e^{-\sqrt{3}|\mu_i|}\int_0^1\int_0^1 e^{\sqrt{3}|\mu_i|\xi}dxd\xi \le K|\mu|^{-3},$$
$$\int_0^1\int_0^1 \left|\frac{\partial B_1}{\partial x}\right|^2 dxd\xi = \int_0^1\int_x^1 \left|\frac{2-e^{-\mu_1}-e^{-\mu_3}}{3\lambda(3-B)}\right|^2 |\mu_2|^4|e^{\mu_2(x-\xi)}|^2 dxd\xi$$
$$+\int_0^1\int_0^x \left|\frac{e^{-\mu_2}-1}{3\lambda(3-B)}\right|^2 |\mu_2|^4|e^{\mu_2(x-\xi)}|^2 dxd\xi$$
$$\le K|\mu|^{-2}\left(e^{-\sqrt{3}|\mu_i|}\int_0^1\int_x^1 e^{-\sqrt{3}|\mu_i|(x-\xi)}d\xi dx + \int_0^1\int_0^x e^{-\sqrt{3}|\mu_i|(x-\xi)}d\xi dx\right)$$
$$\le K|\mu|^{-3}.$$

By these estimates, we have the L^2-estimates for the x-derivative of $R(\mu, x, \xi)$. Here we note that we can obtain the same estimates for the ξ-derivative of $R(\mu, x, \xi)$.

Appendix 2. We prove the following lemma.

LEMMA A.1.

$$I \overset{\text{def}}{=} \left|\int_a^{+\infty} \xi^\alpha e^{i(\xi^3 t+\xi x)}d\xi\right| \le Kt^{-(1+\alpha)/3}(1+|x^3/t|^{(2\alpha-1)/12}),$$

where K is independent of $t > 0$, $x \in \mathbf{R}$, and $0 \le \alpha \le 1$.

Proof. Let $y = \xi t^{1/3}$. Then I becomes

$$I = t^{-(1+\alpha)/3}\left|\int_{at^{1/3}}^{+\infty} y^\alpha \exp(i(y^3+(xt^{-1/3})y))dy\right|.$$

If $\lambda = xt^{-1/3}$, I is

$$I = t^{-(1+\alpha)/3}\left|\int_{at^{1/3}}^{+\infty} y^\alpha e^{i(y^3+\lambda y)}dy\right|.$$

Let $\varphi_0(y)$ be a C^∞-function such that $\varphi_0 \equiv 0$ for $|y| < 1$ and $\varphi_0 \equiv 1$ for $|y| \ge 2$. Thus

$$I \le t^{-(1+\alpha)/3}\left|\int_{at^{1/3}}^{+\infty} y^\alpha e^{i(y^3+\lambda y)}\varphi_0(y)dy\right|$$
$$+ t^{-(1+\alpha)/3}\left|\int_{at^{1/3}}^{+\infty} y^\alpha e^{i(y^3+\lambda y)}(1-\varphi_0(y))dy\right| \overset{\text{def}}{=} I_1 + I_2.$$

Then $|I_2| \le Kt^{-(1+\alpha)/3}$. If $\lambda > -2$, then $3y^2 + \lambda > 1$ for $y \in [at^{1/3}, +\infty) \cap \{|y| \ge 1\}$. Thus, from integration by parts,

$$I_1 \le t^{-(1+\alpha)/3}\left(\left|\int_{\tilde{1}}^{+\infty}(-1)e^{i(y^3+\lambda y)}\left(\frac{y^\alpha\varphi_0(y)}{i(3y^2+\lambda)}\right)_y dy\right| + K\right)$$

$$\le t^{-(1+\alpha)/3}\left(\left|\int_{\tilde{1}}^{+\infty} e^{i(y^3+\lambda y)}\left((i(3y^2+\lambda))^{-1}\left(\frac{y^\alpha\varphi_0(y)}{i(3y^2+\lambda)}\right)_y\right)_y dy\right| + K\right) \le K,$$

where $\tilde{1} = \max(1, at^{1/3})$. In the following we assume $\lambda \le -2$ and $-\lambda = -|\lambda|$. Let $y = |\lambda|^{1/2}\eta$, which yields

$$I_1 = t^{-(1+\alpha)/3}|\lambda|^{(1+\alpha)/2}\left|\int_{\tilde{1}|\lambda|^{-1/2}}^{+\infty}\eta^\alpha e^{i|\lambda|^{3/2}(\eta^3-\eta)}\varphi_0(|\lambda|^{1/2}\eta)d\eta\right|.$$

Let $\psi_1(\eta)$ have a support in $(-\infty, (1/\sqrt{3})-\hat{\delta})$, $\psi_2(\eta)$ have a support in $((1/\sqrt{3})-2\hat{\delta}, (1/\sqrt{3})+2\hat{\delta})$, and $\psi_3(\eta)$ have a support in $((1/\sqrt{3})+\hat{\delta}, +\infty)$ with $\psi_1+\psi_2+\psi_3 = 1$. Thus

$$I_1 = t^{-(1+\alpha)/3}|\lambda|^{(1+\alpha)/2}\left|\int_{\tilde{1}|\lambda|^{-1/2}}^{+\infty}\eta^\alpha e^{i|\lambda|^{3/2}(\eta^3-\eta)}\varphi_0(|\lambda|^{1/2}\eta)(\psi_1(\eta)+\psi_2(\eta)+\psi_3(\eta))d\eta\right|$$

$$\le II_1 + II_2 + II_3.$$

Using integration by parts several times, we have

$$II_3 = t^{-(1+\alpha)/3}|\lambda|^{(1+\alpha)/2}\left|\int_{(1/\sqrt{3})+\hat{\delta}}^{+\infty} e^{i|\lambda|^{3/2}(\xi^3-\xi)}\left(\frac{\xi^\alpha\psi_3(\xi)\varphi_0(|\lambda|^{1/2}\xi)}{|\lambda|^{3/2}(3\xi^2-1)}\right)_\xi d\xi\right|$$

$$\le Kt^{-(1+\alpha)/3}|\lambda|^{(1+\alpha)/2-(3/2)}.$$

By a similar argument, $|II_1| \le Kt^{-(1+\alpha)/3}|\lambda|^{(\alpha-2)/2}$. Finally, using a corollary in [16, p. 311],

$$II_2 = t^{-(1+\alpha)/3}|\lambda|^{(1+\alpha)/2}\left|\int_{(1/\sqrt{3})-2\hat{\delta}}^{(1/\sqrt{3})+2\hat{\delta}}\eta^\alpha e^{i|\lambda|^{3/2}(\eta^3-\eta)}\varphi_0(|\lambda|^{1/2}\eta)\psi_2(\eta)d\eta\right|$$

$$\le Kt^{-(1+\alpha)/3}|\lambda|^{(1+\alpha)/2-(3/4)}$$

since $\lambda \le -2$, and if $\hat{\delta} > 0$ is small enough, $\varphi_0(|\lambda|^{1/2}\eta) = 1$ for $\lambda \le -14$ and $|\lambda|^{1/2}((1/\sqrt{3})-2\hat{\delta}) > 2$. Therefore, for $\lambda \le -2$, $|I_1| \le Kt^{-(1+\alpha)/2}|\lambda|^{(2\alpha-1)/4}$. By the definition of I, we have

$$|I| \le Kt^{-(1+\alpha)/3}\left(1 + |x^3/t|^{(2\alpha-1)/12}\right).$$

Appendix 3. In this appendix, we shall show that A does not generate an analytic semigroup. The proof presented here was given by Komornik [6].

By Lemma 2.1, there are no eigenvalues λ of A on the imaginary axis except $\lambda = 0$. Thus for $\lambda = i\nu$ with either $\nu < 0$ or $\nu > 0$, $(\lambda I - A)^{-1}$ exists. In order to have A generate an analytic semigroup, $(\lambda I - A)^{-1}$ must satisfy

$$\|(\lambda I - A)^{-1}\| \le \frac{C}{|\lambda|} = \frac{C}{|\nu|}$$

for $\lambda = i\nu$ with ν real and large, where C is a fixed constant [10]. However, from (2.6),

$$(\lambda I - A)^{-1}f = \int_0^1 G(\lambda, x, \xi)f(\xi)d\xi$$

for $f \in L^2$, where $G(\lambda, x, \xi)$ is defined in Appendix 1, and in the following, notations from Appendix 1 will be used. Now we estimate only $\|(\lambda T - A)^{-1}\|$ for $\lambda = i\nu$ with $\nu > 0$. Similar estimates can be obtained for $\lambda = i\nu$ with $\nu < 0$. If $\lambda = i\nu$ with $\nu > 0$, then $\mu_1 = \sqrt[3]{\nu}i$, $\mu_2 = ((-\sqrt{3} - i)/2)\sqrt[3]{\nu}$, $\mu_3 = ((\sqrt{3} - i)/2)\sqrt[3]{\nu}$. From Appendix 1,

$$G(\lambda, x, \xi) = (3\lambda)^{-1}\mu_1 e^{\mu_1(x-\xi)}\chi_{(x,1)}(\xi) + R(\mu, x, \xi),$$

where $R(\mu, x, \xi) = A_0 + B_1 + B_2 + A_1 + \cdots + A_6$ and $\chi_{(x,1)}$ is the characteristic function of interval $(x, 1)$. First we show that for $\mu = \mu_1 = \sqrt[3]{\nu}i$ large,

$$\int_0^1 \int_0^1 |R(\mu, x, \xi)|^2 d\xi dx \le K|\nu|^{-5/3},$$

where K is denoted as a generic constant. We need to derive the following estimates:

$$\int_0^1 \int_0^1 |A_i|^2 d\xi dx \le K|\nu|^{-2} \quad \text{for} \quad i = 0, 3, 6,$$

$$\int_0^1 \int_0^1 |A_i|^2 d\xi dx \le K|\nu|^{-5/3} \quad \text{for} \quad i = 1, 2, 4, 5,$$

$$\int_0^1 \int_0^1 |B_i|^2 d\xi dx \le K|\nu|^{-5/3} \quad \text{for} \quad i = 1, 2.$$

Here we check only several of them. The others are similar and left to the reader. Note that $|3 - B| \ge K_1 > 0$ for ν large and $|3 - B|^{-1} \le Ke^{-\sqrt{3}\sqrt[3]{\nu}/2}$. We then have

$$\begin{aligned}
\int_0^1 \int_0^1 |A_0|^2 dx d\xi &= \int_0^1 \int_0^1 |3\lambda(3 - B)|^{-2} |e^{-\mu_1} - 1|^2 |\mu_1|^2 |e^{\mu_1(x-\xi)}|^2 d\xi dx \\
&\le K|\nu|^{-4/3} e^{-\sqrt{3}\sqrt[3]{\nu}} \int_0^1 \int_0^1 |e^{i\sqrt[3]{\nu}(x-\xi)}|^2 d\xi dx \le K|\nu|^{-2}, \\
\int_0^1 \int_0^1 |A_3|^2 dx d\xi &= \int_0^1 \int_0^1 |3\lambda(3 - B)|^{-2} |e^{\mu_3} - e^{-\mu_2}|^2 |\mu_1|^2 |e^{2\mu_2 x - 2\mu_3 \xi}| dx d\xi \\
&\le K|\nu|^{-4/3} e^{-\sqrt{3}\sqrt[3]{\nu}} \int_0^1 \int_0^1 |e^{\mu_3} - e^{-\mu_2}|^2 |e^{-\sqrt{3}\sqrt[3]{\nu}x - \sqrt{3}\sqrt[3]{\nu}\xi}|^2 dx d\xi \le K|\nu|^{-2}, \\
\int_0^1 \int_0^1 |A_1|^2 dx d\xi &= \int_0^1 \int_0^1 |3\lambda(3 - B)|^{-2} |e^{\mu_2} - e^{-\mu_1}|^2 |\mu_3|^2 |e^{2\mu_1 x - 2\mu_2 \xi}| dx d\xi \\
&\le K|\nu|^{-4/3} e^{-\sqrt{3}\sqrt[3]{\nu}} \int_0^1 \int_0^1 e^{\sqrt{3}\sqrt[3]{\nu}\xi} dx d\xi \le K|\nu|^{-5/3}, \\
\int_0^1 \int_0^1 |B_1|^2 dx d\xi &= \int_0^1 \int_x^1 \left| \frac{2 - e^{-\mu_1} - e^{-\mu_3}}{3\lambda(3 - B)} \right|^2 |\mu_2|^2 |e^{\mu_2(x-\xi)}|^2 dx d\xi \\
&\quad + \int_0^1 \int_0^x \left| \frac{e^{-\mu_2} - 1}{3\lambda(3 - B)} \right|^2 |\mu_2|^2 |e^{\mu_2(x-\xi)}|^2 dx d\xi \\
&\le K|\nu|^{-4/3} \left(e^{-\sqrt{3}\sqrt[3]{\nu}} \int_0^1 \int_x^1 e^{-\sqrt{3}\sqrt[3]{\nu}(x-\xi)} d\xi dx + \int_0^1 \int_0^x e^{-\sqrt{3}\sqrt[3]{\nu}(x-\xi)} d\xi dx \right) \\
&\le K|\nu|^{-5/3}.
\end{aligned}$$

Thus from above estimates for $R(\mu, x, \xi)$, we obtain that for $f \in L^2$,

$$\|(\lambda I - A)^{-1} f\|_{L^2} \geq \left\| \int_x^1 (3\lambda)^{-1} \mu_1 e^{\mu_1(x-\xi)} f(\xi) d\xi \right\|_{L^2} - \left\| \int_0^1 R(\mu, x, \xi) f(\xi) d\xi \right\|_{L^2}$$

$$\geq \left\| \int_x^1 (3\lambda)^{-1} \mu_1 e^{\mu_1(x-\xi)} f(\xi) d\xi \right\|_{L^2} - K|\nu|^{-5/6} \|f(\xi)\|_{L^2}.$$

Consider the function $f(x) = e^{ix\sqrt[3]{\nu}} \in L^2$. Then

$$\left\| \int_x^1 (3\lambda)^{-1} \mu_1 e^{\mu_1(x-\xi)} e^{\sqrt[3]{\nu} i\xi} d\xi \right\|_{L^2} = \|(3\lambda)^{-1}(1-x)\mu_1 e^{\mu_1 x}\|_{L^2}$$

$$= 3^{-3/2}|\nu|^{-2/3} \|e^{\mu_1 x}\|_{L^2}.$$

Thus

$$\|(\lambda I - A)^{-1} e^{\mu_1 x}\|_{L^2} \geq (3^{-3/2}|\nu|^{-2/3} - K|\nu|^{-5/6}) \|e^{\mu_1 x}\|_{L^2},$$

which implies $\|(\lambda I - A)^{-1}\| \geq |\nu|^{-2/3}(3^{-3/2} - K|\nu|^{-1/6})$. Therefore, for ν large, we have that $\|(\lambda I - A)^{-1}\| \geq (3^{-3/2}/2)|\nu|^{-2/3}$. Thus, A does not generate an analytic semigroup.

Acknowledgments. The author wishes to thank Professor D. L. Russell for suggesting the problem studied in this paper and for valuable discussions in the course of development of the work.

UNIQUE DETERMINATION OF MULTIPLE CRACKS BY TWO MEASUREMENTS*

GIOVANNI ALESSANDRINI† AND ALVARO DIAZ VALENZUELA‡

Abstract. We study the inverse problem of determining multiple cracks in a planar conductor by electrostatic measurements at the boundary. We prove that two measurements at the boundary suffice to identify multiple cracks with any number of components. We treat the problem under no regularity assumptions on the cracks and on the background conductivity.

Key words. inverse problems, cracks, elliptic equations, level curves

AMS subject classifications. 35R30, 78A30, 31A25

1. Introduction.

The inverse problem of determining cracks by boundary measurements consists of finding the shapes and locations of fractures inside a conductor Ω by applying finitely many current fluxes to the boundary of Ω and measuring the induced potentials on the boundary.

Friedman and Vogelius [F-V] proved that if Ω is a planar domain of known analytic conductivity, then a single crack σ—that is, a (possibly empty) smooth simple curve—is uniquely determined by prescribing two appropriate current fluxes. This result was generalized by Bryan and Vogelius to the case of multiple cracks. In [B-V1] they prove that a collection of N pairwise disjoint smooth simple curves σ_j, $j = 1, \ldots, N$, is uniquely determined by prescribing $N + 1$ appropriate current fluxes.

The main purpose of this paper is to show that two appropriate current fluxes suffice to determine multiple cracks with any number of components. See Theorem 1.1.

It has been known since the paper by Friedman and Vogelius that the crucial step toward uniqueness theorems rests on the description of the shape of the level (equipotential) curves of voltage potentials inside Ω, and this in turn depends on information on the critical (stationary) points of the potentials. Here too we shall elaborate this theme. In fact, we shall make use of a technique, developed by Alessandrini and Magnanini (see [A-M1, A-M2]), which yields a precise evaluation of the number of interior critical points of solutions to elliptic equations in the plane in terms of the number of sign changes of boundary data.

The methods in [A-M2] will enable us to generalize the uniqueness result also in other respects. First we shall consider conductivities in Ω that may be discontinuous and anisotropic; this, we think, may be of some interest for applications with composite materials. Moreover, we shall not require that the components of the multiple crack satisfy any smoothness condition, not even that they be curves. Roughly speaking, we shall only require that each component not be an isolated point (which would have zero capacity) nor break off Ω. A detailed list of our assumptions is given below.

We let Ω be a bounded simply connected open set of $\mathbb{R}^2$ with smooth boundary $\partial\Omega$. We define a *multiple crack* σ in Ω as a possibly empty closed set that is the union of finitely many pairwise disjoint, closed continua $\sigma_1, \ldots, \sigma_N \subset \Omega$ such that $\Omega \backslash \sigma_j$ is connected for every $j = 1, \ldots, N$. Recall that a *continuum* is a connected set with at least two points.

Typical examples of the components σ_j are simple arcs, but, by our definition, sets with dendritic shape are also admitted. Components σ_j may also contain a closed curve γ. In such a case, we have that σ_j must also contain the bounded region surrounded by γ.

We represent the known conductivity at $x \in \Omega$ as a 2×2 matrix $A = A(x)$. We assume that its entries belong to $L^\infty(\Omega)$ and that, for some $\lambda > 0$, the following ellipticity condition is satisfied:

$$A(x)\xi \cdot \xi \geq \lambda |\xi|^2 \quad \text{for almost every } x \in \Omega \text{ and for every } \xi \in \mathbb{R}^2. \tag{1.1}$$

We prescribe the boundary current fluxes as follows. Let $\partial\Omega$ be decomposed into three internally pairwise disjoint simple arcs $\gamma_0, \gamma_1, \gamma_2$. Consider three functions $\eta_0, \eta_1, \eta_2 \in L^2(\partial\Omega)$ that have the following properties:

$$\eta_j \geq 0 \quad \text{on } \partial\Omega, \qquad \operatorname{supp} \eta_j \subset \gamma_j \quad \text{for every } j = 0, 1, 2. \tag{1.2a}$$

$$\int_{\partial\Omega} \eta_j = 1 \quad \text{for every } j = 0, 1, 2. \tag{1.2b}$$

Here, integration is meant with respect to ds, the arclength element along $\partial\Omega$. Next, let us define the functions ψ_1, ψ_2 as

$$\psi_k = \eta_0 - \eta_k, \qquad k = 1, 2. \tag{1.3}$$

In the sequel, we shall also make use of their antiderivatives along $\partial\Omega$, that is,

$$\Psi_k(s) = \int \psi_k(s) ds, \qquad k = 1, 2, \tag{1.4}$$

where the indefinite integration is considered along $\partial\Omega$ with the counterclockwise orientation, again with respect to the arclength parameter. Notice that, due to (1.2b) and (1.3), Ψ_1, Ψ_2 are continuous on all of $\partial\Omega$ and uniquely defined up to an additive constant.

As is customary in this field, we distinguish the cases when σ is assumed to be perfectly conducting or perfectly insulating. The boundary value problems corresponding to these two settings are as follows. We consider the weak solutions $u_k \in W^{1,2}(\Omega)$, $w_k \in W^{1,2}(\Omega \backslash \sigma)$, $k = 1, 2$, of the following boundary value problems:

$$\operatorname{div}(A \nabla u_k) = 0 \quad \text{in } \Omega \backslash \sigma, \tag{1.5a}$$

$$u_k = c_{k,j} \quad \text{on } \sigma_j, \qquad j = 1, \ldots, N, \tag{1.5b}$$

$$A \nabla u_k \cdot \nu = \psi_k \quad \text{on } \partial\Omega, \tag{1.5c}$$

$$\int_\beta A \nabla u_k \cdot \nu = 0 \quad \text{for every smooth Jordan curve } \beta \subset \Omega \backslash \sigma; \tag{1.5d}$$

$$\operatorname{div}(A \nabla w_k) = 0 \quad \text{in } \Omega \backslash \sigma, \tag{1.6a}$$

$$A \nabla w_k \cdot \nu = 0 \quad \text{on } \partial\sigma_j, \qquad j = 1, \ldots, N, \tag{1.6b}$$

$$A \nabla w_k \cdot \nu = \psi_k \quad \text{on } \partial\Omega, \tag{1.6c}$$

where the numbers $c_{k,j}$ are also unknowns and ν denotes unit normal, with outward orientation when on $\partial\Omega$. Problem (1.5) represents the perfectly conducting case, whereas problem (1.6)

describes the perfectly insulating one. Problems (1.5) and (1.6) are to be interpreted rigorously as follows:

(1.5′) To find $u_k \in W^{1,2}(\Omega)$ satisfying $u_k = \text{const}$ weakly on each σ_j and also $\int_\Omega A\nabla u_k \cdot \nabla\phi = \int_{\partial\Omega} \psi_k\phi$ for every $\phi \in W^{1,2}(\Omega)$ such that $\phi = \text{const}$ weakly on each σ_j;

(1.6′) To find $w_k \in W^{1,2}(\Omega\backslash\sigma)$ satisfying $\int_\Omega A\nabla w_k \cdot \nabla\eta = \int_{\partial\Omega} \psi_k\eta$ for every $\eta \in W^{1,2}(\Omega\backslash\sigma)$.

The existence and the uniqueness, up to an additive constant, of solutions to (1.5), (1.6) is straightforward in the framework of elliptic equations in divergence form. Let us also observe that being the sets σ_j continua they have positive capacity and their boundary is composed of regular points for the classical Dirichlet problem; see for instance, the book by Tsuji [T, Thm. I, 11]. In view of the celebrated result of Littman, Stampacchia, and Weinberger [L-S-W], we have that solutions u_k to (1.5), $k = 1, 2$, are continuous in all of Ω. Consequently, also the N-tuple $\{c_{k,j}\}_{j=1}^N$ in (1.5b) is uniquely determined up to an additive constant. Notice, in connection with this, the role of condition (1.5d), which is implicit in the formulation (1.5′) and represents a no-flux condition around the cracks. A conditions analogous to (1.5d) holds automatically when u_k is replaced by w_k.

Now we are in position to state our main result.

THEOREM 1.1. *Let Γ be a nonempty simple arc in $\partial\Omega$. Let σ, σ' be two multiple cracks in Ω, and let u_k', w_k', $k = 1, 2$, be the solutions to* (1.5), (1.6), *respectively, when σ is replaced by σ'. If either*

$$u_k = u_k' \quad \text{on } \Gamma \text{ for all } k = 1, 2 \tag{1.7}$$

or

$$w_k = w_k' \quad \text{on } \Gamma \text{ for all } k = 1, 2, \tag{1.8}$$

then we have $\sigma = \sigma'$.

Note that in this theorem the prescribed current fluxes belong to $L^2(\partial\Omega)$; however, up to minor technical adjustments, even less regular data could be considered. For instance, the functions ψ_k could be replaced by measures, provided that conditions (1.2), (1.3) are preserved. In particular, data modeling concentrated electrodes as in [B-V1] would serve the purpose.

In §2 we prepare for the proof of Theorem 1.1. We state and prove Proposition 2.1, which allows us to extend the duality arguments already used in [F-V, B-V1, B-V2] to our setting. Next, in Proposition 2.2, we introduce the tools from [A-M2] that will be needed later.

In §3, we state Propositions 3.1 and 3.2, which enable us to complete the proof of Theorem 1.1.

Section 4 contains the proofs of Propositions 3.1 and 3.2.

2. Stream functions and geometric critical points. We define $B = (\det A)^{-1}A^{\mathrm{T}}$, where $(\cdot)^{\mathrm{T}}$ denotes transpose, whereas we denote by $(\cdot)^{\perp}$ the rotation by 90° in the counterclockwise direction.

PROPOSITION 2.1. *For each $k = 1, 2$, there exists, and it is unique up to an additive constant, a function $v_k \in W^{1,2}(\Omega\backslash\sigma)$ that satisfies*

$$\nabla v_k = (A\nabla w_k)^{\perp} \quad \text{almost everywhere in } \Omega\backslash\sigma. \tag{2.1}$$

Furthermore, v_k is a weak solution of the following boundary value problem:

$$\operatorname{div}(B\nabla v_k) = 0 \quad \text{in } \Omega\backslash\sigma, \tag{2.2a}$$

$$v_k = d_{k,j} \quad \text{on } \partial\sigma_j, \qquad j = 1, \dots, N, \tag{2.2b}$$

$$v_k = \Psi_k \quad \text{on } \partial\Omega, \tag{2.2c}$$

$$\int_\beta B\nabla v_k \cdot \nu = 0 \quad \text{for every smooth Jordan curve } \beta \subset \Omega\backslash\sigma, \tag{2.2d}$$

where the numbers $d_{k,j}$ are unknown.

Before giving a proof, we start with some remarks.

The function v_k is the so-called *stream function* associated with w_k, and we have that problems (1.6) and (2.2) are equivalent through (2.1). The construction of the stream function associated to a solution of an elliptic boundary value problem like (1.6) is a generalization of the notion of conjugate harmonic function and is well known in the case when the coefficients in A are smooth and σ_j are smooth curves or have smooth boundaries. See the book by Bergman and Schiffer [B-S] and, more specifically, for the case of cracks [B-V2].

Note that v_k is continuous in $\overline{\Omega\backslash\sigma}$; in fact, as we already observed, every point in $\partial(\Omega\backslash\sigma) = \partial\Omega \cup \partial\sigma$ is regular for the Dirichlet problem. Moreover, v_k can be continued to a $W^{1,2}(\Omega) \cap C(\overline{\Omega})$ function by setting $v_k = d_{k,j}$ in σ_j, $j = 1, \dots, N$.

The rigorous formulation of (2.2) takes the following form:

(2.2′) To find $v_k \in W^{1,2}(\Omega)$ satisfying $v_k = \text{const}$ weakly on each σ_j, $v_k = \Psi_k$ on $\partial\Omega$, and also $\int_\Omega B\nabla v_k \cdot \nabla\phi = 0$ for every $\phi \in W_0^{1,2}(\Omega)$ such that $\phi = \text{const}$ weakly on each σ_j.

Stream functions t_k associated to solutions v_k of (1.6) could be constructed as well, and a result completely analogous to Proposition 2.1 could be stated. We avoid the details since we shall make use of t_k only locally, and we shall not need to specify its boundary conditions.

Proposition 2.1 implies that condition (1.8) in Theorem 1.1 is equivalent to

$$B\nabla v_k \cdot \nu = B\nabla v_k' \cdot \nu \quad \text{on } \Gamma \text{ for all } k = 1, 2, \tag{2.3}$$

where v_k' denotes a solution to (2.2) when σ is replaced with σ'. In fact, we shall prove Theorem 1.1 by treating v_k rather than w_k, the advantage being that v_k, like u_k, satisfies Dirichlet-type conditions on σ rather than Neumann-type conditions.

Proof of Proposition 2.1 (sketch). Let us approximate σ by closed sets σ^n such that $\sigma^{n-1} \supset \sigma^n \to \sigma$ as $n \to \infty$ and $\partial\sigma_n$ are smooth and A by smooth matrices A_n satisfying uniform ellipticity conditions and converging to A as $n \to \infty$ in $L^p(\Omega)$ for all $p < \infty$. With such replacements, our thesis holds and we have uniform $W^{1,2}$ bounds on corresponding regularized solutions to (1.6) and (2.2). Next we let $n \to \infty$ and find subsequences of regularized solutions weakly converging in $W^{1,2}(\Omega\backslash\sigma)$ to solutions of the original problems (1.6) and (2.2) that also satisfy (2.1). □

We shall need some properties about the geometric character of level lines of solutions of two-dimensional elliptic equations in divergence form and discontinuous coefficients. This

issue was treated in [A-M2] for the case when the matrix A is symmetric, but the following results hold also in the nonsymmetric case.

PROPOSITION 2.2. *Let $u \in W^{1,2}(D)$ be a weak solution to $\operatorname{div}(A\nabla u) = 0$ in a simply connected domain D, and let t be its stream function. Then we have the representation $u + it = f \circ \chi$ where χ is a quasi-conformal mapping of D onto the disk $B_1(0)$ and f is a holomorphic function on $B_1(0)$.*

Moreover, if $u = A\nabla u \cdot \nu = 0$ in the weak sense on an arc $\Gamma \subset \partial D$, then we have $u = 0$ everywhere in D.

Proof. See [A-M2, Thm. 2.1 and Cor. 2.2] for a proof. □

This representation gives that the geometrical structure of the level lines of u has the same character as that of the harmonic function $h = \operatorname{Re} f$.

A point $z \in D$ is then called a *geometric critical point* for u if $\chi(z)$ is a critical point for h, that is, $\nabla h|_{\chi(z)} = 0$.

Let F be a smooth vector field in a planar domain G with smooth boundary, and let $F \neq 0$ on ∂G. We define the index of F in G by

$$I(G, F) = -\frac{1}{2\pi} \int_{\partial G} \mathrm{d}(\arg F), \tag{2.4}$$

where arg F denotes the angle made by F with a fixed direction, and the integral is taken in the counterclockwise orientation. If ζ is a point where F vanishes we define the index of F at ζ as

$$I(\zeta, F) = \lim_{r \to 0} I(B_r(\zeta), F).$$

In places we shall also deal with the index of complex-valued functions $g = u + it$; for this purpose, we shall identify the function g with the vector field $F = \binom{u}{t}$.

We denote the *geometric index* of ∇u at the point z as the index of the vector field ∇h at $\chi(z)$, namely,

$$I(z, \nabla u) = I(\chi(z), \nabla h);$$

the geometric index coincides with the index defined above when u is smooth (see [A-M2]). Note that, contrary to the customary definition of index (see, for instance, [M]), we have chosen to place the minus sign in the definition (2.4) (and hence, index= −winding number) in such a way that, for solutions of elliptic equations, the geometric index is always a nonnegative integer and positive only at geometric critical points. In fact, we have the following result.

LEMMA 2.3. *Assume that the hypotheses of Proposition 2.2 hold. For every $z \in D$ there exists a neighbourhood U of z such that the level set $\{\zeta \in U | u(\zeta) = u(z)\}$ is composed of $I(z, \nabla u) + 1$ simple arcs whose pairwise intersection consists of $\{z\}$ only.*

Proof. See [A-M2, Lem. 2.5] for a proof of the lemma. □

Proposition 2.2 also implies that the points z where $u(z) = t(z) = 0$ are isolated, unless u is constant. At such points, we may define the index of the complex-valued function $g = u + it$. It is easily seen that we have

$$I(z, g) = I(\chi(z), f) = I(z, \nabla u) + 1 \geq 1. \tag{2.5}$$

3. Proof of Theorem 1.1. The proof of Theorem 1.1 will be based on the following two propositions, whose proofs are postponed to §4.

PROPOSITION 3.1. *If (1.7) holds, then we have $u_k = u'_k$, $k = 1, 2$, everywhere in Ω. Likewise, if (2.3) holds, then we have $v_k = v'_k$, $k = 1, 2$, everywhere in Ω.*

For any $\alpha, \beta \in \mathbb{R}$ such that $\alpha^2 + \beta^2 = 1$, set $u = \alpha u_1 + \beta u_2$ and $v = \alpha v_1 + \beta v_2$. We have that u and v are solutions to problems (1.5) and (2.2), respectively, when ψ_k and Ψ_k are replaced with $\psi = \alpha\psi_1 + \beta\psi_2$ and $\Psi = \alpha\Psi_1 + \beta\Psi_2$, respectively.

PROPOSITION 3.2. *Neither u nor v have geometric critical points in $\Omega\backslash\sigma$.*

Proof of Theorem 1.1. Suppose that (1.7) holds, and assume by contradiction $\sigma'\backslash\sigma \neq \emptyset$. Hence $\sigma'\backslash\sigma$ must contain a continuum δ. By Proposition 3.1, we have that there exists a constant c_k' such that $u_k = u_k' = c_k'$ on δ, $k = 1, 2$. Since solutions to (1.5) are unique up to additive constants, we may assume with no loss of generality that $c_k' = 0$, $k = 1, 2$. Therefore $u = 0$ on δ. We shall show that there exist $\alpha, \beta \in \mathbb{R}$, $\alpha^2 + \beta^2 = 1$, such that u has at least one geometric critical point in $\Omega\backslash\sigma$, and this contradicts Proposition 3.2. The same type of argument applies when (1.8) or, as is the same, (2.3) holds.

Let P be a fixed point in δ, and let D be a disk centered at P with sufficiently small radius in such a way that $D \subset \Omega\backslash\sigma$. Let $P_n \in \delta \cap D$, $n = 1, 2, \ldots$, be points such that $P_n \neq P$ for all n and $P_n \to P$ as $n \to \infty$. Let t_1, t_2 be stream functions for u_1, u_2, respectively. We may also require $t_1(P) = 0$, $t_2(P) = 0$. Obviously, we have that $t = \alpha t_1 + \beta t_2$ is a stream function for u and that $t(P) = 0$. For every $n = 1, 2, \ldots$ we may find $\alpha_n, \beta_n \in \mathbb{R}$ satisfying $\alpha_n^2 + \beta_n^2 = 1$ such that the complex-valued function

$$g_n = \alpha_n(u_1 + it_1) + \beta_n(u_2 + it_2)$$

vanishes at the points P and P_n. We have $I(P, g_n)$, $I(P_n, g_n) \geq 1$. Possibly passing to subsequences, we may set

$$\alpha_0 = \lim_{n\to\infty} \alpha_n, \quad \beta_0 = \lim_{n\to\infty} \beta_n, \quad \alpha_0^2 + \beta_0^2 = 1.$$

Let us denote

$$g_0 = \alpha_0(u_1 + it_1) + \beta_0(u_2 + it_2).$$

By the continuity property of the index, we obtain

$$I(P, g_0) \geq \liminf_{n\to\infty} (I(P, g_n) + I(P_n, g_n)) \geq 2.$$

Hence, by (2.5), $I(P, \nabla u) \geq 1$ when $\alpha = \alpha_0$ and $\beta = \beta_0$; that is, P is a geometric critical point for u. □

4. Proofs of Propositions 3.1 and 3.2.

Proof of Proposition 3.1. Consider the connected component G of $\Omega\backslash(\sigma \cup \sigma')$ such that $\partial G \subset \partial\Omega$. Functions u_k, u_k' are solutions to $\operatorname{div}(A\nabla u) = 0$ in $\Omega\backslash(\sigma \cup \sigma')$, and they have the same Cauchy data on Γ. By Proposition 2.2 and continuity, we obtain $u_k = u_k'$ in $\overline{G}$. Suppose $\Omega\backslash(\sigma \cup \overline{G})$ is nonempty, and let D be any of its connected components. We have that one connected component Δ_1 of ∂D is contained in ∂G and the remaining Δ_h are some of the components σ_j of σ. On Δ_1, we have $u_k = u_k'$; since $\Delta_1 \subset \sigma \cup \sigma'$, we obtain $u_k = \text{const}$ on Δ_1. By conditions (1.5b), (1.5d) we deduce $u_k = \text{const}$ in D; by Proposition 2.2 this implies $u_k = \text{const}$ in Ω, which contradicts (1.5c). Hence $\Omega\backslash(\sigma \cup \overline{G})$ is empty and $u_k = u_k'$ in $\Omega\backslash\sigma$. By reversing the roles of σ and σ', we arrive at $u_k = u_k'$ in $\Omega\backslash(\sigma \cap \sigma')$. Finally, $u_k = u_k'$ in Ω by continuity and conditions (1.5b). The same argument applies to solutions v_k. v_k'. □

Proof of Proposition 3.2. Consider the Neumann boundary data $\psi = \alpha\psi_1 + \beta\psi_2$ for u on $\partial\Omega$. We have $\psi = (\alpha + \beta)\eta_0 - \alpha\eta_1 - \beta\eta_2$; therefore, $\partial\Omega$ can be decomposed into two arcs δ_2, δ_2—one being the union of two of the arcs $\gamma_0, \gamma_1, \gamma_2$, and the other is the remaining one of the three such that $\psi \geq 0$ on δ_1 and $\psi \leq 0$ on δ_2. Note also that the Dirichlet data

$\Psi = \alpha\Psi_1 + \beta\Psi_2$ for v on $\partial\Omega$ is a primitive of ψ, and therefore Ψ is nondecreasing in δ_1 and Ψ is nonincreasing in δ_2.

By using the regularization procedure outlined in the proof of Proposition 2.1 and by recalling the continuity properties of the geometric index (see [A-M2, Proposition 2.6]), it suffices to prove the thesis when A and $\partial\sigma$ are smooth. Notice also that, in the regularization procedure, we may also approximate the boundary data ψ and Ψ. Hence we shall also assume that ψ is smooth, $\psi > 0$ in the interior of δ_1, $\psi < 0$ in the interior of δ_2, and Ψ is still a primitive of ψ.

Let us incidentally remark that a straightforward application of the methods in [A-M1] would give, for both u and v,

$$(\text{number of critical points in } \Omega\backslash\sigma) + \frac{1}{2}(\text{ number of critical points on } \partial\sigma) \leq N,$$

where N is the number of components of σ. Thus, if σ were empty, our thesis would follow immediately. In the sequel we shall deal with the case when σ is nonempty. Roughly speaking, our argument will consist of showing that conditions (1.5d), (2.2d) imply that there are exactly $2N$ critical points on $\partial\sigma$.

We shall prove that, for every domain $G \subset \Omega\backslash\sigma$ such that no geometric critical point of u nor v belongs to ∂G, we have

$$I(G, \nabla u) = I(G, \nabla v) = 0.$$

With no loss of generality, we may assume $\partial G = \Gamma_0 \cup \Gamma_1 \cup \cdots \cup \Gamma_N$ where $\Gamma_0, \ldots, \Gamma_N$ are smooth closed curves such that Γ_0 surrounds $\Gamma_1 \cup \cdots \cup \Gamma_N$ and each Γ_j, $j = 1, \ldots, N$, surrounds σ_j. We have

$$2\pi I(G, \nabla u) = \sum_{j=1}^{N} \int_{\Gamma_j} \mathrm{d}\arg \nabla u - \int_{\Gamma_0} \mathrm{d}\arg \nabla u,$$

and the analogous formula holds for v. By using the fact that $\partial\Omega$ splits into two parts where the Neumann data for u and the tangential derivative of the Dirichlet data for v have constant sign and by the arguments used in the proof of Theorem 2.2 in [A-M1] we have

$$\int_{\Gamma_0} \mathrm{d}\arg \nabla u, \int_{\Gamma_0} \mathrm{d}\arg \nabla v \geq 0.$$

The proof will be completed by showing

$$\int_{\Gamma_j} \mathrm{d}\arg \nabla u \leq 0 \quad \text{for every } j = 1, \ldots, N. \tag{4.1}$$

In fact, we shall obtain $I(G, \nabla u) = 0$ since we already know that such an index is nonnegative. The same argument will be applicable to v since the boundary conditions for u and v on σ_j are of the same type.

Let Σ be the annular region bounded by Γ_j and $\partial\sigma_j$. We may find $R > 0$ and a conformal change of coordinates from Σ to the annulus $B_R(0)\backslash\overline{B_1(0)}$ that is smooth up to the boundary and transforms Γ_j into $\partial B_R(0)$ and σ_j into $\partial B_1(0)$, (see, for instance, [N]). By conformal invariance we have, in the new coordinates,

$$\operatorname{div}(A\nabla u) = 0 \quad \text{in } B_R(0)\backslash\overline{B_1(0)}, \tag{4.2}$$

$$u = c = \text{const} \quad \text{on } \partial B_1(0), \tag{4.3}$$

$$\int_\beta A\nabla u \cdot \nu = 0 \quad \text{for every smooth Jordan curve } \beta \subset B_R(0)\backslash\overline{B_1(0)},$$

and, by continuity,

$$\int_{\partial B_1(0)} A\nabla u \cdot \nu = 0. \tag{4.4}$$

Condition (4.4) implies that both the level sets $\{u > c\}$, $\{u < c\}$ have zero distance from $\partial B_1(0)$. Moreover, by the maximum principle, they also have zero distance from $\partial B_R(0)$. Hence, the level curve $\{u = c\}$ contains at least two arcs, both joining $\partial B_1(0)$ to $\partial B_R(0)$. We want to continue u to a solution of an elliptic equation in the larger annulus $B_R(0)\backslash\overline{B_{1/R}(0)}$ by the inversion $z \to \overline{z}^{-1}$, where $\overline{(\cdot)}$ denotes the complex conjugate. If A is given by

$$A(z) = \begin{bmatrix} a(z) & b(z) \\ c(z) & d(z) \end{bmatrix} \quad \text{for every } z \in \overline{B_R(0)}\backslash B_1(0),$$

then we set

$$A(z) = \begin{bmatrix} a(\overline{z}^{-1}) & -b(\overline{z}^{-1}) \\ -c(\overline{z}^{-1}) & d(\overline{z}^{-1}) \end{bmatrix} \quad \text{for every } z \in \overline{B_1(0)}\backslash B_{1/R}(0)$$

and

$$u(z) = 2c - u(\overline{z}^{-1}) \quad \text{for every } z \in \overline{B_1(0)}\backslash B_{1/R}(0).$$

We easily see that A is continued in such a way that ellipticity is preserved and u is continued to a C^1 solution of

$$\operatorname{div}(A\nabla u) = 0 \quad \text{in } B_R(0)\backslash\overline{B_{1/R}(0)}.$$

The level curve $\left\{ z \in B_R(0)\backslash\overline{B_{1/R}(0)} \;\middle|\; u(z) = c \right\}$ is now composed by the circle $\partial B_1(0)$ and by at least two arcs, both joining $\partial B_{1/R}(0)$ to $\partial B_R(0)$ and hence both intersecting $\partial B_1(0)$. Therefore, either there exist at least two geometric critical points of u on $\partial B_1(0)$ or there exists only one of geometric index of at least 2. In both cases we obtain by Lemma 2.3

$$2 \le I(B_R(0)\backslash\overline{B_{1/R}(0)}, \nabla u) = \frac{1}{2\pi}\left(\int_{\partial B_{1/R}(0)} \mathrm{d}\arg\nabla u - \int_{\partial B_R(0)} \mathrm{d}\arg\nabla u \right),$$

where use is made of the C^1 smoothness of u. On the other hand, by a straightforward calculation based on the continuation by reflection of u we have

$$\frac{1}{2\pi}\left(\int_{\partial B_{1/R}(0)} \mathrm{d}\arg\nabla u + \int_{\partial B_R(0)} \mathrm{d}\arg\nabla u \right) = 2$$

and thus

$$\int_{\partial B_R(0)} \mathrm{d}\arg\nabla u \le 0,$$

which is equivalent to (4.1) by the invariance of the winding number under change of coordinates. □

Appendix. After this paper was accepted, the authors learned that H. Kim and J. K. Seo [*Unique determination of a collection of finite number of cracks from two boundary measurements*, SIAM J. Math. Anal., 27 (1996), to appear] have obtained a result similar to Theorem 1.1 in the case when the background conductivity is smooth and the unknown multiple crack is composed of finitely many disjoint smooth simple curves.

REGULARITY AND EXACT CONTROLLABILITY FOR A BEAM WITH PIEZOELECTRIC ACTUATOR*

MARIUS TUCSNAK†

Abstract. We consider an initial and boundary value problem modelling the vibrations of a Bernoulli-Euler beam with an attached piezoelectric actuator. We show that the Sobolev regularity of the solution is by $\frac{1}{2}+\epsilon$ higher than that one obtains by simply using the Sobolev regularity of the control term. The main results concern the dependence of the space of exactly controllable initial data on the location of the actuator. Our approach is based on the Hilbert uniqueness method introduced by Lions [*Contrôlabilité exacte des systèmes distribués*, Masson, Paris, 1988] combined with some results from the theory of diophantine approximation.

Key words. exact controllability, Hilbert uniqueness method, piezoelectric actuator, diophantine approximation

AMS subject classifications. 93C20, 35B75, 35B60

1. Introduction. In recent years a lot of papers were devoted to the study of elastic structures with piezoelectric actuators (e.g., [2], [3], [5], [6]). The main topics covered in the papers quoted above are modelling (see [2], [5], [6]), LQR, and identification problems (see [3]). Concerning the controllability problems, as far as we know, all published works consider finite-dimensional approximations of the initial distributed control problems (see [6] and references therein). The main purpose of the present paper is to study the exact controllabillity of a beam with piezoelectric actuator by using the theory of infinite-dimensional control systems as developed in [13]. More precisely we consider the initial and boundary value problem modelling the vibrations of a Bernoulli-Euler beam that is subject to the action of an attached piezoelectric actuator. If we suppose that the beam is hinged at both ends and that the actuator is excited in a manner so as to produce pure bending moments, the model for the controlled beam can be written as (cf. [5])

$$w''(x,t)+\frac{\partial^4 w}{\partial x^4}(x,t)=u(t)\frac{d}{dx}[\delta_\eta(x)-\delta_\xi(x)],\qquad 0<x<\pi,\ t>0, \tag{1.1}$$

$$w(0,t)=w(\pi,t)=\frac{\partial^2 w}{\partial x^2}(0,t)=\frac{\partial^2 w}{\partial x^2}(\pi,t)=0,\qquad t\geq 0, \tag{1.2}$$

$$w(x,0)=w^0(x),\quad w'(x,0)=w^1(x),\quad 0<x<\pi. \tag{1.3}$$

In the equations above w represents the transverse deflection of the beam, $\xi,\eta\in(0,\pi)$ stand for the ends of the actuator, and δ_y is the Dirac mass at the point y. Moreover by w', w'' we denote the time derivatives of w. The control is given by the function $u:[0,T]\to\mathbf{R}$ representing the time variation of the voltage applied to the actuator. Our main purpose is to determine the initial data that can be steered to rest by means of the control function u. More precisely we can give the following definition.

DEFINITION 1.1. *We say that the initial data w^0, w^1 are "exactly L^2-controllable in (ξ,η) at time T" if there exists $u\in L^2(0,T)$ such that the solution w of* (1.1)-(1.3) *satisfies the condition*

$$w(x,T)=w'(x,T)=0,\qquad 0<x<\pi. \tag{1.4}$$

*Received by the editors April 4, 1994; accepted for publication (in revised form) January 5, 1995.

†Ecole Polytechnique, Centre de Mathématiques Appliquées, 91128 Palaiseau Cedex, France, and Université de Versailles (tucsnak@cmapx.polytechnique.fr).

The plan of this paper is as follows. The second section contains some notation and preliminaries. In the third section we prove an existence and regularity result for (1.1)-(1.3). The exact controllability is studied in the fourth section. Our approach was inspired by ideas and methods used in [9] and [10] for pointwise control problems.

2. Notation and preliminaries. To study the wellposedness and controllability for (1.1)-(1.3) we introduce the function spaces $(Y_\alpha)_{\alpha\in\mathbf{R}}$ defined as follows. If $\alpha > 0$, then Y_α is the closure in $H^\alpha(\Omega)$ of the set of all functions $y \in C^\infty(\bar{\Omega})$ satisfying the conditions $\frac{d^{2n}y}{dx^{2n}}(0) = \frac{d^{2n}y}{dx^{2n}}(\pi) = 0$ for all $n \geq 0$; for negative α we define Y_α as the dual space of $Y_{-\alpha}$ constructed by means of the inner product of $Y_0 = L^2(\Omega)$.

Let us now consider the homogenous initial and boundary value problem

$$\phi''(x,t) + \frac{\partial^4\phi}{\partial x^4}(x,t) = 0, \qquad 0 < x < \pi,\ t \in (0,T), \tag{2.1}$$

$$\phi(0,t) = \phi(\pi,t) = \frac{\partial^2\phi}{\partial x^2}(0,t) = \frac{\partial^2\phi}{\partial x^2}(\pi,t) = 0, \qquad t \in (0,T), \tag{2.2}$$

$$\phi(x,0) = \phi^0(x), \quad \phi'(x,0) = \phi^1(x), \quad 0 < x < \pi. \tag{2.3}$$

It is by now well known that the initial and boundary value problem (2.1)-(2.3) is well posed in $Y_{\alpha+2} \times Y_\alpha$ for all $\alpha \geq -2$. Moreover, as a consequence of the Hilbert uniqueness method (HUM), introduced in [13], the following result holds.

PROPOSITION 2.1. *All initial data in $Y_{\alpha+2} \times Y_\alpha$ are "exactly L^2-controllable in (ξ,η) at time T" if and only if there exists a constant $c > 0$ such that*

$$\int_0^T \left[\frac{\partial\phi}{\partial x}(\xi,t) - \frac{\partial\phi}{\partial x}(\eta,t)\right]^2 dt \geq c(\|\phi^0\|^2_{H^{-\alpha}(\Omega)} + \|\phi^1\|^2_{H^{-\alpha-2}(\Omega)}] \tag{2.4}$$

for all

$$(\phi^0,\phi^1) \in Y_3 \times Y_1.$$

We shall also need some results from the theory of diophantine approximation. For a real number ρ, we denote by $|||\rho|||$ the difference, taken positively, between ρ and the nearest integer, i.e.,

$$|||\rho||| = \min_{n\in\mathbf{Z}} |\rho - n|.$$

Let us also denote by A the set of all irrationals $\rho \in]0,1[$ such that if $[0, a_1, \ldots, a_n, \ldots]$ is the expansion of ρ as a continued fraction, then (a_n) is bounded. The set A plays a very important role in our control problem. Let us note that A is obviously uncountable and, by classical results on diophantine approximation (cf. [4, p. 120]), its Lebesgue measure is equal to zero. In particular, by the Euler-Lagrange theorem (cf. [11, p. 57]) A contains the irrational quadratic numbers (i.e., satisfying a second-degree equation with rational coefficients). We shall essentially use the fact that the elements of A are badly approximable by rational numbers. More precisely, the following result holds true (cf. [11, p. 24]).

PROPOSITION 2.2. *A number $\rho \in (0,1)$ is in A if and only if there exists a constant $C > 0$ such that*

$$|||q\rho||| \geq \frac{C}{q} \tag{2.5}$$

for all strictly positive integer q.

We shall also use the following result on simultenous approximation (cf. [4, p. 14]).

PROPOSITION 2.3. *Let $\rho_1, \ldots, \rho_k$ be k irrationals in $(0, 1)$. Then there exists a strictly increasing sequence of natural numbers q_n such that*

$$q_n^{\frac{1}{k}} \max_{i=1,k}(|||q_n\rho_1|||, \ldots, |||q_n\rho_i|||, \ldots, |||q_n\rho_k|||) \leq \frac{k}{k+1}, \quad \forall n \geq 1.$$

The next proposition, which is proved in [4, p. 120], shows that an inequality slightly weaker than (2.5) holds for almost all points in $(0, 1)$.

PROPOSITION 2.4. *For any $\epsilon > 0$ there exists a set $B_\epsilon \subset (0, \pi)$ having the Lebesgue measure equal to π and a constant $C > 0$, such that for any $\rho \in B_\epsilon$,*

$$|||q\rho||| \geq \frac{C}{q^{1+\epsilon}} \tag{2.6}$$

for any strictly positive integer q.

Let us notice that by Roth's theorem (cf. [4, p. 104]), for all $\epsilon > 0$, B_ϵ contains all algebraic irrational numbers in $(0, \pi)$.

3. Existence and regularity of solutions. The regularity of the solutions of (1.1)-(1.3) is a problem that is similar in many respects to the regularity for the wave or Euler-Bernoulli equations with interior point control (see [14], [16]). As in the cases mentioned above one can prove that the regularity of the solutions of (1.1)-(1.3) is higher than that one obtains by simply using the Sobolev regularity of the right-hand side of (1.1). More precisely if we denote by Ω the interval $(0, \pi)$ we notice that if $u \in L^2(0, T)$ the function $u(\cdot)\frac{d}{dx}(\delta_\xi - \delta_\eta)$ is in $L^2(0, T; H^{-\frac{3}{2}-\epsilon}(\Omega))$ for any $\epsilon > 0$. Standard regularity for the Bernoulli-Euler equation (cf. [13]) implies the existence and the uniqueness of a solution of (1.1)-(1.3) in

$$C([0, T], Y_{\frac{1}{2}-\epsilon}) \cap C^1([0, T], Y_{-\frac{3}{2}-\epsilon}). \tag{3.1}$$

The main result of this section, given below, shows that the space regularity in (3.1) can be improved by $\frac{1}{2} + \epsilon$.

THEOREM 3.1. *Suppose that $w^0 \in Y_1$, $w^1 \in Y_{-1}$. Then the initial and boundary value problem* (1.1)-(1.3) *admits a unique solution having the regularity*

$$w \in C([0, T], Y_1) \cap C^1([0, T], Y_{-1}). \tag{3.2}$$

Consider $\tau \in [0, T]$. To prove Theorem 3.1, following [14], we introduce the homogenous initial and boundary value problem

$$v''(x, t) + \frac{\partial^4 v}{\partial x^4}(x, t) = 0, \qquad 0 < x < \pi, \ t \in (0, \tau), \tag{3.3}$$

$$v(0, t) = v(\pi, t) = \frac{\partial^2 v}{\partial x^2}(0, t) = \frac{\partial^2 v}{\partial x^2}(\pi, t) = 0, \qquad t \in (0, \tau), \tag{3.4}$$

$$v(x, \tau) = 0, \quad v'(x, \tau) = g(x), \quad 0 < x < \pi. \tag{3.5}$$

The following lemma shows that the solution of (3.3)-(3.5) has a point regularity property that is essential for the proof of Theorem 3.1.

LEMMA 3.2. *For any $g \in Y_{-1}$ the initial and boundary value problem* (3.3)-(3.5) *admits a unique solution having the regularity*

$$v \in C([0, T], Y_1) \cap C^1([0, T], Y_{-1}). \tag{3.6}$$

Moreover, for any $\rho \in (0, \pi)$ the function $\frac{\partial v}{\partial x}(\rho, \cdot)$ is in $L^2(0, T)$ and there exists a constant $C > 0$ such that

$$\left\| \frac{\partial v}{\partial x}(\rho, \cdot) \right\|_{L^2(0,T)} \leq C \|g\|_{Y_{-1}}. \tag{3.7}$$

Proof. The existence and uniqueness of a solution having the regularity (3.6) are standard results for the Bernoulli-Euler equation. To prove (3.7) we put

$$g(x) = \sum_{n=1}^{\infty} n^2 a_n \sin(nx).$$

By density it is enough to show that (3.7) holds for $g \in C_0^\infty(\Omega)$. Obviously the solution of (3.3)-(3.5) is given by

$$v(x, t) = \sum_{n=1}^{\infty} a_n \sin(n^2 t) \sin(nx),$$

which implies that

$$\frac{\partial v}{\partial x}(\rho, t) = \sum_{n=1}^{\infty} n a_n \sin(n^2 t) \cos(n\rho). \tag{3.8}$$

If we consider the right-hand side of (3.8) as a Fourier series in t (see Theorem 4.1 in [7] for details) we obtain the existence of a constant C depending on T such that

$$\left\| \frac{\partial v}{\partial x}(\rho, \cdot) \right\|_{L^2(0,T)} \leq C \sum_{n=1}^{\infty} n^2 a_n^2 < \infty, \tag{3.9}$$

which is exactly (3.7). □

Remark 3.1. The result of Lemma 3.2 is optimal in the sense that one can easily find $g \in Y_{-1}$, $T > 0$, and $\rho \in (0, \pi)$ such that equality holds in (3.9). We also remark that another possible way by which to prove Lemma 3.2 is a multiplier technique, as used in [7] for the wave equation with point control.

Proof of Theorem 3.1. Due to the linearity of (1.1) and to well-known properties of the Bernoulli-Euler equation, it is enough to consider the case $w^0 = w^1 = 0$. Suppose again $g \in C_0^\infty(\Omega)$, and let v be the solution of (3.3)-(3.5). If we multiply (1.1) by v and integrate by parts we easily obtain

$$\int_0^\pi w(x, \tau) g(x) dx = -\int_0^\tau u(t) \left[\frac{\partial v}{\partial x}(\xi, t) - \frac{\partial v}{\partial x}(\eta, t) \right] dt. \tag{3.10}$$

Lemma 3.2 implies that

$$\left| \int_0^\tau u(t) \left[\frac{\partial v}{\partial x}(\xi, t) - \frac{\partial v}{\partial x}(\eta, t) \right] dt \right| \leq C \|u\|_{L^2(0,T)} \|g\|_{Y_{-1}},$$

so, by (3.10), we obtain that $w(\cdot, \tau) \in Y_1$, for all $\tau \in [0, T]$. By replacing τ by $\tau + h$ in (3.10) we easily get that

$$w \in C([0, T], Y_1), \tag{3.11}$$

which implies that

$$\frac{\partial^4 w}{\partial x^4} \in C([0, T], Y_{-3}). \tag{3.12}$$

As w satisfies satisfies (1.1), from (3.12) we obtain that

$$w'' \in L^2((0, T), Y_{-3}). \tag{3.13}$$

From (3.11) and (3.13), by applying the intermediate derivative theorem (cf. [15, p. 19]) it follows that

$$w' \in L^2((0, T), Y_{-1}). \tag{3.14}$$

The conclusion (3.2) is now a consequence of (3.11)-(3.14) and of the general lifting result from [12].

Remark 3.2. As by (3.10) the interior regularity of w is equivalent to a point regularity property, Remark 3.1 implies that the result in Theorem 3.1 is sharp.

4. The exact controllability results. In this section we shall study the space of initial data that are exactly L^2-controllable in (ξ, η) at time T. Let us put

$$\phi^0(x) = \sum_{n=1}^{\infty} a_n \sin(nx), \qquad \phi^1(x) = \sum_{n=1}^{\infty} n^2 b_n \sin(nx). \tag{4.1}$$

A simple calculation shows that the solution of (2.1)-(2.3) is given by

$$\phi(x, t) = \sum_{n \geq 1} [a_n \cos(n^2 t) \sin(nx) + b_n \sin(n^2 t) \sin(nx)],$$

which implies that

$$\begin{aligned} &\int_0^T \left[\frac{\partial \phi}{\partial x}(\xi, t) - \frac{\partial \phi}{\partial x}(\eta, t)\right]^2 dt \\ &= 4 \int_0^T \sum_{n \geq 1} [n a_n \cos(n^2 t) + n b_n \sin(n^2 t)]^2 \sin^2\left[\frac{n(\eta + \xi)}{2}\right] \sin^2\left[\frac{n(\eta - \xi)}{2}\right] dt. \end{aligned} \tag{4.2}$$

Relation (4.2) implies that (2.4) is false for any α if $\frac{\xi+\eta}{2}$ or $\frac{\eta-\xi}{2}$ is rational, and by Proposition 2.1 it follows that the condition

$$\frac{\xi + \eta}{2\pi}, \ \frac{\eta - \xi}{2\pi} \in \mathbf{R} - \mathbf{Q} \tag{4.3}$$

is necessary to have exact controllability of all initial states in $Y_{\alpha+2} \times Y_\alpha$. The following result shows that the condition above is not sufficient in the sense that there are ξ, η satisfying (4.3) that do not allow the control of arbitrary regular initial data. More precisely we have the following result.

PROPOSITION 4.1. *For any $\alpha > -2$ there exist $\xi,\ \eta \in (0, \pi)$ satisfying (4.3) such that the space $Y_{\alpha+2} \times Y_\alpha$ contains initial data that are not exactly L^2-controllable in (ξ, η) at time T, for any $T > 0$.*

Proof. By Proposition 2.1 it is enough to show that (2.4) is false for any $\alpha,\ c > 0$. Let us fix $\alpha > 0$ and $\nu > \frac{3\alpha+2}{2}$. We choose then

$$\frac{\xi + \eta}{2\pi} = \sum_{n=1}^{\infty} \frac{a_n}{10^{n!}}, \tag{4.4}$$

where $a_n \in \{0, 1, \ldots, 9\}$ for all $n \geq 1$, and a_n is not identically zero for great n. According to [17] the right-hand side of (4.4) is a Liouville number; i.e., it is transcendental and there exists a strictly increasing sequence of integers q_n such that

$$\left|\left|\left| q_n \frac{\xi + \eta}{2\pi} \right|\right|\right| \leq \frac{1}{q_n^\nu}, \quad \forall n \geq 1. \tag{4.5}$$

We note that

$$\left|\sin\left(q_n \frac{\xi + \eta}{2}\right)\right| = \left|\sin\left[\pi\left(q_n \frac{\xi + \eta}{2\pi} - p\right)\right]\right| \leq \pi \left|q_n \frac{\xi + \eta}{2\pi} - p\right|,$$

for any integer p. The relation above and (4.5) imply that

$$\left|\sin\left(q_n \frac{\xi + \eta}{2}\right)\right| \leq \frac{\pi}{q_n^\nu}, \quad \forall n \geq 1. \tag{4.6}$$

Now consider the sequence of initial data

$$\phi_n^0(x) = q_n^{\frac{3\alpha}{2}} \sin(q_n x), \quad \phi_n^1(x) = 0, \qquad \forall x \in (0, \pi). \tag{4.7}$$

A simple calculation shows that $\{\phi_n^0, \phi_n^1\} \in Y_{\alpha+2} \times Y_\alpha$, and

$$||\phi_n^0||_{Y_{-\alpha}}^2 + ||\phi_n^1||_{Y_{-\alpha-2}}^2 \to \infty, \quad \forall \alpha > 0. \tag{4.8}$$

Moreover the solution of (1.1)–(1.3) with the initial data given by (4.7) is

$$\phi_n(x, t) = q_n^{\frac{3\alpha}{2}} \cos(q_n^2 t) \sin(q_n x),$$

so, by (4.6) we have

$$\int_0^T \left[\frac{\partial \phi_n}{\partial x}(\xi, t) - \frac{\partial \phi_n}{\partial x}(\eta, t)\right]^2 dt \tag{4.9}$$

$$= 4q_n^{3\alpha+2} \sin^2\left[\frac{q_n(\eta + \xi)}{2}\right] \sin^2\left[\frac{q_n(\eta - \xi)}{2}\right] \int_0^T \cos^2(q_n^2 t) dt$$

$$\leq 4T q_n^{3\alpha+2} \sin^2\left[\frac{q_n(\eta + \xi)}{2}\right] \to 0, \quad \text{when } n \to \infty.$$

Relations (4.8) and (4.9) imply that (2.4) is false for any $\alpha > -2$ and $c > 0$. □

Remark 4.1. The estimates in Proposition 4.1 are not sharp. In fact, it seems likely that the methods developed in [10] can be used to prove the existence of $\xi,\ \eta$ satisfying (4.3) such that $\bigcap_{\alpha \geq 0} Y_{\alpha+2} \times Y_\alpha$ contains initial data that are not exactly L^2-controllable in (ξ, η) at

time T, for any $T > 0$. We also remark that, by standard duality arguments, condition (4.3) implies approximate controllability in $Y_{\alpha+2} \times Y_\alpha$.

Proposition 4.1 shows that to obtain exact controllability, we need assumptions stronger than the irrationality of $\frac{\xi+\eta}{2}$ and $\frac{\eta-\xi}{2}$. At this point we shall use the number theoretic preliminaries stated in the second section. A first result in this direction is as follows.

THEOREM 4.2. *Suppose that that $\frac{\xi+\eta}{2\pi}$ and $\frac{\eta-\xi}{2\pi}$ belong to the set A (introduced in the second section). Than all initial data in $Y_3 \times Y_1$ are exactly L^2-controllable in (ξ, η) at time T, for any $T > 0$.*

Proof. By Proposition 2.1 the conclusion of the theorem is equivalent to the existence of a constant $c > 0$ such that

$$\int_0^T \left[\frac{\partial \phi}{\partial x}(\xi, t) - \frac{\partial \phi}{\partial x}(\eta, t)\right]^2 dt \geq c(\|\phi^0\|^2_{Y_{-1}} + \|\phi^1\|^2_{Y_{-3}}) \tag{4.10}$$

for all

$$(\phi^0, \phi^1) \in Y_3 \times Y_1.$$

By applying the Ball-Slemrod generalization of Ingham's inequality (cf. [1], [8]), from (4) we obtain that there exists a constant $C > 0$ such that

$$\int_0^T \left[\frac{\partial \phi}{\partial x}(\xi, t) - \frac{\partial \phi}{\partial x}(\eta, t)\right]^2 dt \tag{4.11}$$

$$\geq C \sum_{n\geq 1} (n^2 a_n^2 + n^2 b_n^2) \sin^2\left[\frac{n(\eta+\xi)}{2}\right] \sin^2\left[\frac{n(\eta-\xi)}{2}\right] dt.$$

As $\frac{\xi+\eta}{2\pi}$ and $\frac{\xi-\eta}{2\pi}$ are in A, from (2.5) we see that there exists a constant $C > 0$ such that for n large enough we have

$$\left|\sin\left[\frac{n(\eta \pm \xi)}{2}\right]\right| = \left|\sin\left\{\pi\left[\frac{n(\eta \pm \xi)}{2\pi} - p\right]\right\}\right| \geq \left|\sin\left(\frac{\pi C}{n}\right)\right| \geq \frac{C}{n} \ \forall n \geq 1. \tag{4.12}$$

Inequalities (4.11) and (4.12) imply that

$$\int_0^T \left[\frac{\partial \phi}{\partial x}(\xi, t) - \frac{\partial \phi}{\partial x}(\eta, t)\right]^2 dt \geq c \sum_{n\geq 1} (n^{-2} a_n^2 + n^{-2} b_n^2),$$

which is exactly (4.10). □

The following result shows that, for almost all choices of the ends of the actuator, we have exact controllability in Sobolev spaces more regular than $Y_3 \times Y_1$.

THEOREM 4.3. *Suppose that $\epsilon > 0$ is arbitrary, and consider the set B introduced in Proposition 2.4. Then, for any ξ, $\eta \in (0, \pi)$ such that $\frac{\xi+\eta}{2\pi}$, $\frac{\xi-\eta}{2\pi} \in B$, all initial data in $Y_{3+\epsilon} \times Y_{1+\epsilon}$ are exactly L^2-controllable in (ξ, η) at time T for any $T > 0$.*

Proof. As $\frac{\xi+\eta}{2\pi}$, $\frac{\eta-\xi}{2\pi} \in B$, from (2.6) it follows that

$$\left|\sin\left[\frac{n(\eta+\xi)}{2}\right]\right| \geq \frac{C}{n^{1+\epsilon}}, \quad \left|\sin\left[\frac{n(\eta-\xi)}{2}\right]\right| \geq \frac{C}{n^{1+\epsilon}} \ \forall n \geq 1. \tag{4.13}$$

Consider again the solution ϕ of (2.1)-(2.3) with the initial data given by (4.1). By applying (4.2) and (4.13) we obtain

$$\int_0^T \left[\frac{\partial \phi}{\partial x}(\xi, t) - \frac{\partial \phi}{\partial x}(\eta, t)\right]^2 dt \geq c(\|\phi^0\|^2_{Y_{-1-\epsilon}} + \|\phi^1\|^2_{Y_{-3-\epsilon}})$$

for all

$$(\phi^0, \phi^1) \in Y_3 \times Y_1.$$

By Proposition 2.1 it follows that all initial data in $Y_{3+\epsilon} \times Y_{1+\epsilon}$ are exactly L^2-controllable in (ξ, η) at time T, for any $T > 0$. □

Let $y(x, t)$ be the solution of

$$y''(x,t) + \frac{\partial^4 y}{\partial x^4}(x,t) = h(t)\frac{d}{dx}[\delta_\eta(x) - \delta_\xi(x)], \qquad 0 < x < \pi,\ t > 0, \tag{4.14}$$

$$y(0,t) = y(\pi,t) = \frac{\partial^2 y}{\partial x^2}(0,t) = \frac{\partial^2 y}{\partial x^2}(\pi,t) = 0, \qquad t \geq 0, \tag{4.15}$$

$$y(x,0) = 0, \quad y'(x,0) = 0, \quad 0 < x < \pi. \tag{4.16}$$

By Theorem 3.1 we have

$$y \in C([0,T], Y_1) \cap C^1([0,T], Y_{-1}).$$

By reversing the sense of the time t in (1.1)-(1.3) we easily see that Theorems 4.2 and 4.3 imply that the space regularity $y(\cdot, T)$ and $y'(\cdot, T)$ is higher than that one obtains by simply using Theorem 3.1.

COROLLARY 4.4. *Suppose that y is the solution of* (4.14)-(4.16), *where $h \in L^2(0,T)$ and $\frac{\xi+\eta}{2\pi}$, $\frac{\eta-\xi}{2\pi}$ belong to the set A (respectively, to B). Then, for any $T > 0$, the application $h \to \{y(\cdot, T), y'(\cdot, T)\}$ maps $L^2(0,T)$ onto $Y_3 \times Y_1$ (respectively, onto $Y_{3+\epsilon} \times Y_{1+\epsilon}$, $\forall \epsilon > 0$).*

Theorems 4.2 and 4.3 give no information on the controllability of initial data in $Y_{\alpha+2} \times Y_\alpha$, with $\alpha < 1$. A partial answer is given by the following result.

PROPOSITION 4.5. *Suppose that $\epsilon > 0$. Then the set $Y_{2-\epsilon} \times Y_{-\epsilon}$ contains initial data that are not exactly L^2-controllable in (ξ, η) at time T, for any $T > 0$ and $\xi,\ \eta \in [0, \pi]$.*

Proof. By applying Proposition 2.3 we easily obtain the existence of a strictly increasing sequence of positive integers (q_n) such that

$$\left|\sin\left[\frac{q_n(\eta+\xi)}{2}\right]\right| \leq \frac{\pi}{\sqrt{q_n}}, \quad \left|\sin\left[\frac{q_n(\eta-\xi)}{2}\right]\right| \leq \frac{\pi}{\sqrt{q_n}}, \qquad \forall n \geq 1. \tag{4.17}$$

Consider now the sequence of initial data

$$\phi_n^0(x) = \sin(q_n x), \quad \phi_n^1(x) = 0 \quad \forall x \in (0, \pi).$$

We note that

$$\|\phi_n^0\|_{Y_\epsilon}^2 + \|\phi_n^1\|_{Y_{\epsilon-2}}^2 = q_n^{2\epsilon} \to \infty, \quad \text{when } n \to \infty \tag{4.18}$$

A simple calculation that gives the corresponding sequence of solutions of (2.1)-(2.3) is

$$\phi_n(x,t) = \cos(q_n^2 t)\sin(q_n x),$$

so by (4.17) we have

$$\int_0^T \left[\frac{\partial \phi_n}{\partial x}(\xi, t) - \frac{\partial \phi_n}{\partial x}(\eta, t)\right]^2 dt \tag{4.19}$$

$$= q_n^2 \sin^2\left[\frac{q_n(\eta+\xi)}{2}\right] \sin^2\left[\frac{q_n(\eta-\xi)}{2}\right] \int_0^T \cos^2(q_n^2 t)dt \leq K \quad \forall n \geq 1,$$

where K is a positive constant. In a similar manner we can show that (4.18) and (4.19) hold true for the sequence of initial data

$$\phi_n^0(x) = 0, \quad \phi_n^1(x) = q_n^2 \sin(q_n x) \quad \forall x \in (0, \pi),$$

so (2.4) is false for $\alpha = -\epsilon$ and arbitrary $c > 0$. □

Remark 4.2. The exact controllability of initial data in $Y_{\alpha+2} \times Y_\alpha$, with $0 \leq \alpha < 1$, seems an open question.

A DUALITY THEORY FOR SEPARATED CONTINUOUS LINEAR PROGRAMS *

MALCOLM C. PULLAN†

Abstract. This paper presents a detailed duality theory for a class of continuous linear programs called separated continuous linear programs (SCLP), based on a particular dual problem SCLP*. Using weak duality, a notion of complementary slackness is introduced, and several sufficient conditions for optimality of SCLP are derived along with the existence of complementary slack variables for basic feasible solutions for SCLP. Following this, a fairly general condition for the absence of a duality gap between SCLP and SCLP* is given, as are several conditions for the existence of an optimal solution for SCLP*. Finally, using all these ingredients, a strong duality result between SCLP and SCLP* is proven when the problem data are piecewise analytic. A simple counterexample is presented to show that strong duality may not follow if the assumptions of piecewise analyticity do not hold.

Key words. duality, continuous linear programming, linear optimal control

1. Introduction.

In 1953, Bellman [7] introduced a class of optimization problems which he called *bottleneck problems*. These problems have now become known as *continuous linear programs* because they can be formulated as linear programs having variables which are functions of time as follows:

$$\begin{aligned} \text{CLP:} \quad & \text{maximize} \quad \int_0^T c(t)^T x(t)\, dt \\ & \text{subject to} \quad B(t)x(t) + \int_0^t K(s,t)x(s)\, ds \le b(t), \\ & \qquad\qquad x(t) \ge 0, \qquad t \in [0,T], \end{aligned}$$

with $x(t)$, $c(t)$, and the elements of $B(t)$ and $K(s,t)$ being bounded measurable functions.

In this paper we will be considering the following subclass of CLP called *separated continuous linear programs*, first introduced by Anderson [1] in an attempt to model job-shop scheduling problems:

$$\begin{aligned} \text{SCLP:} \quad & \text{minimize} \quad \int_0^T c(t)^T x(t)\, dt \\ (1) \qquad & \text{subject to} \quad \int_0^t Gx(s)\, ds + y(t) = a(t), \\ (2) \qquad & \qquad\qquad Hx(t) + z(t) = b(t), \\ & \qquad\qquad x(t), y(t), z(t) \ge 0, \qquad t \in [0,T]. \end{aligned}$$

Here $x(t)$, $z(t)$, $b(t)$, and $c(t)$ are bounded measurable functions and $y(t)$ and $a(t)$ are absolutely continuous functions. The dimensions of $x(t)$, $y(t)$, and $z(t)$ are n_1, n_2, and n_3, respectively. Thus G is an $n_2 \times n_1$ matrix and H is an $n_3 \times n_1$ matrix. We let $\omega(t)$ denote a complete set of variables for SCLP, i.e., $\omega(t)^T = (x(t)^T, y(t)^T, z(t)^T)$. By differentiating the integral constraint (1) we can see that SCLP is a special type of linear optimal control problem with state positivity but without state feedback.

The usual way to solve CLP (or SCLP) is by discretization (see, for example, Buie and Abrham [10]); however, a number of authors have tried to solve this problem by extending

*Received by the editors October 25, 1993; accepted for publication (in revised form) January 10, 1995.

the simplex method for finite-dimensional linear programming. This was first attempted by Lehman [21] and extended by Drews [12], Hartberger [19], and Segers [35]. The most comprehensive, but a still incomplete, solution method based on the simplex method can be found in Perold [25], later followed up by Perold [26] and Anstreicher [5].

Now the success of the simplex method for finite-dimensional linear programming is due to the existence of a comprehensive duality theory. We can briefly summarise this as follows. A more comprehensive treatment of this may be found in any standard text on linear programming, e.g., Dantzig [11]. Consider the standard finite-dimensional linear program, FLP:

$$\begin{aligned} \text{FLP:} \quad & \text{minimize} && c^T x \\ & \text{subject to} && Ax = b, \\ & && x \geq 0, \end{aligned}$$

where A is an $m \times n$ matrix and $x \in \mathbb{R}^n$. Given FLP, we may define a corresponding finite-dimensional linear program called the *dual problem*, FLP*:

$$\begin{aligned} \text{FLP*:} \quad & \text{maximize} && b^T y \\ & \text{subject to} && A^T y \leq c. \end{aligned}$$

In this context, FLP is often called the *primal problem*. Now FLP and FLP* exhibit two important properties. The first is that if x is any feasible solution for FLP and y is any feasible solution for FLP*, then $b^T y \leq c^T x$ or, more concisely, $V[\text{FLP*}] \leq V[\text{FLP}]$. (Here and throughout the rest of this paper, we use the notation $V[\text{LP}]$ to denote the optimal value of a linear program LP, with the possibility that $V[\text{LP}] = \infty$ if LP is an infeasible minimization problem and $V[\text{LP}] = -\infty$ if LP is an infeasible maximization problem.) This result is known as *weak duality*. The second duality property is crucial to the simplex method, namely, that $V[\text{FLP*}] = V[\text{FLP}]$ (*no duality gap*) and if $V[\text{FLP}]$ is finite, then there exist optimal solutions for both FLP and FLP*. This result is known as *strong duality*.

Now as the concept of duality is at the heart of the simplex method for finite-dimensional linear programming, to extend this algorithm to CLP (or SCLP) it would be necessary to establish a similar duality theory for CLP (or SCLP). Indeed, this concern has been paramount in the development of the partial algorithms in Lehman [21], Drews [12], Hartberger [19], Segers [35], Perold [25], and Anstreicher [5] mentioned above. Moreover, because of this importance of duality results, many papers that deal solely with duality for CLP, and hence for SCLP, have appeared. In fact, the author of the problem CLP, Bellman, introduced in [8] the following dual problem for CLP:

$$\begin{aligned} \text{CLP*}': \quad & \text{minimize} && \int_0^T w(t)^T b(t)\, dt \\ & \text{subject to} && B(t)^T w(t) + \int_t^T K(s,t)^T w(s)\, ds \geq c(t), \\ & && w(t) \geq 0, \qquad t \in [0, T], \end{aligned}$$

where $w(t)$ is in the space of bounded measurable functions. Restricted to SCLP this gives

$$\begin{aligned} \text{SCLP*}': \quad & \text{maximize} && -\int_0^T a(t)^T u(t)\, dt - \int_0^T b(t)^T v(t)\, dt \\ & \text{subject to} && c(t) + \int_t^T G^T u(s)\, ds + H^T v(t) \geq 0, \\ & && u(t), v(t) \geq 0, \qquad t \in [0, T], \end{aligned}$$

with $u(t)$ and $v(t)$ in the space of bounded measurable functions. On introducing the problem, Bellman then readily established the weak duality result $V[\text{CLP}] \leq V[\text{CLP}^{*\prime}]$. The first strong duality results for CLP and CLP$^{*\prime}$ were given in Tyndall [36]. Among other things, the strong duality result required that $B, K, b \geq 0$. Consequently this result is not very useful for SCLP, as many instances of SCLP which are of practical importance (e.g., network problems) give rise to negative entries in G and a and hence also in K and b in the corresponding CLP.

However, Tyndall's work was soon extended by Levinson [23], Tyndall [37] and Grinold [14–16]. Grinold's results were more general than either Levinson's or Tyndall's; however, the problem still remained that many simple instances of CLP, such as network versions of SCLP, were not covered by the results. Using Grinold's results (in particular [15, Thm. 5, p. 42]), however, it is a trivial matter to establish the following result.

THEOREM 1.1 (no duality gap). *Suppose that* SCLP *is feasible and that H is of the form*

$$H = \begin{bmatrix} \bar{H} \\ I \end{bmatrix}.$$

Then SCLP *has an optimal solution and* $V[\text{SCLP}^{*\prime}] = V[\text{SCLP}]$ (*i.e., there is no duality gap between* SCLP *and* SCLP$^{*\prime}$).

Since the work of Grinold, numerous papers on duality for CLP have appeared. These include Schechter [34], Reiland [32], and Levine and Pomerol [22], to name a few; however, in many ways the results of Grinold remain the most general. It is perhaps not surprising that more general results have not been obtained because it is not difficult to construct counterexamples to possible duality results using the dual problem CLP$^{*\prime}$ (see, for example, Grinold [14]). This means that to establish more general strong duality results for CLP or SCLP it is necessary to consider a dual problem different from CLP$^{*\prime}$. This has been noted for a long time by authors trying to develop algorithms for the solution of CLP, e.g., Lehman [21]. In fact, the successive improvements of the algorithms for CLP mentioned above use more general dual problems by allowing δ-functionals in feasible solutions to the dual. Despite this, the need to consider more general dual problems has largely been ignored by authors studying duality for CLP. A notable exception to this, however, is Papageorgiou [24], who poses the dual problem (and the primal problem) in the space of functions of bounded variation.

There have been numerous works on duality theory for general linear programs, and a review of these may be found in Anderson and Nash [2]. The study of duality in the context of optimal control has also attracted many authors. Here it seems that it has been observed for a long time that dual problems such as CLP$^{*\prime}$ for CLP will not suffice. For instance, in Rockafellar [30], the author studied a class of convex optimal control problems and noted that strong duality theorems could be obtained by allowing dual variables to be of bounded variation. This work was later extended to more general problems in Hager and Mitter [18] and Hager [17].

On a more general note, duality theory for general optimization has been a subject of intense study, with a large number of texts and articles devoted solely to this. Two notable general contributions out of many are Rockafellar [31] and Borwein [9].

Now, in Pullan [28], the following dual problem for SCLP was introduced:

$$\begin{aligned} \text{SCLP}^*\text{:} \quad \text{maximize} \quad & -\int_0^T d\pi(t)^T a(t) - \int_0^T \eta(t)^T b(t)\, dt \\ \text{subject to} \quad & c(t) - G^T \pi(t) + H^T \eta(t) \geq 0, \\ & \eta(t) \geq 0, \text{ a.e. on } [0, T], \\ & \pi(t) \text{ monotonic increasing and right continuous} \\ & \text{on } [0, T] \text{ with } \pi(T) = 0, \end{aligned}$$

with the variables $\eta(t)$ Lebesgue-integrable functions on $[0, T]$ and where $\pi(t)$ monotonic increasing means that each component of $\pi(t)$ is monotonic increasing. Here the expression

$$\int_0^T d\pi(t)^T a(t)$$

is understood to be a Lebesgue-Stieltjes integral. We shall make frequent use of such integrals, and the reader is referred to Kolmogorov and Fomin [20] for its definition and important properties.

The dual problem SCLP* is readily seen to be a generalisation of SCLP*′ in that a feasible solution for SCLP*′ generates a feasible solution for SCLP* of the same cost, but not necessarily vice versa (see [28]). The following weak duality result was also established in [28].

LEMMA 1.2 (weak duality). $V[\text{SCLP*}] \leq V[\text{SCLP}]$.

Using this more general dual in [28], Pullan was able to establish a complete algorithm for solving SCLP when $c(t)$ and $a(t)$ were piecewise linear, with $a(t)$ continuous, and $b(t)$ was piecewise constant. As a corollary to the algorithm, the following strong duality result was also established.

THEOREM 1.3 (strong duality). *Suppose that $a(t)$ and $c(t)$ are piecewise linear (with $a(t)$ continuous) and $b(t)$ is piecewise constant on $[0, T]$. Suppose further that the feasible region for* SCLP *is nonempty and bounded; then $V[\text{SCLP}] = V[\text{SCLP*}]$ and there exist optimal solutions for both* SCLP *and* SCLP*.

In fact, although it was not stated in [28], the optimal solutions for SCLP and SCLP* could be chosen with $x(t)$ piecewise constant and with $\pi(t)$ and $\eta(t)$ piecewise linear.

The purpose of this paper is to continue the duality work for SCLP begun in Pullan [28], based on the dual problem SCLP*. In particular, we establish a strong duality result (Theorem 6.9) under the assumption of piecewise analyticity of the problem data. As with the above result, the optimal solutions in this strong duality result are also seen to be of a particularly simple form for both SCLP and SCLP*. A counterexample to a possible strong duality result is also given in §7 in the case when the assumptions of piecewise analyticity do not hold. As well as strong duality results, we also develop a duality theory in three other directions. This is both for its own sake and for its use in proving the strong duality results of §6.

The first of these is the concept of complementary slackness for SCLP (§3). This concept is based on the corresponding one for FLP, which has been extended in Anderson and Nash [2] to more general linear programs. Complementary slackness is a condition that holds at optimality, given that strong duality holds, and thus generates sufficient conditions for optimality of the problem in question. Using these ideas we thus develop several sufficient conditions for optimality of SCLP. Moreover, given mild assumptions on the costs, we show that it is possible to calculate a set of complementary slack variables for any (or at least any sufficiently well behaved) solution for SCLP that is an extreme point of the set of feasible solutions (i.e., a *basic feasible solution*). This is identical to what happens for FLP and forms an important step of the simplex method.

The second preliminary type of duality result we establish is a fairly general condition for the absence of a duality gap between SCLP and SCLP* (§4). Although not as useful as strong duality results, such results can often be used to prove convergence of possible algorithms. Having done this, we note that a fairly general condition also exists to guarantee the existence of an optimal solution for SCLP (Theorem 2.1). Hence, to establish general strong duality results it is necessary only to prove that SCLP* admits an optimal solution. This turns out to be quite difficult for general problem data unless severe restrictions are placed on the problem and in fact may not be true, as shown by Example 7.1. Nevertheless, two general results for

the existence of an optimal solution for SCLP* are established in §5. We conclude this section with a more cryptic result for the existence of an optimal solution for SCLP*. This last result is used in §6 to prove the strong duality.

Before beginning the analysis it is worth noting that the convex optimal control problem considered in Hager and Mitter [18] and Hager [17] can be seen to include SCLP by suitable transformations. Moreover, the Lagrangian dual problem considered in [18] and [17] can be simplified to SCLP*. Using the results in [18], it is possible to derive the following result.

THEOREM 1.4. *Suppose that $a(t)$ is absolutely continuous and that $b(t)$ and $c(t)$ are continuous. Suppose also that there exists a continuous feasible solution $\omega(t)$ for* SCLP *with $\omega_i(t) > 0$ for each i and $t \in [0, T]$. Then V[SCLP] $= V$[SCLP*] and there exists an optimal solution for* SCLP*.

Conditions similar to the existence of a strictly positive solution above are well known to ensure strong duality in various problems and are known as *Slater-type* conditions. However, it is also well known that such conditions often are difficult to verify or fail to hold in practice. As would be expected, by considering only a linear problem, we are able to obtain a much more complete duality theory.

For the purpose of slightly simplifying notation throughout this paper we will rewrite SCLP* in the following equivalent form, obtained by replacing $\eta(t)$ by $-\eta(t)$:

$$\begin{aligned} \text{SCLP*:}\quad & \text{maximize} && \int_0^T \eta(t)^T b(t)\,dt - \int_0^T d\pi(t)^T a(t) \\ (3)\qquad & \text{subject to} && c(t) - G^T\pi(t) - H^T\eta(t) \geq 0, \\ & && \eta(t) \leq 0, \text{ a.e. on } [0, T], \\ & && \pi(t) \text{ monotonic increasing and right continuous} \\ & && \text{on } [0, T] \text{ with } \pi(T) = 0. \end{aligned}$$

We let $\theta(t)$ denote a complete set of variables for SCLP*, i.e., $\theta(t)^T = (\pi(t)^T, \eta(t)^T)$. Also, given $\theta(t)$ we let $\psi(t)$ be the left-hand side of (3). Thus $\psi(t) = c(t) - G^T\pi(t) - H^T\eta(t)$.

We now begin the discussion by introducing some definitions and stating some previous results on SCLP that will be used throughout this paper.

2. Definitions and established results. In this section we introduce some standard definitions and state some previous results on SCLP that will be useful throughout this paper. We begin by introducing some standard notation.

For any $\zeta \in \mathbb{R}^n$, $\zeta \geq 0$, we use the notation

$$\operatorname{supp}(\zeta) = \{ i : \zeta_i > 0 \}$$

to denote the support of ζ.

Let $f : [a, b] \to \mathbb{R}^n$. We shall say that f is *analytic on a neighbourhood of* $[a, b]$ (or $[a, b)$) if there exists $\varepsilon > 0$ and an analytic function $g : (a - \varepsilon, b + \varepsilon) \to \mathbb{R}^n$ such that $f(t) = g(t)$ for all $t \in [a, b]$ (respectively, $[a, b)$). Let $P = \{t_0, t_1, \ldots, t_m\}$ be a partition of $[a, b]$. We say that f is *piecewise analytic on* $[a, b]$ *with breakpoints in* P, or simply, *piecewise analytic on* $[a, b]$, if $f(t)$ is analytic on a neighbourhood of $[t_{i-1}, t_i]$ for $i = 1, \ldots, m$. The smallest such partition P (excluding a and, if f is continuous at b, b) will be called the *breakpoints*. We use similar definitions for piecewise constant, linear, and polynomial. Finally we use the notations $f(t-)$ to denote $\lim_{s \uparrow t} f(s)$ and $f(t+)$ to denote $\lim_{s \downarrow t} f(s)$.

We shall make frequent use of the standard spaces $L_\infty[a, b]$ (bounded measurable functions on $[a, b]$), $L_1[a, b]$ (Lebesgue-integrable functions on $[a, b]$), $C[a, b]$ (continuous functions on $[a, b]$), and $NBV[a, b]$ (functions of bounded variation on $[a, b]$ normalised so that

they are right continuous on $(a, b]$ and have $f(b) = 0$). The way that functions of bounded variation are normalised in $NBV[a, b]$ is slightly nonstandard. We shall also use the notation $X^n[a, b]$ to denote the n-fold product of $X[a, b]$ with itself, where X is any one of L_∞, L_1, C, and NBV.

We shall also make occasional use of dual pairs of vector spaces (see Schaefer [33]). Let (X, Y) be a dual pair of spaces. We shall use the notation $\sigma(X, Y)$ to denote the weak topology on (X, Y).

Finally, by way of preliminary notation, it will be useful to define $F(\text{SCLP})$ to be the feasible region for SCLP, thus

$$F(\text{SCLP}) = \{x(t) \in L_\infty^{n_1}[0, T] : \text{there exists } y(t) \in C^{n_2}[0, T], z(t) \in L_\infty^{n_3}[0, T] \text{ such that } \omega(t)^T = (x(t)^T, y(t)^T, z(t)^T) \text{ is feasible for SCLP}\}.$$

We now summarise previous results relating to SCLP that will be useful in this paper. The first of these may be found in Anderson, Nash, and Perold [3]. As with finite-dimensional linear programming, we use the notation *basic feasible solution* for SCLP to denote an extreme point of the set of feasible solutions for SCLP.

THEOREM 2.1. *If the feasible region for* SCLP *is nonempty and bounded, then there exists an optimal solution for* SCLP *at a basic feasible solution.*

THEOREM 2.2. *A feasible solution, $\omega(t)$, for* SCLP *is basic if and only if the columns of*

$$K = \begin{bmatrix} G & I & 0 \\ H & 0 & I \end{bmatrix}$$

corresponding to the support of $\omega(t)$ are linearly independent for almost all $t \in [0, T]$.

Due to its use in the above theorem, the matrix K will play a significant role throughout this paper. We define K formally as well as some related properties.

DEFINITION 1. *We define*

$$K = \begin{bmatrix} G & I & 0 \\ H & 0 & I \end{bmatrix}.$$

1. *We let L be the number of basis matrices of K.*
2. *Let B be any matrix consisting of columns of K and $\gamma \in \mathbb{R}^{n_1+n_2+n_3}$. We use the notation γ_B to denote those elements of γ corresponding to the columns of K that are in B in the same order. Thus if K_i is the jth column of B, then γ_i is the jth element of γ_B.*

Let B be a basis matrix for K.

3. *Let $\omega(t)^T = (x(t)^T, y(t)^T, z(t)^T)$ be a set of variables for* SCLP. *We let $x_B(t)$ denote $\omega_B(t)$ restricted to $x(t)$. Thus $x_B(t)$ consists of the elements of $x(t)$ corresponding to those of the first n_1 columns of K that are also in B, arranged in the same order as the columns of B.*
4. *Let $\rho(t)$ be a solution to $B\rho(t) = d(t)$ for some $d(t)$ (that is, $\rho(t) = B^{-1}d(t)$). We use the notation $\rho_x(t)$ to denote the elements of $\rho(t)$ corresponding to those of the first n_1 columns of K that are also in B, arranged in the same order as the columns of B.*

In a recent paper [29], a study was made of the possible forms of optimal solutions for SCLP with various types of problem data. The main purpose of this paper was to establish conditions under which an optimal solution existed for SCLP for which $x(t)$ was either piecewise constant or piecewise analytic. We summarise these two main results below. It will be seen that these results coupled with the previous strong duality result (Theorem 1.3) provide

the key to establishing the strong duality results in §6. We first state a preliminary result proven in [29].

LEMMA 2.3. *Let $a(t)$ be any absolutely continuous function and $b(t)$, any bounded measurable function on $[0, T]$. Let $B^{(1)}, \ldots, B^{(L)}$ be the basis matrices for K and let*

$$\rho^{(i)}(t) = B^{(i)^{-1}} \begin{bmatrix} \dot{a}(t) \\ b(t) \end{bmatrix}.$$

Define $x^{(i)}(t)$ by $x^{(i)}_{B^{(i)}}(t) = \rho^{(i)}_x(t)$ with the other components of $x^{(i)}(t)$ set to zero. Let $\omega(t)$ be any basic feasible solution for SCLP; *then for almost all $t \in [0, T]$, $x(t) = x^{(i_t)}(t)$ for some i_t.*

THEOREM 2.4. *Suppose that $a(t)$ is piecewise linear and continuous, $b(t)$ is piecewise constant, and $c(t)$ is piecewise analytic on $[0, T]$. Suppose also that the feasible region for* SCLP *is nonempty and bounded. Then there exists an optimal basic feasible solution for* SCLP *with $x(t)$ piecewise constant on $[0, T]$. Moreover, let $x^{(1)}, \ldots, x^{(L)}$ be given by Lemma 2.3, where L is the number of basis matrices for K, and $P = \{t_0, t_1, \ldots, t_n\}$ be any partition of $[0, T]$ containing the breakpoints of $a(t)$, $b(t)$, and $c(t)$ and with $\dot{c}(t)^T x^{(i)} = \dot{c}(t)^T x^{(j)}$ for all $t \in (t_{m-1}, t_m)$ or $\dot{c}(t)^T x^{(i)} \neq \dot{c}(t)^T x^{(j)}$ for all $t \in (t_{m-1}, t_m)$, for each $i \neq j$ and each m. Then such $x(t)$ may be chosen so that for all m, the maximum number of breakpoints of $x(t)$ in $[t_{m-1}, t_m)$ is L.*

THEOREM 2.5. *Suppose that the costs $c(t)$ and right-hand sides $a(t)$ and $b(t)$ are piecewise analytic on $[0, T]$ (but with $a(t)$ continuous) and that the feasible region for* SCLP *is nonempty and bounded. Then there exists an optimal basic feasible solution for* SCLP *with $x(t)$ piecewise analytic on $[0, T]$.*

3. Complementary slackness results. Consider the finite-dimensional linear program FLP. The statement that strong duality holds between FLP and FLP* can be equivalently written as follows. There exists x feasible for FLP and y feasible for FLP* such that

$$x^T(c - A^T y) = 0, \tag{4}$$

i.e., x and y are *complementary slack*. This statement forms the basis of the simplex method for finite-dimensional linear programming in the following way. Suppose we have a basic feasible solution x for FLP. The next step in the simplex method is to calculate complementary slack variables for this basic feasible solution and test for optimality. In other words, we calculate a set of variables y satisfying (4) and optimality occurs if y is dual feasible.

In this section we mimic these ideas for SCLP. We will define the concept of complementary slackness in an analogous way and show that complementary slack variables can be calculated for any given basic feasible solution for SCLP, given that it and the costs satisfy some mild assumptions. The calculation of complementary slack variables for FLP amounts to solving a system of linear equations involving the costs and a basis matrix. We will see that a similar method applies for SCLP. As strong duality need not necessarily hold between SCLP and SCLP*, the following complementary slackness results can also be seen as sufficient, but not necessary, conditions for optimality.

The basis of our discussion is the following complementary slackness result based on the weak duality result between SCLP and SCLP* proven in Pullan [28].

LEMMA 3.1. *If ω is feasible for* SCLP, *θ is feasible for* SCLP* *and*

$$\int_0^T \psi(t)^T x(t)\, dt = \int_0^T d\pi(t)^T y(t) = \int_0^T \eta(t)^T z(t)\, dt = 0, \tag{5}$$

(where $\psi(t) = c(t) - G^T\pi(t) - H^T\eta(t)$), then ω and θ are optimal for SCLP *and* SCLP*, *respectively. Moreover, strong duality holds between* SCLP *and* SCLP* *if and only if there exists ω feasible for* SCLP *and θ feasible for* SCLP* *such that* (5) *holds.*

Proof. Suppose that ω is feasible for SCLP, θ is feasible for SCLP*, and (5) holds. Then

$$\begin{aligned}
0 &= \int_0^T \psi(t)^T x(t)\,dt + \int_0^T d\pi(t)^T y(t) - \int_0^T \eta(t)^T z(t)\,dt \\
&= \int_0^T c(t)^T x(t)\,dt - \int_0^T \left(G^T\pi(t) + H^T\eta(t)\right)^T x(t)\,dt + \int_0^T d\pi(t)^T y(t) \\
&\quad - \int_0^T \eta(t)^T z(t)\,dt \\
&= \int_0^T c(t)^T x(t)\,dt + \int_0^T d\pi(t)^T \left(\int_0^t Gx(s)\,ds + y(t)\right) - \int_0^T \eta(t)^T (Hx(t) + z(t))\,dt \\
&= \int_0^T c(t)^T x(t)\,dt - \int_0^T \eta(t)^T b(t)\,dt + \int_0^T d\pi(t)^T a(t)
\end{aligned}$$

by integrating by parts (see, for example, Dunford and Schwartz [13, p. 154]) and the feasibility of $\omega(t)$. The first statement of the lemma now follows by weak duality (Lemma 1.2). By reversing this argument we obtain the second statement. □

It would seem that the equation for SCLP corresponding to (4) for FLP is (5). Indeed, it is possible to show that the above result is exactly the restriction to SCLP of the complementary slackness result for general linear programs given by Anderson and Nash [2]. However, the equations (5) by themselves are not easily solved. If, however, feasibility of ω in SCLP and θ in SCLP* is also assumed, then the integrals in (5) may be simplified. With this in mind we now proceed to simplify (5) before defining the notion of complementary slackness. The more difficult expression to simplify is

$$\int_0^T d\pi(t)^T y(t) = 0. \tag{6}$$

To solve this we need to digress briefly and consider the concept of a function increasing at a point.

DEFINITION 2. *Let $f : [a, b] \to \mathbb{R}$ be a monotonic increasing function and $t \in (a, b)$. We say that f is* strictly increasing *at t if for any t_1, $t_2 \in [a, b]$ with $t \in (t_1, t_2)$ we have $f(t_1) < f(t_2)$. For the definition of strictly increasing at $t = a$ or $t = b$ we use the intervals $[a, t_2)$ and $(t_1, b]$, respectively, in place of (t_1, t_2).*

We now derive some useful results based on this definition. It is worth noting the converse of the above definition explicitly, namely, if f is monotonic increasing but *not* strictly increasing at t, then there exists t_1 and t_2 with $t \in (t_1, t_2)$ and $f(t_1) = f(t_2)$; i.e., f is constant on some interval containing t. This statement forms the basis for our next lemma.

LEMMA 3.2. *Suppose $f : [a, b] \to \mathbb{R}$ is monotonic increasing on $[a, b]$. Suppose there is an open interval $(\alpha, \beta) \subseteq [a, b]$ such that f is* not *strictly increasing at any point of (α, β); then f is constant on (α, β).*

Proof. Let $x, y \in (\alpha, \beta)$. Assume $x < y$. Consider the interval $[x, y]$. For any $t \in [x, y]$, f is not strictly increasing at t, so by the remark above, there exists an open interval containing t on which f is constant. By the Heine–Borel theorem (see, for example, Apostol [6]), a finite number of these intervals cover $[x, y]$, and as these intervals are not pairwise disjoint, we see that f is constant on $[x, y]$. In particular $f(x) = f(y)$, and so, as x and y were arbitrary, f is constant on (α, β). □

In most cases f strictly increasing at a point t will imply that either f is discontinuous at t or f is strictly increasing on some interval containing t. In particular, this will be true if f is analytic on some interval containing t (see Pullan [27, Cor. D.2.1]). However, there do exist continuous monotonic increasing functions that have points where they are strictly increasing but which are not strictly increasing on any interval (see [27, Ex. D.1]).

The next result is the main result that will be used concerning the concept of strictly increasing at a point. It is this result that allows us to unpack (6) to give a more satisfactory definition of complementary slackness for SCLP.

LEMMA 3.3. *Let $f : [a, b] \to \mathbb{R}$ be monotonic increasing and $g : [a, b] \to [0, \infty)$ be continuous. Suppose that f is strictly increasing at $t \in [a, b]$ and*

$$\int_a^b g(s)\, df(s) = 0; \tag{7}$$

then $g(t) = 0$. Conversely, if $g(t) = 0$ for every point t at which f is strictly increasing, then (7) holds.

Proof. Suppose that f is monotonic increasing, g is nonnegative on $[a, b]$, and (7) holds. Suppose also that f is strictly increasing for some t but $g(t) > 0$. Then, as g is continuous, there exists an interval I such that $t \in I$ and $g(s) > 0$ for all $s \in I$. Hence, as f is strictly increasing at t,

$$\int_I g(s)\, df(s) > 0.$$

However, as $g(s) \geq 0$ for all $s \in [a, b]$, we have

$$\int_a^b g(s)\, df(s) > 0,$$

which is not possible, so we must have $g(t) = 0$.

Now suppose that $g(t) = 0$ at every point t at which f is strictly increasing. Let $S = \{t : g(t) > 0\}$, then f is not strictly increasing at any point of S. Suppose $S = \bigcup_{n=1}^{N} (\alpha_n, \beta_n)$, $(N \leq \infty)$, where $(\alpha_n, \beta_n) \cap (\alpha_m, \beta_m) = \emptyset$ if $m \neq n$. Then by Lemma 3.2, f is constant on (α_n, β_n). Hence

$$\int_S g(t)\, df(t) = \sum_{n=1}^{N} \int_{(\alpha_n, \beta_n)} g(t)\, df(t) = 0.$$

If either $g(a) > 0$ or $g(b) > 0$, then a similar argument will give that f is constant on some interval containing a if $g(a) > 0$, or b if $g(b) > 0$. Hence

$$\int_{\{a,b\}} g(t)\, df(t) = 0.$$

Finally, $g(t) = 0$ on $(a, b) - S$ and so the result follows. □

We now define the notation of complementary slackness for SCLP.

DEFINITION 3 (complementary slackness). *Let ω be a feasible solution for* SCLP. *We say that $\theta \in NBV^{n_2}[0, T] \times L_1^{n_3}[0, T]$ is* complementary slack with ω *if π is right continuous at zero, and for any α, β, and i,*

1. *if $y_i(t) > 0$ on (α, β), then π_i is constant on $[\alpha, \beta)$;*
2. *if $y_i(T) > 0$, then $\pi_i(T-) = \pi_i(T) = 0$;*
3. *$\psi_i(t) = 0$ a.e. on $\{t : x_i(t) > 0\}$;*
4. *$\eta_i(t) = 0$ a.e. on $\{t : z_i(t) > 0\}$.*

It is worth noting that if θ is also feasible for SCLP*, each of the conditions for complementary slackness has a corresponding contrapositive. For instance, condition (1) can be written equivalently as follows: if π_i is strictly increasing at t, then $y_i(t) = 0$.

Given this definition, we may now write the complementary slackness result, Lemma 3.1 in an analogous manner to that for FLP.

THEOREM 3.4 (complementary slackness). *Suppose that ω is feasible for* SCLP *and that θ is complementary slack with ω. If θ is feasible for* SCLP*, then ω is optimal for* SCLP *and θ is optimal for* SCLP*. Moreover, strong duality holds between* SCLP *and* SCLP* *if and only if there exists ω feasible for* SCLP *and θ feasible for* SCLP* *such that θ is complementary slack with ω.*

Proof. Suppose that strong duality holds between SCLP and SCLP*. Then by Lemma 3.1 there exists ω feasible for SCLP and θ feasible for SCLP* such that

$$\int_0^T \psi(t)^T x(t)\,dt = \int_0^T d\pi(t)^T y(t) = \int_0^T \eta(t)^T z(t)\,dt = 0.$$

Clearly we have $\psi_i(t) = 0$ a.e. on $\{t : x_i(t) > 0\}$ and $\eta_i(t) = 0$ a.e. on $\{t : z_i(t) < 0\}$ for each i. Suppose that $y_i(t) > 0$ on (α, β). Then by Lemma 3.3, π_i is *not* strictly increasing on any point of (α, β). Hence by Lemma 3.2 and as π is right continuous, π_i is constant on $[\alpha, \beta)$. Similarly if $y_i(T) > 0$, then $\pi_i(T-) = \pi_i(T) = 0$. Hence θ is complementary slack with ω.

This establishes the result one way. The proof of the converse is similar. □

Having defined complementary slackness, there still remains the question of how such complementary slack variables should be calculated and, more importantly, if they exist at all. In the finite-dimensional linear program their existence is guaranteed for *basic* feasible solutions. We see that this is essentially true for SCLP as well, in the sense that a θ can be defined satisfying points 1–4 of the definition. This is the content of the next result. However, there is one slight technicality, and that is in ensuring that this θ is in the appropriate space. As the result below shows, this will be true for sufficiently well-behaved costs and a basic feasible solution with sufficiently well-behaved support over time. For example, right continuous costs of bounded variation and a piecewise continuous basic feasible solution would suffice.

THEOREM 3.5. *Let ω be a basic feasible solution for* SCLP *with $B(t)$ the columns of K corresponding to the support of $\omega(t)$. Let $\zeta \in L_\infty^{n_2}[0, T]$ be any arbitrary function such that if $y_j(t) > 0$ on $(\alpha, \beta) \cap [0, T]$ for some α, β, and j, then ζ_j is constant on $[\alpha, \beta) \cap [0, T]$. Let θ be any solution of*

$$\theta(t)^T B(t) = \bar{c}_B(t)^T \tag{8}$$

for almost all $t \in [0, T)$, where

$$\bar{c}(t) = \begin{bmatrix} c(t) \\ \zeta(t) \\ 0 \end{bmatrix}$$

(where 0 is of dimension n_3), with $\pi(t) = \pi(t+)$ for t such that (8) *does not have a solution, if the limit exists, and $\pi(T) = 0$. If this θ is an element of $NBV^{n_2}[0, T] \times L_1^{n_3}[0, T]$, then it is complementary slack with ω. Conversely, any θ complementary slack with ω satisfies* (8) *for some $\zeta(t)$ for almost all $t \in [0, T]$.*

Proof. Let $\zeta(t) : [0, T] \to \mathbb{R}^{n_2}$ be any arbitrary function satisfying ζ_j constant on $[\alpha, \beta)$ if $y_j(t) > 0$ on (α, β). Let $\bar{c}$ be as above. From Theorem 2.2 there exists a solution $\theta(t)$ (although not necessarily unique unless $B(t)$ is square) to (8) for almost all $t \in [0, T]$. To

show that any solution $\theta \in NBV^{n_2}[0, T] \times L_1^{n_3}[0, T]$ is complementary slack with ω we unpack (8) into the three equivalent separate equations to give

$$\left(\pi(t)^T G + \eta(t)^T H\right)_i = c_i(t), \tag{9}$$

$$\pi_j(t) = \zeta_j(t), \tag{10}$$

$$\eta_k(t) = 0. \tag{11}$$

for those indices i, j, and k which correspond to the columns of $B(t)$ (i.e., i such that K_i is in $B(t)$, j such that K_{n_1+j} is in $B(t)$, and k such that $K_{n_1+n_2+k}$ is in $B(t)$). Consider the conditions of Definition 3 in turn.

1. If $y_j(t) > 0$ on (α, β), then by definition of $\zeta(t)$, $\zeta_j(t)$ is constant on $[\alpha, \beta)$. Hence π_j is constant a.e. on $[\alpha, \beta)$ by (10) and hence everywhere as π is right continuous.
2. If $y_j(T) > 0$, then by a similar argument to the above, we have $\pi_j(T-) = \pi_j(T) = 0$.
3. If $x_i(t) > 0$ on a set S, then for almost all $t \in S$ we have by (9)

$$\left(c(t) - G^T \pi(t) - H^T \eta(t)\right)_i = 0,$$

   i.e., $\psi_i(t) = 0$ a.e. on S.
4. If $z_i(t) > 0$ on a set S, then for almost all $t \in S$ we have by (11) that $\eta_i(t) = 0$.

This establishes the result in one direction and the proof of the converse is similar. □

It should be noted that the construction of the complementary slack variables is by no means unique. Even if (8) has a unique solution, in general there will be a countable number of undetermined constants, one for each interval on which $y_j(t) > 0$ for some j. A similar problem frequently occurs in finite-dimensional linear programming. In this case, when there is an arbitrary manner in which to calculate the complementary slack variables, the basic feasible solution is called *degenerate*.

It is worth noting that problems of degeneracy in an infinite-dimensional context have been a major stumbling block in the development of general CLP algorithms. For instance, in Perold [25, 26], the author attempted to give a general pivot operation for CLP. However, the pivot operation only worked under some nondegeneracy assumptions. Similarly in Anderson [1], an initial attempt was made at developing an algorithm for SCLP with the same restrictions on a, b, and c as those considered in Pullan [28] (see §1). Here again, the method failed to work in general due to degeneracy problems. The first algorithm to overcome the degeneracy problem was that for CNP, the single-commodity network version of SCLP given in Anderson and Philpott [4] (under the same assumptions on a, b, and c as those for SCLP in both [1] and [28]). Here the authors encountered and distinguished between the two types of degeneracy we have encountered for SCLP, namely, the possibility of not solving the complementary slackness equations uniquely and, second, of determining the constants associated with the intervals where $y_j(t) > 0$ for some j. The resulting algorithm, however, was very complicated, and great care was needed in the specification of how to handle degeneracy. The success of the more recent algorithm in Pullan [28] for SCLP is due to the fact that for the particular a, b, and c chosen, it is possible to handle the problems of degeneracy by the ordinary simplex method for FLP.

The problems of degeneracy will play a significant role in the development of strong duality results for SCLP. In §6 we will look again at degeneracy and give a concrete definition for a particular SCLP problem to be degenerate for piecewise analytic a and b (Definition 4). We will see, however, that the only type of degeneracy that need concern us here is the possibility of not solving (8) uniquely. In fact, in the absence of such degeneracy, the strong duality results of §6 become much easier. This is not surprising because strong duality is relatively simple to establish between FLP and FLP* in the case where there is no degeneracy present.

Even in general linear programming, the absence of degeneracy, appropriately defined, allows a strong duality result for a general dual problem to be established with ease (see Anderson and Nash [2, Thm. 2.10]).

4. Conditions for the absence of a duality gap. We now consider sufficient conditions to ensure that there is no duality gap between SCLP and SCLP*, i.e., $V[\text{SCLP}] = V[\text{SCLP*}]$. As well as being interesting in its own right, such a result is one of the necessary conditions for strong duality. The main result of this section is Theorem 4.2. The result here is quite general, and so for most practical instances of SCLP we may deduce that there is no duality gap between SCLP and SCLP*. We begin by establishing an important property of $F(\text{SCLP})$, the feasible region for SCLP.

LEMMA 4.1. *The set* $F(\text{SCLP})$ *is closed in the* $\sigma(L_\infty^{n_1}[0, T], L_1^{n_1}[0, T])$ *topology.*

Proof. Suppose $x \notin F$. There are three cases to consider, depending on which constraint is violated. If $x_i(t) < 0$ on some set S of nonzero measure for some i, then define $f \in L_1^{n_1}[0, T]$ by

$$f_j = \begin{cases} 0, & j \neq i, \\ \chi_S, & j = i, \end{cases} \tag{12}$$

where χ_S is the characteristic function of S. Then

$$\int_0^T f(t)^T x(t)\, dt < 0,$$

but for any $\alpha \in F$,

$$\int_0^T f(t)^T \alpha(t)\, dt \geq 0,$$

and so x is contained in some weakly open set that does not intersect with F.

Now suppose that

$$\int_0^t [Gx(s)]_i\, ds > a_i(t)$$

for some index i and $t \in [0, T]$. By the continuity of both the integral and a, this will be true for all t in some open interval $S = (t_1, t_2)$, with equality at the point t_1. Define $f \in L_1^{n_2}[0, T]$ by (12) and set $g = G^T f$. Then

$$\int_0^T g(t)^T x(t)\, dt > \int_S a_i(t)\, dt,$$

and for any $\alpha \in F$,

$$\int_0^T g(t)^T \alpha(t)\, dt \leq \int_S a_i(t)\, dt,$$

so x is again contained in some weakly open set that does not intersect with F.

The remaining case, namely, $[Hx(t)]_i > b_i(t)$ on some set S of nonzero measure for some i, is similar. □

We now prove the main result for the absence of a duality gap between SCLP and SCLP*. The proof involves considering a sequence of linear programs whose optimal values converge to that of SCLP and by using properties of the weak topology.

THEOREM 4.2 (no duality gap). *Suppose that $a(t)$ is absolutely continuous on $[0, T]$ with Riemann-integrable derivative. Suppose also that $c(t)$ and $b(t)$ are Riemann-integrable and that the feasible region for* SCLP *is nonempty. If, furthermore, there exist a continuous piecewise linear function $\bar{a}(t)$ and a piecewise constant function $\bar{b}(t)$ such that $a(t) \leq \bar{a}(t)$ and $b(t) \leq \bar{b}(t)$ on $[0, T]$ and such that the feasible region for the problem* SCLP *with $a(t)$ and $b(t)$ replaced by $\bar{a}(t)$ and $\bar{b}(t)$, respectively, is bounded, then*

$$V[\text{SCLP}] = V[\text{SCLP*}];$$

i.e., there is no duality gap between SCLP *and* SCLP*.

Proof. Let $\{b^{(n)}\}_{n=1}^{\infty}$ and $\{c^{(n)}\}_{n=1}^{\infty}$ be sequences of piecewise constant functions such that $b^{(n)}(t) \leq \bar{b}(t)$, $b^{(n)}(t) \downarrow b(t)$, and $c^{(n)}(t) \uparrow c(t)$ a.e. on $[0, T]$ (see Apostol [6, Thm. 10.11]). By considering a sequence $r^{(n)}(t) \downarrow \dot{a}(t)$ we may also construct a sequence of continuous piecewise linear functions $\{a^{(n)}\}_{n=1}^{\infty}$ such that $a^{(n)}(t) \leq \bar{a}(t)$ and $a^{(n)}(t) \downarrow a(t)$ uniformly on $[0, T]$. Let SCLP_n be the SCLP problem with $a(t)$, $b(t)$, and $c(t)$ replaced by $a^{(n)}(t)$, $b^{(n)}(t)$, and $c^{(n)}(t)$, respectively. Let $F_n = F(\text{SCLP}_n)$ and $F = F(\text{SCLP})$. As $\{a^{(n)}\}_{n=1}^{\infty}$ and $\{b^{(n)}\}_{n=1}^{\infty}$ are monotonic sequences converging to a in $C^{n_2}[0, T]$ and b in $L_{\infty}^{n_3}[0, T]$, respectively, it is not difficult to see that

$$F_{n+1} \subseteq F_n$$

for all n and

$$F = \bigcap_{n=1}^{\infty} F_n.$$

Now by the boundedness assumption, it follows that F_n, for each n, and F are bounded. Moreover F_n, for each n, and F are closed in the $\sigma(L_{\infty}^{n_1}[0, T], L_1^{n_1}[0, T])$ topology by Lemma 4.1.

Let $x^{(n)}(t)$ be an optimal solution for SCLP_n (i.e., the x part of the optimal $\omega^{(n)}(t)$, the existence of which is given by Theorem 2.1). We now construct a subsequence $\{x_{n_k}\}_{k=1}^{\infty}$ and $x \in F$ such that $x_{n_k} \to x$ in the $\sigma(L_{\infty}^{n_1}[0, T], L_1^{n_1}[0, T])$ topology.

To achieve this we recall a result from functional analysis which states that if X is a separable normed linear space (that is, has a countable dense subset), then any norm-bounded sequence in X^* (the dual of X) has a subsequence that converges in the $\sigma(X^*, X)$ topology to an element of X^* (see, for example, Kolmogorov and Fomin [20, Thm. 4, p. 202]). Now it is well known that $L_1[0, T]$, and hence $L_1^{n_1}[0, T]$, is a separable space (see again [20, Thm. 3, p. 382]). Hence, as $L_1^{n_1}[0, T]^* = L_{\infty}^{n_1}[0, T]$, there exists a subsequence, $\{x_{n_k}\}_{k=1}^{\infty}$, of $\{x_n\}_{n=1}^{\infty}$ and $x \in L_{\infty}^{n_1}[a, b]$ such that $x_{n_k} \to x$ in the $\sigma(L_{\infty}^{n_1}[0, T], L_1^{n_1}[0, T])$ topology. Let k be given, and consider the sequence $\{x_{n_l}\}_{l=k}^{\infty} \subseteq F_{n_k}$. This sequence converges to x, and so as F_{n_k} is closed, we have $x \in F_{n_k}$. As k was arbitrary and $F = \bigcap_{n=1}^{\infty} F_n$, $x \in F$. It will be seen in fact that x is optimal for SCLP.

From the construction above we now have $x \in F$ and

$$\lim_{k \to \infty} \int_0^T d(t)^T x^{(n_k)}(t)\, dt = \int_0^T d(t)^T x(t)\, dt$$

for any $d \in L_1^{n_1}[0, T]$. Hence

$$\lim_{k \to \infty} \int_0^T c^{(m)}(t)^T x^{(n_k)}(t)\, dt = \int_0^T c^{(m)}(t)^T x(t)\, dt$$

for any m. Also by Lebesgue's dominated convergence theorem we have

$$\lim_{m \to \infty} \int_0^T c^{(m)}(t)^T x(t)\, dt = \int_0^T c(t)^T x(t)\, dt.$$

Thus, as $c^{(m)}(t) \uparrow c(t)$ a.e. on $[0, T]$, we have

$$\lim_{k\to\infty} \int_0^T c^{(n_k)}(t)^T x^{(n_k)}(t)\, dt = \int_0^T c(t)^T x(t)\, dt. \tag{13}$$

Now by the strong duality result from Pullan [28, Thm. 1.3], there exists $\theta^{(n)}(t)$ feasible for SCLP_n^* such that

$$\int_0^T c^{(n)}(t)^T x^{(n)}(t)\, dt = \int_0^T \eta^{(n)}(t)^T b^{(n)}(t)\, dt - \int_0^T d\pi^{(n)}(t)^T a^{(n)}(t).$$

But $a^{(n)}(t) \geq a(t)$ and $b^{(n)}(t) \geq b(t)$ a.e. on $[0, T]$. Hence

$$\int_0^T c^{(n)}(t)^T x^{(n)}(t)\, dt \leq \int_0^T \eta^{(n)}(t)^T b(t)\, dt - \int_0^T d\pi^{(n)}(t)^T a(t). \tag{14}$$

Now $c^{(n)}(t) \leq c(t)$ a.e. on $[0, T]$ and hence

$$\begin{aligned} c(t) - G^T\pi^{(n)}(t) - H^T\eta^{(n)}(t) &\geq c^{(n)}(t) - G^T\pi^{(n)}(t) - H^T\eta^{(n)}(t) \\ &\geq 0 \end{aligned}$$

a.e. on $[0, T]$ by the feasibility of $\theta^{(n)}$ in SCLP_n^*. Thus $\theta^{(n)}(t)$ is feasible for SCLP*. Hence by weak duality (Lemma 1.2),

$$\int_0^T \eta^{(n)}(t)^T b(t)\, dt - \int_0^T d\pi^{(n)}(t)^T a(t) \leq \int_0^T c(t)^T x(t)\, dt.$$

Combining this with (13) and (14) above we have

$$\lim_{k\to\infty} \left[\int_0^T \eta^{(n_k)}(t)^T b(t)\, dt - \int_0^T d\pi^{(n_k)}(t)^T a(t) \right] = \int_0^T c(t)^T x(t)\, dt,$$

and so the result follows. □

We note that while the boundedness conditions of Theorem 4.2 may look complicated, it is not difficult to show that they will be satisfied if the set $\{\xi : H\xi \leq b(t),\ \xi \geq 0\}$ is bounded for each $t \in [0, T]$. As noted in Pullan [27], this is not that different in practice from insisting that the feasible region be bounded. It is worth noting that the H of Grinold's result in Theorem 1.1 satisfies the condition $\{\xi : H\xi \leq b(t),\ \xi \geq 0\}$ bounded for each $t \in [0, T]$ and $b \in L_\infty^{n_3}[0, T]$.

5. Conditions for the existence of optimal solutions for SCLP*. We now present two general results that establish the existence of an optimal solution for SCLP* and a third, less general result. The first two general results are relatively easy to prove but are not very useful in practice as they tend to be rather restrictive. It is the third result that will be used to prove strong duality in the next section by using the result for the absence of a duality gap (Theorem 4.2) and the result for the existence of a piecewise analytic optimal solution for SCLP (Theorem 2.5).

The first result shows that SCLP* has an optimal solution if its feasible region is a bounded subset of $L_\infty^{n_2+n_3}[0, T]$. As this result is easy to prove and does not form part of the development of the strong duality results in §6, we give only an outline of its proof. To use this result to ensure strong duality, we would need to guarantee the existence of an optimal solution for SCLP. The most readily available condition for this is that the feasible region for SCLP is also

bounded (Theorem 2.1). However, it can be shown (see Pullan [27]), that both the feasible regions for SCLP and SCLP* bounded in the appropriate sense can be very restrictive and thus not a very practical condition to impose on the problem. Note that we make the distinction that the feasible region of SCLP* is a bounded subset of $L_\infty^{n_2+n_3}[0, T]$, because in general, $\eta \in L_1^{n_3}[0, T]$.

THEOREM 5.1. *Suppose that the feasible region of* SCLP* *is a nonempty and bounded subset of* $L_\infty^{n_2+n_3}[0, T]$. *Then there exists an optimal solution for* SCLP*.

Proof. For an explicit proof see Pullan [27]. It involves showing that in this case the feasible region is closed in an appropriate weak topology. The proof is then made complete by using Alaoglu's theorem for weak compactness (see, for example, Dunford and Schwartz [13]). □

The next general result shows that if there exists a sequence of feasible solutions for SCLP* that are of uniformly bounded variation and whose objective function values converge to the optimal value, then SCLP* attains its optimal value.

THEOREM 5.2. *Suppose that there exists a sequence* $\{\theta^{(n)}\}_{n=1}^\infty$ *of feasible solutions for* SCLP* *of uniformly bounded variation; i.e., there exists N such that*

$$\int_0^T \|d\theta^{(n)}(t)\|_\infty \leq N$$

for all n. Suppose also that

$$\lim_{n\to\infty}\left[\int_0^T \eta^{(n)}(t)^T b(t)\,dt - \int_0^T d\pi^{(n)}(t)^T a(t)\right] = V[\text{SCLP*}];$$

then there exists θ *optimal for* SCLP*.

Proof. By the Helly selection principle (see, for example, Kolmogorov and Fomin [20, Thm. 5, p. 372]) there exists a subsequence $\{\theta^{(n_k)}\}_{k=1}^\infty$ and θ of bounded variation on $[0, T]$ such that $\theta^{(n_k)}(t) \to \theta(t)$ for all $t \in [0, T]$. The results now follow by Helly's convergence theorem (see again, Kolmogorov and Fomin, [20, Thm. 4, p. 370]) and Lebesgue's dominated convergence theorem. □

Our final, less general result in this section is the one that we will be using to establish the strong duality results in the following section. It is a specialised version of the previous result and presents a condition that guarantees the existence of a piecewise analytic optimal solution for SCLP* based on a particular sequence of feasible solutions whose objective function values approach the optimal value of SCLP*. Although its statement is more cryptic than the previous two results, it will be made clearer if it is compared with Theorem 3.5 on the calculation of complementary slack variables. It will be in the context of a sequence of suitable complementary slack variables that this result will be used.

LEMMA 5.3. *Suppose that* $a^{(n)} \to a$ *and* $b^{(n)} \to b$ *uniformly. Let* SCLP_n *be the problem* SCLP *with a replaced by* $a^{(n)}$ *and b replaced by* $b^{(n)}$. *Suppose there exists* $\theta^{(n)}$ *optimal for* SCLP_n^* *(the dual of* SCLP_n*) satisfying the following conditions:*

1. *For each n,* $\theta^{(n)}$ *is piecewise analytic on* $[0, T]$ *with breakpoints in the partition* $\{t_0^{(n)}, \ldots, t_{m_n}^{(n)}\}$ *of* $[0, T]$.
2. *For each* $i = 1, \ldots, m_n$ *there exists a basis matrix* $B(t_i^{(n)})$ *for K such that*

$$\theta^{(n)}(t) = \left(B(t_i^{(n)})^{-1}\right)^T \bar{c}^{(n)}_{B(t_i^{(n)})}(t)$$

for $t \in [t_{i-1}^{(n)}, t_i^{(n)})$, *where*

$$\bar{c}^{(n)}(t) = \begin{bmatrix} c(t) \\ \pi^{(n)}(t_i^{(n)}-) \\ 0 \end{bmatrix}$$

for $t \in [t_{i-1}^{(n)}, t_i^{(n)})$.

Suppose also that there exist M *and* N *such that* $m_n \leq M$ *and* $\|\theta^{(n)}\|_\infty \leq N$ *for all* n. *Then there exists a piecewise analytic optimal solution for* SCLP* *with at most* M *breakpoints.*

Proof. By introducing extra artificial breakpoints, if necessary, we can assume that $m_n = M$ for all n, i.e., that each $\theta^{(n)}$ has exactly M breakpoints. Now $\theta^{(n)}(t)$ is uniformly bounded for all n and t, so there exists $\{n_k\}_{k=1}^{\infty}$ and a partition $P = \{t_0, \ldots, t_M\}$ of $[0, T]$ such that $t_i^{(n_k)} \to t_i$ for $i = 0, \ldots, M$ and $\pi^{(n_k)}(t_i^{(n_k)}-)$ converges for $i = 1, \ldots, M$. As there are only a finite number of basis matrices for K, we may also assume that the subsequence $\{n_k\}_{k=1}^{\infty}$ is chosen so that for each i, $B(t_i^{(n_k)}) = B^{(i)}$ for some basis matrix $B^{(i)}$ of K. We now let

$$\bar{c}(t) = \lim_{k\to\infty} \bar{c}^{(n_k)}(t)$$

for $t \in [0, T] - P$ and $\bar{c}(t) = \bar{c}(t+)$ for $t \in P$. These limits exist as $\pi^{(n_k)}(t_i^{(n_k)}-)$ converges for each i. We now define

$$\theta(t) = \left(B^{(i)^{-1}}\right)^T \bar{c}_{B^{(i)}}(t)$$

for $t \in [t_{i-1}, t_i)$ for each $i = 1, \ldots, M$ and $\theta(T) = 0$. We now have $\theta^{(n_k)}(t) \to \theta(t)$ for all $t \in [0, T] - P$ and $\pi^{(n)}(T) = \pi(T)$ for all n. Now by taking a further subsequence, if necessary, we can assume that $\lim_{k\to\infty} \theta^{(n_k)}(t_i)$ exists for $i = 1, \ldots, M-1$. Note that $\theta(t_i)$ may or may not be equal to $\lim_{k\to\infty} \theta^{(n_k)}(t_i)$. Using Helly's convergence theorem and the fact that the Lebesgue–Stieltjes integral is not affected by the value of θ at its breakpoints in $(0, T)$ (see Kolmogorov and Fomin [20, Prob. 7, p. 377]) we have for any continuous function g that

$$\lim_{k\to\infty} \int_0^T d\pi^{(n_k)}(t)^T g(t) = \int_0^T d\pi(t)^T g(t).$$

This will allow us to establish the result that θ is optimal for SCLP*.

Now the feasible region for SCLP$_n^*$ is the same for all n and the same as that for SCLP*. Hence $\theta^{(n_k)}$ is feasible for SCLP*, and thus θ is feasible for SCLP*. We now show that θ is optimal for SCLP*. Now by the remark above and Lebesgue's dominated convergence theorem we have

$$\lim_{k\to\infty} \left[\int_0^T \eta^{(n_k)}(t)^T b^{(m)}(t)\, dt - \int_0^T d\pi^{(n_k)}(t)^T a^{(m)}(t) \right]$$
$$= \int_0^T \eta(t)^T b^{(m)}(t)\, dt - \int_0^T d\pi(t)^T a^{(m)}(t)$$

for all m. Now $a^{(m)} \to a$ in $C^{n_2}[0, T]$, $b^{(m)} \to b$ in $L_1^{n_3}[0, T]$, and θ acts as a continuous linear functional on $C^{n_2}[0, T] \times L_1^{n_3}[0, T]$. Hence we have

$$\lim_{m\to\infty} \left[\int_0^T \eta(t)^T b^{(m)}(t)\, dt - \int_0^T d\pi(t)^T a^{(m)}(t) \right] = \int_0^T \eta(t)^T b(t)\, dt - \int_0^T d\pi(t)^T a(t).$$

Hence, by the uniform convergence of $a^{(m)}$ and $b^{(m)}$, we have

$$\begin{aligned}\lim_{k\to\infty} V[\text{SCLP}^*_{n_k}] &= \lim_{k\to\infty}\left[\int_0^T \eta^{(n_k)}(t)^T b^{(n_k)}(t)\,dt - \int_0^T d\pi^{(n_k)}(t)^T a^{(n_k)}(t)\right]\\ &= \int_0^T \eta(t)^T b(t)\,dt - \int_0^T d\pi(t)^T a(t)\\ &\le V[\text{SCLP}^*]. \qquad (15)\end{aligned}$$

Suppose that $V[\text{SCLP}^*] > \lim_{k\to\infty} V[\text{SCLP}^*_{n_k}]$. Then there exists $\bar{\theta}$ feasible for SCLP* and such that

$$\int_0^T \bar{\eta}(t)^T b(t)\,dt - \int_0^T d\bar{\pi}(t)^T a(t) > \lim_{k\to\infty} V[\text{SCLP}^*_{n_k}].$$

This is a contradiction since, by similar arguments to the above, we would then have that

$$\lim_{m\to\infty}\left[\int_0^T \bar{\eta}(t)^T b^{(m)}(t)\,dt - \int_0^T d\bar{\pi}(t)^T a^{(m)}(t)\right] = \int_0^T \bar{\eta}(t)^T b(t)\,dt - \int_0^T d\bar{\pi}(t)^T a(t),$$

thus giving a feasible solution for $\text{SCLP}^*_{n_k}$ for some n_k with objective function value strictly greater than $V[\text{SCLP}^*_{n_k}]$. Hence (15) is an equality and so θ is optimal for SCLP*. □

6. Strong duality results. We now turn to strong duality results between SCLP and SCLP*. The main result in this section is that strong duality holds between SCLP and SCLP* if $a(t)$, $b(t)$, and $c(t)$ are piecewise analytic, with $a(t)$ also continuous, and the feasible region for SCLP is both nonempty and bounded (Theorem 6.9). It is also shown that in this case optimal solutions exist for both the primal and the dual which are piecewise analytic on $[0, T]$. Before considering the general case, we will first show that strong duality holds between SCLP and SCLP* in the case where $c(t)$ is piecewise analytic, $a(t)$ is piecewise linear and continuous, and $b(t)$ is piecewise constant (Theorem 6.6). Although Theorem 6.6 is just a special case of Theorem 6.9, it is convenient to separate the two in order to bring greater clarity and understanding.

The proofs of the strong duality results in this section are quite long and involved. However, it is possible to break up the proofs into smaller segments. With this in mind we now present several fairly unrelated results that will be used in the proofs of the strong duality results.

6.1. Preliminary results. In Pullan [28], the key to establishing the strong duality result, Theorem 1.3, was a special discretization of SCLP and its properties. Under the appropriate assumptions on the problem data for SCLP it was shown that if we had an optimal solution for SCLP that was piecewise constant, then we could construct an optimal solution for this discretization in a natural way. As the (finite-dimensional) dual of this discretization was a natural discretization of SCLP*, the strong duality theorem of finite-dimensional linear programming allowed the construction of an optimal solution for SCLP*, thus establishing strong duality. The difficult part of the above analysis was showing that an optimal solution for SCLP gave an optimal solution for the discretization. We now extend this result from piecewise linear to piecewise analytic costs. It turns out that the proof of this result is very similar to the corresponding one in [28]. Once established, this result will then be one of the keys to establishing strong duality results. We begin by defining the discretization used in [28].

Let $P = \{t_0, t_1, \ldots, t_m\}$ be a partition of $[0, T]$. Assume that $a(t)$ is piecewise linear and continuous and that $b(t)$ is piecewise constant, both with breakpoints in P. Let

$$u_i = \frac{t_{i-1} + t_i}{2},$$
$$\tau_i = \frac{t_i - t_{i-1}}{2}.$$

The variables in the discretization are $\hat{x}(t_{i-1}+)$, $\hat{x}(t_i-)$, $\hat{y}(t_i)$, $\hat{y}(u_i)$, $\hat{z}(t_{i-1}+)$, and $\hat{z}(t_i-)$, which, as the notation suggests, correspond in some way to the function values of x, y, and z at $t_{i-1}+$, t_i-, and u_i of a feasible solution for SCLP. We define the discretization of SCLP, called AP(P), as follows:

$$\begin{aligned}
\text{AP}(P)\text{: minimize} \quad & \sum_{i=1}^{m} \left(c(t_{i-1}+)^T \hat{x}(t_{i-1}+) + c(t_i-)^T \hat{x}(t_i-) \right) \\
\text{subject to} \quad & G\hat{x}(t_0+) + \hat{y}(u_1) = a(u_1), \\
& G\hat{x}(t_i-) + \hat{y}(t_i) - \hat{y}(u_i) = a(t_i) - a(u_i), \quad i = 1, \ldots, m, \\
& G\hat{x}(t_{i-1}+) + \hat{y}(u_i) - \hat{y}(t_{i-1}) = a(u_i) - a(t_{i-1}), \quad i = 2, \ldots, m, \\
& H\hat{x}(t_{i-1}+) + \hat{z}(t_{i-1}+) = \tau_i b(t_{i-1}+), \quad i = 1, \ldots, m, \\
& H\hat{x}(t_i-) + \hat{z}(t_i-) = \tau_i b(t_i-), \quad i = 1, \ldots, m, \\
& \hat{x}(t_{i-1}+), \hat{x}(t_i-), \hat{y}(t_i), \hat{y}(u_i), \hat{z}(t_{i-1}+), \hat{z}(t_i-) \geq 0, \\
& \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad i = 1, \ldots, m,
\end{aligned}$$

or in matrix form,

$$\begin{aligned}
\text{AP}(P)\text{: minimize} \quad & \hat{c}^T \hat{\omega} \\
\text{subject to} \quad & A\hat{\omega} = \hat{b}, \\
& \hat{\omega} \geq 0,
\end{aligned}$$

where

$$\begin{aligned}
\hat{c}^T &= (c(t_0+)^T, 0^T, c(t_1-)^T, 0^T, c(t_1+)^T, \ldots, c(t_{m-1}+)^T, 0^T, c(t_m-)^T, 0^T), \\
\hat{b}^T &= (a(u_1)^T, \tau_1 b(t_0+)^T, (a(t_1) - a(u_1))^T, \tau_1 b(t_1-)^T, \ldots, (a(t_m) - a(u_m))^T, \\
&\quad \tau_m b(t_m-)^T), \\
\hat{\omega}^T &= (\hat{x}(t_0+)^T, \hat{y}(u_1)^T, \hat{z}(t_0+)^T, \hat{x}(t_1-)^T, \hat{y}(t_1)^T, \hat{z}(t_1-)^T, \ldots, \hat{x}(t_m-)^T, \hat{y}(t_m)^T, \\
&\quad \hat{z}(t_m-)^T),
\end{aligned}$$

where the 0's in $\hat{c}$ are of dimension $n_2 + n_3$ and

$$A = \begin{bmatrix}
G & I & 0 & 0 & 0 & 0 & \ldots & & & & & & \\
H & 0 & I & 0 & 0 & 0 & \ldots & & & & & & \\
0 & -I & 0 & G & I & 0 & \ldots & & & & & & \\
0 & 0 & 0 & H & 0 & I & \ldots & & & & & & \\
0 & 0 & 0 & 0 & -I & 0 & G & \ldots & & & & & \\
0 & 0 & 0 & 0 & 0 & 0 & H & \ldots & & & & & \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & & & & & \\
0 & & & & \ldots & & & & -I & 0 & G & I & 0 \\
0 & & & & \ldots & & & & 0 & 0 & H & 0 & I
\end{bmatrix}.$$

Note that A depends not on the particular partition chosen but only on its size. In fact, in [28], AP(P) was written in a slightly different but equivalent form where A did depend on the partition chosen. We have rewritten AP(P) as above for this reason.

Now AP(P) has the following (finite-dimensional) dual:

$$\begin{aligned} \text{AP}^*(P): \quad & \text{maximize} && \hat{b}^T\hat{\theta} \\ & \text{subject to} && \hat{\theta}^T A \le \hat{c}^T \end{aligned}$$

or, after making a few simplifications,

$$\begin{aligned} \text{AP}^*(P): \quad \text{maximize} \quad & \hat{\pi}(t_0+)^T a(t_0) + \sum_{i=1}^{m} (\hat{\pi}(t_{i-1}+) + \hat{\pi}(t_i-))^T (a(t_i) - a(u_i)) \\ & + \sum_{i=1}^{m} \tau_i (\hat{\eta}(t_{i-1}+) + \hat{\eta}(t_i-))^T b(t_i-) \\ \text{subject to} \quad & c(t_i-) - G^T\hat{\pi}(t_i-) - H^T\hat{\eta}(t_i-) \ge 0, \quad i = 1, \dots, m, \\ & c(t_{i-1}+) - G^T\hat{\pi}(t_{i-1}+) - H^T\hat{\eta}(t_{i-1}+) \ge 0, \quad i = 1, \dots, m, \\ & \hat{\eta}(t_i-), \hat{\eta}(t_{i-1}+) \le 0, \quad i = 1, \dots, m, \\ & \hat{\pi}(t_i-) - \hat{\pi}(t_{i-1}+) \ge 0, \quad i = 1, \dots, m, \\ & \hat{\pi}(t_i+) - \hat{\pi}(t_i-) \ge 0, \quad i = 1, \dots, m-1, \\ & \hat{\pi}(t_m-) \le 0. \end{aligned}$$

The relevant result about AP(P) established in [28] was the following.

THEOREM 6.1. *Suppose that $\omega(t)$ is feasible for* SCLP *with $x(t)$ piecewise constant with breakpoints in $P = \{t_0, t_1, \dots, t_m\}$. Then $\hat{\omega}$ defined by*

$$(16) \qquad \begin{cases} \hat{x}(t_{i-1}+) = \tau_i x(t_{i-1}+), \\ \hat{x}(t_i-) = \tau_i x(t_i-), \\ \hat{y}(t_i) = y(t_i), \\ \hat{y}(u_i) = y(u_i), \\ \hat{z}(t_{i-1}+) = \tau_i z(t_{i-1}+), \\ \hat{z}(t_i-) = \tau_i z(t_i-), \qquad i = 1, \dots, m, \end{cases}$$

is feasible for AP(P). *Moreover, if $c(t)$ is piecewise linear with breakpoints in P and $\omega(t)$ is optimal for* SCLP, *then $\hat{\omega}$ is optimal for* AP(P).

We now proceed to extend Theorem 6.1 to the case of $c(t)$ piecewise analytic.

THEOREM 6.2. *Suppose that $a(t)$ is piecewise linear (and continuous), $b(t)$ is piecewise constant, and $c(t)$ is piecewise analytic, each with breakpoints in the partition $P = \{t_0, t_1, \dots, t_m\}$. Let $\omega(t)$ be feasible for* SCLP *with $x(t)$ piecewise constant with breakpoints in P. Then $\hat{\omega}$, as given by* (16), *is feasible for* AP(P). *Moreover, if $\omega(t)$ is optimal for* SCLP, *then $\hat{\omega}$ is optimal for* AP(P).

Proof. The feasibility of $\hat{\omega}$ follows from Theorem 6.1. Suppose then that $\omega(t)$ is optimal for SCLP with $x(t)$ piecewise constant with breakpoints in P. Let $\hat{\omega}$ be given by (16). Suppose $\hat{\omega}$ is not optimal for AP(P). Then $\hat{\tilde{\omega}}$ exists, feasible for AP(P), with strictly improved objective function, i.e.,

$$\delta \equiv \hat{c}^T\hat{\tilde{\omega}} - \hat{c}^T\hat{\omega} < 0.$$

Following the constructions in [28] (see §4 in [28]), let

$$\tilde{x}(t) = \begin{cases} \dfrac{1}{\tau_i}\hat{\tilde{x}}(t_{i-1}+), & t \in [t_{i-1}, u_i),\ i = 1, \ldots, m, \\ \dfrac{1}{\tau_i}\hat{\tilde{x}}(t_i-), & t \in [u_i, t_i),\ i = 1, \ldots, m, \\ \dfrac{1}{\tau_m}\hat{\tilde{x}}(t_m-), & t = T. \end{cases}$$

Let $\tau = \min\{\, \tau_i : i = 1, \ldots, m \,\}$ and $\varepsilon \in [0, \tau]$. Set $\varepsilon_i = \varepsilon\tau_i/\tau$ and define

$$\bar{x}_\varepsilon(t) = \begin{cases} \tilde{x}(t), & t \in [t_{i-1}, t_{i-1} + \varepsilon_i) \cup [t_i - \varepsilon_i, t_i) \text{ for } i = 1, \ldots, m, \\ x(t) & \text{otherwise.} \end{cases}$$

Let $\bar{y}_\varepsilon(t)$ and $\bar{z}_\varepsilon(t)$ be given by the constraints of SCLP (i.e., so that $\bar{x}_\varepsilon(t)$, $\bar{y}_\varepsilon(t)$, and $\bar{z}_\varepsilon(t)$ satisfy (1) and (2) in place of $x(t)$, $y(t)$, and $z(t)$, respectively). By the same argument as in [28], the resulting $\bar{\omega}_\varepsilon(t)$ is feasible for SCLP.

We now claim that there exists $\varepsilon > 0$ such that $\bar{\omega}_\varepsilon(t)$ is an improved feasible solution for SCLP. For this purpose we use the standard notation $o(h^n)$ for $n \in \mathbb{N}$ to mean a function defined on an interval containing zero such that $\lim_{h \downarrow 0} o(h^n)/h^n = 0$. Now as $c(t)$ is analytic on a neighbourhood of $[t_{i-1}, t_i)$ for $i = 1, \ldots, m$, we have

$$c(t_{i-1} + \rho) = c(t_{i-1}+) + \rho\dot{c}(t_{i-1}+) + o(\rho)$$

for $\rho > 0$. Hence

$$\int_{t_{i-1}}^{t_{i-1}+\varepsilon_i} c(t)\,dt = \varepsilon_i \left(c(t_{i-1}+) + \frac{\varepsilon_i}{2}\dot{c}(t_{i-1}+) + o(\varepsilon_i) \right).$$

Similarly,

$$\int_{t_i-\varepsilon_i}^{t_i} c(t)\,dt = \varepsilon_i \left(c(t_i-) - \frac{\varepsilon_i}{2}\dot{c}(t_i-) + o(\varepsilon_i) \right).$$

Continuing in exactly the same way as in Lemma 4.3 in [28] we establish that

$$\int_0^T c(t)^T \bar{x}_\varepsilon(t)\,dt - \int_0^T c(t)^T x(t)\,dt = \frac{\varepsilon}{\tau}\left(\delta - \frac{\varepsilon\alpha}{\tau} + o(\varepsilon) \right),$$

where

$$\alpha(\omega) = \sum_{i=1}^{m} \frac{\tau_i^2}{2}(x(t_i-) - x(t_{i-1}+))^T \dot{c}(t_i-).$$

Hence

$$\begin{aligned} \lim_{\varepsilon \downarrow 0} \frac{1}{\varepsilon}\left(\int_0^T c(t)^T \bar{x}_\varepsilon(t)\,dt - \int_0^T c(t)^T x(t)\,dt \right) &= \lim_{\varepsilon \downarrow 0} \frac{1}{\tau}\left(\delta - \frac{\varepsilon\alpha}{\tau} + o(\varepsilon) \right) \\ &= \frac{\delta}{\tau} \\ &< 0, \end{aligned}$$

thus contradicting the optimality of $\omega(t)$. □

In §3 we encountered and discussed a notion of degeneracy. This was a problem that arose when trying to calculate complementary slack variables. As with the corresponding notion in FLP, when degeneracy is present, it is not possible to calculate a set of complementary slack variables uniquely. In the conclusion to §3 we noted that there were essentially two types of degeneracy for SCLP. One of these was when there were not enough nonzero variables at any particular time to form a basis matrix for K. We will see that to establish strong duality results, degeneracy is a significant problem. This is not surprising because in the absence of degeneracy in finite-dimensional linear programming, the proof of the strong duality result becomes relatively straightforward. It turns out that only the one type of degeneracy for SCLP mentioned above plays an important part in the strong duality theory for SCLP. As this is the case and as we have not defined degeneracy formally before, we now present the following definition. It will be seen to be very similar to the corresponding one for FLP. As our strong duality results to follow only cover piecewise analytic problem data, we only give a definition of degeneracy for such data.

DEFINITION 4. *Suppose that $a(t)$ and $b(t)$ are piecewise analytic with breakpoints in the partition $P = \{t_0, t_1, \ldots, t_m\}$.*

1. *Let B be any basis matrix of K. Let*

$$\rho(t) = B^{-1}\begin{bmatrix} \dot{a}(t) \\ b(t) \end{bmatrix}.$$

We say that B is a degenerate basis matrix *for* SCLP *if $\rho_i(t) = 0$ for all $t \in [t_{j-1}, t_j)$ for some i and j. Otherwise we say that B is a* nondegenerate basis matrix *for* SCLP.

2. *We say that* SCLP *is* degenerate *if there exists a basis matrix B for K such that B is a degenerate basis matrix for* SCLP. *Otherwise we say that* SCLP *is* nondegenerate.

We now present a simple lemma based on this definition, a result which has an equivalent counterpart in finite-dimensional linear programming.

LEMMA 6.3. *Suppose that* SCLP *is nondegenerate and that $\omega(t)$ is a basic feasible solution for* SCLP. *Suppose there exists $(\alpha, \beta) \subset [0, T]$ such that* $\operatorname{supp}(\omega(t))$ *is constant on (α, β). Then $|\operatorname{supp}(\omega(t))| = n_2 + n_3$ on (α, β), and so there exists a unique basis matrix B of K such that the nonzero variables of $\omega(t)$ are precisely $\omega_B(t)$ on (α, β).*

Proof. Let B be any basis matrix of K that contains the columns of K corresponding to $\operatorname{supp}(\omega(t))$ on (α, β). This exists as $\omega(t)$ is a basic feasible solution. Let

$$\bar{\omega}(t) = \begin{bmatrix} x(t) \\ \dot{y}(t) \\ z(t) \end{bmatrix};$$

then as $\omega(t)$ is feasible for SCLP, we must have

$$\bar{\omega}_B(t) = B^{-1}\begin{bmatrix} \dot{a}(t) \\ b(t) \end{bmatrix}$$

for $t \in (\alpha, \beta)$. However, by the nondegeneracy assumption we have that each component of $\bar{\omega}_B(t)$ is nonzero for all $t \in (\alpha, \beta)$. Hence $\operatorname{supp}(\omega(t))$ has $n_2 + n_3$ elements on (α, β), one for each column of B. □

Our final result in this section is quite unrelated to the previous ones and comes from Pullan [29]. The result shows that the number of zeros in a linear combination of analytic functions is dependent only on the functions involved and not the particular scalars chosen. This is useful in establishing strong duality results for the following reason. As mentioned above, degeneracy will play an important part in the analysis to follow. In fact, as with FLP, we will see that it is relatively easy to establish a strong duality result for nondegenerate problems.

To establish a strong duality result in general we will then approximate a degenerate problem by a sequence of nondegenerate ones. We will then wish to use Lemma 5.3 to produce an optimal solution for SCLP*. To do this we will have to produce a uniform bound on the number of breakpoints in the optimal solutions for the approximating dual problems. The required uniform bound is given by the result below. For this result we use the notation $|S|$ to denote the cardinality of a set S.

LEMMA 6.4. *Let $f : [a, b] \to \mathbb{R}^n$ be a function analytic on a neighbourhood of $[a, b]$. Then there exists $M(f)$ $(< \infty)$ such that for all $\lambda \in \mathbb{R}^n$ if*

$$S(\lambda, f) = \{ t \in [a, b] : \lambda^T f(t) = 0 \},$$

then either $S(\lambda, f) = [a, b]$ or $|S(\lambda, f)| \leq M(f)$.

6.2. Analytic costs. In this section we will be extending the strong duality result in Pullan [28, Thm. 1.3], to SCLP with piecewise analytic costs. We begin by restricting our attention to the case where the problem data contain no breakpoints. We thus introduce the following assumption that we will assume holds for the problem data of SCLP throughout the rest of this section.

Assumption 6.1. The costs $c(t)$ are analytic on a neighbourhood of $[0, T]$, $a(t)$ is linear on $[0, T]$, $b(t)$ is constant on $[0, T]$, and the feasible region for SCLP is nonempty and bounded.

We now proceed to establish a strong duality result under this assumption. This is done in two stages, first for nondegenerate problems and then for degenerate ones (see Definition 4).

We use the following notation. Given a cost $c(t)$ we let

$$\tilde{c}(t) = \begin{bmatrix} c(t) \\ 0 \\ 0 \end{bmatrix},$$

where the 0's are of dimensions n_2 and n_3, respectively. We now define the following sets. Let

$$Q = \left\{ (B^{-1})^T \tilde{\dot{c}}_B : B \text{ is a basis matrix for } K \right\},$$
$$R = \{ \dot{\psi} : \psi = c - G^T \pi - H^T \eta \text{ for some } \theta^T = (\pi^T, \eta^T) \in Q \},$$
$$S = \{ \rho_j : \rho \in Q \cup R \}.$$

Note that S consists of a finite set of analytic functions. Now each of these functions is identically zero or contains a finite number of zeros on $[0, T]$. Let N be the total number of zeros of functions in S that are not identically zero on $[0, T]$. Let $\omega(t)$ be a piecewise constant optimal solution for SCLP with, say, M breakpoints. This exists by Theorem 2.4. We now let $P = \{t_0, t_1, \ldots, t_m\}$ be the partition of $[0, T]$ with at most $M + N + 2$ points that contains all the breakpoints of $\omega(t)$ and all the zeros of functions in S that are not identically zero, as well as the points 0 and T. We now present a lemma showing that such a partition can be used to construct an optimal solution for SCLP* fairly naturally if SCLP is nondegenerate. This lemma makes use of the standard L_∞ matrix norm, which is defined by

$$\|B\|_\infty = \max \left\{ \sum_{j=1}^{n} |b_{i,j}| : i = 1, 2, \ldots, n \right\}$$

for an $n \times n$ matrix B.

LEMMA 6.5. *Suppose that* SCLP *is nondegenerate. Then there exists a piecewise analytic optimal solution θ for* SCLP* *with breakpoints in P (i.e., having at most $M + N + 1$ breakpoints). Moreover, θ satisfies the following:*

1. *For each* $i = 1, \ldots, m$ *there exists a basis matrix* $B^{(i)}$ *for* K *such that*

$$\theta(t) = \left(B^{(i)^{-1}}\right)^T \bar{c}_{B^{(i)}}(t)$$

for $t \in [t_{i-1}, t_i)$, *where*

$$\bar{c}(t) = \begin{bmatrix} c(t) \\ \pi(t_i-) \\ 0 \end{bmatrix}$$

for $t \in [t_{i-1}, t_i)$.

2. $\|\theta\|_\infty \leq \max\{\, \|\hat{B}^{-1}\|_\infty : \hat{B}$ *is a basis matrix for* $\mathrm{AP}(P)\,\}\|c\|_\infty$.

Proof. By Theorem 6.2 we have $\hat{\omega}$, given by (16), optimal for AP(P). Hence, by the strong duality theorem for finite-dimensional linear programming, there exists a basis matrix $\hat{B}$ for AP(P) such that if

$$\hat{\theta} = (\hat{B}^{-1})^T \begin{bmatrix} \tilde{c}(t_0+) \\ \tilde{c}(t_1-) \\ \vdots \\ \tilde{c}(t_m-) \end{bmatrix},$$

then $\hat{\theta}$ is optimal for AP*(P) and complementary slack with $\hat{\omega}$. Note that

$$\|\hat{\theta}\|_\infty \leq \max\{\, \|\hat{B}^{-1}\|_\infty : \hat{B} \text{ is a basis matrix for } \mathrm{AP}(P)\,\}\|c\|_\infty.$$

We will now construct $\theta(t)$ optimal for SCLP* such that

$$\begin{aligned} \theta(t_i+) &= \hat{\theta}(t_i+), \quad i = 0, \ldots, m-1, \\ \theta(t_i-) &= \hat{\theta}(t_i-), \quad i = 1, \ldots, m, \end{aligned}$$

and such that each component of $\theta(t)$ is monotonic on $[t_{i-1}, t_i)$ for $i = 1, \ldots, m$. Such a $\theta(t)$ will then satisfy (2) in the statement of the lemma.

Fix i, and consider the interval (t_{i-1}, t_i). Let B be the basis matrix of K that contains the columns of K corresponding to $\mathrm{supp}(\omega(t))$ on (t_{i-1}, t_i). The existence and uniqueness of this matrix B is given by Lemma 6.3. Let $\bar{c}(t)$ be as given in the statement of the theorem. Then it is clear that $\hat{\theta}$ complementary slack with $\hat{\omega}$ implies

$$\begin{aligned} \hat{\theta}(t_{i-1}+) &= (B^{-1})^T \bar{c}_B(t_{i-1}+), \\ \hat{\theta}(t_i-) &= (B^{-1})^T \bar{c}_B(t_i-). \end{aligned}$$

Now $\dot{\bar{c}}(t) = \dot{\tilde{c}}(t)$ for all t. Hence by the properties of the partition P, for any j, $[(B^{-1})^T \dot{\bar{c}}_B(t)]_j$ contains no isolated zeros in (t_{i-1}, t_i) and so $[(B^{-1})^T \bar{c}_B(t)]_j$ is monotonic on (t_{i-1}, t_i) for each j. Define

$$\theta(t) = (B^{-1})^T \bar{c}_B(t)$$

for $t \in [t_{i-1}, t_i)$. We then have $\theta_j(t)$ monotonic on $[t_{i-1}, t_i)$ for each j. By a similar argument we also have $\psi_j(t) = (c(t) - G^T\pi(t) - H^T\eta(t))_j$ monotonic on $[t_{i-1}, t_i)$ for each j. Hence, by the feasibility of $\hat{\theta}$ for AP*(P), we have

$$\begin{aligned} &c(t) - G^T\pi(t) - H^T\eta(t) \geq 0, \\ &\eta(t) \leq 0, \quad t \in [t_{i-1}, t_i), \\ &\pi(t) \text{ monotonic increasing and right continuous on } [t_{i-1}, t_i). \end{aligned}$$

If this is done for each i and we set $\theta(T) = 0$, we then obtain a feasible solution for SCLP* (note that $\pi(T-) \leq 0$ as $\hat{\pi}(t_m-) \leq 0$). Moreover, by the construction, we have $\theta(t)$ complementary slack with $\omega(t)$ by Theorem 3.5. Hence, by the complementary slackness theorem, Theorem 3.4, $\theta(t)$ is optimal for SCLP*. Finally, by construction, $\theta(t)$ satisfies the remaining requirements of the lemma. □

We now have all the necessary ingredients to establish a strong duality result for SCLP under Assumption 6.1. This is done by approximating SCLP by a sequence of nondegenerate problems and then using Lemma 5.3 to guarantee an optimal solution for SCLP*. The required uniform bounds for the application of this lemma are provided by the result for the existence of a piecewise constant optimal solution for SCLP, Theorem 2.4, and Lemma 6.4. There is one slight problem in establishing this result, however—namely, the need to construct suitable approximating SCLP problems with bounded feasible regions. This is done by adding upper bound constraints to the problem so that any right-hand sides will give a bounded feasible region. The proof is then made complete by showing that the resulting optimal dual variables for the extra constraints are zero by complementary slackness.

THEOREM 6.6 (strong duality). *Suppose that $c(t)$ is piecewise analytic, $a(t)$ is piecewise linear and continuous, $b(t)$ is piecewise constant on $[0, T]$, and the feasible region for* SCLP *is nonempty and bounded. Then V[SCLP] $= V$[SCLP*] and there exist an optimal solution for* SCLP, *with $x(t)$ piecewise constant, and a piecewise analytic optimal solution for* SCLP*.

Proof. It is required only to prove that SCLP* has a piecewise analytic optimal solution. The other statements are given by previous results (Theorem 2.4 and Theorem 4.2; however, the fact that V[SCLP] $= V$[SCLP*] in this case could also be shown directly in the proof to follow). We restrict ourselves to the case where $a(t)$ is linear, $b(t)$ is constant, and $c(t)$ is analytic on a neighbourhood $[0, T]$. The more general case can be dealt with by repeating the argument below a finite number of times.

Assume for the moment that SCLP contains upper bound constraints on $x(t)$, i.e., that H is of the form

$$H = \begin{bmatrix} \bar{H} \\ I \end{bmatrix}. \tag{17}$$

Let $B^{(1)}, \ldots, B^{(L)}$ be all the possible basis matrices for K. Let

$$Q_{i,j} = \{ B^{(j)}\zeta : \zeta \in \mathbb{R}^{n_2+n_3},\ \zeta_i = 0 \}.$$

Then as $B^{(j)}$ has full rank, $Q_{i,j}$ is a $(n_2 + n_3 - 1)$-dimensional subspace of $\mathbb{R}^{n_2+n_3}$ (i.e., a hyperplane). Now $\{ Q_{i,j} : i = 1, \ldots, n_2 + n_3,\ j = 1, \ldots, L \}$ is a finite set of hyperplanes in $\mathbb{R}^{n_2+n_3}$. It is now not difficult to show that for any $\gamma \in \mathbb{R}^{n_2+n_3}$ there exists $\{\gamma^{(n)}\}_{n=1}^{\infty}$ such that $\gamma^{(n)} \downarrow \gamma$ and $\gamma^{(n)} \notin Q_{i,j}$ for each i and j and for all n. In particular there exist $r^{(n)} \downarrow \dot{a}$ and $s^{(n)} \downarrow b$ such that

$$\begin{bmatrix} r^{(n)} \\ s^{(n)} \end{bmatrix} \notin Q_{i,j}$$

for each i and j and for all n. Let

$$a^{(n)}(t) = a(0) + tr^{(n)},$$
$$b^{(n)}(t) = s^{(n)}.$$

Then $\{b^{(n)}\}_{n=1}^{\infty}$ is a set of constant functions and $\{a^{(n)}\}_{n=1}^{\infty}$ a set of linear functions such that $a^{(n)} \downarrow a$ and $b^{(n)} \downarrow b$ uniformly. Let SCLP$_n$ be the problem SCLP with a and b replaced

by $a^{(n)}$ and $b^{(n)}$, respectively. Now as H is of the form given by (17), the feasible region for SCLP_n is both nonempty and bounded. Moreover, by construction, SCLP_n is nondegenerate.

Now by Lemma 6.5 there exists an optimal solution, $\theta^{(n)}(t)$, for SCLP_n^* with at most $M_n + N + 1$ breakpoints, where M_n is the number of breakpoints of a piecewise constant optimal solution for SCLP_n and N is some constant depending only on $c(t)$ and $B^{(1)}, \ldots, B^{(L)}$ and is thus independent of n. We now wish to apply Lemma 5.3 to obtain a piecewise analytic optimal solution for SCLP*. To apply this lemma it will be sufficient to show that there exists Λ, independent of n, such that M_n can be chosen so that $M_n < \Lambda$. This is because

$$\max\{\, \|\hat{B}^{-1}\|_\infty : \hat{B} \text{ is a basis matrix for AP}(P)\,\}$$

depends only on the size of the partition P and not the actual points in the partition (see comment on page 948). Let $x^{(n,i)}$, $i = 1, \ldots, L$ be the possible values of a basic feasible solution for SCLP_n as given by Lemma 2.3. Now by Lemma 6.4 there exists M, independent of n, such that if

$$S_{i,j,n} = \{\, t \in [0, T] : c(t)^T x^{(n,i)} = c(t)^T x^{(n,j)} \,\}$$

for $i \neq j$, then for each $i \neq j$ either $|S_{i,j,n}| \leq M$ or $S_{i,j,n} = [0, T]$. Using the result for the existence of a piecewise constant optimal solution (Theorem 2.4), we may now deduce that an optimal solution $\omega^{(n)}(t)$ exists for SCLP_n for each n with at most $(M+1)L$ breakpoints. This gives the required uniform upper bound on the number of breakpoints for an optimal solution for SCLP_n and establishes the result for H of the form given by (17).

Suppose that H is not of the form given by (17). Let $R > 0$ be such that $\|x\|_\infty \leq R$ for all $x \in F(\text{SCLP})$. Let $\text{SCLP}(R)$ be the problem SCLP with the extra constraints

$$\begin{aligned} x(t) + v(t) &= 2Re, \\ v(t) &\geq 0, \end{aligned}$$

where e is the vector of all ones. By the definition of R, $F(\text{SCLP}) = F(\text{SCLP}(R))$ and $v(t) \geq Re > 0$ for all $t \in [0, T]$ and for any feasible solution for $\text{SCLP}(R)$. Let $\sigma(t)$ denote the dual variables in $\text{SCLP}(R)^*$ corresponding to $v(t)$, and $\eta(t)$ the dual variables in $\text{SCLP}(R)^*$ corresponding to the original constraints $Hx(t) + z(t) = b(t)$ in SCLP, i.e., so that the constraint $\psi(t) \geq 0$ can be written as $c(t) - G^T\pi(t) - H^T\eta(t) - \sigma(t) \geq 0$. By the argument above, there exists $\theta(t)^T = (\pi(t)^T, \eta(t)^T, \sigma(t)^T)$ piecewise analytic on $[0, T]$ and optimal for $\text{SCLP}(R)^*$. Moreover, $\theta(t)$ is complementary slack with some optimal solution $\omega(t)^T = (x(t)^T, y(t)^T, z(t)^T, v(t)^T)$ for $\text{SCLP}(R)$ by the complementary slackness theorem, Theorem 3.4. But $v(t) > 0$ and so we must have $\sigma(t) = 0$ a.e. on $[0, T]$, and hence everywhere as $\sigma(t)$ is piecewise analytic on $[0, T]$. Thus $(\pi(t)^T, \eta(t)^T)$ is an optimal solution for the original SCLP*. This establishes the result. □

It is worth noting as an aside that Lemma 5.3 also ensures that the optimal $\theta(t)$ for SCLP* derived in the proof of the above theorem has at most $(M+1)L + N + 1$ breakpoints, where M is given in the proof of the theorem.

6.3. Analytic right-hand sides. In this section we will be extending the strong duality result in the previous section to SCLP with piecewise analytic costs and right-hand sides. In the result from the previous section, the bulk of the proof was concerned with the case when the problem data had no breakpoints and there were upper bound constraints on $x(t)$. We thus introduce the following assumption that we will assume holds for the problem data of SCLP throughout the rest of this section.

Assumption 6.2. The costs $c(t)$ and the right-hand sides $a(t)$ and $b(t)$ are analytic on a neighbourhood of $[0, T]$, H is of the form

$$H = \begin{bmatrix} \bar{H} \\ I \end{bmatrix},$$

and the feasible region for SCLP is nonempty.

We now concentrate on proving strong duality under Assumption 6.2. The proof involves approximating $a(t)$ and $b(t)$ by sequences of piecewise linear and piecewise constant functions, respectively, and using the ideas from the previous sections. This same general technique was used in Pullan [29] to prove Theorem 2.5 starting from Theorem 2.4. We will thus use some of the ideas from [29]. The first of these is the concept of a change of basis. This concept allows us to distinguish between two types of breakpoints in a basic feasible solution for SCLP when the problem data have breakpoints. One type of breakpoint results from a breakpoint in the problem data. The other results from a change of basis which we now define.

DEFINITION 5. *Let $\omega(t)$ be a piecewise analytic basic feasible solution for* SCLP *and $x^{(1)}(t), \ldots, x^{(L)}(t)$ be given by Lemma 2.3. By a* change of basis *we mean a time $s \in (0, T)$ such that for some $\varepsilon > 0$, $x(t) = x^{(i)}(t)$ for $t \in (s - \varepsilon, s)$ and $x(t) = x^{(j)}(t)$ for $t \in (s, s + \varepsilon)$ for some i and j such that $x^{(i)}(t) \not\equiv x^{(j)}(t)$ on $(s - \varepsilon, s + \varepsilon)$.*

As with [29], we note that if a and b are analytic on a neighbourhood of $[0, T]$, then a change of basis is identical to a breakpoint. However, if a and b are piecewise analytic on $[0, T]$, then in general, the set of changes of basis for a basic feasible solution will be a subset of the set of breakpoints for that solution. This is because some of the breakpoints may be caused by breakpoints in the problem data and not by a change of basis.

We now begin the development of a strong duality result under Assumption 6.2. As with proving Theorem 2.5 in [29] we do this by taking sequences $\{a^{(n)}\}_{n=1}^{\infty}$ and $\{b^{(n)}\}_{n=1}^{\infty}$ of piecewise linear (and continuous) and piecewise constant functions, respectively, so that $a^{(n)} \geq a$, $b^{(n)} \geq b$ with $a^{(n)} \to a$ and $b^{(n)} \to b$ uniformly. The sequences are constructed so that SCLP_n has an optimal basic solution for SCLP_n with a bounded number of changes of basis independent of n, where SCLP_n is the problem SCLP with a and b replaced by $a^{(n)}$ and $b^{(n)}$, respectively. This construction is given in Lemma 4.2 in [29]. To complete the strong duality result under Assumption 6.2 we then construct a corresponding optimal solution for SCLP_n^* (the dual of SCLP_n) and use the bound on the number of changes of basis to apply Lemma 5.3. As might be expected, however, to construct the corresponding optimal solution for SCLP_n^* we need to ensure that SCLP_n is also nondegenerate.

We begin the analysis by establishing the existence of $a^{(n)}$ and $b^{(n)}$ with the required properties.

LEMMA 6.7. *Suppose that Assumption* 6.2 *holds. Then there exist $M \in \mathbb{N}$, a sequence $\{a^{(n)}\}_{n=1}^{\infty}$ of piecewise linear and continuous functions, and a sequence $\{b^{(n)}\}_{n=1}^{\infty}$ of piecewise constant functions with $a^{(n)}(t) \geq a(t)$ and $b^{(n)}(t) \geq b(t)$ on $[0, T]$ for each n, $a^{(n)} \to a$ and $b^{(n)} \to b$ uniformly on $[0, T]$, and such that SCLP_n is nondegenerate and has a piecewise constant basic feasible optimal solution with at most M changes of basis, where SCLP_n is the problem* SCLP *with right-hand sides $a^{(n)}$ and $b^{(n)}$.*

Proof. This lemma, without the nondegeneracy requirement, is precisely Lemma 4.2 in Pullan [29]. Now in the proof of Theorem 6.6 we saw that it was not difficult to ensure that an approximating problem to a given SCLP problem was nondegenerate. This is because any right-hand side can be approximated arbitrarily closely by a right-hand side for a nondegenerate problem. Thus it would be expected that the extra requirement for SCLP_n to be nondegenerate causes no new difficulties. In fact the proof of the current result is virtually identical to the proof of Lemma 4.2 in [29]. As this is the case, and as the proof of the Lemma 4.2 in [29] is also rather long and detailed, we omit the discussion. □

This is actually the bulk of the proof of a strong duality result between SCLP and SCLP* under Assumption 6.2. What remains to do now is prove a result similar to Lemma 6.5 in the previous section that generates an optimal solution, $\theta^{(n)}(t)$, for SCLP_n^* (the dual of SCLP_n as given by the previous lemma) that is uniformly bounded with respect to n. The existence of an optimal $\theta^{(n)}(t)$ for SCLP_n^* follows in a similar way to Lemma 6.5; however, this $\theta^{(n)}(t)$ may have breakpoints at each of the breakpoints of $a^{(n)}(t)$ and $b^{(n)}(t)$. The number of breakpoints in $\theta^{(n)}(t)$ could thus become unbounded and so we would not be able to apply Lemma 5.3 to guarantee an optimal solution for SCLP*. This is where the uniform bound on the number of changes of basis of an optimal solution for SCLP_n is used.

We now set up the same notation to that used in the previous section. Given a cost $c(t)$ we let

$$\tilde{c}(t) = \begin{bmatrix} c(t) \\ 0 \\ 0 \end{bmatrix},$$

where the 0's are of dimensions n_2 and n_3, respectively. We also define the following sets. Let

$$\begin{aligned} Q &= \left\{ (B^{-1})^T \dot{\tilde{c}}_B : B \text{ is a basis matrix for } K \right\}, \\ R &= \{ \dot{\psi} : \psi = c - G^T\pi - H^T\eta \text{ for some } \theta^T = (\pi^T, \eta^T) \in Q \}, \\ S &= \{ \rho_j : \rho \in Q \cup R \}. \end{aligned}$$

As with Lemma 6.5, let N be the total number of zeros of functions in S that are not identically zero on $[0, T]$. Let $\omega^{(n)}(t)$ be a piecewise constant optimal solution for SCLP_n with M changes of basis, where M is given by the previous lemma. We now fix n and define two partitions of $[0, T]$ as follows. Strictly speaking, these partitions depend on n; however, we drop this dependence in the notation for simplicity. Let

$$P = \{t_0, t_1, \ldots, t_m\}$$

be the partition of $[0, T]$ that contains all the changes of basis for $\omega^{(n)}(t)$ and all the zeros of functions in S that are not identically zero. Our next partition of $[0, T]$ is

$$\begin{aligned} \Omega &= \{r_0, r_1, \ldots, r_q\} \\ &= \{s_1^{(0)}, s_1^{(1)}, \ldots, s_{p_1}^{(1)}, s_1^{(2)}, \ldots, s_{p_2}^{(2)}, \ldots, s_{p_m}^{(m)}\}, \end{aligned}$$

which contains P, written in this case as

$$P = \{s_1^{(0)}, s_{p_1}^{(1)}, \ldots, s_{p_m}^{(m)}\},$$

and all the breakpoints of $a^{(n)}(t)$ and $b^{(n)}(t)$. For convenience we set $p_0 = 1$ and $s_0^{(i)} = s_{p_{i-1}}^{(i-1)}$ for $i = 1, \ldots, m$. We now present the result guaranteeing an optimal solution $\theta^{(n)}(t)$ for SCLP_n^* which is uniformly bounded with respect to n.

LEMMA 6.8. *Let* SCLP_n *be given by the previous lemma. Then there exists a piecewise analytic optimal solution* $\theta^{(n)}$ *for* SCLP_n^* *with breakpoints in* P *(i.e., having at most* $M+N+1$ *breakpoints). Moreover,* $\theta^{(n)}$ *satisfies the following:*

1. *For each* $i = 1, \ldots, m$ *there exists a basis matrix* $B^{(i)}$ *for* K *such that*

$$\theta^{(n)}(t) = \left(B^{(i)^{-1}}\right)^T \bar{c}_{B^{(i)}}(t)$$

for $t \in [t_{i-1}, t_i)$, *where*

$$\bar{c}(t) = \begin{bmatrix} c(t) \\ \pi(t_i-) \\ 0 \end{bmatrix}$$

for $t \in [t_{i-1}, t_i)$.

2. $\|\theta^{(n)}\|_\infty \leq \max\{\, \|\hat{B}^{-1}\|_\infty : \hat{B}$ *is a basis matrix for* $\mathrm{AP}(P)\,\}\|c\|_\infty$.

Proof. Using arguments similar to those for the corresponding result in the previous section (Lemma 6.5), we see that there exists an optimal solution $\bar{\omega}$ for AP(Ω) with a corresponding basis matrix $\bar{B}$ for AP(Ω) such that if

$$\bar{\theta} = (\bar{B}^{-1})^T \begin{bmatrix} \tilde{c}(r_0+) \\ \tilde{c}(r_1-) \\ \vdots \\ \tilde{c}(r_q-) \end{bmatrix}, \tag{18}$$

then $\bar{\theta}$ is optimal for AP*(Ω). Moreover, an optimal solution, $\theta^{(n)}(t)$, which is complementary slack with $\omega^{(n)}(t)$, can be defined from $\bar{\theta}$ in the following way. Fix i and consider (t_{i-1}, t_i). As $\mathrm{supp}(\omega^n(t))$ is constant on (t_{i-1}, t_i), there exists a unique basis matrix B of K, given by Lemma 6.3, corresponding to the support of $\omega^{(n)}(t)$ on (t_{i-1}, t_i). The optimal $\theta^{(n)}(t)$ is then defined by

$$\theta^{(n)}(t) = (B^{-1})^T \bar{c}_B(t)$$

for $t \in [t_{i-1}, t_i)$, where

$$\bar{c}(t) = \begin{bmatrix} c(t) \\ \pi(t_i-) \\ 0 \end{bmatrix}$$

for $t \in [t_{i-1}, t_i)$.

Now by the construction of the partition P, the components of $\theta^{(n)}(t)$ are monotonic on $[t_{i-1}, t_i)$. We currently have $\theta^{(n)}$ constructed from (18). This could theoretically produce $\theta^{(n)}$ with a breakpoint at every point in Ω. We now show that this is not possible. In particular, let

$$\hat{\theta} = \begin{bmatrix} \bar{\theta}(t_0+) \\ \bar{\theta}(t_1-) \\ \vdots \\ \bar{\theta}(t_m-) \end{bmatrix}.$$

We will now show that in fact

$$\hat{\theta} = (\hat{B}^{-1})^T \begin{bmatrix} \tilde{c}(t_0+) \\ \tilde{c}(t_1-) \\ \vdots \\ \tilde{c}(t_m-) \end{bmatrix} \tag{19}$$

for some basis matrix $\hat{B}$ for AP(P). This will give us the required bound on the size of $\theta^{(n)}$ stated in the lemma and establish the result. We note that a basis matrix $\hat{B}$ must contain $2m(n_2 + n_3)$ columns of the constraint matrix $\hat{A}$ for AP(P). (Recall that m is the size of the partition P.)

The basic idea of the proof is that as $\text{supp}(\omega^{(n)}(t))$ is constant on (t_{i-1}, t_i) for each i, the essential information for $\bar{B}$ can be compressed into a smaller matrix $\hat{B}$. This idea is quite simple in concept but difficult to notate due to the size of the constraint matrices involved. Recall that the constraint matrix for AP(Ω) is given by

$$\bar{A} = \begin{bmatrix} G & I & 0 & 0 & 0 & 0 & \dots & & & & & \\ H & 0 & I & 0 & 0 & 0 & \dots & & & & & \\ 0 & -I & 0 & G & I & 0 & \dots & & & & & \\ 0 & 0 & 0 & H & 0 & I & \dots & & & & & \\ 0 & 0 & 0 & 0 & -I & 0 & G & \dots & & & & \\ 0 & 0 & 0 & 0 & 0 & 0 & H & \dots & & & & \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & & & & \\ 0 & & & & \dots & & & & -I & 0 & G & I & 0 \\ 0 & & & & \dots & & & & 0 & 0 & H & 0 & I \end{bmatrix},$$

i.e., a matrix with a repeating block structure with $2q(n_1 + n_2 + n_3)$ columns. (Recall that q is the size of the partition Ω.) Similarly, the constraint matrix, $\hat{A}$, for AP(P) will be of the same form but with $2m(n_1 + n_2 + n_3)$ columns.

We begin by making a simple observation. Consider the matrix

$$\Lambda = \begin{bmatrix} G & I & 0 & 0 & 0 \\ H & 0 & I & 0 & 0 \\ 0 & -I & 0 & G & 0 \\ 0 & 0 & 0 & H & I \end{bmatrix},$$

made up of five blocks of columns which we call block 1 to block 5 for convenience. Suppose that Π is a matrix of columns of Λ with the following property: column i of block 1 is in Π if and only if column i of block 4 is in Π, and column i of block 3 is in Π if and only if column i of block 5 is in Π. In other words, the columns of the blocks containing G and H are the same, and the columns of the blocks containing a single I (of dimension n_3) are the same. We claim that for such a Π to have full column rank, it must contain no more than $n_2 + n_3$ columns corresponding to the first three blocks. Suppose that Π contains more than $n_2 + n_3$ columns from the first three blocks. Then there exists $\alpha^T = (u^T, v^T, w^T) \in \mathbb{R}^{n_1+n_2+n_3}$ with $\alpha \neq 0$ and with $i \in \text{supp}(\alpha)$ only if Λ_i is a column in Π, such that

$$K\alpha = \begin{bmatrix} G & I & 0 \\ H & 0 & I \end{bmatrix} \begin{bmatrix} u \\ v \\ w \end{bmatrix} = 0.$$

Define

$$\beta^T = (u^T, v^T, w^T, -u^T, -w^T).$$

Then $\beta \neq 0$, and by the definition of Π, we have $i \in \text{supp}(\beta)$ only if Λ_i is a column in Π. Moreover, $\Lambda\beta = 0$. Thus Π does not have full column rank. Hence, as claimed, if Π has full column rank, then it must contain no more $n_2 + n_3$ columns corresponding to the first three blocks.

With this observation in mind we now return to the basis matrix $\bar{B}$ of the constraint matrix $\bar{A}$ for AP(Ω). Fix i and consider (t_{i-1}, t_i). Consider the columns of $\bar{A}$ corresponding to the variables of $\bar{\omega}$ relating to the times in $\Omega \cap [t_{i-1}, t_i]$ (except for $\bar{y}(s_0^{(i)})$), i.e., corresponding to the variables $\bar{x}(s_0^{(i)}+)$, $\bar{y}((s_0^{(i)} + s_1^{(i)})/2)$, $\bar{z}(s_0^{(i)}+)$, $\bar{x}(s_1^{(i)}-)$, $\bar{y}(s_1^{(i)})$, $\bar{z}(s_1^{(i)}-)$, $\dots$, $\bar{x}(s_{p_i-1}^{(i)}+)$,

$\bar{y}((s^{(i)}_{p_i-1} + s^{(i)}_{p_i})/2)$, $\bar{z}(s^{(i)}_{p_i-1}+)$, $\bar{x}(s^{(i)}_{p_i}-)$, $\bar{y}(s^{(i)}_{p_i})$, and $\bar{z}(s^{(i)}_{p_i}-)$. This can be written as

$$\bar{A}^{(i)} = \begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 & \dots & & 0 & 0 & 0 & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \dots & & \vdots & \vdots & \vdots & \vdots & \vdots \\
G & I & 0 & 0 & 0 & 0 & \dots & & & & & & \\
H & 0 & I & 0 & 0 & 0 & \dots & & & & & & \\
0 & -I & 0 & G & I & 0 & \dots & & & & & & \\
0 & 0 & 0 & H & 0 & I & \dots & & & & & & \\
0 & 0 & 0 & 0 & -I & 0 & G & \dots & & & & & \\
0 & 0 & 0 & 0 & 0 & 0 & H & \dots & & & & & \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots & & & & & \\
0 & & & & \dots & & & & -I & 0 & G & I & 0 \\
0 & & & & \dots & & & & 0 & 0 & H & 0 & I \\
0 & & & & \dots & & & & 0 & 0 & 0 & -I & 0 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \dots & & \vdots & \vdots & \vdots & \vdots & \vdots \\
0 & 0 & 0 & 0 & 0 & 0 & \dots & & 0 & 0 & 0 & 0 & 0
\end{bmatrix}.$$

In this case we refer to each group of $n_1 + n_2 + n_3$ columns as a block. Thus $\bar{A}^{(i)}$ contains $2p_i$ blocks. Now as $\text{supp}(\omega^{(n)}(t))$ is constant on (t_{i-1}, t_i) and has $n_2 + n_3$ elements (as SCLP_n is nondegenerate), $\bar{B}$ contains at least $n_2 + n_3$ columns of $\bar{A}^{(i)}$ from each block, except possibly the last one. (The last block is excluded as we may have $y_j(t_i) = 0$ for some j but $y_j(t) > 0$ for $t \in (t_{i-1}, t_i)$.) Moreover, the columns of $\bar{A}^{(i)}$ that are in $\bar{B}$ are the same for each block in the sense that column j of the first block of $\bar{A}^{(i)}$ is in $\bar{B}$ if and only if column j of each block of $\bar{A}^{(i)}$, except possibly the last one, is in $\bar{B}$. However, by using the observation made above about the matrix Λ (which in some sense is a building block of $\bar{A}^{(i)}$), for $\bar{B}$ to have full column rank it must contain exactly $n_2 + n_3$ columns of $\bar{A}^{(i)}$ from each block, except possibly the last one. This shows that any degenerate columns in $\bar{B}$, i.e., columns corresponding to zero variables in $\bar{\omega}$, must be taken from the last block of $\bar{A}^{(i)}$ for some i. Thus the total number of columns of $\bar{B}$ that are taken from the last block of $\bar{A}^{(i)}$ for some i must be $m(n_2 + n_3)$.

Now consider AP(P). Let $\hat{\omega}$ denote a set of variables for AP(P). Consider the columns of the constraint matrix for AP(P), $\hat{A}$, corresponding to the variables of $\hat{\omega}$ relating to the times t_{i-1} and t_i (except for $\hat{y}(t_{i-1})$), i.e., corresponding to the variables $\hat{x}(t_{i-1}+)$, $\hat{y}((t_{i-1} + t_i)/2)$, $\hat{z}(t_{i-1}+)$, $\hat{x}(t_i-)$, $\hat{y}(t_i)$ and $\hat{z}(t_i-)$. This can be written as

$$\hat{A}^{(i)} = \begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
G & I & 0 & 0 & 0 & 0 \\
H & 0 & I & 0 & 0 & 0 \\
0 & -I & 0 & G & I & 0 \\
0 & 0 & 0 & H & 0 & I \\
0 & 0 & 0 & 0 & -I & 0 \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
0 & 0 & 0 & 0 & 0 & 0
\end{bmatrix}.$$

We refer to the first $n_1 + n_2 + n_3$ and last $n_1 + n_2 + n_3$ columns of $\hat{A}^{(i)}$ as the first and second blocks, respectively. Define a matrix $\hat{B}^{(i)}$ consisting of columns of $\hat{A}^{(i)}$ as follows. If column j of the first block of $\bar{A}^{(i)}$ is in $\bar{B}$ (and hence column j of each block of $\bar{A}^{(i)}$, except possibly the last, is in $\bar{B}$), then column j of the first block of $\hat{A}^{(i)}$ is in $\hat{B}^{(i)}$. This generates $n_2 + n_3$ columns of $\hat{B}^{(i)}$. The remaining columns of $\hat{B}$ are chosen in accordance with the columns of $\bar{B}$ from the last block of $\bar{A}^{(i)}$. In particular, if column j of the last block of $\bar{A}^{(i)}$ is in $\bar{B}$, then column j of the second block of $\hat{A}^{(i)}$ is in $\hat{B}^{(i)}$. By the properties of $\bar{B}$ noted above as well

as (18) we now claim that

$$(\hat{B}^{(i)})^T\hat{\theta} = \begin{bmatrix} \tilde{c}(t_{i-1}+) \\ \tilde{c}(t_i-) \end{bmatrix}. \tag{20}$$

In fact, suppose for instance that $[\bar{\pi}(s_j^{(i)}-) - \bar{\pi}(s_{j-1}^{(i)}+)]_k = 0$ is one equation in (18). Then we must have $y_k(t) > 0$ on (t_{i-1}, t_i) and so the equations $[\bar{\pi}(s_l^{(i)}-) - \bar{\pi}(s_{l-1}^{(i)}+)]_k = 0$ for each $l = 1, \ldots, p_i$ and $[\bar{\pi}(s_l^{(i)}+) - \bar{\pi}(s_l^{(i)}-)]_k = 0$ for each $l = 1, \ldots, p_i - 1$ are in (18). Hence we have $[\bar{\pi}(t_i-) - \bar{\pi}(t_{i-1}+)]_k = 0$. But by definition of $\hat{B}^{(i)}$, this equation is in (20). A similar argument follows for the other equations.

Having defined $\hat{B}^{(i)}$ for each i we set

$$\hat{B} = \begin{bmatrix} \hat{B}^{(1)} & \hat{B}^{(2)} & \ldots & \hat{B}^{(m)} \end{bmatrix};$$

then by the observations made above we see that $\hat{B}$ contains $2m(n_2 + n_3)$ columns of $\hat{A}$, $(n_2 + n_3)$ from each of the first blocks of $\hat{A}^{(i)}$ for each i, and $m(n_2 + n_3)$ in total from the second blocks of each $\hat{A}^{(i)}$. Hence $\hat{B}$ is a square matrix. Moreover, from (20) we see that $\hat{\theta}$ satisfies

$$\hat{B}^T\hat{\theta} = \begin{bmatrix} \tilde{c}(t_0+) \\ \tilde{c}(t_1-) \\ \vdots \\ \tilde{c}(t_m-) \end{bmatrix}.$$

All that remains now is to show that $\hat{B}$ has full column rank. Then $\hat{B}$ will be a basis matrix for AP(P) and so (19) will hold.

Suppose that $\hat{B}$ does not have full column rank. Then there exists $\gamma \neq 0$ such that $i \in \text{supp}(\gamma)$ only if $\hat{A}_i$ is a column in $\hat{B}$ and such that $\hat{A}\gamma = 0$. Suppose $\gamma^T = (\alpha^{(1)^T}, \beta^{(1)^T}, \ldots, \alpha^{(m)^T}, \beta^{(m)^T})$, where $\alpha^{(i)}, \beta^{(i)} \in \mathbb{R}^{n_1+n_2+n_3}$ for each i. Define $\rho^{(i)} \in \mathbb{R}^{n_1+n_2+n_3}$ by $\rho_j^{(i)} = \alpha_j^{(i)}$, if $j = n_1 + 1, \ldots, n_1 + n_2$ and $\rho_j^{(i)} = 0$ otherwise. Define

$$\delta^T = (\alpha^{(1)^T}, \rho^{(1)^T}, \ldots, \rho^{(1)^T}, \beta^{(1)^T}, \ldots, \alpha^{(m)^T}, \rho^{(m)^T}, \ldots, \rho^{(m)^T}, \beta^{(m)^T}),$$

where $\rho^{(i)}$ is repeated $2(p_i - 1)$ times for each i. Then it can be observed that $\bar{A}\delta = 0$, thus showing that $\bar{B}$ does not have full column rank. □

The strong duality result under Assumption 6.2 now follows immediately by appealing to Lemma 5.3 to guarantee the existence of an optimal solution for SCLP*. Note that this lemma guarantees a piecewise analytic optimal solution for SCLP* with at most $M + N + 1$ breakpoints, where M is given by Lemma 6.7. The existence of a piecewise analytic optimal solution for SCLP is given by Theorem 2.5 and the absence of a duality gap by Theorem 4.2. By using the same arguments as in the strong duality result for analytic costs, Theorem 6.6, the result can be extended to include general H that does not necessarily contain the upper bound constraints on $x(t)$. Again we may repeat the overall argument a finite number of times to arrive at the main result of this paper.

THEOREM 6.9 (strong duality). *Suppose that the costs $c(t)$ and the right-hand sides $a(t)$ and $b(t)$ are piecewise analytic on $[0, T]$ (with $a(t)$ continuous) and the feasible region for* SCLP *is nonempty and bounded. Then V[SCLP] = V[SCLP*] and there exist piecewise analytic optimal solutions for both* SCLP *and* SCLP*.

Note that the result for the absence of a duality gap contained in the above result has a less restrictive boundedness assumption than Theorem 4.2.

7. Conclusions and counterexamples. The previous section contained a general strong duality result between SCLP and SCLP*. The proof was largely constructive and involved finding an optimal solution for SCLP*. The proof showed us that, at least locally, an optimal solution $\theta(t)$ for SCLP* satisfies

$$\theta(t) = (B^{-1})^T \bar{c}_B(t)$$

for t in some interval $[\alpha, \beta)$, where

$$\bar{c}(t) = \begin{bmatrix} c(t) \\ \pi(\beta-) \\ 0 \end{bmatrix}$$

for $t \in [\alpha, \beta)$. Hence the optimal $\theta(t)$ has the same properties as the costs $c(t)$. Thus if, for instance, $c(t)$ were a polynomial of degree n, then the optimal $\theta(t)$ would be piecewise polynomial of degree n. Such an observation has also been made about optimal solutions for the primal problem SCLP in the conclusion to Pullan [29], namely, that optimal solutions for the primal reflect the nature of the right-hand sides $a(t)$ and $b(t)$. This leads to many possible variations on the strong duality theorem of the previous section. Recalling one result from the conclusion to [29] we state one of these many possible variations.

THEOREM 7.1 (strong duality). *Suppose that the costs $c(t)$ and the right-hand sides $a(t)$ and $b(t)$ are piecewise polynomial on $[0, T]$ (with $a(t)$ continuous) of degrees n, $m+1$, and m, respectively. Suppose also that the feasible region for* SCLP *is nonempty and bounded. Then V[SCLP] $= V$[SCLP*] and there exist piecewise polynomial optimal solutions of degree m for* SCLP *and degree n for* SCLP*.

It is also interesting to speculate whether strong duality holds between SCLP and SCLP* in more general circumstances, for instance, continuously differentiable problem data. To partially answer this question we present a simple counterexample to show that the result in Theorem 6.9 cannot be extended beyond analytic a and b to, say, n-times continuously differentiable a and b for some n, even if the costs are assumed to be constant. In such a case an optimal solution for the primal problem may have an infinite number of breakpoints. Thus, because of the necessity of complementary slackness for strong duality, it is possible that any potential optimal solution for the dual must have an infinite number of breakpoints, which can cause the potential optimal $\pi(t)$ to be unbounded, i.e., not of bounded variation.

Example 7.1. Consider a simple network of two nodes connected by two arcs (see Figure 7.1). We will consider a network problem over the time interval $[0, 1]$ where storage is permitted at the nodes (in other words, a CNP example as discussed by Anderson and Philpott [4]). Let $x_i(t)$ denote the rate of flow in arc i at time t and $y_i(t)$ denote the amount of storage at time t in node i for $i = 1, 2$. The rate of flow in each of the two arcs is subject to an upper bound of 1, and the cost per unit flow in each arc is 1. Choose $n \geq 1$ and define the supplies, $r_i(t)$, in node i by

$$r_1(t) = \begin{cases} (1-t)^n \sin\left(\dfrac{1}{1-t}\right), & t \in [0, 1), \\ 0, & t = 1, \end{cases}$$
$$r_2(t) = -r_1(t)$$

for $t \in [0, 1]$. We then define

$$a_i(t) = \int_0^t r_i(s)\, ds$$

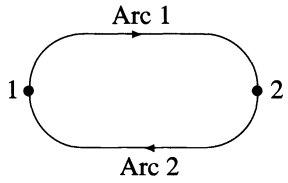

FIG. 7.1. *The network in Example* 7.1.

for $t \in [0, 1]$ and $i = 1, 2$. Then $a_i(t)$ is n-times continuously differentiable. Our SCLP (or CNP) problem is now

$$\begin{aligned}
\text{Ex:}\quad \text{minimize}\quad & \int_0^1 (x_1(t) + x_2(t))\, dt \\
\text{subject to}\quad & \int_0^t (x_1(s) - x_2(s))\, ds + y_1(t) = a_1(t), \\
& \int_0^t (x_2(s) - x_1(s))\, ds + y_2(t) = a_2(t), \\
& x_1(t) + z_1(t) = 1, \\
& x_2(t) + z_2(t) = 1, \\
& x_1(t), x_2(t), y_1(t), y_2(t), z_1(t), z_2(t) \geq 0, \quad t \in [0, 1].
\end{aligned}$$

Let

$$S = \{ t \in [0, 1] : r_1(t) > 0 \};$$

then it is clear that Ex has an optimal solution, $\omega(t)^T = (x_1(t), x_2(t), y_1(t), y_2(t), z_1(t), z_2(t))$, where

$$x_1(t) = \begin{cases} r_1(t), & t \in S, \\ 0, & t \notin S, \end{cases}$$

$$x_2(t) = \begin{cases} 0, & t \in S, \\ r_2(t), & t \notin S. \end{cases}$$

This then gives $y_1(t) = y_2(t) = 0$ and $z_1(t), z_2(t) > 0$ on $[0, 1]$. Now the dual of Ex is given by

$$\begin{aligned}
\text{Ex*:}\quad \text{maximize}\quad & \int_0^1 (\eta_1(t) + \eta_2(t))\, dt - \int_0^1 a_1(t)\, d\pi_1(t) - \int_0^1 a_2(t)\, d\pi_2(t) \\
\text{subject to}\quad & 1 - \pi_1(t) + \pi_2(t) - \eta_1(t) \geq 0, \\
& 1 - \pi_2(t) + \pi_1(t) - \eta_2(t) \geq 0, \\
& \eta_1(t), \eta_2(t) \leq 0, \text{ a.e. on } [0, 1], \\
& \pi_1(t), \pi_2(t) \text{ monotonic increasing and right continuous} \\
& \text{on } [0, 1] \text{ with } \pi_1(1) = \pi_2(1) = 0.
\end{aligned}$$

By a simple application of Theorem 4.2 we see that there is no duality gap between Ex and Ex*. However, as we shall see below, Ex* does not attain its optimal value, and hence strong duality does not hold between Ex and Ex*.

Suppose that strong duality holds, i.e., that Ex* attains its optimal value. Then by the complementary slackness result (Theorem 3.4), there exists $\theta(t)^T = (\pi_1(t), \pi_2(t), \eta_1(t), \eta_2(t))$

optimal for Ex* and complementary slack with $\omega(t)$. Using the definition of complementary slackness, we see that this must imply that

$$1 - \pi_1(t) + \pi_2(t) - \eta_1(t) = 0 \text{ a.e. on } S, \tag{21}$$

$$1 - \pi_2(t) + \pi_1(t) - \eta_2(t) = 0 \text{ a.e. on } [0, 1] - S, \tag{22}$$

$$\eta_1(t) = \eta_2(t) = 0 \text{ a.e. on } [0, 1]. \tag{23}$$

We now proceed to show that these equations cannot be satisfied while maintaining $\theta(t)$ feasible for Ex*.

Suppose that $\pi_2(0) = M$. As $\pi_2(1) = 0$ we must have $M \leq 0$. Now S is an open disconnected set in [0, 1] with an infinite number of components. Suppose then that

$$S = \{0\} \cup \bigcup_{i=1}^{\infty} (t_i, s_i)$$

and that $0 = t_1 < s_1 < t_2 < s_2 \cdots$. Now $(t_1, s_1) \subset S$, so we must have by (21) and (23) that

$$\pi_1(t) = 1 + \pi_2(t) \text{ a.e. on } (t_1, s_1).$$

Hence, as $\pi_2(t) \geq M$ on (t_1, s_1), we must have

$$\pi_1(t) \geq 1 + M \text{ on } (t_1, s_1).$$

Hence $\pi_1(t) \geq 1 + M$ on (t_1, t_2) by the monotonicity of $\pi_1(t)$. Now by repeating the above argument for the interval (s_1, t_2), which is not a component of S, and using (22) and (23) this time, we obtain

$$\pi_2(t) \geq 2 + M \text{ on } (s_1, t_2).$$

Continuing in this manner it is apparent that we may construct $t \in (0, 1)$ such that $\pi_1(t) > 0$. This is a contradiction since $\pi_1(1) = 0$ and $\pi_1(t)$ is monotonic increasing on [0, 1]. Hence no optimal solution for Ex* exists, so strong duality does not hold between Ex and Ex*. □

The question of whether it is possible to extend Theorem 6.6 (i.e., the result with analytic costs, linear $a(t)$, and constant $b(t)$) to include more general costs appears more difficult and remains unresolved.

CYCLE DECOMPOSITIONS AND SIMULATED ANNEALING*

ALAIN TROUVÉ†

Abstract. The behavior of simulated annealing algorithms is tightly related to the hierarchical decomposition of their configuration spaces in cycles. In the generalized annealing framework, this decomposition is defined recursively. In this paper, its structure is extensively studied, and it is shown that the decomposition can be achieved through an implementable algorithm which allows exact computation of the fundamental constants underlying the behavior of these algorithms.

Key words. cycle decomposition, large deviations, generalized simulated annealing, rate of convergence

AMS subject classifications. Primary, 60F10; Secondary, 60J10, 93E25

1. Introduction.

Simulated annealing is now used extensively for optimizing large-scale problems. Its main advantages are its wide applicability and its simplicity, allowing a large variability in the choice of the constraints defining the cost function to be minimized.

Let us recall briefly the theoretical scheme. We consider the problem of finding the configurations minimizing a function $U : E \to \mathbb{R}$ on a finite set E, called the configuration space (or the state space). The function U is generally called the cost function or the energy function. One considers an inhomogeneous Markov chain $X = (X_n)_{n\in\mathbb{N}}$ on E with transition kernel at time n given by $Q_{T_{n+1}}$, where for all $T > 0$ (called the temperature)

$$Q_T(i, j) = q(i, j)e^{-(U(j)-U(i))^+/T}, \tag{1}$$

and q is an irreducible Markov kernel satisfying $q(i, j) = q(j, i)$. The sequence $\mathcal{T} = (T_n)_{n\in\mathbb{N}}$ is a sequence of nonnegative numbers called the cooling schedule. For low temperature, the Markov chain preferably follows configuration paths with decreasing energy value, but hill-climbing moves are allowed with a probability controlled by the temperature. The theory of simulated annealing says that if the cooling schedule is sufficiently slowly decreasing, then we have

$$\sup_{i\in E} P(\, U(X_n) \neq \min U \mid X_0 = i \,) \underset{n\to+\infty}{\to} 0 .$$

Using the large deviation approach of Wentzell and Freidlin [6] one can have much more information on the behavior at low temperature. It appears that the Markov chain performs a hierarchical exploration of the configuration space well described by the cycle decomposition of E introduced in [6]. The role of the cycles becomes clear if we consider the Markov chain under a constant cooling schedule at temperature T. When the Markov chain enters into a cycle, the time to exit from the cycle is of order of $e^{H_e/T}$, where H_e called the exit height is a constant depending only on the cycle and not on the entering point. The smallest cycles are the singletons, and the largest one is the whole space E. Since two cycles are either disjoint or included one in the other, the cycles are structured as a tree, and the Markov chain moves from cycle to cycle along characteristic paths. The generalization of this approach to decreasing temperature schedules for the study of simulated annealing algorithms requires some important work, for which the reader can refer to [2-4, 9, 10].

Let $\mathcal{C}(E)$ denote the set of all the cycles, and for every cycle Π, $H_e(\Pi)$ denotes the exit height of Π. Many of the characteristics of the asymptotic behavior of the sequential

*Received by the editors November 16, 1993; accepted for publication (in revised form) January 16, 1995.

†Laboratoire de Mathématiques de l'Ecole Normale Supérieure/Distributed Intelligent Applications and Mathematics, URA 732, Ecole Normale Supérieure, 45 rue d'Ulm, 75230, Paris cedex 05, France (trouve@ens.ens.fr).

annealing under decreasing cooling schedule can be computed. For instance (see [2, 7]), if $\mathcal{T}$ is a decreasing cooling schedule vanishing to zero, then we have

$$\sup_{i\in E} P(\, U(X_n) \neq \min U \mid X_0 = i\,) \underset{n\to+\infty}{\longrightarrow} 0 \text{ iff } \sum_{n\geq 0} e^{-H_1/T_n} = +\infty, \tag{2}$$

where H_1 denotes $\sup\{\, H_e(\Pi) \mid \Pi \in \mathcal{C}(E) \text{ and } U(\Pi) > \min U \,\}$ and $U(\Pi) = \min_{i\in\Pi} U(i)$. The constant H_1 is called the critical height of the cycle decomposition. Moreover, there exists a positive constant K_1 such that for any cooling schedule $\mathcal{T}$ we have

$$\sup_{i\in E} P(\, U(X_n) > \min U \mid X_0 = i\,) \geq K_1/n^{\alpha_{opt}}, \tag{3}$$

where $\alpha_{opt} = \inf\{\, \frac{U(\Pi)-\min U}{H_e(\Pi)} \mid \Pi \in \mathcal{C}(E) \text{ and } U(\Pi) > \min U \,\}$. The optimality of the exponent α_{opt} is proven by a final result established in [2] which says that there exists a positive constant K such that for all $N > 0$ there exists a cooling schedule for which we have

$$\sup_{i\in E} P(\, U(X_N) > \min U \mid X_0 = i\,) \leq K/N^{\alpha_{opt}}. \tag{4}$$

The number α_{opt} is called the optimal convergence exponent.

In order to have a better convergence speed toward the global minima of U, many computer scientists have proposed parallelized schemes of the usual sequential simulated annealing. The underlying idea is to distribute the amount of computation on several processors (see [1, 13]). It appears that the parallel schemes lead to a more general form of the simulated annealing called the generalized simulated annealing (G.S.A.) introduced by Hwang and Sheu in [10] and which corresponds to a discrete-time and finite-space analogue of the general framework introduced by Wentzell and Freidlin in [6] in their study of random perturbation of dynamical systems. Instead of assuming that the transition kernel Q_T satisfies (1), we just assume that there exists $\kappa \geq 1$ such that

$$\frac{1}{\kappa} q(i,j) e^{-V(i,j)/T} \leq Q_T(i,j) \leq \kappa q(i,j) e^{-V(i,j)/T}, \tag{5}$$

where the family V called the communication cost satisfies $V(i,j) \in [0, +\infty]$ and $V(i,j) = +\infty$ iff $q(i,j) = 0$. This new framework is adapted to the study of many of the extensions (parallel or not) of the usual sequential scheme. One gets from Wentzell and Freidlin's theory that there exists a virtual energy W which plays the same role as the energy U for low temperature since if we denote by μ_T the unique equilibrium probability measure of Q_T, then

$$\lim_{T\to 0} T \ln \mu_T(i) = -(W(i) - \min W),$$

and with the help of the Dobrushin theory of inhomogeneous Markov chains we easily prove that if T is sufficiently slowly decreasing, then

$$\sup_{i\in E} P(\, W(X_n) > \min W \mid X_0 = i\,) \underset{n\to+\infty}{\to} 0.$$

However, if we want to establish more precise results for the general framework, like (2)-(4) (with U replaced by W), we have to deal with an extension of the cycle decomposition. This extension has been proposed in the original work of Wentzell and Freidlin, where they again define cycles for which we keep the crucial property that at constant temperature, the time to exit from a cycle Π is of order of $e^{H_e(\Pi)/T}$, where $H_e(\Pi)$ does not depend on the starting point. Using this extended cycle decomposition, Hwang and Sheu in [10] proved a weak version of (2) for cooling schedules $\mathcal{T}$ satisfying $T_n = c/\ln(n+2)$, and in [13, 14] the author proves the exact analogues of (2)-(4) for the G.S.A. (where U is replaced by W). Hence the cycle

decomposition plays a central role in the asymptotic behavior of the G.S.A. as well as in the computation of H_1 and α_{opt}.

We will in this paper perform an extended study of the cycle decomposition in the generalized annealing framework. In §2, starting from the recursive definition of the cycles, which depends only on the communication cost V (and not on W), we will establish the links between the virtual energy W and the exit height $H_e(\Pi)$ and show that these links lead to a decomposition diagram structuring the cycle decomposition in a valued tree. Then we will introduce the altitude of communication by

$$A_c(i, j) = \inf_{n\in\mathbb{N}} \inf_{i=g_0,g_1,\dots,g_n=j} \sup_{k<n} W(g_k) + V(g_k, g_{k+1}),$$

which will allow us to give a new construction of the cycle decomposition very close to the sequential case construction. We will show also that this altitude of communication is symmetric ($A_c(i, j) = A_c(j, i)$) and that this property characterizes (up to a multiplicative constant) the virtual energy. This will allow us to shed a new light on the weak reversibility of Hajek. Finally, in §3, we propose an implementable algorithm to compute automatically the cycle decomposition as well as all the critical constants H_1 and α_{opt}. This may be useful in order to study the *exact* asymptotic behavior of the G.S.A on small state spaces—for example, when evaluating parallel schemes (see [13]).

2. Generalized simulated annealing.

2.1. Definition. Let us first recall some notation. The set E denotes a finite configuration space, and q an irreducible Markov kernel on E called the communication kernel. The irreducibility of Q means that for all distinct configurations i and j there exists a path $(i_k)_{0\le k\le n}$ satisfying

$$i_0 = i,\ i_n = j, \quad \text{and } q(i_k, i_{k+1}) > 0 \text{ for all } k \le n-1.$$

Let us also consider a real-valued number $\kappa \ge 1$. We can now define precisely the families of kernels we will consider.

DEFINITION 2.1. *Let $(Q_T)_{T>0}$ be a family of Markov kernels on E. We say that $(Q_T)_{T>0}$ is admissible for q and κ if there exists a family of positive real-valued numbers $(V(i, j))_{(i,j)\in E\times E}$ (some of them may take the value $+\infty$) such that*

1. *$V(i, j) < +\infty$ iff $q(i, j) > 0$;*
2. *for all $T > 0$, all $i, j \in E$,*

$$\frac{1}{\kappa} q(i, j) e^{-V(i,j)/T} \le Q_T(i, j) \le \kappa q(i, j) e^{-V(i,j)/T}.$$

The function $V : E \times E \to [0, +\infty]$ is called the communication cost function.

NOTATION 2.2. *The set of all the admissible families $(Q_T)_{T>0}$ will be denoted $\mathcal{A}(q, \kappa)$.*

The set $\mathcal{A}(q, \kappa)$ contains all the families of kernels associated with sequential simulated annealing algorithms and also many parallelized versions of the sequential scheme.

We define now the generalized simulated annealing algorithms.

DEFINITION 2.3. *We say that $(X_n)_{n\in\mathbb{N}}$ is a generalized simulated annealing with parameters $(E, V, q, \kappa, \nu_0, \mathcal{T})$, where ν_0 is a probability measure on E and $\mathcal{T} = (T_n)_{n\in\mathbb{N}}$ is a decreasing sequence of strictly positive real-valued numbers called the cooling schedule, if there exists a family of Markov kernel $(Q_T)_{T>0}$ in $\mathcal{A}(q, \kappa)$ with communication cost function V such that $(X_n)_{n\in\mathbb{N}}$ is a Markov chain on E satisfying*

$$P(X_0 = i) = \nu_0(i), \qquad i \in E,$$

$$P(X_{n+1} = j \mid X_n = i) = Q_{T_{n+1}}(i, j), \qquad i, j \in E.$$

2.2. Virtual energy. Let us consider a family $(Q_T)_{T>0}$ of Markov kernels in $\mathcal{A}(q, \kappa)$ and $V : E \times E \to [0, +\infty]$, the associated communication cost function. In the following definition, we recall the notion of A-graphs as defined by Wentzell and Freidlin in [6]. Like them, $i \to j$ will denote the pair (i, j).

DEFINITION 2.4. *Let $A \subset E$. We say that a set g of arrows $i \to j$ in $A^c \times E$ is an A-graph iff*

1. *for each $i \in A^c$, there exists a unique $j \in E$ such that $i \to j \in g$;*
2. *for each $i \in A^c$, there is a path $i = i_0 \to i_1 \to \cdots \to i_n$ such that $i_k \to i_{k+1} \in g$, ending on a configuration in A.*

We denote by $G(A)$ the set of the A-graphs. Furthermore, for each $g \in G(A)$ we denote

$$V(g) = \sum_{i \to j \in g} V(i, j).$$

We can now define the virtual energy.

DEFINITION 2.5. *We say that $W : E \to \mathbb{R}$ is the virtual energy associated with the communication cost function V if*

$$W(i) = \inf_{g \in G(\{i\})} V(g), \qquad i \in E.$$

The virtual energy will play the same role as the energy U for the sequential simulated annealing, as shown in the proposition below.

PROPOSITION 2.6 (Wentzell and Freidlin). *For all $T > 0$, we denote by μ_T the unique invariant probability measure for Q_T (since q irreducible implies Q_T irreducible). Then we have*

$$T \ln(\mu_T(i)) \underset{T \to 0}{\longrightarrow} -(W(i) - W(E)),$$

$$\text{where } W(E) = \inf_{j \in E} W(j).$$

Hence, the generalized simulated annealing can be seen again as an optimization algorithm minimizing the virtual energy. However, the virtual energy is now only implicitly defined by the communication cost function.

2.3. Decomposition in cycles. The study of the virtual energy is not sufficient to understand the behavior of a generalized simulated annealing algorithm. One can have two communication cost functions giving the same virtual energy but leading to very different asymptotic behaviors. This leads us to the computation of a decomposition in cycles as done for the sequential case [2]. However, the cycles cannot be obtained by a simple substitution of U for W. The correct construction has been given by Wentzell and Freidlin [6] and is reported here with slight modifications. For this purpose, let us give the following preliminary definition.

DEFINITION 2.7. *Let F be a finite set, $C : F \times F \to [0, +\infty]$ be a function, and i and j be two distinct configurations of F.*

1. *We denote by $Pth_F(i, j)$ the set of all paths $(g_k)_{0 \le k \le n}$ in F such that $g_0 = i$ and $g_n = j$. The path-dependent integer n will be denoted by n_g and will be called the length of g.*
2. *For g to be in $Pth_F(i, j)$, define $C(g)$ by*

$$C(g) = \sum_{k=0}^{n_g - 1} C(g_k, g_{k+1}).$$

We adopt the convention that $C(g) = +\infty$ if one of the summation terms is $+\infty$.

The decomposition in cycles is defined in an iterative way. First the set E^0 of cycles of order 0 is defined by

$$E^0 = \{ \{i\} \mid i \in E \}.$$

Let us consider the communication cost function V^0 on E^0 defined by

$$V^0(\{i\}, \{j\}) = V(i, j).$$

Assume that the set E^k of the cycles of order k and a communication cost function V^k on E^k have been constructed. The construction of the pair E^{k+1}, V^{k+1} can be split in several steps:

1. From V^k, we define another communication cost V^k_* on E^k by

$$V^k_*(\Pi, \Pi') = \begin{cases} 0 & \text{if } \Pi = \Pi', \\ V^k(\Pi, \Pi') - H^k_e(\Pi) & \text{otherwise,} \end{cases}$$

$$\text{where } H^k_e(\Pi) = \inf\{V^k(\Pi, \Pi'') \mid \Pi'' \in E^k,\ \Pi'' \neq \Pi \}.$$

2. On E^k, we define the relation $\overset{k}{\to}$ by

$$\Pi \overset{k}{\to} \Pi' \text{ if either } \Pi = \Pi' \text{ or there exists } g \in \mathrm{Pth}_{E^k}(\Pi, \Pi') \text{ such that } V^k_*(g) = 0,$$

and the equivalence relation $\mathcal{R}_k$ by

$$\Pi \mathcal{R}_k \Pi' \text{ if either } \Pi = \Pi' \text{ or } \Pi \overset{k}{\to} \Pi' \text{ and } \Pi' \overset{k}{\to} \Pi.$$

3. Define D^{k+1} by

$$D^{k+1} = \{ \bigcup_{\Pi' \mathcal{R}_k \Pi} \Pi' \mid \Pi \in E^k \},$$

and define on D^{k+1} the partial order $\preceq$ by $\Pi^{k+1}_1 \preceq \Pi^{k+1}_2$ if there exists $\Pi^k_i \subset \Pi^{k+1}_i$ for $i = 1, 2$ such that $\Pi^k_2 \overset{k}{\to} \Pi^k_1$. We denote D^{k+1}_* by the set of the minimal elements of D^{k+1} for the order $\preceq$.

4. Define E^{k+1} by

$$E^{k+1} = D^{k+1}_* \cup \{ \Pi^k \in E^k \mid \exists \Pi^{k+1} \in D^{k+1} \setminus D^{k+1}_*,\ \Pi^k \subset \Pi^{k+1} \}.$$

5. We define now a communication cost V^{k+1} on E^{k+1} by

$$(6)\quad V^{k+1}(\Pi^{k+1}_0, \Pi^{k+1}_1) = H^{k+1}_m(\Pi^{k+1}_0) + \inf\{ V^k_*(\Pi^k_0, \Pi^k_1) \mid (\Pi^k_0, \Pi^k_1) \in E^k \times E^k,\ \Pi^k_0 \subset \Pi^{k+1}_0,\ \Pi^k_1 \subset \Pi^{k+1}_1 \},$$

$$\text{where } H^{k+1}_m(\Pi^{k+1}_0) = \sup\{ H^k_e(\Pi^k_0) \mid \Pi^k_0 \subset \Pi^{k+1}_0,\ \Pi^k_0 \in E^k \}.$$

The construction goes on until $E^k = \{E\}$. We denote the order n_E of the decomposition and the set $\mathcal{C}(E)$ of all the cycles by

$$n_E = \inf\{ k \in \mathbb{N} \mid E^{k+1} = \{E\} \}$$

and

$$\mathcal{C}(E) = \cup_{k=0}^{n_E+1} E^k.$$

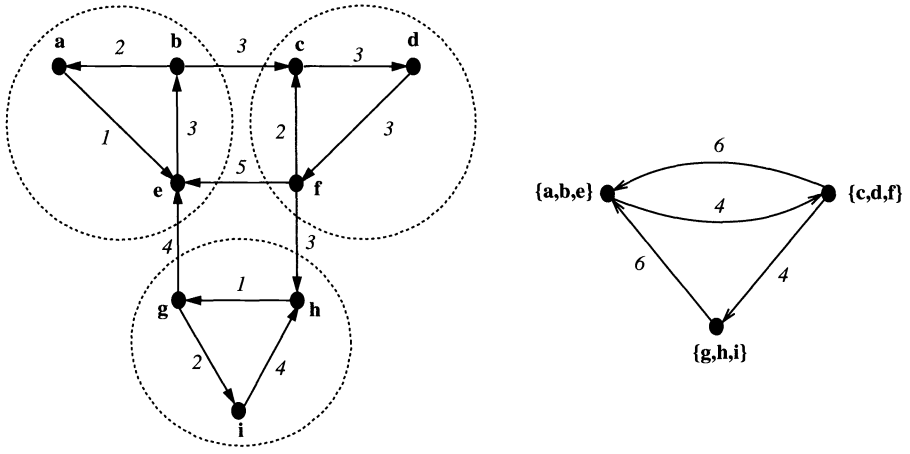

FIG. 1. *Contruction of the cycles.*

TABLE 1.

	H_m^1	H_e^1
$\{a, b, e\}$	3	4
$\{c, d, f\}$	3	4
$\{g, h, i\}$	4	6

TABLE 2.

V^1	$\{a, b, e\}$	$\{c, d, f\}$	$\{g, h, i\}$
$\{a, b, e\}$		4	$+\infty$
$\{c, d, f\}$	6		4
$\{g, h, i\}$	6	$+\infty$	

This procedure gives a hierarchical decomposition of the state space as a tree beginning with the singletons and ending with the whole space.

We shall illustrate this decomposition on a small configuration space:

$$E = \{a, b, c, d, e, f, g, h, i\}.$$

On the left-hand side of Fig. 1, we have represented only edges with finite cost, and their valuation $V(i, j)$ is reported above. The construction of the cycles can be obtained directly on such a small example. We explain here how to obtain the cycles of order 1 since the cycles of greater order can be obtained by iteration of the process. For this purpose, we construct first the *exit graph*, which is a subgraph of the previous graph for which we keep only the edges $i \to j$ satisfying $V(i, j) = \inf_{k \in E, k \neq i} V(i, k)$. The cycles of order 1 are the strongly connected components of the exit graph. We recall that for an oriented graph, a strongly connected component is a family of vertices maximal for the inclusion among all the families which stay connected even if one of their vertices is suppressed. For each cycle Π constructed in this way, we get the quantity $H_m^1(\Pi)$ as the maximal valuation among the edges of the exit graph joining two vertices of Π. Finally, for each pair of distinct cycles Π and Π', we get $V^1(\Pi, \Pi')$ from (6). In our example, we get the following three cycles of order one: $\{a, b, e\}$, $\{c, d, f\}$, and $\{g, h, i\}$. We obtain for H_m^1, H_e^1 and V^1 the values given in Tables 1 and 2. The values of V^1 are reported on the right-hand side of Fig. 1. For the order 2, we have only the whole space E. Hence, we get the decomposition tree in Fig. 2.

2.4. Decomposition diagram. In this section, we will show that we can define as for sequential annealing the bottom of a cycle, its exit height, and any of the quantities defined previously. We will study the links between the exit heights and the potential of the cycles and

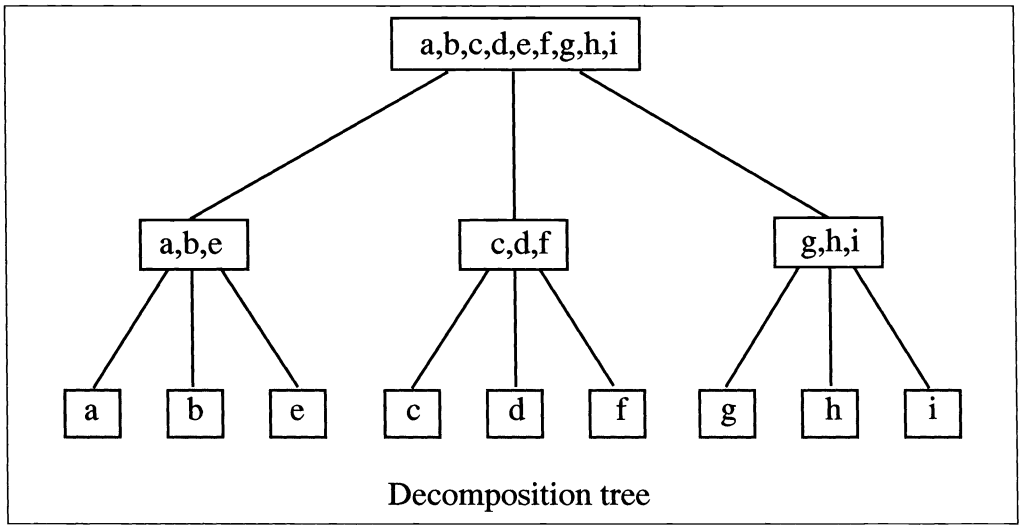

FIG. 2. *Decomposition tree.*

show the existence of an extension of the decomposition diagram introduced in the sequential case.

DEFINITION 2.8. *Let $i \in E$. We define by induction the increasing family of cycles $(i^k)_{0\leq k\leq n_E}$ by $i^0 = \{i\}$ and*

$$i^{k+1} \in E^{k+1}, \quad i^k \subset i^{k+1} \quad \text{for } k \leq n_E.$$

DEFINITION 2.9. *Let $A \subset E$.*

1. *We define the maximal proper partition $\mathcal{M}_*(A)$ of A for $|A| > 1$ by*

$$\mathcal{M}_*(A) = \{\, \Pi \in \mathcal{C}(E) \mid \Pi \text{ is a maximal element in } \mathcal{C}_A^*(E) \,\},$$

$$\text{where } \mathcal{C}_A^*(E) = \{\, \Pi \in \mathcal{C}(E) \mid \Pi \subset A,\ \Pi \neq A \,\}.$$

2. *For all $i \in A$, we call the order of i in A the nonnegative integer $n_{A,i}$ defined by*

$$n_{A,i} = \sup\{\, k \in \mathbb{N} \mid 0 \leq k \leq n_E \text{ and } i^k \subset A \,\}.$$

We will now extend the quantities defined previously on cycles.

DEFINITION 2.10. *Let $\Pi \in \mathcal{C}(E)$. We define*

1. *the order n_Π of Π by*

$$n_\Pi = \inf\{\, k \in \mathbb{N} \mid 0 \leq k \leq n_E \text{ and } \Pi \in E^k \,\};$$

2. *the exit height $H_e(\Pi)$ of Π by*

$$H_e(\Pi) = \begin{cases} \sup\{H_e^k(\Pi) \mid k \leq n_E,\ \Pi \in E^k\} & \text{if } \Pi \neq E, \\ +\infty & \text{otherwise;} \end{cases}$$

3. *the mixing height $H_m(\Pi)$ of Π by*

$$H_m(\Pi) = \begin{cases} \sup\{\, H_e(\Pi') \mid \Pi' \in \mathcal{M}_*(\Pi) \,\} & \text{if } |\Pi| > 1, \\ 0 & \text{if } \Pi \text{ is a singleton;} \end{cases}$$

4. *the potential* $W(\Pi)$ *of* Π *by*

$$W(\Pi) = \inf\{W(i) \mid i \in \Pi\};$$

5. *the bottom* $F(\Pi)$ *of* Π *by*

$$F(\Pi) = \{ i \in \Pi \mid W(i) = W(\Pi) \}.$$

We can make a few comments about these definitions.

Remark 1. The definition of the exit height of a cycle as a *sup* can be surprising. However, we can make the following remark, whose easy verification is left to the reader. Let Π be a cycle of E. If for an integer $k \leq n_E$ we have $\Pi \in E^k \cap E^{k+1}$, then

$$H_m^{k+1}(\Pi) = H_e^{k+1}(\Pi) = H_e^k(\Pi). \tag{7}$$

Hence, $H_e(\Pi) = H_e^k(\Pi)$ as soon as $\Pi \in E^k$.

This remark allows us to use the notation $H_e(i)$ for $H_e^0(\{i\})$.

Remark 2. From the construction of the cycles, for all $\Pi^k \in E^k$ and $\Pi^{k+1} \in E^{k+1}$ such that $\Pi^k \subset \Pi^{k+1}$ and $\Pi^k \neq \Pi^{k+1}$, we get $H_m^{k+1}(\Pi^{k+1}) < H_e^{k+1}(\Pi^{k+1})$. Hence, using Remark 1, we deduce that for each cycle Π such that $|\Pi| > 1$, $H_m(\Pi) < H_e(\Pi)$.

Some parts of the previous definition can be extended to arbitrary subsets of E.

DEFINITION 2.11. *Let* $A \subset E$, $A \neq \emptyset$.

1. *We define the exit height* $H_e(A)$ *of* A *by*

$$H_e(A) = \sup\{ H_e(\Pi) \mid \Pi \in \mathcal{C}(E),\ \Pi \subset A \}.$$

2. *We denote by* $W(A)$ *the real-valued number*

$$W(A) = \inf\{ W(i) \mid i \in A\}.$$

3. *We define the bottom* $F(A)$ *of* A *by*

$$F(A) = \{ i \in A \mid W(i) = W(A) \}.$$

The following proposition reveals the strong link between the decomposition tree and the virtual energy.

PROPOSITION 2.12. *Let* $i \in E$. *Then*

$$W(i) = A_c(E) - \sum_{0 \leq k \leq n_E} (H_e^k(i^k) - H_m^k(i^k)),$$

$$\text{where } A_c(E) = \sum_{k=0}^{n_E} \sum_{\Pi \in E^k} (H_e^k(\Pi) - H_m^k(\Pi)) \tag{8}$$

with the convention $H_m^0(i^0) = 0$.

Proof. The proof is split in four steps.

Step 1: Let $g \in G(\{i\})$. There exists an $\{i\}$-graph g' such that $V(g') \leq V(g)$ and such that for all $\Pi \in E^1 \setminus \{i^1\}$, $\mathcal{H}(\Pi, g')$ is true (recall that i^1 is the cycle of order 1 containing i):

$\mathcal{H}(\Pi, g')$: There exists in g' a unique arrow $e \to f$ going out of Π (e.g., $e \in \Pi$ and $f \notin \Pi$). Moreover if $f' \in \Pi \setminus \{e\}$ and $f' \to f'' \in g'$, then $V(f', f'') - H_e(f') = 0$.

This statement can be proved by induction on the number of $\Pi \in E^1 \setminus \{i^1\}$ such that $\mathcal{H}(\Pi, g)$ is false. Assume that there exists $\Pi \in E^1 \setminus \{i^1\}$ such that $\mathcal{H}(\Pi, g')$ is false. Then consider the following procedure:

1. Define $g_0 = g$ and $A_0 = \{e\}$, where e is an exit point of Π for g for which there exists a path $e = e_0 \to \cdots \to e_n = i$ in g satisfying $e_k \notin \Pi$ for $1 \leq k \leq n$.
2. Assume that (g_k, A_k) has been constructed for $k \leq p$. Then define

$$A_{p+1} = \{ f_1 \in \Pi \setminus \cup_{k \leq p} A_k \mid \exists f_2 \in A_p \text{ such that } V(f_1, f_2)) = H_e(f_1) \}.$$

If $A_{p+1} = \emptyset$, then the construction ends with g_p. Otherwise, for all $f_1 \in A_{p+1}$, we choose $f_2 \in A_p$, denoted $l(f_2)$, such that $V(f_1, f_2) = H_e(f_1)$ and define g_{p+1} by

$$g_{p+1} = \{ j \to k \mid j \notin A_{p+1} \text{ and } j \to k \in g_p \} \cup \{ j \to l(j), \mid j \in A_{p+1} \}.$$

Since Π is a cycle, we verify easily that the procedure ends within at most $|\Pi| - 1$ steps and that at each step, $g_p \in G(\{i\})$ and $V(g_p) \leq V(g_{p-1})$. Moreover, the algorithm ends with an $\{i\}$-graph g_{p_0} for which $\mathcal{H}(\Pi, g_{p_0})$ is true.

Step 2: Let g' be the graph obtained by Step 1. For all $\Pi \in E^1 \setminus \{i^1\}$, we denote by $e(\Pi)$ the unique exit point of Π for g' and by $f(\Pi)$ the unique configuration such that $e(\Pi) \to f(\Pi) \in g'$. Now consider the graph g^1 on E^1 defined by

$$g^1 = \{ e(\Pi)^1 \to f(\Pi)^1 \mid \Pi \in E^1 \setminus \{i^1\} \}.$$

One easily sees that $g^1 \in G^1(\{i^1\})$. We can make $V^1(g^1)$ appear in the computation of $V(g')$:

$$\begin{aligned} V(g') &= \sum_{j \in E} H_e(j) + \sum_{\Pi \in E^1 \setminus \{i^1\}} (V(e(\Pi), f(\Pi)) - H_e(e(\Pi))) - H_e(i) \\ &\geq \sum_{j \in E} H_e(j) + V^1(g^1) - \sum_{\Pi \in E^1} H_m^1(\Pi) - \left[H_e(i) - H_m^1(i^1) \right]. \end{aligned}$$

Step 3: Moreover, if $g^1 \in G^1(\{i^1\})$, there exists $g \in G(\{i\})$ such that

$$V(g) = \sum_{j \in E} H_e(j) + V^1(g^1) - \sum_{\Pi \in E^1} H_m^1(\Pi) - \{H_e(i) - H_m^1(i^1)\}. \tag{9}$$

Such an $\{i\}$-graph g can be obtained by the following procedure: first, for all $\Pi \to \Pi' \in g^1$, we choose $e(\Pi) \in \Pi$ and $f(\Pi) \in \Pi'$ such that

$$V(e(\Pi), f(\Pi)) - H_e(e(\Pi)) = \inf_{j \in \Pi, k \in \Pi'} V(j, k) - H_e(j) = V^1(\Pi, \Pi') - H_m^1(\Pi).$$

1. Define $g_0 = \emptyset$, $A_0 = A_0' = \{i\}$, $B_0 = \{i^1\}$, and $\Pi_0 = i^1$.
2. Assume that g_k, A_k, A_k', B_k, and $\Pi_k \in E^1$ have been constructed for $k \leq p$. Define

$$A_{p+1} = \{ f_1 \in \Pi_k \setminus A_p' \mid \exists f_2 \in A_p \text{ such that } V(f_1, f_2) = H_e(f_1) \}.$$

- If $A_{p+1} = \emptyset$ and $B_p = E^1$, then the algorithm is ended.
- If $A_{p+1} = \emptyset$ and $B_p \neq E^1$, then define $D = \{ \Pi \notin B_p \mid f(\Pi)^1 \in B_p \}$. Choose an element $\Pi_{p+1} \in D$ ($D \neq \emptyset$) and define $A_{p+1} = A_{p+1}' = \{ e(\Pi_{p+1}) \}$, $B_{p+1} = B_p \cup \{\Pi_{p+1}\}$. The graph g_{p+1} is then defined by $g_{p+1} = g_p \cup \{ e(\Pi_{p+1}) \to f(\Pi_{p+1}) \}$.
- If $A_p \neq \emptyset$, define $\Pi_{p+1} = \Pi_p$, $B_{p+1} = B_p$, $A_{p+1}' = A_p' \cup A_{p+1}$, and for all $j \in A_{p+1}$, choose an element $l(j) \in A_p$ such that $V(j, l(j)) = H_e(j)$. The graph g_{p+1} is then defined by $g_{p+1} = g_p \cup \{j \to l(j) \mid j \in A_{p+1}\}$.

One easily verifies that this procedure ends within $|E| - 1$ steps. Moreover, when $A_{p+1} = \emptyset$, we have

$$V(g_p) = \sum_{\Pi \in B_p} \sum_{j \in \Pi} H_e(j) + \sum_{\Pi \in B_p \setminus \{i^1\}, \Pi \to \Pi' \in g^1} (V^1(\Pi, \Pi') - H_m^1(\Pi)) - H_e(i),$$

so (9) is verified for the final graph which belongs to $G(\{i\})$.

Step 4: We deduce from the previous steps that

$$W(i) = \sum_{j \in E} H_e(i) - \sum_{\Pi \in E^1} H_m^1(\Pi) + W^1(i^1) - (H_e(i) - H_m^1(i^1)),$$

where W^k is defined as W with the $\{i^k\}$-graphs on E^k valued by V^k.

From the recursive construction of the family (E^k, V^k), we finally arrive at

$$W(i) = \sum_{k=0}^{n_E} \sum_{\Pi \in E^k} (H_e^k(\Pi) - H_m^k(\Pi)) + W^{n_E}(i^{n_E}) - \sum_{\Pi \in E^{n_E}, \Pi \neq i^{n_E}} H_e^{n_E}(\Pi) - \left(\sum_{k=0}^{n_E} H_e^k(i^k) - H_m^k(i^k) \right).$$

One easily verifies that $W^{n_E}(i^{n_E}) = \sum_{\Pi \in E^{n_E} \setminus \{i^{n_E}\}} H_e^{n_E}(\Pi)$, so the proof of the proposition is ended. □

COROLLARY 2.13. *Let* Π *be a cycle. Then for all* $f \in F(\Pi)$ *we have*

1. $H_e^k(f^k) = H_m^{k+1}(f^{k+1})$ *for* $0 \leq k \leq n_\Pi - 1$,
2. $H_e(\Pi) = H_e(f) + \sum_{k=1}^{n_\Pi} (H_e^k(f^k) - H_m^k(f^k))$.

Proof. From Proposition 2.12, we can write

$$W(j) = A_c(E) - H_e(j) - \sum_{k=1}^{n_E} (H_e^k(j^k) - H_m^k(j^k)).$$

Assume that $j \in \Pi$; then we have

$$W(j) = A_c(E) - H_e(j) - \sum_{k=n_{\Pi,j}+1}^{n_E} (H_e^k(j^k) - H_m^k(j^k)) - \sum_{k=1}^{n_{\Pi,j}} (H_e^k(j^k) - H_m^k(j^k)).$$

One verifies that $n_{\Pi,j} = n_\Pi$ for all $j \in \Pi$. Hence, since $j^{n_\Pi} = \Pi$, the last summation is the only one depending effectively on j for $j \in \Pi$. Thus if $f \in F(\Pi)$, we have

$$H_e(f) + \sum_{k=1}^{n_\Pi} (H_e^k(f^k) - H_m^k(f^k)) = \sup_{j \in \Pi} H_e(j) + \sum_{k=1}^{n_\Pi} (H_e^k(j^k) - H_m^k(j^k)).$$

A straightforward computation gives for $j \in \Pi$

$$H_e(j) + \sum_{k=1}^{n_\Pi} (H_e^k(j^k) - H_m^k(j^k)) = H_e(\Pi) - \sum_{k=1}^{n_\Pi - 1} (H_m^{k+1}(j^{k+1}) - H_e^k(j^k)).$$

Since $H_m^{k+1}(j^{k+1}) - H_e^k(j^k) \geq 0$ we deduce that

$$H_e(j) + \sum_{k=1}^{n_\Pi} (H_e^k(j^k) - H_m^k(j^k)) \leq H_e(\Pi),$$

where the equality is reached for $j_0 \in \Pi$ satisfying

$$H_e^k(j_0^k) = H_m^{k+1}(j_0^{k+1}) \text{ for } 0 \leq k \leq n_\Pi - 1; \tag{10}$$

hence, we obtain points 1. and 2. □

COROLLARY 2.14. *Let* $\Pi \in \mathcal{C}(E)$, $|\Pi| > 1$. *There exists a nonnegative constant* $A_c(\Pi)$ *called the altitude of* Π *such that for all* $\Pi' \in \mathcal{M}_*(\Pi)$, *we have*

$$W(\Pi') + H_e(\Pi') = A_c(\Pi). \tag{11}$$

If Π *is a singleton, we define* $A_c(\Pi) = W(\Pi)$.

Proof. Let Π be a cycle of E which is not a singleton. Consider $\Pi' \in \mathcal{M}_*(\Pi)$ and $f \in F(\Pi')$:

$$W(\Pi') + H_e(\Pi') = W(f) + H_e(f) + \sum_{k=1}^{n_{\Pi',f}} (H_e^k(f^k) - H_m^k(f^k))$$

$$= A_c(E) - \sum_{k=n_{\Pi'}+1}^{n_E} (H_e^k(f^k) - H_m^k(f^k)).$$

However, from Remark 1 it follows that for all $k \in \mathbb{N}$ verifying $n_{\Pi'} + 1 \leq k \leq n_\Pi$ we have $H_e^k(f^k) - H_m^k(f^k) = 0$. Hence, one has

$$W(\Pi') + H_e(\Pi') = A_c(E) - \sum_{k=n_\Pi}^{n_E} (H_e^k(f^k) - H_m^k(f^k)),$$

so we get the result since the summation is now independent of Π'. □

Considering $\Pi' \in \mathcal{M}_*(\Pi)$ such that $H_e(\Pi') = H_m(\Pi)$, we get from equation (11) that $W(\Pi') = W(\Pi)$ and

$$A_c(\Pi) = W(\Pi) + H_m(\Pi). \tag{12}$$

Both equations (11) and (12) reveal that potentials, exit, and mixing heights of the cycles are linked through the altitudes of communication. We will now show that we can deduce from (11) and (12) a top-to-bottom computation of the values of $W(\Pi)$ and $A_c(\Pi)$ for all the cycles as well as the organization of the decomposition tree in a valued graph called the decomposition diagram.

Assume that the quantities $H_e(\Pi)$ and $H_m(\Pi)$ have been computed during the cycle decomposition process.

- We start with the computation of $A_c(E)$ with the help of equation (8):

$$A_c(E) = \sum_{\Pi \in \mathcal{C}(E) \setminus \{E\}} H_e(\Pi) - \sum_{\Pi \in \mathcal{C}(E) \setminus \{E\}} H_m(\Pi)$$

  and obtain $W(E)$ from (12).
- Assume that $A_c(\Pi)$ has been computed for a given cycle Π; then if $\Pi' \in \mathcal{M}_*(\Pi)$, we get $W(\Pi')$ from equation (11) and $A_c(\Pi')$ from equation (12).

Therefore, starting from the cycle E, one can get step by step all the values of $A_c(\Pi)$ and $W(\Pi)$, going from top to bottom in the decomposition tree. This has been done in our example: in Fig. 3, a cycle is represented either with an horizontal bar (and in this case the cycle configurations are given by the usual lines of descent) or with a black point for the cycles reduced to singletons. The mixing height is given by the difference between the horizontal bar associated with the concerned cycle and its lowest configuration. Finally, the exit height is given by the height difference between the horizontal bar immediately above the bar of the concerned cycle and its lowest configuration. We have reported on the figure the values of $H_m(\{g, h, i\})$ and $H_e(\{g, h, i\})$. In our example, we obtain for the points of E the following virtual energies:

Configuration:	a	b	c	d	e	f	g	h	i
$W - W(E)$:	4	3	2	2	2	3	2	3	0

We see that configuration 9 is the global minimum of the virtual energy so that the generalized simulated annealing converges to it for proper cooling schedules.

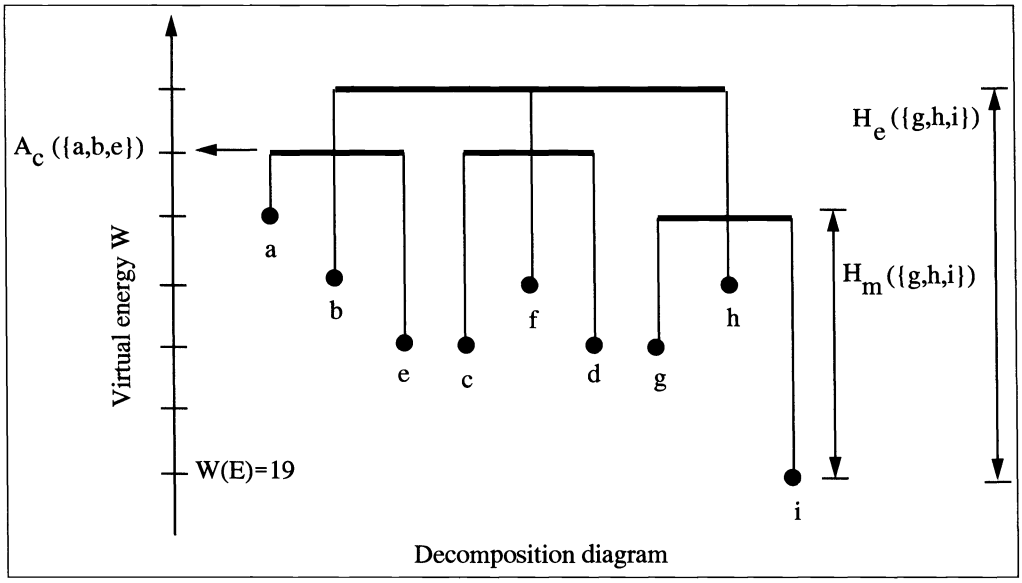

FIG. 3. *Decomposition diagram.*

2.5. Virtual energy and communication altitude. We will extend the notion of altitude introduced in Corollary 2.14 to the definition of the communication altitude between two points. We will see that this function contains in fact all the necessary information to compute the virtual energy (Theorem 2.17) and the decomposition in cycles (Proposition 2.20). Its study will allow us to shed new light on the weak reversibility condition of Hajek (Theorem 2.18).

2.5.1. Characterization of the virtual energy through the communication altitude.

DEFINITION 2.15. *Let $i, j \subset E$. We define the communication altitude from i to j by*

$$A_c(i, j) = \inf_{g \in Pth_E(i,j)} \sup_{0 \le k < n_g} (W(g_k) + V(g_k, g_{k+1})).$$

We adopt the convention that the sup is equal to $W(g_0)$ on a path of length 0.

The link with the definition of the altitude previously introduced in Corollary 2.14 is clarified by the following proposition.

PROPOSITION 2.16.

1. *Let $i, j \in E$; we have*

$$A_c(i, j) = A_c(j, i) = A_c(\Pi_{ij}),$$

where Π_{ij} is the smallest cycle for the inclusion containing i and j.

2. *Let $\Pi \in C(E)$; then*

$$A_c(\Pi) = \sup_{i,j \in \Pi} A_c(i, j).$$

Proof. Point 2 is a straightforward corollary of point 1. We consider now the first point. We prove first the following result.

Let Π be a cycle, $a \in \Pi$, and $b \notin \Pi$. Then we have

$$V(a, b) + W(a) \ge W(\Pi) + H_e(\Pi). \tag{13}$$

We get from Proposition 2.12

$$(14)\quad W(a) - W(\Pi) - H_e(\Pi) + V(a,b) = V(a,b) - \sum_{r=0}^{n_\Pi} H_e^r(a^r) - H_m(a^r)$$
$$= \sum_{r=0}^{n_\Pi - 1} \left(V^r(a^r, b^r) - V^{r+1}(a^{r+1}, b^{r+1}) + H_m^{r+1}(a^{r+1}) - H_e^r(a^r)\right)$$
$$+ \left(V^{n_\Pi}(a^{n_\Pi}, b^{n_\Pi}) - H_e^{n_\Pi}(a^{n_\Pi})\right).$$

We verify easily that each term between parentheses is nonnegative, thus we get (13).

Now consider $i, j \in E$. If $i = j$, then we have $A_c(i,i) = W(i) = A_c(\{i\})$ and thus the result. Assume then that $i \neq j$, and consider $\Pi \in \mathcal{M}_*(\Pi_{ij})$ such that $\Pi \ni i$, where Π_{ij} is the smallest cycle for the inclusion containing i and j. For all paths $g \in \mathrm{Pth}_E(i,j)$, we define $r_g = \inf\{\, 0 \leq k \leq n_g \mid g_k \notin \Pi \,\}$. We have from (14) with $a = i$ and $b = j$

$$\sup_{0 \leq k < n_g} (W(g_k) + V(g_k, g_{k+1})) \geq W(g_{r_g - 1}) + V(g_{r_g - 1}, g_{r_g}) \geq W(\Pi) + H_e(\Pi) = A_c(\Pi_{ij}).$$

Hence we obtain

$$A_c(i,j) \geq A_c(\Pi_{ij}).$$

We will now prove the reverse inequality,

$$(15)\qquad A_c(i,j) \leq A_c(\Pi_{ij}),$$

by induction on $n_{\Pi_{ij}}$. If $n_{\Pi_{ij}} = 0$ then the result is trivial since $i = j$. Now assume that $n_{\Pi_{ij}} = p + 1$ and that (15) is proved for $n_{\Pi_{ij}} \leq p$. There exists $g^p \in \mathrm{Pth}_{E^p}(i^p, j^p)$ such that $V^p(g_k^p, g_{k+1}^p) - H_e^p(g_k^p) = 0$ for all $0 \leq k < n_{g^p}$. Moreover, for all $0 \leq k < n_{g^p}$, we define $a_k \in g_k^p$ and $b_k \in g_{k+1}^p$, satisfying for all $0 \leq r < p - 1$

$$V^{r+1}(a_k^{r+1}, b_k^{r+1}) = H_m^{r+1}(a^{r+1}) + V^r(a_k^r, b_k^r) - H_s^r(a_k^r).$$

Then we get from the equalities (14)

$$V(a_k, b_k) + W(a_k) = H_e(a_k^p) + W(a_k^p) = A_c(\Pi_{ij}).$$

However, defining $b_{-1} = i$ we get from the induction hypothesis that $A_c(b_{k-1}, a_k) \leq A_c(\Pi_{ij})$, so the proposition is proven for $n_{\Pi_{ij}} = p + 1$. □

The symmetry of the communication altitude function ($A_c(i,j) = A_c(j,i)$) proven in Proposition 2.16 is in fact a characterization up to an additive constant of the virtual energy W, as shown in the following theorem.

THEOREM 2.17. *Let $W' : E \to \mathbb{R}$ and $A_{W'} : E \times E \to \mathbb{R}$ such that for all $i, j \in E$, $i \neq j$ we have*

$$A_{W'}(i,j) = \inf_{g \in Pth_E(i,j)} \left(\sup_{0 \leq k < n_g} W'(g_k) + V(g_k, g_{k+1}) \right).$$

If $A_{W'}$ satisfies $A_{W'}(i,j) = A_{W'}(j,i)$ for all $i, j \in E$, $i \neq j$, then there exists $c \in \mathbb{R}$ such that for all $i \in E$

$$W'(i) = W(i) + c.$$

Proof. We will prove by induction on the size of the cycles of E that for all $\Pi \in \mathcal{C}(E)$, there exists $c(\Pi) \in \mathbb{R}$ such that

$$W'(i) = W(i) + c(\Pi), \qquad i \in \Pi.$$

The result is trivial for the singletons. Let $n \geq 1$ and assume that the result is proved for the cycles whose size is smaller or equal to n. Let Π be a cycle of E whose size is $n+1$. We note $(\Pi_l)_{0 \leq l \leq r}$, the family of the elements of $\mathcal{M}_*(\Pi)$, and assume that there exists $c \in \mathbb{R}$ and $0 < l_0 \leq r$ such that $c(\Pi_{l'}) < c < c(\Pi_l)$ for $0 \leq l < l_0 \leq l' \leq r$. Since Π is a cycle, there exists $l' \geq l_0 > l$, $i \in \Pi_{l'}$, and $j \in \Pi_l$ such that $W(i) + V(i, j) = A_c(\Pi)$. Hence

$$A_{W'}(i, j) \leq W(i) + c(\Pi_{l'}) + V(i, j) < A_c(\Pi) + c.$$

However,

$$\begin{aligned} A_{W'}(j, i) &\geq \inf_{a \in \Pi_l,\ b \in \Pi_{l'}} W'(a) + V(a, b) \geq \inf_{a \in \Pi_l,\ b \in \Pi_{l'}} W(a) + c(\Pi_l) + V(a, b) \\ &\geq \inf_{a \in \Pi_l,\ b \in \Pi_{l'}} A_c(a, b) + c(\Pi_l) > A_c(\Pi) + c, \end{aligned}$$

so

$$A_{W'}(j_0, i) - A_{W'}(i, j_0) > 0,$$

which is in contradiction with the symmetry of $A_{W'}$. Hence, all the $c(\Pi_l)$ are equal, and the result is proven for Π. □

2.5.2. Hajek's weak reversibility condition revisited. Theorem 2.17 gives us a new characterization of the virtual energy. In this section, we return to the sequential framework and will deduce from Theorem 2.17 the exact status of the weak reversibility condition of Hajek [7].

In the sequential framework, the communication cost V depends on the energy function U and the communication kernel q and is defined by

$$V(i, j) = \begin{cases} (U(j) - U(i))^+ & \text{if } q(i, j) > 0, \\ +\infty & \text{otherwise.} \end{cases} \tag{16}$$

Moreover, for all $i, j \in E$, $i \neq j$, we define

$$\mathrm{Pth}_q(i, j) = \{g \in \mathrm{Pth}_E(i, j) \mid \forall 0 \leq l < n_g \; q(g_k, g_{k+1}) > 0\}$$

and note

$$D_q(i, j) = \inf_{g \in \mathrm{Pth}_q(i,j)} \sup_{0 \leq k \leq n_g} U(g_k).$$

The weak reversibility condition of Hajek is equivalent to the symmetry of D_q:

$$D_q(i, j) = D_q(j, i), \; i, j \in E. \tag{17}$$

It is well known that for an arbitrary choice of the communication kernel, the energy U is not necessarily the virtual energy associated with V. However, if we assume that the symmetry of the communication kernel q ($q(i, j) = q(j, i)$), then U is the virtual energy up to an additive constant. In [8], Hwang and Sheu prove that the weak reversibility condition of Hajek also is sufficient. In fact, we can go further and deduce from Proposition 2.16 and Theorem 2.17 that Hajek's condition is a necessary and sufficient condition on q to have the equality (up to an additive constant) of U and W.

THEOREM 2.18. *Let V be the communication cost associated with a sequential simulated annealing algorithm (i.e., $V(i,j) = (Uj) - U(i))^+$ for $i \neq j$ and $q(i,j) > 0$), where U is the underlying energy function. Then U is the virtual energy W (up to an additive constant) if and only if the irreducible communication kernel q satisfies the weak reversibility condition* (17) *of Hajek.*

Proof. It is sufficient to note that if A_U is defined by

$$A_U(i,j) = \inf_{g \in \mathrm{Pth}_E(i,j)} \sup_{0 \leq k < n_g} U(g_k) + V(g_k, g_{k+1}), \qquad i, j \in E,$$

then $A_U(i,j) = D_q(i,j)$ since we have

$$U(i') + V(i',j') = \begin{cases} U(i') \vee U(j') & \text{if } q(i',j') > 0, \\ +\infty & \text{if } q(i,j) = 0. \end{cases}$$

Hence, if U is the virtual energy (up to an additive constant) associated with V, then $A_U(i,j) = A_c(i,j) + c$, where $A_c(i,j)$ is the communication altitude from i to j, so that we deduce from point 1 of the Proposition 2.16 that the weak reversibility condition of Hajek (17) is verified. Assume that D_q verifies (17). Then $A_U(i,j) = A_U(j,i)$, so we deduce from Theorem 2.17 that U is the virtual energy up to an additive constant. □

2.5.3. Decomposition in cycle via the communication altitude. We end this section with a proposition which shows that the decomposition in cycles can be computed directly from the values of the communication altitude between configurations. This new characterization of the decomposition in cycles is very close to the definition of the cycles for the sequential case [2] and is its natural extension.

DEFINITION 2.19. *Let $h \in \mathbb{R}$. We note $\mathcal{R}_h$, the equivalence relation defined by*

$$i \mathcal{R}_h j \text{ iff } \begin{cases} i = j \\ \text{or} \\ A_c(i,j) \leq h \quad \text{otherwise.} \end{cases}$$

PROPOSITION 2.20. *We have*

$$\mathcal{C}(E) = \bigcup_{h \in \mathbb{R}} E/\mathcal{R}_h,$$

where $E/\mathcal{R}_h$ denotes the set of the equivalence classes of E for the relation $\mathcal{R}_h$.

Proof. Let $\Pi \in \mathcal{C}(E)$. We want to prove here that $\Pi \in E/\mathcal{R}_h$ for an $h \in \mathbb{R}$. The result is trivial if either Π is a singleton or $\Pi = E$. We consider now the remaining cases and will prove that we can choose $h = A_c(\Pi)$. If $\Pi \notin E/\mathcal{R}_{A_c(\Pi)}$, then there exist $i \in \Pi$ and $j \in \Pi^c$ such that $A_c(i,j) \leq A_c(\Pi)$. Let Π' be the smallest cycle containing i and j. We get from Proposition 2.16 that $A_c(i,j) = A_c(\Pi')$ so that $A_c(\Pi') \leq A_c(\Pi)$ with $\Pi \subset \Pi'$ and $\Pi' \neq \Pi$. However, from (11), (12), and Remark 2 we have

$$A_c(\Pi) = W(\Pi) + H_m(\Pi) < W(\Pi) + H_e(\Pi) = A_c(\Pi'),$$

so we get a contradiction.

Conversely, let $C \in E/\mathcal{R}_h$. If either $C = E$ or C is a singleton, then C is obviously a cycle. We consider the remaining cases. Let Π be the greatest cycle for the inclusion among all the cycles included in C. If $\Pi \neq C$, then we consider $i \in \Pi$ and $j \in C \setminus \Pi$. Since i and j are in C, we have $A_c(i,j) \leq h$. Moreover, $A_c(i,j) = A_c(\Pi_{ij})$, where Π_{ij} is the smallest cycle containing i and j, so $A_c(\Pi_{ij}) \leq h$ and $\Pi_{ij} \subset C$, which is impossible. Hence we get that $\Pi = C$. □

2.6. Optimal exponent. In this part, we will only give the central theorem on the convergence of G.S.A. algorithms, which extends Catoni's result previously stated for the sequential simulated annealing.

DEFINITION 2.21.

1. *We call critical height associated with the decomposition in cycles of E for the communication cost V the real-valued number H_1 defined by*

$$H_1 = H_e(E \setminus F(E)) = \sup_{\Pi \in \mathcal{C}(E), \Pi \cap F(E) = \emptyset} H_e(\Pi).$$

2. *We call optimal exponent for reaching $F(E)$ for the communication cost V the real-valued number α_{opt} defined by*

$$\alpha_{opt} = \inf_{\Pi \in \mathcal{C}(E), \Pi \cap F(E) = \emptyset} \frac{W(\Pi) - W(E)}{H_e(\Pi)}.$$

THEOREM 2.22.

1. *For all decreasing cooling schedules $(T_n)_{n \in \mathbb{N}}$ converging to 0 we have*

$$\sup_{i \in E} P(X_n \notin F(E) \mid X_0 = i) \underset{n \to \infty}{\longrightarrow} 0$$

if and only if

$$\sum_{n=0}^{\infty} e^{-H_1/T_n} = +\infty.$$

2. *We assume that $\alpha_{opt} < +\infty$ and that $Q_T(i, j)\cdot$ is a rational expression of the functions $(e^{a/T})_{a \in \mathbb{R}}$ for any $i, j \in E$. There exist two strictly positive constants R_1 and R_2 such that for all integers $n \geq 1$ we have*

$$\frac{R_1}{n^{\alpha_{opt}}} \leq \inf_{T_1 \geq \cdots \geq T_n \geq 0} \sup_{i \in E} P(W(X_n) \neq W_{\min} \mid X_0 = i) \leq \frac{R_2}{n^{\alpha_{opt}}}.$$

Point 1 of the theorem is the extension of the well-known result of Hajek. It has been proven for the generalized simulated annealing by Hwang and Sheu in [10]. Point 2, which gives the optimal convergence rate toward $F(E)$, has been proven by the author in [13, 14].

3. Energy landscape exploration algorithm. In the previous section we have seen the roles of the critical height H_1 and the optimal exponent α_{opt}. Both depend in a nontrivial way on the communication cost V. Computing these quantities even for very small examples is intractable by hand. However, it can be useful to compute systematically these quantities on medium-size examples in order to be able to test some conjectures on examples and to compute exactly the virtual energy as well as the critical height or the optimal exponent. In this part, we propose a constructive approach to calculate their values on a computer through the recursive construction of the cycle decomposition. We will show that our algorithm has a complexity in $O(|E|^3)$, where $|E|$ is the size of the configuration space.

We call attention here to an alternative approach recently proposed by M. Desai, S. Kumar, and P. R. Kumar in [5] for a direct computation of the virtual energy from the communication cost. Their method is actually not given as a directly implementable algorithm, but this could be done in the spirit of our work with the same complexity. However, since they do not make any explicit reference to the decomposition in cycles, their method is limited to the computation of virtual energy and does not, for instance, provide the critical height H_1 or the optimal exponent α_{opt}.

3.1. Construction of the decomposition tree. The main problem of the effective decomposition in cycles is the construction of a graph isomorphic to the valued graph $\mathcal{G} = (\mathcal{S}, \mathcal{A}, \mathcal{V})$, which is called a decomposition graph and is defined by the following three points.

1. The set $\mathcal{S}$ of the vertices of $\mathcal{G}$ is defined by

$$\mathcal{S} = \bigcup_{k=0}^{n_E+1} E^k \times \{k\}.$$

The subsets $E^k \times \{k\}$ of $\mathcal{S}$ are called the *levels* of $\mathcal{G}$. If $S = E^k \times \{k\}$ and $S' = E^{k'} \times \{k'\}$ are both levels of $\mathcal{G}$, we will say that S' is the level *above* S if $k' = k + 1$. We note S_0, the level $E^0 \times \{0\}$ called the *base* of $\mathcal{G}$.

2. The edge set $\mathcal{A}$ of $\mathcal{G}$ contains the following three types of edges: for all $v = (\Pi, k)$, $w = (\Pi', k') \in \mathcal{S}$,

$v \rightarrow w \in \mathcal{A}$ if $k = k'$ and $V^k(\Pi, \Pi') < +\infty$.
Then we say that w is *a neighbor* of v.

$v \Rightarrow w \in \mathcal{A}$ if $k = k'$ and $V^k(\Pi, \Pi') = H_e^k(\Pi)$.
Then we say that w is the *exit* out of v.

$v \downarrow w \in \mathcal{A}$ if $k = k' + 1$ and $\Pi' \subset \Pi$.
Then we say that v is *the father* of w and that w is *a son* of v.

3. The set $\mathcal{V}$ of the valuations contains the following valuations of the vertices and on the edges:
   (a) For all $v = (\Pi, k) \in \mathcal{S}$

$$\text{mixing\_height}(v) = H_m^k(\Pi),$$
$$\text{exit\_height}(v) = H_e^k(\Pi).$$

   (b) For all $v = (\Pi, k)$ and $w = (\Pi', k')$ in $\mathcal{S}$ such that $v \rightarrow w \in \mathcal{A}$

$$\text{com\_cost}(v, w) = V^k(\Pi, \Pi').$$

One deduces easily from the recursive decomposition in cycles a construction level by level of the decomposition graph from its base. There exists, however, a step in this algorithm which is not obvious. Assume that the level S has been constructed, as have the edges $u \Rightarrow w$ between vertices of S. In order to construct the level S' above S and the son-father edges $(u \downarrow w)$, we have to identify the equivalence classes on S for the equivalence relation $\mathcal{R}$:

$$u \mathcal{R} v \text{ iff } u \overset{*}{\Rightarrow} v \text{ and } v \overset{*}{\Rightarrow} u,$$

where $w \overset{*}{\Rightarrow} w'$ means that there exists $n \in \mathbb{N}$ and a family $(w_l)_{0 \le l \le n}$ of vertices in S such that $w_0 = w$, $w_n = w'$ and the edges $w_l \Rightarrow w_{l+1}$ exist for $0 \le l < n$. However, this problem is equivalent to the computation of the strongly connected components of $G = (S, A)$, where A is the set of edges $u \Rightarrow v$ between the vertices of S.

DEFINITION 3.1. *We say that $C \subset S$ is a strongly connected component of the oriented graph $G = (S, A)$ if both of the following conditions are verified.*

1. *For all $u, v \in C$, we have*

$$u \overset{*}{\Rightarrow} v \text{ and } v \overset{*}{\Rightarrow} u.$$

2. *The set C is maximal among all the subsets of S verifying* 1.

An easy lemma establishes that the equivalence classes for the relation $\mathcal{R}$ in S are exactly the strongly connected component of $G = (S, A)$. However, Robert Tarjan proposes in [11] an algorithm with complexity $O(|S| + |A|)$ to compute the strongly connected components. Hence, we can now define a recursive algorithm to construct the graph $\mathcal{G}$ from the data given by the base S_0, the edges $u \to v$ between the vertices of S_0, and their valuations com_cost(u, v). We give below a pseudocode version.

```
main()
BEGIN
   load the vertices of S0;
   FOR EACH v in S0
      load the edges v→w;
      FOR EACH neighbor w of v
         load com_cost(v, w);
      mixing_height(v) := 0;
   decompose(S0);
END
```

The function **decompose**, which is the main ingredient of the main program, is defined as follows.

```
FUNCTION decompose(S)
BEGIN
   IF (S is not a singleton)
   THEN
      FOR EACH v in S /* Computation of the valuations exit_height */
         exit_height(v):= min{com_cost(v, w) | v→w};
      FOR EACH v in S /* Creation of the edges v⇒w */
         FOR EACH w in S neighbor of v
            IF (exit_height(v) = com_cost(v, w))
            THEN create the edge v⇒w; /* w is an exit out of v */
      /* Creation of the level S' above S and creation of the edges
         son-father between the vertices of S' and those of S */
      next_level(S);
      /* Creation of the edges v→w between the vertices of S' and
         computation of their valuations */
      FOR EACH v in S'
          FOR EACH v' son of v /* e.g. the edge v↓v' exists */
           FOR EACH w' neighbor of v' /* e.g. the edge v'→w' exists */
              IF (the father w of w' is distinct of v)
              THEN
                 tmp:= mixing_height(v)+com_cost(v', w')−exit_height(v');
                 IF the edge v→w does not exists yet
                 THEN
                    create the edge v→w;
                    com_cost(v, w):= tmp;
                 ELSE com_cost(v, w):= min{ com_cost(v, w) , tmp };
      /* Decomposition of the level S' above S */
      decompose(S');
END
```

We have intentionally isolated the function **next_level** since this function is nothing but the Tarjan's algorithm for the search of the strongly connected components in an oriented graph.

In fact, we have to distinguish the minimal components from the others, but this can be easily achieved since this last problem reduces to finding the leaves in a tree.

Our construction algorithm of the decomposition graph $\mathcal{G}$ is completely recursive, so we obtain a simple implementation. From the complexity point of view, for each level, the complexity of the construction of the next level is dominated by the complexity of the Tarjan's algorithm, that is, $O(|S| + |A|)$, where S is the family of vertices of the current level and A is the family of the edges $u \Rightarrow v$ between the vertices of S. This complexity admits an upper bound in $O(|S| + |B|)$, where B is the family of the edges $u \rightarrow v$ between the vertices of S. However, if S' is the level above S and B' is the family of the edges $u \rightarrow v$ between the vertices of S', we have

$$|S'| \leq |S| - 1 \text{ and } |B'| \leq |B| - 1.$$

Since at each level we have the upper bound $|B| \leq |S|^2$, we deduce that the total complexity of the algorithm is in $O(|S_0|^3)$, where S_0 is the base of $\mathcal{G}$. This value of the complexity shows clearly the difficulty of a computation by hand but also the limitation of this approach even on a computer.

3.2. Derivation of the virtual energy and the critical constants. It is now simple to deduce from the graph $\mathcal{G}$ the value of the interesting quantities. We start here by the computation of the virtual energy W. From Corollary 2.14 we deduce that for all $i \in E$ and all $k \leq n_E$ we have the relation

$$W(i^k) = W(i^{k+1}) + H_m^{k+1}(i^{k+1}) - H_e^k(i^k). \tag{18}$$

Thus, on each vertex $v = (\Pi, k)$ of $\mathcal{S}$, if we define the valuation called virtual_energy(v) by

$$\text{virtual\_energy}(v) = W(\Pi),$$

we deduce from (18) that if w is a son of v (e.g., the edge $v \downarrow w$ exists) then

$$\text{virtual\_energy}(w) = \text{virtual\_energy}(v) + \text{mixing\_height}(v) - \text{exit\_height}(w). \tag{19}$$

The relation (19) allows the computation of virtual_energy(v) for each vertex v of $\mathcal{S}$ recursively from the value of virtual_energy(v_∞), where v_∞ denotes the unique vertex of the last level of $\mathcal{G}$ (e.g., $v_\infty = (E, n_E + 1)$). However, virtual_energy(v_∞) is equal to $W(E) = \inf W$, which can be arbitrarily fixed to the value 0 since it is sufficient to compute the virtual energy up to an additive constant. (One should in fact compute the constant with a recursive algorithm.)

We are now interested in the computation of the bottom $F(E)$ of E (global minima of W). In the framework of $\mathcal{G}$, we have to find the vertices v of the base S_0 of $\mathcal{G}$ for which virtual_energy(v) is minimal. This computation can be achieved without having to compute the virtual energy with a recursive procedure. (We use here the characterization of $F(E)$ given by point 1 of Corollary 2.13.) We will note $F(\mathcal{G})$, the family of the vertices $v = (\{i\}, 0)$ of $\mathcal{S}$ for $i \in F(E)$.

```
bottom_exploration(v∞);
FUNCTION bottom_exploration(v)
BEGIN
   IF (v has no son) /* v ∈ S0  */
   THEN add v to the list;
   ELSE
      FOR EACH son w of v
         IF (exit_height(w) = mixing_height(v))
         THEN bottom_exploration(w);
END
```

For the computation of the critical height $H_1 = H(E \setminus F(E))$ it is sufficient to take the maximal value of exit_height(v) for any vertex v which does not have a descendant in $F(\mathcal{G})$. We obtain the following recursive procedure:

```
critical_height:= 0;
compute_critical_height(v∞, critical_height);
FUNCTION compute_critical_height(v, critical_height);
BEGIN
   IF (v has at least one son)
   THEN
      FOR EACH son w of v
         IF (exit_height(w) < mixing_height(v))
         THEN critical_height:= sup{ critical_height , exit_height(w) };
         ELSE compute_critical_height(w, critical_height);
END
```

Finally, we give here a recursive procedure to compute the optimal exponent α_{opt}. We recall its definition,

$$\alpha_{opt} = \inf_{\Pi \in C(E),\ \Pi \cap F(E)} \frac{W(\Pi) - W(E)}{H_e(\Pi)}.$$

In fact, it is not necessary to consider all the cycles. Indeed, if Π is a cycle such that $\Pi \cap F(E) = \emptyset$, then for any cycle $\Pi' \subset \Pi$, we have $W(\Pi') \geq W(\Pi)$ and $H_e(\Pi') \leq H_e(\Pi)$ so that we get the inequality

$$\frac{W(\Pi') - W(E)}{H_e(\Pi')} \geq \frac{W(\Pi) - W(E)}{H_e(\Pi)}.$$

Now, for any cycle Π distinct of E, we note Π^+, the smallest cycle containing Π and distinct from Π. From the previous remark, it is sufficient for computing α_{opt} to consider the cycles Π such that $\Pi \cap F(E) = \emptyset$ and $\Pi^+ \cap F(E) \neq \emptyset$. For such cycles, we have $W(\Pi) + H_e(\Pi) = W(E) + H_m(\Pi^+)$ so that

$$\frac{W(\Pi) - W(E)}{H_e(\Pi)} = \frac{H_m(\Pi^+) - H_e(\Pi)}{H_e(\Pi)}.$$

Thus we can compute directly from the decomposition in cycles the value of α_{opt} without computing before the virtual energy. We propose the following procedure:

```
alpha_opt:= +∞;
compute_alpha_opt(v∞,alpha_opt);
FUNCTION compute_alpha_opt(v,alpha_opt);
BEGIN
   IF (v has at least one son)
   THEN
      FOR EACH son w of v
         IF (exit_height(w) < mixing_height(v))
         THEN
            tmp:= (mixing_height(v) - exit_height(w))/exit_height(w);
            alpha_opt:= min{ tmp , alpha_opt };
         ELSE compute_alpha_opt(w,alpha_opt);
END
```

3.3. Examples. We have used this decomposition algorithm to evaluate the efficiency of a parallel scheme of simulated annealing on spin-glass energies (see [12] for a presentation of this scheme). Let us briefly present the setting. We consider the configuration space $E = \{-1, 1\}^S$, where S is a finite set called the set of sites, and a spin-glass-like energy

$$U(x) = \sum_{s \neq t \in S} J_{s,t} x_s x_t + \sum_{s \in S} h_s x_s,$$

where the couplings $J_{\{s,t\}}$ are independently and identically distributed (i.i.d.) random variables with normal distribution $\mathcal{N}(0, 1)$ and the h_s are i.i.d. random variables with uniform distribution on [0, 1]. This provides us with a large class of energies with a statistical structure relevant to real minimization problems. On a sample of 200 energies, we have performed the cycle decompositions for the communication costs associated with the sequential simulated annealing and the parallel scheme [13]. The values of H_1 and α_{opt} have been computed also for a comparison. We give below the central processing unit (cpu) time (in seconds) on a Sun 4/65 corresponding to our sample for three values of $|S|$:

$\|S\| = 4$	10 s
$\|S\| = 6$	189 s
$\|S\| = 8$	4778 s

As expected from the complexity study, the cpu time is exponentially increasing with $|S|$, so we have been confined in our experimental work to $|S| \leq 10$, that is, $|E| \leq 1024$. (We see that the average time for a cycle decomposition is about 12 s for $|E| = 2^8 = 256$.) Beyond the attractiveness of an exact calculation of the critical constants, one of the appealing aspects of the explicit construction of the cycle decomposition is to give an efficient numerical tool to progress in the badly known cycle structure of random energies.

A CHARACTERIZATION OF BOUNDED-INPUT BOUNDED-OUTPUT STABILITY FOR LINEAR TIME-INVARIANT SYSTEMS WITH DISTRIBUTIONAL INPUTS*

CHI-JO WANG† AND J. DANIEL COBB†

Abstract. We consider linear time-invariant operators defined on the space of distributions with left-bounded support. We argue that in this setting the convolution operators constitute the most natural choice of objects for constructing a linear system theory based on the concept of impulse response. We extend the classical notion of bounded-input bounded-output stability to distributional convolution operators and determine precise conditions under which systems characterized by such maps are stable. A variety of expressions for the "gain" of a stable system is derived. We show that every stable system has a natural threefold decomposition based on the classical decomposition of functions of bounded variation. Our analysis involves certain extensions of the Banach spaces L^p in the space of distributions.

Key words. linear systems, stability, distributions

AMS subject classification. 93

1. Introduction. The concept of impulse response has traditionally played a central role in linear system theory. In spite of this fact, certain fundamental system-theoretic ideas have apparently not been developed on a mathematically rigorous level for systems with arbitrary distributional inputs and outputs. In particular, an extract characterization of the impulse and step responses that correspond to bounded-input bounded-output (BIBO) stable systems has not previously appeared in the literature. As an illustration of the problem, recall that if a linear time-invariant system is described by convolution of its inputs with a measurable function h, then the system is BIBO stable if and only if $h \in L^1$. (See, e.g., [1, p. 388].) This characterization is inadequate, however, for studying classes of systems where h may be a distribution since even a simple all-pass system has impulse response $\delta \notin L^1$. Obtaining a complete description of stable distributional systems is the primary goal of this paper.

A somewhat more limited framework than ours that addresses this problem appears in [2, p. 108], where systems are viewed as convolution operators and the impulse response is restricted to be a measurable function plus a linear combination of time shifts of the unit impulse. (In [2] the time-varying case is also included.) Thus, systems that differentiate the input are not included in [2], nor are more exotic cases such as the examples we present in §5. Our framework includes that of [2] (restricted to the time-invariant setting) and gives a more general framework for linear systems and, in particular, BIBO stable systems.

In §2, we consider the problem of meaningfully characterizing linear time-invariant systems in terms of their impulse responses. To set the stage for stability analysis, in §3 we pose and solve the problem of extending the Banach spaces L^p in the space of distributions for $1 \leq p \leq \infty$. In §4 we define BIBO stability for convolution operators on distribution space and obtain exact conditions on the impulse and step responses of a BIBO stable system. Expressions for the induced norm or "gain" of a stable operator with bounded inputs are also established. Section 5 contains a discussion of a three-fold decomposition applicable to all BIBO stable impulse responses. Our results are summarized in §6.

2. Preliminaries. We need a brief introduction to the theory of distributions. (See [3]–[6].) If $\varphi : \mathbb{R} \to \mathbb{R}$, define the support of φ, i.e., supp φ, as the closure of the set $\{t \mid \varphi(t) \neq 0\}$,

and let $\sigma_\tau\varphi$ be the translation of φ defined by $(\sigma_\tau\varphi)(t) = \varphi(t-\tau)$. Let K be the space of C^∞ functions $\varphi : \mathbb{R} \to \mathbb{R}$ with supp φ bounded, and let K' be the dual space of K. (See [6] for an exact description of the topology of K.) A distribution f is an element of K', i.e., a continuous linear functional $\varphi \to \langle f, \varphi\rangle$ on K. For $f \in K'$, supp f is defined to be the complement of the largest open set $U \subset \mathbb{R}$ such that supp $\varphi \subset U$ implies $\langle f, \varphi\rangle = 0$. We may also define the time shift $\sigma_\tau f$ of a distribution f by $\langle \sigma_\tau f, \varphi\rangle = \langle f, \sigma_{-\tau}\varphi\rangle$ and the derivative $\dot{f}$ of f by $\langle \dot{f}, \varphi\rangle = -\langle f, \dot{\varphi}\rangle$. Denote the ith distributional derivative by $f^{(i)}$. It is easy to show that the time shift and differentiation operators commute and that

$$\frac{d}{d\tau}\langle \sigma_\tau f, \varphi\rangle = \langle \sigma_\tau \dot{f}, \varphi\rangle.$$

The unit impulse δ is defined by $\langle \delta, \varphi\rangle = \varphi(0)$. Also, any function f that is locally L^1 determines a distribution according to $\langle f, \varphi\rangle = \int f\varphi$. (Functions that coincide a.e. are identified.) In this way, we may view functions in L^p as distributions for $1 \le p \le \infty$. In particular, the unit step function θ may be considered a distribution. Define $\delta_\tau = \sigma_\tau\delta$ and $\theta_\tau = \sigma_\tau\theta$. If f is locally L^1 and differentiable a.e. in the classical sense, denote this derivative by f'. It is an important fact that there exist f such that $f \ne \dot{f}$. This may occur in trivial ways (e.g., $\dot{\theta} = \delta$, but $\theta' = 0$ a.e.), but such cases also exist where f is continuous. (See §5.) Define $K'_\tau = \{f \in K' \mid \text{supp } f \subset [\tau, \infty)\}$ and

$$K'_+ = \bigcup_{\tau\in\mathbb{R}} K'_\tau.$$

Convergence in K' is defined via its weak* topology, which has a subbasis consisting of all sets of the form

$$U_{\varphi g} = \{f + g \mid |\langle f, \varphi\rangle| < 1\},$$

where $\varphi \in K$ and $g \in K'$. In terms of convergence, this means that a sequence (or net) f_n converges to f iff $\langle f_n, \varphi\rangle \to \langle f, \varphi\rangle$ for all $\varphi \in K$. Thus a linear operator $T : K'_+ \to K'_+$ is weak* continuous iff $\langle f_n, \varphi\rangle \to 0$ implies $\langle T(f_n), \varphi\rangle \to 0$. A linear operator $T : K'_+ \to K'_+$ is causal iff $\inf(\text{supp } T(f)) \ge \inf(\text{supp } f)$ for all $f \in K'_+$.

We are especially interested in convolution operators; the convolution of any pair $f, g \in K'_+$ is defined as follows. It is shown in [3, p. 100] that the map $\overline{\psi}(t) = \langle g, \sigma_{-t}\varphi\rangle$ defines a C^∞ function. Since φ has bounded support, supp $\overline{\psi}$ is bounded above. Choosing $\psi \in K$ to be any function in K such that $\psi(t) = \overline{\psi}(t)$ for all $t \ge \inf(\text{supp } f)$, we define $\langle f^*g, \varphi\rangle = \langle f, \psi\rangle$. This definition is unambiguous, since $\langle f, \gamma\rangle = 0$ whenever supp $\gamma \cap$ supp $\varphi = \phi$. Convolution can be shown to be commutative and to satisfy $f^*\delta^{(i)} = f^{(i)}$. Also, if $h = f^*g$, $\dot{h} = \dot{f}^*g = f^*\dot{g}$. A *convolution operator* $T : K'_+ \to K'_+$ is an operator of the form $T(u) = h^*u$, where $h \in K'_+$. For any convolution operator, $T(\dot{\theta}) = T(\delta)^*\dot{\theta} = T(\delta)$; T is causal iff $h \in K'_0$. We will often refer to the following basic result from [3, p. 105] concerning continuity of convolution operators.

LEMMA 2.1. *Let T be a convolution operator with $T(v) = h^*v$ for every v, and let $u_n \to u$ be a convergent sequence (or net) in K'_+. If there exists a $\tau \in \mathbb{R}$ such that either* supp $h \subset (-\infty, \tau]$ *or* supp $u_n \subset [\tau, \infty)$ $\forall n$, *then $T(u_n) \to T(u)$.*

Let $C_0 = \{f : \mathbb{R} \to \mathbb{R} \mid f \text{ is continuous}, f(-\infty) = f(\infty) = 0\}$ with norm

$$\|f\|_\infty = \sup_t |f(t)|.$$

We denote by BV the space of functions $f : \mathbb{R} \to \mathbb{R}$ with bounded variation. Set $NBV = \{f \in BV \mid f \text{ is left-continuous}, f(-\infty) = 0\}$, and let $\text{Var}(f)$ be the variation of f. From [7,

Ch. 6], *NBV* is the dual of C_0 with induced norm

$$\|f\|_n = \mathrm{Var}(f).$$

In addition, let $DBV = \{\dot{g} \in K' \mid g \in BV\}$ and define

$$\|\dot{g}\|_d = \mathrm{Var}(g).$$

It is easy to verify that $\|\cdot\|_d$ defines a norm on *DBV* and that *NBV* and *DBV* are isometrically isomorphic under the map $g \to \dot{g}$; hence *DBV* may also be viewed as the dual of C_0. It is easy to show that K is dense in C_0 and that the norm $\|\cdot\|_d$ satisfies

$$\|f\|_d = \sup_{\substack{\varphi \in K \\ \|\varphi\|_\infty = 1}} |\langle f, \varphi\rangle| = \sup_{\substack{\varphi \in K \\ \|\varphi\|_\infty = 1}} \left| \int_{-\infty}^{\infty} \varphi(t) dg(t) \right| \tag{1}$$

for any $f = \dot{g} \in DBV$.

Recall that every $f \in BV$ has a decomposition (unique a.e.) of the form $f = f_1 + f_2 + f_3$, where f_1 is bounded and absolutely continuous, f_2 is a bounded saltus function (i.e., $f_2 = \Sigma \alpha_i \theta_{\tau_i}$, where $\Sigma|\alpha_i| < \infty$), and f_3 is a singular function (i.e., f_3 is continuous and nonconstant, $f_3 \in BV$, and $f_3' = 0$ a.e.).

Define L_+^p, BV_+, and DBV_+ to consist of the L^p, BV, and *DBV* distributions $f \in K'$, respectively, with $\inf(\mathrm{supp} f) > -\infty$. For $p < \infty$, L_+^p is a dense subspace of L^p. On the other hand, the closure of L_+^∞ is a proper subspace of L^∞, namely,

$$L_0^\infty = \left\{ f \in L^\infty \mid \operatorname*{ess\,sup}_{t \in (-\infty, -n]} |f(t)| \to 0 \text{ as } n \to \infty \right\}.$$

Let $L_{[0,\infty)}^\infty$ denote the L^∞ functions f with $\mathrm{supp}\, f \subset [0, \infty)$. Note that $L_{[0,\infty)}^\infty$, L_+^p, BV_+, and DBV_+ may be viewed as subspaces of K_+'.

The first question we address is that of determining which operators $T : K_+' \to K_+'$ can be justifiably called "linear systems." Clearly, T should be linear. Also, since we wish to develop a theory based on the concept of impulse response, we need to establish conditions under which $T(\delta)$ uniquely characterizes the operator T. We will limit ourselves to time-invariant operators, although the results of this section can be generalized considerably. As a first step, we might also impose continuity on T, since continuous linear operators are easier to work with. These constraints and the following lemma lead to Theorem 2.2.

LEMMA 2.2. *Let* $\tau \in \mathbb{R}$ *and*

$$I_\tau = \left\{ f \in K' \mid \exists t_i \geq \tau, \beta_i \text{ such that } f = \sum_{i=1}^{k} \beta_i \delta_{t_i} \right\}.$$

Then I_τ *is weak* dense in* K_τ'.

Proof. Using an overbar to denote weak* closure, it is clear that $I_\tau \subset K_\tau' = \overline{K}_\tau'$, so $\bar{I}_\tau \subset K_\tau'$. We will demonstrate that $\bar{I}_\tau \supset \overline{K}_\tau \supset \overline{K}_{\tau b}' \supset K_\tau'$, where

$$K_\tau = \{\varphi \in K \mid \mathrm{supp}\, \varphi \subset [\tau, \infty)\}, \qquad K_{\tau b}' = \{f \in K_\tau' \mid \mathrm{supp}\, f \text{ is bounded}\}.$$

Let $\varphi \in K$ with $\mathrm{supp}\, \varphi \subset [\tau, \tau + \Delta]$ and define

$$\gamma_n = \sum_{k=0}^{n} \frac{\Delta}{n} \varphi\left(\tau + k\frac{\Delta}{n}\right) \delta\left(t - \tau - k\frac{\Delta}{n}\right).$$

For any $\psi \in K$, $\langle \gamma_n, \Psi \rangle$ is a sequence of Riemann sums converging to $\langle \varphi, \psi \rangle$; hence, $\gamma_n \to \varphi$ weak*. Since φ is arbitrary, $\bar{I}_\tau \supset K_\tau$ and $\bar{I}_\tau \supset \overline{K}_\tau$. Let $\varphi_n \in K_0$, $\varphi_n \to \delta$ weak*, $f \in K'_{\tau b}$, and $\psi_n = f^* \varphi_n$. From Lemma 2.1, $\psi_n \in K_\tau$ and $\psi_n \to f$. Hence, $\overline{K}_\tau \supset K'_{\tau b}$ and $\overline{K}_\tau \supset \overline{K}'_{\tau b}$. Finally, let $g \in K'_\tau$ and let $\eta_n \in K$ satisfy $\eta_n(t) = 1$ for $0 \le t \le n$. Then $\eta_n g \in K'_{\tau b}$ and $\eta_n g \to g$ weak*, so $\overline{K}'_{\tau b} \supset K'_\tau$. □

THEOREM 2.3. *Let $T : K'_+ \to K'_+$ be a weak* continuous, linear, time-invariant operator. Then $T(u) = T(\delta)^* u$ for all $u \in K'_+$.*

Proof. Suppose $u \in K'_\tau$. From Lemma 2.2, for any weak* neighborhood U of u, there exists a $v \in U$ of the form

$$v = \sum_{i=1}^{k} \beta_i \delta_{t_i}$$

with $t_i \ge \tau$ for all i. Let $\varphi \in K$. From linearity and time-invariance of T,

$$\langle T(v), \varphi \rangle = \langle T(\delta), \psi \rangle,$$

where

$$\psi = \sum_{i=1}^{k} \beta_i \sigma_{-t_i} \varphi.$$

Note that $\psi \in K$ and $\psi(t) = \langle v, \sigma_{-t} \varphi \rangle$ for all $t \ge \tau$. Thus

$$\langle T(\delta), \psi \rangle = \langle T(\delta)^* v, \varphi \rangle.$$

Since φ is arbitrary, $T(v) = T(\delta)^* v$. From Lemma 2.1, $T(u) = T(\delta)^* u$. □

Unfortunately, the converse to Theorem 2.3 is false; i.e., a convolution operator may fail to be weak* continuous. From Lemma 2.1, boundedness of $T(\delta)$ is sufficient to guarantee continuity of T. The next result establishes the converse.

THEOREM 2.4. *Let $T : K'_+ \to K'_+$ be a weak* continuous convolution operator. Then* supp $T(\delta)$ *is bounded.*

Proof. Suppose supp $T(\delta)$ is unbounded. Then there exist sequences $\varphi_n \in K$ and $\alpha_n \in \mathbb{R}$ such that supp $\varphi_n \subset [\alpha_n, \alpha_n + 1]$, $\alpha_n \to \infty$, and $\langle T(\delta), \varphi_n \rangle = \beta_n \ne 0$. Let

$$\gamma_n = \max_{\substack{i \le n \\ t \in \mathbb{R}}} \left| \frac{d^i \varphi_i(t)}{dt^i} \right|$$

and $\psi_n = \frac{1}{n\gamma_n} \sigma_{-n} \varphi_n$. From [3, p. 2], $\psi_n \to 0$ in K; hence, $\{\psi_n\}$ is a bounded subset of K. Let

$$f_n = \frac{n\gamma_n}{\beta_n} \delta_{-\alpha_n}.$$

Then $f_n \to 0$ weak*, but

$$\begin{aligned} \sup_m \langle T(\delta)^* f_n, \psi_m \rangle &\ge \langle T(\delta)^* f_n, \psi_n \rangle \\ &= \langle \frac{n\gamma_n}{\beta_n} \sigma_{-\alpha_n} T(\delta), \psi_n \rangle \\ &= \frac{1}{\beta_n} \langle T(\delta), n\gamma_n \sigma_{\alpha_n} \psi_n \rangle \\ &= \frac{1}{\beta_n} \langle T(\delta), \varphi_n \rangle \\ &= 1, \end{aligned}$$

so $T(\delta)^* f_n$ does not converge uniformly to 0 on bounded subsets of K. From [4, pp. 55–56], $T(\delta)^* f_n$ does not converge to 0 weak*, so T is not continuous. □

It follows from Theorem 2.4 that there exist many familiar examples of linear systems that are characterized by weak* discontinuous convolution operators. For example, θ has unbounded support, so a simple integrator is discontinuous. In particular, the sequence $\delta_{-n} \to 0$ weak* as $n \to \infty$, but its integrals θ_{-n} converge to the constant distribution 1. In view of such examples, we choose not to restrict ourselves to weak* continuous operators.

Unfortunately, an arbitrary class of discontinuous operators T in general is not uniquely characterized by the values $T(\delta)$, since $T(\delta)$ only determines the action of a linear time-invariant operator on the proper subspace span $\{\delta_\tau \mid \tau \in \mathbb{R}\} \subset K'_+$. On the other hand, the distributions $T(\delta)$ do uniquely characterize the family of convolution operators. In fact, it is easy to show that $h^*u = 0$ for every $u \in K'_+$ implies $h = 0$, so $T \to T(\delta)$ maps the convolution operators one-to-one onto K'_+. Thus any linear time-invariant nonconvolution operator has the same impulse response as some convolution operator.

Based on these observations, we define a *linear time-invariant system* to be a convolution operator $T : K'_+ \to K'_+$. In the next section, we develop the machinery that will enable us to define and characterize BIBO stability for such systems.

3. Extension of normed linear spaces. In this section we examine the problem of extending L^p in K' for arbitrary p. We do this because L^1 is known to play a role in characterizing BIBO stability of an operator and because L^∞ is used in the definition of stability. Values $p \in (1, \infty)$ are not directly related to stability but can be easily handled along with $p = \infty$ and are therefore included. In fact, the problem can be couched in much more general terms without substantially increasing the level of difficulty.

Let X be a Hausdorff topological vector space over $\mathbb{R}$, and let $Y \subset X$ be a normed linear space. Then Y has two topologies: the norm topology and the one inherited from X. Denote the topology of X by $\mathcal{T}$ (i.e., $\mathcal{T}$ is the family of all open subsets U of X), let $\mathcal{T}_Y$ be the relative topology on Y generated by $\mathcal{T}$ (i.e., $\mathcal{T}_Y$ consists of all sets $U \cap Y$). Also, let $B(y, r) \subset Y$ be the norm ball about y with radius r. We make the following assumptions.

A1) $\forall U \in \mathcal{T}, U \cap Y \neq \phi$.
A2) $\forall U \in \mathcal{T}$ and $\forall y \in U \cap Y, \exists \varepsilon > 0$ such that $B(y, \varepsilon) \subset U$.
A3) $\exists U \in \mathcal{T}$ such that $U \cap Y = Y - B(0, 1)$.

Assumption A1) states that Y is dense in X relative to $\mathcal{T}$. The other two assumptions give upper and lower bounds on $\mathcal{T}_Y$. Assumption A2) states that the norm topology on Y is stronger than or equal to $\mathcal{T}_Y$, while A3) says that $B(0, 1)$ is closed in $\mathcal{T}_Y$.

Suppose Y has norm $\|\cdot\|$, let $x \in X$, and let $\{U_\beta\} \subset \mathcal{T}$ be the family of all neighborhoods of x. Define

$$\|x\|^e = \sup_\beta \inf_{y \in U_\beta \cap Y} \|y\|. \tag{2}$$

In view of A1), $\|x\|^e$ is well defined and determines a function $\|\cdot\|^e : X \to [0, \infty]$. The next result establishes that $\|\cdot\|^e$ is a natural extension of $\|\cdot\|$ to all of X.

PROPOSITION 3.1. 1) $\|\cdot\|$ *and* $\|\cdot\|^e$ *coincide on* Y.

2) $\|\cdot\|^e$ *is lower semicontinuous on* X *relative to* $\mathcal{T}$.

3) *If* $\|x\|^e < \infty$, *then for every* $\varepsilon > 0$ *and* $\mathcal{T}$*-neighborhood* U *of* x *there exists a* $y \in U \cap Y$ *such that*

$$\|y\| < \|x\|^e + \varepsilon.$$

4) *If* $\|\cdot\|^f : X \to [0, \infty]$ *satisfies* 1)–3) *(replacing* e *with* f *throughout), then* $\|\cdot\|^f = \|\cdot\|^e$.

Proof. 1) For $x \in Y$,

$$\inf_{y \in U_\beta \cap Y} \|y\| \leq \|x\|$$

for all β, so $\|x\|^e \leq \|x\|$ follows immediately from (2). Suppose $\|x\|^e < a < \|x\|$. Then (2) states that for every β and $\varepsilon > 0$ there exists a $y \in U_\beta \cap Y$ such that $\|y\| < \|x\|^e + \varepsilon$. Setting $\varepsilon = a - \|x\|^e$ yields $\|y\| < a$. Hence $U_\beta \cap B(0, a) \neq \phi$, and $B(0, a)$ is not closed relative to $\mathcal{T}$. Thus $B(0, 1)$ is also not closed, contradicting A3). Therefore $\|x\|^e = \|x\|$.

2) We need to show that

$$\sum_R = \{x \in X \mid \|x\|^e > R\}$$

is $\mathcal{T}$-open for every $R < \infty$. (See [8, p. 84].) From (2) we have

$$\sum_R = \{x \in X \mid \exists \text{ a } \mathcal{T}\text{-neighborhood } U \text{ of } x \text{ and } \varepsilon > 0 \text{ such that } \|y\| > R + \varepsilon \ \forall y \in U \cap Y\}. \tag{3}$$

If $x \in \sum_R$ for some R, then U and ε are determined by (3). In fact, $U \subset \sum_R$, so $\sum_R$ is open.

3) This follows immediately from (2).

4) If $\|x\|^e = \infty$, $\|x\|^f \leq \|x\|^e$. Suppose that $\|x\|^e < \infty$ and $\varepsilon > 0$ are given. From 2), there exists a β such that $\|y\| \geq \|x\|^f - \frac{\varepsilon}{2}$ for every $y \in U_\beta$. Setting $U = U_\beta$ in 3) guarantees the existence of a $z \in U_\beta \cap Y$ such that $\|z\| < \|x\|^e + \frac{\varepsilon}{2}$. Setting $y = z$ yields $\|x\|^f < \|x\|^e + \varepsilon$. Since ε is arbitrary, $\|x\|^f \leq \|x\|^e$. Interchanging the roles of "e" and "f" and applying the same arguments gives $\|x\|^f \geq \|x\|^e$. □

Let $Y_e = \{x \in X \mid \|x\|^e < \infty\}$. From Proposition 3.1, 1), it is obvious that $Y_e \supset Y$. We refer to Y_e as the *X-extension* of Y. The next result further justifies this terminology.

PROPOSITION 3.2. 1) *Y_e is a subspace of X.*

2) *$\|\cdot\|^e$ is a norm on Y_e.*

Proof. 1) If $x \in Y_e$ and $\alpha \in \mathbb{R}$, then

$$\begin{aligned} \|\alpha x\|^e &= \sup_\beta \inf_{y \in \alpha U_\beta \cap Y} \|y\| \\ &= |\alpha| \sup_\beta \inf_{y \in U_\beta \cap Y} \|y\| \\ &= |\alpha| \, \|x\|^e \\ &< \infty. \end{aligned} \tag{4}$$

Furthermore, if $x_1, x_2 \in Y_e$ and U_β is a neighborhood of $x_1 + x_2$, then there exist neighborhoods V_β and W_β of x_1 and x_2, respectively, such that $V_\beta + W_\beta \subset U_\beta$. Hence,

$$\begin{aligned} \|x_1 + x_2\|^e &= \sup_\beta \inf_{y \in U_\beta \cap Y} \|y\| \\ &\leq \sup_\beta \inf_{\substack{y_1 \in V_\beta \cap Y \\ y_2 \in W_\beta \cap Y}} \|y_1 + y_2\| \\ &\leq \|x_1\|^e + \|x_2\|^e \\ &< \infty. \end{aligned} \tag{5}$$

Thus αx and $x_1 + x_2$ belong to Y_e, and 1) follows.

2) In view of (4) and (5), to demonstrate 2) it remains to show that $\|x\|^e = 0$ implies $x = 0$. Indeed, $\|x\|^e = 0$ implies

$$\inf_{y \in U_\beta \cap Y} \|y\| = 0 \tag{6}$$

for every β. Since X is Hausdorff, for $x \neq 0$ there must exist disjoint $\mathcal{T}$-neighborhoods U_β and V of x and 0, respectively. From assumption A2), there exists an $\varepsilon > 0$ such that $B(0, \varepsilon) \subset V$. Thus $B(0, \varepsilon) \cap U_\beta = \phi$, contradicting (6). □

Roughly speaking, Propositions 3.1 and 3.2 say that 1) $\| \cdot \|^e$ is the smallest possible extension of $\| \cdot \|$ such that $\|x\|^e$ is consistent with $\mathcal{T}$-approximations to x from within Y, and 2) Y_e is the largest subspace of X upon which $\| \cdot \|^e$ is a norm.

We may now specialize these ideas to $X = K'_+$ and $Y = L^p_+$. First note that assumptions A1) and A2) follow easily from [4, §II.4.4] and [3, §I.1.8]. The next result verifies assumption A3).

PROPOSITION 3.3. *$B(0, 1) \subset L^p_+$ is weak* closed (relative to K'_+) for $1 \leq p \leq \infty$.*

Proof. Suppose $B(0, 1)$ is not weak* closed. Then there exist $\varepsilon > 0$ and $f \in L^p_+$ such that $\|f\|_p = 1 + \varepsilon$ and such that, for each $\varphi \in K$, there exists a $g \in L^p_+$ with $\|g\|_p \leq 1$ and $|\langle f - g, \varphi\rangle| < \frac{\varepsilon}{4}$. Let q be conjugate to p. Since K is dense in L^q using $\| \cdot \|_q$ for $q < \infty$, we may choose $\varphi \in K$ such that $\|\varphi\|_q = 1$ and $|\langle f, \varphi\rangle| > 1 + \frac{\varepsilon}{2}$. To handle the case $q = \infty$, we note that K is dense in C_0, so [7, Thm. 6.19] guarantees the existence of a $\varphi \in K$ with $\|\varphi\|_\infty = 1$ and $|\langle f, \varphi\rangle > 1 + \frac{\varepsilon}{2}$. Thus, for arbitrary p, $|\langle g, \varphi\rangle| \leq 1$ and

$$\frac{\varepsilon}{2} < |\langle f, \varphi\rangle| - |\langle g, \varphi\rangle| \leq |\langle f - g, \varphi\rangle| < \frac{\varepsilon}{4}.$$

This is a contradiction, so $B(0, 1)$ is closed. □

Since A1)-A3) are satisfied, the K'_+-extension L^p_{+e} of L^p_+ and its norm $\| \cdot \|^e_p$ are well defined. The following two results characterize L^p_{+e} more precisely.

PROPOSITION 3.4. *Let $1 < p \leq \infty$. Then $L^p_{+e} = L^p_+$.*

Proof. Suppose $f \in K' - L^p_+$, let $M < \infty$ be given, and let q be conjugate to p. Since K is dense in L^q relative to $\| \cdot \|_q$, the dual of K with $\| \cdot \|^q$ imposed on it is just L^p. Thus there exists a $\varphi \in K$ with $\|\varphi\|_q = 1$ such that $|\langle f, \varphi\rangle| > M + 1$. Furthermore, there exists a weak* neighborhood U of f such that $\|g\|_p \geq |\langle g, \varphi\rangle| > M$ for all $g \in U \cap L^p_+$; thus $\|f\|^e_p \geq M$. Since M is arbitrary, $\|f\|^e_p = \infty$ and $f \notin L^p_{+e}$. Hence $L^p_{+e} = L^p_+$. □

The case $p = 1$ is somewhat more challenging.

PROPOSITION 3.5. *$L^1_{+e} = DBV_+$ and $\|x\|^e_1 = \|x\|_d$ for all $x \in DBV_+$.*

Proof. Let

$$\|f\|_D = \begin{cases} \|f\|_d, & f \in DBV, \\ \infty, & f \notin DBV. \end{cases}$$

It suffices to verify 1)-3) in Proposition 3.1. If $f \in L^1$, then $f = \dot{g}$ for some absolutely continuous g. Hence

$$\|f\|_D = \mathrm{Var}(g) = \int_{-\infty}^{\infty} 1|dg(t)| = \int_{-\infty}^{\infty} |\dot{g}(t)|\, dt = \|f\|_1,$$

and 1) holds.

To prove 2), let $R < \infty$ and $\sum_R = \{f \in K' \mid \|f\|_D > R\}$. For $f \in \sum_R$, we have from (1) that

$$\sup_{\substack{\varphi \in K \\ \|\varphi\|_\infty = 1}} |\langle f, \varphi\rangle| = \|f\|_D > R.$$

Hence, there exists a $\varphi \in K$ with $\|\varphi\|_\infty = 1$ such that $|\langle f, \varphi\rangle| > R$. Let

$$U = \{g \in K' \mid |\langle f - g, \varphi\rangle| < |\langle f, \varphi\rangle| - R\}.$$

U is a weak* neighborhood of f. If $g \in U$,

$$|\langle f, \varphi\rangle| - |\langle g, \varphi\rangle| \leq |\langle f - g, \varphi\rangle| < |\langle f, \varphi\rangle| - R,$$

so $|\langle g, \varphi\rangle| > R$. Hence,

$$\|g\|_D = \sup_{\substack{\varphi \in K \\ \|\varphi\|_\infty = 1}} |\langle g, \varphi\rangle| > R.$$

Thus $g \in \sum_R$ and $U \subset \sum_R$. Hence $\sum_R$ is weak* open, and $\|\cdot\|_D$ is lower semicontinuous.

Condition 3) can be proven directly using elementary analytic arguments based on the definition of Var($\cdot$), but here we supply a functional analytic proof that is more amenable to generalization. Let U be a weak* neighborhood of f, and let $\varepsilon > 0$. Then there exist $\varphi_1, \ldots, \varphi_n \in K$ such that $h \in U$ whenever $|\langle f - h, \varphi_i\rangle| < 1$ for all i. If $\beta_1, \ldots, \beta_n \in \mathbb{R}$, then

$$\left|\sum \beta_i \langle f, \varphi_i\rangle\right| = \left|\left\langle f, \sum \beta_i \varphi_i\right\rangle\right| \leq \|f\|_d \left\|\sum \beta_i \varphi_i\right\|_\infty.$$

Noting that $K \subset L^\infty$ and that L^∞ is the dual of the Banach space L^1, it follows from [9, Thm. 5, p. 109] that there exists an $h \in L^1$ such that $\langle h, \varphi\rangle = \langle f, \varphi_i\rangle$ for all i and $\|h\|_1 \leq \|f\|_d + \frac{\varepsilon}{2}$. Note that $|\langle f - h, \varphi_i\rangle| = 0$, so $h \in U$. Since L^1_+ is dense in L^1 relative to $\|\cdot\|_1$ (and therefore also weak*), there exists a $g \in U \cap L^1_+$ such that $\|g\|_1 < \|f\|_d + \varepsilon$. □

We can make slight modifications to the arguments of this section and construct an extension L^p_e of L^p in K'. In this way, results similar to Propositions 3.1, 3.4, and 3.5 are obtained; i.e., $L^p_e = L^p$ for $1 < p \leq \infty$ and $L^1_e = DBV$. This construction has the advantage that L^1_e is a Banach space, while L^1_{+e} is not; however, convolution is not defined on all of L^1_e, so we must restrict ourselves to L^1_{+e}.

Besides stability analysis, another important application of our extension theory occurs in treating minimum-norm optimization problems over K'. For example, the issue of extending a quadratic cost functional on L^2 to K' arose naturally in the earlier work of one of us [10]. It is easily seen that [10, Prop. 1] follows immediately from Proposition 3.1, part 2) and Proposition 3.4.

4. BIBO stability. Proposition 3.4 shows that "boundedness" of a distribution $f \in K'_+$ is most naturally interpreted to mean that $f \in L^\infty_+$. Hence, we define a linear operator $T : K'_+ \to K'_+$ to be *BIBO stable* if $T(L^\infty_+) \subset L^\infty_+$. Clearly, this definition extends the classical one, as long as $u, T(u) \in K'_+$.

Since convolution operators satisfying $T(\delta) \in L^1_+$ are known to be BIBO stable, a natural conjecture is that the convolution operators with kernels in the extension space L^1_{+e} described in Proposition 3.5 coincide exactly with the stable operators. This idea is supported by the fact that $\delta \in L^1_{+e}$, since $\delta = \dot{\theta}$ and $\theta \in BV_+$, and $\delta^{(i)} \notin L^1_{+e}$ for $i = 1, 2, 3, \ldots$, since $\delta^{(i-1)} \notin BV$. It is easy to show that $T(u) = \delta^{(i)} * u$ defines a stable operator iff $i = 0$.

Corresponding to each convolution operator T we may associate a $\widetilde{T} : K \to C^\infty$ defined by

$$\widetilde{T}(\varphi)(t) = \langle T(\delta), \sigma_{-t}\varphi\rangle.$$

Indeed, it is established in [3, p. 100] that $\widetilde{T}$ takes values in C^∞ with $\widetilde{T}(\varphi)(t) = 0$ for all t in some interval $[\tau_\varphi, \infty)$. The following result provides preliminary information about BIBO stable operators.

LEMMA 4.1. *Let $T : K'_+ \to K'_+$ be a convolution operator.*

1) *If T is BIBO stable, then*

$$\sup_{\substack{u \in L^\infty_+ \\ \|u\|_\infty = 1}} \|T(u)\|_\infty < \infty.$$

2) *T is BIBO stable iff*

$$\sup_{\substack{\varphi\in K\\ \|\varphi\|_1=1}} \int_{-\infty}^{\infty} |\tilde{T}(\varphi)(t)|\,dt < \infty.$$

Proof. 1) Let P be the restriction of T to $L^\infty_{[0,\infty)}$. We begin by showing that P is continuous relative to $\|\cdot\|_\infty$.

Let $u, u_i \in L^\infty_{[0,\infty)}$ and $\|u_i - u\|_\infty \to 0$. Suppose there exists a $v \in L^\infty$ such that $\|P(u_i) - v\|_\infty \to 0$. Since weak* topology is weaker than norm topology on L^∞, $u_i \to u$ weak* and $P(u_i) \to v$ weak*. From Lemma 2.1, P is weak* continuous, so $P(u_i) \to P(u)$ weak*. Since weak* topology is Hausdorff, $P(u) = v$. The continuity of P follows from the closed graph theorem.

Now let $u_i \in L^\infty_+$ with $\|u_i\|_\infty \to 0$. For each u_i, there exist τ_i such that $\sigma_{\tau_i} u_i \in L^\infty_{[0,\infty)}$. Also, $\|\sigma_{\tau_i} u_i\|_\infty = \|u_i\|_\infty \to 0$. From the continuity of P and time-invariance of T,

$$\|T(u_i)\|_\infty = \|\sigma_{-\tau_i} P(\sigma_{\tau_i} u_i)\|_\infty = \|P(\sigma_{\tau_i} u_i)\|_\infty \to 0.$$

This shows that T is continuous or, equivalently,

$$\sup_{\substack{u\in L^\infty_+\\ \|u\|_\infty=1}} \|T(u)\|_\infty < \infty.$$

2) (sufficient) Let $u \in L^\infty_+$. From the definition of convolution on K', we have

$$\langle T(u), \varphi\rangle = \int_{-\infty}^{\infty} u(t)\tilde{T}(\varphi)(t)\,dt;$$

hence

$$|\langle T(u), \varphi\rangle| \le \|u\|_\infty \int_{-\infty}^{\infty} |\tilde{T}(\varphi)(t)|\,dt$$

and

$$\sup_{\substack{\varphi\in K\\ \|\varphi\|_1=1}} |\langle T(u), \varphi\rangle| < \infty.$$

Since K is dense in L^1, $T(u)$ extends continuously to a unique linear functional on L^1. Hence, $T(u) \in L^\infty_+$.

(necessary) From 1),

$$\begin{aligned}\sup_{\substack{u\in L^\infty_+\\ \|u\|_\infty=1}} \sup_{\substack{\varphi\in K\\ \|\varphi\|_1=1}} \left|\int_{-\infty}^{\infty} u(t)\tilde{T}(\varphi)(t)\,dt\right| &= \sup_{\substack{u\in L^\infty_+\\ \|u\|_\infty=1}} \sup_{\substack{\varphi\in K\\ \|\varphi\|_1=1}} |\langle T(u), \varphi\rangle| \\ &\le \sup_{\substack{u\in L^\infty_+\\ \|u\|_\infty=1}} \|T(u)\|_\infty \\ &< \infty.\end{aligned}$$

Let $\varphi \in K$ and $u_i(t) = \operatorname{sgn}(\tilde{T}(\varphi)(t))\theta_{-i}(t)$. Then

$$\begin{aligned}\int_{-\infty}^{\infty} |\tilde{T}(\varphi)(t)|\,dt &= \lim_{i\to\infty} \int_{-\infty}^{\infty} u_i(t)\tilde{T}(\varphi)(t)\,dt \\ &\le \sup_{\substack{u\in L^\infty_+\\ \|u\|_\infty=1}} \left|\int_{-\infty}^{\infty} u(t)\tilde{T}(\varphi)(t)\,dt\right|,\end{aligned}$$

so

$$\sup_{\substack{\varphi\in K\\ \|\varphi\|_1=1}} \int_{-\infty}^{\infty} |\tilde{T}(\varphi)(t)|\,dt < \infty. \qquad \square$$

Lemma 4.1, part 1) makes the striking statement that every stable convolution operator is also continuous relative to $\|\cdot\|_\infty$. In system-theoretic jargon, this means that, in the time-invariant case, BIBO stability implies that small changes in the system input give rise to only small changes in the output. It is an interesting fact that this statement is demonstrably false in the time-varying case.

We are now in a position to give our main result.

THEOREM 4.2. *Let $T : K'_+ \to K'_+$ be a convolution operator. The following statements are equivalent.*

1) *T is BIBO stable.*
2) $T(\delta) \in L^1_{+e}$.
3) $T(\theta) \in BV_+$.

Proof. The equivalence of 2) and 3) is obvious from Proposition 3.5. To prove that 3) implies 1), let $\varphi \in K$, $u \in L^\infty_+$, and $s = T(\theta)$ and note that

$$\begin{aligned}
\langle T(u), \varphi\rangle &= \int_{-\infty}^{\infty} u(t)\langle \dot{s}, \sigma_{-t}\varphi\rangle\,dt \\
&= -\int_{-\infty}^{\infty} u(t)\langle s, \sigma_{-t}\dot{\varphi}\rangle\,dt \\
&= -\int_{-\infty}^{\infty}\int_{-\infty}^{\infty} u(t)s(\tau)\dot{\varphi}(t+\tau)d\tau\,dt \\
&= \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} u(t)\varphi(t+\tau)ds(\tau)dt \\
&= \int_{-\infty}^{\infty}\left(\int_{-\infty}^{\infty} u(t-\tau)ds(\tau)\right)\varphi(t)dt,
\end{aligned}$$

so

$$T(u)(t) = \int_{-\infty}^{\infty} u(t-\tau)ds(\tau) \quad \text{a.e.}$$

and

$$|T(u)(t)| \le \|u\|_\infty \operatorname{Var}(s) \quad \text{a.e.}$$

Thus $T(u) \in L^\infty$.

Finally, we show that 1) implies 2). From [11, Thm. 2.3.9] and Lemma 4.1, part 2), we know that there exists a measurable function $g : \mathbb{R}^2 \to \mathbb{R}$ with $g(t,\cdot) \in L^\infty$ for all t, $\int_{-\infty}^{\infty} g(\cdot,\tau)\varphi(\tau)\,d\tau$ absolutely continuous,

$$\operatorname*{ess\,sup}_{\tau} \operatorname{Var}(g(\cdot,\tau)) < \infty$$

and

$$\tilde{T}(\varphi)(t) = \frac{d}{dt}\int_{-\infty}^{\infty} g(t,\tau)\varphi(\tau)\,d\tau$$

for all $\varphi \in K$.

Since $\tilde{T}$ is time-invariant,

$$\frac{d}{dt}\int_{-\infty}^{\infty} g(t,\tau)\varphi(\tau - t_0)\,d\tau = \frac{d}{dt}\int_{-\infty}^{\infty} g(t - t_0,\tau)\varphi(\tau)\,d\tau$$

for all $t, t_0 \in \mathbb{R}$, $\varphi \in L^1$. Integration and a change of variables yield

$$\int_{-\infty}^{\infty} g(t,\tau + t_0)\varphi(\tau)\,d\tau = \int_{-\infty}^{\infty} g(t - t_0,\tau)\varphi(\tau)\,d\tau.$$

Thus $g(t,\tau + t_0) = g(t - t_0,\tau)$ for all t, t_0, τ. Set $s(t) = g(-t, 0)$. Then $s \in BV$ and

$$g(t,\tau) = g(t - \tau, 0) = s(\tau - t),$$

so

$$\tilde{T}(\varphi)(t) = \frac{d}{dt}\int_{-\infty}^{\infty} s(\tau - t)\varphi(\tau)\,dt = \frac{d}{dt}\langle \sigma_t s, \varphi\rangle = \langle \sigma_t \dot{s}, \varphi\rangle$$

for all $\varphi \in K$. Setting $t = 0$ yields $\langle \dot{s}, \varphi\rangle = \langle T(\delta), \varphi\rangle$; hence $T(\delta) \in DBV \cap K_+' = DBV_+$. □

Our next objective is to obtain a more detailed picture of the additional structure imposed on a linear system by stability. We begin by considering certain extensions of the operators T and $\tilde{T}$.

Since every stable T is continuous on L_+^∞ relative to $\|\cdot\|_\infty$, each such operator may be extended uniquely to a continuous linear operator $T_0 : L_0^\infty \to L_0^\infty$. Similarly, Lemma 4.1, part 2) also states that T is BIBO stable iff $\tilde{T}(K) \subset L^1$ and $\tilde{T}$ is bounded using the L^1 norm throughout. In this case, since K is dense in L^1, $\tilde{T}$ extends uniquely to a continuous linear operator $\tilde{T}_e : L^1 \to L^1$. It is easy to show that T_0 and $\tilde{T}_e$ are time-invariant.

THEOREM 4.3. *Suppose $T : K_+' \to K_+'$ is a BIBO stable convolution operator and $s = T(\theta)$. Let $T_e : L^\infty \to L^\infty$ be defined by*

$$T_e(u)(t) = \int_{-\infty}^{\infty} u(t - \tau)\,ds(\tau).$$

Then

1) $T_e(u) = T_0(u)$ *for all* $u \in L_0^\infty$.

2) $\tilde{T}_e(\varphi)(t) = \int_{-\infty}^{\infty} \varphi(t + \tau)\,ds(\tau)$ for all $\varphi \in L^1$.

3) T_e *is the adjoint of* $\tilde{T}_e$.

Proof. 1) As in the proof of Theorem 4.2,

$$T(u)(t) = \int_{-\infty}^{\infty} u(t - \tau)\,ds(\tau)$$

for any $u \in L_+^\infty$. Since T_e is continuous relative to $\|\cdot\|_\infty$, 1) follows immediately.

2) For any $\varphi \in K$,

$$\begin{aligned}\tilde{T}(\varphi)(t) &= \langle \dot{s}, \sigma_{-t}\varphi\rangle \\ &= -\langle s, \sigma_{-t}\dot{\varphi}\rangle \\ &= \int_{-\infty}^{\infty} s(\tau)\dot{\varphi}(t + \tau)\,d\tau \\ &= \int_{-\infty}^{\infty} \varphi(t + \tau)\,ds(\tau).\end{aligned}$$

Thus $\tilde{T}_e(\varphi) = \tilde{T}(\varphi)$ for all $\varphi \in K$. Since $\tilde{T}_e$ is continuous relative to $\|\cdot\|_1$, 2) follows.

3) Let $s \in BV$, $u \in L^\infty$, and $\varphi \in L^1$. Applying Fubini's theorem and a change of variable, we have

$$\int_{-\infty}^{\infty} u(t)\left(\int_{-\infty}^{\infty} \varphi(t+\tau)\,ds(\tau)\right)dt = \int_{-\infty}^{\infty}\left(\int_{-\infty}^{\infty} u(t-\tau)\,ds(\tau)\right)\varphi(t)\,dt$$

or

$$\int_{-\infty}^{\infty} u(t)\widetilde{T}_e(\varphi)(t)\,dt = \int_{-\infty}^{\infty} T_e(u)(t)\varphi(t)\,dt. \qquad \square$$

Note that the proof of Theorem 4.3 applies even if $s \in BV - BV_+$. Hence, the idea of a stable system whose step or impulse response does not have left-bounded support is meaningful; the system may be viewed as an operator on L^∞. However, such an operator does not extend easily to K' or even K'_+.

To conclude this section, we give several equivalent expressions that quantify the "gain" of a stable operator.

THEOREM 4.4. *For any BIBO stable convolution operator* $T : K'_+ \to K'_+$,

$$\sup_{\substack{u\in L^\infty_+ \\ \|u\|_\infty=1}} \|T(u)\|_\infty = \sup_{\substack{u\in L^\infty \\ \|u\|_\infty=1}} \|T_e(u)\|_\infty = \sup_{\substack{\varphi\in L^1 \\ \|\varphi\|_1=1}} \|\widetilde{T}_e(\varphi)\|_1 = \mathrm{Var}(T(\theta)) = \|T(\delta)\|_1^e.$$

Proof. The first equality follows from continuity of T_e. Since the norms of adjoint operators must coincide, the second identity holds. The next equality follows from the representation of $\widetilde{T}_e$ established in Theorem 4.3. The last identity follows immediately from Proposition 3.5. $\square$

5. Additional properties of stable systems. In view of the Theorem 4.2, part 3) the step response of every BIBO system can be decomposed as $T(\theta) = s_1 + s_2 + s_3$, where s_1 is absolutely continuous, s_2 is saltus, and s_3 is singular. (See [12].) Thus, the corresponding impulse response is $T(\delta) = h_1 + h_2 + h_3$, where $h_i = \dot{s}_i$. Since s_1 is bounded and absolutely continuous, $h_1 \in L^1_+$. Also, since s_2 is a saltus function,

$$h_2 = \sum \alpha_i(\delta_{\tau_i}), \tag{7}$$

where $\sum |\alpha_i| < \infty$. Hence the impulse response of any stable system can be uniquely decomposed into the sum of an L^1 function, an impulsive distribution, and the (distributional) derivative of a singular function.

The distribution $h_3 = \dot{s}_3$ is particularly interesting and apparently has not been treated in the literature as a viable impulse response. Distributions of this type illustrate the fact that, for a function $s : \mathbb{R} \to \mathbb{R}$, the operations of differentiation and identification with a distribution do not in general commute, even if s is continuous. Indeed, the derivative s'_3 of s_3 *as a function* vanishes a.e., so s'_3 is identified with the distribution 0. On the other hand, s_3 is by definition not constant a.e., hence its *distributional derivative* $\dot{s}_3$ does not vanish.

A classical example of a singular function on [0, 1] is the Cantor function, which we denote by c_0. (See [12, p. 50].) Define

$$c(t) = \begin{cases} 0, & t < 0, \\ c_0(t), & 0 \le t \le 1, \\ 1, & t > 1. \end{cases}$$

Then c is nondecreasing and singular on $\mathbb{R}$. Since $\mathrm{Var}(c) = 1$, Proposition 3.5 gives $\|\dot{c}\|_1^e = 1$. The support of the distribution $\dot{c}$ is simply the Cantor ternary set, which is uncountable and

has Lebesgue measure zero. (See [12, p. 49].) Note that $\dot{c}$ has a far more elusive structure than a conventional impulsive distribution (7). Nevertheless, Theorem 4.2 guarantees that the system governed by $T(u) = \dot{c} * u$ is BIBO stable.

On the other hand, suppose $T(\delta) = \ddot{c}$. Any attempt to decide the value $\int |T(\delta)|$ by intuitive means would be perilous at best. Using our theory, this case is easily handled by simply noting that $T(\theta) = \dot{c} \notin BV_+$.

Another characterization of stable linear time-invariant systems can be obtained by examining the set $\mathcal{H}$ of Fourier transforms of functions in L_e^1. It follows from [5, p. 189] that the Fourier transform of any $h \in L_e^1$ exists, is a function, and is given by

$$H(\omega) = \int_{-\infty}^{\infty} e^{-i\omega t}\, ds(t), \tag{8}$$

where $s \in BV$ and $\dot{s} = h$. We refer to $\mathcal{H}$ as the set of *BIBO stable transfer functions*. Clearly, a rational function belongs to $\mathcal{H}$ iff it is BIBO stable in the usual sense.

According to Theorem 4.2, the stable transfer functions are generated by letting s vary over BV in (8). Since every function in BV can be written as the difference of two bounded nondecreasing functions, a substantial number of existing results in analysis come into play. For example, working from [13, Ch. VI], we find that all functions in $\mathcal{H}$ are bounded and uniformly continuous. Several complete, albeit abstruse, characterizations of $\mathcal{H}$ are available, perhaps the simplest following from Bochner's theorem: A function H belongs to $\mathcal{H}$ iff H is the difference of two continuous positive semidefinite functions. (See [13, p. 137].)

The Laplace transform

$$H(z) = \int_{-\infty}^{\infty} e^{-zt}\, ds(t)$$

of $h = \dot{s} \in L_{+e}^1$ also exists and is analytic on $\operatorname{Re} z > 0$. It is easy to show that the "boundary function"

$$\omega \to \lim_{\sigma \to 0} H(\sigma + i\omega)$$

is well defined and equals the Fourier transform (8). In fact, if $\operatorname{supp} h \subset [\tau, \infty)$,

$$|H(z)| \leq e^{-\operatorname{Re} z\tau} \operatorname{Var}(s)$$

for all right half-plane z. In particular, if $h \in L_{+e}^1$ with $\tau \geq 0$, then H belongs to the Hardy space $H^\infty(\mathbb{C}^+)$. The converse implication fails, however, since the function

$$H(z) = e^{-\frac{1}{z}}$$

belongs to H^∞, but $H(i\omega)$ is not continuous at $\omega = 0$ and therefore H is not stable. Sufficient conditions on $H(z)$ for stability (other than those on the boundary function) are difficult to obtain. Even analyticity on the whole plane is not sufficient (e.g., let $h = \dot{\delta}$).

Our final comment of this section addresses the issue of linear systems with multiple inputs and outputs. In this case, $T(\delta)$ and its Fourier transform are matrices. Extending the definition of BIBO stability in the obvious way, it is clear that stability simply corresponds to each entry of the matrix being stable in the sense described above.

6. Conclusions. We presented a coherent distributional theory for linear time-invrariant systems based on the concept of impulse response. The property of BIBO stability was shown to be equivalent to a simple condition on either the impulse or step response of the system. We also supplied a somewhat more difficult stability condition related to the system transfer function. The time-varying case is at present under investigation.

FINITE-DIMENSIONAL APPROXIMATION OF A CLASS OF CONSTRAINED NONLINEAR OPTIMAL CONTROL PROBLEMS*

MAX D. GUNZBURGER† AND L. STEVEN HOU‡

Abstract. An abstract framework for the analysis and approximation of a class of nonlinear optimal control and optimization problems is constructed. Nonlinearities occur in both the objective functional and the constraints. The framework includes an abstract nonlinear optimization problem posed on infinite-dimensional spaces, an approximate problem posed on finite-dimensional spaces, together with a number of hypotheses concerning the two problems. The framework is used to show that optimal solutions exist, to show that Lagrange multipliers may be used to enforce the constraints, to derive an optimality system from which optimal states and controls may be deduced, and to derive existence results and error estimates for solutions of the approximate problem. The abstract framework and the results derived from that framework are then applied to three concrete control or optimization problems and their approximation by finite-element methods. The first involves the von Kármán plate equations of nonlinear elasticity, the second the Ginzburg-Landau equations of superconductivity, and the third the Navier-Stokes equations for incompressible, viscous flows.

Key words. optimal control, nonlinear partial differential equations, finite-dimensional approximation, finite-element methods, von Kármán equations, Ginzburg-Landau equations, Navier-Stokes equations

1. Introduction.

The need to solve optimization and control problems arises in many settings. Although in some cases these problems may be easily solved, either analytically or computationally, in many other cases substantial difficulties are encountered. For example, candidate optimal states and controls may belong to infinite-dimensional function spaces and one may have to minimize a nonlinear functional of the state and control variables subject to nonlinear constraints that take the form of a system of partial differential equations whose solutions are in general not unique. In this paper, our goal is to construct and analyze a framework for the approximate solution of many such problems. The setting for our framework is a class of nonlinear control or optimization problems that is general enough to be of use in numerous applications. The major steps in the development and analysis of our framework are as follows:

- define an abstract class of nonlinear control or optimization problems;
- show that, under certain assumptions, optimal solutions exist;
- show that, under certain additional assumptions, Lagrange multipliers exist that may be used to enforce the constraints;
- use the Lagrange multiplier technique to derive an optimality system from which optimal states and controls may be deduced;
- define algorithms for the approximation, in finite-dimensional spaces, of optimal states and controls;
- derive estimates for the error in the approximations to the optimal states and controls.

Two of the key ingredients used to carry out the above plan are a theory given in [21] for showing the existence of Lagrange multipliers and a theory first developed in [6] for the approximation of a class of nonlinear problems. In both of these theories, certain properties of compact operators on Banach spaces play a central role. We point out that the nonuniqueness

of solutions of the nonlinear constraint equations deems it appropriate to employ Lagrange multiplier principles.

After having developed and analyzed the abstract framework, we will apply it to some specific, concrete problems. In each case, we use the abstract framework to analyze the concrete problems by merely showing that the latter fit into the former. The particular applications we consider are

- control problems in structural mechanics having geometric nonlinearities that are governed by the von Kármán equations;
- control problems in superconductivity that are governed by the Ginzburg-Landau equations;
- control problems for incompressible, viscous flows that are governed by the Navier-Stokes equations.

In considering these applications, we will purposely choose different types of controls in order to illustrate how these can be accounted for within the abstract framework. In all three cases, approximation will be effected through the use of finite-element methods.

2. The abstract problem and its analysis. In this section we define and analyze an abstract class of constrained nonlinear control problems; an outline of the definitions and results of this section is as follows.

- In §2.1, the abstract class of constrained control problems that we consider is defined.
- In §2.2, a list of assumptions about the class of abstract problems is given.
- In Theorem 2.1 of §2.3, some of the assumptions listed in §2.2 are used to show that optimal solutions of the abstract problem exist.
- In §2.4, some additional assumptions of §2.2 are used to show that Lagrange multipliers exist that may be used to enforce the constraint; also, first-order necessary conditions are given.
- In Theorems 2.5 and 2.6 of §2.4, the first-order necessary conditions for determining optimal states and controls are simplified under additional assumptions about the control set.
- In §2.5, the optimality system from which optimal controls and states can be determined is made more amenable to approximation by simplifying the dependence of the objective functional on the control.

2.1. The abstract setting. We begin with the definition of the abstract class of nonlinear control or optimization problems that we study.

We introduce the spaces and control set as follows. Let G, X, and Y be reflexive Banach spaces whose norms are denoted by $\|\cdot\|_G$, $\|\cdot\|_X$, and $\|\cdot\|_Y$, respectively. Dual spaces will be denoted by $(\cdot)^*$. The duality pairing between X and X^* is denoted by $\langle\cdot,\cdot\rangle_X$; one similarly defines $\langle\cdot,\cdot\rangle_Y$ and $\langle\cdot,\cdot\rangle_G$. The subscripts are often omitted when there is no chance for confusion. Let Θ, the control set, be a closed convex subset of G. Let Z be a subspace of Y with a compact imbedding. Note that the compactness of the imbedding $Z \subset Y$ will play an important role.

We assume that the functional to be minimized takes the form

$$\mathcal{J}(v,z) = \lambda\,\mathcal{F}(v) + \lambda\,\mathcal{E}(z) \quad \forall\,(v,z) \in X \times \Theta\,, \tag{2.1}$$

where $\mathcal{F}$ is a functional on X, $\mathcal{E}$ is a functional on Θ, and λ is a given parameter that is assumed to belong to a compact interval $\Lambda \subset \mathbb{R}_+$.

The constraint equation $M(v,z) = 0$ relating the state variable v and the control variable z is defined as follows. Let N be a differentiable mapping from X to Y, K a continuous linear operator from Θ to Y, and T a continuous linear operator from Y to X. For any $\lambda \in \Lambda$, we

define the mapping M from $X \times \Theta$ to X by

$$M(v, z) = v + \lambda TN(v) + \lambda TK(z) \quad \forall\, (v, z) \in X \times \Theta\,. \tag{2.2}$$

With these definitions we now consider the constrained minimization problem:

$$\min_{(v,z)\in X\times\Theta} \mathcal{J}(v, z) \quad \text{subject to} \quad M(v, z) = 0\,. \tag{2.3}$$

In (2.3), we seek a global minimizer with respect to the set $\{(v, z) \in X \times \Theta : M(v, z) = 0\}$. Although, under suitable hypotheses, we will show that the problem (2.3) has a solution, in practice, one can only characterize local minima, i.e., points $(u, g) \in X \times \Theta$ such that for some $\epsilon > 0$

$$\begin{aligned} &\mathcal{J}(u, g) \le \mathcal{J}(v, z) \qquad \forall\, (v, z) \in X \times \Theta \text{ such that} \\ &\qquad\qquad M(v, z) = 0 \text{ and } \|u - v\|_X \le \epsilon\,. \end{aligned} \tag{2.4}$$

Thus, when we consider algorithms for locating constrained minima of $\mathcal{J}$, we must be content to find local minima in the sense of (2.4).

After showing that optimal solutions exist and that one is justified in using the Lagrange multiplier rule, we will introduce some simplifications in order to render the abstract problem (2.3), or (2.4), more amenable to approximation. The first is only to consider the control set $\Theta = G$. The second is only to consider Fréchet differentiable functionals $\mathcal{E}(\cdot)$ such that the Fréchet derivative $\mathcal{E}'(g) = E^{-1}g$, where E is an invertible linear operator from G^* to G.

2.2. Hypotheses concerning the abstract problem. The first set of hypotheses will be invoked to prove the existence of optimal solutions. It is given by:

(H1) $\inf_{v\in X} \mathcal{F}(v) > -\infty$;

(H2) there exist constants $\alpha, \beta > 0$ such that $\mathcal{E}(z) \ge \alpha\|z\|^\beta \ \ \forall\, z \in \Theta$;

(H3) there exists a $(v, z) \in X \times \Theta$ satisfying $M(v, z) = 0$;

(H4) if $u^{(n)} \rightharpoonup u$ in X and $g^{(n)} \rightharpoonup g$ in G where $\{(u^{(n)}, g^{(n)})\} \subset X \times \Theta$, then $N(u^{(n)}) \rightharpoonup N(u)$ in Y and $K(g^{(n)}) \rightharpoonup K(g)$ in Y;

(H5) $\mathcal{J}(\cdot, \cdot)$ is weakly lower semicontinuous on $X \times \Theta$;

(H6) if $\{(u^{(n)}, g^{(n)})\} \subset X \times \Theta$ is such that $\{\mathcal{F}(u^{(n)})\}$ is a bounded set in $\mathbb{R}$ and $M(u^{(n)}, g^{(n)}) = 0$, then $\{u^{(n)}\}$ is a bounded set in X.

The second set of assumptions will be used to justify the use of the Lagrange multiplier rule and to derive an optimality system from which optimal states and controls can be determined. The second set is given by

(H7) for each $z \in \Theta$, $v \mapsto \mathcal{J}(v, z)$ and $v \mapsto M(v, z)$ are Fréchet differentiable;

(H8) $z \mapsto \mathcal{E}(z)$ is convex, i.e.,

$$\mathcal{E}\big(\gamma z_1 + (1 - \gamma)z_2\big) \le \gamma\, \mathcal{E}(z_1) + (1 - \gamma)\, \mathcal{E}(z_2) \quad \forall\, z_1, z_2 \in \Theta\,,\ \forall\, \gamma \in [0, 1]\,;$$

(H9) for $v \in X$, $N'(v)$ maps X into Z.

In (H9), N' denotes the Fréchet derivative of N.

A simplified optimality system may be obtained if one invokes the additional assumption:

(H10) $\Theta = G$, and the mapping $z \mapsto \mathcal{E}(z)$ is Fréchet differentiable on G.

Hypotheses (H7)-(H10) allow us to obtain a simplified optimality system for almost all values of the parameter $\lambda \in \Lambda$. In many cases, it is possible to show that the same optimality system holds for all values of λ. The following two additional assumptions, which will only be invoked in case $(1/\lambda)$ is an eigenvalue of $-TN'(u)$, each provides a setting in which this last result is valid:

(H11) if $v^* \in X^*$ satisfies $\big(I + \lambda\,[N'(u)]^*T^*\big)v^* = 0$ and $K^*T^*v^* = 0$, then $v^* = 0$;

(H11)′ the mapping $(v, z) \mapsto v + \lambda\,TN'(u)v + \lambda\,TKz$ is onto from $X \times G$ to Y.

In order to make the optimality system more amenable to approximation and computation, we will invoke the following additional assumption:

(H12) $\mathcal{E}'(g) = E^{-1}g$, where E is an invertible linear operator from G^* to G and g is an optimal control for the constrained minimization problem (2.4).

2.3. Existence of an optimal solution. We first use assumptions (H1)-(H6) to establish that optimal solutions exist.

THEOREM 2.1. *Assume that the functional $\mathcal{J}$ and mapping M defined by* (2.1) *and* (2.2), *respectively, satisfy the hypotheses* (H1)-(H6). *Then, there exists a solution to the minimization problem* (2.3).

Proof. Assumption (H3) simply asserts that there is at least one element of $X \times \Theta$ that satisfies the constraint. Thus, we may choose a minimizing sequence $\{(u^{(n)}, g^{(n)})\} \subset X \times \Theta$ such that

$$\lim_{n\to\infty} \mathcal{J}(u^{(n)}, g^{(n)}) = \inf_{(v,z)\in X\times\Theta} \mathcal{J}(v, z)$$

and

$$M(u^{(n)}, g^{(n)}) = 0\,.$$

By (H1) and (H2), the boundedness of $\{\mathcal{J}(u^{(n)}, g^{(n)})\}$ implies the boundedness of the sequences $\{\|g^{(n)}\|_G\}$ and $\{\mathcal{F}(u^{(n)})\}$. Then, by (H6), we deduce that $\{\|u^{(n)}\|_X\}$ is bounded. Thus, we may extract a subsequence $\{(u^{(n)}, g^{(n)})\}$ such that $u^{(n)} \rightharpoonup u$ in X and $g^{(n)} \rightharpoonup g$ in G. Since Θ is closed and convex, we have $g \in \Theta$. Of course, $u \in X$. We next show that (u, g) satisfies the constraint equation. Using (H4), we have that

$$\lim_{n\to\infty} \langle TN(u^{(n)}), f\rangle = \lim_{n\to\infty} \langle N(u^{(n)}), T^*f\rangle = \langle N(u), T^*f\rangle = \langle TN(u), f\rangle \quad \forall\, f \in X^*$$

and

$$\lim_{n\to\infty} \langle TK(g^{(n)}), f\rangle = \lim_{n\to\infty} \langle K(g^{(n)}), T^*f\rangle = \langle K(g), T^*f\rangle = \langle TK(g), f\rangle \quad \forall\, f \in X^*$$

so that

$$0 = \lim_{n\to\infty} \langle M(u^{(n)}, g^{(n)}), f\rangle = \langle u + \lambda\,TN(u) + \lambda\,TK(g), f\rangle \quad \forall\, f \in X^*\,,$$

i.e., $M(u, g) = 0$. Finally, we use (H5), the weak lower semicontinuity of $\mathcal{J}(\cdot, \cdot)$, to conclude that (u, g) is indeed a minimizer in $X \times \Theta$ satisfying the constraint $M(u, g) = 0$. □

Remark. The hypotheses (H1)-(H6) are not sufficient to guarantee that optimal solutions are unique. Indeed, in many applications to nonlinear problems, including the ones we consider in §4, optimal solutions in the sense of (2.4) are in general not uniquely determined. □

2.4. Existence of Lagrange multipliers. We now wish to use the additional assumptions (H7)-(H9) to show that the Lagrange multiplier rule may be used to turn the constrained minimization problem (2.3) into an unconstrained one. Actually, the Lagrange multiplier rule will only enable us to find local minima in the sense of (2.4). We first quote the following abstract Lagrange multiplier rule whose proof can be found in [21].

THEOREM 2.2. *Let X_1 and X_2 be two Banach spaces and Θ an arbitrary set. Suppose $\mathcal{J}$ is a functional on $X_1 \times \Theta$ and M a mapping from $X_1 \times \Theta$ to X_2. Assume that $(u, g) \in X_1 \times \Theta$ is a solution to the following constrained minimization problem:*

$$\begin{aligned} &M(u, g) = 0 \text{ and there exists an } \epsilon > 0 \text{ such that } \mathcal{J}(u, g) \leq \mathcal{J}(v, z) \\ &\text{for all } (v, z) \in X_1 \times \Theta \text{ such that } \|u - v\|_{X_1} \leq \epsilon \text{ and } M(v, z) = 0. \end{aligned} \tag{2.5}$$

Let U be an open neighborhood of u in X_1. Assume further that the following conditions are satisfied:

(2.6) *for each $z \in \Theta$, $v \mapsto \mathcal{J}(v, z)$ and $v \mapsto M(v, z)$ are Fréchet-differentiable at $v = u$;*

(2.7) *for any $v \in U$, $z_1, z_2 \in \Theta$, and $\gamma \in [0, 1]$, there exists a $z_\gamma = z_\gamma(v, z_1, z_2)$ such that*

$$M(v, z_\gamma) = \gamma M(v, z_1) + (1 - \gamma) M(v, z_2)$$

and

$$\mathcal{J}(v, z_\gamma) \leq \gamma \mathcal{J}(v, z_1) + (1 - \gamma) \mathcal{J}(v, z_2);$$

(2.8) $\operatorname{Range}\big(M_u(u, g)\big)$ *is closed with a finite codimension,*

where $M_u(u, g)$ denotes the Fréchet derivative of M with respect to u. Then, there exists a $k \in \mathbb{R}$ and a $\mu \in X_2^*$ that are not both equal to zero such that

$$k \langle \mathcal{J}_u(u, g), v \rangle - \langle \mu, M_u(u, g) v \rangle = 0 \quad \forall\, v \in X_1$$

and

$$\min_{z \in \Theta} \mathcal{L}(u, z, \mu, k) = \mathcal{L}(u, g, \mu, k),$$

where $\mathcal{L}(u, g, \mu, k) = k\, \mathcal{J}(u, g) - \langle \mu, M(u, g) \rangle$ is the Lagrangian for the constrained minimization problem (2.5) *and where $\mathcal{J}_u(u, g)$ denotes the Fréchet derivative of $\mathcal{J}$ with respect to u. Moreover, if*

(2.9) *the algebraic sum $M_u(u, g) X_1 + M(u, \Theta)$ contains $0 \in X_2$ as an interior point, then we may choose $k = 1$, i.e., there exists a $\mu \in X_2^*$ such that*

$$\langle \mathcal{J}_u(u, g), v \rangle - \langle \mu, M_u(u, g) v \rangle = 0 \quad \forall\, v \in X_1$$

and

$$\min_{z \in \Theta} \mathcal{L}(u, z, \mu, 1) = \mathcal{L}(u, g, \mu, 1).$$

Proof. See [21]. □

Next, we apply Theorem 2.2 to the optimization problem (2.4). In doing so, we will need the following result.

LEMMA 2.3. *Let the spaces X, Y, and Z and operators T and N be defined as in* §2.1. *For $v \in X$, assume that $N'(v)$ maps X into Z. Then, $TN'(v)$ is a compact operator from X to X; therefore, $\sigma\big(-TN'(v)\big)$, the spectrum of the operator $\big(-TN'(v)\big)$, is at most countable with zero being the only possible limit point.*

Proof. Since $Z \hookrightarrow\hookrightarrow Y$, we see that $N'(v)$ is a compact linear operator from X to Y. Also, T is a bounded linear operator from Y to X, so $TN'(v)$ is a compact operator from X to X. Hence, $\sigma\big(-TN'(v)\big)$ is at most countable and consists only of 0 and the eigenvalues of $\big(-TN'(v)\big)$. □

Note that in the following result, the existence of at least one pair (u, g) satisfying (2.4) is guaranteed by Theorem 2.1.

THEOREM 2.4. *Let $\lambda \in \Lambda$ be given. Assume that assumptions* (H1)-(H9) *hold. Let $(u, g) \in X \times \Theta$ be an optimal solution satisfying* (2.4). *Then, there exists a $k \in \mathbb{R}$ and a $\mu \in X^*$ that are not both equal to zero such that*

$$k\,\langle \mathcal{J}_u(u, g), w\rangle - \langle \mu, M_u(u, g)\cdot w\rangle = 0 \quad \forall\, w \in X \tag{2.10}$$

and

$$\min_{z\in\Theta} \mathcal{L}(u, z, \mu, k) = \mathcal{L}(u, g, \mu, k)\,. \tag{2.11}$$

Furthermore, if $(1/\lambda) \notin \sigma\big(-TN'(u)\big)$, we may choose $k = 1$; i.e., for almost all λ, there exists a $\mu \in X^*$ such that

$$\langle \mathcal{J}_u(u, g), w\rangle - \langle \mu, M_u(\lambda, u, g)\cdot w\rangle = 0 \quad \forall\, w \in X \tag{2.12}$$

and

$$\min_{z\in\Theta} \mathcal{L}(u, z, \mu, 1) = \mathcal{L}(u, g, \mu, 1)\,. \tag{2.13}$$

Proof. Let $\lambda \in \Lambda$ be given. To show the existence of k and μ such that (2.10) and (2.11) are valid, we only need to verify that the hypotheses (2.6)-(2.8) of Theorem 2.2 hold with $X_1 = X_2 = X$, since in this case (2.5) reduces to (2.4). Obviously, (2.6) is merely a restatement of (H7). Since Θ is convex and since the mappings T and K are linear, we have that if $z_\gamma = \gamma z_1 + (1-\gamma)z_2$, then

$$\begin{aligned} M(v, z_\gamma) &= v + \lambda TN(v) + \lambda TKz_\gamma \\ &= \gamma\big(v + \lambda TN(v)\big) + (1-\gamma)\big(v + \lambda TN(v)\big) + \gamma\lambda\big(TKz_1 + (1-\gamma)TKz_2\big) \\ &= \gamma M(v, z_1) + (1-\gamma)M(v, z_2)\,. \end{aligned}$$

Moreover, (H8) implies that

$$\begin{aligned} \mathcal{J}(v, z_\gamma) &= \lambda\mathcal{F}(v) + \lambda\mathcal{E}(z_\gamma) = \lambda\mathcal{F}(v) + \lambda\mathcal{E}\big(\gamma z_1 + (1-\gamma)z_2\big) \\ &\le \lambda\mathcal{F}(v) + \lambda\big(\gamma\mathcal{E}(z_1) + (1-\gamma)\mathcal{E}(z_2)\big) = \gamma\,\mathcal{J}(v, z_1) + (1-\gamma)\,\mathcal{J}(v, z_2)\,. \end{aligned}$$

Thus, (2.7) holds. The operator $M_u(u, g)$ from X to X is defined by

$$M_u(u, g)\cdot w = w + \lambda TN'(u)\cdot w \quad \forall\, w \in X$$

or, simply,

$$M_u(u, g) = I + \lambda TN'(u)\,.$$

From (H9) and Lemma 2.3, we have that $TN'(u)$ is a compact operator from X to X. As a result, $M_u(u, g) = I + \lambda TN'(u)$ is a Fredholm operator, so it has a closed range with a finite codimension, i.e., (2.8) holds. Thus, by Theorem 2.2, there exists a $k \in \mathbb{R}$ and a $\mu \in X^*$ that are not both equal to zero such that (2.10) and (2.11) hold.

To show the existence of a μ such that (2.12) and (2.13) are valid, we only need to verify that the additional hypothesis (2.9) of Theorem 2.2 holds. In fact, if in addition $(1/\lambda) \notin \sigma\big(-TN'(u)\big)$, then it follows that $X = \text{Range}\big(I + \lambda TN'(u)\big) = \text{Range}\big(M_u(u, g)\big)$, so $\text{Range}\big(M_u(u, g)\big)$ contains $0 \in X$ as an interior point, i.e., (2.9) holds. Hence, by Theorem 2.2 and Lemma 2.3, we conclude that for almost all λ there exists a $\mu \in X^*$ such that (2.12) and (2.13) hold. □

So far Θ has only been assumed to be a closed and convex subset of G. No smoothness condition on the control variable g has been assumed in the functional or in the constraint. Thus, the necessary condition of optimality with respect to variations in the control variable is expressed in the cumbersome relation (2.11). We now turn to the case where Θ contains a neighborhood of g, where (u, g) is an optimal solution. In particular, we assume that $\Theta = G$. In this case, (2.11) can be given a more concrete structure.

THEOREM 2.5. *Let $\lambda \in \Lambda$ be given. Assume that assumptions* (H1)-(H10) *hold. Let $(u, g) \in X \times G$ be a solution of the problem* (2.4). *Then there exist a $k \in \mathbb{R}$ and a $\mu \in X^*$ that are not both equal to zero such that*

$$k\,\langle \mathcal{J}_u(u, g), w\rangle - \langle \mu, \big(I + \lambda TN'(u)\big)w\rangle = 0 \quad \forall\, w \in X \tag{2.14}$$

and

$$k\langle \mathcal{E}'(g), z\rangle - \langle \mu, TKz\rangle = 0 \quad \forall\, z \in G\,. \tag{2.15}$$

Furthermore, if $(1/\lambda) \notin \sigma\big(-TN'(u)\big)$, we may choose $k = 1$; i.e., there exists a $\mu \in X^*$ such that

$$\langle \mathcal{J}_u(u, g), w\rangle - \langle \mu, \big(I + \lambda TN'(u)\big)w\rangle = 0 \quad \forall\, w \in X \tag{2.16}$$

and

$$\langle \mathcal{E}'(g), z\rangle - \langle \mu, TKz\rangle = 0 \quad \forall\, z \in G \tag{2.17}$$

hold.

Proof. Since the hypotheses imply that $\mathcal{J}(v, z)$ is Fréchet differentiable with respect to z, (2.14)-(2.17) follow easily from Theorem 2.4. □

Remark. If $k = 0$, then there exists a $\mu \neq 0$ such that

$$-\langle \mu, M_u(u, g)w\rangle = 0 \quad \forall\, w \in X\,,$$

so the optimality system necessarily has infinitely many solutions. In fact, for any $C \in \mathbb{R}$, $(C\mu)$ is a solution whenever μ is a solution. This creates both theoretical and numerical difficulties. Thus, it is of great interest to try to eliminate this situation. Fortunately, Lemma 2.3 and Theorem 2.4 tell us that we may set $k = 1 \neq 0$ for almost all values of $(1/\lambda)$, i.e., except for the at most countable set of values in $\sigma\big(-TN'(u)\big)$. □

If the control g enters the constraint in a favorable manner, then we may take $k = 1$ even when $(1/\lambda) \in \sigma\big(-TN'(u)\big)$. Specifically, we invoke one of the assumptions (H11) and (H11)′. We then have the following result.

THEOREM 2.6. *Assume that the hypotheses of Theorem* 2.5 *hold. Assume that if $(1/\lambda) \in \sigma\big(-TN'(u)\big)$, then either* (H11) *or* (H11)′ *holds. Then, for all $\lambda \in \Lambda$, there exists a $\mu \in X^*$ such that* (2.16) *and* (2.17) *hold.*

Proof. Because of Theorem 2.5, we need only to examine the case $(1/\lambda) \in \sigma\big(-TN'(u)\big)$ and to show the algebraic sum $M_u(u, g)X + M(u, G) = X$. If (H11)′ holds, the result is a direct application of Theorem 2.2.

If (H11) holds, let $(1/\lambda)$ be a nonzero eigenvalue of $\big(-TN'(u)\big)$. Then, λ is also an eigenvalue of $\big(-N'(u)^*T^*\big)$ with a finite-dimensional eigenspace having the corresponding eigenfunctions $\{v_i^*\}_{i=1}^m \subset X^*$ as a basis. We claim that $\{K^*T^*v_i^*\}_{i=1}^m \subset G^*$ is a linearly independent set. To see this, we assume $\sum_{i=1}^m \alpha_i\, K^*T^*v_i^* = 0$ with $\alpha_i \in \mathbb{R}$; this expression can be rewritten as $K^*T^*\big(\sum_{i=1}^m \alpha_i\, v_i^*\big) = 0$. Because each v_i^* is an eigenvector, we have $\big(I + \lambda\, N'(u)^*T^*\big)\sum_{i=1}^m \alpha_i\, v_i^* = 0$. Thus, the assumption (H11) implies that $\sum_{i=1}^m \alpha_i\, v_i^* = 0$. Since $\{v_i^*\}_{i=1}^m$ is an eigenbasis and, therefore, a linearly independent set, we have each $\alpha_i = 0$. This shows that $\{K^*T^*v_i^*\}_{i=1}^m$ is a linearly independent set in G^*. Hence, we may choose an orthonormal dual basis $\{z_i\}_{i=1}^m \subset G$ such that $\langle z_i, K^*T^*v_j^*\rangle = \delta_{ij}$.

Now, let $w \in X$ be given. We choose $z = \frac{1}{\lambda}\sum_{i=1}^m \langle w, v_i^*\rangle z_i$. Then $\langle w, v_j^*\rangle - \lambda\langle TKz, v_j^*\rangle = \langle w, v_j^*\rangle - \lambda\langle z, K^*T^*v_j^*\rangle = \langle w, v_j^*\rangle - \sum_{i=1}^m \langle w, v_i^*\rangle\delta_{ij} = 0$ for $j = 1, \ldots, m$. Thus, by Fredholm alternatives, there exists a unique $v \in X$ that satisfies $\big(I + \lambda\, TN'(u)\big)v = w - \lambda\, TKz$ or $\big(I + \lambda\, TN'(u)\big)v + \lambda\, TKz = w$; thus, we have shown that $M_u(u, g)X + M(u, G) = X$. Hence, by Theorem 2.2, there exists a $\mu \in X^*$ such that (2.16) and (2.17) hold. □

2.5. The optimality system. Under the assumptions of Theorem 2.6, an optimal state $u \in X$, an optimal control $g \in G$, and the corresponding Lagrange multiplier $\mu \in X^*$ satisfy the optimality system of equations formed by (2.2), (2.16), and (2.17). From (2.1) we have that $\mathcal{J}_u = \lambda\mathcal{F}'$ and $\mathcal{J}_g = \lambda\mathcal{E}'$, where $\mathcal{F}'$ denotes the obvious Fréchet derivative. Then, (2.16)-(2.17) may be rewritten in the form

$$\mu + \lambda\,[N'(u)]^*T^*\mu - \lambda\,\mathcal{F}'(u) = 0 \quad \text{in } X^* \tag{2.18}$$

and

$$\mathcal{E}'(g) - K^*T^*\mu = 0 \quad \text{in } G^*. \tag{2.19}$$

For purposes of numerical approximations, it turns out to be convenient to make the change of variable $\xi = T^*\mu$. Then, the optimality system (2.2), (2.18), and (2.19) for $u \in X$, $g \in G$, and $\xi \in Y^*$ takes the form

$$u + \lambda\, TN(u) + \lambda\, TKg = 0 \quad \text{in } X, \tag{2.20}$$

$$\xi + \lambda\, T^*[N'(u)]^*\xi - \lambda\, T^*\mathcal{F}'(u) = 0 \quad \text{in } Y^*, \tag{2.21}$$

and

$$\mathcal{E}'(g) - K^*\xi = 0 \quad \text{in } G^*. \tag{2.22}$$

It will also be convenient to invoke an additional simplifying assumption concerning the dependence of the objective functional on the control. Specifically, we assume that (H12) holds. Then, (2.20)-(2.22) can be rewritten as

$$u + \lambda\, TN(u) + \lambda\, TKg = 0 \quad \text{in } X, \tag{2.23}$$

$$\xi + \lambda\, T^*[N'(u)]^*\xi - \lambda\, T^*\mathcal{F}'(u) = 0 \quad \text{in } Y^*, \tag{2.24}$$

and

$$g - EK^*\xi = 0 \quad \text{in } G. \tag{2.25}$$

Remark. Note that the optimality systems, e.g., (2.23)-(2.25), are linear in the adjoint variable ξ. Also, note that the control g may be eliminated from the optimality system (2.23)-(2.25). Indeed, the substitution of (2.25) into (2.23) yields

$$u + \lambda TN(u) + \lambda TKEK^*\xi = 0 \quad \text{in } X. \tag{2.26}$$

Thus, (2.24) and (2.26) determine the optimal state u and adjoint state ξ; subsequently, (2.25) may be used to determine the optimal control g from ξ. This observation serves to emphasize the important, direct role that the adjoint state plays in the determination of the optimal control. □

Remark. Given a $\xi \in Y^*$, it is not always possible to evaluate g exactly from (2.25). For example, the application of the operator E may involve the solution of a partial differential equation. Thus, although it is often convenient to devise algorithms for the approximation of optimal control and states based on the simplified optimality system (2.24) and (2.26), in some other cases it is best to deal with the full form (2.23)-(2.25). Thus, when we consider approximations of optimal controls and states, we will deal with the latter. □

Remark. In many applications we have that $X^* = Y$. Since these spaces are assumed to be reflexive, we also have that $Y^* = X$. In this case, we have that both u and ξ belong to X. □

3. Finite-dimensional approximations of the abstract problem. In this section we define and analyze algorithms for the finite-dimensional approximation of solutions of the optimality system (2.23)-(2.25); an outline of the definitions and results of this section is as follows.

- In §3.1, we define the finite-dimensional approximate problems that we consider.
- In §3.2, a list of assumptions about the approximate problems is given.
- In §3.3, we quote a result of [6] that we will use to analyze approximations obtained as solutions of the approximate problems defined in §§3.1 and 3.2.
- In §3.4, we provide error estimates for the approximation of solutions of the optimality system (2.23)-(2.25).

3.1. Formulation of finite-dimensional approximate problems. A finite-dimensional discretization of the optimality system (2.23)-(2.25) is defined as follows. First, one chooses families of finite-dimensional subspaces $X^h \subset X$, $(Y^*)^h \subset Y^*$, and $G^h \subset G$. These families are parameterized by a parameter h that tends to zero. (For example, this parameter can be chosen to be some measure of the grid size in a subdivision of Ω into finite elements.) Next, we define approximate operators $T^h : Y \to X^h$, $E^h : G^* \to G^h$, and $(T^*)^h : X^* \to (Y^*)^h$. Of course, one views T^h, E^h, and $(T^*)^h$ as approximations to the operators T, E, and T^*, respectively. Note that $(T^*)^h$ is not necessarily the same as $(T^h)^*$. The former is a discretization of an adjoint operator, while the latter is the adjoint of a discrete operator.

Once the approximating subspaces and operators have been chosen, an approximate problem is defined as follows. We seek $u^h \in X^h$, $g^h \in G^h$, and $\xi^h \in (Y^*)^h$ such that

$$u^h + \lambda T^h N(u^h) + \lambda T^h K g^h = 0 \quad \text{in } X^h, \tag{3.1}$$

$$\xi^h + \lambda (T^*)^h [N'(u^h)]^* \xi^h - \lambda (T^*)^h \mathcal{F}'(u^h) = 0 \quad \text{in } (Y^*)^h, \tag{3.2}$$

and

$$g^h - E^h K^* \xi^h = 0 \quad \text{in } G^h. \tag{3.3}$$

3.2. Hypotheses concerning the abstract problem and the approximate problem. We make the following hypotheses concerning the approximate operators T^h, $(T^*)^h$, and E^h:

(H13) $$\lim_{h\to 0} \|(T - T^h)y\|_X = 0 \quad \forall\, y \in Y\,,$$

(H14) $$\lim_{h\to 0} \|(T^* - (T^*)^h)v\|_{Y^*} = 0 \quad \forall\, v \in X^*\,,$$

(H15) $$\lim_{h\to 0} \|(E - E^h)s\|_G = 0 \quad \forall\, s \in G^*\,.$$

We also need the following additional hypotheses on the operators appearing in the definition of the abstract problem (2.4):

(H16) $N \in C^3(X; Y)$ and $\mathcal{F} \in C^3(X; \mathbb{R})$;

(H17) N'', N''', $\mathcal{F}''$, and $\mathcal{F}'''$ are locally bounded, i.e., they map bounded sets to bounded sets;

(H18) for $v \in X$, in addition to (H9), i.e., $N'(v) \in \mathcal{L}(X; Z)$ where $Z \hookrightarrow\hookrightarrow Y$, we have that $[N'(v)]^* \in \mathcal{L}(Y^*; \hat{Z})$ where $\hat{Z} \hookrightarrow\hookrightarrow X^*$, that for $\eta \in Y^*$, $[N''(v)]^* \cdot \eta \in \mathcal{L}(Y^*; \hat{Z})$, and that for $w \in X$, $\mathcal{F}''(v) \cdot w \in \mathcal{L}(X; \hat{Z})$;

(H19) K maps G into Z.

Here, $(\cdot)''$ and $(\cdot)'''$ denote second and third Fréchet derivatives, respectively.

3.3. Quotation of results concerning the approximation of a class of nonlinear problems. The error estimate to be derived in §3.4 makes use of results of [6] and [10] (see also [13]) concerning the approximation of a class of nonlinear problems. These results imply that, under certain hypotheses, the error of approximation of solutions of certain nonlinear problems is basically the same as the error of approximation of solutions of related linear problems. Here, for the sake of completeness, we will state the relevant results, specialized to our needs.

The nonlinear problems considered in [6], [10], and [13] are of the following type. For given $\lambda \in \Lambda$, we seek $\psi \in \mathcal{X}$ such that

(3.4) $$\mathcal{H}(\lambda, \psi) \equiv \psi + \mathcal{T}\mathcal{G}(\lambda, \psi) = 0\,,$$

where $\mathcal{T} \in \mathcal{L}(\mathcal{Y}; \mathcal{X})$, $\mathcal{G}$ is a C^2 mapping from $\Lambda \times \mathcal{X}$ into $\mathcal{Y}$, $\mathcal{X}$ and $\mathcal{Y}$ are Banach spaces, and Λ is a compact interval of $\mathbb{R}$. We say that $\{(\lambda, \psi(\lambda)) : \lambda \in \Lambda\}$ is a *branch of solutions* of (3.4) if $\lambda \to \psi(\lambda)$ is a continuous function from Λ into $\mathcal{X}$ such that $\mathcal{H}(\lambda, \psi(\lambda)) = 0$. The branch is called a *regular branch* if we also have that $\mathcal{H}_\psi(\lambda, \psi(\lambda))$ is an isomorphism from $\mathcal{X}$ into $\mathcal{X}$ for all $\lambda \in \Lambda$. Here, $\mathcal{H}_\psi(\cdot, \cdot)$ denotes the Fréchet derivative of $\mathcal{H}(\cdot, \cdot)$ with respect to the second argument. We assume that there exists another Banach space $\mathcal{Z}$, contained in $\mathcal{Y}$, with continuous imbedding, such that

(3.5) $$\mathcal{G}_\psi(\lambda, \psi) \in \mathcal{L}(\mathcal{X}; \mathcal{Z}) \quad \forall\, \lambda \in \Lambda \text{ and } \psi \in \mathcal{X}\,,$$

where $\mathcal{G}_\psi(\cdot, \cdot)$ denotes the Fréchet derivative of $\mathcal{G}(\cdot, \cdot)$ with respect to the second argument.

Approximations are defined by introducing a subspace $\mathcal{X}^h \subset \mathcal{X}$ and an approximating operator $\mathcal{T}^h \in \mathcal{L}(\mathcal{Y}; \mathcal{X}^h)$. Then, given $\lambda \in \Lambda$, we seek $\psi^h \in \mathcal{X}^h$ such that

(3.6) $$\mathcal{H}^h(\lambda, \psi^h) \equiv \psi^h + \mathcal{T}^h\mathcal{G}(\lambda, \psi^h) = 0\,.$$

Concerning the operator $\mathcal{T}^h$, we assume the approximation properties

$$\lim_{h\to 0} \|(\mathcal{T}^h - \mathcal{T})\omega\|_{\mathcal{X}} = 0 \quad \forall\, \omega \in \mathcal{Y} \tag{3.7}$$

and

$$\lim_{h\to 0} \|(\mathcal{T}^h - \mathcal{T})\|_{\mathcal{L}(\mathcal{Z};\mathcal{X})} = 0\,. \tag{3.8}$$

Note that whenever the imbedding $\mathcal{Z} \subset \mathcal{Y}$ is compact, (3.8) follows from (3.7) and, moreover, (3.5) implies that the operator $\mathcal{T}\mathcal{G}_\psi(\lambda, \psi) \in \mathcal{L}(\mathcal{X}; \mathcal{X})$ is compact.

We can now state the result of [6] or [10] that will be used in the sequel. In the statement of the theorem, $D^2\mathcal{G}$ represents any and all second Fréchet derivatives of $\mathcal{G}$.

THEOREM 3.1. *Let $\mathcal{X}$ and $\mathcal{Y}$ be Banach spaces and Λ a compact subset of $\mathbb{R}$. Assume that $\mathcal{G}$ is a C^2 mapping from $\Lambda \times \mathcal{X}$ into $\mathcal{Y}$ and that $D^2\mathcal{G}$ is bounded on all bounded sets of $\Lambda \times \mathcal{X}$. Assume that* (3.5), (3.7), *and* (3.8) *hold and that $\{(\lambda, \psi(\lambda));\ \lambda \in \Lambda\}$ is a branch of regular solutions of* (3.4). *Then, there exist a neighborhood $\mathcal{O}$ of the origin in $\mathcal{X}$ and, for $h \le h_0$ small enough, a unique C^2 function $\lambda \to \psi^h(\lambda) \in \mathcal{X}^h$ such that $\{(\lambda, \psi^h(\lambda));\ \lambda \in \Lambda\}$ is a branch of regular solutions of* (3.6) *and $\psi^h(\lambda) - \psi(\lambda) \in \mathcal{O}$ for all $\lambda \in \Lambda$. Moreover, there exists a constant $C > 0$, independent of h and λ, such that*

$$\|\psi^h(\lambda) - \psi(\lambda)\|_{\mathcal{X}} \le C\|(\mathcal{T}^h - \mathcal{T})\mathcal{G}(\lambda, \psi(\lambda))\|_{\mathcal{X}} \quad \forall\, \lambda \in \Lambda\,. \tag{3.9}$$ □

3.4. Error estimates for the approximation of solutions of the optimality system. We now apply the result of Theorem 3.1 to study the approximation of solutions of the optimality system. Set $\mathcal{X} = X \times G \times Y^*$, $\mathcal{Y} = Y \times X^*$, $\mathcal{Z} = Z \times \hat{Z}$, and $\mathcal{X}^h = X^h \times G^h \times (Y^*)^h$. (Recall that $\hat{Z}$ was introduced in (H18).) By the hypotheses on Z and $\hat{Z}$, we have that $\mathcal{Z}$ is compactly imbedded into $\mathcal{Y}$. Let $\mathcal{T} \in \mathcal{L}(\mathcal{Y}; \mathcal{X})$ be defined in the following manner: $\mathcal{T}(\tilde{r}, \tilde{\tau}) = (\tilde{u}, \tilde{g}, \tilde{\xi})$ for $(\tilde{r}, \tilde{\tau}) \in \mathcal{Y}$ and $(\tilde{u}, \tilde{g}, \tilde{\xi}) \in \mathcal{X}$ if and only if

$$\tilde{u} + T\tilde{r} = 0\,, \tag{3.10}$$

$$\tilde{\xi} + T^*\tilde{\tau} = 0\,, \tag{3.11}$$

and

$$\tilde{g} - EK^*\tilde{\xi} = 0\,. \tag{3.12}$$

Similarly, the operator $\mathcal{T}^h \in \mathcal{L}(\mathcal{Y}; \mathcal{X}^h)$ is defined as follows: $\mathcal{T}^h(\tilde{r}, \tilde{\tau}) = (\tilde{u}^h, \tilde{g}^h, \tilde{\xi}^h)$ for $(\tilde{r}, \tilde{\tau}) \in \mathcal{Y}$ and $(\tilde{u}^h, \tilde{g}^h, \tilde{\xi}^h) \in \mathcal{X}^h$ if and only if

$$\tilde{u}^h + T^h\tilde{r} = 0\,, \tag{3.13}$$

$$\tilde{\xi}^h + (T^*)^h\tilde{\tau} = 0\,, \tag{3.14}$$

and

$$\tilde{g}^h - E^hK^*\tilde{\xi}^h = 0\,. \tag{3.15}$$

The nonlinear mapping $\mathcal{G} : \Lambda \times \mathcal{X} \to \mathcal{Y}$ is defined as follows: $\mathcal{G}\big(\lambda, (\tilde{u}, \tilde{g}, \tilde{\xi})\big) = (\tilde{r}, \tilde{\tau})$ for $\lambda \in \Lambda$, $(\tilde{u}, \tilde{g}, \tilde{\xi}) \in \mathcal{X}$, and $(\tilde{r}, \tilde{\tau}) \in \mathcal{Y}$ if and only if

$$\tilde{r} = \lambda N(\tilde{u}) + \lambda K\tilde{g} \tag{3.16}$$

and

$$\tilde{\tau} = \lambda\,[N'(\tilde{u})]^*\tilde{\xi} - \lambda\,\mathcal{F}'(\tilde{u})\,. \tag{3.17}$$

It is evident that the optimality system (2.23)-(2.25) and its finite-dimensional counterpart (3.1)-(3.3) can be written as

$$(u, g, \xi) + \mathcal{T}\mathcal{G}\big(\lambda, (u, g, \xi)\big) = 0$$

and

$$(u^h, g^h, \xi^h) + \mathcal{T}^h\mathcal{G}\big(\lambda, (u^h, g^h, \xi^h)\big) = 0\,,$$

respectively, i.e., with $\psi = (u, g, \xi)$ and $\psi^h = (u^h, g^h, \psi^h)$, in the form of (3.4) and (3.6), respectively.

Now we examine the approximation properties of $\mathcal{T}^h$.

LEMMA 3.2. *Let the operators $\mathcal{T}$ and $\mathcal{T}^h$ be defined by* (3.10)-(3.12) *and* (3.13)-(3.15), *respectively. Assume that the hypotheses* (H13)-(H15) *hold. Then*

$$\lim_{h\to 0} \|(\mathcal{T} - \mathcal{T}^h)(r, \tau)\|_{\mathcal{X}} = 0 \quad \forall\,(r, \tau) \in \mathcal{Y}\,. \tag{3.18}$$

Proof. Let $(\tilde{u}, \tilde{g}, \tilde{\xi}) = \mathcal{T}(r, \tau)$; i.e., $(\tilde{u}, \tilde{g}, \tilde{\xi})$ satisfies (3.10)-(3.12). Let $(\tilde{u}^h, \tilde{g}^h, \tilde{\xi}^h) = \mathcal{T}^h(r, \tau)$; i.e., $(\tilde{u}^h, \tilde{g}^h, \tilde{\xi}^h)$ satisfies (3.13)-(3.15). Subtracting the corresponding equations yields that

$$\|\tilde{u} - \tilde{u}^h\|_X = \|(T - T^h)r\|_X\,,$$
$$\big\|\tilde{\xi} - \tilde{\xi}^h\big\|_{Y^*} = \|(T^* - (T^*)^h)\tau\|_{Y^*}\,,$$

and

$$\begin{aligned}\|\tilde{g} - \tilde{g}^h\|_G &= \big\|(E - E^h)K^*\tilde{\xi}^h + EK^*\big(\tilde{\xi} - \tilde{\xi}^h\big)\big\|_G \\ &\le \big\|(E - E^h)K^*\tilde{\xi}^h\big\|_G + \|EK^*\|_{\mathcal{L}(Y^*;G)}\,\big\|\big(\tilde{\xi} - \tilde{\xi}^h\big)\big\|_G\,.\end{aligned}$$

Thus, for some constant $C > 0$,

$$\begin{aligned}&\|(\mathcal{T} - \mathcal{T}^h)(r, \tau)\|_{\mathcal{X}} \\ &\quad\le C\left\{\|(T - T^h)r\|_X + \|(T^* - (T^*)^h)\tau\|_{Y^*} + \|(E - E^h)K^*\tilde{\xi}^h\|_G\right\}.\end{aligned}$$

Then the result of the proposition follows from (H13)-(H15). □

Next, we examine the derivative of the mapping $\mathcal{G}$.

LEMMA 3.3. *Let the mapping $\mathcal{G} : \Lambda \times \mathcal{X} \to \mathcal{Y}$ be defined by* (3.16)-(3.17). *Assume that the hypotheses* (H9), (H16), *and* (H18)-(H19) *hold. Then, for every $\lambda \in \Lambda$ and every $(u, g, \xi) \in \mathcal{X}$, the operator $\mathcal{G}_{(u,g,\xi)}\big(\lambda, (u, g, \xi)\big) \in \mathcal{L}(\mathcal{X}; \mathcal{Z})$.*

Proof. A simple calculation shows that $\mathcal{G}_{(u,g,\xi)}\big(\lambda, (u, g, \xi)\big) \in \mathcal{L}(\mathcal{X}; \mathcal{Y})$ is given by

$$\mathcal{G}_{(u,g,\xi)}\big(\lambda, (u, g, \xi)\big)\cdot\big(\tilde{u}, \tilde{g}, \tilde{\xi}\big) = \lambda\begin{pmatrix} N'(u)\cdot\tilde{u} + K\tilde{g} \\ [N''(u)\cdot\tilde{u}]^*\cdot\xi + [N'(u)]^*\cdot\tilde{\xi} - \mathcal{F}''(u)\cdot\tilde{u}\end{pmatrix}.$$

Then, the result follows from (H9) and (H18)-(H19). □

A solution $\big(u(\lambda), g(\lambda), \xi(\lambda)\big)$ of the optimality system (2.23)–(2.25) is called *regular* if the system (for the unknowns $(\tilde{u}, \tilde{g}, \tilde{\xi})$)

$$\tilde{u} + \lambda T N'(u)\tilde{u} + \lambda T K \tilde{g} = \tilde{x}\,, \tag{3.19}$$

$$\tilde{\xi} + \lambda T^*[N''(u)]^*\tilde{u}\cdot\xi + \lambda T^*[N'(u)]^*\tilde{\xi} - \lambda T^*\mathcal{F}''(u)\tilde{u} = \tilde{y}\,, \tag{3.20}$$

and

$$\tilde{g} - EK^*\tilde{\xi} = \tilde{z} \tag{3.21}$$

is uniquely solvable for any $(\tilde{x}, \tilde{z}, \tilde{y}) \in \mathcal{X} = X \times G \times Y^*$. (Note that the linear operator appearing on the left-hand side of (3.19)–(3.21) is obtained by linearizing the optimality system (2.23)–(2.25) about (u, g, ξ).)

In the following theorem, we will assume that the solution $\big(u(\lambda), g(\lambda), \xi(\lambda)\big)$ of the optimality system (2.23)–(2.25) that we are trying to approximate is a regular solution. The assumptions we have made, in particular (H9), (H18)–(H19), are sufficient to guarantee that for almost all values of λ, this is indeed the case.

LEMMA 3.4. *Assume the hypotheses of Lemma* 3.3. *Then, for almost all* λ, *solutions* $\big(u(\lambda), g(\lambda), \xi(\lambda)\big)$ *of the optimality system* (2.23)–(2.25) *are regular.*

Proof. The system (3.19)–(3.21) is equivalent to

$$\Big(I + \lambda \mathcal{T}\mathcal{S}(u, g, \xi)\Big)(\tilde{u}, \tilde{g}, \tilde{\xi}) = (\tilde{x}, \tilde{z}, \tilde{y})\,, \tag{3.22}$$

where the linear operator $\mathcal{S}(u, g, \xi) : \mathcal{X} \to \mathcal{Y}$ is defined by

$$\begin{aligned}\mathcal{S}(u, g, \xi)\cdot(\tilde{u}, \tilde{g}, \tilde{\xi}) &\equiv \frac{1}{\lambda}\mathcal{G}_{(u,g,\xi)}\big(\lambda, (u, g, \xi)\big)\cdot(\tilde{u}, \tilde{g}, \tilde{\xi}) \\ &= \begin{pmatrix} N'(u)\cdot\tilde{u} + K\tilde{g} \\ [N''(u)\cdot\tilde{u}]^*\cdot\xi + [N'(u)]^*\cdot\tilde{\xi} - \mathcal{F}''(u)\cdot\tilde{u} \end{pmatrix}.\end{aligned}$$

Now, $\mathcal{T} \in \mathcal{L}(\mathcal{Y}; \mathcal{X})$; hence, by Lemma 3.3, $\big(I + \lambda\mathcal{T}\mathcal{S}(u, g, \xi)\big)$ is a compact perturbation of the identity operator from $\mathcal{X}$ to $\mathcal{X}$. Thus, for almost all λ, (3.22), or equivalently (3.19)–(3.21), is uniquely solvable; i.e., for almost all λ, the solution $\big(u(\lambda), g(\lambda), \xi(\lambda)\big)$ of the optimality system (2.23)–(2.25) is regular. □

Using Theorem 3.1, we can now provide an error estimate for approximations of solutions of the abstract problem.

THEOREM 3.5. *Let* $\big(u(\lambda), g(\lambda), \xi(\lambda)\big) \in \mathcal{X}$, *for* $\lambda \in \Lambda$, *be a branch of regular solutions of the optimality system* (2.23)–(2.25). *Assume that the hypotheses* (H13)–(H19) *hold. Then, there exist a* $\delta > 0$ *and an* $h_0 > 0$ *such that for* $h < h_0$ *the discrete optimality system* (3.1)–(3.3) *has a unique solution* $\big(u^h(\lambda), g^h(\lambda), \xi^h(\lambda)\big)$ *satisfying*

$$\big\|\big(u(\lambda), g(\lambda), \xi(\lambda)\big) - \big(u^h(\lambda), g^h(\lambda), \xi^h(\lambda)\big)\big\|_{\mathcal{X}} < \delta\,.$$

Moreover,

$$\lim_{h\to 0}\big\|\big(u(\lambda), g(\lambda), \xi(\lambda)\big) - \big(u^h(\lambda), g^h(\lambda), \xi^h(\lambda)\big)\big\|_{\mathcal{X}} = 0 \tag{3.23}$$

uniformly in $\lambda \in \Lambda$ *and there exists a constant* C, *independent of* h *and* λ, *such that*

$$\begin{aligned}&\lim_{h\to 0}\big\|\big(u(\lambda), g(\lambda), \xi(\lambda)\big) - \big(u^h(\lambda), g^h(\lambda), \xi^h(\lambda)\big)\big\|_{\mathcal{X}} \\ &\quad\le C\lambda\Big\{\big\|(T^h - T)\big(N(u(\lambda)) + Kg(\lambda)\big)\big\|_X + \|(E^h - E)K^*\xi(\lambda)\|_G \\ &\qquad + \big\|\big((T^*)^h - T^*\big)\Big([N'(u(\lambda))]^*\xi - \mathcal{F}'(u(\lambda))\Big)\big\|_{Y^*}\Big\}.\end{aligned} \tag{3.24}$$

Proof. Assumptions (H16) and (H17) ensure that $\mathcal{G} \in C^2(\mathcal{X}, \mathcal{Y})$ and $D^2\mathcal{G}$ maps bounded sets of $\Lambda \times \mathcal{X}$ into bounded sets of $\mathcal{Y}$. By Lemma 3.3, assumptions (H18) and (H19) imply that (3.5) holds. By Lemma 3.2, assumptions (H13)-(H15) imply that (3.7) holds. Then, since $\mathcal{Z}$ is compactly imbedded into $\mathcal{Y}$, (3.7) implies that (3.8) holds. Thus, all the hypotheses of Theorem 3.1 are verified. Then, a direct application of Theorem 3.1 yields (3.23) and (3.24) follows from (3.9). □

It is easily seen that (3.23) and (3.24) are equivalent to

$$\lim_{h\to 0}\Big\{\|u(\lambda) - u^h(\lambda)\|_X + \|g(\lambda) - g^h(\lambda)\|_G + \|\xi(\lambda) - \xi^h(\lambda)\|_{Y^*}\Big\} = 0$$

uniformly in $\lambda \in \Lambda$ and that there exists a constant C, independent of h and λ, such that

$$\begin{aligned}\|u(\lambda) - u^h(\lambda)\|_X &+ \|g(\lambda) - g^h(\lambda)\|_G + \|\xi(\lambda) - \xi^h(\lambda)\|_{Y^*}\\ &\le C\lambda\Big\{\|(T^h - T)\big(N(u(\lambda)) + Kg(\lambda)\big)\|_X + \|(E^h - E)K^*\xi(\lambda)\|_G\\ &\qquad + \|\big((T^*)^h - T^*\big)\big([N'(u(\lambda))]^*\xi(\lambda) - \mathcal{F}'(u(\lambda))\big)\|_{Y^*}\Big\}.\end{aligned}$$

If, in (3.9), the operator $\mathcal{T}$ is invertible, we have, using (3.4), that

$$\|\psi^h(\lambda) - \psi(\lambda)\|_{\mathcal{X}} \le C\|(\mathcal{T}^h\mathcal{T}^{-1} - I)\psi(\lambda)\|_{\mathcal{X}} \quad \forall\, \lambda \in \Lambda\,.$$

Thus, if the operator T from Y to X is invertible, we have that (3.24) is equivalent to

$$\begin{aligned}\|u(\lambda) - u^h(\lambda)\|_X &+ \|g(\lambda) - g^h(\lambda)\|_G + \|\xi(\lambda) - \xi^h(\lambda)\|_{Y^*}\\ &\le C\Big\{\|(T^hT^{-1} - I)u(\lambda)\|_X + \|(E^hE^{-1} - I)g(\lambda)\|_G\\ &\qquad + \|\big((T^*)^h(T^*)^{-1} - I\big)\xi(\lambda)\|_{Y^*}\Big\}.\end{aligned} \tag{3.25}$$

4. Applications. We now apply the framework and analyses developed in §§2 and 3 to some concrete problems, all of which feature constraints on admissible states and controls that take the form of a system of nonlinear partial differential equations. In each application, we use a different control mechanism, so the discussion provided in this section illustrates the treatment of a variety of such mechanisms. However, one could use any of the control mechanisms discussed in any of the applications in any other application or, in fact, use any combination of such mechanisms.

Before examining any specific application, we establish some notation. Further notation will be established as needed when the individual applications are considered.

Throughout, C will denote a positive constant whose meaning and value changes with context. Also, $H^s(\mathcal{D})$ for $s \in \mathbb{R}$ denotes the standard real Sobolev space of order s with respect to the set $\mathcal{D}$, where $\mathcal{D}$ could either be a bounded domain $\Omega \in \mathbb{R}^d$, $d = 2, 3$, or part of the boundary Γ of such a domain. Of particular interest are the spaces $H^0(\mathcal{D}) = L^2(\mathcal{D})$,

$$H^1(\mathcal{D}) = \left\{\phi \in L^2(\mathcal{D}) \;\middle|\; \frac{\partial\phi}{\partial x_j} \in L^2(\mathcal{D}) \quad \text{for } j = 1, \ldots, d\right\},$$

and

$$H^2(\mathcal{D}) = \left\{\phi \in L^2(\mathcal{D}) \;\middle|\; \frac{\partial\phi}{\partial x_j}\,,\ \frac{\partial^2\phi}{\partial x_j\partial x_k} \in L^2(\mathcal{D}) \quad \text{for } j, k = 1, \ldots, d\right\}.$$

Also of interest is the subspace

$$H_0^1(\mathcal{D}) = \left\{ \phi \in H^1(\mathcal{D}) \;\middle|\; \phi = 0 \quad \text{on } \partial\mathcal{D} \right\},$$

where $\partial\mathcal{D}$ denotes the boundary of $\mathcal{D}$.

Dual spaces will be denoted by $(\cdot)^*$. Duality pairings between spaces and their duals will be denoted by $\langle \cdot, \cdot \rangle$. Norms of functions belonging to $H^s(\Omega)$ and $H^s(\Gamma)$ are denoted by $\| \cdot \|_s$ and $\| \cdot \|_{s,\Gamma}$, respectively. Of particular interest are the $L^2(\Omega)$-norm $\| \cdot \|_0$, the $H^1(\Omega)$-norm

$$\|\phi\|_1^2 = \sum_{j=1}^{d} \left\| \frac{\partial \phi}{\partial x_j} \right\|_0^2 + \|\phi\|_0^2,$$

and the $H^2(\Omega)$-norm

$$\|\phi\|_2^2 = \sum_{j,k=1}^{d} \left\| \frac{\partial^2 \phi}{\partial x_j \partial x_k} \right\|_0^2 + \|\phi\|_1^2.$$

Corresponding Sobolev spaces of real, vector-valued functions having r components will be denoted by $\mathbf{H}^s(\mathcal{D})$, e.g., $\mathbf{H}^1(\mathcal{D}) = [H^1(\mathcal{D})]^r$. Of particular interest will be the spaces $\mathbf{L}^2(\mathcal{D}) = \mathbf{H}^0(\mathcal{D}) = [L^2(\mathcal{D})]^r$,

$$\mathbf{H}^1(\mathcal{D}) = \left\{ v_j \in L^2(\mathcal{D}) \;\middle|\; \frac{\partial v_j}{\partial x_k} \in L^2(\mathcal{D}) \quad \text{for } j = 1, \ldots, r \text{ and } k = 1, \ldots, d \right\},$$

and

$$\mathbf{H}^2(\mathcal{D}) = \left\{ v_j \in L^2(\mathcal{D}) \;\middle|\; \frac{\partial v_j}{\partial x_k} \in L^2(\mathcal{D}),\ \frac{\partial^2 v_j}{\partial x_k \partial x_\ell} \in L^2(\Omega) \right.$$
$$\left. \text{for } j = 1, \ldots, r \text{ and } k, \ell = 1, \ldots, d \right\},$$

where v_j, $j = 1, \ldots, r$, denote the components of $\mathbf{v}$. Also of interest is the subspace

$$\mathbf{H}_0^1(\mathcal{D}) = \left\{ \mathbf{v} \in \mathbf{H}^1(\mathcal{D}) \;\middle|\; v_j = 0 \text{ on } \partial\mathcal{D},\ j = 1, \ldots, r \right\}.$$

Norms for spaces of vector-valued functions will be denoted by the same notation as that used for their scalar counterparts. For example,

$$\|\mathbf{v}\|_s^2 = \sum_{j=1}^{r} \|v_j\|_s^2 \quad \text{and} \quad \|\mathbf{v}\|_{s,\Gamma}^2 = \sum_{j=1}^{r} \|v_j\|_{s,\Gamma}^2.$$

We denote the $L^2(\Omega)$ and $\mathbf{L}^2(\Omega)$ inner products by $(\cdot, \cdot)$; i.e., for $p, q \in L^2(\Omega)$ and $\mathbf{u}, \mathbf{v} \in \mathbf{L}^2(\Omega)$

$$(p, q) = \int_\Omega pq \, d\Omega \quad \text{and} \quad (\mathbf{u}, \mathbf{v}) = \int_\Omega \mathbf{u} \cdot \mathbf{v} \, d\Omega.$$

Similarly, we denote by $(\cdot, \cdot)_\Gamma$ the $L^2(\Gamma)$ and $\mathbf{L}^2(\Gamma)$ inner products; i.e., for $p, q \in L^2(\Gamma)$ and $\mathbf{u}, \mathbf{v} \in \mathbf{L}^2(\Gamma)$

$$(p, q)_\Gamma = \int_\Gamma pq \, d\Gamma \quad \text{and} \quad (\mathbf{u}, \mathbf{v})_\Gamma = \int_\Gamma \mathbf{u} \cdot \mathbf{v} \, d\Gamma.$$

Since in all cases L^2-spaces will be used as pivot spaces, the above inner product notation can also be used to denote duality pairings between functions defined on H^s-spaces and their dual spaces.

For details concerning the notation employed, one may consult, e.g., [1].

4.1. Distributed controls for the von Kármán plate equations. For this application we will use distributed controls; i.e., control is effected through a source term in the governing partial differential equations. Let Ω be a bounded, convex polygonal domain in $\mathbb{R}^2$, and let Γ denote the boundary of Ω. The von Kármán equations for a clamped plate are given by (see, e.g., [9] or [18])

$$\Delta^2\psi_1 + \frac{1}{2}[\psi_2, \psi_2] = 0 \quad \text{in } \Omega,$$

$$\Delta^2\psi_2 - [\psi_1, \psi_2] = \lambda g \quad \text{in } \Omega,$$

and

$$\psi_1 = \frac{\partial\psi_1}{\partial n} = \psi_2 = \frac{\partial\psi_2}{\partial n} = 0 \quad \text{on } \Gamma,$$

where

$$[\psi, \phi] = \frac{\partial^2\psi}{\partial x_1^2}\frac{\partial^2\phi}{\partial x_2^2} + \frac{\partial^2\psi}{\partial x_2^2}\frac{\partial^2\phi}{\partial x_1^2} - 2\frac{\partial^2\psi}{\partial x_1 x_2}\frac{\partial^2\phi}{\partial x_1 x_2}.$$

Here, ψ_1 denotes the Airy stress function, ψ_2 the deflection of the plate in the direction normal to the plate, λg is an external load normal to the plate that depends on the loading parameter λ, and $\partial(\cdot)/\partial n$ is the normal derivative in the direction of the outer normal to Γ.

By introducing appropriate rescalings, i.e., by replacing ψ_1 by $\lambda\psi_1$, ψ_2 by $\lambda\psi_2$, and g by λg, we can rewrite the von Kármán equations as follows:

$$\Delta^2\psi_1 + \frac{\lambda}{2}[\psi_2, \psi_2] = 0 \quad \text{in } \Omega, \tag{4.1}$$

$$\Delta^2\psi_2 - \lambda\,[\psi_1, \psi_2] = \lambda\, g \quad \text{in } \Omega, \tag{4.2}$$

and

$$\psi_1 = \frac{\partial\psi_1}{\partial n} = \psi_2 = \frac{\partial\psi_2}{\partial n} = 0 \quad \text{on } \Gamma. \tag{4.3}$$

We introduce the spaces

$$H_0^2(\Omega) = \left\{ \psi \in H^2(\Omega) \;\middle|\; \psi = 0,\ \frac{\partial\psi}{\partial n} = 0 \ \text{ on } \Gamma \right\},$$

$$\mathbf{H}_0^2(\Omega) = [H_0^2(\Omega)]^2, \quad H^{-2}(\Omega) = \left(H_0^2(\Omega)\right)^*, \quad \text{and} \quad \mathbf{H}^{-2}(\Omega) = \left(\mathbf{H}_0^2(\Omega)\right)^*$$

and the bilinear form

$$a(\psi, \phi) = \int_\Omega \Delta\psi\, \Delta\phi\, d\Omega \quad \forall\, \psi, \phi \in H^2(\Omega)$$

in order to define the following weak formulation of the von Kármán equations (4.1)-(4.3). Find $\boldsymbol{\psi} = (\psi_1, \psi_2) \in \mathbf{H}_0^2(\Omega)$ such that

$$a(\psi_1, \phi_1) + \frac{\lambda}{2}\big([\psi_2, \psi_2], \phi_1\big) = 0 \quad \forall\, \phi_1 \in H_0^2(\Omega) \tag{4.4}$$

and

$$a(\psi_2, \phi_2) - \lambda\big([\psi_1, \psi_2], \phi_2\big) = \lambda\langle g, \phi_2\rangle \quad \forall\, \phi_2 \in H_0^2(\Omega). \tag{4.5}$$

Using the identity

$$([\psi, \phi], \zeta) = ([\psi, \zeta], \phi) \quad \forall\, \psi, \phi, \zeta \in H_0^2(\Omega)\,, \tag{4.6}$$

one can show that for each $g \in H^{-2}(\Omega)$, (4.4)-(4.5) possesses at least one solution $\boldsymbol{\psi} = (\psi_1, \psi_2) \in \mathbf{H}_0^2(\Omega)$ and that all solutions of (4.4)-(4.5) satisfy the a priori estimate

$$\|\psi_1\|_2 + \|\psi_2\|_2 \leq C\|g\|_{-2}\,; \tag{4.7}$$

see, e.g., [18], for details. In the sequel a solution to (4.1)-(4.3) will be understood in the sense of (4.4)-(4.5).

Given a desired state $\boldsymbol{\psi}_0 = (\psi_{10}, \psi_{20}) \in \mathbf{L}^2(\Omega)$, we define for any $\boldsymbol{\psi} = (\psi_1, \psi_2) \in \mathbf{H}_0^2(\Omega)$ and $g \in L^2(\Omega)$ the functional

$$\begin{aligned} \mathcal{J}(\boldsymbol{\psi}, g) &= \mathcal{J}(\psi_1, \psi_2, g) \\ &= \frac{\lambda}{2}\int_\Omega \left((\psi_1 - \psi_{10})^2 + (\psi_2 - \psi_{20})^2\right) d\Omega + \frac{\lambda}{2}\int_\Omega g^2\, d\Omega\,. \end{aligned} \tag{4.8}$$

We then consider the following optimal control problem associated with the von Kármán plate equations:

$$\min\left\{\, \mathcal{J}(\boldsymbol{\psi}, g) \mid \boldsymbol{\psi} \in \mathbf{H}_0^2(\Omega)\,,\ g \in \Theta \,\right\} \quad \text{subject to} \quad (4.4)\text{-}(4.5)\,, \tag{4.9}$$

where Θ is a subset of $L^2(\Omega)$.

We define the spaces $X = \mathbf{H}_0^2(\Omega)$, $Y = \mathbf{H}^{-2}(\Omega)$, $G = L^2(\Omega)$, and $Z = \mathbf{L}^1(\Omega)$. By compact imbedding results, $Z \hookrightarrow\hookrightarrow Y$. For the time being, we assume that the admissible set Θ for the control g is a closed, convex subset of $G = L^2(\Omega)$.

Let the continuous linear operator $T \in \mathcal{L}(Y; X)$ be defined as follows. For $\mathbf{f} = (f_1, f_2) \in Y = \mathbf{H}^{-2}(\Omega)$, $T\mathbf{f} = \boldsymbol{\psi} \in X = \mathbf{H}_0^2(\Omega)$ is the unique solution of

$$a(\psi_1, \phi_1) = \langle f_1, \phi_1\rangle \quad \forall\, \phi_1 \in H_0^2(\Omega)$$

and

$$a(\psi_2, \phi_2) = \langle f_2, \phi_2\rangle \quad \forall\, \phi_2 \in H_0^2(\Omega)\,.$$

It can be easily verified that T is self-adjoint.

We define the (differentiable) nonlinear mapping $N : X \to Y$ by

$$N(\boldsymbol{\psi}) = \begin{pmatrix} \frac{1}{2}[\psi_2, \psi_2] \\ -[\psi_1, \psi_2] \end{pmatrix} \quad \forall\, \boldsymbol{\psi} \in X$$

or, equivalently,

$$\langle N(\boldsymbol{\psi}), \boldsymbol{\phi}\rangle = \frac{1}{2}([\psi_2, \psi_2], \phi_1) - ([\psi_1, \psi_2], \phi_2) \quad \forall\, \boldsymbol{\phi} = (\phi_1, \phi_2) \in X$$

and define $K : g \in L^2(\Omega) \to Y$ by

$$Kg = -\begin{pmatrix} 0 \\ g \end{pmatrix}$$

or, equivalently,

$$\langle Kg, \boldsymbol{\phi}\rangle = -\langle g, \phi_2\rangle \quad \forall\, \boldsymbol{\phi} = (\phi_1, \phi_2) \in X\,.$$

Clearly, the constraint equations (4.4)-(4.5) can be expressed as

$$\boldsymbol{\psi} + \lambda\, T N(\boldsymbol{\psi}) + \lambda\, T K g = 0\,,$$

i.e., in the form (2.2). With the obvious definitions for $\mathcal{F}(\cdot)$ and $\mathcal{E}(\cdot)$, i.e.,

$$\mathcal{F}(\boldsymbol{\psi}) = \frac{1}{2}\int_\Omega \Big((\psi_1 - \psi_{10})^2 + (\psi_2 - \psi_{20})^2\Big)\, d\Omega \quad \forall\, \boldsymbol{\psi} \in X$$

and

$$\mathcal{E}(g) = \frac{1}{2}\int_\Omega g^2\, d\Omega \quad \forall\, g \in G\,,$$

the functional (4.8) can be expressed as

$$\mathcal{J}(\boldsymbol{\psi}, g) = \lambda\, \mathcal{F}(\boldsymbol{\psi}) + \lambda\, \mathcal{E}(g)\,,$$

i.e., in the form (2.1). Thus, the minimization problem (4.9) is in the form of the minimization problem (2.3).

We are now in a position to verify, for the minimization problem (4.9), all the hypotheses of §§2 and 3.

4.1.1. Verification of the hypotheses for the existence of optimal solutions. We first verify that the hypotheses (H1)-(H6) hold in the current setting.

(H1) is obviously satisfied with a lower bound 0.

(H2) holds with $\alpha = 1$ and $\beta = 2$.

(H3) is verified with the choice $(\boldsymbol{\psi}^{(0)}, g^{(0)}) \in X \times \Theta$, where $g^{(0)}$ is an arbitrarily chosen element in Θ and $\boldsymbol{\psi}^{(0)} = \big(\psi_1^{(0)}, \psi_2^{(0)}\big)$ is a solution of

$$\Delta^2 \psi_1^{(0)} + \frac{\lambda}{2}[\psi_2^{(0)}, \psi_2^{(0)}] = 0 \quad \text{in } \Omega\,,$$

$$\Delta^2 \psi_2^{(0)} - \lambda\, [\psi_1^{(0)}, \psi_2^{(0)}] = \lambda\, g^{(0)} \quad \text{in } \Omega\,,$$

and

$$\psi_1^{(0)} = \frac{\partial \psi_1^{(0)}}{\partial n} = \psi_2^{(0)} = \frac{\partial \psi_2^{(0)}}{\partial n} = 0 \quad \text{on } \Gamma\,.$$

In order to verify (H4), we assume $\{g^{(n)}\} \subset \Theta$ is a sequence satisfying $g^{(n)} \rightharpoonup g$ in $L^2(\Omega)$; then, we have $g^{(n)} \rightharpoonup g$ in $H^{-2}(\Omega)$, so $\lim_{n\to\infty}\langle g^{(n)}, z\rangle = \langle g, z\rangle$ for all $z \in H^2(\Omega)$, i.e., $Kg^{(n)} \rightharpoonup Kg$ in Y. Assume that the sequence $\{\boldsymbol{\psi}^{(n)}\} \subset \mathbf{H}_0^2(\Omega)$ satisfies $\boldsymbol{\psi}^{(n)} \rightharpoonup \boldsymbol{\psi}$ in $\mathbf{H}_0^2(\Omega)$; then, $(\partial^2 \boldsymbol{\psi}^{(n)}/\partial x_i \partial x_j) \rightharpoonup (\partial^2 \boldsymbol{\psi}/\partial x_i \partial x_j)$ in $\mathbf{L}^2(\Omega)$ and, by using a compact imbedding result, $\boldsymbol{\psi}^{(n)} \to \boldsymbol{\psi}$ in $\mathbf{L}^2(\Omega)$. Now, using the identity (4.6),

$$\begin{aligned}
\langle N(\boldsymbol{\psi}^{(n)}), \boldsymbol{\phi}\rangle &= \frac{1}{2}\Big([\psi_2^{(n)}, \psi_2^{(n)}], \phi_1\Big) - \Big([\psi_1^{(n)}, \psi_2^{(n)}], \phi_2\Big) \\
&= \frac{1}{2}\Big([\psi_2^{(n)}, \phi_1], \psi_2^{(n)}\Big) - \Big([\psi_1^{(n)}, \phi_2], \psi_2^{(n)}\Big) \\
&\to \frac{1}{2}\,([\psi_2, \phi_1], \psi_2) - ([\psi_1, \phi_2], \psi_2) \\
&= \frac{1}{2}\,([\psi_2, \psi_2], \phi_1) - ([\psi_1, \psi_2], \phi_2) = \langle N(\boldsymbol{\psi}), \boldsymbol{\phi}\rangle\,.
\end{aligned}$$

Hence, (H4) is verified.

The verification of (H5) follows directly from the observation that the mappings $\boldsymbol{\phi} \mapsto \mathcal{F}(\boldsymbol{\phi}) = (1/2)\|\boldsymbol{\phi} - \boldsymbol{\psi}_0\|_0^2$ and $g \mapsto \mathcal{E}(g) = (1/2)\|g\|_0^2$ are convex.

The verification of (H6) is a trivial consequence of the a priori estimate (4.7).

It is now just a matter of citing Theorem 2.1 to prove the existence of an optimal solution that minimizes (4.8) subject to (4.4)-(4.5).

THEOREM 4.1. *There exists a* $(\boldsymbol{\phi}, g) \in \mathbf{H}_0^2(\Omega) \times \Theta$ *such that* (4.8) *is minimized subject to* (4.4)-(4.5). □

4.1.2. Verification of the hypotheses for the existence of Lagrange multipliers. We now assume $(\boldsymbol{\psi}, g)$ is an optimal solution and turn to the verification of hypotheses (H7)-(H9).

The validity of (H7) is obvious.

(H8) holds since the mapping $g \mapsto \mathcal{E}(g) = (1/2)\|g\|_0^2$ is convex.

(H9) can be verified as follows. For any $\boldsymbol{\psi} \in X$, the operator $N'(\boldsymbol{\psi}) : X \to Y$ is given by

$$N'(\boldsymbol{\psi}) \cdot \boldsymbol{\phi} = \begin{pmatrix} [\psi_2, \phi_2] \\ -[\psi_1, \phi_2] - [\psi_2, \phi_1] \end{pmatrix} \quad \forall\, \boldsymbol{\phi} = (\phi_1, \phi_2) \in X\,.$$

Thus, using the definition of $[\cdot, \cdot]$, we obtain that $N'(\boldsymbol{\psi}) \cdot \boldsymbol{\phi} \in \mathbf{L}^1(\Omega) = Z$.

The Lagrangian is given by

$$\mathcal{L}(\boldsymbol{\psi}, g, \boldsymbol{\eta}, k) = k\,\mathcal{J}(\boldsymbol{\psi}, g) - \Big\{ a(\psi_1, \eta_1) + \frac{\lambda}{2}\big([\psi_2, \psi_2], \eta_1\big) + a(\psi_2, \eta_2) - \lambda\big([\psi_1, \psi_2], \eta_2\big) - \lambda(g, \eta_2) \Big\}$$

for all $(\boldsymbol{\psi}, g, \boldsymbol{\eta}, k) \in X \times G \times X \times \mathbb{R} = \mathbf{H}_0^2(\Omega) \times L^2(\Omega) \times \mathbf{H}_0^2(\Omega) \times \mathbb{R}$. Note that in this form of the Lagrangian, the Lagrange multiplier $\boldsymbol{\eta} \in X = Y^*$, so we have already introduced the change of variables indicated between (2.17)-(2.18) and (2.19)-(2.21).

Having verified the hypotheses (H7)-(H9), we may apply Theorem 2.4 to conclude that there exist a Lagrange multiplier $\boldsymbol{\eta} \in X = \mathbf{H}_0^2(\Omega)$ and a real number k such that

$$\boldsymbol{\eta} + \lambda\, T^*\big([N'(\boldsymbol{\psi})]^* \cdot \boldsymbol{\eta} - k\,\mathcal{F}'(\boldsymbol{\psi})\big) = \mathbf{0} \tag{4.10}$$

and

$$\mathcal{L}(\boldsymbol{\psi}, g, \boldsymbol{\eta}, k) \le \mathcal{L}(\boldsymbol{\psi}, z, \boldsymbol{\eta}, k) \quad \forall\, z \in \Theta \tag{4.11}$$

and that for almost all values of λ, we may choose $k = 1$.

Recall that T is self-adjoint. Also, note that for any $\boldsymbol{\psi} \in X = \mathbf{H}_0^2(\Omega)$,

$$[N'(\boldsymbol{\psi})]^* \cdot \boldsymbol{\eta} = \begin{pmatrix} -[\psi_2, \eta_2] \\ [\psi_2, \eta_1] - [\psi_1, \eta_2] \end{pmatrix} \quad \forall\, \boldsymbol{\eta} = (\eta_1, \eta_2) \in X\,.$$

Thus, (4.10), with $k = 1$, can be rewritten as

$$a(\zeta_1, \eta_1) - \lambda\big([\psi_2, \eta_2], \zeta_1\big) = \lambda(\psi_1 - \psi_{10}, \zeta_1) \quad \forall\, \zeta_1 \in H_0^2(\Omega) \tag{4.12}$$

and

$$a(\zeta_2, \eta_2) + \lambda\big([\psi_2, \eta_1], \zeta_2\big) - \lambda\big([\psi_1, \eta_2], \zeta_2\big) = \lambda(\psi_2 - \psi_{20}, \zeta_2) \quad \forall\, \zeta_2 \in H_0^2(\Omega)\,. \tag{4.13}$$

Using the definition of the Lagrangian functional, (4.11), with $k = 1$, can be rewritten as

$$\frac{\lambda}{2}(z, z) + \lambda(z, \eta_2) - \frac{\lambda}{2}(g, g) - \lambda(g, \eta_2) \geq 0 \quad \forall\, z \in \Theta\,.$$

Note that, in the above expression, we have already employed hypothesis (H12), which in the current context is trivially satisfied with E the identity operator on $G^* = G = L^2(\Omega)$. For each $\epsilon \in (0, 1)$ and each $t \in \Theta$, set $z = \epsilon t + (1 - \epsilon)g \in \Theta$ in the last equation to obtain

$$\frac{\epsilon^2}{2}(t - g, t - g) + \epsilon\,(t - g, g) + \epsilon\,(t - g, \eta_2) \geq 0 \quad \forall\, t \in \Theta$$

so that, after dividing by $\epsilon > 0$ and then letting $\epsilon \to 0^+$, we obtain

$$(t - g, g + \eta_2) \geq 0 \quad \forall\, t \in \Theta\,. \tag{4.14}$$

We see that for almost all values of λ, necessary conditions for an optimum are that (4.4)-(4.5) and (4.12)-(4.14) are satisfied. The system formed by these equations will be called an *optimality system*.

We now specialize to the case $\Theta = L^2(\Omega)$. Note that the hypothesis (H10) is satisfied. Then, using Theorem 2.5, we see that the inequality (4.14) becomes an equality and, by letting $z = t - g$ vary arbitrarily in $L^2(\Omega)$, we now have, instead of (4.14),

$$(z, g + \eta_2) = 0 \quad \forall\, z \in L^2(\Omega)\,. \tag{4.15}$$

Thus, according to that theorem, we have that for almost all λ, an optimality system of equations is now given by (4.4)-(4.5), (4.12)-(4.13), and (4.15). However, we can go further and verify that the hypothesis (H11)′ is valid, which in turn will justify the existence of a Lagrange multiplier satisfying the optimality system for *all* $\lambda \in \Lambda$. We now assume the domain Ω is a convex polygon with no angles greater than 126°.

Let λ be given such that $1/\lambda$ is an eigenvalue of $-TN'(\boldsymbol{\psi})$, where $(\boldsymbol{\psi}, g) \in \mathbf{H}_0^2(\Omega) \times L^2(\Omega)$ is an optimal pair that minimizes (4.8) subject to (4.4)-(4.5). We wish to show that for each $\tilde{\mathbf{f}} \in \mathbf{H}^{-2}(\Omega)$, there exists a $\tilde{g} \in L^2(\Omega)$ and a $\tilde{\boldsymbol{\psi}} \in \mathbf{H}_0^2(\Omega)$ such that

$$\tilde{\boldsymbol{\psi}} + \lambda\, TN'(\boldsymbol{\psi}) \cdot \tilde{\boldsymbol{\psi}} + \lambda\, TK\tilde{g} = \tilde{\mathbf{f}}\,;$$

i.e.,

$$a(\tilde{\psi}_1, \phi_1) + \lambda\big([\psi_2, \tilde{\psi}_2], \phi_1\big) = \langle \tilde{f}_1, \phi_1 \rangle \quad \forall\, \phi_1 \in H_0^2(\Omega) \tag{4.16}$$

and

$$\begin{aligned} a(\tilde{\psi}_2, \phi_2) - \lambda\big([\tilde{\psi}_1, \psi_2], \phi_2\big) - \lambda\big([\psi_1, \tilde{\psi}_2], \phi_2\big) - \lambda(\tilde{g}, \phi_2) \\ = \langle \tilde{f}_2, \phi_2 \rangle \quad \forall\, \phi_2 \in H_0^2(\Omega)\,. \end{aligned} \tag{4.17}$$

To show this, we first let $\tilde{\boldsymbol{\psi}} \in \mathbf{H}_0^2(\Omega)$ be a solution of

$$a(\tilde{\psi}_1, \phi_1) + \lambda\big([\psi_2, \tilde{\psi}_2], \phi_1\big) = \langle \tilde{f}_1, \phi_1 \rangle \quad \forall\, \phi_1 \in H_0^2(\Omega)$$

and

$$a(\tilde{\psi}_2, \phi_2) - \lambda\big([\tilde{\psi}_1, \psi_2], \phi_2\big) = \langle \tilde{f}_2, \phi_2 \rangle \quad \forall\, \phi_2 \in H_0^2(\Omega)\,.$$

The existence of such a $\tilde{\boldsymbol{\psi}}$ can be shown in a manner similar to that for showing the existence of a solution to the von Kármán equation; the key step is that by adding the two equations with the test function $\boldsymbol{\phi}$ replaced by $\tilde{\boldsymbol{\psi}}$, we have the a priori estimate

$$a(\tilde{\psi}_1, \tilde{\psi}_1) + a(\tilde{\psi}_2, \tilde{\psi}_2) = \langle \tilde{f}_1, \tilde{\psi}_1 \rangle + \langle \tilde{f}_2, \tilde{\psi}_2 \rangle .$$

Then, we choose $\tilde{g} = -[\psi_1, \tilde{\psi}_2]$. Note that regularity results for the biharmonic equation applied to (4.4)-(4.5) yield $\boldsymbol{\psi} \in \mathbf{H}^4(\Omega)$ (see [3]). Hence, using imbedding theorems we deduce that $\tilde{g} \in L^2(\Omega)$. It is obvious that $\tilde{g}$ and $\tilde{\boldsymbol{\psi}}$ satisfy (4.16)-(4.17); i.e., we have verified (H11)′. Hence we conclude that for *all* λ, the optimality system (4.4)-(4.5), (4.12)-(4.13), and (4.15) has a solution. Thus, we have Theorem 2.6, which, in the present context, is given as follows.

THEOREM 4.2. *Let* $(\boldsymbol{\psi}, g) \in \mathbf{H}_0^2(\Omega) \times L^2(\Omega)$ *denote an optimal solution that minimizes* (4.8) *subject to* (4.5)-(4.6). *Then, for all* $\lambda \in \Lambda$, *there exists a nonzero Lagrange multiplier* $\boldsymbol{\eta} \in \mathbf{H}_0^2(\Omega)$ *satisfying the Euler equations* (4.12)-(4.13) *and* (4.15). □

4.1.3. Verification of the hypotheses for approximations and error estimates. We finally verify the hypotheses (H13)-(H19) that are used in connection with approximations and error estimates.

A finite-element discretization of the optimality system (4.4)-(4.5), (4.12)-(4.13), and (4.15) is defined in the usual manner. We first choose families of finite-dimensional subspaces $X^h \subset \mathbf{H}_0^2(\Omega)$ and $G^h \subset L^2(\Omega)$ parameterized by a parameter h that tends to zero and satisfying the following approximation properties. There exist a constant C and an integer r such that

$$\inf_{\boldsymbol{\phi}^h \in X^h} \|\boldsymbol{\phi} - \boldsymbol{\phi}^h\|_2 \le Ch^m \|\boldsymbol{\phi}\|_{m+2} \quad \forall\, \boldsymbol{\phi} \in \mathbf{H}^{m+2}(\Omega),\ 1 \le m \le r , \tag{4.18}$$

and

$$\inf_{z^h \in G^h} \|z - z^h\|_0 \le Ch^m \|z\|_m \quad \forall\, z \in H^m(\Omega),\ 1 \le m \le r . \tag{4.19}$$

One may consult, e.g., [8] for some finite-element spaces satisfying (4.18) and (4.19). For example, one may choose $X^h = V^h \times V^h$ where V^h is the piecewise quintic-$C^1(\overline{\Omega})$ finite-element space constrained to satisfy the given boundary conditions and defined with respect to a family of triangulations of Ω. In this case, h is a measure of the grid size. For simplicity, one may choose $G^h = V^h$.

Once the approximating spaces have been chosen, we may formulate the approximate problem for the optimality system (4.4)-(4.5), (4.12)-(4.13), and (4.15). Seek $\boldsymbol{\psi}^h \in X^h$, $g^h \in G^h$, and $\boldsymbol{\eta}^h \in X^h$ such that

$$a(\psi_1^h, \phi_1^h) + \frac{\lambda}{2}\big([\psi_2^h, \psi_2^h], \phi_1^h\big) = 0 \quad \forall\, \phi_1^h \in V^h , \tag{4.20}$$

$$a(\psi_2^h, \phi_2^h) - \lambda\big([\psi_1^h, \psi_2^h], \phi_2^h\big) = (g^h, \phi_2^h) \quad \forall\, \phi_2^h \in V^h , \tag{4.21}$$

$$a(\zeta_1^h, \eta_1^h) - \lambda\big([\psi_2^h, \eta_2^h], \zeta_1^h\big) = \lambda(\psi_1^h - \psi_{10}, \zeta_1^h) \quad \forall\, \zeta_1^h \in V^h , \tag{4.22}$$

$$a(\zeta_2^h, \eta_2^h) + \lambda\big([\psi_2^h, \eta_1^h], \zeta_2^h\big) - \lambda\big([\psi_1^h, \eta_2^h], \zeta_2^h\big) = \lambda(\psi_2^h - \psi_{20}, \zeta_2^h) \quad \forall\, \zeta_2^h \in V^h , \tag{4.23}$$

and

$$(z^h, g^h + \eta_2^h) = 0 \quad \forall\, z^h \in G^h . \tag{4.24}$$

The operator $T^h \in \mathcal{L}(Y; X^h)$ is defined as follows. For $\mathbf{f} \in Y$, $T^h\mathbf{f} = \boldsymbol{\psi}^h \in X^h$ is the unique solution of

$$a(\psi_1^h, \phi_1^h) = \langle f_1, \phi_1^h \rangle \quad \forall\, \phi_1^h \in V^h$$

and

$$a(\psi_2^h, \phi_2^h) = \langle f_2, \phi_2^h \rangle \quad \forall\, \phi_2^h \in V^h\,.$$

Since $T = T^*$, we define $(T^*)^h = T^h$.

We define the operator $E^h : L^2(\Omega) \to G^h$ as the $L^2(\Omega)$-projection on G^h; i.e., for each $g \in L^2(\Omega)$,

$$(E^h g, \phi^h) = (g, \phi^h) \quad \forall\, \phi^h \in G^h\,.$$

Since $G = L^2(\Omega)$ is reflexive, E^h is in fact an operator from $G^* \to G^h$.

By the well-known results concerning the approximation of biharmonic equations (see, e.g., [2] or [8]), we obtain

$$\|(T - T^h)\mathbf{f}\|_X \to 0$$

as $h \to 0$, for all $\mathbf{f} \in Y$. This is simply a restatement of (H13).

(H14) follows trivially from (H13) and the fact that T is self-adjoint, and we have chosen $(T^*)^h = T^h$.

(H15) follows from the best approximation property of $L^2(\Omega)$-projections and (4.19).

(H16) and (H17) follow from the fact that N and $\mathcal{F}$ are polynomials. Here we also use imbedding theorems and Cauchy inequalities.

We set $\hat{Z} = Z = \mathbf{L}^1(\Omega)$. For each $\boldsymbol{\eta} \in \mathbf{H}_0^2(\Omega)$ and $\boldsymbol{\zeta} \in \mathbf{H}_0^2(\Omega)$, Sobolev imbedding theorems imply that

$$[N'(\boldsymbol{\psi})]^* \cdot \boldsymbol{\eta} = \begin{pmatrix} -[\psi_2, \eta_2] \\ [\psi_2, \eta_1] - [\psi_1, \eta_2] \end{pmatrix} \in \hat{Z}\,,$$

$$\big([N''(\boldsymbol{\psi})]^* \cdot \boldsymbol{\zeta}\big) \cdot \boldsymbol{\eta} = \begin{pmatrix} -[\zeta_2, \eta_2] \\ [\zeta_2, \eta_1] - [\zeta_1, \eta_2] \end{pmatrix} \in \hat{Z}\,,$$

and

$$\big(\mathcal{F}''(\boldsymbol{\psi}) \cdot \boldsymbol{\zeta}\big) \cdot \boldsymbol{\eta} = \begin{pmatrix} \eta_1\zeta_1 \\ \eta_2\zeta_2 \end{pmatrix} \in \hat{Z}\,.$$

These relations verify (H18).

From the definition of the operator K we see that K maps $L^2(\Omega)$ into $\mathbf{L}^1(\Omega)$, i.e., K maps G into Z. Thus (H19) is verified.

Hence, we are now in a position to apply Theorem 3.5 to derive error estimates for the approximate solutions of the optimality system (4.4)–(4.5), (4.12)–(4.13) and (4.15). It should be noted that Lemma 3.4 implies that for almost all values of λ, the solutions of the optimality system are regular.

THEOREM 4.3. *Assume that Λ is a compact interval of $\mathbb{R}_+$ and that there exists a branch $\{(\lambda, \boldsymbol{\psi}(\lambda), g(\lambda), \boldsymbol{\eta}(\lambda)) : \lambda \in \Lambda\}$ of regular solutions of the optimality system* (4.4)–(4.5), (4.12)–(4.13), *and* (4.15). *Assume that the finite-element spaces X^h and G^h satisfy the hypotheses* (4.18)–(4.19). *Then, there exist a $\delta > 0$ and an $h_0 > 0$ such that for $h \leq h_0$, the discrete optimality system* (4.20)–(4.24) *has a unique branch of solutions $\{(\lambda, \boldsymbol{\psi}^h(\lambda), g^h(\lambda), \boldsymbol{\eta}^h(\lambda)) : \lambda \in \Lambda\}$ satisfying*

$$\{\|\boldsymbol{\psi}^h(\lambda) - \boldsymbol{\psi}(\lambda)\|_2 + \|g^h(\lambda) - g(\lambda)\|_0 + \|\boldsymbol{\eta}^h(\lambda) - \boldsymbol{\eta}(\lambda)\|_2\} < \delta \quad \forall\, \lambda \in \Lambda.$$

Moreover,

$$\lim_{h\to 0}\{\|\boldsymbol{\psi}^h(\lambda)-\boldsymbol{\psi}(\lambda)\|_2+\|g^h(\lambda)-g(\lambda)\|_0+\|\boldsymbol{\eta}^h(\lambda)-\boldsymbol{\eta}(\lambda)\|_2\}=0\,,$$

uniformly in $\lambda\in\Lambda$.

If, in addition, the solution of the optimality system satisfies $\big(\boldsymbol{\psi}(\lambda),g(\lambda),\boldsymbol{\eta}(\lambda)\big)\in \mathbf{H}^{m+2}(\Omega)\times H^m(\Omega)\times\mathbf{H}^{m+2}(\Omega)$ *for* $\lambda\in\Lambda$, *then there exists a constant* C, *independent of* h, *such that*

$$\begin{aligned}\|\boldsymbol{\psi}(\lambda)-\boldsymbol{\psi}^h(\lambda)\|_2+\|g(\lambda)-g^h(\lambda)\|_0+\|\boldsymbol{\eta}(\lambda)-\boldsymbol{\eta}^h(\lambda)\|_2\\ \le Ch^m\big(\|\boldsymbol{\psi}(\lambda)\|_{m+2}+\|g(\lambda)\|_m+\|\boldsymbol{\eta}(\lambda)\|_{m+2}\big)\,,\end{aligned}$$

uniformly in $\lambda\in\Lambda$.

Proof. All results follow from Theorem 3.5. For the last result, we also use (3.25) and the estimates (see, e.g., [2] or [8])

$$\|(T^hT^{-1}-I)\boldsymbol{\psi}\|_2\le Ch^m\|\boldsymbol{\psi}\|_{m+2}\qquad\text{for }\boldsymbol{\psi}\in\mathbf{H}^{m+2}(\Omega)\,,$$

$$\|\big((T^*)^h(T^*)^{-1}-I\big)\boldsymbol{\eta}\|_2=\|(T^hT^{-1}-I)\boldsymbol{\eta}\|_2\le Ch^m\|\boldsymbol{\eta}\|_{m+2}\qquad\text{for }\boldsymbol{\eta}\in\mathbf{H}^{m+2}(\Omega)\,,$$

and

$$\|(E^hE^{-1}-I)g\|_0\le Ch^m\|g\|_m\qquad\text{for } g\in H^m(\Omega)\,.$$

In these estimates, the constant C is independent of h, $\boldsymbol{\psi}$, g, $\boldsymbol{\eta}$, and λ. □

Remark. In fact, we obtain from (4.15) that $g=-\eta_2$, so the term $\|g(\lambda)\|_m$ in the right-hand side of the error estimate is redundant. □

Remark. By using (4.15) again, along with (4.24) and the error estimate in Theorem 4.3, we have the following improved error estimate for the approximation of the control g:

$$\|g(\lambda)-g^h(\lambda)\|_2=\|\eta_2(\lambda)-\eta_2^h(\lambda)\|_2\le Ch^m\big(\|\boldsymbol{\psi}(\lambda)\|_{m+2}+\|\boldsymbol{\eta}(\lambda)\|_{m+2}\big)\,.$$

Of course, we also use the fact that we have chosen $G^h=V^h\subset H^2(\Omega)$. □

4.2. Neumann boundary controls for the Ginzburg–Landau superconductivity equations. For this application we will use Neumann boundary controls; i.e., control is effected through the data in a Neumann boundary condition. Let Ω be a bounded open domain in $\mathbb{R}^d$, $d=2$ or 3, and let Γ be its boundary. A simplified Ginzburg–Landau model for superconductivity is given by

$$\begin{aligned}-\Delta\psi_1+\big(\psi_1^2+\psi_2^2+|\mathbf{A}|^2-1\big)\psi_1-\nabla\cdot(\mathbf{A}\psi_2)-\mathbf{A}\cdot\nabla\psi_2=0\quad&\text{in }\Omega\,,\\ -\Delta\psi_2+\big(\psi_1^2+\psi_2^2+|\mathbf{A}|^2-1\big)\psi_2+\nabla\cdot(\mathbf{A}\psi_1)+\mathbf{A}\cdot\nabla\psi_1=0\quad&\text{in }\Omega\,,\\ \mathbf{n}\cdot(\nabla\psi_1+\mathbf{A}\psi_2)=\lambda g_1\quad&\text{on }\Gamma\,,\end{aligned}$$

and

$$\mathbf{n}\cdot(\nabla\psi_2-\mathbf{A}\psi_1)=\lambda g_2\quad\text{on }\Gamma\,.$$

Here, ψ_1 and ψ_2 denote the real and imaginary parts, respectively, of the complex-valued order parameter, $\mathbf{A}$ is a given real magnetic potential, g_1 and g_2 are related to the normal component of the current at the boundary, and $\lambda>0$ is a "current loading" parameter. These equations are a special case of a more general model for superconductivity wherein $\mathbf{A}$ is also unknown;

see, e.g., [22] for a derivation of the general model. It can be shown that in certain limits, e.g., high values of the applied field, the above simpler model is valid; see [7].

By introducing appropriate rescalings, i.e., by replacing ψ_j by $\sqrt{\lambda}\psi_j$ and g_j by $\sqrt{\lambda}g_j$, $j = 1, 2$, we can rewrite the above Ginzburg-Landau equations as follows:

$$-\Delta\psi_1 + (|\mathbf{A}|^2 - 1)\psi_1 - \nabla\cdot(\mathbf{A}\psi_2) - \mathbf{A}\cdot\nabla\psi_2 + \lambda\left(\psi_1^2 + \psi_2^2\right)\psi_1 = 0 \quad \text{in } \Omega\,, \tag{4.25}$$

$$-\Delta\psi_2 + (|\mathbf{A}|^2 - 1)\psi_2 + \nabla\cdot(\mathbf{A}\psi_1) + \mathbf{A}\cdot\nabla\psi_1 + \lambda\left(\psi_1^2 + \psi_2^2\right)\psi_2 = 0 \quad \text{in } \Omega\,, \tag{4.26}$$

$$\mathbf{n}\cdot(\nabla\psi_1 + \mathbf{A}\psi_2) = \lambda g_1 \quad \text{on } \Gamma\,, \tag{4.27}$$

and

$$\mathbf{n}\cdot(\nabla\psi_2 - \mathbf{A}\psi_1) = \lambda g_2 \quad \text{on } \Gamma\,. \tag{4.28}$$

We introduce the bilinear forms

$$a(\psi, \phi) = \int_\Omega \left(\nabla\psi\cdot\nabla\phi + (|\mathbf{A}|^2 - 1)\psi\phi\right) d\Omega \quad \forall\, \psi, \phi \in H^1(\Omega)$$

and

$$b(\psi, \phi) = \int_\Omega \mathbf{A}\cdot(\psi\nabla\phi - \phi\nabla\psi)\, d\Omega \quad \forall\, \psi, \phi \in H^1(\Omega)\,.$$

We assume that $\mathbf{A} \in \mathbf{H}^1(\Omega)$. Note that

$$a(\psi, \phi) = a(\phi, \psi) \quad \text{and} \quad b(\psi, \phi) = -b(\phi, \psi)\,.$$

Then, a weak formulation of the Ginzburg-Landau equations (4.25)-(4.28) is defined as follows. Seek $\boldsymbol{\psi} = (\psi_1, \psi_2) \in \mathbf{H}^1(\Omega)$ such that

$$a(\psi_1, \phi_1) + b(\psi_2, \phi_1) + \lambda\big((\psi_1^2 + \psi_2^2)\psi_1, \phi_1\big) = \lambda\langle g_1, \phi_1\rangle_\Gamma \quad \forall\, \phi_1 \in H^1(\Omega) \tag{4.29}$$

and

$$a(\psi_2, \phi_2) - b(\psi_1, \phi_2) + \lambda\big((\psi_1^2 + \psi_2^2)\psi_2, \phi_2\big) = \lambda\langle g_2, \phi_2\rangle_\Gamma \quad \forall\, \phi_2 \in H^1(\Omega)\,. \tag{4.30}$$

It can be shown that, for each $\mathbf{g} = (g_1, g_2) \in \mathbf{H}^{-1/2}(\Gamma)$, (4.29) and (4.30) possess at least one solution $\boldsymbol{\psi} \in \mathbf{H}^1(\Omega)$ and that all solutions of (4.29) and (4.30) satisfy the a priori estimate

$$\|\psi_1\|_1 + \|\psi_2\|_1 \le C\left(\|g_1\|_{-1/2,\Gamma} + \|g_2\|_{-1/2,\Gamma}\right)\,; \tag{4.31}$$

see, e.g., [11], for details. In the sequel, a solution of (4.25)-(4.28) will be understood in the sense of (4.29)-(4.30).

Given a desired state $\boldsymbol{\psi}_0 = (\psi_{10}, \psi_{20}) \in \mathbf{L}^2(\Omega)$, we define for any $\boldsymbol{\psi} = (\psi_1, \psi_2) \in \mathbf{H}^1(\Omega)$ and $\mathbf{g} = (g_1, g_2) \in \mathbf{L}^2(\Gamma)$ the functional

$$\mathcal{J}(\boldsymbol{\psi}, \mathbf{g}) = \frac{\lambda}{2}\int_\Omega \left((\psi_1 - \psi_{10})^2 + (\psi_2 - \psi_{20})^2\right) d\Omega + \frac{\lambda}{2}\int_\Gamma (g_1^2 + g_2^2)\, d\Gamma\,. \tag{4.32}$$

We then consider the following optimal control problem associated with the Ginzburg-Landau equations for superconductivity:

$$\min\left\{\, \mathcal{J}(\boldsymbol{\psi}, \mathbf{g}) \mid \boldsymbol{\psi} \in \mathbf{H}^1(\Omega)\,,\ \mathbf{g} \in \Theta \,\right\} \quad \text{subject to} \quad (4.29) \text{ and } (4.30)\,, \tag{4.33}$$

where Θ is a subset of $\mathbf{L}^2(\Gamma)$.

We define the spaces $X = \mathbf{H}^1(\Omega)$, $Y = (\mathbf{H}^1(\Omega))^*$, $G = \mathbf{L}^2(\Gamma)$, and $Z = [\mathbf{H}^{1/2+\epsilon}(\Omega)]^*$ where $\epsilon \in (0, 1/2)$ is chosen such that $\mathbf{H}^1(\Omega) \hookrightarrow\hookrightarrow \mathbf{H}^{1/2+\epsilon}(\Omega) \hookrightarrow \mathbf{L}^4(\Omega)$. By compact imbedding results, $\mathbf{L}^{4/3}(\Omega) \hookrightarrow Z \hookrightarrow\hookrightarrow Y$. For the time being, we assume that the admissible set Θ for the control $\mathbf{g}$ is a closed convex subset of $G = \mathbf{L}^2(\Gamma)$.

Let the continuous linear operator $T \in \mathcal{L}(Y; X)$ be defined as follows. For each $\mathbf{f} = (f_1, f_2) \in Y = (\mathbf{H}^1(\Omega))^*$, $T\mathbf{f} = \boldsymbol{\psi} \in X = \mathbf{H}^1(\Omega)$ is the unique solution of

$$a(\psi_1, \phi_1) + b(\psi_2, \phi_1) = \langle f_1, \phi_1 \rangle \quad \forall\, \phi_1 \in H^1(\Omega)$$

and

$$a(\psi_2, \phi_2) - b(\psi_1, \phi_2) = \langle f_2, \phi_2 \rangle \quad \forall\, \phi_2 \in H^1(\Omega)\,.$$

It can be easily verified that T is self-adjoint. Also, it can be shown that for most choices of $\mathbf{A}$, the operator T is well defined; see [11].

We define the (differentiable) nonlinear mapping $N : X \to Y$ by

$$N(\boldsymbol{\psi}) = \begin{pmatrix} (\psi_1^2 + \psi_2^2)\psi_1 \\ (\psi_1^2 + \psi_2^2)\psi_2 \end{pmatrix} \quad \forall\, \boldsymbol{\psi} \in X$$

or, equivalently,

$$\langle N(\boldsymbol{\psi}), \boldsymbol{\phi} \rangle = \big((\psi_1^2 + \psi_2^2)\psi_1, \phi_1\big) + \big((\psi_1^2 + \psi_2^2)\psi_2, \phi_2\big) \quad \forall\, \boldsymbol{\phi} = (\phi_1, \phi_2) \in X$$

and define $K : \mathbf{H}^{-1/2}(\Gamma) \to Y$ as the injection mapping

$$\langle K\mathbf{z}, \mathbf{v} \rangle = -\langle \mathbf{z}, \mathbf{v} \rangle_\Gamma \quad \forall\, \mathbf{z} \in \mathbf{H}^{-1/2}(\Gamma)\,, \forall\, \mathbf{v} \in \mathbf{H}^1(\Omega)\,.$$

Clearly, the constraint equations (4.29)-(4.30) can be expressed as

$$\boldsymbol{\psi} + \lambda\, TN(\boldsymbol{\psi}) + \lambda\, TK\mathbf{g} = 0\,,$$

i.e., in the form (2.2). With the obvious definitions for $\mathcal{F}(\cdot)$ and $\mathcal{E}(\cdot)$, i.e.,

$$\mathcal{F}(\boldsymbol{\psi}) = \frac{1}{2}\int_\Omega \Big((\psi_1 - \psi_{10})^2 + (\psi_2 - \psi_{20})^2\Big)\, d\Omega \quad \forall\, \boldsymbol{\psi} \in X$$

and

$$\mathcal{E}(\mathbf{g}) = \frac{1}{2}\int_\Gamma (g_1^2 + g_2^2)\, d\Gamma \quad \forall\, \mathbf{g} \in G\,,$$

the functional (4.32) can be expressed as

$$\mathcal{J}(\boldsymbol{\psi}, g) = \lambda\, \mathcal{F}(\boldsymbol{\psi}) + \lambda\, \mathcal{E}(\mathbf{g})\,,$$

i.e., in the form (2.1). Thus, the minimization problem (4.33) is in the form of the minimization problem (2.3).

We are now in a position to verify, for the minimization problem (4.33), all the hypotheses of §§2 and 3.

4.2.1. Verification of the hypotheses for the existence of optimal solutions. We first verify that the hypotheses (H1)-(H6) hold in the current setting.

(H1) is obviously satisfied with a lower bound 0.

(H2) holds with $\alpha = 1$ and $\beta = 2$.

(H3) is verified since $\boldsymbol{\psi} = \mathbf{0}$ and $\mathbf{g} = \mathbf{0}$ is obviously a solution of (4.29)-(4.30).

In order to verify (H4), we assume $\{\mathbf{g}^{(n)}\} \subset \Theta \subset \mathbf{L}^2(\Gamma)$ is a sequence satisfying $\mathbf{g}^{(n)} \rightharpoonup \mathbf{g}$ in $\mathbf{L}^2(\Gamma)$; then, we have $\mathbf{g}^{(n)} \rightharpoonup \mathbf{g}$ in $\mathbf{H}^{-1/2}(\Gamma)$, so $\lim_{n\to\infty}\langle \mathbf{g}^{(n)}, \mathbf{v}\rangle_\Gamma = \langle \mathbf{g}, \mathbf{v}\rangle_\Gamma$ for all $\mathbf{v} \in \mathbf{H}^1(\Omega)$, i.e., $K\mathbf{g}^{(n)} \rightharpoonup K\mathbf{g}$ in Y. Assume that the sequence $\{\boldsymbol{\psi}^{(n)}\} \subset \mathbf{H}^1(\Omega)$ satisfies $\boldsymbol{\psi}^{(n)} \rightharpoonup \boldsymbol{\psi}$ in $\mathbf{H}^1(\Omega)$; then, by using the compact imbedding $\mathbf{H}^1(\Omega) \hookrightarrow\hookrightarrow \mathbf{L}^4(\Omega)$, $\boldsymbol{\psi}^{(n)} \to \boldsymbol{\psi}$ in $\mathbf{L}^4(\Omega)$. Now,

$$\begin{aligned}\langle N(\boldsymbol{\psi}^{(n)}), \boldsymbol{\phi}\rangle &= \Big(\big((\psi_1^{(n)})^2 + (\psi_2^{(n)})^2\big)\psi_1^{(n)}, \phi_1\Big) + \Big(\big((\psi_1^{(n)})^2 + (\psi_2^{(n)})^2\big)\psi_2^{(n)}, \phi_2\Big)\\ &\to \Big((\psi_1^2 + \psi_2^2)\psi_1, \phi_1\Big) + \Big((\psi_1^2 + \psi_2^2)\psi_2, \phi_2\Big) = \langle N(\boldsymbol{\psi}), \boldsymbol{\phi}\rangle\,.\end{aligned}$$

Hence, (H4) is verified.

The verification of (H5) follows directly from the observation that the mappings $\boldsymbol{\phi} \mapsto \mathcal{F}(\boldsymbol{\phi}) = (1/2)\|\boldsymbol{\phi} - \boldsymbol{\psi}_0\|_0^2$ and $\mathbf{g} \mapsto \mathcal{E}(\mathbf{g}) = (1/2)\|\mathbf{g}\|_{0,\Gamma}^2$ are convex.

The verification of (H6) is a trivial consequence of the a priori estimate (4.31).

It is now just a matter of citing Theorem 2.1 to prove the existence of an optimal solution that minimizes (4.32) subject to (4.29)-(4.30).

THEOREM 4.4. *There exists a* $(\boldsymbol{\phi}, \mathbf{g}) \in \mathbf{H}^1(\Omega) \times \Theta$ *such that* (4.32) *is minimized subject to* (4.29)-(4.30). □

4.2.2. Verification of the hypotheses for the existence of Lagrange multipliers. We now assume $(\boldsymbol{\psi}, \mathbf{g})$ is an optimal solution and turn to the verification of hypotheses (H7)-(H9).

The validity of (H7) is obvious.

(H8) holds since the mapping $\mathbf{g} \mapsto \mathcal{E}(\mathbf{g}) = (\frac{1}{2})\int_\Gamma |\mathbf{g}|^2\, d\Gamma$ is convex.

(H9) can be verified as follows. For any $\boldsymbol{\psi} \in X$, the operator $N'(\boldsymbol{\psi}) : X \to Y$ is given by

$$N'(\boldsymbol{\psi})\cdot\boldsymbol{\phi} = \begin{pmatrix}(3\psi_1^2 + \psi_2^2)\phi_1 + (2\psi_1\psi_2)\phi_2\\ (3\psi_2^2 + \psi_1^2)\phi_2 + (2\psi_1\psi_2)\phi_1\end{pmatrix} \quad \forall\, \boldsymbol{\phi} = (\phi_1, \phi_2) \in X\,.$$

Thus, we obtain that $N'(\boldsymbol{\psi})\cdot\boldsymbol{\phi} \in \mathbf{L}^{4/3}(\Omega) \hookrightarrow [\mathbf{H}^{1/2+\epsilon}(\Omega)]^* = Z$.

The Lagrangian is given by

$$\begin{aligned}\mathcal{L}(\boldsymbol{\psi}, \mathbf{g}, \boldsymbol{\eta}, k) &= k\,\mathcal{J}(\boldsymbol{\psi}, \mathbf{g})\\ &\quad - \Big\{a(\psi_1, \eta_1) + b(\psi_2, \phi_1) + \lambda\big((\psi_1^2 + \psi_2^2)\psi_1, \eta_1\big) - \lambda(g_1, \eta_1)_\Gamma\\ &\qquad + a(\psi_2, \eta_2) - b(\psi_1, \phi_2) - \lambda\big((\psi_1^2 + \psi_2^2)\psi_2, \eta_2\big) - \lambda(g_2, \eta_2)_\Gamma\Big\}\end{aligned}$$

for all $(\boldsymbol{\psi}, \mathbf{g}, \boldsymbol{\eta}, k) \in X \times G \times X \times \mathbb{R} = \mathbf{H}^1(\Omega) \times \mathbf{L}^2(\Gamma) \times \mathbf{H}^1(\Omega) \times \mathbb{R}$. Note that in this form of the Lagrangian, the Lagrange multiplier $\boldsymbol{\eta} \in X = Y^*$, so we have already introduced the change of variables indicated between (2.17)-(2.18) and (2.19)-(2.21).

Having verified the hypotheses (H7)-(H9), we may apply Theorem 2.4 to conclude that there exist a Lagrange multiplier $\boldsymbol{\eta} \in X = \mathbf{H}^1(\Omega)$ and a real number k such that

$$\boldsymbol{\eta} + \lambda\, T^*\big([N'(\boldsymbol{\psi})]^*\cdot\boldsymbol{\eta} - k\,\mathcal{F}'(\boldsymbol{\psi})\big) = \mathbf{0} \tag{4.34}$$

and

$$\mathcal{L}(\boldsymbol{\psi}, \mathbf{g}, \boldsymbol{\eta}, k) \leq \mathcal{L}(\boldsymbol{\psi}, \mathbf{z}, \boldsymbol{\eta}, k) \quad \forall\, z \in \Theta \tag{4.35}$$

and that for almost all values of λ, we may choose $k = 1$.

Recall that T is self-adjoint. Also, note that for any $\boldsymbol{\psi} \in X = \mathbf{H}^1(\Omega)$,

$$[N'(\boldsymbol{\psi})]^* \cdot \boldsymbol{\eta} = \begin{pmatrix} (3\psi_1^2 + \psi_2^2)\eta_1 + (2\psi_1\psi_2)\eta_2 \\ (3\psi_2^2 + \psi_1^2)\eta_2 + (2\psi_1\psi_2)\eta_1 \end{pmatrix} \quad \forall\, \boldsymbol{\eta} = (\eta_1, \eta_2) \in X\,.$$

Thus, $N'(\boldsymbol{\psi})$ is self-adjoint as well and (4.34), with $k = 1$, can be rewritten as

$$\begin{aligned} a(\zeta_1, \eta_1) - b(\zeta_1, \eta_2) &+ \lambda\big((3\psi_1^2 + \psi_2^2)\eta_1, \zeta_1\big) \\ &+ \lambda\big((2\psi_1\psi_2)\eta_2, \zeta_1\big) = \lambda(\psi_1 - \psi_{10}, \zeta_1) \quad \forall\, \zeta_1 \in H^1(\Omega) \end{aligned} \tag{4.36}$$

and

$$\begin{aligned} a(\zeta_2, \eta_2) + b(\zeta_2, \eta_1) &+ \lambda\big((3\psi_2^2 + \psi_1^2)\eta_2, \zeta_2\big) \\ &+ \lambda\big((2\psi_1\psi_2)\eta_1, \zeta_2\big) = \lambda(\psi_2 - \psi_{20}, \zeta_2) \quad \forall\, \zeta_2 \in H^1(\Omega)\,. \end{aligned} \tag{4.37}$$

Using the definition of the Lagrangian functional, (4.35), with $k = 1$, can be rewritten as

$$\frac{\lambda}{2}(\mathbf{z}, \mathbf{z})_\Gamma + \lambda(\mathbf{z}, \boldsymbol{\eta})_\Gamma - \frac{\lambda}{2}(\mathbf{g}, \mathbf{g})_\Gamma - \lambda(\mathbf{g}, \boldsymbol{\eta})_\Gamma \geq 0 \quad \forall\, \mathbf{z} \in \Theta\,.$$

Note that, in the above expression, we have already employed hypothesis (H12), which in the current context is trivially satisfied with E, the identity operator on $G^* = G = \mathbf{L}^2(\Gamma)$. For each $\epsilon \in (0, 1)$ and each $\mathbf{t} \in \Theta$, set $\mathbf{z} = \epsilon\mathbf{t} + (1 - \epsilon)\mathbf{g} \in \Theta$ in the last equation to obtain

$$\frac{\epsilon^2}{2}(\mathbf{t} - \mathbf{g}, \mathbf{t} - \mathbf{g})_\Gamma + \epsilon\,(\mathbf{t} - \mathbf{g}, \mathbf{g})_\Gamma + \epsilon\,(\mathbf{t} - \mathbf{g}, \boldsymbol{\eta})_\Gamma \geq 0 \quad \forall\, \mathbf{t} \in \Theta\,,$$

so, after dividing by $\epsilon > 0$ and then letting $\epsilon \to 0^+$, we obtain

$$(\mathbf{t} - \mathbf{g}, \mathbf{g} + \boldsymbol{\eta})_\Gamma \geq 0 \quad \forall\, \mathbf{t} \in \Theta\,. \tag{4.38}$$

We see that for almost all values of λ, necessary conditions for an optimum are that (4.29)-(4.30) and (4.36)-(4.38) are satisfied. Again, the system formed by these equations will be called an *optimality system*.

We now specialize to the case $\Theta = \mathbf{L}^2(\Gamma)$. Note that the hypothesis (H10) is satisfied. Then, using Theorem 2.5, we see that the inequality (4.38) becomes an equality and, by letting $\mathbf{z} = \mathbf{t} - \mathbf{g}$ vary arbitrarily in $\mathbf{L}^2(\Gamma)$, we now have, instead of (4.38),

$$(\mathbf{z}, \mathbf{g} + \boldsymbol{\eta})_\Gamma = 0 \quad \forall\, \mathbf{z} \in \mathbf{L}^2(\Gamma)\,. \tag{4.39}$$

Thus, according to that theorem, we have that for almost all λ, an optimality system of equations is now given by (4.29)-(4.30), (4.36)-(4.37), and (4.39). However, we can go further and verify that the hypothesis (H11) is valid, which in turn will justify the existence of a Lagrange multiplier satisfying the optimality system for *all* $\lambda \in \Lambda$.

To verify (H11), we first note that, via the change of variable $\xi = T^*v$, that assumption can be equivalently stated as

$$\text{if } \xi \in Y^* \text{ satisfies } \big(I + \lambda\, T^*[N'(u)]^*\big)\xi = 0 \text{ and } K^*\xi = 0, \text{ then } \xi = 0\,.$$

To verify this version of (H11), we assume that $\boldsymbol{\xi} \in Y^* = \mathbf{H}^1(\Omega)$ satisfies $\left(I + \lambda T^*[N'(\boldsymbol{\psi})]^*\right)\boldsymbol{\xi} = \mathbf{0}$ and $K^*\boldsymbol{\xi} = 0$, i.e.,

$$a(\zeta_1, \xi_1) - b(\zeta_1, \xi_2) + \lambda\left((3\psi_1^2 + \psi_2^2)\xi_1, \zeta_1\right) + \lambda\left((2\psi_1\psi_2)\xi_2, \zeta_1\right) = 0 \quad \forall\, \zeta_1 \in H^1(\Omega),$$

$$a(\zeta_2, \xi_2) + b(\zeta_2, \xi_1) + \lambda\left((3\psi_2^2 + \psi_1^2)\xi_2, \zeta_2\right) + \lambda\left((2\psi_1\psi_2)\xi_1, \zeta_2\right) = 0 \quad \forall\, \zeta_2 \in H^1(\Omega),$$

and

$$\boldsymbol{\xi} = \mathbf{0} \quad \text{on } \Gamma.$$

(Note that $K^*\boldsymbol{\xi} = \boldsymbol{\xi}|_\Gamma$.) Let Ω' be a smooth extension of Ω such that $\overline{\Omega}$ is a compact subset of Ω'. We then define $\boldsymbol{\xi}'$, $\boldsymbol{\psi}'$, and $\mathbf{A}'$ to be the extensions, by zero outside Ω, of $\boldsymbol{\xi}$, $\boldsymbol{\psi}$ and $\mathbf{A}$, respectively. Let the forms $a'(\cdot,\cdot)$, $b'(\cdot,\cdot)$, and $(\cdot,\cdot)'$ defined over Ω' be the analogues of corresponding forms defined over Ω. We may show from the last three equations that

$$\boldsymbol{\xi}' \in \mathbf{H}^1(\Omega'), \qquad \boldsymbol{\psi}' \in \mathbf{L}^6(\Omega'),$$

$$a'(\zeta_1, \xi_1') - b'(\zeta_1, \xi_2') + \lambda\left((3\psi_1'^2 + \psi_2'^2)\xi_1', \zeta_1\right)' + \lambda\left((2\psi_1'\psi_2')\xi_2', \zeta_1\right)' = 0 \quad \forall\, \zeta_1 \in \mathbf{H}_0^1(\Omega'),$$

and

$$a'(\zeta_2, \xi_2') + b'(\zeta_2, \xi_1') + \lambda\left((3\psi_2'^2 + \psi_1'^2)\xi_2', \zeta_2\right)' + \lambda\left((2\psi_1'\psi_2')\xi_1', \zeta_2\right)' = 0 \quad \forall\, \zeta_2 \in \mathbf{H}_0^1(\Omega').$$

In the sense of distribution, $\boldsymbol{\xi}'$ satisfies

$$-\Delta\xi_1' - 2\mathbf{A}' \cdot \nabla\xi_2' + \left(|\mathbf{A}'|^2 + \lambda(3\psi_1'^2 + \psi_2'^2) - 1\right)\xi_1' - (\nabla \cdot \mathbf{A}' - 2\lambda\psi_1'\psi_2')\xi_2' = 0 \quad \text{in } \Omega' \tag{4.40}$$

and

$$-\Delta\xi_2' + 2\mathbf{A}' \cdot \nabla\xi_1' + (\nabla \cdot \mathbf{A}' + 2\lambda\psi_1'\psi_2')\xi_1' + \left(|\mathbf{A}'|^2 + \lambda(3\psi_2'^2 + \psi_1'^2) - 1\right)\xi_2' = 0 \quad \text{in } \Omega'. \tag{4.41}$$

We now quote the following unique continuation result whose proof can be found in [17]. See also [12] and [19].

LEMMA 4.5. *Let Ω' be an open and connected subset of $\mathbb{R}^d$, $d = 2$ or 3. Let the functions $\mathbf{V} \in [L^q_{\text{loc}}(\Omega')]^{d\times d}$ for some $q \geq 2$ and $\mathbf{W} \in [L^{2d-1}_{\text{loc}}(\Omega')]^{d\times d\times d}$ be given. If $\boldsymbol{\xi} \in \mathbf{H}^1_{\text{loc}}(\Omega')$, $-\Delta\xi_i + \sum_{j=1}^d \sum_{k=1}^d W_{ijk}(\partial\xi_k/\partial x_j) + \sum_{j=1}^d V_{ij}\xi_j = 0$ (in the sense of distributions), $i = 1, \ldots, d$, and $\boldsymbol{\xi} = \mathbf{0}$ on an open, nonempty subset of Ω', then $\boldsymbol{\xi} = \mathbf{0}$ on Ω'.* □

Since $\mathbf{A} \in \mathbf{H}^1(\Omega)$ and $\boldsymbol{\psi} \in \mathbf{H}^1(\Omega)$, it is easy to see that the coefficients in (4.40)-(4.41) satisfy the regularity requirements of Lemma 4.5. Also note that $\boldsymbol{\xi}' = \mathbf{0}$ on $(\Omega' \setminus \Omega)$, which contains an open set. Thus we obtain that $\boldsymbol{\xi}' = \mathbf{0}$ in Ω', or $\boldsymbol{\xi} = \mathbf{0}$ in Ω; i.e., (H11) is verified.

Hence we conclude that for *all* λ, the optimality system (4.29)-(4.30), (4.36)-(4.37), and (4.39) has a solution. Thus, we have Theorem 2.6, which, in the present context, is given as follows.

THEOREM 4.6. *Let $(\boldsymbol{\psi}, \mathbf{g}) \in \mathbf{H}^1(\Omega) \times \mathbf{L}^2(\Gamma)$ denote an optimal solution that minimizes* (4.32) *subject to* (4.29)-(4.30). *Then, for all $\lambda \in \Lambda$, there exists a nonzero Lagrange multiplier $\boldsymbol{\eta} \in \mathbf{H}^1(\Omega)$ satisfying the Euler equations* (4.36)-(4.37) *and* (4.39). □

4.2.3. Verification of the hypotheses for approximations and error estimates. We finally verify the hypotheses (H13)-(H19) that are used in connection with approximations and to derive error estimates.

A finite-element discretization of the optimality system (4.29)-(4.30), (4.36)-(4.37), and (4.39) is defined in the usual manner. We first choose families of finite-dimensional subspaces $X^h \subset \mathbf{H}^1(\Omega)$ and $G^h \subset \mathbf{L}^2(\Gamma)$ parameterized by a parameter h that tends to zero and satisfying the following approximation properties. There exists a constant C and an integer r such that

$$\inf_{\boldsymbol{\phi}^h \in X^h} \|\boldsymbol{\phi} - \boldsymbol{\phi}^h\|_1 \le Ch^m \|\boldsymbol{\phi}\|_{m+1} \quad \forall\, \boldsymbol{\phi} \in \mathbf{H}^{m+1}(\Omega)\,,\ 1 \le m \le r\,, \tag{4.42}$$

and

$$\inf_{z^h \in G^h} \|\mathbf{z} - \mathbf{z}^h\|_{0,\Gamma} \le Ch^m \inf_{\mathbf{v} \in \mathbf{H}^{m+1/2}(\Omega),\, \mathbf{v}|_\Gamma = \mathbf{z}} \|\mathbf{v}\|_{m+1/2} \quad \forall\, \mathbf{z} \in \mathbf{H}^{m+1/2}(\Omega)|_\Gamma\,,\ 1 \le m \le r\,. \tag{4.43}$$

One may consult, e.g., [8] and [15], for some finite-element spaces satisfying (4.42) and (4.43). For example, one may choose $X^h = V^h \times V^h$ where V^h is the piecewise linear or quadratic finite-element space defined with respect to a family of triangulations of Ω. In this case, h is a measure of the grid size. For simplicity we may choose $G^h = (X^h)|_\Gamma$, i.e., the functions in G^h are the restrictions to the boundary Γ of functions belonging to X^h.

Once the approximating spaces have been chosen, we may formulate the approximate problem for the optimality system (4.29)-(4.30), (4.36)-(4.37), and (4.39). Seek $\boldsymbol{\psi}^h \in X^h$, $\mathbf{g}^h \in G^h$, and $\boldsymbol{\eta}^h \in X^h$ such that

$$a(\psi_1^h, \phi_1^h) + b(\psi_2^h, \phi_1^h) + \lambda\big\{\big((\psi_1^h)^2 + (\psi_2^h)^2\big)\psi_1^h, \phi_1^h\big\} = \lambda\langle g_1^h, \phi_1^h\rangle_\Gamma \quad \forall\, \phi_1^h \in V^h\,, \tag{4.44}$$

$$a(\psi_2^h, \phi_2^h) - b(\psi_1^h, \phi_2^h) + \lambda\big\{\big((\psi_1^h)^2 + (\psi_2^h)^2\big)\psi_2^h, \phi_2^h\big\} = \lambda\langle g_2^h, \phi_2^h\rangle_\Gamma \quad \forall\, \phi_2^h \in V^h\,, \tag{4.45}$$

$$\begin{aligned} a(\zeta_1^h, \eta_1^h) - b(\zeta_1^h, \eta_2^h) &+ \lambda\big((3(\psi_1^h)^2 + (\psi_2^h)^2)\eta_1^h, \zeta_1^h\big) \\ &+ \lambda\big((2\psi_1^h\psi_2^h)\eta_2^h, \zeta_1^h\big) = \lambda(\psi_1^h - \psi_{10}, \zeta_1^h) \quad \forall\, \zeta_1^h \in V^h\,, \end{aligned} \tag{4.46}$$

$$\begin{aligned} a(\zeta_2^h, \eta_2^h) + b(\zeta_2^h, \eta_1^h) &+ \lambda\big((3(\psi_2^h)^2 + (\psi_1^h)^2)\eta_2^h, \zeta_2^h\big) \\ &+ \lambda\big((2\psi_1^h\psi_2^h)\eta_1^h, \zeta_2^h\big) = \lambda(\psi_2^h - \psi_{20}, \zeta_2^h) \quad \forall\, \zeta_2^h \in V^h\,, \end{aligned} \tag{4.47}$$

and

$$(\mathbf{z}^h, \mathbf{g}^h + \boldsymbol{\eta}^h)_\Gamma = 0 \quad \forall\, \mathbf{z}^h \in G^h\,. \tag{4.48}$$

The operator $T^h \in \mathcal{L}(Y; X^h)$ is defined as follows. For $\mathbf{f} \in Y$, $T^h\mathbf{f} = \boldsymbol{\psi}^h \in X^h$ is the solution for

$$a(\psi_1^h, \phi_1^h) + b(\psi_2^h, \phi_1^h) = \langle f_1, \phi_1^h\rangle \quad \forall\, \phi_1^h \in V^h$$

and

$$a(\psi_2^h, \phi_2^h) - b(\psi_1^h, \phi_2^h) = \langle f_2, \phi_2^h\rangle \quad \forall\, \phi_2^h \in V^h\,.$$

Since $T = T^*$, we define $(T^*)^h = T^h$.

We define the operator $E^h : \mathbf{L}^2(\Gamma) \to G^h$ as the $\mathbf{L}^2(\Gamma)$-projection on G^h; i.e., for each $\mathbf{g} \in \mathbf{L}^2(\Gamma)$,

$$(E^h\mathbf{g}, \mathbf{z}^h)_\Gamma = (\mathbf{g}, \mathbf{z}^h)_\Gamma \quad \forall\, \mathbf{z}^h \in G^h\,.$$

Since $G = \mathbf{L}^2(\Gamma)$ is reflexive, E^h is in fact an operator from $G^* \to G^h$.

By results concerning the approximation of the Ginzburg-Landau equations (see, e.g., [11]), we obtain

$$\|(T - T^h)\mathbf{f}\|_X \to 0$$

as $h \to 0$, for all $\mathbf{f} \in Y$. This is simply a restatement of (H13).

(H14) follows trivially from (H13) and the fact that T is self-adjoint and we have chosen $(T^*)^h = T^h$.

(H15) follows from the best approximation property of $\mathbf{L}^2(\Gamma)$-projections and (4.43).

(H16) and (H17) follow from the fact that N and $\mathcal{F}$ are polynomials. Here we also use imbedding theorems and Cauchy inequalities.

Setting $\hat{Z} = Z = \mathbf{H}^{1/2+\epsilon}(\Omega)$, we have that $\hat{Z} \hookrightarrow\hookrightarrow [\mathbf{H}^1(\Omega)]^* = X^*$. For each $\boldsymbol{\eta} \in \mathbf{H}^1(\Omega)$ and $\boldsymbol{\zeta} \in \mathbf{H}^1(\Omega)$, Sobolev imbedding theorems imply that

$$[N'(\boldsymbol{\psi})]^* \cdot \boldsymbol{\eta} = \begin{pmatrix} (3\psi_1^2 + \psi_2^2)\eta_1 + (2\psi_1\psi_2)\eta_2 \\ (3\psi_2^2 + \psi_1^2)\eta_2 + (2\psi_1\psi_2)\eta_1 \end{pmatrix} \in \mathbf{L}^{4/3}(\Omega) \subset \hat{Z}\,,$$

$$\big([N''(\boldsymbol{\psi})]^* \cdot \boldsymbol{\zeta}\big) \cdot \boldsymbol{\eta} = \begin{pmatrix} (6\psi_1\zeta_1 + 2\psi_2\zeta_2)\eta_1 + (2\psi_1\zeta_2)\eta_2 + (2\zeta_1\psi_2)\eta_2 \\ (6\psi_2\zeta_2 + 2\psi_1\zeta_1)\eta_2 + (2\psi_1\zeta_2)\eta_1 + (2\zeta_1\psi_2)\eta_1 \end{pmatrix} \in \mathbf{L}^{4/3}(\Omega) \subset \hat{Z}\,,$$

and

$$\big(\mathcal{F}''(\boldsymbol{\psi}) \cdot \boldsymbol{\zeta}\big) \cdot \boldsymbol{\eta} = \begin{pmatrix} \eta_1\zeta_1 \\ \eta_2\zeta_2 \end{pmatrix} \in \mathbf{L}^{4/3}(\Omega) \subset \hat{Z}\,.$$

These relations verify (H18).

From the definition of the operator K we see that K maps $\mathbf{L}^2(\Gamma)$ into $[\mathbf{H}^{1/2+\epsilon}(\Omega)]^*$, i.e., K maps G into Z. Thus (H19) is verified.

Hence, we are now in a position to apply Theorem 3.5 to derive error estimates for the approximate solutions of the optimality system (4.29)-(4.30), (4.36)-(4.37), and (4.39). It should be noted that Lemma 3.4 implies that for almost all values of λ, the solutions of the optimality system are regular.

THEOREM 4.7. *Assume that Λ is a compact interval of $\mathbb{R}_+$ and that there exists a branch $\{(\lambda, \boldsymbol{\psi}(\lambda), \mathbf{g}(\lambda), \boldsymbol{\eta}(\lambda)) : \lambda \in \Lambda\}$ of regular solutions of the optimality system* (4.29)-(4.30), (4.36)-(4.37), *and* (4.39). *Assume that the finite-element spaces X^h and G^h satisfy the hypotheses* (4.42)-(4.43). *Then there exist a $\delta > 0$ and an $h_0 > 0$ such that for $h \le h_0$, the discrete optimality system* (4.44)-(4.48) *has a unique branch of solutions $\{\big(\lambda, \boldsymbol{\psi}^h(\lambda), g^h(\lambda), \boldsymbol{\eta}^h(\lambda)\big) : \lambda \in \Lambda\}$ satisfying*

$$\{\|\boldsymbol{\psi}^h(\lambda) - \boldsymbol{\psi}(\lambda)\|_1 + \|\mathbf{g}^h(\lambda) - \mathbf{g}(\lambda)\|_{0,\Gamma} + \|\boldsymbol{\eta}^h(\lambda) - \boldsymbol{\eta}(\lambda)\|_1\} < \delta \quad \forall\, \lambda \in \Lambda.$$

Moreover,

$$\lim_{h\to 0}\{\|\boldsymbol{\psi}^h(\lambda) - \boldsymbol{\psi}(\lambda)\|_1 + \|\mathbf{g}^h(\lambda) - \mathbf{g}(\lambda)\|_{0,\Gamma} + \|\boldsymbol{\eta}^h(\lambda) - \boldsymbol{\eta}(\lambda)\|_1\} = 0\,,$$

uniformly in $\lambda \in \Lambda$.

If, in addition, the solution of the optimality system satisfies $\big(\boldsymbol{\psi}(\lambda), \mathbf{g}(\lambda), \boldsymbol{\eta}(\lambda)\big) \in \mathbf{H}^{m+1}(\Omega) \times \mathbf{H}^{m+1/2}(\Omega)|_\Gamma \times \mathbf{H}^{m+1}(\Omega)$ for $\lambda \in \Lambda$, then there exists a constant C, independent of h, such that

$$\begin{aligned} &\|\boldsymbol{\psi}(\lambda) - \boldsymbol{\psi}^h(\lambda)\|_1 + \|\mathbf{g}(\lambda) - \mathbf{g}^h(\lambda)\|_{0,\Gamma} + \|\boldsymbol{\eta}(\lambda) - \boldsymbol{\eta}^h(\lambda)\|_1 \\ &\quad \le Ch^m\big(\|\boldsymbol{\psi}(\lambda)\|_{m+1} + \inf_{\mathbf{v}\in\mathbf{H}^{m+1/2}(\Omega),\mathbf{v}|_\Gamma=\mathbf{g}} \|\mathbf{v}\|_{m+1/2} + \|\boldsymbol{\eta}(\lambda)\|_{m+1}\big)\,, \end{aligned}$$

uniformly in $\lambda \in \Lambda$.

Proof. All results follow from Theorem 3.5. For the last result, we also use (3.25) and the estimates (see [11])

$$\|(T^h T^{-1} - I)\boldsymbol{\psi}\|_1 \le Ch^m \|\boldsymbol{\psi}\|_{m+1} \qquad \text{for } \boldsymbol{\psi} \in \mathbf{H}^{m+1}(\Omega),$$
$$\|\big((T^*)^h (T^*)^{-1} - I\big)\boldsymbol{\eta}\|_1 = \|(T^h T^{-1} - I)\boldsymbol{\eta}\|_1 \le Ch^m \|\boldsymbol{\eta}\|_{m+1} \qquad \text{for } \boldsymbol{\eta} \in \mathbf{H}^{m+1}(\Omega),$$

and (see, e.g., [2], [8], and [15])

$$\|(E^h E^{-1} - I)\mathbf{g}\|_{0,\Gamma} \le Ch^m \inf_{\mathbf{v} \in \mathbf{H}^{m+1/2}(\Omega), \mathbf{v}|_\Gamma = \mathbf{g}} \|\mathbf{v}\|_{m+1/2} \qquad \text{for } \mathbf{g} \in \mathbf{H}^{m+1/2}(\Omega)|_\Gamma .$$

In these estimates, the constant C is independent of h, $\boldsymbol{\psi}$, $\mathbf{g}$, $\boldsymbol{\eta}$, and λ. □

Remark. In fact, we obtain from (4.39) that $\mathbf{g} = -\boldsymbol{\eta}|_\Gamma$, which implies

$$\inf_{\mathbf{v} \in \mathbf{H}^{m+1/2}(\Omega), \mathbf{v}|_\Gamma = \mathbf{g}} \|\mathbf{v}\|_{m+1/2} \le \|\boldsymbol{\eta}\|_{m+1/2} \le \|\boldsymbol{\eta}\|_{m+1},$$

so the term $\big(\inf_{\mathbf{v} \in \mathbf{H}^{m+1/2}(\Omega), \mathbf{v}|_\Gamma = \mathbf{g}} \|\mathbf{v}\|_{m+1/2}\big)$ in the right-hand side of the error estimate is redundant. □

Remark. By using (4.39) again, along with (4.48) and the error estimate in Theorem 4.7, we have the following improved error estimate for the approximation of the control $\mathbf{g}$:

$$\|\mathbf{g}(\lambda) - \mathbf{g}^h(\lambda)\|_{1/2,\Gamma} \le C\|\boldsymbol{\eta}(\lambda) - \boldsymbol{\eta}^h(\lambda)\|_1 \le Ch^m \big(\|\boldsymbol{\psi}(\lambda)\|_{m+1} + \|\boldsymbol{\eta}(\lambda)\|_{m+1}\big).$$

Of course, we also use the fact that we have chosen $G^h = (X^h)|_\Gamma \subset H^{1/2}(\Gamma)$. □

4.3. Dirichlet boundary control for the Navier–Stokes equations of incompressible, viscous flow. For this application we will use Dirichlet boundary controls, i.e., control is effected through the data in a Dirichlet boundary condition. Let Ω denote a bounded domain in $\mathbb{R}^d$, $d = 2$ or 3, with a boundary denoted by Γ. Let $\mathbf{u}$ and p denote the velocity and pressure fields in Ω. The Navier–Stokes equations for a viscous, incompressible flow are given by (see, e.g., [13], [14], or [20])

$$-\nu \nabla \cdot \big((\nabla \mathbf{u}) + (\nabla \mathbf{u})^T\big) + (\mathbf{u} \cdot \nabla)\mathbf{u} + \nabla p = \mathbf{f} \quad \text{in } \Omega,$$
$$\nabla \cdot \mathbf{u} = 0 \quad \text{in } \Omega,$$

and

$$\mathbf{u} = \mathbf{b} + \mathbf{g} \quad \text{on } \Gamma,$$

where $\mathbf{f}$ is a given body force, $\mathbf{b}$ and $\mathbf{g}$ are boundary velocity data with $\int_\Gamma \mathbf{b} \cdot \mathbf{n}\, d\Gamma = 0$ and $\int_\Gamma \mathbf{g} \cdot \mathbf{n}\, d\Gamma = 0$, and ν denotes the (constant) kinematic viscosity. We have absorbed the constant density into the pressure and the body force. If the variables in these equations are nondimensionalized, then ν is simply the inverse of the Reynolds number Re.

Setting $\lambda = 1/\nu = Re$ and replacing p with p/λ, $\mathbf{b}$ with $\lambda\mathbf{b}$, and $\mathbf{g}$ with $\lambda\mathbf{g}$, we may write the Navier–Stokes equations in the form

$$-\nabla \cdot \big((\nabla \mathbf{u}) + (\nabla \mathbf{u})^T\big) + \nabla p + \lambda \mathbf{u} \cdot \nabla \mathbf{u} = \lambda \mathbf{f} \quad \text{in } \Omega, \tag{4.49}$$

$$\nabla \cdot \mathbf{u} = 0 \quad \text{in } \Omega, \tag{4.50}$$

and

$$\mathbf{u} = \lambda(\mathbf{b} + \mathbf{g}) \quad \text{on } \Gamma. \tag{4.51}$$

We introduce the subspaces

$$L_0^2(\Omega) = \left\{ p \in L^2(\Omega) \;\middle|\; \int_\Omega p \, d\Omega = 0 \right\}$$

and

$$\mathbf{H}_n^1(\Gamma) = \left\{ \mathbf{g} \in \mathbf{H}^1(\Gamma) \;\middle|\; \int_\Gamma \mathbf{g} \cdot \mathbf{n} \, d\Gamma = 0 \right\}.$$

We also introduce the bilinear forms

$$a(\mathbf{u}, \mathbf{v}) = \frac{1}{2} \int_\Omega \left((\nabla \mathbf{u}) + (\nabla \mathbf{u})^T \right) : \left((\nabla \mathbf{v}) + (\nabla \mathbf{v})^T \right) d\Omega \quad \forall\, \mathbf{u}, \mathbf{v} \in \mathbf{H}^1(\Omega)$$

and

$$b(\mathbf{v}, q) = -\int_\Omega q \, \nabla \cdot \mathbf{v} \, d\Omega \quad \forall\, \mathbf{v} \in \mathbf{H}^1(\Omega) \text{ and } \forall\, p \in L^2(\Omega)$$

and the trilinear form

$$c(\mathbf{u}, \mathbf{v}, \mathbf{w}) = \int_\Omega (\mathbf{u} \cdot \nabla) \mathbf{v} \cdot \mathbf{w} \, d\Omega \quad \forall\, \mathbf{u}, \mathbf{v}, \mathbf{w} \in \mathbf{H}^1(\Omega).$$

These forms are continuous over the spaces of definition indicated above. Moreover, we have the coercivity properties

$$a(\mathbf{v}, \mathbf{v}) \geq C_a \|\mathbf{v}\|_1^2 \quad \forall\, \mathbf{v} \in \mathbf{H}_0^1(\Omega) \tag{4.52}$$

and

$$\sup_{\mathbf{0} \neq \mathbf{v} \in \mathbf{H}_0^1(\Omega)} \frac{b(\mathbf{v}, q)}{\|\mathbf{v}\|_1} \geq C_b \|q\|_0 \quad \forall\, q \in L_0^2(\Omega) \tag{4.53}$$

for some constants C_a and $C_b > 0$. For details concerning the notation employed and/or for (4.52)-(4.53), one may consult [13], [14], and [20].

We recast the Navier-Stokes equations (4.49)-(4.51) into the following particular weak form (see, e.g., [15]). Seek $(\mathbf{u}, p, \mathbf{t}) \in \mathbf{H}^1(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{-1/2}(\Gamma)$ such that

$$a(\mathbf{u}, \mathbf{v}) + b(\mathbf{v}, p) - \langle \mathbf{t}, \mathbf{v} \rangle_\Gamma + \lambda\, c(\mathbf{u}, \mathbf{u}, \mathbf{v}) = \lambda \langle \mathbf{f}, \mathbf{v} \rangle \quad \forall\, \mathbf{v} \in \mathbf{H}^1(\Omega), \tag{4.54}$$

$$b(\mathbf{u}, q) = 0 \quad \forall\, q \in L_0^2(\Omega), \tag{4.55}$$

and

$$\langle \mathbf{s}, \mathbf{u} \rangle_\Gamma - \lambda \langle \mathbf{s}, \mathbf{g} \rangle_\Gamma = \lambda \langle \mathbf{s}, \mathbf{b} \rangle_\Gamma \quad \forall\, \mathbf{s} \in \mathbf{H}^{-1/2}(\Gamma). \tag{4.56}$$

Formally we have

$$\mathbf{t} = \left[-p\mathbf{n} + \left(\nabla \mathbf{u} + (\nabla \mathbf{u})^T \right) \cdot \mathbf{n} \right]_\Gamma,$$

i.e., $\mathbf{t}$ is the stress force on the boundary. The existence of a solution $(\mathbf{u}, p, \mathbf{t})$ for the system (4.54)-(4.56) was established in [15].

Given a desired velocity field $\mathbf{u}_0$, we define for any $(\mathbf{u}, p, \mathbf{t}) \in \mathbf{H}^1(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{-1/2}(\Gamma)$ and $\mathbf{g} \in \mathbf{H}_n^1(\Gamma)$ the functional

$$\mathcal{J}(\mathbf{u}, p, \mathbf{t}, \mathbf{g}) = \frac{\lambda}{4} \int_\Omega |\mathbf{u} - \mathbf{u}_0|^4 \, d\Omega + \frac{\lambda}{2} \int_\Gamma \left(|\nabla_s \mathbf{g}|^2 + |\mathbf{g}|^2 \right) d\Gamma, \tag{4.57}$$

where ∇_s denotes the surface gradient.

We define the spaces $X = \mathbf{H}^1(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{-1/2}(\Gamma)$, $Y = [\mathbf{H}^1(\Omega)]^* \times L_0^2(\Omega) \times \mathbf{H}^{1/2}(\Gamma)$, $G = \mathbf{H}_n^1(\Gamma)$, and $Z = \mathbf{L}^{3/2}(\Omega) \times \{0\} \times \mathbf{H}^1(\Gamma)$. By compact imbedding results, Z is compactly imbedded into Y. For the time being, we assume that the admissible set Θ for the control $\mathbf{g}$ is a closed, convex subset of $G = \mathbf{H}_n^1(\Gamma)$.

We then consider the following optimal control problem associated with the Navier-Stokes equations:

$$\min\{\mathcal{J}(\mathbf{u}, p, \mathbf{t}, \mathbf{g}) : (\mathbf{u}, p, \mathbf{t}) \in X, \mathbf{g} \in \Theta\} \quad \text{subject to} \quad (4.54)\text{-}(4.56). \tag{4.58}$$

We define the continuous linear operator $T \in \mathcal{L}(Y; X)$ as follows. For each $(\boldsymbol{\zeta}, \eta, \boldsymbol{\kappa}) \in Y$, $T(\boldsymbol{\zeta}, \eta, \boldsymbol{\kappa}) = (\tilde{\mathbf{u}}, \tilde{p}, \tilde{\mathbf{t}}) \in X$ is the unique solution of

$$a(\tilde{\mathbf{u}}, \mathbf{v}) + b(\mathbf{v}, \tilde{p}) - \langle \tilde{\mathbf{t}}, \mathbf{v} \rangle_\Gamma = \langle \boldsymbol{\zeta}, \mathbf{v} \rangle \quad \forall\, \mathbf{v} \in \mathbf{H}^1(\Omega),$$

$$b(\tilde{\mathbf{u}}, q) = (\eta, q) \quad \forall\, q \in L_0^2(\Omega),$$

and

$$\langle \mathbf{s}, \tilde{\mathbf{u}} \rangle_\Gamma = \langle \mathbf{s}, \boldsymbol{\kappa} \rangle_\Gamma \quad \forall\, \mathbf{s} \in \mathbf{H}^{-1/2}(\Gamma).$$

It can be easily verified that T is self-adjoint.

We define the (differentiable) nonlinear mapping $N : X \to Y$ by

$$N(\mathbf{u}, p, \mathbf{t}) = -\begin{pmatrix} \mathbf{f} - \mathbf{u} \cdot \nabla \mathbf{u} \\ 0 \\ \mathbf{b} \end{pmatrix}$$

or, equivalently,

$$\langle N(\mathbf{u}, p, \mathbf{t}), (\mathbf{v}, q, \mathbf{s}) \rangle = -(\mathbf{f}, \mathbf{v}) + c(\mathbf{u}, \mathbf{u}, \mathbf{v}) - \langle \mathbf{s}, \mathbf{b} \rangle_\Gamma \quad \forall\, (\mathbf{v}, q, \mathbf{s}) \in X$$

and define $K : \mathbf{H}^{1/2}(\Gamma) \to Y$ by

$$K\mathbf{g} = -\begin{pmatrix} 0 \\ 0 \\ \mathbf{g} \end{pmatrix}$$

or, equivalently,

$$\langle K\mathbf{g}, (\mathbf{v}, q, \mathbf{s}) \rangle = -\langle \mathbf{s}, \mathbf{g} \rangle_\Gamma \quad \forall\, \mathbf{g} \in \mathbf{H}^{1/2}(\Gamma), \forall\, (\mathbf{v}, q, \mathbf{s}) \in X.$$

Clearly, the constraint equations (4.54)-(4.56) can be expressed as

$$(\mathbf{u}, p, \mathbf{t}) + \lambda T N(\mathbf{u}, p, \mathbf{t}) + \lambda T K \mathbf{g} = 0,$$

i.e., in the form (2.2). With the obvious definitions for $\mathcal{F}(\cdot)$ and $\mathcal{E}(\cdot)$, i.e.,

$$\mathcal{F}(\mathbf{u}, p, \mathbf{t}) = \frac{1}{4} \int_\Omega |\mathbf{u} - \mathbf{u}_0|^4 \, d\Omega \quad \forall\, (\mathbf{u}, p, \mathbf{t}) \in X$$

and

$$\mathcal{E}(\mathbf{g}) = \frac{1}{2} \int_\Gamma \left(|\nabla_s \mathbf{g}|^2 + |\mathbf{g}|^2 \right) d\Gamma,$$

the functional (4.57) can be expressed as

$$\mathcal{J}(\mathbf{u}, p, \mathbf{t}, \mathbf{g}) = \lambda \mathcal{F}(\mathbf{u}, p, \mathbf{t}) + \lambda \mathcal{E}(\mathbf{g}),$$

i.e., in the form (2.3).

We are now in a position to verify, for the minimization problem (4.58), all the hypotheses of §§2 and 3.

4.3.1. Verification of the hypotheses for the existence of optimal solutions. We first verify the that the hypotheses (H1)-(H6) hold in the current setting.

(H1) is obviously satisfied with a lower bound 0.

(H2) holds with $\alpha = 1$ and $\beta = 2$.

(H3) is verified with the choice $(\mathbf{u}^{(0)}, p^{(0)}, \mathbf{t}^{(0)}, \mathbf{0}) \in X \times \Theta$ where $(\mathbf{u}^{(0)}, p^{(0)})$ is a solution to the Navier-Stokes equations with Dirichlet boundary conditions, and $\mathbf{t}^{(0)} = [-p^{(0)}\mathbf{n} + (\nabla \mathbf{u}^{(0)} + (\nabla \mathbf{u}^{(0)})^T) \cdot \mathbf{n}]_\Gamma$; see, e.g., [13] or [20].

In order to verify (H4), we assume $\{\mathbf{g}^{(n)}\} \subset \Theta \subset \mathbf{H}_n^1(\Gamma)$ is a sequence satisfying $\mathbf{g}^{(n)} \rightharpoonup \mathbf{g}$ in $\mathbf{H}^1(\Gamma)$; then we have $\mathbf{g}^{(n)} \rightharpoonup \mathbf{g}$ in $\mathbf{H}^{1/2}(\Gamma)$, so $\lim_{n\to\infty} \langle \mathbf{g}^{(n)}, \mathbf{v}\rangle_\Gamma = \langle \mathbf{g}, \mathbf{v}\rangle_\Gamma$ for all $\mathbf{v} \in \mathbf{H}^1(\Omega)$, i.e., $K\mathbf{g}^{(n)} \rightharpoonup K\mathbf{g}$ in Y. Assume that the sequence $\{\mathbf{u}^{(n)}\} \subset \mathbf{H}^1(\Omega)$ satisfies $\mathbf{u}^{(n)} \rightharpoonup \mathbf{u}$ in $\mathbf{H}^1(\Omega)$; then $\mathbf{u}^{(n)} \to \mathbf{u}$ in $\mathbf{L}^4(\Omega)$ by the compactness of the imbedding $\mathbf{H}^1(\Omega) \hookrightarrow\hookrightarrow \mathbf{L}^4(\Omega)$. Now,

$$\begin{aligned}\langle N(\mathbf{u}^{(n)}), \mathbf{v}\rangle &= c(\mathbf{u}^{(n)}, \mathbf{u}^{(n)}, \mathbf{v}) = c(\mathbf{u}, \mathbf{u}^{(n)}, \mathbf{v}) + c(\mathbf{u}^{(n)} - \mathbf{u}, \mathbf{u}^{(n)}, \mathbf{v}) \\ &\to c(\mathbf{u}, \mathbf{u}, \mathbf{v}) + 0 = \langle N(\mathbf{u}), \mathbf{v}\rangle \qquad \text{as } n \to \infty .\end{aligned}$$

Hence, (H4) is verified.

The verification of (H5) follows directly from the observation that the mappings $(\mathbf{u}, p, \mathbf{t}) \mapsto \mathcal{F}(\mathbf{u}, p, \mathbf{t}) = (1/4)\,\|\mathbf{u} - \mathbf{u}\|^4_{\mathbf{L}^4(\Omega)}$ and $\mathbf{g} \mapsto \mathcal{E}(\mathbf{g}) = (1/2)\,\|\mathbf{g}\|^2_{1,\Gamma}$ are convex.

To verify (H6), we combine a priori estimates obtained from the constraint equations and the functional. Let $\{\mathbf{u}^{(k)}, p^{(k)}, \mathbf{t}^{(k)}, \mathbf{g}^{(k)}\} \subset \mathbf{H}^1(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{-1/2}(\Gamma) \times \mathbf{H}_n^1(\Gamma)$ be a sequence such that

$$\mathcal{J}(\mathbf{u}^{(k)}, \mathbf{g}^{(k)}) \le C , \tag{4.59}$$

$$a(\mathbf{u}^{(k)}, \mathbf{v}) + b(\mathbf{v}, p^{(k)}) - \langle \mathbf{t}^{(k)}, \mathbf{v}\rangle_\Gamma + \lambda\, c(\mathbf{u}^{(k)}, \mathbf{u}^{(k)}, \mathbf{v}) = \lambda\, \langle \mathbf{f}, \mathbf{v}\rangle \quad \forall\, \mathbf{v} \in \mathbf{H}^1(\Omega) , \tag{4.60}$$

$$b(\mathbf{u}^{(k)}, q) = 0 \quad \forall\, q \in L_0^2(\Omega) , \tag{4.61}$$

and

$$\langle \mathbf{s}, \mathbf{u}^{(k)}\rangle_\Gamma - \lambda \langle \mathbf{s}, \mathbf{g}^{(k)}\rangle_\Gamma = \lambda \langle \mathbf{s}, \mathbf{b}\rangle_\Gamma \quad \forall\, \mathbf{s} \in \mathbf{H}^{-1/2}(\Gamma) . \tag{4.62}$$

First, (4.59) implies that $(\mathbf{u}^{(k)}, \mathbf{g}^{(k)})$ is uniformly bounded in $\mathbf{L}^4(\Omega) \times \mathbf{H}^1(\Gamma)$. For each $\mathbf{g}^{(k)}$, we may choose a $(\mathbf{w}^{(k)}, r^{(k)}) \in \mathbf{H}^1(\Omega) \times L_0^2(\Omega)$ that satisfies the Stokes problem

$$a(\mathbf{w}^{(k)}, \mathbf{v}) + b(\mathbf{v}, r^{(k)}) = \langle \mathbf{f}, \mathbf{v}\rangle \quad \forall\, \mathbf{v} \in \mathbf{H}_0^1(\Omega) , \tag{4.63}$$

$$b(\mathbf{w}^{(k)}, q) = 0 \quad \forall\, q \in L_0^2(\Omega), \tag{4.64}$$

and

$$\mathbf{w}^{(k)} = \lambda(\mathbf{g}^{(k)} + \mathbf{b}) \quad \text{on } \Gamma . \tag{4.65}$$

Furthermore, the estimate

$$\|\mathbf{w}^{(k)}\|_1 \le C(\|\mathbf{f}\|_0 + \|\mathbf{b}\|_{1/2,\Gamma} + \|\mathbf{g}^{(k)}\|_{1,\Gamma}) \tag{4.66}$$

holds. By subtracting (4.63) from (4.60) with $\mathbf{v} = \mathbf{u}^{(k)} - \mathbf{w}^{(k)}$, also using (4.61) and (4.64), we obtain

$$\begin{aligned}a(\mathbf{u}^{(k)} - \mathbf{w}^{(k)}, \mathbf{u}^{(k)} - \mathbf{w}^{(k)}) &= -\lambda\, c(\mathbf{u}^{(k)}, \mathbf{u}^{(k)}, \mathbf{u}^{(k)} - \mathbf{w}^{(k)}) \\ &= \lambda\, c(\mathbf{u}^{(k)}, \mathbf{u}^{(k)} - \mathbf{w}^{(k)}, \mathbf{u}^{(k)}) .\end{aligned} \tag{4.67}$$

Note that

$$
\begin{aligned}
&|c(\mathbf{u}^{(k)}, \mathbf{u}^{(k)} - \mathbf{w}^{(k)}, \mathbf{u}^{(k)})| \\
&= \frac{1}{2}\left|\int_\Omega \mathbf{u}^{(k)} \cdot \left((\nabla(\mathbf{u}^{(k)} - \mathbf{w}^{(k)})) + (\nabla(\mathbf{u}^{(k)} - \mathbf{w}^{(k)}))^T\right) \cdot \mathbf{u}^{(k)}\, d\Omega\right| \\
&\le C \left\|(\nabla(\mathbf{u}^{(k)} - \mathbf{w}^{(k)})) + (\nabla(\mathbf{u}^{(k)} - \mathbf{w}^{(k)}))^T\right\|_0 \left\|\mathbf{u}^{(k)}\right\|_{\mathbf{L}^4(\Omega)} \\
&\le \frac{1}{4\lambda} \left\|(\nabla(\mathbf{u}^{(k)} - \mathbf{w}^{(k)})) + (\nabla(\mathbf{u}^{(k)} - \mathbf{w}^{(k)}))^T\right\|_0^2 + C_\lambda \left\|\mathbf{u}^{(k)}\right\|_{\mathbf{L}^4(\Omega)}^4
\end{aligned}
$$

so that, using (4.67), we have that

$$
\frac{1}{4}\left\|\left(\nabla(\mathbf{u}^{(k)} - \mathbf{w}^{(k)})\right) + \left(\nabla(\mathbf{u}^{(k)} - \mathbf{w}^{(k)})\right)^T\right\|_0^2 \le C_\lambda \left\|\mathbf{u}^{(k)}\right\|_{\mathbf{L}^4(\Omega)}^4 .
$$

Then, by (4.66) and the triangle inequality, we have that

$$
\left\|(\nabla \mathbf{u}^{(k)}) + (\nabla \mathbf{u}^{(k)})^T\right\|_0 \le C\{\|\mathbf{f}\|_0 + \|\mathbf{b}\|_{1/2,\Gamma} + \|\mathbf{g}^{(k)}\|_{1,\Gamma} + \|\mathbf{u}^{(k)}\|_{\mathbf{L}^4(\Omega)}^2\} .
$$

Thus,

$$
\begin{aligned}
&\|(\nabla \mathbf{u}^{(k)}) + (\nabla \mathbf{u}^{(k)})^T\|_0 + \|\mathbf{u}^{(k)}\|_{0,\Gamma} \\
&\le \|(\nabla \mathbf{u}^{(k)}) + (\nabla \mathbf{u}^{(k)})^T\|_0 + \|\mathbf{b}\|_{0,\Gamma} + \|\mathbf{g}^{(k)}\|_{0,\Gamma} \\
&\le C(\|\mathbf{f}\|_0 + \|\mathbf{b}\|_{1/2,\Gamma} + \|\mathbf{g}^{(k)}\|_{1,\Gamma} + \|\mathbf{u}^{(k)}\|_{\mathbf{L}^4(\Omega)}^2) .
\end{aligned}
$$

Since the mapping $\mathbf{u} \mapsto \|\nabla \mathbf{u} + (\nabla \mathbf{u})^T\|_0 + \|\mathbf{u}\|_{0,\Gamma}$ defines a norm on $\mathbf{H}^1(\Omega)$ equivalent to the standard $\mathbf{H}^1(\Omega)$-norm, we have that

$$
\|\mathbf{u}^{(k)}\|_1 \le C\{\|\mathbf{f}\|_0 + \|\mathbf{b}\|_{1/2,\Gamma} + \|\mathbf{g}^{(k)}\|_{1,\Gamma} + \|\mathbf{u}^{(k)}\|_{\mathbf{L}^4(\Omega)}^2\} ;
$$

since $\|\mathbf{u}^{(k)}\|_{\mathbf{L}^4(\Omega)}$ and $\|\mathbf{g}^{(k)}\|_{1,\Gamma}$ are uniformly bounded, we conclude that $\|\mathbf{u}^{(k)}\|_1$ is uniformly bounded as well. One easily concludes from (4.60) that $\|\mathbf{t}^{(k)}\|_{-1/2,\Gamma}$ is uniformly bounded. Thus (H6) is verified.

It is now just a matter of citing Theorem 2.1 to conclude the existence of an optimal solution that minimizes (4.57) subject to (4.54)–(4.56).

THEOREM 4.8. *There exists a* $(\mathbf{u}, p, \mathbf{t}, \mathbf{g}) \in \mathbf{H}^1(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{-1/2}(\Omega) \times \Theta$ *such that* (4.57) *is minimized subject to* (4.54)–(4.56). □

4.3.2. Verification of the hypotheses for the existence of Lagrange multipliers. We now assume $(\mathbf{u}, p, \mathbf{t}, \mathbf{g})$ is an optimal solution and turn to the verification of hypotheses (H7)–(H9).

The validity of (H7) is obvious.

(H8) holds since the mapping $\mathbf{z} \mapsto \mathcal{E}(\mathbf{g}) = (1/2)\int_\Gamma \left(|\nabla_s \mathbf{g}|^2 + |\mathbf{g}|^2\right) d\Gamma$ is convex.

(H9) can be verified as follows. For any $(\mathbf{u}, p, \mathbf{t}) \in X$, the operator $N'(\mathbf{u}, p, \mathbf{t}) : X \to Y$ is given by

$$
N'(\mathbf{u}, p, \mathbf{t}) \cdot (\mathbf{v}, q, \mathbf{s}) = -\begin{pmatrix} \mathbf{u} \cdot \nabla \mathbf{v} + \mathbf{v} \cdot \nabla \mathbf{u} \\ 0 \\ \mathbf{0} \end{pmatrix}
$$

for all $(\mathbf{v}, q, \mathbf{s}) \in \mathbf{H}^1(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{-1/2}(\Gamma)$. Thus we obtain $N'(\mathbf{u}, p, \mathbf{t}) \cdot (\mathbf{v}, q, \mathbf{s}) \in \mathbf{L}^{3/2}(\Omega) \times \{0\} \times \mathbf{H}^1(\Gamma) = Z$.

The Lagrangian is given by

$$\begin{aligned}\mathcal{L}(\mathbf{u}, p, \mathbf{t}, \mathbf{g}, \boldsymbol{\nu}, \phi, \boldsymbol{\tau}, k) &= k\,\mathcal{J}(\mathbf{u}, \mathbf{g}) - \{a(\mathbf{u}, \boldsymbol{\nu}) + \lambda\, c(\mathbf{u}, \mathbf{u}, \boldsymbol{\nu}) + b(\boldsymbol{\nu}, p) + b(\mathbf{u}, \phi) - \langle \boldsymbol{\tau}, \mathbf{u}\rangle_\Gamma \\ &\qquad - \langle \mathbf{t}, \boldsymbol{\nu}\rangle_\Gamma - \lambda\,\langle \mathbf{f}, \boldsymbol{\nu}\rangle_\Gamma + \lambda\,\langle \boldsymbol{\tau}, \mathbf{b}\rangle_\Gamma + \lambda\,\langle \boldsymbol{\tau}, \mathbf{g}\rangle_\Gamma\}\end{aligned}$$

for all $(\mathbf{u}, p, \mathbf{t}, \mathbf{g}, \boldsymbol{\nu}, \phi, \boldsymbol{\tau}, k) \in X \times G \times X \times \mathbb{R} = \mathbf{H}^1(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{-1/2}(\Gamma) \times \mathbf{H}_n^1(\Gamma) \times \mathbf{H}^1(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{-1/2}(\Gamma) \times \mathbb{R}$. Note that in this form of the Lagrangian, the Lagrange multiplier $(\boldsymbol{\nu}, \phi, \boldsymbol{\tau}) \in X = Y^*$, so we have already introduced the change of variables indicated between (2.17)-(2.18) and (2.19)-(2.21).

Having verified the hypotheses (H7)-(H9), we may apply Theorem 2.4 to conclude that there exist a Lagrange multiplier $(\boldsymbol{\nu}, \phi, \boldsymbol{\tau}) \in X = \mathbf{H}^1(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{-1/2}(\Gamma)$ and a real number k such that

$$(\boldsymbol{\nu}, \phi, \boldsymbol{\tau}) + \lambda\, T^*\Big([N'(\mathbf{u}, p, \mathbf{t})]^* \cdot (\boldsymbol{\nu}, \phi, \boldsymbol{\tau}) - k\,\mathcal{F}'(\mathbf{u}, p, \mathbf{t})\Big) = 0 \tag{4.68}$$

and

$$\mathcal{L}(\mathbf{u}, p, \mathbf{t}, \mathbf{z}, \boldsymbol{\nu}, \phi, \boldsymbol{\tau}, k) \le \mathcal{L}(\mathbf{u}, p, \mathbf{t}, \mathbf{g}, \boldsymbol{\nu}, \phi, \boldsymbol{\tau}, k) \quad \forall\, \mathbf{z} \in \Theta \tag{4.69}$$

and that for almost all values of λ, we may choose $k = 1$.

Recall that $T^* = T$. Also, note that for $(\mathbf{u}, p, \mathbf{t}) \in X = \mathbf{H}^1(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{-1/2}(\Gamma)$, the operator $[N'(\mathbf{u}, p, \mathbf{t})]^* : X \to Y$ is given by

$$[N'(\mathbf{u}, p, \mathbf{t})]^* \cdot (\mathbf{v}, q, \mathbf{s}) = \begin{pmatrix} -\mathbf{u} \cdot \nabla \mathbf{v} + \mathbf{v} \cdot (\nabla \mathbf{u})^T \\ 0 \\ \mathbf{0} \end{pmatrix} \quad \forall\, (\mathbf{v}, q, \mathbf{s}) \in X.$$

Thus, (4.68), with $k = 1$, can be rewritten as

$$\begin{aligned} &a(\mathbf{w}, \boldsymbol{\nu}) + \lambda\, c(\mathbf{w}, \mathbf{u}, \boldsymbol{\nu}) + \lambda\, c(\mathbf{u}, \mathbf{w}, \boldsymbol{\nu}) + b(\mathbf{w}, \phi) - \langle \boldsymbol{\tau}, \mathbf{w}\rangle_\Gamma \\ &\qquad = \lambda\,\big((\mathbf{u} - \mathbf{u}_0)^3, \mathbf{w}\big) \quad \forall\, \mathbf{w} \in \mathbf{H}^1(\Omega)\,, \end{aligned} \tag{4.70}$$

$$b(\boldsymbol{\nu}, r) = 0 \quad \forall\, r \in L_0^2(\Omega)\,, \tag{4.71}$$

and

$$\langle \mathbf{y}, \boldsymbol{\nu}\rangle_\Gamma = 0 \quad \forall\, \mathbf{y} \in \mathbf{H}^{-1/2}(\Gamma)\,. \tag{4.72}$$

In the right-hand side of (4.70), we use the notation $(\mathbf{v}^3, \mathbf{w}) = \sum_{j=1}^d (v_j^3, w_j)$.

Using the definition of the Lagrangian functional, (4.69), with $k = 1$, can be rewritten as

$$\begin{aligned} &\frac{\lambda}{2}\,(\nabla_{\mathrm{s}}\mathbf{z}, \nabla_{\mathrm{s}}\mathbf{z})_\Gamma + \frac{\lambda}{2}\,(\mathbf{z}, \mathbf{z})_\Gamma - \frac{\lambda}{2}\,(\nabla_{\mathrm{s}}\mathbf{g}, \nabla_{\mathrm{s}}\mathbf{g})_\Gamma \\ &\qquad - \frac{\lambda}{2}\,(\mathbf{g}, \mathbf{g})_\Gamma - \lambda\langle \boldsymbol{\tau}, \mathbf{z}\rangle_\Gamma + \lambda\langle \boldsymbol{\tau}, \mathbf{g}\rangle_\Gamma \ge 0 \quad \forall\, \mathbf{z} \in \Theta\,. \end{aligned}$$

For each $\epsilon \in (0, 1)$ and each $\mathbf{z} \in \Theta$, by plugging $\epsilon\mathbf{z} + (1 - \epsilon)\mathbf{g} \in \Theta$ into the last inequality we obtain

$$\begin{aligned} &\epsilon\,\big(\nabla_{\mathrm{s}}\mathbf{g}, \nabla_{\mathrm{s}}(\mathbf{z} - \mathbf{g})\big)_\Gamma + \epsilon\,(\mathbf{g}, \mathbf{z} - \mathbf{g})_\Gamma + \frac{\epsilon^2}{2}\,\big(\nabla_{\mathrm{s}}(\mathbf{z} - \mathbf{g}), \nabla_{\mathrm{s}}(\mathbf{z} - \mathbf{g})\big)_\Gamma \\ &\qquad + \frac{\epsilon^2}{2}\,(\mathbf{z} - \mathbf{g}, \mathbf{z} - \mathbf{g})_\Gamma - \epsilon\langle \boldsymbol{\tau}, \mathbf{z} - \mathbf{g}\rangle_\Gamma \ge 0 \quad \forall\, \mathbf{z} \in \Theta\,; \end{aligned}$$

hence, after dividing by $\epsilon > 0$ and then letting $\epsilon \to 0^+$, we obtain

$$(4.73) \qquad \big(\nabla_s \mathbf{g}, \nabla_s(\mathbf{z}-\mathbf{g})\big)_\Gamma + (\mathbf{g}, \mathbf{z}-\mathbf{g})_\Gamma - \langle \boldsymbol{\tau}, \mathbf{z}\rangle_\Gamma \geq 0 \quad \forall\, \mathbf{z} \in \Theta\,.$$

We see that for almost all values of λ, necessary conditions for an optimum are that (4.54)-(4.56), (4.70)-(4.72) and (4.73) are satisfied. Again, the system formed by these equations will be called an *optimality system*.

We now specialize to the case $\Theta = \mathbf{H}_n^1(\Gamma)$. Note that hypothesis (H10) is satisfied. Then using Theorem 2.5, we see that inequality (4.73) becomes an equality, and by letting $\mathbf{z} = \mathbf{k} - \mathbf{g}$ vary arbitrarily in $\mathbf{H}_n^1(\Gamma)$, we now have, instead of (4.73),

$$(4.74) \qquad (\nabla_s \mathbf{g}, \nabla_s \mathbf{z})_\Gamma + (\mathbf{g}, \mathbf{z})_\Gamma - \langle \boldsymbol{\tau}, \mathbf{z}\rangle_\Gamma = 0 \quad \forall\, \mathbf{z} \in \Theta = \mathbf{H}_n^1(\Gamma)\,.$$

Thus, according to that theorem, we have that for almost all λ, an optimality system of equations is now given by (4.54)-(4.56), (4.70)-(4.72) and (4.74). However, we can go further and verify that hypothesis (H11) is valid, which in turn will justify the existence of a Lagrange multiplier satisfying the optimality system for *all* $\lambda \in \Lambda$.

We now verify (H11), which we again note can be equivalently stated as follows.

$$\text{If } \xi \in Y^* \text{ satisfies } \big(I + \lambda\, T^*[N'(u)]^*\big)\xi = 0 \text{ and } K^*\xi = 0, \text{ then } \xi = 0\,.$$

To verify this hypothesis, we assume that $(\boldsymbol{\xi}, \sigma, \boldsymbol{\theta}) \in Y^* = \mathbf{H}^1(\Omega) \times L^2(\Omega) \times \mathbf{H}^{-1/2}(\Gamma)$ satisfies $\big(I + \lambda\, T^*[N'(\mathbf{u}, p, \mathbf{t})]^*\big)(\boldsymbol{\xi}, \sigma, \boldsymbol{\theta}) = (\mathbf{0}, 0, \mathbf{0})$ and $K^*(\boldsymbol{\xi}, \sigma, \boldsymbol{\theta}) = \mathbf{0}$, i.e.,

$$a(\mathbf{w}, \boldsymbol{\xi}) + \lambda\, c(\mathbf{w}, \mathbf{u}, \boldsymbol{\xi}) + \lambda\, c(\mathbf{u}, \mathbf{w}, \boldsymbol{\xi}) + b(\mathbf{w}, \sigma) - \langle \boldsymbol{\theta}, \mathbf{w}\rangle_\Gamma = 0 \quad \forall\, \mathbf{w} \in \mathbf{H}^1(\Omega)\,,$$

$$b(\boldsymbol{\xi}, r) = 0 \quad \forall\, r \in L_0^2(\Omega)\,,$$

$$\langle \mathbf{y}, \boldsymbol{\xi}\rangle_\Gamma = 0 \quad \forall\, \mathbf{y} \in \mathbf{H}^{-1/2}(\Gamma)\,,$$

and

$$\boldsymbol{\theta} = \mathbf{0} \quad \text{on } \Gamma\,.$$

(Note that $K^*(\boldsymbol{\xi}, \sigma, \boldsymbol{\theta}) = \boldsymbol{\theta}$.) Let Ω' be a smooth extension of Ω such that $\overline{\Omega}$ is a compact subset of Ω'. We then set $\boldsymbol{\xi}'$, σ', and $\mathbf{u}'$ to be the extension, by zero outside Ω, of $\boldsymbol{\xi}$, σ, and $\mathbf{u}$, respectively. We may show from the last four equations that

$$\boldsymbol{\xi}' \in \mathbf{H}^1(\Omega')\,, \qquad \sigma' \in L_0^2(\Omega')\,,$$

$$(4.75) \qquad a'(\mathbf{w}, \boldsymbol{\xi}') + \lambda\, c'(\mathbf{w}, \mathbf{u}', \boldsymbol{\xi}') + \lambda\, c'(\mathbf{u}', \mathbf{w}, \boldsymbol{\xi}') + b'(\mathbf{w}, \sigma') = 0 \quad \forall\, \mathbf{w} \in \mathbf{H}_0^1(\Omega')\,,$$

and

$$(4.76) \qquad b'(\boldsymbol{\xi}', r) = 0 \quad \forall\, r \in L_0^2(\Omega')\,,$$

where the forms $a'(\cdot,\cdot)$, $b'(\cdot,\cdot)$, and $c'(\cdot,\cdot,\cdot)$ defined over Ω' are the analogues of corresponding forms defined over Ω. Using a unique continuation result for the system (4.75)-(4.76) that was established in [16] or [17], we obtain $\boldsymbol{\xi}' = \mathbf{0}$ and $\sigma' = 0$ in Ω', or $\boldsymbol{\xi} = \mathbf{0}$ and $\sigma = 0$ in Ω. Thus (H11) is verified.

Hence we conclude that for *all* λ, the optimality system (4.54)-(4.56), (4.70)-(4.72), and (4.74) has a solution. Thus, we have Theorem 2.6, which, in the present context, is given as follows.

THEOREM 4.9. *Let* $(\mathbf{u}, p, \mathbf{t}, \mathbf{g}) \in \mathbf{H}^1(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{-1/2}(\Gamma) \times \mathbf{H}_n^1(\Gamma)$ *denote an optimal solution that minimizes* (4.57) *subject to* (4.54)-(4.56). *Then, for all* $\lambda \in \Lambda$, *there exists a*

nonzero Lagrange multiplier $(\boldsymbol{\nu}, \phi, \boldsymbol{\tau}) \in \mathbf{H}^1(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{-1/2}(\Gamma)$ *satisfying the Euler equations* (4.70)–(4.72) *and* (4.74). □

Note that, in the above expression, we have already employed hypothesis (H12), which in the current context is easily seen to be satisfied with $E : G \to G^*$ defined by

$$\langle E\mathbf{g}, \mathbf{z}\rangle = \int_\Gamma (\nabla_s \mathbf{g} \cdot \nabla_s \mathbf{z} + \mathbf{g} \cdot \mathbf{z})\, d\Gamma \quad \forall\, \mathbf{z} \in \mathbf{H}_n^1(\Gamma) = G\,.$$

We also note that for each fixed $\boldsymbol{\tau}$, (4.74), with $\mathbf{g} \in \mathbf{H}_n^1(\Gamma)$, is equivalent to

$$(\nabla_s \mathbf{g}, \nabla_s \mathbf{k})_\Gamma + (\mathbf{g}, \mathbf{k})_\Gamma + \gamma \int_\Gamma \mathbf{k} \cdot \mathbf{n}\, d\Gamma = \langle \boldsymbol{\tau}, \mathbf{k}\rangle_\Gamma \quad \forall\, \mathbf{k} \in \mathbf{H}^1(\Gamma) \tag{4.77}$$

and

$$\int_\Gamma \mathbf{g} \cdot \mathbf{n}\, d\Gamma = 0\,, \tag{4.78}$$

where $\gamma \in \mathbb{R}$ is an additional unknown constant that accounts for the single integral constraint of (4.78). The equivalence can be shown as follows. First, an application of the Lax–Milgram Lemma to (4.74) on the space $\mathbf{H}_n^1(\Gamma)$ guarantees the existence and uniqueness of a solution $\mathbf{g} \in \mathbf{H}_n^1(\Gamma)$ to (4.74); this solution $\mathbf{g}$ clearly satisfies (4.77)–(4.78) with $\gamma = \int_\Gamma \big(\boldsymbol{\tau} \cdot \mathbf{n} - \nabla_s \mathbf{g} : \nabla_s \mathbf{n} - \mathbf{g} \cdot \mathbf{n}\big)\, d\Gamma$. Conversely, any solution $(\mathbf{g}, \gamma)$ of (4.77)–(4.78) trivially satisfies (4.74). Although (4.74) and (4.77)–(4.78) are equivalent, the latter is more easily discretized.

4.3.3. Verification of the hypotheses for approximations and error estimates. We finally verify hypotheses (H13)–(H19) that are used in connection with approximations and error estimates.

A finite-element discretization of the optimality system (4.54)–(4.56), (4.70)–(4.72), and (4.74) is defined as follows. First, one chooses families of finite-dimensional subspaces $\mathbf{V}^h \subset \mathbf{H}^1(\Omega)$ and $S^h \subset L^2(\Omega)$. These families are parameterized by the parameter h that tends to zero; commonly, this parameter is chosen to be some measure of the grid size in a subdivision of Ω into finite elements. We let $S_0^h = S^h \cap L_0^2(\Omega)$ and $\mathbf{V}_0^h = \mathbf{V}^h \cap \mathbf{H}_0^1(\Omega)$.

One may choose any pair of subspaces $\mathbf{V}^h$ and S^h that can be used for finding finite-element approximations of solutions of the Navier–Stokes equations. Thus, concerning these subspaces, we make the following standard assumptions, which are exactly those employed in well-known finite-element methods for the Navier–Stokes equations. First, we have the approximation properties: there exist an integer k and a constant C, independent of h, $\mathbf{v}$, and q, such that

$$\inf_{\mathbf{v}^h \in \mathbf{V}^h} \|\mathbf{v} - \mathbf{v}^h\|_1 \le Ch^m \|\mathbf{v}\|_{m+1} \quad \forall\, \mathbf{v} \in \mathbf{H}^{m+1}(\Omega)\,,\ 1 \le m \le k\,, \tag{4.79}$$

and

$$\inf_{q^h \in S_0^h} \|q - q^h\|_0 \le Ch^m \|q\|_m \quad \forall\, q \in H^m(\Omega) \cap L_0^2(\Omega)\,,\ 1 \le m \le k\,. \tag{4.80}$$

Next, we assume the *inf-sup condition*, or *Ladyzhenskaya–Babuska–Brezzi condition*: there exists a constant C, independent of h, such that

$$\inf_{0 \ne q^h \in S_0^h} \sup_{0 \ne \mathbf{v}^h \in \mathbf{V}^h} \frac{b(\mathbf{v}^h, q^h)}{\|\mathbf{v}^h\|_1\, \|q^h\|_0} \ge C\,. \tag{4.81}$$

This condition ensures the stability of finite-element discretizations of the Navier-Stokes equations. For thorough discussions of the approximation properties (4.79)-(4.80), see, e.g., [2] or [8]; for like discussions of the stability condition (4.81), see, e.g., [13] or [14]. The latter references may also be consulted for a catalogue of finite-element subspaces that meet the requirements of (4.79)-(4.81).

Next, let $\mathbf{P}^h = \mathbf{V}^h|_\Gamma$; i.e., $\mathbf{P}^h$ consists of the restriction, to the boundary Γ, of functions belonging to $\mathbf{V}^h$. For all choices of conforming finite-element spaces $\mathbf{V}^h$, e.g., Lagrange-type finite-element spaces, we have that $\mathbf{P}^h \subset \mathbf{H}^{-1/2}(\Gamma)$. For the subspaces $\mathbf{P}^h = \mathbf{V}^h|_\Gamma$, we can show the following approximation property: there exist an integer k and a constant C, independent of h and $\mathbf{s}$, such that

$$\begin{aligned} &\inf_{\mathbf{s}^h \in \mathbf{P}^h} \|\mathbf{s} - \mathbf{s}^h\|_{-1/2,\Gamma} \\ &\qquad \le C h^m \inf_{\mathbf{v} \in \mathbf{H}^m(\Omega), \mathbf{v}|_\Gamma = \mathbf{s}} \|\mathbf{v}\|_m \qquad \forall\, \mathbf{s} \in \mathbf{H}^m(\Omega)|_\Gamma\,,\ 1 \le m \le k\,. \end{aligned} \tag{4.82}$$

We also use the following inverse assumption: there exists a constant C, independent of h and $\mathbf{s}^h$, such that

$$\|\mathbf{s}^h\|_{s,\Gamma} \le C h^{s-q} \|\mathbf{s}^h\|_{q,\Gamma} \quad \forall\, \mathbf{s}^h \in \mathbf{P}^h\,,\ -1/2 \le q \le s \le 1/2\,. \tag{4.83}$$

See [2] or [8] for details concerning (4.82) and (4.83). See also [15] for (4.82).

Now, let $\mathbf{Q}^h = \mathbf{V}^h|_\Gamma$; i.e., $\mathbf{Q}^h$ consists of the restriction, to the boundary Γ, of functions belonging to $\mathbf{V}^h$. Again, for all choices of conforming finite-element spaces $\mathbf{V}^h$ we then have that $\mathbf{Q}^h \subset \mathbf{H}^1(\Gamma)$. We can show the approximation property: there exist an integer k and a constant C, independent of h and $\mathbf{k}$, such that for $1 \le m \le k$, $0 \le s \le 1$, and $\mathbf{k} \in \mathbf{H}^{m+1}(\Omega)|_\Gamma$,

$$\inf_{\mathbf{k}^h \in \mathbf{Q}^h} \|\mathbf{k} - \mathbf{k}^h\|_{s,\Gamma} \le C h^{m-s+\frac{1}{2}} \inf_{\mathbf{v} \in \mathbf{H}^{m+1}(\Omega), \mathbf{v}|_\Gamma = \mathbf{k}} \|\mathbf{v}\|_{m+1}\,. \tag{4.84}$$

This property follows from (4.79), once one notes that the same type of polynomials are used in $\mathbf{Q}^h$ as are used in $\mathbf{V}^h$. We set $G^h = \mathbf{Q}^h \cap \mathbf{H}^1_n(\Gamma)$.

Once the approximating subspaces have been chosen we seek $\mathbf{u}^h \in \mathbf{V}^h$, $p^h \in S^h_0$, $\mathbf{t}^h \in \mathbf{P}^h$, $\mathbf{g}^h \in \mathbf{Q}^h$, $\boldsymbol{\nu}^h \in \mathbf{V}^h$, $\phi^h \in S^h_0$, $\boldsymbol{\tau}^h \in \mathbf{P}^h$, and $\gamma^h \in \mathbb{R}$ such that

$$a(\mathbf{u}^h, \mathbf{v}^h) + \lambda\, c(\mathbf{u}^h, \mathbf{u}^h, \mathbf{v}^h) + b(\mathbf{v}^h, p^h) - \langle \mathbf{v}^h, \mathbf{t}^h \rangle_\Gamma = \lambda\, \langle \mathbf{f}, \mathbf{v}^h \rangle \quad \forall\, \mathbf{v}^h \in \mathbf{V}^h\,, \tag{4.85}$$

$$b(\mathbf{u}^h, q^h) = 0 \quad \forall\, q^h \in S^h_0\,, \tag{4.86}$$

$$\langle \mathbf{u}^h, \mathbf{s}^h \rangle_\Gamma - \lambda \langle \mathbf{g}^h, \mathbf{s}^h \rangle_\Gamma = \lambda \langle \mathbf{b}, \mathbf{s}^h \rangle_\Gamma \quad \forall\, \mathbf{s}^h \in \mathbf{P}^h\,, \tag{4.87}$$

$$(\nabla_s \mathbf{g}^h, \nabla_s \mathbf{k}^h)_\Gamma + \langle \mathbf{g}^h, \mathbf{k}^h \rangle_\Gamma + \gamma^h \int_\Gamma \mathbf{k}^h \cdot \mathbf{n}\, d\Gamma = \langle \boldsymbol{\tau}^h, \mathbf{k}^h \rangle_\Gamma \quad \forall\, \mathbf{k}^h \in \mathbf{Q}^h\,, \tag{4.88}$$

$$\int_\Gamma \mathbf{g}^h \cdot \mathbf{n}\, d\Gamma = 0\,, \tag{4.89}$$

$$\begin{aligned} &a(\mathbf{w}^h, \boldsymbol{\nu}^h) + \lambda\, c(\mathbf{w}^h, \mathbf{u}^h, \boldsymbol{\nu}^h) + \lambda\, c(\mathbf{u}^h, \mathbf{w}^h, \boldsymbol{\nu}^h) + b(\mathbf{w}^h, \phi^h) - \langle \mathbf{w}^h, \boldsymbol{\tau}^h \rangle_\Gamma \\ &\qquad = \lambda \left((\mathbf{u}^h - \mathbf{u}_0)^3, \mathbf{w}^h \right) \quad \forall\, \mathbf{w}^h \in \mathbf{V}^h\,, \end{aligned} \tag{4.90}$$

$$b(\boldsymbol{\nu}^h, r^h) = 0 \quad \forall\, r^h \in S^h_0\,, \tag{4.91}$$

and

$$\langle \boldsymbol{\nu}^h, \mathbf{y}^h \rangle = 0 \quad \forall\, \mathbf{y}^h \in \mathbf{P}^h\,. \tag{4.92}$$

Note that if (4.85)-(4.92) are satisfied, then necessarily $\mathbf{g}^h \in G^h$. Also, in the right-hand side of (4.90), we use a notation similar to that used in the right-hand side of (4.70).

The operator $T^h \in \mathcal{L}(Y, X^h)$ is defined as the solution operator for

$$a(\mathbf{u}^h, \mathbf{v}^h) + b(\mathbf{v}^h, p^h) - \langle \mathbf{v}^h, \mathbf{t}^h \rangle_\Gamma = \langle \mathbf{f}, \mathbf{v}^h \rangle \quad \forall\, \mathbf{v}^h \in \mathbf{V}^h\,,$$
$$b(\mathbf{u}^h, q^h) = 0 \quad \forall\, q^h \in S_0^h\,,$$

and

$$\langle \mathbf{u}^h, \mathbf{s}^h \rangle_\Gamma = \langle \mathbf{b}, \mathbf{s}^h \rangle_\Gamma \quad \forall\, \mathbf{s}^h \in \mathbf{P}^h\,;$$

i.e, for each $\mathbf{f} \in Y$, $T^h\mathbf{f} = \boldsymbol{\psi}^h \in X^h$ is the solution of the above system of equations.

Since $T = T^*$, we define $(T^*)^h = T^h$.

We define the operator $E^h : G^* \to G^h$ as follows. For each $\boldsymbol{\tau} \in G^*$, $\mathbf{g}^h = E^h\boldsymbol{\tau}$ if and only if

$$(\nabla_s \mathbf{g}^h, \nabla_s \mathbf{z}^h)_\Gamma + \langle \mathbf{g}^h, \mathbf{z}^h \rangle_\Gamma + \gamma^h \int_\Gamma \mathbf{z}^h \cdot \mathbf{n}\, d\Gamma = \langle \boldsymbol{\tau}^h, \mathbf{z}^h \rangle_\Gamma \quad \forall\, \mathbf{z}^h \in \mathbf{Q}^h$$

and

$$\int_\Gamma \mathbf{g}^h \cdot \mathbf{n}\, d\Gamma = 0\,.$$

The existence and uniqueness of a solution $(\mathbf{g}^h, \gamma^h) \in \mathbf{Q}^h \times \mathbb{R}$ are guaranteed by the Brezzi theory for mixed finite-element methods (see [4] or [5]) and the inequalities

$$(\nabla_s \mathbf{k}^h, \nabla_s \mathbf{k}^h)_\Gamma + (\mathbf{k}^h, \mathbf{k}^h)_\Gamma \geq C\|\mathbf{k}^h\|_{1,\Gamma}^2 \quad \forall\, \mathbf{k}^h \in \mathbf{Q}^h \subset \mathbf{H}^1(\Gamma) \tag{4.93}$$

and

$$\sup_{\mathbf{0} \neq \mathbf{k}^h \in \mathbf{Q}^h} \frac{\gamma^h \int_\Gamma \mathbf{k}^h \cdot \mathbf{n}\, d\Gamma}{\|\mathbf{k}^h\|_{1,\Gamma}} \geq C|\gamma^h| \quad \forall\, \gamma^h \in \mathbb{R}\,. \tag{4.94}$$

The solution necessarily satisfies $\mathbf{g}^h \in G^h$. Thus the operator E^h is well defined.

With these definitions we see that (4.85)-(4.92) can be written in the form (3.1)-(3.3).

By results concerning the approximation of the Navier-Stokes equations with inhomogeneous boundary conditions (see [15]), we obtain

$$\|(T - T^h)f\|_X \to 0$$

as $h \to 0$, for all $f = (\boldsymbol{\zeta}, \eta, \boldsymbol{\kappa}) \in Y$. This is simply a restatement of (H13).

(H14) follows trivially from (H13), the fact that T is selfadjoint, and the choice $(T^*)^h = T^h$.

To verify (H15), we note that the nondiscretized version of (4.93)-(4.94) certainly also holds; i.e.,

$$(\nabla_s \mathbf{k}, \nabla_s \mathbf{k})_\Gamma + (\mathbf{k}, \mathbf{k})_\Gamma \geq C\|\mathbf{k}\|_{1,\Gamma}^2 \quad \forall\, \mathbf{k} \in \mathbf{H}^1(\Gamma)$$

and

$$\sup_{\mathbf{0} \neq \mathbf{k} \in \mathbf{H}^1(\Gamma)} \frac{\gamma \int_\Gamma \mathbf{k} \cdot \mathbf{n}\, d\Gamma}{\|\mathbf{k}\|_{1,\Gamma}} \geq C|\gamma| \quad \forall\, \gamma \in \mathbb{R}\,.$$

Using the Brezzi theory for the mixed finite-element method (see [4] or [5]), we obtain that

$$\|(E - E^h)\boldsymbol{\tau}\|_{1,\Gamma} \to 0 \quad \text{as } h \to 0\,,$$

which verifies (H15).

(H16) and (H17) follow from the fact that N and $\mathcal{F}$ are polynomials. Here we also use imbedding theorems and Cauchy inequalities.

We set $\hat{Z} = \mathbf{L}^{3/2}(\Omega) \times \{0\} \times \{\mathbf{0}\}$. For each $(\mathbf{v}, q, \mathbf{s}) \in X = \mathbf{H}^1(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{-1/2}(\Gamma)$ and $(\mathbf{w}, r, \mathbf{k}) \in X = \mathbf{H}^1(\Omega) \times L_0^2(\Omega) \times \mathbf{H}^{-1/2}(\Gamma)$, Sobolev imbedding theorems imply that

$$[N'(\mathbf{u}, p, \mathbf{t})]^* \cdot (\mathbf{v}, q, \mathbf{s}) = -\begin{pmatrix} -(\mathbf{u} \cdot \nabla)\mathbf{v} + \mathbf{v} \cdot (\nabla \mathbf{u})^T \\ 0 \\ \mathbf{0} \end{pmatrix} \in \hat{Z},$$

$$\big([N''(\mathbf{u}, p, \mathbf{t})]^* \cdot (\mathbf{v}, q, \mathbf{s})\big) \cdot (\mathbf{w}, r, \mathbf{k}) = -\begin{pmatrix} -(\mathbf{w} \cdot \nabla)\mathbf{v} + \mathbf{v} \cdot (\nabla \mathbf{w})^T \\ 0 \\ \mathbf{0} \end{pmatrix} \in \hat{Z},$$

and

$$\big(\mathcal{F}''(\mathbf{u}, p, \mathbf{t}) \cdot (\mathbf{v}, q, \mathbf{s})\big) \cdot (\mathbf{w}, r, \mathbf{k}) = \begin{pmatrix} \begin{pmatrix} 3(u_1 - u_{01})^2 w_1 v_1 \\ \vdots \\ 3(u_d - u_{0d})^2 w_d v_d \end{pmatrix} \\ 0 \\ \mathbf{0} \end{pmatrix} \in \hat{Z},$$

where d (= 2 or 3) is the space dimension. These relations verify (H18).

From the definition of the operator K we see that K maps $\mathbf{H}_n^1(\Gamma)$ into $\mathbf{L}^{3/2}(\Omega) \times \{0\} \times \mathbf{H}^1(\Gamma)$, i.e., K maps G into Z. Thus (H19) is verified.

Hence, we are now in a position to apply Theorem 3.5 to derive error estimates for the approximate solutions of the optimality system (4.54)-(4.56), (4.70)-(4.72) and (4.74). It should be noted that Lemma 3.4 implies that for almost all values of λ, the solutions of the optimality system are regular.

THEOREM 4.10. *Assume that Λ is a compact interval of $\mathbb{R}_+$ and that there exists a branch $\{(\lambda, \mathbf{u}(\lambda), p(\lambda), \mathbf{t}(\lambda), \mathbf{g}(\lambda), \boldsymbol{\nu}(\lambda), \phi(\lambda), \boldsymbol{\tau}(\lambda)) : \lambda \in \Lambda\}$ of regular solutions of the optimality system* (4.54)-(4.56), (4.70)-(4.72), *and* (4.74). *Assume that the finite-element spaces X^h and G^h satisfy the hypotheses* (4.79)-(4.84). *Then there exist a $\delta > 0$ and an $h_0 > 0$ such that for $h \le h_0$, the discrete optimality system* (4.85)-(4.92) *has a unique branch of solutions $\{(\lambda, \mathbf{u}^h(\lambda), p^h(\lambda), \mathbf{t}^h(\lambda), \mathbf{g}^h(\lambda), \boldsymbol{\nu}^h(\lambda), \phi^h(\lambda), \boldsymbol{\tau}^h(\lambda)) : \lambda \in \Lambda\}$ satisfying*

$$\Big(\|\mathbf{u}(\lambda) - \mathbf{u}^h(\lambda)\|_1 + \|p(\lambda) - p^h(\lambda)\|_0 + \|\mathbf{t}(\lambda) - \mathbf{t}^h(\lambda)\|_{-1/2,\Gamma} + \|\mathbf{g}(\lambda) - \mathbf{g}^h(\lambda)\|_{1,\Gamma} + \|\boldsymbol{\nu}(\lambda) - \boldsymbol{\nu}^h(\lambda)\|_1 + \|\phi(\lambda) - \phi^h(\lambda)\|_0 + \|\boldsymbol{\tau}(\lambda) - \boldsymbol{\tau}^h(\lambda)\|_{-1,2,\Gamma}\Big) < \delta \qquad \text{for all } \lambda \in \Lambda.$$

Moreover,

$$\lim_{h \to 0} \Big(\|\mathbf{u}(\lambda) - \mathbf{u}^h(\lambda)\|_1 + \|p(\lambda) - p^h(\lambda)\|_0 + \|\mathbf{t}(\lambda) - \mathbf{t}^h(\lambda)\|_{-1/2,\Gamma} + \|\mathbf{g}(\lambda) - \mathbf{g}^h(\lambda)\|_{1,\Gamma} + \|\boldsymbol{\nu}(\lambda) - \boldsymbol{\nu}^h(\lambda)\|_1 + \|\phi(\lambda) - \phi^h(\lambda)\|_0 + \|\boldsymbol{\tau}(\lambda) - \boldsymbol{\tau}^h(\lambda)\|_{-1,2,\Gamma}\Big) = 0$$

uniformly in $\lambda \in \Lambda$.

If, in addition, the solution satisfies $\big(\mathbf{u}(\lambda), p(\lambda), \mathbf{t}(\lambda), \mathbf{g}(\lambda), \boldsymbol{\nu}(\lambda), \phi(\lambda), \boldsymbol{\tau}(\lambda)\big) \in \mathbf{H}^{m+1}(\Omega) \times H^m(\Omega) \times \mathbf{H}^m(\Omega)|_\Gamma \times \mathbf{H}^{m+1}(\Omega)|_\Gamma \times \mathbf{H}^{m+1}(\Omega) \times H^m(\Omega) \times \mathbf{H}^m(\Omega)|_\Gamma$ for $\lambda \in \Lambda$, then there

exists a constant C, independent of h, such that

$$\Big(\|\mathbf{u}(\lambda)-\mathbf{u}^h(\lambda)\|_1+\|p(\lambda)-p^h(\lambda)\|_0+\|\mathbf{t}(\lambda)-\mathbf{t}^h(\lambda)\|_{-1/2,\Gamma}+\|\mathbf{g}(\lambda)-\mathbf{g}^h(\lambda)\|_{1,\Gamma}$$
$$+\|\boldsymbol{\nu}(\lambda)-\boldsymbol{\nu}^h(\lambda)\|_1+\|\phi(\lambda)-\phi^h(\lambda)\|_0+\|\boldsymbol{\tau}(\lambda)-\boldsymbol{\tau}^h(\lambda)\|_{-1,2,\Gamma}\Big)$$
$$\le Ch^{m-1/2}\Big(\|\mathbf{u}(\lambda)\|_{m+1}+\|p(\lambda)\|_m+\inf_{\mathbf{v}\in\mathbf{H}^m(\Omega),\mathbf{v}|_\Gamma=\mathbf{t}}\|\mathbf{v}\|_m$$
$$+\inf_{\mathbf{v}\in\mathbf{H}^{m+1}(\Omega),\mathbf{v}|_\Gamma=\mathbf{g}}\|\mathbf{v}\|_{m+1}+\|\boldsymbol{\nu}(\lambda)\|_{m+1}+\|\phi(\lambda)\|_m+\inf_{\mathbf{w}\in\mathbf{H}^m(\Omega),\mathbf{w}|_\Gamma=\boldsymbol{\tau}}\|\mathbf{w}\|_m\Big),$$

uniformly in $\lambda\in\Lambda$.

Proof. All results follow from Theorem 3.5. For the last result, we also use (3.25) and the estimates (see, e.g., [16] or [17])

$$\|(T^hT^{-1}-I)(\mathbf{u},p,\mathbf{t})\|_X\le Ch^m(\|\mathbf{u}\|_{m+1}+\|p\|_m+\inf_{\mathbf{v}\in\mathbf{H}^m(\Omega),\mathbf{v}|_\Gamma=\mathbf{t}}\|\mathbf{v}\|_m)$$
$$\text{for } \mathbf{u}\in\mathbf{H}^{m+1}(\Omega),\ p\in H^m(\Omega),\ \text{and } \mathbf{t}\in\mathbf{H}^m(\Omega)|_\Gamma,$$

$$\|\big((T^*)^h(T^*)^{-1}-I\big)(\boldsymbol{\nu},\phi,\boldsymbol{\tau})\|_{Y^*}=\|(T^hT^{-1}-I)(\boldsymbol{\nu},\phi,\boldsymbol{\tau})\|_X$$
$$\le Ch^m(\|\boldsymbol{\nu}\|_{m+1}+\|\phi\|_m+\inf_{\mathbf{w}\in\mathbf{H}^m(\Omega),\mathbf{w}|_\Gamma=\boldsymbol{\tau}}\|\mathbf{w}\|_m)$$
$$\text{for } \boldsymbol{\nu}\in\mathbf{H}^{m+1}(\Omega),\phi\in H^m(\Omega),\ \text{and } \boldsymbol{\tau}\in\mathbf{H}^m(\Omega)|_\Gamma,$$

and

$$\|(E^hE^{-1}-I)\mathbf{g}\|_{1,\Gamma}\le Ch^{m-1/2}\inf_{\mathbf{v}\in\mathbf{H}^{m+1}(\Omega),\mathbf{v}|_\Gamma=\mathbf{g}}\|\mathbf{v}\|_{m+1}\qquad\text{for } \mathbf{g}\in\mathbf{H}^{m+1}(\Omega)|_\Gamma.$$

In these estimates, the constant C is independent of h, $\mathbf{u}$, p, $\mathbf{t}$, $\mathbf{g}$, $\boldsymbol{\nu}$, ϕ, $\boldsymbol{\tau}$, and λ. □

Remark. If the control $\mathbf{g}\in\mathbf{H}^{m+3/2}(\Omega)|_\Gamma$, then the exponent of h in the error estimate of Theorem 4.10 can be increased from $(m-1/2)$ to m. □

TOPOLOGICAL ASPECTS OF UNIVERSAL ADAPTIVE STABILIZATION*

STUART TOWNLEY†

Abstract. In this paper we consider two problems in "non-identifier-based," universal adaptive control within the framework of Mårtensson [*Adaptive Stabilization*, Ph.D. thesis, Lund Institute of Technology, 1986]. In this framework, any linear system stabilizable by constant linear output feedback is adaptively stabilized by an adaptive piecewise-linear output feedback control law. The essential feature we exploit is that of a piecewise-linear output feedback which switches through a set of feedback matrices, with switching controlled by an output-driven differential equation. For each initial condition the state of the system converges to zero and the time-varying gain matrix converges to a "limit gain." In this setting we consider two related problems. The first concerns the sensitivity of closed-loop solutions under small perturbations of the initial data. The second concerns generic properties, with respect to the set of initial conditions, of stabilization by the limit gain. We adopt a topological approach, based on a decomposition of the dynamics of the resultant nonlinear, closed-loop system into a sequence of homeo/diffeomorphisms derived from the switching nature of the dynamics. Using this decomposition we show that the set of initial conditions for which solutions are stable under small perturbations and the limiting gain is stabilizing has full Lebesgue measure and dense interior. This latter result has been conjectured in the literature. The results are illustrated by examples of planar control systems where the sets of initial conditions yielding nonstabilizing limit gains are computed.

Key words. adaptive control systems, adaptive stabilization, sequential switching, feedback control, convergence analysis

AMS subject classifications. 93C40, 93D15, 93D21, 34D04

1. Introduction.

For a known universum, Σ, of linear systems

$$\dot{x}(t) = Ax(t) + Bu(t), \quad x(0) \in \mathbb{R}^n, \tag{1.1a}$$

$$y(t) = Cx(t), \tag{1.1b}$$

with $u(t) \in \mathbb{R}^m$, $y(t) \in \mathbb{R}^p$, a universal adaptive stabilizer is an output feedback control law

$$u(t) = f(y(t), k(t)) \tag{1.2}$$

with a "gain" parameter, $k(t)$, adapted according to the law

$$\dot{k}(t) = g(y(t), k(t), u(t)) \tag{1.3}$$

such that for each (unknown) element of Σ, each $x(0) = x_0 \in \mathbb{R}^n$, and $k(0) = k_0 \in \mathbb{R}$, the state $x(t)$ and gain parameter $k(t)$ given by (1.1)-(1.3) satisfy

$$x(t) \to 0 \text{ and } k(t) \to k(\infty, x_0) < \infty \text{ as } t \to \infty.$$

The pioneering work in this area, by Mårtensson (1986), Morse (1983), Nussbaum (1983), and Willems and Byrnes (1984), opened up the area of universal or "non-identifier-based" adaptive control.

For a detailed survey and comprehensive bibliography, see Ilchmann (1991). The control/adaptation laws are divided into three types according to whether f is smooth, piecewise-smooth, or piecewise-constant in k. Each type of controller is then a universal adaptive stabilizer for certain universa of systems. For example, the Willems-Byrnes *smooth control* law (Willems and Byrnes (1984)),

$$u(t) = k^2(t) \cos k(t)\, y(t), \quad \dot{k}(t) = |y(t)|^2,$$

*Received by the editors June 1, 1992; accepted for publication (in revised form) January 27, 1995.

†Department of Mathematics and Centre for Systems and Control Engineering, University of Exeter, Exeter EX4 4QE, UK.

is a universal adaptive stabilizer for the universum of all *minimum-phase* single-input, single-output systems with $CB \neq 0$.

A second example is the *piecewise-linear* (piecewise-constant in k) dense searching control law

$$u(t) = K_{S(k(t))}y(t), \quad \dot{k}(t) = \|y(t)\|^2 + \|u(t)\|^2,$$

with switching function

$$S(k) = i \text{ if } k \in [\tau_i, \tau_{i+1}),$$

and $K_j = M_i$ if $2j = q(q+1) + 2i$ for some q and i, where $\{M_1, M_2, \ldots\}$ is a dense subset of $\mathbb{R}^{m\times p}$ and $\tau_{i+1} = \tau_i^2$, $\tau_0 > 1$, due to Mårtensson. This controller is a universal adaptive stabilizer for the universum of all systems stabilizable by constant output feedback.

Despite the considerable interest shown in the problem of universal adaptive stabilization, with a few exceptions, the only guaranteed stability properties of the closed-loop system are convergence of the internal state to zero and convergence of the gain parameter. There is no sensitivity analysis for the solutions under small perturbations in the initial conditions nor, for example, guaranteed exponential decay of the solutions. More important, the issue of stabilization of (1.1) by the limiting feedback control

$$u(t) = f(y(t), k(\infty, x_0))$$

has received only minor attention.

There have been attempts to improve asymptotic behaviour by making minor modifications to the control law. In works by Ilchmann and Owens, exponential decay of each solution is guaranteed for the class of minimum-phase, relative-degree-one systems by adding exponential weighting to the adaptation law (1990) or using nondifferential gain adaptation (1991). In Miller and Davison (1991) the adaptation mechanisms are modified to improve transient responses and guarantee arbitrary fast decay of the output to a prespecified neighbourhood of the origin.

As we shall see in §2, if f is linear in y and piecewise-constant right continuous in k so that

$$f(y(t), k(t)) = K(t, x_0)y(t)$$

with $K(t, x_0) \in \mathbb{R}^{m\times p}$, piecewise-constant in t, then exponential decay of each solution is guaranteed. In Ilchmann (1994) universal feedback control laws of this type are constructed for the universum of minimum-phase, relative-degree-one systems, with the property that for each given x_0 the sequence of gain matrices yielding $\sigma(A + BK(\infty, x_0)C) \subset \mathbb{C}_-$ is dense. This result constitutes a preliminary step toward understanding the role of the switching sequence in the adaptation scheme. However, nothing is said either about stability of each solution under small perturbation of the initial data or about exponential stability of the limiting system matrix, $A + BK(\infty, x_0)C$, for a given gain sequence.

In this paper we show, for any universal adaptive stabilization scheme of this piecewise-constant type, that both of these properties are generic (that is, they hold in an open and dense set) for initial conditions $x_0 \in \mathbb{R}^n$. This generic stability property has been conjectured in the literature; see Ilchmann (1991). The significance of this generic property is that a stabilizing gain can be derived from a single closed-loop response (experiment) if the initial condition lies in a certain set of full Lebesgue measure. In addition, the generic properties imply regularity of the apparently erratic dynamics. Our approach is topological, replacing the piecewise-smooth

differential equation with a nonlinear discrete-time dynamical system, described in terms of a sequence of homeomorphisms/diffeomorphisms. Using this approach we can analyse the mapping $x_0 \mapsto k(\infty, x_0)$ from which we deduce our main results.

The paper is organized as follows. Section 2 contains preliminary material which establishes the framework for the remainder of the paper. We motivate the problem by considering the first-order case in detail where we characterize the limiting gain explicitly. The characterization appears in the form of inequalities on the partial sums of series generated by the switching and gain sequences. We close the section with an illustration of the difficulties arising in the second-order case.

In §3 we present our main results on stability of solutions and stabilization by the limiting gain matrix. We show that for all initial conditions in an open and dense set with full Lebesgue measure, the limiting gain is exponentially stabilizing and the solutions are insensitive to small perturbations. In §4 the results are applied to second-order, minimum-phase, relative-degree-one systems.

2. Preliminaries.

2.1. System formulation. We are interested in qualitative properties of closed-loop systems arising from universal adaptive stabilization of m-input, p-output linear systems

$$\dot{x}(t) = Ax(t) + Bu(t), \quad x(0) = x_0 \in \mathbb{R}^n, \tag{2.1}$$

$$y(t) = Cx(t), \tag{2.2}$$

by *piecewise-linear* controllers, that is, where f in (1.2) is piecewise-linear in the output y. Perhaps the most striking example of a universal adaptive stabilizer of this type is the "dense searching" controller in the context of Mårtensson's "existence of a stabilizing regulator is sufficient for universal adaptive stabilization."

Example 2.1 (Mårtensson (1986)). If (2.1), (2.2) is exponentially stabilizable by a proportional feedback $K \in \mathbb{R}^{m\times p}$, then a piecewise-linear universal adaptive stabilizer is given by

$$u(t) = K_{S(k(t))}y(t), \tag{2.3}$$

$$\dot{k}(t) = \|y(t)\|^2 + \|u(t)\|^2, \qquad k(0) = \tau_0, \tag{2.4}$$

where

$S(k) = i$ if $k \in [\tau_i, \tau_{i+1})$,
$(K_0, K_1, K_2, \ldots) = (M_0, M_0, M_1, M_0, M_1, M_2, \ldots)$,
$\tau_{i+1} = \tau_i^2$, $\tau_0 > 1$, and
$\{M_0, M_1, M_2, \ldots\}$ is a dense subset of $\mathbb{R}^{m\times p}$ (so that at least one of the M_i will stabilize).

In this case $f(y, k) = K_{S(k)}y$ and $g(y, k, u) = \|y\|^2 + \|u\|^2$.

A second important example of piecewise-linear universal adaptive stabilization arises when a piecewise-constant *Nussbaum function* is used in the Willems–Byrnes adaptive stabilization of minimum-phase systems.

Example 2.2 (Willems–Byrnes; Ilchmann and Logemann (1992)). Assume that in (2.1), (2.2) $m = p$ and the system is minimum phase so that

$$\text{Rank}\begin{bmatrix} sI - A & B \\ C & 0 \end{bmatrix} = n + m \text{ for all } s \in \mathbb{C}_+. \tag{2.5}$$

We have three cases.

(a) If $\det(CB) \neq 0$, then a piecewise-linear universal adaptive stabilizer is given by

$$u(t) = N(k(t))K_{S(k(t))}y(t), \tag{2.6}$$

$$\dot{k}(t) = \|y(t)\|^2, \qquad k(0) = \tau_0, \tag{2.7}$$

where

$(N(k), S(k)) = (\tau_i, i)$ if $k \in [\tau_i, \tau_{i+1})$;
$(K_0, K_1, K_2, \ldots) = (M_0, M_1, M_2, \ldots, M_L, M_0, M_1, M_2, \ldots)$, preserving the ordering;
$\{M_0, M_1, M_2, \ldots, M_L\}$ is a spectrum unmixing set for $m \times m$ invertible matrices (i.e., for each invertible $m \times m$ matrix M there exists $i \in \{0, 1, 2, \ldots, L\}$ such that $\sigma(M_i M) \subset \mathbb{C}_-$); and
$\{\tau_i\}$ is a sequence of positive real numbers with $\lim_{i\to\infty} \tau_i/\tau_{i+1} = 0$.

In this case $f(y, k) = N(k)K_{S(k)}y$ and $g(y, k, u) = \|y\|^2$.

(b) If $\sigma(CB) \subset \mathbb{C}_-$ or $\mathbb{C}_+$, then we can take $L = 1$, H_0 equal to the $m \times m$ identity matrix, $H_1 = -H_0$, and choose $\tau_i > 0$ so that

$$\inf_{l\to\infty} \frac{\sum_{i=0}^{l}(-1)^i \tau_i(\tau_{i+1} - \tau_i)}{\tau_l - \tau_0} = -\infty, \quad \sup_{l\to\infty} \frac{\sum_{i=0}^{l}(-1)^i \tau_i(\tau_{i+1} - \tau_i)}{\tau_l - \tau_0} = +\infty. \tag{2.8}$$

In this case

$$u(t) = (-1)^j \tau_j y(t) \text{ when } k(t) \in [\tau_j, \tau_{j+1}) \tag{2.9}$$

is a universal adaptive stabilizer.

(c) If it is known a priori that $\sigma(CB) \subset \mathbb{C}_+$, then a universal adaptive stabilizer is given by (2.7) with the simple high-gain feedback

$$u(t) = -\tau_j y(t), \qquad k(t) \in [\tau_j, \tau_{j+1}). \tag{2.10}$$

In this case $\{\tau_i\}$ is any increasing sequence with $\lim_{i\to\infty} \tau_i = \infty$.

Remark 2.3. We will not recall the proofs of universal adaptive stabilization for the systems in Examples 2.1 and 2.2. However, we will have cause to borrow some ideas from these proofs. For those readers not familiar with universal adaptive control, a flavour of this area can be obtained by looking at Proposition 3.20 and Lemma 4.2.

Examples 2.1 and 2.2 have common properties. The dynamics are switched according to the nonlinear adaptation of k, and in between switches in k, the dynamics of the x component are linear. Indeed both examples fit into a single framework of a linear system (2.1), (2.2) and a piecewise-linear (in y) nonlinear adaptive feedback control

$$u(t) = K_i y(t), \tag{2.11}$$

with adaptation

$$\dot{k}(t) = \|C_i x(t)\|^2, \qquad k(0) = \tau_0 \in \mathbb{R}, \tag{2.12}$$

where the right-hand sides of (2.11) and (2.12) are determined by $k(t) \in [\tau_i, \tau_{i+1})$ with $\{\tau_i\}$ an increasing sequence with $\lim_{i\to\infty} \tau_i = \infty$. The particular features of importance are as follows.

- The feedback gain matrix $K(t, x_0)$, defined by

$$K(t, x_0) = K_i, \quad k(t) \in [\tau_i, \tau_{i+1}),$$

is switched according to a nonlinear differential equation-based adaptation law. Note the dependence on x_0.

- $\mathcal{K} = \{K_i\}_{i=1}^{\infty}$ is an ordered set of potential gain matrices. In Example 2.1, $\mathcal{K}$ is determined by recursive searching through a dense subset of $\mathbb{R}^{m\times p}$, whilst in Example 2.2, $\mathcal{K}$ is determined by cycling through the spectrum unmixing set and multiplying by the Nussbaum gain.
- The right-hand side of (2.12) is allowed to depend on k, as is the case in Example 2.1, where

$$C_i = \begin{bmatrix} C \\ K_i C \end{bmatrix} \text{ so that } \|y\|^2 + \|u\|^2 = \|C_i y\|^2.$$

In Example 2.2, $C_i = C$ for all i.

Remark 2.4. Whilst we will state most of the results for the general class of closed-loop systems given by (2.1), (2.2), (2.11), and (2.12), in §4 we will focus on the class of systems given in Example 2.2 in the single-input, single-output case.

A simple consequence of the piecewise-smoothness of (2.1), (2.2), (2.11), and (2.12) is the existence and uniqueness of solutions on maximal intervals of existence. This is summarised in the following lemma.

LEMMA 2.5 (existence and uniqueness of solutions on maximal intervals of existence). *For each $x(0) = x_0 \in \mathbb{R}^n$ and $k(0) = \tau_0 \in \mathbb{R}$ there exists $\omega > 0$ and a unique continuous and piecewise-differentiable solution $(x(t), k(t))$ on the maximal interval $[0, \omega)$, satisfying* (2.1), (2.2), (2.11), *and* (2.12) *almost everywhere.*

Proof. If $k(t)$ is bounded, then there exists $t_j < \infty$ such that $\tau_j \le k(t) < \tau_{j+1}$ for all $t \ge t_j$,

$$\dot{x}(t) = (A + BK_jC)x(t) \text{ for all } t \ge t_j$$

and $\omega = \infty$. If $k(t)$ is unbounded, then by monotonicity of $k(\cdot)$ there exists a sequence of times $t_0 = 0, t_1, t_2, \ldots$ such that $k(t_j) = \tau_j$. Since

$$\dot{x}(t) = (A + BK_jC)x(t) \text{ for all } t \in [t_j, t_{j+1}),$$

$x(\cdot)$ is smooth on $[t_j, t_{j+1})$. If $t_j \to t^* < \infty$, then $\omega = t^* < \infty$; otherwise $\omega = \infty$. □

Remark 2.6. We consider (2.1), (2.2), (2.11), and (2.12) as a class of systems containing the essential features of nonlinear systems arising in universal adaptive stabilization. Recall, in particular, that this means that for each $x(0)$ and $k(0) = \tau_0$, $x(\cdot)$ and $k(\cdot)$ exist for all $t \ge 0$ and

$$\lim_{t\to\infty} x(t) = 0 \text{ and } \lim_{t\to\infty} k(t) = k(\infty, x(0)) < \infty. \tag{2.13}$$

We now assume throughout that (2.11) and (2.12) are a universal adaptive stabilizer for (2.1), (2.2) so that (2.13) holds. We denote by

$$\Phi_t : (x(0), k(0)) \mapsto (x(t), k(t))$$

the flow of the nonlinear system (2.1), (2.2), (2.11), and (2.12), which is defined for all $t \ge 0$.

2.2. Problem motivation. In the context of adaptive stabilization the notion of stability is relaxed so that a priori the only guaranteed properties of the closed-loop system are those specified by (2.13). The aim of this paper is to characterise information obtained as a necessary consequence of universal adaptive stabilization. In particular, we are interested in whether the limiting gain, $K(\infty, x_0)$, given by

$$K(\infty, x_0) = K_i \text{ if } k(\infty, x_0) \le \tau_{i+1} \text{ and } k(t, x_0) \ge \tau_i \text{ for some } t \ge 0,$$

results in an exponentially stable limit system

$$\dot{x}(t) = (A + BK(\infty, x_0)C)x(t). \tag{2.14}$$

Anticipating our results, we are also interested in whether exponential stability of the limit system is a generic (open and dense) property in the parameter space of initial conditions.

To focus ideas, consider the simplest case of a first-order controllable system:

$$\dot{y}(t) = ay(t) + bu(t), \quad \text{where } y = x \text{ and } b \neq 0. \tag{2.15}$$

This system can be stabilized by (2.7) and (2.9). In this simple case the limiting gain can be characterised explicitly and is stabilizing unless $y = 0$.

PROPOSITION 2.7. *If $y_0 \neq 0$, then $u(t) = K(\infty, y_0)y(t)$ is a constant linear stabilizing feedback control for* (2.15). *Moreover,*

$$K(\infty, y_0) = (-1)^{j^*}\tau_{j^*},$$

where j^* is determined by

$$j^* = \inf\left\{ j \mid y_0^2 + 2\sum_{i=0}^{j}(a + (-1)^i b\tau_i)(\tau_{i+1} - \tau_i) \leq 0 \right\}.$$

If $y_0 = 0$, then $K(\infty, 0) = \tau_0$.

Proof. Let y_0 be fixed, and suppose $k(\infty, y_0) \in (\tau_{j^*}, \tau_{j^*+1}]$. We have

$$\frac{d}{dt}(y(t)^2) = 2(a + (-1)^i b\tau_i)\frac{dk}{dt} \quad \text{provided that} \quad k(t) \in [\tau_i, \tau_{i+1}). \tag{2.16}$$

Let t^* be such that $k(t^*) = \tau_{j^*}$. Integrating (2.16) from 0 to t^* we have

$$0 < y^2(t^*) = y_0^2 + 2\sum_{i=0}^{j^*-1}(a + (-1)^i b\tau_i)(\tau_{i+1} - \tau_i). \tag{2.17}$$

Integrating (2.16) from $t = t^*$ to $t = \infty$, we have

$$-y^2(t^*) = 2(a + (-1)^{j^*} b\tau_{j^*})(k(\infty, y_0) - \tau_{j^*}). \tag{2.18}$$

Equation (2.17) implies that $a + (-1)^{j^*} b\tau_{j^*} < 0$. It follows that

$$(a + (-1)^{j^*} b\tau_{j^*})(\tau_{j^*+1} - \tau_{j^*}) \leq -y^2(t^*). \tag{2.19}$$

Adding (2.17) and (2.19) gives

$$y_0^2 + 2\sum_{i=0}^{j^*}(a + (-1)^i b\tau_i(t_{i+1} - \tau_i)) \leq 0. \qquad \square$$

Even in this simplest situation, if τ_0 is not stabilizing and $y_0 = 0$, then $K(\infty, y_0)$ is not stabilizing.

DEFINITION 2.8. *We denote by $\mathcal{U} \subset \mathbb{R}^n$ the set of initial conditions for which the limit system* (2.14) *is not exponentially stable, that is,*

$$\mathcal{U} = \{x_0 \in \mathbb{R}^n \mid \sigma(A + BK(\infty, x_0)C) \cap \overline{\mathbb{C}_+} \neq \emptyset\}. \tag{2.20}$$

The complement of $\mathcal{U}$ is partitioned into two parts, $\mathcal{S}$ and $\mathcal{T}$:

$$\mathcal{S} = \{x_0 \in \mathbb{R}^n \mid x_0 \mapsto K(\infty, x_0) \text{ is continuous}\}, \tag{2.21}$$

$$\mathcal{T} = \{x_0 \in \mathbb{R}^n \mid x_0 \mapsto K(\infty, x_0) \text{ is discontinuous}\}. \tag{2.22}$$

To see that in general $\mathcal{U}$ is not empty nor equal to $\{0\}$, consider the second-order, minimum-phase, relative-degree-one system

$$\dot{x}(t) = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} x(t) + \begin{bmatrix} 1 \\ 0 \end{bmatrix} u(t), \quad y(t) = [1 \;\; 0]\, x(t),$$

which is stabilized by (2.7) and (2.9). Observe that if $x_0 \in \{0\} \times \mathbb{R}$, then $y(t) = 0, \dot{k}(t) = 0$, there are no switches in gain, $K(\infty, x_0) = \tau_0$, and yet $x(t) \to 0$. If τ_0 is not stabilizing, then $K(\infty, x_0)$ is not stabilizing and

$$\{0\} \times \mathbb{R} \subset \mathcal{U}.$$

Of course this observation is hardly surprising since $\operatorname{Ker}[1 \;\; 0] = \{0\} \times \mathbb{R}$ is a stable A-invariant subspace. A more striking example, which we will consider in detail in §4, is obtained if (2.7), (2.10) is applied to a relative-degree-one, minimum-phase, *controllable* and *observable* system.

Example 2.9. Consider the following minimum-phase, relative-degree-one system:

$$\dot{x}(t) = \begin{bmatrix} 0 & 1 \\ 6 & 1 \end{bmatrix} x(t) + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u(t), \quad y(t) = [1 \;\; 1]\, x(t), \tag{2.23}$$

expressed in control canonical form.[1] If we assume that knowledge of the sign of the high-frequency gain is available information, then we can use (2.10) as a universal adaptive stabilizer. Let $\tau_0 = 0$ and $\tau_1 = 3$. If

$$x_0 \in \left\{ \delta \begin{pmatrix} 1 \\ -2 \end{pmatrix} \mid \delta^2 \leq 2\sqrt{3} \right\},$$

then $x(t) = e^{-2t} x_0$, $k(\infty, x_0) \leq 3$, and the first switch is never reached. Hence

$$A + BK(\infty, x_0)C = A + \tau_0 BC = A, \quad \sigma(A + BK(\infty, x_0)C) = \sigma(A) \not\subset \mathbb{C}_-,$$

and

$$\left\{ \delta \begin{pmatrix} 1 \\ -2 \end{pmatrix} \mid \delta^2 \leq 2\sqrt{3} \right\} \subset \mathcal{U}. \tag{2.24}$$

In §4 we will amplify this example, using the control canonical form structure to show that the structure of this bad set $\mathcal{U}$ can be very complicated. The main result of §3 is that despite the possible complexity of $\mathcal{U}$, in measure theoretic and topological terms this bad set is very small.

MAIN RESULT. *$\mathcal{U}$ is a nowhere dense and Lebesgue-measure-zero set. Moreover, $\mathcal{S}$ is open and dense and has full Lebesgue measure.*

Our approach is to exploit the sequential nature of the closed-loop dynamics to essentially replace the flow Φ_t with a sequence of diffeomorphisms. This section is concluded with notation related to this sequence of diffeomorphisms.

[1] The control canonical form is not necessary at this point but is useful for the analysis in §4.

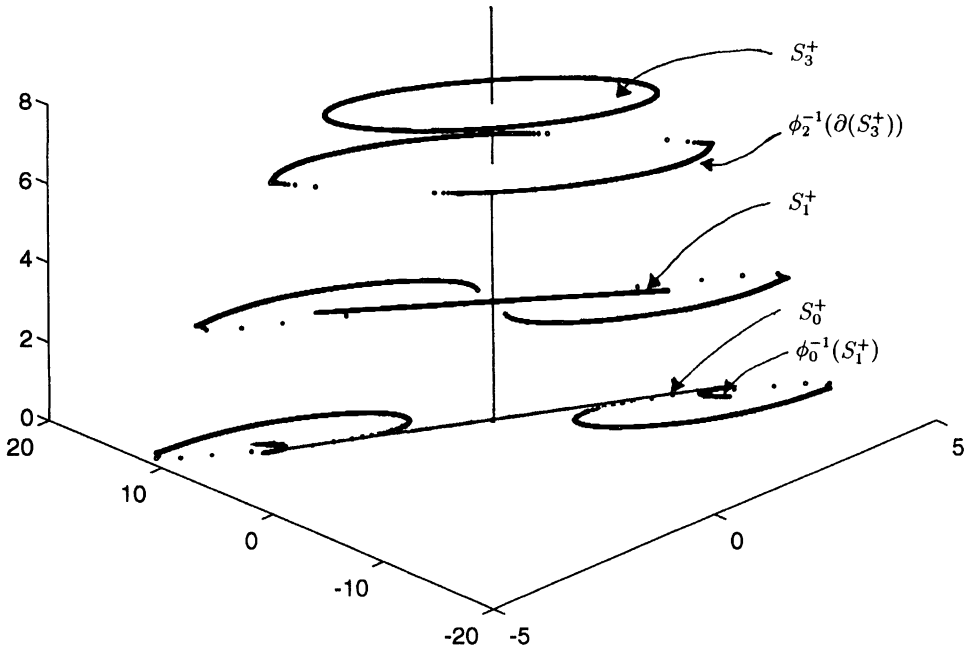

FIG. 1. S_3^+ *mapped to* H_0, *together with* S_0^+, S_1^+, *and* $\phi_0^{-1}(S_1^+)$.

2.3. Notation. Within the natural framework of $\mathbb{R}^{n+1}$ for the dynamics of (2.1), (2.2), (2.11), and (2.12) we adopt the following notation. For each $i \in \mathbb{N}$

(a) $H_i \subset \mathbb{R}^{n+1}$ is the hyperplane

$$H_i = \{(x, k) \mid k = \tau_i\}.$$

(b) $A_i = (A + BK_iC)$ with stable subspace V_i^s and unstable subspace V_i^u.

(c) $W_i(t) = \int_0^t e^{A_i^T \tau} C_i^T C_i e^{A_i \tau} d\tau$ is the observability Gramian at time t for the pair (A_i, C_i).

(d) It is clear from Example 2.9 that certain subsets of $V_i^s \times \{\tau_i\}$ and $V_i^u \times \{\tau_{i+1}\}$ of H_i and H_{i+1}, respectively, defined by the switching condition, will play important roles. These subsets, denoted by S_i^+ and S_{i+1}^-, are defined by

$$S_i^+ = \{(x, \tau_i) \mid \langle x, W_i(\infty)x\rangle \leq \tau_{i+1} - \tau_i\} \subset H_i,$$
$$S_{i+1}^- = \{(x, \tau_{i+1}) \mid \langle x, W_i(-\infty)x\rangle \leq \tau_{i+1} - \tau_i\} \subset H_{i+1}.$$

The subscripts in S_i^+ and S_{i+1}^- refer to the hyperplane in which they are contained, whilst the superscripts refer to the direction of flow defining them.

(e) The complements of S_i^+, S_{i+1}^- are denoted by R_i^+, R_{i+1}^-.

Finally,

(f) $J = \{i \in \mathbb{N}_0 \mid \sigma(A + BK_iC) \cap \overline{\mathbb{C}_+} \neq \emptyset\}$ is the indexing set for nonstabilizing gains.

These are illustrated in Fig. 1.

Remark 2.10. i) Between the hyperplanes H_i and H_{i+1} the dynamics of the state component $x(t)$ evolve according to the linear time invariant system

$$\dot{x}(t) = A_i x(t).$$

ii) S_i^+ is a *closed* subset of the affine space $V_i^s \times \{\tau_i\}$. In Example 2.9

$$S_0^+ = \left\{ \delta \begin{pmatrix} 1 \\ -2 \end{pmatrix} | \delta^2 \leq 2\sqrt{3} \right\} \times \{0\}.$$

S_{i+1}^- is a *closed* subset of the affine space $V_i^u \times \{\tau_{i+1}\}$. S_i^+ and S_{i+1}^- play fundamental roles in our approach. If $(x(t), k(t)) \in S_i^+$ for some $t \geq 0$, then H_{i+1} is not reached, whereas S_{i+1}^- cannot be reached from H_i.

iii) The sets $R_i^+ \subset H_i$ and $R_{i+1}^- \subset H_{i+1}$ are open. They are, respectively, the points in H_i which reach H_{i+1} and the points in H_{i+1} which are reached from H_i under the flow Φ_t. Note that they are naturally homeomorphic. In the case when (A_i, C_i) is an observable pair, they are both punctured n-dimensional space. If $\operatorname{Ker} C_i$ contains a stable A_i-invariant subspace V, then both R_i^+ and R_{i+1}^- are homeomorphic to $\mathbb{R}^n \setminus V$.

3. Generic stability properties of universal adaptive stabilization. In this section we present and prove the main results. We assume throughout that (2.11) and (2.12) result in a universal adaptive stabilizer for (2.1) and (2.2) as defined by (2.13). We show that in the partition

$$\mathbb{R}^n = \mathcal{S} \cup \mathcal{T} \cup \mathcal{U} \tag{3.1}$$

of the set of initial conditions introduced in Definition 2.8,

- $\mathcal{U}$ is nowhere dense and has zero Lebesgue measure,
- $\mathcal{T}$ is nowhere dense and has zero Lebesgue measure,
- S is open and dense and has full Lebesgue measure.

We characterise $\mathcal{S}$, $\mathcal{T}$, and $\mathcal{U}$ explicitly via smooth functions which arise from a decomposition of the flow Φ_t into a sequence of *homeomorphisms* $\{\phi_i : R_i^+ \to R_{i+1}^-\}$.

The first thing to note is the importance of the sets S_i. Indeed, for each $x_0 \in \mathbb{R}^n$, boundedness of $k(t, x_0)$ implies that there are at most finitely many switches in $K(t, x_0)$. It follows that there must exist $t \geq 0$ such that $(x(t), k(t)) \in S_q$ for some $q \geq 0$ and that this, moreover, determines $K(\infty, x_0)$.

LEMMA 3.1. *$K(\infty, x_0) = K_q$ if and only if $(x(t), k(t)) \in S_q^+$ for some $t < \infty$.*

Remark 3.2. As an immediate consequence of Lemma 3.1 and the definition of S_q^+ it follows that for each $x_0 \in \mathbb{R}^n$ there exists $M, \lambda > 0$ (depending on x_0) such that

$$\|x(t)\| \leq Me^{-\lambda t}.$$

(See also Ilchmann (1994).)

If $K(\infty, x_0) = K_q$, then there exists a sequence of times $0 = t_0 < t_1 < \cdots < t_q < \infty$ such that $(x(t_j), k(t_j)) \in R_j^+$, $j = 0, 1, \ldots, q-1$, and $(x(t_q), k(t_q)) \in S_q^+$.

This simple observation is formalised as a decomposition of Φ_t into a sequence of maps ϕ_i.

DEFINITION 3.3. *For each $i \in \mathbb{N}$, $\phi_i : R_i^+ \to R_{i+1}^-$ is defined implicitly as follows: Let $(x, \tau_i) \in R_i^+$, then there exists $t_i(x)$ such that*

$$\tau_{i+1} - \tau_i = \langle x, W_i(t_i(x))x \rangle.$$

We set

$$\phi_i(x, \tau_i) = (e^{A_i(t_i(x))}x, \tau_{i+1}).$$

Remark 3.4. The explicit reference to τ_i and τ_{i+1} is not really important but simply serves to emphasize the domain ($\subset H_i$) and range ($\subset H_{i+1}$) of ϕ_i. Indeed we often think of ϕ_i as a map defined on a subset of $\mathbb{R}^n$ rather than on R_i^+ and drop the explicit reference to τ_i and τ_{i+1}.

Example 3.5. (a) For the first-order system (2.15) and (2.9) with $a = b = 1$,

$$R_i^+ = \{x \mid x^2 + 2(\tau_{i+1} + \tau_i)((-1)^i\tau_i + 1) > 0\} \times \{0\}$$

and

$$\phi_i(x) = \sqrt{x^2 + 2(\tau_{i+1} - \tau_i)((-1)^i\tau_i + 1)}$$

with

$$\phi_i^{-1}(y) = \sqrt{y^2 - 2(\tau_{i+1} - \tau_i)((-1)^i\tau_i + 1)}.$$

(b) Figures 1 and 2(a)-(c) show the typical qualitative effect of ϕ_i^{-1} for second-order systems. Figure 1 shows an ellipse mapped down through the H_i under ϕ_i^{-1} for $i = 2, 1, 0$. Figure 2(a) shows the image of the unit circle under ϕ_i^{-1} when A_i has two positive real eigenvalues, and Fig. 2(b) shows the image when A_i has two negative real eigenvalues. Figure 2(c) shows the hyperbolic case when A_i has one negative and one positive real eigenvalue. Note that if A_i has hyperbolic eigenvalues and $\tau_{i+1} - \tau_i$ is large, then the image of the unit circle is split into two connected components and the image of the unit circle has cusp points (at which, as we will see, ϕ_i has a singular derivative).

The development of the topological approach pivots on smoothness properties of the ϕ_i. A word of caution: for each x, and $i \in \mathbb{N}$ there is a different time $t_i(x)$ required to reach H_{i+1} from H_i, and so ϕ_i is truly nonlinear and not simply the linear flow $x \mapsto e^{A_i t}x$.

PROPOSITION 3.6. *For each $i \in \mathbb{N}$, $\phi_i : R_i^+ \to R_{i+1}^-$ is a homeomorphism.*

Proof. If $(x, \tau_i) \in R_i^+$, then there exists $t(x) < \infty$ such that $\langle x, W_i(t(x))x\rangle = \tau_{i+1} - \tau_i$. Let $\epsilon > 0$ be arbitrary. For each $\hat{x} \in \mathbb{R}^n$ and $\delta > 0$

$$\sqrt{\langle (x + \delta\hat{x}), W_i(t(x) + \epsilon)(x + \delta\hat{x})\rangle} \geq \sqrt{\langle x, W_i(t(x) + \epsilon)x\rangle} - \delta\sqrt{\langle \hat{x}, W_i(t(x) + \epsilon)\hat{x}\rangle}$$

and

$$\sqrt{\langle (x + \delta\hat{x}), W_i(t(x) - \epsilon)(x + \delta\hat{x})\rangle} \leq \sqrt{\langle x, W_i(t(x) - \epsilon)x\rangle} + \delta\sqrt{\langle \hat{x}, W_i(t(x) - \epsilon)\hat{x}\rangle},$$

where $\sqrt{\langle x, W_i(t(x) - \epsilon)x\rangle} < \tau_{i+1} - \tau_i$ and $\sqrt{\langle x, W_i(t(x) + \epsilon)x\rangle} > \tau_{i+1} - \tau_i$. If $\|\hat{x}\| = 1$ and δ is sufficiently small, then

$$\langle (x + \delta\hat{x}), W_i(t(x) + \epsilon)(x + \delta\hat{x})\rangle > \tau_{i+1} - \tau_i$$

and

$$\langle (x + \delta\hat{x}), W_i(t(x) - \epsilon)(x + \delta\hat{x})\rangle < \tau_{i+1} - \tau_i.$$

It follows by continuity of $W_i(\cdot)$ (in the operator topology) that $t(y) \in (t(x) - \epsilon, t(x) + \epsilon)$ for each $y \in B_\delta(x)$. Hence $t(\cdot)$ is continuous at x, and therefore ϕ_i (as a composition and product of continuous functions) is continuous at (x, τ_i). By definition of R_{i+1}^- it follows that ϕ_i is onto. Injectivity of ϕ_i follows from analyticity of $t \mapsto C_i e^{A_i t}x$ together with the fact that ϕ_i is defined only on R_i^+ (those points in H_i reaching H_{i+1}). Hence $\phi_i^{-1} : R_{i+1}^- \to R_i^+$ exists. (In R_{i+1}^- we are interested only in points coming from below H_{i+1}. Those points on H_{i+1} which are on flows of Φ_t lying entirely in H_{i+1} are not in R_{i+1}^-.) A similar argument to the one above, reversing time, shows that ϕ_i^{-1} is continuous and therefore ϕ_i is a homeomorphism. □

Remark 3.7. If $K(\infty, x_0) = K_q$, then a trajectory flows from $(x_0, k_0) \in H_0$ (under Φ_t) via the homeomorphisms ϕ_i through each of the hyperplanes $H_i, i = 1, 2, \ldots, q - 1$ and finally hits S_q^+.

For each $i \in \mathbb{N}$ let $\mathcal{S}_i \subset \mathbb{R}^n$ be defined by

$$\mathcal{S}_i = \{x_0 \in \mathbb{R}^n \mid \Phi_t(x_0, \tau_0) \in S_i^+ \text{ for some } t < \infty\}.$$

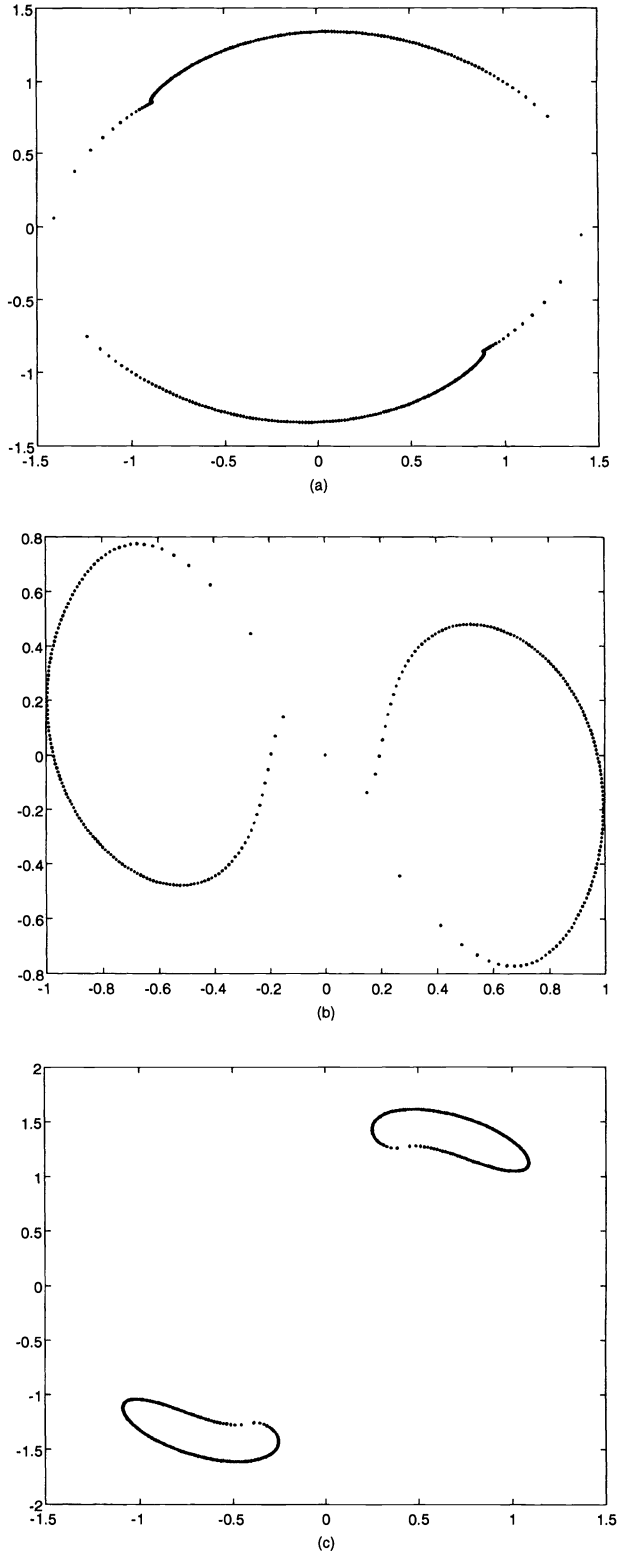

FIG. 2. *The image of the unit circle under* ϕ_i *when* A_i *has* (a) *unstable real,* (b) *stable real, and* (c) *hyperbolic eigenvalues.*

Using the decomposition of the flow Φ_t into the sequence of homeomorphisms ϕ_i, $\mathcal{S}_i$ is defined equivalently by

$$\mathcal{S}_i = \{x_0 \in \mathbb{R}^n \mid \phi_{i-1}(\phi_{i-2}(\ldots(\phi_0(x_0, \tau_0))\ldots)) \in S_i^+\}.$$

LEMMA 3.8. (a) *For each* $i \notin J$

$$\operatorname{int}(\mathcal{S}_i) = \{x_0 \in \mathbb{R}^n \mid \Phi_t(x_0, \tau_0) \in \operatorname{int}(S_i^+) \text{ for some } t \geq 0\}$$

and

(b) $\mathcal{S} = \cup_{i \notin J} (\operatorname{int}(\mathcal{S}_i))$.

Proof. (a) This follows immediately from the homeomorphic structure of the ϕ_i.

(b) It is clear that $\bigcup (\operatorname{int}(\mathcal{S}_i)) \subset \mathcal{S}$. To show the opposite inclusion we must verify that if $x_0 \notin \bigcup (\mathcal{S}_i)$, then $x \mapsto K(\infty, x)$ is discontinuous at x_0, so $x_0 \notin \mathcal{S}$. Now $K(\infty, x_0) = K_j$ for some j, and since $x_0 \notin \operatorname{int}(\mathcal{S}_j)$ there must exist x_j with $(x_j, \tau_j) \in \partial S_j^+$ such that $x(t) = x_j$ for some t. (Here ∂S_j^+ is the boundary of S_j^+.) Since S_j^- cannot be reached from H_{j-1} it is clear that $(x_j, \tau_j) \notin S_j^-$. Hence, we can use the continuity of the ϕ_i^{-1} and the fact that S_j^- is closed to find, given $\epsilon > 0$, a small enough neighbourhood, $\mathcal{N}_j$, of (x_j, τ_j) (in H_j) such that $\|\phi_0^{-1}(\ldots(\phi_{j-1}^{-1}(x, \tau_j))) - (x_0, \tau_0)\| < \epsilon$ for all $(x, \tau_j) \in \mathcal{N}_j$. Finally, using the closedness of S_j^+ we can choose $z_j \in \mathcal{N}_j$ so that with x defined by $(x, \tau_0) = \phi_0^{-1}(\ldots(\phi_{j-1}^{-1}(z_j, \tau_j)))$, we have $\|(x, \tau_0) - (x_0, \tau_0)\| < \epsilon$ and $K(\infty, x) \neq K_j$. □

COROLLARY 3.9. $\mathcal{S}$ *is open.*

$\mathcal{S}$ has very nice properties. By definition, for each $x_0 \in \mathcal{S}$, the limiting gain $K(\infty, x_0)$ is stabilizing. Moreover, as a direct consequence of the homeomorphic structure of the ϕ_i, the continuity of each $x \mapsto t_i(x)$, and the openness of $\mathcal{S}$, we can prove stability of solutions on $[0, \infty)$ under small perturbations of initial data x_0 in $\mathcal{S}$.

THEOREM 3.10. *If* $x_0 \in \mathcal{S}$, *then given* $\epsilon > 0$ *there exists* $\delta > 0$ *so that if* $\|x - x_0\| < \delta$, *then* $\|\Phi_t(x, \tau_0) - \Phi_t(x_0, \tau_0)\| < \epsilon$ *for all* $t \geq 0$.

Remark 3.11. Whilst this result is intuitively clear, the reappearance of time means that a detailed proof is required.

Proof. It is sufficient to prove the result in the case when $1 \notin J$, $\sigma(A_1) \subset \mathbb{C}_-$, and $x_0 \in \operatorname{int}(\mathcal{S}_1)$. The general case follows immediately because only a finite number of ϕ_i are involved.

Let $x_0 \in (\operatorname{int} \mathcal{S}_1)$ and $\epsilon > 0$ be given. Choose $\delta > 0$ small enough so that $B_\delta(\phi_0(x_0)) \subset \operatorname{int} S_1^+$. Here $B_\delta(x) = \{z \in \mathbb{R}^n \mid \|z - x\| < \delta\}$. Now choose $\eta > 0$ so that $\phi_0(B_\eta(x_0)) \subset B_\delta(\phi_0(x_0))$. Given $\mu > 0$, reduce $\eta > 0$ if required so that

$$\left| \max_{x \in B_\eta(x_0)} t(x) - \min_{x \in B_\eta(x_0)} t(x) \right| < \mu.$$

If $x \in B_\eta(x_0)$, then $t_{\min} \leq t_0(x), t_0(x_0) \leq t_{\max}$. Without loss of generality, suppose that $t_0(x_0) \leq t_0(x)$. We now check that $\|x(t, x) - x(t, x_0)\| < \epsilon$ on each interval $[0, t_0(x_0)]$, $(t_0(x_0), t_0(x))$, and $[t_0(x), \infty)$. If $t \geq t_0(x)$, then

$$\|x(t, x) - x(t, x_0)\| = \|e^{A_1(t - t_0(x))}\phi_0(x) - e^{A_1(t - t_0(x_0))}\phi_0(x_0)\|$$

$$\leq \|e^{A_1(t - t_0(x))}(\phi_0(x) - \phi_0(x_0))\|$$

$$+ \|(e^{A_1(t - t_0(x))} - e^{A_1(t - t_0(x_0))})\phi_0(x_0)\| < \epsilon$$

if μ and hence η are small enough. (Here $\phi_0(\cdot)$ means only the x-component.)

If $t \leq t_0(x_0)$ and μ (hence η) is small enough, then

$$\|x(t,x) - x(t,x_0)\| = \|e^{A_0 t}(x - x_0)\| < \epsilon.$$

Finally if $t \in (t_0(x_0), t_0(x))$ and μ is small enough, then

$$\|x(t,x) - x(t,x_0)\| = \|e^{A_0 t}x - e^{A_1(t-t_0(x_0))}e^{A_0 t_0(x_0)}x_0\|$$

$$\leq \|e^{A_0 t}x - e^{A_1(t-t_0(x_0))}e^{A_0(t_0(x_0))}x\| + \|e^{A_1(t-t_0(x_0))}\|\|e^{A_0(t_0(x_0))}\|\|x - x_0\|$$

$$\leq \|[e^{A_0(t-t_0(x_0))} - e^{A_1(t-t_0(x_0))}]e^{A_0 t_0(x_0)}x\| + \frac{\epsilon}{2} < \epsilon.$$

Similar estimates hold for $|k(t,x) - k(t,x_0)|$ (and hence $\|\Phi_t(x,\tau_0) - \Phi_t(x_0,\tau_0)\|$) using continuity of $t_0(\cdot)$ and $W_0(\cdot)$. □

Remark 3.12. Simulations of closed-loop systems derived from universal adaptive control algorithms can exhibit erratic transient behaviour. Theorem 3.10 gives *robustness* of stability of solutions with respect to perturbations of initial data for solutions starting in the open set $\mathcal{S}$. This shows that there is inherent regularity underlying the erratic behaviour, even in the case of the Mårtensson dense search controller of Example 2.1.

Implicit in the analysis above is an algorithm by which we can compute $\mathcal{U}$. Whilst complicated by the restricted domains and codomains of the ϕ_i we have

$$\mathcal{U} = \bigcup_{j \in J} \mathcal{U}_j,$$

where for each $j \in J$, $\mathcal{U}_j$ is defined recursively by

$$\begin{cases} \mathcal{U}_j = \phi_0^{-1}(R_1^+ \cap Z_1), \\ Z_k = \phi_k^{-1}(R_{k+1}^+ \cap Z_{k+1}), \qquad k = 1, \ldots, j-1, \\ Z_j = S_j. \end{cases}$$

The partition of $\mathbb{R}^n$ is completed by setting

$$\mathcal{T} = \mathbb{R}^n \setminus (\mathcal{S} \cup \mathcal{U}) = \bigcup_{j \notin J} \mathcal{T}_j,$$

where $\mathcal{T}_j = \phi_0^{-1}(\ldots(\phi_{j-1}^{-1}(\partial S_j^+)))$.

Both of the sets $\mathcal{U}$ and $\mathcal{T}$ are constructed via *countable* unions of sets derived (by preimage) from sets $\{S_j^+\}_{j \in J}$ and $\{\partial S_j^+\}_{j \notin J}$, which are nowhere dense and have zero Lebesgue measure. It is therefore reasonable to expect that $\mathcal{U}$ and $\mathcal{T}$ are themselves nowhere dense and have zero Lebesgue measure. However, these sets become very complicated as they map under the homeomorphisms ϕ_i^{-1} to H_0. (See §4.) Moreover, homeomorphisms do not, in general, preserve zero Lebesgue measure. To overcome these potential difficulties we establish that if the domains of ϕ_i and ϕ_i^{-1} are restricted still further, then they are diffeomorphisms.

PROPOSITION 3.13. *For each* $i = 0, 1, \ldots,$

i) $\phi_i : R_i^+ \to R_{i+1}^-$ *is continuously differentiable at every* $x \notin \phi_i^{-1}(\operatorname{Ker} C_i)$,

ii) $\phi_i^{-1} = \phi_i^{-1} : R_{i+1}^- \to R_i^+$ *is continuously differentiable at every* $y \notin \phi_i(\operatorname{Ker} C_i)$, *and*

iii) $\phi_i : R_i^+ \setminus ((\operatorname{Ker} C_i) \cup \phi_i^{-1}(\operatorname{Ker} C_i)) \to R_{i+1}^- \setminus ((\operatorname{Ker} C_i) \cup \phi_i(\operatorname{Ker} C_i))$ *is a diffeomorphism.*

Proof. For $x \in R_i^+$, $\phi_i(x) = (e^{A_i t(x)}x, \tau_i)$, where $t(x)$ is defined implicitly by

$$\langle x, W_i(t(x))x\rangle = \tau_{i+1} - \tau_i.$$

Clearly the map $F : \mathbb{R}^{n+1} \to \mathbb{R}$, $(t, x) \mapsto \langle x, W_i(t)x\rangle$ is continuously differentiable with

$$\frac{\partial F}{\partial t}|_{(t,x)} = \|C_i e^{A_i t}x\|^2 \text{ and } \frac{\partial F}{\partial x}|_{(t,x)} = 2x^T W_i(t).$$

If $\phi_i(x) \notin \operatorname{Ker} C_i$, then

$$\frac{\partial F}{\partial t}|_{(t(x),x)} = \|C_i\phi_i(x)\|^2 > 0.$$

It now follows from the implicit function theorem that $t(\cdot)$ is *continuously differentiable* in a neighbourhood of x. Hence ϕ_i is continuously differentiable on $(\phi_i^{-1}(\operatorname{Ker} C_i))^c$ with the derivative of ϕ_i, $D\phi_i$, given by

$$D\phi_i|_x = e^{A_i t(x)} - \frac{2A_i\phi_i(x)x^T W_i(t(x))}{\|C_i\phi_i(x)\|^2}. \tag{3.2}$$

Arguing similarly, reversing time, we have that ϕ_i^{-1} is continuously differentiable on $(\phi_i(\operatorname{Ker} C_i))^c$.

Finally, $y \in \operatorname{Ker} C_i \cup \phi_i(\operatorname{Ker} C_i)$ if and only if $\phi_i^{-1}(y) \in \operatorname{Ker} C_i \cup \phi_i^{-1}(\operatorname{Ker} C_i)$ and

$$\phi_i : R_i^+ \setminus ((\operatorname{Ker} C_i) \cup \phi_i^{-1}(\operatorname{Ker} C_i)) \to R_{i+1}^- \setminus ((\operatorname{Ker} C_i) \cup \phi_i(\operatorname{Ker} C_i))$$

is a diffeomorphism. □

Remark 3.14. We observe that $D\phi_i^{-1}|_x \to \infty$ as either $\phi_i^{-1}(x) \to \operatorname{Ker} C_i$ or $x \to S_{i+1}^-$. Similarly $D\phi_i|_x \to \infty$ as $\phi(x) \to \operatorname{Ker} C_i$ or as $x \to S_i^+$. It follows that $D\phi_i^{-1}|_x$ and $D\phi_i|_x$ become singular as $x \to \operatorname{Ker} C_i$. At first sight this does not seem obvious from (3.2). However, we can use the alternative formula

$$D\phi_i|_x = e^{A_i t(x)} - \frac{2A_i e^{A_i t(x)}xx^T W_i(t(x))}{\|C_i x\|^2 + 2x^T W_i(t(x))A_i x},$$

and now taking determinants we have

$$\operatorname{Det}(D\phi_i|_x) = \operatorname{Det}(e^{A_i t(x)})\operatorname{Det}\left(I - \frac{2A_i xx^T W_i(t(x))}{\|C_i x\|^2 + 2x^T W_i(t(x))A_i x}\right),$$

which is zero since

$$\left(1 - \frac{2x^T W_i(t(x))A_i x}{\|C_i x\|^2 + 2x^T W_i(t(x))A_i x}\right) = 0$$

when $C_i x = 0$.

Example 3.15. (a) In the one-dimensional case

$$\frac{d\phi_i}{dx} = \frac{x}{\sqrt{x^2 + 2(\tau_{i+1} - \tau_i)((-1)^i\tau_i + 1)}}.$$

If $((-1)^i\tau_i + 1) > 0$, then $\frac{d\phi_i}{dx} > 1$ and Φ_t expands the area between R_i^+ and R_{i+1}^-.

(b) If we look again at Fig. 2, we clearly see cusp points in the image of the ellipse. These are due precisely to the singularity of $D\phi_1^{-1}$ on $\operatorname{Ker} C_i$ since functions with singular derivatives do not necessarily map smooth curves to smooth curves. We also see that divergence

of $D\phi_1^{-1}|_x$, as $\phi_1^{-1}(x)$ approaches Ker C_i, is reflected in the sparsity of points in Figs. 2(a)-(c) near Ker C_i.

To establish denseness and, more importantly, full Lebesgue measure of $\mathcal{S}$, we use the differentiability of ϕ_i and a simple result from measure theory, modified slightly to suit our purposes.

LEMMA 3.16. *If $X \subset H_{i+1}$ has zero Lebesgue measure, then $\phi_i^{-1}(X) \subset H_i$ has zero Lebesgue measure.*

Proof. It is well known that diffeomorphisms preserve Lebesgue measure. We have to take care of places where ϕ_i^{-1} is not differentiable. Since S_i^- and KerC_i are *closed sets*, we can decompose $\phi_i^{-1}(X)$ as

$$\phi_i^{-1}(X) = \left(\bigcup_{n=1}^{\infty} \phi_i^{-1}(X_n)\right) \cup (\text{Ker } C_i \cap \phi_i^{-1}(X)),$$

where $X_n = X \setminus B_{\frac{1}{n}}(S_{i+1}^-) \cup \phi(B_{\frac{1}{n}}(\text{Ker } C_i))$. Note continuity of ϕ_i implies that X_n is measurable for each n.

Since ϕ_i^{-1} is differentiable on X_n, it follows that $\phi_i^{-1}(X_n)$ has zero Lebesgue measure for each n and therefore $\phi_i^{-1}(X)$ has zero Lebesgue measure. □

We can now state the main result of this section.

THEOREM 3.17. *If* (2.11), (2.12) *satisfy* (2.13), *then $\mathcal{S}$ is open and dense and has full Lebesgue measure*; *that is, the property that* (2.14) *is exponentially stable is generic.*

Proof. For each $i \notin J$ and $i \in J$, both ∂S_i^+ and S_i^+, respectively, have zero Lebesgue measure. Under each "diffeomorphism" ϕ_k^{-1}, $k = i - 1, \ldots, 0$, it follows from Lemma 3.16 that this zero measure is preserved. Hence, $\mathcal{T}$ and $\mathcal{U}$ have zero Lebesgue measure as countable unions of sets with Lebesgue measure zero. Now

$$\mathbb{R}^n = \mathcal{S} \cup \mathcal{T} \cup \mathcal{U},$$

so $\mathcal{S}$ has full Lebesgue measure. Moreover, since $\mathcal{S}$ is open, $\mathcal{T} \cup \mathcal{U}$ is closed. Therefore, $\mathcal{T} \cup \mathcal{U}$ cannot have interior, and therefore $\mathcal{S}$ is dense. □

COROLLARY 3.18. *Under the conditions of Theorem* 3.17, $\mathbb{R}^n$ *is decomposed as*

$$\mathbb{R}^n = \mathcal{S} \cup \mathcal{T} \cup \mathcal{U},$$

where

- *$\mathcal{U}$ is nowhere dense and has zero Lebesgue measure,*
- *$\mathcal{T}$ is nowhere dense and has zero Lebesgue measure, and*
- *$\mathcal{S}$ is open and dense with full Lebesgue measure.*

Remark 3.19. We see that the set of initial conditions x_0, producing non-stabilizing limit gains $K(\infty, x_0)$, is restricted to a closed set with Lebesgue measure zero. Moreover, Theorem 3.10, concerning stability of solutions under small perturbations, applies to all initial conditions in an open, dense, and full-measure set of initial conditions.

If an *experiment* is defined as the solution $\{\Phi_t(x_0, \tau_0) | \ t \geq 0\}$ of (2.11), (2.12) corresponding to a single initial condition $x_0 \in \mathbb{R}^n$, then except for initial conditions in a Lebesgue measure zero set, a *single experiment* will guarantee the identification of a stabilizing output feedback matrix. Note that $\mathcal{U}$ is made up of a countable union and that any bounded subset of $\mathbb{R}^n$ may intersect infinitely many components of $\mathcal{U}$ corresponding to different limit gains. This would lead to highly sensitive closed-loop dynamics. However, in the case of Examples 2.1 and 2.2 we can rule out this possibility. This adds to the regularity of these control algorithms.

PROPOSITION 3.20. *For each closed-loop system in either Example* 2.1 *or* 2.2 *we have bounded switching number on compact subsets*; *i.e., for each $M > 0$ there exists $\kappa \geq 0$ such that if $\|x_0\| \leq M$, then $k(\infty, x_0) \leq \kappa$.*

Proof. We prove this result for the closed-loop system in Example 2.1. The same ideas work for the closed-loop system in Example 2.2, although the technical details are more involved. The details are omitted.

For each $x_0 \in \mathbb{R}^n$ an upper bound on the number of switches and hence on $k(\infty, x_0)$ is determined as follows. Let M_q be a feedback gain which is stabilizing for the given system. We define sequences of times t_n, t'_n (depending on x_0) such that $k(t_n, x_0) = \tau_{i_n}$ and $k(t'_n, x_0) = \tau_{i_n+1}$ with $K_{i_n} = M_q$. (If no such t_n exists, then $k(\infty, x_0) < \tau_{q(q+1)/2}$.) Now

$$\int_{t_n}^{t'_n} \|y(s)\|^2 + \|u(s)\|^2 ds = \tau_{i_n+1} - \tau_{i_n}.$$

But the feedback gain on the interval $[t_n, t_{n+1})$ is stabilizing so that there exists M (not depending on $\{\tau_i\}$) such that

$$\int_{t_n}^{t'_n} \|y(s)\|^2 + \|u(s)\|^2 ds \leq M\|x(t_n)\|^2$$

and

$$x(t) \leq M\left(\|x_0\| + \sqrt{\int_0^t \|y(s)\|^2 + \|u(t)\|^2 ds}\right).$$

Putting these two inequalities together we obtain

$$\tau_{i_{n+1}} - \tau_{i_n} \leq c\|x_0\| + c(\tau_{i_n} - \tau_0) \tag{3.3}$$

for some c. Switching is, of course, terminated no later than when (3.3) is violated, and since $\|x_0\|$ is bounded, this inequality is violated for some τ_{i_n} independent of x_0. (The subsequence $\{\tau_{i_n}\}$ is determined by the condition that $K_{i_n} = M_q$, and the length of the sequence depends only on x_0. □

So far we have concentrated on qualitative results for the dynamics of the closed-loop system which are necessary consequences of the assumed existence of a universal adaptive stabilizer. We can use the same approach to analyse those properties which are necessarily required of the underlying system.

PROPOSITION 3.21 (a necessary condition for universal adaptive stabilization).
Let

$$\left.\begin{aligned} \dot{x}(t) &= A_i x(t) \\ \dot{k}(t) &= \|C_i x(t)\|^2 \end{aligned}\right\} \text{ for } k \in [\tau_i, \tau_{i+1}).$$

Suppose for each $x_0 \in \mathbb{R}^n$, *with* $k(0) = \tau_0$, *that* $x(t) \to 0$ *and* $k(t) \to k(\infty, x_0) < \infty$. *Then there exists* $j \in \mathbb{N}$ *such that* $\sigma(A_j) \subset \mathbb{C}_-$.

Proof. If no A_i is stabilizing, then by Corollary 3.18 we would have

$$\mathbb{R}^n = \mathcal{U},$$

which is not possible because $\text{int}(\mathcal{U}) = \phi$. □

Remark 3.22. This is the piecewise-constant analogue of the necessary conditions for universal adaptive stabilization established in Byrnes, Helmke, and Morse (1986).

4. Qualitative and topological properties for minimum-phase, relative-degree-one systems. In §3 we saw that in a sequence of "experiments" (i.e., applying the same control to the same system but with differing initial conditions), generically the limiting linear system (2.14) will be exponentially stable. As we have clearly seen in Example 2.9, we cannot really expect better than this, and in most cases $\mathcal{U}$ will be nonempty. Indeed, it is easy to see that if a piecewise-linear universal adaptive stabilizer is designed for a large enough class of systems (containing, of course, some open-loop unstable ones), then $\mathcal{U}$ will be nontrivial for some realization of the system to be controlled.

We now consider the case when only one experiment is performed so that the initial condition is fixed. We focus on the effect that the controller, given by (2.11) and (2.12), has on the stability properties of the limit system (2.14) and in particular whether the limiting system is exponentially stable. We will restrict attention to Example 2.2 in the single-input, single-output case. We have a system

$$\dot{x}(t) = Ax(t) + bu(t), \qquad y(t) = c^T x(t), \tag{4.1}$$

which can be stabilized by (2.9) and (2.7), which we recall is given by

$$u(t) = (-1)^i \tau_i y(t), \ \dot{k}(t) = y^2(t) \ \text{ if } \ k(t) \in [\tau_i, \tau_{i+1}).$$

Note that the controller is parametrized by the sequence $\{\tau_i\}$, which must satisfy (2.8). We refer to such a sequence as a *Nussbaum sequence*.

In this problem x_0 is fixed and the limiting gain k_∞ is now a function of $\{\tau_i\}$ only, and so $k_\infty = k(\infty, \{\tau_i\})$. Using the relative-degree-one structure we can rewrite (4.1) as

$$\begin{aligned} \dot{y}(t) &= ay(t) + c^T bu(t) + a_{12} z(t), \\ \dot{z}(t) &= a_{21} y(t) + A_{22} z(t), \end{aligned}$$

where $a \in \mathbb{R}$, $a_{12} \in \mathbb{R}^{1\times(n-1)}$, $a_{21} \in \mathbb{R}^{(n-1)\times 1}$, $A_{22} \in \mathbb{R}^{(n-1)\times(n-1)}$, and (by minimum phase) $\sigma(A_{22}) \subset \mathbb{C}_-$.

LEMMA 4.1 (Ilchmann and Owens (1991)). *For each x_0 there exists $K > 0$ such that*

$$0 \le y^2(t) \le K + K \int_0^t y^2(s) + c^T b \int_0^t y(s)u(s)ds. \tag{4.2}$$

LEMMA 4.2. *Let $\{\tau_i\}$ be fixed. For each $R > 0$ there exists q such that $k(\infty, \{\hat{\tau}_i\}) \le \tau_q$ for all $\{\hat{\tau}_i\}$ with $\|\{\tau_i\} - \{\hat{\tau}_i\}\|_\infty \le R$.*

Proof. Using Lemma 4.1 and (2.7) we have for each $\{\hat{\tau}_i\}$ that switching terminates before the inequality

$$0 \le y^2(t) + K(\hat{\tau}_i - \hat{\tau}_0) + c^T b \sum (-1)^i \hat{\tau}_i (\hat{\tau}_i - \hat{\tau}_{i-1})$$

is violated. This will be uniformly bounded on $\|\{\tau_i\} - \{\hat{\tau}_i\}\|_\infty \le R$ for $\{\hat{\tau}_i\}$ satisfying (2.8). □

Remark 4.3. If $\{\tau_i\}$ is fixed, then it follows from Lemma 4.2 that any l_∞-neighbourhood of $\{\tau_i\}$ is, with regard to the possible values of the limit gain, essentially an $\mathbb{R}^{q+1}$-neighbourhood of $(\tau_0, \tau_1, \ldots, \tau_q)$ for some q.

In Ilchmann (1994) it is shown that for each fixed x_0 the set of Nussbaum sequences which results in an exponentially stable linear limiting system is dense with full measure. To be precise, let $G(x_0)$, given by

$$G(x_0) = \{\{\tau_i\} \mid (2.14) \text{ is exponentially stable}\},$$

be the totality of all Nussbaum sequences which produce exponentially stable limit systems when (2.9) is applied to (4.1).

PROPOSITION 4.4 (Ilchmann (1994)). *If (A, b, c^T) is controllable and observable and x_0 is fixed, then $G(x_0)$ is dense and has full Lebesgue measure in the following sense: for each $\{\tau_i\}$ and every $\epsilon > 0$, $G(x_0)$ is dense in the l_∞ ϵ-neighbourhood around $\{\tau_i\}$. If q is the uniform bound on the number of switches given in Lemma 4.2 for this ϵ-neighbourhood, then $\Pi_q(G(x_0))$ has full Lebesgue measure in the $\mathbb{R}^{q+1}$ ϵ-neighbourhood around $(\tau_0, \tau_1, \ldots, \tau_q)$.*

Here Π_q is the projection $\{\tau_0, \tau_1, \ldots\} \mapsto (\tau_0, \tau_1, \ldots, \tau_q)$.

We can make a minor improvement to this result by exploiting continuity properties of the ϕ_i with respect to the controller parameters $\{\tau_i\}$.

LEMMA 4.5. *$(\tau_i, \tau_{i+1}) \mapsto e^{A(t_i(x))}x$ is continuous with respect to (τ_i, τ_{i+1}) for every x such that*

$$\langle x, W_i(t)x\rangle > \tau_{i+1} - \tau_i.$$

PROPOSITION 4.6. *$\operatorname{int}(G(x_0))$ is dense in any l_∞-neighbourhood of a Nussbaum sequence.*

Proof. Let

$$IG(x_0) = \{\{\tau_i\} \mid x_0 \in \mathcal{S}(\{\tau_i\})\}.$$

We claim that $IG(x_0)$ is dense in $G(x_0)$ and open.

If $\epsilon > 0$ and $\{\tau_i\}$ are given, choose $\{\hat{\tau}_i\} \in G(x_0)$, using Proposition 4.4, such that $\|\{\hat{\tau}_i\} - \{\tau_i\}\|_\infty < \epsilon$. Let q be such that $x_0 \in \mathcal{S}_q(\{\hat{\tau}_i\})$ for some q.[2] By increasing $\hat{\tau}_{q+1}$ by an arbitrary small amount, we can arrange that $x_0 \in \operatorname{int}(\mathcal{S}_q(\{\hat{\tau}_i\})) \subset \mathcal{S}$ and therefore $IG(x_0)$ is dense.

Almost by definition $IG(x_0)$ is open. To make this precise, let $\{\tau_i\} \in IG(x_0)$. We must show that

$$\{\{\hat{\tau}_i\} \mid \|\{\hat{\tau}_i\} - \{\tau_i\}\|_\infty < \epsilon\} \subset IG(x_0)$$

for some $\epsilon > 0$. By Lemma 4.2 we know that there exists q such that small changes to $\tau_{q+1}, \tau_{q+2}, \ldots$ are unimportant. We therefore have to consider only small perturbations to finitely many of the τ_i, and so the result follows if we can verify the following two claims:

(1) if $(x, \tau_q) \in \operatorname{int}(S_q^+)$, then there exists $\epsilon > 0$ such that $(\hat{x}, \hat{\tau}_q) \in \operatorname{int}(S_q^+(\{\hat{\tau}_q\}))$ for all $\hat{x}$, $\hat{\tau}_q$, and $\hat{\tau}_{q+1}$ with $\|x - \hat{x}\|, |\hat{\tau}_j - \tau_j| < \epsilon$, $j = q, q+1$;

(2) for all $\epsilon > 0$ there exists $\delta > 0$ such that $\|\{\tau_q\} - \{\hat{\tau}_q\}\|_\infty < \delta$ and $\|x - \hat{x}\| < \delta$ implies $\|\phi_q(x) - \hat{\phi}_q(\hat{x})\| < \epsilon$,

since by applying (2) repeatedly we can move from $\hat{H}_q$ to $\hat{H}_0$. (We use the obvious notation of $\hat{\phi}_i$ denoting ϕ_i for $\{\hat{\tau}_i\}$.)

Claim (1) follows from the continuity of $\hat{x}^T \hat{W}_q(\infty)\hat{x} = \tau_{i+1} - \tau_i$ with respect to $\hat{x}$ and $\{\hat{\tau}_q\}$. Claim (2) follows from the continuity of ϕ_q and Lemma 4.5 since

$$\|\phi_q(x) - \hat{\phi}_q(\hat{x})\| \le \|\phi_q(x) - \phi_q(\hat{x})\| + \|\phi_q(\hat{x}) - \hat{\phi}_q(\hat{x})\|. \qquad \square$$

Remark 4.7. Putting these results specific to minimum-phase, relative-degree-one, single-input single-output systems together with the general results of §3 gives a complete picture in that stability of the limit system is a generic and full-Lebesgue-measure property with respect to both plant initial conditions and controller parameters.

[2] Recall $\mathcal{S}_q = \{x_0 \in \mathbb{R}^n \mid \phi_t(x_o, \tau_i) \in S_i^+ \text{ some } t < \infty\}$.

The remainder of this paper concerns a detailed quantitative and qualitative analysis of the second-order case. We assume that $c^T b > 0$ and (A, b, c^T) is minimal. By Proposition 3.20 we have on each compact subset of $\mathbb{R}^2$ a finite partition of $\mathcal{U}$, $\mathcal{T}$, and $\mathcal{S}$ according to a finite number of potential limit gains. The qualitative nature of this partition depends strongly on whether information about the high-frequency gain $c^T b$ is available and on the root locus of the system to be controlled.

i) If the information $c^T b > 0$ is available, then we can simply use (2.10) and (2.7).

ii) If the high-frequency gain information is not available, then we must use (2.9) and (2.7).

It is easy to see that there are five types of second-order, minimum-phase, relative-degree-one systems characterized according to pole-zero locations of the system transfer function

$$c^T(sI - A)^{-1}b = \frac{p(s)}{q(s)} = \frac{c^T b(s - \gamma)}{(s - \lambda)(s - \mu)}.$$

N.B. γ, the zero, is negative.

Case 1 (types I, II, and III) (real poles).

I. $\lambda \leq \mu < \gamma$.

II. $\lambda < \gamma < \mu$ (pole-zero interlacing).

III. $\gamma > \lambda \geq \mu$.

Case 2 (types IV and V) (complex poles).

$\mu = \bar{\lambda}$ with $\mathrm{Im}\lambda \neq 0$.

IV. $\mathrm{Re}\lambda < 0$.

V. $\mathrm{Re}\lambda \geq 0$.

Type I: The root locus lies completely in the left half plane. If $c^T b > 0$ is known, then $\mathcal{U} = \phi$.

Type II: The root locus lies on the real axis for all positive values of gain.

Type III: The root locus has a departure from the real axis at some positive gain.

Types IV and V: The root locus is a subset of the root locus in III. If, for some positive gain τ^*, the root locus intersects the real axis, then the intersection is in the left half plane and all gains greater than τ^* are stabilizing.

If $\mathrm{sign}(c^T b)$ is not known, then the complete $\pm$ gain root locus is relevant. In this case I, II, IV, and V are equivalent up to translation of the complex plane parallel to the real axis.

We are mainly interested in properties of $\mathcal{U}$. Because we have a second-order system, the only contribution to $\mathcal{U}$ can come from those $j \in J$ for which the x-dynamics are hyperbolic (A_j has one positive and one negative eigenvalue). Let

$$J^H = \{j \in J \mid x_j \to e^{A_j t}x \text{ is hyperbolic}\}$$

and, for each $j \in J^H$, λ_j and μ_j be the negative and positive eigenvalues of A_j. How the S_j^+, $j \in J_H$ ultimately contribute to $\mathcal{S}$ is dependent on the overall dynamics, which in turn are determined by the possible transitions between linear x-dynamics as we map down to H_0.

Qualitative and quantitative results when knowledge of $c^T b > 0$ is available. If $c^T b > 0$ is known and we use (2.10), then either $J^H = \emptyset$ or there exists $q \in \mathbb{N}$ such that

$$J^H = \{0, 1, \ldots, q\}.$$

It is important to analyse the transition from one hyperbolic system to another, as this causes the distortion and twisting of S_i^+.

LEMMA 4.8. *If* $i, i + 1 \in J^H$, *then*

i) $\phi_i^{-1}(S_{i+1}^+)$ *lies between* $V_i^s \times \{\tau_i\}$ *and* $V_i^u \times \{\tau_i\}$,

ii) $\overline{\phi_i^{-1}(S_{i+1}^+)} \cap V_i^s = \partial S_i^+ \setminus \{0\} := \{(s_i^+, \tau_i), (-s_i^+, \tau_i)\}$, *where* $\pm s_i^+ = \delta_i \binom{1}{\lambda_i}$ *and* δ_i *is determined by*

$$\delta_i^2 \int_0^\infty \left| c^T e^{\lambda_i t} \begin{pmatrix} 1 \\ \lambda_i \end{pmatrix} \right|^2 dt = \tau_{i+1} - \tau_i,$$

iii) $\phi_i^{-1}(S_{i+1}^+)$ *is smooth and* $\phi_i^{-1}(S_{i+1}^+) \cup S_i^+$ *is continuous.*

Proof. i) Let $V_i^s = \text{span}\{v_i^s\}$, $V_i^u = \text{span}\{v_i^u\}$ with eigenvalues λ_i and μ_i. If $(x, \tau_i) \in S_{i+1}^+$ with $x = \alpha v_i^S + \beta v_i^u$, $\alpha, \beta \in \mathbb{R}$, then

$$\phi_i^{-1}(x) = \alpha \rho^{-\lambda_i} v_i^S + \beta \rho^{-\mu_i} v$$

where $\rho = e^{t(x)} > 1$.[3] The result follows.

ii) Because of the continuity of ϕ_i^{-1} we need only to consider points $(x_\epsilon, \tau_i) \in S_{i+1}^+$, with

$$x_\epsilon = \epsilon \begin{pmatrix} 1 \\ \lambda_{i+1} \end{pmatrix}$$

and $\epsilon \to 0$. Then

$$x_\epsilon = \frac{\epsilon}{(\lambda_i - \mu_i)} \left\{ (\lambda_i - \lambda_{i+1}) \begin{pmatrix} 1 \\ \lambda_i \end{pmatrix} - (\mu_i - \lambda_{i+1}) \begin{pmatrix} 1 \\ \mu_i \end{pmatrix} \right\}$$

and

$$\phi_i^{-1}(x_\epsilon) = \frac{\epsilon}{(\lambda_i - \mu_i)} \left\{ (\lambda_i - \lambda_{i+1}) \rho^{-\lambda_i} \begin{pmatrix} 1 \\ \lambda_i \end{pmatrix} - (\mu_i - \lambda_{i+1}) \rho^{-\mu_i} \begin{pmatrix} 1 \\ \mu_i \end{pmatrix} \right\},$$

where $\rho \to \infty$, $\epsilon \rho^{-\lambda} \to \delta_i$ as $\epsilon \to 0$, and

$$\delta_i^2 \int_o^\infty \left| c^T e^{\lambda t} \begin{pmatrix} 1 \\ \lambda \end{pmatrix} \right|^2 dt = \tau_{i+1} - \tau_i. \tag{4.3}$$

It follows that $\lim_{\epsilon \to 0} \phi_i^{-1}(x_\epsilon) \in \partial S_i^+ = \{(s_i^+, \tau_i), (-s_i^+, \tau_i)\}$,

iii) Note that $\text{Ker}\, c^T = \text{span}\binom{1}{\gamma}$ is positioned anticlockwise between V_i^s and V_i^u. Hence, by i) $\text{Ker}\, c^T \cap \phi_i^{-1}(S_{i+1}^+) = \emptyset$ and $\text{Ker}\,(c^T) \cap S_{i+1}^+ = \emptyset$. Using Proposition 3.13, it follows that $\phi_i^{-1}(S_{i+1}^+)$ is smooth. Finally by ii), $\phi_i^{-1}(S_{i+1}^+) \cup S_i^+$ is a continuous union connected at $\{(s_i^+, \tau_i), (-s_i^+, \tau_i)\}$. □

PROPOSITION 4.9. *If* $(A, b, c^T) \in \mathbb{R}^{2\times 2} \times \mathbb{R}^{2\times 1} \times \mathbb{R}^{1\times 2}$ *is minimal and minimum phase,* $c^T b > 0$ *is known,* (2.10) *is used, and* $J_H \neq \emptyset$, *then* $\mathcal{U}$ *is a closed continuous curve differentiable at all but* $2(|J^H| - 1)$ *points and*

$$\inf\{\|x - y\| \mid x \in \text{Ker} c^T,\ \|x\| = 1,\ y \in \mathcal{U},\ \|y\| = 1\} > 0.$$

Before illustrating some features of $\mathcal{U}$ in the case $c^T b > 0$ known, we have a lemma which further aids the qualitative analysis. This is to cope with transitions caused by switching from stable linear x-dynamics to hyperbolic x-dynamics.

[3] We are treating ϕ_i as a function defined on $\mathbb{R}^2$.

LEMMA 4.10. *If* $i \in J^H$, $(i+1) \notin J$, *and* $S_{i+1}^- \not\subset S_{i+1}^+$, *then* $\phi_i^{-1}(S_{i+1}^+)$ *has exactly two connected components.*

Proof. ϕ_i^{-1} is continuous but not defined on S_{i+1}^-. Hence ϕ_i^{-1} is continuous at each point $x \in S_{i+1}^+ \setminus S_{i+1}^-$. However, since $S_{i+1}^- \not\subset S_{i+1}^+$, S_{i+1}^- cuts S_{i+1}^+ into two halves. Let $(x_\epsilon, \tau_{i+1}) \in S_{i+1}^+$ approach S_{i+1}^- so that

$$x_\epsilon = \epsilon u_i + v_i$$

with $u_i \in V_i^s$, $v_i \in V_i^u$, and $\epsilon \to 0$.

Arguing as in Lemma 4.8 we have that

$$\phi_i^{-1}(x_\epsilon) = \epsilon\rho^{-\lambda_i} u_i + \rho^{-\mu_i} v_i$$

with $\lim_{\epsilon\to 0} \rho = 0$, $\lim_{\epsilon\to 0} \epsilon\rho^{-\lambda} = c^*$, where

$$c^* = \sqrt{\frac{2\mu(\tau_{i+1} - \tau_i) - |c^T v_i|^2}{2\mu |c^T u_i|^2}}.$$

(N.B. $S_{i+1}^- \not\subset S_{i+1}^+$ guarantees that $2\mu\delta\tau_i > |c^T v_i|^2$ for each x_ϵ approaching S_{i+1}^- in S_{i+1}^+.) □

Example 4.11 (Example 2.9 revisited–known high-frequency gain). For the system given in Example 2.9 the open-loop poles and zeros are interlaced so that the root locus, i.e., the zeros of $(s^2 - s - 6) + k(s+1)$, lies entirely on the real axis. We take $\tau_0 = 0$, $\tau_1 = 3$, and $\tau_2 = 6.5$. Simple calculations yield

$$S_0^+ = \left\{ \delta \begin{pmatrix} 1 \\ -2 \end{pmatrix} \mid |\delta| \le 2\sqrt{3} \right\},$$

$$S_1^- = \left\{ \delta \begin{pmatrix} 1 \\ 3 \end{pmatrix} \mid |\delta| \le \frac{\sqrt{3}}{2} \right\},$$

$$S_1^+ = \left\{ \delta \begin{pmatrix} 1 \\ -3 \end{pmatrix} \mid |\delta| \le \sqrt{\frac{10.5}{2}} \right\},$$

$$S_2^- = \left\{ \delta \begin{pmatrix} 1 \\ 1 \end{pmatrix} \mid |\delta| \le 2\sqrt{3.5} \right\}.$$

If τ_3 is not too large, then the line S_2^- is not contained in the ellipse S_2^+. $\tau_3 = 8$ is a suitable choice. Hence by Lemma 4.10, $\phi_1^{-1}(S_2^+)$ has two connected components.

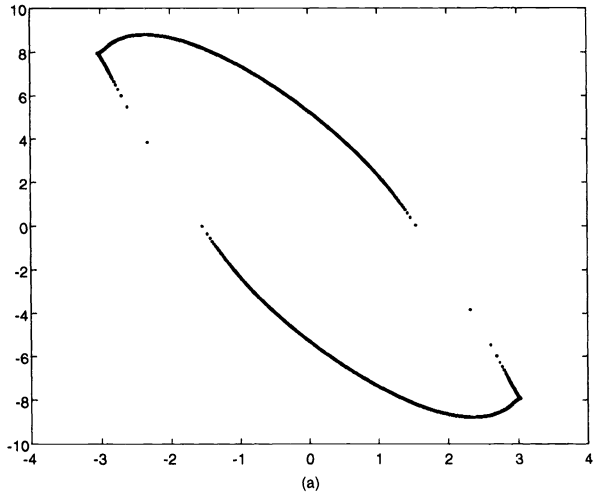
The remainder of the mapping depends on the relative sizes of $\tau_4, \tau_5, \ldots$ and information given by Lemmas 4.8 and 4.10. If $\tau_4 = 10$, then $S_3^- \subset S_3^+$, and therefore by Lemma 4.10, $\phi_2^{-1}(S_3^+)$ is not split into two components. However, $S_2^- \not\subset \phi_2^{-1}(S_3^+)$, and therefore $\phi_1^{-1}(\phi_2^{-1}(\psi_3^+))$ is in two components. These features are illustrated in Fig. 3, where we show S_3^+ mapping under ϕ_2^{-1}, ϕ_1^{-1}, and ϕ_0^{-1} to H_0. Note the cusp features in $\phi_2^{-1}(\partial S_3^+)$ caused by intersection with Ker (c^T).

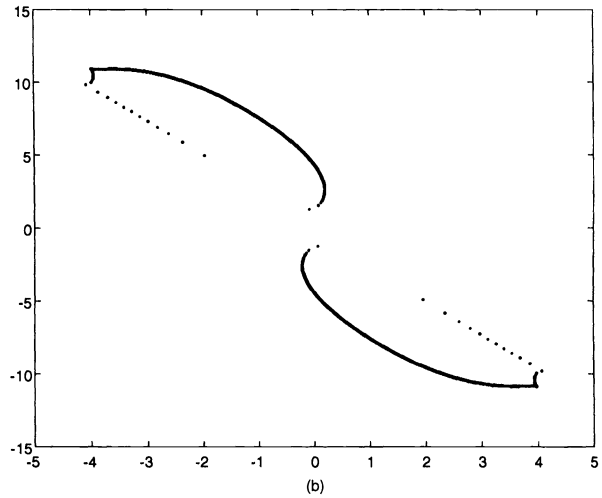
Finally we consider the structure of $\mathcal{U}$. In this case $J = \{0, 1\}$ so that

$$\mathcal{U} = \mathcal{U}_0 \bigcup \mathcal{U}_1.$$

We can calculate $\mathcal{U}_0$ and $\mathcal{U}_1$ explicitly. Indeed,

$$\mathcal{U}_0 = S_0^+$$





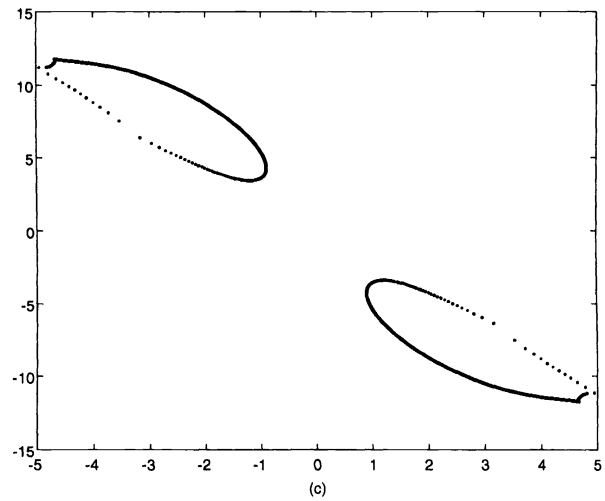


FIG. 3. S_3^+ *mapped to* H_0 *for Example* 4.11.

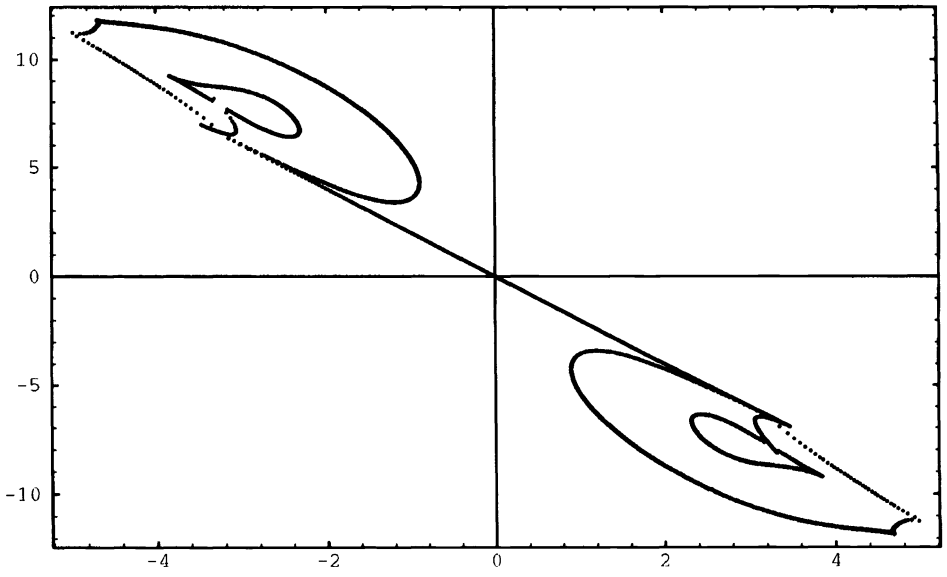

FIG. 4. $\mathcal{U}_0 \cup \mathcal{U}_1 \cup \mathcal{S}_2 \cup \mathcal{S}_3$ *for Example* 4.11.

and

$$\mathcal{U}_1 = \phi_0^{-1}(S_1^+) = \left\{ \phi_0^{-1}\left(\delta \begin{pmatrix} 1 \\ -3 \end{pmatrix} \right) \mid |\delta| \leq \sqrt{5.25} \right\} = \frac{\delta(\rho)}{5} \left\{ 6\rho^2 \begin{pmatrix} 1 \\ -2 \end{pmatrix} - \rho^{-3} \begin{pmatrix} 1 \\ 3 \end{pmatrix} \right\},$$

where

$$\delta(\rho) = \frac{\pm 15\rho^3}{\sqrt{27\rho^{10} + 125\rho^6 - 144\rho^5 - 8}}$$

and $\rho \in [1.41, \infty)$. Figure 4 shows the complete picture for $\mathcal{U}$ together with $\mathcal{T}_2 = \partial\mathcal{S}_2$ and $\mathcal{T}_3 = \partial\mathcal{S}_3$. Note that $\mathcal{U}$ is a closed, continuous curve with two points of non-differentiability as predicted by Proposition 4.9.

Qualitative and quantitative results when knowledge of the sign of the high-frequency gain is not available. If $c^T b > 0$ is unknown, then the structure of $\mathcal{U}$ is more complicated because as k increases, the hyperbolic dynamics are interlaced with source and sink dynamics.

The most interesting feature, which did not occur in the case of known sign of the high-frequency gain, is that caused by transitions from hyperbolic dynamics to complex source dynamics and back to hyperbolic dynamics. Let

$$J^{cs} = \{j \in J \mid \mathrm{Im}(\sigma(A_j)) \neq 0\};$$

i.e., for each $j \in J^{cs}$, $x \mapsto e^{A_j t}x$ has complex source dynamics.

LEMMA 4.12. *If* $j \in J^{cs}$, $(j+1) \in J^H$, *and* $S_{j+1}^+ \not\subset S_{j+1}^-$, *then* $\phi_j^{-1}(S_{j+1}^+) \subset H_j$ *is a doubly infinite spiral about* $\{0\}$.

If, in addition, $(j-1) \in J^H$, *then* $\phi_{j-1}^{-1}(\phi_j^{-1}(S_{j+1}^+))$ *is a pair of infinite spirals centred at* $\partial(S_{j-1}^+) = \{(\pm s_{j-1}^+, \tau_{j-1})\}$.

Proof. Let $(x, \tau_{j+1}) \in S_{j+1}^+ \setminus S_{j+1}^-$, with x parameterized by ϵ, approach S_{j+1}^- as $\epsilon \to 0$. It follows that $\lim_{\epsilon \to 0} t_j(x_\epsilon) = \infty$, where $t_j(\cdot)$ is the time taken to flow from H_{j+1} to H_j. But

$$\phi_j^{-1}(x_\epsilon) = e^{-\sigma t_j(x_\epsilon)}(\alpha_\epsilon \cos w t_j(x_\epsilon)\, u + \beta_\epsilon \sin w t_j(x_\epsilon) v)$$

for some fixed $\sigma > 0$, $w > 0$, $u, v \in \mathbb{R}^2$. Hence $\phi_j^{-1}(S_{j+1}^+)$ is a spiral winding infinitely many times about $(0, \tau_j)$. Arguing as in Lemma 4.10, part of $\phi_j^{-1}(S_{j+1}^+)$ is cut by S_j^-. It follows that all points in $\phi_j^{-1}(\partial S_{j+1}^+)$ which are on one side of S_j^- become an infinite nest of loops, $\phi_{j-1}^{-1}(\phi_j^{-1}(S_{j+1}^+))$. Since the spiral $\phi_j^{-1}(S_{j+1}^+)$ is centred at $(0, \tau_j)$ and $\partial(S_{j-1}^+)$ "maps" to $(0, \tau_j)$ under ϕ_{j-1}, it follows that $\{(\pm s_{j-1}^+, \tau_{j-1})\} = \partial(S_{j-1}^+)$ are the centres of the nested loops. □

If, in Lemma 4.12, $j+2 \notin J$, then S_{j+2}^+ is an ellipse and $\phi_{j+1}^{-1}(S_{j+2}^+)$ contains part of S_{j+1}^+. Hence the infinite spirals $\phi_j(S_{j+1}^+)$ contributing ultimately to $\mathcal{U}$ carry with them contributions to $\mathcal{S}$, with the ellipse S_{j+2}^+ in H_{j+2} becoming an infinitely spiralling band in H_j. These features are illustrated in Example 4.13. However, it is difficult to make general statements as to whether these features will always reach H_0 when greater numbers of switches are considered.

Example 4.13 (unknown sign of the high-frequency gain). Let

$$A = \begin{bmatrix} 0 & 1 \\ 0.2 & 0.8 \end{bmatrix}, \quad b = \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \quad c^T = [1\ 1].$$

If we do not know the sign of $c^T b$, then we use (2.7) and (2.9). If $\tau_0 = 0$, $\tau_1 = 0.6$, $\tau_2 = 0.8$, and $\tau_3 = 1$, then $0, 2 \in J^H$, $1 \in J^{cs}$, and $3 \notin J$. If $\tau_4 = 3.22$, then

$$S_3^+ = \{(x, y) \mid 29x^2 + 10xy + 45y^2 \leq 160/9\},$$

$$S_2^+ = \left\{ \delta \begin{pmatrix} 1 \\ -0.48 \end{pmatrix} \mid |\delta| \in [0.2, 0.84] \right\},$$

$$S_2^- = \{(x, y) \mid 2.65x^2 - 2.5xy + 3.5y^2 \leq 0.2\},$$

$$S_1^+ = \{0\}.$$

In Figs. 5(a)-(c) we show S_3^+ mapping to H_0 (shown in a dotted line) together with S_2^+ in Fig. 5(b) (shown in boldface). Figures 6(a) and 6(b) show part of $\mathcal{U}$ coming from $\mathcal{U}_0$ and $\mathcal{U}_2$ (shown in boldface) together with $\mathcal{T}_3$ (shown dotted). Figure 6(b) is a blow-up of part of Fig. 6(a). In order to emphasize the detail, in Figs. 6(a) and 6(b) we have rotated coordinates, putting S_0^+ on the vertical axis.

In this example we see that even for minimum-phase, relative-degree-one systems, the possibility of unknown sign of the high-frequency gain induces a significant degree of complexity in the partition of $\mathbb{R}^2 = \mathcal{S} \cup \mathcal{T} \cup \mathcal{U}$. In Example 4.13, $J^H = \{0, 2, 4, 6, \ldots\}$ and $J = J^H \cup \{1\}$.

The points exterior to

$$\mathcal{U}_0 \cup \mathcal{U}_2 \cup \mathcal{S}_3,$$

represent those initial conditions whose gain evolution is not terminated until four or more switches in gain have taken place.

Observation. Dropping explicit reference to τ_0, we have in Example 4.13 that $\pm s_0^+$ are the centres of the infinite spirals $\phi_0^{-1}(\phi_1^{-1}(S_2^+)) = \mathcal{S}_2$. Hence, for all $\epsilon > 0$ there exist x_1, x_2, and x_3 within ϵ of s_0 such that

$$K(\infty, s_0^+) = \tau_0, \quad K(\infty, x_1) = \tau_2, \quad K(\infty, x_2) = -\tau_3, \quad K(\infty, x_3) = (-1)^j \tau_j, \quad j \geq 4.$$

Hence, starting arbitrarily close to s_0^+ we have four qualitatively distinct types of closed-loop-systems behaviour, according to none, two, three, and more than four switches switches in gain. However, from Proposition 3.20 we know that on each bounded set we have only finitely many switches so that this erratic nature of the closed-loop system in a neighbourhood of s_0^+ is confined to solutions switching at most a finite number of different times.

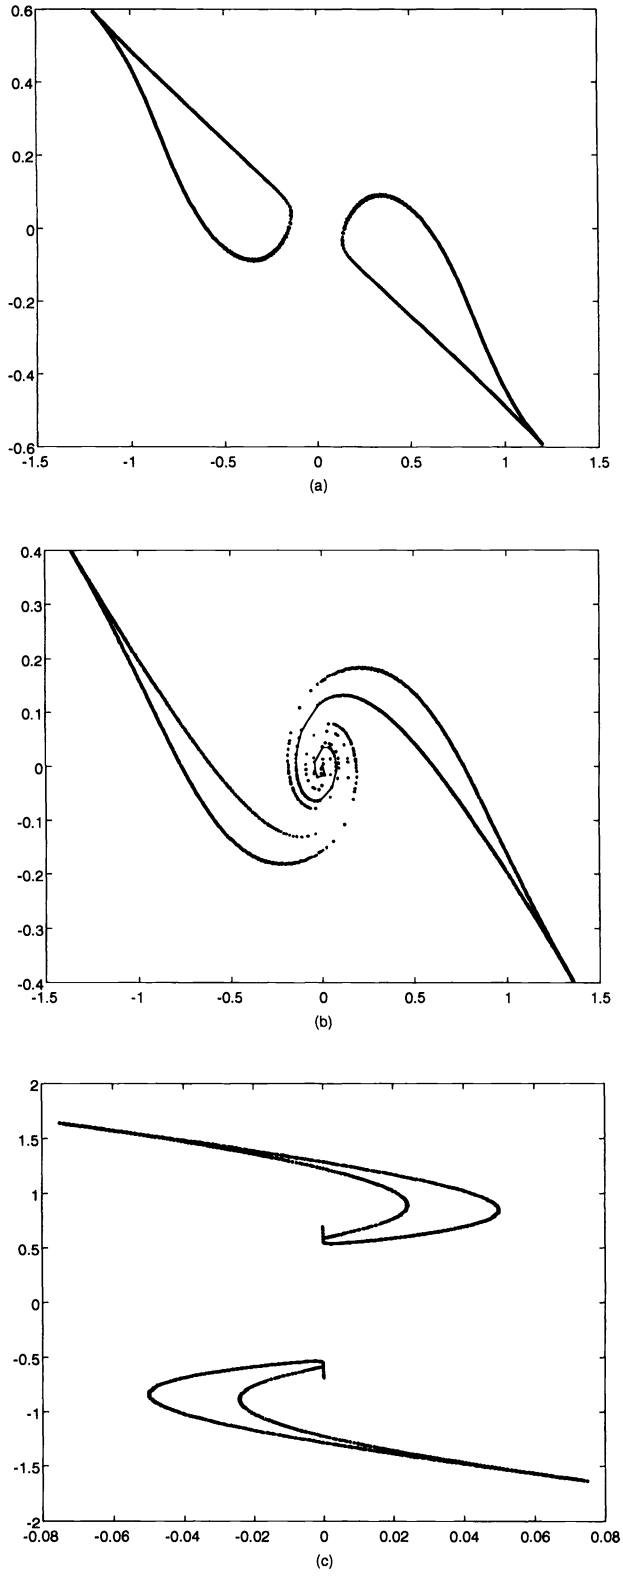

FIG. 5. S_3^+ *mapping to* H_0 *(dotted) and* S_2 *mapping from* H_2 *to* H_1 *(boldface) for Example* 4.13.

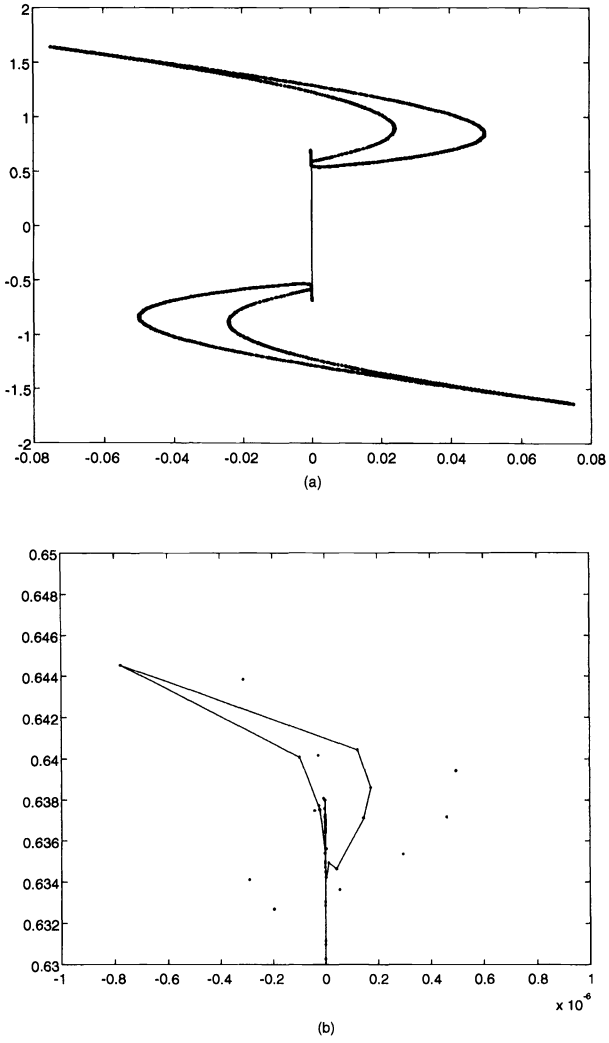

FIG. 6. $\mathcal{U}_0 \cup \mathcal{U}_2 \cup \mathcal{S}_3 \cup \mathcal{T}_3$ *for Example* 4.13. (b) *is a blow-up of part of* (a).

5. Concluding remarks. In this paper we have considered a new approach to an analysis of those nonlinear systems arising from adaptive control of linear time-invariant systems. The particular problems considered were stability of solutions under small perturbation of the initial data and the important question of generic stabilization by the limit gain matrix.

Instead of considering the closed-loop system as a differential equation we reduced the analytical problem to one of the topological properties of a sequence of *flow induced* homeo/diffeomorphisms. The approach is applicable to all universal adaptive stabilization schemes in which the feedback gain matrix is piecewise-constant and right continuous and where the first gain and subsequent ordering of the gains is independent of initial data. This encompasses every known sequential universal adaptive stabilization scheme.

We have established that the totality of initial conditions, $\{x_0 \in \mathbb{R}^n\}$, is partitioned according to

- an open and dense full-Lebesgue-measure set $\mathcal{S}$ on which stability of solutions is preserved under small perturbations and the limit gain is stabilizing,
- a nowhere dense and Lebesgue-measure-zero set $\mathcal{T}$ on which on which stability of solutions is not preserved but the limiting gain is still stabilizing,

• a nowhere dense and Lebesgue-measure-zero set $\mathcal{U}$ on which the limiting gain is not stabilizing.

For the class of minimum-phase, relative-degree-one, second-order systems with known sign of the high-frequency gain we showed the latter to be a closed, connected curve with at most finitely many points of nonsmoothness. We also obtained necessary conditions under which universal adaptive stabilization by switching sequence controllers is possible.

This new approach suggests several interesting problems. For example, how does the geometric structure of the sets $\mathcal{S}$, $\mathcal{T}$, and $\mathcal{U}$ break up as we perturb either the system (A, B, C) or the gain and switching sequences? In particular, is the structure stable under small nonlinear perturbations? Can we exploit knowledge of this structure to specify a finite number of experiments by which a stabilizing gain can be "identified"? Moreover, what happens if the system is *nonlinear* between switches? Can we still conclude these same generic properties?

Finally, in Logemann and Mårtensson (1990) piecewise-constant universal adaptive stabilization is considered for a large class of distributed parameter systems. It would be interesting to investigate the topological structure of $\mathcal{U}$, $\mathcal{S}$, and $\mathcal{T}$ in this case.

Beyond the piecewise-constant case we could also consider generic properties for adaptation laws in which f in (1.1)-(1.3) is smooth or piecewise-smooth. Similar results are anticipated in this case. However, the analytical techniques will be different.

Acknowledgment. I would like to thank B. D. Mestel of the University of Exeter for several illuminating discussions.

$\mathcal{H}_\infty$ CONTROL OF NONLINEAR SYSTEMS: DIFFERENTIAL GAMES AND VISCOSITY SOLUTIONS*

PIERPAOLO SORAVIA†

Abstract. Dealing with disturbances is one of the most important questions for controlled systems. $\mathcal{H}_\infty$ optimal control theory is a deterministic way to tackle the problem in the presence of unfavorable disturbances. The theory of differential games and the study of the associated Hamilton-Jacobi-Isaacs equation appear to be basic tools of the theory. We consider a general, nonlinear system and prove that the existence of a continuous, local viscosity supersolution of the Isaacs equation corresponding to the $\mathcal{H}_\infty$ control problem is sufficient for its solvability. We also show that the existence of a lower semicontinuous viscosity supersolution is necessary.

Key words. $\mathcal{H}_\infty$ control, differential games, viscosity solutions, Isaacs equation, nonlinear systems

AMS subject classifications. viiipt 93B36, 49L25, 90D25

1. Introduction.

In this paper we consider a general, nonlinear, controlled, dynamical system subject to unknown disturbances

$$\dot{y} = f(y, a, b), \tag{1.1}$$

with output or response $h(y, a, b)$, where a is the control and b is the disturbance. The disturbances are modelled deterministically as functions of time, and we want to optimize the performance of the system using the worst case criterion.

We are given a closed set $\mathcal{T}$ with respect to which the undisturbed system ($b = 0$) is (expected to be) stable (or asymptotically stable), and for some prescribed $\gamma > 0$ we look for control functionals (or strategies) $\alpha = \alpha[b]$ of the controller that achieve the stability and such that, for all possible disturbances $b(\cdot)$, the trajectories solutions of (1.1) starting at a point of $\mathcal{T}$ satisfy

$$\int_0^t |h(y, \alpha, b)|^2 ds \leq \gamma^2 \int_0^t |b|^2 ds \quad \text{for all } t > 0. \tag{1.2}$$

If we can find such an α (ideally in feedback form), we say that the $\mathcal{H}_\infty$ suboptimal control problem is solvable with disturbance attenuation level γ. The definition we use, which we basically take from Van der Shaft [30], is here given in an informal way and we refer the reader to the next section, where (1.2) is also generalized in particular to points off $\mathcal{T}$, and to Remarks 2.2 and 2.3, where we discuss the connections with previous literature.

As formulated, the problem appears to be a differential game for the system (1.1), as first observed by Basar and Bernhard [10], and indeed the $\mathcal{H}_\infty$ problem is solvable if and only if a suitably defined, nonnegative value function is zero on $\mathcal{T}$ and admits optimal strategies (for the definition of value function we follow Elliott and Kalton [13]; for a description of the relationship between differential games and viscosity solutions and more recent references, see also Evans and Souganidis [14] and the author [25]). This fact makes the problem similar to that of proving stability and asymptotic stability of dynamical systems with competitive controls, which we studied in [26], [27]. We approach the $\mathcal{H}_\infty$ problem using the same method of the mentioned papers with relevant additional difficulties, namely, the unboundedness of the sets of controls and disturbances, the unboundedness of the dynamics with respect to the parameters, and the fact that the running cost of the trajectories, that is,

$$|h(y, a, b)|^2 - \gamma^2 |b|^2,$$

†Dipartimento di Matematica Pura e Applicata, via Belzoni, 7, 35131 Padova, Italy (soravia@pdmat1.math.unipd.it).

does not have a prescribed sign. To tackle the first two we use a change of variables and adapt to differential games a general, classical method to study unbounded control problems, which consists of the reparametrization of the trajectories. This idea leads to a more regular Hamiltonian while leaving unchanged the value function and was used to this purpose for control problems by Barles [6]. The problem shows also the unusual fact that the payoff functional of the differential game, which we recover from (1.2), is a maximum cost type functional, as previously studied by Lions [24], Barles and Perthame [7], and Barron and Ishii [9] in optimal stopping time control problems and by Barron [8], Krassowski and Subbotin [23], and the author [27] for differential games. There is also the subtle question of the existence of the value of differential games that we have to take into account, and this fact will be discussed in Remarks 2.4 and 3.5.

Our approach is based on the study of the Hamilton-Jacobi-Isaacs equation corresponding to the differential game and the use of the theory of viscosity solutions for fully nonlinear first- (and second-) order partial differential equations initiated by Crandall and Lions [12]. This is due to the fact that, in the case of nonlinear systems even in a special form as nonlinear in the state and affine in the controls, the Isaacs equation does not have in general classical solutions. The goal is to show a rigorous relationship between the $\mathcal{H}_\infty$ problem and the Isaacs equation and to prove necessary and sufficient conditions for its solvability. We prove that if there is a continuous, nonnegative, viscosity supersolution of the Isaacs equation, null on $\mathcal{T}$, then the $\mathcal{H}_\infty$ suboptimal control problem is solvable. Moreover, if the value function is finite, then it is a discontinuous solution of the equation; when it is continuous, it is the minimal nonnegative, continuous supersolution. Our first result can be stated also locally in a neighborhood of $\mathcal{T}$, with a suitable definition of the local $\mathcal{H}_\infty$ suboptimal problem. In our case, the Isaacs equation has no unique solution in general, and this creates a further difficulty for the problem since the usual comparison theorems for viscosity solutions do not apply and we need to look for new optimality principles for supersolutions. The presentation of the results is almost self-contained, and we remark that they can be easily generalized to a wider class of nonlinear differential games.

Our results are the parallel of those of James [20] for dissipative systems, first studied by Willems [32] (see also Hill and Moylan [16]), where, however, the stability requirement is not an issue. In that case, the control $a(\cdot)$ ranges in a set that is a singleton, or equivalently a smooth feedback control $a(x)$ is fixed in the dynamics (1.1); this makes the proof much easier to obtain. However in that special case, the results of James [20] are stronger in the sense that, to prove the sufficiency part, the supersolution is required only to be lower semicontinuous. We could do the same in our situation if the control set A is compact, allowing relaxed strategies or requiring convexity of the sets $(f(x, A, b), h(x, A, b))$. Therefore our results can be extended to contain those of James [20], but the details will be presented elsewhere. One of the referees pointed out to us the recent paper by Ball and Helton [2], where the results in [20] are applied to get necessary conditions for the solution of the nonlinear $\mathcal{H}_\infty$ control problem in the case of nonlinear affine systems using viscosity solutions.

In this paper we consider a system with complete information. However, the $\mathcal{H}_\infty$ control problem for partially observed systems has great relevance for the applications and has been studied by Isidori and Astolfi [18] in the case of nonlinear systems affine in the controls (but see also Basar and Bernhard [10]). Some results in this direction are contained in the paper by the author [28].

It is well known that disturbances can be also modelled as stochastic processes. There is an interesting link between the two theories, by means of the risk-sensitive control approach, where a small parameter is introduced to measure the noise intensity in the stochastic system and to affect the payoff functional, which is in a certain log-exp form. In the limit as the

parameter goes to zero, it can be proven that the related value functions converge to the value function of a differential game that is contained in the class we consider. This result, originally obtained by Jacobson [19] for the linear exponential quadratic gaussian problem and formally by Whittle [31] for nonlinear systems, has been proved by Fleming and McEneaney [15] and independently by James [21], for finite horizon problems.

We finally recall that the $\mathcal{H}_\infty$ control problem was originally formulated for linear systems by Zames [33] in the frequency domain, where the name $\mathcal{H}_\infty$ has a clear meaning. For detailed descriptions of the problem as well as important recent developments of the theory and long lists of references, we also refer to Basar and Bernhard [10], Van der Shaft [29], [30], and Ball, Helton, and Walker [3].

The paper is organized as follows. In §2 we discuss assumptions and definitions. In §3 we state the main results of the paper with some comments. In §4 we prove some results concerning an auxiliary problem. In §5 we give the proofs of the main results. In §6 we briefly discuss the solution of the problem and the existence of optimal strategies in feedback form.

2. Preliminaries and differential games. We consider the following controlled dynamical system:

$$\begin{cases} \dot{y} = f(y,a,b), & y(0) = x \in \mathbb{R}^N, \\ z = h(y,a,b). \end{cases} \tag{2.1}$$

We assume that $A \subset \mathbb{R}^M$ and $0 \in B \subset \mathbb{R}^M$ are closed, $f : \mathbb{R}^N \times A \times B \to \mathbb{R}^N$ and $h : \mathbb{R}^N \times A \times B \to \mathbb{R}$ are continuous, and the following are satisfied:

$$\begin{cases} |f(x,a,b) - f(y,a,b)| \le L(1 + |a|^q + |b|^q)|x - y|, \\ |f(x,a,b)| \le L(1 + |x| + |a|^q + |b|^q) \quad \text{for all } x, y, a, b \text{ and some } 0 \le q < 2, \\ |h(x,a,b) - h(y,a,b)| \le L_R(1 + |a|^2 + |b|^2)|x - y|, \\ C_R^0|a|^2 - L_R(1 + |a|^q + |b|^2) \le h(x,a,b) \le L_R(1 + |a|^2 + |b|^q), \quad (C_R^0 > 0), \\ \text{for all } |x|, |y| \le R, a \in A, b \in B, R > 0, \text{ and some } 0 \le q < 2. \end{cases} \tag{2.2}$$

In our main results, we will also require that

$$h(x,a,0) \ge 0. \tag{2.3}$$

No big changes have to be made if in (2.2) we substitute 2 with $p \ge 1$. In our notation, y is the state space variable, z is the running cost, a is the controlled input, and b is the disturbance on the system. Usually in the applications $h(x,a,b) = |\bar{h}(x,a)|^2$, where $\bar{h} : \mathbb{R}^N \times A \to \mathbb{R}^P$ is the output to be controlled; however, since some results of this paper have independent interest and in order to extend the known results in the case of dissipative systems, we do not restrict ourselves to nonnegative costs, allowing h to depend also on b. The assumptions (2.2), (2.3) are satisfied by the usual linear quadratic model. The same is true for nonlinear systems affine in the controls with quadratic cost.

The admissible controls for our problem are given by the two sets

$$\begin{cases} \mathcal{A} = L^2_{loc}(\mathbb{R}_+, A), \\ \mathcal{B} = L^2_{loc}(\mathbb{R}_+, B); \end{cases}$$

note in particular that they are not required to be small for large times, as usually done in the literature. We will denote by $y_x(\cdot; a, b)$ or simply by $y_x(\cdot)$ or $y(\cdot)$ the unique solution

of (2.1) corresponding to the choice of the controls $a \in \mathcal{A}$, $b \in \mathcal{B}$. We also define the admissible strategies for the controller as *nonanticipating* (or causal) functionals $\alpha : \mathcal{B} \to \mathcal{A}$, i.e., satisfying the condition

$$\text{for all } t > 0,\ b = \bar{b} \text{ a.e. in } [0,t] \text{ implies } \alpha[b] = \alpha[\bar{b}] \text{ a.e. in } [0,t], \tag{2.4}$$

and indicate by Δ the set of such functionals.

Remark 2.1. Definition (2.4), which corresponds to the full-information situation, means that, when acting at time t, the controller a knows completely the control $b(\cdot)$ in the past $[0,t]$ but has no preview of the future behavior of the disturbance. There are at least two typical examples of nonanticipating strategies. The first one is a constant mapping $\alpha[b] \equiv a \in \mathcal{A}$, for all $b \in \mathcal{B}$; the second one is provided by (static state) feedback controls. Let $a : \mathbb{R}^N \to \mathcal{A}$ be a function such that for all $x \in \mathbb{R}^N$ and $b \in \mathcal{B}$, the system $\dot{y} = f(y, a(y), b)$, $y(0) = x$, has a unique, absolutely continuous, global solution. Then for any trajectory $y(\cdot)$ the position $\alpha[b](t) = a(y(t))$ defines a strategy, if $a(\cdot)$ is sufficiently smooth. A little variant of this class of strategies is defined by means of the so-called (see Van der Shaft [30] and the references therein) nonlinear compensators. To the system (2.1) we add the set of equations

$$\dot{\xi} = k(\xi, y), \qquad \xi(0) \in \mathbb{R}^P,$$

and consider a feedback control for this extended system or dynamic state feedback control, $a : \mathbb{R}^{N+P} \to A$. We then define the functional $\alpha[b](t) = a(\xi(t), y(t))$, that, with suitable assumptions on k and a, is a strategy.

We are given a closed set $\mathcal{T} \subset \mathbb{R}^N$, with respect to which we want to study the stability of (2.1). We will not require it as an assumption in the statements, but the following is a necessary condition for fulfilling the assumptions of our main Theorem 3.2, namely: for every $x \in \mathcal{T}$ there is $a \in A$ such that $h(x, a, 0) = 0$ and $f(0, a, 0) = 0$.

Given an open set Ω, we introduce the following functional, or exit time of the trajectories from Ω, as

$$t_x = t_x(a,b) = \inf\{t \geq 0 : y_x(t) \notin \Omega\} \leq +\infty, \tag{2.5}$$

where $t_x = +\infty$ if $y(t) \in \Omega$ for all $t \geq 0$. Observe that trivially if $x \notin \Omega$, then $t_x(a,b) = 0$ for all a, b.

Let $\mathcal{T} \subset \Omega \subset \mathbb{R}^N$ be an open set. We say that the system has *finite gain* in Ω measured by γ if the two following conditions are satisfied:

(i) (Ω is viable for the undisturbed system) For all $x \in \Omega$ there is $a \in \mathcal{A}$ such that the solution $y_x(t; a, 0) \in \Omega$ for all $t \geq 0$ or equivalently $t_x(a, 0) = +\infty$.

(ii) The function

$$V_\gamma^\Omega(x) = \inf_{\alpha \in \Delta_\Omega} \sup_{b \in \mathcal{B}_{\Omega,\alpha}} \sup_{t \in \mathbb{R}_+} \int_0^t (h(y_x, \alpha[b], b) - \gamma^2 |b|^2) ds \tag{2.6}$$

is finite for all $x \in \Omega$ and such that $V_\gamma^\Omega \equiv 0$ and continuous at the points of $\mathcal{T}$.

In (2.6) we denoted

$$\mathcal{B}_{\Omega,\alpha} = \{b \in \mathcal{B} : y_x(t; \alpha[b], b) \in \Omega \text{ for all } t \in \mathbb{R}_+\} \tag{2.7}$$

and set that $\alpha \in \Delta_\Omega$ if and only if $0 \in \mathcal{B}_{\Omega,\alpha}$. We observe that condition (i) implies $\Delta_\Omega \neq \emptyset$ and then $V_\gamma^\Omega \geq 0$ (to prove this fact it is sufficient to select $0 = t \in \mathbb{R}_+$ and $b \equiv 0$ as special values in the right-hand side of (2.6)), but in general V_γ^Ω may assume the value $+\infty$ at some points.

We say that the *local* $\mathcal{H}_\infty$ *suboptimal control problem* with attenuation level index $\gamma > 0$ is solvable if for any open set $\mathcal{U} \supset \mathcal{T}$, there is an open $\mathcal{T} \subset \Omega \subset \mathcal{U}$ such that the system has finite gain in Ω measured by γ.

If instead the undisturbed system is open-loop Lyapunov stable to $\mathcal{T}$ and the system has finite gain in R^N, namely, the (lower) value function

$$V_\gamma(x) = \inf_{\alpha\in\Delta} \sup_{b\in\mathcal{B}} \sup_{t\in\mathbb{R}_+} \int_0^t (h(y, \alpha[b], b) - \gamma^2|b|^2)ds, \tag{2.8}$$

is finite, equal to zero, and continuous on $\mathcal{T}$, that is, the above condition (ii) is satisfied for $\Omega = \mathbb{R}^N$ ((i) is automatically true in this case), we say that the $\mathcal{H}_\infty$ *suboptimal control problem* is solvable.

The solvability of the local $\mathcal{H}_\infty$ suboptimal control problem clearly implies that the undisturbed system is Lyapunov stable with respect to $\mathcal{T}$ by means of open-loop controls even if this is not explicitly required as for the solvability of the $\mathcal{H}_\infty$ suboptimal problem. We recall in fact that open-loop Lyapunov stability to $\mathcal{T}$ of the undisturbed system means that for any neighborhood $\mathcal{U} \supset \mathcal{T}$ there is $\Omega \supset \mathcal{T}$ such that if $x \in \Omega$ we can find a control $a \in \mathcal{A}$ so that the trajectory solution of

$$\dot{y} = f(y, a, 0), \qquad y(0) = x,$$

satisfies $y(t) \in \mathcal{U}$ for all $t \in \mathbb{R}_+$. If we also want our system to be asymptotically stable, then some condition on the sign of h stronger than (2.3) is to be assumed. We will discuss this point in Remark 3.3. We prefer to prove the stability of the system rather than assuming it in advance as in some previous literature, since as we will see in Remark 3.3, as a consequence of the proof of Theorem 3.2, it is almost a consequence of the finite gain condition.

Remark 2.2 (on previous literature). When applied to linear systems, our definition of $\mathcal{H}_\infty$ suboptimal control problem is less restrictive than the standard one (see, e.g., Basar and Bernhard [10] and the references therein), requiring the existence of a feedback control $a : \mathbb{R}^N \to A$ (or at least a dynamic state feedback control) such that the closed-loop system

$$\dot{y} = f(y, a(y), b), \qquad y(0) = x,$$

has a unique solution for all initial conditions, is asymptotically stable when $b \equiv 0$, and has L^2 gain less than or equal to γ; i.e., for all $y(0) = x \in \mathcal{T}$ the solution satisfies

$$\int_0^\infty h(y, a(y), b)ds \le \gamma^2 \int_0^\infty |b|^2 ds \quad \text{for all } b \in \mathcal{B}. \tag{2.9}$$

In fact, let us assume that the $\mathcal{H}_\infty$ suboptimal control problem is solvable in the sense above and h is nonnegative. If there is an optimal strategy for the value function (2.8), i.e., there is $\alpha \in \Delta$ such that

$$V_\gamma(x) = \sup_{b\in\mathcal{B}} \sup_{\mathbb{R}_+} \int_0^t (h(y, \alpha[b], b) - \gamma^2|b|^2)ds,$$

then we immediately obtain

$$\int_0^\infty h(y, \alpha[b], b)ds \le \gamma^2 \int_0^\infty |b|^2 ds + V_\gamma(x) \quad \text{for all } b \in \mathcal{B}. \tag{2.10}$$

If moreover the optimal strategy can be chosen in feedback form and the initial point of the dynamics is $x \in \mathcal{T}$, then (2.9) is satisfied. It is also clear that feedback stabilizability implies

open-loop Lyapunov asymptotic stability. It is important to observe however that the inequality (2.10) gives information about any point of the space (or at least of a neighborhood of $\mathcal{T}$ in the local problem) and not only about those of the equilibrium set. This is a natural additional request for nonlinear systems and was first proposed by Van der Shaft [30]. As a matter of fact, by known results (see, e.g., Van der Shaft [29] and our Theorem 3.2), when the system is linear and asymptotically stabilizable by linear feedback, (2.9) implies (2.10). For general nonlinear systems such an estimate for trajectories starting at points in a neighborhood of $\mathcal{T}$ cannot in general be deduced from (2.9). Note that if (2.10) holds for some strategy $\alpha \in \Delta$, then choosing $b \in \mathcal{B}$ with support in $[0, t]$, we easily obtain that, when h is nonnegative, α is optimal for $V_\gamma(x)$. The extra positive term in the right-hand side of (2.10) is needed when starting the system at $x \notin \mathcal{T}$, as one realizes choosing $b \equiv 0$, if $h(x, a, 0) > 0$ for all $a \in A$.

For nonlinear systems, the choice of the wider class of strategies that we consider is more appropriate than just feedback controls for developing the dynamic programming approach and the connections with the Hamilton-Jacobi equation. One can later look for optimal strategies in smaller classes. The class of so-called feedback strategies, i.e., causal functionals of the state, can also be used in our problem, with the same results that we prove, provided that the Isaacs condition (see Remark 3.3) is satisfied by the system. We will not discuss this point in detail; see, however, [28]. As much as the definition in the nonlinear case is concerned, according to Van der Shaft [30] (but relaxing the set of strategies), we solve the nonlinear $\mathcal{H}_\infty$ suboptimal control problem if we find a nonnegative function $U : \mathbb{R}^N \to \mathbb{R}$, which is null on $\mathcal{T}$, such that for all $x \in \mathbb{R}^N$ there is a strategy $\alpha_x \in \Delta$ satisfying

$$\int_0^t h(y, \alpha_x[b], b)ds \leq \gamma^2 \int_0^t |b|^2 ds + U(x) \quad \text{for all } b \in \mathcal{B} \text{ and } t \geq 0, \tag{2.11}$$

and the controls $\alpha_x[0]$ provide the open-loop local Lyapunov stability. Arguing as above, we can check that this is equivalent to solving the two following steps. First prove the solvability of the problem as previously defined and then prove the existence of optimal strategies at points of $\mathcal{T}$ (ideally showing that they can be chosen in feedback form) and that they satisfy the stability requirement. The main goal of this paper is to find necessary and sufficient conditions for the solution of the first step. Moreover we will show in the proof of Theorem 3.2 that the stability is guaranteed even by almost optimal strategies of the value function V_γ. We refer to the last section for a discussion and some results about the existence of optimal strategies. This part can be studied by fairly classical methods, as far as a nonconstructive proof is concerned, while it is almost open in the general case if we seek explicit formulas for optimal strategies, except for very special systems.

We need to mention that the stronger gain condition (2.10) or (2.11) involving points off $\mathcal{T}$ is not required in some other previous papers (see, e.g., Van der Shaft [29] and Ball, Helton, and Walker [3]); ours is probably the first to require the continuity of V_γ on $\mathcal{T}$. We feel that both requests provide desirable information about the nonlinear system, and as a matter of fact we will get them as consequences of the proof of Theorem 3.2, without need of additional assumptions, so we decided to include them in the definition. Moreover the definition we use allows us to characterize the solvability of the $\mathcal{H}_\infty$ suboptimal control problem in terms of the existence of suitable continuous solutions of the Hamilton-Jacobi-Isaacs equation, extending the results of the linear case.

We remark that the $\mathcal{H}_\infty$ problem is studied in the previous literature only with respect to a single equilibrium point of the system and not to a general closed set. We finally recall that in the literature, the $\mathcal{H}_\infty$ control problem is to find the smallest $\gamma^* \geq 0$ such that the $\mathcal{H}_\infty$ suboptimal control problem is solvable for all $\gamma > \gamma^*$.

Remark 2.3. For the definition of the local $\mathcal{H}_\infty$ suboptimal control problem, again we follow Van der Shaft [30]. However, as an alternative to our finite gain condition in Ω, one

may consider the function

$$V(x) = \inf_{\alpha\in\Delta} \sup_{b\in\mathcal{B}} \sup_{[0,t_x[} \int_0^t (h(y, \alpha[b], b) - \gamma^2|b|^2)ds, \tag{2.12}$$

rather than the one in (2.6). The statement of our main Theorem 3.2 with a similar proof will hold true even if we change (ii) and ask that V in (2.12) is finite in Ω, null and continuous on $\mathcal{T}$.

Remark 2.4. The function in (2.8) is called the lower value function of the differential game (2.1) with payoff functional given by

$$P(x, a, b) = \sup_{\mathbb{R}_+} \int_0^t (h(y, a, b) - \gamma^2|b|^2)ds,$$

which is a maximum cost type functional. The function in (2.6) is a localized version of (2.8) in Ω that we introduce for our problem. In this paper we will mostly study properties of functions like (2.8), and this will lead to prove properties also for the local functions (2.6) or (2.12). Our definition of the lower value function follows Elliott and Kalton [13] and the references therein. The definition is not symmetric since b maximizes using controls while a minimizes using strategies. As usual in the theory of differential games it is not possible, in general, to define a value function in any reasonable way. We decided here to develop the lower value approach, but using the upper value given by

$$\sup_{\beta\in\Gamma} \inf_{a\in\mathcal{A}} P(x, a, \beta[a]),$$

where Γ is the corresponding set of strategies for "player" b, we would obtain completely analogous results with obvious changes in the statements. We will come back to this and to the question of existence of value in Remark 3.5.

3. Viscosity solutions and main results. We start this section by recalling the definition of viscosity solution of a nonlinear, first-order, partial differential equation, in the discontinuous case (we refer to Crandall and Lions [12], Ishii [17], and the more recent Crandall, Ishii, and Lions [11] for more details).

Let $w : \Omega \to \mathbb{R}$, $\Omega \subset \mathbb{R}^N$ open, be a locally bounded function. We define its lower and upper semicontinuous envelopes as, respectively,

$$w_*(x) = \lim_{r\to 0^+} \inf\{w(y) : |x - y| \le r\}, \qquad w^*(x) = \lim_{r\to 0^+} \sup\{w(y) : |x - y| \le r\}.$$

DEFINITION 3.1. *Let $F : \Omega \times \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$ be a continuous function. The lower (resp., upper) semicontinuous function $u : \Omega \to \mathbb{R}$ is a viscosity supersolution (resp., subsolution) of*

$$F(x, u, Du) = 0 \quad \text{in } \Omega,$$

if for all $\varphi \in C^1(\Omega)$ and $x \in \operatorname{argmin}_{x\in\Omega}(u - \varphi)$, (resp., $x \in \operatorname{argmax}_{x\in\Omega}(u - \varphi)$), we have

$$F(x, u(x), D\varphi(x)) \ge 0 \qquad (\text{resp., } F(x, u(x), D\varphi(x)) \le 0).$$

We also say that $D\varphi(x) \in D^- u(x)$, the subdifferential of u at x (resp., $D\varphi(x) \in D^+ u(x)$, the superdifferential). A locally bounded function u is a viscosity solution of $F(x, u, Du) = 0$ if u_* is a supersolution and u^* is a subsolution.

We now state the main results of this paper, whose proof can be found at the end of §5.

THEOREM 3.2. *Consider the system* (2.1) *and assume* (2.2), (2.3). *Let* $\Omega \supset \mathcal{T}$ *be open, and suppose there is a continuous and nonnegative function* $U : \overline{\Omega} \to \mathbb{R}$ *such that* $U(x) \equiv U_0$ *if* $x \in \partial\Omega$, $U(x) < U_0$ *for* $x \in \Omega$, $U \equiv 0$ *on* $\mathcal{T}$, *and* U *is a viscosity supersolution of*

$$(3.1)\quad \mathcal{H}(x, DU(x)) = \inf_{b\in B}\sup_{a\in A}\{-f(x,a,b)\cdot DU(x) - h(x,a,b) + \gamma^2|b|^2\} \geq 0 \qquad \text{in } \Omega.$$

Then the system has finite gain in Ω *measured by* γ. *If the family of open sets* $\{x \in \Omega : U(x) < \varepsilon\}_{\varepsilon>0}$ *is a local base for* $\mathcal{T}$, *then the local* $\mathcal{H}_\infty$ *suboptimal control problem is solvable. If, moreover,* $\Omega = \mathbb{R}^N$, *then the* $\mathcal{H}_\infty$ *control problem is solvable.*

Remark 3.3. Observe that by Definition (3.1) of $\mathcal{H}$, the assumptions of Theorem 3.2 imply that the function U is also a supersolution of

$$\max_{a\in A}\{-f(x,a,0)\cdot DU - h(x,a,0)\} \geq 0 \quad \text{in } \Omega;$$

therefore by the sign condition (2.3) it can be seen as a Liapunov function for the undisturbed control system in the sense we defined in [27]. The stability of the undisturbed system that comes as a consequence of the proof of Theorem 3.2 is then not a surprise. If, moreover, the output h satisfies the condition

$$\text{for all } \varepsilon > 0, \qquad h(x,a,0) \geq C_\varepsilon > 0 \qquad \text{in } (\mathbb{R}^N \backslash B(\mathcal{T},\varepsilon)) \times A,$$

where $B(\mathcal{T},\varepsilon) = \{x : \operatorname{dist}(x,\mathcal{T}) < \varepsilon\}$ and A is compact, then the undisturbed system is also asymptotically stable, as proved in the paper by the author [26]. To achieve asymptotic stability, the previous condition can be relaxed by asking the so-called zero-state detectability, which we do not state here in detail. If the set $\mathcal{T}$ is compact, as for example in the standard case $\mathcal{T} = \{0\}$, then the result follows without the assumption on the sublevel sets of the continuous supersolution U of (3.1) by assuming instead that it is positive outside $\mathcal{T}$. To see this, we can apply the first part of the statement to the family $\{\Omega_\varepsilon\}_{\varepsilon>0}$ of open neighborhoods of $\mathcal{T}$ constructed as follows. Given a family $\{\mathcal{U}_\varepsilon\}_{\varepsilon>0}$ of compact neighborhoods of $\mathcal{T}$, define $\Omega_\varepsilon = \{x \in \mathcal{U}_\varepsilon : U(x) < \min_{\partial\mathcal{U}_\varepsilon} U\}$. Therefore when $\mathcal{T}$ is compact, the finite gain condition implies the open-loop stability if the value function V_γ is continuous and positive outside $\mathcal{T}$.

We observe that if the assumptions of the theorem are satisfied for some $\gamma^* > 0$, then they are obviously satisfied for all $\gamma > \gamma^*$ by the same function U. We also note that, since U of Theorem 3.2 is nonnegative, $U(x) = 0$ implies $0 \in D^-U(x)$; therefore $\mathcal{H}(x,0) \geq 0$, and then, by the assumption (2.3), there is $a \in A$ such that $h(x,a,0) = 0$. This in particular holds on $\mathcal{T}$ and is a necessary condition on the data for the assumptions of Theorem 3.2 to hold.

When studying the local $\mathcal{H}_\infty$ suboptimal control problem, it is interesting to have a priori information on the size of the neighborhood of $\mathcal{T}$ where the gain condition is satisfied. Theorem 3.2 provides an indirect answer to the question, saying that after computing, even locally around $\mathcal{T}$, a nonnegative, continuous viscosity supersolution of the Isaacs equation, which is null on $\mathcal{T}$, the system has a finite gain in any of its sublevel sets.

The next result completes the parallel with the theory of dissipative systems; see for example Willems [32], Hill and Moylan [16], and James [20], where U plays the role of storage function and V_γ defined in (2.8) plays the role of available storage. It also characterizes the lower value function V_γ when it is continuous, and this is useful to prove the existence of the value of the game for our problem; see Remarks 2.3 and 3.2.

THEOREM 3.4. *Assume* (2.2); *let* V_γ *be defined as in* (2.8) *and* $\Omega \subset \mathbb{R}^N$ *be open*; *and suppose that* V_γ *is locally bounded in* Ω.

(i) *Then* V_γ *is a viscosity solution of*

$$(3.2)\qquad \min\{\mathcal{H}(x, DV_\gamma(x)), V_\gamma\} = 0 \quad \text{in } \Omega$$

and, if it is continuous in $\Omega = \mathbb{R}^N$, *is the minimal continuous supersolution of* (3.2).

(ii) *If moreover* (2.3) *holds, then* V_γ *is a viscosity solution of*

$$\mathcal{H}(x, DV_\gamma(x)) = 0 \quad \text{in } \Omega \tag{3.3}$$

and, when continuous, is the minimal, nonnegative, continuous supersolution of (3.3).

Remark 3.5. Theorem 3.4 shows that a necessary condition for the solvability of the $\mathcal{H}_\infty$ suboptimal problem is the existence of a lower semicontinuous, nonnegative viscosity supersolution, null on $\mathcal{T}$ ($V_{\gamma *}$ to be specific), of

$$\mathcal{H}(x, DU(x)) \geq 0 \quad \text{in } \mathbb{R}^N.$$

Theorem 3.2 shows that a sufficient condition for the solvability is the existence of a continuus supersolution with the same sign properties. The gap between necessary and sufficient conditions can be filled up, when A is compact, by further extending the class of strategies, namely, allowing relaxed strategies or instead assuming the convexity of the sets $(f(x, A, b), h(x, A, b))$, for all x, b. The details will be presented elsewhere; see [34].

Our last remark concerns the upper value approach. When considering the upper value, the associated Hamiltonian would be $\overline{\mathcal{H}}(x, p)$ defined as in (3.1), interchanging the roles of inf and sup. We can get analogous results in this case, but of course this requires obvious modifications in the statements of the theorems. When the so-called Isaacs condition holds, namely if $\mathcal{H}(x, p) = \overline{\mathcal{H}}(x, p)$, for all $x, p \in \mathbb{R}^N$, then the two approaches are equivalent even if Theorem 3.4 does not prove, in general, that the lower (2.8) and the upper (see Remark 2.4) values coincide. The value does exist for our problem, as a consequence of the characterization of Theorem 3.4, when both upper and lower values are real valued and continuous in $\mathbb{R}^N$ (and the Isaacs condition holds).

Remark 3.6. Recently many efforts have been made to compute numerically the value function of differential games. We just refer here to the paper of Bardi, Falcone, and the author [1] and the references therein, which are more related to the techniques used in this paper, based on the study of the Isaacs equation. As pointed out in Remark 3.3 and as a result of Theorem 3.2, it looks interesting to study numerically the equations (3.2) or (3.3) to compute a solution (or at least a supersolution) or have a description of its sublevel sets. See also the concluding remark of the last section, where the importance of numerical approximations is pointed out for the computation of optimal strategies and feedbacks. We leave this as a future plan of research. Some results are already available, however, to compute the $\mathcal{H}_\infty$ norm in the case of dissipative systems (when the set A is a singleton) and are contained in a paper by James and Yuliar [22].

4. Some preliminary results. In this section we consider a slightly different problem from that of §2. The connection will become clear in the next section.

For the rest of this section we assume that A, B are closed, but we do not specify the classes of admissible controls $\mathcal{A}$, $\mathcal{B}$. We only require that if $a \in \mathcal{A}$, then $a : \mathbb{R}_+ \to A$ is measurable and that for all $s > 0$ we have $a(\cdot + s) \in \mathcal{A}$. Moreover if $a_1, a_2 \in \mathcal{A}$ and $t_1 > 0$, then also the measurable function defined by

$$a(t) = \begin{cases} a_1(t), & t \in [0, t_1[, \\ a_2(t - t_1), & t \in [t_1, +\infty[, \end{cases}$$

belongs to $\mathcal{A}$. The same properties will hold for the set of controls $\mathcal{B}$.

We also consider continuous functions $\phi : A \times B \to [1, +\infty)$ and $g : \mathbb{R}^P \times A \times B \to \mathbb{R}^P$ such that $g(\cdot, a, b)$ is continuous uniformly in a and b and $g(\cdot, \cdot, b)$ is bounded on $K \times A$ for any $K \subset \mathbb{R}^P$ compact. We assume that for all admissible controls $a \in \mathcal{A}, b \in \mathcal{B}$, there is a unique absolutely continuous, global solution $z(\cdot) = z_x(\cdot) = z_z(\cdot; a, b)$ of the Cauchy

problem

$$\dot{z}(\tau) = g(z(\tau), a(t(\tau)), b(t(\tau))), \quad z(0) = x, \tag{4.1}$$

where $t_{a,b}(\cdot) = t(\cdot) = \tau^{-1}(\cdot)$ and $\tau(\cdot) = \tau_{a,b}(\cdot)$ is the increasing change of parameter

$$\tau(t) = \int_0^t \phi(a(s), b(s))ds,$$

and suppose that it satisfies the condition

$$|z_x(s) - x| \leq \omega_R(\tau) \qquad \text{for all } |x| \leq R, s \in [0, \tau], a \in \mathcal{A}, b \in \mathcal{B}, \tag{4.2}$$

where $\omega_R : \mathbb{R}_+ \to \mathbb{R}_+$ is nondecreasing, continuous at zero and $\omega_R(0) = 0$ (ω_R is a modulus). In particular, from (4.2) we can conclude that $|z_x(\tau) - x| \leq o(1)$, as $\tau \to 0^+$, uniformly in a, b, and for x varying in a compact set. We will briefely denote in the following the reparametrized controls as $a(\tau) = a(t(\tau))$, $b(\tau) = b(t(\tau))$, for all $a \in \mathcal{A}$, $b \in \mathcal{B}$.

Remark 4.1. If, for example, the system (4.1) has unique global solution and g satisfies the growth condition $|g(x, a, b)| \leq L(1 + |x|)$, then for all $a \in \mathcal{A}$ and $b \in \mathcal{B}$, we have that

$$|z_x(s; a, b) - x| \leq \int_0^s |g(z, a, b)|dr \leq L[(1 + |x|)s + \int_0^s |z_x - x|dr] \qquad \text{for all } s \geq 0,$$

and then, by the Gronwall lemma,

$$|z_x(s) - x| \leq L[(1 + |x|)\tau] \exp(L\tau) \quad \text{for } s \in [0, \tau],$$

and (4.2) holds.

Assume also that $h = h(x, a, b)$ is continuous and satisfies the growth condition $|h(x, a, b)| \leq C_R$, for all $|x| \leq R, a \in A, b \in B$. Then we can also derive the estimate

$$\int_0^\tau |h(z_x, a, b)|ds \leq C_{R_\tau}\tau \qquad \text{for all } |x| \leq R, a \in \mathcal{A}, b \in \mathcal{B},$$

where we used the fact that $|z_x(s)| \leq |z_x(s) - x| + |x| \leq L(1 + R)\tau \exp(L\tau) + R =: R_\tau$, for all $|x| \leq R, s \in [0, \tau]$. Therefore also the trajectories $z = (y, r)$ of the dynamical system

$$\begin{cases} y' = g(y, a, b), & y(0) = x, \\ r' = h(y, a, b), & (0) = r_0, \end{cases}$$

have the property (4.2).

We continue considering the following class of functions. Let $\Omega \subset \mathbb{R}^P$ open, $\lambda \geq 0$, and $u : \overline{\Omega} \to \mathbb{R}$ be a continuous function. We define a (lower) value function for the differential game (4.1) by setting

$$V^\lambda(x) = \inf_{\alpha \in \Delta} \sup_{b \in \mathcal{B}} \sup_{[0,\tau_x]} \left\{ \int_0^\tau \exp(-\lambda s) l(z_x(s), \alpha[b](t(s)), b(t(s)))ds \right. \tag{4.3}$$
$$\left. + \exp(-\lambda\tau)\, u(z_x(\tau)) \right\},$$

where $l : \mathbb{R}^P \times A \times B \to \mathbb{R}$ is continuous, $l(\cdot, a, b)$ is continuous uniformly in a, b and satisfies $|l(x, a, b)| \leq C_R$ for all $|x| \leq R, a, b$, $R > 0$, z_x is here the solution of (4.1), and τ_x

is the exit time of $z_x(\cdot)$ from Ω. It is clear by definition that $V^\lambda \geq u$. Throughout this section we will assume that V^λ is locally bounded.

We also denote the Hamiltonian function associated with the differential game as

$$H(x, p) = \inf_{b\in B} \sup_{a\in A}\{-g(x, a, b) \cdot p - l(x, a, b)\}$$

and assume it is continuous in $\mathbb{R}^{2P}$.

We will prove that the value function (4.3), under some assumptions on the functions involved, namely u, l, g, H, and on the superdifferential of V^λ itself, satisfies a suitable variational inequality in the viscosity sense. This proof, besides a technical lemma, combines modifications of several known arguments, in particular of Evans and Souganidis [14], Ishii [17], and the author [27], but we will give it for the sake of completeness. The main new difficulties of which we need to take care are the unboundedness of the control sets and the presence of reparametrized controls in the dynamics (4.1).

Remark 4.2. By the definition of the reparametrization, we observe that for all $a \in \mathcal{A}$, $b \in \mathcal{B}$, and $t_1, t_2 > 0$, we have

$$\tau_{a,b}(t_1 + t_2) = \tau_{a,b}(t_1) + \tau_{a(\cdot+t_1),b(\cdot+t_1)}(t_2),$$

and then for all $\tau_1, \tau_2 > 0$,

$$t_{a,b}(\tau_1 + \tau_2) = t_{a,b}(\tau_1) + t_{a(\cdot+t_{a,b}(\tau_1)),b(\cdot+t_{a,b}(\tau_1))}(\tau_2).$$

As a consequence of this equality, for all $a \in \mathcal{A}$, $b \in \mathcal{B}$, and $\tau_1 > 0$, we get

$$a(t_{a,b}(\tau_1 + \cdot)) = a(t_{a,b}(\tau_1) + t_{a(\cdot+t_{a,b}(\tau_1)),b(\cdot+t_{a,b}(\tau_1))}(\cdot)).$$

Moreover for all $a_1, a_2 \in \mathcal{A}$, $b_1, b_2 \in \mathcal{B}$, $\tau_1 > 0$, if we define

$$a(t) = \begin{cases} a_1(t), & [0, t_{a_1,b_1}(\tau_1)), \\ a_2(t - t_{a_1,b_1}(\tau_1)), & [t_{a_1,b_1}(\tau_1), +\infty), \end{cases}$$

and $b(\cdot)$ correspondingly, then we have

$$\begin{aligned} a(t_{a,b}(\tau)) &= \begin{cases} a(t_{a_1,b_1}(\tau)), & [0, \tau_1), \\ a(t_{a_1,b_1}(\tau_1) + t_{a_2,b_2}(\tau - \tau_1)), & [\tau_1, +\infty), \end{cases} \\ &= \begin{cases} a_1(t_{a_1,b_1}(\tau)), & [0, \tau_1), \\ a_2(t_{a_2,b_2}(\tau - \tau_1)), & [\tau_1, +\infty). \end{cases} \end{aligned}$$

The same properties hold true for the elements of the set of controls $\mathcal{B}$.

The reparametrization functional also has the following nonanticipating property. For any fixed $\overline{\tau} > 0$ and $a_1, a_2 \in \mathcal{A}$, $b_1, b_2 \in \mathcal{B}$, if $a_1 = a_2$ and $b_1 = b_2$ a.e. in $[0, t_{a_1,b_1}(\overline{\tau})]$, then $t_{a_1,b_1}(\overline{\tau}) = t_{a_2,b_2}(\overline{\tau})$. In fact we have by definition

$$\tau_{a_2,b_2}(t_{a_1,b_1}(\overline{\tau})) = \int_0^{t_{a_1,b_1}(\overline{\tau})} \phi(a_2(s), b_2(s))ds = \int_0^{t_{a_1,b_1}(\overline{\tau})} \phi(a_1(s), b_1(s))ds = \overline{\tau}.$$

The following lemma is an important step of the proof and can be viewed as the dynamic programming principle for (4.3) (see also [27]). Main ingredients of the proof are contained in Remark 4.2.

LEMMA 4.3. *For all $\tau \geq 0$ and $x \in \Omega$ we have that*

$$V^\lambda(x) \geq \inf_{\alpha\in\Delta}\sup_{b\in\mathcal{B}}\left\{\int_0^{\tau\wedge\tau_x}\exp(-\lambda s)l(z_x,\alpha[b],b)ds + \exp(-\lambda\tau\wedge\tau_x)\,V^\lambda(z_x(\tau\wedge\tau_x))\right\}. \tag{4.4}$$

Moreover if $V^{\lambda *}(x) > u(x)$, for all sequences $x_n \to x$ such that $V^\lambda(x_n) \to V^{\lambda *}(x)$ there is $\varepsilon > 0$ such that the equality holds in (4.4), *at x_n, for all $\tau \in [0,\varepsilon]$ and $|x_n - x| < \varepsilon$.*

Proof. 1. By Definition (4.3) of the value function, for every $\varepsilon > 0$ there is $\alpha \in \Delta$ such that

$$V^\lambda(x) + \varepsilon \geq \sup_{[0,\tau_x]}\left\{\int_0^\tau \exp(-\lambda s)l(z_x,\alpha[b],b)ds + \exp(-\lambda\tau)\,u(z_x(\tau))\right\} \quad \text{for all } b \in \mathcal{B}.$$

For any fixed $s > 0$, we get, for all $b \in \mathcal{B}$,

$$V^\lambda(x) + \varepsilon \geq \int_0^{s\wedge\tau_x}\exp(-\lambda r)l(z_x,\alpha[b],b)dr + \exp(-\lambda s\wedge\tau_x)\cdot\sup_{[0,\tau_{z_x}(s\wedge\tau_x)]}\left\{\int_0^\tau \exp(-\lambda r)l(z_{z_x(s\wedge\tau_x)},\alpha[b](t(r+s\wedge\tau_x)),b(t(r+s\wedge\tau_x)))dr + \exp(-\lambda\tau)\,u(z_{z_x(s\wedge\tau_x)}(\tau))\right\}.$$

Then we have, also using Remark 4.2 and the properties of the sets $\mathcal{A}$, $\mathcal{B}$,

$$V^\lambda(x) + \varepsilon \geq \int_0^{s\wedge\tau_x}\exp(-\lambda r)l(z_x,\alpha[b],b)dr + \exp(-\lambda s\wedge\tau_x)V^\lambda(z_x(s\wedge\tau_x)) \quad \text{for all } b,$$

and the inequality (4.4) follows since ε is arbitrary.

2. We now assume that $x \in \Omega$ and $V^{\lambda *}(x) > u(x)$. If the statement was false, we could find sequences $|x_n - x| < 1/n$, $0 < \tau_n \leq 1/n$ such that $V^\lambda(x_n) \to V^{\lambda *}(x)$ and

$$V^\lambda(x_n) > \inf_{\alpha\in\Delta}\sup_{b\in\mathcal{B}}\left\{\int_0^{\tau_{x_n}\wedge\tau_n}\exp(-\lambda r)l(z_{x_n},\alpha_n[b_n],b_n)dr + \exp(-\lambda\tau_n\wedge\tau_{x_n})\,V^\lambda(z_{x_n}(\tau_n\wedge\tau_{x_n}))\right\}. \tag{4.5}$$

By definition of $V^\lambda(x_n)$, using Remark 4.2 and (4.5), we can construct appropriately $\alpha_n \in \Delta$, $b_n \in \mathcal{B}$ and choose $\varepsilon_n \to 0^+$ such that

$$\sup_{[\tau_n\wedge\tau_{x_n},\tau_{x_n}]}\left\{\int_0^\tau \exp(-\lambda r)l(z_{x_n},\alpha_n[b_n],b_n)dr + \exp(-\lambda\tau)\,u(z_{x_n}(\tau))\right\} \leq V^\lambda(x_n) - \varepsilon_n < \sup_{[0,\tau_{x_n}]}\left\{\int_0^\tau \exp(-\lambda r)l(z_{x_n},\alpha_n[b_n],b_n)dr + \exp(-\lambda\tau)\,u(z_{x_n}(\tau))\right\}$$

and then

$$V^\lambda(x_n) - \varepsilon_n < \sup_{[0,\tau_n\wedge\tau_{x_n}]}\left\{\int_0^\tau \exp(-\lambda r)l(z_{x_n},\alpha_n[b_n],b_n)dr + \exp(-\lambda\tau)\,u(z_{x_n}(\tau))\right\}.$$

Therefore for some sequence $0 < s_n \le \tau_n \wedge \tau_{x_n} \le 1/n$, we have

$$\int_0^{s_n} \exp(-\lambda r) l(z_{x_n}, \alpha_n[b_n], b_n) dr + \exp(-\lambda s_n)\, u(z_{x_n}(s_n)) > V^\lambda(x_n) - \varepsilon_n. \tag{4.6}$$

By assumption (4.2) we know that

$$\sup_{[0,s_n]} |z_{x_n}(\tau) - x_n| \le \omega(s_n) = o(1) \quad \text{as } n \to +\infty.$$

If n is large, by (4.6) and the assumption on l, we then obtain for some $R > 0$ independent of n that

$$C_R s_n + \exp(-\lambda s_n) \sup_{B(x, o(1)+1/n)} u \ge V^\lambda(x_n) - \varepsilon_n.$$

As $n \to +\infty$ we finally get $u(x) = u^*(x) \ge V^{\lambda *}(x)$, a contradiction. □

We can now prove the relationship between the value function and the corresponding Hamilton-Jacobi equation.

PROPOSITION 4.4. *Assume that the following hold. For all $x_0 \in \Omega$, if $V^{\lambda *}(x_0) > u(x_0)$ and $p_0 \in D^+ V^{\lambda *}(x_0)$*

$$\sup_{a \in A, \sigma > 0} \inf \{-g(x, a, b) \cdot p - l(x, a, b) : |x - x_0| \le \sigma, |p - p_0| \le \sigma, |b| \ge 1/\sigma\} > -\lambda V^{\lambda *}(x_0). \tag{4.7}$$

Then for $\lambda \ge 0$, the value function V^λ is a viscosity solution of

$$\min\{\lambda V + H(x, DV), V - u\} = 0 \qquad \text{in } \Omega.$$

Proof. 1. We start by proving that $V (= V^\lambda)$ is a subsolution. Let $x_0 \in \arg\max(V^* - \varphi)$, where $\varphi \in C^1(\Omega)$ and $V^*(x_0) = \varphi(x_0)$. Observe that $V^*(z) \le \varphi(z)$, if $z \in \Omega$. We assume by contradiction that $V^*(x_0) > u(x_0)$ and

$$\lambda\, \varphi(x_0) + H(x_0, D\varphi(x_0)) > 0. \tag{4.8}$$

By (4.7) at $(x_0, D\varphi(x_0))$, we can find σ, $R > 0$ and $a_0 \in A$ such that

$$\lambda\varphi(z) - g(z, a_0, b) \cdot D\varphi(z) - l(z, a_0, b) \ge r_0 > 0 \quad \text{for all } z \in B(x_0, \sigma), |b| \ge R. \tag{4.9}$$

Moreover by (4.8), for all $\bar{b} \in B$, $|\bar{b}| \le R$, there are $\bar{r} > 0, \bar{a} \in A$ such that

$$\lambda\, \varphi(z) - g(z, \bar{a}, b) \cdot D\varphi(z) - l(z, \bar{a}, b) \ge \bar{r}, \qquad z \in B(x_0, \bar{r}), b \in B(\bar{b}, \bar{r}). \tag{4.10}$$

By the compactness of $\{b \in B : |b| \le R\}$, let $\{B(b_i, r_i)\}_{i=1,\dots,n}$ be a finite cover. Using (4.9) or (4.10), we proved that there are $\varepsilon > 0$ and $a_0, \dots, a_n \in A$ so that for all $b \in B$ there is $i \in \{0, \dots, n\}$ that satisfies

$$\lambda\, \varphi(z) - g(z, a_i, b) \cdot D\varphi(z) - l(z, a_i, b) \ge \varepsilon \quad \text{in } B(x_0, \varepsilon) \subset \Omega.$$

We now define the strategy $\alpha \in \Delta$ by the position

$$\alpha[b](t) = \begin{cases} a_0 & \text{if } |b(t)| > R, \\ \alpha[b](t) = a_i & \text{if } |b(t)| \le R \text{ and } b(t) \in B(b_i, r_i) \setminus \bigcap_{0<j<i} B(b_j, r_j). \end{cases}$$

Therefore by (4.2), we can select some small $\tau > 0$, such that

(4.11)
$$\lambda\,\varphi(z_x(s)) - g(z_x(s), \alpha[b](t(s)), b(t(s))) \cdot D\varphi(z_x(s)) - l(z_x(s), \alpha[b](t(s)), b(t(s))) \geq \varepsilon,$$

for all $b \in \mathcal{B}$, $s \in (0, \tau)$, $x \in B(x_0, \varepsilon/2)$, since we can assume $z_x(s) \in B(x_0, \varepsilon)$, for $s \in (0, \tau)$. If we multiply by $\exp(-\lambda s)$ and integrate on $(0, \tau)$, we obtain (also since $\tau = \tau \wedge \tau_x$ and with the agreement that the right-hand side reads $\varepsilon\tau \wedge \tau_x$ if $\lambda = 0$)

$$\begin{aligned}(4.12)\qquad \varphi(x) - \exp(-\lambda\tau \wedge \tau_x)\,\varphi(z_x(\tau \wedge \tau_x)) - \int_0^{\tau\wedge\tau_x} \exp(-\lambda r) l(z_x, \alpha[b], b)dr \\ \geq \varepsilon(1 - \exp(-\lambda\tau \wedge \tau_x))/\lambda \geq \sigma > 0 \quad \text{for all } b \in \mathcal{B},\ x \in B(x_0, \varepsilon/2).\end{aligned}$$

By Lemma 4.3, we can choose $\delta > 0$ and $x_n \to x$ such that $V(x_n) \to V^*(x_o)$, $|x_n - x_0| < \delta$, and

$$\begin{aligned}(4.13)\quad V(x_n) = \inf_{\alpha\in\Delta} \sup_{b\in\mathcal{B}} \left\{ \int_0^{s\wedge\tau_{x_n}} \exp(-\lambda r) l(z_{x_n}, \alpha[b], b)dr \right. \\ \left. + \exp(-\lambda s \wedge \tau_{x_n})\, V(z_{x_n}(s \wedge \tau_{x_n})) \right\}, \quad s \in (0, \delta).\end{aligned}$$

Using (4.12) at such points x_n for large values of n and the properties of φ, we obtain, for fixed τ,

$$\begin{aligned}V^*(x_0) - \exp(-\lambda\tau \wedge \tau_{x_n})\, V^*(z_{x_n}(\tau \wedge \tau_x)) + \varphi(x_n) - \varphi(x_0) \\ - \int_0^{\tau\wedge\tau_{x_n}} \exp(-\lambda r) l(z_{x_n}, \alpha[b], b)dr \geq \sigma \quad \text{for all } b \in \mathcal{B}.\end{aligned}$$

We now use (4.13) to get (we may suppose $\tau < \delta$)

$$V^*(x_0) \geq \sigma + \varphi(x_0) - \varphi(x_n) + V(x_n).$$

As $n \to +\infty$, we obtain the required contradiction.

2. We now proceed with the easier proof that V is a supersolution. We observe that of course $V_* \geq u$, since $V \geq u$ and u is continuous. Let $x_0 \in \arg\min(V_* - \varphi)$, where $\varphi \in C^1(\Omega)$ and $V_*(x_0) = \varphi(x_0)$. We assume by contradiction that

$$\lambda\,\varphi(x_0) + H(x_0, D\varphi(x_0)) < 0.$$

This implies that we can find $\bar{b} \in B$ and $\sigma > 0$ such that

$$\lambda\,\varphi(x_0) - g(x_0, a, \bar{b}) \cdot D\varphi(x_0) - l(x_0, a, \bar{b}) < -\sigma \text{ for all } a \in A.$$

By the assumptions on g and l, there exists $\varepsilon > 0$ such that

$$\lambda\,\varphi(z) - g(z, a, \bar{b}) \cdot D\varphi(z) - l(z, a, \bar{b}) \leq -\varepsilon \qquad \text{for all } a \in A,\ z \in B(x_0, \varepsilon) \subset \Omega.$$

Let $b(\cdot) \equiv \bar{b}$ be a constant control. By (4.2), we have that $|z_x(s) - x| \leq o(1)$ as $s \to 0^+$, uniformly in $x \in B(x_0, \varepsilon/2)$ and $a \in \mathcal{A}$. Therefore there exists $\tau > 0$ small enough such that $\tau < \tau_x(\alpha[b], b)$, for all $\alpha \in \Delta$, $x \in B(x_0, \varepsilon/2)$, and

$$\begin{aligned}\lambda\,\varphi(z_x(s)) - g(z_x(s), \alpha[b](s), b(s)) \cdot D\varphi(z_x(s)) - l(z_x(s), \alpha[b](s), b(s)) \leq -\varepsilon \\ \text{for all } \alpha \in \Delta,\ s \in (0, \tau).\end{aligned}$$

If we multiply by $\exp(-\lambda s)$ and integrate on $(0, \tau)$, we obtain (again the right-hand side is $-\varepsilon\tau$ if $\lambda = 0$)

$$\varphi(x) - \exp(-\lambda\tau)\,\varphi(z_x(\tau)) - \int_0^\tau \exp(-\lambda r) l(z_x, \alpha[b], b) dr \le -\varepsilon(1 - \exp(-\lambda\tau))/\lambda \le -\sigma < 0.$$

By the properties of φ we then have

$$V_*(x_0) \le -\sigma + \varphi(x_0) - \varphi(x) + \exp(-\lambda\tau)\, V(z_x(\tau)) + \int_0^\tau \exp(-\lambda r) l(z_x, \alpha[b], b) dr \quad \text{for all } \alpha \in \Delta,\ x \in B(x_0, \varepsilon/2).$$

We now use (4.4) and get

$$V_*(x_0) \le -\sigma + \varphi(x_0) - \varphi(x) + V(x) \quad \text{for all } x \in B(x_0, \varepsilon/2),$$

therefore a contradiction. □

5. The $\mathcal{H}_\infty$ suboptimal control problem. We now go back to our problem and recast it into the setting of the previous section. We first recall the Hamiltonian that one expects to be related to the value function (2.8) and precisely

$$\mathcal{H}(x, p) = \inf_{b \in B} \sup_{a \in A} \{-f(x, a, b) \cdot p - h(x, a, b) + \gamma^2 |b|^2\}. \tag{5.1}$$

PROPOSITION 5.1. *Assume* (2.2). *Then the Hamiltonian* (5.1) *satisfies the following. For all $R > 0$, we can find $C_R > 0$ such that*

$$|\mathcal{H}(x, p) - \mathcal{H}(y, p')| \le C_R[(1 + |p| \vee |p'|)^{qr} |p - p'| + (1 + |p| \vee |p'|)^{2r} |x - y|],$$

$$|\mathcal{H}(x, p)| \le C_R(1 + |p| \vee |p'|)^{2/(2-q)} \qquad \textit{for all } |x|, |y| \le R,\ p, p' \in \mathbb{R}^N,$$

where $r = 4/(2 - q)$[3]. *In particular $\mathcal{H}$ is locally Lipschitz continuous in $\mathbb{R}^{2N}$. Moreover for all $|x|, |p| \le R$,*

$$\begin{aligned} \mathcal{H}(x, p) &= \min_{b \in B_R} \sup_{a \in A} \{-f(x, a, b) \cdot p - h(x, a, b) + \gamma^2 |b|^2\} \\ &= \min_{b \in B_R} \max_{a \in A_R} \{-f(x, a, b) \cdot p - h(x, a, b) + \gamma^2 |b|^2\}, \end{aligned} \tag{5.2}$$

where $A_R = \{a \in A : |a| \le C_R\}$, $B_R = \{b \in B : |b| \le C_R\}$.

Proof. To prove the assertions, let $R > 0$ and $|x|, |y| \le R$, $p, p' \in \mathbb{R}^N$. For all $b \in B$ and $\varepsilon > 0$, we can find $a_b \in A$ such that by (2.2)

$$\begin{aligned} \mathcal{H}(x, p) - \varepsilon &\le -f(x, a_b, b) \cdot p - h(x, a_b, b) + \gamma^2 |b|^2 \\ &\le L(1 + |x| + |b|^q)|p| + L_R(1 + |b|^2) + (L|p| + L_R)|a_b|^q - C_R^0 |a_b|^2 \\ &\le C_R[(1 + |p|)^{2/(2-q)} + (1 + |b|^2)(1 + |p|)], \end{aligned} \tag{5.3}$$

as easily checked, where C_R does not depend on b and a_b. In particular for $b = 0$ and since ε is arbitrary,

$$\mathcal{H}(x, p) \le 2C_R(1 + |p|)^{2/(2-q)}.$$

We also have that for $\varepsilon > 0$ there exists $\overline{b} \in B$ such that, with the choice of $a = 0$,

$$\mathcal{H}(y, p') + \varepsilon \geq \sup_{a \in A} \{-f(y, a, \overline{b}) \cdot p' - h(y, a, \overline{b}) + \gamma^2 |\overline{b}|^2\} \tag{5.4}$$
$$\geq -L(1 + |y|)|p'| - L_R - (L|p'| + L_R)|\overline{b}|^q + \gamma^2 |\overline{b}|^2 \geq -C_R(1 + |p'|)^{2/(2-q)},$$

from which, for $(y, p') = (x, p)$, we get the second inequality. Moreover if $|\overline{b}| \geq 1$, we necessarily have by the second inequality in (5.4) that

$$\gamma^2 |\overline{b}|^{2-q} \leq L(1 + |y|)|p'| + 2L_R + L|p'| + \varepsilon + 2C_R(1 + |p'|)^{2/(2-q)},$$

and then

$$|\overline{b}|^2 \leq C_R^{\#}(1 + |p'|)^{4/(2-q)^2} \quad \text{for all } |y| \leq R,\ p' \in \mathbb{R}^N. \tag{5.5}$$

The first inequality of the statement now follows from the estimate (5.5) and the corresponding one for $a_{\overline{b}}$. The latter can be obtained from the second inequality in (5.3) at $\overline{b}$, namely, if $|a_{\overline{b}}| \geq 1$,

$$C_R^0 |a_{\overline{b}}|^{2-q} \leq C_R^{\#\#}(1 + |p| \vee |p'|)^{4/(2-q)^2}. \tag{5.6}$$

Combining the first inequalities in (5.3), (5.4) we finally get, with the choice of $\overline{b}$, $a_{\overline{b}}$ as above,

$$\mathcal{H}(x, p) - \mathcal{H}(y, p') - 2\varepsilon \leq f(y, a_{\overline{b}}, \overline{b}) \cdot p' - f(x, a_{\overline{b}}, \overline{b}) \cdot p + h(y, a_{\overline{b}}, \overline{b}) - h(x, a_{\overline{b}}, \overline{b})$$
$$\leq L(1+|a_{\overline{b}}|^q+|\overline{b}|^q)|p||x-y|+L_R(1+|a_{\overline{b}}|^2+|\overline{b}|^2)|x-y|+L(1+|x|+|a_{\overline{b}}|^q+|\overline{b}|^q)|p-p'|,$$

and then the conclusion by the two estimates (5.5) and (5.6).

The equality (5.2) again follows easily combining the two estimates (5.5), (5.6) and the inequalities (5.3), (5.4). □

The estimates of Proposition 5.1, while proving continuity of $\mathcal{H}$, are not sufficiently good to deal with this Hamiltonian directly, so we are motivated to reformulate the problem in a convenient way.

We now begin with the proof of Theorem 3.2. We will need several steps to prove the result.

LEMMA 5.2. *Assume* (2.2), *and let* $U : \Omega \to \mathbb{R}$ *be a continuous viscosity supersolution of* $\mathcal{H}(x, DU) \geq 0$, *in* Ω. *Let* $\rho : \mathbb{R} \to \mathbb{R}_+$ *be bounded, smooth such that* $M \geq \dot{\rho} > 0$ *and* $\rho(s) \to 0$, *as* $s \to -\infty$. *Define the nonnegative, bounded function* $u(x, r) = \rho(U(x) + r)$. *Then* u *is a viscosity supersolution of*

$$H(z, Du(z)) \geq 0 \quad \text{in } \Omega \times \mathbb{R}, \tag{5.7}$$

where we indicated by $z = (x, r)$, $H(z, p) = \inf_{b \in B} \sup_{a \in A} \{-\overline{g}(z, a, b) \cdot p\}$, $\overline{g}(z, a, b) = g(z, a, b)/(1+|a|^2+|b|^2) = (f(x, a, b), h(x, a, b) - \gamma^2|b|^2)/(1+|a|^2+|b|^2) = (\overline{f}(x, a, b), \overline{h}(x, a, b) - \gamma^2|b|^2/(1 + |a|^2 + |b|^2))$.

Proof. The proof is an easy consequence of the usual formulas of change of variables; see Crandall and Lions [12]. Indeed if $p_z \in D^- u(z)$, then $p_z = \dot{\rho}(\rho^{-1}(u))(p, 1)$, where $p \in D^- U(x)$. Therefore by the definition (5.1), for all $\varepsilon > 0$ and $b \in B$ there is $a_b \in A$ such that

$$-f(x, a_b, b) \cdot p - h(x, a_b, b) + \gamma|b|^2 \geq -\varepsilon;$$

hence

$$-\overline{g}(z, a_b, b) \cdot p_z \geq -\varepsilon\dot{\rho}(\rho^{-1}(u))/(1 + |a|^2 + |b|^2) \geq -M\varepsilon$$

and the conclusion follows. □

Remark 5.3. In this long remark we want to check the assumptions of §4 for the differential game associated with the Hamiltonian H. For all $a \in \mathcal{A}, b \in \mathcal{B}$, we consider the increasing change of parameter

$$\tau(t) = \tau_{a,b}(t) = \int_0^t (1 + |a|^2 + |b|^2)ds = t + ||a||^2_{L^2(0,t)} + ||b||^2_{L^2(0,t)}$$

and set $t(\cdot) = t_{a,b}(\cdot) = \tau^{-1}(\cdot)$. We will briefely denote in the following the reparametrized measurable functions as $a(\tau) = a(t(\tau))$, $b(\tau) = b(t(\tau))$ and, for such controls, solve the dynamical system

$$z'(\tau) = \overline{g}(z(\tau), a(\tau), b(\tau)), \quad z(0) \in \mathbb{R}^{N+1}. \tag{5.8}$$

For all $z(0) \in \mathbb{R}^{N+1}, a \in \mathcal{A}, b \in \mathcal{B}$, there is a unique absolutely continuous global solution to (5.8).

The system with reparametrized controls satisfies (4.2). Indeed by the assumption (2.2) it is immediate to recognize that we can apply Remark 4.1 to the vector field $\overline{g}$. Observe that we can pass from the system (2.1) to (5.8) by means of the above introduced change of parameter on the trajectories solutions. Indeed if $z(\tau)$ solves (5.8), then

$$z(\tau) = (y_x(t(\tau)), r(t(\tau))),$$

where $y_x(\cdot)$ is the solution of (2.1) corresponding to the choice of controls $(a(t), b(t))$ and $r(t(\tau)) = r_0 + \int_0^{t(\tau)} (h(y_x(t), a(t), b(t)) - \gamma^2|b|^2(t))dt$. As a notation, we will indicate by y' the derivative with respect to the new parameter τ, while $\dot{y}$ indicates the derivative with respect to the old one t, i.e., $y'(\tau) = \dot{y}(t(\tau))/(1 + |a|^2 + |b|^2)$.

This idea of reparametrizing trajectories is fairly classical in control theory and was already used in the context of the dynamic programming approach by Barles [6] to study a class of unbounded control problems. Here everything is slightly more complicated since we are not just dealing with controls in L^∞ as in his case and our problem is a differential game.

The Hamiltonian in (5.7) satisfies the following regularity condition, as easily checked:

$$|H(z, p_z) - H(\overline{z}, p_{\overline{z}})| \le L_R(|p_z||z - \overline{z}| + |p_z - p_{\overline{z}}|) \text{ for all } |z|, |\overline{z}| \le R, p_z, p_{\overline{z}} \in \mathbb{R}^{N+1}; \tag{5.9}$$

in particular, it is locally Lipschitz continuous.

Let U, u be as in Lemma 5.2. If $z(\cdot)$ is a solution of (5.8), $z(0) = (x, r_0)$, we easily compute

$$\begin{aligned} u(z(\tau)) &= \rho\left(U(y_x(t(\tau))) + r_0 + \int_0^\tau (h(y, a, b) - \gamma^2|b|^2)/(1 + |a|^2 + |b|^2)\, d\tau\right) \\ &= \rho\left(U(y_x(t(\tau))) + r_0 + \int_0^{t(\tau)} (h(y, a, b) - \gamma^2|b|^2)dt\right). \end{aligned} \tag{5.10}$$

We also observe that the exit time from $\Omega \times \mathbb{R}$ satisfies $\tau_z(a, b) = \tau_x(a, b) = \int_0^{t_x(a,b)} (1 + |a|^2 + |b|^2)dt$, where τ_x denotes the exit time of the first N components of the solution of (5.8) from Ω and, as before, $t_x(a, b)$ is the exit time of the solution of (2.1) from Ω. Therefore for all $\lambda \ge 0$, the value function in (4.3) for the system (5.8), with $l \equiv 0$, takes the form

$$V^\lambda(z) = \inf_{\alpha\in\Delta}\sup_{b\in\mathcal{B}}\sup_{[0,\tau_z)} \exp(-\lambda\tau)u(z(\tau))$$

$$= \inf_{\alpha\in\Delta}\sup_{b\in\mathcal{B}}\sup_{[0,t_x)} \left\{\exp\left(-\lambda\int_0^t (1+|a|^2+|b|^2)dt\right)\right.$$

$$\left.\cdot\rho\big(U(y_x(t))+r_0+\int_0^t (h(y,a,b)-\gamma^2|b|^2)dt\right)\Big\}.$$

Since by definition ρ is nonnegative and bounded, then also V^λ is nonnegative and bounded. In particular, since ρ is increasing, we also have that

$$V^0(x,0) = \rho\left(\inf_{\alpha\in\Delta}\sup_{b\in\mathcal{B}}\sup_{[0,t_x)}\left\{U(y_x(t))+\int_0^t (h(y,a,b)-\gamma^2|b|^2)dt\right\}\right).$$

LEMMA 5.4. *Assume* (2.2), *and let U, u be as in Lemma* 5.2, *U defined and continuous in* $\overline{\Omega}$. *Then for all* $\lambda > 0$, V^λ *is a viscosity solution of*

$$\min\{\lambda V + H(z, DV), V - u\} = 0 \qquad \text{in } \Omega\times\mathbb{R}. \tag{5.11}$$

Proof. 1. Let $z_0 \in \Omega\times\mathbb{R}$. We start proving that, if $p \in D^+V^{\lambda *}(z_0)$ and $V^{\lambda *}(z_0) > 0$, then $p_{N+1} > 0$. We recall that $p \in D^+V^{\lambda *}(z_0)$ is equivalent to

$$\limsup_{z\to z_0} (V^{\lambda *}(z) - V^{\lambda *}(z_0) - p\cdot(z-z_0))/|z-z_0| \le 0.$$

In particular for $e_{N+1} = (0,\dots,0,1)$, this implies

$$\limsup_{\sigma\to 0^+} (V^{\lambda *}(z_0+\sigma e_{N+1}) - V^{\lambda *}(z_0))/\sigma \le p_{N+1}.$$

Let $\bar\varepsilon > 0$ and $z_n \to z_0$ be such that $0 < 2\bar\varepsilon \le V^\lambda(z_n) \to V^{\lambda *}(z_0)$. For all $0 < \varepsilon \le \bar\varepsilon, \sigma > 0$ small enough, and n fixed, we can find $\alpha \in \Delta$ such that

$$V^\lambda(z_n+\sigma e_{N+1}) + \varepsilon\sigma > \sup_{b\in\mathcal{B}}\sup_{[0,\tau_{z_n+\sigma e_{N+1}})} \exp(-\lambda\tau)u(z_{z_n+\sigma e_{N+1}}(\tau)).$$

Then for such α, we can choose $b \in \mathcal{B}$, $\tau \in [0, \tau_{z_n+\sigma e_{N+1}})$ so that (observe that, by Remark 5.3, $\tau_{z_n} = \tau_{z_n+\sigma e_{N+1}}$)

$$\bar\varepsilon \le V^\lambda(z_n) - \varepsilon\sigma \le \exp(-\lambda\tau)u(z_{z_n}(\tau));$$

then $\tau \le C$, $\rho^{-1}(u(z_{z_n}(\tau))) \ge \rho^{-1}(\bar\varepsilon) \ge -C$, and by (4.2) $|z_{z_n}(\tau)| \le C$, where C is independent of ε, n, and σ. Moreover by (5.10) and the definition of u we have that

$$V^\lambda(z_n+\sigma e_{N+1}) - V^\lambda(z_n) + 2\varepsilon\sigma \ge \exp(-\lambda\tau)[u(z_{z_n+\sigma e_{N+1}}(\tau)) - u(z_{z_n}(\tau))] \tag{5.12}$$

$$\ge \exp(-\lambda C)\,[\rho(\rho^{-1}(u(z_{z_n}(\tau))) + \sigma) - \rho(\rho^{-1}(u(z_{z_n}(\tau))))].$$

We also have that by Remark 4.1

$$\int_0^{t(\tau)} h(y_{x_n}, \alpha[b], b)dt = \int_0^\tau \bar h(y_{x_n}, \alpha[b], b)d\tau \le \tau C_1 \le CC_1,$$

where C_1 is also independent of ε, σ, and n, and then, again by Remark 4.1,

$$\rho^{-1}(u(z_{z_n}(\tau))) = U(y_{x_n}(\tau)) + r_n + \int_0^{t(\tau)} (h(y_{x_n}, \alpha[b], b) - \gamma^2|b|^2)dt$$

$$\le \sup_{\overline{\Omega}\cap B(x,C)} U + r_n + CC_1.$$

We conclude by (5.12) and the definition of ρ that

$$V^\lambda(z_n + \sigma e_{N+1}) + 2\varepsilon\sigma \geq V^\lambda(z_n) + K\sigma,$$

where $K = \exp(-\lambda C)\ \min_{[-R,R]} \dot{\rho} > 0$ and R is independent of ε, n, and σ. As $n \to +\infty$

$$V^{\lambda *}(z_0 + \sigma e_{N+1}) + 2\varepsilon\sigma \geq V^{\lambda *}(z_0) + K\sigma,$$

and finally, as $\sigma \to 0^+$ and since ε is arbitrary, $p_{N+1} \geq K > 0$.

2. We now conclude with the proof of the statement. Let $z_0 \in \Omega \times \mathbb{R}$ be such that $V^{\lambda *}(z_0) > u(z_0)$, and let $p^0 \in D^+ V^{\lambda *}(z_0)$. Since u is nonnegative, it follows that $V^{\lambda *}(z_0) > 0$; then by the first part $p^0_{N+1} > 0$ and so by (2.2) and the definition of $\overline{g}$, condition (4.7) is satisfied (with $l \equiv 0$). Let us prove this last statement. Fix any $a \in A$ and $\sigma \in (0, 1)$. Let p, z, b be such that $|p - p^0| < \sigma$, $|z - z_0| < \sigma$, $|b| > 1/\sigma$; and let $R = 1 + |x_0|$. By the definition of $\overline{g}$ and (2.2) we obtain ($p = (\overline{p}, p_{N+1})$)

$$\begin{aligned} -\overline{g}(x,a,b)\cdot p &= (-f(x,a,b)\cdot\overline{p} - h(x,a,b)p_{N+1} + \gamma^2|b|^2 p_{N+1})/(1+|a|^2+|b|^2) \\ &\geq (-L(1+|x|+|a|^q+|b|^q)|\overline{p}| - L_R(1+|a|^2+|b|^q)p_{N+1} + \gamma^2|b|^2 p_{N+1})/(1+|a|^2+|b|^2) \\ &\geq -C(1+|a|^2+|b|^q)/(1+|b|^2) + \gamma^2 p_{N+1}(1+\sigma^2(1+|a|^2)) \\ &\geq -C\sigma^{2-q}(1+(1+|a|^2)\sigma^q)/(1+\sigma^2) + \gamma^2(p^0_{N+1} - \sigma)/(1+\sigma(1+|a|^2)), \end{aligned}$$

where C depends only on R and p^0 and the last inequality holds for σ sufficiently small. It is clear that the right-hand side is positive when a is kept fixed and σ is choosen sufficiently small. Therefore by Proposition 4.4 the function V^λ satisfies (5.11) as a viscosity solution. □

The following lemma is an optimality principle for viscosity supersolutions of equations of type (5.7) in Lemma 5.2.

LEMMA 5.5. *Assume* (2.2), *and let U, u be as in Lemma* 5.2. *Then*

$$u(z) = \inf_{\alpha\in\Delta} \sup_{b\in\mathcal{B}} \sup_{[0,\tau_z)} u(z(\tau)), \qquad z \in \Omega \times \mathbb{R}. \tag{5.13}$$

Proof. We start by proving that, for all $s > 0$, we have

$$u(z) = \inf_{\alpha\in\Delta} \sup_{b\in\mathcal{B}} \sup_{[0,s\wedge\tau_z)} u(z(\tau)). \tag{5.14}$$

1. We first assume that $\overline{g}$ satisfies the global, uniform Lipschitz condition

$$|\overline{g}(z,a,b) - \overline{g}(\overline{z},a,b)| \leq L|z-\overline{z}| \qquad \text{for all } z, \overline{z}, a, b$$

and prove the result for $\Omega = \mathbb{R}^N$ (in this case, for each pair of controls, $\tau_z = +\infty$). Observe that, with this assumption, the Hamiltonian H will satisfy (5.9) with $L = L_R$, independent of R. Let $s > 0$; then we denote

$$v(z) = \inf_{\alpha\in\Delta} \sup_{b\in\mathcal{B}} \sup_{[0,s)} u(z(\tau)).$$

It is obvious that $v(x) \geq u(x)$, so we only need to prove the opposite inequality. Therefore, let $\lambda > 0$. By Lemma 5.5, V^λ is a viscosity solution of

$$\lambda V + \min\{H(z, DV), V - (1+\lambda)u\} = 0 \quad \text{in } \mathbb{R}^{N+1}. \tag{5.15}$$

The nonnegative function u is obviously another solution of (5.15). Moreover the Hamiltonian of (5.15) satisfies the assumptions for the uniqueness of bounded solutions (see, for example, Theorem 1.1 in the paper of Bardi and the author [5]). This implies that

$$V^\lambda = u \quad \text{in } \mathbb{R}^{N+1} \text{ for all } \lambda > 0,$$

and then since u is nonnegative,

$$\exp(-\lambda s)v(z) = \exp(-\lambda s) \inf_{\alpha\in\Delta} \sup_{b\in\mathcal{B}} \sup_{[0,s)} u(z(\tau)) \le V^\lambda(z) = u(z) \quad \text{for all } \lambda > 0,$$

hence the conclusion as $\lambda \to 0^+$.

2. Now let Ω be an arbitrary open set, $\overline{g}$ satisfying (2.2), and $\Gamma = \Omega \times \mathbb{R}$. For $\varepsilon > 0$, let $\zeta_\varepsilon : \mathbb{R}^{N+1} \to \mathbb{R}$ be a smooth function such that $0 \le \zeta_\varepsilon(z) \le 1$, $\zeta_\varepsilon = 0$ on $\Gamma^c_{\varepsilon/2}$, $\zeta_\varepsilon = 1$ in Γ_ε, where $\Gamma_\sigma = \{z = (x, r) \in \Gamma : \operatorname{dist}(x, \partial\Omega) > \sigma, |x| < 1/\sigma\}$ and $\Gamma^c = \mathbb{R}^{N+1}\backslash\Gamma$. We extend u outside $\Gamma_{\varepsilon/2}$ as a continuous, nonnegative, and bounded function in $\mathbb{R}^{N+1}$ and call it u^ε. We therefore obtain that u^ε is a supersolution of

$$\zeta_\varepsilon(z)\, H(z, Du^\varepsilon(z)) = \inf_{b\in B} \sup_{a\in A} \{-\overline{g}_\varepsilon(z, a, b) \cdot Du^\varepsilon(z)\} \ge 0, \quad \mathbb{R}^{N+1},$$

where $\overline{g} = \overline{g}_\varepsilon$ in $\Gamma_\varepsilon \times A \times B$ and $\overline{g}_\varepsilon = 0$ in $\Gamma^c_{\varepsilon/2} \times A \times B$. We can apply the first part of our proof and deduce that for $z \in \Gamma_\varepsilon$ and $s > 0$

$$u(z) = \inf_{\alpha\in\Delta} \sup_{b\in\mathcal{B}} \sup_{[0,s)} u^\varepsilon(z^\varepsilon(\tau)) \ge \inf_{\alpha\in\Delta} \sup_{b\in\mathcal{B}} \sup_{[0,s\wedge\tau^\varepsilon_z)} u(z(\tau)), \tag{5.16}$$

where τ^ε_z is the first exit time of the trajectory $z(\cdot)$ from Γ_ε (obviously $z(\cdot) = z^\varepsilon(\cdot)$ in $[0, s\wedge\tau^\varepsilon_z)$, if $z^\varepsilon(\cdot)$ is the trajectory corresponding to the vector field $\overline{g}_\varepsilon$).

3. We now conclude by the following argument. For fixed $\varepsilon, \eta > 0$, let $\varepsilon_j = \varepsilon/2^j$. If $z_0 = z \in \Gamma_{\varepsilon_0}$, by (5.16) we can find $\alpha_0 \in \Delta$ (we can fix it as a function of $z \in \Gamma_{\varepsilon_0}$) such that

$$\sup_{[0,s\wedge\tau^{\varepsilon_0}_z]} u(z(\tau)) \le u(z) + \eta/2 \qquad \text{for all } b \in \mathcal{B}.$$

For any fixed $b_0 = \overline{b} \in \mathcal{B}$, if $\tau^{\varepsilon_0}_z \ge s$, we have nothing left to prove. Otherwise we set $\tau_1 = \tau^{\varepsilon_0}_z$, $z_1 = z(\tau_1)$, $b_1(\cdot) = b_0(\cdot + t_{\alpha_0[b_0],b_0}(\tau_1))$. Then we can find $\alpha_1 \in \Delta$ (again as a function of $z \in \Gamma_{\varepsilon_1}\backslash\Gamma_{\varepsilon_0}$) such that

$$\sup_{[0,s\wedge\tau^{\varepsilon_1}_{x_1}]} u(z_{z_1}) \le u(z_1) + \eta/2^2.$$

We proceed recursively and construct the strategy α given by the position $\alpha[\overline{b}] = \overline{a}$, where $\overline{a}$ is the control defined by setting

$$\overline{a}(s) = \begin{cases} \alpha_0[b_0](s), & s \in [0, t_{\alpha_0[b_0],b_0}(\tau_1)[, \\ \alpha_1[b_1](s - t_{\alpha_0[b_0],b_0}(\tau_1)), & s \in [t_{\alpha_0[b_0],b_0}(\tau_1), t_{\alpha_0[b_0],b_0}(\tau_1) + t_{\alpha_1[b_1],b_1}(\tau_2)[, \\ \dots. \end{cases}$$

Then, also using Remark 4.2, we easily obtain that with such an α

$$\sup_{[0,s\wedge\tau_{z_0})} u(z_{z_0}) \le u(z_0) + \eta \quad \text{for all } b \in \mathcal{B},$$

and the result follows by the arbitrarity of η, the other inequality to get (5.14) being obvious.

4. We conclude the proof of the proposition using the same technique as in point 3. Let $\eta > 0$. For $z_0 = z \in \Gamma$ and applying (5.14) with $s = 1$, we can find $\alpha_0 \in \Delta$ such that

$$\sup_{[0,\tau_{z_0}\wedge 1]} u(z_{z_0}) \le u(z) + \eta \qquad \text{for all } b \in \mathcal{B}.$$

Fix $b_0 = \overline{b} \in \mathcal{B}$. If $\tau_{z_0} \le 1$, there is nothing left to prove. Otherwise let $z_1 = z_z(1)$, $b_1(\cdot) = b_0(\cdot + t_{\alpha_0[b_0],b_0}(1))$. Then we find $\alpha_1 \in \Delta$ such that

$$\sup_{[0,\tau_{z_1}\wedge 1]} u(z_{z_1}) \le u(z_1) + \eta/2^2 \qquad \text{for all } b \in \mathcal{B}.$$

We proceed recursively and conclude the proof similarly to point 3. □

As a consequence of the previous result and Lemma 5.2, we now prove a general optimality principle for viscosity supersolutions of equations whose Hamiltonian is defined in (5.1). We remark that this result has independent interest, and its peculiarity is to hold with an equality rather than an inequality; see (5.17).

PROPOSITION 5.6. *Assume* (2.2), *and let* $U : \Omega \to \mathbb{R}$ *be a continuous viscosity supersolution of*

$$\mathcal{H}(x, DU(x)) \ge 0 \quad \text{in } \Omega.$$

Then

$$U(x) = \inf_{\alpha\in\Delta} \sup_{b\in\mathcal{B}} \sup_{[0,t_x)} \left\{ \int_0^t (h(y, \alpha[b], b) - \gamma^2|b|^2)ds + U(y_x(t)) \right\}, \qquad x \in \Omega. \tag{5.17}$$

Proof. We define $u(x, r) = \rho(U(x) + r)$ as in Lemma 5.2, and then by that result u is a viscosity supersolution of

$$H(z, Du(z)) \ge 0 \quad \text{in } \Omega \times \mathbb{R}.$$

By Lemma 5.5, Remark 5.3, and (5.10) we conclude that

$$\begin{aligned} u(z) &= \inf_{\alpha\in\Delta} \sup_{b\in\mathcal{B}} \sup_{[0,\tau_z)} u(z(\tau)) \\ &= \inf_{\alpha\in\Delta} \sup_{b\in\mathcal{B}} \sup_{[0,t_x)} \rho\left(\int_0^t (h(y, \alpha[b], b) - \gamma^2|b|^2)ds + U(y_x(t)) + r_0 \right); \end{aligned}$$

hence in particular

$$\rho(U(x)) = u(x, 0) = \rho\left(\inf_{\alpha\in\Delta} \sup_{b\in\mathcal{B}} \sup_{[0,t_x)} \int_0^t (h(y, \alpha[b], b) - \gamma^2|b|^2)ds + U(y_x(t)) \right),$$

and the conclusion follows by the choice of $\rho(\cdot)$. □

We can now give the proof of our main results.

Proof of Theorem 3.2. Let U be as in the statement of the theorem. Let $x \in \Omega$; by (5.17) of Proposition 5.6 we can choose $\varepsilon > 0$ and $\alpha \in \Delta$ so that

$$\sup_{[0,t_x)} \left\{ \int_0^t (h(y, \alpha[b], b) - \gamma^2|b|^2)dt + U(y_x(t)) \right\} \le U(x) + \varepsilon \le U_0 - \varepsilon \quad \text{for all } b \in \mathcal{B}. \tag{5.18}$$

For $b \equiv 0$, and since $h(x, a, 0)$ is nonnegative, (5.18) implies

$$\sup_{[0,t_x)} U(y_x(t)) \leq U_0 - \varepsilon;$$

therefore $t_x(\alpha[0], 0) = +\infty$ by the boundary condition and the lower semicontinuity of U on $\partial\Omega$. So part (i) of the definition is satisfied in Ω with $a = \alpha[0]$ and $\alpha \in \Delta_\Omega$. Moreover since U is nonnegative, by (5.18) we also get

$$\sup_{\mathbb{R}_+} \int_0^t (h(y, \alpha[b], b) - \gamma^2|b|^2)dt \leq U(x) + \varepsilon \qquad \text{for all } b \in \mathcal{B}_{\Omega,\alpha}.$$

Hence since ε is arbitrary and by the definition, we get $0 \leq V_\gamma^\Omega \leq U$ in Ω and also (ii) is satisfied.

Of course the argument can be repeated in each sublevel set $\{x \in \Omega : U(x) < \lambda\}$ for $\lambda \in (0, U_0)$, and if this family of neighborhoods is a local base for $\mathcal{T}$, then we proved the open-loop Lyapunov stability and the fact that the local $\mathcal{H}_\infty$ suboptimal control problem with attenuation level $\gamma > 0$ is solvable.

As for the $\mathcal{H}_\infty$ suboptimal control problem, this is clearly a special case of the above, when $\Omega = \mathbb{R}^N$, and indeed the finite gain condition is an immediate consequence of (5.17). □

Proof of Theorem 3.4. To prove the first statement concerning (3.2), for $a \in \mathcal{A}$, $b \in \mathcal{B}$, we consider again the reparametrized system, as in Remark 5.3,

$$y'(\tau) = \overline{f}(y(\tau), a(\tau), b(\tau)), \quad y(0) = x.$$

We have that, by changing variables,

$$V_\gamma(x) = \inf_{\alpha\in\Delta} \sup_{b\in\mathcal{B}} \sup_{\tau\in\mathbb{R}_+} \left\{ \int_0^\tau [\overline{h}(y, \alpha[b], b) - \gamma^2|b|^2/(1 + |a|^2 + |b|^2)]d\tau \right\}.$$

Therefore, using the results of §4, in particular Proposition 4.4, with $\lambda = 0$, $g(x, a, b) = \overline{f}(x, a, b)$, $l(x, a, b) = \overline{h}(x, a, b) - \gamma^2|b|^2/(1 + |a|^2 + |b|^2)$, and $U \equiv 0$. Since condition (4.7) is easily satisfied in this case, as one can check with the same argument as the one of the proof of point 2 in Lemma 5.4, we can conclude that V_γ, in the open sets where it is locally bounded, is a viscosity solution of the variational inequality

$$\min\{\mathcal{H}^\#(x, DV_\gamma(x)), V_\gamma\} = 0, \tag{5.19}$$

where $\mathcal{H}^\#(x, p) = \inf_{b\in B} \sup_{a\in A}\{-\overline{f}(x, a, b) \cdot p - \overline{h}(x, a, b) + \gamma^2|b|^2/(1 + |a|^2 + |b|^2)\}$. To prove that V_γ is also a solution of (3.2), we will use the fact that, by the proof of Proposition 5.1, if $B_{x,p} \subset\subset B$ satisfies

$$\mathcal{H}(x, p) = \min_{b\in B_{x,p}} \sup_{a\in A}\{-f(x, a, b) \cdot p - h(x, a, b) + \gamma^2|b|^2\},$$

then there is $A_{x,p} \subset\subset A$ such that

$$\mathcal{H}(x, p) = \min_{b\in B_{x,p}} \max_{a\in A_{x,p}} \{-f(x, a, b) \cdot p - h(x, a, b) + \gamma^2|b|^2\}.$$

Let $(x, p) \in \mathbb{R}^{2N}$ be such that $\mathcal{H}^\#(x, p) \geq 0$. Then for all $\varepsilon > 0$ and $b \in B$ we can find $a_b \in A$ such that

$$-f(x, a_b, b) \cdot p - h(x, a_b, b) + \gamma^2|b|^2 \geq -\varepsilon(1 + |a_b|^2 + |b|^2). \tag{5.20}$$

If $b \in B_{x,p}$, then for ε sufficiently small (e.g., $\varepsilon < C_R^0$, $|x|, |p| \le R$, C_R^0 defined in (2.2)), (5.20) implies that $|a_b| \le C_{x,p}$ independent of ε. So we conclude from (5.20) that $\mathcal{H}(x, p) \ge 0$.

On the other hand if $\mathcal{H}^{\#}(x, p) \le 0$, then for $\varepsilon > 0$ we can find $\bar{b} \in B$ such that for all $a \in A$

$$-f(x, a, \bar{b}) \cdot p - h(x, a, \bar{b}) + \gamma^2|\bar{b}|^2 \le \varepsilon(1 + |a|^2 + |\bar{b}|^2). \tag{5.21}$$

If in particular ε is sufficiently small (e.g., $\varepsilon < \gamma^2$) and we set $a = 0$, then (5.21) implies $|\bar{b}| \le C_{x,p}$, independent of ε, and again we conclude by computing (5.21) at the points $a \in A_{x,p}$, where $A_{x,p}$ corresponds to the choice $B_{x,p} = B(0, C_{x,p})$.

The second part of (i) is a consequence of Proposition 5.6 and the fact that supersolution of (3.2) is equivalent to the nonnegative supersolution of $\mathcal{H}(x, DV) \ge 0$.

We now prove the statements concerning (3.3). Since V_γ is a supersolution of (3.2), it is clear that it is also a supersolution of (3.3). On the other hand, by the definition of subsolution, let $p \in D^+V_\gamma^*(x)$. If $V_\gamma^*(x) > 0$, then since V_γ is a subsolution of (3.2), it follows that

$$\mathcal{H}(x, p) \le 0. \tag{5.22}$$

If instead $V_\gamma^*(x) \le 0$, then since V_γ is nonnegative, V_γ is continuous at x, which is also a minimum point of the function. Therefore $0 \in D^-V_\gamma^*(x)$. Being both semidifferentials nonempty and V_γ continuous at x, this implies $p = 0$; see Crandall and Lions [12]. By (2.3) we then have

$$\mathcal{H}(x, p) = \inf_{b \in B} \sup_{a \in A} \{\gamma^2|b|^2 - h(x, a, b)\} \le \sup_{a \in A} \{-h(x, a, 0)\} \le 0,$$

and (5.22) holds also in this case. Threfore V_γ is a subsolution of (3.3).

Again the second part of the statement (ii) is a consequence of Proposition 5.6. □

6. On the solution of the $\mathcal{H}_\infty$ control problem. This section is devoted to some results and remarks concerning the construction of optimal strategies, in particular feedback controls to solve the $\mathcal{H}_\infty$ suboptimal control problem. As a matter of fact, we will only be concerned with checking the finite gain condition, since, as seen in Remark 3.3 and in the proof of Theorem 3.2, the stability of the system is a consequence of it. We will be making considerably strong assumptions in the general case, but the problem appears still to be tough and challenging. In the following we assume that the problem is solvable as previously defined; therefore the value function V_γ is finite in $\mathbb{R}^N$, null, and continuous on $\mathcal{T}$.

We start remarking that, when A is compact, the theory of Elliott and Kalton [13] can be applied to our problem without many additional difficulties (see also the author [28] for some details concerning the full-state information and the partial-information case) and provides the existence of optimal strategies as causal mappings $\alpha : \mathcal{B} \to \mathcal{A}^r$, where $\mathcal{A}^r$ is the set of relaxed controls, namely the set of measurable functions from $\mathbb{R}_+$ to the set of probability measures on A. The optimal strategy is in the class considered in this paper if the sets $(f(x, A, b),\ h(x, A, b))$ are convex for all x, b. Of course the existence of almost optimal strategies is always guaranteed by the very definition of value function. Unfortunately the proof of existence of optimal strategies is not constructive and, therefore, not useful from the practical point of view of the applications. Moreover this class of strategies requires full information of the system; namely, the disturbance has to be known and this is thought to be too restrictive. We describe instead how one can proceed in certain special cases to construct feedback controls. The ideas we outline here contain the known results in the cases of linear and nonlinear-affine systems and show to what extent we can generalize those results. We do not address here the question of the construction of optimal dynamic state feedback controls, where however similar difficulties have to be faced.

We first reduce to the interesting case $\mathcal{T} = \{0\}$ and make the following assumption. (A1): the value function V_γ is of class C^1; therefore, there is a nonnegative, classical solution, null at the origin of the (lower) Isaacs equation

$$\mathcal{H}(x, DU(x)) = 0 \quad \text{in } \mathbb{R}^N.$$

Unfortunately existence of classical solutions (and even uniqueness) is not satisfied in general even locally around the origin, and this was the main reason we used the concept of viscosity solutions. It is clear by its mere definition that V_γ is not likely to be even continuous in general. We will outline in Remark 6.2 how to generalize when the solution is not differentiable.

For any $(x, p) \in \mathbb{R}^{2N}$ we denote

$$F_{x,p}(a, b) = -f(x, a, b) \cdot p - h(x, a, b) + \gamma^2 |b|^2,$$

so that $\mathcal{H}(x, p) = \inf_{b\in B} \sup_{a\in A} F_{x,p}(a, b)$ and $\overline{\mathcal{H}}(x, p) = \sup_{a\in A} \inf_{b\in B} F_{x,p}(a, b)$, and we look for necessary conditions. Assume that the feedback $a(x)$ solves the $\mathcal{H}_\infty$ suboptimal control problem and provides optimal strategies for V_γ; then by (2.10) we have

$$\int_0^t (h(y, a(y), b) - \gamma^2 |b|^2) ds \le V_\gamma(x) \quad \text{for all } b \in \mathcal{B},\ t \ge 0.$$

Therefore by the definition of V_γ, for any fixed $t > 0$, we get

$$\int_0^t (h(y, a(y), b) - \gamma^2 |b|^2) ds + V_\gamma(y(t)) \le V_\gamma(x) \quad \text{for all } b \in \mathcal{B}.$$

Dividing by t and letting $t \to 0^+$, we conclude

$$0 \le F_{x, DV_\gamma(x)}(a(x), b) \quad \text{for all } b \in B;$$

finally by (A1) we must have

$$0 \le \inf_{b\in B} F_{x, DV_\gamma(x)}(a(x), b) \le \overline{\mathcal{H}}(x, DV_\gamma(x)) \le \mathcal{H}(x, DV_\gamma(x)) = 0. \tag{6.1}$$

Therefore equalities hold in (6.1) and V_γ has to be also a solution of the upper Isaacs equation. Of course this is always the case when the Isaacs condition holds, namely when $\mathcal{H}(x, p) = \overline{\mathcal{H}}(x, p)$ for all x, p, and a sufficient, easy-to-check condition for it is the splitting of the system, namely,

$$f(x, a, b) = f_1(x, a) + f_2(x, b),\ \ h(x, a, b) = h_1(x, a) + h_2(x, b).$$

If in particular (6.1) does not hold, then necessarily the value of the game does not exist, and therefore it is somewhat expected that feedback controls will not solve the problem in general. The previous necessary condition of optimality will give us indications about the construction of optimal feedbacks.

In view of (6.1), we proceed and make the second assumption. (A2): There is a nonnegative, classical supersolution U of the upper Isaacs equation

$$\overline{\mathcal{H}}(x, DU(x)) = 0 \quad \text{in } \mathbb{R}^N.$$

We now define the possibly multivalued map

$$A(x, p) = \arg \max_{a\in A} \{\inf_{b\in B} F_{x,p}(a, b)\} \tag{6.2}$$

and assume (A3): there is a selection $a(x) \in A(x, DU(x))$ such that the system

$$\dot{y} = f(y, a(y), b), \qquad y(0) = x,$$

has a unique absolutely continuous solution for all $b \in \mathcal{B}$ and $x \in \mathbb{R}^N$.

PROPOSITION 6.1. *Assume* (A1)-(A3). *Then the feedback control* $a(x)$ *solves the* $\mathcal{H}_\infty$ *suboptimal control problem. If the assumptions are satisfied by* $U = V_\gamma$, *then* $a(x)$ *is optimal.*

Proof. Let us prove that the position $\alpha[b](t) = a(y(t))$ defines a strategy satisfying (2.11); then we conclude by Remark 2.2. It is clear by (A2) and the definition of $a(\cdot)$ that

$$\inf_{b \in B} F_{x, DU(x)}(a(x), b) = \overline{\mathcal{H}}(x, DU(x)) = 0$$

(if $U = V_\gamma$ the necessary condition (6.1) is satisfied by construction); therefore for all $b \in \mathcal{B}$ the solution guaranteed by (A3) satisfies

$$0 \leq -f(y, \alpha[b], b) \cdot DU(y) - h(y, \alpha[b], b) + \gamma^2 |b|^2.$$

Integrating on $[0, t]$, we obtain

$$U(y(t)) + \int_0^t (h(y, \alpha, b) - \gamma^2 |b|^2) ds \leq U(x),$$

and since U is nonnegative, we conclude

$$\sup_{b \in \mathcal{B}} \sup_{t \in \mathbb{R}_+} \int_0^t (h(y, \alpha, b) - \gamma^2 |b|^2) ds \leq U(x),$$

and the result follows.

If $U = V_\gamma$, the same inequality shows the optimality of α for $V_\gamma(x)$. □

Remark 6.2. To our knowledge, there are no general results concerning the existence of optimal feedback controls, i.e., under which condition (A3) is satisfied with $U = V_\gamma$. However, one can call the map $A(x) = A(x, DV_\gamma(x))$ a multivalued feedback synthesis in the sense that any solution of the differential inclusion

$$\dot{y} \in f(y, A(y), b), \qquad y(0) = x,$$

satisfies the gain condition (to prove this, just apply the argument of Proposition 6.1 to a selection $a(t) \in A(y(t))$ such that $\dot{y} = f(y, a, b)$). Moreover, since, as we mentioned, (A1) is too restrictive, we should really use generalized gradients (which are usually sets) and define the feedback control as a selection $a(x) \in A(x, \text{“}DV_\gamma(x)\text{”})$ satisfying (A3). This is also an open problem. Otherwise $A(x) = A(x, \text{“}DV_\gamma(x)\text{”})$ will again be a multivalued feedback synthesis.

The method we presented in Proposition 6.1, under certain nondegeneracy conditions on the cost h, really works for linear systems, as the reader can find out for example in Basar and Bernhard [10], and almost works for nonlinear-affine systems (where $f(x, a, b) = f_1(x) + f_2(x)a + f_3(x)b$ and $h(x, a, b) = |\overline{h}(x, a)|^2$, $\overline{h}(x, a) = h_1(x) + h_2(x)a$), in the sense that (A2) and (A3) are satisfied, as one easily checks (see for example Van der Shaft [30]), since the following explicit formula for (6.2) holds (A is luckily single valued in this case):

$$A(x, p) = -(h_2^T(x)h_2(x))^{-1}(f_2^T(x)p/2 + h_2^T(x)h_1(x)),$$

but again (A1) fails in general. We do not have the space here to discuss a specific counterexample, which is however not too difficult to construct and will be presented elsewhere, but

refer instead to Van der Shaft [30] for some sufficient conditions ensuring that (A1) holds at least locally around the origin.

For general systems, life is even harder. As we already observed, by (6.1) it follows that if (A2) fails, we have no hope for optimal feedback controls. However here is how one might try to proceed in this case to construct optimal strategies. We now define the set-valued map

$$A(x,b) = \arg\max_{a\in A} F_{x,DV_\gamma(x)}(a,b)$$

and assume (A4): for all $b \in \mathcal{B}$ there is an absolutely continuous solution of the differential inclusion

$$\dot{y} \in f(y, A(y,b), b), \qquad y(0) = x.$$

We now indicate by $\mathcal{Y}_{x,b}$ the set of such solutions and assume (A5): we can find a causal selection $\alpha_x[\cdot]$ satisfying: for any $b \in \mathcal{B}$, $\alpha_x[b](t) \in A(y(t), b(t))$ for some $y \in \mathcal{Y}_{x,b}$.

PROPOSITION 6.3. *Assume* (A1), (A4), *and* (A5). *Then the strategy* $\alpha_x \in \Delta$ *is optimal for* $V_\gamma(x)$.

Proof. Observe that for all $b \in \mathcal{B}$, along the solution $y \in \mathcal{Y}_{x,b}$ such that $\alpha_x[b](t) = A(y(t), b(t))$, we have

$$0 = \mathcal{H}(y, DV_\gamma(y)) \le \max_{a\in A} F_{y,DV_\gamma(y)}(a,b) = F_{y,DV_\gamma(y)}(\alpha_x[b], b);$$

then the proof proceeds as in Proposition 6.1. □

Unfortunately we do not know of reasonable sufficient conditions for (A4) and (A5). However the map $A(x,b)$ is again a multivalued optimal synthesis (not feedback in this case) in the sense of Remark 6.2.

Remark 6.4. A more appealing way to proceed would be first to use discretizations of the system (1.1) and the Isaacs equation, then to solve the corresponding discrete-time differential game by feedback controls (this is usually easier to do; see the paper of Bardi and the author [4] and also Bardi, Falcone, and the author [1] for some more details about this procedure), and in the end to prove error estimates when using these feedbacks in the original system. This direction of research looks more promising in the near future.

INFINITE-HORIZON VARIATIONAL PROBLEMS WITH NONCONVEX INTEGRANDS*

ARIE LEIZAROWITZ† AND ALEXANDER J. ZASLAVSKI†

This paper is dedicated to the memory of Avraham Leizarowitz.

Abstract. We study *weakly optimal solutions* of infinite-horizon variational problems with first-order nonconvex integrands. This is a weakened version of the overtaking optimality criterion. These optimal solutions are closely related to the *minimal solutions* studied by Moser, Aubry, and Mather. Such solutions have definite *rotation number*, and we study the relation between the rotation number and the minimal energy growth rate. We establish the existence of a weakly optimal solution for every prescribed initial condition.

We also consider discrete-time infinite-horizon periodic control problems in R^n. Analogous to rotation numbers we consider rotation vectors and study minimization of energy growth rate for a prescribed rotation vector. This constrained problem is related to an unconstrained minimization problem that has the same class of minimizers.

Key words. infinite horizon, weakly optimal solutions, minimal solutions, overtaking optimality, rotation number

AMS subject classification. 49J15

1. Introduction.

In this paper we consider a special class of extremals, the so-called *weakly optimal solutions* of infinite horizon variational problems for real-valued functions.

We consider functionals of the form

$$I(a, b, x) = \int_a^b f(t, x(t), x'(t))\, dt, \tag{1.1}$$

where $-\infty < a < b < +\infty$ and $x \in W^{1,1}(a, b)$. By an appropriate choice of representatives, $W^{1,1}(a, b)$ can be identified with the set of absolutely continuous functions $x : [a, b] \mapsto R^1$, and we will henceforth assume that this has been done.

We will assume the integrand $f = f(t, x, p)$ satisfies the following assumption.

Assumption A. (i) $f \in C^3$, and $f(t, x, p)$ has period 1 in t, x;

(ii) $\delta \le f_{pp}(t, x, p) \le \delta^{-1}$ for every $(t, x, p) \in R^3$;

(iii) $|f_{xp}| + |f_{tp}| \le c(1 + |p|)$, $|f_{xx}| + |f_{xt}| + |f_{tt}| \le c(1 + p^2)$,

with some constants $\delta \in (0, 1)$, $c > 0$.

Clearly Assumption A implies that

$$\delta_0 p^2 - c_0 \le f(t, x, p) \le \delta_0^{-1} p^2 + c_0 \quad \text{for every } (t, x, p) \in R^3 \tag{1.2}$$

for some constants $c_0 > 0$ and $0 < \delta_0 < \delta$.

Given an $x_0 \in R^1$ we study the infinite-horizon problem of minimizing the expression

$$\int_0^T f(t, x(t), x'(t))\, dt \tag{P}$$

as T grows to infinity, where $x(\cdot) \in W^{1,1}_{\text{loc}}([0, \infty))$ satisfies the initial condition $x(0) = x_0$.

Infinite-horizon variational problems are studied mostly by researchers in economics where they are used to model, for example, economic growth. Our original motivation to study these problems came from considering questions related to continuum mechanics and

to dislocations in one-dimensional crystals. Thus, this type of problems has wide-ranging applications.

Our study follows the recent papers by J. Moser [15], [16], who studied the structure of the minimal solutions of the variational problem (P). Moser's theory can be viewed as a development of the work by Aubry [2] and Mather [12] that is concerned with area-preserving mappings of an annulus or a cylinder. The works of Aubry and Mather were begun independently and with different motivations but led to similar results by different methods. While Mather studied area-preserving annulus mappings as they occur as section mappings for Hamiltonian systems of two degrees of freedom, Aubry investigated certain models of solid-state physics related to dislocations in one-dimensional crystals, which are discussed in Aubry [2], Sinai [18], and Zazlavski [19].

It is assumed in Aubry's work that the states of the model are represented by the so-called *minimal energy configurations* (*minimal solutions*). He studied the existence and the structure of such minimal solutions. From the point of view of optimal control he investigated a certain class of discrete-time infinite-horizon control systems employing the notion of minimal solutions. In the spirit of the Aubry–Mather theory, Bylayi and Polterovich [5] and Bangert [3] studied geodesic flows and geodesic rays on Riemannian two-torus. The continuous-time analog of this discrete-time problem seems to be more challenging and is of the type of problem (P) described above.

A function $x(\cdot) \in W^{1,1}_{\text{loc}}(R^1)$ will be called a *minimal solution* of the variational problem (P) if

$$\int_a^b [f(t, y(t), y'(t)) - f(t, x(t), x'(t))]\, dt \geq 0$$

for every real numbers $a < b$ and every $y \in W^{1,1}(a, b)$ satisfy $y(a) = x(a)$ and $y(b) = x(b)$ (see [2], [15], [16], [19]). It was shown in [15], [16] that (under Assumption A) minimal solutions of (P) possess numerous remarkable properties. Thus, for any minimal solution $x(\cdot)$ there exists a real number α satisfying

$$\sup\{|x(t) - \alpha t| : t \in R^1\} < \infty$$

that is called the *rotation number* of $x(\cdot)$, and given any real α, there exists a minimal solution with rotation number α.

While studying infinite-horizon optimal control problems there are several optimality notions that are considered, and the notion of minimal solution given above is the weakest among them. Clearly we can consider the notion of minimal solutions for the class of functions defined on $[0, \infty)$. A more refined optimality criterion known as the *overtaking optimality criterion* was introduced in the economic literature and was also used in studying infinite-horizon optimal control problems (see [1], [4], [6], [8]).

A function $x(\cdot) \in W^{1,1}_{\text{loc}}([0, \infty))$ will be called an *overtaking optimal solution* of the variational problem (P) if

$$\limsup_{T \to \infty} \int_0^T [f(t, x(t), x'(t)) - f(t, y(t), y'(t))]\, dt \leq 0$$

for any $y(\cdot) \in W^{1,1}_{\text{loc}}([0, \infty))$ that satisfies $y(0) = x(0)$.

Usually it is difficult to establish the existence of overtaking optimal solutions, and actually, in general they may fail to exist. Most studies that are concerned with their existence assume convex integrands f. For convex integrands the existence of overtaking optimal solutions may follow from the fact that all good trajectories converge to a unique steady state

(see Brock and Haurie [4] and Leizarowitz [10]). For nonconvex integrands the existence of overtaking optimal solutions is not guaranteed, and in this situation we look for *weakly optimal solutions*, which indeed will be established in this paper.

A function $x(\cdot) \in W^{1,1}_{\text{loc}}([0, \infty))$ will be called a *weakly optimal solution* of the variational problem (P) if

$$\liminf_{T\to\infty} \int_0^T [f(t, x(t), x'(t)) - f(t, y(t), y'(t))]\, dt \leq 0$$

for any $y(\cdot) \in W^{1,1}_{\text{loc}}([0, \infty))$ that satisfies $y(0) = x(0)$.

It will be established in this paper that under certain conditions on f there exists a weakly optimal solution $x(\cdot) \in W^{1,1}_{\text{loc}}([0, \infty))$ for any initial value $x(0) = x_0$. The analogous result also holds for the discrete-time optimal control system corresponding to problem (P) with analogous proofs. We can expect that these results will become useful when applied to Aubry's theory and in the studies of geodesic rays on Riemannian torus.

The first existence result of weakly optimal solutions without convexity assumptions was obtained by Carlson [7] for autonomous optimal control problems with vector-valued functions. Under the assumptions posed in [7], for every good trajectory $x(\cdot)$ defined on $[0, \infty)$,

$$\tau^{-1} \int_0^\tau x(t)\, dt \to \bar{x} \quad \text{as } \tau \to \infty$$

where $\bar{x}$ is a unique steady state. Using this fact, Carlson established the existence of weakly optimal solutions.

In our situation we do not have any kind of convergence property of all the good trajectories to a unique steady state. Our consideration is based on the following observation, which was described in Leizarowitz [11] for a class of variational problems:

For every initial state there exists a weakly optimal solution if all the good trajectories have the same limit point set.

Recently this was used by Zaslavski [20] to establish, for discrete-time control systems, the existence of weakly optimal solutions for generic cost functions and any initial state. Actually we will not prove that all the good trajectories of problem (P) have the same asymptotic behavior, but we will establish a result that is very close to this and is sufficient for our purpose.

We will derive the following results.

THEOREM 1.1. *Let f satisfy Assumption* A. *Then there exist a strictly convex function $E_f : R^1 \to R^1$ satisfying $E_f(\alpha) \to +\infty$ as $|\alpha| \to \infty$ and a monotonically increasing function*

$$\Gamma_f : [0, \infty) \mapsto [0, \infty)$$

such that for each real α and each minimal solution x with rotation number α the relation

$$\left| \int_S^{S+T} f(t, x(t), x'(t))\, dt - E_f(\alpha)T \right| \leq \Gamma_f(|\alpha|) \tag{1.3}$$

holds for all real numbers S and T.

It follows from Theorem 1.1 that if f satisfies Assumption A, then $\inf\{E_f(\alpha) : \alpha \in R^1\}$ is attained at a unique point, which we denote by α_f.

THEOREM 1.2. *Let f satisfy Assumption* A, *and let α_f be the unique minimizer of $\alpha \mapsto E_f(\alpha)$, namely,*

$$E_f(\alpha_f) = \inf\{E_f(\alpha) : \alpha \in R^1\}.$$

Assume that α_f is irrational. Then for any initial value $x_0 \in R^1$ there exists a weakly optimal solution $x(\cdot) \in W^{1,1}_{\text{loc}}([0, \infty))$ satisfying $x(0) = x_0$.

The proofs of these results are based on Moser's theory (see [15], [16]) and the method of reformulating the variational problem in discrete-time terms as developed in [9] and [11]. Theorem 1.1 is an analogue of Mather's theorem about the average energy function for Aubry–Mather sets generated by a diffeomorphism of the infinite cylinder, which consists of finite compositions of exact symplectic monotone twist mappings [13]. Mather's theorem is a generalization of Aubry's unpublished result, which establishes the strict convexity of the average energy function for the Frenkel–Kontorova model. A similar result appeared in Senn [17], where the strict convexity of E_f in multidimensional situations was established. In our discussion, in addition to the strict convexity of E_f, we also need the estimate (1.3), which was not considered in [17].

We also consider discrete-time infinite-horizon control problems. Let $v(\cdot, \cdot)$ be continuous and periodic on $R^n \times R^n$, namely $v(x + m, y + m) = v(x, y)$ for every $x, y \in R^n$ and every $m \in R^n$ with integer components. We consider cost expressions $D_N(\bar{x}) = \sum_{k=0}^{N-1} v(x_k, x_{k+1})$ for programs $\bar{x} = \{x_k\}_{k=0}^{\infty} \subset R^n$. Analogous to rotation numbers we define the *rotation vectors* and study the problem of minimizing the growth rate over all the programs that have a prescribed rotation vector. Let $\Phi_v(\cdot)$ be the discrete-time counterpart of the above-mentioned function $E_f(\cdot)$. It will be proved below that $\Phi_v(\cdot)$ is a convex function.

We will establish the existence of optimal programs with prescribed rotation vectors α, and we will obtain them as optimal programs for the following unconstrained related problem. Supposed that $(\alpha, \Phi_v(\alpha))$ is an exposed point of $\text{epi}\Phi_v$ (the epigraph of $\Phi_v(\cdot)$), and let λ be such that $\Phi_v(\alpha') > \Phi_v(\alpha) + \lambda \cdot (\alpha' - \alpha)$ for every $\alpha' \neq \alpha$. We define

$$v_\alpha(x, y) = v(x, y) + \lambda \cdot (x - y),$$

which like v is continuous and periodic in $R^n \times R^n$. We have the following result.

THEOREM 1.3. *The function $\Phi_v(\cdot)$ is convex. Moreover, if $(\alpha, \Phi_v(\alpha))$ is an exposed point of* $\text{epi}\Phi_v$, *then there exists a minimizer of the growth rate of programs that have a prescribed rotation vector α. This minimizer has definite limits both for the energy growth rate and the rotation vector. Actually it is a minimizer of the unconstrained problem of minimizing the cost expressions*

$$D_N^\alpha(\bar{x}) = \sum_{k=0}^{N-1} v_\alpha(x_k, x_{k+1})$$

as $N \to \infty$. In the case that $\Phi_v(\cdot)$ is strictly convex and every *point $(\alpha, \Phi_v(\alpha))$ is an exposed point of* $\text{epi}\Phi_v$, *then the assertion of this result holds for every $\alpha \in R^n$.*

2. Properties of minimal solutions. We will need the following result (see [14, Thm. 1.8.2]).

PROPOSITION 2.1. *Let $-\infty < a < b < +\infty$, $\{x_k(\cdot)\}_{k=1}^{\infty} \subset W^{1,1}(a, b)$, and $\{x_k'\}_{k=1}^{\infty}$ be a bounded sequence in $L^2[a, b]$. Furthermore, let $x(\cdot) \in W^{1,2}(a, b)$ be such that*

$$x_k(t) \to x(t) \quad \textit{uniformly in } [a, b]$$

and

$$x_k'(\cdot) \to x'(\cdot) \quad \textit{weakly in } L^2[a, b] \textit{ as } k \to \infty.$$

Then

$$I(a, b, x) \leq \liminf_{k\to\infty} I(a, b, x_k).$$

For the proof see [14, Thm. 1.8.2].

For $a, b, \alpha, \beta \in R^1$ such that $a < b$ we define

$$U(a, b, \alpha, \beta) = \inf\{I(a, b, x) : x \in W^{1,1}(a, b), x(a) = \alpha, x(b) = \beta\}. \tag{2.1}$$

Relation (1.2) and Proposition 2.1 imply the following result.

PROPOSITION 2.2. *Let $a, b, \alpha, \beta \in R^1$, $a < b$. Then there exists $x(\cdot) \in W^{1,1}(a, b)$ such that*

$$x(a) = \alpha, \qquad x(b) = \beta, \qquad I(a, b, x) = U(a, b, \alpha, \beta).$$

Assumption A, relation (1.2), and Theorem 1.10.1 in [14] imply the following result.

PROPOSITION 2.3. *Let $a, b, \alpha, \beta \in R^1$, $a < b$, and $x(\cdot) \in W^{1,1}(a, b)$ be such that*

$$x(a) = \alpha, \quad x(b) = \beta, \quad I(a, b, x) = U(a, b, \alpha, \beta).$$

Then $x(\cdot) \in C^2[a, b]$ and it satisfies the Euler–Lagrange equation.

Denote by $\mathbf{Z}$ the set of all integers. We note that for any integers j and k the translations

$$(t, x) \mapsto (t + j, x + k)$$

leave the variational problem invariant. Therefore, if $x(\cdot)$ is a minimal solution, so is $x(\cdot + j) + k$. On the torus this represents, of course, the same curve as does $x(\cdot)$. This motivates the following terminology (see [15], [16]).

We say that a function $x(\cdot) \in W^{1,1}_{\text{loc}}(R^1)$ *has no self-intersections* if for every pair of integers j, k the function $t \mapsto x(t + j) + k - x(t)$ is either always positive or always negative or identically zero. The following results, which will be needed below, were established in [16].

PROPOSITION 2.4. *If $x \in W^{1,1}_{\text{loc}}(R^1)$ is a minimal solution without self-intersections of* (P), *then there exists a unique number α such that*

$$\sup\{|x(t) - \alpha t| : t \in R^1\} < \infty$$

and there exists a constant c_1 depending only on the constants c_0 and δ_0 in (1.2) *so that*

$$|x(t + s) - x(t) - \alpha s| \leq c_1(1 + \alpha^2)^{1/2} \tag{2.2}$$

for all s and t.

Moreover, there exist constants $\epsilon \in (0, 1)$ and $\gamma_1 > 0$ independent of x but depending on $|\alpha|$ and the constants c and δ in Assumption A *such that $\|x'(\cdot)\|_{C^\epsilon} \leq \gamma_1$ (where C^ϵ denotes the space of Hölder continuous functions of order ϵ).*

The number α is uniquely determined by the minimal $x = x(t)$ and is called *the rotation number of x*.

PROPOSITION 2.5. *Given any real α there exists a non–self-intersecting minimal solution with rotation number α.*

We associate with any non–self-intersecting minimal solution $x(\cdot)$ its rotation number α and denote

$$\mathcal{M}(\alpha) = \{\, x(\cdot) : x \text{ is non–self-intersecting minimal solution with rotation number } \alpha\}. \tag{2.3}$$

Moreover, for $A > 0$ we set

$$\mathcal{M}_A = \bigcup\{\mathcal{M}(\alpha) : |\alpha| \le A\}. \tag{2.4}$$

PROPOSITION 2.6 [15, Thm. 7.4] and [16, Cor. 3.3]. *The set $\mathcal{M}_A/\mathbf{Z}$ is compact with respect to the C^1-topology on compact sets in R^1. In other words, any sequence $\{x^s\} \in \mathcal{M}_A$ possesses a subsequence, say $\{x^{s_i}\}_{i=1}^{\infty}$, and a sequence of integers $\{k_i\}_{i=1}^{\infty}$ for which $x^{s_i} - k_i$ converges with first derivatives uniformly on any compact set to a function $x^* \in \mathcal{M}_A$.*

We have the following results (see [16, Thms. 5.1, 5.2, and 5.4 and Cors. 5.5 and 5.3]).

PROPOSITION 2.7. *Let α be a rational number and q be a natural number such that $q\alpha \in \mathbf{Z}$. Set*

$$\mathcal{A}_q = \{x(\cdot) \in W^{1,1}_{\mathrm{loc}}(R^1) : x(t+q) = x(t) \text{ for every } \in R^1\}.$$

Then there exists $\hat{x}^* \in \mathcal{A}_q$ such that $x^* = \alpha t + \hat{x}^*$ minimizes $I(0, q, x)$ over all $x \in W^{(1,1)}_{\mathrm{loc}}(R^1)$ with $x - \alpha t \in \mathcal{A}_q$. Moreover, $x^* \in C^2(R^1)$, and it satisfies the Euler–Lagrange equation.

PROPOSITION 2.8. *Let α be a rational number and q be a natural number satisfying $q\alpha \in \mathbf{Z}$. Set*

$$\bar{\mathcal{A}}_q = \{x \in W^{1,1}_{\mathrm{loc}}(R^1) : x - \alpha t \in \mathcal{A}_q\},$$
$$\mathcal{M}(\alpha, q) = \{x(\cdot) \in \bar{\mathcal{A}}_q : I(0, q, x) \le I(0, q, y) \text{ for every } y \in \bar{\mathcal{A}}_q\}.$$

Then the set $\mathcal{M}(\alpha, q)$ is totally ordered; i.e., if $x, y \in \mathcal{M}(\alpha, q)$, then either $x(t) < y(t)$ for all t or $x(t) > y(t)$ for all t or $x(t) = y(t)$ identically.

COROLLARY 2.1. *If $x \in \mathcal{M}(\alpha, q)$, then $x(\cdot)$ has no self-intersections.*

PROPOSITION 2.9. *Let α be a rational number and q_1 and q_2 be natural numbers such that $q_1\alpha, q_2\alpha \in \mathbf{Z}$. Then $\mathcal{M}(\alpha, q_1) = \mathcal{M}(\alpha, q_2)$.*

For any rational number α we set

$$\mathcal{M}_{\mathrm{per}}(\alpha) = \mathcal{M}(\alpha, q),$$

where q is a natural number satisfying $\alpha \in \mathbf{Z}$.

PROPOSITION 2.10. *Let α be a rational number and $x \in \mathcal{M}_{\mathrm{per}}(\alpha)$. Then x is a non–self-intersecting minimal solution of* (P) *with the rotation number α.*

The following two results were established in [16, §4].

PROPOSITION 2.11. *Let u and v be minimal solutions of* (P). *Then the open set $\{t \in R^1 : u(t) < v(t)\}$ has no bounded components.*

PROPOSITION 2.12. *If u and v are minimal solutions, $u(t) \le v(t)$ for all $t \in R^1$, then either $u(t) = v(t)$ for all t or $u(t) < v(t)$ for all t.*

3. Proof of Theorem 1.1.

PROPOSITION 3.1. *Let $\alpha = m/n$ where m, n are integers, $n \ge 1$. Set*

$$E(\alpha) = \frac{1}{n}\int_0^n f(t, y(t), y'(t))\, dt,$$

where $y \in \mathcal{M}_{\text{per}}(\alpha)$. *Then for* α *there exists a constant* $\Gamma(\alpha)$ *that increases for* $\alpha > 0$ *and decreases for* $\alpha < 0$ *and such that for all numbers* S, T, *with* $T > 0$, *and for every* $x \in \mathcal{M}_{\text{per}}(\alpha)$,

$$\left| \int_S^{S+T} f(t, x(t), x'(t))\, dt - E(\alpha)T \right| \leq \Gamma(\alpha). \tag{3.1}$$

Proof. Let $x \in \mathcal{M}_{\text{per}}(\alpha)$. By Proposition 2.4

$$|x'(t)| \leq \gamma_1(\alpha) \quad \text{for every } t \in R^1,$$

where the constant $\gamma_1(\alpha)$ depends monotonically increasing on $|\alpha|$. We set

$$\begin{aligned} \Gamma_0(\alpha) &= 1 + 4(1 + c_0) + 48\delta_0^{-1}(c_1 + 1)^2(1 + |\alpha|)^2, \\ \beta &= \sup\{|f(t, x, y)| : |y| \leq \gamma_1(\alpha), x, t \in R^1\}, \\ \Gamma(\alpha) &= \Gamma_0(\alpha) + 3(1 + |\alpha|)\beta. \end{aligned}$$

(Recall the constants c_0 and δ_0 in (1.2) and c_1 in (2.2).)

It is easy to verify that

$$|E(\alpha)| \leq \beta|\alpha|,$$

$$\left| \int_{T_1}^{T_2} f(t, x(t), x'(t))\, dt \right| \leq \sup\{|f(t, x, y)| : t, x, y \in R^1,\ |y| \leq \gamma_1(\alpha)\}$$

for all $T_1, T_2 \in R^1$ such that $|T_1 - T_2| \leq 1$. To prove the proposition it is sufficient to show that for every *integers* T and S (with $T > 0$),

$$\left| \int_S^{S+T} f(t, x(t), x'(t))\, dt - E(\alpha)T \right| \leq \Gamma_0(\alpha). \tag{3.2}$$

The validity of (3.2) for *any integers* S and T implies that (3.1) holds for any S and T as asserted in the proposition.

Assume to the contrary that (3.2) does not hold. Then there are integers T, S such that $1 \leq T \leq n - 1, 0 \leq S \leq n - 1$, and

$$\left| \int_S^{S+T} f(t, x(t), x'(t))\, dt - E(\alpha)T \right| > \Gamma_0(\alpha).$$

If

$$\int_S^{S+T} f(t, x(t), x'(t))\, dt - E(\alpha)T > \Gamma_0(\alpha),$$

then

$$\int_{S+T}^{S+n} f(t, x(t), x'(t))\, dt - (n - T)E(\alpha) < -\Gamma_0(\alpha).$$

Therefore, we may assume without loss of generality that

$$\int_S^{S+T} f(t, x(t), x'(t))\, dt - E(\alpha)T < -\Gamma_0(\alpha). \tag{3.3}$$

Choose a large natural number k. We have

$$knE(\alpha)T = \int_S^{S+knT} f(t, x(t), x'(t))\, dt = \sum_{i=0}^{kn-1} \int_{S+iT}^{S+(i+1)T} f(t, x(t), x'(t))\, dt. \tag{3.4}$$

By (3.3) and (3.4) there is an integer j such that $1 \le j \le kn - 1$ and

$$\int_{S+jT}^{S+(j+1)T} f(t, x(t), x'(t))\, dt > E(\alpha)T + (kn)^{-1}\Gamma_0(\alpha). \tag{3.5}$$

We next construct a function $y \in W^{1,1}(S, S + n(kT + 1))$ that is equal to x on the intervals $[S, S + jT - 1]$ and $[S + (j + 1)T + 1, S + n(kT + 1)]$ and equal to the translation of x on the interval $[S + jT, S + (j + 1)T]$. It will follow from its construction and from (3.3) and (3.5) that

$$\int_S^{S+n(kT+1)} [f(t, x(t), x'(t)) - f(t, y(t), y'(t))]\, dt > 0.$$

For $t \in R^1$ we set

$$\text{Int}(t) = \sup\{i : i \in \mathbf{Z},\ i \le t\}.$$

There exists $y \in W^{1,1}(S, S + n(kT + 1))$ such that

$$y(t) = x(t) \quad \text{for every } t \in [S, S + jT - 1] \cup [S + (j + 1)T + 1, S + n(kT + 1)],$$

$$y(t) = x(t - jT) + \text{Int}(\alpha jT) \quad \text{for every } t \in [S + jT, S + (j + 1)T],$$

$$\int_\tau^{\tau+1} f(t, y(t), y'(t))\, dt = U(\tau, \tau + 1, y(\tau), y(\tau + 1)) \quad \text{for every } \tau \in [S + jT - 1, S + (j + 1)T].$$

It follows from the definition of y that

$$\int_S^{S+n(kT+1)} [f(t, x(t), x'(t)) - f(t, y(t), y'(t))]\, dt = \sigma_1 + \sigma_2 + \sigma_3 \le 0, \tag{3.6}$$

where

$$\sigma_1 = \int_{S+jT}^{S+(j+1)T} [f(t, x(t), x'(t)) - f(t, y(t), y'(t))]\, dt,$$

$$\sigma_2 = \int_{S+jT-1}^{S+jT} [f(t, x(t), x'(t)) - f(t, y(t), y'(t))]\, dt,$$

$$\sigma_3 = \int_{S+(j+1)T}^{S+(j+1)T+1} [f(t, x(t), x'(t)) - f(t, y(t), y'(t))]\, dt.$$

By (3.3) and (3.5)

$$\sigma_1 > \Gamma_0(\alpha). \tag{3.7}$$

It follows from (1.2) that

$$-c_0 - 1 - 2\delta_0|a - b| \le U(i, i + 1, a, b) \le c_0 + \delta_0^{-1}|b - a|^2 \tag{3.8}$$

for any integer $i \geq 0$ and every $a, b \in R^1$. It follows from Proposition 2.4 and (2.2) that

$$|x(\tau) - x(\tau + 1)| \leq |\alpha| + c_1(1 + |\alpha|) \quad \text{for every } \tau \in R^1.$$

Since $x \in \mathcal{M}_{\text{per}}(\alpha)$, the last inequality and (3.8) imply that for every $\tau \in [S + jT - 1, S + (j + 1)T]$

$$\left| \int_\tau^{\tau+1} f(t, x(t), x'(t))\, dt \right| \leq c_0 + 1 + 2\delta_0^{-1}[1 + (|\alpha| + c_1(1 + |\alpha|))^2]. \tag{3.9}$$

It follows from Proposition 2.4, the definition of y, and (2.2) that

$$|y(S + jT - 1) - y(S + jT)| \leq |x(S + jT - 1) - x(S) - \alpha jT| + 1 \leq (1 + |\alpha|)(1 + c_1)$$

and

$$\begin{aligned} |y(S + (j + 1)T) - y(S + 1 + (j + 1)T| &= |x(S + T) + \alpha jT - x(S + 1 + (j + 1)T)| + 1 \\ &\leq (1 + |\alpha|)(1 + c_1). \end{aligned}$$

These relations, (3.8), and the definition of y imply that

$$\left| \int_\tau^{\tau+1} f(t, y(t), y'(t))\, dt \right| \leq c_0 + 1 + 2\delta_0^{-1}[1 + (1 + |\alpha|)^2(1 + c_1)^2] \tag{3.10}$$

for $\tau \in [jT + S - 1, S + (j + 1)T]$.

In view of (3.9) and (3.10) we obtain

$$|\sigma_2|, |\sigma_3| \leq 2c_0 + 2 + 4\delta_0^{-1}(1 + (1 + |\alpha|)^2(1 + c_1)^2).$$

We now conclude from this relation, (3.6), (3.7), and the definition of $\Gamma_0(\alpha)$ that

$$0 \geq \sigma_1 + \sigma_2 + \sigma_3 > \Gamma_0(\alpha) - 4c_0 - 4 + 8\delta_0^{-1}(1 + (1 + |\alpha|^2)^2(1 + c_1)^2) > 0.$$

This contradiction concludes the proof of the proposition. □

In the paragraph that followed Proposition 2.4 we defined the rotation number for minimal solutions without self-intersections. In the next proposition we define it for *any* minimal solution.

PROPOSITION 3.2. *If x is a minimal solution of* (P), *then there exists a real number α that is called the rotation number of x such that*

$$|x(t + s) - x(t) - \alpha s| \leq c_1(1 + |\alpha|) + 6$$

for all s and t (where c_1 is as in Proposition 2.4).

Proof. Let x be a minimal solution of (P). For a natural number N set

$$r_N = \max\{i \in \mathbf{Z} : i \leq x(N) - x(-N)\}.$$

There exists $y_N \in \mathcal{M}_{\text{per}}(r_N/2N)$ such that

$$|y_N(-N) - x(-N)| \leq 1.$$

Clearly

$$|y_N(N) - x(N)| = |y_N(-N) + r_N - x(N)| \leq 2.$$

By Proposition 2.12

$$|y_N(t) - x(t)| \leq 3 \quad \text{for every } t \in [-N, N]. \tag{3.11}$$

It follows from Proposition 2.4 that

$$|y_N(t+s) - y_N(t) - (r_N/2N)s| \leq c_1(1 + |r_N|/2N)$$

for all numbers s and t.

We will next prove that the sequence $\{r_N/2N\}_{N=1}^{\infty}$ is bounded. Fix an integer $N_0 > c_1$. For $N \geq N_0$ we have

$$|y_N(N_0) - y_N(0) - (r_N/2N)N_0| \leq c_1(1 + |r_N|/2N),$$

which, in view of (3.11), implies that

$$|x(N_0) - x(0) - (r_N/2N)N_0| \leq 6 + c_1(1 + |r_N|/2N).$$

Dividing the last inequality by $|r_N|/2N$ (whenever it is nonzero) yields

$$\left| \frac{x(N_0) - x(0)}{r_N/2N} - N_0 \right| \leq c_1 + \frac{c_1 + 6}{|r_N|/2N},$$

which implies a contradiction to $N_0 > c_1$ if $\{r_N/2N\}_{N=1}^{\infty}$ is unbounded.

We have thus established that the sequence $\{r_N/2N\}_{N=N_0}^{\infty}$ is bounded, and we have that

$$y_N \in \mathcal{M}_{\text{per}}(r_N/2N) \subset \mathcal{M}(r_N/2N) \quad \text{for every } N \geq N_0$$

(recall (2.3) and (2.4)). By Proposition 2.6 there exists a subsequence $\{y_{N_k}\}_{k=1}^{\infty}$ that converges with first derivatives uniformly on any compact set to a function $z(\cdot) \in \mathcal{M}_A$ where

$$A = \sup \left\{ \frac{|r_N|}{2N} : N \geq N_0 \right\}.$$

There is a number α such that $z(\cdot) \in \mathcal{M}(\alpha)$, and it follows from (3.11) that

$$|z(t) - x(t)| \leq 3 \quad \text{for every real } t.$$

This last relation and Proposition 2.4 imply that

$$|x(t+s) - x(t) - \alpha s| \leq c_1(1 + |\alpha|) + 6$$

for all s and t. The proposition is proved. □

PROPOSITION 3.3. *Assume that x is a minimal solution of* (P), *α is the rotation number of x, and $\{\alpha_i\}$ is a sequence of rational numbers such that $\alpha_i \to \alpha$ as $i \to \infty$. Then there exists a real number $E_f(\alpha)$ such that the following limit exists*

$$E_f(\alpha) = \lim_{i \to \infty} E(\alpha_i)$$

and is independent on the sequence $\{\alpha_i\}_{i=1}^{\infty}$. Moreover, for each α there exists a real number $\Gamma_f(\alpha) > 0$ depending monotonically increasing on $|\alpha|$ such that

$$\left| \int_S^{S+T} f(t, x(t), x'(t))\, dt - E_f(\alpha)T \right| \leq \Gamma_f(\alpha)$$

for all $S, T \in R^1$.

Proof. For every natural number i there is $y_i \in \mathcal{M}_{\text{per}}(\alpha_i)$ such that

$$|y_i(0) - x(0)| \le 1. \tag{3.12}$$

Let $T_1, T_2 \in R^1$, $T_1 < T_2$. It follows from Proposition 3.2 and (3.12) that there exists an integer $i_0 \ge 1$ such that for every integer $i \ge i_0$

$$\sup\{|y_i(t) - x(t)| : t \in R^1,\ |t| \le |T_1| + |T_2| + 1\} \le 2c_1(1 + |\alpha|) + 15. \tag{3.13}$$

Let $i \ge i_0$ be an integer. We will next define a $z \in W^{1,1}_{\text{loc}}(R^1)$ that is equal to x on the intervals $(-\infty, T_1 - 1]$ and $[T_2 + 1, \infty)$ and equal to y_i on the interval $[T_1, T_2]$. We also define $u \in W^{1,1}_{\text{loc}}(R^1)$ that is equal to y_i on the intervals $(-\infty, T_1 - 1]$ and $[T_2 + 1, \infty)$ and equal to x on the interval $[T_1, T_2]$. The fact that x and y_i are minimal solutions and the definitions of z and u will imply that $|I(T_1, T_2, x) - I(T_1, T_2, y_i)|$ is bounded by a bound that depends only on $|\alpha|$.

More explicitly we define $u, z \in W^{1,1}_{\text{loc}}(R^1)$ such that

$$z(t) = \begin{cases} x(t) & \text{for } t \in (-\infty, T_1 - 1] \cup [T_2 + 1, \infty), \\ y_i(t) & \text{for } t \in [T_1, T_2]; \end{cases}$$

$$I(T_1 - 1, T_1, z) = U(T_1 - 1, T_1, x(T_1 - 1), y_i(T_1)),$$
$$I(T_2, T_2 + 1, z) = U(T_2, T_2 + 1, y_i(T_2), x(T_2 + 1));$$

and

$$u(t) = \begin{cases} y_i(t) & \text{for } t \in (-\infty, T_1 - 1] \cup [T_2 + 1, \infty), \\ x(t) & \text{for } t \in [T_1, T_2]; \end{cases}$$

$$I(T_1 - 1, T_1, u) = U(T_1 - 1, T_1, y_i(T_1 - 1), x(T_1)),$$
$$I(T_2, T_2 + 1, z) = U(T_2, T_2 + 1, x(T_2), y_i(T_2 + 1)).$$

Since x and y_i are minimal solutions, we obtain

$$\begin{aligned} I(T_1 - 1, T_2 + 1, x) &\le I(T_1 - 1, T_2 + 1, z), \\ I(T_1 - 1, T_2 + 1, y_i) &\le I(T_1 - 1, T_2 + 1, u). \end{aligned} \tag{3.14}$$

It follows from (3.13) and Proposition 3.2 that

$$|u(\tau) - u(\tau + 1)|, |z(\tau) - z(\tau + 1)| \le c_2(|\alpha| + 1)$$

with $c_2 = 3c_1 + 21$ for $\tau = T_1 - 1$ and $\tau = T_2$. These relations and the definitions of z and u and (1.2) imply that for $\tau = T_1 - 1$ and $\tau = T_2$ and for $v = z$ and $v = u$ we have

$$\begin{aligned} -c_0 &\le \int_\tau^{\tau+1} f(t, v(t), v'(t))\, dt \\ &\le \sup\{|f(t, w, p)| : (t, w, p) \in R^3,\ |p| \le |v(\tau) - v(\tau + 1)|\} \\ &\le \sup\{|f(t, w, p)| : (t, w, p) \in R^3,\ |p| \le c_2(1 + |\alpha|)\}. \end{aligned}$$

We conclude from these relations and (3.14) that

$$\begin{aligned} |I(T_1, T_2, x) - I(T_1, T_2, y_i)| &\le 2c_0 \\ &\quad + 2\sup\{|f(t, w, p)| : (t, w, p) \in R^3,\ |p| \le c_2(1 + |\alpha|)\}. \end{aligned}$$

In view of Proposition 3.1 this relation yields

$$\left|\int_{T_1}^{T_2} [f(t, x(t), x'(t)) - E(\alpha_i)]\, dt\right| \leq \Gamma(\alpha_i) + \Phi(\alpha), \tag{3.15}$$

where

$$\Phi(\alpha) = 2c_0 + 2\sup\{|f(t, w, p)| : (t, w, p) \in R^3,\ |p| \leq c_2(1 + |\alpha|)\}. \tag{3.16}$$

We have thus proved that for each $T_1, T_2 \in R^1$ satisfying $T_1 < T_2$ there exists a natural number i_0 such that for every integer $i \geq i_0$

$$\left|\int_{T_1}^{T_2} [f(t, x(t), x'(t)) - E(\alpha_i)]\, dt\right| \leq \Phi(\alpha) + \max\{\Gamma(\alpha - 1), \Gamma(\alpha + 1)\}.$$

Clearly this implies the existence of $\lim_{i\to\infty} E(\alpha_i)$, which completes the proof of the proposition. □

For any $\alpha \in R$ we set

$$E_f(\alpha) = \lim_{i\to\infty} E(\alpha_i), \tag{3.17}$$

where $\{\alpha_i\}_{i=1}^{\infty}$ is a sequence of rational numbers such that $\alpha_i \to \alpha$ as $i \to \infty$.

By Proposition 3.3 the function $E_f : R \to R$ is well defined. It follows from Propositions 3.3 and 3.1 that $E_f(\alpha) = E(\alpha)$ for every rational α. It follows easily from Proposition 3.3 that $E_f(\cdot)$ is continuous.

PROPOSITION 3.4. *The function E_f is strictly convex.*

Proof. Let $\alpha_1, \alpha_2, \beta$ be rational numbers and $\beta \in (0, 1)$, $\alpha_1 \neq \alpha_2$. We claim that it is sufficient to show that

$$E_f(\beta\alpha_1 + (1 - \beta)\alpha_2) < \beta E_f(\alpha_1) + (1 - \beta)E_f(\alpha_2).$$

This is so since this will imply that E_f is convex, hence it is strictly convex. There are natural numbers n_1, n_2, q_1, q_2 and integers m_1, m_2 satisfying

$$\beta = q_1/q_2, \quad \alpha_i = m_i/n_i, \quad i = 1, 2,$$

and $x_i \in \mathcal{M}_{\text{per}}(\alpha_i)$, $i = 1, 2$. We have

$$\beta\alpha_1 + (1 - \beta)\alpha_2 = [m_1q_1n_2 + m_2(q_2 - q_1)n_1]/(n_1n_2q_2).$$

Fix a large natural number N such that $N/(n_1n_2q_2)$ is an integer, and set

$$k_1 = Nq_1n_2, \qquad k_2 = N(q_2 - q_1)n_1.$$

We may assume without loss of generality that

$$|x_1(k_1n_1) - x_2(0)| \leq 1. \tag{3.18}$$

Let us prove that

$$E_f(\beta\alpha_1 + (1 - \beta)\alpha_2) \leq \beta E_f(\alpha_1) + (1 - \beta)E_f(\alpha_2). \tag{3.19}$$

We will construct a function $x \in W^{1,1}(0, k_1n_1 + k_2n_2)$ that is equal to x_1 on the interval $[0, k_1n_1 - 1]$, is equal to a translation of x_2 on the interval $[k_1n_1, k_1n_1 + k_2n_2 - 1]$, and satisfies

$$x(k_1n_1 + k_2n_2) = x(0) + k_1m_1 + k_2m_2.$$

Using the definition of x we will show that

$$I(0, k_1n_1 + k_2n_2, x) - I(0, k_1n_1, x_1) - I(0, k_2n_2, x_2)$$

does not exceed some constant that depends only on $|\alpha_1|$ and $|\alpha_2|$. Since $E(\beta\alpha_1+(1-\beta)\alpha_2) \le I(0, k_1n_1 + k_2n_2, x)/(q_2n_1n_2N)$, this will imply (3.19).

There exists $x \in W^{1,1}(0, k_1n_1 + k_2n_2)$ such that

$$x(t) = x_1(t)(t \in [0, k_1n_1 - 1]), \qquad x(t) = x_2(t - k_1n_1)(t \in [k_1n_1, k_1n_1 + k_2n_2 - 1]),$$
$$x(k_1n_1 + k_2n_2) = x(0) + k_1m_1 + k_2m_2,$$

$$x(\tau + t) = tx(\tau + 1) + (1 - t)x(\tau) \qquad (t \in (0, 1), \tau \in \{k_1n_1 - 1, k_1n_1 + k_2n_2 - 1\}).$$

It follows from Proposition 2.4 and (3.18) that

$$\begin{aligned} |x_1(k_1n_1 - 1) - x_2(0)| &\le |x_1(k_1n_1 - 1) - x_1(k_1n_1)| + |x_1(k_1n_1) - x_2(0)| \\ &\le c_1(1 + |\alpha_1|) + 1 + |\alpha_1|, \end{aligned}$$

$$\begin{aligned} &|x(k_1n_1 + k_2n_2 - 1) - x(k_1n_1 + k_2n_2)| \\ &\quad \le |x_2(k_2n_2 - 1) - x_2(k_2n_2)| + |x_2(k_2n_2) - x(0) - k_1m_1 - k_2m_2| \\ &\quad \le c_1(1 + |\alpha_2|) + 1 + |\alpha_2|. \end{aligned}$$

From these relations, the definition of x, and (1.2) we conclude that

$$\begin{aligned} &I(0, k_1n_1 + k_2n_2, x) - I(0, k_1n_1, x_1) - I(0, k_2n_2, x_2) \\ &\quad \le I(k_1n_1 - 1, k_1n_1, x) + I(k_1n_1 + k_2n_2 - 1, k_1n_1 + k_2n_2, x) \\ &\qquad - I(k_1n_1 - 1, k_1n_1, x_1) - I(k_2n_2 - 1, k_2n_2, x_2) \\ &\quad \le 2\delta_0 + 2\sup\{|f(t, w, p)| : (t, w, p) \in R^3,\ |p| \le (c_1 + 1)(1 + |\alpha_1| + |\alpha_2|)\}. \end{aligned}$$

This inequality and the relation $x_i \in \mathcal{M}_{\text{per}}(\alpha_i)$ for $i = 1, 2$ yield

$$\begin{aligned} E(\beta\alpha_1 + (1 - \beta)\alpha_2) &\le I(0, k_1n_1 + k_2n_2, x)/(q_2n_1n_2N) \\ &\le (Nq_2n_1n_2)^{-1}[2\delta_0 + 2\sup\{|f(t, w, p)| : (t, w, p) \in R^3, \\ &\qquad |p| \le (c_1 + 1)(1 + |\alpha_1| + |\alpha_2|)\} \\ &\qquad + k_1n_1E(\alpha_1) + E(\alpha_2)k_2n_2] \\ &= \beta E(\alpha_1) + (1 - \beta)E(\alpha_2) + (Nq_2n_1n_2)^{-1} \\ &\qquad \cdot [2\delta_0 + 2\sup\{|f(t, w, p)| : (t, w, p) \in R^3, \\ &\qquad\qquad |p| \le (c_1 + 1)(1 + |\alpha_1| + |\alpha_2|)\}]. \end{aligned}$$

Since this relation holds for any sufficiently large integer N such that $N/q_2n_1n_2$ is an integer, (3.19) is established.

We will next prove that strict inequality holds in (3.19), which will conclude the proof.

We may assume without loss of generality that $\alpha_1 < \alpha_2$. By Proposition 2.3 x_1 and x_2 satisfy Euler's equation. It follows from Propositions 2.4 and 2.11 that there is $\tau_0 \in R^1$ such that

$$x_2(t) > x_1(t) \quad \text{for every } t \in R^1,$$
$$t > \tau_0, \quad x_2(t) < x_1(t) \quad \text{for every } t \in R^1,\ t < \tau_0.$$

There exists $y \in W^{1,1}_{\text{loc}}(R^1)$ such that

$$\begin{aligned} y(t + q_2 n_1 n_2) &= y(t) + q_1 n_2 m_1 + (q_2 - q_1) m_2 n_1 \quad \text{for every } t \in R^1, \\ y(t) &= x_1(t) \quad \text{for every } t \in [\tau_0 - q_1 n_1 n_2, \tau_0], \\ y(t) &= x_2(t) \quad \text{for every } t \in [\tau_0, \tau_0 + (q_2 - q_1) n_1 n_2]. \end{aligned} \tag{3.20}$$

Assume that

$$\begin{aligned} &I(\tau_0 - q_1 n_1 n_2, \tau_0 + (q_2 - q_1) n_1 n_2, y)/q_2 n_1 n_2 \\ &\quad = E([q_1 n_2 m_1 + (q_2 - q_1) m_2 n_1]/q_2 n_1 n_2). \end{aligned}$$

Then y and x_1 satisfy the Euler–Lagrange equation, and by (3.20) $y(t) = x_1(t)$ for every $t \in R^1$. It follows from this and the definition of $y(\cdot)$ that $x_1(t) = x_2(t)$ for every t, contradicting $\alpha_1 \neq \alpha_2$. The resulting contradiction proves that

$$\begin{aligned} E(\beta\alpha_1 + (1 - \beta)\alpha_2) &< (q_2 n_1 n_2)^{-1} I(\tau_0 - q_1 n_1 n_2, \tau_0 + (q_2 - q_1) n_1 n_2, y) \\ &= \beta E(\alpha_1) + (1 - \beta) E(\alpha_2). \end{aligned}$$

The proposition is proved. □

PROPOSITION 3.5. *$E_f(\alpha) \to +\infty$ as $|\alpha| \to \infty$.*

Proof. Let $\alpha \in R$, $x \in \mathcal{M}(\alpha)$. Propositions 2.4 and 3.3 imply that for each $T > 0$

$$|x(T) - x(0) - \alpha T| \leq c_1(1 + |\alpha|), \tag{3.21}$$

$$\left| \int_0^T f(t, x(t), x'(t))\, dt - E_f(\alpha) T \right| \leq \Gamma_f(\alpha). \tag{3.22}$$

It follows from (1.2) that we have for every $T > 0$

$$\int_0^T f(t, x(t), x'(t))\, dt \geq \int_0^T [-c_0 + \delta_0 |x'(t)| - 1]\, dt \geq -(c_0 + 1)T + \delta_0 |x(T) - x(0)|. \tag{3.23}$$

We obtain from (3.21) that

$$|x(T) - x(0)| \geq |\alpha| T - c_1(1 + |\alpha|),$$

which, in view of (3.22) and (3.23),yields

$$T E_f(\alpha) \geq -\Gamma_f(\alpha) - (c_0 + 1)T + \delta_0 |\alpha| T - \delta_0 c_1 (1 + |\alpha|).$$

Dividing the last inequality by T and then letting $T \to \infty$ we obtain

$$E_f(\alpha) \geq |\alpha| \delta_0 - c_0 - 1.$$

This completes the proof of the proposition. □

Theorem 1.1 now follows from Propositions 3.1–3.5.

4. Discrete reformulation of (P). For $x, y \in R^1$ we set

$$v(x, y) = \inf \left\{ \int_0^1 f(t, u(t), u'(t))\, dt : u \in W^{1,1}(0, 1),\ u(0) = x,\ u(1) = y \right\}. \tag{4.1}$$

It is easy to verify that

$$
\begin{aligned}
&v(x+1, y+1) = v(x, y), \qquad x, y \in R^1;\\
&\inf\{v(x, y) : x, y \in R^1\} \geq -c_0;\\
&\qquad\qquad v(x, y) \to +\infty \quad \text{as } |x - y| \to \infty.
\end{aligned} \tag{4.2}
$$

PROPOSITION 4.1. *The function $v : R^2 \to R^1$ is continuous.*

Proof. The lower semicontinuity of v follows from Propositions 2.1 and 2.2, and we will establish the upper semicontinuity of v. Let $a, b \in R^1$; $y \in W^{1,1}(0, 1)$; $y(0) = a$; $y(1) = b$; $v(a, b) = I(0, 1, y)$; $\{a_i\}_{i=1}^{\infty}$, $\{b_i\}_{i=1}^{\infty} \subset R^1$, $a_i \to a$, $b_i \to b$ as $i \to \infty$; and actually $y \in C^2[0, 1]$. For an integer $i \geq 1$ we define

$$\Phi_i(t) = h_i t + d_i \quad \text{for } t \in [0, 1],$$

where $d_i = a_i - a$, $h_i = b_i - b - d_i$. Clearly

$$y(0) + \Phi_i(0) = a_i, \quad y(1) + \Phi_i(1) = b_i \quad \text{for } i \geq 0,$$

$$y(t) + \Phi_i(t) \to y(t), \ y'(t) + \Phi_i'(t) \to y'(t) \text{ uniformly in } [0, 1] \text{ as } i \to \infty.$$

Therefore

$$
\begin{aligned}
\limsup_{i\to\infty} v(a_i, b_i) &\leq \limsup_{i\to\infty} \int_0^1 f(t, y(t) + \Phi_i(t), y'(t) + \Phi_i'(t))\, dt\\
&= \int_0^1 f(t, y(t), y'(t))\, dt = v(a, b).
\end{aligned}
$$

This completes the proof of the proposition. □

Set

$$\mu = \inf\left\{\liminf_{N\to\infty} \frac{1}{N} \sum_{i=0}^{N-1} v(z_i, z_{i+1}) : \{z_i\}_{i=0}^{\infty} \subset R^1\right\}, \tag{4.3}$$

which is the minimal long-run average cost. Similarly to results in [9], with slight changes in the proofs, we obtain the following two results.

PROPOSITION 4.2. *There exists a constant M_0 such that*

(i) *for every sequence $\{z_i\}_{i=0}^{\infty} \subset R^1$ and every integer $N \geq 1$*

$$\sum_{i=0}^{N-1} [v(z_i, z_{i+1}) - \mu] \geq -M_0;$$

(ii) *for every initial value z_0 there is a sequence $\{z_i^*\}_{i=0}^{\infty}$ with $z_0^* = z_0$ that satisfies*

$$\left|\sum_{i=0}^{N-1} [v(z_i^*, z_{i+1}^*) - \mu]\right| \leq 4M_0$$

for all $N \geq 1$;

(iii) *for every sequence $\{z_i\}_{i=0}^{\infty} \subset R^1$ the sequence*

$$\left\{\sum_{i=0}^{N-1} [v(z_i, z_{i+1}) - \mu]\right\}_{N=1}^{\infty}$$

either is bounded or diverges to infinity.

PROPOSITION 4.3. *We define*

$$\pi(a) = \inf\left\{\liminf_{N\to\infty}\sum_{i=0}^{N-1}[v(z_i, z_{i+1}) - \mu] : \{z_i\}_{i=0}^{\infty} \subset R^1,\ z_0 = a\right\},$$

$$\theta(a, b) = v(a, b) - \mu + \pi(b) - \pi(a)$$

for $a, b \in R^1$. *Then the functions* $\pi : R^1 \to R^1$ *and* $\theta : R^2 \to R^1$ *are continuous*;

$$\pi(a + 1) = \pi(a), \quad \theta(a + 1, b + 1) = \theta(a, b) \quad \textit{for all } a, b, \in R^1;$$

the function θ *is nonnegative*; *and the set*

$$F(a) = \{b \in R^1 : \theta(a, b) = 0\}$$

is nonempty for every $a \in R^1$.

THEOREM 4.1. (i) *For each* $x \in W^{1,1}_{\mathrm{loc}}([0, \infty))$ *and each* $T > 0$

$$\int_0^T [f(t, x(t), x'(t)) - \mu]\, dt \geq -M_0 - c_0 - |\mu|.$$

(ii) *There exists a unique number* α_f *such that*

$$E_f(\alpha_f) = \inf\left\{E_f(\beta) : \beta \in R^1\right\} = \mu.$$

Proof. Assertion (i) follows from Proposition 4.2 and (1.2). We will prove assertion (ii). By Propositions 3.4 and 3.5 there exists a unique number α_f such that

$$E_f(\alpha_f) = \inf\{E_f(\beta) : \beta \in R^1\}.$$

Choose $x \in \mathcal{M}(\alpha_f)$. It follows from assertion (i) and Proposition 3.3 that

$$E_f(\alpha_f) \geq \mu. \tag{4.4}$$

There exists a sequence $\{z_i\}_{i=0}^{\infty} \subset R^1$ such that $\theta(z_i, z_{i+1}) = 0$ for $i = 0, 1, \ldots$. By (4.2) the sequence $\{z_i - z_{i+1}\}_{i=0}^{\infty}$ is bounded. For any $i \in \{0, 1, \ldots\}$ there is an integer k_i such that $|z_i - z_0 + k_i| < 1$. For $i \in \{0, 1, \ldots\}$ and $p \in \{-i, -i + 1, \ldots\}$ we set $y_p^i = z_{p+i} + k_i$, $Y^i = \{y_p^i\}_{p=-i}^{\infty}$.

It is easy to verify that for every integer p the set

$$\{y_p^i : i \in Z,\ i \geq \max\{0, -p\}\}$$

is bounded. Therefore there exist a sequence $\{a_p\}_{p=-\infty}^{\infty} \subset R^1$ and a subsequence $\{Y^{i_s}\}_{s=1}^{\infty}$ such that $y_p^{i_s} \to a_p$ as $s \to \infty$ for any integer p. Evidently $\theta(a_p, a_{p+1}) = 0$ for any integer p. Recalling Proposition 2.2 we can find an $x \in W^{1,1}_{\mathrm{loc}}(R^1)$ such that

$$x(p) = a_p, \qquad I(p, p + 1, x) = U(p, p + 1, x(p), x(p + 1)) = v(x(p), x(p + 1))$$

for any integer p.

It is easy to verify that x is a minimal solution of (P) and

$$\sup\left\{\left|\int_i^j [f(t, x(t), x'(t)) - \mu]\, dt\right| : i, j \in Z\right\} < \infty. \tag{4.5}$$

By Proposition 3.2 the minimal solution x has a rotation number α. It follows from (4.5) and Proposition 3.3 that

$$\mu = E_f(\alpha) \geq E_f(\alpha_f),$$

and in view of (4.4) we obtain $E_f(\alpha_f) = \mu$ and $\alpha_f = \alpha$. This completes the proof of the theorem. □

5. Minimal solutions with irrational rotation number. To establish Theorem 1.2 we need to study in more details the structure of minimal solutions with irrational rotation number. Some of the results in this section were established in [16], while others were presented in [15] without proof. We remark that their proof is based on the approach developed by Aubry and Le Daeron [2] for discrete-time systems (see also [19]).

Let x be a minimal solution of (P) that has an irrational rotation number α. The minimal solution x is called *regular* if for every pair of integers j, k

$$x(t+j) - k - x(t) > 0 \quad \text{for all } t \in R^1 \text{ iff } \alpha j - k > 0.$$

We will see in Proposition 5.4 that every minimal solution with irrational rotation number is regular. At this stage we can merely establish the existence of a regular minimal solution with a prescribed irrational rotation number.

Propositions 2.4, 2.6, and 2.10 imply the following result.

PROPOSITION 5.1. *Let α be an irrational number and $\{\alpha_i\}_{i=1}^{\infty}$ be a sequence of rational numbers such that $\alpha_i \to \alpha$ as $i \to \infty$. Assume that $x_i \in \mathcal{M}_{\text{per}}(\alpha_i)$, $|x_i(0)| \leq 1, i = 1, 2, \ldots,$ and that the sequence $\{x_i\}_{i=1}^{\infty}$ converges with first derivatives uniformly on any compact set to a function $x \in W^{1,1}_{\text{loc}}(R^1)$. Then $x \in \mathcal{M}(\alpha)$ is a regular minimal solution.*

COROLLARY 5.1. *For every irrational number α there is a regular minimal solution $x \in \mathcal{M}(\alpha)$.*

Assume that α is an irrational number and $x \in \mathcal{M}(\alpha)$ is regular. Using the regular minimal solution x and following [2], [15], [16], and [19] we will obtain an explicit expression for all minimal solutions with rotation number α. Using this explicit expression we will prove that every minimal solution with rotation number α is regular.

We define a function $U^x(t, \theta)$ by

$$U^x(t, \theta) = x(t+j) - k, \tag{5.1}$$

where $t \in R^1$ and θ is any number of the form $\alpha t + \alpha j - k$ for some integers j and k (see [15], [16]). Clearly the function $U^x(t, \theta)$ is strictly monotone in θ on the dense set on which it is defined. One can extend U^x to functions U^x_+, U^x_- by

$$U^x_+(t, \theta) = \lim_{\theta' \to \theta+} U^x(t, \theta'), \; U^x_-(t, \theta) = \lim_{\theta'' \to \theta-} U^x(t, \theta''), \tag{5.2}$$

where θ' (resp., θ'') are decreasing (resp., increasing) sequences taken from the dense set on which U^x is defined. Clearly the functions $U^x_{\pm}(t, \theta) - \theta$ have period 1 in t, θ,

$$U^x_{\pm}(t+1, \theta) = U^x_{\pm}(t, \theta), \qquad U^x_{\pm}(t, \theta+1) = U^x_{\pm}(t, \theta) + 1. \tag{5.3}$$

Moreover, using Propositions 2.4 and 2.6 one obtains that

$$U^x_{\pm}(t, \alpha t + \beta) \in \mathcal{M}(\alpha) \tag{5.4}$$

for every choice of β.

A minimal solution $u \in \mathcal{M}(\alpha)$ is called *recurrent* if there exist sequences of integers $\{k_p\}_{p=1}^{\infty}$, $\{j_p\}_{p=1}^{\infty}$ such that $|k_p| + |j_p| \to \infty$ as $p \to \infty$, and u is the limit of a sequence of translates $\{u_p\}_{p=1}^{\infty} \subset \mathcal{M}(\alpha)$ in the C^1-topology on compact sets in R^1 where

$$u_p(t) = u(t + j_p) - k_p, \qquad t \in R^1,\ p = 1, 2, \ldots.$$

We have the following result (see [16, Thm. 6.5]).

PROPOSITION 5.2. *The solutions $U_{\pm}^x(t, \alpha t + \beta)$ are recurrent for every β.*

The validity of Proposition 5.2 follows from (5.2) and (5.3).

In the next proposition we will show that all the minimal solutions y that are of the form $y(t) = U_{\pm}^x(t, \alpha t + \beta)$ for some $\beta \in R^1$ have the same limit point set on the torus.

PROPOSITION 5.3. *There exists a closed set $H(\alpha) \subset R^1$ such that for every number β the set $H(\alpha)$ consists of all the points z that are of the form*

$$z = \lim_{p \to \infty} U_+^x(t_p, \alpha t_p + \beta) - i_p$$

for some sequence of integers $\{i_p\}_{p=1}^{\infty}$ and a sequence $\{t_p\}_{p=1}^{\infty} \subset R^1$ with $|t_p| \to \infty$ as $p \to \infty$. Moreover, for every β the set $H(\alpha)$ consists of all the points z that are of the form

$$z = \lim_{p \to \infty} U_-^x(t_p, \alpha t_p + \beta) - i_p$$

for some sequence of integers $\{i_p\}_{p=1}^{\infty}$ and a sequence $\{t_p\}_{p=1}^{\infty} \subset R^1$ with $|t_p| \to \infty$ as $p \to \infty$.

Proof. Let $\beta_1, \beta_2 \in R^1$, $\beta_1 \neq \beta_2$, $\{i_p\}_{p=1}^{\infty}$ be a sequence of integers, and $\{t_p\}_{p=1}^{\infty} \subset R^1$ be a sequence of numbers such that

$$|t_p| \to \infty \quad \text{as } p \to \infty, \quad U_+^x(t_p, \alpha t_p + \beta_2) - i_p \to z \quad \text{as } p \to \infty.$$

It follows from (5.2) that for every integer $p \geq 1$ there exist integers k_p and j_p such that $|j_p| \geq 10p|t_p|$, $\alpha j_p - k_p > \beta_2 - \beta_1$, and

$$U_+^x(t_p, \alpha t_p + \beta_2) > U_+^x(t_p, \alpha t_p + \beta_1 + \alpha j_p - k_p) - p^{-1}.$$

It follows from (5.3) that

$$\begin{aligned} 0 &< U_-^x(t_p + j_p, \alpha(t_p + j_p) + \beta_1) - k_p - U_+^x(t_p, \alpha t_p + \beta_2) \\ &\leq U_+^x(t_p + j_p, \alpha(t_p + j_p) + \beta_1) - k_p - U_+^x(t_p, \alpha t_p + \beta_2) \leq p^{-1} \end{aligned}$$

for any natural number p. Therefore

$$|j_p + t_p| \to \infty, \quad \text{as } p \to \infty, \tag{5.5}$$

$$U_+^x(t_p + j_p, \alpha(t_p + j_p) + \beta_1) - k_p - i_p \to z \quad \text{as } p \to \infty, \tag{5.6}$$

$$U_-^x(t_p + j_p, \alpha(t_p + j_p) + \beta_1) - k_p - i_p \to z \quad \text{as } p \to \infty. \tag{5.7}$$

Analogously we can show that if $\{i_p\}_{p=1}^{\infty}$ is a sequence of integers and $\{t_p\}_{p=1}^{\infty}$ is a sequence of numbers that satisfy

$$|t_p| \to \infty, \quad U_-^x(t_p, \alpha t_p + \beta_2) - i_p \to z \quad \text{as } p \to \infty,$$

then there exist sequences of integers $\{j_p\}_{p=1}^{\infty}$, $\{k_p\}_{p=1}^{\infty}$ such that (5.5), (5.6), and (5.7) hold. This completes the proof of the proposition. □

The following result was presented in [15] without proof. It asserts that every minimal solution with an irrational rotation number α is regular.

PROPOSITION 5.4. *Assume that y is a minimal solution of* (P), *α is the rotation number of y, and j_1, j_2, k_1, k_2 are integers satisfying $\alpha j_1 - k_1 > \alpha j_2 - k_2$. Then*

$$y(t + j_1) - k_1 > y(t + j_2) - k_2 \quad \textit{for all } t \in R^1.$$

Proof. Set $\beta_i = \alpha j_i - k_i$, $i = 1, 2$; $y_i(t) = y(t + j_i) - k_i$ for every $t \in R^1$, $i = 1, 2$. By Proposition 3.2

$$\sup\{|y_2(t) - y_1(t)| : t \in R^1\} < \infty.$$

We will show next that $\limsup_{t\to\infty}[y_1(t) - y_2(t)] > 0$ and $\limsup_{t\to-\infty}[y_1(t) - y_2(t)] > 0$. It follows from Proposition 3.2, (5.3), and (5.4) that there exist numbers $\ell_2 > \ell_1$ for which

$$U_-^x(t, \alpha t + \ell_1) \le y(t) \le U_+^x(t, \alpha t + \ell_2) \quad \text{for every } t \in R^1.$$

For $p = 1, 2$ we have

$$U_-^x(t + j_p, \alpha(t + j_p) + \ell_1) - k_p \le y_p(t) \le U_+^x(t + j_p, \alpha(t + j_p) + \ell_2) - k_p, \qquad t \in R^1;$$

$$U_-^x(t, \alpha t + \beta_p + \ell_1) \le y_p(t) \le U_+^x(t, \alpha t + \beta_p + \ell_2) \quad \text{for every } t \in R^1;$$

$$\sup\{y_p(t) - U_-^x(t, \alpha t + \beta_p + \ell_1) : t \in R^1\}$$
$$\le \sup\{U_+^x(t, \alpha t + \beta_p + \ell_2) - U_-^x(t, \alpha t + \beta_p + \ell_1) : t \in R^1\} < \infty, \qquad p = 1, 2.$$

Clearly

$$\begin{aligned}\limsup_{t\to\infty}[y_1(t) - y_2(t)] &\ge \limsup_{t\to\infty}[y_1(t) - U_-^x(t, \alpha t + \beta_1 + \ell_1)] \\ &\quad - \limsup_{t\to\infty}[y_2(t) - U_-^x(t, \alpha t + \beta_2 + \ell_1)] \\ &\quad + \inf\{U_-^x(t, \alpha t + \beta_1 + \ell_1) - U_-^x(t, \alpha t + \beta_2 + \ell_1) : t \in R^1\} \\ &= \inf\{U_-^x(t, \alpha t + \beta_1 + \ell_1) - U_-^x(t, \alpha t + \beta_2 + \ell_1) : t \in R^1\}\end{aligned} \tag{5.8}$$

since the first two terms in the left-hand side of (5.8) cancel each other. Analogously it is easy to show that

$$\begin{aligned}&\limsup_{t\to-\infty}[y_1(t) - y_2(t)] \ge \\ &\quad \inf\{U_-^x(t, \alpha t + \beta_1 + \ell_1) - U_-^x(t, \alpha t + \beta_2 + \ell_1) : t \in R^1\}.\end{aligned} \tag{5.9}$$

We will show that

$$\inf\{U_-^x(t, \alpha t + \beta_1 + \ell_1) - U_-^x(t, \alpha t + \beta_2 + \ell_1) : t \in R^1\} > 0.$$

Assume the converse. Then there exists a sequence $\{t_p\}_{p=1}^{\infty} \subset R^1$ such that

$$U_-^x(t_p, \alpha t_p + \beta_1 + \ell_1) - U_-^x(t_p, \alpha t_p + \beta_2 + \ell_1) \to 0 \quad \text{as } p \to \infty.$$

For $t \in R^1$ we set

$$[t] = \inf\{p \in \{0, \pm 1, \ldots\} : p \le t\}, \qquad \{t\} = t - [t].$$

Evidently

$$U_-^x(\{t_p\}, \alpha\{t_p\} + \{\alpha[t_p]\} + \beta_1 + \ell_1) - U_-^x(\{t_p\}, \alpha\{t_p\} + \{\alpha[t_p]\} + \beta_2 + \ell_1) \to 0 \quad \text{as } p \to \infty. \tag{5.10}$$

We may assume without loss of generality that

$$\{t_p\} \to \tau, \quad \{\alpha[t_p]\} \to h \quad \text{as } p \to \infty, \tag{5.11}$$

and the sequence $\{\alpha[t_p]\}_{p=1}^{\infty}$ is either nonincreasing or nondecreasing. By (5.4) and Proposition 2.6 one of the conditions below is fulfilled:

$$U_-^x(t, \alpha t + \{\alpha[t_p]\} + \beta_j + \ell_1) \to U_-^x(t, \alpha t + h + \beta_j + \ell_1) \quad \text{as } p \to \infty, \ j = 1, 2,$$

uniformly on any compact subset of R^1, or

$$U_-^x(t, \alpha t + \{\alpha[t_p]\} + \beta_j + \ell_1) \to U_+^x(t, \alpha t + h + \beta_j + \ell_1) \quad \text{as } p \to \infty, \ j = 1, 2,$$

uniformly on any compact subset of R^1.

By (5.10) and (5.11) in the first case we have

$$\begin{aligned} U_-^x(\tau, \alpha\tau + h + \beta_1 + l_1) &= \lim_{p\to\infty} U_-^x(\{t_p\}, \alpha\{t_p\} + h + \beta_1 + l_1) \\ &= \lim_{p\to\infty} U_-^x(\{t_p\}, \alpha\{t_p\} + \{\alpha[t_p]\} + \beta_1 + l_1) \\ &= \lim_{p\to\infty} U_-^x(\{t_p\}, \alpha\{t_p\} + \{\alpha[t_p]\} + \beta_2 + l_1) \\ &= \lim_{p\to\infty} U_-^x(\{t_p\}, \alpha\{t_p\} + h + \beta_2 + l_1) \\ &= U_-^x(\tau, \alpha\tau + h + \beta_2 + l_1). \end{aligned}$$

In the second case we obtain analogously

$$U_+^x(\tau, \alpha\tau + h + \beta_1 + \ell_1) = U_+^x(\tau, \alpha\tau + h + \beta_2 + \ell_1).$$

On the other hand, the functions $U_\pm^x(t, \theta)$ are strictly monotone in θ and $\beta_1 > \beta_2$. The obtained contradiction proves that

$$\limsup_{t\to-\infty}[y_1(t) - y_2(t)] > 0, \limsup_{t\to\infty}[y_1(t) - y_2(t)] > 0.$$

It follows from Propositions 2.11 and 2.12 that $y_1(t) > y_2(t)$ for all $t \in R^1$. The proposition is proved. □

Let x be a minimal solution of (P) with an irrational rotation number α. By Proposition 5.4 x is regular and belongs to $\mathcal{M}(\alpha)$. Consider the functions $U_\pm^x(t, \theta)$, $U^x(t, \theta)$ defined by (5.1), (5.2). It follows from Proposition 2.12 that one of the conditions below holds.

(i) $U_+^x(t, \alpha t) = x(t)$ for every $t \in R^1$.

(ii) $U_-^x(t, \alpha t) = x(t)$ for every $t \in R^1$.

(iii) $U_-^x(t, \alpha t) < x(t) < U_+^x(t, \alpha t)$ for every $t \in R^1$.

PROPOSITION 5.5. *Let x be a minimal solution of* (P), *and let the rotation number of x be an irrational number α. If x is recurrent, then one of the conditions below holds:*

$$U_+^x(t, \alpha t) = x(t) \quad \textit{for every } t \in R^1$$

or

$$U_-^x(t, \alpha t) = x(t) \quad \textit{for every } t \in R^1.$$

Proof. There exist sequences of integers $\{k_p\}_{p=1}^{\infty}$ and $\{j_p\}_{p=1}^{\infty}$ such that

$$|k_p| + |j_p| \to \infty, \quad x(j_p) - k_p \to x(0) \quad \text{as } p \to \infty.$$

It is easy to verify that $x(0) \in \{U_+^x(0, 0), U_-^x(0, 0)\}$. This completes the proof of the proposition. □

The following important result was presented in [15] without proof. It establishes that actually the functions U_+^x and U_-^x do not depend on x.

PROPOSITION 5.6. *Assume that α is an irrational number, $x, y \in \mathcal{M}(\alpha)$, and consider the functions $U^x(t, \theta)$, $U^y(t, \theta)$, $U_\pm^x(t, \theta)$, $U_\pm^y(t, \theta)$ (see* (5.1), (5.2)).

Then there exists a number δ such that

$$U_\pm^x(t, \theta) = U_\pm^y(t, \theta + \delta) \quad \textit{for each } \theta, t \in R^1.$$

Proof. Consider numbers β, γ and define

$$\sigma(t) = U_+^x(t, \alpha t + \beta) - U_+^y(t, \alpha t + \gamma), \qquad t \in R^1.$$

By Proposition 2.4

$$\sup\{|\sigma(t)| : t \in R^1\} < \infty.$$

We will show that either $\sigma(t) \geq 0$ for all $t \in R^1$ or $\sigma(t) \leq 0$ for all $t \in R^1$. Assume to the contrary that there exist numbers S, T satisfying

$$\sigma(T) > h, \qquad \sigma(S) < -h,$$

where h is a positive number. Since the functions $U_+^x(t, \theta)$, $U_+^y(t, \theta)$ are right-continuous in θ, there exists $\epsilon > 0$ such that

$$U_+^x(T, \alpha T + \beta + z) - U_+^y(T, \alpha T + \gamma + z) > h,$$
$$U_+^x(S, \alpha S + \beta + z) - U_+^y(S, \alpha S + \gamma + z) < -h$$

for every $z \in (0, \epsilon)$.

There exist sequences of integers $\{p_i\}_{i=1}^{\infty}$, $\{q_i\}_{i=1}^{\infty}$ such that $\{p_i\alpha + q_i\}_{i=1}^{\infty}$ is a decreasing sequence that converges to zero. We may assume without loss of generality that

$$p_i\alpha + q_i \in (0, \epsilon) \quad \text{for every } i = 1, 2, \ldots.$$

Clearly $|p_i| \to \infty$ as $i \to \infty$. For every natural number i we have

$$\begin{aligned}
&U_+^x(T, \alpha T + \beta + p_i\alpha) - U_+^y(T, \alpha T + \gamma + p_i\alpha) \\
&\quad = U_+^x(T, \alpha T + \beta + p_i\alpha + q_i) - U_+^y(T, \alpha T + \gamma + p_i\alpha + q_i) > h, \\
&\quad U_+^x(S, \alpha S + \beta + p_i\alpha) - U_+^y(S, \alpha S + \gamma + p_i\alpha) \\
&\qquad = U_+^x(S, \alpha S + \beta + p_i\alpha + q_i) - U_+^y(S, \alpha S + \gamma + p_i\alpha + q_i) < -h, \\
&U_+^x(T + p_i, \alpha(T + p_i) + \beta) - U_+^y(T + p_i, \alpha(T + p_i) + \gamma) > h, \\
&U_+^x(S + p_i, \alpha(S + p_i) + \beta) - U_+^y(S + p_i, \alpha(S + p_i) + \gamma) < -h.
\end{aligned}$$

These relations are contradictory to Proposition 2.11. Therefore, one of the conditions below holds:

$$\sigma(t) \geq 0 \quad \text{for every } t \in R^1,$$
$$\sigma(t) \leq 0 \quad \text{for every } t \in R^1.$$

Assume that the first condition holds. It follows from the properties of the functions U_+^x, U_+^y (see (5.3)) that

$$U_+^x(t, \alpha t + \beta + \theta) \geq U_+^y(t, \alpha t + \gamma + \theta)$$

for every $t \in R^1$ and $\theta \in \{\alpha p - q : p, q \text{ are integers}\}$.

Since the functions U_+^x, U_+^y are right-continuous in θ, we conclude that

$$U_+^x(t, \beta + \theta) \geq U_+^y(t, \gamma + \theta) \quad \text{for each } t, \theta \in R^1. \tag{5.12}$$

We have thus proved that for every numbers β, γ either (5.12) or the following relation holds:

$$U_+^x(t, \beta + \theta) \leq U_+^y(t, \gamma + \theta) \quad \text{for each } t, \theta \in R^1.$$

Let E be defined by

$$E = \{\delta : U_+^y(t, \theta + \delta) \geq U_+^x(t, \theta) \text{ for each } t, \theta \in R^1\}.$$

Clearly $E \neq \emptyset$ and

$$\delta_0 = \inf\{\delta : \delta \in E\} > -\infty.$$

It is easy to verify that

$$U_\pm^y(t, \theta + \delta_0) \geq U_\pm^x(t, \theta) \quad \text{for each } t, \theta \in R^1. \tag{5.13}$$

Let $\delta < \delta_0$. Then there exist $t(\delta), \theta(\delta) \in R^1$ such that

$$U_+^x(t(\delta), \theta(\delta)) > U_+^y(t(\delta), \theta(\delta) + \delta).$$

It follows from this that

$$U_+^x(t, \theta) \geq U_+^y(t, \theta + \delta) \quad \text{for each } t, \theta \in R^1.$$

Since this relation holds for every $\delta < \delta_0$, we conclude that

$$U_\pm^y(t, \theta + \delta_0) \leq U_\pm^x(t, \theta) \quad \text{for each } t, \theta \in R^1.$$

Together with (5.13) this implies that

$$U_\pm^y(t, \theta + \delta_0) = U_\pm^x(t, \theta) \quad \text{for each } t, \theta \in R^1.$$

The proposition is proved. □

For every irrational α we set $U_\pm^\alpha = U_\pm^x$ where $x \in \mathcal{M}(\alpha)$. Propositions 5.5 and 5.6 imply the following result.

PROPOSITION 5.7. *Let y be a minimal solution with an irrational rotation number α. If y is recurrent, then there exists a unique number β such that one of the conditions below holds:*

$$y(t) = U_+^\alpha(t, \alpha t + \beta) \quad \textit{for every } t \in R^1,$$
$$y(t) = U_-^\alpha(t, \alpha t + \beta) \quad \textit{for every } t \in R^1.$$

If y is not recurrent, then there exists a number β such that

$$U_-^\alpha(t, \alpha t + \beta) < y(t) < U_+^\alpha(t, \alpha t + \beta) \quad \text{for every } t \in R^1.$$

PROPOSITION 5.8. *Assume that y is a minimal solution with a rotation number s/r, which is an irreducible fraction. Then there exist $z_+, z_- \in \mathcal{M}_{\text{per}}(s/r)$ such that*

$$\sup\{|y(p+t) - z_+(p+t)|, |y'(p+t) - z_+'(p+t)| : t \in [0,1]\} \to 0$$

as $p \to +\infty$ on the integers and

$$\sup\{|y(p+t) - z_-(p+t)|, |y'(p+t) - z_-'(p+t)| : t \in [0,1]\} \to 0$$

as $p \to -\infty$ on the integers.

Proof. Define a minimal solution u as

$$u(t) = y(t+r) - s, \qquad t \in R^1. \tag{5.14}$$

We may assume without loss of generality that $u \neq y$. By Proposition 2.11 there exists a number $t_0 > 0$ such that one of the conditions below holds:

$$y(t) \geq u(t) \quad \text{for every } t \geq t_0,$$
$$y(t) \leq u(t) \quad \text{for every } t \geq t_0.$$

Assume that

$$y(t) \leq u(t) \quad \text{for every } t \geq t_0. \tag{5.15}$$

(The other case may be treated analogously.) We set

$$b(t) = y(t) - st/r, \qquad t \in R^1.$$

By Proposition 3.2

$$|b(t) - b(0)| \leq c_1(1 + |s/r|) + 6 \quad \text{for every } t \in R^1.$$

It follows from (5.14) and (5.15) that

$$b(t+r) \geq b(t) \quad \text{for every } t \in R^1,\ t \geq t_0.$$

Therefore, for any $t \in R^1$ the sequence $\{b(t+kr)\}_{k=0}^\infty$ converges to a number $h(t)$. Evidently $h(t+r) = h(t)$ for every $t \in R^1$. Set

$$z_+(t) = h(t) + st/r \quad \text{for every } t \in R^1.$$

It is easy to see that

$$z_+(t+r) = z_+(t) + s \quad \text{for every } t \in R^1,$$
$$z_+(t) = \lim_{k \to \infty} [y(t+kr) - ks], \quad \text{where } k \text{ is an integer.}$$

Analogously we can prove that for every $t \in R^1$ there exists

$$z_-(t) = \lim_{i \to -\infty} [y(t+ir) - is],$$

where i is an integer satisfying $z_-(t+r) = z_-(t) + s$ for $t \in R^1$. For an integer k we set

$$y_k(t) = y(t+kr) - ks \quad \text{for } t \in R^1.$$

It follows from Proposition 2.6 that $z_+, z_- \in \mathcal{M}_{\text{per}}(s/r)$, and

$$y_k \to z_+ \quad \text{as } k \to +\infty, \qquad y_k \to z_- \quad \text{as } k \to -\infty$$

in the C^1-topology on compact sets in R^1. This completes the proof. □

6. Proof of Theorem 1.2. Consider the continuous function $v : R^2 \to R^1$, where

$$v(x, y) = \inf\left\{\int_0^1 f(t, u(t), u'(t))\, dt : u \in W^{1,1}(0, 1),\ u(0) = x,\ u(1) = y\right\}, \tag{6.1}$$

and set

$$\mu = \inf\left\{\liminf_{N\to\infty} N^{-1} \sum_{i=0}^{N-1} v(z_i, z_{i+1}) : \{z_i\}_{i=0}^{\infty} \subset R^1\right\}. \tag{6.2}$$

Let the functions $\pi : R^1 \to R^1$ and $\theta : R^2 \to R^1$ be as defined in Proposition 4.3. Theorem 4.1 implies the following result.

PROPOSITION 6.1. *For each $x \in W^{1,1}_{\mathrm{loc}}([0, \infty))$ the function*

$$T \to \int_0^T [f(t, x(t), x'(t)) - \mu]\, dt, \qquad T \in R^1,\ T > 0,$$

is either bounded or diverges to $+\infty$ as $T \to +\infty$.

A function $x \in W^{1,1}_{\mathrm{loc}}([0, \infty))$ is called a *good configuration* if

$$\sup\left\{\left|\int_0^T [f(t, x(t), x'(t)) - \mu]\, dt\right| : T \in R^1,\ T > 0\right\} < \infty.$$

For $x \in W^{1,1}_{\mathrm{loc}}([0, \infty))$ denote by $\Omega(x)$ the set of all real numbers z such that there exist sequences of integers $\{i_p\}_{p=1}^{\infty}$ and $\{k_p\}_{p=1}^{\infty}$ such that

$$x(k_p) - i_p \to z, \quad k_p \to +\infty \quad \text{as } p \to \infty.$$

Evidently $\Omega(x)$ is a closed set.

PROPOSITION 6.2. *Assume that $E_f(\alpha_f) = \min\{E_f(\alpha) : \alpha \in R^1\}$, where α_f is irrational and $x \in W^{1,1}_{\mathrm{loc}}([0, \infty))$ is a good configuration. Then*

$$\{y(0) : y \in \mathcal{M}(\alpha_f)\} \supset \Omega(x) \supset \{U_+^{\alpha_f}(0, \tau) : \tau \in R^1\} \cup \{U_-^{\alpha_f}(0, \tau) : \tau \in R^1\}.$$

Proof. Let $z \in \Omega(x)$. We will first show that $z \in \{y(0) : y \in \mathcal{M}(\alpha_f)\}$. There exist sequences of integers $\{i_p\}_{p=1}^{\infty}$, $\{k_p\}_{p=1}^{\infty}$ such that $k_p \to +\infty$, $x(k_p) - i_p \to z$ as $p \to \infty$. We may assume that $1 \le k_p < k_{p+1}$ $(p = 1, \dots)$. For a natural number p we define $x_p \in W^{1,1}(-k_p, k_p)$ as

$$x_p(t) = x(t + k_p) - i_p, \qquad t \in [-k_p, k_p].$$

It follows from Theorem 4.1 that for every natural number N the sequence

$$\left\{\int_{-N}^{N} f(t, x_p(t), x_p'(t))\, dt : p \in \{1, 2, \dots\},\ k_p \ge N\right\}$$

is bounded, and by (1.2) the sequence

$$\{x_p' : p \in \{1, 2, \dots\},\ k_p \ge N\}$$

is bounded in $L^2[-N, N]$. We can assume, by extracting a subsequence and reindexing, that for some $Y \in W^{1,1}_{\mathrm{loc}}(R^1)$

$$x_p' \to Y' \text{ weakly in } L^2[-N, N] \text{ and } x_p \to Y \text{ uniformly in } [-N, N] \text{ as } p \to \infty$$

for each natural number N.

It is easy to verify that $Y(0) = z$, $\theta(x(i), x(i+1)) \to 0$ as $i \to \infty$ and

$$\theta(Y(i), Y(i+1)) = 0 \quad \text{for every } i = 0, \pm 1, \pm 2, \ldots. \tag{6.3}$$

Since x is a good configuration, it follows from Proposition 4.2 that

$$\int_i^{i+1} f(t, x(t), x'(t))\, dt - v(x(i), x(i+1)) \to 0 \quad \text{as } i \to +\infty.$$

Together with Proposition 2.1 this implies that

$$\int_i^{i+1} f(t, Y(t), Y'(t))\, dt = v(Y(i), Y(i+1)) \quad (i = 0, \pm 1, \pm 2, \ldots).$$

It follows from this relation and (6.3) that $Y \in W^{1,1}_{\mathrm{loc}}(R^1)$ is a minimal solution. Evidently for each integers i, j satisfying $i < j$

$$\left| \int_i^j f(t, Y(t), Y'(t))\, dt - (j-i)\mu \right| \le 2 \sup\{|\pi(t)| : t \in R^1\}.$$

By Proposition 3.3 and Theorem 4.1 α_f is the rotation number of Y. Therefore, $z \in \{y(0) : y \in \mathcal{M}(\alpha_f)\}$. Since z is an arbitrary element of $\Omega(x)$, we conclude that

$$\Omega(x) \subset \{y(0) : y \in \mathcal{M}(\alpha_f)\}.$$

Next we will establish that

$$\Omega(x) \supset \{U_+^{\alpha_f}(0, \tau) : \tau \in R^1\} \cup \{U_-^{\alpha_f}(0, \tau) : \tau \in R^1\}.$$

By Proposition 5.6 we may assume without loss of generality that

$$U_\pm^{\alpha_f} = U_\pm^Y.$$

Let

$$r \in \{U_+^{\alpha_f}(0, \tau) : \tau \in R^1\} \cup \{U_-^{\alpha_f}(0, \tau) : \tau \in R^1\}.$$

There exist sequences of integers $\{g_p\}_{p=1}^\infty$, $\{s_p\}_{p=1}^\infty$ such that

$$Y(g_p) - s_p \to r \quad \text{as } p \to \infty.$$

It follows from the definition of Y that $Y(g_p) - s_p \in \Omega(x)$ for each natural number p. Since $\Omega(x)$ is closed, we conclude that $r \in \Omega(x)$. This completes the proof of the proposition. □

PROPOSITION 6.3. *Assume that α_f is an irrational number, $\mu = E_f(\alpha_f)$, $x, y \in W^{1,1}_{\mathrm{loc}}([0, \infty))$, $x(0) = y(0)$, and*

$$\int_i^{i+1} f(t, x(t), x'(t))\, dt = v(x(i), x(i+1)),\ \theta(x(i), x(i+1)) = 0 \quad \textit{for } i = 0, 1, \ldots. \tag{6.4}$$

Then

$$\liminf_{i \to +\infty} \int_0^i [f(t, x(t), x'(t)) - f(t, y(t), y'(t))]\, dt \le 0,$$

where i is an integer. Moreover if

$$\liminf_{i\to+\infty} \int_0^i [f(t, x(t), x'(t)) - f(t, y(t), y'(t))]\, dt = 0,$$

where i is an integer, then

$$\int_i^{i+1} f(t, y(t), y'(t))\, dt = v(y(i), y(i+1)),$$

$$\theta(y(i), y(i+1)) = 0 \quad \textit{for } i = 0, 1, \ldots.$$

Proof. It is easy to verify that x is a good configuration. We may assume without loss of generality that y is a good configuration. There exists

$$\beta_f \in \{U_+^{\alpha_f}(0, \tau) : \tau \in [0, 1]\} \cup \{U_-^{\alpha_f}(0, \tau) : \tau \in [0, 1]\}$$

such that

$$\pi(\beta_f) \geq \pi(U_\pm^{\alpha_f}(0, \tau) \quad \text{for every } \tau \in R^1. \tag{6.5}$$

We will show that there exist sequences of integers $\{G_p\}_{p=1}^\infty$, $\{n_p\}_{p=1}^\infty$, and $\{\tilde{n}_p\}_{p=1}^\infty$ such that

$$x(G_p) - \tilde{n}_p \to \beta_f, \quad G_p \to \infty \quad \text{as } p \to \infty$$

and the following relation holds:

$$\lim_{p\to\infty} [y(G_p) - n_p] \in \{U_\pm^{\alpha_f}(0, t) : t \in R^1\}.$$

By Proposition 6.2 there exist sequences of integers $\{i_p\}_{p=1}^\infty$, $\{k_p\}_{p=1}^\infty$ such that $1 \leq k_p < k_{p+1}$ $(p = 1, \ldots)$, $k_p \to +\infty$, $y(k_p) - i_p \to U_+^{\alpha_f}(0, 0)$ as $p \to \infty$.

We can assume by extracting a subsequence of reindexing that there exist $z_0 \in \Omega(x)$ and a sequence of integers $\{\tilde{i}_p\}_{p=1}^\infty$ such that

$$x(k_p) - \tilde{i}_p \to z_0 \quad \text{as } p \to \infty.$$

For a natural number p we define $x_p, y_p \in W^{1,1}(-k_p, k_p)$ as

$$x_p(t) = x(t + k_p) - \tilde{i}_p, \quad y_p(t) = y(t + k_p) - i_p \quad (t \in [-k_p, k_p]). \tag{6.6}$$

It follows from Theorem 4.1 that for every natural number N the sequences

$$\left\{\int_{-N}^N f(t, x_p(t), x_p'(t))\, dt : p \in \{1, 2, \ldots\},\ k_p \geq N\right\},$$

$$\left\{\int_{-N}^N f(t, y_p(t), y_p'(t))\, dt : p \in \{1, 2, \ldots\},\ k_p \geq N\right\}$$

are bounded, and then (1.2) implies that the sequences

$$\{x_p' : p \in \{1, 2, \ldots\},\ k_p \geq N\}, \qquad \{y_p' : p \in \{1, 2, \ldots\},\ k_p \geq N\}$$

are bounded in $L^2[-N, N]$ for every natural number N. We can assume, by extracting a subsequence and reindexing, that for some $X, Y \in W^{1,1}_{\mathrm{loc}}(R^1)$,

$$x_p' \to X', \ y_p' \to Y' \text{ weakly in } L^2[-N, N] \text{ as } p \to \infty, \tag{6.7}$$

$$x_p \to X, \ y_p \to Y \text{ uniformly in } [-N, N] \text{ as } p \to \infty \tag{6.8}$$

for each natural number N.

It is easy to see that

$$X(0) = z_0, Y(0) = U_+^{\alpha_f}(0, 0). \tag{6.9}$$

Since y is a good configuration, we have $\theta(y(i), y(i+1)) \to 0$ as $i \to \infty$ and

$$\theta(Y(i), Y(i+1)) = 0 \quad \text{for } i = 0, \pm 1, \ldots. \tag{6.10}$$

Clearly

$$\theta(X(i), X(i+1)) = 0 \qquad (i = 0, \pm 1, \ldots). \tag{6.11}$$

Since y is a good configuration, it follows from Proposition 4.2 that

$$\int_i^{i+1} f(t, y(t), y'(t))\, dt - v(y(i), y(i+1)) \to 0 \text{ as } i \to +\infty.$$

It follows from this relation, (6.4), and Proposition 2.1 that

$$\int_i^{i+1} f(t, X(t), X'(t))\, dt = v(X(i), X(i+1)),$$

$$\int_i^{i+1} f(t, Y(t), Y'(t))\, dt = v(Y(i), Y(i+1)) \qquad (i = 0, \pm 1, \ldots).$$

In view of (6.10) and (6.11) this implies that X and Y are minimal solutions. Evidently for each integers i, j satisfying $i < j$

$$\left| \int_i^j f(t, X(t), X'(t))\, dt - (j-i)\mu \right|, \ \left| \int_i^j f(t, Y(t), Y'(t))\, dt - (j-i)\mu \right|$$
$$\leq 2 \sup\{|\pi(t)| : t \in R^1\}.$$

By Proposition 3.3 and Theorem 4.1 we conclude that $X, Y \in \mathcal{M}(\alpha_f)$. It follows from Proposition 5.7 and (6.9) that

$$Y(t) = U_+^{\alpha_f}(t, \alpha_f t) \quad \text{for every } t \in R^1. \tag{6.12}$$

By Proposition 5.6

$$\{U_+^X(0, \tau) : \tau \in R^1\} \cup \{U_-^X(0, \tau) : \tau \in R^1\}$$
$$= \{U_+^{\alpha_f}(0, \tau) : \tau \in R^1\} \cup \{U_-^{\alpha_f}(0, \tau) : \tau \in R^1\}.$$

Therefore, there exist sequences of integers $\{g_p\}_{p=1}^{\infty}, \{s_p\}_{p=1}^{\infty}$ such that

$$X(g_p) - s_p \to \beta_f \quad \text{as } p \to \infty,$$

and the sequence $\{\alpha_f g_p - s_p\}$ converges as $p \to \infty$. For $p = 1, 2, \ldots$ we have

$$Y(g_p) - s_p = U_+^{\alpha_f}(g_p, \alpha_f g_p) - s_p = U_+^{\alpha_f}(0, \alpha_f g_p - s_p).$$

We may assume without loss of generality that the sequence $\{Y(g_p) - s_p\}_{p=1}^{\infty}$ converges to a number

$$\beta \in \{U_+^{\alpha_f}(0, \tau) : \tau \in R^1\} \cup \{U_-^{\alpha_f}(0, \tau) : \tau \in R^1\} \tag{6.13}$$

as $p \to \infty$. Let p be a natural number. It follows from the definition of X, Y (see (6.6) and (6.8)) that

$$X(g_p) = \lim_{q \to \infty} x_q(g_p) = \lim_{q \to \infty} [x(g_p + k_q) - \tilde{i}_q],$$
$$Y(g_p) = \lim_{q \to \infty} y_q(g_p) = \lim_{q \to \infty} [y(g_p + k_q) - i_q].$$

There exists a natural number q_p such that $k_{q_p} \geq p + 1 + 2|g_p|$,

$$|X(g_p) - x(g_p + k_{q_p}) - \tilde{i}_{q_p}| \leq \frac{1}{p},$$
$$|Y(g_p) - y(g_p + k_{q_p}) - i_{q_p}| \leq \frac{1}{p}.$$

We set

$$G_p = g_p + k_{q_p}, \quad n_p = s_p + i_{q_p}, \quad \tilde{n} = s_p + \tilde{i}_{q_p} \quad \text{for } p = 1, 2, \ldots.$$

It is easy to verify (see (6.13) and (6.5)) that

$$\begin{gathered} G_p \geq 1 \quad \text{for } p = 1, 2, \ldots, \quad G_p \to \infty \quad \text{as } p \to \infty, \\ x(G_p) - \tilde{n}_p \to \beta_f, \quad y(G_p) - n_p \to \beta \quad \text{as } p \to \infty, \\ \lim_{p \to \infty} \pi(y(G_p)) = \pi(\beta) \leq \pi(\beta_f) = \lim_{p \to \infty} \pi(x(G_p)). \end{gathered} \tag{6.14}$$

It follows from (6.4) that for $p = 1, 2, \ldots$ we have

$$\begin{aligned} &\int_0^{G_p} [f(t, x(t), x'(t)) - f(t, y(t), y'(t))]\, dt \\ &= \pi(x(0)) - \pi(x(G_p)) - \sum_{i=0}^{G_p - 1} \left[\int_i^{i+1} f(t, y(t), y'(t))\, dt - v(y(i), y(i+1)) \right] \\ &\quad - \sum_{i=0}^{G_p - 1} \theta(y(i), y(i+1)) - (\pi(y(0)) - \pi(y(G_p))) \\ &\leq \pi(y(G_p)) - \pi(x(G_p)). \end{aligned}$$

Together with (6.14) this relation implies the validity of the proposition. □

Theorem 1.2 follows from Propositions 2.2, 4.3, and 6.3 and Theorem 4.1.

7. Lagrange multipliers for the discrete-time problem. Let R^n be the Euclidean n-dimensional space with the norm $\|x\| = \max\{|x_i| : i = 1, \dots, n\}$. Let $v : R^n \times R^n \mapsto R^1$ be lower semicontinuous function, which we call the *value function*. A sequence $\bar{x} = \{x_k\}_{k=0}^{\infty}$ in R^n is called a *program*, and with every program $\bar{x}$ we associate the *cost flow* $\{D_N(\bar{x})\}_{N=1}^{\infty}$, where

$$D_N(\bar{x}) = \sum_{k=0}^{N-1} v(x_k, x_{k+1}). \tag{7.1}$$

We consider the problem of minimizing $D_N(\bar{x})$ as $N \to \infty$ in various senses, e.g., of minimizing the functional $\bar{x} \mapsto \liminf_{N\to\infty} \frac{1}{N} D_N(\bar{x})$.

Denote $I = \{0, \pm 1, \pm 2, \dots\}$. We consider value functions $v(\cdot, \cdot)$ that satisfy

$$v(x + m, y + m) = v(x, y) \quad \text{for every } x, y \in R^n \text{ and } m \in I^n. \tag{7.2}$$

We will furthermore assume that

$$\inf\{v(x, y) : x, y \in R^n\} > -\infty; \tag{7.3}$$

and if we denote

$$K = \{(x, y) \in R^n \times R^n : x_i \le y_i \le x_i + 1,\ i = 1, \dots, n\},$$

then

$$a \equiv \sup\{v(x, y) : (x, y) \in K\} < \infty. \tag{7.4}$$

Finally assume that there exists a number $\Gamma > 0$ such that

$$\inf\{v(x, y) : x, y \in R^n,\ |x - y| > \Gamma\} > a. \tag{7.5}$$

We may assume that $\Gamma > n$.

PROPOSITION 7.1. *For every program $\bar{x} = \{x_k\}_{k=0}^{\infty}$ there exists a program $\bar{y} = \{y_k\}_{k=0}^{\infty}$ that satisfies $y_0 = x_0$,*

$$D_N(\bar{y}) \le D_N(\bar{x}) \quad \textit{for every } N \ge 1, \tag{7.6}$$

and

$$|y_{k+1} - y_k| \le \Gamma \quad \textit{for every } k \ge 0. \tag{7.7}$$

Proof. Suppose that for some $l \ge 0$ we have $|x_{l+1} - x_l| > \Gamma$. Then there exists an $m \in I^n$ such that $(x_l, x_{l+1} - m) \in K$, and then by (7.4) we have that

$$v(x_l, x_{l+1} - m) \le a. \tag{7.8}$$

We define the program $\bar{y}$ as

$$y_k = \begin{cases} x_k & \text{if } \ 0 \le k \le l, \\ x_k - m & \text{if } \ k \ge l + 1. \end{cases}$$

Then by (7.2)

$$v(y_k, y_{k+1}) = v(x_k, x_{k+1}) \quad \text{for every } k \ne l,$$

while by (7.5) and (7.8)

$$v(y_l, y_{l+1}) \leq a < v(x_l, x_{l+1}).$$

This completes the proof of the proposition. □

By Proposition 2.1 we may restrict attention only to programs that satisfy (7.7). More generally we say that $\bar{x}$ is a *program with bounded increments* if there exists a constant $b > 0$ such that $|x_{k+1} - x_k| \leq b$ for every $k \geq 0$.

DEFINITION 7.1. *For a program with bounded increments $\bar{x}$ we define the set of* rotation vectors *as the set of all limit points of the sequence $\{x_k/k\}_{k=1}^{\infty}$. We denote this set by $A(\bar{x})$.*

It is clear that for every program with bounded increments $\bar{x}$ the set $A(\bar{x})$ is nonempty and compact. In the sequel we will consider only programs with bounded increments.

With every program $\bar{x}$ we associate the cost growth rate $\liminf_{N\to\infty} \frac{1}{N} D_N(\bar{x})$ and have the following result.

PROPOSITION 7.2. *For every program $\bar{x}$ there exists a program $\bar{y}$ such that $y_0 = x_0$ and the limit $\lim_{N\to\infty} \frac{1}{N} D_N(\bar{y})$ exists and satisfies*

$$\lim_{N\to\infty} \frac{1}{N} D_N(\bar{y}) \leq \liminf_{N\to\infty} \frac{1}{N} D_N(\bar{x}). \tag{7.9}$$

Proof. Suppose that $\limsup_{N\to\infty} \frac{1}{N} D_N(\bar{x}) > \liminf_{N\to\infty} \frac{1}{N} D_N(\bar{x})$, and denote

$$d = \inf_{k\geq 0} \left\{ \liminf_{N\to\infty} \frac{1}{N} \sum_{j=1}^{N} v(x_{k+j}, x_{k+j+1}) \right\}.$$

Then clearly $d \leq \liminf_{N\to\infty} \frac{1}{N} D_N(\bar{x})$. There exists an $\epsilon_0 > 0$ such that for every $0 < \epsilon < \epsilon_0$ there exists a finite sequence $\{x_{j+1}, \ldots, x_{j+l}\}$ with arbitrarily large l such that

$$\frac{1}{l} \sum_{k=j+1}^{j+l} v(x_k, x_{k+1}) < d + \epsilon. \tag{7.10}$$

(Clearly (7.10) will also hold for smaller integers $l' < l$ with another finite sequence, e.g., if l' is a divisor of l.) Let $\{\epsilon_i\}_{i=0}^{\infty}$ be a decreasing sequence, $\epsilon_i > 0$, $\epsilon_i \to 0$ as $i \to \infty$. For every ϵ_i let j_i and l_i correspond to ϵ_i as j and l corresponded above to ϵ and such that

$$\frac{1}{l_i} \sum_{k=j_i+1}^{j_i+l_i} v(x_k, x_{k+1}) < d + \epsilon_i. \tag{7.11}$$

We denote $N_p = \sum_{i=1}^{p} l_i$ for every $p \geq 1$; define a program $\bar{y}$ as

$$\{y_0, y_1, \ldots, y_{l_1}\} = \{x_0, x_{j_1+1} - m_1, \ldots, x_{j_1+l_1} - m_1\}$$

for some $m_1 \in I^n$ such that $(x_0, x_{j_1} - m_1) \in K$, and for every $p \geq 2$ define

$$(y_{N_{p-1}+1}, \ldots, y_{N_p}) = (x_{j_p+1} - m_p, \ldots, x_{j_p+l_p} - m_p)$$

for some $m_p \in I^n$ such that $(y_{N_{p-1}}, x_{j_p+1} - m_p) \in K$. As mentioned above, we can choose $\{l_i\}_{i=1}^{\infty}$ such that $l_i/N_i \to 0$ as $i \to \infty$. It follows from the periodicity of $v(\cdot, \cdot)$, the definition of d, and from (7.1) that $\bar{y}$ satisfies

$$\lim_{N\to\infty} \frac{1}{N} D_N(\bar{y}) = d.$$

Since $d \leq \liminf_{N\to\infty} \frac{1}{N} D_N(\bar{x})$, this completes the proof of the proposition. □

We next define the function $\alpha \mapsto \Phi(\alpha)$. For every $\alpha \in R^n$ let

$$\mathcal{P}_\alpha = \{\bar{x} : \alpha \in A(\bar{x})\},$$

and define

$$\Phi(\alpha) = \inf\left\{\liminf_{j\to\infty} \frac{1}{N_j}\sum_{k=0}^{N_j-1} v(x_k, x_{k+1}) : \bar{x} \in \mathcal{P}_\alpha,\ \frac{x_{N_j}}{N_j} \to \alpha\right\},$$

where for every $\bar{x} \in \mathcal{P}_\alpha$ the infimum is over all the subsequences $\{N_j\}_{j=1}^\infty$ such that $x_{N_j}/N_j \to \alpha$ as $j \to \infty$.

PROPOSITION 7.3. *The function $\Phi(\cdot)$ is lower semicontinuous.*

Proof. Let $\alpha_i \to \alpha$, and let $\bar{x}^i$ be such that for an increasing sequence of integers $\{n_j(i)\}_{j=1}^\infty$ we have

$$\frac{1}{n_j}x^i_{n_j} \to \alpha_i \quad \text{and} \quad \frac{1}{n_j}\sum_{k=0}^{n_j-1} v(x^i_k, x^i_{k+1}) \to \Phi(\alpha_i) + \epsilon_i$$

with $\epsilon_i \to 0$ as $i \to \infty$. Moreover, we can choose the programs $\{\bar{x}^i\}$ such that $\{x^i_1\}_{i=1}^\infty$ is bounded. (For simplicity we wrote above n_j instead of $n_j(i)$.) We construct an increasing sequence of integers as

$$N_1 = n_1(1),$$
$$N_2 = n_j(2) \quad \text{for some } j \text{ such that } N_2 > N_1$$

and generally for $k > 1$ let

$$N_{k+1} = n_j(k+1) \quad \text{for some } j \text{ such that } N_{k+1} \geq \sum_{i=1}^k N_i.$$

We now define a program $\bar{y}$ as

$$\{y_1, \ldots, y_{N_1}\} = \{x^1_1, \ldots, x^1_{N_1}\},$$
$$\{y_{N_1+1}, \ldots, y_{N_1+N_2}\} = \{x^2_1 + m_2, \ldots, x^2_{N_2} + m_2\}$$

for some $m_2 \in I^n$ such that $(y_{N_1}, y_{N_1} - (x^2_1 + m_2)) \in K$, and more generally we denote $M_k = \sum_{j=1}^k N_j$ and define for every $k \geq 2$

$$\{y_{M_{k+1}}, \ldots, y_{M_k}\} = \{x^k_1 + m_k, \ldots, x^k_{N_k} + m_k\}$$

for some $m_k \in I^n$ such that $(y_{M_{k-1}}, y_{M_{k-1}} - (x^k_1 + m_k)) \in K$. It is easy to see, in view of the condition $N_{k+1} > M_k$ and the boundedness of $\{x^i_1\}_{i=1}^\infty$, that

$$y_{M_k}/M_k \to \alpha \quad \text{as } k \to \infty$$

and

$$\liminf_{k\to\infty} \frac{1}{M_k}\sum_{j=1}^{M_k-1} v(y_j, y_{j+1}) \leq \liminf_{i\to\infty} \Phi(\alpha_i),$$

implying that $\Phi(\alpha) \leq \liminf_{i\to\infty} \Phi(\alpha_i)$. This concludes the proof. □

The following result is implied by the proof of Proposition 7.3:

COROLLARY 7.1. *For every $\alpha \in R^n$ there exists a program $\bar{x}$ such that for some increasing sequence of integers $\{N_j\}_{j=1}^{\infty}$ we have*

$$x_{N_j}/N_j \to \alpha \quad \text{and} \quad N_j^{-1} \sum_{k=0}^{N_j-1} v(x_k, x_{k+1}) \to \Phi(\alpha) \quad \text{as } j \to \infty.$$

The following result is basic in our study of programs with a prescribed rotation vector. For results of a similar type, see Mather [13].

THEOREM 7.1. *The function $\Phi(\cdot)$ is convex on R^n.*

Proof. For every α, $\Phi(\alpha)$ is finite as can be seen by considering the sequence $x_k = k\alpha$, $k \geq 1$. We will prove that it is convex.

Let $\alpha_1, \alpha_2 \in R^n$ and $\epsilon > 0$ be given. We then can find arbitrarily large integers N and M and finite sequences $\{x_k\}_{k=1}^{N}$ and $\{y_k\}_{k=1}^{M}$ such that $|x_1| \leq 1$, $|y_1| \leq 1$, and

$$\left|\frac{x_N}{N} - \alpha_1\right| < \epsilon, \qquad \left|\frac{y_M}{M} - \alpha_2\right| < \epsilon,$$

$$\frac{1}{N}\sum_{k=1}^{N} v(x_k, x_{k+1}) < \Phi(\alpha_1) + \epsilon, \qquad \frac{1}{M}\sum_{k=1}^{M} v(y_k, y_{k+1}) < \Phi(\alpha_2) + \epsilon. \tag{7.12}$$

Given a number $0 < t < 1$ we can find integers p and q such that

$$\left|\frac{pN}{pN + qM} - t\right| < \epsilon. \tag{7.13}$$

We construct a sequence $\{z_k\}_{k=1}^{pN+qM}$ as

$$\{z_1, \ldots, z_N\} = \{x_1, \ldots, x_N\},$$

and for every $j = 1, \ldots, p-1$ we let

$$\{z_{jN+1}, \ldots, z_{(j+1)N}\} = \{x_1 + m_j, \ldots, x_N + m_j\}, \tag{7.14}$$

where $m_j \in I^n$ is such that $(z_{jN}, z_{jN} - x_1 - m_j) \in K$. We then define

$$\{z_{pN+1}, \ldots, z_{pN+M}\} = \{y_1 + l_1, \ldots, y_M + l_1\} \tag{7.15}$$

for some $l_1 \in I^n$ such that $(z_{pN}, z_{pN} - y_1 - l_1) \in K$. Moreover, for every $1 \leq j \leq q-1$ we define

$$\{z_{pN+jM+1}, \ldots, z_{pN+(j+1)M}\} = y_1 + l_{j+1}, \ldots, y_M + l_{j+1}\}, \tag{7.16}$$

where $l_{j+1} \in I^n$ is such that $(z_{pN+jM}, z_{pN+jM} - y_1 - l_{j+1}) \in K$. It is easy to see from (7.12) and the definitions of z in (7.14) and (7.15) that

$$|z_{pN+qM} - pN\alpha_1 - qM\alpha_2| < (pN + qM)\epsilon + p + q,$$

implying

$$\left|(pN + qM)^{-1} z_{pN+qM} - \left(\frac{pN}{pN+qM}\alpha_1 + \frac{qM}{pN+qM}\alpha_2\right)\right| < \epsilon + \frac{1}{N} + \frac{1}{M}.$$

In view of (7.13) this implies

$$|(pN+qM)^{-1}a_{pN+qM} - (t\alpha_1 + (1-t)\alpha_2)| < (1+|\alpha_1|+|\alpha_2|)\epsilon + \frac{1}{N} + \frac{1}{M}.$$

A similar computation for the cost expression yields

$$\sum_{k=1}^{pN+qM-1} v(z_k, z_{k+1}) - pN\Phi(\alpha_1) - qM\Phi(\alpha_2) < (pN+qM)\epsilon + (p+q+1)C_1$$

for some constant $C_1 > 0$, implying that

$$(pN+qM)^{-1}\sum_{k=1}^{pN+qM-1} v(z_k, z_{k+1}) - t\Phi(\alpha_1) - (1-t)\Phi(\alpha_2) \le C_2\left(\epsilon + \frac{1}{N} + \frac{1}{M}\right) \tag{7.17}$$

for some constant $C_2 > 0$.

Since (7.16) and (7.17) hold for arbitrarily small $\epsilon > 0$ and arbitrarily large N and M, it follows that

$$\liminf_{\alpha \to t\alpha_1 + (1-t)\alpha_2} \Phi(\alpha) \le t\Phi(\alpha_1) + (1-t)\Phi(\alpha_2). \tag{7.18}$$

Since $\Phi(\cdot)$ is lower semicontinuous, (7.18) implies that $\Phi(\cdot)$ is convex, concluding the proof of the theorem. □

For every $\alpha \in R^n$ we consider the functional J_α defined by

$$J_\alpha(\bar{x}) = \infty \quad \text{if } \alpha \notin A(\bar{x}),$$

$$J_\alpha(\bar{x}) = \inf\left\{\liminf_{j\to\infty} \frac{1}{N}\sum_{k=0}^{N_j-1} v(x_k, x_{k+1}),\ \frac{x_{N_j}}{M_j} \to \alpha \text{ as } j \to \infty\right\} \quad \text{if } \alpha \in A(\bar{x}),$$

where the infimum is over all the increasing sequences of integers $\{N_j\}_{j=1}^{\infty}$ for which $x_{N_j}/N_j \to \alpha$.

By Theorem 7.1 $\Phi(\cdot)$ is convex and let its epigraph be the set

$$\text{epi}\Phi = \{(\alpha, \beta) \in R^{n+1} : \beta \ge \Phi(\alpha),\ \alpha \in R^n\}.$$

Let $\alpha \in R^n$ be such that $(\alpha, \Phi(\alpha))$ is an exposed point of epiΦ; namely, there exists a $\lambda \in R^n$ such that

$$\Phi(\alpha') > \Phi(\alpha) + \lambda \cdot (\alpha' - \alpha) \quad \text{for every } \alpha' \ne \alpha. \tag{7.19}$$

Clearly if $\Phi(\cdot)$ is strictly convex, then every $\alpha \in R^N$ is such that $(\alpha, \Phi(\alpha))$ is an exposed point of epiΦ.

We will need the following result about the existence of programs with minimal-cost growth rate.

THEOREM 7.2. *There exists a minimizer $\bar{z}^*$ to the functional*

$$\bar{z} \mapsto \liminf_{N\to\infty} \frac{1}{N}\sum_{k=0}^{N-1} v(z_k, z_{k+1}),$$

and it is such that $\lim_{N\to\infty} \frac{1}{N}\sum_{k=0}^{N-1} v(z_k^*, z_{k+1}^*)$ *exists.*

Proof. The proof is essentially the same as that of Theorem 3.1 in Leizarowitz [9], and we will not repeat it here. □

THEOREM 7.3. *Suppose that* $(\alpha, \Phi(\alpha))$ *is an exposed point of* epiΦ. *Then the problem*

$$\text{minimize } \bar{x} \mapsto J_\alpha(\bar{x})$$

has a minimizer $\bar{x}^*$ *that has definite limits both for the rotation vector and the average cost, so that the following limits exist:*

$$\lim_{k\to\infty} \frac{x_k^*}{k} = \alpha \quad \text{and} \quad \liminf_{N\to\infty} \frac{1}{N} \sum_{k=0}^{N-1} v(x_k^*, x_{k+1}^*) = \Phi(\alpha). \tag{7.20}$$

Actually $\bar{x}$ *is a minimizer of the problem*

$$\text{minimize } \liminf_{N\to\infty} \frac{1}{N} \sum_{k=0}^{N-1} v_\alpha(x_k, x_{k+1}),$$

where λ *satisfies* (7.19) *and* $v_\alpha(\cdot,\cdot)$ *is defined by*

$$v_\alpha(x, y) = v(x, y) + \lambda \cdot (x - y). \tag{7.21}$$

If $\Phi(\cdot)$ *is strictly convex, then the assertions of the theorem and* (7.20) *hold for every* $\alpha \in R^n$.

Proof. It is easy to verify that $v_\alpha(\cdot,\cdot)$ satisfies all the assumptions that we had for $v(\cdot,\cdot)$. Let $\bar{x}^*$ be a minimizer of the functional

$$\bar{x} \mapsto \liminf_{N\to\infty} \frac{1}{N} \sum_{k=0}^{\infty} v_\alpha(x_k, x_{k+1}),$$

which, by Theorem 7.2, exists and is such that $\lim_{N\to\infty} \frac{1}{N} \sum_{k=0}^{N-1} v_\alpha(x_k^*, x_{k+1}^*)$ exists. Denote it by c, and we claim that $c = \Phi(\alpha) - \lambda \cdot \alpha$ and that assertions of the theorem hold true for the program $\bar{x}^*$.

Let $\{N_k\}_{k=1}^\infty$ be an increasing sequence of integers, and suppose that $x_{N_k}/N_k \to \alpha'$ for some $\alpha' \in R^n$ (otherwise we consider a subsequence of $\{N_k\}_{k=1}^\infty$). Then by definition of $\Phi(\cdot)$ we have

$$\liminf_{k\to\infty} \frac{1}{N_k} \sum_{k=0}^{N_k-1} v_\alpha(x_k^*, x_{k+1}^*) \geq \Phi(\alpha') - \lambda \cdot \alpha',$$

which, by (7.19), exceeds $c = \Phi(\alpha) - \lambda \cdot \alpha$ whenever $\alpha' \neq \alpha$. However, by Corollary 7.1 there exists a program $\bar{x}$ for which

$$\liminf_{N\to\infty} \frac{1}{N} \sum_{k=0}^{\infty} v_\alpha(x_k, x_{k+1}) = \alpha.$$

It thus follows by Theorem 7.2 that (7.20) holds for $\bar{x}^*$, and $\bar{x}^*$ is a minimizer of $J_\alpha(\cdot)$ since $J_\alpha(\bar{x}^*) = \Phi(\alpha)$. This completes the proof of the theorem. □

The next result follows immediately from Theorem 7.3. We now restrict attention only to programs $\bar{x}$ for which the limit

$$\mu(\bar{x}) = \lim_{N\to\infty} \frac{1}{N} \sum_{k=0}^{N-1} v(x_k, x_{k+1})$$

exists. We call this limit, wherever it exists, the *cost growth rate* of the program $\bar{x}$. If we wish to minimize the functional

$$\bar{x} \mapsto \liminf_{N\to\infty} \frac{1}{N} \sum_{k=0}^{N-1} v(x_k, x_{k+1}),$$

then by Proposition 7.2 we may consider for the minimization only programs $\bar{x}$ for which $\mu(\bar{x})$ is well defined.

THEOREM 7.4. *Suppose that* $(\alpha, \Phi(\alpha))$ *is an exposed point of* $\operatorname{epi}\Phi$. *Then the problem*

$$\text{minimize } \{\mu(\bar{x}) : \alpha \in A(\bar{x})\}$$

has a minimizer $\bar{x}^*$ *such that*

$$\lim_{N\to\infty} \bar{x}^*_N/N = \alpha \quad \text{and} \quad \lim_{N\to\infty} \frac{1}{N} \sum_{k=0}^{N-1} v(x^*_k, x^*_{k+1}) = \phi(\alpha).$$

Namely, the minimal cost growth rate over all the programs with rotation vector α *is attained by a program with a single rotation vector* α. *If* Φ *is strictly convex, then the assertion of the theorem holds for every* $\alpha \in R^n$.

Remark. For continuous-time control problems we discretize time and reduce the problem to the one we studied above. There is then a natural correspondence between continuous-time trajectories on one hand and discrete-time programs on the other hand. The rotation vectors and the cost growth rate are preserved under this correspondence, which enables an easy extension of our results to the continuous-time situation.

COPOSITIVITY AND THE MINIMIZATION OF QUADRATIC FUNCTIONS WITH NONNEGATIVITY AND QUADRATIC EQUALITY CONSTRAINTS*

J. C. PREISIG†

Abstract. The problem of finding the minimum value of a quadratic function on a set defined by nonnegativity and quadratic equality constraints is analyzed. The difficulty in finding the solution to this problem is primarily due to the fact that the feasible region is nonconvex. An algorithm that requires the Hessian of the quadratic constraint function be strictly copositive is developed for finding the minimal value of the quadratic objective function. The problem of finding this global minima can be mapped into the problem of determining whether or not a particular matrix is copositive. This result is equivalent to earlier results characterizing the solutions to a large class of fractional programming problems. A more efficient algorithm for finding solutions that satisfy the Kuhn–Tucker necessary conditions is developed, and its convergence behavior is analyzed. This algorithm requires that the Hessians of the quadratic constraint and objective functions be both positive semidefinite and strictly copositive.

1. Introduction.

This paper addresses the problem of finding the minimal value of a quadratic function with nonnegativity and quadratic equality constraints (Problem 1) and the problem of finding the vector $\mathbf{w}$ that yields this minimal value (Problem 2).

PROBLEM 1. $\lambda_{\text{opt}} = \min_{\substack{w\geq 0 \\ \mathbf{w}^t B\mathbf{w}=b>0}} \mathbf{w}^t A\mathbf{w}.$

PROBLEM 2. $\mathbf{w}_{\text{opt}} = \arg\min_{\substack{w\geq 0 \\ \mathbf{w}^t B\mathbf{w}=b>0}} \mathbf{w}^t A\mathbf{w}.$

Without any loss of generality, the matrices A and B can be assumed to be symmetric and the constant b can be set equal to one. The matrix property of copositivity is used extensively throughout the paper. The following definition of this property is used.

DEFINITION 1. *A matrix Q is copositive if $\mathbf{w} \geq 0$ implies that $\mathbf{w}^t Q\mathbf{w} \geq 0$. A matrix Q is strictly copositive if $\mathbf{w} \geq 0$ and $\mathbf{w} \neq 0$ implies that $\mathbf{w}^t Q\mathbf{w} > 0$.*

Throughout this paper, uppercase letters denote matrix quantities, boldface lowercase letters denote vector quantities, and the superscript t denotes transpose. The development of algorithms to solve Problems 1 and 2 was motivated by an array signal processing problem. This motivating application is described in §2. Section 3 presents an algorithm for solving Problem 1, while §5 presents an algorithm for finding a solution that satisfies the Kuhn–Tucker necessary conditions for Problem 2. The results in §3 are related to results from the field of fractional programming in §4. Finally, a numerical analysis of the efficiency of the two algorithms is presented in §6.

2. An array processing application.

The application that motivated the development of the algorithms described herein involves the processing of signals received at an array of sensors to determine the location of the source of each of the signals received [8]. For each possible source location denoted by ϕ, the array processor estimates the average power in the received signal, which is emitted by a source at that location. Ideally this estimate equals zero if no source is present at the location ϕ. The estimate is denoted by $\hat{\sigma^2}(\phi)$ and is referred to as the ambiguity function. The array processor detailed in [8] creates the ambiguity function by first calculating the sample cross-spectral correlation matrix of the received signal ($\hat{R}$). Then for each possible source location of interest, the processor calculates the signal replica vector,

*Received by the editors July 9, 1993; accepted for publication (in revised form) February 6, 1995. This research was supported by Office of Naval Research grants N00014-90-J-1452 and N00014-91-J-1246. This paper is WHOI Contribution 8427.

†Department of Applied Ocean Physics and Engineering, Woods Hole Oceanographic Institution, Woods Hole, MA 02543, and Department of Electrical and Computer Engineering, Northeastern University, Boston, MA 02115.

denoted by $\mathbf{q}(\phi)$, that is associated with that location. The ambiguity function for that location is then given by

$$\hat{\sigma^2}(\phi) = \frac{1}{\mathbf{q}(\phi)^{\mathrm{h}} \hat{R}^{-1} \mathbf{q}(\phi)},$$

where the superscript h denotes Hermitian.

The signal replica vector mentioned above (i.e., $\mathbf{q}(\phi)$) is a quantitative description of the spatial structure that would characterize any signal emitted by a source at location ϕ as it is received at the array of sensors used by the processor. This spatial structure allows the processor to differentiate between signals emitted by sources at different locations. Unfortunately, the replica vector is highly dependent on the characteristics of the propagation medium between the location of the source and the array of sensors. Thus, if the processor does not have detailed and accurate environmental information as is often the case in problems involving acoustic signals that have propagated through the ocean, the processor may not be able to calculate $\mathbf{q}(\phi)$ accurately for each location.

The array processor in [8] addresses this problem by creating a set of allowable replica vectors, denoted by $\mathbf{Q}(\phi)$, for each location. This set is defined as

$$\mathbf{Q}(\phi) = \left\{ \mathbf{q} \mid \exists w_1, \ldots, w_M;\ w_i \geq 0;\ \mathbf{q} = \sum_{i=1}^{M} w_i \mathbf{q}_i(\phi) \text{ and } |\ \mathbf{q}\ |^2 = 1 \right\}, \tag{2.1}$$

where the vectors $\mathbf{q}_1(\phi)$ through $\mathbf{q}_M(\phi)$ are prototype replica vectors for the location ϕ. That is, $\mathbf{Q}(\phi)$ is the set of all vectors with a norm of one that are expressible as a nonnegative linear combination of the prototype vectors. The selection of the prototype replica vectors depends on the range of the environmental conditions over which the processor is expected to operate. Given the prototype vectors for each location, the processor calculates the ambiguity function as

$$\hat{\sigma^2}(\phi) = \max_{\mathbf{q} \in \mathbf{Q}(\phi)} \frac{1}{\mathbf{q}^{\mathrm{h}} \hat{R}^{-1} \mathbf{q}}. \tag{2.2}$$

Let the matrix $\tilde{Q}(\phi) = \left[\mathbf{q}_1(\phi), \ldots, \mathbf{q}_M(\phi)\right]$. Then (2.1) can be rewritten as

$$\mathbf{Q}(\phi) = \left\{ \mathbf{q} \mid \exists \mathbf{w} \in \mathbb{R}^M;\ \mathbf{w} \geq 0;\ \mathbf{q} = \tilde{Q}(\phi)\mathbf{w} \text{ and } \mathbf{w}^{\mathrm{t}} \tilde{Q}^{\mathrm{h}}(\phi) \tilde{Q}(\phi) \mathbf{w} = 1 \right\}. \tag{2.3}$$

Let $A(\phi) = \mathrm{Real}(\tilde{Q}(\phi)^{\mathrm{h}} \hat{R}^{-1} \tilde{Q}(\phi))$ and $B(\phi) = \mathrm{Real}(\tilde{Q}(\phi)^{\mathrm{h}} \tilde{Q}(\phi))$. Then using (2.3), the problem in (2.2) can be expressed as

$$\hat{\sigma^2}(\phi)^{-1} = \min_{\substack{\mathbf{w} \geq 0 \\ \mathbf{w}^{\mathrm{t}} B(\phi) \mathbf{w} = 1}} \mathbf{w}^{\mathrm{t}} A(\phi) \mathbf{w}.$$

Thus, the inverse of the ambiguity function is the solution to Problem 1 and the associated weights are the solutions to Problem 2.

3. Finding the global minimum. This section addresses the problem of finding the global minimum of a quadratic function subject to a quadratic equality constraint and a nonnegativity constraint (Problem 1). No additional restrictions are placed on the matrix A. However, the matrix B must be strictly copositive. In this section, this problem is shown to be NP-complete and an algorithm is developed for solving the problem.

The following four lemmas, the proofs of which follow directly from the definitions of copositivity and strict copositivity, are required in proving the main result of this section.

LEMMA 3.1. *Let B be a strictly copositive, symmetric matrix. Then the set $\mathbf{w} \geq 0$, $\mathbf{w}^t B\mathbf{w} = 1$ is a compact set.*

LEMMA 3.2. *Let A and B be symmetric matrices, and assume that B is strictly copositive. Then $\exists$ a constant λ_0 s.t.*

$(A - \lambda_0 B)$ *is copositive but not strictly copositive,*
$\forall \lambda < \lambda_0 \quad (A - \lambda B)$ *is strictly copositive, and*
$\forall \lambda > \lambda_0 \quad (A - \lambda B)$ *is not copositive.*

Letting the symbol $\mathbf{e}$ denote the column vector of all ones, the third lemma is as follows.

LEMMA 3.3. $\exists \mathbf{w}_0 \geq 0$, $\mathbf{w}_0 \neq 0$ *s.t.*

$$\mathbf{w}_0^t (A - \lambda_0 B)\, \mathbf{w}_0 = 0$$

and

$$\mathbf{w}_0 = \arg \min_{\substack{\mathbf{w} \geq 0 \\ \mathbf{e}^t \mathbf{w} = 1}} \mathbf{w}^t (A - \lambda_0 B)\, \mathbf{w},$$

where λ_0 is as defined in Lemma 3.2.

The final lemma necessary to prove the main result of this section is as follows.

LEMMA 3.4.

$$\forall \lambda < \lambda_0 \qquad \min_{\substack{\mathbf{w} \geq 0 \\ \mathbf{e}^t \mathbf{w} = 1}} \mathbf{w}^t (A - \lambda B)\, \mathbf{w} > 0$$

and

$$\forall \lambda > \lambda_0 \qquad \min_{\substack{\mathbf{w} \geq 0 \\ \mathbf{e}^t \mathbf{w} = 1}} \mathbf{w}^t (A - \lambda B)\, \mathbf{w} < 0,$$

where λ_0 is as defined in Lemma 3.2.

The main theorem and result of this section relates the constant λ_0 defined above to the solution to Problem 1.

THEOREM 3.5. *Let A and B be symmetric matrices, B be strictly copositive,*

$$\mathbf{w}_{\text{opt}} = \arg \min_{\substack{\mathbf{w} \geq 0 \\ \mathbf{w}^t B \mathbf{w} = 1}} \mathbf{w}^t A \mathbf{w},$$

$$\lambda_{\text{opt}} = \mathbf{w}_{\text{opt}}^t A \mathbf{w}_{\text{opt}},$$

and λ_0 be as defined in Lemma 3.2.

Then $\lambda_{\text{opt}} = \lambda_0$.

Proof. From Lemma 3.1, the feasible region $\{\mathbf{w} \mid \mathbf{w} \geq 0, \mathbf{w}^t B \mathbf{w} = 1\}$ is compact. In addition, the function $\mathbf{w}^t A \mathbf{w}$ is continuous. Therefore, $\mathbf{w}_{\text{opt}}$ exists as defined above. Let $\tilde{\mathbf{w}} = \mathbf{w}_{\text{opt}}/(\mathbf{e}^t \mathbf{w}_{\text{opt}})$. Then $\tilde{\mathbf{w}} \geq 0$, $\mathbf{e}^t \tilde{\mathbf{w}} = 1$, and $\tilde{\mathbf{w}}^t (A - \lambda_{\text{opt}} B) \tilde{\mathbf{w}} = 0$. Then, Lemma 3.4 implies that $\lambda_{\text{opt}} \geq \lambda_0$.

Let $\mathbf{w}_0$ be as defined in Lemma 3.3, and let $\tilde{\mathbf{w}} = \mathbf{w}_0 / \sqrt{\mathbf{w}_0^t B \mathbf{w}_0}$. Then $\tilde{\mathbf{w}}^t (A - \lambda_0 B) \tilde{\mathbf{w}} = 0$, $\tilde{\mathbf{w}}^t B \tilde{\mathbf{w}} = 1$, and $\tilde{\mathbf{w}} \geq 0$. Combining the first two equalities yields $\tilde{\mathbf{w}}^t A \tilde{\mathbf{w}} = \lambda_0$. Noting that $\tilde{\mathbf{w}}$ is contained in the feasible region of the minimization problem that defines $\mathbf{w}_{\text{opt}}$ and λ_{opt}, this last equality implies that $\lambda_{\text{opt}} \leq \lambda_0$.

Thus, $\lambda_{\text{opt}} = \lambda_0$. □

Utilizing Theorem 3.5, the following bisection algorithm can be used to find the solution to Problem 1.

1. Select λ^- and λ^+ such that $A-\lambda^- B$ is strictly copositive and $A-\lambda^+ B$ is not strictly copositive. Various simple strategies can be used to make this initial selection. (For example, choose λ^+ so that at least one element on the main diagonal of $A-\lambda^+ B$ is ≤ 0. If A is strictly copositive, let $\lambda^- = 0$. Otherwise, let $\lambda^- = \frac{\lambda_{\min}|\mathbf{w}_{\min}|^2}{\gamma_{\min}}$, where $\lambda_{\min}$ is the minimum eigenvalue of A, $\mathbf{w}_{\min} = \arg\min_{\substack{\mathbf{w}\geq 0 \\ \mathbf{e}^t\mathbf{w}=1}} \mathbf{w}^t B\mathbf{w}$, and $\gamma_{\min} = \mathbf{w}_{\min}^t B\mathbf{w}_{\min}$.) Select some tolerance, $\epsilon > 0$.

2. Let $\lambda = (\lambda^+ + \lambda^-)/2$.

3. If $A-\lambda B$ is strictly copositive, set $\lambda^- = \lambda$. Otherwise, $\lambda^+ = \lambda$.

4. If $A-\lambda^+ B$ is copositive or if $\lambda^+ - \lambda^- < \epsilon$, then let $\lambda_{\text{opt}} = \lambda^+$ and terminate the algorithm. Otherwise, go to step 2.

At termination, λ_{opt} will be greater than or equal to the solution to Problem 1 and the magnitude of the difference between the two will be no greater than ϵ.

Finding the solution to Problem 1 to within a particular tolerance can be mapped into determining whether or not a matrix is copositive. In addition, the problem of determining whether or not a matrix is copositive can be mapped into solving Problem 1. (Given any symmetric matrix Q, divide it into two symmetric matrices A and B such that $Q = A - B$ and B has all positive elements. Then B is strictly copositive. Then, if the solution to Problem 1 for this A and B equals one, Q is copositive but not strictly copositive. If the solution is less than one, Q is strictly copositive. Otherwise, Q is not copositive.) Since the problem of determining whether or not a matrix is copositive is NP-complete [7], determining the solution to Problem 1 is also NP-complete. Even though the problem of determining whether or not a matrix is copositive is NP-complete, there are a number of procedures available for making this determination [2, 6, 11, 12].

4. Relationship to fractional programming. Since B is assumed to be strictly copositive, Problem 1 can be recast as a fractional programming problem. Then, Theorem 3.5 can be shown to be equivalent to a theorem in [3, 9, 10] that relates the solution of a parametric optimization problem to the solution of a fractional programming problem.

To recast Problem 1 as a fractional programming problem, we use the following lemma.

LEMMA 4.1. *Let* $\lambda_{\text{opt}} = \min_{\substack{\mathbf{w}\geq 0 \\ \mathbf{w}^t B\mathbf{w}=1}} \mathbf{w}^t A\mathbf{w}$ *and* $\lambda_1 = \min_{\substack{\mathbf{w}\geq 0 \\ \mathbf{e}^t\mathbf{w}=1}} \frac{\mathbf{w}^t A\mathbf{w}}{\mathbf{w}^t B\mathbf{w}}$.

Then $\lambda_{\text{opt}} = \lambda_1$.

Proof. Select $\mathbf{w}_1$ s.t. $\mathbf{w}_1 \geq 0$, $\mathbf{w}_1^t B\mathbf{w}_1 = 1$, and $\lambda_{\text{opt}} = \mathbf{w}_1^t A\mathbf{w}_1$. Let $\tilde{\mathbf{w}}_1 = \frac{\mathbf{w}_1}{\mathbf{e}^t\mathbf{w}_1}$. Then

$$\tilde{\mathbf{w}}_1 \geq 0, \quad \mathbf{e}^t\tilde{\mathbf{w}}_1 = 1, \quad \text{and} \quad \lambda_{\text{opt}} = \frac{\tilde{\mathbf{w}}_1^t A\tilde{\mathbf{w}}_1}{\tilde{\mathbf{w}}_1^t B\tilde{\mathbf{w}}_1}.$$

Therefore, $\lambda_1 \leq \lambda_{\text{opt}}$. Select $\mathbf{w}_2$ such that

$$\mathbf{w}_2 \geq 0, \quad \mathbf{e}^t\mathbf{w}_2 = 1, \quad \text{and} \quad \lambda_1 = \frac{\mathbf{w}_2^t A\mathbf{w}_2}{\mathbf{w}_2^t B\mathbf{w}_2}.$$

Let

$$\tilde{\mathbf{w}}_2 = \frac{\mathbf{w}_2}{\sqrt{\mathbf{w}_2^t B\mathbf{w}_2}}.$$

Then

$$\tilde{\mathbf{w}}_2 \geq 0, \quad \tilde{\mathbf{w}}_2^t B\tilde{\mathbf{w}}_2 = 1, \quad \text{and} \quad \lambda_1 = \frac{\mathbf{w}_2^t A\mathbf{w}_2}{\mathbf{w}_2^t B\mathbf{w}_2} = \frac{\tilde{\mathbf{w}}_2^t A\tilde{\mathbf{w}}_2}{\tilde{\mathbf{w}}_2^t B\tilde{\mathbf{w}}_2} = \tilde{\mathbf{w}}_2^t A\tilde{\mathbf{w}}_2.$$

Therefore, $\lambda_{\text{opt}} \leq \lambda_1$.

Therefore, $\lambda_{\text{opt}} = \lambda_1$. □

The result from [3, 9, 10] that relates the solution of a parametric programming problem to the fractional programming problem in Lemma 4.1 can be expressed as

Let $F(\lambda) = \min_{\substack{\mathbf{w}\geq 0 \\ \mathbf{e}^t\mathbf{w}=1}} \mathbf{w}^t (A - \lambda B)\,\mathbf{w}$, and let $\lambda_2 \in \mathbb{R}$ be the unique zero of $F(\lambda)$. Then $\lambda_2 = \min_{\substack{\mathbf{w}\geq 0 \\ \mathbf{e}^t\mathbf{w}=1}} \frac{\mathbf{w}^t A\mathbf{w}}{\mathbf{w}^t B\mathbf{w}}$.

A constraint such as $\mathbf{e}^t\mathbf{w} = 1$ in Lemma 4.1 is necessary to satisfy the requirements of this result from [3, 9, 10] that the feasible region be compact and that the function $F(\lambda)$ have a unique zero. From Lemmas 3.3 and 3.4, $\lambda_0 = \lambda_2$ is the unique zero of $F(\lambda)$. Since Lemma 4.1 relates the solutions of Problem 1 and the fractional programming problem, the results in [3, 9, 10] and Theorem 3.5 state equivalent characterizations of the solution to Problem 1.

References [3, 9, 10] present an algorithm and some modifications for finding the unique zero of the function $F(\lambda)$. However, each iteration of this algorithm or its modifications requires computing $F(\lambda)$ for a new value of λ. Since $F(\lambda)$ is in general the minima of a nonconvex function, this may be a difficult minimization problem. In fact, this problem will be at least as difficult as determining whether or not the matrix $A - \lambda B$ is strictly copositive, copositive but not strictly copositive, or not copositive as required by the algorithm detailed in §3.

5. Finding a Kuhn–Tucker point. The optimization problem arising in the application for which the algorithms developed herein were developed (see §2) often has a dimensionality of approximately 200. Experience has shown that for problems of such high dimensionality, the approach outlined in §3 is too inefficient to be useful. An alternative procedure detailed in this section is efficient enough to handle such problems. Results presented in Section 6 compare the performance of the two algorithms.

Rather than finding the global solution to Problem 1, the algorithm in this section finds a point that satisfies the Kuhn–Tucker necessary conditions for Problem 2. The algorithm is iterative and at each iteration solves a quadratic programming problem (quadratic objective function, nonnegativity and linear equality constraints). At the nth iteration, the linear equality constraint of the quadratic programming problem is derived by replacing the left-hand vector $\mathbf{w}$ in the quadratic equality constraint in Problem 2 with the solution from the previous iteration, $\mathbf{w}_{n-1}$. As $\mathbf{w}_n$ converges to a solution, the linear equality constraint approaches the quadratic equality constraint in Problem 2. The proof of the convergence properties of the algorithm requires that A and B be positive semidefinite and strictly copositive. These requirements will be introduced at the appropriate times in the analysis that follows.

The Kuhn–Tucker necessary conditions for $\mathbf{w}_{\text{opt}}$ to be a solution to Problem 2 are

$$\begin{aligned} \exists\, \mathbf{v},\ \lambda \quad \text{s.t.} \quad A\mathbf{w}_{\text{opt}} - \lambda B\mathbf{w}_{\text{opt}} - \mathbf{v} &= 0, \\ \mathbf{v},\ \mathbf{w}_{\text{opt}} &\geq 0, \\ \mathbf{v}^t\mathbf{w}_{\text{opt}} &= 0, \\ \mathbf{w}_{\text{opt}}^t B\mathbf{w}_{\text{opt}} &= 1. \end{aligned}$$

The algorithm presented and analyzed in this section can be shown to either

a) terminate with a solution satisfying the Kuhn–Tucker necessary conditions or
b) generate an infinite sequence of solutions that contains at least one convergent subsequence for which the limit point satisfies the Kuhn–Tucker necessary conditions.

In addition, it can be shown that the objective function ($\mathbf{w}^t A\mathbf{w}$) strictly decreases with each iteration.

The iterative algorithm is as follows.

1. Select a convergence tolerance ($\epsilon > 0$) and initial $\mathbf{w}$ ($\mathbf{w}_0$ s.t. $\mathbf{w}_0 \geq 0$ and $\mathbf{w}_0^t B \mathbf{w}_0 = 1$). Set $n = 1$.

2. $\tilde{\mathbf{w}}_n = \arg\min_{\substack{\mathbf{w} \geq 0 \\ \mathbf{w}_{(n-1)}^t B \mathbf{w} = 1}} \mathbf{w}^t A \mathbf{w}$.

3. $\mathbf{w}_n = \dfrac{\tilde{\mathbf{w}}_n}{\sqrt{\tilde{\mathbf{w}}_n^t B \tilde{\mathbf{w}}_n}}$.

4. If $\cos^2(\mathbf{w}_{n-1}, \mathbf{w}_n; B) > (1 - \epsilon)$, then $\mathbf{w}_{\text{opt}} = \mathbf{w}_n$. Otherwise, set $n = n + 1$ and go to step 2.

Here, $\cos^2$ is defined as

$$0 \leq \cos^2(\mathbf{w}_{n-1}, \mathbf{w}_n; B) \triangleq \frac{| \mathbf{w}_{n-1}^t B \mathbf{w}_n |^2}{(\mathbf{w}_{n-1}^t B \mathbf{w}_{n-1})(\mathbf{w}_n^t B \mathbf{w}_n)} \leq 1.$$

The analysis of this algorithm begins with the following theorem, which states that the objective function is a strictly decreasing function of n.

THEOREM 5.1. *Let A and B be symmetric matrices, A be copositive, B be strictly copositive, and $\tilde{\mathbf{w}}_n$ and $\mathbf{w}_n$ be as defined in the algorithm detailed earlier in this section.*

If $\cos^2(\mathbf{w}_{n-1}, \mathbf{w}_n; B) < 1$, *then* $\mathbf{w}_n^t A \mathbf{w}_n < \mathbf{w}_{n-1}^t A \mathbf{w}_{n-1}$.

Proof. B is strictly copositive. Therefore $\forall n$ $\mathbf{w}_{n-1}^t B \mathbf{w}_{n-1}, \mathbf{w}_n^t B \mathbf{w}_n > 0$. In addition, $\mathbf{w}_{n-1}, \tilde{\mathbf{w}}_n, \mathbf{w}_n \geq 0$, and $\mathbf{w}_{n-1}^t B \mathbf{w}_{n-1} = \mathbf{w}_{n-1}^t B \tilde{\mathbf{w}}_n = 1$. $\mathbf{w}_{n-1}$ and $\tilde{\mathbf{w}}_n$ are therefore both in the feasible region of the minimization problem in step 2 of the algorithm. Since $\tilde{\mathbf{w}}_n$ is a solution to the problem in step 2 and A is copositive,

$$0 \leq \tilde{\mathbf{w}}_n^t A \tilde{\mathbf{w}}_n \leq \mathbf{w}_{n-1}^t A \mathbf{w}_{n-1}.$$

In addition,

$$\cos^2(\mathbf{w}_{n-1}, \mathbf{w}_n; B) = \cos^2(\mathbf{w}_{n-1}, \tilde{\mathbf{w}}_n; B) = \frac{| \mathbf{w}_{n-1}^t B \tilde{\mathbf{w}}_n |^2}{(\mathbf{w}_{n-1}^t B \mathbf{w}_{n-1})(\tilde{\mathbf{w}}_n^t B \tilde{\mathbf{w}}_n)} = \frac{1}{(\tilde{\mathbf{w}}_n^t B \tilde{\mathbf{w}}_n)}.$$

Assume that $\cos^2(\mathbf{w}_{n-1}, \mathbf{w}_n; B) < 1$. Then

$$\mathbf{w}_n^t A \mathbf{w}_n = \frac{\tilde{\mathbf{w}}_n^t A \tilde{\mathbf{w}}_n}{\tilde{\mathbf{w}}_n^t B \tilde{\mathbf{w}}_n} = \tilde{\mathbf{w}}_n^t A \tilde{\mathbf{w}}_n \cos^2(\mathbf{w}_{n-1}, \mathbf{w}_n; B) < \tilde{\mathbf{w}}_n^t A \tilde{\mathbf{w}}_n \leq \mathbf{w}_{n-1}^t A \mathbf{w}_{n-1},$$

completing the proof. □

The fact that the objective function is a descent function not only shows that successive solutions result in lower values of the objective function but will also be used later to prove the convergence result summarized above. The final intermediate result needed to prove the convergence result is a proof that the mapping carried out by steps 2 and 3 of the algorithm is closed. The definition of a closed mapping is as follows (see [1]).

DEFINITION 2. *Let X and Y be nonempty closed sets in E_p and E_q, respectively. Let $\mathrm{F} : X \to Y$ be a point-to-set map. The map* A *is said to be closed if*

$$x_k \in X, \qquad x_k \to x_0,$$
$$y_k \in \mathrm{F}(x_k), \qquad y_k \to y_0$$

imply that $y_0 \in \mathrm{F}(x_0)$. The map F *is said to be closed on $Z \subset X$ if it is closed at each point in Z.*

The mapping that must be shown to be closed is given by

$$\tilde{\mathbf{y}}_n = \arg\min_{\substack{y \geq 0 \\ \mathbf{x}_n^t B \mathbf{y} = 1}} \mathbf{y}^t A \mathbf{y}, \tag{5.1}$$

$$F(\mathbf{x}_n) \triangleq \mathbf{y}_n = \frac{\tilde{\mathbf{y}}_n}{\sqrt{\tilde{\mathbf{y}}_n^t B \tilde{\mathbf{y}}_n}}. \tag{5.2}$$

The following definitions will be useful in the proof that $F(\mathbf{x}_n)$ is a closed mapping:

$$A_{\min} \triangleq \min_{\substack{\mathbf{x}\geq 0 \\ \mathbf{x}^t\mathbf{x}=1}} \mathbf{x}^t A\mathbf{x},$$

$$A_{\max} \triangleq \max_{\substack{\mathbf{x}\geq 0 \\ \mathbf{x}^t\mathbf{x}=1}} \mathbf{x}^t A\mathbf{x},$$

$$B_{\min} \triangleq \min_{\substack{\mathbf{x}\geq 0 \\ \mathbf{x}^t\mathbf{x}=1}} \mathbf{x}^t B\mathbf{x},$$

$$B_{\max} \triangleq \max_{\substack{\mathbf{x}\geq 0 \\ \mathbf{x}^t\mathbf{x}=1}} \mathbf{x}^t B\mathbf{x}.$$

The following lemma uses these definitions to bound quantities of interest.

LEMMA 5.2. *Let A and B be symmetric, strictly copositive matrices. Assume that $\mathbf{x}_n \geq 0$ and $\mathbf{x}_n^t B\mathbf{x}_n = 1$. Define $\tilde{\mathbf{y}}_n$ and $\mathbf{y}_n$ as in* (5.1) *and* (5.2), *respectively. Then*

$$0 < \left(\frac{A_{\min}B_{\min}}{A_{\max}B_{\max}}\right)^{\frac{1}{2}} \leq (\tilde{\mathbf{y}}_n^t B\tilde{\mathbf{y}}_n)^{-\frac{1}{2}} = \mathbf{x}_n^t B\mathbf{y}_n \leq 1.$$

Proof. A and B are finite and strictly copositive matrices. Therefore,

$$0 < A_{\min} \leq A_{\max} < \infty,$$
$$0 < B_{\min} \leq B_{\max} < \infty.$$

Therefore,

$$0 < \left(\frac{A_{\min}B_{\min}}{A_{\max}B_{\max}}\right)^{\frac{1}{2}}. \tag{5.3}$$

By definition

$$\mathbf{x}_n^t A\mathbf{x}_n \leq |\,\mathbf{x}_n\,|^2 A_{\max},$$
$$\mathbf{x}_n^t B\mathbf{x}_n = 1 \geq |\,\mathbf{x}_n\,|^2 B_{\min}.$$

Combined with the fact that A is strictly copositive this implies that

$$0 < \mathbf{x}_n^t A\mathbf{x}_n = \frac{\mathbf{x}_n^t A\mathbf{x}_n}{\mathbf{x}_n^t B\mathbf{x}_n} \leq \frac{|\,\mathbf{x}_n\,|^2 A_{\max}}{|\,\mathbf{x}_n\,|^2 B_{\min}} = \frac{A_{\max}}{B_{\min}}. \tag{5.4}$$

The definition of $B_{\max}$ and the fact that B is strictly copositive and $\mathbf{x}_n^t B\tilde{\mathbf{y}}_n = 1$ imply that

$$0 < \tilde{\mathbf{y}}_n^t B\tilde{\mathbf{y}}_n \leq |\,\tilde{\mathbf{y}}_n\,|^2 B_{\max}. \tag{5.5}$$

The definition of $A_{\min}$ and the fact that $\mathbf{x}_n$ is in the feasible region of the minimization problem in (5.1) imply that

$$|\,\tilde{\mathbf{y}}_n\,|^2 A_{\min} \leq \tilde{\mathbf{y}}_n^t A\tilde{\mathbf{y}}_n \leq \mathbf{x}_n^t A\mathbf{x}_n. \tag{5.6}$$

Combining (5.5) and (5.6) yields

$$0 < \tilde{\mathbf{y}}_n^t B\tilde{\mathbf{y}}_n \leq \mathbf{x}_n^t A\mathbf{x}_n \frac{B_{\max}}{A_{\min}}. \tag{5.7}$$

Combining (5.3), (5.4), and (5.7) yields

$$0 < \left(\frac{A_{\min}B_{\min}}{A_{\max}B_{\max}}\right)^{\frac{1}{2}} \leq (\tilde{\mathbf{y}}_n^t B\tilde{\mathbf{y}}_n)^{-\frac{1}{2}}. \tag{5.8}$$

Combining the facts that $\mathbf{x}_n^t B\tilde{\mathbf{y}}_n = 1$, $\mathbf{y}_n = \frac{\tilde{\mathbf{y}}_n}{\sqrt{\tilde{\mathbf{y}}_n^t B\tilde{\mathbf{y}}_n}}$, and $\tilde{\mathbf{y}}_n^t B\tilde{\mathbf{y}}_n > 0$ implies that

$$(\tilde{\mathbf{y}}_n^t B\tilde{\mathbf{y}}_n)^{-\frac{1}{2}} = \mathbf{x}_n^t B\mathbf{y}_n. \tag{5.9}$$

The facts that $\mathbf{x}_n^t B\mathbf{x}_n = \mathbf{y}_n^t B\mathbf{y}_n = 1$ and that $\cos^2(\mathbf{x}_n, \mathbf{y}_n; B) = \frac{|\mathbf{x}_n^t B\mathbf{y}_n|^2}{(\mathbf{x}_n^t B\mathbf{x}_n)(\mathbf{y}_n^t B\mathbf{y}_n)} \leq 1$ imply that $\mathbf{x}_n^t B\mathbf{y}_n \leq 1$. Combining this with (5.8) and (5.9) yields

$$0 < \left(\frac{A_{\min}B_{\min}}{A_{\max}B_{\max}}\right)^{\frac{1}{2}} \leq (\tilde{\mathbf{y}}_n^t B\tilde{\mathbf{y}}_n)^{-\frac{1}{2}} = \mathbf{x}_n^t B\mathbf{y}_n \leq 1. \qquad \square$$

The following theorem establishes that the mapping is closed.

THEOREM 5.3. *Assume that A and B are symmetric, strictly copositive matrices and that A is positive semidefinite. Then the mapping $F(x_n)$ defined above is closed on the set* $\mathbf{x} \geq 0$, $\mathbf{x}^t B\mathbf{x} = 1$.

Proof. Assume that $\forall n$, $\mathbf{x}_n \geq 0$, $\mathbf{x}_n^t B\mathbf{x}_n = 1$; that $\mathbf{x}_n \to \mathbf{x}_o$; and that $F(\mathbf{x}_n) = \mathbf{y}_n \to \mathbf{y}_o$. Then

$$0 < \left(\frac{A_{\min}B_{\min}}{A_{\max}B_{\max}}\right)^{\frac{1}{2}} \leq \mathbf{x}_n^t B\mathbf{y}_n \quad \forall n$$

implies that $\mathbf{x}_n^t B\mathbf{y}_n \to \mathbf{x}_o^t B\mathbf{y}_o > 0$.

By (5.2) and Lemma 5.2,

$$\mathbf{y}_n = \frac{\tilde{\mathbf{y}}_n}{\sqrt{\tilde{\mathbf{y}}_n^t B\tilde{\mathbf{y}}_n}} = \tilde{\mathbf{y}}_n(\mathbf{x}_n^t B\mathbf{y}_n).$$

Therefore, $\tilde{\mathbf{y}}_n = \frac{\mathbf{y}_n}{\mathbf{x}_n^t B\mathbf{y}_n}$. Therefore, $\mathbf{x}_o^t B\mathbf{y}_o > 0$ implies that

$$\tilde{\mathbf{y}}_n = \frac{\mathbf{y}_n}{\mathbf{x}_n^t B\mathbf{y}_n} \to \frac{\mathbf{y}_o}{\mathbf{x}_o^t B\mathbf{y}_o} \triangleq \tilde{\mathbf{y}}_o.$$

$\tilde{\mathbf{y}}_n$ satisfies the Kuhn–Tucker necessary and sufficient conditions (sufficient since A is positive semidefinite) for the problem in (5.1), which are

$$\exists\, \tilde{\mathbf{v}}_n,\ \tilde{\lambda}_n \quad \text{s.t.}$$

$$A\tilde{\mathbf{y}}_n - \tilde{\lambda}_n B\mathbf{x}_n - \tilde{\mathbf{v}}_n = 0, \tag{5.10}$$

$$\tilde{\mathbf{v}}_n,\ \tilde{\mathbf{y}}_n \geq 0,$$

$$\tilde{\mathbf{v}}_n^t\tilde{\mathbf{y}}_n = 0, \tag{5.11}$$

$$\mathbf{x}_n^t B\tilde{\mathbf{y}}_n = 1. \tag{5.12}$$

$\forall n$ $\tilde{\mathbf{y}}_n \geq 0$ implies that $\tilde{\mathbf{y}}_o \geq 0$. $\forall n$ $\mathbf{x}_n^t B\tilde{\mathbf{y}}_n = 1$ implies that $\mathbf{x}_o^t B\tilde{\mathbf{y}}_o = 1$.

Left multiply (5.10) by $\tilde{\mathbf{y}}_n$. Then, substituting in (5.11) and (5.12) yields $\tilde{\lambda}_n = \tilde{\mathbf{y}}_n^t A\tilde{\mathbf{y}}_n$. Therefore, $\tilde{\mathbf{y}}_n \to \tilde{\mathbf{y}}_o$ implies that $\tilde{\lambda}_n \to \tilde{\mathbf{y}}_o^t A\tilde{\mathbf{y}}_o \triangleq \tilde{\lambda}_o$.

Then, $\tilde{\mathbf{v}}_n = A\tilde{\mathbf{y}}_n - \tilde{\lambda}_n B\mathbf{x}_n \to A\tilde{\mathbf{y}}_o - \tilde{\lambda}_o B\mathbf{x}_o \triangleq \tilde{\mathbf{v}}_o$. In addition, $\forall n\ \tilde{\mathbf{v}}_n \geq 0$ implies that $\tilde{\mathbf{v}}_o \geq 0$. $\forall n\ \tilde{\mathbf{v}}_n^t \tilde{\mathbf{y}}_n = 0$ implies that $\tilde{\mathbf{v}}_o^t \tilde{\mathbf{y}}_o = 0$.

Combining the above yields

$$\begin{aligned} A\tilde{\mathbf{y}}_o - \tilde{\lambda}_o B\mathbf{x}_o - \tilde{\mathbf{v}}_o &= 0, \\ \tilde{\mathbf{v}}_o,\ \tilde{\mathbf{y}}_o &\geq 0, \\ \tilde{\mathbf{v}}_o^t \tilde{\mathbf{y}}_o &= 0, \\ \mathbf{x}_o^t B\tilde{\mathbf{y}}_o &= 1. \end{aligned}$$

Therefore, $\tilde{\mathbf{y}}_o$ satisfies the Kuhn–Tucker necessary and sufficient conditions for the problem in (5.1) and is a solution to that problem. Then (5.2) and Lemma 5.2 imply that

$$\mathbf{y}_o = \frac{\tilde{\mathbf{y}}_o}{\sqrt{\tilde{\mathbf{y}}_n^t B\tilde{\mathbf{y}}_n}}.$$

Therefore, $\mathbf{y}_o \in F(\mathbf{x}_o)$. Therefore the mapping is closed on $\mathbf{x} \geq 0$, $\mathbf{x}^t B\mathbf{x} = 1$. □

Given the results established in Theorems 5.1 and 5.3, the iteration of steps 2 and 3 of the algorithm satisfies the necessary conditions of the Convergence Theorem in [1] (see Theorem 7.2.3). The algorithm will therefore either terminate in a finite number of steps with a solution or generate an infinite sequence such that every convergent subsequence has a limit satisfying the termination conditions. From Lemma 3.1, the feasible region containing any infinite sequence of solutions is compact. Since all points in the sequence of solutions are contained in this compact set, any infinite sequence of solutions will contain at least one convergent subsequence.

The final point left to establish is that the solution at termination or the limit point of at least one convergent subsequence of solutions satisfies the Kuhn–Tucker necessary conditions for Problem 2. In establishing this result, it is assumed that the termination criterion ϵ is arbitrarily close to zero. Therefore, if the algorithm terminates, $\cos^2(\mathbf{w}_{n_o-1}, \mathbf{w}_{\text{opt}}; B) = 1$ where n_o is the index at termination.

The following theorem establishes the fact that when the algorithm terminates with a solution, that solution is a Kuhn–Tucker point of Problem 2.

THEOREM 5.4. *Assume that B is a symmetric, positive semidefinite, and strictly copositive matrix. Then if the algorithm detailed at the beginning of this section terminates with a solution, that solution is a Kuhn–Tucker point of Problem* 2.

Proof. Let n_o be the index at termination. Then $\tilde{\mathbf{w}}_{n_o}$ satisfies the Kuhn–Tucker necessary conditions for the minimization problem in step 2 of the algorithm. That is,

$$\begin{aligned} &\exists\ \tilde{\mathbf{v}}_o,\ \tilde{\lambda}_o \quad \text{s.t.} \\ A\tilde{\mathbf{w}}_{n_o} - \tilde{\lambda}_o B\mathbf{w}_{n_o-1} - \tilde{\mathbf{v}}_o &= 0, \\ \tilde{\mathbf{v}}_o,\ \tilde{\mathbf{w}}_{n_o} &\geq 0, \\ \tilde{\mathbf{v}}_o^t \tilde{\mathbf{w}}_{n_o} &= 0, \\ \mathbf{w}_{n_o-1}^t B\tilde{\mathbf{w}}_{n_o} &= 1. \end{aligned} \tag{5.13}$$

The facts that B is strictly copositive and that $\mathbf{w}_{\text{opt}} = \tilde{\mathbf{w}}_{n_o}/\sqrt{\tilde{\mathbf{w}}_{n_o}^t B\tilde{\mathbf{w}}_{n_o}}$ imply that

$$\begin{aligned} &\exists\ \mathbf{v}_o,\ \lambda_o' \quad \text{s.t.} \\ A\mathbf{w}_{\text{opt}} - \lambda_o' B\mathbf{w}_{n_o-1} - \mathbf{v}_o &= 0, \\ \mathbf{v}_o,\ \mathbf{w}_{\text{opt}} &\geq 0, \\ \mathbf{v}_o^t \mathbf{w}_{\text{opt}} &= 0, \\ \mathbf{w}_{\text{opt}}^t B\mathbf{w}_{\text{opt}} &= 1, \end{aligned} \tag{5.14}$$

where

$$\mathbf{v}_o \triangleq \frac{\tilde{\mathbf{v}}_o}{\sqrt{\tilde{\mathbf{w}}_{n_o}^t B \tilde{\mathbf{w}}_{n_o}}} \text{ and } \lambda_o' \triangleq \frac{\tilde{\lambda}_o}{\sqrt{\tilde{\mathbf{w}}_{n_o}^t B \tilde{\mathbf{w}}_{n_o}}}.$$

Since B is positive semidefinite, it can be decomposed as $B = \tilde{B}^t \tilde{B}$. Then, $\cos^2(\mathbf{w}_{n_o-1}, \mathbf{w}_{opt}; B) = 1$ can be rewritten as $\cos^2(\tilde{B}\mathbf{w}_{n_o-1}, \tilde{B}\mathbf{w}_{opt}; I) = 1$. Therefore

$$\tilde{B}\mathbf{w}_{n_o-1} = a\tilde{B}\mathbf{w}_{opt} \tag{5.15}$$

for some constant a. Right multiplying both sides of (5.15) by $\tilde{B}^t$ yields $B\mathbf{w}_{n_o-1} = a\, B\mathbf{w}_{opt}$. Substituting this into (5.14) and letting $\lambda_o = a\lambda_o'$ result in

$$\begin{aligned} &\exists\ \mathbf{v}_o,\ \lambda_o \quad \text{s.t.} \\ A\mathbf{w}_{opt} - \lambda_o B\mathbf{w}_{opt} - \mathbf{v}_o &= 0, \\ \mathbf{v}_o,\ \mathbf{w}_{opt} &\geq 0, \\ \mathbf{v}_o^t \mathbf{w}_{opt} &= 0, \\ \mathbf{w}_{opt}^t B\mathbf{w}_{opt} &= 1. \end{aligned}$$

These are the Kuhn–Tucker necessary conditions for Problem 2. Therefore, $\mathbf{w}_{opt}$ is a Kuhn–Tucker point of Problem 2. □

The final theorem establishes an analogous result for the case where the algorithm does not terminate.

THEOREM 5.5. *Assume that B is a symmetric, positive semidefinite, and strictly copositive matrix. Then, if the algorithm detailed at the beginning of this section generates an infinite sequence of solutions, then there exists a convergent subsequence of solutions for which the limit point satisfies the Kuhn–Tucker necessary conditions for Problem* 2.

Proof. Define the vector

$$\mathbf{z}_n \triangleq \begin{bmatrix} \mathbf{w}_{n-1} \\ \mathbf{w}_n \end{bmatrix}$$

and the mapping

$$G(\mathbf{z}_n) \triangleq \mathbf{z}_{n+1} = \begin{bmatrix} \mathbf{w}_n \\ F(\mathbf{w}_n) \end{bmatrix}.$$

The fact that F is closed implies that G is also closed. In addition, the function $q(\mathbf{z}_n) = \mathbf{w}_n^t A \mathbf{w}_n$ has already been shown to be a strictly decreasing function of n. Therefore, the convergence results derived for the iteration of the mapping F also apply to the iteration of the mapping G. The same termination criterion,

$$\cos^2(\mathbf{z}_n; B) \triangleq \cos^2(\mathbf{w}_{n-1}, \mathbf{w}_n; B) > (1 - \epsilon) \to 1,$$

is used for both iterations.

Assume that for particular A, B and initial point $\mathbf{w}_o$ the iteration of F generates an infinite sequence. Then for this same A, B, and initial point, the iteration of G generates an infinite sequence. The set of allowable $\mathbf{z}_n$ is a compact set, so this infinite sequence $\mathbf{z}_n$ contains

at least one convergent subsequence whose limit satisfies the termination criterion. (Note that not every convergent subsequence of $\mathbf{w}_n$ corresponds to a convergent subsequence of $\mathbf{z}_n$ but that at least one convergent subsequence of $\mathbf{w}_n$ corresponds to a convergent subsequence of $\mathbf{z}_n$. In addition, every convergent subsequence of $\mathbf{z}_n$ corresponds to a convergent subsequence of $\mathbf{w}_n$.) Denote this limit by

$$\mathbf{z}_{\text{opt}} = \begin{bmatrix} \mathbf{w}'_{\text{opt}} \\ \mathbf{w}_{\text{opt}} \end{bmatrix}.$$

Then $\mathbf{w}_{\text{opt}} = F(\mathbf{w}'_{\text{opt}})$ and $\cos^2(\mathbf{z}_{\text{opt}}; B) = \cos^2(\mathbf{w}'_{\text{opt}}, \mathbf{w}_{\text{opt}}; B) = 1$. Therefore, the results of Theorem 5.4 can be applied by letting $\mathbf{w}_{n_0-1} = \mathbf{w}'_{\text{opt}}$ in the proof. Therefore, $\mathbf{w}_{\text{opt}}$ satisfies the Kuhn–Tucker necessary conditions for Problem 2. □

This completes the characterization of the solutions generated by the algorithm detailed at the beginning of this section. To summarize the constraints on the matrices A and B in order for all of these results to hold, A and B must be positive semidefinite and strictly copositive matrices.

6. Numerical results. The major advantage of the iterative algorithm in §5 (subsequently referred to as the iterative algorithm) with respect to the global optimization routine in §3 (subsequently referred to as the copositivity algorithm) is its greater numerical efficiency. The numerical results presented in this section demonstrate the relative efficiency of the two algorithms.

The programs that implement the algorithms were written for the Matlab software package and executed on a Sun Sparcstation2 workstation. When compared to compiled code written in Fortran or C, the Matlab code is very slow. In addition, the Sparcstation2 processor is much slower than many other available processors. Therefore, these results should be used to evaluate the relative efficiency of the two algorithms and the rate of growth of the execution time as a function of problem size. The absolute execution times shown here are not indicative of what could be achieved with programs written in Fortran or C.

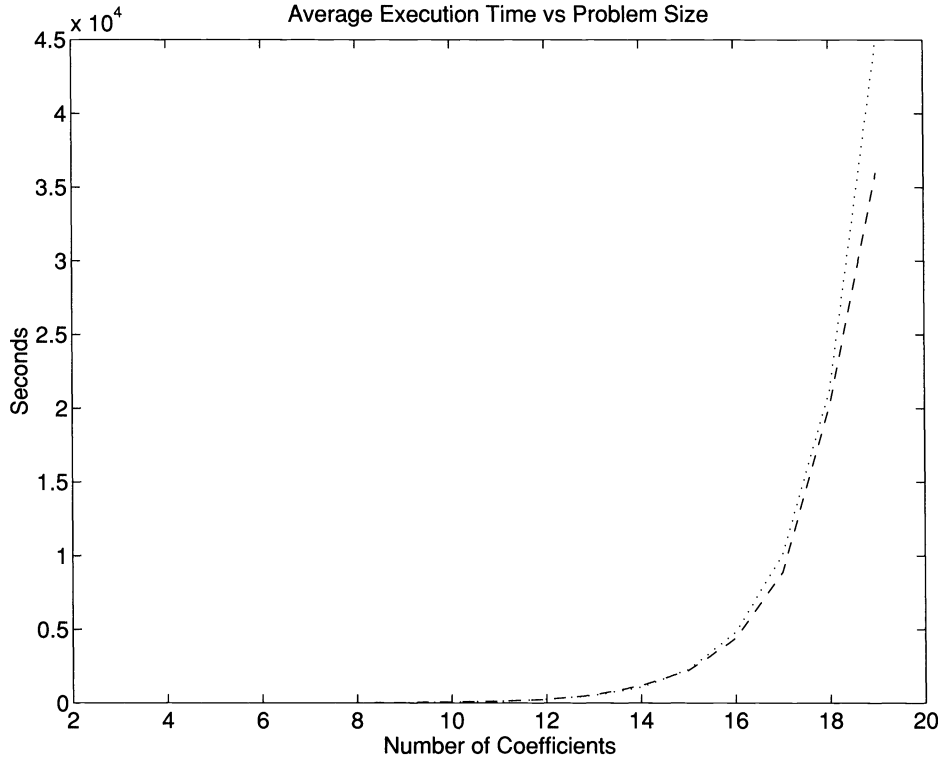
Both algorithms were tested using randomly generated positive semidefinite matrices. A number of trials were run for successively larger problem sizes. Problem size, denoted by n, is the size of the vector $\mathbf{w}$. For each trial, two $n \times n$ random matrices ($\tilde{A}$ and $\tilde{B}$) were generated by Matlab's random number generator. The individual elements of each matrix were Gaussian random variables with a mean of zero and a variance of one. The A and B matrices used by the algorithms for the trial were then given by $A = \tilde{A}^t\tilde{A}$ and $B = \tilde{B}^t\tilde{B}$. No check was conducted to ensure that the matrices A and B were strictly copositive as is required by the iterative algorithm. For the copositivity algorithm, the tolerance of $\epsilon = 10^{-4}$ was used, while for the iterative algorithm, the convergence tolerance of $\epsilon = 0.9999$ was used.

Figures 6.1 and 6.2 show the average execution times ($T[n]$) for the copositivity and iterative algorithms, respectively, as a function of the problem size (i.e., the size of the vector $\mathbf{w}$). In each case, the dashed line shows the measured average execution time while the dotted line shows a parametric model prediction of the average execution time. For the copositivity algorithm, the exponential growth model of

$$\hat{T}[n] = 0.0321 * 2.1057^n$$

was used where $\hat{T}[n]$ is the predicted average execution time in seconds and n is the problem size. For the iterative algorithm, the following polynomial time model was used:

$$\hat{T}[n] = (0.4524 + 0.0340 * n)^{3.5}.$$



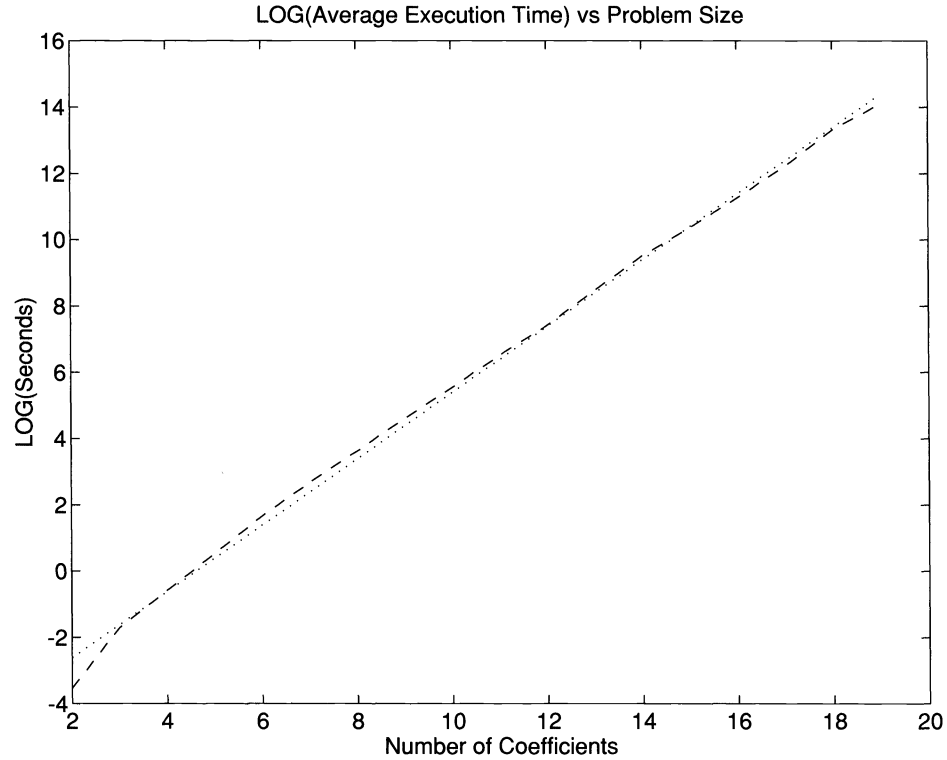


FIG. 6.1. *Average execution times for the copositivity algorithm.*

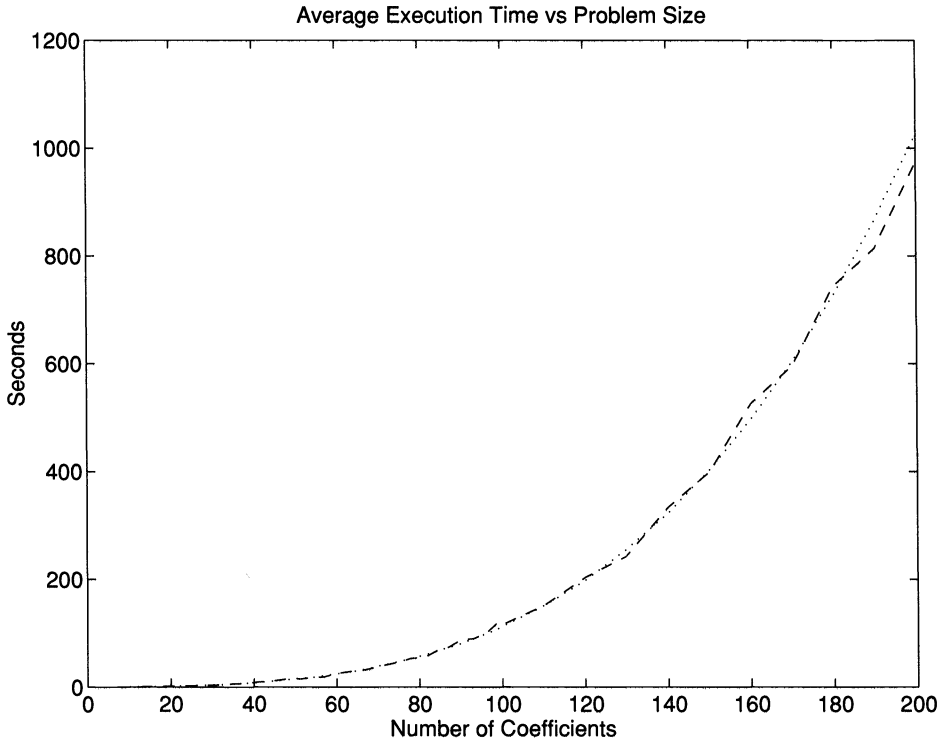

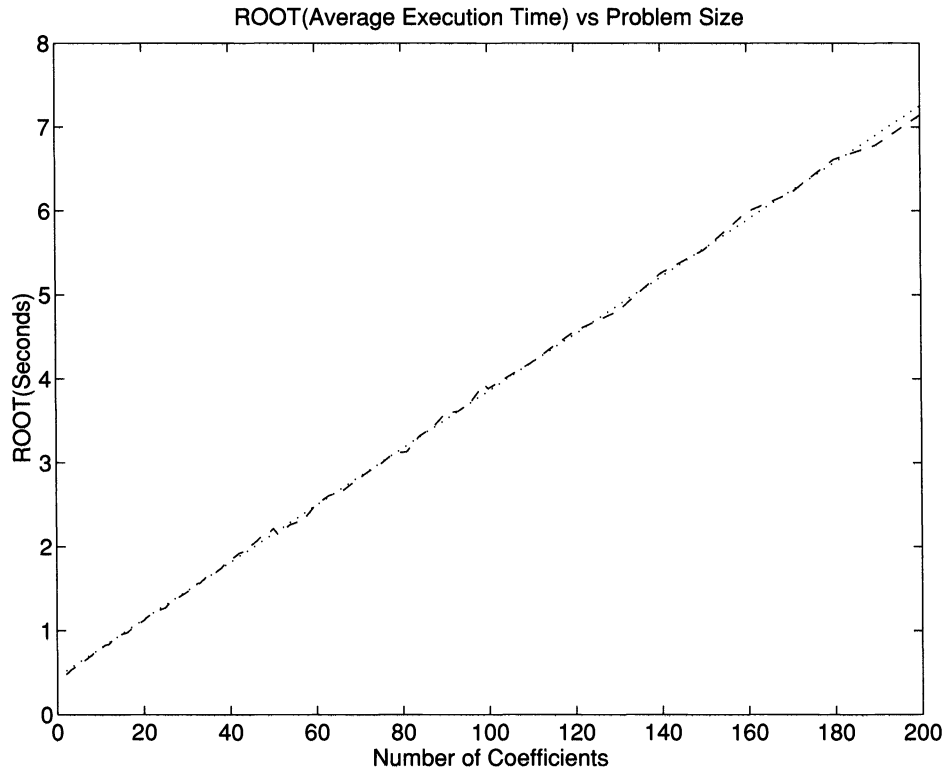

FIG. 6.2. *Average execution times for the iterative algorithm.*

Figures 6.1(a) and 6.2(a) show a strong agreement between the predicted and actual average execution times. In Figure 6.1(b), $\log_{2.1057}(T[n])$ and $\log_{2.1057}(\hat{T}[n]) = n - 4.6182$ are shown while in Figure 6.2(b), $(T[n])^{\frac{1}{3.5}}$ and $(\hat{T}[n])^{\frac{1}{3.5}} = 0.4524 + 0.0340 * n$ are shown. These plots also show strong agreement between the predicted and actual average execution times at all the problem sizes tested. This numerical evidence shows that the copositivity algorithm exhibits exponential growth in execution time while the iterative algorithm exhibits polynomial growth in execution time.

The numerical analysis of the iterative algorithm bears some more discussion. The minimization problem in step 2 of this algorithm is a quadratic programming problem. There are a number of algorithms available for solving this problem, and any of them can be used in implementing the iterative algorithm. The quadratic programming algorithm used to generate the numerical results presented in this section is the complementary pivoting algorithm developed by Lemke [5]. For an explanation and analysis of the complementary pivoting algorithm, see [1, 4, 6]. In general, the complementary pivoting algorithm is guaranteed to terminate with a finite solution if A is positive semidefinite or if A has nonnegative elements and positive diagonal elements (see Theorem 11.2.4 in [1]).

A plot of average execution time per iteration ($\overline{T}[n]$) of the iterative algorithm shows that the majority of the growth in the execution time is due to growth in time per iteration rather than number of iterations. Figures 6.3(a) and (b) show close agreement between the actual average execution time per iteration (dashed line) and that predicted by the model (dotted line)

$$\hat{\overline{T}}[n] = (0.03126 + 0.0179 * n)^{3.23}.$$

Further analysis confirms that the overall polynomial growth term of $n^{3.5}$ for the iterative algorithm can be attributed to a term of $n^{3.23}$ for the growth in average execution time per iteration and a term of $n^{0.27}$ for the growth in average number of iterations required to solve the problem. Further analysis has also shown that approximately 99% of the execution time of each iteration is taken in solving the quadratic programming problem in step 2 of the algorithm. Since quadratic programming algorithms that have better numerical efficiency than Lemke's complementary pivoting algorithm are available, the use of one of these algorithms can make further improvements in the overall numerical efficiency of the iterative algorithm.

7. Conclusions. The algorithms developed above address two problems associated with the minimization of a quadratic objective function subject to nonnegativity and quadratic equality constraints. The first algorithm addresses the problem of finding the global minimum of the quadratic objective function and requires the repeated testing of a particular matrix to determine whether or not it is copositive. The only constraint on the problem is that the Hessian of the quadratic equality constraint (B) be strictly copositive. This problem is NP-complete. The second algorithm addresses the problem of finding a vector that satisfies the Kuhn–Tucker necessary conditions for the minimization problem. The algorithm is shown to converge, and it is further shown that the objective function strictly decreases with each iteration. This algorithm requires the solution of a sequence of quadratic programming problems. The constraints placed on the problem are that the Hessian matrices of both the quadratic objective function (A) and the quadratic constraint function (B) be positive semidefinite and strictly copositive.

Acknowledgments. The author thanks Steven Isabelle and Richard Pawlowicz for their feedback and ideas during the research and the preparation of this paper. In addition, the reviewers are thanked for their constructive input. In particular, their pointing out the relationship of the results herein to previous results in the area of fractional programming was helpful.

PERTURBED OPTIMIZATION IN BANACH SPACES I: A GENERAL THEORY BASED ON A WEAK DIRECTIONAL CONSTRAINT QUALIFICATION*

J. FRÉDÉRIC BONNANS† AND ROBERTO COMINETTI‡

Abstract. Using a directional form of constraint qualification weaker than Robinson's, we derive an implicit function theorem for inclusions and use it for first- and second-order sensitivity analyses of the value function in perturbed constrained optimization. We obtain Hölder and Lipschitz properties and, under a *no-gap* condition, first-order expansions for exact and approximate solutions. As an application, differentiability properties of metric projections in Hilbert spaces are obtained, using a condition generalizing polyhedricity. We also present in the appendix a short proof of a generalization of the convex duality theorem in Banach spaces.

Key words. sensitivity analysis, marginal function, approximate solutions, directional constraint qualification, regularity and implicit function theorems, convex duality

1. Introduction.

This paper is the first of a trilogy devoted to sensitivity analysis of parametrized optimization problems of the form

$$(P_u) \qquad \min_x \{f(x,u) : G(x,u) \in K\}$$

where f and G are C^2 mappings from $X \times \mathbb{R}_+$ to $\mathbb{R}$ and Y, respectively, X and Y are Banach spaces, and K is a closed convex subset of Y.

While the theory is fairly complete in the case of finite-dimensional mathematical programming, that is, optimization problems with finitely many equality and inequality constraints, the sensitivity of perturbed optimization problems in Banach spaces is still being developed. Just to mention a couple of recent works related to this topic, see for instance [3, 8, 9, 11, 19, 21, 26] as well as the monographs [10, 13, 18] and references therein.

Loosely speaking, the assumptions that support a complete sensitivity analysis of the value function and optimal solutions are uniqueness of the optimal solution for the unperturbed problem, constraint qualification, existence of Lagrange multipliers, and second-order sufficient optimality conditions.

Concerning constraint qualification, the standard assumption is Robinson's generalization [23] of the Mangasarian–Fromovitz condition [20]. Following the lines of previous works in mathematical programming [2, 5, 7, 12, 14], in this paper we show that sensitivity analysis is still possible under a weak directional form of constraint qualification that takes into account the nature of perturbations. This condition is used to derive a generalization of Robinson's implicit function theorem for systems of inequalities that, in conjunction with a strong second-order sufficient condition, allows us to obtain first- and second-order upper and under estimates of the marginal function. When these two estimates coincide (we give some sufficient conditions for this) the first-order sensitivity of approximate optimal solutions of (P_u) is obtained.

Our second-order expansion includes a term that takes into account the possible curvature of the boundary of K and does not appear in the classical setting of mathematical programming where K is a polyhedral set. This curvature term, studied in [9, 17] in the context of second-order necessary conditions (see also the previous work [4]), leads to a generalization of the

notion of polyhedric set and to new results on differentiability of metric projections onto convex sets in Hilbert spaces.

We observe that in the case of the trivial perturbation $f(x,u) = f(x,0)$ and $G(x,u) = G(x,0)$ for all u, the directional constraint qualification reduces to Robinson's condition and our upper estimates to the necessary optimality conditions obtained in [9]. Similarly, from our under estimates one can easily derive (new) sufficient conditions for local optimality.

When the strong second-order condition fails, and particularly when the set of Lagrange multipliers is empty, we know that directional differentiability of solutions and of the marginal function may fail [5]. It seems that the directional constraint qualification considered in this paper is too weak to obtain a satisfactory sensitivity analysis in such cases. This motivates a strenghtened form of directional qualification, which is the subject of part II of this work.

Finally, in part III we study the application of both theories to semi-infinite programming, that is to say, optimization problems with X finite dimensional and infinitely many inequality constraints. In that case there is a gap between the upper and lower estimates, so we will fill this gap by computing sharper lower estimates.

We denote the feasible set, optimal value, and solution set of (P_u) as

$$\begin{aligned} F(u) &:= \{x \in X : G(x,u) \in K\}, \\ v(u) &:= \inf\{f(x,u) : x \in F(u)\}, \\ S(u) &:= \{x \in F(u) : f(x,u) = v(u)\}. \end{aligned}$$

Similarly, given an optimization problem (P) we denote by $F(P)$, $v(P)$, and $S(P)$ its feasible set, optimal value, and optimal solution set, respectively.

The set of Lagrange multipliers associated with an optimal solution $x \in S(u)$ is

$$\Lambda_u(x) := \{\lambda \in Y^* : \lambda \in N_K(G(x,u)),\ \mathcal{L}'_x(x,\lambda,u) = 0\}$$

with Y^* denoting the dual space of Y, $N_K(y)$ the normal cone to K at y, and $\mathcal{L}$ the Lagrangian function

$$\mathcal{L}(x,\lambda,u) := f(x,u) + \langle \lambda, G(x,u)\rangle.$$

For the rest of this paper we assume $v(0)$ finite and $S(0)$ nonempty. We also consider a fixed optimal solution $x_0 \in S(0)$ and denote by $\Lambda_0 := \Lambda_0(x_0)$ the corresponding set of multipliers.

Finally, we recall the definition of the first- and second-order tangent sets:

$$T_K(y) := \{h \in Y :\ \text{there exists } o(u) \text{ such that } y + uh + o(u) \in K\},$$

$$T_K^2(y,h) := \left\{k \in Y :\ \text{there exists } o(u^2) \text{ such that } y + uh + \frac{1}{2}u^2 k + o(u^2) \in K\right\}.$$

Throughout this paper $o(u)$ and $o(u^2)$ will be used freely to denote any terms that are negligible compared to u and u^2. Similary, $O(u)$ and $O(u^2)$ denote terms of orders u and u^2.

2. Upper estimates of the value function. We are interested in sensitivity analysis of (P_u), that is to say, the study of differentiability properties of the optimal value function v and the optimal (set-valued) map S. To this end we consider the *linear* and *quadratic* approximating problems:

$$(L) \qquad \min_d \{f'(x_0,0)(d,1) :\ G'(x_0,0)(d,1) \in T_K(G(x_0,0))\},$$

$$(Q) \qquad \min\{v(L_d) :\ d \in S(L)\},$$

$$(L_d) \qquad \min_w \{f'_x(x_0,0)w + \Phi_f(d) :\ G'_x(x_0,0)w + \Phi_G(d) \in T_K^2(d)\},$$

where we have set

$$\Phi_f(d) := f''(x_0, 0)(d, 1)(d, 1),$$
$$\Phi_G(d) := G''(x_0, 0)(d, 1)(d, 1),$$
$$T_K^2(d) := T_K^2(G(x_0, 0), G'(x_0, 0)(d, 1)).$$

The motivation for these approximating problems is the following.

We say that $u \to x_u$ is a *feasible path* if $x_u \in F(u)$ for $u > 0$ small enough and x_u tends to x_0 when $u \downarrow 0$. Suppose that we have a feasible path of the form $x_u = x_0 + ud + o(u)$. A first-order expansion gives $G(x_u, u) = G(x_0, 0) + uG'(x_0, 0)(d, 1) + o(u) \in K$, so d is feasible for (L) and also

$$v(u) \le f(x_u, u) = v(0) + uf'(x_0, 0)(d, 1) + o(u), \tag{1}$$

suggesting that $v(u) \le v(0) + u\ v(L) + o(u)$.

Similarly, if $d \in S(L)$ and $x_u = x_0 + ud + \frac{1}{2}u^2 w + o(u^2)$ is a feasible path, a second-order Taylor expansion of $G(x_u, u)$ shows that $w \in T(L_d)$, and

$$v(u) \le f(x_u, u) = v(0) + u\ v(L) + \frac{1}{2}u^2[f_x'(x_0, 0)w + \Phi_f(d)] + o(u^2), \tag{2}$$

so we may expect $v(u) \le v(0) + u\ v(L) + \frac{1}{2}u^2\ v(Q) + o(u^2)$.

To prove these upper estimates it suffices to show that each $d \in F(L)$ admits an $o(u)$ correction such that $x_0 + ud + o(u) \in F(u)$ and similarly that each $w \in F(L_d)$ admits an $o(u^2)$ correction such that $x_0 + ud + \frac{1}{2}u^2 w + o(u^2) \in F(u)$. The existence of such corrections may be established by using Robinson's regularity theorem [23, Thm. 1], which is based on the constraint qualification condition

$$0 \in \text{int}\,[G(x_0, 0) + G_x'(x_0, 0)X - K]. \tag{CQ}$$

However, this condition does not take into account the specific form of perturbations, so, loosely speaking, it will work uniformly no matter what type of perturbations are being considered. We shall rather use the following refinement of Robinson's regularity theorem proved in Appendix B, which allows us to discriminate those perturbations for which sensitivity analysis can be carried out.

THEOREM B.5. *Let us assume the* directional constraint qualification

$$0 \in \text{int}\,[G(x_0, 0) + G'(x_0, 0)X \times (0, \infty) - K]. \tag{DCQ}$$

Then for each trajectory $x_u = x_0 + O(u)$ there exist constants $c \ge 0, u_0 > 0$ and a second trajectory y_u such that $G(y_u, u) \in K$ and

$$\|y_u - x_u\| \le c\ d(G(x_u, u), K)$$

for all $u \in [0, u_0]$.

It may not be apparent that (CQ) implies (DCQ). To see this we remark (see Appendix B) that the latter is equivalent to

$$0 \in \text{int}\,[G(x_0, 0) + G'(x_0, 0)X \times [0, \infty) - K]. \tag{DCQ}'$$

PROPOSITION 2.1. *Suppose (DCQ) holds. Then* $\limsup_{u \downarrow 0}[v(u) - v(0)]/u \le v(L)$ *and when $v(L) > -\infty$ we have the first-order upper estimate*

$$v(u) \le v(0) + u\ v(L) + o(u). \tag{3}$$

Also, $\limsup_{u\downarrow 0} 2[v(u) - v(0) - u\ v(L)]/u^2 \le v(Q)$ *and when* $v(Q) > -\infty$ *the following second-order upper estimate holds:*

$$v(u) \le v(0) + u\ v(L) + \frac{1}{2}u^2\ v(Q) + o(u^2). \tag{4}$$

Proof. Let d be feasible for (L). Applying Theorem B.5 with $x_u = x_0 + ud$ we find a feasible trajectory y_u such that $\|y_u - x_u\| \le c\ d(G(x_u, u), K) = o(u)$. Then $y_u = x_0 + ud + o(u)$ and the first-order estimate follows from (1).

To prove the second-order estimate, let $d \in S(L)$ and $w \in F(L_d)$. Applying Theorem B.5 with $x_u = x_0 + ud + \frac{1}{2}u^2 w$ we get a feasible trajectory y_u with $\|y_u - x_u\| \le c\ d(G(x_u, u), K) = o(u^2)$. Then $y_u = x_0 + ud + \frac{1}{2}u^2 w + o(u^2)$ and the conclusion follows from (2). □

The above upper estimates are only meaningful if $v(L) < +\infty$ and $v(Q) < +\infty$. Let us then prove the following result.

PROPOSITION 2.2. *Assuming (DCQ) we have* $v(L) < +\infty$. *Moreover, in this case* $v(Q) < +\infty$ *if and only if there exists* $d \in S(L)$ *such that* $T_K^2(d) \ne \phi$.

Proof. Using *(DCQ)* we may find $t > 0$ and $d \in X$ with $G'(x_0, 0)(d, t) \in K - G(x_0, 0)$. Then d/t is feasible for (L) and consequently $v(L) < +\infty$.

Clearly $v(Q) < +\infty$ requires $T_K^2(d) \ne \phi$ for some $d \in S(L)$.

To prove the converse we fix $k \in T_K^2(d)$ so that, according to [9, Prop. 3.1],

$$k + \mathbb{R}_+[T_K(G(x_0, 0)) - G'(x_0, 0)(d, 1)] \subset T_K^2(d). \tag{5}$$

Using *(DCQ)* we find $\mu > 0$ with $\mu[k - \Phi_G(d)] \in G(x_0, 0) + G'(x_0, 0)X \times (0, \infty) - K$, and then for some $z \in X$ and $t > 0$ we get

$$\begin{aligned}\Phi_G(d) &\in k + \frac{1}{\mu}[K - G(x_0, 0) - G'(x_0, 0)(z, t)] \\ &\in k - G'_x(x_0, 0)\frac{z - td}{\mu} + \frac{1}{\mu}[T_K(G(x_0, 0)) - tG'(x_0, 0)(d, 1)].\end{aligned}$$

Letting $w := (z - td)/\mu$ and using (5) we deduce that

$$G'_x(x_0, 0)w + \Phi_G(d) \in k + \frac{t}{\mu}[T_K(G(x_0, 0)) - G'(x_0, 0)(d, 1)] \subset T_K^2(d),$$

proving that (L_d) is feasible and then $v(Q) \le v(L_d) < +\infty$. □

3. Differentiability of the value function and suboptimal trajectories. To find lower estimates of the cost and sufficient conditions for the existence of the right derivative $v'(0)$, we use convex duality theory to get the following characterization for $v(L)$.

PROPOSITION 3.1. *Assume (DCQ). Then* $v(L) = v(D)$ *and* $S(D) \ne \phi$, *where*

$$\max\{\mathcal{L}'_u(x_0, \lambda, 0) : \lambda \in \Lambda_0\}. \tag{D}$$

Moreover, $v(L) > -\infty$ *if and only if* $\Lambda_0 \ne \phi$, *in which case* $S(D)$ *is a nonempty weak* compact subset of* Λ_0.

Proof. This is a consequence of the convex duality theorem of Appendix A, Theorem A.2, applied to problem (L) with the perturbation function

$$\varphi(d, y) := \begin{cases} f'(x_0, 0)(d, 1) & \text{if } G'(x_0, 0)(d, 1) + y \in T_K(G(x_0, 0)), \\ +\infty & \text{otherwise.} \end{cases}$$

Indeed, from (*DCQ*) we get

$$\begin{aligned} Y &= T_K(G(x_0, 0)) - G'(x_0, 0)X \times (0, \infty) \\ &= \mathbb{R}_+ \bigcup_{d \in X} [T_K(G(x_0, 0)) - G'(x_0, 0)(d, 1)], \end{aligned}$$

so $\mathbb{R}_+ \cup_d \operatorname{dom} \varphi(d, \cdot) = Y$ and Theorem A.2 can be used to deduce

$$v(L) = -\min_{\lambda} \varphi^*(0, \lambda). \tag{6}$$

A straightforward computation shows that

$$\varphi^*(x^*, \lambda) = \begin{cases} -\mathcal{L}'_u(x_0, \lambda, 0) & \text{if } \lambda \in N_K(G(x_0, 0)), \mathcal{L}'_x(x_0, \lambda, 0) = x^*, \\ +\infty & \text{otherwise,} \end{cases}$$

which combined with (6) yields the desired conclusions. □

We state our next results using suboptimal paths. We say that x_u is an $o(u)$-*optimal trajectory* if it is a feasible path and $v(u) = f(x_u, u) + o(u)$.

Existence of $o(u)$- and $o(u^2)$-optimal paths requires finiteness of $v(u)$. Conversely, when the latter holds, one may always find $o(u)$ or $o(u^2)$ approximate solutions of (P_u). The fact that these paths do converge to x_0 as u tends to 0 can be proved in a number of particular situations (see for instance [6, 12]).

In addition, we shall either assume Hölder and Lipschitz stability of these suboptimal paths (these assumptions will be discussed in §6) or we shall suppose that problem (P_0) is convex in the sense that for all $y \in K$ and $\lambda \in N_K(y)$ the mapping $\mathcal{L}(\cdot, \lambda, 0)$ is convex. The next result, under the convexity assumption, extends that given by Gol'stein [15].

PROPOSITION 3.2. *Suppose that (DCQ) holds, there exists an $o(u)$-optimal trajectory x_u, and either (P_0) is convex or $x_u = x_0 + o(\sqrt{u})$. Then v is right differentiable at 0 with $v'(0) = v(L)$. Moreover, when $\Lambda_0 \neq \phi$ we have*

$$v(u) = v(0) + u\, v(L) + o(u).$$

Proof. If $\Lambda_0 = \phi$ we have $v(L) = -\infty$ and the result follows immediately from Proposition 2.1. Otherwise, by Proposition 3.1 we may take $\lambda \in S(D) \subset \Lambda_0$ so that

$$\begin{aligned} v(u) - v(0) &= f(x_u, u) - f(x_0, 0) + o(u) \\ &\geq \mathcal{L}(x_u, \lambda, u) - \mathcal{L}(x_0, \lambda, 0) + o(u). \end{aligned}$$

Since $\mathcal{L}'_x(x_0, \lambda, 0) = 0$, when (P_0) is convex we get $\mathcal{L}(x_0, \lambda, 0) \leq \mathcal{L}(x_u, \lambda, 0)$ and when $x_u = x_0 + o(\sqrt{u})$ a second-order expansion gives $\mathcal{L}(x_0, \lambda, 0) = \mathcal{L}(x_u, \lambda, 0) + o(u)$. In both cases we obtain

$$v(u) - v(0) \geq \mathcal{L}(x_u, \lambda, u) - \mathcal{L}(x_u, \lambda, 0) + o(u)$$

and, since x_u tends to x_0, deduce that

$$\liminf_{u \downarrow 0} \frac{v(u) - v(0)}{u} \geq \mathcal{L}'_u(x_0, \lambda, 0) = v(D) = v(L),$$

which combined with Proposition 2.1 yields the desired conclusions. □

As a further consequence we establish a relation between the solution set $S(L)$ and the right derivatives of suboptimal trajectories.

PROPOSITION 3.3. *With the assumptions of Proposition* 3.2 *we have:*

(a) *$S(L)$ is the set of all weak accumulation points of $(x_u - x_0)/u$, where x_u ranges over all possible $o(u)$-optimal trajectories.*

(b) *If $S(L) \neq \phi$, then there exists an $o(u)$-optimal trajectory such that $x_u = x_0 + O(u)$. The converse holds if X is reflexive.*

(c) *If x_u is chosen as in* (b), *then $\Lambda_u(x_u)$ is uniformly bounded for u small. Moreover, if $\lambda_u \in \Lambda_u(x_u)$, then every weak* accumulation point of λ_u belongs to $S(D)$.*

Proof. (a) Let x_u be an $o(u)$-optimal trajectory and $u_k \downarrow 0$ be such that $(x_{u_k} - x_0)/u_k \rightharpoonup d$. Then we have $[G(x_{u_k}, u_k) - G(x_0, 0)]/u_k \rightharpoonup G'(x_0, 0)(d, 1)$ and, since $T_K(G(x_0, 0))$ is weakly closed, deduce that $G'(x_0, 0)(d, 1) \in T_K(G(x_0, 0))$, proving that $d \in F(L)$. Similarly, $[f(x_{u_k}, u_k) - f(x_0, 0)]/u_k \to f'(x_0, 0)(d, 1)$ and then

$$v(u_k) = f(x_{u_k}, u_k) + o(u_k) = v(0) + u_k f'(x_0, 0)(d, 1) + o(u_k),$$

so Proposition 2.1 implies $f'(x_0, 0)(d, 1) \leq v(L)$, which shows $d \in S(L)$.

Conversely, let $d \in S(L)$ and apply Theorem B.5 to the trajectory $x_u = x_0 + ud$ to find $y_u = x_0 + ud + o(u) \in F(u)$. Proposition 3.2 then implies

$$f(y_u, u) = f(x_0, 0) + uf'(x_0, 0)(d, 1) + o(u) = v(0) + u\, v(L) + o(u) = v(u) + o(u),$$

proving that y_u is an $o(u)$-optimal trajectory with $(y_u - x_0)/u \rightharpoonup d$ (notice that the limit can be taken in the strong sense as well).

(b) The argument developed in (a) shows that $S(L) \neq \phi$ implies the existence of $o(u)$-optimal trajectories with $x_u = x_0 + O(u)$. Conversely, if such a trajectory exists, then by reflexivity we may find a sequence $u_k \downarrow 0$ such that $(x_{u_k} - x_0)/u_k$ converges weakly. From (a) the limit belongs to $S(L)$, which is then nonempty.

(c) Let $\lambda_u \in \Lambda_u(x_u)$ and select $r_u \in B_Y$ with $\|\lambda_u\|/2 \leq \langle r_u, -\lambda_u \rangle$. From relation (17) in Lemma B.4, for all u small enough there exist $d_u \in B_X$ and $k_u \in K$ such that

$$u\varepsilon r_u = G(x_u, u) + umG'_x(x_0, 0)d_u - k_u$$

where $\varepsilon > 0$ and $m > 0$ are given constants. Taking the product with $-\lambda_u$ we get

$$\begin{aligned}
\frac{\varepsilon}{2}\|\lambda_u\| &\leq m\langle \lambda_u, G'_x(x_0, 0)d_u \rangle \\
&\leq m\|G'_x(x_0, 0) - G'_x(x_u, u)\|\|\lambda_u\| + m\langle \lambda_u, G'_x(x_u, u)d_u \rangle \\
&\leq \frac{\varepsilon}{4}\|\lambda_u\| - mf'_x(x_u, u)d_u \\
&\leq \frac{\varepsilon}{4}\|\lambda_u\| + m(\|f'_x(x_0, 0)\| + 1)
\end{aligned}$$

for u small, and the desired uniform bound on $\Lambda_u(x_u)$ follows.

Now let $\lambda := \lim_k \lambda_{u_k}$ be a weak* accumulation point of λ_u where $u_k \downarrow 0$. Then

$$\begin{aligned}
&\forall y \in K \qquad \langle \lambda, y - G(x_0, 0) \rangle = \lim_k \langle \lambda_{u_k}, y - G(x_{u_k}, u_k) \rangle \leq 0, \\
&\forall d \in X \qquad \mathcal{L}'_x(x_0, \lambda, 0)d = \lim_k \mathcal{L}'_x(x_{u_k}, \lambda_{u_k}, u_k)d = 0,
\end{aligned}$$

proving that $\lambda \in \Lambda_0 = F(D)$. To show λ is also optimal for (D) we observe that

$$\begin{aligned}
v(u) &\leq f(x_u, u) \\
&\leq f(x_u, u) - \langle \lambda_u, G(x_0, 0) - G(x_u, u) \rangle \\
&= v(0) + \mathcal{L}(x_u, \lambda_u, u) - \mathcal{L}(x_0, \lambda_u, 0) \\
&= v(0) + u\mathcal{L}'_u(x_0, \lambda_u, 0) + o(u + \|x_u - x_0\|).
\end{aligned}$$

Dividing by u and passing to the limit in the subsequence u_k we get $\mathcal{L}'_u(x_0, \lambda, 0) \geq v'(0) = v(D)$, so $\lambda \in S(D)$. □

Remark. In part (a) above we also showed that $S(L)$ is the set of all *strong* limits of differential quotients of the type $(x_{u_k} - x_0)/u_k$ with $u_k \downarrow 0$ and even the set of *continuous* strong limits

$$d := \lim_{u \downarrow 0} \frac{x_u - x_0}{u},$$

where now x_u ranges over all $o(u)$-optimal trajectories for which this limit exists.

4. Second-order expansion of the value function. In this section we supplement Proposition 2.1 by deriving second-order lower estimates for the value function. The next simple result shows that (4) is a sharp bound.

PROPOSITION 4.1. *Suppose (DCQ) holds and assume there exists an $o(u^2)$-optimal path x_u that admits an expansion of the form $x_u = x_0 + ud_0 + \frac{1}{2}u^2 w_0 + o(u^2)$. Then $d_0 \in S(Q)$, $w_0 \in S(L_{d_0})$, and we have*

$$v(u) = v(0) + u\, v(L) + \frac{1}{2}u^2\, v(Q) + o(u^2).$$

Proof. Propositions 3.2 and 3.3(a) imply $v'(0) = v(L)$ and $d_0 \in S(L)$. On the other hand, a second-order expansion of $G(x_u, u)$ shows that $w_0 \in F(L_{d_0})$ and also

$$\begin{aligned} v(u) &= f(x_u, u) + o(u^2) \\ &= f(x_0, 0) + uf'(x_0, 0)(d_0, 1) + \frac{1}{2}u^2[f'_x(x_0, 0)w_0 + \Phi_f(d_0)] + o(u^2) \\ &= v(0) + u\, v(L) + \frac{1}{2}u^2[f'_x(x_0, 0)w_0 + \Phi_f(d_0)] + o(u^2), \end{aligned}$$

which combined with Proposition 2.1 gives the desired conclusions. □

Unfortunately this result is of more theoretical than practical interest since we must ensure a priori the existence of a second-order expansion of x_u. While it is possible to find conditions giving a first-order expansion (see §6), we dispose of no analogue for the second-order case. To overcome this difficulty we tackle the second-order lower estimates using duality theory as was done in the previous section for the first order. Let us then dualize problem (L_d).

PROPOSITION 4.2. *Suppose (DCQ) holds. Then $v(L_d) = v(D_d)$ where*

$$(D_d) \qquad \max\{\mathcal{L}''(x_0, \lambda, 0)(d, 1)(d, 1) - \sigma(\lambda, T_K^2(d)) : \lambda \in S(D)\},$$

and $\sigma(\lambda, T_K^2(d)) := \sup\{\langle \lambda, k\rangle : k \in T_K^2(d)\}$ is the support function of $T_K^2(d)$. Moreover the solution set $S(D_d)$ is nonempty.

Proof. The case $T_K^2(d) = \phi$ being trivial, we shall assume $T_K^2(d) \neq \phi$ (notice that in this case $d \in F(L)$). Let us consider problem (L_d) with the perturbation function

$$\varphi(w, y) := \begin{cases} f'_x(x_0, 0)w + \Phi_f(d) & \text{if } G'_x(x_0, 0)w + \Phi_G(d) + y \in T_K^2(d), \\ +\infty & \text{otherwise.} \end{cases}$$

To apply Theorem A.2 we must check that $\mathbb{R}_+ \cup_w \operatorname{dom} \varphi(w, \cdot) = Y$. To this end we fix $k \in T_K^2(d)$ and use property (5) to get

$$\begin{aligned} \bigcup_w \operatorname{dom} \varphi(w, \cdot) &= T_K^2(d) - G'_x(x_0, 0)X - \Phi_G(d) \\ &\supset k + T_K(G(x_0, 0)) - G'(x_0, 0)X \times (0, \infty) - \Phi_G(d) \\ &= Y, \end{aligned}$$

the last equality since (*DCQ*) implies $T_K(G(x_0, 0)) - G'(x_0, 0)X \times (0, \infty) = Y$.

We may then use the convex duality theorem to deduce

$$v(L_d) = -\min_{\lambda} \varphi^*(0, \lambda)$$

and a straightforward computation to obtain

$$\varphi^*(0, \lambda) = \begin{cases} \sigma(\lambda, T_K^2(d)) - \mathcal{L}''(x_0, \lambda, 0)(d, 1)(d, 1) & \text{if } \mathcal{L}'_x(x_0, \lambda, 0) = 0, \\ +\infty & \text{otherwise.} \end{cases}$$

To complete the proof we note that if λ satisfies $\mathcal{L}'_x(x_0, \lambda, 0) = 0$, we may have $\sigma(\lambda, T_K^2(d)) < +\infty$ only if $\lambda \in S(D)$ (and $d \in S(L)$). Indeed, if $\sigma(\lambda, T_K^2(d)) < +\infty$, property (5) shows that

$$\langle \lambda, h - G'(x_0, 0)(d, 1) \rangle \leq 0 \quad \text{for all } h \in T_K(G(x_0, 0)).$$

This implies $\lambda \in N_K(G(x_0, 0))$; hence $\lambda \in \Lambda_0$, and also $\langle \lambda, G'(x_0, 0)(d, 1) \rangle \geq 0$ so that

$$f'(x_0, 0)(d, 1) \leq \mathcal{L}'(x_0, \lambda, 0)(d, 1) = \mathcal{L}'_u(x_0, \lambda, 0).$$

Since $\lambda \in F(D)$ and $d \in F(L)$, this inequality proves that $\lambda \in S(D)$ and $d \in S(L)$. □

With this result we have the following min-max characterization of $v(Q)$:

$$v(Q) = \min_{d \in S(L)} \max_{\lambda \in S(D)} \mathcal{L}''(x_0, \lambda, 0)(d, 1)(d, 1) - \sigma(\lambda, T_K^2(d)).$$

The term $\sigma(\lambda, T_K^2(d))$ above will be referred to as the "σ-term" for short and is related, loosely speaking, to the curvature of the set K (see also [9, 17]). Neglecting this σ-term we obtain second-order lower estimates that, however, may not be sharp. To be precise, let us consider the function

$$\Gamma(d) := \max_{\lambda \in S(D)} \mathcal{L}''(x_0, \lambda, 0)(d, 1)(d, 1)$$

and the optimization problems

$$(\tilde{Q}) \qquad \min\{\Gamma(d) : d \in S(L)\},$$

$$(\tilde{Q}_\varepsilon) \qquad \min\{\Gamma(d) : d \in S_\varepsilon(L)\},$$

where $S_\varepsilon(L)$ is the set of approximate solutions of (L)

$$S_\varepsilon(L) := \{d \in F(L) : f'(x_0, 0)(d, 1) \leq v(L) + \varepsilon\}.$$

To obtain meaningful second-order lower bounds we must assume that $v(L) > -\infty$. By Proposition 3.3 this amounts to $\Lambda_0 \neq \phi$, in which case $S(D)$ is a weak* compact subset of Λ_0.

PROPOSITION 4.3. *Suppose (DCQ) holds, $\Lambda_0 \neq \phi$, and assume there exists an $o(u^2)$-optimal path x_u such that $x_u = x_0 + O(u)$. Then, for each $\varepsilon > 0$ we have*

$$v(u) \geq v(0) + u\, v(L) + \frac{1}{2} u^2\, v(\tilde{Q}_\varepsilon) + o(u^2). \tag{7}$$

Moreover, if any of the following conditions hold:

(a) *the path may be expanded as $x_u = x_0 + u d_0 + o(u)$,*

(b) *X is reflexive and Γ is weakly l.s.c. at each $d_0 \in S(L)$,*

then the previous lower bound may be strengthened to

$$v(u) \geq v(0) + u\, v(L) + \frac{1}{2}u^2\, v(\tilde{Q}) + o(u^2). \tag{8}$$

Proof. For each $\lambda \in S(D)$ we have

$$\begin{aligned} v(u) &= f(x_u, u) + o(u^2) \\ &\geq f(x_u, u) + \langle \lambda, G(x_u, u) - G(x_0, 0)\rangle + o(u^2) \\ &= v(0) + \mathcal{L}(x_u, \lambda, u) - \mathcal{L}(x_0, \lambda, 0) + o(u^2) \\ &= v(0) + u\, v(L) + \frac{1}{2}\mathcal{L}''(x_0, \lambda, 0)(x_u - x_0, u)(x_u - x_0, u) + o(u^2) \end{aligned} \tag{9}$$

and the small term $o(u^2)$ may be chosen uniform in λ since $S(D)$ is bounded.

Applying Theorem B.4 to the mapping $\tilde{G}(x, u) := G(x_0, 0) + G'(x_0, 0)(x - x_0, u)$ we find a path y_u with $\tilde{G}(y_u, u) \in K$ and

$$\|y_u - x_u\| \leq c\, d(\tilde{G}(x_u, u), K) \leq c\, \|\tilde{G}(x_u, u) - G(x_u, u)\| = o(u). \tag{10}$$

Replacing in (9) we find

$$v(u) \geq v(0) + u\, v(L) + \frac{1}{2}\mathcal{L}''(x_0, \lambda, 0)(y_u - x_0, u)(y_u - x_0, u) + o(u^2)$$

with $o(u^2)$ still independent of λ. Thus, letting $d_u := (y_u - x_0)/u$ and taking the supremum in λ over the bounded set $S(D)$, we get

$$v(u) \geq v(0) + u\, v(L) + \frac{1}{2}u^2\Gamma(d_u) + o(u^2). \tag{11}$$

But $\tilde{G}(y_u, u) \in K$ implies $d_u \in F(L)$, and the equality $v(u) = f(x_u, u) + o(u^2) = f(y_u, u) + o(u)$ implies that for each $\varepsilon > 0$ the vector d_u belongs to $S_\varepsilon(L)$ for u small, so (7) follows immediately from (11).

Let us next choose $u_k \downarrow 0$, realizing the lower limit $\liminf_u 2[v(u) - v(0) - uv(L)]/u^2$. When (a) holds we have $d_{u_k} \to d_0$, while in case (b) we may assume (by eventually passing to a subsequence) that d_{u_k} converges weakly to some d_0. In both cases Proposition 3.3 implies $d_0 \in S(L)$ and using (11) (and the l.s.c. of Γ) we get

$$v(u_k) \geq v(0) + u_k\, v(L) + \frac{1}{2}u_k^2\Gamma(d_0) + o(u_k^2), \tag{12}$$

from which (8) follows. □

5. Asymptotic expansions of suboptimal solutions. In this section we prove the analogue of Proposition 3.3 for the second-order problem (Q). Roughly speaking, the solution set $S(Q)$ is the set of right derivatives of $o(u^2)$-optimal paths.

This result is obtained under a strong assumption, namely, that there exists no gap between the upper and lower estimates (4) and (8). This *no-gap* condition is not true in general—we will see in part III that semi-infinite programming does not satisfy this property—but is still valid for a large class of applications, one of which will be considered in §7.

The next result gives sufficient conditions for having no gap.

PROPOSITION 5.1. (a) *For $\lambda \in S(D)$ and $d \in S(L)$ one has $\sigma(\lambda, T_K^2(d)) \leq 0$.*

(b) *If $d \in S(L)$ and $0 \in T_K^2(d)$, then $\sigma(\lambda, T_K^2(d)) = 0$ for all $\lambda \in S(D)$.*

(c) *If $0 \in T_K^2(d)$ for all d in a (strongly) dense subset of $S(L)$, then $v(Q) = v(\tilde{Q})$.*

Proof. For all $\lambda \in S(D)$ and $d \in S(L)$ we have $\langle \lambda, G'(x_0, 0)(d, 1)\rangle = 0$. Moreover, since $\lambda \in N_K(G(x_0, 0))$, for each $k \in T_K^2(d)$ we get

$$\langle \lambda, G(x_0, 0) + uG'(x_0, 0)(d, 1) + \frac{1}{2}u^2 k + o(u^2) - G(x_0, 0)\rangle \leq 0,$$

from which $\langle \lambda, k\rangle \leq 0$ and (a) follows.

Property (b) is obvious from (a). To prove (c) we notice that (a) implies $v(Q) \geq v(\tilde{Q})$, so we must only show the converse inequality. To this end it suffices to assume $S(L) \neq \phi$, in which case $S(D)$ is weak* compact and then Γ is strongly continuous. The required inequality follows using (b). □

Note that $0 \in T_K^2(y, h)$ when K is polyhedral in the sense that $T_K(y) = \mathbb{R}_+(K - y)$. This is the case for optimization problems with equality constraints and finitely many inequality constraints, where $K = \{0\} \times \mathbb{R}_-^p$. Thus, the condition "$0 \in T_K^2(d)$ for all d in a dense subset of $S(L)$" may be interpreted as a generalization of polyhedrality which, in a certain sense, rules out any curvature of K. We shall refer to this condition as *extended polyhedricity* (see also the discussion at the end of §7).

COROLLARY 5.2. *Let the hypothesis of Proposition* 4.3(b) *be satisfied, and suppose that the extended polyhedricity condition holds. Then* $v(Q) = v(\tilde{Q})$ *and we have*

$$v(u) = v(0) + u\, v(L) + \frac{1}{2}u^2\, v(Q) + o(u^2).$$

The previous results raise the question whether a second-order expansion compatible with curvature may hold. In this sense, we mention that the *sharp* lower estimate

$$v(u) \geq v(0) + u\, v(L) + \frac{1}{2}u^2\, v(Q) + o(u^2) \tag{13}$$

holds under assumption (a) of Proposition 4.3 and the additional hypothesis:

(H) For all sequences $u_n \downarrow 0$ and $y_n = y + u_n h + o(u_n) \in K$, there exists $k_n \in T_K^2(y, h)$ with $y_n = y + u_n h + \frac{1}{2}u_n^2 k_n + o(u_n^2)$.

The proof is similar to that of Proposition 4.3 and is left to the reader. In the case of assumption (b) in Proposition 4.3, (H) must be suitably modified in terms of weakly convergent sequences.

While (H) is not always satisfied, we observe that it holds whenever $0 \in T_K^2(y, h)$. To see that (H) is in fact more general than the latter one may consider the set $K = \{(x, y) \in \mathbb{R}^2 : y \geq x^2\}$ that satisfies (H) but $0 \notin T_K^2(y, h)$. Unfortunately, we do not know an easy way to check (H) in the general case. Nevertheless, in part III of this work we obtain sufficient conditions for obtaining the sharp lower estimate (13) in semi-infinite programming problems.

The next result links $S(Q)$ with the asymptotic behavior of suboptimal paths. Part (b) is a converse of Proposition 4.1.

PROPOSITION 5.3. *Suppose (DCQ) holds,* $\Lambda_0 \neq \phi$, *there exists an* $o(u^2)$*-optimal path* x_u *such that* $x_u = x_0 + O(u)$, *and suppose in addition that* $v(Q) = v(\tilde{Q})$ *and* Γ *is weakly l.s.c. at every* $d \in S(L)$. *Then:*

(a) $S(Q) \subset S(\tilde{Q})$ *and for every* $o(u^2)$*-optimal path* z_u, *the weak accumulation points of* $(z_u - x_0)/u$ *belong to* $S(\tilde{Q})$.

(b) *If* X *is reflexive,* $d_0 \in S(Q)$, *and* $w_0 \in S(L_{d_0})$, *then there exists an* $o(u^2)$*-optimal path of the form* $z_u = x_0 + ud_0 + \frac{1}{2}u^2 w_0 + o(u^2)$.

Proof. (a) Since $v(Q) = v(\tilde{Q})$ and the cost of (Q) dominates the cost of $(\tilde{Q})$, we deduce $S(Q) \subset S(\tilde{Q})$. If d_0 is the weak limit of $(z_{u_k} - x_0)/u$, reasoning as in the proof of (9) and using (4) we obtain $v(Q) \geq \Gamma(d_0)$. But Proposition 3.3 implies $d_0 \in S(L)$, so $\Gamma(d_0) \geq v(\tilde{Q}) = v(Q)$ and then $d_0 \in S(\tilde{Q})$.

(b) Using Theorem B.4 we may find a feasible path $z_u = x_0 + ud_0 + \frac{1}{2}u^2 w_0 + o(u^2)$. Expanding $f(z_u, u)$ we get

$$\begin{aligned} f(z_u, u) &= f(x_0, 0) + uf'(x_0, 0)(d_0, 1) + \frac{1}{2}u^2[f'_x(x_0, 0)w_0 + \Phi_f(d_0)] + o(u^2) \\ &= v(0) + uv(L) + \frac{1}{2}u^2 v(Q) + o(u^2) \\ &= v(0) + uv(L) + \frac{1}{2}u^2 v(\tilde{Q}) + o(u^2) \\ &\leq v(u) + o(u^2), \end{aligned}$$

where the last inequality follows from Proposition 4.3. This shows that z_u is $o(u^2)$-optimal and the proof is complete. □

Remark. In the next section we check that, under some reasonable hypothesis, every $o(u^2)$-optimal path satisfies $x_u = x_0 + O(u)$. When X is reflexive this implies the existence of weak accumulation points of $(x_u - x_0)/u$, so that $S(\tilde{Q})$ is nonempty. We also observe that when $0 \in T_K^2(d)$ for all $d \in S(L)$, the cost function in (Q) and $(\tilde{Q})$ coincide so that $S(Q) = S(\tilde{Q})$.

6. Hölder and Lipschitz properties of suboptimal paths. We discuss next the Hölder and Lipschitz stability properties of suboptimal paths assumed in the previous sections. The results we present are simple variants of known results (e.g., [8, 12, 14, 26]). The essential difference lies in the use of the weaker directional regularity condition (DCQ) and the extension to the infinite-dimensional setting.

Typically, the stability properties follow from different second-order sufficient optimality conditions. More precisely, for each set $\Omega \subset \Lambda_0$ we consider the second-order condition

$$SOC(\Omega) \qquad \text{There exist } \alpha, \eta > 0 \text{ s.t. } \max_{\lambda \in \Omega} \mathcal{L}''_x(x_0, \lambda, 0)dd \geq \alpha \quad \forall\, d \in C_\eta,$$

where

$$C_\eta = \{d \in X : \|d\| = 1,\ f'_x(x_0, 0)d \leq \eta,\ G'_x(x_0, 0)d \in T_K(G(x_0, 0)) + \eta B_Y\}.$$

When the space X is finite dimensional, or more generally when C_η is strongly compact for some $\eta > 0$, this condition is equivalent to the positive definiteness requirement:

$$SOC'(\Omega) \qquad \text{For each } d \in C_0 \text{ we have } \max_{\lambda \in \Omega} \mathcal{L}''_x(x_0, \lambda, 0)dd > 0,$$

where only the *critical cone* C_0 needs to be considered. Also, when (CQ) holds, one can replace C_η by a smaller set (see [8]).

PROPOSITION 6.1. *Assume (DCQ), $\Lambda_0 \neq \phi$, and suppose $SOC(\Omega)$ holds for some bounded $\Omega \subset \Lambda_0$. Then for each $O(u)$-optimal path x_u we have $x_u = x_0 + O(\sqrt{u})$.*

Proof. By contradiction suppose there exists $u_k \downarrow 0$ such that $\lim_k \tau_k^2/u_k = +\infty$, where $\tau_k := \|x_{u_k} - x_0\|$.

Then $\lim_k u_k/\tau_k = 0$ and letting $d_k := (x_{u_k} - x_0)/\tau_k$ we have $G(x_{u_k}, u_k) = G(x_0, 0) + \tau_k G'_x(x_0, 0)d_k + o(\tau_k)$ so that $G'_x(x_0, 0)d_k \in T_K(G(x_0, 0)) + \eta B_Y$ for k large. On the other hand, since x_u is an $O(u)$-optimal path and using Proposition 2.1, we may find a constant M such that for u small

$$f(x_u, u) \leq v(0) + Mu, \tag{14}$$

and since $f(x_{u_k}, u_k) = f(x_0, 0) + \tau_k f'_x(x_0, 0)d_k + o(\tau_k)$, we deduce $f'_x(x_0, 0)d_k \leq \eta$ for all k large enough. The previous argument shows that $d_k \in C_\eta$ for large k.

Now, using (14), for each $\lambda \in \Omega$ we have

$$\mathcal{L}(x_u, \lambda, u) - \mathcal{L}(x_0, \lambda, 0) \leq f(x_u, u) - f(x_0, 0) \leq Mu,$$

and since $\mathcal{L}'_x(x_0, \lambda, 0) = 0$, a second-order expansion of f and G leads to

$$\frac{1}{2}\mathcal{L}''(x_0, \lambda, 0)(x_u - x_0, u)(x_u - x_0, u) \leq [M - \mathcal{L}'_u(x_0, \lambda, 0)]u + (1 + \|\lambda\|)o(\|x_u - x_0\|^2 + u^2)$$

with the small term $o(\|x_u - x_0\|^2 + u^2)$ not depending on λ. Since Ω is bounded, we deduce that

$$\max_{\lambda\in\Omega} \mathcal{L}''(x_0, \lambda, 0)(d_k, u_k/\tau_k)(d_k, u_k/\tau_k) \leq M' \frac{u_k}{\tau_k^2} + M'' \frac{o(\tau_k^2 + u_k^2)}{\tau_k^2}$$

for some constants M' and M'', from which we get

$$\limsup_{k\to\infty} \max_{\lambda\in\Omega} \mathcal{L}''_x(x_0, \lambda, 0)d_k d_k \leq 0,$$

contradicting $SOC(\Omega)$. □

COROLLARY 6.2. *Assume $\Lambda_0 \neq \phi$ and any of the two following conditions:*

(a) *(CQ) and $SOC(\Lambda_0)$,*

(b) *(DCQ), C_η is strongly compact for some $\eta > 0$, and $SOC'(\Lambda_0)$.*

Then for each $O(u)$-optimal path x_u we have $x_u = x_0 + O(\sqrt{u})$.

Proof. In case (a) the set $\Omega := \Lambda_0$ is bounded and the result follows at once from the previous proposition.

In case (b) the set C_0 is compact and then, letting $\Lambda_0^k := \Lambda_0 \cap B(0, k)$, we get

$$\lim_{k\uparrow\infty} \min_{d\in C_0} [\max_{\lambda\in\Lambda_0^k} \mathcal{L}''_x(x_0, \lambda, 0)dd] = \min_{d\in C_0} [\max_{\lambda\in\Lambda_0} \mathcal{L}''_x(x_0, \lambda, 0)dd] > 0.$$

Hence, for k large $SOC'(\Omega)$ holds with $\Omega := \Lambda_0^k$, and we may conclude again using the previous proposition. □

The preceding results are not as strong as to ensure the property $x_u = x_0 + o(\sqrt{u})$ needed in Proposition 3.2. Let us then prove a Lipschitz stability result, valid for general Banach spaces, that can be used to check the hypothesis of both Proposition 4.3 and Proposition 3.2.

PROPOSITION 6.3. *Suppose (DCQ), $\Lambda_0 \neq \phi$, and assume $SOC(\Omega)$ holds for $\Omega := S(D)$. Suppose also that $v(Q) < +\infty$. Then, for each $O(u^2)$-optimal path x_u we have $x_u = x_0 + O(u)$.*

Proof. The proof is similar to that of Proposition 6.1. We proceed by contradiction assuming $\lim_k \tau_k/u_k = +\infty$ for a given sequence $u_k \downarrow 0$ and $\tau_k := \|x_{u_k} - x_0\|$, so that $d_k := (x_{u_k} - x_0)/\tau_k$ belongs to C_η for k large.

Since x_u is an $O(u^2)$-optimal path, using Proposition 2.1 we may find a constant M such that for u small

$$f(x_u, u) \leq v(0) + u\ v(L) + Mu^2,$$

and then for each $\lambda \in S(D)$ we have

$$\mathcal{L}(x_u, \lambda, u) - \mathcal{L}(x_0, \lambda, 0) \leq f(x_u, u) - f(x_0, 0) \leq u\ \mathcal{L}'_u(x_0, \lambda, 0) + Mu^2.$$

Expanding f and G we get

$$\mathcal{L}''(x_0, \lambda, 0)(d_k, u_k/\tau_k)(d_k, u_k/\tau_k) \leq 2M \left(\frac{u_k}{\tau_k}\right)^2 + \frac{o(\tau_k^2 + u_k^2)}{\tau_k^2}$$

with the small term $o(\tau_k^2 + u_k^2)$ not depending on λ (here we use the boundedness of $S(D)$). The conclusion follows as in Proposition 6.1. □

7. Directional differentiability of metric projections. In this section we use the preceding results to compute the directional derivatives of projections onto convex sets in Hilbert spaces. More precisely, the problem is to study the right differentiability of the unique optimal solution of

$$(P_u) \qquad \min\left\{\frac{1}{2}\|x - y_u\|^2 : x \in K\right\},$$

where K is a closed convex subset of a Hilbert space H and $u \to y_u$ is a smooth mapping from $\mathbb{R}_+$ to H. Let us consider the slightly more general format

$$(P'_u) \qquad \min\left\{\frac{1}{2}\|x - y_u\|^2 : G(x, u) \in K\right\},$$

assuming that $G(\cdot, 0)$ is a linear mapping $G(x, 0) = Ax$ and that (DCQ) and $\Lambda_0 \neq \phi$ hold. Notice that these properties are satisfied when we have (CQ), which is obviously the case if A is surjective and particularly if $G(x, 0) = x$ as in (P_u).

Since $G(x, 0)$ is linear, we have $\mathcal{L}''_x(x_0, \lambda, 0) = I$, so $SOC(\Omega)$ is automatically satisfied for $\Omega = S(D)$ and problem $(\tilde{Q})$ is strongly convex. In particular, $S(\tilde{Q})$ is reduced to a singleton.

PROPOSITION 7.1. *Suppose (DCQ), $\Lambda_0 \neq \phi$, and the extended polyhedricity condition. Then the unique solution x_u of (P'_u) may be expanded as*

$$x_u = x_0 + ud_0 + o(u)$$

where d_0 is the unique solution of $(\tilde{Q})$.

Proof. Propositions 6.3 and 5.3(a) imply that $d_u := (x_u - x_0)/u$ converges weakly to d_0, the unique solution of $(\tilde{Q})$. Now, using the second-order bound (4), the equality $v(Q) = v(\tilde{Q}) = \Gamma(d_0)$, and inequality (9), we deduce that

$$\limsup_{u \downarrow 0} \Gamma(d_u) \leq \Gamma(d_0).$$

Since Γ is strongly convex, we conclude that d_u converges strongly to d_0, completing the proof. □

In the special case $G(x, u) = x$ and $y_u = y_0 + uh_0$; that is, when we study directional differentiability of the projection onto K at y_0 in the direction h_0, the set $S(L)$ is just the critical cone

$$S(L) = C_0 = \{d \in T_K(x_0) : d \perp (y_0 - x_0)\},$$

so the problem $(\tilde{Q})$ reduces to

$$\min\{\|d - h_0\|^2 : d \in C_0\}.$$

Hence we get as an immediate consequence the following result.

COROLLARY 7.2. *Assuming the extended polyhedricity condition, the projection x_u of $y_0 + uh_0$ onto K can be expanded as*

$$x_u = x_0 + ud_0 + o(u),$$

where d_0 is the projection of h_0 onto C_0.

Among the papers studying differentiability properties of metric projections we mention [11, 16, 19, 22, 26, 27]. A common hypothesis in these studies is that K has to be *polyhedric* in this sense that for each $x \in K$ and every $\lambda \in N_K(x)$ one has

$$T_K(x) \cap \lambda^\perp = \overline{\mathbb{R}_+(K-x) \cap \lambda^\perp}.$$

Since $S(L) = T_K(x_0) \cap (y_0 - x_0)^\perp$ and $0 \in T_K^2(x_0, d)$ whenever $d \in \mathbb{R}_+(K - x_0)$, the extended polyhedricity condition is in fact a generalization of polyhedricity. Notice that this hypothesis always holds when $y_0 \in K$ since then $C_0 = T_K(G(x_0, 0))$, which was the case studied in [27]. Another extension of polyhedricity is considered in [3].

8. Conclusion and further problems. We have shown that a satisfactory sensitivity analysis for perturbed problems of the form

$$(P_u) \qquad \min_x \{f(x, u) : G(x, u) \in K\}$$

may be obtained under directional constraint qualification conditions that are weaker than the standard Robinson's condition.

Since the results are scattered throughout the paper, we provide a summarized (though necessarily incomplete) version of the main results obtained in the paper. The precise meaning of the stated assumptions and notation is made clear in the preceding sections of the paper, to which the reader is referred.

THEOREM 8.1. *Let the functions f, G defining (P_u) be of class C^2, and suppose X is a reflexive Banach space. Let x_0 be an optimal solution for (P_0) at which the following assumptions are satisfied:*

(i) *directional constraint qualification (DCQ),*
(ii) *existence of multipliers $\Lambda_0 \neq \emptyset$,*
(iii) *second-order sufficient condition SOC(Ω) for $\Omega = S(D)$,*
(iv) *existence of an $o(u^2)$-optimal trajectory,*
(v) *extended polyhedricity,*
(vi) *$d \to \mathcal{L}''_x(x_0, \lambda, 0)dd$ is weakly lower semicontinuous for all $\lambda \in S(D)$.*

Then:

(a) *The optimal value function may be expanded as*

$$v(u) = v(0) + uv(L) + \frac{1}{2}u^2 v(\tilde{Q}) + o(u^2),$$

where (L) and $(\tilde{Q})$ are the linear and quadratic approximating optimizing problems.

(b) *The optimal solutions of (L) are the same as the weak accumulation points of the differential quotients $(x_u - x_0)/u$ where x_u ranges over the set of all possible $o(u)$-optimal trajectories.*

(c) *Every $o(u^2)$-optimal path z_u satisfies $z_u = z_0 + O(u)$, and the weak accumulation points of $(z_u - z_0)/u$ are optimal solutions for $(\tilde{Q})$.*

We remark that a key ingredient for attaining these results is the generalization of Robinson's implicit function theorem presented in Appendix B, which is based on the weak directional constraint qualification condition (*DCQ*).

The main results of this paper are limited to problems for which there is existence of multipliers and satisfying the strong second-order sufficient condition stated as (iii) above, which ensure the existence of suboptimal paths of the form $x_u = x_0 + O(u)$.

In the setting of finite-dimensional mathematical programming we know [5] that this type of expansion may fail. For instance, when $\Lambda_0 \neq \phi$ but only the weak second-order

condition holds, suboptimal paths may only satisfy $x_u = x_0 + O(\sqrt{u})$ and it may happen that $v'(0) < v(L)$. On the other hand, when $\Lambda_0 = \phi$ we may even have $v(u) = v(0) + O(\sqrt{u})$.

It seems that (*DCQ*) is too weak to extend these results to the general framework discussed in the present paper. Theorem B.4 may not be used since it requires the a priori bound $x_u = x_0 + O(u)$, and its refinement Theorem B.1 may only handle those paths such that $\|x_u - x_0\| \leq \gamma\sqrt{u}$ for a sufficiently small γ.

These remarks lead us to consider a strenghtened form of directional constraint qualification, well suited to the analysis of problems of the form

$$\min\{f(x,u) : G_1(x,u) \in K_1,\ G_2(x,u) \in K_2\}$$

where K_1 and K_2 are closed convex subsets of some Banach spaces with $\text{int}(K_2) \neq \phi$. This study will be the subject of part II of this work.

Appendix A. The convex duality theorem in Banach spaces. This short appendix presents a short proof of the convex duality theorem of Robinson [24]. This result is a generalization of [25, Thm. 18(c)] (see also [1, Thm. 1.1]). We include it since the version we present is more directly applicable to the dualization of problems (L) and (L_d) in the previous sections and also since the method of proof is very simple. The basic argument is the following lemma due to Robinson [24] (also used in Appendix B) for which we provide a simplified proof too.

Given a subset $C \subset X \times Y$ we denote by C_X and C_Y the projections of C onto X and Y, respectively.

LEMMA A.1. *Let X, Y be two normed spaces with X complete. Let $C \subset X \times Y$ be a closed convex set with C_X bounded. Then*

$$\text{int}\,(C_Y) = \text{int}\,(\overline{C_Y}).$$

Proof. It clearly suffices to show $\text{int}\,(\overline{C_Y}) \subset C_Y$; that is, given $\overline{y} \in \text{int}\,(\overline{C_Y})$ we must find $\overline{x} \in X$ such that $(\overline{x}, \overline{y}) \in C$. To this end let us take $\varepsilon > 0$ with $B(\overline{y}, \varepsilon) \subset \overline{C_Y}$ and choose an arbitrary point $(x_0, y_0) \in C$ from which we generate a sequence $(x_k, y_k) \in C$ using the following "algorithm."

while $(y_k \neq \overline{y})$ *do*

- Let $\alpha_k = \varepsilon / \|y_k - \overline{y}\|$ so that $w := \overline{y} + \alpha_k(\overline{y} - y_k) \in B(\overline{y}, \varepsilon) \subset \overline{C_Y}$.
- Take $(u, v) \in C$ with $\|v - w\| \leq \frac{1}{2}\|y_k - \overline{y}\|$ and define

$$(x_{k+1}, y_{k+1}) := \frac{\alpha_k}{1+\alpha_k}(x_k, y_k) + \frac{1}{1+\alpha_k}(u, v) \in C.$$

endwhile.

If the algorithm stops, then we have $y_k = \overline{y}$ and we may take $\overline{x} = x_k$. Otherwise, the generated sequence satisfies

$$\text{(i)} \quad \|x_{k+1} - x_k\| = \frac{\|x_k - u\|}{1+\alpha_k} \leq \frac{\text{diam}(C_X)}{\varepsilon}\|y_k - \overline{y}\|,$$

$$\text{(ii)} \quad \|y_{k+1} - \overline{y}\| = \frac{\|v - w\|}{1+\alpha_k} \leq \frac{1}{2}\|y_k - \overline{y}\|.$$

From (ii) it follows that $\|y_k - \overline{y}\| \leq \|y_0 - \overline{y}\|/2^k$. This implies that $y_k \to \overline{y}$ and also, in combination with (i), that (x_k) is a Cauchy sequence. The completeness of X gives the existence of a limit $\overline{x}$ for (x_k), and the closedness of C implies $(\overline{x}, \overline{y}) \in C$ as required. □

We may now proceed by proving the convex duality theorem.

THEOREM A.2. *Let* $\theta(y) := \inf\{\varphi(x, y) : x \in X\}$, *where* $\varphi : X \times Y \to \mathbb{R} \cup \{+\infty\}$ *is a closed proper convex function with* X, Y *Banach spaces and* $\mathbb{R}_+ \cup_x \operatorname{dom} \varphi(x, \cdot) = Y$. *Then* θ *is continuous in a neighborhood of* 0 *and* $\theta(0) < +\infty$.

In particular $\theta(0) = \theta^{**}(0)$, *which can be written as*

$$\inf_{x \in X} \varphi(x, 0) = - \min_{y^* \in Y^*} \varphi^*(0, y^*), \tag{15}$$

and the solution set of the minimum on the right is $\partial\theta(0)$, *which is nonempty and weak*-compact when* $\theta(0)$ *is finite, and the whole space* Y^* *when* $\theta(0) = -\infty$.

Proof. Since θ is convex, the continuity near 0 is equivalent to θ being bounded above in a certain neighborhood of 0. To show this, let $\alpha \in \mathbb{R}$ and $x_0 \in X$ be such that $\varphi(x_0, 0) < \alpha$ and consider the closed convex set

$$C = \{(x, y) : \varphi(x, y) \le \alpha;\ \|x\| \le \|x_0\| + 1\}$$

that is nonempty and has C_X bounded.

Since $\theta(y) \le \alpha$ for all $y \in C_Y$, it suffices to show that C_Y is a neighborhood of 0. From Lemma A.1 this amounts to $0 \in \operatorname{int}(\overline{C_Y})$, which, by Baire's lemma, is a consequence of the fact that C_Y is absorbing as we show next. For any $y \in Y$ there exist $t > 0$ and $x \in X$ with $\varphi(x, ty) < +\infty$, so for $\varepsilon > 0$ small enough we have

$$\begin{aligned} &\|(1 - \varepsilon)x_0 + \varepsilon x\| \le \|x_0\| + 1, \\ &\varphi((1 - \varepsilon)(x_0, 0) + \varepsilon(x, ty)) \le (1 - \varepsilon)\varphi(x_0, 0) + \varepsilon\varphi(x, ty) \le \alpha, \end{aligned}$$

showing that $\varepsilon t y \in C_Y$ for all $\varepsilon > 0$ small.

We observe that $\theta^*(y^*) = \varphi^*(0, y^*)$ so that (15) is just a rewriting of $\theta(0) = \theta^{**}(0)$. From this we also get that $\partial\theta(0)$ is the solution set of $\min \varphi^*(0, y^*)$, and the last claim is a well-known fact in convex analysis (see [25]). □

Appendix B. Regularity theorems under directional constraint qualification conditions. Throughout this section we suppose that $G : X \times \mathbb{R}_+ \to Y$ is a $\mathcal{C}^2$ mapping and the spaces X, Y are Banach. Also $K \subset Y$ is a closed convex set and $x_0 \in X$ is such that $G(x_0, 0) \in K$ and satisfies the constraint qualification

$$0 \in \operatorname{int}\big[G(x_0, 0) + G'(x_0, 0)X \times (0, \infty) - K\big]. \tag{DCQ}$$

We begin by stating the equivalence.

PROPOSITION B.1. *Condition* (*DCQ*) *is equivalent to*

$$0 \in \operatorname{int}\,[G(x_0, 0) + G'(x_0, 0)X \times [0, \infty) - K]. \tag{DCQ}'$$

Proof. Clearly (*DCQ*) implies (*DCQ*)′. Conversely, suppose (*DCQ*)′ holds and choose $\varepsilon > 0$ with

$$\varepsilon B_Y \subset [G(x_0, 0) + G'(x_0, 0)X \times [0, \infty) - K].$$

Let $\delta > 0$ be such that $\delta[B_Y - G'_u(x_0, 0)] \subset \varepsilon B_Y$. Then

$$\delta B_Y \subset [G(x_0, 0) + G'(x_0, 0)X \times [\delta, \infty) - K],$$

from which (*DCQ*) follows. □

THEOREM B.2. *Let x_u be a trajectory such that $\|x_u - x_0\| \leq \gamma\sqrt{u}$, and suppose $d(G(x_u, u), K) \leq mu$ for some constants γ, m and all $u \geq 0$ close to 0. If γ is small enough, we can find constants $c \geq 0$, $u_0 > 0$ and a trajectory y_u with*

$$G(y_u, u) \in K,$$
$$\|y_u - x_u\| \leq \frac{c}{u}(u + \|x_u - x_0\|)d(G(x_u, u), K),$$

for all $u \in (0, u_0]$.

Our proof will be based on the following couple of lemmas.

LEMMA B.3. *Under assumption (DCQ), there exist $\varepsilon > 0$, $\alpha \geq 1$, and $\overline{u} > 0$ such that for all $u \in [0, \overline{u}]$*

$$2u\varepsilon B_Y \subset G(x_0, 0) + uG'_u(x_0, 0) + u\alpha G'_x(x_0, 0)B_X - K.$$

Proof. Letting $A_k := G(x_0, 0) + kG'(x_0, 0)B_X \times [0, 1] - K \cap kB_Y$, condition (*DCQ*) gives

$$0 \in \operatorname{int} \bigcup \{A_k : k \in \mathbb{N}\};$$

thus the completeness of Y implies $0 \in \operatorname{int}(\overline{A_k})$ for some $k \in \mathbb{N}$. But the set A_k can be expressed as the projection over the fourth component of the closed convex set

$$C := \left\{(x, y, t, G(x_0, 0) + G'(x_0, 0)(x, t) - y) : \|x\| \leq k, \|y\| \leq k, y \in K, t \in [0, k]\right\},$$

and since the projection of C onto its first three components is bounded, Lemma A.1 gives $\operatorname{int}(A_k) = \operatorname{int}(\overline{A_k})$. Therefore we may find $\varepsilon > 0$ such that

$$2\varepsilon k B_Y \subset G(x_0, 0) + kG'_u(x_0, 0) - k[0, 1]G'_u(x_0, 0) + kG'_x(x_0, 0)B_X - K,$$

which multiplied by u/k and rearranged becomes

$$2u\varepsilon B_Y \subset G(x_0, 0) + uG'_u(x_0, 0) + uG'_x(x_0, 0)B_X - S, \tag{16}$$

where

$$S := \left(1 - \frac{u}{k}\right) G(x_0, 0) + [0, 1]uG'_u(x_0, 0) + \frac{u}{k}K.$$

Now, (*DCQ*) implies $G'_u(x_0, 0) = [y - G(x_0, 0) - G'_x(x_0, 0)d]/\delta$ for some $y \in K$, $d \in X$, and $\delta > 0$, so

$$S = \bigcup_{\lambda \in [0,1]} \left[\left(1 - \frac{\lambda u}{\delta} - \frac{u}{k}\right) G(x_0, 0) + \frac{\lambda u}{\delta} y + \frac{u}{k}K\right] - \frac{\lambda u}{\delta} G'_x(x_0, 0)d.$$

Since K is convex, we deduce that $S \subset K - [0, 1]\frac{u}{\delta}G'_x(x_0, 0)d$ for all $u \leq \overline{u} := \delta k/(\delta + k)$, which combined with (16) yields the desired conclusion for $\alpha := 1 + \|d\|/\delta$. □

In the next lemma we denote

$$M = \sup\{\|G''(x, u)\| : \|x - x_0\| \leq 1, 0 \leq u \leq \overline{u}\}.$$

LEMMA B.4. *Let $\varphi : \mathbb{R}_+ \to \mathbb{R}_+$ be such that $\varphi(u) \leq \frac{1}{4}\sqrt{u\varepsilon/M}$ for all u sufficiently small. Then there exists $u_0 > 0$ such that, for each trajectory x_u with*

$$\|x_u - x_0\| \leq \varphi(u) \quad \forall u \in [0, u_0],$$

one has for all $u \in [0, u_0]$

$$u\varepsilon B_y \subset G(x_u, u) + (\alpha u + \|x_u - x_0\|)G'_x(x_0, 0)B_X - K. \tag{17}$$

Moreover, we can associate to x_u *another trajectory* y_u *such that for all* $u \in (0, u_0]$

$$\text{(i)} \quad d(G(y_u, u), K) \le \frac{1}{2} d(G(x_u, u), K),$$

$$\text{(ii)} \quad \|y_u - x_u\| \le \frac{2}{u\varepsilon}(\alpha u + \|x_u - x_0\|)d(G(x_u, u), K).$$

Proof. The hypothesis on $\varphi(u)$ ensures the existence of $u_0 \in (0, \overline{u}]$ such that

$$8M[\alpha u + \varphi(u)]^2 \le u\varepsilon \le M \quad \forall\, u \in [0, u_0]. \tag{18}$$

To show (17) we observe from (18) that $\|x_u - x_0\| \le \varphi(u) \le 1$, and then letting $b := G(x_u, u) - G(x_0, 0) - G'(x_0, 0)(x_u - x_0, u)$ we have

$$\|b\| \le M(u + \|x_u - x_0\|)^2 \le M[\alpha u + \varphi(u)]^2 \le u\varepsilon. \tag{19}$$

Thus, Lemma B.3 gives

$$u\varepsilon B_Y - b \subset 2u\varepsilon B_Y \subset G(x_0, 0) + uG'_u(x_0, 0) + u\alpha G'_x(x_0, 0)B_X - K,$$

and then

$$u\varepsilon B_Y \subset G(x_u, u) + G'_x(x_0, 0)[-(x_u - x_0) + u\alpha B_X] - K,$$

from which (17) follows at once.

Let us construct next the trajectory y_u for $u \in (0, u_0]$.

If $G(x_u, u) \in K$ we just take $y_u = x_u$ so that (i) and (ii) hold trivially.

Otherwise we choose r such that $G(x_u, u) + r \in K$ and

$$\|r\| \le 2d(G(x_u, u), K), \tag{20}$$

and we use (17) to select d with $\|d\| \le \alpha u + \|x_u - x_0\|$ such that

$$u\varepsilon \frac{r}{\|r\|} \in G(x_u, u) + G'_x(x_0, 0)d - K. \tag{21}$$

With these choices we define $y_u = x_u + \beta d$, where $\beta := \|r\|/(u\varepsilon + \|r\|) < 1$.

Property (ii) follows immediately from (20) and the inequality

$$\|y_u - x_u\| = \beta\|d\| \le \frac{\|r\|}{u\varepsilon}(\alpha u + \|x_u - x_0\|).$$

To check property (i) we observe that $\|d\| \le \alpha u + \varphi(u)$ and then, using (18),

$$\|y_u - x_0\| \le \alpha u + 2\varphi(u) \le 1.$$

Then we can apply the mean value theorem to find $\xi \in]x_u, y_u[$ with

$$\begin{aligned} \|G(y_u, u) - G(x_u, u) - \beta G'_x(x_0, 0)d\| &\le \|G'_x(\xi, u) - G'_x(x_0, 0)\|\, \|d\|\, \beta \\ &\le M(u + \|\xi - x_0\|)\|d\|\frac{\|r\|}{u\varepsilon} \\ &\le \frac{2M}{u\varepsilon}[\alpha u + \varphi(u)]^2\|r\| \\ &\le \frac{1}{2}d(G(x_u, u), K), \end{aligned} \tag{22}$$

where we have used the bound $u + \|\xi - x_0\| \le 2[\alpha u + \varphi(u)]$, (18), and (20).

Now, from (21) we get

$$G(x_u, u) + \beta G'_x(x_0, 0)d \in (1-\beta)G(x_u, u) + \beta u\varepsilon \frac{r}{\|r\|} + \beta K,$$

since $1 - \beta = \beta u\varepsilon/\|r\|$, we deduce

$$[G(x_u, u) + \beta G'_x(x_0, 0)d \in (1-\beta)(G(x_u, u) + r) + \beta K \subset K,$$

which combined with (22) yields (i). □

Proof of Theorem B.2. Let $\varphi(u) := e^{4m/\varepsilon}(\alpha u + \|x_u - x_0\|)$ and suppose that $\gamma < \frac{1}{4}e^{-4m/\varepsilon}\sqrt{\frac{\varepsilon}{M}}$ so that Lemma B.4 can be used to find u_0.

Starting with $y_u^0 := x_u$ we shall construct recursively a sequence y_u^k such that for all $u \in (0, u_0]$ one has

$$\text{(i)} \quad d(G(y_u^k, u), K) \le \frac{1}{2} d(G(y_u^{k-1}, u), K),$$

$$\text{(ii)} \quad \|y_u^k - y_u^{k-1}\| \le \frac{2}{u\varepsilon}(\alpha u + \|y_u^{k-1} - x_0\|) d(G(y_u^{k-1}, u), K).$$

To prove the existence of such a sequence it suffices to check inductively that

$$\text{(iii)} \quad \|y_u^k - x_0\| \le \varphi(u) \quad \forall\, u \in (0, u_0],$$

so that Lemma B.4 can be used to find the next term y_u^{k+1}. Since (iii) obviously holds for $k = 0$, we only need to prove the inductive step. Suppose $y_0, y_1, \ldots, y_k$ are such that (i) and (ii) hold; then for every $u \in (0, u_0]$ we have

$$\begin{aligned} \|y_u^k - y_u^{k-1}\| &\le \frac{2}{u\varepsilon}(\alpha u + \|y_u^{k-1} - x_0\|) \frac{d(G(x_u, u), K)}{2^{k-1}} \\ &\le \frac{2m}{\varepsilon 2^{k-1}}(\alpha u + \|y_u^{k-1} - x_0\|), \end{aligned} \tag{23}$$

so that letting $a_k := \alpha u + \|y_u^k - x_0\|$ we get

$$a_k \le a_{k-1} + \|y_u^k - y_u^{k-1}\| \le \left(1 + \frac{2m}{\varepsilon 2^{k-1}}\right) a_{k-1}.$$

It follows that

$$\ln a_k \le \ln a_{k-1} + \ln\left(1 + \frac{2m}{\varepsilon 2^{k-1}}\right) \le \ln a_{k-1} + \frac{2m}{\varepsilon 2^{k-1}}$$

and then recursively

$$\ln a_k \le \ln a_0 + \frac{2m}{\varepsilon}\left(\frac{1}{2^0} + \frac{1}{2^1} + \cdots + \frac{1}{2^{k-1}}\right) \le \ln a_0 + \frac{4m}{\varepsilon},$$

from which we obtain the desired conclusion (iii) as

$$\|y_u^k - x_0\| \le a_k \le a_0 e^{4m/\varepsilon} = \varphi(u).$$

The existence of the sequence (y_k) being established, we may use the previous bound $a_k \le \varphi(u)$ and (23) to obtain

$$\|y_u^k - y_u^{k-1}\| \le \frac{2\varphi(u) d(G(x_u, u), K)}{u\varepsilon 2^{k-1}}, \tag{24}$$

which shows that $(y_u^k)_{k\in\mathbb{N}}$ is a Cauchy sequence for each $u \in (0, u_0]$.

Let $y_u := \lim_{k\uparrow\infty} y_u^k$. From (i) we deduce that $G(y_u, u) \in K$, while (24) implies

$$\|y_u - x_u\| \le \frac{4\varphi(u)}{u\varepsilon} d(G(x_u, u), K),$$

proving the theorem with $c := \frac{4}{\varepsilon} e^{4m/\varepsilon}$. □

A careful analysis of the previous proof shows that the result is still valid if G is supposed of class C^1 (or merely strictly differentiable at $(x_0, 0)$) provided we restrict to the case of trajectories $x_u = x_0 + O(u)$. More precisely we have the following theorem.

THEOREM B.5. *Let $G : X \times \mathbb{R} \to Y$ be strictly differentiable at $(x_0, 0)$ and $K \subset Y$ be a closed convex set. Suppose that $G(x_0, 0) \in K$ and (DCQ) holds. Then for each trajectory $x_u = x_0 + O(u)$ there exist constants $c \ge 0$, $u_0 > 0$ and a second trajectory y_u such that*

$$G(y_u, u) \in K,$$
$$\|y_u - x_u\| \le c\, d(G(x_u, u), K),$$

for all $u \in [0, u_0]$.

Proof. It is clear that the result will follow from Theorem B.2, which is applicable since $x_u = x_0 + O(u)$ implies $x_u = x_0 + o(\sqrt{u})$ and $d(G(x_u, u), K) = O(u)$.

However, we must check that Theorem B.2 remains valid under the weaker C^1 assumption on G and the stronger $x_u = x_0 + O(u)$ condition. To this end all we need is to modify Lemma B.4. More specifically, it suffices to adjust the arguments leading to the bounds (19) and (22), which is easily accomplished by fixing $\ell \in \mathbb{R}$ and $u_0 \in (0, \overline{u}]$ such that $\varphi(u) \le \ell u$ for all $u \in [0, u_0]$ and then reducing u_0 so that

$$\|G(y, v) - G(x, u) - G'(x_0, 0)(y - x, v - u)\| \le \frac{\varepsilon}{4(\alpha + \ell)} (\|y - x\| + |v - u|)$$

for each $u, v \in [0, u_0]$ and every $x, y \in B(x_0, (\alpha + 2\ell)u_0)$. □

As a corollary of the preceding result we obtain the following *directional* version of Robinson–Ursescu's regularity theorem for convex multifunctions.

THEOREM B.6. *Let $M : X \longrightarrow 2^Y$ be a multifunction with closed convex graph. Let $y_0 \in M(x_0)$ and let y_u be a C^1 trajectory with $y(0) = y_0$ and*

$$(RU) \qquad 0 \in \operatorname{int}[M(X) - y(0) - (0, \infty)y'(0)].$$

Then for each trajectory $x_u = x_0 + O(u)$ one has

$$d(x_u, M^{-1}(y_u)) \le c\, d(y_u, M(x_u))$$

for a given constant c and all $u \ge 0$ sufficiently small.

Proof. The result follows as a direct application of Theorem B.5 to the function $G(x, u) = (x, y_u)$ and the closed convex set $K = \operatorname{graph}(M)$. □

APPLICATION. As a particular case of the previous result let us consider $y_0 \in M(x_0)$ and suppose that $d \in Y$ is such that

$$[0 \in \operatorname{int}[M(X) - y_0 - (0, \infty)d].$$

Then, for each trajectory $x_u = x_0 + O(u)$ there exists $\tilde{x}_u$ such that

$$y_0 + ud \in M(\tilde{x}_u),$$
$$\|\tilde{x}_u - x_u\| \le c\, d(y_u, M(x_u)).$$

In particular, letting $x_u \equiv x_0$ we obtain the existence of a trajectory $\tilde{x}_u = x_0 + O(u)$ with $y_0 + ud \in M(\tilde{x}_u)$.

PERTURBED OPTIMIZATION IN BANACH SPACES II: A THEORY BASED ON A STRONG DIRECTIONAL CONSTRAINT QUALIFICATION*

J. FRÉDÉRIC BONNANS† AND ROBERTO COMINETTI‡

Abstract. We study the sensitivity of the optimal value and optimal solutions of perturbed optimization problems in two cases. The first one is when multipliers exist but only the weak (and not the strong) second-order sufficient optimality condition is satisfied. The second case is when no Lagrange multipliers exist. To deal with these pathological cases, we are led to introduce a directional constraint qualification stronger than in part I of this paper, which reduces to the latter in the important case of equality-inequality constrained problems. We give sharp upper estimates of the cost based on paths varying as the square root of the perturbation parameter and, under a *no-gap* condition, obtain the first term of the expansion for the cost. When multipliers exist we study the expansion of approximate solutions as well. We show in the appendix that the strong directional constraint qualification is satisfied for a large class of problems, including regular problems in the sense of Robinson.

Key words. sensitivity analysis, marginal function, square root expansion, approximate solutions, directional constraint qualification

1. Introduction.

This paper is the second in a trilogy (see [4, 5]) devoted to the analysis of parametric optimization problems of the form

$$(P_u) \qquad \min_x \{f(x,u) : G(x,u) \in K\}$$

with X and Y Banach spaces, K a closed convex subset of Y, and $f(x,u)$, $G(x,u)$ mappings of class $\mathcal{C}^2$ from $X \times \mathbb{R}$ into $\mathbb{R}$ and Y, respectively. We denote the feasible set, value function, and set of solutions of (P_u) as

$$\begin{aligned} F(u) &:= \{x \in X \ : \ G(x,u) \in K\}, \\ v(u) &:= \inf\{f(x,u) \ : \ x \in F(u)\}, \\ S(u) &:= \{x \in F(u) \ : \ f(x,u) = v(u)\}, \end{aligned}$$

respectively. Similarly $v(P)$, $F(P)$, $S(P)$ will respectively denote the optimal value, feasible set, and solution set of an optimization problem (P).

Our aim is to study the expansion of $v(u)$ and possibly $S(u)$ in the vicinity of a local solution x_0 of (P_0). Such sensitivity analysis usually relies (among other assumptions) upon stability properties of the feasible set $F(u)$ that follow from so-called *constraint qualification conditions*. In part I of this work (see [4]) our study was based on the following generalization of Gollan's constraint qualification (see [1, 10]):

$$(DCQ) \qquad 0 \in \operatorname{int}\left[G(x_0,0) + G'(x_0,0)X \times (0,\infty) - K\right],$$

which is a *directional* version of Robinson's condition [14]

$$(CQ) \qquad 0 \in \operatorname{int}\left[G(x_0,0) + G'_x(x_0,0)X - K\right].$$

Under (DCQ) we obtained the following upper estimate of the optimal value:

$$(1.1) \qquad v'_+(0) \le v(L),$$

where $v'_+(0)$ and $v'_-(0)$ denote the upper and lower Dini derivatives of the value function:

$$v'_+(0) := \limsup_{u \downarrow 0} \frac{v(u) - v(0)}{u},$$

$$v'_-(0) := \liminf_{u \downarrow 0} \frac{v(u) - v(0)}{u},$$

and (L) is the problem with linearized data:

$$(L) \qquad \min_d \{f'(x_0, 0)(d, 1) : \ G'(x_0, 0)(d, 1) \in T_K(G(x_0, 0))\}.$$

Using duality theory we proved that $v(D) = v(L) < \infty$, where (D) is the problem

$$(D) \qquad \max\{\mathcal{L}'_u(x_0, \lambda, 0) : \lambda \in \Lambda_0\},$$

with $\mathcal{L}$ the Lagrangian and Λ_0 the set of multipliers associated with x_0, that is to say, denoting by $N_K(y)$ the cone of outward normals at a point $y \in K$,

$$\mathcal{L}(x, \lambda, u) := f(x, u) + \langle \lambda, G(x, u) \rangle,$$

$$\Lambda_0 := \{\lambda \in Y^* : \lambda \in N_K(G(x_0, 0)); \ \mathcal{L}'_x(x_0, \lambda, 0) = 0\}.$$

Define a *path* as a mapping $u \to x_u$ from $\mathbb{R}_+$ to X, with $x_u \to x_0$ when $u \downarrow 0$. The path is said to be feasible if $G(x_u, u) \in K$ for u small enough. Under a strong second-order condition on the Lagrangian it can be shown [4] that any $o(u^2)$-optimal path x_u, i.e., a feasible path x_u such that $f(x_u, u) \leq v(u) + o(u^2)$, satisfies $x_u = x_0 + O(u)$. In this case $v'(0)$ exists, being equal to $v(L)$, and some estimates for the second-order variation of $v(u)$ can be obtained. In fact, under suitable conditions we proved that

$$(1.2) \qquad v(u) = v(0) + u \ v(L) + \frac{1}{2} u^2 \ v(\tilde{Q}) + o(u^2),$$

where $(\tilde{Q})$ is a subproblem involving the expansion of orders 1 and 2 of the data at $(x_0, 0)$. A remarkable property in this case is that every weak limit of $(x_u - x_0)/u$, with x_u an $o(u^2)$-optimal path, belongs to $S(\tilde{Q})$.

The available perturbation theory for nonlinear programming shows that this is not the end of the story. Under the directional qualification hypothesis of Gollan [10] and the weak second-order sufficient condition, it appears (see [9] by Gauvin and Janin) that $v'(0)$ exists but may be strictly less than $v(L)$. In that case, a path of $O(u)$-optimal solutions satisfies only $x_u = x_0 + O(\sqrt{u})$. One can still formulate (see Bonnans, Ioffe, and Shapiro [6]) a subproblem (M) such that $v'(0) = v(M)$ and $S(M)$ coincides with the limit points of $(x_u - x_0)/\sqrt{u}$ where x_u ranges over the set of all possible $o(u)$-optimal paths. For this it is necessary to assume the existence of at least one multiplier. A similar theory for the case when no multiplier exists was developed in [3] by Bonnans; here the variation of the cost as well that of the solutions is of order $O(\sqrt{u})$.

The aim of this paper is to extend these two theories to the Banach space setting. Our main results are Theorem 3.9 and Theorem 4.6.

The first one, valid under the weak second-order sufficient condition, provides a first-order expansion of the form

$$v(u) = v(0) + uv(\tilde{D}) + o(u),$$

where $(\tilde{D})$ is a problem involving the expansion of orders 1 and 2 of the data. Moreover, it shows that every weak limit point of $(x_u - x_0)/\sqrt{u}$, with x_u an $o(u)$-optimal path, solves $(\tilde{D})$.

The second one is concerned with problems where no Lagrange multipliers exist. In this case we obtain a square root expansion of the form

$$v(u) = v(0) + \sqrt{u}v(\hat{D}) + o(\sqrt{u}),$$

where $(\hat{D})$ is another linear-quadratic approximating problem.

To prove these results we need a constraint qualification that is still directional but, apparently, stronger than (*DCQ*). Specifically, in addition to (*DCQ*) we need a restorability property that, roughly speaking, asserts that to certain almost feasible *square root* paths (i.e., paths satisfying $x_u = x_0 + O(\sqrt{u})$), one can associate a sufficiently close feasible path. In the case of nonlinear programming, that stronger hypothesis (*SDCQ*) reduces to the condition of Gollan (see [1, 10]) used in [9, 3, 6], so we recover the main results of these three references. Let us mention that square root paths have already been used for sensitivity analysis in a Banach space setting (see [2, 11, 12]). However, our qualification condition is weaker than those in these references.

As in part I of this work, in our extension to the Banach space setting, an additional difficulty related to the possible curvature of the convex K appears. To be more precise, let us recall the definition of first- and second-order tangent sets:

$$T_K(y) := \{h \in Y : \text{ there exists } o(t) \text{ such that } y + th + o(t) \in K\},$$

$$T_K^2(y, h) := \left\{k \in Y : \text{ there exists } o(t^2) \text{ such that } y + th + \frac{1}{2}t^2k + o(t^2) \in K\right\}.$$

The fact that in general 0 does not belong to the set $T_K^2(y, h)$ may cause a *gap* between the upper and lower estimates for the cost. Some cases when the curvature makes no contribution to the second-order variation of the cost were analyzed in part I, yielding the expansion (1.2) under a condition of generalized polyhedricity. The results in this paper are obtained under similar assumptions.

The paper is organized as follows. In §2 we describe the strong directional constraint qualification (*SDCQ*). Then in §3 we develop a perturbation theory assuming the set of multipliers Λ_0 to be nonempty, whereas §4 deals with the case when Λ_0 is empty. In both cases we obtain sharp upper estimates as well as some lower estimates of the cost and, under a *no-gap* condition, obtain the first term in the expansion of the cost. Finally in the appendix we discuss sufficient conditions for the strong directional constraint qualification (*SDCQ*).

2. The strong directional qualification condition. Our upper estimates are based on paths that vary as the square root of the perturbation parameter. Specifically, we consider paths satisfying, for given d, w in X, the two conditions

$$x_u = x_0 + \sqrt{u}d + uw + o(u), \tag{2.3}$$

$$\operatorname{dist}(G(x_u, u), K) = o(u). \tag{2.4}$$

Note that we can express (2.4) using the concept of a second-order tangent set. Namely, if x_u satisfies (2.3), then the expansion

$$G(x_u, u) = G(x_0, 0) + \sqrt{u}G_x'(x_0, 0)d + u\left[G'(x_0, 0)(w, 1) + \frac{1}{2}G_x''(x_0, 0)dd\right] + o(u)$$

shows that (2.4) is equivalent to

$$\Psi_G(w, d) \in T_2^K(d), \tag{2.5}$$

where we have set

$$T_2^K(d) := \frac{1}{2}T_K^2(G(x_0,0), G'_x(x_0,0)d),$$

$$\Psi_G(w,d) := G'(x_0,0)(w,1) + \frac{1}{2}G''_x(x_0,0)dd,$$

$$\Psi_f(w,d) := f'(x_0,0)(w,1) + \frac{1}{2}f''_x(x_0,0)dd.$$

Remark. The set $T_2^K(d)$ should not be confused with the set

$$T_K^2(d) := T_K^2(G(x_0,0), G'(x_0,0)(d,1))$$

defined in part I of this paper and which will not be used here.

DEFINITION 1. *We say that x_0 is* restorable *(with respect to G and K) if, given a path x_u satisfying* (2.3) *and* (2.4), *for $\gamma < 1$ close to 1 one can find $w_\gamma \in X$ with $w_\gamma \to w$ and feasible paths of the form*

$$x_u^\gamma = x_0 + \gamma\sqrt{u}d + uw_\gamma + o(u). \tag{2.6}$$

We say that the strong directional constraint qualification *(SDCQ) holds at x_0 if x_0 is restorable and the weak directional constraint qualification (DCQ) holds.*

We discuss some sufficient conditions for *(SDCQ)* in the appendix at the end of this paper. We show in particular that for equality-inequality constrained problems (i.e., when $K = \{0\} \times K_2$ with K_2 a closed convex cone with nonempty interior), property *(SDCQ)* is equivalent to *(DCQ)*. In fact, it may be that the restorability property is always a consequence of *(DCQ)*, but we do not have a proof nor a counterexample for this.

Before proceeding with the sensitivity analysis we summarize in the next lemma four general properties that will be of constant use throughout the paper. Here $\sigma(\lambda, T_2^K(d)) := \sup\{\langle\lambda, k\rangle : k \in T_2^K(d)\}$ denotes the support function of $T_2^K(d)$.

LEMMA 2.1. *For every $d \in X$ we have the following.*

(P1) $T_2^K(d) + T_K(G(x_0,0)) - \mathbb{R}_+G'_x(x_0,0)d \subset T_2^K(d)$.

(P2) If (DCQ) holds, then $0 \in \operatorname{int}[T_K(G(x_0,0)) - G'(x_0,0)X \times \{1\}]$.

(P3) $T_2^K(\gamma d) = \gamma^2 T_2^K(d)$ *for all* $\gamma > 0$.

(P4) If $T_2^K(d) \neq \phi$, *then the following are equivalent:*

(a) $\sigma(\lambda, T_2^K(d)) \leq 0$.

(b) $\sigma(\lambda, T_2^K(d))$ *is finite.*

(c) $\lambda \in N_K(G(x_0,0))$ *and* $\langle\lambda, G'_x(x_0,0)d\rangle = 0$.

Proof. Properties *(P1)* and *(P2)* are straightforward consequences of [8, Prop. 3.1] and [4, Lem. B.3], respectively, while *(P3)* is an easy exercise.

Let us prove *(P4)*. Since $T_2^K(d) \neq \phi$, the implication (a) $\Rightarrow$ (b) is straightforward. Also, the nonemptyness of $T_2^K(d)$ implies $G'_x(x_0,0)d \in T_K(G(x_0,0))$ and then (b) $\Rightarrow$ (c) follows from property *(P1)*. To prove (c) $\Rightarrow$ (a) let us pick $y \in T_2^K(d)$ and choose $y_t \to y$ with $z_t := G(x_0,0) + tG'_x(x_0,0)d + t^2y_t \in K$. Using (c) we deduce

$$0 \geq \langle\lambda, z_t - G(x_0,0)\rangle = \langle\lambda, tG'_x(x_0,0)d + t^2y_t\rangle = t^2\langle\lambda, y_t\rangle,$$

so that $\langle\lambda, y\rangle = \lim\langle\lambda, y_t\rangle \leq 0$, proving (a). □

3. Perturbation analysis assuming the existence of multipliers. In this section we study the case when $\Lambda_0 \neq \phi$. First we give an upper estimate of $v'_+(0)$, which we can express as a supremum of a certain function over Λ_0. We then rely on second-order conditions to obtain lower estimates for $v'_-(0)$ and to investigate the coincidence of both estimates.

3.1. Sharp first-order upper estimates of the cost. Let C_0 denote the cone of critical directions at x_0, i.e.,

$$C_0 := \{d \in X : \ f'_x(x_0, 0)d \leq 0; \ G'_x(x_0, 0)d \in T_K(G(x_0, 0))\}.$$

When $\Lambda_0 \neq \phi$ one has in fact $f'_x(x_0, 0)d = 0$ for all $d \in C_0$. To a path satisfying (2.3) and (2.4) is associated the constraint (2.5), whereas $\Psi_f(w, d)$ is the first term of the expansion of the cost. This leads to the problem

$$(L^d) \qquad \inf_{w \in X} \{\Psi_f(w, d) : \Psi_G(w, d) \in T_2^K(d)\},$$

which admits the dual

$$(D^d) \qquad \sup_{\lambda \in \Lambda_0} \left\{ \mathcal{L}'_u(x_0, \lambda, 0) + \frac{1}{2}\mathcal{L}''_x(x_0, \lambda, 0)dd - \sigma(\lambda, T_2^K(d)) \right\}.$$

We also consider the problem

$$(\tilde{L}) \qquad \inf_d \{v(L^d) : d \in C_0\},$$

which plays a role in the following upper estimate of the cost.

THEOREM 3.1. *Assume Λ_0 to be nonempty and (SDCQ). Then*

$$v'_+(0) \leq v(\tilde{L}) = \inf_{d \in C_0} v(D^d) \leq v(L) < \infty.$$

In particular, if $v(\tilde{L})$ is finite, then

$$v(u) \leq v(0) + uv(\tilde{L}) + o(u).$$

The theorem is an immediate consequence of the next two lemmas. The first one gives the primal upper estimate of $v'_+(0)$.

LEMMA 3.2. *Assuming (SDCQ) we have*

$$v'_+(0) \leq v(\tilde{L}) \leq v(L) < \infty.$$

Proof. Let $d \in C_0$ and take a feasible $w \in F(L^d)$. Using the restorability property we may find $w_\gamma \to w$ and feasible paths of the form

$$x_u^\gamma = x_0 + \gamma\sqrt{u}d + uw_\gamma + o(u).$$

Expanding $f(x_u^\gamma, u)$ and using the fact that d is critical, it follows that

$$v(u) \leq f(x_u^\gamma, u) \leq f(x_0, 0) + u\Psi_f(w_\gamma, \gamma d) + o(u)$$

so that $v'_+(0) \leq \Psi_f(w_\gamma, \gamma d)$. Passing to the limit when $\gamma \uparrow 1$ we deduce that $v'_+(0) \leq \Psi_f(w, d)$, and taking the infimum over $w \in F(L^d)$ and $d \in C_0$ we get

$$v'_+(0) \leq v(\tilde{L}).$$

We conclude by noting that for $d = 0$ problem (L^d) reduces to problem (L) and that $v(L) < \infty$ by [4, Prop. 2.2]. □

Let us prove next the dual expression for $v(\tilde{L})$.

LEMMA 3.3. *Assume Λ_0 to be nonempty and (SDCQ). For each $d \in C_0$ we have the following.*

(i) $v(D^d) \le v(L^d)$.

(ii) *If* (L^d) *is feasible, then for all* $\gamma \in (0,1)$, $v(D^{\gamma d}) = v(L^{\gamma d}) \in \mathbb{R}$ *and* $S(D^{\gamma d})$ *is nonempty and bounded.*

(iii) *If* (L^d) *is infeasible, then* $v(D^{\gamma d}) = \infty$ *for all* $\gamma > 1$.

(iv) $\limsup_{\gamma \uparrow 1} v(D^{\gamma d}) \le v(D^d)$.

As a consequence we obtain

$$v(\tilde{L}) = \inf_{d \in C_0} v(D^d). \tag{3.7}$$

Proof. Let us begin by showing that (3.7) is a consequence of (i)–(iv). The inequality $v(\tilde{L}) \ge \inf_{d \in C_0} v(D^d)$ is obvious from (i). To show the converse inequality it suffices to check that $v(D^d) \ge v(\tilde{L})$ for those $d \in C_0$ such that $v(D^d) < \infty$. By (iii) this implies $(L^{\gamma d})$ is feasible for each $\gamma \in (0,1)$, and then (ii) gives $v(D^{\gamma d}) = v(L^{\gamma d}) \ge v(\tilde{L})$ for all $\gamma \in (0,1)$. We conclude by letting $\gamma \uparrow 1$ and using (iv).

We now prove properties (i)–(iv).

(i) It suffices to show that if w and λ are feasible for (L^d) and (D^d), respectively, then the dual cost is not greater than the primal one. From the primal constraint it follows that

$$\sigma(\lambda, T_2^K(d)) \ge \langle \lambda, \Psi_G(w,d) \rangle,$$

which implies

$$\begin{aligned} \Psi_f(w,d) &\ge \Psi_f(w,d) + \langle \lambda, \Psi_G(w,d) \rangle - \sigma(\lambda, T_2^K(d)) \\ &= \mathcal{L}_u'(x_0, \lambda, 0) + \frac{1}{2}\mathcal{L}_x''(x_0, \lambda, 0)dd - \sigma(\lambda, T_2^K(d)), \end{aligned}$$

as was to be proved.

(ii) We first claim that $v(L^d)$ and $v(D^d)$ are finite and equal with $S(D^d)$ nonempty and bounded, whenever

$$Y = \mathbb{R}_+ \left[T_2^K(d) - G'(x_0,0)X \times \{1\} - \frac{1}{2}G_x''(x_0,0)dd \right]. \tag{3.8}$$

To motivate this relation, let us consider the family of problems obtained by perturbing additively the constraint of (L^d), that is, $\min_{w \in X} \varphi(w,y)$ with

$$\varphi(w,y) := \begin{cases} \Psi_f(w,d) & \text{if } \Psi_G(w,d) + y \in T_2^K(d), \\ \infty & \text{otherwise.} \end{cases}$$

Property (3.8) amounts to $Y = \mathbb{R}_+ \cup_w \operatorname{dom} \varphi(w,\cdot)$, so we may apply the convex duality theorem of part I [4, Thm. A.2] to deduce

$$v(L^d) = \inf_{w \in X} \varphi(w,0) = -\min_{\lambda \in Y^*} \varphi^*(0,\lambda) \tag{3.9}$$

as well as the boundedness and nonemptiness of the set of dual solutions. Now we compute

$$\begin{aligned} \varphi^*(0,\lambda) &= \sup_{w \in X, y \in Y} \{\langle \lambda, y \rangle - \Psi_f(w,d) : \Psi_G(w,d) + y \in T_2^K(d)\} \\ &= \sup_{w \in X} \left\{ \sigma(\lambda, T_2^K(d)) - \mathcal{L}'(x_0, \lambda, 0)(w,1) - \frac{1}{2}\mathcal{L}_x''(x_0, \lambda, 0)dd \right\}. \end{aligned}$$

Maximizing over w we deduce that $\varphi^*(0,\lambda) = \infty$ if $\mathcal{L}_x'(x_0, \lambda, 0) \ne 0$, and then using $(P4)$ we get

$$\varphi^*(0,\lambda) = \begin{cases} \sigma(\lambda, T_2^K(d)) - \mathcal{L}_u'(x_0, \lambda, 0) - \frac{1}{2}\mathcal{L}_x''(x_0, \lambda, 0)dd & \text{if } \lambda \in \Lambda_0, \\ \infty & \text{otherwise.} \end{cases}$$

This and (3.9) imply the equality $v(L^d) = v(D^d)$. Moreover, since the dual is attained, property $(P4)$ shows that this common value is finite. This proves our claim.

In view of the previous discussion, to prove (ii) it suffices to check that for each $\gamma \in (0, 1)$ property (3.8) holds with d replaced by $d_\gamma := \gamma d$. To see this let us choose a feasible $w \in F(L^d)$, that is,

$$G'(x_0, 0)(w, 1) + \frac{1}{2}G''_x(x_0, 0)dd \in T_2^K(d).$$

Multiplying by γ^2 and using $(P3)$ we deduce that

$$G'(x_0, 0)(\gamma^2 w, \gamma^2) + \frac{1}{2}G''_x(x_0, 0)d_\gamma d_\gamma \in T_2^K(d_\gamma).$$

From this and $(P1)$ we get

$$T_K(G(x_0, 0)) - G'(x_0, 0)X \times \{1 - \gamma^2\} \subset T_2^K(d_\gamma) - G'(x_0, 0)X \times \{1\} - \frac{1}{2}G''_x(x_0, 0)d_\gamma d_\gamma,$$

which multiplied by $\mathbb{R}_+$ and using $(P2)$ yields (3.8) for d_γ as required.

(iii) Let $\gamma > 1$ and set $d_\gamma := \gamma d$ as before. If $T_2^K(d)$ is empty, by $(P3)$ so is $T_2^K(d_\gamma)$ and then $\sigma(\lambda, T_2^K(d_\gamma)) = -\infty$, hence $v(D^{\gamma d}) = \infty$.

Let us then assume $T_2^K(d)$ to be nonempty. Since (L^d) is infeasible, the convex set $T_2^K(d) - G'(x_0, 0)X \times \{1\}$ does not contain $\frac{1}{2}G''_x(x_0, 0)dd$. But $(P1)$ and $(P2)$ show that this convex set has a nonempty interior, so that the Hahn–Banach theorem gives a nonzero $\mu \in Y^*$ that separates the set and the point, that is,

$$\left\langle \mu, G'(x_0, 0)(w, 1) + \frac{1}{2}G''_x(x_0, 0)dd \right\rangle \geq \sigma(\mu, T_2^K(d)) \quad \text{for all } w \in X. \tag{3.10}$$

This inequality and property $(P4)$ imply $\mu \in N_K(G(x_0, 0))$. Also, taking the infimum over $w \in X$ we deduce $\mu \circ G'_x(x_0, 0) = 0$ (that is to say, μ is a *singular multiplier*, as defined in the next section) so that for each $\lambda \in \Lambda_0$ and $t > 0$ we have $\lambda + t\mu \in \Lambda_0$. Since $S(D)$ is bounded (see [4, Prop. 3.1]), it follows that

$$\langle \mu, G'_u(x_0, 0)\rangle < 0.$$

With these observations property (3.10) reduces to

$$\Xi(\mu, d) := \left\langle \mu, G'_u(x_0, 0) + \frac{1}{2}G''_x(x_0, 0)dd \right\rangle - \sigma(\mu, T_2^K(d)) \geq 0,$$

which multiplied by γ^2 and using $(P3)$ gives

$$\Xi(\mu, d_\gamma) \geq (1 - \gamma^2)\langle \mu, G'_u(x_0, 0)\rangle > 0. \tag{3.11}$$

Let us fix $\lambda \in \Lambda_0$. Since $\Xi(\cdot, d_\gamma)$ is positively homogeneous and concave, and since $\lambda + t\mu \in \Lambda_0$, it follows that

$$\begin{aligned} v(D^{\gamma d}) &\geq f'_u(x_0, 0) + \frac{1}{2}f''_x(x_0, 0)d_\gamma d_\gamma + \Xi(\lambda + t\mu, d_\gamma) \\ &\geq f'_u(x_0, 0) + \frac{1}{2}f''_x(x_0, 0)d_\gamma d_\gamma + \Xi(\lambda, d_\gamma) + t\Xi(\mu, d_\gamma). \end{aligned}$$

To conclude we observe that $(P4)$ implies the finiteness of $\Xi(\lambda, d_\gamma)$, so that letting $t \uparrow \infty$ and using (3.11) we get $v(D^{\gamma d}) = \infty$.

(iv) Using $(P3)$ we obtain

$$\begin{aligned} v(D^{\gamma d}) &= \sup_{\lambda \in \Lambda_0} \left\{ \mathcal{L}'_u(x_0, \lambda, 0) + \frac{\gamma^2}{2} \mathcal{L}''_x(x_0, \lambda, 0)dd - \gamma^2 \sigma(\lambda, T_2^K(d)) \right\} \\ &\leq \sup_{\lambda \in \Lambda_0} \{(1-\gamma^2)\mathcal{L}'_u(x_0, \lambda, 0) + \gamma^2 v(D^d)\} \\ &= (1-\gamma^2)v(L) + \gamma^2 v(D^d). \end{aligned}$$

As $v(L) < \infty$, passing to the limit with $\gamma \uparrow 1$ we get the desired inequality. □

When (CQ) holds, for every $d \in C_0$ problem (L^d) is feasible and then $v(D^d) = v(L^d)$. Otherwise the previous lemma shows that $v(D^{\gamma d}) = v(L^{\gamma d})$ except for at most an exceptional value γ_0. The optimal values are finite for $\gamma < \gamma_0$ and equal to $+\infty$ for $\gamma > \gamma_0$. The following lemma shows that $\gamma_0 = 0$ iff $T_2^K(d)$ is empty. It will be useful in §4 as well.

LEMMA 3.4. *Assume (DCQ) and suppose $T_2^K(d)$ is not empty. Then letting $d_\gamma := \gamma d$ we have $F(L^{d_\gamma}) \neq \phi$ for all $\gamma > 0$ sufficiently small.*

Proof. Taking $k \in T_2^K(d)$ and using $(P2)$ we get

$$\frac{\gamma^2}{2} G''_x(x_0, 0)dd - \gamma^2 k \in T_K(G(x_0, 0)) - G'(x_0, 0)X \times \{1\}$$

for all $\gamma > 0$ sufficiently small. Then, using $(P1)$ and $(P3)$ we deduce

$$\frac{1}{2} G''_x(x_0, 0)d_\gamma d_\gamma \in T_2^K(d_\gamma) - G'(x_0, 0)X \times \{1\},$$

so we may find $w \in X$ with $\Psi_G(w, d_\gamma) \in T_2^K(d_\gamma)$. □

We end this section by giving a condition under which the upper estimate of Theorem 3.1 coincides with $v(L)$. Using $(P4)$, it is easy to see that this condition is satisfied in particular if (P_0) is *convex* in the sense that for all $y \in K$ and $\lambda \in N_K(y)$, the mapping $\mathcal{L}(\cdot, \lambda, 0)$ is convex. In that case the right-derivative $v'(0)$ is actually equal to $v(L)$ (see [4, Prop. 3.2]).

PROPOSITION 3.5. *Assume $(SDCQ)$. Then $v(\tilde{L}) = v(L)$ whenever*

$$\inf_{d \in C_0} \sup_{\lambda \in S(D)} \left\{ \frac{1}{2} \mathcal{L}''_x(x_0, \lambda, 0)dd - \sigma(\lambda, T_2^K(d)) \right\} \geq 0.$$

Proof. By Lemma 3.3 and using the equality $v(L) = v(D)$ we get

$$\begin{aligned} v(\tilde{L}) &= \inf_{d \in C_0} v(D^d) \\ &\geq \inf_{d \in C_0} \sup_{\lambda \in S(D)} \left\{ \mathcal{L}'_u(x_0, \lambda, 0) + \frac{1}{2} \mathcal{L}''_x(x_0, \lambda, 0)dd - \sigma(\lambda, T_2^K(d)) \right\} \\ &\geq v(L) + \inf_{d \in C_0} \sup_{\lambda \in S(D)} \left\{ \frac{1}{2} \mathcal{L}''_x(x_0, \lambda, 0)dd - \sigma(\lambda, T_2^K(d)) \right\} \\ &\geq v(L), \end{aligned}$$

and we conclude with Lemma 3.2. □

3.2. Lower estimates and expansion of solutions. We derive next some lower estimates for $v'_-(0)$. As $v'_-(0) \le v'_+(0) \le v(\tilde{L})$ whenever (*SDCQ*) holds, this is only of interest if $v(\tilde{L}) > -\infty$. We give conditions that imply $v'_-(0) > -\infty$, based on a result of part I (see [4, Prop. 6.1]) that we recall for the convenience of the reader.

For each set $\Omega \subset \Lambda_0$ we consider the second-order condition

$$SOC(\Omega) \qquad \text{There exist } \alpha, \epsilon > 0 \text{ s.t. } \max_{\lambda\in\Omega} \mathcal{L}''_x(x_0, \lambda, 0)dd \ge \alpha\|d\|^2 \quad \forall\, d \in C_\epsilon,$$

where

$$C_\epsilon := \{d \in X : f'_x(x_0, 0)d \le \epsilon\|d\|,\ G'_x(x_0, 0)d \in T_K(G(x_0, 0)) + \epsilon\|d\|B_Y\}.$$

Note that for $\epsilon = 0$ the *extended critical cone* C_ϵ reduces to the critical cone C_0.

PROPOSITION 3.6. *Assume (DCQ) and suppose SOC(Ω) holds for some bounded $\Omega \subset \Lambda_0$. Then, for each $O(u)$-optimal path x_u, we have $x_u = x_0 + O(\sqrt{u})$.*

Now consider the function

$$\Pi(d) := \sup_{\lambda\in\Lambda_0} \left\{ \mathcal{L}'_u(x_0, \lambda, 0) + \frac{1}{2}\mathcal{L}''_x(x_0, \lambda, 0)dd \right\}$$

and the problems

$$(\tilde{D}) \qquad \min\{\Pi(d) : d \in C_0\},$$

$$(\tilde{D}_\epsilon) \qquad \min\{\Pi(d) : f'_x(x_0, 0)d \le \epsilon,\ G'_x(x_0, 0)d \in T_K(G(x_0, 0))\}.$$

Note that $v(\tilde{D}_\epsilon)$ is a nonincreasing function of ϵ; in particular, $\lim_{\epsilon\downarrow 0} v(\tilde{D}_\epsilon) \le v(\tilde{D})$. Moreover, from $(P4)$ we get $\Pi(d) \le v(D^d)$, so under the conditions of Theorem 3.1 we deduce that

$$\lim_{\epsilon\downarrow 0} v(\tilde{D}_\epsilon) \le v(\tilde{D}) \le v(\tilde{L}). \tag{3.12}$$

PROPOSITION 3.7. *Assume (DCQ), the existence of an $o(u)$-optimal path, and SOC(Ω) for some bounded $\Omega \subset \Lambda_0$. Then $v'_-(0) > -\infty$ and*

(i) *if (CQ) holds, then for each $\varepsilon > 0$ we have*

$$v'_-(0) \ge v(\tilde{D}_\varepsilon); \tag{3.13}$$

(ii) *if any of the following conditions hold:*

(a) *the path may be expanded as $x_u = x_0 + \sqrt{u}d_0 + o(\sqrt{u})$,*

(b) *X is reflexive and $d \to \mathcal{L}''_x(x_0, \lambda, 0)dd$ is weakly lower semicontinuous at each $d \in C_0$,*

then the previous lower bound may be strengthened to

$$v'_-(0) \ge v(\tilde{D}). \tag{3.14}$$

Proof. Let x_u be an $o(u)$-optimal path. By Proposition 3.6 $d_u := (x_u - x_0)/\sqrt{u}$ stays bounded as $u \downarrow 0$, and then for each $\lambda \in \Lambda_0$ we have

$$\begin{aligned} v(u) &= f(x_u, u) + o(u) \\ &\ge v(0) + \mathcal{L}(x_u, \lambda, u) - \mathcal{L}(x_0, \lambda, 0) + o(u) \\ &\ge v(0) + u\left[\mathcal{L}'_u(x_0, \lambda, 0) + \frac{1}{2}\mathcal{L}''_x(x_0, \lambda, 0)d_u d_u\right] + o_\lambda(u), \end{aligned} \tag{3.15}$$

with $\|o_\lambda(u)\|/u \to 0$ uniformly when λ varies over bounded sets. From this and the boundedness of d_u, it follows that $v'_-(0) > -\infty$.

To prove (i) we apply Robinson's theorem [14] to the mapping $\tilde{G}(x) := G(x_0, 0) + G'_x(x_0, 0)(x - x_0)$ in order to find $\tilde{x}_u = x_u + o(\sqrt{u})$ such that $\tilde{G}(\tilde{x}_u) \in K$. Then, by suitably modifying the small term $o_\lambda(u)$, in (3.15) we can replace d_u by $\tilde{d}_u := (\tilde{x}_u - x_0)/\sqrt{u}$. Moreover, under (CQ) we know that Λ_0 is bounded so that taking the supremum over λ we get

$$v(u) \geq v(0) + u\Pi(\tilde{d}_u) + o(u),$$

from which (3.13) follows.

To show (ii), let us choose $u_k \downarrow 0$ realizing the lower limit $v'_-(0)$. When (a) holds we have $d_{u_k} \to d_0$, while in case (b) we may assume that $d_{u_k} \rightharpoonup d_0$. In both cases, $d_0 \in C_0$, and using (3.15) we get

$$v'_-(0) \geq \mathcal{L}'_u(x_0, \lambda, 0) + \frac{1}{2}\mathcal{L}''_x(x_0, \lambda, 0)d_0 d_0,$$

where in case (b) we use the weak lower semicontinuity of $\mathcal{L}''_x(x_0, \lambda, 0)dd$. Taking the supremum over $\lambda \in \Lambda_0$ we conclude (3.14). □

We now analyze under which conditions the gap between the estimate of Theorem 3.1 and (3.14) is null. We start with sufficient conditions for the equality between the optimal values of the subproblems giving the upper and lower estimates. We define *extended polyhedricity of the second kind* (for problem (P_0) at point x_0) as

$$0 \in T_2^K(d) \text{ for all } d \text{ in a dense subset of } C_0.$$

We note that in the definition of *extended polyhedricity* given in part I, the set $S(L)$ was considered instead of C_0. If the constraints are unperturbed, then $S(L) = C_0$ and both definitions coincide.

PROPOSITION 3.8. *Assume Λ_0 nonempty and $(SDCQ)$. If one of the two following conditions hold:*

(a) $0 \in T_2^K(d)$ *for all d in C_0,*

(b) (CQ) *and extended polyhedricity of the second kind hold,*

then $v(\tilde{L}) = v(\tilde{D})$ and $S(\tilde{L}) \subset S(\tilde{D})$.

Proof. From $(P4)$ it follows that when $0 \in T_2^K(d)$ we have $\sigma(\lambda, T_2^K(d)) = 0$ for all $\lambda \in \Lambda_0$, and then $\Pi(d) = v(D^d)$. Consider now a minimizing sequence $\{d^k\}$ for $(\tilde{D})$ satisfying $\sigma(\lambda, T_2^K(d^k)) = 0$. The existence of such a sequence is obvious in case (a); while in case (b) it is a consequence of the fact that, due to (CQ), $\Pi(d)$ is continuous. Along this sequence we have, by Theorem 3.1, $\Pi(d^k) = v(D^{d^k}) \geq v(\tilde{L})$. It follows that $v(\tilde{L}) \leq v(\tilde{D})$. Reminding (3.12), we get $v(\tilde{L}) = v(\tilde{D})$. The inclusion $S(\tilde{L}) \subset S(\tilde{D})$ follows easily from this. □

The following is our main result in this section. It provides a formula for the derivative of the marginal value function $v'(0)$ and analyzes the behavior of paths of approximate solutions, for problems with existence of multipliers and satisfying the weak (but not the strong) second-order sufficient optimality condition.

THEOREM 3.9. *Assume X reflexive, the existence of an $o(u)$-optimal path, $\mathcal{L}''_x(x_0, \lambda, 0)dd$ weakly lower semicontinuous and one of the two hypotheses below.*

(i) (CQ), $SOC(\Lambda_0)$, *and extended polyhedricity of the second kind;*

(ii) $(SDCQ)$, $SOC(\Omega)$ *for some bounded $\Omega \subset \Lambda_0$, and $0 \in T_2^K(d)$ for all d in C_0.*

Then:

(a) *There exists $v'(0) = v(\tilde{L}) = v(\tilde{D})$, and $S(\tilde{L}) \subset S(\tilde{D})$.*

(b) *For every $o(u)$-optimal path x_u, the weak accumulation points of $(x_u - x_0)/\sqrt{u}$ belong to $S(\tilde{D})$.*

(c) *If $d_0 \in S(\tilde{L})$ and $w_0 \in S(L^{d_0})$, then there exists an $o(u)$-optimal path of the form $x_u = x_0 + \sqrt{u}d_0 + o(\sqrt{u})$.*

Proof. (a) This follows by combining Theorem 3.1 and Propositions 3.7 and 3.8.

(b) Let d_0 be a weak limit point of $(x_u - x_0)/\sqrt{u}$. Expanding the Lagrangian as in (3.15) we get $v(\tilde{D}) = v'(0) \geq \Pi(d_0)$. As d_0 is feasible for $v(\tilde{D})$, d_0 is a solution of $v(\tilde{D})$.

(c) Using (*SDCQ*) let us select $w_\gamma \to w_0$ and feasible paths of the form $x_u^\gamma = x_0 + \gamma\sqrt{u}d_0 + uw_\gamma + o_\gamma(u)$, with (for each γ) $\|o_\gamma(u)\|/u \to 0$ when $u \to 0$. Take $\gamma_k \uparrow 1$ and choose a strictly decreasing sequence $u_k \downarrow 0$ such that

$$\|o_{\gamma_k}(u)\| \leq \frac{u}{k} \qquad \forall u \in [0, u_k]$$

from which we construct the feasible path

$$x_u = x_u^{\gamma_k} \qquad \forall u \in [u_{k+1}, u_k).$$

Then we have

$$\|x_u - x_0 - \sqrt{u}d_0\| \leq \sqrt{u}(1 - \gamma_k)\|d_0\| + u\|w_{\gamma_k}\| + \frac{u}{k} \qquad \forall u \in [u_{k+1}, u_k)$$

from which we get $x_u = x_0 + \sqrt{u}d_0 + o(\sqrt{u})$. Also, a second-order expansion implies that for $u \in [u_{k+1}, u_k)$ we have

$$f(x_u, u) = f(x_0, 0) + u\left[f'(x_0, 0)(w_{\gamma_k}, 1) + \frac{1}{2}f_x''(x_0, 0)d_0d_0\right] + o(u)$$

so that

$$\begin{aligned} f(x_u, u) &= f(x_0, 0) + u\Psi_f(w_0, d_0) + o(u) \\ &= v(0) + uv(\tilde{L}) + o(u) = v(u) + o(u). \end{aligned}$$

The conclusion follows. □

4. Perturbation analysis assuming nonexistence of multipliers.

4.1. Preliminaries. In this section we analyze the situation when the set of multipliers Λ_0 is empty, extending the theory of perturbed singular nonlinear programs of [3]. The qualitative behavior is radically different from the case studied in §3, so we are led to introduce some new objects. Indeed, if Λ_0 is empty we have $v(L) = -\infty$ and by part I it follows that $v'(0) = -\infty$.

We will check that, under suitable second-order assumptions, the variation of the cost is of order $O(\sqrt{u})$. This leads us to define, analogously to the Dini derivatives, the following quantities:

$$v^\#(0) := \limsup_{u \downarrow 0} \frac{v(u) - v(0)}{\sqrt{u}},$$

$$v_\#(0) := \liminf_{u \downarrow 0} \frac{v(u) - v(0)}{\sqrt{u}}.$$

We define the singular Lagrangian, the set of singular multipliers (at x_0, for problem (P_0)), and the set of *normalized* singular multipliers as

$$\begin{aligned} \hat{\mathcal{L}}(x, \lambda, u) &:= \langle \lambda, G(x, u) \rangle, \\ \Lambda^s &:= \{\lambda \in Y^* \setminus \{0\} : \ \lambda \in N_K(G(x_0, 0)), \ \hat{\mathcal{L}}_x'(x_0, \lambda, 0) = 0\}, \\ \Lambda_N^s &:= \{\lambda \in \Lambda^s : \|\lambda\| \leq 1\}. \end{aligned}$$

The next proposition shows that Λ_0 and Λ^s are both empty only in some very special situations.

PROPOSITION 4.1. *If both Λ_0 and Λ^s are empty, then the set*

$$\mathcal{A} := \mathbb{R}_+[K - G(x_0, 0)] - G'_x(x_0, 0)X$$

is dense in Y but not equal to Y.

Proof. If $\mathcal{A} = Y$ we know that $\Lambda_0 \neq \phi$ [13, 14]. Suppose next that $\mathcal{A}$ is not dense in Y and select $y \in Y$ not belonging to the closure of $\mathcal{A}$. By the Hahn–Banach theorem there exists $\lambda \in Y^* \setminus \{0\}$ such that

$$\langle \lambda, y\rangle > \langle \lambda, t[k - G(x_0, 0)] - G'_x(x_0, 0)w\rangle \quad \text{for all } w \in X,\ k \in K,\ t > 0.$$

Taking the supremum over $w \in X$, we get $\lambda \circ G'_x(x_0, 0) = 0$, and letting $t \uparrow \infty$ we deduce $\langle \lambda, k - G(x_0, 0)\rangle \leq 0$ for all $k \in K$, so $\lambda \in N_K(G(x_0, 0))$ and then $\Lambda^s \neq \phi$. □

4.2. Upper estimate of the cost. To obtain upper estimates for $v^{\#}(0)$ we consider the following optimization problems:

$$(\hat{L}) \qquad \min_{d \in C_0} \left\{ f'_x(x_0, 0)d : \frac{1}{2}G''_x(x_0, 0)dd \in T_2^K(d) - G'(x_0, 0)X \times \{1\} \right\}$$

and

$$(\hat{D}) \qquad \min_{d \in C_0} \left\{ f'_x(x_0, 0)d : \frac{1}{2}G''_x(x_0, 0)dd \in \overline{T_2^K(d) - G'(x_0, 0)X \times \{1\}} \right\}.$$

Problem $(\hat{L})$ will give an upper estimate of the value function whereas $(\hat{D})$, which has the same optimal value as $(\hat{L})$, will provide a comparison with the lower estimate of $v_{\#}(0)$. We remark that, when Λ^s is not empty, problem $(\hat{D})$ is equivalent to

$(\hat{D}')$

$$\min_{d \in C_0} \left\{ f'_x(x_0, 0)d : \hat{\mathcal{L}}'_u(x_0, \lambda, 0) + \frac{1}{2}\hat{\mathcal{L}}''_x(x_0, \lambda, 0)dd \leq \sigma(\lambda, T_2^K(d)),\ \text{for all } \lambda \in \Lambda^s \right\}.$$

To prove this equivalence it suffices to check that the constraints in $(\hat{D})$ and $(\hat{D}')$ coincide, which follows from the next result applied with $y = G'_u(x_0, 0) + \frac{1}{2}G''_x(x_0, 0)dd$.

PROPOSITION 4.2. *If $\Lambda^s \neq \phi$, then the following are equivalent.*

(a) $y \in \overline{T_2^K(d) - G'_x(x_0, 0)X}$.

(b) $\langle \lambda, y\rangle \leq \sigma(\lambda, T_2^K(d))$ *for all* $\lambda \in \Lambda^s$.

Proof. Both (a) and (b) are false if $T_2^K(d)$ is empty, so we may assume the contrary. The implication (a) $\Rightarrow$ (b) is straightforward and the converse follows by a separation argument. Indeed, if (a) fails we may find a *strictly* separating hyperplane, that is, $\lambda \in Y^* \setminus \{0\}$ and $\alpha \in \mathbb{R}$ such that

$$\langle \lambda, y\rangle > \alpha \geq \langle \lambda, k - G'_x(x_0, 0)w\rangle$$

for all $k \in T_2^K(d)$, $w \in X$. Taking the supremum over $w \in X$ it follows that $\lambda \circ G'_x(x_0, 0) = 0$, and then taking the supremum over k we deduce that

$$\langle \lambda, y\rangle > \alpha \geq \sigma(\lambda, T_2^K(d)). \tag{4.16}$$

Using this and $(P4)$ we get $\lambda \in N_K(G(x_0, 0))$, so $\lambda \in \Lambda^s$ and (4.16) contradicts (b). □

We now state the upper estimate.

THEOREM 4.3. *If (SDCQ) holds, then*

$$v^{\#}(0) \leq v(\hat{L}) = v(\hat{D}) \leq 0,$$

so when $v(\hat{L})$ is finite, we have

$$v(u) \le v(0) + \sqrt{u}v(\hat{L}) + o(\sqrt{u}).$$

In addition, $v(\hat{L}) < 0$ iff there exists a direction d such that $f'_x(x_0,0)d < 0$ and $T_2^K(d) \neq \phi$.

Proof. We begin by showing $v^{\#}(0) \le v(\hat{L}) \le 0$. Let $d \in F(\hat{L})$ and select $w \in X$ such that $G'(x_0,0)(w,1) + \frac{1}{2}G''_x(x_0,0)dd \in T_2^K(d)$. Using the restorability property we may find feasible paths of the form $x_u^\gamma = x_0 + \gamma\sqrt{u}d + uw_\gamma + o(u)$ with $w_\gamma \to w$ as $\gamma \uparrow 1$. Expanding f it follows that

$$v(u) \le f(x_u^\gamma, u) = f(x_0,0) + \gamma\sqrt{u}\, f'_x(x_0,0)d + o(\sqrt{u}),$$

from which we deduce

$$v^{\#}(0) \le \gamma f'_x(x_0,0)d.$$

Letting $\gamma \uparrow 1$ and then taking the infimum over $d \in F(\hat{L})$ we get $v^{\#}(0) \le v(\hat{L})$. Moreover, $(P2)$ implies $0 \in F(\hat{L})$, so $v(\hat{L}) \le 0$.

We prove next $v(\hat{L}) = v(\hat{D})$. Since clearly $v(\hat{D}) \le v(\hat{L})$, it suffices to show that $v(\hat{L}) \le f'_x(x_0,0)d$ for each $d \in F(\hat{D})$. Let $d \in F(\hat{D})$ and select sequences $k_n \in T_2^K(d)$, $w_n \in X$ such that $\frac{1}{2}G''_x(x_0,0)dd = \lim_n[k_n - G'(x_0,0)(w_n,1)]$. Using $(P2)$ we find that given any $t > 0$ we will have for all n large enough

$$\frac{1}{2}tG''_x(x_0,0)dd - tk_n + tG'(x_0,0)(w_n,1) \in T_K(G(x_0,0)) - G'(x_0,0)X \times \{1\},$$

which rearranged gives

$$\frac{1}{2}\frac{t}{1+t}G''_x(x_0,0)dd \in \frac{t}{1+t}k_n + T_K(G(x_0,0)) - G'(x_0,0)X \times \{1\}. \tag{4.17}$$

Letting $d_t := \sqrt{t/(1+t)}d$ and using $(P1)$ and $(P3)$ we deduce that

$$\frac{1}{2}G''_x(x_0,0)d_td_t \in T_2^K(d_t) - G'(x_0,0)X \times \{1\}.$$

Hence $d_t \in F(\hat{L})$ and then

$$v(\hat{L}) \le f'_x(x_0,0)d_t.$$

Letting t tend to $+\infty$ we conclude that $v(\hat{L}) \le f'_x(x_0,0)d$, as required.

We conclude by proving the sufficient condition for $v(\hat{L}) < 0$ (the necessity is evident). If $d \in X$ is such that $f'_x(x_0,0)d < 0$ and $T_2^K(d) \neq \phi$, from Lemma 3.4 we get $\alpha d \in F(\hat{L})$ for all $\alpha > 0$ sufficiently small, so that $v(\hat{L}) \le \alpha f'_x(x_0,0)d < 0$. □

Remark. From the estimate (1.1) we already know that $v_{\#}(0) \le 0$. Henceforth Theorem 4.3 improves the upper estimate of the cost only if $v(\hat{L}) < 0$.

4.3. Lower estimates and expansion of solutions. As in the case when $\Lambda_0 \neq \phi$, we will give a lower estimate of the cost that is sharp when the contribution of the curvature of K happens to be null.

We consider the *singular* second-order conditions

$$\text{there exist } \alpha, \epsilon > 0 \text{ s.t. } \sup_{\lambda \in \Lambda_N^s} \hat{\mathcal{L}}''_x(x_0,\lambda,0)dd \ge \alpha\|d\|^2 \quad \forall\, d \in C_\epsilon. \tag{SSOC}$$

PROPOSITION 4.4. *If (SSOC) holds, then for each $O(\sqrt{u})$-optimal path x_u we have $x_u = x_0 + O(\sqrt{u})$.*

Proof. Let x_u be an $O(\sqrt{u})$-optimal path and let $\beta_u := \|x_u - x_0\|$, $d_u := (x_u - x_0)/\beta_u$. For each $\lambda \in \Lambda_N^s$ we have

$$\begin{aligned} 0 &\geq \hat{\mathcal{L}}(x_u, \lambda, u) - \hat{\mathcal{L}}(x_0, \lambda, 0) \\ &= u\hat{\mathcal{L}}'_u(x_0, \lambda, 0) + \frac{\beta_u^2}{2}\hat{\mathcal{L}}''_x(x_0, \lambda, 0)d_u d_u + o(u) + o(\beta_u^2). \end{aligned}$$

The small terms $o(u)$ and $o(\beta_u^2)$ may be chosen independent of $\lambda \in \Lambda_N^s$, so we may take the supremum to deduce that

$$\beta_u^2 \max_{\lambda \in \Lambda_N^s} \mathcal{L}''_x(x_0, \lambda, 0)d_u d_u \leq O(u) + o(\beta_u^2). \tag{4.18}$$

If for some sequence $u_n \downarrow 0$ one has $\beta_{u_n}^2/u_n \uparrow \infty$, then for n large enough d_{u_n} is in C_ϵ. With (*SSOC*) and (4.18), we obtain a contradiction. □

To obtain the desired lower estimate for $v_\#(0)$ we consider a *relaxed* version of problem $(\hat{D})$, namely,

$$(\hat{R}) \qquad \min_{d \in C_0} \left\{ f'_x(x_0, 0)d : \frac{1}{2}G''_x(x_0, 0)dd \in \overline{T_K(G(x_0, 0)) - G'(x_0, 0)X \times \{1\}} \right\}.$$

As for problem $(\hat{D})$, when Λ^s is not empty one may use Proposition 4.2 (with $d = 0$) to derive the following equivalent formulation for $(\hat{R})$:

$$(\hat{R}') \qquad \min_{d \in C_0} \left\{ f'_x(x_0, 0)d : \hat{\mathcal{L}}'_u(x_0, \lambda, 0) + \frac{1}{2}\hat{\mathcal{L}}''_x(x_0, \lambda, 0)dd \leq 0 \text{ for all } \lambda \in \Lambda^s \right\}.$$

Comparing with $(\hat{D}')$ and using $(P4)$, we see that $F(\hat{D}') \subset F(\hat{R}')$. As these two problems have the same cost, it follows that

$$v(\hat{R}) = v(\hat{R}') \leq v(\hat{D}') = v(\hat{D}). \tag{4.19}$$

PROPOSITION 4.5. *Assume there exists an $o(\sqrt{u})$-optimal path x_u. If (SSOC) is satisfied, then $v_\#(0) > -\infty$. Moreover, if any of the two following properties hold:*

(a) *the path may be expanded as $x_u = x_0 + \sqrt{u}d_0 + o(\sqrt{u})$,*

(b) *X is reflexive and for each $\lambda \in \Lambda^s$ the mapping $d \to \hat{\mathcal{L}}''_x(x_0, \lambda, 0)dd$ is weakly lower semicontinuous at every $d_0 \in C_0$,*

then

$$v_\#(0) \geq v(\hat{R}). \tag{4.20}$$

Proof. By Proposition 4.4 we have $x_u = x_0 + O(\sqrt{u})$ and then

$$v(u) = f(x_u, u) + O(\sqrt{u}) = f(x_0, 0) + O(\sqrt{u}),$$

so $v_\#(0) > -\infty$.

Now let us choose $u_n \downarrow 0$ realizing the lower limit $v_\#(0)$, and let $d_n := (x_{u_n} - x_0)/\sqrt{u_n}$. When (a) holds we have $d_n \to d_0$, while in case (b) we may assume that $d_n \rightharpoonup d_0$ for some $d_0 \in X$. In both cases, $d_0 \in C_0$ and we have

$$v_\#(0) = f'_x(x_0, 0)d_0.$$

On the other hand for all $\lambda \in \Lambda^s$

$$\begin{aligned} 0 &\geq \hat{\mathcal{L}}(x_u, \lambda, u) - \hat{\mathcal{L}}(x_0, \lambda, 0) \\ &= u\hat{\mathcal{L}}'_u(x_0, \lambda, 0) + \frac{u}{2}\hat{\mathcal{L}}''_x(x_0, \lambda, 0)d_u d_u + o(u), \end{aligned}$$

so, using in case (b) the lower semicontinuity of $\hat{\mathcal{L}}''_x(x_0, \lambda, 0)dd$ we get

$$0 \geq \hat{\mathcal{L}}'_u(x_0, \lambda, 0) + \frac{1}{2}\hat{\mathcal{L}}''_x(x_0, \lambda, 0)d_0 d_0.$$

It follows that $d_0 \in F(\hat{R}')$. Combining with (4.19) we get

$$v(\hat{R}) = v(\hat{R}') \leq f'_x(x_0, 0)d_0 = v_\#(0),$$

as was to be proved. □

Let us put together the different bounds obtained so far. If (*SDCQ*) and the assumptions of Proposition 4.5 hold, then

$$v(\hat{R}) = v(\hat{R}') \leq v_\#(0) \leq v^\#(0) \leq v(\hat{D}') = v(\hat{D}) = v(\hat{L}) \leq 0.$$

In our next statement, which is our main result for problems with nonexistence of multipliers, we give a condition for all these optimal values to be equal. This gives the first term of the expansion of the optimal value $v(u)$.

THEOREM 4.6. *Assume the existence of an $O(\sqrt{u})$-optimal path x_u, (SSOC), X reflexive, the lower semicontinuity of $d \to \hat{\mathcal{L}}''_x(x_0, \lambda, 0)dd$ for each $\lambda \in \Lambda^s$, (SDCQ), and finally*

$$0 \in T_2^K(d) \quad \text{for all } d \in C_0.$$

Then $v(\hat{R}) = v(\hat{D})$, $S(\hat{R}) = S(\hat{D})$, and

$$v(u) = v(0) + \sqrt{u}\, v(\hat{D}) + o(\sqrt{u}). \tag{4.21}$$

Proof. The equivalence between $(\hat{R})$ and $(\hat{D})$ follows by noting that when $0 \in T_2^K(d)$ (see [8, Prop. 3.1])

$$T_2^K(d) = \overline{T_K(G(x_0, 0)) - \mathbb{R}_+ G'_x(x_0, 0)d},$$

from which we deduce

$$\overline{T_2^K(d) - G'(x_0, 0)X \times \{1\}} = \overline{T_K(G(x_0, 0)) - G'(x_0, 0)X \times \{1\}}.$$

The expansion of $v(u)$ then follows from Theorem 4.3 and Proposition 4.5. □

5. Appendix: Checking the strong directional constraint qualification. We give some sufficient conditions for checking (*SDCQ*) in the case of *decomposed* constraints of the form: $Y := Y_1 \times Y_2$ with Y_1 and Y_2 Banach spaces and $K := K_1 \times K_2$ with K_1 and K_2 closed convex subsets of Y_1 and Y_2. We denote by $G = (G_1, G_2)$ the components of G, and we consider the decomposed directional constraint qualification:

$$(DDCQ) \quad \begin{cases} \text{(i)} & 0 \in \operatorname{int}[G_1(x_0, 0) + G'_1(x_0, 0)X \times \{0\} - K_1], \\ \text{(ii)} & \text{there exists } \bar{w} \in X \text{ such that } G'_1(x_0, 0)(\bar{w}, 1) \in \operatorname{Rec}(K_1) \text{ and} \\ & G_2(x_0, 0) + \alpha G'_2(x_0, 0)(\bar{w}, 1) \in \operatorname{int} K_2 \text{ for some } \alpha > 0, \end{cases}$$

where $\mathrm{Rec}(K_1)$ denotes the recession cone of K_1, that is,

$$\mathrm{Rec}(K_1) := \limsup_{t\to\infty} \frac{K_1}{t}.$$

To illustrate this condition, let us mention two particular cases. The first one is when $K_2 = Y_2$ so that the constraint is only with K_1. Then (*DDCQ*) reduces to Robinson's condition [14]. The second case is when $K_1 = \{0\}$. Then (*DDCQ*) (i) amounts to the surjectivity of $G'_{1x}(x_0, 0)$ and (*DDCQ*) appears as a natural generalization of Gollan's condition [10] used in the aforementioned literature devoted to nonlinear programming.

THEOREM 5.1. *(DDCQ) implies (SDCQ).*

Proof. We first prove that x_0 is restorable. Let x_u be a path satisfying (2.3) and (2.4). Choose $w_\gamma := \gamma^2 w + (1-\gamma^2)\bar{w}$ and consider

$$y_u := x_0 + \gamma\sqrt{u}d + uw_\gamma. \tag{5.22}$$

Expanding in series we get

$$\begin{aligned} G(y_u, u) &= G(x_0, 0) + \gamma\sqrt{u}G'_x(x_0, 0)d + u\Psi_G(w_\gamma, \gamma d) + o(u) \\ &= G(x_0, 0) + \gamma\sqrt{u}G'_x(x_0, 0)d + \gamma^2 u\Psi_G(w, d) \\ &\quad + (1-\gamma^2)uG'(x_0, 0)(\bar{w}, 1) + o(u) \\ &= G(x(\gamma^2 u), \gamma^2 u) + (1-\gamma^2)uG'(x_0, 0)(\bar{w}, 1) + o(u). \end{aligned}$$

Using (*DDCQ*) (ii) and (2.4) we deduce $d(G_1(y_u, u), K_1) = o(u)$. Then (*DDCQ*) (i) allows us to use Robinson's theorem to find a small correction x_u^γ of y_u,

$$x_u^\gamma = x_0 + \gamma\sqrt{u}d + uw_\gamma + o(u), \tag{5.23}$$

such that $G_1(x_u^\gamma, u) \in K_1$.

Expanding $G_2(x_u^\gamma, u)$ as above, we get

$$G_2(x_u^\gamma, u) = G_2(x(\gamma^2 u), \gamma^2 u) + (1-\gamma^2)uG'_2(x_0, 0)(\bar{w}, 1) + o(u), \tag{5.24}$$

so that letting $z := G'_2(x_0, 0)(\bar{w}, 1)$ and using (2.4) we have

$$G_2(x_u^\gamma, u) = t_u + (1-\gamma^2)uz + o(u)$$

for some $t_u \in K_2$, $t_u \to G_2(x_0, 0)$. Moreover, letting $\alpha_u := (1-\gamma^2)u/\alpha$ we may write $G_2(x_u^\gamma, u) = (1-\alpha_u)t_u + \alpha_u r_u$ with

$$r_u = t_u + \alpha z + \alpha o(u)/(1-\gamma^2)u = t_u + \alpha z + o(1).$$

By (*DDCQ*) (i) we have $r_u \in K_2$ for u small; since also $t_u \in K_2$ and $\alpha_u \in (0, 1)$, it follows that $G_2(x_u^\gamma, u) \in K_2$. Hence x_u^γ is a feasible path and x_0 is restorable.

We now check that (*DCQ*) is satisfied. By (*DDCQ*) (i) (see [14]) there exist $\epsilon > 0$ and $\beta > 0$ such that, whenever $y_1 \in Y_1$ satisfies $\|y_1\| < \epsilon$, there exist $\hat{d} \in X$ and $k_1 \in K_1$ such that $\|\hat{d}\| < \beta\|y_1\|$ and

$$G_1(x_0, 0) + G'_1(x_0, 0)(\hat{d}, 0) - k_1 = y_1.$$

Now take d of the form $d = \hat{d} + \alpha\bar{w}$. Then

$$G_1(x_0, 0) + G'_1(x_0, 0)(d, \alpha) - [k_1 + \alpha G'(x_0, 0)(\bar{w}, 1)] = y_1$$

and

$$G_2(x_0, 0) + G_2'(x_0, 0)(d, \alpha) - y_2 = G_2(x_0, 0) + \alpha G_2'(x_0, 0)(\bar{w}, 1) + G_2'(x_0, 0)(\hat{d}, 0) - y_2.$$

We may choose ϵ small so that for all $\|y_1\| < \epsilon$, $\|y_2\| < \epsilon$ we have $\|G_2'(x_0, 0)(\hat{d}, 0) - y_2\|$ small enough to deduce, using (*DDCQ*) (ii), that the left-hand side above is in K_2. From this (*DCQ*) follows easily. □

Remark. We do not know (even for nonlinear programming problems) if the property $d(G(x_0 + \sqrt{u}d + uw, u), K) = o(u)$ together with (*DCQ*) suffices or not to construct a feasible path of the form $x_u = x_0 + \sqrt{u}d_0 + uw + o(u)$ (without γ and w_γ).

Our final result shows that, for the important class of equality-inequality constrained problems, the restorability property is a consequence of the directional constraint qualification condition (*DCQ*). So in this case the strong qualification (*SDCQ*) is equivalent to (*DCQ*).

PROPOSITION 5.2. *If* $K := \{0\} \times K_2$ *with* $\operatorname{int}(K_2)$ *nonempty, then* (*DCQ*), (*SDCQ*), *and* (*DDCQ*) *are equivalent and are satisfied iff the condition* (*EDCQ*) *holds.*

$$(EDCQ) \qquad \begin{cases} \text{(i)} & G_1'(x_0, 0)X \times \{0\} = Y_1, \\ \text{(ii)} & \text{there exists } \bar{w} \in X \text{ such that } G_1'(x_0, 0)(\bar{w}, 1) = 0 \text{ and} \\ & G_2(x_0, 0) + \alpha G_2'(x_0, 0)(\bar{w}, 1) \in \operatorname{int} K_2 \text{ for some } \alpha > 0. \end{cases}$$

Proof. Obviously each of the conditions (*DCQ*), (*SDCQ*), (*DDCQ*), and (*EDCQ*) is a consequence of the one that follows. Therefore it suffices to prove that (*DCQ*) implies (*EDCQ*). From (*DCQ*), $G_1'(x_0, 0)X \times (0, \infty)$ contains a neighborhood of 0. Being a cone, this set is equal to Y_1. In particular there exist $d_0 \in X, \alpha_0 > 0$ such that $G_1'(x_0, 0)(d_0, \alpha_0) = 0$, i.e., $G_u'(x_0, 0) \in G_1'(x_0, 0)X \times \{0\}$. We deduce that

$$Y_1 = G_1'(x_0, 0)X \times (0, \infty) = G_1'(x_0, 0)X \times \{0\},$$

i.e., (*EDCQ*) (i) holds. Now pick $a \in \operatorname{int}(K_2)$ close enough to $G_2(x_0, 0)$ so that there exist $d \in X$ and $\tilde{\alpha} > 0$ such that $(0, a - G_2(x_0, 0)) \in G(x_0, 0) + G'(x_0, 0)(d, \tilde{\alpha}) - K$. It is easily checked that (*EDCQ*) (ii) is satisfied with $\bar{w} := d/\tilde{\alpha}, \alpha := \tilde{\alpha}/2$. □

ON FINITE-GAIN STABILIZABILITY OF LINEAR SYSTEMS SUBJECT TO INPUT SATURATION*

WENSHENG LIU†, YACINE CHITOUR†, AND EDUARDO SONTAG†

Abstract. This paper deals with (global) finite-gain input/output stabilization of linear systems with saturated controls. For neutrally stable systems, it is shown that the linear feedback law suggested by the passivity approach indeed provides stability, with respect to every L^p-norm. Explicit bounds on closed-loop gains are obtained, and they are related to the norms for the respective systems without saturation.

These results do not extend to the class of systems for which the state matrix has eigenvalues on the imaginary axis with nonsimple (size > 1) Jordan blocks, contradicting what may be expected from the fact that such systems are globally asymptotically stabilizable in the state-space sense; this is shown in particular for the double integrator.

Key words. small input saturations, linear systems, finite-gain stability, Lyapunov functions, dissipative systems

1. Introduction.

In this work we are interested in those nonlinear systems that are obtained when cascading a linear system with a memory-free input nonlinearity:

$$(\Sigma) \qquad \dot{x} = Ax + B\sigma(u), \quad y = Cx\,.$$

The nonlinearity σ is of a "saturation" type (definitions are given later). Figure 1 shows the type of system being considered, where the linear part has transfer function $W(s)$ and the function σ shown is the standard semilinear saturation (results will apply to more general σ's).

Linear systems with actuator saturation constitute one of the most important classes of nonlinear systems encountered in practice. Surprisingly, until recently few general theoretical results were available regarding global feedback design problems for them. One such general result was given in [14], which showed that global state-space stabilization for such systems is possible under the assumptions that all the eigenvalues of A are in the closed left-hand plane, plus stabilizability and detectability of (A, B, C). (These conditions are best possible, since they are also necessary. The controller consists of an observer followed by a smooth static nonlinearity.) For more recent work, see [20], which showed—based upon techniques introduced in [16] for a particular case—how to simplify the controller that had been proposed in [14]. See also [8] for closely related work showing that such systems can be semiglobally (that is, on compact sets) stabilized by means of linear feedback.

In this paper, we are interested in studying not merely closed-loop *state-space* stability, but also stability with respect to measurement and actuator noise. This is the notion of stability that is often found in input/output studies. The problem is to find a controller C so that the operator $(u_1, u_2) \mapsto (y_1, y_2)$ defined by the standard systems interconnection

$$\begin{aligned} y_1 &= P(u_1 + y_2), \\ y_2 &= C(u_2 + y_1) \end{aligned}$$

is well posed and finite-gain stable, where P denotes the input/output behavior of the original plant Σ. See Fig. 2. (In our main results, we will take for simplicity the initial state to be zero. However, nonzero initial states can be studied as well, and some remarks in that regard

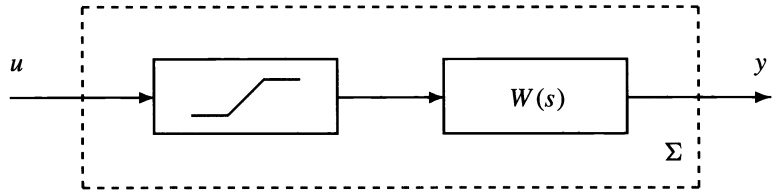

FIG. 1. *Input-saturated linear system.*

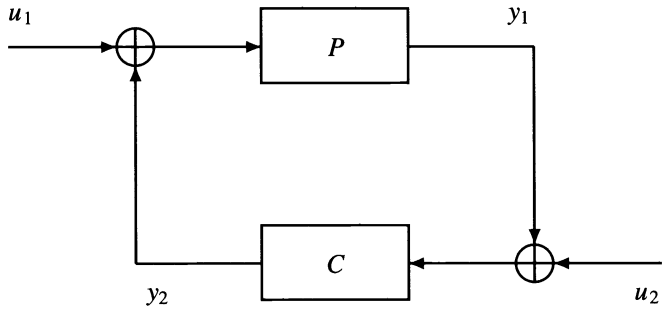

FIG. 2. *Standard closed loop.*

are presented in a latter section of the paper.) Once such input/output stability is achieved, geometric operator-theoretic techniques can be applied; see for instance [3] and the references therein. For other work on computing norms for nonlinear systems in state-space form, see for instance [18] and the references given therein.

We focus on a case which would be trivial if one were only interested in state stability, specifically when the original matrix A is neutrally stable; that is, we focus on the case where all eigenvalues have nonpositive real parts and there are no nontrivial Jordan blocks for eigenvalues in the imaginary axis. (The whole point of [14] and [20] was of course to deal with such possible nontrivial blocks, e.g., multiple integrators.) In this case, a standard passivity approach suggests the appropriate stabilization procedure. For instance, assume that σ is the identity (so the original system is linear), $A + A' \leq 0$, and $C = B'$. Then the system is passive, with storage function $V(x) = \|x\|^2/2$, since integrating the inequality $dV(x(t))/dt \leq y(t)'u(t)$ gives $\int_0^t y(s)'u(s)ds \geq V(x(t)) - V(x(0))$. Thus the negative feedback interconnection with the identity (strictly passive system), that is, $u = -y$, results in finite-gain stability. For this calculation and more discussion on passivity, see for instance [7] and the references given therein. (For the use of the same formulas for just *state-space* stabilization with applications to linear systems with saturations, see [5] and [9]; see also the discussion on the Jurdevic–Quinn method in [13].)

In this paper, we essentially generalize the passivity technique to systems with saturations. We first establish finite-gain stability in the various p-norms, using linear state feedback stabilizers. Then we show how outputs can be incorporated into the framework. Our work is very much in the spirit of the well-known absolute stability area, but we have not been able to find a way to deduce our results from that classical literature.

These results do not extend to the class of systems for which the state matrix has eigenvalues on the imaginary axis with nonsimple (size> 1) Jordan blocks, contradicting what may be expected from the fact that such systems are globally asymptotically stabilizable in the state-space sense; this is shown in particular for the double integrator.

We make one remark on terminology. In the operator approach to nonlinear systems, see, e.g., [19], a "system" is typically defined as a partially defined operator between normed spaces, and "stability" means that the domain of this operator is the entire space. In that context, finite-gain stability is the requirement that the operator be everywhere defined and bounded; the norm of the operator is by definition the gain of the system. In this paper, we use simply the term L^p-stability to mean this stronger finite-gain condition.

The reader is referred to the companion paper [2] for results complementary to those in this paper, dealing with Lipschitz continuity ("incremental gain stability") and continuity of the operators in question. The two papers are technically independent.

Organization of Paper. In §2 we provide definitions and statements of the main results, as well as some related comments. Proofs of the main results are given in §3. Section 4 estimates gains in terms of the corresponding gains for systems without saturation, in particular for $p = 2$ (H_∞-norms). Results regarding nonzero initial states and global asymptotic stability of the origin are collected in §5. Section 6 shows how to enlarge the class of input nonlinearities even more, so as to include nonsaturations as well. The paper closes with §7, which contains the double integrator counterexample.

2. Statements of main results. We introduce now the class of saturation functions to be considered, and state the main results on finite-gain stability. Some remarks are also provided. Proofs are deferred to a later section.

2.1. Saturation functions. We next formally define what we mean by a saturation. Essentially, we ask only that this be a function which has the same sign as its argument, stays away from zero at infinity, is bounded, and is not horizontal near zero.

DEFINITION 1. *We call* $\sigma : \mathbb{R} \to \mathbb{R}$ *a* saturation *function if it satisfies the following two conditions:*

(i) σ *is locally Lipschitz and bounded*;

(ii) $t\sigma(t) > 0$ *if* $t \neq 0$, $\liminf_{t\to 0} \frac{\sigma(t)}{t} > 0$, *and* $\liminf_{|t|\to\infty} |\sigma(t)| > 0$.

For convenience we will simply call a saturation function σ an *S-function*. We say that σ is an $\mathbb{R}^n$*-valued S-function* if $\sigma = (\sigma_1, \ldots, \sigma_n)'$, where each component σ_i is an S-function and

$$\sigma(x) \stackrel{\text{def}}{=} (\sigma_1(x_1), \ldots, \sigma_n(x_n))'$$

for $x = (x_1, \ldots, x_n)' \in \mathbb{R}^n$. Here we use $(\cdots)'$ to denote the transpose of the vector $(\cdots)$.

Remark 1. It follows directly from Definition 1 that most reasonable saturation-type functions are indeed S-functions in our sense. Included are $\arctan(t)$, $\tanh(t)$, and the standard saturation function $\sigma_0(t) = \operatorname{sign}(t) \min\{|t|, 1\}$, i.e.,

$$\sigma_0(t) = \begin{cases} 1 & \text{if } t > 1, \\ t & \text{if } |t| \leq 1, \\ -1 & \text{if } t < -1. \end{cases}$$

Remark 2. It is easy to see that if σ satisfies a bound $|\sigma(t)| \leq M|t|$ for t near zero (in particular if $\sigma(0) = 0$ and (i) in Definition 1 holds), then Condition (ii) in Definition 1 is equivalent to the following condition:

(c) There exist positive numbers a, b, K and a measurable function $\tau : \mathbb{R} \to [a, b]$ such that for all $t \in \mathbb{R}$ we have $|\sigma(t) - \tau(t)t| \leq Kt\sigma(t)$.

It is clear that (c) implies (ii). To see the converse, let $\delta > 0$ be such that $|\sigma(t)| \leq M|t|$ for $|t| \leq \delta$. Then just let

$$\tau(t) = \begin{cases} 1 & \text{if } t = 0, \\ \frac{\sigma(t)}{t} & \text{if } t \in [-\delta, \delta]/\{0\}, \\ \frac{\sigma(\delta)}{\delta} & \text{if } t > \delta, \\ -\frac{\sigma(-\delta)}{\delta} & \text{if } t < -\delta. \end{cases}$$

It is easily verified that there exist positive constants a, b, K such that (c) holds for this τ.

DEFINITION 2. *We say that a constant $K > 0$ is an S-bound for σ if there exist $a, b > 0$ and a measurable function $\tau : \mathbb{R} \to [a, b]$ such that, for all $t \in \mathbb{R}$,*

(i) $b \leq K$,
(ii) $|\sigma(t)| \leq K$,
(iii) $|\sigma(t)| \leq K|t|$,
(iv) $|\sigma(t) - \tau(t)t| \leq Kt\sigma(t)$.

The above discussion shows that such (finite) S-bounds always exist.

A constant $K > 0$ is called an S-bound for an $\mathbb{R}^m$-valued S-function σ if K is an S-bound for each component of σ.

2.2. L^p-Stability. Consider the initialized control system given by

$$\begin{aligned} \dot{x} &= f(x, u), \\ x(0) &= 0, \end{aligned} \tag{1}$$

where the state x and the control u take, respectively, values in $\mathbb{R}^n$ and $\mathbb{R}^m$. We assume that the function $f : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$ is locally Lipschitz with respect to (x, u). Terminology for systems will be as in any standard reference, such as [13].

Throughout this paper, if ξ is a point in $\mathbb{R}^n$, we use $\|\xi\| = (\sum_{i=1}^n \xi_i^2)^{1/2}$ to denote the usual Euclidean norm. For each matrix S, $\|S\|$ denotes the induced operator norm, and $\|S\|_F$ denotes the Frobenius norm, i.e, $\|S\|_F = \mathrm{Tr}(SS')^{1/2}$, where $\mathrm{Tr}(\cdot)$ denotes trace. Recall that $\|S\| \leq \|S\|_F$.

For each $1 \leq p \leq \infty$ and each integrable (essentially bounded, for $p = \infty$) vector-valued function $x \in L^p([0, \infty), \mathbb{R}^n)$, we let $\|x\|_{L^p}$ denote the usual L^p-norms:

$$\|x\|_{L^p} = \left(\int_0^\infty \|x(t)\|^p dt \right)^{1/p},$$

if $p < \infty$, and

$$\|x\|_{L^\infty} = \text{ess sup}_{0 \leq t < \infty} \|x(t)\|.$$

DEFINITION 3. *Let $1 \leq p \leq \infty$ and $0 \leq M \leq \infty$. We say that (1) has L^p-gain less than or equal to M if for any $u \in L^p([0, \infty), \mathbb{R}^m)$, the solution x of (Σ) corresponding to u is in $L^p([0, \infty), \mathbb{R}^n)$ and satisfies*

$$\|x\|_{L^p} \leq M\|u\|_{L^p}.$$

The infimum of such numbers M will be called the L^p-gain of (Σ). We say that system (Σ) is L^p-stable if its L^p-gain is finite.

By a *neutrally stable* $n \times n$ matrix A we mean one for which all solutions of $\dot{x} = Ax$ are bounded; equivalently, A has no eigenvalues with positive real part and each Jordan block corresponding to a purely imaginary eigenvalue has size 1. Another well-known characterization of such matrices is that they are the ones for which there exists a symmetric positive definite matrix Q such that $A'Q + QA \leq 0$.

We now state our main result.

THEOREM 1. *Let A, B be $n \times n, n \times m$ matrices respectively. Let σ be an $\mathbb{R}^m$-valued S-function. Assume that A is neutrally stable. Then there exists an $m \times n$ matrix F such that the system*

$$\begin{aligned} \dot{x} &= Ax + B\sigma(Fx + u), \\ x(0) &= 0 \end{aligned} \tag{2}$$

is L^p-stable for all $1 \leq p \leq \infty$.

Theorem 1 is an immediate consequence of the more general technical result contained in Theorem 2 below. To state that theorem in great generality, we recall first a standard notion. Let (Σ) $\dot{x} = Ax + Bu$ be a linear system, where x and u take values in $\mathbb{R}^n$ and $\mathbb{R}^m$, respectively. For each measurable and locally essentially bounded $u : [0, \infty) \to \mathbb{R}^m$ and each $x_0 \in \mathbb{R}^n$, let $x_u(t, x_0)$ be the solution of (Σ) corresponding to u with $x_u(0, x_0) = x_0$. Following the terminology of [6], the *stabilizable subspace* $S(A, B)$ of (A, B) is the subspace of $\mathbb{R}^n$ which consists of all those initial states $x_0 \in \mathbb{R}^n$ for which there is some u so that $x_u(t, x_0) \to 0$ as $t \to \infty$. In other words, $S(A, B)$ is the subspace of $\mathbb{R}^n$ made up of all the states that can be asymptotically controlled to zero (so this includes in particular the reachable subspace). Observe that the pair (A, B) is stabilizable (asymptotically null controllable) iff $S(A, B) = \mathbb{R}^n$.

THEOREM 2. *Let A and B be $n \times n$ and $n \times m$ matrices, respectively. Let $S(A, B)$ be the stabilizable subspace of (A, B). Let σ be an $\mathbb{R}^m$-valued S-function and let $\theta : \mathbb{R}^k \to S(A, B) \subseteq \mathbb{R}^n$ be a locally Lipschitz function such that $\|\theta(\xi)\| \leq \min\{L, L\|\xi\|\}$ for all $\xi \in \mathbb{R}^k$, where $L > 0$ is a constant and $k > 0$ is some integer. Assume that A is neutrally stable. Then there exist an $m \times n$ matrix F and an $\varepsilon > 0$ such that the system*

$$\begin{aligned} \dot{x} &= Ax + B\sigma(Fx + u) + \varepsilon\theta(v), \\ x(0) &= 0 \end{aligned} \tag{3}$$

is L^p-stable for each $1 \leq p \leq \infty$, i.e., there exists for each p a finite constant $M_p > 0$ such that for any $u \in L^p([0, \infty), \mathbb{R}^m)$, $v \in L^p([0, \infty), \mathbb{R}^k)$,

$$\|x\|_{L^p} \leq M_p(\|u\|_{L^p} + \|v\|_{L^p}).$$

The proof is deferred to §3.

Theorem 2 implies Theorem 1 (just take $\theta \equiv 0$) as well as a result dealing with small "nonmatching" state perturbations.

Remark 3. It is possible to make the result even more general by weakening the Lipschitz assumption on θ. Moreover, even the Lipschitz property of σ is not needed. The main problem in dropping this last assumption is that uniqueness of solutions of the closed-loop system is then not guaranteed, so that there is no well-defined input-to-state operator. Nonetheless, one could rephrase all statements by asserting that all possible solutions satisfy the stated bounds. This is consistent with the way stability is defined in some texts on input/output stability, where well-posedness (existence and uniqueness of solutions) is stated as a property independent of stability itself.

2.3. Output stabilization. Consider the initialized linear input/output system

$$\begin{aligned} (\Sigma_{ao})\ \dot{x} &= Ax + B\sigma(u), \\ x(0) &= 0, \\ y &= Ex, \end{aligned}$$

where A, B, and E are, respectively, $n \times n$, $n \times m$, $r \times n$ matrices. Assume that system (Σ_{ao}) is *asymptotically observable* (that is, it is *detectable*). Our main result for input/output systems is as follows.

THEOREM 3. *Assume that system (Σ_{ao}) is asymptotically observable, A is neutrally stable, and the $\mathbb{R}^m$-valued S-function σ is globally Lipschitz. Then there exist an $m \times n$ matrix F and an $n \times r$ matrix L such that the following property holds. Let $1 \leq p \leq \infty$. Pick any $u_1 \in L^p([0, \infty), \mathbb{R}^m)$ and $u_2 \in L^p([0, \infty), \mathbb{R}^r)$, and consider the solution $x = (x_1, x_2)$ of*

$$\dot{x_1} = Ax_1 + B\sigma(y_2 + u_1), \quad y_1 = Ex_1,$$

$$\dot{x_2} = (A + LE)x_2 + B\sigma(Fx_2) - L(y_1 + u_2), \quad y_2 = Fx_2,$$

with $x(0) = 0$. Consider the total output function $y = (y_1, y_2) = (Ex_1, Fx_2)$. Then y is in $L^p([0, \infty), \mathbb{R}^{r+m})$ and

$$\|y\|_{L^p} \leq M_p(\|u_1\|_{L^p} + \|u_2\|_{L^p})$$

for some constant $M_p > 0$.

2.4. Not every feedback stabilizes. One may ask whether *any* F that would stabilize when the saturation is not present would also provide finite gain for (2). Not surprisingly, the answer is negative. In order to give an example, we need first a simple technical remark.

LEMMA 1. *Consider the system $\dot{x} = Ax + B\sigma(Fx + u)$, where the matrix A is assumed to have all eigenvalues in the imaginary axis and where each component of σ is a continuous function whose range contains a neighborhood of the origin (this holds, for instance, if it is an S-function). Furthermore, assume that the pair (A, B) is controllable. Then, given any state $x_0 \in \mathbb{R}^n$, there is some measurable essentially bounded control u steering the origin to x_0 in finite time.*

Proof. Since all eigenvalues of A have zero real part and the pair (A, B) is controllable, for each $\varepsilon > 0$ there is some control v_0 for the system $\dot{x} = Ax + Bu$ so that $|v_0(t)| < \varepsilon$ for all t and v_0 drives in finite time the origin to x_0 (see, e.g., [12]). Considering that the range of σ contains a neighborhood of the origin and using a measurable selection (Fillipov's Theorem), we see that there is a measurable control v which achieves the same transfer, for the system $\dot{x} = Ax + B\sigma(u)$. Now let, along the corresponding trajectory, $u(t) = v(t) - Fx(t)$. It follows that this achieves the desired transfer for $\dot{x} = Ax + B\sigma(Fx + u)$. □

The next two examples show that even if A is neutrally stable, Theorem 1 may not be true if F only satisfies the condition that $A + BF$ is Hurwitz.

Example 1. Let

$$A = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad F = -(1/2,\ 1),$$

and any σ so that $\sigma(1/2) = 1$. Then both the origin and $(-1, 0)'$ are equilibrium points of the system

$$\dot{x} = Ax + B\sigma(Fx).$$

By Lemma 1, there is some input u_0 that steers the origin to $(-1, 0)'$ in some finite time T_0. Consider the input u_1 equal to u_0 for $0 \leq t \leq T_0$ and to zero for $t > T_0$. Then if x is the trajectory of (2) corresponding to u_1, we have that $x(t) = (-1, 0)'$ for all $t \geq T_0$. Clearly, for any $1 \leq p < \infty$, $u_1 \in L^p([0, \infty), \mathbb{R})$ and $x \notin L^p([0, \infty), \mathbb{R}^2)$. Therefore, system (3) is not L^p-stable for any $1 \leq p < \infty$. If we use multiple inputs, a different example which includes $p = \infty$ is as follows.

Example 2. Assume that $m = n = 2$. Let

$$A = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad F = \begin{pmatrix} -3 & 7 \\ -1 & 2 \end{pmatrix}.$$

Then $A + BF = F$ is Hurwitz. Let $\sigma = (\sigma_0, \sigma_0)'$, where σ_0 is the standard saturation function. Then the system

$$\begin{aligned} \dot{x} &= \sigma(Fx + u), \\ x(0) &= (0, 0)' \end{aligned} \tag{4}$$

is not L^p-stable for any $1 \leq p \leq \infty$. To see this, take a control v on some interval $[0, T]$ that steers $(0, 0)'$ to $(1, 1)'$. Let $u = v$ on $[0, T]$ and $u = (0, 0)'$ on (T, ∞). Let $x = (x_1, x_2)'$ be the solution of (4) corresponding to u. Then on $[T, \infty)$, we have $x_1(t) = x_2(t) = t - T + 1$. Thus (4) is not L^p-stable for any $1 \leq p \leq \infty$. (In fact, the trajectory is not even bounded for a bounded input.)

3. Proofs of the main results. For notational convenience (to avoid having too many negative signs in the formulas) we will prove the main theorem for systems written in the form

$$\begin{aligned} \dot{x} &= Ax - B\sigma(Fx + u) + \varepsilon\theta(v), \\ x(0) &= 0. \end{aligned} \tag{5}$$

A trivial remark is needed before we start.

Remark 4. Assume that $\sigma_1 : \mathbb{R}^{k_1} \to \mathbb{R}^m$ and $\sigma_2 : \mathbb{R}^{k_2} \to \mathbb{R}^n$ each satisfy a growth estimate of the type $\|\sigma_1(u)\| \leq C\|u\|$, $\|\sigma_2(v)\| \leq C\|v\|$ for $u \in \mathbb{R}^{k_1}$, $v \in \mathbb{R}^{k_2}$. It follows from classical linear systems theory that if the system $\dot{x} = Ax$ is globally asymptotically stable—that is, A is a Hurwitz matrix—then the controlled system $\dot{x} = f(x, u, v) = Ax + B\sigma_1(u) + \sigma_2(v)$ is automatically also L^p-stable for all $1 \leq p \leq \infty$. We will be interested in the case in which A is merely stable, but this remark will be used at various points.

We now prove Theorem 2. First note that we can assume that (A, B) is controllable.

3.1. Reduction to the controllable case. Suppose Theorem 2 is already known to be true for controllable (A, B); we show how the general case follows. It is an elementary linear system exercise to show that the stabilizable subspace $S(A, B)$, for any two A, B, is invariant under A; this follows for instance from its characterization as a sum of the reachable subspace and the space of stable modes. Thus the restriction of A to $S(A, B)$ is well defined, and it is again neutrally stable. Now since θ takes values in $S(A, B)$, the trajectories of (5) lie in $S(A, B)$. So we may assume that (A, B) is stabilizable, i.e., $S(A, B) = \mathbb{R}^n$, since otherwise we can restrict ourselves to $S(A, B)$. Then, up to a change of coordinates, we may assume that

$$A = \begin{pmatrix} A_1 & A_2 \\ 0 & A_3 \end{pmatrix}, \qquad B = \begin{pmatrix} B_1 \\ 0 \end{pmatrix},$$

where (A_1, B_1) is controllable and A_1 is neutrally stable. Assume that A_1 is an $r \times r$ matrix and B_1 is an $r \times m$ matrix.

Let $\tilde{\theta} : \mathbb{R}^r \to \mathbb{R}^r$ be given by $\tilde{\theta}(\xi) = (\tilde{\theta}_0(\xi_1), \ldots, \tilde{\theta}_0(\xi_r))'$ for $\xi \in \mathbb{R}^r$, where $\tilde{\theta}_0$ is the standard saturation function, i.e., $\tilde{\theta}_0(t) = \text{sign}\,(t)\,\min\{1, |t|\}$.

By our assumption that the result is known in the controllable case, there exists an $m \times r$ matrix F_1 and $\varepsilon_1 > 0$ so that the system

$$\begin{aligned} \dot{x}_1 &= A_1 x_1 - B_1\sigma(F_1 x_1 + u) + \varepsilon_1\tilde{\theta}(w), \\ x_1(0) &= 0 \end{aligned} \tag{6}$$

is L^p-stable for all $1 \leq p \leq \infty$. Let Γ_p be the L^p-gain of this system, so $\|x_1\|_{L^p} \leq \Gamma_p(\|u\|_{L^p} + \|w\|_{L^p})$ for all $u \in L^p([0,\infty), \mathbb{R}^m)$ and $w \in L^p([0,\infty), \mathbb{R}^r)$.

Since (A, B) is stabilizable, we can find an $m \times n$ matrix E such that $A + BE$ is Hurwitz. Then the system

$$\begin{aligned} \dot{y} &= (A + BE)y + v\,, \\ y(0) &= 0 \end{aligned} \tag{7}$$

is L^p-stable for any $1 \leq p \leq \infty$. Let γ_p be the L^p-gain of (7), so $\|y\|_{L^p} \leq \gamma_p \|v\|_{L^p}$.

Take an $\varepsilon > 0$ such that $\varepsilon L \gamma_\infty \|BE\| \leq \varepsilon_1$. Let $F = (F_1, 0)$. We show that for this choice of F and ε, system (5) is L^p-stable for any $1 \leq p \leq \infty$. For this purpose, let $u \in L^p([0,\infty), \mathbb{R}^m)$, $v \in L^p([0,\infty), \mathbb{R}^k)$. Let x be the solution of (5) corresponding to u, v. Let y be the solution of

$$\begin{aligned} \dot{y} &= (A + BE)y + \varepsilon\theta(v)\,, \\ y(0) &= 0\,. \end{aligned} \tag{8}$$

Then we have $\|y\|_{L^\infty} \leq \varepsilon L \gamma_\infty$ and $\|y\|_{L^p} \leq \varepsilon L \gamma_p \|v\|_{L^p}$ (note that $\|\theta(\xi)\| \leq \min\{L, L\|\xi\|\}$ for all $\xi \in \mathbb{R}^k$). Let $z = x - y$. Then z satisfies

$$\begin{aligned} \dot{z} &= Az - B\sigma(Fz + Fy + u) - BEy\,, \\ z(0) &= 0\,. \end{aligned}$$

Write $z = (z_1, z_2)'$. Then we have $z_2 \equiv 0$ and z_1 satisfies

$$\begin{aligned} \dot{z}_1 &= A_1 z_1 - B_1 \sigma(F_1 z_1 + Fy + u) - B_1 Ey\,, \\ z_1(0) &= 0\,. \end{aligned}$$

Since $\|B_1 Ey\|_{L^\infty} \leq \|B_1 E\|\,\|y\|_{L^\infty} \leq \varepsilon L \gamma_\infty \|B_1 E\| \leq \varepsilon_1$, we have

$$-\frac{B_1 Ey}{\varepsilon_1} = \tilde{\theta}\left(-\frac{B_1 Ey}{\varepsilon_1}\right).$$

Then z_1 satisfies

$$\begin{aligned} \dot{z}_1 &= A_1 z_1 - B_1 \sigma(F_1 z_1 + Fy + u) + \varepsilon_1 \tilde{\theta}\left(\frac{-B_1 Ey}{\varepsilon_1}\right), \\ z_1(0) &= 0\,. \end{aligned}$$

By the L^p-stability of (6) we get that

$$\begin{aligned} \|z\|_{L^p} = \|z_1\|_{L^p} &\leq \Gamma_p\left(\|Fy + u\|_{L^p} + \left\|\frac{B_1 Ey}{\varepsilon_1}\right\|_{L^p}\right) \\ &\leq \Gamma_p\left(\|F\|\,\|y\|_{L^p} + \|u\|_{L^p} + \frac{\|B_1 E\|\,\|y\|_{L^p}}{\varepsilon_1}\right) \\ &\leq \Gamma_p\left(\|u\|_{L^p} + \left(\frac{\|B_1 E\|}{\varepsilon_1} + \|F\|\right)\varepsilon L \gamma_p \|v\|_{L^p}\right). \end{aligned}$$

This shows that (5) is L^p-stable, which concludes the proof that we may assume that (A, B) is controllable.

3.2. Proof of Theorem 2 assuming controllability. From elementary linear algebra, we know that any neutrally stable matrix A is similar to a matrix

$$\begin{pmatrix} A_1 & 0 \\ 0 & A_2 \end{pmatrix}, \tag{9}$$

where A_1 is an $r \times r$ Hurwitz matrix and A_2 is an $(n-r) \times (n-r)$ skew–symmetric matrix. So, up to a change of coordinates, we may assume that A is already in the form (9). In these coordinates, we write

$$B = \begin{pmatrix} B_1 \\ B_2 \end{pmatrix},$$

where B_2 is an $(n-r) \times m$ matrix, and we write vectors as $x = (x_1, x_2)'$ and also $\theta = (\theta_1, \theta_2)'$. Consider the feedback law $F = (0, B_2')$. Then system (5), with this choice of F, can be written as

$$\begin{aligned} \dot{x}_1 &= A_1 x_1 - B_1 \sigma(B_2' x_2 + u) + \varepsilon \theta_1(v)\,, \\ \dot{x}_2 &= A_2 x_2 - B_2 \sigma(B_2' x_2 + u) + \varepsilon \theta_2(v)\,, \\ x_1(0) &= 0, \quad x_2(0) = 0\,. \end{aligned} \tag{10}$$

Since A_1 is Hurwitz, it will be sufficient to show that there exists an $\varepsilon > 0$ such that the x_2-subsystem is L^p-stable (we may think of x_2 as an additional input to the first subsystem and apply Remark 4).

The controllability assumption on (A, B) implies that the pair (A_2, B_2) is also controllable. Since A_2 is skew–symmetric, the matrix $\tilde{A} := A_2 - B_2 B_2'$ is Hurwitz. (Just observe that the Lyapunov equation $\tilde{A}' I_{n-r} + I_{n-r} \tilde{A} = -2 B_2 B_2'$ holds, and the pair $(\tilde{A}, B_2)$ is controllable; see [13, Ex. 4.6.7].) Therefore, the theorem is a consequence of the following lemma. This is where the main parts of our argument lie (except for a small technical point, whose proof is deferred to §3.5).

LEMMA 2. *Let σ, θ be as in Theorem 2. Let A be a skew–symmetric matrix. Assume that $\tilde{A} := A - BB'$ is Hurwitz. Then there exists an $\varepsilon > 0$ such that the system*

$$\begin{aligned} \dot{x} &= Ax - B\sigma(B'x + u) + \varepsilon \theta(v)\,, \\ x(0) &= 0 \end{aligned} \tag{11}$$

is L^p-stable for all $1 \le p \le \infty$.

Proof. Assume that $\sigma = (\sigma_1, \ldots, \sigma_m)'$. Let $0 < a \le b < \infty$, $K > 0$ be constants and $\tau_i : \mathbb{R} \to [a, b]$, $i = 1, \ldots, m$, be measurable functions so that the components σ_i of σ satisfy (i)–(iv) in Definition 2 with the respective τ_i's. We may assume that K is large enough such that $K \ge L$. Let

$$\Gamma \stackrel{\text{def}}{=} \min_{i=1,\ldots,m} \liminf_{|\xi| \to \infty} |\sigma_i(\xi)|.$$

Then $\Gamma > 0$. Let $\varepsilon > 0$ satisfy

$$\varepsilon < \frac{\Gamma}{K \gamma_\infty \sqrt{m} \|B\|}\,, \tag{12}$$

where γ_∞ is the L^∞-gain of the initialized linear control system

$$\begin{aligned} \dot{y} &= (A - BB')y + u\,, \\ y(0) &= 0. \end{aligned} \tag{13}$$

By (12) there exists a $\delta \in (0, 1/2]$ such that

$$\varepsilon \leq \frac{(1-2\delta)\Gamma}{K\gamma_\infty \sqrt{m}\|B\|}.$$

Let $u \in L^p([0,\infty), \mathbb{R}^m)$, $v \in L^p([0,\infty), \mathbb{R}^k)$. Let y be the solution of

$$\begin{aligned} \dot{y} &= (A - BB')y + \varepsilon\theta(v), \\ y(0) &= 0. \end{aligned} \tag{14}$$

Let x be the solution of (11) corresponding to u, v and let $z = x - y$. Then z satisfies

$$\begin{aligned} \dot{z} &= Az - B\sigma(B'z + u + B'y) + BB^T y, \\ z(0) &= 0. \end{aligned} \tag{15}$$

Let $\tilde{u} = u + B'y$ and $\tilde{v} = B'y$. Then we get

$$\|\tilde{v}\|_{L^\infty} \leq \|B\|\,\|y\|_{L^\infty} \leq \varepsilon\|B\|\gamma_\infty\|\theta\|_{L^\infty} \leq \frac{(1-2\delta)\Gamma}{\sqrt{m}}. \tag{16}$$

Now (15) can be written as

$$\begin{aligned} \dot{z} &= Az - B\left(\sigma(B'z + \tilde{u}) - \tilde{v}\right), \\ z(0) &= 0. \end{aligned} \tag{17}$$

(We have brought the problem to one of a "matched uncertainty" type, in robust control terms, if we think of $\tilde{v}$ as representing a source of uncertainty.)

Let $\tilde{z}(t) = B'z(t) + \tilde{u}(t)$. For each $1 \leq p < \infty$, consider the function $V_{0,p} : \mathbb{R}^n \to \mathbb{R}$ given by

$$V_{0,p}(x) = \frac{\|x\|^{p+1}}{p+1}.$$

Along the trajectories of (17), we have

$$\begin{aligned} \dot{V}_{0,p}(z(t)) &= -\|z(t)\|^{p-1}z'(t)B\left(\sigma\left(B'z(t) + \tilde{u}(t)\right) - \tilde{v}(t)\right) \\ &= -\|z(t)\|^{p-1}\tilde{z}'(t)\left[\sigma\left(\tilde{z}(t)\right) - \tilde{v}(t)\right] + \|z(t)\|^{p-1}\tilde{u}'(t)\left[\sigma\left(\tilde{z}(t)\right) - \tilde{v}(t)\right]. \end{aligned}$$

Since K is an S-bound for σ and considering (16), we have the following decay estimate:

$$\begin{aligned} \dot{V}_{0,p}(z(t)) \leq{}& -\|z(t)\|^{p-1}\tilde{z}'(t)\left(\sigma\left(\tilde{z}(t)\right) - \tilde{v}(t)\right) \\ &+ \left(K + \frac{(1-2\delta)\Gamma}{\sqrt{m}}\right)\|z(t)\|^{p-1}\|\tilde{u}(t)\|. \end{aligned} \tag{18}$$

We next need to bound the first term in the right-hand side of (18). For that purpose, we will partition $[0,\infty)$ into two subsets. By the definition of Γ, there is some $M_1 \geq 1$ so that

$$\min_{i=1,\ldots,m} \inf_{|\xi|\geq M_1} |\sigma_i(\xi)| \geq (1-\delta)\Gamma.$$

The first subset consists of those t for which $\|\tilde{z}'(t)\| \leq M_1\sqrt{m}$. For such t, trivially,

$$\tilde{z}'(t)\left(\sigma\left(\tilde{z}(t)\right) - \tilde{v}(t)\right) \geq \tilde{z}'(t)\sigma\left(\tilde{z}(t)\right) - M_1\sqrt{m}\|\tilde{v}(t)\|. \tag{19}$$

Next we consider those t for which $\|\tilde{z}'(t)\| > M_1\sqrt{m}$. First we note some general facts about any vector $\xi \in \mathbb{R}^m$ for which

$$\|\xi\| > M_1\sqrt{m}\,. \tag{20}$$

If we pick i_0 so that $|\xi_{i_0}| = \max_{i=1,\dots,m}\{|\xi_i|\}$, then $|\xi_{i_0}| > M_1$, and therefore, by the choice of M_1, $|\sigma_{i_0}(\xi_{i_0})| \geq (1-\delta)\Gamma$. We conclude that if ξ satisfies (20) then

$$\xi'\sigma(\xi) \geq \xi_{i_0}\sigma_{i_0}(\xi_{i_0}) \geq \frac{\|\xi\|}{\sqrt{m}}(1-\delta)\Gamma\,,$$

or equivalently

$$\|\xi\| \leq \frac{\sqrt{m}\,\xi'\sigma(\xi)}{(1-\delta)\Gamma}\,.$$

From this and (16) we have if $\|\tilde{z}(t)\| > M_1\sqrt{m}$,

$$\begin{aligned}
\tilde{z}'(t)\left(\sigma\left(\tilde{z}(t)\right) - \tilde{v}(t)\right) &\geq \tilde{z}'(t)\sigma\left(\tilde{z}(t)\right) - \|\tilde{z}'(t)\|\,\|\tilde{v}(t)\| \\
&\geq \tilde{z}'(t)\sigma\left(\tilde{z}(t)\right) - \frac{\sqrt{m}\|\tilde{v}\|_{L^\infty}}{(1-\delta)\Gamma}\tilde{z}'(t)\sigma\left(\tilde{z}(t)\right) \\
&\geq \left(1 - \frac{1-2\delta}{1-\delta}\right)\tilde{z}'(t)\sigma\left(\tilde{z}(t)\right) \\
&= \frac{\delta}{1-\delta}\tilde{z}'(t)\sigma\left(\tilde{z}(t)\right). \qquad (21)
\end{aligned}$$

Note also that $\frac{\delta}{1-\delta} \leq 1$ for $0 < \delta \leq 1/2$. Combining (19) and (21) we have a common estimate valid for all $t \geq 0$:

$$\tilde{z}'(t)\left(\sigma\left(\tilde{z}(t)\right) - \tilde{v}(t)\right) \geq \frac{\delta}{1-\delta}\tilde{z}'(t)\sigma\left(\tilde{z}(t)\right) - M_1\sqrt{m}\|\tilde{v}(t)\|\,.$$

Using this and (18) we get

$$\begin{aligned}
\dot{V}_{0,p}(z(t)) \leq &-\frac{\delta}{1-\delta}\|z(t)\|^{p-1}\tilde{z}'(t)\sigma\left(\tilde{z}(t)\right) \\
&+\|z(t)\|^{p-1}\left(\left(K + \frac{\Gamma}{\sqrt{m}}\right)\|\tilde{u}(t)\| + M_1\sqrt{m}\|\tilde{v}(t)\|\right). \qquad (22)
\end{aligned}$$

Let $\tau = \operatorname{diag}(\tau_1, \dots, \tau_m)$ with $\tau(\xi) = \operatorname{diag}(\tau_1(\xi_1), \dots, \tau_m(\xi_m))$ for $\xi \in \mathbb{R}^m$. Then $aI \leq \tau(\xi) \leq bI$ for all $\xi \in \mathbb{R}^m$. We have for any $\xi \in \mathbb{R}^m$,

$$\begin{aligned}
\|\tau(\xi)\xi - \sigma(\xi)\| &= \left(\sum_{i=1}^m |\tau_i(\xi_i)\xi_i - \sigma_i(\xi_i)|^2\right)^{1/2} \\
&\leq K\left(\sum_{i=1}^m \xi_i^2(\sigma_i(\xi_i))^2\right)^{1/2} \leq K\xi'\sigma(\xi). \qquad (23)
\end{aligned}$$

Now we rewrite (17) in the form

$$\begin{aligned}
&\dot{z} = \bar{A}(t)z + B\left[\tau\left(\tilde{z}(t)\right)\tilde{z}(t) - \sigma\left(\tilde{z}(t)\right) - \tau\left(\tilde{z}(t)\right)\tilde{u}(t) + \tilde{v}(t)\right], \qquad (24) \\
&z(0) = 0,
\end{aligned}$$

where $\bar{A}(t) = A - B\tau(\tilde{z}(t))B'$. Then $\bar{A}$ satisfies the conditions of Corollary 1 below. Therefore, for each $1 < p < \infty$, there exist a differentiable function $V_{1,p}$ and positive real numbers a_p, b_p, and c_p such that

(P1) $a_p\|x\|^p \leq V_{1,p}(x) \leq b_p\|x\|^p$,

(P2) $\|DV_{1,p}(x)\| \leq c_p\|x\|^{p-1}$,

(P3) $DV_{1,p}(x)\bar{A}(t)x \leq -\|x\|^p$,

for all $x \in \mathbb{R}^n$ and $t \geq 0$. (Note that the constants a_p, b_p, c_p depend only on A, B, a, b.) Moreover $V_{1,p}$ can be chosen so that

(P4) $\limsup_{p\to 1+} c_p = c_1 < \infty$, and the limit $V_{1,1}(x) = \lim_{p\to 1+} V_{1,p}(x)$ exists for all $x \in \mathbb{R}^n$.

Using (23) and (24), we get, for $1 < p < \infty$,

$$\begin{aligned}\frac{dV_{1,p}(z(t))}{dt} &\leq -\|z(t)\|^p + c_p\|B\|\|z(t)\|^{p-1}(\|\tilde{v}(t)\| + b\|\tilde{u}(t)\|)\\ &\quad + c_p\|B\|\|z(t)\|^{p-1}\{\|\tau(\tilde{z}(t))\tilde{z}(t) - \sigma(\tilde{z}(t))\|\}\\ &\leq -\|z(t)\|^p + c_p\|B\|\|z(t)\|^{p-1}(\|\tilde{v}(t)\| + b\|\tilde{u}(t)\|)\\ &\quad + c_pK\|B\|\|z(t)\|^{p-1}\tilde{z}'(t)\sigma(\tilde{z}(t))\,. \qquad (25)\end{aligned}$$

For $1 \leq p < \infty$, let

$$\lambda_p = \frac{K\|B\|c_p(1-\delta)}{\delta}. \qquad (26)$$

(Observe that this constant does not depend on the particular u and v being considered, it depends only on the system and on p.) Finally, consider, for each $1 \leq p < \infty$, the following function:

$$V_p = \lambda_p V_{0,p} + V_{1,p}\,, \qquad (27)$$

where λ_p is given in (26). Using (22), (25), and the fact that $b \leq K$, for $1 < p < \infty$, we have along trajectories of (17),

$$\frac{dV_p(z(t))}{dt} \leq -\|z(t)\|^p + \kappa_p\|z(t)\|^{p-1}(\|\tilde{u}(t)\| + \|\tilde{v}(t)\|)\,, \qquad (28)$$

where

$$\kappa_p = \lambda_p \max\left\{1 + K + \frac{\Gamma}{\sqrt{m}}, \frac{1}{K} + \sqrt{m}M_1\right\}.$$

For any $t \geq 0$, integrating (28) from zero to t, we have

$$V_p(z(t)) + \int_0^t \|z(s)\|^p ds \leq \kappa_p \int_0^t \|z(s)\|^{p-1}(\|\tilde{u}(s)\| + \|\tilde{v}(s)\|)ds\,.$$

When $p = 1$, this inequality is also true as an easy consequence of the Lebesgue dominated convergence theorem (applied to a sequence $\{p^j\}_{j=1}^{\infty}$ decreasing to 1). Thus the inequality is true for all $1 \leq p < \infty$.

Applying Hölder's inequality to $\int_0^t \|z(s)\|^{p-1}(\|\tilde{u}(s)\| + \|\tilde{v}(s)\|)ds$, we conclude that for all $1 \leq p < \infty$ and $t \geq 0$,

$$V_p(z(t)) + \|z\|^p_{L^p[0,t]} \leq \kappa_p\|z\|^{p-1}_{L^p[0,t]}(\|\tilde{u}\|_{L^p} + \|\tilde{v}\|_{L^p})\,. \qquad (29)$$

Since $V_p \geq 0$, we get that $z \in L^p([0,\infty),\mathbb{R}^n)$ and

$$\|z\|_{L^p} \leq \kappa_p(\|\tilde{u}\|_{L^p} + \|\tilde{v}\|_{L^p})\,. \tag{30}$$

Now since $z = x - y$, $\tilde{u} = u + B'y$, $\tilde{v} = B'y$, we have

$$\|\tilde{v}\|_{L^p} \leq \|B\|\,\|y\|_{L^p} \leq \varepsilon K\gamma_p\|B\|\|v\|_{L^p},$$

$$\|\tilde{u}\|_{L^p} \leq \|u\|_{L^p} + \varepsilon K\gamma_p\|B\|\|v\|_{L^p}\,,$$

$$\|z\|_{L^p} \geq \|x\|_{L^p} - \|y\|_{L^p} \geq \|x\|_{L^p} - \varepsilon K\gamma_p\|v\|_{L^p}\,,$$

where γ_p is the L^p-gain of (13). Combining this with (30) we have

$$\|x\|_{L^p} \leq \kappa_p\|u\|_{L^p} + \varepsilon K\gamma_p(1 + 2\kappa_p\|B\|)\|v\|_{L^p}\,.$$

This finishes the proof of the lemma, and hence our main theorem, for the case when $1 \leq p < \infty$.

We now prove the lemma for $p = \infty$. For this, we need to show that system (11) has the *uniform bounded input bounded state* property, i.e., there exists a finite constant M such that $\|x\|_{L^\infty} \leq M(\|u\|_{L^\infty} + \|v\|_{L^\infty})$ for all $u \in L^\infty([0,\infty),\mathbb{R}^m)$ and $v \in L^\infty([0,\infty),\mathbb{R}^k)$. Letting $p = 2$, from (28) we have

$$\frac{dV_2(z(t))}{dt} \leq -\|z(t)\|\,(\|z(t)\| - \kappa_2(\|\tilde{u}\|_{L^\infty} + \|\tilde{v}\|_{L^\infty}))\,. \tag{31}$$

Let $\beta = \|\tilde{u}\|_{L^\infty} + \|\tilde{v}\|_{L^\infty}$. Thus, $\dot{V}_2$ is negative outside the ball of radius $\kappa_2\beta$ centered at the origin. It follows that

$$V_2(z(t)) \leq \sup_{\|\xi\|\leq\kappa_2\beta} V_2(\xi) \leq \frac{\lambda_2\kappa_2^3}{3}\beta^3 + b_2\kappa_2^2\beta^2\,.$$

First assume that $\beta \leq 1$. Then we have

$$a_2\|z(t)\|^2 \leq V_2(z(t)) \leq \left(\frac{\lambda_2\kappa_2^3}{3} + b_2\kappa_2^2\right)\beta^2\,,$$

which implies that

$$\|z\|_{L^\infty} \leq \left\{\frac{\lambda_2\kappa_2^3 + 3b_2\kappa_2^2}{3a_2}\right\}^{1/2}\beta\,.$$

If $\beta > 1$, we have

$$\frac{\lambda_2\|z(t)\|^3}{3} \leq V_2(z(t)) \leq \left(\frac{\lambda_2\kappa_2^3}{3} + b_2\kappa_2^2\right)\beta^3\,.$$

We then get that

$$\|z\|_{L^\infty} \leq \left\{\frac{\lambda_2\kappa_2^3 + 3b_2\kappa_2^2}{\lambda_2}\right\}^{1/3}\beta\,.$$

Let

$$\bar{G}_\infty = \max\left\{\left\{\frac{\lambda_2\kappa_2^3 + 3b_2\kappa_2^2}{3a_2}\right\}^{1/2}, \left\{\frac{\lambda_2\kappa_2^3 + 3b_2\kappa_2^2}{\lambda_2}\right\}^{1/3}\right\}.$$

We have $\|z\|_{L^\infty} \leq \bar{G}_\infty \beta$. Now

$$\beta = \|\tilde{u}\|_{L^\infty} + \|\tilde{v}\|_{L^\infty} \leq \|u\|_{L^\infty} + 2\varepsilon K \gamma_\infty \|B\| \, \|v\|_{L^\infty}$$

and

$$\|z\|_{L^\infty} \geq \|x\|_{L^\infty} - \varepsilon K \gamma_\infty \|v\|_{L^\infty} .$$

We conclude that

$$\|x\|_\infty \leq \bar{G}_\infty \|u\|_{L^\infty} + \varepsilon K \gamma_\infty (1 + 2\bar{G}_\infty \|B\|) \|v\|_{L^\infty} .$$

Now the proof of Lemma 2 is complete. □

3.3. Proof of the output feedback theorem. We now provide a proof of Theorem 3. We will show a somewhat stronger statement, namely, that the state trajectory x also satisfies an estimate as required. The proof will be the usual Luenberger-observer construction, but a bit of care has to be taken because of the nonlinearities.

Asymptotic observability means that there is some $n \times r$ matrix L such that $A + LE$ is Hurwitz. Let F be as in Theorem 2. Let $e = x_1 - x_2$. Then $(x_1, e)'$ satisfies

$$\begin{aligned} \dot{x_1} &= Ax_1 + B\sigma(Fx_1 - Fe + u_1) , \\ \dot{e} &= (A + LE)e + B\,(\sigma(Fx_1 - Fe + u_1) - \sigma(Fx_1 - Fe)) + Lu_2 . \end{aligned}$$

Let $\tilde{v} = \sigma(Fx_1 - Fe + u_1) - \sigma(Fx_1 - Fe)$. Since $\|\tilde{v}(t)\| \leq K\|u_1(t)\|$ (here K is a Lipschitz constant for σ) and $A + LE$ is Hurwitz, we know that e is in $L^p([0, \infty), \mathbb{R}^n)$ and $\|e\|_{L^p} \leq \widehat{M}(\|u_1\|_{L^p} + \|u_2\|_{L^p})$ for some constant $\widehat{M} > 0$. Then the conclusion follows from Theorem 2 applied to the x_1-subsystem.

Note that the conclusion of this theorem can be restated in terms of the finite-gain stability of a standard systems interconnection

$$\begin{aligned} y_1 &= P(u_1 + y_2), \\ y_2 &= C(u_2 + y_1), \end{aligned}$$

where P denotes the input/output behavior of the original system Σ and C is the input/output behavior of the controller with state space x_2 and output y_2.

3.4. Operator stability among different norms. We can actually prove a result stronger than that stated in Theorem 2, namely, that the input-to-state operator $(u, v) \to x$ from $L^p([0, \infty), \mathbb{R}^m) \times L^p([0, \infty), \mathbb{R}^k)$ to $L^p([0, \infty), \mathbb{R}^n)$ is a bounded operator from $L^p([0, \infty), \mathbb{R}^m) \times L^p([0, \infty), \mathbb{R}^k)$ to $L^q([0, \infty), \mathbb{R}^n)$, for any $q \geq p$.

Remark 5. From (29), (30) we get that, for $u \in L^p([0, \infty), \mathbb{R}^m)$, $v \in L^p([0, \infty), \mathbb{R}^k)$, and $t \geq 0$,

$$a_p \|z(t)\|^p \leq V_p(z(t)) \leq \kappa_p \|z\|_{L^p}^{p-1} \| (\|\tilde{u}\|_{L^p} + \|\tilde{v}\|_{L^p}) \leq \kappa_p^p (\|\tilde{u}\|_{L^p} + \|\tilde{v}\|_{L^p})^p ;$$

then, $\|z\|_{L^\infty} \leq C_1(\|\tilde{u}\|_{L^p} + \|\tilde{v}\|_{L^p})$ with $C_1 = \kappa_p a_p^{-1/p}$. Therefore we obtain for $q \geq p$,

$$\|z\|_{L^q}^q \leq \|z\|_{L^\infty}^{q-p} \|z\|_{L^p}^p \leq C_1^{q-p} \kappa_p^p (\|\tilde{u}\|_{L^p} + \|\tilde{v}\|_{L^p})^q . \tag{32}$$

From this one can easily deduce that for any $q \geq p$ the solution x of (11) satisfies

$$\|x\|_{L^q} \leq M_{p,q}(\|u\|_{L^p} + \|v\|_{L^p})$$

for some constants $M_{p,q} > 0$. The same results then hold for the original system in Theorem 2, as is clear from the reduction to (11). That is, for any $u \in L^p([0, \infty), \mathbb{R}^m)$, $v \in L^p([0, \infty), \mathbb{R}^k)$, the solution x of (5) satisfies a similar inequality.

3.5. A remark on robustness of a linear feedback. It is worth pointing out that the same method used to prove Lemma 2 allows us to establish the next proposition, which is a result regarding time-varying multiplicative uncertainties on a linear feedback law $u = -B'x$. For that, we need the following lemma.

LEMMA 3. *Fix two positive real numbers c, d. Let A be an $n \times n$ skew–symmetric matrix, let B be an $n \times m$ matrix, and assume that the pair (A, B) is controllable (or, equivalently, that $A - BB'$ is Hurwitz). Then there is a symmetric positive definite matrix P so that*

$$P(A - BDB') + (A' - BD'B')P \leq -I, \tag{33}$$

for all those $m \times m$ matrices D so that $D + D' \geq cI$ and $\|D\| \leq d$.

Proof. Since (A, B) is controllable, the same is true for (A, rB) for any $r > 0$; thus $A - rBB'$ is Hurwitz for any $r > 0$. Pick $P_1 > 0$ so that $P_1(A - cBB') + (A' - cBB')P_1 = -2I$. We will choose P of the form $P_1 + \beta I$ for a suitable β. Note that

$$2x'P_1(A - BDB')x = -2\|x\|^2 + 2x'P_1B(cI - D)B'x,$$

where the last term has norm bounded above by $C\|x\|\|B'x\|$ for some constant C which depends on c and d. On the other hand,

$$2\beta x'(A - BDB')x = -2\beta x'BDB'x \leq -c\beta\|B'x\|^2.$$

Thus $2x'P(A - BDB')x \leq -2\|x\|^2 + C\|x\|\|B'x\| - \beta c\|B'x\|^2$ and picking β large enough guarantees that this quadratic form is always less than $-\|x\|^2$. □

COROLLARY 1. *Let A and B be as in Lemma 3. Let $c, d > 0$ and $\bar{A}(t) = A - BD(t)B'$, where $D(t)$ is any measurable $m \times m$ matrix such that $D(t) + D'(t) \geq cI$, for almost all t in $[0, \infty)$, and $\sup\{\|D(t)\| : t \in [0, \infty)\} \leq d$. Then for each $1 < p < \infty$, there exist a differentiable function V_p and positive real numbers a_p, b_p, and c_p such that*

(P0) *V_p, a_p, b_p, c_p depend only on A, B, c, d;*

and for all $x \in \mathbb{R}^n$, $t \in [0, \infty)$,

(P1) $a_p\|x\|^p \leq V_p(x) \leq b_p\|x\|^p$;

(P2) $\|DV_p(x)\| \leq c_p\|x\|^{p-1}$;

(P3) $DV_p(x)\bar{A}(t)x \leq -\|x\|^p$.

Moreover, we may choose V_p so that

(P4) $\limsup_{p\to 1+} c_p = c_1 < \infty$, *and the limit $V_1(x) := \lim_{p\to 1+} V_p(x)$ exists for all $x \in \mathbb{R}^n$.*

Proof. Take $V_p(x) = \alpha_p(x'Px)^{p/2}$, where $\alpha_p > 0$ is a proper constant and P is chosen as in Lemma 3. □

As a direct application of Corollary 1, we get Corollary 2.

COROLLARY 2. *Let A be an $n \times n$ skew–symmetric matrix and B be an $n \times m$ matrix. Assume that $A - BB'$ is Hurwitz. Let $D(t)$ be a measurable $m \times m$ matrix with bounded entries. Assume also that there exists a constant $a > 0$ such that $D(t) + D'(t) \geq aI$ for almost all t in $[0, \infty)$. Then the initialized system*

$$(\tilde{\Sigma}) \qquad \begin{aligned} \dot{x} &= \bar{A}(t)x + u, \\ x(0) &= 0, \end{aligned}$$

where $u \in L^p([0, \infty), \mathbb{R}^n)$ and $\bar{A}(t) := A - BD(t)B'$, is L^p-stable for $1 \leq p \leq \infty$, and the L^p-gain depends only on p, a, A, B, and $M = \sup\{\|D(t)\| : t \in [0, \infty)\}$.

Proof. Let V_p be a function satisfying Conditions (P0)–(P3) in Corollary 1 with respect to $\bar{A}$. Along the trajectories of $(\tilde{\Sigma})$, we have

$$\dot{V}_p(x(t)) \leq -\|x(t)\|^p + c_p\|x(t)\|^{p-1}\|u(t)\|,$$

for some $c_p > 0$. The conclusion follows after applying Hölder's inequality. □

4. Comparison with linear gains. From the proof of Lemma 2, we can also obtain explicit bounds for the L^p-gain for (11). For simplicity, we deal only with the case when $\theta \equiv 0$ and we will assume that each component σ_i of σ satisfies a stronger estimate:

$$\forall t \in \mathbb{R}, \quad |\sigma_i(t) - a_i t| \leq K t \sigma_i(t),$$

where $a_i > 0$ are some constants. Of course this implies that $(d\sigma_i(t)/dt)|_{t=0} = a_i$. Specifically, we will compare these bounds with the L^p-gain of the system that is obtained by linearizing (11):

$$\begin{aligned} \dot{x} &= \tilde{A}x - BDu\,, \\ x(0) &= 0\,, \end{aligned} \tag{34}$$

where $\tilde{A} = A - BDB'$ with $D = \operatorname{diag}(a_1, \ldots, a_m)$. (Note that $\tilde{A}$ is Hurwitz.) For the cases $p = 1, 2$ we have the following.

COROLLARY 3. *Let A, B be as in Lemma 2 and σ be as above. Let G_1 and G_2 be, respectively, the L^1- and L^2-gains of the system*

$$\begin{aligned} \dot{x} &= Ax - B\sigma(B'x + u)\,, \\ x(0) &= 0\,. \end{aligned} \tag{35}$$

Let γ_1, γ_2 be, respectively, the L^1- and L^2-gains of (34) *and let $d = \min\{a_1, \ldots, a_m\}$. Then we have*

1. $G_1 \leq (\frac{K^2}{d} + 1)\gamma_1$,
2. $G_2 \leq 2\frac{\sqrt{n}}{d}(K^2 + K)\gamma_2$.

(In the literature, γ_2 is called the "H_∞-norm" of (34) and is usually denoted by $\|W\|_\infty$, where $W(s)$ is the transfer matrix for system (34).)

Proof. For each $u \in L^p([0, \infty), \mathbb{R}^m)$, let x be the solution of (35) corresponding to u. Let $\tilde{x} = B'x + u$.

For the case $p = 1$, consider the derivative of $V = \|x\|^2/2$ along the trajectories of (35). We get

$$\begin{aligned} \dot{V}(x) &= -\tilde{x}'\sigma(\tilde{x}) + u'\sigma(\tilde{x}) \\ &\leq -\tilde{x}'\sigma(\tilde{x}) + K\|u\|\,. \end{aligned}$$

Integrating the above inequality from zero to ∞, we obtain

$$\int_0^\infty \tilde{x}'(s)\sigma(\tilde{x}(s))\,ds \leq K\|u\|_{L^1}. \tag{36}$$

Let

$$v(t) = -\tilde{x}(t) + D^{-1}\sigma(\tilde{x}(t)) + u(t).$$

Then, we have

$$\begin{aligned} \int_0^\infty \|v(s)\|ds &\leq \int_0^\infty \left\{\|D^{-1}\|\,\|D\tilde{x}(s) - \sigma(\tilde{x}(s))\| + \|u(s)\|\right\}ds \\ &\leq \int_0^\infty \left\{\frac{K}{d}\tilde{x}'(s)\sigma(\tilde{x}(s)) + \|u(s)\|\right\}ds \\ &\leq \left(\frac{K^2}{d} + 1\right)\|u\|_{L^1}\,. \end{aligned}$$

Now (35) can be written as

$$\begin{aligned} \dot{x} &= \tilde{A}x - BDv(t)\,, \\ x(0) &= 0\,. \end{aligned}$$

By the definition of γ_1 we have $\|x\|_{L^1} \leq \gamma_1 \|v\|_{L^1} \leq (\frac{K^2}{d} + 1)\gamma_1 \|u\|_{L^1}$. Therefore

$$G_1 \leq \left(\frac{K^2}{d} + 1\right)\gamma_1,$$

and Conclusion 1 is then proved.

Now we show Conclusion 2. Since $\tilde{A}$ is Hurwitz, we take

$$V_2(x) \;=\; \frac{c\|x\|^3}{3} + x'Px,$$

where $c = 2K\|PB\|$ and P is the positive definite symmetric matrix satisfying

$$\tilde{A}'P + P\tilde{A} = -I\,. \tag{37}$$

Then, rewriting (35) as

$$\dot{x} = \tilde{A}x + B\,(D\tilde{x} - \sigma(\tilde{x}) - Du)$$

and proceeding similarly to the proof of Lemma 2, we have

$$\begin{aligned} \dot{V}_2(x) &= -c\|x\|\tilde{x}'\sigma(\tilde{x}) + c\|x\|u'\sigma(\tilde{x}) \\ &\quad -\|x\|^2 + 2x'PB\,(D\tilde{x} - \sigma(\tilde{x}) - Du) \\ &\leq -\|x\|^2 + 2(\|D\| + K^2)\,\|PB\|\,\|x\|\,\|u\|\,. \end{aligned}$$

From this we can get

$$G_2 \leq 2(\|D\| + K^2)\|PB\| \leq 2(K^2 + K)\|PB\|\,. \tag{38}$$

Next we want to compare $\|PB\|$ with γ_2. First, let us compare $\|PBD^{1/2}\|$ with $\widehat{\gamma}_2$, where $\widehat{\gamma}_2$ is the L^2-gain of

$$\begin{aligned} \dot{x} &= \tilde{A}x + BD^{1/2}u\,, \\ x(0) &= 0\,. \end{aligned} \tag{39}$$

Notice that $\widehat{\gamma}_2 \leq \|D^{-1/2}\|\gamma_2$. We now consider the *Hankel norm* $\|W\|_{\text{hankel}}$ for system (39). Note that the matrix P is the *observability Gramian* for (39) (the output is just the state in our case). The *controllability Gramian* for system (39) is defined to be the symmetric matrix $Q \geq 0$ which satisfies

$$\tilde{A}Q + Q\tilde{A}' + BDB' = 0\,. \tag{40}$$

We know that the Hankel norm for (39) is equal to

$$\|W\|_{\text{hankel}} = (\lambda_{\max}(PQ))^{1/2}\,, \tag{41}$$

where $\lambda_{\max}(\cdot)$ denotes the largest eigenvalue, cf. [1]. We also know that the H_∞-norm $\widehat{\gamma}_2$ for (39) is related to the Hankel norm by the following inequalities:

$$\widehat{\gamma}_2 \leq (2n+1)\|W\|_{\text{hankel}} \leq (2n+1)\widehat{\gamma}_2\,. \tag{42}$$

Now in our case, since $\tilde{A} = A - BDB'$ and $\tilde{A}' = -A - BDB'$, the controllability Gramian Q is equal to $I/2$. Therefore the Hankel norm for (39) is just

$$\|W\|_{\text{hankel}} = (\lambda_{\max}(P/2))^{1/2} .$$

Since P satisfies

$$(A' - BDB')P + P(A - BDB') + I = PA - AP - BDB'P - PBDB' + I = 0,$$

multiplying both sides by P on the right, we get

$$PAP - APP - BDB'PP - PBDB'P + P = 0. \tag{43}$$

Now taking trace to both sides of (43), we get that

$$\|PBD^{1/2}\|_F^2 = \operatorname{Tr}(P/2).$$

On the other hand we know that $\operatorname{Tr}(P/2)$ is equal to the sum of all the eigenvalues of $P/2$. Therefore $\operatorname{Tr}(P/2) \leq n\lambda_{\max}(P/2)$. Finally we get $\|PB\| \leq \|D^{-1/2}\| \, \|PBD^{1/2}\| \leq \sqrt{n}\|D^{-1/2}\|\lambda_{\max}^{1/2}(P/2) \leq \sqrt{n}\|D^{-1/2}\|\widehat{\gamma}_2 \leq \sqrt{n}\|D^{-1}\|\gamma_2$. Thus

$$G_2 \leq 2\frac{\sqrt{n}}{d}(K^2 + K)\gamma_2 ,$$

and this completes the proof. □

Remark 6. The dimension of the state space does not appear in the bound of the estimate in Conclusion 1 of Corollary 3. We suspect also that the estimate for G_2 should be independent of the dimension of the state space.

5. Nonzero initial states. We now turn to nonzero initial states. We start with an easy observation.

Remark 7. Consider systems as in Theorem 2, but without controls, that is, any system (S) given by $\dot{x} = Ax + B\sigma(Fx)$, where A, B, σ are as in Theorem 2 and F is chosen as in its proof. It is well known that the origin is globally asymptotically stable, assuming for instance controllability of the matrix pair (A, B). It is interesting to see that this fact also can be shown as a consequence of our arguments. From the proof of Theorem 2, it is enough to show that the system $(\widehat{S})$ $\dot{x} = Ax - B\sigma(B'x)$, with A skew–symmetric and (A, B) controllable, is globally asymptotically stable with respect to the origin. But this follows trivially from (28), since we have along the trajectories of $(\widehat{S})$ that $dV_2(x(t))/dt \leq -\|x(t)\|^2$. Thus V_2 is a strict Lyapunov function for this system without controls.

The previous remark suggests the study of relationships between L^p-stability and global asymptotic stability of the origin. We prove below that, even for nonlinear feedback laws, L^p-stability for finite p implies asymptotic stability.

5.1. Relations between state-space stability and L^p-stability. We consider initialized control systems of the type (1). If this system is L^p-stable for some $p \in [1, \infty)$ and if, in addition, f satisfies some growth or regularity assumptions, we are able to draw conclusions regarding the asymptotic behavior of the solutions of

$$\dot{x} = f(x, 0). \tag{44}$$

We next define the various alternative properties of f under which we will be able to obtain several such conclusions:

$(H_{1,p})$: there exist $\alpha \in [0, p]$, $\delta > 0$, $K_1, K_2 \geq 0$, such that for all $x \in \mathbb{R}^n$ with $\|x\| < \delta$ and for all $u \in \mathbb{R}^m$ we have

$$\|f(x,u)\| \leq K_1(\|x\| + \|u\|) + K_2(\|x\|^\alpha + \|u\|^\alpha);$$

$(H_{2,p})$: there exist $\alpha \in [0, p]$, $K_1, K_2 \geq 0$, such that for all $(x, u) \in \mathbb{R}^n \times \mathbb{R}^m$ we have

$$\|f(x,u)\| \leq K_1(\|x\| + \|u\|) + K_2(\|x\|^\alpha + \|u\|^\alpha);$$

(H_3) : the function f is differentiable at $(0, 0)$ with $A \stackrel{\text{def}}{=} D_x f(0,0)$ and $B \stackrel{\text{def}}{=} D_u f(0,0)$.

Then we have the following lemma.

LEMMA 4. *Let $f : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$ be a locally Lipschitz function. Assume that the system*

$$\dot{x} = f(x,u), \quad x(0) = 0 \tag{45}$$

is L^p-stable for some $p \in [1, \infty)$ with L^p-gain G_p. For each $u \in L^p([0,\infty), \mathbb{R}^m)$, let x_u denote the corresponding solution of (45). *We can make the following conclusions.*

(1) *If f satisfies $(H_{1,p})$, then, for each u, $\lim_{t\to\infty} x_u(t) = 0$.*

(2) *If f satisfies $(H_{2,p})$, then there exists a constant $C > 0$ so that, for each u.*

$$\|x_u\|_{L^\infty} \leq C \max\left(\|u\|_{L^p}, \|u\|_{L^p}^{p/(p+1-\alpha)}\right). \tag{46}$$

(3) *If f satisfies (H_3), then the linearized system*

$$\dot{x} = Ax + Bu, \quad x(0) = 0$$

is L^p-stable with L^p-gain $\gamma_p \leq G_p$ (so, in this case, if (A, B) is controllable, then A must be Hurwitz and the system (44) *is locally exponentially stable).*

Note that if system (45) is L^p-stable, then $f(0,0) = 0$.

Proof. In what follows we write x_u simply as x, when the control is clear from the context.

(1) Assume that the conclusion is not true for some $u \in L^p([0,\infty), \mathbb{R}^m)$. Then there exists $\delta_1 > 0$ so that $\limsup_{t\to\infty} \|x(t)\| \geq 2\delta_1$. Without loss of generality, we may assume that $\delta_1 \leq \min(1, \delta)$.

Take $\varepsilon > 0$ and fix a time $T_0 > 0$ so that

$$\|u\|_{L^p[T_0,\infty)} \leq \varepsilon, \quad \|x\|_{L^p[T_0,\infty)} \leq \varepsilon.$$

Since $\liminf_{t\to\infty} x(t) = 0$, there exist $T_1, T_2 > T_0$ such that

(a) $\frac{\delta_1}{2} \leq \|x(t)\| \leq \delta_1$, for $t \in [T_1, T_2]$;

(b) $\|x(T_2) - x(T_1)\| \geq \frac{\delta_1}{2}$.

Then using $(H_{1,p})$ and applying Hölder's inequality, we obtain

$$\begin{aligned} \frac{\delta_1}{2} \leq \|x(T_2) - x(T_1)\| &\leq \int_{T_1}^{T_2} \|f(x(s), u(s))\| ds \\ &\leq 2K_1\varepsilon(T_2 - T_1)^{(p-1)/p} + 2K_2\varepsilon^\alpha(T_2 - T_1)^{(p-\alpha)/p}, \end{aligned} \tag{47}$$

$$(T_2 - T_1)\left(\frac{\delta_1}{2}\right)^p \leq \int_{T_1}^{T_2} \|x(t)\|^p dt \leq \varepsilon^p. \tag{48}$$

Using (47) and (48), we get

$$\frac{\delta_1}{2} \leq 2\left(\frac{K_1}{(\frac{\delta_1}{2})^{p-1}} + \frac{K_2}{(\frac{\delta_1}{2})^{p-\alpha}}\right)\varepsilon^p.$$

Since ε is arbitrary, we obtain a contradiction.

(2) For each $T > 0$, let $\beta_T = \sup_{t\in[0,T]} \|x(t)\|$ and fix an interval $[T_1, T_2]$ in $[0, T]$ such that

(a) $\frac{\beta_T}{2} \leq \|x(t)\| \leq \beta_T$, for $t \in [T_1, T_2]$;

(b) $\|x(T_2) - x(T_1)\| = \frac{\beta_T}{2}$.

Since $(H_{2,p})$ holds, we obtain, using the L^P-stability of (45) and Hölder's inequality, that

$$\frac{\beta_T}{2} \leq C_1(T_2 - T_1)^{(p-1)/p}\|u\|_{L^p} + C_2(T_2 - T_1)^{(p-\alpha)/p}\|u\|_{L^p}^{\alpha} \tag{49}$$

for appropriate constants C_1, C_2, and

$$(T_2 - T_1)\left(\frac{\beta_T}{2}\right)^p \leq C_3\|u\|_{L^p}^p \tag{50}$$

for some constant $C_3 > 0$. From (49) and (50) we can easily conclude

$$\beta_T \leq C \max\left(\|u\|_{L^p}, \|u\|_{L^p}^{p/(p+1-\alpha)}\right), \tag{51}$$

where $C > 0$ is a constant independent of T. Since T is arbitrary, (46) holds.

(3) For each control u and $\varepsilon \neq 0$, let x_ε be the trajectory of (45) corresponding to εu. Then it is easy to see that $z_\varepsilon(t) \overset{\text{def}}{=} \frac{x_\varepsilon(t)}{\varepsilon}$ converges, for each t as $\varepsilon \to 0$, to the solution $z(t)$ of

$$\dot{z} = Az + Bu, \quad z(0) = 0.$$

We have $\|z_\varepsilon\|_{L^p} \leq G_p\|u\|_{L^p}$. From this we can prove that $\|z\|_{L^p} \leq G_p\|u\|_{L^p}$, which implies that $\gamma_p \leq G_p$; cf. also [18]. □

Remark 8. One can notice that the finiteness of G_p was not used in the proof of Statement (1). Only the fact that inputs in L^p produce state trajectories in L^p is used.

If we assume reachability conditions on (45), together with L^p-stability of the system for some $p \in [1, \infty)$ and a hypothesis as in Lemma 4, we can obtain information on the asymptotic stability of system (45). We will focus on a special class of systems described by (45) and our results are contained in the next lemma.

LEMMA 5. *Let A be an $n \times n$ matrix, B be an $n \times m$ matrix, σ be an $\mathbb{R}^m$-valued S-function, and f be a locally Lipschitz function from $\mathbb{R}^n$ to $\mathbb{R}^m$. We assume that (A, B) is controllable. Consider the system of differential equations*

$$\dot{x} = Ax + B\sigma(f(x)) \tag{52}$$

and the control system

$$\begin{aligned} \dot{x} &= Ax + B\sigma(f(x) + u), \\ x(0) &= 0. \end{aligned} \tag{53}$$

We can make the following conclusions.

(i) *If system* (53) *is L^p-stable for some $p \in [1, \infty)$, then system* (52) *is locally asymptotically stable with respect to the origin*;

(ii) *If the reachable set from zero of* (53) *is equal to $\mathbb{R}^n$ and if system* (53) *is L^p-stable for some $p \in [1, \infty)$, then system* (52) *is globally asymptotically stable with respect to the origin.*

Proof. We first show (i). Note that the system (53) satisfies $(H_{2,p})$ (with $\alpha = 0$). Fix a $u \in L^p([0, \infty), \mathbb{R}^m)$. Let x_u be the solution of (53) corresponding to u. From Lemma 4 we know that $x_u(t) \to 0$ as $t \to \infty$.

To prove stability, we need some elementary reachability results for linear systems. By our assumption we know that the system

$$\dot{x} = Ax + Bu \tag{54}$$

is controllable. Any point $x_0 \in \mathbb{R}^n$ can be reached from zero by trajectories of (54) at time 1. Moreover we can choose a u_{x_0} on $[0, 1]$ that steers zero to x_0 and satisfies $\|u_{x_0}\|_{L^\infty[0,1]} \leq C\|x_0\|$, where $C > 0$ is a constant depending on A, B (cf., e.g., [13]). By a measurable selection it is also true that there is a measurable control v that steers zero to x_0 for the system (S) $\dot{x} = Ax + B\sigma(v)$, provided that x_0 is small enough. Moreover $\|v\|_{L^\infty[0,1]}$ can be made small if $\|x_0\|$ is small. So if we let $u = v(t) - f(x(t))$ on $[0, 1]$, where x is the solution of (S), then u steers zero to x_0 for (S) at time 1. Let U be an open neighborhood of 0. For each $\delta > 0$, let $\theta(\delta) > 0$ be small enough such that, for each x_0 with $\|x_0\| \leq \theta(\delta)$, there exists a u_{x_0} that steers zero to x_0 for (53) with $\|u_{x_0}\|_{L^p[0,1]} < \delta$. If x is the solution of (52) starting at x_0, and if we let $u(t) = u_{x_0}(t)$ on $[0, 1]$ and $u(t) = 0$ on $(1, \infty)$, then the solution x_u of (53) satisfies $x_u(t) = x(t - 1)$ on $[1, \infty)$. By (46) we can take a $\delta > 0$ small enough such that for any x_0 with $\|x_0\| \leq \theta(\delta)$, the solution x of (52) starting at x_0 stays in U. So system (52) is locally stable.

We next show (ii). Local stability follows as in (i). To prove global attraction, note that the reachability assumption implies that any trajectory x of (52) can be seen as a part of a trajectory of (53) corresponding to a control in L^p. Now Lemma 4 provides that $x(t) \to 0$. □

5.2. Dissipation inequality and input-to-state stability. Next we give a slightly different proof of Theorem 2, which results in a weaker statement (we now allow ε to depend on p) but which is somewhat simpler. Moreover, it results in a simple dissipation-type inequality, from which conclusions about nonzero initial states will be evident. We will only sketch the steps, as they parallel those in the previous proofs.

Assume that A is skew–symmetric and $A - BB'$ is Hurwitz. Fix a $1 \leq p < \infty$ first. Let $\tau, a, b, K, V_{0,p}, V_{1,p}$ be as in the proof of Lemma 2. Let

$$\lambda_p = K\|B\|c_p\,,$$
$$\varepsilon_p = \frac{1}{2K\lambda_p}\,.$$

Consider the system

$$\dot{x} = Ax - B\sigma(B'x + u) + \varepsilon_p\theta(v), \tag{55}$$

where the initial states are now arbitrary. Write $\tilde{x}(t) = B'x(t) + u(t)$.

Along the trajectories of (55), we have

$$\begin{aligned}\dot{V}_{0,p}(x(t)) &= -\|x(t)\|^{p-1}\tilde{x}'(t)\sigma(\tilde{x}(t)) \\ &\quad + \|x(t)\|^{p-1}\left(\varepsilon_p x'(t)\theta(v(t)) + u'(t)\sigma(\tilde{x}(t))\right) \\ &\leq -\|x(t)\|^{p-1}\tilde{x}'(t)\sigma(\tilde{x}(t)) \\ &\quad + K\|x(t)\|^{p-1}\|u(t)\| + K\varepsilon_p\|x(t)\|^p. \end{aligned} \tag{56}$$

(Compare this with (22).) Similar to (25) we can get (for $p > 1$)

$$\dot{V}_{1,p}(x(t)) \leq -\|x(t)\|^p + Kc_p\|B\|\,\|x(t)\|^{p-1}\tilde{x}'(t)\sigma(\tilde{x}(t))$$

$$+ c_p K\|x(t)\|^{p-1}\left(\|B\|\,\|u(t)\| + \varepsilon_p\|v(t)\|\right). \tag{57}$$

Again letting $V_p(x) = \lambda_p V_{0,p}(x) + V_{1,p}(x)$, we obtain

$$\dot{V}_p(x(t)) \leq -(1 - K\lambda_p\varepsilon_p)\|x(t)\|^p + \|x(t)\|^{p-1}\left((K+1)\lambda_p\|u(t)\| + c_pK\varepsilon_p\|v(t)\|\right)$$

$$= -\frac{1}{2}\|x(t)\|^p + \|x(t)\|^{p-1}\left((K+1)\lambda_p\|u(t)\| + c_pK\varepsilon_p\|v(t)\|\right).$$

Let

$$\kappa_p = \max\{(K+1)\lambda_p, c_pK\varepsilon_p\}.$$

Thus, for $p > 1$,

$$\dot{V}_p(x(t)) \leq -\frac{1}{2}\|x(t)\|^p + \kappa_p\|x(t)\|^{p-1}(\|u(t)\| + \|v(t)\|). \tag{58}$$

Arguing as in the proof of Lemma 2, we see that this provides L^p-stability provided that $x(0) = 0$. But we also note in this case that it is possible to rewrite (58) in a "dissipation inequality" form, as follows. First, by Young's inequality, we have for any $\alpha, \mu, \nu > 0$ and $p > 1$,

$$\mu^{p-1}\nu \leq \frac{p-1}{p}\alpha^{p/(p-1)}\mu^p + \frac{\nu^p}{p\alpha^p}.$$

Let

$$\alpha_p = \left[\frac{p}{4(p-1)\kappa_p}\right]^{(p-1)/p}.$$

Then (58) can be written as

$$\dot{V}_p(x(t)) \leq -\frac{1}{4}\|x(t)\|^p + \frac{\kappa_p}{p\alpha_p^p}(\|u(t)\| + \|v(t)\|)^p.$$

So if we let $\tilde{V}_p = 4V_p$, $r_p = \frac{4\kappa_p}{p\alpha_p^p}$, we finally conclude, along all solutions of (55),

$$\dot{\tilde{V}}_p(x(t)) \leq -\|x(t)\|^p + r_p(\|u(t)\| + \|v(t)\|)^p. \tag{59}$$

This is sometimes called a *dissipation inequality*; see [7].

Take in particular $p = 2$ and write $V = \tilde{V}_2$. The estimate (59) shows that $V(x(t))$ must decrease if $\|x(t)\|$ is larger than $\sqrt{r_2}$ times the input magnitude. Thus, irrespective of the initial state, the state trajectory is ultimately bounded, assuming that the inputs u and v are bounded, and this asymptotic bound depends on an asymptotic bound on u and v. One way to summarize this conclusion is by means of the estimate

$$\|x(t)\| \leq \beta(\|x(0)\|, t) + \gamma\left(\|(u,v)\|_{L^\infty[0,t]}\right) \tag{60}$$

valid for all $x(0)$, all $t \geq 0$, and all essentially bounded u, v, where γ is a function of class K and β is a class-KL function (that is, $\beta : \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ is so that for each fixed

$t \geq 0$, $\beta(\cdot, t)$ is a class-K function, and for each fixed $s \geq 0$, $\beta(s, \cdot)$ is decreasing to zero as $t \to \infty$). This is the notion of *ISS stability* discussed in, e.g., [11, 10, 17, 15]; equation (60) is a consequence of (59), which says that V is a *Lyapunov ISS* function. In fact, in our case one can say more about the function γ; namely, it can be taken to be *linear*. Indeed, from the proof in [11, p. 441] one can take any $\gamma \geq \alpha_1^{-1} \circ \alpha_2 \circ \alpha_4$, where $\alpha_4(l) = \sqrt{r_2}l$ and where the α_i's are class-K functions, so that

$$\alpha_1(\|x\|) \leq V(x) \leq \alpha_2(\|x\|)$$

for all $x \in \mathbb{R}^n$. Here we can choose $\alpha_2 = c\alpha_1$, for some $c > 1$, where α_1 is of the form $\alpha(l) = a_1 l^2 + a_2 l^3$ and is thus a convex function. Since for any increasing convex function α and $c > 1$, and any $d > 0$, $\alpha^{-1}(c\alpha(dl)) \leq cdl$ for all l, this gives a linear γ as claimed.

6. More general input nonlinearities. Now we consider a broader class of input nonlinearities, allowing unbounded functions as well. The main result will be extended to this case.

DEFINITION 4. *We call $\Sigma : \mathbb{R} \to \mathbb{R}$ an $\widetilde{S}$-function if it can be written as $\Sigma(t) = \alpha t g(t) + \sigma(t)$, where*

- *$\alpha \geq 0$ is a constant,*
- *$g : \mathbb{R} \to [a, b]$ is measurable and a, b are strictly positive real numbers,*
- *$\sigma : \mathbb{R} \to \mathbb{R}$ is an S-function.*

We say that $\Sigma = (\Sigma_1, \ldots, \Sigma_m)'$ is an $\mathbb{R}^m$-valued $\widetilde{S}$-function if each Σ_i is an $\widetilde{S}$-function. As before if $\xi = (\xi_1, \ldots, \xi_m)' \in \mathbb{R}^m$, then $\Sigma(\xi) = (\Sigma_1(\xi_1), \ldots, \Sigma_m(\xi_m))'$.

With this definition we have the following generalization of Theorem 1.

THEOREM 4. *Let A, B be $n \times n$, $n \times m$ matrices, respectively, and Σ be an $\mathbb{R}^m$-valued $\widetilde{S}$-function. Assume that A is neutrally stable. Then there exists an $m \times n$ matrix F such that the system*

$$\begin{aligned} \dot{x} &= Ax + B\Sigma(Fx + u), \\ x(0) &= 0 \end{aligned} \tag{61}$$

is L^p-stable for all $1 \leq p \leq \infty$.

Proof. As in the proof of Theorem 2, we can assume without loss of generality that A is skew–symmetric and (A, B) is controllable.

Assume that $\Sigma = (\Sigma_1, \ldots, \Sigma_m)'$ with $\Sigma_i(t) = \alpha_i t g_i(t) + \sigma_i(t)$. Let $\sigma = (\sigma_1, \ldots, \sigma_m)'$ and $G = \operatorname{diag}(\alpha_1 g_1, \ldots, \alpha_m g_m)$ with $G(\xi) = \operatorname{diag}(\alpha_1 g_1(\xi_1), \ldots, \alpha_m g_m(\xi_m))$ for $\xi \in \mathbb{R}^m$. Then $\Sigma(\xi) = G(\xi)\xi + \sigma(\xi)$.

The α_i's split into two sets, $\Lambda_1 = \{\alpha_i, \alpha_i > 0\}$ and $\Lambda_2 = \{\alpha_i, \alpha_i = 0\}$. We can assume without loss of generality that

$$\Lambda_1 = \{\alpha_1, \ldots, \alpha_r\} \text{ and } \Lambda_2 = \{\alpha_{r+1}, \ldots, \alpha_m\}, \quad r \leq m.$$

Therefore system (61) becomes

$$\dot{x} = Ax + B \left(\begin{array}{ccc|c} \alpha_1 g_1 & & & \\ & \ddots & \mathrm{O} & \mathrm{O} \\ \mathrm{O} & \ddots & & \\ & & \alpha_r g_r & \\ \hline & \mathrm{O} & & \mathrm{O} \end{array}\right) (Fx + u) + B\sigma(Fx + u).$$

Write $B = (B_1, B_2)$, $F = \binom{F_1}{F_2}$, $u = \binom{u_1}{u_2}$, $\sigma = \binom{\sigma^1}{\sigma^2}$, and let $G_1 = \operatorname{diag}(\alpha_1 g_1, \ldots, \alpha_r g_r)$ with $G_1(\xi) = \operatorname{diag}(\alpha_1 g_1(\xi_1), \ldots, \alpha_r g_r(\xi_r))$ for $\xi \in \mathbb{R}^r$. The sizes of the matrices B_1, B_2, F_1, F_2

are, respectively, $n \times r$, $n \times (m-r)$, $r \times n$, $(m-r) \times n$. As for u_1, u_2, they are, respectively, elements of $\mathbb{R}^r$ and $\mathbb{R}^{m-r}$. The S-functions σ^1, σ^2 are, respectively, $\mathbb{R}^r$- and $\mathbb{R}^{m-r}$-valued. We rewrite (61) as

$$\begin{aligned} \dot{x} &= Ax + B_1 G_1(F_1 x + u_1)(F_1 x + u_1) \\ &\quad + B_1 \sigma^1(F_1 x + u_1) + B_2 \sigma^2(F_2 x + u_2), \\ x(0) &= 0. \end{aligned} \tag{62}$$

Let $R(A, B_1) : \mathbb{R}^{rn} \to \mathbb{R}^n$ be the reachability matrix of (A, B_1). (Here and below we will identify matrices with the corresponding linear maps.)

Let $D = \mathrm{Im}R(A, B_1)$ and $H = D^{\perp}$. We have $D \oplus H = \mathbb{R}^n$. Clearly the subspace D is invariant under A and $\mathrm{Im}(B_1) \subseteq D$. Since A is skew–symmetric, the subspace H is also invariant under A. So there exists an orthogonal $n \times n$ matrix U such that

$$UAU' = \begin{pmatrix} A_1 & O \\ O & A_2 \end{pmatrix}, \tag{63}$$

where A_1 and A_2 are skew–symmetric and are restrictions of A to G and H, respectively. So, up to an orthonormal change of basis, we can assume that A is already of the form (63). According to this decomposition, $D = \mathrm{Im}\ R(A, B_1)$. Let $s = \dim D = \mathrm{rank}\ R(A, B_1)$. Consider now

$$x = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \qquad B_1 = \begin{pmatrix} B_{11} \\ B_{12} \end{pmatrix}, \qquad B_2 = \begin{pmatrix} B_{21} \\ B_{22} \end{pmatrix},$$

$$F_1 = (F_{11},\ F_{12}), \qquad F_2 = (F_{21},\ F_{22}).$$

Here, $x_1 \in \mathbb{R}^s$, $x_2 \in \mathbb{R}^{n-s}$ and the sizes of B_{11}, B_{12}, B_{21}, B_{22} and F_{11}, F_{12}, F_{21}, F_{22} are, respectively, $s \times r$, $(n-s) \times r$, $s \times (m-r)$, $(n-s) \times (m-r)$ and $r \times s$, $r \times (n-s)$, $(m-r) \times s$, $(m-r) \times (n-s)$.

Since $\mathrm{Im}B_1 \subset D$, we have $B_{12} = 0$. Now system (62) becomes

$$\begin{aligned} \dot{x}_1 &= A_1 x_1 + B_{11} G_1(F_{11} x_1 + F_{12} x_2 + u_1)(F_{11} x_1 + F_{12} x_2 + u_1) \\ &\quad + B_{11} \sigma^1(F_{11} x_1 + F_{12} x_2 + u_1) + B_{21} \sigma^2(F_{21} x_1 + F_{22} x_2 + u_2), \\ \dot{x}_2 &= A_2 x_2 + B_{22} \sigma^2(F_{21} x_1 + F_{22} x_2 + u_2)\ . \end{aligned}$$

Choose now $F_{12} = F_{21} = 0$, $F_{11} = -B_{11}'$, and $F_{22} = -B_{22}'$. We obtain

$$\begin{aligned} \dot{x}_1 &= \left(A_1 - B_{11} G_1(-B_{11}' x_1 + u_1) B_{11}'\right) x_1 + B_{11} G_1(-B_{11}' x_1 + u_1) u_1 \\ &\quad + B_{11} \sigma^1(-B_{11}' x_1 + u_1) + B_{21} \sigma^2(-B_{22}' x_2 + u_2), \\ \dot{x}_2 &= A_2 x_2 + B_{22} \sigma^2(-B_{22}' x_2 + u_2). \end{aligned}$$

In the above system, replacing $\sigma(\cdot)$ by $-\sigma(-\cdot)$ (still denoted by σ), the system becomes

$$\begin{aligned} \dot{x}_1 &= \left(A_1 - B_{11} G_1(-B_{11}' x_1 + u_1) B_{11}'\right) x_1 + B_{11} G_1(-B_{11}' x_1 + u_1) u_1 \\ &\quad - B_{11} \sigma^1(B_{11}' x_1 - u_1) - B_{21} \sigma^2(B_{22}' x_2 - u_2), \\ \dot{x}_2 &= A_2 x_2 - B_{22} \sigma^2(B_{22}' x_2 - u_2). \end{aligned}$$

Since (A, B) is controllable, (A_2, B_{22}) is also controllable. It follows from Theorem 2 that the x_2-subsystem is L^p-stable for all $1 \le p \le \infty$. So there exists $C_p^1 > 0$ such that $\|x_2\|_{L^p} \le C_p^1 \|u_2\|_{L^p}$.

For $i = 1, \ldots, r$, let $d_i(t) = \sigma_i^1(t)/t$, if $t \neq 0$, and $d_i(t) = 0$, if $t = 0$. Let $\tilde{G}_1(\xi) = \operatorname{diag}(d_1(\xi_1), \ldots, d_r(\xi_r))$. Then we can rewrite the x_1-subsystem as

$$\dot{x}_1 = [A_1 - B_{11}(G_1(-B_{11}'x_1 + u_1) + \tilde{G}_1(B_{11}'x_1 - u_1))B_{11}']x_1 + v,$$

where

$$v = B_{11}G_1(-B_{11}'x_1 + u_1)u_1 + B_{11}\tilde{G}_1(B_{11}'x_1 - u_1)u_1 - B_{21}\sigma^2(B_{22}'x_2 - u_2).$$

We have

$$\|v\| \leq C(\|u_1\| + \|x_2\| + \|u_2\|)$$

for some $C > 0$.

If we let $\widetilde{D}(t) = G_1(-B_{11}'x_1(t) + u_1(t)) + \tilde{G}_1(B_{11}'x_1(t) - u_1(t))$, then the above equation can be written as

$$\dot{x}_1(t) = (A_1 - B_{11}\widetilde{D}(t)B_{11}')x_1(t) + v(t)\,.$$

By definition of an S-function and an $\widetilde{\mathrm{S}}$-function, there exist two real numbers δ_1 and δ_2 such that $0 < \delta_1 \leq \delta_2$, and if we write $\widetilde{D}(t) = \operatorname{diag}(\tilde{d}_1(t), \cdots, \tilde{d}_r(t))$, then

$$\delta_1 \leq \tilde{d}_i(t) \leq \delta_2$$

for $i = 1, \ldots, r$. Since (A, B) is controllable, (A_1, B_{11}) is controllable too. Then it follows from Corollary 2 that

$$\|x_1\|_{L^p} \leq \bar{C}_p^2 \|v\|_{L^p}\,,$$

for some $\bar{C}_p^2 > 0$ depending on A_1, B_{11}, δ_1, δ_2, and p. But we know that

$$\|v\|_{L^p} \leq C(\|u_1\|_{L^p} + \|u_2\|_{L^p} + \|x_2\|_{L^p}) \leq C\|u_1\|_{L^p} + C(1 + C_p^1)\|u_2\|_{L^p}\,.$$

Therefore we have $\|x_1\|_{L^p} \leq C_p^2 \|u\|_{L^p}$ for some constant $C_p^2 > 0$. □

7. Counterexample: The *n*th order scalar integrator. The next result is a negative one, and it concerns systems such as those in equation (2), except that the matrix A is not neutrally stable but instead is assumed to have a nonsimple Jordan block for the zero eigenvalue. In that case, we show that for any possible F which stabilizes the corresponding linear control system

$$\begin{aligned} \dot{x} &= Ax + B(Fx + u)\,, \\ x(0) &= 0\,, \end{aligned}$$

the resulting system (Σ_u) is *not* in general L^p-stable for any $1 \leq p \leq \infty$. We first consider the simplest case, namely the double integrator. The proof is of interest because the origin of the corresponding system without inputs (but *with* the saturation) *is* globally asymptotically stable. Thus the result is quite surprising. In the end we discuss the n-integrator for $n \geq 3$.

PROPOSITION 1. *Let $1 \leq p \leq \infty$. Consider the following 2-dimensional initialized control system:*

$$(S_{a,b}) \qquad \begin{aligned} \dot{x} &= y\,, \\ \dot{y} &= -\sigma(ax + by + u)\,, \\ x(0) &= y(0) = 0\,, \end{aligned}$$

where $a, b > 0$, σ is a scalar S-function, and inputs u belong to $L^p([0, \infty), \mathbb{R})$. Then $(S_{a,b})$ is not L^p-stable.

Proof. Up to a reparameterization of the time and a linear change of variables, it is enough to show that the initialized control system

$$\begin{aligned} \dot{x} &= y\,, \\ \dot{y} &= -\lambda\sigma(x + y + u)\,, \\ x(0) &= y(0) = 0\,, \end{aligned}$$

where $\lambda > 0$, is not L^p-stable. Now replacing $\lambda\sigma$ by σ (note $\lambda\sigma$ is still an S-function) we may assume that $\lambda = 1$. Therefore all we need to show is that the system

$$(S) \qquad \begin{aligned} \dot{x} &= y\,, \\ \dot{y} &= -\sigma(x + y + u)\,, \\ x(0) &= y(0) = 0 \end{aligned}$$

is not L^p-stable. The proof is quite technical, but the idea is not difficult to understand. It is based on the fact that the feedback $u = -y$ makes the system (S) have periodic trajectories, with a control u whose norm is proportional to that of the y-coordinate. But the x-coordinate is the integral of y, so the ratio between the p-norms of x and u can be made to be large for $p < \infty$. (For $p = \infty$, one modifies the argument to reach states of large magnitude.)

Let us first fix a p in $[1, \infty)$. Assume that (S) is L^p-stable. Then the following holds: there exists $C_p > 0$ so that, if $u \in L^p([0, \infty), \mathbb{R})$, then

$$\|y_u^2\|_{L^p} \leq C_p \, \|u\|_{L^p}, \tag{64}$$

where y_u is the second coordinate of (x_u, y_u), the solution of (S) associated to u.

To see this, let $q = 2(p - 1) \geq 0$ and

$$V_q(x, y) = -\frac{xy|y|^q}{q + 1}\,.$$

Then along the trajectory (x_u, y_u) of (S) we have

$$\dot{V}_q = -\frac{1}{q + 1}\,|y_u|^{q+2} + x_u\sigma(x_u + y_u + u)|y_u|^q.$$

Therefore,

$$\dot{V}_q + \frac{1}{q + 1}\,|y_u|^{q+2} \leq K|x_u||y_u|^q\,, \tag{65}$$

where K is an S-bound for σ. From Lemma 4 we know that $\lim_{t\to\infty}(x_u, y_u) = (0, 0)$. Integrating (65) from zero to t and letting $t \to \infty$, we end up with

$$\frac{1}{q + 1}\int_0^\infty |y_u|^{q+2} \leq K\int_0^\infty |x_u||y_u|^q.$$

Therefore, if $p = 1$, we get that $\|y_u^2\|_{L^1} \leq K\|x\|_{L^1}$. If $p > 1$, applying Hölder's inequality, we get

$$\frac{1}{q + 1}\int_0^\infty |y_u|^{2p} \leq K\|x_u\|_{L^p}\left(\int_0^\infty |y_u|^{qp/(p-1)}\right)^{(p-1)/p}.$$

But $q\frac{p}{p-1} = 2(p-1)\frac{p}{p-1} = 2p$. Therefore

$$\|y_u^2\|_{L^p} \leq (2p-1)K\|x_u\|_{L^p}. \tag{66}$$

Since (S) is L^p-stable, $\|x_u\|_{L^p} \leq G_p\|u\|_{L^p}$, where G_p is the L^p-gain of (S). So (64) indeed holds.

Now we construct trajectories of (S) which contradict (64).

We consider the level sets of the following Lyapunov function:

$$V(x, y) = y^2 + G(x),$$

where $G(x) = 2\int_0^x \sigma(s)ds$.

Let $\rho_1 = 2\inf_{|t|\geq 1}|\sigma(t)| > 0$ and define $H : \mathbb{R} \to \mathbb{R}$ by

$$H(x) = \begin{cases} 0 & \text{if } |x| \leq 1, \\ \rho_1(|x|-1) & \text{if } |x| > 1. \end{cases}$$

We have

$$y^2 + H(x) \leq V(x, y) \leq y^2 + 2K|x|. \tag{67}$$

Note that along trajectories of

$$(\widehat{S}) \qquad \begin{aligned} \dot{x} &= y, \\ \dot{y} &= -\sigma(x), \end{aligned}$$

V is constant.

Let us fix a constant $V_0 \geq \max\{1, 2K\}$ and let $x^- < 0$ and $x^+ > 0$ be such that $G(x^+) = G(x^-) = V_0$. Since (S) is controllable, there exist a $T_1 > 0$ and a u_0 in $L^p([0, T_1], \mathbb{R})$ such that $\big(x_{u_0}(T_1), y_{u_0}(T_1)\big) = (0, \sqrt{V_0})$. We can also assume that $u_0(t) = 0$ for $t > T_1$. For $t \geq 0$, consider $(\bar{x}_0(t), \bar{y}_0(t))$, the solution of $(\widehat{S})$ with $(\bar{x}_0(0), \bar{y}_0(0)) = (0, \sqrt{V_0})$. Note that $V(\bar{x}_0(t), \bar{y}_0(t)) \equiv V_0$. Clearly this trajectory is periodic, since it lies in the closed curve $V(x) \equiv V_0$ and there are no equilibria there. Assume that the period is T.

Consider the sequence $\{u_n\}_{n=1}^{\infty}$ of inputs defined as follows:

$$u_n(t) = \begin{cases} u_0(t) & \text{on } [0, T_1], \\ -\bar{y}_0(t - T_1) & \text{on } (T_1, T_1 + nT], \\ 0 & \text{on } (T_1 + nT, \infty). \end{cases}$$

Then if (x_n, y_n) denotes the solution of (S) associated to u_n, we have for $t \in [T_1, T_1 + nT]$,

$$(x_n(t), y_n(t)) = (\bar{x}_0(t - T_1), \bar{y}_0(t - T_1)).$$

In this case (note that $y_n(t) = y_{u_0}(t)$ for $t \in [0, T_1]$ and $y_n(t) = y_{u_0}(t - nT)$ for $t \in [T_1 + nT, \infty)$)

$$\begin{aligned} \int_0^{\infty} |u_n(s)|^p\, ds &= \int_0^{T_1} |u_0(s)|^p\, ds + n\int_0^T |\bar{y}_0(s)|^p\, ds, \\ \int_0^{\infty} |y_n^2(s)|^p\, ds &= \int_0^{\infty} |y_{u_0}^2(s)|^p\, ds + n\int_0^T |\bar{y}_0^2(s)|^p\, ds. \end{aligned}$$

We conclude that

$$\lim_{n\to\infty} \frac{\|y_n^2\|_{L^p}}{\|u_n\|_{L^p}} = \frac{\left(\int_0^T |\bar{y}_0^2(s)|^p ds\right)^{1/p}}{\left(\int_0^T |\bar{y}_0(s)|^p ds\right)^{1/p}} \stackrel{\text{def}}{=} L_{p,V_0}.$$

According to (64), this quotient should be bounded independently of the choice of V_0. We next derive a contradiction by showing that this is not so.

Notice that for any $r \geq 1$, since $\dot{\bar{x}}_0(t) = \bar{y}_0(t)$, we have

$$\int_0^T |\bar{y}_0(s)|^r ds = \int_0^T |\bar{y}_0(s)|^{r-1} |\dot{\bar{x}}_0(s)| ds.$$

Since $V(x, y) = V(x, -y)$, we have

$$\int_0^T |\bar{y}_0(s)|^r ds = \int_0^T |\bar{y}_0(s)|^{r-1} |\dot{\bar{x}}_0(s)| ds = 2 \int_{x^-}^{x^+} |\bar{y}(x)|^{r-1} dx\,, \tag{68}$$

where $|\bar{y}(x)| = \sqrt{V_0 - G(x)}$ for x between x^- and x^+. (Note that the curve $V(x) = V_0$ can be written as the union of the graphs of the functions $y(x) = \pm\sqrt{V_0 - G(x)}$. Thus we can reparameterize the orbit in each of these two parts in terms of the variable x.)

Considering (67), we have $V_0/(2K) \leq |x^-|, x^+ \leq V_0/\rho_1 + 1$. Then it follows from (68) that

$$\int_0^T |\bar{y}_0(s)|^p ds \leq 2V_0^{(p-1)/2}(x^+ - x^-) \leq 4V_0^{(p-1)/2}(V_0/\rho_1 + 1) \leq C_1 V_0^{(p+1)/2}\,,$$

$$\int_0^T |\bar{y}_0^2(s)|^p ds \geq 4 \int_0^{V_0/(2K)} (V_0 - 2Kx)^{p-1/2}\, dx \geq C_2 V_0^{p+1/2}\,,$$

where $C_1, C_2 > 0$ are some constants. Finally, we get $L_{p,V_0} \geq C V_0^{1/2}$ for some $C > 0$. But according to (64), $L_{p,V_0} \leq C_p$. Therefore, for V_0 large enough we get a contradiction. So (S) cannot be L^p-stable for $1 \leq p < \infty$.

We still need to establish the special case $p = \infty$. We use again the level sets of V. Let u^0 on $[0, T_0]$ for some $T_0 > 0$ be an input such that $(x_{u^0}(T_0), y_{u^0}(T_0)) = (0, \sqrt{V_0})$, for some $V_0 > 0$ which will be fixed below.

From $(0, \sqrt{V_0})$, follow the trajectory of

$$(I) \qquad \begin{aligned} \dot{x} &= y, \\ \dot{y} &= \rho_2, \end{aligned}$$

on $[T_0, T_0 + 1]$, where $\rho_2 = -\sigma(-1) > 0$. The trajectory (x, y) of (I), hence, reaches $(\sqrt{V_0} + \rho_2/2, \sqrt{V_0} + \rho_2)$. Let

$$V_1 = (\sqrt{V_0} + \rho_2)^2 + G(\sqrt{V_0} + \rho_2/2) \geq V_0 + 2\rho_2\sqrt{V_0}.$$

Note that also $V_1 \leq V_0 + C(\sqrt{V_0} + 1)$ for some $C > 0$. Furthermore, the trajectory of (I) can be viewed as a trajectory of (S) with $u^1(t) = -1 - x(t) - y(t)$ for $T_0 < t \leq T_0 + 1$. Let

$$u_1 = -u^1(T_0 + 1) = 1 + \sqrt{V_0} + \rho_2/2 + \sqrt{V_0} + \rho_2 = 2\sqrt{V_0} + 3/2\rho_2 + 1.$$

Then, for $T_0 + 1 < t \leq T_1$, follow the trajectory $(\bar{x}, \bar{y})$ of $(\widehat{S})$ from $(\sqrt{V_0} + \rho_2/2, \sqrt{V_0} + \rho_2)$ until the resulting trajectory reaches $(0, \sqrt{V_1})$ at $t = T_1$. This trajectory can also be considered as a trajectory of (S) with $u^1(t) = -\bar{y}(t)$ on $(T_0 + 1, T_1]$. Note that $|u^1(t)| \leq \sqrt{V_1}$ for $T_0 + 1 < t \leq T_1$. Fix V_0 such that $\sqrt{V_1} \leq u_1 \leq 3\sqrt{V_0}$. It is clear that on $[T_0, T_1]$, $|u^1(t)| \leq u_1$.

If we iterate the above construction, we can build three sequences $\{V_n\}_{n=0}^{\infty}$, $\{u_n\}_{n=1}^{\infty}$, and $\{T_n\}_{n=0}^{\infty}$ such that

(1) $V_{n+1} = (\sqrt{V_n} + \rho_2)^2 + G(\sqrt{V_n} + \rho_2/2) \geq V_n + 2\rho_2\sqrt{V_n}$;
(2) $u_n = 2\sqrt{V_{n-1}} + 3/2\rho_2 + 1 \leq 3\sqrt{V_{n-1}}$;
(3) on $[T_n, T_{n+1}]$, there exists an input u^n such that $\sup\{|u^n(t)| : t \in [T_n, T_{n+1}]\} = u_n$ and the trajectory of (S) associated to u^n goes from $(0, \sqrt{V_n})$ to $(0, \sqrt{V_{n+1}})$.

Clearly $\lim_{n\to\infty} V_n = \infty$ and then $\lim_{n\to\infty} u_n = \infty$. Furthermore, let $x_n^- < 0$ be such that $G(x_n^-) = V_n$. Then $|x_n^-| \geq 1/(2K)V_n$ for n large enough, which implies that $\lim_{n\to\infty} |x_n^-| = \infty$.

Let $\{\bar{u}^n\}_{n=0}^{\infty}$ be the sequence of inputs which is equal to the concatenation of $u^0, u^1, \ldots, u^n$ on $[0, T_n]$ and zero for $t > T_n$. For n large enough, we have

$$\|(x_{\bar{u}^n}, y_{\bar{u}^n})\|_\infty \geq |x_n^-|,$$
$$\|\bar{u}^n\|_\infty = u_n .$$

Since $|x_n^-/u_n| \geq 1/(2K)\sqrt{V_n}$ for n large enough, (S) is not L^∞-stable. □

For n integrators and $n > 2$, the proof that L^p-stabilization is not possible is simpler (but the result is far less interesting). We can argue as follows. Let σ be a scalar S-function. It was proved in [4, 21] that, if $n \geq 3$, the n-integrator

$$\begin{aligned} \dot{x}_1 &= x_2 , \\ &\vdots \\ \dot{x}_{n-1} &= x_n , \\ \dot{x}_n &= -\sigma(u) \end{aligned}$$

is not globally asymptotically stabilizable by any possible linear feedback. With this, it follows from Lemma 5 that, if $n \geq 3$, the system

$$\begin{aligned} \dot{x}_1 &= x_2 , \\ &\vdots \\ \dot{x}_{n-1} &= x_n , \\ \dot{x}_n &= -\sigma(Fx + u) , \\ x(0) &= 0 \end{aligned}$$

is not L^p-stable for any $1 \leq p < \infty$ and any row vector F.

Acknowledgment. We wish to thank Malcolm C. Smith for asking questions that led directly to the problems studied in this paper.

ON SOME RELATIONS BETWEEN CHANEY'S GENERALIZED SECOND-ORDER DIRECTIONAL DERIVATIVE AND THAT OF BEN-TAL AND ZOWE*

L. R. HUANG† AND K. F. NG‡

Abstract. For a locally Lipschitz real-valued function f on $\mathbb{R}^n$ and x, u in $\mathbb{R}^n$ our main result implies that if x^* is in Clarke's subdifferential $\partial f(x)$ "coming from the direction u" (in Chaney's sense) such that $x^*(u)$ equals the directional derivative $f'(x; u)$, then Chaney's second-order directional derivative $f''(x; x^*, u)$, when it exists, coincides with the value at x^* of the conjugate function of the Ben-Tal–Zowe second-order directional derivative, provided that this value is finite.

Key words. nonsmooth analysis, generalized second-order directional derivative, conjugate function, subdifferential

1. Introduction.

Throughout this paper we consider a locally Lipschitz real-valued function f on $\mathbb{R}^n$. In connection with second-order nonsmooth optimization problems, different kinds of generalized second-order directional derivatives have been introduced, among which are $D^2 f(x; u, w)$ and $f''(x; x^*, u)$, respectively, due to Ben-Tal and Zowe [2, 3] and Chaney [4–8] (their definitions are given in §§2 and 3). Since they do not always exist, one can consider f''_-, f''_+ as in [4–8] and $D^2_- f$, $D^2_+ f$. Our definitions for D^2_-, D^2_+ given in §3 are distinct from those given by Penot [18] and Studniarski [24]. In their framework, some relations between the second-order directional derivative of Ben-Tal and Zowe and the second-order epiderivative of Rockafellar were recently obtained by Penot [19]. As noted in [14] our approach has the advantage that if $D^2_- f = D^2_+ f$ at $(x; u, w)$, then $f'(x; u)$ exists, and our definition degenerates to that of Ben-Tal and Zowe [3]. In the case where f is C^2, it is well known and easy to verify that the second-order derivatives of Chaney and Ben-Tal–Zowe are given by

$$f''(x; x^*, u) = \frac{1}{2}\langle u, \nabla^2 f(x)u\rangle,$$

$$D^2 f(x; u, w) = \frac{1}{2}\langle u, \nabla^2 f(x)u\rangle + x^*(w),$$

where $x^* = \nabla f(x)$ (see (2.1) and (3.5)). This implies the following relationship between the two derivatives:

$$f''(x; x^*, u) = D^2 f(x; u, w) - x^*(w), \quad \forall w. \tag{1.1}$$

This relationship persists in some nonsmooth cases; for example, (1.1) is true if $\partial_u f(x) = \{x^*\}$ and $f''(x; x^*, u)$ exists (see Definition 2.2 and Corollary 4.2). But (1.1) may fail to hold in general. A simple max-function given in §6 shows that the right-hand side of (1.1) may not be a constant function (of w); indeed it may be a (convex and) nonaffine function of w. Based on the works of Ben-Tal and Zowe [3] the following weaker relation was established by Chaney [5]:

$$f''(x; x^*, u) = \inf\{D^2 f(x; u, w) - x^*(w) : w \in \mathbb{R}^n\} (\in \mathbb{R}) \tag{1.2}$$

for a very special class of nonsmooth functions. Here we show in Theorem 4.5 that (1.2) holds in general provided that both sides of (1.2) exist in $\mathbb{R}$. When f'', $D^2 f$ do not exist, some (inequality) relationships for f''_+, f''_-, D^2_+, and D^2_- are also established. In addition to the references cited above, studies of second-order directional derivatives (based on different definitions or approach) have also been made in [10–13, 16, 20–22].

We end this section with a few standard definitions. Recall that Clarke's generalized upper directional derivative $f^0(x; u)$ of f at x in the direction u and subdifferential $\partial f(x)$ of f at x are defined respectively [9] by

$$f^0(x; u) := \limsup_{\substack{y \to x \\ t \downarrow 0}} \frac{1}{t}\{f(y + tu) - f(y)\}$$

and

$$\partial f(x) := \{x^* \in \mathbb{R}^n : x^*(u) \leq f^0(x; u) \text{ for any } u \in \mathbb{R}^n\},$$

while the lower and upper Dini directional derivatives of f at x in the direction u are defined by

$$D_- f(x; u) := \liminf_{t \downarrow 0} \frac{1}{t}\{f(x + tu) - f(x)\}$$

and

$$D_+ f(x; u) := \limsup_{t \downarrow 0} \frac{1}{t}\{f(x + tu) - f(x)\}.$$

If $D_- f(x; u) = D_+ f(x; u)$, then the common value is denoted by $f'(x; u)$, i.e., the directional derivative of f at x in the direction u. We denote the open and closed balls centered at x with radius δ by

$$B(x, \delta) := \{y \in \mathbb{R}^n : \|y - x\| < \delta\} \quad \text{and} \quad B[x, \delta] := \{y \in \mathbb{R}^n : \|y - x\| \leq \delta\},$$

respectively.

2. Chaney's generalized second-order directional derivatives. To begin, let us recall a few definitions from Chaney [5].

DEFINITION 2.1. *Let u be a vector in $\mathbb{R}^n$. Suppose that the sequence (x_k) in $\mathbb{R}^n$ converges to x. We say that (x_k) converges to x in the direction u, denoted by $(x_k) \to_u x$, if $x_k \neq x$ and the sequence $\|u\|((x_k - x)/\|x_k - x\|)$ converges to u.*

DEFINITION 2.2. *Let u be a vector in $\mathbb{R}^n$. Define the subset $\partial_u f(x)$ of $\mathbb{R}^n$ by*

$$\partial_u f(x) := \{x^*: \text{there exist sequences } (x_k) \text{ and } x_k^* \in \partial f(x_k) \text{ such that } (x_k) \to_u x \text{ and } (x_k^*) \to x^*\}.$$

Thus, $\partial_u f(x)$ is nonempty and $\partial_u f(x) \subseteq \partial f(x)$ since the multifunction ∂f is upper semi-continuous [9]; *loosely speaking, $\partial_u f(x)$ consists of all those x^* in $\partial f(x)$ coming from the direction u.*

DEFINITION 2.3. *Let u be a vector in $\mathbb{R}^n$. Suppose that $x^* \in \partial_u f(x)$. Then $f''_-(x; x^*, u)$ is defined to be the infimum of all (extended real) numbers*

$$\liminf_{k \to \infty} \frac{1}{t_k^2}\{f(x_k) - f(x) - x^*(x_k - x)\}$$

taken over all triples of sequences (x_k), (x_k^*), and (t_k) for which

(a) $t_k > 0$ *for each* k *and* (x_k) *converges to* x,
(b) (t_k) *converges to* 0 *and* $((x_k - x)/t_k)$ *converges to* u,
(c) (x_k^*) *converges to* x^* *with* x_k^* *in* $\partial f(x_k)$ *for each* k.

Similarly, $f''_+(x; x^*, u)$ *is defined by the supremum of all (extended real) numbers*

$$\limsup \frac{1}{t_k^2}\{f(x_k) - f(x) - x^*(x_k - x)\},$$

taken over all triples of sequences (x_k), (x_k^*), *and* (t_k) *for which* (a), (b), *and* (c) *all hold. Clearly,* $f''_-(x; x^*, u) \le f''_+(x; x^*, u)$. *Further, if* $f''_-(x; x^*, u) = f''_+(x; x^*, u)$, *then we denote this common value by* $f''(x; x^*, u)$ *and call it Chaney's generalized second-order directional derivative of* f *at* x, x^* *in the direction* u. *It is easy to see that if* f *is a* C^2*-function, then*

$$f''(x; \nabla f(x), u) = \frac{1}{2} u \cdot \nabla^2 f(x) u. \tag{2.1}$$

The following lemma will be used in §4.

LEMMA 2.4. *Let* $x, u \in \mathbb{R}^n$ *and* $g, h: \mathbb{R}^n \to \mathbb{R}$ *be locally Lipschitz at* x. *Let* $f = g + h$. *Then one has*

(i) $x^* \in \partial_u f(x)$ *if and only if* $-x^* \in \partial_u(-f)(x)$. *Moreover, if* $x^* \in \partial_u f(x)$, *then*

$$(-f)''_-(x; -x^*, u) = -f''_+(x; x^*, u).$$

(ii) $\partial_u f(x) \subseteq \partial_u g(x) + \partial_u h(x)$. *Equality holds if* $\partial_u h(x)$ *is a singleton.*
(iii) *The set* $\partial_u h(x)$ *contains vectors* x_+^* *and* x_-^* *such that*

$$x_+^*(u) = D_+h(x; u) \text{ and } x_-^*(u) = D_-h(x; u).$$

(iv) *if* $\partial_u h(x) = \{x^*\}$, *then* $h'(x; u)$ *exists and* $h'(x; u) = x^*(u)$.

Proof. Part (i) follows readily from Definitions 2.2 and 2.3. For part (ii), suppose that $x^* \in \partial_u f(x)$. By Definition 2.2 there exist sequences (x_k) and (x_k^*) such that $(x_k) \to_u x$ and $x_k^* \in \partial f(x_k)$ with $(x_k^*) \to x^*$. Thus, $x_k^* \in \partial g(x_k) + \partial h(x_k)$ by [9, Prop. 2.3.3], so there exist $y_k^* \in \partial g(x_k)$ and $z_k^* \in \partial h(x_k)$ with $y_k^* + z_k^* = x_k^*$ for each k. Since ∂f takes values locally in a compact set [9], by considering a subsequence if necessary we can assume that the sequences (y_k^*) and (z_k^*) are convergent to some $y^* \in \partial g(x)$ and some $z^* \in \partial h(x)$, respectively. By Definition 2.2, $y^* \in \partial_u g(x)$ and $z^* \in \partial_u h(x)$. It follows that $x^* = y^* + z^*$ is in $\partial_u g(x) + \partial_u h(x)$, so the inclusion in (ii) holds. Similarly, by (i), we also have

$$\partial_u g(x) \subseteq \partial_u f(x) + \partial_u(-h)(x) = \partial_u f(x) - \partial_u h(x).$$

Consequently,

$$\partial_u f(x) \subseteq \partial_u g(x) + \partial_u h(x) \subseteq \partial_u f(x) - \partial_u h(x) + \partial_u h(x)$$

and all equalities must hold if $\partial_u h(x)$ is a singleton. Part (iii) is taken from [13, Lem. 2.3], and clearly (iv) follows from (iii). □

Below we give a simple example of a convex (so semismooth [17]) function that satisfies assumption (iv).

Example 2.5. Let $f: \mathbb{R} \to \mathbb{R}$ be defined by $f(x) = |x|$. Then $\partial f(0) = [-1, 1]$, $\partial f(x) = \{1\}$ for $x > 0$, and $\partial f(x) = \{-1\}$ for $x < 0$. Hence $\partial_1 f(0) = \{1\}$ and $\partial_{-1} f(0) = \{-1\}$.

3. Ben-Tal and Zowe's generalized second-order directional derivatives. We begin with the following definition extending that introduced by Ben-Tal and Zowe in [3] who considered the case when $f'(x; u)$ exists.

DEFINITION 3.1. *The Ben-Tal and Zowe lower and upper generalized second-order directional derivatives of f at x in the directions u, w are defined, respectively, by*

$$D^2_- f(x; u, w) := \liminf_{t \downarrow 0} \frac{1}{t^2}\{f(x + tu + t^2 w) - f(x) - t D_+ f(x; u)\} \tag{3.1}$$

and

$$D^2_+ f(x; u, w) := \limsup_{t \downarrow 0} \frac{1}{t^2}\{f(x + tu + t^2 w) - f(x) - t D_- f(x; u)\}. \tag{3.2}$$

If the values in (3.1) *and* (3.2) *are equal, then the common value is simply denoted by $D^2 f(x; u, w)$. We note that it may be finite or infinite.*

For all $x, u \in \mathbb{R}^n$, it is easy to see that $D^2_+ f(x; u, \cdot)$ is a locally Lipschitz function for all $x, u \in \mathbb{R}^n$ (since f is locally Lipschitz), provided that this function is finite-valued. In general, the Lipschitz constant K for f satisfies

$$D^2_+ f(x; u, w_1) \le D^2_+ f(x; u, w_2) + K\|w_1 - w_1\| \quad \forall w_1, w_2 \in \mathbb{R}^n.$$

Similar remarks for $D^2_- f(x; u, \cdot)$ are of course also valid. Note also that

$$D^2_- f(x; u, w) \le D^2_+ f(x; u, w), \tag{3.3}$$

$$-D^2_- f(x; u, w) = D^2_+(-f)(x; u, w). \tag{3.4}$$

Similar but different notions have appeared in the literature, e.g., in Penot [18] and Studniarski [24]; these authors use $D_+ f$ and $D_- f$ in the above definitions to replace $D_- f$ and $D_+ f$ respectively. An advantage of our adoption over the earlier approach is evidenced by the following lemma taken from [14]. We include a proof here for the reader's convenience (for contrast to an earlier approach, see [24, Ex. 3.6]).

LEMMA 3.2. *If $D^2_- f(x; u, w)$ and $D^2_+ f(x; u, w)$ are equal and finite, then $f'(x; u)$ exists.*

Proof. Take a sequence $(t_k) \downarrow 0$ with

$$D^2_+ f(x; u, w) = \lim_{k \to \infty} \frac{1}{t_k^2}\{f(x + t_k u + t_k^2 w) - f(x) - t_k D_- f(x; u)\}.$$

By assumption,

$$\begin{aligned} 0 &= D^2_- f(x; u, w) - D^2_+ f(x; u, w) \\ &\le \liminf_{k \to \infty} \frac{1}{t_k^2}\{f(x + t_k u + t_k^2 w) - f(x) - t_k D_+ f(x; u)\} \\ &\quad - \lim_{k \to \infty} \frac{1}{t_k^2}\{f(x + t_k u + t_k^2 w) - f(x) - t_k D_- f(x; u)\} \\ &= \liminf_{k \to \infty} \frac{1}{t_k}\{D_- f(x; u) - D_+ f(x; u)\} \le 0. \end{aligned}$$

Hence equality holds throughout, and consequently one must have $D_- f(x; u) = D_+(x; u)$. □

Remark. Thus, in the situation of Lemma 3.2, one may use $f'(x; u)$ to replace $D_+ f(x; u)$ and $D_- f(x; u)$ in Definition 3.1; that is, Definition 3.1 coincides with Ben-Tal and Zowe's definition in this special situation.

The following result was proved in [3] for the special case when f is strictly differentiable.

LEMMA 3.3. *Let $x \in \mathbb{R}^n$. If $\partial_u f(x) = \{x^*\}$, then for any $w \in \mathbb{R}^n$ one has*

$$D_-^2 f(x; u, w) = x^*(w) + D_-^2 f(x; u, 0) \quad \text{and} \quad D_+^2 f(x; u, w) = x^*(w) + D_+^2 f(x; u, 0).$$

Proof. By Lebourg's mean value theorem [9, Thm. 2.3.7], for each $t > 0$, there exists $\theta_t \in (0, 1)$ and $x_t^* \in \partial f(x + tu + \theta_t t^2 w)$ such that

$$x_t^*(w) = \frac{1}{t^2}\{f(x + tu + t^2 w) - f(x + tu)\}.$$

Consider any sequence $(t_k) \downarrow 0$ and notice that $x + t_k u + \theta_{t_k} t_k^2 w \to_u x$; it follows that any cluster point of $(x_{t_k}^*)$ must be in $\partial_u f(x) = \{x^*\}$ by Definition 2.2 and the assumption. Since ∂f takes values locally in a compact set [9], we conclude that $x_t^* \to x^*$ as $t \downarrow 0$. Now the first desired equality of this lemma follows from the definition of D_-^2, that is,

$$\begin{aligned} D_-^2 f(x; u, w) &= \liminf_{t \downarrow 0} \frac{1}{t^2}\{t^2 x_t^*(w) + [f(x + tu) - f(x) - tf'(x; u)]\} \\ &= x^*(w) + D_-^2 f(x; u, 0), \end{aligned}$$

where $f'(x; u)$ exists by Lemma 2.4(iv). Similar considerations apply to D_+^2. □

Remark. From the above lemma it is clear that if f is a C^2-function, then

$$D^2 f(x; u, w) = f'(x; w) + \frac{1}{2} u \cdot \nabla^2 f(x) u. \tag{3.5}$$

4. Conjugacy of f'' to $D^2 f$. Recall from convex analysis [23] that if ϕ, ψ are real-valued functions on $\mathbb{R}^n$, then the ("lower" and "upper") conjugate functions ϕ_* and ψ^* are, respectively, defined by

$$\begin{aligned} \phi_*(x^*) &= \inf\{\phi(w) - x^*(w) : w \in \mathbb{R}^n\}, \\ \psi^*(x^*) &= \sup\{\psi(w) - x^*(w) : w \in \mathbb{R}^n\} \end{aligned}$$

for all $x^* \in \mathbb{R}^n$. In this section, we shall show, with reasonable conditions, that if $x^* \in \partial_u f(x)$, then the value of the (lower) conjugate function at x^* of the function $D_-^2 f(x; u, \cdot)$ lies between $f_-''(x; x^*, u)$, $f_+''(x; x^*, u)$ and hence equals $f''(x; x^*, u)$ when the latter exists. Two different sufficient conditions to ensure that this happens are given in Theorems 4.1 and 4.5. Similar results are also discussed for $D_+^2 f(x; u, \cdot)$. The proof for Theorem 4.5 is rather lengthy; we will construct an appropriate triple of sequences satisfying (a), (b), and (c) of Definition 2.3 for the Chaney derivative $f_-''(x; x^*, u)$ from very mild assumptions of the theorem. The proof of Theorem 4.1 is relatively easier, as an appropriate triple of sequences is at hand because of the assumption that $\partial_u f(x)$ is a singleton.

THEOREM 4.1. *Let $u, x \in \mathbb{R}^n$ with $\partial_u f(x) = \{x^*\}$. Then for any $w \in \mathbb{R}^n$, one has*

$$f_-''(x; x^*, u) \le D_-^2 f(x; u, w) - x^*(w) \le D_+^2 f(x; u, w) - x^*(w) \le f_+''(x; x^*, u). \tag{4.1}$$

Consequently,

$$\begin{aligned} f_-''(x; x^*, u) &\le \inf\{D_-^2 f(x; u, w) - x^*(w) : w \in \mathbb{R}^n\} \\ &\le \sup\{D_+^2 f(x; u, w) - x^*(w) : w \in \mathbb{R}^n\} \le f_+''(x; x^*, u). \end{aligned} \tag{4.2}$$

Remark. Both the infimum and the supremum in (4.2) may be infinite (see Examples 6.1 and 6.2).

Proof. Consider any sequence $(t_k) \downarrow 0$ and take $x_k^* \in \partial f(x + t_k u + t_k^2 w)$. Then, as in the proof of Lemma 3.3, we have $x + t_k u + t_k^2 w \to_u x$ and $x_k^* \to x^*$ thanks to the assumption $\partial_u f(x) = \{x^*\}$. Thus, the triple of sequences $(x + t_k u + t_k^2 w)$, (x_k^*), (t_k) satisfies the properties (a), (b), and (c) in Definition 2.3 for $f''_{\pm}(x; x^*, u)$. Hence,

$$\begin{aligned} f''_-(x; x^*, u) &\le \liminf_{k\to\infty} \frac{1}{t_k^2}\{f(x + t_k u + t_k^2 w) - f(x) - x^*(t_k u + t_k^2 w)\} \\ &= \liminf_{k\to\infty} \frac{1}{t_k^2}\{f(x + t_k u + t_k^2 w) - f(x) - t_k x^*(u)\} - x^*(w) \\ &\le \limsup_{k\to\infty} \frac{1}{t_k^2}\{f(x + t_k u + t_k^2 w) - f(x) - t_k x^*(u)\} - x^*(w) \\ &\le f''_+(x; x^*, u). \end{aligned}$$

Since, by Lemma 2.4(iv), $x^*(u)$ may be replaced by $f'(x; u)$, (4.1) is seen to hold. As (4.2) follows immediately from (4.1), the proof is complete. □

COROLLARY 4.2. *Let $x, u \in X$ and $\partial_u f(x) = \{x^*\}$. If $f''(x; x^*, u)$ exists, then so does $D^2 f(x; u, w)$ and $f''(x; x^*, u) = D^2 f(x; u, w) - x^*(w) = D^2 f(x; u, 0)$ for each $w \in \mathbb{R}^n$.*

To prepare for the proof of our main result (Theorem 4.5), we need the following technical proposition. Part (i) is due to Ioffe [15, Prop. 1]; Part (ii) may be regarded as a second-order version of (i). For convenience, we include both proofs here.

PROPOSITION 4.3. *Let $x, u \in \mathbb{R}^n$, and suppose that $D^2_- f(x; u, v) \ge 0$ for all v in $\mathbb{R}^n$. Then for any $\varepsilon, M > 0$, there exists $T > 0$ such that*

(i) *if the given u is zero, then*

$$f(x) \le f(x + tv) + \varepsilon t\|v\|$$

for any $t \in [0, T]$ and $v \in B[0, M]$;

(ii) *if the given u is nonzero, then*

$$f(x) \le f(x + tu + t^2 v) - tD_+ f(x; u) + \varepsilon t^2 \|u + tv\|^2 \tag{4.3}$$

for any $t \in [0, T]$ and $v \in B[0, M]$.

Proof. If the desired conclusion in (ii) is false, then there exist $\varepsilon_0, M_0 > 0$, a sequence $(t_k) \downarrow 0$, and a sequence (v_k) in $B[0, M_0]$ such that

$$f(x) > f(x + t_k u + t_k^2 v_k) - t_k D_+ f(x; u) + \varepsilon_0 t_k^2 \|u + t_k v_k\|^2.$$

By considering a subsequence if necessary, we can assume that $v_k \to v_0$. Hence, we have

$$\begin{aligned} -\varepsilon_0\|u\|^2 &\ge \liminf_{k\to\infty} \frac{1}{t_k^2}\{f(x + t_k u + t_k^2 v_k) - f(x) - t_k D_+ f(x; u)\} \\ &= \liminf_{k\to\infty} \frac{1}{t_k^2}\{f(x + t_k u + t_k^2 v_0) - f(x) - t_k D_+ f(x; u)\} \\ &\ge D^2_- f(x; u, v_0), \end{aligned}$$

where the equality holds because f is Lipschitzian near x. But this contradicts the assumption that $D^2_- f(x; u, v_0) \ge 0$.

For (i), one notes that $D_-^2 f(x; 0, v) = D_- f(x; v) \geq 0$ for all v by the definitions and the assumption. Further, if (i) is not true, then one has $\varepsilon_0 > M_0 > 0$, a sequence $(t_k) \downarrow 0$, and a sequence (v_k) in $B[0, M_0]$ such that

$$f(x) > f(x + t_k v_k) + \varepsilon_0 t_k \|v_k\|.$$

Then, $v_k \neq 0$, so without loss of generality one can suppose that $w_k := v_k/\|v_k\| \to w$. Note that $\tau_k := t_k\|v_k\| \to 0$ and

$$-\varepsilon_0 > \frac{f(x + \tau_k w_k) - f(x)}{\tau_k}.$$

Therefore, one has $-\varepsilon_0 \geq D_- f(x; w)$, contradicting the given assumption. □

PROPOSITION 4.4. *Let $F : \mathbb{R}^n \to \mathbb{R}$ be a locally Lipschitz function; and suppose $u \neq 0$, x are vectors in $\mathbb{R}^n$ such that*

(I) $D_+ F(x; u) = 0$,

(II) $\inf\{D_-^2 F(x; u, w) : w \in \mathbb{R}^n\} \geq 0$.

If $D_-^2 F(x; u, w) < \varepsilon$ for some $w \in \mathbb{R}^n$ and $0 < \varepsilon < 1/2(2 + \|u\|)^2$, then there exist sequences $(t_k) \downarrow 0$ and (ξ_k) in $\mathbb{R}^n$ with the following properties for each k:

(1) $\xi_k \in B(x + t_k u + t_k^2 w, t_k^2)$, *and so* $(\xi_k) \to x$;

(2) $\|(x + t_k u + t_k^2 w - \xi_k)/t_k^2\| \leq (2\varepsilon)^{1/2}(2 + \|u\|)$;

(3) $(x + t_k u + t_k^2 w - \xi_k)/t_k^2 \in \partial F(\xi_k)$;

(4) $(F(\xi_k) - F(x))/t_k^2 < \varepsilon$;

(5) $(F(\xi_k) - F(x))/t_k^2 \geq -\varepsilon$.

Proof. By assumptions (I), (II), applying Proposition 4.3(ii) with ε and $M := \|w\| + 1$ one can find $T > 0$ such that

$$-\varepsilon t^2 \|u + tv\|^2 \leq F(x + tu + t^2 v) - F(x) \tag{4.4}$$

for all $t \in [0, T]$ and $v \in B[0, \|w\| + 1]$. On the other hand, because of (I) and the assumption $D_-^2 F(x; u, w) < \varepsilon$ one can find a sequence $(t_k) \downarrow 0$ such that

$$\frac{1}{t_k^2}\{F(x + t_k u + t_k^2 w) - F(x)\} < \varepsilon \tag{4.5}$$

for all k. In addition, we can of course assume that

$$t_k \in [0, T]. \tag{4.6}$$

Let $B_k := B[x + t_k u + t_k^2 w, t_k^2]$. Motivated by the Moreau-Yosida approximation [1], let ξ_k be a minimum point of the function

$$y \mapsto F(y) + \frac{1}{2t_k^2}\|y - (x + t_k u + t_k^2 w)\|^2 \quad \text{on } B_k.$$

In particular,

$$F(\xi_k) + \frac{1}{2t_k^2}\|\xi_k - (x + t_k u + t_k^2 w)\|^2 \leq F(x + t_k u + t_k^2 w). \tag{4.7}$$

By definition of B_k, one can express ξ_k in the form

$$\xi_k = x + t_k u + t_k^2(w + v_k)$$

with some $v_k \in B[0, 1]$; it follows from (4.4) and (4.7) that

$$\begin{aligned} -\varepsilon t_k^2 \|u + t_k(w + v_k)\|^2 &\le F(\xi_k) - F(x) \\ &\le F(x + t_k u + t_k^2 w) - F(x) - \frac{1}{2t_k^2}\|\xi_k - (x + t_k u + t_k^2 w)\|^2. \end{aligned} \tag{4.8}$$

Dividing by t_k^2 it follows from (4.5) that

$$-\varepsilon\|u + t_k(w + v_k)\|^2 \le \varepsilon - \frac{1}{2t_k^4}\|\xi_k - (x + t_k u + t_k^2 w)\|^2$$

and so

$$\begin{aligned} \frac{1}{t_k^2}\|\xi_k - (x + t_k u + t_k^2 w)\| &\le (2\varepsilon)^{1/2}(1 + \|u + t_k(w + v_k)\|^2)^{1/2} \\ &\le (2\varepsilon)^{1/2}(2 + \|u\|) < 1 \end{aligned}$$

(provided that k is sufficiently large), because $\varepsilon < 1/2(2 + \|u\|)^2$. Thus by deleting finitely many terms if necessary, one can suppose that each ξ_k is in the interior of B_k. Therefore, (2) and (1) hold. It follows from the minimality of ξ_k and results of Clarke [9, Props. 2.3.2 and 2.3.3] that

$$0 \in \partial F(\xi_k) + \frac{\xi_k - (x + t_k u + t_k^2 w)}{t_k^2},$$

so (3) holds. Part (4) follows clearly from (4.7) and (4.5). Finally, since the sequence (v_k) is bounded, we can assume without loss of generality that it converges, say to some v_0. Then, by (I) and the Lipschitz property of F, we have

$$\begin{aligned} D_-^2 F(x; u, w + v_0) &\le \liminf_{k\to\infty} \frac{F(x + t_k u + t_k^2(w + v_0)) - F(x)}{t_k^2} \\ &= \liminf_{k\to\infty} \frac{F(x + t_k u + t_k^2(w + v_k)) - F(x)}{t_k^2} \\ &= \liminf_{k\to\infty} \frac{F(\xi_k) - F(x)}{t_k^2}. \end{aligned}$$

By (II), it follows that $-\varepsilon < D_-^2 F(x; u, w + v_0) \le \liminf_{k\to\infty}[(F(\xi_k) - F(x))/t_k^2]$; thus, by deleting finitely many terms if necessary, (5) holds. □

Remark. In view of assumption (II), w may be regarded as an "approximate minimum point" of $D_-^2 f(x; u, \cdot)$ on $\mathbb{R}^n$. If $u = 0$, then as $D_-^2 f(x; u, \cdot) = D_- f(x; \cdot)$ the true minimum point (namely, zero) always exists; in this case, the natural choice for w is zero. Explicitly we have the following counterpart of Proposition 4.4.

PROPOSITION 4.4*. *Let $F : \mathbb{R}^n \to \mathbb{R}$ be a locally Lipschitz function and x in $\mathbb{R}^n$ such that*

(II)* $D_- F(x; v) \ge 0$ *for all* $v \in \mathbb{R}^n$.

Let $0 < \varepsilon$ with $(2\varepsilon)^{1/2} < 1$. Then there exist sequences $(t_k) \downarrow 0$ and (ξ_k) in $\mathbb{R}^n$ with the following properties for each k:

(1)* $\xi_k \in B(x, t_k^2)$, so $(\xi_k) \to x$;

(2)* $\|(x - \xi_k)/t_k^2\| \le (2\varepsilon)^{1/2}$;

(3)* $(x - \xi_k)/t_k^2 \in \partial F(\xi_k)$;

(4)* $(F(\xi_k) - F(x))/t_k^2 \leq 0$;

(5)* $(F(\xi_k) - F(x))/t_k^2 \geq -\varepsilon$.

Proof. Let $M = 1$. By assumption (II)*, applying Proposition 4.3(i) one can find $T > 0$ such that

$$-\varepsilon t^2\|v\| \leq F(x + t^2 v) - F(x) \quad \forall t^2 \in [0, T],\ v \in B[0, 1]. \tag{4.4)*}$$

Take a sequence (t_k) in $[0, T^{1/2}]$ such that $(t_k) \downarrow 0$. Let $\xi_k := x + t_k^2 v_k$ be a minimum point of the function

$$y \mapsto F(y) + \|y - x\|^2/2t_k^2 \quad \text{on } B[x, t_k^2],$$

where each $v_k \in B[0, 1]$. Then

$$F(\xi_k) \leq F(\xi_k) + \|\xi_k - x\|^2/2t_k^2 \leq F(x) \leq F(\xi_k) + \varepsilon t_k^2\|v_k\| \tag{4.9}$$

and in particular $\|\xi_k - x\|/t_k^2 \leq (2\varepsilon)^{1/2}\|v_k\|^{1/2} \leq (2\varepsilon)^{1/2} < 1$, showing that ξ_k is in the interior of $B[x, t_k^2]$ so, as before, $0 \in \partial F(\xi_k) + (\xi_k - x)/t_k^2$. Thus, (1)*, (2)*, and (3)* are established. Parts (4)* and (5)* also follow immediately from (4.9). □

THEOREM 4.5. *Let $x, u, x^* \in \mathbb{R}^n$ satisfy the following properties:*

(I) $x^* \in \partial_u f(x)$ *and* $x^*(u) = D_+ f(x; u)$.

(II) $\alpha := \inf\{D_-^2 f(x; u, w) - x^*(w) : w \in \mathbb{R}^n\}$ *is a finite number.*

Then

$$f''_-(x; x^*, u) \leq \inf\{D_-^2 f(x; u, w) - x^*(w) : w \in \mathbb{R}^n\} \leq f''_+(x; x^*, u).$$

Consequently, whenever $f''(x; x^*, u)$ exists and (I), (II) *are satisfied, we have*

$$f''(x; x^*, u) = \inf\{D_-^2 f(x; u, w) - x^*(w) : w \in \mathbb{R}^n\}.$$

Remark 1. (I) is automatically satisfied by any $x^* \in \partial_u f(x)$ if either (a) $\partial_u f(x)$ is a singleton (see Lemma 2.4(iv)) or (b) f is semismooth (for definitions and basic properties see [17]).

Remark 2. In the terminology of convex analysis reviewed at the beginning of this section, the number α is the value at x^* of the conjugate function of $D_-^2 f(x; u, \cdot)$. Thus, this theorem implies that this value coincides with $f''(x; x^*, u)$ if the latter exists, and (I), (II) are satisfied.

Remark 3. Theorems 4.1 and 4.5 are independent; neither implies the other (see §6).

Proof of Theorem 4.5. We first consider the case when $u \neq 0$. Then we define

$$F := f - x^* - h, \tag{4.10}$$

where $h(\cdot) = (\alpha\|\cdot - x\|^2)/\|u\|^2$. A list of some properties of F are as follows.

(i) $D_+ F(x; u) = 0$.

(ii) $\inf\{D_-^2 F(x; u, w) : w \in \mathbb{R}^n\} = 0$.

(iii) $D_-^2 F(x; u, w) = D_-^2 f(x; u, w) - x^*(w) - \alpha$.

(iv) $0 \in \partial_u F(x)$.

(v) $F''_-(x; 0, u) = f''_-(x; x^*, u) - \alpha$ and $F''_+(x; 0, u) = f''_+(x; x^*, u) - \alpha$.

In fact, since $\partial h(x) = \{0\}$, (i) follows from (I), (iii) follows from

$$\begin{aligned} D_-^2 F(x; u, w) &= D_-^2 f(x; u, w) - D^2 x^*(x; u, w) - D^2 h(x; u, w) \\ &= D_-^2 f(x; u, w) - x^*(w) - \alpha, \end{aligned}$$

and (iv) follows from the assumption $x^* \in \partial_u f(x)$ and Lemma 2.4(ii). Clearly (ii) follows from (iii) and the definition of α. By (iv) the second-order derivatives in (v) are well defined. Moreover, the sequences (x_k), (x_k^*), (t_k) satisfy (a), (b), and (c) in Definition 2.3 for $f''_-(x; x^*, u)$ if and only if (x_k), $(x_k^* - x^*)$, (t_k) satisfy the same for $F''_-(x; 0, u)$ (note that, by Lemma 2.4 again, $x_k^* \in \partial f(x_k)$ if and only if $x_k^* - x^* \in \partial F(x_k)$). Passing to the appropriate limits in

$$\frac{1}{t_k^2}\{F(x_k) - F(x) - 0\} = \frac{1}{t_k^2}\{f(x_k) - f(x) - x^*(x_k - x) - [h(x_k) - h(x)]\},$$

(v) is seen to hold.

Take $(\varepsilon_m) \downarrow 0$ such that $\varepsilon_m < 1/2(2 + \|u\|)^2$ for all m. By (ii), there exists $w_m \in \mathbb{R}^n$ such that $D_-^2 F(x; u, w_m) < \varepsilon_m$. With any fixed m, one may apply Proposition 4.4 to the pair (ε_m, w_m) to obtain sequences $(t_{mk})_k \downarrow 0$ and $(\xi_{mk})_k$ satisfying the corresponding properties (1)–(5) of Proposition 4.4 (with ε_m, w_m in place of ε, w); for example, (1) reads

$$\|\xi_{mk} - (x + t_{mk}u + t_{mk}^2 w_m)\| < t_{mk}^2 \quad \forall k,$$

which implies that

$$\left\| \frac{\xi_{mk} - x}{t_{mk}} - u \right\| < t_{mk} + t_{mk}\|w_m\|.$$

Do this for each m and select some k_m such that $t_{mk_m}\|w_m\| < \varepsilon_m$; in general one can ensure further that $(t_{mk_m})_m \downarrow 0$. For convenience we denote the sequences $(t_{mk_m})_m$ and $(\xi_{mk_m})_m$ by (τ_m), (η_m), respectively. Then we have, for all m, that

(1) $\eta_m \in B(x + \tau_m u + \tau_m^2 w_m, \tau_m^2)$, and so $\eta_m \to x$;
(2) $\|(x + \tau_m u + \tau_m^2 w_m - \eta_m)/\tau_m^2\| \le (2\varepsilon_m)^{1/2}(2 + \|u\|)$;
(3) $(x + \tau_m u + \tau_m^2 w_m - \eta_m)/\tau_m^2 \in \partial F(\eta_m)$;
(4) $(F(\eta_m) - F(x))/\tau_m^2 < \varepsilon_m$;
(5) $(F(\eta_m) - F(x))/\tau_m^2 > -\varepsilon_m$.

Since $\tau_m w_m \to 0$, it follows from (1), (2), and (3) that the three sequences

$$(\eta_m), \left(\frac{x + \tau_m u + \tau_m^2 w_m - \eta_m}{\tau_m^2}\right), \text{ and } (\tau_m)$$

have the properties (a), (b), and (c) in Definition 2.3 for $F''_-(x; 0, u)$; hence it follows from (4) that

$$F''_-(x, 0, u) \le \liminf_{m\to\infty} \frac{F(\eta_m) - F(x)}{\tau_m^2} \le 0,$$

which implies, by (v), that $f''_-(x; x^*, u) \le \alpha$. Similarly, by (5) and (v), we have

$$0 \le \limsup_{m\to\infty} \frac{F(\eta_m) - F(x)}{\tau_m^2} \le F''_+(x; 0, u),$$

so $\alpha \le f''_+(x; x^*, u)$. This proves the theorem for the case when $u \neq 0$. Henceforth, we let $u = 0$. Then note that

$$D_- f(x; 0) = 0 \quad \text{and} \quad D_-^2 f(x; 0, w) = D_- f(x; w)$$

for any $w \in \mathbb{R}^n$. Hence, by (II), we have

$$\alpha = \inf\{D_- f(x; w) - x^*(w); w \in \mathbb{R}^n\} \le 0.$$

Since the function $w \mapsto D_-f(x; w) - x^*(w)$ is positively homogeneous, the finiteness assumption of α implies that α must be zero. Thus, in place of (4.10) if one defines $F := f - x^*$, then it still satisfies (i)–(v) listed at the beginning of our proof (with $\alpha = 0$, $u = 0$). Take $(\varepsilon_m) \downarrow 0$ such that $(2\varepsilon_m)^{1/2} < 1$ for all m. By (ii), with any fixed m, one may apply Proposition 4.4* to obtain sequences $(t_{mk})_k \downarrow 0$ and $(\xi_{mk})_k$ satisfying (1)*–(5)* (with ε_m in place of ε); then the triple of sequences (η_m), $((x - \eta_m)/\tau_m^2)$, (τ_m) (where η_m and τ_m are defined as in the first part of the proof) satisfies properties (a), (b), and (c) of Definition 2.3 for $F''_+(x; 0, 0)$. Hence, the proof is completed as above for the case when $u \neq 0$. □

Dually, we have the following result.

THEOREM 4.6. *Let $x, u, x^* \in \mathbb{R}^n$ satisfy the properties:*

(I) $x^* \in \partial_u f(x)$ *and* $x^*(u) = D_-f(x; u)$;

(II) $\gamma := \sup\{D^2_+ f(x; u, w) - x^*(w) : w \in \mathbb{R}^n\}$ *is a finite number.*

Then

$$f''_+(x; x^*, u) \geq \sup\{D^2_+ f(x; u, w) - x^*(w) : w \in \mathbb{R}^n\} \geq f''_-(x; x^*, u).$$

Consequently, whenever $f''(x; x^*, u)$ exists and (I), (II) *are satisfied, we have*

$$f''(x; x^*, u) = \sup\{D^2_+ f(x; u, w) - x^*(w) : w \in \mathbb{R}^n\}.$$

Proof. It follows from Lemma 2.4(i) that $x^* \in \partial_u f(x)$ if and only if

$$-x^* \in \partial_u(-f)(x) \quad \text{and} \quad (-f)''_-(x; -x^*, u) = -f''_+(x; x^*, u).$$

Note also that $D^2_-(-f)(x; u, w) = -D^2_+ f(x; u, w)$. Thus, replacing f and x^* in Theorem 4.5 by $-f$ and $-x^*$, respectively, we obtain the required results. □

Combining Theorem 4.5 and Theorem 4.6, we have the following result.

THEOREM 4.7. *Let $x, u, x^* \in \mathbb{R}^n$ satisfy the properties:*

(I) $x^* \in \partial_u f(x)$ *and* $x^*(u) = f'(x; u)$;

(II) *both constants α and γ appearing in Theorems* 4.5 *and* 4.6 *are finite*;

(III) $f''(x; x^*, u)$ *exists.*

Then $D^2 f(x; u, w)$ exists, and

$$f''(x; x^*, u) = D^2 f(x; u, w) - x^*(w) = D^2 f(x; u, 0)$$

for all $w \in \mathbb{R}^n$.

Proof. Combining Theorems 4.6 and 4.7 we have

$$\begin{aligned} f''(x; x^*, u) &= \inf\{D^2_- f(x; u, w) - x^*(w) : w \in \mathbb{R}^n\} \\ &= \sup\{D^2_+ f(x; u, w) - x^*(w) : w \in \mathbb{R}^n\}. \end{aligned} \tag{4.11}$$

It follows that $D^2_- f(x; u, w) \geq D^2_+ f(x; u, w)$ and consequently $D^2 f(x; u, w)$ exists. Thus, (4.11) implies that

$$f''(x; x^*, u) = D^2 f(x; u, w) - x^*(w),$$

for all $w \in \mathbb{R}^n$. □

5. On a special class of functions. In this section we apply the results in the preceding one to real-valued functions f of the form $f(x) = \sum_{i=1}^m g_i(h_i(x))$, studied in [3] and [5]. Here the real-valued functions g_i and h_i are as follows. It is assumed that

$$h_i(x) = \max\{h_{ij}(x) : j = 1, 2, \ldots, p_i\}$$

and each h_{ij} is of class C^2 on $\mathbb{R}^n$. Moreover, it is assumed that each g_i is of the class C^2 on a neighborhood of the set $h_i(\mathbb{R}^n)$. Finally, we assume that for some x_0 in $\mathbb{R}^n$, $g_i'(h_i(x_0)) \geq 0$ for each $i = 1, 2, \ldots, m$. We shall henceforth keep x_0 fixed.

In [3], Ben-Tal and Zowe showed that $D^2 f(x_0; u, w)$ exists for any $u, w \in \mathbb{R}^n$ and gave the explicit formula

(5.1)

$$D^2 f(x_0; u, v) = \frac{1}{2} \sum_{i=1}^{m} g_i''(h_i(x_0))[h_i'(x_0; u)]^2 + \sum_{i=1}^{m} g_i'(h_i(x_0)) \max\{\nabla h_{ij}(x_0) \cdot v + \frac{1}{2} u \cdot \nabla^2 h_{ij}(x_0) u : j \in I_i(x_0, u)\},$$

where for each i

$$I_i(x_0, u) = \{j \in I_i(x_0) : \nabla h_{ij}(x_0) \cdot u = \max_{j \in I_i(x_0)} \nabla h_{ij}(x_0) \cdot u\}$$

and

$$I_i(x_0) = \{j : h_{ij}(x_0) = \max_{1 \leq j \leq p_i} h_{ij}(x_0)\}$$

(we emphasize that here $D^2 f(x_0; u, v)$ is finite thanks to (5.1)). Likewise, Chaney showed in [5, Thm. 4.2] that for functions of this form, his second-order directional derivative $f''(x; x^*, u)$ exists for each $x^* \in \partial_u f(x)$.

Let $z \in \mathbb{R}^n$ and $z^* \in \partial f(z)$. We recall from [9, Props. 2.3.12 and 2.3.9] that z^* has the form

$$z^* = \sum_{i=1}^{m} g_i'(h_i(z)) \sum_{j=1}^{p_i} w_{ij} \nabla h_{ij}(z), \tag{5.2}$$

where for each i, $\sum_{j=1}^{p_i} w_{ij} = 1$, $w_{ij} \geq 0$, and $w_{ij} = 0$ if $j \notin I_i(z)$. Similarly, we have the following description for elements of $\partial_u f(x)$.

LEMMA 5.1. *Let $x_0^* \in \partial_u f(x_0)$. Then there exist $\lambda_{ij} \geq 0$, $i = 1, 2, \ldots, m$, $j = 1, 2, \ldots, p_i$, such that*

(1) *for each i, $\sum_{j=1}^{p_i} \lambda_{ij} = 1$, $\lambda_{ij} \geq 0$, and $\lambda_{ij} = 0$ if $j \notin I_i(x_0, u)$;*

(2) $x_0^* = \sum_{i=1}^{m} g_i'(h_i(x_0)) \sum_{j=1}^{p_i} \lambda_{ij} \nabla h_{ij}(x_0)$.

Consequently, we have

(3) $x_0^*(u) = f'(x_0; u)$.

Proof. By Definition 2.2 there exist sequences $(x_k) \to_u x_0$ and $x_k^* \in \partial f(x_k)$ with $(x_k^*) \to x_0^*$. By (5.2) each x_k^* has the form

$$x_k^* = \sum_{i=1}^{m} g_i'(h_i(x_k)) \sum_{j=1}^{p_i} \lambda_{ij}^{(k)} \nabla h_{ij}(x_k)$$

where for each i, $\sum_{j=1}^{p_i} \lambda_{ij}^{(k)} = 1$, $\lambda_{ij}^{(k)} \geq 0$, and $\lambda_{ij}^{(k)} = 0$ if $j \notin I_i(x_k)$. By considering a subsequence if necessary, we can assume that $(\lambda_{ij}^{(k)})_k \to \lambda_{ij}$; hence,

$$x_0^* = \sum_{i=1}^{m} g_i'(h_i(x_0)) \sum_{j=1}^{p_i} \lambda_{ij} \nabla h_{ij}(x_0),$$

verifying (2). For (1), suppose $\lambda_{ij} > 0$. Then $\lambda_{ij}^{(k)} > 0$ for large k and so $j \in I_i(x_k)$ for large k. Thus, $j \in I_i(x_0)$ since $I_i(x_k) \subseteq I_i(x_0)$ for large k. Hence

$$\begin{aligned} h_i'(x_0; u) &= \lim_{k\to\infty} \frac{\|u\|}{\|x_k - x_0\|}\{h_i(x_k) - h_i(x_0)\} \\ &= \lim_{k\to\infty} \frac{\|u\|}{\|x_k - x_0\|}\{h_{ij}(x_k) - h_{ij}(x_0)\} = \nabla h_{ij}(x_0)u, \end{aligned} \tag{5.3}$$

showing that $j \in I_i(x_0; u)$. Therefore (1) holds. Finally, (5.3) also implies that $\sum_{j=1}^{p_i} \lambda_{ij} \times \nabla h_{ij}(x_0)u = h_i'(x_0; u)$ and hence (3) follows from (2) and the chain rule [3, Lem. 3.1]. □

We are now ready to provide a short proof of the following result of Chaney [5].

THEOREM 5.2. *Let $x_0^* \in \partial_u f(x_0)$. Then*

$$f''(x_0; x_0^*, u) = \inf\{D^2 f(x_0; u, v) - x_0^*(v) : v \in \mathbb{R}^n\} \tag{5.4}$$

and the common value is finite.

Proof. By (5.1) the right-hand side is not $+\infty$. We will show it is not $-\infty$. To do this, we express x_0^* in the form stated in the preceding lemma. Since $g_i'(h_i(x_0)) \geq 0$ by assumption and since the maximum of any finite set of real numbers majorizes their convex combinations, the formula (5.1) implies that

$$D^2 f(x_0; u, v) \geq Q + \sum_{i=1}^{m} g_i'(h_i(x_0)) \sum_{j=1}^{p_i} \lambda_{ij}\{\nabla h_{ij}(x_0)v + \frac{1}{2}u \cdot \nabla^2 h_{ij}(x_0)u\}, \tag{5.5}$$

where $Q := \frac{1}{2}\sum_{i=1}^{m} g_i''(h_i(x_0))[h_i'(x_0; u)]^2$. Taking the difference of (5.5) with (2) in Lemma 5.1, we have for all $v \in \mathbb{R}^n$ that

$$D^2 f(x_0; u, v) - x_0^*(v) \geq Q + \frac{1}{2}\sum_{i=1}^{m} g_i'(h_i(x_0)) \sum_{j=1}^{p_i} \lambda_{ij} u \cdot \nabla^2 h_{ij}(x_0)u,$$

where the right-hand side is independent of v. Therefore condition (II) of Theorem 4.5 is satisfied. Since condition (I) is also satisfied by assumption and part (3) of Lemma 5.1, we see that Theorem 5.2 follows from Theorem 4.5.

6. Examples. In this section we give examples to show that Theorems 4.1 and 4.5 are independent; that is, neither implies the other. Moreover, the relations established in these theorems between Chaney's generalized second-order directional derivative and that of Ben-Tal and Zowe do not necessarily degenerate to the simpler relation (1.1), valid for C^2-functions. Even in the case when $\partial_u f(x_0)$ is a singleton, Examples 6.1 and 6.2 show that both the infimum and supremum in (4.2) may still be $+\infty$ or $-\infty$. Thus, the assumption $\partial_u f(x) = \{x^*\}$ in Theorem 4.1 does not imply the finiteness of α in Theorem 4.5, and therefore Theorem 4.1 is not a corollary of Theorem 4.5. On the other hand, it may happen that α is finite but $\partial_u f(x)$ is not a singleton, as Example 6.3 shows; therefore, Theorem 4.5 is not a corollary of Theorem 4.1.

Example 6.1. Consider the C^1-function $f(x) := x^{3/2}$ on $\mathbb{R}$. Let $x_0 = 0$, $u = 1$. Then $\partial_u f(x_0) = \{\nabla f(x_0)\} = \{0\}$. Since for any $u_t \to u$,

$$\lim_{t\downarrow 0} \frac{f(x_0 + tu_t) - f(x_0)}{t^2} = \lim_{t\downarrow 0} \frac{(tu_t)^{3/2}}{t^2} = +\infty,$$

it is seen that $f''(x_0; 0, u) = +\infty$. One can compute directly or apply (4.1) to conclude that $D^2 f(x_0; u, w) = +\infty$ for each $w \in \mathbb{R}$.

$-f$ provides an example showing that this phenomenon can also happen for $-\infty$ in place of $+\infty$.

Example 6.2. Let $f(x) = x^{3/2}\sin(x^{-1/3})$ for $x \neq 0$, and let $f(0) = 0$. Then f is a C^1-function and $\nabla f(0) = 0$. Let $x_0 = 0$, $u = 1$, $x_0^* = 0$. Then $\partial_u f(x_0) = \{x_0^*\}$. Now we take a sequence $(t_k) \downarrow 0$ with $(t_k + t_k^2)^{-1/3} = 2k\pi - \frac{\pi}{2}$. Then $\sin(t_k + t_k^2)^{-1/3} = -1$ for each k, so

$$D_-^2 f(x_0; u, u) = \liminf_{t \downarrow 0} \frac{f(t + t^2)}{t^2} \leq \liminf_{k \to \infty} \left(\frac{t_k + t_k^2}{t_k^{4/3}} \right)^{3/2} (-1) = -\infty.$$

By Theorem 4.1, it follows that $f''_-(x_0; x_0^*, u) = -\infty$. Similarly, we also have

$$D_+^2 f(x_0; u, u) \geq +\infty \quad \text{and} \quad f''_+(x_0; x_0^*, u) = +\infty.$$

Thus, the infimum appearing in (4.2) (for $x = x_0$, $u = 1$) is $-\infty$ while the supremum is $+\infty$, even though $\partial_u f(x_0)$ is a singleton.

Example 6.3. Let $h\colon \mathbb{R}^2 \to \mathbb{R}$ be defined by

$$h(x) = \max\{f_1(x), f_2(x)\} \qquad (x \in \mathbb{R}^2),$$

where $f_1(x_1, x_2) = (x_1)^2 + x_2$ and $f_2(x_1, x_2) = x_1 + (x_2)^2$ for all $x = (x_1, x_2) \in \mathbb{R}^2$. Let $x_0 = (a, a) \in \mathbb{R}^2$. By symmetry, it is clear that

$$h(\cdot) = f_1(\cdot) = f_2(\cdot) \quad \text{and} \quad \nabla f_1(x_0)(\cdot) = \nabla f_2(x_0)(\cdot) = h'(x_0; \cdot)$$

on the subset G of $\mathbb{R}^2$ consisting of vectors of the form (c, c) with $c \in \mathbb{R}$. Note also that

$$\nabla^2 f_1(x_0)(u, u) = \nabla^2 f_2(x_0)(u, u), \quad \forall u \in G.$$

Hence, by the formula of Ben-Tal and Zowe (see (5.1)), one has for each $v \in \mathbb{R}^2$, $u \in G$ that

$$\begin{aligned} D^2 h(x_0; u, v) &= \max\left\{ \nabla f_i(x_0)v + \frac{1}{2}\nabla^2 f_i(x_0)(u, u)\colon\ i = 1, 2 \right\} \\ &= \frac{1}{2}\nabla^2 f_1(x_0)(u, u) + \max\{\nabla f_i(x_0)v\colon\ i = 1, 2\}. \end{aligned}$$

Note that the right-hand side is clearly convex but not affine in v since $\nabla f_1(x_0) \neq \nabla f_2(x_0)$. Therefore, the function

$$D^2 h(x_0; u, \cdot) - x_0^*(\cdot) \tag{6.1}$$

is also convex but not affine on $\mathbb{R}^2$, where $x_0^* \in \partial_u h(x_0)$. In particular, if we denote the infimum and the supremum of the function (6.1) on $\mathbb{R}^2$ by α and γ, respectively, then α must be strictly smaller than γ. By Theorem 5.2, this α must be finite and must equal $h''(x_0; x_0^*, u)$. It follows from Theorem 4.7 that γ must be $+\infty$ (this can also be seen directly from the fact that the function is convex and nonaffine). Moreover, consider any sequence (x_k) of vectors in $\mathbb{R}^2$ convergent to x_0 in the direction u. Then, since

$$\partial h(x_k) = \operatorname{co}\{\nabla f_1(x_k), \nabla f_2(x_k)\}$$

thanks to [9, Prop. 2.3.12], it is easily seen that

$$\partial_u h(x_0) = \operatorname{co}\{\nabla f_1(x_0), \nabla f_2(x_0)\} = \operatorname{co}\{(2a, 1), (1, 2a)\},$$

which is a nondegenerate line segment. Thus, Theorems 5.2 and 4.5 are not corollaries of Theorem 4.1.

Acknowledgments. The authors would like to thank the referees and the associate editor for some valuable suggestions that, in particular, prompted the authors to produce the examples given in §6.

CONSISTENT APPROXIMATIONS FOR OPTIMAL CONTROL PROBLEMS BASED ON RUNGE–KUTTA INTEGRATION*

A. SCHWARTZ† AND E. POLAK†

Abstract. This paper explores the use of Runge–Kutta integration methods in the construction of families of finite-dimensional, consistent approximations to nonsmooth, control and state constrained optimal control problems. Consistency is defined in terms of epiconvergence of the approximating problems and hypoconvergence of their optimality functions. A significant consequence of this concept of consistency is that stationary points and global solutions of the approximating discrete-time optimal control problems can only converge to stationary points and global solutions of the original optimal control problem. The construction of consistent approximations requires the introduction of appropriate finite-dimensional subspaces of the space of controls and the extension of the standard Runge–Kutta methods to piecewise-continuous functions.

It is shown that in solving discrete-time optimal control problems that result from Runge–Kutta integration, a non-Euclidean inner product and norm must be used on the control space to avoid potentially serious ill-conditioning effects.

Key words. optimal control, discretization theory, consistent approximations, Runge–Kutta integration

1. Introduction.

We consider approximations to constrained optimal control problems resulting from the replacement of the differential equations that describe the system dynamics with difference equations that arise from Runge–Kutta integration of those differential equations. In particular, we show that there is a class of higher order, explicit *Runge–Kutta* (RK) methods that provide *consistent approximations* to the original problem, with consistency defined according to [24]. Consequently, we are assured that stationary points of the approximating problems converge to stationary points of the original problem and that global solutions (or strict local solutions with nonvanishing radii of attraction) of the approximating problems converge to global (or local) solutions of the original problem, as the step-size of the RK method is decreased.

The theory in [24] requires that the approximating problems be defined on finite-dimensional subspaces of the control space to which RK methods can be extended. The selection of the control subspaces affects both the accuracy of numerical integration and the accuracy with which solutions of the original problem are approximated. Once the approximating problems are defined, their numerical solution is carried out by means of standard mathematical programming algorithms in the space of coefficients associated with the bases that define the control subspaces. We construct two such families of control subspaces. The "natural" basis functions for one family are piecewise polynomial functions and, for the other, piecewise constant functions. Neither of these sets of basis functions is orthonormal. Hence, to preserve the L_2 inner product and norm used in the control subspace, a nonstandard inner product and norm must be used in the associated space of coefficients. Failing to do so introduces a "changed metric" effect that can adversely affect the performance of algorithms. The possible severity of this phenomenon is demonstrated by our computational results in §6. To remove the need to modify nonlinear programming software written for problems defined on a Euclidean space, we introduce coordinate transformations that change our original bases in the control space to an orthonormal set and change the associated coefficient space to a Euclidean space.

Daniel [13] presents one of the first attempts at characterizing, in a general framework, consistency of approximations to an optimization problem as well as an application of this

*Received by the editors May 9, 1994; accepted for publication (in revised form) February 25, 1995. This research was sponsored by National Science Foundation grant ECS-93-02926.

†Department of Electrical Engineering and Computer Sciences, University of California at Berkeley, Berkeley, CA 94720.

framework to approximations of optimal control problems obtained using the Euler integration formula. It can be shown that Daniel's conditions for consistency imply epiconvergence [2, 14], i.e., the convergence, in the Kuratowski sense [3], of the constrained epigraphs of the approximating problems to the constrained epigraph of the original problem. Epiconvergence ensures convergence of the global minimizers (or strict local minimizers with nonvanishing radii of attraction) of the approximating problems to global minimizers (or local minimizers) of the original problem.

Polak, in [24], characterizes first-order optimality conditions in terms of zeros of *optimality functions*. To define consistency of approximations, he augments the requirement of epiconvergence of the approximating problems with a related requirement for their optimality functions. As a result, consistency, in the Polak sense, ensures convergence of global (local) solutions, and stationary points, of the approximating problems to global (local) solutions, and stationary points, of the original problem. Furthermore, the Polak definition of consistency indirectly imposes the requirement that the mathematical characterization of the constraints of the approximating problems satisfy certain congruence conditions and that derivatives of the approximating problem functions converge to those of the original problem. In addition to a definition of consistency, we find in [24] diagonalization strategies, in the form of master algorithms, that call nonlinear programming algorithms as subroutines. These algorithms enable one to obtain efficiently an approximate, numerical "solution" to an original infinite-dimensional problem.

With the exception of [13] and [24], the analysis of the approximating properties of numerical integration techniques (see, e.g., [7, 10, 11, 19, 20, 30]) in optimal control is not carried in the framework of a general theory.[1] Convergence of global solutions, or in some cases, of stationary points, of approximating problems obtained using Euler integration to those of the original problem was established in [7, 10, 11, 13, 19, 20, 24]. Of these, perhaps the most extensive treatment can be found in [20]. The rate of convergence of stationary points of approximating problems, obtained from discretization of unconstrained optimal control problems using a class of RK methods, to those of the original problem was explored in [15].

Organization. This paper is organized as follows. Section 2 summarizes the theory of consistent approximations. Section 3 defines the optimal control problem and develops an optimality function for it. In §4 the approximating problems are constructed and epiconvergence of the approximating problems is proved. In §5 optimality functions for the approximating problems are derived and are shown to hypoconverge to the optimality function for the original problem. This completes the proof that the approximating problems are consistent approximations to the original problem. Section 6 introduces a transformation that defines orthonormal bases for the control subspaces and presents a rate of convergence result for the most commonly used RK method, that is, RK4. Some numerical results are also included.

Because of the complexity of the notation in this paper, to assist the reader, we begin with a glossary of notation.

Notation.

Spaces and elements.

$\mathbb{R}^n$	Euclidean n-space
$\underset{r}{\times} \mathbb{R}^m$	Cartesian product of r copies of $\mathbb{R}^m$
$L^m_{\infty,2}[0,1]$	$(L^m_\infty[0,1], \langle\cdot,\cdot\rangle_{L^m_2[0,1]}, \|\cdot\|_{L^m_2[0,1]})$
L^i_N	finite-dimensional subspace of $L^m_{\infty,2}[0,1]$, $i = 1, 2$

[1] This is also true for collocation and other techniques (see, e.g., [12, 21, 26, 29, 31]).

$\bar{L}_N^i$	time samples of elements in L_N^i, $i = 1, 2$
$H_{\infty,2}$	$\mathbb{R}^n \times L_{\infty,2}^M[0, 1]$
H_N	$\mathbb{R}^n \times L_N^1$ or $\mathbb{R}^n \times L_N^2$, $H_N \subset H_{\infty,2}$
$\bar{H}_N$	$\mathbb{R}^n \times \bar{L}_N^1$ or $\mathbb{R}^n \times \bar{L}_N^2$
$\bar{u}_k$	$(\bar{u}_k^1, \ldots, \bar{u}_k^r) \in \mathbb{R}^m \times \cdots \times \mathbb{R}^m$
$\bar{u}$	$(\bar{u}_0, \ldots, \bar{u}_{N-1}) \in \bar{L}_N$
η	$\eta = (\xi, u) \in H_{\infty,2}$
η_N	$\eta_N = (\xi, u_N) \in H_N$
$\bar{\eta}$	$\bar{\eta} = (\xi, \bar{u}) \in \bar{H}_N$

Functions.

$\langle \cdot, \cdot \rangle_{\mathcal{H}}$	inner product in Hilbert space $\mathcal{H}$
$\| \cdot \|_{\mathcal{H}}$	norm in Hilbert space $\mathcal{H}$
$V_{\mathbf{A},N}$	$V_{\mathbf{A},N} : L_N \to \bar{L}_N$
$W_{\mathbf{A},N}$	$W_{\mathbf{A},N} : H_N \to \bar{H}_N$, $W_{\mathbf{A},N}((\xi, u)) = (\xi, V_{\mathbf{A},N}(u))$
t_k	$k\Delta$, $\Delta = 1/N$
$\tau_{k,i}$	$t_k + c_i \Delta$
$u[\tau_{k,i}]$	control sample at time $\tau_{k,i}$
$\nabla g(\eta)$	$g_\eta(\eta)^T$
$d\psi(\eta; h)$	directional derivative
$F(x, w)$	right-hand side of difference equation produced by RK discretization

Sets.

$\mathbb{N}$	$\{0, 1, 2, \ldots\}$
$\mathbf{N}$	$\{d^n\}_{n=1}^{\infty}$, d an integer
$\mathcal{N}$	$\{0, 1, 2, \ldots, N-1\}$
$\mathbf{q}$	$\{1, \ldots, q\}$
$\mathbf{r}$	$\{1, \ldots, r\}$
$\mathbf{A}$	Runge–Kutta parameters
$B(x, \rho)$	$\{x' \in \mathcal{H} \mid \|x' - x\|_{\mathcal{H}} \le \rho\}$

Constraint sets.

$U \subset \mathbb{R}^m$	pointwise control constraint set
$\mathbf{U} \subset L_{\infty,2}$	set of feasible controls
$\bar{\mathbf{U}}_N \subset \bar{\mathbf{L}}_N$	$u \in \bar{\mathbf{U}}_N \Rightarrow \bar{u}_k^j \in U$
$\mathbf{U}_N$	$\mathbf{U}_N = V_{\mathbf{A},N}^{-1}(\bar{\mathbf{U}}_N) \subset L_{\infty,2}$
$\mathbf{H}$	$\mathbf{H} = \mathbb{R}^n \times \mathbf{U} \subset H_{\infty,2}$
$\bar{\mathbf{H}}_N$	$\bar{\mathbf{H}}_N = \mathbb{R}^n \times \bar{\mathbf{U}}_N \subset \bar{H}_N$
$\mathbf{H}_N$	$\mathbf{H}_N = \mathbb{R}^n \times V_{\mathbf{A},N}^{-1}(\bar{\mathbf{U}}_N)$

Differential and difference equations.

$x^\eta(t)$	solution at time t of differential equation given $\eta = (\xi, u)$: initial condition ξ and control input u
$\bar{x}_k^{\bar{\eta}}$	solution at time step k of difference equation, resulting from RK discretization, for $\bar{\eta} = (\xi, \bar{u})$: initial condition ξ and control samples $\bar{u}$
$\bar{x}_k^{\eta_N}$	$\bar{x}_k^{\eta_N} = \bar{x}_k^{\bar{\eta}_N}$ with $\bar{\eta} = W_{\mathbf{A},N}(\eta_N)$

Sequences.

$\underline{\lim}_{i \to \infty} x_i$	limit inferior
$\overline{\lim}_{i \to \infty} x_i$	limit superior
$x_i \to^K x$	$\{x_i\}_{i \in K}$ converges to x

2. Consistent approximations. Let $\mathcal{H}$ be a normed linear space and $\mathbf{B} \subset \mathcal{H}$ a convex set, and consider the problem

$$\text{(2.1a)}\quad \mathbf{P} \qquad \min_{\eta \in \mathbf{F}} \psi(\eta)$$

where $\psi : \mathbf{B} \to \mathbb{R}$ is (at least) lower semicontinuous and $\mathbf{F} \subset \mathbf{B}$ is the feasible set. Next, let $\mathbb{N} \triangleq \{1, 2, 3, \ldots\}$, let $\mathbf{N}$ be an infinite subset of $\mathbb{N}$, and let $\{\mathcal{H}_n\}_{N \in \mathbf{N}}$ be a family of finite-dimensional subspaces of $\mathcal{H}$ such that $\mathcal{H}_{N_1} \subset \mathcal{H}_{N_2}$ for all $N_1, N_2 \in \mathbf{N}$ such that $N_1 < N_2$. Now consider a family of approximating problems

$$\text{(2.1b)}\quad \mathbf{P}_N \qquad \min_{\eta_N \in \mathbf{F}_N} \psi_N(\eta_N), \qquad N \in \mathbf{N},$$

where $\psi_N : \mathcal{H}_N \to \mathbb{R}$ is (at least) lower semicontinuous and $\mathbf{F}_N \subset \mathcal{H}_N \cap \mathbf{B}$.

In [24] we find a characterization of the consistency of the approximating problems $\mathbf{P}_N$ in terms of two concepts. The first is epiconvergence of the $\mathbf{P}_N$ to $\mathbf{P}$ [2], which can be shown to be equivalent to Kuratowski convergence [3] of the restricted epigraphs of the cost functions of the approximating problems to the restricted epigraph of the original problem. Epiconvergence does not involve derivatives of the cost function nor the specific description of the constraint sets, hence it is a kind of "zero-order" property. The second concept consists of the characterization of stationary points as zeros of an "optimality function" and a kind of upper semicontinuity property of the optimality functions of the approximating problems. Optimality functions do depend on derivatives and the specific description of the constraint set, hence they add important first-order and structural information.

DEFINITION 2.1. *We will say that the problems in the family* $\{\mathbf{P}_N\}_{N \in \mathbf{N}}$ converge epigraphically *(or* epiconverge*) to* $\mathbf{P}$ ($\mathbf{P}_N \to^{\text{Epi}} \mathbf{P}$) *if*

(a) *for every* $\eta \in \mathbf{F}$, *there exists a sequence* $\{\eta_N\}_{N \in \mathbf{N}}$, *with* $\eta_N \in \mathbf{F}_N$, *such that* $\eta_N \to \eta$ *and* $\overline{\lim} \psi_N(\eta_N) \leq \psi(\eta)$;

(b) *for every infinite sequence* $\{\eta_N\}_{N \in K}$, $K \subset \mathbf{N}$, *satisfying* $\eta_N \in \mathbf{F}_N$ *for all* $N \in K$ *and* $\eta_N \to^K \eta$, *we have that* $\eta \in \mathbf{F}$ *and* $\underline{\lim}_{N \in K} \psi_N(\eta_N) \geq \psi(\eta)$.

There are two subsets involved in our formulation of this definition. The subset $\mathbf{N}$ is used to provide nesting of the finite-dimensional subspaces $\mathcal{H}_N$. The subset $K \subset \mathbf{N}$ is required so that Definition 2.1 is equivalent to Kuratowski convergence.

In [2, 14, 24] we find the following result.

THEOREM 2.2. *Suppose that* $\mathbf{P}_N \to^{\text{Epi}} \mathbf{P}$.

(a) *If, for* $N \in \mathbf{N}$, $\hat{\eta}_N$ *is a global minimizer of* $\mathbf{P}_N$ *and* $\hat{\eta}$ *is any accumulation point of the sequence* $\{\hat{\eta}_N\}_{N \in \mathbf{N}}$, *then* $\hat{\eta}$ *is a global minimizer of* $\mathbf{P}$.

(b) *If, for* $N \in \mathbf{N}$, $\hat{\eta}_N$ *is a strict local minimizer of* $\mathbf{P}_N$ *whose radius of attraction is bounded away from zero and* $\hat{\eta}$ *is any accumulation point of the sequence* $\{\hat{\eta}_N\}_{N \in \mathbf{N}}$, *then* $\hat{\eta}$ *is a local minimizer of* $\mathbf{P}$. □

Epigraphical convergence does not eliminate the possibility of stationary points of $\mathbf{P}_N$ converging to a nonstationary point of $\mathbf{P}$—a most inconvenient outcome from a numerical optimization point of view. For example, let $\mathcal{H} = \mathbb{R}^2$ with $\eta = (x, y)$, and let $f(\eta) = f_N(\eta) = (x-2)^2$, $N \in \mathbb{N}$. Choose

$$\text{(2.2a)}\qquad \mathbf{F} \triangleq \{(x, y) \in \mathbb{R}^2 | x^2 + y^2 - 2 \leq 0\},$$

$$\text{(2.2b)}\quad \mathbf{F}_N \triangleq \{(x, y) \in \mathbb{R}^2 | (x-y)^2(x^2+y^2-2) \leq 0,\ x^2 + y^2 \leq 2 + 1/N\}, \qquad N \in \mathbb{N}.$$

Then we see that $\mathbf{P}_N \to^{\text{Epi}} \mathbf{P}$. Nevertheless, the point (1,1) is feasible and satisfies the F. John optimality condition for all $\mathbf{P}_N$ but is not a stationary point for the problem $\mathbf{P}$. The reason for

this is an incompatibility of the constraint sets $\mathbf{F}_N$ with the constraint set $\mathbf{F}$ which shows up only at the level of optimality conditions. Hypotheses precluding this pathology, at least for first-order nonstationary points, were introduced in [24] using optimality functions as a tool for ensuring a kind of "first-order" approximation result that implicitly enforces convergence of derivatives and restricts the forms chosen for the description of the sets $\mathbf{F}$ and $\mathbf{F}_N$.

DEFINITION 2.3. *We will say that a function* $\theta : \mathbf{B} \to \mathbb{R}$ *is an* optimality function *for* $\mathbf{P}$ *if* (i) $\theta(\cdot)$ *is (at least) upper semicontinuous*; (ii) $\theta(\eta) \leq 0$ *for all* $\eta \in \mathbf{B}$; *and* (iii) *for* $\hat{\eta} = \mathbf{F}$, $\theta(\hat{\eta}) = 0$ *if* $\hat{\eta}$ *is a local minimizer for* $\mathbf{P}$. *Similarly, we will say that function* $\theta_N : H_N \to \mathbb{R}$ *is an* optimality function *for* $\mathbf{P}_N$ *if* (i) $\theta_N(\cdot)$ *is (at least) upper semicontinuous*; (ii) $\theta_N(\eta_N) \leq 0$ *for all* $\eta_N \in H_N$; *and* (iii) *if* $\hat{\eta}_N \in \mathbf{F}_N$ *is a local minimizer for* $\mathbf{P}_N$, *then* $\theta_N(\hat{\eta}_N) = 0$.

DEFINITION 2.4. *Consider the problems* $\mathbf{P}$, $\mathbf{P}_N$, *defined in* (2.1a,b). *Let* $\theta(\cdot)$, $\theta_N(\cdot)$, $N \in \mathbf{N}$, *be optimality functions for* $\mathbf{P}$, $\mathbf{P}_N$, *respectively. We will say that the pairs* $(\mathbf{P}_N, \theta_N)$ *in the sequence* $\{(\mathbf{P}_N, \theta_N)\}_{N \in \mathbf{N}}$ *are* consistent approximations *to the pair* $(\mathbf{P}, \theta)$, *if* (i) $\mathbf{P}_N \to^{\text{Epi}} \mathbf{P}$ *and* (ii) *for any sequence* $\{\eta_N\}_{N \in K}$, $K \subset \mathbf{N}$, *with* $\eta_N \in \mathbf{F}_N$ *for all* $N \in K$, *such that* $\eta_N \to^K \eta$, $\overline{\lim}\, \theta_N(\eta_N) \leq \theta(\eta)$.

Note that part (ii) of Definition 2.4 rules out the possibility of stationary points (points such that $\theta_N(\eta_N) = 0$) for the approximating problems converging to nonstationary points of the original problem. In the sequel, we will prove a stronger condition than is required by Definition 2.4, namely, Kuratowski convergence of the hypographs of $\theta_N(\cdot)$ to the hypograph of $\theta(\cdot)$ (that is, $-\theta_N \to^{\text{Epi}} -\theta$).

In addition to the characterization of consistency, the theory of consistent approximations in [24] includes various master algorithm models for efficiently solving problems such as $\mathbf{P}$. Given a level of discretization defined by N, the master algorithms construct an approximating problem $\mathbf{P}_N$, execute a nonlinear programming or discrete-time optimal control algorithm as a subroutine for a certain number of iterations on $\mathbf{P}_N$, and then increase N. Then the process is repeated. For specific examples, see [16, 25].

3. Problem definition. We will consider optimal control problems with dynamics described by ordinary differential equations of the form

$$\dot{x}(t) = h(x(t), u(t)) \quad \text{a.e. for } t \in [0, 1], \ x(0) = \xi, \tag{3.1}$$

where $x(t) \in \mathbb{R}^n$, $u(t) \in \mathbb{R}^m$, and hence $h : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$.

To establish continuity and differentiability of solutions of (3.1) with respect to controls, one must assume that the controls are bounded in $L_\infty^m[0, 1]$. However, the finite-dimensional approximating control subspaces that we will introduce must be treated as Hilbert spaces. This can cause complications in establishing the required approximation properties of the optimality functions for the approximating problems that we will construct. To circumvent this difficulty, we will, as in [24], assume that the controls are elements of the pre-Hilbert space

$$L_{\infty,2}^m[0, 1] \triangleq (L_\infty^m[0, 1], \langle \cdot, \cdot \rangle_2, \| \cdot \|_2), \tag{3.2a}$$

which consists of the elements of $L_\infty^m[0, 1]$ but is endowed with the $L_2^m[0, 1]$ inner product and norm. Note that $L_{\infty,2}^m[0, 1]$ is dense in $L_2^m[0, 1]$.

We will define our optimal control problems on the pre-Hilbert space

$$H_{\infty,2} \triangleq \mathbb{R}^n \times L_{\infty,2}^m[0, 1] \triangleq (\mathbb{R}^n \times L_\infty^m[0, 1], \langle \cdot, \cdot \rangle_H, \| \cdot \|_H), \tag{3.2b}$$

whose elements η consist of pairs of initial states and controls, i.e., $\eta = (\xi, u)$. Note that $H_{\infty,2}$ is a dense subspace of the Hilbert space

$$H_2 = \mathbb{R}^n \times L_2^m[0, 1]. \tag{3.2c}$$

The inner product $\langle \cdot, \cdot \rangle_H$ and norm $\| \cdot \|_H$ on H_2, and hence also on $H_{\infty,2}$, are defined as follows. For any $\eta = (\xi, u) \in H_2$ and $\eta' = (\xi', u') \in H_2$,

$$\langle \eta, \eta' \rangle_H \triangleq \langle \xi, \xi' \rangle + \langle u, u' \rangle_2, \tag{3.2d}$$

where $\langle \xi, \xi' \rangle$ denotes the Euclidean inner product, and the L_2 inner product $\langle u, u' \rangle_2$ is defined by $\langle u, u' \rangle_2 \triangleq \int_0^1 \langle u(t), u'(t) \rangle \, dt$. Consequently, for any $\eta = (\xi, u) \in H_2$,

$$\|\eta\|_H^2 \triangleq \langle \eta, \eta \rangle_H = \|\xi\|^2 + \|u\|_2^2. \tag{3.2e}$$

Next, we introduce a compact, convex control constraint set $U \subset B(0, \rho_{\max}) \triangleq \{u \in \mathbb{R}^m | \|u\| \leq \rho_{\max}\}$, where $\rho_{\max}$ is assumed to be sufficiently large to ensure that all the controls $u(\cdot)$ with which we expect to deal take values in the interior of $B(0, \rho_{\max})$. We then define the set of admissible controls by

$$\mathbf{U} \triangleq \{u \in L_{\infty,2}^m[0, 1] | u(t) \in U, \text{ a.e. on } [0,1]\} \tag{3.3a}$$

and the set of admissible initial state-control pairs by

$$\mathbf{H} \triangleq \mathbb{R}^n \times \mathbf{U} \subset H_{\infty,2}. \tag{3.3b}$$

The set $\mathbf{H}$ is contained in the larger set

$$\mathbf{B} \triangleq \mathbb{R}^n \times \{u \in L_{\infty,2}^m[0, 1] | u(t) \in B(0, \rho_{\max}), \text{ a.e. on } [0,1]\} \subset H_{\infty,2} \tag{3.3c}$$

inside which all of our results concerning differential equations are valid. Finally, solutions of (3.1) corresponding to a particular $\eta \in \mathbf{B}$ will be denoted by $x^\eta(\cdot)$.

We will consider the canonical constrained minimax optimal control problem

$$\mathbf{CP} \qquad \min_{\eta \in \mathbf{H}} \{\psi_o(\eta) | \psi_c(\eta) \leq 0\}, \tag{3.4a}$$

where the objective function $\psi_o : \mathbf{B} \to \mathbb{R}$ and the state endpoint constraint function $\psi_c : \mathbf{B} \to \mathbb{R}$ are defined by

$$\psi_o(\eta) \triangleq \max_{\nu \in \mathbf{q}_o} f^\nu(\eta), \qquad \psi_c(\eta) \triangleq \max_{\nu \in \mathbf{q}_c + q_o} f^\nu(\eta), \tag{3.4b}$$

where the νth function $f^\nu : \mathbf{H} \to \mathbb{R}$ is defined by

$$f^\nu(\eta) \triangleq \zeta^\nu(\xi, x^\eta(1)), \tag{3.4c}$$

with $\zeta^\nu : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$, and $\mathbf{q}_o \triangleq \{1, 2, \ldots, q_o\}$, $\mathbf{q}_c \triangleq \{1, 2, \ldots, q_c\}$ (with q_o and q_c positive integers). The set $\mathbf{q}_c + q_o \triangleq \{1 + q_o, \ldots, q_c + q_o\}$. In what follows, we will let $\mathbf{q} \triangleq \{1, 2, \ldots q\}$ with $q = q_o + q_c$. By defining the feasible set $\mathbf{F} \triangleq \{\eta \in \mathbf{H} | \psi_c(\eta) \leq 0\}$, we can write **CP** in the equivalent form of problem **P** in (2.1a).

Various optimal control problems, such as nonautonomous, integral cost, and free-time problems, can be transcribed into this canonical form. Also, the endpoint constraint in (3.4a) can be discarded by setting $\psi_c(\eta) \equiv -\infty$, and control unconstrained problems can be included by setting $U = \mathbf{B}(0, \rho_{\max})$ and choosing $\rho_{\max}$ sufficiently large to ensure that the solutions $u^*(\cdot)$ of **CP** take values in the interior of U.

Properties of the defining functions. We will require the following assumptions.

Assumption 3.1. (a) The function $h(\cdot, \cdot)$ in (3.1) is continuously differentiable, and there exists a Lipschitz constant $\kappa < \infty$ such that for all $x', x'' \in \mathbb{R}^n$ and $v', v'' \in B(0, \rho_{\max})$ the following relations hold:

$$\|h(x', v') - h(x'', v'')\| \leq \kappa[\|x' - x''\| + \|v' - v''\|], \tag{3.5a}$$

$$\|h_x(x', v') - h_x(x'', v'')\| \leq \kappa[\|x' - x''\| + \|v' - v''\|], \tag{3.5b}$$

$$\|h_u(x', v') - h_u(x'', v'')\| \leq \kappa[\|x' - x''\| + \|v' - v''\|], \tag{3.5c}$$

(b) The functions $\zeta^\nu(\cdot, \cdot)$, $\zeta^\nu_\xi(\cdot, \cdot)$, and $\zeta^\nu_x(\cdot, \cdot)$, with $\nu \in \mathbf{q}$, are Lipschitz continuous on bounded sets.

The following results can be found in [4].

THEOREM 3.2. *If Assumption* 3.1 *is satisfied, then*

(i) *there exists a* $\kappa < \infty$ *such that for all* $\eta', \eta'' \in \mathbf{B}$ *and for all* $t \in [0, 1]$

$$\|x^{\eta'}(t) - x^{\eta''}(t)\| \leq \kappa \|\eta' - \eta''\|_H;$$

(ii) *there exists an* $L < \infty$ *such that for all* $\eta \in \mathbf{B}$ *and all* $t \in [0, 1]$

$$\|x^\eta(t)\| \leq L(1 + \|\xi\|);$$

(iii) *the functions* $\psi_0 : \mathbf{B} \to \mathbb{R}$ *and* $\psi_c : \mathbf{B} \to \mathbb{R}$ *are Lipschitz continuous on bounded sets*;

(iv) *the functions* $f^\nu(\cdot)$, $\nu \in \mathbf{q}$, *have continuous Gateaux differentials* $Df^\nu : \mathbf{B} \times H_{\infty,2} \to \mathbb{R}$ *that have the form* $Df^\nu(\eta; \delta\eta) = \langle \nabla f^\nu(\eta), \delta\eta \rangle_H$;

(v) *the gradients* $\nabla f^\nu : \mathbf{B} \to H_{\infty,2}$, $\nabla f^\nu(\eta) = (\nabla_\xi f^\nu(\eta), \nabla_u f^\nu(\eta))$, $\nu \in \mathbf{q}$, *are given by*

$$\nabla_\xi f^\nu(\eta) = \nabla_\xi \zeta^\nu(\xi, x^\eta(1)) + p^{\nu,\eta}(0), \tag{3.6a}$$

$$\nabla_u f^\nu(\eta)(t) = h_u(x(t), u(t))^T p^{\nu,\eta}(t), \quad \forall t \in [0, 1], \tag{3.6b}$$

where $p^{\nu,\eta}(t) \in \mathbb{R}^n$ *is the solution to the adjoint equation*

$$\dot{p}^\nu = -h_x(x^\eta, u)^T p^\nu, \qquad p^\nu(1) = \nabla_x \zeta^\nu(\xi, x^\eta(1)), \quad t \in [0, 1], \tag{3.6c}$$

and are Lipschitz continuous on bounded sets in $\mathbf{B}$.

An optimality function. Referring to [9], the following result holds because of Theorem 3.2.

THEOREM 3.3. *For any* $\eta \in \mathbf{B}$ *let*

$$\psi_c(\eta)_+ \triangleq \max\{0, \psi_c(\eta)\}, \tag{3.7a}$$

and for any $\eta, \eta' \in \mathbf{B}$ *and* $\sigma > 0$ *let*

$$\Psi(\eta, \eta') \triangleq \max\{\psi_0(\eta) - \psi_0(\eta') - \sigma\psi_c(\eta')_+, \psi_c(\eta) - \psi_c(\eta')_+\}. \tag{3.7b}$$

If Assumption 3.1 *is satisfied and* $\hat{\eta} \in \mathbf{H}$ *is a local minimizer of the problem* **CP**, *then*

$$d_2\Psi(\hat{\eta}, \hat{\eta}; \eta - \hat{\eta}) \geq 0, \quad \forall \eta \in \mathbf{H}, \tag{3.8}$$

where $d_2\Psi$ *indicates the directional derivative of* $\Psi(\cdot, \cdot)$ *with respect to its second argument.*

Next we define an optimality function $\theta : \mathbf{B} \to \mathbb{R}$ for **CP**. For any $\eta, \eta' \in \mathbf{B}$ and $\nu \in \mathbf{q}$, we define a first-order quadratic approximation to $f^\nu(\cdot)$ at η by

$$\tilde{f}^\nu(\eta, \eta') \triangleq f^\nu(\eta) + \langle \nabla f^\nu(\eta), \eta' - \eta \rangle_H + \frac{1}{2}\|\eta' - \eta\|_H^2. \tag{3.9a}$$

We define the optimality function, with the same fixed $\sigma > 0$ used in (3.7b), by

$$\theta(\eta) \triangleq \min_{\eta' \in \mathbf{H}} \max \left\{ \max_{\nu \in \mathbf{q}_o} \tilde{f}^\nu(\eta, \eta') - \psi_o(\eta) - \sigma\psi_c(\eta)_+, \max_{\nu \in \mathbf{q}_c + q_o} \tilde{f}^\nu(\eta, \eta') - \psi_c(\eta)_+ \right\}. \tag{3.9b}$$

The existence of the minimum in (3.9b) follows from the convexity of the constraint set **H** and of the max functions in (3.9b) with respect to η' and the fact that $\tilde{f}^\nu(\eta, \eta') \to \infty$ as $\|\eta'\| \to \infty$ [6, Cor. III.20, p. 46]. Note that if $f^\nu(\eta) \equiv -\infty$ for all $\nu \in \mathbf{q}_c + q_o$, so that $\psi_c(\eta) \equiv -\infty$, then (3.9b) reduces to

$$\theta(\eta) \triangleq \min_{\eta' \in \mathbf{H}} \max_{\nu \in \mathbf{q}_o} f^\nu(\eta) + \langle \nabla f^\nu(\eta), \eta' - \eta \rangle_H + \frac{1}{2}\|\eta' - \eta\|_H^2 - \psi_o(\eta). \tag{3.9c}$$

Referring once again to [4], we find the following result.

THEOREM 3.4. *Let* $\theta : \mathbf{B} \to \mathbb{R}$ *be defined by* (3.9b). *If Assumption* 3.1 *holds, then* (i) $\theta(\cdot)$ *is negative valued and continuous and* (ii) *the relation* (3.8) *holds if and only if* $\theta(\hat{\eta}) = 0$.

4. Approximating problems. The construction of a family of approximating problems for our problem **CP**, in (3.4a), satisfying the axioms of the theory of consistent approximations, requires the construction of nested families of finite-dimensional subspaces of the initial state-control space $H_{\infty,2}$, approximating cost functions, and approximating constraint sets. Our selection of these approximations is largely determined by our intention to use explicit, fixed step-size Runge–Kutta (RK) methods [8,17] for integrating the dynamic equations (3.1).

Finite-dimensional initial-state-control subspaces. We begin by defining families of finite-dimensional subspaces H_N, with $H_N = \mathbb{R}^n \times L_N \subset H_{\infty,2}$, where the L_N are finite-dimensional subspaces of $L^m_{\infty,2}[0, 1]$, spanned by piecewise-continuous functions to which RK methods can be extended. Hence, given an explicit, fixed step-size RK integration method, using step-size $\Delta = 1/N$, we impose the following conditions on the subspaces L_N.

(i) For any bounded subset S of **B**, there exists a $\kappa < \infty$ such that for any $\eta \in S \cap H_N$ the RK method results in an integration error no greater than κ/N in solving the differential equation (3.1).

(ii) The data used by the RK integration method are an initial state and a set of control samples.[2] We will require that each set of control samples correspond to a unique element $u \in L_N$.

Condition (i) will be needed to prove that our approximating problems epiconverge to the original problem. For the subspaces L_N that we will present, we will actually be able to prove more than first-order accuracy. Condition (ii) facilitates the definition of the approximating problems and makes it possible to define gradients for the approximating cost and constraint functions.

We will now show how the choice of an RK integration method affects the selection of the subspaces L_N. The generic, explicit fixed step-size, s-stage RK method computes an approximate solution to a differential equation of the form

$$\dot{x}(t) = \tilde{h}(t, x(t)), \quad x(0) = \xi, \quad t \in [0, 1], \tag{4.1a}$$

[2]The term *control samples* will be clarified shortly.

where $\tilde{h} : \mathbb{R} \times \mathbb{R}^n \to \mathbb{R}^n$ is continuous in t and Lipschitz continuous in x. It does so by solving the difference equation

$$\bar{x}_{k+1} = \bar{x}_k + \Delta \sum_{i=1}^{s} b_i K_{k,i}, \quad \bar{x}_0 = x(0) = \xi, \quad k \in \mathcal{N} \triangleq \{0, 1, \ldots, N-1\}, \tag{4.1b}$$

with $\Delta = 1/N$, $t_k \triangleq k\Delta$, and $K_{k,i}$ defined by the recursion

$$K_{k,1} = \tilde{h}(t_k + c_1\Delta, \bar{x}_k), \quad K_{k,i} = \tilde{h}\left(t_k + c_i\Delta, \bar{x}_k + \Delta \sum_{j=1}^{i-1} a_{i,j} K_{k,j}\right), \quad i = 2, \ldots, s. \tag{4.1c}$$

The variable $\bar{x}_k$ is the computed estimate of $x(t_k)$.

The parameters $a_{i,j}$, c_i, and b_i in (4.1b) and (4.1c) determine the RK method. These parameters are collected in the Butcher array $\mathbf{A} = [c, A, b]$. The following assumption on the b parameters will hold throughout this paper (conditions on the c parameters will be added later).

Assumption 4.1. For all $i \in \mathbf{s}$, $b_i > 0$ and $\sum_{i=1}^{s} b_i = 1$.

Remark 4.2. The condition $\sum_{i=1}^{s} b_i = 1$ is satisfied by all convergent RK methods. Other conditions must be satisfied to achieve higher order convergence for multistage RK methods.

Now, in our case, $\tilde{h}(t, x) = h(x, u(t))$ and the elements $u(\cdot)$ of the subspaces L_N will be allowed to be discontinuous from the left at the points $t_k + c_i\Delta$ (i.e., $\lim_{t \uparrow \tau} u(t) \neq u(\tau)$, for $\tau = t_k + c_i\Delta$). To obtain an accurate integration method for such functions, the values $u(t_k + c_i\Delta)$ must sometimes be replaced by left limits, as appropriate for the particular choice of the subspace L_N. We will refer to these values as "control samples" and denote them by $u[\tau_{k,i}]$, where we have introduced the notation

$$\tau_{k,i} \triangleq t_k + c_i\Delta. \tag{4.2}$$

The times $\tau_{k,i}$ at which $u[\tau_{k,i}]$ is a left-limit are dictated by the definition of L_N. Clearly if $u(\cdot)$ is continuous at $t_k + c_i\Delta$, then $u[t_k + c_i\Delta] = u(t_k + c_i\Delta)$.

The recursion (4.1c) evaluates $\tilde{h}(\cdot, \cdot)$ s times for each time step $k \in \mathcal{N}$. If we collect the corresponding s control samples into a matrix $\omega_k \triangleq (u[\tau_{k,1}] \ldots u[\tau_{k,s}])$, we can replace (4.1b) and (4.1c) with

$$\bar{x}_{k+1} = \bar{x}_k + \Delta \sum_{i=1}^{s} b_i K_{k,i}, \quad \bar{x}_0 = x(0) = \xi, \quad k \in \mathcal{N}, \tag{4.3a}$$

where $K_{k,i} \triangleq K_i(\bar{x}_k, \omega_k)$, which is defined by the recursion

$$K_1(x, \omega) = h(x, \omega^1), \qquad K_i(x, \omega) = h\left(x + \Delta \sum_{j=1}^{i-1} a_{i,j} K_j(x, \omega), \omega^i\right), \quad i = 2, \ldots, s, \tag{4.3b}$$

where ω^i is the ith column of ω.

We will define the control subspace L_N in such a way that there is a one-to-one correspondence between elements $u \in L_N$ and the samples of $u[t_k + c_i\Delta]$ used by the RK method. The definition of L_N is somewhat complicated by the fact that some of the c_i elements of the Butcher array may have the same value. This causes the RK method to use samples at times $t_k + c_i\Delta$ more than once and hence leads to a reduction of the dimension in the associated subspace L_N. To keep track of the distinct values of the c_i elements of the Butcher array, we define the ordered set of indices

$$I \triangleq \{i_1, i_2, \ldots, i_r\} = \{i \in \mathbf{s} | c_j \neq c_i, \ \forall j \in \mathbf{s}, \ j < i\} \tag{4.4a}$$

and let

$$I_j \triangleq \{i \in \mathbf{s} | c_i = c_{i_j},\ i_j \in I\}, \qquad j \in \mathbf{r}. \tag{4.4b}$$

Thus, the total number of distinct values taken by the elements c_i in the Butcher array is r. For example, if $c = \{0, 1/2, 1/2, 1\}$ (as in the most commonly used fourth-order RK method), then $r = 3$, $I = \{i_1 = 1, i_2 = 2, i_3 = 4\}$, $I_1 = \{1\}$, $I_2 = \{2, 3\}$, and $I_3 = \{4\}$. If each c_i is distinct, then $r = s$, $i_j = j$, and I_j is the singleton $\{j\}$. Otherwise, $r < s$ and $i_j \geq j$.

Clearly, the r distinct sampling times in the interval $[t_k, t_{k+1}]$, $k \in \mathcal{N}$, are given by τ_{k,i_j}, $j \in \mathbf{r}$, $i_j \in I$. Corresponding to each sampling time there is a control sample $u[\tau_{k,i_j}]$. The collection of these control samples can be viewed as a vector $\bar{u} \in \times_N \times_r \mathbb{R}^m$, where the symbol $\times_N$ indicates the Cartesian product of N spaces. We will partition vectors $\bar{u} \in \times_N \times_r \mathbb{R}^m$ into N blocks as

$$\bar{u} = (\bar{u}_0, \bar{u}_1, \ldots, \bar{u}_{N-1}), \tag{4.5a}$$

where each block $\bar{u}_k \in \times_r \mathbb{R}^m$, $k \in \mathcal{N}$, is of the form

$$\bar{u}_k = (\bar{u}_k^1, \ldots, \bar{u}_k^r), \tag{4.5b}$$

and $\bar{u}_k^j \in \mathbb{R}^m$, $j \in \mathbf{r}$, corresponds to the samples $u[\tau_{k,i_j}]$, $i_j \in I$, used by the RK integration during the kth time interval. Our algebraic expressions are simplified if we treat $\bar{u}$ as the $m \times Nr$ matrix $[\bar{u}_0^1 \ldots \bar{u}_0^r \ldots \bar{u}_{N-1}^1 \ldots \bar{u}_{N-1}^r]$; i.e., we will identify $\times_N \times_r \mathbb{R}^m$ with the space $\mathbb{R}^{m \times Nr}$ of $m \times Nr$ matrices. Similarly, in algebraic expressions, we will treat $\bar{u}_k$ as the $m \times r$ matrix $[\bar{u}_k^1 \ldots \bar{u}_k^r]$. The standard inner product on $\times_N \times_r \mathbb{R}^m$ is the l_2 inner product given by

$$\langle \bar{u}, \bar{v} \rangle_{l_2} = \sum_{N=0}^{N-1} \sum_{j=1}^{r} \langle \bar{u}_k^j, \bar{v}_k^j \rangle. \tag{4.5c}$$

Let G be the $r \times s$ matrix defined by

$$G = \begin{bmatrix} \mathbf{1}_1 & & & \\ & \mathbf{1}_2 & & \\ & & \ddots & \\ & & & \mathbf{1}_r \end{bmatrix}, \tag{4.5d}$$

where, for each $j \in \mathbf{r}$, $\mathbf{1}_j = (1, 1, \ldots, 1)$ is a row vector of dimension $|I_j|$ ($|I_j|$ is the number of elements in I_j). Then we can associate the components $\bar{u}_k$, $k \in \mathcal{N}$, of a vector $\bar{u} \in \times_N \times_r \mathbb{R}^m$, with the matrices ω_k used by the RK method (4.3a,b) by setting $\omega_k = \bar{u}_k G = [\bar{u}_k^1 \ldots \bar{u}_k^r] G$, $k \in \mathcal{N}$.

We now present two control representations that define subspaces $L_N^i \subset L_{\infty,2}^m[0, 1]$, $i = 1, 2$, $N \in \mathbb{N}$, of dimension Nrm, such that $\bigcup_{N=1}^{\infty} L_N^1$ and $\bigcup_{N=1}^{\infty} L_N^2$ are dense in $L_{\infty,2}^m[0, 1]$. Both representations reduce to simple square pulses for Euler's method ($r = 1$). The basis functions $\{e_l \Phi_{N,k,j}^i\}_{j=1,k=1,l=1}^{N,r,m}$, $i = 1, 2$, with e_l the lth unit vector in $\mathbb{R}^m$ and $\Phi_{N,l,k}^i : [0, 1] \to \mathbb{R}$, that we use to construct the spaces L_N^i are not orthonormal. Hence, for numerical calculations, we associate with these spaces Nrm-dimensional spaces of real coefficients of the form

$$\bar{L}_N^i \triangleq \left(\underset{N}{\times} \underset{r}{\times} \mathbb{R}^m, \langle \cdot, \cdot \rangle_{\bar{L}_N^i}, \| \cdot \|_{\bar{L}_N^i} \right), \qquad i = 1, 2,\ N \in \mathbb{N}, \tag{4.5e}$$

where the inner products and norms are chosen so that for any $u, u' \in L_N^i$, with $u(t) = \sum_{j=1,k=1}^{N,r} \bar{u}_k^j \Phi_{N,j,k}^i(t)$ and $u'(t) = \sum_{j=1,k=1}^{N,r} \bar{u}_k'^j \Phi_{N,j,k}^i(t)$, $t \in [0, 1]$,

$$\langle u, u' \rangle_2 = \langle \bar{u}, \bar{u}' \rangle_{\bar{L}_N^i}, \qquad \|u\|_2 = \|\bar{u}\|_{\bar{L}_N^1}, \tag{4.5f}$$

where $\bar{u} \in \bar{L}_N^i$ is defined as in (4.5a, b). The spaces $\bar{L}_N^i$ will be needed in defining gradients for the cost and constraint functions of the approximating problems as well as in setting up numerical implementations of optimal control algorithms. The reason that we choose an L_2 norm preserving, nonstandard inner product on $\bar{L}_N^i$ is that if we had elected to use the standard l_2 inner product and norm on $\bar{L}_N^i$ (as is commonly done), we might have, unwittingly, caused serious deterioration in the performance of numerical algorithms that solve the approximating problems in the coefficient spaces $\bar{L}_N^i$. The extent of this ill-conditioning effect is illustrated in §6. Of course, if our basis for L_N had been orthonormal, then a standard l_2 inner product would be the appropriate choice.

Representation (R1). Piecewise rth-order polynomials.

Assumption 4.3. For all $i \in \mathbf{s}$, $c_i \in [0, 1]$.

For each $k \in \mathcal{N}$, define the sub-intervals $T_k^1 \triangleq [t_k, t_{k+1})$ and define pulse functions

$$\Pi_{N,k}^1(t) \triangleq \begin{cases} 1 & \text{if } t \in T_k^1, \\ 0 & \text{elsewhere;} \end{cases} \tag{4.6a}$$

and let

$$L_N^1 \triangleq \{u \in L_2^m[0, 1] | u(t) = \sum_{k=0}^{N-1} \sum_{j=1}^{r} \bar{u}_k^j \Phi_{N,k,j}^1(t),\ \bar{u}_{k,j} \in \mathbb{R}^m,\ \forall t \in [0, 1]\}, \tag{4.6b}$$

where

$$\Phi_{N,k,j}^1(t) \triangleq \phi_{N,k,j} \Pi_{N,k}^1(t), \qquad k \in \mathcal{N}, \tag{4.6c}$$

and $\phi_{N,k,j}(t)$ is the jth Lagrange polynomial for the points $\{\tau_{k,i_j}\}_{j=1}^r$, $i_j \in I$, defined by

$$\phi_{N,k,j}(t) \triangleq \prod_{\substack{l=1 \\ (l \neq j)}}^{r} \frac{(t - \tau_{k,i_l})}{(\tau_{k,i_j} - \tau_{k,i_l})}, \qquad k \in \mathcal{N},\ j \in \mathbf{r}, \tag{4.6d}$$

with the property that $\phi_{N,k,j}(\tau_{k,i_l}) = 1$ if $l = j$ and $\phi_{N,k,j}(\tau_{k,i_l}) = 0$ if $l \neq j$. By construction of the set I, $i_l, i_j \in I$ implies that $\tau_{k,i_j} \neq \tau_{k,i_l}$ if $l \neq j$. Hence, the functions $\phi_{N,k,j}(\cdot)$ are well defined and the functions $\Phi_{N,k,j}^1(\cdot)$ are linearly independent. For L_N^1 we define the control samples as

$$u[\tau_{k,i}] \triangleq \begin{cases} u(\tau_{k,i}) & \text{if } \tau_{k,i} \in T_k^i, \\ \lim\limits_{t \uparrow \tau_{k,i}} u(t) & \text{if } \tau_{k,i} = t_{k+1}, \end{cases} \quad k \in \mathcal{N}, i \in I. \tag{4.6e}$$

PROPOSITION 4.4. *Let L_N^1 be defined as in* (4.6b), *and let $V_{\mathbf{A},N}^1 : L_N^1 \to \times_N \times_r \mathbb{R}^m$ be defined by $V_{\mathbf{A},N}^1(u) = \bar{u}$, with $\bar{u}_k^j = u[\tau_{k,i_j}]$, $i_j \in I$, $j \in \mathbf{r}$, $k \in \mathcal{N}$. Suppose Assumption* 4.3 *holds. Then $V_{\mathbf{A},N}^1$ is invertible.*

Proof. Let $u(t) = \sum_{j=0}^{N-1} \sum_{k=1}^{r} \bar{u}_k^j \Phi_{N,k,j}^1(t)$ be an arbitrary element of L_N^1. Assumption 4.3 implies that $\tau_{k,i_j} \in [t_k, t_{k+1}]$. Next, it follows from (4.6e) that $u[\tau_{k,i_j}] = \sum_{j=1}^{r} \bar{u}_k^j \phi_{N,k,j}(\tau_{k,i_j}) = \bar{u}_k^j$ because of the interpolation property of Lagrange polynomials. Hence $V_{\mathbf{A},N}^1$ is invertible. □

The polynomial pulse functions $\{\Phi^1_{N,k,j}(t)\}_{k=0,j=0}^{N-1,r-1}$ are linearly independent but are neither orthogonal nor normal with respect to the L_2 inner product and norm. To complete the definition of the spaces $\bar{L}^1_N$ in (4.5e), we now define the required inner product, which, in turn, defines the norm. First, let $u \in L^1_N$ and note that we can write each rth-order polynomial piece $\sum_{j=1}^r \bar{u}^j_k \phi_{N,k,j}(t)$ in (4.6b) as a power series $\alpha_k P(t - t_k)$, where α_k is an $m \times r$ matrix of coefficients and the function $P : \mathbb{R} \to \mathbb{R}^r$ is defined by

$$P(t) \triangleq [1 \; t/\Delta \ldots (t/\Delta)^{r-1}]^T. \tag{4.7}$$

If $\bar{u} = V^1_{\mathbf{A},N}(u)$, then from Proposition 4.4, $\bar{u}^j_k = \alpha_k P(c_{i_j}\Delta)$, $j \in \mathbf{r}$, $i_j \in I$. Hence, $\bar{u}_k = [\bar{u}^1_k \ldots \bar{u}^r_k] = \alpha_k T^{-1}$, where

$$T^{-1} \triangleq \left[P(c_{i_1}\Delta)P(c_{i_2}\Delta)\ldots P(c_{i_r}\Delta)\right] = \begin{bmatrix} 1 & 1 & \cdots & 1 \\ c_{i_1} & c_{i_2} & & c_{i_r} \\ \vdots & & \ddots & \\ c_{i_1}^{r-1} & c_{i_2}^{r-1} & & c_{i_r}^{r-1} \end{bmatrix}_{r\times r}. \tag{4.8}$$

The matrix T^{-1} is a Vandermonde matrix and the r values c_{i_j}, $i_j \in I$, are distinct. Therefore, T^{-1} is nonsingular and $\alpha_k = \bar{u}_k T$. Hence, for each $k \in \mathcal{N}$, $u(t) = \bar{u}_k T P(t - t_k)$ for $t \in [t_k, t_{k+1})$.

We now define the inner product between two vectors $\bar{u}, \bar{v} \in \bar{L}^1_N$, with $u = (V^1_{\mathbf{A},N})^{-1}(\bar{u})$ and $v = (V^1_{\mathbf{A},N})^{-1}(\bar{v})$, by

$$\begin{aligned} \langle \bar{u}, \bar{v}\rangle_{\bar{L}^1_N} = \langle u, v\rangle_2 &= \sum_{k=0}^{N-1} \int_0^\Delta \langle u(t_k + t), v(t_k + t)\rangle \, dt \\ &= \sum_{k=0}^{N-1} \int_0^\Delta \langle \bar{u}_k T P(t), \bar{v}_k T P(t)\rangle \, dt \\ &= \Delta \sum_{k=0}^{N-1} \operatorname{trace}\left(\bar{u}_k T \frac{1}{\Delta}\int_0^\Delta P(t)P(t)^T \, dt T^T \bar{v}_k^T\right) \\ &= \Delta \sum_{k=0}^{N-1} \operatorname{trace}(\bar{u}_k M_1 \bar{v}_k^T), \end{aligned} \tag{4.9a}$$

where T was defined by (4.8), $P(\cdot)$ was defined in (4.6d), and

$$M_1 \triangleq T\left[\frac{1}{\Delta}\int_0^\Delta P(t)P(t)^T \, dt\right]T^T = T \operatorname{Hilb}(r) T^T \tag{4.9b}$$

is an $r \times r$ symmetric, positive definite matrix with

$$\operatorname{Hilb}(r) = \begin{bmatrix} 1 & 1/2 & 1/3 & & 1/r \\ 1/2 & 1/3 & 1/4 & \cdots & 1/(r+1) \\ 1/3 & 1/4 & 1/5 & & \\ & \vdots & & \ddots & \\ 1/r & 1/(r+1) & & & 1/(2r-1) \end{bmatrix}_{r\times r} \tag{4.9c}$$

the Hilbert matrix whose i, jth entry is $1/(i + j - 1)$. Note that both $\operatorname{Hilb}(r)$ and T are ill-conditioned matrices. However, the product in (4.9b) is well-conditioned (the product corresponds to switching from the power-series polynomial representation back to the Lagrange

expansion). The matrix M_1 is positive definite because Hilb(r) is positive definite and T is nonsingular. Given $\bar{u} \in \bar{L}_N^1$, its norm is $\|\bar{u}\|_{\bar{L}_N^1}^2 = \langle \bar{u}, \bar{u} \rangle_{\bar{L}_N^1}$.

Remark 4.5. A special class of functions with representation R1 is the subspace of rth-order, m-dimensional splines [5]. The dimension of the spline subspace is only a fraction of the dimension of L_N^1. Our results for R1 can be extended to splines; this extension is presented in [28].

Representation (R2). Piecewise constant functions.

For $j \in \mathbf{r}$, I_j defined in (4.4b), let

$$\tilde{b}_j \triangleq \sum_{i \in I_j} b_i, \tag{4.10a}$$

$$d_j \triangleq \Delta \sum_{i=1}^{j} \tilde{b}_i, \qquad d_0 \triangleq 0. \tag{4.10b}$$

If all the c_i elements of the Butcher array have distinct values, then $d_j = \Delta \sum_{i=1}^{j} b_i$. At this point, we can replace Assumption 4.1 with the following weaker assumption.

Assumption 4.1′. For all $j \in \mathbf{r}$, $\tilde{b}_j > 0$ and $d_r = \Delta$.

Note that Assumption 4.1′ implies that for all $j \in \mathbf{r}$, $d_j > d_{j-1}$ and that $t_k + d_j \in [t_k, t_{k+1}]$, $k \in \mathcal{N}$.

Next, we introduce an additional assumption which is stronger than Assumption 4.3.

Assumption 4.6. For $j \in \mathbf{r}$ and $i_j \in I$, $d_{j-1} \le c_{i_j} \Delta \le d_j$, so that $\tau_{k,i_j} \in [t_k + d_{j-1}, t_k + d_j]$.

With $T_{k,j}^2 \triangleq [t_k + d_{j-1}, t_k + d_j)$ define the basis functions $\Phi_{N,k,j}^2 : \mathbb{R} \to \mathbb{R}$, $k \in \mathcal{N}$, $j \in \mathbf{r}$, by

$$\Phi_{N,k,j}^2(t) \triangleq \begin{cases} 1 & \text{if } t \in T_{k,j}^2, \\ 0 & \text{elsewhere} \end{cases} \tag{4.11a}$$

and let

$$L_N^2 \triangleq \{u \in L_2^m[0,1] | u(t) = \sum_{k=0}^{N-1} \sum_{j=1}^{r} \bar{u}_k^j \Phi_{N,k,j}^2(t),\ \bar{u}_k^j \in \mathbb{R}^m,\ \forall t \in [0,1]\}. \tag{4.11b}$$

For L_N^2, we define the control samples as

$$u[\tau_{k,i_j}] \triangleq \begin{cases} u(\tau_{k,i_j}) & \text{if } \tau_{k,i_j} \in T_{k,j}^2, \\ \lim\limits_{t \uparrow \tau_{k,i_j}} u(t) & \text{if } \tau_{k,i_j} = t_k + d_j, \end{cases} \qquad k \in \mathcal{N},\ i_j \in I,\ j \in \mathbf{r}. \tag{4.11c}$$

PROPOSITION 4.7. *Let L_N^2 be defined as in* (4.11b); *and let $V_{\mathbf{A},N}^2 : L_N^2 \to \times_N \times_r \mathbb{R}^m$ be defined by $V_{\mathbf{A},N}^2(u) = \bar{u}$, with $\bar{u}_k^j = u[\tau_{k,i_j}]$, $j \in \mathbf{r}$, $i_j \in I$, $k \in \mathcal{N}$. Suppose Assumptions* 4.1′ *and* 4.6 *hold. Then $V_{\mathbf{A},N}^2$ is invertible.*

Proof. Assumption 4.1′ ensures that the support for each $\Phi_{N,k,j}^2(\cdot)$ is of nonzero length. This ensures a one-to-one correspondence between the elements of L_N^2 and the vector coefficients $\bar{u}_k^j$ in (4.11b). Next, Assumption 4.6 together with the definition (4.11c) of $u[\cdot]$ implies that for any $u \in L_N^2$, with $u(t) = \sum_{k=0}^{N-1} \sum_{j=1}^{r} \bar{u}_k^j \Phi_{N,k,j}^2(t)$, $u[\tau_{k,j}] = \bar{u}_k^j$ for all $k \in \mathcal{N}$ and $j \in \mathbf{r}$. Hence, $V_{\mathbf{A},N}^2$ is invertible. □

To complete the definition, in (4.5e), of the spaces $\bar{L}_N^2$ we will now define the required inner product and norm. We define the inner product between two vectors $\bar{u}, \bar{v} \in \bar{L}_N^2$, with

$u = (V^2_{\mathbf{A},N})^{-1}(\bar{u})$ and $v = (V^2_{\mathbf{A},N})^{-1}(\bar{v})$, by

$$\begin{aligned}\langle \bar{u}, \bar{v}\rangle_{\bar{L}^2_N} = \langle u, v\rangle_2 &= \sum_{k=0}^{N-1}\sum_{j=1}^{r}\int_{d_{j-1}}^{d_j}\langle u(t_k+t), v(t_k+t)\rangle\, dt \\ &= \Delta\sum_{k=0}^{N-1}\sum_{j=1}^{r}\tilde{b}_j\langle \bar{u}_k^j, \bar{v}_k^j\rangle\, dt \\ &= \Delta\sum_{k=0}^{N-1}\operatorname{trace}(\bar{u}_k M_2 \bar{v}_k), \qquad (4.12a)\end{aligned}$$

where

$$M_2 = \begin{bmatrix} \tilde{b}_1 & & 0 \\ & \ddots & \\ 0 & & \tilde{b}_r \end{bmatrix}. \qquad (4.12b)$$

Since all $\tilde{b}_j > 0$, M_2 is diagonal, positive definite. Given $\bar{u} \in \bar{L}^2_N$, its norm is $\|\bar{u}\|^2_{\bar{L}^2_N} = \langle \bar{u}, \bar{u}\rangle_{\bar{L}^2_N}$.

Remark 4.8. In place of (4.10b), we could have used the alternate definition $d_j \triangleq \Delta\sum_{i=1}^{j} b_i$ and set $\bar{u}_k^j = u[\tau_{k,j}]$ for all $j \in \mathbf{s}$, $k \in \mathcal{N}$. In this way, samples corresponding to repeated values of c_j in the Butcher array would be treated as independent values and the space L_N would have to be correspondingly enlarged. However, Proposition 6.1 in §6 indicates that (4.10b) is the preferable definition.

Definition of approximating problems. For $N \in \mathbb{N}$ let

$$H_N \triangleq \mathbb{R}^n \times L_N, \qquad (4.13a)$$

where $L_N = L^1_N$ for representation R1 or $L_N = L^2_N$ for representation R2. Since $H_N \subset H_{\infty,2}$, it inherits the inner product from $H_{\infty,2}$ which, for $\eta', \eta'' \in H_N$, with $\eta' = (\xi', u')$ and $\eta = (\xi'', u'')$, is given by

$$\langle \eta', \eta''\rangle_H \triangleq \langle \xi', \xi''\rangle + \langle u', u''\rangle_2. \qquad (4.13b)$$

Also, for any $\eta \in H_N$, $\|\eta\|^2_H = \langle \eta, \eta\rangle_H$. Similarly, for $N \in \mathbb{N}$, we define the coefficient spaces $\overline{H}_N$ by

$$\overline{H}_N \triangleq \mathbb{R}^n \times \bar{L}_N, \qquad (4.14a)$$

where $\bar{L}_N = \bar{L}^1_N$ or $\bar{L}_N = \bar{L}^2_N$. The inner product on $\overline{H}_N$ is defined by

$$\langle \bar{\eta}', \bar{\eta}''\rangle_{\bar{H}_N} \triangleq \langle \xi', \xi''\rangle + \langle \bar{u}', \bar{u}''\rangle_{\bar{L}_N}, \qquad (4.14b)$$

and the norm correspondingly. Let $W_{\mathbf{A},N} : H_N \to \overline{H}_N$ be defined by $W_{\mathbf{A},N}(\eta) = (\xi, V^1_{\mathbf{A},N}(u))$ for representation R1 and $W_{\mathbf{A},N}(\eta) = (\xi, V^2_{\mathbf{A},N}(u))$ for representation R2, where $\eta = (\xi, u)$. Then we see that $W_{\mathbf{A},N}$ is a nonsingular map and, with our definition of the norms on $\overline{H}_N$, provides an isometric isomorphism between H_N and $\overline{H}_N$. Thus, we can use the spaces H_N and $\overline{H}_N$ interchangeably.

Next, we define control constraint sets for the approximating problems as follows. Let U be the convex, compact set used to define $\mathbf{U}$ in (3.3a). Then, with $\kappa_U < \infty$, we define

$$\overline{\mathbf{U}}^1_N \triangleq \left\{\bar{u} \in \bar{L}^1_N \,|\, \bar{u}^j_k \in U,\ j \in \mathbf{r},\ \|\bar{u}_k T_j\|_\infty \le \frac{\Delta}{(j-1)(r-1)}\kappa_U,\ j = 2, \ldots, r,\ \forall k \in \mathcal{N}\right\}, \qquad (4.15a)$$

$$\overline{\mathbf{U}}^2_N \triangleq \left\{\bar{u} \in \bar{L}^2_N \,|\, \bar{u}^j_k \in U,\ \forall j \in \mathbf{r},\ k \in \mathcal{N}\right\}, \qquad (4.15b)$$

where T_j is the jth column of the matrix T, defined by its inverse in (4.8), and $\Delta = 1/N$, as before. Finally, we define the constraint sets for the approximating problems by

$$\mathbf{H}_N \triangleq \mathbb{R}^n \times V_{\mathbf{A},N}^{-1}(\overline{U}_N) \subset H_N, \tag{4.15c}$$

and their reflections in coefficient space by

$$\overline{H}_N \triangleq \mathbb{R}^n \times \overline{\mathbf{U}}_N \subset \overline{H}_N, \tag{4.15d}$$

with $\overline{\mathbf{U}}_N = \overline{\mathbf{U}}_N^1$ and $V_{\mathbf{A},N} = V_{\mathbf{A},N}^1$ for representation R1 and $\overline{\mathbf{U}}_N = \overline{\mathbf{U}}_N^2$ and $V_{\mathbf{A},N} = V_{\mathbf{A},N}^2$ for representation R2. We assume that $\rho_{\max}$ was chosen large enough in (3.3c) to ensure that $\mathbf{H}_N \subset \mathbf{B}$.

Remark 4.9. The constraints on $\|\bar{u}_k T_j\|_\infty$ appearing in the definition of $\mathbf{U}_N^1$ were introduced to ensure that each polynomial piece, $\sum_{j=1}^r \bar{u}_k^j \Phi_{N,k,j}^1(\cdot)$, of $u = V_{\mathbf{A},N}^{-1}(\bar{u})$ is Lipschitz continuous on $[t_k, t_{k+1}]$ with Lipschitz constant κ_U, independent of N. This is needed to establish that the accuracy of the RK integration increases at least linearly with decreasing step-size (Lemmas A.1 and 4.10(i), but see Remark A.2) and for the proofs of Theorems 4.2 and 5.6. When the system dynamics are linear and time-invariant with respect to u and the RK method is of order r, Lemma 4.10(i) is valid without this Lipschitz constant, and hence, the constraints in the definition of $\mathbf{U}_N^1$ are not needed. It is not clear if the constraints on $\|\bar{u}_k T_j\|_\infty$ are needed in practice because if a sequence of controls converges to a piecewise Lipschitz continuous function, then the members of that sequence will all be piecewise Lipschitz continuous (see Remark 4.13 and Conjecture 5.11 added to the end of this paper).

Next, with $\eta = (\xi, u) \in H_N$ and $\bar{\eta} = (\xi, \bar{u}) = W_{\mathbf{A},N}(\eta)$, we will denote the solutions of (4.3a,b), with $\omega_k = \bar{u}_k G$, $k \in \mathcal{N}$, by $\{\bar{x}_k^\eta\}_{k=0}^N$ or, equivalently, $\{\bar{x}_k^{\bar{\eta}}\}_{k=0}^N$. The variable $\bar{x}_k^{\bar{\eta}}$ is thus the computed estimate of $x^\eta(t_k)$. Finally, for $\nu \in \mathbf{q}$, let $f_N^\nu : H_N \to \mathbb{R}$ and $\bar{f}_N^\nu : \overline{H}_N \to \mathbb{R}$ be defined by

$$f_N^\nu(\eta) \triangleq \zeta^\nu(\xi, \bar{x}_N^\eta) \equiv \bar{f}_N^\nu(\bar{\eta}) \triangleq \zeta^\nu(\xi, \bar{x}_N^{\bar{\eta}}), \qquad \nu \in \mathbf{q}, \tag{4.16}$$

where $\zeta^\nu(\cdot,\cdot)$ was used to define $f^\nu(\cdot)$ in (3.4c). We can now state the approximating problems as

$$\mathbf{CP}_N \qquad \min_{\eta \in \mathbf{H}_N} \{\psi_{o,N}(\eta) | \psi_{c,N}(\eta) \le 0\}, \tag{4.17a}$$

where $\psi_{o,N}(\eta) \triangleq \max_{\nu \in \mathbf{q}_o} f_N^\nu(\eta)$ and $\psi_{c,N}(\eta) \triangleq \max_{\nu \in \mathbf{q}_c + q_o} f_N^\nu(\eta)$, or equivalently, in the form in which they must be solved numerically as

$$\overline{\mathbf{CP}}_N \qquad \min_{\bar{\eta} \in \overline{\mathbf{H}}_N} \{\bar{\psi}_{o,N}(\bar{\eta}) | \bar{\psi}_{c,N}(\bar{\eta}) \le 0\}, \tag{4.17b}$$

where $\bar{\psi}_{o,N}(\bar{\eta}) \triangleq \max_{\nu \in \mathbf{q}_o} \bar{f}_N^\nu(\bar{\eta})$ and $\bar{\psi}_{c,N}(\bar{\eta}) \triangleq \max_{\nu \in \mathbf{q}_c + q_o} \bar{f}_N^\nu(\bar{\eta})$. By defining the feasible set as $\mathbf{F}_N \triangleq \{\eta \in \mathbf{H}_N | \psi_{c,N}(\eta) \le 0\}$, we can write $\mathbf{CP}_N$ in the equivalent form of problem $\mathbf{P}_N$ in (2.1b).

Note that for any $u \in \mathbf{U} \cap L_N^i$, $i = 1, 2$, where $\mathbf{U}$ was defined in (3.3a), $\bar{u} = V_{\mathbf{A},N}^1(u)$ satisfies $\bar{u}_k^j \in U$, for $k \in \mathcal{N}$, $j \in \mathbf{r}$, because $u(t) \in U$ for all $t \in [0, 1]$. Hence, for representation R2, (4.15b,c) imply that $\mathbf{H} \cap H_N \subset \mathbf{H}_N$. Conversely, $\bar{u} \in \overline{\mathbf{U}}_N^2 \Leftrightarrow (V_{\mathbf{A},N}^2)^{-1}(\bar{u}) \in \mathbf{U}$, and therefore $\mathbf{H}_N \subset \mathbf{H} \cap H_N$. Consequently, for representation R2, $\mathbf{H}_N = \mathbf{H} \cap H_N$. Unfortunately, for representation R1 $\mathbf{H}_N \ne \mathbf{H} \cap H_N$. First, $\mathbf{H} \cap H_N \not\subset \mathbf{H}_N$ because elements $u \in \mathbf{U} \cap L_N^1$ do not necessarily satisfy the Lipschitz continuity constraint imposed by (4.15a). Second, if $r \ge 2$ (except for the case $r = 2$ and the Butcher array elements $c = (0, 1)$), $\mathbf{H}_N \not\subset \mathbf{H} \cap H_N$ because, given $\bar{u} \in \bar{L}_N^1$, generally $\|V_{\mathbf{A},N}^1(\bar{u})\|_\infty > \|\bar{u}\|_\infty$, [5, p. 24]. Hence, if $\{\eta_N = (\xi, u_N)\}_{N \in \mathbf{N}}$, $\mathbf{N} \subset \mathbb{N}$, is a sequence of approximate solutions to the problems $\mathbf{CP}_N$ using representation R1,

it is possible for η_N to violate the control constraints in **CP**. However, as we will see, the limit points of such a sequence do satisfy the control constraints in **CP**. This problem of constraint violations for representation R1 could have been avoided by choosing $\mathbf{H}_N \triangleq \mathbf{H} \cap H_N$ (as in [24]) and letting $\overline{\mathbf{H}}_N \triangleq W_{A,N}(\mathbf{H}_N)$. But the set $\overline{\mathbf{H}}_N$ would then be difficult to characterize and we would have to impose a Lipschitz continuity constraint directly on the set **H** which would be unacceptable.

Nesting. The theory of consistent approximations is stated in terms of nested subspaces H_N. This allows the approximate solution of an approximating problem $\mathbf{CP}_{N_1}$ to be used as a "warm-start" for an algorithm solving an approximating problem $\mathbf{CP}_{N_2}$ with a higher discretization level ($N_2 > N_1$) (see [16, 25]).

For representation R1, for any $N \in \mathbb{N}$, $N \geq 1$, $L^1_N \subset L^1_{2N}$, and therefore doubling the discretization level nests the subspaces. If $u \in L^1_N$, then $\bar{v} = V^1_{\mathbf{A},2N}(u)$ can be determined from $\bar{u} = V^1_{\mathbf{A},N}(u)$ using (4.7) and (4.8), as follows. For $k \in \mathcal{N}$ and $j \in \mathbf{r}$, $\bar{v}^j_{2k} = \bar{u}_k T P(c_j/2N)$ and $\bar{v}^j_{2k+1} = \bar{u}_k T P((c_j + 1)/2N)$. For representation R2, $L^2_N \subset L^2_{dN}$, where d is the smallest common denominator of the parameters b_j, $j \in \mathbf{s}$, in the Butcher array, which is finite assuming, as is typically the case, that the b_j are rational. Thus, the discretization level must be increased by factors of d to achieve nesting. If $u \in L^2_N$ and $\bar{u} = V^2_{\mathbf{A},N}(u)$, then $\bar{v} = V^2_{\mathbf{A},dN}(u)$ is given, for $k \in \mathcal{N}$, $i, j \in \mathbf{r}$, and $l = 1, \ldots, d$, by $\bar{v}^i_{dk+l} = \bar{u}^j_k$ for $d_{j-1} \leq l/d < d_j$, where d_j is defined in (4.10b).

Epiconvergence. We are now ready to establish the epiconvergence of the approximating problems. First we present convergence properties for the solutions computed by Runge–Kutta integration on H_N. The proof of the following lemma, given in the appendix, differs from standard Runge–Kutta results because of the presence of (possibly discontinuous) controls in the differential equations.

LEMMA 4.10. *For representation* R1, *suppose that Assumptions* 3.1(a), 4.1′, *and* 4.3 *hold. For representation* R2, *suppose that Assumptions* 3.1(a), 4.1′, *and* 4.6 *hold.*

(i) *Convergence. For any bounded subset $S \subset \mathbf{B}$, there exist $\kappa < \infty$ and $N^* < \infty$, such that for any $\eta \in S \cap \mathbf{H}_N$ and $N \geq N^*$,*

$$\|x^\eta(t_k) - \bar{x}^\eta_k\| \leq \frac{\kappa}{N}, \qquad k \in \{0, 1, \ldots, N\}. \tag{4.18a}$$

(ii) *Order of Convergence. Additionally, suppose the Runge–Kutta method is order ρ (see* [8, 17]*), and $h(\cdot, \cdot)$ is $\rho - 1$ times Lipschitz continuously differentiable. Let*

$$\mathbf{H}^{(\rho)}_N \triangleq \left\{ \eta = (\xi, u) \in \mathbf{H}_N \,\middle|\, \left\| \frac{d^{\rho-1}}{dt^{\rho-1}}(u(t_1) - u(t_2)) \right\| \leq \kappa', \ \forall t_1, t_2 \in [t_k, t_{k+1}), \ k \in \mathcal{N} \right\}, \tag{4.18b}$$

where $\kappa' < \infty$ is independent of N. Then for representation R1, *there exist $\kappa < \infty$ and $N^* < \infty$ such that, if $\eta \in S \cap \mathbf{H}^{(\rho)}_N$, or if $\eta \in S \cap \mathbf{H}_N$ and $h(x, u) = \tilde{h}(x) + Bu$, where B is an $n \times m$ constant matrix, then for any $N \geq N^*$*

$$\|x^\eta(t_k) - \bar{x}^\eta_k\| \leq \frac{\kappa}{N^\rho}, \qquad k \in \{0, 1, \ldots, N\}. \tag{4.18c}$$

The same result holds for representation R2 *for any $\eta \in S \cap \mathbf{H}_N$ if $h(x, u) = \tilde{h}(x) + Bu$.*

In proving consistency, we will need to add a version of Slater's constraint qualification on the problem **CP**.

Assumption 4.11. For every $\eta \in \mathbf{H}$ such that $\Psi_c(\eta) \leq 0$, there exists a sequence $\{\eta_i\}_{i=1}^\infty$ such that $\eta_i \in \mathbf{H}$, $\Psi_c(\eta_i) < 0$, and $\eta_i \to \eta$ as $i \to \infty$.

THEOREM 4.12 (Epiconvergence). *For representation* R1, *suppose that Assumptions* 3.1, 4.1′, 4.3, *and* 4.11 *hold and let $d = 2$. For representation* R2, *suppose that Assumptions*

3.1, 4.1′, 4.6, *and* 4.11 *hold and let* d *be the least common denominator for the elements* b_j, $j \in \mathbf{s}$, *of the Butcher array. Let* $\mathbf{N} = \{d^l\}_{l=1}^{\infty}$. *Then the problems* $\{\mathbf{CP}_N\}_{N\in\mathbf{N}}$ *converge epigraphically to the problem* $\mathbf{CP}$ *as* $N \to \infty$.

Proof. Let $S \subset \mathbf{B}$ be bounded. Then, by Assumption 3.1(b) and Lemma 4.10(i), there exist $\kappa', \kappa < \infty$ such that for any $v \in \mathbf{q}$ and for any $\eta_N \in S \cap \mathbf{H}_N$

$$|f^v(\eta_N) - f_N^v(\eta_N)| = |\zeta^v(\xi_N, x^{\eta_N}(1)) - \zeta^v(\xi_N, \bar{x}_N^{\eta_N})| \le \kappa' \|x^{\eta_N}(1) - \bar{x}_N^{\eta_N}\| \le \frac{\kappa}{N}. \tag{4.19a}$$

Now, let $v' \in \mathbf{q}_o$ be such that $\Psi_o(\eta_N) = f^{v'}(\eta_N)$. Then,

$$\Psi_o(\eta_N) - \Psi_{o,N}(\eta_N) = f^{v'}(\eta_N) - \Psi_{o,N}(\eta_N) \le f^{v'}(\eta_N) - f_N^{v'}(\eta_N) \le \frac{\kappa}{N}. \tag{4.19b}$$

By reversing the roles of $\Psi_o(\eta_N)$ and $\Psi_{o,N}(\eta_N)$ we can conclude that

$$|\Psi_o(\eta_N) - \Psi_{o,N}(\eta_N)| \le \frac{\kappa}{N}. \tag{4.20a}$$

Similarly,

$$|\Psi_c(\eta_N) - \Psi_{c,N}(\eta_N)| \le \frac{\kappa}{N}. \tag{4.20b}$$

Now, given $\eta \in \mathbf{H}$ such that $\Psi_c(\eta) \le 0$, there exists, by Assumption 4.11, a sequence $S = \{\eta_i\}_{i\in\mathbf{N}}$, with $\eta_i \in \mathbf{H}$, such that $\eta_i \to \eta$ as $i \to \infty$ (hence S is a bounded set) and $\Psi_c(\eta_i) < 0$ for all i. Now, clearly for each i, there exist $N_i \in \mathbf{N}$ and $\eta'_{N_i} \in \mathbf{H}_{N_i}$ such that (a) $\kappa/N_i \le -1/2\Psi_c(\eta_i)$; (b) $\|\eta'_{N_i} - \eta_i\| \le 1/N_i$, since, for both control representations the union of the subspaces H_N is dense in H_2, which contains $H_{\infty,2}$ and $\mathbf{H} \cap H_N \subset \mathbf{H}_N$; (c) $\Psi_c(\eta'_{N_i}) \le 1/2\Psi_c(\eta_i)$ due to Theorem 3.2(iii); and (d) $N_i < N_{i+1}$. It follows from (4.20b) that $\Psi_{c,N_{i+k}}(\eta'_{N_i}) \le \Psi_c(\eta'_{N_i}) + \kappa/N_i \le 1/2\Psi_c(\eta_i) + \kappa/N_i \le 0$ for any $i, k \in \mathbb{N}$. Now consider the sequence $S'' = \{\eta''_M\}_{M\in\mathbf{N}}$ defined as follows. If $M = N_i$ for some $i \in \mathbf{N}$, then $\eta''_M = \eta'_{N_i}$ for $M = N_i, N_i + d, N_i + 2d, \ldots, N_{i+1} - d$. Then we see that $\Psi_{c,M}(\eta''_M) \le 0$ for all $M \in \mathbf{N}$, $\eta''_M \to \eta$ as $M \to \infty$ (hence S'' is bounded), and by (4.20a) and Theorem 3.2(iii) that $\lim_{M\in\mathbf{N}} \Psi_{o,M}(\eta''_M) = \Psi_o(\eta)$. Thus, part (a) of Definition 2.1 is satisfied.

Now let $S = \{\eta_N\}_{N\in K}$, $K \subset \mathbf{N}$, be a sequence with $\eta_N = (\xi_N, u_N) \in \mathbf{H}_N$ and $\Psi_{c,N}(\eta_N) \le 0$ for all $N \in K$, and suppose that $\eta_N \to^K \eta = (\xi, u)$. First, we want to show that $\eta \in \mathbf{H}$. For any $v \in \mathbb{R}^m$, let $d(v, U) \triangleq \min_{v'\in U} \|v - v'\|$. Since $\bar{u} = V^i_{\mathbf{A},N}(u_N) \in \overline{\mathbf{U}}^i_N$, $i = 1, 2$, for each N, $\bar{u}^j_k \in U$ for all $k \in \mathcal{N}$, $j \in \mathbf{r}$. For representation R1, $\overline{\lim}_{t\in[0,1],N\in K} d(u_N(t), U) = 0$ since elements $u_N \in \mathbf{U}^1_N$ are piecewise Lipschitz continuous polynomials, with Lipschitz constant independent of N, defined over progressively smaller intervals.[3] For representation R2, $d(u_N(t), U) = 0$ for all $N \in \mathbf{N}$ and $t \in [0, 1]$ since $u_N \in \mathbf{U}^2_N$ is piecewise constant. This implies that $u \in \mathbf{U}$; hence $\eta \in \mathbf{H}$. Furthermore, $\Psi_c(\eta) \le 0$ by (4.20b) and the continuity of $\Psi_c(\cdot)$. Finally, by (4.20a) and Theorem 3.2(iii), $\lim_{N\in K} \Psi_{o,N}(\eta_N) = \Psi_o(\eta)$. Thus, part (b) of Definition 2.1 holds. □

Remark 4.13. In [15], Hager empirically observes that methods with $b_j = 0$ for some j, such as the modified Euler method, cannot be used to discretize optimal control problems. This requirement, formalized in Assumption 4.1, is used in our proof of epiconvergence. However, for representation R1, epiconvergence of $\mathbf{P}_N$ to $\mathbf{P}$ can be established even if, for some j, $\tilde{b}_j \le 0$. This is because of the Lipschitz continuity constraint imposed on the set $\mathbf{U}^1_N$ in (4.15a); see Conjecture 5.11 added to the end of this paper.

[3] It can also be shown by contradiction that $d(u_N(\cdot), U) \to 0$ a.e. on [0,1] without requiring, in (4.15a), elements of $\mathbf{U}^1_N$ to have a uniform piecewise Lipschitz constant.

Nonetheless, our experimental evidence suggests that using an RK method with $\tilde{b}_j \leq 0$ is unwise. For example, the third-order method with Butcher array $b = (-1/6, 8/9, 5/18)$, $c = (0, 1/4, 1)$ and nonzero entries of A given by $a_{2,1} = 1/4, a_{3,1} = -7/5, a_{3,2} = 12/5$ was used to discretize the problem (6.3) with discretization level $N = 10$. The solutions u_N^* for different values of Lipschitz constant κ_U are plotted in Figure 1(a). For comparison, the solutions of the approximating problems produced with the third-order RK method with Butcher array $b = (1/6, 2/3, 1/6)$, $c = (0, 1/2, 1)$ and nonzero entries of A given by $a_{2,1} = 1/2, a_{3,1} = -1$, $a_{3,2} = 2$ are presented in Figure 1(b). For both, with κ_U small, the quadratic polynomial pieces in each time interval are forced to be fairly flat. But, as κ_U is increased, the solutions for the "bad" method become increasingly worse and the control solutions remain pushed against the Lipschitz continuity constraints. On the other hand, the solutions for the "good" method become better as κ_U is increased. In fact, when κ_U is bigger than the Lipschitz constant of the true solution u^*, the Lipschitz continuity constraints are inactive for the "good" method (see Remark 4.9). This is seen in Figure 1(b) since the solutions for $\kappa_U = 1$ and $\kappa_U = 10$ are identical. As κ_U is increased from 0.1 to 10, the error $\max_{k,j} |u_N^*[\tau_{k,j}] - u^*(\tau_{k,j})|$ goes from 0.0332 to 7.9992e-4 for the "good" method and goes from 0.0332 to 1.9119 for the "bad" method.

The conditions imposed by Assumptions 4.3 and 4.6 on the c parameters of the Butcher array are needed because of the discontinuites in the controls $u \in L_N^i$, $i = 1, 2$.

Factors in selecting the control representation. The choice of selecting $L_N = L_N^1$ versus $L_N = L_N^2$ depends on the relative importance of approximation error versus constraint satisfaction. It follows from the proof of epiconvergence that irrespective of which representation is used, if $\{\eta_N\}_{N\in\mathbf{N}}$ is a sequence such that $\eta_N \in \mathbf{H}_N$ and $\eta_N \to \eta$, then $\eta \in \mathbf{H}$. Thus η satisfies the control constraints. However, as mentioned earlier, if representation R1 is used, then η_N may not satisfy the control constraints for any finite N (except for the case $r = 2$ and $c = (0, 1)$). Since a numerical solution must be obtained after a finite number of iterations, representation R2 should be used if absolute satisfaction of control constraints is required.

If some violation of control constraints is permissible, then representation R1 may be preferable to representation R2 (although, see comment about transformation of simple control bounds in §6) because a tighter bound for the error of the approximate solution can be established for R1 than for R2. To see this, let $\eta_N^* = (\xi_N^*, u_N^*)$, $N \in \mathbb{N}$, be a local minimizer of the finite-dimensional problem $\mathbf{CP}_N$. This solution is computed by setting $\eta_N^* = W_{\mathbf{A},N}^{-1}(\bar{\eta}_N^*)$, where $\bar{\eta}_N^*$ is the result of a numerical algorithm implemented on a computer using the formulae to be presented in the following sections. The error, $\|u^* - u_N^*\|_2$, of the approximate control solutions u_N^* can be determined as follows. Assume that $u_N^* \to u^*$ as $N \to \infty$ and that u^* is a local minimizer of **CP** (if the u_N^* solutions are uniformly strict minimizers, then u^* must be a local minimizer by Theorem 2.2). Let $\bar{u}^* \in \times_N \times_r \mathbb{R}^m$ be such that $\bar{u}_k^{*j} = u^*(\tau_{k,j})$ for $k \in \mathcal{N}$, $j \in \mathbf{r}$ (assuming $u^*(\tau_{k,j})$ exists). Then, with $\bar{u}_N^* = V_{\mathbf{A},N}(u_N^*)$,

$$\|u^* - u_N^*\|_2 \leq \|u^* - V_{\mathbf{A},N}^{-1}(\bar{u}^*)\|_2 + \|V_{\mathbf{A},N}^{-1}(\bar{u}^*) - u_N^*\|_2 = \|u^* - V_{\mathbf{A},N}^{-1}(\bar{u}^*)\|_2 + \|\bar{u}^* - \bar{u}_N^*\|_{\bar{L}_N}. \tag{4.21}$$

By Proposition 5.5, the quantity $\|\bar{u}^* - \bar{u}_N^*\|_{\bar{L}_N}$ is not affected by the choice of control representations. For smooth, unconstrained problems discretized by symmetric RK methods, a bound for $\|\bar{u}^* - \bar{u}_N^*\|_{l_\infty}$ can be found in [16, Thm. 3.1] (see Proposition 6.1 in this paper for an improved bound for RK4). The quantity $\|u^* - V_{\mathbf{A},N}^{-1}(\bar{u}^*)\|_2$ is the error between u^* and the element of L_N^1 or L_N^2 that interpolates $u^*(t)$ at $t = \tau_{k,j}$, $k \in \mathcal{N}$, and $j \in \mathbf{r}$. The piecewise polynomials of representation R1 are generally better interpolators for $u^*(\cdot)$, except for non-

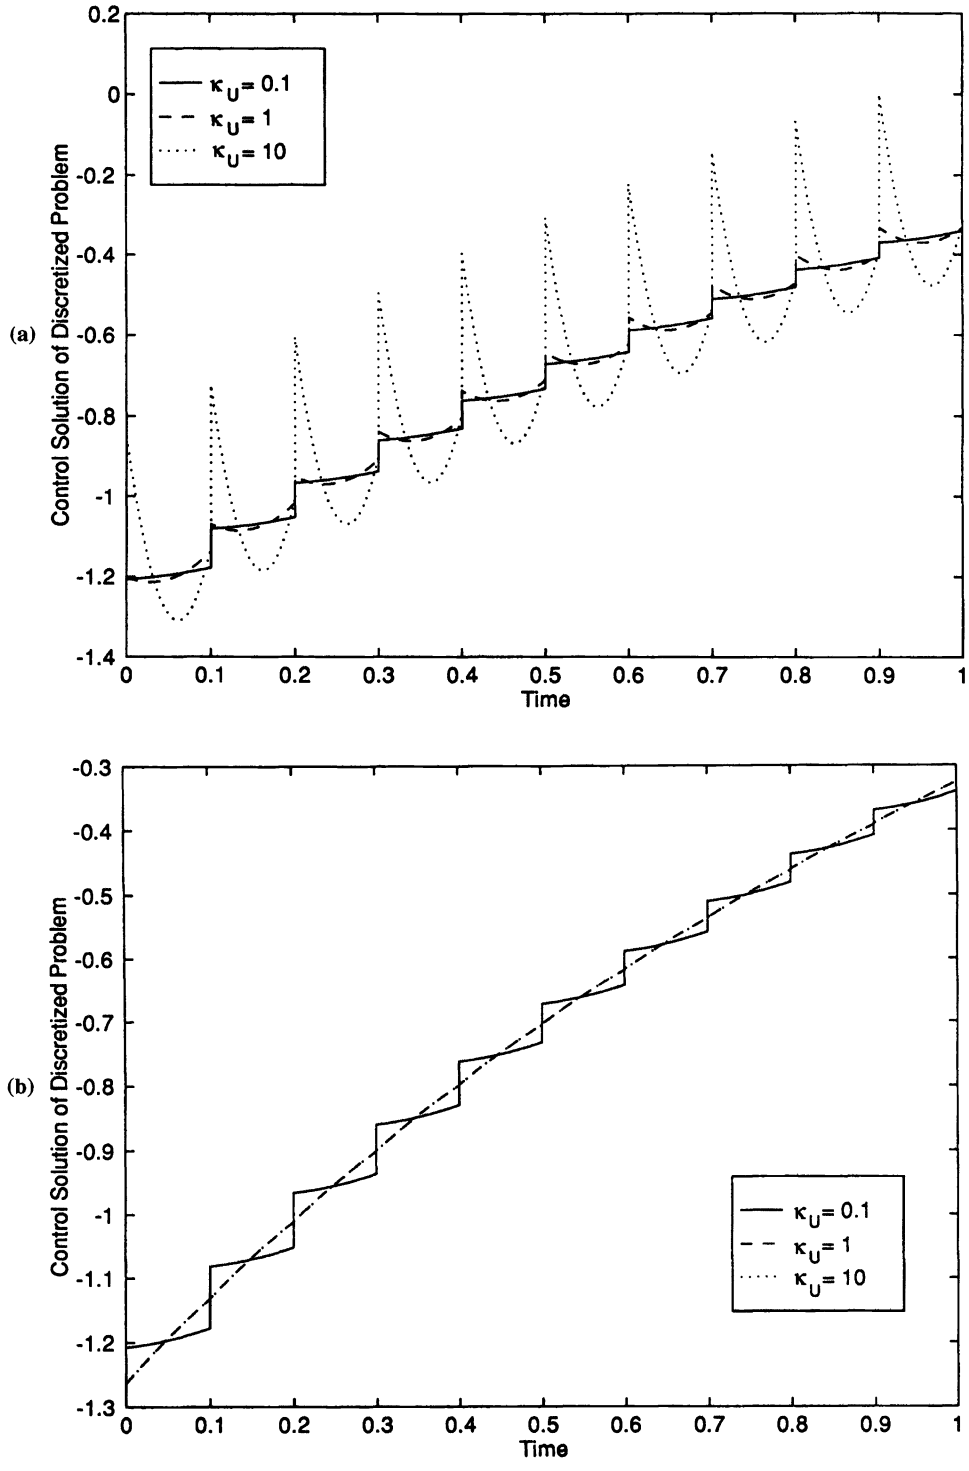

FIG. 1. *Effect of the Lipschitz constant* κ_U *on the solution of problem* (6.3) *discretized with an RK method that has* (a) $b_1 < 0$ *and gets worse as* κ_U *is increased and* (b) *all* $b_j > 0$ *and gets better as* κ_U *is increased until the point where the Lipschitz continuity constraints on* u_N^* *become inactive, as is the case for* $\kappa_U = 1$ *and* $\kappa_U = 10$.

smooth points, than the functions of R2. For $u^*(\cdot)$ sufficiently smooth, $\|u^* - V_{\mathbf{A},N}^{-1}(\bar{u}^*)\|_\infty$ is of order r for representation R1 (see [5]) but only first order of representation R2.

5. Optimality functions for the approximating problems. To develop optimality functions for our approximating problems, we must determine the gradients of the cost and constraint functions for the approximating problems.

At each time step, the RK integration formula is a function of the current state estimate $\bar{x}_k$ and the r control samples $\bar{u}_k = (\bar{u}_k^1, \ldots, \bar{u}_k^r)$. So, let $F : \mathbb{R}^n \times (\times_s \mathbb{R}^m) \to \mathbb{R}^n$ be defined by

$$F(x, w) = x + \Delta \sum_{i=1}^{s} b_i K_i(x, wG), \tag{5.1}$$

where $w = (w^1, \ldots, w^r) \in \times_r \mathbb{R}^m$ is being treated as the $m \times r$ matrix $[w^1 \cdots w^r]$, G was defined in (4.5d), and $K_i(x, \omega)$ was defined in (4.3b) ($\omega = wG \in \mathbb{R}^{m \times s}$). Then, referring to (4.3a,b), we see that for any $\bar{\eta} = (\xi, \bar{u}) \in \bar{H}_N$, with $\bar{H}_N$ defined in (4.14a),

$$\bar{x}_{k+1}^{\bar{\eta}} = F(\bar{x}_k, \bar{u}_k), \quad \bar{x}_0 = \xi, \quad k \in \mathcal{N}. \tag{5.2}$$

The derivative of $F(\cdot, \cdot)$ with respect to the jth component of w is, with I_j defined in (4.4b),

$$\begin{aligned} F_{w^j}(x, w) &= \Delta \frac{\partial}{\partial w^j} \sum_{i=1}^{s} b_i K_i(x, wG) \\ &= \Delta \sum_{l \in I_j} \frac{\partial}{\partial \omega^l} \sum_{i=1}^{s} b_i K_i(x, \omega) \\ &= \Delta \sum_{l \in I_j} \left[b_l h_u(Y_l(x, \omega), w^j) + \Delta \sum_{i=1}^{s} b_i h_x(Y_i(x, \omega), \omega^j) \sum_{p=1}^{i-1} \frac{\partial}{\partial \omega^l} K_p(x, \omega) \right], \end{aligned} \tag{5.3}$$

where $\omega = wG$ and $Y_i(x, \omega) \triangleq x + \Delta \sum_{j=1}^{i-1} a_{i,j} K_j(x, \omega)$.

The next theorem provides an expression for the gradients of the functions $f_N^\nu(\cdot)$, $\nu \in \mathbf{q}$, given by (4.16).

THEOREM 5.1. *Let $N \in \mathbb{N}$, $\eta \in H_N$, and $\bar{\eta} = W_{\mathbf{A},N}(\eta)$. Also, let $\mathbf{M}_N \in \mathbb{R}^{Nr \times Nr}$ be the N-block diagonal matrix defined by*

$$\mathbf{M}_N \triangleq \operatorname{diag}[\Delta M, \Delta M, \ldots, \Delta M], \tag{5.4}$$

where $M = M_1$ for representation R1 *and $M = M_2$ for representation* R2. *Then, for each $\nu \in \mathbf{q}$, the gradient of $f_N^\nu(\cdot)$, $\nabla f_N^\nu : H_N \to H_N$, is given by*

$$\nabla f_N^\nu(\eta) = \left(\nabla_\xi f_N^\nu(\eta), \nabla_u f_N^\nu(\eta)\right) = \left(\bar{\gamma}_\xi^\nu(\bar{\eta}), V_{\mathbf{A},N}^{-1}\left(\bar{\gamma}_u^\nu(\bar{\eta})\mathbf{M}_N^{-1}\right)\right), \tag{5.5a}$$

where $V_{\mathbf{A},N} = V_{\mathbf{A},N}^1$ for representation R1, *$V_{\mathbf{A},N} = V_{\mathbf{A},N}^2$ for representation* R2, *and $\bar{\gamma}^\nu(\bar{\eta}) = (\bar{\gamma}_\xi^\nu(\bar{\eta}), \bar{\gamma}_u^\nu(\bar{\eta})) \in \overline{H}_N$ is defined by*

$$\bar{\gamma}_\xi^\nu(\bar{\eta}) = \nabla_\xi \zeta^\nu(\xi, \bar{x}_N^{\bar{\eta}}) + \bar{p}_0^{\nu,\bar{\eta}}, \tag{5.5b}$$

$$\bar{\gamma}_u^\nu(\bar{\eta})_k^j = F_{w_j}(\bar{x}_k^{\bar{\eta}}, \bar{u}_k)^T \bar{p}_{k+1}^{\nu,\bar{\eta}}, \qquad k \in \mathcal{N}, \ j \in \mathbf{r}, \tag{5.5c}$$

with $\bar{p}_k^{\nu,\bar{\eta}}$ determined by the adjoint equation

$$\bar{p}_k^\nu = F_x(\bar{x}_k^{\bar{\eta}}, \bar{u}_k)^T \bar{p}_{k+1}^\nu, \quad \bar{p}_N^\nu = \zeta_x^\nu(\xi, \bar{x}_N^{\bar{\eta}})^T, \quad k \in \mathcal{N}, \tag{5.5d}$$

and where $F_x(\cdot, \cdot)$ and $F_{w^j}(\cdot, \cdot)$ denote the partial derivatives of $F(x, w)$ with respect to x and the jth component of w.

Proof. First, we note that $V_{\mathbf{A},N}^1$ is invertible by Proposition 4.4 and $V_{\mathbf{A},N}^2$ is invertible by Proposition 4.7. Next, referring to [23, p. 68], we see that $\bar{\gamma}_\xi^\nu(\bar{\eta})$ is the gradient of $\bar{f}_N^\nu(\bar{\eta})$ with

respect to ξ. Similarly, $\bar{\gamma}_u^\nu(\bar{\eta})$ is the gradient of $\bar{f}_N^\nu(\bar{\eta})$ with respect to $\bar{u} \in \times_N \times_r \mathbb{R}^m$ endowed with the standard l_2 inner product. Hence, the Gateaux differential of f_N^ν is given by

$$\begin{aligned} Df_N^\nu(\eta_N; \delta\eta_N) = D\bar{f}_N^\nu(\bar{\eta}; \delta\bar{\eta}) &= \langle \bar{\gamma}_\xi^\nu(\bar{\eta}), \delta\xi\rangle + \langle \bar{\gamma}_u^\nu(\bar{\eta}), \delta\bar{u}\rangle_{l_2} \\ &= \langle \bar{\gamma}_\xi^\nu(\bar{\eta}), \delta\xi\rangle + \langle \bar{\gamma}_u^\nu(\bar{\eta})\mathbf{M}_N^{-1}, \delta\bar{u}\rangle_{\bar{L}_N} \\ &= \langle \gamma_\xi^\nu(\bar{\eta}), \delta\xi\rangle + \langle V_{\mathbf{A},N}^{-1}(\gamma_u^\nu(\bar{\eta})\mathbf{M}_N^{-1}), \delta u\rangle_2, \end{aligned} \tag{5.6}$$

where $\delta\eta_N = (\delta\xi, \delta u_N) \in H_N$ and $\delta\bar{\eta} = (\delta\xi, \delta\bar{u}) = W_{\mathbf{A},N}(\delta\eta_N)$. Since by the definition of $\nabla f_N^\nu(\eta_N)$, $Df_N^\nu(\eta_N; \delta\eta_N) = \langle \nabla f_N^\nu(\eta_N), \delta\eta_N\rangle_H$ for all $\delta\eta_N \in H_N$, the desired result follows from (5.6). □

A simpler expression for $\bar{\gamma}_u(\bar{\eta})$ for a certain class of RK methods can be found in [15].

Note that for $\eta \in H_N$, $\bar{\eta} = W_{\mathbf{A},N}(\eta)$, we have $\bar{\gamma}_u^\nu(\bar{\eta})_k \in \underset{r}{\times} \mathbb{R}^m$ and

$$\left(\nabla_u f_N^\nu(\eta)[\tau_{k,i_1}] \cdots \nabla_u f_N^\nu(\eta)[\tau_{k,i_r}]\right) = \frac{1}{\Delta}\left(\bar{\gamma}_u^\nu(\bar{\eta})_k^1 \cdots \bar{\gamma}_u^\nu(\bar{\eta})_k^r\right) M^{-1}, \tag{5.7}$$

where $i_j \in I$, $j \in \mathbf{r}$, and $\nabla_u f_N^\nu(\eta_N)[\tau_{k,i_j}]$ is computed according to (4.6e) or (4.11c).

Remark 5.2. At this point, we can draw one very important conclusion. For every $\nu \in \mathbf{q}$, the steepest descent direction, in $\overline{H}_N$, for the function $\bar{f}_N^\nu(\cdot)$, at $\bar{\eta}$, is given by $-(\bar{\gamma}_\xi^\nu(\bar{\eta}), \bar{\gamma}_u^\nu(\bar{\eta})\mathbf{M}_N^{-1})$ and not by $-(\bar{\gamma}_\xi^\nu(\bar{\eta}), \bar{\gamma}_u^\nu(\bar{\eta}))$, which is the steepest descent direction that one would obtain using the standard l_2 inner product on $\times_N \times_r \mathbb{R}^m$. The naive approach of solving the discrete-time optimal control problem $\mathbf{CP}_N$ using the latter steepest descent directions amounts to a change of metric that can result in severe ill-conditioning, as we will illustrate in §6.

We can now define optimality functions for the approximating problems using the form of the optimality function presented in (3.9b) for the original problem. For $\mathbf{CP}_N$, we define $\theta_N : H_N \to \mathbb{R}$, with $\sigma > 0$ and the set $\mathbf{H}_N$ defined in (4.15c) by

$$\theta_N(\eta) \triangleq \min_{\eta' \in \mathbf{H}_N} \max\left\{ \max_{\nu \in \mathbf{q}_o} \tilde{f}_N^\nu(\eta, \eta') - \psi_{o,N}(\eta) - \sigma\psi_{c,N}(\eta)_+, \max_{\nu \in \mathbf{q}_c + q_o} \tilde{f}_N^\nu(\eta, \eta') - \psi_{c,N}(\eta)_+ \right\}, \tag{5.8a}$$

where $\psi_{c,N}(\eta)_+ \triangleq \max\{0, \psi_{c,N}(\eta)\}$, and for $\nu \in \mathbf{q}$,

$$\tilde{f}_N^\nu(\eta, \eta') \triangleq f_N^\nu(\eta) + \langle \nabla f_N^\nu(\eta), \eta' - \eta\rangle_H + \frac{1}{2}\|\eta' - \eta\|_H^2. \tag{5.8b}$$

If needed for a particular numerical algorithm (e.g., [22]), $\theta_N(\eta) = \bar{\theta}_N(\bar{\eta})$, where $\bar{\eta} = W_{\mathbf{A},N}(\eta)$ and

$$\bar{\theta}_N(\bar{\eta}) \triangleq \min_{\bar{\eta}' \in \overline{\mathbf{H}}_N} \frac{1}{2}\|\bar{\eta}' - \bar{\eta}\|_{\bar{H}_N}^2 + \Theta_N(\bar{\eta}, \bar{\eta}'), \tag{5.9a}$$

with

$$\begin{aligned} \Theta_N(\bar{\eta}, \bar{\eta}') = \max\{ &\max_{\nu \in \mathbf{q}_o} \bar{f}_N^\nu(\bar{\eta}) + \langle (\bar{\gamma}_\xi^\nu(\bar{\eta}), \bar{\gamma}_u^\nu(\bar{\eta})\mathbf{M}_N^{-1}), \bar{\eta}' - \bar{\eta}\rangle_{\bar{H}_N} - \bar{\psi}_{o,N}(\bar{\eta}) - \sigma\bar{\psi}_{c,N}(\bar{\eta})_+, \\ &\max_{\nu \in \mathbf{q}_c + q_o} \bar{f}_N^\nu(\bar{\eta}) + \langle (\bar{\gamma}_\xi^\nu(\bar{\eta}), \bar{\gamma}_u^\nu(\bar{\eta})\mathbf{M}_N^{-1}), \bar{\eta}' - \bar{\eta}\rangle_{\bar{H}_N} - \bar{\psi}_{c,N}(\bar{\eta})_+\}, \end{aligned} \tag{5.9b}$$

and the set $\overline{\mathbf{H}}_N$ is defined in (4.15d).

It should be obvious that these optimality functions are well defined because of the form of the quadratic term and the fact that the minimum is taken over a set of finite dimension.

The following theorem confirms that (5.8a) satisfies the definition for an optimality function. The proof is essentially the same as the proof in [4, Thms. 3.6 and 3.7].

THEOREM 5.3. (i) $\theta_N(\cdot)$ *is continuous.*

(ii) *For every* $\eta \in H_N$, $\theta_N(\eta) \leq 0$.

(iii) *If* $\hat{\eta} \in \mathbf{H}_N$ *is a local minimizer for* $\mathbf{CP}_N$, *then* $\theta_N(\hat{\eta}) = 0$.

Remark 5.4. It can also be shown that $\theta_N(\hat{\eta}) = 0$ for $\hat{\eta} \in \mathbf{H}_N$ if and only if $d_2\Psi_N(\hat{\eta}, \hat{\eta}; \eta - \hat{\eta}) \geq 0$ for all $\eta \in \mathbf{H}_N$ where $\Psi_N(\eta, \eta') \triangleq \max\{\psi_{o,N}(\eta) - \psi_{o,N}(\eta') - \sigma\psi_{c,N}(\eta')_+, \psi_{c,N}(\eta) - \psi_{c,N}(\eta')_+\}$.

PROPOSITION 5.5. *The stationary points for problem* $\overline{\mathbf{CP}}_N$, *that is, the points* $\bar{\eta} \in \overline{\mathbf{H}}_N$ *such that* $\bar{\theta}_N(\bar{\eta}) = 0$, *do not depend on the control representation.*

Proof. First, $\bar{\eta} \in \overline{\mathbf{H}}_N$ is such that $\bar{\theta}_N(\bar{\eta}) = 0$ if and only if $\Theta_N(\bar{\eta}, \bar{\eta}') = 0$ for all $\bar{\eta}' \in \overline{\mathbf{H}}_N$. The "if" direction is obvious. For the "only if" direction, $\bar{\theta}_N(\bar{\eta}) = \min_{\bar{\eta}' \in \overline{\mathbf{H}}_N}\{1/2\|\bar{\eta}' - \bar{\eta}\|^2_{\bar{H}_N} + \Theta_N(\bar{\eta}, \bar{\eta}')\} = 0$. This implies that $\Theta_N(\bar{\eta}, \bar{\eta}') = 0$ because $\Theta_N(\bar{\eta}, \bar{\eta}')$ is linear in $\bar{\eta}'$ whereas $1/2\|\bar{\eta}' - \bar{\eta}\|^2_{\bar{H}_N}$ is quadratic in $\bar{\eta}'$. Second, let $\delta\bar{\eta} = (\delta\xi, \delta\bar{u}) = \bar{\eta}' - \bar{\eta}$. Then, for each $\nu \in \mathbf{q}$,

$$\langle(\bar{\gamma}^\nu_\xi(\bar{\eta}), \bar{\gamma}^\nu_u(\bar{\eta})\mathbf{M}_N^{-1}), \bar{\eta}' - \bar{\eta}\rangle_{\bar{H}_N} = \langle\bar{\gamma}^\nu_\xi(\bar{\eta}), \delta\bar{\xi}\rangle + \langle\bar{\gamma}^\nu_u(\bar{\eta}), \delta\bar{u}\rangle_{l_2}, \tag{5.9c}$$

since $\mathbf{M}_N$ is nonsingular. Hence, $\Theta_N(\bar{\eta}, \bar{\eta}')$ does not depend on the control representation. Thus, the points $\bar{\eta}$ such that $\bar{\theta}_N(\bar{\eta}) = 0$ do not depend on the control representations. □

Consistency of the approximations. To complete our demonstration of consistency of approximations we will show that the optimality functions of the approximating problems hypoconverge to the optimality function of the original problem. First we will present a simple algebraic condition that implies convergence of the gradients. We will use the column vector $\tilde{b} = (\tilde{b}_1 \ldots \tilde{b}_r)^T \in \mathbb{R}^r$, with components $\tilde{b}_j$ defined in (4.10a), and the values d_j defined in (4.10b).

THEOREM 5.6. *For representation* R1, *suppose that Assumptions* 3.1, 4.1′, *and* 4.3 *hold. For representation* R2, *suppose that Assumptions* 3.1, 4.1′, *and* 4.6 *hold. For* $N \in \mathbb{N}$, *let* H_N *be defined as in* (4.13a), *with* $L_N = L^1_N$ *or* $L_N = L^2_N$, *and let* $f^\nu_N : H_N \to \mathbb{R}$, $\nu \in \mathbf{q}$, *be defined by* (4.16). *Let* $M = M_1$ *if* $L_N = L^1_N$, *and let* $M = M_2$ *if* $L_N = L^2_N$. *Let* S *be a bounded subset of* $\mathbf{B}$. *If*

$$M^{-1}\tilde{b} = \mathbf{1}, \tag{5.10a}$$

where $\mathbf{1}$ *is a column vector of* r *ones, then there exist a* $\kappa < \infty$ *and an* $N^* < \infty$ *such that for all* $\eta = (\xi, u) \in S \cap \mathbf{H}_N$ *and* $N \geq N^*$,

$$\|\nabla f^\nu(\eta) - \nabla f^\nu_N(\eta)\|_H \leq \frac{\kappa}{N}. \tag{5.10b}$$

Proof. To simplify notation, we replace $\bar{x}^{\bar{\eta}}_k$ by $\bar{x}_k$ and $\bar{p}^{\nu,\bar{\eta}}_k$ by $\bar{p}^\nu_k$. Let $S \subset \mathbf{B}$ be bounded, and let $\eta = (\xi, u) \in S \cap \mathbf{H}_N$. Let $\bar{u} = V_{\mathbf{A},N}(u)$ and $\bar{\eta} = (\xi, \bar{u})$ where $V_{\mathbf{A},N} = V^1_{\mathbf{A},N}$ for representation R1 and $V_{\mathbf{A},N} = V^2_{\mathbf{A},N}$ for representation R2. For each $j \in \mathbf{r}$ and $k \in \mathcal{N}$, $F_{w^j}(\bar{x}_k, \bar{u}_k)$ is given by (5.3). So, with $Y_{k,i} \triangleq \bar{x}_k + \Delta\sum_{j=1}^{i-1} a_{i,j}K_j(\bar{x}_k, \omega_k)$ and $\omega_k = \bar{u}_k G$, there exists $\kappa_1 < \infty$ such that

$$\begin{aligned}
&\|F_{w^j}(\bar{x}_k, \bar{u}_k) - \Delta\tilde{b}_j h_u(\bar{x}_k, \bar{u}^j_k)\| \\
&\leq \left\|F_{w^j}(\bar{x}_k, \bar{u}_k) - \Delta\sum_{l\in I_j} b_l h_u(Y_{k,l}, \bar{u}^j_k)\right\| + \left\|\Delta\sum_{l\in I_j} b_l h_u(Y_{k,l}, \bar{u}^j_k) - \Delta\tilde{b}_j h_u(\bar{x}_k, \bar{u}^j_k)\right\| \\
&\leq \Delta^2\left\|\sum_{l\in I_j}\sum_{i=1}^{s} b_i h_x(Y_{k,i}, \omega^i_k)\sum_{p=1}^{i-1}\frac{\partial}{\partial\omega^l}K_p(\bar{x}_k, \omega_k)\right\| + \Delta\sum_{l\in I_j} b_l\|h_u(Y_{k,l}, \bar{u}^j_k) - h_u(\bar{x}_k, \bar{u}^j_k)\| \\
&\leq \kappa_1\Delta^2,
\end{aligned} \tag{5.11a}$$

where we used the Lipschitz continuity of $h_u(\cdot,\cdot)$ and the fact that S bounded implies that $\bar{x}_k$ and $\bar{u}_k^j$ are bounded, which implies that for all $j \in \mathbf{r}$, $\|h_u(\bar{x}_k, \bar{u}_k^j)\|$ and $\|h_x(\bar{x}_k, \bar{u}_k^j)\|$ are bounded. Therefore, it follows from (5.5c) that

$$\bar{\gamma}_u^\nu(\bar{\eta})_k = [F_{w^1}(\bar{x}_k, \bar{u}_k)^T \bar{p}_{k+1}^\nu \cdots F_{w^r}(\bar{x}_k, \bar{u}_k)^T \bar{p}_{k+1}^\nu]$$

$$= \Delta[\tilde{b}_1 h_u^T(\bar{x}_k, \bar{u}_k^1)\bar{p}_{k+1}^\nu \cdots \tilde{b}_r h_u^T(\bar{x}_k, \bar{u}_k^r)\bar{p}_{k+1}^\nu] + O(\Delta^2), \tag{5.11b}$$

where $\lim_{\Delta\to 0} |O(\Delta)/\Delta| < \infty$. From (5.5a), $V_{\mathbf{A},N}(\nabla_u f_N^\nu(\eta)) = \bar{\gamma}_u^\nu(\bar{\eta})\mathbf{M}_N^{-1}$. Therefore, from (5.11b) we obtain

$$V_{\mathbf{A},N}(\nabla_u f_N^\nu(\eta))_k = \frac{\Delta}{\Delta}(\tilde{b}_1 h_u(\bar{x}_k, \bar{u}_k^1)^T \bar{p}_{k+1}^\nu \cdots \tilde{b}_r h_u(\bar{x}_k, \bar{u}_k^r)^T \bar{p}_{k+1}^\nu)M^{-1} + \frac{O(\Delta^2)}{\Delta}, \quad k \in \mathcal{N}. \tag{5.11c}$$

At this point we must deal with our two control representations separately. For representation R1, $u(\cdot) \in \mathbf{U}_N^1$ is a Lipschitz continuous polynomial on each interval $[t_k, t_{k+1})$, with Lipschitz constant κ_U given in (4.15a). Thus, for any $i_j, i_l \in I$, with $j, l \in \mathbf{r}$ and I defined in (4.4a),

$$\|\bar{u}_k^j - \bar{u}_k^l\| = \|u[\tau_{k,i_j}] - u[\tau_{k,i_l}]\| \le \kappa_U \|\Delta(c_{i_j} - c_{i_l})\| \le \kappa_U \Delta, \tag{5.12}$$

where Assumption 4.3 was used to justify the last inequality. Now, let

$$D \triangleq [\tilde{b}_1 h_u^T(\bar{x}_k, \bar{u}_k^1)\bar{p}_{k+1}^\nu \cdots \tilde{b}_r h_u^T(\bar{x}_k, \bar{u}_k^r)\bar{p}_{k+1}^\nu]M^{-1}, \tag{5.13a}$$

and let D^j, $j \in \mathbf{r}$, denote the jth column of D, so that, from (5.11c),

$$\nabla_u f_N^\nu(\eta)[\tau_{k,i_j}] = V_{\mathbf{A},N}(\nabla_u f_N^\nu(\eta))_k^j = D^j + O(\Delta). \tag{5.13b}$$

It follows from Assumptions 3.1(a) and 4.1′, (5.12), and the fact that $\bar{p}_{k+1}^\nu$ is bounded for any $\eta \in S$ that there exists $\kappa_2, \kappa_3 < \infty$, such that for any $j \in \mathbf{r}$ and $i_j \in I$, and with $M_{i,j}^{-1}$ denoting the i, jth entry of M^{-1},

$$\|D^j - h_u(\bar{x}_k, \bar{u}_k^j)^T p_{k+1}^\nu \sum_{i=1}^r \tilde{b}_i M_{i,j}^{-1}\| \le \left\| \sum_{i=1}^r \tilde{b}_i [h_u(\bar{x}_k, \bar{u}_k^i) - h_u(\bar{x}_k, \bar{u}_k^j)]^T p_{k+1}^\nu M_{i,j}^{-1} \right\|$$

$$\le \sum_{i=1}^r \kappa_2 \|\bar{u}_k^i - \bar{u}_k^j\| \|p_{k+1}^\nu M_{i,j}^{-1}\| \le \kappa_3 \Delta. \tag{5.13c}$$

Also, if $M^{-1}\tilde{b} = \mathbf{1}$, then $\sum_{i=1}^r M_{i,j}^{-1}\tilde{b}_i = 1$ since M is symmetric. Hence for any $j \in \mathbf{r}$,

$$\|D^j - h_u(x_k, u_k^j)^T \bar{p}_{k+1}^\nu\| \le \kappa_3 \Delta. \tag{5.13d}$$

Therefore, from (5.13b),

$$\nabla_u f_N^\nu(\eta)[\tau_{k,i_j}] = h_u(x_k, \bar{u}_k^j)^T \bar{p}_{k+1}^\nu + O(\Delta). \tag{5.13e}$$

For representation R2, $\bar{u}(\cdot)$ is not Lipschitz continuous on $[t_k, t_{k+1})$, so (5.12) does not hold. However, since $M = M_2$ is diagonal, (5.13e) is seen to be true directly from (5.11c) if $M^{-1}\tilde{b} = \mathbf{1}$.

Next, since S is bounded, (i) by Lemmas 4.10(i) and A.4 there exists $\kappa_4 < \infty$ such that $\|\bar{x}_k - x^\eta(t_k)\| \le \kappa_4 \Delta$ and $\|\bar{p}_{k+1}^\nu - p^{\eta,\nu}(t_{k+1})\| \le \kappa_4 \Delta$ and (ii) $\bar{p}_{k+1}^\nu$ and $h_u(\bar{x}^k, u[\tau_{k,i_j}])$ are bounded. Thus, making use of Theorem 3.2(v), (5.13e), the fact that both $x^\eta(\cdot)$ and $p^{\nu,\eta}(\cdot)$ are Lipschitz continuous, and $u[\tau_{k,i_j}] = \bar{u}_k^j$, we conclude that there exists $\kappa_5 < \infty$ such that

$$\|\nabla_u f^\nu(\eta)[\tau_{k,i_j}] - \nabla_u f_N^\nu(\eta)[\tau_{k,i_j}]\|$$

$$= \|h_u(x^\eta(\tau_{k,i_j}), u[\tau_{k,i_j}])^T p^{\nu,\eta}(\tau_{k,i_j}) - h_u(\bar{x}_k, u[\tau_{k,i_j}]^T \bar{p}_{k+1}^\nu)\| + O(\Delta) \le \kappa_5 \Delta. \tag{5.14}$$

Next, for $j \in \mathbf{r}$, $i_j \in I$, $k \in \mathcal{N}$, and $t \in [0, 1]$ we have that

$$\begin{aligned}\|\nabla_u f^\nu(\eta)(t) - \nabla_u f_N^\nu(\eta)(t)\| \leq\ & \|\nabla_u f^\nu(\eta)(t) - \nabla_u f^\nu(\eta)[\tau_{k,i_j}]\| \\ & + \|\nabla_u f^\nu(\eta)[\tau_{k,i_j}] - \nabla_u f_N^\nu(\eta)[\tau_{k,i_j}]\| \\ & + \|\nabla_u f_N^\nu(\eta)[\tau_{k,i_j}] - \nabla_u f_N^\nu(\eta)(t)\|. \end{aligned} \tag{5.15a}$$

The second term in (5.15a) is of order $O(\Delta)$ by (5.14). We will show that the first and third terms in (5.15a) are also of order $O(\Delta)$. First consider representation R1. It follows by inspection of (3.6b) in Theorem 3.2(v) that $\nabla_u f^\nu(\eta)(\cdot)$ is Lipschitz continuous on $t \in [t_k, t_{k+1})$, $k \in \mathcal{N}$, because $u \in L_N^1$ is Lipschitz continuous on these intervals. Since $\nabla_u f_N^\nu(\eta)(\cdot) \in L_N$, it is also Lipschitz continuous on these intervals. Finally, by Assumption 4.3, $\tau_{k,i_j} \in [t_k, t_{k+1}]$ for all $k \in \mathcal{N}$. Thus, the first and third terms are of order $O(\Delta)$ for all $t \in [0, 1]$. For representation R2, $\nabla_u f_N^\nu(\eta)(\cdot) \in H_N$ is constant on $t \in [t_k + d_{j-1}, t_k + d_j)$, $j \in \mathbf{r}$, and $k \in \mathcal{N}$. Since $u \in L_N^2$ is constant on these intervals, it again follows by inspection of (3.6b) in Theorem 3.2(v) that $\nabla_u f^\nu(\eta)(\cdot)$ is Lipschitz continuous on these intervals. Finally, by Assumption 4.6, $\tau_{k,i_j} \in [t_k + d_{j-1}, t_k + d_j]$, for all $k \in \mathcal{N}$ and $j \in \mathbf{r}$. Since $d_0 = 0$ and $d_r = \Delta$, the first and third terms are of order $O(\Delta)$ for all $t \in [0, 1]$. We conclude that there exist $\kappa_6 < \infty$ such that

$$\|\nabla_u f^\nu(\eta)(t) - \nabla_u f_N^\nu(\eta)(t)\| \leq \kappa_6 \Delta, \qquad t \in [0, 1], \tag{5.15b}$$

which implies that

$$\|\nabla_u f^\nu(\eta) - \nabla_u f_N^\nu(\eta)\|_2 \leq \kappa_6 \Delta. \tag{5.15c}$$

Next we consider the gradient with respect to initial conditions ξ. From Theorem 3.2(v) and (5.5b), $\|\nabla_\xi f^\nu(\eta) - \bar{\gamma}_\xi^\nu(\eta)\| \leq \|\nabla_\xi \zeta^\nu(\xi, x^\eta(1)) - \nabla_\xi \zeta^\nu(\xi, \bar{x}_N)\| + \|p^{\nu,\eta}(0) - \bar{p}_0^\nu\|$. Thus, since S is bounded, it follows from Assumption 3.1(b) and Lemmas 4.10 and A.4 that there exists $\kappa_7 < \infty$ such that

$$\|\nabla_\xi f^\nu(\eta) - \bar{\gamma}_\xi^\nu(\eta)\| \leq \kappa_7(\|x^\eta(1) - \bar{x}_N\| + \|p^{\nu,\eta}(0) - \bar{p}_0^\nu\|) \leq \kappa_7 \Delta. \tag{5.16}$$

Combining (5.15c) and (5.16), we see that there exists $\kappa < \infty$ such that for any $\eta_N \in S \cap H_N$

$$\|\nabla f^\nu(\eta_N) - \nabla f_N^\nu(\eta_N)\|_H \leq \frac{\kappa}{N}. \qquad \square \tag{5.17}$$

The following proposition states conditions for (5.10a) to hold.

PROPOSITION 5.7. (a) *Suppose* $M = M_1$. *Then* (5.10a) *holds if and only if the coefficients of the Butcher array satisfy*

$$\sum_{j=1}^{s} b_j c_j^{l-1} = \frac{1}{l}, \qquad l = 1, \ldots, r. \tag{5.18}$$

(b) *Suppose* $M = M_2$. *Then* (5.10a) *holds if and only if for all* $j \in \mathbf{r}$, $\tilde{b}_j \neq 0$.

Proof. (a) For $M = M_1$, it follows from (4.9b) that $M^{-1}\tilde{b} = \mathbf{1}$ if and only if

$$T^{-T} \operatorname{Hilb}(s)^{-1} T^{-1} \tilde{b} = \mathbf{1}. \tag{5.19a}$$

Now, it is easy to see that

$$T^{-1}\tilde{b} = \begin{bmatrix} \sum_{j=1}^{r} \tilde{b}_j \\ \sum_{j=1}^{r} \tilde{b}_j c_{i_j} \\ \vdots \\ \sum_{j=1}^{r} \tilde{b}_j c_{i_j}^{r-1} \end{bmatrix} = \begin{bmatrix} \sum_{j=1}^{s} b_j \\ \sum_{j=1}^{s} b_j c_j \\ \vdots \\ \sum_{j=1}^{s} b_j c_j^{r-1} \end{bmatrix} = \begin{bmatrix} 1 \\ 1/2 \\ \vdots \\ 1/r \end{bmatrix}, \tag{5.19b}$$

where the last equality holds if and only if (5.18) holds. Note that $T^{-1}\tilde{b}$ is then the first column of Hilb(r). Consequently,

$$\text{Hilb}(r)^{-1}T^{-1}\tilde{b} = \text{Hilb}(r)^{-1}\begin{bmatrix} 1 \\ 1/2 \\ \vdots \\ 1/r \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix}, \tag{5.19c}$$

which leads us to conclude that

$$M^{-1}\tilde{b} = T^{-T}\begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix} = \begin{bmatrix} 1 & c_{i_1} & \cdots & c_{i_1}^{r-1} \\ 1 & c_{i_2} & & c_{i_2}^{r-1} \\ & & \ddots & \\ 1 & c_{i_r} & \cdots & c_{i_r}^{r-1} \end{bmatrix}\begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{bmatrix}. \tag{5.19d}$$

(b) For $M = M_2$, given by (4.12b), M^{-1} is nonsingular if and only if $\tilde{b}_j \neq 0$. Also, (5.10a) holds if and only if $M\mathbf{1} = \tilde{b}$. Clearly then, if $\tilde{b}_j \neq 0$, (5.10a) holds because

$$M\mathbf{1} = \begin{bmatrix} \tilde{b}_1 & & \\ & \ddots & \\ & & \tilde{b}_r \end{bmatrix}\begin{bmatrix} 1 \\ \vdots \\ 1 \end{bmatrix} = \tilde{b}. \qquad \square \tag{5.20}$$

Remark 5.8. The conditions (5.18) on the coefficients of the Butcher array for representation R1 are necessary conditions for the RK methods to be rth-order accurate [8, 17]. The condition with $l = 1$ in (5.18) is the same as the second part of Assumption 4.1′.

THEOREM 5.9. *For representation* R1, *suppose that Assumptions* 3.1, 4.1′, *and* 4.3 *and* (5.18) *hold and let* $d = 2$. *For representation* R2, *suppose that Assumptions* 3.1, 4.1′, *and* 4.6 *hold and let* d *be the least common denominator for the elements* b_j, $j \in \mathbf{s}$, *of the Butcher array. Let* $\mathbf{N} \triangleq \{d^l\}_{l=1}^{\infty}$ *and suppose that* $\{\eta_N\}_{N\in K}$, $K \subset \mathbf{N}$, *is such that* $\eta_N \in \mathbf{H}_N$ *for all* $N \in K$ *and* $\eta_N \to \eta$ *as* $N \to \infty$. *Then* $\theta_N(\eta_N) \to^K \theta(\eta)$ *as* $N \to \infty$.

Proof. Let $\tilde{\Psi} : \mathbf{H} \times \mathbf{H} \to \mathbb{R}$ be defined by

$$\tilde{\Psi}(\eta, \eta') \triangleq \max\left\{\max_{\nu\in\mathbf{q}_o} \tilde{f}^{\nu}(\eta, \eta') - \psi_o(\eta) - \sigma\psi_c(\eta)_+, \max_{\nu\in\mathbf{q}_c+q_o} \tilde{f}^{\nu}(\eta, \eta') - \psi_c(\eta)_+\right\}, \tag{5.21a}$$

and let $\tilde{\Psi}_N : \mathbf{H}_N \times \mathbf{H}_N \to \mathbb{R}$ be defined by

$$\tilde{\Psi}_N(\eta, \eta') \triangleq \max\left\{\max_{\nu\in\mathbf{q}_o} \tilde{f}_N^{\nu}(\eta, \eta') - \psi_{o,N}(\eta) - \sigma\psi_{c,N}(\eta)_+, \max_{\nu\in\mathbf{q}_c+q_o} \tilde{f}_N^{\nu}(\eta, \eta') - \psi_{c,N}(\eta)\right\}, \tag{5.21b}$$

so that $\theta(\eta) = \min_{\eta' \in \mathbf{H}} \tilde{\Psi}(\eta, \eta')$ and $\theta_N(\eta) = \min_{\eta' \in \mathbf{H}_N} \tilde{\Psi}_N(\eta, \eta')$. Now, suppose that $\{\eta_N\}_{N \in K}$ is a sequence such that, for all N, $\eta_N \in \mathbf{H}_N$ and $\eta_N \to^K \eta$. From the proof of Theorem 4.12, $\eta \in \mathbf{H}$. Let $\hat{\eta} \in \mathbf{H}$ be such that $\theta(\eta) = \tilde{\Psi}(\eta, \hat{\eta})$, and let $\{\eta'_N\}_{N \in K}$ be any sequence such that, for all N, $\eta'_N \in \mathbf{H}_N$ and $\eta'_N \to^K \hat{\eta}$. Then,

$$\begin{aligned}\theta_N(\eta_N) &\leq \tilde{\Psi}_N(\eta_N, \eta'_N)\\ &\leq \tilde{\Psi}(\eta_N, \eta'_N) + \max\Big\{\max_{\nu \in \mathbf{q}_o}\{\tilde{f}^\nu_N(\eta_N, \eta'_N) - \tilde{f}^\nu(\eta_N, \eta'_N)\}\\ &\qquad -[\psi_{o,N}(\eta_N) - \psi_o(\eta_N)] - [\sigma\psi_{c,N}(\eta_N)_+ - \sigma\psi_c(\eta_N)_+],\\ &\qquad \max_{\nu \in \mathbf{q}_c + q_o}\{\tilde{f}^\nu_N(\eta_N, \eta'_N) - \tilde{f}^\nu(\eta_N, \eta'_N)\} - [\psi_{c,N}(\eta_N) - \psi_c(\eta_N)]\Big\}.\end{aligned} \tag{5.22}$$

It follows from Theorem 4.12, Theorem 5.6, Proposition 5.7, and the fact that $\{\eta_N\}_{N \in K}$ is a bounded set that each part of the max term on the right-hand side of (5.22) converges to zero as $N \to \infty$. The quantity $\tilde{\Psi}(\eta_N, \eta'_N)$ converges to $\theta(\eta)$ since $\eta_N \to^K \eta$, $\eta'_N \to^K \hat{\eta}$, and $\tilde{\Psi}(\cdot, \cdot)$ is continuous. Thus, taking limits of both sides of (5.22), we obtain that $\overline{\lim}\theta_N(\eta_N) \leq \theta(\eta)$ (this proves that Definition 2.4 holds for the optimality functions of the approximating problems). Now, for all $N \in K$, let $\hat{\eta}_N \in \mathbf{H}_N$ be such that $\theta_N(\eta_N) = \tilde{\Psi}_N(\eta_N, \hat{\eta}_N)$. Then, $\theta(\eta_N) \leq \tilde{\Psi}(\eta_N, \hat{\eta}_N)$ and proceeding in a similar fashion as (5.22) and taking limits, we see that $\theta(\eta) \leq \underline{\lim}\theta_N(\eta_N)$. Hence, together with the previous result, we can conclude that $\theta_N(\eta_N) \to^K \theta(\eta)$ as $N \to \infty$. □

Since the union of the spaces H_N is dense in $H_{\infty,2}$ and Theorem 5.9 holds, it follows that the hypographs of the optimality functions $\theta_N(\cdot)$ converge to the hypograph of the optimality function $\theta(\cdot)$, in the Kuratowski sense, i.e., the $-\theta_N \to^{\text{Epi}} -\theta$.

The following corollary is a direct result of Theorem 4.12 (epiconvergence) and Theorem 5.9.

COROLLARY 5.10 (consistency). *For representation* R1, *suppose that Assumptions* 3.1, 4.1′, 4.3, *and* 4.11 *and* (5.18) *hold. For representation* R2, *suppose that Assumptions* 3.1, 4.1′, 4.6, *and* 4.11 *hold. Let* $\mathbf{N} = \{d^l\}_{l=1}^\infty$ *where* $d = 2$ *for representation* R1 *and* d *is the least common denominator of the* $\tilde{b}_j$, $j \in \mathbf{s}$, *for representation* R2. *Then, the approximating pairs* $(\mathbf{CP}_N, \theta_N)$, $N \in \mathbf{N}$ *are consistent approximations to the pair* $(\mathbf{CP}, \theta)$.

6. Numerical results. The problems $\overline{\mathbf{CP}}_N$ can be solved using existing optimization methods (e.g., [18] and [22]). These methods, however, are defined on a Euclidean space and existing code would have to be modified for use on the coefficient spaces $\tilde{L}^i_N$, $i = 1, 2$. To avoid this difficulty, we will now define a change of coordinates in coefficient space that implicitly defines an orthonormal basis for the subspace L^i_N and, hence, turns the coefficient space into a Euclidean space.

Let $L_N = L^1_N$ or L^2_N and, correspondingly, $V_{\mathbf{A},N} = V^1_{\mathbf{A},N}$ or $V^2_{\mathbf{A},N}$. Recall from (5.5a) that, for $\eta = (\xi, u) \in H_N$ and $\nu \in \mathbf{q}$, $\nabla_u f^\nu_N(\eta) = V^{-1}_{\mathbf{A},N}(\bar{\gamma}^\nu_u(\bar{\eta})\mathbf{M}^{-1}_N)$, where $\bar{\eta} = (\xi, \bar{u}) = W_{\mathbf{A},N}(\eta)$ and $\bar{\gamma}^\nu_u(\bar{\eta})$, defined in (5.5c), is the gradient of $\bar{f}^\nu_N(\cdot)$ with respect to the standard l_2 inner product on $\underset{N}{\times}\,\underset{r}{\times}\,\mathbb{R}^m$. The gradient of $\bar{f}^\nu_N(\cdot)$ with respect to the inner product on $\tilde{L}_N$ is given by $\nabla_u \bar{f}^\nu_N(\bar{\eta}) = V_{\mathbf{A},N}(\nabla_u f^\nu_N(\eta)) = \bar{\gamma}^\nu_u(\bar{\eta})\mathbf{M}^{-1}_N$ and satisfies

$$\langle \nabla_u f^\nu_N(\eta), \delta u\rangle_2 = \langle \nabla_u \bar{f}^\nu_N(\bar{\eta}), \delta\bar{u}\rangle_{\tilde{L}_N} = \langle \bar{\gamma}^\nu_u(\bar{\eta}), \delta\bar{u}\rangle_{l_2} \tag{6.1}$$

for any $\delta u \in H_N$ and $\delta\bar{u} = V_{\mathbf{A},N}(\delta u)$. Introduce a new coefficient space, $\tilde{L}_N = \times_N \times_r \mathbb{R}^m$, endowed with the standard l_2 inner product and norm, and the transformation $Q : \tilde{L}_N \to \tilde{L}_N$

defined by

$$\tilde{u} = Q(\bar{u}) = \bar{u}\mathbf{M}_N^{1/2}, \tag{6.2a}$$

where $\mathbf{M}_N$ is defined in (5.4). Let $\tilde{\eta} = (\xi, \tilde{u})$, and for each $\nu \in \mathbf{q}$ let $\tilde{f}_N^\nu : \mathbb{R}^n \times \tilde{L}_N \to \mathbb{R}$ be defined by

$$\tilde{f}_N^\nu(\tilde{\eta}) \triangleq \bar{f}_N^\nu((\xi, Q^{-1}(\tilde{u}))). \tag{6.2b}$$

Finally, let $\bar{\eta} = (\xi, Q^{-1}(\tilde{u}))$. Then, by the chain rule,

$$\nabla_{\tilde{u}} \tilde{f}_N^\nu(\tilde{\eta}) = Q^{-1}(\nabla_{\bar{u}} \bar{f}_N^\nu(\bar{\eta})) = \bar{\gamma}_u^\nu(\bar{\eta})\mathbf{M}_N^{-1/2}. \tag{6.2c}$$

Thus, $\langle \nabla_{\tilde{u}} \tilde{f}_N^\nu(\tilde{\eta}), \delta\tilde{u}\rangle_{l_2} = \langle \nabla_{\bar{u}} \bar{f}_N^\nu(\bar{\eta}), \delta\bar{u}\rangle_{\bar{L}_N} = \langle \nabla_u f_N^\nu(\eta_N), \delta u_N\rangle_2$, where $\delta\tilde{u} = Q(\delta\bar{u})$.

Implicitly, the transformation Q creates an orthonormal basis for L_N because under this transformation the inner-product and norm on L_N are equal to the l_2 inner-product and norm on the coefficient space. With this transformation, the approximating problems $\overline{\mathbf{CP}}_N$ can be solved using standard nonlinear programming methods without introducing ill-conditioning. It is important to note, however, that control constraints are also transformed. Thus, the constraint $\bar{u} \in \overline{\mathbf{U}}_N$ becomes $\tilde{u}\mathbf{M}_N^{-1/2} \in \overline{\mathbf{U}}_N$. For representation R1, since $\mathbf{M}_N^{-1/2}$ is not diagonal (except if $r = 1$), this means that the transformed control constraints will, for each $k \in \mathcal{N}$, involve linear combinations of the control samples $\tilde{u}_k^j$, $j \in \mathbf{r}$.

We will now present a numerical example that shows, in particular, that this transformation can make a substantial difference in the performance of an algorithm.

Example. Consider the linear-quadratic problem taken from [15]

$$\min_{u \in \mathbf{U}} f(u), \qquad f(u) \triangleq x_2^u(1), \tag{6.3a}$$

where $x(t) = (x_1(t), x_2(t))^T$ and

$$\dot{x} = \begin{bmatrix} 0.5x_1 + u \\ 0.625x_1^2 + 0.5x_1u + 0.5u^2 \end{bmatrix}, \quad x(0) = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \quad t \in [0, 1]. \tag{6.3b}$$

The solution to this problem is given by

$$u^*(t) = -(\tanh(1-t) + 0.5)\cosh(1-t)/\cosh(1), \qquad t \in [0, 1], \tag{6.4}$$

with optimal cost $x_2^*(1) = e^2 \sinh(2)/(1+e^2)^2 \approx 0.380797$.

The approximating cost functions are $f_N(u) = (0\ 1)\bar{x}_N^u$ where $\{\bar{x}_k^u\}_{k=0}^N$ is the RK solution for a given control $u \in L_N$. We discretized the dynamics using two common RK methods. The first is a third-order method defined by the Butcher array $\mathbf{A}_1 = [c, A, b]$ with $c = (0, 1/2, 1)$, $b = (1/6, 2/3, 1/6)$, and the nonzero entries of A are $a_{2,1} = 1/2$, $a_{3,1} = -1$, and $a_{3,2} = 2$. The matrices $\mathbf{M}_N$ used to define the transformation Q in (6.2a) are given by (5.4) with

$$M = M_1 = \frac{1}{30}\begin{bmatrix} 4 & 2 & -1 \\ 2 & 16 & 2 \\ -1 & 2 & 4 \end{bmatrix}, \qquad M = M_2 = \frac{1}{6}\begin{bmatrix} 1 & 0 & 0 \\ 0 & 4 & 0 \\ 0 & 0 & 1 \end{bmatrix}. \tag{6.5}$$

We solved the approximating problems using steepest descent with the step-size determined by an Armijo rule augmented with a quadratic fit based on the value of $f_N(\cdot)$ at the last

TABLE 1

two evaluations in the line search. The stopping criterion[4] was $\|\bar{\gamma}_u\|_2 \leq (3.1e-4)/N$; and the initial guess was $u(t) = 0, t \in [0, 1]$. Table 1 shows the number of iterations required to solve the approximating problems for different discretization levels N with and without the transformation (6.2a,b). We see that solving the discretized problems without the transformation requires about five times the number of iterations required for solving the problem with the transformation. The situation can be even worse for other RK methods. The choice of representation R1 versus representation R2 had no effect on the number of iterations required.

The second RK method is the fourth-order method RK4 defined by the Butcher array $\mathbf{A}_2 = [c, A, b]$ with $c = (0, 1/2, 1/2, 1)$, $b = (1/6, 1/3, 1/3, 1/6)$ and the nonzero entries of A are $a_{2,1} = a_{3,2} = 1/2$ and $a_{4,3} = 1$. The matrices M_1 and M_2, equation (6.5), are the same for this method, since $c_2 = c_3 = 1/2$ implies $r = 3$ and $\tilde{b}_2 = 2/3$. We use this method because it is very common and demonstrates the advantage of treating the samples arising from repeated c_i values in the Butcher array as the same sample (see Remark 4.8).

To see this advantage, let $\{u_N^*\}_{N \in \mathbf{N}}$, $\mathbf{N} \subset \mathbb{N}$, be solutions of $\mathbf{CP}_N$, and suppose $u_N^* \to u^*$ where u^* is a solution of $\mathbf{CP}$. In [16, Thm. 3.1], Hager establishes, for symmetric RK methods [1, 27], a tight upper bound on the error $E_N^u \triangleq \|V_{\mathbf{A},N}(u^*) - V_{\mathbf{A},N}(\bar{u}_N^*)\|_\infty$, of second order in $\Delta = 1/N$ for smooth, unconstrained problems. Note that $V_{\mathbf{A},N}(u^*)_k^j = u^*(\tau_{k,j})$, $k \in \mathcal{N}$ and $j \in \mathbf{r}$, because $u^*(\cdot)$ is smooth for smooth problems [26]. Hager used the problem given in (6.4a) to demonstrate the tightness of this bound. For the particular RK method given by the Butcher array $\mathbf{A}_2$, we can state the following improved result (which, according to Proposition 5.5, does not depend on the control representation).

PROPOSITION 6.1. *Let* $\mathbf{CP} \triangleq \min_{u \in \mathbf{U}} f(x^u(1))$, *u unconstrained. Suppose the approximating problems* $\mathbf{CP}_N$ *are produced by discretizing* $\mathbf{CP}$ *with the fourth-order RK method with Butcher array* $\mathbf{A}_2 : c = (0, 1/2, 1/2, 1)$, $b = (1/6, 1/3, 1/3, 1/6)$ *and the nonzero entries of A are* $a_{2,1} = a_{3,2} = 1/2$ *and* $a_{4,3} = 1$. *Further suppose that the conditions of Lemma* 4.10(ii) *hold with* $\rho = 4$. *Let* $\{u_N^*\}_{N \in \mathbf{N}}$, $\mathbf{N} \subset \mathbb{N}$, *be solutions of* $\mathbf{CP}_N$, *and suppose* $u_N^* \to u^*$ *where* u^* *is a solution of* $\mathbf{CP}$. *Then* $E_N^u \triangleq V_{\mathbf{A},N}(u^*) - V_{\mathbf{A},N}(u_N^*)\|_\infty = O(\Delta^3)$.

Sketch of Proof. In [15], it is shown, using a reasonable nonsingularity assumption on the Hessians of $f_N(\cdot)$, that the accuracy of the solutions of the approximating problems is determined by N times the size of the discrete-time gradient (using the standard l_2 inner-product) of the approximating problem at $\bar{u}^* \triangleq V_{\mathbf{A},N}(u^*)$, that is, $E_N^u \sim \|\bar{\gamma}_u(\bar{u}^*)\|$. This, in turn, is a function of the accuracy of the state and adjoint approximations. For the RK method under consideration, Hager shows that, for $k \in \mathcal{N}$, the variables $\bar{u}_k^{*1} = u^*(t_k)$ and $\bar{u}_k^{*3} = u(t_k + \Delta)$ are third-order approximations to $u^*(t_k)$ and $u^*(t_k + \Delta)$, respectively. Thus, we need only show that $\bar{u}_k^{*2} = u^*(t_K + \Delta/2)$ is a third-order approximation to $u^*(t_k + \Delta/2)$.

Let $Y_{k,2} = \bar{x}_k + \Delta/2h(\bar{x}_k, \bar{u}_k^{*1})$ and $Y_{k,3} = \bar{x}_k + \Delta/2h(Y_{k,2}, \bar{u}_k^{*2})$ represent certain intermediate values used by the RK method at the kth time step. In Hager's notation, $Y_{k,2} = y(1, k)$ and $Y_{k,3} = y(2, k)$. Hager introduces a clever transformation, specific to symmetric

[4]Higher precision was difficult to achieve when the Q transformation was not used.

RK methods, for the adjoint variables so that they can be viewed as being calculated with the same RK method used to compute the state variables but run backward in time. The intermediate adjoint variables of interest here are denoted by $q(2, k)$ and $q(1, k)$. With this transformation, the discrete-time gradients for the approximating problems have the same form as the continuous-time gradient for the original problem. Since $c_2 = c_3 = 1/2$, $\bar{\gamma}_u(\bar{u}^*)_k^2 = 2\Delta/3[1/2h_u(Y_{k,2}, \bar{u}_k^{*2})^T q(1, k) + 1/2h_u(Y_{k,3}, \bar{u}_k^{*2})^T q(2, k)]$. Further, since $2\Delta/3h_u(x^{u^*}(t_k + \Delta/2), u^*(t_k + \Delta/2))^T p^{u^*}(t_k + \Delta/2) = 0$, $\|\bar{\gamma}_u(\bar{u}^*)_k^2\|$ is bounded by $\frac{2}{3}\Delta$ times the maximum of $\|(Y_{k,2} + Y_{k,3})/2 - x^{u^*}(t_k + \Delta/2)\|$ and $\|(q(2, k) + q(1, k))/2 - p^{u^*}(t_k + \Delta/2)\|$. Let

$$w(k) \triangleq \frac{Y_{k,2} + Y_{k,3}}{2} = \bar{x}_k + \frac{\Delta}{4}\left[h(\bar{x}_k, u_k^{*1}) + h\left(\bar{x}_k + \frac{\Delta}{2}h(\bar{x}_k, \bar{u}_k^{*1}), \bar{u}_k^{*2}\right)\right]$$

$$= \bar{x}_k + \frac{\Delta'}{2}[h(\bar{x}_k, u_k^{*1}) + h(\bar{x}_k + \Delta' h(\bar{x}_k, \bar{u}_k^{*1}), \bar{u}_k^{*2})], \tag{6.6}$$

where $\Delta' = \Delta/2$. Thus, $w(k)$ is produced by the improved Euler rule applied to $\bar{x}_k$. Since the local truncation error for the improved Euler rule is of order $O(\Delta^3)$ and $\bar{x}_k$ is of order $O(\Delta^4)$, $\|w(k) - x^{u^*}(t_k + \Delta/2)\|$ is of order $O(\Delta^3)$. In the same way, it can be shown that $\|q(2, k) + q(1, k))/2 - p^{u^*}(t_k + \Delta/2)\|$ is $O(\Delta^3)$. Thus, we can conclude that $\|\bar{\gamma}_u(\bar{u}^*)_k^2\| = O(\Delta^4)$ for all $k \in \mathcal{N}$. This implies that the solutions of the approximating problems satisfy $\|\bar{u}_{N,k}^{*j} - u^*(\tau_{k,j})\| = O(\Delta^3)$ for all $k \in \mathcal{N}$ and $j \in \mathbf{r}$. □

Table 2 summarizes our numerical results using the RK method with Butcher array $\mathbf{A}_2$. The first column gives the discretization level. Columns 2 and 3 show that doubling the discretization results in an eightfold reduction in the control error. Thus, as predicted by Proposition 6.1, E_N^u is $O(\Delta^3)$. The next two columns, agreeing with Hager's observations that the optimal trajectories of the approximating problem converge to those of the original problem with the same order as the order of the symmetric RK method, show that $E_N^f \triangleq |f(u^*) - f_N(\bar{u}_N^*)|$ is of order $O(\Delta^4)$. The numbers in columns 2 and 4 were obtained by solving the discretized problems to full precision. Finally, we include in the last two columns the number of iterations required to solve the approximate problem with and without the transformation Q. The stopping criterion was the same as used for Table 1. As with the previous method, the effect of the Q transformation is quite significant. The solution of the untransformed problem requires about five times the number of iterations required to solve the transformed problem.

The last table shows the accuracy of the gradients for the approximating problems produced with the second RK method (Butcher array $\mathbf{A}_4$) evaluated at the control $u(t) = -1 + 2t$. The first column shows the discretization level N. The second and third columns confirm that the gradients, $\nabla \bar{f}_N(\bar{u}) = \bar{\gamma}_u \mathbf{M}_N^{-1}$, for the approximating problems converge to the gradients of the original problem. Note that, based on the proof of Theorem 5.6, it is enough to show that the gradients converge at the points τ_{k,i_j}, $k \in \mathcal{N}$, $j \in \mathbf{r}$, and $i_j \in I$. The fourth column of Table 3 shows that the gradients that result if one uses the standard l_2 inner product on $\times_N \times_r \mathbb{R}^m$ do not converge.

TABLE 3
Convergence of gradients.

7. Conclusion. We have shown that a large class of Runge–Kutta integration methods can be used to construct consistent approximations to continuous-time optimal control problems. The construction of consistent approximations is not unique: it is determined by the selection of families of finite-dimensional subspaces of the control space. Because the elements of these subspaces are discontinuous functions, appropriate extensions of Runge–Kutta methods must be used. Not all convergent Runge–Kutta methods, however, produce consistent approximations. This was observed both numerically and by failure to prove consistency of approximation with these methods. We have considered two selections of control subspaces in this paper, one defined by piecewise polynomial functions and one by piecewise constant functions. Splines can also be used and are treated in [28]. Each selection has some advantages and some disadvantages. A final selection has to be made on the basis of secondary considerations such as the importance of approximate solutions satisfying the original control constraints, the form that the control constraints take in the discrete-time optimal problems or the accuracy with which the differential equation is integrated.

As in our case, the basis functions that are used implicitly to define the finite-dimensional control subspaces may turn out to be nonorthonormal. In this case care must be taken to introduce a nonstandard inner product and corresponding norm in solving the resulting approximating discrete-time optimal control problems. Neglecting to do so amounts to a change of coordinates that can lead to serious ill-conditioning. This ill-conditioning is demonstrated in §6.

Finally, the use of the framework of consistent approximations opens up the possibility of developing optimal discretization strategies, such as those considered for semi-infinite programming in [16]. Such a strategy provides rules for selecting the number of approximating problems to be used as well as the discretization level, the order of the RK method, and the number of iterations of a particular optimization algorithm to be applied for each such approximating problem, so as to minimize the computing time needed to reach a specified degree of accuracy in solving an optimal control problem.

Appendix A. In this appendix we collect a few results used in the analysis of §§4 and 5. We will continue to use the notation of §4, that is, $\Delta = 1/N$, $t_k = k\Delta$, and $\tau_{k,i} = t_k + c_i\Delta$.

LEMMA A.1. *For the representation* R1, *suppose that Assumptions* 3.1(a), 4.1′, *and* 4.3 *hold. For representation* R2, *suppose that Assumptions* 3.1(a), 4.1′, *and* 4.6 *hold. For any bounded subset* $S \subset \mathbf{B}$, *there exists a* $\kappa < \infty$ *such that for any* $\eta = (\xi, u) \in S \cap \mathbf{H}_N$, $\|\delta_k\| \leq \kappa\Delta^2$ *for all* $k \in \mathcal{N}$, *where*

$$\delta_k \triangleq x^\eta(t_k) - x^\eta(t_{k+1}) + \Delta \sum_{i=1}^{s} b_i h(x^\eta(t_k), u[\tau_{k,i}]), \qquad k \in \mathcal{N}, \tag{A.1}$$

with $x^\eta(\cdot)$ *the solution of the differential equation* (3.1) *and* $u[\tau_{k,i}]$ *defined by* (4.6e) *for representation* R1 *and* (4.11c) *for representation* R2.

Proof. Let $\tilde{b}_j$ and d_j be as defined in (4.10), and for $j \in \mathbf{r}$ let $i_j \in I$ where I is given by (4.4a). Then, writing $x(\cdot) = x^\eta(\cdot)$, since the solution of (3.1) satisfies $x(t_{k+1}) = x(t_k) + \int_{t_k}^{t_{k+1}} h(x(t), u(t))\,dt$, we see that

$$\begin{aligned}\delta_k &= \Delta \sum_{i=1}^{s} b_i h(x(t_k), u[\tau_{k,i}]) - \int_{t_k}^{t_{k+1}} h(x(t), u(t))\,dt \\ &= \sum_{j=1}^{r} \int_{t_k+d_{j-1}}^{t_k+d_j} h(x(t_k), u[\tau_{k,i_j}])\,dt - \sum_{j=1}^{r} \int_{t_k+d_{j-1}}^{t_k+d_j} h(x(t), u(t))\,dt \qquad \text{(A.2a)}\end{aligned}$$

because $d_j - d_{j-1} = \Delta\tilde{b}_j$, $u[\tau_{k,i_j}] = u[\tau_{k,i}]$ for all $i \in I_j$, $d_0 = 0$ and, by Assumption 4.1′, $d_r = \Delta \sum_{j=1}^{r} \tilde{b}_j = \Delta \sum_{j=1}^{s} b_j = \Delta$. Since $d_j - d_{j-1} > 0$ by Assumption 4.1′, we have that

$$\begin{aligned}\|\delta_k\| &\le \sum_{j=1}^{r} \int_{t_k+d_{j-1}}^{t_k+d_j} \|h(x(t_k), u[\tau_{k,i_j}]) - h(x(t), u(t))\|\,dt \\ &\le \sum_{j=1}^{r} \int_{t_k+d_{j-1}}^{t_k+d_j} \kappa_1[\|x(t_k) - x(t)\| + \|u[\tau_{k,i_j}] - u(t)\|]\,dt, \qquad \text{(A.2b)}\end{aligned}$$

where $\kappa_1 < \infty$ is as in Assumption 3.1(a). Now, for $t \in [t_k, t_{k+1}]$, there exists $\kappa_2 < \infty$ such that

$$\|x(t_k) - x(t)\| \le \int_{t_k}^{t} \|h(x(t), u(t))\|\,dt \le \int_{t_k}^{t_{k+1}} \kappa_2[\|x(t)\| + 1]\,dt \qquad \text{(A.3)}$$

by Assumption 3.1(a) and the fact that S is bounded. Also because S is bounded, it follows from Theorem 3.2(ii) that there exists $L < \infty$ such that $\|x(t)\| \le \kappa_3[\|\xi\| + 1] \le L$. Thus, for $t \in [t_k, t_{k+1}]$, $\|x(t_k) - x(t)\| \le \int_{t_k}^{t_{k+1}} \kappa_2[L+1]\,dt = \Delta\kappa_2(L+1)$. Next, for representation R1, for any $k \in \mathcal{N}$, $j \in \mathbf{r}$, and $t \in [t_k + d_{j-1}, t_k + d_j)$, $\|u[\tau_{k,i_j}] - u(t)\| \le \kappa_U \Delta$, where κ_U is used in (4.15a), since by construction, $\bar{u} \in \mathbf{U}_N^1$ is a Lipschitz continuous polynomial on $[t_k, t_{k+1})$ with Lipschitz constant κ_U independent of N, $\tau_{k,i_j} \in [t_k, t_k + \Delta]$ by Assumption 4.3, and $0 \le d_j \le \Delta$ for $j = 0, \ldots, r$ by Assumption 4.1′, which implies that $[t_k + d_{j-1}, t_k + d_j) \subset [t_k, t_k + \Delta)$. The same holds for representation R2, since $u \in L_N^2$ is constant on $t \in [t_k + d_{j-1}, t_k + d_j)$ and $\tau_{k,i_j} \in [t_k + d_{j-1}, t_k + d_j]$ by Assumption 4.6. Therefore,

$$\|\delta_k\| \le \sum_{j=1}^{r} \int_{t_k+d_{j-1}}^{t_k+d_j} \kappa_1(\kappa_2(L+1) + \kappa_U)\Delta\,dt = \kappa\Delta \sum_{j=1}^{r} \int_{t_k+d_{j-1}}^{t_k+d_j} dt = \kappa\Delta^2, \qquad \text{(A.4)}$$

where $\kappa = \kappa_1(\kappa_2(L+1) + \kappa_U)$. This completes our proof. □

Remark A.2. The result in Lemma A.1 can be shown to hold even if the constraints on $\|u_K T_j\|$ in the definition (4.15a) of $\overline{\mathbf{U}}_N^1$ were removed if $h(x, u) = \tilde{h}(x) + Bu$ and the RK method is of order r. Starting from (A.2a), we have

$$\delta_k = \sum_{j=1}^{r} \int_{t_k+d_{j-1}}^{t_k+d_j} \tilde{h}(x(t_k)) - \tilde{h}(x(t))\,dt + \Delta \sum_{j=1}^{r} \tilde{b}_j B u[\tau_{k,j}] - \int_{t_k}^{t_{k+1}} Bu(t)\,dt. \qquad \text{(A.5a)}$$

The first term is $O(\Delta^2)$ by the argument already presented. For the remaining part, we see that

$$B\left[\Delta \sum_{j=1}^{r} \tilde{b}_j u[\tau_{k,j}] - \int_0^{\Delta} u(t + t_k)\,dt\right] = 0, \qquad \text{(A.5b)}$$

since a ρth-order Runge–Kutta method, $\rho \geq r$, integrates the equation $\dot{x} = u(t + t_k)$ exactly for any rth order polynomial u.

The next lemma concerns the functions $K_{k,i} = K_i(\bar{x}_k, \omega_k)$ of the RK method defined by (4.3a,b). The proof of this result is easily obtained from the proof for Lemma 222A in [8, p. 131].

LEMMA A.3. *Suppose Assumption* 3.1(a) *holds. Let* $S \subset \mathbf{B}$ *be bounded. Then there exists* $L < \infty$ *and* $N^* < \infty$ *such that for all* $N \geq N^*$, $\eta \in S \cap H_N$, $k \in \mathcal{N}$, *and* $i \in \mathbf{s}$,

$$\|K_{k,i} - h(\bar{x}_k, u[\tau_{k,i}])\| \leq L\Delta. \tag{A.6}$$

Next, we present a proof of Lemma 4.10.

Proof of Lemma 4.10. (i) Convergence. Let $\eta = (\xi, u) \in S \cap \mathbf{H}_N$, and for $k \in \mathcal{N}$ let $e_k \triangleq \bar{x}_k^\eta - x^\eta(t_k)$. Then $\|e_0\| = 0 \leq \kappa\Delta$ and by adding and subtracting terms,

$$\begin{aligned} e_{k+1} &= \bar{x}_k^\eta + \Delta \sum_{i=1}^{s} b_i K_{k,i} - x^\eta(t_{k+1}) \\ &= e_k + \left[x^\eta(t_k) - x^\eta(t_{k+1}) + \Delta \sum_{i=1}^{s} b_i h(x^\eta(t_k), u[\tau_{k,i}]) \right] \\ &\quad + \Delta \sum_{i=1}^{s} b_i \left[K_{k,i} - h(x^\eta(t_k), u[\tau_{k,i}]) \right]. \end{aligned} \tag{A.7}$$

The norm of the second term in this expression is bounded by $\kappa_1\Delta^2$ by Lemma A.1 where $\kappa_1 < \infty$. Using Lemma A.3, Assumption 3.1(a), and the fact that $|b_i| \leq 1$ by Assumption 4.1′, we conclude for the third term that there exists $\kappa_2 < \infty$ such that

$$\begin{aligned} &\Delta \left\| \sum_{i=1}^{s} b_i \left[K_{k,i} - h(x^\eta(t_k), u[\tau_{k,i}]) \right] \right\| \\ &\quad \leq \Delta \sum_{i=1}^{s} \|K_{k,i} - h(\bar{x}_k^\eta, u[\tau_{k,i}])\| + \Delta \sum_{i=1}^{s} \|h(\bar{x}_k^\eta, u[\tau_{k,i}]) - h(x^\eta(t_k), u[\tau_{k,i}])\| \\ &\quad \leq \Delta^2 Ls + \Delta\kappa_2 s \|e_k\|. \end{aligned} \tag{A.8}$$

Thus, for all $k \in \mathcal{N}$,

$$\|e_{k+1}\| \leq (1 + \kappa_2\Delta s)\|e_k\| + \kappa_3\Delta^2, \tag{A.9}$$

where $\kappa_3 = \kappa_1 + Ls$. Solving (A.9), we see that for all $k \in \mathcal{N}$, $\|e_k\| \leq (1 + \kappa_2\Delta s)^N \|e_0\| + \kappa_3'\Delta \leq \kappa\Delta$. This proves (4.18a).

(ii) Order of Convergence. We prove (4.18c) in two steps. First suppose that $H_N = H_N^1 = \mathbb{R}^n \times L_N^1$ and let $\eta_1 = (\xi, u_1) \in S \cap H_N^1$ be given. The expansion based on higher order derivatives (see [8]) needed to prove (4.18c) requires smoothness of $h(x, u)$ between time steps. The stated assumptions provide enough smoothness if uniform piecewise smoothness of $u_1(\cdot)$ is assumed. Alternatively, the result can also be shown to hold without this assumption on u_1 if the differential equations describing the system dynamics are linear and time-invariant with respect to u (as in Remark A.2). In either case, using the same type of reasoning as in the proof of Lemma A.1, we conclude that there exists $\kappa < \infty$, independent of η, such that (4.18c) holds for representation R1. Next, to prove (4.18c) for representation R2, let $H_N = H_N^2 = \mathbb{R}^n \times L_N^2$. Let $\eta_2 = (\xi, u_2) \in S \cap H_N^2$ be given, and let $\eta_1 = (\xi, u_1) \in H_N^1$ with

$u_1 = (V^1_{\mathbf{A},N})^{-1}(V^2_{\mathbf{A},N}(u_2))$ so that $V^1_{\mathbf{A},N}(u_1) = V^2_{\mathbf{A},N}(u_2)$. Then for any $t \in [0, 1]$,

$$\begin{aligned}\|x^{\eta_1}(t) - x^{\eta_2}(t)\| &= \left\| \int_0^t h(x^{\eta_1}(s), u_1(s)) - h(x^{\eta_2}(s), u_2(s))\, ds \right\| \\ &\le \left\| \int_0^t \tilde{h}(x^{\eta_1}(s)) - \tilde{h}(x^{\eta_2}(s)) + B(u_1(s) - u_2(s))\, ds \right\| \\ &\le \kappa_1 \int_0^t \|x^{\eta_1}(s) - x^{\eta_2}(s)\|\, ds + \left\| \int_0^t B(u_1(s) - u_2(s))\, ds \right\|, \end{aligned} \tag{A.10a}$$

by Assumption 3.1(a). Using the Bellman–Gronwall lemma, we conclude that for any $t \in [0, 1]$

$$\|x^{\eta_1}(t) - x^{\eta_2}(t)\| \le \kappa_1 e^{\kappa_1} \|B\| \left\| \int_0^t (u_1(s) - u_2(s))\, ds \right\|. \tag{A.10b}$$

Now, let $\dot{z}^1(t) \triangleq u_1(t)$, $t \in [0, 1]$, $z^1(0) = \xi$ and $\dot{z}^2(t) \triangleq u_2(t)$, $t \in [0, 1]$, $z^2(0) = \xi$. Let $\bar{z}^1_k$ and $\bar{z}^2_k$, $k \in \mathcal{N}$, be the computed solutions of $z^1(t)$ and $z^2(t)$, respectively, using the RK method under consideration. We note that $\bar{z}^1_k = \bar{z}^2_k$ for all $k \in \mathcal{N}$ since $V^1_{\mathbf{A},N}(u_1) = V^2_{\mathbf{A},N}(u_2)$. Then, since u^1 is an rth-order polynomial, any pth-order RK method, $p \ge r$, integrates $\dot{z}^1(t)$ exactly. Thus $\bar{z}^1_k = z^1(t_k)$ for all $k \in \mathcal{N}$. Also, from (4.3a,b),

$$\bar{z}^2_{k+1} = \bar{z}^2_k + \sum_{i=1}^{s} b_i u_2[\tau_{k,i}] = \bar{z}^2_k + \sum_{j=1}^{r} \int_{t_k + d_{j-1}}^{t_k + d_j} u_2(s)\, ds = z^2(t_{k+1}), \tag{A.10c}$$

since $\tau_{k,j} \in [\tau_k + d_{j-1}, t_k + d_j)$ (by Assumption 4.6) with $u_2(\cdot)$ constant on these intervals and $d_r = \Delta$ by Assumption 4.1′. Since $\bar{z}^1_k = \bar{z}^2_k$, we must have

$$z^1(t_k) - z^2(t_k) = \bar{z}^1_k - \bar{z}^2_k = 0 \quad \forall k \in \mathcal{N}. \tag{A.10d}$$

Hence, we conclude that

$$\left\| \int_0^{t_k} (u_1(s) - u_2(s))\, ds \right\| = \|z^1(t_k) - z^2(t_k)\| = 0. \tag{A.10e}$$

Therefore,

$$\|x^{\eta_2}(t_k) - \bar{x}^{\eta_2}_k\| \le \|x^{\eta_2}(t_k) - x^{\eta_1}(t_k)\| + \|x^{\eta_1}(t_k) - \bar{x}^{\eta_1}_k\| + \|\bar{x}^{\eta_1}_k - \bar{x}^{\eta_2}_k\| \le \kappa'/N^\rho \quad \forall k \in \mathcal{N}, \tag{A.10f}$$

where we have used (A.10b) and (A.10e), the fact that $\|x^{\eta_1}(t_k) - \bar{x}^{\eta_1}_k\| \le \kappa_2/N^\rho$ since (4.18c) holds for $\eta_1 \in S \cap H^1_N$ by the first part of this discussion, and the fact that $\bar{x}^{\eta_1}_k = \bar{x}^{\eta_2}_k$ since $u_1[\tau_{k,i}] = u_2[\tau_{k,i}]$. Thus (4.18c) holds for representation R2 under the stated conditions. □

LEMMA A.4. *Suppose that Assumptions* 3.1, 4.1′, *and* 4.3 *hold for representation* R1 *and that Assumptions* 3.1, 4.1′, *and* 4.6 *hold for representation* R2. *For any* $S \subset \mathbf{B}$ *bounded, there exist* $\kappa < \infty$ *and* $N^* < \infty$ *such that for any* $\eta \in S \cap \mathbf{H}_N$ *and* $N \ge N^*$

$$\|\bar{p}^\nu_k - p^\nu(t_k)\| \le \frac{\kappa}{N}, \qquad k \in \{0, \ldots, N\},\ \nu \in \mathbf{q}, \tag{A.11}$$

where $p^\nu(\cdot)$ *is the solution to the adjoint differential equation* (3.6c) *and* $\{\bar{p}^\nu_k\}_{k=0}^N$ *is the solution to the corresponding adjoint difference equation* (5.5d).

Proof. Proceeding as in the proof of Lemma 4.10(i), if we define $e_{k+1} \triangleq \bar{p}^{\nu}_{k+1} - p^{\nu}(t_{k+1})$ we can show that

$$\|e_k\| \leq L_1\|e_{k+1}\| + L_2\Delta^2, \qquad k \in \mathcal{N}, \tag{A.12}$$

where $L_1, L_2 < \infty$, using (i) the fact that

$$\bar{p}^{\nu}_k = F_x(\bar{x}_k, \bar{u}_k)^T \bar{p}_{k+1} = \bar{p}^{\nu}_{k+1} + \Delta \sum_{i=1}^{s} b_i h_x(\bar{x}_k, u[\tau_{k,i}])^T \bar{p}_{k+1} + O(\Delta^2), \tag{A.13}$$

(ii) Lemma A.1 with $h(x(t_k), u[\tau_{k,i}])$ replaced by $-h_x(x(t_k), u[\tau_{k,i}])^T p^{\nu}(t_{k+1})$, and (iii) the result of Lemma 4.10(i) that $\|x(t_k) - \bar{x}_k\| \leq \kappa\Delta$ for all $k \in \mathcal{N}$. Now, by Assumption 3.1(b) and Lemma 4.10(i), there exists $\kappa_1 < \infty$ such that

$$\|e_N\| = \|\bar{p}^{\nu}_N - p^{\nu}(1)\| \leq \|\zeta_x(\xi, \bar{x}_N)^T - \zeta_x(\xi, x(1))^T\| \leq \kappa_1\|\bar{x}_N - x(1)\| \leq \kappa_2\Delta, \tag{A.14}$$

where $\kappa_2 = \kappa\kappa_1$. Thus, solving (A.15) we conclude that for all $k \in \mathcal{N}$,

$$\|e_k\| \leq (L_1)^N\|e_N\| + L_2'\Delta,$$

which, with (A.17), proves (A.14). □

Acknowledgments. We wish to thank the referees and associate editor for carefully reading this paper, for pointing out an error in one of our proofs, and for their suggestions for improving readability.

Note added in proof. The following conjecture concerns the constraints on $\|\bar{u}_k T_j\|_{\infty}$ used to define $\overline{\mathbf{U}}^1_N$ in (4.15a). Recall from Remark 4.9 that these constraints impose a Lipschitz continuity constraint on the individual polynomial pieces of $u \in \mathbf{U}^1_N = V^{-1}_{\mathbf{A},N}(\overline{\mathbf{U}}^1_N)$ that is needed to ensure accurate RK integration for controls defined by representation R1. Clearly, the addition of these constraints, which do not appear in the original problem **CP**, is a nuisance. Conjecture 5.11 proposes conditions under which these constraints are not needed to define consistent approximating problems $(\mathbf{CP}_N, \theta_N)$ using control representation R1. Assumption 4.6 (needed for control representation R2) is required in place of Assumption 4.3.

CONJECTURE 5.11. *Suppose that the approximating problems* $\mathbf{CP}_N$ *are defined according to* (4.17a) *with* $\mathbf{H}_N \doteq \mathbb{R} \times V^{-1}_{\mathbf{A},N}(\overline{\mathbf{U}}^1_N)$, *where*

$$\overline{\mathbf{U}}^1_N \doteq \{\bar{u} \in \bar{L}^1_N | \bar{u}^j_k \in U \ \forall j \in \mathbf{r}, k \in \mathcal{N}\}. \tag{5.23}$$

Furthermore, assume that Assumptions 3.1, 4.1′, 4.6, *and* 4.11 *and* (5.18) *hold. Let* $\mathbf{N} = \{2^l\}_{l=1}^{\infty}$. *Then the approximating pairs* $(\mathbf{CP}_N, \theta_N)$, $N \in \mathbf{N}$, *are consistent approximations to the pair* $(\mathbf{CP}, \theta)$. □

The basis for this conjecture is the fact that, according to Proposition 5.5, the control samples of the approximating problem solutions do not depend on the control representation and consistency for approximating problems defined with control representation R2 does not require a piecewise Lipschitz continuity contraint on the controls. More details are provided in [28].

ON L^2 SUFFICIENT CONDITIONS AND THE GRADIENT PROJECTION METHOD FOR OPTIMAL CONTROL PROBLEMS*

J. C. DUNN†

Abstract. L^2-local convergence and active constraint identification theorems are proved for gradient projection iterates in sets of L^∞ functions on [0, 1] with range in a polyhedron $U \subset \mathbb{R}^m$. These theorems extend earlier results for $U = [0, \infty) \subset \mathbb{R}^1$ and are based on an infinite-dimensional variant of the Karush–Kuhn–Tucker second-order sufficient conditions in polyhedral subsets of $\mathbb{R}^n$. The new sufficient conditions and convergence results proved here are directly applicable to continuous-time optimal control problems with smooth nonconvex nonquadratic objective functions and Hamiltonians that are quadratic in the control input vector u. In particular, these theorems apply to nonconvex nonquadratic regulator problems with control-linear state equations and vector-valued inputs $u(t)$ satisfying unqualified affine inequality constraints at almost all t in [0, 1].

Key words. gradient projection, infinite-dimensional programs, affine inequality constraints, nonconvex objectives, L^2-local optimality, second-order sufficient conditions, L^2-local convergence, active constraint identification, optimal control, constrained inputs

AMS subject classifications. 49M07, 49M10, 49K15, 65K10, 90C06

1. Introduction.

Infinite-dimensional extensions of the Karush–Kuhn–Tucker (KKT) second-order sufficient conditions in nonnegative orthants are closely linked to the local convergence properties of gradient projection iterates in the cone of nonnegative L^2 functions [1]–[3]. Similar L^2-local convergence and active constraint identification theorems are based here on second-order sufficient conditions related to those in [4] for infinite-dimensional constrained minimization problems

$$\min_{\Omega} J(u), \tag{1.1a}$$

$$\Omega = \{u \in L^\infty_m[0, 1] : u(t) \overset{\text{a.e.}}{\in} U\}, \tag{1.1b}$$

where U is a nonempty polyhedral convex set in $\mathbb{R}^m$, $L^\infty_m[0, 1]$ is the vector space of essentially bounded measurable functions $u : [0, 1] \to \mathbb{R}^m$, and J is a nonconvex real-valued function with first and second Gâteaux differentials satisfying structure and continuity assumptions that are justifiable in a control-theoretic context, as explained below and in [2].

We assume that for all u in $L^\infty_m[0, 1]$, there exist $\phi(u) \in L^\infty_m[0, 1]$, $S(u) \in L^\infty_{m\times m}[0, 1]$, and $\mathcal{K}(u) \in L^2_{m\times m}([0, 1] \times [0, 1])$, such that

$$d^1J(u\,;\,v) = \langle \nabla J(u), v\rangle_2 = \int_0^1 \langle \nabla J(u)(t), v(t)\rangle dt, \tag{1.2a}$$

$$\nabla J(u)(t) = \phi(u)(t) + S(u)(t)u(t), \tag{1.2b}$$

$$d^2J(u\,;\,v, w) = \langle v, \nabla^2 J(u)w\rangle_2 = \int_0^1 \langle v(t), (\nabla^2 J(u)w)(t)\rangle dt, \tag{1.3a}$$

$$(\nabla^2 J(u)v)(t) = S(u)(t)v(t) + \int_0^1 \mathcal{K}(u)(t, s)v(s)ds, \tag{1.3b}$$

*Received by the editors April 15, 1994; accepted for publication (in revised form) March 9, 1995. This research was supported by NSF research grant DMS-9205240.

†Mathematics Department, Box 8205, North Carolina State University, Raleigh, NC 27695-8205.

for all v and w in $L_m^\infty[0, 1]$, and almost all t in $[0, 1]$ and (s, t) in $[0, 1] \times [0, 1]$, with

$$\lim_{\|v-u\|_2 \to 0} \|\phi(v) - \phi(u)\|_\infty \overset{\text{def}}{=} \lim_{\|v-u\|_2 \to 0} \operatorname{ess\,sup}_{t \in [0,1]} \|\phi(v)(t) - \phi(u)(t)\| = 0, \tag{1.4a}$$

$$\lim_{\|v-u\|_2 \to 0} \|S(v) - S(u)\|_\infty \overset{\text{def}}{=} \lim_{\|v-u\|_2 \to 0} \operatorname{ess\,sup}_{t \in [0,1]} \|S(v)(t) - S(u)(t)\| = 0, \tag{1.4b}$$

(1.4c)

$$\lim_{\|v-u\|_2 \to 0} \|\mathcal{K}(v) - \mathcal{K}(u)\|_2 \overset{\text{def}}{=} \lim_{\|v-u\|_2 \to 0} \left(\int_0^1 \int_0^1 \|\mathcal{K}(v)(t, s) - \mathcal{K}(u)(t, s)\|^2 dt ds \right)^{\frac{1}{2}} = 0.$$

We also assume that the $m \times m$ matrices $S(u)(t)$ and $\mathcal{K}(u)(t, s)$ are symmetric with $\mathcal{K}(u)(t, s) = \mathcal{K}(u)(s, t)$ and that the vector and matrix norms on $\mathbb{R}^m$ and $\mathbb{R}^{m \times m}$ in (1.2)–(1.4) are induced by the standard Euclidean inner product $\langle \xi, \eta \rangle = \sum_{i=1}^m \xi_i \eta_i$ on $\mathbb{R}^m$. Portions of these conditions are invoked in the L^2-local optimality sufficiency analysis of [4] and the convergence analysis of [2]; together, they insure that J is twice continuously Fréchet differentiable on the pre-Hilbert space $\{L_m^\infty[0, 1], \|\cdot\|_2\}$ and permit infinite-dimensional extensions of established proof strategies for sufficient conditions, active constraint identification theorems, and local convergence theorems for gradient projection iterations in polyhedral subsets of $\mathbb{R}^m$.

Section 6 in [2] shows that conditions (1.2)–(1.4) are met by a large class of continuous-time optimal control problems with Bolza objective functions

$$J(u) = P(x(u)(1)) + \int_0^1 f_0(t, x(u)(t), u(t))\, dt, \tag{1.5a}$$

where $x(u) : [0, 1] \to \mathbb{R}^n$ is the unique (absolutely continuous) solution of an initial value problem

$$\frac{dx}{dt}(t) \overset{\text{a.e.}}{=} f(t, x(t), u(t)), \tag{1.5b}$$

$$x(0) = x^0, \tag{1.5c}$$

corresponding to u in $L_m^\infty[0, 1]$. In these equations, x^0 is fixed in $\mathbb{R}^n$, and the functions P, f, and f_0 map $\mathbb{R}^n$ to $\mathbb{R}^1$, $(\mathbb{R}^1 \times \mathbb{R}^n \times \mathbb{R}^m)$ to $\mathbb{R}^n$, and $(\mathbb{R}^1 \times \mathbb{R}^n \times \mathbb{R}^m)$ to $\mathbb{R}^1$, respectively, and satisfy suitable smoothness and growth restrictions. In particular, conditions (1.2)–(1.4) are implied by Assumptions A1–A3 in [2], repeated below (or analogous weaker assumptions of the Carathéodory type [40]).

ASSUMPTION 1.1.

(i) *P is twice continuously differentiable.*

(ii) *For $i = 0, \ldots, n$,*

$$f_i(t, x, u) = q_i(t, x) + \langle r_i(t, x), u \rangle + \frac{1}{2} \langle u, s_i(t, x)u \rangle,$$

where $s_i(t, x) \in \mathbb{R}^{m \times m}$ is symmetric, and the functions $q_i : \mathbb{R}^1 \times \mathbb{R}^n \to \mathbb{R}^1$, $r_i : \mathbb{R}^1 \times \mathbb{R}^n \to \mathbb{R}^m$, and $s_i : \mathbb{R}^1 \times \mathbb{R}^n \to \mathbb{R}^{m \times m}$ and their first and second partial derivatives with respect to x are continuous on $\mathbb{R}^1 \times \mathbb{R}^n$.

(iii) *For $i = 1, \ldots, n$, the first partial derivatives of q_i, r_i, and s_i with respect to x are bounded on $\mathbb{R}^1 \times \mathbb{R}^n$.*

In such cases, conditions (1.2)–(1.4) hold with $\phi(u)(t)$, $S(u)(t)$, and $\mathcal{K}(u)(t, s)$ obtained from partial Hessians of the Hamiltonian

$$H(t, \psi, x, u) = \langle \psi, f(t, x, u) \rangle + f_0(t, x, u),$$

solutions $\psi(u)$ of the costate (adjoint) equations

$$\frac{d\psi}{dt}(t) \overset{\text{a.e.}}{=} -\frac{\partial f}{\partial x}(t, x(t), u(t))^t \psi - \nabla f_0(t, x(t), u(t)),$$
$$\psi(1) = \nabla P(x(u)(1)),$$

and fundamental solution matrices of the equations of variation for (1.5b) [2]. More specifically, Assumption 1.1 implies that conditions (1.2)–(1.4) hold with

$$\begin{aligned} S(u)(t) &= \nabla_{uu} H(t, \psi(u)(t), x(u)(t), u(t)) \\ &= s_0(t, x(u)(t)) + \sum_{i=1}^{n} \psi_i(u)(t) s_i(t, x(u)(t)), \\ \nabla J(u)(t) &= \nabla_u H(t, \psi(u)(t), x(u)(t), u(t)) \\ &= \phi(u)(t) + S(u)(t)u(t), \end{aligned}$$

where

$$\phi(u)(t) = r_0(t, x(u)(t)) + \sum_{i=1}^{n} \psi_i(u)(t) r_i(t, x(u)(t)).$$

In these expressions, the symbols ψ, x, and u refer to vectors in $\mathbb{R}^n$ or $\mathbb{R}^m$ when they appear in $H(t, \psi, x, u)$, $\nabla_u H(t, \psi, x, u)$, and $\nabla_{uu} H(t, \psi, x, u)$ and to vector-valued *functions* on $[0, 1]$ with range in $\mathbb{R}^n$ or $\mathbb{R}^m$ when they appear in $\psi(u)$ and $x(u)$. Note that the structure condition in Assumption 1.1(ii) holds iff H is quadratic in the control input vector $u \in \mathbb{R}^m$; this happens for the important subclass of Bolza problems with nonconvex control-quadratic running costs f_0 and control-linear state equations (where 1.1(ii) holds with $s_i(t, x) = 0$, for $i = 1, \ldots, n$). Note also that Assumption 1.1 can be weakened if conditions (1.2)–(1.4) are needed only in some L^2 neighborhood of a function u_* for which unique solutions $x(u_*)$ and $\psi(u_*)$ of the state and costate equations are already known to exist. Local versions of (1.2)–(1.4) are actually enough for the local optimality conditions in §4 (cf. [4]) and the local convergence analysis in §§5 and 6. We impose (1.2)–(1.4) in their global form to simplify the exposition.

The gradient projection scheme investigated here employs a Goldstein–Levitin–Polyak iteration map [5], [6] and Bertsekas step length rule [7], i.e.,

$$u \to G(u) = g(a(u), u), \tag{1.6a}$$

$$g(a, u) = P_\Omega(u - a\nabla J(u)), \tag{1.6b}$$

with

$$a(u) = \min a \tag{1.6c}$$

subject to

$$a \in \{\overline{a}, \overline{a}\beta, \overline{a}\beta^2, \ldots\} \tag{1.6d}$$

and

$$J(u) - J(g(a, u)) \geq \sigma \langle \nabla J(u), u - g(a, u) \rangle_2, \tag{1.6e}$$

where $\overline{a}$ is fixed in $(0, \infty)$, σ and β are fixed in $(0, 1)$, and P_Ω is the L^2 metric projection map for Ω. The map P_Ω exists for the set Ω in (1.1b), even though $\{\mathsf{L}^\infty_m[0, 1], \|\cdot\|_2\}$ is incomplete. To see this, note that P_U is continuous and nonexpansive and satisfies the Euclidean minimum distance condition

$$\|u - P_U u\| = \min_{\xi \in U} \|u - \xi\|,$$

for all u in $\mathbb{R}^m$. Hence, the rule

$$v(t) \overset{\text{a.e.}}{=} P_U(u(t)) \tag{1.7}$$

defines a mapping from $L_m^\infty[0, 1]$ to Ω that satisfies the L^2 minimum distance condition

$$\|u - v\|_2 = \min_{\xi \in \Omega} \|u - \xi\|_2,$$

for all u in $L_m^\infty[0, 1]$ and v defined by (1.7). Even in a pre-Hilbert space, there is at most one such v for each u; hence $v = P_\Omega u$ and

$$(P_\Omega u)(t) \overset{\text{a.e.}}{=} P_U(u(t)) \tag{1.8}$$

(cf. the projection theorem proof in [8]). We can now see that if $\nabla J(u)$ is in $L_m^\infty[0, 1]$ for all u in $L_m^\infty[0, 1]$, then $g(a, \cdot)$ is defined for all $a > 0$. Finally, if $\nabla J(\cdot)$ is continuous with respect to the L^2 metric, then the Bertsekas step length $a(u)$ also exists (the Hilbert space proof for this assertion in [9] does not depend on completeness and transfers directly to $\{L_m^\infty[0, 1], \|\cdot\|_2\}$).

In view of (1.8), the projection operator P_Ω is readily computed for (1.1b) when U is an orthant, box, simplex, or some such simple polyhedral set, as is often the case for optimal control problems; moreover, the required gradients are also often cheaply computed for the specially structured objective functions J in optimal control problems. Under these circumstances, the efficacy of a gradient projection method turns on the convergence behavior of its approximate or asymptotically exact implementations in finite-dimensional subspaces converging to $L_m^\infty[0, 1]$ from below. Computational experience [23], [29] and some theoretical studies [24]–[29] show that convergence theories for the underlying infinite-dimensional algorithm can play an important role in predicting this behavior, particularly when new *qualitative* differences emerge in the infinite-dimensional limit. In the present context, L^2-local and L^∞-local convergence theorems are qualitatively different in $L_m^\infty[0, 1]$, and this fact has definite *quantitative* computational implications even though all norms are (qualitatively) equivalent on $\mathbb{R}^n$ (see [23] and the opening paragraphs in §5).

The convergence analysis in §§5 and 6 proceeds from certain fundamental geometric properties of the solution sets of finite systems of affine inequalities in $\mathbb{R}^m$, i.e., the polyhedral convex sets

$$U = \{u \in \mathbb{R}^m : \langle a_i, u\rangle + b_i \leq 0;\ i = 1, \ldots, k\}. \tag{1.9}$$

These properties are derived from the algebraic representation (1.9); however, (1.9) itself is not needed and does not appear explicitly in our theorems or proofs. As in [26], [30], [31], [4], key proof ideas are more readily grasped (and discovered) in this geometric framework, and constraint qualifications are not required. In §2 we give the pertinent properties of polyhedral convex sets $U \subset \mathbb{R}^m$, and in §3 we sketch the proofs of second-order optimality conditions and local convergence theorems for gradient projection iterates in polyhedra. The geometric sufficiency proof strategy outlined in §3 is then adapted in §4 to the specially structured infinite-dimensional programs (1.1) satisfying (1.2)–(1.4). The resulting second-order sufficient conditions for L^2-local optimality in Theorem 4.1 consist of an L^2-coercivity restriction on $\nabla^2 J$ formally analogous to the standard coercivity condition in polyhedra, a norm-independent pointwise counterpart of strict complementarity in Cartesian products of polyhedra, and a third requirement that amounts to a stronger version of Pontryagin's necessary condition in the ordinary differential equation (ODE) control problem context.

Theorem 4.1 adds significantly to the L^2-local sufficiency analysis in [4]. In [4], a two-norm L^∞-local optimality growth estimate of the form

$$\exists \delta_\infty, c_\infty > 0\ \forall u \in \Omega\ \left(\|u - u_*\|_\infty < \delta_\infty \Rightarrow J(u) - J(u_*) \geq c_\infty \|u - u_*\|_2^2\right) \tag{1.10}$$

is deduced from the L^2-coercivity condition, a weakened L^∞ strict complementarity condition, and additional technical constraints imposed near point τ in [0, 1], where $u_*(t)$ passes from one open facet in the polyhedron U to another. The growth condition (1.10) then appears along with the strengthened Pontryagin condition as a *hypothesis* in the L^2-local optimality sufficiency theorem in [4]. In contrast, the proof technique employed here permits weaker regularity hypotheses and strict complementarity conditions by fully exploiting the Pontryagin condition. For additional ground-breaking L^∞-local optimality sufficiency theorems and related applications, see [10]–[22].

The convergence theorem in §5 and the active constraint identification theorem in §6 are based directly on a corollary of Theorem 4.1 that applies when the matrices $S(u_*)(t)$ are essentially uniformly positive-definite on [0, 1] at a minimizer u_*, i.e., when there is a positive number c_P such that

$$(1.11) \qquad \left(\forall \xi \in \mathbb{R}^m \quad \langle \xi, S(u_*)(t)\xi \rangle \geq c_P \|\xi\|^2\right) \qquad \text{a.e. in } [0, 1].$$

Condition (1.11) is a natural requirement for nonconvex regulator problems with control-quadratic running costs and control-linear state equations. For such problems,

$$S(u)(t) = \nabla^2_{uu} H(t, \psi(u)(t), x(u)(t), u(t)) = s_0(t, x(u)(t)),$$

and s_0 is often *constant* or dependent on t only. An example in [23] shows that the weaker Pontryagin-like hypothesis imposed in Theorem 4.1 will not support an L^2-local convergence theory for gradient projection methods, hence (1.11) assumes a special importance for these algorithms. In the control problem context, (1.11) is a strong variant of Legendre's necessary condition.

2. Polyhedra. Each nonempty polyhedron U in (1.9) is a union of d polyhedral faces $\mathcal{F}_1, \ldots, \mathcal{F}_d$. Let $aff\ \mathcal{F}_i$ denote the *affine hull* of $\mathcal{F}_i$, i.e., the smallest linear variety (translated subspace) containing $\mathcal{F}_i$. Let $ri\ \mathcal{F}_i$ and $rb\ \mathcal{F}_i$ denote the *relative interior* and *relative boundary* of $\mathcal{F}_i$, i.e., the interior and boundary of $\mathcal{F}_i$ relative to $aff\ \mathcal{F}_i$. It is shown in [32] that the sets $ri\ \mathcal{F}_i$ make a partition for U, i.e.,

$$(2.12a) \qquad U = \bigcup_{i=1}^{d} ri\ \mathcal{F}_i,$$

$$(2.12b) \qquad ri\ \mathcal{F}_i \cap ri\ \mathcal{F}_j = \emptyset, \qquad i \neq j.$$

In [17], the sets $ri\ \mathcal{F}_i$ are called *open facets*.

At each u in U, let $\mathcal{F}(u)$ be the unique face in $\{\mathcal{F}_1, \ldots, \mathcal{F}_d\}$ containing u in its relative interior, and let $\mathcal{N}_U(u)$ be the corresponding *normal cone*:

$$\mathcal{N}_U(u) = \{w \in \mathbb{R}^m : \forall v \in U \quad \langle w, v - u \rangle \leq 0\},$$

with

$$\mathsf{N}(u) = span\ \mathcal{N}_U(u), \qquad \mathsf{T}(u) = \mathsf{N}(u)^\perp.$$

In polyhedra U, the set-valued maps $\mathcal{N}_U(\cdot)$, $\mathsf{N}(\cdot)$, and $\mathsf{T}(\cdot)$ are *constant* on each open facet $ri\ \mathcal{F}_i$ [30], [31], i.e., there exist cones $\mathcal{N}_1, \ldots, \mathcal{N}_d$ and subspace pairs $(\mathsf{N}_1, \mathsf{T}_1), \ldots, (\mathsf{N}_d, \mathsf{T}_d)$ such that

$$(2.13a) \qquad \mathcal{N}_U(u) = \mathcal{N}_i, \qquad \mathsf{N}(u) = \mathsf{N}_i, \qquad \mathsf{T}(u) = \mathsf{T}_i,$$

for all $i = 1, \ldots, d$ and u in $ri\ \mathcal{F}_i$; moreover,

$$aff\ \mathcal{F}_i = u + \mathsf{T}_i \tag{2.13b}$$

and

$$\mathcal{F}_i = (u + \mathsf{T}_i) \cap U. \tag{2.13c}$$

The partition (2.12) and the Euclidean projection map P_U induce a corresponding partition of $\mathbb{R}^m$ that plays a central role in geometric characterizations of the convergence behavior of gradient projection iterates in polyhedra [30], [31] and in the sets (1.1b) considered here. For nonempty polyhedra U, the projection theorem asserts that P_U is defined on $\mathbb{R}^m$ and that

$$u = P_U(x) \quad \Leftrightarrow \quad x - u \in \mathcal{N}_U(u),$$

for all x in $\mathbb{R}^m$ and u in U. Hence (2.12) implies that

$$P_U^{-1}[ri\ \mathcal{F}_i] = ri\ \mathcal{F}_i + \mathcal{N}_i$$

for $i = 1, \ldots, d$, and therefore

$$\mathbb{R}^m = \bigcup_{i=1}^{d} (ri\ \mathcal{F}_i + \mathcal{N}_i),$$

with

$$(ri\ \mathcal{F}_i + \mathcal{N}_i) \cap (ri\ \mathcal{F}_j + \mathcal{N}_j) = \emptyset, \qquad i \neq j.$$

Furthermore, each of the sets $P_U^{-1}[ri\ \mathcal{F}_i]$ has a nonempty interior in $\mathbb{R}^m$ obtained by adding the relative interiors of $\mathcal{F}_i$ and $\mathcal{N}_i$. This essential fact is noted in [33] and restated below in our first lemma; a closely related result is proved in [31].

For $x \in \mathbb{R}^m$, $Y \subset \mathbb{R}^m$, and $r \geq 0$, let $dist\ (x, Y) = \inf_{y \in Y} \|y - x\|$ and $\overline{B(x; r)} = \{y \in \mathbb{R}^m : \|y - x\| \leq r\}$. For all y in Y, it can be seen that

$$dist\ (y, rb\ Y) = \sup\{r \geq 0 : \overline{B(y; r)} \cap aff\ Y \subset Y\},$$

with $dist\ (y, rb\ Y) > 0$ for all y in $ri\ Y$.

LEMMA 2.1. *Let U be a polyhedral convex set in $\mathbb{R}^m$ with faces $\mathcal{F}_1, \ldots, \mathcal{F}_d$. Then for $i = 1, \ldots, d$,*

$$\operatorname{int} P_U^{-1}[ri\ \mathcal{F}_i] = ri\ \mathcal{F}_i + ri\ \mathcal{N}_i.$$

Moreover, suppose that $u \in ri\ \mathcal{F}_i$, $v \in ri\ \mathcal{N}_i$, $w = u + v$, and $\Delta w \in \mathbb{R}^m$, with

$$\|\Delta w\| < s = \min\{dist\ (u, rb\ \mathcal{F}_i), dist\ (v, rb\ \mathcal{N}_i)\}.$$

Then $P_U(w + \Delta w) \in ri\ \mathcal{F}_i$ and $dist\ (P_U(w + \Delta w), rb\ \mathcal{F}_i) \geq s - \|\Delta w\|$.

Proof. Suppose that $\Delta w \in \mathbb{R}^m$ and $\|\Delta w\| < s$. Write $w + \Delta w = x + y$, with $x = u + P_{\mathsf{T}_i} \Delta w$ and $y = v + P_{\mathsf{N}_i} \Delta w$. Note that $\|P_{\mathsf{T}_i} \Delta w\| < \|\Delta w\|$ and $\|P_{\mathsf{N}_i} \Delta w\| < \|\Delta w\|$. Hence $x \in ri\ \mathcal{F}_i$, $y \in ri\ \mathcal{N}_i$, and therefore $x = P_U(w + \Delta w)$. This proves that $dist\ (P_U(w + \Delta w), rb\ \mathcal{F}_i) \geq s - \|\Delta w\|$ and that $ri\ \mathcal{F}_i + ri\ \mathcal{N}_i \subset \operatorname{int} P_U^{-1}[ri\ \mathcal{F}_i]$.

Conversely, suppose that $w \in \operatorname{int} P_U^{-1}[ri\ \mathcal{F}_i]$. Then there exist vectors $u \in ri\ \mathcal{F}_i$ and $v \in \mathcal{N}_i$, and a real number $r > 0$, such that $w = u + v$ and $(w + \Delta v) \in P_U^{-1}[ri\ \mathcal{F}_i]$ for all

$\Delta v \in \mathsf{N}_i$, with $\|\Delta v\| < r$. Now note that if $\Delta v \in \mathsf{N}_i$ and $P_U(u + v + \Delta v) = u' \in ri\ \mathcal{F}_i$, then $(u + v + \Delta v - u') \in \mathcal{N}_U(u') = \mathcal{N}_i \subset \mathsf{N}_i$, with $(u - u') \in \mathsf{T}_i$ and $(v + \Delta v) \in \mathsf{N}_i$. But in this case, $(u - u') = 0$ and $(v + \Delta v) \in \mathcal{N}_i$. This proves that $v \in ri\ \mathcal{N}_i$ and hence $ri\ \mathcal{F}_i + ri\ \mathcal{N}_i \supset \text{int}\ P_U^{-1}[ri\ \mathcal{F}_i]$. □

Note 2.1. Theorem 2.8 in [31] asserts that int $(\mathcal{F}_i + \mathcal{N}_i) = ri\ \mathcal{F}_i + ri\ \mathcal{N}_i$. The first part of Lemma 2.1 is a corollary of this result; however, the sets $P_U^{-1}[ri\ \mathcal{F}_i]$ have a more immediate intuitive significance for our analysis, and the direct proof for Lemma 2.1 given here is shorter than the proof in [31].

3. Optimality conditions and convergence theorems in polyhedra. In polyhedral sets $U \subset \mathbb{R}^m$, the essential contents of the KKT optimality conditions and the local convergence theorems for gradient projection iterates are best expressed in a representation-free, multiplier-free geometric language. We pursue this further below to motivate proof constructions for the set Ω in (1.1), which is in some sense an infinite-dimensional limit of k-fold polyhedral Cartesian products $\Omega_k = U \times \cdots \times U$.

If $J : \mathbb{R}^m \to \mathbb{R}^1$ is twice continuously differentiable and if u_* is a local minimizer for J in the polyhedron $U \subset \mathbb{R}^m$, then

$$-\nabla J(u_*) \in \mathcal{N}_U(u_*), \tag{3.14a}$$

$$\forall v \in \mathsf{T}(u_*) \quad \langle v, \nabla^2 J(u_*)v\rangle \geq 0. \tag{3.14b}$$

Conversely, if

$$-\nabla J(u_*) \in ri\ \mathcal{N}_U(u_*) \tag{3.15a}$$

and

$$\exists c_{\mathsf{T}} > 0\ \forall v \in \mathsf{T}(u_*) \quad \langle v, \nabla^2 J(u_*)v\rangle \geq c_{\mathsf{T}}\|v\|^2, \tag{3.15b}$$

then u_* is a local minimizer for J in U, and

$$\exists c > 0\ \exists \delta > 0\ \forall u \in U \cap B(u_*; \delta) \quad J(u) - J(u_*) \geq c\|u - u_*\|^2. \tag{3.16}$$

Local minimizers that satisfy the sufficient conditions (3.15) are said to be *nonsingular*.

If u_* lies in the interior of U in $\mathbb{R}^m$, then $ri\ \mathcal{N}_U(u_*) = rb\ \mathcal{N}_U(u_*) = \mathcal{N}_U(u_*) = \{0\}$, and (3.14b) and (3.15b) reduce to the standard second-order necessary condition and sufficient condition for unconstrained local minimizers. If u_* is a frontier point of U, then $ri\ \mathcal{N}_U(u_*)$ is a nonempty proper subset of $\mathcal{N}_U(u_*)$ and (3.15a) is stronger than (3.14a); however, $rb\ \mathcal{N}_U(u_*)$ is nowhere dense in the subspace $\mathsf{N}(u_*)$ and is negligibly small compared with $ri\ \mathcal{N}_U(u_*)$ in a measure-theoretic sense. Similarly, in $\mathbb{R}^m$, the coercivity condition (3.15b) is *equivalent* to the positive-definiteness condition

$$\forall v \in \mathsf{T}(u_*) \quad v \neq 0 \Rightarrow \langle v, \nabla^2 J(u_*)v\rangle > 0, \tag{3.17}$$

and positive-definiteness is generic in the class of linear operators that are positive-semidefinite on a subspace $T \subset \mathbb{R}^m$. In this sense, the gap between the standard necessary conditions (3.14) and sufficient conditions (3.15) is not large in a polyhedron $U \subset \mathbb{R}^m$. We note that the geometric nondegeneracy condition (3.15a) proposed in [30] is equivalent to algebraic strict complementarity in the KKT sufficient conditions [31].

The first-order necessary condition (3.14a) merely says that for all u in U, the corresponding directional derivatives $\langle \nabla J(u_*), u - u_*\rangle$ can't be negative if u_* is a local minimizer; this

is clearly true in *any* convex set U. Since $\mathsf{T}(u_*)$ is the orthogonal complement of $\mathcal{N}_U(u_*)$, it follows at once from (3.14a) that $\langle \nabla J(u_*), v\rangle = 0$ for all v in $\mathsf{T}(u_*)$. This result and the second-order necessary condition (3.14b) are also immediately seen by noting that u_* lies in one of the open facets $ri\ \mathcal{F}_i$, and hence u_* is a local minimizer for the restriction of J to the translated subspace $aff\ \mathcal{F}_i = u_* + \mathsf{T}_i = u_* + \mathsf{T}(u_*)$. The sufficiency of conditions (3.15) for local optimality likewise rests on two simple observations. By continuity, the second-order condition (3.15b) implies a similar coercivity condition in sufficiently small *cones* $C_\epsilon(u_*) = \{v \in \mathbb{R}^m : \|P_{\mathsf{N}(u_*)}\, v\| \le \epsilon\|v\|\}$ containing the subspace $\mathsf{T}(u_*)$. Hence, by Taylor's formula and (3.14a), the increments $J(u) - J(u_*)$ must grow like $\|u-u_*\|^2$ in the intersection of U with the translated cone $u_* + C_\epsilon(u_*)$ and sufficiently small balls $B(u_*, \delta) = \{u \in \mathbb{R}^m : \|u - u_*\| < \delta\}$. On the other hand, if $c_{\mathsf{N}} = dist\ (-\nabla J(u_*), rb\ \mathcal{N}_U(u_*))$, then it follows easily from the first-order condition (3.15a) that $\langle \nabla J(u_*), u - u_*\rangle \ge c_{\mathsf{N}}\ \|P_{\mathsf{N}(u_*)}\ (u - u_*)\|$ for all u in U. In particular, for all u_* in the intersection of U, $B(u_*; \delta)$, and $u_* + C_\epsilon(u_*)^c$, we then have $\langle \nabla J(u_*), u-u_*\rangle \ge \epsilon c_{\mathsf{N}}\|u-u_*\| \ge \epsilon c_{\mathsf{N}}\delta^{-1}\|u-u_*\|^2$. Since the second-order term in Taylor's formula is of order $O(\|u - u_*\|^2)$, it now follows that $J(u) - J(u_*)$ grows like $\|u - u_*\|^2$ in the intersection of U with $u_* + C_\epsilon(u_*)^c$ and $B(u_*, \delta)$, for sufficiently small $\delta > 0$. A similar argument is made in the proof of Theorem 4.1.

For polyhedral sets $U \subset \mathbb{R}^m$, the counterpart of the gradient projection iteration map in §1 is

$$u \to G(u) = g(a(u), u) = P_U(u - a(u)\nabla J(u)), \tag{3.18a}$$

with

$$a(u) = \min\ a \tag{3.18b}$$

subject to

$$a \in \{\overline{a}, \overline{a}\beta, \overline{a}\beta^2, \ldots\}, \tag{3.18c}$$

and

$$J(u) - J\ (g(a, u)) \ge \sigma\ \langle \nabla J(u), u - g(a, u)\rangle. \tag{3.18d}$$

The fundamental local convergence theorem for (3.18) asserts that an iterate sequence $\{u_i\}$ passing sufficiently close to a nonsingular local minimizer u_* will eventually enter and remain in the open facet $ri\ \mathcal{F}(u_*)$ and become an Armijo steepest descent sequence that converges to u_* r-linearly in the translated subspace $u_* + \mathsf{T}(u_*)$. The key elements in the proof for this theorem are already present in the analyses of [7], [36], [37], and [35] for iterates of (3.18) in the images of orthants and boxes under invertible linear transformations. Reference [30] provides a self-contained fully geometric representation-free expression of this proof strategy for arbitrary polyhedral sets and more generally for closed convex sets with embedded open facets. The salient points in the geometric proof for nonsingular local minimizers u_* in polyhedral sets U are outlined below, in the language of §2.

Proof Outline 3.1. (i) Iterate sequences $\{u_i\}$ generated by (3.18) remain in any specified neighborhood of u_* provided u_0 lies in a sufficiently small subneighborhood of u_* in U, i.e., u_* is a *stable* fixed point of the map (3.18).

(ii) The step lengths $a(u)$ are bounded away from 0 in U near u_*.

(iii) Since $\mathcal{N}_U(u_*)$ is a cone, the strict complementarity condition (3.15a), Lemma 2.1, and (ii) imply that $u - a(u)\nabla J(u) \in P_U^{-1}[ri\ \mathcal{F}(u_*)]$ and hence $G(u) \in ri\ \mathcal{F}(u_*)$ in U near u_*.

(iv) The coercivity condition (3.15b) implies that the restriction of J to $u_* + \mathsf{T}(u_*)$ is locally convex and grows like $\|u - u_*\|^2$ near u_*.

(v) In $ri\ \mathcal{F}(u_*)$ near u_*, $G(u) = u - a(u)P_{\mathsf{T}(u_*)}\nabla J(u)$ and G reduces to an unconstrained Armijo steepest descent iteration map for the restriction of J to $u_* + \mathsf{T}(u_*) \supset ri\ \mathcal{F}(u_*)$.

(vi) The Armijo steepest descent iteration in $u_* + \mathsf{T}(u_*)$ is locally linearly convergent to u_*.

Note 3.2. References [34] and [31] provide an active facet identification proof for C^1 cost functions J and arbitrary stationary points u_* satisfying the nondegeneracy condition (3.15a); however, this proof *assumes* that the iterate sequence $\{u_i\}$ converges to u_*. In contrast, the active facet identification step in the foregoing proof outline is used to *prove* convergence of iterate sequences confined to sufficiently small neighborhoods of u_*. Other local convergence proof strategies which do not require the active facet identification step are developed in [30] and [33] for C^1 cost functions and proper local minimizers that are isolated stationary points. Extensions of the basic local convergence theorem have been proved for gradient projection iterations in solution sets of finite systems of smooth inequality constraints [38] and in unions of pairwise disjoint class C^p-identifiable surfaces analogous to open facets [39].

4. L^2-Local optimality sufficient conditions. The normal cone $\mathcal{N}_U(u)$, the associated subspaces $\mathsf{N}(u)$ and $\mathsf{T}(u)$, and the optimality conditions in §3 all have formal counterparts for the set Ω in (1.1b). The formal necessary conditions are actually valid even though Ω is not a polyhedron [4]; however, infinite-dimensional formal counterparts of the KKT sufficient conditions need not imply local optimality in any norm [10] . These points are developed further below.

For u in $\mathsf{L}^\infty_m[0, 1]$ and t in $[0, 1]$ such that $u(t) \in U$, let

$$\mathsf{N}(u)(t) = span\ \mathcal{N}_U(u(t)), \qquad \mathsf{T}(u)(t) = \mathsf{N}(u)(t)^\perp$$

and put

$$\mathcal{N}_\Omega(u) = \{w \in \mathsf{L}^\infty_m[0, 1] : w(t) \overset{\text{a.e}}{\in} \mathcal{N}_U(u(t))\},$$

$$\mathsf{N}(u) = \{w \in \mathsf{L}^\infty_m[0, 1] : w(t) \overset{\text{a.e}}{\in} \mathsf{N}(u)(t)\},$$

$$\mathsf{T}(u) = \{w \in \mathsf{L}^\infty_m[0, 1] : w(t) \overset{\text{a.e}}{\in} \mathsf{T}(u)(t)\}.$$

In addition, let

$$\alpha_i(u) = u^{-1}[ri\ \mathcal{F}_i], \quad i = 1, \ldots, d,$$

where $\mathcal{F}_i$ is the ith polyhedral face in U. Note that for u in Ω, the corresponding sets $\alpha_i(u) \subset [0, 1]$ are measurable and pairwise disjoint, and their union differs from $[0, 1]$ by a set of measure zero; moreover, the set-valued maps $\mathcal{N}_U(u(\cdot))$, $\mathsf{N}(u)(\cdot)$, and $\mathsf{T}(u)(\cdot)$ are *constant* on each set $\alpha_i(u)$ (§2). It is therefore not difficult to prove that in the pre-Hilbert space $\{\mathsf{L}^\infty_m[0, 1], \|\cdot\|_2\}$, the set $\mathcal{N}_\Omega(u)$ is the cone of outer normals to Ω at u, the subspace $\mathsf{N}(u)$ is the closure of the span of $\mathcal{N}_\Omega(u)$, and for each v in $\mathsf{L}^\infty_m[0, 1]$, the rule

$$v_{\mathsf{N}}(t) \overset{\text{a.e.}}{=} P_{\mathsf{N}(u)(t)}v(t), \qquad v_{\mathsf{T}}(t) \overset{\text{a.e.}}{=} P_{\mathsf{T}(u)(t)}v(t) \tag{4.19}$$

defines essentially bounded measurable functions $v_{\mathsf{N}} \in \mathsf{N}(u)$ and $v_{\mathsf{T}} \in \mathsf{T}(u)$, with $v = v_{\mathsf{N}} + v_{\mathsf{T}}$ and $\langle v_{\mathsf{N}}, v_{\mathsf{T}}\rangle_2 = 0$ [4]. Thus, $\mathsf{N}(u)$ and $\mathsf{T}(u)$ are complementary orthogonal closed subspaces in $\{\mathsf{L}^\infty_m[0, 1], \|\cdot\|_2\}$, and v_{N} and v_{T} are the L^2 metric projections of v into $\mathsf{N}(u)$ and $\mathsf{T}(u)$. In fact, $\mathsf{N}(u)$ and $\mathsf{T}(u)$ are clearly *pointwise orthogonal* in the sense that

$$\forall v \in \mathsf{N}(u)\ \forall w \in \mathsf{T}(u) \quad \langle v(t), w(t)\rangle \overset{\text{a.e.}}{=} 0. \tag{4.20}$$

Formal counterparts of the KKT necessary conditions in polyhedra may now be stated as follows. Suppose that $J : \mathsf{L}_m^\infty[0, 1] \to \mathbb{R}^1$ has first and second Gâteaux differential representations (1.2a) and (1.3a), with gradient vectors $\nabla J(u)$ in $\mathsf{L}_m^\infty[0, 1]$ and Hessian operators $\nabla^2 J(u) : \mathsf{L}_m^\infty[0, 1] \to \mathsf{L}_m^\infty[0, 1]$. If u_* is a local minimizer for the restriction of J to any line in Ω, then

$$-\nabla J(u_*) \in \mathcal{N}_\Omega(u_*), \tag{4.21a}$$

$$\forall v \in \mathsf{T}(u_*) \quad \langle v, \nabla^2 J(u_*)v\rangle_2 \geq 0. \tag{4.21b}$$

The inclusion (4.21a) is just a special case of the well-known elementary first-order necessary condition for optimality in convex feasible sets; however, the second-order condition (4.21b) is a nontrivial assertion since Ω is not a polyhedron and the subspace $T(u_*)$ is not contained in the cone of feasible directions to Ω at u_*. When the map $w \to \langle w, \nabla^2 J(u_*)w\rangle_2$ is continuous with respect to the norm $\|\cdot\|_2$, condition (4.21b) can be proved by demonstrating that $T(u_*)$ is a subspace in the L^2 *closure* of the cone of feasible directions at u_* [4]. It is also shown in [4] that (4.21b) is generally *false* if the mapping $w \to \langle w, \nabla^2 J(u_*)w\rangle_2$ is merely continuous in the L^∞ norm.

Conditions (4.21) apply if u_* is any local minimizer on lines in Ω; however, more can be said when u_* is an L^2-local minimizer in Ω, and the structure/continuity conditions (1.2)–(1.4) are met. Under these circumstances, it is shown in [4] that for almost all t in [0, 1],

$$\forall \xi \in U \quad H(u_*\,;\, \xi, t) - H(u_*\,;\, u_*(t), t) \geq 0, \tag{4.22a}$$

where

$$H(u_*\,;\, \xi, t) = \langle \nabla J(u_*)(t), \xi - u_*(t)\rangle + \frac{1}{2}\langle \xi - u_*(t),\, S(u_*)(t)\,(\xi - u_*(t))\rangle. \tag{4.22b}$$

In the control problem context, condition (4.22) amounts to the Pontryagin minimum principle. We note that (4.22) has no analogue in $\mathbb{R}^n$, where all norms are equivalent.

The KKT strict complementarity and coercivity conditions in (3.15) have obvious formal counterparts as well in the pre-Hilbert space $\{\mathsf{L}_m^\infty[0, 1], \|\cdot\|_2\}$, namely,

$$-\nabla J(u_*) \in ri\ \mathcal{N}_\Omega(u_*) \tag{4.23}$$

and

$$\exists c_\mathsf{T} > 0\ \forall v \in \mathsf{T}(u_*) \quad \langle v, \nabla^2 J(u_*)v\rangle_2 \geq c_\mathsf{T}\, \|v\|_2^2, \tag{4.24}$$

where *ri* now means interior relative to the subspace $\mathsf{N}(u_*)$ and the L^2 norm. Unfortunately, these conditions are *vacuous* in Ω since the L^2 relative interior of the normal cone $\mathcal{N}(u_*)$ is typically empty. Nonvacuous sufficient conditions for L^∞-local optimality are obtained in [4] by interpreting *ri* as the interior of $\mathcal{N}(u_*)$ relative to $\mathsf{N}(u_*)$ and the L^∞ norm (4.23); however, this L^∞ strict complementarity condition is quite stringent, since it amounts to requiring that the distance from $-\nabla J(u_*)(t)$ to the relative boundary of $\mathcal{N}_U(u_*(t))$ in $\mathsf{N}_U(u_*(t))$ is essentially bounded away from zero on [0, 1]. The latter condition typically can't hold in commonly encountered situations where $\nabla J(u_*)(\cdot)$ and $u_*(\cdot)$ are continuous at points in the set

$$\gamma(u_*) = \{\tau \in [0, 1] : \exists j \in \{1, \ldots, d\}, \quad \tau \in \partial\alpha_j(u_*)\}.$$

(Here $\partial\alpha_j(u_*)$ denotes the boundary of $\alpha_j(u_*)$ *relative to* [0, 1].) Improved sufficient conditions for L^∞-local optimality are based in [4] on the much weaker strict complementarity condition

$$\mu\big[\gamma(u_*)\big] = 0, \tag{4.25a}$$

$$\text{(4.25b)} \qquad \forall \beta \subset \bigcup_{i=1}^{d} \operatorname{int} \alpha_i(u_*) \quad \left(\beta \text{ compact} \Rightarrow \exists c_\beta > 0 \ \Delta(u_*)(t) \geq c_\beta \text{ a.e. in } \beta\right),$$

where

$$\text{(4.25c)} \qquad \Delta(u_*)(t) = dist\ (-\nabla J(u_*)(t), rb\, \mathcal{N}_U(u_*(t)))$$

and

$$\text{(4.25d)} \qquad rb\, \mathcal{N}_U(u_*(t)) = \mathcal{N}_U(u_*(t)) \setminus ri\, \mathcal{N}_U(u_*(t)).$$

We note that vanishingly small values of $\Delta(u_*)(t)$ are likely to occur only near points in the set $\gamma(u_*)$, where $-\nabla J(u_*)(t)$ crosses a common boundary of contiguous normal cones in U. Condition (4.25b) merely requires that $\Delta(u_*)(t)$ is essentially bounded away from zero in the *exterior* of any open neighborhood of $\gamma(u_*)$ in $[0, 1]$.

It is shown in [4] that (4.24) and (4.25) imply the L^∞-local optimality growth estimate (1.10) when (1.2)–(1.3) hold with a weaker two-norm version of (1.4) and when $\nabla J(u_*)(\cdot)$, $S(u_*)(\cdot)$, and the set-valued map $\mathsf{T}(u_*)(\cdot)$ meet certain additional local restrictions near points in the set $\gamma(u_*)$; the latter restrictions compensate for the weakened L^∞ strict complementarity condition (4.25) by insuring that (4.24) lifts from $\mathsf{T}(u_*)$ to a larger subspace $\hat{\mathsf{T}}$. It is also shown in [4] that the L^∞-local optimality growth condition (1.10) implies L^2-local optimality when (1.2)–(1.4) hold and u_* satisfies the following strengthened variant of the Pontryagin condition (4.22) for some $c_P > 0$ and almost all t in $[0, 1]$:

$$\text{(4.26)} \qquad \forall \xi \in U \quad H(u_*\,;\ \xi, t) - H(u_*\,;\ u_*(t), t) \geq \frac{1}{2}\, c_P \|\xi - u_*(t)\|^2.$$

We now make full use of (4.26) to prove sharper L^2-local optimality sufficient conditions directly. In the following theorem, the weakened L^∞ strict complementarity condition (4.25) is replaced by the still weaker norm-independent pointwise strict complementarity condition

$$\text{(4.27)} \qquad -\nabla J(u_*)(t) \in ri\, \mathcal{N}_U(u_*(t)) \quad \text{a.e. in } [0, 1].$$

We note that (4.22) (and a fortiori, (4.26)) need not hold at an L^∞-local minimizer. We also note that (4.27) is the natural norm-independent formal counterpart of the geometric KKT strict complementarity condition in finite-dimensional k-fold Cartesian products $U \times \cdots \times U$ and that (4.27) *cannot* replace (4.25) in the L^∞-local optimality sufficiency analysis of [4]. Condition (4.27) works in the present L^2 analysis only because of the strengthened Pontryagin condition (4.26).

THEOREM 4.1. *Suppose that J satisfies the structure/continuity requirements* (1.2a), (1.3), (1.4b), *and* (1.4c) *with $\nabla J(u) \in \mathsf{L}^\infty_m[0, 1]$. In addition, assume that the L^2-coercivity condition* (4.24), *the strengthened Pontryagin condition* (4.26), *and the pointwise strict complementarity condition* (4.27) *hold at the point u_* in the set Ω in* (1.1b). *Then u_* is an L^2-local minimizer of J in Ω; more specifically, for each c_2 in the interval $0 < c_2 < \min\{c_\mathsf{T}, c_P\}$, there is a corresponding $\delta_2 > 0$ such that*

$$\text{(4.28)} \qquad J(u) - J(u_*) \geq \frac{1}{2} c_2 \|u - u_*\|_2^2,$$

for all u in the intersection of Ω and the ball

$$B_2(u_*; \delta_2) = \{u \in \mathsf{L}^\infty_m[0, 1] : \|u - u_*\|_2 < \delta_2\}.$$

Proof. For each u in Ω, let φ be a corresponding measurable set in $[0, 1]$, and put $v_u(t) = u_*(t)$ for t in φ, $v_u(t) = u(t)$ for t in $\varphi^c = [0, 1] \setminus \varphi$, and $w_u = v_u - u_*$. Now write $(\varphi^c \times \varphi^c)^c = ([0, 1] \times [0, 1]) \setminus (\varphi^c \times \varphi^c)$, and

$$J(u) - J(u_*) = \langle \nabla J(u_*), w_u \rangle_2 + \frac{1}{2} \langle w_u, \nabla^2 J(u_*) w_u \rangle_2$$

$$+ \int_\varphi \left[\langle \nabla J(u_*)(t), u(t) - u_*(t) \rangle + \frac{1}{2} \langle u(t) - u_*(t), S(u_*)(t)\,(u(t) - u_*(t)) \rangle \right] dt$$

$$+ \frac{1}{2} \int \int_{(\varphi^c \times \varphi^c)^c} \langle u(t) - u_*(t), \mathcal{K}(u_*)(t, s)\,(u(t) - u_*(t)) \rangle dt ds + r(u_* ;\ u - u_*).$$

The growth condition (4.28) is obtained by estimating each term in the right side of the foregoing expression with appropriate choices for φ.

Recall that $\mu \left[[0, 1] \setminus \bigcup_{i=1}^d \alpha_i(u_*) \right] = 0$ and $\mathcal{N}_U(u_*(t)) = \mathcal{N}_i$ for $i = 1, \ldots, d$ and $t \in \alpha_i(u_*) = u^{-1}[ri\ \mathcal{F}_i]$. Note that the function $dist\ (\cdot\ , rb\ \mathcal{N}_i) : \mathbb{R}^m \to \mathbb{R}^1$ is continuous, and

$$\forall t \in \alpha_i(u_*) \quad \Delta(u_*)(t) = dist\ (-\nabla J(u_*)(t), rb\ \mathcal{N}_i),$$

for $i = 1, \ldots, d$. Since $\nabla J(u_*)(\cdot)$ is measurable and u_* satisfies the pointwise strict complementarity condition (4.27), it follows that $\Delta(u_*)(\cdot)$ is measurable, with

$$\Delta(u_*)(t) > 0 \quad \text{a.e. in } [0,1],$$

and, therefore,

$$\lim_{n \to \infty} \mu \left[\left\{ t \in [0, 1] : \Delta(u_*)(t) < \frac{1}{n} \right\} \right] = 0.$$

Consequently, for each $\rho > 0$ there is a measurable set $\beta \subset [0, 1]$ and a positive number c_β such that

$$\mu\ [\beta^c] < \rho, \tag{4.29a}$$

$$\forall t \in \beta \quad \Delta(u_*)(t) \geq c_\beta, \tag{4.29b}$$

where $\beta^c = [0, 1] \setminus \beta$.

Now fix c_2 in the interval $0 < c_2 < \min\{c_T, c_P\}$. Choose $\nu > 0$ so that for all measurable sets $\varphi \subset [0, 1]$,

$$\mu[\varphi] \leq \nu \Rightarrow \left(\int \int_{(\varphi^c \times \varphi^c)^c} \|\mathcal{K}(u_*)(t, s)\|^2 dt ds \right)^{\frac{1}{2}} \leq \frac{1}{4} (\min\{c_T, c_P\} - c_2).$$

By (4.27) and (4.29), there is a measurable set $\beta \subset [0, 1]$ and a $c_\beta > 0$ such that

$$\mu\ [\beta^c] < \frac{\nu}{2}$$

and

$$\forall t \in \beta\ \forall \eta \in \mathsf{N}(u_*)(t) \quad \|\eta\| \leq c_\beta \Rightarrow -\nabla J(u_*)(t) + \eta \in \mathcal{N}_U(u_*(t)). \tag{4.30}$$

Fix $\epsilon \in (0, 1]$, with

$$\left(1 - \epsilon^2\right) c_{\mathsf{T}} - 3\epsilon \|\nabla^2 J(u_*)\|_2 \geq \frac{1}{2} \left(\min\{c_{\mathsf{T}}, c_P\} + c_2\right).$$

By (1.2a), (1.3), (1.4b), (1.4c), and Taylor's theorem in $\mathbb{R}^1$, there is a sufficiently small $\delta \in (0, c_\beta]$ such that

$$\frac{\epsilon^2 c_\beta}{\delta} - \frac{1}{2}\|\nabla^2 J(u_*)\|_2 \geq \frac{1}{4} \left(\min\{c_{\mathsf{T}}, c_P\} + c_2\right)$$

and

$$\forall u \in B_2(u_*; \delta), \quad |r(u_* ; u - u_*)| \leq \frac{1}{8} \left(\min\{c_{\mathsf{T}}, c_P\} - c_2\right) \|u - u_*\|_2^2.$$

Put $\delta_2 = \delta\sqrt{\nu/2}$, $\theta = \{t \in [0, 1] : \|u(t) - u_*(t)\| \leq \delta\}$, and $\varphi = \theta^c \cup \beta^c = (\theta \cap \beta)^c$. Note that for all u in $\Omega \cap B_2(u_*; \delta_2)$, $\mu[\theta^c] \leq \frac{\nu}{2}$, $\mu[\varphi] \leq \nu$ and $\|w_u\|_\infty \leq \delta \leq c_\beta$. Hence, (4.26) and the preceding estimates imply that

$$J(u) - J(u_*) \geq \langle \nabla J(u_*), w_u \rangle_2 + \frac{1}{2} \langle w_u, \nabla^2 J(u_*) w_u \rangle_2$$

$$+ \frac{1}{2} c_P \int_\varphi \|u(t) - u_*(t)\|^2 dt - \frac{1}{4} \left(\min\{c_{\mathsf{T}}, c_P\} - c_2\right) \|u - u_*\|_2^2,$$

for all u in $\Omega \cap B_2(u_*; \delta_2)$. We now complete the proof by estimating the sum of the derivatives on the right side of this inequality.

Let $(w)_{\mathsf{N}}$ and $(w)_{\mathsf{T}}$ be the L^2 metric projections of w into $\mathsf{N}(u_*)$ and $\mathsf{T}(u_*)$, and consider the cone $C_\epsilon = \{w \in \mathsf{L}^\infty_m[0, 1] : \|(w)_{\mathsf{N}}\|_2 \leq \epsilon \|w\|_2\}$. Suppose that $u \in \Omega$ and $w_u = v_u - u_* \in C_\epsilon$. Then conditions (4.27) and (4.24) imply that $\langle \nabla J(u_*), w_u \rangle_2 \geq 0$ and

$$\begin{aligned}
\langle w_u, \nabla^2 J(u_*) w_u \rangle_2 &\geq \langle (w_u)_{\mathsf{T}}, \nabla J(u_*)(w_u)_{\mathsf{T}} \rangle_2 \\
&\quad - \|\nabla^2 J(u_*)\|_2 \left(2\|(w_u)_{\mathsf{N}}\|_2 \|(w_u)_{\mathsf{T}}\|_2 + \|(w_u)_{\mathsf{N}}\|_2^2\right) \\
&\geq \left(\left(1 - \epsilon^2\right) c_{\mathsf{T}} - 3\epsilon \|\nabla^2 J(u_*)\|_2\right) \|w_u\|_2^2 \\
&\geq \frac{1}{2} \left(\min\{c_{\mathsf{T}}, c_P\} + c_2\right) \|w_u\|_2^2,
\end{aligned}$$

and, therefore,

$$\langle \nabla J(u_*), v_u - u_* \rangle_2 + \frac{1}{2} \langle v_u - u_*, \nabla^2 J(u_*)(v_u - u_*) \rangle_2 \tag{4.31}$$

$$\geq \frac{1}{4} \left(\min\{c_{\mathsf{T}}, c_P\} + c_2\right) \int_{\varphi^c} \|u(t) - u_*(t)\|^2 dt.$$

On the other hand, suppose that $u \in \Omega \cap B_2(u_*; \delta_2)$ and $w_u \in C_\epsilon^c$. Put $\zeta = c_\beta \delta^{-1} (w_u)_{\mathsf{N}}$ and, note that $\zeta \in \mathsf{N}(u_*)$ and $\|\zeta\|_\infty \leq c_\beta$ since $\mathsf{N}(u_*)$ and $\mathsf{T}(u_*)$ are pointwise orthogonal; therefore, $\|(w_u)_{\mathsf{N}}(t)\| = \|P_{\mathsf{N}(u_*)(t)} w_u(t)\| \leq \|w_u(t)\|$ almost everywhere in $[0, 1]$. According to (4.30), we then have $-\nabla J(u_*) + \zeta \in \mathcal{N}_\Omega(u_*)$, in which case $\langle -\nabla J(u_*) + \zeta, w_u \rangle_2 \leq 0$ and, therefore,

$$\langle \nabla J(u_*), w_u \rangle_2 \geq \frac{c_\beta}{\delta} \|(w_u)_{\mathsf{N}}\|_2^2 \geq \frac{\epsilon^2 c_\beta}{\delta} \|w_u\|_2^2.$$

Hence, (4.31) holds once again, and thus

$$J(u) - J(u_*) \geq \frac{1}{4}(\min\{c_T, c_P\} + c_2) \int_{\varphi^c} \|u(t) - u_*(t)\|^2 dt + \frac{1}{2} c_P \int_{\varphi} \|u(t) - u_*(t)\|^2 dt$$

$$-\frac{1}{4}(\min\{c_T, c_P\} - c_2) \|u - u_*\|_2^2$$

$$\geq \frac{1}{2} c_2 \|u - u_*\|_2^2,$$

for all u in $\Omega \cap B_2(u_*; \delta_2)$. □

COROLLARY 4.2. *Assume that the hypotheses of Theorem* 4.1 *hold, with the Pontryagin condition* (4.26) *replaced by the stronger Legendre coercivity condition* (1.11). *Then* u_* *is an* L^2*-local minimizer of* J *in* Ω, *and the growth condition* (4.28) *holds near* u_*.

Note 4.1. For Bolza cost functions (1.5) satisfying (1.2a), (1.3), (1.4b), and (1.4c), the function H in the necessary condition (4.22) coincides with the Hamiltonian H in §1, and condition (4.22) reduces to the Pontryagin minimum principle.

Note 4.2. For the special case $U = [0, \infty)$ treated in [1], conditions (1.11) and (4.26) are *equivalent*. In general, (1.11) is considerably stronger than (4.26), but is still a natural hypothesis for nonconvex nonquadratic regulator optimal control problems with control-quadratic running costs and control-linear dynamic equations in (1.5).

5. L^2-Local convergence. It can happen that iterate sequences $\{u_i\}$ generated by (1.6) converge to a minimizer u_* in the norm $\|\cdot\|_2$ from all u_0 in some L^∞ neighborhood of u_*, and yet fail to converge to u_* in the norm $\|\cdot\|_2$ from starting points u_0 that are *arbitrarily close* to u_* in the L^2 sense [2]. In such cases, refined approximate finite-dimensional implementations of (1.6) are sure to converge (nearly) to u_* only from starting points u_0 that are exceedingly close to u_* in quadrature approximations of the norm $\|\cdot\|_2$. For practical purposes, this means that the location of jump discontinuities in u_* or thin boundary layers, where $u_*(t)$ is changing rapidly, must be known very precisely in advance and built into u_0, or (1.6) may not improve u_0 in any useful sense. As in [2], we therefore seek conditions on u_* that insure L^2 convergence of the iterates of (1.6) from all starting points u_0 in some L^2 neighborhood of u_*.

Note that every L^∞-local minimizer is a fixed point of the gradient projection map (1.6) since all such minimizers satisfy the necessary condition (4.21a). Moreover, the sufficient conditions in Theorem 4.1 can hold at u_* and yet every L^2 neighborhood of u_* can contain a *continuum* of L^∞-local minimizers that are actually L^∞-local *stable attractors* for (1.6) [23, Ex. 4]. Something more than the hypotheses in Theorem 4.1 is therefore needed to support an L^2-local convergence theory for gradient projection methods, or any other standard nonlinear programming algorithms that have a fixed point at each u_* satisfying (4.21a). In the following analysis, hypothesis (4.26) is replaced by the stronger Legendre coercivity condition (1.11) on $S(u_*)$, and Corollary 4.2 and (1.11) are then used much as the proof outline of §3 uses the KKT strict complementarity and coercivity conditions in $\mathbb{R}^m$. More specifically, the hypotheses in Corollary 4.2, the structure/continuity conditions (1.2b)–(1.4a), and local bounds for the step lengths $a(u)$ in (1.6) imply that for each u in small L^2 neighborhoods of u_* in Ω, there is a corresponding subspace $\hat{T}(u) \supset T(u^*)$ such that $G(u)$ falls in $(u_* + \hat{T}(u)) \cap \Omega$ and $\nabla^2 J(u_*)$ is coercive on $\hat{T}(u)$ (condition (1.11) is the key to the extension of coercivity from $T(u_*)$ to $\hat{T}(u)$). Furthermore, since u_* is an L^2-locally stable fixed point of G when the uniform growth condition (4.28) is satisfied [30], it follows that for $\|u_0 - u_*\|_2$ sufficiently small, the subsequent G-iterates u_i are confined to an L^2 neighborhood where the preceding assertions are true and where J is *convex* near u_* on the translated subspaces $u_* + \hat{T}(u_{i-1})$. Although G

no longer reduces to an unconstrained Armijo steepest descent map in the infinite-dimensional setting of (1.1), it is now possible to prove local convergence for $\{u_i\}$ *directly*, with estimates from [9] for gradient projection iteration maps and convex cost functions.

LEMMA 5.1. *Let J satisfy the structure/continuity requirements* (1.2)–(1.4) *and suppose that the Legendre coercivity condition* (1.11), *the* L^2*-coercivity condition* (4.24), *and the pointwise strict complementarity condition* (4.27) *in Corollary* 4.2 *hold at a point u_* in the set Ω in* (1.1b). *Then for some $\epsilon > 0$ and each u in $\Omega \cap B_2(u_*; \epsilon)$, there is a corresponding subspace $\hat{\mathsf{T}}(u) \supset \mathsf{T}(u_*)$ in $\mathsf{L}^\infty_m[0, 1]$ such that*

$$G(u) \in (u_* + \hat{\mathsf{T}}(u)) \cap \Omega \tag{5.32a}$$

and

$$\forall v \in B_2(u_*; \epsilon)\ \forall w \in \hat{\mathsf{T}}(u) \quad \langle w, \nabla^2 J(v)w\rangle_2 \geq 0, \tag{5.32b}$$

where G is the gradient projection map (1.6) *on Ω.*

Proof. Recall that for each u in U, $\mathcal{F}(u)$ is the unique face $\mathcal{F}_i \subset U$ such that $u \in ri\ \mathcal{F}_i$ (see §2). Thus, for all u in Ω and almost all t in $[0, 1]$, $\mathcal{F}(u(t))$ is defined and $u(t) \in ri\,\mathcal{F}(u(t))$. We will prove that for some $\epsilon > 0$ and $\rho > 0$, and for each u in $\Omega \cap B_2(u_*; \epsilon)$, there is a corresponding set $\varphi \subset [0, 1]$ such that

$$\min\{dist\ (u_*(t), rb\ \mathcal{F}(u_*(t))), dist\ (-a(u)\nabla J(u_*)(t), rb\ \mathcal{N}_U(u_*)(t))\} \geq \rho, \tag{5.33a}$$

$$\|u(t) - a(u)\nabla J(u)(t) - (u_*(t) - a(u)\nabla J(u_*)(t))\| < \rho, \tag{5.33b}$$

for all t in $\varphi^c = [0, 1] \setminus \varphi$. Hence, by Lemma 2.1,

$$G(u)(t) = P_U(u(t) - a(u)\nabla J(u)(t)) \in ri\ \mathcal{F}(u_*(t)) \subset u_*(t) + \mathsf{T}(u_*)(t),$$

for all t in φ^c; thus (5.32a) holds with

$$\hat{\mathsf{T}}(u) = \{v \in \mathsf{L}^\infty_m[0, 1] : v(t) \overset{\text{a.e.}}{\in} \hat{\mathsf{T}}(u)(t)\} \tag{5.34a}$$

and

$$\hat{\mathsf{T}}(u)(t) = \begin{cases} \mathbb{R}^m, & t \in \varphi, \\ \mathsf{T}(u_*)(t), & t \in \varphi^c. \end{cases} \tag{5.34b}$$

Moreover, $\mu[\varphi]$ and ϵ are small enough to insure that the coercivity condition (4.24) extends from $\mathsf{T}(u_*)$ to the larger subspace $\hat{\mathsf{T}}(u)$ and also that (5.32b) holds in the ball $B_2(u_*; \epsilon)$.

Conditions (1.2a), (1.3), (1.4b), and (1.4c) imply that J is twice continuously Fréchet differentiable relative to the norm $\|\cdot\|_2$, hence ∇J is locally Lipschitz continuous near u_* in this norm. A minor modification of the proof for Lemma A.2 in [38] shows that there are numbers $\delta > 0$ and $\underline{a} > 0$ such that for all u in $\Omega \cap B_2(u_*; \delta)$,

$$a(u) \geq \underline{a} \quad \text{and} \quad \|\nabla^2 J(u) - \nabla^2 J(u_*)\|_2 \leq \frac{1}{2} \min\{c_\mathsf{T}, c_P\},$$

where c_T and c_P are the positive numbers in the coercivity conditions (4.24) and (1.11), and $a(u)$ is the step length in (1.6). Now choose $\nu \in (0, 1]$ so that for all measurable sets $\varphi \subset [0, 1]$,

$$\mu[\varphi] \leq \nu \Rightarrow \left(\int\int_{(\varphi^c \times \varphi^c)^c} \|\mathcal{K}(u)(t, s)\|^2 dt ds\right)^{\frac{1}{2}} \leq \frac{1}{2} \min\{c_\mathsf{T}, c_P\}.$$

With reference to (4.27) and the resulting condition (4.29) in the proof of Theorem 4.1, there is a measurable set β in $[0, 1]$ and a number $c_\beta > 0$ such that $\mu[\beta^c] \leq \nu/3$, $-\nabla J(u_*)(t) \in ri\ \mathcal{N}_U(u_*(t))$, and $dist\ (-\nabla J(u_*)(t), rb\ \mathcal{N}_U(u_*)(t)) \geq c_\beta$, for all t in β. Since $\mathcal{N}_U(u_*(t))$ is a cone, it follows that for all $a > 0$,

$$-a\nabla J(u_*)(t) \in ri\ \mathcal{N}_U(u_*(t))$$

and

$$dist\ (-a\nabla J(u_*)(t), rb\ \mathcal{N}_U(u_*)(t)) \geq ac_\beta,$$

for all t in β. Furthermore, by construction, the set-valued map $\mathcal{F}(u_*(\cdot))$ is *constant* on each of the measurable sets $\alpha_i(u_*)$, with $u_*(t) \in ri\ \mathcal{F}(u_*)(t)$ almost everywhere in $[0, 1]$. Hence $dist\ (u_*(\cdot), rb\ \mathcal{F}(u_*(\cdot))$ is measurable and positive almost everywhere in $[0, 1]$, and there is a number $c_\omega > 0$ and a corresponding set

$$\omega = \{t \in [0, 1] : dist\ (u_*(t), rb\ \mathcal{F}(u_*(t))) \geq c_\omega\}$$

such that $\mu[\omega^c] \leq \nu/3$. The estimate (5.33a) is now seen to hold for all t in $(\omega^c \cup \beta^c)^c = \omega \cap \beta$ with $\rho = \min\{c_\omega, \underline{a}c_\beta\}$. By (1.2b) and (1.4), δ can be reduced further if necessary, so that for some $L > 0$ and all u in $B_2(u_*; \delta)$,

$$\|\nabla J(u)(t) - \nabla J(u_*)(t)\| \leq \frac{\rho}{2\overline{a}} + L\|u(t) - u_*(t)\|$$

almost everywhere in $[0, 1]$, and $(1 + \overline{a}L)\,\delta < \frac{\rho}{2}$, where $\overline{a}$ is the step length *upper* bound in (1.6). For u in Ω, let $\theta = \{t \in [0, 1] : \|u(t) - u_*(t)\| \leq \delta\}$ and $\varphi = \theta^c \cup \omega^c \cup \beta^c$. Put $\epsilon = \delta\sqrt{\nu/3}$ and note that for all u in $\Omega \cap B_2(u_*; \epsilon)$, conditions (5.33) hold almost everywhere in φ^c with $\rho = \min\{c_\omega, \underline{a}c_\beta\}$. Finally, note that $\mu[\theta^c] \leq \frac{\nu}{3}$ and $\mu[\varphi] \leq \nu$, and construct $\hat{\mathsf{T}}(u)$ with (5.34) for u in $\Omega \cap B_2(u_*; \epsilon)$. With (4.24) and (1.11), we now find that for all u in $\Omega \cap B_2(u_*; \epsilon)$ and w in $\hat{\mathsf{T}}(u)$,

$$\begin{aligned}
\langle w, \nabla^2 J(u_*)w\rangle_2 &= \int_{\varphi^c} \langle w(t), S(u_*)(t)w(t)\rangle dt + \int_{\varphi} \langle w(t), S(u_*)(t)w(t)\rangle dt \\
&\quad + \int\int_{\varphi^c \times \varphi^c} \langle w(t), \mathcal{K}(u_*)(t, s)w(t)\rangle dtds \\
&\quad + \int\int_{(\varphi^c \times \varphi^c)^c} \langle w(t), \mathcal{K}(u_*)(t, s)w(t)\rangle dtds \\
&\geq c_{\mathsf{T}} \int_{\varphi^c} \|w(t)\|^2 dt + c_P \int_{\varphi} \|w(t)\|^2 dt - \frac{1}{2} \min\{c_{\mathsf{T}}, c_P\}\|w\|_2^2 \\
&\geq \frac{1}{2} \min\{c_{\mathsf{T}}, c_P\}\|w\|_2^2.
\end{aligned}$$

Hence, $\langle w, \nabla^2 J(v)w\rangle_2 \geq \langle w, \nabla^2 J(u_*)w\rangle_2 - \|\nabla^2 J(v) - \nabla^2 J(u_*)\|_2\|w\|_2^2 \geq 0$, for all v in $B_2(u_*; \epsilon)$ and w in $\hat{\mathsf{T}}(u)$. □

Note 5.1. Reference [36] establishes a positive lower bound for $a(u)$ on bounded subsets of simple polyhedra in $\mathbb{R}^m$ when ∇J is Lipschitz continuous on bounded sets. In infinite-dimensional spaces, this Lipschitz continuity hypothesis does not automatically follow from continuity of the second derivative of J, since closed bounded sets are not compact in such spaces. On the other hand, the step length bound in [38] applies when ∇J is merely Lipschitz continuous near stationary points, and this local property *is* implied by continuity of the second derivative.

THEOREM 5.2. *Let J satisfy the structure/continuity requirements* (1.2)–(1.4) *and suppose that the Legendre coercivity condition* (1.11), *the* L^2*-coercivity condition* (4.24), *and the pointwise strict complementarity condition* (4.27) *in Corollary* 4.2 *hold at a point u_* in the set Ω in* (1.1b). *Then there are numbers $\delta > 0$ and $\lambda \in [0, 1)$ such that for each sequence $\{u_i\}$ generated by the gradient projection iteration* (1.6),

$$u_0 \in \Omega \cap B_2(u_*; \delta) \Rightarrow \forall i \geq 1 \quad J(u_{i+1}) - J(u_*) \leq \lambda \ (J(u_i) - J(u_*)) .$$

Furthermore, the corresponding norms $\|u_i - u_*\|_2$ are bounded above by a real sequence that converges to zero geometrically, with ratio $\sqrt{\lambda}$.

Proof. By Corollary 4.2 and Lemma 5.1, there are positive numbers ϵ and $\underline{a}$ such that $a(u)$ is bounded away from zero by $\underline{a}$ and conditions (4.28) and (5.32) hold at each u in $\Omega \cap B_2(u_*; \epsilon)$. Condition (4.28) and the basic continuity and descent properties of G insure that u_* is an L^2 stable fixed point of G [30]. Hence, there is a $\delta \in (0, \epsilon]$ such that for all sequences $\{u_i\}$ generated by (1.6),

$$u_0 \in \Omega \cap B_2(u_*, \delta) \Rightarrow \forall i \geq 0, \quad u_i \in \Omega \cap B_2(u_*; \epsilon).$$

The remainder of the proof employs local versions of estimates developed in [9] for convex J.

Assume that the G-iterate sequence $\{u_i\}$ is confined to $\Omega \cap B_2(u_*; \epsilon)$. By (5.32a), we then have

$$u_i \in (u_* + \hat{\mathrm{T}}(u_{i-1})) \cap \Omega \cap B_2(u_*; \epsilon),$$

for $i \geq 1$. By (5.32b), this implies that

$$J(u_i) - J(u_*) \leq \langle \nabla J(u_i), u_i - u_* \rangle_2,$$

for $i \geq 1$. Since $u_{i+1} = P_\Omega (u_i - a(u_i)\nabla J(u_i))$, the orthogonality condition in the projection theorem gives

$$\langle u_i - a(u_i)\nabla J(u_i) - u_{i+1}, u_* - u_{i+1} \rangle_2 \leq 0$$

and

$$\langle u_i - a(u_i)\nabla J(u_i) - u_{i+1}, u_i - u_{i+1} \rangle_2 \leq 0.$$

Hence,

$$\begin{aligned} \langle \nabla J(u_i), u_i - u_* \rangle_2 &= \langle \nabla J(u_i), u_i - u_{i+1} \rangle_2 + \langle \nabla J(u_i), u_{i+1} - u_* \rangle_2 \\ &\leq \langle \nabla J(u_i), u_i - u_{i+1} \rangle_2 + \frac{1}{\sqrt{a(u_i)}} \|u_{i+1} - u_*\|_2 \ \langle \nabla J(u_i), u_i - u_{i+1} \rangle_2^{\frac{1}{2}}, \end{aligned}$$

for all $i \geq 1$. Now put $r_i = J(u_i) - J(u_*)$ and note that $a(u_i)$ is bounded below by $\underline{a}$ and that $\sigma \langle \nabla J(u_i), u_i - u_{i+1} \rangle_2$ is bounded above by $r_i - r_{i+1}$, where σ is the step length rule parameter in (1.6). Note also that $c_2 \|u_{i+1} - u_*\|_2^2$ is bounded above by $2r_{i+1}$, and hence by $2r_i$. Consequently, for all $i \geq 1$,

$$0 \leq r_i \leq \frac{r_i - r_{i+1}}{\sigma} + \left(\frac{2r_i}{c_2 \underline{a}}\right)^{\frac{1}{2}} \left(\frac{r_i - r_{i+1}}{\sigma}\right)^{\frac{1}{2}}.$$

By completing the square on the right side of this estimate, we find that for $i \geq 1$,

$$0 \leq r_{i+1} \leq \lambda r_i$$

and

$$\|u_i - u_*\|_2 \leq \sqrt{\frac{2r_i}{c_2}},$$

with

$$\lambda = 1 - \frac{2c_2\underline{a}\sigma}{(1+\sqrt{1+2c_2\underline{a}})^2}. \qquad \square$$

6. L^2-Local active facet identification. In [31], it is shown that if ∇J is continuous and u_* satisfies the geometric strict complementarity condition (3.15a) in a polyhedral set $U \subset \mathbb{R}^m$, then iterates of the projection map (3.18) that converge to u_* are eventually confined to the *active facet* $ri\ \mathcal{F}(u_*)$ at u_*. A similar conclusion can be reached by the analysis in [30] under the stronger local Lipschitz continuity hypothesis needed for the local convergence theory (see Note 3.2). We now prove an *asymptotic* counterpart of the latter result for the gradient projection map (1.6). This theorem subsumes the active constraint identification result in [2] for $U = [0, \infty)$. Results of a similar nature are established in [41] and [42] for constrained compact fixed point problems and discrete-time approximations to optimal control problems. Reference [43] formulates an active constraint identification theorem *and* a local convergence theorem for an infinite-dimensional variant of the projected Newton scheme in [36] applied to optimal control problems with bounded scalar inputs.

Fix u_* in Ω and for each u in Ω put

$$\mathcal{I}(u) = \{t \in [0,1] : u(t) \in U, u_*(t) \in U \text{ and } \mathcal{F}(u(t)) = \mathcal{F}(u_*(t))\}. \tag{6.35}$$

By construction, u *identifies* the active facets $ri\ \mathcal{F}(u_*(t))$ for t in the index set $\mathcal{I}(u)$.

THEOREM 6.1. *Suppose that J is twice continuously Fréchet differentiable relative to the norm $\|\cdot\|_2$ and satisfies conditions* (1.2), (1.4a), *and* (1.4b). *Assume that the pointwise strict complementarity condition* (4.27) *holds at point u^* in the set Ω in* (1.1b). *Then for all gradient projection iterate sequences $\{u_i\}$ generated by* (1.6),

$$\lim_{i\to\infty} \|u_i - u_*\|_2 = 0 \Rightarrow \lim_{i\to\infty} \mu[\mathcal{I}(u_i)^c] = 0,$$

where $\mathcal{I}(u_i)$ is defined by (6.35) *and $\mathcal{I}(u_i)^c = [0,1] \setminus \mathcal{I}(u_i)$.*

Proof. For $u \in \Omega$ and $j = 1, \ldots, d$, let $\alpha_j(u) = u^{-1}\ [ri\ \mathcal{F}_j]$ as before. By construction, $\alpha_j(u) \cap \alpha_k(u) = \emptyset$ for $j \neq k$, with

$$\mu\left[[0,1] \setminus \bigcup_{j=1}^{d} \alpha_j(u)\right] = 0,$$

and thus

$$\mu\left[[0,1] \setminus \bigcup_{j,k=1}^{d} \left(\alpha_j(u) \cap \alpha_k(u_*)\right)\right] = 0.$$

Note that

$$\mathcal{I}(u) = \bigcup_{j=1}^{d} \left(\alpha_j(u) \cap \alpha_j(u_*)\right).$$

Hence $[0,1] \setminus \mathcal{I}(u)$ differs from $\bigcup_{j\neq k} \left(\alpha_j(u) \cap \alpha_k(u_*)\right)$ by a set of measure zero, and it therefore suffices to show that for all $j, k = 1, \ldots, d$,

$$j \neq k \Rightarrow \lim_{i\to\infty} \mu[\alpha_j(u_i) \cap \alpha_k(u_*)] = 0. \tag{6.36}$$

We now use Lemma 2.1 to prove (6.36).

Suppose that $\{u_i\}$ is generated by (1.6) and that $\lim_{i\to\infty} \|u_i - u_*\|_2 = 0$. Since J is twice continuously differentiable relative to $\|\cdot\|_2$, the map $\nabla J(\cdot)$ is locally Lipschitz continuous relative to $\|\cdot\|_2$; hence, for some $\underline{a} > 0$, the step lengths $a(u_i)$ are bounded away from zero by $\underline{a}$ for all i. Fix $\epsilon > 0$, k and $j \neq k$. By (4.27) and the resulting condition (4.29), there is a measurable set $\beta \subset \alpha_k(u_*)$ and a $c_\beta > 0$ such that $\mu[\alpha_k(u_*) \setminus \beta] \leq \frac{\epsilon}{3}$, $-\nabla J(u_*)(t) \in ri\ \mathcal{N}_U(u_*(t))$, and $dist\ (-\nabla J(u_*)(t), rb\ \mathcal{N}_U(u_*(t))) \geq c_\beta$, for all t in β. Since $dist\ (u_*(\cdot), rb\ \mathcal{F}_k)$ is measurable and positive on $\alpha_k(u_*)$, there is a measurable set $\omega \subset \alpha_k(u_*)$ and a $c_\omega > 0$ such that $\mu[\alpha_k(u_*)\setminus\omega] \leq \frac{\epsilon}{3}$, $u_*(t) \in ri\ \mathcal{F}_k$, and $dist\ (u_*(t), rb\ \mathcal{F}_k) \geq c_\omega$, for all t in ω. Put $\rho = \min\{c_\omega, \underline{a}c_\beta\}$, and note that $\mathcal{N}_U(u_*(t))$ is a cone. Hence, for all i and all t in $\beta \cap \omega$,

$$\min\{dist\ (-a(u_i)\nabla J(u_*)(t), rb\ \mathcal{N}_U(u_*(t))), dist\ (u_*(t), rb\ \mathcal{F}(u_*(t)))\} \geq \rho.$$

Since $\lim_{i\to\infty} \|u_i - u_*\|_2 = 0$, conditions (1.4a), (1.4b) imply that for some $L \geq 0$ and all sufficiently large i,

$$\|\nabla J(u_i)(t) - \nabla J(u_*)(t)\| \leq \frac{\rho}{2\bar{a}} + L\|u_i(t) - u_*(t)\|$$

almost everywhere in $[0, 1]$, where $\bar{a}$ is the step length upper bound in (1.6). Now let $\eta = \frac{\rho}{2(1+\bar{a}L)}$ and $\theta_i = \{t \in \alpha_k(u_*) : \|u_i(t) - u_*(t)\| < \eta\}$, and note that for sufficiently large i and almost all t in θ_i,

$$\|u_i(t) - a(u_i)\nabla J(u_i)(t) - (u_*(t) - a(u_i)\nabla J(u_*)(t))\| < \rho.$$

Hence, Lemma 2.1 insures that for sufficiently large i,

$$u_{i+1}(t) = P_U(u_i(t) - a(u_i)\nabla J(u_i)(t)) \in ri\ \mathcal{F}(u_*(t)) = ri\ \mathcal{F}_k$$

almost everywhere in $\beta \cap \omega \cap \theta_i$; thus

$$\mu[\alpha_j(u_{i+1}) \cap \alpha_k(u_*) \cap \beta \cap \omega \cap \theta_i] = 0,$$

since $ri\ \mathcal{F}_j \cap ri\ \mathcal{F}_k = \emptyset$ for $j \neq k$. In addition, since convergence in the norm $\|\cdot\|_2$ implies convergence in measure, it follows that $\mu[\alpha_k(u_*) \setminus \theta_i] \leq \frac{\epsilon}{3}$ and, therefore, $\mu[\alpha_k(u_*) \setminus (\beta \cap \omega \cap \theta_i)] \leq \epsilon$, for sufficiently large i. In the limit as $i \to \infty$, we now obtain

$$\begin{aligned} 0 &\leq \limsup_{i\to\infty}\ \mu[\alpha_j(u_{i+1}) \cap \alpha_k(u_*)] \\ &\leq \limsup_{i\to\infty}\ \mu[\alpha_j(u_{i+1}) \cap \alpha_k(u_*) \cap \beta \cap \omega \cap \theta_i] \\ &\quad + \limsup_{i\to\infty}\ \mu[\alpha_j(u_{i+1}) \cap \alpha_k(u_*) \cap (\alpha_k(u_*) \setminus (\beta \cap \omega \cap \theta_i))] \\ &\leq \epsilon. \end{aligned}$$

Since ϵ is an arbitrarily small positive number, this proves (6.36). □

Note 6.1. Theorem 6.1 and its proof remain valid for objective functions J with gradients that are locally Lipschitz continuous relative to the norm $\|\cdot\|_2$; this weaker hypothesis automatically holds for the twice continuously Fréchet differentiable functions of interest here.

Acknowledgment. The author is grateful to the referees for several helpful comments on exposition and a valuable observation pertaining to the proof of Theorem 4.1. In the original version of this paper, Theorem 4.1 invoked the strict complementarity condition (4.25), and one of the referees noticed that the weaker condition (4.29) seemed to serve equally well in

place of (4.25). The proof originally designed for (4.25) does indeed work for (4.29), and appears here virtually unchanged, apart from notational adjustments and new material in the second paragraph. The new material establishes measurability of $\Delta(u_*)(\cdot)$, proves that the proposed condition (4.29) is actually equivalent to the weak pointwise strict complementarity condition (4.27), and links (4.29) to KKT strict complementarity in Cartesian products of polyhedra.

LARGE-TIME LOCAL CONTROLLABILITY VIA HOMOGENEOUS APPROXIMATIONS*

HENRY HERMES†

Abstract. If all points in a neighborhood of a rest solution of an n-dimensional, affine control system can be attained in some sufficiently large time $t_1 > 0$, we say that the system is large-time locally controllable at the rest solution. Sufficient conditions for large-time local controllability are given in terms of small-time local controllability of homogeneous approximating systems. The major result, Theorem 3, is a geometric test for large-time local controllability in terms of the (coordinate-free) structure of Lie products of the vector fields which define the system, evaluated at the rest solution. Large-time local controllability has implications for the problem of the existence of an asymptotically stabilizing feedback control.

AMS subject classifications. 93B29, 93B05, 57R27, 17B70

Introduction. We study the problem of when, for sufficiently large time, can one reach all points in a neighborhood of the origin by solutions of the nonlinear, affine, single input control system on $\mathbb{R}^n$

$$\dot{x} = X(x) + uY(x), \quad X(0) = 0,\ Y(0) \neq 0 \tag{1}$$

with initial data $x(0) = 0$. Here X and Y are assumed real analytic vector fields on $\mathbb{R}^n$, while the admissible control set, denoted Ω^α, consists of Lebesgue-measurable functions $u : [0, \infty) \to [-\alpha, \alpha]$, $\alpha > 0$. The attainable set at time t, i.e., the set of all points that can be reached in time t by solutions of (1) using controls $u \in \Omega^\alpha$, will be denoted $A_1^\alpha(t)$. System (1) is *small-time locally controllable* (STLC) at zero if given any $t_1 > 0, \alpha > 0, 0 \in \text{int} A_1^\alpha(t_1)$. We define system (1) to be *large-time locally controllable* (LTLC) at zero if given any $\alpha > 0$ there exists a $t_1 > 0$ such that $0 \in \text{int} A_1^\alpha(t_1)$. STLC corresponds to the ability to correct small deviations from the reference solution, corresponding to $u = 0$, in arbitrarily small time. It has been extensively studied (see [4]–[6], [9]) with a major computable, sufficient condition given by Sussmann in [11]. Large-time local controllability is more basic to the question of asymptotic stabilization of the zero solution of (1) via feedback control. Indeed, if the time reversal system of system (1), i.e., $\dot{x} = -X(x) + vY$, is LTLC at zero, it follows that for any point p in some neighborhood of zero there exists a control $u \in \Omega^\alpha$ such that the corresponding solution $x(t, u)$ of system (1) for initial data $x(0) = p$ satisfies $\lim_{t\to\infty} x(t, u) = 0$. This is an obvious necessary condition for the existence of an asymptotically stabilizing feedback control [1]. Our sufficient condition for large-time local controllability will be given in terms of Lie brackets of X and Y evaluated at zero; hence it suffices to study system (1) since the bracket structure of the time-reversed system is the same (up to signs) as that of system (1).

The methods, here, depend on high-order homogeneous approximations of system (1). A *dilation*, δ_ε^r, is a map from $\mathbb{R}^n$ to $\mathbb{R}^n$ of the form $\delta_\varepsilon^r x = (\varepsilon^{r_1} x_1, \ldots, \varepsilon^{r_n} x_n)$, $\varepsilon > 0$, $1 \leq r_1 \leq r_2 \leq \cdots \leq r_n$ integers. A polynomial $h : \mathbb{R}^n \to \mathbb{R}^1$ is homogeneous of degree m with respect to δ_ε^r if $h(\delta_\varepsilon^r x) = \varepsilon^m h(x)$. The set of polynomials homogeneous of degree m will be denoted P_m. P_0 consists of constant functions, and we set $P_m = \{0\}$ if $m < 0$. A vector field $X(x) = \sum_{j=1}^n a_j(x)\partial/\partial x_j$ on $\mathbb{R}^n$ is homogeneous of degree m with respect to δ_ε^r if $a_j \in P_{r_j+m-1}$. This definition (while not universally used; e.g., see [8], [4]) agrees with the classical definition; i.e., a vector field $X(x) = Ax$ linear in the local coordinates is homogeneous of degree 1 with respect to the *standard dilation* δ_ε^1 having $r_1 = r_2 = \cdots = r_n = 1$.

†Department of Mathematics, University of Colorado, Boulder, CO 80309.

A vector field X homogeneous of degree m will usually be denoted $X^{(m)}$. In §1, we will not make local coordinate changes, and it is convenient for later results of §2 to *not* necessarily assume $Y(x) = \partial/\partial x_1$ in the given coordinates. Expand X and Y in terms of homogeneous vector fields as

$$\begin{aligned} X(x) &= X^{(m)}(x) + X^{(m+1)}(x) + \cdots, \\ Y(x) &= Y^{(1-\ell)}(x) + Y^{(2-\ell)}(x) + \cdots, \end{aligned} \tag{2}$$

where $X(0) = 0$ implies $X^{(m)}(0) = 0$ and $Y(0) \neq 0$ implies $\ell \geq 1$ and we assume that the leading terms $X^{(m)}$, $Y^{(1-\ell)}$ are not zero vector fields. The homogeneous approximation of (1) relative to the dilation δ_ε^r used in (2) is

$$\dot{x} = X^{(m)}(x) + vY^{(1-\ell)}(x). \tag{3}$$

A basic result in the study of STLC is the following theorem.

THEOREM 1 (see [9], [2]). *If there exists a dilation δ_ε^r for which $m = 1$ in the expansion of X (or $m \leq 1$ and $m + \ell - 1 \geq 0$) and the approximating system* (3) *is STLC at zero, then system* (1) *is STLC at zero. If system* (3) *is STLC at zero and has $m > 1$, then system* (1) *is LTLC.*

The first statement in the above theorem can be found in [9, Thm. 3.2]. The second statement is a consequence of [2, Rem. 2.5]. The basic idea in the proof is to make the variable changes $\tau = e^{-(m-1)s}t$ or $t = t(\tau) = e^{(m-1)s}\tau$ and $x^s(\tau) = \delta_{e^s}^r x(t(\tau), u)$. Let $A_1^\alpha(t)$ denote the attainable set, at time t, of system (1) with controls $u \in \Omega^\alpha$; let $A_3^\alpha(\tau)$ denote the attainable set, at time τ, of the approximating system (3) with controls in Ω^α and $A_s^\alpha(\tau)$ denote the attainable set at time τ for the system x^s satisfies. Then one can show

$$A_s^\alpha(\tau) = \delta_{e^s}^r A_1^{\alpha e^{-s(m+\ell-1)}}(e^{(m-1)s}\tau)$$

and $0 \in \operatorname{int} A_3^\alpha(\tau)$ implies $0 \in \operatorname{int} A_s^\alpha(\tau)$ for s sufficiently large. Thus if $m = 1$, the first statement of Theorem 1 follows, but for $m > 1$, the time $e^{(m-1)s}\tau$ may be very large for large s. Indeed $s = s(\tau)$ and hence $e^{(m-1)s(\tau)}\tau$ need not tend to zero as $\tau \to 0$ (Example 1.1 has such behavior), so for $m > 1$ we cannot conclude that STLC of (3) implies STLC of (1).

Examples are given of systems for which the only STLC homogeneous approximating systems have $m \geq 2$; i.e., the original system is LTLC and can be shown to not be STLC at zero. These examples involve guessing a dilation; the results that can be concluded depend on the dilation chosen. Furthermore, no changes in the local coordinates used to initially describe the vector fields in (1) are made.

In §2 the main result is Theorem 3, which gives a "geometric" sufficient condition for large-time local controllability in terms of the (coordinate-free) structure of Lie products of X and Y evaluated at zero. Example 2.1 illustrates the nature of Theorem 3 and introduces some notation. The proof of Theorem 3 uses weight-induced filtrations of the Lie algebra, $L(X, Y)$, generated by X and Y and is constructive in that the preferred local coordinates, dilation, and STLC approximating system can be computed, although this is not necessary for applications of the theorem. This construction is illustrated in Example 2.2.

Our notation will be $(\operatorname{ad} X, Y) = [X, Y]$, the Lie product of vector fields X, Y, and inductively $(\operatorname{ad}^{k+1} X, Y) = [X, (\operatorname{ad}^k X, Y)]$. For S a subset of $L(X, Y)$, $S(0)$ denotes the elements of S evaluated at zero. We assume, throughout, that $\dim L(X, Y)(0) = n$, and all examples will satisfy this. For X a smooth vector field on $\mathbb{R}^n$ and $p \in \mathbb{R}^n$, we will often use $\exp(X)(p)$ to denote the solution, at time t, of $\dot{x} = X(x)$, $x(0) = p$.

1. Examples.

Example 1.1. We consider the system

$$\dot{x}_1 = u, \quad \dot{x}_2 = x_1^3, \quad \dot{x}_3 = x_2^3 + x_1^4. \tag{4}$$

Here $X(x) = x_1^3 \partial/\partial x_2 + (x_2^3 + x_1^4)\partial/\partial x_3$, $Y = \partial/\partial x_1$. If one chooses the standard dilation δ_ε^1, then $X(x) = X^{(3)}(x) + X^{(4)}(x)$ with $X^{(3)}(x) = x_1^3\ \partial/\partial x_2 + x_2^3\ \partial/\partial x_3$, $X^{(4)}(x) = x_1^4\ \partial/\partial x_3$, and $Y = Y^{(0)} = \partial/\partial x_1$. The homogeneous approximating system (3) becomes $\dot{x} = X^{(3)}(x) + u(t)Y$ and is STLC. Indeed, this is an "odd" system; i.e., the brackets which are linearly independent at zero are Y, $(\mathrm{ad}^3 Y, X)$ and $(\mathrm{ad}^3(\mathrm{ad}^3 Y, X), X)$, which all have an odd number of factors Y. This approximating system is a cubic integrator and hence admits a smooth asymptotic stabilizing feedback control (see [3]), which is therefore a local asymptotically stabilizing feedback control for (4). By Theorem 1, system (4) is LTLC. However, in the original system, the bracket $(\mathrm{ad}^4 Y, X)(0)$ is linearly independent of Y, $(\mathrm{ad}^3 Y, X)(0)$ and is an obstruction to small-time local controllability (see [10]); i.e., the original system is not STLC. Had one chosen the dilation as δ_ε^r with $r = (1, 3, 4)$, the expansion of X becomes $X(x) = X^{(1)}(x) + X^{(6)}(x)$ with $X^{(1)}(x) = x_1^3\ \partial/\partial x_2 + x_1^4\ \partial/\partial x_3$, $X^{(6)}(x) = x_2^3\ \partial/\partial x_3$, $Y = Y^{(0)}$, and the approximating system $\dot{x} = X^{(1)}(x) + u(t)Y$ is *not* STLC. □

This example illustrates the importance of the choice of dilation. This choice, and the proper choice of local coordinates, will be dealt with in §2.

Example 1.2. On $\mathbb{R}^3$, consider the system

$$\dot{x}_1 = u, \quad \dot{x}_2 = x_1^3 + x_1^2 x_3, \quad \dot{x}_3 = x_3^2 + x_2^5, \tag{5}$$

i.e., $X(x) = (x_1^3 + x_1^2 x_3)\ \partial/\partial x_2 + (x_3^2 + x_2^5)\ \partial/\partial x_3$, $Y = \partial/\partial x_1$. If we choose the standard dilation δ_ε^1, then the homogeneous approximating system is $\dot{x} = X^{(2)}(x) + uY^{(0)}$ with $X^{(2)}(x) = x_3^2\ \partial/\partial x_3$, $Y^{(0)} = Y$. This system is not STLC, and we gain no information.

If we choose δ_ε^r with $r = (1, 1, 3)$, then $x_1^3 \in P_3 = P_{r_2+3-1}$, $x_2^5 \in P_5 = P_{r_3+3-1}$, and the homogeneous approximating system is $\dot{x} = X^{(3)}(x) + uY^{(0)}$ with $X^{(3)}(x) = x_1^3\ \partial/\partial x_2 + x_2^5\ \partial/\partial x_3$. This approximating system is an "odd" system; the relevant brackets which are linearly independent at zero are Y, $(\mathrm{ad}^3 Y, X)$ and $(\mathrm{ad}^5\ (\mathrm{ad}^3 Y, X), X)$. Theorem 1 applies with $m > 1$, showing that the original system is LTLC.

However, had we chosen δ_ε^r with $r = (1, 3, 15)$, then $x_1^3 \in P_3 = P_{r_2+1-1}$, $x_2^5 \in P_{15} = P_{r_3+1-1}$, while the remaining terms are of higher homogeneous order. Relative to this dilation, the approximating system is $\dot{x} = X^{(1)}(x) + uY^{(0)}$ with $X^{(1)}(x) = x_1^3\ \partial/\partial x_2 + x_2^5\ \partial/\partial x_3$. This approximation is STLC; since the approximating vector field of X is homogeneous of degree one, Theorem 1 applies with $m = 1$, and system (5) is actually STLC. □

In §1 we have not changed local coordinates; i.e., in the examples the dilation was changed but the local coordinates relative to which the vector fields were described were not changed. Linearity of a vector field, in chosen local coordinates, is homogeneity of degree one with respect to the standard dilation δ_ε^1. But linearity is not a coordinate-free notion, and neither is homogeneity relative to a given dilation. Example 1.2 illustrates the role of choosing the "correct" dilation, but the approach was by guessing, i.e., not constructive. Section 2 will deal with a coordinate-free construction based on the bracket structure, at zero, of the original vector fields X, Y. If the construction can be accomplished, system (1) will be LTLC. Behind the scenes (as seen in the proof of Theorem 3) the construction leads to the proper local coordinates and dilation relative to which the approximating system should be considered.

2. A constructive test for large-time local controllability. Before stating and proving the main theorem of this section, we give an example to illustrate notation and ideas which will be involved in this theorem.

FIG. 1.

Example 2.1. On $\mathbb{R}^3$, consider the system

$$\dot{x}_1 = u, \quad \dot{x}_2 = x_1, \quad \dot{x}_3 = x_1^2 + x_2^3, \tag{6}$$

i.e., $X(x) = x_1\,\partial/\partial x_2 + (x_1^2 + x_2^3)\partial/\partial x_3$, $Y = \partial/\partial x_1$. The relevant brackets are $[X, Y](x) = \partial/\partial x_2 + 2x_1\,\partial/\partial x_3$, $(\mathrm{ad}^2 Y, X) = 2\partial/\partial x_3$, and $(\mathrm{ad}^3[X, Y], X) = -6\,\partial/\partial x_3$. We denote a bracket with k factors Y and ℓ factors X to be a bracket of type (k, ℓ) and graph them on integer lattice points of the plane as in Figure 1.

Since small-time local controllability at zero implies large-time local controllability, one should certainly first check the constructive sufficient conditions for the former as given in [11]; see also [6], [7]. In this example, one does not have small-time local controllability; the (2,1) bracket gives an obstruction (see [10]).

The brackets in Figure 1 which do not vanish at zero are marked with an ×. In general, we begin by examining the first row (i.e., brackets of the form $(\mathrm{ad}^j X, Y)$, $j = 0, 1, 2, \ldots$) and let m be such that the brackets $(1, \ell)$, $\ell \geq (m + 1)$ are zero when evaluated at zero. Note that we may have brackets of type $(1, \ell)$, $\ell \leq m$, equal to zero when evaluated at zero. If a $(1, j)$ bracket is ever zero at zero, since $X(0) = 0$, we will have the $(1, \ell)$ brackets zero at zero for $\ell \geq j$. In the above example choose $m = 1$. Now for any integer $k \geq 1$, we consider a line through the point $(1, m) = (1, 1)$ with slope $-k/(mk + 1)$. In the above example, choose $k = 2$. If we can find such a line so that all brackets to its right vanish at zero, while if we slide the line to the left parallel to itself, the increases in rank of the set of brackets (evaluated at zero) encountered occur at brackets of type (odd, anything) or (even, even), i.e., "good" brackets in the sense of Sussmann [11], then the original system is LTLC. In this example, the original line encounters the brackets (1,1) and (3,4). As we slide the line to the left, the next bracket which is not zero at zero is (1,0), and these three, at zero, span $\mathbb{R}^3$. Thus system (6) is LTLC. □

This illustrates the idea, and an example, of the application of Theorem 3. The proof will proceed by showing that the existence of such a line implies that we can choose local coordinates and a dilation relative to which the approximating system of (1) has the form $\dot{x} = X^{(k+1)}(x) + uY^{(-mk)}(x)$, or for system (6) in the above example, $\dot{x} = X^{(3)}(x) + uY^{(-2)}(x)$, which is STLC at zero. Then large-time local controllability follows by Theorem 1.

Before stating and proving Theorem 3, some preliminary results on homogeneous vector fields are needed.

PROPOSITION 2.1. *If $V^{(m)}$ is a vector field homogeneous of degree m with respect to a dilation δ_ε^r and $V^{(m)}(x) = \sum_{j=1}^n a_j(x)\,\partial/\partial x_j$, then $a_j(0) = 0$ if $r_j \neq (1 - m)$.*

Proof. $V^{(m)}$ homogeneous of degree m implies $a_j \in P_{r_j+m-1}$. Recall that $P_\ell = \{0\}$ if $\ell < 0$; P_0 consists of constant polynomials, and polynomials in P_ℓ vanish at zero if $\ell > 0$. Thus $a_j(0) = 0$ except when $r_j = 1 - m$. □

PROPOSITION 2.2. *Let* $W(x) = \sum_{j=1}^{n} b_j(x)\,\partial/\partial x_j$ *and have expansion in terms of homogeneous vector fields relative to a dilation* δ_ε^r, $W(x) = W^{(m)}(x) + W^{(m+1)}(x) + \cdots$. *Let* $W^{(k)}(x) = \sum_{j=1}^{n} b_j^{(k)}(x)\,\partial/\partial x_j$. *Then* $b_j(0) = b_j^{(m)}(0)$ *for* $r_j = 1 - m$, $b_j(0) = b_j^{(m+1)}(0)$ *for* $r_j = -m$, $b_j(0) = b_j^{(m+2)}(0)$ *for* $r_j = -m - 1$, *etc.*

Proof. This follows immediately from Proposition 2.1.

PROPOSITION 2.3. X *is homogeneous of degree* m *if and only if* $Xh \in P_{k+m-1}$ *whenever* $h \in P_k$.

Proof. If $X(x) = \sum a_j(x)\,\partial/\partial x_j$ is homogeneous of degree m, $a_j \in P_{r_j+m-1}$, while $h \in P_k$ implies $\partial h/\partial x_j \in P_{k-r_j}$. Thus $Xh = \sum a_j\,\partial h/\partial x_j \in P_{k+m-1}$. Conversely, if $\sum a_j\,\partial h/\partial x_j \in P_{k+m-1}$ for $h \in P_k$, this implies $a_j \in P_{r_j+m-1}$ or X is homogeneous of degree m. □

PROPOSITION 2.4. *If* $X^{(m)}$ *is homogeneous of degree* m *and* $Y^{(\ell)}$ *is homogeneous of degree* ℓ, *then* $[X^{(m)}, Y^{(\ell)}]$ *is homogeneous of degree* $(m + \ell - 1)$.

Proof. By Proposition 2.3, for $h \in P_k$, $[X^{(m)}, Y^{(\ell)}]h = X^{(m)}(Y^{(\ell)}h) - Y^{(\ell)}(X^{(m)}h) \in P_{k+m+\ell-2} = P_{k+(m+\ell-1)-1}$, which implies that $[X^{(m)}, Y^{(\ell)}]$ is homogeneous of degree $(m + \ell - 1)$. □

DEFINITION. *An extended filtration,* $\mathcal{F}$, *of* $L(X, Y)$ *at zero is a sequence of subspaces* $\{F_j : -\infty < j < \infty\}$ *of* $L(X, Y)$ *such that for all integers* i, j

(i) $F_j \subset F_{j+1}$,

(ii) $[F_i, F_j] \subset F_{i+j}$,

(iii) $\bigcup_j F_j = L(X, Y)$,

(iv) $X \in F_j$ *with* $j \leq 0$ *implies* $X(0) = 0$.

Such filtrations of $L(X, Y)$ will be constructed as follows. Assign integer weights to X, Y, denoted wt X, wt Y (negative integers are permitted), and let the weight of a Lie product be the sum of the weights of its factors. The weight-induced filtration $\mathcal{F}$ then has subspace F_j consisting of all elements in $L(X, Y)$ having weight $i \leq j$. Note that condition (iv) puts a severe restriction on the admissible weights that one can assign to X and Y.

Filtration-induced local coordinates and dilations. Let $\mathcal{F} = \{F_j : -\infty < j < \infty\}$ be an extended filtration of $L(X, Y)$ at zero and $n_k = \dim F_k(0)$, $-\infty < k < \infty$. Property (iv) shows that $n_k = 0$ if $k \leq 0$, while $\dim L(X, Y)(0) = n$ means $\dim F_N(0) = n$ for some integer N. Choose $X_{\pi_1}, \ldots, X_{\pi_{n_1}} \in F_1$ such that they are linearly independent at zero. Adjoin $X_{\pi_{n_1+1}}, \ldots, X_{\pi_{n_2}} \in F_2$ such that $X_{\pi_1}(0), \ldots, X_{\pi_{n_2}}(0)$ are linearly independent, and continue in this fashion to get $X_{\pi_1}, \ldots, X_{\pi_n}$ with

$$X_{\pi_i} \in F_j, \qquad n_{j-1} + 1 \leq i \leq n_j. \tag{7}$$

Let $j \geq 1$ be the smallest integer such that $n_j \neq 0$. Choose $r_i = j$ for $1 \leq i \leq n_j$, $r_i = j + 1$ for $n_j \leq i \leq n_{j+1}$, and so on. The dilation δ_ε^r with $r = (r_1, \ldots, r_n)$ chosen as above is called the *filtration-induced dilation.* In a specific problem, vector fields are initially given relative to some local coordinates—say, $x = (x_1, \ldots, x_n)$—for a neighborhood of zero. Define a local coordinate change $y = \varphi^{-1}(x)$, where

$$x = \varphi(y) = (\exp y_1 X_{\pi_1}) \circ \cdots \circ (\exp y_n X_{\pi_n})(0). \tag{8}$$

Then φ is a local diffeomorphism with $\varphi(0) = 0$, and the coordinates $y = (y_1, \ldots, y_n)$ are *local coordinates induced* by the filtration.

As mentioned in the introduction, in some recent papers a vector field $X(x) = \sum_{j=1}^{n} a_j(x)\,\partial/\partial x_j$ was defined to be homogeneous of degree m if $a_j \in P_{r_j-m}$, $j = 1, \ldots, n$. We have instead changed the definition to $a_j \in P_{r_j+m-1}$ in order to be in keeping with classical terminology.

The next theorem is merely a translation of [4, Thm. 2.1] from the previous definition of vector field homogeneity to the one being used here.

THEOREM 2 (see [4, Thm. 2.1]). *Let $\mathcal{F} = \{F_j : -\infty < j < \infty\}$ be an extended filtration at zero for $L(X, Y)$ with $y = (y_1, \ldots, y_n)$ induced local coordinates and δ_ε^r the induced dilation. Then if $X \in F_{1-m}$,*

$$X(y) = X^{(m)}(y) + X^{(m+1)}(y) + \cdots, \tag{9}$$

where $X^{(j)}$ is homogeneous of degree j with respect to δ_ε^r.

Now assume that a lattice of bracket types (k, ℓ) as in Figure 1 has been drawn. The main result of this section is the following theorem.

THEOREM 3. *Assume* $\dim L(X, Y)(0) = n$ *for system* (1) *and that there exists an m such that the bracket $(1, m+1)$, evaluated at zero, is zero (and hence this will be true for brackets of type $(1, \ell)$, $\ell \geq m+1$, since $X(0) = 0$). If for some integer $k \geq 1$ one can draw a line through the $(1, m)$ point in the lattice with slope $-k/(mk+1)$ such that*

(a) *all brackets to the right of the line vanish at zero. All (even, odd) brackets on the line vanish at zero.*

(b) *as you slide the line to the left parallel to itself, each time that you reach a bracket of type (even, odd) which when evaluated at zero is not zero, its value at zero is a linear combination of brackets (at zero) to the right of the line.*

Then system (1) *is LTLC.*

Remark 1. If we were to allow $k = 0$, the line would have slope zero. Condition (a) is vacuously satisfied with "to the right" replaced as above. If condition (b) is satisfied as you slide the line down (rather than to the left), the original system would be STLC at zero.

Remark 2. If $m = 0$, i.e., $(\text{ad } X, Y)(0) = 0$, one can consider a line through the (1,0) point of slope $-k$ with $k \geq 1$ arbitrary. However, if $m \geq 1$, the limiting (but not attainable) possible slope is $-1/m$. Indeed, the possible slope values lie in the interval $(-1/m, -1/(m+1))$. Choosing m large may be advantageous.

Remark 3. There is no loss of generality in assuming that the local coordinates are such that $Y = \partial/\partial x_1$ and, using some feedback if necessary, $X(x) = \sum_{j=2}^n a_j(x)\partial/\partial x_j$. This ensures that $\partial/\partial x_1$ cannot also occur as some nontrivial product of the vector fields X, Y evaluated at zero. Thus if we expand Y as a sum of homogeneous vector fields relative to a (weight) filtration-induced dilation as in Theorem 2, the leading term will not vanish at zero.

Proof. Assign $\text{wt } X = -k$, $\text{wt } Y = mk + 1$. This makes the weight of the $(1, m)$ bracket one; brackets of types (i, j) which lie on the line will have weight one, and those to the right of the line will have weights less than or equal to zero and hence belong to F_j with $j \leq 0$, where $\mathcal{F} = \{F_j : -\infty < j < \infty\}$ is our candidate for a weight-induced filtration. But by (a), such brackets vanish at zero; hence condition (iv) of an extended filtration at zero is satisfied, and our weight assignment does give such a filtration. Brackets of type (i, j) which lie on or to the left of the line will have positive weights, and their values at zero could be nonzero.

Let δ_ε^r be the filtration-induced dilation and $y = (y_1, \ldots, y_n)$ be the induced local coordinates. By Theorem 3, in these coordinates and relative to this dilation, we can write

$$\begin{aligned} X(y) &= X^{(k+1)}(y) + X^{(k+2)}(y) + \cdots, \\ Y(y) &= Y^{(-mk)}(y) + Y^{(1-mk)}(y) + \cdots. \end{aligned} \tag{10}$$

The homogeneous approximation of system (1) is then

$$\dot{y} = X^{(k+1)}(y) + uY^{(-mk)}(y) \tag{11}$$

with $Y^{(-mk)}(0) \neq 0$ by Remark 3. The proof proceeds by showing that condition (b) implies that system (11) is STLC at zero. In particular, we first show that if W is an ordered product of X, Y of (even, odd) type which does not vanish at zero but is a linear combination of brackets

(evaluated at zero) already encountered, then this same ordered product of $X^{(k+1)}$, $Y^{(-mk)}$ vanishes at zero.

LEMMA 1. *Let $W \in F_k$; hence in the induced local coordinates, and relative to the induced dilation, by Theorem* 2

$$W(y) = W^{(1-k)}(y) + W^{(2-k)}(y) + \cdots.$$

If $W(0) \neq 0$ but is a linear combination of elements in $F_\ell(0)$ for $\ell < k$, then $W^{(1-k)}(0) = 0$.

Proof. Suppose $W(y) = \sum_{j=1}^n b_j(y)\, \partial/\partial y_j$. Then $W(0)$, a linear combination of elements of $F_\ell(0)$ for $\ell < k$, implies $b_j(0) = 0$ for $r_j = k$ by Proposition 2.2. Now let $W^{(m-k)}(y) = \sum_{j=1}^n b_j^{(m)}(y)\, \partial/\partial y_j$, $m = 1, 2, \ldots$. From Proposition 2.1 we see $b_j^{(m)}(0) = 0$ except if $r_j = 1 + k - m$. In other words, $b_j(0) = b_j^{(m)}(0)$ for $r_j = 1 + k - m$. Then with $m = 1$ we have $0 = b_j(0) = b_j^{(1)}(0)$ for $r_j = k$ and hence $W^{(1-k)}(0) = 0$. □

We continue with the proof of Theorem 3. Suppose that W is an ordered product of X, Y of type (s, ℓ) and hence of weight $(smk + s - \ell k)$ which we call m_1, i.e., $W \in F_{m_1}$ and

$$W(y) = W^{(1-m_1)}(y) + W^{(2-m_1)}(y) + \cdots. \tag{12}$$

Then the term of lowest homogeneous order, i.e., $W^{(1-m_1)}$, is the same ordered product of $X^{(k+1)}$ and $Y^{(-mk)}$. Hypothesis (b), together with Lemma 1, shows that any product of the vector fields $X^{(k+1)}$, $Y^{(-mk)}$ of type (even, odd) vanishes at zero.

LEMMA 2. $\dim L(X, Y)(0) = n$ *implies* $\dim L(X^{(k+1)}, Y^{(-mk)})(0) = n$.

Proof. Let $W \in F_\ell$ be a product of factors X, Y such that $W(0) \notin F_{\ell-1}(0)$. As in (12), expand W as $W(y) = W^{(1-\ell)}(y) + W^{(2-\ell)}(y) + \cdots$. Then $W^{(1-\ell)}$ will be the same ordered product of $X^{(k+1)}$, $Y^{(-mk)}$ as W was of X, Y. From Proposition 2.2, if we write $W(0) = \xi + \eta$ with ξ in the quotient space $F_\ell(0)/F_{\ell-1}(0)$, $\eta \in F_{\ell-1}(0)$, then $W^{(1-\ell)}(0) = \xi$. If we assign $\operatorname{wt} X^{(k+1)} = -k$, $\operatorname{wt} Y^{(-mk)} = mk + 1$ and let $\mathcal{G} = \{G_j : -\infty < j < \infty\}$ be the weight-induced filtration of $L(X^{(k+1)}, Y^{(-mk)})$, this shows $\dim G_j(0) = \dim F_j(0)$ for all j, from which the result follows. □

To complete the proof of Theorem 3, we again note that hypothesis (b) and Lemma 1 imply that for the approximating system (11), the (even, odd) brackets evaluated at zero are zero. Since $\dim L(X^{(k+1)}, Y^{(-mk)})(0) = n$, Sussmann's theorem [11] applied to the approximating system shows that it is STLC at zero. Theorem 1 now applies to make system (1) LTLC. □

We next give another example to illustrate the use of Theorem 3 to show large-time local controllability. Furthermore, to see how the details of the proof of this theorem work in a specific example, we compute the filtration-induced local coordinates and dilation and the approximating system relative to them. Then Lemma 1 can be illustrated as we check small-time local controllability of the approximating system.

Example 2.2. On $\mathbb{R}^5$ we consider a system of the form (1) with

$$X(x) = x_1 \frac{\partial}{\partial x_2} + (x_1^4 + x_1^2 x_4)\frac{\partial}{\partial x_3} + x_5 \frac{\partial}{\partial x_4} + x_1^3 \frac{\partial}{\partial x_5}, \qquad Y(x) = \frac{\partial}{\partial x_1}. \tag{13}$$

The relevant brackets, which do not vanish at zero, are

$$Y(0) = \frac{\partial}{\partial x_1}, \quad (\operatorname{ad} X, Y)(0) = \frac{\partial}{\partial x_2}, \quad (\operatorname{ad}^3 Y, X)(0) = -6\frac{\partial}{\partial x_5},$$

$$(\operatorname{ad}^4 Y, X)(0) = \frac{\partial}{\partial x_3}, \quad [(\operatorname{ad}^3 Y, X), X](0) = 6\frac{\partial}{\partial x_4}, \quad \text{and}$$

$$V(0) = [(\operatorname{ad}^3 Y, X),\ [(\operatorname{ad}^2 Y, X),\ X]](0) = 12\frac{\partial}{\partial x_3}.$$

These are, respectively, of types (1,0), (1,1), (3,1), (4,1), (3,2), and (5,3).

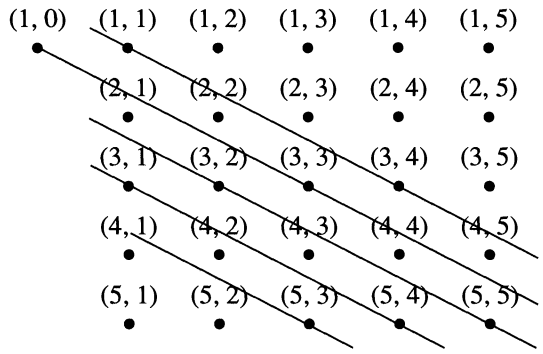

FIG. 2.

Here the (1,1) bracket is linearly independent of the (1,0) bracket, while brackets of the form $(1, \ell)$, $\ell \geq 2$, vanish at zero. We choose $m = 1$. The "bad" bracket is that of type (4,1), and we see that we need a line having a slope so that the (5,3) bracket is encountered before the (4,1). Choose $k = 2$, giving a line of slope $-2/3$ through the point (1,1). As seen in Figure 2, this line meets the requirements of Theorem 3, and the system is LTLC.

It is instructive to essentially follow the steps of the proof of Theorem 3 for this example. For $m = 1$ and $k = 2$, the weight assignments are $\operatorname{wt} X = -2$ and $\operatorname{wt} Y = 3$. Then $\operatorname{wt}(\operatorname{ad} X, Y) = 1$, $\operatorname{wt}(\operatorname{ad}^3 Y, X) = 7$, $\operatorname{wt}(\operatorname{ad}^4 Y, X) = 10$, $\operatorname{wt}[(\operatorname{ad}^3 Y, X), X] = 5$, and $\operatorname{wt}[(\operatorname{ad}^3 Y, X), [(\operatorname{ad}^2 Y, X), X]] = 9$. The weight-induced filtration is δ_ε^r with $r = (1, 3, 5, 7, 9)$. Also, $X_{\pi_1} = (\operatorname{ad} X, Y) \in F_1$, $X_{\pi_2} = Y \in F_3$, $X_{\pi_3} = [(\operatorname{ad}^3 Y, X), X] \in F_5$, $X_{\pi_4} = (\operatorname{ad}^3 Y, X) \in F_7$, and $X_{\pi_5} = [(\operatorname{ad}^3 Y, X), [(\operatorname{ad}^2 Y, X), X]] \in F_9$. The filtration-induced local coordinates are obtained from the diffeomorphism

$$x = \varphi(y) = (\exp y_1 X_{\pi_1}) \circ \cdots \circ (\exp y_5 X_{\pi_5})(0) = \begin{pmatrix} y_2 \\ y_1 \\ 4y_2^3 y_1 + 12 y_1 y_2 y_3 + 12 y_5 \\ 6y_3 \\ 3y_2^2 y_1 - 6y_4 \end{pmatrix}.$$

Abusing notation by letting $X(y)$, $Y(y)$ again denote the original vector fields X, Y in the new y-coordinates, the system $\dot{x} = X(x) + uY$ with $X(x)$, $Y(x)$ given by (13) transforms into

$$\dot{y} = \begin{pmatrix} y_2 \\ 0 \\ (1/2) y_1 y_2^2 - y_4 \\ y_2^3/3 \\ (y_2^4/12) - (y_2^2 y_3/2) - (y_1^2 y_2^3/2) + y_1 y_2 y_4 \end{pmatrix} + u \begin{pmatrix} 0 \\ 1 \\ 0 \\ y_1 y_2 \\ -y_1 y_2^2 - y_1 y_3 \end{pmatrix} \tag{14}$$
$$= X(y) + uY(y).$$

Then relative to the filtration-induced dilation, $X(y) = X^{(3)}(y) + X^{(4)}(y)$, $Y(y) = Y^{(-2)}(y) + Y^{(-1)}(y)$, where

$$X^{(3)}(y) = y_2 \frac{\partial}{\partial y_1} + ((y_1 y_2^2/2) - y_4) \frac{\partial}{\partial y_3} + (y_2^3/3) \frac{\partial}{\partial y_4},$$
$$+ (y_1 y_2 y_4 - (y_2^2 y_3/2) - (y_1^2 y_2^3/2)) \frac{\partial}{\partial y_5},$$

$$X^{(4)}(y) = (y_2^4/12)\frac{\partial}{\partial y_5},$$

$$Y^{(-2)}(y) = \frac{\partial}{\partial y_2} + y_1 y_2 \frac{\partial}{\partial y_4} - y_1 y_3 \frac{\partial}{\partial y_5},$$

$$Y^{(-1)}(y) = -y_1 y_2^2 \frac{\partial}{\partial y_5}.$$

The homogeneous approximating system is $\dot{y} = X^{(3)}(y) + uY^{(-2)}(y)$, which is STLC (it is an "odd" system). One should note that $(\mathrm{ad}^4 Y^{(-2)}, X^{(3)})(0) = 0$ as promised by Lemma 1; i.e., the approximation is such that the "bad brackets" of the original system vanish at zero for the approximating system.

Example 2.3. On $\mathbb{R}^5$ consider system (1) with

$$X(x) = x_1 \frac{\partial}{\partial x_2} + (x_1^4 + x_1^2 x_5)\frac{\partial}{\partial x_3} + x_5 \frac{\partial}{\partial x_4} + x_1^3 \frac{\partial}{\partial x_5}, \qquad Y = \frac{\partial}{\partial x_1}.$$

The relevant brackets not vanishing at zero are $Y(0) = \partial/\partial x_1$, $(\mathrm{ad}\, X, Y)(0) = \partial/\partial x_2$, $(\mathrm{ad}^3 Y, X)(0) = -6\ \partial/\partial x_5$, $[(\mathrm{ad}^3 Y, X), X](0) = 6\ \partial/\partial x_4$, $[(\mathrm{ad}^3 Y, X), (\mathrm{ad}^2 Y, X)](0) = -12\ \partial/\partial x_3$, and $(\mathrm{ad}^4 Y, X)(0) = 24\ \partial/\partial x_3$. These are, respectively, of types (1,0), (1,1), (3,1), (3,2), (5,2), and (4,1). Plotting them on Figure 2, one sees that no line through a $(1, m)$, $m \geq 1$ point, with slope $-1/m < -k/(km+1) \leq -1/(m+1)$, can encounter the (5,2) bracket before the (4,1). Thus Theorem 3 will not apply. □

EQUIVALENT SUBGRADIENT VERSIONS OF HAMILTONIAN AND EULER–LAGRANGE EQUATIONS IN VARIATIONAL ANALYSIS*

R. TYRRELL ROCKAFELLAR†

Abstract. Much effort in recent years has gone into generalizing the classical Hamiltonian and Euler–Lagrange equations of the calculus of variations so as to encompass problems in optimal control and a greater variety of integrands and constraints. These generalizations, in which nonsmoothness abounds and gradients are systematically replaced by subgradients, have succeeded in furnishing necessary conditions for optimality that reduce to the classical ones in the classical setting, but important issues have remained unsettled, especially concerning the exact relationship of the subgradient versions of the Hamiltonian equations versus those of the Euler–Lagrange equations. Here it is shown that new, tighter subgradient versions of these equations are actually equivalent to each other. The theory of epi-convergence of convex functions provides the technical basis for this development.

Key words. Euler–Lagrange equations, Hamiltonian equations, variational analysis, nonsmooth analysis, subgradients, optimality

AMS subject classifications. 49B10, 49B34

1. Introduction.

In the classical theory of minimization problems involving an integral functional $\int_{t_0}^{t_1} L\big(t, x(t), \dot{x}(t)\big)dt$ with Lagrangian expression $L(t, x, v)$ on $[t_0, t_1] \times \mathbb{R}^n \times \mathbb{R}^n$, a key role in analyzing the optimality of an arc $x(\cdot) : [t_0, t_1] \to \mathbb{R}^n$ is played by the Euler–Lagrange equation

$$\dot{p}(t) = \nabla_x L\big(t, x(t), \dot{x}(t)\big) \quad \text{for} \quad p(t) = \nabla_v L\big(t, x(t), \dot{x}(t)\big). \tag{1.1}$$

When $L(t, x, v)$ is twice differentiable and the Hessian matrix in v is positive definite, the Legendre transform can be applied in the v argument to get a Hamiltonian $H(t, x, p)$ in terms of which the Euler–Lagrange equation can be expressed equivalently as the Hamiltonian system

$$\dot{x}(t) = \nabla_p H\big(t, x(t), p(t)\big), \qquad -\dot{p}(t) = \nabla_x H\big(t, x(t), p(t)\big). \tag{1.2}$$

The differentiability assumptions in this scheme have long posed difficulties, however.

Many problems of interest fail to meet all the criteria for utilizing the Legendre transform; in such cases (1.2) may only be a consequence of (1.1), not equivalent to it. Then the arcs $x(\cdot)$ and $p(\cdot)$ can have "corners" where their derivatives are discontinuous. Tonelli's theory for the existence of optimal arcs demands an even broader setting; that is, problems must be studied with $x(\cdot)$ merely assumed to be absolutely continuous, so that (1.1) and (1.2), to the degree that they are valid, have to be interpreted in an almost everywhere sense.

Questions of existence have also challenged the suitability of classical assumptions in other ways. Tonelli showed that the convexity of $L(t, x, v)$ in v is a crucial property. If this is lacking, a convexification process can be introduced to achieve it as a justifiable sort of regularization (or relaxation) of a given problem, but convexification can disrupt differentiability. Thus, Lagrangians L need to be admitted for which certain derivatives may be absent. The theory of optimal control has pushed this direction of generalization much further through the recognition that a vast range of applications can be covered "neoclassically" in terms of Lagrangians that are not even continuous everywhere and can take on the value ∞, as a device for representing constraints on $x(t)$ and $\dot{x}(t)$ through infinite penalization when they are violated.

As far as possible in the face of this far-reaching extension of the classical framework, one would nonetheless like to make sense of the Euler–Lagrange and Hamiltonian equations as necessary conditions for optimality. The Hamiltonian can always be defined by appealing to the Legendre–Fenchel transform of convex analysis [1] instead of the Legendre transform as

$$H(t, x, p) = \sup_{v \in \mathbb{R}^n} \{\langle p, v\rangle - L(t, x, v)\}, \tag{1.3}$$

where $\langle p, v\rangle$ denotes the inner product of two vectors p and v in $\mathbb{R}^n$. Provided that $L(t, x, v)$ as a function of v is convex and lower semicontinuous, one has

$$L(t, x, v) = \sup_{p \in \mathbb{R}^n} \{\langle p, v\rangle - H(t, x, p)\}, \tag{1.4}$$

so that a one-to-one correspondence is set up between Lagrangians and Hamiltonians without calling for their differentiability. In the possible absence of gradients of L and H, the idea is to try to rewrite (1.1) and (1.2) in terms of some kind of "subgradients."

This program was first carried out in the fully convex case, where $L(t, x, v)$ is convex as a function of (x, v) (rather than just v), which corresponds to $H(t, x, p)$ being concave in x and convex in p. Subgradients of convex analysis were used by Rockafellar [2], [3], [4] to establish an Euler–Lagrange condition

$$\big(\dot{p}(t), p(t)\big) \in \partial L\big(t, x(t), \dot{x}(t)\big) \quad \text{a.e. } t \tag{1.5}$$

and a Hamiltonian condition

$$\big(-\dot{p}(t), \dot{x}(t)\big) \in \partial H\big(t, x(t), p(t)\big) \quad \text{a.e. } t, \tag{1.6}$$

where in (1.5) the subgradients are those of $L(t, \cdot, \cdot)$ as a convex function while in (1.6) they are those of $H(t, \cdot, \cdot)$ in the special sense employed for concave-convex functions. The equivalence of these Euler–Lagrange and Hamiltonian conditions was shown through the dualization rules for subgradient relations in convex analysis.

In a major advance, Clarke [5], [6] developed a robust concept of subgradient that could serve for nonconvex functions and be used in pushing the Euler–Lagrange and Hamiltonian conditions further. This concept has evolved considerably since its introduction, both in the pattern of definition and the role of the convex hull operation. The subgradients in question can now be described in several ways, but for purposes here it is easiest to start with proximal subgradients and then take limits.

Consider a function $f : \mathbb{R}^d \to \overline{\mathbb{R}}$ (where $\overline{\mathbb{R}}$ denotes the extended reals). A vector z is a *proximal subgradient* of f at $\bar{y}$ if $f(\bar{y})$ is finite, and for some $\rho \geq 0$ and $\delta > 0$ one has

$$f(y) \geq f(\bar{y}) + \langle z, y - \bar{y}\rangle - \tfrac{1}{2}\rho|y - \bar{y}|^2 \quad \text{when} \quad |y - \bar{y}| \leq \delta.$$

It is a *subgradient in the general sense*, expressed by $z \in \partial f(\bar{y})$, if there are sequences $y^\nu \to \bar{y}$ and $z^\nu \to z$ such that z^ν is a proximal subgradient of f at y^ν and $f(y^\nu) \to f(\bar{y})$. It is a *subgradient in the horizon sense*, expressed by $z \in \partial^\infty f(\bar{y})$, if this condition holds with the modification that, instead of $z^\nu \to z$, one has $\lambda^\nu z^\nu \to z$ for some sequence of scalars $\lambda^\nu \searrow 0$. (In these expressions and below, we use the superscript ν as the generic index for sequences.)

When f is continuously differentiable, $\partial f(\bar{y})$ consists of just the gradient $\nabla f(\bar{y})$, while $\partial^\infty f(\bar{y})$ has just the zero vector. When f is convex, $\partial f(\bar{y})$ is a closed, convex set, the same as the subgradient set of convex analysis, which if nonempty has $\partial^\infty f(\bar{y})$ as its recession cone. In general, however, $\partial f(\bar{y})$ and $\partial^\infty f(\bar{y})$ are not convex, although they are always closed. Seeking

a subgradient set that always would be both closed and convex, Clarke, although his notation was different and his definition followed an alternate route, ended up with the set

$$\bar{\partial} f(\bar{y}) \;=\; \text{cl con}\big[\partial f(\bar{y}) + \partial^{\infty} f(\bar{y})\big],$$

where "cl" stands for closure and "con" for convex hull. He especially emphasized the case where f is Lipschitz continuous around $\bar{y}$; then $\partial f(\bar{y})$ is a nonempty compact set, whereas $\partial^{\infty} f(\bar{y}) = \{0\}$, so the formula simplifies to $\bar{\partial} f(\bar{y}) = \text{con}\,\partial f(\bar{y})$. See Loewen [7] for a recent exposition furnishing the details.

Nowadays the convexification in this definition is no longer seen as essential for most applications, thanks to improvements in subgradient calculus achieved by Mordukhovich, Ioffe, and others. In the treatment of the class of problems under discussion here, which was Clarke's chief concern, it has a natural genesis in taking weak limits, however, and the question of the extent to which it is needed has been harder to answer.

With full recourse to such convexification, Clarke was able to demonstrate in some situations where $L(t, \cdot, \cdot)$ is locally Lipschitz continuous [8] the necessity of the Euler–Lagrange condition in the form

$$\big(\dot{p}(t), p(t)\big) \in \bar{\partial} L\big(t, x(t), \dot{x}(t)\big) \quad \text{a.e. } t, \tag{1.7}$$

where the subgradient set $\bar{\partial} L\big(t, x(t), \dot{x}(t)\big)$ refers to the function $L(t, \cdot, \cdot)$ at $\big(x(t), \dot{x}(t)\big)$ and, because of the Lipschitz continuity, equals $\text{con}\,\partial L\big(t, x(t), \dot{x}(t)\big)$. On the other hand, he established in some other situations [9] where $H(t, \cdot, \cdot)$ is locally Lipschitz continuous the necessity of the Hamiltonian condition in the form

$$\big(-\dot{p}(t), \dot{x}(t)\big) \in \bar{\partial} H\big(t, x(t), p(t)\big) \quad \text{a.e. } t, \tag{1.8}$$

where the subgradient set $\bar{\partial} H\big(t, x(t), \dot{x}(t)\big)$ is that of $H(t, \cdot, \cdot)$ at $\big(x(t), p(t)\big)$ and, again because of the Lipschitz continuity, is the same as $\text{con}\,\partial H\big(t, x(t), p(t)\big)$. (See [6], [10] for an overview of this development.)

Although Clarke's conditions (1.7) and (1.8) reduce to (1.1) and (1.2) in the classical case and to (1.5) and (1.6) in the convex case, and then are equivalent, neither necessarily implies the other in general, even when both $L(t, \cdot, \cdot)$ and $H(t, \cdot, \cdot)$ are locally Lipschitz continuous. Their precise relationship has therefore been a mystery.

Loewen and Rockafellar [11] showed, in building on Clarke's results, that for a major class of problems the Euler–Lagrange condition (1.7) and Hamiltonian condition (1.8) do at least have to hold simultaneously for some arc $p(\cdot)$ when $x(\cdot)$ is optimal. Rockafellar proved in [12, Thm. 5.1] that when $H(t, \cdot, \cdot)$ is locally Lipschitz continuous the Hamiltonian condition implies

$$\big(\dot{p}(t), \dot{x}(t)\big) \in \text{con}\,\big\{(-w, v) \;\big|\; \big(w, p(t)\big) \in \partial L(t, x(t), v),\ \ p(t) \in \partial_v L(t, x(t), v)\big\}, \tag{1.9}$$

which is a form of the Euler–Lagrange condition suggested by Mordukhovich [13], [14], [15]. For Hamiltonians arising from bounded differential inclusions, Ioffe [16] established that this implication is an equivalence. Also identified in Rockafellar [12, Thm. 3.4] is a broadly applicable case, beyond the known classical and convex ones, where (1.7) and (1.8) are equivalent even with $\bar{\partial} L$ replaced by ∂L.

More recent work of Loewen and Rockafellar in [17] raised the possibility of establishing the Euler–Lagrange condition in the form

$$\dot{p}(t) \in \text{con}\,\big\{w \;\big|\; \big(w, p(t)\big) \in \partial L\big(t, x(t), \dot{x}(t)\big)\big\} \quad \text{a.e. } t \tag{1.10}$$

with the companion property that

$$p(t) \in \partial_v L\big(t, x(t), \dot{x}(t)\big) \quad \text{a.e. } t. \tag{1.11}$$

They were able to do this in a case where L is the indicator of a possibly unbounded differential inclusion, which should allow extension to other Lagrangians L through consideration of epigraphical mappings. This case also covers, for instance, the case where L is the indicator of a Lipschitz continuous differential inclusion of the kind underlying Clarke's Hamiltonian results. Such an Euler–Lagrange condition has also been obtained by Mordukhovich [18] for a class of nonconvex differential inclusions and by Ioffe and Rockafellar [19] for certain finite functions L. In the special case where $L(t, x, v)$ is essentially strictly convex in v, which corresponds in the theory of the Legendre–Fenchel transform to $H(t, x, p)$ being smooth in p, a case used as a technical stepping stone in [17], (1.9) comes out as saying the same thing as (1.10) and (1.11). In general, though, the combination of (1.10) with (1.11) is distinctly sharper than the versions of Euler–Lagrange in (1.7) and (1.9) because the process of convexification is much more limited.

Here we sidestep the exploration of the full range of situations in which the Euler–Lagrange condition in the form of (1.10) might be necessary for the optimality of an arc $x(\cdot)$. Instead we focus on the relationship between (1.10) and a corresponding version of the Hamiltonian condition, namely,

$$\dot{p}(t) \in \operatorname{con}\big\{w \,\big|\, \big(-w, \dot{x}(t)\big) \in \partial H\big(t, x(t), p(t)\big)\big\} \quad \text{a.e. } t \tag{1.12}$$

along with

$$\dot{x}(t) \in \partial_p H\big(t, x(t), p(t)\big) \quad \text{a.e. } t. \tag{1.13}$$

This is sharper than the Hamiltonian condition (1.8) and has not previously been considered. We'll show it is in fact equivalent to (1.10) in the kinds of circumstances that are typically present in derivations of necessary conditions for the optimality of an arc $x(\cdot)$. Efforts aimed at enlarging the range of cases in which the Euler–Lagrange condition holds in the version (1.10) can thus count on the side benefit of improving Clarke's Hamiltonian condition in a hitherto unsuspected way.

The following theorem is our main result. Through [17] it brings to light, among other things, that (1.8) can be strengthened to (1.12) in Clarke's context [9].

In stating this theorem, we say that the Lagrangian L has the *epi-continuity property along* $x(\cdot)$ if, for almost every t, there is an open set $O(t)$ containing $x(t)$ such that:

(a) $L(t, \cdot, \cdot)$ is lower semicontinuous on $O(t) \times \mathbb{R}^n$;

(b) for every point $(\bar{x}, \bar{v}) \in O(t) \times \mathbb{R}^n$ with $L(t, \bar{x}, \bar{v}) < \infty$, and every sequence $x^\nu \to \bar{x}$, there is a sequence $v^\nu \to \bar{v}$ with $L(t, x^\nu, v^\nu) \to L(t, \bar{x}, \bar{v})$.

Clearly (a) and (b) are satisfied in particular when $L(t, \cdot, \cdot)$ is continuous on $O(t) \times \mathbb{R}^n$.

THEOREM 1.1. *Let $L(t, x, v)$ be convex in v (possibly with the value ∞), and let $H(t, x, p)$ be defined by* (1.3). *Let $x(\cdot)$ be an arc along which L has the epi-continuity property. Suppose for almost every t that*

$$(w, 0) \in \partial^\infty L\big(t, x(t), \dot{x}(t)\big) \implies w = 0, \tag{1.14}$$

this being true in particular if $L(t, \cdot, \cdot)$ is Lipschitz continuous around $\big(x(t), \dot{x}(t)\big)$. Then version (1.10) *of the Euler–Lagrange condition is equivalent to version* (1.12) *of the Hamiltonian condition and automatically entails* (1.11) *and* (1.13). *The same holds when* (1.14) *is replaced by*

$$(w, 0) \in \partial^\infty H\big(t, x(t), p(t)\big) \implies w = 0, \tag{1.15}$$

this being true in particular if $H(t, \cdot, \cdot)$ is Lipschitz continuous around $\big(x(t), p(t)\big)$.

The epi-continuity property invoked in Theorem 1.1 concerns the continuity of the set-valued mapping that associates with each x the epigraph of the function $L(t, x, \cdot)$, as will become clearer in the next section. Assumption (1.14) concerns a kind of localized Lipschitz continuity of this mapping. Such properties of epigraphical mappings have long been implicit in most developments of the subject, in consequence for instance of Lipschitz assumptions placed on L or H, or on some underlying differential inclusion mapping, but their effects on subgradients have not been explored directly. Here they emerge finally in the foreground. Also coming on stage for the first time in such a setting, through the technique we will use to prove Theorem 1.1, will be a number of tools of convex analysis. These include Fenchel's duality theorem in convex optimization, Moreau's theory of proximal regularizations of convex functions, Wijsman's epi-continuity theorem for the Legendre-Fenchel transform, and Attouch's theorem on convergence of subgradients.

2. Dualization framework and epi-continuity. For the task to be accomplished, the t argument doesn't matter; all questions revolve around properties that hold for a fixed t. We therefore suppress t. We consider an open subset O of $\mathbb{R}^m$ and take $L(x, v)$ to be an expression defined for $(x, v) \in O \times \mathbb{R}^n$ such that, for each $x \in O$, $L(x, \cdot)$ is a convex, lower semicontinuous (lsc) function on $\mathbb{R}^n$ that is *proper*, i.e., although possibly extended real-valued does not take on $-\infty$ and is not identically ∞. In the targeted applications to Euler–Lagrange and Hamiltonian conditions we'll have $m = n$, but for the sake of other potential uses of the results to be obtained we allow the dimensions m and n to differ. We define $H(x, p)$ for $(x, p) \in O \times \mathbb{R}^n$ by

$$H(x, p) = \sup_{v \in \mathbb{R}^n} \{\langle p, v\rangle - L(x, v)\}. \tag{2.1}$$

The Legendre–Fenchel transformation, on which this formula is based, has the property that for each $x \in O$, $H(x, \cdot)$ is, like $L(x, \cdot)$, a proper, convex, lsc function on $\mathbb{R}^n$, moreover with

$$L(x, v) = \sup_{p \in \mathbb{R}^n} \{\langle p, v\rangle - H(x, p)\}. \tag{2.2}$$

This symmetric relationship between L and H will enable us to apply any result proved for either function to the other function as well. We can later interpret O as a neighborhood of some particular point of $\mathbb{R}^m$ that happens to be under scrutiny.

The lower semicontinuity of $L(x, v)$ in v and of $H(x, p)$ in p has already been incorporated into our framework, but nothing has been said yet about continuity properties relative to x. At the very least we'll need $L(x, v)$ to be lsc in $(x, v) \in O \times \mathbb{R}^n$ and similarly for $H(x, p)$ in (x, p); but we're going to go further, clarifying along the way the property that provides the simplest dualization scheme and best supports our subsequent analysis. We'll be working with the concept of epi-continuity in the dependence of the functions $L(x, \cdot)$ and $H(x, \cdot)$ on x.

Recall that the *epigraph* of a function $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ is the set

$$\operatorname{epi} f = \{(y, \alpha) \in \mathbb{R}^n \times \mathbb{R} \mid \alpha \geq f(y)\}.$$

In general, a sequence of functions $f^\nu : \mathbb{R}^n \to \overline{\mathbb{R}}$ is said to *epi-converge* to a function $f : \mathbb{R}^n \to \overline{\mathbb{R}}$ if the corresponding epigraphs converge, meaning that

$$\operatorname{epi} f = \limsup_{\nu \to \infty} \operatorname{epi} f^\nu = \liminf_{\nu \to \infty} \operatorname{epi} f^\nu$$

in the Painlevé–Kuratowski sense as subsets of $\mathbb{R}^n \times \mathbb{R}$. This is true if and only if

$$\text{(2.3)} \qquad \begin{cases} \liminf_\nu f^\nu(v^\nu) \geq f(v) & \text{for every sequence } v^\nu \to v, \\ \limsup_\nu f^\nu(v^\nu) \leq f(v) & \text{for some sequence } v^\nu \to v. \end{cases}$$

Epi-convergence was introduced for proper, lsc, convex functions by Wijsman [20], who proved that the Legendre–Fenchel transformation was continuous with respect to it. For more background on this topic, see Wets [21] and Salinetti and Wets [22].

PROPOSITION 2.1. *The following six properties are equivalent and imply in particular that L and H are lsc in both arguments jointly, as functions on $O \times \mathbb{R}^n$.*

(a) *The set* epi $L(x, \cdot)$ *in* $\mathbb{R}^n \times \mathbb{R}$ *depends continuously on* $x \in O$.

(b) *Whenever* $x^\nu \to \bar{x}$ *in* O, *the function* $L(x^\nu, \cdot)$ *epi-converges to* $L(\bar{x}, \cdot)$.

(c) *For any* $(\bar{x}, \bar{v}) \in O \times \mathbb{R}^n$ *and sequence* $x^\nu \to \bar{x}$, *one has*

$$\begin{cases} \liminf_\nu L(x^\nu, v^\nu) \geq L(\bar{x}, \bar{v}) & \text{for every sequence } v^\nu \to \bar{v}, \\ \limsup_\nu L(x^\nu, v^\nu) \leq L(\bar{x}, \bar{v}) & \text{for some sequence } v^\nu \to \bar{v}. \end{cases}$$

(d) *The set* epi $H(x, \cdot)$ *in* $\mathbb{R}^n \times \mathbb{R}$ *depends continuously on* $x \in O$.

(e) *Whenever* $x^\nu \to \bar{x}$ *in* O, *the function* $H(x^\nu, \cdot)$ *epi-converges to* $H(\bar{x}, \cdot)$.

(f) *For any* $(\bar{x}, \bar{p}) \in O \times \mathbb{R}^n$ *and sequence* $x^\nu \to \bar{x}$, *one has*

$$\begin{cases} \liminf_\nu H(x^\nu, p^\nu) \geq H(\bar{x}, \bar{p}) & \text{for every sequence } p^\nu \to \bar{p}, \\ \limsup_\nu H(x^\nu, p^\nu) \leq H(\bar{x}, \bar{p}) & \text{for some sequence } p^\nu \to \bar{p}. \end{cases}$$

Proof. Conditions (a) and (b) mean the same, by the definition of epi-convergence, and (c) characterizes this property in accordance with the facts just cited. This pattern holds for (d), (e), and (f) as well. But because $L(x^\nu, \cdot)$ and $H(x^\nu, \cdot)$ are proper convex functions conjugate to each other under the Legendre–Fenchel transformation, which preserves epi-convergence according to Wijsman's theorem, (b) is equivalent to (e). Hence, all the conditions are equivalent to each other. □

For short, we'll say that the *epi-continuity assumption* is satisfied when the six equivalent properties in Proposition 2.1 are present. Obviously this is true in particular when L is continuous on $O \times \mathbb{R}^n$ (through (c)), or when H is continuous on $O \times \mathbb{R}^n$ (through (f)). In typical applications the epi-continuity assumption merely means (through property (c)) that, in addition to taking $L(x, v)$ to be lsc in (x, v), rather than just in x, we suppose that whenever $(\bar{x}, \bar{v})$ is a point of $O \times \mathbb{R}^n$ where L is finite and $\{x^\nu\}$ is a sequence in O converging to $\bar{x}$, there must be a sequence $\{v^\nu\}$ converging to $\bar{v}$ for which $L(x^\nu, v^\nu)$ converges to $L(\bar{x}, \bar{v})$.

Note that the epi-continuity condition used in the hypothesis of Theorem 1.1 merely requires for almost every t that this should hold relative to some neighborhood $O(t)$ of $x(t)$. Proposition 2.1 shows that the condition in question could be expressed in terms of the Hamiltonian just as well as the Lagrangian. It's actually symmetric between the two functions (as long as the Lagrangian is lsc and convex with respect to v).

The study of subgradients of L and H with respect to both of their arguments in $O \times \mathbb{R}^n$ requires working with the definition in §1 in terms of limits of proximal subgradients. But subgradients of L in the v argument and of H in the p argument enjoy the benefits of convexity. Convex analysis informs us that

$$\text{(2.4)} \qquad p \in \partial_v L(x, v) \iff v \in \partial_p H(x, p) \iff L(x, v) + H(x, p) = \langle p, v \rangle$$

(cf. [1, Thm. 23.5]), where from (2.1) and (2.2) we know that $L(x, v) + H(x, p) \geq \langle v, p \rangle$ for all choices of $(x, v, p) \in O \times \mathbb{R}^n \times \mathbb{R}^n$.

PROPOSITION 2.2. *Under the epi-continuity assumption,*

$$\begin{aligned} (w, p) \in \partial L(x, v) &\implies p \in \partial_v L(x, v), \\ (w, v) \in \partial H(x, p) &\implies v \in \partial_p H(x, p). \end{aligned} \tag{2.5}$$

Proof. Due to symmetry, it suffices to deal with the first of these implications. Suppose $(\bar{w}, \bar{p}) \in \partial L(\bar{x}, \bar{v})$. By definition there exist $(x^\nu, v^\nu) \to (\bar{x}, \bar{v})$ and $(w^\nu, p^\nu) \to (\bar{w}, \bar{p})$ such that (w^ν, p^ν) is a proximal subgradient of L at (x^ν, v^ν), and $L(x^\nu, v^\nu) \to L(\bar{x}, \bar{v})$. The proximal subgradient condition refers to the existence of $\rho^\nu \geq 0$ and $\delta^\nu > 0$ such that

$$L(x, v) \geq L(x^\nu, v^\nu) + \langle (w^\nu, p^\nu), (x, v) - (x^\nu, v^\nu) \rangle - \tfrac{1}{2}\rho^\nu \big(|x - x^\nu|^2 + |v - v^\nu|^2\big)$$

when $|(x - x^\nu, v - v^\nu)| \leq \delta^\nu$. In taking $x = x^\nu$ we see that the convex function

$$f^\nu(v) := L(x^\nu, v) - \langle p^\nu, v - v^\nu \rangle + \tfrac{1}{2}\rho^\nu |v - v^\nu|^2$$

must have a local minimum at v^ν. This implies that $0 \in \partial f^\nu(v^\nu) = \partial_v L(x^\nu, v^\nu) - p^\nu$ or, in other words, $p^\nu \in \partial_v L(x^\nu, v^\nu)$, a subgradient condition that, because of the convexity of $L(x, v)$ in v, can be written as the inequality

$$L(x^\nu, v) \geq L(x^\nu, v^\nu) + \langle p^\nu, v - v^\nu \rangle \quad \text{for all } v \in \mathbb{R}^n.$$

Consider now an arbitrary $v \in \mathbb{R}^n$ for which $L(\bar{x}, v) < \infty$. Our epi-continuity assumption ensures the existence of a sequence $\hat{v}^\nu \to v$ with $L(x^\nu, \hat{v}^\nu) \to L(x^\nu, v)$. For each index ν we have

$$L(x^\nu, \hat{v}^\nu) \geq L(x^\nu, v^\nu) + \langle p^\nu, \hat{v}^\nu - v^\nu \rangle.$$

In passing to the limit as $\nu \to \infty$ and using the fact that $L(x^\nu, v^\nu) \to L(\bar{x}, v)$ in particular, we obtain

$$L(\bar{x}, v) \geq L(\bar{x}, \bar{v}) + \langle \bar{p}, v - \bar{v} \rangle.$$

We have shown this inequality to hold for any v with $L(\bar{x}, v)$ finite, but it holds trivially when $L(\bar{x}, v) = \infty$. Hence it holds for all $v \in \mathbb{R}^n$, confirming that $\bar{p} \in \partial_v L(\bar{x}, \bar{v})$. □

Proposition 2.2 suggests approaching the subgradients of L and H in general by looking at the set

$$M := \{(x, v, p) \in O \times \mathbb{R}^n \times \mathbb{R}^n \mid \text{properties (2.4) hold}\} \tag{2.6}$$

and the set-valued mappings

$$\begin{aligned} S_L &: (x, v, p) \mapsto \{w \mid (w, p) \in \partial L(x, v)\}, \\ S_H &: (x, v, p) \mapsto \{w \mid (w, v) \in \partial H(x, p)\}. \end{aligned} \tag{2.7}$$

The graph of S_L, consisting by definition of all (x, v, p, w) such that $w \in S_L(x, v, p)$, is the same then as the graph of ∂L, except for a permutation of arguments; likewise for the graph of S_H in comparison with the graph of ∂H.

PROPOSITION 2.3. *Under the epi-continuity assumption, M is closed in $O \times \mathbb{R}^n \times \mathbb{R}^n$ and the functions $(x, v, p) \mapsto L(x, v)$ and $(x, v, p) \mapsto H(x, p)$ are finite and continuous on M. Moreover, the effective domains of the set-valued mappings S_L and S_H on $O \times \mathbb{R}^n \times \mathbb{R}^n$ (the effective domains being the sets on which the mappings are nonempty-valued) lie in M, and the graphs of these mappings are closed as subsets of $O \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^n$.*

Proof. We can view M as the graph of the mapping G that associates with each $x \in O$ the set of all $(v, p) \in \mathbb{R}^n \times \mathbb{R}^n$ such that p is a subgradient of the convex function $L(x, \cdot)$ at v. According to Attouch's theorem on subgradient convergence (see [23]), the epi-convergence of $L(x^\nu, \cdot)$ to $L(x, \cdot)$ implies the set convergence of $G(x^\nu)$ to $G(x)$. In particular, this entails the closedness of the graph of G in $O \times \mathbb{R}^n \times \mathbb{R}^n$.

As functions of (x, v, p), both $L(x, v)$ and $H(x, p)$ are lower semicontinuous by Proposition 2.1 and never take on $-\infty$. But on M they are related by $H(x, p) = \langle v, p\rangle - L(x, v)$ and $L(x, v) = \langle v, p\rangle - H(x, p)$, so they cannot take on ∞ either and must be upper semicontinuous as well. Hence they are finite and continuous on M.

The assertion about the effective domains of S_L and S_H just restates Proposition 2.2. Verifying the closedness of the graphs of S_L and S_H comes down to verifying the closedness of the graphs of ∂L and ∂H. The graph of ∂L consists by definition of the closure, in a special way relative to $O \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^n$, of the set of all (x, v, w, p) such that (w, p) is a proximal subgradient of L at (x, v). The closure consists of all limits of sequences $(x^\nu, v^\nu, w^\nu, p^\nu)$ that not only converge themselves but have the additional property that the values $L(x^\nu, v^\nu)$ converge. But whenever (w^ν, p^ν) is a proximal subgradient of L at (x^ν, v^ν) we have in particular that p^ν is a proximal subgradient of the convex function $L(x^\nu, \cdot)$ at v^ν. This implies $p^\nu \in \partial_v L(x^\nu, v^\nu)$, hence $(x^\nu, v^\nu, p^\nu) \in M$. The convergence of the values $L(x^\nu, v^\nu)$ is then automatic because L is continuous as a function on M. Thus, the special feature of the closure process falls away, and the graph of ∂L is seen to be a closed set in the ordinary sense relative to $O \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^n$. For ∂H the argument is parallel. □

Our strategy for proving Theorem 1.1 is now perhaps becoming clear. Under the epi-continuity assumption, we need only come up with additional conditions on a point $(\bar{x}, \bar{v}, \bar{p}) \in M$ that guarantee the sets $S_L(\bar{x}, \bar{v}, \bar{p})$ and $-S_H(\bar{x}, \bar{v}, \bar{p})$ have the same convex hull. The fact that these sets don't necessarily agree in advance of taking convex hulls is evident from simple examples. For instance, if $L(x, v) = c(x) + l(v)$ for a finite, continuous function c on $\mathbb{R}^m$ and a proper, lsc, convex function l on $\mathbb{R}^n$, we have $H(x, p) = -c(x) + h(p)$ with h the proper, lsc, convex function on $\mathbb{R}^n$ conjugate to l. Then M is the product of $\mathbb{R}^m$ with the graph of ∂l, and for $(\bar{x}, \bar{v}, \bar{p}) \in M$ we see that

$$S_L(\bar{x}, \bar{v}, \bar{p}) = \partial c(\bar{x}), \qquad S_H(\bar{x}, \bar{v}, \bar{p}) = -\partial(-c)(\bar{x}).$$

While $\partial c(\bar{x})$ is the set of subgradients of c at $\bar{x}$ as defined in the manner explained, from limits of proximal subgradients introduced "from below," $-\partial(-c)(\bar{x})$ has the analogous interpretation with proximal subgradients introduced instead "from above." These two sets are known often to differ for a nonsmooth function c, although they have the same convex hull when c is Lipschitz continuous on a neighborhood of $\bar{x}$.

The key to further progress will be the following *regularized functions* associated with L and H:

$$\begin{aligned} R_L(x, u) &:= \inf_{v \in \mathbb{R}^n} \left\{ L(x, v) + \tfrac{1}{2}|v - u|^2 \right\}, \\ R_H(x, u) &:= \inf_{p \in \mathbb{R}^n} \left\{ H(x, p) + \tfrac{1}{2}|p - u|^2 \right\}, \end{aligned} \tag{2.8}$$

where $|\cdot|$ is the Euclidean norm. Also important will be the corresponding *proximal mappings*:

$$\begin{aligned} P_L(x, u) &:= \arg\min_{v \in \mathbb{R}^n} \left\{ L(x, v) + \tfrac{1}{2}|v - u|^2 \right\}, \\ P_H(x, u) &:= \arg\min_{p \in \mathbb{R}^n} \left\{ H(x, p) + \tfrac{1}{2}|p - u|^2 \right\}. \end{aligned} \tag{2.9}$$

In dealing with these regularized functions and proximal mappings for a fixed u, we draw heavily on the theory of Moreau [24]; see also Rockafellar [1, Thm. 31.5]. For any fixed $x \in O$, the functions $u \mapsto R_L(x, u)$ and $u \mapsto R_H(x, u)$ are finite, convex, and continuously differentiable on $\mathbb{R}^n$. They satisfy the identity

$$R_L(x, u) + R_H(x, u) = \tfrac{1}{2}|u|^2. \tag{2.10}$$

The mappings $u \mapsto P_L(x, u)$ and $u \mapsto P_H(x, u)$ are single-valued from $\mathbb{R}^n$ into $\mathbb{R}^n$ and nonexpansive—globally Lipschitz continuous with constant 1—and related by

$$P_L(x, u) + P_H(x, u) = u, \tag{2.11}$$

$$P_L(x, u) = \nabla_u R_H(x, u), \qquad P_H(x, u) = \nabla_u R_L(x, u). \tag{2.12}$$

The proximal mappings P_L and P_H are especially of interest in providing a convenient parameterization of M in terms of (x, u).

PROPOSITION 2.4. *Under the epi-continuity assumption, $R_L(x, u)$ and $R_H(x, u)$ are not just continuous in u but with respect to $(x, u) \in O \times \mathbb{R}^n$. This holds also for $P_L(x, u)$ and $P_H(x, u)$. The one-to-one correspondence between points $(x, v, p) \in M$ and points $(x, u) \in O \times \mathbb{R}^n$ that is set up by the relations*

$$u = v + p, \qquad (v, p) = \big(P_L(x, u), P_H(x, u)\big)$$

is then a homeomorphism.

Proof. From the theory of epi-convergence [21], [23], the convex functions $L(x^\nu, \cdot)$ epi-converge to $L(x, \cdot)$ if and only if the regularized functions $R_L(x^\nu, \cdot)$ converge pointwise on $\mathbb{R}^n$ to $R_L(x, \cdot)$. These regularized functions being not only convex but finite, their pointwise convergence implies uniform convergence on all bounded subsets of $\mathbb{R}^n$ (cf. [1, Thm. 10.8]), and then their gradient mappings $\nabla R_L(x^\nu, \cdot)$ converge in such a manner to $\nabla R_H(x, \cdot)$ as well [1, Thm. 24.5]. The assertions about R_L and P_L, and similarly those about R_H and P_H, thus follow from the meaning of the epi-continuity assumption as designating the six conditions in Proposition 2.1. (The indicated correspondence is one-to-one because the elements $v = P_L(x, u)$ and $p = P_H(x, u)$ satisfy (2.11) and are characterized by the relations $0 \in \partial_v L(x, v) + (v - u)$ and $0 \in \partial_p H(x, p) + (v - p)$.) □

The gradients of $R_L(x, u)$ and $R_H(x, u)$ with respect to u are pinpointed by (2.12); but we can also determine, or at least estimate, subgradients with respect to (x, u).

PROPOSITION 2.5. *Under the epi-continuity assumption, consider any $(\bar{x}, \bar{u}) \in O \times \mathbb{R}^n$ and let $\bar{v} = P_L(\bar{x}, \bar{u})$ and $\bar{p} = P_H(\bar{x}, \bar{u})$. Then*

$$\begin{aligned}
\partial R_L(\bar{x}, \bar{u}) &\subset \big\{(w, p) \,\big|\, p = \bar{p},\ (w, \bar{p}) \in \partial L(\bar{x}, \bar{v})\big\},\\
\partial^\infty R_L(\bar{x}, \bar{u}) &\subset \big\{(w, p) \,\big|\, p = 0,\ (w, 0) \in \partial^\infty L(\bar{x}, \bar{v})\big\},\\
\partial R_H(\bar{x}, \bar{u}) &\subset \big\{(w, v) \,\big|\, v = \bar{v},\ (w, \bar{v}) \in \partial H(\bar{x}, \bar{p})\big\},\\
\partial^\infty R_H(\bar{x}, \bar{u}) &\subset \big\{(w, v) \,\big|\, v = 0,\ (w, 0) \in \partial^\infty H(\bar{x}, \bar{p})\big\}.
\end{aligned}$$

Proof. Let $f(x, v, u) = L(x, v) + \frac{1}{2}|v - u|^2$, so that $R_L(x, u) = \min_v f(x, v, u)$. For $(\bar{x}, \bar{u})$ the minimum is attained uniquely at $\bar{v}$. A general calculus rule in [25, Thm. 3.1] gives us

$$\begin{aligned}
\partial R_L(\bar{x}, \bar{u}) &\subset \big\{(w, p) \,\big|\, (w, 0, p) \in \partial f(\bar{x}, \bar{v}, \bar{u})\big\},\\
\partial^\infty R_L(\bar{x}, \bar{u}) &\subset \big\{(w, p) \,\big|\, (w, 0, p) \in \partial^\infty f(\bar{x}, \bar{v}, \bar{u})\big\},
\end{aligned}$$

but also in terms of the smooth function $f_0(x, v, u) := \frac{1}{2}|v-u|^2$ we have (cf. [7, Lem. 5A.1]) that

$$\begin{aligned} \partial f(\bar{x}, \bar{v}, \bar{u}) &= \big[\partial L(\bar{x}, \bar{v}) \times \{0\}\big] + \nabla f_0(\bar{x}, \bar{v}, \bar{u}), \\ \partial^\infty f(\bar{x}, \bar{v}, \bar{u}) &= \big[\partial^\infty L(\bar{x}, \bar{v}) \times \{0\}\big], \end{aligned}$$

where $\nabla f_0(\bar{x}, \bar{v}, \bar{u}) = (0, \bar{v}-\bar{u}, \bar{u}-\bar{v})$. The combination of these two sets of relations yields the inclusions claimed in the proposition for $\partial R_L(\bar{x}, \bar{u})$ and $\partial^\infty R_L(\bar{x}, \bar{u})$. Those for $\partial R_H(\bar{x}, \bar{u})$ and $\partial^\infty R_H(\bar{x}, \bar{u})$ follow by symmetry. □

Lipschitz continuity of the regularized functions with respect to x will be critical to us at a certain stage. This property is the subject of the next proposition.

PROPOSITION 2.6. *Under the epi-continuity assumption, the following four properties are equivalent to each other at a point* $(\bar{x}, \bar{u}) \in O \times \mathbb{R}^n$.

(a) R_L *is Lipschitz continuous around* $(\bar{x}, \bar{u})$.

(b) $R_L(x, \bar{u})$ *is Lipschitz continuous in* x *around* $\bar{x}$.

(c) R_H *is Lipschitz continuous around* $(\bar{x}, \bar{u})$.

(d) $R_H(x, \bar{u})$ *is Lipschitz continuous in* x *around* $\bar{x}$.

These properties are present in particular when the unique vectors $\bar{v}$ *and* $\bar{p}$ *satisfying* $\bar{u} = \bar{v} + \bar{p}$ *and* $(\bar{x}, \bar{v}, \bar{p}) \in M$ *are such that*

$$(w, 0) \in \partial^\infty L(\bar{x}, \bar{v}) \implies w = 0 \tag{2.13}$$

or such that

$$(w, 0) \in \partial^\infty H(\bar{x}, \bar{p}) \implies w = 0. \tag{2.14}$$

As a special case, the first of these two conditions is implied by L *being Lipschitz continuous around* $(\bar{x}, \bar{v})$, *whereas the second is implied by* H *being Lipschitz continuous around* $(\bar{x}, \bar{p})$.

Proof. The equivalence is apparent from the identity in (2.10) and the fact that $R_L(x, u)$ and $R_H(x, u)$ are finite, convex functions of u, hence locally Lipschitz continuous in u. (As a matter of fact, they are globally Lipschitz continuous in u with constant 1.)

By a result of Rockafellar [26], the function R_L, because of its lower semicontinuity on $O \times \mathbb{R}^n$ (Proposition 2.1), is Lipschitz continuous around $(\bar{x}, \bar{u})$ if and only if the set $\partial^\infty R_L(\bar{x}, \bar{u})$ contains only $(0, 0)$. This is true under (2.13) by virtue of the second inclusion in Proposition 2.5. In the same way, (2.14) suffices for Lipschitz continuity of R_H.

If L is Lipschitz continuous around $(\bar{x}, \bar{v})$, so that $\partial^\infty L(\bar{x}, \bar{v}) = \{(0, 0)\}$ by the result cited, we have (2.13) trivially. Likewise, if H is Lipschitz continuous around $(\bar{x}, \bar{p})$, so that $\partial^\infty H(\bar{x}, \bar{p}) = \{(0, 0)\}$, we have (2.14) trivially. □

For the record, conditions (2.13) and (2.14) aren't equivalent to each other, and they therefore cannot actually be equivalent to the Lipschitz continuity property in Proposition 2.6 but merely sufficient for it. This is seen through the example of $L(x, v) = x^{4/3}v^2$ on $\mathbb{R}^1 \times \mathbb{R}^1$, which is convex in v and continuously differentiable in (x, v). Since $\nabla L(0, 0) = (0, 0)$, the point $(\bar{x}, \bar{v}, \bar{p}) = (0, 0, 0)$ belongs to M. We have $\partial^\infty L(0, 0) = \{(0, 0)\}$ because L is Lipschitz continuous around $(0, 0)$; thus (2.13) is satisfied. But (2.14) isn't satisfied, which is seen as follows. Our choice of L corresponds to

$$H(x, p) = \begin{cases} p^2/4x^{4/3} & \text{when } x \neq 0, \\ 0 & \text{when } x = 0 \text{ and } p = 0, \\ \infty & \text{when } x = 0 \text{ and } p \neq 0. \end{cases}$$

Away from $x = 0$, H is twice continuously differentiable, so its gradients $\nabla H(x, p) = \big(-p^2/3x^{7/3},\ p/2x^{4/3}\big)$ are proximal subgradients. We aim at constructing a nonzero vector

$(\bar{w}, 0)$ in $\partial^\infty H(0,0)$ in accordance with the definition of that set in terms of limits of proximal subgradients. Consider any sequence $t^\nu \searrow 0$ and let $x^\nu = (t^\nu)^6$, $p^\nu = (t^\nu)^5$. Then $(x^\nu, p^\nu) \to (\bar{x}, \bar{p}) = (0,0)$ and $H(x^\nu, p^\nu) = (t^\nu)^2/4 \to 0$. Let $(w^\nu, v^\nu) = \nabla H(x^\nu, p^\nu) = \big(-(t^\nu)^{-4}, (t^\nu)^{-3}/2\big)$. Then for $\lambda^\nu = (t^\nu)^4$ we have $\lambda^\nu \searrow 0$ and $\lambda^\nu(w^\nu, v^\nu) = (-1, t^\nu/2) \to (-1, 0)$. This limit vector belongs to $\partial^\infty H(0,0)$ and demonstrates that (2.14) fails.

3. The main arguments. With this foundation in place, we can turn to the subgradient arguments that lead to the equivalence relation in Theorem 1.1.

LEMMA 3.1. *Under the epi-continuity assumption, suppose that $(\bar{w}, \bar{p})$ is a proximal subgradient to L at a point $(\bar{x}, \bar{v}) \in O \times \mathbb{R}^n$; in other words, $L(\bar{x}, \bar{v})$ is finite and there exist $\rho > 0$ and $\delta > 0$ such that*

$$L(x,v) \geq L(\bar{x},\bar{v}) + \langle \bar{w}, x-\bar{x}\rangle + \langle \bar{p}, v-\bar{v}\rangle - \tfrac{1}{2}\rho|x-\bar{x}|^2 - \tfrac{1}{2}\rho|v-\bar{v}|^2 \quad \text{when } x \in O,\ |x-\bar{x}| \leq \delta,\ |v-\bar{v}| \leq \delta. \tag{3.1}$$

Then there exists $\varepsilon \in (0, \delta)$ such that

$$L(x,v) \geq L(\bar{x},\bar{v}) + \langle \bar{w}, x-\bar{x}\rangle + \langle \bar{p}, v-\bar{v}\rangle - \tfrac{1}{2}\rho|x-\bar{x}|^2 - \tfrac{1}{2}\rho|v-\bar{v}|^2 \quad \text{for all } v \in \mathbb{R}^n \text{ when } x \in O,\ |x-\bar{x}| \leq \varepsilon. \tag{3.2}$$

Proof. We can write (3.1) equivalently as

$$\rho^{-1}L(\bar{x},\bar{v}) + \langle \rho^{-1}\bar{w}, x-\bar{x}\rangle - \tfrac{1}{2}|x-\bar{x}|^2 \leq f(x) \quad \text{when} \quad x \in O,\ |x-\bar{x}| \leq \delta, \tag{3.3}$$

where

$$\begin{aligned} f(x) :&= \inf_{|v-\bar{v}|\leq\delta} \big\{\rho^{-1}L(x,v) + \tfrac{1}{2}|v-\bar{v}|^2 - \langle \rho^{-1}\bar{p}, v-\bar{v}\rangle\big\} \\ &= \inf_{|v-\bar{v}|\leq\delta} \big\{\rho^{-1}L(x,v) + \tfrac{1}{2}\big|v-(\bar{v}+\rho^{-1}\bar{p})\big|^2\big\} - \tfrac{1}{2}|\rho^{-1}\bar{p}|^2. \end{aligned}$$

The question is whether (3.3) will continue to hold when the constraint $|v-\bar{v}| \leq \delta$ is dropped in the definition of f, at least if δ is replaced by some smaller value in (3.3).

We can answer this by applying the facts about proximal regularization to the function

$$\widehat{L}(x,v) := \begin{cases} \rho^{-1}L(x,v) & \text{when } |v-\bar{v}| \leq \delta, \\ \infty & \text{when } |v-\bar{v}| > \delta, \end{cases}$$

in terms of which we have $f(x) = R_{\widehat{L}}(x, \bar{u})$ for $\bar{u} = \bar{v} + \rho^{-1}\bar{p}$. Here $\widehat{L}(x, \cdot)$ is the sum of two convex functions, namely $\rho^{-1}L(x,\cdot)$ and the indicator of $\{v \mid |v-\bar{v}| \leq \delta\}$. For $x = \bar{x}$, the effective domain of the first function meets the interior of the effective domain of the second, and this is enough to guarantee through the convergence theorem of McLinden and Bergstrom [27] that whenever $x^\nu \to \bar{x}$ and $L(x^\nu, \cdot)$ epi-converges to $L(\bar{x}, \cdot)$, the sum $\widehat{L}(x^\nu, \cdot)$ epi-converges to $\widehat{L}(\bar{x}, \cdot)$. It follows then from our epi-continuity assumption that, for x in some open neighborhood O' of $\bar{x}$ within O, $\widehat{L}(x, \cdot)$ depends epi-continuously on x.

Through Proposition 2.4 we conclude that the associated proximal mapping $P_{\widehat{L}}$, which gives the unique minimizing v in the formula for f, is continuous on $O' \times \mathbb{R}^n$. Moreover, the minimum defining $f(\bar{x})$ is attained at $\bar{v}$ because of the proximal subgradient inequality; thus, $P_{\widehat{L}}(\bar{x}, \bar{u}) = \bar{v}$. There must, then, exist an $\varepsilon \in (0, \delta)$ such that when $x \in O'$ and $|x-\bar{x}| \leq \varepsilon$ we have $\big|P_{\widehat{L}}(x, \bar{u}) - \bar{v}\big| < \delta$. For such x the constraint $|v-\bar{v}| \leq \delta$ in the formula for $f(x)$ is inactive. Since the function of v being minimized in this formula is convex, the constraint can in this case be suppressed without affecting the minimum value that is attained. □

LEMMA 3.2. *Under the epi-continuity assumption, suppose* $(\bar{w}, \bar{p})$ *is a proximal subgradient of* L *at a point* $(\bar{x}, \bar{v}) \in O \times \mathbb{R}^n$, *and let* $\bar{u} = \bar{v} + \bar{p}$. *If* R_H *is Lipschitz continuous around* $(\bar{x}, \bar{u})$, *then* $(-\bar{w}, \bar{v}) \in \bar{\partial} R_H(\bar{x}, \bar{u}) = \operatorname{con} \partial R_H(\bar{x}, \bar{u})$.

Proof. We start by noting that in particular $(\bar{w}, \bar{p}) \in \partial L(\bar{x}, \bar{v})$, hence $\bar{p} \in \partial_v L(\bar{x}, \bar{v})$ by Proposition 2.2. Thus $(\bar{x}, \bar{v}, \bar{p}) \in M$. We have

$$\bar{v} = \nabla_u R_H(\bar{x}, \bar{u}) \tag{3.4}$$

by (2.11); this will be needed later.

Through Lemma 3.1 the proximal subgradient condition can be identified with the existence of $\rho > 0$ and $\varepsilon > 0$ such that (3.2) holds. Replacing the second occurrence of ρ in (3.2) by $\rho + 1$, which certainly maintains the inequality, we get

$$F(\bar{x}) + \langle \bar{v}, x - \bar{x} \rangle - \tfrac{1}{2}\rho |x - \bar{x}|^2 \le F(x) \quad \text{when} \quad |x - \bar{x}| \le \varepsilon \tag{3.5}$$

for the function

$$F(x) := \inf_{v \in \mathbb{R}^n} \left\{ L(x, v) - \langle \bar{p}, v - \bar{v} \rangle + \tfrac{1}{2}(\rho + 1)|v - \bar{v}|^2 \right\},$$

which has $F(\bar{x}) = L(\bar{x}, \bar{v})$. As a consequence of (3.5) we certainly have $\bar{w} \in \partial F(\bar{x})$.

To carry the analysis of $\bar{w}$ further, we'll make use of Fenchel's duality theorem [1, Thm. 31.1] to represent F in a different way. For any fixed x the definition of $F(x)$ can be interpreted as saying that

$$F(x) = \inf_{v \in \mathbb{R}^n} \left\{ \varphi(v) - \psi(v) \right\}$$

for the convex function $\varphi(v) := L(x, v) + \frac{1}{2}|v - \bar{v}|^2$ and the concave function $\psi(v) := \langle \bar{p}, v - \bar{v} \rangle - \frac{1}{2}\rho |v - \bar{v}|^2$. Because ψ is finite everywhere, the effective domains of these functions overlap in the manner required by the duality theorem in question, and we are able to conclude from it that

$$-F(x) = \inf_{p \in \mathbb{R}^n} \left\{ \varphi^*(p) - \psi^*(p) \right\}$$

for the functions φ^* and ψ^* conjugate to φ and ψ. From the definition of the convex conjugate φ^* we calculate that

$$\begin{aligned} \varphi^*(p) &= \sup_{v \in \mathbb{R}^n} \left\{ \langle p, v \rangle - L(x, v) - \tfrac{1}{2}|v - \bar{v}|^2 \right\} \\ &= - \inf_{v \in \mathbb{R}^n} \left\{ L(x, v) + \tfrac{1}{2}|v|^2 - \langle \bar{v} + p, v \rangle + \tfrac{1}{2}|\bar{v} + p|^2 - \tfrac{1}{2}|\bar{v} + p|^2 + \tfrac{1}{2}|\bar{v}|^2 \right\} \\ &= \tfrac{1}{2}|\bar{v} + p|^2 - \tfrac{1}{2}|\bar{v}|^2 - R_L(x, \bar{v} + p) = R_H(x, \bar{v} + p) - \tfrac{1}{2}|\bar{v}|^2, \end{aligned}$$

where the final steps use definition (2.8) and the identity (2.10). The definition of the concave conjugate ψ^* yields

$$\psi^*(p) = \inf_{v \in \mathbb{R}^n} \left\{ \langle p, v \rangle - \langle \bar{p}, v - \bar{v} \rangle + \tfrac{1}{2}\rho |v - \bar{v}|^2 \right\} = \langle p, \bar{v} \rangle - \tfrac{1}{2}\rho^{-1}|p - \bar{p}|^2.$$

Out of these calculations we get

$$-F(x) = \inf_{p \in \mathbb{R}^n} \left\{ R_H(x, \bar{v} + p) - \tfrac{1}{2}|\bar{v}|^2 - \langle p, \bar{v} \rangle + \tfrac{1}{2}\rho^{-1}|p - \bar{p}|^2 \right\},$$

which can be transformed to

$$-\rho F(x) = \inf_{p\in\mathbb{R}^n} \{\rho R_H(x, \bar{v} + p) + \tfrac{1}{2}|p - (\rho\bar{v} + \bar{p})|^2\} - \tfrac{1}{2}\rho(\rho + 1)|\bar{v}|^2. \tag{3.6}$$

In terms of $\widetilde{H}(x, p) := \rho R_H(x, \bar{v} + p)$ this has the interpretation that

$$\rho F(x) = -R_{\widetilde{H}}(x, \tilde{u}) + \tfrac{1}{2}\rho(\rho + 1)|\bar{v}|^2 \quad \text{for} \quad \tilde{u} = \rho\bar{v} + \bar{p}. \tag{3.7}$$

Proposition 2.4 assures us that $\widetilde{H}(x, p)$ is finite and continuous in $(x, p) \in O \times \mathbb{R}^n$. It is convex in p besides. We can therefore apply our proximal regularization results to this function in place of H. By assumption, $\widetilde{H}$ is Lipschitz continuous around $(\bar{x}, \bar{p})$. We have $\rho\bar{v} \in \partial_p\widetilde{H}(\bar{x}, \bar{p})$ by (3.4), hence also $\bar{p} = P_{\widetilde{H}}(\bar{x}, \tilde{u})$ and $\rho\bar{v} = \nabla_u R_{\widetilde{H}}(\bar{x}, \tilde{u})$.

By means of Proposition 2.6 we see that $R_{\widetilde{H}}$ is Lipschitz continuous around $(\bar{x}, \tilde{u})$. The fact that $\bar{w} \in \partial F(\bar{x})$ gives us in (3.7) that $\rho\bar{w} \in \partial_x(-R_{\widetilde{H}})(\bar{x}, \tilde{u})$. But by the Lipschitz continuity of $R_{\widetilde{H}}(\cdot, \tilde{u})$ at $\bar{x}$ the Clarke subgradient relation $\bar{\partial}_x(-R_{\widetilde{H}})(\bar{x}, \tilde{u}) = -\bar{\partial}_x R_{\widetilde{H}}(\bar{x}, \tilde{u})$ holds, i.e., $\operatorname{con}\partial_x(-R_{\widetilde{H}})(\bar{x}, \tilde{u}) = -\operatorname{con}\partial_x R_{\widetilde{H}}(\bar{x}, \tilde{u})$ (cf. [5], [7]). Therefore

$$-\rho\bar{w} \in \operatorname{con}\partial_x R_{\widetilde{H}}(\bar{x}, \tilde{u}). \tag{3.8}$$

Next we analyze the set $\partial_x R_{\widetilde{H}}(\bar{x}, \tilde{u})$. Because of the Lipschitz continuity of $R_{\widetilde{H}}$ around $(\bar{x}, \tilde{u})$, the rule holds that

$$\partial_x R_{\widetilde{H}}(\bar{x}, \tilde{u}) \subset \{w \mid \exists\, v \text{ with } (w, v) \in \partial R_{\widetilde{H}}(\bar{x}, \tilde{u})\}$$

(see [7, Lem. 5A.3]). Now Proposition 2.5, as applied with $\widetilde{H}$ in place of H (using the fact that $\tilde{u} = \rho\bar{v} + \bar{p}$ with $\rho\bar{v} \in \partial_p R_{\widetilde{H}}(\bar{x}, \tilde{u})$), says that

$$\partial R_{\widetilde{H}}(\bar{x}, \tilde{u}) \subset \{(w, v) \mid v = \rho\bar{v},\ (w, \rho\bar{v}) \in \partial\widetilde{H}(\bar{x}, \bar{p})\},$$

where from the choice of $\widetilde{H}$ we have $\partial\widetilde{H}(\bar{x}, \bar{p}) = \rho\partial R_H(\bar{x}, \bar{u})$. In combination with (3.8), this gives us $(-\bar{w}, \bar{v}) \in \operatorname{con}\partial R_H(\bar{x}, \bar{u})$, as claimed. □

THEOREM 3.3. *Under the epi-continuity assumption, consider the mappings S_L and S_H of (2.7) at a point $(\bar{x}, \bar{v}, \bar{p})$ such that either $S_L(\bar{x}, \bar{v}, \bar{p})$ or $S_H(\bar{x}, \bar{v}, \bar{p})$ is nonempty or merely $(\bar{x}, \bar{v}, \bar{p}) \in M$. Suppose for $\bar{u} = \bar{v} + \bar{p}$ that $R_L(\cdot, \bar{u})$ is Lipschitz continuous around $\bar{x}$ or, equivalently, that $R_H(\cdot, \bar{u})$ is Lipschitz continuous around $\bar{x}$. Then both $S_L(\bar{x}, \bar{v}, \bar{p})$ and $S_H(\bar{x}, \bar{v}, \bar{p})$ are nonempty and compact, and*

$$\operatorname{con} S_L(\bar{x}, \bar{v}, \bar{p}) = -\operatorname{con} S_H(\bar{x}, \bar{v}, \bar{p}).$$

Proof. In all cases we have $(\bar{x}, \bar{v}, \bar{p}) \in M$, since otherwise both $S_L(\bar{x}, \bar{v}, \bar{p})$ and $S_H(\bar{x}, \bar{v}, \bar{p})$ are empty by Proposition 2.3. The equivalence of the Lipschitz continuity assumptions is shown by Proposition 2.6, which also reveals that they imply that R_L and R_H are Lipschitz continuous around $(\bar{x}, \bar{u})$.

It will be demonstrated that there is a compact set W such that whenever $\bar{w} \in S_L(\bar{x}, \bar{v}, \bar{p})$ we have $\bar{w} \in W$ and $-\bar{w} \in \operatorname{con} S_H(\bar{x}, \bar{v}, \bar{p})$. The full conclusion of the theorem will follow then by symmetry.

By the definition of subgradients in general, the relation $\bar{w} \in S_L(\bar{x}, \bar{v}, \bar{p})$ implies the existence of proximal subgradients (w^ν, p^ν) to L at points $(x^\nu, v^\nu) \to (\bar{x}, \bar{v})$ such that $(w^\nu, p^\nu) \to (\bar{w}, \bar{p})$. The points $u^\nu = v^\nu + p^\nu$ then converge to $\bar{u}$ so that eventually (x^ν, u^ν) lies in the neighborhood of $(\bar{x}, \bar{u})$ in which R_H is Lipschitz continuous. Once this is true, we can apply Lemma 3.2 at (x^ν, u^ν) to ascertain that $(-w^\nu, v^\nu) \in \bar{\partial} R_H(x^\nu, u^\nu)$. In the limit this

yields $(-\bar{w}, \bar{v}) \in \bar{\partial} R_H(\bar{x}, \bar{u})$. In particular, $\bar{w}$ belongs to the image W of $\bar{\partial} R_H(\bar{x}, \bar{u})$ under the projection $(w, v) \mapsto -w$. This image set W is compact because $\bar{\partial} R_H(\bar{x}, \bar{u})$ is compact (in consequence of the Lipschitz continuity of R_H). Since $\bar{\partial} R_H(x^\nu, u^\nu) = \operatorname{con} \partial R_H(x^\nu, u^\nu)$, the inclusion for $\partial R_H(\bar{x}, \bar{u})$ in Proposition 2.5 gives us

$$(-\bar{w}, \bar{v}) \in \operatorname{con}\big\{(-w, v) \,\big|\, v = \bar{v},\ (-w, \bar{v}) \in \partial H(\bar{x}, \bar{p})\big\}.$$

This implies that $-\bar{w} \in \operatorname{con} S_H(\bar{x}, \bar{v}, \bar{p})$ as required. □

The proof of Theorem 3.3 discloses an additional property of the mappings S_L and S_H, which is worth noting. Recall that a set-valued mapping is *locally bounded* at a given point if some neighborhood of that point has bounded image under the mapping.

PROPOSITION 3.4. *Under the hypothesis of Theorem* 3.3, *the mappings S_L and S_H are locally bounded at $(\bar{x}, \bar{v}, \bar{p})$. The same is true also of the mappings $(x, v, p) \mapsto \operatorname{con} S_L(x, v, p)$ and $(x, v, p) \mapsto \operatorname{con} S_H(x, v, p)$, which in this case must, like S_L and S_H, have closed graphs relative to some neighborhood of $(\bar{x}, \bar{v}, \bar{p})$.*

Thus, whenever $(x^\nu, v^\nu, p^\nu) \to (\bar{x}, \bar{v}, \bar{p})$ and $w^\nu \in \operatorname{con} S_L(x^\nu, v^\nu, p^\nu)$, the sequence $\{w^\nu\}$ must be bounded, and all of its cluster points must belong to $\operatorname{con} S_L(\bar{x}, \bar{v}, \bar{p})$; likewise with S_L replaced by S_H.

Proof. This comes from the observation in the proof of Theorem 3.3 that when $(x, v + p)$ belongs to the neighborhood of $(\bar{x}, \bar{v} + \bar{p})$ on which R_H is Lipschitz continuous, we have $S_L(x, v, p) \subset \big\{w \,\big|\, (-w, v) \in \bar{\partial} R_L(x, v)\big\}$. The mapping $\bar{\partial} R_L$ is known to be locally bounded on such a neighborhood. The local boundedness of S_L along with the closedness of its graph (Proposition 2.3) ensures the same properties of the mapping $\operatorname{con} S_L$. The case of S_H follows by symmetry. □

In conclusion we summarize how the results we have obtained fit together to produce the main result stated in §1.

Proof of Theorem 1.1. Let $L_t = L(t, \cdot, \cdot)$ and $H_t = H(t, \cdot, \cdot)$. The assumption that L has the epi-continuity property along the arc $x(\cdot)$ puts us for almost every t in the picture of L_t and H_t satisfying the epi-continuity assumption of §2 relative to some open set $O(t)$ containing $x(t)$. Then by Proposition 2.2, if either $\big(w, p(t)\big) \in \partial L_t\big(x(t), \dot{x}(t)\big)$ or $\big(-w, \dot{x}(t)\big) \in \partial H_t\big(x(t), p(t)\big)$ we have $p(t) \in \partial_v L_t\big(x(t), \dot{x}(t)\big)$ and $\dot{x}(t) \in \partial_p H_t\big(x(t), p(t)\big)$. Thus, the Euler–Lagrange condition (1.10) and the Hamiltonian condition (1.12) automatically give (1.11) and (1.13). The equivalence of (1.10) and (1.12) follows from Theorem 3.3 whenever the regularized function R_{L_t} happens to be Lipschitz continuous around $\big(x(t), \dot{x}(t)\big)$ for almost every t, or equivalently, the function R_{H_t} is Lipschitz continuous around $\big(x(t), p(t)\big)$ for almost every t. Proposition 2.6 shows that such cases occur under the additional assumptions furnished in Theorem 1.1. □

AN A PRIORI ESTIMATE FOR DISCRETE APPROXIMATIONS IN NONLINEAR OPTIMAL CONTROL*

ASEN L. DONTCHEV†

Abstract. We examine the convergence of an approximate discretization applied to the first-order optimality conditions for a nonlinear optimal control problem with convex control constraints. Under an assumption of the coercivity type we prove the existence of an optimal control for the original problem such that its L^∞ distance from the approximating sequence is proportional to the error. In a corollary we give conditions for Riemann integrability of the optimal control.

Key words. optimal control, discrete approximations, error estimates

AMS subject classifications. 49M25, 65K10

1. Introduction.

In this paper we obtain an a priori error estimate for a discrete approximation provided by the Euler scheme to a nonlinear optimal control problem with convex control constraints. We show that if the sequence of successive approximations satisfies a coercivity-type condition, then for a sufficiently fine approximation there exists an optimal control, the L^∞ distance from which to the approximating sequence is proportional to the error.

An excellent survey of earlier works on computational optimal control, including discrete approximations, is contained in Polak [48]. Based on an unpublished work by J.-P. Aubin and J.-L. Lions, Daniel [16] (see also his papers [14], [15]) developed an abstract approach for proving convergence of discrete approximations of optimal control problems, parallel to the direct method of the calculus of variations (but formally independent of it; see also [55]). In a series of papers Cullum [11]–[13] showed value and solution convergence of Euler approximations, applying virtually the same idea. In [11] the problem is linear-convex, [12] considers problems of Mayer's type that are linear in control, and [13] is an extension of [12] for a state and control constrained problem. More recent results on convergence analysis of algorithms involving discrete approximations are contained in [26], [37], [46], [49]–[51], [61]. There is also a body of work in Russian focusing mainly on convergence of discrete approximations combined with Tikhonov's regularization; see [2], [5]–[7], [28], [38], [54].

As typical in perturbation analysis of optimal control, the sequence of optimal values of perturbed (approximating) problems converges to the optimal value of the corresponding relaxed problem (e.g., in the sense of Warga [59]); then the value convergence is equivalent to the relaxability of the continuous problem. This was observed first by Mordukhovich [43]; see also [44] and [25, Ch. 6]. In an earlier paper Cullum [13] proved that a sequence of solutions of the discretized problem converges to a solution of the relaxed problem; instead of relaxability she used necessary conditions for optimality of the relaxed problem.

Compared with the extensive literature on computational optimal control, see the monographs [30], [39], [47], [53], [54]; there are relatively few results available providing *error estimates* for discrete approximations in optimal control. Hager [33] considered higher order schemes applied to unconstrained problems, obtaining error estimates under appropriate smoothness assumptions. Related results are given in [52]. Error estimates for the Euler scheme applied to state and control constrained convex optimal control problems were derived in [17]; see also [1], [40]–[42]. As usual in numerical analysis, the estimation of the error provided by a discrete approximation is limited by the regularity of the solution. In a

recent paper [21] we consider a nonlinear optimal control problem obtaining an a posteriori error estimate. More specifically, we show in [21] that, if an optimal solution of the continuous problem satisfies a coercivity-type condition, then for a sufficiently small mesh spacing h there exists a local minimizer of the corresponding discrete problem at a distance from the optimal solution that is proportional to the averaged modulus of continuity $\tau(u^*; h)$ of the optimal control u^*. The only assumption for the regularity of the optimal control is Riemann integrability; i.e., the optimal control may have infinitely many points of discontinuity (but must be almost everywhere continuous). If the optimal control is of bounded variation, then we automatically obtain that the error is $O(h)$.

In a series of papers Hager [32], [34]–[36] studied approximations to dual problems in optimal control. Dual problems can be defined in various ways, depending on the assumed spaces for the variables and the constraints. By choosing appropriate spaces one may obtain dual problems that are tractable numerically. The dual approach is exceptionally efficient when one deals with entropy-like minimization problems; see, e.g., [4]. In [19], [20] we applied dual methods to a class of best approximation problems with applications in computer-aided geometric design.

Another approach is based on the dynamic programming formulation related to the Hamilton–Jacobi equation. The Hamilton–Jacobi equation typically has a nonsmooth (viscosity) solution whose computation requires special procedures. An overview of a priori error estimates for the approximation of optimal control problems by discrete models is given in [9]; see also [3], [8], [10], [29], [31].

Related to the subject of the present paper is the work on discrete approximations of differential inclusions; for a survey see [24]. In a recent paper [23] we approximated the Hausdorff distance between the sets of solutions to a controlled boundary value problem and its discrete approximation. For other results in this direction, including higher order schemes and error estimates for the reachable set, see [56]–[58], [60].

Although discrete approximations are primarily intended for computations, they are also a useful tool for obtaining purely theoretical results. The idea of using broken lines to prove existence of solutions to differential equations goes back to Euler. Apparently one can use various approximations, depending on the purpose of the study. For instance, one can derive necessary optimality conditions from necessary conditions for a discretized problem by passing to a limit when the step size goes to zero; for a recent paper using this approach see [45]. Depending on the kind of approximation one may obtain various necessary or sufficient optimality conditions.

In §2 we present our error estimate. A proof of this result is given in §3 and is based on an abstract lemma of inverse mapping type for a sequence of set-valued maps. As a corollary we obtain that if the problem has a unique optimal control and a certain coercivity condition is fulfilled for any regular partition, then the optimal control is Riemann integrable. Section 4 contains a discussion of numerical results.

2. The error estimate. We consider the nonlinear optimal control problem

$$\text{minimize} \int_0^1 g(x(t), u(t))dt \tag{1}$$

subject to

$$\dot{x}(t) = f(x(t), u(t)) \quad \text{for a.e. } t \in [0, 1], x(0) = a;$$

$$u(t) \in U \quad \text{for a.e. } t \in [0, 1], u \in L^\infty, x \in W^{1,\infty},$$
