INFINITE-HORIZON LINEAR-QUADRATIC REGULATOR PROBLEMS FOR NONAUTONOMOUS PARABOLIC SYSTEMS WITH BOUNDARY CONTROL*

PAOLO ACQUISTAPACE† AND BRUNELLO TERRENI‡

Abstract. This paper concerns the classical linear-quadratic regulator problem for general nonautonomous parabolic systems with boundary control over infinite time horizon from the point of view of semigroup theory. Under appropriate assumptions we prove existence and uniqueness of the optimal pair, as well as existence, uniqueness, and further properties of the solution of the associated Riccati equation. Several examples are discussed in detail.

Key words. optimal control, parabolic systems, boundary control, infinite horizon, Riccati equation

AMS subject classifications. 49J20, 49N10, 49L20, 34G20

Introduction. This paper concerns the classical linear-quadratic regulator (LQR) problem for general nonautonomous parabolic systems with boundary control over infinite time horizon. Under appropriate assumptions we prove here existence and uniqueness of the optimal pair as well as existence, uniqueness, and further properties of the solution of the associated Riccati equation. Such results generalize the similar ones known in the autonomous case [F3], [LT2], [BDDM] and those of [DI3] relative to nonautonomous problems with distributed control; they also constitute a development of the theory of [AFT] concerning the case of finite time horizon.

Our assumptions are, generally speaking, not uniform with respect to t, with few exceptions concerning the spectra of the elliptic operators $A(t)$ appearing in the state equation and the regularity of the Green maps $G(t)$ associated with them: see Hypotheses 1.1 and 1.3 below. In particular, we do not assume any global exponential estimate for the evolution operator $U(t,s)$ or any boundedness for $G(t)$ and the operators appearing in the cost functional.

On the other hand, some uniform requirements arise in the study of certain features of the Riccati equation. Thus, in order to construct a minimal solution $P_\infty(t)$ of such an equation and to solve the synthesis, we need the "finite cost condition" (Hypothesis 2.2), which is necessary and sufficient; moreover a uniform version of this condition (Hypothesis 3.1) is necessary and sufficient for the existence of a bounded solution of the Riccati equation. Further uniform assumptions (Hypotheses 3.4, 3.5, 3.6 and 3.9) guarantee other properties, such as stability of the optimal state and uniqueness of $P_\infty(t)$. The periodic case is also analyzed. All these results seem to be new even in the case of distributed control of [DI3].

We now list some notations. If X is a Hilbert space, we denote the inner product and the norm of X by $(\cdot\,,\cdot)_X$ and $\|\cdot\|_X$. If Y is another Hilbert space, $\mathcal{L}(X,Y)$ is the Banach space of bounded linear operators from X into Y, and $|\cdot|_{\mathcal{L}(X,Y)}$ denotes its usual norm; we write $\mathcal{L}(X)$ instead of $\mathcal{L}(X,X)$.

If $A : D(A) \subseteq X \to Y$ is a closed linear operator with dense domain, the adjoint operator $A^* : D(A^*) \subseteq Y^* \to X^*$ is defined in the usual way. In particular we denote by $\Sigma(X)$ the set of operators $A \in \mathcal{L}(X)$ such that $A = A^*$, and we set

$$\Sigma^+(X) := \{A \in \Sigma(X) : (Ax,x)_X \geq 0 \ \forall x \in X\},$$
$$\Sigma^{++}(X) := \{A \in \Sigma^+(X) : \exists \nu > 0 : (Ax,x)_X \geq \nu\|x\|_X \ \forall x \in X\}.$$

If $I \subseteq \mathbb{R}$ is an interval, we will use the spaces $L^p(I,X) := \{f : I \to X : f$ is strongly

measurable and $\int_I \|f(t)\|_X^p\, dt < \infty\}$ $(1 \le p < \infty)$, and $L^\infty(I,X)$, $C(I,X)$, whose definitions are similar. Finally we will also use the spaces

$$L^p_{\mathrm{loc}}(I,X) := \bigcap_{J \subset\subset I} L^p(J,X) \quad (1 \le p \le \infty).$$

1. Problem formulation and hypotheses.

1.1. Abstract formulation of a parabolic differential system. Let $\Omega \subset R^d$ be a bounded open domain with boundary $\partial\Omega$ of class C^2, and consider the following parabolic system:

$$\begin{cases} y_t(t,x) = \mathcal{A}(t,x,D)y(t,x) & \text{in } [0,\infty[\times \Omega, \\ \mathcal{B}(t,x,D)y(t,x) = u(t,x) & \text{in } [0,\infty[\times \partial\Omega, \\ y(0,x) = y_0(x) & \text{in } \Omega. \end{cases} \tag{1.1}$$

Here the strongly elliptic differential operators $\{\mathcal{A}(t,\cdot\,,D)\}_{t\ge 0}$ and the boundary operators $\{\mathcal{B}(t,\cdot\,,D)\}_{t\ge 0}$ are assumed to be such that the abstract hypotheses listed in the next subsection are satisfied (see, for instance, the conditions of [AFT, §2.2]).

For each $t \ge 0$ we define $A(t)$ as the realization in $L^2(\Omega)$ of the operator $\mathcal{A}(t,\cdot\,,D)$ with homogeneous boundary conditions determined by $\mathcal{B}(t,\cdot\,,D)$, i.e.,

$$\begin{aligned} &D_{A(t)} := \{y \in L^2(\Omega) \mid \mathcal{A}(t,\cdot\,,D)y \in L^2(\Omega) \text{ and } \mathcal{B}(t,\cdot\,,D)y = 0 \text{ on } \partial\Omega\}, \\ &A(t)y := \mathcal{A}(t,\cdot\,,D)y \quad \forall\, y \in D_{A(t)}. \end{aligned}$$

If we choose $\lambda_0 \in \mathbb{R}$ large enough, we can define simultaneously (for $t \ge 0$) the fractional powers $(\lambda_0 - A(t))^\alpha$ with $0 < \alpha < 1$. We also require that for each $u \in L^2(\partial\Omega)$ we can solve (in the sense of [AFT, §2.4]) simultaneously for $t \ge 0$ the following elliptic problems:

$$\begin{cases} \lambda_0\Phi - \mathcal{A}(t,\cdot\,,D)\Phi = 0 & \text{in } \Omega, \\ \mathcal{B}(t,\cdot\,,D)\Phi = u & \text{on } \partial\Omega; \end{cases} \tag{1.2}$$

in other words, we can define the map $G : [0,\infty) \times L^2(\partial\Omega) \to L^2(\Omega)$ as $G(t)u := \Phi$, where Φ is the unique solution of problem (1.2). In the next section we shall need certain regularity properties for $G(t)$: for instance, we shall assume that

$$t \to (\lambda_0 - A(t))^\alpha G(t) \in L^\infty_{\mathrm{loc}}([0,\infty[; \mathcal{L}(L^2(\partial\Omega), L^2(\Omega)))$$

for some $\alpha \in]0,1[$. It is shown in [AFT] that systems of type (1.1) fulfill this condition.

We remark also that the map G depends on the initial choice of λ_0.

Let

$$z(t) := e^{-\lambda_0 t} y(t),$$

where y solves problem (1.1); then z solves the following problem:

$$\begin{cases} z_t = (\mathcal{A}(t,\cdot\,,D) - \lambda_0)z & \text{in } [0,\infty[\times \Omega, \\ \mathcal{B}(t,\cdot\,,D)z = e^{-\lambda_0 t}u(t) & \text{on } [0,\infty[\times \partial\Omega, \\ z(0) = y_0 & \text{in } \Omega, \end{cases}$$

so using the representation formula proved in [AFT, §2.5] we have

$$z(t) = U_{\lambda_0}(t,0)y_0 + \int_0^t U_{\lambda_0}(t,s)(\lambda_0 - A(s))G(s)u(s)e^{-\lambda_0 s}\, ds. \tag{1.3}$$

Here $U_{\lambda_0}(t,s) := e^{-\lambda_0(t-s)}U(t,s)$ where $U(t,s)$ is the evolution operator associated with $\{A(t)\}_{t\geq 0}$. Thus

$$y(t) = U(t,0)y_0 + \int_0^t U(t,s)(\lambda_0 - A(s))G(s)u(s)\,ds. \tag{1.4}$$

We must recall that formula (1.4) is very useful for our calculations, but we understand that its exact form is

$$y(t) = U(t,0)y_0 + \int_0^t [(\lambda_0 - A(s)^*)^{1-\alpha}U(t,s)^*]^*((\lambda_0 - A(s))^\alpha G(s)u(s)\,ds; \tag{1.5}$$

for more details we refer to [AFT, (2.80) – (2.74)].

Throughout this paper, equation (1.4) or (1.5) will be considered the state equation for our abstract control problem.

1.2. Standing assumptions. In the following discussion we will consider three Hilbert spaces: H (state space), U (control space), and V (space of observations), and we will study the optimal control of equation (1.4) over an unbounded time interval I (which could be $[T_0,\infty[$ for some $T_0 \in \mathbb{R}$, or even $\mathbb{R}$, as for instance in the periodic case). We will consider equation (1.4) as an abstract evolution equation in the Hilbert space H, subject to the abstract assumptions listed below. Thus, equation (1.4) can also cover concrete problems different from those explicitly described above and in the examples in §4. We assume the following hypotheses.

Hypothesis 1.1. $\{A(t)\}_{t\in I}$ is a family of infinitesimal generators of analytic semigroups in H; the spectrum of $A(t)$ is such that the fractional powers $(\lambda_0 - A(t))^\alpha$ are well defined for any $\alpha > 0$, simultaneously with respect to $t \in I$, for some fixed $\lambda_0 \in \mathbb{R}$.

Hypothesis 1.2. The assumptions of [AFT] hold locally, i.e., over every bounded interval $J \subset\subset I$, possibly with constants depending on the interval. More precisely, given $J = [a,b] \subset I$, we assume

(i) the evolution operators $U(t,s)$ and $U(t,s)^*$ are strongly continuous in $\bar{\Delta}$, where $\Delta := \{(t,s) \in [a,b]^2 : t > s\}$, and there exists $M_0 > 0$ such that

$$|U(t,s)|_{\mathcal{L}(H)} + |U(t,s)^*|_{\mathcal{L}(H)} \leq M_0 \quad \forall\,(t,s) \in \bar{\Delta};$$

(ii) for every $\beta,\ \mu \in [-1,1]$ and $(t,s) \in \Delta$ the operators

$$(\lambda_0 - A(t))^\beta U(t,s)(\lambda_0 - A(s))^{-\mu}, \qquad (\lambda_0 - A(s)^*)^\beta U(t,s)^*(\lambda_0 - A(t)^*)^{-\mu}$$

have continuous extensions to H, the maps

$$(t,s) \to (\lambda_0 - A(t))^\beta U(t,s)(\lambda_0 - A(s))^{-\mu}, \quad (t,s) \to (\lambda_0 - A(s)^*)^\beta U(t,s)^*(\lambda_0 - A(t)^*)^{-\mu}$$

are strongly continuous, and there exists $M_{\beta,\mu} > 0$ such that

$$\begin{aligned} &|(\lambda_0 - A(t))^\beta U(t,s)(\lambda_0 - A(s))^{-\mu}|_{\mathcal{L}(H)} + |(\lambda_0 - A(s)^*)^\beta U(t,s)^*(\lambda_0 - A(t)^*)^{-\mu}|_{\mathcal{L}(H)} \\ &\qquad \leq M_{\beta,\mu}[(t-s)^{\mu-\beta} + 1] \quad \forall\,(t,s) \in \Delta. \end{aligned} \tag{1.6}$$

Hypothesis 1.3. There exists $\alpha \in\,]0,1]$ such that, for each $t \in I$, $G(t)$ maps U into the domain of $(\lambda_0 - A(t))^\alpha$, and $(\lambda_0 - A(\cdot))^\alpha G(\cdot)$ is strongly measurable and bounded over each $[a,b] \subset I$.

Remark 1.4. (i) The only novelty with respect to [AFT] is the uniformity with respect to t in Hypotheses 1.1 and 1.3 for the choices of λ_0 and α, respectively. In particular, we do not assume any global exponential estimate for $U(t,s)$ and $(\lambda_0 - A(t))^\beta U(t,s)(\lambda_0 - A(s))^{-\mu}$ or uniform boundedness for $(\lambda_0 - A(t)^*)^\alpha G(t)$, $C(t)$, $N(t)$, and $N(t)^{-1}$ (defined below). Under these assumptions, the representation formulas (1.4), (1.5) can be studied as in [AFT] over any bounded time interval $[a,b]$.

(ii) In §2 the sentence "c depends on $[a,b]$" will mean that c in fact depends, besides $[a,b]$ itself, on all constants involved in estimating functions and operators defined in $[a,b]$. In §3 some questions of stability are treated, and there we shall assume the necessary uniformities and point out the independence of the constants.

(iii) We formulated Hypothesis 1.2 in terms of the evolution operators $U(t,s)$ and $U(t,s)^*$, rather than of the family $\{A(t)\}_{t\geq 0}$; this choice is motivated by the existence in the literature of many independent sets of assumptions on the family $\{A(t)\}_{t\geq 0}$, each of which implies Hypothesis 1.2. In [AT1] and [A1] one can find a review of these assumptions.

1.3. Formulation of the infinite-horizon LQR problem. Given $t_0 \in I$ and $y_0 \in H$, we will consider the problem of minimizing the cost functional

$$J_{t_0,\infty}(u) := \int_{t_0}^{\infty} [\|C(t)y(t)\|_V^2 + (N(t)u(t), u(t))_U]\, dt \tag{1.7}$$

over all $u \in L^2_{\text{loc}}(t_0, \infty; U)$, subject to the state equation (1.5).

Concerning $C(\cdot)$ and $N(\cdot)$ we assume the following hypothesis.

Hypothesis 1.5. For every interval $[a,b] \subset I$,

$$C(\cdot) \in L^\infty([a,b]; \mathcal{L}(H,V)) \quad \text{and} \quad N(\cdot) \in L^\infty([a,b]; \Sigma^{++}(U)).$$

(This means that there exists $\nu > 0$, possibly depending on $[a,b]$, such that $N(t) \geq \nu\, \forall\, t \in [a,b]$, i.e., $(N(t)u,u)_U \geq \nu \|u\|_U^2\, \forall\, u \in U$, $\forall\, t \in [a,b]$.)

2. Solutions of the Riccati equation and related questions. The aim of this section is to solve the integral Riccati equation

$$\begin{aligned} Q(s) &= U(t,s)^* Q(t) U(t,s) \\ &\quad + \int_s^t U(r,s)^* [C(r)^* C(r) \\ &\qquad - Q(r)(\lambda_0 - A(r)) G(r) N(r)^{-1} G(r)^* (\lambda_0 - A(r)^*) Q(r)] U(r,s)\, dr, \end{aligned} \tag{2.1}$$

with $s,\ t \in I,\ s \leq t$, and to prove some further results related to this equation. We follow here along the lines of [F3], *mutatis mutandis*; in particular we shall need a new local existence result (see Theorem 2.5 below).

We recall that a solution $Q(\cdot)$ of equation (2.1) is an operator-valued function $Q \in C_s(I; \Sigma^+(H))$ such that (i) $t \to (\lambda_0 - A(t)^*)^{1-\alpha} Q(t)$ is well defined and strongly continuous from I into $\mathcal{L}(H)$, and (ii) $Q(\cdot)$ satisfies the following meaningful version of (2.1):

$$\begin{aligned} Q(s) &= U(t,s)^* Q(t) U(t,s) \\ &\quad + \int_s^t U(r,t)^* [C(r)^* C(r) \\ &\qquad - [(\lambda_0 - A(r)^*)^{1-\alpha} Q(r)]^* K(r) [(\lambda_0 - A(r)^*)^{1-\alpha} Q(r)]] U(r,s)\, dr \end{aligned}$$

with $s,\ t \in I,\ s \le t$, and where

$$K(r) := [(\lambda_0 - A(r))^{\alpha} G(r)] N(r)^{-1} [(\lambda_0 - A(r))^{\alpha} G(r)]^*;$$

but in order to simplify our calculations and for sake of clearness we will always use equation (2.1).

2.1. Definition of the operator $P_\infty(t)$. Let us denote by $P_T(t)$ the solution, defined for every $t \le T$ (and $t \in I$; we will not repeat this detail in the following discussion), of Riccati equation (2.1) with value 0 at $t = T$:

$$P_T(t) = \int_t^T U(r,t)^* [C(r)^* C(r) - [(\lambda_0 - A(r)^*)^{1-\alpha} P_T(r)]^* K(r) [(\lambda_0 - A(r)^*)^{1-\alpha} P_T(r)]] U(r,s)\, dr. \tag{2.2}$$

This equation was solved in [AFT, Thm. 3.13]. We recall that

$$(P_T(t_0) y_0, y_0)_H = \min_u J_{t_0,T}(u) \tag{2.3}$$

under the condition $y(t_0) = y_0$, where for each $u \in L^2_{\mathrm{loc}}(t_0, \infty; U)$ the functional $J_{t_0,T}(u)$ is defined as

$$J_{t_0,T}(u) = \int_{t_0}^T [\|C(t) y(t)\|_V^2 + (N(t) u(t), u(t))_U]\, dt$$

and y satisfies the state equation (1.4).

Let us introduce the following important condition:

$$(2.4_{t_0}) \quad \begin{cases} \text{there exists } c = c(t_0) > 0 \text{ such that to each } y_0 \in H \text{ there corresponds} \\ \text{a control } u = u(y_0) \in L^2_{\mathrm{loc}}(t_0, \infty; U) \text{ for which } J_{t_0,\infty}(u) \le c \|y_0\|_H^2; \end{cases}$$

in other words condition (2.4_{t_0}) requires the existence of an admissible control with respect to a given $t_0 \in I$ for each initial state $y_0 \in H$.

The following lemma holds.

LEMMA 2.1. *Under Hypotheses* 1.1 – 1.3 *and* 1.5, *we have*

(i) $P_{T_1}(t) \le P_{T_2}(t)$ *for each* $t \le T_1 \le T_2$;

(ii) *condition* (2.4_{t_1}) *implies condition* (2.4_t) *for each* $t \le t_1$;

(iii) *if condition* (2.4_{t_0}) *holds, then* $\sup_{T \ge t_0} |P_T(t_0)|_{\mathcal{L}(H)} < \infty$ *and there exists* $P_\infty(t_0) \in \Sigma^+(H)$ *such that* $P_T(t_0) \uparrow P_\infty(t_0)$ *strongly as* $T \uparrow \infty$.

(iv) *if condition* (2.4_{t_0}) *holds, then for each fixed* $\tau_0 < t_0$ *we have*

$$\sup_{\tau_0 \le t \le t_0, T > t_0} |P_T(t)|_{\mathcal{L}(H)} < \infty; \tag{2.5}$$

moreover $P_\infty(t)$ *is well defined for each* $t \le t_0$, *and*

$$P_\infty(s) \le U(t,s)^* P_\infty(t) U(t,s) + \int_s^t U(r,s)^* C(r)^* C(r) U(r,s)\, dr; \tag{2.6}$$

in particular, for each fixed $\tau_0 < t_0$ *we have*

$$\sup_{\tau_0 \le t \le t_0} |P_\infty(t)|_{\mathcal{L}(H)} < \infty. \tag{2.7}$$

Proof. It is standard and follows from [F1], [AFT]. □

Our main assumption in order to obtain a solution of equation (2.1) is the following hypothesis.

Hypothesis 2.2. Condition (2.4_t) is satisfied for every $t \in I$.

By the preceding lemma, if Hypothesis 2.2 holds, we can define $P_\infty(t)$ for each $t \in I$; this operator-valued function is the candidate solution of the Riccati equation.

Remark 2.3. As we will see, Hypothesis 2.2 is necessary and sufficient to construct $P_\infty(t)$ and to solve the synthesis; hence it is important to know when it is satisfied in concrete examples. Two general remarks in this direction are the following:

(i) if system (1.4) is exactly controllable at 0 in finite time, starting from any time t_0 and initial position y_0, then Hypothesis 2.2 holds;

(ii) if (1.4) is exponentially stabilizable, starting from any t_0, and if $C(t)$ and $N(t)$ are uniformly bounded, then Hypothesis 2.2 holds.

The analysis of these properties in concrete cases is under investigation; however, for certain classes of systems property (ii), hence Hypothesis 2.2, has been proved to hold true (see, for instance, Example 4.2 below). Note also that in the case of periodic systems it is sufficient to show that (2.4_t) is satisfied for some $t \in \mathbb{R}$, because this implies that (2.4_s) holds for each $s < t$ and thus for each s by periodicity.

2.2. A priori bound on $(\lambda_0 - A(t)^*)^\mu P_T(t)$. The following result plays a basic role in solving the Riccati equation (2.1). The same result was proved in [F1] in the case of autonomous parabolic systems, but the proof given in [F1] cannot be extended (at least in an obvious way) to the present case; thus, the proof given here is new. See also [F2], where a similar proof provides the a priori bound needed to get a global solution over a finite time horizon.

LEMMA 2.4. *Assume Hypotheses* 1.1 – 1.3, 1.5, *and* 2.2. *Then for each* $\beta \in]0, 1/2[$ *and each interval* $[a, b] \subset I$, *we have*

$$\sup_{a \le t \le b+1, T > b+2} |(\lambda_0 - A(t)^*)^\beta P_T(t)(\lambda_0 - A(t))^\beta|_{\mathcal{L}(H)} =: c_1(\beta, [a, b]) < +\infty, \tag{2.8}$$

$$\sup_{a \le t \le b+1} |(\lambda_0 - A(t)^*)^\beta P_\infty(t)(\lambda_0 - A(t))^\beta|_{\mathcal{L}(H)} < +\infty. \tag{2.9}$$

Proof. Let us fix an interval $[a, b] \subset I$. Fix $t \in [a, b+1]$, $x \in D((\lambda_0 - A(t))^\beta)$ and set $y_1 := U(b+2, t)(\lambda_0 - A(t))^\beta x$. By Hypothesis 2.2 there exists a control $\bar{u}$ belonging to $L^2_{\mathrm{loc}}(b+2, \infty; U)$ such that $J_{b+2,\infty}(\bar{u}) \le c\|y_1\|_H^2$; hence by Hypothesis 1.2(ii) we also have $J_{b+2,\infty}(\bar{u}) \le c\|x\|_H^2$. Consider the control $\tilde{u} \in L^2_{\mathrm{loc}}(t, \infty; U)$ defined by

$$\tilde{u}(s) = \begin{cases} 0 & \text{for } t \le s < b+2, \\ \bar{u}(s) & \text{for } b+2 \le s < \infty. \end{cases}$$

Using (2.3) we have

$$\begin{aligned} &(P_T(t)(\lambda_0 - A(t))^\beta x, (\lambda_0 - A(t))^\beta x)_H \\ &\quad \le J_{t,T}(\tilde{u}) \\ &\quad = \int_t^{b+2} \|C(s)U(s,t)(\lambda_0 - A(t))^\beta x\|_V^2 \, ds + J_{b+2,\infty}(\bar{u}) \\ &\quad \le \left[c \int_t^{b+2} |U(s,t)(\lambda_0 - A(t))^\beta|^2_{\mathcal{L}(H)} \, ds + c \right] \|x\|_H^2 \le c\|x\|_H^2. \end{aligned} \tag{2.10}$$

Recalling that $P_T(t) \geq 0$, by (2.10) we easily obtain (2.8); moreover, as $P_\infty(t) \geq 0$ too, (2.9) follows by letting $T \to \infty$ in (2.10). □

We state now the following local existence theorem, proved in the Appendix. Its proof is the nonautonomous version of that of [F2, Lem. 2.1].

THEOREM 2.5. *Assume Hypotheses* 1.1 – 1.3, 1.5, *and* 2.2; *fix* $\beta \in]1/2 - \alpha, 1/2[$, $t \in I$, $r_0 > 0$, *and let* $Q_t \in \Sigma^+(H)$ *be such that* $|(\lambda_0 - A(t)^*)^\beta Q_t (\lambda_0 - A(t))^\beta|_{\mathcal{L}(H)} \leq r_0$. *Then there exists* $\tau_0 = \tau_0(r_0, \beta) > 0$ *such that the Riccati equation*

$$
\begin{aligned}
Q(s) = {} & U(t,s)^* Q_t U(t,s) \\
& + \int_s^t U(r,s)^* [C(r)^* C(r) \\
& \qquad - Q(r)(\lambda_0 - A(r)) G(r) N(r)^{-1} G(r)^* (\lambda_0 - A(r)^*) Q(r)] U(r,s)\, dr
\end{aligned}
\tag{2.11}
$$

has a unique solution $Q(\cdot)$ *in* $[t - \tau_0, t[$ *such that* $Q(s) \in \Sigma^+(H)$ *for each* $s \in [t - \tau_0, t[$ *and*

$$
|(\lambda_0 - A(s)^*)^{1-\alpha} Q(s)|_{\mathcal{L}(H)} \leq c(\beta, \alpha, r_0)(t-s)^{\beta+\alpha-1} \quad \forall\, s \in [t - \tau_0, t[. \tag{2.12}
$$

LEMMA 2.6. *Assume Hypotheses* 1.1 – 1.3, 1.5 *and* 2.2. *Then for each* $\mu \in]0, 1[$ *and each interval* $[a, b] \subset I$, *we have*

$$
\sup_{a \leq s \leq b, T > b+2} |(\lambda_0 - A(s)^*)^\mu P_T(s)|_{\mathcal{L}(H)} := c_2(\mu, [a,b]) < \infty. \tag{2.13}
$$

Proof. Using Theorem 2.5 and estimate (2.8) (having fixed any $\beta \in]0, 1/2[$), we find two constants $\tau \in]0, 1]$ and $c' > 0$, depending only on $[a, b]$ and on the constant c_1 of (2.8), such that for each $s, t \in [a, b+1]$ with $s < t$ and $t - s \leq \tau$ we have

$$
(t-s)^{1-\alpha-\beta} |(\lambda_0 - A(s)^*)^{1-\alpha} P_T(s)|_{\mathcal{L}(H)} \leq c'. \tag{2.14}
$$

Fix $s \in [a, b]$ and choose $t_1 := s + \tau/2 < t_2 := s + \tau \leq b + 1$. As $P_T(s)$, in particular, solves (2.2) for $s \leq t_1$ with final datum $P_T(t_1)$, we deduce

$$
\begin{aligned}
P_T(s) = {} & U(t_1, s)^* P_T(t_1) U(t_1, s) + \int_s^{t_1} U(r,s)^* C(r)^* C(r) U(r,s)\, ds \\
& - \int_s^{t_1} U(r,s)^* [(\lambda_0 - A(r)^*)^{1-\alpha} P_T(r)]^* K(r) [(\lambda_0 - A(r)^*)^{1-\alpha} P_T(r)] U(r,s)\, dr.
\end{aligned}
$$

Applying the operator $(\lambda_0 - A(s)^*)^\mu$ to both sides and using Hypothesis 1.2(ii) (and the estimate (2.12) with $t = t_2$), we get

$$
\begin{aligned}
|(\lambda_0 - A(s)^*)^\mu P_T(s)|_{\mathcal{L}(H)} \leq {} & \frac{c}{(t_1 - s)^\mu} |P_T(t_1)|_{\mathcal{L}(H)} + \int_s^{t_1} \frac{c}{(r-s)^\mu}\, ds \sup_{r \in [a,b]} |C(r)|^2_{\mathcal{L}(H,V)} \\
& + c \int_s^{t_1} \frac{c_2^2}{(r-s)^\mu (t_2 - r)^{2(1-\alpha-\beta)}}\, dr \leq c(\tau, c', \beta, [a,b], \mu),
\end{aligned}
$$

and the proof is complete. □

2.3. Existence of solutions of the Riccati equation. We prove here the following result.

THEOREM 2.7. *Assume Hypotheses* 1.1 – 1.3, 1.5, *and* 2.2. *Then*

(i) *for each* $\mu \in]0,1[$ *and* $t \in I$ *the operator* $P_\infty(t)$, *defined in Lemma* 2.1, *maps* H *into the domain of* $(\lambda_0 - A(t)^*)^\mu$ *and*

$$(\lambda_0 - A(t)^*)^\mu P_T(t) \to (\lambda_0 - A(t)^*)^\mu P_\infty(t) \quad \textit{strongly as } T \to \infty; \tag{2.15}$$

(ii) *the operator* $P_\infty(\cdot)$ *is a solution of equation* (2.1); *i.e., for each* t, $s \in I$ *with* $s \le t$ *we have*

$$\begin{aligned} P_\infty(s) = {} & U(t,s)^* P_\infty(t) U(t,s) \\ & + \int_s^t U(r,s)^* [C(r)^* C(r) \\ & \qquad - P_\infty(r)(\lambda_0 - A(r))G(r)N(r)^{-1}G(r)^*(\lambda_0 - A(r)^*)P_\infty(r)] \\ & \times U(r,s)\, dr. \end{aligned}$$

Remark 2.8. (i) It is possible to show that the convergence in (2.15) is uniform in t over bounded intervals. However, we omit the proof because we do not need this result in what follows.

(ii) In the special case where the resolvent of $A(t)$ is compact, the proof of Theorem 2.7 is very simple (see Theorem 2 in [F1]). However, we prefer to deal here with the general case, where the proof is considerably more difficult, since it is easy to construct examples with lack of compactness (see the remark at the end of Example 4.1).

The proof of Theorem 2.7 is based on the following lemma, which has also other applications (see, for instance, [F3]). Consider the following Riccati equation for $s \in [t_0, t[$, with fixed $t_0, t \in I$:

$$\begin{aligned} Q(s) = {} & U(t,s)^* \bar{Q}_t U(t,s) \\ & + \int_s^t U(r,s)^* [C(r)^* C(r) \\ & \qquad - Q(r)(\lambda_0 - A(r)^*)G(r)N(r)^{-1}G(r)^*(\lambda_0 - A(r)^*)Q(r)]U(r,s)dr \end{aligned} \tag{2.16}$$

under the assumption that $\bar{Q}_t \in \Sigma^+(H)$ and that the operator $(\lambda_0 - A(t)^*)^\beta \bar{Q}_t(t)(\lambda_0 - A(t))^\beta$ belongs to $\mathcal{L}(H)$; denote by $Q(s; \bar{Q}_t)$ its solution in a suitable interval $[t - r_0, t[$, given by Theorem 2.5.

LEMMA 2.9. *Assume Hypotheses* 1.1 – 1.3, 1.5, *and* 2.2, *and fix* $\beta \in]0, 1/2[$. *Let* $\{Q_{t,n}\}_{n > n_0}$ *be a family of operators in* $\Sigma^+(H)$ *such that*

(i) *there exists a constant* $c_3 > 0$ *such that*

$$|(\lambda_0 - A(t)^*)^\beta Q_{t,n}(\lambda_0 - A(t))^\beta|_{\mathcal{L}(H)} \le c_3 \quad \forall\, n > n_0;$$

(ii) $Q_{t,n}$ *converges strongly as* $n \to \infty$ *to an operator* $Q_t \in \Sigma^+(H)$ *for which the operator* $(\lambda_0 - A(t)^*)^\beta Q_t (\lambda_0 - A(t))^\beta$ *also belongs to* $\mathcal{L}(H)$.

Then for each $s \in [t - r_0, t[$

$$(\lambda_0 - A(s)^*)^{1-\alpha} Q(s; Q_{t,n}) \to (\lambda_0 - A(s)^*)^{1-\alpha} Q(s; Q_t) \quad \textit{strongly as } n \to \infty.$$

Proof of Lemma 2.9. This proof is adapted from [F3]. We denote by $[\Gamma(Q)](s)$ and $[\Gamma_n(Q)](s)$ the right-hand side of (2.16) when we consider the final data Q_t and $Q_{t,n}$, respectively. Thus equation (2.16) can be rewritten as

$$Q(s) = [\Gamma(Q)](s), \qquad s \in [t_0, t], \tag{2.17}$$

if the final datum is Q_t, and

$$Q(s) = [\Gamma_n(Q)](s), \qquad s \in [t_0, t], \tag{2.17$_n$}$$

if the final datum is $Q_{t,n}$.

Next set $\gamma := \min\{1-\alpha-\beta, \beta\}$ and consider the following space:

$$\begin{aligned} X(t-r_0,t) := \{\, & Q : [t-r_0,t] \to \Sigma^+(H) :\ Q(s) \text{ maps } H \text{ into the domain of} \\ & (\lambda_0 - A(s)^*)^{1-\alpha} \text{for each } s \in [t-r_0,t[, \text{ and both } (\lambda_0 - A(\cdot)^*)^{1-\alpha}Q(\cdot) \\ & \text{and its adjoint are strongly continuous in } [t-r_0,t[; \text{ moreover} \\ & |(\lambda_0 - A(s)^*)^{1-\alpha}Q(s)|_{\mathcal{L}(H)} \\ & \quad \le c(Q)[1+(t-s)^{-(1-\alpha-\beta)}] \quad \forall\, s \in [t-r_0,t[, \\ & |(\lambda_0 - A(s)^*)^{1-\alpha}Q(s)U(s,r)(\lambda_0 - A(s))^{\beta}|_{\mathcal{L}(H)} \\ & \quad \le c(Q)(t-r)^{\gamma}[1+(t-s)^{-(1-\alpha-\beta)}](s-r)^{-\beta} \\ & \quad\ \forall\, s \in [t-r_0,t[,\ \forall\, r \in [0,s[\}, \end{aligned}$$

endowed with the norm

$$|Q|_X := \max\{A, B\},$$

where

$$A := \sup_{s\in[t-r_0,t]} (t-s)^{1-\alpha-\beta}|(\lambda_0 - A(s)^*)^{1-\alpha}Q(s)|_{\mathcal{L}(H)},$$

$$\begin{aligned} B := & \sup_{t-r_0\le r<s<t} \frac{(s-r)^{\beta}[1+(t-s)^{1-\alpha-\beta}]}{(t-r)^{\gamma}} \\ & \times|(\lambda_0 - A(s)^*)^{1-\alpha}Q(s)U(s,r)(\lambda_0 - A(r))^{\beta}|_{\mathcal{L}(H)}. \end{aligned}$$

It can be easily shown, arguing as in the Appendix below, that the maps Γ_n and Γ are equicontractions on any sufficiently large ball of $X(t_0,t)$, provided that r_0 is suitably small. Hence, possibly replacing the constant c_3 in (i) by a larger one, we may say that Γ and Γ_n are equicontractions on the ball

$$B(t-r_0,t;c_3) := \{Q \in X(t-r_0,t) : |Q|_X \le c_3\}. \tag{2.18}$$

Now we apply the contraction principle to equations (2.17$_n$) in the ball $B(t-r_0,t;c_3)$ uniformly with respect to n. Namely, let $Q_0(\cdot)$ be the initial iteration point in $B(t-r_0,t;c_3)$ for Γ and Γ_n; then, remarking that

$$\lim_{k\to\infty} |Q(\cdot\,, Q_{t,n}) - [(\Gamma_n)^k(Q)]|_X = 0 \quad \text{uniformly with respect to } n, \tag{2.19}$$

$$\lim_{k\to\infty} |Q(\cdot\,, Q_t) - [(\Gamma)^k(Q)]|_X = 0, \tag{2.20}$$

we deduce for each $k \in \mathbb{N}^+$, $s \in [t-r_0,t]$, and $x \in H$

$$\begin{aligned} & \|(\lambda_0 - A(s)^*)^{1-\alpha}Q(s;Q_{t,n})x - (\lambda_0 - A(s)^*)^{1-\alpha}Q(s;Q_t)x\|_H \\ & \le |Q(\cdot;Q_{t,n}) - [(\Gamma_n)^k(Q_0)]|_X\, \|x\|_H \\ & \quad + \|(\lambda_0 - A(s)^*)^{1-\alpha}[(\Gamma_n)^k(Q_0)](s)x - (\lambda_0 - A(s)^*)^{1-\alpha}[(\Gamma)^k(Q_0)](s)x\|_H \\ & \quad + |[(\Gamma)^n(Q_0)] - Q(\cdot\,;Q_t)|_X\, \|x\|_H. \end{aligned} \tag{2.21}$$

Thus we just need to show that for each $k \in \mathbb{N}^+$ and $s \in [t - r_0, t]$

$$(\lambda_0 - A(s)^*)^{1-\alpha}[(\Gamma_n)^k(Q_0)](s) \to (\lambda_0 - A(s)^*)^{1-\alpha}[(\Gamma)^k(Q_0)](s) \quad \text{strongly as } n \to \infty.$$

This result is obviously true when $k = 1$, since for each $s \in [t - r_0, t]$ and $x \in H$

$$\begin{aligned}(\lambda_0 - A(s)^*)^{1-\alpha}&[[\Gamma_n(Q_0)](s) - [\Gamma(Q_0)](s)]x \\ &= (\lambda_0 - A(s)^*)^{1-\alpha}U(t,s)^*(Q_{t,n} - Q_t)U(t,s)x;\end{aligned} \tag{2.22}$$

on the other hand, if the result is true for the integer $k - 1$, then we have

$$\begin{aligned}&(\lambda_0 - A(s)^*)^{1-\alpha}[[(\Gamma_n)^k(Q_0)](s) - [(\Gamma)^k(Q_0)](s)]x \\ &\quad = (\lambda_0 - A(s)^*)^{1-\alpha}U(t,s)^*(Q_{t,n} - Q_t)U(t,s)x \\ &\qquad - \int_s^t (\lambda_0 - A(s)^*)^{1-\alpha}U(r,s)^*[(\lambda_0 - A(r)^*)^{1-\alpha}(\Gamma_n)^{k-1}(Q_0)(r)]^* \\ &\qquad \times K(r)(\lambda_0 - A(r)^*)^{1-\alpha}[(\Gamma_n)^{k-1}(Q_0)(r) - (\Gamma)^{k-1}(Q_0)(r)]U(r,s)x\,dr \\ &\qquad - \int_s^t (\lambda_0 - A(s)^*)^{1-\alpha}U(r,s)^*[(\lambda_0 - A(r)^*)^{1-\alpha}[(\Gamma_n)^{k-1}(Q_0)(r) - (\Gamma)^{k-1}(Q_0)(r)]]^* \\ &\qquad \times K(r)(\lambda_0 - A(r)^*)^{1-\alpha}(\Gamma)^{k-1}(Q_0)(r)U(r,s)x\,dr,\end{aligned} \tag{2.23}$$

and remarking that $(\Gamma_n)^{k-1}(Q_0)$ and $(\Gamma)^{k-1}(Q_0)$ belong to $B(t - r_0, t; c_3)$ by the induction hypothesis we get the result for the integer k. This proves Lemma 2.9. □

Proof of Theorem 2.7. Fix $t, t_0 \in I$ with $t > t_0$. We have to show that

$$P_\infty(s) = Q(s, P_\infty(t)) \quad \forall\, s \in [t_0, t[. \tag{2.24}$$

We apply Lemma 2.9 with $Q_t = P_\infty(t)$, $Q_{t,n} = P_n(t)$ (i.e., the solution of equation (2.2) with final time $T = n$); this is allowed by Lemmas 2.4 and 2.1. As a consequence we get

$$(\lambda_0 - A(s)^*)^{1-\alpha}[Q(s, P_n(t)) - Q(s, P_\infty(t))] \to 0 \quad \text{strongly in } [t - r_0, t[\text{ as } n \to \infty.$$

On the other hand we have

$$Q(s, P_n(t)) \equiv P_n(s) \to P_\infty(s) \quad \text{strongly in } [t - r_0, t] \text{ as } n \to \infty,$$

and (2.24) follows for each $s \in [t - r_0, t[$. The same result for all $s \in [t_0, t[$ follows now by standard uniqueness arguments. □

2.4. Minimality property of P_∞. Let $\hat{P} \in C_s(I, \Sigma^+(H))$ be any solution of equation (2.1), and consider the evolution operator $\hat{\Phi}(t,r)$ corresponding to $\hat{P}(\cdot)$, i.e., the operator-valued function defined for r, $t \in I$, $r \le t$, by the following equation:

$$\begin{aligned}\hat{\Phi}(t,r) &= U(t,r) \\ &\quad - \int_r^t U(t,s)(\lambda_0 - A(s))G(s)N(s)^{-1}G(s)^*(\lambda_0 - A(s)^*)\hat{P}(s)\hat{\Phi}(s,r)\,ds.\end{aligned} \tag{2.25}$$

We know (see, e.g., [G], [LT1]) that for each $s,\ t \in I$ with $s \le t$ the following identities hold:

$$\hat{P}(s) = \hat{\Phi}(t,s)^* P(t)\hat{\Phi}(t,s) + \int_s^t \Phi(v,s)^* \times [C(v)^*C(v) + \hat{P}(v)(\lambda_0 - A(v))G(v)N(v)^{-1}G(v)(\lambda_0 - A(v)^*)\hat{P}(v)]\hat{\Phi}(v,s)\,dv, \tag{2.26}$$

$$\hat{P}(s) = U(t,s)^*\hat{P}(t)\hat{\Phi}(t,s) + \int_s^t U(v,s)^*C(v)^*C(v)\hat{\Phi}(v,s)\,dv. \tag{2.27}$$

We have the following proposition.

PROPOSITION 2.10. *Assume Hypotheses* 1.1 – 1.3, *and* 1.5. *Then*

(i) *equation* (2.1) *has a solution if and only if Hypothesis* 2.2 *holds*;

(ii) *if this is the case, the function* $P_\infty(\cdot)$ *defined in Lemma* 2.1 *is the minimal solution of equation* (2.1); *i.e., for any solution* $\hat{P}(\cdot)$ *of equation* (2.1) *we have*

$$P_\infty(t) \le \hat{P}(t) \quad \forall\, t \in I.$$

Proof. (i) Theorem 2.7 shows the if part of the proposition. Conversely, if $\hat{P}(\cdot)$ is a solution of (2.1) and $y_0 \in H,\ t_1 \in I$ are given, we consider the control

$$\hat{u}(t) = -N(t)^{-1}G(t)^*(\lambda_0 - A(t)^*)\hat{P}(t)\hat{\Phi}(t,t_1)y_0, \qquad t \ge t_1.$$

A simple calculation shows that the corresponding state is $\hat{y}(t) = \hat{\Phi}(t,t_1)y_0$. Using equation (2.26) we easily obtain

$$(\hat{P}(t_1)y_0, y_0)_H = (\hat{P}(t)\hat{y}(t), \hat{y}(t))_H + \int_{t_1}^t [\|C(v)\hat{y}(v)\|_V^2 + (N(v)\hat{u}(v), \hat{u}(v))_U]\,dv.$$

Hence for each $t \ge t_1$ we have

$$\int_{t_1}^t [\|C(v)\hat{y}(v)\|_V^2 + (N(v)\hat{u}(v), \hat{u}(v))_U]\,dv \le (\hat{P}(t_1)y_0, y_0)_H;$$

consequently

$$J_{t_1,\infty}(\hat{u}) \le (\hat{P}(t_1)y_0, y_0)_H \le |\hat{P}(t_1)|_{\mathcal{L}(H)}\|y_0\|_H^2. \tag{2.28}$$

By the local coercivity of $N(\cdot)$ (Hypothesis 1.5) we then get $\hat{u} \in L^2_{\text{loc}}(t_1,\infty;U)$, so condition (2.4_{t_1}) holds.

(ii) Using (2.3) we obtain

$$(P_T(t_1)y_0, y_0)_H \le J_{t_1,T}(u) \quad \forall\, t_1 \in I,\ \forall\, T > t_1,\ \forall\, y_0 \in H,\ \forall u \in L^2_{\text{loc}}(t_1,\infty;U),$$

and consequently we have

$$(P_T(t_1)y_0, y_0)_H \le J_{t_1,\infty}(u) \quad \forall\, t_1 \in I,\ \forall T > t_1,\ \forall\, y_0 \in H,\ \forall\, u \in L^2_{\text{loc}}(t_1,\infty;U);$$

letting $T \to \infty$ we obtain

$$(P_\infty(t_1)y_0, y_0)_H \le J_{t_1,\infty}(u) \quad \forall\, t_1 \in I,\ \forall\, y_0 \in H,\ \forall\, u \in L^2_{\text{loc}}(t_1,\infty;U) \tag{2.29}$$

so that, in particular, by (2.28)

$$(P_\infty(t_1)y_0, y_0)_H \le J_{t_1,\infty}(\hat{u}) \le (\hat{P}(t_1)y_0, y_0)_H \quad \forall\, t_1 \in I,\ \forall\, y_0 \in H, \tag{2.30}$$

and the result follows. □

2.5. Synthesis of the infinite-horizon LQR problem. We use the properties of the operator $P_\infty(\cdot)$ to solve the problem of the synthesis. We have the following theorem.

THEOREM 2.11. *Assume Hypotheses* 1.1 – 1.3, 1.5, *and* 2.2. *Let* $t_0 \in I$ *and* $y_0 \in H$ *be given. Then*

(i) *there exists a unique optimal control* $u^* \in L^2_{\text{loc}}(t_0, \infty; U)$ *for problem* (1.7);

(ii) *if* (u^*, y^*) *is the optimal pair and* $P_\infty(\cdot)$ *is defined by Lemma* 2.1, *then*

$$u^*(t) = -N(t)^{-1}G(t)^*(\lambda_0 - A(t)^*)P_\infty(t)y^*(t) \quad \forall\, t \geq t_0;$$

(iii) *the optimal cost is*

$$J_{t_0,\infty}(u^*) = (P_\infty(t_0)y_0, y_0)_H;$$

(iv) *the optimal state is given by*

$$y^*(t) = \Phi_\infty(t, t_0)y_0,$$

where $\Phi_\infty(t, s)$ *is the evolution operator defined by equation* (2.25) *with* $P_\infty(\cdot)$ *in place of* $\hat{P}(t)$.

Proof. Given $t_0 \in I$ and $y_0 \in H$, set

$$u^*(t) := -N(t)^{-1}G(t)^*(\lambda_0 - A(t)^*)P_\infty(t)\Phi_\infty(t, t_0)y_0, \qquad t \geq t_0;$$

by the same arguments in the proof of Proposition 2.10 we easily see that $u^* \in L^2_{\text{loc}}(t_0, \infty; U)$ is an admissible control with respect to t_0, whereas $y^*(t) := \Phi_\infty(t, t_0)y_0$ is the state corresponding to u^*. By (2.29) and (2.30), with $\hat{P}$ replaced by P_∞, $\hat{u}$ by u^*, and t_1 by t_0, we obtain

$$(P_\infty(t_0)y_0, y_0)_H = \min_u J_{t_0,\infty}(u) = J_{t_0,\infty}(u^*);$$

i.e., u^* is an optimal control.

Finally it is clear that Hypothesis 1.5 on $N(\cdot)$ implies the strict convexity of $J_{t_0,\infty}$, so the optimal control is unique. □

3. Further properties of solutions of the Riccati equation.

3.1. Bounded solutions. In many cases it is important to know whether some bounded solution of Riccati equation (2.1) exists. In order to obtain boundedness we have to assume some uniformity in Hypothesis 2.2. Thus, following [DI3], we introduce a stronger version of that assumption.

Hypothesis 3.1. There exists a constant $\bar{c} > 0$ such that for each $t \in I$ and $y_0 \in H$ there exists a control $u \in L^2_{\text{loc}}(t, \infty; U)$ such that

$$J_{t,\infty}(u) < \bar{c}\,\|y_0\|^2_H.$$

We have the following proposition.

PROPOSITION 3.2. *Assume Hypotheses* 1.1 – 1.3, *and* 1.5. *Then there exists a bounded solution of Riccati equation* (2.1) *if and only if Hypothesis* 3.1 *holds.*

Proof. If Hypothesis 3.1 holds, then in particular Hypothesis 2.2 holds too, so that by the results of §2 the function $P_\infty(\cdot)$, defined in Lemma 2.1, is a solution of equation (2.1). In addition we have for each $t \in I$, $T > t$, and $y \in H$

$$(P_T(t)y, y)_H \leq \min_u J_{t,T}(u) \leq \bar{c}\,\|y\|^2_H;$$

thus letting $T \to \infty$ we get

$$(P_\infty(t)y, y)_H \le \bar{c}\,\|y\|_H^2 \quad \forall t \in I, \forall y \in H,$$

and recalling that $P_\infty(t) \ge 0$ we obtain

$$\sup_{t\in I} |P_\infty(t)|_{\mathcal{L}(H)} \le \bar{c}.$$

Conversely, if there exists a bounded solution $\hat{P}(\cdot)$ of (2.1), then we can repeat the argument of Proposition 2.10(i), and (2.28) shows that Hypothesis 3.1 holds with

$$\bar{c} = \sup_{t\in I} |P_\infty(t)|_{\mathcal{L}(H)}.$$

Remark 3.3. Hypothesis 3.1 is fulfilled in several cases.

(i) In the periodic case of [L1], [F], [DI2] (see §3.4), if condition (2.4_t) is satisfied for some $t \in \mathbb{R}$, then Hypothesis 3.1 holds.

(ii) If system (1.4) is stabilizable, i.e., there exists $K \in L^\infty(I, \mathcal{L}(H,U))$ such that the evolution operator associated with the family $\{[A-(\lambda_0-A)GK](t)\}$ is stable, and in addition the operators $C(\cdot), N(\cdot)$ are bounded, then Hypothesis 3.1 holds (compare with the comments after Hypothesis (H3) in [DI3]).

(iii) In Example 4.2 below, Hypothesis 3.1 holds naturally.

3.2. Stability of the perturbed evolution operator. Theorem 2.11 shows, under suitable assumptions, the existence of a unique optimal pair (u^*, y^*) for problem (1.7) with $t_0 = 0$; we also know that

$$y^* = \Phi_\infty(\cdot\,, 0)y_0, \qquad u^* = -[N^{-1}G^*(\lambda_0 - A^*)P_\infty y^*].$$

(From now on we will drop the indication of the variable t if unnecessary.) Here $P_\infty(t)$ is the minimal solution of Riccati equation (2.1) and $\Phi_\infty(t,s)$ is the evolution operator associated to the closed-loop operator family

$$\{A - G(\lambda_0 - A)N^{-1}G^*(\lambda_0 - A^*)P_\infty\}$$

by the integral equation (2.25); in other words, $\Phi_\infty(t,s)$ is the solution, for $t, s \in I$, $t \ge s$, of

$$\begin{aligned}\Phi_\infty(t,s) &= U(t,s)\\ &\quad - \int_s^t U(t,r)(\lambda_0 - A(r))G(r)N(r)^{-1}G(r)^*(\lambda_0 - A(r)^*)P_\infty(r)\Phi_\infty(r,s)\,dr.\end{aligned} \tag{3.1}$$

In this subsection, following the ideas of [DI1], [DI2] and [BDDM, Chap. IV.2, §3.2], we will prove a stability result for $y^*(t) = \Phi_\infty(t,0)$ as $t \to \infty$. In order to do this we have to assume that Hypotheses 1.2, 1.3, and 1.5 hold uniformly over the time interval I. More precisely we formulate the following hypothesis.

Hypothesis 3.4. (i) The evolution operators $U(t,s)$ and $U(t,s)^*$ are strongly continuous in $\bar{\Delta}_I$, where $\Delta_I := \{(t,s) \in I^2 : t > s\}$ and there exist $M_0 > 0$ and $\omega \in \mathbb{R}$ such that

$$|U(t,s)|_{\mathcal{L}(H)} + |U(t,s)^*|_{\mathcal{L}(H)} \le M_0 \exp(\omega_0(t-s)) \quad \forall (t,s) \in \Delta_I;$$

(ii) for each β, $\mu \in [-1,1]$ and $(t,s) \in \Delta_I$, the operators

$$(\lambda_0 - A(t))^\beta U(t,s)(\lambda_0 - A(s))^{-\mu}, \qquad (\lambda_0 - A(s)^*)^\beta U(t,s)^*(\lambda_0 - A(t)^*)^{-\mu}$$

have continuous extensions to H, the maps

$$(t,s) \to (\lambda_0 - A(t))^\beta U(t,s)(\lambda_0 - A(s))^{-\mu}, \quad (t,s) \to (\lambda_0 - A(s)^*)^\beta U(t,s)^*(\lambda_0 - A(t)^*)^{-\mu}$$

are strongly continuous, and there exists $M_{\beta,\mu} > 0$ such that

$$|(\lambda_0 - A(t))^\beta U(t,s)(\lambda_0 - A(s))^{-\mu}|_{\mathcal{L}(H)} + |(\lambda_0 - A(s)^*)^\beta U(t,s)^*(\lambda_0 - A(t)^*)^{-\mu}|_{\mathcal{L}(H)} \leq M_{\beta,\mu}[(t-s)^{\mu-\beta} + 1]\exp(\omega_0(t-s)) \quad \forall\, (t,s) \in \Delta_I.$$

Hypothesis 3.5. There exists $\alpha \in]0,1]$ such that, for each $t \in I$, $G(t)$ maps U into the domain of $(\lambda_0 - A(t))^\alpha$, and $(\lambda_0 - A(\cdot))^\alpha G(\cdot)$ is strongly measurable and bounded over I.

Hypothesis 3.6. We have

$$C(\cdot) \in L^\infty(I; \mathcal{L}(H,V)), \qquad N(\cdot) \in L^\infty(I; \Sigma^{++}(U)).$$

(This means that there exists $\nu > 0$ such that $N(t) \geq \nu$, $\forall\, t \in I$.)

Under the assumption listed above we can revisit the proof of Lemma 2.6, and we get the following lemma.

LEMMA 3.7. *Assume Hypotheses* 1.1, 3.4–3.6, *and* 3.1. *Then for each* $\mu \in]0,1[$ *we have*

$$\sup_{s \in I} |(\lambda_0 - A(s)^*)^\mu P_\infty(s)|_{\mathcal{L}(H)} < \infty.$$

Proof. Fix $t \in I$, $0 \leq \beta < 1/2$, $x \in D[(\lambda_0 - A(t))^\beta]$, and set $y_1 := U(t+1,t)(\lambda_0 - A(t))^\beta x$. By Hypothesis 3.1 there exists a control $\bar{u} \in L^2_{\text{loc}}(t+1, \infty; U)$ such that

$$J_{t+1,\infty}(\bar{u}) \leq \bar{c}\, \|y_1\|_H^2,$$

and by Hypothesis 3.4(ii) we also have

$$J_{t+1,\infty}(\bar{u}) \leq c\, \|x\|_H^2. \tag{3.2}$$

Consider the control $\tilde{u} \in L^2_{\text{loc}}(t, \infty; U)$ defined by

$$\tilde{u}(s) = \begin{cases} 0 & \text{if } t \leq s < t+1, \\ \bar{u}(s) & \text{if } t+1 \leq s < \infty. \end{cases}$$

Using Theorem 2.11(iii) and (3.2) we have

$$\begin{aligned}
(P_\infty(t)(\lambda_0 - A(t))^\beta x, (\lambda_0 - A(t))^\beta x)_H &\leq J_{t,\infty}(\tilde{u}) \\
&= \int_t^{t+1} \|C(s)U(s,t)(\lambda_0 - A(t))^\beta x\|_V^2\, ds + J_{t+1,\infty}(\bar{u}) \\
&\leq \left(\|C\|^2_{L^\infty(I;\mathcal{L}(V,H))} \int_t^{t+1} |U(s,t)(\lambda_0 - A(t))^\beta|^2_{\mathcal{L}(H)}\, ds + c \right) \|x\|_H^2 \\
&\leq \left(|C|^2_{L^\infty(I;\mathcal{L}(V,H))} M^2_{\beta,0} \exp(\omega_0) + c \right) \|x\|_H^2 \leq c \|x\|_H^2.
\end{aligned}$$

Recalling that $P_\infty(t) \geq 0$, the above estimate shows that

$$\sup_{t \in I} |(\lambda_0 - A(t)^*)^\beta P_\infty(t)(\lambda_0 - A(t))^\beta|_{\mathcal{L}(H)} =: L < +\infty.$$

We now repeat the argument of the proof of Lemma 2.6; invoking Theorem 2.5 and noting that our assumptions are uniform in t now, we find two constants $\tau \in]0, 1]$ and $c' > 0$, depending on L and β but independent of $t \in I$, for which the analogue of (2.14) holds, i.e.,

$$(t-s)^{1-\alpha-\beta}|(\lambda_0 - A(s)^*)^{1-\alpha}P_\infty(s)|_{\mathcal{L}(H)} \le c' \quad \forall\, s \in I \cap [t-\tau, t[.$$

Arguing as in the proof of Lemma 2.6, one arrives easily at the estimate

$$\sup_{s\in I} |(\lambda_0 - A(s)^*)^{\mu}P_\infty(s)|_{\mathcal{L}(H)} \le c(\tau, c', \beta, L, \mu),$$

which concludes the proof. □

Using the result of Lemma 3.7 it is easy to show that the evolution operator $\Phi_\infty(t, s)$ has an exponential growth. Namely, we have the following lemma.

LEMMA 3.8. *Under Hypotheses* 1.1, 3.4–3.6, *and* 3.1, *there exist* $M_1 > 0$ *and* $\omega_1 > \omega_0$ *such that*

$$|\Phi_\infty(t, s)|_{\mathcal{L}(H)} \le M_1 \exp(\omega_1(t-s)) \quad \forall\, (t, s) \in \bar{\Delta}_I.$$

Proof. The result follows easily by equation (3.1), using our assumptions and the result of Lemma 3.7. □

It is important, in some applications, to give conditions under which the evolution operator Φ_∞ is exponentially stable, i.e., there exist $M > 0$ and $\gamma > 0$ such that

$$\|\Phi_\infty(t, 0)\|_{\mathcal{L}(H)} \le M \exp(-\gamma t).$$

A simple situation where this occurs is when the operator $C(s)$ is invertible for each $s \in I$, and C^{-1} belongs to $L^\infty(I; \mathcal{L}(V, H))$ (see [BDDM]); indeed, if this is the case, we fix $x \in H$ and argue as in the proof of Proposition 2.10, replacing t_1 with t_0, $\hat{\Phi}$ with Φ_∞, $\hat{P}$ with P_∞, $\hat{y}$ with $y^* := \Phi(\cdot\,, 0)x$, and $\hat{u}$ with u^*. Then we obtain, for each $t \in I$,

$$\int_{t_0}^{t} [\|Cy^*\|_V^2 + \|N^{-1/2}G^*(\lambda_0 - A^*)P_\infty y^*\|_H^2]\, ds \le (P_\infty(0)x, x)_H \le \bar{c}\,\|x\|_H^2.$$

So we have

$$C(\cdot)\Phi_\infty(\cdot\,, 0)x = Cy^* \in L^2(t_0, \infty; V), \tag{3.3}$$

$$N^{-1/2}G^*(\lambda_0 - A^*)P_\infty y^* \in L^2(t_0, \infty; H), \tag{3.4}$$

and by (3.3) we deduce that $\Phi_\infty(\cdot\,, 0)x \in L^2(I; H)$; thus by the classical results of Datko [D], we obtain the exponential stability of Φ_∞.

A sufficient condition yielding the same property, even if C is not invertible, is given by the following detectability condition [F1], [DI1], [DI3].

Hypothesis 3.9. The family $\{(A, C)\}$ is detectable; this means that there exists a mapping $K : I \to \mathcal{L}(V, H)$, strongly measurable and bounded, such that the evolution operator $U_{A-KC}(t, s)$ associated with$\{A - KC\}$ is stable; i.e., there exist two constants $M_2 > 0$, $\omega_2 > 0$ such that

$$|U_{A-KC}(t, s)|_{\mathcal{L}(H)} \le M_2 \exp(-\omega_2(t-s)) \quad \forall\, (t, s) \in \Delta_I. \tag{3.5}$$

LEMMA 3.10. *Assume Hypotheses* 3.4, 3.6, *and* 3.9. *Then there exists a constant* $c > 0$ *such that for each* $(t, s) \in \Delta_I$ *the operator* $U_{A-KC}(t, s)(\lambda_0 - A(s))^{1-\alpha}$ *has a continuous extension to* H *and*

$$|U_{A-KC}(t, s)(\lambda_0 - A(s))^{1-\alpha}|_{\mathcal{L}(H)} \le c(t-s)^{\alpha-1} \exp(-\omega_2(t-s)) \quad \forall\, (t, s) \in \Delta_I.$$

Proof. By Hypotheses 3.6 and 3.9 it follows that $KC \in L^\infty(I;\mathcal{L}(H))$ and the construction of $U_{A-KC}(t,s)$ is standard. Next, for each $s \in I$ set

$$V(t,s)x := U_{A-KC}(t,s)(\lambda_0 - A(s))^{1-\alpha}x, \qquad t \geq s,\ x \in D((\lambda_0 - A(s))^{1-\alpha});$$

then it is immediately seen that

$$V(t,s)x = U(t,s)(\lambda_0 - A(s))^{1-\alpha}x + \int_s^t U(t,r)K(r)C(r)V(r,s)x\,dr, \qquad (t,s) \in \Delta_I.$$

Using Hypothesis 3.4 we easily get

$$\|V(t,s)x\|_H \leq c(t-s)^{\alpha-1}\|x\|_H \quad \forall\,(t,s) \in \Delta_I \text{ with } t-s \leq 1;$$

hence, taking (3.3) into account we easily get the result. □

As a simple consequence of the above lemma we have the following theorem.

THEOREM 3.11. *Assume Hypotheses* 1.1, 3.1, 3.4–3.6, *and* 3.9. *Then* $\Phi_\infty(\cdot\,,0)$ *is exponentially stable.*

Proof. We have

$$U_{A-KC}(t,s) = U(t,s) + \int_s^t U(t,r)K(r)C(r)U_{A-KC}(r,s)\,dr, \quad (t,s) \in I. \tag{3.6}$$

Comparing with (3.1) we easily obtain for each $(t,s) \in I$

$$\Phi_\infty(t,s) = U_{A-KC}(t,s) - \int_s^t U_{A-KC}(t,r)[KC - (\lambda_0 - A)GN^{-1}G^*(\lambda_0 - A^*)P_\infty](r)\Phi_\infty(r,s)\,dr.$$

Now using (3.5), Lemma 3.10, Hypothesis 3.6, and the boundedness of K, by Young's inequality we deduce that $\Phi_\infty(\cdot\,,0) \in L^2(I;H)$, and finally the exponential stability is a consequence of the results of Datko [D]. □

3.3. Uniqueness of the solution of the Riccati equation. By Proposition 2.10 it is clear that if a bounded solution $\hat{P}$ of equation (2.1) exists, then P_∞ also is bounded. Under suitable assumptions on the LQR system we are able to show uniqueness of bounded solutions.

We have the following result, which generalizes [F1, Thm. 4].

THEOREM 3.12. *Assume Hypotheses* 1.1–1.3, 1.5, *and* 3.1; *in addition, assume that the optimal trajectory* $y^*(\cdot)$ *is stable. Then the only bounded solution of equation* (2.1) *is* P_∞.

Proof. By Proposition 3.2 we know that P_∞ is a bounded solution of (2.1). Now let $\hat{P}$ be another bounded solution of (2.1); by Proposition 2.10 we know that

$$P_\infty(t) \leq \hat{P}(t) \quad \forall\, t \in I,$$

so it is sufficient to prove the converse inequality.

Fix $y_0 \in H$ and $t_1 \in I$; by [AFT, Thm. 3.14] we deduce that

$$(\hat{P}(t_1)y_0, y_0)_H \leq J_{t_1,t}(u) + (\hat{P}(t)y(t), y(t))_H \quad \forall\, u \in L^2(t_1,t;U),\ \forall\, t > t_1, \tag{3.7}$$

where $y(\cdot)$ satisfies the state equation (1.4).

We apply (3.7), using the optimal control $u^* = -N^{-1}G^*(\lambda_0 - A^*)P_\infty y^*$; we recall that the optimal trajectory is given by $y^*(t) = \Phi_\infty(t, t_1)y_0$. We obtain

$$\begin{aligned}(\hat{P}(t_1)y_0, y_0)_H &\le \int_{t_1}^{t} [\|Cy^*\|_V^2 + (Nu^*, u^*)_U]\, dv + (\hat{P}(t)y^*(t), y^*(t))_H \\ &\le J_{t_1,\infty}(u^*) + (\hat{P}(t)y^*(t), y^*(t))_H \\ &= (P_\infty(t_1)y_0, y_0)_H + (\hat{P}(t)y^*(t), y^*(t))_H.\end{aligned}$$

By assumption we have $y^*(t) \to 0$ as $t \to \infty$, whereas $\hat{P}$ is bounded; hence, as $t \to \infty$ we obtain

$$(\hat{P}(t_1)y_0, y_0)_H \le (P_\infty(t_1)y_0, y_0)_H.$$

This shows that $\hat{P} \le P_\infty$. □

3.4. Periodic case and autonomous case. We consider now two special cases of equation (2.1): the periodic case and the time-invariant case. We assume the following hypothesis.

Hypothesis 3.13. There exists $\vartheta > 0$ such that $A(t + \vartheta) = A(t)$, $G(t + \vartheta) = G(t)$, $C(t + \vartheta) = C(t)$, and $N(t + \vartheta) = N(t)$ for all $t \in \mathbb{R}$. If this is the case we say that the system is ϑ-periodic.

Remark 3.14. If the system is ϑ-periodic, then

(i) evidently all assumptions concerning the uniform behaviour of the operators follow from the local assumptions listed in §1;

(ii) if $\hat{P}(t)$ is a bounded solution of (2.1), then $\hat{P}_\vartheta(t) := \hat{P}(t + \vartheta)$, $t \in \mathbb{R}$, is also a bounded solution;

(iii) some stabilizability results for equation (1.4) can be found in [L2].

As in [DI3, Prop. 3.4] we have the following proposition.

PROPOSITION 3.15. *Assume Hypotheses* 1.1 – 1.3, 1.5, 2.2, *and* 3.13. *Then the minimal solution* P_∞ *of* (2.1) *is* ϑ*-periodic. If Hypothesis* 3.9 *holds too, then* P_∞ *is the unique nonnegative* ϑ*-periodic solution of* (2.1) *and the corresponding optimal trajectory for problem* (1.7) *is exponentially stable.*

Proof. The periodicity of P_∞ follows from the same argument as in [DI3, Prop. 3.4]; the stability of the optimal trajectory is a direct consequence of Theorem 3.11. □

Finally assume that A, G, C, and N are independent of t. Then our assumptions correspond to those assumed by Flandoli [F1], and the corresponding result is the following proposition.

PROPOSITION 3.16. *Suppose that* A *is the infinitesimal generator of an analytic semigroup* e^{tA}, *and let* $G \in \mathcal{L}(U, D((\lambda_0 - A)^\alpha))$, $C \in \mathcal{L}(U, V)$, $N, N^{-1} \in \Sigma^+(U)$. *In addition assume that condition* (2.4_0) *holds* (*i.e., there exists an admissible control*). *Then* $P_\infty(t) \equiv P_\infty$ *is independent of* t, *and it is the minimal solution of the algebraic Riccati equation*

$$A^*Q + QA + C^*C - Q(\lambda_0 - A)^{1-\alpha}[(\lambda_0 - A)^\alpha G]N^{-1}[(\lambda_0 - A)^\alpha G]^*(\lambda_0 - A^*)^{1-\alpha}Q = 0. \tag{3.8}$$

Furthermore, if (A, C) *is detectable, then* P_∞ *is the unique nonnegative solution of* (3.8). □

4. Examples.

4.1. A finite-dimensional example. Consider the family of 2×2 matrices $\{A(t)\} = \{(1+t)A_1\}_{t\geq 0}$, where

$$A_1 = \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}.$$

In $\mathbb{R}^2$ consider the state equation

$$y'(t) = A(t)y(t) + B(t)u(t), \qquad t \geq 0, \quad y(0) = (x_1, x_2) \in \mathbb{R}^2, \tag{4.1}$$

where $u \in L^2_{\mathrm{loc}}(\mathbb{R}^+, \mathbb{R}^2)$ is the control and $B(t) = b(t)I$ (I is the identity matrix), with $b(\cdot)$ a nonzero continuous function with polynomial growth as $t \to \infty$. We want to minimize the quadratic cost functional given by

$$J_{0,\infty}(u) = \int_0^\infty [\|C(t)y(t)\|^2_{\mathbb{R}^2} + (N(t)u(t), u(t))_{\mathbb{R}^2}]\, dt,$$

with y, u subject to equation (4.1); here $C(t) = (2\sqrt{2(1+t)^2 - 1})I$, $N(t) = b(t)^2 I$.

In this situation the eigenvalues of the matrix $A(t)$ are $(1+t, \pm(1+t)i)$ and

$$U(t,s) = \exp([(t^2 - s^2)/2 + (t-s)]A_1).$$

For a given $t_0 \geq 0$ an admissible feedback control relative to t_0 is easily found by choosing $\hat{u}(t) = K(t)\hat{y}(t)$, with

$$K(t) = b(t)^{-1}(t+1)\begin{pmatrix} -2 & -1 \\ 1 & -2 \end{pmatrix},$$

so all our assumptions hold locally over the time interval $[0, +\infty[$.

The Riccati equation (2.1) becomes, in this simple situation,

$$P'(t) + (1+t)[A_1^* P(t) + P(t)A_1] + 4[2(1+t)^2 - 1]I - P(t)^2 = 0, \qquad t \geq 0. \tag{4.2}$$

The nonnegative symmetric solution $P_T(\cdot)$ of equation (4.2) over the interval $[0, T]$, with final datum $P(T) = 0$, is given by

$$P_T(t) = 4(1+t)I - v_T(t)^{-1} I,$$

where

$$v_T(t) = \frac{\exp[3(T^2 - t^2) + 6(T-t)]}{4(1+T)} - \int_t^T \exp[3(s^2 - t^2) + 6(s-t)]\, ds.$$

It is easily seen that $v_T(t) > 0$ for each $t \in [0, T]$ and that $\lim_{T\to\infty} v_T(t) = +\infty$; hence for each $t \geq 0$

$$P_T(t) \uparrow P_\infty(t) := 4(1+t)I \quad \text{as } T \uparrow \infty.$$

The optimal control u^* is given by $u^*(t) = -4b(t)^{-1}(1+t)Iy^*(t)$, and the optimal trajectory y^* is the solution of the closed-loop system

$$y'(t) = (1+t)A_2 y, \quad t \geq 0, \quad y(0) = (x_1, x_2),$$

where

$$A_2 = \begin{pmatrix} -3 & 1 \\ -1 & -3 \end{pmatrix}.$$

We remark that the optimal trajectory is stable. Furthermore it can be seen that $P_\infty(t) = 4(1+t)I$ $(t \geq 0)$ is the only positive solution of the Riccati equation (4.2).

An infinite-dimensional example can be easily obtained by the above example, by just adding to it, as a direct sum, a control problem with unbounded time-invariant operators. In a similar way one can easily arrange things in such a way that the resolvent operator of $A(t)$ is not compact for any $t \geq 0$, using, for instance, multiplicative operators in infinite-dimensional spaces (compare with Remark 2.8(ii)).

4.2. Parabolic equations in noncylindrical domains. Let Ω_0 be a bounded open set of $\mathbb{R}^n$ with smooth boundary Γ_0. Following [DZ], [A2] we consider the family of mappings $\{T_t(\cdot) : \mathbb{R}^n \to \mathbb{R}^n,\ t \geq 0\}$ associated with a family of regular vector fields $\{V(t,\cdot) : \mathbb{R}^n \to \mathbb{R}^n,\ t \geq 0\}$ by the dynamic system

$$\frac{\partial}{\partial t} T_t(x) = V(t, T_t(x)), \quad T_0(x) = x, \quad t \geq 0,\ x \in \mathbb{R}^n.$$

Consider the sets $\Omega_t := T_t(\Omega_0)$ with boundary $\Gamma_t := T_t(\Gamma)$, and the evolution domain $Q = \cup_{t>0}\{t\} \times \Omega_t$ with boundary $\Sigma = \cup_{t>0}\{t\} \times \Gamma_t$.

We want to apply the results of the preceding sections to the following problem: minimize among all $u \in L^2_{\text{loc}}(\Sigma)$ the functional

$$J(u) = \int_0^\infty \int_{\Omega_t} |y(t,\xi)|^2 d\xi\, dt + \int_\Sigma |u(t,\xi)|^2\, d\Sigma(t,\xi), \tag{4.3}$$

where y is the solution of the parabolic boundary problem

$$\begin{cases} y_t(t,\xi) = \Delta y(t,\xi), & t \geq 0,\ \xi \in \Omega_t, \\ y(t,\xi) = u(t,\xi) \quad \text{or} \quad \dfrac{\partial y}{\partial \nu_t}(t,\xi) = u(t,\xi), & t \geq 0,\ \xi \in \Gamma_t, \\ y(0,\xi) = y_0(\xi), & \xi \in \Omega_0. \end{cases} \tag{4.4}$$

(ν_t is the outward normal to Γ_t.)

Denote by DT_t the Jacobian matrix of T_t and by J_t its determinant; then the change of variable

$$z(t,x) = y(t, T_t(x)), \quad t \geq 0, \quad x \in \Omega_0, \quad v(t,x) = u(t, T_t(x)), \quad t \geq 0, \quad x \in \Gamma_0,$$

transforms problem (4.3), (4.4) into the following one: minimize among all $v \in L^2_{\text{loc}}(\partial\Omega \times \mathbb{R}^+)$ the functional

$$\begin{aligned} J_0(v) = &\int_0^\infty \int_{\Omega_0} |z(t,x)|^2 J_t(x)\, dx\, dt \\ &+ \int_0^\infty \int_{\partial\Omega_0} |v(t,\xi)|^2 J_t(x) B(t,x)\, dH_{n-1}(x)\, dt, \end{aligned} \tag{4.5}$$

where z is the solution of the parabolic boundary problem

$$\begin{cases} z_t(t,x) = \mathcal{A}(t,x,D)y, & t \geq 0,\ x \in \Omega_0, \\ z(t,x) = v(t,x) \quad \text{or} \quad \dfrac{\partial z(t,x)}{\partial \nu_{A(t)}} = v(t,x)\beta(t,x), & t \geq 0,\ x \in \Gamma_0, \\ z(0,x) = y_0(x), & x \in \Omega_0, \end{cases} \tag{4.6}$$

with

$$\begin{aligned} B(t,x) &:= \sqrt{1+[(V(t,x),n_t(x))_{\mathbb{R}^n}]^2}, \\ \mathcal{A}(t,x,D)w &:= -J_t(x)^{-1}\,\mathrm{div}\,((DT_t(x)^{-1})(DT_t(x)^{-1})^*\cdot Dw(x)) \\ &\quad +((DT_t(x)^{-1})\cdot Dw(x),V(t,x))_{\mathbb{R}^n}, \\ \beta(t,x) &:= J_t(x)|(DT_t(x)^{-1})^*\cdot n_0(x)|, \\ \nu_{A(t)} &:= (DT_t(x)^{-1})(DT_t(x)^{-1})^*\cdot \nu_0(x). \end{aligned}$$

Problem (4.5) – (4.6) can be studied with the methods of this paper. It is shown in [DZ] (in the case of Dirichlet boundary control) and in [A2] (in the case of Neumann boundary control) that an admissible control exists; more precisely, in both cases Hypothesis 3.1 holds true.

4.3. Strongly damped wave equation. Let $\Omega\subset\mathbb{R}^n$ be a bounded open set with smooth boundary $\partial\Omega$. Consider the Dirichlet or Neumann boundary control problem for the damped wave equation in $]0,\infty[\times\Omega$:

$$\text{(4.7)}\qquad \begin{cases} y_{tt}(t,x)=\Delta y(t,x)+\rho(t)\Delta y_t(t,x), & t>0,\ x\in\Omega, \\ y(0,x)=y_0(x), \quad y_t(0,x)=w_0(x), & x\in\Omega, \\ By(t,x)=u(t,x), \quad t>0,\ x\in\partial\Omega & \left[B=I \text{ or } B=\dfrac{\partial}{\partial\nu}\right]; \end{cases}$$

here ρ is a scalar function belonging to $C^{\varepsilon+1/2}([0,\infty[)$; the data y_0, w_0 belong to $H^1(\Omega)$ and $L^2(\Omega)$, respectively; and Δ is the Laplace operator. The cost functional

$$\text{(4.8)}\qquad \begin{aligned} J(u)=\int_0^\infty \{ &\|C_1(t)y(t,\cdot)\|^2_{L^2(\Omega)}+\|C_2(t)y_t(t,\cdot)\|^2_{L^2(\Omega)}+\|C_3(t)Dy(t,\cdot)\|^2_{L^2(\Omega)} \\ &+(N_1(t)u(t,\cdot),u(t,\cdot))_{L^2(\partial\Omega)}+(N_2(t)u_t(t,\cdot),u_t(t,\cdot))_{L^2(\partial\Omega)}\}\,dt \end{aligned}$$

has to be minimized among all $u\in W^{1,2}_{\mathrm{loc}}(0,\infty;L^2(\partial\Omega))$, with y subject to (4.7); the operators C_1, C_2, C_3 and N_1, N_2 belong to $L^\infty_{\mathrm{loc}}(0,\infty;\mathcal{L}(L^2(\Omega)))$ and $L^\infty_{\mathrm{loc}}(0,\infty;\Sigma^{++}(L^2(\partial\Omega)))$, respectively.

In order to apply the results of this paper we rewrite problem (4.7) – (4.8) in abstract form. Define

$$\text{(4.9)}\qquad \begin{cases} D_A=\{y\in H^2(\Omega)\colon By=0 \text{ on } \partial\Omega\}, \\ Ay=\Delta y, \end{cases}$$

$$\text{(4.10)}\qquad G: L^2(\partial\Omega)\to L^2(\Omega), \qquad Gu=z \Leftrightarrow \begin{cases} \Delta z=z & \text{in } \Omega, \\ Bz=u & \text{in } \partial\Omega. \end{cases}$$

Then, following [B2], it is easy to see that if $u\in W^{2,2}_{\mathrm{loc}}(0,\infty;L^2(\partial\Omega))$ then the function

$$Z:=\begin{pmatrix} y \\ y_t \end{pmatrix}-G\begin{pmatrix} u \\ u_t \end{pmatrix}$$

solves

$$\text{(4.11)}\qquad \begin{cases} Z_t=\begin{pmatrix} 0 & 1 \\ \Delta & \rho(t)\Delta \end{pmatrix}Z+\begin{pmatrix} 0 \\ Gu+\rho(t)Gu_t-Gu_{tt} \end{pmatrix}, & t>0,\ x\in\Omega, \\ Z(0)=\begin{pmatrix} y_0-Gu(0) \\ w_0-Gu_t(0) \end{pmatrix}, \quad x\in\Omega; \quad BZ=0, \quad t>0,\ x\in\partial\Omega. \end{cases}$$

Now set $H := H^1(\Omega) \times L^2(\Omega)$, $U := L^2(\partial\Omega)$, $V := H$, and

$$\begin{cases} D_{\mathcal{A}(t)} = \left\{ \begin{pmatrix} y \\ w \end{pmatrix} \in H : y + \rho(t)w \in D_A \right\}, \\ \mathcal{A}(t) \begin{pmatrix} y \\ w \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ \Delta & \rho(t)\Delta \end{pmatrix} \begin{pmatrix} y \\ w \end{pmatrix}; \end{cases}$$

then it is shown in [L3] that (i) the operators $\mathcal{A}(t)$ generate analytic semigroups in H, and (ii) they satisfy the assumptions of [AT1], [AT2] and [AT3,§6]; this in turn yields that the evolution operator $U_{\mathcal{A}}(t,s)$ associated with $\{\mathcal{A}(t)\}$ exists and fulfills the hypotheses of this paper. (We remark that by choosing $H = L^2(\Omega) \times L^2(\Omega)$, as done in [B1], [B2] in the autonomous case, we still would have (i), but (ii) would no longer be true.)

Consequently we can write the mild form of (4.11), and after integrating by parts we get

$$\begin{aligned} Z(t) = U_{\mathcal{A}}(t,0) \begin{pmatrix} y_0 \\ w_0 \end{pmatrix} - \begin{pmatrix} 0 \\ Gu'(t) \end{pmatrix} + \int_0^t U_{\mathcal{A}}(t,s) \begin{pmatrix} 0 \\ Gu(s) + \rho(s)u'(s) \end{pmatrix} ds \\ - \int_0^t U_{\mathcal{A}}(t,s)\mathcal{A}(s)G \begin{pmatrix} 0 \\ u'(s) \end{pmatrix} ds, \qquad t \geq 0 \end{aligned}$$

(where the last term has to be interpreted as in (1.4)–(1.5)); by density we see that this formula holds for all $u \in W^{1,2}_{\mathrm{loc}}(0,\infty; L^2(\partial\Omega))$. Hence, setting $L := \binom{G}{0}$, $M := \binom{0}{G}$ for the sake of simplicity, we obtain, for $Y := \binom{y}{y_t} \in L^2_{\mathrm{loc}}(0,\infty; H)$,

$$\begin{aligned} Y(t) = U_{\mathcal{A}}(t,0) \begin{pmatrix} y_0 \\ w_0 \end{pmatrix} + Lu(t) + \int_0^t U_{\mathcal{A}}(t,s)Mu(s)\,ds \\ + \int_0^t U_{\mathcal{A}}(t,s)[\rho(s) - \mathcal{A}(s)]Mu'(s)\,ds. \end{aligned}$$

Now, as in [B1], [B2], we regard the control u as an auxiliary component of the state and define u' as a new control; namely, we set $v := u'$, $X := (Y,u)$, $\bar{H} := H \times U$, $\bar{U} := U$, and $\bar{V} := \bar{H}$ and look for the state equation satisfied by X. As shown in [B1,§2], $X(t)$ is the mild solution of

$$\begin{cases} X'(t) = \mathcal{B}(t)X(t) + Q(t)v(t), \qquad t > 0, \\ X(0) = X_0, \end{cases}$$

where

$$\text{(4.12)} \qquad \begin{cases} D_{\mathcal{B}(t)} = \left\{ \begin{pmatrix} Y \\ u \end{pmatrix} \in \bar{H} : Y - Lu \in D_{\mathcal{A}(t)} \right\} \\ \mathcal{B}(t) = \begin{pmatrix} \mathcal{A}(t) & M - \mathcal{A}(t)L \\ 0 & 0 \end{pmatrix}, \end{cases}$$

$$Q(t) = \begin{pmatrix} L + [\rho(t) - \mathcal{A}(t)]M \\ 1 \end{pmatrix}, \qquad X_0 = \begin{pmatrix} Y(0) \\ u(0) \end{pmatrix}.$$

It is easy to see that the operators $\mathcal{B}(t)$ possess in $\bar{H}$ the same properties enjoyed by the operators $\mathcal{A}(t)$ in H; in particular $\rho(\mathcal{B}(t)) = \rho(\mathcal{A}(t))$ and

$$\begin{aligned} &[\lambda - \mathcal{B}(t)]^{-1} \\ &= \begin{pmatrix} [\lambda - \mathcal{A}(t)]^{-1} & [\lambda - \mathcal{A}(t)]^{-1}M - \mathcal{A}(t)[\lambda - \mathcal{A}(t)]^{-1}L \\ 0 & 1 \end{pmatrix} \quad \forall\, \lambda \in \rho(\mathcal{B}(t)). \end{aligned}$$

In addition the evolution operator $U_{\mathcal{B}}(t,s)$ associated with $\{\mathcal{B}(t)\}$ exists; it fulfills the hypotheses of this paper and has the following explicit representation:

$$U_{\mathcal{B}}(t,s) = \begin{pmatrix} U_{\mathcal{A}}(t,s) & \int_s^t U_{\mathcal{A}}(t,\sigma)M\,d\sigma + [1 - U_{\mathcal{A}}(t,s)]L \\ 0 & 1 \end{pmatrix}.$$

The operator $Q(t)$ may be also written (improperly but usually) as $Q(t) = [1 - \mathcal{B}(t)]\mathcal{G}(t)$, where $\mathcal{G}(t) = [1 - \mathcal{B}(t)]^{-1}Q(t)$ is given, after some manipulations, by

$$\mathcal{G}(t) = \begin{pmatrix} L + M + \rho(t)[1 - \mathcal{A}(t)]^{-1}M \\ 1 \end{pmatrix}.$$

Hence the state $X(t)$ solves the equation

$$X(t) = U_{\mathcal{B}}(t,0)X_0 + \int_0^t U_{\mathcal{B}}(t,s)[1 - \mathcal{B}(s)]\mathcal{G}(s)v(s)\,ds, \qquad t \geq 0. \tag{4.13}$$

We remark that, conversely, if $X(t)$ is given by this formula, then, setting $X(t) = (Y(t), u(t))$, the second component of X' gives $u' = v$, and from the first component it is easy to go back to (4.11) and hence to the solution y of the original problem.

Concerning the cost functional $J(u)$, we can rewrite it as $\bar{J}(v)$, where

$$\bar{J}(v) = \int_0^\infty \left\{ \|C(t)X(t)\|_{\bar{H}}^2 + (N(t)v(t), v(t))_{\bar{U}} \right\} dt, \tag{4.14}$$

with $C(t)$ and $N(t)$ given by

$$C(t)\begin{pmatrix} Y \\ u \end{pmatrix} \equiv C(t)\begin{pmatrix} Y_1 \\ Y_2 \\ u \end{pmatrix} = C_1(t)Y_1 + C_2(t)Y_2 + C_3(t)DY_1 + [N_1(t)]^{1/2}u,$$
$$N(t)v = N_2(t)v.$$

Thus the original control problem (4.7)–(4.8) is equivalent to minimizing $\bar{J}(v)$ among all $v \in L^2_{\mathrm{loc}}(0,\infty;\bar{U})$, with X subject to equation (4.13).

In order to apply the theory of this paper we still need to verify Hypothesis 1.3 for $\mathcal{G}(t)$ (and this follows by the results of [B1], [B2]) and the finite cost condition (Hypothesis 2.2). Concerning the latter, in the case of Dirichlet boundary control it is satisfied by choosing $u = 0$, as the following proposition shows.

PROPOSITION 4.1. *Let $J(u)$ be given by* (4.8), *where y satisfies* (4.7) *with $B = I$, and assume that $\rho_1 \geq \rho(t) \geq \rho_0 > 0$ for each $t > 0$. Then we have $J(0) < \infty$.*

Proof. Multiply the partial differential equation (PDE) in (4.7) by y_t and integrate over Ω; then

$$\frac{1}{2}\frac{d}{dt}\int_\Omega |y_t(t,x)|^2\,dx = -\frac{1}{2}\frac{d}{dt}\int_\Omega |Dy(t,x)|^2\,dx - \rho(t)\int_\Omega |Dy_t(t,x)|^2\,dx.$$

Integrating over $]0,T[$ we get

$$\int_\Omega |y_t(T,x)|^2\,dx + \int_\Omega |Dy(T,x)|^2\,dx$$
$$= \int_\Omega |w_0|^2\,dx + \int_\Omega |Dy_0|^2\,dx - 2\int_0^T \rho(t)\int_\Omega |Dy_t(t,x)|^2\,dx\,dt;$$

this implies that

$$\sup_{T>0}\left[\int_\Omega |y_t(T,x)|^2\,dx+\int_\Omega |Dy(T,x)|^2\,dx\right]+\int_0^\infty \rho(t)\int_\Omega |Dy_t(t,x)|^2\,dx\,dt \le c\left[\int_\Omega |w_0|^2\,dx+\int_\Omega |Dy_0|^2\,dx\right]. \tag{4.15}$$

As $\rho(t)\ge\rho_0$, by the Poincaré inequality we also get

$$\int_0^\infty\int_\Omega |y_t(t,x)|^2\,dx\,dt \le c\left[\int_\Omega |w_0|^2\,dx+\int_\Omega |Dy_0|^2\,dx\right]. \tag{4.16}$$

On the other hand, multiplying the PDE in (4.7) by y and integrating over $]0,T[\times\Omega$, we obtain after some integrations by parts

$$\begin{aligned}&\int_\Omega y_t(T,x)y(T,x)\,dx-\int_\Omega w_0y_0\,dx\\ &\quad=\int_0^T\int_\Omega |y_t(t,x)|^2\,dx\,dt-\int_0^T\int_\Omega |Dy(t,x)|^2\,dx\,dt\\ &\quad\quad-\int_0^T\rho(t)\int_\Omega Dy_t(t,x)\cdot Dy(t,x)\,dx\,dt,\end{aligned}$$

which implies

$$\begin{aligned}&\int_0^T\int_\Omega |Dy(t,x)|^2\,dx\,dt\\ &\quad\le\int_\Omega w_0y_0\,dx+\frac12\int_\Omega |y(T,x)|^2\,dx+\frac12\int_\Omega |y_t(T,x)|^2\,dx\\ &\quad\quad+\frac{1}{\eta}\rho_1\int_0^T\int_\Omega |Dy_t|^2\,dx\,dt+\eta\rho_1\int_0^T\int_\Omega |Dy|^2\,dx\,dt;\end{aligned}$$

hence if η is sufficiently small, again using the Poincaré inequality we get

$$\begin{aligned}&\int_0^\infty\int_\Omega |y(t,x)|^2\,dx\,dt+\int_0^\infty\int_\Omega |Dy(t,x)|^2\,dx\,dt\\ &\quad\le c\left[\int_\Omega w_0y_0\,dx+\int_\Omega |y(T,x)|^2\,dx+\int_\Omega |y_t(T,x)|^2\,dx+\int_0^T\int_\Omega |Dy_t|^2\,dx\,dt\right],\end{aligned}$$

and by (4.15) we finally obtain

$$\int_0^\infty\int_\Omega |y|^2\,dx\,dt+\int_0^\infty\int_\Omega |Dy|^2\,dx\,dt\le c\left[\int_\Omega |w_0|^2\,dx+\int_\Omega |y_0|^2\,dx+\int_\Omega |Dy_0|^2\,dx\right]. \tag{4.17}$$

The result now follows by (4.8), (4.17), and (4.16). □

Remark 4.2. The above proposition and the results of [D] imply that the evolution operator $U_{\mathcal{A}}(t,s)$ associated with $\{\mathcal{A}(t)\}$ is exponentially stable; i.e., it satisfies

$$\|U_{\mathcal{A}}(t,s)\|_{\mathcal{L}(H)}\le c\,e^{-\beta(t-s)}\quad\forall\,0\le s\le t$$

for some $\beta>0$.

In the case of Neumann boundary control, the finite cost condition is fulfilled too; indeed, we have the following proposition.

PROPOSITION 4.3. *Let $J(u)$ be given by* (4.8), *where y satisfies* (4.7) *with $B = \partial/\partial\nu$, and assume that $\rho_1 \geq \rho(t) \geq \rho_0 > 0$ for each $t > 0$. Then there exists $u \in L^2(0,\infty; L^2(\partial\Omega))$ such that $J(u) < \infty$.*

Proof. Multiply the PDE in (4.7) by y_t and integrate over Ω; then

$$\frac{1}{2}\frac{d}{dt}\int_\Omega |y_t(t,x)|^2\,dx = \int_{\partial\Omega} u(t,x)y_t(t,x)\,d\sigma_x + \rho(t)\int_{\partial\Omega} u_t(t,x)y_t(t,x)\,d\sigma_x$$
$$-\frac{1}{2}\frac{d}{dt}\int_\Omega |Dy(t,x)|^2\,dx - \rho(t)\int_\Omega |Dy_t(t,x)|^2\,dx.$$

Choose the feedback control $u = -y|_{\partial\Omega}$; we then have

$$\frac{1}{2}\frac{d}{dt}\int_\Omega |y_t(t,x)|^2\,dx + \frac{1}{2}\frac{d}{dt}\int_\Omega |Dy(t,x)|^2\,dx + \frac{1}{2}\frac{d}{dt}\int_{\partial\Omega} |y(t,x)|^2\,d\sigma_x$$
$$= -\rho(t)\int_{\partial\Omega} |y_t(t,x)|^2\,d\sigma_x - \rho(t)\int_\Omega |Dy_t(t,x)|^2\,dx$$

so that integrating over $]0,T[$ we get

$$\int_\Omega |y_t(T,x)|^2\,dx + \int_\Omega |Dy(T,x)|^2\,dx + \int_{\partial\Omega} |y(T,x)|^2\,d\sigma_x$$
$$= \int_\Omega |w_0|^2\,dx + \int_\Omega |Dy_0|^2\,dx + \int_{\partial\Omega} |y_0|^2\,d\sigma_x$$
$$-2\int_0^T \rho(t)\int_{\partial\Omega} |y_t(t,x)|^2\,d\sigma_x\,dt - 2\int_0^T \rho(t)\int_\Omega |Dy_t(t,x)|^2\,dx\,dt.$$

This implies that

$$\sup_{T>0}\left[\int_\Omega |y_t(T,x)|^2\,dx + \int_\Omega |Dy(T,x)|^2\,dx + \int_{\partial\Omega} |y(T,x)|^2\,d\sigma_x\right]$$
$$+\int_0^\infty \rho(t)\int_\Omega |Dy_t(t,x)|^2\,dx\,dt + \int_0^\infty \rho(t)\int_{\partial\Omega} |y_t(t,x)|^2\,d\sigma_x\,dt \tag{4.18}$$
$$\leq c\left[\int_\Omega |w_0|^2\,dx + \int_\Omega |Dy_0|^2\,dx + \int_{\partial\Omega} |y_0|^2\,d\sigma_x\right].$$

On the other hand, multiplying the PDE in (4.7) by y and integrating over $]0,T[\times\Omega$, we obtain after some integrations by parts

$$\int_\Omega y_t(T,x)y(T,x)\,dx - \int_\Omega w_0y_0\,dx + \int_0^T\int_{\partial\Omega} |y(t,x)|^2\,d\sigma_x\,dt$$
$$= \int_0^T\int_\Omega |y_t(t,x)|^2\,dx\,dt - \int_0^T\int_\Omega |Dy(t,x)|^2\,dx\,dt$$
$$-\int_0^T \rho(t)\int_{\partial\Omega} y_t(t,x)y(t,x)\,d\sigma_x\,dt - \int_0^T \rho(t)\int_\Omega Dy_t(t,x)\cdot Dy(t,x)\,dx\,dt;$$

hence by (4.18) one easily finds that

$$\begin{aligned}\frac{1}{2}\int_0^\infty\int_\Omega |Dy(t,x)|^2\,dx\,dt + \frac{1}{2}\int_0^\infty\int_{\partial\Omega} |y(t,x)|^2\,d\sigma_x\,dt \\ \leq \int_\Omega |y(T,x)|^2\,dx + c\left[\int_\Omega |w_0|^2\,dx + \int_\Omega |Dy_0|^2\,dx + \int_\Omega |y_0|^2\,dx\right. \\ \left. + \int_{\partial\Omega} |y_0|^2\,d\sigma_x + \int_0^\infty\int_\Omega |y_t(t,x)|^2\,dx\,dt\right].\end{aligned} \tag{4.19}$$

Now we have the following lemma.

LEMMA 4.4. *There exists $c > 0$ such that*

$$\|f\|_{L^2(\Omega)} \leq c\left[\|Df\|_{L^2(\Omega)} + \|f\|_{L^2(\partial\Omega)}\right] \quad \forall f \in H^1(\Omega).$$

Proof. The proof is by contradiction; otherwise there should exist a sequence $\{f_k\}$ in $H^1(\Omega)$ such that

$$\|f_k\|_{L^2(\Omega)} > k\left[\|Df_k\|_{L^2(\Omega)} + \|f_k\|_{L^2(\partial\Omega)}\right] \quad \forall k \in \mathbb{N}^+.$$

In particular, the right member is not zero (since in that case $f_k \equiv 0$). Then if we set

$$g_k(x) = \frac{f_k(x)}{\|Df_k\|_{L^2(\Omega)} + \|f_k\|_{L^2(\partial\Omega)}},$$

we have

$$\|g_k\|_{L^2(\Omega)} > k, \quad \|Dg_k\|_{L^2(\Omega)} + \|g_k\|_{L^2(\partial\Omega)} = 1 \quad \forall k \in \mathbb{N}^+.$$

Hence for a suitable subsequence we get $Dg_k \to z$ weakly in $L^2(\Omega)$ and $g_k \to w$ weakly in $L^2(\partial\Omega)$.

Now let $\varphi \in L^2(\Omega)$ and take the solution $\Phi \in H^2(\Omega) \cap H_0^1(\Omega)$ of $\Delta\Phi = \varphi$ in Ω. Then as $k \to \infty$ we have

$$\begin{aligned}\int_\Omega g_k\varphi\,dx &= \int_\Omega g_k\,\Delta\Phi\,dx \\ &= \int_{\partial\Omega} g_k\frac{\partial\Phi}{\partial\nu}d\sigma_x - \int_\Omega Dg_k\cdot D\Phi\,dx \to \int_{\partial\Omega} w\frac{\partial\Phi}{\partial\nu}d\sigma_x - \int_\Omega z\cdot D\Phi\,dx,\end{aligned}$$

which implies that $\{g_k\}$ is weakly convergent in $L^2(\Omega)$, but this is impossible since $\{g_k\}$ is not bounded in $L^2(\Omega)$.

Let us return to (4.19); by Lemma 4.4 and (4.18) we obtain

$$\begin{aligned}&\int_0^\infty\int_\Omega |Dy(t,x)|^2\,dx\,dt + \int_0^\infty\int_{\partial\Omega} |y(t,x)|^2\,d\sigma_x\,dt \\ &\quad + \int_0^\infty\int_\Omega |Dy_t(t,x)|^2\,dx\,dt + \int_0^\infty\int_{\partial\Omega} |y_t(t,x)|^2\,d\sigma_x\,dt \\ &\quad \leq c\left[\int_\Omega |w_0|^2\,dx + \int_\Omega |Dy_0|^2\,dx + \int_\Omega |y_0|^2\,dx + \int_{\partial\Omega} |y_0|^2\,d\sigma x\right],\end{aligned}$$

and consequently the choice $u = y|_{\partial\Omega}$ implies $J(u) < \infty$. □

Remark 4.4. We have in fact verified that Hypothesis 3.1 holds too.

Remark 4.5. A more general approach to problem (4.7)–(4.8) in the autonomous case, which allows one to take controls $u \in L^2(0,\infty;L^2(\partial\Omega))$, can be found in [LLP], [T].

4.4. Structurally damped plate equation. Let $\Omega \subset \mathbb{R}^n$ be a bounded open set with smooth boundary $\partial\Omega$. Consider the following Dirichlet or Neumann boundary control problem for the structurally damped plate equation in $]0,\infty[\times \Omega$:

$$\text{(4.20)} \quad \begin{cases} y_{tt}(t,x) = -\Delta^2 y(t,x) + \rho(t)\Delta y_t(t,x), & t>0,\ x\in\Omega, \\ y(0,x) = y_0(x), \quad y_t(0,x) = w_0(x), & x\in\Omega, \\ By(t,x) = 0, \quad By_t(t,x) = u(t,x), & t>0,\ x\in\partial\Omega \end{cases} \left[B = I \text{ or } B = \frac{\partial}{\partial\nu}\right].$$

Here ρ is a scalar function belonging to $C^\varepsilon([0,\infty[)$; the data y_0, w_0 belong to $H^2(\Omega)$ and $L^2(\Omega)$, respectively. The cost functional

$$\text{(4.21)} \quad \begin{aligned} J(u) = \int_0^\infty \{ &\|y(t,\cdot)\|^2_{L^2(\Omega)} + \|y_t(t,\cdot)\|^2_{L^2(\Omega)} + \|Dy(t,\cdot)\|^2_{L^2(\Omega)} \\ &+ \|D^2 y(t,\cdot)\|^2_{L^2(\Omega)} \\ &+ \|u(t,\cdot)\|^2_{L^2(\partial\Omega)} + \|u_t(t,\cdot)\|^2_{L^2(\partial\Omega)}\}\, dt \end{aligned}$$

has to be minimized among all $u \in W^{1,2}_{\text{loc}}(0,\infty; L^2(\partial\Omega))$, with y subject to (4.20). Following the same method of the preceding example, we define A, G as in (4.9), (4.10), set $H = D_A \times L^2(\Omega)$, $U = L^2(\partial\Omega)$, and finally rewrite the problem in abstract form. It turns out that if $u \in W^{2,2}_{\text{loc}}(0,\infty; L^2(\partial\Omega))$, the function

$$Z := \begin{pmatrix} y \\ y_t \end{pmatrix} - G\begin{pmatrix} u \\ u_t \end{pmatrix}$$

solves

$$\begin{cases} Z'(t) = \mathcal{A}(t)Z(t) + F(t), & t>0, \\ Z(0) = Z_0, \end{cases}$$

where

$$\mathcal{A}(t) := \begin{pmatrix} 0 & 1 \\ -\Delta^2 & \rho(t)\Delta \end{pmatrix}, \qquad Z_0 := \begin{pmatrix} y_0 + (1-A)^{-1}Gu(0) \\ w_0 + (1-A)^{-1}Gu'(0) \end{pmatrix},$$

$$F(t) := \begin{pmatrix} 0 \\ -2Gu(t) + \rho(t)Gu'(t) + (1-A)^{-1}[Gu''(t) - \rho(t)Gu'(t) + Gu(t)] \end{pmatrix}.$$

As $\mathcal{A}(t)$ fulfills the assumptions of [AT1], [AT2], and [AT3, §6], there exists its evolution operator $U_{\mathcal{A}}(t,s)$; hence setting $Y := \binom{y}{y_t}$ and integrating by parts we get

$$\begin{aligned} Y(t) &= Z(t) - \begin{pmatrix} (1-A)^{-1}Gu(t) \\ (1-A)^{-1}Gu'(t) \end{pmatrix} \\ &= U_{\mathcal{A}}(t,0)\begin{pmatrix} y_0 + (1-A)^{-1}Gu(0) \\ w_0 \end{pmatrix} - \begin{pmatrix} (1-A)^{-1}Gu(t) \\ 0 \end{pmatrix} \\ &\quad + \int_0^t U_{\mathcal{A}}(t,s)\begin{pmatrix} (1-A)^{-1}Gu'(s) \\ (1-A)^{-1}Gu(s) - 2Gu(s) \end{pmatrix} ds, \end{aligned}$$

i.e., defining

$$L := \begin{pmatrix} (1-A)^{-1}G \\ 0 \end{pmatrix}, \quad M := \begin{pmatrix} 0 \\ 2G - (1-A)^{-1}G \end{pmatrix}, \quad Y_0 := \begin{pmatrix} y_0 + (1-A)^{-1}Gu(0) \\ w_0 \end{pmatrix},$$

$$Y(t) = U_{\mathcal{A}}(t,0)(Y_0 - Lu(0)) - Lu(t) + \int_0^t U_{\mathcal{A}}(t,s)(Lu'(s) + Mu(s))\,ds.$$

This formula holds for $u \in W^{1,2}_{\mathrm{loc}}(0,\infty; L^2(\partial\Omega))$ as well.

Now, as in the preceding example, we set $\bar{H} := H \times U$, $\bar{U} := U$, and $v(t) := u'(t)$, $X(t) := (Y(t), u(t))$. The state X satisfies

$$\begin{cases} X'(t) = \mathcal{B}(t)X(t) + Qv(t), & t > 0, \\ X(0) = X_0, \end{cases}$$

where $\mathcal{B}(t)$ is defined as in (4.12) and

$$Q := \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \qquad X_0 := \begin{pmatrix} Y_0 \\ u(0) \end{pmatrix}.$$

Arguing as in the preceding example we arrive again to the state equation (4.13) for $X(t)$, where now

$$\mathcal{G}(t) := \begin{pmatrix} (1-\mathcal{A}(t))^{-1}M - \mathcal{A}(t)(1-\mathcal{A}(t))^{-1}L \\ 1 \end{pmatrix}.$$

Note that $\mathcal{G}(t)$ is uniformly bounded in $]0,\infty[$ as an element of $\mathcal{L}(\bar{U}, D_{\mathcal{A}(t)})$. The cost functional (4.21) transforms into

$$\bar{J}(v) = \int_0^\infty \{\|X(t)\|^2_{\bar{H}} + \|v(t)\|^2_{\bar{U}}\}\,dt, \tag{4.22}$$

and our abstract theory applies to the control problem (4.13), (4.22), provided that we verify the finite cost condition (Hypothesis 2.2). Now it turns out that in the case of Dirichlet boundary conditions ($B = I$) one can choose the control $u = 0$, whereas in the case of Neumann boundary conditions $\left(B = \frac{\partial}{\partial\nu}\right)$ one can choose the feedback control $u = y + y_t$. The proof that the cost is finite can be done by adapting the arguments of Propositions 4.1 and 4.3.

Remark 4.6. A more general approach to problem (4.20) – (4.21) in the autonomous case, which allows one to take controls $u \in L^2(0,\infty; L^2(\partial\Omega))$, can be found in [LLP], [T].

Appendix: Proof of Theorem 2.5. We are going to use the contraction principle on a suitable Banach space. For fixed $T_0, T \in \mathbb{R}$ with $T_0 < T$ we set, as in the proof of Lemma 2.9,

$$\begin{aligned} X(T_0,T) := \{\ & P : [T_0,T] \to \Sigma(H) \text{ such that} \\ & \text{(i) } (\lambda_0 - A^*(\cdot))^{1-\alpha}P(\cdot) \in C_s([T_0,T], \mathcal{L}(H)); \\ & \text{(ii) } |[\lambda_0 - A(t)^*]^{1-\alpha}P(t)|_{\mathcal{L}(H)} \le c[1 + (T-t)^{\beta+\alpha-1}]\ \forall t \in [T_0,T[; \\ & \text{(iii) } |[\lambda_0 - A(t)^*]^{1-\alpha}P(t)U(t,s)[\lambda_0 - A(s)]^{\beta}|_{\mathcal{L}(H)} \\ & \quad \le c(T-s)^{\gamma}[1 + (T-t)^{\beta+\alpha-1}](t-s)^{-\beta}\ \forall T_0 \le s < t < T\} \end{aligned} \tag{A.1}$$

with $\gamma := \min\{1-\alpha-\beta, \beta\}$. We endow $X(T_0,T)$ by its natural norm, i.e.,

$$\|P\|_{X(T_0,T)} := \max\{A, B\},$$

where

$$A := \sup_{t\in[T_0,T[} [1+(T-t)^{1-\alpha-\beta}]|[\lambda_0 - A(t)^*]^{1-\alpha}P(t)|_{\mathcal{L}(H)},$$

$$B := \sup_{T_0\le s<t<T} \frac{[1+(T-t)^{1-\alpha-\beta}](t-s)^{\beta}}{(T-s)^{\gamma}} |[\lambda_0 - A(t)^*]^{1-\alpha}P(t)U(t,s)[\lambda_0 - A(s)]^{\beta}|_{\mathcal{L}(H)}.$$

We also set

$$B(\rho) := \{P \in X(T_0,T) : \|P\|_{X(T_0,T)} \le \rho\}.$$

Theorem 2.5 will be a consequence of the following lemma.

LEMMA A.1. *For each $\rho_0 > 0$ there exist $T_0 < T$ and $\rho > 0$ such that for any P_T satisfying*

$$|[\lambda_0 - A(T)^*]^{\beta}P_T[\lambda_0 - A(T)]^{\beta}|_{\mathcal{L}(H)} \le \rho_0$$

the Riccati equation

$$P(t) = U(T,t)^*P_TU(T,t) + \int_t^T U(r,t)^* \times [C(r)^*C(r) - P(r)(\lambda_0 - A(r))G(r)N(r)^{-1}G(r)^*(\lambda_0 - A(r)^*)P(r)]U(r,t)\,dr, \quad t \in [T_0,T[, \tag{A.2}$$

has a unique solution $P(\cdot)$ in $B(\rho)$.

Proof. First set

$$Q_T = (\lambda_0 - A(T)^*)^{\beta}P_T(\lambda_0 - A(T))^{\beta}. \tag{A.3}$$

Now fix $\rho_0 > 0$ and let P_T be such that $|Q_T|_{\mathcal{L}(H)} \le \rho_0$. Consider the map Γ defined on $B(\rho)$ in the following way:

$$[\Gamma(P)](t) = U(T,t)^*P_TU(T,t) + \int_t^T U(r,t)^* \times [C(r)^*C(r) - [(\lambda_0 - A(r)^*)^{1-\alpha}P(r)]^*K(r)[(\lambda_0 - A(r)^*)^{1-\alpha}P(r)]]U(r,t)\,dr, \tag{A.4}$$

where $t \in [T_0,T[$ and

$$K(r) := [(\lambda_0 - A(r))^{\alpha}G(r)]^*N(r)^{-1}[[(\lambda_0 - A(r))^{\alpha}G(r)]^*. \tag{A.5}$$

We remark that $K(\cdot) \in L^{\infty}(]T_0,T[,\mathcal{L}(H))$ by Hypothesis 1.3.

We will show that for suitable T_0 and ρ (independent of the choice of P_T) the map Γ is a contraction in $B(\rho)$.

We start with the following estimate, which is true for $t < r < T$ and follows by (A.1(iii)) and (1.6):

$$\begin{aligned} &|(\lambda_0 - A(r)^*)^{1-\alpha}P(r)U(r,t)(\lambda_0 - A(t))^{1-\alpha}|_{\mathcal{L}(H)} \\ &\le \left|(\lambda_0 - A(r)^*)^{1-\alpha}P(r)U\left(r,\frac{r+t}{2}\right)\left(\lambda_0 - A\left(\frac{r+t}{2}\right)\right)^{\beta}\right|_{\mathcal{L}(H)} \\ &\quad \times \left|\left(\lambda_0 - A\left(\frac{r+t}{2}\right)\right)^{-\beta}U\left(\frac{r+t}{2},t\right)(\lambda_0 - A(t))^{1-\alpha}\right|_{\mathcal{L}(H)} \\ &\le c\,\rho\,(T-t)^{\gamma}[1+(T-r)^{\alpha+\beta-1}](r-t)^{\alpha-1}. \end{aligned} \tag{A.6}$$

By (1.6), (A.5), and (A.4) we deduce (with Q_T and $K(r)$ given by (A.3) and (A.5))

$$
\begin{aligned}
&|(\lambda_0 - A(t)^*)^{1-\alpha}\Gamma(P)(t)|_{\mathcal{L}(H)} \\
&\quad \le |(\lambda_0 - A(t)^*)^{1-\alpha}U(T,t)^*(\lambda_0 - A(T)^*)^{-\beta}Q_T(\lambda_0 - A(T))^{-\beta}U(T,t)|_{\mathcal{L}(H)} \\
&\qquad + \left| \int_t^T (\lambda_0 - A(t)^*)^{1-\alpha}U(r,t)^*C(r)^*C(r)U(r,t)\,dr \right|_{\mathcal{L}(H)} \\
&\qquad + \left| \int_t^T [(\lambda_0 - A(t)^*)^{1-\alpha}U(r,t)^*P(r)(\lambda_0 - A(r))^{1-\alpha}] \right. \\
&\qquad\qquad \left. \times K(r)[(\lambda_0 - A(r)^*)^{1-\alpha}P(r)]U(r,t)\,dr \right|_{\mathcal{L}(H)} \\
&\quad \le c\,\rho_0[1 + (T-t)^{\beta+\alpha-1}] + c(T-t)^{\alpha} \\
&\qquad + c\,\rho^2 \int_t^T (T-t)^{\gamma}[1 + (T-r)^{(\alpha+\beta-1)}]^2(r-t)^{\alpha-1}\,dr \\
&\quad \le c[\rho_0 + 1 + \rho^2(T-t)^{\min\{\gamma+\alpha,\gamma+\beta+2\alpha-1\}}][1 + (T-t)^{\alpha+\beta-1}] \quad \forall t \in [T_0, T[.
\end{aligned}
$$

On the other hand, for $T_0 \le s < t < T$ we have by (A.4), (1.6), and (A.1(ii))–(A.1(iii))

$$
\begin{aligned}
&|(\lambda_0 - A(t)^*)^{1-\alpha}[\Gamma(P)](t)U(t,s)(\lambda_0 - A(s))^{\beta}|_{\mathcal{L}(H)} \\
&\quad \le |(\lambda_0 - A(t)^*)^{1-\alpha}U(T,t)^*(\lambda_0 - A(T)^*)^{-\beta} \\
&\qquad \times Q_T(\lambda_0 - A(T))^{-\beta}U(T,s)(\lambda_0 - A(s))^{\beta}|_{\mathcal{L}(H)} \\
&\qquad + \left| \int_t^T (\lambda_0 - A(t)^*)^{1-\alpha}U(r,t)^*C(r)^*C(r)U(r,s)(\lambda_0 - A(s))^{\beta}\,dr \right|_{\mathcal{L}(H)} \\
&\qquad + \left| \int_t^T [(\lambda_0 - A(t)^*)^{1-\alpha}U(r,t)^*P(r)(\lambda_0 - A(r))^{1-\alpha}] \right. \\
&\qquad\qquad \left. \times K(r)[(\lambda_0 - A(r)^*)^{1-\alpha}P(r)]U(r,s)(\lambda_0 - A(s))^{\beta}\,dr \right|_{\mathcal{L}(H)} \\
&\quad \le c\,\rho_0[1 + (T-t)^{\beta+\alpha-1}] + c(T-t)^{\alpha}(t-s)^{-\beta} \\
&\qquad + c\,\rho^2 \int_t^T (T-t)^{\gamma}[1 + (T-r)^{\beta+\alpha-1}]^2(r-t)^{\alpha-1}(T-s)^{\gamma}(r-s)^{-\beta}\,dr \\
&\quad \le c[\rho_0[1 + (T-t)^{\beta+\alpha-1}] + (T-t)^{\alpha}(t-s)^{-\beta} \\
&\qquad + \rho^2[(T-t)^{\gamma+\alpha} + (T-t)^{\gamma+2\beta+3\alpha-2}](T-s)^{\gamma}(t-s)^{-\beta}] \\
&\quad \le c(T-s)^{\gamma}[1 + (T-t)^{\beta+\alpha-1}](t-s)^{-\beta}\,[\rho_0 + 1 + \rho^2(T-t)^{\min\{\gamma+\alpha,\gamma+\beta+2\alpha-1\}}].
\end{aligned}
$$

The above estimates show that

$$
\|\Gamma(P)\|_{X(T_0,T)} \le c[\rho_0 + 1 + \rho^2(T-t)^{\min\{\gamma+\alpha,\gamma+\beta+2\alpha-1\}}].
$$

As $\gamma = \min\{\beta, 1-\alpha-\beta\}$ and $\beta > 1/2 - \alpha$, we have in any case $\gamma + \beta + 2\alpha - 1 > 0$. Hence we can find a large ρ and a T_0 sufficiently close to T such that

$$
\Gamma(P) \in B(\rho) \quad \forall\, P \in B(\rho). \tag{A.7}
$$

Now we have to prove that the map Γ is a contraction in $B(\rho)$. Indeed, if $P, Q \in B(\rho)$ we can estimate the $X(T_0,T)$-norm of $\Gamma(P) - \Gamma(Q)$ exactly as before (and the calculation is even simpler); the result is

$$
\|\Gamma(P) - \Gamma(Q)\|_{X(T_0,T)} \le c\,\rho\,\|P - Q\|_{X(T_0,T)}(T - T_0)^{\min\{\gamma+\alpha,\gamma+\beta+2\alpha-1\}}. \tag{A.8}
$$

Hence we can find a large ρ and a T_0 sufficiently close to T such that both (A.7) and (A.8) hold, and the result follows by the contraction principle. □

ON THE AVERAGED STOCHASTIC APPROXIMATION FOR LINEAR REGRESSION*

LÁSZLÓ GYÖRFI† AND HARRO WALK‡

Abstract. For a linear regression function the average of stochastic approximation with constant gain is considered. In case of ergodic observations almost sure convergence is proved, where the limit is biased with small bias for small gain. For independent and identically distributed observations and also under martingale and mixing assumptions, asymptotic normality with $(n^{-1/2})$-convergence order is obtained. In the martingale case the asymptotic covariance matrix is close to the optimum one if the gain is small.

Key words. averaged stochastic approximation, constant gains, linear regression, adaptive filtering, ergodicity, mixing, martingales, almost sure convergence, asymptotic normality

AMS subject classifications. 62L20, 62J05, 93E12

1. Introduction.

According to one of the most important recent results on stochastic approximation the optimal convergence order $n^{-1/2}$, together with an optimal (with respect to the trace) asymptotic covariance matrix, can be achieved if the output of the conventional stochastic approximation is averaged, where the corresponding stochastic approximation has a gain sequence decreasing to zero slower than the usual choice constant/n [21], [24].

In the following discussion $(\cdot,\cdot)$ denotes the inner product in the Euclidean space $\mathbf{R}^d$ and $\|\cdot\|$ stands for the norm of either a d-dimensional vector or a linear operator on $\mathbf{R}^d$. Let I denote the $d\times d$ identity matrix and $\lambda(B)$ and $\Lambda(B)$ denote the smallest and the largest eigenvalues of a symmetric matrix B, respectively; χ is used for denoting an indicator function.

The general assumption is that a sequence of random symmetric positive semidefinite $d \times d$ matrices A_n and a sequence of random d-dimensional vectors V_n, $n = 0, \pm 1, \pm 2, \dots$, are given, where $((A_n, V_n))$ is stationary and ergodic with $\mathbb{E}\|A_n\| < \infty$, $\mathbb{E}\|V_n\| < \infty$. Let $A := \mathbb{E}A_n$, $V := \mathbb{E}V_n$. Assume that A^{-1} exists. The aim is to estimate

$$\vartheta := A^{-1}V$$

on the basis of observations of A_n, V_n for $n \geq 1$.

For this purpose as a primary algorithm a stochastic approximation in $\mathbf{R}^d$ with constant gain $\alpha > 0$ is introduced:

$$X_{n+1} = X_n - \alpha(A_{n+1}X_n - V_{n+1}), \quad n \geq 0, \tag{1.1}$$

with an arbitrary X_0. It is followed by an averaging,

$$Y_n = \frac{1}{n}\sum_{i=1}^{n} X_i. \tag{1.2}$$

For reasons of simplicity X_0 is assumed to be deterministic. (In view of assertions on mean convergence one would have to impose integrability assumptions on X_0.)

In the case of independent and identically distributed (i.i.d.) observations with $A_n = A$ almost surely (a.s.), for sufficiently small gain $\alpha > 0$ the rate of convergence of (Y_n) and the asymptotic covariance matrix do not depend on α and are optimal [21], [22]. Unfortunately this property does not hold in general if the sequence (A_n) is random.

The usual motivation of using a constant gain algorithm is to deal with nonstationary cases where the algorithm (1.1) is expected to have some tracking abilities for the time-varying parameters. In this paper we deal only with stationary cases. Here consistency does not hold for the process X_n, but for the averages Y_n. Without averaging it is applied in practice if the computational complexity of the algorithm is a question of interest. Although the main purpose of this paper is to study the properties of the averaging rule (1.2), as a by-product we get some interesting features of (1.1) too, under the very general condition that the observation sequence is ergodic; therefore, the results may be interesting for readers who apply constant gain rule without averaging.

The paper is organized as follows. Let

$$A_{n,k}(\alpha) := (I - \alpha A_n) \dots (I - \alpha A_k) \quad \text{for} \quad k \le n,$$
$$A_{n,n+1}(\alpha) := I.$$

In §2 it will be shown that under the above general conditions for sufficiently small $\alpha > 0$ the almost sure limit δ_α of $(Y_n - \vartheta)$ exists, if

$$U_\alpha := \alpha \sum_{n=1}^{\infty} \|A_{n,1}(\alpha)(V_0 - A_0\vartheta)\| \quad (< \infty \text{ a.s. })$$

is integrable; for the asymptotic bias δ_α one has

$$\delta_\alpha = EX_0^* - \vartheta,$$

where $(X_n^*)_{n \ge 0}$ defined by

$$X_n^* := \vartheta + \alpha \sum_{i=-\infty}^{0} A_{n,n+i+1}(\alpha)(V_{n+i} - A_{n+i}\vartheta)$$

is a stationary and ergodic sequence satisfying recursion (1.1) (Theorem 2.1). In §2, by an averaging argument we also study assumptions (uniform integrability of X_0^* with respect to α, fulfilled under φ- or α-mixing together with uniform boundedness or under M-dependence together with moment conditions) under which $\delta_\alpha \to 0$ $(\alpha \to 0)$ (Theorem 2.7); mixing conditions are often assumed in adaptive filtering, and boundedness or moment conditions prevent the constant gain algorithm from exploding. Under more restrictive assumptions on the dependence of the observations (independence and also martingale case) it is proved in §3 that $\delta_\alpha = 0$ for sufficiently small α (Theorems 3.1 and 3.2). It should be mentioned that in the case of a nonlinear regression function even under i.i.d. observations there is an asymptotic bias. Section 4 concerns asymptotic normality, with $(n^{-1/2})$-convergence order, in the case of not necessarily vanishing δ_α (Theorem 4.1). The more special situation of §3 is studied in more detail in §5, where the $(n^{-1/2})$-convergence order of $Y_n - \vartheta$ to 0, together with

an asymptotic covariance matrix differing from the optimal one by a term of order α, is obtained (Theorems 5.3 and 5.6).

Without averaging the constant gain stochastic approximation has been mainly applied for adaptive filtering, when based on an observed random d-dimensional vector R one has to construct a linear estimate (x, R) of the unobserved real random variable Z such that the vector x^* minimizes the mean square error

$$\mathbb{E}((x, R) - Z)^2.$$

If a training sequence $(R_n, Z_n), n = 0, \pm 1, \pm 2, \ldots$, is given such that (R_n, Z_n) has the same distribution as (R, Z), then (1.1) can be applied with

$$A_n = R_n R_n^T$$

and

$$V_n = Z_n R_n.$$

In this case (1.1) can be written as

$$X_{n+1} = X_n - \alpha((R_{n+1}, X_n) - Z_{n+1})R_{n+1},$$

where there are no matrix operations, and if α is a negative integer power of 2, then one can save some multiplications, which is very important for high-speed communication and signal processing applications. (References on the possible application can be seen, for example, in [12] and [6].)

Remark 1.1. It is easy to construct a 3-dependent sequence for (A_n, V_n) for which $\delta_\alpha \neq 0$, i.e., Y_n is asymptotically biased: let $\{W_i\}$ be i.i.d., ± 1 valued, $EW_i = 0$, and one wants to predict $W_i + W_{i+1}$ from $W_{i-1} + W_i$; this is a one-step prediction problem for a moving average process. Then $d = 1$ and

$$\begin{aligned} A_i &= (W_{i-1} + W_i)^2 = 2(1 + W_{i-1}W_i), \\ V_i &= (W_{i-1} + W_i)(W_i + W_{i+1}) = 1 + W_{i-1}W_i + W_iW_{i+1} + W_{i-1}W_{i+1}, \end{aligned}$$

and $\vartheta = 1/2$. Obviously the observation sequences are 3-dependent. In this example, with the notation

$$d_n = \alpha\mathbb{E}(A_{n,2}(\alpha)(V_1 - A_1\vartheta)), \quad n \geq 2,$$

one has

$$\begin{aligned} &\mathbb{E}(A_{n,2}(\alpha)(V_1 - A_1\vartheta) \mid W_0, \ldots, W_{n-1}) \\ &\quad = \mathbb{E}(1 - \alpha A_n \mid W_0, \ldots, W_{n-1})A_{n-1,2}(\alpha)(V_1 - A_1\vartheta) \\ &\quad = (1 - 2\alpha)A_{n-1,2}(\alpha)(V_1 - A_1\vartheta), \quad n \geq 3, \\ d_2 &= \alpha\mathbb{E}\left((1 - \alpha A_2)(V_1 - A_1\vartheta)\right) = -\alpha^2\mathbb{E}\left(A_2(V_1 - A_1\vartheta)\right) = -2\alpha^2, \end{aligned}$$

and thus

$$\delta_\alpha = \sum_{n=2}^{\infty} d_n = \sum_{n=2}^{\infty}(-2\alpha^2)(1 - 2\alpha)^{n-2} = -\alpha;$$

therefore, Y_n is asymptotically biased, but the bias is small if α is small. It will be shown that this is true for much more general conditions on dependence, too.

The following list of assumptions will be explained in their interdependence and used later.

Assumption A1. There is some $\alpha' > 0$ such that U_α is integrable for $0 < \alpha < \alpha'$.

Assumption A2. A_1 is bounded a.s.; there is some $\alpha'' > 0$ such that X_0^* is uniformly integrable with respect to $0 < \alpha < \alpha''$.

Assumption B1. $E\|A_1\|^q < \infty$, $E\|V_1\|^q < \infty$ for all $q > 0$; there is some $M \in \mathbf{N}$ such that the sequence $((A_n, V_n))$ is M-dependent, i.e., $\sigma(A_0, V_0, A_{-1}, V_{-1}, \ldots)$ and $\sigma(A_{M+1}, V_{M+1}, A_{M+2}, V_{M+2}, \ldots)$ are independent.

Assumption B2a. A_1 and V_1 are bounded a.s.; the sequence $((A_n, V_n))$ is α-mixing, i.e.,

$$\begin{aligned}\alpha_n := \sup\{&|P(B \cap D) - P(B)P(D)|;\ \ B \in \sigma(A_0, V_0, A_{-1}, V_{-1}, \ldots),\\ &D \in \sigma(A_n, V_n, A_{n+1}, V_{n+1}, \ldots)\}\\ &\to 0 \ \ (n \to \infty),\end{aligned}$$

with $\sum \alpha_n < \infty$.

Assumption B2b. A_1 and V_1 are bounded a.s.; the sequence $((A_n, V_n))$ is φ-mixing, i.e.,

$$\begin{aligned}\varphi_n := \sup\{&|P(B \cap D) - P(B)P(D)|P(B)^{-1};\\ &B \in \sigma(A_0, V_0, A_{-1}, V_{-1}, \ldots),\ \ D \in \sigma(A_n, V_n, A_{n+1}, V_{n+1}, \ldots)\}\\ &\to 0 \ \ (n \to \infty).\end{aligned}$$

Assumption B2c. A_1 and V_1 are bounded a.s.; the sequence $((A_n, V_n))$ is φ-mixing (and thus α-mixing) with $\alpha_n = O(n^{-\tau})$ for some $\tau > 1$ or is α-mixing with $\alpha_n = O(n^{-\tau})$ for some $\tau > 2$.

2. Ergodic observations. We note the above-mentioned general assumptions that $((A_n, V_n),\ n = 0, \pm 1, \pm 2, \ldots)$ is stationary and ergodic with existence of the $d \times d$ matrix $\mathbb{E}A_1 =: A$ and of the d-dimensional vector $\mathbb{E}V_1 =: V$ and that the random matrices A_n are symmetric, positive semidefinite, A^{-1} exists. For ergodic observations the standard stochastic approximation works; namely if

$$\alpha_n = \frac{\text{constant}}{n},$$

then

$$X_n \to \vartheta \quad \text{a.s.},$$

which was proved by [3], [5], [15], [18], and [27] for $\|A_1\| < 1$ a.s., $\mathbb{E}\|A_1\|^2 < \infty$, and $\mathbb{E}\|A_1\| < \infty$, respectively. For constant gain α, X_n generally does not converge, but Y_n is a.s. convergent, as the following theorem states. Different choices of X_0 lead to different versions of the process (X_n). The first assertion of Theorem 2.1 tells that there exists a stationary and ergodic version of the process and that each of these versions is asymptotically close to it.

THEOREM 2.1. a) *There exists an* $\alpha''' > 0$ *such that for all* $0 < \alpha < \alpha'''$

$$U_\alpha := \alpha \sum_{n=1}^{\infty} \|A_{n,1}(\alpha)(V_0 - A_0\vartheta)\| \tag{2.1}$$

and

$$\alpha \sum_{i=-\infty}^{0} \|A_{0,i+1}(\alpha)(V_i - A_i\vartheta)\|$$

are a.s. finite. The random elements

$$X_n^* := \vartheta + \alpha \sum_{i=-\infty}^{0} A_{n,n+i+1}(\alpha)(V_{n+i} - A_{n+i}\vartheta), \quad n \geq 0, \tag{2.2}$$

are a.s. defined. (X_n^*) *satisfies recursion* (1.1) *and is stationary and ergodic; further*

$$X_n - X_n^* \to 0 \quad (n \to \infty) \text{ a.s.} \tag{2.3}$$

b) *Suppose that the random element* X_0^* *is integrable; then*

$$Y_n \to \mathbb{E}X_0^* =: \vartheta + \delta_\alpha \quad (n \to \infty) \text{ a.s.} \tag{2.4}$$

Remark 2.2. a) Under assumption A1, for $0 < \alpha < \alpha' (\leq \alpha''')$ the random element X_0^* is integrable. This follows from the relation

$$\alpha \sum_{i=-\infty}^{0} \mathbb{E}\|A_{0,i+1}(\alpha)(V_i - A_i\vartheta)\| = \mathbb{E}U_\alpha$$

obtained by stationarity of $((A_n, V_n), \ n = 0, \pm 1, \pm 2, \ldots)$.

b) Assumption A1 is satisfied under each of the conditions B1, B2a, and B2b.

c) Obviously the integrability of X_0^* is a necessary condition for almost sure convergence of (Y_n).

The proof of Theorem 2.1 requires Lemmas 2.3 and 2.4, which will be proved first. Remark 2.2b) is immediately proved by Lemma 2.6 and the moment or boundedness conditions on A_1 and V_1; Lemma 2.6 will be stated and proved after Remark 2.5.

LEMMA 2.3. *For all* $\alpha > 0$

$$\lim_{n\to\infty} \frac{1}{n} \mathbb{E} \log \|A_{n,1}(\alpha)\| = E \tag{2.5}$$

exists and $E < \infty$; *moreover*

$$\lim_{n\to\infty} \frac{1}{n} \log \|A_{n,1}(\alpha)\| = E \quad \text{a.s.} \tag{2.6}$$

Proof. Introduce the notations

$$M_n = I - \alpha A_n,$$
$$E_n = \frac{1}{n} \mathbb{E} \log \|M_n M_{n-1} \ldots M_1\|.$$

According to Furstenberg and Kesten [4], for a stationary and ergodic sequence of square matrices M_n with $\mathbb{E}\{(\log \|M_1\|)^+\} < \infty$ the limit

$$E = \lim_{n\to\infty} E_n \tag{2.7}$$

exists and $E < \infty$; moreover

$$\lim_{n\to\infty} \frac{1}{n} \log \|M_n M_{n-1} \dots M_1\| = E \quad \text{a.s.} \tag{2.8}$$

This result can be applied here since

$$\mathbb{E}\{(\log \|M_1\|)^+\} \le \mathbb{E}\{\log(1 + \alpha\|A_1\|)\} \le \mathbb{E}\{\alpha\|A_1\|\} < \infty. \qquad \square$$

LEMMA 2.4. *There exists an $\alpha''' > 0$ such that for all $0 < \alpha < \alpha'''$ the relation $E < 0$ holds. Consequently*

$$\|A_{n,1}(\alpha)\| \le e^{-n\varepsilon} \quad \text{a.s.} \tag{2.9}$$

for large n, with $\varepsilon > 0$ depending on $\alpha \in (0, \alpha''')$.

Proof. First, one shows

$$\lim_{n\to\infty} E_n = \inf_n E_n. \tag{2.10}$$

Obviously

$$\lim_{n\to\infty} E_n \ge \inf_n E_n.$$

In view of the reverse inequality one obtains for all integers n, N

$$E_{nN} = \frac{1}{nN}\mathbb{E}\log\|M_{nN}M_{nN-1}\dots M_1\| \le \frac{1}{nN}\mathbb{E}\sum_{k=1}^{n}\log\|M_{kN}M_{kN-1}\dots M_{(k-1)N+1}\|$$

$$= \frac{1}{N}\mathbb{E}\log\|M_N M_{N-1}\dots M_1\| = E_N;$$

therefore,

$$\lim_n E_{nN} \le E_N,$$

which implies

$$\lim_n E_n \le \inf_n E_n.$$

Because of (2.10) it is enough to find an integer N^* such that

$$E_{N^*} < 0.$$

By Jensen's inequality

$$E_n \le \log \mathbb{E}\|A_{n,1}(\alpha)\|^{1/n};$$

thus it is sufficient to show that there is an integer N^* such that

$$\mathbb{E}\|A_{N^*,1}(\alpha)\|^{1/N^*} < 1 \tag{2.11}$$

for α sufficiently small. (A_n) is ergodic; therefore

$$\left\| \frac{1}{n}\sum_{i=1}^{n} A_i - A \right\| \to 0 \text{ a.s.}$$

where A is positive definite. Because of Fatou's lemma there is an integer N^* such that

$$\lambda_n := \mathbb{E}\lambda\left(\frac{1}{n}\sum_{i=1}^{n} A_i\right) > 0 \text{ for all } n \geq N^*. \tag{2.12}$$

One shows (2.11) for this N^*. In view of this one proves that

$$\overline{\lim_{\alpha \downarrow 0}} \frac{\mathbb{E}\|A_{N^*,1}(\alpha)\|^{1/N^*} - 1}{\alpha} \leq -\lambda_{N^*}. \tag{2.13}$$

Obviously

$$\begin{aligned}\|A_{N^*,1}(\alpha)\|^{1/N^*} &\leq (\|I - \alpha A_{N^*}\| \, \|I - \alpha A_{N^*-1}\| \ldots \|I - \alpha A_1\|)^{1/N^*} \\ &\leq \left(\prod_{i=1}^{N^*}(1 + \alpha\|A_i\|)\right)^{1/N^*} \\ &\leq 1 + \alpha\frac{1}{N^*}\sum_{i=1}^{N^*}\|A_i\|;\end{aligned}$$

therefore,

$$\frac{\|A_{N^*,1}(\alpha)\|^{1/N^*} - 1}{\alpha} \leq \frac{1}{N^*}\sum_{i=1}^{N^*}\|A_i\|,$$

and because

$$\mathbb{E}\left(\frac{1}{N^*}\sum_{i=1}^{N^*}\|A_i\|\right) = \mathbb{E}\|A_1\| < \infty$$

one can apply Fatou's lemma:

$$\overline{\lim_{\alpha \downarrow 0}} \frac{\mathbb{E}\|A_{N^*,1}(\alpha)\|^{1/N^*} - 1}{\alpha} \leq \mathbb{E}\,\overline{\lim_{\alpha \downarrow 0}} \frac{\|A_{N^*,1}(\alpha)\|^{1/N^*} - 1}{\alpha}.$$

Further, one notices

$$\left\|A_{N^*,1}(\alpha) - \left[I - \alpha\sum_{i=1}^{N^*} A_i\right]\right\| \leq \alpha^2 \prod_{i=1}^{N^*}(1 + \|A_i\|) \text{ for } 0 < \alpha \leq 1, \tag{2.14}$$

$$\left\|I - \alpha\sum_{i=1}^{N^*} A_i\right\| = 1 - \alpha\lambda\left(\sum_{i=1}^{N^*} A_i\right) \text{ for } \alpha \text{ sufficiently small} \tag{2.15}$$

by positive semidefiniteness of $\sum_{i=1}^{N^*} A_i$, and thus obtains (2.13). □

Proof of Theorem 2.1. a) The first assertion immediately follows from Lemmas 2.3 and 2.4. For the second assertion, after a transposition of the matrices one argues in the same way, noting also the a.s. ergodic theorem for $(\|V_i - A_i\vartheta\|)$; the further argument is based on the reverse extension of (1.1). Thus the random element

$$X_0^* := \vartheta + \alpha\sum_{i=-\infty}^{0} A_{0,i+1}(\alpha)(V_i - A_i\vartheta)$$

is a.s. defined. Analogously one obtains for general $n = 0, 1, \ldots$ that X_n^* in (2.2) is a.s. defined. By induction with respect to n, noting

$$(I - \alpha A_{n+1}) \sum_{i=-\infty}^{0} A_{n,n+i+1}(\alpha)(V_{n+i} - A_{n+i}\vartheta)$$
$$= \sum_{i=-\infty}^{-1} A_{n+1,n+i+2}(\alpha)(V_{n+1+i} - A_{n+1+i}\vartheta),$$

one shows that (X_n^*) satisfies recursion (1.1). By (2.2), (X_n^*) is a time-invariant function of the stationary and ergodic sequence $((A_i, V_i))$; thus it is stationary and ergodic, too, where the latter follows by an application of Proposition 4.3 in [11, Chap. 1] to $((A_n, V_n))$ with reversed order of indices. Moreover

$$X_n - X_n^* = A_{n,1}(\alpha)(X_0 - X_0^*) \to 0 \qquad (n \to \infty) \quad \text{a.s.} \tag{2.16}$$

because of (2.9) in Lemma 2.4.

b) If X_0^* is integrable with $\mathbb{E}X_0^* =: \vartheta + \delta_\alpha$, by the almost sure ergodic theorem

$$\frac{1}{n}\sum_{i=1}^{n} X_i^* \to \vartheta + \delta_\alpha \qquad (n \to \infty) \quad \text{a.s.}$$

This and (2.16) yield

$$Y_n \to \vartheta + \delta_\alpha \qquad (n \to \infty) \quad \text{a.s.} \qquad \square$$

Remark 2.5. Unfortunately Lemma 2.4 proves only the existence of α'''. There is a special case of A_n where α''' can be given explicitly. Consider the case of $\|A_1\| < C$ a.s. Choose $\alpha''' = \min\{1/C, 1\}$. Then a.s.

$$\|A_{n,1}(\alpha)\| \le \|1 - \alpha A_n\| \, \|1 - \alpha A_{n-1}\| \ldots \|1 - \alpha A_1\| \le 1 \text{ for } \alpha < \alpha''';$$

therefore, (2.11) is proved if

$$\mathbb{P}\{\|A_{n,1}(\alpha)\| < 1\} > 0.$$

Let $N(A_i)$ be the null-space of A_i; then

$$\|A_{n,1}(\alpha)\| = 1$$

iff

$$\bigcap_{i=1}^{n} N(A_i) \neq 0.$$

A_1 is positive semidefinite; therefore

$$\bigcap_{i=1}^{n} N(A_i) = N\left(\sum_{i=1}^{n} A_i\right) = N\left(\frac{1}{n}\sum_{i=1}^{n} A_i\right).$$

Because of ergodicity

$$\frac{1}{n}\sum_{i=1}^{n} A_i \to A \quad \text{a.s.},$$

and A is invertible; therefore, there is an n such that

$$\mathbb{P}\left\{N\left(\frac{1}{n}\sum_{i=1}^{n}A_i\right)=0\right\}=\mathbb{P}\left\{\frac{1}{n}\sum_{i=1}^{n}A_i \text{ is invertible}\right\}>0.$$

LEMMA 2.6. a) *Under Assumption* B1 *or* B2b, *for each* $q\in\mathbf{N}$ *there exist real numbers* $K>0$, $\alpha^*>0$, $\rho>0$ *such that*

$$\mathbb{E}\|A_{n,1}(\alpha)\|^q\le Ke^{-\alpha\rho n} \text{ for all } n\in\mathbf{N} \text{ and } 0<\alpha<\alpha^*.$$

If the second version of Assumption B2c *holds, then for each* $q\in\mathbf{N}$ *and* $p\in\mathbf{N}$ *there exist real numbers* $K>0$, $\alpha^*>0$ *such that*

$$\mathbb{E}\|A_{n,1}(\alpha)\|^q\le Kn^{-p} \text{ for all } n\in\mathbf{N} \text{ and } 0<\alpha<\alpha^*.$$

b) *Under Assumption* B2a

$$\sum_n \mathbb{E}\|A_{n,1}(\alpha)\|<\infty \text{ for sufficiently small } \alpha>0.$$

Proof. a) Choose N^* according to (2.12). First assume B1. Let $k^*:=\max\{N^*,M,2\}$. Because of the moment condition and by the Cauchy–Schwarz inequality, it suffices to show a corresponding assertion for $\|A_{nk^*,1}(\alpha)\|^{2q}$, $n\in\{2,3,\dots\}$. One obtains

$$\begin{aligned}
&\mathbb{E}\|A_{nk^*,1}(\alpha)\|^{2q}\\
&=\mathbb{E}\|A_{nk^*,(n-1)k^*+1}(\alpha)A_{(n-1)k^*,(n-2)k^*+1}(\alpha)\dots A_{k^*,1}(\alpha)\|^{2q}\\
&\le\mathbb{E}\left(\prod_{j=0}^{[\frac{n-1}{2}]}\|A_{(2j+1)k^*,2jk^*+1}(\alpha)\|^{2q}\prod_{j=1}^{[\frac{n}{2}]}\|A_{2jk^*,(2j-1)k^*+1}(\alpha)\|^{2q}\right)\\
&\le\left(\prod_{j=0}^{[\frac{n-1}{2}]}\mathbb{E}\|A_{(2j+1)k^*,2jk^*+1}(\alpha)\|^{4q}\right)^{\frac12}\left(\prod_{j=1}^{[\frac{n}{2}]}\mathbb{E}\|A_{2jk^*,(2j-1)k^*+1}(\alpha)\|^{4q}\right)^{\frac12}\\
&=\left(\mathbb{E}\|A_{k^*,1}(\alpha)\|^{4q}\right)^{\frac{n}{2}},
\end{aligned}$$

where for the second inequality one uses the Cauchy–Schwarz inequality once more and M-dependence. (2.14) for k^* instead of N^* yields

$$\begin{aligned}
&\|A_{k^*,1}(\alpha)\|\\
&\le\left\|I-\alpha\sum_{i=1}^{k^*}A_i\right\|+\alpha^2\prod_{i=1}^{k^*}(1+\|A_i\|)\\
&\le 1-\alpha\lambda\left(\sum_{i=1}^{k^*}A_i\right)+2\alpha\Lambda\left(\sum_{i=1}^{k^*}A_i\right)\chi_{\{\alpha\lambda(\sum_{i=1}^{k^*}A_i)\ge1\}}+\alpha^2\prod_{i=1}^{k^*}(1+\|A_i\|)\\
&\le 1-\alpha\lambda\left(\sum_{i=1}^{k^*}A_i\right)+2\alpha^2\Lambda\left(\sum_{i=1}^{k^*}A_i\right)^2+\alpha^2\prod_{i=1}^{k^*}(1+\|A_i\|).
\end{aligned}$$

Each of the terms

$$\lambda\left(\sum_{i=1}^{k^*} A_i\right),\ \Lambda\left(\sum_{i=1}^{k^*} A_i\right)^2,\ \prod_{i=1}^{k^*}(1+\|A_i\|)$$

is majorized by

$$2^{k^*+1}\max\left\{1, \|A_1\|^{k^*}, \ldots, \|A_{k^*}\|^{k^*}\right\}.$$

Now by the trivial inequality

$$(1+x)^n \le 1 + nx + 2^n \max\{x^2, |x|^n\} \quad (x \in \mathbf{R},\ n \in \mathbf{N})$$

one obtains

$$\begin{aligned}&\|A_{k^*,1}(\alpha)\|^{4q}\\ &\le 1 - 4q\alpha\lambda\left(\sum_{i=1}^{k^*} A_i\right) + \alpha^2 2^{4q(k^*+4)+1}\max\left\{1, \|A_1\|^{4qk^*}, \ldots, \|A_{k^*}\|^{4qk^*}\right\}\end{aligned}$$

and thus

$$\begin{aligned}&\mathbb{E}\|A_{k^*,1}(\alpha)\|^{4q}\\ &\le 1 - 4q\alpha\mathbb{E}\lambda\left(\sum_{i=1}^{k^*} A_i\right) + \alpha^2 2^{4q(k^*+4)+1}\left(1 + k^*\mathbb{E}\|A_1\|^{4qk^*}\right)\end{aligned}$$

for $0 < \alpha \le 1$, which together with (2.12) and the moment condition yields the assertion.

Now assume B2b. Because of almost sure boundedness of $\|A_1\|$ and stationarity of (A_n),

$$A^* := \operatorname{ess\,sup} \|A_n\| < \infty$$

is independent of n. Neglecting a set of $\mathbb{P}$-measure zero, one has

$$\sup_{n,\omega} \|A_n(\omega)\| \le A^*.$$

In view of the assertion it suffices to show a corresponding assertion for $\|A_{nN^*,1}\|^q$, $n \in \mathbf{N}$. According to (2.14) and (2.15) one has—for $0 < \alpha < \min\left\{1, \frac{1}{N^*A^*}\right\}$—the representation

$$\|A_{nN^*,(n-1)N^*+1}(\alpha)\| = 1 - \alpha T_n(\alpha),\quad n \in \mathbf{N},$$

with

$$T_n(\alpha) \ge 0,\ |T_n(\alpha) - \lambda(A_{(n-1)N^*+1}(\alpha) + \cdots + A_{nN^*}(\alpha))| \le \alpha(1+A^*)^{N^*}.$$

Let $\delta^* := \frac{1}{2}\mathbb{E}\lambda(A_1 + \ldots + A_{N^*}) > 0$. For $0 < \alpha < \min\left\{1, \frac{1}{N^*A^*}, \frac{\delta^*}{2(1+A^*)^{N^*}}\right\}$ one now obtains

$$\|A_{nN^*,1}(\alpha)\|^q$$

$$
\begin{aligned}
&\leq \|A_{nN^*,(n-1)N^*+1}(\alpha)\|^q \dots \|A_{N^*,1}(\alpha)\|^q \\
&= (1-\alpha T_n(\alpha))^q \dots (1-\alpha T_1(\alpha))^q \\
&\leq e^{-\alpha q(T_1(\alpha)+\dots+T_n(\alpha))} \\
&\leq e^{-\alpha q(T_1(\alpha)+\dots+T_n(\alpha))} \chi_{\left\{\left|\frac{T_1(\alpha)+\dots+T_n(\alpha)}{n} - E\lambda(A_1+\dots+A_{N^*})\right| \leq \delta^*\right\}} \\
&\quad + \chi_{\left\{\left|\frac{T_1(\alpha)+\dots+T_n(\alpha)}{n} - E\lambda(A_1+\dots+A_{N^*})\right| > \delta^*\right\}} \\
&\leq e^{-\alpha q \delta^* n} + \chi_{B_n}
\end{aligned}
$$

with

$$B_n = \left\{\left|\frac{\xi_1 + \dots + \xi_n}{n}\right| > \frac{\delta^*}{2}\right\},$$

where

$$\xi_n = \lambda\left(A_{(n-1)N^*+1} + \dots + A_{nN^*}\right) - \mathbb{E}\lambda(A_{(n-1)N^*+1} + \dots + A_{nN^*}), \quad n \in \mathbf{N}.$$

The sequence (ξ_n) is bounded and φ-mixing. Thus, according to an inequality of Collomb [2] (see the details in Györfi et al. [7, pp. 19, 20]) a constant $c_0 > 0$ exists with

$$P(B_n) \leq e^{-c_0 n}, \quad n \in \mathbf{N}.$$

Therefore,

$$\mathbb{E}\|A_{nN^*,1}\|^q \leq e^{-\min\{\alpha q \delta^*, c_0\} n}, \quad n \in \mathbf{N}.$$

If the second version of B2c is assumed, one argues as before, noting

$$
\begin{aligned}
P(B_n) &\leq (n\delta^*/2)^{-2p} \mathbb{E}\|\xi_1 + \dots + \xi_n\|^p \\
&\leq c_1 n^{-p}, \quad n \in \mathbf{N},
\end{aligned}
$$

with a suitable constant $c_1 < \infty$, where for the latter inequality Theorem 2 in [10] is used instead of Collomb's inequality.

b) We use the notations in the second part of a). As there, one obtains

$$
\begin{aligned}
\sum_{n=1}^{\infty} \mathbb{E}\|A_{n,1}(\alpha)\| &= \sum_{n=1}^{\infty} \sum_{k=(n-1)N^*+1}^{nN^*} \mathbb{E}\|A_{k,1}(\alpha)\| \\
&\leq N^* \sum_{n=1}^{\infty} \mathbb{E}\|A_{(n-1)N^*,1}(\alpha)\| \\
&\leq N^* \left(\sum_{n=0}^{\infty} e^{-\alpha\delta^* n} + \sum_{n=1}^{\infty} \mathbb{P}(B_n)\right)
\end{aligned}
$$

for sufficiently small $\alpha > 0$. (ξ_n) is α-mixing where the corresponding mixing coefficients α'_n fulfill $\sum \alpha'_n < \infty$. According to Ibragimov and Linnik [9, Lem. 18.5.2 and its proof] one has, with a suitable constant $c < \infty$,

$$\sum_{n=1}^{\infty} \mathbb{P}(B_n) \leq \left(\frac{2}{\delta^*}\right)^4 \sum_{n=1}^{\infty} n^{-4} \mathbb{E}\left\|\sum_{j=1}^{n} \xi_j\right\|^4$$

$$\leq c \sum_{n=1}^{\infty} n^{-2} \sum_{j=1}^{n} j\alpha_j$$

$$= c \sum_{j=1}^{\infty} \left(\sum_{n=j}^{\infty} n^{-2} \right) j\alpha_j < \infty. \qquad \square$$

The theorem below concerns the asymptotic mean estimation error of (X_n) and the asymptotic bias δ_α of (Y_n) for small α. Its proof is based on an argument of Sanchez-Palencia [25] concerning the averaging method for deterministic differential equations (compare also [26, §4.2]). The first assertion in Theorem 2.7b), under an assumption similar to B2a and under Assumption B1, is due to Kushner and Shwartz [13, especially p. 180] and to Macchi and Eweda [16], respectively. A corresponding result for an algorithm with projection has been obtained by Krieger and Masry [12] under conditions concerning α-mixing and finite moments.

THEOREM 2.7. a) *Under Assumption* A2,

$$\lim_n \mathbb{E}\|X_n - \vartheta\| \to 0 \quad (\alpha \to 0)$$

holds and therefore

$$\delta_\alpha \to 0 \quad (\alpha \to 0).$$

b) *If Assumption* B2a *or* B1 *is fulfilled, then*

$$\lim_n \mathbb{E}\|X_n - \vartheta\| = O(\alpha^{1/2}), \quad \delta_\alpha = O(\alpha^{1/2}) \quad (\alpha \to 0).$$

The following remark is proved similarly to Remark 2.2b).

Remark 2.8. Assumption A2 is satisfied under each of the conditions B2a and B2b.

Proof of Theorem 2.7. Via the recursion for $(X_n - \vartheta)$, without loss of generality $V = \vartheta = 0$ may be assumed.

a) Choose (X_n^*) as in (2.2). Let A^* be a uniform bound of $\|A_n\|$ as in the proof of Lemma 2.6. Noting that A_1 is bounded and positive semidefinite, and noting stationarity of (A_n) and relation (2.9) in Lemma 2.4, one obtains for α sufficiently small

$$\mathbb{E}\|X_n - X_n^*\| = \mathbb{E}\|A_{n,1}(\alpha)(X_0 - X_0^*)\| \to 0 \quad (n \to \infty)$$

by Lebesgue's dominated convergence theorem. Therefore, without loss of generality $X_0 = X_0^*$ may be assumed. Since (X_n) is then stationary and ergodic, in view of the first assertion it suffices to prove

$$H(\alpha) := \mathbb{E}\|X_n\| = \mathbb{E}\|X_0\| \to 0 \quad (\alpha \to 0).$$

$\lambda(A) > 0$ yields

$$\|(I - \alpha A)^n\| \leq (1 - \alpha\lambda(A))^n \leq e^{-\alpha\lambda(A)n}$$

for all $0 < \alpha < \lambda(A)^{-1}$ and $n \in \mathbf{N}$. Choose Q such that $e^{-\lambda(A)Q} = \frac{1}{2}$, $D := D(\alpha) := [\frac{Q}{\alpha}] + 1$; thus $\|(1 - \alpha A)^D\| \leq \frac{1}{2}$ for all $0 < \alpha < \lambda(A)^{-1}$. Further choose an integer $T = T(\alpha)$ such that

$$\frac{1}{4} < e^{\alpha\|A\|D}\alpha(T+1)(2A^* + \alpha D A^{*^2}) < \frac{1}{2},$$

which is possible for all $0 < \alpha < \tilde{\alpha}$ with some $\tilde{\alpha} \leq \min\{\lambda(A)^{-1}, \alpha''\}$. In the following discussion, let $0 < \alpha < \tilde{\alpha}$. Further, let

$$g(n, y) := A_{n+1}y - V_{n+1},$$
$$g_T(n, y) := \frac{1}{T}\sum_{i=1}^{T} g(n+i, y), \quad n \geq 0, \quad y \in \mathbf{R}^m.$$

Thus

$$X_{n+1} = X_n - \alpha g(n, X_n) = X_{DN} - \alpha \sum_{k=DN}^{n} g(k, X_k), \quad n \geq DN, \quad N \geq 0.$$

Let

$$Y_{n+1}^N := Y_n^N - \alpha g_T(n, Y_n^N), \quad DN \leq n \leq D(N+1) - 1$$

with

$$Y_{DN}^N := X_{DN}.$$

Thus

$$Y_{n+1}^N = Y_{DN}^N - \alpha \sum_{k=DN}^{n} g_T(k, Y_k^N), \quad DN \leq n \leq D(N+1) - 1.$$

With

$$\phi(n, N) := \sum_{j=DN}^{n} g(j, X_j)$$

one has

$$X_{n+1} = X_{DN} - \alpha\phi(n, N), \quad DN \leq n,$$

and

$$\begin{aligned} & X_{n+1} - Y_{n+1}^N \\ &= -\alpha\left[\phi(n, N) - \sum_{k=DN}^{n} g_T(k, Y_k^N)\right] \\ &= -\alpha\left[(\phi(n, N) - \phi_T(n, N)) + \left(\phi_T(n, N) - \sum_{k=DN}^{n} g_T(k, X_k)\right)\right. \\ &\qquad \left. + \sum_{k=DN}^{n} \left(g_T(k, X_k) - g_T(k, Y_k^N)\right)\right] \end{aligned}$$

for $DN \leq n \leq D(N+1) - 1$, where

$$\phi_T(n, N) := \frac{1}{T}\sum_{k=1}^{T} \phi(n+k, N).$$

Now

$$\begin{aligned}&\phi(n,N)-\phi_T(n,N)\\&=\frac{1}{T}\sum_{k=1}^{T}\big(\phi(n,N)-\phi(n+k,N)\big)\\&=-\frac{1}{T}\sum_{k=1}^{T}\sum_{j=n+1}^{n+k}(A_{j+1}X_j-V_{j+1})\end{aligned}$$

for $DN\le n\le D(N+1)-1$. Further

$$\begin{aligned}&\phi_T(n,N)\\&=\frac{1}{T}\sum_{k=1}^{T}\sum_{j=DN+k}^{n+k}g(j,X_j)+\frac{1}{T}\sum_{k=1}^{T}\sum_{j=DN}^{DN+k-1}g(j,X_j)\\&=\sum_{j=DN}^{n}g_T(j,X_j)+\sum_{j=DN}^{n}\frac{1}{T}\sum_{k=1}^{T}\big[g(j+k,X_{j+k})-g(j+k,X_j)\big]\\&\quad+\frac{1}{T}\sum_{k=1}^{T}\sum_{j=DN}^{DN+k-1}g(j,X_j)\\&=\sum_{j=DN}^{n}g_T(j,X_j)+\sum_{j=DN}^{n}\frac{1}{T}\sum_{k=1}^{T}A_{j+k+1}\left(\alpha\sum_{l=j}^{j+k-1}(A_{l+1}X_l-V_{l+1})\right)\\&\quad+\frac{1}{T}\sum_{k=1}^{T}\sum_{j=DN}^{DN+k-1}(A_{j+1}X_j-V_{j+1}),\\&\quad\sum_{k=DN}^{n}\big(g_T(k,X_k)-g_T(k,Y_k^N)\big)\\&=\sum_{k=DN}^{n}\frac{1}{T}\sum_{i=1}^{T}A_{k+i+1}\big(X_k-Y_k^N\big)\end{aligned}$$

for $DN\le n\le (D+1)N-1$. In the next step, set

$$Z_{n+1}^N:=Z_n^N-\alpha AZ_n^N,\quad DN\le n\le D(N+1)-1,$$

with

$$Z_{DN}^N:=X_{DN}.$$

Then

$$\begin{aligned}&Y_{n+1}^N-Z_{n+1}^N\\&=-\alpha\sum_{k=DN}^{n}g_T\big(k,Y_k^N\big)+\alpha\sum_{k=DN}^{n}AZ_k^N\\&=-\alpha A\sum_{k=DN}^{n}\big(Y_k^N-Z_k^N\big)-\alpha\sum_{k=DN}^{n}\left[\frac{1}{T}\sum_{j=k+1}^{k+T}(A_{j+1}-A)Y_k^N\right]\end{aligned}$$

$$+\alpha\frac{1}{T}\sum_{k=DN}^{n}\sum_{j=k+1}^{k+T}V_{j+1}.$$

Now

$$\begin{aligned}(2.17)\qquad & X_{n+1}-Z_{n+1}^N\\ &=-\alpha A\sum_{k=DN}^{n}\left(X_k-Z_k^N\right)-\alpha\sum_{k=DN}^{n}\frac{1}{T}\sum_{i=1}^{T}(A_{k+i+1}-A)X_k\\ &\quad+\alpha\frac{1}{T}\sum_{k=1}^{T}\left(\sum_{j=n+1}^{n+k}A_{j+1}X_j-\sum_{j=DN}^{DN+k-1}A_{j+1}X_j\right)\\ &\quad-\alpha^2\sum_{j=DN}^{n}\frac{1}{T}\sum_{k=1}^{T}A_{j+k+1}\sum_{l=j}^{j+k-1}A_{l+1}X_l\\ &\quad-\alpha\frac{1}{T}\sum_{k=1}^{T}\left(\sum_{j=n+1}^{n+k}V_{j+1}-\sum_{j=DN}^{DN+k-1}V_{j+1}\right)\\ &\quad+\alpha^2\sum_{j=DN}^{n}\frac{1}{T}\sum_{k=1}^{T}A_{j+k+1}\sum_{l=j}^{j+k-1}V_{l+1}\\ &\quad+\alpha\frac{1}{T}\sum_{k=DN}^{n}\sum_{j=k+1}^{k+T}V_{j+1}\end{aligned}$$

for $DN\le n\le D(N+1)-1$. Thus

$$\begin{aligned}&\mathbb{E}\|X_{n+1}-Z_{n+1}^N\|\\ &\le\alpha\|A\|\sum_{k=DN}^{n}\mathbb{E}\|X_k-Z_k^N\|+\kappa(\alpha,D,T),\quad DN\le n\le D(N+1)-1,\end{aligned}$$

where

$$\begin{aligned}\kappa(\alpha,D,T)&=\alpha D\mathbb{E}\left\|\frac{1}{T}\sum_{i=1}^{T}(A_{i+1}-A)X_0\right\|+\alpha(T+1)A^*\mathbb{E}\|X_0\|\\ &\quad+\alpha^2D\frac{T+1}{2}A^{*^2}\mathbb{E}\|X_0\|+2\alpha\frac{1}{T}\sum_{k=1}^{T}\mathbb{E}\left\|\sum_{j=1}^{k}V_j\right\|\\ &\quad+\alpha^2DA^*\frac{1}{T}\sum_{k=1}^{T}\mathbb{E}\left\|\sum_{l=1}^{k}V_l\right\|+\alpha D\frac{1}{T}\mathbb{E}\left\|\sum_{j=1}^{T}V_j\right\|.\end{aligned}$$

By induction one obtains

$$\begin{aligned}&\mathbb{E}\|X_n-Z_n^N\|\\ &\le e^{\alpha\|A\|(n-DN)}\kappa(\alpha,D,T)\\ &\le e^{\alpha\|A\|D}\kappa(\alpha,D,T)=:\sigma(\alpha)\end{aligned}$$

for $DN \le n \le D(N+1)$. Let

$$Z_{n+1} := Z_n - \alpha A Z_n, \quad n \ge 0,$$

with $Z_0 := X_0$. Noting

$$\left\| Z_{D(N+1)} - Z^N_{D(N+1)} \right\| \le \frac{1}{2} \left\| Z_{DN} - Z^N_{DN} \right\| = \frac{1}{2} \left\| Z_{DN} - X_{DN} \right\|$$

one obtains

$$\mathbb{E}\|X_{D(N+1)} - Z_{D(N+1)}\| \le \sigma(\alpha) + \frac{1}{2}\mathbb{E}\|Z_{DN} - X_{DN}\|$$

and thus by induction

$$\mathbb{E}\|X_{DN} - Z_{DN}\| \le 2\sigma(\alpha), \quad N \ge 0.$$

Because

$$\mathbb{E}\|Z_{DN}\| \le \|(I - \alpha A)^{DN}\| \, \mathbb{E}\|X_0\| \to 0 \quad (N \to \infty)$$

one has

$$H(\alpha) \le 2\sigma(\alpha).$$

Moreover

$$H(\alpha) \le 4e^{\alpha\|A\|D} \left[\alpha D \mathbb{E} \left\| \frac{1}{T} \sum_{i=1}^{T} (A_{i+1} - A) X_0 \right\| \right.$$
$$\left. + (2 + \alpha D A^*) \alpha \frac{1}{T} \sum_{k=1}^{T} \mathbb{E} \left\| \sum_{j=1}^{k} V_j \right\| + \alpha D \frac{1}{T} \mathbb{E} \left\| \sum_{j=1}^{T} V_j \right\| \right].$$

Noting $D(\alpha) = O(\frac{1}{\alpha})$, $T(\alpha) = O(\frac{1}{\alpha})$, $T(\alpha) \to \infty$ $(\alpha \to 0)$,

$$\sup_{0<\alpha<\tilde{\alpha}} \mathbb{E}\left(\|X_0\| \chi_{[\|X_0\| > c]} \right) \to 0 \quad (c \to \infty)$$

(uniform integrability of X_0), boundedness of A_1, and

$$\mathbb{E} \left\| \frac{1}{n} \sum_{i=1}^{n} (A_i - A) \right\| \to 0, \quad \mathbb{E} \left\| \frac{1}{n} \sum_{i=1}^{n} V_i \right\| \to 0 \quad (n \to \infty)$$

(mean ergodic theorem), one obtains $H(\alpha) \to 0$ $(\alpha \to 0)$. $\delta_\alpha \to 0$ $(\alpha \to 0)$ now follows from

$$\|\delta_\alpha\| = \lim \|\mathbb{E} Y_n\| \le \underline{\lim}_n \mathbb{E}\|Y_n\| \le \underline{\lim}_n \mathbb{E}\|X_n\| = H(\alpha).$$

b) First assume B2a. Consider α sufficiently small and choose $D = D(\alpha)$ and $T = T(\alpha)$ as in a). Without loss of generality $X_0 = X_0^*$ may be assumed. According to the proof of Lemma 2.6 one obtains

$$\mathbb{E} \left\| \frac{1}{T} \sum_{i=1}^{T} (A_{i+1} - A) X_0 \right\|$$
$$\le C \mathbb{E} \left\| \frac{1}{T} \sum_{i=1}^{T} (A_{i+1} - A) \right\| + 2A^* C \alpha \sum_{n=1}^{\infty} \mathbb{P}(B_n)$$

with a suitable constant $C < \infty$ and $\sum \mathbb{P}(B_n) < \infty$. Because

$$\mathbb{E}\left\|\sum_{i=1}^{n}(A_i - A)\right\| = O(n^{\frac{1}{2}}), \quad \mathbb{E}\left\|\sum_{i=1}^{n} V_i\right\| = O(n^{\frac{1}{2}})$$

according to Ibragimov and Linnik [9, proof of Thm. 18.5.4], one has

$$H(\alpha) = O\left(T(\alpha)^{-\frac{1}{2}} + \alpha T(\alpha)^{\frac{1}{2}}\right) = O\left(\alpha^{\frac{1}{2}}\right), \quad \alpha \to 0;$$

further, $\delta_\alpha = O(\alpha^{1/2})$ $(\alpha \to 0)$.

Now assume B1. One uses the stationary sequence (X_n^*) defined by (2.2) for sufficiently small $\alpha > 0$ and notes

$$\mathbb{E}\|X_0^*\|^2 = O(1) \quad (\alpha \to 0).$$

This relation follows by an argument similar to that in the proof of Lemma 2.6b. In fact, it suffices to prove

$$\begin{aligned}
&\sum_{n=1}^{\infty} \mathbb{E}\|A_{nk^*,(n-1)k^*+1}(\alpha) \dots A_{k^*,1}(\alpha)\|^4 \\
&+ \sum_{1 \le m < n} \mathbb{E}(\|A_{nk^*,(n-1)k^*+1}(\alpha) \dots A_{(m+1)k^*,mk^*+1}(\alpha)\|^2 \\
&\qquad \cdot \|A_{mk^*,(m-1)k^*+1}(\alpha) \dots A_{k^*,1}(\alpha)\|^4) \\
&\le c\alpha^{-2}
\end{aligned}$$

with $k^* = \max\{N^*, M\}$ (N^* according to (2.12)) for sufficiently small $\alpha > 0$ with a suitable constant c. Because of M-dependence the left side is majorized by

$$\sum_{n=1}^{\infty} n \left(\max\left\{\mathbb{E}\|A_{k^*,1}(\alpha)\|^4, \mathbb{E}\|A_{k^*,1}(\alpha)\|^8\right\}\right)^n$$

and thus, via Lemma 2.6a), by

$$\sum_{n=1}^{\infty} n(1 - \rho\alpha)^n = O\left(\frac{1}{(\rho\alpha)^2}\right), \quad \alpha \to 0,$$

with a suitable constant $\rho > 0$. Square integrability of X_0^* and Lemma 2.6a) with $q = 4$, together with M-dependence, yield

$$\mathbb{E}\|X_n - X_n^*\| = \mathbb{E}\|A_{n,1}(\alpha)(X_0 - X_0^*)\| \to 0 \quad (n \to \infty).$$

Thus, as in a), without loss of generality $X_0 = X_0^*$ may be assumed. It suffices to prove

$$\mathbb{E}\|X_0\| = O(\alpha^{\frac{1}{2}}), \quad \alpha \to 0.$$

One uses a modification of the argument in a). Q and $D = D(\alpha)$ are chosen as in a); the integer $T = T(\alpha)$ is chosen in such a way that

$$\frac{1}{4} < e^{\alpha\|A\|D}\alpha(T+1)\|A\|(2 + \alpha D\mathbb{E}\|A_1\|) < \frac{1}{2}.$$

First a refined treatment of the third and the fourth terms in the right side of (2.17) will be given. By partial summation and use of (1.1) one obtains

$$\sum_{j=1}^{k}(A_{j+1}-A)X_j$$
$$=\sum_{j=1}^{k}(A_{j+1}-A)X_k+\alpha\sum_{j=1}^{k-1}\left(\sum_{i=1}^{j}(A_{i+1}-A)\right)(A_{j+1}X_j-V_{j+1})$$

for $k=1,2,\dots$. Thus, by stationarity, one has

$$\alpha\mathbb{E}\frac{1}{T}\left\|\sum_{k=1}^{T}\left(\sum_{j=n+1}^{n+k}A_{j+1}X_j-\sum_{j=DN}^{DN+k-1}A_{j+1}X_j\right)\right\|$$
$$\le\alpha(T+1)\|A\|\mathbb{E}\|X_0\|+2\alpha\frac{1}{T}\mu(\alpha,T)$$

for $DN\le n\le D(N+1)-1$ with

$$\mu(\alpha,T)=\sum_{k=1}^{T}\mathbb{E}\left(\left\|\sum_{j=1}^{k}(A_{j+1}-A)\right\|\,\|X_k\|\right)$$
$$+\alpha\sum_{k=1}^{T}\sum_{j=1}^{k-1}\mathbb{E}\left(\left\|\sum_{i=1}^{j}(A_{i+1}-A)\right\|\,\|A_{j+1}\|\,\|X_j\|\right)$$
$$+\alpha\sum_{k=1}^{T}\sum_{j=1}^{k-1}\mathbb{E}\left(\left\|\sum_{i=1}^{j}(A_{i+1}-A)\right\|\,\|V_{j+1}\|\right).$$

Noting $\mathbb{E}\|X_0\|^2=O(1)$, $\alpha\to 0$, the moment conditions on A_1 and the assumption of M-dependence, one further obtains

$$\alpha^2\mathbb{E}\left\|\sum_{j=DN}^{n}\frac{1}{T}\sum_{k=1}^{T}A_{j+k+1}\sum_{l=j}^{j+k-1}A_{l+1}X_l\right\|$$
$$\le\alpha^2D\|A\|\frac{1}{T}\sum_{k=1}^{T}\mathbb{E}\left(\|A_{k+2}\|\sum_{l=1}^{k}\|X_l\|\right)$$
$$+\alpha^2D\frac{1}{T}\sum_{k=1}^{T}\mathbb{E}\left(\|A_{k+2}\|\left\|\sum_{l=1}^{k}(A_{l+1}-A)X_l\right\|\right)$$
$$\le\alpha^2D\|A\|\frac{1}{T}\sum_{k=M}^{T}\mathbb{E}\left(\|A_{k+2}\|\sum_{l=1}^{k-M+1}\|X_l\|\right)$$
$$+\alpha^2D\|A\|\frac{1}{T}\sum_{k=M}^{T}\mathbb{E}\left(\|A_{k+2}\|\left\|\sum_{l=1}^{k-M+1}(A_{l+1}-A)X_l\right\|\right)$$
$$+c\alpha^2D$$
$$\le\frac{1}{2}\alpha^2D\|A\|(T+1)\mathbb{E}\|A_1\|\,\mathbb{E}\,\|X_0\|$$
$$+\alpha^2D\|A\|\,\mathbb{E}\,\|A_1\|\frac{1}{T}\mu(\alpha,T)+c\alpha^2D$$

for $DN \le n \le D(N+1)-1$ with a suitable $c \in \mathbf{R}_+$. Set

$$\begin{aligned}
&\kappa^*(\alpha, D, T)\\
&:= \alpha D \mathbb{E}\left\| \frac{1}{T}\sum_{i=1}^{T}(A_{i+1}-A)X_0 \right\| + \alpha(T+1)\|A\|\,\mathbb{E}\,\|X_0\|\\
&\quad + \frac{1}{2}\alpha^2 D\|A\|(T+1)\mathbb{E}\|A_1\|\,\mathbb{E}\,\|X_0\|\\
&\quad + (2\alpha + \alpha^2 D\|A\|\,\mathbb{E}\,\|A_1\|)\frac{1}{T}\mu(\alpha, T) + c\alpha^2 D\\
&\quad + 2\alpha\frac{1}{T}\sum_{k=1}^{T}\mathbb{E}\left\|\sum_{j=1}^{k}V_j\right\| + \alpha^2 D\frac{1}{T}\sum_{k=1}^{T}\mathbb{E}\left(\|A_{k+1}\|\left\|\sum_{l=1}^{k}V_l\right\|\right)\\
&\quad + \alpha D\frac{1}{T}\mathbb{E}\left\|\sum_{j=1}^{T}V_j\right\|,\\
&\sigma^*(\alpha) := e^{\alpha\|A\|D}\kappa^*(\alpha, D, T).
\end{aligned}$$

As in a) one obtains

$$H(\alpha) \le 2\sigma^*(\alpha);$$

moreover

$$\begin{aligned}
H(\alpha) \le 4e^{\alpha\|A\|D}\Bigg[&\alpha D\mathbb{E}\left\|\frac{1}{T}\sum_{i=1}^{T}(A_{i+1}-A)X_0\right\|\\
&+(2\alpha + \alpha^2 D\|A\|E\|A_1\|)\frac{1}{T}\mu(\alpha, T) + c\alpha^2 D\\
&+2\alpha\frac{1}{T}\sum_{k=1}^{T}\mathbb{E}\left\|\sum_{j=1}^{k}V_j\right\| + \alpha^2 D\frac{1}{T}\sum_{k=1}^{T}\mathbb{E}\left(\|A_{k+1}\|\left\|\sum_{l=1}^{k}V_l\right\|\right)\\
&+\alpha D\frac{1}{T}\mathbb{E}\left\|\sum_{j=1}^{T}V_j\right\|\Bigg].
\end{aligned}$$

The right-hand side is $O(\alpha^{1/2})$, $\alpha \to 0$. To show this one uses the Cauchy–Schwarz inequality several times, notes $D(\alpha) = O(1/\alpha)$, $T(\alpha) = O(1/\alpha)$, $T(\alpha)^{-1} = O(\alpha)$, and the moment conditions; further one uses

$$\mathbb{E}\left\|\sum_{k=1}^{n}(A_k - A)\right\|^2 = O(n), \quad \mathbb{E}\left\|\sum_{k=1}^{n}V_k\right\|^2 = O(n)$$

according to Billingsley [1, §20, Lem. 3] and Ibragimov and Linnik [9, Thm. 18.5.2] (compare also Peligrad [19, Thm. 1.1]), and

$$\mathbb{E}\|X_0\|^2 = O(1), \quad \alpha \to 0.$$

Here in view of $\mu(\alpha, T)$ one notes, by M-dependence,

$$E\left(\left\|\sum_{i=1}^{j-M-1}(A_{i+1}-A)\right\|\|A_j\|\right)^2 = O(j). \qquad \square$$

3. Consistency under independence or martingale assumptions. In this section it will be shown that in the case of independence and in the martingale case the assertion of Theorem 2.1b) on (Y_n) holds with $\delta_\alpha = 0$. This means that Y_n is strongly consistent and asymptotically unbiased.

THEOREM 3.1. *If the random elements (A_n, V_n), $n = 0, \pm 1, \pm 2, \ldots$, are i.i.d., then there exists an α^* with $0 < \alpha^* \leq \alpha'''$ such that for all $0 < \alpha < \alpha^*$*

$$Y_n \to \vartheta \quad (n \to \infty) \text{ a.s. and in the first mean.} \tag{3.1}$$

Proof. One chooses N^* according to (2.12) and argues similarly to the last part of the proof of Lemma 2.4. By the independence assumption, $E\|A_1\| < \infty$, and Lebesgue's dominated convergence theorem for $\alpha \to 0$, one obtains

$$\mathbb{E}\|A_{N^*,1}(\alpha)\| \leq 1 - \frac{1}{2}\alpha \mathbb{E}\lambda\left(\sum_{i=1}^{N^*} A_i\right)$$

for sufficiently small α, and then $\mathbb{E}\|U_\alpha\| < \infty$. Now Theorem 2.1b) yields the first part of the assertion, where obviously $\delta_\alpha = 0$. Further one obtains $E\|X_n - X_n^*\| \to 0$ for X_n^* in (2.2) and then, by the mean ergodic theorem for (X_n^*), together with $\mathbb{E}X_0^* = \vartheta$, the second assertion. □

For the special case of nonrandom $A_n = A$ almost sure convergence in (3.1) was proved by Pflug [20] and Polyak and Juditsky [22]. In what follows we extend Theorem 3.1 for martingale differences that are not necessarily stationary and ergodic.

THEOREM 3.2. *Assume that $((A_n - A, V_n - V), \mathcal{F}_{n-1})$ is a martingale difference sequence such that*

$$c^2 := \sup_{n,\omega} \mathbb{E}\left(\|A_n - A\|^2 \mid \mathcal{F}_{n-1}\right)(\omega) < \infty \tag{3.2}$$

and

$$\sup_n \mathbb{E}\|V_n\|^2 < \infty. \tag{3.3}$$

Then for all $0 < \alpha < 2/\Lambda(A)$ satisfying

$$\frac{\alpha^2 c^2}{1 - \|1 - \alpha A\|^2} < 1 \tag{3.4}$$

the relations

$$\sup_n \mathbb{E}\|X_n\|^2 < \infty, \quad \overline{\lim_n} \mathbb{E}\|X_n - \vartheta\|^2 = O(\alpha) \quad (\alpha \to 0)$$

hold and

$$Y_n \to \vartheta \quad (n \to \infty) \text{ a.s. and in the second mean.} \tag{3.5}$$

Proof. Noting the recursion for $(X_n - \vartheta)$ and the equivalence of (3.3) and

$$\sup_n \mathbb{E}\|V_n - A_n\vartheta\|^2 < \infty$$

(because of (3.2)), one may assume $V = \vartheta = 0$ without loss of generality. (1.1) can be written in the form

$$X_{n+1} = X_n - \alpha A X_n + \alpha W_{n+1}, \quad n \geq 0,$$

where $W_{n+1} = -(A_{n+1} - A)X_n + V_{n+1}$. Obviously $\mathbb{E}(W_{n+1}, X_n) = 0$; therefore, for all sufficiently small $\epsilon > 0$

$$\begin{aligned} &\mathbb{E}\|X_{n+1}\|^2 \\ &\leq \|1 - \alpha A\|^2 \mathbb{E}\|X_n\|^2 + \alpha^2 \mathbb{E}\|W_{n+1}\|^2 \\ &\leq \rho \mathbb{E}\|X_n\|^2 + \alpha^2 \left(1 + \frac{1}{\epsilon}\right) \mathbb{E}\|V_{n+1}\|^2 \end{aligned}$$

with $\rho = \|1 - \alpha A\|^2 + \alpha^2(1+\epsilon)c^2 < 1$, because of (3.2) and (3.4). This, together with (3.3), yields the assertions on (X_n). In the special case $V_n = 0$, here with $\epsilon = 0$, one obtains

$$X_n = A_{n,1}(\alpha) X_0,$$

$$\mathbb{E}\|X_{n+1}\|^2 \leq \rho \mathbb{E}\|X_n\|^2,$$

and thus

$$\mathbb{E}\|A_{n,1}(\alpha) X_0\|^2 = O(\rho^n).$$

The further specialization to unit vectors X_0 yields

$$\mathbb{E}\|A_{n,1}(\alpha)\|^2 = O(\rho^n) \tag{3.6}$$

and then

$$\|A_{n,1}(\alpha)\| \to 0 \quad (n \to \infty) \text{ a.s.} \tag{3.7}$$

Therefore, in view of (3.5), without loss of generality $X_0 = 0$ may be assumed. It is easy to verify

$$Y_{n+1} = Y_n - \alpha A Y_n - \frac{I - \alpha A}{n+1} Y_n + \frac{\alpha}{n+1} \sum_{k=1}^{n+1} W_k.$$

Moreover

$$\frac{1}{n+1} \sum_{k=1}^{n+1} (A_k - A) X_{k-1} \to 0 \quad \text{a.s. and in the second mean}$$

because

$$\mathbb{E}((A_k - A) X_{k-1} \mid \mathcal{F}_{k-1}) = 0$$

and

$$\mathbb{E}\|(A_k - A) X_{k-1}\|^2 \leq c^2 \mathbb{E}\|X_{k-1}\|^2 = O(1).$$

From this and from

$$\frac{1}{n+1} \sum_{k=1}^{n+1} V_k \to 0 \text{ a.s.},$$

by $\|I - \alpha A\| < 1$ one obtains relation (3.5) (compare [28, Lem. 2b]). □

4. Asymptotic normality. In this section it will be shown that the sequence (Y_n) of arithmetic means under rather weak assumptions has convergence order $n^{-1/2}$; there holds a (functional) central limit theorem.

THEOREM 4.1. *If Assumption* B1 *or* B2c *holds, then for α sufficiently small, $\sqrt{n}(Y_n-\vartheta-\delta_\alpha)$, i.e., $n^{-1/2}\sum_{k=1}^n(X_k-\vartheta-\delta_\alpha)$, converges in distribution to a Gaussian random vector with zero expectation.*

Remark 4.2. Theorem 4.1 may be generalized to a weak invariance principle of Donsker type.

Proof of Theorem 4.1. Without loss of generality $(X_n) = (X_n^*)$, with X_n^* as in (2.2), may be assumed, because for the corresponding arithmetic means one has

$$\begin{aligned}\sqrt{n}\|Y_n - Y_n^*\| &\le n^{-\frac{1}{2}} \sum_{k=1}^{n} \|A_{k,1}\| \, \|X_0 - X_0^*\| \\ &\le n^{-\frac{1}{2}} \sum_{k=1}^{\infty} \|A_{k,1}\| \, \|X_0 - X_0^*\| \to 0 \quad \text{a.s.}\end{aligned}$$

by Theorem 2.1a). Let

$$\tilde{X}_n := X_n - \vartheta - \delta_\alpha = \alpha \sum_{i=-\infty}^{0} A_{n,n+i-1}(\alpha)(V_{n+i} - A_{n+i}\vartheta) - \delta_\alpha,$$

$$\tilde{X}_n^{(l)} := \alpha \sum_{i=-l}^{0} A_{n,n+i+1}(\alpha)(V_{n+i} - A_{n+i}\vartheta) - \delta_\alpha, \quad n \in \mathbf{N}, \quad l \in \mathbf{N}.$$

One has

$$\mathbb{E}\tilde{X}_n = 0,$$

and further (compare [1, §21, especially p. 183], [8])

$$\begin{aligned}&[\mathbb{E}\|\tilde{X}_0^{(l)} - E(\tilde{X}_0|A_l, V_l, \ldots, A_0, V_0, \ldots, A_{-l}, V_{-l})\|^2]^{\frac{1}{2}} \\ &\le [\mathbb{E}\{\mathbb{E}(\|\tilde{X}_0^{(l)} - \tilde{X}_0\|^2|A_l, V_l, \ldots, A_0, V_0, \ldots, A_{-l}, V_{-l})\}]^{\frac{1}{2}} \\ &= [\mathbb{E}\|\tilde{X}_0^{(l)} - \tilde{X}_0\|^2]^{\frac{1}{2}} \\ &= \alpha \left[\mathbb{E}\left\|\sum_{i=-\infty}^{-l-1} A_{0,i+1}(\alpha)(V_i - A_i\vartheta)\right\|^2\right]^{\frac{1}{2}} \\ &\le \alpha \left[\mathbb{E}\left(\sum_{i=-\infty}^{-l-1} \|A_{0,i+1}(\alpha)(V_i - A_i\vartheta)\|\right)^2\right]^{\frac{1}{2}} \\ &= \alpha \left[\mathbb{E} \sum_{i,j\in\{-l-1,-l-2,\ldots\}} \|A_{0,i+1}(\alpha)(V_i - A_i\vartheta)\| \, \|A_{0,j+1}(\alpha)(V_j - A_j\vartheta)\|\right]^{\frac{1}{2}} \\ &\le \alpha \left[\sum_{i,j\in\{-l-1,-l-2,\ldots\}} \left(\mathbb{E}(\|A_{0,i+1}(\alpha)\|^2\|V_i - A_i\vartheta\|^2)\right)^{\frac{1}{2}}\right.\end{aligned}$$

$$\left. \left(\mathbb{E}(\|A_{0,j+1}(\alpha)\|^2 \|V_j - A_j\vartheta\|^2) \right)^{\frac{1}{2}} \right]^{\frac{1}{2}}$$

$$= \alpha \sum_{i \in \{-l-1, -l-2, \ldots\}} \left(\mathbb{E}(\|A_{0,i+1}\|^2 \|V_i - A_i\vartheta\|^2) \right)^{\frac{1}{2}}$$

$$= \alpha \sum_{n=l+1}^{\infty} \left(\mathbb{E}(\|A_{n,1}(\alpha)\|^2 \|V_0 - A_0\vartheta\|^2) \right)^{\frac{1}{2}}.$$

By Lemma 2.6a) one obtains

$$\sum_{l=1}^{\infty} \left(\mathbb{E}\|\tilde{X}_0^{(l)} - E(\tilde{X}_0 | A_l, V_l, \ldots, A_0, V_0, \ldots, A_{-l}, V_{-l})\|^2 \right)^{\frac{1}{2}} < \infty;$$

further, in a similar way,

$$\mathbb{E}\|\tilde{X}_0\|^q < \infty \text{ for each } q \in \mathbf{N}.$$

One uses Theorem 18.6.2 (and Remark 18.6.1) in [9], or Theorem 4.2 in [17], for which the statement after Corollary (3.9) there concerning $\sigma^2 = 0$ also holds, together with Definition (2.4) and the remarks in §§2 and 3 there, and obtains then the assertion by the Cramér–Wold device. □

5. Asymptotic normality and covariance. In this section we assume that the observations either are independent or form a martingale difference sequence. Polyak and Juditsky [22] considered asymptotic normality in the martingale case too.

THEOREM 5.1 (see [22, Thm. 1], [21, Thm. 1]). *Consider the iteration*

$$X_0 \quad \textit{arbitrary},$$

$$X_{n+1} = X_n - \alpha(AX_n - V - W_{n+1}), \quad n \geq 0, \tag{5.1}$$

where $0 < \alpha < 2/\Lambda(A)$, *under the assumption that* $(W_n, \mathcal{F}_{n-1})$ *is a martingale difference sequence.*

a) *If*

$$\sup_n \mathbb{E}(\|W_n\|^2 \mid \mathcal{F}_{n-1}) < \infty \quad a.s., \tag{5.2}$$

$$\lim_{C \to \infty} \overline{\lim_{n \to \infty}} \mathbb{E}(\|W_n\|^2 \chi_{[\|W_n\| > C]} \mid \mathcal{F}_{n-1}) = 0 \quad \textit{in probability, and} \tag{5.3}$$

$$\lim_{n \to \infty} \mathbb{E}(W_n W_n^T \mid \mathcal{F}_{n-1}) = S \quad \textit{in probability}, \tag{5.4}$$

where S *is positive semidefinite, then*

$$n^{\frac{1}{2}}(Y_n - \vartheta) \to \mathcal{N}(0, A^{-1}SA^{-1}) \quad \textit{in distribution.} \tag{5.5}$$

b) *If* X_0 *is square integrable and*

$$\lim_{n \to \infty} \mathbb{E}(W_n W_n^T) = S, \tag{5.6}$$

then

$$\lim_{n\to\infty} n\mathbb{E}\left((Y_n-\vartheta)(Y_n-\vartheta)^T\right) = A^{-1}SA^{-1}. \tag{5.7}$$

We need a slight modification of Theorem 5.1a.

LEMMA 5.2. *Consider iteration* (5.1), *where* $0<\alpha<2/\Lambda(A)$ *and* $(W_n,\mathcal{F}_{n-1})$ *is a stationary and ergodic martingale difference sequence such that*

$$\mathbb{E}(W_1W_1^T) = S$$

with S *positive semidefinite. Then*

$$n^{\frac{1}{2}}(Y_n-\vartheta) \to \mathcal{N}(0, A^{-1}SA^{-1}) \text{ in distribution.}$$

Proof. Without loss of generality we may assume $V=\vartheta=0$ and, according to the proof of Theorem 3.2 with $\rho = \|I-\alpha A\|^2$, also $X_0=0$. One obtains

$$X_k = \alpha\sum_{l=1}^{k}\left(I-\alpha A\right)^{k-l}W_l;$$

therefore,

$$\begin{aligned} Y_n &= \alpha\frac{1}{n}\sum_{k=1}^{n}\sum_{l=1}^{k}\left(I-\alpha A\right)^{k-l}W_l = \alpha\frac{1}{n}\sum_{k=1}^{n}\left(\sum_{l=0}^{n-k}\left(I-\alpha A\right)^{l}\right)W_k \\ &= \alpha\frac{1}{n}\sum_{k=1}^{n}\left((I-(I-\alpha A)^{n-k+1})(\alpha A)^{-1}\right)W_k \\ &= \frac{1}{n}\sum_{k=1}^{n}A^{-1}W_k - \frac{1}{n}\sum_{k=1}^{n}\left(I-\alpha A\right)^{n-k+1}A^{-1}W_k. \end{aligned}$$

On the one hand

$$n^{\frac{1}{2}}\frac{1}{n}\sum_{k=1}^{n}A^{-1}W_k \to \mathcal{N}(0, A^{-1}SA^{-1}) \text{ in distribution}$$

according to Billingsley [1, Thm. 23.1] and the Cramér–Wold device, and on the other hand

$$n^{\frac{1}{2}}\frac{1}{n}\sum_{k=1}^{n}\left(I-\alpha A\right)^{n-k+1}A^{-1}W_k \to 0$$

in probability; therefore, the proof is complete. □

Although $A_n = A$ is a special case, (5.5) and (5.7) are surprises: the asymptotic covariance does not depend on α and is the best possible covariance. Unfortunately it is not true for random A_n; the asymptotic covariance differs from the best possible covariance by a term $O(\alpha)$. In the following X_0 is considered as a random vector.

THEOREM 5.3. *Assume that* $(A_n,V_n), n=0,\pm1,\pm2,\dots,$ *are i.i.d.,* $\mathbb{E}\|A_1\|^2<\infty$, *and* $\mathbb{E}\|V_1\|^2<\infty$.

a) *Let X_0 be square integrable. Then there is an $\alpha^* > 0$ such that for all $0 < \alpha < \alpha^*$ the limits*

$$\lim_{n\to\infty} \mathbb{E}((X_n - \vartheta)(X_n - \vartheta)^T) = \Sigma_\alpha \tag{5.8}$$

and

$$\lim_{n\to\infty} n\mathbb{E}((Y_n - \vartheta)(Y_n - \vartheta)^T) = \Sigma \tag{5.9}$$

exist, and

$$\Sigma = A^{-1}SA^{-1} + \mathbb{E}((A^{-1}A_0 - I)\Sigma_\alpha(A^{-1}A_0 - I)^T), \tag{5.10}$$

where

$$S = \mathbb{E}((V_1 - A_1\vartheta)(V_1 - A_1\vartheta)^T). \tag{5.11}$$

b) *Furthermore, with X_0 not necessarily square integrable, for $0 < \alpha < \alpha^*$ with suitable α^*,*

$$n^{\frac{1}{2}}(Y_n - \vartheta) \to \mathcal{N}(0, \Sigma) \text{ in distribution.} \tag{5.12}$$

Remark 5.4. It is well known [13], [20] that $\Sigma_\alpha = O(\alpha)$; therefore,

$$\Sigma = A^{-1}SA^{-1} + O(\alpha).$$

Proof of Theorem 5.3. a) Without loss of generality one may assume $V = \vartheta = 0$ and $X_0 = 0$, the latter because of (3.6) for sufficiently small $\alpha > 0$ in the proof of Theorem 3.2. Then

$$X_n = \sum_{i=1}^{n} B_{ni}V_i, \tag{5.13}$$

where

$$B_{ni} = \alpha A_{n,i+1}(\alpha),$$

and

$$\begin{aligned} &\mathbb{E}(X_nX_n^T) \\ &= \mathbb{E}\left(\sum_{i=1}^{n} B_{ni}V_i\left(\sum_{j=1}^{n} B_{nj}V_j\right)^T\right) = \mathbb{E}\left(\sum_{i=1}^{n}\sum_{j=1}^{n} B_{ni}V_i(B_{nj}V_j)^T\right) \\ &= \sum_{i=1}^{n}\sum_{j=1}^{n} \mathbb{E}\left(B_{ni}V_i(B_{nj}V_j)^T\right) = \sum_{i=1}^{n}\sum_{j=1}^{n} \mathbb{E}\left(B_{ni}V_iV_j^TB_{nj}^T\right) \\ &= \sum_{i=1}^{n} \mathbb{E}\left(B_{ni}V_iV_i^TB_{ni}^T\right) = \sum_{i=1}^{n} \mathbb{E}\left(B_{ni}SB_{ni}^T\right) =: \Sigma_{\alpha,n}. \end{aligned} \tag{5.14}$$

Using (3.6) once more one obtains that $\mathbb{E}\|A_1\|^2 < \infty$ implies the existence of an $\alpha^* > 0$ such that for all $0 < \alpha < \alpha^*$

$$\sum_{n=1}^{\infty} \mathbb{E}\|B_{n1}\|^2 < \infty;$$

consequently

$$\begin{aligned} \lim_{n\to\infty} \Sigma_{\alpha,n} &= \lim_{n\to\infty} \sum_{i=1}^{n} \mathbb{E}\left(B_{ni} S B_{ni}^T\right) \\ &= \lim_{n\to\infty} \sum_{i=1}^{n} \mathbb{E}\left(B_{i1} S B_{i1}^T\right) = \sum_{i=1}^{\infty} \mathbb{E}\left(B_{i1} S B_{i1}^T\right) = \Sigma_\alpha \end{aligned} \tag{5.15}$$

exists and is finite. From (5.13) and (5.15) one obtains

$$\Sigma_\alpha - \mathbb{E}((I - \alpha A_0)\Sigma_\alpha (I - \alpha A_0)) = \alpha^2 S$$

or equivalently

$$A\Sigma_\alpha + \Sigma_\alpha A - \alpha \mathbb{E}(A_0 \Sigma_\alpha A_0) = \alpha S;$$

thus

$$\Sigma_\alpha A^{-1} + A^{-1}\Sigma_\alpha - \alpha A^{-1}\mathbb{E}(A_0 \Sigma_\alpha A_0)A^{-1} = \alpha A^{-1} S A^{-1}. \tag{5.16}$$

Moreover

$$n\mathbb{E}(Y_n Y_n^T) = \frac{1}{n}\mathbb{E}\left(\sum_{k=1}^{n} X_k X_k^T + \sum_{k=1}^{n-1}\sum_{l=k+1}^{n} X_k X_l^T + \sum_{l=1}^{n-1}\sum_{k=l+1}^{n} X_k X_l^T\right). \tag{5.17}$$

Then

$$\frac{1}{n}\mathbb{E}\left(\sum_{k=1}^{n} X_k X_k^T\right) = \frac{1}{n}\sum_{k=1}^{n} \Sigma_{\alpha,k} \to \Sigma_\alpha. \tag{5.18}$$

For $k < l$

$$\begin{aligned} \mathbb{E}(X_k X_l^T) &= \mathbb{E}\left(\sum_{i=1}^{k} B_{ki} V_i \left(\sum_{j=1}^{l} B_{lj} V_j\right)^T\right) = \mathbb{E}\left(\sum_{i=1}^{k}\sum_{j=1}^{l} B_{ki} V_i (B_{lj} V_j)^T\right) \\ &= \sum_{i=1}^{k}\sum_{j=1}^{l} \mathbb{E}\left(B_{ki} V_i (B_{lj} V_j)^T\right) = \sum_{i=1}^{k}\sum_{j=1}^{l} \mathbb{E}\left(B_{ki} V_i V_j^T B_{lj}^T\right) \\ &= \sum_{i=1}^{k} \mathbb{E}\left(B_{ki} V_i V_i^T B_{li}^T\right) = \sum_{i=1}^{k} \mathbb{E}\left(B_{ki} S B_{li}^T\right) \\ &= \sum_{i=1}^{k} \mathbb{E}\left(B_{ki} S B_{ki}^T\right)(I - \alpha A)^{l-k} = \Sigma_{\alpha,k}(I - \alpha A)^{l-k}; \end{aligned}$$

therefore,

$$\begin{aligned}(5.19)\qquad &\frac{1}{n}\mathbb{E}\left(\sum_{k=1}^{n-1}\sum_{l=k+1}^{n} X_k X_l^T\right)\\ &= \frac{1}{n}\sum_{k=1}^{n-1}\sum_{l=k+1}^{n}\Sigma_{\alpha,k}\,(I-\alpha A)^{l-k} = \frac{1}{n}\sum_{k=1}^{n-1}\Sigma_{\alpha,k}\sum_{l=k+1}^{n}(I-\alpha A)^{l-k}\\ &= \frac{1}{n}\sum_{k=1}^{n-1}\Sigma_{\alpha,k}\left(I-(I-\alpha A)^{n-k}\right)(\alpha A)^{-1}(I-\alpha A)\\ &\to \Sigma_\alpha(\alpha A)^{-1}(I-\alpha A) = \Sigma_\alpha(\alpha A)^{-1} - \Sigma_\alpha.\end{aligned}$$

In the same way one obtains

$$(5.20)\qquad \frac{1}{n}\mathbb{E}\left(\sum_{l=1}^{n-1}\sum_{k=l+1}^{n} X_k X_l^T\right) \to (\alpha A)^{-1}\Sigma_\alpha - \Sigma_\alpha.$$

By (5.17)–(5.20) one obtains

$$(5.21)\qquad \Sigma = (\Sigma_\alpha A^{-1} + A^{-1}\Sigma_\alpha)/\alpha - \Sigma_\alpha.$$

(5.16) and (5.21) imply (5.9).

b) Without loss of generality $V = \vartheta = 0$ is assumed. For sufficiently small $\alpha > 0$ the random variable U_α defined by (2.1) is integrable. Let (X_n^*) be defined by (2.2) and

$$Y_n^* := \frac{1}{n}\sum_{k=1}^{n} X_k^*;$$

then

$$Y_n^* - Y_n = \frac{1}{n}\sum_{k=1}^{n}\left(X_k^* - X_k\right) = \frac{1}{n}\sum_{k=1}^{n} A_{k,1}(\alpha)(X_0^* - X_0),$$

and thus because of (2.9) in Lemma 2.4

$$\begin{aligned}n^{\frac{1}{2}}\|Y_n^* - Y_n\| &\le n^{-\frac{1}{2}}\left(\sum_{k=1}^{n}\|A_{k,1}(\alpha)\|\right)\|X_0^* - X_0\|\\ &\le n^{-\frac{1}{2}}\left(\sum_{k=1}^{\infty}\|A_{k,1}(\alpha)\|\right)\|X_0^* - X_0\| \to 0 \quad \text{a.s.}\end{aligned}$$

Therefore, it suffices to consider only X_n^*. Now one applies Lemma 5.2 for $W_{n+1} = -(A_{n+1} - A)X_n^* + V_{n+1}$, noting square integrability of X_0^* (see Lemma 5.5 below) with $\mathbb{E}(X_0^* X_0^{*T}) = \Sigma_\alpha$ by a) and (5.9), (5.10). □

In order to treat the convergence behaviour in the martingale case the following lemma will be used.

LEMMA 5.5. *Assume that* $((A_n - A, V_n - V), \mathcal{F}_{n-1})$ *is a stationary and ergodic martingale difference sequence such that*

$$E(\|A_1\|^2 \mid \mathcal{F}_0) \le c^2 < \infty \quad a.s.$$

and

$$E\|V_1\|^2 < \infty.$$

Assume X_0 square integrable and let $\alpha > 0$ be sufficiently small.

a) *U_α defined by* (2.1) *is integrable.*

Let (X_n^*) be defined by (2.2). *Then*

b) $E\|X_0^*\|^2 < \infty$, *even* $E\|X_0^* - \vartheta\|^2 = O(\alpha)$;

c) $E\|X_n - X_n^*\|^2 \to 0\,(n \to \infty)$.

Proof. a) The proof is established by (3.6).

b) Because (X_n^*) is stationary and ergodic (by Theorem 2.1), for arbitrary fixed $M \in \mathbf{N}$ the sequence $(Z_{k,M})_{k\in\mathbf{N}}$ with

$$Z_{k,M} = \begin{cases} \|X_k^*\|^2 & \text{if } \|X_k^*\|^2 \le M, \\ M & \text{otherwise} \end{cases}$$

is stationary and ergodic, thus

$$\frac{1}{n}\sum_{k=1}^{n} Z_{k,M} \to \mathbb{E}Z_{1,M} \quad (n \to \infty) \text{ a.s.},$$

$$\mathbb{E}Z_{1,M} = \mathbb{E}\lim_n \frac{1}{n}\sum_{k=1}^{n} Z_{k,M} \le \mathbb{E}\varliminf_n \frac{1}{n}\sum_{k=1}^{n} \|X_k^*\|^2, \qquad M \in \mathbf{N},$$

$$\mathbb{E}\|X_0^*\|^2 \le \mathbb{E}\varliminf_n \frac{1}{n}\sum_{k=1}^{n} \|X_k^*\|^2.$$

Because of $\|X_n - X_n^*\| \to 0$ a.s. (by (3.7)) and

$$\frac{1}{n}\sum_{k=1}^{n} \|X_k + X_k^*\| \le \frac{1}{n}\sum_{k=1}^{n} \|X_k - X_k^*\| + 2\frac{1}{n}\sum_{k=1}^{n} \|X_k^*\| \to 2\mathbb{E}\|X_0^*\| < \infty \quad \text{a.s.}$$

(by a), Remark 2.2a), and stationarity and ergodicity of (X_n^*)), one obtains

$$\begin{aligned} &\frac{1}{n}\left|\sum_{k=1}^{n}\left(\|X_k^*\|^2 - \|X_k\|^2\right)\right| \\ &= \frac{1}{n}\left|\sum_{k=1}^{n}(X_k^* + X_k,\, X_k^* - X_k)\right| \\ &\le \frac{1}{n}\sum_{k=1}^{n} \|X_k^* + X_k\|\,\|X_k^* - X_k\| \to 0 \quad \text{a.s.} \end{aligned}$$

and thus

$$\varliminf_n \frac{1}{n}\sum_{k=1}^{n} \|X_k^*\|^2 = \varliminf_n \frac{1}{n}\sum_{k=1}^{n} \|X_k\|^2.$$

Therefore, by Fatou's lemma and Theorem 3.2,

$$\mathbb{E}\|X_0^*\|^2 \le \mathbb{E}\varliminf_n \frac{1}{n}\sum_{k=1}^{n} \|X_k\|^2$$

$$\leq \underline{\lim_n} \mathbb{E}\left(\frac{1}{n}\sum_{k=1}^{n}\|X_k\|^2\right)$$
$$\leq \sup_n \mathbb{E}\|X_n\|^2 < \infty\,.$$

$\mathbb{E}\|X_0^* - \vartheta\|^2 = O(\alpha)$ will follow from c), stationarity of (X_n^*), and $\overline{\lim_n}\,\mathbb{E}\|X_n - \vartheta\|^2 = O(\alpha)$ $(\alpha \to 0)$ (by Theorem 3.2).

c) One uses square integrability of X_0 and X_0^* and employs (3.6). □

THEOREM 5.6. *Under the conditions of Lemma* 5.5 *there is an* $\alpha^* > 0$ *such that for all* $0 < \alpha < \alpha^*$

$$\lim_{n\to\infty} \mathbb{E}\dot{(}(X_n - \vartheta)(X_n - \vartheta)^T) = \Sigma_\alpha^*, \tag{5.22}$$

where

$$\Sigma_\alpha^* = \mathbb{E}((X_0^* - \vartheta)(X_0^* - \vartheta)^T),$$

and

$$\lim_{n\to\infty} n\mathbb{E}((Y_n - \vartheta)(Y_n - \vartheta)^T) = \Sigma^*, \tag{5.23}$$

where

$$\Sigma^* = \mathbb{E}(BB^T)$$

with

$$B = (A^{-1}A_1 - I)(X_0^* - \vartheta) - (A^{-1}V_1 - A^{-1}A_1\vartheta) = (A^{-1}A_1 - I)X_0^* + \vartheta - A^{-1}V_1.$$

It holds that

$$\Sigma^* - A^{-1}SA^{-1} = \begin{cases} O(\alpha) & \text{if } \mathbb{E}(A_1(X_0^* - \vartheta)V_1^T) = 0, \\ O(\alpha^{\frac{1}{2}}) & \text{otherwise.} \end{cases} \tag{5.24}$$

Furthermore, with X_0 *not necessarily square integrable,*

$$n^{\frac{1}{2}}(Y_n - \vartheta) \to \mathcal{N}(0, \Sigma^*) \text{ in distribution.} \tag{5.25}$$

Proof. Without loss of generality $V = \vartheta = 0$ and, according to (3.6) in the proof of Theorem 3.2, $X_0 = 0$ may be assumed. Let $\alpha > 0$ be sufficiently small. By Lemma 5.5 and the auxiliary formula $\|CC^T - DD^T\| \leq \|C - D\|(\|C\| + \|D\|)$ for d-dimensional vectors or $d \times d$ matrices C, D one obtains

$$\|\mathbb{E}(X_n X_n^T) - \mathbb{E}(X_0^* X_0^{*T})\|$$
$$= \|\mathbb{E}(X_n X_n^T) - \mathbb{E}(X_n^* X_n^{*T})\| \leq \mathbb{E}(\|X_n - X_n^*\|(\|X_n\| + \|X_n^*\|))$$
$$\leq (\mathbb{E}\|X_n - X_n^*\|^2)^{\frac{1}{2}}[(\mathbb{E}\|X_n\|^2)^{\frac{1}{2}} + (\mathbb{E}\|X_0^*\|^2)^{\frac{1}{2}}] \to 0 \quad (n \to \infty),$$

which proves (5.22). In order to prove (5.23) one applies Theorem 5.1b) for $W_{n+1} = -(A_{n+1} - A)X_n + V_{n+1}$, which form a martingale difference sequence. It is sufficient to verify (5.6), i.e.,

$$\mathbb{E}(W_n W_n^T) \to \mathbb{E}\left(((A_1 - A)X_0^* - V_1)((A_1 - A)X_0^* - V_1)^T\right).$$

As before, as an upper bound for the difference one obtains, with a suitable constant c,

$$\mathbb{E}(\|A_{n+1} - A\|\|X_n - X_n^*\|[\|A_{n+1} - A\|(\|X_n\| + \|X_n^*\|) + 2\|V_{n+1}\|])$$

$$\leq c(\mathbb{E}\|X_n - X_n^*\|^2)^{\frac{1}{2}}[(\mathbb{E}\|X_n\|^2)^{\frac{1}{2}} + (\mathbb{E}\|X_n^*\|^2)^{\frac{1}{2}} + (\mathbb{E}\|V_{n+1}\|^2)^{\frac{1}{2}}],$$

which tends to 0 because of Lemma 5.5. (5.24) also follows from this lemma. (5.25) concerns asymptotic normality, which can be proved as that of Theorem 5.3b). □

6. Conclusion. The method treated above is of low computational complexity with the following disadvantages: (i) for general (dependent) observations it is usually asymptotically biased, (ii) for weakly dependent observations it is asymptotically normal with $(n^{-1/2})$-convergence order but with a nonoptimal covariance matrix, even in the i.i.d. case. In order to avoid these disadvantages one can use decreasing gains, e.g., $a_n = \alpha n^{-\gamma}$ $(\alpha > 0, \quad 3/4 < \gamma < 1)$. Under assumptions close to ergodicity (see (10) and (11) in [28] and (2.15a), (2.15b) in [15]) Ljung [15] proved that X_n is a.s. convergent to ϑ (asymptotically unbiased) and therefore Y_n also is. Under the assumption that a functional central limit theorem for $(V_k - A_k x)$ holds, $x \in \mathbf{R}^d$ (see [17] for sufficient conditions) with asymptotic covariance matrix S in the case $x = \vartheta$, and under the assumptions

$$\mathbb{E}\left\|\sum_{k=1}^{n}(A_k - A)\right\|^2 = O(n), \qquad \mathbb{E}\left\|\sum_{k=1}^{n}(V_k - V)\right\|^2 = O(n)$$

we proved for the above gains, besides almost sure convergence, asymptotic normality with the best possible covariance matrix $A^{-1}SA^{-1}$. This problem has been considered by Polyak and Juditsky [22] under i.i.d. observations and by Yin [29] under φ-mixing and bounded observations. The window averaging version of the decreasing gain algorithm has been investigated by Kushner and Yang [14].

Acknowledgment. The authors are grateful to the referees for making useful suggestions and raising relevant questions which led to a considerable improvement and extension of this paper.

Note added in proof. As to Theorem 2.7b), considering $\|\mathbb{E}X_n\|$ instead of $\mathbb{E}\|X_n\|$ in its proof, one can show

$$\delta_\alpha = O(\alpha) \qquad (\alpha \to 0),$$

if Assumption B1 or B2c is fulfilled. The auxiliary result that

$$\sum_{i=1}^{n}\|\mathbb{E}(A_{i+1} - A)X_0\| \quad \text{and} \quad \sum_{i=1}^{n}\|\mathbb{E}(A_i - A)(V_1 - AX_0)\|$$

are uniformly bounded with respect to n and α is obtained by use of Lemma 3.5 $(p = 1)$ in [17], Collomb's [2] inequality, and Theorem 2 in [10].

The authors thank L. Gerencsér for a stimulating discussion.

ON A CERTAIN PARAMETER OF THE DISCRETIZED EXTENDED LINEAR-QUADRATIC PROBLEM OF OPTIMAL CONTROL*

CIYOU ZHU†

Abstract. The number $\gamma := \|\hat{Q}^{-\frac{1}{2}}\hat{R}\hat{P}^{-\frac{1}{2}}\|$ is an important parameter for the extended linear-quadratic programming (ELQP) problem associated with the Lagrangian $L(\hat{u},\hat{v}) = \hat{p}\cdot\hat{u} + \frac{1}{2}\hat{u}\cdot\hat{P}\hat{u} + \hat{q}\cdot\hat{v} - \frac{1}{2}\hat{v}\cdot\hat{Q}\hat{v} - \hat{v}\cdot\hat{R}\hat{u}$ over polyhedral sets $\hat{U}\times\hat{V}$. Some fundamental properties of the problem, as well as the convergence rates of certain newly developed algorithms for large-scale ELQP, are all related to γ.

In this paper, we derive an estimate of γ for the ELQP problems resulting from discretization of an optimal control problem. We prove that the parameter γ of the discretized problem is bounded independently of the number of subintervals in the discretization.

Key words. extended linear-quadratic programming, minimax problem, optimal control, primal-dual projected gradient algorithm

AMS subject classifications. 65K05, 65K10, 90C20

1. Introduction.

The extended linear-quadratic programming (ELQP) problem, in its standard minimax form, is to find a saddle point of the Lagrangian

$$L(\hat{u},\hat{v}) = \hat{p}\cdot\hat{u} + \tfrac{1}{2}\hat{u}\cdot\hat{P}\hat{u} + \hat{q}\cdot\hat{v} - \tfrac{1}{2}\hat{v}\cdot\hat{Q}\hat{v} - \hat{v}\cdot\hat{R}\hat{u} \quad \text{over} \quad \hat{U}\times\hat{V}, \tag{1.1}$$

where $\hat{U}$ and $\hat{V}$ are polyhedral sets in $\mathbb{R}^{\hat{k}}$ and $\mathbb{R}^{\hat{l}}$, respectively, and $\hat{P}\in\mathbb{R}^{\hat{k}\times\hat{k}}$ and $\hat{Q}\in\mathbb{R}^{\hat{l}\times\hat{l}}$ are symmetric positive semidefinite matrices [1]. The associated primal and dual problems are

$$(\hat{\mathcal{P}}) \qquad \text{minimize } f(\hat{u}) \text{ over all } \hat{u}\in\hat{U}, \text{ where } f(\hat{u}) := \sup_{\hat{v}\in\hat{V}} L(\hat{u},\hat{v}),$$

$$(\hat{\mathcal{Q}}) \qquad \text{maximize } g(\hat{v}) \text{ over all } \hat{v}\in\hat{V}, \text{ where } g(\hat{v}) := \inf_{\hat{u}\in\hat{U}} L(\hat{u},\hat{v}).$$

The problem is called *fully quadratic* if both P and Q are positive definite.

The number

$$\gamma := \|\hat{Q}^{-\frac{1}{2}}\hat{R}\hat{P}^{-\frac{1}{2}}\| \tag{1.2}$$

introduced by Rockafellar [2] is an important parameter for the problem in the fully quadratic case. (We use the Euclidean norm for vectors and the associated operator norm for matrices unless otherwise specified.) It serves as a Lipschitz constant for the mappings $F:\mathbb{R}^{\hat{k}}\to\mathbb{R}^{\hat{l}}$ and $G:\mathbb{R}^{\hat{l}}\to\mathbb{R}^{\hat{k}}$ defined as

$$F(\hat{u}) = \operatorname*{argmax}_{\hat{v}\in\hat{V}} L(\hat{u},\hat{v}) \quad \text{and} \quad G(\hat{v}) = \operatorname*{argmin}_{\hat{u}\in\hat{U}} L(\hat{u},\hat{v}),$$

respectively [2]. It also plays a central role in the convergence results of several newly developed algorithms for large-scale ELQP problems.

Let $\varepsilon_\nu = f(u^\nu) - g(v^\nu)$ be the νth duality gap related to the primal-dual pair of iterates (u^ν, v^ν). Rockafellar proved that the sequence $\{(u^\nu, v^\nu)\}$ generated by the finite-envelope algorithm [2] satisfies

$$\frac{\varepsilon_{\nu+1}}{\varepsilon_\nu} \leq 1 - \frac{1}{4(1+\gamma^2)}. \tag{1.3}$$

In [10], Zhu proved that the sequence $\{(u^\nu, v^\nu)\}$ generated by certain variants of the primal-dual steepest descent algorithm developed in [9] satisfies

$$\frac{\varepsilon_{\nu+1}}{\varepsilon_\nu} \leq \begin{cases} \frac{\gamma^2}{2-\gamma^2} & \text{if } 0 \leq \gamma^2 < \frac{1}{2}, \\ 1 - \frac{1}{2\gamma^2+0.5} & \text{if } \gamma^2 \geq \frac{1}{2}. \end{cases} \tag{1.4}$$

One of the variants uses a "fixed step length" strategy [10], where the step lengths are also related to γ. In [6], [7], S. J. Wright described interior point algorithms for linear complementarity problems (LCPs). If the ELQP problem is formulated as an LCP and if the standard conjugate gradient algorithm is used to solve the resulting linear equations, the convergence rate for the "inner iterations" [8] will be

$$\frac{\varepsilon_{\nu+1}}{\varepsilon_\nu} \leq 1 - \frac{2}{1 + (1+\gamma^2)^{\frac{1}{2}}}. \tag{1.5}$$

The right-hand sides of (1.3)–(1.5) all depend on the parameter γ of the problem. The smaller the value of γ, the faster the convergence for these algorithms.

In this paper, we consider the ELQP problem resulting from discretizing a continuous-time optimal control problem with time-independent data. As we show in §2, the matrix $\hat{R}$ for such problem consists of a large number of nonzero blocks, each of which is a product of infinite series in terms of the matrices in the original continuous-time problem. It is usually impractical to compute γ from the definition (1.2). Actually, a primary goal in algorithm design is to avoid computations involving the $\hat{R}$ matrix, because of its size and density. All three of the above-mentioned algorithms for the discretized ELQP problem could be implemented in such a way that this goal is reached by taking advantage of the discretized system dynamics in their computations [3], [4], [8].

Mathematically, however, an unanswered question is the dependence of γ on the data of the original continuous-time problem and on the number of subintervals used in the discretization. Zhu and Rockafellar [9] observe that the number of iterations needed for their algorithms to converge remains essentially unchanged as the discretization is refined. This observation suggests strongly that the value of γ approaches a constant, or is at least bounded above, as the number of subintervals increases. In this paper, we will prove this conjecture on γ. In §2, we derive expressions for the matrices $\hat{P}$, $\hat{Q}$, and $\hat{R}$ in the Lagrangian (1.1) for the discretized problem. In §3, we give an estimate of γ in terms of the matrices in the original continuous-time extended linear-quadratic problem of optimal control, an estimate that is independent of the mesh width.

2. Data matrices in the Lagrangian for the discretized problem. The continuous-time extended linear-quadratic problem of optimal control (with time-independent data and normalized time interval) is

$(\mathcal{P}^{\text{cont}})$ minimize $\mathcal{F}(u_e, u)$

$$= \int_0^1 [p{\cdot}u(t) + \tfrac{1}{2}u(t){\cdot}Pu(t) - c{\cdot}x(t)]dt + [p_e{\cdot}u_e + \tfrac{1}{2}u_e{\cdot}P_eu_e - c_e{\cdot}x(1)]$$
$$+ \int_0^1 \rho_{V,Q}\big(q - Cx(t) - Du(t)\big)dt + \rho_{V_e,Q_e}\big(q_e - C_ex(1) - D_eu\big)$$

over the state trajectory

$$\dot{x}(t) = Ax(t) + Bu(t) + b \quad \text{a.e.}, \quad x(0) = B_eu_e + b_e \quad (x(t) \in \mathbb{R}^m)$$

with the control space

$$\mathcal{U} = \{(u_e, u) \in \mathbb{R}^{k_e} \times \mathcal{L}_k^\infty[0,1] \,\big|\, u_e \in U_e, u(t) \in U \text{ a.e. }\}$$

(Rockafellar [1]). Here U, U_e, V, and V_e are polyhedral convex sets, and P, P_e, Q, and Q_e are symmetric positive semidefinite matrices. Each ρ term, defined as

$$\rho_{V,Q}(s) = \sup_{v \in V}\{s{\cdot}v - \tfrac{1}{2}v{\cdot}Qv\},$$

is a lower semicontinuous convex piecewise linear-quadratic function [1, Prop. 2.3]. The dual problem is

$(\mathcal{Q}^{\text{cont}})$ maximize $\mathcal{G}(v, v_e)$

$$= \int_0^1 [q{\cdot}v(t) - \tfrac{1}{2}v(t){\cdot}Qv(t) - b{\cdot}y(t)]dt + [q_e{\cdot}v_e + \tfrac{1}{2}v_e{\cdot}Q_ev_e - b_e{\cdot}y(0)]$$
$$- \int_0^1 \rho_{U,P}\big(B^Ty(t) + D^Tv(t) - p\big)dt - \rho_{U_e,P_e}\big(B_e^Ty(0) + D_e^Tv - p_e\big)$$

over the state trajectory

$$-\dot{y}(t) = A^Ty(t) + C^Tv(t) + c \quad \text{a.e.}, \quad y(1) = C_e^Tv_e + c_e \quad (y(t) \in \mathbb{R}^m)$$

with the control space

$$\mathcal{V} = \{(v, v_e) \in \mathcal{L}_l^\infty[0,1] \times \mathbb{R}^{l_e} \,\big|\, v(t) \in V \text{ a.e., } v_e \in V_e\},$$

where

$$\rho_{U,P}(r) = \sup_{u \in U}\{r{\cdot}u - \tfrac{1}{2}u{\cdot}Pu\}.$$

Problems $(\mathcal{P}^{\text{cont}})$ and $(\mathcal{Q}^{\text{cont}})$ differ from the conventional linear-quadratic models in optimal control in that they allow for piecewise linear-quadratic penalty terms in the objective functionals, as well as constraints on the controls. See Rockafellar [1] for a detailed presentation.

Problems $(\mathcal{P}^{\text{cont}})$ and $(\mathcal{Q}^{\text{cont}})$ are equivalent to a saddle point problem under certain *finiteness conditions* (which will be satisfied if, for example, the matrices P, Q, P_e, and Q_e, are positive definite) [1, Thm. 6.1 and Coro. 6.4]. The saddle point problem is

$$(\mathcal{S}^{\text{cont}}) \qquad \underset{(u_e,u)\in\mathcal{U},(v,v_e)\in\mathcal{V}}{\text{minimax}} \mathcal{J}(u_e,u;v,v_e),$$

where

$$\mathcal{J}(u_e,u;v,v_e)=\int_0^1 J(u(t),v(t))dt+J_e(u_e,v_e)-\langle(u_e,u);(v,v_e)\rangle$$

with

$$J(u,v)=p\cdot u+\tfrac{1}{2}u\cdot Pu+q\cdot v-\tfrac{1}{2}v\cdot Qv-v\cdot Du \text{ for } u\in\mathbb{R}^k, v\in\mathbb{R}^l,$$
$$J_e(u_e,v_e)=p_e\cdot u_e+\tfrac{1}{2}u_e\cdot P_e u_e+q_e\cdot v_e-\tfrac{1}{2}v_e\cdot Q_e v_e \text{ for } u_e\in\mathbb{R}^{k_e}, v\in\mathbb{R}^{l_e},$$

and

$$\begin{aligned}\langle(u_e,u);(v,v_e)\rangle&=\int_0^1 x(t)\cdot(C^Tv(t)+c)dt+x(1)\cdot(C_e^Tv_e+c_e)\\&=\int_0^1 y(t)\cdot(Bu(t)+b)dt+y(0)\cdot(B_eu_e+b_e).\end{aligned}$$

A numerical solution of $(\mathcal{S}^{\text{cont}})$ can be obtained by discretizing the problem into the following approximate version [4], [5]:

$$(\mathcal{S}_{\text{n}}^{\text{cont}}) \qquad \underset{\mathcal{U}_n\times\mathcal{V}_n}{\text{minimax}} \mathcal{J}(u_e,u;v,v_e),$$

where

$$\mathcal{U}_n=\left\{(u_e,u)\in\mathcal{U}\,\middle|\,u(t) \text{ is constant on } \left(\frac{\tau-1}{n},\frac{\tau}{n}\right),\ \tau=1,\dots,n\right\},$$
$$\mathcal{V}_n=\left\{(v,v_e)\in\mathcal{V}\,\middle|\,v(t) \text{ is constant on } \left(\frac{\tau-1}{n},\frac{\tau}{n}\right),\ \tau=1,\dots,n\right\}.$$

If we denote the constant values of $u(t)$ and $v(t)$ on $\left(\frac{\tau-1}{n},\frac{\tau}{n}\right)$ by u_τ and v_τ, respectively, for $\tau=1,\dots,n$, problem $(\mathcal{S}_{\text{n}}^{\text{cont}})$ can be written in the form of a finite-dimensional discrete-time saddle point problem as

$$(\mathcal{S}_{\text{n}}^{\text{disc}}) \qquad \underset{U_n\times V_n}{\text{minimax}} \mathcal{J}_n(u_e,u_1,\dots,u_n;\ v_1,\dots,v_n,v_e),$$

where

$$\begin{aligned}&\mathcal{J}_n(u_e,u_1,\dots,u_n;\ v_1,\dots,v_n,v_e)\\&\quad=\sum_{\tau=1}^{n}J_n(u_\tau,v_\tau)+J_e(u_e,v_e)-\langle(u_e,u_1,\dots,u_n);\ (v_1,\dots,v_n,v_e)\rangle_n\end{aligned}\tag{2.1}$$

with

$$\begin{aligned}J_n(u_\tau,v_\tau)&=p_n\cdot u_\tau+q_n\cdot v_\tau+\tfrac{1}{2}u_\tau\cdot P_nu_\tau-\tfrac{1}{2}v_\tau\cdot Q_nv_\tau-v_\tau\cdot D_nu_\tau+d_n,\\J_e(u_e,v_e)&=p_e\cdot u_e+q_e\cdot v_e+\tfrac{1}{2}u_e\cdot P_eu_e-\tfrac{1}{2}v_e\cdot Q_ev_e,\end{aligned}\tag{2.2}$$

and

$$\begin{aligned}&\langle (u_e, u_1, \ldots, u_n); (v_1, \ldots, v_n, v_e)\rangle_n \\ &= \sum_{\tau=1}^{n} y_{\tau+1}\cdot(B_n u_\tau + b_n) + y_1\cdot(B_e u_e + b_e) \\ &= \sum_{\tau=1}^{n} x_{\tau-1}\cdot(C_n^T v_\tau + c_n) + x_n\cdot(C_e^T v_e + c_e).\end{aligned} \tag{2.3}$$

The trajectories are given by the discretized system dynamics

(2.4)
$$\begin{aligned}&x_\tau = A_n x_{\tau-1} + B_n u_\tau + b_n \text{ for } \tau = 1, \ldots, n, \quad x_0 = B_e u_e + b_e \quad (x_\tau \in \mathbb{R}^m), \\ &y_\tau = A_n^T y_{\tau+1} + C_n^T v_\tau + c_n \text{ for } \tau = 1, \ldots, n, \quad y_{n+1} = C_e^T v_e + c_e \quad (y_\tau \in \mathbb{R}^m),\end{aligned}$$

where we impose

$$\begin{aligned}(u_e, u_1, \ldots, u_n) \in U_n :=& U_e \times (U)^n \subseteq \mathbb{R}^{k_e} \times (\mathbb{R}^k)^n, \\ (v_1, \ldots, v_n, v_e) \in V_n :=& (V)^n \times V_e \subseteq (\mathbb{R}^l)^n \times \mathbb{R}^{l_e}.\end{aligned}$$

The transformation of the data is

$$A_n = I + M_n A, \tag{2.5a}$$

$$B_n = M_n B, \qquad b_n = M_n b, \tag{2.5b}$$

$$C_n = C M_n, \qquad c_n = M_n^T c, \tag{2.5c}$$

$$D_n = \frac{1}{n} D + C S_n B, \qquad d_n = -c\cdot S_n b, \tag{2.5d}$$

$$P_n = \frac{1}{n} P, \qquad p_n = \frac{1}{n} p - B^T S_n^T c, \tag{2.5p}$$

$$Q_n = \frac{1}{n} Q, \qquad q_n = \frac{1}{n} q - C S_n b, \tag{2.5q}$$

where

$$S_n = \sum_{i=2}^{\infty} \frac{1}{i!} \left(\frac{1}{n}\right)^i A^{i-2}, \qquad M_n = \frac{1}{n} I + A S_n. \tag{2.6}$$

(Wright [4], [5]). The associated primal and dual problems are

$(\mathcal{P}_{\mathrm{n}}^{\mathrm{disc}})$ minimize $f(u)$ over $u \in U_n$, where
$$f(u_e, u_1, \ldots, u_n) := \max_{v \in V_n} \mathcal{J}_n(u_e, u_1, \ldots, u_n;\, v_1, \ldots, v_n, v_e)$$

and

$(\mathcal{Q}_{\mathrm{n}}^{\mathrm{disc}})$ maximize $g(v)$ over $v \in V_n$, where
$$g(v_1, \ldots, v_n, v_e) := \min_{u \in U_n} \mathcal{J}_n(u_e, u_1, \ldots, u_n;\, v_1, \ldots, v_n, v_e).$$

Problems $(\mathcal{P}_{\mathrm{n}}^{\mathrm{disc}})$ and $(\mathcal{Q}_{\mathrm{n}}^{\mathrm{disc}})$ are ELQP in the multistage format, which could be solved directly by the techniques mentioned in §1 without forming the huge $\hat{R}$ matrix in the Lagrangian (1.1) of its standard form. However, in order to get an expression for γ in terms of the matrices A, B, C, D, P, and Q from the continuous-time problem, we

eliminate the state variables x_τ and y_τ in the expression of $\mathcal{J}_n$. From the discretized system dynamics (2.4), we obtain

$$\begin{bmatrix} x_e \\ x_1 \\ \cdot \\ \cdot \\ x_n \end{bmatrix} = \begin{bmatrix} B_e & & & & \\ A_nB_e & B_n & & & \\ \cdot & \cdot & \cdots & & \\ \cdot & \cdot & \cdots & & \\ A_n^nB_e & A_n^{n-1}B_n & \cdots & A_nB_n & B_n \end{bmatrix} \begin{bmatrix} u_e \\ u_1 \\ \cdot \\ \cdot \\ u_n \end{bmatrix} + \begin{bmatrix} b_e \\ A_nb_e + b_n \\ \cdot \\ \cdot \\ A_n^nb_e + A_n^{n-1}b_n + \ldots + b_n \end{bmatrix}$$

$$= \begin{bmatrix} I & & & & \\ A_n & I & & & \\ \cdot & \cdot & \cdots & & \\ \cdot & \cdot & \cdots & \cdot & \cdot \\ A_n^n & A_n^{n-1} & \cdots & A_n & I \end{bmatrix} \left(\begin{bmatrix} B_eu_e \\ B_nu_1 \\ \cdot \\ \cdot \\ B_nu_n \end{bmatrix} + \begin{bmatrix} b_e \\ b_n \\ \cdot \\ \cdot \\ b_n \end{bmatrix} \right). \tag{2.7}$$

By substituting (2.7) in the second expression of (2.3), we obtain

$$\begin{aligned} &\langle (u_e, u_1, \ldots, u_n); (v_1, \ldots, v_n, v_e) \rangle_n \\ &= \begin{bmatrix} c_n \\ \cdot \\ \cdot \\ c_n \\ c_e \end{bmatrix} \cdot \begin{bmatrix} x_e \\ x_1 \\ \cdot \\ \cdot \\ x_n \end{bmatrix} + \begin{bmatrix} v_1 \\ \cdot \\ \cdot \\ v_n \\ v_e \end{bmatrix} \cdot \begin{bmatrix} C_n & & & \\ & \cdots & & \\ & & C_n & \\ & & & C_e \end{bmatrix} \begin{bmatrix} x_e \\ x_1 \\ \cdot \\ \cdot \\ x_n \end{bmatrix} \\ &= \begin{bmatrix} c_n \\ \cdot \\ \cdot \\ c_n \\ c_e \end{bmatrix} \cdot \begin{bmatrix} B_e & & & & \\ A_nB_e & B_n & & & \\ \cdot & \cdot & \cdots & & \\ \cdot & \cdot & \cdots & \cdot & \\ A_n^nB_e & A_n^{n-1}B_n & \cdots & A_nB_n & B_n \end{bmatrix} \begin{bmatrix} u_e \\ u_1 \\ \cdot \\ \cdot \\ u_n \end{bmatrix} \\ &\quad + \begin{bmatrix} v_1 \\ \cdot \\ \cdot \\ v_n \\ v_e \end{bmatrix} \cdot \begin{bmatrix} C_nB_e & & & & \\ C_nA_nB_e & C_nB_n & & & \\ \cdot & \cdot & \cdots & & \\ \cdot & \cdot & \cdots & \cdot & \\ C_eA_n^nB_e & C_eA_n^{n-1}B_n & \cdots & C_eA_nB_n & C_eB_n \end{bmatrix} \begin{bmatrix} u_e \\ u_1 \\ \cdot \\ \cdot \\ u_n \end{bmatrix} \\ &\quad + \begin{bmatrix} v_1 \\ \cdot \\ \cdot \\ v_n \\ v_e \end{bmatrix} \cdot \begin{bmatrix} C_n & & & & \\ C_nA_n & C_n & & & \\ \cdot & \cdot & \cdots & & \\ \cdot & \cdot & \cdots & \cdot & \\ C_eA_n^n & C_eA_n^{n-1} & \cdots & C_eA_n & C_e \end{bmatrix} \begin{bmatrix} b_e \\ b_n \\ \cdot \\ \cdot \\ b_n \end{bmatrix} \\ &\quad + \begin{bmatrix} c_n \\ \cdot \\ \cdot \\ c_n \\ c_e \end{bmatrix} \cdot \begin{bmatrix} I & & & & \\ A_n & I & & & \\ \cdot & \cdot & \cdots & & \\ \cdot & \cdot & \cdots & \cdot & \\ A_n^n & A_n^{n-1} & \cdots & A_n & I \end{bmatrix} \begin{bmatrix} b_e \\ b_n \\ \cdot \\ \cdot \\ b_n \end{bmatrix}. \end{aligned} \tag{2.8}$$

Similarly, we have from (2.2) that

$$\begin{aligned} &\sum_{\tau=1}^{n} J_n(u_\tau, v_\tau) + J_e(u_e, v_e) \\ &= \begin{bmatrix} p_e \\ p_n \\ \cdot \\ \cdot \\ p_n \end{bmatrix} \cdot \begin{bmatrix} u_e \\ u_1 \\ \cdot \\ \cdot \\ u_n \end{bmatrix} + \begin{bmatrix} q_n \\ \cdot \\ \cdot \\ q_n \\ q_e \end{bmatrix} \cdot \begin{bmatrix} v_1 \\ \cdot \\ \cdot \\ v_n \\ v_e \end{bmatrix} + \frac{1}{2} \begin{bmatrix} u_e \\ u_1 \\ \cdot \\ \cdot \\ u_n \end{bmatrix} \cdot \begin{bmatrix} P_e & & & \\ & P_n & & \\ & & \cdots & \\ & & & P_n \end{bmatrix} \begin{bmatrix} u_e \\ u_1 \\ \cdot \\ \cdot \\ u_n \end{bmatrix} \end{aligned}$$

$$-\frac{1}{2}\begin{bmatrix} v_1 \\ \cdot \\ \cdot \\ v_n \\ v_e \end{bmatrix} \cdot \begin{bmatrix} Q_n & & \cdots & & \\ & Q_n & & & \\ & & & Q_e & \end{bmatrix} \begin{bmatrix} v_1 \\ \cdot \\ \cdot \\ v_n \\ v_e \end{bmatrix}$$

$$-\begin{bmatrix} v_1 \\ \cdot \\ \cdot \\ v_n \\ v_e \end{bmatrix} \cdot \begin{bmatrix} 0 & D_n & & & \\ & \cdots & \cdots & & \\ & & 0 & D_n & \\ & & & 0 & \end{bmatrix} \begin{bmatrix} u_e \\ u_1 \\ \cdot \\ \cdot \\ u_n \end{bmatrix} \tag{2.9}$$

By substituting (2.8) and (2.9) in (2.1), we obtain equality of $\mathcal{J}_n$ with the Lagrangian $L(\hat{u}, \hat{v})$ in (1.1) by noting the identities

$$\hat{P} = \operatorname{diag}[P_e, P_n, \cdots, P_n], \qquad \hat{Q} = \operatorname{diag}[Q_n, \cdots, Q_n, Q_e], \tag{2.10}$$

$$\hat{R} = \begin{bmatrix} C_nIB_e & D_n & & & & & \\ C_nA_nB_e & C_nIB_n & D_n & & & & \\ C_nA_n^2B_e & C_nA_nB_n & C_nIB_n & D_n & & & \\ \cdot & \cdot & \cdot & \cdot & \cdots & & \\ \cdot & \cdot & \cdot & \cdot & \cdots & \cdot & \\ C_nA_n^{n-1}B_e & C_nA_n^{n-2}B_n & \cdot & \cdot & \cdots & C_nIB_n & D_n \\ C_eA_n^nB_e & C_eA_n^{n-1}B_n & \cdot & \cdot & \cdots & C_eA_nB_n & C_eIB_n \end{bmatrix}, \tag{2.11}$$

$$\hat{p} = \begin{bmatrix} p_e \\ p_n \\ \cdot \\ \cdot \\ p_n \end{bmatrix} - \begin{bmatrix} B_e^Tc_n + \ldots + B_e^T(A_n^T)^{n-1}c_n + B_e^T(A_n^T)^nc_e \\ B_n^Tc_n + \ldots + B_n^T(A_n^T)^{n-2}c_n + B_n^T(A_n^T)^{n-1}c_e \\ \cdot \\ \cdot \\ B_n^Tc_n + B_n^TA_n^Tc_e \\ B_n^Tc_e \end{bmatrix},$$

$$\hat{q} = \begin{bmatrix} q_n \\ \cdot \\ \cdot \\ q_n \\ q_e \end{bmatrix} - \begin{bmatrix} C_nb_e \\ C_nA_nb_e + C_nb_n \\ \cdot \\ \cdot \\ C_nA_n^{n-1}b_e + C_nA_n^{n-2}b_n + \ldots + C_nb_n \\ C_eA_n^nb_e + C_eA_n^{n-1}b_n + \ldots + C_eb_n \end{bmatrix}$$

with

$$\hat{u} = (u_e, u_1, \cdots, u_n), \qquad \hat{v} = (v_1, \cdots, v_n, v_e).$$

(The additive constants in $\mathcal{J}_n$ are dropped since they play no role in the problem.)

3. Estimation of the parameter γ of the discretized problem. In this section, we prove the following estimate of the parameter γ of the discretized problem in terms of the continuous-time problem data.

THEOREM 3.1. *Suppose the matrices P, Q, P_e, and Q_e in the continuous-time extended linear-quadratic problems $(\mathcal{P}^{\text{cont}})$ and $(\mathcal{Q}^{\text{cont}})$ of optimal control are positive definite. Then the parameter γ_n of the discretized versions $(\mathcal{P}_n^{\text{disc}})$ and $(\mathcal{Q}_n^{\text{disc}})$ satisfies*

$$\begin{aligned} \gamma_n \le\ & \|Q^{-\frac{1}{2}}C\|\|B_eP_e^{-\frac{1}{2}}\|e^{(n-1)\|A\|/n} \\ & + \|Q_e^{-\frac{1}{2}}C_e\|\|BP^{-\frac{1}{2}}\|e^{(n-1)\|A\|/n} + \|Q_e^{-\frac{1}{2}}C_e\|\|B_eP_e^{-\frac{1}{2}}\|e^{\|A\|} \\ & + \|Q^{-\frac{1}{2}}DP^{-\frac{1}{2}}\| + \|Q^{-\frac{1}{2}}C\|\|BP^{-\frac{1}{2}}\|\frac{1-e^{(n-1)\|A\|/n}}{n(1-e^{\|A\|/n})} + O(n^{-1}), \end{aligned} \tag{3.1}$$

where n is the number of equal-length subintervals used in the discretization. Moreover,

$$\begin{aligned}\limsup_{n\to\infty}\gamma_n \le\ & \|Q^{-\frac{1}{2}}C\|\|B_eP_e^{-\frac{1}{2}}\|e^{\|A\|} \\ & + \|Q_e^{-\frac{1}{2}}C_e\|\|BP^{-\frac{1}{2}}\|e^{\|A\|} + \|Q_e^{-\frac{1}{2}}C_e\|\|B_eP_e^{-\frac{1}{2}}\|e^{\|A\|} \\ & + \|Q^{-\frac{1}{2}}DP^{-\frac{1}{2}}\| + \|Q^{-\frac{1}{2}}C\|\|BP^{-\frac{1}{2}}\|\frac{e^{\|A\|}-1}{\|A\|}.\end{aligned} \tag{3.2}$$

Two conclusions follow immediately from Theorem 3.1:

(i) The parameter γ_n of the discretized problem, as a function of n, is bounded above when $n \to \infty$. Hence for the algorithms with their convergence rates having an upper bound determined solely by γ_n, the number of iterations needed for convergence should remain essentially the same as n increases. If, in addition, the algorithm has only $O(n)$ operations in each iteration, then the total central processing unit time needed for convergence should be proportional to n. These results are consistent with the observations of Zhu and Rockafellar [9].

(ii) The only part of the original data that has an exponential contribution to γ_n is the norm of the matrix A in the system dynamics as the coefficient of the state variables. The norms of all the other matrices contribute linearly.

Before proving the theorem, we first state two simple propositions. The proofs of these propositions are elementary and therefore skipped.

PROPOSITION 3.2. *Suppose matrix E can be partitioned as*

$$E = \begin{bmatrix} E_{11} & E_{12} & \cdots & E_{1s} \\ \cdot & \cdot & \cdots & \cdot \\ \cdot & \cdot & \cdots & \cdot \\ E_{r1} & E_{r2} & \cdots & E_{rs} \end{bmatrix}.$$

Then

$$\|E\| \le \sum_{i=1}^{r}\sum_{j=1}^{s}\|E_{ij}\|.$$

PROPOSITION 3.3. *Suppose matrix E is of block diagonal form*

$$E = \operatorname{diag}[E_1, E_2, \ldots, E_r].$$

Then

$$\|E\| = \max_{1\le i\le r}\{\|E_i\|\}.$$

Proof of the theorem. Let $\Gamma := \hat{Q}^{-\frac{1}{2}}\hat{R}\hat{P}^{-\frac{1}{2}}$. Then $\gamma_n = \|\Gamma\|$. Observe that the matrix $\hat{R}$ in (2.11) is block lower Hessenberg, while the matrices $\hat{P}$ and $\hat{Q}$ in (2.10) are block diagonal with the corresponding block structure. Hence the matrix $\Gamma = \hat{Q}^{-\frac{1}{2}}\hat{R}\hat{P}^{-\frac{1}{2}}$ is also of block lower Hessenberg with the same block structure as that of $\hat{R}$. Partition Γ as

$$\Gamma = \begin{bmatrix} \Gamma_{ne} & \Gamma_{nn} \\ \Gamma_{ee} & \Gamma_{en} \end{bmatrix}, \tag{3.3}$$

where

$$\Gamma_{ne} = \begin{bmatrix} Q_n^{-\frac{1}{2}} C_n I B_e P_e^{-\frac{1}{2}} \\ Q_n^{-\frac{1}{2}} C_n A_n B_e P_e^{-\frac{1}{2}} \\ \cdot \\ \cdot \\ \cdot \\ Q_n^{-\frac{1}{2}} C_n A_n^{n-1} B_e P_e^{-\frac{1}{2}} \end{bmatrix}, \quad \Gamma_{ee} = \left[Q_e^{-\frac{1}{2}} C_e A_n^n B_e P_e^{-\frac{1}{2}} \right], \tag{3.4}$$

$$\Gamma_{en} = \left[Q_e^{-\frac{1}{2}} C_e A_n^{n-1} B_n P_n^{-\frac{1}{2}} \quad \cdots \quad Q_e^{-\frac{1}{2}} C_e A_n B_n P_n^{-\frac{1}{2}} \quad Q_e^{-\frac{1}{2}} C_e I B_n P_n^{-\frac{1}{2}} \right], \tag{3.5}$$

and

(3.6)

$$\Gamma_{nn} = \begin{bmatrix} Q_n^{-\frac{1}{2}} D_n P_n^{-\frac{1}{2}} & & & \\ Q_n^{-\frac{1}{2}} C_n I B_n P_n^{-\frac{1}{2}} & Q_n^{-\frac{1}{2}} D_n P_n^{-\frac{1}{2}} & & \\ \cdot & \cdot & \cdots & \\ \cdot & \cdot & \cdots & \cdot \\ Q_n^{-\frac{1}{2}} C_n A_n^{n-2} B_n P^{-\frac{1}{2}} & Q_n^{-\frac{1}{2}} C_n A_n^{n-3} B_n P^{-\frac{1}{2}} & \cdots & Q_n^{-\frac{1}{2}} C_n I B_n P_n^{-\frac{1}{2}} \quad Q_n^{-\frac{1}{2}} D_n P_n^{-\frac{1}{2}} \end{bmatrix}.$$

It follows from (2.6) that

$$S_n = \sum_{i=2}^{\infty} \frac{1}{i!} \left(\frac{1}{n}\right)^i A^{i-2} = \frac{1}{2n^2} I + O(n^{-3}), \tag{3.7a}$$

$$M_n = \frac{1}{n} I + A S_n = \frac{1}{n} I + O(n^{-2}). \tag{3.7b}$$

Hence, by equations (2.5), we have the following first-order approximations for the matrices in the discretized problem:

$$A_n = I + M_n A = \sum_{i=0}^{\infty} \frac{1}{i!} \left(\frac{A}{n}\right)^i = e^{A/n}, \tag{3.8a}$$

$$B_n = M_n B = \frac{1}{n} B + O(n^{-2}), \tag{3.8b}$$

$$C_n = C M_n = \frac{1}{n} C + O(n^{-2}), \tag{3.8c}$$

$$D_n = \frac{1}{n} D + C S_n B = \frac{1}{n} D + O(n^{-2}), \tag{3.8d}$$

$$P_n = \frac{1}{n} P, \tag{3.8p}$$

$$Q_n = \frac{1}{n} Q, \tag{3.8q}$$

Applying Proposition 3.2 to the partitioned form of Γ in (3.3), we have

$$\|\Gamma\| \leq \|\Gamma_{ne}\| + \|\Gamma_{ee}\| + \|\Gamma_{en}\| + \|\Gamma_{nn}\|. \tag{3.9}$$

Now we estimate the norms on the right-hand side of (3.9). The matrix Γ_{ne} in (3.4) can be written as

(3.10)
$$\Gamma_{ne} = \operatorname{diag}[Q_n^{-\frac{1}{2}} C_n B_e P_e^{-\frac{1}{2}}, Q_n^{-\frac{1}{2}} C_n A_n B_e P_e^{-\frac{1}{2}}, \ldots, Q_n^{-\frac{1}{2}} C_n A_n^{n-1} B_e P_e^{-\frac{1}{2}}][I \ \cdots \ I]^T.$$

However,

$$\begin{aligned}
&\| \operatorname{diag}[Q_n^{-\frac{1}{2}} C_n B_e P_e^{-\frac{1}{2}}, Q_n^{-\frac{1}{2}} C_n A_n B_e P_e^{-\frac{1}{2}}, \ldots, Q_n^{-\frac{1}{2}} C_n A_n^{n-1} B_e P_e^{-\frac{1}{2}}] \| \\
&\quad = \max_{0 \le i \le n-1} \{ \| Q_n^{-\frac{1}{2}} C_n A_n^i B_e P_e^{-\frac{1}{2}} \| \} \\
&\quad \le \max_{0 \le i \le n-1} \{ \| Q_n^{-\frac{1}{2}} C_n \| \| A_n^i \| \| B_e P_e^{-\frac{1}{2}} \| \} \\
&\quad \le \| Q_n^{-\frac{1}{2}} C_n \| \| B_e P_e^{-\frac{1}{2}} \| \max_{0 \le i \le n-1} \| A_n \|^i \} \\
&\quad \le \| Q_n^{-\frac{1}{2}} C_n \| \| B_e P_e^{-\frac{1}{2}} \| \max\{1, \| A_n \|^{n-1}\} \qquad (3.11)
\end{aligned}$$

by Proposition 3.3. It follows from (3.8a) and (3.8c) that

$$\| A_n \|^{n-1} \le e^{(n-1)\|A\|/n}, \qquad (3.12)$$

$$\| Q_n^{-\frac{1}{2}} C_n \| = n^{-\frac{1}{2}} \| Q^{-\frac{1}{2}} C \| + O(n^{-\frac{3}{2}}). \qquad (3.13)$$

Substituting (3.12) and (3.13) in (3.11), and using $\| [I \ \cdots \ I]^T \| = n^{\frac{1}{2}}$, we obtain

$$\begin{aligned}
\| \Gamma_{ne} \| &\le \big(\| Q^{-\frac{1}{2}} C \| + O(n^{-1}) \big) \| B_e P_e^{-\frac{1}{2}} \| \max\{1, e^{(n-1)\|A\|/n}\}, \\
&\le \| Q^{-\frac{1}{2}} C \| \| B_e P_e^{-\frac{1}{2}} \| e^{(n-1)\|A\|/n} + O(n^{-1}). \qquad (3.14)
\end{aligned}$$

We can show in a similar way that

$$\| \Gamma_{en} \| \le \| Q_e^{-\frac{1}{2}} C_e \| \| B P^{-\frac{1}{2}} \| e^{(n-1)\|A\|/n} + O(n^{-1}). \qquad (3.15)$$

For the matrix Γ_{ee}, it is obvious by (3.8a) that

$$\| \Gamma_{ee} \| = \| Q_e^{-\frac{1}{2}} C_e e^A B_e P_e^{-\frac{1}{2}} \| \le \| Q_e^{-\frac{1}{2}} C_e \| \| B_e P_e^{-\frac{1}{2}} \| e^{\|A\|}. \qquad (3.16)$$

Next, we estimate $\|\Gamma_{nn}\|$. Let $\Gamma_{nn}^{(0)}$ be the matrix obtained by zeroing out all the blocks of Γ_{nn} except the diagonal blocks. Let $\Gamma_{nn}^{(i)}$, $i = 1, \ldots, n-1$, be the matrix obtained by zeroing out all the blocks of Γ_{nn} except the blocks on the ith subdiagonal. Then by Propositions 3.2 and 3.3, we have

$$\| \Gamma_{nn}^{(0)} \| = \| Q_n^{-\frac{1}{2}} D_n P_n^{-\frac{1}{2}} \| = \| Q^{-\frac{1}{2}} D P^{-\frac{1}{2}} \| + O(n^{-1})$$

and

$$\| \Gamma_{nn}^{(i)} \| = \| Q_n^{-\frac{1}{2}} C_n A_n^{i-1} B_n P_n^{-\frac{1}{2}} \| = \frac{1}{n} \| Q^{-\frac{1}{2}} C e^{(i-1)A/n} B P^{-\frac{1}{2}} \| + O(n^{-2})$$

for $i = 1, \ldots, n-1$, where the first-order approximations in (3.8) are used to get the right-hand sides. Hence

$$\begin{aligned}\|\Gamma_{nn}\| &\le \|\Gamma_{nn}^{(0)}\| + \sum_{i=1}^{n-1} \|\Gamma_{nn}^{(i)}\| \\ &= \|Q^{-\frac{1}{2}} D P^{-\frac{1}{2}}\| + \frac{1}{n} \sum_{i=1}^{n-1} \|Q^{-\frac{1}{2}} C e^{(i-1)A/n} B P^{-\frac{1}{2}}\| + O(n^{-1}) \\ &\le \|Q^{-\frac{1}{2}} D P^{-\frac{1}{2}}\| + \frac{1}{n} \|Q^{-\frac{1}{2}} C\| \|B P^{-\frac{1}{2}}\| \sum_{i=1}^{n-1} \|e^{(i-1)A/n}\| + O(n^{-1}).\end{aligned}$$

But

$$\sum_{i=1}^{n-1} \|e^{(i-1)A/n}\| \le \sum_{i=1}^{n-1} e^{(i-1)\|A\|/n} = \frac{1 - e^{(n-1)\|A\|/n}}{1 - e^{\|A\|/n}}.$$

Therefore

$$\|\Gamma_{nn}\| \le \|Q^{-\frac{1}{2}} D P^{-\frac{1}{2}}\| + \|Q^{-\frac{1}{2}} C\| \|B P^{-\frac{1}{2}}\| \frac{1 - e^{(n-1)\|A\|/n}}{n(1 - e^{\|A\|/n})} + O(n^{-1}). \tag{3.17}$$

Substituting (3.14), (3.15), (3.16), and (3.17) in (3.9), we get the inequality (3.1) in Theorem 3.1. Taking limsup on both sides of (3.1), we obtain (3.2). □

In all the above discussions, we assume time-independent data in the optimal control problem. As a final remark, we point out that it would not be difficult to derive a similar bound for the ELQP problem arising from the Euler difference scheme when the optimal control data is time dependent. Actually the proof of Theorem 3.1, with minor adaptations, still works in this latter case if the data elements in

$$A(t), B(t), C(t), D(t), b(t), c(t), P(t), Q(t), p(t), q(t), U(t), V(t)$$

are all Lipschitzian in t. A detailed exposition for this kind of time-dependent case will be presented elsewhere.

Acknowledgments. The author is indebted to S. J. Wright and the associate editor for their helpful comments and suggestions and to an anonymous referee for remarks on the time-dependent case. The final remark in the last section was due to this referee.

BELLMAN EQUATIONS OF RISK-SENSITIVE CONTROL*

H. NAGAI†

Dedicated to Professor M. Fukushima on the occasion of his sixtieth birthday

Abstract. Risk-sensitive control problems are considered. Existence of a nonnegative solution to the Bellman equation of risk-sensitive control is shown. The result is applied to prove that no breaking down occurs. Asymptotic behaviour of the nonnegative solution is studied in relation to ergodic control problems and the relationship between the asymptotics and the large deviation principle is noted.

Key words. risk-sensitive control, Bellman equation, ergodic control, breaking down, asymptotic behaviour, large deviation

AMS subject classifications. 93E20, 49L20, 35K55, 60F10, 60H30

Introduction. Let us consider the following stochastic control problem minimizing

$$I(T,x;z,\theta)=\frac{1}{\theta}\log E\left[e^{\theta\int_0^T\{V(X_s)+\phi(X_s,z_s)\}ds}\right],\quad \theta\in R\backslash\{0\},\tag{0.1}$$

subject to controlled processes governed by the stochastic differential equation

$$\begin{cases} dX_t=\sigma(X_t)dB_t+b(X_t)dt+c(X_t,z_t)dt,\\ X_0=x, \end{cases}$$

where B_t is a standard Brownian motion process defined on a probability space $(\Omega,\mathcal{F},P)$ and z_t is a control process assuming its value on a control region $Z\subset R^{N_1}$. The constant θ is called a risk-sensitive parameter and its meaning is realized by considering the asymptotics as $\theta\to 0$:

$$I(T,x;z,\theta)=E[\Phi_T]+\theta\mathrm{Var}[\Phi_T]+O(\theta^2),$$

where $\Phi_T=\int_0^T\{V(X_s)+\phi(X_s,z_s)\}ds$. The case where $\theta>0$ is called risk averse and $\theta<0$, risk seeking. We assume that V and ϕ are nonnegative functions such that $V(x)\to\infty$ as $|x|\to\infty$ and $\phi(x,z)\to\infty$ as $|z|\to\infty$, and therefore it may occur in risk-averse cases that (0.1) never has finite value for any control process z_t. We then say that the control problem breaks down. Thus we are led to the problem of finding the conditions where no breaking down occurs.

It is natural to relate the problem with the existence of the solution to the Bellman equation from the control theoretical point of view since the value function should satisfy the equation if it has finite value and sufficient regularity. Actually we shall first study the existence of a nonnegative solution to the Bellman equation:

$$\begin{cases} \frac{\partial u}{\partial t}=\frac{1}{2}a^{ij}D_{ij}u+b^iD_iu+Q_0(x,\nabla u)+V(x),\\ u(0,x)=0, \end{cases}\tag{0.2}$$

with

$$Q_0(x,p) = \frac{\theta}{2}a^{ij}p_ip_j + \inf_{z\in Z}\{c^i(x,z)p_i + \phi(x,z)\}, \quad p \in R^N$$

(cf. Theorem 1.1) and then prove in §2 that no breaking down occurs under the assumptions of Theorem 1.1. To obtain the existence theorem the estimate (1.28) plays a key role and the assumption (1.16) is essential to deriving the estimate. Moreover the assumption indicates the bound of the size of the risk-sensitive parameter θ ensuring finiteness of the value function for any terminal time T in the risk-averse case. In fact, Theorem 2.3 combined with Theorem 1.1 shows that no breaking down occurs under the assumption besides other conditions of Theorem 1.1 (cf. §2.2 and Remark 1.2). The linear exponential quadratic Gaussian (LEQG) case is covered by our assumptions. More general examples are illustrated in §1.5. LEQG refers to the case where V (resp., ϕ) is a quadratic function of x (resp., z), b (resp., c) a linear function of x (resp., z), and σ a constant matrix, and it has been studied from various points of view (cf. Jacobson [15], Whittle [25], Bensoussan and Van Schuppen [3]).

The next problem is to see how the value function $I^*(T,x;\theta) = \inf I(T,x;z,\theta)$ behaves as $T \to \infty$. Related to this problem we shall study the asymptotic behaviour of the nonnegative solution $u(t,x)$ to the Bellman equation (0.2) as $t \to \infty$. We shall prove in a specialized case of $Q_0(x,p) = a^{ij}p_ip_j$ that $u(t,x) - u(t,0)$ converges to a function v and $\frac{\partial u}{\partial t}$ to a constant χ, characterized by the following Bellman equation of ergodic type:

$$\text{(0.3)} \qquad \begin{cases} \chi = \frac{1}{2}a^{ij}D_{ij}v + b^iD_iv + Q_0(x,\nabla v) + V(x), & x \in R^N, \\ \chi \equiv \text{constant}, \quad v \in C^2(R^N). \end{cases}$$

We find as its corollary that

$$\text{(0.4.)} \qquad \lim_{T\to\infty}\frac{u(T,x)}{T} = \lim_{T\to\infty}\frac{\partial u}{\partial t}(T,x) = \chi.$$

Several authors so far (cf. [1], [4], [21], [11], [19]) have deduced an equation such as (0.3) from the Bellman equation of discounted type as the discounted factor tends to 0, with the most far-reaching study on the matter by Bensoussan and Frehse [2]. We further mention the studies on the asymptotic behaviour of the solution u in the case of LEQG done by several authors, e.g., by Whittle [25], Glover and Doyle [12], Runolfsson [23], and in other cases by Fleming and McEneaney [9].

We note the relationship between the asymptotics and large deviation principle due to Donsker and Varadhan [7], which has been noticed by Runolfsson [23]. We illustrate a typical example in §3.3 indicating the relationship, where χ is realized as the constant relating to the principal eigenvalue of a Schrödinger operator.

1. Existence.

1.1. Statement of Theorem 1.1. Let $(\Omega, \mathcal{F}, P)$ be a probability space with filtration $\mathcal{F}_t$, $t \geq 0$, B_t a standard N-dimensional $\mathcal{F}_t$- Brownian motion process, and z_t a progressively measurable process with the value on a Borel subset Z of R^{N_1}. We consider the following stochastic differential equation (SDE):

$$\text{(1.1)} \qquad \begin{cases} dX_s^i = \sigma_j^i(X_s)dB_s^j + b^i(X_s)ds + c^i(X_s,z_s)ds, & i = 1,\dots,N, \\ X_0 = x \end{cases}$$

and introduce the value functions J_+^* and J_-^* as follows:

$$J_+^*(t,x;T,\theta) = \inf_{\mathcal{A}_{T-t}} E_x[e^{\theta\Phi_{T-t}}], \quad \theta > 0, \tag{1.2}$$

$$J_-^*(t,x;T,\theta) = \sup_{\mathcal{A}_{T-t}} E_x[e^{\theta\Phi_{T-t}}], \quad \theta < 0, \tag{1.3}$$

where

$$\Phi_t = \int_0^t \{V(X_s) + \phi(X_s, z_s)\}ds$$

and $\mathcal{A}_{T-t}$ is the totality of $(\Omega, \mathcal{F}, \mathcal{F}_s, P, B_s, z_s)_{0\le s<T-t}$ such that (1.1) has a unique solution for $0 \le s < T-t$. In this paper we employ the summation convention that in cases where the same indices appear in a term twice, the symbol of summation is omitted. We assume the following conditions:

(1.4) σ, b, c, V, and ϕ are smooth,

(1.5) $\|\sigma(x) - \sigma(y)\| \le M|x-y|$, $|b(x) - b(y)| \le M|x-y|$, $\exists M > 0$,

(1.6) all derivatives of σ, b, and $V$are dominated by $M(1+|x|)^m$, $\exists m > 0$,

(1.7) $|c(x,z)| \le c_0(z)$ for some locally bounded function $c_0(z)$,

(1.8) $V(x) \ge 0$ and $\lim_{|x|\to\infty} V(x) = \infty$,

(1.9) $\phi(x,z) \ge 0$ and

$$\lim_{|z|\to\infty} \phi(x,z) = \infty, \quad \lim_{|z|\to\infty} \frac{|c(x,z)|}{\phi(x,z)} = 0 \text{ uniformly in } x,$$

(1.10) $a^{ij}\xi_j\xi_j \ge \nu|\xi|^2$, $\xi \in R^N$ $\exists \nu > 0$,

where $a^{ij} = (\sigma\sigma^*)^{ij}$. In the case where $\theta > 0$ the Bellman equation for the stochastic control problem (1.2) is formally written as

$$\begin{cases} \mathcal{L}J_+ + \inf_{z\in Z}\{c^i(x,z)D_iJ_+ + \theta(V(x)+\phi(x,z))J_+\} = 0, & [0,T)\times R^N, \\ J_+(T,x) = 1, \end{cases} \tag{1.11}$$

where

$$\mathcal{L}J_+ = \frac{\partial J_+}{\partial t} + \frac{1}{2}a^{ij}D_{ij}J_+ + b^iD_iJ_+$$

and

$$D_{ij} = \frac{\partial^2}{\partial x_i \partial x_j}, \quad D_i = \frac{\partial}{\partial x_j}.$$

For $\theta < 0$, replace inf by sup in equation (1.11) and denote it as (1.11′). We put the solution to the equation J_-. In both cases, taking a transformation $e^{\theta w(t,x)} = J_\pm(t,x)$, we obtain the equation

$$\begin{cases} \mathcal{L}w + Q_0(x,\nabla w) + V(x) = 0, & [0,T)\times R^N, \\ w(T,x) = 0, \end{cases} \tag{1.12}$$

where

$$Q_0(x,p) = \frac{\theta}{2}a^{ij}p_ip_j + \inf_{z\in Z}\{c^i(x,z)p_i + \phi(x,z)\}, \quad p \in R^N. \tag{1.13}$$

Let us set

$$u(t,x) = w(T-t,x), \quad 0 \le t \le T. \tag{1.14}$$

Then we have the equation

$$\begin{cases} \frac{\partial u}{\partial t} = \frac{1}{2}a^{ij}D_{ij}u + b^iD_iu + Q_0(x,\nabla u) + V(x), \\ u(0,x) = 0 \end{cases} \tag{1.15}$$

on $[0,T]\times R^N$. If we have the solution u to (1.15) on $[0,\infty)\times R^N$, taking $T>0$ and setting $w(t,x) = u(T-t,x)$, we obtain the solution w to (1.12), and accordingly the solution $J_\pm = e^{\theta w(t,x)}$ to (1.11) or (1.11′), respectively. Now we are going to consider the existence of the solution to (1.15). For that we further assume that

$$-\frac{k_1}{2}a^{ij}p_ip_j \le Q_0(x,p) \le -\frac{k_2}{2}a^{ij}p_ip_j, \quad \exists k_i, k_2 > 0 \tag{1.16}$$

and that $Q_0(x,p)$ is a smooth function such that

$$\left|\frac{\partial Q_0(x,p)}{\partial p}\right| \le M_1|p| + M_2, \quad \left|\frac{\partial Q_0(x,p)}{\partial x}\right| \le M_1|p|^2 + M_2 \tag{1.17}$$

for some locally bounded functions M_1 and M_2. Then we have the following theorem.

THEOREM 1.1. *Under the assumptions* (1.4)–(1.10), (1.16), *and* (1.17), *equation* (1.15) *has a nonnegative solution* $u \in C^{1+\frac{\alpha}{2},2+\alpha}((0,\infty)\times R^N)\cap C([0,\infty)\times R^N)$. *Moreover it satisfies the following estimates*:

$$\frac{\partial u}{\partial t} \ge 0, \tag{1.18}$$

$$t\left(|\nabla u|^2 + \gamma\frac{\partial u}{\partial t}\right) \le tK_{r,\gamma} + L_{r,\gamma}, \quad (0,\infty)\times B_r \tag{1.19}$$

for $\gamma > \frac{2}{k_2\nu}$, *where* $K_{r,\gamma}$ *and* $L_{r,\gamma}$ *are the constants independent of* t.

Remark 1.1. Examples satisfying assumptions (1.16) and (1.17) are illustrated in §1.5. Example 1 deals with our main concerns. More general cases where c grows like z and ϕ like $|z|^2$ for large and small z can be also covered (cf. Examples 4 and 5). However, we don't assume that V is quadratic but admit any function V growing to infinity as $|x|\to\infty$ with at most polynomial growth rate.

Remark 1.2. Assumption (1.16) indicates the bound of the size of the risk-sensitive parameter θ ensuring the existence of a solution of the Bellman equation (1.15). We will see in Theorem 2.3 that it implies the finiteness of the value function (1.2). Thus we will see that (1.16) gives a condition of θ under which no breaking down occurs. The condition is more clearly seen in the examples in §1.5.

1.2. Dirichlet problem. Let us consider the following SDE:

$$\begin{cases} dY_s^i = \sigma_j^i(Y_s)dB_s^j + b^i(Y_s)ds, \quad i = 1,\dots,N, \\ Y_0 = x \end{cases} \tag{1.20}$$

and set

$$\psi_l(t,x) = E_x[e^{-k_l\int_0^t V(Y_s)ds}], \quad l = 1,2. \tag{1.21}$$

Owing to our assumptions, ψ_l is a smooth function on $[0,\infty) \times R^N$ and satisfies the equation

$$\text{(1.22)} \qquad \begin{cases} \frac{\partial \psi_l}{\partial t} = \frac{1}{2} a^{ij} D_{ij} \psi_l + b^i D_i \psi_l - k_l V, \\ \psi_l(0,x) = 1 \end{cases}$$

for each $l = 1, 2$ (cf. [14], [16]). Put

$$u_l(t,x) = -\frac{1}{k_l} \log \psi_l(t,x), \quad l = 1,2,$$

which turns out to be the solution to the equation

$$\begin{cases} \frac{\partial u_l}{\partial t} = \frac{1}{2} a^{ij} D_{ij} u_l + b^i D_i u_l - \frac{k_l}{2} a^{ij} D_i u_l D_j u_l + V(x), \\ u_l(0,x) = 0 \end{cases}$$

for each $l = 1, 2$. Therefore we see that u_1 (resp., u_2) is a nonnegative subsolution (resp., supersolution) to the equation (1.15) because of assumption (1.16). We furthermore see that $u_1(t,x) \leq u_2(t,x)$ by using Hölder's inequality in Kac's representation (1.21). We shall find a nonnegative solution u to (1.15) such that $u_1 \leq u \leq u_2$. For that we first consider the following Dirichlet problem:

$$\text{(1.23)} \qquad \begin{cases} \frac{\partial u}{\partial t} = \frac{1}{2} a^{ij} D_{ij} u + Q(x, \nabla u) + V(x), \quad (0,T] \times B_R \equiv U_{T,R}, \\ u(t,x) = u_1(t,x), \quad \partial' U_{T,R}, \end{cases}$$

where $Q(x,p) = Q_0(x,p) + b^i p_i$, $\partial' U_{T,R} = \{(0,x); x \in \overline{B_R}\} \cup \{(t,x);\ 0 \leq t \leq T, x \in \partial B_R\}$, and $B_R = \{x \in R^N; |x| \leq R\}$. Owing to Theorem 6.1 in §6 of [17, Chap. V] we have the solution to (1.23). In fact, we consider the family of linear problems

$$\text{(1.23')} \qquad \begin{cases} Lv = (1-\tau) L u_1 + \tau(Q(x, \nabla \eta) + V), \quad x \in U_{T,R}, \\ v(t,x) = u_1(t,x), \quad x \in \partial' U_{T,R} \end{cases}$$

for $\eta \in C^{\frac{1}{2}+\frac{\alpha}{2}, 1+\alpha}$, where

$$Lv = \frac{\partial v}{\partial t} - \frac{1}{2} a^{ij} D_{ij} v.$$

These linear problems define an operator $\Phi(\eta; \tau)$ which associates each function $\eta \in C^{\frac{1}{2}+\frac{\alpha}{2}, 1+\alpha}$ with a solution v of (1.23'). The fixed points of ϕ for $\tau = 1$ are solutions of the problem (1.23). Let u^τ be one of the fixed points of the transformation $\Phi(\eta; \tau)$: $u^\tau = \Phi(u^\tau; \tau)$. Then u^τ is a solution of the nonlinear problem

$$\begin{cases} Lu^\tau = (1-\tau) L u_1 + \tau(Q(x, Du^\tau) + V), \quad x \in U_{T,R}, \\ u^\tau = u_1(t,x), \quad x \in \partial' U_{T,R}. \end{cases}$$

It can be seen that

$$\sup_{U_{T,R}} |u^\tau(t,x)| \leq K_1, \quad \tau \in [0,1]$$

by Theorem 2.9 in [17, Chap. I] and then we can obtain the estimate

$$\sup_{U_{T,R}} |\nabla u^\tau(t,x)| \leq K_2, \quad \tau \in [0,1]$$

in a way similar to the preceding discussion of Theorem 6.1 in [17, Chap. V], where K_2 is a constant depending only on K_1, ν, $\sup_{U_{T,R}} |a^{ij}(x)|$, $\sup_{B_R} |M_i(x)|$, $i = 1, 2$, k_1, k_2, $\sup_{B_R} |V(x)|$, $\sup_{B_R} |\nabla V|$, and $\sup_{\partial B_R} |\nabla u_1(x)|$. By (1.17), $Q(x,p)$ is uniformly Hölder continuous on $B_R \times \{|p| \leq K_2\}$, $\frac{\partial Q}{\partial p}$ is bounded on the set, and all other

assumptions in Theorem 6.1 in [17, Chap. 17] are satisfied. Thus we can obtain the following lemma.

LEMMA 1.2. *There exists a unique solution* $u \in C^{1+\frac{\alpha}{2},2+\alpha}(\overline{U}_{T,R})$ *to the Dirichlet problem* (1.23).

Now we give a probabilistic representation of the solution. Let $u_R(t,x)$ be the solution to (1.23) and set $J_R(t,x) = e^{\theta u(T-t,x)}$, $0 \le t \le T$. Then J_R satisfies the following equation on $[0,T) \times B_R \equiv \hat{U}_{T,R}$:

(1.24)
$$\begin{cases} \mathcal{L}J_R + \inf_{z\in Z}\{c^i(x,z)D_iJ_R + \theta(\phi(x,z)+V(x))J_R\} = 0, & (t,x) \in \hat{U}_{T,R}, \\ J_R(t,x) = e^{\theta u_1(T-t,x)}, & (t,x) \in \partial'\hat{U}_{T,R} \end{cases}$$

in the case that $\theta > 0$. If $\theta < 0$, replacing inf by sup in (1.24), we obtain the corresponding equation. By standard arguments using Ito's formula we obtain the following lemma.

LEMMA 1.3. *If* $\theta > 0$ *we have*

$$J_R(t,x) = \inf_{\tilde{\mathcal{A}}_{T-t}} E_x[e^{\theta\Phi_{(T-t)\wedge\tau}}\hat{\psi}_1(t+(T-t)\wedge\tau, X_{(T-t)\wedge\tau})], \tag{1.25}$$

where $\hat{\psi}_1(t,x) = e^{\theta u_1(T-t,x)}$, $\tau = \inf\{t; X_t \in \partial B_R\}$ *and* $\tilde{\mathcal{A}}_{T-t}$ *is the subset of* $\mathcal{A}_{T-t}$ *such that* z_s *is bounded.*

Proof. The inequality $\le$ can be seen by applying Ito's formula to $J_+(t+\cdot,\cdot)$ on the solution to the SDE (1.1). The converse inequality is proven by taking the ϵ-optimal Markovian strategy $z^\epsilon(t+\cdot,\cdot)$. It is possible since $Z \subset R^{N_1}$ is a separable metric space and c and ϕ are nice functions (cf. [16]). □

If $\theta < 0$, (1.25) holds by replacing inf by sup in the right-hand side.

Remark 1.3. From Lemma 1.3 it follows that $J_R(t,x) \ge J_R(t',x)$, $t < t'$ for $\theta > 0$ and accordingly

$$u_R(t,x) \le u_R(t',x), \quad t < t'. \tag{1.26}$$

In fact, we see that $\hat{\psi}_1(t+(T-t)\wedge\tau, X_{(T-t)\wedge\tau}) \ge \hat{\psi}_1(t'+(T-t')\wedge\tau, X_{(T-t)\wedge\tau})$ for $t < t'$. It is obvious that $e^{\theta\Phi_{(T-t)\wedge\tau}} \ge e^{\theta\Phi_{(T-t')\wedge\tau}}$ and we obtain $J_R(t,x) \ge J_R(t',x)$, $t < t'$. In the case where $\theta < 0$, $J_R(t,x) \le J_R(t',x)$, $t < t'$ holds and implies (1.26).

1.3. Gradient estimate. We first prepare a lemma on linear algebra.

LEMMA 1.4. *Let* A *be a symmetric nonnegative definite* $N \times N$*-matrix with the maximum eigenvalue* λ *and* B *a symmetric matrix. Then we have*

$$\{\mathrm{tr}(AB)\}^2 \le N\lambda\,\mathrm{tr}(AB^2).$$

Proof. By taking a orthogonal matrix T, diagonalize the matrix A

$$TAT^* = \begin{pmatrix} \lambda_1 & 0 & \dots & 0 \\ 0 & \lambda_2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \lambda_N \end{pmatrix} \equiv \Lambda$$

with $0 \le \lambda_1 \le \lambda_2, \dots, \lambda_N \le \lambda$. Here T^* stands for the transposed matrix of T. We then have $\mathrm{tr}(AB) = \sum_{i=1}^N \lambda_i b_{ii}$, where $b_{ij} = (TBT^*)_{ij}$. Therefore

$$\{\mathrm{tr}(AB)\}^2 = \sum_{i=1}^N \lambda_i^2 b_{ii}^2 + \sum_{i,j=1, i\neq j}^N \lambda_1\lambda_j b_{ii}b_{jj}. \tag{1.27}$$

On the other hand

$$\operatorname{tr}((AB)^2) = \sum_{i=1}^{N} \lambda_1^2 b_{ii}^2 + \sum_{i \neq j} \lambda_i \lambda_j b_{ij}^2,$$

since TBT^* is symmetric. Thus we obtain

$$\begin{aligned} N \operatorname{tr}((AB)^2) - \{\operatorname{tr}(AB)\}^2 &\geq (N-1) \sum_{i=1}^{N} \lambda_1^2 b_{ii}^2 - \sum_{i \neq j} \lambda_i \lambda_j b_{ii} b_{jj} \\ &= \frac{1}{2} \sum_{i \neq j} (\lambda_i b_{ii} - \lambda_j b_{jj})^2 \geq 0. \end{aligned}$$

Hence we conclude that

$$\{\operatorname{tr}(AB)\}^2 \leq N \operatorname{tr}((AB)^2) \leq N\lambda \sum_{i,j=1}^{N} \lambda_i b_{ij}^2 = N\lambda \operatorname{tr}(AB^2). \qquad \square$$

The following lemma plays an essential role in the following arguments. Similar kinds of estimates have been studied by Li and Yau [18] to obtain parabolic Harnack's inequalities for positive solutions to heat equations (cf. also Davies [5], Nagai [22]).

LEMMA 1.5. *Let u_R be the solution to* (1.23). *Then we have the following estimate*:

$$t\left(|\nabla u_R|^2 + \gamma \frac{\partial u_R}{\partial t}\right) \leq tK_{r,\gamma} + L_{r,\gamma}, \quad [0,T] \times B_r \tag{1.28}$$

for $r < \frac{1}{2}R$, $\gamma > \frac{2}{k_2 \nu}$, where $K_{r,\gamma}$ and $L_{r,\gamma}$ are the constants independent of t, R, and T.

Proof. Let us take a point $\alpha \in B_r$, $0 < r < \frac{1}{2}R$ and a cut-off function $\tau(x)$ such that

$$\begin{aligned} &0 \leq \tau(x) \leq \tau(\alpha) = 1, \quad a^{ij} D_i \tau D_j \tau \leq \frac{c_1 \tau}{r^2}, \quad a^{ij} D_{ij} \tau \geq -\frac{2c_2}{r^2}, \\ &\tau(x) = 0, \quad x \notin B_r(\alpha) = \{x; |x - \alpha| < r\}. \end{aligned} \tag{1.29}$$

In fact, set

$$\tau(x) = \begin{cases} (\frac{|x-\alpha|^2}{r^2} - 1)^2, & |x - \alpha| \leq r, \\ 0, & |x - \alpha| > 0. \end{cases} \tag{1.30}$$

Then it satisfies (1.29). Set

$$F(t,x) = t\left(|\nabla u|^2 + \gamma \frac{\partial u}{\partial t}\right), \quad u = u_R. \tag{1.31}$$

Then $F(t,x) \geq 0$ since $\frac{\partial u}{\partial t} \geq 0$ by (1.26). Let us take a maximum point (s,x) of the function τF in $[0,t] \times B_r(\alpha)$. Then it is obvious that $s > 0$. To see (1.28) it suffices to prove that

$$(\tau F)(s,x) \leq sK_{r,\gamma} + L_{r,\gamma} \tag{1.32}$$

for some constants $K_{r,\gamma}$ and $L_{r,\gamma}$ independent of t, T, and R. In fact, from (1.32) it follows that

$$\begin{aligned} F(t,\alpha) = \tau(\alpha) F(t,\alpha) &\leq \tau(x) F(s,x) \\ &\leq sK_{r,\gamma} + L_{r,\gamma} \leq tK_{r,\gamma} + L_{r,\gamma} \end{aligned}$$

for each $(t,\alpha) \in [0,T] \times B_r$. We note that at the point (s,x)

$$\nabla(\tau F) = 0, \quad a^{ij} D_{ij}(\tau F) \le 0, \quad \frac{\partial F}{\partial s} \ge 0. \tag{1.33}$$

Therefore we have

$$\begin{aligned} \frac{\tau F}{s} &\ge \frac{1}{2} a^{ij} D_{ij}(\tau F) + \frac{\partial Q}{\partial p_i}(x, \nabla u) D_i(\tau F) - \tau \frac{\partial F}{\partial s} + \frac{\tau F}{s} \\ &= \tau \left(\frac{1}{2} a^{ij} D_{ij} F + \frac{\partial Q}{\partial p_i}(x, \nabla u) D_i F - \frac{\partial F}{\partial s} + \frac{F}{s} \right) \\ &\quad \frac{1}{2}(a^{ij} D_{ij} \tau) F - a^{ij} \frac{D_i \tau D_j \tau}{\tau} F + \left(\frac{\partial Q}{\partial p_i}(x, \nabla u) D_i \tau \right) F. \end{aligned} \tag{1.34}$$

Here we have used the equality $\nabla F = -F \frac{\nabla \tau}{\tau}$, which follows from (1.33). Put

$$\Gamma(F) = \frac{1}{2} a^{ij} D_{ij} F + \frac{\partial Q}{\partial p_i}(x, \nabla u) D_i F - \frac{\partial F}{\partial s} + \frac{F}{s}. \tag{1.35}$$

Then from (1.29) and (1.34) it follows that

$$\frac{\tau F}{s} \ge \tau \Gamma(F) - \frac{c_2}{r^2} F - \frac{c_1}{r^2} F - \frac{c_3 \sqrt{\tau}}{r} \left| \frac{\partial Q}{\partial p}(x, \nabla u) \right| F. \tag{1.36}$$

Set $G = |\nabla u|^2$ and $H = s \frac{\partial u}{\partial s}$. Then we have

$$\Gamma(H) = 0. \tag{1.37}$$

In fact,

$$\begin{aligned} \frac{\partial H}{\partial s} &= \frac{\partial u}{\partial s} + s \frac{\partial^2 u}{\partial s^2} \\ &= \frac{H}{s} + \frac{1}{2} a^{ij} D_{ij} H + \frac{\partial Q}{\partial p_i}(x, \nabla u) D_i H. \end{aligned}$$

Thus we obtain

$$\begin{aligned} \Gamma(F) &= \frac{s}{2} a^{ij} D_{ij} G + s \frac{\partial Q}{\partial p_i}(x, \nabla u) D_i G - s \frac{\partial G}{\partial s} \\ &= s a^{ij} D_{ki} u D_{kj} u + s a^{ij} D_k D_{ijk} u \\ &\quad + 2s \frac{\partial Q}{\partial p_j}(x, \nabla u) D_i u D_{ij} u - 2s D_i u D_{is} u. \end{aligned} \tag{1.38}$$

By taking a derivative in equation (1.23) with respect to x_k, we have

$$\begin{aligned} a^{ij} D_{ijk} u &= 2 D_{ks} u - D_k a^{ij} D_{ij} u - 2 \frac{\partial Q}{\partial x_k}(x, \nabla u) \\ &\quad - 2 \frac{\partial Q}{\partial p_j}(x, \nabla u) D_{kj} u - 2 D_k V. \end{aligned} \tag{1.39}$$

Therefore

$$\begin{aligned} \Gamma(F) &= s a^{ij} D_{ki} u D_{kj} u - s D_k u D_k a^{ij} D_{ij} u \\ &\quad - 2s D_k u \frac{\partial Q}{\partial x_k}(x, \nabla u) - 2s D_k u D_k V. \end{aligned} \tag{1.40}$$

Since

$$D_k u(D_k a^{ij})D_{ij}u \le \frac{\epsilon}{2}(D_{ij}u)^2 + \frac{1}{2\epsilon}(D_k u)^2(D_k a^{ij})^2$$

for each i, j, k and $\epsilon > 0$, we obtain from (1.40)

$$\begin{aligned}\Gamma(F) \ge{}& s a^{ij} D_{ki}u D_{kj}u - \frac{Ns\epsilon}{2}\sum_{ij}(D_{ij}u)^2 \\ &- \frac{1}{2\epsilon}\sum_{ij}(D_k u)^2(D_k a^{ij})^2 - 2s|\nabla u|\left|\frac{\partial Q}{\partial x}(x,\nabla u)\right| - 2s|\nabla u||\nabla V|.\end{aligned} \tag{1.41}$$

Taking ϵ such that $\nu \ge N\epsilon$ and utilizing Lemma 1.4, we have

$$\begin{aligned}\Gamma(F) \ge{}& \frac{s}{2N\lambda_r}(a^{ij}D_{ij}u)^2 - \frac{N^2K_r}{2\epsilon}|\nabla u|^2 \\ &- 2s|\nabla u|\left|\frac{\partial Q}{\partial x}(x,\nabla u)\right| - 2s|\nabla u||\nabla V|,\end{aligned} \tag{1.42}$$

where λ_r is the upper bound of the largest eigenvalues of the matrix $a^{ij}(x)$ in B_r and K_r is the constant such that $|\nabla a^{ij}| \le K_r$. From (1.23) and (1.42) it follows that

$$\begin{aligned}\Gamma(F) \ge{}& \frac{2s}{N\lambda_r}\left(\frac{\partial u}{\partial s} - Q(x,\nabla u) - V\right)^2 \\ &- \frac{sN^2K_r}{2\epsilon}|\nabla u|^2 - 2s|\nabla u|\left|\frac{\partial Q}{\partial x}(x,\nabla u)\right| - 2s|\nabla u||\nabla V|.\end{aligned} \tag{1.43}$$

Note that from (1.16), (1.17), and (1.13) it follows that

$$-\frac{k_1'}{2}a^{ij}p_ip_j - K(x) \le Q(x,p) \le -\frac{k_2'}{2}a^{ij}p_ip_j + K(x), \tag{1.44}$$

$$\left|\frac{\partial Q}{\partial x}(x,p)\right| \le K_1|p|^2 + K_2, \tag{1.45}$$

$$\left|\frac{\partial Q}{\partial p}(x,p)\right| \le K_1|p| + K_2, \tag{1.46}$$

for some locally bounded functions K, K_1, and K_2 and some positive constants k_1' and k_2'. Since $\frac{\partial u}{\partial s} = \frac{F}{s\gamma} - \frac{G}{\gamma}$, we have

$$\begin{aligned}-\frac{k_1'}{2}a^{ij}D_iuD_ju - 2K - \frac{F}{s\gamma} + \frac{G}{\gamma} &\le Q(x,\nabla u) - \frac{\partial u}{\partial s} - K \\ &\le -\frac{k_2'}{2}a^{ij}D_iuD_ju - \frac{F}{s\gamma} + \frac{G}{\gamma}.\end{aligned}$$

Note that $\frac{k_2\nu}{2} - \frac{1}{\gamma} > 0$ and k_2' can be taken as $\frac{k_2'\nu}{2} - \frac{1}{\gamma} > 0$. Therefore, setting $G = \beta F$, we obtain

$$\left(Q - \frac{\partial u}{\partial s} - K\right)^2 \ge \left(\left(k - \frac{1}{\gamma}\right)\beta + \frac{1}{s\gamma}\right)^2 F^2, \quad k = \frac{k_2'\nu}{2}. \tag{1.47}$$

Thus from (1.36), (1.43), and (1.47) we obtain

$$\frac{\tau F}{s} \geq \frac{2s\tau}{N\lambda_r}\left\{\left(\frac{1}{s\gamma}+\left(k-\frac{1}{\gamma}\right)\beta\right)^2 F^2 - 2(K+V)\left(\frac{1}{s\gamma}+\left(k'-\frac{1}{\gamma}\right)\beta\right)F - K'\right\}$$

(1.48)

$$\begin{aligned}&- \frac{s\tau N^2 K_r}{\epsilon}|\nabla u|^2 - 2s\tau|\nabla u|\left|\frac{\partial Q}{\partial x}(x,\nabla u)\right| - 2s\tau|\nabla u||\nabla V| \\ &- \frac{c_1+c_2}{r^2}F - \frac{c_3\sqrt{\tau}}{r}\left|\frac{\partial Q}{\partial p}(x,\nabla u)\right|F,\end{aligned}$$

where $k' = \frac{k_1\lambda_r}{2}$ and $K' = 4K(K+V)$. Therefore, using (1.45) and (1.46), we have

$$\begin{aligned}\frac{\tau F}{s} &\geq \frac{2s\tau}{N\lambda_r}\left\{\left(\frac{1}{s\gamma}+\left(k-\frac{1}{\gamma}\right)\beta\right)^2 F^2 - 2(K+V)\left(\frac{1}{s\gamma}+\left(k'-\frac{1}{\gamma}\right)\beta\right)F - K'\right\} \\ &- \frac{s\tau N^2 K_r}{\epsilon}\beta F - 2s\tau K_1\beta^{\frac{3}{2}}F^{\frac{3}{2}} - 2s\tau K_2\beta^{\frac{1}{2}}F^{\frac{1}{2}} - 2s\tau|\nabla V|\beta^{\frac{1}{2}}F^{\frac{1}{2}} \\ &- \frac{c_1+c_2}{r^2}F - \frac{c_2\sqrt{\tau}}{r}K_1\beta^{\frac{1}{2}}F^{\frac{3}{2}} - \frac{c_3\sqrt{\tau}}{r}K_2 F.\end{aligned}$$

Now we can assume that $F(s,x) \geq K'(x)s$ and $F(s,x) \geq s(K_2(x)+|\nabla V|)$. In fact, otherwise (1.32) holds already. Therefore

$$\begin{aligned}\frac{F}{s} \geq \frac{\tau F}{s} &\geq \frac{2s\tau}{N\lambda_r}\left(\frac{1}{s\gamma}+\left(k-\frac{1}{\gamma}\right)\beta\right)^2 F^2 - \frac{4s\tau}{N\lambda_r}(K+V)\left(\frac{1}{s\gamma}+\left(k'-\frac{1}{\gamma}\right)\beta\right)F \\ &- \frac{2\tau F}{N\lambda_r} - \frac{s\tau N^2 K_r}{\epsilon}\beta F - 2s\tau K_1\beta^{\frac{3}{2}}F^{\frac{3}{2}} - 2\beta^{\frac{1}{2}}\tau F^{\frac{3}{2}} \\ &- \frac{c_1+c_2}{r^2}F - \frac{c_3\sqrt{\tau}}{r}K_1\beta^{\frac{1}{2}}F^{\frac{3}{2}} - \frac{c_3\sqrt{\tau}}{r}K_2 F.\end{aligned}$$

Multiplying by $\frac{s}{F}$, we obtain

$$\begin{aligned}&1 + \frac{4s^2}{N\lambda_r}(K+V)\left(\frac{1}{s\gamma}+\left(k'-\frac{1}{\gamma}\right)\beta\right) + \frac{2s}{N\lambda_r} + \frac{N^2K_r\beta}{\epsilon}s^2 \\ &+ \frac{c_1+c_2}{r^2}s + \frac{c_3K_2}{r}s \geq \frac{2s^2}{N\lambda_r}\left(\frac{1}{s\gamma}+\left(k-\frac{1}{\gamma}\right)\beta\right)^2\tau F \\ &- 2s^2K_1\beta^{\frac{3}{2}}\tau^{\frac{1}{2}}F^{\frac{1}{2}} - \left(2+\frac{c_3K_1}{r}\right)\beta^{\frac{1}{2}}s\tau^{\frac{1}{2}}F^{\frac{1}{2}}.\end{aligned} \tag{1.49}$$

Let us set $X = \tau^{\frac{1}{2}}F^{\frac{1}{2}}$ and $k\gamma - 1 = \delta$. Then the right-hand side of (1.49)

$$\begin{aligned}&= \frac{2}{N\lambda_r\gamma^2}(1+\delta\beta s)^2X^2 - \beta^{\frac{1}{2}}s(2K_1\beta s + c_r)X, \qquad c_r = 2 + \frac{c_3K_1}{r} \\ &= \frac{2}{N\lambda_r\gamma^2}(1+\delta\beta s)\left(1+\frac{\delta\beta s}{2}\right)X^2 + \frac{\delta\beta(1+\delta\beta s)}{N\lambda_r\gamma^2}X^2 - \beta^{\frac{1}{2}}s(2K_1\beta s + c_r)X \\ &\geq \frac{2}{N\lambda_r\gamma^2}(1+\delta\beta s)\left(1+\frac{\delta\beta s}{2}\right)X^2 - \frac{sN\lambda_r\gamma^2}{(1+\delta\beta s)\delta}(2K_1\beta s + c_r)^2,\end{aligned}$$

where $c_r = 2 + \frac{c_3 K_1}{r}$. Hence we obtain

$$X^2 \le \frac{N\lambda_r\gamma^2}{2(1+\delta\beta s)(1+\frac{\delta\beta s}{2})} + \frac{(N\lambda_r\gamma^2)^2}{2\delta}\frac{(2K_1\beta s + c_r)^2}{(1+\delta\beta s)(1+\frac{\delta\beta s}{2})}s$$
$$+ 2(K+V)\frac{(1+(k'\gamma-1)\beta s)}{(1+\delta\beta s)(1+\frac{\delta\beta s}{2})}s + \frac{\gamma^2 s}{(1+\delta\beta s)(1+\frac{\delta\beta s}{2})}$$
$$+ \frac{N^3\lambda_r\gamma^2 K_r}{2\epsilon}\frac{\beta s}{(1+\delta\beta s)(1+\frac{\delta\beta s}{2})}s + \frac{N\lambda_r\gamma^2(c_1+c_2+c_3K_2r)}{2r^2(1+\delta\beta s)(1+\frac{\delta\beta s}{2})}s.$$

Since $\frac{1}{(1+\delta\beta s)(1+\frac{\delta\beta s}{2})}$, $\frac{(c_r+2K_1\beta s)^2}{(1+\delta\beta s)(1+\frac{\delta\beta s}{2})}$, $\frac{1+(k'\gamma-1)\beta s}{(1+\delta\beta s)(1+\frac{\delta\beta s}{2})}$, and $\frac{\beta s}{(1+\delta\beta s)(1+\frac{\delta\beta s}{2})}$ are dominated by a constant independent of β and s, we conclude that

$$X^2 \le sK_{r,\gamma} + L_{r,\gamma}$$

for some constants $L_{r,\gamma}$ and $L_{r,\gamma}$. □

1.4. Proof of Theorem 1.1. According to [17] we formulate a generalized solution to the equation

$$\frac{\partial u}{\partial t} = \frac{1}{2}a^{ij}D_{ij}u + Q(x,\nabla u) + V(x), \quad (0,T)\times R^N. \tag{1.50}$$

Take ϵ and T_1 such that $0 < \epsilon < T_1 < T$ and $r > 0$ and define $W_2^{1,1}(U^\epsilon_{T_1,r})$ as the Hilbert space with an inner product

$$(u,v) = \iint_{U^\epsilon_{T_1,r}} \left(uv + \nabla u\cdot\nabla v + \frac{\partial u}{\partial t}\frac{\partial v}{\partial t}\right) dxdt, \tag{1.51}$$

where $U^\epsilon_{T_1,r} = (\epsilon, T_1)\times B_r$. Let us set

$$V_2^{1,0} = L^2(\epsilon, T_1; H^1(B_r)) \cap C([\epsilon, T_1]; L^2(B_r)).$$

The norm of the Banach space $V_2^{1,0}$ is defined by

$$\|v\| = \max_{\epsilon\le t\le T_1}\|v(t,x)\|_{2,B_r} + \|\nabla v\|_{2,U^\epsilon_{T_1,\epsilon}},$$

where $\|v\|_{2,B} = \int_B |v(t,x)|^2 dx$. We say that u is a generalized solution to (1.50) if, for each ϵ, T_1, and r, u belongs to $V_2^{1,0}(U^\epsilon_{T_1,r})$ and satisfies

$$\iint_{U^\epsilon_{T_1,r}} u\frac{\partial\eta}{\partial t}dxdt - \frac{1}{2}\iint_{U^\epsilon_{T_1,r}} a^{ij}D_iuD_j\eta dxdt - \frac{1}{2}\iint_{U^\epsilon_{T_1,r}}\frac{\partial a^{ij}}{\partial x^j}D_iu\eta dxdt$$
$$+ \iint_{U^\epsilon_{T_1,r}} Q(x,\nabla u)\eta dxdt + \iint_{U^\epsilon_{T_1,r}} V(x)\eta dxdt = 0 \tag{1.52}$$

for each $\eta \in \overset{\circ}{W}{}_2^{1,1}(U^\epsilon_{T_1,r})$ such that $\eta(\epsilon,x) = \eta(T_1,x) = 0$. Now we have the following lemma.

LEMMA 1.6. *Let $u_R = u(t,x;T,R)$ be a solution to (1.23). Then for each $r > 0$, ϵ, and T_1 such that $0 < \epsilon < T_1 < T$, there exists $\{R_n\} \subset R_+$ such that u_{R_n} converges weakly in $W_2^{1,1}(U^\epsilon_{T_1,r})$ to $u \in W_2^{1,1}(U^\epsilon_{T_1,r})$, which satisfies (1.52).*

Proof. Let u_R be a solution to (1.23) and take $r' > 0$, ϵ' and T_1' such that $r' > r$, $0 < \epsilon' < \epsilon < T_1 < T_1' < T$. Then by Lemma 1.5 and (1.26) we see that $\{u_R\}_{R>2r'}$ is a bounded subset of the Hilbert space $W_2^{1,1}(U^{\epsilon'}_{T_1',r'})$ and has a subsequence

$\{u_{R_n}\}$ converging weakly in $W_2^{1,1}(U^{\epsilon'}_{T_1',r'})$ and strongly in $L^2(U^{\epsilon'}_{T_1',r'})$ to some function $u \in W_2^{1,1}(U^{\epsilon'}_{T_1',r'})$. To see that this u satisfies (1.52) we shall prove that ∇u_{R_n} converges to ∇u strongly in $L^2(U^{\epsilon}_{T_1,r})$. Take a function $s(t,x) \in C_0^\infty(U^{\epsilon'}_{T_1',r'})$ such that $s(t,x) = 1$ on $U^{\epsilon}_{T_1,r}$. Then, by taking $s(u_n - u)$ as a test function, we have

$$
\begin{aligned}
0 = &\iint_{U^{\epsilon'}_{T_1',r'}} u_n \frac{\partial s(u_n-u)}{\partial t} dxdt - \frac{1}{2}\iint_{U^{\epsilon'}_{T_1',r'}} a^{ij} D_i u_n D_j (s(u_n-u))dxdt \\
&- \frac{1}{2}\iint_{U^{\epsilon'}_{T_1',r'}} \frac{\partial a^{ij}}{\partial x^j} D_i u_n s(u_n-u)dxdt + \iint_{U^{\epsilon'}_{T_1',r'}} Q(x,\nabla u_n)s(u_n-u)dxdt \\
&+ \iint_{U^{\epsilon'}_{T_1',r'}} V(x)s(u_n-u)dxdt,
\end{aligned} \tag{1.53}
$$

where $u_n = u_{R_n}$. Therefore we deduce that

$$
\begin{aligned}
&\frac{1}{2}\iint_{U^{\epsilon'}_{T_1',r'}} a^{ij} D_i(u_n-u) D_j(u_n-u) s dxdt \\
&= \iint_{U^{\epsilon'}_{T_1',r'}} \frac{\partial u_n}{\partial t} s(u_n-u)dxdt - \frac{1}{2}\iint_{U^{\epsilon'}_{T_1',r'}} a^{ij} D_i u D_j(u_n-u) s dxdt \\
&- \iint_{U^{\epsilon'}_{T_1',r'}} a^{ij} D_i u_n D_j s (u_n-u)dxdt - \frac{1}{2}\iint_{U^{\epsilon'}_{T_1',r'}} \frac{\partial a^{ij}}{\partial x^j} D_i u_n (u_n-u) s dxdt \\
&+ \iint_{U^{\epsilon'}_{T_1',r'}} Q(x,\nabla u_n)s(u_n-u)dxdt + \iint_{U^{\epsilon'}_{T_1',r'}} V(x)s(u_n-u)dxdt.
\end{aligned} \tag{1.54}
$$

It is easy to see that the right-hand side of (1.54) converges to 0 as $n \to \infty$, by Lemma 1.5, (1.26), and (1.44). Thus, by using uniform ellipticity of a^{ij}, we can prove that ∇u_n converges to ∇u strongly in $L^2(U^{\epsilon}_{T_1,r})$ and also almost everywhere (a.e.) by taking a subsequence, if necessary. Hence we see that u satisfies (1.52). □

Because of Lemma 1.6 we see that there exists a generalized nonnegative solution $u \in W^{1,1}_{2,loc}((0,T)\times R^N)$. Moreover regularity theorems for parabolic equations imply that $u \in C^{1+\frac{\alpha}{2},2+\alpha}((0,T)\times R^N)$, since Q satisfies (1.44) and $|\nabla u| \in L^\infty_{loc}$ (cf. Theorem 12.1 and Theorem 12.2 in §12 of [17, Chap. III]). We furthermore note that the solution u satisfies (1.18) and (1.28) for each r.

Now we prepare two lemmas to see that u is continuous on $[0,T)\times R^N$ and that $u(0,x) = 0$.

LEMMA 1.7. *Let u_1 and u_2 be functions defined by* (1.21) *and u_R the solution to* (1.23). *Then we have*

$$
u_1(t,x) \le u_R(t,x) \le u_2(t,x). \tag{1.55}
$$

Proof. These inequalities follow from the maximum principle. In fact, let us assume that $u_1(t_0,x_0) > u_R(t_0,x_0)$ for some point $(t_0,x_0) \in \overline{U}_{T,R}$. Set

$$
\rho(t,x) = e^{-\lambda t}(u_1(t,x) - u_R(t,x)), \quad \lambda > 0
$$

and take a maximum point (t_1, x_1) of $\rho(t,x)$ in $\overline{U}_{T,R}$

$$\rho(t_1,x_1) = \sup_{\overline{U}_{T,R}} \rho(t,x) > 0. \tag{1.56}$$

Then it is obvious that $t_1 > 0$ and that $x_1 \in B_R$ because $u_1 = u_R$ on $\partial' U_{T,R}$. At (t_1, x_1) we have

$$\frac{\partial \rho}{\partial t} \geq 0, \quad \nabla \rho = 0, \quad a^{ij} D_{ij} \rho \leq 0. \tag{1.57}$$

If we set $\bar{u}_1 = e^{-\lambda t} u_1$ and $\bar{u}_R = e^{-\lambda t}$ then we have

$$\frac{\partial \bar{u}_R}{\partial t} = \frac{1}{2} a^{ij} D_{ij} \bar{u}_R + e^{-\lambda t} Q(x, e^{\lambda t} \nabla \bar{u}_R) + e^{-\lambda t} V - \lambda \bar{u}_R$$

and

$$\frac{\partial \bar{u}_1}{\partial t} \leq \frac{1}{2} a^{ij} D_{ij} \bar{u}_1 + e^{-\lambda t} Q(x, e^{\lambda t} \nabla \bar{u}_1) + e^{-\lambda t} V - \lambda u_1.$$

$D\bar{u}_1(t_1,x_1) = D\bar{u}_R(t_1,x_1)$ by (1.57) and $Q(x_1, e^{\lambda t}\nabla \bar{u}_R) = Q(x_1, e^{\lambda t}\nabla \bar{u}_1)$. Therefore we obtain

$$\frac{\partial}{\partial t}(\bar{u}_1 - \bar{u}_R) \leq \frac{1}{2} a^{ij} D_{ij}(\bar{u}_1 - \bar{u}_R) - \lambda(\bar{u}_1 - \bar{u}_R).$$

Hence it follows from (1.57) that $0 \leq -\lambda \rho(t_1, x_1)$, which contradicts (1.56). The other inequality is proven in a similar way since $u_R(t,x) \leq u_2(t,x)$ on $\partial' U_{T,R}$. □

LEMMA 1.8. *Let u_R be a solution to* (1.23). *Then $\{u_R\}_{R>3r}$ are equicontinuous on $[0,T) \times B_r$ for each r.*

Proof. For each $\epsilon > 0$ there exists $\delta > 0$ such that $0 \leq u_2(t,x) < \epsilon$, $t < 2\delta$, $x \in B_r$. Take (t_1, x_1) and (t_2, x_2) such that $|x_1 - x_2| + |t_1 - t_2|^{\frac{1}{2}} < \delta_1$, $(t_i, x_i) \in U_{T,r}$, $i = 1, 2$, where $\delta_1 = \delta \wedge \epsilon^2$. In the case where $t_1 < \frac{\delta}{2}$ or $t_2 < \frac{\delta}{2}$ we have

$$|u_R(t_1,x_1) - u_R(t_2,x_2)| \leq 2\epsilon,$$

because $|t_1 - t_2|^{\frac{1}{2}} < \delta_1$ implies $t_1, t_2 < 2\delta$. If $t_1, t_2 > \frac{\delta}{2}$ it follows from Lemma 1.5 that

$$|u_R(t_1,x_1) - u_R(t_2,x_2)| \leq |u_R(t_1,x_1) - u_R(t_1,x_2)| + |u(t_1,x_2) - u(t_2,x_2)| \leq c_r \epsilon, \tag{1.58}$$

where c_r is a constant independent of R. In fact, by Lemma 1.5 and (1.26) we have

$$|\nabla u_R(t,x)|^2, \left| \frac{\partial u_R}{\partial t}(t,x) \right| \leq \frac{c_r'}{\delta}, \quad t \geq \frac{\delta}{2}, \, x \in B_r$$

and the mean value theorem implies (1.58). Thus we conclude this lemma. □

Let u_R be a solution to (1.23). Then because of Lemmas 1.7 and 1.8 there exists a subsequence $\{u_{R_n}\} \subset \{u_R\}$ such that u_{R_n} converges uniformly to a solution to (1.50) on each compact subset of $[0,T) \times R^N$ and we see that $u \in C([0,T) \times R^N)$ and $u(0,x) = 0$. Thus we find a nonnegative solution u to (1.15) on $[0,T) \times R^N$. The estimate (1.28) is independent of T and we can obtain a nonnegative solution u to (1.15) on $[0,\infty) \times R^N$ in a similar way as we did above. The solution also satisfies $\frac{\partial u}{\partial t} \geq 0$ and (1.28) on $(0,\infty) \times B_r$ for each r. Hence we complete the proof of Theorem 1.1.

1.5. Examples.

Example 1. Let $Z = R^N$, $c^i(x,z) = B^i_k(x) z^k$, and $\phi(x,z) = \frac{1}{2} S_{ij}(x) z^i z^j$, where $(S_{ij}(x))$ is a symmetric matrix such that $S_{ij}(x)\xi^i\xi^j \geq \mu|\xi|^2$, $\forall \xi \in R^N$, $\mu > 0$, and

each component is a smooth function. Then

$$
\begin{aligned}
Q_0(x,p) &= \frac{\theta}{2}a^{ij}p_ip_j + \inf_{z\in R^N}\left\{B_k^i z^k p_i + \frac{1}{2}S_{ij}z^i z^j\right\} \\
&= \frac{\theta}{2}a^{ij}p_ip_j - \frac{1}{2}(BS^{-1}B^*)p_ip_j.
\end{aligned} \tag{1.59}
$$

We assume that $B_k^i(x)$ is a bounded function for each i and k and

$$
k_2 a^{ij}p_ip_j \le ((BS^{-1}B^*) - \theta a)^{ij}p_ip_j, \quad \forall p \in R^N \tag{1.60}
$$

for some positive constant k_2. Then (1.16) and (1.17) are satisfied. Let $\lambda(x)$ be the smallest eigenvalue of the matrix $BS^{-1}B^*$ and $\bar{\nu}(x)$ the largest one of a. If

$$
\theta < \inf_x \frac{\lambda(x)}{\bar{\nu}(x)}, \tag{1.61}
$$

then (1.60) is satisfied. We moreover assume that (σ^{ij}), (b^i), and V satisfy the assumptions of Theorem 1.1. Then Theorem 1.1 applies to this example and includes the case of LEQG.

Example 2. Let us specialize the above example. We moreover assume that $BS^{-1}B^* = ka$ for some positive constant k such that

$$
\theta < k.
$$

It is then obvious that this example satisfies all assumptions of Theorem 1.1. In this case equation (1.15) is reduced to

$$
\begin{cases}
\frac{\partial u}{\partial t} = \frac{1}{2}a^{ij}D_{ij}u + b^iD_iu - \frac{k-\theta}{2}a^{ij}D_iuD_ju + V, \\
u(0,x) = 0.
\end{cases} \tag{1.62}
$$

Let Y_t be a solution to the SDE (1.20) and set

$$
u(t,x) = -\frac{1}{k-\theta}\log E[e^{-\int_0^t (k-\theta)V(Y_s)ds}]. \tag{1.63}
$$

Then $u(t,x)$ defined by (1.63) turns out to be a unique nonnegative solution to (1.62). The uniqueness follows from that of the bounded solution to the linear equation (1.22).

Example 3. We specialize Example 1 to the LEQG case, namely the case where $b^i(x) = A_j^i x^j$, $V(x) = \frac{1}{2}R_{ij}x^ix^j$, and σ_j^i, A_j^i, B_k^i, S_{ij}, and R_{ij} are constant matrices. Then (1.12) reads

$$
\begin{cases}
\frac{\partial w}{\partial t} + \frac{1}{2}a^{ij}D_{ij}w + A_j^i x^j D_i w + \left\{\frac{\theta}{2}a^{ij} - \frac{(BS^{-1}B^*)^{ij}}{2}\right\}D_iwD_jw \\
\qquad + \frac{1}{2}R_{ij}x^ix^j = 0, \\
w(T,x) = 0,
\end{cases}
$$

which has the following nonnegative solution w:

$$
w(t,x) = \frac{1}{2}P_{ij}(t)x^ix^j + G(t),
$$

where $P(t)$ and $G(t)$ satisfy the ordinary differential equations

$$
\begin{cases}
\frac{dP}{dt} + R + PA + A^*P - P(BS^{-1}B^* - \theta a)P = 0, \\
P(T) = 0
\end{cases}
$$

and

$$\begin{cases} \frac{dG}{dt} + \mathrm{tr}(Pa) = 0, \\ G(T) = 0. \end{cases}$$

Example 4. Let $Z = R^1$, $c(x,z) = z$, $\phi(x,z) = \phi(z) = c_1 z^2 + c_2 z \arctan z$, $c_1 > c_2 > 0$, and $\nu_1 \le a(x) \le \nu_2$. Then $Q_0(x,p) = \frac{\theta}{2} a p^2 + Q_1(p)$, where

$$Q_1(p) = \inf_{z \in R^1} \{zp + c_1 z^2 + c_2 z \arctan z\}.$$

Note that $\phi(z)$ is convex and $0 < 2c_1 \le \frac{d^2\phi(z)}{dz^2} \le 2(c_1 + c_2)$. Let $q(p)$ be an inverse function of $\phi'(z)$. Then we have $\frac{1}{2(c_1+c_2)} \le q'(p) \le \frac{1}{2c_1}$. We can see that

$$Q_1(p) = pq(-p) + c_1 q(-p)^2 + c_2 q(-p) \arctan q(-p)$$

and that it satisfies

$$-\frac{c_1 + 2c_2}{4c_1(c_1 + c_2)} p^2 \le Q_1(p) \le -\frac{c_1 - c_2}{4c_1(c_1 + c_2)} p^2.$$

Therefore it is easy to see that if

$$\theta < \frac{c_1 - c_2}{2c_1(c_1 + c_2)\nu_2},$$

then (1.16) and (1.17) are satisfied. We moreover assume that σ, b, and V satisfy the other assumptions of Theorem 1.1, and so it applies.

Example 5. Let $Z = R^1$, $c(x,z) = z + c_1 \arctan z$, $\phi(x,z) = c_2 z^2$, $0 < c_1 < 1$, $c_2 > 0$, and $\nu_1 \le a(x) \le \nu_2$. Then we set

$$Q_1(p) = \inf_{z \in R^1} \{zp + c_1 \arctan z + c_2 z^2\} \equiv \inf_z s(z;p).$$

Note that $s'(z) = (\frac{1+c_1+z^2}{1+z^2})p + 2c_2 z$ and that $g(z) = \frac{2c_2 z(1+z^2)}{1+c_1+z^2}$ is monotone increasing and $0 < \frac{2c_2}{1+c_1} \le g'(z) \le 2c_2 + \frac{c_1 c_2}{4(1+c_1)}$. Let $q(p)$ be an inverse function of $g(z)$. Then

$$\frac{4(1+c_1)}{8c_2 + 9c_1 c_2} \le q'(p) \le \frac{1+c_1}{2c_2}.$$

Therefore we can see that similarly,

$$Q_1(p) = pq(-p) + c_1 p \arctan q(-p) + c_2 q(-p)^2$$

and

$$-\beta_1 p^2 \le Q_1(p) \le -\beta_2 p^2$$

for some $\beta_1, \beta_2 > 0$. Thus we see that if

$$\theta < \frac{2\beta_2}{\nu_2},$$

then (1.16) and (1.17) are satisfied.

2. No breaking down. In the present section we always assume the assumptions of Theorem 1.1 and shall show that no breaking down occurs in the stochastic control problem (1.1) under the assumptions, namely, $J_+^*(t,x;T)$ has finite value for each t, T, and x.

2.1. ϵ-optimal diffusion processes. The following lemma is useful for studying ϵ-optimal diffusion processes. The proof is a modification into a parabolic case of that of Theorem 3.2 in [2].

LEMMA 2.1. *Let $u \in C^{1,2}((0,T) \times R^N)$ be a supersolution to (1.15) bounded below:*

$$\frac{\partial u}{\partial t} \geq \frac{1}{2}a^{ij}D_{ij}u + Q(x, Du) + V, \quad (0,T] \times R^N. \tag{2.1}$$

Then $\lim_{|x|\to\infty} u(t,x) = \infty$, $0 < t \leq T$.

Proof. We can assume that u is nonnegative. In fact, if $u(t,x)$ satisfies (2.1), so does $u(t,x) - c$ for each constant c. By assumption (1.16) we have

$$\frac{\partial u}{\partial t} - \frac{1}{2}a^{ij}D_{ij}u - b^iD_iu + \frac{k_1}{2}a^{ij}D_iuD_ju - V \geq 0. \tag{2.2}$$

Let us take a point x_ρ such that $|x_\rho| = \rho$, $\rho > 0$ and define a function R by

$$R(t,x) = c_\rho\left(1 - \frac{4|x - x_\rho|^2}{\rho^2} - \frac{T-t}{T}\right), \quad 0 \leq t \leq T,\ |x - x_\rho| \leq \frac{\rho}{2}, \tag{2.3}$$

where c_ρ is a constant prescribed later. Let us set $z(t,x) = u(t,x) - R(t,x)$, $D_{T,\rho} = (0,T] \times \{x; |x - x_\rho| \leq \frac{\rho}{2}\}$ and

$$\partial' D_{T,\rho} = \left\{(0,x); |x - x_\rho| \leq \frac{\rho}{2}\right\} \cup \left\{(t,x); |x - x_\rho| = \frac{\rho}{2},\ 0 \leq t \leq T\right\}.$$

Then $z(t,x) \geq u(t,x) \geq 0$ on $\partial' D_{T,\rho}$. On the other hand, by (2.2) and (2.3) we have

$$\begin{aligned}
&\frac{\partial z}{\partial t} - \frac{1}{2}a^{ij}D_{ij}z - b^iD_iz \\
&\quad \geq -\frac{k_1}{2}a^{ij}D_iuD_ju + V - \left(\frac{\partial R}{\partial t} - \frac{1}{2}a^{ij}D_{ij}R - b^iD_iR\right) \\
&\quad = -\frac{k_1}{2}a^{ij}D_i(u+R)D_j(u-R) - \frac{k_1}{2}a^{ij}D_iuD_ju + \frac{1}{2}a^{ij}D_{ij}R \\
&\quad + b^iD_iR - \frac{\partial R}{\partial t} + V
\end{aligned}$$

in $D_{T,\rho}$. Therefore

$$\begin{aligned}
\frac{\partial z}{\partial t} - \frac{1}{2}a^{ij}D_{ij}z - b^iD_iz + \frac{k_1}{2}a^{ij}D_i(u+R)D_jz \\
\geq -\frac{k_1}{2}a^{ij}D_iRD_jR + \frac{1}{2}a^{ij}D_{ij}R + b^iD_iR - \frac{c_\rho}{T} + V \\
\geq -Kc_\rho^2 - Kc_\rho - \frac{c_\rho}{T} + V
\end{aligned} \tag{2.4}$$

for some constant $K > 0$ because σ and b are at most linear growth. Since $V(x) \to \infty$ as $|x| \to \infty$ we can take c_ρ such that $c_\rho \to \infty$ as $\rho \to \infty$ and

$$-Kc_\rho^2 - Kc_\rho - \frac{c_\rho}{T} + V(x) > 0, \quad |x - x_\rho| \leq \frac{\rho}{2} \tag{2.5}$$

holds for sufficiently large ρ. Then we have $z(t,x) \geq \inf_{\partial' D_{T,\rho}} z(s,y) \geq 0$ in $D_{T,\rho}$ by the maximum principle. In particular, at $(t,x) = (t,x_\rho)$ we have

$$z(t,x_\rho) = u(t,x_\rho) - c_\rho\frac{t}{T} \geq 0. \tag{2.6}$$

Hence we see that $u(t, x_\rho) \to \infty$ as $\rho \to \infty$ for each $t > 0$. □

Let u be a nonnegative solution to (1.15) on $[0, \infty) \times R^N$, the existence of which is assured by Theorem 1.1. We take $T > 0$ and define $w(t, x) = u(T - t, x)$, $0 \le t \le T$. Then w satisfies (1.12). For each $\epsilon > 0$ there exists a Borel function $z^\epsilon(t, x)$ (cf. Krylov [16]) such that

$$\inf_{z \in Z} \{c^i(x, z) D_i w(t, x) + \phi(x, z)\} \ge c^i(x, z^\epsilon(t, x)) D_i w(t, x) + \phi(x, z^\epsilon(t, x)) - \epsilon, \tag{2.7}$$

since Z is a separable metric space and c, ∇w, and ϕ are nice functions. We further note that $z^\epsilon(t, x)$ becomes locally bounded because of our assumption (1.9). Let us consider the following SDE:

$$\begin{cases} dX_s = \sigma(X_s) dB_s + b(X_s) ds + c(X_s, z^\epsilon(t + s, X_s)) ds, & 0 \le s \le T - t, \\ X_0 = x. \end{cases} \tag{2.8}$$

Since $c(x, z^\epsilon(t + s))$ is locally bounded and σ and b satisfy the conditions in Theorem 1.1, we can see that SDE (2.8) has a unique solution if no explosion occurs. Namely, we consider the martingale problem for the SDE

$$\begin{cases} dX_s = \sigma_n(X_s) dB_s + b_n(X_s) ds + c_n(s, X_s) ds, & 0 \le s \le T - t, \\ X_0 = x, \end{cases} \tag{2.9}$$

with a_n, b_n, and c_n defined as follows: $a_n = \chi_n + (1 - \chi_n) I$, $b_n = \chi_n$, and $c_n = \chi_n \tilde{c}$, where $\tilde{c}(s, x) = c(x, z^\epsilon(t + s, x))$ and χ_n is a smooth function such that

$$\chi_n = \begin{cases} 1 & B_n, \\ 0 & B_{n+1}^c. \end{cases}$$

Let (P_x^n, X_s) be a solution to the martingale problem. If we have

$$\lim_{n \to \infty} P_x^n \left(\sup_{0 \le s \le T_0 - t} |X_s| > n \right) = 0, \quad \forall T_0 < T, \tag{2.10}$$

then (2.8) has a unique solution for $0 \le s < T - t$ (cf. Stroock and Varadhan [24]).

LEMMA 2.2. *Equation* (2.10) *holds.*

Proof. We first note that

$$\lim_{|x| \to \infty} \inf_{0 \le s \le T_0} w(s, x) = \infty, \quad \forall T_0 < T$$

holds because of Lemma 2.1 and (1.55). Let us set

$$\mathcal{G}(z) w = \frac{\partial w}{\partial t} + \frac{1}{2} a^{ij}(x) D_{ij} w + b^i(x) D_i w + c^i(x, z) D_i w \tag{2.11}$$

and

$$\mathcal{B} w = \inf_{z \in Z} \{\mathcal{G}(z) w + \phi(x, z)\}. \tag{2.12}$$

We then obtain by Ito's formula

$$\begin{aligned} w(t + s \wedge \zeta_n, X_{s \wedge \zeta_n}) - w(t, X_0) &= \int_0^{s \wedge \zeta_n} \mathcal{G}(z^\epsilon(t + \tau, X_\tau)) w(t + \tau, X_\tau) d\tau \\ &+ \int_0^{s \wedge \zeta_n} \sigma_j^i(X_\tau) D_i w(t + \tau, X_\tau) dB_\tau^j, \end{aligned}$$

where $\zeta_n = \inf\{s; |X_s| \geq n\}$. Therefore we have

$$\begin{aligned}
&E_x^n[w(t+(T_0-t)\wedge\zeta_n, X_{(T_0-t)\wedge\zeta_n})] \\
&\quad \leq w(t,x) + E_x^n\left[\int_0^{(T_0-t)\wedge\zeta_n} (\mathcal{B}w(t+\tau, X_\tau) + \epsilon)d\tau\right] \\
&\quad - E_x^n\left[\int_0^{(T_0-t)\wedge\zeta_n} \phi(X_\tau, z^\epsilon(t+\tau, X_\tau))d\tau\right] \\
&\quad \leq w(t,x) - E_x^n\left[\int_0^{(T_0-t)\wedge\zeta_n} \{V(X_\tau) + \frac{\theta}{2}a^{ij}D_iwD_jw(t+\tau, X_\tau)\}d\tau\right] \\
&\quad + \epsilon(T_0-t) - E_x^n\left[\int_0^{(T_0-t)\wedge\zeta_n} \phi(X_\tau, z^\epsilon(t+\tau, X_\tau)d\tau\right] \\
&\quad \leq w(t,x) + \epsilon(T_0-t).
\end{aligned}$$

Put $\Lambda_n = \inf\{w(t+s,x);\ 0 \leq s \leq T_0 - t, |x| = n\}$. Then $\lim_{n\to\infty}\Lambda_n = \infty$. Hence (2.10) follows from the inequalities

$$\begin{aligned}
\Lambda_n P_x^n(\zeta_n \leq T_0 - t) &\leq E_x^n[w(t+(T_0-t)\wedge\zeta_n, X_{(T_0-t)\wedge\zeta_n})] \\
&\leq w(t,x) + \epsilon(T_0-t). \qquad \square
\end{aligned}$$

Remark 2.1. We don't assume controlled processes have any stability. But we see that the above-defined ϵ-optimal diffusion process has some kind of stability. In fact, it is defined up to time T. For large T it behaves like a recurrent diffusion process with finite recurrence time since $w(t,x) \geq 0$ and

$$\frac{\partial w}{\partial t} + a^{ij}D_{ij}w + b^iD_iw + c^i(x, z^\epsilon(t,x))D_iw \leq -V(x) + \epsilon \leq -1$$

for $0 \leq t < T$, $|x| \geq R$ for sufficiently large R (cf. Theorem 7.1 in [13, p. 98]).

2.2. Finiteness of the value function. The following theorem implies the finiteness of the value function (1.2) in a risk-averse case under the assumptions of Theorem 1.1. We note the bound of θ ensuring the finiteness is determined by assumption (1.16) (cf. Remark 1.2).

THEOREM 2.3. *Let u be a nonnegative solution to* (1.15) *on* $[0,\infty)\times R^N$, *the existence of which has been shown in Theorem* 1.1. *For* $T > 0$, *set* $w(t,x) = u(T-t,x)$, $0 \leq t \leq T$, *and* $J_+(t,x;T) = e^{\theta w(t,x)}$. *Then*

$$J_+^*(t,x;T) \leq J_+(t,x;T), \quad 0 \leq t \leq T, \tag{2.13}$$

where $J_+^*(t,x;T)$ *is the value function defined by* (1.2).

Proof. For each $\epsilon > 0$ take a Borel function $z^\epsilon(t,x)$ satisfying (2.7) and consider the SDE (2.8). Then, in the same way as in the proof of Lemma 2.2, we have

$$\begin{aligned}
&w(t+s, X_s) - w(t, X_0) \\
&\qquad \leq -\int_0^s \{V(X_\tau) + \phi(X_\tau, z_\tau^\epsilon)\}d\tau + \int_0^s \sigma_j^i(X_\tau)D_iw(t+\tau, X_\tau)dB_\tau^j \\
&\qquad - \frac{\theta}{2}\int_0^s a^{ij}D_iwD_jw(t+\tau, X_\tau)d\tau + \epsilon s, \quad 0 \leq s < T-t,
\end{aligned}$$

where $z_\tau^\epsilon = z^\epsilon(t+\tau, X_\tau)$. Therefore

$$e^{\theta\int_0^s\{V(X_\tau)+\phi(X_\tau,z_\tau^\epsilon)\}d\tau+\theta w(t+s,X_s)} \le e^{\theta(\epsilon s+w(t,x))}e^{M_s-\frac{1}{2}\langle M\rangle_s},$$

where $M_s = \theta\int_0^s \sigma_j^i(X_\tau)D_i w(t+\tau, X_\tau)dB_\tau^j$. Since M_s is a local martingale and $M_0 = 0$, we have

$$E_x[e^{M_s-\frac{1}{2}\langle M\rangle_s}] \le 1.$$

Thus we obtain

$$E_x[e^{\theta\int_0^s\{V(X_\tau)+\phi(X_\tau,z_\tau^\epsilon)\}d\tau}] \le e^{\theta(\epsilon s+w(t,x))}, \quad 0 \le s < T-t,$$

since $w \ge 0$. Hence we complete the proof of our theorem as $s \to T-t$ and $\epsilon \to 0$. □

Let us consider Example 1 in §1.5. We consider the nonnegative solution u to (1.15) with (1.59) and set w as above. Let us define a feedback control

$$z(t+s,x) = -S^{-1}B^*\nabla w(t+s,x), \quad 0 \le s < T-t \tag{2.14}$$

and consider the following SDE:

$$\begin{cases} dX_s = \sigma(X_s)dB_s + b(X_s)ds + B(X_s)z(t+s,X_s)ds, & 0 \le s < T-t, \\ X_0 = x. \end{cases} \tag{2.15}$$

We then have the following proposition.

PROPOSITION 2.4. *Put $J_+(t,x) = e^{\theta w(t,x)}$. Then we have*

$$J_+(t,x) = E_x[e^{\theta\int_0^{T-t}\{V(X_s)+\frac{1}{2}S_{ij}(X_s)z_s^i z_s^j\}ds}], \tag{2.16}$$

where $z_s^i = z^i(t+s, X_s)$.

Proof. We first note that the infimum in (1.59) is attained by $z = -S^{-1}B^*p$. By Ito's formula, we then obtain in a similar way as above

$$\begin{aligned} &e^{\theta\int_0^s\{V(X_\tau)+\frac{1}{2}S_{ij}(X_\tau)z_\tau^i z_\tau^j\}d\tau+\theta w(t+s,X_s)} \\ &= e^{\theta w(t,x)}e^{\theta M_s-\frac{\theta^2}{2}\langle M\rangle_s}, \end{aligned} \tag{2.17}$$

where $M_s = \int_0^s \sigma_j^i(X_\tau)D_i w(X_\tau)dB_\tau^j$. Therefore we have

$$E_x[e^{\theta\int_0^s\{V(X_\tau)+\frac{1}{2}S_{ij}(X_\tau)z_\tau^i z_\tau^j\}d\tau}] \le e^{\theta w(t,x)}, \quad s < T-t. \tag{2.18}$$

Thus we see by Fatou's lemma that

$$E_x[e^{\theta\int_0^{T-t}\frac{1}{2}S_{ij}(X_s)z_s^i z_s^j ds}] < \infty.$$

Because of (1.60), $\theta a < BS^{-1}B^*$ as quadratic forms and

$$S_{ij}z_s^i z_s^j = (BS^{-1}B^*)^{ij}D_i w D_j w(t+s, X_s).$$

Therefore

$$E_x[e^{\frac{\theta^2}{2}\langle M\rangle_{T-t}}] < \infty. \tag{2.19}$$

Owing to Novikov's theorem (cf. Theorem 6.1 in [20]), (2.19) implies that

$$L_s = e^{\theta M_s-\frac{\theta^2}{2}\langle M\rangle_s}, \quad 0 \le s \le T-t$$

is a martingale and we have $E_x[L_{T-t}] = 1$. From (2.17) and (2.18) it follows that $\lim_{s\to T-t} e^{\theta w(t+s,X_s)}$ exists and that the limit is nothing but one because of (1.8). Hence (2.17) implies (2.16). □

3. Asymptotics.

3.1. General view of asymptotics. Let us study the asymptotic behaviour as $T \to \infty$ of a nonnegative solution to (1.15) on $[0,\infty) \times R^N$, the existence of which has been proven in Theorem 1.1. We first show the following lemma.

LEMMA 3.1. *Let us assume that the conditions of Theorem* 1.1 *and* u *are a nonnegative solution to* (1.15) *on* $[0,\infty)\times R^N$. *Then there exists a subsequence* $\{T_i\} \subset R_+$ *such that* $u(T_i,x) - u(T_i,0)$ *converges to a function* $v \in C^2(R^N)$ *uniformly on each compact set and strongly in* $W^1_{2,loc}$ *and* $\frac{\partial u}{\partial t}(T_i,x)$ *to* $\chi(x) \in C(R^N)$ *uniformly on each compact set. Moreover* $(v(x),\chi(x))$ *satisfies*

$$\chi(x) = \frac{1}{2}a^{ij}D_{ij}v(x) + Q(x,\nabla v) + V(x), \quad x \in R^N. \tag{3.1}$$

Proof. Let us set $\tilde{u}(T,x) = u(T,x) - u(T,0)$. Then $\{\tilde{u}(T,x)\}_T$ turns out to be a family of uniformly bounded and equicontinuous functions of x on each compact set because of (1.19). Therefore it has a subsequence $\{\tilde{u}(T_i,x)\}$ converging to a function $v(x) \in C(R^N)$ uniformly on each compact set. Moreover the estimates (1.18) and (1.19) imply that $\{\tilde{u}(T,\cdot)\}$ forms a bounded subset of the Hilbert space $W^1_2(B_r)$ for each r and we see that there exists a subsequence $\{\tilde{u}(T_i',\cdot)\}$ converging to $\tilde{v} \in W^1_{2,loc}$ weakly in $W^1_{2,loc}$ and strongly in L^2_{loc}. Taking a subsequence, if necessary, we can see that $\tilde{u}(T_i',x) \to \tilde{v}(x)$ a.e. and that $\tilde{v}(x) = v(x)$. We furthermore see that $\nabla\tilde{u}(T_i',x) \to \tilde{v}(x)$ strongly in L^2_{loc} in a similar way to the proof of Lemma 1.6.

Put $\xi(x) = \frac{\partial u}{\partial t}$. Then we obtain from (1.15)

$$\frac{\partial \xi}{\partial t} = \frac{1}{2}a^{ij}D_{ij}\xi + \frac{\partial Q}{\partial p_i}(x,\nabla u)D_i\xi, \quad (0,\infty)\times R^N. \tag{3.2}$$

Since ξ is bounded on $(\epsilon,\infty)\times B_r$ because of (1.18) and (1.19), the regularity theorem for parabolic equations implies that $\{\xi(T,\cdot)\}$ forms a family of Hölder equicontinuous functions on $(\epsilon,\infty)\times B_r$ for each r. Thus we have a subsequence $\{\xi(T_i'',x)\}$ converging to a function $\chi(x) \in C(R^N)$ uniformly on each compact set. In a similar way to the proof of Lemma 1.6 we obtain equation (3.1). □

Equation (3.1) with $\chi(x) \equiv$ constant is called a Bellman equation of ergodic type. We shall show the uniqueness of the solution to the equation in a similar fashion to Theorem 4.1 in Bensoussan and Frehse [2].

LEMMA 3.2. *Besides the assumptions of Theorem* 1.1 *we assume that*

$$Q_0(x,\beta p) \geq \beta^2 Q_0(x,p) - \frac{\kappa}{2}\beta(1-\beta)a^{ij}p_ip_j - \beta(1-\beta)L(x), \quad 0<\beta<1 \tag{3.3}$$

for $\kappa < k_2$ *and locally bounded function* $L(x)$ *such that*

$$V(x) - L(x) \to \infty, \quad |x| \to \infty. \tag{3.4}$$

Then the solution (v,χ) *to equation* (3.5) *such that* $v(x) \to \infty$ *as* $|x| \to \infty$ *is unique, admitting additive constants with respect to* v:

$$\begin{cases} \chi = \frac{1}{2}a^{ij}D_{ij}v + b^iD_iv + Q_0(x,\nabla v) + V(x), & R^N, \\ \chi \equiv \textit{constant}, \quad v \in C^2(R^N). \end{cases} \tag{3.5}$$

Proof. Let (v_1,χ_1) and (v_2,χ_2) be solutions to (3.5) such that $v_i(x) \to \infty$, $|x| \to \infty$, $i = 1,2$. We assume that $\chi_1 \leq \chi_2$ and take α such that $v_1(x_0) + \alpha > v_2(x_0)$ holds for some x_0. Let us set

$$z = e^{-\gamma(v_1+\alpha)} - e^{-\gamma v_2}, \quad \gamma > 0. \tag{3.6}$$

Then we see that $\inf_{x\in R^N} z(x)$ is attained by some $x_\gamma \in R^N$ since $\lim_{|x|\to\infty} z(x) = 0$ and $z(x_0) < 0$. Then

$$\frac{1}{2}a^{ij}D_{ij}z(x_\gamma) \geq 0, \quad \nabla z(x_\gamma) = 0, \quad z(x_\gamma) < 0. \tag{3.7}$$

We therefore have at x_γ

$$\begin{aligned}
0 &\leq \frac{1}{2}a^{ij}D_{ij}z + b^iD_iz \\
&= \left\{-\frac{\gamma}{2}a^{ij}D_{ij}v_1 + \frac{\gamma^2}{2}a^{ij}D_iv_1D_jv_1 - \gamma b^iD_iv_1\right\}e^{-\gamma(v_1+\alpha)} \\
&+ \left\{\frac{\gamma}{2}a^{ij}D_{ij}v_2 - \frac{\gamma^2}{2}a^{ij}D_iv_2D_jv_2 + \gamma b^iD_iv_2\right\}e^{-\gamma v_2} \\
&= -\gamma\left(\chi_1 - V - Q_0(x_\gamma, \nabla v_1) - \frac{\gamma}{2}a^{ij}D_iv_1D_jv_1\right)e^{-\gamma(v_1+\alpha)} \\
&+ \gamma\left(\chi_2 - V - Q_0(x_\gamma, \nabla v_2) - \frac{\gamma}{2}a^{ij}D_iv_2D_jv_2\right)e^{-\gamma v_2}.
\end{aligned}$$

Thus we obtain

$$\begin{aligned}
&e^{-\gamma(v_1+\alpha)}\left(Q_0(x_\gamma, \nabla v_1) + \frac{\gamma}{2}a^{ij}D_iv_1D_jv_1\right) \\
&- e^{-\gamma v_2}\left(Q_0(x_\gamma, \nabla v_2) + \frac{\gamma}{2}a^{ij}D_iv_2D_jv_2\right) \geq (\chi_1 - V)e^{-\gamma(v_1+\alpha)} - (\chi_2 - V)e^{-\gamma v_2}.
\end{aligned} \tag{3.8}$$

Because of (3.7), $\nabla v_2 = \nabla v_1 e^{\gamma v_2 - \gamma(v_1+\alpha)}$ holds at x_γ and $e^{\gamma v_2 - \gamma(v_1+\alpha)} < 1$. Therefore from (3.3) it follows that the left-hand side of (3.8)

$$\begin{aligned}
&\leq e^{-\gamma(v_1+\alpha)}\left(Q_0(x_\gamma, \nabla v_1) + \frac{\gamma}{2}a^{ij}D_iv_1D_jv_1\right) \\
&- e^{\gamma v_2 - 2\gamma(v_1+\alpha)}\left(Q_0(x_\gamma, \nabla v_1) + \frac{\gamma}{2}a^{ij}D_iv_1D_jv_1\right) \\
&+ e^{\gamma v_2 - \gamma(v_1+\alpha)}\left(e^{-\gamma v_2} - e^{-\gamma(v_1+\alpha)}\right)\left(\frac{\kappa}{2}a^{ij}D_iv_1D_jv_1 + L\right) \\
&\leq e^{\gamma v_2 - \gamma(v_1+\alpha)}\left(e^{-\gamma v_2} - e^{-\gamma(v_1+\alpha)}\right)\left\{-\left(\frac{k_2}{2} - \frac{\gamma+\kappa}{2}\right)a^{ij}D_iv_1D_jv_1 + L\right\}.
\end{aligned}$$

Taking $\gamma < k_2 - \kappa$, we have

$$\begin{aligned}
&e^{\gamma v_2 - \gamma(v_1+\alpha)}(e^{-\gamma v_2} - e^{-\gamma(v_1+\alpha)})L \\
&\qquad \geq (\chi_1 - V)e^{-\gamma(v_1+\alpha)} - (\chi_2 - V)e^{-\gamma v_2} \\
&\qquad \geq (\chi_1 - V)(e^{-\gamma(v_1+\alpha)} - e^{-\gamma v_2})
\end{aligned} \tag{3.9}$$

because $\chi \geq \chi_2$. Thus we obtain $L(x_\gamma) \geq V(x_\gamma) - \chi_1$. Therefore from (3.4) it follows that $x_\gamma \in \overline{B}_{r_0}$ for some r_0 and, taking a subsequence if necessary, $\exists \lim_{\gamma\to 0} x_\gamma = \hat{x} \in \overline{B}_{r_0}$. From (3.9) it follows that $0 \geq \chi_1 - \chi_2$ by letting γ tend to 0. Hence we conclude $\chi_1 = \chi_2$.

On the other hand we have

$$e^{-\gamma(v_1(x_\gamma)+\alpha)} - e^{-\gamma v_2(x_\gamma)} \leq e^{-\gamma(v_1(x)+\alpha)} - e^{-\gamma v_2(x)}$$

for each x since x_γ is a maximum point of z. Therefore by dividing both sides by γ and letting γ tend to 0 we obtain

$$v_2(x) - v_2(\hat{x}) - (v_1(x) - v_1(\hat{x}) \geq 0, \quad \forall x.$$

Put $\psi(x) = v_2(x) - v_2(\hat{x}) - (v_1(x) - v_1(\hat{x}))$. Then $\psi(x) \geq 0$ and $\inf_{x \in B_r(\hat{x})} \psi(x) = \psi(\hat{x})$ for each r. Since $Q_0(x,p)$ is C^1 in p, there exists a continuous R^N-valued function R such that $Q_0(x,p) - Q_0(x,p') = R \cdot (p - p')$. We therefore have

$$\frac{1}{2} a^{ij} D_{ij} \psi + b^i D_i \psi + R \cdot \nabla \psi = 0.$$

By Harnack's inequality $\sup_{x \in B_r(\hat{x})} \psi(x) \leq c_1 \inf_{x \in B_r(\hat{x})} \psi(x) = 0$ for some positive constant c_1. Hence we obtain $\psi(x) \equiv 0$ on $B_r(\hat{x})$. By repeating the same arguments on a ball centered at each point on $\partial B_r(\hat{x})$ we have $\psi(x) \equiv 0$ on $B_{2r}(\hat{x})$. By continuing this procedure we conclude that $\psi \equiv 0$. □

Remark 3.1. Condition (3.3) is rather technical but we can see that Example 1 in §1.5 satisfies the condition. A more specified case, Example 2, will be studied in the following subsection.

LEMMA 3.3. *Let us assume the conditions of Theorem* 1.1 *and* u *to be a nonnegative solution to* (1.15). *Then* $u(t,x) - u(t,0)$ *is bounded below.*

Proof. Put $\eta(t,x) = e^{u(t,0) - u(t,x)}$. Then it suffices to show that

$$\eta(t,x) \leq c_1 \tag{3.10}$$

for some constant $c_1 > 0$. Since we have $0 < \sup_{t_0 \leq t \leq T} \eta(t,x) \leq e^{u(T,0) - u(t_0,x)}$ and $\lim_{|x| \to \infty} e^{u(T,0) - u(t_0,x)} = 0$, there exists $(t_T, x_T) \in [t_0, T] \times R^N$ such that $\eta(t_t, x_T) = \sup_{[t_0,T] \times R^N} \eta(t,x)$. We can assume that $t_0 < t_T$ because otherwise we have nothing to prove. We then have at (t_T, x_T)

$$\frac{\partial \eta}{\partial t} \geq 0, \quad \nabla \eta = 0, \quad a^{ij} D_{ij} \eta \leq 0. \tag{3.11}$$

It follows from (3.11) that $\nabla u(t_T, x_T) = 0$. Therefore we obtain

$$\begin{aligned} 0 &\leq \frac{\partial \eta}{\partial t} - \frac{1}{2} a^{ij} D_{ij} \eta - b^i D_i \eta \\ &= \left(\frac{\partial u}{\partial t}(t_T, 0) - V(x_T) \right) e^{u(t_T,0) - u(t_T,x_T)}. \end{aligned}$$

Thus we have $V(x_T) \leq \frac{\partial u}{\partial t}(t_T, 0) \leq M$ for some positive constant M, which implies that $x_T \in B_R$ for some R. Hence

$$\sup_{[t_0,T] \times R^N} \eta(t,x) \leq e^{u(t_T,0) - u(t_T,x_T)} = e^{\nabla u(t_T, \beta x_T) \cdot x_T}, \quad 0 < \beta < 1$$

and (1.18) and (1.19) imply (3.10). □

Remark 3.2. Owing to Lemma 3.3, $v(x)$ in Lemma 3.1 is bounded below and we can see that $v(x) \to \infty$ as $|x| \to \infty$ in a similar way to the proof of Lemma 2.1.

3.2. The case of Example 2. In the present subsection we specialize the problem to the case of Example 2 in §1.5, namely we consider the following equation:

$$\begin{cases} \frac{\partial u}{\partial t} = \frac{1}{2} a^{ij} D_{ij} u + b^i D_i u - \frac{\kappa}{2} a^{ij} D_i u D_j u + V, \\ u(0,x) = 0 \end{cases} \tag{3.12}$$

with $\kappa > 0$. We then have the following theorem.

THEOREM 3.4. *Let us assume* (1.4)–(1.6), (1.8), *and* (1.10), *and* u *to be a non-negative solution to* (3.12). *Then* $u(t,x)-u(t,0)$ *converges to a function* $v(x)$ *in* $W^1_{2,loc}$ *and uniformly on each compact set, and* $\frac{\partial u}{\partial t}(t,x)$ *to a constant* χ *on each compact set as* $t \to \infty$. *The pair* (v,χ) *is the unique solution to* (3.5) *with* $Q_0(x,p) = -\kappa a^{ij}p_ip_j$.

COROLLARY. *Let us set* $J_\pm(t,x;T) = e^{\theta u(T-t,x)}$. *Then*

$$\lim_{T\to\infty}\frac{1}{T}\log J_\pm(0,x;T) = \lim_{T\to\infty}\frac{\theta u(T,x)}{T} = \lim_{T\to\infty}\theta\frac{\partial u}{\partial t}(T,x) = \theta\chi.$$

Lemma 3.1 applies to the present case and it suffices to show that $\chi(x) \equiv$ constant because of Lemma 3.2, Lemma 3.3 and Remark 3.1. To show this we must prepare some auxiliary facts. Put $\xi(t,x) = \frac{\partial u}{\partial t}(t,x)$. Then it satisfies

$$\frac{\partial \xi}{\partial t} = \frac{1}{2}a^{ij}D_{ij}\xi + b^iD_i\xi - \kappa a^{ij}D_juD_i\xi, \quad (0,\infty)\times R^N \tag{3.13}$$

and the estimate

$$|\xi(t,x)| \le M_{r,\epsilon}, \quad x \in B_r, \quad t \ge \epsilon > 0 \tag{3.14}$$

(cf. Theorem 1.1). For each t we set $w(s,x) = u(t-s,x)$, $0 \le s \le t$, and consider the following SDE:

$$\begin{cases} dX_s^i = \sigma_j^i(X_s)dB_s^j + b^i(X_s)ds - \kappa a^{ij}D_jw(s,X_s)ds, & 0 \le s < t, \\ X_0 = x, \end{cases} \tag{3.15}$$

the solution of which is denoted by $(P^{t,x}, X_t)$. Let us set $\hat{\mathcal{L}}(s) = \frac{\partial}{\partial t} + \frac{1}{2}a^{ij}D_{ij} + b^iD_i - \kappa a^{ij}D_jw(s,x)D_i$. Then we have by Ito's formula

(3.16)

$$\begin{aligned} w(s,X_s) - w(0,X_0) &= \int_0^s \sigma_j^iD_iw(\tau,X_\tau)dB_\tau^j + \int_0^s \hat{\mathcal{L}}(\tau)w(\tau,X_\tau)d\tau \\ &= \int_0^s \sigma_j^iD_iw(\tau,X_\tau)dB_\tau^j - \int_0^s \left\{\frac{\kappa}{2}a^{ij}D_iwD_jw(\tau,X_\tau) + V(X_\tau)\right\}d\tau, \end{aligned}$$

since w satisfies $\hat{\mathcal{L}}(s)w + \frac{\kappa}{2}a^{ij}D_iwD_jw + V = 0$. Take a constant μ such that $\kappa > \mu > 0$. Then from (3.16) it follows that

$$\begin{aligned} &e^{\mu\int_0^s\{\frac{\kappa-\mu}{2}a^{ij}D_iwD_jw(\tau,X_\tau)+V(X_\tau)\}d\tau+\mu w(s,X_s)} \\ &= e^{\mu w(0,x)+\mu\int_0^s\sigma_j^iD_iw(\tau,X_\tau)dB_\tau^j-\frac{\mu^2}{2}\int_0^s a^{ij}D_iwD_jw(\tau,X_\tau)d\tau} \end{aligned}$$

and we obtain

$$E^{t,x}[e^{\mu\int_0^s\{\frac{\kappa-\mu}{2}a^{ij}D_iwD_jw(\tau,X_\tau)+V(X_\tau)\}d\tau+\mu w(s,X_s)}] \le e^{\mu u(t,x)}$$

for $0 \le s < t$. Therefore Jensen's inequality implies that

$$E^{t,x}\left[\int_0^s\left\{\frac{\kappa-\mu}{2}a^{ij}D_iwD_jw(\tau,X_\tau) + V(X_\tau)\right\}d\tau + w(s,X_s)\right] \le u(t,x). \tag{3.17}$$

Thus we see that $\int_0^s \sigma_j^iD_iw(\tau,X_\tau)dB_\tau^j$, $0 \le s < t$, is a martingale.

LEMMA 3.5. *For each $\epsilon > 0$, $t_0 > 0$, and a compact set K, there exist $R > 0$ and $T > 1$ such that*

$$P^{t,x}(X_s \notin B_R, t-(t_0+T) < s < t-t_0) < \epsilon, \quad t > t_0+T, \quad x \in K. \tag{3.18}$$

Proof. In the same way as above we see that

$$\begin{aligned} &w(t-t_0, X_{t-t_0}) - w(t-(t_0+T), X_{t-(t_0+T)}) \\ &= -\int_{t-(t_0+T)}^{t-t_0} \left\{ \frac{\kappa}{2} a^{ij} D_i w D_j w(\tau, X_\tau) + V(X_\tau) \right\} d\tau + \text{ martingale difference.} \end{aligned}$$

We therefore obtain

$$\begin{aligned} &E^{t,x}\left[\int_{t-(t_0+T)}^{t-t_0} \left\{ \frac{\kappa}{2} a^{ij} D_i w D_j w(\tau, X_\tau) + V(X_\tau \right\} d\tau \right] \\ &= E^{t,x}[w(t-(t_0+T), X_{t-(t_0+T)})] - E^{t,x}[w(t-t_0, X_{t-t_0})] \\ &\le E^{t,x}[u(t_0+T, X_{t-(t_0+T)})]. \end{aligned} \tag{3.19}$$

Put $\eta(t,x) = E^{t,x}[u(t_0+T, X_{t-(t_0+T)})]$. Then it satisfies

$$\begin{cases} \frac{\partial \eta}{\partial t} = \frac{1}{2} a^{ij} D_{ij} \eta + b^i D_i \eta - \kappa a^{ij} D_j u(t,x) D_i \eta, & t > t_0+T, \\ \eta(t_0+T, x) = u(t_0+T, x). \end{cases} \tag{3.20}$$

Setting $f(t,x) = e^{-\kappa u(t,x)} \eta(t,x)$, we have

$$\begin{cases} \frac{\partial f}{\partial t} = \frac{1}{2} a^{ij} D_{ij} f + b^i D_i f - \kappa V f, & t > t_0+T, \\ f(t_0+T, x) = e^{-\kappa u(t_0+T, x)} u(t_0+T, x) \end{cases} \tag{3.21}$$

and accordingly, by using Kac's representation, we obtain

$$\begin{aligned} f(t,x) &= E_x[e^{-\int_0^{t-t_1} \kappa V(Y_s) ds} e^{-\kappa u(t_1, Y_{t-t_1})} u(t_1, Y_{t-t_1})] \\ &\le K E_x[e^{-\int_0^{t-t_1} \kappa V(Y_s) ds}] = K e^{-\kappa u(t-t_1, x)}, \end{aligned}$$

where $K = (\kappa e)^{-1}$, $t_1 = t_0 + T$, and (P_x, Y_s) is a solution to (1.20). Thus we have

$$\begin{aligned} \eta(t,x) &= e^{\kappa u(t,x)} f(t,x) \le K e^{\kappa u(t,x) - \kappa u(t-t_1, x)} \\ &\le K e^{\kappa t_1 \frac{\partial u}{\partial t}(s,x)} \le K e^{t_1 M_r}, \quad t - t_1 < \exists s < t, \quad x \in B_r \end{aligned}$$

by using (1.8) and (1.9). For each $\epsilon > 0$, $r > 0$, and $t_0 > 0$, take N_1 and $T > 1$ such that

$$\frac{K e^{\kappa(t_0+T) M_r}}{N_1 T} < \epsilon$$

and R such that $B_R^c \subset \{x; V(x) \ge N_1\}$. Then from (3.19) it follows that

$$\begin{aligned} N_1 T P^{t,x}(X_s \notin B_R, t-(t_0+T) < s < t-t_0) &\le E^{t,x}\left[\int_{t-(t_0+T)}^{t-t_0} V(X_s) ds \right] \\ &\le K e^{\kappa(t_0+T) M_r}. \end{aligned}$$

Hence we obtain our lemma. □

LEMMA 3.6. *For each $\epsilon > 0$, $t_0 > 0$, and a compact set K, there exist R_1 and T such that*

$$P^{t,x}(X_{t-t_0} \in B_{R_1}) > 1 - \epsilon, \quad \forall t > t_0 + T, \quad x \in K. \tag{3.22}$$

Proof. Put $\tau_R = \inf\{s \geq t-(t_0+T), X_s \in B_R\}$ and $\sigma_R = \inf\{s \geq \tau_R, X_s \notin B_{R_1}\}$, $R < R_1$. Then from Lemma 3.5 it follows that for each $\epsilon > 0$, $t_0 > 0$, and a compact set K, there exist R and $T > 1$ such that

$$P^{t,x}(\tau_R \leq t - t_0) > 1 - \frac{\epsilon}{2}, \quad t > t_0 + T, \quad x \in K. \tag{3.23}$$

On the other hand we have by Ito's formula

$$\begin{aligned} &w((t-t_0) \wedge \sigma_{R_1}, X_{(t-t_0)\wedge\sigma_{R_1}}) - w((t-t_0) \wedge \tau_R, X_{(t-t_0)\wedge\tau_R}) \\ &= -\int_{(t-t_0)\wedge\tau_R}^{(t-t_0)\wedge\sigma_{R_1}} \left\{\frac{\kappa}{2} a^{ij} D_i w D_j w(s, X_s) + V(X_s)\right\} ds \\ &+ \int_{(t-t_0)\wedge\tau_R}^{(t-t_0)\wedge\sigma_{R_1}} \sigma_j^i D_i w(s, X_s) dB_s^j, \end{aligned}$$

from which it follows that

$$\begin{aligned} &E^{t,x}[w((t-t_0) \wedge \sigma_{R_1}, X_{(t-t_0)\wedge\sigma_{R_1}}); \{\tau_R \leq t - t_0\}] \\ &\quad \leq E^{t,x}[w((t-t_0) \wedge \tau_R, X_{(t-t_0)\wedge\tau_R}); \{\tau_R \leq t - t_0\}]. \end{aligned}$$

Thus we obtain

$$\begin{aligned} &\inf_{t_0 \leq s \leq t_0+T, x \in \partial B_{R_1}} u(s,x) P^{t,x}(\sigma_{R_1} \leq t - t_0, \tau_R \leq t - t_0) \\ &\qquad \leq \sup_{t_0 \leq t \leq t_0+T, x \in \overline{B}_R} u(s,x). \end{aligned}$$

By Lemma 2.1 $\inf_{t_0 \leq s \leq t_0+T, \partial B_{R_1}} u(s,x) \to \infty$ as $R_1 \to \infty$. Therefore for each $\epsilon > 0$ there exists R_1 such that

$$P^{t,x}(\sigma_{R_1} \leq t - t_0, \tau_R \leq t - t_0) < \frac{\epsilon}{2}. \tag{3.24}$$

Hence from (3.23) and (3.24) it follows that

$$P^{t,x}(\sigma_{R_1} > t - t_0, \tau_R \leq t - t_0) > 1 - \epsilon, \quad x \in K, \quad t > t_0 + T,$$

which implies (3.22). □

LEMMA 3.7. *For each compact set K, relative compact open set G, and $t_0 > 0$, there exists $T > 0$ such that*

$$P^{t,x}(X_{t-t_0} \in G) \geq \delta_G > 0, \quad t \geq t_0 + T, \quad x \in K. \tag{3.25}$$

Proof. By Lemma 3.5 for each compact set K, there exists T, $R > 0$ such that

$$P^{t,x}(\tau_R \leq t - (t_0 + 1)) > \frac{1}{2}, \quad t > t_0 + T > t_0 + 1, \quad x \in K.$$

Therefore we have

$$\begin{aligned} P^{t,x}(X_{t-t_0} \in G) &\geq P^{t,x}(\tau_R \leq t-(t_0+1), X_{t-t_0} \in G) \\ &= \int_{\overline{B}_R} \int_{t_0+1}^{t_0+T} P^{t,x}(\tau_R \in t-ds, X_{\tau_R} \in dy) P^{s,y}(X_{s-t_0} \in G) \\ &\geq \inf_{y \in \overline{B}_R, t_0+1 \leq s \leq t_0+T} P^{s,y}(X_{s-t_0} \in G) P^{t,x}(\tau_R \leq t-(t_0+1)) \\ &\geq \frac{1}{2} \inf_{t_0+1 \leq s \leq t_0+T, y \in \overline{B}_R} P^{s,y}(X_{s-t_0} \in G) \geq \frac{1}{2}\delta_G > 0 \end{aligned}$$

by using a strong Markov property. □

Proof of Theorem 3.4. Now we give the proof of Theorem 3.4. By Lemma 3.1 there exists a subsequence $\{t_k\}$ such that $\xi(t_k, x)$ converges uniformly on each compact set. Put $\bar{\xi}(x) = \lim_{k\to\infty} \xi(t_k, x) \geq 0$ and assume that $\bar{\xi}(x) \neq$ constant. Set $m_2 = \inf_{x \in R^N} \bar{\xi}(x)$. Then there exists $x_1 \in R^N$ such that $m_1 = \bar{\xi}(x_1) > m_2$. Setting $2\sigma = m_1 - m_2$, there exists an open neighborhood G of x_1 such that $\bar{\xi}(x) > m_1 - \sigma$, $x \in G$. Take a point x_2 such that $\bar{\xi}(x_2) < m_2 + \sigma\delta_G$, where δ_G is a constant defined in Lemma 3.7. For each $\epsilon > 0$ and $R > 0$ there exist $\bar{t}$ such that

$$|\bar{\xi}(\bar{t}, x) - \bar{\xi}(x)| < \epsilon, \quad |x| < R.$$

Take a compact set K such that $x_2 \in K$ and sufficiently large R such that $G \subset B_R$ and $B_{R_1} \subset B_R$, where R_1 is defined in Lemma 3.6 with $t_0 = \bar{t}$, ϵ, and K. Then for $x \in K$ and sufficiently large t we have

$$\begin{aligned} \xi(t,x) &= E^{t,x}[\xi(\bar{t}, X_{t-\bar{t}})] \\ &= E^{t,x}[\xi(\bar{t}, X_{t-\bar{t}}); X_{t-\bar{t}} \in G] + E^{t,x}[\xi(\bar{t}, X_{t-\bar{t}}); X_{t-\bar{t}} \in G^c \cap B_R] \\ &+ E^{t,x}[\xi(\bar{t}, X_{t-\bar{t}}); X_{t-\bar{t}} \in B_R^c] \\ &\geq (m_1 - \sigma - \epsilon) P^{t,x}(X_{t-\bar{t}} \in G) + (m_2 - \epsilon) P^{t,x}(X_{t-\bar{t}} \in G^c \cap B_R) \\ &\geq \sigma\delta_G + (m_2 - \epsilon)(1 - \epsilon) \\ &\geq \sigma\delta_G + m_2 - \epsilon(m_2 + 1). \end{aligned}$$

Letting $t = t_k$ tend to ∞ we obtain

$$\bar{\xi}(x) \geq \sigma\delta_G + m_2 - \epsilon(m_2 + 1), \quad x \in K, \quad \epsilon > 0.$$

Hence we have $\bar{\xi}(x_2) \geq \sigma\delta_G + m_2$, which is a contradiction. □

3.3. Principal eigenvalue and large deviation. We illustrate an example of Theorem 3.4. Let us consider equation (3.12) with $a^{ij} = \delta^{ij}$, $b^i = 0$, and $\kappa = 1 - \theta > 0$, namely

$$\begin{cases} \frac{\partial u}{\partial t} = \frac{1}{2}\Delta u - \frac{1-\theta}{2}|\nabla u|^2 + V, \\ u(0,x) = 0. \end{cases} \tag{3.26}$$

It corresponds to the risk-sensitive control problem

$$\begin{aligned} \text{minimize} \quad & \frac{1}{\theta} \log E_x[e^{\theta \int_0^{T-t} \{V(X_s) + \frac{1}{2}|z_s|^2 ds\}}] \\ \text{subject to} \quad & dX_s = dB_s + Z_s ds, \quad X_0 = x, \end{aligned}$$

where the control region $Z = R^N$. Let u be a nonnegative solution to (3.26) and for each $T > 0$ we set $w(t,x) = u(T-t,x)$ and consider the SDE

$$\begin{cases} dY_s = dB_s - \nabla w(s, Y_s)ds, \\ Y_0 = x. \end{cases}$$

Then, owing to Proposition 2.4, we have

$$J_+(t,x) = e^{\theta w(t,x)} = E_x[e^{\theta \int_0^{T-t}\{V(Y_s)+\frac{1}{2}|\nabla w(s,Y_s)|^2\}ds}].$$

We furthermore have by Theorem 3.4

$$\begin{aligned} \lim_{T\to\infty} \frac{1}{\theta T} \log J_+(0,x;T) &= \lim_{T\to\infty} \frac{u(T,x)}{T} \\ &= \lim_{T\to\infty} \frac{\partial u}{\partial t}(T,x) = \chi, \end{aligned}$$

where χ is a constant defined by the equation

$$\chi = \frac{1}{2}\Delta v - \frac{1-\theta}{2}|\nabla v|^2 + V. \tag{3.27}$$

On the other hand, $u(t,x)$ has the representation

$$u(t,x) = -\frac{1}{1-\theta} \log E_x[e^{-(1-\theta)\int_0^t V(B_s)ds}]$$

and we see that

$$\lim_{T\to\infty} \frac{u(T,x)}{T} = \frac{\lambda_1(\theta)}{1-\theta},$$

where λ_1 is the principal eigenvalue of $-\frac{1}{2}\Delta + (1-\theta)V$. Thus we see that $\chi = \frac{\lambda_1(\theta)}{1-\theta}$, hence

$$\lim_{T\to\infty} \frac{1}{T} \log J_+(0,x;T) = \frac{\theta\lambda_1(\theta)}{1-\theta}.$$

On the other hand, by Theorem 3.4 $u(T,x) - u(T,0)$ converges to the solution v to (3.27). We consider the temporally homogeneous diffusion process (P_x, X_t) associated with the Dirichlet form on $L^2(\rho^2 dx)$ defined by

$$\mathcal{E}(f,g) = \frac{1}{2}\int \nabla f \cdot \nabla g \rho^2 dx,$$

where $\rho = e^{-v}$ (cf. Fukushima [10]). Then the Donsker–Varadhan large deviation principle asserts that

$$\begin{aligned} &\lim_{T\to\infty} \frac{1}{T} \log E_x[e^{\theta \int_0^T \{V(X_s)+\frac{1}{2}|\nabla v|^2(X_s)\}ds}] \\ &\quad = \sup_f \left[\theta \int \left\{V(x) + \frac{1}{2}|\nabla v|^2\right\} f^2\rho^2 dx - \mathcal{E}(f,f)\right] \\ &\quad = \frac{\theta\lambda_1(\theta)}{1-\theta} \end{aligned}$$

(cf. Deuschel and Stroock [6], Donsker and Varadhan [7], [8]).

OPTIMAL CONTROL OF THE BLOWUP TIME*

EMMANUEL N. BARRON† AND WENXIONG LIU‡

Abstract. The problem of optimal control of the blowup time of a system of nonlinear controlled ordinary differential equations is considered in this paper. The blowup time is defined to be the first time that the norm of the trajectory becomes infinite. When one seeks to maximize the blowup time the pair $(V(x), \Omega)$ comes under consideration, where $x \in R^n \mapsto V(x) \in [0, \infty]$ is the value function and $\Omega \subset R^n$ is the blowup set. This is the set of initial points from which finite time blowup will occur for any control. We prove that (V, Ω) is the unique viscosity solution of the equation $1 + \max_z D_x V(x) \cdot f(x, z) = 0, x \in \Omega$ and conditions $\lim_{|x| \to \infty} V(x) = 0, \lim_{x \to \partial\Omega} V(x) = +\infty$. Finally, we derive the Pontryagin maximum principle for an optimal control. Some generalizations are also discussed.

AMS subject classifications. 49C20, 49C05, 35B99

1. Introduction.

In the modern theory of reaction diffusion equations the phenomenon of blowup in finite time is under study by many researchers too numerous to list here. The usual problem considered is modelled by the semilinear parabolic equation $u_t - \Delta u = u^p$, $p > 1$. It is known that for certain initial data the solution will blow up, i.e., become infinite, in finite time. It is the superlinear growth in the term u^p that leads to the explosion. Models with superlinear growth arise in many contexts including thermal and chemical explosions, population dynamics, biological processes, and some models in economics.

We pose the natural problem of controlling a system which may blow up in finite time. In certain circumstances it is obviously of interest to maximize the time at which the blowup will occur. For example, one may want to raise the temperature in a chemical reaction as much as possible prior to the actual explosion. In other circumstances one might want to minimize the blowup time. Fuel efficiency in a car engine is one case where minimizing the blowup time is desirable. These are natural problems to consider as optimal control problems. In addition, it may be of practical importance to maximize the blowup time under the worst possible environmental assumptions, or vice versa. In this case a differential game model of blowup would be appropriate.

To initiate the optimal blowup problem, in this paper we will consider optimal control of the blowup time when the dynamical system governing the underlying process is a system of ordinary differential equations. Assuming superlinear growth in the dynamics leads to the possibility that the trajectories may blow up in finite time. Most, if not all, prior work in optimal control with ordinary differential equations has assumed the trajectories will exist globally in time. This is not our interest here.

A notable study of optimal control of systems which may blow up is the book by J. L. Lions [12]. Lions considers the question of optimally controlling a distributed system which, for a fixed control, may blow up in finite time. The model problem he considers is $u_t - \Delta u - u^3 = z$ where z is the control. But Lions views the problem in a

† Department of Mathematical Sciences, Loyola University of Chicago, Chicago, IL 60626 (enb@math.luc.edu). This research was supported in part by NSF grant DMS-9102967.

‡ Department of Mathematical Sciences, Loyola University of Chicago, Chicago, IL 60626 (wliu@math.luc.edu).

way completely different from our point of view. He considers the *pair* (u, z) together as *admissible* if and only if u exists globally in time. The requirement of global existence in time is imposed on the control functions. This is a different problem from what we consider in this paper since blowup is then precluded. Our interest is precisely the case when the solution may in fact blow up in finite time.

The focus in this paper is the system $d\xi/d\tau = f(\xi(\tau), \zeta(\tau))$, $\tau > 0$ with $\xi(0) = x \in R^n$. The control function is $\zeta(\cdot)$. The trajectory may blow up at time $T_x(\zeta)$, where we indicate the dependence on the initial point x as well as the control which is used. The blowup time is considered as a map $x \mapsto T_x(\zeta) \in [0, \infty]$. For any fixed control it is certainly possible that the blowup time is infinite, i.e., finite time blowup does not occur. Indeed this will happen at equilibrium points of the system. If we are trying to maximize the blowup time we might seek to steer the trajectory toward equilibrium points.

When the goal is to maximize the blowup time, one considers the value function

$$V(x) = \sup_{\zeta} T_x(\zeta), \qquad V : R^n \to [0, \infty].$$

The blowup set is defined to be the set of initial points of the trajectory at which finite time blowup will occur for any control used: $\Omega = \{x \in R^n : V(x) < +\infty\}$. Of course, Ω is not known a priori. We will characterize the pair (V, Ω) as the unique continuous viscosity solution of the Hamilton–Jacobi equation

$$1 + \max_{z \in Z} D_x V(x) \cdot f(x, z) = 0, \qquad x \in \Omega,$$

satisfying the conditions

$$\lim_{|x| \to \infty} V(x) = 0, \qquad \lim_{x \to \partial\Omega} V(x) = +\infty.$$

If no control is used, so $f = f(x)$, this equation will also hold without the max. It may be useful to know the problem satisfied by the blowup time even for the uncontrolled case.

The theory of necessary conditions for an optimal control for the blowup problem is developed in §5. The Pontryagin principle is derived on the basis of the Hamilton–Jacobi equation.

In a subsequent paper [8] we look at the problem of controlled diffusions which may explode. This problem has the distinctive feature that for nondegenerate diffusions, if finite time blowup occurs at any point $x \in R^n$, then, because of the properties of diffusions, finite time blowup will occur everywhere. Thus, $\Omega = R^n$ for the case of nondegenerate diffusions.

Our original motivation for studying optimal control of blowups was the problem governed by a distributed system, i.e., a partial differential equation (PDE). This problem turns out to be substantially more difficult than the case of ordinary differential equations because of the difficulties with obtaining the regularity of the blowup time with respect to the initial data. Since the initial data is now in a function space we need to determine the Frechet or Gateaux differentiability of the blowup time and the regularity of the associated value function. Differentiability of the blowup time is not known even for the uncontrolled case with the semilinear parabolic model problem $u_t - \Delta u = u^p$. On the other hand, it may be possible to bypass this difficulty using the Crandall and Lions theory of viscosity solutions in infinite dimensions extended by [15]. We hope to return to this problem in a future paper.

Finally, by transforming all of our dynamics from R^n to the stereographic sphere in R^{n+1}, in principle it looks like our problem can be formulated as the problem of maximizing the time at which we hit the north pole, which is mapped to points in R^n with infinite norm. Of course when we want to minimize the blowup time this would be the same as minimizing the time at which we hit the north pole. We see that there is an intimate connection between our problem of blowup and the minimum time problem studied so effectively by Bardi, Soravia, Falcone, Staicu, and others [3]–[6], [14]. Indeed, if we formally consider the target set $\mathcal{T} = \{\infty\}$, then our blowup problem is nothing more than maximizing the time to hit $\mathcal{T}$. Using this point of view, we adapt some arguments of [3]–[5], and [14] in order to prove some of our basic results.

For the convenience of the reader we record here the definition of viscosity solution.

DEFINITION 1.1. *A lower (upper) semicontinuous continuous function v is a viscosity subsolution (supersolution) of*

$$H(x, v, Dv) = 0, \quad x \in \Omega,$$

where Ω is an open set, if for any $\varphi \in C^1(\Omega)$

$$x_0 \in \arg\max(v - \varphi)(x) \Longrightarrow H(x_0, v(x_0), D\varphi(x_0)) \geq 0$$

(respectively, for any $\varphi \in C^1(\Omega)$ and

$$x_0 \in \arg\min(v - \varphi)(x) \Longrightarrow H(x_0, v(x_0), D\varphi(x_0)) \leq 0).$$

The reader is encouraged to look at [9], [10], and especially [11] for the primary results in viscosity solution theory.

2. Basic properties of the blowup time. Consider the autonomous controlled system of ordinary differential equations

$$\begin{aligned} &d\xi(t)/dt = f(\xi(t), \zeta(t)), \ t > 0, \\ &\xi(0) = x \in R^n. \end{aligned} \tag{2.1}$$

The control functions $\zeta(\cdot)$ are chosen from the class of functions $\mathcal{Z} = \{\zeta : [0, \infty) \to Z \mid \zeta \text{ is Lebesgue measureable}\}$, where Z is a fixed compact subset of some euclidean space R^q. Z is referred to as the control set. A solution of (2.1) which starts at $x \in R^n$ is denoted by $\xi_x(t)$ or by $\xi(t; x)$ to indicate the dependence on the initial condition.

We will assume that $f : R^n \times Z \to R^n$ is jointly continuous and is C^1 in x uniformly in $z \in Z$. This guarantees that f is locally Lipschitz in x. That is, for any $x_0 \in R^n$ and $\delta > 0$ there is a constant $K(x_0, \delta)$ such that

$$|f(x, z) - f(x', z)| \leq K(x_0, \delta)|x - x'|, \quad \forall x, x' \in B_\delta(x_0), \tag{2.2}$$

where $B_\delta(x_0)$ denotes, here and generally, the ball of radius δ centered at x_0.

It is well known that if f is assumed to be *uniformly* Lipschitz continuous then there is for each control $\zeta \in \mathcal{Z}$ a unique *global* solution of (2.1) for any initial position $x \in R^n$. This is also true if one assumes that f has linear growth in x. Since we are only assuming that f is locally Lipschitz in x, we can only conclude in general that, for each control $\zeta \in \mathcal{Z}$, there is a unique solution on a maximal interval of existence,

which we shall denote by $[0, T_x(\zeta))$. The time $T_x(\zeta) \in [0, +\infty]$ is called the *blowup time* for the initial position x when the control used is ζ. When the control is fixed we will also denote the blowup time as simply $T(x)$. We wish to study the blowup time as a function $T : R^n \to [0, \infty]$. If $T(x) = +\infty$ for some $x \in R^n$ then this says that the trajectory does not blow up in finite time. Conversely, if $T(x) < \infty$ for some $x \in R^n$, ξ leaves every compact subset of R^n in finite time.

When $T(x) < +\infty$ the only possible behavior of the trajectory is to blow up to $+\infty$ at time $T(x)$. Therefore, we may also describe T using

$$T(x) = \inf \left\{ s \in [0, \infty] : \lim_{t \to s-0} \|\xi(t)\| = +\infty \right\}.$$

Finally, the fact that finite time blowup means that ξ leaves every compact set in finite time motivates the useful characterization

$$T(x) = \lim_{R \to \infty} \tau_x^R(\zeta),$$

where τ_x^R is the exit time of the trajectory from $\overline{B_R(x)}$. The limit exists (since $R \mapsto \tau^R$ is not decreasing) in the extended sense and can be $+\infty$, if, for example, a trajectory stays in a compact set for all time. This characterization is particularly useful in §3.

The starting points of trajectories which are of interest to us are those for which blowup is inevitable no matter what control is used.

DEFINITION 2.1. *The blowup set $\Omega \subset R^n$ is defined by*

$$\Omega = \left\{ x \in R^n : \sup_{\zeta \in \mathcal{Z}} T_x(\zeta) < +\infty \right\}.$$

For a fixed control $\zeta \in \mathcal{Z}$ define the set

$$\Omega(\zeta) = \{x \in R^n : T_x(\zeta) < +\infty\}.$$

Obviously, $\Omega \subset \Omega(\zeta)$, $\forall \zeta \in \mathcal{Z}$.

We will need the following assumptions.

(Ai) For some $p > 1$,

$$\frac{x \cdot f(x, z)}{|x|^{p+1}} \to 1 \qquad \text{as } |x| \to \infty, \tag{2.3}$$

uniformly in $z \in Z$.

(Aii) For some $M > 0$,

$$|f(x, z)| \leq M(1 + |x|^p). \tag{2.4}$$

Conditions (2.2), (2.3), and (2.4) will be assumed to hold throughout this paper.

Condition (Ai) means that $f(\cdot, z)$ behaves like $|x|^p$ for any $z \in Z$ when $|x|$ is large. For example, $f(x, z) = |x|^{p-1}x + |x|^{q-1}x + g(z)$, where $1 < q < p$ and g is continuous, satisfies these conditions.

We may also consider dynamical systems which grow exponentially fast as $|x| \to \infty$. In that case we need an assumption like $x \cdot f(x, z)/(|x|e^{|x|}) \to 1$ as $|x| \to \infty$.

In what follows we will use the notation that $C^k(A, B)$ is the class of k times continuously differentiable functions from A to B. When $k = 0$ this is the class of

continuous functions and will be denoted simply as $C(A,B)$. If $B = R^1$ we will write $C^k(A)$.

Under condition (2.3) we will prove that the blowup set Ω, and therefore also $\Omega(\zeta)$, $\forall \zeta \in \mathcal{Z}$, contains points of sufficiently large norm for any ζ and is therefore always nonempty.

PROPOSITION 2.1. *If* (2.3) *holds, then* Ω *is nonempty and unbounded. In fact, there is a constant* $K > 0$ *such that* $\{|x| \geq K\} \subset \Omega$.

Proof. By (2.3), for any $\varepsilon > 0$, there is a $K > 0$ so that when $|x| \geq K$,

$$1 - \varepsilon \leq \frac{x \cdot f(x,z)}{|x|^{p+1}} \leq 1 + \varepsilon. \tag{2.5}$$

In particular this is true for any fixed ε, say $\varepsilon = \frac{1}{2}$.

Consider the set $M \equiv \{x \in R^n : |x| \geq K\}$. We will prove that M is an invariant set for any control $\zeta \in \mathcal{Z}$ for the corresponding trajectory given by (2.1). Indeed, define $\Phi(x) = K - |x|$. Then $M \equiv \Phi^{-1}(-\infty, 0]$, $\Phi \in C^1(M, R^1)$, and $D_x\Phi(x) = -x/|x| \neq 0$ for any $|x| = K$. For any $z \in Z$, if $|x| = K$ we have

$$D_x\Phi(x) \cdot f(x,z) = \frac{-x \cdot f(x,z)}{|x|} = \frac{-x \cdot f(x,z)}{|x|^{p+1}} K^p \leq -K^p(1-\varepsilon) < 0.$$

Therefore, $\max_{z \in Z}(D_x\Phi(x) \cdot f(x,z)) \leq 0$ if $|x| = K$. Consequently, by [1, p. 218], for example, M is (positively) invariant and this is true for any control.

Now, let $x \in M$ be the starting point of the trajectory ξ which corresponds to an arbitrary control $\zeta \in \mathcal{Z}$. We will prove that this trajectory blows up in finite time. Define $\gamma(t) = |\xi(t)|$. Then, since M is invariant, $\gamma(t) \geq K$ for all $0 \leq t \leq T_x(\zeta)$. Consequently, by (2.5),

$$\gamma'(t) = \frac{\xi(t) \cdot f(\xi(t), \zeta(t))}{|\xi(t)|} \geq (1-\varepsilon)|\xi(t)|^p = (1-\varepsilon)\gamma(t)^p. \tag{2.6}$$

Set $\eta(\cdot)$ as the solution of

$$\begin{aligned} \frac{d\eta(t)}{dt} &= (1-\varepsilon)\,|\eta(t)|^p, \quad t > 0, \\ \eta(0) &= |x|. \end{aligned}$$

The solution of this problem is given by

$$\eta(t) = [|x|^{1-p} + t\,(1-\varepsilon)\,(1-p)]^{1/1-p}, \tag{2.7}$$

which blows up at the finite time

$$T^\eta(x) = \frac{1}{|x|^{p-1}\,(p-1)\,(1-\varepsilon)} > 0. \tag{2.8}$$

Using (2.6) and the fact that $\gamma(0) = |x|$, we deduce that $\gamma(t) \geq \eta(t)$ for all $0 \leq t \leq T_x(\zeta) \wedge T^\eta(x)$. Then, it must be the case that $T_x(\zeta) \leq T^\eta(x) < +\infty$. Consequently, since ζ was arbitrary, $x \in \Omega$.

We have shown that $M \subset \Omega$. Therefore, Ω is an unbounded set. Finally, in the last statement of the proposition observe that K is found for any $0 < \varepsilon < 1$ such that the first inequality in (2.5) holds. □

COROLLARY 2.2. $\lim_{|x|\to\infty} T_x(\zeta) = 0$, *uniformly in* $\zeta \in \mathcal{Z}$.

Proof. This follows immediately from the proof of the proposition noting that $\lim_{|x|\to\infty} T^\eta(x) = 0$. □

We will need the following estimates.

LEMMA 2.3. *Fix a control* $\zeta \in \mathcal{Z}$ *and an initial point* $x \in \Omega(\zeta)$. *Set* $\beta = 1/(p-1)$. *For any* $\varepsilon > 0$, *there is a* $\delta > 0$, *independent of the control* ζ, *such that at any time* t *for which* $T_x(\zeta) > t > T_x(\zeta) - \delta$, *we have*

$$\beta^\beta((1+\varepsilon)(T_x - t))^{-1/(p-1)} \le |\xi(t)| \tag{2.9}$$

and, for all $0 < t < T_x$,

$$|\xi(t)| \le \max\{\beta^\beta((1-\varepsilon)(T_x - t))^{-1/(p-1)},\ K\}, \tag{2.10}$$

where K *is given so that* (2.5) *holds.*

Proof. From (2.1) it follows that

$$\frac{1}{2}(|\xi(\tau)|^2)' = \xi(\tau)\cdot f(\xi(\tau),\zeta(\tau)). \tag{2.11}$$

Dividing the above equation by $|\xi(\tau)|^{p+1}$ and integrating it over (t, T_x), we get after change of variable

$$\int_{|\xi(t)|}^{\infty} \frac{1}{u^p}du = \frac{1}{p-1}|\xi(t)|^{1-p} = \int_t^T \frac{\xi(s)\cdot f(\xi(s),\zeta(s))}{|\xi(s)|^{p+1}}ds. \tag{2.12}$$

According to (2.5), when $|\xi(t)| \ge K$

$$1 - \varepsilon \le \frac{\xi(t)\cdot f(\xi(t),\zeta(t))}{|\xi(t)|^{p+1}} \le 1 + \varepsilon. \tag{2.13}$$

Furthermore, by the proof of Proposition 2.1, if $|\xi(s)| \ge K$, then $|\xi(t)| \ge K$ for all $s \le t \le T_x$. Let $s \ge 0$ be the first time that $|\xi| \ge K$. On $[0, s]$, $|\xi| \le K$. On $[s, T_x]$ we integrate (2.13) from t to T_x, with $s \le t < T_x$, use (2.12), and rearrange the terms to get

$$|\xi(t)| \le \beta^\beta((1-\varepsilon)(T_x - t))^{-1/(p-1)},\ s \le t < T_x.$$

Since $|\xi(t)| \le K$ on $[0, s]$ we combine these two bounds to obtain (2.10).

To obtain (2.9), because of the fact that $|\xi(t)| \to \infty$ as $t \to T_x$, there exists $\gamma = \gamma(\zeta) > 0$ such that (2.13) holds whenever $T_x > t > T_x - \gamma$. Using (2.12), (2.9) follows for $T_x > t > T_x - \gamma$ again by integration of (2.13) and rearrangement.

We need this estimate with γ independent of ζ. To get it, choose $\delta > 0$ so that for any time t with $\delta > T_x(\zeta) - t$ we have that

$$K \le \beta^\beta((1+\varepsilon)(T_x - t))^{-1/(p-1)}.$$

Notice that δ is independent of ζ but t does depend on ζ. Now, if $\gamma = \gamma(\zeta) \ge \delta$ we are done. If $\gamma(\zeta) < \delta$, we set $\eta(\zeta) = \inf\{\gamma : |\xi(t)| \ge K, t \in (T_x(\zeta) - \gamma, T_x(\zeta))\}$. Clearly $\eta(\zeta) \ge \delta$ and (2.9) is true for all $t \in (T_x(\zeta) - \eta(\zeta), T_x(\zeta))$. This completes the proof. □

The next lemma gives us a condition under which we know that a trajectory is uniformly bounded on a given interval.

LEMMA 2.4. *Fix a control $\zeta \in \mathcal{Z}$ and fix $x \in R^n$.*

(a) *If $T(x) = +\infty$ then there is a constant $C > 0$ such that $||\xi_x|| \leq C$ on the time interval $[0, \infty)$. In fact $C = K$, and K is given so that* (2.5) *holds for some fixed $0 < \varepsilon < 1$.*

(b) *If $T(x) < +\infty$, then on $[0, T(x) - \delta]$, there is a constant C_δ such that $||\xi_x|| \leq C_\delta$, for any $\delta > 0$.*

Proof. (a) If $T(x) = +\infty$ then $\xi_x(t)$ exists for all $t \in [0, \infty)$. If the conclusion of (a) is not true, then there is a time t so that $|\xi_x(t)| > K$, where $K > 0$ is fixed so that (2.5) holds. By Proposition 2.1, this implies that $x \in \Omega(\zeta)$ which contradicts $T(x) = +\infty$.

(b) If $T(x) < +\infty$, set $S = T(x)$ and let $S - \delta > 0$. Then the proof is immediate from (2.10) of Lemma 2.3 □

For the next estimate, which is used later to prove the differentiability of the blowup time, we will need the following additional assumption.

(Aiii) For some $0 < \alpha < p + 2$,

$$| \, |x|^2 (f + x \, f_x) - (p+1)(x \cdot f)x \, | \leq M|x|^\alpha \qquad \text{as } |x| \to \infty, \tag{2.14}$$

and, for some $\varepsilon > 0$,

$$| \, f_x(x, z) \, | \leq p(1 + \varepsilon) \, |x|^{p-1}, \qquad \text{as } |x| \to \infty. \tag{2.15}$$

When the matrix f_x is symmetric (2.15) is not necessary, since then (2.14) implies (2.15). Notice that (Aiii) states that the derivative of f behaves like $p|x|^{p-1}$ for large $|x|$.

It is well known from the standard theory of ordinary differential equations (see for example [1]) that on the interval of existence $[0, T_x(\zeta))$, $y(t) \equiv D_x\xi(t; x)$ exists and satisfies the system

$$dy/dt = D_x f(\xi(t), \zeta(t)) \, y(t), \qquad 0 < t < T_x(\zeta), \tag{2.16}$$

$$y(0) = I. \tag{2.17}$$

Using (2.16), (2.17), and (2.15) we can obtain the asymptotic behavior of $D_x\xi(t; x)$ as t approaches the blowup time $T_x(\zeta)$.

LEMMA 2.5. *Assume that* (Aiii) *holds in addition to the basic assumptions. Let $x \in \Omega(\zeta)$. For any $\varepsilon > 0$, there exists an $M > 0$ and $\delta > 0$, independent of the control, such that when $T_x(\zeta) > t > T_x(\zeta) - \delta$ we have*

$$|D_x\xi(t; x)| \leq M \, (T_x(\zeta) - t)^{-p(1+\varepsilon)/(p-1)}.$$

Proof. Consider, say, $y_j(t) = D_{x_j}\xi(t; x)$. From (2.16),

$$\frac{1}{2}(|y|^2)' = y^t D_x f(x, z) y,$$

where y^t is the transpose of y. Using Lemma 2.3 and (2.15), we see that for any $\varepsilon > 0$,

$$|y|' \leq \frac{p(1+\varepsilon)}{(p-1)(T_x(\zeta) - t)} |y|$$

for $t > T_x(\zeta) - \delta$. The conclusion of the lemma follows by integration. □

LEMMA 2.6. *Let $\zeta \in \mathcal{Z}$ be fixed. The set $\Omega(\zeta)$ is open and $T_x(\zeta) = T(x)$ is locally bounded on $\Omega(\zeta)$.*

Proof. Let $x_0 \in \Omega(\zeta)$ and let ξ be the associated trajectory on $[0, T(x_0))$. Let K be such that (2.5) holds. If $\Omega(\zeta)$ is not open then there is a sequence of points $\{x_n\}$ such that $x_n \to x_0$ and $T(x_n) = +\infty$. Thus, the trajectory starting at x_n with the fixed control ζ, $\xi_n = \xi(\cdot; x_n)$ exists for all time. Obviously, we must have $|x_n| \leq K, \forall n$. From Lemma 2.4, $\{\xi_n\}$ is uniformly bounded (by K), for every n. Let $M > 0$ be arbitrary. On $[0, M]$ ξ_n and also ξ_n' are uniformly bounded. Since $x_n \to x_0$, there is a subsequence, with the same notation, such that $\xi_n \to \xi^*$ uniformly on $[0, M]$ and ξ^* is the trajectory starting from x_0 associated with ζ. By uniqueness, $\xi^* = \xi$. But then $T(x_0) > M$ and since M was arbitrary, this means that $T(x_0) = +\infty$, a contradiction.

Now we prove that $T(x_0)$ is locally bounded. Indeed, if this is not the case, then we can find a sequence of starting points $x_n \to x_0$ such that $\lim_{n\to\infty} T(x_n) = +\infty$. Let $M = T(x_0)$ and n sufficiently large that $T(x_n) \geq M + 1$. Then $\{\xi_n\}$ is uniformly bounded on $[0, M + \frac{1}{2}]$ and so a subsequence converges uniformly to $\xi(\cdot; x_0)$ on this interval. This contradicts the fact that ξ blows up at time $T(x_0) = M$. □

The next lemma proves that for any fixed control the blowup time is a continuous function of the starting position.

LEMMA 2.7. *Fix a control $\zeta \in \mathcal{Z}$. $T(x)$ is continuous in $x \in \Omega(\zeta)$.*

Proof. For $n = 1, 2, \ldots$, let $x_n \in \Omega(\zeta)$ with $x_n \to x \in \Omega(\zeta)$. Let ξ_n and ξ be the corresponding solutions of (2.1) for the same control ζ, and let T_n and T denote the corresponding blowup times. Lemma 2.6 allows us to assume that $T_n < +\infty$ for all n.

We first prove that $\liminf_n T_n \geq T$. To this end, we want to show that for any $\delta > 0$, $T_n \geq T - \delta$ holds for all sufficiently large n. Suppose it is not the case. Then there exists a subsequence, again labeled as T_n, such that $T_n \leq T - \delta$. By taking yet another subsequence, we may assume that $T_n \to T_0 \leq T - \delta$. Given $\varepsilon > 0$, by Lemma 2.4, the sequence $\{\xi_n\}$ is uniformly bounded in $[0, T_0 - \varepsilon]$ for all large n. Now the argument is completed just as in the proof of Lemma 2.6.

Next we show that $\limsup_n T_n \leq T$. We again argue by contradiction. So assume that there exists a subsequence T_n such that $\lim_n T_n \geq T + \delta$ for some $\delta > 0$. From Lemma 2.4, it follows that $\{\xi_n\}$ is uniformly bounded in $[0, T)$. The argument we used above implies that $\xi_n \to \xi$ uniformly in $[0, T)$; hence ξ is also bounded in $(0, T)$, which is a contradiction to the fact that T is the blowup time of ξ. The proof is complete. □

The next lemma tells us that if we also assume condition (Aiii), the blowup time is, in fact, continuously differentiable for each fixed control.

LEMMA 2.8. *Assume, in addition to the basic assumptions, condition* (Aiii). *Fix a control $\zeta \in \mathcal{Z}$. The blowup time $T_x(\zeta) = T(x)$ is a C^1 function of $x \in \Omega(\zeta)$.*

Proof. Divide (2.11) by $1 + |\xi(\tau)|^{p+1}$ and integrate the result over $[0, T(x))$ to get

$$\int_{|x|}^{\infty} \frac{u}{u^{p+1} + 1}\, du = \int_0^{T(x)} \frac{\xi(s) \cdot f(\xi(s), \zeta(s))}{1 + |\xi(s)|^{p+1}}\, ds. \tag{2.18}$$

The equation (2.18) defines T as a function of x implicitly. Indeed, if we set

$$g(t, x) = \begin{cases} \dfrac{\xi(t; x) \cdot f(\xi(t; x), \zeta(t))}{|\xi(t; x)|^{p+1} + 1}, & \text{if } t < T(x), \\ 1, & \text{if } t \geq T(x), \end{cases}$$

and

$$F(T,x) = \int_x^\infty \frac{u}{u^{p+1}+1}\,du - \int_0^T g(t,x)\,dt,$$

then $F(T(x),x) = 0$ and

$$\frac{\partial F}{\partial T}(T(x),x) = -\lim_{|x|\to\infty} \frac{x\cdot f(x,z)}{|x|^{p+1}+1} = -1.$$

If we can show further that $D_x F(T,x)$ exists and is continuous, then the conclusion of the lemma follows from the classical implicit function theorem in calculus.

Since for t near $T(x)$, $t > T(x) - \delta$, using (Aii) and (Aiii)

$$\begin{aligned}
&\left|\frac{\partial g(x,t)}{\partial x_i}\right| = \\
&\quad\left|\frac{[\xi_{x_i}\cdot f(\xi,\zeta) + \xi\cdot(f_x(\xi,\zeta)\xi_{x_i})](|\xi|^{p+1}+1) - (p+1)|\xi|^{p-1}(\xi\cdot\xi_{x_i})(\xi\cdot f(\xi,\zeta))}{(1+|\xi|^{p+1})^2}\right| \\
&\le \frac{||\xi|^2(f+\xi\, f_x) - (p+1)(\xi\cdot f)\,\xi||\xi_{x_i}|\,|\xi|^{p-1}}{(1+|\xi|^{p+1})^2} + \frac{|f+\xi\cdot f_x|\,|\xi_{x_i}|}{(1+|\xi|^{p+1})^2} \\
&\le \frac{M|\xi_{x_i}|}{|\xi|^{p+3-\alpha}+1},
\end{aligned}$$

we conclude, by using Lemma 2.5, that

$$\int_0^{T(x)} \frac{\partial g(x,t)}{\partial x}\,dt = \int_0^{T(x)} (T(x)-t)^{-\mu}\,dt < \infty,$$

where $0 < \mu < 1$. Combining this fact with Lemma 2.7, we see that $D_x F$ is continuous and therefore $T(x)$ is C^1. □

REMARK 2.1. *Differentiate* (2.18) *with respect to* x *to obtain*

$$\begin{aligned}
|D_x T(x)| &\le \frac{|x|}{|x|^{p+1}+1} + \int_0^{T(x)} |D_x g|\,dt \\
&\le \frac{|x|}{|x|^{p+1}+1} + M\int_0^{T(x)} (T(x)-t)^{-\mu}\,dt.
\end{aligned} \tag{2.19}$$

Observe that (2.19) *shows that* $|D_x T(x)| \to 0$ *as* $|x| \to \infty$.

3. The optimal control problem. In this section we will formulate the basic optimal control problem for the blowup time, namely the problem of maximizing the blowup time. This corresponds to the case in which one desires to delay the inevitable explosion as long as possible.

In this section we will assume only the basic assumptions (2.2), (Ai), and (Aii).

DEFINITION 3.1. *The value function* $V : R^n \to [0,\infty]$ *is defined by*

$$V(x) = \sup\{T_x(\zeta) : \zeta \in \mathcal{Z}\}.$$

The blowup set can then be expressed as $\Omega = \{x \in R^n : V(x) < +\infty\}$. Of course, the blowup set is not known a priori.

The main objective in this section is to prove that the value function is continuous. We begin by establishing that the blowup set is open and V is locally bounded on this set.

We introduce the relaxed control problem which will be needed for the proof. Let $M(Z)$ denote the space of bounded measures on Z. Viewing $M(Z)$ as the dual space of $C(Z)$ = continuous functions on Z, we endow $M(Z)$ with the weak star topology of $C(Z)^*$. Let the space of relaxed controls be given by

$$\widehat{\mathcal{Z}} = \{\mu \in L^\infty([0,\infty); M(Z)) \mid \mu(\tau) \text{ is a probability measure a.e. } \tau \in [0,\infty)\}.$$

Let $\mathcal{M}(Z)$ be the set of probability measures on Z. Then we may write that $\widehat{\mathcal{Z}} = L^\infty([0,\infty); \mathcal{M}(Z))$, the space of essentially bounded, Lebesgue measureable maps $\mu : [0,\infty) \to \mathcal{M}(Z)$.

For any relaxed control $\mu(\cdot) \in \widehat{\mathcal{Z}}$ there is a relaxed trajectory given by

$$\widehat{\xi}(\tau) = x + \int_0^\tau \int_Z f(\widehat{\xi}(s), z)\, \mu(s, dz) ds \tag{3.1}$$

on the maximal interval of existence $[0, \widehat{T}_x(\mu))$. We are using the notation that $\widehat{T}_x(\mu)$ is the blowup time for the relaxed trajectory starting from x when the relaxed control is μ. To simplify the presentation, given any $\mu \in \mathcal{M}(Z)$ define the function

$$\widehat{f}(x, \mu) = \int_Z f(x, z)\, \mu(dz). \tag{3.2}$$

It is clear that $\widehat{f}$ enjoys the same continuity and growth properties as does f, i.e., $\widehat{f}$ satisfies (2.2), (Ai), and (Aii). Consequently, the lemmas of the preceding section also hold for the relaxed problem.

Define the relaxed value function $\widehat{V} : R^n \to [0,\infty]$ as

$$\widehat{V}(x) = \sup_{\mu \in \widehat{\mathcal{Z}}} \widehat{T}_x(\mu).$$

Denote the relaxed blowup set $\widehat{\Omega} = \{x \in R^n : \widehat{V}(x) < +\infty\}$.

We are now ready to prove the following proposition.

PROPOSITION 3.1. *The blowup set Ω is open and V is locally bounded on Ω.*

Proof. Clearly, $V(x) \le \widehat{V}(x)$ and $\widehat{\Omega} \subset \Omega$. We will first establish that $\Omega = \widehat{\Omega}$.

Let $x_0 \in \Omega$. Then $T_{x_0}(\zeta) \le V(x_0) = M < +\infty$ for any $\zeta \in \mathcal{Z}$. If there is a $\mu \in \widehat{\mathcal{Z}}$ for which $T_{x_0}(\mu) \ge M + 1$, this says that the relaxed trajectory $\widehat{\xi}(\cdot)$, corresponding to μ, starting from x_0, exists for all $t \in [0, M + \frac{1}{2}]$. Then there is a constant K (see Lemma 2.4) such that $|\widehat{\xi}| \le K$ on this interval. Since $f(x,z)$ is uniformly Lipschitz on $B_K(0) \times Z$ we may apply the relaxation theorem [2] to obtain, for any given $\varepsilon > 0$, an ordinary trajectory $\xi(\cdot)$ starting from x_0 and a control $\zeta \in \mathcal{Z}$, such that $||\xi - \widehat{\xi}|| < \varepsilon$ in the sup norm on $[0, M + \frac{1}{2}]$. Therefore $M = V(x_0) \ge T_{x_0}(\zeta) > M + \frac{1}{2}$. This is a contradiction and we conclude that $\Omega = \widehat{\Omega}$.

Next, for any sequence of starting points $\{x_n\}$ such that $x_n \to x_0$, and relaxed controls $\{\mu_n\} \subset \widehat{\mathcal{Z}}$, we know that, at least on a subsequence, $\mu_n \to \mu \in \widehat{\mathcal{Z}}$ weak-*. Denote the associated relaxed trajectories by $\widehat{\xi}_n$ starting at x_n and $\widehat{\xi}$ starting at x_0. We claim that

$$\liminf_{n \to \infty} T_{x_n}(\mu_n) \le T_{x_0}(\mu). \tag{3.3}$$

To prove this claim, suppose it is not true. Then, there is a $\delta > 0$ for which

$$\liminf_{n\to\infty} T_{x_n}(\mu_n) \geq T_{x_0}(\mu) + \delta.$$

Hence, by Lemma 2.4 a subsequence of $\{\widehat{\xi}_n\}$, still denoted as $\{\widehat{\xi}_n\}$, is uniformly bounded on $[0, T_{x_0}(\mu) + \gamma]$ for any $0 < \gamma < \delta$. Therefore, a further subsequence converges uniformly to $\widehat{\xi}$ on $[0, T_{x_0}(\mu) + \gamma]$. But then $\widehat{\xi}$ is also bounded on this time interval, which contradicts the fact that $T_{x_0}(\mu)$ is the blowup time of $\widehat{\xi}$. We have proved that (3.3) must hold.

Now, to show that Ω, or equivalently, $\widehat{\Omega}$, is open, we must find an open neighborhood of x_0 contained in $\widehat{\Omega}$. If this cannot be done then we can find a sequence of points $\{x_n\}$ and a sequence of relaxed controls $\{\mu_n\} \subset \widehat{\mathcal{Z}}$, such that $T_{x_n}(\mu_n) \to +\infty$, and $x_n \to x_0$ as $n \to \infty$.

Set $T_0 \equiv \widehat{V}(x_0) < +\infty$. Select $\varepsilon > 0$, and fix N at least large enough so that $T_{x_n}(\mu_n) > T_0 + 1$ and $x_n \in B_\varepsilon(x_0)$, for all $n \geq N$. Let $\widehat{\xi}_n$ be the relaxed trajectory associated with μ_n starting from x_n. Since $T_{x_n}(\mu_n) > T_0 + 1$, we have that $\{\widehat{\xi}_n\}$ is uniformly bounded on $[0, T_0]$. Thus, there is a relaxed control $\mu \in \widehat{\mathcal{Z}}$ and corresponding relaxed trajectory $\widehat{\xi}$ starting from x_0 such that on a convergent subsequence $\mu_n \to \mu$ weak-* and $\widehat{\xi}_n \to \widehat{\xi}$ uniformly on $[0, T_0]$. Using (3.3), we have

$$T_0 + 1 < \liminf_{n\to\infty} T_{x_n}(\mu_n) \leq T_{x_0}(\mu) \leq \widehat{V}(x_0) = T_0,$$

which is a contradiction. Hence $\widehat{\Omega} = \Omega$ is open.

The proof that V is locally bounded follows the same line of proof. Since $V \leq \widehat{V}$ we may show that $\widehat{V}$ is locally bounded. If $\widehat{V}$ is not locally bounded at $x_0 \in \Omega$, this would again mean that there is a sequence of points $\{x_n\}$, $x_n \to x_0$, and a sequence of relaxed controls μ_n, such that $T_{x_0}(\mu_n) < +\infty$ but $\lim_{n\to\infty} T_{x_n}(\mu_n) = +\infty$. □

REMARK 3.1. *It is not difficult to verify, using the relaxation theorem that* $V = \widehat{V}$.

We are now ready to prove the following theorem.

THEOREM 3.2. *The function* $V(x) = \sup_{\zeta\in\mathcal{Z}} T_x(\zeta)$ *is continuous on* Ω. *Furthermore,* $V(x) \to 0$ *as* $|x| \to \infty$.

Proof. For any $R > 0$ let $\mathcal{T}_R = \{x : |x| < R\}$. Set $\Omega_R = \Omega \cap \mathcal{T}_R = \{x \in \Omega : |x| < R\}$. Let $\tau_x^R(\zeta)$ denote the first exit time of the trajectory from $\mathcal{T}_R$ when we use the control $\zeta \in \mathcal{Z}$. More precisely, $\tau_x^R(\zeta)$ is the first time that ξ_x is in $\partial\mathcal{T}_R$. If the trajectory never exits $\mathcal{T}_R$ we set $\tau_x^R(\zeta) = +\infty$.

It follows from the definition of blowup time that

$$T_x(\zeta) = \lim_{R\to\infty} \tau_x^R(\zeta). \tag{3.4}$$

Clearly, $\tau_x^R(\zeta)$ increases when R increases. We claim that

$$V(x) = \lim_{R\to\infty} V_R(x), \qquad x \in \Omega, \tag{3.5}$$

where V_R is the maximal (over controls) exit time from $\mathcal{T}_R$, that is, $V_R(x) = \sup_{\zeta\in\mathcal{Z}} \tau_x^R(\zeta)$.

Using assumption (Ai), one has that $f(x,z) \cdot x/|x| > (1-\varepsilon)R^p > 0$ for all sufficiently large $|x| = R$, say $R > R_0$. Indeed, R_0 can be taken as the constant K from Proposition 2.1. Since $\nu = x/|x|$ is the outward pointing normal to the boundary

of the ball of radius R, we have $\nu \cdot f > 0$. It follows from [5, Prop. 5.2] that this implies that $V_R(x)$ is continuous on Ω_R for all $R > R_0$.

For any $R > R_0$, from [5, Thm. 6.1] V_R is the unique continuous viscosity solution of the problem

$$\max_{z \in Z} (f(x,z) \cdot DV_R) + 1 = 0, \quad x \in \Omega_R, \tag{3.6}$$

$$\lim_{x \to \partial\Omega_R^\infty} V_R(x) = \infty, \tag{3.7}$$

and

$$V_R(x) = 0, \quad |x| = R, \tag{3.8}$$

where $\partial\Omega_R^\infty \equiv \partial\Omega_R - \{|x| = R\}$. From Proposition 2.1, $\{|x| > R_0\} \subset \Omega$ and so $\partial\Omega_R^\infty = \partial\Omega$ for $R > R_0$. Consequently, (3.7) implies that for all $R > R_0$,

$$\lim_{x \to \partial\Omega} V_R(x) = \infty. \tag{3.9}$$

It is clear that $R \leq R'$ implies that $V_R \leq V_{R'}$ and $\Omega_{R'} \subset \Omega_R$. Furthermore, $V(x) \geq V_R(x)$ for all $R > 0$.

Let $x \in \Omega$. Using (3.4) we have, for a given $\delta > 0$, the existence of a control $\zeta^* \in \mathcal{Z}$, and $R' > 0$ such that

$$V(x) \leq T_x(\zeta^*) + \delta \leq \tau_x^{R'}(\zeta^*) + 2\delta \leq V_{R'}(x) + 2\delta \leq \lim_{R \to \infty} V_R(x) + 2\delta,$$

which allows us to conclude that (3.5) is true on Ω.

Now we will show that the convergence in (3.5) is uniform on compact subsets of Ω, which allows us to conclude that $V(x)$ is continuous on Ω.

First, from Corollary 2.2, we immediately have that $V(x) \to 0$ as $|x| \to \infty$. In addition, simply from $V(x) \geq V_R(x) \geq 0$, we see that $V_R(x) \to 0$ as $|x| \to \infty$, uniformly in R. Consequently, for any $\delta > 0$, there is an R_δ such that $0 \leq V_R(x) \leq \delta$ if $|x| \geq R_\delta$. We may also assume that R_δ is sufficiently large such that (2.5) holds. For any $R_2 > R_1 > R_\delta$, we have that if $|x| = R_1$

$$0 \leq V_{R_2}(x) - V_{R_1}(x) = V_{R_2}(x) \leq \delta.$$

Therefore, $V_{R_1} \geq V_{R_2} - \delta$ on $\{|x| = R_1\}$. We have that in Ω_{R_1}, V_{R_1} is a supersolution and $V_{R_2} - \delta$ is a subsolution. By the comparison principle for viscosity solutions of (3.6)–(3.8), for example, [14, Thm. 2.1], we conclude that

$$0 \leq V_{R_2}(x) - V_{R_1}(x) \leq \delta, \quad x \in \Omega_{R_1}$$

and therefore this inequality holds also for all $x \in \Omega_{R_\delta} \subset \Omega_{R_1}$. We have shown that for any sequence $\{R_k\}$, with $R_k \to \infty$ as $k \to \infty$, the sequence $\{V_{R_k}(x)\}$ is a Cauchy sequence, uniformly in $x \in \Omega_{R_1}$, for any $R_1 > R_\delta$. Therefore, $V_{R_k}(x) \to V(x)$ uniformly on compact subsets of Ω. □

4. The Bellman equation for the value function. We have seen in the previous section that V is a continuous function on Ω. The main goal of this section is to characterize V by proving that it must satisfy, in the viscosity sense, a Hamilton–Jacobi equation with a free boundary. Then we will prove that V is the only viscosity solution of the problem.

In this section we assume only that the basic assumptions (2.2), (Ai), and (Aii) hold.

THEOREM 4.1. *The value function V is a continuous viscosity solution of the free boundary problem*

$$1 + \max_{z \in Z} D_x V(x) \cdot f(x,z) = 0, \quad x \in \Omega, \tag{4.1}$$

$$\lim_{x \to \partial\Omega} V(x) = +\infty, \tag{4.2}$$

$$\lim_{|x| \to \infty} V(x) = 0. \tag{4.3}$$

Proof. Referring to the proof of Theorem 3.2, we have that $V \geq V_R$ and $V_R \to \infty$ as $x \to \partial\Omega$, and (4.2) follows.

We need to verify that V solves (4.1). This follows immediately from the proof of Theorem 3.2 since we showed there that V is the uniform limit of V_R and V_R is the solution of (3.6). We will give a direct proof however. The proof is based on the dynamic programming principle:

$$V(x) = \sup_{\zeta \in \mathcal{Z}} (t \wedge T_x(\zeta) + \chi_{t \leq T_x(\zeta)} V(\xi_x(t))) \tag{4.4}$$

for any $t \geq 0$, where $\xi_x(\cdot)$ is the trajectory starting at x at time 0 associated with the control $\zeta \in \mathcal{Z}$. We use the notation that χ_A is the characteristic function of the set A and $a \wedge b = \min(a,b)$.

The proof of (4.4) is standard and will not be given here (see, for example, [3]).

Now suppose that $V - \varphi$ achieves a zero minimum at the point $x_0 \in \Omega$, with $\varphi \in C^1(\Omega)$. Let $z \in Z$ be arbitrary and set $\zeta(t) \equiv z$ for all time. The corresponding trajectory starting at x_0 will be denoted by $\xi(\cdot)$. Since the interval of existence of the trajectory is open [1, Thm. 8.3], for any $0 < t < T_x(z)$, sufficiently small, using (4.4)

$$\begin{aligned} \varphi(x_0) = V(x_0) &= \sup_{\zeta \in \mathcal{Z}} (t \wedge T_{x_0}(\zeta) + \chi_{t \leq T_{x_0}(\zeta)} V(\xi(t))) \\ &\geq t \wedge T_{x_0}(z) + \chi_{t \leq T_{x_0}(z)} V(\xi(t)) \\ &\geq t \wedge T_{x_0}(z) + \chi_{t \leq T_{x_0}(z)} \varphi(\xi(t)) \\ &= t + \varphi(\xi(t)). \end{aligned}$$

We have used the fact that, since f is locally Lipschitz, for any $R > 0$ there is a $\delta > 0$ independent of $z \in Z$ such that $\xi(t) \in B_R(x_0)$ if $0 < t < \delta$. Therefore, for t sufficiently small,

$$1 + \frac{\varphi(\xi(t)) - \varphi(x_0)}{t} \leq 0$$

and so, letting $t \to 0+$, using the fact that φ is smooth and ξ is differentiable (since we are using a constant control), we obtain from the arbitrariness of $z \in Z$ that

$$1 + \max_{z \in Z}(D_x\varphi(x_0) \cdot f(x_0, z)) \leq 0. \tag{4.5}$$

This proves that V is a supersolution of (4.1).

Suppose next that $V - \varphi$ achieves a zero maximum at the point $x_0 \in \Omega$, with $\varphi \in C^1(\Omega)$. Suppose that

$$1 + \max_{z \in Z}(D_x\varphi(x_0) \cdot f(x_0, z)) \leq -C < 0. \tag{4.6}$$

Let $\zeta \in \mathcal{Z}$ be arbitrary. For a given $\delta > 0$, set $M = \sup\{|f(x, z)| : x \in B_\delta(x_0), z \in Z\}$. Then the trajectory $\xi(\cdot)$ starting at x_0 will exist at least for $t \in [0, \delta/M)$ (see, for example, [1]). Notice that this is true independently of the control ζ which is chosen. Thus, we know that $\xi(t) \in B_{\delta\, M}(x_0)$ for all $0 \leq t < t_0 < T_{x_0}(\zeta)$ for some $t_0 > 0$ independent of ζ. Using (4.6) we have that

$$1 + D_x\varphi(x_0) \cdot f(x_0, \zeta(t)) \leq -C, \qquad 0 < t < t_0.$$

Then, for sufficiently small t, say $0 < t < t_1 < t_0$,

$$1 + D_x\varphi(\xi(t)) \cdot f(\xi(t), \zeta(t)) \leq -C/2, \qquad 0 < t < t_1 < T_{x_0}(\zeta),$$

since φ is smooth and $f(x, z)$ is locally Lipschitz. Now we integrate this from 0 to t_1 to get

$$t_1 + \varphi(\xi(t_1)) - \varphi(x_0) \leq -(C/2)t_1.$$

Rearranging this tells us that

$$t_1 + \varphi(\xi(t_1)) \leq \varphi(x_0) - (C/2)t_1 < \varphi(x_0).$$

But this contradicts the dynamic programming principle (4.4). Therefore, V is a subsolution of (4.1) as well. □

We will prove next that V is the only continuous viscosity solution of (4.1) which satisfies (4.2) and (4.3). The proof of uniqueness is based on the uniqueness theorems of Bardi and Soravia [5], [14] for pursuit-evasion differential games. Viewing the optimal control problem as a one-player differential game, we will state their theorem in the form suitable for our problem.

THEOREM 4.2 (see [5, Thm. 3.1]). *Assume that $f(x, z)$ is uniformly Lipschitz. Let Λ be an open set containing the closed target set $\mathcal{T}$. Let $U \in C(\Lambda - \mathcal{T})$ be a viscosity solution of*

$$\begin{aligned} &1 + \max_{z \in Z} DU \cdot f(x, z) = 0, \qquad x \in \Lambda - \mathcal{T}, \\ &U(x) = g(x), \quad x \in \partial\mathcal{T}, \qquad U(x) \to +\infty, \quad x \to \partial\Lambda. \end{aligned} \tag{4.7}$$

Define $W : R^n \to R^1 \cup \{\infty\}$ by

$$W(x) = \sup_{\zeta \in \mathcal{Z}} g(\xi(\sigma_x)) + \sigma_x(\zeta),$$

where g is a given continuous function and $\sigma_x(\zeta) = \inf\{t : \xi_x(t) \in \partial\mathcal{T}\}$ and $\sigma_x(\zeta) = +\infty$ if $\partial\mathcal{T}$ is never achieved. Then $U \equiv W$ and $\Lambda = \{x : W(x) < +\infty\}$.

Clearly this theorem gives us the uniqueness result for the blowup time problem with the target set taken to be $\mathcal{T} = \{\infty\}$. All we need to do is phrase it in terms which do not use the point at infinity.

We are ready to prove the following theorem.

THEOREM 4.3. *Assume* (2.2), (Ai), *and* (Aii). *Let* Λ *be any open set. Let* $U \in C(\Lambda)$ *be a viscosity solution of*

$$\begin{cases} 1 + \max_{z \in Z} (DU \cdot f(x,z)) = 0, & x \in \Lambda, \\ \lim_{|x| \to \infty} U(x) = 0, \qquad \lim_{x \to \partial\Lambda} U(x) = +\infty. \end{cases} \tag{4.8}$$

Then $U = V$ *and* $\Lambda = \Omega$. *That is,* U *must be the value function for the blowup time and* Λ *must be the blowup set* Ω.

Proof. Let $\varepsilon > 0$. Define the target set $\mathcal{T}_K = \{x : |x| \geq K\}$, where K is fixed large enough so that $|U(x)| < \varepsilon$ and so that $\mathcal{T}_K \subset \Omega$. This can be done according to Proposition 2.1. Then U is a viscosity solution of (4.7) if we take $\mathcal{T} = \mathcal{T}_K$ and $g(x) = U(x)$ restricted to $\{|x| = K\}$. Consequently, using Bardi and Soravia's theorem

$$U(x) = \sup_{\zeta \in \mathcal{Z}} \left(g(\xi_x(\tau_x^K)) + \tau_x^K(\zeta) \right) \tag{4.9}$$

and $\Lambda = \{x : \sup_{\zeta \in \mathcal{Z}} \left(g(\xi_x(\tau_x^K)) + \tau_x^K(\zeta) \right) < +\infty\}$. Here $\tau_x^K(\zeta)$ is the exit time from $\Lambda - \mathcal{T}_K$. Note that Bardi and Soravia's theorem requires uniform Lipschitz continuity of the vector field $f(x,\cdot)$. Since we are working in the set $\Lambda - \mathcal{T}_K$, which is bounded, under assumption (2.2), f is uniformly Lipschitz in that set.

Now, observe that $U(x) < +\infty$ if and only if $V(x) < +\infty$. Indeed, if $V(x) < +\infty$ any trajectory must exit the ball of radius K before it explodes, so $\tau_x^K(\zeta) < V(x) < +\infty$, which implies by (4.9) that $U(x) < +\infty$. If $U(x) < +\infty$ then an arbitrary trajectory hits $\mathcal{T}_K$ in finite time. Once it hits $\mathcal{T}_K$, since we chose K large enough so that $\mathcal{T}_K \subset \Omega$, it is in the blowup set Ω. Thus the starting position of the trajectory must have been in Ω as well. Therefore $\Lambda = \Omega$. Furthermore, we let $\varepsilon \to 0$, and therefore $K \to \infty$ in (4.9), and conclude that $U = V$ (refer to (3.5) in the proof of Theorem 3.2). □

The next result we want to prove gives us a way of calculating V and Ω without having to solve the free boundary problem (4.8). To this end, following Bardi and Soravia [5], we consider the Kruzhkov transform of V:

$$w(x) = \psi(V(x)) \equiv 1 - \exp(-V(x)), \qquad x \in \Omega. \tag{4.10}$$

The Kruzhkov transform was introduced for viscosity solutions in [9].

The proof of the following lemma is a simple consequence of the properties of $\psi(\cdot)$ and the definition of viscosity solution (cf. [3], [9]).

LEMMA 4.4. *The function* w *is a viscosity solution of*

$$1 - w + \max_{z \in Z} D_x w(x) \cdot f(x,z) = 0, \qquad x \in \Omega = \{x \in R^n : w(x) < 1\}, \tag{4.11}$$

$$\lim_{x \to \partial\Omega} w(x) = 1, \tag{4.12}$$

$$\lim_{|x| \to \infty} w(x) = 0. \tag{4.13}$$

The fact that w goes to 0 when $|x| \to \infty$ will be the key property that gives a unique solution of the problem (4.11)–(4.13).

The problem with dealing with (4.11) directly is the fact that it holds only on Ω which is unknown a priori since it too depends on w. But Bardi and Falcone in [4] showed how to avoid this problem when it also arose for the minimum time problem. We will do the same thing here. Namely, we consider the same problem for w but we solve it in R^n:

$$1 - w + \max_{z \in Z} D_x w(x) \cdot f(x,z) = 0, \qquad x \in R^n. \tag{4.14}$$

We drop the boundary condition (4.12) and only impose the condition (4.13).

LEMMA 4.5. *Assume* (2.2), (Ai), *and* (Aii). *A continuous viscosity solution of* (4.14), (4.13) *is given by*

$$w(x) = \begin{cases} 1 - \exp(-V(x)), & \text{if } x \in \Omega, \\ 1, & \text{if } x \in R^n - \Omega. \end{cases} \tag{4.15}$$

Proof. We know that w is continuous and bounded. Also, by Proposition 2.1, $w(x) \to 0$ as $|x| \to \infty$. Noting that ψ is an increasing function, we may write w as follows:

$$w(x) = \sup_{\zeta \in \mathcal{Z}} \int_0^{T_x(\zeta)} e^{-s}\, ds, \qquad x \in R^n,$$

which shows that w itself is the value function of a control problem up to the time of blowup with a discount factor. Using a standard dynamic programming argument, we can now prove in a straightforward way that w is a viscosity solution of (4.14). □

Now we will prove that (4.15) is the only solution of (4.14) satisfying (4.13). We phrase the theorem in the form of a comparison principle.

THEOREM 4.6. *Let u be a lower semicontinuous and v an upper semicontinuous function on R^n such that u is a bounded viscosity subsolution and v is a bounded viscosity supersolution of* (4.14) *both satisfying condition* (4.13). *Then $u \le v$ on R^n. In particular, if both u and v are continuous viscosity solutions, then $u \equiv v$.*

REMARK 4.1. *In general, when the function f has superlinear growth in x this theorem is false without the condition* (4.13).

REMARK 4.2. *The proof of the last assertion of the theorem follows from Theorem* 4.3. *Indeed, if u and v are both continuous viscosity solutions of* (4.14), *then the pairs $(U, \Omega(U))$ and $(V, \Omega(V))$, where $U = -\log(1-u), \Omega(U) = \{x : u(x) < 1\}$ and $V = -\log(1-v), \Omega(V) = \{x : v(x) < 1\}$ are both continuous viscosity solutions of* (4.8). *Then, by Theorem* 4.3, *$\Omega(U) = \Omega(V) = \Omega$, the blowup set, and $U = V$ must be the value function for the blowup time. The proof below gives us the comparison principle for discontinuous solutions which is used in* [8].

Proof. The proof is standard, with the only new point being that boundary condition (4.13) allows us to find points of maximum of the doubled function, Φ below, in a compact set. We sketch the proof for completeness.

Define the function $\vartheta(x,y) = u(x) - v(y)$. Let $\varphi \in C^1(R^{2n})$ and let (x_0, y_0) be a maximum point of $\vartheta - \varphi$. Then $x \mapsto \vartheta(x, y_0) - \varphi(x, y_0)$ achieves a maximum at x_0

and $y \mapsto -\vartheta(x_0, y) + \varphi(x_0, y)$ achieves a minimum at y_0. Since u is a subsolution and v is a supersolution of (4.14), we have that

$$1 - u(x_0) + \max_{z \in Z} D_x \varphi(x_0, y_0) \cdot f(x_0, z) \geq 0, \tag{4.16}$$

and

$$1 - v(y_0) + \max_{z \in Z} (-D_y \varphi(x_0, y_0)) \cdot f(y_0, z) \leq 0. \tag{4.17}$$

Subtract (4.17) from (4.16) to get

$$-\vartheta(x_0, y_0) + \max_{z \in Z} D_x \varphi(x_0, y_0) \cdot f(x_0, z) - \max_{z \in Z} (-D_y \varphi(x_0, y_0)) \cdot f(y_0, z) \geq 0.$$

This says that ϑ is a viscosity subsolution of

$$-\vartheta(x_0, y_0) + \max_{z \in Z} D_x \vartheta(x_0, y_0) \cdot f(x_0, z) - \max_{z \in Z} (-D_y \vartheta(x_0, y_0)) \cdot f(y_0, z) = 0. \tag{4.18}$$

Suppose now that there exists a point $x' \in R^n$ for which $u(x') > v(x')$. Then $\vartheta(x', x') > 0$. Consider the function

$$\Phi(x, y) = \vartheta(x, y) - \frac{1}{2\varepsilon} |x - y|^2, \qquad \varepsilon > 0.$$

For each $\varepsilon > 0$, Φ is a continuous function and $\Phi(x', x') > 0$. Since $u \to 0$ and $v \to 0$ as $|x|, |y| \to \infty$, we have that $\limsup_{|x|,|y| \to \infty} \Phi(x, y) \leq 0$. Therefore, for each $\varepsilon > 0$, Φ achieves a positive maximum at, say, $(x_\varepsilon, y_\varepsilon) \in R^{2n}$. Furthermore, we have that if we set

$$M_\varepsilon = \sup_{(x,y) \in R^{2n}} \Phi(x, y),$$

then $\lim_{\varepsilon \to 0} \frac{1}{2\varepsilon} |x_\varepsilon - y_\varepsilon|^2 = 0$ and $\lim_{\varepsilon \to 0} M_\varepsilon = \sup_{x \in R^n} \vartheta(x, x) > 0$.

Using the test function $\frac{1}{2\varepsilon} |x - y|^2$ for the function ϑ, since ϑ is a viscosity subsolution of (4.18) we have that

$$-\vartheta(x_\varepsilon, y_\varepsilon) + \max_{z \in Z} \frac{1}{\varepsilon} (x_\varepsilon - y_\varepsilon) \cdot f(x_\varepsilon, z) - \max_{z \in Z} \frac{1}{\varepsilon} (x_\varepsilon - y_\varepsilon) \cdot f(y_\varepsilon, z) \geq 0. \tag{4.19}$$

Given any $\delta > 0$, we may assume that ε is chosen sufficiently small, for example, $\varepsilon < \varepsilon_0$, so that $|x_\varepsilon - y_\varepsilon| \leq \delta$. Define the point $z_\varepsilon \in Z$ by

$$\max_{z \in Z} \frac{1}{\varepsilon} (x_\varepsilon - y_\varepsilon) \cdot f(x_\varepsilon, z) = \frac{1}{\varepsilon} (x_\varepsilon - y_\varepsilon) \cdot f(x_\varepsilon, z_\varepsilon).$$

Then rearranging equation (4.19) and using the local Lipschitz continuity of f (uniform in z), we obtain

$$\begin{aligned}
\vartheta(x_\varepsilon, y_\varepsilon) &\leq \max_{z \in Z} \frac{1}{\varepsilon} (x_\varepsilon - y_\varepsilon) \cdot f(x_\varepsilon, z) - \max_{z \in Z} \frac{1}{\varepsilon} (x_\varepsilon - y_\varepsilon) \cdot f(y_\varepsilon, z) \\
&\leq \frac{1}{\varepsilon} (x_\varepsilon - y_\varepsilon) \cdot f(x_\varepsilon, z_\varepsilon) - \frac{1}{\varepsilon} (x_\varepsilon - y_\varepsilon) \cdot f(y_\varepsilon, z_\varepsilon) \\
&= \frac{1}{\varepsilon} (x_\varepsilon - y_\varepsilon) \cdot (f(x_\varepsilon, z_\varepsilon) - f(y_\varepsilon, z_\varepsilon)) \\
&\leq \frac{1}{\varepsilon} |x_\varepsilon - y_\varepsilon|^2 \, K_\delta.
\end{aligned}$$

The last expression goes to 0 as $\varepsilon \to 0$. But

$$\lim_{\varepsilon \to 0} \vartheta(x_\varepsilon, y_\varepsilon) \geq \lim_{\varepsilon \to 0} \Phi(x_\varepsilon, y_\varepsilon) > 0.$$

This is a contradiction and so we have established that $u \leq v$ everywhere. □

Consequently, $w = 1 - e^{-V}$ is the only viscosity solution of (4.14) satisfying (4.13). Therefore, in order to find V, the most practical way to do this is to solve (4.14), (4.13) for w and then

$$V(x) = -\log(1 - w(x)), \qquad \Omega = \{x \in R^n : w(x) < 1\}$$

is the unique viscosity solution of (4.1), (4.2), and (4.3), i.e., V is the value function for the blowup time.

5. Pontryagin maximum principle. In this section we will derive the Pontryagin maximum principle for our problem. Our approach will use the results of the previous sections. It is based on the use of the Bellman equation. This approach was first developed for use in the finite horizon problem of Lagrange in [7].

Fix a point $y \in \Omega$ and suppose that there exists an optimal control for this initial point, $\zeta^* \in \mathcal{Z}$. Let ξ^* denote the optimal trajectory with $\xi^*(0) = y$. Since the control ζ^* is fixed, we will denote the blowup time from the starting point y as simply $T(y) < +\infty$. Finally, define the function $w \in C^1(\Omega, R^1)$ by $w(x) = T_x(\zeta^*)$. In other words, w gives the blowup time from starting position x when we use the fixed control ζ^*. From the results of §2, we know that if we assume also condition (Aiii), w is continuously differentiable.

THEOREM 5.1. *Assume* (2.2), (Ai)–(Aiii). *Set* $p(t) \equiv D_x w(\xi^*(t))$ *for* $0 \leq t \leq T(y)$. *Then* ζ^* *must satisfy the maximum principle*

$$\max_{z \in Z}(p(t) \cdot f(\xi^*(t), z)) = p(t) \cdot f(\xi^*(t), \zeta^*(t)) \tag{5.1}$$

for almost all $0 < t < T(y)$. *Furthermore,* p *is given as the solution of*

$$\frac{dp}{dt} = -p(t) \cdot D_x f(\xi^*(t), \zeta^*(t)), \qquad 0 < t < T(y) \tag{5.2}$$

with terminal condition

$$p(T(y)) = 0 \tag{5.3}$$

and p *satisfies the condition*

$$1 + p(t) \cdot f(\xi^*(t), \zeta^*(t)) = 0, \qquad a.e. \quad 0 \leq t < T(y). \tag{5.4}$$

Proof. Begin by observing that if $y \in \Omega$, then $\xi^*(t) \in \Omega$ for all $0 \leq t < T(y)$. Therefore, $t \mapsto w(\xi^*(t))$ is finite. Since the optimal trajectory is absolutely continuous in t and w is continuously differentiable, $p(\cdot)$ is absolutely continuous.

By definition of V and w, we have immediately that $w(x) \leq V(x)$ for every $x \in \Omega$ and also, since ξ^* is optimal, $w(\xi^*(t)) = V(\xi^*(t))$ for all $t \in [0, T(y)]$. But this says that $V - w$ achieves a minimum of zero at each point of the optimal trajectory $\xi^*(t)$. Since w is continuously differentiable, it may be used as a test function in the

definition of supersolution for (4.1). Thus, at each point of differentiability of ξ^*, that is, for almost every $t \in [0, T(y)]$, we have that

$$1 + \max_{z \in Z} D_x w(\xi^*(t)) \cdot f(\xi^*(t), z) \leq 0. \tag{5.5}$$

On the other hand, since $w(\xi^*(t)) = T(\xi^*(t))$ is a.e. differentiable, we have that

$$1 + D_x w(\xi^*(t)) \cdot f(\xi^*(t), \zeta^*(t)) = 0, \qquad \text{a.e. } 0 \leq t < T(y). \tag{5.6}$$

This follows easily from the fact that for any $t < \tau < T(y)$, we have that $T(\xi^*(t)) = T(\xi^*(\tau; t, \xi^*(t))) + (\tau - t)$. By definition of p, (5.6) is the same as (5.4). It also follows from (5.4) that p cannot be identically zero.

From (5.6), we obtain

$$1 + \max_{z \in Z} D_x w(\xi^*(t)) \cdot f(\xi^*(t), z) \geq 0. \tag{5.7}$$

Then, combining (5.7) with (5.5) and using (5.6) allow us to conclude that (5.1) must be true.

Next, it follows from Remark 2.1 (see (2.19)) that $p(T(y)) = 0$.

Finally, we need to verify (5.2). We will use the fact that the function $\Phi(t, s) \equiv D_x \xi^*(t; s, x)$ satisfies the linear variational systems

$$\partial \Phi / \partial t = D_x f(\xi^*(t), \zeta^*(t)) \cdot \Phi, \qquad \partial \Phi / \partial s = -\Phi \cdot D_x f(\xi^*(s), \zeta^*(s)), \qquad 0 \leq s < t, \tag{5.8}$$

and $\Phi(s, s) = \mathbf{1}$. Again, using the fact that for any $t < \tau < T(y)$, $T(\xi^*(t)) = T(\xi^*(\tau; t, \xi^*(t))) + (\tau - t)$ and (5.8), we compute

$$\begin{aligned} p(t) = D_x w(\xi^*(t)) &= DT(\xi^*(\tau; t, \xi^*(t))) \frac{\partial \xi^*(\tau; t, \xi^*(t))}{\partial x} \\ &= DT(\xi^*(\tau; t, \xi^*(t)))(1 + \int_t^\tau \frac{\partial \xi^*(\tau; r, \xi^*(r))}{\partial x} \cdot D_x f(\xi^*(r), \zeta^*(r))\, dr) \\ &= DT(\xi^*(\tau; t, \xi^*(t))) + \int_t^\tau p(r) \cdot D_x f(\xi^*(r), \zeta^*(r))\, dr. \end{aligned}$$

The last equality follows from the fact that $T(\xi^*(\tau; t, \xi^*(t))) = T(\xi^*(\tau; r, \xi^*(r)))$ for all $t \leq r < \tau$. Letting $\tau \to T(y)$, since $DT(\xi^*(\tau; t, \xi^*(t))) \to 0$ (see (2.19) and Remark 2.1) we have that

$$p(t) = \int_t^{T(y)} p(r) \cdot D_x f(\xi^*(r), \zeta^*(r))\, dr. \tag{5.9}$$

Even though the integrand in (5.9) has a singularity at $r = T(y)$ (because $|\xi^*(T(y))| = +\infty$), the integral exists because the left side is always finite, according to (5.4) and the fact that $p(r) \to 0$ as $r \to T(y)$. □

6. Example. In this section we will present a simple example to illustrate the results of this paper. We look at the problem with dynamics

$$\frac{d\xi}{dt} = \xi^2 + \zeta, \qquad t > 0, \tag{6.1}$$

$$\xi(0) = x \in R^1. \tag{6.2}$$

The control set is taken to be $Z = [-1, 1]$. It is clear that our assumptions (2.2), (Ai)–(Aiii) are satisfied. Observe that for any $\zeta \leq 0$, the dynamics have equilibrium solutions which certainly do not blow up in finite time. At equilibrium starting points we have $T(x) = +\infty$.

The Bellman equation for the maximal blowup time $V(x)$ is

$$1 + \max_{-1 \leq z \leq 1} V'(x)(x^2 + z) = 1 + V'(x)x^2 + |V'(x)| = 0, \qquad x \in \Omega. \tag{6.3}$$

The maximum is achieved with $z = V'(x)/|V'(x)|$. Clearly, from (6.3), it is not possible for $V'(x) = 0$ on Ω.

Now we claim that $\Omega = (1, \infty)$. To see formally why this is true, we begin by noting that, from (6.3), it is not possible to have $V'(x) \geq 0$. Thus, $V'(x) < 0$ on Ω and so $z \equiv -1$, and (6.3) becomes.

$$1 + V'(x)(x^2 - 1) = 0, \qquad x \in \Omega. \tag{6.4}$$

If $|x| \leq 1$, (6.4) cannot be satisfied. Therefore, $\Omega \subset \{|x| > 1\}$. Next, if $x \to -1, x \in \Omega$, and -1 is a boundary point, we know that $V(x) \to +\infty$. But then $V'(x) \to +\infty$, which contradicts the fact that $V'(x) < 0$. Thus, $\Omega \subset \{x > 1\}$. We also know that $(\lambda, \infty) \subset \Omega$ for some $\lambda \geq 1$. Suppose $\lambda > 1$. From the fact that $\lambda^2 - 1 > 0$ and $V'(x) \to -\infty$ as $x \to \lambda$ we obtain a contradiction to (6.4). We conclude that $\Omega = (1, \infty)$.

The unique viscosity solution of (6.4) on $(1, \infty)$ converging to 0 at ∞ and growing to ∞ at $x = 1$ is given by

$$V(x) = \begin{cases} \frac{1}{2} \log \frac{x+1}{x-1}, & \text{if } x > 1, \\ +\infty, & \text{otherwise.} \end{cases} \tag{6.5}$$

Therefore, we have discovered that the value function is given by (6.5) and the blowup set is $\Omega = (1, \infty)$. Finally, the optimal control is $\zeta^*(t) \equiv -1$.

Now we illustrate the use of the maximum principle on this problem. Fix $x \in \Omega$. The optimal control, with assocoiated optimal trajectory ξ^*, satisfies

$$\max_{-1 \leq z \leq 1} p(t)(\xi^2(t) + z) = p(t)\xi^2(t) + |p(t)|,$$

with $\zeta^*(t) = p(t)/|p(t)|$ and $p(t)$ is given by the solution of the adjoint equation

$$\frac{dp}{dt} = -p(t) \cdot 2\xi^*(t), \qquad 0 < t < T(x), \qquad p(T(x)) = 0,$$

where $T(x) = T_x(\zeta^*)$ is the maximal blowup time for position x. The solution of this problem is

$$p(t) = p(0) \exp\left(- \int_0^t 2\xi^*(r)\, dr \right)$$

since $\int_0^{T(x)} \xi^*(r)\, dr = +\infty$. Finally, using condition (5.4) we obtain $1 + p(t)\xi^*(t)^2 + |p(t)| = 0$ and this implies that $p(t) < 0$. Thus, at $t = 0$ we get $p(0) = -1/(x^2 - 1)$ Therefore,

$$p(t) = \frac{-1}{x^2 - 1} \exp\left(- \int_0^t 2\xi^*(r)\, dr \right)$$

is the adjoint variable. The optimal control is again seen to be $\zeta^*(t) = -1$.

Finally we shall look at a two-dimensional problem:

$$\frac{d\xi}{d\tau} = -\eta + \xi(\xi^2 + \eta^2 - \zeta), \tag{6.6}$$

$$\frac{d\eta}{d\tau} = \xi + \eta(\xi^2 + \eta^2 - \zeta), \tag{6.7}$$

if $\tau > 0$ and $(\xi(0), \eta(0)) = (x, y) \in R^2$ We assume that the control set is $Z = [-1, 1]$. The Bellman equation for the value function $V(x, y)$ becomes

$$1 + x\, V_y - y\, V_x + (x^2 + y^2)\,(x\, V_x + y\, V_y) + |x\, V_x + y\, V_y| = 0. \tag{6.8}$$

The feedback control is

$$z = -\frac{x\, V_x + y\, V_y}{|x\, V_x + y\, V_y|}.$$

It is clearly a much more difficult problem to determine the blowup set Ω from equation (6.8) than in the one-dimensional case. Fortunately, we can calculate that the solution of (6.8) satisfying the conditions

$$\lim_{x^2+y^2\to\infty} V(x, y) = 0, \qquad \lim_{(x,y)\to\partial\Omega} V(x, y) = +\infty$$

is given by

$$V(x, y) = \begin{cases} \frac{1}{2}\log\frac{x^2+y^2}{x^2+y^2-1}, & \text{if } x^2 + y^2 > 1, \\ +\infty, & \text{otherwise.} \end{cases}$$

The blowup set is therefore $\Omega = \{x^2 + y^2 > 1\}$ and the optimal control is $\zeta^*(t) \equiv +1$.

7. Some generalizations. 1. The results of this paper carry over with very little change to the more general problem with value function

$$V(x) = \sup_{\zeta\in\mathcal{Z}} \int_0^{T_x(\zeta)} h(\xi(r), \zeta(r))\, dr + g(T_x(\zeta)),$$

where $g(0) = 0$.

2. When we want to minimize the blowup time, $V(x) = \inf_{\zeta\in\mathcal{Z}} T_x(\zeta)$, then the blowup set $\Omega = \{x \in R^n : V(x) < \infty\}$ is now the set in which the blowup time is finite for some control ζ rather than for every control. The Bellman equation is the same as that in §3 with $\max_{z\in Z}$ replaced by $\min_{z\in Z}$.

3. The corresponding differential game also is of interest. In this case we have two opposing players, ζ and η, where ζ is trying to minimize the blowup time and η is attempting to maximize it. We have an upper value, $V^+(x)$, in which player ζ makes the first move. For the lower value, $V^-(x)$, the maximizer makes the first move. The game has value if $V^+ = V^-$. From a practical point of view the differential game is the appropriate model when the designer is very conservative. That is, if one wants to minimize the blowup time under the worst possible circumstances, one should assume that there is an opposing player who has the opposite goal. In many cases the opposing player can be taken as nature.

The upper value V^+ is the viscosity solution of

$$1 + \min_{z \in Z} \max_{y \in Y} D_x V^+(x) \cdot f(x, y, z) = 0$$

and the lower value satisfies the same equation with min and max interchanged. The proofs of these statements, as well as the various continuity results regarding the value functions, are substantially different than those in this paper.

4. It is also possible to consider a nonautonomous version of our problem. That is, suppose that the vector field depends on time, $f = f(t, x, z)$. In that case, we consider the value function as depending on the initial time and state of the problem, $V = V(t, x)$, as does the blowup time, $T_{t,x}(\zeta)$. This would be the first time in the finite time interval $[t, S]$ that the trajectory becomes infinite. If the trajectory does not blow up within that time interval, then the blowup time is defined as S. The Bellman equation becomes

$$V_t + \max_{z \in Z} D_x V \cdot f(t, x, z) = 0, \qquad (t, x) \in \Omega,$$

where the blowup set $\Omega = \{(t, x) \in [0, S) \times R^n : V(t, x) < +\infty\}$. We now have the additional terminal condition that $V(S, x) = S$.

Acknowledgments. The authors are indebted to the referees whose careful reading of the original version of the paper turned up several errors. In addition, this final version was significantly improved by the use of the results of Bardi and Soravia, which allowed us to drop the use of assumption (Aiii) in the proof of continuity of V and the uniqueness of viscosity solutions.

A SMOOTH CONVERSE LYAPUNOV THEOREM FOR ROBUST STABILITY*

YUANDAN LIN†, EDUARDO D. SONTAG‡, AND YUAN WANG§

Abstract. This paper presents a converse Lyapunov function theorem motivated by robust control analysis and design. Our result is based upon, but generalizes, various aspects of well-known classical theorems. In a unified and natural manner, it (1) allows arbitrary bounded time-varying parameters in the system description, (2) deals with global asymptotic stability, (3) results in smooth (infinitely differentiable) Lyapunov functions, and (4) applies to stability with respect to not necessarily compact invariant sets.

Key words. nonlinear stability, stability with respect to sets, Lyapunov function techniques, robust stability

AMS subject classifications. 93D05, 93D09, 93D20, 34D20

1. Introduction.

This work is motivated by problems of robust nonlinear stabilization. One of our main contributions is to provide a statement and proof of a converse Lyapunov function theorem in a form particularly useful for the study of such feedback control analysis and design problems. We provide a single (and natural) unified result that

1. applies to stability with respect to not necessarily compact invariant sets;
2. deals with global (as opposed to merely local) asymptotic stability;
3. results in smooth (infinitely differentiable) Lyapunov functions;
4. most importantly, applies to stability in the presence of bounded time-varying parameters in the system.

(This last property is sometimes called "total stability" and it is equivalent to the stability of an associated differential inclusion.)

The interest in stability with respect to possibly noncompact sets is motivated by applications to areas such as output control (one needs to stabilize with respect to the zero set of the output variables) and Luenberger-type observer design ("detectability" corresponds to stability with respect to the diagonal set $\{(x, x)\}$, as a subset of the composite state/observer system). Such applications and others are explored in [16, Chap. 5].

Smooth Lyapunov functions, as opposed to merely continuous or once-differentiable ones, are required in order to apply "backstepping" techniques in which a feedback law is built by successively taking directional derivatives of feedback laws obtained for a simplified system. (See for instance [9] for more on backstepping design.)

Finally, the effect of parameter uncertainty and the study of associated Lyapunov functions are topics of interest in robust control theory. An application of the result

proved in this paper to the study of "input to state stability" is provided in [27].

1.1. Organization of paper. The paper is organized as follows. The next section provides the basic definitions and the statement of the main result. Actually, two versions are given, one that applies to global asymptotic stability with respect to arbitrary invariant sets, but assuming completeness of the system (that is, global existence of solutions for all inputs) and another version which does not assume completeness but only applies to the special case of compact invariant sets (in particular, to the usual case of global asymptotic stability with respect to equilibria).

Equivalent characterizations of stability by means of decay estimates have proved very useful in control theory (see e.g. [25]) and this is the subject of §3. Some technical facts about Lyapunov functions, including a result on the smoothing of such functions around an attracting set, are given in §4. After this, §5 establishes some basic facts about complete systems needed for the main result.

Section 6 contains the proof of the main result for the general case. Our proof is based upon, and follows to a great extent, the outline of the one given by Wilson in [31], who provided in the late 1960s a converse Lyapunov function theorem for local asymptotic stability with respect to closed sets. There are however some major differences from that work: we want a global rather than a local result, and several technical issues appear in that case; moreover, and most importantly, we have to deal with parameters, which makes the careful analysis of uniform bounds of paramount importance. (In addition, even for the case of no parameters and local stability, several critical steps in the proof are only sketched in [31], especially those concerning Lipschitz properties and smoothness around the attracting set. Later the author of [21] rederived the results, but only for the case when the invariant set is compact. Thus it seems useful to have an expository detailed and self-contained proof in the literature.) A needed technical result on smoothing functions, also based closely on [31], is placed in an appendix for convenience. Section 7 deals with the compact case, essentially by reparameterization of trajectories.

An example, motivated by related work of Tsinias and Kalouptsidis in [7] and [29], is given in §8 to show that the analogous theorems are false for unbounded parameters.

Obviously in a topic such as this one, there are many connections to previous work. While it is likely that we have missed many relevant references, we discuss in §9 some relationships between our work and other results in the literature. Relations to work using "prolongations" are particularly important, and are detailed further in §10.

2. Definitions and statements of main results. Consider the following system:

$$\dot{x}(t) = f(x(t),\, d(t))\,, \tag{1}$$

where for each $t \in \mathbb{R}$, $x(t) \in \mathbb{R}^n$ and $d(t) \in \mathcal{D}$, and where $\mathcal{D}$ is a compact subset of $\mathbb{R}^m$, for some positive integers n and m. The map $f : \mathbb{R}^n \times \mathcal{D} \to \mathbb{R}^n$ is assumed to satisfy the following two properties:

- f is continuous.
- f is locally Lipschitz on x uniformly on d, that is, for each compact subset K of $\mathbb{R}^n$ there is some constant c so that $|f(x,\mathbf{d}) - f(z,\mathbf{d})| \leq c\,|x - z|$ for all $x, z \in K$ and all $\mathbf{d} \in \mathcal{D}$, where $|\cdot|$ denotes the usual Euclidian norm.

Note that these properties are satisfied, for instance, if f extends to a continuously differentiable function on a neighborhood of $\mathbb{R}^n \times \mathcal{D}$.

Let $\mathcal{M}_\mathcal{D}$ be the set of all measurable functions from $\mathbb{R}$ to $\mathcal{D}$. We will call functions $d \in \mathcal{M}_\mathcal{D}$ *time-varying parameters*. For each $d \in \mathcal{M}_\mathcal{D}$, we denote by $x(t, x_0, d)$ (and sometimes simply by $x(t)$ if there is no ambiguity from the context) the solution at time t of (1) with $x(0) = x_0$. This is defined on some maximal interval $(T^-_{x_0,d}, T^+_{x_0,d})$ with $-\infty \leq T^-_{x_0,d} < 0 < T^+_{x_0,d} \leq +\infty$.

Sometimes we will need to consider time-varying parameters d that are defined only on some interval $I \subseteq \mathbb{R}$ with $0 \in I$. In those cases, by abuse of notation, $x(t, x_0, d)$ will still be used, but only times $t \in I$ will be considered.

The system is said to be *forward complete* if $T^+_{x_0,d} = +\infty$ for all x_0 and all $d \in \mathcal{M}_\mathcal{D}$. It is *backward complete* if $T^-_{x_0,d} = -\infty$ for all x_0 and all $d \in \mathcal{M}_\mathcal{D}$, and it is *complete* if it is both forward and backward complete.

We say that a closed set $\mathcal{A}$ is an *invariant set* for (1) if

$$\forall x_0 \in \mathcal{A},\ \forall d \in \mathcal{M}_\mathcal{D},\ T^+_{x_0,d} = +\infty \ \text{ and } \ x(t, x_0, d) \in \mathcal{A}, \quad \forall t \geq 0.$$

Remark 2.1. An equivalent formulation of invariance is in terms of the associated differential inclusion

$$\dot{x} \in F(x)\,, \tag{2}$$

where $F(x) = \{f(x, \mathbf{d}),\ \mathbf{d} \in \mathcal{D}\}$. The set $\mathcal{A}$ is invariant for (1) if and only if it is invariant with respect to (2) (see e.g. [1]). The notions of stability to be considered later can be rephrased in terms of (2) as well.

We will use the following notation: for each nonempty subset $\mathcal{A}$ of $\mathbb{R}^n$ and each $\xi \in \mathbb{R}^n$, we denote

$$|\xi|_\mathcal{A} \stackrel{\text{def}}{=} d(\xi, \mathcal{A}) = \inf_{\eta \in \mathcal{A}} d(\xi, \eta)\,,$$

the common point-to-set distance, and $|\xi|_{\{0\}} = |\xi|$ is the usual norm.

Let $\mathcal{A} \subseteq \mathbb{R}^n$ be a closed, invariant set for (1). We emphasize that we do not require $\mathcal{A}$ to be compact. We will assume throughout this work that the following mild property holds:

$$\sup_{\xi \in \mathbb{R}^n} \{|\xi|_\mathcal{A}\} = \infty\,. \tag{3}$$

This is a minor technical assumption, satisfied in all examples of interest, which will greatly simplify our statements and proofs. (Of course, this property holds automatically whenever $\mathcal{A}$ is compact, and in particular in the important special case in which $\mathcal{A}$ reduces to an equilibrium point.)

DEFINITION 2.2. *System* (1) *is* (absolutely) uniformly globally asymptotically stable (UGAS) *with respect to the closed invariant set* $\mathcal{A}$ *if it is forward complete and the following two properties hold:*

1. *Uniform Stability. There exists a* $\mathcal{K}_\infty$*-function* $\delta(\cdot)$ *such that for any* $\varepsilon \geq 0$,

$$|x(t, x_0, d)|_\mathcal{A} \leq \varepsilon \ \text{ for all } d \in \mathcal{M}_\mathcal{D}, \ \text{ whenever } |x_0|_\mathcal{A} \leq \delta(\varepsilon) \text{ and } t \geq 0\,. \tag{4}$$

2. *Uniform Attraction. For any* $r, \varepsilon > 0$, *there is a* $T > 0$, *such that for every* $d \in \mathcal{M}_\mathcal{D}$,

$$|x(t, x_0, d)|_\mathcal{A} < \varepsilon \tag{5}$$

whenever $|x_0|_\mathcal{A} < r$ *and* $t \geq T$. □

For the definitions of the standard comparison classes of $\mathcal{K}_\infty$- and $\mathcal{KL}$-functions, we refer the reader to the appendices.

Observe that when $\mathcal{A}$ is compact the forward completeness assumption is redundant, since in that case property (4) already implies that all solutions are bounded.

In the particular case in which the set $\mathcal{D}$ consists of just one point, the above definition reduces to the standard notion of set asymptotic stability of differential equations. (Note, however, that this definition differs from those in [3] and [31], which are not global.) If, in addition, $\mathcal{A}$ consists of just an equilibrium point x_0, this is the usual notion of global asymptotic stability for the solution $x(t) \equiv x_0$.

Remark 2.3. It is an easy exercise to verify that an equivalent definition results if one replaces $\mathcal{M}_\mathcal{D}$ by the subset of piecewise constant time-varying parameters.

Remark 2.4. Note that the uniform stability condition is equivalent to the statement that there is a $\mathcal{K}_\infty$-function φ so that

$$|x(t, x_0, d)|_\mathcal{A} \leq \varphi(|x_0|_\mathcal{A}), \quad \forall x_0, \ \forall t \geq 0, \quad \text{and } \forall d \in \mathcal{M}_\mathcal{D}\,.$$

(Just let $\varphi = \delta^{-1}$.)

The following characterization of the UGAS property will be extremely useful.

PROPOSITION 2.5. *The system* (1) *is UGAS with respect to a closed, invariant set* $\mathcal{A} \subseteq \mathbb{R}^n$ *if and only if it is forward complete and there exists a* $\mathcal{KL}$*-function* β *such that, given any initial state* x_0*, the solution* $x(t, x_0, d)$ *satisfies*

$$|x(t, x_0, d)|_\mathcal{A} \leq \beta(|x_0|_\mathcal{A}\,, t)\,, \quad \textit{for any } t \geq 0\,, \tag{6}$$

for any $d \in \mathcal{M}_\mathcal{D}$.

Observe that when $\mathcal{A}$ is compact the forward completeness assumption is again redundant, since in that case property (6) implies that solutions are bounded.

Next we introduce Lyapunov functions with respect to sets. For any differentiable function $V : \mathbb{R}^n \longrightarrow \mathbb{R}$, we use the standard Lie derivative notation

$$L_{f_\mathbf{d}} V(\xi) \stackrel{\text{def}}{=} \frac{\partial V(\xi)}{\partial x} \cdot f_\mathbf{d}(\xi)\,,$$

where for each $\mathbf{d} \in \mathcal{D}$, $f_\mathbf{d}(\cdot)$ is the vector field defined by $f(\cdot, \mathbf{d})$. By "smooth" we always mean infinitely differentiable.

DEFINITION 2.6. *A* Lyapunov function *for the system* (1) *with respect to a nonempty, closed, invariant set* $\mathcal{A} \subseteq \mathbb{R}^n$ *is a function* $V : \mathbb{R}^n \longrightarrow \mathbb{R}$ *such that* V *is smooth on* $\mathbb{R}^n \backslash \mathcal{A}$ *and satisfies*

1. *there exist two* $\mathcal{K}_\infty$*-functions* α_1 *and* α_2 *such that for any* $\xi \in \mathbb{R}^n$,

$$\alpha_1(|\xi|_\mathcal{A}) \leq V(\xi) \leq \alpha_2(|\xi|_\mathcal{A})\,; \tag{7}$$

2. *there exists a continuous, positive definite function* α_3 *such that for any* $\xi \in \mathbb{R}^n \backslash \mathcal{A}$, *and any* $\mathbf{d} \in \mathcal{D}$,

$$L_{f_\mathbf{d}} V(\xi) \leq -\alpha_3(|\xi|_\mathcal{A})\,. \tag{8}$$

A smooth *Lyapunov function is one which is smooth on all of* $\mathbb{R}^n$.

Remark 2.7. Continuity of V on $\mathbb{R}^n \backslash \mathcal{A}$ and property 1 in Definition 2.6 imply:

- V is continuous on all of $\mathbb{R}^n$;
- $V(x) = 0 \iff x \in \mathcal{A}$; and
- $V : \mathbb{R}^n \stackrel{\text{onto}}{\longrightarrow} \mathbb{R}_{\geq 0}$ (recall the assumption in equation (3)).

Our main results will be two converse Lyapunov theorems. The first one is for general closed, invariant sets and assumes completeness of the system.

THEOREM 2.8. *Assume that the system* (1) *is complete. Let* $\mathcal{A} \subseteq \mathbb{R}^n$ *be a nonempty, closed, invariant subset for this system. Then,* (1) *is UGAS with respect to* $\mathcal{A}$ *if and only if there exists a smooth Lyapunov function* V *with respect to* $\mathcal{A}$.

The following result does not assume completeness but instead applies only to compact $\mathcal{A}$.

THEOREM 2.9. *Let* $\mathcal{A} \subseteq \mathbb{R}^n$ *be a nonempty, compact, invariant subset for the system* (1). *Then,* (1) *is UGAS with respect to* $\mathcal{A}$ *if and only if there exists a smooth Lyapunov function* V *with respect to* $\mathcal{A}$.

3. Some preliminaries about UGAS. It will be useful to have a restatement of the second condition in the definition of UGAS stated in terms of uniform attraction times.

LEMMA 3.1. *The uniform attraction property defined in Definition* 2.2 *is equivalent to the following: there exists a family of mappings* $\{T_r\}_{r>0}$ *with*

- *for each fixed* $r > 0$, $T_r : \mathbb{R}_{>0} \xrightarrow{\text{onto}} \mathbb{R}_{>0}$ *is continuous and is strictly decreasing;*
- *for each fixed* $\varepsilon > 0$, $T_r(\varepsilon)$ *is (strictly) increasing as* r *increases and* $\lim_{r\to\infty} T_r(\varepsilon) = \infty$;

such that, for each $d \in \mathcal{M}_{\mathcal{D}}$,

$$|x(t, x_0, d)|_{\mathcal{A}} < \varepsilon \quad \text{whenever } |x_0|_{\mathcal{A}} < r \text{ and } t \geq T_r(\varepsilon)\,. \tag{9}$$

Proof. Sufficiency is clear. Now we show the necessity part. For any $r, \varepsilon > 0$, let

$$A_{r,\varepsilon} \stackrel{\text{def}}{=} \{T \geq 0 : \forall\, |x_0|_{\mathcal{A}} < r,\ \forall t \geq T, \forall d \in \mathcal{M}_{\mathcal{D}},\ |x(t, x_0, d)|_{\mathcal{A}} < \varepsilon\} \subseteq \mathbb{R}_{\geq 0}\,. \tag{10}$$

Then from the assumptions, $A_{r,\varepsilon} \neq \emptyset$ for any $r, \varepsilon > 0$. Moreover,

$$A_{r,\varepsilon_1} \subseteq A_{r,\varepsilon_2}, \text{ if } \varepsilon_1 \leq \varepsilon_2, \text{ and } A_{r_2,\varepsilon} \subseteq A_{r_1,\varepsilon}, \text{ if } r_1 \leq r_2\,.$$

Now define $\bar{T}_r(\varepsilon) \stackrel{\text{def}}{=} \inf A_{r,\varepsilon}$. Then $\bar{T}_r(\varepsilon) < \infty$, for any $r, \varepsilon > 0$, and it satisfies

$$\bar{T}_r(\varepsilon_1) \geq \bar{T}_r(\varepsilon_2), \text{ if } \varepsilon_1 \leq \varepsilon_2, \text{ and } \bar{T}_{r_1}(\varepsilon) \leq \bar{T}_{r_2}(\varepsilon), \text{ if } r_1 \leq r_2.$$

So we can define for any $r, \varepsilon > 0$,

$$\tilde{T}_r(\varepsilon) \stackrel{\text{def}}{=} \frac{2}{\varepsilon}\int_{\varepsilon/2}^{\varepsilon} \bar{T}_r(s)\, ds\,. \tag{11}$$

Since $\bar{T}_r(\cdot)$ is decreasing, $\tilde{T}_r(\cdot)$ is well defined and is locally absolutely continuous. Also

$$\tilde{T}_r(\varepsilon) \geq \frac{2}{\varepsilon}\bar{T}_r(\varepsilon)\int_{\varepsilon/2}^{\varepsilon} ds = \bar{T}_r(\varepsilon)\,. \tag{12}$$

Furthermore,

$$\begin{aligned}
\frac{d\tilde{T}_r(\varepsilon)}{d\varepsilon} &= -\frac{2}{\varepsilon^2}\int_{\varepsilon/2}^{\varepsilon} \bar{T}_r(s)\, ds + \frac{2}{\varepsilon}\left(\bar{T}_r(\varepsilon) - \frac{1}{2}\bar{T}_r\left(\frac{\varepsilon}{2}\right)\right) \\
&= \frac{1}{\varepsilon}\left[\bar{T}_r(\varepsilon) - \frac{2}{\varepsilon}\int_{\varepsilon/2}^{\varepsilon} \bar{T}_r(s)\, ds\right] + \frac{1}{\varepsilon}\left[\bar{T}_r(\varepsilon) - \bar{T}_r\left(\frac{\varepsilon}{2}\right)\right] \\
&= \frac{1}{\varepsilon}\left[\bar{T}_r(\varepsilon) - \tilde{T}_r(\varepsilon)\right] + \frac{1}{\varepsilon}\left[\bar{T}_r(\varepsilon) - \bar{T}_r\left(\frac{\varepsilon}{2}\right)\right] \leq 0, \quad \text{a.e.},
\end{aligned} \tag{13}$$

hence $\tilde{T}_r(\cdot)$ decreases (not necessarily strictly). Since $\bar{T}_{(\cdot)}(\varepsilon)$ increases, from the definition, $\tilde{T}_{(\cdot)}(\varepsilon)$ also increases. Finally, define

$$T_r(\varepsilon) \stackrel{\text{def}}{=} \tilde{T}_r(\varepsilon) + \frac{r}{\varepsilon}. \tag{14}$$

Then it follows that

- for any fixed r, $T_r(\cdot)$ is continuous, maps $\mathbb{R}_{>0} \stackrel{\text{onto}}{\longrightarrow} \mathbb{R}_{>0}$, and is strictly decreasing;
- for any fixed ε, $T_r(\varepsilon)$ is increasing as r increases, and $\lim_{r\to\infty} T_r(\varepsilon) = \infty$.

So the only thing left to be shown is that T_r defined by (14) satisfies (9). To do this, pick any x_0 and t with $|x_0|_{\mathcal{A}} < r$ and $t \geq T_r(\varepsilon)$. Then

$$t \geq T_r(\varepsilon) > \tilde{T}_r(\varepsilon) \geq \bar{T}_r(\varepsilon)\,.$$

Hence, by the definition of $\bar{T}_r(\varepsilon)$, $|x(t, x_0, d)|_{\mathcal{A}} < \varepsilon$, as claimed. □

3.1. Proof of characterization via decay estimate. We now provide a proof of Proposition 2.5.

[$\Longleftarrow$] Assume that there exists a $\mathcal{KL}$-function β such that (6) holds. Let

$$c_1 \stackrel{\text{def}}{=} \sup \beta(\cdot, 0) \leq \infty\,,$$

and choose $\delta(\cdot)$ to be any $\mathcal{K}_\infty$-function with

$$\delta(\varepsilon) \leq \bar{\beta}^{-1}(\varepsilon), \quad \text{for any } 0 \leq \varepsilon < c_1\,,$$

where $\bar{\beta}^{-1}$ denotes the inverse function of $\bar{\beta}(\cdot) \stackrel{\text{def}}{=} \beta(\cdot, 0)$. (If $c_1 = \infty$, we can simply choose $\delta(\varepsilon) \stackrel{\text{def}}{=} \bar{\beta}^{-1}(\varepsilon)$.) Clearly $\delta(\varepsilon)$ is the desired $\mathcal{K}_\infty$-function for the uniform stability property.

The uniform attraction property follows from the fact that for every fixed r, $\lim_{t\to\infty} \beta(r, t) = 0$.

[$\Longrightarrow$] Assume that (1) is UGAS with respect to the closed set $\mathcal{A}$, and let δ be as in the definition. Let $\varphi(\cdot)$ be the $\mathcal{K}$-function $\delta^{-1}(\cdot)$. As mentioned in Remark 2.4, it follows that $|x(t, x_0, d)|_{\mathcal{A}} \leq \varphi(|x_0|_{\mathcal{A}})$ for any $x_0 \in \mathbb{R}^n$, any $t \geq 0$, and any $d \in \mathcal{M}_{\mathcal{D}}$.

Let $\{T_r\}_{r\in(0,\infty)}$ be as in Lemma 3.1, and for each $r \in (0, \infty)$ denote $\psi_r \stackrel{\text{def}}{=} T_r^{-1}$. Then, for each $r \in (0, \infty)$, $\psi_r : \mathbb{R}_{>0} \longrightarrow \mathbb{R}_{>0}$ is again continuous, onto, and strictly decreasing. We also write $\psi_r(0) = +\infty$, which is consistent with the fact that

$$\lim_{t\to 0^+} \psi_r(t) = +\infty\,.$$

(Note: The property that $T_{(\cdot)}(t)$ increases to ∞ is not needed here.)

CLAIM. *For any $|x_0|_{\mathcal{A}} < r$, any $t \geq 0$, and any $d \in \mathcal{M}_{\mathcal{D}}$, $|x(t, x_0, d)|_{\mathcal{A}} \leq \psi_r(t)$.*

Proof. It follows from the definition of the maps T_r that, for any r, $\varepsilon > 0$, and for any $d \in \mathcal{M}_{\mathcal{D}}$,

$$|x_0|_{\mathcal{A}} < r, \quad t \geq T_r(\varepsilon) \implies |x(t, x_0, d)|_{\mathcal{A}} < \varepsilon\,.$$

As $t = T_r(\psi_r(t))$ if $t > 0$, we have, for any such x_0 and d,

$$|x(t, x_0, d)|_{\mathcal{A}} < \psi_r(t)\,, \ \forall t > 0\,. \tag{15}$$

The claim follows by combining (15) and the fact that $\psi_r(0) = +\infty$. □

Now for any $s \geq 0$ and $t \geq 0$, let

$$\bar{\psi}(s, t) \stackrel{\text{def}}{=} \min\left\{\varphi(s), \inf_{r \in (s, \infty)} \psi_r(t)\right\}. \tag{16}$$

Because of the definition of φ and the above claim, we have, for each x_0, $d \in \mathcal{M}_{\mathcal{D}}$, and $t \geq 0$,

$$|x(t, x_0, d)|_{\mathcal{A}} \leq \bar{\psi}(|x_0|_{\mathcal{A}}, t). \tag{17}$$

If $\bar{\psi}$ were of class $\mathcal{KL}$, we would be done. This may not be the case, so we next majorize $\bar{\psi}$ by such a function.

By its definition, for any fixed t, $\bar{\psi}(\cdot, t)$ is an increasing function (not necessarily strictly). Also, because for any fixed $r \in (0, \infty)$, $\psi_r(t)$ decreases to 0 (this follows from the fact that $\psi_r : \mathbb{R}_{>0} \stackrel{\text{onto}}{\longrightarrow} \mathbb{R}_{>0}$ is continuous and strictly decreasing), it follows that

$$\text{for any fixed } s, \quad \bar{\psi}(s, t) \text{ decreases to 0 as } t \to \infty.$$

Next we construct a function $\tilde{\psi} : \mathbb{R}_{[0, \infty)} \times \mathbb{R}_{\geq 0} \longrightarrow \mathbb{R}_{\geq 0}$ with the following properties:

- for any fixed $t \geq 0$, $\tilde{\psi}(\cdot, t)$ is continuous and strictly increasing;
- for any fixed $s \geq 0$, $\tilde{\psi}(s, t)$ decreases to 0 as $t \to \infty$;
- $\tilde{\psi}(s, t) \geq \bar{\psi}(s, t)$.

Such a function $\tilde{\psi}$ always exists; for instance, it can be obtained as follows. Define first

$$\hat{\psi}(s, t) \stackrel{\text{def}}{=} \int_s^{s+1} \bar{\psi}(\varepsilon, t)\, d\varepsilon. \tag{18}$$

Then $\hat{\psi}(\cdot, t)$ is an absolutely continuous function on every compact subset of $\mathbb{R}_{\geq 0}$, and it satisfies

$$\hat{\psi}(s, t) \geq \bar{\psi}(s, t) \int_s^{s+1} d\varepsilon = \bar{\psi}(s, t).$$

It follows that

$$\frac{\partial \hat{\psi}(s, t)}{\partial s} = \bar{\psi}(s+1, t) - \bar{\psi}(s, t) \geq 0, \text{ a.e.},$$

and hence $\hat{\psi}(\cdot, t)$ is increasing. Also since for any fixed s, $\bar{\psi}(s, \cdot)$ decreases, so does $\hat{\psi}(s, \cdot)$. Note that

$$\bar{\psi}(s, t) \leq \bar{\psi}(s, 0) = \min\left\{\inf_{r \in (s, \infty)} \psi_r(0), \varphi(s)\right\} = \varphi(s)$$

(recall that $\psi_r(0) = +\infty$), so by the Lebesgue-dominated convergence theorem, for any fixed $s \geq 0$,

$$\lim_{t \to \infty} \hat{\psi}(s, t) = \int_s^{s+1} \lim_{t \to \infty} \bar{\psi}(\varepsilon, t)\, d\varepsilon = 0.$$

Now we see that the function $\hat{\psi}(s, t)$ satisfies all of the requirements for $\tilde{\psi}(s, t)$ except possibly for the strictly increasing property. We define $\tilde{\psi}$ as follows:

$$\tilde{\psi}(s, t) \stackrel{\text{def}}{=} \hat{\psi}(s, t) + \frac{s}{(s+1)(t+1)}.$$

Clearly it satisfies all the desired properties.

Finally, define

$$\beta(s, t) \stackrel{\text{def}}{=} \sqrt{\varphi(s)}\sqrt{\tilde{\psi}(s, t)}.$$

Then it follows that $\beta(s, t)$ is a $\mathcal{KL}$-function, and for all x_0, t, d,

$$|x(t, x_0, d)|_{\mathcal{A}} \leq \sqrt{\varphi(|x_0|_{\mathcal{A}})}\sqrt{\tilde{\psi}(|x_0|_{\mathcal{A}}, t)} \leq \beta(|x_0|_{\mathcal{A}}, t),$$

which concludes the proof of Proposition 2.5.

4. Some preliminaries about Lyapunov functions. In this section we provide some technical results about set Lyapunov functions. A lemma on differential inequalities is also given, for later reference.

Remark 4.1. One may assume in Definition 2.6 that all of $\alpha_1, \alpha_2, \alpha_3$ are smooth in $(0, +\infty)$ and of class $\mathcal{K}_\infty$. For α_1 and α_2, this is proved simply by finding two functions $\tilde{\alpha}_1, \tilde{\alpha}_2$ in $\mathcal{K}_\infty$, smooth in $(0, +\infty)$ so that

$$\tilde{\alpha}_1(s) \leq \alpha_1(s) \leq \alpha_2(s) \leq \tilde{\alpha}_2(s), \text{ for all } s.$$

For α_3, a new Lyapunov function W and a function $\tilde{\alpha}_3$ which satisfies (8) with respect to W, but is smooth in $(0, +\infty)$ and of class $\mathcal{K}_\infty$, can be constructed as follows. First, pick $\tilde{\alpha}_3$ to be any $\mathcal{K}_\infty$-function, smooth in $(0, +\infty)$, such that

$$\tilde{\alpha}_3(s) \leq s\alpha_3(s), \ \forall s \in [0, \alpha_1^{-1}(1)].$$

This is possible since α_3 is positive definite. Then let

$$\gamma : \mathbb{R}_{\geq 0} \longrightarrow \mathbb{R}_{\geq 0}$$

be a $\mathcal{K}_\infty$-function, smooth in $(0, +\infty)$, such that

- $\gamma(r) \geq \alpha_1^{-1}(r)$ for all $r \in [0, 1]$;
- $\gamma(r) > \tilde{\alpha}_3(\alpha_1^{-1}(r))/\alpha_3(\alpha_1^{-1}(r))$ for all $r > 1$.

Now define $\beta(s) \stackrel{\text{def}}{=} \int_0^s \gamma(r)\, dr$. Note that β is a $\mathcal{K}_\infty$-function, smooth in $(0, +\infty)$. Let $W(\xi) \stackrel{\text{def}}{=} \beta(V(\xi))$. This is smooth on $\mathbb{R}^n \backslash \mathcal{A}$, and $\beta \circ \alpha_1$, $\beta \circ \alpha_2$ bound W as in equation (7). Moreover,

$$\beta'(V(\xi)) = \gamma(V(\xi)) \geq \gamma(\alpha_1(|\xi|_{\mathcal{A}})),$$

so

$$L_{f_d} W(\xi) = \beta'(V(\xi)) L_{f_d} V(\xi) \leq -\gamma(\alpha_1(|\xi|_{\mathcal{A}}))\alpha_3(|\xi|_{\mathcal{A}}). \tag{19}$$

We claim that this is bounded by $-\tilde{\alpha}_3(|\xi|_{\mathcal{A}})$. Indeed, if $s \stackrel{\text{def}}{=} |\xi|_{\mathcal{A}} \leq \alpha_1^{-1}(1)$, then from the first item above and the definition of $\tilde{\alpha}_3$,

$$\gamma(\alpha_1(s)) \geq s \geq \frac{\tilde{\alpha}_3(s)}{\alpha_3(s)};$$

if instead $s > \alpha_1^{-1}(1)$, then from the second item, also

$$\gamma(\alpha_1(s)) \geq \frac{\tilde{\alpha}_3(s)}{\alpha_3(s)}\,.$$

In either case, $\gamma(\alpha_1(s))\alpha_3(s) \geq \tilde{\alpha}_3(s)$, as desired. From now on, whenever necessary, we assume that α_1, α_2, α_3 are $\mathcal{K}_\infty$-functions, smooth in $(0, +\infty)$.

4.1. Smoothing of Lyapunov functions. When dealing with control system design, one often needs to know that V can be taken to be globally smooth, rather than just smooth outside of $\mathcal{A}$.

PROPOSITION 4.2. *If there is a Lyapunov function for* (1) *with respect to* $\mathcal{A}$, *then there is also a smooth such Lyapunov function.*

The proof relies on constructing a smooth function of the form $W = \beta \circ V$, where

$$\beta : \mathbb{R}_{\geq 0} \longrightarrow \mathbb{R}_{\geq 0}$$

is built using a partition of unity.

Again let $\mathcal{A} \subseteq \mathbb{R}^n$ be nonempty and closed. For a multi-index $\varrho = (\varrho_1, \varrho_2, \ldots, \varrho_n)$, we use $|\varrho|$ to denote $\sum_{i=1}^n \varrho_i$. The following regularization result will be needed; it generalizes to arbitrary $\mathcal{A}$ the analogous (but simpler, due to compactness) result for equilibria given in [13, Thm. 6].

LEMMA 4.3. *Assume that* $V : \mathbb{R}^n \longrightarrow \mathbb{R}_{\geq 0}$ *is* C^0, *the restriction* $V|_{\mathbb{R}^n \setminus \mathcal{A}}$ *is* C^∞, *and also* $V|_{\mathcal{A}} = 0$, $V|_{\mathbb{R}^n \setminus \mathcal{A}} > 0$. *Then there exists a* $\mathcal{K}_\infty$*-function* β, *smooth on* $(0, \infty)$ *and so that* $\beta^{(i)}(t) \to 0$ *as* $t \to 0^+$ *for each* $i = 0, 1, \ldots$, *and having* $\beta'(t) > 0$, $\forall t > 0$, *such that*

$$W \stackrel{\text{def}}{=} \beta \circ V$$

is a C^∞ *function on all of* $\mathbb{R}^n$.

Proof. Let $K_1, K_2, \ldots$, be compact subsets of $\mathbb{R}^n$ such that $\mathcal{A} \subseteq \bigcup_{i=1}^\infty \operatorname{int}(K_i)$. For any $k \geq 1$, let

$$I_k \stackrel{\text{def}}{=} \left(\frac{1}{k+2}, \frac{1}{k}\right) \subseteq \mathbb{R}$$

and $I_0 \stackrel{\text{def}}{=} I_1$. Pick for any $k \geq 1$ a smooth (C^∞) function $\gamma_k : \mathbb{R}_{>0} \to [0, 1]$ satisfying

- $\gamma_k(t) = 0$ if $t \notin I_k$; and
- $\gamma_k(t) > 0$ if $t \in I_k$.

Define for any $k \geq 1$,

$$\mathcal{G}_k \stackrel{\text{def}}{=} \left\{ x \in \mathbb{R}^n : \; x \in \bigcup_{i=1}^k K_i, \; V(x) \in \operatorname{clos} I_k \right\}.$$

Then $\mathcal{G}_k$ is compact (because of compactness of the sets K_i and continuity of V). Observe that each derivative $\gamma_k^{(i)}$ has a compact support included in $\operatorname{clos} I_k$, so it is bounded. For each $k = 1, 2, \ldots$, let $c_k \in \mathbb{R}$ satisfy

1. $c_k \geq 1$;
2. $c_k \geq |(D^\varrho V)(x)|$ for any multi-index $|\varrho| \leq k$ and any $x \in \mathcal{G}_k$; and
3. $c_k \geq |\gamma_k^{(i)}(t)|$, for any $i \leq k$ and any $t \in \mathbb{R}_{>0}$.

Choose the sequence d_k to satisfy

$$0 < d_k < \frac{1}{2^k(k+1)!c_k^k}\,,\ k = 1, 2, \ldots. \tag{20}$$

Let $\alpha : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ be a C^∞ function such that $\alpha \equiv 0$ on $\left[0, \frac{1}{3}\right]$ and $\alpha \geq 1$ on $\left[\frac{1}{2}, \infty\right)$. Define $\gamma(0) \stackrel{\text{def}}{=} 0$ and

$$\gamma(t) \stackrel{\text{def}}{=} \sum_{k=1}^{\infty} d_k \gamma_k(t) + \alpha(t)\,,\ \forall t > 0\,. \tag{21}$$

Notice that for any $t \in (0, 1)$, if $k \stackrel{\text{def}}{=} \left\lfloor \frac{1}{t} \right\rfloor \geq 1$ denotes the largest integer $\leq \frac{1}{t}$, then $t \in I_{k-1}$ and

$$t \notin I_j \quad \text{if} \quad j \neq k, k-1\,.$$

Hence the sum in (21) consists of at most three terms (for $t \geq 1$ the sum is just $\gamma = \alpha$), and so γ is C^∞ at each $t \in (0, \infty)$.

CLAIM. *For any $i \geq 0$, $\lim_{t \to 0^+} \gamma^{(i)}(t) = 0$.*

Proof. Fix any $i \geq 0$. Given any $\varepsilon > 0$, let $k_0 \in \mathbb{Z}$ be such that $\varepsilon > \frac{1}{k_0} > 0$. Let

$$T \stackrel{\text{def}}{=} \min\left\{\frac{1}{k_0}, \frac{1}{i+1}, \frac{1}{3}\right\}.$$

We will show that $t \in (0, T) \implies \left|\gamma^{(i)}(t)\right| < \varepsilon$. Indeed, as $0 < t < \min\left\{\frac{1}{k_0}, \frac{1}{i+1}, \frac{1}{3}\right\}$, it follows that $k \stackrel{\text{def}}{=} \left\lfloor \frac{1}{t} \right\rfloor \geq \max\{i+1, k_0, 3\}$. So

$$\gamma^{(i)}(t) \leq d_{k-1}\gamma_{k-1}^{(i)}(t) + d_k \gamma_k^{(i)}(t)\,,$$

and noticing that

$$i \leq k-1 < k \implies c_k \geq \left|\gamma_k^{(i)}(t)\right|\,,\ c_{k-1} \geq \left|\gamma_{k-1}^{(i)}(t)\right|\,,$$

we have

$$\left|\gamma^{(i)}(t)\right| \leq d_{k-1}c_{k-1} + d_k c_k \leq \frac{1}{2k!} + \frac{1}{2(k+1)!} < \frac{1}{k!} < \frac{1}{k} \leq \frac{1}{k_0} < \varepsilon\,,$$

as wanted.

Note also that if $t \geq \frac{1}{2}$, then $\gamma(t) \geq \alpha(t) \geq 1 > 0$; and if $t \in \left(0, \frac{1}{2}\right)$, then $\gamma(t) \geq d_{k-1}\gamma_{k-1}(t) > 0$ with $k \stackrel{\text{def}}{=} \left\lfloor \frac{1}{t} \right\rfloor \geq 2$, so the function

$$\beta(t) \stackrel{\text{def}}{=} \int_0^t \gamma(s)\, ds \tag{22}$$

is also a $\mathcal{K}_\infty$-function, smooth on $(0, \infty)$. Furthermore, β satisfies $\beta^{(i)}(t) \to 0$ as $t \to 0^+$ for each $i = 0, 1, \ldots$.

Finally, we show that $W = \beta \circ V$ is C^∞. For this, it is enough to show that $D^{\varrho_0} W(x_n) \to 0$ as $x_n \to \bar{x} \in \partial\mathcal{A}$, for each multi-index ϱ_0 and each sequence $\{x_n\} \subseteq$

$\mathbb{R}^n \backslash \mathcal{A}$ converging to a point $\bar{x}$ in the boundary of $\mathcal{A}$. (In general—see, e.g., [4, p. 52]—if $\mathcal{A} \subseteq \mathbb{R}^n$ is closed and $\varphi : \mathbb{R}^n \longrightarrow \mathbb{R}$ satisfies that $\varphi|_{\mathcal{A}} = 0$, $\varphi|_{\mathbb{R}^n \backslash \mathcal{A}}$ is C^∞, and for each boundary point a of $\mathcal{A}$ and all multi-indices $\varrho = (\varrho_1, \varrho_2, \ldots, \varrho_n)$, it holds that $\lim_{\substack{x \to a \\ x \notin \mathcal{A}}} D^\varrho \varphi(x) = 0$, then φ is C^∞ on $\mathbb{R}^n$.)

Pick one such ϱ_0 and any sequence $\{x_n\}$ with $x_n \to \bar{x} \in \partial\mathcal{A}$. If $|\varrho_0| = 0$, one only needs to show that $W(x_n) \to 0$, which follows easily from the fact that $\beta \in \mathcal{K}_\infty$ and $V(x_n) \to 0$. So from now on, we can assume that $|\varrho_0| \stackrel{\text{def}}{=} i \geq 1$. As $\mathcal{A} \subseteq \cup_{j=0}^{\infty} \text{int}\, K_j$, $\bar{x} \in \text{int}\, K_l$ for some l, and without loss of generality we may assume that there is some fixed l so that

$$\cdot x_n \in K_l, \quad \text{for all } n.$$

Pick any $\varepsilon > 0$. We will show that there exists some N such that

$$n > N \implies |D^{\varrho_0} W(x_n)| < \varepsilon\,.$$

Let $k \in \mathbb{Z}$ be so that

$$k > \max\left\{i,\, \log_2\left(\frac{1}{\varepsilon}\right),\, l\right\}$$

and let $T \in (0, \frac{1}{3})$ be such that $T < \frac{1}{k+2}$. Observe that if $t < T$, then $t \notin I_1 \cup \cdots \cup I_k$.

As V is C^0 everywhere, $V = 0$ at $\mathcal{A}$, $V(x_n) \to V(\bar{x}) = 0$. So there exists N such that $V(x_n) < T$ whenever $n > N$. Fix an N like this. Then for any $n > N$,

$$\gamma_s^{(j)}\left(V(x_n)\right) = 0,\ \forall j,\ \forall s = 1, 2, \ldots, k$$

(since γ_s vanishes outside I_s). Pick any $j \in \mathbb{N}$ with $j \leq i$, any $h \in \mathbb{N}$ with $h \leq i$, and $\varrho_1, \ldots, \varrho_h$ multi-indices such that $|\varrho_\mu| \leq i,\ \forall \mu = 1, \ldots, h$. Then for any $q \in \mathbb{N}$ with $q > k$, by the way we chose c_k,

$$\left|\gamma_q^{(j)}\left(V(x_n)\right)\right| \leq c_q\,,$$

since $q > k > i \geq j$. Also, if $V(x_n) \in I_q$, then again by the properties of the sequence c_k,

$$|D^{\varrho_\mu} V(x_n)| \leq c_q$$

(since $q > k > l$ and $x_n \in K_l$ imply $x_n \in K_1 \cup \cdots \cup K_q$, and $|\varrho_\mu| \leq i < k < q$). Therefore, for such q, if $V(x_n) \in I_q$,

$$\left|\gamma_q^{(j)}\left(V(x_n)\right)\right| |D^{\varrho_1} V(x_n)| \cdots |D^{\varrho_h} V(x_n)| \leq c_q^{h+1} \leq c_q^{i+1} < c_q^q\,. \tag{23}$$

If instead it were the case that $V(x_n) \notin I_q$, then $\gamma_q^{(j)}\left(V(x_n)\right) = 0$, and hence the inequality (23) still holds. Since

$$\gamma^{(j)}\left(V(x_n)\right) = \sum_{q=k+1}^{\infty} d_q \gamma_q^{(j)}\left(V(x_n)\right)\,,$$

we also have

$$\left|\gamma^{(j)}\left(V(x_n)\right)\right| \left|D^{\varrho_1}V(x_n)\right| \cdots \left|D^{\varrho_h}V(x_n)\right| \leq \sum_{q=k+1}^{\infty} d_q c_q^q < \sum_{q=k+1}^{\infty} \frac{1}{2^q(q+1)!}$$

$$< \left(\sum_{q=k+1}^{\infty} \frac{1}{2^q}\right) \frac{1}{(k+1)!} = \frac{1}{2^k(k+1)!} < \frac{\varepsilon}{(k+1)!}\,. \tag{24}$$

Now observe that

$$\left(D^{\varrho_0}W\right)(x) = \left(D^{\varrho_0}(\beta \circ V)\right)(x)$$

is a sum of $\leq i!$ terms (recall $0 < i = |\varrho_0|$), each of which is of the form

$$\beta^{(p)}\left(V(x)\right)\left(D^{\varrho_1}V\right)(x) \cdots \left(D^{\varrho_h}V\right)(x)\,,$$

where $0 < p \leq i$, $h \leq i$, and each $|\varrho_\mu| \leq i$. Each

$$\beta^{(p)}\left(V(x)\right) = \gamma^{(j)}\left(V(x)\right)\,,\ j = p-1 \leq i-1\,,$$

so (24) applies, and we conclude

$$\left|\left(D^{\varrho_0}W\right)(x_n)\right| \leq i!\frac{\varepsilon}{(k+1)!} < \varepsilon\,,$$

(since $k > i$.) □

Now let us return to the proof of Proposition 4.2.

Proof of Proposition 4.2. Assume $\mathcal{A}$, V, and $\alpha_1, \alpha_2, \alpha_3$ are as defined in Definition 2.6. Let β, W be as in Lemma 4.3. We show that W is a smooth Lyapunov function as required.

Let $\hat{\alpha}_i \stackrel{\text{def}}{=} \beta \circ \alpha_i, i = 1, 2$. These are again $\mathcal{K}_\infty$-functions, and they satisfy

$$\hat{\alpha}_1(|\xi|_{\mathcal{A}}) \leq W(\xi) \leq \hat{\alpha}_2(|\xi|_{\mathcal{A}})\,.$$

We define, for $s > 0$,

$$\check{\beta}(s) \stackrel{\text{def}}{=} \min_{t \in [\alpha_1(s),\, \alpha_2(s)]} \beta'(t) > 0\,.$$

Also let $\check{\beta}(0) \stackrel{\text{def}}{=} 0$. Define $\hat{\alpha}_3(s) \stackrel{\text{def}}{=} \check{\beta}(s)\alpha_3(s)$. Then $\hat{\alpha}_3$ is a continuous, positive definite function. Also, for any $\xi \in \mathbb{R}^n \backslash \mathcal{A}$,

$$\begin{aligned} L_{f_{\mathrm{d}}}W(\xi) = \beta'(V(\xi))L_{f_{\mathrm{d}}}V(\xi) &\leq -\beta'(V(\xi))\alpha_3(|\xi|_{\mathcal{A}}) \\ &\leq -\check{\beta}(|\xi|_{\mathcal{A}})\alpha_3(|\xi|_{\mathcal{A}}) = -\hat{\alpha}_3(|\xi|_{\mathcal{A}})\,, \end{aligned}$$

which concludes the proof of Proposition 4.2. □

4.2. A useful estimate. The following lemma establishes a useful comparison principle.

LEMMA 4.4. *For each continuous and positive definite function α, there exists a $\mathcal{KL}$-function $\beta_\alpha(s, t)$ with the following property: if $y(\cdot)$ is any (locally) absolutely*

continuous function defined for $t \geq 0$ and with $y(t) \geq 0$ for all t, and $y(\cdot)$ satisfies the differential inequality

$$\dot{y}(t) \leq -\alpha(y(t)), \quad \textit{for almost all} \quad t \tag{25}$$

with $y(0) = y_0 \geq 0$, then it holds that

$$y(t) \leq \beta_\alpha(y_0, t)$$

for all $t \geq 0$.

Proof. Define for any $s > 0$, $\eta(s) \stackrel{\text{def}}{=} -\int_1^s \frac{dr}{\alpha(r)}$. This is a strictly decreasing differentiable function on $(0, \infty)$. Without loss of generality, we will assume that $\lim_{s\to 0^+} \eta(s) = +\infty$. If this were not the case, we could consider instead the following function:

$$\bar{\alpha}(s) \stackrel{\text{def}}{=} \min\{s, \alpha(s)\}.$$

This function is again continuous, positive definite, satisfies $\bar{\alpha}(s) \leq \alpha(s)$ for any $s \geq 0$, and

$$\lim_{s\to 0^+} \int_s^1 \frac{dr}{\bar{\alpha}(r)} \geq \lim_{s\to 0^+} \int_s^1 \frac{dr}{r} = +\infty .$$

Moreover, if $\dot{y}(t) \leq -\alpha(y(t))$ then also $\dot{y}(t) \leq -\bar{\alpha}(y(t))$, so $\beta_{\bar{\alpha}}$ could be used to bound solutions.

Let

$$0 < a \stackrel{\text{def}}{=} -\lim_{s\to+\infty} \eta(s) .$$

Then the range of η, and hence also the domain of η^{-1}, is the open interval $(-a, \infty)$. (We allow the possibility that $a = \infty$.) For $(s, t) \in \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0}$, define

$$\beta_\alpha(s, t) \stackrel{\text{def}}{=} \begin{cases} 0, & \text{if } s = 0, \\ \eta^{-1}(\eta(s) + t), & \text{if } s > 0. \end{cases}$$

We claim that for any $y(\cdot)$ satisfying the conditions in the lemma,

$$y(t) \leq \beta_\alpha(y_0, t), \quad \text{for all } t \geq 0 . \tag{26}$$

As $\dot{y}(t) \leq -\alpha(y(t))$, it follows that $y(t)$ is nonincreasing, and if $y(t_0) = 0$ for some $t_0 \geq 0$, then $y(t) \equiv 0$, $\forall t \geq t_0$. Without loss of generality, assume that $y_0 > 0$. Let

$$t_0 \stackrel{\text{def}}{=} \inf\{t : \ y(t) = 0\} \leq +\infty .$$

It is enough to show (26) holds for $t \in [0, t_0)$.

As η is strictly decreasing, we only need to show that $\eta(y(t)) \geq \eta(y_0) + t$, that is,

$$-\int_1^{y(t)} \frac{dr}{\alpha(r)} \geq -\int_1^{y_0} \frac{dr}{\alpha(r)} + t ,$$

which is equivalent to

$$\int_{y(t)}^{y_0} \frac{dr}{\alpha(r)} \geq t . \tag{27}$$

From (25), one sees that

$$\int_0^t \frac{\dot{y}(\tau)}{\alpha(y(\tau))}\, d\tau \;\leq\; -\int_0^t d\tau \;=\; -t\,.$$

Changing variables in the integral, this gives (27).

It only remains to show that β_α is of class $\mathcal{KL}$. The function β_α is continuous since both η and η^{-1} are continuous in their domains, and $\lim_{r\to\infty} \eta^{-1}(r) = 0$. It is strictly increasing in s for each fixed t since both η and η^{-1} are strictly decreasing. Finally, $\beta_\alpha(s,\, t) \to 0$ as $t \to \infty$ by construction. So β_α is a $\mathcal{KL}$-function. □

5. Some properties of complete systems. We first need to establish some technical properties that hold for complete systems, and in particular a Lipschitz continuity fact.

For each $\xi \in \mathbb{R}^n$ and $T > 0$, let

$$\mathcal{R}^T(\xi) \stackrel{\text{def}}{=} \{\eta :\; \eta = x(T,\, \xi, d),\; d \in \mathcal{M}_{\mathcal{D}}\}\,.$$

This is the reachable set of (1) from ξ at time T. We use $\mathcal{R}^{\leq T}(\xi)$ to denote $\bigcup_{0\leq t\leq T} \mathcal{R}^t(\xi)$. If S is a subset of $\mathbb{R}^n$, we write

$$\mathcal{R}^T(S) \stackrel{\text{def}}{=} \bigcup_{\xi\in S} \mathcal{R}^T(\xi)\,,\quad \mathcal{R}^{\leq T}(S) \stackrel{\text{def}}{=} \bigcup_{\xi\in S} \mathcal{R}^{\leq T}(\xi)\,.$$

In what follows we use $\overline{S}$ to denote the closure of S for any subset S of $\mathbb{R}^n$.

PROPOSITION 5.1. *Assume that* (1) *is forward complete. Then for any compact subset* K *of* $\mathbb{R}^n$ *and any* $T > 0$, *the set* $\overline{\mathcal{R}^{\leq T}(K)}$ *is compact.*

To prove Proposition 5.1, we first need to make a couple of technical observations.

LEMMA 5.2. *Let* K *be a compact subset of* $\mathbb{R}^n$ *and let* $T > 0$. *Then the set* $\overline{\mathcal{R}^{\leq T}(K)}$ *is compact if and only if* $\overline{\mathcal{R}^{\leq T}(\xi)}$ *is compact for each* $\xi \in K$.

Proof. It is clear that the compactness of $\overline{\mathcal{R}^{\leq T}(K)}$ implies the compactness of $\overline{\mathcal{R}^{\leq T}(\xi)}$ for any $\xi \in K$.

Now assume, for $T > 0$ and a compact set K, that $\overline{\mathcal{R}^{\leq T}(\xi)}$ is compact for each $\xi \in K$. Pick any $\xi \in K$, and let $\mathcal{U} = \{\eta :\; d(\eta,\, \overline{\mathcal{R}^{\leq T}(\xi)}) < 1\}$. Then $\overline{\mathcal{U}}$ is compact. Let C be a Lipschitz constant for f with respect to x on $\overline{\mathcal{U}}$, and let $r = e^{-CT}$. For each $d \in \mathcal{M}_{\mathcal{D}}$ and each η with $|\eta - \xi| < r$, let $\tilde{t} = \inf\{t \geq 0 :\; |x(t,\, \eta,\, d) - x(t,\, \xi,\, d)| \geq 1\}$. Then, using Gronwall's lemma, one can show that $\tilde{t} \geq T$, from which it follows that

$$\mathcal{R}^{\leq T}(\eta) \subseteq \overline{\mathcal{U}}, \quad \forall |\eta - \xi| < r.$$

Thus, for each $\xi \in K$, there is a neighborhood $\mathcal{V}_\xi$ of ξ such that $\overline{\mathcal{R}^{\leq T}(\mathcal{V}_\xi)}$ is compact. By compactness of K, it follows that $\overline{\mathcal{R}^{\leq T}(K)}$ is compact. □

LEMMA 5.3. *For any subset* S *of* $\mathbb{R}^n$ *and any* $T > 0$,

$$\mathcal{R}^T(\overline{S}) \subseteq \overline{\mathcal{R}^T(S)},\quad \mathcal{R}^{\leq T}(\overline{S}) \subseteq \overline{\mathcal{R}^{\leq T}(S)}\,.$$

In particular, $\overline{\mathcal{R}^{\leq T}(\overline{S})} = \overline{\mathcal{R}^{\leq T}(S)}$.

Proof. The first conclusion follows from the continuity of solutions on initial states; see [26, Thm. 1]. The second is immediate from there. □

We now return to the proof of Proposition 5.1. By Lemma 5.2, it is enough to show that $\overline{\mathcal{R}^{\leq T}(\xi)}$ is compact for each $\xi \in \mathbb{R}^n$ and each $T > 0$. Pick any $\xi_0 \in \mathbb{R}^n$, and let

$$\tau = \sup\{T \geq 0 : \ \overline{\mathcal{R}^{\leq T}(\xi_0)} \text{ is compact } \}.$$

Note that $\tau > 0$. This is because $|x(t, \xi_0, d) - \xi_0| \leq 1$ for any $0 \leq t < 1/M$ and any $d \in \mathcal{M}_{\mathcal{D}}$, where

$$M = \max\{|f(\xi, \mathbf{d})| : \ |\xi - \xi_0| \leq 1, \mathbf{d} \in \mathcal{D}\}.$$

We must show that $\tau = \infty$.

Assume that $\tau < \infty$. Using the same argument as above, one can show that if $\overline{\mathcal{R}^{\leq t}(\xi_0)}$ is compact for some $t > 0$ then there is some $\delta > 0$ such that $\overline{\mathcal{R}^{\leq (t+\delta)}(\xi_0)}$ is compact. From here it follows that $\overline{\mathcal{R}^{\leq \tau}(\xi_0)}$ is not compact. By definition, $\overline{\mathcal{R}^{\leq t}(\xi_0)}$ is compact for any $t < \tau$.

Let $\tau_1 = \tau/2$. Then there is some $\eta_1 \in \overline{\mathcal{R}^{\tau_1}(\xi_0)}$ such that $\overline{\mathcal{R}^{\leq (\tau-\tau_1)}(\eta_1)}$ is not compact; otherwise, by Lemma 5.2, $\overline{\mathcal{R}^{\leq (\tau-\tau_1)}(\overline{\mathcal{R}^{\tau_1}(\xi_0)})}$ would be compact. This, in turn, would imply that $\overline{\mathcal{R}^{\leq \tau}(\xi_0)}$ is compact, since

$$\mathcal{R}^{\leq \tau}(\xi_0) \subseteq \mathcal{R}^{\leq \tau_1}(\xi_0) \bigcup \mathcal{R}^{\leq (\tau-\tau_1)}(\mathcal{R}^{\tau_1}(\xi_0)) \subseteq \overline{\mathcal{R}^{\leq \tau_1}(\xi_0)} \bigcup \overline{\mathcal{R}^{\leq (\tau-\tau_1)}\left(\overline{\mathcal{R}^{\tau_1}(\xi_0)}\right)}.$$

On the other hand, combining Lemma 5.3 with the fact that $\overline{\mathcal{R}^{\leq t}(\mathcal{R}^{\tau_1}(\xi_0))}$ is compact for any $0 \leq t < \tau - \tau_1$, one sees that $\overline{\mathcal{R}^{\leq t}(\eta_1)}$ is compact for any $0 \leq t < \tau - \tau_1$.

Since $\eta_1 \in \overline{\mathcal{R}^{\tau_1}(\xi_0)}$, there exists a sequence $\{z_n\} \to \eta_1$ with $z_n \in \mathcal{R}^{\tau_1}(\xi_0)$. Assume, for each n, that $z_n = x(\tau_1, \xi_0, d_n)$ for some $d_n \in \mathcal{M}_{\mathcal{D}}$. For each $d \in \mathcal{M}_{\mathcal{D}}$ and each $s \in \mathbb{R}$, we use d_s to denote the function defined by $d_s(t) = d(s + t)$. Then by uniqueness, one has that for each n, $x(s, z_n, (d_n)_{\tau_1}) \in K_1$ for any $-\tau_1 \leq s \leq 0$, where $K_1 = \overline{\mathcal{R}^{\leq \tau_1}(\xi_0)}$. We want to claim next that, by compactness of K_1 and Gronwall's lemma,

$$|x(-\tau_1, \eta_1, (d_n)_{\tau_1}) - \xi_0| = |x(-\tau_1, \eta_1, (d_n)_{\tau_1}) - x(-\tau_1, z_n, (d_n)_{\tau_1})| \longrightarrow 0, \quad \text{as } n \to \infty.$$

The only potential problem is that the solution $x(-\tau_1, \eta_1, (d_n)_{\tau_1})$ may fail to exist a priori. However, it is possible to modify $f(x, \mathbf{d})$ outside a neighborhood of $K_1 \times \mathcal{D}$ so that it now has compact support and is hence globally bounded. The modified dynamics is complete. Now the above limit holds for the modified system, and a fortiori it also holds for the original system.

Choose n_0 such that

$$|x(-\tau_1, \eta_1, (d_{n_0})_{\tau_1}) - \xi_0| < \frac{1}{2}. \tag{28}$$

Let $v_1 = d_{n_0}$, and let $\eta_0 = x(-\tau_1, \eta_1, (d_{n_0})_{\tau_1})$. Then, by continuity on initial conditions, there is a neighborhood $\mathcal{U}_1$ of η_1 contained in $B(\eta_1, 1)$ such that

$$|x(-\tau_1, \xi, (v_1)_{\tau_1}) - \eta_0| < \frac{1}{2}, \quad \forall \xi \in \mathcal{U}_1, \tag{29}$$

where $B(\eta, r)$ denotes the open ball centered at η with radius r. Combining (28) and (29), one has

$$x(-\tau_1, \xi, (v_1)_{\tau_1}) \in \mathcal{U}_0, \quad \forall \xi \in \mathcal{U}_1,$$

where $\mathcal{U}_0 = B(\xi_0, 1)$.

Let $\tau_2 = \tau_1/2 = (\tau - \tau_1)/2$. Applying the above argument with ξ_0 replaced by η_1, τ replaced by $(\tau - \tau_1)$, and τ_1 replaced by τ_2, one shows that there exists some $\eta_2 \in \overline{\mathcal{R}^{\tau_2}(\eta_1)}$ such that $\overline{\mathcal{R}^{\leq t}(\eta_2)}$ is compact for any $0 \leq t < \tau - \sigma_2$, and $\overline{\mathcal{R}^{\leq(\tau-\sigma_2)}(\eta_2)}$ is not compact, where $\sigma_2 = \tau_1 + \tau_2$, and there exist some v_2 defined on $[0, \tau_2)$ and some neighborhood $\mathcal{U}_2$ of η_2 contained in $B(\eta_2, 1)$, such that

$$x(-\tau_2, \xi, (v_2)_{\tau_2}) \in \mathcal{U}_1, \quad \forall \xi \in \mathcal{U}_2 .$$

By induction, one can get for each $k \geq 1$ a point η_k, a neighborhood $\mathcal{U}_k$ of η_k contained in $B(\eta_k, 1)$, and a function v_k defined on $[0, \tau_k)$ (where $\tau_k = 2^{-k}\tau$) such that

- $\overline{\mathcal{R}^{\leq(\tau-\sigma_k)}(\eta_k)}$ is not compact, where $\sigma_k = \tau_1 + \tau_2 + \cdots + \tau_k = \tau(1 - 2^{-k}) \to \tau$;
- $x(-\tau_k, \xi, (v_k)_{\tau_k}) \in \mathcal{U}_{k-1}$, for any $\xi \in \mathcal{U}_k$.

Now define v on $[0, \tau)$ by concatenating all the v_k's. That is, $v(t) = v_k(t)$ for $t \in [\sigma_{k-1}, \sigma_k)$ (with $\sigma_0 \stackrel{\text{def}}{=} 0$). Then $v \in \mathcal{M}_{\mathcal{D}}$. For each k, let

$$\zeta_k = x(-\sigma_k, \eta_k, (v^k)_{\sigma_k}) ,$$

where v^k is the restriction of v to $[0, \sigma_k)$. By induction,

$$x\Big(-(\sigma_k - \sigma_i), \eta_k, (v^k)_{\sigma_k}\Big) \in \mathcal{U}_{k-i} ,$$

for each $0 \leq i \leq k$, from which it follows that $\zeta_k \in \mathcal{U}_0$ for each k. By compactness of $\overline{\mathcal{U}_0}$, there exists some subsequence of $\{\zeta_k\}$ converging to some point $\zeta_0 \in \mathbb{R}^n$. For ease of notation, we still use $\{\zeta_k\}$ to denote this convergent subsequence. Our aim is next to prove that the solution starting at ζ_0 and applying the measurable function v does not exist for time τ, contradicting forward completeness.

First notice that for any compact set S, there exists some k such that $\eta_k \notin S$. Otherwise, assume that there exists some compact set S such that $\eta_k \in S$ for all k. Let $S_1 = \{\eta : d(\eta, S) \leq 1\}$. The compactness of S implies that there exists some $\delta > 0$ such that

$$\mathcal{R}^{\leq t}(\eta) \subseteq S_1$$

for any $\eta \in S$ and any $t \in [0, \delta]$. In particular, it implies that $\overline{\mathcal{R}^{\leq(\tau-\sigma_k)}(\eta_k)} \subseteq S_1$ for k large enough so that $\tau - \sigma_k < \delta$. This contradicts the fact that $\overline{\mathcal{R}^{\leq(\tau-\sigma_k)}(\eta_k)}$ is not compact for each k.

Assume that $x(\tau, \zeta_0, v)$ is defined. By continuity on initial conditions, this would imply that $x(t, \zeta_k, v)$ is defined for all $t \leq \tau$ and for all k large enough, and that it converges uniformly to $x(t, \zeta_0, v)$. Thus, $x(t, \zeta_k, v)$ remains in a compact set for all $t \in [0, \tau]$ and all k. But

$$x(\sigma_k, \zeta_k, v) = x(\sigma_k, \zeta_k, v^k) = \eta_k ,$$

contradicting what was just proved. So $x(\tau, \zeta_0, v)$ is not defined, which contradicts the forward completeness of the system. □

Remark 5.4. For $T > 0$ and $\xi \in \mathbb{R}^r$, let

$$\mathcal{R}^{-T}(\xi) = \{\eta : \ \eta = x(-T, \xi, d), \ d \in \mathcal{M}_{\mathcal{D}}\} \quad \text{and} \quad \mathcal{R}^{\geq -T}(\xi) = \bigcup_{t \in [-T, 0]} \mathcal{R}^t(\xi) .$$

These are the reachable sets from ξ for the time-reversed system

$$\dot{x}(t) = -f(x(t), d(t)) . \tag{30}$$

Similarly, one defines $\mathcal{R}^{-T}(S)$ and $\mathcal{R}^{\geq -T}(S)$ for subsets S of $\mathbb{R}^n$. If (1) is backward complete, that is, if (30) is forward complete, and applying Proposition 5.1 to (30), one concludes, for system (1), that $\overline{\mathcal{R}^{\geq -T}(K)}$ is compact for any $T > 0$ and any compact subset K of $\mathbb{R}^n$. In particular, for systems that are (forward and backward) complete,

$$\overline{\mathcal{R}^{\geq -T}(K) \bigcup \mathcal{R}^{\leq T}(K)}$$

is compact for any compact set K and any $T > 0$.

Combining the above conclusion and Gronwall's lemma, one has the following fact.

PROPOSITION 5.5. *Assume that* (1) *is complete. For any fixed* $T > 0$ *and any compact* $K \subseteq \mathbb{R}^n$, *there is a constant* $C > 0$ (*which only depends on the set* K *and* T), *such that for the trajectories* $x(t, x_0, d)$ *of the system* (1),

$$|x(t, \xi, d) - x(t, \eta, d)| \leq C|\xi - \eta|$$

for any $\xi, \eta \in K$, *any* $|t| \leq T$, *and any* $d \in \mathcal{M}_{\mathcal{D}}$.

6. Proof of the first converse Lyapunov theorem.

Proof. [$\Longleftarrow$] Pick any $x_0 \in \mathbb{R}^n$ and any $d \in \mathcal{M}_{\mathcal{D}}$, and let $x(\cdot)$ be the corresponding trajectory. Then we have

$$\frac{dV(x(t))}{dt} \leq -\alpha_3(|x(t)|_{\mathcal{A}}) \leq -\alpha(V(x(t))) , \text{ a.e. } t \geq 0 ,$$

where α is the $\mathcal{K}_\infty$-function defined by

$$\alpha(\cdot) \stackrel{\text{def}}{=} \alpha_3(\alpha_2^{-1}(\cdot)) .$$

Now let β_α be the $\mathcal{KL}$-function as in Lemma 4.4 with respect to α, and define

$$\beta(s, t) \stackrel{\text{def}}{=} \alpha_1^{-1}\big(\beta_\alpha(\alpha_2(s), t)\big) . \tag{31}$$

Then β is a $\mathcal{KL}$-function, since both α_1 and α_2 are $\mathcal{K}_\infty$-functions. By Lemma 4.4,

$$V(x(t)) \leq \beta_\alpha\big(V(x_0), t\big) , \quad \text{for any } t \geq 0 .$$

Hence

$$|x(t)|_{\mathcal{A}} \leq \beta(|x_0|_{\mathcal{A}} , t) , \text{ for any } t \geq 0 .$$

Therefore the system (1) is UGAS with respect to $\mathcal{A}$, by Proposition 2.5.

[$\Longrightarrow$] We will show the existence of a not necessarily smooth Lyapunov function; then the existence of a smooth function will follow from Proposition 4.2. Assume that the system is UGAS with respect to the set $\mathcal{A}$. Let δ and T_r be as in Definition 2.2 and Lemma 3.1.

Define $g : \mathbb{R}^n \longrightarrow \mathbb{R}$ by

$$g(\xi) \stackrel{\text{def}}{=} \inf_{t \leq 0, d \in \mathcal{M}_{\mathcal{D}}} \{|x(t, \xi, d)|_{\mathcal{A}}\} . \tag{32}$$

Note that, by uniqueness of solutions, for each $t_0 > 0$ and each d, it holds that

$$x(t - t_0,\, x(t_0,\, \xi,\, d),\, d_{t_0}) \;=\; x(t,\, \xi, d)\,,$$

where d_{t_0} is defined by $d_{t_0}(t) = d(t + t_0)$. Pick any $d \in \mathcal{M}_{\mathcal{D}}$, $\xi \in \mathbb{R}^n$, and $t_1 > 0$. Let $\xi_1 = x(t_1,\, \xi,\, d)$. Then for any $t < 0$, and $v \in \mathcal{M}_{\mathcal{D}}$,

$$x(t,\, \xi, v) \;=\; x(t - t_1,\, \xi_1,\, v_{t_1} \# d_{t_1})\,,$$

where

$$v_{t_1} \# d_{t_1}(s) \;=\; \begin{cases} d(s + t_1), & \text{if } -t_1 \le s \le 0, \\ v(s + t_1), & \text{if } s < -t_1. \end{cases}$$

Thus,

$$\begin{aligned} g(\xi) &= \inf_{t \le 0, v \in \mathcal{M}_{\mathcal{D}}} |x(t,\, \xi,\, v)|_{\mathcal{A}} = \inf_{t \le 0, d \in \mathcal{M}_{\mathcal{D}}} \left|x(t - t_1,\, \xi_1,\, v_{t_1} \# d_{t_1})\right|_{\mathcal{A}} \\ &= \inf_{\tau \le -t_1, v \in \mathcal{M}_{\mathcal{D}}} \left|x(\tau,\, \xi_1,\, v_{t_1} \# d_{t_1})\right|_{\mathcal{A}} \;\ge\; \inf_{\tau \le 0, v \in \mathcal{M}_{\mathcal{D}}} \left|x(\tau,\, \xi_1,\, v)\right|_{\mathcal{A}} \\ &= g(\xi_1)\,. \end{aligned}$$

This implies that

$$g\big(x(t,\, \xi,\, d)\big) \le g(\xi), \quad \forall t > 0\,, \quad \forall d \in \mathcal{M}_{\mathcal{D}}\,. \tag{33}$$

Also one has

$$\delta(|\xi|_{\mathcal{A}}) \le g(\xi) \le |\xi|_{\mathcal{A}}\,. \tag{34}$$

The second half of (34) is obvious from $x(0,\, \xi,\, d) = \xi$. On the other hand, if the first half were not true, then there would be some $d \in \mathcal{M}_{\mathcal{D}}$ and some $t_0 \le 0$ such that

$$\delta(|\xi|_{\mathcal{A}}) > |x(t_0,\, \xi,\, d)|_{\mathcal{A}}\,.$$

Pick any $0 < \varepsilon < |\xi|_{\mathcal{A}}$ so that $|x(t_0,\, \xi,\, d)|_{\mathcal{A}} < \delta(\varepsilon)$. By the uniform stability property, applied with $t = -t_0$ and $x_0 = x(t_0,\, \xi,\, d)$,

$$|\xi|_{\mathcal{A}} = |x(-t_0,\, x(t_0,\, \xi,\, d),\, d_{t_0})|_{\mathcal{A}} < |\xi|_{\mathcal{A}}\,,$$

which is a contradiction.

For any $0 < \varepsilon < r$, define $K_{\varepsilon, r} \stackrel{\text{def}}{=} \{\xi \in \mathbb{R}^n :\; \varepsilon \le |\xi|_{\mathcal{A}} < r\}$.

FACT 1. *For all ε and r with $0 < \varepsilon < r$, there exists $q_{\varepsilon, r} \le 0$, such that*

$$\xi \in K_{\varepsilon, r},\; d \in \mathcal{M}_{\mathcal{D}}, \quad \textit{and} \quad t < q_{\varepsilon, r} \;\;\Longrightarrow\;\; |x(t,\, \xi,\, d)|_{\mathcal{A}} \ge r\,.$$

Proof. If the statement were not true, then there would exist ε, r with $0 < \varepsilon < r$ and three sequences $\{\xi_k\} \subseteq K_{\varepsilon, r}$, $\{t_k\} \subseteq \mathbb{R}$, and $d_k \in \mathcal{M}_{\mathcal{D}}$ with $\lim_{k \to \infty} t_k = -\infty$ such that for all k

$$|x(t_k,\, \xi_k, d_k)|_{\mathcal{A}} < r\,.$$

Pick k large enough so that $-t_k > T_r(\varepsilon)$. Then by the uniform attraction property,

$$|\xi_k|_{\mathcal{A}} = |x(-t_k,\, x(t_k,\, \xi_k,\, d_k),\, (d_k)_{t_k})|_{\mathcal{A}} < \varepsilon\,,$$

which is a contradiction. This proves the fact.

Therefore, for any $\xi \in K_{\varepsilon,r}$,

$$g(\xi) = \inf\{|x(t, \xi, d)|_{\mathcal{A}} : \ t \in [q_{\varepsilon,r}, 0], d \in \mathcal{M}_{\mathcal{D}}\}.$$

LEMMA 6.1. *The function $g(\xi)$ is locally Lipschitz on $\mathbb{R}^n \backslash \mathcal{A}$ and continuous everywhere.*

Proof. Fix any $\xi_0 \in \mathbb{R}^n \backslash \mathcal{A}$, and let $s = |\xi_0|_{\mathcal{A}}/2$. Let $\bar{B}(\xi_0, s)$ denote the closed ball centered at ξ_0 and with radius s. Then $\bar{B}(\xi_0, s) \subseteq K_{\sigma,r}$ for some $0 < \sigma < r$. Pick a constant C as in Proposition 5.5 with respect to this closed ball and $T = |q_{\sigma,r}|$. Pick any $\zeta, \eta \in \bar{B}(\xi_0, s)$. For any $\varepsilon > 0$, there exist some $d_{\eta,\varepsilon}$ and $t_{\eta,\varepsilon} \in [q_{\sigma,r}, 0]$ such that $g(\eta) \geq |x(t_{\eta,\varepsilon}, \eta, d_{\eta,\varepsilon})|_{\mathcal{A}} - \varepsilon$. Thus

$$g(\zeta) - g(\eta) \leq |x(t_{\eta,\varepsilon}, \zeta, d_{\eta,\varepsilon})|_{\mathcal{A}} - |x(t_{\eta,\varepsilon}, \eta, d_{\eta,\varepsilon})|_{\mathcal{A}} + \varepsilon \leq C|\zeta - \eta| + \varepsilon. \tag{35}$$

Note that (35) holds for all $\varepsilon > 0$, so it follows that

$$g(\zeta) - g(\eta) \leq C\,|\zeta - \eta|\,.$$

Similarly, $g(\eta) - g(\zeta) \leq C|\zeta - \eta|$. This proves that g is locally Lipschitz on $\mathbb{R}^n \backslash \mathcal{A}$.

Note that g is 0 on $\mathcal{A}$, and for $\xi \in \mathcal{A}$, $\eta \in \mathbb{R}^n$,

$$|g(\eta) - g(\xi)| = |g(\eta)| \leq |\eta|_{\mathcal{A}} \leq |\eta - \xi|\,,$$

thus g is globally continuous. (We are not claiming that g is locally Lipschitz on $\mathbb{R}^n$, though.) □

Now define $U : \mathbb{R}^n \longrightarrow \mathbb{R}_{\geq 0}$ by

$$U(\xi) \stackrel{\text{def}}{=} \sup_{t \geq 0, d \in \mathcal{M}_{\mathcal{D}}} \Big\{ g\big(x(t, \xi, d)\big)\, k(t) \Big\}, \tag{36}$$

where $k : R_{\geq 0} \longrightarrow \mathbb{R}_{>0}$ is any strictly increasing, smooth function that satisfies:

- there are two constants $0 < c_1 < c_2 < \infty$ such that $k(t) \in [c_1, c_2]$ for all $t \geq 0$;
- there is a bounded, positive decreasing, continuous function $\tau(\cdot)$, such that

$$k'(t) \geq \tau(t) \quad \text{for all} \quad t \geq 0\,.$$

(For instance, $(c_1 + c_2 t)/(1 + t)$ is one example of such a function.) Observe that

$$U(\xi) \leq \sup_{t \geq 0}(g(\xi)\, k(t)) \leq c_2 g(\xi) \leq c_2\, |\xi|_{\mathcal{A}}\,, \tag{37}$$

and

$$U(\xi) \geq \sup_{d \in \mathcal{M}_{\mathcal{D}}} g(x(t, \xi, d))\, k(t)\big|_{t=0} \geq c_1 g(\xi) \geq c_1 \delta(|\xi|_{\mathcal{A}})\,. \tag{38}$$

For any $\xi \in \mathbb{R}^n$, since

$$|x(t, \xi, d)|_{\mathcal{A}} \leq \beta(|\xi|_{\mathcal{A}}, t), \ \ \forall d, \ \ \forall t \geq 0,$$

for some $\mathcal{KL}$-function β, and $0 \leq g(x(t, \xi, d)) \leq |x(t, \xi, d)|_{\mathcal{A}}$ for all $t \geq 0$, it follows that

$$\lim_{t \to +\infty} \sup_{d} g(x(t, \xi, d)) = 0\,.$$

Thus there exists some $\tau_\xi \in [0, \infty)$ such that

$$U(\xi) = \sup_{0\le t\le \tau_\xi, d\in\mathcal{M}_\mathcal{D}} g(x(t, \xi, d))\, k(t)\,.$$

In fact, we can get the following explicit bound.

FACT 2. *For any* $0 < |\xi|_\mathcal{A} < r$,

$$U(\xi) = \sup_{0\le t\le t_\xi, d\in\mathcal{M}_\mathcal{D}} g\big(x(t, \xi, d)\big)k(t)\,,$$

where $t_\xi = T_r(\frac{c_1}{2c_2}\delta(|\xi|_\mathcal{A}))$.

Proof. If the statement is not true, then for any $\varepsilon > 0$, there exists some $t_\varepsilon > T_r(\frac{c_1}{2c_2}\delta(|\xi|_\mathcal{A}))$ and some d_ε such that

$$U(\xi) \le g(x(t_\varepsilon, \xi, d_\varepsilon))k(t_\varepsilon) + \varepsilon\,.$$

So we have

$$\begin{aligned}\delta(|\xi|_\mathcal{A}) &\le \frac{1}{c_1}U(\xi) \le \frac{1}{c_1}g(x(t_\varepsilon, \xi, d_\varepsilon))\,k(t_\varepsilon) + \frac{\varepsilon}{c_1}\\ &\le \frac{c_2}{c_1}g(x(t_\varepsilon, \xi, d_\varepsilon)) + \frac{\varepsilon}{c_1} \le \frac{c_2}{c_1}|x(t_\varepsilon, \xi, d_\varepsilon)|_\mathcal{A} + \frac{\varepsilon}{c_1} < \frac{\delta(|\xi|_\mathcal{A})}{2} + \frac{\varepsilon}{c_1}\,.\end{aligned}$$

Taking the limit as ε tends to 0 results in a contradiction.

For any compact set $K \subseteq \mathbb{R}^n\backslash\mathcal{A}$, let

$$t_K \stackrel{\text{def}}{=} \max_{\xi\in K} t_\xi < \infty\,.$$

(Finiteness follows from Fact 2, as $K \subseteq \{\xi :\ 0 < |\xi|_\mathcal{A} < r\}$ for some $r > 0$.)

LEMMA 6.2. *The function* $U(\cdot)$ *defined by* (36) *is locally Lipschitz on* $\mathbb{R}^n\backslash\mathcal{A}$ *and continuous everywhere.*

Proof. For $\xi_0 \notin \mathcal{A}$, pick up a compact neighborhood K_0 of ξ_0 so that $K_0 \cap \mathcal{A} = \emptyset$. By (38), one knows that

$$U(\xi) > r_0\,,\quad \forall \xi \in K_0\,,$$

for some constant $r_0 > 0$. Let $r_1 = r_0/(2c_2)$ and let

$$K_1 = K_0 \bigcap \Big\{\eta :\ |\eta - \xi_0| \le \frac{r_1}{4C}\Big\}\,,$$

where C is a constant such that

$$|x(t, \xi, d) - x(t, \eta, d)| \le C\,|\xi - \eta|\,,\quad \forall \xi, \eta \in K_0,\ 0 \le t \le t_{K_0},\ d \in \mathcal{M}_\mathcal{D}. \tag{39}$$

In what follows we will show that there exists some $L > 0$ such that for any $\xi, \eta \in K_1$, it holds that

$$|U(\xi) - U(\eta)| \le L\,|\xi - \eta|\,. \tag{40}$$

First of all, for any $\xi \in K_1$ and any $\varepsilon \in (0, r_0/2)$, there exists $t_{\xi,\varepsilon} \in [0, t_{K_0}]$ and $d_{\xi,\varepsilon} \in \mathcal{M}_\mathcal{D}$ such that

$$U(\xi) \le g(x(t_{\xi,\varepsilon}, \xi, d_{\xi,\varepsilon}))k(t_{\xi,\varepsilon}) + \varepsilon \le c_2\,|x(t_{\xi,\varepsilon}, \xi, d_{\xi,\varepsilon})|_\mathcal{A} + \varepsilon\,,$$

from which it follows that

$$|x(t_{\xi,\varepsilon},\, \xi,\, d_{\xi,\varepsilon})|_{\mathcal{A}} \geq r_1 \,.$$

It follows from (39) that for any $\eta \in K_1$,

$$|x(t_{\xi,\varepsilon},\, \eta,\, d_{\xi,\varepsilon})|_{\mathcal{A}} \geq |x(t_{\xi,\varepsilon},\, \xi,\, d_{\xi,\varepsilon})|_{\mathcal{A}} - |x(t_{\xi,\varepsilon},\, \xi,\, d_{\xi,\varepsilon}) - x(t_{\xi,\varepsilon},\, \eta,\, d_{\xi,\varepsilon})| \geq \frac{r_1}{2} \,.$$

By Proposition 5.1 one knows that there exists some compact set K_2 such that

$$x(t,\, \xi,\, d) \in K_2, \quad \forall \xi \in K_1,\ \forall t \in [0,\, t_{K_1}], \text{ and } \forall d \in \mathcal{M}_{\mathcal{D}} \,.$$

Again, applying Lemma 6.1 to the compact set $K_2 \bigcap \{\zeta :\ |\zeta|_{\mathcal{A}} \geq r_1/2\}$, one sees that

$$|g(x(t_{\xi,\varepsilon},\, \xi,\, d_{\xi,\varepsilon})) - g(x(t_{\xi,\varepsilon},\, \eta,\, d_{\xi,\varepsilon}))| \leq C_1\, |x(t_{\xi,\varepsilon},\, \xi,\, d_{\xi,\varepsilon}) - x(t_{\xi,\varepsilon},\, \eta,\, d_{\xi,\varepsilon})| \,,$$

for some $C_1 > 0$. Therefore, we have the following:

$$\begin{aligned} U(\xi) - U(\eta) &\leq g(x(t_{\xi,\varepsilon},\, \xi,\, d_{\xi,\varepsilon}))k(t_{\xi,\varepsilon}) + \varepsilon - g(x(t_{\xi,\varepsilon},\, \eta,\, d_{\xi,\varepsilon}))k(t_{\xi,\varepsilon}) \\ &\leq c_2\, |g(x(t_{\xi,\varepsilon},\, \xi,\, d_{\xi,\varepsilon})) - g(x(t_{\xi,\varepsilon},\, \eta,\, d_{\xi,\varepsilon}))| + \varepsilon \\ &\leq C_1 c_2\, |x(t_{\xi,\varepsilon},\, \xi,\, d_{\xi,\varepsilon}) - x(t_{\xi,\varepsilon},\, \eta,\, d_{\xi,\varepsilon})| + \varepsilon \\ &\leq L\, |\xi - \eta| + \varepsilon \,, \end{aligned}$$

for some constant L that depends only on the compact set K_1. Note that the above holds for any $\varepsilon \in (0,\, r_0/2)$, thus,

$$U(\xi) - U(\eta) \leq L\, |\xi - \eta| \,, \quad \forall \xi, \eta \in K_1 \,.$$

By symmetry, one proves (40).

To prove the continuity of U on $\mathbb{R}^n$, note that for any $\xi \in \mathcal{A}$, it holds that $U(\xi) = 0$, and so for all $\eta \in \mathbb{R}^n$

$$|U(\xi) - U(\eta)| = U(\eta) \leq c_2\, |\eta|_{\mathcal{A}} \leq c_2\, |\xi - \eta| \,.$$

The proof of Lemma 6.2 is thus concluded. □

We next start proving that U decreases along trajectories. Now pick any $\xi \notin \mathcal{A}$. Let $h_0 > 0$ be such that

$$|x(t,\, \xi,\, \mathbf{d})|_{\mathcal{A}} \geq \frac{|\xi|_{\mathcal{A}}}{2}, \quad \forall \mathbf{d} \in \mathcal{D},\ \forall t \in [0,\, h_0] \,,$$

where $\mathbf{d}$ denotes the constant function $d(t) \equiv \mathbf{d}$. Such an h_0 exists by continuity. Pick any $h \in [0,\, h_0]$. For each $\mathbf{d} \in \mathcal{D}$, let $\eta_{\mathbf{d}} = x(h,\, \xi,\, \mathbf{d})$. For any $\varepsilon > 0$, there exist some $t_{\mathbf{d},\varepsilon}$ and $d_{\mathbf{d},\varepsilon} \in \mathcal{M}_{\mathcal{D}}$ such that

$$\begin{aligned} U(\eta_{\mathbf{d}}) &\leq g(x(t,\, \eta_{\mathbf{d}},\, d_{\mathbf{d},\varepsilon}))k(t_{\mathbf{d},\varepsilon}) + \varepsilon \\ &= g(x(t_{\mathbf{d},\varepsilon} + h,\, \xi,\, \tilde{d}_{\mathbf{d},\varepsilon}))k(t_{\mathbf{d},\varepsilon} + h) \left(1 - \frac{k(t_{\mathbf{d},\varepsilon} + h) - k(t_{\mathbf{d},\varepsilon})}{k(t_{\mathbf{d},\varepsilon} + h)}\right) + \varepsilon \\ &\leq U(\xi) \left(1 - \frac{k(t_{\mathbf{d},\varepsilon} + h) - k(t_{\mathbf{d},\varepsilon})}{c_2}\right) + \varepsilon \,, \end{aligned} \tag{41}$$

where $\tilde{d}_{\mathbf{d},\varepsilon}$ is the concatenation of $\mathbf{d}$ and $d_{\mathbf{d},\varepsilon}$. Still for these ξ and h, and for any $r > |\xi|_{\mathcal{A}}$, define

$$T^r_{\xi,h} \stackrel{\text{def}}{=} \max_{0\le \bar{t}\le h, \mathbf{d}\in\mathcal{D}} T_r\left(\frac{c_1}{2c_2}\delta(|x(\bar{t},\,\xi,\,\mathbf{d})|_{\mathcal{A}})\right). \tag{42}$$

CLAIM. *$t_{\mathbf{d},\varepsilon} + h \le T^r_{\xi,h}$, for all $\mathbf{d}\in\mathcal{D}$ and for all $\varepsilon \in (0,\, \frac{c_1}{2}\delta(\frac{|\xi|_{\mathcal{A}}}{2}))$.*

Proof. If this were not true, then there would exist some $\tilde{\mathbf{d}}$ and some $\tilde{\varepsilon}\in(0,\,\frac{c_1}{2}\delta(\frac{|\xi|_{\mathcal{A}}}{2}))$ such that $t_{\tilde{\mathbf{d}},\tilde{\varepsilon}} + h > T^r_{\xi,h}$, and hence in particular for $\bar{t} = h$ and $\mathbf{d} = \tilde{\mathbf{d}}$ it holds that

$$t_{\tilde{\mathbf{d}},\tilde{\varepsilon}} + h > T_r\left(\frac{c_1}{2c_2}\delta(|\eta_{\tilde{\mathbf{d}}}|_{\mathcal{A}})\right),$$

which implies that

$$\left|x(t_{\tilde{\mathbf{d}},\tilde{\varepsilon}},\,\eta_{\tilde{\mathbf{d}}},\,d_{\tilde{\mathbf{d}},\tilde{\varepsilon}})\right|_{\mathcal{A}} = \left|x(t_{\tilde{\mathbf{d}},\tilde{\varepsilon}}+h,\,\xi,\,v)\right|_{\mathcal{A}} < \frac{c_1}{2c_2}\delta(|\eta_{\tilde{\mathbf{d}}}|_{\mathcal{A}}),$$

where v is the concatenated function defined by

$$v(t) = \begin{cases} \tilde{\mathbf{d}}, & \text{if } 0\le t\le h,\\ d_{\tilde{\mathbf{d}},\tilde{\varepsilon}}(t-h), & \text{if } t > h.\end{cases}$$

Using (38), one has

$$\begin{aligned}\delta\left(|\eta_{\tilde{\mathbf{d}}}|_{\mathcal{A}}\right) &\le \frac{1}{c_1}U(\eta_{\tilde{\mathbf{d}}}) \le \frac{1}{c_1}g(x(t_{\tilde{\mathbf{d}},\tilde{\varepsilon}},\,\eta_{\tilde{\mathbf{d}}},\,d_{\tilde{\mathbf{d}},\tilde{\varepsilon}}))k(t_{\tilde{\mathbf{d}},\tilde{\varepsilon}}) + \frac{\tilde{\varepsilon}}{c_1}\\ &\le \frac{c_2}{c_1}\left|x(t_{\tilde{\mathbf{d}},\tilde{\varepsilon}},\,\eta_{\tilde{\mathbf{d}}},\,d_{\tilde{\mathbf{d}},\tilde{\varepsilon}})\right|_{\mathcal{A}} + \frac{\tilde{\varepsilon}}{c_1} < \frac{1}{2}\delta\left(|\eta_{\tilde{\mathbf{d}}}|_{\mathcal{A}}\right) + \frac{\tilde{\varepsilon}}{c_1},\end{aligned}$$

which is a contradiction, since $\tilde{\varepsilon} < \frac{c_1}{2}\delta(\frac{|\xi|_{\mathcal{A}}}{2}) \le (c_1\delta(|\eta_{\tilde{\mathbf{d}}}|_{\mathcal{A}}))/2$. This proves the claim.

From (41), we have for any $\mathbf{d}\in\mathcal{D}$ and for any $\varepsilon > 0$ small enough,

$$U(x(h,\,\xi,\,\mathbf{d})) - U(\xi) \le -U(\xi)\frac{(k(t_{\mathbf{d},\varepsilon}+h) - k(t_{\mathbf{d},\varepsilon}))}{c_2} + \varepsilon = -\frac{U(\xi)}{c_2}\,k'(t_{\mathbf{d},\varepsilon}+\theta h)h + \varepsilon,$$

where θ is some number in $(0,\,1)$. Hence, by the assumptions made on the function k, we have

$$U(x(h,\,\xi,\,\mathbf{d})) - U(\xi) \le -\frac{U(\xi)}{c_2}\tau(t_{\mathbf{d},\varepsilon}+\theta h)h + \varepsilon \le -\frac{U(\xi)}{c_2}\tau(T^r_{\xi,h})\,h + \varepsilon.$$

Again, since ε can be chosen arbitrarily small, we have

$$U(x(h,\,\xi,\,\mathbf{d})) - U(\xi) \le -\frac{U(\xi)}{c_2}\tau(T^r_{\xi,h})h, \quad \forall \mathbf{d}\in\mathcal{D}.$$

Thus we showed that for any $\mathbf{d}$ and any $h > 0$ small enough,

$$\frac{U(x(h,\,\xi,\,\mathbf{d})) - U(\xi)}{h} \le -\frac{U(\xi)}{c_2}\tau(T^r_{\xi,h}).$$

Since U is locally Lipschitz on $\mathbb{R}^n\backslash\mathcal{A}$, it is differentiable almost everywhere in $\mathbb{R}^n\backslash\mathcal{A}$, and hence for any $\mathbf{d}\in\mathcal{D}$ and for any $r>|\xi|_{\mathcal{A}}$,

$$\begin{aligned} L_{f_{\mathbf{d}}}U(\xi) &= \lim_{h\to 0^+}\frac{U(x(h,\xi,\mathbf{d}))-U(\xi)}{h} \le -\lim_{h\to 0^+}\frac{U(\xi)}{c_2}\tau(T^r_{\xi,h}) \\ &= -\frac{U(\xi)}{c_2}\tau\left(\lim_{h\to 0^+}T^r_{\xi,h}\right) = -\frac{U(\xi)}{c_2}\tau\left(T_r\left(\frac{c_1}{2c_2}\delta(|\xi|_{\mathcal{A}})\right)\right) \\ &\le -\frac{c_1\delta(|\xi|_{\mathcal{A}})}{c_2}\tau\left(T_r\left(\frac{c_1}{2c_2}\delta(|\xi|_{\mathcal{A}})\right)\right) \qquad (43) \\ &= -\bar{\alpha}_r(|\xi|_{\mathcal{A}}),\ \text{a.e.}\ , \qquad (44) \end{aligned}$$

where

$$\bar{\alpha}_r(s) = \frac{c_1\delta(s)}{c_2}\tau\left(T_r\left(\frac{c_1}{2c_2}\delta(s)\right)\right).$$

Now define the function $\bar{\alpha}$ by

$$\bar{\alpha}(s) = \sup_{r>s}\bar{\alpha}_r(s).$$

Note that $\bar{\alpha}_r(0)=0$ for any $r>0$, so $\bar{\alpha}(0)=0$. Also, applying to $r=2s$, we have

$$\bar{\alpha}(s) \ge \frac{c_1\delta(s)}{c_2}\tau\left(T_{2s}\left(\frac{c_1}{2c_2}\delta(s)\right)\right) > 0$$

for all $s>0$. Notice that (44) holds for any $r>|\xi|_{\mathcal{A}}$, so it follows that for every $\mathbf{d}\in\mathcal{D}$, $L_{f_{\mathbf{d}}}U(\xi)\le -\bar{\alpha}(|\xi|_{\mathcal{A}})$ for almost all $\xi\in\mathbb{R}^n\backslash\mathcal{A}$. Now let

$$\check{\alpha}(s) = \frac{c_1\delta(s)}{c_2}\int_{2s}^{2s+1}\tau\left(T_r\left(\frac{c_1}{2c_2}\delta(s)\right)\right)dr$$

for $s>0$, and let $\check{\alpha}(0)=0$. Then $\check{\alpha}$ is continuous on $[0,\infty)$ (the continuity at $s=0$ is because τ is bounded and $\delta(0)=0$), and for $s>0$, it holds that

$$0<\check{\alpha}(s)\le\frac{c_1\delta(s)}{c_2}\tau\left(T_{2s}\left(\frac{c_1}{2c_2}\delta(s)\right)\right)$$

because of the monotonicity properties of T and τ. Furthermore,

$$L_{f_{\mathbf{d}}}U(\xi)\le-\bar{\alpha}(|\xi|_{\mathcal{A}})\le-\check{\alpha}(|\xi|_{\mathcal{A}}),$$

for almost all $\xi\in\mathbb{R}^n\setminus\mathcal{A}$.

By Theorem B.1 provided in the appendix, there exists a C^∞ function $V:\mathbb{R}^n\backslash\mathcal{A}\longrightarrow\mathbb{R}_{\ge 0}$ such that for almost all $\xi\in\mathbb{R}^n\backslash\mathcal{A}$,

$$|V(\xi)-U(\xi)|<\frac{U(\xi)}{2}\ \text{ and }\ L_{f_{\mathbf{d}}}V(\xi)\le-\frac{1}{2}\check{\alpha}(|\xi|_{\mathcal{A}}),\ \forall\mathbf{d}\in\mathcal{D}.$$

Extend V to $\mathbb{R}^n$ by letting $V|_{\mathcal{A}}=0$ and again denote the extension by V. Note that V is continuous on $\mathbb{R}^n$. So V is a Lyapunov function, as desired, with $\alpha_1(s)=\frac{c_1}{2}\delta(s)$, $\alpha_2(s)=\frac{3c_2}{2}s$ and $\alpha_3(s)=\frac{1}{2}\check{\alpha}(s)$. □

7. Proof of the second converse Lyapunov theorem. We need a couple of lemmas. The first one is trivial, so we omit its proof.

LEMMA 7.1. *Let $f : \mathbb{R}^n \times \mathcal{D} \longrightarrow \mathbb{R}^n$ be continuous, where $\mathcal{D}$ is a compact subset of $\mathbb{R}^l$. Then there exists a smooth function $a_f : \mathbb{R}^n \longrightarrow \mathbb{R}$, with $a_f(x) \geq 1$ everywhere, such that $|f(x, \mathbf{d})| \leq a_f(x)$ for all x and all $\mathbf{d}$.*

Now for any given system

$$\Sigma : \quad \dot{x} = f(x, \mathbf{d}),$$

not necessarily complete, consider the following system:

$$\Sigma_b : \quad \dot{x} = \frac{1}{a_f(x)} f(x, \mathbf{d}).$$

Note that the system Σ_b is complete since $\frac{|f(x,\mathbf{d})|}{a_f(x)} \leq 1$ for all $x, \mathbf{d}$. We let $x_b(\cdot, x_0, d)$ denote the trajectory of Σ_b corresponding to the initial state x_0 and the time-varying parameter d. The following result is a simple consequence of the fact that the trajectories of Σ are the same as those of Σ_b up to a rescaling of time. We provide the details to show clearly that the uniformity conditions are not violated.

LEMMA 7.2. *Assume that $\mathcal{A}$ is a compact set. Suppose that system Σ is UGAS with respect to $\mathcal{A}$. Then, system Σ_b is UGAS with respect to $\mathcal{A}$.*

Proof. Pick a time-varying parameter $d \in \mathcal{M}_{\mathcal{D}}$ and an initial state $x_0 \in \mathbb{R}^n$. Let $\gamma_b(t)$ denote $x_b(t, x_0, d)$. Let $\tau_{\gamma_b}(t)$ denote the solution for $t \geq 0$ of the following initial value problem:

$$\dot{\tau} = a_f(\gamma_b(\tau)), \quad \tau(0) = 0. \tag{45}$$

Since a_f is smooth, and γ_b is Lipschitz, $a_f \circ \gamma_b$ is locally Lipschitz as well. It follows that a unique $\tau_{\gamma_b}(t)$ is at least defined in some interval $[0, \bar{t})$. Note that τ_{γ_b} is strictly increasing, so $\bar{t} < +\infty$ would imply $\lim_{t \to \bar{t}^-} \tau_{\gamma_b}(t) = +\infty$.

CLAIM. *For every trajectory γ_b of Σ_b, $\tau_{\gamma_b}(t)$ is defined for all $t \geq 0$.*

Proof. If the claim is not true, then there exist some trajectory γ_b of Σ_b and some $t_1 > 0$ such that $\lim_{t \to t_1^-} \tau_{\gamma_b}(t) = \infty$. Now for $t \in [0, t_1)$, one has

$$\begin{aligned} \frac{d}{dt}\gamma_b(\tau_{\gamma_b}(t)) &= \frac{1}{a_f(\gamma_b(\tau_{\gamma_b}(t)))} f\Big(\gamma_b\big(\tau_{\gamma_b}(t)\big), d\big(\tau_{\gamma_b}(t)\big)\Big) \frac{d}{dt}\tau_{\gamma_b}(t) \\ &= f\Big(\gamma_b\big(\tau_{\gamma_b}(t)\big), d\big(\tau_{\gamma_b}(t)\big)\Big). \end{aligned} \tag{46}$$

Thus $\gamma_b(\tau_{\gamma_b}(t))$ is a solution of Σ on $[0, t_1)$. By the stability of Σ, it follows that

$$|\gamma_b(\tau_{\gamma_b}(t))|_{\mathcal{A}} < \delta^{-1}(|x_0|_{\mathcal{A}}), \quad t \in [0, t_1),$$

where $x_0 = \gamma_b(0)$, and δ is the function for Σ as defined in Definition 2.2. (Cf. Remark 2.4.) Let $c = \delta^{-1}(|x_0|_{\mathcal{A}})$, and let $M = \sup_{|\xi|_{\mathcal{A}} \leq c} a_f(\xi)$. ($M$ is finite because the set $\{\xi : |\xi|_{\mathcal{A}} \leq c\}$ is a compact set.) From here one sees that $|\tau_{\gamma_b}(t)| \leq Mt_1$ for any $t \in [0, t_1)$. This is a contradiction. Thus $\tau_{\gamma_b}(t)$ is defined for all $t \geq 0$. This proves the claim.

Since $a_f(s) \geq 1$ and, for every trajectory γ_b of Σ_b, $\tau_{\gamma_b}(0) = 0$, it follows that $\tau_{\gamma_b}(\cdot) \in \mathcal{K}_\infty$ for each trajectory γ_b of Σ_b. From (46), one also sees that if $\gamma_b(t)$ is a trajectory of Σ_b, then $\gamma_b(\tau_{\gamma_b}(t))$ is a trajectory of Σ, and furthermore,

$$|\gamma_b(\tau_{\gamma_b}(s))|_{\mathcal{A}} < \varepsilon \quad \forall s \geq 0, \quad \text{if } |\gamma_b(0)|_{\mathcal{A}} \leq \delta(\varepsilon).$$

It follows that

$$|\gamma_b(t)|_{\mathcal{A}} = \left|\gamma_b(\tau_{\gamma_b}(\tau_{\gamma_b}^{-1}(t)))\right|_{\mathcal{A}} < \varepsilon, \quad \forall t \geq 0, \quad \text{whenever } |\gamma_b(0)|_{\mathcal{A}} \leq \delta(\varepsilon)\,.$$

This shows that condition (1) of Definition 2.2 holds for Σ_b, with the same function δ.

Fix any $r, \varepsilon > 0$. Pick any x_0 with $|x_0|_{\mathcal{A}} < r$ and any $d \in \mathcal{M}_{\mathcal{D}}$. Again let $\gamma_b(t)$ denote the corresponding trajectory of Σ_b. Then

$$|\gamma_b(t)|_{\mathcal{A}} = \left|\gamma_b(\tau_{\gamma_b}(\tau_{\gamma_b}^{-1}(t)))\right|_{\mathcal{A}} < \delta^{-1}(r), \quad \forall t \geq 0\,.$$

Let

$$L = \sup\{a_f(\xi) : \ |\xi|_{\mathcal{A}} \leq \delta^{-1}(r)\}.$$

Then one sees that $|\dot{\tau}(t)| \leq L$, which implies that $\tau_{\gamma_b}(t) \leq Lt$ for all $t \geq 0$. Note that for the given $r, \varepsilon > 0$, by the UGAS property for Σ, there exists $T > 0$ such that for every $d \in \mathcal{M}_{\mathcal{D}}$,

$$|\gamma_b(\tau_{\gamma_b}(s))|_{\mathcal{A}} < \varepsilon$$

whenever $|\gamma_b(0)|_{\mathcal{A}} < r$ and $s \geq T$. This implies that

$$|\gamma_b(t)|_{\mathcal{A}} < \varepsilon$$

whenever $|\gamma_b(0)|_{\mathcal{A}} < r$ and $t \geq \tau_{\gamma_b}(T)$. Combining this with the fact that $\tau_{\gamma_b}(t) \leq Lt$, one proves that for any $d \in \mathcal{M}_{\mathcal{D}}$, it holds that

$$|\gamma_b(t)|_{\mathcal{A}} < \varepsilon$$

whenever $|\gamma_b(0)|_{\mathcal{A}} < r$ and $t \geq LT$. Hence we conclude that Σ_b is UGAS. □

In Lemma 7.2, the assumption that $\mathcal{A}$ is compact is crucial. Without this assumption, the conclusion may fail as the following example shows.

Example 7.3. Consider the following system Σ:

$$\dot{x} = -(1+y^2)\tanh x, \quad \dot{y} = y^4\,. \tag{47}$$

(Here f is independent of d.) Let $\mathcal{A} = \{(x, y) : \ x = 0\}$. Clearly the system is UGAS with respect to $\mathcal{A}$. For this system, a natural choice of a_f is $2 + y^4$. Thus, the corresponding Σ_b is as follows:

$$\dot{x} = -(\tanh x)\frac{1+y^2}{2+y^4}, \quad \dot{y} = \frac{y^4}{2+y^4}.$$

However, the system Σ_b is not UGAS with respect to $\mathcal{A}$. This can be seen as follows. Assume that Σ_b is UGAS. Then for $\varepsilon = \frac{1}{2}$, there exists some $T > 0$ such that for any solution $(x(t), y(t))$ of Σ_b with $x(0) = 1$, it holds that

$$|x(t)| < \frac{1}{2}, \quad \forall t \geq T\,. \tag{48}$$

Since $(1+y^2)/(2+y^4) \to 0$ as $y \to \infty$, it follows that there exists some $y_0 > 0$ such that

$$\left|\frac{1+y^2}{2+y^4}\right| < \frac{1}{3T}, \quad \forall y \geq y_0\,.$$

Now consider the trajectory $(x(t), y(t))$ of Σ_b with $x(0) = 1, y(0) = y_0$, where y_0 is as above. Clearly $y(t) \geq y_0$ for all $t \geq 0$, and thus,

$$\dot{x} = -(\tanh x)\frac{1+y^2}{2+y^4} \geq -(\tanh x)\,\frac{1}{3T} \geq -\frac{1}{3T}\,,$$

which implies that

$$|x(T)| \;\geq\; 1 - \frac{1}{3T}\,T = \frac{2}{3}\,.$$

This contradicts (48). From here one sees that Σ_b is not UGAS with respect to $\mathcal{A}$.

We now prove Theorem 2.9.

The proof of the sufficiency part is the same as in the proof of Theorem 2.8. Observe that the fact that $V(\xi)$ is nonincreasing along trajectories implies, by compactness of $\mathcal{A}$, that trajectories are bounded, so $x(t)$ is defined for all $t \geq 0$. We now prove necessity.

Let a_f be a function for f as in Lemma 7.1, and let Σ_b be the corresponding system. Then by Lemma 7.2, one knows that the system Σ_b is UGAS. Applying Theorem 2.8 to the complete system Σ_b, one knows that there exists a smooth Lyapunov function V for Σ_b such that

$$\alpha_1(|\xi|_{\mathcal{A}}) \leq V(\xi) \leq \alpha_2(|\xi|_{\mathcal{A}})\,, \quad \forall \xi \in \mathbb{R}^n\,,$$

and

$$L_{\tilde{f}_{\mathbf{d}}} V(\xi) \leq -\alpha_3(|\xi|_{\mathcal{A}})\,, \quad \forall \xi \notin \mathcal{A}\,,\ \forall \mathbf{d} \in \mathcal{D}\,,$$

for some $\mathcal{K}_\infty$ functions α_1, α_2 and some positive definite function α_3, where

$$\tilde{f}_{\mathbf{d}}(\xi) \;=\; \frac{f(\xi, \mathbf{d})}{a_f(\xi)}\,.$$

Since $a_f(\xi) \geq 1$ everywhere, it follows that

$$L_{f_{\mathbf{d}}} V(\xi) \leq -\alpha_3(|\xi|_{\mathcal{A}}), \quad \forall \xi \notin \mathcal{A},\ \forall \mathbf{d} \in \mathcal{D}\,.$$

Thus, one concludes that V is also a Lyapunov function of Σ.

8. An example. In general, for a noncompact parameter value set $\mathcal{D}$, the converse Lyapunov theorem will fail, even if the vector fields $f(\xi, \mathbf{d})$ are locally Lipschitz uniformly on $\mathbf{d}$ on any compact subset of $\mathcal{D}$ (for instance, if f is smooth everywhere). To illustrate this fact, consider the common case of systems affine in controls:

$$\dot{x} = f(x) + g(x)\mathbf{d},$$

where for simplicity we consider only the unconstrained single-input case, that is, $\mathcal{D} = \mathbb{R}$. Assume that there would exist a Lyapunov function V for this system in the sense of Definition 2.6. Then, calculating Lie derivatives, we have that, in particular,

$$L_f V(\xi) + \mathbf{d} L_g V(\xi) < 0, \quad \forall \xi \neq 0, \quad \forall \mathbf{d} \in \mathbb{R},$$

which implies that

$$L_g V(\xi) \;=\; 0, \quad \forall \xi \neq 0.$$

Thus V must be constant along all the trajectories of the differential equation

$$\dot{x} = g(x).$$

In general, such a property will contradict the properness or the positive definiteness of V, unless the vector field g is very special. As a way to construct counterexamples, consider the following property of a vector field g, which is motivated by the prolongation ideas in [28].

Consider the closure $W(\xi_0)$ of the trajectory through ξ_0 with respect to the vector field g. Note that if $\xi_1 \in W(\xi_0)$, then the fact that V is constant on trajectories, coupled with continuity of V, implies that $V(\xi_1) = V(\xi_0)$. Now assume that there is a chain $\xi_0, \xi_1, \xi_2, \ldots$ so that for each $i = 1, 2, \ldots$, $\xi_i \in W(\xi_{i-1})$. Then we conclude that $V(\xi_i) = V(\xi_0)$ for all i. If the sequence $\{\xi_i\}$ converges to zero (and $\xi_0 \neq 0$) or diverges to infinity, we contradict positive definiteness or properness of V, respectively. For an example, take the following two-dimensional system, which was used in [7] to show essentially the same fact.

Let $\mathfrak{S}$ be the spiral that describes the solution of the differential equation

$$\dot{x} = -x - y, \quad \dot{y} = x - y,$$

passing through the point $(1, 0)$. Explicitly, $\mathfrak{S}$ can be parameterized as $x = e^{-t}\cos t$, $y = e^{-t}\sin t$, $-\infty < t < \infty$. In polar coordinates, the spiral is given by $r = e^{-\theta}$, $-\infty < \theta < \infty$. Let $a(x, y)$ be any nonnegative smooth function which is zero exactly on the closure of the spiral $\mathfrak{S}$ (that is, $\mathfrak{S}$ plus the origin). (Such a function always exists since any closed subset of Euclidean space can be described as the zero set of a smooth function; see for instance [6].) Now consider the system

$$\begin{aligned} \dot{x} &= -x - y + xa(x, y)\mathbf{d}, \\ \dot{y} &= \ \ x - y + ya(x, y)\mathbf{d}. \end{aligned} \tag{49}$$

Note that the system is smooth everywhere. Let $\mathcal{D} = \mathbb{R}$, and let $\mathcal{A}$ be the origin. In polar coordinates, the system (49) on $\mathbb{R}^2\backslash\{0\}$ satisfies the equations

$$\dot{r} = -r + ra(r\cos\theta, r\sin\theta)\mathbf{d}, \quad \dot{\theta} = 1. \tag{50}$$

(This can be seen as a system on $\mathbb{R}_{>0} \times S^1$.) In polar coordinates, then, the trajectory passing through $(r, \theta) = (1, 0)$ is precisely the spiral $r = e^{-\theta}$, for any $d \in \mathcal{M}_{\mathcal{D}}$. Pick any trajectory $(r(t), \theta(t))$ with $(r(0), \theta(0)) = (r_0, \theta_0)$, where $\theta_0 \in [0, 2\pi)$. Then there exists some integer $k \geq 0$ such that $r_0 < e^{-\theta_0 + 2k\pi}$.

CLAIM. *It holds that*

$$r(t) < e^{-\theta_0 + 2k\pi - t} \leq e^{2k\pi - t}, \quad \forall t \geq 0. \tag{51}$$

Assume that (51) is not true. Then there exists some $t_1 > 0$ such that

$$r(t_1) = e^{-\theta_0 + 2k\pi - t_1}.$$

Note that we also have $\theta(t_1) = \theta_0 + t_1$. Now let $(\bar{r}(t), \bar{\theta}(t)) = (e^{-\theta_0 + 2k\pi - t}, \theta_0 - 2k\pi + t)$. Then $(\bar{r}(t), \bar{\theta}(t))$ is a trajectory of the system, and furthermore, $(\bar{r}(0), \bar{\theta}(0))$ and $(r(0), \theta_0)$ are different points since $\bar{r}(0) \neq r(0)$. However, the points $(r(t_1), \theta(t_1))$ and $(\bar{r}(t_1), \bar{\theta}(t_1))$ are the same point on the xy plane. This violates the uniqueness of solutions. Therefore, (51) holds for $t \geq 0$.

Note that in the above discussion, one can always choose $k \leq r_0 + 1$. It then follows from (51) that for any trajectory of the system with $r(0) = r_0$, it holds that

$$r(t) \leq e^{2(r_0+1)\pi - t}, \quad \forall t \geq 0, \quad \forall d. \tag{52}$$

Thus we conclude that the system is UGAS.

However, this system fails to admit a Lyapunov function. In this example, the vector field g is $(xa(x,y), ya(x,y))$. Consider the sequence of points in the xy plane $\{\xi_k\}$ with $\xi_k = (e^{2k\pi}, 0)$ for $k \geq 0$. Note that for each $k \geq 1$,

$$\xi_k \in W(\xi_{k-1}^j),$$

where $\xi_k^j = (e^{2k\pi} + \frac{1}{j}, 0)$. Therefore, $V(\xi_k) = V(\xi_{k-1}^j)$ for any j and any k. This implies that

$$V(\xi_k) = V(\xi_0), \quad \forall k \geq 1,$$

contradicting the properness of V. This shows that it is impossible for the system to have a Lyapunov function.

It is worthwhile to note that by the same argument, one sees that not only is there no smooth Lyapunov function for the system, but also there is not even a Lyapunov function which is merely continuous (in the sense that V is not even smooth away from $\mathcal{A}$, and the Lie derivative condition is replaced by a condition asking that V should decrease along trajectories).

In [17], a simple example is given illustrating that uniform global asymptotic stability with respect merely to *constant* parameters is also not sufficient to guarantee the existence of Lyapunov functions.

9. Relation to other work. The study of smooth converse Lyapunov theorems has a long history. In the special case of stability with respect to equilibria, and for systems without parameters, the first complete work was that done in the early 1950s by Massera and Kurzweil; see for instance the papers [18] and [13]. (Although we are more general because we deal with set stability and time-varying parameters, there is one important aspect in which our results are weaker than some of this classical work, especially that of Kurzweil: we assume enough regularity on the original system so that there are unique solutions and there is continuous dependence. We do so because lack of regularity is not an issue in the main applications in which we are interested. Of course, the proofs become much simpler under regularity assumptions.) In the late 1960s, Wilson, in [31], extended the Massera and Kurzweil results to a converse Lyapunov function theorem for local asymptotic stability with respect to closed sets. But some details of critical steps were omitted in [31]. In 1990, Nadzieja [21] rederived the results given in [31] for the special case when the invariant set is compact. As explained earlier, our proof is modeled along the lines of [31]. See also the textbooks [32] and [12] for many of these classical results.

Nondifferentiable Lyapunov functions have been studied in many papers and textbooks. Among these we may mention the classic book [3] by Bhatia and Szegö, as well as Zubov's work (see for instance [33]), which study in detail continuous Lyapunov function characterizations for global asymptotic stability with respect to arbitrary closed invariant sets. Also, in [29] and [28] and related work, the authors obtained the existence of continuous Lyapunov functions for systems which are stable, uniformly on parameters (or inputs) and with respect to compact sets, assuming various

additional conditions involving prolongations of dynamical systems. (The next section provides some more details on the prolongation approach.) Many results on converse Lyapunov functions with respect to sets can also be found in the many books and articles by Lakshmikantham and several coauthors. For instance, in [14, Thm. 3.4.1], a Massera-type proof is provided of a general converse theorem on local asymptotic stability with respect to two $\mathcal{K}$ functions that provides a Lipschitz Lyapunov function. As the authors point out, their theorem immediately provides a set-stability result (when using distance to the set as one of the comparison functions). In a very recent work [22], the author considered asymptotic stability for systems with merely measurable right-hand sides, and proved the existence of locally Lipschitz Lyapunov functions for such systems. Note that in our case, we obtained the existence of locally Lipschitz Lyapunov functions as an intermediate result, but our regularity assumption on the vector fields made it possible to obtain the existence of smooth Lyapunov functions.

The questions addressed in this paper are related to studies of "total stability," which typically ask about the preservation of stability when considering a new system $\dot{x} = f(x) + R(x,t)$, where $R(x,t)$ is a perturbation. (Sometimes the original system may be allowed to be time varying, that is, it has equations $\dot{x} = f(x,t)$; in that case, its stability can in turn be interpreted in terms of stability of the set $\{x = 0\}$ for the extended system $\dot{x} = f(x,z)$, $\dot{z} = 1$.) In [15], Lefschetz discussed stability with respect to equilibria under perturbations (referred to by the author as quasi-stability). In [12] and [32] one can find such studies and relationships to the special case of $\dot{x} = f(x) + d(t)$, with results proved regarding stability under integrable perturbations (not arbitrary bounded ones).

Under suitable technical conditions, systems with time-varying parameters can also be treated as general dynamical systems, or general control systems, as in [24], [33], [23], [10], [11]. In these works, systems were defined in terms of set-valued maps associated with reachable sets (or attainable sets). A similar treatment was also adopted in [29] and related work, where the prolongation sets of reachable sets were used to study stability. In [23], the author established the existence of different types of Lyapunov functions (not necessarily continuous) for both stability and weak stability with respect to closed invariant sets, where "weak stability" means the existence of a stable trajectory from every point outside the invariant set. In [10], the author provided Lyapunov characterizations for both local asymptotic stability and weak asymptotic stability. See [11] for an excellent survey of work along these lines.

It is also possible to reformulate stability for systems with time-varying parameters in terms of differential inclusions, as explained earlier; see for example [1] and [2]. The first of these books employs Lyapunov functions in sufficiency characterizations of viability properties (not the same as stability with respect to all solutions), while the second one (see Chapter 6, and especially §4) shows various converse theorems that result in nondifferentiable Lyapunov functions, connecting their existence with the solution of optimal control problems. In a recent work [20], one can find conclusions analogous to those in this paper but only for the very special case of linear differential inclusions, resulting in homogeneous "quasiquadratic" Lyapunov functions. Finally, let us mention the work [19] on systems with time-varying parameters, in which the author established, under the assumption of *exponential* stability, the existence of differentiable Lyapunov functions on compact sets, for the special case of equilibria.

10. Relations to stability of prolongations. In [7], [8], [28]–[30], the authors considered various notions of stability for systems of the type (1) (with $\mathcal{D}$ not nec-

essarily compact). These properties are defined in terms of the "prolongations" of the original system. The above papers investigated the relationships between such stability notions and the existence of continuous, not necessarily smooth, Lyapunov functions. In this section, we briefly discuss relations between UGAS stability and the notions considered in those papers, with the purpose of clarifying relations to this related previous work. For more details on the definitions and elementary properties of prolongation maps and the corresponding stability concepts, we refer the reader to the papers mentioned above.

We start with some abstract definitions. Let $F : \mathbb{R}^n \times \mathbb{R}_{\geq 0} \to 2^{\mathbb{R}^n}$, $(\xi, t) \mapsto F(\xi, t) \subseteq \mathbb{R}^n$ be any map from $\mathbb{R}^n \times \mathbb{R}_{\geq 0}$ to the set of subsets of $\mathbb{R}^n$. Associated to F, one defines $\mathfrak{D}F$ and $\mathfrak{J}F$ by

$$\mathfrak{D}F(\xi, t) = \big\{\eta \in \mathbb{R}^n : \text{ there exist sequences } \xi_n,\ \eta_n \in \mathbb{R}^n, \text{ and } t_n \geq 0 \text{ with } \xi_n \to \xi,\ \eta_n \to \eta,\ t_n \to t,\ \eta \in F(\xi_n, t_n)\big\},$$

$$\mathfrak{J}F(\xi, t) = \Big\{\eta \in \mathbb{R}^n : \text{ there exist } t_1, t_2, \ldots, t_k \geq 0 \text{ with } \sum_{i=1}^{k} t_i = t, \text{ such that } \eta \in F\big(F\big(\ldots F(F(\xi_n, t_1), t_2)\ldots, t_{k-1}\big), t_k\big)\Big\},$$

where $F(S, t) \stackrel{\text{def}}{=} \bigcup_{\xi \in S} F(\xi, t)$ for any subset S of $\mathbb{R}^n$.

The map F is called *cluster* if $\mathfrak{D}F = F$, and F is called *transitive* if $\mathfrak{J}F = F$.

For any system (1), consider the reachable set $\mathcal{R}^t(\xi)$ defined in §5, seen now as a set-valued map. The prolongation map Γ associated with (1) is then defined by letting $\Gamma(\xi, t)$ be the smallest set containing $\mathcal{R}^t(\xi)$ such that Γ is both transitive and cluster. For further discussion regarding the definition of the map Γ, we refer the reader to [28] and to the other papers mentioned above.

For subsets A and B of $\mathbb{R}^n$, we denote the usual distance between the two sets by $d(A, B) = \inf\{d(\xi, \eta) : \xi \in A,\ \eta \in B\}$. We say that a system (1) is T-stable (we use here the "T" for the name of the author of [28] who, in turn, was inspired by previous work [8]) with respect to a closed, invariant set $\mathcal{A}$ if the following two properties hold:

- There exists a $\mathcal{K}_\infty$-function $\delta(\cdot)$ such that for any $\varepsilon > 0$,

$$d(\Gamma(\xi, t), \mathcal{A}) < \varepsilon, \quad \text{whenever } |\xi|_{\mathcal{A}} \leq \delta(\varepsilon), \text{ and } t \geq 0;$$

- For any $r, \varepsilon > 0$, there is a $T > 0$ such that

$$d(\Gamma(\xi, t), \mathcal{A}) < \varepsilon, \quad \text{whenever } |\xi|_{\mathcal{A}} < r, \text{ and } t \geq T.$$

Note that this is the same as what is called "global absolute asymptotic stability" (global AAS) in [28] for the special case when $\mathcal{A}$ is compact. Clearly, if a system is T-stable, then it is UGAS. It was shown in [28], under some extra technical assumptions but without the compactness of $\mathcal{D}$, that global AAS implies the existence of a continuous, not necessarily smooth, Lyapunov function (meaning that V is globally merely continuous; the condition $L_{f_d} V(\xi) \leq -\alpha_3(|\xi|_{\mathcal{A}})$ is replaced by a condition that V should decrease along trajectories).

We will show next that, at least when $\mathcal{D}$ is compact, UGAS implies (and is therefore equivalent to) T-stability. So in what follows in this section, we assume that $\mathcal{D}$ is compact, and also that all systems involved are forward complete. We first need the following fact.

LEMMA 10.1. *For system* (1), $\Gamma(\xi, t) = \overline{\mathcal{R}^t(\xi)}$ *for any* $\xi \in \mathbb{R}^n$ *and any* $t \geq 0$.

Proof. First note that the cluster property of Γ implies that $\Gamma(\xi, t)$ is closed for each $\xi \in \mathbb{R}^n$ and each $t \geq 0$. Thus it is enough to show that the map $\mathfrak{R} : (\xi, t) \mapsto \overline{\mathcal{R}^t(\xi)}$ is cluster and transitive.

Take $\xi_0 \in \mathbb{R}^n$ and $\tau > 0$. (The case when $t = 0$ is trivial.) Pick $\eta_0 \in \mathfrak{D}\mathfrak{R}(\xi_0, \tau)$. Then, by definition, there exist sequences $\{\xi_n\}$, $\{\eta_n\}$, and $\{t_n\}$ with $t_n \geq 0$ such that $\xi_n \to \xi_0$, $\eta_n \to \eta_0$, $t_n \to \tau$, and $\eta_n \in \overline{\mathcal{R}^{t_n}(\xi_n)}$.

Note then that for each n, there exists d_n such that

$$|\eta_n - x(t_n, \xi_n, d_n)| < \frac{1}{n}.$$

Let $\zeta_n = x(t_n, \xi_n, d_n)$. Then $\zeta_n \in \mathcal{R}^{t_n}(\xi_n)$ and $\zeta_n \to \eta_0$. Let K_0 be a compact set such that $\xi_n \in K_0$ for each n, and let $T > 0$ be such that $t_n \leq T$ for any n. Then by Proposition 5.1, there exists a compact set K_1 such that $\mathcal{R}(K_0, T) \subseteq K_1$. Let L be a Lipschitz constant for f with respect to states in K_1. Then it follows from Gronwall's Lemma that, for n large enough so that $|\xi_n - \xi_0| < e^{-LT}$, it holds that

$$|x(t, \xi_0, d_n) - x(t, \xi_n, d_n)| \leq |\xi_0 - \xi_n| e^{LT}$$

for any $0 \leq t \leq T$. Let $\kappa_n = x(\tau, \xi_0, d_n)$. Then

$$\begin{aligned} |\kappa_n - \zeta_n| &= |x(\tau, \xi_0, d_n) - x(t_n, \xi_n, d_n)| \\ &\leq |x(\tau, \xi_0, d_n) - x(\tau, \xi_n, d_n)| + |x(\tau, \xi_n, d_n) - x(t_n, \xi_n, d_n)| \\ &\leq |\xi_0 - \xi_n| e^{\tau L} + M|\tau - t_n|, \end{aligned}$$

where $M = \max\{|f(\xi, \mathbf{d})|,\ d(\xi, K_1) \leq 1,\ \mathbf{d} \in \mathcal{D}\}$. It then follows that $\kappa_n \in \mathcal{R}^\tau(\xi_0)$ for each n and $\kappa_n \to \eta_0$. Thus, we conclude that $\eta_0 \in \overline{\mathcal{R}^\tau(\xi_0)}$. Hence we showed that $\mathfrak{D}\overline{\mathcal{R}^\tau(\xi_0)} = \overline{\mathcal{R}^\tau(\xi_0)}$ for any $\tau > 0$ and any $\xi_0 \in \mathbb{R}^n$, that is, the map $\mathfrak{R}$ is cluster.

To show the transitivity of $\mathfrak{R}$, first note that, by induction, it is enough to show that

$$\mathfrak{R}(\mathfrak{R}(\xi, t_1),\ t_2) \subseteq \mathfrak{R}(\xi, t_1 + t_2) \tag{53}$$

for any $\xi \in \mathbb{R}^n$ and any $t_1, t_2 \geq 0$.

Applying Lemma 5.3 to $S = R^{t_1}(\xi)$, together with the fact that

$$\mathcal{R}^{t_2}\left(\mathcal{R}^{t_1}(\xi)\right) = \mathcal{R}^{t_1+t_2}(\xi),$$

one immediately gets (53). □

Rewriting the definition of UGAS in terms of reachable sets, one has that a system (1) is UGAS if and only if the following properties hold:

- There exists a $\mathcal{K}_\infty$-function $\delta(\cdot)$ such that for any $\varepsilon > 0$,

$$d\left(\mathcal{R}^t(\xi), \mathcal{A}\right) < \varepsilon, \quad \text{whenever } |\xi|_{\mathcal{A}} \leq \delta(\varepsilon), \text{ and } t \geq 0;$$

- For any $r, \varepsilon > 0$, there is a $T > 0$ such that

$$d\left(\mathcal{R}^t(\xi), \mathcal{A}\right) < \varepsilon, \quad \text{whenever } |\xi|_{\mathcal{A}} < r, \text{ and } t \geq T.$$

The following conclusion then follows immediately from the continuity of the function $\xi \mapsto d(\xi, \mathcal{A})$ and Lemma 10.1:

PROPOSITION 10.2. *For compact $\mathcal{D}$, a system* (1) *is* UGAS *with respect to $\mathcal{A}$ if and only if it is T-stable.*

Remark 10.3. In the special case when $\mathcal{A}$ is compact, a UGAS system is always forward complete. Thus in that case Proposition 10.2 is still true without completeness.

Remark 10.4. The compactness condition on $\mathcal{D}$ is essential. Without the compactness of $\mathcal{D}$, Proposition 10.2 is in general not true. For instance, the system defined by (50) in §8 is UGAS with respect to the origin $(0, 0)$. However the system is not T-stable, since $\Gamma(0, t) = \mathbb{R}^2$ for any $t > 0$. Note that for this example, $\overline{R^t(0, t)} = \{0\}$ for any $t > 0$ which is different from $\Gamma(0, t)$. The inconsistency with the conclusion of Lemma 10.1 is caused by the noncompactness of $\mathcal{D}$.

Appendix A. Some basic definitions. In this section we recall some standard concepts from stability theory.

A function $\gamma : \mathbb{R}_{\geq 0} \longrightarrow \mathbb{R}_{\geq 0}$ is:

- a *$\mathcal{K}$-function* if it is continuous, strictly increasing and $\gamma(0) = 0$;
- a *$\mathcal{K}_\infty$-function* if it is a $\mathcal{K}$-function and also $\gamma(s) \to \infty$ as $s \to \infty$;
- a *positive definite* function if $\gamma(s) > 0$ for all $s > 0$, and $\gamma(0) = 0$.

A function $\beta : \mathbb{R}_{\geq 0} \times \mathbb{R}_{\geq 0} \longrightarrow \mathbb{R}_{\geq 0}$ is a *$\mathcal{KL}$-function* if:

- for each fixed $t \geq 0$ the function $\beta(\cdot, t)$ is a $\mathcal{K}$-function, and
- for each fixed $s \geq 0$ it is decreasing to zero as $t \to \infty$.

Note that we are not requiring β to be continuous in both variables simultaneously; however it turns out in our results that this stronger property will usually hold.

Appendix B. Smooth approximations of locally Lipschitz functions. In the proof of the converse Lyapunov theorem, we used a parameterized version of an approximation theorem given in [31]. For convenience of reference, and to make this work self-contained and expository, we next provide the needed variation of the theorem and its proof. (Several details, missing in the proof in [31], have been included as well.)

THEOREM B.1. *Let $\mathcal{O}$ be an open subset of $\mathbb{R}^n$, and let $\mathcal{D}$ be a compact subset of $\mathbb{R}^l$, and assume given:*

- *a locally Lipschitz function $\Phi : \mathcal{O} \longrightarrow \mathbb{R}$;*
- *a continuous map $f : \mathbb{R}^n \times \mathcal{D} \longrightarrow \mathbb{R}^n$, $(x, \mathbf{d}) \mapsto f(x, \mathbf{d})$ which is locally Lipschitz on x uniformly on $\mathbf{d}$;*
- *a continuous function $\alpha : \mathcal{O} \longrightarrow \mathbb{R}$ and continuous functions $\mu, \nu : \mathcal{O} \longrightarrow \mathbb{R}_{>0}$*

such that for each $\mathbf{d} \in \mathcal{D}$,

$$L_{f_\mathbf{d}}\Phi(\xi) \leq \alpha(\xi), \quad a.e.\ \xi \in \mathcal{O}, \tag{B.54}$$

where $f_\mathbf{d}$ is the vector field defined by $f_\mathbf{d}(\cdot) = f(\cdot, \mathbf{d})$. (Recall that $\nabla\Phi$ is defined a.e., since Φ is locally Lipschitz, by Rademacher's theorem, see e.g. [5, p. 216].) *Then there exists a smooth function $\Psi : \mathcal{O} \longrightarrow \mathbb{R}$ such that*

$$|\Phi(\xi) - \Psi(\xi)| < \mu(\xi), \quad \forall \xi \in \mathcal{O}$$

and for each $\mathbf{d} \in \mathcal{D}$,

$$L_{f_\mathbf{d}}\Psi(\xi) \leq \alpha(\xi) + \nu(\xi), \quad \forall \xi \in \mathcal{O}.$$

To prove the theorem, we first need some easy facts about regularization. Let $\psi : \mathbb{R}^n \longrightarrow \mathbb{R}$ be a smooth nonnegative function which vanishes outside of the unit

disk and satisfies

$$\int_{\mathbb{R}^n} \psi(s)\, ds \;=\; 1\,.$$

For any measurable, locally essentially bounded function $\Phi : \mathcal{O} \longrightarrow \mathbb{R}$ and $0 < \sigma \leq 1$, define the function Φ_σ by convolution with $\frac{1}{\sigma^n}\,\psi(\frac{s}{\sigma})$, that is:

$$\Phi_\sigma(\xi) \;\stackrel{\text{def}}{=}\; \int_{\mathbb{R}^n} \Phi(\xi + \sigma s)\psi(s)\, ds\,. \tag{B.55}$$

We think of this function as defined only for those ξ so that $\xi + \sigma s \in \mathcal{O}$ for all $|s| \leq 1$. Note that the integral is finite, as the integrand is essentially bounded and of compact support. The following observation is a standard approximation exercise, so we omit its proof.

LEMMA B.2. *For each compact subset K of $\mathcal{O}$, there exists some $\sigma_0 > 0$ such that Φ_σ is defined on K, and smooth there, for all $\sigma < \sigma_0$. Moreover, if Φ is continuous, then Φ_σ approaches Φ uniformly on K, as σ tends to 0.*

Now assume that Φ is a locally Lipschitz function. Then, for each $\mathbf{d} \in \mathcal{D}$, $L_{f_\mathbf{d}}\Phi$ is defined almost everywhere, and furthermore, on any compact subset $K \subseteq \mathcal{O}$,

$$|L_{f_\mathbf{d}}\Phi(\xi)| \;\leq\; k\,|f(\xi, \mathbf{d})|\,, \quad \text{a.e. } \xi \in K\,,\ \forall \mathbf{d} \in \mathcal{D}\,,$$

where k is a Lipschitz constant for Φ on K. Therefore, for each $\mathbf{d}$ (omitting from now on the $\mathbb{R}^n$ in integrals)

$$\left(L_{f_\mathbf{d}}\Phi\right)_\sigma(\xi) = \int \left(L_{f_\mathbf{d}}\Phi\right)(\xi + \sigma s)\psi(s)\, ds$$

is well defined as long as $\xi + \sigma s \in \mathcal{O}$ for all $|s| \leq 1$. Applying Lemma B.2 to $(L_{f_\mathbf{d}}\Phi)_\sigma$, this is smooth for any $\sigma > 0$ small.

Suppose that for all $\mathbf{d} \in \mathcal{D}$,

$$L_{f_\mathbf{d}}\Phi(\xi) \leq \alpha(\xi)\,, \quad \text{a.e. } \xi \in \mathcal{O}\,, \tag{B.56}$$

for some continuous function α. Pick any compact subset $K \subseteq \mathcal{O}$. On this set K, we have

$$\begin{aligned}\left(L_{f_\mathbf{d}}\Phi\right)_\sigma(\xi) &= \int \left(L_{f_\mathbf{d}}\Phi\right)(\xi + \sigma s)\psi(s)\, ds \;\leq\; \int \alpha(\xi + \sigma s)\psi(s)\, ds \\ &\leq \alpha(\xi) + \max_{|s|\leq 1,\, \xi \in K} |\alpha(\xi + \sigma s) - \alpha(\xi)|\,.\end{aligned}$$

From here we get the following conclusion.

LEMMA B.3. *For any compact subset K of $\mathcal{O}$, $(L_{f_\mathbf{d}}\Phi)_\sigma$ is a C^∞ function defined on K for all σ small enough, and, if* (B.56) *holds for all $\mathbf{d} \in \mathcal{D}$ and all $\xi \in \mathcal{O}$, then for any $\varepsilon > 0$ given, there exists some $\sigma_0 > 0$ such that*

$$(L_{f_\mathbf{d}}\Phi)_\sigma(\xi) \;\leq\; \alpha(\xi) + \varepsilon$$

for all $\sigma \leq \sigma_0$, all $\mathbf{d} \in \mathcal{D}$, and all $\xi \in K$.

The following lemma illustrates the relationship between $L_{f_\mathbf{d}}(\Phi_\sigma)$ and $(L_{f_\mathbf{d}}\Phi)_\sigma$.

LEMMA B.4. *On any compact subset K of $\mathcal{O}$,*

$$\sup_{\mathbf{d}\in\mathcal{D}, \xi \in K} \left|L_{f_\mathbf{d}}(\Phi_\sigma)(\xi) - \left(L_{f_\mathbf{d}}\Phi\right)_\sigma(\xi)\right| \;\to\; 0$$

as σ tends to 0.

Proof. For each $\xi \in \mathcal{O}$, we use $\varphi(t, \xi, \mathbf{d})$ to denote the solution of the differential equation

$$\dot{x} = f(x, \mathbf{d})$$

with the initial condition $\varphi(0, \xi, \mathbf{d}) = \xi$. It follows from the assumptions on f and compactness of K and $\mathcal{D}$ that there exist some compact neighborhood V of K and some $\tau_1 > 0$ and $\sigma_0 > 0$ such that $\varphi(t, \xi + \sigma s, \mathbf{d}) \in V$ for all $\xi \in K$, $|s| \leq 1$, $\sigma \leq \sigma_0$, $\mathbf{d} \in \mathcal{D}$, and $|t| \leq \tau_1$.

For the Lipschitz function Φ, we have, for all $\xi, \mathbf{d}$ and $\sigma \leq \sigma_0$,

$$\begin{aligned} L_{f_{\mathbf{d}}}(\Phi_\sigma)(\xi) &= \frac{d}{dt}\Big|_{t=0} \Phi_\sigma(\varphi(t, \xi, \mathbf{d})) = \frac{d}{dt}\Big|_{t=0} \int \Phi(\varphi(t, \xi, \mathbf{d}) + \sigma s)\psi(s)\, ds \\ &= \lim_{t \to 0} \frac{1}{t} \int (\Phi(\varphi(t, \xi, \mathbf{d}) + \sigma s) - \Phi(\xi + \sigma s))\psi(s)\, ds\,, \end{aligned}$$

and

$$(L_{f_{\mathbf{d}}}\Phi)_\sigma(\xi) = \int L_{f_{\mathbf{d}}}\Phi(\xi + \sigma s)\psi(s)\, ds \tag{B.57}$$

$$= \int \frac{d}{dt}\Big|_{t=0} \Phi(\varphi(t, \xi + \sigma s, \mathbf{d}))\psi(s)\, ds \tag{B.58}$$

$$= \lim_{t \to 0} \frac{1}{t} \int [\Phi(\varphi(t, \xi + \sigma s, \mathbf{d})) - \Phi(\xi + \sigma s)]\, \psi(s)\, ds\,. \tag{B.59}$$

Notice that the integrand in (B.57) equals that in (B.58) almost everywhere on s (for each fixed ξ and σ) and that (B.59) follows from (B.58) because of the Lebesgue dominated convergence theorem and the following fact:

$$\begin{aligned} &\frac{1}{|t|} |\Phi(\varphi(t, \xi + \sigma s, \mathbf{d})) - \Phi(\xi + \sigma s)|\, \psi(s) \\ &\leq \frac{k}{|t|} |\varphi(t, \xi + \sigma s, \mathbf{d}) - (\xi + \sigma s)|\, \psi(s) \leq kC\psi(s)\,, \quad \forall t \in [-\tau_1, \tau_1]\,, \end{aligned}$$

where $C \stackrel{\text{def}}{=} \max_{\xi \in V, \mathbf{d} \in \mathcal{D}} |f(\xi, \mathbf{d})|$ and k is a Lipschitz constant for Φ on V.

Now one sees that

$$L_{f_{\mathbf{d}}}(\Phi_\sigma)(\xi) - (L_{f_{\mathbf{d}}}\Phi)_\sigma(\xi) = \lim_{t \to 0} \frac{1}{t} \int [\Phi(\varphi(t, \xi, \mathbf{d}) + \sigma s) - \Phi(\varphi(t, \xi + \sigma s, \mathbf{d}))]\psi(s)\, ds.$$

Thus it is enough to show that for any $\varepsilon > 0$, there exist some $\delta > 0$ and $\tau^* > 0$ such that the above integral is bounded by ε for all $\mathbf{d} \in \mathcal{D}$, $\xi \in K$, $|t| < \tau^*$, and $\sigma < \delta$. This is basically a standard argument on continuous dependence on initial conditions, but we provide the details. For $0 \leq \tau \leq \tau_1$, let

$$\gamma(\tau) \stackrel{\text{def}}{=} \sup \{|f(\varphi(t, \zeta, \mathbf{d}), \mathbf{d}) - f(\zeta, \mathbf{d})| : \ |t| \leq \tau, \ \zeta \in V, \ \mathbf{d} \in \mathcal{D}\}\,.$$

Then $\gamma(0) = 0$, and γ is nondecreasing and continuous at $t = 0$, because

$$|f(\varphi(t, \zeta, \mathbf{d}), \mathbf{d}) - f(\zeta, \mathbf{d})| \leq C_3 |\varphi(t, \zeta, \mathbf{d}) - \zeta| \leq C_3 C_4 |t|\,,$$

where C_3 is a (uniform) Lipschitz constant for f on V_1, C_4 is an upper bound for $|f(\xi, \mathbf{d})|$ on V_1, and V_1 is some compact neighborhood of V such that $\varphi(t, \zeta, \mathbf{d}) \in V_1$ for any $\zeta \in V$, $\mathbf{d} \in \mathcal{D}$, and $|t| \leq \tau_1$. For any $\zeta \in V$, $\mathbf{d} \in \mathcal{D}$, and $|t| \leq \tau_1$,

$$|\varphi(t, \zeta, \mathbf{d}) - (\zeta + tf(\zeta, \mathbf{d}))| \leq \int_0^{|t|} \gamma(\tau)\, d\tau \leq |t|\, \gamma(|t|)\,.$$

Now for $\xi \in K$, we have

$$\begin{aligned}
&|\Phi(\varphi(t, \xi, \mathbf{d}) + \sigma s) - \Phi(\varphi(t, \xi + \sigma s), \mathbf{d})| \\
&\quad \leq k\, |\varphi(t, \xi, \mathbf{d}) + \sigma s - \varphi(t, \xi + \sigma s, \mathbf{d})| \\
&\quad \leq k\, |\xi + \sigma s + tf(\xi, \mathbf{d}) - (\xi + \sigma s + tf(\xi + \sigma s, \mathbf{d}))| \\
&\qquad + k\, |\varphi(t, \xi, \mathbf{d}) - (\xi + tf(\xi, \mathbf{d}))| + k|\varphi(t, \xi + \sigma s, \mathbf{d}) \\
&\qquad - (\xi + \sigma s + tf(\xi + \sigma s, \mathbf{d}))| \\
&\quad \leq k\, |t|\, |f(\xi, \mathbf{d}) - f(\xi + \sigma s, \mathbf{d})| + 2k\, |t|\, \gamma(|t|)\,. \qquad \text{(B.60)}
\end{aligned}$$

Finally, for $\varepsilon > 0$, let δ and τ^* be such that

$$\gamma(\tau) < \frac{\varepsilon}{3k} \quad \text{and} \quad |f(\xi, \mathbf{d}) - f(\xi + \sigma s, \mathbf{d})| < \frac{\varepsilon}{3k}$$

for any $\xi \in K$, $\mathbf{d} \in \mathcal{D}$, $|s| \leq 1$, $\sigma < \delta$, and $|t| < \tau^*$. It then follows from (B.60) that

$$\frac{1}{|t|} \int [\Phi(\varphi(t, \xi, \mathbf{d}) + \sigma s) - \Phi(\varphi(t, \xi + \sigma s, \mathbf{d}))]\psi(s)\, ds < \int \varepsilon \psi(s)\, ds = \varepsilon$$

for any $\xi \in K$, $\mathbf{d} \in \mathcal{D}$, $|t| < \tau^*$, and $\sigma < \delta$, which implies

$$|L_{f_\mathbf{d}}(\Phi_\sigma)(\xi) - (L_{f_\mathbf{d}}\Phi)_\sigma(\xi)| < \varepsilon$$

for any $\sigma < \sigma_0$, $\mathbf{d} \in \mathcal{D}$, and $\xi \in K$. □

Combining the previous three lemmas, we obtain the following conclusion.

LEMMA B.5. *Let K be a compact subset of $\mathcal{O}$. Then for any given $\varepsilon > 0$, there exists some smooth function Ψ defined on K such that*

$$|\Psi(\xi) - \Phi(\xi)| < \varepsilon \quad \textit{and} \quad L_{f_\mathbf{d}}\Psi(\xi) \leq \alpha(\xi) + \varepsilon$$

for all $\xi \in K$, $\mathbf{d} \in \mathcal{D}$.

Now we are ready to complete the proof of Theorem B.1. For the open subset $\mathcal{O}$ of $\mathbb{R}^n$, let $\{\mathcal{U}_i\}$ be a locally finite, countable cover of $\mathcal{O}$ with $\bar{\mathcal{U}}_i$ compact and $\bar{\mathcal{U}}_i \subseteq \mathcal{O}$. Let $\{\beta_i\}$ be a partition of unity on $\mathcal{O}$ subordinate to $\{\mathcal{U}_i\}$. For any given positive functions $\mu(\cdot)$ and $\nu(\cdot)$, let

$$\varepsilon_i \stackrel{\text{def}}{=} \min\left\{\inf_{\xi \in \mathcal{U}_i} \mu(\xi),\ \inf_{\xi \in \mathcal{U}_i} \nu(\xi)\right\}.$$

For each i, it follows from Lemma B.5 that there exists some smooth function Ψ_i defined on $\bar{\mathcal{U}}_i$ such that

$$|\Phi(\xi) - \Psi_i(\xi)| < \frac{\varepsilon_i}{2^{i+1}(1 + \tau_i)} \quad \text{and} \quad L_{f_\mathbf{d}}\Psi_i(\xi) \leq \alpha(\xi) + \frac{\varepsilon_i}{2}$$

on $\bar{\mathcal{U}}_i$, where $\tau_i \stackrel{\text{def}}{=} \max\{|L_{f_{\mathbf{d}}}\beta_i(\xi)| : \xi \in \bar{\mathcal{U}}_i, \mathbf{d} \in \mathcal{D}\}$. We define $\Psi = \sum_i \beta_i \Psi_i$. Clearly Ψ is a smooth function defined on $\mathcal{O}$, and

$$\begin{aligned}|\Psi(\xi) - \Phi(\xi)| &\leq \sum_{j \in \mathcal{J}_\xi} \beta_j(\xi)\, |\Psi_j(\xi) - \Phi(\xi)| \\ &< \max_{j \in \mathcal{J}_\xi} \varepsilon_j \;\leq\; \mu(\xi)\,,\end{aligned}$$

where $\mathcal{J}_\xi \stackrel{\text{def}}{=} \{j : \xi \in \mathcal{U}_j\}$.

For $L_{f_{\mathbf{d}}}\Psi$, one has

$$\begin{aligned}L_{f_{\mathbf{d}}}\Psi(\xi) &= L_{f_{\mathbf{d}}}\Phi(\xi) + L_{f_{\mathbf{d}}}\left(\sum_i \beta_i(\Psi_i - \Phi)\right)(\xi) \\ &= L_{f_{\mathbf{d}}}\Phi(\xi) + \sum \left(L_{f_{\mathbf{d}}}\beta_i\right)(\Psi_i - \Phi)(\xi) + \sum \beta_i \left(L_{f_{\mathbf{d}}}\Psi_i(\xi) - L_{f_{\mathbf{d}}}\Phi(\xi)\right) \\ &= \sum_{j \in \mathcal{J}_\xi} \left(L_{f_{\mathbf{d}}}\beta_j\right)(\Psi_j - \Phi)(\xi) + \sum_{j \in \mathcal{J}_\xi} \beta_j L_{f_{\mathbf{d}}}\Psi_j(\xi) \\ &< \sum_{j \in \mathcal{J}_\xi} \frac{\varepsilon_j}{2^{j+1}} + \sum_{j \in \mathcal{J}_\xi} \beta_j(\xi)\left(\alpha(\xi) + \frac{\varepsilon_i}{2}\right) \\ &\leq \frac{1}{2}\max_{j \in \mathcal{J}_\xi}\{\varepsilon_j\} + \alpha(\xi) + \frac{1}{2}\max_{j \in \mathcal{J}_\xi}\{\varepsilon_j\} \\ &\leq \alpha(\xi) + \nu(\xi)\,.\end{aligned}$$

We conclude that Ψ is the desired function. □

DETERMINISTIC APPROXIMATION FOR STOCHASTIC CONTROL PROBLEMS*

R. SH. LIPTSER†, W. J. RUNGGALDIER‡, AND M. TAKSAR§

Abstract. We consider a class of stochastic control problems where uncertainty is due to driving noises of general nature as well as to rapidly fluctuating processes affecting the drift. We show that, when the noise "intensity" is small and the fluctuations become fast, the stochastic problems can be approximated by a deterministic one. We also show that the optimal control of the deterministic problem is asymptotically optimal for the stochastic problems.

Key words. stochastic and deterministic control, stochastic differential equations, weak convergence, asymptotic optimality

1. Introduction.

There are only few stochastic control problems that can be solved in closed form. A lot of effort has therefore been put into developing approximation techniques for such problems. One approach in this direction is to consider, instead of the original model, a model where the underlying processes are replaced by simpler ones. This approach makes it possible to construct nearly optimal controls for the original model, based on the solution to the simpler model. This simpler model may involve underlying processes that are diffusions ("diffusion approximation"), but it may also simply be a deterministic model ("fluid approximation"). A general tool, especially for diffusion approximations, is techniques of weak convergence of random processes [1], [3], [6], [15] combined with an averaging principle [5]. This methodology is actively used in various practical problems of engineering, manufacturing, queuing, inventory, and others and is studied, e.g., in [7]–[13].

The underlying idea of this methodology is actually rather simple, but the mathematics required for its implementation are in general quite sophisticated. Although there exist some general approaches (see, e.g., [9]), in each particular case the rigorous verification of the convergence of the controlled systems requires specific technical tools and ideas.

In the present paper we apply "fluid approximation" techniques to a rather general stochastic control model with convex control cost function. In this model the controlled process X is described by a stochastic differential equation with respect to a general (not necessarily continuous) martingale M. The control affects the drift of X; this drift is furthermore affected by a rapidly fluctuating exogenous process ξ. To implement the

approximation approach, we embed the given model into a family of similar models, parametrized by a small parameter $\varepsilon > 0$. We consider the case when the "intensity" of the random noise disturbance M becomes small with ε, while the "contaminating" process ξ fluctuates with increasing speed. For such a case the limiting model becomes deterministic, and it is possible to obtain asymptotically (as $\varepsilon \downarrow 0$) optimal controls for the prelimit models by using the optimal control of the limiting deterministic system.

Although we consider explicitly only the case when the controlled state process X can be completely observed, our results nevertheless hold in the same form when the state is only partially observed.

In a more formal way, we have a family of controlled stochastic systems, parametrized by a small (positive) parameter ε ($\varepsilon \downarrow 0$), with dynamics

$$dX_t^\varepsilon = \left[a(X_t^\varepsilon, \xi_{t/\varepsilon}) + b(X_t^\varepsilon)u^\varepsilon(t)\right] dt + dM_t^\varepsilon \tag{1.1}$$

and initial condition X_0^ε. Here $X^\varepsilon = (X_t^\varepsilon)$ is the controlled state (or signal) process, $\xi = (\xi_t)$ is the "contamination" process affecting the drift of X^ε, and $M^\varepsilon = (M_t^\varepsilon)$ is a process representing the noise in the system. The random function $u^\varepsilon = (u^\varepsilon(t))$ is the control that affects the drift of X^ε in a linear way and satisfies the usual requirements for admissibility (see Definition 2.1 below).

Given a finite horizon $T > 0$, with each control u^ε we associate the cost

$$J^\varepsilon(u^\varepsilon) = E\left\{\int_0^T [p(X_t^\varepsilon) + q(u^\varepsilon(t))]dt + r(X_T^\varepsilon)\right\}, \tag{1.2}$$

where $p(x), q(u)$, and $r(x)$ are nonnegative functions on the real line referred to as holding cost, control cost, and terminal cost functions, respectively. The objective is to find

$$V^\varepsilon = \inf_{u^\varepsilon} J^\varepsilon(u^\varepsilon) \tag{1.3}$$

and an optimal (minimizing) control. For practical purposes one may just as well be interested in finding a nearly optimal control or, as will be the case here, an asymptotically (as $\varepsilon \downarrow 0$) optimal control.

To describe the limiting control model, we assume that the following ergodic properties hold:

$$P - \lim_{\varepsilon \to 0} X_0^\varepsilon = x_0, \quad x_0 \in \mathbf{R}, \tag{1.4}$$

$$\overline{a}(x) = P - \lim_{t \to \infty} \frac{1}{t} \int_0^t a(x, \xi_s)ds; \quad x \in \mathbf{R}, \tag{1.5}$$

$$P - \lim_{\varepsilon \to 0} \sup_{t \le T} |M_t^\varepsilon| = 0. \tag{1.6}$$

In the next section we formulate conditions under which (1.4)–(1.6) are valid.

The dynamics of the limiting system is given by the following ordinary differential equation:

$$dx(t) = [\overline{a}(x(t)) + b(x(t))u(t)]\, dt; \quad x(0) = x_0. \tag{1.7}$$

Here $x(t)$ is a (deterministic) controlled process and $u(t)$ is a (deterministic) control. Define

$$j(u) := \int_0^T [p(x(t)) + q(u(t))]\, dt + r(x(T)) \tag{1.8}$$

and

$$v := \inf_u j(u), \tag{1.9}$$

where the infimum is taken over all (deterministic) measurable functions on $[0, T]$.

Our main results are the following two theorems.

THEOREM 1.1. *The following relation holds:*

$$\lim_{\varepsilon \to 0} V^\varepsilon = v.$$

THEOREM 1.2. *Let $u^*(t)$, $0 \le t \le T$, be an optimal deterministic control for* (1.7)–(1.9). *Then $u^*(t)$ is asymptotically optimal for* (1.1)–(1.3) *in the sense that*

$$\lim_{\varepsilon \to 0} |J^\varepsilon(u^*) - V^\varepsilon| = 0.$$

Remark 1. If for the limit model there exists a feedback control

$$u^*(t) = u^\circ(t, x^*(t)),$$

where $x^*(t)$ is the controlled process defined by the differential equation (1.7) with $u(t) = u^*(t)$, and the function $u^\circ(t, x)$ is Lipschitz continuous in x uniformly in $t \in [0, T]$, then the statement of Theorem 1.2 remains true with $u^\circ(t, X_t^\varepsilon)$ replacing $u^*(t)$; i.e., the feedback control $u^\circ(t, X_t^\varepsilon)$ is asymptotically optimal.

Remark 2. The results obtained here for the one-dimensional control problem can be extended to an n-dimensional problem. The motivation to consider just the scalar case is to present the main ideas in the simplest form.

The main contribution of this paper is twofold: from a more theoretical point of view we obtain a stability result for the optimal control of a deterministic system in the sense that this control is asymptotically optimal for a large class of stochastic control problems of a rather complicated nature. From a practical point of view our results allow one to compute an asymptotically optimal control for a variety of problems under quite general conditions, where a direct approach would be impossible.

The proof consists of two parts carried out in §§3 and 4: first we show that v is an asymptotically lower bound for the optimal cost functions V^ε. Then we show that the deterministic optimal control of the limiting problem can be applied to the pre-limit models, yielding asymptotically optimal cost. Results of more technical nature, interesting in their own right, are moved to appendices (§§5, 6, and 7).

2. Main assumptions and notations. For simplicity we assume $\varepsilon \in (0, 1]$. For each ε let $SB := (\Omega, \mathcal{F}, \mathbf{F}^\varepsilon = (\mathcal{F}_t^\varepsilon)_{t \ge 0}, P)$ be a fixed stochastic basis, where $(\Omega, \mathcal{F}, P)$ is a complete probability space and $\mathbf{F}^\varepsilon$ is a filtration satisfying the "usual assumptions" (see [2]). The initial value X_0^ε of the state process is $\mathcal{F}_0^\varepsilon$-measurable, while $(\xi_{t/\varepsilon}), (M_t^\varepsilon)$ are $\mathbf{F}^\varepsilon$-adapted.

DEFINITION 2.1. *The control process* $u^\varepsilon = (u^\varepsilon(t))_{t\geq 0}$ *is said to be admissible if it is* $\mathbf{F}^\varepsilon$*-adapted and*

$$\int_0^T |u^\varepsilon(t)|\,dt < \infty, \quad P-a.s. \tag{2.1}$$

Throughout the paper we make the following assumptions:

(A.1) The control cost function $q(u)$ is nonnegative *convex* satisfying
$q(u) \geq c|u|^{1+\gamma}, \quad c, \gamma > 0.$

(A.2) The cost functions $p(x)$ and $r(x)$ are continuous nonnegative satisfying
$p(x),\ r(x) \leq c_1(1+|x|^{\gamma_1}), \quad c_1, \gamma_1 > 0.$

(A.3) There exist $x_0 \in \mathbf{R}$ and positive constants c_2, γ_2 such that
(i) $P - \lim_{\varepsilon\to 0} X_0^\varepsilon = x_0$,
(ii) $E|X_0^\varepsilon|^{2n^*} < c_2$,
where n^* is the smallest integer such that $\gamma_1 < n^*$.

(A.4) The function $a(x,y)$ is measurable in (x,y) and satisfies the linear growth and Lipschitz conditions in x (uniformly in y); i.e., there exists $\ell > 0$ such that
(i) $|a(x,y)| \leq \ell(1+|x|), \quad x, y \in \mathbf{R}$,
(ii) $|a(x',y) - a(x'',y)| \leq \ell|x' - x''|, \quad x', x'', y \in \mathbf{R}$.

(A.5) The function $b(x)$ is bounded and Lipschitz; i.e.,
(i) $|b(x)| \leq \ell$,
(ii) $|b(x') - b(x'')| \leq \ell|x' - x''|, \quad x', x'' \in \mathbf{R}$.

(A.6) The random process $\xi = (\xi_t)_{t\geq 0}$ is ergodic; namely, there exists a probability measure $\lambda(dy)$ on $\mathbf{R}$ such that for any bounded and measurable function $g(y)$

$$P - \lim_{t\to\infty} \frac{1}{t}\int_0^t g(\xi_s)\,ds = \int_{\mathbf{R}} g(y)\,\lambda(dy).$$

(A.7) The process $M^\varepsilon = (M_t^\varepsilon)_{t\geq 0}$ is a square integrable martingale with paths in the Skorokhod space $D[0,\infty)$ whose predictable quadratic variation $\langle M^\varepsilon\rangle_t$ satisfies
(i) $\langle M^\varepsilon\rangle_t = \varepsilon\int_0^t m_s^\varepsilon\,ds$
with bounded density m_s^ε. The latter means that there exists a constant c_3 such that
(ii) $m_t^\varepsilon \leq c_3; \quad t \leq T \quad P-$a.s.
The jumps $\Delta M_s^\varepsilon := M_s^\varepsilon - \lim_{v\uparrow s} M_v^\varepsilon$ are bounded, i.e., there exists a constant $L > 0$ such that
(iii) $|\Delta M_t^\varepsilon| \leq L; \quad t \leq T, \quad \varepsilon \in (0,1]$.

Note that by assumptions (A.4) and (A.5) equation (1.1) has a unique strong solution X^ε for every admissible control u^ε. We shall refer to X^ε as the state process associated with u^ε. The only requirement for the "contamination" process ξ is its ergodicity; no stationarity of ξ or independence from other processes is required. We furthermore remark that our results remain valid if M^ε is any process with paths in D satisfying
i) $\sup_{t\leq T}|M_t^\varepsilon| \xrightarrow{P} 0 \quad \forall T > 0$ (see derivations (4.5) and (6.3) below),
ii) $\sup_\varepsilon E\sup_{t\leq T}|M_t^\varepsilon|^{2n} < \infty$, $n \geq 1$ (see §7).
In this more general case, a rigorous representation of the dynamics of the system should be made in the integral form below rather than in the differential form (1.1):

$$X_t^\varepsilon = X_0^\varepsilon + \int_0^t \left[a(X_s^\varepsilon, \xi_{s/\varepsilon}) + b(X_s^\varepsilon)u^\varepsilon(s)\right]ds + M_t^\varepsilon.$$

Finally, note that our assumptions on the cost functions are quite natural and represent a minimal set of assumptions for the problem to be meaningful: (A.1) guarantees that we stay within the classical control problems rather than having also to deal with singular controls (e.g., see [14]), while (A.2) is the usual polynomial growth condition assumption.

3. Asymptotic lower bound for the optimal cost functions. Let v and V^ε be the optimal cost functions, corresponding to the deterministic and the original control problems respectively (see (1.7)–(1.9) and (1.1)–(1.3)). The aim of this section is to prove the following theorem.

THEOREM 3.1. *Let the assumptions of* §2 *be satisfied. Then*

$$\liminf_{\varepsilon\to 0} V^\varepsilon \geq v.$$

Proof. We may limit ourselves to the case when $\liminf_{\varepsilon\to 0} J^\varepsilon(u^\varepsilon) = \beta < \infty$. Take a subsequence $\varepsilon_k \to 0$ $(k \to \infty)$ such that $\lim_k J^{\varepsilon_k}(u^{\varepsilon_k}) = \liminf_{\varepsilon\to 0} J^\varepsilon(u^\varepsilon)$. Then for k large enough

$$J^{\varepsilon_k}(u^{\varepsilon_k}) \leq 2\beta. \tag{3.1}$$

(For notational convenience we shall assume that (3.1) holds for all k.) From (3.1) and (1.2) it follows that

$$E\int_0^T q(u_t^{\varepsilon_k})\,dt < 2\beta. \tag{3.2}$$

Let X^{ε_k} be the state process associated with u^{ε_k}.

Given (3.2), we may apply Theorem 6.1 to conclude that the sequence $(X^{\varepsilon_k}, U^{\varepsilon_k}, ||U^{\varepsilon_k}||)$, $k \geq 1$, is relatively compact, where $U_t^{\varepsilon_k} = \int_0^t u^{\varepsilon_k}(s)ds$ and $||U^{\varepsilon_k}||_t = \int_0^t |u^{\varepsilon_k}(s)|ds$. Let $(X^{\varepsilon_{\tilde{k}}}, U^{\varepsilon_{\tilde{k}}}, ||U^{\varepsilon_{\tilde{k}}}||)$ be a weakly converging subsequence with limit $(X, U, ||U||)$. Then, by Theorem 6.1, we have

$$\begin{aligned} X_t &= x_0 + \int_0^t [\overline{a}(X_s) + b(X_s)u(s)]\,ds, \\ U(t) &= \int_0^t u(s)ds, \end{aligned} \tag{3.3}$$

where x_0 is the "limit of X_0^ε" (see assumption (A.3)), $\overline{a}(x)$ is defined in (1.5), and $b(x)$ is the same as in (1.1). Since

$$\liminf_{\varepsilon\to 0} J^\varepsilon(u^\varepsilon) = \lim_{\tilde{k}\to 0} J^{\varepsilon_{\tilde{k}}}(u^{\varepsilon_{\tilde{k}}}), \tag{3.4}$$

where $(\varepsilon_{\tilde{k}})$ is any subsequence of (ε_k), we use (3.4) with $(\varepsilon_{\tilde{k}})$ corresponding to the weakly converging sequence $(X^{\varepsilon_{\tilde{k}}}, U^{\varepsilon_{\tilde{k}}}, ||U^{\varepsilon_{\tilde{k}}}||)$. Then by Theorems 5.1 and 6.1 we get

$$\lim_{\tilde{k}} J^{\varepsilon_{\tilde{k}}}(u^{\varepsilon_{\tilde{k}}}) \geq E\left\{\int_0^T [p(X_t) + q(u(t))]\,dt + r(X_T)\right\}. \tag{3.5}$$

From (3.4) and (3.5) we derive

$$\liminf_{\varepsilon\to 0} J^\varepsilon \geq v. \tag{3.6}$$

If an optimal control exists, then the statement of the theorem is a consequence of (3.6). Otherwise we approximate the optimal value function by the cost associated with δ-optimal controls.

4. Proofs of Theorems 1.1 and 1.2. It follows from Theorem 3.1 that the lower limit of the optimal costs is bounded from below by the optimal cost corresponding to the deterministic model (1.7)–(1.9). The existence of an optimal control u^* for problem (1.7)–(1.9) can be shown by standard arguments (see the remark at the end of §6 or the proof of Theorem III.4.1 in [4]). Notice also that assumption (A.1) implies

$$\int_0^T |u^*(t)|^{1+\gamma} dt < \infty. \tag{4.1}$$

Next let $x^*(t)$ be the (deterministic) solution of (1.7) corresponding to the control $u^*(t)$ and $X^{*,\varepsilon} = (X_t^{*,\varepsilon})_{0\le t\le T}$ be the (stochastic) state process associated with the control $u_t^\varepsilon \equiv u^*(t)$ via (1.1).

We first show that

$$P - \lim_{\varepsilon\to 0} \sup_{t\le T} |X_t^{*,\varepsilon} - x^*(t)| = 0. \tag{4.2}$$

Let

$$\Delta_t^\varepsilon := |X_t^{*,\varepsilon} - x^*(t)|. \tag{4.3}$$

Using (1.1) and (1.7), we get the inequality

$$\Delta_t^\varepsilon \le |X_0^\varepsilon - x_0| + \int_0^t \left[\, |\overline{a}(X_s^{*,\varepsilon}) - \overline{a}(x^*(s))| + |b(X_s^{*,\varepsilon}) - b(x^*(s))||u^*(s)| \,\right] ds$$
$$+ \sup_{t\le T} \left| \int_0^t [a(X_s^{*,\varepsilon}, \xi_{s/\varepsilon}) - \overline{a}(X_s^{*,\varepsilon})]\, ds \right| + \sup_{t\le T} |M_t^\varepsilon|.$$

By the Lipschitzianity of $\overline{a}(x)$ and $b(x)$ (see assumptions (A.4) and (A.5)) it follows that

$$\Delta_t^\varepsilon \le \left\{ |X_0^\varepsilon - x_0| + \sup_{t\le T} \left| \int_0^t [a(X_s^{*,\varepsilon}, \xi_{s/\varepsilon}) - \overline{a}(X_s^{*,\varepsilon})]\, ds \right| + \sup_{t\le T} |M_t^\varepsilon| \right\}$$
$$+ \ell \int_0^t (1 + |u^*(s)|)\, |\Delta_s^\varepsilon|\, ds.$$

Therefore, by the Gronwall–Bellman inequality

$$\sup_{t\le T} |\Delta_t^\varepsilon| \le \left\{ |X_0^\varepsilon - x_0| + \sup_{t\le T} \left| \int_0^t [a(X_s^{*,\varepsilon}, \xi_{s/\varepsilon}) - \overline{a}(X_s^{*,\varepsilon})]\, ds \right| \right.$$
$$\left. + \sup_{t\le T} |M_t^\varepsilon| \right\} \exp\left(\ell \int_0^T [1 + |u^*(s)|]\, ds \right). \tag{4.4}$$

Now, by assumption (A.2) we have $P - \lim_{\varepsilon\to 0} |X_0^\varepsilon - x_0| = 0$; furthermore, using a similar argument as in the proof of (6.8) below, we get

$$P - \lim_{\varepsilon\to 0} \sup_{t\le T} \left| \int_0^t [a(X_s^{*,\varepsilon}, \xi_{s/\varepsilon}) - \overline{a}(X_s^{*,\varepsilon})]\, ds \right| = 0. \tag{4.5}$$

Finally, by assumption (A.7) and by Problem 1.9.2 in [15], $P-\lim_{\varepsilon\to 0}\sup_{t\le T}|M_t^\varepsilon| = 0$.

Thus, (4.2) holds. As a consequence of (4.2) we have

$$\begin{aligned} &P-\lim_{\varepsilon\to 0} p(X_t^{*,\varepsilon}) = p(x^*(t)), \quad t\in[0,T], \\ &P-\lim_{\varepsilon\to 0} r(X_T^{*,\varepsilon}) = r(x^*(T)). \end{aligned} \tag{4.6}$$

Next we need to prove that the families $p(X_t^{*,\varepsilon})$ of functions on $[0,T]\times\Omega$ and of random variables $r(X_T^{*,\varepsilon})$ are uniformly integrable with respect to the measures $dt\times dP$ and dP on $[0,T]\times\Omega$ and Ω, respectively. To this end it is sufficient to show that there exists a constant $c>0$ such that

$$E\,[p(X_t^{*,\varepsilon})]^2 \le c, \qquad E\,[r(X_T^{*,\varepsilon})]^2 \le c. \tag{4.7}$$

By assumption (A.2) we have $p(x), r(x) \le c_1(1+|x|^{\gamma_1})$. Let n^* be the smallest integer such that $\gamma_1 < n^*$. Evidently, (4.7) holds if there exists a constant c' such that

$$E\sup_{t\le T}|X_t^{*,\varepsilon}|^{2n^*} \le c'. \tag{4.8}$$

Using (1.1) as well as assumptions (A.4) and (A.5), we get

$$\sup_{s\le t}|X_s^{*,\varepsilon}| \le |X_0^\varepsilon| + \ell\int_0^t\left(1+\sup_{\tau\le s}|X_\tau^{*,\varepsilon}|\right)ds + \ell\int_0^T|u^*(t)|\,dt + \sup_{s\le T}|M_t^\varepsilon|.$$

The Gronwall–Bellman inequality implies

$$\sup_{s\le T}|X_s^{*,\varepsilon}| \le e^{\ell T}\left\{|X_0^\varepsilon| + \ell T + \ell\int_0^T|u^*(t)|\,dt + \sup_{s\le T}|M_t^\varepsilon|\right\}. \tag{4.9}$$

From (7.1) we have

$$E\sup_{t\le T}|M_t^\varepsilon|^{2n^*} \le \text{const}. \tag{4.10}$$

Inequality (4.8) is therefore a consequence of (4.9), (4.10), and assumption (A.3).

By virtue of (4.8) and Theorem 5.4 in [1]

$$\begin{aligned} \lim_{\varepsilon\to 0} J^\varepsilon(u^*) &= \lim_{\varepsilon\to 0} E\left\{\int_0^T[p(X_t^{*,\varepsilon}) + q(u^*(t))]\,dt + r(X_T^{*,\varepsilon})\right\} \\ &= \int_0^T[p(x^*(t)) + q(u^*(t))]\,dt + r(x^*(T)) = v. \end{aligned} \tag{4.11}$$

Since $V^\varepsilon \le J^\varepsilon(u^*)$, we have $\limsup_{\varepsilon\to 0} V^\varepsilon \le v$. This inequality and Theorem 3.1 imply Theorem 1.1, which together with (4.11), in turn implies Theorem 1.2.

5. Relative compactness of $(U^\varepsilon, ||U^\varepsilon||)$.

Let $q(u)$ be the control cost function from (1.2). Assume

$$\sup_{\varepsilon\le 1} E\int_0^T q(u^\varepsilon(t))dt < \infty. \tag{5.1}$$

Recall that $U^\varepsilon(t) = \int_0^t u^\varepsilon(s)ds$ and denote its total variation in the time interval $[0,t]$ by

$$||U^\varepsilon||_t = \int_0^t |u^\varepsilon(s)|ds. \tag{5.2}$$

The process $||U^\varepsilon||_t, 0 \le t \le T$ has paths in a subset of $C_{[0,T]}$ of continuous increasing functions $C^+_{[0,T]}$. Also, ρ will be used for designating of the uniform metric in $C_{[0,T]}$.

THEOREM 5.1. *Let assumption* (A.1) *and* (5.1) *be satisfied. Then the family of random processes* $(U^\varepsilon, ||U^\varepsilon||) = (U^\varepsilon(t), ||U^\varepsilon||_t)_{0\le t\le T}, \varepsilon \le 1$ *is relatively compact in the metric space* $\big(C_{[0,T]} \times C^+_{[0,T]}, \rho \times \rho\big)$.

If $(U^{\varepsilon_k}, ||U^{\varepsilon_k}||)$ *is any weakly converging sequence with limit* $(U, ||U||)$, *then there exists a measurable process* $(u(t))_{0\le t\le T}$ *such that*

1. $E\int_0^T |u(t)|^{1+\gamma}dt < \infty$;
2. *for any* $t \le T$ *and* P*-a.s.*

$$U(t) = \int_0^t u(s)ds, \quad ||U||_t = \int_0^t |u(s)|ds;$$

3.

$$\liminf_{k\to\infty} E\int_0^T q(u^{\varepsilon_k}(t)) \ge E\int_0^T q(u(t))dt. \tag{5.3}$$

Proof. Since $C^+_{[0,T]}$ is closed in $C_{[0,T]}$ in the metric ρ, by virtue of Prokhorov's theorem (see, e.g., [1]) only tightness of the family in $C_{[0,T]} \times C^+_{[0,T]}$ has to be checked. Due to Theorems 8.2 and 15.2 in [1], we verify two conditions:

$$\begin{aligned} &\lim_{c\to\infty} \limsup_{\varepsilon\to 0} P\big(\sup_{t\le T} ||U^\varepsilon||_t > c\big) = 0, \\ &\lim_{\delta\to 0} \limsup_{\varepsilon\to 0} P\Big(\sup_{t,s\le T:|t-s|\le\delta} \Big|||U^\varepsilon||_t - ||U^\varepsilon||_s\Big| > \nu\Big) = 0 \quad \forall \nu > 0 \end{aligned} \tag{5.4}$$

and the same conditions for U^ε. Conditions (A.1) and (5.1) imply

$$\sup_{\varepsilon\le 1} E\int_0^T |u^\varepsilon(t)|^{1+\gamma}dt < \infty. \tag{5.5}$$

Thereby, conditions (5.4) are verified by Hölder's inequality. Namely,

$$\sup_{t\le T} ||U^\varepsilon||_t = ||U^\varepsilon||_T \le T^{\gamma/(1+\gamma)}\Big(\int_0^T |u^\varepsilon(t)|^{(1+\gamma)}dt\Big)^{1/(1+\gamma)}, \tag{5.6}$$

and for any random $t, s \le T : |t-s| \le \delta$

$$\Big|||U^\varepsilon||_t - ||U^\varepsilon||_s\Big| \le \delta^{\gamma/(1+\gamma)}\Big(\int_0^T |u^\varepsilon(t)|^{(1+\gamma)}dt\Big)^{1/(1+\gamma)}. \tag{5.7}$$

We conclude by using Chebyshev's inequality. The validity of the conditions of the type (5.4) for U^ε is proved analogously.

Let $W(t)$ be any random process with paths from $C_{[0,T]}$ and let $I^n = \{s_i = \frac{iT}{2^n}, i = 0, 1, \ldots, 2^n\}, n \geq 1$ be subdivisions of the time interval $[0, T]$. Put

$$w_n(t) = \frac{W_{s_i} - W_{s_{i-1}}}{s_i - s_{i-1}}, \quad s_{i-1} \leq t < s_i. \tag{5.8}$$

It is known (see [16]) that under the assumption

$$\sup_n E \int_0^T |w_n(t)|^2 dt < \infty \tag{5.9}$$

the process $W(t)$ is absolutely continuous (with respect to Lebesgue measure $\Lambda(dt) = dt$); i.e., there exists a measurable process $w(t)$ such that for any $t \leq T$ and P-a.s.

$$W(t) = \int_0^t w(s) ds, \quad E \int_0^T |w(t)|^2 dt < \infty, \tag{5.10}$$

and additionally

$$w(t, \omega) = \lim_n w_n(t, \omega), \quad \Lambda \times P \text{ - a.s.} \tag{5.11}$$

The same proof shows that under the assumption that for some $\gamma > 0$

$$\sup_n E \int_0^T |w_n(t)|^{1+\gamma} dt < \infty \tag{5.12}$$

we have that (5.10) with $E \int_0^T |w(t)|^{1+\gamma} dt < \infty$ and (5.11) hold.

Let $W(t) \equiv U(t)$ and, correspondingly, $u_n(t) \equiv w_n(t)$. Therefore, statements 1. and 2. of Theorem 5.1 take place if, for γ the same as in (A.1),

$$\sup_n E \int_0^T |u_n(t)|^{1+\gamma} dt < \infty. \tag{5.13}$$

To this end, defining $u_n^{\varepsilon_k}(t)$ in the same way as $w_n(t)$ but with $W(t) \equiv U^{\varepsilon_k}(t)$, we find

$$\mathcal{E}_n(U^{\varepsilon_k}) = \int_0^T |u_n^{\varepsilon_k}(t)|^{1+\gamma} dt = \sum_{i=1}^{2^n} \left| \frac{\int_{\frac{i-1}{2^n}}^{\frac{i}{2^n}} u^{\varepsilon_k}(t) dt}{2^{-n}} \right|^{1+\gamma} 2^{-n}.$$

On the other hand, due to Jensen's inequality and assumption (A.1),

$$\begin{aligned} \sum_{i=1}^{2^n} \left| \frac{\int_{\frac{i-1}{2^n}}^{\frac{i}{2^n}} u^{\varepsilon_k}(t) dt}{2^{-n}} \right|^{1+\gamma} 2^{-n} &\leq \sum_{i=1}^{2^n} \int_{\frac{i-1}{2^n}}^{\frac{i}{2^n}} |u^{\varepsilon_k}(t)|^{1+\gamma} dt = \int_0^T |u^{\varepsilon_k}(t)|^{1+\gamma} dt \\ &\leq \frac{1}{c} \int_0^T q(u^{\varepsilon_k}(t)) dt. \end{aligned} \tag{5.14}$$

By virtue of the weak convergence of U^{ε_k} and assumption (5.1), for any $N \geq 1$ we get

$$E \min \left[N, \mathcal{E}_n(U)\right] = \lim_k E \min \left[N, \mathcal{E}_n(U^{\varepsilon_k})\right] \leq \sup_{\varepsilon \leq 1} E \int_0^T |u^{\varepsilon}(t)|^{1+\gamma} dt < \infty.$$

By the monotone convergence theorem, $\sup_n E\,\mathcal{E}_n(U) < \infty$, and thus, noting that $\mathcal{E}_n(U) = \int_0^T |u_n(t)|^{1+\gamma} dt$, we conclude that (5.13) holds.

To prove statement 3. of Theorem 5.1, introduce

$$\mathcal{E}_{n,q}(U^{\varepsilon_k}) = \int_0^T q(u_n^{\varepsilon_k}(t))dt = \sum_{i=1}^{2^n} q\left(\frac{\int_{\frac{i-1}{2^n}}^{\frac{i}{2^n}} u^{\varepsilon_k}(t)dt}{2^{-n}}\right)2^{-n}.$$

Since by Jensen's inequality

$$\int_0^T q(u_n^{\varepsilon_k}(t))dt = \sum_{i=1}^{2^n} q\left(\frac{\int_{\frac{i-1}{2^n}}^{\frac{i}{2^n}} u^{\varepsilon_k}(t)dt}{2^{-n}}\right)2^{-n} \le \int_0^T q(u^{\varepsilon_k}(t))dt,$$

we derive statement 3. by Fatou's lemma and by (5.11), reformulated for $u_n(t)$:

$$\begin{aligned}
\liminf_k E\int_0^T q(u^{\varepsilon_k}(t))dt &\ge \liminf_n \lim_{N\to\infty} \lim_k E\,\min\left[N, \mathcal{E}_{n,q}(U^{\varepsilon_k})\right] \\
&= \liminf_n \lim_{N\to\infty} E\,\min\left[N, \mathcal{E}_{n,q}(U)\right] \\
&= \liminf_n E\,\mathcal{E}_{n,q}(U) = \liminf_n E\int_0^T q(u_n(t))dt \\
&\ge E\int_0^T \liminf_n q(u_n(t))dt = E\int_0^T q(u(t))dt.
\end{aligned}$$

6. Relative compactness of $(X^\varepsilon, U^\varepsilon, ||U^\varepsilon||)$. Let $X^\varepsilon = (X_t^\varepsilon)_{t\ge 0}$ be defined as in (1.1) and $||U^\varepsilon||_t$ in (5.2). We consider the triple $(X^\varepsilon, U^\varepsilon, ||U^\varepsilon||) = (X_t^\varepsilon, U_t^\varepsilon, ||U^\varepsilon||_t)_{0\le t\le T}$ with values in $D_{[0,T]} \times C_{[0,T]} \times C^+_{[0,T]}$, where $D_{[0,T]}$ is Skorokhod's space.

THEOREM 6.1. *Let the assumptions of* §2 *and* (5.1) *be satisfied. Then the family* $(X^\varepsilon, U^\varepsilon, ||U^\varepsilon||), \varepsilon \le 1$, *is relatively compact in the metric space* $\left(D_{[0,T]} \times C_{[0,T]} \times C^+_{[0,T]}, \rho\times\rho\times\rho\right)$. *If* $(X^{\varepsilon_k}, U^{\varepsilon_k}, ||U^{\varepsilon_k}||)$ *is any weakly converging sequence with limit* $(X, U, ||U||)$, *then the statements of Theorem* 5.1 *hold and*

$$X_t = x_0 + \int_0^t [\,\bar{a}(X_s) + b(X_s)u(s)\,]\,ds, \quad t \le T, \tag{6.1}$$

where $\bar{a}(x)$ *is defined as in* (1.5) *and* $u(s)$ *is the process from Theorem* 5.1. *For any continuous nonnegative functions* $p(x)$ *and* $r(x)$,

$$\liminf_k E\left\{\int_0^T p(X_t^{\varepsilon_k})dt + r(X_T^{\varepsilon_k})\right\} \ge E\left\{\int_0^T p(X_t)dt + r(X_T)\right\}. \tag{6.2}$$

Proof. Parallel to X_t^ε, introduce a process $X_t^{\varepsilon,\circ}$ defined by (compare to (1.1))

$$X_t^{\varepsilon,\circ} = X_0^\varepsilon + \int_0^t \left[a(X_s^{\varepsilon,\circ}, \xi_{s/\varepsilon}) + b(X_s^{\varepsilon,\circ})u^\varepsilon(s)\right]ds. \tag{6.3}$$

Due to (1.1), (6.3), and assumptions (A.4) and (A.5), the process $Y_t^\varepsilon = \sup_{s\le t}\left|X_s^\varepsilon - X_s^{\varepsilon,\circ}\right|$ satisfies the inequality

$$Y_t^\varepsilon \le \ell\int_0^t Y_s^\varepsilon d[s + ||U^\varepsilon||_s] + \sup_{s\le T}|M_s^\varepsilon|, \quad t \le T,$$

and thus by the Gronwall–Bellman inequality we get

$$Y_T^\varepsilon \le \ell \sup_{s\le T} |M_s^\varepsilon| \exp\{\ell[T + ||U^\varepsilon||_T]\}.$$

By virtue of assumption (A.7) and Problem 1.9.2 in [15], $\sup_{t\le T} |M_t^\varepsilon| \to 0, \varepsilon \to 0$, in probability and $||U^\varepsilon||_T$ satisfies (5.4). Consequently $Y_T^\varepsilon \to 0, \varepsilon \to 0$, in probability, and by Theorem 4.1, Chapter 1 in [1] the result of the theorem remains true if its statements are proved only for the triple $(X^{\varepsilon,\circ}, U^\varepsilon, ||U^\varepsilon||)$.

By virtue of (5.4), it is sufficient to verify only the following two conditions (see Theorems 8.2 and 15.2 in [1]):

$$\lim_{c\to\infty} \limsup_{\varepsilon\to 0} P\left(\sup_{t\le T} |X_t^{\varepsilon,\circ}| > c\right) = 0$$

$$\lim_{\delta\to 0} \limsup_{\varepsilon\to 0} P\left(\sup_{t,s\le T:|t-s|\le\delta} |X_t^{\varepsilon,\circ} - X_s^{\varepsilon,\circ}| > \nu\right) = 0 \quad \forall \nu > 0. \tag{6.4}$$

It follows from (6.3) and assumptions (A.4) and (A.5) that for any $t \le T$

$$\sup_{s\le t} |X_s^{\varepsilon,\circ}| \le |X_0^\varepsilon| + \ell \int_0^t \left[1 + \sup_{\tau\le s} |X_\tau^{\varepsilon,\circ}|\right] ds + ||U^\varepsilon||_T,$$

and thus, using Gronwall–Bellman's inequality, we get

$$\sup_{s\le T} |X_s^{\varepsilon,\circ}| \le e^{\ell T}\big(|X_0^\varepsilon| + \ell||U^\varepsilon||_T\big).$$

Evidently, the first condition in (6.4) holds by the proof of Theorem 5.1 and by assumption (A.3.i).

For any $t - s < \delta$ we can apply assumptions (A.4) and (A.5) to write

$$\begin{aligned} |X_t^{\varepsilon,\circ} - X_s^{\varepsilon,\circ}| &\le \ell \int_{t\wedge s}^{t\vee s} \left[1 + \sup_{\tau\le T} |X_\tau^{\varepsilon,\circ}|\right] d\tau + \ell\big(||U^\varepsilon||_{t\vee s} - ||U^\varepsilon||_{t\wedge s}\big) \\ &\le \ell\delta \left[1 + \sup_{\tau\le T} |X_\tau^{\varepsilon,\circ}|\right] + \ell\big(||U^\varepsilon||_{t\vee s} - ||U^\varepsilon||_{t\wedge s}\big). \end{aligned}$$

Therefore, the validity of the second condition in (6.4) follows from the proof of Theorem 5.1 and from the first condition in (6.4), which has already been proved.

Let $(X^{\varepsilon_k,\circ}, U^{\varepsilon_k}, ||U^{\varepsilon_k}||)$, $k \ge 1$, be a weakly converging sequence with limit $(X, U, ||U||)$. Denote by Q the distribution of the limit $(X, U, ||U||)$; i.e., Q is a probability measure on $C_{[0,T]} \times C_{[0,T]} \times C^+_{[0,T]}$. For any element $(X, U, ||U||)$ from $C_{[0,T]} \times C_{[0,T]} \times C^+_{[0,T]}$ put

$$\Phi_t(X, U, ||U||) := X_t - x_0 - \int_0^t \overline{a}(X_s)\, ds - \int_0^t b(X_s)\, dU(s), \tag{6.5}$$

where the function $\overline{a}(x)$ is defined by (1.5) and x_0 is the same as in assumption (A.3.i). The second statement of Theorem 6.1. holds if

$$\sup_{t\le T} |\,\Phi_t(X, U, ||U||)\,| = 0 \qquad Q - \text{a.s.} \tag{6.6}$$

To prove the validity of (6.6), we show that the functional $\sup_{t\le T}|\,\Phi_t(X,U,||U||)\,|$ is continuous in the product-metric $\rho^3=\rho\times\rho\times\rho$. Let $(X^0,U^0,||U^0||)$ and $(X^n,U^n,||U^n||)$, $n\ge 1$, be elements of $C_{[0,T]}\times C_{[0,T]}\times C^+_{[0,T]}$ such that

$$\lim_n \rho^3((X^0,U^0,||U^0||),(X^n,U^n,||U^n||)=0.$$

We show that $\lim_n \sup_{t\le T}|\,\Phi_t(X^n,U^n,||U^n||)=\sup_{t\le T}|\,\Phi_t(X^0,U^0,||U^0||)$. Taking (6.5) into account, we get

$$\begin{aligned}
L^n &:= \Big|\sup_{t\le T}|\Phi_t(X^n,U^n,||U^n||)|-\sup_{t\le T}|\Phi_t(X^0,U^0,||U^0||)|\,\Big|\\
&\le \sup_{t\le T}\Big|\,\Phi_t(X^n,U^n,||U^n||)-\Phi_t(X^0,U^0,||U^0||)\,\Big|\\
&\le 2\sup_{t\le T}|X^n_t-X^0_t|+\int_0^T|\,\overline{a}(X^n_s)-\overline{a}(X^0_s)\,|\,ds\\
&\quad+\int_0^T|\,b(X^n_s)-b(X^0_s)\,|\,d||U^n||_s+\sup_{t\le T}\Big|\int_0^t b(X^0_s)\,d[U^n(s)-U^0(s)]\,\Big|.
\end{aligned}$$

Using the Lipschitzianity of the functions $\overline{a}(x)$ (it is inherited from $a(x,y)$; see (A.4.ii)) and $b(x)$, we obtain the following upper bound for L^n:

$$L^n\le\rho(X^n,X^0)\left\{2+\ell T+\ell||U^0||_T+\ell\rho(||U^n||,||U^0||)\right\}+L^n_b,$$

where

$$L^n_b:=\sup_{t\le T}\Big|\int_0^t b(X^0_s)\,d[U^n(s)-U^0(s)]\,\Big|.$$

The quantity L^n_b can be evaluated from above in the following way ($[\alpha]$ below stands for the integer part of α):

$$\begin{aligned}
L^n_b\le&\sup_{t\le T}\Big|\int_0^t b(X^0_{\frac{[Ns]}{N}})\,d[U^n(s)-U^0(s)]\,\Big|\\
&+\ell\sup_{|s'-s''|\le\frac{1}{N}}|X^0_{s'}-X^0_{s''}|\,[\,(||U^n||_T+||U^0||)_T\,].
\end{aligned}$$

Therefore, $\limsup_n L^n_b\le 2\ell||U^0||_T\sup_{|s'-s''|\le\frac{1}{N}}|X^0_{s'}-X^0_{s''}|\to 0$ for $N\to\infty$; i.e., $\sup_{t\le T}|\,\Phi_t(X,U,||U||)\,|$ is continuous functional.

Using this fact, the equality

$$Q\Big(\sup_{t\le T}|\,\Phi_t(X,U,||U||)\,|\ge\nu\Big)=\lim_k P\left(\sup_{t\le T}|\,\Phi_t(X^{\varepsilon_k,\circ},U^{\varepsilon_k},||U^{\varepsilon_k}||)\,|\ge\nu\right),\quad \nu>0,$$

is implied by the weak convergence mentioned above, and by the estimate

$$\sup_{t\le T}|\,\Phi_t(X^{\varepsilon_k,\circ},U^{\varepsilon_k},||U^{\varepsilon_k}||)\,|\le|X^{\varepsilon_k}_0-x_0|+\sup_{t\le T}\Big|\int_0^t[a(X^{\varepsilon_k}_s,\xi_{s/\varepsilon_k})-\overline{a}(X^{\varepsilon_k}_s)]ds\Big|,\tag{6.7}$$

we can conclude that (6.6) holds if the right-hand side of (6.7) goes to zero in probability as $k\to\infty$. Taking assumption (A.3.i) into account, for the validity of (6.6) only

$$P-\lim_k\sup_{t\le T}\Big|\int_0^t[a(X^{\varepsilon_k}_s,\xi_{s/\varepsilon_k})-\overline{a}(X^{\varepsilon_k}_s)]ds\Big|=0\tag{6.8}$$

has to be checked.

Evidently, for a piecewise constant function such that $\phi(t) = \phi\left(\frac{i}{n}\right)$ for $\frac{i}{n} \le t < \frac{i+1}{n}$,

$$P - \lim_{k\to\infty} \left| \int_0^t [\, a(\phi(s), \xi_{s/\varepsilon_k}) - \overline{a}(\phi(s)) \,]\, ds \right| = 0 \quad \forall t \le T \tag{6.9}$$

holds. Notice also that (6.9) remains true when $a(x,z)$ and $\overline{a}(x)$ are replaced with $a^{\pm}(x,z)$ and $\overline{a}^{\pm}(x)$, where $e^+ = \max[0,e]$ and $e^- = -\min[0,e]$. Then, by Problem 5.5.2 in [15] we get

$$P - \lim_{k\to\infty} \sup_{t\le T} \left| \int_0^t [\, a(\phi(s), \xi_{s/\varepsilon_k}) - \overline{a}(\phi(s)) \,]\, ds \right| = 0, \tag{6.10}$$

Then approximate the process $(X_t^{\varepsilon_k})_{0\le t\le T}$ by a sequence $X^{k,m,n} = (X_t^{k,m,n})_{0\le t\le T}$, $n \ge 1$, $m \ge 1$, where

$$X_t^{k,m,n} = \sum_{j=-\infty}^{\infty} \frac{j-1}{m}\, I\left(\frac{j-1}{m} \le X_{i/n}^{\varepsilon_k} < \frac{j}{m} \right), \quad \frac{i}{n} \le t < \frac{i+1}{n}.$$

The process $X^{k,m,n}$ has piecewise constant paths, and on the set $\{\sup_{t\le T} |X_t^{\varepsilon_k}| \le c\}$ the number of its paths is finite and does not depend on k. Therefore, using (6.10), we see that for any $c > 0$, $m \ge 1$, $n \ge 1$ and putting $\xi_s^k = \xi_{s/\varepsilon_k}$

$$P - \lim_k I\left(\sup_{t\le T} |X_t^{\varepsilon_k}| \le c \right) \sup_{t\le T} \left| \int_0^t [\, a(X_s^{k,m,n}, \xi_s^k) - \overline{a}(X_s^{k,m,n}) \,]\, ds \right| = 0. \tag{6.11}$$

On the other hand, taking into account the weak convergence of $(X_t^{\varepsilon_k})_{0\le t\le T}$, which implies $\lim_k \limsup_{c\to\infty} P\left(\sup_{t\le T} |X_t^{\varepsilon_k}| > c\right) = 0$, for the validity of (6.8) it remains to show that

$$P - \lim_{m,n\to\infty} \lim_k \int_0^T |\, a(X_s^{\varepsilon_k}, \xi_s^k) - a(X_s^{k,m,n}, \xi_s^k) \,|\, ds = 0,$$

$$P - \lim_{m,n\to\infty} \lim_k \int_0^T |\, \overline{a}(X_s^{\varepsilon_k}) - \overline{a}(X_s^{k,m,n}) \,|\, ds = 0.$$

Taking into account the Lipschitzianity of the function $a(x,y)$ (see assumption (A.4)), which is also inherited by the function $\overline{a}(x)$, it is sufficient to show

$$P - \lim_{m,n\to\infty} \lim_k \int_0^T |\, X_s^{\varepsilon_k} - X_s^{k,m,n} \,|\, ds = 0. \tag{6.12}$$

To this end, put $X_t^{k,n} = X_{\frac{[nt]}{n}}^{\varepsilon_k}$, where $[\alpha]$ is the integer part of α. Then

$$|\, X_s^{\varepsilon_k} - X_s^{k,m,n} \,| \le |\, X_s^{\varepsilon_k} - X_s^{k,n} \,| + |\, X_s^{k,n} - X_s^{k,m,n} \,|.$$

Obviously $|\, X_s^{k,n} - X_s^{k,m,n} \,| \le \frac{1}{m}$. Consequently

$$\int_0^T |\, X_s^{\varepsilon_k} - X_s^{k,m,n} \,|\, ds \le \frac{T}{m} + \int_0^T |\, X_s^{\varepsilon_k} - X_{\frac{[ns]}{n}}^{k} \,|\, ds \le \frac{T}{m} + T \sup_{s,t\le T:|s-t|\le 1/n} |X_t^{\varepsilon_k} - X_s^k|.$$

Therefore, for any $\nu > 0$

(6.13)
$$P\left(\int_0^T |X_s^{\varepsilon_k} - X_s^{k,m,n}|\,ds > \nu\right) \le P\left(\sup_{s,t\le T:|s-t|\le 1/n} |X_t^{\varepsilon_k} - X_s^k| > \frac{\nu}{T} - \frac{1}{m}\right).$$

As a result, (6.12) follows from weak convergence of $(X_t^{\varepsilon_k})_{0\le t\le T}$, which implies the convergence to zero of the right-hand side of (6.13).

It remains to prove (6.2). Due to the weak convergence of $(X_t^{\varepsilon_k})_{0\le t\le T}, k \ge 1$, we find

$$\liminf_k E\left\{\int_0^T p(X_t^{\varepsilon_k})dt + r(X_T^{\varepsilon_k})\right\} \ge \lim_k E\left\{\int_0^T \big(N \wedge p(X_t^{\varepsilon_k})\big)dt + N \wedge r(X_T^{\varepsilon_k})\right\}$$
$$= E\left\{\int_0^T \big(N \wedge p(X_t)\big)dt + N \wedge r(X_T)\right\} \quad \forall N \ge 1$$

and conclude by using the monotone convergence theorem.

Remark. The method of proof of Theorem 6.1 can be adapted to the following deterministic problem. Let $u^n(t)$, $n \ge 1$, be a sequence of measurable functions satisfying

$$\sup_n \int_0^T |u^n(t)|^{1+\gamma}dt < \infty, \qquad \gamma > 0.$$

For each n consider the differential equation

$$\frac{dx^n(t)}{dt} = \bar{a}(x^n(t)) + b(x^n)u^n(t)$$

with the initial condition $x^n(0) = x_0$. Put

$$U^n(t) = \int_0^t u^n(s)\,ds, \qquad ||U||_t^n = \int_0^t |u^n(s)|\,ds,$$

By the same technique as in the proof of Theorem 6.1, one can show that the family $(x^n(t), U^n(t), ||U||_t^n)_{0\le t\le T}$, $n \ge 1$ is uniformly bounded and equicontinuous. Then by the Arzelà–Ascoli theorem this family is relatively compact and there exists a subsequence $(x^{n_k}(t), U^{n_k}(t), ||U||_t^{n_k})_{0\le t\le T}$ converging uniformly to a limit

$$(x^0(t), U^0(t), ||U||_t^0)_{0\le t\le T}$$

with absolutely continuous $U^0(t)$; i.e., there exists a measurable function $u^0(t)$ such that $U^0(t) = \int_0^t u^0(s)ds$. Furthermore, $x^0(t)$ is the unique solution of the differential equation

$$\frac{dx^0(t)}{dt} = \bar{a}(x^0(t)) + b(x^0)u^0(t)$$

with the initial condition $x^0(0) = x_0$.

7. Upper bound for $E\sup_{t\le T}|M_t^\varepsilon|^{2n}$. In this section we prove, under assumption (A.7), that for any $n > 1$ and $T > 0$

(7.1)
$$\sup_{\varepsilon\le 1} E \sup_{t\le T} |M_t^\varepsilon|^{2n} < \infty.$$

In the case of $E\,|M_T^\varepsilon|^{2n} < \infty$, we can apply Doob's inequality (see, e.g., [15]) to obtain

$$E \sup_{t\le T} |M_t^\varepsilon|^{2n} \le \left(\frac{2n}{2n-1}\right)^{2n} E\,|M_T^\varepsilon|^{2n}.$$

Thus, it suffices to show that

$$\sup_{\varepsilon\le 1} E\,|M_T^\varepsilon|^{2n} < \infty. \tag{7.2}$$

We shall use the notations k, N_t, and V_t to denote a generic positive constant depending on (c_3, L, n), a local martingale, and a nondecreasing process (with paths in $D_{[0,\infty)}$), respectively, where N_t and V_t are adapted to the filtration $\mathbf{F}^\varepsilon$. (All these objects might be different in different formulas.)

To check the validity of (7.2), we shall show that $(M_t^\varepsilon)^{2n}$ admits the representation

$$(M_t^\varepsilon)^{2n} = k\int_0^t [1 + (M_s^\varepsilon)^{2n}]ds + N_t - V_t. \tag{7.3}$$

From (7.3) the desired result follows immediately. In fact, by Ito's formula we find

$$\begin{aligned} e^{-kt}(M_t^\varepsilon)^{2n} &= 1 - e^{-kt} + \int_0^t e^{-ks}dN_s - \int_0^t e^{-ks}dV_s \\ &\le 1 + \int_0^t e^{-ks}dN_s. \end{aligned} \tag{7.4}$$

The Ito integral $\int_0^t e^{-ks}dN_s$ is a local martingale. Denote its localizing sequence of stopping times by $(\tau_j)_{j\ge 1}$; i.e., for any $t > 0$, $E\int_0^{t\wedge\tau_j} e^{-ks}dN_s = 0$, $\quad j \ge 1$.

Therefore, from (7.4) it follows that

$$E\,e^{-k(T\wedge\tau_j)}(M_{T\wedge\tau_j}^\varepsilon)^{2n} \le 1, \quad j \ge 1,$$

and so we conclude by using Fatou's lemma.

Thus, only (7.3) has to be proved.

By Ito's formula

$$\begin{aligned} (M_t^\varepsilon)^{2n} &= 2n\int_0^t (M_{s-}^\varepsilon)^{2n-1}dM_s^\varepsilon + n(2n-1)\int_0^t (M_{s-}^\varepsilon)^{2n-2}d\langle M^{\varepsilon,c}\rangle_s \\ &\quad + \sum_{s\le t}\left[(M_s^\varepsilon)^{2n} - (M_{s-}^\varepsilon)^{2n} - 2n(M_{s-}^\varepsilon)^{2n-1}\Delta M_s^\varepsilon\right], \end{aligned} \tag{7.5}$$

where $\langle M^{\varepsilon,c}\rangle_t$ is the predictable quadratic variation of the continuous part of the martingale M_t^ε.

The representation (7.5) is nothing but

$$(M_t^\varepsilon)^{2n} = N_t + B_t \tag{7.6}$$

with the local martingale

$$N_t = 2n\int_0^t (M_{s-}^\varepsilon)^{2n-1}dM_s^\varepsilon \tag{7.7}$$

and the nondecreasing process

(7.8)
$$B_t = n(2n-1)\int_0^t (M^\varepsilon_{s-})^{2n-2} d\langle M^{\varepsilon,c}\rangle_s + \sum_{s\le t}\left[(M^\varepsilon_s)^{2n} - (M^\varepsilon_{s-})^{2n} - 2n(M^\varepsilon_{s-})^{2n-1}\Delta M^\varepsilon_s\right].$$

Denote by $\mu^\varepsilon(dt,dz)$ the measure of jumps of the martingale M^ε_t and by $\nu^\varepsilon(dt,dz)$ its compensator. Since $(R^\circ = R\setminus\{0\})$

$$\sum_{s\le t}\left[(M^\varepsilon_s)^{2n} - (M^\varepsilon_{s-})^{2n} - 2n(M^\varepsilon_{s-})^{2n-1}\Delta M^\varepsilon_s\right] = \int_0^t\int_{R^\circ}\left[(M^\varepsilon_{s-}+z)^{2n} - (M^\varepsilon_{s-})^{2n} - 2n(M^\varepsilon_{s-})^{2n-1}z\right]\mu^\varepsilon(ds,dz)$$

and the process

$$N_t = \int_0^t\int_{R^\circ}\left[(M^\varepsilon_{s-}+z)^{2n} - (M^\varepsilon_{s-})^{2n} - 2n(M^\varepsilon_{s-})^{2n-1}z\right]\mu^\varepsilon(ds,dz) - \int_0^t\int_{R^\circ}\left[(M^\varepsilon_{s-}+z)^{2n} - (M^\varepsilon_{s-})^{2n} - 2n(M^\varepsilon_{s-})^{2n-1}z\right]\nu^\varepsilon(ds,dz)$$

is a local martingale too, we arrive to a new decomposition of the type (7.6) with local martingale

$$N_t = 2n\int_0^t (M^\varepsilon_{s-})^{2n-1} dM^\varepsilon_s + \int_0^t\int_{R^\circ}\left[(M^\varepsilon_{s-}+z)^{2n} - (M^\varepsilon_{s-})^{2n} - 2n(M^\varepsilon_{s-})^{2n-1}\right][\mu^\varepsilon - \nu^\varepsilon](ds,dz) \tag{7.9}$$

and nondecreasing process

$$B_t = n(2n-1)\int_0^t (M^\varepsilon_{s-})^{2n-2} d\langle M^{\varepsilon,c}\rangle_s + \int_0^t\int_{R^\circ}\left[(M^\varepsilon_{s-}+z)^{2n} - (M^\varepsilon_{s-})^{2n} - 2n(M^\varepsilon_{s-})^{2n-1}z\right]\nu^\varepsilon(ds,dz). \tag{7.10}$$

Using the fact that $|\Delta M^\varepsilon_s| \le L$, we get $\nu^\varepsilon(ds,dz) = I(|z|\le L)\nu^\varepsilon(ds,dz)$. Therefore, by virtue of Taylor's expansion for the function $f(x) = x^{2n}$ and Hölder's inequality one can find a constant k such that

$$dB_t \le n(2n-1)(M^\varepsilon_{t-})^{2n-2} d\langle M^{\varepsilon,c}\rangle_t + k\int_{|z|\le L}(M^\varepsilon_{s-})^{2n-2}(1+z^2)\nu^\varepsilon(dt,dz).$$

Recall that the quadratic variation $[M^\varepsilon, M^\varepsilon]_t$ of M^ε_t is defined as

$$[M^\varepsilon, M^\varepsilon]_t = \langle M^{\varepsilon,c}\rangle_t + \sum_{s\le t}(\Delta M^\varepsilon_s)^2 = \langle M^{\varepsilon,c}\rangle_t + \int_0^t\int_{R^\circ} z^2\nu^\varepsilon(dt,dz).$$

Consequently, taking into account that $x^{2n-2} \le 1 + x^{2n}$ we obtain

$$dB_t \le 2[n(2n-1)+k](M^\varepsilon_{t-})^{2n-2} d[M^\varepsilon, M^\varepsilon]_t \le 2[n(2n-1)+k](1+M^\varepsilon_{t-})^{2n} d[M^\varepsilon, M^\varepsilon]_t.$$

Define a nondecreasing process

$$V_t = 2[n(2n-1)+k] \int_0^t (1 + M^\varepsilon_{s-})^{2n} d[M^\varepsilon, M^\varepsilon]_s - B_t.$$

Then for $(M^\varepsilon_t)^{2n}$ we have the following decomposition:

$$(M^\varepsilon_t)^{2n} = N_t + 2[n(2n-1)+k] \int_0^t (1 + M^\varepsilon_{s-})^{2n} d[M^\varepsilon, M^\varepsilon]_s - V_t, \tag{7.11}$$

where the local martingale N_t is defined in (7.9). Since $[M^\varepsilon, M^\varepsilon]_t - \langle M^\varepsilon \rangle_t$ is a local martingale, we arrive at a new representation for $(M^\varepsilon_t)^{2n}$:

$$(M^\varepsilon_t)^{2n} = N_t + 2[n(2n-1)+k] \int_0^t (1 + M^\varepsilon_{s-})^{2n} d\langle M^\varepsilon \rangle_s - V_t \tag{7.12}$$

with the same nondecreasing process V_t and a new local martingale N_t.

Due to assumption (A.7) we have (for $\varepsilon \le 1$) $d\langle M^\varepsilon \rangle_t \le c_3 dt$; i.e.,

$$V'_t = 2[n(2n-1)+k] \Big[\int_0^t (1 + M^\varepsilon_s)^{2n} c_3 ds - \int_0^t (1 + M^\varepsilon_{s-})^{2n} d\langle M^\varepsilon \rangle_s \Big] \tag{7.13}$$

is a nondecreasing process.

Thus, (7.3) is implied by (7.12) and (7.13).

FINITE-DIMENSIONAL FILTERS WITH NONLINEAR DRIFT IV: CLASSIFICATION OF FINITE-DIMENSIONAL ESTIMATION ALGEBRAS OF MAXIMAL RANK WITH STATE–SPACE DIMENSION 3*

JIE CHEN†, STEPHEN S.-T. YAU†, AND CHI-WAH LEUNG‡

Abstract. The idea of using estimation algebras to construct finite-dimensional nonlinear filters was first proposed by Brockett and Mitter independently. It turns out that the concept of estimation algebra plays a crucial role in the investigation of finite-dimensional nonlinear filters. In his talk at the International Congress of Mathematics in 1983, Brockett proposed a classification of all finite-dimensional estimation algebras. Chiou and Yau classify all finite-dimensional estimation algebras of maximal rank with dimension of the state space less than or equal to two. In this paper we succeed in classifying all finite-dimensional estimation algebras of maximal rank with state–space dimension equal to three. Thus from the Lie algebraic point of view, we have now understood generically all finite dimensional filters with state–space dimension less than four.

Key words. finite-dimensional filter, estimation algebra of maximal rank, nonlinear drift

AMS subject classifications. 17B30, 35J15, 60G35, 93E11

1. Introduction.

In the sixties and early seventies, the basic approach to nonlinear filtering theory was via the "innovation methods" originally proposed by Kailath and subsequently rigorously developed by Fujisaki, Kallianpur, and Kunita [FKK] in 1972. As pointed out by Mitter [Mi], the difficulty with this approach is that the innovations process is not, in general, explicitly computable (except in the well-known Kalman–Bucy case). In the late seventies, Brockett and Clark [BrCl], Brockett [Br], and Mitter [Mi] proposed the idea of using estimation algebras to construct finite-dimensional nonlinear filters. In a previous paper [Ya], Yau has studied the general class of nonlinear filtering systems which included both Kalman–Bucy and Benes filtering systems as special cases. He gives necessary and sufficient conditions for an estimation algebra of such filtering systems to be finite dimensional. Using the Wei–Norman approach, he constructed explicitly finite-dimensional recursive filters for such nonlinear filtering systems.

In his talk at the International Congress of Mathematics in 1983, Brockett proposed classification of all finite-dimensional estimation algebras. Since then, the concept of estimation algebras has proved to be an invaluable tool in the study of nonlinear filtering problems. In [ChYa], Chiou and Yau introduced the concept of an estimation algebra of maximal rank. They were able to classify all finite-dimensional estimation algebras of maximal rank with state–space dimension less than or equal to two. The novelty of their theorem is that there is no assumption on the drift term of the nonlinear filtering system. On the other hand, if the drift term has a potential function (i.e., drift term is a gradient vector field), then the corresponding estimation algebra is called exact. In [TWY], Tam, Wong, and Yau classified all finite-dimensional ex-

act estimation algebras of maximal rank with arbitrary state–space dimension. This paper is a natural continuation of [ChYa]. We shall classify all finite-dimensional estimation algebras of maximal rank with state–space dimension equal to 3 (without any assumption on the drift term). The following is our main theorem.

THEOREM 1 (main theorem). *Suppose that the state space of the filtering system* (2.0) *is of dimension three. If E is the finite-dimensional estimation algebra of maximal rank, then the drift term f must be a linear vector field (i.e., each component is a polynomial of degree one) plus a gradient vector field, and E is a real vector space of dimension eight with bases given by* 1, x_1, x_2, x_3, D_1, D_2, D_3, *and* L_0.

This kind of nonlinear filtering system was studied by Yau [Ya]. Therefore, from the Lie algebraic point of view, we have shown that the finite-dimensional filters considered in [Ya] are the most general.

Let $\omega_{ij} = \frac{\partial f_j}{\partial x_i} - \frac{\partial f_i}{\partial x_j}$, which was first introduced by Wong [Wo2]. Our strategy is to prove ω_{ij} constant for all i, j. Then we can apply the result of [Ya] to finish the proof. This involves two steps. The first step is to prove that ω_{ij} is a degree-one polynomial. The second step is to prove that ω_{ij} is a constant. Let n be the dimension of the state space. Unlike the case $n = 2$, where there is only one unknown, ω_{12}, the case $n = 3$ for the treatment of the first step is more difficult because there are three unknowns: ω_{12}, ω_{13}, and ω_{23}, and they cannot be separated and thus they cannot be treated individually. For the second step, which is the hard part of the paper, we have to introduce a new concept and technique in addition to the method used in [ChYa] to overcome the difficulties.

The paper is in essence a continuation of [Ya], [ChYa], and we strongly recommend that readers familiarize themselves with the results in [Ya], [ChYa]. However, every effort will be made to make this paper as self-contained as possible with minimal duplication of the previous papers.

2. Basic concepts. In this section, we shall recall some basic concepts and results from [Ya]. Consider a filtering problem based on the following signal observation model:

$$\begin{cases} dx(t) = f(x(t))dt + g(x(t))dv(t), & x(0) = x_0, \\ dy(t) = h(x(t))dt + dw(t), & y(0) = 0, \end{cases} \tag{2.0}$$

in which x, v, y, and w are, respectively, $\mathbf{R}^n$-, $\mathbf{R}^p$-, $\mathbf{R}^m$-, and $\mathbf{R}^m$-valued processes, and v and w have components which are independent, standard Brownian processes. We further assume that $n = p, f, h$ are C^∞ smooth, and that g is an orthogonal matrix. We shall refer to $x(t)$ as the state of the system at time t and to $y(t)$ as the observation at time t.

Let $\rho(t, x)$ denote the conditional density of the state given the observation $\{y(s) : 0 \leq s \leq t\}$. It is well known (see [DaMa], for example) that $\rho(t, x)$ is given by normalizing a function, $\sigma(t, x)$, which satisfies the Duncan–Mortensen–Zakai equation.

$$d\sigma(t, x) = L_0\sigma(t, x)dt + \sum_{i=1}^{m} L_i\sigma(t, x)dy_i(t), \qquad \sigma(0, x) = \sigma_0, \tag{2.1}$$

where

$$L_0 = \frac{1}{2}\sum_{i=1}^{n} \frac{\partial^2}{\partial x_i^2} - \sum_{i=1}^{n} f_i \frac{\partial}{\partial x_i} - \sum_{i=1}^{n} \frac{\partial f_i}{\partial x_i} - \frac{1}{2}\sum_{i=1}^{m} h_i^2$$

and for $i = 1, \ldots, m$, L_i is the zero-degree differential operator of multiplication by h_i and σ_0 is the probability density of the initial point x_0. In this paper, we will assume σ_0 is a C^∞ function.

Equation (2.1) is a stochastic partial differential equation. The stochastic differential is a Stratonovich one, not an Ito one. In real applications, we are interested in constructing state estimators from observed sample paths with some property of robustness. Davis [Da] studied this problem and proposed some robust algorithms. In our case, his basic idea reduces to defining a new, unnormalized density

$$\xi(t,x) = \exp\Big(-\sum_{i=1}^{m} h_i(x)y_i(t)\Big)\sigma(t,x).$$

It is easy to show that $\xi(t,x)$ satisfies the following time-varying partial differential equation:

$$\frac{\partial \xi}{\partial t}(t,x) = L_0\xi(t,x) + \sum_{i=1}^{m} y_i(t)[L_0, L_i]\xi(t,x) \cdot \frac{1}{2}\sum_{i=1}^{m}\sum_{j=1}^{m} y_i(t)y_j(t)[[L_0, L_i], L_j]\xi(t,x) \tag{2.2}$$

where $[\cdot,\cdot]$ is the Lie bracket defined as follows.

DEFINITION. *If X and Y are differential operators, the Lie bracket of X and Y, $[X,Y]$, is defined by $[X,Y]\phi = X(Y\phi) - Y(X\phi)$ for any C^∞ function ϕ.*

DEFINITION. *The estimation algebra E of a filtering problem* (2.0) *is defined as the Lie algebra generated by $\{L_0, L_1, \ldots, L_m\}$. E is said to be an estimation algebra of maximal rank if, for any $1 \le i \le n$, there exists a constant c_i such that $x_i + c_i$ is in E.*

Most of the known finite-dimensional estimation algebras are maximal. For example, if the equation (2.0) is linear, i.e., $f(x) = Ax$, $g(x) = B$, and $h(x) = Cx$, and if also (A, B, C) is minimal, then the corresponding estimation algebra is maximal [Ha].

In [Ya], the following proposition is proven.

PROPOSITION 1 (Yau). *$\omega_{ij} = \frac{\partial f_j}{\partial x_i} - \frac{\partial f_i}{\partial x_j}$ are constant functions for all i and j if and only if $(f_1, \ldots, f_n) = (l_1, \ldots, l_n) + (\frac{\partial \phi}{\partial x_1}, \ldots, \frac{\partial \phi}{\partial x_n})$, where $l_1, \ldots, l_n$ are polynomials of degree one and ϕ is a C^∞ function.*

We need the following basic result for later discussion.

THEOREM 2 (Ocone). *Let E be a finite-dimensional estimation algebra. If a function ξ is in E, then ξ is a polynomial of degree ≤ 2.*

Define

$$D_i = \frac{\partial}{\partial x_i} - f_i,$$

$$\eta = \sum_{i=1}^{n} \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^{n} f_i^2 + \sum_{i=1}^{m} h_i^2.$$

Then

$$L_0 = \frac{1}{2}\Big(\sum_{i=1}^{n} D_i^2 - \eta\Big).$$

The following theorem proved in [Ya] plays a fundamental role in the classification of finite-dimensional estimation algebras.

THEOREM 3 (Yau). *Let E be a finite-dimensional estimation algebra of* (2.0) *such that $\omega_{ij} = \frac{\partial f_j}{\partial x_i} - \frac{\partial f_i}{\partial x_j}$ are constant functions. If E is of maximal rank, then E is a real vector space of dimension $2n+2$ with bases given by $1, x_1, x_2, \ldots, x_n, D_1, D_2, \ldots, D_n$, and L_0.*

For the convenience of readers, we also list the following elementary lemmas without proof. The lemmas were proven in [Ya] and [ChYa].

LEMMA 4. (i) $[XY, Z] = X[Y, Z] + [X, Z]Y$ *where X, Y and Z are differential operators.*

(ii) $[gD_i, h] = g\frac{\partial h}{\partial x_i}$, *where $D_i = \frac{\partial}{\partial x_i} - f_i, g$ and h are functions defined on $\mathbf{R}^n$.*

(iii) $[gD_i, hD_j] = -gh\omega_{ij} + g\frac{\partial h}{\partial x_i}D_j - h\frac{\partial g}{\partial x_j}D_i$, *where $\omega_{ji} = [D_i, D_j] = \frac{\partial f_i}{\partial x_j} - \frac{\partial f_j}{\partial x_i}$.*

(iv) $[gD_i^2, h] = 2g\frac{\partial h}{\partial x_i}D_i + g\frac{\partial^2 h}{\partial x_i^2}$.

(v) $[D_i^2, hD_j] = 2\frac{\partial h}{\partial x_i}D_iD_j - 2h\omega_{ij}D_i + \frac{\partial^2 h}{\partial x_i^2}D_j - h\frac{\partial \omega_{ij}}{\partial x_i}$.

(vi) $[D_i^2, D_j^2] = 4\omega_{ji}D_jD_i + 2\frac{\partial \omega_{ji}}{\partial x_j}D_i + 2\frac{\partial \omega_{ji}}{\partial x_i}D_j + \frac{\partial^2 \omega_{ji}}{\partial x_i \partial x_j} + 2\omega_{ji}^2$.

(vii) $[D_k^2, hD_iD_j] = 2\frac{\partial h}{\partial x_k}D_kD_iD_j + 2h\omega_{jk}D_iD_k + 2h\omega_{ik}D_kD_j + \frac{\partial^2 h}{\partial x_k^2}D_iD_j + 2h\frac{\partial \omega_{jk}}{\partial x_i}D_k + h\frac{\partial \omega_{jk}}{\partial x_k}D_i + h\frac{\partial \omega_{ik}}{\partial x_k}D_j + h\frac{\partial^2 \omega_{jk}}{\partial x_i \partial x_k}$.

(viii) $[gD_iD_j, hD_k] = g\frac{\partial h}{\partial x_j}D_iD_k + g\frac{\partial h}{\partial x_i}D_jD_k + gh\omega_{kj}D_i + gh\omega_{ki}D_j + g\frac{\partial^2 h}{\partial x_i \partial x_j}D_k + gh\frac{\partial \omega_{kj}}{\partial x_i} - h\frac{\partial g}{\partial x_k}D_iD_j$.

LEMMA 5. (i) $[L_0, x_j + c_j] = D_j$, *where $L_0 = \frac{1}{2}(\sum_{i=1}^n D_i^2 - \eta)$.*

(ii) $[D_i, x_j + c_j] = \delta_{ij}$.

(iii) $[D_i, D_j] = \omega_{ji}$.

(iv) $Y_j := [L_0, D_j] = \sum_{i=1}^n (\omega_{ji}D_i + \frac{1}{2}\frac{\partial \omega_{ji}}{\partial x_i}) + \frac{1}{2}\frac{\partial \eta}{\partial x_j}$.

(v) $[Y_j, \omega_{kl}] = \sum_{i=1}^n \omega_{ji}\frac{\partial \omega_{kl}}{\partial x_i}$.

(vi) $[Y_j, D_k] = \sum_{i=1}^n (\omega_{ji}\omega_{ki} - \frac{\partial \omega_{ji}}{\partial x_k}D_i) - \frac{1}{2}\sum_{i=1}^n \frac{\partial^2 \omega_{ji}}{\partial x_k \partial x_i} - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_k \partial x_j}$.

Consider $\tilde{x} = Rx$, where R is an orthogonal matrix. Then (2.0) becomes

$$\text{(2.3)} \qquad \begin{cases} d\tilde{x}(t) = \tilde{f}(\tilde{x}(t))dt + \tilde{g}(\tilde{x}(t))d\tilde{v}(t), & \tilde{x}(0) = \tilde{x}_0 := Rx_0, \\ d\tilde{y}(t) = \tilde{h}(\tilde{x}(t))dt + d\tilde{w}(t), & \tilde{y}(0) = 0, \end{cases}$$

where

$$\tilde{f}(\tilde{x}) = Rf(x),\ \tilde{g}(\tilde{x}) = Rg(x),$$
$$\tilde{v} = v, \qquad \tilde{w} = w,$$
$$\tilde{y} = y, \qquad \tilde{h}(\tilde{x}) = h(x).$$

It was observed for instance in [TWY] and [ChYa] that $\tilde{L}_0 = \frac{1}{2}\sum_{i=1}^n \frac{\partial^2}{\partial \tilde{x}_i^2} - \sum_{i=1}^n \tilde{f}_i \frac{\partial}{\partial \tilde{x}_i} - \sum_{i=1}^n \frac{\partial \tilde{f}_i}{\partial \tilde{x}_i} - \frac{1}{2}\sum_{i=1}^m \tilde{h}_m^2$ is equal to L_0. Hence the Lie algebra $\tilde{E} = \langle \tilde{L}_0, \tilde{L}_1, \ldots, \tilde{L}_m \rangle_{L.A.}$ is isomorphic to $E = \langle L_0, L_1, \ldots, L_m \rangle_{L.A.}$.

Let $\Omega = (\omega_{ij})$ and $\tilde{\Omega} = (\tilde{\omega}_{ij})$ where $\omega_{ij} = \frac{\partial f_j}{\partial x_i} - \frac{\partial f_i}{\partial x_j}$ and $\tilde{\omega}_{ij} = \frac{\partial \tilde{f}_j}{\partial \tilde{x}_i} - \frac{\partial \tilde{f}_i}{\partial \tilde{x}_j}$. It was shown in [ChYa] that the following lemma is true.

LEMMA 6. $\tilde{\Omega} = R\Omega R^{-1}$.

3. Proof of the main theorem. In this section, we shall classify all finite-dimensional estimation algebras with maximal rank for dimension of state space equal to three. By Lemma 5, we know that ω_{ij} is in E and in view of Ocone's result, ω_{ij} is a polynomial of degree at most two for all i, j. The first step is to prove ω_{ij} is a

degree-one polynomial for all i, j. This step was carried out in detail in our Conference on Decision and Control paper [YaLe]. So we have

$$\begin{pmatrix} \omega_{12} \\ \omega_{13} \\ \omega_{23} \end{pmatrix} = \begin{pmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} + \begin{pmatrix} c_{12} \\ c_{13} \\ c_{23} \end{pmatrix}.$$

Now we have to deal with the hard part of the proof. We are going to prove that ω_{ij}'s are constants. For this, we introduce an invariant $r_{\max}$ of the estimation algebra E as follows.

DEFINITION. *Let $p(x)$ be a quadratic polynomial. The rank of $p(x), r(p)$ is defined as the rank of the Hessian matrix $(\frac{\partial^2 p}{\partial x_i \partial x_j})$.*

Denote

$$\begin{aligned} Q &= \text{space of homogeneous polynomials of degree 2,} \\ P_i &= \text{space of polynomials of degree at most } i, \\ U_k &= \text{space of differential operators with order at most } k. \end{aligned}$$

LEMMA 7. *Let E be a finite-dimensional estimation algebra of maximal rank. Then $P_1 \subseteq E$. If $p(x)$ is a polynomial of degree two in E, then the homogeneous degree-two part of $p(x)$ is also in E.*

Proof. This follows immediately from Lemma 5 and the definition of maximal rank. □

DEFINITION. *Let $E_Q = E \cap Q$. Define $r_{\max} = \text{Max}\{\text{rank } p(x) : p(x) \in E_Q\}$.*

Remark. Observe that $r_{\max}$ is invariant under orthogonal change of coordinates and $0 \leq r_{\max} \leq 3$ in this paper.

3.1. Case $r_{\max} = 3$. There exists homogeneous $p(x) \in E$ with rank $(p(x)) = 3$. By applying an orthogonal change of coordinates, if necessary, we may assume without loss of generality that

$$p(x) = k_1 x_1^2 + k_2 x_2^2 + k_3 x_3^2,$$

where $k_i \neq 0$ for $i = 1, 2, 3$. There are three possibilities.

Case I: all k_i's are distinct. By Lemmas 4 and 5,

$$\begin{aligned} [D_i^2, x_j^2] &= \delta_{ij}(4x_j D_j + 2), \\ [L_0, p(x)] &= \frac{1}{2}\sum_{i=1}^{3}[D_i^2, p(x)] = \sum_{j=1}^{3}(2k_j x_j D_j + 1). \end{aligned}$$

So $\sum_{j=1}^{3} k_j x_j D_j \in E$ and

$$\left[\sum_{i=1}^{3} k_i x_i D_i, \frac{1}{2}p(x)\right] = \sum_{i=1}^{3} k_i^2 x_i^2 \in E.$$

Replacing $p(x)$ by $\sum_{i=1}^{3} k_i^2 x_i^2$, we deduce that $\sum_{i=1}^{3} k_i^3 x_i^2 \in E$. Since the matrix

$$\begin{pmatrix} k_1 & k_2 & k_3 \\ k_1^2 & k_2^2 & k_3^2 \\ k_1^3 & k_2^3 & k_3^3 \end{pmatrix}$$

is nonsingular, we conclude that $x_1^2, x_2^2, x_3^2 \in E$. Now for $i \neq j$,

$$\begin{aligned}[[L_0, x_i^2], [L_0, x_j^2] &= [2x_iD_i + 1, 2x_jD_j + 1]] \\ &= -4x_ix_j\omega_{ij} \in E.\end{aligned}$$

Since $x_ix_j\omega_{ij}$ is a polynomial of degree at most 2 by Ocone's result, we deduce that ω_{ij} is constant.

Case II: two of the k_i's are equal. In this case we may take $p(x) = k_1x_1^2 + k_2(x_2^2 + x_3^2)$. By evaluating $[[L_0, p(x)], p(x)]$, we can obtain $k_1^2x_1^2 + k_2^2(x_2^2 + x_3^2) \in E$. It follows that $x_1^2 \in E$ and $x_2^2 + x_3^2 \in E$. Since $[L_0, x_i^2] = 2x_iD_i + 1$, we have $x_1D_1, x_2D_2 + x_3D_3 \in E$. So we have

$$\begin{aligned}&- [x_1D_1, x_2D_2 + x_3D_3] = x_1x_2\omega_{12} + x_1x_3\omega_{13} \\ &= a_{11}x_1^2x_2 + a_{21}x_1^2x_3 + a_{12}x_1x_2^2 + a_{23}x_1x_3^2 + (a_{13} + a_{22})x_1x_2x_3 \qquad \mod P_2 \\ &\in E.\end{aligned}$$

By Ocone's result, $[x_1D_1, x_2D_2 + x_3D_3] \in P_2$. We deduce immediately that

$$a_{11} = a_{21} = a_{12} = a_{23} = 0, \quad a_{13} + a_{22} = 0.$$

Furthermore, from the cyclic relation $\frac{\partial\omega_{12}}{\partial x_3} + \frac{\partial\omega_{23}}{\partial x_1} + \frac{\partial\omega_{31}}{\partial x_2} = 0$, we have $a_{13} + a_{31} - a_{22} = 0$ and

$$A = \begin{pmatrix} 0 & 0 & -a_{22} \\ 0 & a_{22} & 0 \\ 2a_{22} & a_{32} & a_{33} \end{pmatrix}.$$

Recall that

$$\begin{aligned}Y_1 &= [L_0, D_1] = \omega_{12}D_2 + \omega_{13}D_3 \qquad \mod U_0, \\ Y_2 &= [L_0, D_2] = \omega_{21}D_1 + \omega_{23}D_3 \qquad \mod U_0, \\ Y_3 &= [L_0, D_3] = \omega_{31}D_1 + \omega_{32}D_2 \qquad \mod U_0.\end{aligned}$$

Then

$$\begin{aligned}&\frac{1}{2}[Y_2, x_2^2 + x_3^2] = \omega_{23}x_3 = a_{31}x_1x_3 + a_{32}x_2x_3 + a_{33}x_3^2 \qquad \mod P_1 \\ &- \frac{1}{2}[Y_3, x_2^2 + x_3^2] = \omega_{23}x_2 = a_{31}x_1x_2 + a_{32}x_2^2 + a_{33}x_2x_3 \qquad \mod P_1, \\ &\left[x_1D_1, \frac{1}{2}[Y_2, x_2^2 + x_3^2]\right] = a_{31}x_1x_3 \qquad \mod U_0, \\ &a_{31}(x_1D_3 + x_3D_1), a_{31}x_1x_3] = a_{31}^2(x_1^2 + x_3^2) \qquad \mod P_0.\end{aligned}$$

Choose k such that $k \neq \pm a_{31}^2, 0$. Then $a_{31}^2(x_1^2 + x_3^2) + k(x_2^2 + x_3^2) = a_{31}^2x_1^2 + kx_2^2 + (a_{31}^2 + k)x_3^2$ is in E. If $a_{31} \neq 0$, then we are back in Case I and we are done. So we have $a_{31} = 0 = a_{13} = a_{22}$ and

$$A = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & a_{32} & a_{33} \end{pmatrix}.$$

$a_{31} = 0$ implies $a_{32}x_2x_3 + a_{33}x_3^2$ and $a_{32}x_2^2 + a_{33}x_2x_3$ are in E.

$$
\begin{aligned}
&[L_0, a_{32}x_2x_3 + a_{33}x_3^2] = a_{32}(x_2D_3 + x_3D_2) + a_{33}(2x_3D_3 + 1)\\
&\qquad \Rightarrow a_{32}x_3D_2 + (a_{32}x_2 + 2a_{33}x_3)D_3 \in E,\\
&[L_0, a_{32}x_2^2 + a_{33}x_2x_3] = a_{32}(2x_2D_2 + 1) + a_{33}(x_2D_3 + x_3D_2)\\
&\qquad \Rightarrow (2a_{32}x_2 + a_{33}x_3)D_2 + a_{33}x_2D_3 \in E,\\
&[a_{32}x_3D_2 + (a_{32}x_2 + 2a_{33}x_3)D_3, a_{32}x_2x_3 + a_{33}x_3^2]\\
&\qquad = a_{32}^2x_3^2 + a_{32}x_2(a_{32}x_2 + 2a_{33}x_3) + 2a_{33}x_3(a_{32}x_2 + 2a_{33}x_3)\\
&\qquad = a_{32}^2x_2^2 + 4a_{32}a_{33}x_2x_3 + (a_{32}^2 + 4a_{33}^2)x_3^2 \in E, \qquad (3.1)\\
&[(2a_{32}x_2 + a_{33}x_3)D_2 + a_{33}x_2D_3, a_{32}x_2^2 + a_{33}x_2x_3]\\
&\qquad = (2a_{32}x_2 + a_{33}x_3)^2 + a_{33}^2x_2^2\\
&\qquad = (a_{33}^2 + 4a_{32}^2)x_2^2 + 4a_{32}a_{33}x_2x_3 + a_{33}^2x_3^2 \in E. \qquad (3.2)
\end{aligned}
$$

From (3.1) and (3.2), we have

$$(-a_{33}^2 - 3a_{32}^2)x_2^2 + (a_{32}^2 + 3a_{33}^2)x_3^2 \in E.$$

Recall that $x_2^2 + x_3^2 \in E$. If

$$\det \begin{pmatrix} 1 & 1 \\ -a_{33}^2 - 3a_{32}^2 & a_{32}^2 + 3a_{33}^2 \end{pmatrix} = 4(a_{32}^2 + a_{33}^2)$$

is nonzero, then x_2^2 and x_3^2 are in E. So ω_{ij} = constant for all i, j in view of the argument in Case I. On the other hand if the determinant above is zero, then $a_{32}^2 + a_{33}^2 = 0$, which implies $a_{32} = a_{33} = 0$. So $A = 0$, which means that ω_{ij}'s are constants.

Case III: all k_i's are the same. In this case, we may take $p(x) = x_1^2 + x_2^2 + x_3^2 \in E$. If there exists quadratic form $q(x)$ with $0 < \operatorname{rank}(q(x)) < 3$, we can find an orthogonal transformation R such that

$$
\begin{aligned}
q(x) &\longmapsto \tilde{q}(\tilde{x}) = \tilde{x}_1^2 \quad \text{or} \quad \tilde{x}_1^2 + \tilde{x}_2^2,\\
p(x) &\longmapsto \tilde{p}(\tilde{x}) = \tilde{x}_1^2 + \tilde{x}_2^2 + \tilde{x}_3^2,
\end{aligned}
$$

so that $\tilde{E}$ contains either $\tilde{x}_1^2, \tilde{x}_2^2 + \tilde{x}_3^2$ or $\tilde{x}_1^2 + \tilde{x}_2^2, \tilde{x}_3^2$, for which the proof in Case II works. Therefore we shall assume without loss of generality that $E_Q = \langle x_1^2 + x_2^2 + x_3^2 \rangle$.

Recall from Lemma 5, $Y_j = \sum_{i=1}^3 \omega_{ji}D_i \bmod U_0$ is in E.

$$
\begin{aligned}
&[Y_1, p(x)] = [\omega_{12}D_2 + \omega_{13}D_3, p(x)] = 2(x_2\omega_{12} + x_3\omega_{13})\\
&\qquad = 2(a_{11}x_1x_2 + a_{12}x_2^2 + a_{13}x_2x_3 + a_{21}x_1x_3 + a_{22}x_2x_3 + a_{23}x_3^2) \mod P_1.
\end{aligned}
$$

So $a_{11}x_1x_2 + a_{12}x_2^2 + (a_{13} + a_{22})x_2x_3 + a_{21}x_1x_3 + a_{23}x_3^2$ is in E_Q and hence equal to $c_1(x_1^2 + x_2^2 + x_3^2)$. Comparing coefficients of x_1^2 allows us to conclude that $c_1 = 0$. Thus $a_{11} = a_{21} = a_{12} = a_{23} = 0, a_{13} + a_{22} = 0$, and

$$A = \begin{pmatrix} 0 & 0 & a_{13} \\ 0 & -a_{13} & 0 \\ a_{31} & a_{32} & a_{33} \end{pmatrix}.$$

Similarly,

$$\begin{aligned}[Y_2, p(x)] &= [\omega_{21}D_1 + \omega_{23}D_3, p(x)] = 2(-x_1\omega_{12} + x_3\omega_{23}) \\ &= 2(-a_{11}x_1^2 - a_{12}x_1x_2 - a_{13}x_1x_3 + a_{31}x_1x_3 + a_{32}x_2x_3 + a_{33}x_3^2) \mod P_1 \\ &= 2((a_{31} - a_{13})x_1x_3 + a_{32}x_2x_3 + a_{33}x_3^2) \mod P_1.\end{aligned}$$

So $(a_{31} - a_{13})x_1x_3 + a_{32}x_2x_3 + a_{33}x_3^2$ is in E_Q and hence equal to $c_2(x_1^2 + x_2^2 + x_3^2)$. Thus $c_2 = 0$ and $a_{32} = a_{33} = 0, a_{31} = a_{13}$.

$$A = a_{13}\begin{pmatrix} 0 & 0 & 1 \\ 0 & -1 & 0 \\ 1 & 0 & 0 \end{pmatrix}.$$

Finally, the cyclic relation $\frac{\partial\omega_{12}}{\partial x_3} + \frac{\partial\omega_{23}}{\partial x_1} + \frac{\partial\omega_{31}}{\partial x_2} = 0$ allows us to conclude that $a_{13} = 0$. Therefore A is a zero matrix and we are done.

3.2. Case $r_{\max} = 2$. There exists homogeneous polynomial $p(x) \in E$ with $\operatorname{rank}(p(x)) = 2$. Without loss of generality, we shall assume that

$$p(x) = k_1x_1^2 + k_2x_2^2,$$

where $k_1k_2 \neq 0$. We remark that E cannot contain x_3^2 since $r_{\max} = 2$.

Case I: $k_1 \neq k_2$. By evaluating $[[L_0, p(x)], p(x)]$, we can obtain $k_1^2x_1^2 + k_2^2x_2^2$ in E. It follows that x_1^2, x_2^2 are in E.

$$\begin{aligned}&[L_0, x_1^2] = 2x_1D_1 + 1 \qquad \text{and} \qquad [L_0, x_2^2] = 2x_2D_2 + 1 \\ &\Rightarrow x_1D_1 \in E \qquad \text{and} \qquad x_2D_2 \in E \\ &\Rightarrow x_1x_2\omega_{12} = -[x_1D_1, x_2D_2] \in E \\ &\Rightarrow \omega_{12} = c_{12} = \text{constant} \qquad \text{by Ocone's result.}\end{aligned}$$

LEMMA 8. *Suppose that x_1D_1, x_2D_2 are in E. If $q(x) = q_{11}x_1^2 + q_{12}x_1x_2 + q_{13}x_1x_3 + q_{22}x_2^2 + q_{23}x_2x_3 + q_{33}x_3^2$ is in E, then each individual $q_{ij}x_ix_j$ is in E.*

Proof.

$$\begin{aligned}[x_1D_1, q(x)] &= x_1\frac{\partial q}{\partial x_1} = 2q_{11}x_1^2 + q_{12}x_1x_2 + q_{13}x_1x_3 \\ [x_1D_1, [x_1D_1, q(x)]] &= 4q_{11}x_1^2 + q_{12}x_1x_2 + q_{13}x_1x_3.\end{aligned}$$

These imply $q_{11}x_1^2 \in E$ and $q_{12}x_1x_2 + q_{13}x_1x_3 \in E$.

$$[x_2D_2, q_{12}x_1x_2 + q_{13}x_1x_3] = q_{12}x_1x_2 \in E.$$

This implies $q_{13}x_1x_3 \in E$.

$$\begin{aligned}&[x_2D_2, q_{22}x_2^2 + q_{23}x_2x_3 + q_{33}x_3^2 = 2q_{22}x_2^2 + q_{23}x_2x_3 \in E \\ &[x_2D_2, 2q_{22}x_2^2 + q_{23}x_2x_3] = 4q_{22}x_2^2 + q_{23}x_2x_3 \in E.\end{aligned}$$

These imply $q_{22}x_2^2 \in E, q_{23}x_2x_3 \in E$ and $q_{23}x_3^2 \in E$. □

We now claim that $x_1x_3 \notin E$. If $x_1x_3 \in E$, then

$$\begin{aligned}
&[L_0, x_1x_3] = \frac{1}{2}[D_1^2 + D_2^2 + D_3^2, x_1x_3] = x_3D_1 + x_1D_3 \in E \\
&\Rightarrow\ [x_1D_3 + x_3D_1, x_1x_3] = x_1^2 + x_3^2 \in E \\
&\Rightarrow\ x_1^2 + x_2^2 + x_3^2 \in E \qquad \text{and} \qquad \operatorname{rank}(x_1^2 + x_2^2 + x_3^2) = 3.
\end{aligned}$$

This gives a contradiction. So we conclude that $x_1x_3 \notin E$. Similarly we conclude that $x_2x_3 \notin E$. Clearly $x_3^2 \notin E$. In view of Lemma 8, we have

$$\langle x_1^2, x_2^2 \rangle \subseteq E_Q \subseteq \langle x_1^2, x_2^2, x_1x_2 \rangle.$$

By Lemma 5,

$$-[x_1D_1, D_3] = x_1\omega_{13} = a_{21}x_1^2 + a_{22}x_1x_2 + a_{23}x_1x_3 \in E.$$

In view of Lemma 8, we have $a_{23}x_1x_3 \in E$, which implies $a_{23} = 0$. Similarly,

$$[x_2D_2, D_3] = x_2\omega_{23} = a_{31}x_1x_2 + a_{32}x_2^2 + a_{33}x_2x_3 \in E$$

implies $a_{33} = 0$. Then

$$A = \begin{pmatrix} 0 & 0 & 0 \\ a_{21} & a_{22} & 0 \\ a_{31} & a_{32} & 0 \end{pmatrix}.$$

Let $Z_1 = x_1D_1$,

$$\begin{aligned}
Z_2 :=& [L_0, Z_1] = \frac{1}{2}\sum_{i=1}^{3}\left(2\frac{\partial x_1}{\partial x_i}D_iD_1 - 2x_1\omega_{i1}D_i\right) \mod U_0 \\
=& D_1^2 + c_{12}x_1D_2 + x_1\omega_{13}D_3 \mod U_0, \\
Z_3 :=& [L_0, Z_2] = \frac{1}{2}\sum_{i=1}^{3}[D_i^2, D_1^2 + c_{12}x_1D_2 + x_1\omega_{13}D_3] \mod U_1 \\
=& \sum_{i=1}^{3}\left(2\omega_{1i}D_iD_1 + \frac{\partial(c_{12}x_1)}{\partial x_i}D_iD_2 + \frac{\partial(x_1\omega_{13})}{\partial x_i}D_iD_3\right) \mod U_1 \\
=& 2\omega_{12}D_2D_1 + 2\omega_{13}D_3D_1 + c_{12}D_1D_2 + \left(\omega_{13} + x_1\frac{\partial\omega_{13}}{\partial x_1}\right)D_1D_3 \\
&+ x_1\frac{\partial\omega_{23}}{\partial x_2}D_2D_3 \mod U_1 \\
=& 3c_{12}D_1D_2 + (4a_{21}x_1 + 3a_{22}x_2 + 3c_{13})D_1D_3 + a_{32}x_1D_2D_3 \mod U_1, \\
[Z_3, Z_1] =& [3c_{12}D_1D_2 + (4a_{21}x_1 + 3a_{22}x_2 + 3c_{13})D_1D_3 + a_{32}x_1D_2D_3, x_1D_1] \\
&\mod U_1 \\
=& 3c_{12}D_1D_2 + (4a_{21}x_1 + 3a_{22}x_2 + 3c_{13})D_1D_3 - 4a_{21}x_1D_1D_3 - a_{32}x_1D_2D_3 \\
&\mod U_1 \\
=& 3c_{12}D_1D_2 + 3a_{22}x_2 + 3c_{13})D_1D_3 - a_{32}x_1D_2D_3 \mod U_1 \\
Z_4 =& \frac{1}{2}[Z_3, Z_1] + \frac{1}{2}Z_3 = 3c_{12}D_1D_2 + (2a_{21}x_1 + 3a_{22}x_2 + 3c_{13})D_1D_3 \mod U_1, \\
[Z_4, Z_1] =& [3c_{12}D_1D_2 + (2a_{21}x_1 + 3a_{22}x_2 + 3c_{13})D_1D_3, x_1D_1] \mod U_1
\end{aligned}$$

$$
\begin{aligned}
&= 3c_{12}D_1D_2 + (2a_{21}x_1 + 3a_{22}x_2 + 3c_{13})D_1D_3 - 2a_{21}x_1D_1D_3 \mod U_1\\
&= 3c_{12}D_1D_2 + (3a_{22}x_2 + 3c_{13})D_1D_3 \mod U_1,\\
Z_5 &= \frac{1}{2}(Z_4 - [Z_4, Z_1]) = a_{21}x_1D_1D_3 \mod U_1,\\
[L_0, Z_5] &= \frac{1}{2}[D_1^2 + D_2^2 + D_3^2, a_{21}x_1D_1D_3] \mod U_2\\
&= a_{21}D_1^2D_3 \mod U_2,\\
[[L_0, Z_5], Z_5] &= [a_{21}D_1^2D_3, a_{21}x_1D_1D_3] \mod U_3\\
&= a_{21}^2D_1^2D_3^2 \mod U_3.
\end{aligned}
$$

By induction, we get infinite elements in E of the form

$$(-1)^n Ad_{Z_5}^n(L_0) = a_{21}^n D_1^2 D_3^n \mod U_{n+1}.$$

Since E is finite dimensional, we conclude that

$$a_{21} = 0. \tag{3.3}$$

$$
\begin{aligned}
W_1 &:= x_2D_2 \in E\\
W_2 &:= [L_0, W_1] = \frac{1}{2}\sum_{i=1}^{3}[D_i^2, x_2D_2] \mod U_0\\
&= \frac{1}{2}\sum_{i=1}^{3}\left(2\frac{\partial x_2}{\partial x_i}D_iD_2 - 2x_1\omega_{i2}D_i\right) \mod U_0\\
&= D_2^2 - x_1c_{12}D_1 + x_1\omega_{23}D_3 \mod U_0,\\
W_3 &:= [L_0, W_2]\\
&= \frac{1}{2}\sum_{i=1}^{3}[D_i^2, D_2^2 - c_{12}x_1D_1 + x_1\omega_{23}D_3] \mod U_1\\
&= \sum_{i=1}^{3}\left(2\omega_{2i}D_iD_2 - \frac{\partial(c_{12}x_1)}{\partial x_i}D_iD_1 + \frac{\partial(x_1\omega_{23})}{\partial x_i}D_iD_3\right) \mod U_1\\
&= 2\omega_{21}D_1D_2 + 2\omega_{23}D_3D_2 - c_{12}D_1^2 + \left(\omega_{23} + x_1\frac{\partial\omega_{23}}{\partial x_1}\right)D_1D_3\\
&\quad + x_1\frac{\partial\omega_{23}}{\partial x_2}D_2D_3 \mod U_1\\
&= (-2a_{22}x_2)D_1D_2 + (2a_{31}x_1 + 2a_{32}x_2)D_2D_3 - c_{12}D_1^2\\
&\quad + (2a_{31}x_1 + a_{32}x_2)D_1D_3 + a_{32}x_1D_2D_3 \mod U_1\\
&= (-2a_{22}x_2)D_1D_2 + [(2a_{31} + a_{32})x_1 + 2a_{32}x_2]D_2D_3 - c_{12}D_1^2 \qquad (3.4)\\
&\quad + (2a_{31}x_1 + a_{32}x_2)D_1D_3 \mod U_1,\\
[W_3, W_1] &= [(-2a_{22}x_2)D_1D_2 + ((2a_{31} + a_{32})x_1 + 2a_{32}x_2)D_2D_3 - c_{12}D_1^2\\
&\quad + (2a_{31}x_1 + a_{32}x_2)D_1D_3, x_2D_2] \mod U_1\\
&= -2a_{22}x_2D_1D_2 + ((2a_{31} + a_{32})x_1 + 2a_{32}x_2)D_2D_3 + 2a_{22}x_2D_1D_2\\
&\quad - 2a_{32}x_2D_2D_3 - a_{32}x_2D_1D_3 \mod U_1\\
&= (2a_{31} + a_{32})x_1D_2D_3 - a_{32}x_2D_1D_3 \mod U_1,
\end{aligned}
$$

$$
\begin{aligned}
[[W_3, W_1], Z_1] &= [(2a_{31} + a_{32}x_1D_2D_3 - a_{32}x_2D_1D_3, x_1D_1] \mod U_1 \\
&= -a_{32}x_2D_1D_3 - (2a_{31} + a_{32})x_1D_2D_3 \mod U_1 \\
-\frac{1}{2}([W_3, W_1] + [[W_3, W_1], Z_1]) &= a_{32}x_2D_1D_3 \mod U_1. \qquad (3.5) \\
\frac{1}{2}([W_3, W_1] - [[W_3, W_1], Z_1]) &= (2a_{31} + a_{32})x_1D_2D_3 \mod U_1. \qquad (3.6)
\end{aligned}
$$

It follows from (3.4), (3.5), and (3.6) that

$$
\begin{aligned}
W_4 &:= -2a_{22}x_2D_1D_2 + 2a_{32}x_2D_2D_3 - c_{12}D_1^2 + 2a_{31}x_1D_1D_3 \mod U_1, \\
[W_4, Z_1] &= [-2a_{22}x_2D_1D_2 + 2a_{32}x_2D_2D_3 - c_{12}D_1^2 + 2a_{31}x_1D_1D_3, x_1D_1] \\
&\quad \mod U_1 \\
&= -2a_{22}x_2D_1D_2 - 2c_{12}D_1^2 \mod U_1, \\
W_5 &:= -\frac{1}{2}[W_4, Z_1] \mod U_1 \\
&= a_{22}x_2D_1D_2 + c_{12}D_1^2 \mod U_1, \\
[L_0, W_5] &= \frac{1}{2}[D_1^2 + D_2^2 + D_3^2, a_{22}x_2D_1D_2 + c_{12}D_1^2] \mod U_2 \\
&= a_{22}D_1D_2^2 \mod U_2, \\
[[L_0, W_5], W_5] &= [a_{22}D_1D_2^2, a_{22}x_2D_1D_2 + c_{12}D_1^2] \mod U_3 \\
&= 2a_{22}^2D_1^2D_2^2 \mod U_3.
\end{aligned}
$$

By induction, we have

$$(-1)^n Ad_{W_5}^n(L_0) = 2^{n-1}a_{22}^n D_1^n D_2^2 \mod U_{n+1}.$$

Since E is finite dimensional, we conclude that

$$a_{22} = 0. \qquad (3.7)$$

By the cyclic relation $\frac{\partial \omega_{12}}{\partial x_3} + \frac{\partial \omega_{23}}{\partial x_1} + \frac{\partial \omega_{31}}{\partial x_2} = 0$, we get

$$a_{13} + a_{31} - a_{22} = 0.$$

From (3.3) and (3.7), we get $a_{31} = 0$. It follows that

$$
\begin{aligned}
W_4 &= 2a_{32}x_2D_2D_3 - c_{12}D_1^2 \mod U_1, \\
\left[L_0, \frac{1}{2}W_4\right] &= \frac{1}{2}\left[D_1^2 + D_2^2 + D_3^2, a_{32}x_2D_2D_3 - \frac{1}{2}c_{12}D_1^2\right] \mod U_2 \\
&= a_{32}D_2^2D_3 \mod U_2, \\
\left[\left[L_0, \frac{1}{2}W_4\right], \frac{1}{2}W_4\right] &= \left[a_{32}D_2^2D_3, a_{32}x_2D_2D_3 - \frac{1}{2}c_{12}D_1^2\right] \mod U_3 \\
&= 2a_{32}^2D_2^2D_3^2 \mod U_3, \\
(-1)^n Ad_{\frac{1}{2}W_4}^n(L_0) &= 2^{n-1}a_{32}^n D_2^2 D_3^n \mod U_{n+1}.
\end{aligned}
$$

Since E is finite dimensional, we have $a_{32} = 0$. Therefore, the ω_{ij}'s are constants for all i, j.

Case II: $k_1 = k_2$. Without loss of generality, we may take $p(x) = x_1^2 + x_2^2$. In view of Case I, we shall assume that E does not contain x_1^2, x_2^2.

LEMMA 9. *Under the Case* II *assumption,* $\langle x_1^2 + x_2^2 \rangle \subseteq E_Q \subseteq \langle x_1^2, x_2^2, x_1x_2 \rangle$.

Proof. Let $q(x) \in E_Q$. Then

$$q(x) = q_{11}x_1^2 + q_{22}x_2^2 + q_{33}x_3^2 + q_{12}x_1x_2 + q_{13}x_1x_3 + q_{23}x_2x_3.$$

Recall that $x_1D_1 + x_2D_2$ is in E. By applying $x_1D_1 + x_2D_2$ repeatedly to $q(x)$, we see immediately that $q_{11}x_1^2 + q_{22}x_2^2 + q_{12}x_1x_2$, $q_{13}x_1x_3 + q_{23}x_2x_3, q_{33}x_3^2 \in E$. These imply $q_{33} = 0$ (since $r_{\max} = 2$) and $\frac{1}{2}(x_1^2 + x_2^2) + (q_{13}x_1x_3 + q_{23}x_2x_3) \in E$.

$$Hess\left[\frac{1}{2}(x_1^2 + x_2^2) + (q_{13}x_1x_3 + q_{23}x_2x_3)\right] = \begin{pmatrix} 1 & 0 & q_{13} \\ 0 & 1 & q_{23} \\ q_{13} & q_{23} & 0 \end{pmatrix}.$$

The determinant of the above matrix is $-(q_{13}^2 + q_{23}^2)$. Since $r_{\max} = 2 < 3$, we have $q_{13}^2 + q_{23}^2 = 0$ which implies $q_{13} = 0 = q_{23}$. □

We deduce from Lemma 9 that $1 \leq \dim E_Q \leq 3$.

If $\dim E_Q = 3$, then $E_Q = \langle x_1^2, x_2^2, x_1x_2 \rangle$ and we are in Case I.

If $\dim E_Q = 2$, then we may take $E_Q = \langle x_1^2 + x_2^2, q_{11}x_1^2 + q_{12}x_1x_2 \rangle$. If $q_{12} = 0$, then E_Q contains both x_1^2 and x_2^2 and we are back in Case I. Therefore we can assume that $q_{12} \neq 0$. Furthermore if $q_{11} = 0$, then E_Q is actually $\langle x_1^2 + x_2^2, x_1x_2 \rangle$. We consider the following particular orthogonal transformation:

$$\tilde{x} = Rx \qquad R = \begin{pmatrix} \frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} & 0 \\ \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & 0 \\ 0 & 0 & 1 \end{pmatrix},$$

such that it gives rise to

$$\begin{aligned} x &= R^T\tilde{x} \\ x_1^2 + x_2^2 &\longmapsto \tilde{x}_1^2 + \tilde{x}_2^2 \\ x_1x_2 &\longmapsto \frac{\tilde{x}_1^2 + \tilde{x}_2^2}{\sqrt{2}} \frac{-\tilde{x}_1^2 + \tilde{x}_2^2}{\sqrt{2}} = \frac{-\tilde{x}_1^2 + \tilde{x}_2^2}{2} \\ E_Q &\longmapsto \tilde{E}_Q = \left\langle \tilde{x}_1^2 + \tilde{x}_2^2, \frac{-\tilde{x}_1^2 + \tilde{x}_2^2}{2} \right\rangle = \langle \tilde{x}_1^2, \tilde{x}_2^2 \rangle. \end{aligned}$$

Thus, $\tilde{E}$ contains $\tilde{x}_1^2$ and $\tilde{x}_2^2$. By Case I, the $\tilde{\omega}_{ij}$'s are constants and so are the ω_{ij}'s as $\Omega = R^T\tilde{\Omega}R$. Hence we may also assume that $q_{11} \neq 0$. So $E_Q = \langle x_1^2 + x_2^2, x_1^2 + 2kx_1x_2 \rangle$ for $k \neq 0$. Observe that if we can find a quadratic form $p_0 \in E_Q$ with $r(p_0) = 1$, then there exists an orthogonal transformation such that E_Q is mapped into $\tilde{E}_Q$, which contains both $\tilde{x}_1^2$ and $\tilde{x}_2^2$, and we are done. So we try to find such a p_0 below. Consider

$$p_0 = \lambda(x_1^2 + x_2^2) + \sigma(x_1^2 + 2kx_1x_2).$$

Its underlying symmetric matrix is

$$A_{p_0} = \lambda \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + \sigma \begin{pmatrix} 1 & k \\ k & 0 \end{pmatrix} = \begin{pmatrix} \lambda + \sigma & \sigma k \\ \sigma k & \lambda \end{pmatrix}$$

and $\det A_{p_0} = \lambda^2 + \sigma\lambda - \sigma^2 k^2$. Fix $\sigma \neq 0$ (say $\sigma = k$) and choose

$$\lambda = \sigma \frac{-1 + \sqrt{1+4k^2}}{2}.$$

Then $r(p_0) = 1$. We are done for $\dim E_Q = 2$.

If $\dim E_Q = 1$, then $E_Q = \langle x_1^2 + x_2^2 \rangle$. Recall from Lemma 5 that Y_j's are in E where $Y_1 = \omega_{12}D_2 + \omega_{13}D_3 \bmod U_0$, $Y_2 = \omega_{21}D_1 + \omega_{23}D_3 \bmod U_0$, and $Y_3 = \omega_{31}D_1 + \omega_{32}D_2 \bmod U_0$.

$$\begin{aligned}
\frac{1}{2}[Y_1, x_1^2 + x_2^2] &= x_2\omega_{12} = a_{11}x_1x_2 + a_{12}x_2^2 + a_{13}x_1x_3 \mod P_1 \\
&\Rightarrow \quad a_{11}x_1x_2 + a_{12}x_2^2 + a_{13}x_1x_3 \in E_Q = \langle x_1^2 + x_2^2 \rangle \\
&\Rightarrow \quad a_{11} = a_{12} = a_{13} = 0, \\
-\frac{1}{2}[Y_3, x_1^2 + x_2^2] &= x_1\omega_{13} + x_2\omega_{23} \\
&= a_{21}x_1^2 + (a_{22} + a_{31})x_1x_2 + a_{32}x_2^2 + a_{23}x_1x_3 + a_{33}x_2x_3 \mod P_1 \\
&\Rightarrow \quad a_{21}x_1^2 + (a_{22} + a_{31})x_1x_2 + a_{32}x_2^2 + a_{23}x_1x_3 + a_{33}x_2x_3 \in \langle x_1^2 + x_2^2 \rangle \\
&\Rightarrow \quad a_{21} = a_{32}, a_{22} + a_{31} = 0, a_{23} = a_{33} = 0.
\end{aligned}$$

By the cyclic relation $\frac{\partial \omega_{12}}{\partial x_3} + \frac{\partial \omega_{23}}{\partial x_1} + \frac{\partial \omega_{31}}{\partial x_2} = 0$, we have $a_{13} + a_{31} - a_{22} = 0$. It follows that $a_{22} = a_{31} = 0$ and

$$A = a_{21} \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}.$$

In order to prove that $a_{21} = 0$, we consider the following sequence of elements in E.

$$\begin{aligned}
K_1 &:= x_1D_1 + x_2D_2, \\
K_2 &:= [L_0, K_1] = \frac{1}{2}\sum_{i=1}^{3}[D_i^2, x_1D_1] + \frac{1}{2}\sum_{i=1}^{3}[D_i^2, x_2D_2] \mod U_0 \\
&= D_1^2 + x_1\omega_{12}D_2 + x_1\omega_{13}D_3 + D_2^2 + x_2\omega_{21}D_1 + x_2\omega_{23}D_3 \mod U_0 \\
&= D_1^2 + D_2^2 + x_2\omega_{21}D_1 + x_1\omega_{12}D_2 + (x_1\omega_{13} + x_2\omega_{23})D_3 \mod U_0, \\
K_3 &:= [L_0, K_2] \\
&= \frac{1}{2}\sum_{i=1}^{3}[D_i^2, D_1^2 + D_2^2 + x_2\omega_{21}D_1 + x_1\omega_{12}D_2 + (x_1\omega_{13} + x_2\omega_{23})D_3] \\
&\quad \bmod U_1 \\
&= 2(\omega_{12}D_1D_2 + \omega_{13}D_1D_3 + \omega_{21}D_2D_1 + \omega_{23}D_2D_3) \\
&\quad - c_{12}D_2D_1 + c_{12}D_1D_2 \\
&\quad + (\omega_{13}D_1D_3 + a_{21}x_1D_1D_3 + \omega_{23}D_2D_3 + a_{32}x_2D_2D_3) \mod U_1 \\
&= (3\omega_{13} + a_{21}x_1)D_1D_3 + (3\omega_{23} + a_{21}x_2)D_2D_3 \mod U_1 \\
&= 4a_{21}(x_1D_1 + x_2D_2)D_3 \mod U_1, \\
(-1)Ad_{K_3}(K_2) &= [K_2, K_3] \\
&= [D_1^2 + D_2^2, 4a_{21}(x_1D_1 + x_2D_2)D_3] \mod U_2 \\
&= 4a_{21}([D_1^2, x_1D_1] + [D_2^2, x_2D_2])D_3 \mod U_2 \\
&= 8a_{21}(D_1^2 + D_2^2)D_3 \mod U_2.
\end{aligned}$$

Inductively, we have

$$(-1)Ad^n_{K_3}(K_2) = (8a_{21})^n(D_1^2 + D_2^2)D_3^n \mod U_{n+1}.$$

Since $\dim E < \infty$, $a_{21} = 0$ and we have $A = 0$. So ω_{ij}'s are constant for all i, j.

3.3. Case $r_{\max} = 1$. In this case, we may assume that $p(x) = x_1^2 \in E$ and $E_Q = \langle x_1^2 \rangle$.

$$[Y_2, p(x)] = [\omega_{21}D_1 + \omega_{23}D_3, x_1^2] = 2\omega_{21}x_1 \in E_Q$$
$$[Y_3, p(x)] = [\omega_{31}D_1 + \omega_{32}D_2, x_1^2] = 2\omega_{31}x_1 \in E_Q.$$

Thus, ω_{12} and ω_{13} depend only on x_1 because $E_Q = \langle x_1^2 \rangle$. So

$$A = \begin{pmatrix} a_{11} & 0 & 0 \\ a_{21} & 0 & 0 \\ a_{31} & a_{32} & a_{33} \end{pmatrix}.$$

The cyclic relation $\frac{\partial \omega_{12}}{\partial x_3} + \frac{\partial \omega_{23}}{\partial x_1} + \frac{\partial \omega_{31}}{\partial x_2} = 0$ implies $a_{31} = 0$ and implies $a_{31} = 0$ and

$$A = \begin{pmatrix} a_{11} & 0 & 0 \\ a_{21} & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

Now $x_1^2 \in E$ implies $x_1 D_1 \in E$. Let

$$\begin{aligned}
X_1 &:= x_1 D_1, \\
X_2 &:= [L_0, X_1] = \frac{1}{2}\sum_{i=1}^{3}[D_i^2, x_1 D_1] \mod U_0 \\
&= \frac{1}{2}\sum_{i=1}^{3}\left(2\frac{\partial x_1}{\partial x_i}D_iD_1 - 2x_1\omega_{i1}D_i + \frac{\partial^2 x_1}{\partial x_i^2}D_1\right) \mod U_0 \\
&= D_1^2 + x_1\omega_{12}D_2 + x_1\omega_{13}D_3 \mod U_0 \\
&= D_1^2 + (a_{11}x_1^2 + c_{12}x_1)D_2 + (a_{21}x_1^2 + c_{13}x_1)D_3 \mod U_0 \\
&= D_1^2 \mod U_1, \\
X_3 &:= [L_0, X_2] \\
&= \frac{1}{2}\sum_{i=1}^{3}[D_i^2, D_1^2 + (a_{11}x_1^2 + c_{12}x_1)D_2 + (a_{21}x_1^2 + c_{13}x_1)D_3] \mod U_1 \\
&= \sum_{i=1}^{3}\left(2\omega_{1i}D_1D_i + \frac{\partial(a_{11}x_1^2 + c_{12}x_1)}{\partial x_i}D_iD_2 + \frac{\partial(a_{21}x_1^2 + c_{13}x_1)}{\partial x_i}D_iD_3\right) \mod U_1 \\
&= 2(a_{11}x_1 + c_{12})D_1D_2 + 2(a_{21}x_1 + c_{13})D_1D_3 + (2a_{11}x_1 + c_{12})D_1D_2 \\
&\quad + (2a_{21}x_1 + c_{13})D_1D_3 \mod U_1 \\
&= (4a_{11}x_1 + 3c_{12})D_1D_2 + (4a_{21}x_1 + 3c_{13})D_1D_3 \mod U_1.
\end{aligned}$$

We are going to show that $a_{11} = 0$. Suppose $a_{11} \neq 0$. Denote $a = \frac{a_{21}}{a_{11}}$ and define

$$\alpha := \frac{1}{4a_{11}}X_3 = \left(x_1 + \frac{3c_{12}}{a_{11}}\right)D_1D_2 + \left(ax_1 + \frac{3c_{13}}{a_{11}}\right)D_1D_3 \mod U_1.$$

LEMMA 10. *If* $a_{11} \neq 0$, *let* $\alpha := \frac{1}{4a_{11}} X_3, a = \frac{a_{21}}{a_{11}}$. *Then for* $j \geq 1$

$$\frac{(-1)^j Ad_\alpha^j(X_2)}{2^j} = D_1^2(D_2 + aD_3)^j \mod U_{j+1}.$$

Proof. We shall prove this by induction.

$$\begin{aligned}
\frac{(-1)Ad_\alpha(X_2)}{2} &= \frac{1}{2}[X_2, \alpha] \\
&= \frac{1}{2}\left[D_1^2, \left(x_1 + \frac{3c_{12}}{a_{11}}\right)D_1D_2 + \left(ax_1 + \frac{3c_{13}}{a_{11}}\right)D_1D_3\right] \mod U_2 \\
&= \frac{\partial}{\partial x_1}\left(x_1 + \frac{3c_{12}}{a_{11}}\right)D_1^2D_2 + \frac{\partial}{\partial x_1}\left(ax_1 + \frac{3c_{13}}{a_{11}}\right)D_1^2D_3 \mod U_2 \\
&= D_1^2(D_2 + aD_3) \mod U_2, \\
\frac{(-1)^{j+1}Ad_\alpha^{j+1}(X_2)}{2^{j+1}} &= \left(-\frac{1}{2}\right)Ad_\alpha \frac{(-1)^j Ad_\alpha^j(X_2)}{2^j} \\
&= \frac{1}{2}\left[\frac{(-1)^j Ad_\alpha^j(X_2)}{2^j}, \alpha\right] \\
&= \frac{1}{2}\left[D_1^2(D_2 + aD_3)^j, \left(x_1 + \frac{3c_{13}}{a_{11}}\right)D_1D_2 + \left(ax_1 + \frac{3c_{13}}{a_{11}}\right)D_1D_3\right] \\
&\quad \mod U_{j+2} \\
&= D_1^2(D_2 + aD_3)^j D_2 + aD_1^2(D_2 + aD_3)^j D_3 \mod U_{j+2} \\
&= D_1^2(D_2 + aD_3)^j(D_2 + aD_3) \mod U_{j+2} \\
&= D_1^2(D_2 + aD_3)^{j+1} \mod U_{j+2}. \qquad \square
\end{aligned}$$

The above lemma implies that E is infinite dimensional, contradicting the finite-dimensionality of E. Hence $a_{11} = 0$. Then

$$\begin{aligned}
A &= \begin{pmatrix} 0 & 0 & 0 \\ a_{21} & 0 & 0 \\ 0 & a_{32} & a_{33} \end{pmatrix}, \\
X_2 &= D_1^2 + c_{12}x_1D_2 + (a_{21}x_1^2 + c_{13}x_1)D_3 \mod U_0, \\
X_3 &= 3c_{12}D_1D_2 + (4a_{21}x_1 + 3c_{13})D_1D_3 \mod U_1.
\end{aligned}$$

Next we shall see that $a_{21} = 0$. Suppose $a_{21} \neq 0$. Consider

$$\begin{aligned}
\beta := \frac{1}{4a_{21}}X_3 &= \frac{3c_{12}}{4a_{21}}D_1D_2 + \left(x_1 + \frac{3c_{13}}{4a_{21}}\right)D_1D_3 \mod U_1, \\
(-1)Ad_\beta(X_2) = [X_2, \beta] &= \left[D_1^2, \frac{3c_{12}}{4a_{21}}D_1D_2 + \left(x_1 + \frac{3c_{13}}{4a_{21}}\right)D_1D_3\right] \mod U_2 \\
&= 2D_1^2D_3 \mod U_2.
\end{aligned}$$

We claim that $(-1)^j Ad_\beta^j(X_2) = 2^j D_1^2 D_3^j \mod U_{j+1}$. This can be seen by induction.

$$\begin{aligned}
(-1)^{j+1}Ad_\beta^{j+1}(X_2) &= (-1)Ad_\beta((-1)Ad_\beta^j(X_2)) \\
&= [(-1)^j Ad_\beta^j(X_2), \beta] \\
&= \left[2^j D_1^2 D_3^j, \frac{3c_{12}}{4a_{21}}D_1D_2 + \left(x_1 + \frac{3c_{13}}{4a_{21}}\right)D_1D_3\right] \mod U_{j+2} \\
&= 2^{j+1}D_1^2D_3^{j+1} \mod U_{j+2}.
\end{aligned}$$

Then E contains an infinite-dimensional subspace, which is impossible. Hence $a_{21} = 0$ and

$$A = \begin{pmatrix} o & o & o \\ 0 & 0 & 0 \\ 0 & a_{32} & a_{33} \end{pmatrix}.$$

Consider the expression of $[Y_j, D_k]$ in Lemma 5(vi). Noting that ω_{ij}'s are linear, the following elements belong to E:

$$K_{jk} = \sum_{i=1}^{3} \omega_{ji}\omega_{ki} - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_k \partial x_j}.$$

K_{jk} is symmetric about j, k (Table 1) and is a polynomial of degree at most two, which in turn forces η to be a polynomial of degree at most four.

TABLE 1.

(j,k)	K_{jk}
(1,1)	$\omega_{12}^2 + \omega_{13}^2 - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_1^2}$
(1,2)	$\omega_{13}\omega_{23} - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_1 \partial x_2}$
(1,3)	$\omega_{12}\omega_{32} - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_1 \partial x_3}$
(2,2)	$\omega_{21}^2 + \omega_{23}^2 - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_2^2}$
(2,3)	$\omega_{21}\omega_{31} - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_2 \partial x_3}$
(3,3)	$\omega_{31}^2 + \omega_{32}^2 - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_3^2}$

Recall our notation:

$$\begin{pmatrix} \omega_{12} \\ \omega_{13} \\ \omega_{23} \end{pmatrix} = A \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} + \begin{pmatrix} c_{12} \\ c_{13} \\ c_{23} \end{pmatrix}, \qquad A = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & a_{32} & a_{33} \end{pmatrix}.$$

Since $K_{jk} \in P_2$ and $E_Q = \langle x_1^2 \rangle$ in this case $r_{\max} = 1$, we have

$$K_{jk} = k x_1^2 \mod P_1.$$

So we can form the following relationships:

$$\begin{aligned} \frac{1}{2}\frac{\partial^2 \eta}{\partial x_2^2} &= a_{32}^2 x_2^2 + 2a_{32}a_{33}x_2x_3 + a_{33}x_3^2 + a x_1^2 \mod P_1, \\ \frac{1}{2}\frac{\partial^2 \eta}{\partial x_3^2} &= a_{32}^2 x_2^2 + 2a_{32}a_{33}x_2x_3 + a_{33}x_3^2 + b x_1^2 \mod P_1, \\ \frac{1}{2}\frac{\partial^2 \eta}{\partial x_2 \partial x_3} &= c x_1^2 \mod P_1. \end{aligned}$$

Observe that the term $a_{33}x_3^2$ in $\frac{1}{2}\frac{\partial^2 \eta}{\partial x_2^2}$ must come from the $x_2^2 x_3^2$ term in η. Let η contain the term $\alpha x_2^2 x_3^2$. Since

$$\frac{1}{2}\frac{\partial^2 \alpha x_2^2 x_3^2}{\partial x_2^2} = \alpha x_3^2, \quad \frac{1}{2}\frac{\partial^2 \alpha x_2^2 x_3^2}{\partial x_3^2} = \alpha x_2^2, \quad \frac{1}{2}\frac{\partial^2 \alpha x_2^2 x_3^2}{\partial x_2 \partial x_3} = 2\alpha x_2 x_3,$$

by comparing coefficients we obtain

$$\alpha = a_{33}^2, \quad \alpha = a_{32}^2, \quad 2\alpha = 0.$$

So, $a_{32} = a_{33} = 0$ and accordingly

$$\Omega = O_{3\times 3} \mod P_0.$$

Hence Case $r_{\max} = 1$ is done.

3.4. Case $r_{\max} = 0$. In this case $E_Q = \phi$. All functions in E are automatically linear.

Recall that

$$m_{jk} = -\sum_{i=1}^{3} \omega_{ji}\omega_{ki} + \frac{1}{2}\frac{\partial^2 \eta}{\partial x_k \partial x_j} \in E_Q.$$

This expression is written in element form. It's more insightful to view it in matrix form.

Let $M = (m_{jk})_{3\times 3}$ and note that the Ω matrix is antisymmetric. Then we have

$$\begin{aligned} M &= -\Omega\Omega^T + \frac{1}{2}Hess(\eta) \\ &= \Omega^2 + \frac{1}{2}Hess(\eta), \end{aligned}$$

where $Hess(\eta) = (\frac{\partial^2 \eta}{\partial x_k \partial x_j})_{3\times 3}$ is the Hessian matrix of η.

Let $\Omega = Dx_1 + Bx_2 + Cx_3 \pmod{P_0}$, where $D = (\alpha_{ij})_{3\times 3}, B = (\beta_{ij})_{3\times 3}, C = (\gamma_{ij})_{3\times 3}$ are skew-symmetric matrices. We make use of $\Omega^2 + \frac{1}{2}Hess(\eta) = 0 \mod P_1$ to infer that $D = B = C = (0)_{3\times 3}$ as follows. Writing

$$\begin{aligned} H =& \Omega^2 \\ =& H_{11}x_1^2 + H_{22}x_2^2 + H_{33}x_3^2 + H_{12}x_1x_2 + H_{13}x_1x_3 + H_{23}x_2x_3 \\ =& D^2x_1^2 + B^2x_2^2 + C^2x_3^2 + (DB + BD)x_1x_2 + (DC + CD)x_1x_3 \\ &+ (BC + CB)x_2x_3, \end{aligned}$$

we have

$$H_{11} = D^2 = -DD^T, \qquad \text{where} \quad D = \begin{pmatrix} 0 & \alpha_{12} & \alpha_{13} \\ -\alpha_{12} & 0 & \alpha_{23} \\ -\alpha_{13} & -\alpha_{23} & 0 \end{pmatrix}.$$

So

$$H_{11} = -\begin{pmatrix} \alpha_{12}^2 + \alpha_{13}^2 & \alpha_{13}\alpha_{23} & -\alpha_{12}\alpha_{23} \\ \alpha_{13}\alpha_{23} & \alpha_{12}^2 + \alpha_{23}^2 & \alpha_{12}\alpha_{13} \\ -a_{12}a_{23} & a_{12}a_{13} & a_{13}^2 + a_{23}^2 \end{pmatrix}.$$

The other H_{ij} matrices can be obtained similarly and they are listed explicitly at the end of this section.

We consider terms in η and relationships derived from $\Omega^2 + \frac{1}{2}Hess(\eta) = 0 \mod P_1$ in terms of entries in H_{ij} matrices. The coefficient of $x_1^2x_2^2$ in $-\eta = H_{11}[2,2] =$

$H_{22}[1,1] = \frac{1}{2}H_{12}[1,2]$. Similarly, $H_{11}[3,3] = H_{33}[1,1] = \frac{1}{2}H_{13}[1,3]$ and $H_{22}[3,3] = H_{33}[2,2] = H_{23}[2,3]$ ($H_{ij}[p,q]$ means the (p,q)-entry of matrix H_{ij}). We have

$$\alpha_{12}^2 + \alpha_{23}^2 = \beta_{12}^2 + \beta_{13}^2 = \frac{1}{2}(\alpha_{13}\beta_{23} + \alpha_{23}\beta_{13}), \tag{3.8}$$

$$\alpha_{13}^2 + \alpha_{23}^2 = \gamma_{12}^2 + \gamma_{13}^2 = -\frac{1}{2}(\alpha_{12}\gamma_{23} + \alpha_{23}\gamma_{12}), \tag{3.9}$$

$$\beta_{13}^2 + \beta_{23}^2 = \gamma_{12}^2 + \gamma_{23}^2 = \frac{1}{2}(\beta_{12}\gamma_{13} + \beta_{13}\gamma_{12}). \tag{3.10}$$

Together with the simple majorization relationship between any two real numbers, $2ab \le a^2 + b^2$, we can rewrite (3.8), (3.9) and (3.10) to obtain

$$\begin{aligned}
2(\alpha_{12}^2 + \alpha_{23}^2 + \beta_{12}^2 + \beta_{13}^2) &= 2(\alpha_{13}\beta_{23} + \alpha_{23}\beta_{13}) \le \alpha_{13}^2 + \beta_{23}^2 + \alpha_{23}^2 + \beta_{13}^2, \\
2(\alpha_{13}^2 + \alpha_{23}^2 + \gamma_{12}^2 + \gamma_{13}^2) &= -2(\alpha_{12}\gamma_{23} + \alpha_{23}\gamma_{12}) \le \alpha_{12}^2 + \gamma_{23}^2 + \alpha_{23}^2 + \gamma_{12}^2, \\
2(\beta_{13}^2 + \beta_{23}^2 + \gamma_{12}^2 + \gamma_{23}^2) &= 2(\beta_{12}\gamma_{13} + \beta_{13}\gamma_{12}) \le \beta_{12}^2 + \gamma_{13}^2 + \beta_{13}^2 + \gamma_{12}^2.
\end{aligned}$$

Summing these three inequalities and simplifying, we have

$$\alpha_{12}^2 + \alpha_{13}^2 + 2\alpha_{23}^2 + \beta_{12}^2 + 2\beta_{13}^2 + \beta_{23}^2 + 2\gamma_{12}^2 + \gamma_{13}^2 + \gamma_{23}^2 \le 0,$$

which implies that

$$\alpha_{12} = \alpha_{13} = \alpha_{23} = \beta_{12} = \beta_{13} = \beta_{23} = \gamma_{12} = \gamma_{13} = \gamma_{23} = 0,$$

i.e.,

$$D = B = C = O_{3\times 3}.$$

Hence

$$\Omega = O_{3\times 3} \mod P_0.$$

Case $r_{\max} = 0$ is done.

For reference we list the H_{ij} matrices below:

$$H_{11} = -\begin{pmatrix} \alpha_{12}^2 + \alpha_{13}^2 & \alpha_{13}\alpha_{23} & -\alpha_{12}\alpha_{23} \\ \alpha_{13}\alpha_{23} & \alpha_{12}^2 + \alpha_{23}^2 & \alpha_{12}\alpha_{13} \\ -\alpha_{12}\alpha_{23} & \alpha_{12}\alpha_{13} & \alpha_{13}^2 + \alpha_{23}^2 \end{pmatrix};$$

$$H_{22} = -\begin{pmatrix} \beta_{12}^2 + \beta_{13}^2 & \beta_{13}\beta_{23} & -\beta_{12}\beta_{23} \\ \beta_{13}\beta_{23} & \beta_{12}^2 + \beta_{23}^2 & \beta_{12}\beta_{13} \\ -\beta_{12}\beta_{23} & \beta_{12}\beta_{13} & \beta_{13}^2 + \beta_{23}^2 \end{pmatrix};$$

$$H_{33} = -\begin{pmatrix} \gamma_{12}^2 + \gamma_{13}^2 & \gamma_{13}\gamma_{23} & -\gamma_{12}\gamma_{23} \\ \gamma_{13}\gamma_{23} & \gamma_{12}^2 + \gamma_{23}^2 & \gamma_{12}\gamma_{13} \\ -\gamma_{12}\gamma_{23} & \gamma_{12}\gamma_{13} & \gamma_{13}^2 + \gamma_{23}^2 \end{pmatrix};$$

$$H_{12} = -\begin{pmatrix} 2\alpha_{12}\beta_{12} + 2\alpha_{13}\beta_{13} & \alpha_{13}\beta_{23} + a_{23}b_{13} & -\alpha_{12}\beta_{23} - \beta_{23}\beta_{12} \\ \alpha_{13}\beta_{23} + \alpha_{23}\beta_{13} & 2\alpha_{12}\beta_{12} + 2\alpha_{23}\beta_{23} & \alpha_{12}\beta_{13} + \alpha_{13}\beta_{12} \\ -\alpha_{12}\beta_{23} - \alpha_{23}\beta_{12} & \alpha_{12}\beta_{13} + \alpha_{13}\beta_{12} & 2\alpha_{13}\beta_{13} + 2\alpha_{23}\beta_{23} \end{pmatrix};$$

$$H_{13} = -\begin{pmatrix} 2\alpha_{12}\gamma_{12} + 2\alpha_{13}\gamma_{13} & \alpha_{13}\gamma_{23} + \alpha_{23}\gamma_{13} & -\alpha_{12}\gamma_{23} - \alpha_{23}\gamma_{12} \\ \alpha_{13}\gamma_{23} + \alpha_{23}\gamma_{13} & 2\alpha_{12}\gamma_{12} + 2\alpha_{23}\gamma_{23} & \alpha_{12}\gamma_{13} + \alpha_{13}\gamma_{12} \\ -\alpha_{12}\gamma_{23} - \alpha_{23}\gamma_{12} & \alpha_{12}\gamma_{13} + \alpha_{13}\gamma_{12} & 2\alpha_{13}\gamma_{13} + 2\alpha_{23}\gamma_{23} \end{pmatrix};$$

$$H_{23} = -\begin{pmatrix} 2\beta_{12}\gamma_{12} + 2\beta_{13}\gamma_{13} & \beta_{13}\gamma_{23} + \beta_{23}\gamma_{13} & -\beta_{12}\gamma_{23} - \beta_{23}\gamma_{12} \\ \beta_{13}\gamma_{23} + \beta_{23}\gamma_{13} & 2\beta_{12}\gamma_{12} + 2\beta_{23}\gamma_{23} & \beta_{12}\gamma_{13} + \beta_{13}\gamma_{12} \\ -\beta_{12}\gamma_{23} - \beta_{23}\gamma_{12} & \beta_{12}\gamma_{13} + \beta_{13}\gamma_{12} & 2\beta_{13}\gamma_{13} + 2\beta_{23}\gamma_{23} \end{pmatrix}.$$

Acknowledgments. We would like to thank the referee for many helpful comments, especially for pointing out the very interesting Ph.D. thesis by M. Cohen de Lara [La], in which the links between finite-dimensional estimation algebras and finite-dimensional filters were discussed.

DYNAMIC PROGRAMMING FOR NONLINEAR SYSTEMS DRIVEN BY ORDINARY AND IMPULSIVE CONTROLS*

MONICA MOTTA† AND FRANCO RAMPAZZO†

Abstract. A dynamic programming approach is considered for a class of minimum problems with impulses. The minimization domain consists of trajectories satisfying an ordinary differential equation whose right-hand side depends not only on a measurable control v but also on a second control u and on its time derivative $\dot{u}$. For this reason, the control u and the differential equation are called *impulsive*.

The value function of the considered minimum problem turns out to depend on the time, the state, the u variable, and the variation allowed to the impulsive control. It is shown that the value function satisfies, in a generalized sense, a dynamic programming equation (DPE), which is obtained from a dynamic programming principle involving space–time trajectories. Moreover the value function is the unique map-solving equation (DPE) satisfying either an inequality condition or a supersolution condition at each point of the boundary. Incidentally this extends a result by Barron, Jensen, and Menaldi [Nonlinear Anal., 21 (1993), pp. 241–268], where the impulsive control is scalar monotone and the corresponding vector field is independent of the state variable. Next, a maximum principle is proved, and the well-known relationship between adjoint variables and value function is suitably extended to impulsive control systems. A fully elaborated example concludes the paper.

Key words. impulsive control, minimum problem, dynamic programming

1. Introduction.

The optimal control problem. This paper concerns the dynamic programming approach to minimum problems involving impulsive control systems of the form

$$\text{(E)} \qquad \begin{aligned} \dot{x} &= g_0(t,x,u,v) + \sum_{i=1}^{m} g_i(t,x,u,v)\dot{u}_i, \\ x(\bar{t}) &= \bar{x}, \end{aligned}$$

where the state x belongs to $\mathbb{R}^n$ and the controls u and v map a time interval $[\bar{t}, T]$ into a closed subset $U \subset \mathbb{R}^m$ and a compact subset $V \subset \mathbb{R}^q$, respectively. Moreover u is subject to the directional constraint $\dot{u} \in C$, where $C \subset \mathbb{R}^m$ is a closed cone. Optimum problems involving a dynamics of the form (E) arise in applications to rational mechanics [13]–[15], [35], economics [17], space navigation [25], [29], [33], and advertising strategy [20], [39].

Because of the presence of the derivative $\dot{u}$ on the right-hand side of (E) the state can jump in consequence of a discontinuity of the control u. However, the notion of solution to (E) is provided by the Carathéodory theory of ordinary differential equations only if the control u is absolutely continuous. Moreover, it is known—see, e.g., [9]–[12], [19], [21], [23], [28], [30], [32], [37], [41]—that whenever the fields $g_1, \ldots, g_m$ depend on x, u, and v, a mere measure-theoretic extension of this notion to the case of a discontinuous u does not agree with elementary requirements of continuity

† Dipartimento di Matematica Pura e Applicata, Università di Padova, via Belzoni 7, I-35131 Padova, Italy (motta@pdmath1.math.unipd.it), (rampazzo@pdmath1.math.unipd.it).

of the input–output map. In order to overcome this difficulty, in [10], [32], [34] one extends system (E) to the space–time system

$$x' = g_0(t,x,u,v)t' + \sum_{i=1}^{m} g_i(t,x,u,v)u_i', \tag{STE}$$

where the *controls* $t(s), u(s)$ are Lipschitz continuous and the superscript denotes differentiation with respect to the pseudo–time parameter $s \in [0,1]$. In this space–time setting a discontinuous control $u(t)$ is regarded as the space projection of a space–time control $t(s), u(s)$ whose first component $t(s)$ is allowed to be nondecreasing. We just recall—see, e.g., [10], [30], [32], [37]—that, because of the noncommutativity of the vector fields $g_1, \dots, g_m$, the evolution of x depends on the particular space–time control $t(s), u(s)$ which *completes* the graph of $u(t)$. Incidentally we remark that in the standard impulse control theory there is no need of considering space–time controls. Indeed, in that case the fields $g_1, \dots, g_m$ $(m = n)$ coincide with the canonical basis; in particular they commute. As a consequence each completion of a control u produces the same trajectory which in turn coincides with the unique trajectory resulting from the measure–theoretic approach; see, e.g., [3].

As a prototype of a minimum problem initially formulated for the original system (E) we consider an unconstrained Mayer problem with finite horizon and a bound on the total variation of u.

More precisely, let $\Phi : \mathbb{R}^n \times U \to \mathbb{R}$ be a continuous map, C be a closed cone of $\mathbb{R}^m$, and $K > 0$ be an upper bound for the total variation of the control u. For every $(\bar{t}, \bar{x}, \bar{u}, \bar{k}) \in [0,T) \times \mathbb{R}^n \times U \times [0,K]$, we consider the following problem:

$$(\mathcal{P}_{(\bar{t},\bar{x},\bar{u},\bar{k})}) \qquad \text{minimize } \{\Phi(x(T), u(T))\}$$

over all end points $(x(T), u(T))$ of (E) corresponding to control policies $(u(\cdot), v(\cdot))$, where $v : [\bar{t}, T] \to V$ is a Borel-measurable map and $u : [\bar{t}, T] \to U$ is an absolutely continuous map which satisfies

$$u(\bar{t}) = \bar{u}, \quad V_{\bar{t}}^{T}(u) \le K - \bar{k}, \quad \text{and} \quad \dot{u}(t) \in C \text{ for a.e. } t \in [\bar{t}, T].$$

($V_{\bar{t}}^{T}(u)$ denotes the total variation of $u(\cdot)$ on the interval $[\bar{t}, T]$.) Since the unbounded control $\dot{u}$ appears linearly on the right-hand side of (E), problem $\mathcal{P}_{(\bar{t},\bar{x},\bar{u},\bar{k})}$ does not display anyone of the standard coercivity assumptions which guarantee the existence of an optimal control. This justifies the introduction of the extended system (STE) and of the corresponding space–time reformulation of problem $\mathcal{P}_{(\bar{t},\bar{x},\bar{u},\bar{k})}$. Actually this extension is *proper*, i.e., the infimum of the original problem turns out to coincide with the infimum of the extended problem. Hence the value functions determined by the two problems coincide. Moreover the set of original controls is dense in the set of space–time controls, and under some further assumptions, there exists an optimal control $(t(s), u(s), v(s))$ for the extended problem; see [32].

The dynamic programming approach. We call *value function* the map $\mathcal{V} : [0,T) \times \mathbb{R}^n \times U \times [0,K] \to \mathbb{R}$ which associates the infimum of problem $\mathcal{P}_{(\bar{t},\bar{x},\bar{u},\bar{k})}$ to every $(\bar{t}, \bar{x}, \bar{u}, \bar{k})$. Actually $\mathcal{V}$ can be identified with the value function corresponding to the extended problem, for the two maps turn out to coincide on $[0,T) \times \mathbb{R}^n \times U \times [0,K]$. Moreover, in the extended setting $\mathcal{V}$ can be defined also at $\bar{t} = T$.

In the particular case when the control u is a scalar nondecreasing map (i.e., $m = 1$, $\dot{u} \in C \doteq \mathbb{R}^+$, and $u \equiv k \in [0,K]$) and the vector field g_1 *does not depend on* x *and* u, the dynamic programming approach has been already pursued by E. N. Barron,

R. Jensen, and J. L. Menaldi [8]. Their main result consisted in proving that the value function $\mathcal{V}$ is the unique continuous map which satisfies (in the viscosity sense) a certain Hamilton–Jacobi–Bellman equation together with the following, quite natural, Dirichlet conditions:

$(BC)_1$ $\mathcal{V}$ coincides with the value function of the corresponding nonimpulsive problem ($\dot{u} = 0$) on the strip $[0,T] \times \mathbb{R}^n \times \{K\}$ (where all the available variation of u has run out);

$(BC)_2$ $\mathcal{V}$ coincides with the value function of the corresponding purely impulsive problem ($g_0 = 0$) on the region $\{T\} \times \mathbb{R}^n \times [0,K]$(where no more time is available).

Moreover, Barron, Jensen, and Menaldi left the following questions as open problems:

a) *Can the well-known relationship between the adjoint variables of the maximum principle and the value function be extended in some way to impulsive problems?*

b) *Can we state a rigorous result (i.e., a verification theorem) which relates the dynamic programming equation with the problem of testing the optimality of a given control?*

c) *What can be said when g_1 depends also on x and u?*

This paper is also a trial to give an answer to the above questions, not only in the scalar control case but also in the general situation where u is vector valued. More precisely, we begin by proving that, under suitable assumptions on the set U and the cone C, the value function $\mathcal{V}$ is continuous on $[0,T] \times \mathbb{R}^n \times U \times [0,K]$. Next, via a dynamic programming principle involving space–time trajectories, we prove that the value function $\mathcal{V}$ is a viscosity solution on $[0,T[\times\mathbb{R}^n \times \overset{\circ}{U} \times [0,K[$ of the dynamic programming equation

$$\text{(DPE)} \qquad -H\left(t,x,u,\frac{\partial \mathcal{V}}{\partial t},\frac{\partial \mathcal{V}}{\partial x},\frac{\partial \mathcal{V}}{\partial u},\frac{\partial \mathcal{V}}{\partial k}\right) = 0,$$

where, for every $(p_t,p_x,p_u,p_k) \in \mathbb{R}^{1+n+m+1}$, the Hamiltonian function H is defined by

$$H(t,x,u,p_t,p_x,p_u,p_k) \doteq \min\left\{ \begin{array}{c} (p_t + p_x \cdot g_0(t,x,u,v))w_0 + \sum_{i=1}^{m}(p_x \cdot g_i(t,x,u,k) + p_{u_i})w_i + p_k|w|, \\ |(w_0,\dots,w_m)| = 1,\ w_0 \geq 0,\ w = (w_1,\dots,w_m) \in C,\ v \in V \end{array} \right\}.$$

Furthermore, $\mathcal{V}$ turns out to be the unique solution of (DPE) satisfying the following boundary conditions:

$(BC)'_1$ $\mathcal{V}$ is a (viscosity) *supersolution* of (DPE) at all points of $[0,T[\times\mathbb{R}^n \times \partial U \times [0,K[\cup [0,T[\times\mathbb{R}^n \times U \times \{K\}$;

$(BC)'_2$ at each boundary point $(T,x,u,k)\mathcal{V} \leq \Phi$ either $\mathcal{V}$ is a supersolution of (DPE) or it satisfies the relation $\mathcal{V}(T,x,u,k) = \Phi(x,u)$.

We remark that, unlike conditions $(BC)_1$ and $(BC)_2$ above, boundary conditions $(BC)'_1$ and $(BC)'_2$ do not involve any auxiliary minimum problem and refer only to the cost function Φ and to equation (DPE).

We also prove a verification theorem (Theorem 5.1), which incidentally provides a possible answer to the open question b) mentioned above.

Finally, by applying standard results to the space–time embedding, we are able to clarify the relationship occurring between the adjoint variables of the maximum principle and the value function $\mathcal{V}$. This provides a possible answer to the open

question a) above, while the answer to question c) is inherent to the general setting of the problem, for the vector fields $g_1, \dots, g_m$ *do depend* on x and u.

The paper ends with a simple, elaborated example where the theoretical results proved throughout the paper are explicitly applied to test the optimality of a feedback control previously computed by means of the maximum principle.

2. The minimum problem. Let us consider the control system

$$\dot{x} = g_0(t,x,u,v) + \sum_{i=1}^{m} g_i(t,x,u,v)\dot{u}_i(t), \tag{2.1}$$

$$x(\bar{t}) = \bar{x}, \qquad u(\bar{t}) = \bar{u} \tag{2.2}$$

defined on a time interval $[\bar{t}, T]$, where the state x ranges in $\mathbb{R}^n$ while the controls u and v take values on a closed arcwise connected subset $U \subset \mathbb{R}^m$ and a compact subset $V \subset \mathbb{R}^q$, respectively. Moreover the control u is subject to the directional constraint $\dot{u} \in C$, where $C \subset \mathbb{R}^m$ denotes a given closed cone.

Let K be a positive constant, and for every $\bar{k} \in [0, K]$ let us define the set

$$W_{K-\bar{k}}(\bar{t},\bar{u}) \doteq \left\{ \begin{array}{l} (u,v) \in AC([\bar{t},T],U) \times \mathcal{B}([\bar{t},T],V) \ : \ u(\bar{t}) = \bar{u}, \\ \dot{u}(t) \in C \text{ for a.e. } t \in [\bar{t},T] \text{ and } V_{\bar{t}}^{T}(u) \le K - \bar{k} \end{array} \right\}, \tag{2.3}$$

where $AC\big([\bar{t},T],U\big)$ denotes the set of absolutely continuous functions from $[\bar{t},T]$ into U, $\mathcal{B}\big([\bar{t},T],V\big)$ is the set of Borel-measurable functions from $[\bar{t},T]$ into V, and $V_{\bar{t}}^{T}(u)$ denotes the total variation of u on the interval $[\bar{t},T]$. We call $W_{K-\bar{k}}(\bar{t},\bar{u})$ the set of *admissible regular controls from* $(\bar{t},\bar{u})$ *such that the variation of* u *is less than or equal to* $K - \bar{k}$.

Let Φ be a continuous function defined on $\mathbb{R}^n \times U$. For any $(\bar{t},\bar{x},\bar{u},\bar{k}) \in [0,T[\times\mathbb{R}^n \times U \times [0,K]$ we consider the following minimum problem of Mayer type:

$$(\mathcal{P}_{(\bar{t},\bar{x},\bar{u},\bar{k})}) \qquad \underset{(u,v)\in W_{K-\bar{k}}(\bar{t},\bar{u})}{\text{minimize}} \Phi\big(x[\bar{t},\bar{x},\bar{u};u,v](T),u(T)\big),$$

where $x[\bar{t},\bar{x},\bar{u};u,v](\cdot)$ denotes the solution of (2.1), (2.2) corresponding to the control (u,v).

Throughout this paper we assume the following hypothesis **(H1)** on the vector fields $g_0, \dots, g_m$ and the function Φ:

(H1) $g_0, \dots, g_m$ and Φ are continuous in all of its variables, and there is a positive constant M such that

$$|g_i(t,x,u,v)| \le M\big(1 + |(x,u)|\big), \quad |\Phi(x,u)| \le M$$
$$\forall (t,x,u,v) \in [0,T] \times \mathbb{R}^n \times U \times V \quad (i = 0, \dots, m).$$

Moreover, for any compact subset $Q \subset \mathbb{R}^n \times U$ there is a constant L such that

$$|g_i(t,x,u,v) - g_i(t,\bar{x},u,v)| \le L|x - \bar{x}|$$
$$\forall (t,x,u,v),(t,\bar{x},u,v) \in [0,T] \times Q \times V \quad (i = 0, \dots, m).$$

In the following discussion, whenever the compact set Q is specified, we will denote by $\omega_{g_0}, \dots, \omega_{g_m}$ and ω_Φ the modulus of uniform continuity of the restrictions of the functions $g_0, \dots, g_m$ and Φ to $[0,T] \times Q \times V$ and Q, respectively.

Remark 2.1. The condition $|\Phi(x,u)| \le M$ implies that the value function is globally bounded, which turns out to be very convenient for applying the theory of viscosity

solutions. On the other hand one can skip such a limitation by replacing the cost function Φ with the bounded cost function $\arctan \Phi$. It is obvious that this transformation will not affect the essential character of the problem.

Since the right-hand side of (2.1) depends linearly on the derivative $\dot{u}$, in general no optimal controls can be found within the class $W_{K-\bar{k}}(\bar{t}, \bar{u})$. Hence, denoting the triple (t, x, u) by y, on the basis of the results in [10], [32], we embed (2.1) into the space–time system

$$y' = \hat{g}_0(y, v)t'(s) + \sum_{i=1}^{m} \hat{g}_i(y, v)u_i'(s) \tag{2.4}$$

together with the initial condition·

$$y(0) = (\bar{t}, \bar{x}, \bar{u}). \tag{2.5}$$

In (2.4) the superscript denotes differentiation with respect to the new parameter $s \in [0, 1]$ and for every $i = 0, \ldots, m$ the vector field $\hat{g}_i$ coincides with the ith column of the $(1 + n + m) \times (1 + m)$ matrix

$$\hat{G}(y, v) \doteq \begin{pmatrix} 1 & 0 & \ldots & 0 \\ g_{0_1} & g_{1_1} & \cdots & g_{m_1} \\ \vdots & \vdots & \ddots & \vdots \\ g_{0_n} & g_{1_n} & \cdots & g_{m_n} \\ 0 & 1 & \ldots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & 1 \end{pmatrix}.$$

DEFINITION 2.1. *The control system* (2.4) *is called the* space–time control system *relative to* (2.1), *and a map*

$$(t, u, v) : [0, 1] \to [\bar{t}, T] \times U \times V$$

is called a space–time control *for* (2.4), (2.5) *whenever the following hold:*

(i) $(t, u)(0) = (\bar{t}, \bar{u})$;

(ii) $(t, u) : [0, 1] \to [\bar{t}, T] \times U$ *is Lipschitz continuous and* $u'(s) \in C$ *for almost every* $s \in [0, 1]$;

(iii) $t : [0, 1] \to [\bar{t}, T]$ *is surjective and nondecreasing*;

(iv) $v : [0, 1] \to V$ *is Borel measurable.*

The set of space–time controls will be denoted by $\Gamma(\bar{t}, \bar{u})$. *A solution of the space–time control system* (2.4) *will be called a* space–time trajectory.

We remark again—see the introduction—that a mere interpretation of the original system (2.1) as an equation in measure would lead to an ill-posed problem, for the dependence of $g_1, \ldots, g_m$ on x and u makes it impossible to define a concept of (univalued) trajectory as a map of the original parameter t.

We refer to the appendix for some basic facts concerning the concept of *canonical parametrization* and the related topology on the set of space–time controls. Briefly, the parametrization of a space–time control (t, u, v) is called canonical if the norm $|(t', u')|$ is constant almost everywhere in $[0, 1]$. Any space–time control can be reparametrized in such a way that the resulting space–time control turns out to be canonical. And, up to reparametrization, the corresponding trajectories coincide (see Proposition A.2).

Observe that after introducing new equations we regard t and u both as state variables and as control variables. This allows us to embed problem $\mathcal{P}_{(\bar{t}, \bar{x}, \bar{u}, \bar{k})}$ into the

extended problem

$$(\mathcal{P}^e_{(\bar t,\bar x,\bar u,\bar k)}) \qquad \underset{(t,u,v)\in\Gamma_{K-\bar k}(\bar t,\bar u)}{\text{minimize}} \Phi\big(y[\bar t,\bar x,\bar u;t,u,v](1)\big),$$

where

$$\Gamma_{K-\bar k}(\bar t,\bar u) \doteq \big\{(t,u,v)\in\Gamma(\bar t,\bar u)\ :\ V_0^1(u)\le K-\bar k\big\} \tag{2.6}$$

is the set of admissible space–time controls and $y[\bar t,\bar x,\bar u;t,u,v](\cdot)$ denotes the solution of (2.4), (2.5) corresponding to the space–time control (t,u,v).

Remark 2.2. We point out that Φ is a function of the only variables (x,u). With abuse of notation we write $\Phi(y)$, where $y=(t,x,u)$, instead of $\Phi(x,u)$, just to remind the reader that we are now referring to the space–time extension (2.4).

It is clear that in the space–time setting the original set $W_{K-\bar k}(\bar t,\bar u)$ of admissible controls has to be identified with the subset $\Gamma^+_{K-\bar k}(\bar t,\bar u)\subset\Gamma_{K-\bar k}(\bar t,\bar u)$ formed by the Lipschitz continuous reparametrizations of the graphs of the elements belonging to $W_{K-\bar k}(\bar t,\bar u)$.

The subset $\Gamma^+_{K-\bar k}(\bar t,\bar u)$ turns out to be dense—see [32] and the Appendix—in the set $\Gamma_{K-\bar k}(\bar t,\bar u)$ of space–time controls.

We now prove that the infimum of the extended problem $\mathcal{P}^e_{(\bar t,\bar x,\bar u,\bar k)}$ coincides with the infimum of the original problem $\mathcal{P}_{(\bar t,\bar x,\bar u,\bar k)}$.

THEOREM 2.1. *For every initial condition* $(\bar t,\bar x,\bar u,\bar k)\in[0,T)\times\mathbb{R}^n\times U\times[0,K]$ *one has*

$$\inf_{(t,u,v)\in\Gamma_{K-\bar k}(\bar t,\bar u)}\Phi\big(y[\bar t,\bar x,\bar u;t,u,v](1)\big)=\inf_{(u,v)\in W_{K-\bar k}(\bar t,\bar u)}\Phi\big(x[\bar t,\bar x,\bar u;u,v](T),u(T)\big). \tag{2.7}$$

Proof. Let $(\bar t,\bar x,\bar u,\bar k)$ be a fixed initial datum and let us observe that Gronwall's lemma, together with the bound on the total variation of u, guarantees that there is some positive constant M' such that

$$\begin{aligned} &|y[\bar t,\bar x,\bar u;t,u,v](s)|\le M',\\ &|g_i\big(y[\bar t,\bar x,\bar u;t,u,v](s),v(s)\big)|\le M'\quad (i=0,\dots,m)\quad\text{for a.e. } s\in[0,1]\end{aligned} \tag{2.8}$$

for all $(t,u,v)\in\Gamma_{K-\bar k}(\bar t,\bar u)$. Hence, setting $Q\doteq B_{n+m}[0,M']\cap\mathbb{R}^n\times U$ (where $B_{n+m}[0,M']$ denotes the closed ball of center 0 and radius M' in $\mathbb{R}^{n+m}$), we can identify the vector fields $g_0,\dots,g_m$ and the function Φ with their restrictions to the compact sets $[0,T]\times Q\times V$ and Q, respectively.

By the definition of $\Gamma^+_{K-\bar k}(\bar t,\bar u)$, proving (2.7) is equivalent to checking that the identity

$$\inf_{(t,u,v)\in\Gamma^+_{K-\bar k}(\bar t,\bar u)}\Phi\big(y[\bar t,\bar x,\bar u;t,u,v](1)\big)=\inf_{(t,u,v)\in\Gamma_{K-\bar k}(\bar t,\bar u)}\Phi\big(y[\bar t,\bar x,\bar u;t,u,v](1)\big)$$

holds true. Hence it suffices to show that

$$\inf_{(t,u,v)\in\Gamma^+_{K-\bar k}(\bar t,\bar u)}\Phi\big(y[\bar t,\bar x,\bar u;t,u,v](1)\big)\le\inf_{(t,u,v)\in\Gamma_{K-\bar k}(\bar t,\bar u)}\Phi\big(y[\bar t,\bar x,\bar u;t,u,v](1)\big). \tag{2.9}$$

Since these infima are bounded, for any $\varepsilon>0$ there is a space–time control $(t,u,v)\in\Gamma_{K-\bar k}(\bar t,\bar u)$ verifying

$$\inf_{(\tilde t,\tilde u,\tilde v)\in\Gamma_{K-\bar k}(\bar t,\bar u)}\Phi\big(y[\bar t,\bar x,\bar u;\tilde t,\tilde u,\tilde v](1)\big)\ge\Phi\big(y[\bar t,\bar x,\bar u;t,u,v](1)\big)-\varepsilon/2. \tag{2.10}$$

Note that on the basis of Proposition A.2 it is not restrictive to assume that the norm $|(t', u')|$ is constant almost everywhere in $[0, 1]$, this constant being less than $K + T$. Then, by setting

$$t_\varepsilon(s) \doteq \bar{t} + (T - \bar{t})\frac{(t(s) - \bar{t}) + s\rho_\varepsilon}{(T - \bar{t} + \rho_\varepsilon)} \qquad \forall s \in [0, 1]$$

for a $\rho_\varepsilon \in (0, (T - \bar{t})/2]$ to be chosen, we obtain a space–time control $(t_\varepsilon, u, v) \in \Gamma^+_{K-\bar{k}}(\bar{t}, \bar{u})$ such that

$$|t_\varepsilon(s) - t(s)| \leq 2\rho_\varepsilon \qquad \forall s \in [0, 1],$$

and the corresponding trajectory $x_\varepsilon \doteq x[\bar{t}, \bar{x}, \bar{u}; t_\varepsilon, u, v]$ satisfies

$$\begin{aligned}
|x_\varepsilon(s) - x(s)| &\leq \int_0^s \big|g_0\big(t_\varepsilon(\sigma), x_\varepsilon(\sigma), u(\sigma), v(\sigma)\big) - g_0\big(t(\sigma), x(\sigma), u(\sigma), v(\sigma)\big)\big| t'(\sigma)\, d\sigma \\
&\quad + \int_0^s \sum_{i=1}^m \big|g_i\big(t_\varepsilon(\sigma), x_\varepsilon(\sigma), u(\sigma), v(\sigma)\big) - g_i\big(t(\sigma), x(\sigma), u(\sigma), v(\sigma)\big)\big|\, |u_i'(\sigma)|\, d\sigma \\
&\qquad + \frac{\rho_\varepsilon}{T - \bar{t} + \rho_\varepsilon} \int_0^s \big|g_0\big(t_\varepsilon(\sigma), x_\varepsilon(\sigma), u(\sigma), v(\sigma)\big)\big| [(T - \bar{t}) + t'(\sigma)]\, d\sigma \\
&\leq (K+T) \sum_{i=0}^m \omega_{g_i}(2\rho_\varepsilon) + (m+1)(K+T)L \int_0^s |x_\varepsilon(\sigma) - x(\sigma)|\, d\sigma + 2\frac{T - \bar{t}}{T - \bar{t} + \rho_\varepsilon} M' \rho_\varepsilon.
\end{aligned}$$

By Gronwall's lemma it follows that

$$\big|\Phi\big(x_\varepsilon(1), u(1)\big) - \Phi\big(x(1), u(1)\big)\big| \leq \omega_\Phi\left((2M'\rho_\varepsilon + (K+T)\sum_{i=0}^m \omega_{g_i}(2\rho_\varepsilon))e^{(m+1)(K+T)L}\right).$$

Hence for a ρ_ε small enough from (2.10) we have

$$\inf_{(\tilde{t}, \tilde{u}, \tilde{v}) \in \Gamma_{K-\bar{k}}(\bar{t}, \bar{u})} \Phi\big(y[\bar{t}, \bar{x}, \bar{u}; \tilde{t}, \tilde{u}, \tilde{v}](1)\big) \geq \Phi\big(x_\varepsilon(1), u(1)\big) - \varepsilon,$$

which by the arbitrariness of $\varepsilon > 0$ yields (2.9). □

3. The value function. In this section we introduce the so-called value function for the problem $\mathcal{P}_{(\bar{t}, \bar{x}, \bar{u}, \bar{k})}$ and study its regularity properties.

DEFINITION 3.1. *The map*

$$\mathcal{F}(\bar{t}, \bar{x}, \bar{u}, \bar{k}) \doteq \inf_{(u,v) \in W_{K-\bar{k}}(\bar{t}, \bar{u})} \Phi\big(x[\bar{t}, \bar{x}, \bar{u}; u, v](T), u(T)\big) \tag{3.1}$$

from $[0, T) \times \mathbb{R}^n \times U \times [0, K]$ *into* $\mathbb{R}$ *is called the* value function of the original minimum problem.

DEFINITION 3.2. *The map*

$$\mathcal{V}(\bar{t}, \bar{x}, \bar{u}, \bar{k}) \doteq \inf_{(t,u,v) \in \Gamma_{K-\bar{k}}(\bar{t}, \bar{u})} \Phi\big(y[\bar{t}, \bar{x}, \bar{u}; t, u, v](1)\big) \tag{3.2}$$

from $[0, T] \times \mathbb{R}^n \times U \times [0, K]$ *into* $\mathbb{R}$ *is called the* value function of the extended minimum problem.

The following result follows from Theorem 2.1.

COROLLARY 3.1. *The value function $\mathcal{F}$ of the original minimum problem is bounded and coincides with the value function $\mathcal{V}$ of the extended minimum problem.*

Let us observe that the value function $\mathcal{V}$ of the extended problem is defined even at time $\bar{t} = T$. Furthermore, in Theorem 3.1 below we show that $\mathcal{V}$ is continuous

provided that one of the following two hypotheses on the cone C and the closed set U holds:

(H2)$_C$ The set U coincides with the whole $\mathbb{R}^m$.

(H2)$_U$ the cone C coincides with the whole $\mathbb{R}^m$; moreover for any $\varepsilon > 0$ and $u_1 \in U$ there exists a $\delta > 0$ such that for each $u_2 \in U \cap B(u_1, \delta)$, there is a path $\gamma_{12} \in AC([0,1], U)$ satisfying $\gamma_{12}(0) = u_1$, $\gamma_{12}(1) = u_2$, and

$$\int_0^1 |\gamma'_{12}(s)|\, ds \leq \varepsilon.$$

THEOREM 3.1. *Let $Q_x \subset \mathbb{R}^n$, $Q_u \subset U$ be compact subsets. Then for every $(\bar{t}, \bar{x}, \bar{u}, \bar{k}) \in [0,T] \times Q_x \times Q_u \times [0,K]$ one has the following:*

i) *the functions $x \mapsto \mathcal{V}(\bar{t}, x, \bar{u}, \bar{k})$, $t \mapsto \mathcal{V}(t, \bar{x}, \bar{u}, \bar{k})$, and $k \mapsto \mathcal{V}(\bar{t}, \bar{x}, \bar{u}, k)$ are continuous on Q_x, $[0,T]$, and $[0,K]$, respectively, uniformly with respect to the remaining variables on $[0,T] \times Q_x \times Q_u \times [0,K]$; furthermore, $k \mapsto \mathcal{V}(\bar{t}, \bar{x}, \bar{u}, k)$ is nondecreasing*;

ii) *in addition, if either hypothesis* **(H2)**$_C$ *or hypothesis* **(H2)**$_U$ *is assumed, then the function $u \mapsto \mathcal{V}(\bar{t}, \bar{x}, u, \bar{k})$ is continuous on Q_u, uniformly with respect to the remaining variables on $[0,T] \times Q_x \times Q_u \times [0,K]$. In particular the value function $\mathcal{V}$ is continuous on its domain.*

Proof. By (2.8) the trajectories starting from points of $[0,T] \times Q_x \times Q_u$ lie in the compact set $[0,T] \times B_{n+m}[Q_x \times Q_u; M'] \cap (\mathbb{R}^n \times U)$. Let ω_{g_i} denote the modulus of uniform continuity of g_i $(i = 0, \ldots, m)$ on $[0,T] \times B_{n+m}[Q_x \times Q_u; M'] \cap (\mathbb{R}^n \times U) \times V$, and let ω_Φ be the modulus of continuity of Φ on $B_{n+m}[Q_x \times Q_u; M'] \cap (\mathbb{R}^n \times U)$.

Let $x_1, x_2 \in Q_x$, and consider the difference

$$\mathcal{V}(\bar{t}, x_2, \bar{u}, \bar{k}) - \mathcal{V}(\bar{t}, x_1, \bar{u}, \bar{k}),$$

which can be assumed nonnegative. For any $\varepsilon > 0$ let $(t, u, v) \in \Gamma_{K-\bar{k}}(\bar{t}, \bar{u})$ be a space–time control satisfying

$$\mathcal{V}(\bar{t}, x_1, \bar{u}, \bar{k}) \geq \Phi\big(y[\bar{t}, x_1, \bar{u}; t, u, v](1)\big) - \varepsilon. \tag{3.3}$$

Thus by the definition of $\mathcal{V}$ we have

$$\mathcal{V}(\bar{t}, x_2, \bar{u}, \bar{k}) - \mathcal{V}(\bar{t}, x_1, \bar{u}, \bar{k}) \leq \Phi\big(y[\bar{t}, x_2, \bar{u}; t, u, v](1)\big) - \Phi\big(y[\bar{t}, x_1, \bar{u}; t, u, v](1)\big) + \varepsilon. \tag{3.4}$$

Furthermore standard estimates for the trajectories of (2.4) yield

$$\big|x[\bar{t}, x_2, \bar{u}; t, u, v](s) - x[\bar{t}, x_1, \bar{u}; t, u, v](s)\big| \leq |x_2 - x_1| e^{L(1+m)(K+T)s} \tag{3.5}$$

for all $s \in [0,1]$. Hence (3.4) and (3.5) imply

$$\mathcal{V}(\bar{t}, x_2, \bar{u}, \bar{k}) - \mathcal{V}(\bar{t}, x_1, \bar{u}, \bar{k}) \leq \omega_\Phi\big(e^{L(1+m)(K+T)} |x_2 - x_1|\big) + \varepsilon,$$

which, by the arbitrariness of $\varepsilon > 0$, proves that $x \mapsto \mathcal{V}(\bar{t}, x, \bar{u}, \bar{k})$ is continuous uniformly with respect to $(\bar{t}, \bar{u}, \bar{k})$.

Now let $t_1, t_2 \in [0,T]$, $t_1 \neq t_2$, and consider the difference

$$\mathcal{V}(t_2, \bar{x}, \bar{u}, \bar{k}) - \mathcal{V}(t_1, \bar{x}, \bar{u}, \bar{k}),$$

which can be assumed nonnegative. For any $\varepsilon > 0$, let (t, u, v) be a space–time control for $(t_1, \bar{x}, \bar{u}, \bar{k})$ satisfying

$$\mathcal{V}(t_1, \bar{x}, \bar{u}, \bar{k}) \geq \Phi\big(y[t_1, \bar{x}, \bar{u}; t, u, v](1)\big) - \varepsilon,$$

and consider the space–time control $(\tilde{t}, u, v) \in \Gamma_{K-\bar{k}}(t_2, \bar{u})$, where $\tilde{t}$ is defined as follows:
if $t_1 < t_2$, set

$$\tilde{t}(s) = \begin{cases} t_2, & s \in [0, \bar{s}], \\ t(s), & s \in [\bar{s}, 1], \end{cases}$$

where

$$\bar{s} \doteq \min\{s \in [0,1] \ : \ t(s) = t_2\};$$

if $t_1 \geq t_2$, set

$$\tilde{t}(s) = t(s) - (t_1 - t_2)(1 - s), \qquad s \in [0,1].$$

In both cases the definition of $\tilde{t}$ and Gronwall's lemma imply
(3.6)

$$|\tilde{t}(s) - t(s)| \leq |t_2 - t_1|,$$

$$\big|\tilde{x}(s) - x(s)\big| \leq \big[M'|t_2 - t_1| + (K+T)\sum_{i=0}^{m} \omega_{g_i}(|t_2 - t_1|)\big] e^{L(1+m)(K+T)} \quad \forall s \in [0,1],$$

where we have set $\tilde{x}(\cdot) \doteq x[t_2, \bar{x}, \bar{u}; \tilde{t}, u, v](\cdot)$, $x(\cdot) \doteq x[t_1, \bar{x}, \bar{u}; t, u, v](\cdot)$. It follows that

$$\begin{aligned} &\mathcal{V}(t_2, \bar{x}, \bar{u}, \bar{k}) - \mathcal{V}(t_1, \bar{x}, \bar{u}, \bar{k}) \\ &\quad \leq \omega_\Phi\big(\big[M'|t_2 - t_1| + (K+T)\sum_{i=0}^{m} \omega_{g_i}(|t_2 - t_1|)\big] e^{L(1+m)(K+T)}\big) + \varepsilon, \end{aligned}$$

which, by the arbitrariness of ε, implies that $t \mapsto \mathcal{V}(t, \bar{x}, \bar{u}, \bar{k})$ is continuous uniformly with respect to the remaining variables $(\bar{x}, \bar{u}, \bar{k})$.

Now let $k_1, k_2 \in [0, K]$, with $k_1 \neq k_2$. Since the map $k \mapsto \mathcal{V}(\bar{t}, \bar{x}, \bar{u}, k)$ is nondecreasing, it is not restrictive to consider only the case $k_2 > k_1$. Choose a space–time control for $(\bar{t}, \bar{x}, \bar{u}, k_1)$ satisfying

$$\mathcal{V}(\bar{t}, \bar{x}, \bar{u}, k_1) \geq \Phi\big(y[\bar{t}, \bar{x}, \bar{u}; t, u, v](1)\big) - \varepsilon,$$

and set

$$\tilde{u}(s) = \begin{cases} u(s), & s \in [0, \bar{s}], \\ u(\bar{s}), & s \in [\bar{s}, 1], \end{cases}$$

where

$$\bar{s} \doteq \max\{s \in [0,1] \ : \ V_0^s(u) \leq K - k_2\}.$$

Observe that either $K - k_2 < V_0^1(u) \leq K - k_1$ and $V_0^{\bar{s}}(u) = K - k_2$ with $\bar{s} < 1$, or $\bar{s} = 1$; furthermore, $V_0^1(\tilde{u}) = V_0^{\bar{s}}(u) \leq K - k_2$ so that $(t, \tilde{u}, v) \in \Gamma_{K-k_2}(\bar{t}, \bar{u})$. For every $s \in [\bar{s}, 1)$ one has

$$V_{\bar{s}}^s(u) \leq V_{\bar{s}}^1(u) = V_0^1(u) - V_0^{\bar{s}}(u) = V_0^1(u) - K + k_2 \leq k_2 - k_1.$$

Hence, from the definition of $\tilde{u}$ and applying Gronwall's lemma one obtains

$$\begin{aligned} |\tilde{u}(s) - u(s)| &\leq V_{\bar{s}}^1(u) \leq k_2 - k_1, \\ \big|x[\bar{t}, \bar{x}, \bar{u}; t, \tilde{u}, v](s) - x[\bar{t}, \bar{x}, \bar{u}; t, u, v](s)\big| &\leq \big[mM' V_{\bar{s}}^s(u) + \omega_{g_0}(T|k_2 - k_1|)\big] e^{L(K+T)} \\ &\leq \big[mM'|k_2 - k_1| + T\omega_{g_0}(|k_2 - k_1|)\big] e^{L(K+T)} \quad \forall s \in [0,1]. \end{aligned}$$

This implies

(3.7)

$$\mathcal{V}(\bar t,\bar x,\bar u,k_2)-\mathcal{V}(\bar t,\bar x,\bar u,k_1)\le \omega_\Phi\big(\big[(1+mM')|k_2-k_1|+T\omega_{g_0}(|k_2-k_1|)\big]e^{L(K+T)}\big)+\varepsilon;$$

thence $k\mapsto \mathcal{V}(\bar t,\bar x,\bar u,k)$ is continuous uniformly with respect to the variables $(\bar t,\bar x,\bar u)$. Thus thesis i) of the theorem is proved.

In order to prove ii), let $\varepsilon>0$ and, for a $\delta>0$ to be determined later, let $u_1,u_2\in Q_u$ satisfy $|u_i-\bar u|\le\delta$, $i=1,2$. Let us consider the difference

$$\mathcal{V}(\bar t,\bar x,u_2,\bar k)-\mathcal{V}(\bar t,\bar x,u_1,\bar k),$$

which it is not restrictive to assume is nonnegative. Let $(t,u,v)\in\Gamma_{K-\bar k}(\bar t,u_1)$ be a control satisfying

$$\mathcal{V}(\bar t,\bar x,u_1,\bar k)\ge\Phi\big(y[\bar t,\bar x,u_1;t,u,v](1)\big)-\varepsilon/2.$$

If $\mathbf{(H2)}_C$ is assumed, then the control $(t,\tilde u,v)\doteq(t,u_2-u_1+u(s),v)$ is in $\Gamma_{K-\bar k}(\bar t,u_2)$. The definitions of $\omega_{g_0},\dots,\omega_{g_m}$ and ω_Φ together with standard estimates for the trajectories of (2.4) imply

$$\begin{aligned}\mathcal{V}(\bar t,\bar x,u_2,\bar k)&-\mathcal{V}(\bar t,\bar x,u_1,\bar k)\\&\le\Phi\big(y[\bar t,\bar x,u_2;t,\tilde u,v](1)\big)-\Phi\big(y[\bar t,\bar x,u_1;t,u,v](1)\big)+\varepsilon/2\\&\le\omega_\Phi\big(|u_2-u_1|+(K+T)\sum_{i=0}^m\omega_{g_i}(|u_2-u_1|)e^{L(1+m)(K+T)}\big)+\varepsilon/2.\end{aligned}$$

This yields the continuity of the map $u\mapsto\mathcal{V}(\bar t,\bar x,u,\bar k)$ uniformly with respect to the remaining variables.

We conclude by proving ii) under hypothesis $\mathbf{(H2)}_U$. Let $\rho_\varepsilon\in(0,1)$. If $K-\bar k\le\rho_\varepsilon$, by setting $\tilde u(s)=u_2\ \ \forall s\in[0,1]$ we obtain

(3.8)
$$\begin{aligned}\mathcal{V}(\bar t,\bar x,u_2,\bar k)&-\mathcal{V}(\bar t,\bar x,u_1,\bar k)\\&\le\Phi\big(y[\bar t,\bar x,u_2;t,u_2,v](1)\big)-\Phi\big(y[\bar t,\bar x,u_1;t,u,v](1)\big)+\varepsilon/2\\&\le\omega_\Phi\big(|u_2-u_1|+\rho_\varepsilon+(T\omega_{g_0}(|u_2-u_1|+\rho_\varepsilon)+mM'\rho_\varepsilon)e^{L(1+m)(K+T)}\big)+\varepsilon/2.\end{aligned}$$

Suppose on the contrary that $K-\bar k>\rho_\varepsilon$. Then by $\mathbf{(H2)}_U$ there exists a $\bar\delta>0$ such that if $|u_1-\bar u|<\bar\delta$, $|u_2-\bar u|<\bar\delta$ one has

$$V_0^1(\gamma_{21})\le\rho_\varepsilon/2\qquad(<1)$$

for some path $\gamma_{21}:[0,1]\to U$ such that $\gamma_{21}(0)=u_2$, $\gamma_{21}(1)=u_1$. We set

$$u_{\bar s}(s)=\begin{cases}u(s), & s\in[0,\bar s],\\ u(\bar s), & s\in[\bar s,1],\end{cases}$$

where

$$\bar s\doteq\max\{s\in[0,1]\ :\ V_0^s(u)\le K-\bar k-V_0^1(\gamma_{21})\}.$$

Hence for any $\nu\in V$ the control defined by

$$(\tilde t,\tilde u,\tilde v)=\begin{cases}(\bar t,\gamma_{21}(s/\sigma),\nu), & s\in[0,\sigma],\\ (t,u_{\bar s},v)((s-\sigma)/(1-\sigma)), & s\in[\sigma,1],\end{cases}$$

where $\sigma\doteq V_0^1(\gamma_{21})$ is in $\Gamma_{K-\bar k}(\bar t,u_2)$. Standard estimates yield

$$|\tilde u(s)-u(s)|\le|u_2-u_1|+(3+K+T)V_0^1(\gamma_{21}),$$

from which proceeding as in the previous case one obtains an inequality similar to (3.8). Hence, by choosing $\delta \doteq \min\{\rho_\varepsilon/2, \bar{\delta}\}$, there exists some $\rho_\varepsilon > 0$ such that we have

$$\mathcal{V}(\bar{t}, \bar{x}, u_2, \bar{k}) - \mathcal{V}(\bar{t}, \bar{x}, u_1, \bar{k}) \leq \varepsilon,$$

which implies the continuity of $u \to \mathcal{V}(\bar{t}, \bar{x}, u, \bar{k})$ on Q_u uniformly with respect to the variables $(\bar{t}, \bar{x}, \bar{k})$.

Thus the continuity of the value function $\mathcal{V}$ is proved. □

4. Dynamic programming principle and dynamic programming equation. Let us define the Hamiltonian function $H : [0,T] \times \mathbb{R}^n \times U \times \mathbb{R}^{1+n+m+1} \to \mathbb{R}$ by setting

$$(4.1)\quad H(t,x,u,p_0,p_1,\dots,p_n,p_{n+1},\dots,p_{n+m},p_\infty) \doteq \min_{\substack{v\in V\\(w_0,w)\in S^m_+}} \mathcal{H}(t,x,u,p_0,p_1,\dots,p_n,p_{n+1},\dots,p_{n+m},p_\infty,w_0,w,v),$$

where $\mathcal{H}$ denotes the unminimized Hamiltonian

$$(4.2)\quad \mathcal{H}(t,x,u,p_0,p_1,\dots,p_n,p_{n+1},\dots,p_{n+m},p_\infty,w_0,w,v) \doteq \left\{ \Big(p_0 + \sum_{i=1}^{n} p_i g_0^i(t,x,u,v)\Big) w_0 + \sum_{\substack{i=1,\dots,n\\j=1,\dots,m}} \big(p_i g_j^i(t,x,u,v) + p_{j+n}\big) w^j + p_\infty |w| \right\},$$

while S^m_+ is the intersection of $[0,+\infty[\times C$ and the unit sphere $S^m = \{(w_0,w) \in \mathbb{R}^{1+m} : |(w_0,w)| = 1\}$.

We shall prove that $\mathcal{V}$ solves the dynamic programming equation

$$(\text{DPE})\qquad -H\big(t,x,u,\nabla\mathcal{V}\big) = 0,$$

where $\nabla\mathcal{V}$ stands for $(\nabla_t\mathcal{V}, \nabla_x\mathcal{V}, \nabla_u\mathcal{V}, \nabla_k\mathcal{V})$, and $\nabla_t\mathcal{V}$, $\nabla_x\mathcal{V}$, $\nabla_u\mathcal{V}$, and $\nabla_k\mathcal{V}$ denote the gradients of $\mathcal{V}$ with respect to t, x, u, and k, respectively. The presence of the minus sign in (DPE) is motivated by the fact that we wish to be consistent with the terminology of the theory of viscosity solutions. In fact, like in the nonimpulsive case, the value function $\mathcal{V}$ fails in general to be continuously differentiable, so it can satisfy (DPE) only in a generalized sense. Aiming at self–consistency we recall the definition of viscosity solution of a first-order partial differential equation; see, e.g., [18].

DEFINITION 4.1. *Let E be a subset of $\mathbb{R}^N$. A function $\mathcal{V} \in C^0(E)$ is a* viscosity subsolution *of* (DPE) *at $(t,x,u,k) \in E$ if for any $\lambda \in C^\infty(\mathbb{R}^N)$ such that (t,x,u,k) is a local maximum point of $\mathcal{V} - \lambda$ on E one has*

$$-H\big(t,x,u,\nabla\lambda(t,x,u,k)\big) \leq 0.$$

$\mathcal{V} \in C^0(E)$ is a viscosity supersolution *of* (DPE) *at $(t,x,u,k) \in E$ if for any $\lambda \in C^\infty(\mathbb{R}^N)$ such that (t,x,u,k) is a local minimum point of $\mathcal{V} - \lambda$ on E one has*

$$-H\big(t,x,u,\nabla\lambda(t,x,u,k)\big) \geq 0.$$

$\mathcal{V} \in C^0(E)$ is a viscosity solution *of* (DPE) *at (t,x,u,k) if it is both a viscosity subsolution and a viscosity supersolution.*

In order to state Theorem 4.1 below, let us introduce the domain

$$\Omega \doteq [0,T) \times \mathbb{R}^n \times \overset{\circ}{U} \times [0,K)$$

and the boundary's subsets

$$\begin{aligned} \partial_T\Omega &\doteq \{T\}\times\mathbb{R}^n\times U\times[0,K], \\ \partial'\Omega &\doteq \partial\Omega\setminus\partial_T\Omega. \end{aligned} \tag{4.3}$$

THEOREM 4.1 (dynamic programming equation and boundary conditions). *Assume either hypothesis* $\mathbf{(H2)}_C$ *or hypothesis* $\mathbf{(H2)}_U$. *Then*

a) $\mathcal{V}$ *is a viscosity solution on* Ω *of the dynamic programming equation* (DPE);

b) $\mathcal{V}$ *satisfies*

$$\mathcal{V}(T,x,u,k)\le\Phi(x,u)\qquad\forall(T,x,u,k)\in\partial_T\Omega; \tag{4.4}$$

c) $\mathcal{V}$ *is a viscosity supersolution of* (DPE) *on* $\partial'\Omega$ *and at any point* $(T,x,u,k)\in\partial_T\Omega$ *such that* $\mathcal{V}(T,x,u,k)<\Phi(x,u)$.

Remark 4.1. Note that although the cone $[0,+\infty[\times(T_uU\cap C)$ (where T_uU denotes the contingent cone to U at u; see, e.g., [1]) could be considered the natural range of the control's derivative $(t',u_1',\dots,u_m')$, the minimum in (4.1) is searched over the *compact* set S_+^m. This is due essentially to the bound on the variation of u and to the possibility of replacing any space–time control with its canonical parametrization (see the appendix). On the other hand, the positive homogenity of $\mathcal{H}$ in the variable (w_0,w) allows us to use S_+^m in the definition of H instead of $B_+^{1+m}\doteq[0,+\infty)\times C\cap\{(w_0,w):|(w_0,w)|\le 1\}$. Actually by allowing the elements $(w_0,w,v)\equiv(0,0,v)$ in the domain of minimization of $\mathcal{H}$, we would obtain an equation lacking uniqueness properties; see §5. As a direct consequence of having replaced the unbounded set $[0,+\infty)\times(T_uU\cap C)$ with a compact set, we achieve the continuity of the Hamiltonian H. Incidentally we observe that this approach presents some analogies with the one adopted by G. Barles [5] in an infinite horizon problem.

Remark 4.2. The fact that the domain of minimization of (w_0,w) is independent of u is strictly related to the very definition of viscosity supersolution on a closed set. Indeed it is well known (see, e.g., [40]) that the supersolution condition together with the subsolution condition on the interior accounts for a constraint on the state variables. Actually, in our case the situation is slightly different, since at the boundary points we have an alternative between supersolution condition and an inequality condition; a similar situation is encountered, e.g., in [2], [16], [24].

The proof of Theorem 4.1 will be based on the following dynamic programming principle, whose proof is an obvious adaptation to the parameter–free extended problem $(\mathcal{P}^e_{(\bar t,\bar x,\bar u,\bar k)})$ of the standard reasonings which yield to the dynamic programming principle in the ordinary case.

PROPOSITION 4.1 (dynamic programming principle). *The value function* $\mathcal{V}$ *has the following properties:*

i) *For an initial condition* $(\bar t,\bar x,\bar u,\bar k)\in[0,T]\times\mathbb{R}^n\times U\times[0,K]$ *and an admissible control* $(t,u,v)\in\Gamma_{K-\bar k}(\bar t,\bar u)$, *let* $y\doteq y[\bar t,\bar x,\bar u;t,u,v]$ *be the corresponding trajectory of the extended system* (2.4), (2.5). *Then the map*

$$s\mapsto\mathcal{V}\big(y(s),\bar k+V_0^s(u)\big) \tag{4.5}$$

is nondecreasing.

ii) *If in* i) *the control* (t,u,v) *is optimal, then the map* (4.5) *is constant.*

Proof. Assume by contradiction that there exist s_1, s_2, $0\le s_1<s_2\le 1$, and $\varepsilon>0$ such that

$$\mathcal{V}\big(y(s_2),\bar k+V_0^{s_2}(u)\big)=\mathcal{V}\big(y(s_1),\bar k+V_0^{s_1}(u)\big)-\varepsilon. \tag{4.6}$$

By the definition of $\mathcal{V}$ there is a space–time control $(\check{t}, \check{u}, \check{v}) \in \Gamma_{K-(\bar{k}+V_0^{s_2}(u))}\big((t,u)(s_2)\big)$ satisfying

$$\Phi\big(y[y(s_2);\check{t},\check{u},\check{v}](1)\big) \le \mathcal{V}\big(y(s_2), \bar{k} + V_0^{s_2}(u)\big) + \varepsilon/2. \tag{4.7}$$

Define the space–time control $(\hat{t}, \hat{u}, \hat{v})$ by

$$(\hat{t},\hat{u},\hat{v})(s) \doteq \begin{cases} (t,u,v)(s_1 + 2s(s_2 - s_1)), & s \in [0, 1/2], \\ (\check{t},\check{u},\check{v})(2(s-1/2)), & s \in (1/2, 1], \end{cases}$$

and set $\hat{y} \doteq y[y(s_1);\hat{t},\hat{u},\hat{v}]$. Note that $(\hat{t},\hat{u},\hat{v}) \in \Gamma_{K-(\bar{k}+V_0^{s_1}(u))}\big(t,u)(s_1)\big)$, for we have

$$V_0^1(\hat{u}) = V_{s_1}^{s_2}(u) + V_0^1(\check{u}) \le V_{s_1}^{s_2}(u) + K - \bar{k} - V_0^{s_2}(u) = K - (\bar{k} + V_0^{s_1}(u)).$$

Moreover, by the parameter–free character of the extended system (2.4)—see Proposition A.2—we have

$$\begin{aligned} \hat{y}(1/2) &= y(s_2), \\ \hat{y}(1) &= y[y(s_2);\check{t},\check{u},\check{v}](1). \end{aligned}$$

Hence, by (4.6) and (4.7), we obtain

$$\begin{aligned} \mathcal{V}\big(y(s_1), \bar{k} + V_0^{s_1}(u)\big) &\le \Phi\big(\hat{y}(1)\big) = \Phi\big(y[y(s_2);\check{t},\check{u},\check{v}](1)\big) \\ &\le \mathcal{V}\big(y(s_2), \bar{k} + V_0^{s_2}(u)\big) + \varepsilon/2 = \mathcal{V}\big(y(s_1), \bar{k} + V_0^{s_1}(u)\big) - \varepsilon/2. \end{aligned}$$

Since $\varepsilon > 0$, this proves i).

To prove ii) it is enough to observe that whenever the control (t,u,v) is optimal, on the basis of i) one has

$$\mathcal{V}(\bar{t},\bar{x},\bar{u},\bar{k}) \le \mathcal{V}\big(y(s), \bar{k} + V_0^s(u)\big) \le \Phi\big(y(1)\big) = \mathcal{V}(\bar{t},\bar{x},\bar{u},\bar{k})$$

for every $s \in [0,1]$. □

Proof of Theorem 4.1. We begin by proving that $\mathcal{V}$ is a viscosity subsolution of (DPE) on Ω. Fix a point $(\bar{y},\bar{k}) = (\bar{t},\bar{x},\bar{u},\bar{k}) \in \Omega$ and consider a map $\lambda \in C^\infty(\mathbb{R}^{1+n+m+1})$ such that $\mathcal{V}(\bar{y},\bar{k}) = \lambda(\bar{y},\bar{k})$ and $\mathcal{V} - \lambda$ has a local maximum at $(\bar{y},\bar{k})$. Then

$$\mathcal{V}(t,x,u,k) \le \lambda(t,x,u,k) \qquad \forall (t,x,u,k) \in \Omega \cap B\big((\bar{y},\bar{k}), r\big)$$

for a sufficiently small $r > 0$. Choose $v \in V$ and $w = (w_1,\dots,w_m) \in B^m[0,1] \cap C$, where $B^m[0,1] = \{w \in \mathbb{R}^m : |w| \le 1\}$, and set $w_0 \doteq \sqrt{1-|w|^2}$. Since $\bar{t} < T$, $\bar{u} \in \overset{\circ}{U}$, and $\bar{k} < K$, there exists some $\varepsilon \in (0,1)$ such that the control (t,u,v) defined by

$$(t,u,v)(s) \doteq \begin{cases} (\bar{t} + sw_0, \bar{u} + sw, v), & s \in [0,\varepsilon], \\ (\bar{t} + \varepsilon w_0 + (T - \bar{t} - \varepsilon w_0)(s-\varepsilon)/(1-\varepsilon), \bar{u} + \varepsilon w, v), & s \in (\varepsilon, 1], \end{cases}$$

is in $\Gamma_{K-\bar{k}}(\bar{t},\bar{u})$. Then by the dynamic programming principle one has

$$\lambda(\bar{y},\bar{k}) = \mathcal{V}(\bar{y},\bar{k}) \le \mathcal{V}\big(y[\bar{t},\bar{x},\bar{u};t,u,v](s), \bar{k}+V_0^s(u)\big) \le \lambda\big(y[\bar{t},\bar{x},\bar{u};t,u,v](s), \bar{k}+V_0^s(u)\big),$$

provided $0 < s \le \rho$, with ρ small enough. Dividing the last inequality by s one has

$$\frac{\lambda\big(y[\bar{t},\bar{x},\bar{u};t,u,v](s), \bar{k} + V_0^s(u)\big) - \lambda(\bar{y},\bar{k})}{s} \ge 0 \tag{4.8}$$

for every $s \in (0, \rho]$. Passing to the limit in (4.8) as $s \to 0^+$, we obtain

$$\big(\nabla_t\lambda(\bar t,\bar x,\bar u,\bar k)+\nabla_x\lambda(\bar t,\bar x,\bar u,\bar k)g_0(\bar t,\bar x,\bar u,v)\big)w_0+\nabla_x\lambda(\bar t,\bar x,\bar u,\bar k)\sum_{i=1}^m g_i(\bar t,\bar x,\bar u,v)w^i + \nabla_u\lambda(\bar t,\bar x,\bar u,\bar k)w+\nabla_k\lambda(\bar t,\bar x,\bar u,\bar k)|w|\ge 0.$$

Since w and v are arbitrary in $B^m[0,1]\cap C$ and V, respectively, it follows that

$$-H\big(\bar t,\bar x,\bar u,\nabla\lambda(\bar t,\bar x,\bar u,\bar k)\big)\le 0.$$

Hence $\mathcal{V}$ is a subsolution of (DPE) on Ω.

Let us prove that $\mathcal{V}$ is a supersolution of (DPE) on $\Omega\cup\partial'\Omega$ and at any point $(t,x,u,k)\in\partial_T\Omega$ where $\mathcal{V}(t,x,u,k)<\Phi(x,u)$. Let $(\bar y,\bar k)=(\bar t,\bar x,\bar u,\bar k)\in\overline{\Omega}$ and consider a function $\lambda\in C^\infty(\mathbb{R}^{1+n+m+1})$ such that $\mathcal{V}-\lambda$ has a local minimum on $\overline{\Omega}$ at $(\bar y,\bar k)$ and $\mathcal{V}(\bar y,\bar k)=\lambda(\bar y,\bar k)$. Then

$$\mathcal{V}(t,x,u,k)\ge\lambda(t,x,u,k)\qquad\forall(t,x,u,k)\in\overline{\Omega}\cap B\big((\bar y,\bar k),r\big)$$

for a sufficiently small $r>0$. For any $n\in\mathbb{N}\setminus\{0\}$ let $(t_n,u_n,v_n)\in\Gamma_{K-\bar k}(\bar t,\bar u)$ be a space–time control such that the corresponding trajectory y_n satisfies

$$\Phi\big(y_n(1)\big)\le\mathcal{V}(\bar y,\bar k)+1/n^2. \tag{4.9}$$

The dynamic programming principle yields

$$\lambda\big(y_n(s),\bar k+V_0^s(u_n)\big)\le\mathcal{V}\big(y_n(s),\bar k+V_0^s(u_n)\big)\le\mathcal{V}(\bar y,\bar k)+1/n^2=\lambda(\bar y,\bar k)+1/n^2,$$

provided $0<s\le\rho$, with ρ small enough. By choosing $s=1/n$ and dividing by $1/n$ we obtain

$$n\int_0^{1/n}\mathcal{H}\big(y_n,\nabla\lambda\big(y_n,\bar k+V_0^s(u_n)\big),{t_n}',{u_n}',v_n\big)\,ds\le 1/n \tag{4.10}$$

for every n sufficiently large. Since it is not restrictive to assume that the controls (t_n,u_n,v_n) coincide with their canonical parametrizations, we have $|({t_n}',{u_n}')|(s)=V_0^1(t_n,u_n)$ for almost every $s\in[0,1]$. Now if $(\bar y,\bar k)\in\Omega\cup\partial'\Omega$, one has $V_0^1(t_n,u_n)\ge V_0^1(t_n)\ge T-\bar t>0$. Hence by the continuity —on the bounded set $\overline{\Omega}\cap B\big((\bar t,\bar x,\bar u,\bar k),r\big)$— of all the considered functions, there exists a map $\varepsilon:\mathbb{R}^+\to\mathbb{R}^+$ such that $\lim_{n\to\infty}\varepsilon(n)=0$ and

$$\begin{aligned}\varepsilon(n)&\ge n\int_0^{1/n}\mathcal{H}\big(\bar t,\bar x,\bar u,\bar k,\nabla\lambda(\bar t,\bar x,\bar u,\bar k),{t_n}',{u_n}',v_n\big)\,ds\\ &\ge nV_0^1(t_n,u_n)\int_0^{1/n}\min_{\substack{v\in V\\(w_0,w)\in S^m_+}}\mathcal{H}\big(\bar t,\bar x,\bar u,\bar k,\nabla\lambda(\bar t,\bar x,\bar u,\bar k),w_0,w,v\big)\,ds\\ &\ge(T-\bar t)H\big(\bar t,\bar x,\bar u,\nabla\lambda(\bar t,\bar x,\bar u,\bar k)\big).\end{aligned} \tag{4.11}$$

Therefore, as n tends to infinity, one has

$$-H\big(\bar t,\bar x,\bar u,\nabla\lambda(\bar t,\bar x,\bar u,\bar k)\big)\ge 0,$$

i.e., $\mathcal{V}$ is a viscosity supersolution of (DPE) at $(\bar t,\bar x,\bar u,\bar k)$.

Now let $(\bar y,\bar k)=(T,\bar x,\bar u,\bar k)\in\partial_T\Omega$ and observe that any space–time control $(t,u,v)\in\Gamma(T,\bar u)$ having components $t(s)$,$u(s)$ coinciding with T,$\bar u$, respectively, gives

rise to the constant trajectory $y \equiv (T, \bar{x}, \bar{u})$. Hence thesis b) holds true by the very definition of $\mathcal{V}$; in particular the condition

$$\mathcal{V}(T, \bar{x}, \bar{u}, \bar{k}) = \Phi(\bar{x}, \bar{u}) \tag{4.12}$$

is equivalent to the optimality of any space–time control (t, u, v) with $t(s) \equiv T$ and $u(s) \equiv \bar{u}$. On the contrary, if (4.4) is satisfied as a strict inequality, set

$$\eta = \Phi(\bar{x}, \bar{u}) - \mathcal{V}(T, \bar{x}, \bar{u}, \bar{k}). \tag{4.13}$$

In order to show that $\mathcal{V}$ is a viscosity supersolution of (DPE) at $(T, \bar{x}, \bar{u}, \bar{k})$ we claim the existence of a sequence of controls $(t_n, u_n, v_n) \equiv (T, u_n, v_n)$ enjoying the following properties: i) there exists two positive constants δ, $\bar{n}$ such that

$$V_0^1(u_n) \geq \delta \qquad \forall n \geq \bar{n}; \tag{4.14}$$

ii) the trajectories $y_n \doteq y[\bar{t}, \bar{x}, \bar{u}; t_n, u_n, v_n]$ satisfy (4.9).

In order to prove this claim, assume by contradiction that for any minimizing sequence $\big((T, u_n, v_n)\big)_{n\in\mathbb{N}}$ whose corresponding solutions satisfy (4.9) and for any $\delta > 0$, $\bar{n} > 0$ there exists a $n > \bar{n}$ such that

$$V_0^1(u_n) < \delta.$$

Then one can determine a subsequence, still denoted by $\big((T, u_n, v_n)\big)_{n\in\mathbb{N}}$, such that the corresponding trajectories y_n satisfy

$$|y_n(s) - (T, \bar{x}, \bar{u})| \leq \sum_{i=1}^{m} \int_0^s |\hat{g}_i\big(y_n(s), v_n(s)\big)||u_{in}'(s)|\, ds \leq M' m V_0^s(u_n) < M' m \delta.$$

Then, choosing δ such that $\omega_\Phi(mM'\delta) \leq \eta/4$, for any $n \geq 2/\sqrt{\eta}$ we obtain

$$\big|\Phi(y_n(1)) - \Phi(\bar{x}, \bar{u})\big| \leq \eta/4, \qquad 1/n^2 \leq \eta/4.$$

These inequalities and (4.9) provide a contradiction, for

$$\Phi(\bar{x}, \bar{u}) - \eta/2 \leq \Phi(y_n(1)) - 1/n^2 \leq \mathcal{V}(T, \bar{x}, \bar{u}, \bar{k}) = \Phi(\bar{x}, \bar{u}) - \eta.$$

Hence a sequence of controls (T, u_n, v_n) satisfying (4.14) exists, and the proof is completed by replacing $T - \bar{t}$ with δ in (4.11). □

We conclude this section by showing that (DPE) can be replaced by a quasi–variational inequality. We point out that the latter can be regarded as a generalization of the dynamic programming equation which was obtained in [8] in the special case where m is equal to 1, g_1 is independent of x and u, and C coincides with $[0, +\infty)$. Set

$$\tilde{H}(t, x, u, p) \doteq \min\big\{H_1(t, x, u, p), H_2(t, x, u, p)\big\}, \tag{4.15}$$

where H_1, H_2 are defined by

$$\begin{aligned} H_1(t, x, u, p) &\doteq \min_{v\in V}\Big\{p_0 + \sum_{i=1}^{n} p_i g_0^i(t, x, u, v)\Big\}, \\ H_2(t, x, u, p) &\doteq \min_{\substack{v\in V \\ |w|=1, w\in C}} \Big\{p_\infty + \sum_{\substack{i=1,\dots,n \\ j=1,\dots,m}} p_i g_j^i(t, x, u, v) w^j + \sum_{j=1}^{m} p_{n+j} w^j\Big\}. \end{aligned} \tag{4.16}$$

THEOREM 4.2 (dynamic programming equation in the form of quasi-variational inequality). *Assume either hypothesis* $\mathbf{(H2)}_C$ *or hypothesis* $\mathbf{(H2)}_U$. *Then the following hold:*

a) $\mathcal{V}$ *is a viscosity solution of*

$$-\tilde{H}(t,x,u,\nabla\mathcal{V}) = 0, \tag{DPE}_{(\mathrm{QVI})}$$

on Ω;

b) $\mathcal{V}$ *satisfies*

$$\mathcal{V}(t,x,u,k) \le \Phi(x,u) \qquad \forall (t,x,u,k) \in \partial_T\Omega;$$

c) $\mathcal{V}$ *is a viscosity supersolution of* $(\mathrm{DPE})_{(\mathrm{QVI})}$ *on* $\partial'\Omega$ *and at any point* $(t,x,u,k) \in \partial_T\Omega$ *such that* $\mathcal{V}(t,x,u,k) < \Phi(x,u)$.

Proof. Since $H(t,x,u,p) \le \tilde{H}(t,x,u,p)$ for all $(t,x,u,p) \in \Omega \times \mathbb{R}^{1+n+m+1}$, by the fact that $\mathcal{V}$ is a viscosity subsolution of (DPE) on Ω it follows straightforwardly that $\mathcal{V}$ is a viscosity subsolution of $(\mathrm{DPE})_{(\mathrm{QVI})}$ on Ω.

Now suppose that either $(\bar{y},\bar{k}) \doteq (\bar{t},\bar{x},\bar{u},\bar{k})$ belongs to $\Omega \cup \partial'\Omega$ or it belongs to $\partial_T\Omega$, and assume that $\mathcal{V}(\bar{t},\bar{x},\bar{u},\bar{k}) < \Phi(\bar{x},\bar{u})$. By Theorem 4.1 it follows that for any $\lambda \in C^\infty(\mathbb{R}^{1+n+m+1})$ such that $\mathcal{V} - \lambda$ has a local minimum on $\overline{\Omega}$ at $(\bar{y},\bar{k})$ and $\mathcal{V}(\bar{y},\bar{k}) = \lambda(\bar{y},\bar{k})$, there is a pair $(v,w) \in V \times B^m[0,1] \cap C$ satisfying

$$\begin{aligned}(4.17)\quad &\big(\nabla_t\lambda(\bar{y},\bar{k}) + \nabla_x\lambda(\bar{y},\bar{k})g_0(\bar{t},\bar{x},\bar{u},v)\big)w_0 + \nabla_x\lambda(\bar{y},\bar{k})\sum_{i=1}^m g_i(\bar{t},\bar{x},\bar{u},v)w^i \\ &\qquad + \nabla_u\lambda(\bar{y},\bar{k})w + \nabla_k\lambda(\bar{y},\bar{k})|w| \le 0,\end{aligned}$$

where $w_0 \doteq \sqrt{1-|w|^2}$. If $w = 0$ or $|w| = 1$, then $\mathcal{V}$ is a supersolution of $(\mathrm{DPE})_{(\mathrm{QVI})}$. Otherwise, i.e., if $0 < |w| < 1$, divide (4.17) by $|w|$ and observe that either the first term or the sum of the remaining terms must be nonpositive. Hence $\mathcal{V}$ is a supersolution of $(\mathrm{DPE})_{(\mathrm{QVI})}$. □

Remark 4.3. Theorem 4.2 exhibits a certain analogy of the considered problem with standard impulse control problems; see, e.g., [3], [8]. Indeed the value functions of the latter satisfy certain quasi-variational inequalities, which replace the usual Bellman equation. Actually, the dynamics considered in standard impulse theory can be considered as the simplest case of the dynamics considered in this paper, namely, the case where the vector fields $g_1,\dots,g_m$ are constant. Yet the comparison between the two approaches cannot be pushed further, for the two corresponding minimum problems are not equivalent. Instead, a more strict relation can be recognized between the problems considered here and the questions adressed in E. N. Barron and R. Jensen's paper [6], where (nonimpulsive) controls $\eta(\cdot)$ with bounded variation are considered. Indeed by adding the trivial (impulsive) equation $\dot{z} = \dot{\eta}$ the control system studied in [6] will be reduced to the form considered in this paper.

5. Uniqueness of the solution of (DPE) and verification theorem. In this section we prove a comparison result for viscosity solutions of (DPE). As a consequence we obtain a uniqueness result and a verification theorem for the extended problem $\mathcal{P}^e_{(t,x,u,k)}$.

We assume hypothesis **(H3)** below on the boundary of U. Hypothesis **(H3)**, which excludes the presence of zero-amplitude corners in ∂U, is quite standard in problems involving state constraints; see, e.g., [40].

(H3) There exist a map $\eta \in BUC(U, \mathbb{R}^m)$ and two positive numbers q, r such that

$$B\big(u + t\eta(u), rt\big) \subset \overset{\circ}{U} \qquad \text{for } u \in \partial U \text{ and } 0 < t \leq q.$$

THEOREM 5.1. *Assume hypothesis* **(H3)** *and either* $\mathbf{(H2)}_C$ *or* $\mathbf{(H2)}_U$. *Let* $\mathcal{V}_1$ *be a bounded continuous viscosity subsolution of* (DPE) *in* Ω *which satisfies*

$$\mathcal{V}_1(t, x, u, k) \leq \Phi(x, u) \qquad \forall (t, x, u, k) \in \partial_T \Omega. \tag{5.1}$$

Let $\mathcal{V}_2$ *be a bounded continuous viscosity supersolution of* (DPE) *in* $\Omega \cup \partial'\Omega$ *such that for any* $(t, x, u, k) \in \partial_T \Omega$ *either* $\mathcal{V}_2$ *satisfies the inequality*

$$\mathcal{V}_2(t, x, u, k) \geq \Phi(x, u) \tag{5.2}$$

or it is a viscosity supersolution of (DPE).

Then

$$\mathcal{V}_1 \leq \mathcal{V}_2 \qquad \text{on } \overline{\Omega}. \tag{5.3}$$

Proof. For every $(t, k) \in [0, T] \times [0, K]$ let us define the map $\mathcal{T}_{t,k} : \mathbb{R}^+ \to \mathbb{R}$ by setting

$$\mathcal{T}_{t,k}(r) \doteq \frac{\log r}{1 + t + k}.$$

Let M be a lower bound for the maps $\Phi, \mathcal{V}_1$, and $\mathcal{V}_2$, and let us set

$$Z_i(t, x, u, k) \doteq \mathcal{T}_{t,k}\big(\mathcal{V}_i(T - t, x, u, K - k) - M + 1\big), \qquad i = 1, 2,$$
$$\psi(t, x, u, k) \doteq \mathcal{T}_{t,k}(\Phi(x, u) - M + 1).$$

Then, on the one hand, the map Z_1 turns out to be a bounded continuous subsolution of

(TDPE)

$$Z + \max_{(v, w_0, w) \in V \times S^m_+} \left\{ \frac{1 + t + k}{w_0 + |w|} \mathcal{H}(T - t, x, u, \nabla_t Z, -\nabla_x Z, -\nabla_u Z, \nabla_k Z, v, w_0, w) \right\} = 0$$

in Ω, where $\mathcal{H}$ is the unminimized Hamiltonian defined in (4.2); moreover Z_1 satisfies

$$Z_1(t, x, u, k) \leq \psi(t, x, u, k)$$

on $\partial_0 \Omega \doteq \{0\} \times \mathbb{R}^n \times U \times [0, K]$.

On the other hand, Z_2 is a bounded continuous supersolution of (TDPE) on $\overline{\Omega} \backslash \partial_0 \Omega$. Furthermore, at each point $(0, x, u, k) \in \partial_0 \Omega$, Z_2 either satisfies the inequality $Z_2(0, x, u, k) \geq \psi(0, x, u, k)$ or is a viscosity supersolution of (TDPE). Hence, a straightforward application of Theorem 1.1 in [2] implies that

$$Z_1 \leq Z_2$$

on $\overline{\Omega}$, which in turn yields the thesis. □

THEOREM 5.2 (uniqueness). *Assume hypothesis* **(H3)** *and either* $\mathbf{(H2)}_C$ *or* $\mathbf{(H2)}_U$. *Then the value function* $\mathcal{V}$ *is the unique bounded continuous viscosity solution of* (DPE) *on* Ω *which satisfies the following boundary conditions:*

$(BC)'_1$ $\mathcal{V}$ *is a viscosity supersolution of* (DPE) *at all points of* $[0, T[\times \mathbb{R}^n \times \partial U \times [0, K[\cup [0, T[\times \mathbb{R}^n \times U \times \{K\}$;

$(BC)'_2$ *at each boundary point* (T, x, u, k) *one has* $\mathcal{V}(T, x, u, k) \leq \Phi(x, u)$ *and, moreover, either* $\mathcal{V}$ *is a supersolution of* (DPE) *or it satisfies the relation* $\mathcal{V}(T, x, u, k) = \Phi(x, u)$.

Remark 5.1. By using the same arguments as in the previous theorem a uniqueness result for $(\mathrm{DPE})_{(\mathrm{QVI})}$ can be proved as well. Hence (DPE) and $(\mathrm{DPE})_{(\mathrm{QVI})}$ turn out to be equivalent as soon as one assumes the boundary conditions $(BC)'_1$, $(BC)'_2$. It is worthwhile comparing the latter conditions with the boundary conditions of Dirichlet type assumed by Barron, Jensen, and Menaldi [8] in the particular case when $m = 1$, $u \equiv k \in [0, K]$, g_1 is independent of (x, u), and $C = [0, +\infty)$. Barron–Jensen–Menaldi's conditions can be stated as follows:

$(BC)_1$ the map $\mathcal{V}$ coincides with the value function

$$h_T(\bar{x}, \bar{k}) \doteq \inf_{(T,u,v)\in\Gamma_{K-\bar{k}}(T,\bar{k})} \Phi\big(z[\bar{x}, \bar{k}; u, v](1)\big)$$

on the strip $\{T\}\times\mathbb{R}^n\times[0, K)$, where $z[\bar{x}, \bar{k}; u, v](\cdot)$ is the solution of the *purely impulsive* (integrable) Cauchy problem

$$\begin{cases} z' = \hat{g}_1(T, v(s))u'(s), \\ z(0) = (\bar{x}, \bar{k}); \end{cases}$$

$(BC)_2$ the map $\mathcal{V}$ coincides with the value function

$$h_K(\bar{t}, \bar{x}) \doteq \inf_{v\in\mathcal{B}([\bar{t},T],V)} \Phi\big(x[\bar{t}, \bar{x}; v](T), K\big)$$

on the strip $[0, T) \times \mathbb{R}^n \times \{K\}$, where $x[\bar{t}, \bar{x}; v](\cdot)$ is the solution of the *nonimpulsive* Cauchy problem

$$\begin{cases} \dot{x} = g_0(t, x(t), K, v(t)), \\ x(\bar{t}) = \bar{x}. \end{cases}$$

In particular, in order to construct the maps h_T and h_K one needs solving a class of auxiliary optimization problems whose difficulty is often comparable to the difficulty of the original problem. Instead, conditions $(BC)'_1$, $(BC)'_2$ of Theorem 5.2 refer only to equation (DPE) and to the known function Φ (see also the example in §7).

We conclude this section with a verification theorem, which incidentally provides an answer—in the present, more general, framework—to the question posed by Barron, Jensen, and Menaldi [8] (see the introduction, question b)) about the relationship between optimal controls and dynamic programming equation.

THEOREM 5.3 (verification theorem). *Let $Z \in C(\overline{\Omega})$ be a bounded viscosity subsolution of* (DPE) *in Ω which satisfies the condition $Z \le \Phi$ on $\partial_T\Omega$. Then*

$$Z \le \mathcal{V} \qquad \text{on } \overline{\Omega}. \tag{5.5}$$

Moreover, if for a given $(\bar{t}, \bar{x}, \bar{u}, \bar{k}) \in \overline{\Omega}$ there exists a space–time control $(t, u, v) \in \Gamma_{K-\bar{k}}(\bar{t}, \bar{u})$ such that

$$\Phi\big(y[\bar{t}, \bar{x}, \bar{u}; t, u, v](1)\big) \le Z(\bar{t}, \bar{x}, \bar{u}, \bar{k}),$$

then the control (t, u, v) is optimal and

$$Z(\bar{t}, \bar{x}, \bar{u}, \bar{k}) = \mathcal{V}(\bar{t}, \bar{x}, \bar{u}, \bar{k}).$$

6. Costate, maximum principle, and gradient of the value function. In ordinary control theory it is well known that the costate involved in the Pontryagin's maximum principle coincides—when no endpoint constraints are imposed—with the gradient of the value function evaluated along an optimal trajectory. More generally,

if the value function is not differentiable at some point, the costate belongs to the supergradient of the value function; see, e.g., [7], [22].

It is clear that in order to prove an analogous result for an impulsive system we need to understand the behaviour of the costate in the presence of spatial jumps of the trajectory.

In the special case where $m = 1$ and g_1 is independent of (x, u) (and $C = [0, +\infty)$) the question is posed as an open problem in [8] (see the introduction, question a)). Since the problem with impulses has been reduced to a standard nonimpulsive control problem, under hypothesis $\mathbf{(H2)}_C$ and by simply applying standard arguments (see [7], [22]), it is now easy to provide an answer to the above question in the general case treated in the present paper.

Throughout this section we assume that the vector fields $g_0, \dots, g_m$ and the map Φ are continuously differentiable with respect to the variables t, x and u.

We recall that the space–time Hamiltonian equations in the variables (y, k) and (p, p_k) have the form

$$\begin{aligned} y' &= \nabla_p \mathcal{H}(y, p, p_k, t', u', v), \\ k' &= \nabla_{p_k} \mathcal{H}(y, p, p_k, t', u', v), \\ p' &= -\nabla_y \mathcal{H}(y, p, p_k, t', u', v), \\ p'_k &= -\nabla_k \mathcal{H}(y, p, p_k, t', u', v), \end{aligned} \tag{6.1}$$

where $\mathcal{H}$ is the unminimized Hamiltonian introduced in §4. In components we have

$$\begin{cases} t' = t', \\ x' = g_0(t, x, u, v)t' + \sum_{j=1}^{m} g_j(t, x, u, v)u'_j, \\ u' = u', \\ k' = |u'|, \end{cases} \tag{6.2}$$

$$\begin{cases} p'_0 = -\langle p_x, \nabla_t g_0(t, x, u, v)t' \rangle - \sum_{j=1}^{m} \langle p_x, \nabla_t g_j(t, x, u, v)u'_j \rangle, \\ p'_x = -\langle p_x, \nabla_x g_0(t, x, u, v)t' \rangle - \sum_{j=1}^{m} \langle p_x, \nabla_x g_j(t, x, u, v)u'_j \rangle, \\ p'_u = -\langle p_x, \nabla_u g_0(t, x, u, v)t' \rangle - \sum_{j=1}^{m} \langle p_x, \nabla_u g_j(t, x, u, v)u'_j \rangle, \\ p'_k = 0. \end{cases} \tag{6.3}$$

Note that (6.2) is nothing but the control system (2.4) supplemented with the equation $k' = |u'|$.

By saying that a control $(t(\cdot), u(\cdot), v(\cdot))$ evolves instantaneously at a time $\bar{t} \in [0, T]$ we mean that the preimage $t^{\leftarrow}(\bar{t})$ is a nondegenerate interval $[s_1, s_2]$ on which the component $u(\cdot)$ is not constant. Accordingly, one can compute the *jumps* at time $\bar{t}$ of both the state (y, k) and the costate (p, p_k) by solving the Hamiltonian equations (6.2), (6.3) on the interval $[s_1, s_2]$.

In order to state a maximum principle for the extended problem $\mathcal{P}^e_{(\bar{t}, \bar{x}, \bar{u}, \bar{k})}$ in the

unconstrained case defined by hypothesis $\mathbf{(H2)}_C$ we recall that it is not restrictive to assume that the norm of the derivative $(\hat{t}'(s), \hat{u}'(s))$ is equal to the constant value $V_0^1(\hat{t}, \hat{u}) = \int_0^1 |(\hat{t}'(s), \hat{u}'(s))| ds$ almost everywhere in $[0,1]$; see the appendix.

THEOREM 6.1 (maximum principle). *Let us assume* $\mathbf{(H2)}_C$, *i.e.,* $U = \mathbb{R}^m$. *Fix* $(\bar{t}, \bar{x}, \bar{u}, \bar{k}) \in [0,T] \times \mathbb{R}^{n+m} \times [0,K]$ *and let* $(\hat{t}, \hat{u}, \hat{v})$ *be an optimal control for the extended problem* $\mathcal{P}^e_{(\bar{t},\bar{x},\bar{u},\bar{k})}$, *with* $|(\hat{t}', \hat{u}')| = L$ *almost everywhere in* $[0,1]$ *for some positive constant* L. *Moreover denote the corresponding optimal trajectory by* $(\hat{y}, \hat{k}) = (\hat{t}, \hat{x}, \hat{u}, \hat{k})$.

Then there exists a costate map $(\hat{p}, \hat{p}_k) = (\hat{p}_0, \hat{p}_x, \hat{p}_u, \hat{p}_k) : [0,1] \to \mathbb{R}^{1+n+m+1}$ *such that*

i) $(\hat{y}, \hat{k}, \hat{p}, \hat{p}_k)$ *is a solution of the Hamiltonian equations* (6.1) *corresponding to the control* $(\hat{t}, \hat{u}, \hat{v})$ *and satisfies the boundary conditions*

$$
\begin{aligned}
&(\hat{t}(0), \hat{x}(0), \hat{u}(0), \hat{k}(0)) = (\bar{t}, \bar{x}, \bar{u}, \bar{k}),\\
&\hat{p}_x(1) = \nabla_x \Phi\big(\hat{x}(1), \hat{u}(1)\big), \qquad \hat{p}_u(1) = \nabla_u \Phi\big(\hat{x}(1), \hat{u}(1)\big),\\
&H\big(T, \hat{x}(1), \hat{u}(1), \hat{p}_0(1), \hat{p}_x(1), \hat{p}_u(1), \hat{p}_k(1)\big) = 0,
\end{aligned}
\tag{6.4}
$$

where the Hamiltonian H *is defined as in* §2;

ii) *the minimum relation*

$$
\begin{aligned}
&\mathcal{H}\left(\hat{t}(s), \hat{x}(s), \hat{u}(s), \hat{p}_0(s), \hat{p}_x(s), \hat{p}_u(s), \hat{p}_k(s), \frac{\hat{t}'(s)}{L}, \frac{\hat{u}'(s)}{L}, v(s)\right)\\
&\quad = H\left(\hat{t}(s), \hat{x}(s), \hat{u}(s), \hat{p}_0(s), \hat{p}_x(s), \hat{p}_u(s), \hat{p}_k(s)\right)
\end{aligned}
\tag{6.5}
$$

holds for almost every $s \in [0,1]$, *and the equality*

$$
H\left(\hat{t}(s), \hat{x}(s), \hat{u}(s), \hat{p}_0(s), \hat{p}_x(s), \hat{p}_u(s), \hat{p}_k(s)\right) = 0 \tag{6.6}
$$

holds for all $s \in [0,1]$;

iii) *if* $\hat{u}$ *verifies* $V_0^1(\hat{u}) < K - \bar{k}$, *one has* $\hat{p}_k = 0$ *identically on* $[0,1]$.

This theorem, whose proof will be given after the statement of Theorem 6.2, is a straightforward consequence of the Pontryagin maximum principle when the latter is applied to the extended (nonimpulsive) control problem.

We point out that in the case when the fields g_i are independent of (x,u), some versions of the maximum principle already exist in the literature; see, e.g., [33], [36], [38], [42]. What is more, up to some formal changes a maximum principle for the general case considered here can be already found in [31]. Yet since our main goal is to establish a relationship between the costate and the value function, we prefer to give here a statement and a proof of the maximum principle in the theoretical framework introduced in the previous sections.

In order to state a relationship between the costate and the value function let us introduce the family of maps defined by

$$
\begin{aligned}
&\mathcal{V}^{t,k} : \mathbb{R}^{n+m} \to \mathbb{R}, \qquad (t,k) \in [0,T] \times [0,K],\\
&\mathcal{V}^{t,k}(x,u) \doteq \mathcal{V}(t,x,u,k) \qquad \forall (x,u) \in \mathbb{R}^{n+m}.
\end{aligned}
$$

Moreover, let us recall the definition of superdifferential of a continuous map.

DEFINITION 6.1. *Let* f *be a function in* $C(\mathbb{R}^N)$. *Then for every* $x \in \mathbb{R}^N$ *the subset* $\nabla^+ f(x) \subset \mathbb{R}^N$ *defined by*

$$
\nabla^+ f(x) \doteq \left\{ p \in \mathbb{R}^N : \limsup_{y \to x} \frac{f(y) - f(x) - \langle p\ ,\ y - x \rangle}{|y - x|} \leq 0 \right\}
$$

is called the superdifferential *of* f *at* x.

In the statement of the following theorem $(\hat{t}, \hat{x}, \hat{u}, \hat{k})$ and $(\hat{p}, \hat{p}_k) = (\hat{p}_0, \hat{p}_x, \hat{p}_u, \hat{p}_k)$ have the same meaning as in Theorem 6.1.

THEOREM 6.2 (costate and value function). *For every* $s \in [0,1]$ *one has*

$$(\hat{p}_x(s), \hat{p}_u(s)) \in \nabla^+ \mathcal{V}^{\hat{t}(s),\hat{k}(s)}\big(\hat{x}(s), \hat{u}(s)\big). \tag{6.7}$$

Proof of Theorem 6.1. This theorem follows straightforwardly from the Pontryagin maximum principle for nonimpulsive control systems. Indeed, thanks to the fact that we can restrict the family of controls to the subfamily formed by canonically parametrized control strategies, a control $(\hat{t}, \hat{u}, \hat{v})$ is optimal for problem $\mathcal{P}^e_{(\bar{t},\bar{x},\bar{u},\bar{k})}$ if and only if the control $(\hat{w}_0, \hat{w}, \hat{v}) \doteq (\hat{t}', \hat{u}', \hat{v})$ is optimal for the following ordinary control problem with endpoint constraints:

$$\text{minimize } \Phi\big(z[\bar{t}, \bar{x}, \bar{u}, \bar{k}; w_0, w, v](1)\big)$$

over the trajectories $(z[\bar{t}, \bar{x}, \bar{u}, \bar{k}; (w_0, w, v)](\cdot)$ of

$$\begin{aligned} z' &= \hat{g}_0(z(s), v(s))w_0 + \sum_{i=1}^{m} \hat{g}_i(z(s), v(s))w_i(s), \\ z_k' &= |w|, \\ (z(0), z_k(0)) &= (\bar{t}, \bar{x}, \bar{u}, \bar{k}), \end{aligned}$$

satisfying the endpoint constraints

$$z_0(1) = T, \qquad z_k(1) \le K$$

and corresponding to measurable control maps (w_0, w, v) from $[0,1]$ into

$$\big\{(w_0, w, v) \in [0, +\infty) \times C \times V : \quad |(w_0, w)| \le T + K\big\}.$$

By applying the Pontryagin's maximum principle (see [26]) to this problem we obtain a statement which is equivalent to Theorem 6.1 except that relation (6.5) must be replaced by

(6.8)

$$\begin{aligned} &\mathcal{H}\left(\hat{t}(s), \hat{x}(s), \hat{u}(s), \hat{p}_0(s), \hat{p}_x(s), \hat{p}_u(s), \hat{p}_k(s), \frac{\hat{t}'(s)}{L}, \frac{\hat{u}'(s)}{L}, v(s)\right) \\ &= \min_{(w_0,w,v) \in B_+^{m+1}\left[\frac{T+K}{L}\right] \times V} \left\{\mathcal{H}\left(\hat{t}(s), \hat{x}(s), \hat{u}(s), \hat{p}_0(s), \hat{p}_x(s), \hat{p}_u(s), \hat{p}_k(s), w_0, w, v\right)\right\}, \end{aligned}$$

where

$$B_+^{m+1}\left[\frac{T+K}{L}\right] \doteq \left\{(w_0, w) \in [0, +\infty) \times C : \ |(w_0, w)| \le \frac{T+K}{L}\right\}.$$

On the other hand, since $|(\hat{t}'(s), \hat{u}'(s))| = L$ almost everywhere, in the minimum relation (6.8) one can replace $B_+^{m+1}\left[\frac{T+K}{L}\right]$ with the set S_+^m. Hence (6.8) reduces to (6.5), and the theorem is proved. □

We observe that the proof of Theorem 6.2 cannot be derived directly from analogous results concerning nonimpulsive systems. Indeed, to our knowledge these results concern problems without endpoint constraints, while the trajectories of system (6.2) are subject to

$$\hat{t}(1) = T, \quad \hat{k}(1) \le K.$$

However, since the coordinates $(\hat{x}(1), \hat{u}(1))$ are not constrained, the arguments we use to prove Theorem 6.2 are substantially the same as the ones used in the nonimpulsive case without endpoint constraints; see, e.g., [7], [22].

Proof of Theorem 6.2. By the definition of optimal trajectory there exists a measurable map $\hat{v}$ such that the solution corresponding to the space–time control $(\hat{t}, \hat{u}, \hat{v})$ coincides with the optimal trajectory $(\hat{t}, \hat{x}, \hat{u}, \hat{k})$. Let $s^* \in [0,1]$ and for every initial point $(\tilde{x}, \tilde{u}) \in \mathbb{R}^n \times \mathbb{R}^m$ define the control map

$$\hat{u}_{\tilde{u}} : [s^*, 1] \to \mathbb{R}^m, \qquad \hat{u}_{\tilde{u}}(s) \doteq \hat{u}(s) + \tilde{u} - \hat{u}(s^*).$$

Next consider the cost functional

$$J(\tilde{x}, \tilde{u}) \doteq \Phi\big(\hat{x}[\tilde{x}, \tilde{u}](1), \hat{u}_{\tilde{u}}(1)\big),$$

where $\hat{x}[\tilde{x}, \tilde{u}](\cdot)$ denotes the solution on the interval $[s^*, 1]$ of the Cauchy problem

$$x' = g_0\left(\hat{t}(s), x(s), \hat{u}_{\tilde{u}}(s), \hat{v}(s)\right)\hat{t}'(s) + \sum_{i=1}^{m} g_i\left(\hat{t}(s), x(s), \hat{u}_{\tilde{u}}(s), \hat{v}(s)\right)\hat{u}_i'(s),$$
$$x(s^*) = \tilde{x}.$$

Up to a reparametrization from the interval $[s^*, 1]$ into the standard interval $[0,1]$, the control $(\hat{t}, \hat{u}_{\tilde{u}}, \hat{v}) : [s^*, 1] \to \mathbb{R}^{1+m} \times V$ is feasible for the initial point $(\hat{t}(s^*), \tilde{x}, \tilde{u}, \hat{k}(s^*))$. Hence one has

$$\mathcal{V}\left(\hat{t}(s^*), \tilde{x}, \tilde{u}, \hat{k}(s^*)\right) = \mathcal{V}^{\hat{t}(s^*), \hat{k}(s^*)}(\tilde{x}, \tilde{u}) \leq J(\tilde{x}, \tilde{u})$$

for every $(\tilde{x}, \tilde{u}) \in \mathbb{R}^{n+m}$, and, by the optimality of $(\hat{t}, \hat{u}, \hat{v})$,

$$J(\hat{x}(s^*), \hat{u}(s^*)) = \mathcal{V}^{\hat{t}(s^*), \hat{k}(s^*)}(\hat{x}(s^*), \hat{u}(s^*)).$$

Therefore by the definition of superdifferential of $\mathcal{V}^{\hat{t}(s^*), \hat{k}(s^*)}$ it is sufficient to prove that $J(\tilde{x}, \tilde{u})$ is differentiable at $(\hat{x}(s^*), \hat{u}(s^*))$ and satisfies

$$(p_x(s^*), p_u(s^*)) = \nabla_{x,u} J(\hat{x}(s^*), \hat{u}(s^*)). \tag{6.9}$$

By standard computations involving the differentiability of the solutions of (6.2) with respect to the initial data we obtain

$$\nabla_{x,u} J(\hat{x}(s^*), \hat{u}(s^*)) = \langle \nabla_{x,u} \Phi(\hat{x}(1), \hat{u}(1)) \ , \ Z(1) \rangle, \tag{6.10}$$

where the $(n+m) \times (n+m)$ matrix $Z(\cdot)$ is the solution in $[s^*, 1]$ of the variational Cauchy problem

$$Z'(s) = \left\langle \left[\nabla_{x,u} g_0\big(\hat{t}(s), \hat{x}(s), \hat{u}(s), \hat{v}(s)\big)\hat{t}'(s) + \sum_{i=1}^{m} \nabla_{x,u} g_i\big(\hat{t}(s), \hat{x}(s), \hat{u}(s), \hat{v}(s)\big)\hat{u}_i'(s) \right], Z(s) \right\rangle,$$
$$Z(s^*) = Id.$$

Since $(\hat{p}_x, \hat{p}_u)$ coincides with the unique solution to the adjoint Cauchy problem

$$\begin{aligned}(p'_x(s), p'_u(s)) = -\Big\langle (p_x(s), p_u(s)), \big[\nabla_{x,u} g_0\big(\hat{t}(s), \hat{x}(s), \hat{u}(s), \hat{v}(s)\big)\hat{t}'(s) + \\ + \sum_{i=1}^{m} \nabla_{x,u} g_i(\hat{t}(s), \hat{x}(s), \hat{u}(s), \hat{v}(s))\hat{u}'_i(s)\big]\Big\rangle, \\ (p_x(1), p_u(1)) = \nabla_{x,u}\Phi\left(\hat{x}(1), \hat{u}(1)\right),\end{aligned}$$

one has

$$\frac{d}{ds}\langle (\hat{p}_x(s), \hat{p}_u(s)), Z(s)\rangle = 0$$

on the whole interval $[s^*, 1]$, from which it follows that

$$(\hat{p}_x(s^*), \hat{p}_u(s^*)) = \langle (\hat{p}_x(s^*), \hat{p}_u(s^*)), Id\rangle = \langle \nabla_{x,u}\Phi\left(\hat{x}(s^*), \hat{u}(s^*)\right), Z(1)\rangle.$$

The latter equality and (6.10) yield (6.9), and the theorem is proved. □

7. Example. We apply the results proved in the previous sections to a simple minimum problem. In particular we check the optimality of a certain feedback control by showing that the corresponding cost function satisfies equation (DPE) and the boundary conditions $(\mathrm{BC})'_1$, $(\mathrm{BC})'_2$.

Let T, K, and c be positive constants, and for any $(\bar{t}, \bar{x}, \bar{k}) \in [0, T) \times \mathbb{R} \times [0, K]$ consider the minimum problem:

$$(\mathcal{P}_{(\bar{t},\bar{x},\bar{k})}) \qquad \text{minimize } \arctan\big(x(T)\big)$$

over all the endpoints of the trajectories of

$$\begin{aligned} &\dot{x} = c + \dot{u}_1(t) + x\dot{u}_2(t) \qquad \forall t \in (\bar{t}, T], \\ &x(\bar{t}) = \bar{x}, \end{aligned} \tag{7.1}$$

corresponding to the absolutely continuous controls (u_1, u_2) satisfying $V_{\bar{t}}^T(u_1, u_2) \leq K - \bar{k}$. Moreover assume that the derivatives $(\dot{u}_1, \dot{u}_2)$ belong (for a.e. $t \in [\bar{t}, T]$) to the closed cone

$$C \doteq \big\{(w_1, w_2) \in \mathbb{R}^2 : \ w_1 \leq 0, \ w_2 \geq 0\big\}. \tag{7.2}$$

Following §2, let us consider the extended system relative to (7.1), (7.2):

$$\begin{aligned} &x' = ct'(s) + u'_1(s) + xu'_2(s) \qquad \forall s \in [0, 1], \\ &(t, x)(0) = (\bar{t}, \bar{x}), \quad (u'_1, u'_2)(s) \in C \ \text{ for a.e. } s \in [0, 1]. \end{aligned} \tag{7.3}$$

The form of the equation in (7.3) implies that the optimal solution of problem $\mathcal{P}_{(\bar{t},\bar{x},\bar{k})}$ —and hence the value function $\mathcal{V}$— is independent of the initial values $u_1(\bar{t})$ and $u_2(\bar{t})$ of the controls. Moreover, by the definition of space–time control one has $t'(s) \geq 0$ for a.e. $s \in [0, 1]$. Since both $\dot{u}_1$ and $x\dot{u}_2$ are negative whenever x is negative, heuristics suggests the following strategy: at the initial time let the state jump to the minimum x reachable by spending all the available variation $K - \bar{k}$. After the jump set $\dot{u}_1 \equiv 0 \equiv \dot{u}_2$ and let the state evolve in time (with constant derivative equal to c). The maximum

principle (6.5) yields

$$(w_0, w_1, w_2)(x, s) = \begin{cases} -(K - \bar{k} + T - \bar{t})(1 + x^2)^{-1/2}(0, 1, x) & \text{if } x < 0, \\ -(K - \bar{k} + T - \bar{t})(0, 1, 0) & \text{if } x \geq 0,\ s \in [0, \frac{K-\bar{k}}{K-\bar{k}+T-\bar{t}}], \\ (K - \bar{k} + T - \bar{t})(1, 0, 0) & \text{if } x \geq 0,\ s \in [\frac{K-\bar{k}}{K-\bar{k}+T-\bar{t}}, 1], \end{cases} \tag{7.4}$$

as a control candidate to be optimal. Accordingly, for each initial condition $(\bar{t}, \bar{x}, \bar{k})$ the corresponding terminal position $\hat{x}(T; \bar{t}, \bar{x}, \bar{k})$ is given by

$$\hat{x}(T; \bar{t}, \bar{x}, \bar{k}) = \begin{cases} \sinh\big(\operatorname{arc\,sinh}(\bar{x}) - (K - \bar{k})\big) + c(T - \bar{t}), & \bar{x} \leq 0,\ 0 \leq \bar{k} \leq K, \\ \sinh\big(\bar{x} - (K - \bar{k})\big) + c(T - \bar{t}), & \bar{x} > 0,\ \bar{x} + \bar{k} < K,\ 0 \leq \bar{k} \leq K, \\ \bar{x} - (K - \bar{k}) + c(T - \bar{t}), & \bar{x} > 0,\ \bar{x} + \bar{k} \geq K,\ 0 \leq \bar{k} \leq K, \end{cases}$$

so that the resulting cost is given by $\mathcal{V}(\bar{t}, \bar{x}, \bar{k}) \doteq \arctan\big(\hat{x}(T; \bar{t}, \bar{x}, \bar{k})\big)$. We claim that $\mathcal{V}(t, x, k)$ is the optimal cost; i.e., it coincides with the value function of problem $\mathcal{P}_{(t,x,k)}$. Since $\mathcal{V}$ is continuously differentiable on $\Omega \doteq (0, T) \times \mathbb{R} \times (0, K)$, on the basis of the uniqueness of Theorem 5.2 it is sufficient to verify that i) $\mathcal{V}$ is a classical solution on Ω of (DPE) equation

$$\min\left\{(\nabla_t \mathcal{V} + \nabla_x \mathcal{V} c) w_0 + \nabla_x \mathcal{V}(w_1 + x w_2) + \mathcal{V}_k \sqrt{w_1^2 + w_2^2} : \ (w_0, w_1, w_2) \in S_+^2 \right\} = 0; \tag{7.5}$$

ii) $\mathcal{V}$ is a viscosity supersolution of (DPE) on $\partial\Omega \setminus \big(\{T\} \times \mathbb{R} \times \{K\}\big)$ and satisfies

$$\mathcal{V}(T, x, K) = \arctan(x) \qquad \forall x \in \mathbb{R}. \tag{7.6}$$

Relations (7.5) and (7.6) can be checked by means of straightforward calculations. Hence it only remains to check the supersolution inequality for every $(t, x, k) \in \partial\Omega \setminus \big(\{T\} \times \mathbb{R} \times \{K\}\big)$. If $\lambda \in C^\infty(\overline{\Omega})$ is a map such that $\mathcal{V} - \lambda$ has a local minimum at (t, x, k), then it satisfies the following relations:

$$\nabla_t \lambda(t, x, k) \geq \nabla_t \mathcal{V}(t, x, k), \quad (\nabla_x \lambda, \nabla_k \lambda)(t, x, k) = (\nabla_x \mathcal{V}, \nabla_k \mathcal{V})(t, x, k) \quad \text{if } t = T$$

and

$$\nabla_k \lambda(t, x, k) \geq \nabla_k \mathcal{V}(t, x, k), \quad (\nabla_t \lambda, \nabla_x \lambda)(t, x, k) = (\nabla_t \mathcal{V}, \nabla_x \mathcal{V})(t, x, k) \quad \text{if } k = K.$$

Moreover observe that relation (7.5) holds at any $(t, x, k) \in \partial\Omega \setminus \big(\{T\} \times \mathbb{R} \times \{K\}\big)$ and the minimum in the right-hand side of (7.5) is achieved by a vector $(\bar{w}_0, \bar{w}_1, \bar{w}_2)$ verifying $\bar{w}_0 = 0$ if $t = T$ and $(\bar{w}_1, \bar{w}_2) = 0$ if $k = K$. It follows that

$$(\nabla_t \lambda + \nabla_x \lambda c) \bar{w}_0 + \nabla_x \lambda(\bar{w}_1 + x \bar{w}_2) + \nabla_k \lambda \sqrt{\bar{w}_1^2 + \bar{w}_2^2} = 0 \qquad \text{on } \partial\Omega \setminus \big(\{T\} \times \mathbb{R} \times \{K\}\big).$$

Hence $\mathcal{V}$ is a viscosity supersolution on $\partial\Omega \setminus \big(\{T\} \times \mathbb{R} \times \{K\}\big)$, so we can conclude that $\mathcal{V}$ coincides with the value function of problem $\mathcal{P}_{(t,x,k)}$ $\forall (t, x, k) \in \overline{\Omega}$. In particular the controls (7.4) are optimal.

Appendix.

Canonical parametrizations. We recall the notion of *canonical parametrization* from [32]. For this purpose, if (t, u) is not identically constant let us introduce the

map σ from $[0,1]$ onto itself defined by

$$\sigma(s) \doteq \frac{V_0^s(t,u)}{V_0^1(t,u)} = \frac{\int_0^s |(t',u')|ds}{\int_0^1 |(t',u')|ds}.$$

If (t,u) is constant on the whole interval $[0,1]$, we set

$$(t^c,u^c,v^c) \doteq (t,u,v).$$

If (t,u) is not constant, we set

$$(t^c,u^c,v^c)(\sigma) \doteq (t,u,v)(s), \qquad \sigma = \sigma(s). \tag{D}$$

In principle (D) defines a multivalued map. Yet (t^c,u^c) turns out to be univalued, while v^c is uniquely determined almost everywhere. More precisely we have the following proposition.

PROPOSITION A.1. *The relation* (D) *defines a Lipschitz-continuous map* (t^c,u^c) *on* $[0,1]$, *and the derivative* $(t^{c\prime},u^{c\prime})$, *which exists almost everywhere, has constant norm equal to* $V_0^1(t,u)$. *Moreover* (D) *defines a univalued Borel-measurable map* v^c *almost everywhere in* $[0,1]$.

Thanks to Proposition 1 we can give the notion of *canonical parametrization.*

DEFINITION A.1. *The space–time control* (t^c,u^c,v^c) *defined by relation* (D) *is called the* canonical parametrization *of* (t,u,v).

DEFINITION A.2. *Let* (t_1,u_1,v_1), (t_2,u_2,v_2) *be two space–time controls and let* (t_1^c,u_1^c,v_1^c), (t_2^c,u_2^c,v_2^c) *be the corresponding canonical parametrizations. The space–time control* (t_1,u_1,v_1) *is called* equivalent to (t_2,u_2,v_2) *if* $(t_1^c,u_1^c)(s) = (t_2^c,u_2^c)(s)$ $\forall s \in [0,1]$ *and* $v_1^c(s) = v_2^c(s)$ *for almost every* s *in* $[0,1]$.

Proposition A.2 below illustrates the relationship between the trajectory $y[t,u,v]$ corresponding to a space–time control (t,u,v) and the trajectory $y[t^c,u^c,v^c]$ corresponding to the canonical parametrization (t^c,u^c,v^c) of (t,u,v).

PROPOSITION A.2. *Fix the initial condition* $y(0) = (t_1,x_1,u_1)$. *Then the trajectories* $y[t,u,v]$, $y[t^c,u^c,v^c]$ *satisfy the relation*

$$y[t^c,u^c,v^c](\xi) = y[t,u,v]\,(\sigma^{\leftarrow}(\{\xi\}))$$

for every $\xi \in [0,1]$.

A pseudometric for space–time controls. The notion of canonical parametrization allows us to introduce a pseudometric δ^c on the space $\Gamma(\bar t,\bar u)$ of space–time controls. For every two space–time controls (t_1,u_1,v_1), (t_2,u_2,v_2) let us set

$$\delta^c\big((t_1,u_1,v_1),(t_2,u_2,v_2)\big) \doteq \|(t^c{}_1,u^c{}_1) - (t^c{}_2,u^c{}_2)\| + \|v_1^c - v_2^c\|_1,$$

where $\|\cdot\|$ and $\|\cdot\|_1$ denote the C^0 norm and the L^1 norm, respectively. In particular two space–time controls have δ^c pseudodistance equal to zero if and only if they are equivalent, so δ^c induces a metric on the quotient space.

The following density result was proved in [32].

PROPOSITION A.3. *Any set* $\Gamma^+_{K-\bar k}(\bar t,\bar u)$ *of regular controls is dense, in the topology induced by* δ^c, *in the corresponding set* $\Gamma_{K-\bar k}(\bar t,\bar u)$ *of space–time controls.*

Acknowledgments. The authors wish to thank Martino Bardi and Pierpaolo Soravia for their very useful bibliographical suggestions.

ASYMPTOTIC STABILITY OF THE OPTIMAL FILTER WITH RESPECT TO ITS INITIAL CONDITION*

DANIEL OCONE† AND ETIENNE PARDOUX‡

Abstract. Consider the problem of estimation of a diffusion signal observed in additive white noise. If the solution to the filtering equations, initialized with an incorrect prior distribution, approaches the true conditional distribution asymptotically in time, then the filter is said to be asymptotically stable with respect to perturbations of the initial condition. This paper presents asymptotic stability results for linear filtering problems and for signals with limiting ergodic behavior. For the linear case, stability of the Riccati equation of Kalman filtering is used to derive almost sure asymptotic stability of linear filters for possibly non-Gaussian initial conditions. In the nonlinear case, asymptotic stability in a weak convergence sense is shown for filters of signal diffusions which converge in law to an invariant distribution.

Key words. nonlinear filtering, asymptotic stability, ergodicity in filtering, forgetting of initial conditions

AMS subject classifications. 93E11, 60G35

1. Introduction.

Let $X = (X_t)_{t\geq 0}$ be a Markov process taking values in $\mathbb{R}^d$, W be an $\mathbb{R}^p$-valued Brownian motion independent of X, and h be a function $h : \mathbb{R}^d \to \mathbb{R}^p$, and set

$$Y_t = \int_0^t h(X_s)\, ds + W_t, \quad t \geq 0. \tag{1}$$

Supposing that we can observe only Y but wish to know X, we would like to compute the conditional distribution

$$\pi_t(A) = E[\mathbf{1}_A(X_t)/\mathcal{Y}_t]$$

of X_t given $\mathcal{Y}_t = \sigma\{Y_s | 0 \leq s \leq t\}$. This is the classical problem of filtering a signal in independent, additive white noise, and we shall call π_t the *exact* filter.

The computation of $(\pi_t)_{t\geq 0}$ is Bayesian in character. Let π_0 denote the distribution of X_0. Knowledge of π_0 and the transition probability laws of X fixes the prior law of X, while π_t is the a posteriori law of X_t based on observing $\{Y_s,\ s \leq t\}$. In this paper, we discuss the sensitivity of the calculation of π_t to errors in the choice of π_0. Suppose that we mistakenly think that another probability measure $\overline{\pi}_0 \neq \pi_0$ is the initial distribution and that we compute a corresponding filter $\overline{\pi}_t$ using this erroneous prior. We want to know how well the *erroneous filter* $\overline{\pi}_t$ will perform as the time t gets large. In particular, it is interesting to find conditions under which

$$\overline{\pi}_t - \pi_t \text{ tends to zero in some sense as } t \to \infty\ . \tag{2}$$

In other words, for large time intervals, the strength of the observations, or the ergodic properties of X itself, correct for erroneous initial conditions in the computation of

a posteriori distributions. We shall describe a situation in which a property like (2) holds by saying that the filter is asymptotically stable with respect to perturbations of the initial conditions. Of course, this is not a mathematically precise definition, and we shall use the term *asymptotically stable* only in this heuristic sense. The precise sense of convergence that can be achieved in (2) will depend on the filtering model and the techniques used.

The Kushner–Stratonovich equation provides a dynamical system interpretation of our stability question. Let L denote the infinitesimal generator of X, and for a measure μ on $\mathbb{R}^d$ and $\phi : \mathbb{R}^d \to \mathbb{R}$, let $\mu(\phi) = \int \phi(x)\, d\mu(x)$. Let $\mathcal{P}(\mathbb{R}^d)$ denote the space of probability measures on $\mathbb{R}^d$. Then, given a probability measure ν on $\mathbb{R}^d$, a process $(\rho_t)_{t\geq 0}$ taking values in $\mathcal{P}(\mathbb{R}^d)$ satisfies the Kushner–Stratonovich equation with initial condition ν if $(\rho_t)_{t\geq 0}$ is adapted to Y and if it satisfies

$$\rho_t(\phi) = \nu(\phi) + \int_0^t \rho_s(L\phi)\, ds + \int_0^t [\rho_s(h\phi) - \rho_s(h)\rho_s(\phi)]\, [dY_s - \rho_s(h)ds] \tag{3}$$

$$\forall\, \phi \in \text{ Domain } (L).$$

When π_0 is the initial distribution of X, $(\pi_t)_{t\geq 0}$ will be the unique solution of (3) with initial condition π_0 once appropriate regularity assumptions are satisfied (see [9]). Given an erroneous initial condition $\overline{\pi}_0$, the erroneous filter $\overline{\pi}_t$ is the solution of (3) with initial condition $\bar{\pi}_0$. Asymptotic stability means roughly that the solution of (3) forgets its initial condition and acquires an asymptotic behavior determined solely by the observation process Y and the generator L.

When X satisfies a linear stochastic differential equation with a Gaussian initial law and h is linear, the Kalman filtering equations compute the exact filter π_t. The study of the asymptotic stability of the Kalman filter has been of course a central feature of Kalman filtering theory from its inception (Kalman and Bucy [6]), and the insensitivity of Kalman filters to initial conditions, given simple controllability and detectability assumptions on the signal-observation dynamics, is of fundamental applied importance. (See Kwakernaak and Sivan [10] for an expository treatment; we don't even try to reference the huge technical literature on this point.) Usually, this stability is stated in terms of stability in law; that is, the erroneous filter $\overline{\pi}_t$ performs as well in the limit as the exact filter and has the same limiting law. It is interesting to note that these results do not require asymptotic ergodic behavior of the signal itself, which may be transient.

Beyond the linear case, general qualitative results on asymptotic filter stability with respect to initial condition perturbation are few. Stettner [15] provides conditions under which the process $(\overline{\pi}_t,\, X_t)_{t\geq 0}$ is ergodic, from which strong stability properties in the sense of (2) follow immediately, in the special case of a discrete-time, discrete-state-space model. Delyon and Zeitouni [2] prove almost sure (a.s.) exponential decay of the total variation $\|\pi_t - \overline{\pi}_t\|$ for filtering an ergodic, finite-state, continuous-time Markov chain whose observations are sufficiently rich. Closely related and, as we shall see, very relevant studies have been carried out by Kunita [7], [8] and Stettner [14] on the behavior of filters when the Markov transition semigroup of the signal is ergodic so that the signal itself forgets its initial conditions. Roughly, they show that when the signal converges in law to an invariant measure independent of the initial law, the exact filter $(\pi_t)_{t\geq 0}$ inherits a similar property. Namely, $(\pi_t)_{t\geq 0}$, itself a Markov process with state space $\mathcal{P}(\mathbb{R}^d)$, will also converge in law to an invariant distribution $M \in \mathcal{P}(\mathcal{P}(\mathbb{R}^d))$, where M is independent of the initial distribution. The filter $(\overline{\pi}_t)_{t\geq 0}$

computed with an incorrect initial condition is not a Markov process, but the pair $(\overline{\pi}_t, X_t)_{t\geq 0}$ is.

This paper presents several results on the asymptotic stability question. The purpose of §2 is to state the strongest possible results in the case of linear system and observation dynamics so as to establish a standard for evaluating progress in nonlinear problems. The results of §2 seem largely known, but it is difficult to find the precise statements we make, and so we have provided proofs. In particular, we emphasize the a.s. weak convergence of $\overline{\pi}_t - \pi_t$ to 0 and the case of non-Gaussian initial conditions, handled by Makowski's [11] reference probability transformation technique. Makowski and Sowers [12] state discrete-time versions of this result. Delyon and Zeitouni [2] also derive a.s. convergence results using Lyapunov exponent techniques.

In §3, we study the ergodic case of Kunita and Stettner. We show that when the signal tends in law to a unique invariant measure independent of the initial law and when $\pi_0 \ll \overline{\pi}_0$, then

$$\lim_{t\to\infty} E|\bar{\pi}_t(\phi) - \pi_t(\phi)| = 0$$

for any bounded continuous ϕ. Briefly, the Stettner–Kunita theory allows one to choose time lengths T so that the conditional expectation

$$E[\varphi(X_t) \ / \ Y_s - Y_{t-T} \ , \ t - T \leq s \leq t],$$

based on the observation of Y for the past T units of time, approximates $\pi_t(\phi)$ to within arbitrary accuracy, uniformly in t, and similarly for $\bar{\pi}_t(\phi)$. These approximations depend only on the observations and on the prior distribution of X_{t-T} under π_0 and $\overline{\pi_0}$, respectively. Since X_{t-T} converges to an invariant distribution independent of π_0 or $\overline{\pi}_0$ as $t \to \infty$, filter stability follows.

Roughly paraphrased, the result of §3 says that if the signal forgets its initial condition, then so does the filter. But we know from the linear case that ergodicity of the signal is not necessary for asymptotic filter stability. In future work we hope to obtain asymptotic filter stability with respect to initial condition perturbations for signals which have nonlinear dynamics and are not necessarily ergodic.

2. Asymptotic stability of the time-invariant Kalman filter. In this section we shall study the filtering problem defined by the linear system

$$dX_t = BX_t\, dt + F dV_t + G dY_t, \tag{4}$$

$$dY_t = HX_t\, dt + dW_t, \quad Y_0 = 0, \tag{5}$$

where $B \in \mathbb{R}^{d\times d}$, $F \in \mathbb{R}^{d\times q}$, $G \in \mathbb{R}^{d\times p}$, $H \in \mathbb{R}^{p\times d}$, and V and W are independent standard Brownian motions taking values in $\mathbb{R}^q$ and $\mathbb{R}^p$, respectively. X_0 is assumed to be a random vector independent of (V, W). Throughout, we shall let $\hat{X}_t$ denote the conditional expectation $E[X_t/\mathcal{Y}_t]$, where $\mathcal{Y}_t = \sigma\{Y_s,\, 0 \leq s \leq t\}$.

We shall let $(Z_t^{z,R},\, P_t^R)$ denote the solution to the Kalman filtering equations initialized at (z, R), where $z \in \mathbb{R}^d$ and R is a symmetric, nonnegative definite, $d \times d$ matrix:

$$\begin{aligned} dZ_t^{z,R} &= BZ_t^{z,R}\, dt + G dY_t + P_t^R H^*[dY_t - HZ_t^{z,R}\, dt], \\ Z_0^{z,R} &= z, \end{aligned} \tag{6}$$

$$\dot{P}_t^R = BP_t^R + P_t^R B^* + FF^* - P_t^R H^* H P_t^R,$$

(7)

$$P_0^R = R.$$

If X_0 is normal with mean $\bar{x}_0$ and variance R_0,

$$\hat{X}_t = Z_t^{\bar{x}_0, R_0}, \quad P_t^{R_0} = E[(X_t - \hat{X}_t)\,(X_t - \hat{X}_t)^*],$$

as is well known.

We shall be concerned with the asymptotic behavior of $\hat{X}_t - Z_t^{z,R}$ as $t \to \infty$, given an arbitrary, square-integrable, initial state X_0. The study of the asymptotic stability of the Kalman filtering equations (6)–(7) is classical and dates to the origins of the Kalman filter theory. Here we shall state a few complements to the theory relating to the question of a.s. convergence of filters. These seem essentially known, but we have not found a good reference, especially in the case of non-Gaussian initial conditions for continuous-time problems.

The classical stability theory introduces the fundamental assumption:

There exists a solution $P_\infty \geq 0$ to the algebraic Riccati equation

(8)
$$0 = BP_\infty + P_\infty B^* + FF^* - P_\infty H^* H P_\infty$$

such that $B - P_\infty H^* H$ is asymptotically stable.

Remark 2.1. If (8) holds and if $P_t^R \to P_\infty$ as $t \to \infty$, then

(9)
$$P_t^R \to P_\infty \text{ as } t \to \infty \text{ exponentially fast.}$$

In fact, for any $0 < \sigma < \inf\{-Re\lambda;\ \lambda \text{ is an eigenvalue of } B - P_\infty H^* H\}$, there is a constant K_σ such that

$$\|P_t^R - P_\infty\| \leq K_\sigma e^{-\sigma t}.$$

The last fact can be proved by observing that

$$\frac{d}{dt}(P_t^R - P_\infty) = [B - 1/2(P_t^R + P_\infty)H^* H](P_t^R - P_\infty) + (P_t^R - P_\infty)[B - 1/2(P_t^R + P_\infty)H^* H]^*$$

and carrying out an analysis similar to that proving (16) in the proof of Theorem 2.3.

The virtue of (8) is that there is a well-known and simple sufficient condition for (8) to hold (see Kwakernaak and Sivan [10]), and it has strong consequences.

LEMMA 2.2. *If (B, H) is detectable and (B, F) is stabilizable, then* (8) *holds, P_∞ is the unique nonnegative definite solution to the algebraic Riccati equation, and $P_t^R \to P_\infty$ exponentially fast for any initial condition $P_0^R = R \geq 0$.*

Proof. Kwakernaak and Sivan [10, Thm. 4.11] may be referred to for the uniqueness of P_∞ and the convergence of $P_t^R \to \infty$. The exponential speed of convergence is shown above. □

Some classical stability statements that follow from this result are as follows.

(a) If (B, H) is detectable, (B, F) is stabilizable, and X_0 is normal with mean z and variance $\sum_0$, the *steady state filter* Z_t^{z, P_∞} is asymptotically optimal in the sense that

$$\lim_{t\to\infty} E[(X_t - Z_t^{z,P_\infty})^*(X_t - Z_t^{z,P_\infty})] = \lim_{t\to\infty} E[(X_t - \hat{X}_t)^*(X_t - \hat{X}_t)] = \operatorname{tr} P_\infty.$$

(b) If, again, (B, H) is detectable and (B, F) is stabilizable but the initial distribution π_0 of X_0 is arbitrary, then

$$Z_t^{0,R} - X_t \text{ converges weakly to } N(0, P_\infty), \tag{10}$$

where $N(0, P_\infty)$ denotes the normal law on $\mathbb{R}^d$ with mean 0 and covariance matrix P_∞. See Vintner [16] for a proof of (10) in an infinite-dimensional state space.

We shall state here some a.s. limit theorems. The first is a rather immediate consequence of condition (8) and Remark 2.1. Define the constant $\bar{\lambda} = \min\{-\mathrm{Re}\lambda | \lambda$ is an eigenvalue of $B - P_\infty H^* H\}$; condition (8) implies that $\bar{\lambda} > 0$.

THEOREM 2.3. *Assume* (8). *Let* X_0 *be normal with mean* m_0 *and covariance* R_0. *Let* $R_1 \geq 0$, *and assume*

$$\lim_{t\to\infty} P_t^{R_0} = P_\infty = \lim_{t\to\infty} P_t^{R_1}. \tag{11}$$

Then for any $z \in \mathbb{R}^d$ *and any* $0 < \sigma < \bar{\lambda}$

$$\lim_{t\to\infty} (\hat{X}_t - Z_t^{z,R_1})\, e^{\sigma t} = 0 \quad \textit{almost surely.} \tag{12}$$

Proof. Recall that $\hat{X}_t = Z_t^{m_0,R_0}$ and that $P_t^{R_0}$ is the error covariance of the optimal filter. For simplicity of notation, set $P_t^0 = P_t^{R_0}$, $P_t^1 = P_t^{R_1}$, and $Z_t = Z_t^{z,R_1}$. Let $d\nu_t = dY_t - H\hat{X}_t\, dt$ define the innovations process, which is a Brownian motion, and observe that

$$d\hat{X}_t = B\hat{X}_t\, dt + G dY_t + P_t^0 H^* d\nu_t, \quad \hat{X}_0 = m_0. \tag{13}$$

From equation (6) for Z_t and from (13)

$$d(\hat{X}_t - Z_t) = (B - P_t^1 H^* H)(\hat{X}_t - Z_t)\, dt + (P_t^0 - P_t^1) H^*\, d\nu_t,$$

$$\hat{X}_0 - Z_0 = m_0 - z. \tag{14}$$

Let $\Phi(t) \in \mathbb{R}^{d\times d}$ be the state transition matrix associated with $B - P_t^1 H^* H$; that is,

$$\dot{\Phi}(t) = (B - P_t^1 H^* H)\, \Phi(t),\ \Phi(0) = I. \tag{15}$$

The proof of Theorem 2.3 is a consequence of the following facts: for every $0 < \sigma < \bar{\lambda}$ there exist an $M_\sigma < \infty$ and a $t_\sigma < \infty$ such that

$$\|\Phi(t)\, \Phi^{-1}(s)\| \leq M_\sigma e^{-\sigma(t-s)} \quad \text{for } t > s \geq t_\sigma, \tag{16}$$

and

$$\|P_t^0 - P_t^1\| \leq M_\sigma e^{-\sigma t} \quad \text{for all } t. \tag{17}$$

We have already seen (17) in Remark 2.1. (16) is very natural in view of the fact that $B - P_t^1 H^* H \to B - P_\infty H^* H$ as $t \to \infty$, and we return to its proof in a moment.

Now from (14) we have

$$\hat{X}_t - Z_t = \Phi(t)(m_0 - z) + \int_0^t \Phi(t)\, \Phi^{-1}(s)[P_s^0 - P_s^1] H^*\, d\nu_s. \tag{18}$$

Clearly (16) implies

$$\lim_{t\to\infty} e^{\sigma t}\,\Phi(t)(m_0 - z) = 0 \quad \text{if} \quad \sigma < \bar{\lambda}. \tag{19}$$

Because ν is Brownian, if $\sigma < \bar{\lambda}$ there is a constant $K_\sigma < \infty$ such that

$$\begin{aligned} &E\left|\int_0^t \Phi(t)\Phi^{-1}(s)[P_s^0 - P_s^1]H^*\,d\nu_s\right|^2 \\ &= \int_0^t \operatorname{tr}\left[\Phi(t)\Phi^{-1}(s)\,[P_s^0 - P_s^1]\,H^*H\,[P_s^0 - P_s^1]\,\Phi^{-1}(s)^*\Phi(t)^*\right] ds \\ &\le K_\sigma\, e^{-2\sigma t}, \end{aligned} \tag{20}$$

where we have used (16) and (17) to derive the last estimate. Also, (19) and (20) show that for any $0 < \sigma < \bar{\lambda}$ there is a K_σ such that

$$E[|\hat{X}_t - Z_t|^2] \le K_\sigma\, e^{-2\sigma t}. \tag{21}$$

By applying the Borel–Cantelli lemma to $\hat{X}_n - Z_n$ and

$$\sup_{n\le t\le n+1} |\hat{X}_t - Z_t - (\hat{X}_n - Z_n)|,$$

we obtain from (21) that

$$\lim_{t\to\infty} |\hat{X}_t - Z_t|\, e^{\sigma t} = 0 \quad \text{almost surely}$$

for any $0 < \sigma < \hat{\lambda}$, which was to be proved.

Finally, we consider (16). This is a consequence of the estimate

$$\|\psi(t)\,\psi^{-1}(s)\| \le M\, e^{-\beta(t-s)}$$

for the solution to $\dot{\psi}(t) = A(t)\psi(t)$, $\psi(0) = I$, where

$$\begin{aligned} &\|e^{A(t)\tau}\| \le Ke^{\gamma\tau} \quad \forall\, t \ge 0,\ \forall \tau \ge 0, \\ &\|\dot{A}(t)\| \le \delta \quad \forall\, t, \end{aligned}$$

and $0 < \beta = \gamma - (\delta K \log K)^{1/2}$, $M = K^2$; see Harris and Miles [5, Thm. 5.10, p. 146]. Apply this to $A(t) = B - P_t^1 H^*H$, using the fact $\dot{P}_t^1 \to 0$ as $t \to \infty$ and the fact that the eigenvalues of $B - P_t^1 H^*H$ will have real parts less than $-\sigma$ for all large enough t, to derive (16). □

We can deduce from Theorem 2.3 a statement about the convergence of probability measures. For a vector m and matrix $Q \ge 0$ let $N(m, Q)$ denote the Gaussian distribution with mean m and covariance Q. We shall write

$$N(m, Q)(\varphi) := \int \varphi(x)\, N(m, Q)\,(dx).$$

In the context of Theorem 2.3, if X_0 has the distribution $N(m_0, R_0)$, then $\pi_t = N(\hat{X}_t, P_t^{R_0})$ is the conditional distribution of X_t given $\mathcal{Y}_t$. On the other hand

$$\bar{\pi}_t := N(Z_t^{z,R_1}, P_t^{R_1})$$

would be the conditional distribution that we would think we were getting if we had started with the wrong initial conditions z and R_1. $\bar{\pi}_t$ solves the Kushner–Stratonovich equation for the conditional distribution starting from the initial condition $N(z, R_1)$.

For a continuous function f on $\mathbb{R}^d$, let

$$||f||_{BL} := \sup_{x\in\mathbb{R}^d} |f(x)| + \sup_{x,y\in\mathbb{R}^d} |x-y|^{-1}|f(x)-f(y)|,$$

and define the metric

$$\beta(\mu,\nu) := \sup\left\{\int f\,(d\mu - d\nu) \;:\; ||f||_{BL} \le 1\right\}$$

on $\mathcal{P}(\mathbb{R}^d)$. It is well known that β metrizes the topology of weak convergence on $\mathcal{P}(\mathbb{R}^d)$. It is easy to prove the following lemma.

LEMMA 2.4. *If* $m_t - m'_t \to 0$ *as* $t \to \infty$ *and if* $\lim_{t\to\infty} Q_t = Q_\infty = \lim_{t\to\infty} Q'_t$, *then*

$$\lim_{t\to\infty} ||N(m_t, Q_t) - N(m'_t, Q'_t)||_{BL} = 0.$$

Theorem 2.3 and Lemma 2.4 immediately imply the following.

COROLLARY 2.5. *Let the assumptions of Theorem* 2.3 *hold. Then*

$$\lim_{t\to\infty} ||\pi_t - \bar{\pi}_t||_{BL} = 0 \quad \textit{almost surely,}$$

where $\pi_t = N(\hat{X}_t, P_t^{R_0})$ *and* $\bar{\pi}_t = N(Z_t^{z,R_1}, P_t^{R_1})$.

We next want to present a similar result for the case in which the initial condition X_0 is not Gaussian. A discrete time version of this result may be found in Sowers [13] and Makowski and Sowers [12]. We shall present the convergence result under the assumption

(22) $\qquad (B, H)$ is detectable and (B, F) is stabilizable.

THEOREM 2.6. *Let* (X, Y) *denote the solution of* (4)–(5). *Assume that* (22) *holds and* $E[|X_0|^2] < \infty$. *Then*

(23) $$\lim_{t\to\infty} \hat{X}_t - Z_t^{z,R} = 0 \quad \textit{almost surely,}$$

and in the L^2 *sense for* any $z \in \mathbb{R}^d$, $R \ge 0$. *Moreover, if* π_t *denotes the conditional distribution of* X_t *given* $\mathcal{Y}_t$,

(24) $$\lim_{t\to\infty} \pi_t(\varphi) - N(Z_t^{z,R}, P_t^R)(\varphi) = 0 \quad \textit{almost surely}$$

for every bounded, uniformly continuous φ.

Proof. The proof uses a formula, due to Makowski [11] and Beneš and Karatzas [1], which expresses the optimal filter for a linear system with non-Gaussian initial conditions in terms of the solution to a Kalman filtering equation. The idea is to decompose the signal X as

(25) $$X_t = e^{Bt} X_0 + \overline{X}_t,$$

where

$$\overline{X}_t := \int_0^t e^{B(t-s)} F dV_s + \int_0^t e^{B(t-s)} G dY_s,$$

and to introduce the new measure $\overline{\mathbb{P}}$ defined by

$$\frac{d\overline{\mathbb{P}}}{d\mathbb{P}} = \exp\left[\int_0^T -\langle He^{Bs}X_0,\, dW_s\rangle - \frac{1}{2}\int_0^T |He^{Bs}X_0|^2\, ds\right].$$

Then on $(\Omega, \overline{\mathbb{P}})$

$$\overline{W}_t := \int_0^t He^{Bs}X_0\, ds + W_t, \qquad t \le T,$$

is a Brownian motion, and X_0 is independent of $(V_t, \overline{W}_t)_{t\le T}$. Moreover

$$\overline{\mathbb{P}}(X_0 \in A) = \mathbb{P}(X_0 \in A)$$

for all Borel A (i.e., the law of X_0 remains unchanged).

Let

$$L_t := \exp\left[\int_0^t \langle He^{Bs}X_0,\, d\overline{W}_s\rangle - \frac{1}{2}\int_0^t |He^{Bs}X_0|^2\, ds\right]$$

(note that $L_T^{-1} = \frac{d\overline{\mathbb{P}}}{d\mathbb{P}}$). Then for any nonnegative measurable function θ of $(X_0, \overline{X}_t)$ (or equivalently of (X_0, X_t))

$$E[\theta(X_0, \overline{X}_t)/\mathcal{Y}_t] = \frac{\overline{E}[\theta(X_0, \bar{X}_t)L_t/\mathcal{Y}_t]}{\bar{E}[L_t/\mathcal{Y}_t]}. \tag{26}$$

From the above formula for $\overline{X}_t$ and the fact that X_0 and $(\overline{W}, Y)$ are $\overline{\mathbb{P}}$-independent, both the numerator and the denominator may be expressed by an integral involving the Kalman filter for the process $(\overline{X}_t, \overline{W}_t)$, given $\mathcal{Y}$, whose equations we now write. Let (Z_t, P_t^0) denote the solution of (6)–(7) with initial conditions $(Z_0, P_t^0) = (0, 0)$. Define (S_t, Q_t, M_t) and $\widetilde{Z}_t$ by the equations

$$\dot{S}_t = BS_t - P_t^0 H^* H(e^{Bt} + S_t), \quad S_0 = 0,$$

$$\dot{Q}_t = -e^{B^* t}H^* HS_t - S_t^* H^* He^{Bt} - S_t^* H^* HS_t, \quad Q_0 = 0, \tag{27}$$

$$\dot{M}_t = e^{B^* t}H^* He^{Bt}, \quad M_0 = 0, \text{ and}$$

$$d\widetilde{Z}_t = (e^{Bt} + S_t)^* H^*(dY_t - HZ_t\, dt), \quad \widetilde{Z}_0 = 0. \tag{28}$$

We then have that

(29)

$$\overline{E}[\theta(X_0, \overline{X}_t)L_t/\mathcal{Y}_t] = \int_{\mathbb{R}^d} \pi_0(dx)\, e^{-1/2\langle M_t x, x\rangle} \left\{\int_{\mathbb{R}^{2d}} \theta(x, r_1) e^{\langle x, r_2\rangle} n_t(dr_1, dr_2)\right\},$$

where n_t is the Gauss measure with mean

$$\begin{pmatrix} Z_t \\ \widetilde{Z}_t \end{pmatrix}$$

and covariance

$$C_t = \begin{pmatrix} P_t^0 & S_t \\ S_t & Q_t \end{pmatrix}.$$

Note that

$$\int_{\mathbb{R}^{2d}} e^{i\langle\lambda,r_1\rangle+i\langle\mu,r_2\rangle+\langle x,r_2\rangle}\, n_t(dr_1\, dr_2) \tag{30}$$
$$= e^{i\langle\lambda,Z_t\rangle+i\langle\mu-ix,\widetilde{Z}_t\rangle} \times e^{-1/2\,\langle C_t\binom{\lambda}{\mu-ix},\binom{\lambda}{\mu-ix}\rangle}$$

$$= e^{1/2\langle Q_t x,x\rangle+\langle x,\widetilde{Z}_t\rangle} \times \exp\Big[i\langle\lambda, Z_t + S_t x\rangle + i\langle\mu, \widetilde{Z}_t + Q_t x\rangle \tag{31}$$
$$\cdot -1/2\left\langle C_t\begin{pmatrix}\lambda\\ \mu\end{pmatrix},\begin{pmatrix}\lambda\\ \mu\end{pmatrix}\right\rangle\Big].$$

Thus

$$\bar{n}_t(dr_1, dr_2) := e^{-1/2\langle Q_t x,x\rangle-\langle x,\widetilde{Z}_t\rangle} e^{\langle x,r_2\rangle} n_t(dr_1, dr_2)$$

is the normal distribution with mean

$$\begin{pmatrix} Z_t \\ \widetilde{Z}_t \end{pmatrix} + \begin{pmatrix} S_t \\ Q_t \end{pmatrix} x$$

and variance C_t since it has the correct characteristic functional by (30). For each t, let U_t denote a $N(0, P_t^0)$ random variable. Then by (26) and (29)

$$E[\varphi(X_t)/\mathcal{Y}_t] = E[\varphi(e^{Bt}x + \overline{X}_t)/\mathcal{Y}_t]$$

$$= \frac{\int \pi_0(dx)\, e^{1/2\langle(Q_t-M_t)x,x\rangle+\langle x,\widetilde{Z}_t\rangle} \int \varphi(e^{Bt}x + r_1)\bar{n}_t(dr_1, dr_2)}{\int \pi_0(dx)\, e^{1/2\langle(Q_t-M_t)x,x\rangle+\langle x,\widetilde{X}_t\rangle}} \tag{32}$$

$$= \frac{\int \pi_0(dx)\, e^{1/2\langle(Q_t-M_t)x,x\rangle+\langle x,\widetilde{Z}_t\rangle} E[\varphi(Z_t + (e^{Bt} + S_t)x + U_t)]}{\int \pi_0(dx)\, e^{1/2\langle(Q_t-M_t)x,x\rangle+\langle x,\widetilde{Z}_t\rangle}}.$$

In the case $\varphi(x) = x$, (32) gives

$$\hat{X}_t = Z_t + E[(e^{Bt} + S_t)X_0/\mathcal{Y}_t]. \tag{33}$$

Note that

$$\frac{d}{dt}(e^{Bt} + S_t) = (F - P_t^0 H^* H)(e^{Bt} + S_t)$$

as follows directly from equation (27) for S_t. Thus $e^{Bt} + S_t$ is the state transition matrix for $B - P_t^0 H^* H$. Since $P_t^0 \to P_\infty$ where $B - P_\infty H^* H$, the same argument as

in the proof of Theorem 2.3 (see (16)) shows that for any $0 < \sigma < \bar{\lambda} = \min\{|\mathrm{Re}\lambda|\,;\ \lambda$ is an eigenvalue of $B - P_\infty H^* H\}$ there exists M such that

$$\|(e^{Bt} + S_t)\| \le M e^{-\sigma t}. \tag{34}$$

Furthermore $E[X_0|\mathcal{Y}_t]$ is a square-integrable martingale, and hence its sample paths are bounded. Thus it follows easily from (33) and (34) that

$$\lim_{t\to\infty} \hat{X}_t - Z_t^{0,0} = 0 \quad \text{almost surely and in } L^2. \tag{35}$$

(Recall $Z_t := Z_t^{0,0}$.) To complete the proof of (23) it only remains to show that

$$\lim_{t\to\infty} Z_t - Z_t^{z,R} = 0 \quad \text{almost surely} \tag{36}$$

and in the L^2-sense for any $z \in \mathbb{R}$ and $R \ge 0$. To do this, we apply the argument of Theorem 2.3 to

$$\begin{aligned} d(Z_t - Z_t^{z,R}) &= (B - P_t^R H^* H)(Z_t - Z_t^{z,R})\, dt + (P_t^0 - P_t^R) H^*\, d\nu_t \\ &\quad + (P_t^0 - P_t^R) H^* H(\hat{X}_t - Z_t)\, dt, \end{aligned} \tag{37}$$

where ν is the innovations process, $\nu_t = Y_t - \int_0^t H\hat{X}_s\, ds$. The details are completely analogous, and we omit them. We remark that (35) is used to handle the effect of the third term in (36).

Finally we consider the proof (24). Because of (25) and Lemma 2.4 it suffices to prove

$$\lim_{t\to\infty} \pi_t(\varphi) - N_t(Z_t, P_t^0)(\varphi) = 0 \quad \text{almost surely} \tag{38}$$

for any bounded, uniformly continuous φ. By (32) and the definition of U_t.

$$\begin{aligned} &\pi_t(\varphi) - N(Z_t, P_t^0)(\varphi) \\ &\quad = \frac{\int \pi_0(x)\, e^{[1/2\langle (Q_t - M_t)x, x\rangle + \langle x, \widetilde{Z}_t\rangle]}\, E[\varphi(Z_t + U_t) - \varphi(Z_t + U_t + (e^{Bt} + S_t)x)]}{\int \pi_0\,(dx)\, \exp[1/2\langle (Q_t - M_t)x, x\rangle + \langle x, \widetilde{Z}_t\rangle]} \end{aligned} \tag{39}$$

Decompose the integral in the numerator into the sum of the integral over the region $|(e^{Bt} + S_t)x| < \delta$ and the integral over the region $|(e^{Bt} + S_t)x| \ge \delta$. Then from (38)

$$\begin{aligned} |\pi_t(\varphi) - N_t(Z_t, P_t^0)(\varphi)| &\le \sup_{|y-y'|<\delta} |\varphi(y) - \varphi(y')| \\ &\quad + 2\|\varphi\|_\infty\, E\{\mathbf{1}_{\{|(e^{Ft} + S_t)X_0| \ge \delta\}} | \mathcal{Y}_t\} \\ &\le \sup_{|y-y'|<\delta} |\varphi(y) - \varphi(y')| + \frac{2\|\varphi\|_\infty}{\delta^2}\, \|e^{Bt} + S_t\|^2\, E[|X_0|^2 | \mathcal{Y}_t]. \end{aligned}$$

By first letting $t \to \infty$ and then using uniform continuity, we arrive at (38) and thus complete the proof. □

Remark 2.7. By being a bit more careful, we can prove, as in Theorem 2.3, that

$$\lim_{t\to\infty} e^{\sigma t}[\hat{X}_t - Z_t^{z,R}] = 0 \quad \text{almost surely}$$

for any $0 < \sigma < \bar{\lambda}$ under the hypotheses of Theorem 2.6.

3. Stability in the case of signal ergodicity. In this section, we prove stability of filters for a class of signals which themselves forget their initial condition in the sense that they converge in law to a unique invariant measure. A result of Stettner [14] and Kunita [7] shows that the conditional distribution $(\pi_t)_{t\geq 0}$ inherits a similar ergodic property, and we use this to obtain stability.

3.1. Filtering model. Rather than model the signal X directly by a stochastic differential equation, we begin more abstractly with a locally compact, complete separable metric space E and a Markov semigroup $(S_t)_{t\geq 0}$ on $C_b(E)$ specifying the transition laws of X. (Note that S_t was used in the previous section to denote part of a covariance matrix; we change that notation from here on.) More precisely, we suppose throughout that $(S_t)_{t\geq 0}$ is a strongly continuous, positive, and conservative ($S_t 1 = 1$) contraction semigroup on $C_b(E)$. We shall assume that Markov processes associated to $(S_t)_{t\geq 0}$ admit càdlàg sample paths. That is, if X denotes the canonical process on the Skorohod space $D([0,\infty) : E)$, we suppose that for each $x \in E$ there is a probability measure P_x on $D([0,\infty) : E)$ for which X is a Markov process with transition semigroup $(S_t)_{t\geq 0}$ and $P_x[X_0 = x] = 1$. In addition, we assume throughout that $x \to P_x(A)$ is measurable for all Borel sets in $D([0,\infty) : E)$ for the topology of uniform convergence on compact time intervals. The measure

$$P^\nu(A) = \int_E P_x(A)\,\nu(dx), \quad A \in \sigma(X_s,\ 0 \leq s < \infty),$$

where $\nu \in \mathcal{P}(E)$, then defines the law of the process corresponding to $(S_t)_{t\geq 0}$ with initial condition ν.

We note for future use the following consequence of the Feller assumption. Let $\{\nu^n\}$ be a sequence of probability laws on E converging weakly to the law ν and $\{X^n\}$ and X denote the Markov processes associated to $(S_t)_{t\geq 0}$ with respective initial laws $\{\nu^n\}$ and ν. Then

$$X^n \Rightarrow X \tag{40}$$

as $n \to \infty$, where $\Rightarrow$ denotes weak convergence of X^n to X in $D([0,\infty) : E)$. Corollary 3.3.2 in Ethier and Kurtz [3] says that to show this it is enough to show that X^n converges weakly to X in $D([0,\infty); E^\triangle)$, where $E^\triangle$ is the one-point compactification of E. However, Theorems 3.9.4 and 3.9.1 in [3] and the fact that the generator of $(S_t)_{t\geq 0}$ is dense in $C_b(E)$ imply that X^n is relatively compact in $D([0,\infty); E^\triangle)$, and the Feller property implies that $(X^n(t_1),\ldots,X^n(t_k)) \Rightarrow (X(t_1),\ldots,X(t_k))$ for any finite set of nonnegative times $t_1,\ldots,t_k$, just as in the proof of Theorem 4.2.5 of [3]. These two facts imply the desired weak convergence (see Theorem 3.7.8 in [3]).

Our filtering model is then specified by the signal-observation pair (X, Y) defined on a probability space $(\Omega, \mathcal{F}, \mathbb{P})$ as follows:

$$X = (X_t)_{t\geq 0} \text{ is a càdlàg, } E\text{-valued Markov process with law } P^{\pi_0}; \tag{41}$$

$$Y_t = \int_0^t h(X_s)\,ds + W_t, \tag{42}$$

where W is an $\mathbb{R}^p$-valued Brownian motion independent of X and

$$h : E \to \mathbb{R}^p \text{ is bounded and continuous.} \tag{43}$$

In the model (41)–(42), note that π_0 denotes the initial distribution of X. As usual, π_t shall denote the conditional distribution of X_t given $\mathcal{Y}_t = \sigma(Y_s,\ 0 \le s \le t)$.

It is convenient to work throughout on the canonical probability space $\Omega = D([0,\infty) : E) \times C_0([0,\infty) : \mathbb{R}^p)$ for the signal-observation pair. Henceforth, we let (X, Y) denote the canonical process on Ω. For a probability measure $\nu \in \mathcal{P}(E)$, let Q^ν be the measure on Ω corresponding to the filtering model (41)–(42) when ν is the probability measure of X_0; that is, the marginal of Q^ν on $D([0,\infty) : E)$ is P^ν and, on $(\Omega,\ Q^\nu)$, $Y_t - \int_0^t h(X_s)\,ds$ is a Brownian motion independent of X. Sometimes, to emphasize that we are working on $(\Omega,\ Q^\nu)$, we shall write $(X^\nu,\ Y^\nu)$ for the canonical process. We use $E^\nu[\cdot]$ to denote expectations with respect to Q^ν and $\pi^\nu = (\pi_t^\nu)_{t\ge 0}$ to denote the conditional distribution of X_t given $\sigma\{Y_s,\ s \le t\}$ on $(\Omega,\ Q^\nu)$.

This canonical formulation is useful because we shall need to consider (41)–(42) for arbitrary initial laws ν for X_0. In particular, it allows us to define a semigroup for the conditional law process. Endow $\mathcal{P}(E)$ with the topology of weak convergence. For $F \in C_b(\mathcal{P}(E))$, define

$$(M_t F)(\nu) = E^\nu[F(\pi_t^\nu)], \quad t \ge 0,\ \nu \in \mathcal{P}(E).$$

Given the assumptions above made on $(S_t)_{t\ge 0}$ and in (41)–(42), $(M_t)_{t\ge 0}$ defines a Feller, Markov transition semigroup on $C_b(\mathcal{P}(E))$; see Stettner [14].

3.2. Ergodicity assumptions. We formulate next the precise ergodicity assumptions that we require of the signal semigroup.

$(S_t)_{t\ge 0}$ admits a unique invariant measure μ and

$$\text{(H1)} \qquad \limsup_{t\to 0} \int_E |S_t f(x) - \mu(f)|\,\mu(dx) = 0 \quad \forall\, f \in C_b(E).$$

For $\nu \in \mathcal{P}(E)$, let νS_t denote the law of X_t^ν. We say that S_t forgets ν for μ if

$$\text{(H2)} \qquad \nu S_t \to \mu \text{ weakly as } t \to \infty.$$

The main point of (H1) and (H2) is Stettner's result, Theorem 3 in [14], lifting ergodic properties of $(S_t)_{t\ge 0}$ to $(M_t)_{t\ge 0}$.

LEMMA 3.1. a) *If $(S_t)_{t\ge 0}$ satisfies* (H1), *there is a unique measure M on $\mathcal{P}(E)$ such that M is $(M_t)_{t\ge 0}$-invariant and*

$$\int_{\mathcal{P}(E)} \eta(\phi)\, M(d\eta) = \mu(\phi) \quad \forall \phi \in C_b(E).$$

b) *If, in addition, ν satisfies* (H2), *then for every $F \in C_b(\mathcal{P}(E))$*

$$\lim_{t\to\infty} (M_t F)(\nu) = \int F(\eta)\, M(d\eta) =: M(F).$$

3.3. Stability result. Our stability theorem compares the correct estimate $\pi_t(\phi)$ for a fixed function ϕ to a filter $\overline{\pi}_t(\phi)$ computed with an erroneous initial condition $\overline{\pi}_0$. Rather than work with the Kushner–Stratonovich equation, we construct π_t and $\overline{\pi}_t$ by means of the Kallianpur–Striebel formula. It is convenient to do this on the canonical space $\Omega = D([0,\infty) : E) \times C_0([0,\infty) : \mathbb{R}^p)$ with the canonical process (X, Y). Let λ denote Wiener measure on $C_0([0,\infty)\,;\,\mathbb{R}^p)$ and y denote an element of $C_0([0,\infty)\,;\,\mathbb{R}^p)$.

Let

$$L_t(X,Y) = \exp\left\{\int_0^t h(X_s)\cdot dY_s - \frac{1}{2}\int_0^t |h(X_s)|^2\, ds\right\}.$$

Recall the definition of P^ν on $D([0,\infty)\,;\,E)$ from §3.1. Then we may define

$$\rho_t(\phi)(\nu\,;\,y) := \frac{E^{P^\nu\times\lambda}[\phi(X_t)\,L_t(X,Y)\;/\;Y_s,\ s\le t](y)}{E^{P^\nu\times\lambda}[L_t(X,Y)\;/\;Y_s,\ s\le t](y)},$$

where the dependence on $y\in C_0([0,\infty)\,:\,\mathbb{R}^p)$ is explicitly indicated. Then for the filtering model (X,Y) specified in (41), (42) with initial condition π_0

$$\pi_t(\phi) = \rho_t(\phi)(\pi_0\,;\,Y). \tag{44}$$

In other words, on (Ω, Q^{π_0}), $\rho_t(\phi)(\pi_0, Y)$ defines a version of the optimal filter $E^{\pi_0}[\phi(X_t)|\mathcal{Y}_t]$. Now fix $\overline{\pi}_0\in\mathcal{P}(E)$, $\overline{\pi}_0\neq\pi_0$, and define

$$\overline{\pi}_t(\phi) = \rho_t(\phi)(\overline{\pi}_0\,;\,Y). \tag{45}$$

On $(\Omega, Q^{\overline{\pi}_0})$, $\overline{\pi}_t(\phi)$ computes the optimal filter, but on (Ω, Q^{π_0}) it corresponds to a filter computed with the incorrect initial condition $\overline{\pi}_0$. (The perturbed filter $\overline{\pi}_t(\phi)$ will satisfy the Kushner–Stratonovich equation on $(\Omega, Q^{\overline{\pi}_0})$ and hence also on (Ω, Q^{π_0}) because the laws of Y^{π_0} and $Y^{\overline{\pi}_0}$ are mutually absolutely continuous up to any finite time.) We wish to assess the performance of $\overline{\pi}_t(\phi)$ on (Ω, Q^{π_0}), that is, when π_0 is the true initial measure.

Given an initial distribution ν for X_0, let R^ν denote the marginal of Q^ν on $C_0([0,\infty)\,:\,\mathbb{R}^p)$; that is, R^ν is the law of the observation process when X_0 has distribution ν.

THEOREM 3.2. *Assume*

(i) $(S_t)_{t\ge0}$ *satifies* (H1);

(ii) π_0 *and* $\overline{\pi}_0$ *both satisfy* (H2) (*that is,* (H2) *is true when* ν *is replaced by* π_0 *and* $\overline{\pi}_0$);

(iii) $R^{\pi_0}\ll R^{\overline{\pi}_0}$.

Then for every bounded, continuous $\varphi : E\to\mathbb{R}$

$$\lim_{t\to\infty} E^{\pi_0}[(\pi_t(\varphi)-\overline{\pi}_t(\varphi))^2] = 0.$$

Remark 3.3. 1. Condition (iii) says roughly that on supp R^{π_0}, it is impossible to distinguish with certainty from the entire history of the observations, whether the initial condition is π_0 or $\overline{\pi}_0$. Condition (iii) is certainly satisfied if $\pi_0\ll\overline{\pi}_0$ as one may easily see by conditioning Y^ν on $\sigma(X_0^\nu)$.

2. The choice of $E^{\overline{\pi}_0}(\pi_t(\phi)-\overline{\pi}_t(\phi))^2$ to measure the difference of $\pi_t(\phi)$ and $\overline{\pi}_t(\phi)$ is made for convenience of calculation. In fact, because $|\pi_t(\phi)|$, $|\overline{\pi}_t(\phi)|\le\|\phi\|_\infty$ almost surely for all t, $\pi_t(\phi)-\overline{\pi}_t(\phi)\to0$ in $L^p(Q^{\overline{\pi}_0})$ for all $p\ge1$.

Proof of Theorem 3.2. The proof takes several steps. The first step is to establish a uniform finite memory approximation of $\pi_t(\phi)$ and $\overline{\pi}_t(\phi)$.

Let $\mathcal{Y}_t^s = \sigma\{Y_r - Y_s\,;\,s\le r\le t\}$ be the σ-algebra of the increments of the observations on $[s,t]$. We shall call

$$\pi_{t-T,t}(\phi) := E^{\pi_0}[\phi(X_t)/\mathcal{Y}_t^{t-T}]$$

the (exact) filter of memory length T. Because of the time-homogeneity of X, computing $\pi_{t-T,t}(\phi)$ is the same as computing the filter on $[0,T]$ when the initial condition is $\pi_0 S_{t-T}$ since $\pi_0 S_{t-T}$ is the law of X_{t-T} when X_0 has distribution π_0. In other words,

$$\pi_{t-T,t}(\phi) = \rho_T(\phi)(\pi_0 S_{t-T},\, Y_{t-T+\cdot} - Y_{t-T}) \tag{46}$$

(see (44)). Likewise, we define the finite memory filter computed with the wrong initial condition:

$$\overline{\pi}_{t-T,t}(\phi) = \rho_T(\phi)(\overline{\pi}_0 S_{t-T},\, Y_{t-T+\cdot} - Y_{t-T}). \tag{47}$$

LEMMA 3.4. *Let hypotheses* (i)–(iii) *of Theorem* 3.2 *be satisfied. Then for every* $\varepsilon > 0$ *there is a* T_ε *and a* t_ε *such that*

$$E[(\pi_t(\phi) - \pi_{t-T_\varepsilon,t}(\phi))^2] < \varepsilon \quad \forall\, t \geq t_\varepsilon \tag{48}$$

and

$$E[(\overline{\pi}_t(\phi) - \overline{\pi}_{t-T_\varepsilon,t}(\phi))^2] < \varepsilon \quad \forall\, t \geq t_\varepsilon. \tag{49}$$

Remark 3.5. We obtain in (48) and (49) an estimate for a fixed-length finite memory filter uniform in t for all large t. The expectations in (48) and (49) are both evaluated assuming that π_0 is the initial law of X.

Proof. We shall first establish (48). (49) will follow, using a similar argument and the absolute continuity of R^{π_0} with respect to $R^{\overline{\pi}_0}$.

Let the continuous bounded function $F_\phi : \mathcal{P}(E) \to \mathbb{R}$ be given by $F_\phi(\eta) = \eta^2(\phi)$. Observe that

$$\begin{aligned} &E^{\pi_0}[(\pi_t(\phi) - \pi_{t-T,t}(\phi))^2] \\ &\quad = E^{\pi_0}[(\pi_t(\phi))^2] - 2E^{\pi_0}\{E^{\pi_0}[\phi(X_t)/\mathcal{Y}_t]\, E^{\pi_0}[\phi(X_t)/\mathcal{Y}_t^{t-T}]\} \\ &\qquad + E^{\pi_0}[(\pi_{t-T,t}(\phi))^2] \\ &\quad = E^{\pi_0}(\pi_t(\phi))^2 - E^{\pi_0}(\pi_{t-T,t}(\phi))^2 \\ &\quad = (M_t F_\phi)(\pi_0) - (M_T F_\phi)(\pi_0 S_{t-T}), \end{aligned} \tag{50}$$

where the last line follows from (46). Lemma 3.1 implies that there exists a T_ε such that

$$|(M_t F_\phi)(\mu) - M(F_\phi)| < \varepsilon/3 \quad \forall t \geq T_\varepsilon \tag{51}$$

and

$$|(M_t F_\phi)(\pi_0) - M(F_\phi)| < \varepsilon/3 \quad \forall t \geq T_\varepsilon. \tag{52}$$

Since $(M_t)_{t\geq 0}$ is Feller, so that $\eta \to M_t F_\phi(\eta)$ is continuous in η in the weak topology (see Stettner [14]), and since $\pi_0 S_t \to \mu$ weakly as $t \to \infty$, we may choose t_ε so that, with T_ε already fixed,

$$|M_{T_\varepsilon} F_\phi(\mu) - M_{T_\varepsilon} F_\phi(\pi_0 S_{t-T_\varepsilon})| < \varepsilon/3 \quad \forall\, t \geq t_\varepsilon. \tag{53}$$

Combining (51)–(53) gives the result (48).

To establish (49), we work on the canonical space for the observations. By (45) and (47)

$$(\overline{\pi}_t(\phi) - \overline{\pi}_{t-T,t}(\phi))^2 = \psi(t-T,t\,;\,Y),$$

where

$$\psi(t-T,t\,;\,y) := (\rho_t(\phi)(\overline{\pi}_0\,;\,y) - \rho_T(\phi)(\overline{\pi}_0 S_{t-T}\,;\,y_{t-T+\cdot} - y_{t-T}))^2$$

for $y \in C_0([0,\infty)\,:\,\mathbb{R}^p)$.

Thus, since the law of Y is R^{π_0} and by hypothesis (iii) $R^{\pi_0} \ll R^{\overline{\pi}_0}$,

$$E^{\pi_0}[(\overline{\pi}_t(\phi) - \overline{\pi}_{t-T,t}(\phi))^2] = \int_{C_0([0,\infty):\mathbb{R}^p)} \psi(T-t,t\,;\,y)\, R^{\pi_0}(dy)$$

(54)

$$= \int \psi(T-t,t\,;\,y) \frac{dR^{\pi_0}}{dR^{\overline{\pi}_0}}(y)\, R^{\overline{\pi}_0}(dy).$$

However,

$$\int \psi(T-t,t\,;\,y)\, R^{\overline{\pi}_0}(dy) = E^{\overline{\pi}_0}(\pi_t^{\overline{\pi}_0}(\phi) - \pi_{t-T,t}^{\overline{\pi}_0}(\phi))^2,$$

where in the right-hand side $E^{\overline{\pi}_0}$ denotes expectation on a space where $\overline{\pi}_0$ is the true distribution of X_0 and $\pi_t^{\overline{\pi}_0}(\phi)$ is the true conditional estimate. By the same argument as above, for each $\delta > 0$ we can choose $\bar{t}_\delta$ and $\overline{T}_\delta$ so that $E^{\overline{\pi}_0}[(\pi_t^{\overline{\pi}_0}(\phi) - \pi_{t-T_\delta,t}^{\overline{\pi}_0}(\phi))^2] < \delta$ for all $t \geq t_\delta$. Now fix $\varepsilon > 0$ and choose $K \geq 1$ so large that

$$\int \frac{dR^{\pi_0}}{dR^{\overline{\pi}_0}}(y)\, \mathbf{1}_{\left\{\frac{dR^{\pi_0}}{dR^{\overline{\pi}_0}}(y) \geq K\right\}} dR^{\overline{\pi}_0}(y) < \frac{\varepsilon}{8\|\phi\|_\infty^2}. \tag{55}$$

Then let $T_\varepsilon = \overline{T}_{\varepsilon/2K}$, $t_\varepsilon = \bar{t}_{\varepsilon/2K}$. Using (54), (55), and the fact that

$$|\psi(T-t,t\,;\,y)| \leq 4\|\phi\|_\infty^2, \quad R^{\overline{\pi}_0} \text{ almost surely},$$

we get

$$E^{\pi_0}[(\overline{\pi}_t(\phi) - \overline{\pi}_{t-T_\varepsilon,t}(\phi))^2] < \varepsilon \quad \forall\, t \geq t_\varepsilon,$$

thereby proving (49). It is clear that we can find T_ε and t_ε that work simultaneously for (48) and (49) as in the statement of the lemma. □

The second step of the proof will be to demonstrate the following lemma.

LEMMA 3.6. *For any fixed* T

$$\lim_{t\to\infty} E[(\pi_{t-T,t}(\phi) - \overline{\pi}_{t-T,t}(\phi))^2] = 0. \tag{56}$$

Before giving the proof of (56) we show how to use it to complete the proof of the stability result Theorem 3.2. The idea is simply to write for $t \geq t_\varepsilon$, where t_ε and T_ε are from Lemma 3.4,

$$\begin{aligned}
&E^{\pi_0}[(\pi_t(\phi) - \overline{\pi}_t(\phi))^2] \\
&\quad \leq 3\{E^{\pi_0}[(\pi_t(\phi) - \pi_{t-T_\varepsilon,t}(\phi))^2] + E^{\pi_0}[(\overline{\pi}_t(\phi) - \overline{\pi}_{t-T_\varepsilon,t}(\phi))^2] \\
&\qquad + E^{\pi_0}[(\pi_{t-T_\varepsilon,t}(\phi) - \overline{\pi}_{t-T_\varepsilon,t}(\phi))^2]\} \\
&\quad \leq 3\{\varepsilon + E^{\pi_0}[(\pi_{t-T_\varepsilon,t}(\phi) - \overline{\pi}_{t-T_\varepsilon,t}(\phi))^2]\} \quad \forall\, t \geq T_\varepsilon.
\end{aligned}$$

By first taking $t \to \infty$ and using Lemma 3.6 and then taking $\varepsilon \downarrow 0$, we obtain the result

$$\lim_{t\to\infty} E[(\pi_t(\phi) - \overline{\pi}_t(\phi))^2] = 0,$$

and that proves Theorem 3.2.

Proof of Lemma 3.6. The idea of the proof is that as t increases, $\pi_0 S_{t-T}$ and $\overline{\pi}_0 S_{t-T}$ converge weakly to the same limit, and hence, using (45) and (47), $\overline{\pi}_{t-T,t}(\phi)$ and $\pi_{t-T,t}(\phi)$ also converge. Indeed, if for every path y the function taking the path x to $\phi(X_T)L_T(x,y)$ were continuous in x, then the weak convergence of $\pi_0 S_{t-T}$ and $\overline{\pi}_0 S_{t-T}$ would imply that $\overline{\pi}_{t-T,t}(\phi)(y)$ converges to $\pi_{t-T,t}(\phi)(y)$. This is not the case, but by using Skorohod's representation theorem we can complete the argument. The arguments we use very much follow the techniques of Goggin [4], who establishes conditions for weak convergence of filters. As in [4], we shall use the following inequality, here stated abstractly.

LEMMA 3.7. *Let Z, Z' be nonnegative, integrable random variables, U be a bounded random variable, and $\mathcal{G}$ be a sub-σ-algebra. Then*

$$E\left[Z\left|\frac{E[UZ/\mathcal{G}]}{E[Z/\mathcal{G}]} - \frac{E[UZ'/\mathcal{G}]}{E[Z'/\mathcal{G}]}\right|\right] \le 2\|U\|_\infty E[|Z - Z'|],$$

where $\|U\|_\infty = \operatorname{ess\,sup}|U|$ and, by convention,

$$(E[Z/\mathcal{G}])^{-1} \equiv 0 \text{ on } \{E[Z/\mathcal{G}] = 0\},$$

and similarly for Z'.

Proof of Lemma 3.7.

$$\begin{aligned}
&E\left[Z\left|\frac{E[UZ/\mathcal{G}]}{E[Z/\mathcal{G}]} - \frac{E[UZ'/\mathcal{G}]}{E[Z'/\mathcal{G}]}\right|\right] \\
&= E\left[Z\left|\frac{E[U(Z-Z')/\mathcal{G}]}{E[Z/\mathcal{G}]} + \frac{E[UZ'/\mathcal{G}]}{E[Z/\mathcal{G}]} - \frac{E[UZ'/\mathcal{G}]}{E[Z'/\mathcal{G}]}\right|\right] \\
&= E\left[Z\left|\frac{E[U(Z-Z')/\mathcal{G}]}{E[Z/\mathcal{G}]} + \frac{E[UZ'/\mathcal{G}]}{E[Z'/\mathcal{G}]} \times \frac{E[Z'-Z/\mathcal{G}]}{E[Z/\mathcal{G}]}\right|\right] \\
&\le \|U\|_\infty E\left[Z\frac{E[|Z-Z'|/\mathcal{G}]}{E[Z/\mathcal{G}]}\right] + \|U\|_\infty E\left[Z\frac{E[|Z'-Z|/\mathcal{G}]}{E[Z/\mathcal{G}]}\right] \\
&= 2\|U\|_\infty E|Z'-Z|. \qquad \square
\end{aligned}$$

T being given, we proceed by constructing for each $t > T$ a measure $\tilde{P}_t$ on a probability space $\tilde{\Omega}$ with processes $(X, \bar{X}, W)$ such that

$$\begin{cases} W & \text{is a Brownian motion independent of } (X, \overline{X}), \\ X & \text{is a Markov process with initial condition } \pi_0 S_{t-T} \text{ and semigroup } (S_s)_{s\ge 0}, \\ \overline{X} & \text{is a Markov process with initial condition } \overline{\pi}_0 S_{t-T} \text{ and semigroup } (S_s)_{s\ge 0}. \end{cases} \tag{57}$$

The purpose of this construction is to have a common probability space for evaluating the expectations defining $\rho_T(\phi)(\overline{\pi}_0 S_{t-T}, Y)$ and $\rho_T(\phi)(\pi_0 S_{t-T}, Y)$. To explain, we define

$$Y_s = \int_0^s h(X_u)\, du + W_s.$$

If

$$\frac{d\tilde{Q}_T}{d\tilde{P}_t} := L_T^{-1}(X,Y)$$

it is clear by the usual Girsanov argument that, under $\overline{Q}_t$, Y is a Brownian motion independent of $(X,\overline{X})$. Thus, referring to the definition of $\rho_t(\phi)(\nu\,;\,y)$,

$$\rho_T(\phi)(\overline{\pi}_0\,S_{t-T},\,Y) = \frac{E^{\tilde{Q}_T}[\phi(\overline{X}_T)\,L_T\,(\overline{X},Y)/Y_s,\,0\le s\le T]}{E^{\tilde{Q}_T}[L_T(\overline{X},Y)/Y_s,\,0\le s\le T]},\ \tilde{P}_t \text{ almost surely,} \tag{58}$$

because under $\tilde{Q}_T$ the law of $(\overline{X},Y)$ is $P_{\overline{\pi}_0 S_{t-T}}\times\lambda$. Likewise

$$\rho_T(\phi)(\pi_0\,S_{t-T},Y) = \frac{E^{\tilde{Q}_T}[\phi(X_T)\,L_T\,(X,Y)/Y_s,\,0\le s\le T]}{E^{\tilde{Q}_T}[L_T(X,Y)/Y_s,\,0\le s\le T]}. \tag{59}$$

Since $|\rho_T(\phi)(\nu,\cdot)|\le\|\phi\|_\infty$ almost surely for any ν, it follows that

$$\begin{aligned}
&E[(\pi_{t-T,t}(\phi)-\overline{\pi}_{t-T,t}(\phi))^2]\\
&\quad\le 2\|\phi\|_\infty E^{\tilde{P}_t}[|\rho_T(\phi)(\pi_0\,S_{t-T},\,Y)-\rho_T(\phi)(\overline{\pi}_0\,S_{t-T},Y)|]\\
&\quad= 2\|\phi\|_\infty\,E^{\tilde{Q}_t}[L_T(X,Y)|\,\rho_T(\phi)(\pi_0\,S_{t-T},\,Y)-\rho_T(\phi)(\overline{\pi}_0\,S_{t-T},\,Y)|]
\end{aligned}$$

Now set $\mathcal{G}=\sigma\{Y_s,\,0\le s\le T\}$, write (59) as

$$\begin{aligned}
&\frac{E^{\tilde{Q}_T}[\phi(\overline{X}_T)\,L_T\,(X,Y)/\mathcal{G}]}{E^{\tilde{Q}_T}[L_T(X,Y)/\mathcal{G}]}+\frac{E^{\tilde{Q}_T}[(\phi(X_T)-\phi(\overline{X}_T))L_T(X,Y)/\mathcal{G}]}{E^{\tilde{Q}_T}[L_T(X,Y)/\mathcal{G}]}\\
&=\frac{E^{\tilde{Q}_T}[\phi(\overline{X}_T)\,L_T\,(X,Y)/\mathcal{G}]}{E^{\tilde{Q}_T}[L_T(X,Y)/\mathcal{G}]}+E^{\tilde{P}_T}[\phi(X_T)-\phi(\overline{X}_T)]/\mathcal{G}],
\end{aligned}$$

and use Lemma 3.7 to derive

$$\begin{aligned}
&E[(\pi_{t-T,t}(\phi)-\overline{\pi}_{t-T,t}(\phi))^2]\\
&\quad\le 2\|\phi\|_\infty\{2\|\phi\|_\infty\,E^{\tilde{Q}_t}|L_T(X,Y)-L_T(\overline{X},Y)|\\
&\qquad\qquad+E^{\tilde{P}_t}|\phi(X_T)-\phi(\overline{X}_T)|\}.
\end{aligned} \tag{60}$$

Note that (60) is true regardless of the joint law of X and $\overline{X}$.

To complete the proof it is necessary to show that the right-hand side of (60) approaches 0 along any sequence of times $\{t_n\}$ such that $t_n\to 0$. Let X^n denote the sequence of $D([0,\infty):E)$-valued Markov processes corresponding to the semigroup $(S)_{t\ge0}$ and initial laws $\pi_0\,S_{t_k-T}$, and let $\overline{X}^k$ denote that sequence corresponding to initial laws $\overline{\pi}_0\,S_{t_k-T}$. Since $\pi_0\,S_{t_k-T}$ and $\overline{\pi}_0\,S_{t_k-T}$ both converge weakly to the invariant measure μ as $k\to\infty$ by assumption (ii) of Theorem 2.3, it follows from the discussion at (40) that $X^k\Rightarrow\hat{X}$ and $\overline{X}^k\Rightarrow\tilde{X}$, where $\tilde{X}$ is the stationary process with initial law μ and transition semigroup $(S_t)_{t\ge0}$. By Skorohod's representation theorem, as stated and proved in Theorem 3.1.8 in [3], we may assume that there is a common probability space $(\tilde{\Omega}.\tilde{P})$ on which $\tilde{X}$ and the sequences X^k and $\overline{X}^k$ are defined such that the convergence is almost sure in $D([0,\infty):E)$. Let this probability

space also support a Brownian motion Y independent of the other processes. On this probability space, (60) translates into

$$
\begin{aligned}
&E[(\pi_{t-T,t}(\phi) - \overline{\pi}_{t-T,t}(\phi))^2] \\
&\quad \le 2\|\phi\|_\infty \{2\|\phi\|_\infty E^{\tilde{P}} |L_T(X^n, Y) - L_T(\overline{X}^n, Y)| \\
&\qquad + E^{\tilde{P}} |\phi(X_T^n) - \phi(\overline{X}_T^n)|\}.
\end{aligned} \tag{61}
$$

It is immediate that the second term on the right-hand side converges to 0 as $n \to \infty$. As for the first term, note that $\{L_T(X^n, Y) - L_T(\overline{X}^n, Y\}$ converges to 0 in probability and, because h is bounded, is uniformly integrable. Hence the first term also converges to 0, which completes the proof. □

Acknowledgments. We wish to thank Professor H. J. Kushner for bringing the asymptotic stability question for filters to our attention. We also thank the anonymous reviewers for their comments, which helped to generalize and simplify the proof of Theorem 3.2, and for other improvements.

NONDEGENERATE SOLUTIONS AND RELATED CONCEPTS IN AFFINE VARIATIONAL INEQUALITIES*

M. C. FERRIS† AND J. S. PANG‡

This paper is dedicated to Professor O. L. Mangasarian on the occasion of his 60th birthday (January 12, 1994). We submitted this paper for publication on Professor Mangasarian's birthday to a journal that he has been associated with for many years, the SIAM Journal on Control and Optimization. *He has made many significant contributions to the topics addressed in this paper, namely, error bounds, weak sharp minima, minimum principle sufficiency, and complementarity problems. We are both indebted to him for his constant encouragement, advice, and fruitful collaborations over many years. Without his help and guidance, this paper would not have been possible.*

Abstract. The notion of a strictly complementary solution for complementarity problems is extended to that of a nondegenerate solution of variational inequalities. Several equivalent formulations of nondegeneracy are given. In the affine case, an existence theorem for a nondegenerate solution is given in terms of several related concepts which are shown to be equivalent in this context. These include a weak sharp minimum, the minimum principle sufficiency, and error bounds. The gap function associated with the variational inequality plays a central role in this existence theorem.

Key words. Variational inequalities, nondegenerate solutions, weak sharp minima, minimum principle, error bounds

1. Introduction.

Strict complementarity is a familiar notion in the context of optimization problems and complementarity theory. A classical result proved in [17, Cor. 2A] shows that a solvable linear complementarity problem defined by a skew-symmetric matrix must possess a strictly complementary solution. In general, the property of strict complementarity of a solution to an optimization or a complementarity problem plays an important role in many aspects of such a problem. Historically, Fiacco and McCormick [14] used this property to develop the first sensitivity theory of nonlinear programs under perturbation. Robinson [40] has introduced a generalized notion of strict complementarity and considered its role in parametric nonlinear programming.

In recent years, the strict complementarity property was given a renewed emphasis in the analysis of many iterative algorithms for solving linear and nonlinear programs and complementarity problems. Dunn [10] and Burke and Moré [6] used a geometric definition of a strictly complementary solution to a nonlinear program and showed how such a solution was essential for the successful identification of active constraints in a broad class of gradient based methods for solving constrained optimization problems. Güler and Ye [19] showed that many interior-point algorithms for linear programs generated a sequence of iterates whose limit points satisfied the

strict complementarity condition; they also extended the result to a monotone linear complementarity problem having a strictly complementary solution. Monteiro and Wright [36] demonstrated that the existence of a strictly complementary solution was essential for the fast convergence of these interior-point algorithms for a monotone linear complementarity problem.

The theory of error bounds for inequality systems has in recent years become an active area of research within the field of mathematical programming. In this regard, Hoffman [21] obtained the first error bound for a system of finitely many linear inequalities. The generalizations of Hoffman's result are too numerous to be mentioned here. There are several factors that have motivated this proliferation of activities. In general, an error bound is an inequality that bounds the distance function from a test vector to the solutions of a system of inequalities in terms of a residual function. Part of the importance of an error bound is that it provides the foundation for exact penalization of mathematical programs [24], [30]; this in turn is strongly connected to the theory of optimality conditions for nonlinear programs [4]. Error bounds play an important role in the convergence analysis (particularly in establishing the convergence rates) of many iterative algorithms for solving various mathematical programs. These include the the matrix splitting methods for linear complementarity problems [8, Chap. 5] and affine variational inequalities [25], various descent methods for convex minimization problems [26]–[28], and interior-point methods for linear programs and extensions [23], [35], [42]. Error bounds can also be used to design inexact iterative methods [37], [16].

The concept of a weak sharp minimum for a constrained optimization problem was introduced in [11]. The usefulness of this concept in establishing the finite convergence of various iterative algorithms was discussed in several subsequent papers [12], [5], [1]. Among the classes of optimization problems that possess weak sharp minima are linear programs [32] and certain convex quadratic programs and monotone linear complementarity problems [5].

Finally, the minimum principle [29] is a well-known set of conditions that must be satisfied by any local minimum of a nonlinear program with a convex feasible region. One way to state this principle is in terms of the gap function [20] of the nonlinear program; informally, this principle states that a local minimum of a nonlinear program must be a global minimizer of the gap function over the same convex feasible region of the program. In [13], Ferris and Mangasarian studied the "converse" of this principle for the class of convex programs and coined the term *minimum principle sufficiency* when this converse was valid. They also showed (Theorem 6 in [13]) that for a convex quadratic program, the minimum principle sufficiency is equivalent to the existence of weak sharp minima of the program and that of a nondegenerate solution in the primal-dual linear complementarity formulation of the quadratic program. This somewhat unexpected result therefore links up the various concepts that we have discussed so far.

The present research is motivated by the desire to gain a better understanding of the concepts of strict complementarity, error bounds, weak sharp minima, and minimum principle sufficiency for various mathematical programs and how these concepts are related. The results in [13], [31] suggest that for a monotone linear complementarity problem and its "natural" convex quadratic program [8, Chap. 3], all these concepts are equivalent (to be made precise later). In this paper, we shall extend the equivalences to a monotone affine variational inequality.

By adding appropriate multipliers to the constraints of an affine variational in-

equality, this problem becomes equivalent to a linear complementarity problem [38]. In view of the results available for the linear complementarity problem [13], [31], this transformation therefore raises the question of whether the intended generalized equivalences for the affine variational inequality are of any significant interest. We shall argue that the results derived herein are potentially useful for two reasons: (i) they do not rely on the multipliers of the constraints and hence are independent of the representation of the defining set of the affine variational inequality; and (ii) as it turns out, we shall use a nondifferentiable optimization problem as the bridge to connect the various concepts in question. The latter approach raises the issue of the extent to which these equivalences will remain valid for more general nondifferentiable optimization problems. The full treatment of this last issue is, regrettably, beyond the scope of the present work.

2. Definitions and review. For a given mapping $F : R^n \to R^n$, the nonlinear complementarity problem, which we shall denote NCP (F), is to find a vector $x \in R^n$ such that

$$x \geq 0, \quad F(x) \geq 0, \quad x^T F(x) = 0.$$

A solution $\hat{x}$ of this problem is said to be *strictly complementary*, or *nondegenerate*, if $\hat{x} + F(\hat{x}) > 0$. For an optimization problem of the form

$$\begin{aligned} &\text{minimize} && f(x) \\ &\text{subject to} && x \in C, \end{aligned} \tag{2.1}$$

where $f : R^n \to R$ is continuous and $C \subseteq R^n$ is convex, different forms of nondegeneracy abound in the literature. Dunn [10] and Burke and Moré [6] use the relative interior condition

$$-\nabla f(\hat{x}) \in \operatorname{ri} N_C(\hat{x}) \tag{2.2}$$

to define an optimal solution $\hat{x}$ of (2.1) as being nondegenerate. Here $\operatorname{ri} S$ denotes the relative interior of the convex set S and $N_C(x)$ denotes the normal cone to the convex set C at the point $x \in R^n$, which is defined by

$$N_C(x) \equiv \begin{cases} \{y \in R^n \mid y^T(c - x) \leq 0 \text{ for all } c \in C\} & \text{if } x \in C, \\ \emptyset & \text{otherwise.} \end{cases}$$

Robinson [40] uses the dual form: $T_C(\hat{x}) \cap \nabla f(\hat{x})^{\perp}$ is a subspace where the tangent cone, $T_C(x)$, to C at x is the polar of the normal cone at x; i.e.,

$$T_C(x) \equiv \{z \in R^n \mid z^T y \leq 0 \text{ for all } y \in N_C(x)\}.$$

It is easy to show (see [40, Lem. 2.1] for a proof) that the definition (2.2) is equivalent to the subspace definition. In general, for a convex set $S \subseteq R^n$, the negative of the polar of S is the dual cone of S, which is denoted by S^*.

It is not difficult to extend the notion of strict complementarity to the context of a variational inequality (VI) of the following form: find $x \in C$ such that

$$F(x)^T(y - x) \geq 0 \quad \text{for all } y \in C, \tag{2.3}$$

where $C \subseteq R^n$ is a nonempty closed convex set and $F : R^n \to R^n$ is a continuous mapping. We shall denote this problem by VI (F, C); its (possibly empty) solution

set is denoted $\mathrm{SOL}(F, C)$. When F is affine and given by $F(x) \equiv q + Mx$ for some vector $q \in R^n$, some matrix $M \in R^{n \times n}$, and all vectors $x \in R^n$, we shall append the word "affine" to describe this VI and denote it by AVI (q, M, C); the notation $\mathrm{SOL}(q, M, C)$ will be used to denote the solution set of this AVI.

Given a vector $\hat{x} \in \mathrm{SOL}(F, C)$ by simply replacing $\nabla f(\hat{x})$ by $F(\hat{x})$ in either (2.2) or in Robinson's dual definition, we obtain a definition for $\hat{x}$ to be a nondegenerate solution of the VI (F, C). Thus, $\hat{x}$ is a nondegenerate solution of the VI (F, C) if

$$-F(\hat{x}) \in \operatorname{ri} N_C(\hat{x}). \tag{2.4}$$

A justification for this definition of nondegeneracy for the VI is the well-known fact that the VI (F, C) is equivalent to the generalized equation

$$0 \in F(x) + N_C(x),$$

or equivalently

$$-F(x) \in N_C(x),$$

which easily leads to the generalized definition.

When C is a polyhedron, it is possible to give some further characterizations for the nondegeneracy of a solution $\hat{x} \in \mathrm{SOL}(F, C)$. We shall summarize these characterizations in Proposition 2.2 below. The additional characterizations rely heavily on the face structure of a polyhedral convex set. It is well known that the relative interiors of the faces of a convex set C form a partition of C [41, Thm. 18.2]. Throughout this paper, we will use the notation $\mathcal{F}(x)$ to denote the face of C which contains a vector $x \in C$ in its relative interior. According to [41, Thm. 18.1], $\mathcal{F}(x)$ is the "minimal" face of C containing $x \in C$, minimal in terms of set inclusion. The following result was established in [6].

LEMMA 2.1. *The normal cone to a polyhedral convex set C is constant for all $x \in \operatorname{ri} \mathcal{F}$, where $\mathcal{F}$ is a face of C, henceforth labeled $\mathcal{N}_{\mathcal{F}}$. Furthermore,*

$$\operatorname{aff} \mathcal{F} - x = \operatorname{lin} T_C(x) = (\operatorname{aff} \mathcal{N}_{\mathcal{F}})^{\perp}.$$

As a consequence of this lemma, it follows that $\mathcal{F} - \mathcal{N}_{\mathcal{F}}$ has full dimension and hence has a nonempty interior. This observation will be used in the proof of the following proposition which gives a number of equivalent conditions for a given solution of the VI (F, C) to be nondegenerate. Among these conditions, condition (iv) has been used by Reinoza [39].

PROPOSITION 2.2. *Suppose $\hat{x}$ solves VI (F, C) and C is polyhedral. Let $\mathcal{F} = \mathcal{F}(\hat{x})$ so that $-F(\hat{x}) \in \mathcal{N}_{\mathcal{F}}$. The following statements are equivalent:*

(i) $\hat{x} + F(\hat{x}) \in \operatorname{int}(\mathcal{F} - \mathcal{N}_{\mathcal{F}})$,

(ii) $-F(\hat{x}) \in \operatorname{ri} \mathcal{N}_{\mathcal{F}}$,

(iii) $T_C(\hat{x}) \cap F(\hat{x})^{\perp}$ *is a subspace,*

(iv) $\hat{x}$ *is in the relative interior of the face of C exposed by $-F(\hat{x})$.*

If F is monotone and any one of the above four conditions holds, then $\mathrm{SOL}(F, C) \subseteq \mathcal{F}(\hat{x})$.

Proof. The equivalence of (ii) and (iii) has been noted before. The equivalence of (ii) and (iv) is by [7, Thm. 2.4]. Since $\hat{x} \in \operatorname{ri} \mathcal{F}$ and $-F(\hat{x}) \in \operatorname{ri} \mathcal{N}_{\mathcal{F}}$, it follows that $\hat{x} + F(\hat{x}) \in \operatorname{ri} \mathcal{F} + \operatorname{ri}(-\mathcal{N}_{\mathcal{F}}) = \operatorname{ri}(\mathcal{F} - \mathcal{N}_{\mathcal{F}})$ which, as we have noted, has a nonempty

interior. Thus (ii) implies (i). We now show that (i) implies (ii). First note that $\hat{x} + F(\hat{x}) \in \operatorname{ri} \mathcal{F} + \operatorname{ri}(-\mathcal{N}_{\mathcal{F}})$, so suppose

$$\hat{x} + F(\hat{x}) = y + z$$

with $y \in \operatorname{ri} \mathcal{F}$ and $z \in \operatorname{ri}(-\mathcal{N}_{\mathcal{F}})$. Then $y - \hat{x} \in \operatorname{aff} \mathcal{F} - \hat{x}$, $F(\hat{x}) - z \in \operatorname{aff} \mathcal{N}_{\mathcal{F}}$, and these two subspaces are orthogonal. Hence $y - \hat{x} = 0 = F(\hat{x}) - z$ as required.

For the final statement of the proposition, let $z \in \operatorname{SOL}(F, C)$ be arbitrary. Since F is monotone, it follows that (see, e.g., [3])

$$F(c)^T(c - z) \geq 0 \quad \text{for all } c \in C,$$

which implies, since $\hat{x} \in C$, that $F(\hat{x})^T(\hat{x} - z) \geq 0$. However, $\hat{x}$ also solves the VI (F, C), so

$$F(\hat{x})^T(c - \hat{x}) \geq 0 \quad \text{for all } c \in C,$$

implying $F(\hat{x})^T(\hat{x} - z) = 0$. Hence,

$$z \in \{c \in C \mid F(\hat{x})^T(c - \hat{x}) = 0\},$$

which is $\mathcal{F}(\hat{x})$ by [7, Thm. 2.4]. □

In the remainder of this paper, we shall focus on the AVI (q, M, C). As stated before, our goal is to establish the equivalence of the existence of a nondegenerate solution to this problem and a number of related concepts. In what follows, we shall describe each of these concepts more formally.

The notion of a weak sharp minimum was introduced in [11] and extensively analyzed in [5], [13]. The formal definition is as follows.

DEFINITION 2.3. *Let $f : R^n \to R \cup \{\infty\}$ and $C \subseteq R^n$. A nonempty subset $S \subseteq C$ is a set of* weak sharp minima *for the problem* (2.1) *if there is a scalar $\alpha > 0$ such that for all $x \in C$ and all $y \in S$*

$$f(x) \geq f(y) + \alpha \operatorname{dist}(x \mid S), \tag{2.5}$$

where

$$\operatorname{dist}(x \mid S) \equiv \inf\{\|z - x\| : z \in S\}$$

is the distance from the point x to S measured by any norm.

Note that a set of weak sharp minima for (2.1), if it exists, must be equal to the set of global minimizers of f over C. In general, for the problem (2.1), it would be useful to know when a set of weak sharp minima exists. As mentioned in the introduction, an affirmative answer to this question is known for a linear program and certain convex quadratic programs.

Observe that if the problem (2.1) has a weak sharp minimum, then the inequality (2.5), which is equivalent to

$$\operatorname{dist}(x \mid S) \leq \alpha^{-1}(f(x) - f_{\min}) \quad \text{for all } x \in C, \tag{2.6}$$

where $f_{\min}$ is the minimum value of f on C, can be interpreted as providing an *error bound* for an arbitrary feasible point x to the set of minimizers of (2.1), with the residual given by the deviation of the objective value $f(x)$ from its minimum value. Consequently, a necessary and sufficient condition for the existence of a weak sharp

minimum for the problem (2.1) is the existence of an error bound of the type (2.6) where S is the set of minimizers of (2.1).

The notion of minimum principle sufficiency was introduced in [13]. The minimum principle is a well-known necessary optimality condition for a program of the form (2.1), where C is convex; this principle states that, for a continuously differentiable function f, if $\bar{x}$ solves (2.1) then $\bar{x} \in \mathrm{SOL}(\nabla f, C)$. Roughly speaking, minimum principle sufficiency is the converse assumption; nevertheless, in order to make this precise, it will be necessary for us to introduce the gap function associated with the VI (F, C). Specifically, the gap function for the latter problem is the extended-valued function $g : R^n \to R \cup \{\infty\}$ given by

$$g(x) \equiv x^T F(x) - \omega(x) \quad \text{for all } x \in R^n, \tag{2.7}$$

where

$$\omega(x) \equiv \inf\{z^T F(x) : z \in C\}. \tag{2.8}$$

The function ω was introduced in [18], where it was used for stability analysis of the AVI. Let

$$\Omega(x) \equiv \operatorname{argmin}\{z^T F(x) : z \in C\};$$

it is understood that if the minimum value in $\omega(x)$ is not attained, then $\Omega(x)$ is defined to be the empty set. We note that if C is polyhedral, then $\omega(x)$ is the optimum objective value of a linear program.

The following proposition summarizes some important properties of the two functions g and ω. No proof is needed for these properties.

PROPOSITION 2.4. *Let $F : R^n \to R^n$ be a mapping and C be a closed convex subset of R^n. The following statements are valid.*

(i) *The function $\omega : R^n \to R \cup \{-\infty\}$ is concave and extended-valued; if F is a monotone affine function, then g is convex.*

(ii) *The function g is nonnegative on C.*

(iii) *A vector $x \in \mathrm{SOL}(F, C)$ if and only if $x \in \Omega(x)$ or, equivalently, $x \in C$ and $g(x) = 0$.*

(iv) *If C is polyhedral, then*

$$\begin{aligned} \operatorname{dom}\omega &\equiv \{x \in R^n \mid \omega(x) > -\infty\} \\ &= \{x \in R^n \mid F(x) \in (\operatorname{rec} C)^*\}, \end{aligned}$$

where $(\operatorname{rec} C)^*$ is the dual of the recession cone of C.

(v) *If C is polyhedral and F is affine, then ω is piecewise linear and g is piecewise quadratic.*

Returning to the problem (2.1) and letting $F \equiv \nabla f$, we see that the minimum principle for this problem can be stated simply as: if x is a local minimizer of (2.1), then $x \in \Omega(x)$. Obviously, if f is a convex function, then every vector $x \in C$ with the property that $x \in \Omega(x)$ must be a global minimizer of (2.1). For a convex function f, the minimum principle sufficiency stipulates that for all optimal solutions x of (2.1), or equivalently, for all x such that $x \in \Omega(x)$, if $x' \in \Omega(x)$, then x' is also a global minimizer of (2.1). In what follows, we shall give several equivalent formulations for this sufficiency property, one of which will be the basis for generalization to a nondifferentiable function f.

PROPOSITION 2.5. *Let $f : R^n \to R$ be a continuously differentiable convex function and $C \subseteq R^n$ be a closed convex set. Assume that $\mathcal{S} \equiv \operatorname{argmin}\{f(x) : x \in C\} \neq \emptyset$. The following statements are equivalent.*

(a) *The minimum principle sufficiency holds for the minimization problem* (2.1).

(b) *For all $x \in \mathcal{S}$, $\mathcal{S} = \Omega(x)$, where $\Omega(x) \equiv \operatorname{argmin}\{z^T \nabla f(x) : z \in C\}$.*

(c) *For all $x \in \mathcal{S}$,*

$$[z \in C,\ \nabla f(x)^T(z - x) = 0] \Rightarrow z \in \mathcal{S}.$$

If in addition, C is polyhedral and $\mathcal{S} \neq \emptyset$, then any one of the above statements is further equivalent to

(d) *$\mathcal{S}$ is a set of weak sharp minima for* (2.1).

Proof. Since $\mathcal{S} \subseteq \Omega(x)$ for all optimal solutions x of (2.1), the equivalence of (a) and (b) is obvious. That (c) is also equivalent to (a) or (b) is equally obvious because x solves (2.1) if and only if $x \in \Omega(x)$. Finally, the equivalence of (d) and the above statements was proved in [5, Thm. 4.2]. □

Remark. Theorem 4.2 in [5] shows that in the above proposition, (d) always implies (a) for an arbitrary closed convex set C; nevertheless, Example 4.3 in [5] shows that the polyhedrality of C is needed for the reverse implication.

3. Miscellaneous preliminary results. We have now defined all the concepts we shall deal with in this paper. Our ultimate goal is to link them together for the monotone AVI (q, M, C), where M is assumed to be positive semidefinite and C is polyhedral. The linkage is via the gap function g for this AVI. Motivation for using this function g stems partly from statement (iii) in Proposition 2.4, which suggests that g is a likely candidate for a residual function for the AVI. This choice is also supported by some error bound results in [18] which are derived with the aid of some additional properties of the monotone AVI. In what follows, we shall summarize the relevant results for later use. Throughout the rest of this paper, we shall fix the vector $q \in R^n$, the matrix $M \in R^{n \times n}$, and the set $C \subseteq R^n$. We shall assume that M is positive semidefinite and C is a polyhedral. We shall further assume that $\mathrm{SOL}(q, M, C) \neq \emptyset$.

There are two important constants associated with the solution set of the monotone AVI (q, M, C). Indeed, by results in [18], there exist a vector $d \in R^n$ and a scalar $\sigma \in R_+$, both dependent on the data (q, M, C), such that

$$d = (M + M^T)x, \quad \sigma = x^T M x \tag{3.1}$$

for all $x \in \mathrm{SOL}(q, M, C)$. Furthermore, $\mathrm{SOL}(q, M, C)$ can be characterized, using these constants, as

$$\mathrm{SOL}(q, M, C) = \{x \in C \mid \omega(x) - (q^T x + \sigma) \geq 0, (M + M^T)x = d\}.$$

Since, for every $x \in \mathrm{SOL}(q, M, C), \omega(x) \leq (q + Mx)^T x = (q + d - M^T x)^T x = (q + d)^T x - \sigma$, simple algebra gives the alternative characterization:

$$\begin{aligned} \mathrm{SOL}(q, M, C) &= \{x \in C \mid \omega(x) - (q + d)^T x + \sigma \geq 0, (M + M^T)x = d\} \\ &= \{x \in C \mid \omega(x) - (q + d)^T x + \sigma = 0, (M + M^T)x = d\}. \end{aligned}$$

For a given polyhedral cone $K \subseteq R^n$, the AVI (q, M, K) is equivalent to a generalized linear complementarity problem which is to find a vector $y \in R^n$ such that

$$y \in K, \quad q + My \in K^*, \quad \text{and} \quad y^T(q + My) = 0,$$

where

$$K^* \equiv \{y \in R^n \mid y^T x \geq 0 \ \forall x \in K\}$$

is the dual cone of K. In this case, we shall use the prefix GLCP instead of AVI to describe the problem. The feasible region of GLCP (q, M, K) is given by

$$\text{FEA}(q, M, K) \equiv \{y \in K \mid q + My \in K^*\}. \tag{3.2}$$

Since $\mathcal{F} - \mathcal{N}_{\mathcal{F}} \subseteq K + K^*$ and both have full dimension, it follows from Proposition 2.2 that if $\hat{y}$ is a strictly complementary solution of the GLCP (q, M, K), then

$$\hat{y} + q + M\hat{y} \in \text{int}(K + K^*).$$

It is known [38] that the AVI (q, M, C) is equivalent to a mixed linear complementarity problem in higher dimensions. In what follows, we shall establish a connection between the nondegenerate solutions of these two problems. For this purpose, we shall represent C as

$$C = \{x \in R^n \mid Ax \geq b\} \tag{3.3}$$

for some matrix $A \in R^{m \times n}$ and vector $b \in R^m$. Then a vector $x \in C$ is a solution of AVI (q, M, C) if and only if there exists a vector $\lambda \in R^m$ such that the following conditions hold:

$$\begin{aligned} 0 &= q + Mx - A^T\lambda, \\ w &= Ax - b, \\ w \geq 0, &\quad \lambda \geq 0, \quad w^T\lambda = 0. \end{aligned}$$

These conditions define the GLCP (p, N, K) where the variable y and the data (p, N, K) are given by

$$y \equiv \begin{pmatrix} x \\ \lambda \end{pmatrix}, \quad p \equiv \begin{pmatrix} q \\ -b \end{pmatrix}, \quad N \equiv \begin{bmatrix} M & -A^T \\ A & 0 \end{bmatrix}, \tag{3.4}$$

and $K \equiv R^n \times R^m_+$. Specializing Proposition 2.2 to the latter GLCP, we can show that a solution $(\hat{x}, \hat{\lambda})$ of GLCP (p, N, K) is nondegenerate if and only if $\hat{w} + \hat{\lambda} > 0$, where $\hat{w} \equiv A\hat{x} - b$. Based on this observation, the following result is easy to prove.

PROPOSITION 3.1. *Let C be given by (3.3). A solution $\hat{x}$ of the AVI (q, M, C) is nondegenerate if and only if for some $\hat{\lambda}$, $(\hat{x}, \hat{\lambda})$ is a nondegenerate solution of the GLCP (p, N, K).*

Proof. Let

$$\mathcal{I} \equiv \{i \mid (A\hat{x} = b)_i\}$$

be the index set of active constraints at $\hat{x}$. By the definition of $\mathcal{F} = \mathcal{F}(\hat{x})$, we have

$$\mathcal{F} = \{x \in C \mid (Ax = b)_i \text{ for all } i \in \mathcal{I}\}$$

and $\hat{x} \in \text{ri}\,\mathcal{F}$. Hence,

$$\mathcal{N}_{\mathcal{F}} = \{A^T\lambda \mid \lambda \in R^m_-, \lambda_i = 0, \text{ for all } i \notin \mathcal{I}\}.$$

From the theory of convex polyhedra, particularly [41, Thm. 6.6], we have

$$\operatorname{ri}\mathcal{F} = \{x \in \mathcal{F} \mid (Ax > b)_i \text{ for all } i \notin \mathcal{I}\}$$
$$\operatorname{ri}\mathcal{N}_{\mathcal{F}} = \{A^T\lambda \mid \lambda_i < 0 \text{ for all } i \in \mathcal{I};\ \lambda_i = 0 \text{ for all } i \notin \mathcal{I}\}.$$

Hence, according to Proposition 2.2, $\hat{x}$ is nondegenerate if and only if $\hat{x} \in \operatorname{ri}\mathcal{F}$ and $-(q + M\hat{x}) \in \operatorname{ri}\mathcal{N}_{\mathcal{F}}$. From this, the existence of the desired $\hat{\lambda}$ is obvious. □

The GLCP (p, N, K) defined above is related to the linear program defining the function $\omega(x)$, which is given by

$$\omega(x) \equiv \min\{z^T(q + Mx) : z \in C\};$$

see (2.8). The dual of this linear program, denoted $\Delta(x)$, is

$$\begin{aligned} &\text{maximize} && b^T\lambda \\ &\text{subject to} && q + Mx - A^T\lambda = 0, \quad \lambda \geq 0. \end{aligned}$$

We shall let $\Lambda(x)$ denote the (possibly empty) optimal solution set of $\Delta(x)$. The following result summarizes an important relation between the dual program $\Delta(x)$ and the GLCP (p, N, K) as well as two properties of $\Delta(x)$ as a parametric linear program with a changing right-hand side in the constraints.

PROPOSITION 3.2. *The following three statements hold:*

(a) *if $\hat{x} \in \mathrm{SOL}(q, M, C)$, then a pair $(\hat{x}, \hat{\lambda})$ solves the GLCP (p, N, K) if and only if $\hat{\lambda} \in \Lambda(\hat{x})$;*

(b) *there exists a constant $\alpha > 0$ such that for all $x \in R^n$ with $\Lambda(x) \neq \emptyset$ and all λ feasible to $\Delta(x)$,*

$$-b^T\lambda + \omega(x) \geq \alpha \operatorname{dist}(\lambda \mid \Lambda(x)); \tag{3.5}$$

(c) *there exists a constant $\beta > 0$ such that for all x and x' in R^n with $\Lambda(x) \neq \emptyset$ and $\Lambda(x') \neq \emptyset$,*

$$\Lambda(x) \subseteq \Lambda(x') + \beta\|x - x'\|\mathcal{B}(0, 1),$$

where $\mathcal{B}(0, 1)$ is the unit Euclidean ball in R^m.

Proof. Statement (a) is obvious. For statement (b), observe that if $\Lambda(x) \neq \emptyset$ for some x, then $\omega(x)$ is finite and equal to the optimal objective value of $\Delta(x)$. By [32, Lem. A.1], every solvable linear program has a nonempty set of weak sharp minima. A careful look at the proof of this result reveals that the constant associated with such a set of weak sharp minima is independent of the right-hand side in the constraints of the program. Thus (b) follows. Statement (c) follows from the Lipschitzian property of the solutions to a parametric right-hand sided linear program as proved in [33, Thm. 2.4]. □

We shall associate the following optimization problem with the AVI (q, M, C):

$$\begin{aligned} &\text{minimize} && g(x) \\ &\text{subject to} && x \in C, \end{aligned} \tag{3.6}$$

where g is the gap function defined in (2.7) with $F(x) \equiv q + Mx$. By Proposition 2.4, the function g is convex, piecewise quadratic, and possibly extended-valued; it is in general not Fréchet differentiable. We should mention that recently there have been

several differentiable optimization problems introduced for the study of a monotone VI [2], [15], [34]; since the objective functions of the latter optimization problems are not known to be convex even for a monotone AVI, it is therefore not clear whether our results can be extended to these other (possibly nonconvex) optimization formulations of the AVI.

Since C is polyhedral, it can be represented as

$$C = \operatorname{conv} G + \operatorname{rec} C \tag{3.7}$$

for some finite point set $G \subseteq R^n$, where $\operatorname{conv} G$ denotes the convex hull of G and $\operatorname{rec} C$ denotes the recession cone of C. When C is a cone, we have $G = \{0\}$ and $C = \operatorname{rec} C$. Clearly, the problem (3.6) can be equivalently stated as

$$\begin{array}{ll} \text{minimize} & x^T(q + Mx) - \tilde{\omega}(x) \\ \text{subject to} & x \in C, \quad q + Mx \in (\operatorname{rec} C)^*, \end{array} \tag{3.8}$$

where

$$\tilde{\omega}(x) \equiv \min\{z^T(q + Mx) : z \in G\}. \tag{3.9}$$

When C is a cone, the latter formulation reduces to

$$\begin{array}{ll} \text{minimize} & x^T(q + Mx) \\ \text{subject to} & x \in \operatorname{FEA}(q, M, C), \end{array}$$

since $C = \operatorname{rec} C$ and $\tilde{\omega}(x)$ is identically equal to zero in this case; see (3.2) for the definition of $\operatorname{FEA}(q, M, C)$.

Unlike the function $\omega(x)$, $\tilde{\omega}(x)$ is finite valued for all $x \in R^n$, and it is dependent on the point set G (in particular, on the representation of C). Nevertheless, $\omega(x) = \tilde{\omega}(x)$ for all $x \in \operatorname{dom} \omega$; recall that by Proposition 2.4, $\operatorname{dom} \omega$ consists of all vectors x satisfying $q + Mx \in (\operatorname{rec} C)^*$. The function $\tilde{\omega}(x)$ will play an important part in the proofs (but not the statements) of the results involving the AVI (q, M, C). We shall let $\operatorname{FEA}(q, M, C)$ denote the feasible region of the problem (3.8). This coincides with the previous definition (3.2) when C is a cone. Trivially, we have $\operatorname{SOL}(q, M, C) \subseteq \operatorname{FEA}(q, M, C)$. Moreover, the problem (3.6) is equivalent to

$$\begin{array}{ll} \text{minimize} & g(x) \\ \text{subject to} & x \in \operatorname{FEA}(q, M, C). \end{array} \tag{3.10}$$

Although the function g is not Fréchet differentiable, it is directionally differentiable at every vector in $\operatorname{FEA}(q, M, C)$ along all feasible directions. This fact is made precise in the following result.

PROPOSITION 3.3. *Let $q \in R^n$ and $M \in R^{n \times n}$ be arbitrary; let $C \subseteq R^n$ be a polyhedral set. For any vectors $\bar{x}$ and x in $\operatorname{FEA}(q, M, C)$, the directional derivative*

$$\omega'(\bar{x}; x - \bar{x}) \equiv \lim_{\tau \downarrow 0} \frac{\omega(\bar{x} + \tau(x - \bar{x})) - \omega(\bar{x})}{\tau}$$

exists, is finite, and is equal to

$$\min\{u^T M(x - \bar{x}) : u \in \Omega(\bar{x})\},$$

where $\Omega(\bar{x}) \equiv \operatorname{argmin}\{z^T(q + M\bar{x}) : z \in C\}$; *hence,* $g'(\bar{x}; x - \bar{x})$ *exists and is equal to*

$$(x - \bar{x})^T(q + (M + M^T)\bar{x}) - \omega'(\bar{x}; x - \bar{x}).$$

Proof. Since $q + M\bar{x} \in (\operatorname{rec} C)^*$, $\Omega(\bar{x}) \neq \emptyset$. It suffices to verify that

$$\omega'(\bar{x}; x - \bar{x}) = \min\{u^T M(x - \bar{x}) : u \in \Omega(\bar{x})\},$$

and that this derivative is finite. Since both $\bar{x}$ and x are in $\operatorname{FEA}(q, M, C)$, it follows that

$$\omega(\bar{x} + \tau(x - \bar{x})) = \tilde{\omega}(\bar{x} + \tau(x - \bar{x}))$$

for all $\tau \in [0, 1]$. Hence, we have

$$\omega'(\bar{x}; x - \bar{x}) = \tilde{\omega}'(\bar{x}; x - \bar{x}) = \min\{u^T M(x - \bar{x}) : u \in \tilde{\Omega}(\bar{x})\},$$

where

$$\tilde{\Omega}(\bar{x}) \equiv \operatorname{argmin}\{z^T(q + M\bar{x}) : z \in G\}$$

is a nonempty, finite subset of $\Omega(\bar{x})$. Since $\tilde{\omega}'(\bar{x}; x - \bar{x})$ is finite, thus so is $\omega'(\bar{x}; x - \bar{x})$. Moreover, we have

$$\omega'(\bar{x}; x - \bar{x}) \geq \min\{u^T M(x - \bar{x}) : u \in \Omega(\bar{x})\}. \tag{3.11}$$

Since

$$\begin{aligned} \omega(\bar{x} + \tau(x - \bar{x})) &= \min\{z^T(q + M\bar{x}) + \tau z^T M(x - \bar{x}) : z \in C\} \\ &\leq \min\{z^T(q + M\bar{x}) + \tau z^T M(x - \bar{x}) : z \in \Omega(\bar{x})\} \\ &= \omega(\bar{x}) + \tau \min\{u^T M(x - \bar{x}) : u \in \Omega(\bar{x})\}, \end{aligned}$$

it follows that the reverse inequality in (3.11) also holds. Consequently, equality holds in (3.11). □

Note that if $\bar{x} \in \operatorname{SOL}(q, M, C)$ and M is positive semidefinite, then Proposition 3.3 yields

$$g'(\bar{x}; x - \bar{x}) = (x - \bar{x})^T(q + d) - \omega'(\bar{x}; x - \bar{x}) \tag{3.12}$$

for all $x \in \operatorname{FEA}(q, M, C)$, where $d = (M + M^T)\bar{x}$ is one of the two constants associated with the solutions of the AVI (q, M, C). With the above proposition, we can now discuss the extension of the minimum principle sufficiency to the nondifferentiable gap minimization problem (3.6) or equivalently to (3.10). Some related work on error bounds for convex, piecewise quadratic minimization problems, of which (3.6) is a special case, can be found in [22]. The following result establishes two properties of solutions to the AVI (q, M, C).

PROPOSITION 3.4. *Let* $q \in R^n$ *be arbitrary,* $M \in R^{n \times n}$ *be positive semidefinite, and* $C \subseteq R^n$ *be a polyhedral set. If* x *and* $\bar{x}$ *are any two vectors in* $\operatorname{SOL}(q, M, C)$, *then* $g'(\bar{x}; x - \bar{x}) = 0$ *and*

$$\omega(x) = \omega(\bar{x}) + \omega'(\bar{x}; x - \bar{x}). \tag{3.13}$$

Proof. Since $\mathrm{SOL}(q, M, C)$ is convex, $\bar{x}+\tau(x-\bar{x}) \in \mathrm{SOL}(q, M, C)$ for all $\tau \in [0, 1]$. Hence for all such τ,

$$g(\bar{x} + \tau(x - \bar{x})) = 0,$$

which easily implies $g'(\bar{x}; x - \bar{x}) = 0$.

Since x and $\bar{x}$ belong to $\mathrm{SOL}(q, M, C)$, we have

$$\begin{aligned}
&\omega(x) = x^T(q + Mx) \\
&= x^T(q + M\bar{x}) + x^T M(x - \bar{x}) \\
&= \bar{x}^T(q + M\bar{x}) + (x - \bar{x})^T(q + M\bar{x}) + \bar{x}^T M(x - \bar{x}) + (x - \bar{x})^T M(x - \bar{x}) \\
&\geq \omega(\bar{x}) + \min\{u^T M(x - \bar{x}) : u \in \Omega(\bar{x})\} \\
&= \omega(\bar{x}) + \omega'(\bar{x}; x - \bar{x}) \geq \omega(x),
\end{aligned}$$

where the last inequality follows from the concavity of ω. □

Alternatively stated, Proposition 3.4 says that for a monotone AVI (q, M, C) and any $\bar{x} \in \mathrm{SOL}(q, M, C)$, we have

$$\begin{aligned}
&\mathrm{SOL}(q, M, C) \\
&\subseteq \{x \in \mathrm{FEA}(q, M, C) \mid g'(\bar{x}; x - \bar{x}) = 0, \omega(x) = \omega(\bar{x}) + \omega'(\bar{x}; x - \bar{x})\}.
\end{aligned} \tag{3.14}$$

We say that the *restricted minimum principle sufficiency* (RMPS) holds for the problem (3.10) if for any $\bar{x} \in \mathrm{SOL}(q, M, C)$, equality holds in (3.14); or equivalently, the implication holds:

$$\left.\begin{aligned} x \in \mathrm{FEA}(q, M, C), g'(\bar{x}; x - \bar{x}) = 0 \\ \omega(x) = \omega(\bar{x}) + \omega'(\bar{x}; x - \bar{x}) \end{aligned}\right\} \Rightarrow x \in \mathrm{SOL}(q, M, C). \tag{3.15}$$

The word *restricted* that describes this property reflects the additional restriction—equation (3.13)—that the vector x has to satisfy in order for it to be a solution of AVI (q, M, C). If ω is a smooth (linear) function on $\mathrm{FEA}(q, M, C)$ (instead of a piecewise linear function), the latter restriction is redundant. In particular, this is the case when C is a cone.

The following two results give some necessary and sufficient conditions for the two conditions, $g'(\bar{x}; x - \bar{x}) = 0$ and (3.13), to hold separately. Although these results are not needed in the proof of the main theorem in the next section, they give some insights into the RMPS property of the AVI.

PROPOSITION 3.5. *Let $q \in R^n$ and $M \in R^{n \times n}$ be arbitrary; let $C \subseteq R^n$ be a polyhedral set. Let $\bar{x} \in \mathrm{SOL}(q, M, C)$ and $x \in \mathrm{FEA}(q, M, C)$ be given. Then $g'(\bar{x}; x - \bar{x}) = 0$ if and only if $x \in \Omega(\bar{x})$ and*

$$(u - \bar{x})^T(q + Mx) \geq 0 \quad \textit{for all } u \in \Omega(\bar{x}). \tag{3.16}$$

Proof. Indeed, by Proposition 3.3, we have $g'(\bar{x}; x - \bar{x}) = 0$ if and only if

$$(x - \bar{x})^T \left(q + (M + M^T)\bar{x}\right) = \min\{u^T M(x - \bar{x}) : u \in \Omega(\bar{x})\},$$

or equivalently

$$(x - \bar{x})^T(q + M\bar{x}) = \min\{(u - \bar{x})^T M(x - \bar{x}) : u \in \Omega(\bar{x})\}.$$

Since $\bar{x} \in \mathrm{SOL}(q, M, C)$ and $x \in C$, the left-hand side is nonnegative, whereas the right-hand side is nonpositive because $\bar{x} \in \Omega(\bar{x})$. Consequently, $g'(\bar{x}; x - \bar{x}) = 0$ if and only if

$$0 = (x - \bar{x})^T (q + M\bar{x}) = \min\{(u - \bar{x})^T M(x - \bar{x}) : u \in \Omega(\bar{x})\}.$$

The first equality is equivalent to $x \in \Omega(\bar{x})$. Moreover, for all $u \in \Omega(\bar{x})$, we have $(u - \bar{x})^T (q + M\bar{x}) = 0$; hence,

$$(u - \bar{x})^T M(x - \bar{x}) = (u - \bar{x})^T (q + Mx).$$

Consequently,

$$\min\{(u - \bar{x})^T M(x - \bar{x}) : u \in \Omega(\bar{x})\} = 0$$

if and only if (3.16) holds. □

PROPOSITION 3.6. *Let $q \in R^n$ and $M \in R^{n \times n}$ be arbitrary; let $C \subseteq R^n$ be a polyhedral set. Let $\bar{x}$ and x be any two vectors in* $\mathrm{FEA}(q, M, C)$. *Then the following are equivalent:*

(i) (3.13) *holds,*
(ii) $\Omega(x) \cap \Omega(\bar{x}) \neq \emptyset$,
(iii) *for all* $\lambda \in (0, 1)$,

$$\omega(\lambda x + (1 - \lambda)\bar{x}) = \lambda\omega(x) + (1 - \lambda)\omega(\bar{x}).$$

Proof. Suppose (3.13) holds. Then for any $u \in \Omega(\bar{x})$ such that $u^T M(x - \bar{x}) = \omega'(\bar{x}; x - \bar{x})$, we have

$$\begin{aligned} \omega(x) &\leq u^T (q + Mx) \\ &= u^T (q + M\bar{x}) + u^T M(x - \bar{x}) \\ &= \omega(\bar{x}) + \omega'(\bar{x}; x - \bar{x}). \end{aligned}$$

Hence $\omega(x) = u^T (q + Mx)$, which implies $u \in \Omega(x) \cap \Omega(\bar{x})$. Conversely, if $u \in \Omega(x) \cap \Omega(\bar{x})$, then

$$\begin{aligned} \omega(x) &= u^T (q + Mx) \\ &= u^T (q + M\bar{x}) + u^T M(x - \bar{x}) \\ &\geq \omega(\bar{x}) + \omega'(\bar{x}; x - \bar{x}). \end{aligned}$$

By the concavity of ω, we have

$$\omega(x) \leq \omega(\bar{x}) + \omega'(\bar{x}; x - \bar{x}).$$

Thus (i) is equivalent to (ii). The equivalence of (ii) and (iii) follows from the fact that $\Omega(x)$ is the subdifferential of the support function of C at $-(Mx + q)$ and [9, Lem. 5.3]. □

4. The main result. We are now ready to state the main result of this paper. This result gives various necessary and sufficient conditions for the existence of a nondegenerate solution for a monotone AVI.

THEOREM 4.1. *Let $q \in R^n$ be arbitrary, $M \in R^{n \times n}$ be positive semidefinite, and $C \subseteq R^n$ be a polyhedral set. Suppose* $\mathrm{SOL}(q, M, C) \neq \emptyset$. *Let $d \in R^n$ and $\sigma \in R_+$ be the two constants associated with the AVI (q, M, C); see* (3.1). *The following statements are equivalent:*

(a) *The AVI* (q, M, C) *has a nondegenerate solution; that is,* (2.4) *holds.*
(b) *The set* $\mathrm{SOL}(q, M, C)$ *is a set of weak sharp minima for the problem* (3.6).
(c) *There exists a constant* $\gamma > 0$ *such that for all* $x \in C$

$$\mathrm{dist}\,(x \mid \mathrm{SOL}(q, M, C)) \leq \gamma g(x). \tag{4.1}$$

(d) *The representation*

$$\mathrm{SOL}(q, M, C) = \{x \in C \mid \omega(x) - (q + d)^T x + \sigma \geq 0\} \tag{4.2}$$

holds.
(e) *The restricted minimum principle sufficiency holds for the problem* (3.10); *i.e., the implication* (3.15) *holds.*

As it turns out, the proof of this theorem, except for the equivalence of (b) and (c), is rather complicated. We shall divide the entire proof into several parts. Throughout the proof we will assume, if necessary, that C is written in the form (3.3) or (3.7). Note that since the function ω is in general not differentiable, the equivalence of (b) and (e) does not follow from Proposition 2.5.

The easiest part is the equivalence of (b) and (c); this follows from the remark made after Definition 2.3 and the observation that $g_{\min} = 0$. Note that effectively, the inequality (4.1) concerns only those vectors $x \in \mathrm{FEA}(q, M, C)$; indeed, since $g(x) = \infty$ for all $x \in C \setminus \mathrm{FEA}(q, M, C)$, (4.1) trivially holds for the latter vectors x.

The following lemma establishes (a) $\Rightarrow$ (d).

LEMMA 4.2. *Under the assumptions of Theorem* 4.1, *statement* (a) *implies statement* (d).

Proof. Let S denote the right-hand set in (4.2). It suffices to verify

$$S \subseteq \mathrm{SOL}(q, M, C),$$

because the reverse inclusion is always valid. Let $x \in S$ and let $\hat{x}$ be a nondegenerate solution of AVI (q, M, C). Since $\omega(x)$ is finite, its dual program $\Delta(x)$ has an optimal solution λ that satisfies

$$b^T \lambda = \omega(x).$$

Since $\hat{x} \in \mathrm{SOL}(q, M, C)$ is nondegenerate, by Propositions 3.1 and 3.2 there exists a $\hat{\lambda} \in \Lambda(\hat{x})$ satisfying

$$\hat{\lambda}^T (A\hat{x} - b) = 0 \quad \text{and} \quad \hat{\lambda} + A\hat{x} - b > 0.$$

We have

$$\begin{aligned} \omega(x) &\geq (q + d)^T x - \sigma \\ &= (q + (M + M^T)\hat{x})^T x - \hat{x}^T M \hat{x} \\ &= (q + M\hat{x})^T x + \hat{x}^T M (x - \hat{x}) \\ &= \hat{\lambda}^T A x + (\lambda - \hat{\lambda})^T A \hat{x} \\ &= \hat{\lambda}^T (Ax - b) + \lambda^T (A\hat{x} - b) + \lambda^T b, \end{aligned}$$

which yields

$$0 \geq \hat{\lambda}^T (Ax - b) + \lambda^T (A\hat{x} - b) \geq 0.$$

Since $\hat{\lambda} + A\hat{x} - b > 0$ and λ and $Ax - b$ are both nonnegative, it follows easily that $\lambda^T(Ax - b) = 0$. Thus $x \in \mathrm{SOL}(q, M, C)$ as desired. □

Next we prove (d) $\Rightarrow$ (c). The proof of this implication uses the following consequence of the famous Hoffman error bound for systems of linear inequalities [21]. Let P be a polyhedral set in R^n, and let E and f be, respectively, a matrix and vector of compatible dimensions. If the polyhedron

$$S \equiv \{x \in P : Ex \geq f\}$$

is nonempty, then there exists a constant $c > 0$ such that

$$\mathrm{dist}\,(x \mid S) \leq c\|(Ex - f)_-\|_\infty \quad \text{for all } x \in P,$$

where the subscript $_-$ denotes the nonpositive part of a vector.

LEMMA 4.3. *Under the assumptions of Theorem* 4.1, *statement* (*d*) *implies statement* (*c*).

Proof. Invoking the function $\tilde{\omega}(x)$ defined in (3.9), we can express (4.2) equivalently as

$$\begin{aligned}&\mathrm{SOL}(q, M, C)\\ &\quad = \{x \in \mathrm{FEA}(q, M, C) \mid z^T(q + Mx) - (q + d)^T x + \sigma \geq 0, \forall z \in G\}.\end{aligned}$$

By the aforementioned consequence of Hoffman's result, we deduce the existence of a constant $\gamma > 0$ such that for all $x \in \mathrm{FEA}(q, M, C)$,

$$\mathrm{dist}\,(x \mid \mathrm{SOL}(q, M, C)) \leq \gamma \max_{z \in G} \left(z^T(q + Mx) - (q + d)^T x + \sigma\right)_- .$$

To complete the proof, it remains to verify that for all $x \in \mathrm{FEA}(q, M, C)$ and all $z \in G$

$$\left(z^T(q + Mx) - (q + d)^T x + \sigma\right)_- \leq x^T(q + Mx) - \omega(x).$$

Since $x^T(q+Mx) \geq \omega(x)$ for all $x \in C$, it suffices to show that for all $x \in \mathrm{FEA}(q, M, C)$ and $z \in G$

$$(q + d)^T x - \sigma - z^T(q + Mx) \leq x^T(q + Mx) - \omega(x);$$

in turn, since $z^T(q + Mx) \geq \omega(x)$, it suffices to verify

$$(q + d)^T x - \sigma \leq x^T(q + Mx).$$

For some $\bar{x} \in \mathrm{SOL}(q, M, C)$, the left-hand side of the above inequality is equal to

$$\begin{aligned}&(q + (M + M^T)\bar{x})^T x - \bar{x}^T M \bar{x}\\ &\quad = (q + Mx)^T x - (\bar{x} - x)^T M(\bar{x} - x) \leq (q + Mx)^T x,\end{aligned}$$

where the last inequality follows by the positive semidefiniteness of M. □

We next show that (d) and (e) are equivalent. The proof of this equivalence is based on the following lemma which shows that the two sets on the right-hand sides of (3.14) and (4.2) are equal.

LEMMA 4.4. *Under the assumptions of Theorem* 4.1,

$$\begin{aligned}&\{x \in \mathrm{FEA}(q, M, C) \mid \omega(x) - (q + d)^T x + \sigma \geq 0\}\\ &\quad = \{x \in \mathrm{FEA}(q, M, C) \mid g'(\bar{x}; x - \bar{x}) = 0, \omega(x) = \omega(\bar{x}) + \omega'(\bar{x}; x - \bar{x})\}\end{aligned} \tag{4.3}$$

for any $\bar{x} \in \mathrm{SOL}(q, M, C)$; *hence statements* (d) *and* (e) *are equivalent.*

Proof. Let x be any vector belonging to the right-hand set in (4.3). Combining (3.12) and (3.13), we deduce

$$\omega(x) = \omega(\bar{x}) + (x - \bar{x})^T(q + d).$$

Thus

$$\omega(x) - (q + d)^T x + \sigma = \omega(\bar{x}) - (q + d)^T \bar{x} + \sigma = 0,$$

where the last equality holds because $\bar{x} \in \mathrm{SOL}(q, M, C)$. This establishes one inclusion in (4.3). To show the reverse inclusion, let x belong to the left-hand set in (4.3). By the concavity of ω, we have

$$\begin{aligned} 0 &\leq \omega(x) - (q + d)^T x + \sigma \\ &\leq \omega(\bar{x}) - (q + d)^T \bar{x} + \sigma - (q + d)^T (x - \bar{x}) + \omega'(\bar{x}; x - \bar{x}) \\ &= -g'(\bar{x}; x - \bar{x}) \leq 0. \end{aligned}$$

Thus equality holds throughout and (4.3) follows. The equivalence of statements (d) and (e) is now obvious. □

Finally, we show that (c) ⇒ (a). Before presenting the details of the proof, we explain the key steps involved. First, we recall the GLCP (p, N, K) that is equivalent to the AVI (q, M, C); see (3.4) for the definition of this GLCP. Consider the convex quadratic program in the variable (x, λ):

$$\begin{aligned} &\text{minimize} && x^T(q + Mx) - b^T\lambda \\ &\text{subject to} && 0 = q + Mx - A^T\lambda \\ &&& Ax - b \geq 0, \quad \lambda \geq 0; \end{aligned} \tag{4.4}$$

this is the "natural" quadratic program associated with the GLCP (q, N, K). We will show that condition (c) in Theorem 4.1 implies that this program has a nonempty set of weak sharp minima; the proof of this implication will use Proposition 3.2. Thus by Proposition 2.5, the minimum principle sufficiency holds for (4.4). Next by using a similar proof technique as in [13, Thm. 13], we will establish that the GLCP (p, N, K) has a nondegenerate solution. Proposition 3.1 will then imply that the AVI (q, M, C) has a nondegenerate solution.

In what follows, let $y \equiv (x, \lambda)$; also let $f(y)$ denote the objective function of (4.4). Note that $f(y) = y^T(p + Ny)$ and the matrix N is positive semidefinite; moreover, the feasible region of (4.4) is precisely $\mathrm{FEA}(p, N, K)$.

LEMMA 4.5. *Under the assumptions of Theorem* 4.1, *statement* (c) *implies that*

$$\mathrm{SOL}(p, N, K) = \{y \in \mathrm{FEA}(p, N, K) \mid \nabla f(\bar{y})^T(y - \bar{y}) \leq 0\} \tag{4.5}$$

for any $\bar{y} \in \mathrm{SOL}(p, N, K)$.

Proof. Since $\mathrm{SOL}(q, M, C) \neq \emptyset$, it follows that $\mathrm{SOL}(p, N, K) \neq \emptyset$; moreover, the optimal solution set of (4.4) is equal to $\mathrm{SOL}(p, N, K)$. The claimed equation (4.5) is a consequence of the minimum principle sufficiency holding for (4.4); see Proposition 2.5. Thus by the analysis made above, it suffices to show that condition (c) in Theorem 4.1 implies that there exists a constant $\gamma' > 0$ such that

$$x^T(q + Mx) - b^T\lambda \geq \gamma' \mathrm{dist}\,(y \mid \mathrm{SOL}(p, N, K)) \tag{4.6}$$

for all $y \equiv (x, \lambda) \in \mathrm{FEA}(p, N, K)$. Let y be any such vector. Then $x \in \mathrm{FEA}(q, M, C)$ and λ is feasible to $\Delta(x)$. Thus $\Lambda(x) \neq \emptyset$ and the inequality (3.5) is valid for this pair (x, λ). We have

$$\begin{aligned} x^T(q + Mx) - b^T\lambda &= g(x) + \omega(x) - b^T\lambda \\ &\geq \gamma^{-1}\mathrm{dist}\,(x \mid \mathrm{SOL}(q, M, C)) + \alpha\mathrm{dist}\,(\lambda \mid \Lambda(x))\,, \end{aligned}$$

where the last inequality follows from (3.5) and (4.1). Pick $(x', \lambda') \in \mathrm{SOL}(q, M, C) \times \Lambda(x)$ such that

$$\|x - x'\| = \mathrm{dist}\,(x \mid \mathrm{SOL}(q, M, C)) \quad \text{and} \quad \|\lambda - \lambda'\| = \mathrm{dist}\,(\lambda \mid \Lambda(x))\,.$$

Since $x' \in \mathrm{SOL}(q, M, C)$, it follows that $\omega(x')$ is finite and thus $\Lambda(x') \neq \emptyset$. By part (c) of Proposition 3.2, there exists $\tilde{\lambda} \in \Lambda(x')$ satisfying

$$\|\lambda' - \tilde{\lambda}\| \leq \beta\|x - x'\|.$$

By part (a) of the same proposition, the pair $(x', \tilde{\lambda}) \in \mathrm{SOL}(p, N, K)$. Consequently, we have

$$\begin{aligned} &\mathrm{dist}\,(y \mid \mathrm{SOL}(q, N, K)) \\ &\leq \|x - x'\| + \|\lambda - \tilde{\lambda}\| \\ &\leq \mathrm{dist}\,(x \mid \mathrm{SOL}(q, M, C)) + \mathrm{dist}\,(\lambda \mid \Lambda(x)) + \|\lambda' - \tilde{\lambda}\| \\ &\leq (1 + \beta)\mathrm{dist}\,(x \mid \mathrm{SOL}(q, M, C)) + \mathrm{dist}\,(\lambda \mid \Lambda(x))\,. \end{aligned}$$

Thus by letting

$$\gamma' \equiv \min\left(\frac{1}{\gamma(1+\beta)}, \alpha\right),$$

it is easy to see that (4.6) must hold. □

LEMMA 4.6. *Under the assumptions of Theorem* 4.1, *statement* (c) *implies statement* (a).

Proof. It suffices to show that the GLCP (p, N, K) has a nondegenerate solution. By the expression of $\mathrm{SOL}(p, N, K)$ given in Lemma 4.5 and by expanding $\nabla f(\bar{y})^T(y - \bar{y})$, such a solution exists if and only if the following linear program in the variables $(x, \lambda, \varepsilon)$ has a feasible solution with a negative objective value:

$$\begin{aligned} \text{minimize} \quad & -\varepsilon \\ \text{subject to} \quad & 0 = q + Mx - A^T\lambda, \\ & Ax - b \geq 0, \quad \lambda \geq 0, \\ & \left(q + (M + M^T)\bar{x}\right)^T (x - \bar{x}) - b^T(\lambda - \bar{\lambda}) \leq 0, \\ & \lambda + Ax - b \geq \varepsilon e, \end{aligned}$$

where e is the vector of all ones and $(\bar{x}, \bar{\lambda})$ is an arbitrary solution of the GLCP (p, N, K). Assume that the GLCP (p, N, K) does not have a nondegenerate solution. Since the above linear program is feasible, with $(x, \lambda, \varepsilon) \equiv (\bar{x}, \bar{\lambda}, 0)$ as a feasible solution, the assumption implies that the program has an optimal solution with zero

objective value. By letting (u, v, ζ, w) be an optimal dual solution, we have

$$\begin{aligned}
&M^T u + A^T(v+w) - \zeta\left(q + (M+M^T)\bar{x}\right) = 0,\\
&-Au + b\zeta + w \le 0,\\
&e^T w = 1,\\
&v, \zeta, w \ge 0,\\
&-q^T u + b^T(v+w) + \zeta\left(b^T\bar{\lambda} - \bar{x}^T(q + (M+M^T)\bar{x})\right) = 0.
\end{aligned}$$

Premultiplying the first equation by u^T, the second constraint by $(v+w)^T$, and the last equation by $-\zeta$, adding the resulting constraints, using the fact that $b^T\bar{\lambda} - \bar{x}^T(q + M\bar{x}) = 0$, and simplifying, we deduce

$$(u - \zeta\bar{x})^T M(u - \zeta\bar{x}) + (v+w)^T w \le 0.$$

Since M is positive semidefinite and both w and v are nonnegative, the last inequality implies that $w = 0$, which contradicts the equation $e^T w = 1$. □

Combining the above lemmas, we have the following proof of Theorem 4.1.

Proof of main theorem. From Lemmas 4.2–4.4 and 4.6, as well as the previously mentioned equivalence of (b) and (c), we see that the following implications are valid:

$$\begin{array}{ccccc}
\text{(a)} & \Rightarrow & \text{(d)} & \Leftrightarrow & \text{(e)}\\
 & & \Downarrow & & \\
 & & \text{(c)} & \Rightarrow & \text{(a)}\\
 & & \Updownarrow & & \\
 & & \text{(b)} & &
\end{array}$$

Consequently, all five statements (a)–(e) are equivalent. □

In summary, Theorem 4.1 has shown that for a monotone AVI, the following five properties are equivalent: (a) existence of a nondegenerate solution, (b) existence of a nonempty set of weak sharp minima for the gap minimization problem, (c) validity of an error bound in terms of the gap function alone, (d) a simplified representation of the solution set, and (e) validity of the restricted minimum principle sufficiency for the gap minimization problem.

We conclude this paper by giving an application of Theorem 4.1 that generalizes the classical result of Goldman and Tucker [17] mentioned in the beginning of this paper.

COROLLARY 4.7. *Let $q \in R^n$ be arbitrary, $M \in R^{n\times n}$ be positive semidefinite, and $C \subseteq R^n$ be a polyhedral set. Suppose* $\mathrm{SOL}(q, M, C) \neq \emptyset$ *and* $\mathrm{FEA}(q, M, C)$ *is contained in the null space of $M + M^T$. Then the AVI (q, M, C) has a nondegenerate solution.*

Proof. Since $\mathrm{FEA}(q, M, C)$ is contained in the null space of $M + M^T$, it follows that $x^T M x = 0$ for all $x \in \mathrm{FEA}(q, M, C)$. Thus the two constants, d and σ, of the AVI (q, M, C) are both equal to zero. Moreover, it is easy to verify that the right-hand set in (4.2) reduces to

$$\{x \in C \mid u^T(q + Mx) - x^T(q + Mx) \ge 0 \text{ for all } u \in C\},$$

which is exactly $\mathrm{SOL}(q, M, C)$. Thus property (d) of Theorem 4.1 holds, and the corollary is established. □

CONSTRAINED LQR PROBLEMS IN ELLIPTIC DISTRIBUTED CONTROL SYSTEMS WITH POINT OBSERVATIONS*

ZHONGHAI DING†, LINK JI‡, AND JIANXIN ZHOU†

Abstract. In this paper, we study (bound constrained) LQR problems in distributed control systems governed by the elliptic equation with point observations, which are motivated by problems in corrosion engineering and contemporary "smart materials." Several regularity and characterization theorems have been established. In particular, three decomposition formulas are obtained to characterize the optimal control and optimal layer density, and are used to direct the numerical computations. These results cannot be obtained by the traditional Galerkin variational method. In the process, several useful lemmas are established, which are of independent interest. We point out that the classical Lagrangian multiplier method (LMM) may fail to provide a reliable numerical algorithm. Based on our characterization results and the boundary element method, two algorithms are proposed to carry out numerical computations. It has been shown by our numerical experiments that both algorithms are efficient and insensitive to the partition number of the boundary. An adaptive local refinement scheme has also been designed to handle the rough behavior of the optimal solution around sensor locations.

Key words. linear-quadratic regulator, distributed boundary control, point observation, potential theory, boundary element method, numerical method

1. Introduction.

Let Ω be an (interior or exterior) open domain in $\Re^{\mathcal{N}}$ ($\mathcal{N} = 2, 3$) with bounded smooth boundary $\Gamma = \Gamma_0 \cup \Gamma_c$ (i.e., Γ is a C^∞ surface). We study the following linear-quadratic regulator (LQR) problem in a distributed parameter control system governed by the elliptic equation

$$\text{LQR} \left\{ \begin{array}{l} \min\limits_{u\in\mathcal{U}} J(u) = \sum\limits_{k=1}^{M} \mu_k |w(P_k) - Z_k|^2 + \gamma \int_{\Gamma_c} u^2(x) d\sigma_x, \\ \text{subject to (1.1)} \left\{ \begin{array}{rcll} \Delta w(x) & = & f(x), & \text{in } \Omega, \\ \dfrac{\partial w(x)}{\partial n} & = & g(x), & \text{on } \Gamma_0, \\ \dfrac{\partial w(x)}{\partial n} & = & u(x), & \text{on } \Gamma_c, \\ \int_{\Gamma_c} u(x) d\sigma_x & = & -\int_{\Gamma_0} g(x) d\sigma_x & + \int_{\Omega} f(x) dx, \end{array} \right. \end{array} \right.$$

where

$f(x)$ is a given (loading) function in Ω,
$\frac{\partial}{\partial n}$ is the outward normal derivative,
$g(x)$ is a given Neumann type boundary data on Γ_0,
$u \in \mathcal{U}$, is a Neumann type boundary control on Γ_c,
$\mathcal{U} \subset L^2(\Gamma_c)$, is the admissible control set,
$\gamma, \mu_k > 0, 1 \le k \le M$, are given weighting factors,
$P_k \in \partial\Omega, 1 \le k \le M$, are prescribed "sensor locations,"
$Z_k \in \Re, 1 \le k \le M$, are prescribed "target" values at P_k.

In the above setting of the LQR problem, the loading function $f(x)$, Neumann boundary data $g(x)$ and the admissible control set $\mathcal{U}$ will be chosen such that the solution $w(x)$ of Neumann problem (1.1) is continuous on $\overline{\Omega}$, otherwise point observations $w(P_k)$ $(1 \leq k \leq M)$ will be meaningless. In fact, f can be any given function in $H^r(\Omega)$, $r > -1$ when $\mathcal{N} = 2$ and $r > -\frac{1}{2}$ when $\mathcal{N} = 3$; g can be any given function in $L^2(\Gamma_0)$ when $\mathcal{N} = 2$ and in $L^p(\Gamma_0)$ $(p > 2)$ when $\mathcal{N} = 3$. The admissible control set will be specified later (see (2.3) and (3.4)).

The study of the above system is motivated by problems in cathodic protection systems in corrosion engineering (see [13] and [14]). Cathodic protection systems have been employed extensively in ships, offshore structures and pipeline networks, and other structures in a corrosive environment. The physical domain Ω occupied by a "corrosive fluid" can be either finite, as in the case of electrolyte container protection, or infinite with a bounded boundary, as in the case of ship propeller protection where Ω is the sea surrounding the ship. The boundary Γ is the walls of the container or the surface of the ship, and Γ_0 is the insulated (or painted) part of the boundary. The only control is the current $(\frac{\partial w}{\partial n} = u)$ on the part Γ_c of the boundary. So the LQR problem is to obtain an optimal current $u(x)$ on Γ_c (anodes) that produces a desired potential distribution $w(x)$ in a certain interested area (cathode) which is to be protected. For contemporary "smart materials," $P_k, 1 \leq k \leq M$, are the locations of piezoelectric sensors to measure the deformation at these points and $w(P_k), 1 \leq k \leq M$, are called point observations. We wish to find the values of $u(x)$ on Γ_c such that at sensor locations $P_k, 1 \leq k \leq M$, the observation values $w(P_k)$ are as close as possible to the target values Z_k with least possible control cost $\int_{\Gamma_c} u^2(x) d\sigma_x$. The formulation of LQR can also be adjusted to meet other physical interest.

General LQR problems governed by elliptic equations on smooth domains were first studied by J. L. Lions in Chapter 2 of [9] and were based essentially upon the Galerkin variational method, which leads to a characterization formula of optimal control coupled with an adjoint system. Unfortunately it is not directly applicable to our LQR problem. Recently, Ji and Chen [7] studied the above LQR problem by using the potential theory and boundary element method (BEM). Their approach has been shown to provide certain important advantages over the traditional Galerkin variational approach. It can provide rather explicit information about the control and state, and it is amenable to direct numerical computation through BEM. Motivated by the observation of their numerical results and computer graphics, Ji and Chen [7] proved some regularity results. They show that for $\mathcal{N} = 3$, LQR has no nontrivial solution and for $\mathcal{N} = 2$, LQR has a unique solution that may contain certain singularities at sensor locations. At the end of their paper, they proposed to study the LQR problems with a bound constraint on the control. Once an inequality constraint is added to the LQR problems, numerically it becomes very difficult to handle. The optimal control behaves roughly, especially around the sensor locations. The unknown singularities around sensor locations may result in divergence and instability in numerical computations.

Motivated by Ji and Chen's results, we will use the potential theory to study the constrained and unconstrained LQR problems. We first prove certain regularity and characterization results for unconstrained LQR. From our characterization theorem and the singularity decomposition formula of optimal control, we point out that the classical Lagrangian multiplier method (LMM) is not reliable to provide numerical solution for unconstrained LQR. Then we establish several regularity and characterization theorems for the constrained LQR. Our singularity decomposition formulas

play key roles in characterizing the singularities in optimal controls and optimal layer densities. In the course of the proofs, several useful lemmas have been established, which are of independent interest. Based upon our (decomposed) characterization results for the constrained LQR, a gradient truncation method and an iterative truncation method have been developed to carry out numerical computations on several test problems. In both methods, truncation techniques have been proposed to handle the bound constraints. An adaptive local refinement scheme is proposed in the iterative truncation method to enhance the convergence and stability in numerical computations. Our test problems show that both methods are efficient and insensitive to the partition number of the boundary of domain. This is a significant advantage of our methods over other numerical methods. Since the optimal control problem under consideration is governed by a partial differential equation, the partition number of the boundary can be very large and any numerical method sensitive to the partition number of boundary may fail to carry out numerical computations.

The results in this paper are derived for interior domain problems. For exterior domain problems, parallel results can also be obtained with suitable modifications.

Before the discussion of LQR problems, let us briefly recall the potential theory, BEM, and Ji and Chen's results.

Let $E(x,\xi)$ be the fundamental solution of the Laplacian, i.e.,

$$\Delta_\xi E(x,\xi) = -\delta(x-\xi), \quad x,\xi \in \Re^{\mathcal{N}}. \tag{1.2}$$

It is well known [1, p. 214] that

$$E(x,\xi) = \begin{cases} -\dfrac{1}{2\pi}\ln|x-\xi|, & x,\xi \in \Re^2, \\ \dfrac{1}{4\pi}\dfrac{1}{|x-\xi|}, & x,\xi \in \Re^3. \end{cases} \tag{1.3}$$

According to [1, Chap. 6], any solution w of (1.1) can be represented as a sum of a volume potential and a simple-layer-potential:

$$w(x) = \left[-\int_\Omega E(x,\xi)f(\xi)d\xi\right] + \int_\Gamma E(x,\xi)\eta(\xi)d\sigma_\xi, \quad x \in \Omega, \tag{1.4}$$

where η is called a layer density, to be determined from the boundary integral equation (BIE)

$$\frac{1}{2}\eta(x) + \int_\Gamma \frac{\partial E(x,\xi)}{\partial n_x}\eta(\xi)d\sigma_\xi = \frac{\partial w(x)}{\partial n} + \frac{\partial}{\partial n_x}\int_\Omega E(x,\xi)f(\xi)d\xi, \quad x \in \Gamma. \tag{1.5}$$

Since the last term of (1.5) is known and fixed once the inhomogeneous term $f(x)$ is given, without loss of generality, from now on we assume $f(x) \equiv 0$. Then the BIE for the layer density $\eta(x)$ becomes

$$\begin{cases} \dfrac{1}{2}\eta(x) + \displaystyle\int_\Gamma \frac{\partial E(x,\xi)}{\partial n_x}\eta(\xi)d\sigma_\xi = g(x), & x \in \Gamma_0, \\ \dfrac{1}{2}\eta(x) + \displaystyle\int_\Gamma \frac{\partial E(x,\xi)}{\partial n_x}\eta(x)d\sigma_\xi = u(x), & x \in \Gamma_c. \end{cases} \tag{1.6}$$

Once the layer density η is found, the solution $w(x)$ of (1.1) can be computed from (1.4). Because BIE (1.6) is linear in terms of η, g, and u, for simplicity, throughout of this paper we assume $g(x) \equiv 0$.

In BEM, the boundary $\Gamma = \Gamma_0 \cup \Gamma_c$ is divided into N pieces (elements). N is called the partition number of the boundary. Assume that the layer density $\eta(x)$ is piecewise smooth, e.g., piecewise constant, piecewise linear, ..., etc.; then the BIE (1.6) becomes a linear algebraic system of order N. This system can be solved for $\eta(x_i)$ and then $w(x)$ can be computed from a discretized version of (1.4) for any $x \in \overline{\Omega}$.

The following example for LQR was considered by Ji and Chen in [7].

EXAMPLE 1. *For LQR, let* $\mathcal{N} = 2$ *and* Ω *be the unit circle centered at the origin. Assume that* $M = 3$, $P_k = k\frac{\pi}{2}, 1 \le k \le 3, Z_{(1,2,3)} = (1, 0, 1)$, *and* $\Gamma_0 = \emptyset, \Gamma_c = \Gamma$.

They have applied the LMM to reformulate the optimization problem of Example 1 and implemented numerically by BEM. Since only linear equality constraints are involved in the LQR problem, LMM leads to solving a linear system. They obtained Fig. 1 for the optimal controls with different boundary partition number N.

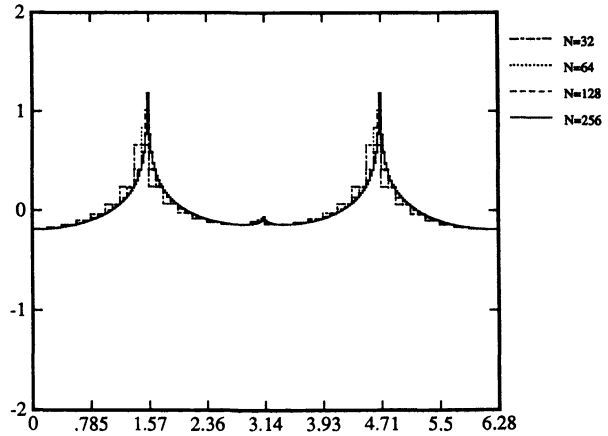

FIG. 1. *Optimal controls* $u(x)$ *of the LQR in Example* 1, *computed by LMM, for different boundary partition number* N.

In observing Fig. 1, they found that when the boundary partition number N increases, the magnitudes of the optimal control $u(x)$ at sensor locations P_k increase without bound. Motivated by this observation, Ji and Chen proved the following theorem.

THEOREM 1.1 (see [7]). (i) *For* $\mathcal{N} = 3$ *and* $\Gamma_0 = \emptyset$, *LQR does not have any nontrivial optimal control* u^* *in* $L^2(\Gamma_c)$;

(ii) *For* $\mathcal{N} = 2$, *LQR has a unique optimal control* u^* *that is differentiable at every point* $x \in \Gamma_c, x \neq P_k, 1 \le k \le M$. *While around* $P_k, 1 \le k \le M, u^*$ *has at worst a logarithmic singularity of magnitude* $\mathcal{O}(\ln|x - P_k|)$.

They were unable to characterize singularities in the optimal control of LQR. In this paper, the singularities in optimal controls of constrained and unconstrained LQR problems are displayed explicitly (see Theorems 3.9 and 4.4).

Naturally, for practical and numerical purpose, a bound constraint of control, $|u(x)| \le B$, should be added to LQR.

2. Constrained LQR problems and gradient projection method. Consider the following constrained LQR problem:

$$\text{Constrained LQR} \begin{cases} \min J(u) = \sum_{k=1}^{M} \mu_k |w(P_k) - Z_k|^2 + \gamma \int_{\Gamma_c} u^2(x) d\sigma_x, \\ \text{subject to (2.2)} \begin{cases} \Delta w(x) = 0, & \text{in } \Omega, \\ \dfrac{\partial w(x)}{\partial n} = 0, & \text{on } \Gamma_0, \\ \dfrac{\partial w(x)}{\partial n} = u(x), & \text{on } \Gamma_c, \end{cases} \\ u \in \mathcal{U}, \end{cases} \tag{2.1}$$

where

$$\mathcal{U} = \left\{ v \in L^2(\Gamma_c) \mid \int_{\Gamma_c} u(x) d\sigma_x = 0, \ \mid v(x) \mid \leq B \ \text{ on } \ \Gamma_c \right\}. \tag{2.3}$$

Let

$$L_0^p(\Gamma_c) = \left\{ f \in L^p(\Gamma_c) \mid \int_{\Gamma_c} f(\xi) d\sigma_\xi = 0 \right\}, \quad 1 \leq p < \infty.$$

When $\mathcal{N} = 2$, $\mathcal{U}$ is a bounded, closed, and convex subset of $L_0^2(\Gamma_c)$. By [10] and the Sobolev imbedding theorem, (2.1) admits a solution $w(x)$, unique up to a constant, in $H^{\frac{3}{2}}(\Omega) \subset C^{0,\alpha}(\overline{\Omega})$ where $0 < \alpha < \frac{1}{2}$ for any $u \in L_0^2(\Gamma_c)$. When $\mathcal{N} = 3$, $\mathcal{U}$ is a bounded, closed and convex subset of $L_0^p(\Gamma_c)$ for any $p > 2$. By [4], [5], and the Sobolev imbedding theorem, (2.1) admits a solution $w(x)$, unique up to a constant, in $W^{1+\frac{1}{p},p}(\Omega) \subset C^{0,\alpha}(\overline{\Omega})$ where $0 < \alpha < \frac{p-2}{p}$ for any $u \in \mathcal{U}$. Thus the point observation makes sense. For each given $u \in \mathcal{U}$, (2.1) has a unique solution $w \in C(\overline{\Omega})$ such that

$$\sum_{k=1}^{M} \mu_k |w(P_k) - Z_k|^2 = \min_{c \in \Re} \sum_{k=1}^{M} \mu_k |w(P_k) + c - Z_k|^2.$$

A calculation shows that $w(x)$ must satisfy

$$\sum_{k=1}^{M} \mu_k (w(P_k) - Z_k) = 0. \tag{2.4}$$

Therefore the constrained LQR problem is well posed. Once an optimal control is found, the optimal state can be obtained by solving (2.1) and (2.4).

By [4], [5], [10], the solution Tu of (2.1) satisfying

$$\sum_{k=1}^{M} \mu_k w(P_k) = 0$$

defines a linear bounded operator T from $L_0^2(\Gamma_c)$ to $C^{0,\alpha}(\overline{\Omega})$ with $0 < \alpha < \frac{1}{2}$ for $\mathcal{N} = 2$ and from $L_0^p(\Gamma_c)$ to $C^{0,\alpha}(\overline{\Omega})$ with $0 < \alpha < \frac{p-2}{p}$ and $p > 2$ for $\mathcal{N} = 3$. Thus

the solution $w(x)$ of (2.1) and (2.4) can be expressed as

$$w(x) = Tu(x) + \frac{1}{\sum_{k=1}^{M} \mu_k} \sum_{k=1}^{M} \mu_k Z_k.$$

THEOREM 2.1. *The constrained LQR problem has a unique optimal control* $u^* \in \mathcal{U}$ *and a unique optimal state* $w^* \in C(\overline{\Omega})$ *satisfying* (2.1) *and* (2.4), *such that*

$$J(v) \geq J(u^*), \quad \forall v \in \mathcal{U}. \tag{2.5}$$

Proof. When $\mathcal{N} = 2$, the constrained LQR problem is well posed in Hilbert space $L^2(\Gamma_c)$. By applying Theorem 1.1 of Chapter I of [9], we obtain that the constrained LQR problem admits a unique optimal control $u^* \in \mathcal{U}$ and a unique optimal state $w^* \in C(\overline{\Omega})$ satisfying (2.1) and (2.4) such that (2.5) holds. When $\mathcal{N} = 3$, the constrained LQR problem is no longer in Hilbert space. Hence Theorem 1.1 of Chapter I of [9] cannot be applied directly to the above constrained LQR problem. Let $p > 2$ and $L = \inf\{J(u) : u \in \mathcal{U}\}$. Assume $\{u_n\} \subset \mathcal{U}$ and $\{w_n(x)\}$, the solution of (2.1) and (2.4) with $u(x) = u_n(x)$, such that

$$L \leq J(u_n) \leq L + \frac{1}{n}.$$

Since $\mathcal{U}$ is bounded, closed, and convex (therefore weakly closed) in $L^p(\Gamma_c)$, there exists a subsequence $\{u_{n_m}\} \subset \{u_n\}$ and $u^* \in \mathcal{U}$ such that

$$\lim_{m \to \infty} u_{n_m} = u^* \quad \text{weakly in } L^p(\Gamma_c). \tag{2.6}$$

Hence

$$\lim_{k \to \infty} Tu_{n_m} = Tu^* \quad \text{weakly in } C^{0,\alpha}(\overline{\Omega}), \quad 0 < \alpha < \frac{p-2}{p}.$$

Let $w^*(x)$ be the solution of (2.1) and (2.4) with $u(x) = u^*(x)$. Then

$$\lim_{k \to \infty} w_{n_m} = w^* \quad \text{weakly in } C^{0,\alpha}(\overline{\Omega}), \quad 0 < \alpha < \frac{p-2}{p}.$$

Noticing that the injection from $C^{0,\alpha_1}(\overline{\Omega})$ to $C^{0,\alpha_2}(\overline{\Omega})$ is compact for any $0 < \alpha_2 < \alpha_1 < 1$, we obtain

$$\lim_{m \to \infty} w_{n_m} = w^* \quad \text{strongly in } C^{0,\alpha}(\overline{\Omega}), \quad 0 < \alpha < \frac{p-2}{p}.$$

Hence

$$\lim_{m \to \infty} \sum_{k=1}^{M} \mu_k \left| w_{n_m}(P_k) - Z_k \right|^2 = \sum_{k=1}^{M} \mu_k \left| w^*(P_k) - Z_k \right|^2.$$

By (2.6), we have

$$\lim_{m \to \infty} \gamma \int_{\Gamma_c} (u_{n_m}(x))^2 d\sigma_x \geq \gamma \int_{\Gamma_c} (u^*(x))^2 d\sigma_x.$$

Thus

$$L = \lim_{m\to\infty} J(u_{n_m}) \geq J(u^*) \geq L.$$

Therefore the existence of optimal control of the constrained LQR problem is proved when $\mathcal{N} = 3$. The uniqueness of optimal control can be easily obtained by using the strict convexity of $J(u)$ on $\mathcal{U}$. □

Thus the existence and uniqueness of the optimal control of the constrained LQR problem is established. But with this constraint—an inequality constraint, numerically the problem becomes very tough to handle. There are three major difficulties in numerical computations:

(1) The consistency condition $\int_{\Gamma_c} u(x)d\sigma_x = 0$ — a linear equality constraint;

(2) The Neumann boundary condition

$$\begin{cases} \dfrac{\partial w(x)}{\partial n} &= 0, & x \in \Gamma_0, \\ \dfrac{\partial w(x)}{\partial n} &= u(x), & x \in \Gamma_c. \end{cases}$$

For each $u(x)$, equation (2.1) has many solutions $w(x)$, which is unique up to a constant;

(3) The bound constraint on control, $|u(x)| \leq B, \quad x \in \Gamma_c$—an inequality constraint.

Basically there are two types of approaches in numerical algorithm design for the (constrained) LQR problems. The first is to use the layer density η as the variable of the LQR problem. The state variable w and control variable u are expressed as functions of η. Then difficulties (1) and (2) are automatically resolved. But difficulty (3) becomes much more complicated. The second is to use the control u as the variable of the LQR problem. Then difficulty (3) becomes more direct but difficulty (2) remains and difficulties (1) and (3) are mixed up.

Due to (1.4) and (1.6), the gradient ∇J of the objective functional J with respect to either the control variable u or the layer density variable η can be computed directly without invoking any adjoint systems.

Using the layer density as the variable, we apply the gradient projection method (GPM), a classical method, to solve the constrained LQR problem. So the state, control, and objective functional are all represented as functions of the layer density. Therefore the only difficulty is to deal with the inequality constraint. This method can be briefly stated as following:

Step 0: Given initial guess η_0;
Step 1: Using (1.4) and (1.6) to solve for state variable w_0 and control variable u_0;
Step 2: Compute $\nabla J(\eta_0)$;
Step 3: If some constraints are active, project $\nabla J(\eta_0)$ to the constraint surface;
Step 4: Find $\alpha_0 = \arg\min_{\alpha\in\Re} J(\eta_0 - \alpha\nabla J(\eta_0))$ subjected to $|u(\eta_0 - \alpha\nabla J(\eta_0))| \leq B$ and set $\eta = \eta_0 - \alpha_0\nabla J(\eta_0)$;
Step 5: If $|\eta - \eta_0|_{L^2(\Gamma)} < \varepsilon_\eta$ then compute $u(\eta_0 - \alpha_0\nabla J(\eta_0))$, output, and stop else set $\eta_0(x) = \eta(x) \quad x \in \Gamma$, goto Step 1.

REMARK 1. (1) Step 1 can be performed numerically by BEM [1].

(2) In Step 4, the linear search is still an inequality constrained minimization problem.

(3) More technical details have been omitted in Step 3 because this method is not important in this paper.

The GPM has been used to solve the test problem stated in Example 1. The numerical values of the cost $J_{\min}$ corresponding to different partition numbers N of the boundary and different bounds B are presented in the first column of Table 2. The optimal controls are shown in Fig. 2.

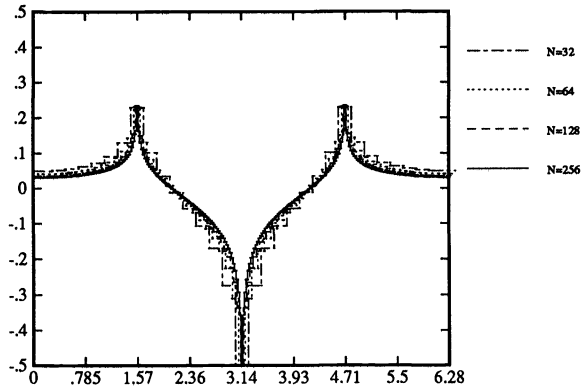

FIG. 2. *Optimal controls $u(x)$ of the LQR in Example 1, computed by GPM, for different boundary partition number N with $B = 0.5$.*

From Table 2, we found that, when the bound B is fixed and the partition number N of the boundary increases, the value of $J_{\min}$ increases. This is certainly not what we expect. The reason can be explained as follows. In the above GPM, the inequality constraint is treated *pointwisely*. When the partition number of the boundary increases, more inequality constraints are involved, hence the value of $J_{\min}$ may increase. So this method is *sensitive* to the partition number of the boundary. And compared to the two numerical algorithms developed in this paper, this method is also rather slow.

Observe that the profiles of Figs. 1 and 2 are quite different. Since the control bound used in Fig. 2 is considerably large and is active only on a very small part of the boundary, the profile of Fig. 2 should be quite close to that of Fig. 1. What is wrong? To answer this question, we need more information about the optimal control.

3. Characterizations of optimal control for LQR problems. Before giving the main results of characterization of optimal control, let us first introduce the simple layer potential $\mathcal{S}$, boundary operators $\mathcal{K}$ and $\mathcal{K}^*$, and several basic properties of these operators.

For any $f \in L^2(\Gamma)$ and $x \in \Re^{\mathcal{N}}$, define the simple layer potential by

$$\mathcal{S}(f)(x) = \int_\Gamma E(x,\xi) f(\xi) d\sigma_\xi = \begin{cases} \dfrac{1}{4\pi} \displaystyle\int_\Gamma \frac{1}{|x-\xi|} f(\xi) d\sigma_\xi, & \mathcal{N} = 3, \\ -\dfrac{1}{2\pi} \displaystyle\int_\Gamma \ln|x-\xi|\, f(\xi) d\sigma_\xi, & \mathcal{N} = 2. \end{cases} \tag{3.1}$$

The simple layer potential $\mathcal{S}$ is well defined and is continuous across the boundary Γ (see [1, pp. 223–225]). For any $f \in L^2(\Gamma)$ and $x \in \Gamma$, define the boundary operator

$\mathcal{K}$ and $\mathcal{K}^*$ by

$$
\begin{aligned}
(\mathcal{K}f)(x) &= p.v.\int_\Gamma \frac{\partial}{\partial n_\xi}E(x,\xi)f(\xi)d\sigma_\xi \\
&\equiv \lim_{\epsilon\to 0+}\int_{\Gamma\bigcap\{|x-\xi|>\epsilon\}} \frac{\partial}{\partial n_\xi}E(x,\xi)f(\xi)d\sigma_\xi \\
&= \begin{cases} \dfrac{1}{4\pi}\lim\limits_{\epsilon\to 0+}\displaystyle\int_{\Gamma\bigcap\{|x-\xi|>\epsilon\}} \dfrac{< n_\xi, x-\xi >}{|x-\xi|^3}f(\xi)d\sigma_\xi, & \mathcal{N}=3, \\ \dfrac{1}{2\pi}\lim\limits_{\epsilon\to 0+}\displaystyle\int_{\Gamma\bigcap\{|x-\xi|>\epsilon\}} \dfrac{< n_\xi, x-\xi >}{|x-\xi|^2}f(\xi)d\sigma_\xi, & \mathcal{N}=2, \end{cases}
\end{aligned} \tag{3.2}
$$

$$
\begin{aligned}
(\mathcal{K}^*f)(x) &= p.v.\int_\Gamma \frac{\partial}{\partial n_x}E(x,\xi)f(\xi)d\sigma_\xi \\
&\equiv \lim_{\epsilon\to 0+}\int_{\Gamma\bigcap\{|x-\xi|>\epsilon\}} \frac{\partial}{\partial n_x}E(x,\xi)f(\xi)d\sigma_\xi \\
&= \begin{cases} -\dfrac{1}{4\pi}\lim\limits_{\epsilon\to 0+}\displaystyle\int_{\Gamma\bigcap\{|x-\xi|>\epsilon\}} \dfrac{< n_x, x-\xi >}{|x-\xi|^3}f(\xi)d\sigma_\xi, & \mathcal{N}=3, \\ -\dfrac{1}{2\pi}\lim\limits_{\epsilon\to 0+}\displaystyle\int_{\Gamma\bigcap\{|x-\xi|>\epsilon\}} \dfrac{< n_x, x-\xi >}{|x-\xi|^2}f(\xi)d\sigma_\xi, & \mathcal{N}=2. \end{cases}
\end{aligned} \tag{3.3}
$$

For the operators defined above, the following results are well known.

THEOREM 3.1 (see [1], [3]). *Let $1 \le p < +\infty$ and $0 \le s \le 1$; the following operators are continuous:*

$$
\begin{aligned}
\mathcal{K} &: W^{s,p}(\Gamma) \longmapsto W^{s,p}(\Gamma); \\
\mathcal{K}^* &: W^{s,p}(\Gamma) \longmapsto W^{s,p}(\Gamma).
\end{aligned}
$$

In addition, $\mathcal{K}$ ($\mathcal{K}^*$, resp.) is the adjoint operator of $\mathcal{K}^*$ ($\mathcal{K}$, resp.) in $L^2(\Gamma)$. Here $W^{s,p}(\Gamma)$ denotes the usual Sobolev space.

THEOREM 3.2 (see [1]). *Let $s \ge 0$ and $f \in L^2(\Gamma)$; then*

$$
\mathcal{S} : H^s(\Gamma) \longmapsto H^{s+\frac{3}{2}}(\Omega)
$$

is a linear bounded operator, hence a linear bounded operator from $H^s(\Gamma)$ to $H^{s+1}(\Gamma)$, and

$$
\lim_{x\in\Omega, x\to y}\frac{\partial}{\partial n_x}\mathcal{S}(f)(x) = \frac{1}{2}f(y) + \mathcal{K}^*(f)(y), \quad a.e. \quad on\ \Gamma,
$$

where $H^s(\Gamma) = W^{s,2}(\Gamma)$.

THEOREM 3.3 ([8], [11]). *There exists an absolute constant $\varepsilon = \varepsilon(\Gamma) > 0$ such that for $2-\varepsilon \le p < +\infty$, the operator $\frac{1}{2}I + \mathcal{K}^*$ is invertible in $L_0^p(\Gamma)$, where $L_0^p(\Gamma) = \{f \in L^p(\Gamma) | \int_\Gamma f(\xi)d\sigma_\xi = 0\}$.*

Notice the fact that the operator $\frac{1}{2}I + \mathcal{K}^*$ is a linear and bounded operator from $L^p(\Gamma)$ into $L_0^p(\Gamma)$ for $1 < p < +\infty$. Then there exists a unique $f_0 \in L^p(\Gamma)$ such that

$$
\left(\frac{1}{2}I + \mathcal{K}^*\right)f_0 = 0, \qquad \int_\Gamma f_0(\xi)d\sigma_\xi = 1.
$$

It is known (see pp. 286–287 in [1]) that $\mathcal{S}f_0 = \text{constant} \neq 0$ for any $\Omega \subset \Re^3$ and $\mathcal{S}f_0 = \text{constant} \neq 0$ for "most" domains $\Omega \subset \Re^2$. Indeed, $\mathcal{S}f_0 \neq 0$ for any domain $\Omega \subset \Re^2$ with diameter $= \sup\{|x_1 - x_2| \mid x_1, x_2 \in \Omega\} < 1$ [6], and any bounded domain $\Omega \subset \Re^2$ can be transformed into a domain with diameter less than 1 by a scale transform $x \to x/k$, $x \in \Re^2$, with a sufficiently large $k > 0$. Thus, throughout this paper we assume $\mathcal{S}f_0 \neq 0$ for $\Omega \subset \Re^2$. Define

$$L^p_{\perp f_0}(\Gamma) = \left\{ g \in L^p(\Gamma) \Big| \int_\Gamma g(\xi) f_0(\xi) d\sigma_\xi = 0 \right\}.$$

Applying the interpolation theorem [10] and the results in [8], [11], we can easily prove the following theorem.

THEOREM 3.4. *For $0 \leq s \leq 1$ and $1 < p \leq 2 + \varepsilon$, where ε is an absolute constant that depends on Γ, $\frac{1}{2}I + \mathcal{K} : H^s(\Gamma) \bigcap L^2_0(\Gamma) \longmapsto H^s(\Gamma) \bigcap L^2_{\perp f_0}(\Gamma)$ is invertible and $\frac{1}{2}I + \mathcal{K} : L^p_0(\Gamma) \longmapsto L^p_{\perp f_0}(\Gamma)$ is invertible.*

With the above theorems, we can prove the first main theorem, a characterization result of optimal controls for LQR problems in $\Re^2$ with the admissible control set

$$\mathcal{U} = L^2_0(\Gamma_c) = \left\{ u \in L^2(\Gamma_c) \Big| \int_{\Gamma_c} u(x) d\sigma_x = 0 \right\}. \tag{3.4}$$

THEOREM 3.5. *Let $\Omega \subset \Re^2$. The LQR problem admits a unique optimal control $u^* \in \mathcal{U} = L^2_0(\Gamma_c)$ and a unique optimal state $w^* \in C(\overline{\Omega})$ satisfying (2.1) and (2.4) such that*

$$J(v) \geq J(u^*), \quad \forall v \in L^2_0(\Gamma_c). \tag{3.5}$$

Furthermore the optimal control is characterized by

$$u^*(x) = -\frac{1}{\gamma} \left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \sum_{k=1}^{M} \mu_k (w^*(P_k) - Z_k) E(P_k, \cdot)(x) + C_0, \quad x \in \Gamma_c, \tag{3.6}$$

where

$$C_0 = -\frac{1}{\gamma |\Gamma_c|} \int_{\Gamma_0} \left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \sum_{k=1}^{M} \mu_k (w^*(P_k) - Z_k) E(P_k, \cdot)(x) d\sigma_x \tag{3.7}$$

and

$$u^* \in H^{\frac{1}{2}-\varepsilon}(\Gamma_c), \quad w^* \in H^{2-\varepsilon}(\Omega) \quad \forall\, 0 < \varepsilon \leq \frac{1}{2}. \tag{3.8}$$

Proof. Since the LQR problem is well posed in Hilbert space $L^2(\Gamma_c)$, the existence and uniqueness of the optimal control $u^* \in L^2_0(\Gamma_c)$ and optimal state w^*, as well as (3.5) can be obtained by applying Theorem 1.1 in [9] and the Sobolev imbedding theorem. We need only prove (3.6)–(3.8). From (1.4) and (1.6), $w(x) = \mathcal{S} \circ (\frac{1}{2} + \mathcal{K}^*)^{-1} \tilde{u}(x) + C$ is the solution of equation (2.1), where C is an arbitrary constant and

$$\tilde{u}(x) = \begin{cases} 0, & x \in \Gamma_0, \\ u(x) & x \in \Gamma_c \end{cases} \tag{3.9}$$

as well as $u \in L_0^2(\Gamma_c)$. Hence

$$w^*(x) = \mathcal{S} \circ \left(\frac{1}{2}I + \mathcal{K}^*\right)^{-1} \tilde{u}^*(x) + C^*, \tag{3.10}$$

where C^* is determined from (2.4), i.e.,

$$C^* = -\frac{1}{\sum_{k=1}^M \mu_k} \sum_{k=1}^M \mu_k \left(\mathcal{S} \circ \left(\frac{1}{2}I + \mathcal{K}^*\right)^{-1} \tilde{u}^*(P_k) - Z_k\right). \tag{3.11}$$

Therefore, from (3.5) we have

$$\tilde{J}(u) \geq \tilde{J}(u^*), \qquad \forall u \in L_0^2(\Gamma_c), \tag{3.12}$$

where

$$\tilde{J}(u) = \sum_{k=1}^M \mu_k \left| \left(\mathcal{S} \circ \left(\frac{1}{2}I + \mathcal{K}^*\right)^{-1} \tilde{u}\right)(P_k) - Z_k + C^* \right|^2 + \gamma \int_{\Gamma_c} u^2(x) d\sigma_x.$$

For any $u \in L_0^2(\Gamma_c)$, $u^* + \theta(u - u^*) \in L_0^2(\Gamma_c)$ $\forall \theta \in [0,1]$,

$$\lim_{\theta \to 0+} \frac{1}{\theta}[\tilde{J}(u^* + \theta(u - u^*)) - \tilde{J}(u^*)] \geq 0.$$

Denote

$$\beta_k = \mu_k(w^*(P_k) - Z_k).$$

We obtain

$$\sum_{k=1}^M \beta_k \mathcal{S} \circ \left(\frac{1}{2}I + \mathcal{K}^*\right)^{-1} (\tilde{u} - \tilde{u}^*)(P_k) + \gamma \int_{\Gamma_c} u^*(u - u^*) d\sigma_\xi \geq 0, \quad \forall u \in L_0^2(\Gamma_c).$$

Using the definition of the simple layer $\mathcal{S}$, we have

$$\int_\Gamma \left\{\sum_{k=1}^M \beta_k E(P_k, \xi)\right\} \cdot \left(\frac{1}{2}I + \mathcal{K}^*\right)^{-1} (\tilde{u} - \tilde{u}^*)(\xi) d\sigma_\xi + \gamma \int_{\Gamma_c} u^*(\xi)(u(\xi) - u^*(\xi)) d\sigma_\xi \geq 0, \quad \forall u \in L_0^2(\Gamma_c). \tag{3.13}$$

Note that $E(P_k, \xi) = -\frac{1}{2\pi} \ln |P_k - \xi|$ and $E(P_k, \cdot) \in H^s(\Gamma)$ for $0 \leq s < \frac{1}{2}$ ([7]). It is easy to verify that

$$\sum_{k=1}^M \beta_k E(P_k, \cdot) \in H^s(\Gamma) \bigcap L^2_{\perp f_0}(\Gamma), \quad 0 \leq s < \frac{1}{2}. \tag{3.14}$$

Thus, applying Theorems 3.1 and 3.4, we have

$$\int_{\Gamma_c} \left[\frac{1}{\gamma}\left(\frac{1}{2}I + \mathcal{K}\right)^{-1} \sum_{k=1}^M \beta_k E(P_k, \xi) + u^*(\xi)\right](u(\xi) - u^*(\xi)) d\sigma_\xi \geq 0, \quad \forall u \in L_0^2(\Gamma_c). \tag{3.15}$$

Since $L_0^2(\Gamma_c)$ is a linear space, we obtain

$$\int_{\Gamma_c} \left[\frac{1}{\gamma} \left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \sum_{k=1}^{M} \beta_k E(P_k, \xi) + u^*(\xi) \right] u(\xi) d\sigma_\xi = 0, \quad \forall u \in L_0^2(\Gamma_c). \tag{3.16}$$

For any $u \in L^2(\Gamma_c)$,

$$u - \frac{1}{|\Gamma_c|} \int_{\Gamma_c} u(\xi) d\sigma_\xi \in L_0^2(\Gamma_c).$$

Thus, by the Fubini theorem, we have

$$\int_{\Gamma_c} \left[\frac{1}{\gamma} \left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \sum_{k=1}^{M} \beta_k E(P_k, \xi) + C + u^*(\xi) \right] u(\xi) d\sigma_\xi = 0, \quad \forall u \in L^2(\Gamma_c), \tag{3.17}$$

where

$$C = -\frac{1}{\gamma |\Gamma_c|} \int_{\Gamma_c} \left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \sum_{k=1}^{M} \beta_k E(P_k, \cdot)(x) d\sigma_x. \tag{3.18}$$

By Theorem 3.4, $(\frac{1}{2} I + \mathcal{K})^{-1} \sum_{k=1}^{M} \beta_k E(P_k, \cdot) \in L_0^2(\Gamma)$, we have

$$C = \frac{1}{\gamma |\Gamma_c|} \int_{\Gamma_0} \left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \sum_{k=1}^{M} \beta_k E(P_k, \cdot)(x) d\sigma_x. \tag{3.19}$$

It follows from (3.17) that

$$\frac{1}{\gamma} \left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \sum_{k=1}^{M} \beta_k E(P_k, \xi) + C + u^*(\xi) = 0, \quad \text{a.e. on } \Gamma_c.$$

Therefore

$$u^*(x) = -\frac{1}{\gamma} \left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \sum_{k=1}^{M} \beta_k E(P_k, \cdot)(x) - C, \quad \text{a.e. on } \Gamma_c, \tag{3.20}$$

where C is determined by (3.18) or (3.19). By (3.14) and Theorem 3.4,

$$u^* \in H^{\frac{1}{2}-\epsilon}(\Gamma_c), \qquad 0 < \epsilon \leq \frac{1}{2}. \tag{3.21}$$

By Theorems 3.2 and 3.3, it follows from (3.11) and (3.22) that

$$w^* \in H^{2-\epsilon}(\Omega), \qquad 0 < \epsilon \leq \frac{1}{2}.$$

Thus we have proved (3.6)–(3.8). □

To see the profile of the optimal control u^*, we need to know more information (i.e., singular behavior) of $u^*(x)$ at each sensor location $P_k, 1 \leq k \leq M$. The singularities of the optimal control u^* around sensor locations are displayed through Theorem 3.9. Let us first establish the following two lemmas.

LEMMA 3.6. *For $\Omega \subset \Re^{\mathcal{N}}$ $(\mathcal{N} = 2, 3)$ and $P \in \Gamma$, we have*

$$\mathcal{K}E(P,\cdot)(x) = \mathcal{S}\left(\frac{\partial}{\partial n_\xi}E(P,\xi)\right)(x), \quad \forall x \in \Gamma. \tag{3.22}$$

Proof. For $x \in \Gamma$ and $x \neq P$, let $\Omega_\epsilon = \Omega \setminus \{B(x,\epsilon) \bigcup B(P,\epsilon)\}$ and $\Gamma_\epsilon = \partial\Omega_\epsilon$ for any sufficiently small $\epsilon > 0$, where $B(x,\epsilon)$ is the ball of radius ϵ centered at x. Let n_ξ always denote the unit outward normal along Γ_ϵ for $\xi \in \Gamma_\epsilon$. It follows from the divergence theorem that

$$\int_{\Gamma_\epsilon}\left[\frac{\partial}{\partial n_\xi}E(x,\xi)\right]E(P,\xi)d\sigma_\xi = \int_{\Gamma_\epsilon}\left[\frac{\partial}{\partial n_\xi}E(P,\xi)\right]E(x,\xi)d\sigma_\xi. \tag{3.23}$$

Thus we have

$$\begin{aligned}
&\mathcal{K}E(P,\cdot)(x)\\
&\quad = p.v.\int_\Gamma \frac{\partial}{\partial n_\xi}E(x,\xi)E(P,\xi)d\sigma_\xi\\
&\quad \equiv \lim_{\epsilon\to 0+}\int_{\Gamma\bigcap\{|x-\xi|>\epsilon\}\bigcap\{|P-\xi|>\epsilon\}} \frac{\partial}{\partial n_\xi}E(x,\xi)E(P,\xi)d\sigma_\xi\\
&\quad = \lim_{\epsilon\to 0+}\left\{\int_{\Gamma_\epsilon}\frac{\partial}{\partial n_\xi}E(x,\xi)E(P,\xi)d\sigma_\xi - \int_{\Omega\bigcap\partial B(x,\epsilon)}\frac{\partial}{\partial n_\xi}E(x,\xi)E(P,\xi)d\sigma_\xi\right.\\
&\qquad\qquad \left. - \int_{\Omega\bigcap\partial B(P,\epsilon)}\frac{\partial}{\partial n_\xi}E(x,\xi)E(P,\xi)d\sigma_\xi\right\}\\
&\quad = \lim_{\epsilon\to 0+}\left\{\int_{\Gamma_\epsilon}\frac{\partial}{\partial n_\xi}E(P,\xi)E(x,\xi)d\sigma_\xi - \int_{\Omega\bigcap\partial B(x,\epsilon)}\frac{\partial}{\partial n_\xi}E(x,\xi)E(P,\xi)d\sigma_\xi\right.\\
&\qquad\qquad \left. - \int_{\Omega\bigcap\partial B(P,\epsilon)}\frac{\partial}{\partial n_\xi}E(x,\xi)E(P,\xi)d\sigma_\xi\right\}\\
&\quad = \lim_{\epsilon\to 0+}\left\{\int_{\Gamma\bigcap\{|x-P|>\epsilon\}\bigcap\{|P-\xi|>\epsilon\}}\frac{\partial}{\partial n_\xi}E(P,\xi)E(x,\xi)d\sigma_\xi\right.\\
&\qquad\qquad + \int_{\Omega\bigcap\partial B(x,\epsilon)}\left(\frac{\partial}{\partial n_\xi}E(P,\xi)E(x,\xi) - E(P,\xi)\frac{\partial}{\partial n_\xi}E(x,\xi)\right)d\sigma_\xi\\
&\qquad\qquad \left. + \int_{\Omega\bigcap\partial B(P,\epsilon)}\left(\frac{\partial}{\partial n_\xi}E(P,\xi)E(x,\xi) - E(P,\xi)\frac{\partial}{\partial n_\xi}E(x,\xi)\right)d\sigma_\xi\right\}.
\end{aligned}$$

Therefore

$$\begin{aligned}
&\mathcal{K}E(P,\cdot)(x)\\
&\quad = \int_\Gamma \frac{\partial}{\partial n_\xi}E(P,\xi)E(x,\xi)d\sigma_\xi\\
&\qquad + \lim_{\epsilon\to 0+}\int_{\Omega\bigcap\partial B(x,\epsilon)}\left(\frac{\partial}{\partial n_\xi}E(P,\xi)E(x,\xi) - E(P,\xi)\frac{\partial}{\partial n_\xi}E(x,\xi)\right)d\sigma_\xi\\
&\qquad + \lim_{\epsilon\to 0+}\int_{\Omega\bigcap\partial B(P,\epsilon)}\left(\frac{\partial}{\partial n_\xi}E(P,\xi)E(x,\xi) - E(P,\xi)\frac{\partial}{\partial n_\xi}E(x,\xi)\right)d\sigma_\xi
\end{aligned}$$

$$= \int_\Gamma \frac{\partial}{\partial n_\xi} E(P,\xi)E(x,\xi)d\sigma_\xi - \frac{1}{2}E(P,x) + \frac{1}{2}E(P,x)$$
$$= \int_\Gamma E(x,\xi)\frac{\partial}{\partial n_\xi} E(P,\xi)d\sigma_\xi.$$

Hence the lemma is proved. □

LEMMA 3.7. *Let $\Omega \subset \Re^{\mathcal{N}}$ ($\mathcal{N} = 2, 3$) be a bounded domain with smooth boundary Γ. Then there exists a constant $C = C(\Gamma)$ such that*

$$|\langle n_\xi, x - \xi\rangle| \le C(\Gamma)|x - \xi|^2, \quad \forall x, \xi \in \Gamma.$$

Proof. See [1, p. 222]. □

LEMMA 3.8. *For $\Omega \subset \Re^2$, let $\{P_k\}_{k=1}^M \subset \Gamma$ and $\{\beta_k\}_{k=1}^M \subset \Re$ satisfying*

$$\sum_{k=1}^M \beta_k = 0.$$

Then

$$\left(\frac{1}{2}I + \mathcal{K}\right)^{-1} \sum_{k=1}^M \beta_k E(P_k,\cdot)(x)$$
$$= 2\sum_{k=1}^M \beta_k E(P_k,x) - 2\left(\frac{1}{2}I + \mathcal{K}\right)^{-1} \sum_{k=1}^M \beta_k \mathcal{S}\left(\frac{\partial}{\partial n_\xi} E(P_k,\xi)\right)(x) \tag{3.24}$$
$$- \sum_{k=1}^M \frac{2\beta_k}{|\Gamma|} \int_\Gamma E(P_k,\xi)d\sigma_\xi$$

and

$$\left(\frac{1}{2}I + \mathcal{K}\right)^{-1} \sum_{k=1}^M \beta_k \mathcal{S}\left(\frac{\partial}{\partial n_\xi} E(P_k,\xi)\right) \in C(\Gamma).$$

Proof. From Lemma 3.6, we can see that

$$\sum_{k=1}^M \beta_k E(P_k,x) = \left(\frac{1}{2}I + \mathcal{K}\right)(2\sum_{k=1}^m \beta_k E(P_k,\xi) + C_0)(x) - 2\mathcal{S}(\eta)(x), \tag{3.25}$$

where

$$\eta(\xi) = \sum_{k=1}^M \beta_k \frac{\partial}{\partial n_\xi} E(P_k,\xi), \tag{3.26}$$

$$C_0 = -\frac{2}{|\Gamma|}\int_\Gamma \sum_{k=1}^M \beta_k E(P_k,x)d\sigma_x. \tag{3.27}$$

Applying Theorem 3.4, we obtain that

$$\left(\frac{1}{2}I + \mathcal{K}\right)^{-1} \sum_{k=1}^M \beta_k E(P_k,\cdot)(x)$$

$$= 2\sum_{k=1}^{M}\beta_k E(P_k,x) - 2\left(\frac{1}{2}I+\mathcal{K}\right)^{-1}\sum_{k=1}^{M}\beta_k\mathcal{S}\left(\frac{\partial}{\partial n_\xi}E(P_k,\xi)\right)(x)$$
$$-\sum_{k=1}^{M}\frac{2\beta_k}{|\Gamma|}\int_\Gamma E(P_k,\xi)d\sigma_\xi.$$

Since

$$\frac{\partial}{\partial n_\xi}E(P_k,\xi) = \frac{1}{2\pi}\cdot\frac{< n_\xi, P_k-\xi >}{|P_k-\xi|^2}$$

and Γ is smooth, we obtain

$$\frac{\partial}{\partial n_\xi}E(P_k,\xi)\in L^\infty(\Gamma) \tag{3.28}$$

by applying Lemma 3.7. Hence by Theorem 3.2, we have

$$\mathcal{S}(\frac{\partial}{\partial n_\xi}E(P_k,\xi))\in H^1(\Gamma),$$

and by Theorem 3.4 and the Sobolev imbedding theorem

$$\left(\frac{1}{2}I+\mathcal{K}\right)^{-1}\sum_{k=1}^{M}\beta_k\mathcal{S}\left(\frac{\partial}{\partial n_\xi}E(P_k,\xi)\right)\in C(\Gamma). \qquad \square$$

Applying Lemma 3.8, we obtain our second main theorem—the singularity decomposition formula of the optimal control.

THEOREM 3.9. *Under the assumptions of Theorem* 3.5, *the optimal control can be decomposed as*

$$u^*(x) = -\frac{1}{\gamma}\left(\frac{1}{2}I+\mathcal{K}\right)^{-1}\sum_{k=1}^{M}\mu_k(w^*(P_k)-Z_k)E(P_k,\cdot)(x)+C_0$$
$$= -\frac{2}{\gamma}\sum_{k=1}^{M}\mu_k(w^*(P_k)-Z_K)E(P_k,x)$$
$$+\frac{2}{\gamma}\left(\frac{1}{2}I+\mathcal{K}\right)^{-1}\sum_{k=1}^{M}\mu_k(w^*(P_k)-Z_k)\mathcal{S}\left(\frac{\partial}{\partial n_\xi}E(P_k,\xi)\right)(x)+C \tag{3.29}$$

and

$$\left(\frac{1}{2}I+\mathcal{K}\right)^{-1}\sum_{k=1}^{M}\mu_k(w^*(P_k)-Z_k)\mathcal{S}\left(\frac{\partial}{\partial n_\xi}E(P_k,\xi)\right)\in C(\Gamma),$$

where

$$C = C_0+\frac{1}{\gamma}\sum_{k=1}^{M}\frac{2\mu_k}{|\Gamma|}\int_\Gamma(w^*(P_k)-Z_k)E(P_k,\xi)d\sigma_\xi.$$

TABLE 1
The values of optimal control at sensor locations.

	LMM	GPM	(3.29)
Z_k	$w^*(P_k)$	$w^*(P_k)$	$u^*(P_k)$
1	0.7562	0.7799	$+\infty$
0	0.4876	0.4402	$-\infty$
1	0.7562	0.7799	$+\infty$

From Theorem 3.9, we can see that the first term of the right-hand side of (3.29) contains all possible singular terms and that at sensor location $P_k, 1 \le k \le M$, the sign of the singular term is completely determined by the sign of the term $(w^*(P_k) - Z_k)$. Now we return to Example 1 and utilize (3.29) to answer the question asked at the end of §2. Let us examine the values of the optimal controls u^* of the LQR and the constrained LQR at three sensor locations, which are computed by LMM and by our GPM.

From Table 1, we can see that the profiles of u^*'s in Fig. 2 computed by GPM are correct and the profiles of u^*'s in Fig. 1 computed by LMM are not correct because the middle cusp, according to (3.29), should be pointed to $-\infty$.

Next we analyze the failure of LMM. Notice that in the numerical computation of LQR problems, LMM is implemented by BEM with the layer density η as the variable of the problems. The next theorem indicates that the optimal layer density η^* behaves just like the optimal control u^*. It can also be decomposed into a singular part and a bounded part.

THEOREM 3.10. *Under the assumption of Theorem* 3.5 *and* $\Gamma_0 = \emptyset$, *the optimal layer density* η^* *has the same possible singularities as that of the optimal control* u^* *and can be decomposed into following singular part and bounded part:*

$$\eta^*(x) = \left(\frac{1}{2}I + \mathcal{K}^*\right)^{-1} u^*(x)$$

$$= -\frac{4}{\gamma}\sum_{k=1}^{M} \mu_k(w^*(P_k) - Z_k)E(P_k, x) \tag{3.30}$$

$$+\frac{4}{\gamma}\left(\frac{1}{2}I + \mathcal{K}\right)^{-1}\sum_{k=1}^{M} \mu_k(w^*(P_k) - Z_k)\mathcal{S}\left(\frac{\partial}{\partial n_\xi}E(P_k, \xi)\right)(x) + 2C \tag{3.31}$$

$$-2\left(\frac{1}{2}I + \mathcal{K}^*\right)^{-1} \circ \mathcal{K}^* u^*(x), \tag{3.32}$$

where C *is defined in Theorem* 3.9.

Proof. From Theorem 3.9, we already knew that

$$\frac{4}{\gamma}\left(\frac{1}{2}I + \mathcal{K}\right)^{-1}\sum_{k=1}^{M} \mu_k(w^*(P_k) - Z_k)\mathcal{S}\left(\frac{\partial}{\partial n_\xi}E(P_k, \xi)\right) + 2C \in C(\Gamma).$$

It then follows from Theorem 3.5 that $u^* \in H^s(\Gamma), 0 \le s < \frac{1}{2}$. Since $\Omega \subset \Re^2$ has bounded smooth boundary Γ, $\mathcal{K}^*$ is a linear bounded operator from $H^s(\Gamma)$ to $C^\infty(\Gamma)$ [1, pp. 249–250]. Therefore

$$\mathcal{K}^* u^* \in C^\infty(\Gamma).$$

By Theorem 3.3, we have

$$\left(\frac{1}{2}I + \mathcal{K}^*\right)^{-1} \circ \mathcal{K}^* u^* \in C(\Gamma).$$

Hence (3.31) and (3.32) are bounded. To prove the theorem, we only need to note that

$$u^*(x) = 2\left(\frac{1}{2}I + \mathcal{K}^*\right) u^*(x) - 2\mathcal{K}^* u^*(x).$$

Thus

$$\begin{aligned}\eta^*(x) &= \left(\frac{1}{2}I + \mathcal{K}^*\right)^{-1} u^*(x) \\ &= 2u^*(x) - 2\left(\frac{1}{2}I + \mathcal{K}^*\right)^{-1} \mathcal{K}^* u^*(x). \qquad \square\end{aligned}$$

In BEM, the layer density η is approximated by piecewise smooth elements. Since the optimal layer density has the same possible (logarithmic) singularities at sensor locations as the optimal control, many elements are required around each sensor location for a good approximation. But this will cause the system size to be too large to handle. The following facts show how poor the approximation is.

$$\left[\int_{-\delta}^{\delta} \left(\ln|x| - (\ln\delta - 1)\right)^2 dx\right]^{\frac{1}{2}} = \min_{y\in\Re}\left[\int_{-\delta}^{\delta} \left(\ln|x| - y\right)^2 dx\right]^{\frac{1}{2}} = (2\delta)^{\frac{1}{2}}, \tag{3.33}$$

$$\left\|\ln x - \frac{3}{\delta}x - \left(\ln\delta - \frac{5}{2}\right)\right\|_{L^2(0,\delta)} = \min_{a,b\in\Re} \|\ln x - (ax+b)\|_{L^2(0,\delta)} = \frac{\sqrt{3}}{2}\delta^{\frac{1}{2}}, \tag{3.34}$$

$$\begin{aligned}&\left\|\ln x - \left(\frac{3}{\delta^2}x^2 - \frac{4}{\delta}x + \ln\delta - \frac{1}{3}\right)\right\|_{L^2(0,\delta)} \\ &\quad = \min_{a,b,c\in\Re} \|\ln x - (ax^2 + bx + c)\|_{L^2(0,\delta)} \\ &\quad = \left[2\delta\left(\frac{7}{3} - 2\ln\delta\right)\right]^{\frac{1}{2}} + \text{higher-order terms.}\end{aligned} \tag{3.35}$$

In other words, to have an accuracy of order 10^{-4} for the optimal layer density, one must let the length 2δ of element be of order 10^{-8}. So LMM cannot provide us a reliable numerical solution.

Since the GPM is sensitive to the partition number of the boundary and rather slow, we wish to develop some fast and reliable numerical methods for the constrained LQR problem. The next section will be devoted to this purpose and the derivation of some characterizations of optimal control of constrained LQR problems.

4. Characterizations of optimal control for constrained LQR problems. We first establish the following important lemma.

LEMMA 4.1. *Let $-\infty < a < b < +\infty$, $f(x)$ be a Lebesgue measurable function on (a,b), and $B > 0$ be given. Then there is a $C \in \Re$ such that*

$$\int_a^b [f(x)+C]_B dx = 0, \tag{4.1}$$

where

$$[f(x)+C]_B = \begin{cases} B & \text{if } f(x)+C > B, \\ f(x)+C & \text{if } -B \le f(x)+C \le B, \\ -B & \text{if } f(x)+C < -B, \end{cases} \tag{4.2}$$

is the truncation of the function $f(x)+C$ by the bound B, and the map $\phi : \Re \to \Re$ defined by

$$\phi(\lambda) = \int_a^b [f(x)+\lambda]_B dx, \quad \lambda \in \Re$$

is continuous and increasing.

Proof. The function $\phi(\lambda)$ is obviously well-defined on $\Re$ and

$$-B(b-a) \le \phi(\lambda) \le B(b-a).$$

First we will prove that $\phi(\lambda)$ is an increasing continuous function. Suppose λ_1, $\lambda_2 \in \Re$, $\lambda_1 \le \lambda_2$, and $\lambda_2 - \lambda_1 < 2B$, and let

$$\begin{aligned} I_1 &= \{x \in (a,b) |\ f(x) > B - \lambda_1\}, \\ I_2 &= \{x \in (a,b) |\ B - \lambda_2 < f(x) \le B - \lambda_1\}, \\ I_3 &= \{x \in (a,b) |\ -B - \lambda_1 \le f(x) \le B - \lambda_2\}, \\ I_4 &= \{x \in (a,b) |\ -B - \lambda_2 \le f(x) < -B - \lambda_1\}, \\ I_5 &= \{x \in (a,b) |\ f(x) < -B - \lambda_2\}. \end{aligned}$$

Then

$$I_1 \bigcup I_2 \bigcup I_3 \bigcup I_4 \bigcup I_5 = (a,b) \text{ and } I_i \bigcap I_j = \emptyset, \ \forall i \ne j.$$

Therefore

$$\begin{aligned} \phi(\lambda_2) - \phi(\lambda_1) &= \int_a^b ([f(x)+\lambda_2]_B - [f(x)+\lambda_1]_B) dx \\ &= \int_{I_1} ([f(x)+\lambda_2]_B - [f(x)+\lambda_1]_B) dx \\ &\quad + \int_{I_2} ([f(x)+\lambda_2]_B - [f(x)+\lambda_1]_B) dx \\ &\quad + \int_{I_3} ([f(x)+\lambda_2]_B - [f(x)+\lambda_1]_B) dx \\ &\quad + \int_{I_4} ([f(x)+\lambda_2]_B - [f(x)+\lambda_1]_B) dx \\ &\quad + \int_{I_5} ([f(x)+\lambda_2]_B - [f(x)+\lambda_1]_B) dx \\ &= \int_{I_2} (B - [f(x)+\lambda_1]_B) dx + \int_{I_3} (\lambda_2 - \lambda_1) dx \\ &\quad + \int_{I_4} ([f(x)+\lambda_2]_B + B) dx \ge 0. \end{aligned}$$

Hence

$$\phi(\lambda_1) \leq \phi(\lambda_2), \ \forall \lambda_1 \leq \lambda_2,$$

and

$$\begin{aligned} 0 &\leq \phi(\lambda_2) - \phi(\lambda_1) \\ &= \int_{I_2} (B - [f(x) + \lambda_1]_B) dx + \int_{I_3} (\lambda_2 - \lambda_1) dx + \int_{I_4} ([f(x) + \lambda_2]_B + B) dx \\ &\leq 2B\text{mes}(\{x \in (a,b)| \ -B - \lambda_2 \leq f(x) < -B - \lambda_1\}) \\ &\quad +(b-a)(\lambda_2 - \lambda_1) + 2B\text{mes}(\{x \in (a,b)| \ B - \lambda_2 < f(x) \leq B - \lambda_1\}). \end{aligned}$$

Applying Lusin's theorem, we have that for any given $\epsilon > 0$, $\exists \delta > 0$ such that if $|\lambda_2 - \lambda_1| < \delta$, then

$$|\phi(\lambda_2) - \phi(\lambda_1)| < \epsilon. \tag{4.3}$$

Thus $\phi(\lambda)$ is an increasing continuous function. Note

$$\lim_{\lambda \to +\infty} \text{mes}(\{x \in (a,b)| \ f(x) > B - \lambda\}) = b - a$$

and

$$\lim_{\lambda \to -\infty} \text{mes}(\{x \in (a,b)| \ f(x) < -B - \lambda\}) = b - a.$$

Thus

$$\lim_{\lambda \to +\infty} \phi(\lambda) = B(b-a),$$

$$\lim_{\lambda \to -\infty} \phi(\lambda) = -B(b-a).$$

Therefore there exists a $C \in \Re$ such that

$$\phi(C) = 0. \qquad \square$$

Using the same method, we can prove the following lemma.

LEMMA 4.2. *Let $f(x)$ be a Lebesgue measurable function on Γ_c and let $B > 0$ be given. Then there exists a $C \in \Re$ such that*

$$\int_{\Gamma_c} [f(x) + C]_B d\sigma_x = 0, \tag{4.4}$$

where

$$[f(x) + C]_B = \begin{cases} B, & \text{if } f(x) + C > B, \\ f(x) + C, & \text{if } -B \leq f(x) + C \leq B, \\ -B, & \text{if } f(x) + C < -B. \end{cases} \tag{4.5}$$

Denote

$$\mathcal{U} = \{v \in L_0^2(\Gamma_c)| \ |v(\xi)| \leq B, \qquad \text{a.e. on } \Gamma_c\}. \tag{4.6}$$

THEOREM 4.3. *The constrained LQR problem has a unique optimal control* $u^* \in \mathcal{U}$ *and a unique optimal state* $w^* \in C(\overline{\Omega})$ *satisfying* (2.1) *and* (2.4). *The optimal control is characterized by*

$$u^*(\xi) = -\left[\frac{1}{\gamma}\left(\frac{1}{2}I + \mathcal{K}\right)^{-1}\sum_{k=1}^{M}\mu_k(w^*(P_k) - Z_k)E(P_k,\xi) + C\right]_B, \quad \forall x \in \Gamma_c, \tag{4.7}$$

where C *is a constant such that*

$$\int_{\Gamma_c}\left[\frac{1}{\gamma}\left(\frac{1}{2}I + \mathcal{K}\right)^{-1}\sum_{k=1}^{M}\mu_k(w^*(P_k) - Z_k)E(P_k,\xi) + C\right]_B d\sigma_\xi = 0. \tag{4.8}$$

Proof. The existence and uniqueness of the optimal control $u^* \in \mathcal{U}$ and the optimal state w^* follow from Theorem 2.1. So we only have to prove (4.7) and (4.8). Denote

$$\beta_k = \mu_k(w^*(P_k) - Z_k).$$

For $\Omega \subset \Re^2$, repeating the same argument as (3.9)–(3.15) in the proof of Theorem 3.5, we have

$$\int_{\Gamma_c}\left[\frac{1}{\gamma}\left(\frac{1}{2}I + \mathcal{K}\right)^{-1}\sum_{k=1}^{M}\beta_k E(P_k,\xi) + u^*(\xi)\right](u(\xi) - u^*(\xi))d\sigma_\xi \geq 0, \quad \forall u \in \mathcal{U}. \tag{4.9}$$

Since $u,\ u^* \in \mathcal{U}$, we obtain

$$\int_{\Gamma_c}\left[\frac{1}{\gamma}\left(\frac{1}{2}I + \mathcal{K}\right)^{-1}\sum_{k=1}^{M}\beta_k E(P_k,\xi) + C + u^*(\xi)\right](u(\xi) - u^*(\xi))d\sigma_\xi \geq 0, \forall u \in \mathcal{U}, \tag{4.10}$$

where $C \in \Re$ is a constant in Lemma 4.2 such that

$$\int_{\Gamma_c}\left[\frac{1}{\gamma}\left(\frac{1}{2}I + \mathcal{K}\right)^{-1}\sum_{k=1}^{M}\beta_k E(P_k,\xi) + C\right]_B d\sigma_\xi = 0. \tag{4.11}$$

Let

$$G(\xi) = \frac{1}{\gamma}\left(\frac{1}{2}I + \mathcal{K}\right)^{-1}\sum_{k=1}^{M}\beta_k E(P_k,\xi) + C, \tag{4.12}$$

$$\tilde{u}(\xi) = -[G(\xi)]_B = -\left[\frac{1}{\gamma}\left(\frac{1}{2}I + \mathcal{K}\right)^{-1}\sum_{k=1}^{M}\beta_k E(P_k,\xi) + C\right]_B; \tag{4.13}$$

then $\tilde{u} \in \mathcal{U}$. For any $v \in \mathcal{U}$ we have

$$\begin{aligned}
&\int_{\Gamma_c}\left\{\frac{1}{\gamma}\left(\frac{1}{2}I + \mathcal{K}\right)^{-1}\sum_{k=1}^{M}\beta_k E(P_k,\xi) + C + \tilde{u}(\xi)\right\}(v(\xi) - \tilde{u}(\xi))d\sigma_\xi \\
&= \int_{\Gamma_c}(G(\xi) + \tilde{u}(\xi))(v(\xi) - \tilde{u}(\xi))d\sigma_\xi \qquad (4.14)\\
&= \int_{\Gamma_c^+}(G(\xi) - B)(v(\xi) + B)d\sigma_\xi + \int_{\Gamma_c^-}(G(\xi) + B)(v(\xi) - B)d\sigma_\xi \\
&\geq 0,
\end{aligned}$$

where

$$\Gamma_c^+ = \{x \in \Gamma_c | G(x) > B\} \quad \text{and} \quad \Gamma_c^- = \{x \in \Gamma_c | G(x) < -B\}.$$

Let $u(\xi) = \tilde{u}(\xi)$ in (4.10) and $v(\xi) = u^*(\xi)$ in (4.14). We have

$$\int_{\Gamma_c} \left\{ \frac{1}{\gamma} \left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \sum_{k=1}^{M} \beta_k E(P_k, \xi) + C + u^*(\xi) \right\} (\tilde{u}(\xi) - u^*(\xi)) d\sigma_\xi \geq 0, \tag{4.15}$$

and

$$\int_{\Gamma_c} \left\{ \frac{1}{\gamma} \left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \sum_{k=1}^{M} \beta_k E(P_k, \xi) + C + \tilde{u}(\xi) \right\} (u^*(\xi) - \tilde{u}(\xi)) d\sigma_\xi \geq 0. \tag{4.16}$$

Adding (4.15) to (4.16), we obtain

$$\int_{\Gamma_c} (u^*(\xi) - \tilde{u}(\xi))^2 d\sigma_\xi \leq 0.$$

Therefore

$$u^*(\xi) = \tilde{u}(\xi) \qquad \text{a.e. on } \Gamma_c.$$

Thus we have proved (4.7) and (4.8). For $\Omega \subset \Re^3$, using Theorems 3.3 and 3.4, the proof of (4.7) and (4.8) is exactly the same as above. □

REMARK 2. The constant C in (4.7), the expression of optimal control, is uniquely determined from (4.8), if Γ_c is connected. When Γ_c is not connected, the constant C may be not unique. In this case, the set of all such C's is a bounded closed interval. For all C in this interval, the value of the optimal control remains the same.

For $\Omega \subset \Re^2$, coupled with the decomposition formula (3.29), the characterization formula (4.7) can be applied in numerical algorithm to compute the exact value of the optimal control at any point $x \in \Gamma$. Unfortunately, the decomposition formula (3.29) is only valid for $\Omega \subset \Re^2$. For the same purpose, we will establish a decomposition formula for $\Omega \subset \Re^3$. The proof is different and much harder.

THEOREM 4.4. *Let $\Omega \subset \Re^3$ be a bounded domain with smooth boundary Γ. Let $\{\beta_k\}_{k=1}^M \subset \Re$ satisfy*

$$\sum_{k=1}^{M} \beta_k = 0.$$

Then the following decomposition formula holds:

$$\left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \sum_{k=1}^{M} \beta_k E(P_k, \cdot)(x)$$

$$= 2 \sum_{k=1}^{M} \beta_k E(P_k, x) - 4 \sum_{k=1}^{M} \beta_k \mathcal{S} \left(\frac{\partial E(P_k, \xi)}{\partial n_\xi} \right)(x) \tag{4.17}$$

$$+4 \left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \sum_{k=1}^{M} \beta_k \mathcal{S} \circ \mathcal{K}^* \left(\frac{\partial E(P_k, \xi)}{\partial n_\xi} \right)(x) + C_0 \tag{4.18}$$

with

$$C_0 = -\frac{1}{|\Gamma|}\int_\Gamma \left[2\sum_{k=1}^{M}\beta_k E(P_k,\xi) - 4\sum_{k=1}^{M}\beta_k \mathcal{S}\left(\frac{\partial E(P_k,\xi)}{\partial n_\xi}\right)\right] d\sigma_\xi,$$

where (4.17) *is the singular part with a dominant term* $2\sum_{k=1}^{M}\beta_k E(P_k,x)$ *and* (4.18) *is the bounded part.*

To prove the theorem, we need several lemmas.

LEMMA 4.5. *Let* $\Omega \subset \Re^3$ *be a bounded domain with smooth boundary* Γ. *For any* $P \in \Gamma$,

$$E(P,\cdot) \in L^\alpha(\Gamma), \quad 1 \le \alpha < 2,$$

and

$$E(P,\cdot) \notin L^2(\Gamma).$$

Proof. See [2]. □

By Theorem 3.4 and Lemma 4.5, the function $(\frac{1}{2}I+\mathcal{K})^{-1}\sum_{k=1}^{M}\beta_k E(P_k,\cdot)$ is well defined only in $L^\alpha(\Gamma)$ with $2-\varepsilon < \alpha < 2$, where ε is defined in Theorem 3.4.

LEMMA 4.6. *For* $x, y > 0$ *and* $0 < \alpha < 1$, *we have the following inequality:*

$$\left|\frac{1}{x} - \frac{1}{y}\right| \le M(\alpha)|x-y|^\alpha \max\left\{\frac{1}{x^{1+\alpha}}, \frac{1}{y^{1+\alpha}}\right\},$$

where $M(\alpha) = (\frac{1-\alpha}{\alpha})^{1-\alpha}$.

Proof. See [2]. □

LEMMA 4.7. *Let* $\Omega \subset \Re^3$ *be a bounded domain with smooth boundary* Γ, *and* $0 < \alpha < 2$. *There exists a constant* $C = C(\Gamma,\alpha)$ *such that*

$$\int_\Gamma \frac{1}{|x-\xi|^\alpha} d\sigma_\xi \le C(\Gamma,\alpha), \quad \forall x \in \Gamma.$$

Proof. The proof follows from a direct calculation, and thus is omitted. □

LEMMA 4.8. *For any* $x, y \in \Gamma, 0 \le \alpha < 1, \alpha < \beta < \frac{1+\alpha}{2}$ *there exists a constant* $C(\Gamma,\alpha,\beta) > 0$ *such that*

$$\int_\Gamma \frac{1}{|x-\xi|^{1+\alpha}} \cdot \frac{1}{|y-\xi|} d\sigma_\xi \le C(\Gamma,\alpha,\beta) \cdot \frac{1}{|x-y|^\beta}.$$

Proof. Using the inequality $(a+b)^\beta \le a^\beta + b^\beta$, $a > 0$, $b > 0$, $0 < \beta < 1$, we have

$$\begin{aligned}
&\int_\Gamma \frac{|x-y|^\beta}{|x-\xi|^{1+\alpha}|y-\xi|} d\sigma_\xi \\
&\quad \le \int_\Gamma \frac{|x-\xi|^\beta + |y-\xi|^\beta}{|x-\xi|^{1+\alpha}|y-\xi|} d\sigma_\xi \\
&\quad = \int_\Gamma \frac{1}{|x-\xi|^{1-(\beta-\alpha)}} \cdot \frac{1}{|y-\xi|} d\sigma_\xi + \int_\Gamma \frac{1}{|x-\xi|^{1+\alpha}} \cdot \frac{1}{|y-\xi|^{1-\beta}} d\sigma_\xi \\
&\quad \le \left(\int_\Gamma \frac{1}{|x-\xi|^{p_1(1-(\beta-\alpha))}} d\sigma_\xi\right)^{\frac{1}{p_1}} \cdot \left(\int_\Gamma \frac{1}{|y-\xi|^{q_1}} d\sigma_\xi\right)^{\frac{1}{q_1}} \\
&\qquad + \left(\int_\Gamma \frac{1}{|x-\xi|^{p_2(1+\alpha)}} d\sigma_\xi\right)^{\frac{1}{p_2}} \cdot \left(\int_\Gamma \frac{1}{|y-\xi|^{q_2(1-\beta)}} d\sigma_\xi\right)^{\frac{1}{q_2}}.
\end{aligned}$$

The last inequality follows from the Hölder inequality, where $2 < p_1 < \frac{2}{1-(\beta-\alpha)}, q_1 = \frac{p_1}{p_1-1}$ and $\frac{2}{1+\beta} < p_2 < \frac{2}{1+\alpha}, q_2 = \frac{p_2}{p_2-1}$; thus $1 < p_1(1-(\beta-\alpha)) < 2, 1 < q_1 < 2$ and $1 < p_2(1+\alpha) < 2, 1 < q_2(1-\beta) < 2$. Here we have used the fact $0 \le \alpha < 1, \alpha < \beta < \frac{\alpha+1}{2}$. By using Lemma 4.7, we obtain

$$\int_\Gamma \frac{|x-y|^\beta}{|x-\xi|^{1+\alpha}|y-\xi|} d\sigma_\xi \le C(\Gamma,\alpha,\beta),$$

where $C(\Gamma,\alpha,\beta)$ is a constant depending on Γ, α, and β. Thus the lemma is proved. □

LEMMA 4.9. *Let $f \in L^q(\Gamma)$, $\frac{4}{3} < q < 2$. Let $0 < \alpha < \frac{3q-4}{q}$. Then*

$$\mathcal{S} \circ \mathcal{K}^* : L^q(\Gamma) \to C^{0,\alpha}(\Gamma)$$

is a linear continuous mapping and there exists a constant $C = C(\Gamma,\alpha,q)$ such that

$$|\mathcal{S} \circ \mathcal{K}^*(f)(x) - \mathcal{S} \circ \mathcal{K}^*(f)(y)| \le C|x-y|^\alpha \|f\|_{L^q(\Gamma)}, \quad \forall x, y \in \Gamma.$$

Proof. For $x \in \Gamma$, by Fubini's theorem, we have

$$\begin{aligned}\mathcal{S} \circ \mathcal{K}^*(f)(x) &= -\frac{1}{16\pi^2} \int_\Gamma \left[\frac{1}{|x-\xi|} \int_\Gamma \frac{\langle n_\xi, \xi-\eta\rangle}{|\xi-\eta|^3} f(\eta) d\sigma_\eta \right] d\sigma_\xi \\ &= -\frac{1}{16\pi^2} \int_\Gamma \left[\frac{1}{|x-\xi|} \int_\Gamma \frac{\langle n_\xi, \xi-\eta\rangle}{|\xi-\eta|^3} d\sigma_\xi \right] f(\eta) d\sigma_\eta.\end{aligned}$$

It follows from Lemma 3.7 that for any $x, y \in \Gamma$,

$$\begin{aligned}&|\mathcal{S} \circ \mathcal{K}^*(f)(x) - \mathcal{S} \circ \mathcal{K}^*(f)(y)| \\ &\le \frac{1}{16\pi^2} \int_\Gamma \left| \int_\Gamma \left(\frac{1}{|x-\xi|} - \frac{1}{|y-\xi|} \right) \frac{\langle n_\xi, \xi-\eta\rangle}{|\xi-\eta|^3} d\sigma_\xi \right| |f(\eta)| d\sigma_\eta \\ &\qquad \text{(by Lemma 3.7)} \\ &\le \frac{C(\Gamma)}{16\pi^2} \int_\Gamma \left\{ \int_\Gamma \left| \frac{1}{|x-\xi|} - \frac{1}{|y-\eta|} \right| \frac{1}{|\xi-\eta|} d\sigma_\xi \right\} |f(\eta)| d\sigma_\eta \\ &\qquad \text{(by Lemma 4.6)} \\ &\le \frac{C(\Gamma)M(\alpha)}{16\pi^2} \int_\Gamma \left\{ \int_\Gamma |x-y|^\alpha \max\left\{ \frac{1}{|x-\xi|^{1+\alpha}}, \frac{1}{|y-\xi|^{1+\alpha}} \right\} \frac{1}{|\xi-\eta|} d\sigma_\xi \right\} |f(\eta)| d\sigma_\eta \\ &\le \frac{C(\Gamma)M(\alpha)}{16\pi^2} |x-y|^\alpha \int_\Gamma \left\{ \int_\Gamma \left(\frac{1}{|x-\xi|^{1+\alpha}} + \frac{1}{|y-\xi|^{1+\alpha}} \right) \frac{1}{|\xi-\eta|} d\sigma_\xi \right\} |f(\eta)| d\sigma_\eta \\ &\qquad \text{(apply Lemma 4.8 with } \alpha < \beta < \tfrac{1+\alpha}{2}\text{)} \\ &\le \frac{C(\Gamma)M(\alpha)}{16\pi^2} |x-y|^\alpha C(\Gamma,\alpha,\beta) \int_\Gamma \left[\frac{1}{|x-\eta|^\beta} + \frac{1}{|y-\eta|^\beta} \right] |f(\eta)| d\sigma_\eta \\ &\le \frac{C(\Gamma)M(\alpha)}{16\pi^2} C(\Gamma,\alpha,\beta) |x-y|^\alpha \|f\|_{L^q(\Gamma)} \left\{ \left[\int_\Gamma \frac{d\sigma_\eta}{|x-\eta|^{\beta p}} \right]^{\frac{1}{p}} + \left[\int_\Gamma \frac{d\sigma_\eta}{|y-\eta|^{\beta p}} \right]^{\frac{1}{p}} \right\} \\ &\le C|x-y|^\alpha \|f\|_{L^q(\Gamma)},\end{aligned}$$

where the last ineqality follows from Lemma 4.7 with the fact that $\alpha < \beta < \frac{1+\alpha}{2}$, $p = \frac{q}{q-1}$, and $0 < \alpha < \frac{2q-2}{q}$ imply $0 < \beta p < 2$; and where the constant C depends only on q, Γ, α. □

Proof of Theorem 4.4. From [12, p. 56], we have

$$\mathcal{S} \circ \mathcal{K}^* = \mathcal{K} \circ \mathcal{S}.$$

Thus by Lemma 3.6, it is easy to verify that

$$\sum_{k=1}^{M} \beta_k E(P_k, \xi) = \left(\frac{1}{2} I + \mathcal{K}\right) \left(2 \sum_{k=1}^{M} \beta_k E(P_k, \xi) - 4 \sum_{k=1}^{M} \beta_k \mathcal{S} \left(\frac{\partial E(P_k, \xi)}{\partial n_\xi}\right) + C_0\right)$$
$$+4 \sum_{k=1}^{M} \beta_k \mathcal{S} \circ \mathcal{K}^* \left(\frac{\partial E(P_k, \xi)}{\partial n_\xi}\right).$$

Upon using Theorem 3.4, we get

$$\left(\frac{1}{2} I + \mathcal{K}\right)^{-1} \sum_{k=1}^{M} \beta_k E(P_k, \xi) = 2 \sum_{k=1}^{M} \beta_k E(P_k, \xi) - 4 \sum_{k=1}^{M} \beta_k \mathcal{S} \left(\frac{\partial E(P_k, \xi)}{\partial n_\xi}\right) + C_0$$
$$+4 \left(\frac{1}{2} I + \mathcal{K}\right)^{-1} \sum_{k=1}^{M} \beta_k \mathcal{S} \circ \mathcal{K}^* \left(\frac{\partial E(P_k, \xi)}{\partial n_\xi}\right).$$

From Lemmas 3.7 and 4.5, we have

$$\frac{\partial E(P_k, \xi)}{\partial n_\xi} \in L^q(\Gamma), \quad 1 < q < 2$$

and

$$\frac{\partial E(P_k, \xi)}{\partial n_\xi} \notin L^2(\Gamma).$$

Applying Lemma 4.8, for $0 < \beta < 1$, we have

$$\left|\mathcal{S}\left(\frac{\partial E(P_k, \xi)}{\partial n_\xi}\right)(x)\right| \leq C(\Gamma, \beta) \frac{1}{|x - P_k|^\beta}, \quad 1 \leq k \leq M,$$

where $C(\Gamma, \beta)$ depends on Γ and β. Therefore the dominant term of the singular part (4.17) is

$$2 \sum_{k=1}^{M} \beta_k E(P_k, x).$$

By Lemma 4.9, for $0 < \alpha < 1$, we have

$$\mathcal{S} \circ \mathcal{K}^* \left(\frac{\partial E(P_k, \xi)}{\partial n_\xi}\right) \in C^{0,\alpha}(\Gamma), \quad 1 \leq k \leq M.$$

Since

$$\frac{1}{2} \left(\frac{1}{2} I + \mathcal{K}\right)^{-1} \sum_{k=1}^{M} \beta_k \mathcal{S} \circ \mathcal{K}^* \left(\frac{\partial E(P_k, \xi)}{\partial n_\xi}\right)$$
$$= \sum_{k=1}^{M} \beta_k \mathcal{S} \circ \mathcal{K}^* \left(\frac{\partial E(P_k, \xi)}{\partial n_\xi}\right) - \mathcal{K} \circ \left(\frac{1}{2} I + \mathcal{K}\right)^{-1} \sum_{k=1}^{M} \beta_k \mathcal{S} \circ \mathcal{K}^* \left(\frac{\partial E(P_k, \xi)}{\partial n_\xi}\right),$$

by Theorem 3.4, Lemma 4.9, and [1], we have

$$\left(\frac{1}{2}I+\mathcal{K}\right)^{-1}\sum_{k=1}^{M}\beta_k\mathcal{S}\circ\mathcal{K}^*\left(\frac{\partial E(P_k,\xi)}{\partial n_\xi}\right)\in C(\Gamma).$$

Therefore (4.18) is continuous and then bounded on Γ. □

REMARK 3. It is worthwhile to indicate the importance of the decomposed results, Theorems 3.9 and 4.4. When $x\to P_{k_0}$ for some $1\le k_0\le M$, $E(P_{k_0},x)\to+\infty$. The original characterization formulas (3.6) and (4.7) are not computable and fail to provide further information about the optimal control u^* around the singular point P_k. Due to Theorems 3.9 and 4.4, we cannot only determine the sign of u^* at P_k but also compute the exact value of $u^*(P_k)$. These results also make it possible to develop numerical algorithms. We also obtained Theorem 4.3 from Theorem 3.9—a decomposed characterization of the optimal layer density. With this result, we are able to detect the failure of the classical LMM in providing reliable numerical solutions.

5. Numerical algorithms for solving constrained LQR problems. Motivated by characterization results obtained so far, we will develop two numerical algorithms in this section to solve the constrained LQR problems. Observe that due to equation (2.4), the optimal state w^* is uniquely determined by the optimal control. We formulate the constrained LQR problem in terms of the control variable u, so the bound constraint on controls becomes more directly handleable. The first algorithm is called the gradient truncation method (GTM) and the second one is called the iterative truncation method (ITM). Our numerical examples show that these algorithms are efficient and insensitive to the partition number of the boundary, a significant advantage over other methods. Theorems 3.9, 4.3, and 4.4, and Lemma 3.8 are used in the development of these algorithms.

The GTM is constructed using the gradient of cost functional and characterization results in §4.

Step 0: Give initial guess $u_0\in\mathcal{U}$;
Step 1: Use the potential theory and BEM (see §1) to solve $w(x)$ from

$$\begin{cases}\Delta w(x)=0 & \text{in }\Omega,\\ \dfrac{\partial w(x)}{\partial n}=0 & \text{on }\Gamma_0,\\ \dfrac{\partial w(x)}{\partial n}=u_0(x) & \text{on }\Gamma_c;\end{cases}$$

Step 2: Find C_0 such that

$$\sum_{k=1}^{M}\mu_k(w(P_k)+C_0-Z_k)=0$$

and set $w_0(x)=w(x)+C_0\quad x\in\Gamma$;
Step 3: Compute $\nabla J(u_0)$;
Step 4: Find $\alpha_0=\arg\min_\alpha J\left(u_0-\alpha*\nabla J(u_0)\right)$;
Step 5: Find C_1 such that

$$\int_{\Gamma_c}\left[u_0(x)-\alpha_0\nabla J(u_0)+C_1\right]_B d\sigma_x=0$$

and set $u(x)=\left[u_0(x)-\alpha_0\nabla J(u_0)+C_1\right]_B\quad x\in\Gamma_c$;

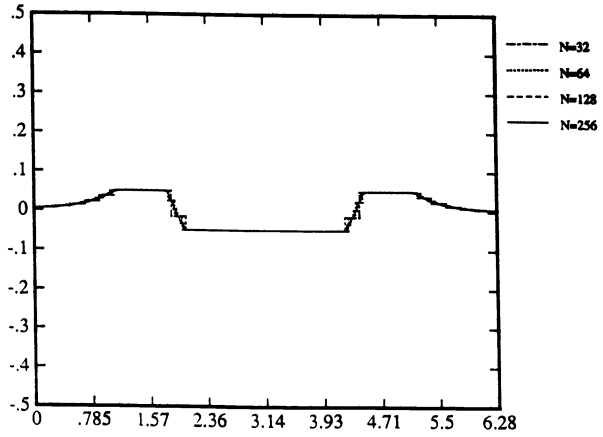

FIG. 3. *Optimal controls* $u^*(x)$ *of the constrained LQR in Example* 1, *computed by GTM with* $B = 0.05$.

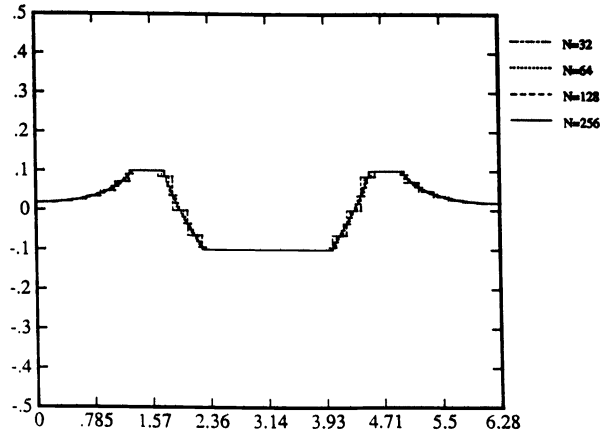

FIG. 4. *Optimal controls* $u^*(x)$ *of the constrained LQR in Example* 1, *computed by GTM with* $B = 0.1$.

Step 6: If $|u - u_0|_{L^2(\Gamma_c)} < \varepsilon_u$ then output and stop
else set $u_0(x) = u(x) \quad x \in \Gamma_c$, goto Step 1.

REMARK 4. (1) Step 4 in GTM is a minimization problem without constraints, while Step 4 of GPM solves a constrained minimization problem;

(2) Step 5 is motivated by our characterization result (4.7) and (4.8). It takes care of the consistency condition and handles the bound constraint uniformly.

Applying the GTM to the constrained LQR problem in Example 1, we obtain the second column in Table 2 and Figs. 3, 4, and 5. From Table 2, it can be seen that this method is efficient in the comparison to GPM. From Figs. 3, 4, and 5, when the control bound B increases, we observed that u^* does not reach the bound B at sensor locations where $w^*(P_k) - Z_k \neq 0$. This is different from our characterization formula (4.7) in Theorem 4.3. The reason is that GTM does not use (4.7) and (4.8) exactly (see the difference between Step 5 in GTM and (4.7)). So if we want to catch the characterization of the optimal control described in (4.7), we have to develop a numerical algorithm based on it. The ITM is constructed this way and considers the

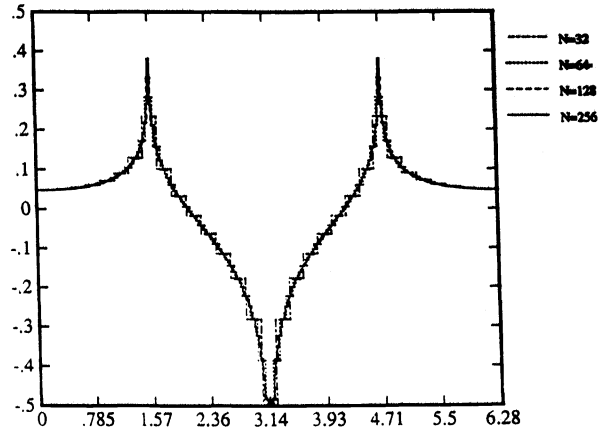

FIG. 5. *Optimal controls $u^*(x)$ of the constrained LQR in Example* 1, *computed by GTM with* $B = 0.5$.

optimal control u^* as a fixed point of (4.7).

Step 0: Given initial guess $u_0 \in \mathcal{U}$;
Step 1: Use the potential theory and BEM (see §1) to solve $w(x)$ from

$$\begin{cases} \Delta w(x) = 0 & \text{in } \Omega, \\ \dfrac{\partial w(x)}{\partial n} = 0 & \text{on } \Gamma_0, \\ \dfrac{\partial w(x)}{\partial n} = u_0(x) & \text{on } \Gamma_c; \end{cases}$$

Step 2: Find C_0 such that

$$\sum_{k=1}^{M} \mu_k (w(P_k) + C_0 - Z_k) = 0,$$

and set $w_0(x) = w(x) + C_0 \quad x \in \Gamma$;
Step 3: To compute $u(x)$, for $\mathcal{N} = 2$, use (4.7) and (3.29), for $\mathcal{N} = 3$ use (4.7), (4.17), and (4.18);
Step 4: If $|u - u_0|_{L^2(\Gamma_c)} < \varepsilon_u$ then output and stop,
else set $u_0(x) = \frac{1}{2}[u_0(x) + u(x)] \quad x \in \Gamma_c$, goto Step 1.

All the formulas in Step 3 of the ITM scheme treat the bound constraint uniformly, so it can handle only uniform bound constraints. Originally the last formula in Step 4 of the ITM scheme was

$$u_0(x) = u(x) \quad x \in \Gamma_c.$$

But this diverges in some of our numerical experiments. The current formula $u_0(x) = \frac{1}{2}[u_0(x) + u(x)] \quad x \in \Gamma_c$, a relaxation formula, is used to enhance the stability of convergence. All of our numerical experiments have confirmed this and have shown that this method is efficient and catches the characterization of the optimal control. Applying ITM and the adaptive local refinement scheme (to be explained next) to the constrained LQR problems in Example 1, we obtain Table 2 and Figs. 6, 7, and 8.

256	27	0.4720	7	0.4427	11	0.4428

In Table 2, the error control is $\varepsilon_u = 10^{-4}$. One can see that both GTM and ITM are efficient in the comparison to GPM. If we compare the minimum values $J_{\min}$ w.r.t. the partition number N of the boundary, we find that both the GTM and ITM schemes are insensitive to the partition number of the boundary. This is a significant advantage of GTM and ITM schemes over other algorithms. Since the optimal control problems under consideration are governed by partial differential equations, the partition number of the boundary can be very large, therefore any numerical method sensitive to the partition number may fail to carry out the numerical computation.

Figs. 6, 7, and 8 show that the ITM scheme does catch the characterization of the optimal control at sensor locations $P_k, 1 \leq k \leq M$, no matter how large the bound is. However, this will also cause the divergence of the scheme. Since the optimal control of the LQR problem has singularities around the sensor locations, even after truncation around the sensor locations, the peak in the graph of u^* around the sensor locations may still be very narrow. When the partition number of the boundary is fixed, the length of each element in BEM is fixed. If the control bound B is large, the property that u^* reaches the bound at sensor locations will causes too much control around sensor locations and result in the divergence of the scheme. This is why ITM diverges in computing the constrained LQR problems in Example 1 for $B = 1.5$. Piecewise linear or quadratic elements are not helpful in this situation (see (3.33)–(3.35)). Refining the partition of the boundary can relieve the problem, but this will enlarge the size of the problem. To overcome this difficulty, the following adaptive local refinement scheme is proposed.

For $N = 2$, add two nodal points around each sensor location. Then carry out the ITM scheme. If ITM converges then continue. If ITM still does not converge, move two added nodal points closer to the sensor location and go on.

For $N = 3$, the basic idea is the same. When the adaptive local refinement goes on around each sensor location, the partition number of the boundary is fixed. After we coupled this scheme with the ITM scheme, the algorithm converged in all our numerical examples. The adaptive local refinement scheme can be expected to

be useful in other numerical algorithms where the solution has singularities at some points.

Finally we point out that although the motivations of GTM and ITM are quite different, it can be shown that they are essentially the same,[1] that is, Step 3 of ITM is essentially equal to Step 4 of GTM with $\alpha_0 = \frac{1}{2\gamma}$. Of course, a relaxation formula has to be added in ITM to enhance the convergence stability. Since singularities are treated differently in GTM and ITM, both methods have different advantages and disadvantages. The GTM works for the problem with any bound constraints on the control, but the numerical solution of optimal control may fail to reach the control bound around some sensor locations where, according to characterizations of optimal control, the optimal control should reach the control bound. While the numerical solution of the optimal control computed by ITM does catch the characterization of the optimal control, it may also cause stability problems in the convergence of ITM. To remedy this defect, an adaptive local refinement scheme is proposed to handle the rough behavior of the optimal control around sensor locations without enlarging the size of the problem considered. The ITM coupled with an adaptive local refinement scheme works very well for the LQR problem with any bound constraint on the control; in particular, it has a potential in solving bound-constrained LQR problems on nonsmooth domains where some sensors are placed at vertex points of the boundary (see [2]). Many details are omitted in both numerical algorithms because of space constraints, e.g., most of the integrals involved are singular integrals, and careful treatments are necessary to have a successful computation. The convergence analysis of GTM and ITM will be discussed in a separate paper.

6. Conclusion. In this paper, several regularity and characterization theorems for LQR and constrained LQR problems have been established. In particular, three decomposition formulas are proved to characterize the optimal control and the optimal layer density and to direct numerical computations. These results cannot be obtained by the traditional Galerkin variational method. Along with the proofs, several useful lemmas are established, which are of independent interest. We point out that the classical Lagrangian multiplier method is not reliable to provide numerical algorithms for this kind of problem due to the existence of singularities in the solutions. Based upon the characterization results, two numerical algorithms, GTM and ITM, have been developed to carry out the numerical computations of the constrained LQR problems. Both methods are efficient and insensitive to the partition number of the boundary, a significant advantage over other algorithms. Both algorithms have been carried out for several numerical examples and the numerical results confirm our analysis.

Finally, we point out that all of the above results are valid if the boundary Γ is a piecewise C^2 surface with point sensors placed at smooth points of the boundary. But the constrained LQR problems on nonsmooth domains with some sensors placed at the vertex points of the boundary are quite different. The theoretical analysis is much tougher. The related results are presented in a forthcoming paper [2].

Acknowledgments. The authors thank Professor G. Chen for his comments, suggestions, and constant interest in our work. We also thank two referees for their valuable suggestions and comments.

AVERAGE OPTIMALITY IN MARKOV CONTROL PROCESSES VIA DISCOUNTED-COST PROBLEMS AND LINEAR PROGRAMMING*

ONÉSIMO HERNÁNDEZ-LERMA† AND JEAN B. LASSERRE‡

Abstract. This paper shows the existence of solutions to the average-cost problem for Markov control processes on Borel spaces, with possibly unbounded costs and noncompact control constraint sets. This is done via a combination of the well-known "vanishing discount" approach and recent results on the linear programming formulation for both discounted- and average-cost Markov control problems.

Key words. (discrete-time) Markov control processes, average-cost criterion, discounted-cost criterion, linear programming (in general vector spaces)

AMS subject classifications. 93E20, 90C40

1. Introduction.

Among the several ways available to analyze average-cost (AC) Markov control processes, two of the most commonly used are the "vanishing discount" and the linear programming (LP) approaches. In the latter case, one introduces a suitable linear program and its dual and gives conditions for their value to coincide and for their common value to equal the value of the AC problem. In the former approach, on the other hand, one defines discounted-cost problems with a discount factor $\alpha \in (0,1)$ and shows that under suitable assumptions, appropriately normalized functions converge to the AC value as $\alpha \uparrow 1$. These approaches are not directly comparable: they require (apparently) independent settings.

This paper presents, for Markov control processes on Borel spaces, a combination of the two approaches: First, for each $\alpha \in (0,1)$, we introduce a "discounted" linear program (P_α) and its dual (P_α^*), and then we give conditions for some modified, equivalent versions, (MP_α) and (MP_α^*), to converge in some sense, as $\alpha \uparrow 1$, to programs (MP_1), (MP_1^*) related to the AC problem. Our main results are that (MP_1) and the AC problem are both solvable, with the same value J^*, and that there is no duality gap, i.e., $J^* = \sup(MP_1^*)$. These conclusions are of course not new. What is indeed new is the way we obtain them here, via the linear programs (MP_α)–(MP_α^*). In particular, in contrast with the usual hypotheses [2], [15], [16], we do not require the discounted differential cost (h_α in Assumption 5.1) to be majorized by a finite function. Thus, on the one hand, we obtain a new set of conditions ensuring solvability of the AC problem, and on the other, we provide a setting for the comparison of the vanishing-discount and the LP approaches.

Related literature. This paper is essentially a sequel to [8] and [7], where we developed the LP formulation of AC and discounted-cost problems, respectively, for Markov control processes with *Borel* state and action spaces, allowing *unbounded* one-stage costs and *noncompact* control constraint sets. [7] and [8]—see also, e.g., [2], [3], [12], [13]—present many related references. For the vanishing-discount approach see, e.g., [2], [6], [15], [16]. The LP terminology we use is based on [1, Chap. 3].

Organization of the paper. Section 2 introduces the Markov control problems we are interested in. The linear programs $(P_\alpha) - (MP_\alpha)$ and their duals $(P_\alpha^*) - (MP_\alpha^*)$, $0 < \alpha < 1$, are defined in §3, together with conditions for them to be consistent. For $\alpha = 1$, the linear program (MP_1) and the AC problem are both shown to be solvable in §4; it is also shown that they are equivalent in the sense that they have the same optimal value. In §5 it is proved that there is no duality gap for (MP_1), i.e., (MP_1) and its dual (MP_1^*) have the same value. In the last section, §6, we briefly compare the usual vanishing-discount-factor approach with the version presented here, and we also make some comments on how one can get deterministic (as opposed to randomized) policies with optimality properties.

2. Markov control processes.

Notation. We essentially use the same notation as in [7], [8]. In particular, if S is a Borel space, $\mathcal{B}(S)$, $C(S)$, and $\mathcal{P}(S)$ stand for the Borel σ-algebra, the space of bounded and continuous functions, and the set of probability measures on S, respectively. If S and T are Borel spaces, then the family of stochastic kernels on S given T is denoted by $\mathcal{P}(S|T)$.

Let (X, A, Q, c) be a stationary *Markov control model* [2], [4], [5], [10] satisfying the following conditions. The *state space* X and the *action* (or control) *set* A are both Borel spaces. To each $x \in X$ is associated a nonempty set $A(x) \in \mathcal{B}(A)$ whose elements are the feasible control actions when the system is in state x. The set

$$K := \{(x, a) |\ x \in X,\ a \in A(x)\} \tag{2.1}$$

of admissible state-actions pairs is assumed to be a Borel subset of $X \times A$.

The *transition law* Q, or $Q(B|x, a)$ with $B \in \mathcal{B}(X)$ and $(x, a) \in K$, is a stochastic kernel on X given K, which is assumed to be *weakly continuous*, i.e., $\int v(y)Q(dy|.)$ is in $C(K)$ whenever $v \in C(X)$. The *one-stage cost* c is a nonnegative lower semicontinuous function on K.

To ensure that the set $\mathcal{F}$ defined next is nonempty, we will assume that K contains the graph of a measurable map. (Conditions for the latter to hold are given by so-called "measurable selection theorems" [2], [4], [5], [10].)

DEFINITION 2.1. *$\mathcal{F}$ denotes the set of all measurable functions $f : X \to A$ such that $f(x) \in A(x)$ for all $x \in X$, and Φ stands for the set of all stochastic kernels $\varphi \in \mathcal{P}(A|X)$ that satisfy $\varphi(A(x)|x) = 1$ for all $x \in X$.*

DEFINITION 2.2. *Let $H_0 := X$ and $H_t := K \times H_{t-1}$, $t = 1, 2, \ldots$. A (control) policy is a sequence $\delta = \{\delta_t\}$ of stochastic kernels $\delta_t \in \mathcal{P}(A|H_t)$ that satisfy the constraint $\delta_t(A(x_t)|h_t) = 1$ for all $h_t = (x_0, a_0, \ldots, x_{t-1}, a_{t-1}, x_t)$ in H_t, $t = 0, 1, \ldots$. The set of all policies is denoted by Δ. A policy δ is said to be* relaxed *(or randomized stationary) if there exists $\varphi \in \Phi$ such that $\delta_t(.|h_t) = \varphi(.|x_t)$ for all $h_t \in H_t$, $t = 0, 1, \ldots$, and it is called* deterministic stationary *if, for some $f \in \mathcal{F}$, $\delta_t(.|h_t)$ is concentrated at $f(x_t)$ for all $h_t \in H_t$, $t = 0, 1, \ldots$.*

We shall identify $\mathcal{F}$ (resp., Φ) with the set of all deterministic stationary (resp., relaxed) policies.

Let $(\Omega, \mathcal{E})$ be the measurable space that consists of the sample space $\Omega := (X \times A)^\infty$ and the corresponding product σ-algebra $\mathcal{E}$. Then for every policy δ and initial distribution $\nu \in \mathcal{P}(X)$ a probability P_ν^δ and a stochastic process $\{(x_t, a_t),\ t = 0, 1, \ldots\}$ are defined on $(\Omega, \mathcal{E})$ in a canonical way (see, e.g., [10, p. 80]), where x_t and a_t denote the state and action at time t, respectively. The expectation operator with respect to

P_ν^δ is denoted by E_ν^δ. If ν is concentrated at some initial state $x_0 = x$, we write P_ν^δ and E_ν^δ as P_x^δ and E_x^δ, respectively.

Performance criteria. For every $\alpha \in (0,1)$, let

$$V_\alpha(\delta,\nu) := E_\nu^\delta\left[\sum_{t=0}^{\infty}\alpha^t c(x_t,a_t)\right] \tag{2.2}$$

be the total expected α-discounted cost when using the policy δ, given the initial distribution ν. We may write

$$V_\alpha(\delta,\nu) := \int_X V_\alpha(\delta,x)\nu(dx), \quad \text{where } V_\alpha(\delta,x) := E_x^\delta\left[\sum_{t=0}^{\infty}\alpha^t c(x_t,a_t)\right].$$

Let us define

$$V_\alpha^*(\nu) := \inf_\delta V_\alpha(\delta,\nu), \quad \nu \in \mathcal{P}(X).$$

For a given ν, δ is said to be *α-discount ν-optimal* if $V_\alpha(\delta,\nu) = V_\alpha^*(\nu)$, whereas if $V_\alpha(\delta,x) = V_\alpha^*(x)$ for all $x \in X$, then δ is said to be *pointwise α-discount optimal.*

Now we define the long-run expected AC when using the policy δ, given the initial distribution ν, as

$$J(\delta,\nu) := \limsup_{n\to\infty}\, n^{-1}E_\nu^\delta\left[\sum_{t=0}^{n-1}c(x_t,a_t)\right], \tag{2.3}$$

and let

$$J^* := \inf_\nu \inf_\delta J(\delta,\nu). \tag{2.4}$$

(In [8], J^* is written as $\inf_\Delta$ AC.) A pair (δ^*,ν^*) consisting of a policy δ^* and an initial distribution ν^* is said to be a *minimum pair* [8], [11] if $J(\delta^*,\nu^*) = J^*$. The problem of finding a minimum pair is sometimes referred to as the *AC problem*, and J^* is called the *value* of the AC problem.

This AC problem has been studied by Kurano [11] using Doeblin's (ergodicity) condition and in [8] using an LP approach. Here we again use the LP approach, but not directly on the AC problem itself as in [8]; we use instead linear programs associated with the α-discount problems [7]. This requires, to begin with, that J^* is finite. We will thus make the following assumption.

Assumption 2.3. $J(\hat\delta,\hat\nu) < \infty$ for some $\hat\delta \in \Delta$ and $\hat\nu \in \mathcal{P}(X)$.

Assumption 2.3 ensures, of course, that J^* is finite, but it also guarantees that $V_\alpha(\hat\delta,\hat\nu)$ is finite for every $\alpha \in (0,1)$, since by a well-known Tauberian theorem (see, e.g., [2], [15], [16])

$$\limsup_{\alpha\uparrow 1}\,(1-\alpha)V_\alpha(\hat\delta,\hat\nu) \le J(\hat\delta,\hat\nu). \tag{2.5}$$

Note that the latter inequality implies

$$\limsup_{\alpha\uparrow 1}\,(1-\alpha)V_\alpha^*(\hat\nu) \le J(\hat\delta,\hat\nu). \tag{2.6}$$

In the next section we consider linear programs associated with the problem of minimizing $V_\alpha(\delta,\hat\nu)$ over Δ, which are then used in §4 to obtain a minimum pair.

3. Linear programs. The plan of this section is as follows. First, for every $\alpha \in (0,1)$, we state linear programs (P_α) and (P_α^*) associated with the α-discounted cost problem, which are then shown to be equivalent to modified linear programs (MP_α), (MP_α^*). For $\alpha = 1$, the latter are programs associated with the AC problem. (The LP terminology that we use is borrowed from [1, Chap. 3].)

We begin with the introduction of two dual pairs of vector spaces, which are the same already used in [7], [8].

Dual pairs. Let K be the set in (2.1) and $b: K \to R$ the function

$$b(x,a) := c_0 + c(x,a), \tag{3.1}$$

where c_0 is a given positive number. (Recall that, by assumption, the one-stage cost is nonnegative; hence $b \geq c_0$.) We define $F(K)$ as the vector space of all real-valued measurable functions v on K such that

$$\|v\|_b := \sup_{(x,a)} |v(x,a)|/b(x,a) \ < \infty. \tag{3.2}$$

Note that c is in $F(K)$. (If necessary, a function $v \in F(K)$ is considered to be extended to all of $X \times A$ in an arbitrary way as long as measurability and (3.2) are preserved.) Now let $M(K)$ be the vector space consisting of all the finite signed measures μ on $X \times A$ concentrated on K and such that

$$\int b d|\mu| \ < \infty,$$

where $|\mu|$ denotes the total variation of μ. Then $(M(K),\ F(K))$ is a dual pair with respect to the bilinear form $\langle \mu, v \rangle := \int v d\mu$.

Similarly, let $b_1 : X \to R$ be a positive measurable function bounded away from zero and define $F(X)$ as the vector space of all the real-valued measurable functions u on X such that

$$\|u\|_{b_1} := \sup_x \ |u(x)|/b_1(x) \ < \infty,$$

and let $M(X)$ be the vector space of all the finite signed measures ν on X for which $\int b_1 d|\nu| \ < \infty$. Then $(M(X),\ F(X))$ is a dual pair with respect to the bilinear form $\langle \nu, u \rangle := \int u d\nu$.

Remark. We adopt here the convention that, unless explicitly stated otherwise, a vector space in a dual pair is *always* endowed with the *weak topology* [1]. Convergence in this topology will be denoted $\xrightarrow{\sigma}$. However, for finite nonnegative—in particular, probability—measures, we will also use the usual notion of "weak convergence," noted $\xrightarrow{w}$ or w-convergence. Thus, e.g., $\mu^n \xrightarrow{w} \mu$ (resp., $\mu^n \xrightarrow{\sigma} \mu$) in $M^+(K) := \{\mu \in M(K) | \mu \geq 0\}$ means that

$$\langle \mu^n, v \rangle \to \langle \mu, v \rangle \quad \forall v \in C(K) \quad (\text{resp., } \forall v \in F(K)).$$

Clearly, σ-convergence implies w-convergence.

To guarantee that the linear programs (P_α) and (P_α^*) below are properly defined, throughout the following we suppose the following assumption.

Assumption 3.1. (a) $\hat{\nu}$ is in $M(X)$, i.e., $\int b_1 d\hat{\nu} \ < \infty$.

(b) $b(x,a) \geq b_1(x) \geq c_1$ for all $(x,a) \in K$ and some positive number c_1.

(c) $\int b_1(y) Q(dy|.)$ is in $F(K)$, i.e., $\sup_{(x,a)} \int b_1(y) Q(dy|x,a)/b(x,a) \ < \infty$.

Linear programs. For each positive $\alpha \leq 1$, let $T_\alpha : M(K) \to M(X)$ and $T_\alpha^* : F(X) \to F(K)$ be the linear operators defined as

$$(T_\alpha \mu)(B) := \mu_1(B) - \alpha \int Q(B|x,a)\mu(d(x,a)) \tag{3.3}$$

for all $\mu \in M(K)$, $B \in \mathcal{B}(X)$, where $\mu_1(B) := \mu(B \times A)$ is the *projection* (or marginal) of μ on X, and

$$(T_\alpha^* u)(x,a) := u(x) - \alpha \int u(y) Q(dy|x,a), \quad u \in F(X), \ (x,a) \in K. \tag{3.4}$$

In view of Assumption 3.1, these linear operators are continuous. Moreover, T_α^* is the *adjoint* of T_α, i.e.,

$$\langle T_\alpha \mu, u \rangle = \langle \mu, T_\alpha^* u \rangle \quad \forall \mu \in M(K), \ u \in F(X). \tag{3.5}$$

Consider the following linear programs:
(P_α) minimize $\langle \mu, c \rangle$ subject to

$$\mu \in M^+(K) \ \text{ and } \ T_\alpha \mu = \hat{\nu}; \tag{3.6}$$

(P_α^*) maximize $\langle \hat{\nu}, u \rangle$ subject to

$$u \in F(X) \ \text{ and } \ T_\alpha^* u \leq c. \tag{3.7}$$

The linear program (P_α^*) is the *dual* of (P_α) [1]. Under Assumptions 2.3 and 3.1, it has been shown in [7, §4] that (P_α) and the problem of minimizing $V_\alpha(., \hat{\nu})$ are equivalent, i.e, $V_\alpha^*(\hat{\nu}) = \inf(P_\alpha)$, and by weak duality,

$$V_\alpha^*(\hat{\nu}) = \inf(P_\alpha) \geq \sup(P_\alpha^*). \tag{3.8}$$

Moreover, under the additional Assumption 3.2(a) below, (P_α) is solvable and, under Assumption 3.2(b), equality holds in (3.8), i.e.,

$$V_\alpha^*(\hat{\nu}) = \min(P_\alpha) = \sup(P_\alpha^*). \tag{3.9}$$

Before we state Assumption 3.2, note that if μ is feasible for (P_α), then $(1-\alpha)\mu(K) = 1$. Thus $\mu'(.) := (1-\alpha)\mu(.)$ is a probability measure on K.

Assumption 3.2. (a) If $\{\mu^n\}$ is a sequence of feasible solutions for (P_α) such that $\sup_n \int c d\mu^n \leq r$ for some $r > 0$, then $\{\mu^n\}$ is tight.

(b)If $\{\mu^n\}$ is a sequence of probability measures in $M(K)$ such that $\sup_n \int c d\mu^n \leq r$ for some $r > 0$, then $\{\mu^n\}$ is tight.

Assumption 3.2 holds, e.g., if the one-stage cost c is a "moment" (see [8, Rem. 5.6 and §6]). Observe also that Assumption 3.2(b) implies 3.2(a)

We now wish to relate (P_α) and (P_α^*) to the minimum-pair problem. To do this, we modify these programs as follows.

Modified linear programs. Consider the dual pair $(R \times M(X), \ R \times F(X))$ with the bilinear form

$$\langle (r,\nu), (\rho, u) \rangle := r\rho + \langle \nu, u \rangle.$$

For every positive $\alpha \leq 1$, let $L_\alpha : M(K) \to R \times M(X)$ be the linear operator defined as

$$L_\alpha \mu := (\bar{\mu}, T_\alpha \mu) \ \text{ with } \ \bar{\mu} := \mu(K), \ \mu \in M(K).$$

Consider the adjoint $L_\alpha^* : R \times F(X) \to F(K)$ of L_α, i.e.,

$$L_\alpha^*(\rho, u) := \rho + T_\alpha^* u.$$

Now, instead of $(P_\alpha) - (P_\alpha^*)$, the corresponding linear programs are
(MP_α) minimize $\langle \mu, c \rangle$ subject to

$$L_\alpha \mu = (1, (1-\alpha)\hat{\nu}), \quad \mu \in M^+(K); \tag{3.10}$$

(MP_α^*) maximize $(\rho + (1-\alpha)\langle \hat{\nu}, u \rangle)$ $[= \langle (1, (1-\alpha)\hat{\nu}), (\rho, u) \rangle]$ subject to

$$L_\alpha^*(\rho, u) \le c, \quad (\rho, u) \in R \times F(X). \tag{3.11}$$

In particular, for $\alpha = 1$ we obtain linear programs associated with the AC problem [8]:
(MP_1) minimize $\langle \mu, c \rangle$ subject to

$$L_1 \mu = (1, 0), \quad \mu \in M^+(K); \tag{3.12}$$

(MP_1^*) maximize ρ $[= \langle (1,0), (\rho, u) \rangle]$ subject to

$$L_1^*(\rho, u) \le c, \quad (\rho, u) \in R \times F(X). \tag{3.13}$$

It turns out that, for positive $\alpha < 1$, the modified linear programs are equivalent to the original programs in the following sense.

PROPOSITION 3.3. *For every $0 < \alpha < 1$, we have the following:*

(a) *if μ is feasible for (P_α), then $\mu'(.) = (1-\alpha)\mu(.)$ is feasible for (MP_α) and*

$$\langle \mu, c \rangle = \langle \mu', c \rangle / (1-\alpha).$$

(b) *Conversely, if μ is feasible for (MP_α), then $\tilde{\mu}(.) := \mu(.)/(1-\alpha)$ is feasible for (P_α) and*

$$\langle \tilde{\mu}, c \rangle = \langle \mu, c \rangle / (1-\alpha).$$

Hence

$$\inf(P_\alpha) = (1-\alpha)^{-1} \inf(MP_\alpha). \tag{3.14}$$

Similarly for the dual problems:

(c) *If u is feasible for (P_α^*), then for any real number m, the pair (ρ, u') defined as $\rho = (1-\alpha)m$ and $u'(.) := u(.) - m$ is feasible for (MP_α^*) and*

$$\langle \hat{\nu}, u \rangle = [\rho + (1-\alpha)\langle \hat{\nu}, u' \rangle] / (1-\alpha).$$

(d) *If (ρ, u) is feasible for (MP_α^*), then $u'(.) := u(.) + \rho/(1-\alpha)$ is feasible for (P_α^*) and*

$$\langle \hat{\nu}, u' \rangle = [\rho + (1-\alpha)\langle \hat{\nu}, u \rangle] / (1-\alpha).$$

Hence

$$\sup(P_\alpha^*) = (1-\alpha)^{-1} \sup(MP_\alpha^*). \tag{3.15}$$

We omit the easy proof.

From (3.8)–(3.9) and (3.14)–(3.15), we obtain the following.

COROLLARY 3.4. *If Assumptions* 2.3 *and* 3.1 *hold, then for every* $0 < \alpha < 1$,

(a) $(1-\alpha)V_\alpha^*(\hat{\nu}) = \inf(MP_\alpha) \geq \sup(MP_\alpha^*)$.

If, in addition, Assumption 3.2 *holds, then*

(b) (MP_α) *is solvable and*

$$(1-\alpha)V_\alpha^*(\hat{\nu}) = \min(MP_\alpha) = \sup(MP_\alpha^*). \tag{3.16}$$

In part (b) of the corollary, solvability of (MP_α), $0 < \alpha < 1$, means, of course, that there is a measure $\mu^\alpha \in M(K)$ that satisfies (3.10) and

$$\min(MP_\alpha) = \int c d\mu^\alpha. \tag{3.17}$$

In the next two sections we show that (3.16) holds "in the limit as $\alpha \uparrow 1$," so that

$$J^* = \min(MP_1) = \sup(MP_1^*), \tag{3.18}$$

with J^* as in (2.4). In particular, the solvability of (MP_1) is equivalent to the existence of a minimum pair. The first equality in (3.18) is proved in §4; the second, in §5.

4. Existence of minimum pairs. To prove the first equality in (3.18), let us first note the following elementary fact. (Recall the notation introduced in the remark preceding Assumption 3.1.)

LEMMA 4.1. *Let* μ *and* μ^α, $0 < \alpha < 1$, *be measures in* $M(K)$ *such that* $\mu^\alpha \xrightarrow{\sigma} \mu$ *as* $\alpha \uparrow 1$, *i.e.,*

$$\lim_{\alpha \uparrow 1} \langle \mu^\alpha, v \rangle = \langle \mu, v \rangle \quad \forall v \in F(K). \tag{4.1}$$

Then $T_\alpha \mu^\alpha \xrightarrow{\sigma} T_1 \mu$ *and* $L_\alpha \mu^\alpha \xrightarrow{\sigma} L_1 \mu$. *If, moreover,* μ^α *is feasible for* (MP_α), $0 < \alpha < 1$, *then* μ *is feasible for* (MP_1). *If we have instead* $\mu^\alpha \xrightarrow{w} \mu$ *in* $M^+(K)$ *as* $\alpha \uparrow 1$, *all of the conclusions hold replacing* $\xrightarrow{\sigma}$ *by* $\xrightarrow{w}$.

Proof. For any $B \in \mathcal{B}(X)$, $T_\alpha \mu^\alpha(B) = T_1 \mu^\alpha(B) - (1-\alpha) \int Q(B|k) \mu^\alpha(dk)$. Therefore, as $\alpha \uparrow 1$,

$$\lim T_\alpha \mu^\alpha = \lim T_1 \mu^\alpha = T_1 \mu, \tag{4.2}$$

where the latter equality is due to (4.1) and the continuity of T_1. Furthermore, letting $v(.) \equiv 1$ in (4.1), we obtain $\overline{\mu^\alpha} \to \overline{\mu}$. Thus $L_\alpha \mu^\alpha \xrightarrow{\sigma} L_1 \mu$, completing the proof of the first statement. Now if each μ^α satisfies (3.10), then $\overline{\mu} = 1$, and from (4.2),

$$T_1 \mu(B) = \lim_{\alpha \uparrow 1} (1-\alpha) \hat{\nu}(B) = 0 \quad \forall B \in \mathcal{B}(X),$$

i.e., μ satisfies (3.12) and therefore is feasible for (MP_1). Finally, to prove the last statement it suffices to note that $\mu^\alpha \xrightarrow{w} \mu$ implies w-convergence of the projections, i.e., $\mu_1^\alpha \xrightarrow{w} \mu_1$, and also

$$\int_K Q(.|k) \mu^\alpha(dk) \xrightarrow{w} \int_K Q(.|k) \mu(dk) \quad \text{in} \quad M^+(X)$$

by the weak continuity of Q. □

THEOREM 4.2. *Suppose that Assumptions* 2.3, 3.1, *and* 3.2(a) *hold, and for every* $\alpha \in (0,1)$, *let* μ^α *be an optimal solution for* (MP_α), *i.e.* (*from the first equality in* (3.16)),

$$(1-\alpha)V_\alpha^*(\hat{\nu}) = \min(MP_\alpha) = \int c d\mu^\alpha, \quad 0 < \alpha < 1. \tag{4.3}$$

Then

(a) *there exist a sequence* $\alpha(n) \uparrow 1$, *a number* $j^* \le J(\hat{\delta}, \hat{\nu})$, *and a measure* μ^* *feasible for* (MP_1) *such that*

$$j^* = \lim_n (1-\alpha(n))V_{\alpha(n)}^*(\hat{\nu}) \ge \int c d\mu^*. \tag{4.4}$$

(b) *If* j^* *is such that, for any initial distribution* ν,

$$j^* \le \lim_n (1-\alpha(n))V_{\alpha(n)}^*(\nu), \tag{4.5}$$

then there exists a minimum pair (φ^*, ν^*), *where* $\varphi^* \in \Phi$ *is a relaxed policy,* $\nu^* = \mu_1^*$ (*the projection of* μ^* *on* X), *and*

$$j^* = J(\varphi^*, \mu_1^*) = J^*. \tag{4.6}$$

Hence

(c) μ^* *is optimal for* (MP_1) *and*

$$J^* = \min(MP_1) = \int c d\mu^*. \tag{4.7}$$

Proof. (a) From (2.6), there is a sequence $\alpha(n) \uparrow 1$ and a number $j^* \le J(\hat{\delta}, \hat{\nu})$ such that

$$j^* = \lim_n (1-\alpha(n))V_{\alpha(n)}^*(\hat{\nu}) = \lim_n \int c d\mu^{\alpha(n)}.$$

By Assumption 3.2(a), with $r = j^* + \epsilon$ for some $\epsilon > 0$, $\{\mu^{\alpha(n)}\}$ has a weakly convergent subsequence. Combining this with Lemma 4.1, there is a subsequence $\{\alpha(n_i)\}$ of $\{\alpha(n)\}$ and a measure μ^* feasible for (MP_1) such that $\mu^{\alpha(n_i)} \xrightarrow{w} \mu^*$; in particular, since c is lower semicontinuous, we obtain (4.4) with $\{\alpha(n_i)\}$ in lieu of $\{\alpha(n)\}$.

(b) By (3.12) and a well-known result ([4, p. 89, Thm. 2]; [10, Cor. 12.7]; [8 Lem. 4.7]), the measure μ^* can be "disintegrated" into a relaxed policy φ^* and a probability measure $\nu^* = \mu_1^*$ so that

$$\mu^*(B \times C) = \int_B \varphi^*(C|x)\mu_1^*(dx) \quad \forall B \in \mathcal{B}(X),\ C \in \mathcal{B}(A),$$

and such that

$$\int c d\mu^* = J(\varphi^*, \mu_1^*). \tag{4.8}$$

Thus, by (4.4) and the definition of J^* in (2.4), $j^* \ge J^*$. The reverse inequality, $j^* \le J^*$, follows from (4.5) and (2.6).

(c) From the "disintegration" result referred to in part (b), for any feasible measure μ for (MP_1) there is a relaxed policy φ and an initial distribution $\nu(=\mu_1)$ such that $\int c d\mu = J(\varphi, \nu)$. Since this is true for any such μ, $\inf(MP_1) \geq J^*$. This inequality, together with (4.6), yields (c). □

Remark 4.3. A sufficient condition for (4.5) is Assumption 5.1(b), as shown in the proof of Theorem 5.3.

Part (c) in Theorem 4.2 shows that solving (MP_1) and finding a minimum pair are "equivalent" problems in the sense that $J^* = \min(MP_1)$; i.e., the first equality in (3.18) holds. In the next section we prove the second equality in (3.18).

5. Absence of duality gap. A standard argument (see, e.g., [8, Lem. 4.5]) shows that if (ρ, u) is feasible for (MP_1^*) and (δ, ν) is any policy-initial-distribution pair with $J(\delta, \nu) < \infty$, then $\rho \leq J(\delta, \nu)$; hence $\rho \leq J^*$. This implies

$$\sup(MP_1^*) \leq J^*. \tag{5.1}$$

To get the equality in (5.1) we shall use Assumption 5.1 below on the pointwise α-discount value function $V_\alpha^*(x)$, $x \in X$, $0 < \alpha < 1$.

Assumption 5.1. For every $\alpha \in (0,1)$ and $x \in X$, $V_\alpha^*(x) < \infty$ and

(a) V_α^* satisfies the dynamic programming equation

$$V_\alpha^*(x) = \min_{a \in A(x)} \left[c(x,a) + \alpha \int V_\alpha^*(y) Q(dy|x,a) \right], \quad x \in X; \tag{5.2}$$

(b) for some state $z \in X$, $N \geq 0$, and $\alpha_0 \in [0,1)$, the function $h_\alpha(x) := V_\alpha^*(x) - V_\alpha^*(z)$, $x \in X$, satisfies $h_\alpha(x) \geq -N \ \ \forall x \in X$, $\alpha \in (\alpha_0, 1)$.

(c) V_α^* belongs to $F(X)$.

Sufficient conditions for (5.2) are well known (see, e.g., [2], [4], [5], [9], [10]). (Observe that, from (2.6), $V_\alpha^*(x) < \infty$ for every $\alpha \in (0,1)$ and $\hat{\nu}$-almost all $x \in X$.)

On the other hand, the conditions (b) and (c) in Assumption 5.1 are model dependent and usually have to be verified directly, which is easily done in some cases: For (b), see [15], [16], [2, §§5.2, 6.2]; and for (c), a sufficient condition is, for example, the existence of a policy $\pi \in \Delta$ with a bounded average cost. In this case, by a well-known Tauberian theorem,

$$\limsup_{\alpha \uparrow 1} (1-\alpha) V_\alpha^*(x) \leq J(x, \pi) \leq g \ \ \forall x \in X,$$

so that, for every fixed discount factor $\alpha \in (0,1)$ and some constant $K > 0$,

$$\sup_x \frac{V_\alpha^*(x)}{b_1(x)} \leq \sup_x \frac{(g+K)}{(1-\alpha) b_1(x)} < \infty$$

since $b_1(.)$ is bounded away from zero. Hence $V_\alpha^* \in F(X)$ for every $\alpha \in (0,1)$.

Note that in contrast to previous work (see, e.g., [2], [15], [16]), *we do not require* h_α *to be majorized* by some function independent of α. The latter condition implies the "unichain" assumption for average optimal policies. We shall return to this point in §6.

LEMMA 5.2. *If* (a) *and* (c) *of Assumption* 5.1 *hold, then* (P_α^*) *and* (MP_α^*) *are solvable for every* $0 < \alpha < 1$, *and*

$$\max(MP_\alpha^*) = (1-\alpha)\max(P_\alpha^*) = (1-\alpha)\langle \hat{\nu}, V_\alpha^* \rangle. \tag{5.3}$$

Proof. If V_α^* is in $F(X)$ and satisfies (5.2), then it obviously satisfies (3.7), i.e., V_α^* is feasible for (P_α^*). Hence, $\int V_\alpha^* d\hat{\nu} \le \sup(P_\alpha^*)$. The reverse inequality is also true, since $u \le V_\alpha^*$ whenever u satisfies (3.7); see, e.g., [9]. Therefore $\max(P_\alpha^*) = \int V_\alpha^* d\hat{\nu}$, which together with (3.15) yields (5.3). □

Throughout the remainder of this section, let $z \in X$ be the fixed state in Assumption 5.1(b), and let $\hat{\nu}$ the initial distribution in Assumption 2.3 be the Dirac measure at z. Then, under the assumptions of Theorem 4.2(a), (4.4) becomes

$$j^* = \lim_n (1 - \alpha(n)) V_{\alpha(n)}^*(z) = \lim \rho_{\alpha(n)} \tag{5.4}$$

for some sequence $\alpha(n) \uparrow 1$, where $\rho_\alpha := (1 - \alpha) V_\alpha^*(z)$. Moreover, it is convenient to rewrite (5.2) in the form

$$\rho_\alpha + h_\alpha(x) = \min_{a \in A(x)} \left[c(x,a) + \alpha \int h_\alpha(y) Q(dy|x,a) \right]. \tag{5.5}$$

Finally, without loss of generality, we may assume that h_α is *nonnegative* (cf. Assumption 5.1(b)), for if (ρ, u) is feasible for (MP_α^*), then so is $(\rho - (1-\alpha)N, u + N)$ for any constant N.

THEOREM 5.3. *If Assumption* 5.1 *and the hypotheses of Theorem* 4.2(a) *hold, then*

$$\sup(MP_1^*) = J^* \quad (= \min(MP_1)). \tag{5.6}$$

Proof. If, as assumed above, $\hat{\nu}$ is the Dirac measure at z, then, by (5.3) and (5.5), (ρ_α, h_α) is optimal for (MP_α^*), $0 < \alpha < 1$, with $h_\alpha(.) \ge 0$ and $\max(MP_\alpha^*) = \rho_\alpha$. We also note that if (ρ, u) is feasible for (MP_α^*) and $u \ge 0$, then (ρ, u) is feasible for (MP_β^*) for all $\beta \in [\alpha, 1]$ since

$$\begin{aligned} \rho + u(x) &\le c(x,a) + \alpha \int u(y) Q(dy|x,a) \\ &\le c(x,a) + \beta \int u(y) Q(dy|x,a) \quad \forall \alpha \le \beta \le 1. \end{aligned}$$

Therefore, from the definition of (MP_α^*), $\forall \alpha_0 < \alpha < 1$,

$$\begin{aligned} \rho_\alpha &= \max(MP_\alpha^*) \\ &= \sup\{\rho + (1-\alpha)u(z) |\ (\rho, u) \ \text{ satisfies (3.11)}\} \\ &= \sup\{\rho + (1-\alpha)u(z) |\ (\rho, u) \ \text{ satisfies (3.11), } u \ge 0\} \\ &\le \sup(MP_1^*) + \sup\{(1-\alpha)u(z) |\ (\rho, u) \text{ satisfies (3.13)}\}. \end{aligned}$$

Thus, from (5.4) and letting $\alpha \uparrow 1$, $j^* \le \sup(MP_1^*)$. To prove the reverse inequality note first that Assumption 5.1(b) implies (4.5) since, for any initial distribution ν,

$$\begin{aligned} (1-\alpha) V_\alpha^*(\nu) &\ge (1-\alpha) \int V_\alpha^*(x) \nu(dx) \\ &= (1-\alpha) \int h_\alpha(x) \nu(dx) + (1-\alpha) V_\alpha^*(z) \\ &\ge -(1-\alpha)N + (1-\alpha) V_\alpha^*(z). \end{aligned}$$

Hence, by weak duality and (4.6)–(4.7),

$$\sup(MP_1^*) \le \inf(MP_1) = J^* = j^*.$$

This completes the proof of (5.6). □

From the proof of Theorem 5.3, observe that the pair (ρ_α, h_α) is maximizing for (MP_1^*) since (ρ_α, h_α) is feasible for that problem and $\rho_\alpha \to J^*$ as $\alpha \uparrow 1$.

6. Existence of pointwise optimal policies. The objectives of this final section are to make a brief comparison between the standard "vanishing discount" approach and the version presented in the previous sections and to comment on the existence of "pointwise" optimal policies—as opposed to minimum pairs—that can be derived from our results.

In the standard vanishing discount approach [2], [15], [16] one tries to obtain the so-called *average-cost optimality equation*

$$J^* + h(x) = \min_{a \in A(x)} \left[c(x,a) + \int h(y) Q(dy|x,a) \right], \quad x \in X, \tag{6.1}$$

or the *optimality inequality*

$$J^* + h(x) \geq \min_{a \in A(x)} \left[c(x,a) + \int h(y) Q(dy|x,a) \right], \quad x \in X, \tag{6.2}$$

starting from the dynamic programming equation (5.2). The basic idea is to rewrite (5.2) in the form (5.5) and give conditions on ρ_α and $h_\alpha(.)$ under which, for some sequence $\alpha \uparrow 1$, $\rho_\alpha \to J^*$ and $h_\alpha(.) \to h(.)$, with $(J^*, h(.))$ satisfying (6.1) or (6.2). Finally, if $h(.)$ is bounded from below and if a deterministic stationary policy $f \in \mathcal{F}$ is such that $f(x) \in A(x)$ attains the minimum in the right-hand side of (6.1) or (6.2) for all $x \in X$, then f satisfies

$$J(f,x) = \inf_\delta J(\delta, x) = J^* \quad \text{for } \textit{all } x \in X \tag{6.3}$$

provided that in Assumption 5.1(b) we impose the *additional* requirement

$$h_\alpha(x) \leq g(x) \quad \forall x \in X, \ \alpha \in (\alpha_0, 1), \tag{6.4}$$

for some *finite-valued* function g [15], [16]. Without (6.4) we cannot guarantee (6.3) for *all* x. To see what can go wrong consider the following elementary "multichain" example.

Example 6.1. $X := \{1,2,3\}$, $A = \{1\}$, and $c(x,1) = c_x > 0$, with $c_1 < c_2, c_3$. The transition law $Q(\{y\}|x,1)$, which we write as $P_{xy}(1)$, is given by

$$P_{xx}(1) = 1 \ \text{ if } x = 1,2; \ P_{31}(1) = \beta = 1 - P_{32}, \ \text{ where } 0 < \beta < 1.$$

Then $V_\alpha^*(x) = c_x/(1-\alpha)$ if $x = 1,2$, and $V_\alpha^*(3) = c_3 + \alpha(1-\alpha)^{-1}[\beta c_1 + (1-\beta)c_2]$, and V_α^* satisfies assumptions 5.1(a) and (c). To verify Assumption 5.1(b), it suffices to take $z = 1$ and $\alpha_0 := c_1/c_2$ so that $c_1 < \alpha c_2$ $(< c_2)$ for all $\alpha \in (\alpha_0, 1)$. This yields $h_\alpha \geq 0$. (If we take $z = 2$ or 3, then h_α does not satisfy Assumption 5.1(b).)

Moreover, $h(x) := \lim_{\alpha \uparrow 1} h_\alpha(x) = 0$ if $x = z = 1$, and $h(x) = +\infty$ if $x = 2,3$; therefore, (6.4) does *not* hold for a *finite*-valued function g. However, the "minimum" cost, given the initial state $x \in X$, is $J^*(x) = c_x$ if $x = 1,2$, and $J^*(3) = \beta c_1 + (1-\beta)c_2$, so that $J^* := \inf_x J^*(x) = c_1$, i.e.,

$$J^* = j^* := \lim_{\alpha \uparrow 1} (1-\alpha) V_\alpha^*(z) = c_1.$$

Thus the pair (J^*, h) trivially satisfies (6.1), but (6.3) does *not* hold for *all* $x \in X$. □

Example 6.1 suggests that a "unichain" assumption is implicit somehow in (6.4). Since we have not made any such assumption here nor assumed (6.4), we would expect to get a pointwise result such as (6.1)–(6.2) or (6.3) only for states in a proper subset of X. In the next theorem we identify such a subset in the context of Theorem 5.3.

THEOREM 6.2. *Suppose that Assumption* 5.1 *and the hypotheses of Theorem* 4.2(a) *hold, and let* $\mu*$ *and* (φ^*, μ_1^*) *be as in* (4.6)–(4.7). *Then*

(a) *the randomized policy* φ^* *is average optimal for* μ_1^**-almost all* (*a.a.*) *initial states, i.e.,*

$$J(\varphi^*, x) = J^* \quad \text{for } \mu_1^*\text{-a.a. } x \in X; \tag{6.5}$$

(b) *there exists a measurable function* h *on* X *bounded from below and such that*

$$J^* + h(x) \geq c(x,a) + \int h(y)Q(dy|x,a) \tag{6.6}$$

for μ^**-a.a.* $(x,a) \in K$;

(c) *if the set* $S := \{x \in X |$ (6.6) *holds and* $h(x) < \infty\}$ *is nonempty, then there exists a deterministic stationary policy* $f \in \mathcal{F}$ *such that*

$$J^* + h(x) \geq c(x, f(x)) + \int h(y)Q(dy|x, f(x)) \quad \forall x \in S, \tag{6.7}$$

and

$$J(f, x) = J^* \quad \forall x \in S. \tag{6.8}$$

For instance, a sufficient condition for S *to be nonempty is that, for some constant* $g < \infty$,

$$\limsup_{\alpha \uparrow 1} |V_\alpha(z) - J^*/(1-\alpha)| < g < \infty$$

(*where* z *is as in Assumption* 5.1).

Remark. The above sufficient condition simply states that the optimal discounted cost in state z converges sufficiently fast to the AC and can be checked in many problems (see, e.g., the linear-quadratic regulator problem [4]). In fact, we may obtain (6.6) directly from (4.6)–(4.7) or the stronger result (6.2) from Assumptions 2.3 and 5.1. However, we chose the above form of Theorem 6.2 because we wish to relate the vanishing-discount-factor approach with the LP results in §§3–5.

Proof of Theorem 6.2. (a) As in the proof of Theorem 4.2(b), disintegrate μ^* as $\mu^*(d(x,a)) = \varphi^*(da|x)\mu_1(dx)$ and note that the condition $T_1\mu^* = 0$ in (3.12) can also be written as

$$\mu_1^*(B) = \int_X Q(B|x, \varphi^*)\mu_1^*(dx) \quad \forall B \in \mathcal{B}(X), \tag{6.9}$$

where $Q(.|x, \varphi^*) := \int_A Q(.|x,a)\varphi^*(da|x)$. In other words, (6.9) says that μ_1^* is an invariant probability measure for the stochastic kernel $Q(.|., \varphi^*)$. We also have that

$$J^* = \int c d\mu^* = \int c(x, \varphi^*)\mu_1^*(dx),$$

where $c(.,\varphi^*) := \int_A c(.,a)\varphi^*(da|.)$. Thus $c(x,\varphi^*)$, the one-stage cost of the randomized policy φ^*, is μ_1^*-integrable, and then the individual ergodic theorem (see, e.g., Theorem 6 in [17, p. 388]) yields that the limit

$$J(\varphi^*,x) := \lim_{n\to\infty} n^{-1}E_x^{\varphi^*}\left[\sum_{t=0}^{n-1} c(x_t,\varphi^*)\right]$$

exists for μ_1^*-a.a. $x \in X$ and satisfies

$$(*) \qquad \int_X c(x,\varphi^*)\mu_1^*(dx) = \int_X J(\varphi^*,x)\mu_1^*(dx) = J^*.$$

Finally, to conclude that (6.5) holds, let $B := \{x|\ J(\varphi^*,x) > J^*\}$ and note that, by (2.4), the complement of B is $B^c := \{x|\ J(\varphi^*,x) = J^*\}$. Hence, from the second equality in (*),

$$J^* = \int_B J(\varphi^*,x)\mu_1^*(dx) + J^*\mu_1^*(B^c),$$

which is equivalent to

$$\int_B J(\varphi^*,x)\mu_1^*(dx) = J^*\mu_1^*(B),$$

that is,

$$\int_B [J(\varphi^*,x) - J^*]\mu_1^*(dx) = 0,$$

which, in view of (2.4), implies $\mu_1^*(B) = 0$. This completes the proof of (6.5).

(b) Let N be as in Assumption 5.1(b) and define

$$\rho_{\alpha,N} := \rho_\alpha - (1-\alpha)N, \quad h_{\alpha,N}(x) := h_\alpha(x) + N, \quad x \in X,\ \alpha \in (\alpha_0,1).$$

Then we may rewrite (5.5) as

$$\rho_{\alpha,N} + h_{\alpha,N}(x) = \min_{a\in A(x)}\left[c(x,a) + \alpha\int h_{\alpha,N}(y)Q(dy|x,a)\right] \quad \forall x \in X,$$

and therefore, since $h_{\alpha,N}(.) \geq 0$ and $\alpha < 1$, the pair $(\rho_{\alpha,N}, h_{\alpha,N})$ is feasible for (MP_1^*), i.e.,

$$\rho_{\alpha,N} + h_{\alpha,N}(x) \leq c(x,a) + \int h_{\alpha,N}(y)Q(dy|x,a) \quad \forall (x,a) \in K.$$

Let $u_\alpha(x,a)$ be a "slack variable," i.e., u_α is a measurable nonnegative function such that, $\forall (x,a) \in K$,

$$(6.10) \qquad \rho_{\alpha,N} + h_{\alpha,N}(x) + u_\alpha(x,a) = c(x,a) + \int h_{\alpha,N}(y)Q(dy|x,a).$$

Thus, defining

$$(6.11) \qquad v(x,\varphi^*) := \int_A v(x,a)\varphi^*(da|x) \quad \text{for all } x \in X,\ v \in F(K),$$

integration of both sides of (6.10) with respect to μ^* yields (by (6.9))

$$\rho_{\alpha,N} + \int h_{\alpha,N} d\mu_1^* + \int u_\alpha d\mu_1^* = \int c d\mu^* + \int h_{\alpha,N} d\mu_1^*,$$

i.e., from (4.7)

$$\int u_\alpha d\mu^* = J^* - \rho_{\alpha,N}.$$

In the last step, note that we may indeed cancel out the integral $\int h_{\alpha,N} d\mu_1^*$ since, by Assumption 5.1(c), this integral is finite. Notice also that with $\alpha(n)$ as in (5.4)

$$\lim_n \rho_{\alpha(n),N} = j^* = J^*,$$

where the last equality comes from (5.6). Therefore, $\lim_n \int u_{\alpha(n)} d\mu^* = 0$, which in turn, using Fatou's lemma (recall that $u_\alpha \geq 0$), yields

$$\liminf_n u_{\alpha(n)}(x,a) = 0 \quad \text{for } \mu^* - a.a.\ (x,a) \in K. \tag{6.12}$$

Finally, define

$$h(x) := \liminf_n h_{\alpha(n)}(x) = \liminf_n h_{\alpha(n),N}(x) - N \geq -N, \qquad x \in X.$$

Let x be an arbitrary state for which (6.12) holds for some $a \in A(x)$, and then take the $\lim_i$ in (6.10) over a subsequence $\alpha(n_i)$ of $\alpha(n)$ for which $h_{\alpha(n_i)}(x) \to h(x)$ and $u_{\alpha(n_i)}(x,a) \to 0$. This yields, by Fatou's lemma again,

$$J^* + h(x) - N \geq c(x,a) + \int h(y) Q(dy|x,a) - N,$$

i.e., $J^* + h(x) \geq c(x,a) + \int h(y) Q(dy|x,a)$. Hence, since $(x,a) \in K$ was an arbitrary pair for which (6.12) holds, we conclude (6.6).

(c) We will first prove the last statement, i.e., the set S is nonempty if

$$\limsup_{\alpha \uparrow 1} |V_\alpha(z) - J^*/(1-\alpha)| < g < \infty.$$

Indeed, from the optimality equation (5.2) we have

$$(1-\alpha) V_\alpha^*(z) + h_\alpha(x) \leq c(x,a) + \alpha \int h_\alpha(y) Q(dy|x,a) \quad \forall x, a$$

so that integrating both sides with respect to μ^* and using

$$\begin{aligned} T_\alpha \mu^*(B) &= T_1 \mu^*(B) + (1-\alpha) \int Q(B|k) \mu^*(dk) \\ &= (1-\alpha) \mu_1^*(B) \quad \forall B \in \mathcal{B}(X) \end{aligned}$$

(see §4) yields

$$(1-\alpha) V_\alpha^*(z) + (1-\alpha) \int h_\alpha d\mu_1^* \leq \int c d\mu^* = J^*$$

and thus

$$0 \leq \int (h_\alpha + N) d\mu_1^* \leq \frac{J^* - (1-\alpha)V_\alpha^*(z)}{1-\alpha} + N \leq 2g + N$$

for all α sufficiently close to 1. Then, by Fatou's lemma,

$$0 \leq \int (h + N) d\mu_1^* < \infty,$$

which in turn implies that h is finite μ_1^*-a.e.

This and (6.6) prove that the set S is nonempty. It contains the support of the invariant probability measure μ_1^*.

Integrating both sides of (6.6) with respect to the measure $\varphi^*(da|x)$ yields

$$J^* + h(x) \geq \int_A \left[c(x,a) + \int h(y) Q(dy|x,a) \right] \varphi^*(da|x) \quad \mu_1^* - \text{a.e.} \tag{6.13}$$

Since $J^* + h(x) < \infty$ for each $x \in S$, the right-hand side of (6.13) is a finite-valued function on S. Therefore, by the measurable selection theorem of Blackwell and Ryll-Nardzewski (see, e.g., [4]) there exists a deterministic stationary policy $f \in \mathcal{F}$ satisfying

$$\int_A \left[c(x,a) + \int h(y) Q(dy|x,a) \right] \varphi^*(da|x) \geq c(x, f(x)) + \int h(y) Q(dy|x, f(x))$$

for all $x \in S$, which together with (6.13) yields (6.7). Moreover, S is "absorbent" in the sense that if $x \in S$, then $Q(S|x, f(x)) = 1$ for μ_1^*-a.a. $x \in S$; otherwise we would get a contradiction to (6.6). This fact and (6.7) yield (6.8) by a standard recursion argument [2], [15], [16].

It is worth noting that the converse of Theorem 6.2(b) holds, which provides a "minimum pair" version of (6.2)–(6.3). That is, if a measure μ^* is feasible for (MP_1) and (6.6) holds μ^*-a.e., then μ^* is optimal for (MP_1), (φ^*, μ_1^*) is a minimum pair, and (4.6)–(4.7) hold.

Theorem 6.2, vis-à-vis (6.1)–(6.3), is perhaps not surprising. Previous works for *countable* (mainly finite) Markov decision processes in the multichain case (e.g., [3], [12]) have shown that what the LP approach does is to identify the set of states of an ergodic chain with minimum cost rate, as in Example 6.1. In our general (Borel) state case, our *guess* is that such a set is precisely the set S in Theorem 6.2(c). However, a precise answer on this issue requires further research on "ergodic decompositions" for *controlled* Markov processes, which for practical purposes is an untouched problem. In fact, to our knowledge, the only related work is Kurano's [11] for the very special case in which the state space is *compact* and *Doeblin's condition* holds. (For noncontrolled Markov chains, see, e.g., [14].)

APPROXIMATIONS IN DYNAMIC ZERO-SUM GAMES I*

MABEL M. TIDBALL† AND EITAN ALTMAN‡

Abstract. We develop a unifying approach for approximating a "limit" zero-sum game by a sequence of approximating games. We discuss both the convergence of the values and the convergence of optimal (or "almost" optimal) strategies. Moreover, based on optimal policies for the limit game, we construct policies which are almost optimal for the approximating games. We then apply the general framework to state approximations of stochastic games, to convergence of finite horizon problems to infinite horizon problems, and to convergence in the discount factor and in the immediate reward.

Key words. zero-sum games, approximations, stochastic games

AMS subject classifications. 90D05, 93E05

1. Introduction.

In many cases, one encounters dynamic games for which time and space are continuous and possibly unbounded. In general, numerical solution of such games involve discretization both in time and in space. In pursuit evasion games in particular (see Bardi, Falcone, and Soravia [6] and Pourtallier and Tidball [21]) and in differential games in general (see Pourtallier and Tolwinsky [22], Tidball and González [25]), the time and space discretization often leads to dynamic programming that has a stochastic game interpretation. The numerical solution then typically requires a finite state approximation.

Approximations in dynamic games has therefore been an active area of research for several decades. Several schemes for discretization of time and space and for approximations have been developed for differential games [6], [7], [21], [22], [25]. In stochastic games, much attention was devoted to approximations of infinite-horizon problems by (long) finite-horizon ones, e.g., [14], [19], [24], [27]; discretization of the state space has further been considered by Nowak [20] and Whitt [31], [32] (who also discretizes the actions spaces). Except for [20], [31], all the above references consider approximation of the value function of the games.

The aim of this paper is to study in a systematic way approximations in games, not only of the values but also for the policies. We begin by developing a general framework for establishing the convergence of the upper and lower values of a sequence of games G_n, $n = 1, 2, \ldots$, to a value R (which we assume exists) of a limit game $G = G_\infty$. We are further interested in the following questions: (i) Do (almost) optimal policies converge (in some sense)? (ii) Assume that u and v are (almost) optimal for some approximating game G_n (where n is large enough in some sense). Can we construct from these almost optimal policies for the limit game? (iii) Assume that u and v are (almost) optimal for the limit game. Can we use them to construct almost optimal policies for the approximating game G_n for n large enough?

Problem (ii) above arises in the following situation. Suppose that two players use some approximating numerical schemes to obtain "good" policies, e.g., time discretization. Each player might be using a different discretization scheme. Yet each

player would like to ensure that regardless of the discretization scheme used by the other player, he or she can guarantee some value, which would be "almost" the value of the nondiscretized game. In fact, since the real game that is played is the nondiscretized one, the desired discretization should perform well even if the adversary uses an optimal policy for the nondiscretized game.

Problem (iii), on the other hand, arises in the opposite situation, and this serves as an additional motivation for studying approximations in games. There are many examples of dynamic games where one can solve an infinite limiting game easier, where problems related to the boundaries are avoided. Indeed, examples are given in §8 of stochastic games with (large) finite state space for which the natural approach for constructing almost optimal policies is to solve a limit game with a countable state space.

After establishing the general theory for approximations in §2, we apply it to several approximation problems in discrete-time stochastic games with discounted reward and denumerable state space. Applications to other dynamic games are the subject of future research. The basic model of the stochastic games is presented in §3. We then present three schemes for state approximation in §4 for the case of infinite horizon. This generalizes many results on the convergence of the optimal value in Markov decision processes (i.e., stochastic games with a single player), e.g., [11], [15], [?], [29], [30]. Other related work on finite state approximations in Markov decision processes are [1], [2], [26]. In §5 we extend the results on state approximations for infinite horizon to the case of finite horizon by a transformation of the state space. In §6 we study the convergence of the finite-horizon problem to the infinite-horizon one, and we combine state approximations with approximation of the horizon. In §7 we study the stability of stochastic games in the discount factor and in the immediate reward. Applications of approximation methods developed in this paper are presented in §8, and some generalizations are finally discussed in §9.

2. Key theorems for approximations. We consider the sequence $G_n = (S_n, U_n, V_n)$, $n = 1, 2, \ldots, \infty$, of generic zero-sum games, where U_n is the set of strategies of player I and V_n is the set of strategies of player II for the nth game. We assume that both U_n and V_n are endowed with some topology. $S_n : U_n \times V_n \to \mathbb{R}$ is a measurable function for all n. We define the upper (lower) value of the game:

$$\overline{R_n} = \inf_{v \in V_n} \sup_{u \in U_n} S_n(u, v) \quad \left(\underline{R_n} = \sup_{u \in U_n} \inf_{v \in V_n} S_n(u, v) \right).$$

$G = (S, U, V) \stackrel{\text{def}}{=} (S_\infty, U_\infty, V_\infty)$ will be called the limit game. It will be assumed that it has a value $R \stackrel{\text{def}}{=} R_\infty$.

An example where G_n does not have a value but G does will be given in §6.3 for computing almost optimal stationary policies for stochastic games with long (but finite) horizon.

A strategy $u^* \in U_n$ is said to be ϵ-optimal for player one in game n if

$$\inf_{v \in V_n} S_n(u^*, v) \geq \inf_{v \in V_n} S_n(u, v) - \epsilon \qquad \forall u \in U_n, \tag{1}$$

which is equivalent to $\inf_{v \in V_n} S_n(u^*, v) \geq \underline{R}_n - \epsilon$. It is said to be strongly ϵ-optimal for player one in game n if it satisfies

$$\inf_{v \in V_n} S_n(u^*, v) \geq \overline{R}_n - \epsilon.$$

A strategy $v^* \in V_n$ is said to be ϵ-optimal for player two in game n if

$$\sup_{u \in U_n} S_n(u, v^*) \leq \sup_{u \in U_n} S_n(u, v) + \epsilon \qquad \forall v \in V_n, \tag{2}$$

which is equivalent to $\sup_{u \in U_n} S_n(u, v^*) \leq \overline{R}_n + \epsilon$. It is said to be strong ϵ-optimal if

$$\sup_{u \in U_n} S_n(u, v^*) \leq \underline{R}_n + \epsilon.$$

Note that strong ϵ-optimality implies ϵ-optimality. If a game has a value $\underline{R}_n = \overline{R}_n$, then strong ϵ-optimality is equivalent to ϵ-optimality.

Assume that (S_n, U_n, V_n) converge (in some sense) to (S, U, V). We are interested in the following questions:

(Q1) Convergence of the values: Does $\underline{R}_n$ (or $\overline{R}_n$) converge to R?

(Q2) Convergence of policies: Fix some $\epsilon \geq 0$. Let ϵ_n be a sequence of positive real numbers such that $\overline{\lim}_{n \to \infty} \epsilon_n \leq \epsilon$. Assume that u_n^* and v_n^* are ϵ_n-optimal policies for the nth game. Are u_n^* and v_n^* "almost" optimal for the limit game for all n large enough?

(Q3) Let $\overline{u} \in U$ (resp., $\overline{v} \in V$) be some limit point of u_n^* (resp., v_n^*), defined above. Is $\overline{u}$ (resp., $\overline{v}$) ϵ-optimal for the limit game?

(Q4) Robustness of the optimal policy: If u^* (resp. v^*) is ϵ-optimal for the limit game, can we derive from it an "almost" (strongly) optimal policy for the nth approximating game for all n large enough?

In most applications that we discuss in this paper, $U_n = U$, $V_n = V$ do not depend on n. However, in several applications this is not the case, e.g., approximations in pursuit evasion games; see Bernhard and Shinar [7]. Another example is given for a state approximation scheme for solving stochastic games; see §4.3.

THEOREM 2.1. *Assume that there exist sequences of functions* $\pi_n^1 : U_n \to U$, $\pi_n^2 : V_n \to V$, $\sigma_n^1 : U \to U_n$, $\sigma_n^2 : V \to V_n$, $n = 1, 2, \ldots$, *such that*

$(\mathcal{A}1)$ $\overline{\lim}_{n \to \infty} [S_n(u, \sigma_n^2(v)) - S(\pi_n^1(u), v)] \leq 0$ *uniformly in* $u \in U_n$ *for each* $v \in V$.

$(\mathcal{A}2)$ $\underline{\lim}_{n \to \infty} [S_n(\sigma_n^1(u), v) - S(u, \pi_n^2(v))] \geq 0$ *uniformly in* $v \in V_n$ *for each* $u \in U$.

Then

(1) $\lim_{n \to \infty} \underline{R}_n = \lim_{n \to \infty} \overline{R}_n = R$.

(2) *For any* $\epsilon' > \epsilon$, *there exists* N *such that* $\pi_n^1(u_n^*)$ *(resp.,* $\pi_n^2(v_n^*)$; *see definitions in* (Q2)) *is* ϵ'*-optimal for the limit game for all* $n \geq N$.

(3) *Let* u^* *(resp.,* v^**) be* ϵ*-optimal for the limit game. Then for all* $\epsilon' > \epsilon$, *there exists* $N(\epsilon')$ *such that* $\sigma_n^1(u^*)$ *(resp.,* $\sigma_n^2(v^*)$*) is strongly* ϵ'*-optimal for the* n*th approximating game for all* $n \geq N(\epsilon')$.

(4) *Suppose*

$(\mathcal{A}3)$ $S(u, v)$ *is a lower semicontinuous function in* u,

$(\mathcal{A}4)$ $S(u, v)$ *is an upper semicontinuous function in* v.

Suppose $\bar{u} \in U$ *(resp.,* $\bar{v} \in V$*) is a limit point of* $\pi_n^1(u_n^*)$ *(resp.,* $\pi_n^2(v_n^*)$*). Then* $\bar{u}$ *(resp.,* $\bar{v}$*) is* ϵ*-optimal for the limit game.*

Remark 2.1. Part (1) of Theorem 2.1 is a generalization of Lemma 1 in [14].

Proof. (1) Choose $\epsilon > 0$. Let $u^* \in U$ and $v^* \in V$ be ϵ-optimal for the limit game G, and choose some sequence $\epsilon(n)$ such that $\lim_{n \to \infty} \epsilon(n) = 0$. Let $u_n \in U_n$

be an $\epsilon(n)$-best response to the policy $\sigma_n^2(v^*)$ in game G_n (i.e., $S_n(u_n, \sigma_n^2(v^*)) \geq S_n(u, \sigma_n^2(v^*)) - \epsilon(n)$ for all $u \in U_n$). Similarly, let $v_n \in V_n$ be an $\epsilon(n)$-best response to the policy $\sigma_n^1(u^*)$ in game G_n.

Choose some $\delta > 0$. By $(\mathcal{A}1)$, there exists N such that for all $n \geq N$ and $u \in U_n$, $S_n(u, \sigma_n^2(v^*)) - S(\pi_n^1(u), v^*) < \delta$. Then for all $n \geq N$

$$\begin{aligned}
\overline{R}_n - R &= \inf_{v \in V_n} \sup_{u \in U_n} S_n(u, v) - \inf_{v \in V} \sup_{u \in U} S(u, v) \\
&\leq \sup_{u \in U_n} S_n(u, \sigma_n^2(v^*)) - \sup_{u \in U} S(u, v^*) + \epsilon \\
&\leq S_n(u_n, \sigma_n^2(v^*)) - S(\pi_n^1(u_n), v^*) + \epsilon + \epsilon(n) \\
&\leq \delta + \epsilon + \epsilon(n).
\end{aligned}$$

Hence $\overline{\lim}_{n\to\infty} \overline{R}_n \leq R + \delta + \epsilon$.

Similarly, by $(\mathcal{A}2)$, one shows that $R \leq \underline{\lim}_{n\to\infty} \underline{R}_n + \delta + \epsilon$. Since $\underline{R}_n \leq \overline{R}_n$, this implies that $\overline{\lim}_{n\to\infty} |R - \underline{R}_n| \leq \delta + \epsilon$ and $\overline{\lim}_{n\to\infty} |R - \overline{R}_n| \leq \delta + \epsilon$. The result follows since ϵ and δ can be chosen arbitrarily small.

(2) Fix some $\delta > 0$. By $(\mathcal{A}1)$, as u_n^* is $\epsilon(n)$-optimal for G_n, and by part (1), there exists $N(\epsilon, \delta)$ such that for $n > N(\epsilon, \delta)$ we have

$$(3) \quad \forall v \in V: \quad S_n(u_n^*, \sigma_n^2(v)) - S(\pi_n^1(u_n^*), v) < \delta, \quad \epsilon(n) < \epsilon + \delta, \quad |\underline{R}_n - R| < \delta,$$

and thus

$$\begin{aligned}
\inf_{v \in V} S(\pi_n^1(u_n^*), v) &\geq \inf_{v \in V} S_n(u_n^*, \sigma_n^2(v)) - \delta \\
&\geq \inf_{v \in V_n} S_n(u_n^*, v) - \delta \geq \underline{R}_n - \delta - \epsilon(n) \geq R - 3\delta - \epsilon.
\end{aligned}$$

So $\pi_n^1(u_n^*)$ is ϵ'-optimal for S with $\epsilon' = 3\delta + \epsilon$.

In the same way, by assumption $(\mathcal{A}2)$ and considering an $\epsilon(n)$-optimal policy v_n^* for G_n, we obtain that $\pi_n^2(v_n^*)$ is ϵ'-optimal for S for all large enough n. The proof follows from the fact that δ was chosen arbitrarily.

(3) Fix some $\delta > 0$. As u^* is an ϵ-optimal strategy in the limit game G and by $(\mathcal{A}2)$, for all n large enough we have

$$\begin{aligned}
\inf_{v \in V_n} S_n(\sigma_n^1(u^*), v) &\geq \inf_{v \in V_n} S(u^*, \pi_n^2(v)) - \delta \\
&\geq \inf_{v \in V} S(u^*, v) - \delta \geq R - \delta - \epsilon \geq \overline{R}_n - 2\delta - \epsilon.
\end{aligned}$$

The proof for v^* is obtained in the same way.

(4) Let $\hat{v} \in V$ be such that $\inf_{v \in V} S(\bar{u}, v) \geq S(\bar{u}, \hat{v}) - \delta$. By $(\mathcal{A}1)$, $(\mathcal{A}3)$, and part (1) of Theorem 2.1, for all $\delta > 0$ there exists $N(\delta)$ such that $n > N(\delta)$ implies $\epsilon(n) < \epsilon + \delta$, and

$$\begin{aligned}
\inf_{v \in V} S(\bar{u}, v) \geq S(\bar{u}, \hat{v}) - \delta &\geq S(\pi_n^1(u_n^*), \hat{v}) - 2\delta \\
&\geq S_n(u_n^*, \sigma_n^2(\hat{v})) - 3\delta \\
&\geq \underline{R}_n - 3\delta - \epsilon(n) \\
&\geq R - 4\delta - \epsilon(n);
\end{aligned}$$

hence, $\bar{u}$ is ϵ'-optimal with $\epsilon' = \epsilon + 5\delta$. In the same way, by $(\mathcal{A}2)$ and $(\mathcal{A}4)$ we prove that $\bar{v}$ is ϵ'-optimal for S. The proof follows from the fact that δ was chosen arbitrarily. □

Remark 2.2. (i) In the rest of the paper, whenever $U_n = U$ and $V_n = V$ do not depend on n, π_n and σ_n will be chosen as the identity maps.

(ii) It follows from the proof of part (1) in the above theorem that if for all G_n, $n = 1, 2, \ldots, \infty$, there exist optimal policies for both players and if $U_n = U$ and $V_n = V$ do not depend on n, then

$$|\overline{R}_n - R| \leq \sup_{u,v} |S_n(u,v) - S(u,v)|, \qquad |\underline{R}_n - R| \leq \sup_{u,v} |S_n(u,v) - S(u,v)|.$$

3. Stochastic games: The model. We will use the results from the previous section to study approximations of zero-sum stochastic games.

- Let $\mathbf{I}$ be a denumerable set of states.
- $\mathbf{A}_i$ ($\mathbf{B}_i$) is a compact metric set of actions for player I (resp., II) at state i. Let $K = \{i, \mathbf{A}_i, \mathbf{B}_i\}_{i \in I}$.
- $r : K \to \mathbb{R}$ is a bounded immediate reward function. (The boundedness condition can be relaxed; see §9.) Let $M \stackrel{\text{def}}{=} \sup_{i,a,b} |r(i,a,b)|$.
- $P(a,b) = [p(i,a,b,E)]_{i,E}$, $a \in \mathbf{A}_i$, $b \in \mathbf{B}_i$ is a (sub) probability transition (from state i to a set $E \subset \mathbf{I}$) when the players use actions a and b.
- β is the discount factor satisfying $0 \leq \beta < 1$.

We shall use the following standard assumption (see, e.g., Nowak [18]):

(M_1) : $r(i, \bullet, \bullet)$ and $p(i, \bullet, \bullet, E)$ are continuous in both actions for any $E \subset \mathbf{I}$.

The game is played in stages $t = 0, 1, 2, \ldots$. If at some stage t the state is i, then the players independently choose actions $a \in \mathbf{A}_i$, $b \in \mathbf{B}_i$. Player II then pays player I the amount $r(i,a,b)$, and at stage $t+1$ the new state is chosen according to the transition probabilities $p(i,a,b,\bullet)$. The game continues at this new state.

Let U and V be the set of behavioral strategies for both players. A strategy $u \in U$ is a sequence $u = (u_0, u_1, \ldots)$, where u_t is a probability measure over the available actions, given the whole history of previous states and of previous actions of both players as well as the current state.

A Markov policy $q = \{q_0, q_1, \ldots\}$ is a policy (for either player I or player II) where q_t is allowed to depend only on t and on the state at time t.

A *stationary* (*mixed*) *policy* g for player one is characterized by a conditional distribution $p^g(\bullet \mid j)$ over $\mathbf{A}_j$, so that $p^g(\mathbf{A}_j \mid j) = 1$, which is interpreted as the distribution over the actions available at state j which player I uses when it is in state j. With some abuse of notation, we shall set $g(\bullet \mid j) = p^g(\bullet \mid j)$ for stationary g. Let S^A be the set of stationary policies for player I, and define similarly the stationary policies S^B for player II. If both players use stationary policies, say u and v, then $\{X_t\}$ becomes a Markov chain with stationary transition probabilities, given by

$$p(j,u,v,k) = \int_{\mathbf{A}_j} \int_{\mathbf{B}_j} p(j,a,b,k) u(da|j) v(db|j). \tag{4}$$

In the following section we are concerned with the infinite-horizon discounted problem. It is known that under (M_1), optimal stationary policies exist for both players; i.e., if u and v are optimal policies for both players when both of them are restricted to stationary policies, then each one of these policies is also optimal against an arbitrary policy of his or her opponent. We shall therefore restrict the game to stationary mixed policies, without loss of generality (see [12], [17]).

Next we introduce a topology on the sets of stationary policies. For any compact metric set Γ, let $M(\Gamma)$ denote the set of probability measures on Γ endowed with the weak topology $\xi(\Gamma)$ (see [18]). The class of stationary policies for player I (and

similarly for player II) can be identified with the set $\prod_{i\in\mathbf{I}} M(\mathbf{A}_i)\times M(\mathbf{B}_i)$; moreover, it is compact with respect to the product topology $\prod_{i\in\mathbf{I}} \xi(\mathbf{A}_i)\times\xi(\mathbf{B}_i)$.

Let (u,v) be a pair of strategies and $i\in\mathbf{I}$ be a fixed initial state. Let I_t, A_t, B_t, $t=0,\dots,$ be the resulting stochastic process of the states and actions of the players. Let $E_i^{u,v}$ denote the expectation with respect to the measure defined by u,v,i. Define the β-discounted game payoff

$$S(i,u,v) = E_i^{u,v}\sum_{t=0}^{\infty}\beta^t r(I_t,A_t,B_t). \tag{5}$$

Let $R(i)$ denote the value of the stochastic game for initial state i. For stationary policies u and v, let the expected current payoff be defined by

$$r(i,u,v) = \int_{\mathbf{A}_i}\int_{\mathbf{B}_i} r(i,a,b)u(da|i)v(db|i). \tag{6}$$

Consider the following (contracting) map:

$$(T_{u,v}f)(i) \stackrel{\text{def}}{=} r(i,u,v) + \beta\sum_{j\in\mathbf{I}} p(i,u,v,j)f(j). \tag{7}$$

Then $S(i,u,v)$ is known to be the unique solution of (7). The value $R(i)$ is the unique solution of

$$R(i) = val\left[r(i,a,b) + \beta\sum_{j\in\mathbf{I}} p(i,a,b,j)R(j)\right]. \tag{8}$$

Moreover, any stationary policies u^* and v^* that choose at any state j the mixed strategies that are optimal for the game

$$\left[r(i,a,b) + \beta\sum_{j\in\mathbf{I}} p(i,a,b,j)R(j)\right]_{a,b}$$

are known to be optimal for the stochastic game S (see [18] for these statements).

Remark 3.1. $S(i,\bullet,\bullet): S^A\times S^B\to\mathbb{R}$ are continuous for all states i. This follows from Corollary 2.2 in Borkar [10]. It will thus follow below that assumptions $(\mathcal{A}3)$ and $(\mathcal{A}4)$ hold.

4. State approximations: Infinite-horizon case. We introduce below several approximating schemes. All of them involve some sequence $\mathbf{I}_n\subset\mathbf{I}$ of sets of states, which are naturally chosen to be increasing. We shall assume

$$\mathbf{I}_n\subset\mathbf{I}_{n+1}, \qquad \bigcup_n \mathbf{I}_n = \mathbf{I}. \tag{$\mathcal{B}1$}$$

The following property will imply conditions $(\mathcal{A}1)$–$(\mathcal{A}2)$ in the various schemes that we consider below:

$$\text{For all integers } r, \qquad \epsilon(r,n) = \sup_{a,b,i\in\mathbf{I}_r}\left\{\sum_{j\notin\mathbf{I}_n} p(i,a,b,j)\right\}\to 0 \text{ as } n\to\infty. \tag{$\mathcal{B}2$}$$

Remark 4.1. Consider the case that the sets $\mathbf{I}_r$ are all finite. Condition (M_1) as well as the compactness of $\mathbf{A}_i$ and $\mathbf{B}_i$ then implies $(\mathcal{B}2)$. Indeed, assume that $(\mathcal{B}2)$ does not hold. Then, there exists some $\alpha > 0$ such that for some i,

$$\overline{\lim_{n\to\infty}} \max_{a,b} \left(\sum_{j\in\mathbf{I}} p(i,a,b,j) 1\{j \notin \mathbf{I}_n\} \right) = \alpha. \tag{9}$$

Let a_n and b_n be some actions achieving the max. (The fact that the max is achieved follows from the compactness and continuity assumption (M_1).) Choose a subsequence $n(\ell), \ell = 1, 2, \ldots$, along which the limsup is obtained and along which a_n and b_n converge to some actions a^* and b^*. Then $p(i, a_{n(\ell)}, b_{n(\ell)}, \bullet)$ converges (pointwise) to the probability $p(i, a^*, b^*, \bullet)$ as $\ell \to \infty$ (by (M_1)). But then it follows from a dominant convergence theorem [23, Chap. 11, §4] and $(\mathcal{B}1)$ that

$$\lim_{\ell\to\infty} \sum_{j\in\mathbf{I}} p(i, a_{n(\ell)}, b_{n(\ell)}, j) 1\{j \notin \mathbf{I}_{n(\ell)}\} = \sum_{j\in\mathbf{I}} p(i, a^*, b^*, j) \cdot 0 = 0,$$

which contradicts (9). Hence $(\mathcal{B}2)$ is established.

For the case of a single player, $(\mathcal{B}2)$ was introduced as an assumption for several approximating schemes by Cavazos-Cadena [11]. Note, however, that in [11], (M_1) and the compactness of the action spaces are not assumed. In order to obtain conditions $(\mathcal{A}1)$ and $(\mathcal{A}2)$ for the approximating schemes below (and hence obtain statements (1), (2), and (3) in Theorem 2.1) one could relax the compactness assumption as well as (M_1); in that case one would indeed need to impose $(\mathcal{B}2)$ as an assumption. The compactness and (M_1) (or other similar assumptions, such as (M_2) or (M_3) from [18]) are required, however, to establish the continuity conditions $(\mathcal{A}3)$ and $(\mathcal{A}4)$ required to establish statement (4) in Theorem 2.1.

Other typical assumptions that imply $(\mathcal{B}2)$ have often been used in the literature; see White [29] and Hernández-Lerma [15] as well as $(\mathcal{B}3)$, introduced in Altman [1], which will be used occasionally below:

$(\mathcal{B}3)$ From any state k, only a finite set of states X_k can be reached.

In all approximations in this section, the approximating games G_n have a value, i.e., $R_n(i) = \underline{R}_n(i) = \overline{R}_n(i)$. Moreover, they will have a saddle point among the stationary policies.

4.1. Approximation scheme I. We define

$$\left(H^1_{u,v} f\right)(i) \stackrel{\text{def}}{=} \begin{cases} r(i,u,v) + \beta \sum_{j\in\mathbf{I}_n} p(i,u,v,j) f(j) & \text{if } i \in \mathbf{I}_n, \\ 0 & \text{if } i \notin \mathbf{I}_n. \end{cases} \tag{10}$$

For this approximating problem we define $S^1_n(i,u,v)$ to be the solution of

$$\left(H^1_{u,v} f\right)(i) = f(i) \qquad \forall i \in \mathbf{I}. \tag{11}$$

S^1_n is thus the total discounted payoff (defined in (5)) for the stochastic game whose transition probabilities are $\bar{p}$ instead of p, where $\bar{p}(i,u,v,j) = p(i,u,v,j)$ if $\{i, j \in \mathbf{I}_n\}$, 0 if $\{i, j \notin \mathbf{I}_n\}$. The value of the game G^1_n is the unique solution of

$$R_n(i) = \begin{cases} val\left[r(i,a,b) + \beta \sum_{j\in\mathbf{I}_n} p(i,a,b,j) R_n(j)\right] & \text{if } i \in \mathbf{I}_n, \\ 0 & \text{if } i \notin \mathbf{I}_n. \end{cases} \tag{12}$$

Moreover, optimal stationary policies u_n^* and v_n^* for the game G_n^1 are obtained by chosing at any state $i \in \mathbf{I}_n$ the mixed strategies that are optimal for the game

$$\left[r(i,a,b) + \beta \sum_{j \in \mathbf{I}_n} p(i,a,b,j) R_n(j) \right]_{a,b}.$$

The proof of the following theorem will enable us to evaluate the precision of the approximation. More precisely, it will enable us to get a bound on $|R_n(\bullet) - R(\bullet)|$ which will be uniform in $i \in J$ where J is an arbitrary fixed subset of $\mathbf{I}$.

THEOREM 4.1. *Assume* (M_1) *and* $(\mathcal{B}2)$. *All statements of Theorem* 2.1 *hold for approximating scheme* I, *where the reward* S *for the limit game* G *is defined in* (5) *and for approximating game* G_n^1 *it is* S_n^1.

Proof. The proof uses an idea by Cavazos-Cadena [11]. We need first to introduce some definitions. Let $\epsilon > 0$. We define

$$g^0(\epsilon, r) = r, \qquad g^k(\epsilon, r) = g(\epsilon, g^{k-1}(\epsilon, r)), \qquad k = 1, 2, \ldots,$$

where

$$g(\epsilon, r) = \min \{m : \epsilon(r, m) \leq \epsilon\}$$

and $\epsilon(r, m)$ is defined in property $(\mathcal{B}2)$. To understand the meaning of $g^s(\epsilon, r)$, we consider first $\epsilon = 0$. Then $\mathbf{I}_{g^{s+1}(0,r)}$ is the set of neighbors of $\mathbf{I}_{g^s(0,r)}$ in the sense that states that are not contained in $\mathbf{I}_{g^{s+1}(0,r)}$ are not reachable from any state in $\mathbf{I}_{g^s(0,r)}$. For $\epsilon > 0$, $\mathbf{I}_{g^{s+1}(\epsilon,r)}$ is the set of "ϵ-neighbors" of $\mathbf{I}_{g^s(\epsilon,r)}$ in the sense that for any state i in $\mathbf{I}_{g^s(\epsilon,r)}$, the states that are not contained in $\mathbf{I}_{g^{s+1}(\epsilon,r)}$ are reachable from i with probability smaller than or equal to ϵ. Note that for any $r \geq 0$

$$\sum_{j \notin \mathbf{I}_{g^{l+1}(\epsilon,r)}} p(i,u,v,j) \leq \epsilon \qquad \forall i \in \mathbf{I}_{g^l(\epsilon,r)},\ \forall l \geq 0,\ \forall u, v. \tag{13}$$

Note also that $g^l(\epsilon, r)$ need not be increasing in l.

Let $J \subset \mathbf{I}$, $\epsilon(J) = \min \{m : J \subset \mathbf{I}_m\}$, and suppose $\epsilon(J) < +\infty$. (This is the case if J is chosen to be finite.) We define

$$m_k(\epsilon, \epsilon(J)) = \max \left\{ \epsilon(J), g(\epsilon, \epsilon(J)), \ldots, g^k(\epsilon, \epsilon(J)) \right\}, \qquad k = 0, 1, 2, \ldots. \tag{14}$$

We show that assumptions $(\mathcal{A}1)$–$(\mathcal{A}4)$ hold for $S_n^1(i,u,v)$ and $S(i,u,v)$ defined above.

Below, ϵ and J are fixed, so for simplicity of notation we shall write g^l instead of $g^l(\epsilon, \epsilon(J))$. Let $n \geq m_k(\epsilon, \epsilon(J))$. Then for all $i \in J$

$$\begin{aligned} |S_n^1(i,u,v) - S(i,u,v)| \leq{}& \beta \sum_{j \in \mathbf{I}_{g^1}} p(i,u,v,j)\, |S_n^1(j,u,v) - S(j,u,v)| \\ &+ \beta \sum_{j \notin \mathbf{I}_{g^1}} p(i,u,v,j)\, |S_n^1(j,u,v) - S(j,u,v)|. \end{aligned} \tag{15}$$

Note that for any state j, $|S_n^1(j,u,v)| \leq M/(1-\beta)$ and $|S(j,u,v)| \leq M/(1-\beta)$. Hence by (13), (15), and $(\mathcal{B}2)$ we obtain

$$|S_n^1(i,u,v) - S(i,u,v)|$$

$$\leq \beta \sum_{j \in \mathbf{I}_{g^1}} p(i,u,v,j)\, |S_n^1(j,u,v) - S(j,u,v)| + \epsilon \frac{2M\beta}{1-\beta}$$

$$\leq \beta \max_{j \in \mathbf{I}_{g^1}} |S_n^1(j,u,v) - S(j,u,v)| + \epsilon \frac{2M\beta}{1-\beta}$$

$$\leq \beta \max_{j \in \mathbf{I}_{g^1}} \left\{ \beta \sum_{\ell \in \mathbf{I}_{g^2}} p(j,u,v,\ell)\, |S_n^1(\ell,u,v) - S(\ell,u,v)| \right.$$

$$\left. + \beta \sum_{\ell \notin \mathbf{I}_{g^2}} p(j,u,v,\ell)\, |S_n^1(\ell,u,v) - S(\ell,u,v)| \right\} + \epsilon \frac{2M\beta}{1-\beta}$$

$$\leq \beta^2 \max_{\ell \in \mathbf{I}_{g^2}} |S_n^1(\ell,u,v) - S(\ell,u,v)| + \epsilon \frac{2M\beta^2}{1-\beta} + \epsilon \frac{2M\beta}{1-\beta} \tag{16}$$

$$\leq \beta^k \max_{\ell \in \mathbf{I}_{g^k}} |S_n^1(\ell,u,v) - S(\ell,u,v)| + 2\epsilon \frac{M\beta}{1-\beta} \sum_{\ell=0}^{k-1} \beta^\ell.$$

The first inequality follows by (13) since $n \geq m_k \geq g^1$ and since $i \in J \subset \mathbf{I}_{g^0}$. Similarly, (16) follows by (13) since $n \geq m_k \geq g^2$ and since $\ell \in \mathbf{I}_{g^1}$. So we have

$$|S_n^1(j,u,v) - S(j,u,v)| \leq 2M \frac{\beta(1-\beta^k)\epsilon/(1-\beta) + \beta^k}{1-\beta}. \tag{17}$$

Hence $(\mathcal{A}1)$ and $(\mathcal{A}2)$ hold true (whereas $(\mathcal{A}3)$–$(\mathcal{A}4)$ are established in Remark 3.1). □

Combining (17) with Remark 2.2 yields the following corollary.

COROLLARY 4.2. *For any $i \in J$, if n is chosen such that $n \geq m_k(\epsilon, \epsilon(J))$, then*

$$|R_n(i) - R(i)| \leq 2M \frac{\beta(1-\beta^k)\epsilon/(1-\beta) + \beta^k}{1-\beta}. \tag{18}$$

In the previous theorem, the sets $\{\mathbf{I}_n\}$ where given a priori. Next we consider a special choice of $\{\mathbf{I}_n\}$ that will be especially useful under assumption $(\mathcal{B}3)$ for a finite set J. This construction will enable us to express in a simple way the sets $\mathbf{I}_n$ needed in (10) in order to approximate R by R_n with a given error. This is especially desirable when it is not easy to compute $m_k(\epsilon, \epsilon(J))$ (and thus Corollary 4.2 cannot be used).

Let J be a given set (for which we would like to get a computable uniform bound on the error of the approximation), and set $Y(i) = \{j : p(i,u,v,j) > 0 \text{ for some } u, v\}$. Then we define $\mathbf{I}_n$ in the following way:

$$\mathbf{I}_0 = J, \qquad \mathbf{I}_{n+1} = \bigcup_{i \in \mathbf{I}_n} Y(i) \bigcup \mathbf{I}_n. \tag{19}$$

Remark 4.2. Note that if J is finite and if $(\mathcal{B}3)$ holds, then all sets $\mathbf{I}_n$ are finite. This construction might be especially useful if the number of states reachable from any given state is small. In that case $\mathbf{I}_n$ do not grow too quickly. We now consider $S_n(i,u,v)$ the solution of (11) with $\mathbf{I}_n$ defined in (19). We have that the following theorem (analogous to (4.1)) holds.

THEOREM 4.3. *Assume* (M_1) *and* $(\mathcal{B}3)$.

(i) *Fix a state $i \in J$. Then all statements of Theorem* 2.1 *hold for the approximating scheme I, where the reward S of the limit game G is defined in* (5) *and the reward S_n for the approximating game G_n is the solution of* (11) *with $\mathbf{I}_n$ defined in* (19).

(ii) *For any $i \in J$ and $n = 0, 1, \ldots$, $|R_n(i) - R(i)| \leq 2M\beta^n/(1-\beta)$.*

Proof. It suffices to prove that $(\mathcal{A}1)$ and $(\mathcal{A}2)$ are satisfied. Let $i \in J$. Then

$$\begin{aligned}
|S_n(i,u,v) - S(i,u,v)| &\leq \beta \sum_{j \in Y(i)} p(i,u,v,j)|S_n(j,u,v) - S(j,u,v)| \\
&\leq \beta \max_{j \in \mathbf{I}_1} |S_n(j,u,v) - S(j,u,v)| \\
&\leq \beta^2 \max_{j \in \mathbf{I}_1} \sum_{k \in Y(j)} p(j,u,v,k)|S_n(k,u,v) - S(k,u,v)| \\
&\quad \cdot \\
&\quad \cdot \\
&\quad \cdot \\
&\leq \beta^n \max_{j \in \mathbf{I}_n} |S_n(j,u,v) - S(j,u,v)| \leq \frac{2M\beta^n}{1-\beta}.
\end{aligned}$$

The proof of (ii) then follows from Remark 2.2. □

As suggested in Remark 4.2, the above method is useful specially when the approximating games have finite states (i.e., $\mathbf{I}_n$ are finite) and the typical number of states (neighbors) is reachable from a state is not too high. If, however, the typical number of neighbors is high, then the sets $\mathbf{I}_n$ become large very rapidly, which suggests that obtaining good estimates of optimal value and policies might require an unacceptably high complexity of computations. We thus present an alternative more general way of constructing finite sets $\mathbf{I}_n$ (even when $(\mathcal{B}3)$ does not hold), which will result in a simple expression for $m_k(\epsilon, \epsilon(J))$ and will thus enable use of Corollary 4.2 to obtain a uniform computable error bound for the approximation for any $i \in J$.

We define a parametrized family $\{\mathbf{I}_n(\epsilon)\}$, where ϵ is a positive real number. Define $\mathbf{I}_0(\epsilon) = J$. $\{\mathbf{I}_n(\epsilon)\}$ are then chosen to be an arbitrary sequence increasing to $\mathbf{I}$ that satisfies the following. If for some $l > 0$, say $l = \hat{l}$,

$$\sup_{a,b,i \in \mathbf{I}_l(\epsilon)} \sum_{j \notin \mathbf{I}_l(\epsilon)} p(i,a,b,j) \leq \epsilon,$$

then $\mathbf{I}_n(\epsilon) = \mathbf{I}$ for all $n > \hat{l}$. Otherwise, $\mathbf{I}_{l+1}$ is chosen such that

$$\sup_{a,b,i \in \mathbf{I}_l(\epsilon)} \sum_{j \notin \mathbf{I}_{l+1}(\epsilon)} p(i,a,b,j) \leq \epsilon.$$

It follows that $\epsilon(J) = 0$, $g^0 = 0$, and hence $g^k = k$ and $m_k(\epsilon, \epsilon(J)) = g^k = k$ for $k \leq \hat{l}$. (The above quantities were defined in the proof of Theorem 4.1.) If J is finite, then it follows from the same arguments as in Remark 4.2 that $\mathbf{I}_n(\epsilon)$ can be chosen to be finite for $n \leq \hat{l}$ and hence in particular $\mathbf{I}_{\hat{l}}(\epsilon)$, which is the truncated state space that should be used to perform approximation scheme I in order to obtain a precision as in Corollary 4.2.

In this setting, Theorem 4.3 (ii) becomes a special case of Corollary 4.2 with $\epsilon = 0$.

4.2. Approximation scheme II. In the previous approximation scheme, the dynamics are seen to be a result of transition probabilities that need not sum to one, even if in the limit game they do sum to one. Indeed, (10) can be considered a stochastic game where we set $p(i,u,v,j) = 0$ for $j \notin \mathbf{I}_n$. In many applications this may be undesirable, and one would like $p(i,u,v,\bullet)$ to remain a probability measure. This is especially the case when we want to learn about the optimal value and (almost) optimal policies for a given specific stochastic games with large finite state space by approximating them through an infinite state game. Indeed, there are cases where one can solve an infinite game more easily, since some boundary problems are avoided. Examples are given in §8.

We assume that $\sum_{j\in\mathbf{I}} p(i,a,b,j) = 1$ for all $a \in \mathbf{A}_i, b \in \mathbf{B}_i$. We define the following sequence of games. We let $\mathbf{I}_n \subset \mathbf{I}$ be an increasing sequence of sets, converging to $\mathbf{I}$, as in the previous section. Define

$$\left(H^2_{u,v}f\right)(i) = \begin{cases} r(i,u,v) + \beta \sum_{j\in\mathbf{I}_n} p^*(i,u,v,j) f(j) & \text{if } i \in \mathbf{I}_n, \\ 0 & \text{if } i \notin \mathbf{I}_n, \end{cases} \tag{20}$$

where

$$p^*(i,u,v,j) = \begin{cases} p(i,u,v,j) + q_n(i,u,v,j) & \text{if } i \in \mathbf{I}_n,\ j \in \mathbf{I}_n, \\ 0 & \text{if } i \notin \mathbf{I}_n \text{ or } j \notin \mathbf{I}_n. \end{cases} \tag{21}$$

$q_n(i,u,v,\bullet)$ is some nonnegative measure satisfying $\sum_{j\in\mathbf{I}_n} (p(i,u,v,j) + q_n(i,u,v,j)) = 1$. Hence,

$$\sum_{j\in\mathbf{I}_n} q_n(i,u,v,j) = \sum_{j\notin\mathbf{I}_n} p(i,u,v,j). \tag{22}$$

We define S^2_n to be the solution of

$$\left(H^2_{u,v}f\right)(i) = f(i). \tag{23}$$

S^2_n is thus the total discounted payoff (defined in (5)) for the stochastic game whose transition probabilities are p^* instead of p.

Assume (M_1) and $(\mathcal{B}2)$. Then all the results of §4.1 still hold. We demonstrate this with the proof of the analogue of Theorem 4.1. It suffices to show that $(\mathcal{A}1)$–$(\mathcal{A}2)$ hold. With the same notation as in §4.1 we obtain

$$\begin{aligned} |S^2_n(i,u,v) - S(i,u,v)| \le{}& \beta \sum_{j\in\mathbf{I}_{g^1}} p(i,u,v,j)\, |S^2_n(j,u,v) - S(j,u,v)| \\ &+ \beta \sum_{j\in\mathbf{I}_{g^1}} q(i,u,v,j)\, |S^2_n(j,u,v) - S(j,u,v)| \\ &+ \beta \sum_{j\notin\mathbf{I}_{g^1}} p(i,u,v,j)\, |S^2_n(j,u,v) - S(j,u,v)|, \end{aligned}$$

and by (22)

$$\begin{aligned} |S^2_n(i,u,v) - S(i,u,v)| &\le \beta \sum_{j\in\mathbf{I}_{g^1}} p(i,u,v,j)\, |S^2_n(j,u,v) - S(j,u,v)| \\ &\quad + 2\beta \sum_{j\notin\mathbf{I}_{g^1}} p(i,u,v,j)\, |S^2_n(j,u,v) - S(j,u,v)| \\ &\le \beta \sum_{j\in\mathbf{I}_{g^1}} p(i,u,v,j)\, |S^2_n(j,u,v) - S(j,u,v)| + 2\epsilon \frac{2M\beta}{1-\beta}. \end{aligned}$$

So continuing as in the proof of Theorem 4.1 we have

$$|S_n^2(j,u,v) - S(j,u,v)| \le 2M\frac{2\beta(1-\beta^k)\epsilon/(1-\beta)+\beta^k}{1-\beta} \tag{24}$$

for $n \ge m_k(\epsilon, \epsilon(J))$.

4.3. Approximation scheme III. The basic idea of the approximation scheme is to fix some stationary policies for both players and use them in all states except for a subset $\mathbf{I}_n$. The problem is then of determining the optimal mixed strategies for both players in the remaining set of states $\mathbf{I}_n$. We are interested in studying the asymptotic behavior of this approach as $\mathbf{I}_n \to \mathbf{I}$. Similar approaches were used in a framework of Markov decision processes (e.g., [2]), where $\mathbf{I}_n$ were assumed finite. We first fix some arbitrary policies $\hat{u} \in U$, $\hat{v} \in V$. We shall now use the framework of Theorem 2.1. Define

$$U_n = \{u \in U : u(i) = \hat{u}(i),\ \forall i \notin \mathbf{I}_n\}, \qquad V_n = \{v \in V : v(i) = \hat{v}(i),\ \forall i \notin \mathbf{I}_n\}.$$

Fix some $i \in \mathbf{I}$. The limit game is defined as $S(u,v) = S(i,u,v)$, where $S(i,u,v)$ is given in (5). For any $u \in U_n, v \in V_n$, define $S_n(u,v) = S(u,v)$ We set π_n^1 and π_n^2 to be the identity mappings and

$$\sigma_n^1(u)(i) = \begin{cases} u(i) & \text{if } i \in \mathbf{I}_n, \\ \hat{u}(i) & \text{if } i \notin \mathbf{I}_n; \end{cases} \qquad \sigma_n^2(v)(i) = \begin{cases} v(i) & \text{if } i \in \mathbf{I}_n, \\ \hat{v}(i) & \text{if } i \notin \mathbf{I}_n. \end{cases}$$

THEOREM 4.4. *Assume* (M_1) *and* ($\mathcal{B}2$), *and fix a state* i. *Then*
(i) *All statements of Theorem* 2.1 *hold for approximation scheme* III.
(ii) R_n *is the unique fixed point of the equation*

$$R_n(k) = \begin{cases} val\left[r(k,a,b) + \beta\sum_{j\in\mathbf{I}} p(k,a,b,j)R_n(j)\right], & k \in \mathbf{I}_n, \\ r(k,\hat{u},\hat{v}) + \beta\sum_{j\in\mathbf{I}} p(k,\hat{u},\hat{v},j)R_n(j), & k \notin \mathbf{I}_n. \end{cases} \tag{25}$$

(iii) *Optimal stationary policies* u_n *and* v_n *for both players are obtained by using at any state* $k \in \mathbf{I}_n$ *mixed strategies that achieve the value in* (25).

The proof of this theorem is similar to the proof of Theorem 4.1.

5. State approximations for the case of finite horizon. Consider the model in §3 with, however, a finite-horizon reward criterion instead of (5):

$$S^{[m]} = E_i^{u,v}\left[\sum_{t=0}^{m} \beta^t r(I_t, A_t, B_t)\right]. \tag{26}$$

It is well known that there exist optimal policies for both players within the class of Markov policies. The value R of $S^{[m]}$ is obtained by the recursion

$$R^{m+1} \stackrel{\text{def}}{=} 0, \tag{27}$$

$$R^k(i) \stackrel{\text{def}}{=} val\left[r(i,u,v) + \beta\sum_{j\in\mathbf{I}} p(i,u,v,j)R^{k+1}(j)\right], \qquad k = 0,\dots,m,$$

$$R \stackrel{\text{def}}{=} R^0.$$

Define $U[m] = (U^0[m], U^1[m], \ldots, U^m[m])$, $V[m] = (V^0[m], V^1[m], \ldots, V^m[m])$, where $U^k[m], V^k[m]$ are the set of mixed strategies which are optimal for the matrix game

$$\left[r(i,a,b) + \beta \sum_{j \in \mathbf{I}} p(i,a,b,j) R^{k+1}(j) \right]_{a,b}, \quad k = 0, \ldots, m, \tag{28}$$

for all $i \in \mathbf{I}$. Then, any Markov policies (u, v) such that $u_t \in U^t$, $v_t \in V^t$, $t = 0, \ldots, m$, are optimal for the stochastic game $S^{[m]}$.

In order to apply the results from §4 to the finite-horizon case we make the following observation. The finite-horizon model is equivalent to the following infinite-horizon model with enlarged state space:

- $\hat{\mathbf{I}} = \mathbf{I} \times \{0, \ldots, m\}$;
- $\hat{\mathbf{A}}_{(i,k)} = \mathbf{A}_i$, $\hat{\mathbf{B}}_{(i,k)} = \mathbf{B}_i$;
- $\hat{r}((i,k), a, b) = r(i, a, b)$;
- $\hat{p}((i,k), a, b, (j,l)) = \begin{cases} p(i,a,b,j) & \text{if } k+1 = l \leq m, \\ 0 & \text{otherwise;} \end{cases}$
- $\hat{\beta} = \beta$.

Define

$$\hat{S}(\hat{i}, \hat{u}, \hat{v}) = E_{\hat{i}}^{\hat{u},\hat{v}} \sum_{t=0}^{\infty} \beta^t r(\hat{I}_t, \hat{A}_t, \hat{B}_t).$$

There is a one-to-one correspondence between stationary policies in the new model and Markov policies in the original one; if $\hat{u}, \hat{v}$ are stationary in the new model, then the corresponding Markov policies in the original model are given by

$$u_t(\bullet|x) = \hat{u}(\bullet|(x,t)), \qquad v_t(\bullet|x) = \hat{v}(\bullet|(x,t)) \tag{29}$$

and vice versa. Moreover, we have

$$S^{[m]}(u, v) = \hat{S}(\hat{u}, \hat{v}).$$

Consequently, the state approximation schemes from the previous section also hold for the case of finite-horizon models. The computation of the (approximating) values and (almost) optimal policies can be done by using the above infinite-horizon model with enlarged state space and then applying (29). $\hat{\mathbf{I}}_n$ may be chosen, for example, as $\hat{\mathbf{I}}_n = \mathbf{I}_n \times \{0, \ldots, m\}$. Note that condition $(\mathcal{B}2)$ will hold for $\hat{\mathbf{I}}_n$ if it holds for $\mathbf{I}_n$.

6. Successive approximations. We study in this section several new aspects of successive approximations. The convergence of the value of successive approximation is already well known [19], [24], [27]. By applying Theorem 2.1, we establish in the following subsection the convergence of (almost) optimal policies. We then study the application of both state approximation and finite horizon approximation. Finally, we discuss the restriction of games with finite horizon to stationary policies.

6.1. Convergence of policies for successive approximations. An interesting application of the results in the previous subsections is the observation that successive approximations (or value iteration) can be viewed as a special case of state approximations. One can define game G_n such that $S_n = S^{[n]}$, where $S^{[n]}$ is given in (26), and consider the limit game $G = G_\infty$ where S is defined in (5). Let u_n^* and v_n^* be

a pair of optimal (or ϵ_n-optimal, where $\lim_{n\to\infty}\epsilon_n = 0$) Markov policies for G_n. Let u^* and v^* be any ϵ-optimal stationary (or Markov) policies for the infinite-horizon game G. If we use for both G_n and G, the equivalent infinite-horizon model with the enlarged state space defined in §5, then u_n^*, v_n^*, u^* and v^* all have an equivalent representation as stationary policies. The problem becomes one of approximating the state space $\mathbf{I}' = (\mathbf{I}\times\mathbb{N})$ by the subsets $\mathbf{I}'_n = (\mathbf{I}\times\{0,1,\dots,n\})$. Note that condition $(\mathcal{B}2)$ holds in this case since the probability of going from any state in $\mathbf{I}'_r$ to any state in $\mathbf{I}'_n$ is zero for $n > r+1$. Then using Theorems 2.1 and 4.1, we conclude with the following theorem.

THEOREM 6.1. *Assume that* $(\mathbf{M_1})$ *holds. Then*

(1) $\lim_{n\to\infty} R_n = R$.

(2) *For any* $\epsilon' > \epsilon$, *there exists* N *such that* u_n^* *(resp.,* v_n^**) is* ϵ'*-optimal for the infinite-horizon game for all* $n \geq N$.

(3) *Let* $\bar{u} \in U$ *(resp.,* $\bar{v} \in V$*) be a limit point of* u_n^* *(resp.,* v_n^**). Then* $\bar{u}$ *(resp.,* $\bar{v}$*) is* ϵ*-optimal for the limit game.*

(4) *For all* $\epsilon' > \epsilon$, *there exists* $N(\epsilon')$ *such that* u^* *is* ϵ'*-optimal for the* n*th approximating game for all* $n \geq N(\epsilon')$.

6.2. Successive approximation and finite state approximation. We use the above approach to combine state approximations with finite horizon reward criterion. Such a combination may be specially useful for computational purposes, where $\mathbf{I}_n$ can be chosen to be finite. We can now compute R_n and (Markov) policies which are optimal for G_n, using approximating schemes introduced in the previous sections, in order to approximate the optimal value R and an almost optimal strategy for the original limit game G. Let again $\mathbf{I}_n \subset \mathbf{I}$ be an increasing sequence of sets of states converging to $\mathbf{I}$. One can repeat the construction of a model with enlarged state space (that includes both the original state space and the time) so that the state space for the nth game G_n is $\hat{\mathbf{I}}_n = (\mathbf{I}_n \times \{0,1,\dots,n\})$ and for the limit game G is $\hat{\mathbf{I}} = (\mathbf{I}\times\mathbb{N})$. This would establish the correctness of approximations based on value iteration for a problem with truncated state space. For example, if we adapt the first approach in §4, we get the approximating values R_n and Markov policies by performing the following iterations:

$$R_n^{n+1}(j) \stackrel{\text{def}}{=} 0,$$

$$R_n^k(j) \stackrel{\text{def}}{=} \begin{cases} val\left[r(i,a,b) + \beta\sum_{j\in\mathbf{I}_n} p(i,a,b,j)R^{k+1}(j)\right] & \text{if } i \in \mathbf{I}_n, \\ 0 & \text{if } i \notin \mathbf{I}_n, \end{cases} \qquad k = 0,\dots,n,$$

$$R_n \stackrel{\text{def}}{=} R_n^0.$$

Define $U_n = (U_n^0, U_n^1, \dots, U_n^n)$, $V_n[m] = (V_n^0, V_n^1, \dots, V_n^n)$, where U_n^k, V_n^k are the set of mixed strategies which are optimal for the game

$$val\left[r(i,a,b) + \beta\sum_{j\in\mathbf{I}_n} p(i,a,b,j)R_n^{k+1}(j)\right]_{a,b}, \qquad k = 0,\dots,m, \tag{30}$$

for any $i \in \mathbf{I}_n$. Then any Markov policies (u,v) such that $u_t \in U_n^t$, $v_t \in V_n^t$, $t = 0,\dots,m$, are optimal for the stochastic game G_n.

6.3. Finite horizon and stationary policies. For simplicity of implementation, one may be interested in restricting to the class of stationary policies in a

stochastic game rather than using Markovian policies (or others). It is well known, however, that finite-horizon games do not have a value within the class of stationary policies. However, it is immediately seen that the conditions $(\mathcal{A}1)$–$(\mathcal{A}4)$ hold when there is restriction to stationary policies, and thus we conclude from Theorem 2.1 that the optimal stationary policies for both players converge (in the sense of Theorem 2.1 (3)) to the strongly optimal policy of the infinite-horizon game as the horizon goes to infinity. Moreover, the lower and upper values converge to the value of the infinite-horizon game.

7. Convergence of the discount factor and immediate reward. We establish in this section the robustness of values and optimal policies with respect to the discount factor and immediate reward. This may be of importance in case that these parameters are not known precisely. One can similarly establish robustness for the random time-varying discount factor and immediate reward. We consider a horizon m which is the same for both the limit and the approximating game and which may be either infinite or finite.

We consider a sequence of stochastic games G_n, $n = 0, 1, 2, \ldots$, where the quantities defining each one of them are as in §3, Eq. (5), if m is infinite or as in §5, Eq. (26), if m is finite. However, the immediate reward and discount factor are replaced by $\beta_n = \beta + \delta_n$, $r_n = r + \rho_n$, where δ_n and ρ_n converge to zero as $n \to \infty$ uniformly in the states and actions. Denote by $S_n(i, u, v)$ the reward for game G_n (as defined either in (5) or in (26)). Then

$$\begin{aligned} &|S(i,u,v) - S_n(i,u,v)| \\ &\leq E_i^{u,v} \sum_{t=0}^{m} \left(|[\beta^t - (\beta+\delta_n)^t]|M + |(\beta+\delta_n)^t \rho_n(I_t, A_t, B_t)| \right), \end{aligned}$$

and we obtain convergence to zero uniformly over all Markovian policies u and v (to which we may restrict ourselves, without loss of generality, as in §5). This implies conditions $(\mathcal{A}1)$ and $(\mathcal{A}2)$, and hence, by Remark 3.1, we see that all statements of Theorem 2.1 hold. This establishes the continuity of the value of the stochastic game as a function of the discount factor β in the open interval $\beta \in (0, 1)$ and as a function of the immediate reward. Moreover, it establishes the convergence of (almost) optimal policies (in the sense of Theorem 2.1).

An especially interesting case is the asymptotics of stochastic games as $\beta \to 1$. We restrict for simplicity to the case of finite state and action spaces. The asymptotic behavior of the value of the game was studied by Bewley and Kohlberg [8]. In fact they establish the convergence of $(1 - \beta)R_\beta(i)$ to the value $R_{average}$ of the expected long run time-average game (where $R_\beta(i)$ is the value of the game with discount factor β and initial state i).

When trying to apply the approximating Theorem 2.1 to the limit as $\beta \to 1$, we are faced with the following problems:

(i) The limit game does not have a value among the stationary (nor even the Markov) policies (see the "big match" by Blackwell and Ferguson [9]).

(ii) The value of the limit game (with the expected average reward) is in general not continuous in the policies (and thus assumptions $(\mathcal{A}3)$ and $(\mathcal{A}4)$ do not hold in general). This is the case even for a single controller, for which it is known that the value may exhibit discontinuity in the parameters (see Gaitsgory and Pervozvanskii [13, p. 407]).

However, both problems are avoided in the case when we restrict ourselves either to games with perfect information or to irreducible games (see Gillette [14]). Games with perfect information (resp., irreducible games) have a saddle point within the class of stationary deterministic policies (resp., stationary mixed policies), and ($\mathcal{A}1$) and ($\mathcal{A}2$) hold; see [14]. Within these classes of policies, ($\mathcal{A}3$) and ($\mathcal{A}4$) also hold; indeed, for the perfect information case this follows from the fact that there is only a finite number of stationary deterministic policies. For the irreducible case, this follows, e.g., from [1].

8. Applications. We present in this section a few problems that motivated our research on approximations in stochastic games. As mentioned in the introduction, many discretization schemes of differential games yield dynamic programming that can be interpreted as representing some stochastic game. In some pursuit evasion games, such as the game of the two cars [22], an additional finite state approximation is then required. The calculations in [22] was done following scheme I (introduced in §4.1). The state transition in the discretized model satisfied property ($\mathcal{B}3$), and, in fact, each state had at most four neighbors (i.e., four states reachable in one transition). This feature motivates the use of Theorem 4.3 for such applications, which not only establishes the convergence but also gives the rate of convergence (or, more precisely, enables computation of n for obtaining any required precision).

Another application of the theory we developed in previous sections are stochastic games appearing in queueing systems. Such problems may serve as models for situations of conflicts between users in telecommunication systems or for worst-case control situations in the presence of some unknown disturbance (in production systems or again in telecommunications applications). An interesting feature in the control of queueing networks is that, often, infinite queues are easier to handle than finite queues, as some boundary problems are avoided. Moreover, the optimal policies for infinite-horizon problems, being stationary, are easier to implement than those for finite-horizon problems. In real applications, however, queues are always finite; moreover, one is often interested in finite-horizon problems (e.g., controlling manufacturing during working hours, etc.). Our results may thus be applied to obtain almost optimal policies for these cases. Here are some examples:

(i) Altman considered in [3] a stochastic game with an infinite state space in order to solve a flow control problem with an infinite buffer. The solution of the problem with a finite buffer [4] seems more involved and was obtained only under an important restriction on the actions of the flow controller (namely, it had to contain an action that corresponds to rejection of arriving customers).

(ii) Altman and Koole [5] solved a game where one or more servers has to be assigned to customers of different classes. In a telecommunication context, the different classes may represent different traffic types, such as voice, video, and data, and the servers may represent a channel through which the traffic has to be transmitted. A controller has to decide a customer of which class will be served next (which traffic will have access to the channel). The input traffic was assumed to be controlled as well, e.g., it may have been the output of some dynamic routing mechanism or dynamic flow control. The problem was posed as a zero-sum stochastic game between the service controller and "nature" which represented the unknown input control mechanism. Simple structural results were obtained for the case of infinite queues. In the case of finite queues, the structure of optimal policies is unknown, even in the case of uncontrolled input. By applying our second state approximation scheme, it follows that the policies obtained for the problem of infinite queues are almost optimal for

the case of finite queues which are large enough.

9. Further generalizations. Although we considered in this paper bounded rewards, it is well known that different sets of conditions exist for which problems with unbounded reward can be transformed into ones with bounded reward. Such transformations have been used in the past for finite state approximations of Markov decision processes; see White [30]. The generalization of such conditions to games are straightforward (see, e.g., Wessels [28]). (For examples of stochastic games with unbounded costs, see [3], [5].)

There are many other useful directions where the general approximation theorems are applicable, on which we continue our investigation. Among these are

(i) Differential games in which a standard problem is to discretize both space and time. Several works have been done in this direction; see [6], [7], [21], [22], [25], where the convergence (and rate of convergence; see [21]) of the values of the approximating games have been established. However, little is known about the convergence of policies. Theorem 2.1 seems to be a suitable tool for approaching these issues.

(ii) Discretization of stochastic games with general state and action spaces. Some results were obtained in the case of a single controller; see §6 of Hernandez-Lerma [15] and references therein. Further results for stochastic games on the convergence of the value and some results on convergence of policies were obtained by Whitt [31] and then generalized to N-person games in [32] and by Nowak [20].

ON AN INVESTMENT-CONSUMPTION MODEL WITH TRANSACTION COSTS*

MARIANNE AKIAN†, JOSÉ LUIS MENALDI‡, AND AGNÈS SULEM§

Abstract. This paper considers the optimal consumption and investment policy for an investor who has available one bank account paying a fixed interest rate and n risky assets whose prices are log-normal diffusions. We suppose that transactions between the assets incur a cost proportional to the size of the transaction. The problem is to maximize the total utility of consumption. Dynamic programming leads to a variational inequality for the value function. Existence and uniqueness of a viscosity solution are proved. The variational inequality is solved by using a numerical algorithm based on policies, iterations, and multigrid methods. Numerical results are displayed for $n = 1$ and $n = 2$.

Key words. portfolio selection, transaction costs, viscosity solution, variational inequality, multigrid methods

1. Introduction.

This paper concerns the theoretical and numerical study of a portfolio selection problem. Consider an investor who has available one riskless bank account paying a fixed rate of interest r and n risky assets modeled by log-normal diffusions with expected rates of return $\alpha_i > r$ and rates of return variation σ_i^2. The investor consumes at rate $c(t)$ from the bank account. Any movement of money between the assets incurs a transaction cost proportional to the size of the transaction, paid from the bank account. The investor is allowed to have a short position in one of the holdings, but his position vector must remain in the closed solvency region $\mathcal{S}$ defined as the set of positions for which the net wealth is nonnegative. The investor's objective is to maximize over an infinite horizon the expected discounted utility of consumption with a HARA (hyperbolic absolute risk aversion)–type utility function.

This problem was formulated for $n = 1$ by Magill and Constantinides [21], who conjectured that the no-transaction region is a cone in the two-dimensional space of position vectors. This fact was proved in a discrete-time setting by Constantinides [8], who proposed an approximate solution based on some assumptions on the consumption process. Davis and Norman proved, in continuous time and without this restriction, that the optimal strategy confines indeed the investor's portfolio to a wedge-shaped region in the portfolio plane [10]. An analysis of the optimal strategy, together with regularity results for the value function, can be found in Fleming and Soner [13, Chap. 8.7] and Shreve and Soner [28]. Taksar, Klass, and Assaf [31] consider a model without consumption and study the problem of maximizing the long-run average growth of wealth. A deterministic model is solved by Shreve, Soner, and Xu [29] with a general utility function which is not necessarily a HARA-type function. A stochastic model driven by a finite-state Markov chain rather than a Brownian motion and with a general but bounded utility function has been investigated in Zariphopoulou [32]. She supposes that the amount of money allocated in

the assets must remain nonnegative and shows that the value function is the unique constrained viscosity solution of a system of variational inequalities with gradient constraints. Fitzpatrick and Fleming [12] study numerical methods for the optimal investment-consumption model with possible borrowing. They examine a Markov chain discretization of the original continuous problem similar to Kushner's numerical schemes [18]. The convergence arguments rely on viscosity solution techniques.

We consider here Davis and Norman's model [10] in the case where more than one risky asset is allowed. We restrict to power utility functions of the form $\frac{c^\gamma}{\gamma}$ with $0 < \gamma < 1$.

The purpose of the paper is to prove an existence and uniqueness result for the dynamic programming equation associated with this problem and then solve this equation by using an efficient numerical method, the convergence of which is ensured by the uniqueness result.

The mathematical formulation of the problem is given in §2. In §3, we prove that the value function is the unique viscosity solution of a variational inequality. Since the utility and the drift functions are not bounded, uniqueness is not derived from classical results. For the numerical study, an adequate change of variables performed in §4 reduces the dimension of the problem. Then, in §5, the variational inequality is discretized by finite-difference schemes and solved by using an algorithm based on the "Howard algorithm" (policy iteration) and the multigrid method. Numerical results are presented in §6 in the case of one bank account and one or two risky asset(s). They provide the optimal strategy and indicate the shape of the transaction and no-transaction regions. Finally, in §7, a theoretical study of the optimal strategy is done by using properties of the variational inequality; this analysis corroborates the numerical results.

2. Formulation of the problem. Let $(\Omega, \mathcal{F}, P)$ be a fixed complete probability space and $(\mathcal{F}_t)_{t\geq 0}$, a given filtration. We denote by $s_0(t)$ (resp., $s_i(t)$ for $i = 1, \ldots, n$) the amount of money in the bank account (resp., in the ith risky asset) at time t and refer by $s(t) = (s_i(t))_{i=0,\ldots,n}$ the investor position at time t. We suppose that the evolution equations of the investor holdings are

$$(1) \qquad \begin{cases} ds_0(t) = (rs_0(t) - c(t))dt + \displaystyle\sum_{i=1}^{n}(-(1+\lambda_i)d\mathcal{L}_i(t) + (1-\mu_i)d\mathcal{M}_i(t)), \\ ds_i(t) = \alpha_i s_i(t)dt + \sigma_i s_i(t)dW_i(t) + d\mathcal{L}_i(t) - d\mathcal{M}_i(t), \quad i = 1, \ldots, n, \end{cases}$$

with initial values

$$(2) \qquad s_i(0^-) = x_i, \quad i = 0, \ldots, n,$$

where $W_i(t)$, $i = 1, \ldots, n$, are independent Wiener processes, $\mathcal{L}_i(t)$ and $\mathcal{M}_i(t)$ represent cumulative purchase and sale of stock i on $[0, t]$, respectively, and $s(t^-)$ denotes the left-hand limit of the process s at time t. The coefficients λ_i and μ_i represent the proportional transaction costs.

A policy for investment and consumption is a set $(c(t), (\mathcal{L}_i(t), \mathcal{M}_i(t))_{i=1,\ldots,n})$ of adapted processes such that

1. $c(t,\omega) \geq 0$, $\int_0^t c(s,\omega)ds < \infty$ for (t,ω) a.e.,
2. $\mathcal{L}_i(t)$, $\mathcal{M}_i(t)$ are right-continuous and nondecreasing and $\mathcal{L}_i(0^-) = \mathcal{M}_i(0^-) = 0$.

The process $s(t)$ is thus right continuous with the left-hand limit and equations (1) and (2) are equivalent to

$$\begin{cases} s_0(t) &= x_0 + \displaystyle\int_0^t (rs_0(\theta) - c(\theta))d\theta + \sum_{i=1}^n (-(1+\lambda_i)\mathcal{L}_i(t) + (1-\mu_i)\mathcal{M}_i(t)), \\ s_i(t) &= x_i + \displaystyle\int_0^t \alpha_i s_i(\theta)d\theta + \int_0^t \sigma_i s_i(\theta)dW_i(\theta) + \mathcal{L}_i(t) - \mathcal{M}_i(t), \quad i = 1, \ldots, n, \end{cases}$$

for $t \geq 0$.

We define the solvency region as

$$\mathcal{S} = \{x = (x_0, x_1, \ldots, x_n) \in \mathbb{R}^{n+1}, \quad \mathcal{W}(x) \geq 0\},$$

where

$$\mathcal{W}(x) = x_0 + \sum_{i=1}^n \min((1-\mu_i)x_i, (1+\lambda_i)x_i) \tag{3}$$

represents the net wealth, that is, the amount of money in the bank account after performance of the transactions that bring the holdings in the risky assets to zero.

Suppose that the investor is given an initial endowment x in $\mathcal{S}$. A policy is admissible if the bankruptcy time $\overline{\tau}$ defined as

$$\overline{\tau} = \inf\{t \geq 0, s(t) \notin \mathcal{S}\} \tag{4}$$

is infinite. We denote by $\mathcal{U}(x)$ the set of admissible policies. The investor's objective is to maximize over all policies $\mathcal{P}$ in $\mathcal{U}(x)$ the discounted utility of consumption

$$J_x(\mathcal{P}) = E_x \int_0^\infty e^{-\delta t} u(c(t))dt, \tag{5}$$

where E_x denotes expectation given that the initial endowment x, δ is a positive discount factor and $u(c)$ is a utility function defined by

$$u(c) = \frac{c^\gamma}{\gamma}, \quad 0 < \gamma < 1. \tag{6}$$

We define the value function V as

$$V(x) = \sup_{\mathcal{P} \in \mathcal{U}(x)} J_x(\mathcal{P}). \tag{7}$$

We are facing a singular control problem. We refer to Menaldi and Robin [23] and Chow, Menaldi, and Robin [7] for various treatments of singular stochastic control problems.

Remark 2.1. When the process $s(t)$ reaches the boundary $\partial\mathcal{S}$ at time t, i.e., $s(t^-) \in \partial\mathcal{S}$, the only admissible policy is to jump immediately to the origin and remain there with a null consumption (see Shreve, Soner, and Xu [29]). Consequently, if the initial endowment x is on the boundary, then $V(x) = 0$.

Remark 2.2. Let τ denote the exit time of the interior of $\mathcal{S}$, defined as

$$\tau = \inf\left\{t \geq 0, s(t) \notin \mathring{\mathcal{S}}\right\}. \tag{8}$$

For all admissible policies $\mathcal{P}$, we have

$$J_x(\mathcal{P}) = E_x \int_0^\tau e^{-\delta t} u(c(t))dt. \tag{9}$$

On the other hand, for any policy $\mathcal{P}$, we can construct an admissible policy which coincides with $\mathcal{P}$ until time τ (such that the process $s(t)$ jumps to the origin at time τ). The value function can then be rewritten as

$$V(x) = \sup_{\mathcal{P}\in\mathcal{U}} E_x \int_0^\tau e^{-\delta t} u(c(t))dt, \tag{10}$$

where $\mathcal{U}$ is the set of all policies.

We make the assumptions

$$\delta > \gamma\left(r + \frac{1}{2(1-\gamma)}\sum_{i=1}^{n}\left(\frac{\alpha_i - r}{\sigma_i}\right)^2\right), \tag{A.1}$$

$$0 \le \mu_i < 1, \quad \lambda_i \ge 0, \quad \lambda_i + \mu_i > 0 \quad \forall i = 1, \dots, n. \tag{A.2}$$

Remark 2.3. When the transaction costs are equal to zero (Merton's problem), the value function V is finite iff Assumption (A.1) is satisfied (see Davis and Norman [10] for $n = 1$, Karatzas et al. [17], and §7 below).

3. The variational inequality. We state the main theorem.

THEOREM 3.1. *Under Assumptions* (A.1) *and* (A.2),

(i) *the value function V defined in* (7) *or* (10) *is γ-Hölder continuous and concave in $\mathcal{S}$ and nondecreasing with respect to x_i for $i = 0, \dots, n$.*

(ii) *V is the unique viscosity solution of the variational inequality (VI):*

$$\max\left\{AV + u^*\left(\frac{\partial V}{\partial x_0}\right), \max_{1\le i\le n} L_i V, \max_{1\le i\le n} M_i V\right\} = 0 \quad \text{in } \mathring{\mathcal{S}}, \tag{11}$$

$$V = 0 \quad \text{on } \partial\mathcal{S}, \tag{12}$$

where

$$AV = \frac{1}{2}\sum_{i=1}^{n}\sigma_i^2 x_i^2 \frac{\partial^2 V}{\partial {x_i}^2} + \sum_{i=1}^{n}\alpha_i x_i \frac{\partial V}{\partial x_i} + r x_0 \frac{\partial V}{\partial x_0} - \delta V, \tag{13}$$

$$L_i V = -(1+\lambda_i)\frac{\partial V}{\partial x_0} + \frac{\partial V}{\partial x_i}, \tag{14}$$

$$M_i V = (1-\mu_i)\frac{\partial V}{\partial x_0} - \frac{\partial V}{\partial x_i}, \tag{15}$$

and u^* is the convex Legendre transform of u defined by

$$\begin{aligned} u^*(p) &= \max_{c\ge 0}(-cp + u(c)) \\ &= \left(\frac{1}{\gamma} - 1\right) p^{\frac{\gamma}{\gamma-1}}. \end{aligned} \tag{16}$$

The solvency region $\mathcal{S}$ is divided as follows:

$$B_i = \{x \in \mathcal{S},\ L_iV(x) = 0\}, \tag{17}$$

$$S_i = \{x \in \mathcal{S},\ M_iV(x) = 0\}, \tag{18}$$

$$NT_i = \mathcal{S} \setminus (B_i \cup S_i), \tag{19}$$

$$NT = \bigcap_{i=1}^{n} NT_i. \tag{20}$$

NT is the no-transaction region. Outside NT, an instantaneous transaction brings the position to the boundary of NT: buy stock i in B_i, sell stock i in S_i. After the initial transaction, the agent position remains in

$$\overline{NT} = \left\{ x \in \mathcal{S}, AV + u^*\left(\frac{\partial V}{\partial x_0}\right) = 0 \right\},$$

and further transactions occur only at the boundary (see [10]).

We shall first recall the definition of viscosity solutions and then prove points (i) and (ii) of Theorem 3.1 in §3.2 and §3.3, respectively.

3.1. Viscosity solutions of nonlinear elliptic equations. For simplicity, we restrict ourselves to equations with Dirichlet boundary conditions. Consider fully nonlinear elliptic equations of the form

$$F(D^2v, Dv, v, x) = 0 \quad \text{in } \mathcal{O}, \tag{21}$$

$$v = 0 \quad \text{on } \partial\mathcal{O}, \tag{22}$$

where F is a given continuous function in $S^N \times \mathbb{R}^N \times \mathbb{R} \times \mathcal{O}$, S^N is the space of symmetric $N \times N$ matrices, $\mathcal{O}$ is an open domain of $\mathbb{R}^N$, and the ellipticity of (21) is expressed by

$$F(A, p, v, x) \geq F(B, p, v, x) \quad \text{if } A \geq B,\ A, B \in S^N,\ p \in \mathbb{R}^N,\ v \in \mathbb{R},\ x \in \mathcal{O}. \tag{23}$$

A special case of (21) is given by

$$F(X, p, v, x) = \max_{\eta \in U} \left\{ \sum_{i,j=1}^{N} a_{ij}(x, \eta) X_{ij} + \sum_{i=1}^{N} b_i(x, \eta) p_i - \beta(x, \eta) v + u(x, \eta) \right\}, \tag{24}$$

where (23) is satisfied when the matrix $(a_{ij}(x, \eta))_{i,j}$ is symmetric nonnegative in $\mathcal{O} \times U$.

Bellman equations are clearly equations of this type, whereas variational inequalities like (11)–(12) can also be formulated in this form by using an additive discrete control which selects the equation which satisfies the maximum.

DEFINITION 3.2. *Let $v \in C(\overline{\mathcal{O}})$. Then v is a viscosity solution of* (21)–(22) *if the following relations hold, together with* (22):

$$F(X, p, v(x), x) \geq 0 \quad \forall (p, X) \in J^{2,+}v(x),\ \forall x \in \mathcal{O}, \tag{25}$$

$$F(X, p, v(x), x) \leq 0 \quad \forall (p, X) \in J^{2,-}v(x),\ \forall x \in \mathcal{O}, \tag{26}$$

where $J^{2,+}$ and $J^{2,-}$ are the second-order "superjets" defined by

$$J^{2,+}v(x) = \Big\{ (p, X) \in \mathbb{R}^N \times S^N,$$

$$\limsup_{\substack{y \to x \\ y \in \mathcal{O}}} \left[v(y) - v(x) - (p, y - x) - \frac{1}{2}(X(y - x), y - x) \right] |y - x|^{-2} \leq 0 \Big\}$$

and

$$J^{2,-}v(x) = \Big\{(p,X) \in \mathbb{R}^N \times S^N,$$
$$\liminf_{\substack{y \to x \\ y \in \mathcal{O}}} \Big[v(y) - v(x) - (p, y-x) - \frac{1}{2}(X(y-x), y-x)\Big] |y-x|^{-2} \geq 0\Big\}.$$

A viscosity subsolution (resp., supersolution) of (21) is similarly defined as an upper semicontinuous function satisfying (25) (resp., a lower semicontinuous function satisfying (26)) (see Crandall, Ishii, and Lions [9]).

3.2. Properties of the value function.

PROPOSITION 3.3. *The value function V is concave in $\mathcal{S}$.*

Proof. The dynamic (1) is linear, and the solvency region $\mathcal{S}$ is convex. Hence, for any θ in $[0,1]$, x and x' in $\mathcal{S}$, $\mathcal{P}$ in $\mathcal{U}(x)$, and $\mathcal{P}'$ in $\mathcal{U}(x')$, we have $\theta\mathcal{P}+(1-\theta)\mathcal{P}' \in \mathcal{U}(y)$ for $y = \theta x + (1-\theta)x'$ and

$$V(y) \geq J_y(\theta\mathcal{P} + (1-\theta)\mathcal{P}') = E\int_0^{+\infty} e^{-\delta t} u(\theta c(t) + (1-\theta)c'(t))dt.$$

Since u is concave we infer

$$V(y) \geq \theta J_x(\mathcal{P}) + (1-\theta) J_{x'}(\mathcal{P}').$$

Taking now the supremum over all $\mathcal{P}$ and $\mathcal{P}'$, we obtain that V is concave. □

As a consequence, V is locally Lipschitz continuous in $\overset{\circ}{\mathcal{S}}$. The continuity of V at the boundary is a consequence of the Proposition 3.5 below. First let us state the following lemma.

LEMMA 3.4. *Suppose* (A.1) *holds. Then there exists a positive constant a such that the functions*

$$(27)\quad \varphi_\nu(x) = a\left(x_0 + \sum_{i=1}^n (1-\nu_i)x_i\right)^\gamma \quad \text{with } \nu = (\nu_1, \ldots, \nu_n),\ \nu_i = -\lambda_i \text{ or } \mu_i,$$

are classical supersolutions of equation (11). *Consequently, the function*

$$(28)\qquad \varphi(x) = a\left(x_0 + \sum_{i=1}^n \min((1-\mu_i)x_i, (1+\lambda_i)x_i)\right)^\gamma$$

is a viscosity supersolution of equation (11) *such that $\varphi = 0$ on $\partial\mathcal{S}$.*

Proof. Denote

$$(29)\qquad \mathcal{W}_\nu(x) = x_0 + \sum_{i=1}^n (1-\nu_i)x_i.$$

Then

$$(30)\qquad \varphi_\nu(x) = a\mathcal{W}_\nu(x)^\gamma$$

and we have

$$(31)\qquad L_i\varphi_\nu(x) = -(\lambda_i + \nu_i)a\gamma\mathcal{W}_\nu(x)^{\gamma-1} \leq 0,$$

$$M_i\varphi_\nu(x) = (\mu_i - \nu_i)a\gamma\mathcal{W}_\nu(x)^{\gamma-1} \le 0, \tag{32}$$
$$A\varphi_\nu(x) = a\gamma\mathcal{W}_\nu(x)^{\gamma-2}G(x)$$

with

$$G(x) = \frac{1}{2}\sum_{i=1}^{n}\sigma_i^2 x_i^2(1-\nu_i)^2(\gamma-1) + \mathcal{W}_\nu(x)\left(\sum_{i=1}^{n}(\alpha_i - r)x_i(1-\nu_i)\right) + \mathcal{W}_\nu(x)^2\left(r - \frac{\delta}{\gamma}\right).$$

From Assumption (A.1), there exists $\eta > 0$ such that

$$\frac{\delta}{\gamma} - r - \eta \ge \frac{1}{2(1-\gamma)}\sum_{i=1}^{n}\left(\frac{\alpha_i - r}{\sigma_i}\right)^2.$$

This implies

$$G(x) \le -\eta\mathcal{W}_\nu(x)^2$$

and

$$A\varphi_\nu(x) \le -a\gamma\eta\mathcal{W}_\nu(x)^\gamma = -\gamma\eta\varphi_\nu(x). \tag{33}$$

Moreover

$$u^*\left(\frac{\partial\varphi_\nu}{\partial x_0}(x)\right) = u^*(a\gamma\mathcal{W}_\nu(x)^{\gamma-1}) = \left(\frac{1}{\gamma} - 1\right)(a\gamma)^{\frac{\gamma}{\gamma-1}}\mathcal{W}_\nu(x)^\gamma = (1-\gamma)(a\gamma)^{\frac{1}{\gamma-1}}\varphi_\nu(x).$$

The constant a can then be chosen such that

$$A\varphi_\nu + u^*\left(\frac{\partial\varphi_\nu}{\partial x_0}\right) \le 0 \quad \text{in } \mathring{\mathcal{S}}. \tag{34}$$

Since (31), (32), and (34) hold and $\varphi_\nu \ge 0$ on $\partial\mathcal{S}$, φ_ν is a classical supersolution of (11) (continuous in $\mathcal{S}$ and twice continuously differentiable in $\mathring{\mathcal{S}}$).

Now, φ can be rewritten as

$$\varphi = \min_\nu \varphi_\nu.$$

Consequently, φ is a viscosity supersolution of (11) as the minimum of continuous supersolutions and clearly vanishes on $\partial\mathcal{S}$. □

PROPOSITION 3.5. *Suppose* (A.1) *holds. The value function* V *satisfies*

$$0 \le V(x) \le \varphi(x) \qquad \forall x \in \mathcal{S}, \tag{35}$$

where φ *is the supersolution defined by* (28). *Consequently,* V *is continuous in* $\mathcal{S}$.

Proof. Consider $x \in \mathcal{S}$ and $\mathcal{P} \in \mathcal{U}$ and denote by τ the first exit time of $\mathring{\mathcal{S}}$ of the process $s(t)$ defined by (1) with $s(0^-) = x$. The function φ_ν defined in (27) has $\mathcal{C}^2$-regularity and is a classical supersolution of (11). Denote by A^c the operator

$A - c\frac{\partial}{\partial x_0}$ and by $\mathcal{L}_i^c(t)$ and $\mathcal{M}_i^c(t)$ the continuous parts of $\mathcal{L}_i(t)$ and $\mathcal{M}_i(t)$. We apply Ito's formula for càdlàg processes (see Meyer [25]) to $e^{-\delta t}\varphi_\nu(s(t))$. For any stopping time θ, the process

$$
\begin{aligned}
&e^{-\delta(\theta\wedge\tau)}\varphi_\nu(s(\theta\wedge\tau)) \\
&-\int_0^{\theta\wedge\tau} e^{-\delta t}\left\{A^{c(t)}\varphi_\nu(s(t))dt + \sum_{i=1}^n [L_i\varphi_\nu(s(t))d\mathcal{L}_i^c(t) + M_i\varphi_\nu(s(t))d\mathcal{M}_i^c(t)]\right\} \\
&-\sum_{0\le t\le\theta\wedge\tau} e^{-\delta t}[\varphi_\nu(s(t)) - \varphi_\nu(s(t^-))]
\end{aligned}
$$

is a martingale.

Since $s(t)$ has a jump only when $\mathcal{L}_i(t)$ or $\mathcal{M}_i(t)$ is discontinuous, we have

$$
\begin{aligned}
\mathcal{W}_\nu(s(t)) &= \mathcal{W}_\nu(s(t^-)) \\
&\quad -\sum_{i=1}^n [(\lambda_i+\nu_i)(\mathcal{L}_i(t) - \mathcal{L}_i(t^-)) + (\mu_i - \nu_i)(\mathcal{M}_i(t) - \mathcal{M}_i(t^-))] \\
&\le \mathcal{W}_\nu(s(t^-)).
\end{aligned}
$$

Hence,

$$\varphi_\nu(s(t)) \le \varphi_\nu(s(t^-)).$$

In addition, $\mathcal{L}_i^c$ and $\mathcal{M}_i^c$ are nondecreasing. Consequently

$$M_t^\nu = e^{-\delta(t\wedge\tau)}\varphi_\nu(s(t\wedge\tau)) + \int_0^{t\wedge\tau} e^{-\delta\theta}u(c(\theta))d\theta \tag{36}$$

is a supermartingale, as is the process $\min_\nu M_t^\nu$. Therefore

$$E\int_0^\tau e^{-\delta t}u(c(t))dt \le \varphi(x).$$

Taking the supremum over all policies $\mathcal{P}\in\mathcal{U}$, we get $V(x)\le\varphi(x)$. As $V(x)\ge 0$, we conclude that $V(x) = 0$ on ∂S and that V is continuous on ∂S. Since V is locally Lipschitz continuous in $\mathring{\mathcal{S}}$, V is continuous in $\mathcal{S}$. □

The regularity of V can be stated as follows.

PROPOSITION 3.6. *Suppose* (A.1) *holds. Then V is uniformly γ-Hölder continuous in $\mathcal{S}$, that is,*

$$\exists C>0,\quad |V(x)-V(x')| \le C\|x-x'\|^\gamma \qquad \forall x,x'\in\mathcal{S}. \tag{37}$$

Proof. Consider two initial positions x and x', and denote by τ (resp., τ') the first exit time of $\mathring{\mathcal{S}}$ of the process $s(t)$ (resp., $s'(t)$) defined by (1) and $s(0^-) = x$ (resp., $s'(0^-) = x'$). We have

$$
\begin{aligned}
V(x) - V(x') &= \sup_{\mathcal{P}\in\mathcal{U}} E\int_0^\tau e^{-\delta t}u(c(t))dt - \sup_{\mathcal{P}\in\mathcal{U}} E\int_0^{\tau'} e^{-\delta t}u(c(t))dt \\
&\le \sup_{\mathcal{P}\in\mathcal{U}} E\left(\int_0^\tau e^{-\delta t}u(c(t))dt - \int_0^{\tau'} e^{-\delta t}u(c(t))dt\right) \\
&\le \sup_{\mathcal{P}\in\mathcal{U}} E\int_{\tau\wedge\tau'}^\tau e^{-\delta t}u(c(t))dt.
\end{aligned}
$$

Using the supermartingale property of $\min_{\nu} M_t^{\nu}$ defined in (36), we get

$$E\int_{\tau\wedge\tau'}^{\tau} e^{-\delta t}u(c(t))dt \le E(e^{-\delta(\tau\wedge\tau')}\varphi(s(\tau\wedge\tau')) - e^{-\delta\tau}\varphi(s(\tau))),$$

and since φ vanishes on $\partial\mathcal{S}$, we have

$$V(x) - V(x') \le \sup_{\mathcal{P}\in\mathcal{U}} E(e^{-\delta\tau'}(\varphi(s(\tau')) - \varphi(s'(\tau')))1_{\tau'<\tau}),$$

where 1_A denotes the characteristic function of the set A.

Let us fix for instance $\|x\| = \sup_{i=0,\dots,n}|x_i|$. The function φ is γ-Hölder continuous, that is,

$$|\varphi(x) - \varphi(x')| \le C\|x - x'\|^{\gamma}$$

for some positive constant C. We thus get

$$V(x) - V(x') \le C\sup_{\mathcal{P}\in\mathcal{U}} E(e^{-\delta\tau'}\|(s(\tau') - s'(\tau')\|^{\gamma}1_{\tau'<\tau}). \tag{38}$$

The process $\Sigma(t) = s(t) - s'(t)$ is a diffusion process with generator $A + \delta I$ and initial value $\Sigma(0) = x - x'$.

If the function $\psi(x) = \|x\|^{\gamma}$ would satisfy $A\psi \le 0$, then $\psi(\Sigma(\tau\wedge t))e^{-\delta(\tau\wedge t)}$ would be a supermartingale which would readily lead to (37). Because ψ is not smooth, we consider the function $\psi_\beta(x) = \sum_{i=0}^{n}(x_i^2 + \beta)^{\gamma/2}$ with $\beta > 0$. We have

$$A\psi_\beta = \gamma(x_0^2+\beta)^{(\frac{\gamma}{2}-1)}\left(\left(r - \frac{\delta}{\gamma}\right)x_0^2 - \frac{\delta}{\gamma}\beta\right) + \sum_{i=1}^{n}\gamma(x_i^2+\beta)^{(\frac{\gamma}{2}-2)}f_i$$

with

$$f_i = x_i^4\left(\frac{1}{2}\sigma_i^2(\gamma-1) + \alpha_i - \frac{\delta}{\gamma}\right) + x_i^2\beta\left(\frac{1}{2}\sigma_i^2 + \alpha_i - \frac{2\delta}{\gamma}\right) - \frac{\delta}{\gamma}\beta^2.$$

Assumption (A.1) implies

$$r - \frac{\delta}{\gamma} < 0 \quad \text{and} \quad \frac{1}{2}\sigma_i^2(\gamma-1) + \alpha_i - \frac{\delta}{\gamma} < 0.$$

Consequently, there exists a positive constant C such that

$$A\psi_\beta \le C\beta^{\gamma/2}.$$

Applying Ito's formula to ψ_β, we obtain

$$E(e^{-\delta(\tau'\wedge\tau)}\psi_\beta(\Sigma(\tau'\wedge\tau))) \le \psi_\beta(x - x') + \frac{C}{\delta}\beta^{\gamma/2}. \tag{39}$$

Taking the limit of (39) when β goes to zero and using

$$\psi(x) \le \psi_0(x) \le (n+1)\psi(x)$$

we get

$$E(e^{-\delta(\tau'\wedge\tau)}\psi(\Sigma(\tau'\wedge\tau))) \le (n+1)\psi(x - x'),$$

which leads, together with (38), to the desired estimate (37). □

PROPOSITION 3.7. *V is nondecreasing with respect to x_i for $i = 0, \dots, n$.*

Proof. Let us denote explicitly by $s(t,x)$ the process $s(t)$ defined in (1) with initial value x and by τ_x the exit time of $\overset{\circ}{\mathcal{S}}$ of $s(t,x)$. Because

$$V(x) = \sup_{\mathcal{P}\in\mathcal{U}} E \int_0^{\tau_x} e^{-\delta t} u(c(t))dt$$

and u is positive, it is enough to prove the nondecreasing property of the stopping time τ_x for any control process $\mathcal{P}$.

Define $y(t,x)$ by

$$\begin{cases} y_0(t,x) &= e^{-rt} s_0(t,x), \\ y_i(t,x) &= e^{-(\alpha_i - \frac{1}{2}\sigma_i^2)t - \sigma_i W_i(t)} s_i(t,x), \quad i = 1, \dots, n. \end{cases}$$

The process $y(t,x)$ evolves according to

$$(40)\begin{cases} dy_0(t,x) &= e^{-rt}\left(-c(t)dt + \sum_{i=1}^{n}(-(1+\lambda_i)d\mathcal{L}_i(t) + (1-\mu_i)d\mathcal{M}_i(t))\right), \\ dy_i(t,x) &= e^{-(\alpha_i - \frac{1}{2}\sigma_i^2)t - \sigma_i W_i(t)}(d\mathcal{L}_i(t) - d\mathcal{M}_i(t)) \end{cases}$$

and satisfies $y(0,x) = x$. Hence, we can write

$$y(t,x) = x + Y(t,\mathcal{P}),$$

where $Y(t,\mathcal{P})$ depends only on $\mathcal{P}$. Consequently,

$$(41) \qquad s(t,x) = (e^{rt}x_0, (e^{(\alpha_i - \frac{1}{2}\sigma_i^2)t + \sigma_i W_i(t)} x_i)_{i=1,\dots,n}) + S(t,\mathcal{P}),$$

where $S(t,\mathcal{P})$ is a process which is independent of x.

Consider $\tilde{x} \geq x$ (i.e., $\tilde{x}_i \geq x_i \ \forall i = 0, \dots, n$) and fix $\mathcal{P}$ in $\mathcal{U}$. We have from (41)

$$s(t,x) \leq s(t,\tilde{x})$$

and

$$\mathcal{W}(s(t,x)) \leq \mathcal{W}(s(t,\tilde{x})),$$

where $\mathcal{W}$ is defined in (3).

Since

$$\tau_{\tilde{x}} = \inf\{t \geq 0,\ \mathcal{W}(s(t,\tilde{x})) \leq 0\}$$

for any $t > \tau_{\tilde{x}}$, there exists t' such that $\tau_{\tilde{x}} < t' < t$ and $\mathcal{W}(s(t',\tilde{x})) \leq 0$. This implies $\mathcal{W}(s(t',x)) \leq 0$ and $t > t' \geq \tau_x$. Consequently, $\tau_{\tilde{x}} \geq \tau_x$ and $V(\tilde{x}) \geq V(x)$. □

3.3. Existence and uniqueness results. First, we show that the value function V is a viscosity solution of the variational inequality (11). The problem is reduced to prove a weak dynamic programming principle (see Fleming and Soner [13]).

LEMMA 3.8. *There exists $C > 0$ such that*

$$(42) \qquad |J_x(\mathcal{P}) - J_{x'}(\mathcal{P})| \leq C\|x - x'\|^\gamma \quad \forall x, x' \in \mathcal{S}, \quad \forall \mathcal{P} \in \mathcal{U},$$

where $J_x(\mathcal{P})$ is given in (9).

Proof. Estimate (42) is readily obtained from the proof of Proposition 3.6. □

PROPOSITION 3.9. *The weak dynamic programming principle is satisfied for the value function V, that is,*

$$V(x) = \sup_{\mathcal{P}\in\mathcal{U}} E\left(\int_0^{\theta\wedge\tau} e^{-\delta t}u(c(t))dt + e^{-\delta(\theta\wedge\tau)}V(s((\theta\wedge\tau)^-))\right) \quad \forall x \in \mathcal{S} \tag{43}$$

for any stopping time θ.

Proof. By means of the Markov property, we have for all $\mathcal{P}$ in $\mathcal{U}$

$$E^{\mathcal{F}^{\theta\wedge\tau}}\int_0^{\tau} e^{-\delta t}u(c(t))dt = \int_0^{\theta\wedge\tau} e^{-\delta t}u(c(t))dt + e^{-\delta(\theta\wedge\tau)}J_{s((\theta\wedge\tau)^-)}(\mathcal{P}'),$$

with $\mathcal{P}'$ equal to $\mathcal{P}$ "shifted" by $\theta\wedge\tau$. Note that $\mathcal{P}'$ may not be admissible. The correct method would be to proceed with admissible systems composed with a filtration $(\Omega, \mathcal{F}_t, P)$, a Wiener process $W = (W_i)_{i=1,\dots,n}$ in $\mathbb{R}^n$, and an admissible control process $\mathcal{P}$ and consider V as the supremum of $J_x(\mathcal{P})$ over all admissible systems instead of the supremum over all admissible policies. We give here a formal proof. Rigorous proofs are given in Fleming and Soner [13], Nisio [26], El Karoui [11], and Lions [19]. Thus,

$$\begin{aligned} J_x(\mathcal{P}) &= E\left(\int_0^{\theta\wedge\tau} e^{-\delta t}u(c(t))dt + e^{-\delta(\theta\wedge\tau)}J_{s((\theta\wedge\tau)^-)}(\mathcal{P}')\right) \\ &\le E\left(\int_0^{\theta\wedge\tau} e^{-\delta t}u(c(t))dt + e^{-\delta(\theta\wedge\tau)}V(s((\theta\wedge\tau)^-))\right). \end{aligned}$$

By taking the supremum over all policies $\mathcal{P}$, we deduce one inequality side of (43). For the reverse inequality, we need to construct nearly optimal controls for each initial state x in a measurable way. To that purpose, consider $\varepsilon > 0$ and $\{\mathcal{S}^k\}_{k=1}^{\infty}$ a sequence of disjoint subsets of $\mathcal{S}$ such that

$$\bigcup_{k=1}^{\infty} \mathcal{S}^k = \mathcal{S}, \qquad \text{diameter}(\mathcal{S}^k) < \varepsilon.$$

For any k, take x^k in $\mathcal{S}^k$ and $\mathcal{P}^k = (c^k, (\mathcal{L}_i^k, \mathcal{M}_i^k)_{i=1,\dots,n})$ in $\mathcal{U}$ such that

$$V(x^k) - \varepsilon \le J_{x^k}(\mathcal{P}^k). \tag{44}$$

Now, for a given stopping time θ and an arbitrary policy $\mathcal{P}$ in $\mathcal{U}$, we define $\mathcal{P}^\theta = (c^\theta, (\mathcal{L}_i^\theta, \mathcal{M}_i^\theta)_{i=1,\dots,n})$ with

$$\begin{aligned} c^\theta(t) &= c(t)1_{t<\theta} + c^k(t-\theta)1_{t\ge\theta}, \\ \mathcal{L}_i^\theta(t) &= \mathcal{L}_i(t)1_{t<\theta} + (\mathcal{L}_i(\theta^-) + \mathcal{L}_i^k(t-\theta))1_{t\ge\theta}, \\ \mathcal{M}_i^\theta(t) &= \mathcal{M}_i(t)1_{t<\theta} + (\mathcal{M}_i(\theta^-) + \mathcal{M}_i^k(t-\theta))1_{t\ge\theta} \end{aligned}$$

for $s(\theta^-) \in \mathcal{S}^k$. Using (42) and (44) we have

$$\begin{aligned} J_{s(\theta^-)}(\mathcal{P}^k) &= (J_{s(\theta^-)}(\mathcal{P}^k) - J_{x^k}(\mathcal{P}^k)) + J_{x^k}(\mathcal{P}^k) \\ &\ge -C\varepsilon^\gamma - \varepsilon + V(x^k) \\ &\ge -2C\varepsilon^\gamma - \varepsilon + V(s(\theta^-)). \end{aligned}$$

Denote by I the right-hand side of (43). There exists a policy $\mathcal{P}$ such that

$$I - \varepsilon \leq E\left(\int_0^{\theta\wedge\tau} e^{-\delta t}u(c(t))dt + e^{-\delta(\theta\wedge\tau)}V(s((\theta\wedge\tau)^-))\right),$$

and using the Markov property, we get

$$I - \varepsilon \leq J_x(\mathcal{P}^{\theta\wedge\tau}) + (2C\varepsilon^\gamma + \varepsilon)$$

and

$$I - 2C\varepsilon^\gamma - 2\varepsilon \leq J_x(\mathcal{P}^{\theta\wedge\tau}) \leq V(x),$$

which leads to (43). □

COROLLARY 3.10. *The value function $V(x)$ defined by* (10) *is a viscosity solution of the variational inequality* (11)–(12).

In the case of pure diffusion processes, this is a standard result of the theory of viscosity solutions (see Lions [20]). For singular stochastic control problems, we refer to Fleming and Soner [13, Chap. 8, Thm. 5.1].

PROPOSITION 3.11. *Under Assumptions* (A.1) *and* (A.2), *the value function V is the unique viscosity solution of the variational inequality* (11)–(12) *in the class of continuous functions in $\mathcal{S}$ which satisfy*

$$|V(x)| \leq C(1 + \|x\|^\gamma) \qquad \forall x \in \mathcal{S}. \tag{45}$$

Proof. By Corollary 3.10 and equation (35), the value function V is a viscosity solution of (11)–(12) and satisfies (45). Uniqueness is a consequence of the following maximum principle.

LEMMA 3.12. *If v is a viscosity subsolution and v' is a viscosity supersolution of* (11) *which satisfy* (45) *and $v \leq v'$ on $\partial\mathcal{S}$, then $v \leq v'$ in $\mathcal{S}$.*

Indeed, a viscosity solution of (11)–(12) is both a subsolution and a supersolution with the boundary condition $v = 0$ on $\partial\mathcal{S}$. We prove Lemma 3.12 by using the Ishii technique; in particular we adapt the proofs of Theorems 3.3 and 5.1 of Crandall, Ishii, and Lions [9]. They are themselves based on the following corollary of Theorem 3.2 of [9].

LEMMA 3.13. *Let V be an upper semicontinuous function and V' be a lower semicontinuous function in an open domain $\mathcal{O}$ of $\mathbb{R}^N$. Consider $W(x,y) = V(x) - V'(y) - \frac{k}{2}|x-y|^2$ with $k > 0$ and suppose that $(\hat{x},\hat{y})$ is a local maximum of W. Then there exist two matrices X and Y in S^N such that*

$$(k(\hat{x}-\hat{y}), X) \in \overline{J}^{2,+}V(\hat{x}), \quad (k(\hat{x}-\hat{y}), Y) \in \overline{J}^{2,-}V'(\hat{y})$$

and

$$\begin{pmatrix} X & 0 \\ 0 & -Y \end{pmatrix} \leq 3k \begin{pmatrix} I & -I \\ -I & I \end{pmatrix}. \tag{46}$$

In this statement, $|.|$ denotes the euclidian norm and I the identity $N \times N$ matrix and $\overline{J}^{2,+}$ is defined as follows:

$$\overline{J}^{2,+}v(x) = \{(p,X) \in \mathbb{R}^N \times S^N,\ \exists (x_n, p_n, X_n) \in \mathcal{O} \times \mathbb{R}^N \times S^N,$$
$$(p_n, X_n) \in J^{2,+}v(x_n),\ \text{and}\ (x_n, v(x_n), p_n, X_n) \underset{n\to\infty}{\to} (x, v(x), p, X)\}.$$

$\overline{J}^{2,-}$ is similarly defined. If F is a continuous function in $S^N \times \mathbb{R}^N \times \mathbb{R} \times \mathcal{O}$ satisfying the elliptic condition (23), and v is a viscosity subsolution of (21), we have

$$F(X, p, v(x), x) \geq 0 \quad \forall (p, X) \in \overline{J}^{2,+} v(x), \quad \forall x \in \mathcal{O}. \tag{47}$$

Consider now v and v' as in Lemma 3.12 and argue by contradiction in order to prove $v \leq v'$ in $\mathcal{S}$. Suppose that there exists z in $\mathcal{S}$ such that $v(z) - v'(z) > 0$. For $k > 0$, define the function w_k in $\mathcal{S} \times \mathcal{S}$ as

$$w_k(x, y) = v(x) - v'(y) - \frac{k}{2}|x - y|^2 - \varepsilon(\mathcal{W}_\nu(x)^{\gamma'} + \mathcal{W}_\nu(y)^{\gamma'}),$$

where

$$\mathcal{W}_\nu(x) = x_0 + \sum_{i=1}^{n} (1 - \nu_i) x_i$$

and ν, ε, and γ' are parameters which will be chosen further. In addition, denote

$$m_k = \sup_{(x,y) \in \mathcal{S} \times \mathcal{S}} w_k(x, y).$$

In the following, C, C_1, and C_2 denote generic constants.

LEMMA 3.14. *For $\nu = (\nu_i)_{i=1,\ldots,n}$ with $-\lambda_i < \nu_i < \mu_i$, there exist C_1 and $C_2 > 0$ such that*

$$C_1|x| \leq \mathcal{W}_\nu(x) \leq C_2|x| \quad \forall x \in \mathcal{S}. \tag{48}$$

Proof. The second inequality of (48) is straightforward. To obtain the first inequality, we use the nonnegativity of $\mathcal{W}$ (defined in (3)) in $\mathcal{S}$:

$$\mathcal{W}_\nu(x) = \mathcal{W}(x) - \sum_{i=1}^{n} \min((\nu_i - \mu_i)x_i, (\nu_i + \lambda_i)x_i) \geq C \sum_{i=1}^{n} |x_i| \geq 0.$$

Moreover,

$$|x_0| = \left| \mathcal{W}_\nu(x) - \sum_{i=1}^{n} (1 - \nu_i) x_i \right| \leq \mathcal{W}_\nu(x) + C \sum_{i=1}^{n} |x_i| \leq C \mathcal{W}_\nu(x).$$

Consequently,

$$|x| \leq C \mathcal{W}_\nu(x). \qquad \square$$

Fix $\gamma' > \gamma$ such that Assumption (A.1) is still valid with γ' instead of γ, and ν as in Lemma 3.14. This guarantees $m_k < +\infty$ (see Lemma 3.15). On the other hand, we have

$$m_k \geq \overline{m} = \sup_{x \in \mathcal{S}} \{v(x) - v'(x) - 2\varepsilon \mathcal{W}_\nu(x)^{\gamma'}\} \geq v(z) - v'(z) - 2\varepsilon \mathcal{W}_\nu(z)^{\gamma'}.$$

As $v(z) > v'(z)$, there exists $\varepsilon > 0$ such that $m_k \geq \overline{m} > 0$ for any k; in the following, we consider such ε.

LEMMA 3.15. *Consider $\gamma' > \gamma$ and ν as in Lemma 3.14. There exist x_k, y_k in $\mathcal{S}$ such that*

$$m_k = w_k(x_k, y_k) < +\infty,$$

$$k|x_k - y_k|^2 \underset{k\to\infty}{\to} 0, \tag{49}$$

and

$$m_k \underset{k\to\infty}{\to} \overline{m} \equiv \sup_{x\in\mathcal{S}}\{v(x) - v'(x) - 2\varepsilon\mathcal{W}_\nu(x)^{\gamma'}\}. \tag{50}$$

Proof. Since v and v' satisfy (45), we have

$$m_k \le C + \sup_{x\in\mathcal{S}}(C_1|x|^\gamma - C_2|x|^{\gamma'}) < +\infty.$$

Let (x^n, y^n) be a maximizing sequence:

$$w_k(x^n, y^n) \ge m_k - \frac{1}{n} \ge \overline{m} - \frac{1}{n},$$

which implies that

$$C_2|x^n|^{\gamma'} - C_1|x^n|^\gamma \le C.$$

Hence, x^n is bounded, and similarly y^n is bounded. Consequently, there exists a converging subsequence of (x^n, y^n), and the limit $(x_k, y_k) \in \mathcal{S}\times\mathcal{S}$ realizes the maximum of w_k. As

$$v(x_k) - v'(y_k) - \varepsilon(\mathcal{W}_\nu(x_k)^{\gamma'} + \mathcal{W}_\nu(y_k)^{\gamma'}) = m_k + \frac{k}{2}|x_k - y_k|^2 \ge 0$$

for any k, we conclude that x_k, y_k, and $k|x_k - y_k|^2$ are bounded. Moreover, for any subsequence of (x_k, y_k) converging to $(\hat{x}, \hat{y})$ when k goes to infinity, we have $\hat{x} = \hat{y}$, and using $m_k \ge \overline{m}$, we get

$$\limsup_{k\to\infty} \frac{k}{2}|x_k - y_k|^2 \le v(\hat{x}) - v'(\hat{x}) - 2\varepsilon\mathcal{W}_\nu(\hat{x})^{\gamma'} - \overline{m} \le 0.$$

Consequently, (49) and (50) are satisfied. □

Now, since $\overline{m} > 0$ and $v \le v'$ on $\partial\mathcal{S}$, the limit $\hat{x}$ of x_k and y_k is in $\mathring{\mathcal{S}}$; then for any converging subsequence of (x_k, y_k), we have $(x_k, y_k) \in \mathring{\mathcal{S}}\times\mathring{\mathcal{S}}$ for large k. Applying Lemma 3.13 with $V = v - \varepsilon\mathcal{W}_\nu{}^{\gamma'}$ and $V' = v' + \varepsilon\mathcal{W}_\nu{}^{\gamma'}$ at the point (x_k, y_k) in $\mathring{\mathcal{S}}\times\mathring{\mathcal{S}}$, we obtain that there exist X, Y in S^{n+1} satisfying (46) such that

$$\begin{aligned}(p_k, X_k) &\equiv \Big(k(x_k - y_k) + \varepsilon\gamma'\mathcal{W}_\nu(x_k)^{\gamma'-1}\hat{p}, X + \varepsilon\gamma'(\gamma'-1)\mathcal{W}_\nu(x_k)^{\gamma'-2}A\Big)\\ &\in \overline{J}^{2,+}v(x_k),\end{aligned} \tag{51}$$

$$\begin{aligned}(p'_k, Y_k) &\equiv \Big(k(x_k - y_k) - \varepsilon\gamma'\mathcal{W}_\nu(y_k)^{\gamma'-1}\hat{p}, Y - \varepsilon\gamma'(\gamma'-1)\mathcal{W}_\nu(y_k)^{\gamma'-2}A\Big)\\ &\in \overline{J}^{2,-}v'(y_k)\end{aligned} \tag{52}$$

with $\hat{p} = (1, 1-\nu_1, \dots, 1-\nu_n)$ and $A = \hat{p}^t\hat{p}$.

Denote

$$F(X,p,v,x) = \max\left(F_0(X,p,v,x) + u^*(p_0), \max_{1\le i\le n} G_i(p), \max_{1\le i\le n} H_i(p)\right),$$

$$F_0(X,p,v,x) = \frac{1}{2}\sum_{i=1}^{n}\sigma_i^2 x_i^2 X_{ii} + \sum_{i=1}^{n}\alpha_i x_i p_i + r x_0 p_0 - \delta v,$$

$$G_i(p) = -(1+\lambda_i)p_0 + p_i,$$

$$H_i(p) = (1-\mu_i)p_0 - p_i,$$

where $X = (X_{ij})_{i,j=0,\dots,n}$, $p = (p_i)_{i=0,\dots,n}$.

Note that although F is continuous, F takes its values in $\mathbb{R}\cup\{+\infty\}$, since $F = +\infty$ when $p_0 \le 0$. This leads to a difficulty to obtain a uniform continuity property similar to [9, eq. (3.14)], and consequently straightforward application of the results of [9] cannot be used. Moreover, as the discount factor δ appears only in the F_0 component of F and not in G_i and F_i, property [9, eq. (3.13)], that is,

$$F(X,p,v,x) - F(X,p,v',x) \le -\lambda(v-v') \text{ for } v \ge v', \text{ with } \lambda > 0,$$

is not satisfied.

Using that v is a viscosity subsolution and v' is a viscosity supersolution of (11) (that is, of $F(D^2v, Dv, v, x) = 0$ in $\mathring{\mathcal{S}}$) and using (51) and (52), we get

$$F(X_k, p_k, v(x_k), x_k) \ge 0,$$
$$F(Y_k, p'_k, v'(y_k), y_k) \le 0.$$

This last inequality implies $G_i(p'_k) \le 0$ and $H_i(p'_k) \le 0$, and by linearity of G_i and H_i, we obtain

$$G_i(p_k) = G_i(p'_k) - \varepsilon\gamma'(\mathcal{W}_\nu(x_k)^{\gamma'-1} + \mathcal{W}_\nu(y_k)^{\gamma'-1})(\lambda_i+\nu_i) < 0$$

and

$$H_i(p_k) = H_i(p'_k) + \varepsilon\gamma'(\mathcal{W}_\nu(x_k)^{\gamma'-1} + \mathcal{W}_\nu(y_k)^{\gamma'-1})(\nu_i-\mu_i) < 0.$$

This leads to

$$F_0(X_k, p_k, v(x_k), x_k) + u^*((p_k)_0) \ge 0 \ge F_0(Y_k, p'_k, v'(y_k), y_k) + u^*((p'_k)_0).$$

Using now that u^* is nonincreasing and $(p'_k)_0 < (p_k)_0$, we obtain

$$F_0(X_k, p_k, v(x_k), x_k) - F_0(Y_k, p'_k, v'(y_k), y_k) \ge 0.$$

Hence,

$$\begin{aligned}(53)\qquad 0 \le{}& \frac{1}{2}\sum_{i=1}^{n}\sigma_i^2((x_k)_i^2 X_{ii} - (y_k)_i^2 Y_{ii})\\ &+k\left(\sum_{i=1}^{n}\alpha_i((x_k)_i - (y_k)_i)^2 + r((x_k)_0 - (y_k)_0)^2\right)\\ &-\delta(v(x_k) - v'(y_k) - \varepsilon(\mathcal{W}_\nu(x_k)^{\gamma'} + \mathcal{W}_\nu(y_k)^{\gamma'}))\\ &+\varepsilon(f(x_k) + f(y_k)),\end{aligned}$$

where

$$\begin{aligned} f(x) &= \frac{1}{2}\sum_{i=1}^{n}\sigma_i^2 x_i^2\gamma'(\gamma'-1)\mathcal{W}_\nu(x)^{\gamma'-2}A_{ii} \\ &\quad + \sum_{i=1}^{n}\alpha_i x_i\gamma'\mathcal{W}_\nu(x)^{\gamma'-1}\hat{p}_i + rx_0\gamma'\mathcal{W}_\nu(x)^{\gamma'-1}\hat{p}_0 \\ &\quad - \delta\mathcal{W}_\nu(x)^{\gamma'} \\ &= \gamma'\mathcal{W}_\nu(x)^{\gamma'}\left[r - \frac{\delta}{\gamma'} + \sum_{i=1}^{n}(\alpha_i - r)y_i + \frac{(\gamma'-1)}{2}\sum_{i=1}^{n}\sigma_i^2 y_i^2\right] \end{aligned}$$

with

$$y_i = \frac{(1-\nu_i)x_i}{\mathcal{W}_\nu(x)}.$$

We have

$$f(x) \le \gamma'\mathcal{W}_\nu(x)^{\gamma'}\left[r - \frac{\delta}{\gamma'} + \frac{1}{2(1-\gamma')}\sum_{i=1}^{n}\left(\frac{\alpha_i - r}{\sigma_i}\right)^2\right],$$

and since γ' is such that (A.1) is satisfied, $f(x) \le 0 \ \ \forall x \in \mathbb{R}^{n+1}$. Using (46), we see that the first term of the right-hand side of (53) is bounded by $Ck|x_k - y_k|^2$. Hence,

$$0 \le Ck|x_k - y_k|^2 - \delta m_k \underset{k\to\infty}{\to} -\delta\overline{m} < 0.$$

We thus get a contradiction, and Lemma 3.12 and Proposition 3.11 are proven. □

4. Change of variables.

4.1. Reduction of the state dimension. The value function V defined by (7) has the homothetic property (see [10])

$$\forall \rho > 0,\ V(\rho x) = \rho^\gamma V(x). \tag{54}$$

Consequently, the $(n+1)$-dimensional VI (11)–(12) satisfied by V can be reduced to a n-dimensional VI by using the following homogeneous model, that is, by considering the new state variables:

$$\begin{cases} \rho = x_0 + \sum_{i=1}^{n}(1-\mu_i)x_i & \text{(net wealth)}, \\ y_i = \dfrac{(1-\mu_i)x_i}{\rho}, \quad i = 1,\dots,n & \text{(fraction of net wealth invested in stock } i) \end{cases} \tag{55}$$

and the new control variable

$$C = \frac{c}{\rho} \quad \text{(fraction of net wealth dedicated to consumption)}. \tag{56}$$

The function $V(x)$ can be written as

$$\begin{aligned} V(x) &= V\left(\rho\left(1 - \sum_{i=1}^{n} y_i\right), \frac{\rho y_1}{(1-\mu_1)}, \dots, \frac{\rho y_n}{(1-\mu_n)}\right) \\ &= \rho^\gamma W(y), \end{aligned} \tag{57}$$

where the function

$$W(y) = V\left(1 - \sum_{i=1}^{n} y_i, \frac{y_1}{(1-\mu_1)}, \ldots, \frac{y_n}{(1-\mu_n)}\right) \tag{58}$$

is defined in

$$\tilde{\mathcal{S}} = \left\{ y = (y_1, \ldots, y_n) \in \mathbb{R}^n,\ 1 - \sum_{i=1}^{n} \frac{\lambda_i + \mu_i}{1-\mu_i} \{y_i\}^- \geq 0 \right\}$$

with $\{y\}^- = \max(0, -y)$.

Using inequality (35) we deduce that the function W is bounded in $\tilde{\mathcal{S}}$:

$$0 \leq W(y) \leq \varphi\left(1 - \sum_{i=1}^{n} y_i, \frac{y_1}{(1-\mu_1)}, \ldots, \frac{y_n}{(1-\mu_n)}\right) \leq a. \tag{59}$$

The function W is the unique viscosity solution of

$$\max\left(\tilde{A}W + u^*(BW), \max_{1\leq i\leq n} \tilde{L}_i W, \max_{1\leq i\leq n} \tilde{M}_i W\right) = 0 \quad \text{in } \overset{\circ}{\tilde{\mathcal{S}}}, \tag{60}$$

$$W = 0 \quad \text{on } \partial\tilde{\mathcal{S}}, \tag{61}$$

where

$$\tilde{A}W = \sum_{j,k=1}^{n} a_{jk} \frac{\partial^2 W}{\partial y_j \partial y_k} + \sum_{j=1}^{n} b_j \frac{\partial W}{\partial y_j} - \beta W, \tag{62}$$

$$BW = \gamma W - \sum_{j=1}^{n} y_j \frac{\partial W}{\partial y_j}, \tag{63}$$

$$\tilde{L}_i W = \frac{\partial W}{\partial y_i} - \left(\frac{\lambda_i + \mu_i}{1-\mu_i}\right) BW, \tag{64}$$

$$\tilde{M}_i W = -\frac{\partial W}{\partial y_i} \tag{65}$$

and

$$a_{jk} = \frac{y_j y_k}{2} \sum_{i=1}^{n} \sigma_i^2 (\delta_{ki} - y_i)(\delta_{ji} - y_i), \tag{66}$$

$$b_j = y_j \sum_{i=1}^{n} [(\gamma - 1)\sigma_i^2 y_i + \alpha_i - r](\delta_{ij} - y_i), \tag{67}$$

$$\beta = \delta - \gamma\left(r + \sum_{i=1}^{n} \left[(\alpha_i - r)y_i + \frac{\gamma - 1}{2}\sigma_i^2 y_i^2\right]\right). \tag{68}$$

The symbol δ_{ij} denotes the Kronecker index, which is equal to 0 when $i \neq j$ and equal to 1 when $i = j$.

Using the properties of V and (60), we deduce that W is concave, nonnegative, and nondecreasing with respect to each coordinate y_i.

Remark 4.1. Equations (60)–(61) depend only on $\nu = (\nu_i)_{i=1\ldots n}$ with $\nu_i = (\lambda_i + \mu_i)/(1 - \mu_i)$, and so does the function W. Denote by $V_{\lambda,\mu}$ the value function (7) in order to express explicitly the dependency of V on the transaction costs and by $W_{\lambda,\mu}$ the solution of (60)–(61). We have

$$\begin{aligned} W_{\lambda,\mu}(y) &= W_{\nu,0}(y) \\ &= V_{\nu,0}\left(1 - \sum_{i=1}^{n} y_i, y_1, \ldots, y_n\right). \end{aligned} \tag{69}$$

Using (54), we get

$$V_{\lambda,\mu}(x) = V_{\nu,0}(x_0, (1-\mu_1)x_1, \ldots, (1-\mu_n)x_n). \tag{70}$$

Consequently, it is sufficient to compute the value function V when the transaction costs on sale are equal to zero.

This remark could have been observed directly from the model. Indeed, the quantity $s_i(t)$ represents the amount of money in the ith risky asset at time t, that is, the quantity of the ith asset multiplied by the reference price $P_i(t)$. This reference price is useless in practice unless the transaction costs are time dependent. What matters for the investor is the buying price $(1 + \lambda_i)P_i$ and the selling price (or net price) $(1 - \mu_i)P_i$. The relevant quantity to consider is the net value of the ith asset, that is, $(1 - \mu_i)s_i$. Purchase of dL_i units of the ith asset increases the net value of this asset by $dL'_i = (1 - \mu_i)dL_i$ and requires a payment of $(1 + \nu_i)dL'_i$, whereas sale of dM_i units reduces the net value by $dM'_i = (1 - \mu_i)dM_i$ and realizes effectively dM'_i in cash. Consequently, by using a formulation of the problem based on the net values $(1 - \mu_i)s_i$ of the assets, the value function depends only on the coefficients ν_i, where ν_i represents the proportional transaction cost on purchase with respect to the net price of the ith asset.

4.2. Additional treatment for numerical purpose. Our purpose is now to solve equations (60)–(61).

In order to simplify the numerical computation, we restrict the admissible region $\mathcal{S}$ to

$$\mathcal{S}^+ = \left\{ x \in \mathbb{R}^{n+1},\ x_1, \ldots, x_n \geq 0,\ x_0 + \sum_{i=1}^{n} (1 - \mu_i)x_i \geq 0 \right\};$$

that is, we suppose that the amounts of money allocated in the risky assets are nonnegative, while the amount of money in the bank account can be negative as long as the net wealth remains nonnegative. This is not restrictive since, when $\alpha_i > r$, the no-transaction cone is inside $\mathcal{S}^+$ and a trajectory which starts in $\mathcal{S}^+$ remains in $\mathcal{S}^+$ (see [10] for $n = 1$).

This leads to the study of VI (60) in the domain $(\mathbb{R}^+)^n$:

$$\max\left(\tilde{A}W + u^*(BW), \max_{1\leq i\leq n} \tilde{L}_i W, \max_{1\leq i\leq n,\ y_i>0} \tilde{M}_i W\right) = 0 \quad \text{in } (\mathbb{R}^+)^n. \tag{71}$$

This VI degenerates at the boundary and is valid up to the boundary, but the controls which make the trajectory go out of the domain are not admissible. Note that the function W has bounded derivatives in $(\mathbb{R}^+)^n$.

We proceed with a technical change of variables which brings $(\mathbb{R}^+)^n$ to $[0,1]^n$, namely,

$$\text{(72)} \qquad \begin{cases} \psi(z) = \theta(z)W(y), \\ \theta(z) = \displaystyle\prod_{i=1}^{n}(1-z_i), \\ z_i = \dfrac{y_i}{1+y_i}, \quad i = 1,\dots,n. \end{cases}$$

The function ψ is bounded and concave with respect to z_i, $i = 1,\dots,n$, has bounded derivatives, and satisfies

$$\text{(73)} \qquad \begin{cases} \max\left(\overline{A}\psi + \sup\limits_{C\geq 0}\left(-C\overline{B}\psi + \theta(z)\dfrac{C^\gamma}{\gamma}\right), \max\limits_{1\leq i\leq n}\overline{L}_i\psi, \max\limits_{i,\, z_i>0}\overline{M}_i\psi\right) = 0 \quad \text{in } [0,1)^n, \\ \psi = 0 \quad \text{on } [0,1]^n \cap \{z_i = 1\} \quad \forall i = 1,\dots,n, \end{cases}$$

where

$$\begin{aligned} \overline{A}\psi &= \sum_{j,k=1}^{n} a'_{jk}\frac{\partial^2\psi}{\partial z_j \partial z_k} + \sum_{j=1}^{n} b'_j\frac{\partial\psi}{\partial z_j} - \beta'\psi, \\ \overline{B}\psi &= \left(\gamma - \sum_{j=1}^{n} z_j\right)\psi - \sum_{j=1}^{n} z_j(1-z_j)\frac{\partial\psi}{\partial z_j}, \\ \overline{L}_i\psi &= (1-z_i)\left(\psi + (1-z_i)\frac{\partial\psi}{\partial z_i}\right) - \lambda_i\overline{B}\psi, \\ \overline{M}_i\psi &= -(1-z_i)\left(\psi + (1-z_i)\frac{\partial\psi}{\partial z_i}\right), \end{aligned}$$

with

$$\begin{aligned} a'_{jk} &= \frac{1}{2}z_j(1-z_j)z_k(1-z_k)\overline{a}_{jk}, \\ b'_j &= z_j(1-z_j)\left(\overline{b}_j + \sum_{\substack{k=1 \\ k\neq j}}^{n} z_k\overline{a}_{jk}\right), \\ \beta' &= \beta - \sum_{j=1}^{n} z_j\overline{b}_j - \sum_{\substack{j,k=1 \\ j\neq k}}^{n} \overline{a}_{jk}\frac{z_j z_k}{2}, \\ \overline{a}_{jk} &= \sum_{i=1}^{n}\sigma_i^2\left(\delta_{ki} - \frac{z_i}{1-z_i}\right)\left(\delta_{ji} - \frac{z_i}{1-z_i}\right), \\ \overline{b}_j &= \sum_{i=1}^{n}\left((\gamma-1)\sigma_i^2\frac{z_i}{1-z_i} + \alpha_i - r\right)\left(\delta_{ij} - \frac{z_i}{1-z_i}\right) \end{aligned}$$

and β defined in (68).

The numerical study is organized as follows: equation (73) is solved by using the numerical methods explained in §5 below. Then a reverse change of variable is performed in order to display the numerical results for equation (71) (see §6).

5. Numerical methods. We consider equations of the form

$$\begin{cases} \max\limits_{P \in \mathcal{P}_{ad}} (A^P W + u(P)) = 0 & \text{in } \Omega = [0,1]^m \setminus \Gamma, \\ W = 0 & \text{on } \Gamma, \end{cases} \tag{74}$$

where A^P is a second-order degenerate elliptic operator

$$A^P W(x) = \sum_{i,j=1}^{m} a_{ij}(x,P) \frac{\partial^2 W}{\partial x_i \partial x_j}(x) + \sum_{i=1}^{m} b_i(x,P) \frac{\partial W}{\partial x_i}(x) - \beta(x,P) W(x)$$

with

$$\sum_{i,j=1}^{m} a_{ij}(x,P)\eta_i\eta_j \geq 0, \qquad \beta(x,P) \geq 0 \qquad \forall x \in \Omega,\ \eta \in \mathbb{R}^m,\ P \in \mathcal{P}_{ad}.$$

$\mathcal{P}_{ad}$ is a closed subset of $\mathbb{R}^k$ (which may depend on x) and Γ is a part of the boundary $\partial\Omega$, which consists of faces of the m-cube $[0,1]^m$. On $\partial\Omega \setminus \Gamma$, the operator A^P is degenerate.

In §3, we have proven that the value function (7), within a change of variables, is the unique viscosity solution of an equation of type (74). This solution can be approximate by the following numerical method: (i) Discretize (74) by using a consistent finite-difference approximation which satisfies the discrete maximum principle (DMP) (recalled below). (ii) Solve the discrete equation by means of the value iteration (successive approximation) algorithm or the Howard algorithm (policy iteration). This method does not require any stronger regularity condition on the viscosity solution (see Barles and Souganidis [3], Fleming and Soner [13]). The algorithms mentioned in (ii) may be replaced by the (full) multigrid–Howard algorithm (FMGH), introduced in Akian [1], [2] and based on the Howard algorithm and the multigrid method. This algorithm is more efficient, but proof of convergence has been obtained only when the DMP is satisfied, the feedbacks are regular, and the Bellman equation is strongly elliptic.

For the numerical solution of (74), we use a classical finite-difference discretization in a regular grid and the FMGH algorithm. Convergence arguments used in [1], [2] cannot be applied here since the DMP is not satisfied (because of the presence of mixed derivatives), the equation is degenerate, and the control is singular. Nevertheless, numerical experiments show that this numerical method converges.

This procedure and the computer implementation are treated by using the expert system *Pandore* (see Chancelier, et al. [6], Akian [2]), which has been developed to automate studies in stochastic control.

5.1. Discretization. Let $h = 1/N$ ($N \in \mathbb{N}^*$) denote the finite-difference step in each coordinate direction, e_i the unit vector in the ith coordinate direction, and $x = (x_1, \ldots, x_m)$ a point of the uniform grid $\Omega_h = \Omega \cap (h\mathbb{Z})^m$. Equation (74) is discretized by replacing the first- and second-order derivatives of W by the following approximation:

$$\frac{\partial W}{\partial x_i} \sim \frac{W(x + he_i) - W(x - he_i)}{2h} \tag{75}$$

or

$$\frac{\partial W}{\partial x_i} \sim \begin{cases} \dfrac{W(x+he_i)-W(x)}{h} & \text{when} \quad b_i(x,P) \geq 0, \\ \dfrac{W(x)-W(x-he_i)}{h} & \text{when} \quad b_i(x,P) < 0. \end{cases} \tag{76}$$

$$\frac{\partial^2 W}{\partial x_i^2}(x) \sim \frac{W(x+he_i)-2W(x)+W(x-he_i)}{h^2}, \tag{77}$$

$$\begin{aligned} \frac{\partial^2 W}{\partial x_i \partial x_j}(x) \sim{}& \frac{W(x+he_i+he_j)-W(x+he_i-he_j)}{4h^2} \\ &+ \frac{W(x-he_i-he_j)-W(x-he_i+he_j)}{4h^2} \qquad \text{for } i \neq j. \end{aligned} \tag{78}$$

Approximation (75) may be used when A is uniformly elliptic, whereas (76) has to be used when A is degenerate (see Kushner [18]). These differences are computed in the entire grid Ω_h by extending W to the "boundary" of Ω_h in $(h\mathbb{Z})^m$:

$$\begin{aligned} W(x) &= 0 \qquad \forall x \in \Gamma \cap (h\mathbb{Z})^m, \\ W(x-he_i) &= W(x) \quad \forall x \in \{x_i = 0\} \cap \Omega_h, \\ W(x+he_i) &= W(x) \quad \forall x \in \{x_i = 1\} \cap \Omega_h. \end{aligned}$$

We obtain a system of N_h nonlinear equations of N_h unknowns $\{W_h(x),\ x \in \Omega_h\}$:

$$\max_{P \in \mathcal{P}_{ad}} (A_h^P W_h + u(P))(x) = 0 \quad \forall x \in \Omega_h, \tag{79}$$

where $N_h = \sharp\Omega_h \sim 1/h^m$. Let $\mathcal{P}_h$ denote the set of control functions $P : \Omega_h \to \mathcal{P}_{ad}$ and $\mathcal{V}_h$ the set of functions from Ω_h into $\mathbb{R}$. Equation (79) can be rewritten

$$\max_{P \in \mathcal{P}_h} (A_h^P W_h + u(P)) = 0, \quad W_h \in \mathcal{V}_h.$$

Then, the operator A_h^P, depending on P in $\mathcal{P}_h$, maps $\mathcal{V}_h$ into itself (or is a $N_h \times N_h$ matrix).

Because of the degeneracy of the operator A^P at some points of the closed m-cube $\overline{\Omega}$ and the presence of mixed derivatives, A_h^P does not satisfy the usual DMP (i.e., $(A_h^P W_h(x) \leq 0 \ \ \forall x \in \Omega_h) \Rightarrow (W_h(x) \geq 0 \ \ \forall x \in \Omega_h)$). Consequently, equation (79) may not be stable, even for small step h. However, A_h^P can be written as the sum of a symmetric negative definite operator and an operator which satisfies the DMP; we thus infer the stability of A_h^P, which is confirmed by numerical experiments.

We describe below the available algorithms to solve equation (79).

5.2. The value iteration method. Suppose that the $N_h \times N_h$ matrix A_h^P satisfies

$$(A_h^P)_{ij} \geq 0 \ \ \forall i \neq j, \qquad \sum_{j=1}^{N_h} (A_h^P)_{ij} = -\lambda < 0 \ \ \forall i, \tag{80}$$

which implies that A_h^P satisfies the DMP. Equation (79) can be rewritten as

$$W_h = \frac{1}{1+\lambda k} \max_{P \in \mathcal{P}_h} (M^P W_h + k u(P)), \tag{81}$$

where $k > 0$ and $M^P = I + k(A_h^P + \lambda I)$ is a Markov matrix. (I is the $N_h \times N_h$ identity matrix.) Equation (79) can then be interpreted as the dynamic programming equation of a control problem of Markov chain with discount factor $1/(1+\lambda k)$, instantaneous cost $ku(P)$, and transition matrix M^P:

$$\max_{(P_n)} \sum_{n=0}^{\tau} \frac{k}{(1+\lambda k)^{n+1}} u(X_n, P_n).$$

The value iteration method (see Bellman [5]) consists in the contraction iteration

$$W^{n+1} = \frac{1}{1+\lambda k} \max_{P \in \mathcal{P}_h} (M^P W^n + ku(P)). \tag{82}$$

The contracting factor is $1/(1+\lambda k) = 1 - \mathcal{O}(h^2)$ and the complexity[1] of the method is

$$C_h = \mathcal{O}\left(\frac{-\log h}{h^2} N_h\right) = \mathcal{O}(-h^{-(2+m)} \log h) = \mathcal{O}(N_h^{1+2/m} \log N_h).$$

When the operator A_h^P does not satisfy the DMP, equation (79) cannot be interpreted as a discrete Bellman equation. Nevertheless, the iterative method (82) can still be used if we find λ and k such that the L^2 norm of M^P (which is no more a Markov matrix) is lower than 1 for all P. This condition may be obtained for instance when the discount factor $\beta(x, P)$ is large enough.

An example of the use of the value iteration algorithm is given in Sulem [30] for solving the one-dimensional investment-consumption problem.

5.3. The multigrid–Howard algorithm. Another classical algorithm is the Howard algorithm (see Howard [16], Bellman [4], [5]), also named policy iteration. It consists of an iteration algorithm on the control and value functions (starting from P^0 or W^0):

$$\text{for } n \geq 1, \quad P^n \in \operatorname*{Argmax}_{P \in \mathcal{P}_h} (A_h^P W^{n-1} + u(P)), \tag{83}$$

$$\text{for } n \geq 0, \quad W^n \text{ is the solution of } A_h^{P^n} W + u(P^n) = 0. \tag{84}$$

When A_h^P satisfies the DMP, the sequence W^n decreases and converges to the solution of (79) and the convergence is in general superlinear [4], [5], [1], [2].

The exact computation of step (84) is expensive in dimension $m \geq 2$. (The complexity of a direct method is $\mathcal{O}(N_h^{3-2/m})$.) We thus use the multigrid–Howard algorithm introduced in [1], [2]: in (84), W^n is computed by a multigrid method with initial value W^{n-1}. The advantage is that each multigrid iteration takes a computing time of $\mathcal{O}(N_h)$ and contracts the error by a factor independent of the discretization step h. For a detailed description of the multigrid algorithm, see, for example, McCormick [22], Hackbusch [14], and Hackbusch and Trottenberg [15].

Let $\mathcal{M}^P$ denote the operator of an iteration of the multigrid method associated with the equation $A_h^P W + u(P) = 0$. Starting from W^0, we proceed with the following iteration:

$$\left\{ \begin{array}{l} (83), \\ \text{for } n \geq 1 \left\{ \begin{array}{l} W^{n,0} = W^{n-1}, \\ \text{for } i = 1 \text{ to } m_n, \ W^{n,i} = \mathcal{M}^{P^n}(W^{n,i-1}), \\ W^n = W^{n,m_n}. \end{array} \right. \end{array} \right. \tag{85}$$

[1] The number of elementary operations for computing an approximation of the solution of (79) with an error in the order of the discretization error.

This algorithm converges to the solution W_h^* of (79) if W^0 is sufficiently close to W_h^* and m_n is large enough (independently of the step h) [1], [2].

We introduce now the FMGH algorithm, which solves equation (79) from any initial value W^0.

5.4. The FMGH algorithm. This algorithm [1], [2] fully uses the idea of the full multigrid method (see, for example, Hackbusch and Trottenberg [15]).

Consider the sequence of grids $(\Omega_k)_{k\geq 1}$ of steps $h_k = 2^{-k}$ and denote by $\mathcal{I}_k^{k+1}$ the operator of the m-linear interpolation from $\mathcal{V}_{h_k}$ into $\mathcal{V}_{h_{k+1}}$.

If $W_k \in \mathcal{V}_{h_k}$, $W_{k+1} = \mathcal{I}_k^{k+1} W_k$ is defined by

$$\begin{cases} W_{k+1}(x) = W_k(x) & \forall x \in \Omega_k \subset \Omega_{k+1}, \\ W_{k+1}\left(\dfrac{x+y}{2}\right) = \dfrac{W_{k+1}(x) + W_{k+1}(y)}{2} & \forall x, y \in \Omega_{k+1} \text{ such that } \dfrac{x+y}{2} \in \Omega_{k+1} \\ & \text{and } x,\ y \text{ are in the same cell of } \Omega_k, \end{cases}$$

where a cell of Ω_h is a m-cube of width h included in $\overline{\Omega}$ and with vertices in $(h\mathbb{Z})^m$.

The FMGH algorithm is defined as

For $1 \leq k \leq \overline{k}$,

$W_k^{\overline{n}}$ is the $\overline{n}$th iteration of the sequence defined by (85) in the grid Ω_k of initial value W_k^0.

For $1 \leq k < \overline{k}$,

$W_{k+1}^0 = \mathcal{I}_k^{k+1} W_k^{\overline{n}}$.

Under appropriate assumptions (strong ellipticity, DMP, regularity of the feedback; see [1], [2]), the error between $W_k^{\overline{n}}$ and the solution W_k^* of (79) with $h = h_k$ is in the order of the discretization error for any k. This property is realized for any initial value W_1^0, if the numbers m_n and $\overline{n}$ are large enough (but independent of the level k). Consequently, this algorithm solves equation (79) (with an error in the order of the discretization error) with a computing time of $\mathcal{O}(N_h)$.

6. Numerical results. Equation (71) is solved in $(\mathbb{R}^+)^n$ by using the FMGH algorithm for $n = 1$ and $n = 2$ and various numerical values of the parameters.

Remark 6.1. The regions B_i and S_i defined in (17) and (18) are characterized by

$$B_i = \{x \in \mathcal{S},\ \tilde{L}_i W(y) = 0,\ y \text{ given by (55)}\},$$
$$S_i = \{x \in \mathcal{S},\ \tilde{M}_i W(y) = 0,\ y \text{ given by (55)}\},$$

where the operators $\tilde{L}_i$ and $\tilde{M}_i$ are defined in (64) and (65). By extension we use the notation

$$B_i = \{y \in (\mathbb{R}^+)^n,\ \tilde{L}_i W(y) = 0\},$$
$$S_i = \{y \in (\mathbb{R}^+)^n,\ \tilde{M}_i W(y) = 0\},$$
$$NT_i = (\mathbb{R}^+)^n \backslash (B_i \cup S_i), \tag{86}$$
$$NT = \bigcap_{i=1}^{n} NT_i.$$

6.1. One risky asset. Numerical tests are performed with $\gamma = 0.3$, $\delta = 10\%$, $r = 7\%$, $\alpha_1 = 11\%$, $\sigma_1 = 30\%$, $\nu = \nu_1 = (\lambda_1 + \mu_1)/(1 - \mu_1) = 0.1, 0.3, 0.5, 1, 2, 3$ or 4%. These values of ν are obtained for example when $\lambda_1 = \mu_1 \simeq \nu/2 = 0.05$, 0.15, 0.25, 0.5, 1, 1.5, 2%.

When $\nu > 0$, the regions B_1 and S_1 are of the form (see §7) : $B_1 = [0, \pi^-]$ and $S_1 = [\pi^+, +\infty)$ with $0 < \pi^- < \pi^+$. When $\nu = 0$ (no transaction costs), the optimal policy is to keep a constant proportion of risky asset equal to π_1^* (given by (90) below), that is $\pi^+ = \pi^- = \pi_1^*$. In our example, $\pi_1^* = 0.635$. The values of π^+ and π^- are given in Table 1 and displayed in Fig. 1 as functions of ν.

TABLE 1.

ν (%)	0.1	0.3	0.5	1	2	3	4
π^-	0.56	0.54	0.52	0.47	0.42	0.39	0.36
π^+	0.68	0.68	0.68	0.68	0.68	0.68	0.68

The graphs of π^+ and π^- are similar to those obtained by Davis and Norman [10] who already observed that the "sell-barrier" is very insensitive to the transaction cost, while the "buy-barrier" decreases rapidly as ν increases. Indeed, even if the selling cost is high, the risky asset must be sold before it can be realized for consumption. On the other hand, it may not be worthwhile to invest in the risky asset if the transaction costs are too high.

The value function W, solution of (71), and the optimal consumption C are displayed in Figs. 2 and 3.

From equations (71) and (86), we obtain $W(y) = c(1 + \nu y)^\gamma$ in B_1, where c is a constant depending on ν. In S_1, W is constant and seems insensitive to the transaction costs. This means that when the initial proportion in the risky asset is in S_1, the probability of a future purchase is small. On the other hand, if the initial proportion invested in stock is in B_1, loss of profit (when ν increases) is due mainly to the first transaction.

The values of C are not relevant in B_1 and S_1 since the investor makes transactions and thus does not consume. As expected, C decreases in $[\pi^-, \pi^+]$, as does the fraction of wealth in cash.

6.2. Two risky assets. We set $\gamma = 0.3$, $\delta = 10\%$, and $r = 7\%$ and fix the parameters of the first risky asset to $\alpha_1 = 11\%$, $\sigma_1 = 30\%$, and $\nu_1 = (\lambda_1 + \mu_1)/(1 - \mu_1) = 1\%$.

Four tests are performed:

test 1: $\alpha_2 = 15\%$, $\sigma_2 = 35\%$, $\nu_2 = 2\%$,
test 2: $\alpha_2 = 15\%$, $\sigma_2 = 35\%$, $\nu_2 = 0.5\%$,
test 3: $\alpha_2 = 15\%$, $\sigma_2 = 35\%$, $\nu_2 = 1\%$,
test 4: $\alpha_2 = 20\%$, $\sigma_2 = 50\%$, $\nu_2 = 1\%$.

For test 1, the value function W, the optimal consumption C, and their contour lines are displayed in Figs. 4–7.

The partition of the domain is displayed for each test in Figs. 8–11. As expected, nine regions appear: buy (resp., sell) asset i when y_i is below (resp., above) a critical level π_i^- (resp., π_i^+) depending on y_j ($j \neq i$) and no transaction between π_i^- and π_i^+.

After the first transaction, the position of the investor evolves as a diffusion process with reflection on the boundary of NT. The direction of the reflection is given by the equation $L_i W = 0$ on the frontier with B_i and $M_i W = 0$ on the frontier with S_i.

Note that the no-transaction interval for the first asset $NT_1 \cap \{y_2 = \text{constant}\} \simeq [0.39, 0.78]$ is much larger than the no-transaction interval $[0.47, 0.68]$ obtained in dimension 1, when only one asset (with same parameters) is available. This is not surprising since the second asset has larger expected rate of return; it is thus more interesting to make transactions on the second asset.

We observe that the boundaries of the regions B_i and S_i seem at first to be straight lines (y_i = constant). This would mean that the investment policies are decoupled although the dynamics are correlated. In fact, when the cost for purchase ν_2 grows, the region NT_2 grows as expected but the boundaries of S_1 and B_1 are also perturbed. Moreover, a variation of α_2 and σ_2 affect both NT_2 and NT_1. A theoretical study of the boundaries is done below in order to confirm these remarks.

7. Theoretical analysis of the optimal strategy.

7.1. No transaction costs: The Merton problem. When the transaction costs are equal to zero, the optimal investment strategy is to keep a constant fraction of total wealth in each risky asset (see Merton [24], Sethi and Taksar [27], Karatzas, et al. [17], and Davis and Norman [10]). Indeed, set $\lambda = \mu = 0$ in equation (71). We obtain

$$(87)\quad \max\left(\tilde{A}W + u^*(BW),\ \max_{1\le i\le n} \frac{\partial W}{\partial y_i},\ \max_{1\le i\le n,\ y_i>0}\left(-\frac{\partial W}{\partial y_i}\right)\right) = 0 \quad \text{in } (\mathbb{R}^+)^n,$$

which is equivalent to

$$\begin{cases} W = \text{ constant}, \\ -\beta(y)W + u^*(\gamma W) \leq 0 \quad \forall y \in (\mathbb{R}^+)^n, \end{cases} \tag{88}$$

with $\beta(y)$ defined in (68). Uniqueness of the solution of (88) is not guaranteed since Assumption (A.2) is not satisfied, but the function W defined in (58) is the minimal solution of VI (87). Hence, we have

$$\max_{y \in (\mathbb{R}^+)^n} \{-\beta(y)W + u^*(\gamma W)\} = 0. \tag{89}$$

Equation (89) coincides with the Bellman equation of the problem where the proportion y_i is considered as a control variable (see [10]). Under Assumption (A.1), the optimal proportion denoted by π_i^* and called the Merton proportion is given by

$$\pi_i^* = \frac{\alpha_i - r}{\sigma_i^2(1-\gamma)}. \tag{90}$$

The optimal fraction of wealth dedicated to consumption is

$$C^* = \frac{1}{1-\gamma}\left(\delta - \gamma\left(r + \frac{1}{2(1-\gamma)}\sum_{i=1}^{n}\left(\frac{\alpha_i - r}{\sigma_i}\right)^2\right)\right),$$

and the value function W is equal to

$$W = \frac{C^{*(\gamma-1)}}{\gamma}.$$

The regions "sell i" and "buy i" are characterized by

$$B_i = \{y \in (\mathbb{R}^+)^n,\ y_i \leq \pi_i^*\},$$
$$S_i = \{y \in (\mathbb{R}^+)^n,\ y_i \geq \pi_i^*\}.$$

Note that these regions are not obtained by merely setting $\lambda = \mu = 0$ in (86) but by taking the limit of these expressions when λ and μ tend to 0.

7.2. A general shape of the transaction regions. In this section, we derive formally from VI (71), without numerical computation, the general shape of the transaction regions, given in Fig. 12. To that purpose, we assume the function W to be $\mathcal{C}^2$ in the interior of $(\mathbb{R}^+)^n$. Although this is not true in general, what is done below can be adapted by using the theory of viscosity solutions. This approach is used for example in Fleming and Soner [13] to obtain regularity results for the value function V and general properties of the transaction regions for $n = 1$.

From (71), we have $\tilde{M}_i W \leq 0$; in addition, the concavity of W implies that $\tilde{M}_i W = -\frac{\partial W}{\partial y_i}$ is nondecreasing with respect to y_i. Consequently, the region S_i defined in (86) can be written as

$$S_i = \{y \in (\mathbb{R}^+)^n,\ y_i \geq \pi_i^+(\hat{y})\},$$

where π_i^+ is some mapping of

$$\hat{y} = (y_1, \ldots, y_{i-1}, y_{i+1}, \ldots, y_n).$$

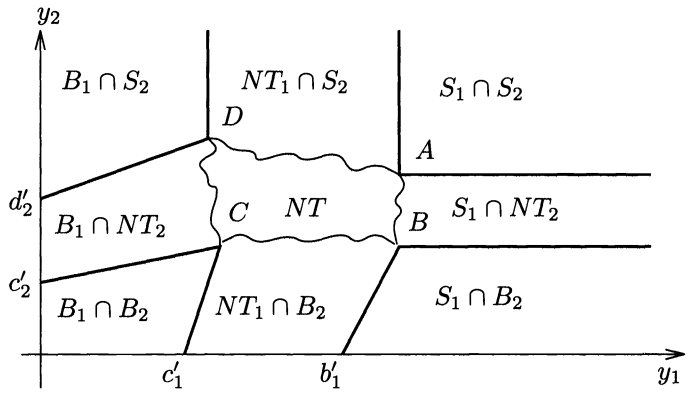

FIG. 12. *General shape of the transaction regions.*

To obtain a similar characterization for B_i, we consider another change of variables (ρ', y') obtained by substituting $-\lambda_i$ for μ_i in (55) for some fixed $i \in \{1, \dots, n\}$. Proceeding as above, and using Remark 6.1, we obtain

$$B_i = \{y \in (\mathbb{R}^+)^n,\ y_i' \leq \pi_i'^{-}(\hat{y}')\} \tag{91}$$

with

$$y_i' = \frac{(1+\nu_i)y_i}{1+\nu_i y_i} \quad \text{and} \quad \hat{y}' = \frac{1}{1+\nu_i y_i}\hat{y}, \tag{92}$$

where ν_i is defined in Remark 4.1. Since y_i' is non decreasing with respect to y_i, we get

$$B_i = \left\{ y \in (\mathbb{R}^+)^n,\ y_i \leq \pi_i^- \left(\frac{1}{1+\nu_i y_i}\hat{y} \right) \right\}.$$

Suppose $\pi_i^+ < +\infty$ and $\pi_i^- > 0$. This implies that π_i^+ and π_i^- are continuous functions and that the regions S_i and B_i are connected.

We restrict ourselves to the case $n = 2$, but what is done below can easily be generalized to $n > 2$.

In S_1, $\tilde{M}_1 W = -\frac{\partial W}{\partial y_1} = 0$. The function W is thus constant with respect to y_1 in S_1. Consequently the parts of the boundaries ∂B_2 and ∂S_2 included in S_1 are straight lines of equation $y_2 =$ constant. Similarly, using the change of variables (92) with $i = 1$, we infer that the parts of the boundaries ∂B_2 and ∂S_2 included in B_1 are straight lines of equation

$$y_2' = \frac{y_2}{1+\nu_1 y_1} = \text{constant}.$$

By symmetry, we get similar properties for the boundaries ∂B_1 and ∂S_1 as displayed in Fig. 12. No other property has been obtained for the boundary of NT.

A question which arises now is how is located the "Merton proportion" π^*. In general, π^* is not necessarily in the region NT. Nevertheless, we have the following proposition.

PROPOSITION 7.1. *We use the notation of Fig.* 12:

$$A = (a_1, a_2) = \partial S_1 \cap \partial S_2, \qquad B = (b_1, b_2) = \partial S_1 \cap \partial B_2,$$

$$C = (c_1, c_2) = \partial B_1 \cap \partial B_2, \qquad D = (d_1, d_2) = \partial B_1 \cap \partial S_2,$$

$$c_1' = \frac{c_1}{1+\nu_2 c_2}, \quad b_1' = \frac{b_1}{1+\nu_2 b_2}, \quad c_2' = \frac{c_2}{1+\nu_1 c_1}, \quad d_2' = \frac{d_2}{1+\nu_1 d_1}$$

and set

$$\tilde{\pi}_i^* = \begin{cases} \dfrac{\pi_i^*}{1+\nu_i - \nu_i \pi_i^*} & \text{if} \quad \pi_i^* < 1 + \dfrac{1}{\nu_i}, \\ +\infty & \text{otherwise.} \end{cases}$$

Then

$$\pi_1^* \le a_1, b_1', \quad \pi_2^* \le a_2, d_2'$$

and

$$d_1, c_1' \le \tilde{\pi}_1^*, \quad b_2, c_2' \le \tilde{\pi}_2^*.$$

Proof. We prove $\pi_i^* \le a_i$, $i = 1, 2$. The other inequalities are obtained similarly by using the change of variables (92). In $S_1 \cap S_2$, the function W is equal to a constant W_0 and satisfies (71), which reduces to

$$-\beta(y) W_0 + u^*(\gamma W_0) \le 0$$

with $\beta(y)$ given in (68). Hence,

$$-\beta(y) + (1-\gamma)\gamma^{\frac{1}{\gamma-1}} W_0^{\frac{1}{\gamma-1}} \le 0 \quad \forall y \in S_1 \cap S_2.$$

On the other hand, the point A is in $S_1 \cap S_2 \cap \overline{NT}$. Assuming that W is C^2 at point A, we obtain

$$\tilde{A} W + u^*(BW) = 0 \tag{93}$$

and

$$-\beta(A) + (1-\gamma)\gamma^{1/\gamma - 1} W_0^{\frac{1}{\gamma-1}} = 0.$$

Consequently

$$\beta(y) \ge \beta(A) \quad \forall y \in S_1 \cap S_2 = [a_1, +\infty) \times [a_2, +\infty).$$

As the function $\beta(y)$ is of the form $\beta_1(y_1) + \beta_2(y_2)$ with quadratic functions β_i, we get

$$\beta_i(y_i) \ge \beta_i(a_i) \quad \forall y_i \ge a_i.$$

Consequently, $a_i \ge \operatorname{Argmin} \beta_i = \pi_i^*$. □

7.3. Special case of no transaction cost for one of the risky assets. We suppose here $n = 2$, $\nu_1 = 0$, $\nu_2 > 0$. The VI (71) then reduces to

$$\max\left(\tilde{A}W + u^*(BW), \frac{\partial W}{\partial y_1}, \frac{\partial W}{\partial y_2} - \nu_2 BW, \max_{i=1,2,\, y_i>0}\left(-\frac{\partial W}{\partial y_i}\right)\right) = 0, \tag{94}$$

which implies that the function W is independent of y_1. Consequently the boundaries of B_2 and S_2 are horizontal straight lines of equation $y_2 = \pi_2^-$ and $y_2 = \pi_2^+$, respectively. Since equation (94) holds for all $y_1 \geq 0$ and W is the minimal solution of (94), we have

$$\max\left(\max_{y_1\geq 0}(\tilde{A}W + u^*(BW)), \frac{\partial W}{\partial y_2} - \nu_2 BW, -\frac{\partial W}{\partial y_2}\right) = 0 \quad \text{for } y_2 > 0.$$

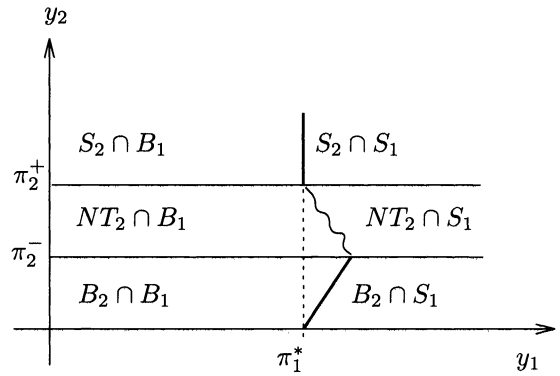

FIG. 13. *Boundaries of the transaction regions in the case of no transaction cost for the first risky asset.*

The regions B_1 and S_1 are delimited by the curve of equation $y_1 = \pi_1(y_2)$, where

$$\pi_1(y_2) = \operatorname*{Argmax}_{y_1\geq 0}(\tilde{A}W + u^*(BW))$$

is the solution of

$$y_1\sigma_1^2 y_2^2 \frac{\partial^2 W}{\partial y_2^2} - (2(\gamma-1)\sigma_1^2 y_1 + (\alpha_1 - r))y_2 \frac{\partial W}{\partial y_2} + \gamma((\alpha_1 - r) + (\gamma-1)\sigma_1^2 y_1)W = 0.$$

Consequently

$$\pi_1(y_2) = \frac{\pi_1^* BW}{BW + \dfrac{y_2}{1-\gamma}\dfrac{\partial BW}{\partial y_2}}.$$

In particular $\pi_1(0) = \pi_1^*$ and $\pi_1(y_2) = (1 + \nu_2 y_2)\pi_1^*$ in B_2. In S_2, W is constant and $\pi_1(y_2) = \pi_1^*$ (see Fig. 13). Moreover, by using the concavity of W, we obtain the estimate

$$0 < \pi_1(y_2) \leq \frac{\pi_1^*}{1 - \nu_2 y_2}.$$

ADAPTIVE CONTROL VIA A SIMPLE SWITCHING ALGORITHM*

JI FENG ZHANG† AND PETER E. CAINES‡

Abstract. In this paper we present an adaptive stabilization control for systems with unknown constant parameters and stochastic disturbances, which may be neither open-loop stable nor minimum phase. The ideas come from previous works [J. F. Zhang and H. F. Chen, *Adaptive stabilization under the weakest condition*, Proc. 31st Control and Design Conference, December 14–18, 1992, pp. 3620–3621, and H. F. Chen, *Continuous-Time Stochastic Adaptive Control Stabilizing the System and Minimizing the Quadratic Loss Function*, Tech. Report, Institute of Systems Science, Academia Sinica, Beijing, 1992], but here we not only simplify the construction procedure of an adaptive control but also reduce the computational load significantly, so that the adaptive control in this paper is more practical. Furthermore, parameter estimation is carried out in only a finite time period and, unlike previous work, the parameter estimates are generated by ordinary differential equations rather than stochastic differential equations.

Key words. adaptive control, parameter estimation, switching algorithm, continuous time, stochastic system

AMS subject classifications. 93C40, 93E15, 93E35

1. Introduction.

The switching control strategies of Zhang and Chen [1991] and Chen [1992] show that an alternation of excitation and control regimes can yield stabilizing controls. The idea is that, if a certain prediction error test fails at a specified instant, then a signal which is (in the limit) persistently exciting is applied. On the other hand, if the test is passed, then a particular certainty equivalence control law using the current estimate is applied. This strategy has common-sense appeal, despite the fact that the laws are somewhat complex in their present form. It is shown in the analysis of these laws that eventually the prediction error tests must always be passed, and hence it is shown that the system "locks on" to an acceptable control law. In summary, the adaptive control algorithms used in Zhang and Chen [1992] and Chen [1992] are as follows:

Step A) Introduce an appropriate criterion to judge whether or not the parameter estimate is satisfactory (for instance, a prediction error criterion).

Step B) Apply an excitation signal to the system, and estimate the unknown parameters via a least-squares (or related) algorithm until a "satisfactory" estimate is obtained according to the criterion; and after this,

Step C) construct a control law via the previously obtained "satisfactory" parameter estimates and use this law to control the system until some "unsatisfactory" property appears according to the criterion; and then

Step D) repeat this procedure through Steps B) and C).

If no "unsatisfactory" property appears at some stage in Step C), then the designed adaptive control law is used forever.

It is worth noticing that in some previous works (i) one or both of the derivatives dx_t and dy_t of the system state x and observation process y are required to be measurable in the parameter estimation procedure (see, e.g., Caines [1992]; Chen [1992];

Chen and Guo [1990]; Chen and Moore [1987]; Duncan and Pasik-Duncan [1990], [1991]; Gevers, Goodwin, and Wertz [1991]; Goodwin, et al. [1991]; Moore [1988]; Christopeit [1986]); (ii) the criteria used in steps A through C have to be verified at all time instants, which is an uncountable procedure because of the nature of the continuous time model (see, e.g., Chen [1992] and Zhang and Chen [1991]); (iii): the unknown parameters are always estimated no matter whether they are needed or not (see, e.g., Chen [1992]; Chen and Zhang [1992]; and Zhang and Chen [1991]); (iv) some external stochastic excitation signals are invoked (see, e.g., Chen and Zhang [1992] and Zhang and Chen [1992]).

In this paper, we formulate an adaptive control algorithm which (i) avoids use of dx_t or dy_t and the introduction of external stochastic signals in the procedures of parameter estimation and adaptive control, (ii) simplifies the criteria in steps A through C so that they are required to be verified at discrete time instants only, (iii) stop the parameter estimation procedure when it is not needed in order to make the adaptive control law more practical, and finally, (iv) does not use an external stochastic excitation signal. (In effect the Brownian motion w driving the system is exploited for this purpose.)

It may be conjectured that such an alternation of identification and control regimes will work in certain time-varying cases.

2. Full observation systems. In this section we consider the LQ adaptive control problem for the following system model:

$$dx_t = Ax_t dt + Bu_t dt + Cdw_t, \quad t \geq 0, \tag{2.1}$$

where $x_t \in \mathbb{R}^n$ and $u_t \in \mathbb{R}$ are the state and input of the system and $\{w_t, \mathcal{F}_t\}$ is a standard Wiener process in $\mathbb{R}^m$.

Using controls which at any instant t are based only on information available up to time t, we wish to stabilize the system (2.1). In this paper, this is achieved by the use of controls which are certain time-interleaved versions of an excitation signal and a signal designed via the certainty equivalence principle for the following quadratic loss function:

$$\min_{u \in \mathcal{U}} \limsup_{t \to \infty} J_t(u), \tag{2.2}$$

where

$$\mathcal{U} = \left\{ \{u_t : \ u_t \in \mathcal{F}_t \triangleq \sigma\{x_\tau, \ u_s, \ 0 \leq \tau \leq t, \ 0 \leq s < t\}, \ t \geq 0 \right\}, \tag{2.3}$$

$$J_t(u) = \frac{1}{t} \int_0^t (x_s^T Q_1 x_s + Q_2 u_s^2) ds, \quad Q_1 \geq 0, \quad Q_2 > 0. \tag{2.4}$$

This problem has been investigated in previous work; see, for instance, Zhang and Chen [1991], Chen [1992], where these authors presented the first rigorous stability analysis for such adaptive stabilization of a system, which might be neither open-loop stable nor minimum phase and might be subject to disturbances with an unknown bound.

Specification of the adaptive control law. First, we define a causal system which shall generate a disturbance input u', which shall be employed over an at most countable set of intervals; second, we define a linear state feedback control law, which shall be used over the intervals which interleave those during which the disturbance

is used; then, third, we give a rule for determining the switching times which depend solely upon the history of the system inputs and outputs.

Following the procedure described from step A to step D, we now find an adaptive stabilization control for model (2.1).

Assume that the control input u is defined on the interval $[0,t)$; then the input u' and a countable sequence of stopping times with no finite accumulation point are defined as follows:

Let $T>1$ and α be positive constants chosen arbitrarily. Define for $i=1, 2, \ldots, n+1$

$$\beta_i=(-1)^{i+1}\alpha^i\frac{(n+1)!}{i!\times(n+1-i)!} \quad \text{with} \quad 0!\triangleq 1,\ i!\triangleq 1\times 2\times\cdots\times i \tag{2.5}$$

and for some integer $k\geq 0$

$$u'_t=L_{T^k}+\beta_1 S_k u'_t+\cdots+\beta_{n+1}S_k^{n+1}u'_t,\quad t\in[T^k,\ T^{k+1}), \tag{2.6}$$

where $S_k u_t=\int_{T^k}^t u_s ds$ and $L_t=1+\int_0^t(\|\psi_s\|^2+\|z_s\|^2+u_s^2)ds$ with $\psi_t=[Sx_t^\tau,\ Su_t]^\tau$ and $z_t=[S\overline{x}_t^\tau,\ S\overline{u}_t]^\tau$. Here, S is the integral operator $Sx_t=\int_0^t x_s ds$; x_t and u_t are, respectively, the system state and system input, which is recursively given by (2.5)–(2.12); $\overline{x}_t$ and $\overline{u}_t$ are the solutions of the following equations, respectively:

$$(S+1)\overline{x}_t=x_t,\quad (S+1)\overline{u}_t=u_t,$$

i.e.,

$$\overline{x}_t=x_t-\int_0^t e^{-(t-\lambda)}x_\lambda d\lambda,\quad \overline{u}_t=u_t-\int_0^t e^{-(t-\lambda)}u_\lambda d\lambda.$$

It will be seen below that the function u which appears in the definitions above is equal to u' during the time intervals when the excitation input to the system is in use and is given as a linear function of the state x during the periods when u' is not being used as a system input.

Set $\theta=[A,\ B]^\tau$. Choosing an arbitrary θ_0, the unknown parameter θ is estimated via the least-squares method, which is modified so as to be active only over a sequence of intervals $[T^{\tau_{i-1}},T^{\sigma_i})$. Specifically, the estimate $\theta_t=[A_t,\ B_t]^\tau$ is given by

$$\dot{\theta}_t=P_t\psi'_t(\overline{x}_t-\theta_t^\tau\psi'_t)\quad \text{with}\quad P_t=\left(I+\int_0^t\psi'_s\psi_s'^\tau ds\right)^{-1} \tag{2.7}$$

and

$$\psi'_t=\begin{cases} z_t & \text{if } t\in[0,T^{\tau_0}) \text{ or } t\in[T^{\tau_{i-1}},T^{\sigma_i}) \\ 0 & \text{if } t\in[T^{\sigma_i},T^{\tau_i})\end{cases}\quad \forall i\geq 1, \tag{2.8}$$

where $\{\tau_i\}$ and $\{\sigma_i\}$ are two stopping time sequences defined as follows: $0=\tau_0<\sigma_1<\tau_1<\sigma_2<\tau_2<\cdots$,

$$\begin{aligned}\sigma_i=\inf\{k>\tau_{i-1}:\ & k\in\mathcal{N},\quad (A_{T^k},B_{T^k},D) \text{ is controllable and observable,}\\ & \text{where here, and hereafter, } \mathcal{N} \text{ denotes the set of all positive}\\ & \text{integers, and } D \text{ is any square matrix such that } D^\tau D=Q_1\},\end{aligned} \tag{2.9}$$

$$\tau_i = \inf\left\{k > \sigma_i : k \in \mathcal{N}, \quad \int_0^{T^k} \|x_s\|^2 ds > T^{\sigma_i} \int_0^{T^{\sigma_i}} (\|x_s\|^2 + \|u_s''\|^2) ds \right.$$

$$\left. + T^{\sigma_i} T^k + T^{\sigma_i} \right\} \tag{2.10}$$

with the excitation input u'' given by

$$u_t'' = \begin{cases} u_t' & \text{if } t \in [0, T^{\tau_0}) \text{ or } t \in [T^{\tau_{i-1}}, T^{\sigma_i}) \\ 0 & \text{if } t \in [T^{\sigma_i}, T^{\tau_i}) \end{cases} \quad \forall i \geq 1. \tag{2.11}$$

Here Q_1 is given in (2.4) and u_t' is defined by (2.6).

The adaptive control u is generated by interleaving the excitation input u' and a linear feedback input as follows:

$$u_t = \begin{cases} u_t' & \text{if } t \in [0, T^{\tau_0}) \text{ or } t \in [T^{\tau_{i-1}}, T^{\sigma_i}) \text{ for some } i \geq 1, \\ -Q_2^{-1} B_{T^{\sigma_i}}^\tau R_{T^{\sigma_i}} x_t & \text{if } t \in [T^{\sigma_i}, T^{\tau_i}) \text{ for some } i \geq 1, \end{cases} \tag{2.12}$$

where Q_2 is the positive constant in (2.4), $B_{T^{\sigma_i}}$ is the estimate for B at time instant T^{σ_i} given by (2.7) and (2.8), and $R_{T^{\sigma_i}}$ is a solution of the following algebraic Riccati equation:

$$A_{T^{\sigma_i}}^\tau R_{T^{\sigma_i}} + R_{T^{\sigma_i}} A_{T^{\sigma_i}} - R_{T^{\sigma_i}} B_{T^{\sigma_i}} Q_2^{-1} B_{T^{\sigma_i}}^\tau R_{T^{\sigma_i}} + D^\tau D = 0.$$

Here $A_{T^{\sigma_i}}$ is the estimate for A at time instant T^{σ_i} given by (2.7) and (2.8).

Remark 2.1. From the definition (2.12) of u_t, it is easy to see that τ_i and σ_i are Markov times, i.e., $\sigma\{T^{\tau_i} \leq t\} \in \mathcal{F}_t$ and $\sigma\{T^{\sigma_i} \leq t\} \in \mathcal{F}_t$. Thus, $u \in \mathcal{U}$ and $\psi_t' \in \mathcal{F}_t$.

Remark 2.2. The excitation signal in (2.12) is generated by (2.6), in which a designer needs only determine the deterministic coefficients β_i. No additional stochastic signal is introduced except L_{T^k}, so we call this a deterministic-like excitation signal.

Remark 2.3. In (2.9), to get σ_i, the only thing one should do is to check the controllability and observability of (A_{T^k}, B_{T^k}, D) for every integer k at time instant T^k. While in (2.10), one need only check whether or not

$$\int_0^{T^k} \|x_s\|^2 ds > T^{\sigma_i} \int_0^{T^{\sigma_i}} (\|x_s\|^2 + \|u_s''\|^2) ds + T^{\sigma_i} T^k + T^{\sigma_i}$$

for every integer k at time instant T^k and such a set of time instants is evidently countable.

Remark 2.4. By (2.7) and (2.8) it is easy to see that $\theta_t = \theta_{T^{\sigma_i}}$ for all $t \in [T^{\sigma_i}, T^{\tau_i})$. In other words, unlike in Zhang and Chen [1991] or in Chen [1992], the LS parameter estimation is not carried out in the time interval $[T^{\sigma_i}, T^{\tau_i})$. Thus, if adaptive control (2.12) results in an integer i such that $\sigma_i < \infty$ and $\tau_i = \infty$, then the unknown parameter estimates will be locked on an acceptable value $\theta_{T^{\sigma_i}}$ forever.

LEMMA 2.1. *Let* $\lambda_{\min}^{(t)}$ *denote the smallest eigenvalue of matrix* P_t^{-1}. *Then the parameter estimate* θ_t *given by* (2.7)–(2.12) *has the following property:*

$$\|\theta_t - \theta\|^2 \leq \frac{c(t+1)}{\lambda_{\min}^{(t)}} \quad \forall t \geq 0,$$

where here and hereafter $c \geq 0$ *is a possibly random quantity which is independent of* t.

Proof. Let $\tilde{\theta}_t = \theta_t - \theta$. Then from (2.1) it follows that

$$x_t = x_0 + \theta^\tau \psi_t + Cw_t.$$

Substituting this into the first equation of (2.7) and noting (2.8), $(S+1)\overline{x}_t = x_t$, and $(S+1)z_t = \psi_t$ we get

$$\dot{\tilde{\theta}}_t = -P_t\psi_t'\psi_t'^\tau\tilde{\theta}_t + P_t\psi_t'[(S+1)^{-1}(Cw_t) + \varepsilon_t],$$

where here and hereafter ε_t denotes a time function which exponentially converges to zero.

From this and the second equation of (2.7) we obtain

$$\frac{d(\tilde{\theta}_t^\tau P_t^{-1}\tilde{\theta}_t)}{dt} = -(\tilde{\theta}_t^\tau\psi_t')^2 + 2\tilde{\theta}_t^\tau\psi_t'[(S+1)^{-1}(Cw_t) + \varepsilon_t],$$

which implies that

$$\begin{aligned} 0 &\le \tilde{\theta}_t^\tau P_t^{-1}\tilde{\theta}_t \\ &= \tilde{\theta}_0^\tau P_0^{-1}\tilde{\theta}_0 - \int_0^t (\tilde{\theta}_s^\tau\psi_s')^2 ds + 2\int_0^t \tilde{\theta}_s^\tau\psi_s'[(S+1)^{-1}(Cw_s) + \varepsilon_s]ds \\ &\le \tilde{\theta}_0^\tau P_0^{-1}\tilde{\theta}_0 + \int_0^t [(S+1)^{-1}(Cw_s) + \varepsilon_s]^2 ds = O(t), \end{aligned}$$

where for the last inequality we have invoked $\int_0^t[(S+1)^{-1}(Cw_s)]^2 ds = O(t+1)$ a.s. (e.g., Chen and Guo [1990]).

Therefore, Lemma 2.1 is true. □

LEMMA 2.2. *In system* (2.1), *if* (A, B) *is controllable and* $u_t = u_t'$ *for some* k *and all* $t \in (T^k, T^{k+1}]$, *then there exist* $c > 0$, $a > 1$, *and* $k_0 > 0$ *such that*

$$\lambda_{\min}^{(T^{k+1})} \ge ca^{T^{k+1}} L_{T^k} \quad \forall k \ge k_0. \tag{2.13}$$

Proof. See Appendix A.

THEOREM 2.1. *If* $\mathrm{Span}(B) \subset \mathrm{Span}(C)$ *and* (A, B, D) *is controllable and observable with* $D^\tau D = Q_1$, *then under the adaptive control* (2.12) *it is the case that*

(a) *there is an integer* i *such that* $\sigma_i < \infty$, $\tau_i = \infty$, *and* $\theta_t = \theta_{T^{\sigma_i}}$ $\forall t \ge T^{\sigma_i}$;

(b) $\lim_{t\to\infty} \frac{1}{t}\int_0^t x_s x_s^\tau ds$ *and* $\lim_{t\to\infty} \frac{1}{t}\int_0^t u_s^2 ds$ *exist and are finite a.s.*

Here and hereafter by $\mathrm{Span}(X)$ *we mean the linear space spanned by the column vectors of* X.

Proof. Let R be the solution of the following algebraic Riccati equation:

$$A^\tau R + RA - RBQ_2^{-1}B^\tau R + D^\tau D = 0.$$

Then it is well known that $\Phi \triangleq A - BQ_2^{-1}B^\tau R$ is stable, and hence there is a positive matrix P such that

$$P\Phi + \Phi^\tau P = -I.$$

From this, it is easy to see that there exists a small enough positive constant ε such that

$$P\Phi_t + \Phi_t^\tau P \le -\frac{1}{2}I \quad \forall \Phi_t \in \{\Phi_t : \|\Phi_t - \Phi\| < \varepsilon\}. \tag{2.14}$$

We now define

$$\Phi_t = \begin{cases} A & \text{if } t \in [0, T^{\tau_0}) \text{ or } t \in [T^{\tau_{i-1}}, T^{\sigma_i}), \\ A - BQ_2^{-1}B_{T^{\sigma_i}}^{\tau} R_{T^{\sigma_i}} & \text{if } t \in [T^{\sigma_i}, T^{\tau_i}). \end{cases}$$

Then the adaptive control system defined above is expressed as

$$dx_t = \Phi_t x_t dt + Bu_t'' dt + C dw_t.$$

From the definitions (2.9) and (2.10) of sequences $\{\sigma_i\}$ and $\{\tau_i\}$ we see that only three cases can possibly hold. The first case is that there exists an integer i such that $\tau_{i-1} < \infty$ and $\sigma_i = \infty$; the second is that $\sigma_i < \tau_i < \infty$ for every integer $i \geq 1$, and the third is there exists an integer i such that $\sigma_i < \infty$ and $\tau_i = \infty$. We shall now show the first two cases are impossible.

Case 1. It is impossible that an integer i such that $\tau_{i-1} < \infty$ and $\sigma_i = \infty$ exists.

From Lemmas 2.1 and 2.2, it is easy to see that if there were an integer i such that $\tau_{i-1} < \infty$ and $\sigma_i = \infty$, then there would be

$$A_{T^k} \xrightarrow[k \to \infty]{} A \text{ and } B_{T^k} \xrightarrow[k \to \infty]{} B.$$

Thus, by the assumption that (A, B, D) is controllable and observable, we see that there would exist a k such that $T^k \geq T^{\tau_{i-1}}$ and (A_{T^k}, B_{T^k}, D) is controllable and observable. This contradicts $\sigma_i = \infty$.

Case 2. It is impossible that $\sigma_i < \tau_i < \infty$ for every integer $i \geq 1$.

If for every integer $i \geq 1$, $\sigma_i < \tau_i < \infty$, then by Lemmas 2.1 and 2.2 it is easy to see that $\Phi_{T^{\sigma_i}} \xrightarrow[i \to \infty]{} \Phi$. Therefore, there exists i_0 such that for all $i \geq i_0$,

$$\|\Phi_{T^{\sigma_i}} - \Phi\| < \varepsilon,$$

which together with (2.14) implies that

$$\|\Phi_t\| \leq c \quad \text{and} \quad P\Phi_{T^{\sigma_i}} + \Phi_{T^{\sigma_i}}^{\tau} P \leq -\frac{1}{2} I. \tag{2.15}$$

Using Ito's formula (cf. Schwartz [1984]) we find that for $k \in [\sigma_i, \tau_i) \cap \mathcal{N}$

$$\begin{aligned} x_{T^k}^{\tau} P x_{T^k} \leq x_0^{\tau} P x_0 + \int_0^{T^{\sigma_i}} x_s^{\tau}(P\Phi_s + \Phi_s^{\tau} P) x_s ds - \frac{1}{2}\int_{T^{\sigma_i}}^{T^k} \|x_s\|^2 ds \\ +2\int_0^{T^{\sigma_i}} x_s^{\tau} P B u_s'' ds + 2\int_0^{T^k} x_s^{\tau} P C dw_t + \operatorname{tr}(C^{\tau} P C) T^k, \end{aligned} \tag{2.16}$$

where here and hereafter $\operatorname{tr}(X)$ denotes the trace of X.

Note that by Lemma 4 of Christopeit [1986], there exist random numbers c', c'', independent of t, such that for all k sufficiently large, say, for all $k \geq \sigma_m$,

$$\int_0^{T^k} x_s^{\tau} P C dw_s \leq c' \left(\int_0^{T^k} \|x_s^{\tau}\|^2 ds\right)^{\eta + \frac{1}{2}} + c' \leq c'' + \frac{1}{8}\int_0^{T^k} \|x_s^{\tau}\|^2 ds, \quad \eta \in \left(0, \frac{1}{2}\right).$$

Then from (2.16), for some random number c''' independent of time, we have

$$\begin{aligned} x_{T^k}^{\tau} P x_{T^k} \leq c''' + c''' \int_0^{T^{\sigma_m}} \|x_s\|^2 ds - \frac{3}{8}\int_{T^{\sigma_m}}^{T^k} \|x_s\|^2 ds \\ +c\int_0^{T^{\sigma_m}} \|u_s''\|^2 ds + \operatorname{tr}(C^{\tau} P C) T^k, \end{aligned}$$

and hence, for some random number c independent of time,

$$\int_0^{T^k} \|x_s\|^2 ds \le c \int_0^{T^{\sigma_m}} (\|x_s\|^2 + \|u_s''\|^2) ds + cT^k + c \quad \forall k \ge \sigma_m. \tag{2.17}$$

Now there exists i sufficiently large that $T^{\sigma_i} \ge c$, and so by (2.17) this gives

$$\int_0^{T^k} \|x_s\|^2 ds \le T^{\sigma_i} \int_0^{T^{\sigma_i}} (\|x_s\|^2 + \|u_s''\|^2) ds + T^{\sigma_i} T^k + T^{\sigma_i} \quad \forall k \ge \sigma_i,$$

which contradicts $\tau_i < \infty$.

So, there must exist an integer i such that $\sigma_i < \infty$ and $\tau_i = \infty$.

Thus by (2.7) and (2.8) we get Assertion (a) of Theorem 2.1. Furthermore, (2.10) together with $\tau_i = \infty$ implies that

$$\limsup_{k\to\infty} \frac{1}{T^k} \int_0^{T^k} \|x_s\|^2 ds < \infty \quad \text{a.s.} \tag{2.18}$$

Notice that $\text{Span}(B) \subset \text{Span}(C)$ and (A, B) is controllable implies that $(\Phi_{T^{\sigma_i}}, C)$ is controllable. Then by (2.18) and Lemma B.1 in Appendix B we see that $\Phi_{T^{\sigma_i}}$ is stable. Therefore, from Lemma 3 of Chen and Guo [1990] it follows that

$$\lim_{t\to\infty} \frac{1}{t} \int_0^t x_s x_s^\tau ds \quad \text{exists and is finite a.s.},$$

which together with (2.12) implies that

$$\lim_{t\to\infty} \frac{1}{t} \int_0^t u_s^2 ds = Q_2^{-2} B_{T^{\sigma_i}}^\tau R_{T^{\sigma_i}} \left(\lim_{t\to\infty} \frac{1}{t} \int_0^t x_s x_s^\tau ds \right) (B_{T^{\sigma_i}}^\tau R_{T^{\sigma_i}})^\tau \text{ exists and is finite a.s.}$$

This proves Assertion (b) of Theorem 2.1. □

3. Partially observed system.

3.1. Problem statement. In this section we consider the single-input single-output continuous-time system described by

$$A(S)y_t = y_0 + SB(S)u_t + C(S)w_t + S\eta_t \quad \forall t \ge 0, \tag{3.1}$$

where $A(S)$, $B(S)$, and $C(S)$ are polynomials in S with unknown coefficients:

$$A(S) = 1 + \sum_{i=1}^{p} a_i S^i, \quad B(S) = \sum_{i=1}^{q} b_i S^{i-1}, \quad C(S) = \sum_{i=0}^{l} c_i S^i; \tag{3.2}$$

$\{w_t, \mathcal{F}_t\}$ is a standard Wiener process with respect to a nondecreasing σ-algebras $\{\mathcal{F}_t\}$ defined on a probability space; y_t and u_t are the system output and input, respectively, and measurable with respect to $\mathcal{F}_t$; and η_t is unknown disturbance or unmodeled dynamics which is measurable with respect to $\mathcal{F}_t$.

As Zhang and Chen (1991) show, model (3.1) subject to (3.2) is very general and includes some widely used models. For instance, in the case where $l = p$ and $c_p = ga_p$, the input-output properties of (3.1) are equivalent to those of the following well-known

state-space representation (e.g., Gevers, Goodwin, and Wertz [1991]; Goodwin, et al. [1991]; Caines [1992]):

$$dx_t = Ax_t dt + Bu_t dt + Cdw_t + D\eta_t dt,$$
$$dy_t = D^\tau x_t dt + gdw_t,$$

with

$$A = \begin{bmatrix} -a_1 & 1 & & \\ -a_2 & & \ddots & \\ \vdots & & & 1 \\ -a_m & & & 0 \end{bmatrix}, \quad B = \begin{bmatrix} b_1 \\ \vdots \\ b_m \end{bmatrix}, \quad C = \begin{bmatrix} c_0 - ga_0 \\ \vdots \\ c_{m-1} - ga_{m-1} \end{bmatrix}, \quad D = \left.\begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix}\right\} m,$$

where $m = \max\{p, q\}$ and here and hereafter we set $a_0 = 1$, $a_i = 0$ for $i > p$, $b_j = 0$ for $j > q$, and $c_k = 0$ for $k > l$.

Let us denote the collection of unknown coefficients of $A(S)$ and $B(S)$ by θ:

$$\theta = [-a_1, \ldots, -a_p, \ b_1, \ldots, b_q]^\tau. \tag{3.3}$$

Let

$$F(S) = 1 + f_1 S + \cdots + f_{l+1} S^{l+1} \quad \text{with } f_{l+1} \neq 0$$

be an arbitrarily given stable polynomial of S; i.e., every S that satisfies $F(S) = 0$ has negative real part.

Denote by y_t^f and u_t^f the filtered value, respectively:

$$F(S)y_t^f = y_t, \quad F(S)u_t^f = u_t \tag{3.4}$$

and

$$\varphi_t^f = [Sy_t^f, \ldots, S^p y_t^f, \quad Su_t^f, \ldots, S^q u_t^f]^\tau. \tag{3.5}$$

Define

$$\varphi_t' = \begin{cases} \varphi_t^f & \text{if } t \in [0, T^{\tau_0}) \text{ or } t \in [T^{\tau_{i-1}}, T^{\sigma_i}) \text{ for some } i \geq 1, \\ 0 & \text{if } t \in [T^{\sigma_i}, T^{\tau_i}) \text{ for some } i \geq 1, \end{cases} \tag{3.6}$$

where $\{\tau_i\}$ and $\{\sigma_i\}$ are two stopping time sequences such that $\varphi_t^f \in \mathcal{F}_t$.

Then the unknown parameter θ is estimated as follows:

$$\dot{\theta}_t = P_t \varphi_t' (y_t^f - \theta_t^\tau \varphi_t') \quad \text{with} \quad P_t = \left(I + \int_0^t \varphi_s' \varphi_s'^\tau ds \right)^{-1}, \tag{3.7}$$

where θ_0 is a constant chosen arbitrarily.

The purpose of this paper is to design a θ_t-based adaptive control so that the closed-loop system is stabilized in the sense that

$$\sup_{t \geq 0} \frac{1}{t+1} \int_0^t (y_s^2 + u_s^2) ds < \infty \quad \text{a.s.} \tag{3.8}$$

under the following assumptions:

A.1. $A(S)$ and $SB(S)$ are coprime, $b_q \neq 0$, $l \leq \min\{p, q-1\}$, and p and q are known.

A.2. $\sup_{t\geq 0} \frac{1}{t+1} \int_0^t \eta_s^2 ds < \infty$.

From Zhang and Chen [1991] it follows that Assumptions A.1 and A.2 are as weak as the following necessary and sufficient ones even when θ is known:

A.1′. The greatest common factor of $A(S)$ and $SB(S)$ is 1 or a stable polynomial, $b_q \neq 0$, the order of the greatest common factor, $l \leq \min\{p, q-1\}$, and p and q are known.

A.2′. $\sup_{t\geq 0} \frac{1}{t+1} \int_0^t \eta_s^2 ds < \infty$ a.s.

However, for simplicity of notation, in this paper we use Assumptions A.1 and A.2.

Remark 3.1. We now look at how to calculate the filtered values y_t^f and u_t^f of y_t and u_t, respectively, with respect to filter $F(S)$ in (3.4).

Let

$$D_F = \begin{bmatrix} -f_1 & -f_2 & \cdots & -f_{l+1} \\ 1 & 0 & \cdots & 0 \\ & \ddots & \ddots & \vdots \\ 0 & & 1 & 0 \end{bmatrix}, \quad Y_t = \begin{bmatrix} y_t^f \\ Sy_t^f \\ \vdots \\ S^l y_t^f \end{bmatrix}, \quad H_l = \left.\begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix}\right\} l+1.$$

Then from (3.4) we see that

$$Y_t = D_F S Y_t + H_l y_t,$$

which is equivalent to

$$Y_t = D_F \int_0^t e^{D_F(t-\lambda)} H_l y_\lambda d\lambda + H_l y_t.$$

Thus we have

$$y_t^f = H_l^\tau Y_t = y_t + H_l^\tau D_F \int_0^t e^{D_F(t-\lambda)} H_l y_\lambda d\lambda.$$

Similarly, we can get

$$u_t^f = u_t + H_l^\tau D_F \int_0^t e^{D_F(t-\lambda)} H_l u_\lambda d\lambda.$$

3.2. Adaptive control. We first look at what the stabilization control is in the case where θ is known. To see this, we introduce the following lemma (e.g., Chen and Guo [1990]).

LEMMA 3.1. *Let $k \geq 0$ be an integer and $E(S) = 1 + e_1 S + \cdots + e_k S^k$ be a stable polynomial with $e_k \neq 0$. Then there is a (nonrandom) constant $C_e \geq 1$ (depending on $E(S)$ only) such that*

$$\sum_{i=0}^{k} \int_0^t \left(\frac{S^i}{E(S)} z_\lambda \right)^2 d\lambda \leq C_e \int_0^t z_\lambda^2 d\lambda$$

for any square-integrable process $\{z_t\}$.

If $A(S)$, $SB(S)$ are coprime and $b_q \neq 0$, then for any polynomial

$$E(S) = 1 + e_1 S + \cdots + e_{p+q} S^{p+q} \quad \text{with} \quad e_{p+q} \neq 0, \tag{3.9}$$

there exists a unique polynomial pair $(G(S), H(S))$ such that

$$A(S)G(S) - SB(S)H(S) = E(S) \quad \text{with } \partial(G(S)) \leq q-1 \text{ and } \partial(H(S)) = p, \tag{3.10}$$

where here and hereafter $\partial(X(S))$ denotes the degree of the polynomial $X(S)$ in S.

From (3.10) and (3.1) it is clear that

$$\begin{aligned} E(S)y_t &= A(S)G(S)y_t - SB(S)H(S)y_t \\ &= G(S)[A(S)y_t - SB(S)u_t] + SB(S)[G(S)u_t - H(S)y_t] \\ &= G(S)[y_0 + C(S)w_t + S\eta_t] + SB(S)[G(S)u_t - H(S)y_t] \end{aligned}$$

and

$$\begin{aligned} E(S)u_t &= A(S)G(S)u_t - SB(S)H(S)u_t \\ &= H(S)[A(S)y_t - SB(S)u_t] + A(S)[G(S)u_t - H(S)y_t] \\ &= H(S)[y_0 + C(S)w_t + S\eta_t] + A(S)[G(S)u_t - H(S)y_t]. \end{aligned}$$

Therefore, in the case where θ is known, $l \leq \min\{p, q-1\}$ and Assumptions A.1 and A.2 hold, for any given stable $E(S)$ subject to (3.9), if the control is defined as follows:

$$G(S)u_t - H(S)y_t = 0, \quad t \geq 0,$$

then the system is stabilized in the average sense (3.8).

Similar to §2, we now introduce a deterministic-like excitation signal u'_t. Let $T > 1$ and α be positive constants chosen arbitrarily. Define for $i = 1, 2, \ldots, p+q$,

$$\beta_i = (-1)^{i+1}\alpha^i \frac{(p+q)!}{i! \times (p+q-i)!} \quad \text{with} \quad 0! \triangleq 1, \ i! \triangleq 1 \times 2 \times \cdots \times i,$$

and for some integer $k \geq 0$,

$$u'_t = L_{T^k} + \beta_1 S_k u'_t + \cdots + \beta_{p+q} S_k^{p+q} u'_t, \quad t \in [T^k, T^{k+1}),$$

where $S_k u_t = \int_{T^k}^t u_s ds$ and $L_t = 1 + \int_0^t (\|\varphi_s^f\|^2 + \|\varphi_s\|^2 + u_s^2) ds$ with φ_t^f defined by (3.5) and φ_t defined by

$$\varphi_t = [Sy_t, \ldots, S^p y_t, \quad Su_t, \ldots, S^q u_t]^\tau. \tag{3.11}$$

For any $k \geq 1$, write θ_{T^k} in the component form

$$\theta_{T^k} = [-a_{1T^k}, \ldots, -a_{pT^k}, \quad b_{1T^k}, \ldots, b_{qT^k}]^\tau$$

and set

$$A_k(S) = 1 + \sum_{i=1}^p a_{iT^k} S^i, \quad B_k(S) = \sum_{i=1}^q b_{iT^k} S^{i-1}. \tag{3.12}$$

Let $E(S)$ be a stable polynomial subject to (3.9). Then by Lemma 3.1 there is a constant C_e (depending on $E(S)$ only) such that

$$\sum_{i=0}^{p+q} \int^t \left(\frac{S^i}{E(S)} z_\lambda \right)^2 d\lambda \leq C_e \int_0^t z_\lambda^2 d\lambda \tag{3.13}$$

for any square-integrable process $\{z_\lambda\}$.

Let $R(S)$ be a stable polynomial of S with $\partial(R(S)) = \min\{p+1, q\}$ and let ξ_t^u, ξ_t^y denote the filtered values of u_t, y_t with respect to $R(S)$, respectively:

$$R(S)\xi_t^u = u_t, \quad R(S)\xi_t^y = y_t \quad \forall t \geq 0. \tag{3.14}$$

Actually, the filtered values ξ_t^u and ξ_t^y can be calculated as in Remark 3.1.

Set $\zeta_t = [S\xi_t^y, \dots, S^p\xi_t^y, S\xi_t^u, \dots, S^q\xi_t^u]^\tau$. Then by (3.11) and (3.14) we get

$$R(S)\zeta_t = \varphi_t. \tag{3.15}$$

In the following discussion, for a given polynomial $Z(S) = z_0 + z_1 S + \cdots + z_r S^r$, its norm is defined as

$$\|Z(S)\| = \left(\sum_{i=0}^{r} z_i^2\right)^{1/2}.$$

Define switching times $1 = \tau_0 < \sigma_1 < \tau_1 < \sigma_2 < \tau_2 \cdots$ as follows:

$$\begin{aligned}\sigma_i = \inf\Big\{ k > \tau_{i-1} :\ & A_k(S)G_k(S) - SB_k(S)H_k(S) = E(S) \text{ is solvable} \\ & \text{with respect to } G_k(S) \text{ and } H_k(S) \text{ subject to} \\ & \partial(G_k(S)) \leq q-1 \quad \text{and} \quad \partial(H_k(S)) = p; \quad \text{and} \\ & \|G_k(S)\|^2 + \|H_k(S)\|^2 \leq \frac{k}{2C_e(p+q+1)}; \\ & \int_0^{T^k} [\xi_s^y - \theta_{T^k}^\tau \zeta_s]^2\, ds \leq k^{-2} f(k, T^k) \Big\},\end{aligned} \tag{3.16}$$

$$\begin{aligned}\tau_i = \min\Big\{ k > \sigma_i :\ & \text{there exists } t \in (T^{\sigma_i}, T^k] \text{ such that} \\ & \int_0^t [\xi_s^y - \theta_{T^{\sigma_i}}^\tau \zeta_s]^2\, ds > \sigma_i^{-2} f(\sigma_i, t) \Big\},\end{aligned} \tag{3.17}$$

where C_e is given in (3.13), and

$$f(x,t) = (t+1) \sup_{0 \leq \lambda \leq t} \left\{ x^3 + \frac{1}{\lambda+1} \int_0^\lambda \left[\sum_{j=0}^{p+1} (S^j \xi_s^y)^2 + \sum_{j=0}^{q} (S^j \xi_s^u)^2 \right] ds \right\}. \tag{3.18}$$

Similar to (2.12) we define the adaptive control u_t as follows:

$$u_t = \begin{cases} u_t' & \text{if } t \in [0, T^{\tau_0}) \text{ or } t \in [T^{\tau_{i-1}}, T^{\sigma_i}) \text{ for some } i \geq 1, \\ H_{\sigma_i}(S)y_t - (G_{\sigma_i}(S) - 1)u_t & \text{if } t \in [T^{\sigma_i}, T^{\tau_i}) \text{ for some } i \geq 1, \end{cases} \tag{3.19}$$

where $H_{\sigma_i}(S)$ and $G_{\sigma_i}(S)$ are generated by (3.16), (3.12), and (3.4)–(3.7).

In this case, similar to Lemmas 2.1 and 2.2 we may obtain the following results.

LEMMA 3.2. *Let $\lambda_{\min}^{(t)}$ denote the smallest eigenvalue of matrix R_t^{-1}. Then the parameter estimate θ_t given by* (3.4)–(3.7) *has the following property:*

$$\|\theta_t - \theta\|^2 \leq \frac{c(t+1)}{\lambda_{\min}^{(t)}} \quad \forall t \geq 0$$

for some time-independent random variable $c \geq 0$.

Proof. Let $\widetilde{\theta}_t = \theta_t - \theta$. Then from (3.1)–(3.3) and (3.5) it follows that

$$y_t^f = \theta^\tau \varphi_t^f + F^{-1}(S)[C(S)w_t + S\eta_t] + \varepsilon_t,$$

where we recall that ε_t denotes a function of time decaying exponentially to zero. Substituting this into the first equation of (3.7) and noting (3.6), we get

$$\dot{\widetilde{\theta}}_t = -P_t \varphi_t' \varphi_t'^\tau \widetilde{\theta}_t + P_t \varphi_t' \left[F^{-1}(S)(C(S)w_t + S\eta_t) + \varepsilon_t\right].$$

Then combining this with the second equation of (3.7) gives

$$\frac{d(\widetilde{\theta}_t^\tau P_t^{-1} \widetilde{\theta}_t)}{dt} = -(\widetilde{\theta}_t^\tau \varphi_t')^2 + 2\widetilde{\theta}_t^\tau \varphi_t' \left[F^{-1}(S)(C(S)w_t + S\eta_t) + \varepsilon_t\right],$$

which together with $\int_0^t [F^{-1}(S)(C(S)w_s]^2 ds = O(t)$ (cf. Lemma 3 of Chen and Guo [1990]) implies that

$$\begin{aligned} 0 &\leq \widetilde{\theta}_t^\tau P_t^{-1} \widetilde{\theta}_t \\ &\leq \widetilde{\theta}_0^\tau P_0^{-1} \widetilde{\theta}_0 - \int_0^t (\widetilde{\theta}_s^\tau \varphi_s')^2 ds + 2 \int_0^t \widetilde{\theta}_s^\tau \varphi_s' \left[F^{-1}(S)(C(S)w_s + S\eta_s) + \varepsilon_t\right] ds \\ &\leq \widetilde{\theta}_0^\tau P_0^{-1} \widetilde{\theta}_0 + \int_0^t \left[F^{-1}(S)(C(S)w_s + S\eta_s) + \varepsilon_t\right]^2 ds = O(t+1), \end{aligned}$$

where for the final bound we have used Lemma 3.1 and Assumption A.2. □

LEMMA 3.3. *Under Assumptions* A.1 *and* A.2, *if* $u_t = u_t'$ *for some* k *and any* $t \in (T^k, T^{k+1}]$, *then there exist* $c > 0$, $a > 1$, *and* $k_0 > 0$ *such that*

$$\lambda_{\min}^{(T^{k+1})} \geq c a^{T^{k+1}} L_{T^k} \quad \forall k \geq k_0.$$

Proof. The proof resembles that of Lemma 2.2 and is given in Appendix C.

THEOREM 3.1. *Under Assumptions* A.1 *and* A.2 *and the adaptive control* (3.4)–(3.7), (3.16)–(3.19), *we get that*

(a) *there is an integer* i *such that* $\sigma_i < \infty$, $\tau_i = \infty$, *and* $\theta_t = \theta_{T^{\sigma_i}}$ $\forall t \geq T^{\sigma_i}$;

(b) $\sup_{t \geq 0} \frac{1}{t+1} \int_0^t (y_s^2 + u_s^2) ds < \infty$ *a.s.*

Proof. We first show that it is impossible that $\tau_i < \infty$ and $\sigma_{i+1} = \infty$ on a sample set $\mathcal{D}$ with positive probability for an integer-valued random variable $i \geq 0$.

In fact, if there were a sample set $\mathcal{D}$ of positive probability, i.e., for which $P(\mathcal{D}) > 0$, which was such that for every sample $\omega \in \mathcal{D}$, there were an $i(\omega) \geq 0$ (for simplicity, we drop ω below) such that $\tau_i < \infty$ and $\sigma_{i+1} = \infty$, then $u_t = u_t'$ for all $t \geq \tau_i$. Thus, by Lemmas 3.2 and 3.3 we would have that for some constant $a > 1$

$$\|\theta_{T^k} - \theta\|^2 = O\left(\frac{T^k}{a^{T^k} L_{T^k}}\right) = O\left(\frac{1}{k^3}\right) \quad \text{a.s. on } \mathcal{D} \quad \forall k > \tau_i, \tag{3.20}$$

which together with Lemma D.1 in Appendix D implies that there exists an integer $k_1 \geq 0$ such that for any $k \geq k_1$, $A_k(S)G_k(S) - SB_k(S)H_k(S) = E(S)$ is solvable with respect to $G_k(S)$ and $H_k(S)$ subject to $\partial(G_k(S)) \leq q - 1$ and $\partial(H_k(S)) = p$, and $\|G_k(S)\|^2 + \|H_k(S)\|^2 \leq k/(2C_e(p+q+1))$.

From Lemma 3 of Chen and Guo [1990] and the fact that $\partial(R(S)) \geq \partial(C(S)) + 1$ it follows that

$$\int_0^t \left(\frac{C(S)}{R(S)} w_s\right)^2 ds = O(t) \quad \text{a.s.},$$

while from (3.1), (3.3), (3.14), and (3.15) it follows that

$$\xi_s^y - \theta_t^\tau \zeta_s = (\theta - \theta_t)^\tau \zeta_s + \frac{C(S)}{R(S)} w_s + \frac{S}{R(S)} \eta_s + \varepsilon_t \quad \forall t,\ s \geq 0.$$

Therefore, by Assumption A.2, Lemma 3.1, and (3.18) we find that

$$\begin{aligned}
&\frac{1}{f(k, T^k)} \int_0^{T^k} [\xi_s^y - \theta_{T^k}^\tau \zeta_s]^2 \, ds \\
&\leq \frac{4}{f(k, T^k)} \left[\int_0^{T^k} ((\theta - \theta_{T^k})^\tau \zeta_s)^2 \, ds + \int_0^{T^k} \left(\frac{C(S)}{R(S)} w_s\right)^2 ds \right. \\
&\quad \left. + \int_0^{T^k} \left(\frac{S}{R(S)} \eta_s\right)^2 ds + \int_0^{T^k} (\varepsilon_s)^2 \, ds \right] \\
&= O\left(\|\theta_{T^k} - \theta\|^2 + \frac{1}{k^3} \right) = O\left(\frac{1}{k^3}\right) \quad \text{a.s. on } \mathcal{D}, \qquad (3.21)
\end{aligned}$$

where (3.20) is invoked for the last equality.

From (3.21) we conclude that there exists an integer $k_2 \geq k_1$ such that for any $k \geq k_2$,

$$\frac{1}{f(k, T^k)} \int_0^{T^k} [\xi_s^y - \theta_{T^k}^\tau \zeta_s]^2 \, ds \leq k^{-2} \quad \text{a.s. on } \mathcal{D}. \qquad (3.22)$$

Thus, $\sigma_{i+1} < \infty$ a.s. on $\mathcal{D}$. This contradicts $\sigma_{i+1} = \infty$ on $\mathcal{D}$ and $P(\mathcal{D}) > 0$.

We now prove that $\tau_i = \infty$ a.s. for some integer-valued random variable $i \geq 1$.

In fact, from Lemmas 3.2 and 3.3 it follows that for some $a > 1$,

$$\|\theta_{T^{\sigma_i}} - \theta\|^2 = O\left(\frac{T^{\sigma_i}}{a^{T^{\sigma_i}} L_{T^{\sigma_i}}}\right) = O\left(\frac{1}{\sigma_i^3}\right). \qquad (3.23)$$

As in (3.21) we would have

$$\frac{1}{f(\sigma_i, t)} \int_0^t [\xi_s^y - \theta_{T^{\sigma_i}}^\tau \zeta_s]^2 \, ds = O\left(\|\theta_{T^{\sigma_i}} - \theta\|^2 + \frac{1}{\sigma_i^3} \right) = O\left(\frac{1}{\sigma_i^3}\right) \leq \sigma_i^{-2},$$

where the last inequality is valid for some large enough i and $t \geq T^{\sigma_i}$ because of (3.23). Hence there must be $\tau_i = \infty$ for some i; i.e., assertion (a) is true. We now prove assertion (b). From assertion (a) and (3.19) it follows that for some $i \geq 1$,

$$H_{\sigma_i}(S) y_t - G_{\sigma_i}(S) u_t = 0, \quad t \geq T^{\sigma_i}. \qquad (3.24)$$

Henceforth, for simplicity of notation, we shall write $\theta_{\sigma_i}^\tau$ for $\theta_{T^k}^\tau$.

In view of (3.16) we get

$$\begin{aligned} E(S)S^k y_t &= S^k A_{\sigma_i}(S)G_{\sigma_i}(S)y_t - S^{k+1}B_{\sigma_i}(S)H_{\sigma_i}(S)y_t \\ &= S^k G_{\sigma_i}(S)[A_{\sigma_i}(S)y_t - SB_{\sigma_i}(S)u_t] \\ &\quad +S^{k+1}B_{\sigma_i}(S)[G_{\sigma_i}(S)u_t - H_{\sigma_i}(S)y_t], \quad k=0,\ 1,\dots,p+1; \end{aligned} \tag{3.25}$$

$$\begin{aligned} E(S)S^k u_t &= S^k H_{\sigma_i}(S)[A_{\sigma_i}(S)y_t - SB_{\sigma_i}(S)u_t] \\ &\quad +S^k A_{\sigma_i}(S)[G_{\sigma_i}(S)u_t - H_{\sigma_i}(S)y_t], \quad k=0,\ 1,\dots,q. \end{aligned} \tag{3.26}$$

Thus, noting that $A_{\sigma_i}(S)y_t - SB_{\sigma_i}(S)u_t = y_t - \theta_{\sigma_i}^\tau S\varphi_t$, by (3.14), (3.25), and inequality $(a+b)^2 \le 2a^2 + 2b^2$ we get

$$\begin{aligned} S^j\xi_t^y &= R(S)^{-1}S^j y_t \\ &= E(S)^{-1}S^j G_{\sigma_i}(S)R(S)^{-1}(y_t - \theta_{\sigma_i}^\tau\varphi_t) \\ &\quad +E(S)^{-1}R(S)^{-1}S^{j+1}B_{\sigma_i}(S)[G_{\sigma_i}(S)u_t - H_{\sigma_i}(S)y_t] \\ &= E(S)^{-1}S^j G_{\sigma_i}(S)(\xi_t^y - \theta_{\sigma_i}^\tau\zeta_t) \\ &\quad +E(S)^{-1}R(S)^{-1}S^{j+1}B_{\sigma_i}(S)[G_{\sigma_i}(S)u_t - H_{\sigma_i}(S)y_t] \\ &\quad j=0,\ 1,\dots,p+1, \end{aligned}$$

and, furthermore, we have

$$\begin{aligned} \sum_{j=0}^{p+1}(S^j\xi_s^y)^2 &\le 2\|G_{\sigma_i}(S)\|^2\sum_{j=0}^{p+1}\sum_{k=0}^{q-1}[S^{j+k}E^{-1}(S)(\xi_s^y - \theta_{\sigma_i}^\tau\zeta_s)]^2 \\ &\quad +2\sum_{j=0}^{p+1}\left(E^{-1}(S)R^{-1}(S)S^{j+1}B_{\sigma_i}(S)[G_{\sigma_i}(S)u_s - H_{\sigma_i}(S)y_s]\right)^2 \\ &\le 2\|G_{\sigma_i}(S)\|^2(p+q+1)\sum_{j=0}^{p+q}[S^jE^{-1}(S)(\xi_s^y - \theta_{\sigma_i}^\tau\zeta_s)]^2 \\ &\quad +2\sum_{j=0}^{p+1}\left(E^{-1}(S)R^{-1}(S)S^{j+1}B_{\sigma_i}(S)[G_{\sigma_i}(S)u_s - H_{\sigma_i}(S)y_s]\right)^2, \end{aligned} \tag{3.27}$$

and similarly, by (3.26) we get

$$\begin{aligned} \sum_{j=0}^{q}(S^j\xi_s^u)^2 &\le 2\|H_{\sigma_i}(S)\|^2\sum_{j=0}^{q}\sum_{k=0}^{p}[S^{j+k}E^{-1}(S)(\xi_s^y - \theta_{\sigma_i}^\tau\zeta_s)]^2 \\ &\quad +2\sum_{j=0}^{q}\left(E^{-1}(S)R^{-1}(S)S^jA_{\sigma_i}(S)[G_{\sigma_i}(S)u_s - H_{\sigma_i}(S)y_s]\right)^2 \\ &\le 2\|H_{\sigma_i}(S)\|^2(p+q+1)\sum_{j=0}^{p+q}[S^jE^{-1}(S)(\xi_s^y - \theta_{\sigma_i}^\tau\zeta_s)]^2 \\ &\quad +2\sum_{j=0}^{q}\left(E^{-1}(S)R^{-1}(S)S^jA_{\sigma_i}(S)[G_{\sigma_i}(S)u_s - H_{\sigma_i}(S)y_s]\right)^2. \end{aligned} \tag{3.28}$$

By Lemma 3.1 and (3.24) we see that

$$\limsup_{t\to\infty}\frac{1}{t+1}\sum_{j=0}^{p+1}\int_0^t\left(E^{-1}(S)R^{-1}(S)S^{j+1}B_{\sigma_i}(S)[G_{\sigma_i}(S)u_s - H_{\sigma_i}(S)y_s]\right)^2 ds < \infty \quad \text{a.s.}$$

and that

$$\limsup_{t\to\infty}\frac{1}{t+1}\sum_{j=0}^{q}\int_0^t \left(E^{-1}(S)R^{-1}(S)S^jA_{\sigma_i}(S)[G_{\sigma_i}(S)u_s - H_{\sigma_i}(S)y_s]\right)^2 ds < \infty \quad \text{a.s.}$$

Therefore, by (3.27), (3.28), and Lemma 3.1 we conclude that for some $\nu_1 < \infty$ which is independent of t

(3.29)

$$\begin{aligned}
&\frac{1}{t+1}\int_0^t \left[\sum_{k=0}^{p+1}(S^k\xi_s^y)^2 + \sum_{k=0}^{q}(S^k\xi_s^u)^2\right] ds \\
&\le 2(p+q+1)[\|G_{\sigma_i}(S)\|^2 + \|H_{\sigma_i}(S)\|^2]\frac{1}{t+1}\sum_{j=0}^{p+q}\int_0^t \left[\frac{S^j}{E(S)}(\xi_s^y - \theta_{\sigma_i}^\tau\zeta_s)\right]^2 ds + \nu_1 \\
&\le \frac{2(p+q+1)\sigma_i}{2C_e(p+q+1)}\cdot\frac{C_e}{t+1}\int_0^t(\xi_s^y - \theta_{\sigma_i}^\tau\zeta_s)^2 ds + \nu_1 \\
&\le \sigma_i\cdot\sigma_i^{-2}\frac{1}{t+1}f(\sigma_i,t) + \nu_1 \quad \text{a.s.}, \quad t \ge T^{\sigma_i},
\end{aligned}$$

where (3.17), $\sigma_i < \infty$, and $\tau_i = \infty$ a.s. have been used for the last inequality.

Set

$$\nu_2 = \nu_1 + \sup_{0\le\lambda\le T^{\sigma_i}}\left\{\frac{1}{\lambda+1}\int_0^\lambda\left[\sum_{k=0}^{p+1}(S^k\xi_s^y)^2 + \sum_{k=0}^{q}(S^k\xi_s^u)^2\right] ds\right\}.$$

Then from (3.29) and (3.18) it follows that

$$\begin{aligned}
&\sup_{0\le\lambda\le t}\left\{\frac{1}{\lambda+1}\int_0^\lambda\left[\sum_{k=0}^{p+1}(S^k\xi_s^y)^2 + \sum_{k=0}^{q}(S^k\xi_s^u)^2\right] ds\right\} \le \sigma_i^{-1}\frac{1}{t+1}f(\sigma_i,t) + \nu_2 \\
&\le \sigma_i^2 + \nu_2 + \sigma_i^{-1}\sup_{0\le\lambda\le t}\left\{\frac{1}{\lambda+1}\int_0^\lambda\left[\sum_{k=0}^{p+1}(S^k\xi_s^y)^2 + \sum_{k=0}^{q}(S^k\xi_s^u)^2\right] ds\right\} \quad \text{a.s.},
\end{aligned}$$

i.e.,

$$\begin{aligned}
&\limsup_{t\to\infty}\sup_{0\le\lambda\le t}\left\{\frac{1}{\lambda+1}\int_0^\lambda\left[\sum_{k=0}^{p+1}(S^k\xi_s^y)^2 + \sum_{k=0}^{q}(S^k\xi_s^u)^2\right] ds\right\} \\
&\le (1-\sigma_i^{-1})^{-1}\left[\nu_2 + \sigma_i^2\right] < \infty \quad \text{a.s.}
\end{aligned}$$

From this and (3.14), assertion (b) follows. □

Appendix A. Proof of Lemma 2.2. Let

$$N = \begin{bmatrix} \beta_1 & \beta_2 & \dots & \beta_{n+1} \\ 1 & 0 & \dots & 0 \\ & \ddots & \ddots & \vdots \\ 0 & & 1 & 0 \end{bmatrix}, \quad H = [1, \underbrace{0,\dots,0}_{n}]^\tau, \tag{A.1}$$

and, for any $t \in [T^k,\ T^{k+1})$,

$$U_t(k) = [u_t,\ S_k u_t, \dots, S_k^n u_t]^\tau.$$

Then from the definition of u_t it follows that for any $t \in (T^k,\ T^{k+1})$,

$$\frac{dU_t(k)}{dt} = NU_t(k) \quad \text{with } U_{T^k}(k) = HL_{T^k}, \tag{A.2}$$

i.e.,

$$S_kU_t(k) = N^{-1}U_t(k) - N^{-1}HL_{T^k} \quad \forall t \in [T^k,\ T^{k+1}). \tag{A.3}$$

We first to show that there exist constants $c > 0$, $\gamma > 1$ and k_0 such that

$$\lambda_{\min}\left(\int_{T^k}^{T^{k+1}} (S_kU_s(k))(S_kU_s(k))^\tau ds\right) \geq c\gamma^{T^{k+1}}L_{T^k}^2 \quad \forall k \geq k_0, \tag{A.4}$$

where here and hereafter $\lambda_{\min}(X)$ denotes the minimal eigenvalue of matrix X.

From (2.5) and (A.1) we see that the characteristic polynomial $\det(xI-N) = (x-\alpha)^{n+1}$ of N coincides with the minimal polynomial of N. Thus there is a nonsingular $(n+1)\times(n+1)$ matrix P such that

$$\overline{\Lambda} \triangleq P^{-1}NP = \begin{bmatrix} \alpha & & & \\ 1 & \ddots & & \\ & \ddots & \ddots & \\ & & 1 & \alpha \end{bmatrix}_{(n+1)\times(n+1)}. \tag{A.5}$$

Let $\overline{U}_t(k) = P^{-1}U_t(k)$ and $\overline{H} = P^{-1}H$. Then (A.2) is equivalent to

$$\frac{d\overline{U}_t(k)}{dt} = \overline{\Lambda}\cdot\overline{U}_t(k) \quad \text{with } \overline{U}_{T^k}(k) = \overline{H}L_{T^k} \quad \forall t \in (T^k,\ T^{k+1}). \tag{A.6}$$

Noting that for a given positive semidefinite matrix U,

$$\lambda_{\min}(PUP^\tau) \geq \lambda_{\min}(PP^\tau)\lambda_{\min}(U)$$

and $\lambda_{\max}(PP^\tau) \leq \|P\|^2$, by (A.3) and inequality $a^2 \geq \frac{1}{2}b^2 - (b-a)^2$ we have

$$\begin{aligned}
&\lambda_{\min}\left(\int_{T^k}^{T^{k+1}} (S_kU_s(k))(S_kU_s(k))^\tau ds\right) \\
&\geq \frac{1}{2}\lambda_{\min}(N^{-1}N^{-\tau})\lambda_{\min}\left(\int_{T^k}^{T^{k+1}} U_s(k)U_s^\tau(k)ds\right) - \|N^{-1}\|^2T^{k+1}L_{T^k}^2 \\
&\leq \frac{1}{2}\lambda_{\min}(N^{-1}N^{-\tau})\lambda_{\min}(PP^\tau)\,\lambda_{\min}\left(\int_{T^k}^{T^{k+1}} \overline{U}_s(k)\overline{U}_s^\tau(k)ds\right) - \|N^{-1}\|^2T^{k+1}L_{T^k}^2.
\end{aligned}$$

Thus, in order to show (A.4), it suffices to prove that there exist constants $c > 0$, $\gamma > 1$, and k_0 such that

$$\lambda_{\min}\left(\int_{T^k}^{T^{k+1}} \overline{U}_s(k)\overline{U}_s^\tau(k)ds\right) \geq c\gamma^{T^{k+1}}L_{T^k}^2 \quad \forall k \geq k_0. \tag{A.7}$$

From (A.6) it follows that

$$\overline{U}_t(k) = e^{\overline{\Lambda}t}\overline{H}L_{T^k} \quad \forall t \in [T^k, T^{k+1}),$$

which implies that

$$\begin{aligned}\int_{T^k}^{T^{k+1}} \overline{U}_s(k)\overline{U}_s^\tau(k)ds &= L_{T^k}^2 \int_{T^k}^{T^{k+1}} e^{\overline{\Lambda}s}\overline{H}\cdot\overline{H}^\tau e^{\overline{\Lambda}^\tau s}ds \\ &\geq L_{T^k}^2 \int_{T^{k+1}-1}^{T^{k+1}} e^{\overline{\Lambda}s}\overline{H}\cdot\overline{H}^\tau e^{\overline{\Lambda}^\tau s}ds \\ &= L_{T^k}^2 e^{\overline{\Lambda}(T^{k+1}-1)}\left(\int_0^1 e^{\overline{\Lambda}s}\overline{H}\cdot\overline{H}^\tau e^{\overline{\Lambda}^\tau s}ds\right)e^{\overline{\Lambda}^\tau(T^{k+1}-1)} \\ &\geq L_{T^k}^2\lambda_{\min}\left(\int_0^1 e^{\overline{\Lambda}s}\overline{H}\cdot\overline{H}^\tau e^{\overline{\Lambda}^\tau s}ds\right)e^{\overline{\Lambda}(T^{k+1}-1)}e^{\overline{\Lambda}^\tau(T^{k+1}-1)}. \qquad \text{(A.8)}\end{aligned}$$

Note that (N, H) is controllable and hence $(\overline{\Lambda}, \overline{H})$ is controllable. Therefore,

$$\lambda_{\min}\left(\int_0^1 e^{\overline{\Lambda}s}\overline{H}\cdot\overline{H}^\tau e^{\overline{\Lambda}^\tau s}ds\right) > 0. \qquad \text{(A.9)}$$

Set

$$\Sigma_t = \begin{bmatrix} 1 & & & \\ (t-1) & \ddots & & \\ \vdots & \ddots & \ddots & \\ \dfrac{(t-1)^n}{n!} & \cdots & (t-1) & 1 \end{bmatrix}.$$

Then from (A.5) we see that

$$e^{\overline{\Lambda}(t-1)} = e^{\alpha(t-1)}\Sigma_t. \qquad \text{(A.10)}$$

It is evident that

$$\det(\Sigma_t\Sigma_t^\tau) = 1 \quad \text{and} \quad \lambda_{\max}(\Sigma_t\Sigma_t^\tau) \leq (n+1)\sum_{i=0}^{n}(t-1)^{2i},$$

where $\lambda_{\max}(X)$ denotes the maximum eigenvalues of X.

Thus, from the fact that $\det(X) = \prod_{i=1}^{n+1}\lambda_i(X)$ for any $(n+1)\times(n+1)$ matrix with eigenvalues $\lambda_i(X)$ $(i = 1, \ldots, n+1)$ it follows that

$$\lambda_{\min}(\Sigma_t\Sigma_t^\tau) \geq [\lambda_{\max}(\Sigma_t\Sigma_t^\tau)]^{-n} \geq \left[(n+1)\sum_{i=0}^{n}(t-1)^{2i}\right]^{-n}$$

$$\geq (n+1)^{-2n}(t-1)^{-2n^2} \quad \forall t \geq 2.$$

From this and (A.10) we get that

$$\lambda_{\min}\left(e^{\overline{\Lambda}(t-1)}e^{\overline{\Lambda}^\tau(t-1)}\right) \geq e^{2\alpha(t-1)}\cdot(n+1)^{-2n}(t-1)^{-2n^2} \quad \forall t \geq 2,$$

which together with $\alpha > 0$, (A.9), and (A.8) implies the desired result (A.7). Therefore, (A.4) is true.

We are now in a position to prove (2.13).

Write

$$\operatorname{Adj}(I - AS) = I + A_1 S + \cdots + A_{n-1} S^{n-1},$$
$$A(S) \triangleq \det(I - AS) = a_0 + a_1 S + \cdots + a_n S^n$$

and set

$$M = \begin{bmatrix} 0 & B & A_1 B & \dots & A_{n-1} B \\ a_0 & a_1 & a_2 & \dots & a_n \end{bmatrix},$$

where I denotes $n \times n$ identity matrix.

Clearly, we have

$$A(S)\psi_\lambda = \begin{bmatrix} \operatorname{Adj}(I - AS) S^2 B u_\lambda + \operatorname{Adj}(I - AS)(x_0 \lambda + CSw_\lambda) \\ A(S) S u_\lambda \end{bmatrix}$$
$$= MSU_t + \begin{bmatrix} \operatorname{Adj}(I - AS)(x_0 \lambda + CSw_\lambda) \\ 0 \end{bmatrix},$$

where

$$U_t = [u_t,\ Su_t, \dots, S^n u_t]^\tau.$$

Therefore, we get

$$\lambda_{\min}\left(\int_{T^k}^t [A(S)\psi_s][A(S)\psi_s]^\tau ds\right)$$
$$\geq \frac{1}{2}\lambda_{\min}\left(M \int_{T^k}^t (SU_s)(SU_s)^\tau ds M^\tau\right) - c\sum_{i=0}^n \int_0^t \left[s^{2i} + \|S^i w_s\|^2\right] ds. \tag{A.11}$$

Using the argument in, e.g., Zhang and Chen [1991] we can obtain

$$\int_0^t \|S^i w_s\|^2 ds \leq c t^{2i+3}, \quad i = 0, 1, 2, \dots, n, \tag{A.12}$$

and

$$\lambda_{\min}\left(\int_{T^k}^t [A(S)\psi_s][A(S)\psi_s]^\tau ds\right) = \min_{\|x\|=1} \int_{T^k}^t \left|\sum_{i=0}^n a_i S^i x^\tau \psi_s\right|^2 ds$$
$$\leq c\sum_{i=0}^n t^{2i+1} \lambda_{\min}\left(\int_{T^k}^t \psi_s \psi_s^\tau ds\right) + c\left(\sum_{i=0}^n t^{2i+1}\right) \int_0^{T^k} \|\psi_s\|^2 ds. \tag{A.13}$$

From (A.11)–(A.13) we have

$$\lambda_{\min}\left(\int_{T^k}^t \psi_s \psi_s^\tau ds\right) \geq \frac{1}{c}\lambda_{\min}(MM^\tau)\left(\sum_{i=0}^n t^{2i+1}\right)^{-1} \lambda_{\min}\left(\int_{T^k}^t (SU_s)(SU_s)^\tau ds\right)$$
$$-c\left(\sum_{i=0}^n t^{2i+1}\right)^{-1}\left(\sum_{i=0}^{n+1} t^{2i+1}\right) - \int_0^{T^k} \|\psi_s\|^2 ds. \tag{A.14}$$

By induction we can show that

$$|S^i u_t - S_k^i u_t| \le t^{i-1} \int_0^{T^k} |u_s| ds \quad \forall i = 1, 2, \dots, \quad \forall t \in [T^k, T^{k+1}).$$

From this we see that for any $x \in I\!R^{n+1}$ with $\|x\| = 1$ and $t \in [T^k, T^{k+1})$,

$$\begin{aligned}
\int_{T^k}^t (x^\tau S U_s)^2 ds &\ge \frac{1}{2} \int_{T^k}^t [x^\tau S_k U_s(k)]^2 ds - \int_{T^k}^t \|S_k U_s(k) - S U_s\|^2 ds \\
&\ge \frac{1}{2} \int_{T^k}^t [x^\tau S_k U_s(k)]^2 ds - \int_{T^k}^t \sum_{i=1}^{n+1} |S^i u_s - S_k^i u_s|^2 ds \\
&\ge \frac{1}{2} \int_{T^k}^t [x^\tau S_k U_s(k)]^2 ds - \sum_{i=1}^{n+1} \left(\int_0^{T^k} |u_s| ds \right)^2 \int_{T^k}^t s^{2(i-1)} ds \\
&\ge \frac{1}{2} \int_{T^k}^t [x^\tau S U_s(k)]^2 ds - \sum_{i=1}^{n+1} \left(\int_0^{T^k} u_s^2 ds \right) T^{2i(k+1)} \\
&\ge \frac{1}{2} \int_{T^k}^t [x^\tau S U_s(k)]^2 ds - (n+1) T^{2(n+1)(k+1)} \int_0^{T^k} u_s^2 ds,
\end{aligned}$$

which implies that

$$\begin{aligned}
\lambda_{\min} \left(\int_{T^k}^{T^{k+1}} (S U_s)(S U_s)^\tau ds \right) \ge \frac{1}{2} \lambda_{\min} &\left(\int_{T^k}^{T^{k+1}} (S_k U_s(k))(S_k U_s(k))^\tau ds \right) \\
&- (n+1) T^{2(n+1)(k+1)} L_{T^k}.
\end{aligned} \tag{A.15}$$

This together with (A.4) and (A.14) leads to

$$\lambda_{\min} \left(\int_{T^k}^{T^{k+1}} \psi_s \psi_s^\tau ds \right) \ge c^{-1} T^{-(2n+1)(k+1)} \gamma^{T^{k+1}} L_{T^k}^2 - c T^{(2n+3)(k+1)} L_{T^k}. \tag{A.16}$$

With $(S+1) z_t = \psi_t$ in mind, we get

$$\begin{aligned}
\lambda_{\min} \left(\int_{T^k}^{T^{k+1}} \psi_s \psi_s^\tau ds \right) &= \lambda_{\min} \left(\int_{T^k}^{T^{k+1}} [(S+1) z_s][(S+1) z_s]^\tau ds \right) \\
&= \min_{\|x\|=1} \int_{T^k}^{T^{k+1}} |x^\tau z_s + S x^\tau z_s|^2 ds \\
&\le 4 T^{2(k+1)} \lambda_{\min} \left(\int_{T^k}^{T^{k+1}} z_s z_s^\tau ds \right) + 2 T^{2(k+1)} \int_0^{T^k} \|z_s\|^2 ds,
\end{aligned}$$

i.e.,

$$\begin{aligned}
\lambda_{\min} \left(\int_{T^k}^{T^{k+1}} z_s z_s^\tau ds \right) \ge 4^{-1} T^{-2(k+1)} &\lambda_{\min} \left(\int_{T^k}^{T^{k+1}} \psi_s \psi_s^\tau ds \right) \\
&- 2^{-1} \int_0^{T^k} \|z_s\|^2 ds.
\end{aligned}$$

From this, (A.16), and the definition of L_{T^k} it follows that

$$\lambda_{\min}\left(\int_{T^k}^{T^{k+1}} z_s z_s^\tau ds\right) \geq c^{-1}T^{-(2n+3)(k+1)}\gamma^{T^{k+1}}L_{T^k}^2 - cT^{(2n+1)(k+1)}L_{T^k},$$

which implies the desired result (2.13). □

Appendix B. The following lemma is based on Chen [1992].

LEMMA B.1. *If $T > 1$ is a constant, (F, C) is controllable, $F \in \mathcal{F}_\sigma$ with $\sigma < \infty$ a.s. being a stopping time, and if*

$$\limsup_{k\to\infty} \frac{1}{T^k}\int_0^{T^k} \|x_s\|^2 ds < \infty \quad a.s. \tag{B.1}$$

for the system

$$dx_t = Fx_t dt + C dw_t, \quad t \geq \sigma, \tag{B.2}$$

then F must be stable a.s.

Proof. Assume that F^τ has an eigenvalue λ with $\Re(\lambda) \geq 0$, where $\Re(x)$ denotes the real part of a complex number x. Let y be the corresponding eigenvector, i.e., $F^\tau y = \lambda y$. Then by (B.2) we get

$$d[\Re(y^\tau x_t) + i\Im(y^\tau x_t)] = [\Re(\lambda) + i\Im(\lambda)][\Re(y^\tau x_t) + i\Im(y^\tau x_t)]dt + y^\tau C dw_t \quad \forall t \geq \sigma,$$

i.e.

$$dz_t = \begin{bmatrix} \Re(\lambda) & -\Im(\lambda) \\ \Im(\lambda) & \Re(\lambda) \end{bmatrix} z_t dt + \begin{bmatrix} \Re(y^\tau C) \\ \Im(y^\tau C) \end{bmatrix} dw_t, \tag{B.3}$$

where $\Im(x)$ denotes the imaginary part of a complex number x and

$$z_t = \begin{bmatrix} \Re(y^\tau x_t) \\ \Im(y^\tau x_t) \end{bmatrix}.$$

Using Ito's formula, by (B.3) we obtain

$$\begin{aligned} dz_t^\tau z_t &= 2z_t^\tau \begin{bmatrix} \Re(\lambda) & -\Im(\lambda) \\ \Im(\lambda) & \Re(\lambda) \end{bmatrix} z_t dt + 2z_t^\tau \begin{bmatrix} \Re(y^\tau C) \\ \Im(y^\tau C) \end{bmatrix} dw_t + \|y^\tau C\|^2 dt \\ &= 2\Re(\lambda)\|z_t\|^2 dt + 2z_t^\tau \begin{bmatrix} \Re(y^\tau C) \\ \Im(y^\tau C) \end{bmatrix} dw_t + \|y^\tau C\|^2 dt, \end{aligned}$$

which implies (Christopeit [1986]) that for any $\eta \in (0, 1/2)$,

$$\|z_t\|^2 = \|z_\sigma\|^2 + 2\Re(\lambda)\int_\sigma^t \|z_s\|^2 ds + O\left(\left(\int_\sigma^t \|z_s\|^2 ds\right)^{\frac{1}{2}+\eta}\right) + \|y^\tau C\|^2(t-\sigma). \tag{B.4}$$

Noting that (B.1) implies that

$$\limsup_{k\to\infty} \frac{1}{T^k}\int_\sigma^{T^k} \|z_s\|^2 ds < \infty, \tag{B.5}$$

by (B.4) we have

$$\text{(B.6)}\quad \|z_t\|^2 = \|z_\sigma\|^2 + 2\Re(\lambda)\int_\sigma^t \|z_s\|^2 ds + O\left(t^{\frac{1}{2}+\eta}\right) + \|y^\tau C\|^2(t-\sigma) \quad \forall \eta \in (0, 1/2).$$

From controllability of (F, C) it is easy to see that $\|y^\tau C\| \neq 0$, and hence from (B.6) and $\Re(\lambda) \geq 0$ it follows that for some $t_0 \geq \sigma$ and $c > 0$,

$$\|z_t\|^2 \geq ct \quad \forall t \geq t_0, \quad t_0 \text{ random},$$

which contradicts (B.5). □

Appendix C. Proof of Lemma 3.3. As in Appendix A, we can show that there exist constants $c > 0$, $\gamma > 1$, and k_0 such that

$$\text{(C.1)}\qquad \lambda_{\min}\left(\int_{T^k}^{T^{k+1}} (S_k U_s(k))(S_k U_s(k))^\tau ds\right) \geq c\gamma^{T^{k+1}} L_{T^k}^2 \quad \forall k \geq k_0,$$

where here and hereafter

$$U_t(k) = [u_t,\ S_k u_t, \ldots, S_k^{p+q-1} u_t]^\tau.$$

Set $W_t = y_0 t + SC(S)w_t + S^2\eta_t$ and $M = [M_1,\ M_2]^\tau$ with

$$M_1^\tau \triangleq \left(\begin{array}{cccccccccc} \overbrace{0 & b_1 & \ldots & \ldots & \ldots & \ldots & b_q & 0 & \ldots & 0}^{p+q} \\ 0 & 0 & \ddots & & & & & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & & & & & \ddots & 0 \\ 0 & \ldots & 0 & 0 & b_1 & \ldots & \ldots & \ldots & \ldots & b_q \end{array}\right)\Bigg\}\, p$$

and

$$M_2^\tau \triangleq \left(\begin{array}{cccccccccc} \overbrace{1 & a_1 & \ldots & \ldots & \ldots & \ldots & a_q & 0 & \ldots & 0}^{p+q} \\ 0 & 1 & \ddots & & & & & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & & & & & \ddots & 0 \\ 0 & \ldots & 0 & 1 & a_1 & \ldots & \ldots & \ldots & \ldots & a_q \end{array}\right)\Bigg\}\, q.$$

Then from (3.1) and (3.11) it follows that

$$\text{(C.2)}\qquad A(S)\varphi_t = MSU_t + [W_t,\ SW_t, \ldots, S^{p-1}W_t,\ \underbrace{0, \ldots, 0}_{q}]^\tau,$$

where here and hereafter,

$$\text{(C.3)}\qquad U_t = [u_t,\ Su_t, \ldots, S^{p+q-1}u_t]^\tau.$$

Notice that by Assumption A.2, for $i = 1, 2, \ldots, p$,

$$\int_0^t (S^i\eta_s)^2 ds \leq \int_0^t \frac{t^{2i} - s^{2i}}{2i(2i-1)[(i-1)!]^2}\eta_s^2 ds \leq ct^{2i+1}.$$

Then similar to (A.11)–(A.14), by (C.2) we obtain

$$\lambda_{\min}\left(\int_{T^k}^{t}\varphi_s\varphi_s^\tau ds\right) \geq \frac{1}{c}\left(\sum_{i=0}^{p}t^{2i+1}\right)^{-1}\lambda_{\min}\left(\int_{T^k}^{t}(SU_s)(SU_s)^\tau ds\right)$$

$$-c\left(\sum_{i=0}^{p}t^{2i+1}\right)^{-1}\sum_{i=0}^{p+l}(t+1)^{2i+1}-\int_0^{T^k}\|\varphi_s\|^2 ds. \tag{C.4}$$

By (C.3) and along the argument of (A.15) we get

$$\lambda_{\min}\left(\int_{T^k}^{T^{k+1}}(SU_s)(SU_s)^\tau ds\right) \geq \frac{1}{2}\lambda_{\min}\left(\int_{T^k}^{T^{k+1}}(S_kU_s(k))(S_kU_s(k))^\tau ds\right)$$

$$-(p+q)T^{2(p+q)(k+1)}L_{T^k}.$$

This together with (C.1) and (C.4) leads to

$$\lambda_{\min}\left(\int_{T^k}^{T^{k+1}}\varphi_s\varphi_s^\tau ds\right) \geq c^{-1}T^{-(2p+1)(k+1)}\gamma^{T^{k+1}}L_{T^k}^2 - cT^{2(p+q+l+2)(k+1)}L_{T^k}. \tag{C.5}$$

With $F(S)\varphi_t^f = \varphi_t$ in mind, as in (A.13) we get

$$\lambda_{\min}\left(\int_{T^k}^{T^{k+1}}\varphi_s\varphi_s^\tau ds\right) = \lambda_{\min}\left(\int_{T^k}^{T^{k+1}}(F(S)\varphi_s^f)(F(S)\varphi_s^f)^\tau ds\right)$$

$$= \min_{\|x\|=1}\int_{T^k}^{T^{k+1}}\left|\sum_{i=0}^{l+1}f_iS^ix^\tau\varphi_s^f\right|^2 ds$$

$$\leq cT^{(2l+3)(k+1)}\lambda_{\min}\left(\int_{T^k}^{T^{k+1}}\varphi_s^f(\varphi_s^f)^\tau ds\right) + cT^{(2l+3)(k+1)}\int_0^{T^k}\|\varphi_s^f\|^2 ds,$$

i.e.,

$$\lambda_{\min}\left(\int_{T^k}^{T^{k+1}}\varphi_s^f(\varphi_s^f)^\tau ds\right) \geq cT^{-(2l+3)(k+1)}\lambda_{\min}\left(\int_{T^k}^{T^{k+1}}\varphi_s\varphi_s^\tau ds\right)$$

$$-\int_0^{T^k}\|\varphi_s^f\|^2 ds.$$

From this, (C.5) and the definition of L_{T^k} it follows that

$$\lambda_{\min}\left(\int_{T^k}^{T^{k+1}}\varphi_s^f(\varphi_s^f)^\tau ds\right) \geq c^{-1}T^{-2(p+l+2)(k+1)}\gamma^{T^{k+1}}L_{T^k}^2 - cT^{2(p+q+l+2)(k+1)}L_{T^k},$$

which implies the desired result, Lemma 3.3. □

Appendix D.

LEMMA D.1. *If $A(S)$ and $SB(S)$ are coprime, $b_q \neq 0$ and*

$$\theta_{T^k} \xrightarrow[k\to\infty]{} \theta \ \text{a.s.},$$

then there is an integer-valued K, possibly depending on a sample path such that for all $k \geq K$, $A_k(S)G_k(S) - SB_k(S)H_k(S) = E(S)$ is solvable with respect to $G_k(S)$ and $H_k(S)$ subject to $\partial(G_k(S)) \leq q-1$ and $\partial(H_k(S)) = p$, and such that $\|G_k(S)\|^2 + \|H_k(S)\|^2 \leq k/(2C_e(p+q+1))$.

Proof. Let

$$\text{(D.1)}\quad M_3^\tau = \overbrace{\begin{pmatrix} 1 & a_1 & \dots & \dots & \dots & \dots & a_p & 0 & \dots & 0 & 0 \\ 0 & 1 & \ddots & & & & & \ddots & \ddots & \vdots & \vdots \\ \vdots & \ddots & \ddots & \ddots & & & & & \ddots & 0 & 0 \\ 0 & \dots & 0 & 1 & a_1 & \dots & \dots & \dots & \dots & a_p & 0 \end{pmatrix}}^{p+q+1} \Bigg\} q,$$

$$\text{(D.2)}\quad M_4^\tau = \overbrace{\begin{pmatrix} 0 & -b_1 & \dots & \dots & \dots & \dots & -b_q & 0 & \dots & 0 \\ 0 & 0 & \ddots & & & & & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & & & & & \ddots & 0 \\ 0 & \dots & 0 & 0 & -b_1 & \dots & \dots & \dots & \dots & -b_q \end{pmatrix}}^{p+q+1} \Bigg\} p+1,$$

$$\text{(D.3)}\quad M' = [M_3,\ M_4],$$

$$H_e = [1,\ e_1,\ \dots,\ e_{p+q}]^\tau.$$

Replacing a_i and b_j by their estimates a_{iT^k} and b_{jT^k}, respectively, in (D.1)–(D.3) for $i = 1, \dots, p$ and $j = 1, \dots, q$, we correspondingly denote M_3, M_4, and M' by $M_{3,k}$, $M_{4,k}$, and M_k'. Furthermore, if M_k' is nonsingular, we set $\Psi_k = (M_k')^{-1}H_e$.

Since $A(S)$ and $SB(S)$ are coprime and $b_q \neq 0$, we see that M' given by (D.1)–(D.3) is nonsingular. Let $\Psi = (M')^{-1}H_e$ and $G(S) = \sum_{i=0}^{q-1} g_i S^i$, $H(S) = \sum_{i=0}^{p} h_i S^i$ with

$$[g_0,\ g_1, \dots, g_{q-1},\quad h_0,\ h_1, \dots, h_p] \triangleq \Psi.$$

Then recalling that

$$\theta_{T^k} \xrightarrow[k \to \infty]{} \theta,$$

we see that there is an integer $K' \geq 0$ such that for all $k \geq K'$, M_k' is nonsingular,

$$M_k' \xrightarrow[k \to \infty]{} M', \text{ and } \Psi_k \xrightarrow[k \to \infty]{} \Psi.$$

Furthermore for all $k \geq K'$, if we set $G_k(S) = \sum_{i=0}^{q-1} g_{i,k} S^i$, $H_k(S) = \sum_{i=0}^{p} h_{i,k} S^i$ with

$$[g_{0,k},\ g_{1,k}, \dots, g_{q-1,k},\quad h_{0,k},\ h_{1,k}, \dots, h_{p,k}] \triangleq \Psi_k,$$

then we have $\partial(G_k(S)) \leq q-1$, $\partial(H_k(S)) = p$ and

$$A_k(S)G_k(S) - SB_k(S)H_k(S) = E(S).$$

Noting that

$$\Psi_k \xrightarrow[k \to \infty]{} \Psi$$

we see that there exists an integer $K \geq K'$ such that for all $k \geq K$, $\|G_k(S)\|^2 + \|H_k(S)\|^2 = \|\Psi_k\|^2 \leq k/(2C_e(p+q+1))$. □

MULTIPLICATIVE INTERIOR GRADIENT METHODS FOR MINIMIZATION OVER THE NONNEGATIVE ORTHANT*

ALFREDO N. IUSEM†, B. F. SVAITER†, AND MARC TEBOULLE‡

Abstract. We introduce a new class of multiplicative iterative methods for solving minimization problems over the nonnegative orthant. The algorithm is akin to a natural extension of gradient methods for unconstrained minimization problems to the case of nonnegativity constraints, with the special feature that it generates a sequence of iterates which remain in the interior of the nonnegative orthant. We prove that the algorithm combined with an appropriate line search is weakly convergent to a saddle point of the minimization problem, when the minimand is a differentiable function with bounded level sets. If the function is convex, then weak convergence to an optimal solution is obtained. Moreover, by using an appropriate regularized line search, we prove that the level set boundeness hypothesis can be removed, and full convergence of the iterates to an optimal solution is established in the convex case.

AMS subject classifications. 90C25, 90C30

1. Introduction.

Consider the problem of minimizing a continuously differentiable function $f : \mathbf{R}^n \to \mathbf{R}$ over the nonnegative orthant of $\mathbf{R}^n$,

$$P: \quad \min\{f(x) : x \in \mathbf{R}^n_+\},$$

where $\mathbf{R}^n_+ = \{x \in \mathbf{R}^n : x_j \geq 0 \ \ (1 \leq j \leq n)\}$. From now on, we assume that problem P has solutions.

In this paper, we are interested in multiplicative iterative methods, which starting with an initial point in the interior $\mathbf{R}^n_{++}$ of the nonnegative orthant, will generate a sequence of feasible interior points $\{x^k\} \in \mathbf{R}^n_{++}$ through an iteration of the form

$$x^{k+1}_j = x^k_j M(\nabla f(x^k)_j, \lambda_k), \quad j = 1, \ldots, n \tag{1}$$

where M is an appropriate mapping, $\nabla f(x^k)_j$ denotes the jth component of the gradient of f, and λ_k is a given positive parameter. As shown below, this class of methods can be seen as a natural extension of gradient methods for unconstrained minimization problems, with the special feature that they generate iterates in the interior of the nonnegative cone. Accordingly, such methods will be called *multiplicative interior gradient* algorithms.

The fact that all the iterates of these algorithms remain in the interior of the nonnegative orthant connects them with interior points methods for linear programming, which became popular after Karmarkar's method [9] proved to be computationally efficient. These methods apply a transformation to the current iterate x^k so as to

move it away from the boundary of the orthant, and then use minus the gradient of the objective at x^k (projected onto the corresponding affine manifold, if there are linear equality constraints besides positivity) as the moving direction. Then a stepsize is chosen so as to preserve positivity, a new point is obtained, and finally the transformation is reversed. Typical transformations include projective transformations, as in [9], and affine scalings, as in [3], possibly the first among methods of this kind. A survey on this type of algorithms can be found in [6]. In this paper we consider only positivity constraints (so that no projection onto a linear manifold is needed), and we use a distancelike function, called a φ-divergence, which has a penalization effect. We use $-\nabla f(x^k)$ and the φ-divergence in order to generate the direction, and it is automatically ensured that a unit stepsize in this direction will produce a fully positive point. No transformation or change of variables is explicitly performed.

The motivation for considering multiplicative interior gradient algorithms stems from the recent work of Eggermont [4], who studied algorithms of the form (1) with particular choices of the mapping M. As demonstrated in [4], multiplicative iterative algorithms are useful in various interesting applications such as image reconstruction and inverse problems. For further details, we refer the reader to [4] and references therein.

The construction of the family of multiplicative interior gradient algorithms introduced here for solving problem P is derived by imitating the classical gradient method, which can be interpreted as solving

$$x^{k+1} = \operatorname{argmin}\{x^t \nabla f(x^k) + (2\lambda_k)^{-1} \|x - x^k\|^2\}, \tag{2}$$

where $\|\cdot\|$ denotes the Euclidean norm in $\mathbf{R}^n$. This algorithm can alternatively be also viewed as an *explicit* realization of the proximal regularization method for solving $\inf\{f(x)\colon x \in \mathbf{R}^n\}$; for the proximal minimization algorithm, see, e.g., Rockafellar [12] and Lemaire [10]. To incorporate the nonnegativity constraints of problem P, we replace here the quadratic kernel by a distancelike function, based on the φ-divergence of Csiszár (see, e.g., [2]).

Let $\varphi\colon (0,\infty) \to [0,\infty)$ be a strictly convex and thrice continuously differentiable function which satisfies

$$\varphi(1) = \varphi'(1) = 0, \quad \varphi''(1) > 0, \quad \lim_{t\to 0} \varphi'(t) = -\infty.$$

The class of such functions will be denoted by Φ_1. Define $d_\varphi\colon \mathbf{R}^n_{++} \times \mathbf{R}^n_{++} \to \mathbf{R}_+$ as

$$d_\varphi(x,y) = \sum_{j=1}^{n} y_j \varphi\left(\frac{x_j}{y_j}\right). \tag{3}$$

When $\varphi \in \Phi_1$, d_φ is said to be a φ-divergence. In the context of proximal methods, φ-divergences are studied in [13], where several of their properties are presented. It is easily seen that $d_\varphi(x,y) \geq 0$, with equality if and only if $x = y$, and thus d_φ can be interpreted as a kind of (nonsymmetric) distance between two points in the positive orthant of $\mathbf{R}^n$. In analogy with (2), we define the basic multiplicative interior gradient algorithm (BMIG) as a method generating a sequence $\{x^k\} \subset \mathbf{R}^n_{++}$ according to

$$x^0 > 0, \tag{4}$$

$$x^{k+1} = \operatorname*{argmin}_{x\in\mathbf{R}^n_+}\{x^t \nabla f(x^k) + \lambda_k d_\varphi(x, x^k)\} \tag{5}$$

with $\varphi \in \Phi_1$.

Alternatively, BMIG can also be seen as an explicit version of the φ-divergence proximal algorithm we recently introduced in [8]:

$$x^0 > 0, \tag{6}$$

$$x^{k+1} = \operatorname*{argmin}_{x \in \mathbf{R}^n_+} \{f(x) + \lambda_k d_\varphi(x, x^k)\}, \tag{7}$$

where the function f in (7) is replaced by its linear approximation around x^k in (5). For a convergence analysis and applications of (6)–(7) see [8]. Noting that (5) basically reduces to solving, for x^{k+1},

$$\varphi'\left(\frac{x_j}{x_j^k}\right) = -\lambda_k^{-1} \nabla f(x^k)_j, \quad j = 1, \ldots, n, \tag{8}$$

and assuming that φ' can be easily inverted (as in the case of most relevant examples), we get the explicit formula which is the basis of our algorithm:

$$x_j^{k+1} = x_j^k (\varphi')^{-1}(-\lambda_k^{-1} \nabla f(x^k)_j). \tag{9}$$

Before discussing in the next section the advantages and drawbacks of this approach, we present some of the multiplicative algorithms resulting from iteration (5) for several relevant choices of φ, illustrating the unified framework emerging from our approach to generate multiplicative algorithms.

Example 1. Let $\varphi_1(t) = t - \log t - 1$; then (9) gives

$$x_j^{k+1} = x_j^k (1 + \lambda_k^{-1} \nabla f(x_k)_j)^{-1}, \qquad j = 1, \ldots, n.$$

Example 2. $\varphi_2(t) = t \log t - t + 1$,

$$x_j^{k+1} = x_j^k \exp(-\lambda_k^{-1} \nabla f(x_k)_j)^{-1}, \qquad j = 1, \ldots, n.$$

Example 3. $\varphi_3(t) = (\sqrt{t} - 1)^2$,

$$x_j^{k+1} = x_j^k (1 + \lambda_k^{-1} \nabla f(x_k)_j)^{-2}, \qquad j = 1, \ldots, n.$$

Example 4. $\varphi_4(t) = \frac{1}{2}(t-1)^2$,

$$x_j^{k+1} = x_j^k (1 - \lambda_k^{-1} \nabla f(x_k)_j), \qquad j = 1, \ldots, n.$$

The algorithm in Example 1 was introduced and studied in Eggermont [4], which under appropriate assumptions proved its convergence in the convex case. The algorithms in Examples 2 and 3 appear to be new in the literature and can also be seen as explicit realizations of the φ-divergence proximal methods (see also §7 in [8]). Note that for the first three examples $\varphi \in \Phi_1$. The algorithm which emerges from Example 4 was also pointed out by Eggermont as another possible iterative method for solving P in the convex case; however, no convergence results were established. Note that since φ_4 is not in the class Φ_1, positivity-preserving safeguards are needed; see [7] for the analysis of such an algorithm and its application to maximum-likelihood estimation problems. We also observe the interesting similarity between the algorithms of Examples 2 and 4, the latter being just a "linearization" of the algorithm of Example 2, although it is not clear that this can be used in the analysis of the algorithm given in Example 4. As discussed in the following section, in order to obtain satisfactory convergence results, a linear search must be added to algorithm BMIG, producing the complete form of the multiplicative interior gradient (MIG), which we present in §3.

The iterative formulae for MIG with φ as in Examples 1–3 can be found in (50)–(52), where α_k is the optimal stepsize found in the linear search.

2. Preliminary discussion. The reason for considering iteration (5) as an algorithm for problem P follows from the fact that its fixed points are easily seen to be closely connected to the solutions of problem P. If we take $\lambda_k = \lambda$ a fixed positive constant, and x^* a fixed point of (9) we have

$$x_j^* = x_j^*(\varphi')^{-1}(-\lambda^{-1}\nabla f(x^*)_j), \tag{10}$$

and therefore either $x_j^* = 0$ or $\lambda^{-1}\nabla f(x^*)_j = \varphi'(1) = 0$, implying $\nabla f(x^*)_j = 0$. It follows that if the sequence $\{x^k\}$ generated by (5) is convergent, then its limit x^* satisfies $x^* \geq 0$, $\nabla f(x^*)^t x^* = 0$, and it can be proved that when f is convex, we also have $\nabla f(x^*) \geq 0$, in which case x^* is a solution of P (see §4).

Iteration (5) seems therefore, in view of the explicit formula (9), also an appealing option for implementing an approximate version of the φ-divergence proximal method. However, in its bare formulation given in (5) and (9), the method exhibits some serious problems. The first one refers to the existence of solutions of (5). While in the case of the φ-divergence proximal method, existence of solutions for (7) are guaranteed by the existence of solutions of problem P together with positivity and strict convexity of d_φ, this is not true anymore for (5), since the objective $\nabla f(x^k)^t x$ may fail to attain its minimum on $\mathbf{R}^n_+$ (in fact this happens whenever $\nabla f(x^k)_j < 0$ for some j). In terms of (8), lack of solution of the subproblem in (5) translates as $-\lambda_k^{-1}\nabla f(x^k)_j^t x$ not belonging to $\mathrm{Im}\varphi'$, the range of φ'. Since $\varphi \in \Phi_1$, it holds that $\lim_{t\to 0}\varphi'(t) = -\infty, \varphi'(1) = 0$, and φ' is increasing so that $\mathrm{Im}\varphi' = (-\infty, \eta)$ with $\eta = \lim_{t\to\infty}\varphi'(t) > 0$. If $-\lambda_k^{-1}\nabla f(x^k)_j > \eta$, then the minimization problem in (5) has no solutions. This cannot happen if $\eta = \infty$, as for φ_2 of Example 2, but it can occur with φ_1 of Example 1, for which $\eta = 1$. In this case the right-hand side in that example could be negative so that the iterate x^{k+1} would not be a solution of the subproblem given by (5). There are two ways to overcome this obstacle. One is to demand that φ satisfies $\lim_{t\to\infty}\varphi'(t) = \infty$, but then we must exclude several interesting choices of φ's from the analysis, such as φ_1 and φ_3 of Examples 1 and 3 (for both of which $\eta = 1$). Another option, which will be followed in this paper, is to adjust the regularization coefficients λ_k so that $-\nabla f(x^k)_j\lambda_k^{-1} < \eta$ for all k.

The second difficulty with iteration (5) is far more serious and stems from the fact that, while the fixed points of (5) are, in general, solutions of P, they are not necessarily attractors for the iteration. Another way to see this obstacle is the following: it is easy to check that iteration (7) implies $f(x^{k+1}) \leq f(x^k)$, and this descent feature of algorithm (7) is a key in the proof of its convergence [8]. This desirable property is not shared by BMIG, as the following examples show.

Example 5. Take $n = 1, \lambda_k = 1$ for all k, and $\varphi = \varphi_2$ as in Example 2. Here, $\mathrm{Im}\varphi_2' = (-\infty, \infty)$ so that x^{k+1} is always well defined by (5). Consider first the objective function $f(x) = ax^2 - bx$, with $a = 2/e - 1, b = (e+1)/(e-1)$. Note that f is a strongly convex quadratic function and the solution of problem P is $x^* = (e+1)/2$. If we start with $x^0 = 1$, then $x^1 = e, x^2 = 1$, and the sequence oscillates between 1 and e, forever missing x^*, which is the midpoint between these two limit points. For this choice of f the sequence $\{x^k\}$ is at least bounded, but this is not always the case. Consider now for instance $f(x) = 1/x + x^2$. This f is also strictly convex and the solution of P is $x^* = 2^{-1/3}$. It can be verified that if $x^0 > x^*$, then $\lim_{k\to\infty} x^{2k} = \infty$, $\lim_{k\to\infty} x^{2k+1} = 0$, and the values of such limits reverse when $x^0 < x^*$. Of course for

$x^0 = x^*$ we get $x^k = x^*$ for all k, but x^* is a repeller, rather than an attractor, for iteration (5), so that even a local convergence result is not attainable.

This obstacle can also be removed by choosing a sufficiently large value for λ_k, but the trouble is that such value cannot be determined with the information available at iteration k. Another way to overcome this difficulty is suggested by the fact that the direction $(x^{k+1} - x^k)$, with x^{k+1} given by (5), is a descent one. More precisely, the directional derivative of f at x^k in this direction is given by

$$(x^{k+1} - x^k)^t \nabla f(x^k) = \lambda_k \sum_{j=1}^{n} (x_j^k - x_j^{k+1}) \varphi'(x_j^{k+1}/x_j^k) \leq 0. \tag{11}$$

It follows that adding a line search in the segment between x^k and x^{k+1} to iteration (5) will at least produce a sequence with decreasing functional values. This will be the approach taken in this paper. We remark that even with the line search, iteration (5) is far easier to implement than the φ-divergence proximal method (6)–(7), since minimization in a segment substitutes for minimization in an orthant of $\mathbf{R}^n$ (i.e., for the solution of the $n \times n$ nonlinear system (8)).

The issue arises of what function should be minimized in the segment between x^k and the point given by the left-hand side of (8) (which we call y^k, reserving x^{k+1} for the result of the line search). Two obvious candidates are $f(x)$ and $f(x) + \lambda_k d_\varphi(x, x^k)$; both guarantee a decreasing (and henceforth convergent) objective-value sequence $\{f(x^k)\}$. From the point of view of the convergence analysis neither of these is the best choice. The reason is the following. In order to establish convergence of $\{x^k\}$ we will follow the approach developed in [8], proving quasi-Fejér convergence of $\{x^k\}$ to the set of solutions of problem P, meaning that x^{k+1} cannot be much farther away than x^k from any solution z (see definition and properties in §5). Quasi-Fejér convergence implies boundedness of $\{x^k\}$ and ultimately convergence to a solution. Under the choices given above for the line search objective we are not able to prove quasi-Fejér convergence. We have developed, however, in §4 some convergence results which hold when we choose just $f(x)$ as the minimand of the line search. We enforce boundedness of $\{x^k\}$ by assuming that f has one bounded level set which contains x^0 and get a so-called *weak convergence* result in the following sense:

DEFINITION 1. *A sequence $\{x^k\} \subset \mathbf{R}^n$ is said to be weakly convergent to a set $S \subset \mathbf{R}^n$ if*

(i) *the sequence is bounded,*

(ii) $\lim_{k\to\infty}(x^{k+1} - x^k) = 0$,

(iii) *all limit points of $\{x^k\}$ belong to S.*

In §4 we prove that for $\varphi \in \Phi_1$, arbitrary f, and λ_k in an appropriate interval, $\{x^k\}$ is weakly convergent to the set of points u which satisfy

$$u \geq 0, \quad u_j \nabla f(u)_j = 0, \quad j = 1, \ldots, n,$$

i.e., two of the three Karush–Kuhn–Tucker optimality conditions for problem P. We do not get $\nabla f(u) \geq 0$, so a limit point of $\{x^k\}$ could fail to be a solution of P. However, for a convex f, we prove $\nabla f(u) \geq 0$ for every limit point u, so $\{x^k\}$ is weakly convergent to the set of solutions of P. It follows that for a strictly convex f the sequence $\{x^k\}$ converges to the unique solution of P (boundedness of a level set is redundant in this case).

In §5 we prove that, adding an appropriately chosen regularization term to $f(x)$ in the line search, we can eliminate the level set boundedness hypothesis and furthermore

get full convergence when f is convex and φ is in a subset of the class of functions in Φ_1 defined by

$$\Psi := \{\varphi \in \Phi_1 : \ \varphi'(t) \leq \varphi''(1)\log t, \ \ \forall t > 0\}.$$

Note that the functions φ_i in the Examples 1–3 satisfy the above inequality. The function φ_4 of Example 4 does not belong to Ψ.

We decided to keep the weaker results for the nonregularized line search of §4 for three reasons. First, they hold for a wider choice of f and φ; second, most of these results will be used in the proofs of §5, so there is no duplication; and finally, it can be argued that our algorithm is akin to a natural extension to the case of positivity constraints of the steepest descent method for unconstrained optimization in the sense that in both of them a descent direction is chosen and a line search is performed in this line. The descent direction of our algorithm is not the steepest one but one which automatically takes care of the positivity constraints, so it is interesting to compare convergence results when the same objective, namely $f(x)$, is used in the line search of both algorithms, and it turns out that the results of §4 are the same that hold for the steepest-descent method under similar hypotheses on f (see, e.g., Polyak [11]).

3. Formal definition of algorithm MIG. Take $\varphi \in \Phi_1$. Let $\eta = \lim_{t\to\infty} \varphi'(t)$. It follows from the definition of Φ_1 that $\eta > 0$ (possibly $\eta = \infty$). For any vector $x \in \mathbf{R}^n$ let $x^- \in \mathbf{R}^n$ be defined by $x_j^- = \max\{0, -x_j\}$, and $||x||_\infty = \max_{1\leq j\leq n} |x_j|$ denotes the l_∞-norm. In order to define the algorithm we need four exogenous real constants $\hat{\beta}, \tilde{\beta}, \hat{\lambda}, \tilde{\lambda}$ satisfying

$$1 < \hat{\beta} \leq \tilde{\beta}, \tag{12}$$

$$0 < \hat{\lambda} \leq \tilde{\lambda}. \tag{13}$$

$\hat{\lambda}, \tilde{\lambda}$ are a priori candidates for lower and upper bounds of the regularization parameters λ_k. $\hat{\beta}$ and $\tilde{\beta}$ will be used to generate surrogate bounds $\hat{\gamma}_k, \tilde{\gamma}_k$ for λ_k, required in the dynamical adjustment of the λ_k's which guarantees that the minimization problem in (5) has solutions, even when $\eta < \infty$ (both $\hat{\gamma}_k$ and $\tilde{\gamma}_k$ are zero when $\eta = \infty$). The constants in (13) guarantee that the sequence $\{\lambda_k\}$ is bounded.

The multiplicative interior gradient algorithm (MIG).

Initialization.

$$x^0 > 0. \tag{14}$$

Iterative step. Given $x^k > 0$, define

$$\hat{\gamma}_k = \frac{\hat{\beta}}{\eta} \left\|\nabla f(x^k)^-\right\|_\infty, \tag{15}$$

$$\tilde{\gamma}_k = \frac{\tilde{\beta}}{\eta} \left\|\nabla f(x^k)^-\right\|_\infty, \tag{16}$$

and choose any $\lambda_k \in \mathbf{R}$ such that

$$\max\{\hat{\gamma}_k, \hat{\lambda}\} \leq \lambda_k \leq \max\{\tilde{\gamma}_k, \tilde{\lambda}\}. \tag{17}$$

Compute

$$y^k = \operatorname*{argmin}_{x\geq 0}\{\nabla f(x^k)^t x + \lambda_k d_\varphi(x, x^k)\}, \tag{18}$$

$$\alpha_k = \operatorname*{argmin}_{\alpha\in[0,1]}\{f(x^k + \alpha(y^k - x^k))\}, \tag{19}$$

$$x^{k+1} = x^k + \alpha_k(y^k - x^k). \tag{20}$$

We remark that if $\alpha_\ell = 0$ for some ℓ, then it follows from (14)–(20) that $x^{\ell+1} = x^\ell$ and consequently $x^k = x^\ell$ for all $k \geq \ell$; i.e., in practice the computation stops at $k = \ell$. It is not difficult to show that in such a case $\nabla f(x^\ell) = 0$; i.e., x^ℓ is a stationary point for problem P, but there is no need to prove this fact, because by considering that the sequence $\{x^k\}$ is always infinite (even if it stays always at the same point), our convergence proof simultaneously covers the cases of finite and infinite termination.

4. Convergence analysis for the MIG algorithm. The next two propositions and corollary do not use the specific form of the minimand in the line search given by (19), and so they hold also for the algorithm considered in §5. We start with an elementary property of φ and $\hat{\varphi}(t) := (t-1)\varphi'(t)$.

PROPOSITION 1. *Take* $\varphi \in \Phi_1$, $\{y^k\}, \{z^k\} \subset \mathbf{R}^n_{++}$, $\{z^k\}$ *bounded. It holds that*

i) *if* $\lim_{k\to\infty} d_\varphi(y^k, z^k) = 0$, *then* $\lim_{k\to\infty}(y^k - z^k) = 0$,

ii) *if* $\lim_{k\to\infty} d_{\hat{\varphi}}(y^k, z^k) = 0$, *then* $\lim_{k\to\infty}(y^k - z^k) = 0$.

Proof. i). Assume that the result is false so that there exists subsequences $\{y^{\ell_k}\}, \{z^{\ell_k}\}$ of $\{y^k\}, \{z^k\}$, respectively, such that $|y_j^{\ell_k} - z_j^{\ell_k}| > \varepsilon$ for some j and some $\varepsilon > 0$. Take ξ such that $z_j^k \leq \xi$ for all k, j. If $|y_j^{\ell_k} - z_j^{\ell_k}| > \varepsilon$, then either $z_j^{\ell_k} \geq y_j^{\ell_k} + \varepsilon > \varepsilon$ or $y_j^{\ell_k} \geq z_j^{\ell_k} + \varepsilon > \varepsilon$. In the first case $y_j^{\ell_k}/z_j^{\ell_k} \leq 1 - \varepsilon/z_j^{\ell_k} \leq 1 - \varepsilon/\xi < 1$ so that $\varphi(y_j^{\ell_k}/z_j^{\ell_k}) > \varphi(1 - \varepsilon/\xi) > 0$ (recall that $\varphi(t)$ is decreasing for $0 < t < 1$) and therefore

$$d_\varphi(y^{\ell_k}, z^{\ell_k}) \geq z_j^{\ell_k}\varphi(y_j^{\ell_k}/z_j^{\ell_k}) > \varepsilon\varphi\left(1 - \frac{\varepsilon}{\xi}\right). \tag{21}$$

In the second case $y_j^{\ell_k}/z_j^{\ell_k} \geq 1 + \varepsilon/z_j^{\ell_k} > 1$ so that

$$\varphi(y_j^{\ell_k}/z_j^{\ell_k}) \geq \varphi(1+\varepsilon/z_j^{\ell_k}) \geq \varphi(1+\varepsilon/2z_j^{\ell_k}) + \varphi'(1+\varepsilon/2z_j^{\ell_k})\varepsilon/2z_j^{\ell_k} \geq \varphi'(1+\varepsilon/2\xi)\varepsilon/2z_j^{\ell_k} \tag{22}$$

using convexity of φ and $\varphi(t) > 0$, $\varphi'(t) > 0$ for $t > 1$. It follows from (22) that

$$d_\varphi(y^{\ell_k}, z^{\ell_k}) \geq z_j^{\ell_k}\varphi(y_j^{\ell_k}/z_j^{\ell_k}) \geq \frac{\varepsilon}{2}\varphi'\left(1 + \frac{\varepsilon}{2\xi}\right). \tag{23}$$

From (21), (23), $d_\varphi(y^{\ell_k}, z^{\ell_k}) \geq \varepsilon \min\{\varphi(1 - \frac{\varepsilon}{\xi}), \frac{1}{2}\varphi'(1 + \frac{\varepsilon}{2\xi})\} > 0$, in contradiction with $\lim_{k\to\infty} d_\varphi(y^k, z^k) = 0$.

ii) The proof follows from (i) using (11). □

The next proposition just checks that the MIG algorithm is well defined and preserves positivity. From now on $\{x^k\}$ refers to the sequence generated by (14)–(20).

PROPOSITION 2. x^k *is well defined and* $x^k > 0$ *for all* k.

Proof. The proof is by induction. The result holds for $k = 0$ by (14). Assume $x^k > 0$. We establish first the following facts:

a) There exists a unique $t_j^k > 0$ such that $\varphi'(t_j^k) = -\frac{\nabla f(x^k)_j}{\lambda_k}$.

b) If $\eta < \infty$, then there exists $\tilde{t} < \infty$ such that $t_j^k \leq \tilde{t}$ for all j, k.

Since $\varphi \in \Phi_1$, we know that φ' is increasing and $\lim_{t\to 0}\varphi'(t) = -\infty$. It follows that the equation $\varphi'(t) = s$, in the unknown t, has a unique solution for all $s \in \mathbf{R}$ if

$\eta = \infty$ and for all $s < \eta$ if $\eta < \infty$, so that (a) holds when $\eta = \infty$. We now prove (a) and (b) for $\eta < \infty$.

$$-\frac{\nabla f(x^k)_j}{\lambda_k} \leq \frac{\left\|\nabla f(x^k)^-\right\|_\infty}{\lambda_k} \leq \frac{\left\|\nabla f(x^k)^-\right\|_\infty}{\hat{\gamma}_k} = \frac{\eta}{\hat{\beta}} < \eta$$

using (17), (15), and (12). It follows that t_j^k exists (solving $\varphi'(t) = -\nabla f(x^k)_j/\lambda_k$) and, taking $\tilde{t}$ as the solution of $\varphi'(t) = \frac{\eta}{\tilde{\beta}}$, we conclude that $t_j^k \leq \tilde{t}$ from the fact that φ' is increasing. (a) and (b) have been established.

The gradient of the minimand in (18) has jth component equal to

$$\nabla f(x^k)_j + \lambda_k \varphi'\left(\frac{x_j}{x_j^k}\right). \tag{24}$$

Taking $x_j = t_j^k x_j^k$, it follows from (b) that (24) vanishes. Since the minimand in (18) is convex, we conclude that the vector y^k with components $y_j^k = t_j^k x_j^k$ is the solution of (18). Since $t_j^k > 0$ by (a) and $x_j^k > 0$ by inductive hypothesis, we get $y^k > 0$. A minimizer $\alpha_k \in [0, 1]$ of (19) exists by continuity of f. Hence $x^k > 0$, $y^k > 0$, and (20) imply $x^{k+1} > 0$. □

COROLLARY 1. *For all* $k \geq 0$

$$\varphi'\left(\frac{y_j^k}{x_j^k}\right) = -\frac{\nabla f(x^k)_j}{\lambda_k}.$$

Proof. The proof is immediate from Proposition 2. □

The following proposition establishes the monotonicity and boundedness properties of the algorithm under the hypothesis that x^0 belongs to a bounded level set of f.

For $\rho \in \mathbf{R}$, let $L(\rho) = \{x \in \mathbf{R}_+^n : f(x) \leq \rho\}$ and $f^* = \min\{f(x) : x \in \mathbf{R}_+^n\}$.

PROPOSITION 3. *If there exists* $\rho \in \mathbf{R}$ *such that* $L(\rho)$ *is bounded and* $x^0 \in L(\rho)$, *then*

i) $f^* \leq f(x^{k+1}) \leq f(x^k)$ *for all* k,

ii) $\{f(x^k)\}$ *converges,*

iii) $\{x^k\}$ *is bounded,*

iv) $\{\lambda_k\}$ *is bounded,*

v) $\{y^k\}$ *is bounded.*

Proof. i) The left inequality follows from Proposition 2, and the right one from (19), (20).

ii) The proof follows from (i).

iii) $f(x^k) \leq f(x^0)$ for all k by (i) so that $x^k \in L(\rho)$ for all k.

iv) Let $\mu = \max_{x \in L(\rho)}\{\|\nabla f(x)^-\|_\infty\} \cdot \mu < \infty$ by continuous differentiability of f and compactness of $L(\rho)$. From (16) and (iii) $\tilde{\gamma}_k \leq \frac{\tilde{\beta}}{\eta}\mu$, and from (17) $\lambda_k \leq \max\{\frac{\tilde{\beta}}{\eta}\mu, \tilde{\lambda}\}$.

v) $y_j^k = t_j^k x_j^k$ with t_j^k as in (a) of the proof of Proposition 2, which also gives $y^k > 0$. If $\eta < \infty$ we have $y_j^k < \tilde{t} x_j^k$ by (b) of the proof of Proposition 2, and the result follows from (iii). If $\eta = \infty$, then, using Corollary 1, (17), and μ as in (iv),

$$\varphi'(t_j^k) = \varphi'(\frac{y_j^k}{x_j^k}) = -\frac{\nabla f(x^k)_j}{\lambda_k} \leq \frac{\left\|\nabla f(x^k)^-\right\|_\infty}{\lambda_k} \leq \frac{\mu}{\tilde{\lambda}}$$

so that $t_j^k \leq (\varphi')^{-1}(\frac{\mu}{\lambda})$; i.e., t_j^k is bounded and the result follows from (iii). □

The next proposition establishes the second requirement in the definition of weak convergence.

PROPOSITION 4. *Under the hypothesis of Proposition* 3, $\lim_{k\to\infty}(x^{k+1} - x^k) = 0$.

Proof. Assume the result is false. Then by Proposition 3(iii) there exists a subsequence $\{x^{\ell_k}\}$ of $\{x^k\}$ such that $\lim_{k\to\infty} x^{\ell_k} = u \neq v = \lim_{k\to\infty} x^{\ell_k+1}$. Define h_k, $h\colon [0,1] \to \mathbf{R}$ as $h_k(t) = f((1-t)x^k + tx^{k+1})$, $h(t) = f((1-t)u + tv)$, so that $\lim_{k\to\infty} h_{\ell_k}(t) = h(t)$ for all $t \in [0,1]$. By Corollary 1, for all k

$$h_k'(0) = \nabla f(x^k)^t(x^{k+1} - x^k) = \alpha_k \nabla f(x^k)^t(y^k - x^k) = -\alpha_k \lambda_k \sum_{j=1}^n \varphi'\left(\frac{y_j^k}{x_j^k}\right)(y_j^k - x_j^k)$$

(25)

$$= -\alpha_k \lambda_k d_{\hat{\varphi}}(y^k, x^k) \leq 0.$$

From (25)

$$h'(0) = \lim_{k\to\infty} h_{\ell_k}'(0) \leq 0. \tag{26}$$

By (19), (20), $h_k(1) \leq h_k(t)$ for all $t \in [0,1]$, implying

$$h(1) \leq h(t) \qquad (t \in [0,1]). \tag{27}$$

By Proposition 3(ii) and the definitions of u and v, $f(u) = f(v)$, implying

$$h(0) = h(1). \tag{28}$$

From (27), (28), $h(0) \leq h(t)$ for all $t \in [0,1]$, implying $h'(0) \geq 0$, and therefore, using (26),

$$0 = h'(0) = \nabla f(u)^t(v - u). \tag{29}$$

We may assume, refining the subsequence $\{x^{\ell_k}\}$ if necessary, that $\lim_{k\to\infty} \alpha_{\ell_k} = \overline{\alpha}$ and, using Proposition 3(v), that $\lim_{k\to\infty} y^{\ell_k} = y$. From (20)

$$v - u = \overline{\alpha}(y - u). \tag{30}$$

$u \neq v$ implies $\overline{\alpha} \neq 0$. Replacing (30) in (29) and using Corollary 1

(31)

$$0 = \nabla f(u)^t(y - u) = \lim_{k\to\infty} \lambda_{\ell_k} \sum_{j=1}^n \varphi'\left(\frac{y_j^{\ell_k}}{x_j^{\ell_k}}\right)\left(y_j^{\ell_k} - x_j^{\ell_k}\right) = -\lim_{k\to\infty} \lambda_{\ell_k} d_{\hat{\varphi}}(y^{\ell_k}, x^{\ell_k}).$$

Since $\lambda_{\ell_k} \geq \hat{\lambda} > 0$, we conclude from (31) that $\lim_{k\to\infty} d_{\hat{\varphi}}(y^{\ell_k}, x^{\ell_k}) = 0$ and then, from Proposition 1(ii), that $y = u$, in which case we get, from (30), $u = v$, in contradiction with the assumption. □

The next proposition completes our weak convergence result for a general (i.e., not necessarily convex) f.

PROPOSITION 5. *Let u be a limit point of $\{x^k\}$. Under the hypothesis of Proposition* 3, *$u \geq 0$ and $u_j \nabla f(u)_j = 0$ for all j.*

Proof. $u \geq 0$ follows from Proposition 2. In order to prove $u_j \nabla f(u)_j = 0$, we define

$$\overline{h}_k(\alpha) = f((1-\alpha)x^k + \alpha y^k);$$

i.e., $\overline{h}_k(\alpha)$ is the minimand of (19), so that $\overline{h}_k'(\alpha_k) = \nabla f(x^{k+1})^t(y^k - x^k)$, and we have $\overline{h}_k'(\alpha_k) \geq 0$ if $\alpha_k = 0$, $\overline{h}_k'(\alpha_k) = 0$ if $\alpha_k \in (0,1)$, $\overline{h}_k'(\alpha_k) \leq 0$ if $\alpha_k = 1$. Let $\{x^{\ell_k}\}$ be a subsequence of $\{x^k\}$ such that $\lim_{k\to\infty} x^{\ell_k} = u$. Without loss of generality, i.e., refining the subsequence if necessary, we may assume, in view of Proposition 3(iv), 3(v), and (17), that $\lim_{k\to\infty} y^{\ell_k} = y$, $\lim_{k\to\infty} \lambda_{\ell_k} = \lambda > 0$. We claim that $y = u$. We consider two cases:

i) there exists a subsequence $\{x^{i_k}\}$ of $\{x^{\ell_k}\}$ such that $\alpha_{i_k} = 1$ for all k. In this case, by (20), $x^{i_k+1} = y^{i_k}$ and, using Proposition 4, $u = \lim_{k\to\infty} x^{i_k} = \lim_{k\to\infty} x^{i_k+1} = \lim_{k\to\infty} y^{i_k} = y$, and the claim holds.

ii) If (i) does not occur, then $\alpha_{\ell_k} \in [0,1)$ for large enough k, implying

$$0 \leq \overline{h}_k'(\alpha_{\ell_k}) = \nabla f(x^{\ell_k+1})^t(y^{\ell_k} - x^{\ell_k}). \tag{32}$$

From (32), using Corollary 1 and (17)

$$\begin{aligned}(\nabla f(x^{\ell_k+1}) - \nabla f(x^{\ell_k}))^t(y^{\ell_k} - x^{\ell_k}) &\geq -\nabla f(x^{\ell_k})^t(y^{\ell_k} - x^{\ell_k}) \\ &= \lambda_{\ell_k} \sum_{j=1}^{n} \varphi'(y_j^{\ell_k}/x_j^{\ell_k})(y_j^{\ell_k} - x_j^{\ell_k}) \\ &= \lambda_{\ell_k} d_{\hat{\varphi}}(y^{\ell_k}, x^{\ell_k}) \\ &\geq \hat{\lambda} d_{\hat{\varphi}}(y^{\ell_k}, x^{\ell_k}) \geq 0. \qquad (33)\end{aligned}$$

Taking limits in (33) as k goes to ∞, and using Propositions 3(iii), 3(v), and 4, $0 = \lim_{k\to\infty} d_{\hat{\varphi}}(y^{\ell_k}, x^{\ell_k})$. By Proposition 1(ii) $y - u = \lim_{k\to\infty}(y^{\ell_k} - x^{\ell_k}) = 0$ and the claim holds.

Take j such that $u_j \neq 0$. By Corollary 1, $-\nabla f(u)_j = -\lim_{k\to\infty} \nabla f(x^{\ell_k})_j = \lim_{k\to\infty} \lambda_{\ell_k} \varphi'(y_j^{\ell_k}/x_j^{\ell_k}) = \lambda\varphi'(y_j/u_j) = \lambda\varphi'(1) = 0$. We have shown that $\nabla f(u)_j = 0$ whenever $u_j \neq 0$, and the result is established. □

We summarize the results obtained up to now in the following theorem.

THEOREM 1. *If there exists ρ such that $L(\rho)$ is bounded and $x^0 \in L(\rho)$, then the sequence $\{x^k\}$ generated by MIG satisfies the following:*

i) *$\{x^k\}$ is bounded.*

ii) $\lim_{k\to\infty}(x^{k+1} - x^k) = 0$.

iii) *If u is a limit point of $\{x^k\}$, then $u \geq 0$ and $u_j \nabla f(u)_j = 0$ for all j.*

Proof. The proof follows from Propositions 3(iii), 4, and 5. □

For convex f, the result of Theorem 1 can be improved and weak convergence to the solution set of problem P can be established. We need first a preliminary lemma.

LEMMA 1. *Take $g: \mathbf{R}^n \to \mathbf{R}$ convex and continuously differentiable and $\{z^k\} \subset \mathbf{R}^n_{++}$. Let $S = \{u \in \mathbf{R}^n : u \geq 0, u_j \nabla g(u)_j = 0 \ (1 \leq j \leq n)\}$ and T equal the set of solutions of $\min g(x)$ such that $x \geq 0$, so that $T \subset S$. If*

i) *$\{z^k\}$ is weakly convergent to S,*

ii) *there exists g^* such that $g(u) = g^*$ for any limit point u of $\{z^k\}$,*

iii) *$z_j^{k+1} > z_j^k$ if and only if $\nabla g(z^k)_j < 0$,*

then $\{z^k\}$ is weakly convergent to T.

Proof. By convexity of g, $T = \{u \in \mathbf{R}^n : u \geq 0, \nabla g(u) \geq 0, u^t \nabla g(u) = 0\} = \{u \in S : \nabla g(u) \geq 0\}$, so it suffices to prove that $\nabla g(u) \geq 0$ for any limit point u of $\{z^k\}$. Take a limit point u of $\{z^k\}$ and assume that there exists j such that $\nabla g(u)_j < 0$, i.e., that $\emptyset \neq J = \{j : \nabla g(u)_j < 0\}$. Let $K = \{1, \ldots, n\} \backslash J$ and $V = \{x \in \mathbf{R}^n_+ : x_j = 0$ for $j \in J\}$. It follows from (i) that $u \in S$ and, from the definition of S, that $u \in V$.

Therefore, for all $j \in K$ it holds that $u_j \geq 0$, $\nabla g(u)_j \geq 0$, $u_j \nabla g(u)_j = 0$ which are precisely the Karush–Kuhn–Tucker conditions of $\min g(x)$ such that $x \in V$. By convexity of g, u minimizes g on V. Let $B = \{x \in \mathbf{R}^n_+ : \nabla f(x)_j < 0 \text{ for } j \in J\}$. By definition, $u \in B$ which is open as a subset of $\mathbf{R}^n_+$. Take a subsequence $\{z^{\ell_k}\}$ of $\{z^k\}$ such that $\lim_{k\to\infty} z^{\ell_k} = u$ and $\{z^{\ell_k}\} \subset B$.

Let $p_k = \max\{q < \ell_k : z^q \notin B\}$ (set $p_k = 0$ if $z^q \in B$ for all $q < \ell_k$). Then $z^q \in B$ for $p_k + 1 \leq q \leq \ell_k$ and, using (iii) iteratively,

$$z_j^{\ell_k} \geq z_j^{p_k+1} \quad \text{for all } j \in J. \tag{34}$$

If there exists p such that $p_k = p$ for large enough k (i.e., if the sequence $\{z^k\}$ stays in B for large enough k), then we get $0 = u_j = \lim_{k\to\infty} x_j^{\ell_k} \geq x_j^{p+1} > 0$ for all $j \in J$ (where $u_j = 0$ follows from $u \in S$ and the definition of J), which is a contradiction. It follows that $\lim_{k\to\infty} p_k = \infty$, so that $\{z^{p_k}\}$ is a subsequence of $\{z^k\}$. By (34), for $j \in J$, $\lim_{k\to\infty} z_j^{p_k+1} \leq \lim_{k\to\infty} z_j^{\ell_k} = u_j = 0$, implying $\lim_{k\to\infty} z_j^{p_k+1} = 0$, and by (i) and condition (ii) of Definition 1, we get $\lim_{k\to\infty} z_j^{p_k} = 0$ for all $j \in J$. By definition of p_k, we have $z^{p_k} \notin B$ whenever $p_k > 1$. Take a subsequence $\{z^{i_k}\}$ of $\{z^k\}$, which converges, say, to v. (Existence of $\{z^{i_k}\}$ follows from (i) and condition (i) in Definition 1.) Since B is open in $\mathbf{R}^n_+$, $v \notin B$ and therefore there exists $m \in J$ such that

$$\nabla g(v)_m \geq 0. \tag{35}$$

Let $W = \{x \in \mathbf{R}^n_+ : x_j = 0 \text{ for } j \in J \backslash \{m\}\}$. The Karush–Kuhn–Tucker conditions for $\min g(x)$ such that $x \in W$ are

$$x_j \geq 0, \quad \nabla g(x)_j \geq 0, \quad x_j \nabla g(x)_j \geq 0 \quad \text{for } j \in K \cup \{m\}. \tag{36}$$

We claim that v satisfies (36). Consider first $j \in K$. Note that for $j \in J$, $v_j = \lim_{k\to\infty} z_j^{i_k} = \lim_{k\to\infty} z_j^{p_k} = 0$, so that $v \in V$. By (ii), $g(v) = g(u) = g^*$. Since u minimizes g on V, we conclude that v also minimizes g on V, and therefore it satisfies the Karush–Kuhn–Tucker conditions for $\min g(x)$ such that $x \in V$, which are precisely (36) with $j \in K$. Consider now $j = m$. The first and third conditions, in (36) hold by (i), and the second by (35). So v satisfies (36) and, by convexity of g, v minimizes g on W. Since $u \in V \subset W$ and $g(u) = g(v)$ by (ii), it follows that u also minimizes g on W, and therefore, it satisfies (36). In particular $\nabla g(u)_m \geq 0$. Since $m \in J$ this contradicts the definition of J. It follows that $J = \emptyset$ and therefore $\nabla g(u) \geq 0$. □

Next we give the weak convergence result for convex f.

THEOREM 2. *If there exists ρ such that $L(\rho)$ is bounded, and $x^0 \in L(\rho)$ and f is convex, then the sequence $\{x^k\}$ generated by Algorithm MIG satisfies the following:*

i) *$\{x^k\}$ is bounded.*

ii) $\lim_{k\to\infty}(x^{k+1} - x^k) = 0$.

iii) *Every limit point u of $\{x^k\}$ solves problem P.*

Proof. The statement of the theorem just says that $\{x^k\}$ is weakly convergent to the set of solutions of problem P. We use Lemma 1 with $\{z^k\} = \{x^k\}$, $g = f$. Hypotheses (i) and (ii) of Lemma 1 hold by Theorem 1 and Proposition 3(i), respectively. For hypothesis (iii) of Lemma 1, since $x_j^{k+1} - x_j^k = \alpha_k(y_j^k - x_j^k)$ with $\alpha_k \geq 0$ by (20), we have $x_j^{k+1} - x_j^k > 0$ iff $y_j^k > x_j^k$ iff $\varphi'(y_j^k/x_j^k) > 0$ iff $\nabla f(x^k)_j < 0$, using Corollary 1 and $\lambda_k > 0$. □

COROLLARY 2. *If f is strictly convex, then the sequence $\{x^k\}$ generated by algorithm MIG converges to the solution x^* of problem P.*

Proof. Note first that existence of solutions of problem P and strict convexity of f imply that all level sets of f are bounded, and so the hypothesis that $x^0 \in L(\rho)$ in Theorem 2 is redundant. By Theorem 2(iii) any limit point of $\{x^k\}$ is a solution of problem P. For strictly convex f problem P has a unique solution, so there is a unique limit point and the result follows. □

5. The algorithm with regularized line searches. In this section we present a regularization of the line search in (19) which allows us to establish full convergence of $\{x^k\}$ to a solution of problem P when f is convex and $\varphi \in \Psi$, without any hypothesis on boundedness of the level sets of f. Before presenting this modification of algorithm MIG, which will be called algorithm RMIG, we need some additional notation.

Given $\varphi \in \Phi_1$, define $\hat{\varphi}$ as

$$\hat{\varphi}(t) = (t-1)\varphi'(t).$$

Although $\hat{\varphi}$ may fail to belong to Φ_1, because it may not be convex, $d_{\hat{\varphi}}$, as defined by (3) with $\hat{\varphi}$ substituting for φ, shares most properties of φ-divergences. Also, since φ is convex and $\varphi(1) = 1$, we have

$$\varphi(t) = \varphi(t) - \varphi(1) \leq (t-1)\varphi'(t) = \hat{\varphi}(t),$$

which implies $d_\varphi(x,y) \leq d_{\hat{\varphi}}(x,y)$ for all $x, y > 0$.

RMIG is defined by (14)–(20) except that (19) is replaced by

$$\alpha_k = \operatorname*{argmin}_{\alpha \in [0,1]} \{f(x^k + \alpha(y^k - x^k)) + \sigma\alpha\}, \tag{37}$$

where

$$\sigma = \delta\lambda_k d_{\hat{\varphi}}(y^k, x^k) \tag{38}$$

with $\delta \in (0,1)$.

The motivation behind the choice of a linear regularization term is the following. For x in the segment between x^k and y^k we have

$$d_\varphi(x, x^k) = d_\varphi((1-\alpha)x^k + \alpha y^k, x^k) \leq \alpha d_\varphi(y^k, x^k) \leq \alpha d_{\hat{\varphi}}(y^k, x^k)$$

using convexity of d_φ in its first variable. Note that $\alpha d_{\hat{\varphi}}(y^k, x^k)$ is a linear function of α with positive slope. So we take a linear regularization term; i.e., we minimize $f((1-\alpha)x^k + \alpha y^k) + \sigma\alpha$ with $\alpha \in [0,1]$. It can be seen, using (3) and (18), that the derivative of this function with respect to α at $\alpha = 0$ is $\sigma - \lambda_k d_{\hat{\varphi}}(y^k, x^k)$. Since we want a descent direction, such derivative must be negative and so we take $\sigma = \delta\lambda_k d_{\hat{\varphi}}(y^k, x^k)$ with $\delta \in (0,1)$. With this regularized line search we prove in this section quasi-Fejér convergence of $\{x^k\}$ to the solution set of problem P for f convex and $\varphi \in \Psi$, and as a consequence full convergence to a solution, without any level set boundedness assumption.

Possibly the use of $\sigma\alpha$ instead of $d_\varphi(x, x^k)$ is not essential and due just to our proof techniques, but we mention that computationally a linear term is easier to handle than $d_\varphi(x, x^k)$. Note also that adding either $\sigma\alpha$ or the restriction of $d_\varphi(x, x^k)$ to the segment does not make the linear search any harder: for convex f the regularized minimand is still convex, therefore unimodal, and both nonderivative methods (e.g., Fibonacci search) and a derivative one (e.g., Newton's method) are equally easy to implement with or without the regularization term.

We proceed to the convergence analysis of this algorithm. From now on $\{x^k\}$ refers to the sequence generated by algorithm RMIG.

The next proposition extends the result of Propositions 3(i), 3(ii), and 4 to the sequence generated by algorithm RMIG. Define

$$\hat{h}_k(\alpha) = f((1-\alpha)x^k + \alpha y^k) + \sigma\alpha. \tag{39}$$

PROPOSITION 6. i) $f^* \leq f(x^{k+1}) + \alpha_k \delta \lambda_k d_{\hat{\varphi}}(y^k, x^k) \leq f(x^k)$,
ii) $\{f(x^k)\}$ *is decreasing and convergent,*
iii) $\lim_{k\to\infty}(x^{k+1} - x^k) = 0$,
iv) $\sum_{k=0}^{\infty} \alpha_k d_{\hat{\varphi}}(y^k, x^k) < \infty$.

Proof. i) By (37)–(39), $\hat{h}_k(\alpha_k) \leq \hat{h}_k(0)$, which gives the rightmost inequality. The leftmost one is trivial.

ii) The proof follows from (i), because $\alpha_k \delta \lambda_k d_{\hat{\varphi}}(y^k, x^k) \geq 0$.

iii) Use convexity of d_φ in its first variable, (17), (11), and (i) to get

$$\begin{aligned} 0 \leq \delta\hat{\lambda} d_\varphi(x^{k+1}, x^k) &= \delta\hat{\lambda} d_\varphi((1-\alpha_k)x^k + \alpha_k y^k, x^k) \leq \delta\hat{\lambda}\alpha_k d_{\hat{\varphi}}(y^k, x^k) \\ &\leq \delta\lambda_k\alpha_k d_{\hat{\varphi}}(y^k, x^k) \leq f(x^k) - f(x^{k+1}). \end{aligned} \tag{40}$$

Since $\delta\hat{\lambda} > 0$ and the right-hand side of (40) converges to 0 by (ii), we conclude that $\lim_{k\to\infty} d_\varphi(y^k, x^k) = 0$ and the result follows from Proposition 1(i).

iv) From (40), $\alpha_k d_{\hat{\varphi}}(y^k, x^k) \leq (1/\delta\hat{\lambda})(f(x^k) - f(x^{k+1}))$ so that

$$\sum_{k=0}^{\infty} \alpha_k d_{\hat{\varphi}}(y^k, x^k) \leq (1/\delta\hat{\lambda})(f(x^0) - \lim_{k\to\infty} f(x^k)) < \infty. \qquad \square$$

Next we introduce the concept of quasi-Fejér convergence. This notion was introduced in [5] and discussed for the case of φ-divergences in [8]. Take $\varphi \in \Phi$ and $U \subset \mathbf{R}^n_{++}$.

DEFINITION 2. *A sequence* $\{z^k\} \subset \mathbf{R}^n_{++}$ *is said to be quasi-Fejér convergent to* U *with respect to* d_φ *if for each* $u \in U$ *there exists a sequence of real numbers* $\varepsilon_k \geq 0$ *such that* $\sum_{k=0}^{\infty} \varepsilon_k < \infty$ *and* $d_\varphi(u, z^{k+1}) \leq d_\varphi(u, z^k) + \varepsilon_k$.

We will use the following result on quasi-Fejér convergence.

THEOREM 3. *If a sequence* $\{z^k\}$ *is quasi-Fejér convergent to a nonempty set* U, *then* $\{z^k\}$ *is bounded and* $\{d_\varphi(u, z^k)\}$ *is bounded for all* $u \in U$. *If furthermore at least one limit point of* $\{z^k\}$ *belongs to* U, *then* $\{z^k\}$ *converges.*

Proof. The proof can be found in [8, Thm. 4.1]. $\square$

We will prove quasi-Fejér convergence of the sequence $\{x^k\}$ generated by algorithm RMIG to a set which contains all solutions of problem P, not with respect to d_φ used in the algorithm but with respect to a specific φ-divergence, namely d_{φ_2}, with φ_2 as in Example 2 in §1. We will use the notation ψ instead of φ_2; i.e., $\psi(t) = t\log t - t + 1$, and

$$d_\psi(x, y) = \sum_{j=1}^{n} (x_j \log \frac{x_j}{y_j} + y_j - x_j) \tag{41}$$

is the Kullback–Leibler divergence and has several interesting properties. One of them is that it can be continuously extended to $\mathbf{R}^n_+ \times \mathbf{R}^n_{++}$; i.e., it admits vectors with zero components in its first variable. It can be seen that Theorem 3 holds in this case also for $U \subset \mathbf{R}^n_+$.

Let $T^* = \{x \in \mathbf{R}^n_+ : f(x) \leq \lim_{k\to\infty} f(x^k)\}$. T^* is well defined by Proposition 6(ii), and contains the solutions of problem P, so it is nonempty. Next we prove

quasi-Fejér convergence of $\{x^k\}$ to T^* with respect to d_ψ. We need first a technical result.

PROPOSITION 7. *Take $\varphi \in \Phi_1$ and let $\theta = 1/\varphi''(1)$. There exists $\nu > 0$ such that $(t-1) - \theta\varphi'(t) \leq \nu(t-1)\varphi'(t)$ for all $t > 0$.*

Proof. It suffices to prove that $\overline{\varphi}$, defined as

$$\overline{\varphi}(t) = \frac{t - 1 - \theta\varphi'(t)}{(t-1)\varphi'(t)} = \frac{1}{\varphi'(t)} - \frac{\theta}{t-1},$$

is bounded above. Since $\overline{\varphi}$ is trivially continuous at any $t \neq 1$, it is enough to prove that $\limsup_{t\to 0} \overline{\varphi}(t) < \infty$, $\limsup_{t\to\infty} \overline{\varphi}(t) < \infty$, $\lim_{t\to 1} \overline{\varphi}(t) < \infty$. Since φ' is increasing for all t, negative for $t < 1$, and positive for $t > 1$ we have

$$\limsup_{t\to 0} \overline{\varphi}(t) \leq -\lim_{t\to 0} \frac{\theta}{t-1} = \theta < \infty$$

$$\limsup_{t\to\infty} \overline{\varphi}(t) \leq \frac{1}{\varphi'(2)} - \lim_{t\to\infty} \frac{\theta}{t-1} = \frac{1}{\varphi'(2)} < \infty.$$

For $t = 1$, expanding φ' around 1, and using $\varphi'(1) = 0$, $\varphi''(1) = \frac{1}{\theta}$, we get

$$\lim_{t\to 1} \overline{\varphi}(t) = -\frac{\theta^2}{2}\varphi'''(1) < \infty. \qquad \square$$

PROPOSITION 8. *If f is convex and $\varphi \in \Psi$ (i.e., $\varphi'(t) \leq \varphi''(1)\log t$ for all $t > 0$) then $\{x^k\}$ is quasi-Fejér convergent to T^* with respect to d_ψ.*

Proof. Take $z \in T^*$ and let $\theta = 1/\varphi''(1) > 0$. Since $\{f(x^k)\}$ decreases by Proposition 6(i), we have $f(z) \leq f(x^k)$ for all k and therefore

$$0 \leq \theta\frac{\alpha_k}{\lambda_k}(f(x^k) - f(z)) \leq \theta\frac{\alpha_k}{\lambda_k}\nabla f(x^k)^t(x^k - z) = \theta\alpha_k \sum_{j=1}^n \varphi'(y_j^k/x_j^k)(z_j - x_j^k) \tag{42}$$

using convexity of f and Corollary 1. Use now convexity of d_ψ in its second variable and (41) to get

$$\begin{aligned} d_\psi(z, x^{k+1}) - d_\psi(z, x^k) &= d_\psi(z, (1-\alpha_k)x^k + \alpha_k y^k) - d_\psi(z, x^k) \\ &\leq \alpha_k(d_\psi(z, y^k) - d_\psi(z, x^k)) \\ &= \alpha_k \sum_{j=1}^n z_j(\log(x_j^k/y_j^k) + y_j^k - x_j^k). \end{aligned} \tag{43}$$

Let $t_j^k = y_j^k/x_j^k$ and add (42) and (43) together

$$\begin{aligned} d_\psi(z, x^{k+1}) - d_\psi(z, x^k) &\leq \alpha_k \left[\sum_{j=1}^n z_j(\theta\varphi'(t_j^k) - \log t_j^k) + \sum_{j=1}^n x_j^k(t_j^k - 1 - \theta\varphi'(t_j^k))\right] \\ &\leq \alpha_k \sum_{j=1}^n x_j^k(t_j^k - 1 - \theta\varphi'(t_j^k)) \leq \nu\alpha_k \sum_{j=1}^n x_j^k(t_j^k - 1)\varphi'(t_j^k) \\ &= \nu\alpha_k d_{\hat{\varphi}}(y^k, x^k), \end{aligned} \tag{44}$$

where we use $\varphi \in \Psi$ in the second inequality and Proposition 7 in the third inequality. From (44), $d_\psi(z, x^{k+1}) \leq d_\psi(z, x^k) + \nu\alpha_k d_{\hat{\varphi}}(y^k, x^k)$. The result follows from Definition 2 with $\varepsilon_k = \nu\alpha_k d_{\hat{\varphi}}(y^k, x^k)$ and Proposition 6(iv). $\square$

COROLLARY 3. *If f is convex and $\varphi \in \Psi$, then*
i) *the sequence $\{x^k\}$ converges,*
ii) *$\{\lambda_k\}$ is bounded,*
iii) *$\{y^k\}$ is bounded.*

Proof. (i) follows from Proposition 8 and Theorem 3, since all limit points of $\{x^k\}$ belong to T^*. For (ii) and (iii) we use the proofs of Proposition 3(iv) and 3(v), respectively, with a bounded set D containing $\{x^k\}$ in place of $L(\rho)$ in the definition of μ. □

We present next the main result of this section.

THEOREM 4. *If f is convex and $\varphi \in \Psi$, then the sequence generated by algorithm RMIG converges to a solution of Problem P.*

Proof. $\{x^k\}$ converges by Corollary 3(i). Let x^* be its limit. By convexity of f it suffices to check that x^* satisfies the Karush–Kuhn–Tucker conditions of problem P, namely,

$$x^* \geq 0, \tag{45}$$

$$\nabla f(x^*) \geq 0, \tag{46}$$

$$\nabla f(x^*)_j x_j^* = 0 \qquad (1 \leq j \leq n). \tag{47}$$

Proof. (45) follows from Proposition 2. We look now at (47). We could attempt a direct proof using the fact that $\{x^k\}$ is fully convergent, but we take advantage of the proof of Proposition 5, which holds for this case almost verbatim, using Corollary 3 and Proposition 6(iii) instead of Proposition 3(iii)–(v) and 4. The only difference is that we must use $\hat{h}_k$ defined in (39) instead of $\overline{h}_k$. Since $\hat{h}_k'(\alpha) = \overline{h}_k(\alpha) + \sigma$, we have, instead of (32), (33), $0 \leq \hat{h}_{\ell_k}'(\alpha_{\ell_k}) = \nabla f(x^{e_{k+1}})^t(y^{\ell_k} - x^{\ell_k}) + \sigma$, implying

$$\begin{aligned}(\nabla f(x^{\ell_k+1}) - \nabla f(x^{\ell_k}))^t(y^{\ell_k} - x^{\ell_k}) &\geq -\nabla f(x^{\ell_k})^t(y^{\ell_k} - x^{\ell_k}) - \sigma \\ &= \lambda_{\ell_k} d_{\hat{\varphi}}(y^{\ell_k}, x^{\ell_k}) - \delta\lambda_{\ell_k} d_{\hat{\varphi}}(y^{\ell_k}, x^{\ell_k}) \\ &= (1-\delta)\lambda_{\ell_k} d_{\hat{\varphi}}(y^{\ell_k}, x^{\ell_k}) \\ &\geq (1-\delta)\hat{\lambda} d_{\hat{\varphi}}(y^{\ell_k}, x^{\ell_k}) \geq 0\end{aligned}$$

using $\delta \in (0,1)$. The remainder of the proof is exactly as in Proposition 5 after (33). Finally we can establish (46) using Lemma 1 as in Theorem 2, but we prefer to give a direct proof to show to what extent Lemma 1 simplifies under the hypothesis of convergence of $\{x^k\}$. Since $\nabla f(x^*)_j = 0$, whenever $x_j^* > 0$ by (47) it suffices to prove that $\nabla f(x^*)_j \geq 0$ for j such that $x_j^* = 0$. Assume $\nabla f(x^*)_j < 0$ for any such j. Then there exists k_0 such that $\nabla f(x^k)_j < 0$ for $k > k_0$; i.e., we have $0 > \nabla f(x^k)_j = -\lambda_k \varphi'(y_j^k / x_j^k)$, implying $\varphi'(y_j^k/x_j^k) > 0$ so that $y_j^k > x_j^k$ and therefore $x_j^{k+1} \geq x_j^k$ for all $k > k_0$. Then $0 = x_j^* = \lim x_j^k \geq x_j^{k_0} > 0$, which is a contradiction. (This corresponds to the case $p_k = p$ for large enough k in the proof of Lemma 1.) The proof is complete. □

6. Final remarks. We discuss here three possible extensions of our results, which hold in fact under weaker hypotheses than those imposed in the previous sections. We have excluded these extensions from our exposition for the sake of clarity, since they demand more involved proofs, with technicalities which would obscure, perhaps, more substantial arguments. The first two extensions refer to the class of

admissible objective functions, which we have assumed to be convex and continuously differentiable. Both assumptions can be relaxed.

In the first place, all our results hold if we assume that f is pseudoconvex rather than convex. We recall that f is pseudoconvex if and only if $\nabla f(x)^t(y-x)$ implies $f(y) \geq f(x)$. The use of convexity in our proofs has been twofold. First we use it in Lemma 1 and Theorem 4 in the form of sufficiency of the Karush–Kuhn–Tucker conditions for optimality. This is true for pseudoconvex functions (see [1, p. 152]). Then we use it in (42) of Proposition 8 to prove that $\nabla f(x^k)^t(x^k - z) \geq 0$ for any $z \in T^*$. We claim that this is also true for pseudoconvex f. Assume on the contrary that $\nabla f(x^k)^t(z - x^k) > 0$. Then, by definition of pseudoconvexity, using Propositions 6(i) and (ii) and $z \in T^*$

$$f(z) \geq f(x^k) \geq f(x^{k+1}) + \lambda_k \alpha_k d_{\hat{\varphi}}(y^k, x^k) \geq f(x^{k+1}) \geq \lim_{k\to\infty} f(x^k) \geq f(z)$$

so that $\alpha_k d_{\hat{\varphi}}(y^k, x^k)) = 0$; i.e., either $\alpha_k = 0$ or $d_{\hat{\varphi}}(y^k, x^k) = 0$. If $\alpha_k = 0$, then $0 \leq \hat{h}'_k(0) = -\left\|\nabla f(x^k)\right\|^2$, implying $\nabla f(x^k) = 0$. If $d_{\hat{\varphi}}(y^k, x^k) = 0$, then $y^k = x^k$ and so $\nabla f(x^k) = 0$ by Corollary 1. In both cases $\nabla f(x^k) = 0$ in contradiction with the assumption above. The claim is established.

In the second place, we would like to assume just nonemptiness of the subdifferential of f at any x in its effective domain, rather than continuous differentiability, among other reasons, to be able to accommodate in our analysis the case of additional convex constraints besides nonnegativity, because by dropping the continuously differentiability assumption, such constraints (particularly linear equality constraints) can be transferred to the objective, in which case MIG transforms an inequality constrained problem into a sequence of equality constrained ones, a reduction which has proved to be quite useful in many instances. Extension of our results to the case of nondifferentiable f is more complicated. It is possible to go through the convergence results of §4 with a subgradient of f at x substituting for $\nabla f(x)$ up to Theorem 1, but we have no proof of Lemma 1 without differentiability of f and so Theorem 2 does not hold. The situation is better for the results of §5, because we have full convergence of $\{x^k\}$ to x^*. For the φ-divergence proximal algorithm given by iteration (7) it has been proved in [8, Prop. 4.3] that if the sequence $\{x^k\}$ converges to x^* and there exists a solution z of problem P satisfying $z_j = 0$ for all j such that $x^*_j = 0$, then x^* is a solution of problem P, without assumming differentiability of f. This proof can be extended to the sequence $\{x^k\}$ generated by algorithm RMIG. Since $\{x^k\}$ converges by Corollary 3, such a result is enough. The hypothesis on the null components of x^* holds because $d_\psi(z, x^k)$ is bounded, by Proposition 8 and Theorem 3, for any solution z, while if x^k_j approaches 0 for some j such that $z_j > 0$ we get $d_\psi(z, x^k)$ unbounded. There are several other involved technicalities to be dealt with in the nondifferentiable case.

The third extension is to admit overrelaxation in (19) or (37), i.e., replace $[0, 1]$ by an interval $[0, \pi_k]$ with π_k possibly larger than 1. In this case, some restrictions must be imposed upon π_k to guarantee $x^k > 0$ for all k. One way to incorporate these positivity-preserving safeguards is the following.

Take $\zeta \in (0, 1)$, a sequence $\{\zeta_k\} \subset (\zeta, 1)$, and $\tau > 0$. Let $J(x) = \{j : \nabla f(x)_j < 0\}$. Define after (18)

$$\omega_k = \begin{cases} \min\limits_{j \in J(x^k)} \{\frac{y^k_j}{x^k_j}\} & \text{if } J(x^k) \neq \emptyset, \\ 0 & \text{otherwise,} \end{cases} \tag{48}$$

$$\pi_k = \frac{\zeta_k}{1+\tau-\omega_k}, \tag{49}$$

and finally substitute $[0, \pi_k]$ for $[0, 1]$ in (19) or (37). It is easy to check that $1-\omega_k > 0$ and that this choice of π_k guarantees positivity of $\{x^k\}$. (In [7], we use this approach in a similar setting.) Regarding the convergence analysis, the situation is to some extent the opposite to the nondifferentiability extension discussed above: in this case the results of §4, but not those of §5, hold. For §4, there are only some technical complications (e.g., $\tau > 0$ is required to get $\{\pi^k\}$ bounded, which is required in the proof of Proposition 4). For §5, when x^{k+1} is not in the segment between x^k and y^k, (43) does not hold and we do not get quasi-Fejér convergence. The issue of full convergence under an overrelaxed line search requires further study.

Finally, we present the full form of the algorithms corresponding to the choices of φ introduced in the examples in §1.

1. $\varphi_1(t) = t - \log t - 1$,

$$x_j^{k+1} = x_j^k \left(1 - \frac{\alpha_k \nabla f(x^k)_j}{\lambda_k + \nabla f(x^k)_j}\right). \tag{50}$$

2. $\varphi_2(t) = t \log t - t + 1$,

$$x_j^{k+1} = x_j^k \left\{1 + \alpha_k \left[\exp\left(-\frac{\nabla f(x^k)_j}{\lambda_k}\right) - 1\right]\right\}. \tag{51}$$

3. $\varphi_3(t) = (\sqrt{t} - 1)^2$,

$$x_j^{k+1} = x_j^k \left[1 - \frac{\alpha_k \nabla f(x^k)_j (2\lambda_k + \nabla f(x^k)_j)}{(\lambda_k + \nabla f(x^k)_j)^2}\right]. \tag{52}$$

Since $\varphi_i \in \Psi$ $(i = 1, 2, 3)$ all the convergence results of §5 hold for iterations (50), (51), and (52) when λ_k satisfies (17) and α_k is given by (37). If α_k is given by (19), or when the interval $[0, 1]$ in (19) is replaced by $[0, \pi_k]$, with π_k as in (48), (49), the convergence results of section 4 hold for (50), (51), and (52). For $\varphi(t) = \varphi_4(t) = \frac{1}{2}(t-1)^2$ we get $x_j^{k+1} = x_j^k(1 - \frac{\alpha_k}{\lambda_k}\nabla f(x^k)_j)$. Our analysis does not include this case, because $\varphi_4 \notin \Phi_1$, and y^k given by (18) may fail to be positive. In this case the positivity-preserving safeguards are always needed and other adjustments are required. A convergence analysis tailored for this iteration can be found in [7].

EPSILON-MAXIMUM PRINCIPLE OF PONTRYAGIN TYPE AND PERTURBATION ANALYSIS OF CONVEX OPTIMAL CONTROL PROBLEMS*

MOHAMMED MOUSSAOUI† AND ALBERTO SEEGER†

Abstract. In this paper we study the first-order behaviour of the optimal-value function associated with a convex parametric problem of optimal control. A formula for the subdifferential of the optimal-value function is derived without assuming the existence of optimal solutions to the unperturbed problem. The so-called epsilon-maximum principle is a key ingredient in the writing of our main sensitivity result.

Key words. optimal control problem, sensitivity analysis, approximate subdifferential, Pontryagin's principle, transversality condition

AMS subject classifications. 49N99, 90C31

1. Introduction.

The sensitivity analysis of the optimal-value function associated with a convex parametric program has been the main concern of numerous papers in past decades. Formulas for the directional derivative and/or the subdifferential of the optimal-value function have been derived under various types of assumptions. As a standard rule, it is assumed that the unperturbed problem admits at least one optimal solution. This hypothesis is, however, quite restrictive in some cases, especially in the context of infinite dimensional programs. For this reason, Moussaoui and Seeger [MS1, MS2] have recently developed a sensitivity analysis theory well suited for dealing with convex parametric programs with possibly empty solution sets. In a subsequent paper, Seeger [Se1] has applied this general theory to the specific case of a convex parametric problem of calculus of variations written in the Bolza form

$$\underset{x\in X}{\text{minimize}} \left\{ H(x(0),x(1),\alpha) + \int_0^1 L(t,x(t),\dot{x}(t),\theta(t))\,dt \right\}. \tag{1.1}$$

Here α and θ are interpreted as perturbation parameters affecting the endpoint cost and the integral cost, respectively. The sensitivity results obtained in [Se1] are stated in terms of concepts such as approximate Euler–Lagrange inclusion and approximate transversality condition.

The purpose of the present paper is to apply the above-mentioned theory to the case of a convex parametric problem of optimal control. Our work is influenced by [Se1] and can be viewed as an extension of it. Although it is possible to write an optimal control problem as a Bolza problem of calculus of variations, we follow, however, a completely different approach. (See §5 for further discussion.)

Next we describe the basic model of parametric optimal control problem to be considered in this paper. The control $u \in U$ and the trajectory $x \in X$ are related by means of the state equation

$$\dot{x}(t) = A(t)x(t) + B(t)u(t) + \gamma(t) \quad \text{for a.e. } t \in [0,1]. \tag{1.2}$$

The space of controls is defined as

$$U = L_p^d := L_p([0,1];\mathbb{R}^d) \quad (\text{with } 1 \le p < +\infty),$$

and the space of trajectories

$$X = A_p^n := A_p([0,1];\mathbb{R}^n)$$

consists of the absolutely continuous functions $x : [0,1] \to \mathbb{R}^n$ whose derivatives $\dot{x}$ belong to $L_p^n := L_p([0,1];\mathbb{R}^n)$. The velocity vector $\dot{x}(t)$ is defined of course for all $t \in [0,1]$ except on a set of measure zero. In (1.2), the term $\gamma \in \Gamma$ is regarded as an external perturbation function affecting the dynamics of the system.

In this work we are concerned with a convex parametric problem of optimal control written in the form

$$\text{minimize}\{J(x,u,\alpha,\theta) : (x,u) \in F(\gamma)\},$$

where the feasible set $F(\gamma)$ consists of all pairs $(x,u) \in X \times U$ satisfying the state equation (1.2). The cost functional

$$J(x,u,\alpha,\theta) := H(x(0),x(1),\alpha) + \int_0^1 L(t,x(t),u(t),\theta(t))\,dt \tag{1.3}$$

involves a perturbation function $\theta \in \Theta$ affecting the integral term and a perturbation vector $\alpha \in \mathbb{R}^k$ affecting the endpoint term.

The aim of this paper is to study the first-order behaviour of the optimal-value function

$$(\alpha,\theta,\gamma) \mapsto V(\alpha,\theta,\gamma) = \text{Inf}\{J(x,u,\alpha,\theta) : (x,u) \in F(\gamma)\} \tag{1.4}$$

around a given point, say, $(\alpha_0,\theta_0,\gamma_0) \in \mathbb{R}^k \times \Theta \times \Gamma$. This point represents the reference level or nominal value of the parameters. Thus,

$$\text{minimize}\{J(x,u,\alpha_0,\theta_0) : (x,u) \in F(\gamma_0)\} \tag{1.5}$$

is regarded as the "unperturbed" optimal control problem.

There is a long history behind the study of an optimal-value function like (1.4). For instance, sensitivity results for smooth parametric optimal control problems can be found in works by Oniki [On] and Tu [Tu, §10], to mention just a few names. Parametric optimal control problems involving locally Lipschitz data have been discussed by Clarke [C1, C2, C3], Loewen [Lo], and Clarke and Loewen [CL1, CL2], among others. In such a setting, the concept of Clarke's generalized subdifferential is a suitable tool for studying the first-order behaviour of the function V. In this paper all the data are assumed to be convex, so we will characterize the subdifferential of V in the sense of convex analysis. The precise definition of this concept will be recalled in §2. In contrast with the sensitivity results found in the literature, in our approach the unperturbed problem (1.5) is not required to be solvable. In fact, convex optimal control problems with empty solution sets are encountered quite often in practice. The following examples are just academic but serve to illustrate the range of applicability of our sensitivity results.

Example 1.1. For each $\theta \in L_1[0,1]$ and $\gamma \in L_1[0,1]$, consider the problem of minimizing the cost

$$\int_0^1 t^2[u_1^2(t) + u_2^2(t) + \theta^2(t)]^{1/2}\,dt$$

among all controls $u_1,\ u_2 \in L_1\,[0,1]$ and trajectories $x \in A_1\,[0,1]$ satisfying

$$\begin{cases} \dot{x}(t) = b_1\,u_1(t) + b_2\,u_2(t) + \gamma(t), & \text{for a.e. } t \in [0,1], \\ x(0) = 0, \quad x(1) = 1. \end{cases}$$

Here $b_1 \neq 0$ and $b_2 \neq 0$ are two given real numbers. Denote by $V(\theta,\gamma)$ the optimal value of the above problem. Setting the parameters θ and γ at the reference level

$$\theta_0(t) = 0 \quad \text{and } \gamma_0(t) = 0 \quad \text{for a.e. } t \in [0,1],$$

one gets a nonsmooth convex optimal control problem with optimal value equal to zero. To see this, consider the minimizing sequence $(u_1^{(k)}, u_2^{(k)})$ given by

$$u_i^{(k)} = \begin{cases} \dfrac{k}{2\,b_i} & \text{on} \left[0, \frac{1}{k}\right[\\ \\ 0 & \text{on} \left[\dfrac{1}{k}, 1\right] \end{cases} \quad \text{for } i = 1, 2.$$

However, the optimal value $V(\theta_0, \gamma_0) = 0$ is not attained. Observe that the controls

$$u_1(t) = u_2(t) = 0 \quad \text{for a.e. } t \in [0, 1]$$

do not steer the system from $x(0) = 0$ to $x(1) = 1$. How does the function V behave around (θ_0, γ_0)?

Example 1.2. Consider the problem of minimizing the endpoint cost

$$H(x(1)) = [\exp(x_1(1)) + x_2^2(1)]^{1/2}$$

among all controls $u \in L_1[0, 1]$ and trajectories $x \in A_1([0, 1]; \mathbb{R}^2)$ satisfying

$$\begin{cases} \dot{x}_1(t) = -2x_1(t) + 3x_2(t) + u(t) + \gamma_1(t), \\ \dot{x}_2(t) = x_2(t) + \gamma_2(t), \\ x_1(0) = 0, \quad x_2(0) = 0. \end{cases}$$

Setting the parameter function $\gamma = (\gamma_1, \gamma_2) \in L_1([0, 1]; \mathbb{R}^2)$ at the reference level

$$\gamma_0(t) = (0, 0) \quad \text{for a.e. } t \in [0, 1],$$

one gets a nonsmooth convex optimal control problem whose optimal value $V(\gamma_0) = 0$ is finite but not attained. How does one compute in this case the subdifferential of V at γ_0?

2. General results on subdifferentials of optimal-value functions. As is customary in the context of convex analysis, we work in the setting of two real linear spaces, say, Ξ and Ξ^*, which have been paired by means of a bilinear form $\langle \cdot, \cdot \rangle : \Xi \times \Xi^* \mapsto \mathbb{R}$. The topologies on Ξ and Ξ^* are supposed to be compatible with respect to the pairing (see [Ro1, §3] for details).

Given a convex function $V : \Xi \to \mathbb{R} \cup \{+\infty\}$, the *subdifferential* of V at $\xi_0 \in \Xi$ is defined by

$$\partial V(\xi_0) = \{\eta \in \Xi^* : V(\xi) \geq V(\xi_0) + \langle \xi - \xi_0, \eta \rangle \text{ for all } \xi \in \Xi\}. \tag{2.1}$$

Each element of (2.1) is called a *subgradient* of V at ξ_0. An equivalent definition of this set is

$$\partial V(\xi_0) = \{\eta \in \Xi^* : V^*(\eta) + V(\xi_0) - \langle \xi_0, \eta \rangle = 0\},$$

where

$$\eta \in \Xi^* \mapsto V^*(\eta) := \operatorname*{Sup}_{\xi \in \Xi} \{\langle \xi, \eta \rangle - V(\xi)\}$$

stands for the Fenchel conjugate of V.

The set $\partial V(\xi_0)$ reflects the first-order behaviour of the function V around the point $\xi_0 \in \Xi$. Calculus rules for computing subdifferentials can be found in standard references like Ioffe

and Tihomirov [IT], Laurent [La], and Rockafellar [Ro1]. The next calculus rule serves, for instance, for computing the subdifferential of the optimal-value function

$$\xi \in \Xi \mapsto f_K(\xi) := \operatorname*{Inf}_{z \in Z} \{f(z) : Kz = \xi\}.$$

The elements in the space Ξ are regarded here as parameters. The space Z of minimization variables is supposed to be paired with another real linear space, say, Z^*.

LEMMA 2.1. *Suppose that the following general assumption is true*:

$$\text{(2.2)} \qquad \begin{cases} f : Z \to \mathbb{R} \cup \{+\infty\} & \text{is a convex proper function,} \\ K : Z \to \Xi & \text{is a continuous linear operator,} \\ f_K & \text{is finite at } \xi_0 \in \Xi. \end{cases}$$

Let z_0 be any element in the solution set

$$S(\xi_0) := \{z \in Z : Kz = \xi_0,\ f(z) = f_K(\xi_0)\}.$$

Then

$$\text{(2.3)} \qquad \partial f_K(\xi_0) = \{\eta \in \Xi^* : K^*\eta \in \partial f(z_0)\},$$

where $K^* : \Xi^* \to Z^*$ stands for the adjoint operator of $K : Z \to \Xi$.

The above result can be found in Hiriart-Urruty [Hi] and Zalinescu [Za], for instance. The writing of formula (2.3) makes sense only if an element z_0 in the solution set $S(\xi_0)$ does exist, but here we want to evaluate the subdifferential mapping ∂f_K at a point ξ_0 at which the solution set is possibly empty. To handle this more complicated situation we invoke a recent result by Moussaoui and Seeger [MS1, MS2]. Recall that the *ε-subdifferential* of f at a point $z_0 \in Z$ is the set

$$\partial_\varepsilon f(z_0) = \{\omega \in Z^* : f(z) \geq f(z_0) + \langle z - z_0, \omega\rangle - \varepsilon \text{ for all } z \in Z\}.$$

The above set is also known as the approximate subdifferential of f at z_0. The (exact) subdifferential $\partial f(z_0)$ corresponds of course to the case $\varepsilon = 0$.

LEMMA 2.2 [MS1, Thm. 1]. *Suppose that the general assumption* (2.2) *is true. Then*

$$\text{(2.4)} \qquad \partial f_K(\xi_0) = \bigcap_{\varepsilon > 0} \bigcup_{Kz = \xi_0} \{\eta \in \Xi^* : K^*\eta \in \partial_\varepsilon f(z)\}.$$

Observe that if z satisfies $Kz = \xi_0$ and $\{\eta \in \Xi^* : K^*\eta \in \partial_\varepsilon f(z)\} \neq \emptyset$, then z belongs necessarily to the set

$$S_\varepsilon(\xi_0) := \{z \in Z : Kz = \xi_0,\ f(z) \leq f_K(\xi_0) + \varepsilon\}.$$

Thus formula (2.4) can also be written in the form

$$\partial f_K(\xi_0) = \bigcap_{\varepsilon > 0} \bigcup_{z \in S_\varepsilon(\xi_0)} \{\eta \in \Xi^* : K^*\eta \in \partial_\varepsilon f(z)\}.$$

For subsequent use we need to adjust Lemma 2.2 to the case in which f is defined as a sum of two convex functions, say, f_1 and f_2. We also incorporate a linear operator R defined over the space of parameters Ξ and with values in another linear space, say, Π. The notation $\operatorname{Im} R := \{R\xi : \xi \in \Xi\}$ refers to the range of R, and $C^\perp$ stands for the orthogonal complement of C. The indicator function of the set

$$K^{-1}(\operatorname{Im} R) := \{z \in Z : Kz \in \operatorname{Im} R\}$$

is by definition

$$z \in Z \mapsto \psi_{K^{-1}(\operatorname{Im} R)}(z) := \begin{cases} 0 & \text{if } Kz \in \operatorname{Im} R, \\ +\infty & \text{otherwise.} \end{cases}$$

LEMMA 2.3. *Let $f_1, f_2 : Z \to \mathbb{R} \cup \{+\infty\}$ be two proper convex functions and $K : Z \to \Pi$ and $R : \Xi \to \Pi$ be two continuous linear operators. Suppose that the optimal-value function*

$$\xi \in \Xi \mapsto V(\xi) = \inf_{z \in Z} \{f_1(z) + f_2(z) : Kz = R\xi\}$$

is finite at $\xi_0 \in \Xi$. Then the subdifferential $\partial V(\xi_0)$ admits the following inner estimate:

$$\partial V(\xi_0) \supset \bigcap_{\varepsilon > 0} \bigcup_{Kz = R\xi_0} \{R^*\varphi : K^*\varphi \in \partial_\varepsilon f_1(z) + \partial_\varepsilon f_2(z)\}. \tag{2.5}$$

Moreover, one can write the formula

$$\partial V(\xi_0) = \bigcap_{\varepsilon > 0} \bigcup_{Kz = R\xi_0} \{R^*\varphi : K^*\varphi \in \partial_\varepsilon f_1(z) + \partial_\varepsilon f_2(z)\} \tag{2.6}$$

if one adds the following constraint qualification hypotheses:

$$\operatorname{Im} R \quad \textit{and} \quad \operatorname{Im} R^* \textit{ are closed sets}, \tag{2.7}$$

$$K^*([\operatorname{Im} R]^\perp) \textit{ is a closed set}, \tag{2.8}$$

$$\begin{aligned} &(f_1 + f_2 + \psi_{K^{-1}(\operatorname{Im} R)})^*(w) \\ &\quad = \inf_{\omega_1 + \omega_2 + \omega_3 = \omega} \{f_1^*(\omega_1) + f_2^*(\omega_2) + \psi^*_{K^{-1}(\operatorname{Im} R)}(\omega_3)\} \quad \textit{for all } w \in Z^*. \end{aligned} \tag{2.9}$$

Proof. Denote by Ω the set appearing on the right-hand side of (2.5), and let η be an arbitrary element in Ω. To prove that $\eta \in \partial V(\xi_0)$, it suffices to show the inequality

$$V(\xi) \geq V(\xi_0) + \langle \xi - \xi_0, \eta \rangle - 2\varepsilon \quad \text{for all } \xi \in \Xi \text{ and } \varepsilon > 0. \tag{2.10}$$

Then fix $\xi \in \Xi$ and $\varepsilon > 0$. Since $\eta \in \Omega$, there exist $z_\varepsilon \in Z$ and $\varphi_\varepsilon \in \Pi^*$ such that

$$Kz_\varepsilon = R\xi_0, \quad R^*\varphi_\varepsilon = \eta, \quad \text{and} \quad K^*\varphi_\varepsilon \in \partial_\varepsilon f_1(z_\varepsilon) + \partial_\varepsilon f_2(z_\varepsilon). \tag{2.11}$$

Momentarily decompose $K^*\varphi_\varepsilon$ in the form

$$K^*\varphi_\varepsilon = \omega_1 + \omega_2 \quad \text{with } \omega_1 \in \partial_\varepsilon f_1(z_\varepsilon) \text{ and } \omega_2 \in \partial_\varepsilon f_2(z_\varepsilon).$$

Now take any $z \in Z$ satisfying $Kz = R\xi$. By summing up the inequalities

$$f_i(z) \geq f_i(z_\varepsilon) + \langle z - z_\varepsilon, \omega_i \rangle - \varepsilon, \qquad i = 1, 2,$$

one gets

$$f_1(z) + f_2(z) \geq f_1(z_\varepsilon) + f_2(z_\varepsilon) + \langle z - z_\varepsilon, K^*\varphi_\varepsilon \rangle - 2\varepsilon,$$

and therefore,

$$f_1(z) + f_2(z) \geq V(\xi_0) + \langle R\xi - R\xi_0, \varphi_\varepsilon \rangle - 2\varepsilon.$$

Since $z \in Z$ was an arbitrary vector satisfying $Kz = R\xi$, one gets finally

$$\operatorname*{Inf}_{Kz=R\xi}\{f_1(z) + f_2(z)\} \geq V(\xi_0) + \langle R\xi - R\xi_0, \varphi_\varepsilon \rangle - 2\varepsilon.$$

This completes the proof of inequality (2.10). We prove now the reverse inclusion $\partial V(\xi_0) \subset \Omega$. Take any $\eta \in \partial V(\xi_0)$ and $\varepsilon > 0$. We need to exhibit a pair $(z_\varepsilon, \varphi_\varepsilon) \in Z \times \Pi^*$ satisfying (2.11). Taking into account hypothesis (2.7) and Lemma A.1 (see Appendix), we can write $\eta = R^*\varphi'$ for some $\varphi' \in \Pi^*$. Since $\eta \in \partial V(\xi_0)$, this element $\varphi' \in \Pi^*$ satisfies

$$V^*(R^*\varphi') + V(\xi_0) - \langle \xi_0, R^*\varphi' \rangle = 0. \tag{2.12}$$

As a matter of computation one has

$$\begin{aligned} V^*(R^*\varphi') &= \operatorname*{Sup}_{\xi\in\Xi}\{\langle \xi, R^*\varphi' \rangle - \operatorname*{Inf}_{Kz=R\xi}\{f_1(z) + f_2(z)\}\} \\ &= \operatorname*{Sup}_{\xi\in\Xi} \operatorname*{Sup}_{Kz=R\xi}\{\langle R\xi, \varphi' \rangle - f_1(z) - f_2(z)\} \\ &= \operatorname*{Sup}_{Kz\in \operatorname{Im} R}\{\langle z, K^*\varphi' \rangle - f_1(z) - f_2(z)\} \\ &= [f_1 + f_2 + \psi_{K^{-1}(\operatorname{Im} R)}]^*(K^*\varphi'). \end{aligned}$$

Here the constraint qualifications (2.7)–(2.9) come into play. In fact, they allow us to write

$$\begin{aligned} V^*(R^*\varphi') &= \operatorname*{Inf}_{\omega_1+\omega_2+\omega_3=K^*\varphi'}\{f_1^*(\omega_1) + f_2^*(\omega_2) + \psi^*_{K^{-1}(\operatorname{Im} R)}(\omega_3)\} \\ &= \operatorname*{Inf}_{\omega_1,\omega_2}\{f_1^*(\omega_1) + f_2^*(\omega_2) : K^*\varphi' - \omega_1 - \omega_2 \in K^*([\operatorname{Im} R]^\perp)\}. \end{aligned}$$

So we can select $\omega_1 \in Z^*$, $\omega_2 \in Z^*$, and $\varphi'' \in [\operatorname{Im} R]^\perp$ in such a way that

$$K^*\varphi' - \omega_1 - \omega_2 = K^*\varphi'' \quad \text{and} \quad f_1^*(\omega_1) + f_2^*(\omega_2) \leq V^*(R^*\varphi') + \frac{\varepsilon}{2}. \tag{2.13}$$

Independently, we pick up an element $z \in Z$ satisfying

$$Kz = R\xi_0 \quad \text{and} \quad f_1(z) + f_2(z) \leq V(\xi_0) + \frac{\varepsilon}{2}. \tag{2.14}$$

The combination of (2.12)–(2.14) yields

$$\left\{f_1^*(\omega_1) + f_2^*(\omega_2) - \frac{\varepsilon}{2}\right\} + \left\{f_1(z) + f_2(z) - \frac{\varepsilon}{2}\right\} - \langle \xi_0, R^*\varphi' \rangle \leq 0.$$

Rearranging terms, one finally gets

$$[f_1^*(\omega_1) + f_1(z) - \langle z, \omega_1 \rangle] + [f_2^*(\omega_2) + f_2(z) - \langle z, \omega_2 \rangle] + [\langle z, \omega_1 + \omega_2 \rangle - \langle R\xi_0, \varphi' \rangle] \leq \varepsilon.$$

Observe that the last term

$$\langle z, \omega_1 + \omega_2 \rangle - \langle R\xi_0, \varphi' \rangle = -\langle z, K^*\varphi' - \omega_1 - \omega_2 \rangle = -\langle z, K^*\varphi'' \rangle$$

is equal to zero. Indeed, z and $K^*\varphi''$ are orthogonal with respect to the duality product $\langle \cdot, \cdot \rangle : Z \times Z^* \to \mathbb{R}$. Now, according to the classical Young–Fenchel inequality, the first two terms enclosed by the square brackets are nonnegative. This implies in particular that

$$\omega_1 \in \partial_\varepsilon f_1(z) \quad \text{and} \quad \omega_2 \in \partial_\varepsilon f_2(z).$$

Thus we have found elements $z \in Z$, $\varphi' \in \Pi^*$, and $\varphi'' \in \Pi^*$ satisfying $Kz = R\xi_0$, $R^*\varphi' = \eta$, $\varphi'' \in [\operatorname{Im} R]^\perp$, and $K^*(\varphi' - \varphi'') \in \partial_\varepsilon f_1(z) + \partial_\varepsilon f_2(z)$. From the condition $\varphi'' \in [\operatorname{Im} R]^\perp$, it follows that $R^*\varphi'' = 0$. Setting $\varphi = \varphi' - \varphi''$, one sees that the pair $(z, \varphi) \in Z \times \Pi^*$ solves the system

$$Kz = R\xi_0, \quad R^*\varphi = \eta, \quad \text{and} \quad K^*\varphi \in \partial_\varepsilon f_1(z) + \partial_\varepsilon f_2(z).$$

The proof is complete in this way. □

Remark 2.1. If $\operatorname{Im} K \subset \operatorname{Im} R$, then $K^{-1}(\operatorname{Im} R) = Z$ and $K^*([\operatorname{Im} R]^\perp) = \{0\}$. Thus, (2.8) holds trivially, and (2.9) takes the simpler form

$$(f_1 + f_2)^*(\omega) = \inf_{\omega_1 + \omega_2 = \omega} \{f_1^*(\omega_1) + f_2^*(\omega_2)\} \quad \text{for all } \omega \in Z^*.$$

The above equality holds, for instance, if the function f_2 is continuous at a point in which f_1 is finite. See also Attouch and Brezis [AB] and Rockafellar [Ro1, Thm. 20].

3. Sensitivity results for convex optimal control problems. In this section we study the first-order behaviour of the optimal-value function

$$(\alpha, \theta, \gamma) \mapsto V(\alpha, \theta, \gamma) := \operatorname{Inf}\{J(x, u, \alpha, \theta) : (x, u) \in F(\gamma)\} \tag{3.1}$$

around the reference level $(\alpha_0, \theta_0, \gamma_0) \in \mathbb{R}^k \times \Theta \times \Gamma$. We want to characterize the subdifferential $\partial V(\alpha_0, \theta_0, \gamma_0)$ in terms of the data of our optimal control problem. These data belong essentially to two different categories. First, one has the endpoint cost H and the Lagrangian L, that is to say, the terms appearing in the definition of the total cost

$$J(x, u, \alpha, \theta) := H(x(0), x(1), \alpha) + \int_0^1 L(t, x(t), u(t), \theta(t))\, dt. \tag{3.2}$$

And second, one has the matrix-valued functions A and B, which appear in the definition of the feasible set

$$F(\gamma) := \{(x, u) \in X \times U : \dot{x}(t) = A(t)\, x(t) + B(t)\, u(t) + \gamma(t) \quad \text{for a.e. } t \in [0, 1]\}. \tag{3.3}$$

The general assumptions on these data are presented next. First, a word on the space $\mathbb{R}^k \times \Theta \times \Gamma$ of parameters. The choice of the space Θ is dictated by the need of manipulating an integral function of the form

$$I_L(x, u, \theta) := \int_0^1 L(t, x(t), u(t), \theta(t))\, dt. \tag{3.4}$$

In what follows we suppose that Θ is a certain *decomposable* space of measurable functions $\theta : [0, 1] \to \mathbb{R}^m$ (see Rockafellar [Ro1, p. 59] for the precise definition of decomposability). Those not familiar with this concept can retain the particular choice

$$\Theta = L_s^m := L_s([0, 1]; \mathbb{R}^m) \qquad (1 \le s < +\infty). \tag{3.5}$$

By assumption, the decomposable space Θ is paired with Θ^* by means of a bilinear form $\langle \cdot, \cdot \rangle : \Theta \times \Theta^* \to \mathbb{R}$. As way of example, the decomposable space (3.5) is paired with $\Theta^* = L_r^m$ by means of the bilinear form

$$\langle \theta, \nu \rangle = \int_0^1 \theta(t) \cdot \nu(t)\, dt, \qquad \theta \in \Theta,\ \nu \in \Theta^*.$$

Here $r = s/(s-1)$ is the conjugate number of s, and the dot "$\cdot$" stands for the usual Euclidean product. Concerning the space of functions perturbing the dynamics of the system, we set

$$\Gamma = L_p^n := L_p([0,1]; \mathbb{R}^n).$$

This space is paired with $\Gamma^* = L_q^n$, where $q = p/(p-1)$ is the conjugate number of p, by means of the bilinear form

$$\langle \gamma, \lambda \rangle = \int_0^1 \gamma(t) \cdot \lambda(t)\, dt, \qquad \gamma \in \Gamma,\ \lambda \in \Gamma^*.$$

Since the space of trajectories $X = A_p^n$ is not decomposable, the integral function (3.4) is regarded as a function defined over the space $L_q^n \times U \times \Theta$.

The sensitivity results presented in this section rely upon the following basic hypotheses:

(3.6) $\begin{cases} \text{the matrix-valued functions } A : [0,1] \to M_{n,n}(\mathbb{R}) \text{ and } B : [0,1] \to M_{n,d}(\mathbb{R}) \\ \text{are measurable and essentially bounded;} \end{cases}$

(3.7) $\begin{cases} \text{the endpoint cost function } H : \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^k \to \mathbb{R} \cup \{+\infty\} \text{ is proper convex} \\ \text{lower-semicontinuous;} \end{cases}$

(3.8) $\begin{cases} \text{the Lagrangian } L : [0,1] \times \mathbb{R}^n \times \mathbb{R}^d \times \mathbb{R}^m \to \mathbb{R} \cup \{+\infty\} \text{ is measurable, and} \\ L(t, \cdot, \cdot, \cdot) \text{ is a proper convex lower-semicontinuous function for a.e. } t \in [0,1]; \end{cases}$

(3.9) $\begin{cases} \text{for all } (x,u,\theta) \in L_q^n \times U \times \Theta, \text{ the negative part of the integrand} \\ t \mapsto L(t, x(t), u(t), \theta(t)) \text{ is summable over } [0,1]. \end{cases}$

Hypothesis (3.9) is introduced to avoid all confusion regarding the sum of $+\infty$ and $-\infty$. The integral (3.4) has a classical value, possibly $+\infty$ but never $-\infty$. We need to take into account also a constraint qualification condition on the cost functional, namely,

(3.10) $\begin{cases} \text{there exist } x \in X,\ u \in U,\ \alpha \in \mathbb{R}^k, \text{ and } \theta \in \Theta \\ \text{such that } H \text{ is finite at } (x(0), x(1), \alpha) \\ \text{and } I_L : L_q^n \times U \times \Theta \to \mathbb{R} \cup \{+\infty\} \text{ is continuous at } (x,u,\theta). \end{cases}$

Our first sensitivity result is somewhat standard. It deals with the "easy" case in which the unperturbed problem

(3.11) $$\text{minimize}\{J(x,u,\alpha_0,\theta_0) : (x,u) \in F(\gamma_0)\}$$

admits at least one optimal solution. Whether an element $(\beta_0, \nu_0, \lambda_0)$ belongs to the subdifferential $\partial V(\alpha_0, \theta_0, \gamma_0)$ will depend on the existence of a "dual" trajectory satisfying a given set of extremality conditions. The space of dual trajectories is defined as follows:

(3.12) $$Y := \begin{cases} A_p^n & \text{if } p \in [1,2] \text{ or } A = 0, \\ A_q^n & \text{otherwise.} \end{cases}$$

The above definition takes into account the choice of the space $X = A_p^n$ of "primal" trajectories and the matrix-valued function A appearing in the "autonomous" system

$$\dot{x}(t) = A(t)\,x(t) \quad \text{for a.e. } t \in [0,1].$$

The particular cases $p = 1$ and $p = 2$ deserve special mention since they are encountered quite often in practice. For these particular choices one has $X = Y = A_p^n$. Without further ado we write the following theorem.

THEOREM 3.1. *With assumptions* (3.6)–(3.10), *let the optimal-value function V be finite at $(\alpha_0, \theta_0, \gamma_0) \in \mathbb{R}^k \times \Theta \times \Gamma$ and $(x_0, u_0) \in X \times U$ be an optimal solution of the unperturbed problem* (3.11), *i.e.*,

$$(3.13)\quad \begin{cases} \dot{x}_0(t) = A(t)x_0(t) + B(t)u_0(t) + \gamma_0(t) \quad \textit{for a.e. } t \in [0,1], \\ V(\alpha_0, \theta_0, \gamma_0) = H(x_0(0), x_0(1), \alpha_0) + \displaystyle\int_0^1 L(t, x_0(t), u_0(t), \theta_0(t))\,dt. \end{cases}$$

Then $(\beta_0, \nu_0, \lambda_0) \in \mathbb{R}^k \times \Theta^* \times \Gamma^*$ is a subgradient of V at $(\alpha_0, \theta_0, \gamma_0)$ if and only if there exists a dual trajectory $y \in Y$ (necessarily unique) such that

$$(3.14)\qquad \lambda_0(t) = -y(t) \quad \textit{for a.e. } t \in [0,1],$$

$$(3.15)\qquad (y(0), -y(1), \beta_0) \in \partial H(x_0(0), x_0(1), \alpha_0) \quad (\textit{transversality condition}),$$

and

$$(3.16)\qquad (\dot{y}(t) + A^T(t)y(t), B^T(t)y(t), \nu_0(t)) \in \partial L(t, x_0(t), u_0(t), \theta_0(t)) \quad \textit{for a.e. } t \in [0,1]\ (\textit{Pontryagin's principle}).$$

Proof. To prove this result, the reader can adjust the proof of the next theorem. □

Remark 3.1. The symbol ∂L stands for the subdifferential mapping of $L(t,\cdot,\cdot,\cdot) : \mathbb{R}^n \times \mathbb{R}^d \times \mathbb{R}^m \to \mathbb{R} \cup \{+\infty\}$. (Subdifferentiation will never refer to the time variable.)

We are ready to state the main result of this paper. Now the existence of an optimal solution to the unperturbed problem (3.11) is no longer assumed. We emulate the technique described in Seeger [Se1, §3]; that is to say, we enlarge the subdifferential mappings ∂H and ∂L by introducing a parameter $\varepsilon > 0$. The extremality conditions (3.15) and (3.16) are now written in terms of the enlarged mappings $\partial_\varepsilon H$ and $\partial_{\sigma(t)} L(t,\cdot,\cdot,\cdot)$. Here σ refers to a nonnegative function with total weight equal to ε. More precisely, σ belongs to the set

$$(3.17)\qquad \Sigma(\varepsilon) := \left\{ \sigma \in L_1[0,1] : \int_0^1 \sigma(t)\,dt = \varepsilon,\ \sigma(t) \geq 0 \text{ for a.e. } t \in [0,1] \right\}.$$

THEOREM 3.2. *With the assumptions* (3.6)–(3.10), *let the optimal-value function V be finite at $(\alpha_0, \theta_0, \gamma_0) \in \mathbb{R}^k \times \Theta \times \Gamma$. Then the element $(\beta_0, \nu_0, \lambda_0) \in \mathbb{R}^k \times \Theta^* \times \Gamma^*$ is a subgradient of V at $(\alpha_0, \theta_0, \gamma_0)$ if and only if for all $\varepsilon > 0$ there exist a trajectory $x \in X$, a control $u \in U$, a dual trajectory $y \in Y$ (necessarily unique), and a function $\sigma \in \Sigma(\varepsilon)$ such that*

$$(3.18)\qquad \dot{x}(t) = A(t)x(t) + B(t)u(t) + \gamma_0(t) \quad \textit{for a.e. } t \in [0,1],$$

$$(3.19)\qquad \lambda_0(t) = -y(t) \quad \textit{for a.e. } t \in [0,1],$$

(3.20) $(y(0), -y(1), \beta_0) \in \partial_\varepsilon H(x(0), x(1), \alpha_0)$ (ε-*transversality condition*),

and

(3.21) $$(\dot{y}(t) + A^T(t)y(t), B^T(t)y(t), \nu_0(t)) \in \partial_{\sigma(t)} L(t, x(t), u(t), \theta_0(t))$$
for a.e. $t \in [0,1]$ (ε- *maximum principle*).

Proof. A trajectory in $X = A_p^n$ will be represented by an initial point, say, $a \in \mathbb{R}^n$, and a velocity vector, say, $v \in L_p^n$. Observe that the linear operator

$$G : Z \to X,$$
$$(a, v) \mapsto G(a, v) = a + \int_0^{(\cdot)} v(\tau)\, d\tau$$

maps $Z = \mathbb{R}^n \times L_p^n$ onto the space X. In terms of these new variables, the cost term

$$H(x(0), x(1), \alpha) + \int_0^1 L(t, x(t), u(t), \theta(t))\, dt$$

becomes

(3.22) $$H(a, a + Ev, \alpha) + \int_0^1 L(t, G(a, v)(t), u(t), \theta(t))\, dt,$$

where E stands for the linear operator

$$E : L_p^n \to \mathbb{R}^n$$
$$v \mapsto \int_0^1 v(\tau)\, d\tau.$$

If one writes the state equation

$$\dot{x}(t) = A(t)x(t) + B(t)u(t) + \gamma(t) \quad \text{for a.e. } t \in [0,1]$$

in integral form, one gets

$$x(\cdot) - x(0) = \int_0^{(\cdot)} A(\tau)x(\tau)\, d\tau + \int_0^{(\cdot)} B(\tau)u(\tau)\, d\tau + \int_0^{(\cdot)} \gamma(\tau)\, d\tau.$$

The above linear equation can be regarded as an equality

$$G(a, v) - a = R_A G(a, v) + R_B u + R_I \gamma$$

in the space

$$\mathcal{H} = \{h \in A_p^n : h(0) = 0\},$$

where the operators $R_A : X \to \mathcal{H}$, $R_B : U \to \mathcal{H}$, and $R_I : \Gamma \to \mathcal{H}$ are defined in the obvious way, namely,

$$R_A x = \int_0^{(\cdot)} A(\tau)x(\tau)\, d\tau,$$
$$R_B u = \int_0^{(\cdot)} B(\tau)u(\tau)\, d\tau,$$
$$R_I \gamma = \int_0^{(\cdot)} \gamma(\tau)\, d\tau.$$

Thus $V(\alpha, \theta, \gamma)$ is the optimal value of the convex parametric program

$$\text{(3.23)} \qquad \begin{cases} \text{minimize } H(a, a + Ev, \alpha) + \displaystyle\int_0^1 L(t, G(a,v)(t), u(t), \theta(t))\, dt, \\ (a, v, u) \in Z \times U, \\ M(a, v, u) = R_I \gamma, \end{cases}$$

where $M : Z \times U \to \mathcal{H}$ is the linear operator given by

$$M(a, v, u) = G(a, v) - a - R_A G(a, v) - R_B u.$$

We prefer to write (3.23) in the form

$$\text{(3.24)} \qquad \begin{cases} \text{minimize } H(a, a + Ev, \alpha') + \displaystyle\int_0^1 L(t, G(a,v)(t), u(t), \theta'(t))\, dt, \\ (a, v, u, \alpha', \theta') \in Z \times U \times \mathbb{R}^k \times \Theta, \\ \alpha' = \alpha, \\ \theta' = \theta, \\ M(a, v, u) = R_I \gamma, \end{cases}$$

because the later formulation fits exactly into the general scheme of Lemma 2.3. To see this, just introduce the convex functions $f_1, f_2 : Z \times U \times \mathbb{R}^k \times \Theta \to \mathbb{R} \cup \{+\infty\}$ defined by

$$\begin{aligned} f_1(a, v, u, \alpha, \theta) &:= H(a, a + Ev, \alpha), \\ f_2(a, v, u, \alpha, \theta) &:= \int_0^1 L(t, G(a,v)(t), u(t), \theta(t))\, dt, \end{aligned}$$

and the linear operators

$$\begin{aligned} K : Z \times U \times \mathbb{R}^k \times \Theta &\to \mathbb{R}^k \times \Theta \times \mathcal{H}, \\ (a, v, u, \alpha, \theta) &\mapsto K(a, v, u, \alpha, \theta) = (\alpha, \theta, M(a, v, u)), \end{aligned}$$

$$\begin{aligned} R : \mathbb{R}^k \times \Theta \times \Gamma &\to \mathbb{R}^k \times \Theta \times \mathcal{H}, \\ (\alpha, \theta, \gamma) &\mapsto R(\alpha, \theta, \gamma) = (\alpha, \theta, R_I \gamma). \end{aligned}$$

The remaining part of the proof consists of applying Lemma 2.3 to the particular case

$$V(\alpha, \theta, \gamma) = \operatorname{Inf}\{(f_1 + f_2)(a, v, u, \alpha', \theta') : K(a, v, u, \alpha', \theta') = R(\alpha, \theta, \gamma)\},$$

where the infimum is taken with respect to $(a, v, u, \alpha', \theta') \in Z \times U \times \mathbb{R}^k \times \Theta$. If all the assumptions in Lemma 2.3 were fulfilled, then we could assert that $(\beta_0, \nu_0, \lambda_0) \in \partial V(\alpha_0, \theta_0, \gamma_0)$ if and only if for all $\varepsilon > 0$ there exist

$$(a, v, u, \alpha', \theta') \in Z \times U \times R^k \times \Theta \quad \text{and} \quad (\beta, \nu, \mu) \in \mathbb{R}^k \times \Theta^* \times \mathcal{H}^*$$

such that

$$\begin{aligned} K(a, v, u, \alpha', \theta') &= R(\alpha_0, \theta_0, \gamma_0), \\ (\beta_0, \nu_0, \lambda_0) &= R^*(\beta, \nu, \mu), \\ K^*(\beta, \nu, \mu) &\in \partial_\varepsilon f_1(a, v, u, \alpha', \theta') + \partial_\varepsilon f_2(a, v, u, \alpha', \theta'). \end{aligned}$$

This amounts to saying that for all $\varepsilon > 0$ there exist

$$(a, v, u) \in Z \times U \quad \text{and} \quad (\beta, \nu, \mu) \in \mathbb{R}^k \times \Theta^* \times \mathcal{H}^*$$

such that

$$\begin{cases} M(a, v, u) = R_I \gamma_0, \\ (\beta_0, \nu_0, \lambda_0) = R^*(\beta, \nu, \mu), \\ K^*(\beta, \nu, \mu) \in \partial_\varepsilon f_1(a, v, u, \alpha_0, \theta_0) + \partial_\varepsilon f_2(a, v, u, \alpha_0, \theta_0). \end{cases} \tag{3.25}$$

Our task now is to evaluate the adjoint operators K^* and R^* and the subdifferential mappings $\partial_\varepsilon f_1$ and $\partial_\varepsilon f_2$. For the sake of the exposition we divide this task into three steps.

Step 1 (computation of K^* and R^*). We start by pairing $Z = \mathbb{R}^n \times L_p^n$ with the space $Z^* = A_q^n$ by means of the bilinear form

$$\langle (a, v), w \rangle = a \cdot w(0) + \int_0^1 v(\tau) \cdot \dot{w}(\tau)\, d\tau, \qquad (a, v) \in Z,\ w \in Z^*.$$

The space $\mathcal{H} = \{h \in A_p^n : h(0) = 0\}$ is paired with $\mathcal{H}^* = L_q^n$ by means of

$$\langle h, \mu \rangle = \int_0^1 \dot{h}(\tau) \cdot \mu(\tau)\, d\tau, \qquad h \in \mathcal{H},\ \mu \in \mathcal{H}^*.$$

The spaces $U = L_p^d$ and $U^* = L_q^d$ are paired in the usual way, i.e.,

$$\langle u, \ell \rangle = \int_0^1 u(\tau) \cdot \ell(\tau)\, d\tau, \qquad u \in U,\ \ell \in U^*.$$

Similarly, the spaces $\Gamma = L_p^n$ and $\Gamma^* = L_q^n$ are paired by means of

$$\langle \gamma, \lambda \rangle = \int_0^1 \gamma(\tau) \cdot \lambda(\tau)\, d\tau, \qquad \gamma \in \Gamma,\ \lambda \in \Gamma^*.$$

With respect to these pairings, the linear operators K and R are continuous. Moreover, the adjoint operator K^* of K is given by

$$\begin{cases} K^* : \mathbb{R}^k \times \Theta^* \times \mathcal{H}^* \to Z^* \times U^* \times \mathbb{R}^k \times \Theta^*, \\ (\beta, \nu, \mu) \mapsto (w_\mu, \ell_\mu, \beta, \nu), \end{cases} \tag{3.26}$$

where

$$\begin{cases} w_\mu(0) = -\displaystyle\int_0^1 A^T(\tau)\mu(\tau)\, d\tau, \\ \dot{w}_\mu(t) = \mu(t) - \displaystyle\int_t^1 A^T(\tau)\mu(\tau)\, d\tau \quad \text{for a.e. } t \in [0, 1], \\ \ell_\mu(t) = -B^T(t)\mu(t) \quad \text{for a.e. } t \in [0, 1]. \end{cases} \tag{3.27}$$

The expression of the adjoint operator R^* of R is less involved. One has simply

$$\begin{aligned} R^* : \mathbb{R}^k \times \Theta^* \times \mathcal{H}^* &\to \mathbb{R}^k \times \Theta^* \times \Gamma^*, \\ (\beta, \nu, \mu) &\mapsto (\beta, \nu, R_I^* \mu), \end{aligned} \tag{3.28}$$

where $R_I^* : \mathcal{H}^* \to \Gamma^*$ is given by

$$[R_I^* \mu](t) = \mu(t) \quad \text{for a.e. } t \in [0,1]. \tag{3.29}$$

Step 2 (computation of $\partial_\varepsilon f_1$). Observe first that the convexity and the properness of the function f_1 are ensured by hypothesis (3.7). The function f_1 is just the composition $H \circ T$ of the endpoint cost function $H : \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^k \to \mathbb{R} \cup \{+\infty\}$ and the continuous linear operator

$$\begin{aligned} T : Z \times U \times \mathbb{R}^k \times \Theta &\to \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^k, \\ (a, v, u, \alpha, \theta) &\mapsto (a, a + Ev, \alpha). \end{aligned}$$

Since we are working under appropriate constraint qualification hypotheses (cf. [Ro1, Thm. 19b]), we can apply the general formula [Hi, Thm. 2.2]

$$\partial_\varepsilon (H \circ T)(a, v, u, \alpha_0, \theta_0) = T^* \partial_\varepsilon H(T(a, v, u, \alpha_0, \theta_0)).$$

A simple calculus shows that the adjoint operator T^* of T is given by

$$\begin{aligned} T^* : \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R}^k &\to Z^* \times U^* \times \mathbb{R}^k \times \Theta^*, \\ (c, e, \beta) &\mapsto \left(c + e + \int_0^{(\cdot)} \tilde{e}(\tau)\, d\tau, 0, \beta, 0 \right), \end{aligned}$$

where $\tilde{e} \in L_q^n$ is defined as

$$\tilde{e}(t) = e \quad \text{for a.e. } t \in [0,1].$$

One gets in this way

$$\partial_\varepsilon f_1(a, v, u, \alpha_0, \theta_0) = \left\{ \left(c + e + \int_0^{(\cdot)} \tilde{e}(\tau)\, d\tau, 0, \beta, 0 \right) : (c, e, \beta) \in \partial_\varepsilon H(a, a + Ev, \alpha_0) \right\}. \tag{3.30}$$

Step 3 (computation of $\partial_\varepsilon f_2$). Hypotheses (3.8) – (3.10) imply the convexity and properness of the function f_2. To evaluate the approximate subdifferential of f_2, we represent this function as the composition $I_L \circ P$ of the integral functional $I_L : L_q^n \times U \times \Theta \to \mathbb{R} \cup \{+\infty\}$ and the continuous linear operator

$$\begin{aligned} P : Z \times U \times \mathbb{R}^k \times \Theta &\to L_q^n \times U \times \Theta, \\ (a, v, u, \alpha, \theta) &\mapsto (G(a, v), u, \theta). \end{aligned}$$

In this case

$$\operatorname{Im} P = X \times U \times \Theta \subset L_q^n \times U \times \Theta.$$

Hypothesis (3.10) implies that there exists an element in the range of P at which the proper convex function I_L is continuous. Under this constraint qualification hypothesis, one can write [Hi, Thm. 2.2]

$$\partial_\varepsilon (I_L \circ P)(a, v, u, \alpha_0, \theta_0) = P^* \partial_\varepsilon I_L(P(a, v, u, \alpha_0, \theta_0)).$$

Here the adjoint operator $P^* : L_p^n \times U^* \times \Theta^* \to Z^* \times U^* \times \mathbb{R}^k \times \Theta^*$ takes the form

$$P^*(s, \ell, \nu) = (\delta_s, \ell, 0, \nu),$$

where $\delta_s \in Z^*$ is given by

$$\delta_s(0) = \int_0^1 s(\tau)\, d\tau, \qquad \dot{\delta}_s(t) = \int_t^1 s(\tau)\, d\tau \quad \text{for a.e. } t \in [0,1]. \tag{3.31}$$

Hence

$$\partial_\varepsilon f_2(a,v,u,\alpha_0,\theta_0) = \{(\delta_s,\ell,0,\nu) : (s,\ell,\nu) \in \partial_\varepsilon I_L(G(a,v),u,\theta_0)\}. \tag{3.32}$$

To compute the approximate subdifferential of the integral functional I_L, we invoke the decomposability principle stated in [Bu, Prop. 2.2.1]. We are working under hypotheses which allow us to apply this principle, and so we can write

(3.33)

$$(s,\ell,\nu) \in \partial_\varepsilon I_L(G(a,v),u,\theta_0) \Longleftrightarrow \begin{cases} \text{there exists } \sigma \in \Sigma(\varepsilon) \text{ such that} \\ (s(t),\ell(t),\nu(t)) \in \partial_{\sigma(t)} L(t, G(a,v)(t), u(t), \theta_0(t)) \\ \text{for a.e. } t \in [0,1]. \end{cases}$$

Step 3 is thus complete.

Before proceeding to join all the pieces together, we briefly check the hypotheses (2.7)–(2.9) in Lemma 2.3. First, observe that condition (2.7) holds if $\operatorname{Im} R_I = \{R_I\gamma : \gamma \in \Gamma\}$ is closed in $\mathcal{H}$ and $\operatorname{Im} R_I^* = \{R_I^*\mu : \mu \in \mathcal{H}^*\}$ is closed in Γ^*. But one can easily see that $\operatorname{Im} R_I$ is the whole space $\mathcal{H}$, and $\operatorname{Im} R_I^*$ is the whole space Γ^*. Second, condition (2.8) amounts to saying that $M^*([\operatorname{Im} R_I]^\perp)$ is a closed set in $Z^* \times U^*$. But since $\operatorname{Im} R_I$ is the whole space $\mathcal{H}$, the set $M^*([\operatorname{Im} R_I]^\perp)$ reduces to the origin in $Z^* \times U^*$. Finally, a word on condition (2.9). As mentioned in Remark 2.1, this condition holds, for instance, if f_2 is continuous at a point in which f_1 is finite. Of course, hypothesis (3.10) takes care of this constraint qualification requirement.

In short, we are allowed to apply Lemma 2.3. By combining (3.25), (3.26), (3.28), (3.30), and (3.32), we can assert that $(\beta_0,\nu_0,\lambda_0) \in \partial V(\alpha_0,\theta_0,\gamma_0)$ if and only if for all $\varepsilon > 0$ there exist

$$(a,v) \in Z, \quad u \in U, \quad \mu \in \mathcal{H}^*, \quad (c,e) \in \mathbb{R}^n \times \mathbb{R}^n, \quad s \in L_p^n$$

such that

$$\begin{cases} M(a,v,u) = R_I\gamma_0, \\ \lambda_0 = R_I^*\mu, \\ w_\mu = c + e + \displaystyle\int_0^{(\cdot)} \tilde{e}(\tau)\, d\tau + \delta_s, \\ (c,e,\beta_0) \in \partial_\varepsilon H(a, a+Ev, \alpha_0), \\ (s,\ell_\mu,\nu_0) \in \partial_\varepsilon I_L(G(a,v),u,\theta_0). \end{cases}$$

Now we write these conditions in full extent by incorporating the information given in (3.27), (3.29), (3.31), and (3.33). One can assert that $(\beta_0,\nu_0,\lambda_0) \in \partial V(\alpha_0,\theta_0,\gamma_0)$ if and only if for all $\varepsilon > 0$ there exist

$$(a,v) \in Z, \quad u \in U, \quad \mu \in \mathcal{H}^*, \quad (c,e) \in \mathbb{R}^n \times \mathbb{R}^n, \quad s \in L_p^n, \quad \sigma \in \Sigma(\varepsilon)$$

such that

$$M(a,v,u) = R_I\gamma_0, \tag{3.34}$$

$$\lambda_0(t) = \mu(t) \quad \text{for a.e. } t \in [0,1], \tag{3.35}$$

$$-\int_0^1 A^T(\tau)\,\mu(\tau)\,d\tau = c + e + \int_0^1 s(\tau)\,d\tau, \tag{3.36}$$

$$\mu(t) - \int_t^1 A^T(\tau)\mu(\tau)\,d\tau = e + \int_t^1 s(\tau)\,d\tau \quad \text{for a.e. } t \in [0,1], \tag{3.37}$$

$$(c, e, \beta_0) \in \partial_\varepsilon H(a, a + Ev, \alpha_0), \tag{3.38}$$

and

$$(s(t), -B^T(t)\mu(t), \nu_0(t)) \in \partial_{\sigma(t)} L(t, G(a,v)(t), u(t), \theta_0(t)) \quad \text{for a.e. } t \in [0,1]. \tag{3.39}$$

One obtains in this way a complete characterization of the subdifferential $\partial V(\alpha_0, \theta_0, \gamma_0)$. However, the above conditions are not easy to manipulate, and their meaning is somewhat obscure. These conditions can be stated in a simpler manner if one introduces a space of dual trajectories. To this end, it is convenient to inspect closely the following function:

$$t \in [0,1] \mapsto y(t) = c + \int_0^t [s(\tau) + A^T(\tau)\mu(\tau)]\,d\tau.$$

We regard y as a dual trajectory emanating from the point $y(0) = c$ and whose velocity $\dot{y}$ is given by

$$\dot{y}(t) = s(t) + A^T(t)\mu(t) \quad \text{for a.e. } t \in [0,1].$$

Observe that

$$\dot{y} \in \begin{cases} L_p^n & \text{if } p \in [1,2] \text{ or } A = 0, \\ L_q^n & \text{otherwise.} \end{cases}$$

Thus y belongs to the space Y introduced in (3.12). Now from (3.36) one gets

$$-\int_0^1 [s(\tau) + A^T(\tau)\mu(\tau)]\,d\tau = c + e, \tag{3.40}$$

and therefore $y(1) = -e$. By using (3.37) and (3.40), one obtains

$$\mu(t) = e - \left(c + e + \int_0^t [s(\tau) + A^T(\tau)\mu(\tau)]\,d\tau\right) \quad \text{for a.e. } t \in [0,1],$$

and thus

$$\mu(t) = -y(t) \quad \text{for a.e. } t \in [0,1].$$

In short, the elements $(c, e) \in \mathbb{R}^n \times \mathbb{R}^n$, $\mu \in \mathcal{H}^*$, and $s \in L_p^n$ are related to the dual trajectory $y \in Y$ in the manner described below:

$$\begin{cases} c = y(0), \quad e = -y(1), \\ \mu(t) = -y(t) \quad \text{for a.e. } t \in [0,1], \\ s(t) = \dot{y}(t) + A^T(t)y(t) \quad \text{for a.e. } t \in [0,1]. \end{cases} \tag{3.41}$$

Of course, the relation between $(a, v) \in Z$ and the primal trajectory $x \in X$ is simply

$$a = x(0), \quad v(t) = \dot{x}(t) \quad \text{for a.e. } t \in [0, 1]. \tag{3.42}$$

To complete the proof, it suffices to plug (3.41) and (3.42) into the conditions (3.34) – (3.35) and (3.38) – (3.39). □

The ε-transversality condition (3.20) and the ε-maximum principle (3.21) take various forms depending on the structure of the cost function H and the Lagrangian L, respectively. Let us illustrate this fact with the help of two important examples.

Example 3.1 (L does not depend on state variables). If the Lagrangian L is independent of the vector of state variables, then the ε-maximum principle (3.21) decomposes into the *dual-state equation*

$$\dot{y}(t) + A^T(t)y(t) = 0 \quad \text{for a.e. } t \in [0, 1] \tag{3.43}$$

plus the differential inclusion

$$(B^T(t)y(t), \nu_0(t)) \in \partial_{\sigma(t)} L(t, u(t), \theta_0(t)) \quad \text{for a.e. } t \in [0, 1]. \tag{3.44}$$

If L is also independent of external parameters, then (3.44) reduces further to

$$B^T(t)y(t) \in \partial_{\sigma(t)} L(t, u(t)) \quad \text{for a.e. } t \in [0, 1].$$

The above condition amounts to saying that, for almost every $t \in [0, 1]$, the control vector $u(t)$ solves the problem

$$\text{maximize } \{y(t) \cdot B(t)z - L(t, z) : z \in \mathbb{R}^d\} \tag{3.45}$$

within a tolerance $\sigma(t)$. The difference with respect to the classical maximum principle of Pontryagin is that $u(t)$ does not need to be an exact solution of (3.45).

Example 3.2 (a Mayer problem of optimal control). Suppose that the cost term to be minimized is simply $h(x(1))$; that is to say, it depends only on the final state $x(1)$. Consider also a perturbed and controlled system of the form

$$\begin{cases} \dot{x}(t) = A(t)x(t) + B(t)u(t) + \gamma(t) & \text{for a.e. } t \in [0, 1], \\ x(0) = 0. \end{cases}$$

As we have seen in the previous example, the ε-maximum principle (3.21) takes here the form

$$\begin{aligned} \dot{y}(t) + A^T(t)y(t) &= 0 \\ B^T(t)y(t) &= 0 \end{aligned} \qquad \text{for a.e. } t \in [0, 1].$$

In order to write the ε-transversality condition (3.20), one has to recognize first the form of the cost term H. In the present example one clearly has

$$H(x(0), x(1)) = \begin{cases} h(x(1)) & \text{if } x(0) = 0, \\ +\infty & \text{if } x(0) \neq 0. \end{cases}$$

Thus (3.20) reduces to

$$\begin{cases} -y(1) \in \partial_\varepsilon h(x(1)), \\ x(0) = 0, \quad y(0) \in \mathbb{R}^n \quad \text{(i.e., } y(0) \text{ is unconstrained)}. \end{cases}$$

To illustrate how Theorem 3.2 works in practice, consider the specific case of Example 1.2. Here (3.18) and (3.19) take, respectively, the forms

$$\dot{x}_1(t) = -2x_1(t) + 3x_2(t) + u(t), \quad \dot{x}_2(t) = x_2(t) \quad \text{for a.e. } t \in [0,1]$$

and

$$\lambda_1(t) = -y_1(t), \quad \lambda_2(t) = -y_2(t) \quad \text{for a.e. } t \in [0,1].$$

The ε-maximum principle (3.21) yields simply

$$\begin{aligned} &\dot{y}_1(t) = 2y_1(t) \\ &\dot{y}_2(t) = -3y_1(t) - y_2(t) \quad \text{for a.e. } t \in [0,1], \\ &y_1(t) = 0, \end{aligned}$$

and the ε-transversality condition (3.20) reads

$$\begin{cases} -(y_1(1), y_2(1)) \in \partial_\varepsilon h(x_1(1), x_2(1)), \\ x_1(0) = 0, \quad x_2(0) = 0, \end{cases} \tag{3.46}$$

where $h : \mathbb{R}^2 \to \mathbb{R}$ is given by

$$h(x_1(1), x_2(1)) = [\exp(x_1(1)) + x_2^2(1)]^{1/2}.$$

We can draw a lot of information from the above conditions. Writing $e = \exp(1)$, we get

$$x_2(t) = 0, \quad y_1(t) = 0, \quad y_2(t) = y_2(0)e^{-t} \quad \text{for all } t \in [0,1]$$

and

$$\lambda_1(t) = 0, \quad \lambda_2(t) = -y_2(0)e^{-t} \quad \text{for a.e. } t \in [0,1].$$

Plugging $y_1(1) = 0$, $y_2(1) = y_2(0)e^{-1}$, and $x_2(1) = 0$ into (3.46), one obtains

$$-(0, y_2(0)e^{-1}) \in \partial_\varepsilon h(x_1(1), 0). \tag{3.47}$$

Now we take into account the specific structure of h and write (3.47) in the more explicit form

$$\exp\left[\frac{1}{2}x_1(1)\right] \le \varepsilon, \qquad |y_2(0)| \le e.$$

Summarizing, $(\lambda_1, \lambda_2) \in \partial V(0,0)$ if and only if for all $\varepsilon > 0$ there exist $x_1 \in A_1[0,1], u \in L_1[0,1]$, and $c \in \mathbb{R}$ such that

$$\begin{aligned} &\dot{x}_1(t) = -2x_1(t) + u(t) \\ &\lambda_1(t) = 0 \qquad\qquad\qquad \text{for a.e. } t \in [0,1] \\ &\lambda_2(t) = ce^{-t} \end{aligned}$$

and

$$\exp\left[\frac{1}{2}x_1(1)\right] \le \varepsilon, \quad x_1(0) = 0, \quad c \in [-e, e].$$

This amounts to saying that

$$(\lambda_1, \lambda_2) \in \partial V(0,0) \Longleftrightarrow \begin{cases} \text{for some constant} \quad c \in [-e, e], \\ \lambda_1(t) = 0 \quad \text{and} \quad \lambda_2(t) = ce^{-t} \quad \text{for a.e. } t \in [0,1]. \end{cases}$$

In the present example, one can also compute $\partial V(0,0)$ by evaluating first the optimal-value function V. As a matter of computation one obtains

$$V(\gamma_1, \gamma_2) = e \left| \int_0^1 e^{-t} \gamma_2(t)\, dt \right|.$$

4. Extensions. In this section we explore the case in which the optimal control problem

$$\text{minimize } \{J(x, u, \alpha, \theta) : (x, u) \in F(\gamma)\}$$

involves explicit constraints on the control function $u \in U$. Such a case is important in applications and deserves further discussion. In what follows, U_{ad} denotes the set of "admissible" controls, i.e., those functions u in U such that

$$u(t) \in \Omega(t) \quad \text{for a.e. } t \in [0,1]. \tag{4.1}$$

The feasible set $F(\gamma)$ is understood as the set of all pairs $(x, u) \in X \times U_{ad}$ satisfying the state equation (1.2).

To remain within the realm of convex analysis, we suppose that

(4.2)
$\Omega : [0,1] \to \mathbb{R}^d$ is a measurable multifunction with nonempty closed convex values.

In principle, one can take care of the admissibility concern (4.1) by working with the modified Lagrangian

$$\tilde{L}(t, x, z, \theta) := L(t, x, z, \theta) + \psi_{\Omega(t)}(z), \tag{4.3}$$

where $\psi_{\Omega(t)}$ stands for the indicator function of the set $\Omega(t)$. In this case the ε-maximum principle (3.21) is stated in terms of the approximate subdifferential mapping $\partial_{\sigma(t)} \tilde{L}$. But since $\tilde{L}$ is only an auxiliary tool, we should express $\partial_{\sigma(t)} \tilde{L}$ in terms of L and Ω. By applying Kutateladze's rule (cf. [Hi, Thm. 2.1]) on the approximate subdifferential of the sum of two functions, one gets

$$\partial_{\sigma(t)} \tilde{L}(t, x, z, \theta) = \bigcup_{\substack{\varepsilon_1 \geq 0, \varepsilon_2 \geq 0 \\ \varepsilon_1 + \varepsilon_2 = \sigma(t)}} \{\partial_{\varepsilon_1} L(t, x, z, \theta) + \{0\} \times \partial_{\varepsilon_2} \psi_{\Omega(t)}(z) \times \{0\}\}. \tag{4.4}$$

Formula (4.4) not only requires an additional constraint qualification assumption but also leads to the formulation of an ε-maximum principle that is very cumbersome and of little practical interest. For this reason we prefer to avoid the use of Kutateladze's rule and return to the proof of Theorem 3.2. In the next result we keep the same assumptions as in Theorem 3.2, except that the constraint qualification condition (3.10) is replaced with

$$\begin{cases} \text{there exist } x \in X,\ u \in U_{ad},\ \alpha \in \mathbb{R}^k, \text{ and } \theta \in \Theta \text{ such that } H \text{ is continuous at} \\ (x(0), x(1), \alpha) \text{ and } I_L : L_q^n \times U \times \Theta \to \mathbb{R} \cup \{+\infty\} \text{ is continuous at } (x, u, \theta). \end{cases} \tag{4.5}$$

THEOREM 4.1. *With the assumptions* (3.6)–(3.9), (4.2), *and* (4.5), *let the optimal-value function* V *be finite at* $(\alpha_0, \theta_0, \gamma_0) \in \mathbb{R}^k \times \Theta \times \Gamma$. *Then* $(\beta_0, \nu_0, \lambda_0) \in \mathbb{R}^k \times \Theta^* \times \Gamma^*$ *is a subgradient of* V *at* $(\alpha_0, \theta_0, \gamma_0)$ *if and only if for all* $\varepsilon > 0$ *there exist a trajectory* $x \in X$, *a control* $u \in U$, *a function* $r \in U^*$, *a dual trajectory* $y \in Y$ *(necessarily unique), and functions* σ *and* δ *in* $\Sigma(\varepsilon)$ *such that the conditions* (3.18)–(3.20) *hold, together with the* ε*-maximum principle*

(4.6)
$$(\dot{y}(t) + A^T(t)y(t), B^T(t)y(t) - r(t), \nu_0(t)) \in \partial_{\sigma(t)} L(t, x(t), u(t), \theta_0(t)) \quad \textit{for a.e. } t \in [0,1]$$

and the ε*-normality condition*

(4.7)
$$r(t) \in \partial_{\delta(t)} \psi_{\Omega(t)}(u(t)) \quad \textit{for a.e. } t \in [0,1].$$

Proof. We follow the same steps as in the proof of Theorem 3.2, except that now we have the extra function

$$f_3(a, v, u, \alpha, \theta) := \int_0^1 \psi_{\Omega(t)}(u(t))\, \mathrm{dt} = F_\Omega(u).$$

One can modify Lemma 2.3 and write formula (2.6) with the extra term $\partial_\varepsilon f_3(z)$. Of course this requires an adjustment in the constraint qualification hypotheses (2.9). This explains why we have replaced the assumption (3.10) with (4.5).

But as a matter of computation one has

$$\partial_\varepsilon f_3(a, v, u, \alpha_0, \theta_0) = \{0\} \times \partial_\varepsilon F_\Omega(u) \times \{0\} \times \{0\},$$

with

$$\partial_\varepsilon F_\Omega(u) = \bigcup_{\delta \in \Sigma(\varepsilon)} \{r \in U^* : r(t) \in \partial_{\delta(t)} \psi_{\Omega(t)}(u(t)) \quad \text{for a.e. } t \in [0,1]\}.$$

The rest of the proof is now routine. □

Remark 4.1. The ε-normality condition (4.7) says that $u \in U$ is admissible in the sense of (4.1) and that for a.e. $t \in [0,1]$, the vector $r(t)$ is $\delta(t)$-normal to $\Omega(t)$ at $u(t)$, i.e.,

$$r(t) \cdot (z - u(t)) \leq \delta(t) \quad \text{for all } z \in \Omega(t).$$

Remark 4.2. An inclusion like (4.6) appears already in a paper by Rockafellar [Ro2, p. 217]. However, that inclusion does not involve parameters and is stated in terms of the exact subdifferential mapping ∂L.

5. Final remarks. This paper follows as close as possible the methodology used by the second author [Se1] in the context of a Bolza problem of calculus of variations. It is shown in [Se1] that if $V(\alpha, \theta)$ denotes the optimal-value of the Bolza problem (1.1), then a subgradient (β_0, ν_0) of V at (α_0, θ_0) is characterized in terms of the ε-transversality condition (3.20) and the approximate Euler–Lagrange inclusion

$$(\dot{y}(t), y(t), \nu_0(t)) \in \partial_{\sigma(t)} L(t, x(t), \dot{x}(t), \theta_0(t)) \quad \text{for a.e. } t \in [0,1].$$

In principle it is possible to write our optimal control problem as a Bolza problem of calculus of variations (see, for instance, [Ro2, §4] or [IT, Chap. 2]). This can be done by introducing a suitable Lagrangian $\tilde{L}$ that incorporates the dynamics of the system, that is to

say, the state equation (1.2). Although this approach seems quite natural, there are several reasons why we do not recommend it.

(a) First, it is of no interest to state the approximate Euler–Lagrange inclusion in terms of the modified Lagrangian $\tilde{L}$. One has of course to evaluate $\partial_{\sigma(t)}\tilde{L}$ in terms of the original Lagrangian L and of the data appearing in the state equation. This can be done only at a very heavy price. One encounters the same kind of difficulties as with the modified Lagrangian (4.3); in particular, one needs to introduce additional constraint qualification assumptions.

(b) Second, this approach leads to the formulation of an ε-maximum principle that is not as simple as the one established in Theorem 3.2.

(c) Third, one should keep in mind that writing the approximate Euler–Lagrange inclusion in terms of $\tilde{L}$ is just the starting point of an alternative proof. Most of the heavy work is left in the evaluation of $\partial_{\sigma(t)}\tilde{L}$. It is not without reason that the proof of Theorem 3.2 took us around five pages.

Finally, we would like to mention that our proof of Theorem 3.2 cannot be obtained from that of [Se1, Thm. 2] by minor modifications. Our proof contains several steps and results proper to the framework of an optimal control problem.

Appendix. The following result is probably known, but we have not been able to find it in the literature. It has to do with the subdifferential of a composite function like

$$\xi \in \Xi \mapsto (\Phi \circ R)(\xi) := \Phi(R\xi),$$

where

$$\text{(A)} \qquad \begin{cases} R : \Xi \to \Pi & \text{is a continuous linear operator,} \\ \Phi : \Pi \to \overline{\mathbb{R}} & \text{is a convex function.} \end{cases}$$

The spaces Ξ and Π are as in §2.

LEMMA A.1. *With assumption* (A), *let* $\Phi \circ R$ *be finite at the point* $\xi_0 \in \Xi$. *Then the subdifferential* $\partial(\Phi \circ R)(\xi_0)$ *is contained in the closure of* $\operatorname{Im} R^*$.

Proof. Take $\eta \in \partial(\Phi \circ R)(\xi_0)$, and suppose that η does not belong to the closure of

$$\operatorname{Im} R^* = \{R^*\varphi : \varphi \in \Pi^*\}.$$

By a separation argument, there exists $\tilde{\xi} \in \Xi$ such that

$$\langle \tilde{\xi}, \eta \rangle > \langle \tilde{\xi}, R^*\varphi \rangle \quad \text{for all } \varphi \in \Pi^*.$$

Thus, $R\tilde{\xi} = 0$ and $\langle \tilde{\xi}, \eta \rangle > 0$. Since η is supposed to be in $\partial(\Phi \circ R)(\xi_0)$, one can write

$$\Phi(R\xi) \geq \Phi(R\xi_0) + \langle \xi - \xi_0, \eta \rangle \quad \text{for all } \eta \in \Xi.$$

Setting $\xi = \xi_0 + t\tilde{\xi}$ $(t > 0)$, one gets

$$\Phi(R\xi_0) \geq \Phi(R\xi_0) + t\langle \tilde{\xi}, \eta \rangle,$$

that is to say, $\langle \tilde{\xi}, \eta \rangle \leq 0$. This is clearly a contradiction. □

The above lemma provides only very rough information on the subdifferential $\partial(\Phi \circ R)(\xi_0)$. However, it does not require any constraint qualification hypothesis.

Acknowledgment. The original title of this paper was "Approximate Pontryagin's principle and perturbation analysis of convex optimal control problems." As kindly pointed out by one of the referees, the name "approximate Pontryagin's principle" has been already used, although in a different context (see, e.g., the works of B. Mordukhovich [M1, M2, M3]). Following the recommendation of the referees, we have added §§4 and 5. We are grateful to them for their criticism and remarks.

SOLAR CARS AND VARIATIONAL PROBLEMS EQUIVALENT TO SHORTEST PATHS*

D. J. GATES† AND M. WESTCOTT†

Abstract. A classical theorem of Hardy, Littlewood, and Pólya on rearrangements of functions is used to prove the equivalence of a class of variational problems. As a consequence, solutions are shortest paths and can be computed numerically via quadratic programming. Applications include solar cars and reservoirs.

Key words. optimization, solar-powered car, storage, quadratic program, rearrangements of functions, convex envelopes, variational problem

AMS subject classifications. 49J05, 49J40, 49K05, 49N10

1. Introduction.

During our study of driving strategy for the 1993 Darwin-to-Adelaide solar-powered car race, we encountered variational problems of the following form: minimize

$$\Gamma(F) = \int_0^1 \phi[F'(t)]dt \tag{1}$$

with respect to F, subject to

$$A(t) \le F(t) \le B(t), \tag{2}$$

$$F(0) = F_0, \qquad F(1) = F_1, \tag{3}$$

where ϕ is a convex function, F' is the derivative of F (assumed to exist almost everywhere), $A(t)$ and $B(t)$ are given functions on $[0,1]$, and F_0 and F_1 are given constants satisfying $A(0) \le F_0 \le B(0)$, $A(1) \le F_1 \le B(1)$. There are many applications of this problem.

Example 1. One wishes to travel by the shortest two-dimensional path $(t, F(t))$ starting from $(0, F_0)$ and reaching destination $(1, F_1)$ while remaining between boundaries defined by $(t, A(t))$ and $(t, B(t))$. These boundaries might be the banks of a river, if travelling by boat, or the edges of a track or road or gully, if travelling by land. In this case

$$\phi(f) = (1 + f^2)^{1/2}$$

and $\Gamma(F)$ is the length of path F. Of course, one knows intuitively the solution to this problem (Figure 1).

Example 2. Replace the traveller in Example 1 by a piece of string, and pull the string tight. This problem is mathematically identical to Example 1, and one understands intuitively why the solutions are the same.

Example 3. A solar-powered car has a battery of capacity K which stores electrical energy perfectly efficiently. The speed of the car is $v[g(t)]$, where $g(t)$ is the power delivered to the motor at time t, so

$$\int_0^1 v[g(t)]dt \tag{4}$$

* Received by the editors December 15, 1993; accepted for publication (in revised form) October 17, 1994.

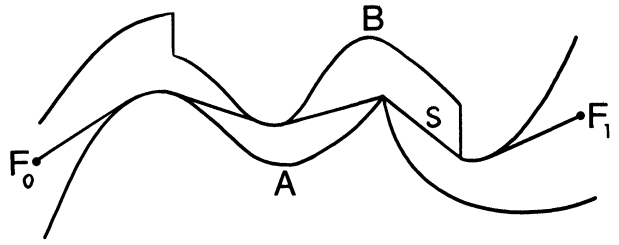

FIG. 1.

is the distance travelled in time interval $[0, 1]$. Here, v is an increasing, *concave* function, a typical example being

$$v(g) = cg^{1/3}$$

for constant c, this implying that the car faces a resistive force proportional to the square of the speed. Then maximizing the distance travelled is equivalent to minimizing Γ with $\phi = -v$.

The constraints arise from the battery capacity. Let $P(t)$ be the power generated by the solar panel, assumed known. Then the energy content of the battery at time t is

$$E(t) = E(0) + \int_0^t [P(s) - g(s) - h(s)]\, ds, \tag{5}$$

where $h(s)$ is the power *overflow*, i.e., the power which is available at the panel but is rejected because the battery is full and the motor is not drawing enough power to use this energy. Then the constraints are

$$0 \le E(t) \le K. \tag{6}$$

Because $h(s)$ depends on $P(s)$ and $g(s)$, the constraints are not of the form (2). But putting

$$f(t) \equiv g(t) + h(t) \ge g(t) \tag{7}$$

implies that

$$\int_0^1 v[f(t)]dt \ge \int_0^1 v[g(t)]dt; \tag{8}$$

i.e., it is always better to divert the overflow through the motor. Then (6) reduces to (2) with $F(t) = \int_0^t f(s)ds$ and

$$\begin{aligned} B(t) &= E(0) + \int_0^t P(s)ds, \\ A(t) &= B(t) - K, \end{aligned} \tag{9}$$

while $F_0 = 0$ and

$$F_1 = E(0) - E(1) + \int_0^1 P(t)dt. \tag{10}$$

Thus the variational problem is of the form (1) to (3).

Example 4. Water flow from a reservoir of capacity K (litres, say) drives a generator and produces power output $\Pi[g(t)]$, where $g(t)$ is the flow rate (litres per second, say) of water through the turbine at time t. Due to decreased efficiency of the system at higher flow rates, $\Pi(g)$ is concave, although it is increasing. Then

$$\int_0^1 \Pi[g(t)]dt \tag{11}$$

is the total energy generated during $[0, 1]$. Putting $\phi = -\Pi$ and minimizing Γ amount to maximizing the energy output of the system.

Now let $P(t)$ be the rate of input (litres per second) to the reservoir (from runoff and direct rainfall). If $E(t)$ is the water content of the reservoir and $h(t)$ is the overflow rate, then we again have equations (5) to (10) and a variational problem of the form (1) to (3).

Example 5. A commodity, such as salt, is supplied to a stockpile of fixed capacity and sold at a time-varying, irregular but known rate (on arrival of ships) at a fixed price per ton. The total cost is the supply to the stockpile, and this cost is an increasing, convex function of the supply rate. (Higher supply rates are increasingly costly due to overtime pay and the like.) What is the optimal supply rate? The mathematical formulation follows previous examples and is left to the reader.

Example 6. Suppose an unknown distribution function $F(t)$ satisfies conditions (2) and (3) with $F_0 = 0$ and $F_1 = 1$. These might arise from a model or perhaps from confidence intervals constructed from data. Then the maximum entropy (information) $F(t)$ is the solution of the variational problem with

$$\phi(f) = f \log f.$$

For a related problem, see [6, §3a.6].

Example 7. Make the path in Example 1 as straight as possible in the sense that

$$\int_0^1 [F'(t)]^2 dt$$

is minimized, or equivalently

$$\int_0^1 [F'(t) - \bar{F}'(t)]^2 dt$$

is minimized, where

$$\bar{F}(t) = F_0 + (F_1 - F_0)t.$$

Thus one is making the direction as uniform as possible or the route as direct as possible by penalizing large deviations from the direct route.

The main result of this paper is that the solutions to all these problems are independent of ϕ, provided that it is convex. Consequently the shortest path (Example 1) solves all of them.

For the solar car, this means that, in the sense of Example 7, the power consumption of the motor should be as uniform as possible over time. Similarly, the power generation in the hydroelectric example should be as uniform as possible, the supply

to the stockpile should be as uniform as possible, and the probability distribution in Example 6 should be as uniform as possible.

Another useful consequence follows from Example 7; since the problem with

$$\phi(f) = f^2$$

has the common solution, all such problems can be solved by quadratic programming, for which very fast algorithms exist. This fact is exploited in our computer program SOLARMAX, which was used by the Aurora Q1 solar-car team to study optimal driving strategies for the 1993 Darwin-to-Adelaide solar-powered car race.

Problems resembling Example 1 have, of course, a long history and were the motivating force behind the early development of the calculus of variations. For example, the problems of Jakob Bernoulli and Fermat take the following form: minimize

$$\int_0^1 \phi[F'(t)]\psi[F(t), t]dt$$

subject to fixed $F(0)$ and $F(1)$. Evidently, our problem is broadly of this type if we take

$$\psi(F, t) = \begin{cases} 1 & \text{if } A(t) \leq F \leq B(t) \\ \infty & \text{if not.} \end{cases}$$

However, our task is not to find explicit solutions but to prove the equality of solutions of a class of problems. Here lies the crux of our problem: to prove that a class of functionals have their minima at the same point without explicitly knowing that point.

2. Preliminary results.

DEFINITION. *A function C is called* piecewise hollow *(PWH) if there is a finite set of points $0 < t_1 < \cdots < t_n < 1$ such that C is differentiable and either convex or concave in (t_{i-1}, t_i) $(i = 1, \ldots, n)$. We call these* intervals of hollowness.

Note that PWH functions are continuous, except perhaps at $t_1, \ldots, t_n$, and have one-sided limits everywhere [3, §3.18].

Assumptions. 1. A, B are PWH.

2. $F \in \mathcal{F}$, the class of absolutely continuous functions on $[0, 1]$.

We use the notation $f \equiv F'$ for $F \in \mathcal{F}$, which exists almost everywhere (a.e.).

The conditions on A and B are appropriate for our applications and simplify the proofs somewhat. We now proceed to prove the main result in the absence of one or other of the bounds A, B and then use these special cases to establish the main theorem.

DEFINITION. *The* convex envelope *of a function C, denoted $C_\cup$, is the* maximal *convex function not exceeding C. (Equivalently $C_\cup$ is the envelope of convex functions not exceeding C).*

The definition is not vacuous because the set of convex functions $\leq C$ obviously has a supremum which is unique. Its convexity is easily proved directly [4, p. 103].

DEFINITION. *The* concave envelope *of C, denoted by $C_\cap$, is the* minimal *concave function not exceeded by C.*

DEFINITION. *Let C stand for either A or B. Then C^* is given by*

$$\begin{aligned} C^*(t) &= C(t) \quad \text{if } 0 < t < 1, \\ C^*(0) &= F_0, \\ C^*(1) &= F_1. \end{aligned} \tag{12}$$

By $A^*_\cap$ we mean $(A^*)_\cap$, not $(A_\cap)^*$. Note that $A^* \le F \le B^*$ and $A^*_\cap(0) = B^*_\cup(0) = F_0$, $A^*_\cap(1) = B^*_\cup(1) = F_1$. Further, $A^*_\cap, B^*_\cup \in \mathcal{F}$ since they are concave/convex [3, p. 130].

DEFINITION. *For any function $g(t)$, its* (decreasing) rearrangement *is*

$$\bar{g}(t) \equiv \sup\{y \ : \ m(y) > t\},$$

where $m(y)$ is the measure of the set

$$\{t \ : \ g(t) > y\}.$$

The notion of rearrangement is discussed in [3, §10.12] and [5, p. 15].

THEOREM 1. *If A is PWH and $B \equiv \infty$,*

$$\inf_{F \in \mathcal{F}} \Gamma(F) = \Gamma(A^*_\cap) \tag{13}$$

for any convex ϕ. If ϕ is strictly convex, $A^*_\cap$ is the unique minimum.

Proof. For notational simplicity, write $Q(t) \equiv A^*_\cap(t)$. Form the rearrangements of f, for any $F \in \mathcal{F}$, and of Q'; both derivatives exist a.e. Then, using [3, eq. (10.12.2)], and $F \in \mathcal{F}$,

$$G_1(t) \equiv F_0 + \int_0^t \bar{f}(s)ds \ge F_0 + \int_0^t f(s)ds = F(t). \tag{14}$$

Obviously $G_1(0) = F_0$, while $G_1(1) = F(1) = F_1$ by a basic property of rearrangements [3, p. 277]. Since $\bar{f}$ is decreasing, $G_1(t)$ is concave, with $G_1 \ge A^*$ by (14), whence $G_1 \ge Q$. Because Q' is decreasing, $\overline{Q'} = Q'$, so

$$Q(t) = F_0 + \int_0^t Q'(s)ds = F_0 + \int_0^t \overline{Q'}(s)ds \tag{15}$$

since $Q \in \mathcal{F}$. From (14) and (15),

$$\int_0^t \bar{f}(s)ds \ge \int_0^t \overline{Q'}(s)ds \quad \text{for} \quad 0 \le t < 1,$$

$$\int_0^1 \bar{f}(s)ds = \int_0^1 \overline{Q'}(s)ds. \tag{16}$$

So by a classical theorem of Hardy, Littlewood and Pólya [2] (see also [5, p. 15]),

$$\int_0^1 \phi[Q'(t)]dt \le \int_0^1 \phi[f(t)]dt \tag{17}$$

for any $F \in \mathcal{F}$ and any convex ϕ. Since $Q \in \mathcal{F}$, (14) follows.

To prove uniqueness, suppose $F \in \mathcal{F}$ is any other function with $A \le F$. Then clearly the convex combination $F_\theta \equiv \theta F + (1-\theta)Q$, $0 < \theta < 1$, is also in $\mathcal{F}$ and $A \le F_\theta$. Now Γ is a *strictly* convex functional if ϕ is strictly convex, so $\Gamma(F_\theta) < \theta\Gamma(F) + (1-\theta)\Gamma(Q)$ and hence $\Gamma(F_\theta) - \Gamma(Q) < \theta\{\Gamma(F) - \Gamma(Q)\}$. But the left side is ≥ 0, since Q is a minimum, and $\theta > 0$, so $\Gamma(F) > \Gamma(Q)$. Since F is arbitrary, uniqueness follows and the theorem is proved.

THEOREM 2. *If B is PWH and $A \equiv -\infty$,*

$$\inf_{F \in \mathcal{F}} \Gamma(F) = \Gamma(B^*_{\cup}) \tag{18}$$

for any convex ϕ. If ϕ is strictly convex, $B^*_{\cup}$ is the unique minimum.

Proof. Let $R(t) \equiv B^*_{\cup}(t) \in \mathcal{F}$. Then, as before, for any $F \in \mathcal{F}$,

$$G_2(t) \equiv \int_0^t \overline{(-f')}(s)ds - F_0 \geq -F(t), \tag{19}$$

$G_2(0) = -F_0$, $G_2(1) = -F_1$, $G_2(t)$ is concave, and $G_2 \geq -B^*$. Hence $G_2 \geq -R$, since the convex envelope of B^* is the concave envelope of $-B^*$. So we again get

$$\int_0^1 \phi[-R'(t)]dt \leq \int_0^1 \phi[-f(t)]dt \tag{20}$$

for any $F \in \mathcal{F}$ and any convex ϕ. Since $\phi(-x)$ is convex if $\phi(x)$ is convex, and $R \in \mathcal{F}$, (20) proves (18). Uniqueness follows as above.

3. The main results. To prove our main theorem, we need to suitably characterize the shortest path $S(t)$, which, as mentioned in the introduction, turns out to give the minimum of Γ. We call it the "string function," since it is the mathematical equivalent of a piece of string fixed at $P_0 \equiv (0, F_0)$, threaded through the "tube" between A and B, and pulled tight at $P_1 \equiv (1, F_1)$ (cf. Example 2).

DEFINITION. *$S(t)$ is the unique solution to the variational problem when $\phi(f) = (1 + f^2)^{1/2}$.*

Clearly, $S(t)$ is the shortest path between P_0 and P_1 lying between the curves A and B, because $\mathcal{L}(F) \equiv \int_0^1 [1 + f^2(t)]^{1/2} dt$ is the length of $F \in \mathcal{F}$. Note that any $F \in \mathcal{F}$ has a length.

It is evident from Theorems 1 and 2 that the minimizing envelope functions $A^*_{\cap}, B^*_{\cup}$ are the (unique) shortest paths between P_0 and P_1 above A and below B, respectively. For $A^*_{\cap}$ minimizes $\Gamma(F)$ for $F \geq A$ and *any* convex ϕ, hence for $\Gamma = \mathcal{L}$.

We must first establish that the definition is not vacuous in general. The *existence* of *a* solution to the shortest path problem is intuitively obvious but requires a little effort to prove formally. Initially we work with the wider class of functions of bounded variation, which also have lengths.

LEMMA 1. *Suppose $F \in \mathcal{B}$, the class of functions of bounded variation on $[0, 1]$ which satisfy* (2) *and* (3), *with the length $L(F)$ of F defined as the total variation of F over $[0, 1]$* [1, §7.3]. *Then there is an $F_\star \in \mathcal{B}$ which minimizes L.*

Proof. Let K be the closure of the subset of the plane lying between A and B. It is clear that there is at least one path of finite length between P_0 and P_1 lying in K; call its length λ. Now define

$$\mathcal{C} = \{F : F \in \mathcal{B}, L(F) \leq \lambda\}.$$

The graph of F, $(t, F(t))$ for $t \in [0, 1]$, is in K.

By the Hilbert compactness theorem [1, Thm. 7.10] $\mathcal{C}$ is sequentially compact, while L is lower semicontinuous [1, Thm. 7.6]. The lemma now follows from [1, Thm. 7.1].

Remark. Theorems 1 and 2 also hold in this wider context. (Use the inscribed polygons whose limits give the variational length L.)

If in fact $F_\star \in \mathcal{F}$, then we can take $S = F_\star$, because then $L = \mathcal{L}$ [1, Thm. 9.7]. For general PWH A and B this is not true (see §4). We now prove $F_\star \in \mathcal{F}$ for suitable A and B.

DEFINITION. *$A \prec B$, for PWH A, B, means that $A(t+0) < B(t-0)$ for all $t \in (0,1)$.*

The next lemma establishes the required properties of $F_\star$, which, although intuitively obvious, need to be deduced from its definition.

LEMMA 2. *Suppose A, B are PWH and $A \prec B$. Then*

(a) *There is a* finite *partition of $[0,1]$ into intervals I_j such that, throughout any I_j, either $F_\star = A$ or $F_\star = B$, or $A < F_\star < B$.*

(b) *If $F_\star = A$ ($F_\star = B$) throughout I_j, $F_\star$ is concave (convex) throughout I_j.*

(c) *If $A < F_\star < B$ throughout I_j, $F_\star$ is a straight line thoughout I_j.*

Proof. Define $T_A \equiv \{t : F_\star(t) = A^*(t)\}$. Any $t' \in T_A$ either is one of the finite number of points of nondifferentiability of A^* or belongs to one of the finite number of intervals of hollowness of A^* by properties of PWH functions. If $t', t'' \in T_A$ are in the *same* interval of hollowness, then

(i) A is concave in this interval;

(ii) $[t', t''] \subset T_A$.

If $t' \in T_A$ is interior to an interval of convexity of A, we can modify $F_\star$ into the straight line between two points on opposite sides of t', keeping above A (by convexity) and below B, thereby producing a shorter path, contrary to the definition of $F_\star$. So (i) holds, while (ii) follows obviously from the above remark. We conclude that T_A consists of a finite number of isolated points (which are degenerate intervals) and a finite number of disjoint intervals each a subinterval of an interval of concavity of A.

Next define $T_B \equiv \{t : F_\star(t) = B^*(t)\}$. Since $A \prec B$, $T_A \cap T_B = \{0,1\}$. Similar reasoning shows that T_B consists of a finite number of isolated points and a finite number of disjoint intervals, each a subinterval of an interval of convexity of B.

The set $T \equiv [0,1] - T_A - T_B$, where $A < F_\star < B$, is made up of a finite number of disjoint intervals (which may have end points in common). Since $F_\star$ is effectively unconstrained over each of these intervals, it must be a straight line. This proves (a)–(c) and hence the lemma.

It is clear that a function with the properties deduced in Lemma 2 is in $\mathcal{F}$. So $F_\star$ is *a* solution to the variational problem; its uniqueness follows easily since ϕ is strictly convex here. Hence we may now write $S = F_\star$.

THEOREM 3. *If A, B are PWH and $A \prec B$,*

$$\inf_{F \in \mathcal{F}} \Gamma(F) = \Gamma(S) \tag{21}$$

for any convex ϕ. If ϕ is strictly convex, S is the unique minimum.

Proof (see Figure 2). Consider the partition $\{I_j\}$ in the preceding lemma for S, and combine adjacent I's if necessary to produce a new partition $\{J_j\}$ with the following properties. Over J_1, $S \neq$ one boundary—say, B—without loss of generality, and $S = A$ at each end of J_1. Over J_2, $A < S < B$, so S is a straight line. Over J_3, $S \neq A$ and $S = B$ at each end of J_3. Over J_4, $A < S < B$, and so on.

Now choose any other $F \in \mathcal{F}$. At the right-hand end of J_1, $F \geq A = S$, while at the left end of J_3, $F \leq B = S$. So since F and S are continuous over J_2, there is at least one point in J_2—t_2, say—where $S = F$. Then over the interval $[0, t_2]$ we have a one-boundary problem like that of Theorem 1, because we have ensured that both F

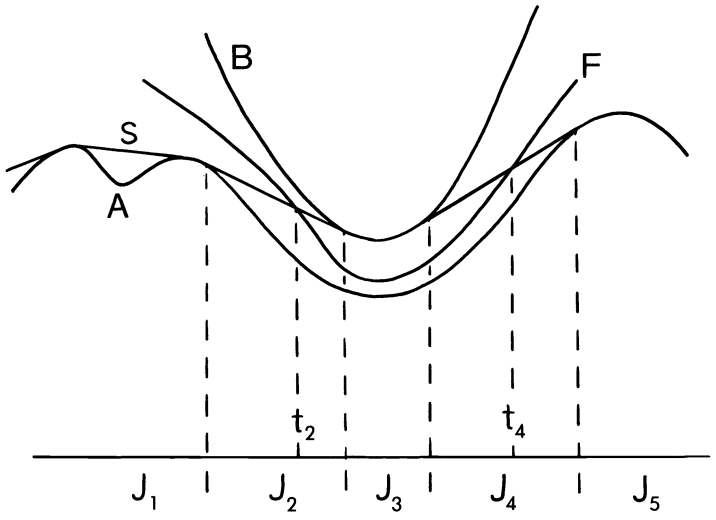

FIG. 2.

and S have the same end points. By Theorem 1, then,

$$\int_0^{t_2} \phi[F'(s)]ds \geq \int_0^{t_2} \phi[S'(s)]ds \tag{22}$$

for any convex ϕ, since we have already deduced that $S = A^*_\cap$ over this interval.

Similarly, there will be a t_4 in J_4 where $S = F$, and then we have a one-boundary problem like that of Theorem 2 over $[t_2, t_4]$. So

$$\int_{t_2}^{t_4} \phi[F'(s)]ds \geq \int_{t_2}^{t_4} \phi[S'(s)]ds. \tag{23}$$

We can continue to produce a finite number of such intervals $[t_{2n}, t_{2n+2}]$ over which a result like (23) holds, finishing with an interval $[t_{2n}, 1]$. Combining (22) and all those other inequalities proves (21), since F is arbitrary. The proof of uniquness follows that in Theorem 1.

The following functions provide alternative characterizations of S, more analogous to $A^*_\cap$ and $B^*_\cup$.

DEFINITION. *$V(t)$ is the* minimal *function that satisfies $A^* \leq V \leq B^*$ on $[0,1]$ and is* concave *on any interval where it is not equal to B^*.*

DEFINITION. *$U(t)$ is the* maximal *function that satisfies $A^* \leq U \leq B^*$ on $[0,1]$ and is* convex *on any interval where it is not equal to A^*.*

THEOREM 4. *Suppose A, B are PWH and $A \prec B$. Then $S = V = U$.*

Proof. From Lemma 2, S is concave when it is not equal to B^*, and clearly $A^* \leq S \leq B^*$. So $V \leq S$. Now it is an easy deduction from Theorem 1 that $S = A^*_\cap$ over the intervals $J_1, J_5, \ldots$ defined in the proof of Theorem 3, so $S = V$ over these intervals. Again it follows from Lemma 2 that S is convex over the interval $J_2 \cup J_3 \cup J_4$ while $V(\leq S)$ is concave unless it is equal to B. But we have just shown that $S = V$ at each end of this interval, so $S = V$ throughout. Hence $S = V$ on $[0,1]$. The proof that $S = U$ is similar.

4. Extensions. An extension which sometimes proves useful is the relaxation of the condition $A \prec B$. Without this condition, $F_\star \in \mathcal{F}$ may not hold, as is clear from inspection of Figure 3. However, we can proceed as follows.

Suppose that we allow $A = B$ over a finite number of intervals (which can degenerate into points) or require only that $A(t-0) \leq B(t-0)$ and $A(t+0) \leq B(t+0)$ at jump points. These restrictions mean that if A, B have a jump-point in common the jumps can partially overlap or even be exactly equal (cf. Figure 3). In this case the

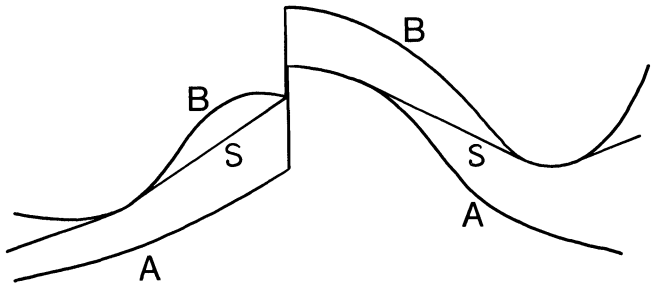

FIG. 3.

string function $S(t)$ is still formally the unique solution, provided that we recognize that it may be completely constrained at points where $A = B$ or where jumps overlap. A proof proceeds by breaking up the problem into a finite number of problems where these constraints operate only at the ends of intervals as before. For example, if $A \equiv B$ over $[a, b] \subset [0, 1]$ but nowhere else, we get the solution as $S(t)$ between P_0 and $(a, A(a))$ and between $(b, A(b))$ and P_1, and $A(t)$ over $[a, b]$, provided that A and B have the necessary properties outside $[a, b]$.

Acknowledgments. We are grateful to colleagues at Aurora Q1 Vehicles, the University of South Australia, and CSIRO for helpful discussions and to Aurora Q1 Vehicles for financial support. We thank the referees and an associate editor for constructive comments.

A DYNAMICAL SYSTEM APPROACH TO STOCHASTIC APPROXIMATIONS*

MICHEL BENAIM†

Abstract. It is known that some problems of almost sure convergence for stochastic approximation processes can be analyzed via an ordinary differential equation (ODE) obtained by suitable averaging. The goal of this paper is to show that the asymptotic behavior of such a process can be related to the asymptotic behavior of the ODE without any particular assumption concerning the dynamics of this ODE. The main results are as follows: a) The limit sets of trajectory solutions to the stochastic approximation recursion are, under classical assumptions, almost surely nonempty compact connected sets invariant under the flow of the ODE and contained in its set of chain-recurrence. b) If the gain parameter goes to zero at a suitable rate depending on the *expansion rate* of the ODE, any trajectory solution to the recursion is almost surely asymptotic to a forward trajectory solution to the ODE.

Key words. stochastic approximations, ordinary differential equations, chain-recurrence, neural networks

AMS subject classifications. 62L20, 34D05, 34C29

Introduction. The classical theory of stochastic approximations, born with the papers of Robbins and Monro (1951) and Kiefer and Wolfowitz (1952), concerns the study of stochastic algorithms whose general form can be written as

$$w_{n+1} - w_n = \gamma_n H(w_n, \xi_n), \tag{1}$$

where $H : \mathbf{R}^m \times \mathbf{R}^d \mapsto \mathbf{R}^m$ is a measurable function that characterizes the algorithm, $\{w_n\}_{n\geq 0} \in \mathbf{R}^m$ is the sequence of parameters to be recursively updated, $\{\xi_n\}_{n\geq 0} \in \mathbf{R}^d$ is a sequence of random inputs where $H(w_n, \xi_n)$ is observable, and $\{\gamma_n\}_{n\geq 0}$ is a sequence of "small" nonnegative scalar gains.

At each time step, the vector ξ_n is a new observation that causes w_n to be updated to take new information into account. The gain sequence $\{\gamma_n\}_{n\geq 0}$ can be chosen to be constant or decreasing. In this paper we restrict attention to algorithms with *decreasing gain sequence.* More precisely, we shall always assume that $\{\gamma_n\}_{n\geq 0}$ is a decreasing sequence of positive numbers which satisfies the classical relations

$$\lim_{n\to\infty} \gamma_n = 0$$

and

$$\sum_{n\geq 0} \gamma_n = +\infty.$$

To analyze the asymptotic behavior of the algorithm (1) it is convenient to introduce the averaged ordinary differential equation (ODE)

$$\frac{dw}{dt} = \overline{H}(w), \tag{2}$$

where

$$\overline{H}(w) = \lim_{n\to\infty} E(H(w, \xi_n))$$

and $E(.)$ denotes the mathematical expectation.

This method, called the *method of ordinary differential equation*, was introduced by Ljung (1977) and Kushner and Clark (1978) and widely studied thereafter. It has inspired a number of important works, such as the book by Kushner and Clark (1978), numerous articles by Kushner, and, more recently, the book by Benveniste, Métivier, and Priouret (1990). The main idea of the method is to describe the asymptotic behavior of the algorithm in terms of the behavior of the ODE. For stochastic algorithms having a decreasing gain sequence, the classical result stating the relationship between the algorithm (1) and the ODE (2) has the following form:

> *Let $w*$ be a stable equilibrium for the ODE. If $\{\gamma_n\}_{n\geq 0}$ goes to zero at a suitable rate and if the sequence $\{w_n\}_{n\geq 0}$ enters infinitely often a compact subset of the domain of attraction of $w*$, then $\{w_n\}_{n\geq 0}$ converges almost surely toward w^*.*

This kind of result has been obtained by Ljung (1977); Kushner and Clark (1978); Métivier and Priouret (1984, 1987); Benveniste, Métivier, and Priouret (1990); and Kuan and White (1992), among others, under fairly general conditions. It relies the asymptotic behavior of the algorithm with a strong notion of recurrence for the ODE: the notion of *fixed point.*

With increasing interest in *artificial neural networks* and due to some limitations of the standard *backpropagation* algorithm, "heuristic" learning rules for feedforward neural networks have been recently proposed and experimentally studied. The ODE associated with these algorithms is not given by a gradient vectorfield (as is the case for backpropagation), and the classical convergence results on stochastic gradient algorithms cannot be successfully applied. The consideration of these algorithms led us to formulate the following problem:

> *Without any particular assumption on the dynamics of $\overline{H}$, is it again possible to describe the asymptotic behavior of* (1) *in terms of the asymptotic behavior of* (2)*?*

The main goal of this paper is to address this question.

In §§1 and 2 we relate the behavior of the algorithm to a weak notion of recurrence for the ODE: the notion of *chain recurrence.* We state a theorem which asserts that under the assumptions of the Kushner and Clark lemma (1978) the limit sets of the trajectory solutions to (1) are nonempty compact connected sets invariant under the flow of the ODE and contained in its set of chain-recurrence.

This result shows that the limit sets of (1) look like the omega limit sets of (2), and we ask the question of their exact relationship. We address this question in §5. It is shown that it may happen that the limit set of a trajectory solution to (1) never coincides with an omega limit set of (2), but that it always does if the gain parameter goes to zero at a suitable rate depending on the vectorfield $\overline{H}$. Our approach, in this section, is essentially based on "shadowing" results recently proved by Morris W. Hirsch together with L^q estimates of the distance between the trajectory solutions to (1) and (2).

In §8 we apply the results of §§1–5 to prove some convergence theorems for the neural network learning algorithms mentioned above.

Main theorems are proved in §§4 and 7. Several applications are considered in §§3 and 6.

1. A deterministic theorem. In order to introduce the main result of this section we begin with a few notations and classical definitions from dynamical systems.

Notation and definitions. Let Γ be a topological space and $\Phi : \mathbf{R} \times \Gamma \mapsto \Gamma$ be a continous map denoted by $\Phi(t, x) = \Phi_t(x)$. The family $\{\Phi_t\}_{t \in \mathbf{R}}$ is called a *flow* on Γ if it satisfies the group property

$$\Phi_0 = \text{Identity},$$

$$\forall (t, s) \in \mathbf{R}^2,\ \Phi_t \circ \Phi_s = \Phi_{t+s}.$$

Let $\overline{H}$ denote a continous vectorfield defined on $\mathbf{R}^m$ with unique integral curves. The *flow* of $\overline{H}$ is the family of mappings defined on $\Gamma = \mathbf{R}^m$ by

$$\frac{d}{dt}\Phi_t(w) = \overline{H}(\Phi_t(w)).$$

A set X is said to be *invariant* (respectively, *positively invariant*) under the flow Φ if for all $t \in \mathbf{R}, \Phi_t(X) \subset X$ (respectively, for all $t \geq 0$). In this case we let $\Phi|X$ denote the restricted flow (respectively, semiflow).

A point x is an *equilibrium* if $\Phi_t(x) = x$ for all $t \in \mathbf{R}$. When Φ is induced by the vectorfield $\overline{H}$, equilibria coincide with zeros of $\overline{H}$. A point x is a *periodic point* if there exists $T > 0$ such that $\Phi_T(x) = x$. Equilibria and periodic points are clearly recurrent points. In general, we may say that a point is recurrent if it somehow returns near where it was under time evolution.

A notion of recurrence related to slightly perturbed orbits is the notion of *chain recurrence*. Suppose Γ is a metric space with a metric d. Let $\delta > 0$ and $T > 0$. A point x is said to be (δ, T) *recurrent* if there exist an integer k, some points y_i in Γ, and numbers $t_i, 0 \leq i \leq k-1$, such that

$$t_i \geq T; \quad d(y_0, x) < \delta; \quad d(\Phi_{t_i}(y_i),\ y_{i+1}) < \delta \quad \text{for } i = 0, \ldots, k-1; \quad x = y_k.$$

Intuitively (δ, T) recurrent points are points that one would take to be periodic if the position of points were only known with a finite accuracy δ. If x is (δ, T) recurrent for any $\delta > 0$ and $T > 0$, x is said to be *chain-recurrent*. We denote by $CR(\Phi)$ the set of chain-recurrent points. If Φ is induced by the vectorfield $\overline{H}$, we may also use the notation $CR(\overline{H})$ for $CR(\Phi)$. The set $CR(\Phi)$ has the property to be closed and invariant.

A subset $X \subset \Gamma$ is said *internally chain-recurrent* if X is a nonempty compact invariant set of which every point is chain-recurrent for the restricted flow $\Phi|X$ (i.e., $CR(\Phi|X) = X$).

For example, if Γ is compact, Conley (1978) proved that $CR(\Phi)$ is internally chain-recurrent.

The sets which describe the asymptotic behavior of the orbits of the flow Φ are the *omega limit sets*. The omega limit set of $w \in \Gamma$, denoted by $\omega(w)$, is the set of $x \in \Gamma$ such that $\lim_{k \to \infty} \Phi_{t_k}(w) = x$ for some sequence $t_k > 0$ with $\lim_{k \to \infty} t_k = +\infty$. If the forward trajectory $\{\Phi_t(w); t \geq 0\}$ has compact closure, $\omega(w)$ is a nonempty compact connected set internally chain-recurrent. The alpha limit set $\alpha(w)$ of w is defined as the omega limit set of w for the reversed flow $\{\Phi_{-t}\}_{t \geq 0}$.

To recapitulate, if we note $Per(\Phi)$ the set of periodic points (including the equilibria) and $\mathcal{L}^+(\Phi) = \bigcup_{w \in \Gamma} \omega(w)$, the following inclusions hold:

$$Per(\Phi) \subset \mathcal{L}^+(\Phi) \subset CR(\Phi).$$

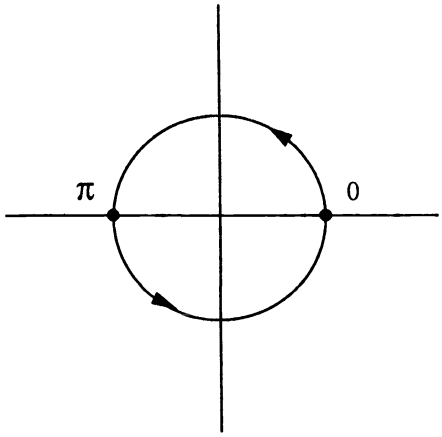

FIG. 1.

EXAMPLE 1.1. *Consider the flow on the unit circle* $S^1 = \mathbf{R}/2\pi\mathbf{Z}$ *induced by the differential equation*

$$\frac{d\theta}{dt} = f(\theta),$$

where f *is a* 2π*-periodic smooth nonnegative function such that*

$$f^{-1}(0) = \{k\pi : k \in \mathbf{Z}\}.$$

See Fig. 1.
We have

$$Per(\Phi) = \{0, \pi\} = \mathcal{L}^+(\Phi)$$

and

$$CR(\Phi) = S^1.$$

Internally chain-recurrent sets are $\{0\}, \{\pi\}$, *and* S^1. *Note that the set* $X = [0, \pi]$ *is a compact invariant set consisting of chain-recurrent points. However,* X *is not internally chain-recurrent.*

A deterministic theorem. To describe the asymptotic behavior of the algorithm (1) we introduce the limit set of the sequence $\{w_n\}_{n\geq 0}$. We denote this limit set by $L(\{w_n\}_{n\geq 0})$. It is the set of $x \in \mathbf{R}^m$ such that $\lim_{k\to\infty} w_{n_k} = x$ for some subsequence $\{n_k\}_{k\geq 0}$ with $\lim_{k\to\infty} n_k = +\infty$.

The following theorem is a deterministic result that will be applied in §2 to show that the limit sets of the trajectories solutions to the algorithm (1) have basically the same properties as the omega limit sets of the trajectories solution to the ODE (2). The assumptions A1, A2, and A3 of this theorem are the assumptions of the Kushner and Clark lemma (1978).

We use the following notation:

$$\tau_0 = 0,$$

$$\tau_n = \sum_{i=0}^{n-1} \gamma_i.$$

We let $\|.\|$ denote a norm on $\mathbf{R}^m$.

THEOREM 1.2. *Let $\overline{H} : \mathbf{R}^m \mapsto \mathbf{R}^m$ be a continuous vectorfield with unique integral curves. Let $\{w_n\}_{n\geq 0}$ be solution to the recursion*

$$w_{n+1} - w_n = \gamma_n(\overline{H}(w_n) + u_n + b_n), \tag{3}$$

where $\{\gamma_n\}_{n\geq 0}$ is a decreasing gain sequence. Assume that

- A1) *$\{w_n\}_{n\geq 0}$ is bounded.*
- A2) *$\lim_{n\to\infty} b_n = 0$.*
- A3) *For each $T > 0$,*

$$\lim_{n\to\infty} \left(\sup_{\{k\,;\,0\leq \tau_k - \tau_n \leq T\}} \left\| \sum_{i=n}^{k-1} \gamma_i . u_i \right\| \right) = 0.$$

Then $L(\{w_n\}_{n\geq 0})$ is a connected set internally chain-recurrent for the flow Φ induced by $\overline{H}$.

The next theorem shows that Theorem 1.2 gives the best result that can be expected under the Kushner and Clark assumptions. It justifies the fact that the chain recurrence is a notion well suited to the description of the asymptotic behavior of (1).

Assume given a locally Lipschitz vectorfield $\overline{H} : \mathbf{R}^m \mapsto \mathbf{R}^m$ and a decreasing gain sequence $\{\gamma_n\}_{n\geq 0}$.

THEOREM 1.3. *Let $L \subset \mathbf{R}^m$ be a connected set internally chain-recurrent for the flow induced by $\overline{H}$. There exist sequences $\{b_n\}_{n\geq 0}$, $\{u_n\}_{n\geq 0}$, and $\{w_n\}_{n\geq 0}$ such that*

(a) *Conditions* A1, A2, *and* A3 *of Theorem* 1.2 *are satisfied.*

(b) *The sequence $\{w_n\}_{n\geq 0}$ is the solution to* (3) *and admits L as a limit set.*

Theorem 1.3 follows easily from the following proposition (see Benaim and Hirsch (1995b)).

PROPOSITION 1.4. *Let $L \subset \mathbf{R}^m$ be a connected set internally chain-recurrent for the flow induced by $\overline{H}$. There exists a continuous function $u : \mathbf{R}_+ \mapsto \mathbf{R}^m$ and a point $w_0 \in \mathbf{R}^m$ such that*

(a) *$\lim_{t\to\infty} u(t) = 0$.*

(b) *The solution to the nonautonomous system*

$$\frac{dw}{dt} = \overline{H}(w) + u(t)$$

with initial condition $w(0) = w_0$ is bounded and admits L as a limit set.

To prove Theorem 1.3 we let $w_n = w(\tau_n)$ and $u_n = u(\tau_n)$, where $w(.)$ and $u(.)$ are the functions of Proposition 1.4. Then we have

$$w_{n+1} - w_n = \gamma_n(\overline{H}(w_n) + u_n) + O(\gamma_n^2)$$

and Theorem 1.3 follows from Proposition 1.4.

REMARK 1.5. *Throughout this paper the process $\{w_n\}_{n\geq 0}$ will be assumed to be bounded. Several conditions ensuring that this assumption is fulfilled are discussed in the literature on stochastic approximations. They usually rely on the existence of*

some convergent supermartingale for the process (1) (*see, e.g., Theorem* 5.2, *chapter* 2, *of Nevel'son and Has'minskii* (1974) *or Theorem* 8 *of Fort and Pagès* (1994)).

In the spirit of this section, we give a simple condition which is purely deterministic.

PROPOSITION 1.6. *Assume that* $\overline{H}$ *is globally Lipschitz. Assume the existence of a function* $V : \mathbf{R}^m \to \mathbf{R}_+$ *uniformly continuous such that*

(i) $\lim_{||x||\to\infty} V(x) = \infty$.

(ii) *There exist positive numbers* δ, r, *and* T *such that*

$$\forall x \in \mathbf{R}^m,\ ||x|| \geq r \Longrightarrow V(\Phi_T(x)) - V(x) \leq -\delta.$$

Then conditions A2 *and* A3 *of Theorem* 1.2 *imply condition* A1.

The proof of this result follows easily from Lemma 4.4 and is left to the reader.

Note that if V is smooth, condition (ii) holds if the following more easily checked condition is satisfied: there exists $\delta' > 0$ such that for all $||x|| \geq r$

$$\langle \nabla V(x), \overline{H}(x) \rangle \leq -\delta',$$

where ∇ denotes the gradient.

2. Limit sets of stochastic approximation processes. In this section, we assume that $\{\xi_n\}_{n\geq 0}$ is a sequence of $\mathbf{R}^d$-valued random variables defined on a probability space $(\Omega, \mathcal{F}, \mathcal{P})$. We note $\mathcal{F}_n^m$, the σ field generated by $\{\xi_i;\ n \leq i \leq m\}$ for $m \geq n$. For $q \in [1, \infty]$ we let $\|.\|_q$ denote the $L^q(\Omega)$ norm for random variables ($\|X\|_q = E(\|X\|^q)^{1/q}$) and $\|.\|_\infty$ the $L^\infty(\Omega)$ norm ($\|X\|_\infty = \operatorname{ess\,sup}\|X\|$).

In applications of Theorem 1.2 to the stochastic approximation (1) one may choose

$$\overline{H}(w) = \lim_{n\to\infty} E(H(w, \xi_n)),$$

$$u_n = H(w_n, \xi_n) - \int H(w_n, \xi)\mu_n(d\xi),$$

and

$$b_n = \int H(w_n, \xi)\mu_n(d\xi) - \overline{H}(w_n),$$

where μ_n is the distribution of ξ_n. Then we try to verify assumptions A2 and A3 by use of some regularity properties of H and maximal inequalities for sum of random variables. Let us mention two examples.

Independent inputs. The first example is a classical Robbins–Monro algorithm in which the observations are assumed to be independent and identically distributed. This yields a simple martingale access to condition A3 as in Gladyshev (1965) and Hall and Heyde (1980).

We let M denote a given subset of $\mathbf{R}^m$ (not necessarily compact).

PROPOSITION 2.1. *Let* $\{w_n\}_{n\geq 0}$ *be the solution to* (1). *Assume that*

- A1) $\{\xi_n\}_{n\geq 0}$ *is a sequence of independent and identically distributed random variables.*
- A2) $P(\{w_n\}_{n\geq 0}$ *is bounded*$) = 1$ *and* $P(\forall n \in N, w_n \in M) = 1$.
- A3) $w \mapsto \overline{H}(w) = E(H(w, \xi_0))$ *is continuous with a unique flow.*

There exists $q \geq 2$ *such that*

- A4) $w \mapsto \|H(w,\xi_0)\|_q$ *is bounded on* M.
- A5) $\sum_{n=0}^{\infty} \gamma_n^{1+q/2} < +\infty$.

Then the conclusions of Theorem 1.2 *hold with probability one.*

Proof. To see that, we let $b_n = 0$ and $u_n = H(w_n,\xi_n) - \overline{H}(w_n)$. Then $E(u_n/\mathcal{F}_0^{n-1}) = 0$. For $q = 2$, assumptions A4 and A5 imply $\sum_n \gamma_n^2 . \|u_n\|_2^2 < +\infty$, and condition A3 of Theorem 1.2 is a direct consequence of the L^2-bounded martingale convergence theorem. For $q > 2$, it follows from a result of Métivier and Priouret (1987, Cor. 11). (See also Benveniste, Métivier, and Priouret (1990, Cor. 8, p. 297).) Note that in this case the sequence $\{\sum_n \gamma_n . u_n\}_{n\geq 0}$ is not necessarily convergent. □

Mixing inputs. The following example extends this result to situations in which the observable inputs are nonindependent and nonstationary random variables which satisfy a strong mixing condition. Such situations arise naturally in some applications of feedforward neural networks as forecasting, prediction of time series, or chaos modelling.

Here our approach is motivated by the work of Kuan and White (1992), who have proved some convergence results for stochastic approximation procedures by using the theory of *mixingales* developed by McLeish (1975). Conditions A1–A6 can be compared with conditions of Kuan and White's theorems (Thm. 2.2.1 and Cors. 2.2.3 and 2.3.5). The condition A6′ gives a generalization which allows a gain parameter of the order of $\frac{1}{n^\alpha}$ with $\alpha < 1$. The price for this is a strengthening of the boundness condition.

For $n \geq 0, m \geq 0$ define

$$\phi_{n,m} = \sup_{\{A\in\mathcal{F}_0^n, B\in\mathcal{F}_{n+m}^{n+m}\}} | P(B/A) - P(B) |,$$

$$\alpha_{n,m} = \sup_{\{A\in\mathcal{F}_0^n, B\in\mathcal{F}_{n+m}^{n+m}\}} | P(B\cap A) - P(B)P(A) |,$$

$$\phi_m = \sup_{n\geq 0} \phi_{n,m},$$

$$\alpha_m = \sup_{n\geq 0} \alpha_{n,m}.$$

We shall say that the process $\{\xi_n\}_{n\geq 0}$ is ϕ mixing (respectively, α mixing) if $\lim_{n\to\infty} \phi_n = 0$ (respectively, $\lim_{n\to\infty} \alpha_n = 0$). Observe, however, that this condition is a weakening of the classical ϕ mixing (respectively, α mixing) definition (see, for instance, Billingsley (1968, §20, p. 166)). It would be the same if $\mathcal{F}_{n+m}^{n+m}$ were replaced by $\mathcal{F}_{n+m}^{+\infty}$. This weaker definition is motivated by our use of McLeish's results (1975).

PROPOSITION 2.2. *Let* $\{w_n\}_{n\geq 0}$ *be the solution to* (1). *Assume that*

- A1) $\{\xi_n\}_{n\geq 0}$ *is a* ϕ *mixing (respectively,* α *mixing) process.*
- A2) $\{w_n\}_{n\geq 0}$ *is bounded with probability one.*
- A3) $\overline{H}(w) = \lim_{n\to\infty} E(H(w,\xi_n))$ *exists.*
- A4) *There exists a measurable function* $k(.)$ *such that*

$$\forall x, y \in \mathbf{R}^m \|H(x,\xi) - H(y,\xi)\| \leq k(\xi)\|x - y\|.$$

There exists $r \in [2,\infty]$ *such that*

- A5) *The map* $w \mapsto \sup_{n\geq 0} \|H(w,\xi_n)\|_r$ *is bounded on any bounded set and* $\sup_{n\geq 0} \|k(\xi_n)\|_r < +\infty$.
- A6) *(L^r case). If* $r < \infty$, $\phi_n = O(\frac{1}{n^\beta})$ *for some* $\beta > \frac{r}{2r-2}$ *(respectively,* $\alpha_n = O(\frac{1}{n^\beta})$ *for some* $\beta > \frac{r}{r-2}$*) and*

$$\sum_{n=0}^{\infty} \gamma_n^2 < +\infty.$$

- A6′) *(L^∞ case). If* $r = \infty$, $\phi_n = O(\frac{1}{n^\beta})$ *for some* $\beta > \frac{1}{2}$ *(respectively,* $\alpha_n = O(\frac{1}{n^\beta})$ *for some* $\beta > 1$*) and*

$$\sum_{n=0}^{\infty} \gamma_n^{1+q/2} < +\infty$$

for some $q \in [2, 2\beta + 1[$.

Then the conclusions of Theorem 1.2 *hold with probability one.*

The proof of this result is given in the appendix (§9).

In view of the fact that the assumptions of Theorem 1.2 are the assumptions of the Kushner and Clark lemma, several other examples of application can be found in the literature. We refer the reader to the book by Kushner and Clark (1978, Chap. II) for such examples. In the case where the input process $\{\xi_n\}_{n\geq 0}$ is a Markov process or, more generally, a Markov process controlled by the parameter w, condition A3 of Theorem 1.2 can be derived from the analysis provided in the articles by Ljung (1977) and Métivier and Priouret (1987, Cor. 11) (see also Benveniste, Métivier, and Priouret (1990, Cor. 8, p. 297)).

3. Applications. In this section we give a few examples to illustrate how results of §§1 and 2 can be used to describe the global asymptotic behavior of stochastic approximation processes.

In the remainder of this section $\overline{H}$ is a vectorfield on $\mathbf{R}^m$ with unique integral curves. The sequence $\{w_n\}_{n\geq 0}$ denotes either a deterministic sequence solution to (3) under assumptions of Theorem 1.2 or a random sequence solution to (1) under assumptions of Proposition 2.1 or 2.2. In this last case, all the properties stated below have to be understood as "almost sure" properties.

Local behavior. First, note that Theorem 1.2 generalizes the classical result mentioned in the introduction.

An equilibrium w^* of $\overline{H}$ is said *asymptotically stable* if there exists an open neighborhood U of w^* such that

$$\lim_{t\to\infty} \Phi_t(w) = w^*$$

uniformly in $w \in U$. The *domain of attraction* of w^* is the set of all points whose forward trajectories are attracted by w^*.

PROPOSITION 3.1. *Let* w^* *be an asymptotically stable equilibrium of* $\overline{H}$. *Assume that* $\{w_n\}_{n\geq 0}$ *enters infinitely often a compact subset—say,* Q*—of the domain of attraction of* w^*. *Then*

$$\lim_{n\to\infty} w_n = w^*.$$

Proof. According to Theorem 1.2, $L(\{w_n\}_{n\geq 0}) \cap Q$ is nonempty and is contained in $CR(\overline{H}) \cap Q$. On the other hand, it is not difficult[1] to show that $CR(\overline{H}) \cap Q = \{w^*\}$. Thus $\{w^*\} = L(\{w_n\}_{n\geq 0}) \cap Q$ and, as $L(\{w_n\}_{n\geq 0})$ is connected, $L(\{w_n\}_{n\geq 0}) = \{w^*\}$. □

Gradientlike systems. Let Φ be a flow on a metric space Γ and $\Lambda \subset \Gamma$ be an invariant set.

A C^0 map $V : \Gamma \mapsto \mathbf{R}$ is said to be a *Lyapunov function* for Λ if for all $x \in \Gamma$ the function $t \in \mathbf{R}_+ \mapsto V(\Phi_t(x))$ is constant for $x \in \Lambda$ and strictly decreasing for $x \notin \Lambda$.

If Λ equals the equilibria set, V is called a *strict Lyapunov function* and Φ is called a *gradientlike system.*

PROPOSITION 3.2. *Assume that Γ is compact. Let $\Lambda \subset \Gamma$ be a compact invariant set and $V : \Gamma \mapsto \mathbf{R}$ a Lyapounov function for Λ. Assume that the cardinal of $V(\Lambda)$ is finite. Then*

$$CR(\Phi) \subset \Lambda.$$

COROLLARY 3.3. *Assume that $\overline{H}$ admits a strict Lyapunov function and isolated equilibria. Then $\{w_n\}_{n\geq 0}$ converges toward an equilibrium.*

Proof. We apply Proposition 3.2 to the flow induced by $\overline{H}$ on $\Gamma = L(\{w_n\}_{n\geq 0})$. It follows from Theorem 1.2 that $L(\{w_n\}_{n\geq 0})$ consists of equilibria. As it is a connected set and equilibria are isolated, $L(\{w_n\}_{n\geq 0})$ is an equilibrium. □

REMARK 3.4. *Note that Corollary 3.3 applies to stochastic gradient algorithms for which $\overline{H}$ is the gradient of a cost function $C : \mathbf{R}^m \mapsto \mathbf{R}$,*

$$\overline{H}(w) = \nabla C(w).$$

In §8 we will give another application of Proposition 3.2 to a class of learning processes which are not given by a stochastic gradient.

Proof of Proposition 3.2. Let $V(\Lambda) = \{v_1, \ldots, v_l\}, v_1 < v_2 < \cdots < v_l$. Choose real numbers $v_1', v_2', \ldots, v_l'$ such that $v_1 < v_1' < v_2 < \cdots < v_{l-1}' < v_l < v_l'$, and define $M_i = \{x \in \Gamma / V(x) \leq v_i'\}$.

Let $\Lambda_i = \Lambda \cap V^{-1}(v_i)$; Λ_i is the largest invariant set contained in $M_i - M_{i-1}$. Indeed, let $A \subset M_i - M_{i-1}$ be an invariant set and let $x \in A$. By a standard theorem on Lyapunov functions, $\alpha(x) \cup \omega(x) \subset \Lambda$. So $V(\alpha(x)) = V(\omega(x)) = v_i$, and as V is strictly decreasing along any trajectory outside Λ, x is necessarily in Λ_i.

Let $T > 0$. By compactness of the sets M_j, there exists $\epsilon > 0$ such that

$$\forall x \in M_j, V(\Phi_T(x)) \leq v_j' - \epsilon.$$

Pick $\delta > 0$ such that

$$\forall (x, y) \in \Gamma \times \Gamma, d(x, y) \leq \delta \Rightarrow | V(x) - V(y) | \leq \epsilon.$$

It follows that any (δ, T) chain $\{y_0, y_1, \ldots, y_k\}$ (i.e., $d(\Phi_{t_i}(y_i), y_{i+1}) < \delta$ for some $t_i \geq T$) with $y_0 \in M_j$ is included in M_j. Therefore, the set $CR_j = CR(\Phi) \cap (M_j - M_{j-1})$ is invariant. Hence, $CR_j \subset \Lambda_j$ and $CR(\Phi) \subset \Lambda$. □

[1] This follows, for example, from Proposition 3.10.

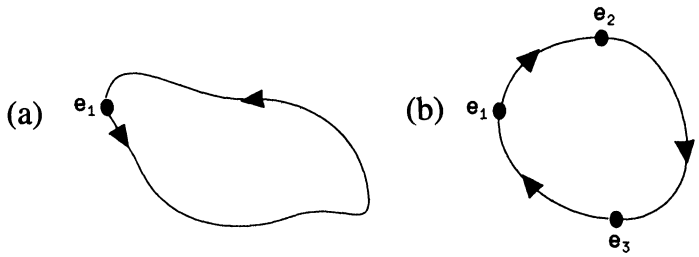

FIG. 2. (a) *A one-equilibrium cycle.* (b) *A three-equilibrium cycle.*

No-cycle systems. Let Φ be a flow on a metric space Γ. We say that Φ has *simple dynamics* if for every $x \in \Gamma$ the alpha and omega limit sets of x are equilibria. This means that every backward and forward trajectory converges toward an equilibrium. If Φ is induced by the vectorfield $\overline{H}$, we say that $\overline{H}$ has simple dynamics if $\Phi|L$ has simple dynamics for each compact invariant set $L \subset \mathbf{R}^m$.

For a flow with simple dynamics, we say that the equilibrium e_1 goes to the equilibrium e_2 if there exists a nonequilibrium orbit $\gamma \subset \Gamma$ such that $\alpha(\gamma) = e_1$ and $\omega(\gamma) = e_2$. γ is called a *connecting* orbit. To indicate that e_1 goes to e_2, we write $e_1 \rightsquigarrow e_2$. To indicate that γ is the connecting orbit from e_1 to e_2, we write $\gamma : e_1 \rightsquigarrow e_2$.

A *cycle of equilibria* is an union

$$A = \bigcup_{j=1}^{n} (\{e_j\} \cup \gamma_j)$$

consisting of equilibria e_j, $j = 1, \ldots, n$, and connecting orbits γ_j, $j = 1, \ldots, n$, such that

(i) $\gamma_j : e_j \rightsquigarrow e_{j+1}$, $j = 1, \ldots, n-1$.

(ii) $\gamma_n : e_n \rightsquigarrow e_1$.

REMARK 3.5. *A cycle of equilibria is connected internally chain-recurrent (Fig. 2).*

PROPOSITION 3.6. *Assume that Γ is compact and Φ has a finite number of equilibria, simple dynamics, and no cycle. Then $CR(\Phi)$ is the equilibria set.*

COROLLARY 3.7. *Assume that $\overline{H}$ has isolated equilibria, simple dynamics, and no cycle. Then $\{w_n\}_{n\geq 0}$ converges toward an equilibrium.*

Proof. We apply Proposition 3.6 to the flow induced by $\overline{H}$ on $\Gamma = L(\{w_n\}_{n\geq 0})$ and conclude exactly as in the proof of Corollary 3.3. □

Fort and Pagès (1994) recently proved a result similar to Corollary 3.7 by using the Kushner and Clark lemma. Systems with cycle of equilibria will be considered in §6.

The notion of *simple dynamics* and *no-cycle property* can be extended to nonconvergent situations. Denote by $\mathcal{L}(\Phi)$ the union of all alpha and omega limit sets of Φ. Assume that there exist nonempty compact disjoint invariant subsets $\Lambda_j \subset \Gamma$, $j = 1, \ldots, n$, such that

$$\mathcal{L}(\Phi) \subset \Lambda = \bigcup_{j=1}^{n} \Lambda_j.$$

If there exists $x \notin \Lambda$ such that $\alpha(x) \subset \Lambda_1$ and $\omega(x) \subset \Lambda_2$, we write $\Lambda_1 \rightsquigarrow \Lambda_2$ and define cycles among the Λ_j exactly as in the simple dynamics case.

PROPOSITION 3.8. *Assume* Γ *is compact and there is no cycle among the* Λ_j. *Then* $CR(\Phi) \subset \Lambda$.

Proof. Let $\hat{\Gamma}$ be the topological quotient space obtained by collapsing each Λ_i to a point. It is not difficult to check that $\hat{\Gamma}$ is a regular space with a countable basis. Therefore, by the Urysohn theorem, $\hat{\Gamma}$ is metrizable. Let π denotes the quotient map $\pi : \Gamma \to \hat{\Gamma}$. The flow Φ induces a flow $\hat{\Phi}$ on $\hat{\Gamma}$ defined by $\hat{\Phi} \circ \pi = \pi \circ \Phi$, which has simple dynamics, no cycle, and the Λ_j as equilibria. Therefore, by Proposition 3.6, chain-recurrent points of $\hat{\Phi}$ are equilibria. If $x \in \Gamma$ is chain-recurrent for Φ it is clear, by definition of chain-recurrence and uniform continuity of π, that $\pi(x)$ is chain-recurrent for $\hat{\Phi}$. Thus $CR(\Phi) \subset \Lambda$. □

COROLLARY 3.9. *Assume there exist nonempty compact disjoint subsets* $\Lambda_j \subset \mathbf{R}^m$, $j = 1, \ldots, n$, *invariant under the flow of* $\overline{H}$ *such that every alpha or omega limit point belongs to* $\Lambda = \bigcup_{j=1}^n \Lambda_i$. *Assume there is no cycle among the* Λ_j. *Then there exists* $j \in \{1, \ldots, n\}$ *such that* $L(\{w_n\}_{n \geq 0}) \subset \Lambda_j$.

Proof of Proposition 3.6. There are several ways to prove Proposition 3.6. For example it can be easily deduced from the "filtration theory" exposed in Shub (1986). Here, for simplicity we decided to deduce it from elementary properties of chain-recurrent sets. On the other hand these properties are very useful and give a good understanding of the notion of chain-recurrence.

Let $Y \subset \Gamma$. The forward trajectory of Y is the set $Y \cdot [0, \infty) = \Phi([0, \infty) \times Y) = \{\Phi_t(y);\ t \geq 0;\ y \in Y\}$.

The omega limit set (respectively, alpha limit set) of Y, denoted by $\omega(Y)$ (respectively, $\alpha(Y)$) is defined as the maximal invariant set in $\text{clos}(Y \cdot [0, \infty))$ (respectively, $\text{clos}(Y \cdot (-\infty, 0])$), where "clos" denotes closure.

A nonempty compact invariant set $A \subset X$ is an *attractor* if A has an open neighborhood U in X such that $\omega(U) = A$ or a *repeller* if $\alpha(U) = A$. An attractor or repeller is *proper* provided that it is not open in X.

The following proposition follows from §§5 and 6 of Conley (1978, Chap. 2).

PROPOSITION 3.10 (Conley (1978)).

(a) *Let* $N \subset \Gamma$ *be a compact set. Let* $A \subset \Gamma$ *be the maximal invariant set contained in* N. *If* A *is nonempty and* not *an attractor, there exists* $p \in \partial N \subset \Gamma$ *such that the backward orbit* $\gamma_-(p) \subset N$ *and* $\alpha(p)$ *is a nonempty subset of* A.

(b) *A internally chain-recurrent set has no proper attractor or repeller.*

(c) *The chain-recurrent set is internally chain-recurrent.*

Let us now prove Proposition 3.6. Let X be a connected component of $CR(\Phi)$. By assertion (c) of Proposition 3.10, X is internally chain-recurrent. Consider the flow $\Psi = \Phi | X$ and let $Equ(\Psi) = \{e_i,\ i = 1, \ldots, n\}$ denote the equilibria set of Ψ. Since Φ has simple dynamics and no cycle the relation $\rightsquigarrow$ induces a partial ordering on $Equ(\Psi)$.

Assume e_n is minimal for this partial ordering. We claim that e_n is an attractor for Ψ. It follows from assertion (b) of Proposition 3.10 that e_n is open and closed in X. Thus $X = \{e_n\}$.

It remains to prove that e_n is an attractor for Ψ. Let N be a compact neighborhood of e_n which separates e_n from other equilibria. The maximal invariant set in N is e_n; otherwise it would exist a entire orbit disjoint from e_n inside N. The dynamics being simple, this orbit would have to connect e_n to itself. Since we assume that there is no cycle, this is impossible.

Now we use assertion (a) of Proposition 3.10. If e_n is not an attractor, there

exists $p \in \partial N$ with $\alpha(p) = e_n$, but this contradicts the fact that e_n is minimal for the partial ordering $\rightsquigarrow$. □

Morse–Smale systems. In this subsection we mention briefly an application of the previous results to a class of stochastic approximation processes and urn models which have been recently considered by Benaim and Hirsch (1995a). For more details the reader is referred to that paper.

Assume $\overline{H}$ is C^r $(r \geq 1)$. $\overline{H}$ is called *Morse–Smale* if

(i) $\overline{H}$ has a global compact attractor (i.e., the point at infinity is a source);

(ii) all periodic orbits and equilibria are hyperbolic;

(iii) stable and unstable manifolds of periodic orbits (and equilibria) intersect only transversely;

(iv) every alpha or omega limit set is a periodic orbit or an equilibrium.

It is known that these conditions imply that there are only finitely many periodic orbits.

Suppose $\overline{H}$ is a Morse–Smale vector field. Denote by $\mathcal{L}(\overline{H})$ the union of all alpha and omega limit sets of $\overline{H}$, and by $Per(\overline{H})$ the union of all periodic orbits and equilibria. If $\overline{H}$ is Morse–Smale, $\mathcal{L}(\overline{H})$ decomposes as

$$\mathcal{L}(\overline{H}) = Per(\overline{H}) = \Lambda_1 \cup \cdots \cup \Lambda_n,$$

where the Λ_i are the distinct hyperbolic periodic orbits and equilibria. On the other hand, it follows from the transversal condition (iii) that there is no cycle among the Λ_i (see, e.g., Proposition 3.2 of Palis (1969)). Thus, we have the following corollary.

COROLLARY 3.11. *Assume $\overline{H}$ is Morse–Smale. Then $L(\{w_n\}_{n\geq 0})$ is an equilibrium or a periodic orbit.*

Proof. By Corollary 3.9, $L(\{w_n\}_{n\geq 0}) \subset \Lambda_i$ for some i. Since $L(\{w_n\}_{n\geq 0})$ is invariant and Λ_i is a periodic orbit or an equilibrium, we must have $L(\{w_n\}_{n\geq 0}) = \Lambda_i$. □

Nonconvergence toward unstable periodic orbits is considered in Benaim and Hirsch (1995a).

Planar systems. For planar systems it is possible to give a complete description of $L(\{w_n\}_{n\geq 0})$. A planar flow is a flow defined on a open subset of $\mathbf{R}^2$. The following theorem is proved in Benaim and Hirsch (1995c).

THEOREM 3.12. *Let Φ be a planar flow with isolated equilibria and L be an internally chain-recurrent set for Φ. Every point $x \in L$ satisfies one of the following conditions:*

(i) *x is an equilibrium.*

(ii) *x is a periodic point (i.e., x belongs to a periodic orbit).*

(iii) *There exists a cycle of equilibria in L which contains x.*

COROLLARY 3.13. *If $\overline{H}$ is a planar vectorfield with isolated equilibria, $L(\{w_n\}_{n\geq 0})$ is a connected union of equilibria, periodic orbits, and cycles of equilibria.*

Using the same kind of result, a Poincaré–Bendixson theorem for a class of stochastic differential equations is given in Benaim (1995b).

4. Proof of Theorem 1.2. We denote by 1_A the indicator function of the set A (i.e., $1_A(x) = 1$ if $x \in A$ and $1_A(x) = 0$ if $x \notin A$).

For any sequence $\{z_n\}_{n\geq 0} \in \mathbf{R}^m$ we denote by $Z(.)$ the function defined for all $t \geq 0$ by

$$Z(t) = \sum_{n\geq 0} z_n 1_{[\tau_n, \tau_{n+1}[}(t)$$

and by $Z^0(.)$ the interpolated process defined for all $t \geq 0$ by

$$Z^0(t) = \sum_{n\geq 0} \left[(z_{n+1} - z_n).\frac{(t-\tau_n)}{\gamma_n} + z_n \right] 1_{[\tau_n, \tau_{n+1}[}(t).$$

With these notations, the recursion satisfied by $\{w_n\}_{n\geq 0}$ can be rewritten as

$$W^0(t) - W^0(0) = \int_0^t \overline{H}(W(s))ds + \int_0^t U(s)ds + \int_0^t B(s)ds. \tag{4}$$

Remark that the assumptions A1, A2, and A3 are equivalent to

- A1′) $\{W^0(t), t \geq 0\}$ is bounded.
- A2′) $\lim_{t\to\infty} B(t) = 0$.
- A3′) For each $T > 0$,

$$\lim_{t\to\infty} \left(\sup_{h\in[0,T]} \left\| \int_t^{t+h} U(s)ds \right\| \right) = 0.$$

The function $t \mapsto W^0(t)$ is uniformly continous. This follows easily from the integral formula (4) and conditions A1′, A2′, A3′. This can also be deduced from the Kushner and Clark lemma (1978) (see Theorem 4.5).

We denote by $L(W^0)$ the limit set of $\{W^0(t), t \geq 0\}$ and let Q denote a compact subset of $\mathbf{R}^m$ which contains $\{W^0(t), t \geq 0\}$.

LEMMA 4.1. $L(\{w_n\}_{n\geq 0}) = L(W^0)$.

Proof. It is clear that $L(\{w_n\}_{n\geq 0}) \subset L(W^0)$. Conversely, let

$$w* = \lim_{t_k\to+\infty} W^0(t_k),$$

a limit point of W^0. Define the map $m : \mathbf{R}_+ \mapsto \mathbb{N}$ by

$$m(t) = \sup\{p \in \mathbb{N}/\tau_p \leq t\}. \tag{5}$$

One has $\lim_{t\to+\infty}(t - \tau_{m(t)}) = 0$ because $\lim_{n\to+\infty} \gamma_n = 0$. The uniform continuity of W^0 implies $\lim_{t_k\to+\infty} W^0(\tau_{m(t_k)}) = w*$. This proves the lemma. □

LEMMA 4.2. *For all* $T > 0$,

$$\lim_{t\to+\infty} \sup_{h\in[-T,T]} ||W^0(t+h) - \Phi_h(W^0(t))|| = 0.$$

For convenience, the proof of this lemma is postponed to the end of the section.

COROLLARY 4.3. $L(\{w_n\}_{n\geq 0})$ *is internally chain-recurrent.*

Proof. Since W^0 is continuous and bounded, $L(W^0)$ is a nonempty compact connected set.

Let us verify that $L(W^0)$ is invariant under Φ. Let $p \in L(W^0)$, $p = \lim_{t_i\to\infty} W^0(t_i)$ for some sequence $t_i \to \infty$. Let $T \in \mathbf{R}$. If $T > 0$, then

$$\lim_{t_i\to\infty} d(\Phi_T(W^0(t_i)), W^0(t_i + T)) = 0$$

by Lemma 4.2. Therefore $\Phi_T(p) = \lim_{t_i\to\infty} W^0(t_i + T) \in L(W^0)$. If $T < 0$, the proof is analogous.

It remains to prove that $L(W^0)$ is chain-recurrent for the restricted flow $\Phi|L(W^0)$. Here we adopt a method used by Robinson (1977) to show that a diffeomorphism on

a compact manifold is chain-recurrent on the set of chain-recurrence. Recall that $Q \subset \mathbf{R}^m$ denotes a compact set which contains $\{W^0(t), t \geq 0\}$.

Claim 1. Let $n \in \mathbf{N}$, $T > 0$, $p \in L(W^0)$. There exists a finite sequence

$$n \leq a_0^n \leq \cdots \leq a_{k(n)}^n$$

such that, with the notations

$$y_i^n = W^0(a_i^n), \qquad i = 0, \ldots, k(n),$$

and

$$t_i^n = a_{i+1}^n - a_i^n, \qquad i = 0, \ldots, k(n) - 1,$$

the following hold:

(a) $d(y_0^n, p) \leq \frac{1}{n}$ and $d(y_{k(n)}^n, p) \leq \frac{1}{n}$.

(b) $T \leq t_i^n \leq 2T$, $i = 0, \ldots, k(n) - 1$.

(c) $d(\Phi_{t_i^n}(y_i^n), y_{i+1}^n) \leq \frac{1}{n}$, $i = 0, \ldots, k(n) - 1$.

Proof. Let $n \in \mathbf{N}$. Lemma 4.2 shows that there exists $A_n > 0$ such that for any $t \geq A_n$ and for all $0 \leq h \leq 2T$, $d(\Phi_h(W^0(t)), W^0(t+h)) \leq \frac{1}{n}$.

As $p \in L(W^0)$ there exists $a_0^n \geq \sup(A_n, n)$ such that $d(W^0(a_0^n), p) \leq \frac{1}{n}$ and there exists $T' > T$ such that $d(W^0(a_0^n + T'), p) \leq \frac{1}{n}$. Write $a_0^n + T' = kT + r$, where $k \in \mathbf{N}$ and $0 \leq r < T$. Then define $a_i^n = a_0^n + i(T + \frac{r}{k})$, $i = 0, \ldots, k$. □

Let $C_n = \{y_i^n, i = 0, \ldots, k(n)\}$, where y_i^n is defined as in Claim 1. As C_n is a compact set, we may extract from $\{C_n\}_{n \geq 0}$ a subsequence which converges toward a compact set C for the Haussdorf metric in Q. It is clear that $C \subset L(W^0)$.

Claim 2. Let $\delta > 0$ and $T > 0$; then p is (δ, T) recurrent for the restricted flow $\Phi | L(W^0)$.

Proof. By uniform continuity of the flow on Q there exists $\alpha > 0$ such that $d(x, y) \leq \alpha$ implies $d(\Phi_t(x), \Phi_t(y)) \leq \delta/3$ uniformly in $t \in [0, 2T]$. We may always assume $\alpha \leq \delta/3$. Choose n large enough such that $1/n \leq \delta/3$ and $d(C_n, C) \leq \alpha$. Then we construct a finite sequence $Z_0, \ldots, Z_{k(n)} \in C$ such that $d(Z_i, y_i^n) \leq \alpha$ for $i = 0, \ldots, k(n)$. Then

$$d(Z_0, p) \leq \alpha + 1/n \leq \delta,$$

$$d(Z_{k(n)}, p) \leq \alpha + 1/n \leq \delta,$$

and

$$d(\Phi_{t_i^n}(Z_i), Z_{i+1}) \leq d(\Phi_{t_i^n}(Z_i), \Phi_{t_i^n}(y_i^n)) + d(\Phi_{t_i^n}(y_i^n), y_{i+1}^n) + d(y_{i+1}^n, Z_{i+1})$$

$$\leq \delta/3 + \frac{1}{n} + \alpha \leq \delta. \qquad \square$$

Proof of Lemma 4.2.

The Lipschitz case. Here we assume that $\overline{H}$ is locally Lipschitz. We let $L(Q)$ denote the Lipschitz constant of $\overline{H}$ on Q and $\|\overline{H}\|_Q$ the uniform norm of $\overline{H}$ on Q. The next lemma proves Lemma 4.2 with an estimate. This estimate will be useful to prove the main result of §5.

LEMMA 4.4. *For all* $T > 0$ *and all* $t \geq 0$,

$$\sup_{h\in[0,T]} \|W^0(t+h) - \Phi_h(W^0(t))\| \leq e^{L(Q)\,T}[2\epsilon(t,T)(1+TL(Q)) + TL(Q)\|\overline{H}\|_Q\gamma_{m(t)}],$$

where

$$\epsilon(t,T) = \sup_{\{k;\ 0\leq\tau_k-\tau_{m(t)}\leq T+1\}} \left\| \sum_{i=m(t)}^{k-1} \gamma_i.u_i \right\| + (T+1)\left[\sup_{\{k;0\leq\tau_k-\tau_{m(t)}\leq T+1\}} \|b_k\|\right].$$

Proof. We begin with a simple inequality:

$$\forall u, v \in [\tau_{m(t)}, \tau_{m(t+T)+1}[\ \left\| \int_u^v (U(s)+B(s))ds \right\| \leq 2\epsilon(t,T). \tag{6}$$

To prove (6) we note that for any $u \geq \tau_{m(t)}$ there exists $\alpha \in [0,1]$ for which

$$\int_{\tau_{m(t)}}^{u} (U(s)+B(s))ds = \alpha \int_{\tau_{m(t)}}^{\tau_{m(u)}} (U(s)+B(s))ds + (1-\alpha)\int_{\tau_{m(t)}}^{\tau(m(u)+1)} (U(s)+B(s))ds.$$

As for $u, v \in [\tau_{m(t)}, \tau_{m(t+T)+1}[$,

$$\int_u^v (U(s)+B(s))ds = -\int_{\tau_{m(t)}}^{u} (U(s)+B(s))ds + \int_{\tau_{m(t)}}^{v} (U(s)+B(s))ds.$$

Inequality (6) follows.

According to (4),

$$\begin{aligned} W^0(t+h) - \Phi_h(W^0(t)) = \int_0^h \overline{H}(W(t+s))ds - \int_0^h \overline{H}(\Phi_s(W^0(t))ds \\ + \int_t^{t+h} (U(s)+B(s))ds. \end{aligned} \tag{7}$$

Let

$$A(h) = \|W^0(t+h) - \Phi_h(W^0(t))\|.$$

Equation (7) implies

$$\begin{aligned} A(h) \leq L(Q)\int_0^h A(s)ds + \int_0^h \|\overline{H}(W^0(t+s)) - \overline{H}(W(t+s))\|ds \\ + \left\| \int_t^{t+h} (U(s)+B(s))ds \right\|. \end{aligned} \tag{8}$$

On the other hand, for any $h \in [0,T]$

$$\|W^0(t+h) - W(t+h)\| = \left\| \int_{\tau_{m(t+h)}}^{t+h} [\overline{H}(W(s)) + U(s) + B(s)]ds \right\|,$$

and inequality (6) implies

$$\|W^0(t+h) - W(t+h)\| \leq \gamma_{m(t+h)} \|\overline{H}\|_Q + 2\epsilon(t,T). \tag{9}$$

From inequalities (8) and (9), we deduce that for any $h \in [0,T]$

$$A(h) \leq L(Q) \int_0^h A(s)ds + 2\epsilon(t,T)(1 + TL(Q)) + TL(Q)\gamma_{m(t)} \|\overline{H}\|_Q,$$

and we conclude by using Gronwall's inequality. □

The non-Lipschitz case. Here we prove Lemma 4.2, assuming only that $\overline{H}$ is continous with unique integral curves. The key of the proof is to use the Kushner and Clark lemma (1978). Let $W^s()$ be the function defined for any $s \geq 0$ by

$$\forall t \geq -s, W^s(t) = W^0(t+s)$$

and

$$\forall t < -s, W^s(t) = w_0.$$

The Kushner and Clark lemma is the following.

THEOREM 4.5 (Kushner and Clark (1978)). *Under the assumptions* A1, A2, *and* A3 *of Theorem* 1.2, $\{W^s(.)\}_{s\geq 0}$ *is relatively compact in* $C^0(\mathbf{R}, \mathbf{R}^m)$ *with respect to the topology of uniform convergence on bounded intervals (i.e., from every sequence of the set* $\{W^s(.)\}_{s\geq 0}$ *it is possible to select a subsequence which converges uniformly on bounded intervals), and the limit of each convergent subsequence is the solution to the ODE.*

What we want to prove (i.e., Lemma 4.2) is equivalent to

$$\lim_{s\to\infty} sup_{h\in[-T,T]} \|W^s(h) - \Phi_h(W^s(0))\| = 0 \tag{10}$$

for all $T > 0$. Let D denote a distance on $C^0(\mathbf{R}, \mathbf{R}^m)$ induced by the topology of uniform convergence on bounded intervals; then (10) can be rewritten as

$$\lim_{s\to\infty} D(W^s(.), \Phi(., W^s(0))) = 0. \tag{11}$$

Let W^* be an arbitrary limit point of $\{W^s(.)\}_{s\geq 0}$. By Theorem 4.5 W^* is a solution to the ODE, and by uniqueness of integral curves $W^*(t) = \Phi(t, W^*(0))$ for all t. Thus, $W^*(.) = \Phi(., W^*(0))$. This proves (11). □

5. L^q estimates and shadowing. In this section we consider the following question:

Given $\{w_n\}_{n\geq 0}$, *a trajectory solution to* (1), *does there exist a solution to* (2) *whose omega limit set is* $L(\{w_n\}_{n\geq 0})$*?*

Theorem 1.3 shows that (at least under assumptions of Theorem 1.2) the answer is generally negative since $L(\{w_n\}_{n\geq 0})$ can be an arbitrary internally chain-recurrent set. However, it is useful to understand what kind of conditions ensure a positive answer to this question. A case of particular interest in applications is given by the following problem:

Assume that each solution to (2) *converges toward an equilibrium.*

Does every solution to (1) *converge also toward an equilibrium?*

We saw in §3 several examples for which $CR(\overline{H})$ is the set of equilibria and the theorems of §§1 and 2 were applied to answer positively. But it may happen that $CR(\overline{H})$ contains nonequilibrium points (see Example 6.3) and further conditions are required.

We begin with a simple example.

EXAMPLE 5.1. *Consider the recursion which is defined in polar coordinates* $\rho \geq 0$, $\theta \in \mathbf{R}/(2\pi\mathbf{Z})$ *by*

$$\rho_{n+1} - \rho_n = \gamma_n(g(\rho_n) + 1_{[0.5\,,3]}(\rho_n).\xi_n),$$

$$\theta_{n+1} - \theta_n = -\gamma_n,$$

where $\{\xi_n\}_{n\geq 0}$ *is a sequence of independently and identically distributed random variables with uniform distribution on* $[-\frac{1}{2}, \frac{1}{2}]$, $\gamma_n = \frac{1}{n^\alpha}$ *for some* $0 < \alpha \leq 1$, *and* $g : \mathbf{R}_+ \to \mathbf{R}$ *is a smooth function which is zero on* $\{0\} \cup [1, 2]$, *positive on* $]0, 1[$, *and negative on* $]2, \infty)$. *The ODE associated with this recursion is defined by*

$$\frac{d\rho}{dt} = g(\rho),$$

$$\frac{d\theta}{dt} = -1.$$

The phase portrait of this ODE is given by Fig. 3.

We see that any connected internally chain recurrent set of this ODE is either the equilibrium $0_{\mathbf{R}^2}$ *or a cylinder of periodic orbits*

$$C_{a,b} = \{\rho : a \leq \rho \leq b\} \times \{\theta \in \mathbf{R}/(2\pi\mathbf{Z})\},\ 1 \leq a \leq b \leq 2.$$

Assume that the initial condition of the process is not $0_{\mathbf{R}^2}$. *Therefore, according to Proposition* 2.1, *the limit set* $L(\{w_n\}_{n\geq 0})$ *of the process has to be a cylinder. In fact, it is not difficult to show that*

(a) *if* $\alpha > \frac{1}{2}$, $L(\{w_n\}_{n\geq 0})$ *is almost surely a periodic orbit* $L(\{w_n\}_{n\geq 0}) = C_{a,a}$ *for some* $1 \leq a \leq 2$;

(b) *if* $\alpha < \frac{1}{2}$, $L(\{w_n\}_{n\geq 0}) = C_{1,2}$.

The main reason is that the sum $\sum_n \gamma_n \xi_n$ *converges for* $\alpha > \frac{1}{2}$, *while*

$$\limsup_{n\to\infty} \sum_n \gamma_n \xi_n = -\liminf_{n\to\infty} \sum_n \gamma_n \xi_n = +\infty$$

for $\alpha < \frac{1}{2}$ (*see, e.g., Neveu* (1964, *p.* 138)).

In case (a) $L(\{w_n\}_{n\geq 0})$ *is an omega limit set of the ODE. Case* (b) *gives an example for which the asymptotic behavior of* (1) *is quite different from the asymptotic behavior of* (2).

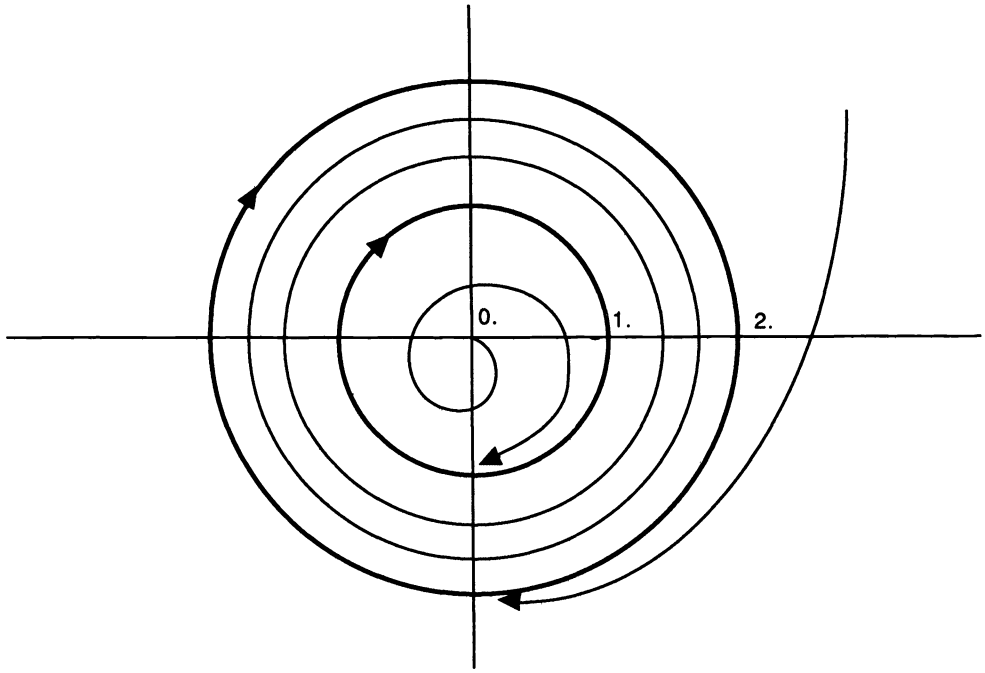

FIG. 3.

Expansion rate. In the previous example, the condition $\alpha < 1$ means, intuitively, that the convergence of $\{\gamma_n\}_{n\geq 0}$ to zero is not fast enough to ensure the convergence of $\{w_n\}_{n\geq 0}$ toward the omega limit sets of the ODE. We now formalize this idea and show that, conversely, if $\{\gamma_n\}_{n\geq 0}$ goes to zero at a suitable rate depending on the *expansivity* of the ODE, then $\{w_n\}_{n\geq 0}$ is in some sense asymptotic to a forward trajectory of (2).

Here we make crucial use of the ideas and methods introduced by Morris W. Hirsch in a recent paper (1993). The main idea of what follows is to use a shadowing theorem proved in Hirsch (1993) together with L^q estimates of the error which is made when (1) is replaced by (2).

To avoid technicalities, we will assume throughout the remainder of this section that $\overline{H}$ is a C^1 vectorfield on $\mathbf{R}^m$ with the point at infinity as a source. By ∞ as a source we mean that there exists a bounded nonempty open set $U \subset \mathbf{R}^m$ such that for all $w \in \mathbf{R}^m$

$$\lim_{t\to\infty} d(\Phi_t(w), \operatorname{clos}(U)) = 0$$

and for some $T > 0$

$$\Phi_T(\operatorname{clos}(U)) \subset U.$$

Let K denote a nonempty compact set positively invariant under the flow of $\overline{H}$. The *expansion rate* of $\overline{H}$ in K is defined in Hirsch (1993) (see also Hirsch and Pugh (1970)). For convenience, we introduce it in a logarithmic form:

$$l_{exp}(\overline{H}, K) = \lim_{t\to+\infty} \left[\min_{w\in K} \frac{\log(\|(D\Phi_t(w))^{-1}\|^{-1})}{t}\right],$$

where $D\Phi_t(w)$ denote the differential of Φ_t at w. The limit exists by subadditivity. We call $l_{exp}(\overline{H}, K)$ the "log-expansion rate" of $\overline{H}$ in K. This real number measures

the expansivity of the dynamical system induced by $\overline{H}$. It is zero if the flow is isometric, positive if the flow has a tendency to be expansive, and negative otherwise. Let $\mathrm{clos}(\mathcal{L}(\overline{H}))$ be the closure of all alpha and omega limit points of the trajectories solution to (2). As we assume that "∞" is a source, $\mathrm{clos}(\mathcal{L}(\overline{H}))$ is a compact nonempty invariant set. We define the "log-expansion rate" of $\overline{H}$ as

$$l_{exp}(\overline{H}) = l_{exp}(\overline{H}, \mathrm{clos}(\mathcal{L}(\overline{H}))).$$

This definition makes sense and is motivated by the following important property (Hirsch (1993)): If L is a compact invariant subset of K containing all alpha and omega limit points in K, then $l_{exp}(\overline{H}, K) = l_{exp}(\overline{H}, L)$. Some properties of $l_{exp}(\overline{H})$ are given in §6.

A shadowing theorem. Let $\{\alpha_n\}_{n\geq 0}$ denote a sequence of nonnegative real numbers.

Define the "log-convergence rate" of $\{\alpha_n\}_{n\geq 0}$ with respect to the time scale $\tau_n = \sum_{i=0}^{n-1} \gamma_i$ as

$$l_\tau(\alpha) = \limsup_{n\to+\infty} \frac{\log(\alpha_n)}{\tau_n}.$$

Now consider the same recursion as in Theorem 1.2 in a probabilistic framework:

$$w_{n+1} - w_n = \gamma_n \overline{H}(w_n) + \gamma_n u_n + \gamma_n b_n, \tag{12}$$

where $\{\gamma_n\}_{n\geq 0}$ is a decreasing gain sequence, $\{u_n\}_{n\geq 0}$ and $\{b_n\}_{n\geq 0}$ are two sequences of $\mathbf{R}^m$-valued random variables defined on the probability space $(\Omega, \mathcal{F}, \mathcal{P})$, and $\overline{H} : \mathbf{R}^m \mapsto \mathbf{R}^m$ is a C^1 vectorfield with ∞ as a source.

Recall that $\|.\|_q$ denotes the $L^q(\Omega)$ norm. For each $T > 0$ and each $q \in [1, +\infty[$ let

$$\alpha_n^{q,T} = \left\| \sup_{\{k\,;0\leq\tau_k-\tau_n\leq T\}} \left\| \sum_{i=n}^{k-1} \gamma_i u_i \right\| \right\|_q$$

and

$$\beta_n^{q,T} = \left\| \sup_{\{k\,;0\leq\tau_k-\tau_n\leq T\}} \|b_k\| \right\|_q .$$

THEOREM 5.2. *Let $\{w_n\}_{n\geq 0}$ be solution to the recursion* (12). *Assume that there exists $q \geq 1$ such that*

- A1) $E(\sup_{n\geq 0} \|\{w_n\}_{n\geq 0}\|^q) < +\infty$.
- A2) *For each $T > 0$,*

$$l_\tau(\beta^{q,T}) < \min(0, l_{exp}(\overline{H})),$$

$$l_\tau(\alpha^{q,T}) < \min(0, l_{exp}(\overline{H})),$$

$$l_\tau(\gamma) < \min(0, l_{exp}(\overline{H})).$$

Then

- a) *there exists a random vector* w' *such that*

$$\lim_{n\to+\infty} \|w_n - \Phi_{\tau_n}(w')\| = 0$$

almost surely.

- b) *If there exists a compact* $Q \subset \mathbf{R}^m$ *such that* $\{w_n\}_{n\geq 0}$ *remains in* Q *almost surely (in which case A1 is obviously satisfied), then the following estimate holds:*

$$l_\tau(\{\|w_n - \Phi_{\tau_n}(w')\|_q\}_{n\geq 0}) \leq \sup(l_\tau(\beta^{q,T}), l_\tau(\alpha^{q,T}), l_\tau(\gamma)).$$

REMARK 5.3. *Conclusion* (a) *of Theorem* 5.2 *implies that* $L(\{w_n\}_{n\geq 0}) = \omega(w')$ *almost surely.*

As in §2 we apply the previous result to the stochastic approximation (1), where $\{\xi_n\}_{n\geq 0}$ is a sequence of random variables defined on $(\Omega, \mathcal{F}, \mathcal{P})$. Maximal inequalities for sum of random variables reduce condition A2 to a simple condition on $l_\tau(\gamma)$. First of all, note that for any $\lambda > 0$,

$$l_{\lambda\tau}(\lambda\gamma) = \frac{1}{\lambda} l_\tau(\gamma).$$

If $\gamma_n = f(n)$ for some positive decreasing function f with $\int_1^{+\infty} f(s)ds = +\infty$, then

$$l_\tau(\gamma) = \limsup_{x\to+\infty} \frac{\log(f(x))}{\int_1^x f(s)ds}.$$

For example, if

$$\gamma_n = \frac{1}{n^\alpha \log(n)^\beta},$$

then $l_\tau(\gamma) = 0$ for $0 < \alpha < 1$ and $\beta \geq 0$, $l_\tau(\gamma) = -1$ for $\alpha = 1$ and $\beta = 0$, and $l_\tau(\gamma) = -\infty$ for $\alpha = 1$ and $0 < \beta \leq 1$.

Independent inputs. As in Proposition 2.1, we let M denote a subset of $\mathbf{R}^m$.

PROPOSITION 5.4. *Let* $\{w_n\}_{n\geq 0}$ *be the solution to* (1). *Assume that*

- A1) $\{\xi_n\}_{n\geq 0}$ *is a sequence of independent and identically distributed random variables.*
- A2) $P(\forall n \in N, w_n \in M) = 1$.
- A3) $w \mapsto \overline{H}(w) = E(H(w, \xi_0))$ *is* C^1 *with* ∞ *as a source.*

There exists $q \geq 2$ *such that*

- A4) $E(\sup_{n\geq 0} \|\{w_n\}_{n\geq 0}\|^q) < +\infty$ *and* $w \mapsto \|H(w, \xi_0)\|_q$ *is bounded on* M.
- A5) $l_\tau(\gamma) < 2\min(0, l_{exp}(\overline{H}))$.

Then

- a) *The conclusion* a) *of Theorem* 5.2 *holds.*
- b) *If* M *is compact,* $l_\tau(\{\|w_n - \Phi_{\tau_n}(w')\|_q\}_{n\geq 0}) \leq \frac{1}{2} l_\tau(\gamma)$.

Proof. Let $b_n = 0$ and $u_n = H(w_n, \xi_n) - \overline{H}(w_n)$. As already noted, $\{u_n\}_{n\geq 0}$ is a martingale difference. For $q = 2$, Doob's inequality for L^2 martingales gives

$$\alpha_n^{2,T} \leq \left[C(M) \sum_{i=n}^{m(\tau_n+T)-1} \gamma_i^2 \right]^{\frac{1}{2}},$$

where $C(M)$ is a positive constant and $m(T)$ is defined by (5). So

$$\alpha_n^{2,T} \leq [C(M)\gamma_n T]^{\frac{1}{2}}.$$

Then $l_\tau(\alpha^{2,T}) \leq \frac{1}{2} l_\tau(\gamma)$ and the condition A2 of Theorem 5.2 is satisfied. For $q > 2$,

$$\alpha_n^{q,T} \leq \left[C(M,T) \sum_{i=n}^{m(\tau_n+T)-1} \gamma_i^{1+q/2} \right]^{\frac{1}{2}}$$

for some constant $C(M,T)$. This inequality is proved, in a more general context, in Métivier and Priouret (1987, Prop. 8). Therefore,

$$\alpha_n^{q,T} \leq [C(M,T)T]^{\frac{1}{q}} \gamma_n^{1/2},$$

and the result follows. □

REMARK 5.5. *It is interesting to note that the condition* A5 *of Proposition* 5.4 *is always satisfied for* $\gamma_n = \frac{1}{n \log(n)}$. *For* $\gamma_n = \frac{\epsilon}{n+n_0}$, *it reduces to the condition* $\epsilon < -\frac{1}{2 l_{exp}(\overline{H})}$.

Mixing inputs. In the case corresponding to Proposition 2.2, in which the observations are given by a mixing process, our approach of condition A2 in Theorem 5.2 is based on some kind of uniform maximal inequalities. Unfortunately, these estimates depend on the dimension of the parameter space and the condition we obtain presents the "curse of dimensionality." Here we shall assume that $\{\xi_n\}_{n\geq 0}$ is stationary to facilitate the verification of assumption A2 of Theorem 5.2.

PROPOSITION 5.6. *Let* $\{w_n\}_{n\geq 0}$ *be the solution to* (1). *Assume that*

- A1) $\{\xi_n\}_{n\geq 0}$ *is a stationary* ϕ *mixing (respectively,* α *mixing) process.*
- A2) *There exists a compact set* $Q \subset \mathbf{R}^m$ *such that* $P(\forall n \geq 0, w_n \in Q) = 1$.
- A3) $\overline{H}(w) = \lim_{n\to\infty} E(H(w,\xi_n))$ *exists.*
- A4) *There exists a measurable function* $k(.)$ *such that*

$$\forall x, y \in \mathbf{R}^m \|H(x,\xi) - H(y,\xi)\| \leq k(\xi)\|x - y\|.$$

There exists $r \in [2,\infty]$ *such that*

- A5) *The map* $w \mapsto \sup_{n\geq 0} \|H(w,\xi_n)\|_r$ *is bounded on* Q *and* $\sup_{n\geq 0} \|k(\xi_n)\|_r < +\infty$.
- A6) *(L^r case). If* $r < \infty$, $\phi_n = O(\frac{1}{n^\beta})$ *for some* $\beta > \frac{r}{2r-2}$ *(respectively,* $\alpha_n = O(\frac{1}{n^\beta})$ *for some* $\beta > \frac{r}{r-2}$*).*
- A6′) *(L^∞ case). If* $r = \infty$, $\phi_n = O(\frac{1}{n^\beta})$ *for some* $\beta > \frac{1}{2}$ *(respectively,* $\alpha_n = O(\frac{1}{n^\beta})$ *for some* $\beta > 1$*).*
- A7) $l_\tau(\gamma) < 2(m+1)\min(0, l_{exp}(\overline{H}))$.

Then the conclusions of Theorem 5.2 *hold with probability one.*

The proof is given in appendix (§9).

6. Applications. Here again $\overline{H}$ denotes a C^1 vectorfield with ∞ as a source.

Convergent systems. We say that $\overline{H}$ is a *convergent system* if $\overline{H}$ admits a finite number of equilibria $\{e_1,\ldots,e_n\}$ and

$$\mathcal{L}(\overline{H}) = \{e_1,\ldots,e_n\}.$$

Equivalently, this means that the flow induced by $\overline{H}$ on $S^m = \mathbf{R}^m \cup \{\infty\}$ (the compactification of $\mathbf{R}^m$) has simple dynamics and finitely many equilibria.

Let $\{\lambda_i^j,\ j = 1, \ldots, m\}$ denote the set of eigenvalues of the matrix $D\overline{H}(e_i)$. Define

$$\beta(e_i) = \min\{\mathrm{Re}(\lambda_i^j) : j = 1, \ldots, m\},$$

where Re denotes the real part. Since e_i is a fixed point, $D\Phi_t(e_i) = exp(tD\overline{H}(e_i))$. Therefore

$$\lim_{t\to\infty} \frac{\log(\|(D\Phi_t(e_i))^{-1}\|^{-1})}{t} = \beta(e_i),$$

and by definition of the log-expansion rate we deduce the following proposition.

PROPOSITION 6.1. *If $\overline{H}$ is a convergent system with equilibria $\{e_1, \ldots, e_n\}$, then*

$$l_{exp}(\overline{H}) = \min\{\beta(e_i) : i = 1, \ldots, n\}.$$

COROLLARY 6.2. *Let $\{w_n\}_{n\geq 0}$ be the solution to* (1). *Assume that conditions* A1–A4 (*respectively,* A1–A6, A6′) *of Proposition* 5.4 (*respectively,* 5.6) *are satisfied. Assume that the averaged vectorfield $\overline{H}$ defined by* A3 *is convergent and that*

$$\forall i \in \{1, \ldots, n\},\ l_\tau(\gamma) < 2\min(0, \beta(e_i))$$

(respectively, $l_\tau(\gamma) < 2(m+1)\min(0, \beta(e_i))$). Then $\{w_n\}_{n\geq 0}$ converges almost surely toward an equilibrium.

EXAMPLE 6.3. *Consider the following stochastic approximation process defined on $\mathbf{R}^2$ by*

$$x_{n+1} - x_n = \frac{\epsilon}{n} H_1(x_n, y_n, \xi_n),$$

$$y_{n+1} - y_n = \frac{\epsilon}{n} H_2(x_n, y_n, \xi_n),$$

where $\{\xi_n\}_{n\geq 0}$ is a sequence of independently and identically distributed random variables uniformly distributed on $[-1, 1]$.

$$H_1(x, y, \xi) = (1 - (x^2 + y^2))x - yf(y) + \xi,$$

$$H_2(x, y, \xi) = (1 - (x^2 + y^2))y + xf(y) + \xi,$$

where $f(y) = y^2$. The phase portrait of the averaged ODE is given by Fig. 4.

We see that this system is convergent but admits $S^1 = \{(x, y) : x^2 + y^2 = 1\}$ as a cycle of equilibria. Therefore, the theorems of §§2 and 3 *are not sufficent to ensure the convergence of the process $\{x_n, y_n\}_{n\geq 0}$.*

The equilibria of this system are $e_1 = (0, 0)$, $e_2 = (1, 0)$, and $e_3 = (-1, 0)$. A simple computation shows that 0 *and* -2 *are the eigenvalues of the linearized ODE at points e_2 and e_3, and* 1 *is a double eigenvalue at point e_1. Thus,*

$$\beta(e_1) = 1,\ \beta(e_2) = \beta(e_3) = -2.$$

For $\gamma_n = \frac{\epsilon}{n}$ we have $l_\tau(\gamma) = -\frac{1}{\epsilon}$. Therefore, according to Corollary 6.2, *if $\epsilon < \frac{1}{4}$, the sequence $\{x_n, y_n\}_{n\geq 0}$ converges almost surely toward an equilibrium. Furthermore, a theorem of Pemantle* (1990) *can be used to show that this equilibrium cannot be the hyperbolic unstable equilibrium e_1.*

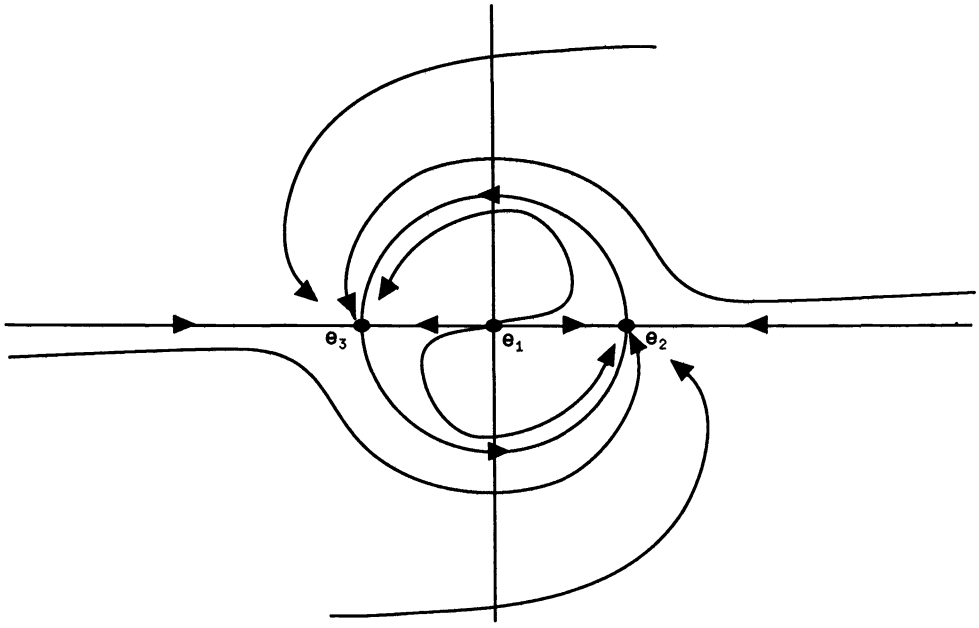

FIG. 4.

Globally convergent systems. A convergent system $\overline{H}$ with one unique equilibrium $\{e_1\}$ is said *globally convergent.*

The L^q estimate given by assertion (b) of Theorem 5.2 can be used to bound the L^q rate of convergence of algorithms associated to globally convergent ODEs. We mention here a corollary based on Proposition 5.4. Other estimates based on Proposition 5.6 or Theorem 5.2 are possible. Define

$$\rho(e_1) = \sup\{\mathrm{Re}(\lambda_1^j) : j = 1, \ldots, m\},$$

where $\{\lambda_1^j : j = 1, \ldots, m\}$ are the eigenvalues of $D\overline{H}(e_1)$.

Note that $\beta(e_1) \leq \rho(e_1) \leq 0$.

COROLLARY 6.4. *Let* $\{w_n\}_{n\geq 0}$ *be the solution to* (1). *Assume that conditions* A1–A4 *of Proposition* 5.4 *are satisfied and* M *is compact. Assume that the averaged vectorfield* $\overline{H}$ *defined by* A3 *is globally convergent and that* $l_\tau(\gamma) < 2\min(0, \beta(e_1))$. *Then*

$$l_\tau(||w_n - e_1||_q) \leq \rho(e_1).$$

Proof. Proposition 6.1 and (b) of Proposition 5.4 imply that $l_\tau(||w_n - \Phi_{\tau_n}(w')||_q) \leq \beta(e_1)$ for some random variable $w' \in M$. Since $\overline{H}$ is globally convergent and M is compact, we have the estimate $l_\tau(||\Phi_{\tau_n}(w') - e_1||) \leq \rho(e_1)$. Thus $l_\tau(||w_n - e_1||_q) \leq l_\tau(||\Phi_{\tau_n}(w') - e_1||_q + ||w_n - \Phi_{\tau_n}(w')||_q) \leq \sup(\rho(e_1), \beta(e_1)) = \rho(e_1)$. □

For $\gamma_n = \frac{\epsilon}{n+n_0}$ and $\epsilon < \frac{1}{2|\beta(e_1)|}$ this gives the following estimate: For all $\delta > 0$

there exists $n(\delta) \geq 0$ such that

$$\forall n \geq n(\delta),\ \|w_n - e_1\|_q \leq \frac{1}{n^{\epsilon(|\rho(e_1)|-\delta)}}.$$

This estimate can be compared with L^2 upper bounds given in Eweda and Macchi (1983) and Benveniste, Métivier, and Priouret (1990, Thms. 22 and 24, pp. 244, 246). It is slightly weaker but requires a weaker condition on the vectorfield.

Nonconvergent systems. For a general vectorfield $\overline{H}$ the log-expansion rate can be difficult to compute. The following proposition is useful to estimate it.

PROPOSITION 6.5 (Hirsch (1993)).

(a) *Let $\beta_s(w)$ be the smallest eigenvalue of the symmetric matrix*

$$\frac{1}{2}(D\overline{H}(w) + D\overline{H}(w)^T),$$

where ^{T} denotes the transpose operation. Then

$$l_{exp}(\overline{H}) \geq \min\{\beta_s(w) : w \in \operatorname{clos}(\mathcal{L}(\overline{H}))\}.$$

(b) *$l_{exp}(\overline{H})$ is invariant by C^1 change of coordinates.*

Assertion (a) is proved in Hirsch (1993). Assertion (b) is easy to check from the definition.

EXAMPLE 6.6. *Consider the stochastic approximation process defined in Example 6.3, where the function $f(.)$ which appears in the definition of H_1 and H_2 is now chosen to be the function $f(y) = 1$. The averaged ODE admits two internally chain-recurrent sets: the unstable equilibrium $0_{\mathbf{R}^2}$ and the stable limit cycle $S^1 = \{(x, y) : x^2 + y^2 = 1\}$. By a theorem of Pemantle already mentioned, $L(\{w_n\}_{n\geq 0})$ cannot be $0_{\mathbf{R}^2}$. Thus, according to Proposition 2.1, $L(\{w_n\}_{n\geq 0}) = S^1$.*

Note that this result is true for all values of $\epsilon > 0$. Let us now show how it can be sharpened by use of the log-expansion rate. To compute the log-expansion rate we use (b) of Proposition 6.5. In polar coordinates, the averaged ODE takes the simple form

$$\frac{d\rho}{dt} = \rho(1 - \rho^2), \qquad \frac{d\theta}{dt} = 1$$

from which it is easy to deduce that the log-expansion rate is given as $l_{exp}(\overline{H}) = \min\{-2, 1, 0\} = -2$. Let θ_n be the angular variable which measures the angle between the x-axis and the vector (x_n, y_n). If $\epsilon < \frac{1}{4}$, Proposition 5.4 applies and we deduce the "asymptotic phase property":

$$\lim_{n\to\infty} \theta_n - [\epsilon log(n)] \bmod 2\pi = \theta^*,$$

where θ^* is a random variable taking values in $[0, 2\pi]$.

7. Proof of Theorem 5.2.

LEMMA 7.1. *Under the assumptions of Theorem 5.2, the conditions of Theorem 1.2 are satisfied.*

Proof. Assumption A1 of Theorem 5.2 implies condition A1 of Theorem 1.2. Now check conditions A2 and A3. Let $\{n_j\}_{j\geq 0}$ be the sequence defined by $n_j = m(jT)$ for $j \geq 0$, where $m(.)$ is defined by (5). For any integer $n \in [n_j, n_{j+1}[$,

$$\|b_n\| \leq \sup_{\{k;\ 0\leq\tau_k-\tau_{n_j}\leq T\}} \|b_k\|.$$

Thus

$$E\left(\sup_{n\geq n_p}\|b_n\|^q\right)\leq E\left(\sup_{j\geq p}\sup_{\{k;\,0\leq\tau_k-\tau_{n_j}\leq T\}}\|b_k\|^q\right)\leq\sum_{j\geq p}\beta_{n_j}^{q,T}.$$

Now, assumption A2 of Theorem 1.2 implies

$$\beta_{n_j}^{q,T}\leq Ce^{-\lambda\tau_{n_j}}\leq C'e^{-(\lambda T)j}$$

for some constants $C, C', \lambda > 0$. It follows that

$$E\left(\sup_{n\geq n_p}\|b_n\|^q\right)\leq\sum_{j\geq p}C'e^{-(\lambda T)j}<+\infty$$

and the Cauchy criterion implies that condition A2 of Theorem 1.2 holds almost surely.

For A3, remark that for any integer $n\in[n_j,n_{j+1}[$,

$$\sum_{i=n_j}^{k-1}\gamma_iu_i=\sum_{i=n_j}^{n_{j+1}-1}\gamma_iu_i-\sum_{i=n_j}^{n-1}\gamma_iu_i+\sum_{i=n_{j+1}}^{k-1}\gamma_iu_i$$

with the convention $\sum_i^j=-\sum_j^i$. Working as previously, we deduce

$$E\left(\sup_{n\geq n_p}\sup_{\{k;\,0\leq\tau_k-\tau_n\leq T\}}\left\|\sum_{i=n}^{k-1}\gamma_iu_i\right\|^q\right)\leq 3^q\sum_{j\geq p}\alpha_{n_j}^{q,T}$$

and conclude exactly as for A2. □

The following definitions and theorem are due to Morris W. Hirsch. The main result of §5 will be derived from this theorem.

Let (E,d) be a metric space and $G: E\mapsto E$ be a map. Let $0\leq\lambda<1$. A sequence $\{Y_k\}_{k\geq 0}$ in E is called a *λ-pseudoorbit* for G if

$$\limsup_{k\to+\infty}d(G(Y_k);Y_{k+1})^{\frac{1}{k}}\leq\lambda.$$

A point $Z\in E$ is said to *λ-shadow* the sequence $\{Y_k\}_{k\geq 0}$ if

$$\limsup_{k\to+\infty}d(G^k(Z);Y_{k+m})^{\frac{1}{k}}\leq\lambda$$

for some integer m.

The following theorem is a consequence of Hirsch (1993, Thm. 3.2) (more precisely, a consequence of its proof).

THEOREM 7.2 (Hirsch (1993)). *Assume E is a complete metric space. Assume there exists $\rho_*>0$ and $\mu>0$ such that for all $0\leq\rho\leq\rho_*$*

$$\forall X\in E\ B(G(X),\rho\mu)\subset G(B(X,\rho)).$$

Let $\{Y_k\}_{k\geq 0}$ a λ-pseudoorbit *for G in E such that*

$$0<\lambda<\min(1,\mu).$$

Then

- a) *there exists* $Z \in E$ *which* λ*-shadows* $\{Y_k\}_{k\geq 0}$;
- b) *if* $Z, Z' \in E$ *both* λ*-shadow* $\{Y_k\}_{k\geq 0}$, *then there exists natural numbers* l, r *such that* $G^l(Z) = G^r(Z')$.

Now we prove Theorem 5.2. Consider the recursion

$$v_{n+1} - v_n = \gamma_n.(f(v_n)\overline{H}(v_n) + u_n + b_n), \tag{13}$$

where $\{u_n\}_{n\geq 0}$ and $\{b_n\}_{n\geq 0}$ are the sequences of recursion (12), v_0 is in $L^q(\Omega)$, and f is a smooth function which is 1 on a closed ball $\overline{B(0,r)}$ which contains $CR(\overline{H})$ and is zero outside $B(0, r+1)$.

The proof decomposes in two steps. The first step is to prove that, under the assumptions of Theorem 5.2, $\{v_n\}_{n\geq 0}$ is asymptotic to a trajectory solution to (2). The second step is to show that any trajectory solution to (12) is asymptotically a solution to (13).

Step 1. Let $\{\Psi\}_{t\in\mathbf{R}}$ be the flow of the vectorfield $f\overline{H}$. The set of all α and ω limit points for $f\overline{H}$ is the disjoint union of $\mathcal{L}(\overline{H})$ and $\{x \in \mathbf{R}^m; \|x\| \geq r+1\}$. Therefore,

$$l_{exp}(f\overline{H}) = \min(0, l_{exp}(\overline{H})).$$

Note $\nu = l_{exp}(f\overline{H})$. Assumption A2 of Theorem 5.2 allows us to choose two real numbers ν'', ν' such that $0 < \nu'' < \nu' < \nu$ and

$$\sup(l_\tau(\beta^{q,T}), l_\tau(\alpha^{q,T}), l_\tau(\gamma)) < \nu''. \tag{14}$$

Because $\nu' < \nu$, there exists $T > 0$ such that for all $x \in \mathbf{R}^m$ and all $t \geq T$

$$\|D\Psi_t(x)^{-1}\|^{-1} \geq e^{\nu' t}. \tag{15}$$

Let $E = L^q(\Omega)$ and G be the map defined by $G(X) = \Psi_T(X)$. First we note that G is well defined (G maps E into E). Indeed, for any random vector $X \in L^q(\Omega)$,

$$E(\|G(X)\|^q) = E(\|G(X)\|^q 1_{X\in B(0,r+1)}) + E(\|G(X)\|^q 1_{X\notin B(0,r+1)}).$$

The first term on the right of this equality is bounded by continuity of the flow and the second term is finite because $G(x) = x$ outside $B(0, r+1)$.

Let $\mu = e^{-\nu' T}$. Inequality (15) implies

$$\forall x, y \in \mathbf{R}^m \|\Psi_T^{-1}(y) - x\| \leq \mu\|y - \Psi_T(x)\|,$$

so, for all X, Y in E,

$$\|G^{-1}(Y) - X\|_q \leq \mu\|Y - G(X)\|_q.$$

Therefore,

$$B(G(X), \mu\rho) \subset G(B(X, \rho))$$

for any $\rho > 0$.

In order to apply Theorem 7.2, it remains to construct a λ-pseudoorbit for G in E with $0 < \lambda < \min(1, \mu)$. With this purpose let $V^0(.)$ be the interpolated process associated to the sequence $\{v_n\}_{n\geq 0}$ (see §4 for the definition of the interpolated process) and define $Y_n = V^0(nT)$ for all integers n. As v_0, u_n, and b_n are in $L^q(\Omega)$, a

simple induction shows that v_n is in $L^q(\Omega)$ for all n. Hence $\{Y_n\}_{n\geq 0}$ is a sequence of L^q.

As $\overline{H}$ is C^1, $f\overline{H}$ is Lipschitz and bounded. Let L denote a Lipschitz constant for $f\overline{H}$ and K denote a bound for $\|f\overline{H}(x)\|$. Lemma 4.4, applied to V^0 and $f\overline{H}$, gives

$$\|V^0((n+1)T) - \Psi_T(V^0(nT))\| \leq e^{L.T}[2\epsilon(nT,T)(1+TL) + TLK\gamma_{m(nT)}], \tag{16}$$

where $\epsilon(t,T)$ is defined as in Lemma 4.4.

Let $\lambda = e^{-\nu''T}$. From (14) and (16) $\{Y_n\}_{n\geq 0}$ is a λ-pseudoorbit for G. As $0 < \lambda < \min(1,\mu)$, the Theorem 7.2 applies. Thus, there exists $Z \in E$ such that for any $\lambda < \lambda_1 < \inf(1,\mu)$ and k large enough

$$\|G^k(Z) - Y_{k+m}\|_q \leq \lambda_1^k \tag{17}$$

for some integer m. The Borel–Cantelli lemma now implies

$$\lim_{k\to+\infty} (G^k(Z) - Y_{k+m}) = 0$$

almost surely. Let $Z' = \Psi_{-mT}(Z)$. We have

$$\lim_{k\to+\infty} (G^k(Z') - Y_k) = 0. \tag{18}$$

For any $t > 0$, write $t = kT + r$ with $k \in N$ and $0 \leq r < T$. Thus

$$\begin{aligned}\Psi_t(Z') - V^0(t) = [\Psi_r(\Psi_{kT}(Z')) - \Psi_r(V^0(kT))] \\ +[\Psi_r(V^0(kT)) - V^0(kT+r)].\end{aligned} \tag{19}$$

Uniform continuity of the flow on $[0,T]$ and relation (18) imply that the first term on the right of equality (19) goes to zero. The second term goes to zero by Lemma 4.2. Then

$$\lim_{t\to+\infty} \Psi_t(Z') - V^0(t) = 0$$

almost surely. This concludes step 1.

The equality (19) also proves part (b) of Theorem 5.2. Indeed, if $\{w_n\}_{n\geq 0}$ remains in a compact Q almost surely, the ball $B(0,r)$ can be chosen large enough to contain Q and $\{w_n\}_{n\geq 0}$ is solution to (13). The first term on the right side of equality (19) can be bounded in $L^q(\Omega)$, using (17) and the fact that $x \mapsto \Psi_r(x)$ is Lipschitz uniformly in $r \in [0,T]$. The second term can be bounded in $L^q(\Omega)$ by using (14) and (16). □

Step 2. Let x be a vector arbitrary chosen outside $B(0,r)$. For any integer k define

$$\Omega_k = \cap_{n\geq k}\{w_n \in B(0,r)\} \cap \{w_{k-1} \notin B(0,r)\}$$

with the convention $w_1 = x$. Let $\Omega' = \cup_{k\in N}\Omega_k$. Because $CR(\overline{H}) \subset B(0,r)$ and $L(\{w_n\}_{n\geq 0}) \subset CR(\overline{H})$ almost surely (Theorem 1.2), we have $P(\Omega') = 1$.

Let $\{v_n^k\}_{n\geq k}$ be the sequence solution to (13) defined by the initial condition $v_k^k = w_k$. As $w_k \in L^q(\Omega)$, $v_k^k \in L^q(\Omega)$. Therefore, we deduce from Step 1 the existence of a vector $Z_k \in L^q(\Omega)$ such that

$$\lim_{n\to+\infty} (v_n^k - \Psi_{\tau_n}(Z_k)) = 0$$

almost surely. Define $Z = \sum_{k\in N} 1_{\Omega_k} Z_k$. Because $v_n^k = w_n$ on Ω_k for $n \geq k$, we have

$$\lim_{n\to+\infty} (w_n - \Phi_{\tau_n}(Z)) = 0$$

almost surely. □

8. An application to neural network learning. In this section we show briefly how the previous result can be applied to prove the consistency of some "hybrid" learning rules recently proposed in the neural network area.

A feedforward neural network can be seen as a function $G : I \times W \mapsto O$ mapping the Cartesian product of an *input space* I and a *weight space* W into an *output space* O. The dimension of I and O are the number of input units and the number of output units, respectively. Without loss of generality we take $O \subset \mathbf{R}$, $I \subset \mathbf{R}^{d-1}$, and $W \subset \mathbf{R}^m$. The function G embodies the network architecture. Given an input $x \in I$ and a weight vector $w \in W$, the network's output is given as $G(x, w)$. At this level of description, the form of G is not of particular importance. We only assume that G is smooth enough. For more details and an in-depth presentation of feedforward neural networks in the framework of approximation theory we refer the reader to the excellent book by Halbert White and co-workers (1992).

The goal of learning is to adapt the weight vector w in such a way that the network realizes some specific relationship between the input space and the output space. This relationship is generally expressed by an "environmental" probability law μ defined on $I \times O$. A "training set" is a sequence $\{\xi_n\}_{n\geq 0} \subset I \times O$ asymptotically stationary with μ as limiting law. We let $\xi_n = (x_n, y_n)$, x_n is referred to as the "input vector" and y_n is referred to as the "desired output" or "target." A general learning rule for feedforward net can be written as (1). The gain γ_n is called the "learning rate" in the connectionist jargon.

The most popular example is the classical "backpropagation algorithm." Given a pair of input and target $\xi = (x, y)$ and weight w, the network error is given as $Er(w, \xi) = e(G(x, w), y)$ where $e : \mathbf{R} \times \mathbf{R} \mapsto \mathbf{R}^+$ is a smooth "error function" (usually, $e(o, y) = (y - o)^2$). The algorithm is given by (1) with $H(w, \xi) = -\nabla_w Er(w, \xi)$. Here $\nabla_w Er(w, \xi)$ denotes the gradient of the map $w \mapsto Er(w, \xi)$. Therefore, assuming that interchange of derivative and expectation is possible, the ODE associated with the backpropagation is a gradient vectorfield:

$$\frac{dw}{dt} = -\nabla \overline{Er}(w), \tag{20}$$

where

$$\overline{Er}(w) = \int Er(w, \xi)\mu(d\xi).$$

Convergence of the backpropagation can be analyzed by using classical results on stochastic gradients (see, e.g., Nevel'son and Has'minskii (1974). See also Benveniste, Métivier, and Priouret (1990, p. 91) for a presentation of the backpropagation as a stochastic gradient). It is also a direct application of Corollary 3.3 restated here for convenience.

PROPOSITION 8.1. *Let* $\{w_n\}_{n\geq 0}$ *be the solution to* (1). *Assume that the assumptions of Proposition* 2.1 *or* 2.2 *hold with* $\overline{H}$ *given by* (20). *Assume that critical points of* $\overline{Er}$ (*i.e., the zeros of* (20)) *are isolated. Then* $\{w_n\}_{n\geq 0}$ *converges almost surely toward a critical point of* $\overline{Er}$.

"Hybrid" learning rules have been considered by Moody and Darken (1989), Poggio and Girosi (1990), Nowlan (1990), Benaim and Tomasini (1991, 1992), and Benaim (1995c) among others for neural architectures with "nonsigmoid" units. The main idea of these algorithms is to train each layer according to different learning rules.

Consider, for simplicity, a single hidden-layer network. (Extension to multilayers is easy.) Formally, $G(x, w) = G_2(G_1(x, w_1), w_2)$, where $w = (w_1, w_2) \in \mathbf{R}^{m_1} \times \mathbf{R}^{m_2}$,

$m_1 + m_2 = m$, $G_1 : \mathbf{R}^{d-1} \times \mathbf{R}^{m_1} \mapsto \mathbf{R}^k$, $G_2 : \mathbf{R}^k \times \mathbf{R}^{m_2} \mapsto \mathbf{R}$. The integer k is the number of hidden units, G_1 embodies the architecture of the (input-layer, hidden-layer) subnet and G_2 the architecture of the (hidden-layer, output-unit) subnet. The subnet G_1 is trained according to an "unsupervised" learning rule (for example, a data clustering algorithm (Moody and Darken (1989)) or a maximum likelihood algorithm (Nowlan (1990), Benaim and Tomasini (1992)), and the subnet G_2 is trained according to a "supervised" algorithm (backpropagation). This leads to an ODE of the form

$$\frac{dw_1}{dt} = -\nabla \overline{E_1}(w_1), \tag{21}$$

$$\frac{dw_2}{dt} = -\nabla_{w_2} \overline{E_2}(w_1, w_2) \tag{22}$$

for some smooth functions $E_1 : \mathbf{R}^{m_1} \mapsto \mathbf{R}$, $E_2 : \mathbf{R}^{m_1} \times \mathbf{R}^{m_2} \mapsto \mathbf{R}$. Remark that such an ODE is not a gradient vectorfield. It is a *cascade* of gradients.

It is often assumed that the output unit is linear: $G_2(G_1, w_2) = \langle w_2, G_1 \rangle$, and the performance of the subnet G_2 is measured by the squared error function, $e(o, y) = (y - o)^2$. In that case the equation (22) has the particular form

$$\frac{dw_2}{dt} = -A(w_1)w_2 + B(w_1), \tag{23}$$

where $A(w_1)$ is the $k \times k$ matrix defined by

$$A(w_1) = \int G_1(x, w_1).G_1(x, w_1)^T \nu(dx)$$

with $\nu(.) = \int \mu(., dy)$ and $B(w_1)$ is the k-dimensional vector

$$B(w_1) = \int y G_1(x, w_1) \mu(dx, dy).$$

PROPOSITION 8.2. *Let $\{w_n\}_{n \geq 0}$ be the solution to* (1). *Assume that assumptions of Proposition* 2.1 *or* 2.2 *hold with $\overline{H}$ given by the system* (21), (23). *Assume that equilibria of* (21) *are isolated. Then $L(\{w_n\}_{n \geq 0})$ is almost surely a connected compact subset of the equilibria set of $\overline{H}$.*

Proof. Write $w_n = (w_{1,n}, w_{2,n}) \in \mathbf{R}^{m_1} \times \mathbf{R}^{m_2}$. Proposition 8.1 shows that $\{w_{1,n}\}_{n \geq 0}$ converges almost surely toward an equilibrium of (21), say, ${w_1}^*$. Thus, $L(\{w_n\}_{n \geq 0}) = \{{w_1}^*\} \times L'$ for some set $L' \subset \mathbf{R}^{m_2}$. According to Proposition 2.1 (or 2.2), L' is compact and invariant under the dynamics

$$\frac{dw_2}{dt} = A({w_1}^*)w_2 - B({w_1}^*). \tag{24}$$

Since $A({w_1}^*)$ is a symmetric matrix, any compact invariant set for (24) is contained in the equilibria set of (24). This concludes the proof. □

For the more general system (21), (22), we shall use the fact that $L(\{w_n\}_{n \geq 0})$ is *internally* chain-recurrent combined with Proposition 3.2.

PROPOSITION 8.3. *Let $\{w_n\}_{n \geq 0}$ be a solution to* (1). *Assume that assumptions of Proposition* 2.1 *or* 2.2 *hold with $\overline{H}$ given by the system* (21), (22). *Assume that equilibria of* (21) *and $\overline{H}$ are isolated. Then, $L(\{w_n\}_{n \geq 0})$ is almost surely a equilibrium of $\overline{H}$.*

Proof. We begin exactly as in the proof of Proposition 8.2. Write $w_n = (w_{1,n}, w_{2,n}) \in \mathbf{R}^{m_1} \times \mathbf{R}^{m_2}$. Using Proposition 8.1 we see that $L(\{w_n\}_{n\geq 0}) = \{w_1{}^*\} \times L'$, where $w_1{}^*$ is an equilibrium of (21) and $L' \subset \mathbf{R}^{m_2}$ is a compact connected set invariant under the dynamics of

$$\frac{dw_2}{dt} = -\nabla \overline{E_2}(w_1^*, w_2). \tag{25}$$

Since $L(\{w_n\}_{n\geq 0})$ is *internally* chain-recurrent, every point of L' has to be chain-recurrent for the flow induced by (25). Since (25) is a gradient vectorfield with isolated equilibria, it follows from Proposition 3.2 that L' consists of equilibria. By connectedness, L' is an equilibrium of (25). □

9. Appendix.

Proof of Proposition 2.2. We denote by $\mathcal{F}_n^m$ the σ field generated by $\{\xi_i; n \leq i \leq m\}$ for $m \geq n \geq 0$ and let $\mathcal{F}_0^n = \{\emptyset, \Omega\}$ for $n < 0$.

DEFINITION 9.1. *Let $\{X_n\}_{n\geq 0}$ be a sequence of random variables belonging to $L^2(\Omega)$. $\{X_n\}_{n\geq 0}$ is said to be a mixingale process if there are sequences of finite nonnegative constants $\{c_n\}_{n\geq 0}$ and $\{\psi_m\}_{m\geq 0}$, where $\lim_{n\to\infty} \psi_m = 0$, such that for all $n \geq 1$ and $m \geq 0$*

- a) $\|E(X_n/\mathcal{F}_0^{n-m})\|_2 \leq c_n.\psi_m$,
- b) $\|X_n - E(X_n/\mathcal{F}_0^{n+m})\|_2 \leq c_n.\psi_{m+1}$.

Throughout this section we will only consider sequence of random variables $\{X_n\}_{n\geq 0}$ such that each X_n is measurable $\mathcal{F}_0^n$ so that condition b) holds automatically.

The following lemma relates the concept of mixing process to that of mixingale. It is due to McLeish (1975, Lem. 2.1).

LEMMA 9.2 (McLeish (1975)). *Suppose that $\{\xi_n\}_{n\geq 0}$ is a ϕ mixing (respectively, α mixing) process. Let $\{X_n\}_{n\geq 0}$ be a sequence of random variables such that each X_n is measurable $\mathcal{F}_0^n$ and $E(X_n) = 0$.*

Then, for $2 \leq r \leq +\infty$, $n, m \geq 0$,

- a) $\|E(X_n/\mathcal{F}_0^{n-m}\|_2 \leq 2\phi_m^{1-1/r}\|X_n\|_r$,
- b) $\|E(X_n/\mathcal{F}_0^{n-m}\|_2 \leq 2(1+\sqrt{2})\alpha_m^{1/2-1/r}\|X_n\|_r$.

REMARK. *It follows from this lemma that $\{X_n\}_{n\geq 0}$ is a mixingale with $c_n = \|X_n\|_r$ and $\psi_m = 2\phi_m^{1-1/r}$ in the ϕ mixing case or $\psi_m = 2(1+\sqrt{2})\alpha_m^{1/2-1/r}$ in the α mixing case.*

The following lemma is the main result of this section. The proof of the lemma follows closely the proof of McLeish's Theorem 1.6 (1975), but instead of using Doob's inequality for martingales (as McLeish does) we use the Burkholder inequality together with the ideas involved in the proof of Métivier and Priouret's Proposition 8 (1987). Note that for $q = 2$ the lemma is a direct consequence of McLeish's Theorem 1.6 (1975).

LEMMA 9.3. *Let $\{X_n\}_{n\geq 0}$ be a sequence of real random variables. Let $S_n = \sum_{k=0}^n \gamma_k.X_k$. We assume that*

- *X_n is measurable $\mathcal{F}_0^n$;*
- *$X_n \in L^q(\Omega)$ for some $q \geq 2$;*
- *$\{X_n\}_{n\geq 0}$ is a mixingale with sequences $\{c_n\}_{n\geq 0}$ and $\{\psi_m\}_{m\geq 0}$.*

We assume that there exists a positive decreasing sequence $\{a_n\}_{n\geq -1}$ such that

- $\sum_{k\geq 0} \psi_k^2(a_k^{-1} - a_{k-1}^{-1}) < +\infty$;
- $\sum_{k\geq 0} a_k^{1/(q-1)} < +\infty$.

Then

$$E\left(\sup_{m\le n} \mid S_m \mid^q\right) \le \tau_{n+1}^{q/2-1} D(q) \sum_{i=0}^{n} \gamma_i^{1+q/2} c_i^2 \| X_i^{q-2} \|_\infty,$$

where $D(q) > 0$ *is a constant.*

Proof. Let $Z_{i,k} = E(X_i/\mathcal{F}_0^{i-k}) - E(X_i/\mathcal{F}_0^{i-k-1})$ for $i \ge 0, k \ge 0$. Let $Y_{n,k} = \sum_{i=0}^{n} \gamma_i Z_{i,k}$. Since $E(X_i/\mathcal{F}_0^i) = X_i$ and $E(X_i/\mathcal{F}_0^{i-k}) = E(X_i) = 0$ for $k > i$, it is clear that

$$X_i = \sum_{k=0}^{i} Z_{i,k} = \sum_{k\ge 0} Z_{i,k}.$$

Thus $S_n = \sum_{k\ge 0} Y_{n,k}$ and by Hölder's inequality we have

$$\mid S_n \mid^q \le \sum_{k\ge 0} \frac{\mid Y_{n,k} \mid^q}{a_k} \left(\sum_{k\ge 0} a_k{}^l\right)^{1/l}, \tag{26}$$

where $l = \frac{1}{q-1}$.

Observe that $E(Z_{n,k}/\mathcal{F}_0^{n-k}) = 0$. So by Burkholder and Rosenthal's inequalities (Hall and Heyde (1980, Thms. 2.10–2.12)):

$$E\left(\sup_{m\le n} \mid Y_{m,k} \mid^q\right) \le C(q) E\left(\left(\sum_{i=0}^{n} \gamma_i^2 Z_{i,k}^2\right)^{q/2}\right). \tag{27}$$

Now, exactly as in Métivier and Priouret (1987), we shall apply the following form of Hölder's inequality:

$$\left(\sum_i \mid \alpha_i \beta_i \mid\right)^u \le \left(\sum_i \alpha_i^{\delta u/(u-1)}\right)^{u-1} \left(\sum_i \alpha_i^{(1-\delta)u} \mid \beta_i \mid^u\right) \tag{28}$$

for $\alpha_i \ge 0, \beta_i \in \mathbf{R}, u > 1, 0 < \delta < 1$.

Applying (28) to (27)) with $\alpha_i = \gamma_i^2, \beta_i = \mid Z_{i,k} \mid^2, u = \frac{q}{2}$, and $\delta = \frac{q-2}{2q}$ we obtain

$$E\left(\sup_{m\le n} \mid Y_{m,k} \mid^q\right) \le C(q) \tau_{n+1}^{(q/2-1)} \sum_{i=0}^{n} E(\mid Z_{i,k} \mid^q) \gamma_i^{1+q/2}, \tag{29}$$

and by using (26), we deduce

$$E\left(\sup_{m\le n} \mid S_m \mid^q\right) \le \sum_{k\ge 0} (a_k^l)^{1/l} C(q) \tau_{n+1}^{(q/2-1)} \sum_{k\ge 0} a_k^{-1} \sum_{i=0}^{n} E(\mid Z_{i,k} \mid^q) \gamma_i^{1+q/2}. \tag{30}$$

On the other hand we have

$$E(\mid Z_{i,k} \mid^q) \le \| Z_{i,k}^{q-2} \|_\infty E(\mid Z_{i,k} \mid^2),$$

and from the Pythagorean theorem in $L^2(\Omega)$,

$$E(\mid Z_{i,k} \mid^2) = \| E(X_i/\mathcal{F}_0^{i-k}) \|_2^2 - \| E(X_i/\mathcal{F}_0^{i-k-1}) \|_2^2.$$

It follows that

$$\sum_{k\geq 0} a_k^{-1} \sum_{i=0}^{n} E(|\, Z_{i,k}\,|^q)\gamma_i^{1+q/2} \leq$$

$$\sum_{k\geq 0} \psi_k^2(a_k^{-1} - a_{k-1}^{-1}).\sum_{i=0}^{n} \gamma_i^{1+q/2} c_i^2 \|X_i^{q-2}\|_\infty. \tag{31}$$

Putting together (30) and (31) and letting $D(q) = \sum_{k\geq 0}(a_k^l)^{1/l} C(q) \sum_{k\geq 0} \psi_k^2(a_k^{-1} - a_{k-1}^{-1})$ conclude the proof. □

From this lemma we shall deduce the following lemma, which is analogous to Corollary 11 of Métivier and Priouret (1987).

LEMMA 9.4. *Let* $\{X_n\}_{n\geq 0}$ *be as in Lemma* 9.3. *Then*

- a) *for all* $T \geq 0$,

$$E\left(\sup_{\tau_n\geq\tau_p}\left(\sup_{0\leq\tau_k-\tau_n\leq T}\left|\sum_{i=n}^{k-1}\gamma_i X_i\right|^q\right)\right) \leq T^{q/2-1} D(q) \sum_{i\geq p} \gamma_i^{1+q/2} c_i^2 \|X_i^{q-2}\|_\infty;$$

- b) *if* $\sum_{i\geq 0} \gamma_i^{1+q/2} c_i^2 \|X_i^{q-2}\|_\infty < +\infty$, *then*

$$\lim_{n\to\infty}\left(\sup_{\{0\leq\tau_k-\tau_n\leq T\}}\left|\sum_{i=n}^{k-1}\gamma_i X_i\right|\right) = 0$$

with probability one.

The proof is exactly the same as the proof of Corollary 11 in Métivier and Priouret (1987).

COROLLARY 9.5. *Suppose that* $\{\xi_n\}_{n\geq 0}$ *is a* ϕ *mixing (respectively,* α *mixing) process. Let* $\{X_n\}_{n\geq 0}$ *be a sequence of random variables such that*

- *each* X_n *is measurable* $\mathcal{F}_0^n$ *and* $E(X_n) = 0$;
- $\sup_n \|X_n\|_r < +\infty$ *for some* $r \in [0, +\infty]$;
- *if* $r < \infty$, $\phi_n = O(\frac{1}{n^\beta})$ *for some* $\beta > \frac{r}{2r-2}$ *(respectively,* $\alpha_n = O(\frac{1}{n^\beta})$ *for some* $\beta > \frac{r}{r-2}$*) and* $\sum_{n=0}^{\infty} \gamma_n^2 < +\infty$;
- *if* $r = \infty$, $\phi_n = O(\frac{1}{n^\beta})$ *for some* $\beta > \frac{1}{2}$ *(respectively,* $\alpha_n = O(\frac{1}{n^\beta})$ *for some* $\beta > 1$*) and* $\sum_{n=0}^{\infty} \gamma_n^{1+q/2} < +\infty$ *for some* $q \in [2, 2\beta + 1[$.

Then

- a) $\lim_{n\to\infty}(\sup_{k;\, 0\leq\tau_k-\tau_n\leq T} |\sum_{i=n}^{k-1} \gamma_i X_i\,|) = 0$;
- b) *there exists a constant* $D(q, r)$ *such that*

$$E\left(\sup_{k;\, 0\leq\tau_k-\tau_n\leq T}\left|\sum_{i=n}^{k-1}\gamma_i X_i\right|^q\right) \leq T^{q/2-1} D(q,r) \sum_{i=n}^{m(\tau_n+T)-1} \gamma_i^{1+q/2},$$

where $q = 2$ *for* $r < +\infty$ *and* $q \in [2, 2\beta + 1[$ *for* $r = +\infty$.

Proof. The proof follows from Lemma 9.2, the remark which follows Lemma 9.2, and Lemma 9.3 for part (a) and the Lemma 9.4 for part (b). □

We are now able to prove Proposition 2.2. Let $\{w_n\}_{n\geq 0}$ be a solution to (1). Let

$$u_n(w) = H(w, \xi_n) - E(H(w, \xi_n)),$$

$$u_n = u_n(w_n),$$

$$b_n(w) = E(H(w, \xi_n)) - \overline{H}(w),$$

$$b_n = b_n(w_n).$$

We suppose that conditions A1 to A6 of Proposition 2.2 hold. Let $K = \sup_n \|k(\xi_n)\|_r$. We remark that $\overline{H}$ is K Lipschitz. Indeed, for any x, y,

$$\|\overline{H}(x) - \overline{H}(y)\| = \lim_{n\to\infty} \|E(H(x, \xi_n) - H(y, \xi_n))\|$$

but

$$\|E(H(x, \xi_n) - H(y, \xi_n))\| \leq E(k(\xi_n))\|x - y\| \leq K\|x - y\|$$

by application of Jensen's inequality. Using the same kind of argument we see that

$$\|b_n(x) - b_n(y)\| \leq 2K\|x - y\|, \tag{32}$$

$$\|u_n(x) - u_n(y)\| \leq K\|x - y\| + k(\xi_n)\|x - y\|. \tag{33}$$

Let us now verify the conditions A1, A2, and A3 of Theorem 1.2. A1 is true by assumption (assumption A2 of Proposition 2.2). The inequality (33) shows that the sequence $\{b_n(.)\}_{n\geq 0}$ is equicontinuous, and assumption A3 of the Proposition 2.2 means that $\{b_n(w)\}_{n\geq 0}$ converges to zero for any $w \in \mathbf{R}^m$. It follows that $\{b_n(.)\}_{n\geq 0}$ converges to zero uniformly on any compact set of $\mathbf{R}^m$, and as $\{w_n\}_{n\geq 0}$ is assumed to be bounded, $\{b_n\}_{n\geq 0}$ converges to zero. This proves assumption A2 of Theorem 1.2.

We now check the condition A3 of Theorem 1.2. Let $T \geq 0$ and let

$$S_n^T(w) = \sup_{\{k,\ 0\leq \tau_k - \tau_n \leq T\}} \left| \sum_{i=n}^{k} \gamma_i u_i(w) \right|,$$

$$Z_n^T = \sup_{\{k,\ 0\leq \tau_k - \tau_n \leq T\}} \sum_{i=n}^{k} \gamma_i k(\xi_i).$$

From inequalities (32) and (33) it follows that for any $w, w' \in \mathbf{R}^d$

$$\left| \sum_{i=n}^{k} \gamma_i u_i(w) \right| \leq \left| \sum_{i=n}^{k} \gamma_i u_i(w') \right| + K|w - w'| \sum_{i=n}^{k} \gamma_i + |w - w'| \sum_{i=n}^{k} \gamma_i k(\xi_i).$$

Thus

$$0 \leq S_n^T(w) \leq S_n^T(w') + TK|w - w'| + Z_n^T|w - w'|. \tag{34}$$

Lemma 9.4(b) shows that under the assumptions A1 and A6, A6′ of Proposition 2.2, $\lim_{n\to\infty} Z_n^T = 0$ and $\lim_{n\to\infty} S_n^T(w) = 0$ for any $w \in \mathbf{R}^m$. From inequality (34) it is easy to see that $\{S_n^T(w)\}_{n\geq 0}$ converges to zero uniformly on any compact set of $\mathbf{R}^m$ so that $\lim_{n\to\infty} S_n^T(w_n) = 0$. □

Proof of Proposition 5.6. Let Q be a compact set. Let $\epsilon_n > 0$ such that $\lim_{n\to+\infty} \epsilon_n = 0$ and let $\{B(x_i, \epsilon_n)\}_{i\in I_n}$ be a finite cover of Q by balls of radius ϵ_n. From (34), we deduce

$$\sup_{w\in Q} S_n^T(w) \leq \sum_{i\in I_n} S_n^T(x_i) + KT\epsilon_n + \epsilon_n Z_n^T.$$

Therefore, Corollary 9.5(b) implies

$$\left\| \sup_{w\in Q} S_n^T(w) \right\|_q \leq (A.\#(I_n) + B\epsilon_n) \left(\sum_{i=n}^{m(\tau_n+T)-1} \gamma_i^{1+q/2} \right)^{1/q} + KT\epsilon_n \tag{35}$$

for some constants A and B depending on $Q, q, T, \overline{H}$, and $\#(I_n)$ denotes the cardinal of I_n.

Since Q is a compact subset of $\mathbf{R}^m$, the family $\{x_i\}_{i\geq 0}$ can be chosen such that $\#(I_n) \leq C.\epsilon_n^{-m}$ for some $C > 0$. Noting that

$$\sum_{i=n}^{m(\tau_n+T)-1} \gamma_i^{1+q/2} \leq T\gamma_n^{q/2},$$

inequality (35) gives

$$\left\| \sup_{w\in Q} S_n^T(w) \right\|_q \leq (A.C.\epsilon_n^{-m} + B\epsilon_n)T\gamma_n^{q/2} + KT\epsilon_n.$$

Therefore, with α_q^T as defined in §5,

$$\begin{aligned} l_\tau(\alpha^{q,T}) &\leq \sup\left(\frac{1}{2}l_\tau(\gamma) - ml_\tau(\epsilon), l_\tau(\epsilon), \frac{1}{2}l_\tau(\gamma) + l_\tau(\epsilon)\right) \\ &\leq \sup\left(\frac{1}{2}l_\tau(\gamma) - ml_\tau(\epsilon), l_\tau(\epsilon)\right). \end{aligned} \tag{36}$$

Now we choose a sequence $\{\epsilon_n\}_{n\geq 0}$ such that

$$l_\tau(\epsilon) = \min_{\{l<0\}} \sup\left(l, \frac{1}{2}l_\tau(\gamma) - ml\right).$$

This easily gives

$$l_\tau(\epsilon) = \frac{l_\tau(\gamma)}{2(1+m)}.$$

For example, one may choose $\epsilon_n = \gamma_n^{1/(2+2m)}$.

Acknowledgment. I am particulary grateful to Morris W. Hirsch for many comments and fruitful discussions on the topics in this paper. A large part of this work makes a crucial use of some of his ideas and results on "shadowing."

NONLINEAR BOUNDARY CONTROL OF SEMILINEAR PARABOLIC SYSTEMS*

N. U. AHMED† AND X. XIANG‡

Abstract. Nonlinear boundary control problems for a class of semilinear parabolic systems are considered, from the point of view of semigroup theory. The method is based on some recent general results on parabolic evolution equations with nonlinear boundary conditions. Existence of optimal (boundary) controls is proved using the theory of measurable selections and the Cesari property for multifunctions. Three results are presented covering relaxed controls and controls with state constraints. This generalizes, in a substantial way, existing results on linear boundary control problems [M.C. Delfour and M. Sorine, *Control of Distributed Parameter Systems*, Pergamon Press, Oxford, 1983, pp. 87–90], [I. Lasiecka, *Appl. Math. Optim.*, 6 (1980), pp. 287–383], [P. Acquistapace, et al., *SIAM J. Control Optim.*, 29 (1991), pp. 89–118]. The result presented can be further extended to differential inclusions. Two examples are presented for illustration.

Key words. semilinear parabolic system, nonlinear boundary controls, optimal control, existence, multifunctions, measurable selections

AMS subject classifications. 49A, 49B, 34H, 35K

Introduction. Boundary control of systems governed by partial differential equations is one of the most important problems in control theory; see [1]–[7], [11]. In the case of parabolic equations, both variational and semigroup methods have been successfully applied (see, for instance, [4]–[7]). Most of these papers deal with linear quadratic regulator problems for autonomous and nonautonomous linear parabolic equations giving feedback controls via the associated Riccati equations.

This paper is concerned with the question of the existence of optimal boundary controls for semilinear problems with nonlinear boundary operators containing controls. For motivation we present Example 2 (see §3) arising in steel manufacturing, where specific power nonlinearities appear in the boundary data. Nonlinear boundary control problems are difficult, in general. To the best of the authors' knowledge, nonlinear boundary control problems in this very general setting have not been widely considered in the literature. Some results in this direction are available in [11], where both identification and relaxed control problems have been considered using different techniques. Here we prove the existence of optimal boundary controls using selection theorems for measurable multifunctions by following an approach similar to that in [2], [12]. In the case of nonlinear problems, the classical technique based on lower semicontinuity and compactness arguments does not apply unless restrictive assumptions are imposed on the nonlinear boundary operator, such as control linearity or weak continuity. In fact for nonlinear problems, weak compactness of solution trajectories, compact embeddings, and selection arguments have become the standard tools (see [2], [12], [16], [17]). In contrast for linear problems with quadratic cost, existence results and necessary conditions of optimality can be obtained simultaneously and relatively easily through the study of Riccati equations [5]–[7]. For nonlinear problems also, existence of optimal feedback controls and necessary conditions of optimality can

be obtained provided viscosity solutions of the associated Hamilton–Jacobi–Bellman equation on infinite-dimensional spaces are better understood. This is a very difficult problem and not well developed as yet.

In §1, using some recent results of Amann [8], we derive a representation formula for the solution of abstract semilinear evolution equations with nonlinear boundary operators containing controls. Since the notation of Amann [8] is rather involved, we review only some relevant results for the convenience of our readers. Section 2 is devoted to the question of the existence of optimal boundary controls, which is the main concern of this paper. Here we present three existence results: Theorem 2.1 for ordinary controls, Theorem 2.2 for controls with state constraints, and Theorem 2.3 for relaxed controls. We give a complete proof of the first result. In the last section, we first present an example of a system of second-order semilinear parabolic equations with nonlinear boundary controls illustrating the applicability of our results. Then we present a practical example that arises in steel manufacturing.

1. Abstract parabolic systems with nonlinear boundary controls. In this section, we study a class of abstract evolution equations corresponding to semilinear parabolic systems with nonlinear boundary operators containing controls. Based on the results of Amann [8], we establish a representation formula for the solutions which is useful from the point of view of control theory.

Throughout this paper all vector spaces are assumed over the complex field.

Let X and Y be locally convex Hausdorff topological vector spaces. We denote by X' the dual of X endowed with the strong topology and by $\langle \bullet, \bullet \rangle_X : X' \times X \to C$, the corresponding duality pairing. Observe that $\langle u, v \rangle_X = \langle v, u \rangle_{X'}$ if X is reflexive.

We write $X \hookrightarrow Y (X \hookrightarrow\hookrightarrow Y)$ to denote continuous (dense, compact) embeddings.

If $X \hookrightarrow Y$ and $B : D(B) \subset Y \to Y$ is a linear operator in Y, we define the X-realization B_X of B to be the linear operator in X given by

$$D(B_X) = \{x \in D(B) \cap X, Bx \in X\}, \quad B_X x = Bx, \text{ for } x \in D(B_X).$$

In general we denote by $\mathcal{L}(X, Y)$ the vector space of all continuous linear operators from X to Y. Moreover $\mathcal{L}(X) = \mathcal{L}(X, X)$ and $\mathcal{L}(X, Y)$ are given the usual norm topologies if X and Y are normed vector spaces. Further, $\mathcal{L}^2(X \times Y, C)$ denotes the class of complex-valued bilinear forms on $X \times Y$.

We use the notation of Amann [8]. Suppose $W, W^1, W_\#, W^1_\#$ are Banach spaces. W is reflexive, $W_\# = W'$. ∂W, ∂W^1, $\partial_1 W^1$ as well as $\partial W_\#$, $\partial W^1_\#$, $\partial_1 W^1_\#$ are reflexive Banach spaces such that $\partial W_\# = (\partial W)'$. The topological vector spaces mentioned above satisfy the assumptions (A_1)–(A_4) of Amann [8] (see also [1, pp. 206–209]). Formally the system is governed by the following semilinear initial boundary value problem:

$$\begin{aligned} \dot{x} + \mathcal{A}(t)x &= f(t, x), \\ \mathcal{B}(t)x &= g(t, x, u), \quad 0 \le t \le T \equiv I, \\ x(0) &= x_0, \end{aligned} \tag{1.1}$$

where x denotes the state and u denotes the control to be defined precisely later. The basic assumptions are as follows.

The spatial operator and its formal adjoint satisfy the following assumption.

Assumption A_1.

$$\begin{aligned} &\mathcal{A}(\bullet) \in C([0, T], \mathcal{L}(W^1, W)), \\ &\mathcal{A}^\#(\bullet) \in C([0, T], \mathcal{L}(W^1_\#, W_\#)). \end{aligned} \tag{1.2}$$

The boundary operator $\mathcal{B}(.)$ along with its complimentary counterpart $\ell(.)$, as defined below, and the corresponding duals satisfy the following basic assumptions.

Assumption B_1.

$$\begin{aligned} &\mathcal{T}(\bullet) \equiv (\mathcal{B}(\bullet), \ell(\bullet)) \in C([0,T], \mathcal{L}(W^1, \partial W^1 \times \partial_1 W^1)), \\ &\mathcal{T}^{\#}(\bullet) = (\mathcal{B}^{\#}(\bullet), \ell^{\#}(\bullet)) \in C([0,T], \mathcal{L}(W^1_{\#}, \partial W^1_{\#} \times \partial_1 W^1_{\#})). \end{aligned} \tag{1.3}$$

The operators $\mathcal{T}(\bullet), \mathcal{T}^{\#}(\bullet)$ are retractions such that the following Green's formula holds for all $u \in W^1, v \in W^1_{\#}$:

$$\langle v, \mathcal{A}(t)u\rangle + \langle \ell^{\#}(t)v, \mathcal{B}(t)u\rangle_{\partial} = \langle \mathcal{A}^{\#}(t)v, u\rangle + \langle \mathcal{B}^{\#}(t)v, \ell(t)u\rangle_{\partial'}, \quad t \geq 0. \tag{1.4}$$

Define

$$\begin{aligned} &\mathring{W}^1 \equiv \operatorname{Ker}(\mathcal{T}) \quad \text{and} \quad \mathring{W}^1_{\#} \equiv \operatorname{Ker}(\mathcal{T}^{\#}), \\ &W^1_{\mathcal{B}} \equiv \operatorname{Ker}(\mathcal{B}) \quad \text{and} \quad W^1_{\#\mathcal{B}^{\#}} \equiv \operatorname{Ker}(\mathcal{B}^{\#}). \end{aligned} \tag{1.5}$$

Introduce the operators

$$A(t) = \mathcal{A}(t)|_{W^1_{\mathcal{B}}} \quad \text{and} \quad A^{\#}(t) = \mathcal{A}^{\#}(t)|_{W^1_{\#\mathcal{B}^{\#}}} \tag{1.6}$$

and consider these as (unbounded) linear operators in W and $W^{\#}$, respectively. We assume that these operators satisfy all the Assumptions AP1–AP3 of Amann [8, §11].

We present some of the relevant assumptions of Amann.

Assumption A_2. $A(t), t \in I$, is a family of closed and densely defined linear operators in $E = W$ such that there exist constants M_0 and $\sigma \in R$ with $\rho(-A(t)) \supset \sigma + \Sigma_0$, and $\|(\lambda + A(t))^{-1}\| \leq M_0/(1+|\lambda|)$. It is well known that (see [3]) under this assumption, for each fixed $t \geq 0$, $A(t)$ is the infinitesimal generator of an analytic semigroup on E.

In the following we let

$$\|x\|_{k,t} = \|A^k(t)x\|, \quad x \in D(A^k(t)), \quad k \in Z,$$

and define $E_k(t) = (D(A^k(t)), \|\bullet\|_{k,t})$ if $k \geq 0, E \equiv E_0$, and let $E_k(t)$ be the completion of $(E, \| \bullet \|_{k,t})$ if $k < 0$. Moreover we denote by $A_k(t)$ the $E_k(t)$-realization of $A(t)$ if $k \geq 0$, and the closed extension of $A(t)$ in E_k if $k < 0$. Finally we let $E_\alpha(t) = (E_k(t), E_{k+1}(t))_{\alpha-k}$, $k < \alpha < k+1$, $k \in Z$, where $(\bullet, \bullet)_{\alpha-k}$ are standard interpolation functors (see [1]).

We denote by $A_\alpha(t)$ the $E_\alpha(t)$-realization of $A_k(t)$ for $k < \alpha < k+1$ and $k \in Z$.

For uniform notation we set

$$W^{\alpha}_{\mathcal{B}(t)} = E_\alpha(t), \quad W^{\alpha}_{\#\mathcal{B}^{\#}(t)} = E^{\#}_\alpha(t), \quad \alpha \in R, \ t \in I.$$

Assumption A_3. There exists $\beta \in [0,1]$ such that

$$E_\beta(t) = E_\beta(0) = E_\beta, \quad E_{\beta-1}(t) = E_{\beta-1}.$$

Assumption A_4. There exist $\rho \in (0,1)$ and

$$a(\bullet) \in C^\rho([0,T], \mathcal{L}^2(E^{\#}_{1-\beta} \times E_\beta, C)), \quad \beta \in [0,1],$$

such that

$$a(t)(v,u) = \langle v, A(t)u\rangle, \quad (u,v) \in E_\beta(t) \times E^{\#}_{1-\beta}(t). \tag{1.7}$$

Observe that $E^{\#}_{1-\beta} = E^{\#}_{1-\beta}(t)$ is independent of t for $\beta \in [0,1]$ since $E^{\#}_{1-\beta} = (E_{\beta-1})'$ (see Theorem 8.1 of [8]). Also, we assume that $a(\bullet)$ is independent of $\beta \in [0,1]$ (in an obvious sense). The assumptions above imply, in particular, that the following condition is also satisfied independently of $t \geq 0$.

Assumption A_5. There exists $\sigma \in C$ such that $\sigma \in \rho(-A) \cap \rho(-A^{\#})$, where $\rho(\bullet)$ denotes the resolvent set.

It follows from Theorem 6.3 of [8] that, for $0 \leq \theta \leq 1$, the Dirichlet map $R_\theta(\bullet)$ has the following regularity property:

$$R_\theta(\bullet) \equiv (\sigma + \mathcal{A}(\bullet), \mathcal{B}(\bullet))^{-1}|_{\{0\}\times\partial W^{-1+2\theta}} \in C([0,T], \mathcal{L}(\partial W^{-1+2\theta}, W^\theta)). \tag{1.8}$$

Further it is clear that $R_\alpha(t) = R_\beta(t)|_{\partial W^{-1+2\alpha}}$, $\beta < \alpha \leq 1$, where $\partial W^{-1+2\theta} = (\partial W^{-1}, \partial W^1)_\theta$, $0 \leq \theta \leq 1$. We now fix for each $\theta \in [0,1]$ a closed linear subspace $\partial_0 W^{-1+2\theta}$ of $\partial W^{-1+2\theta}$ such that $\partial_0 W^{-1+2\alpha} \subset \partial_0 W^{-1+2\beta}$, for $\alpha > \beta$, and that $R_\beta(t)(\partial_0 W^{-1+2\beta}) \subset W^\beta_{\mathcal{B}}$, for $t \in I$.

Assumption B_2. $[(y,z) \to \langle \ell^{\#}(t)y, z\rangle_\partial] \in \mathcal{L}^2(W^{1-\beta}_{\#\mathcal{B}^\#} \times \partial_0 W^{-1+2\beta}, C)$ for each $\beta \in [0,1]$ and $t \in I$.

Assumption F_1. For $0 \leq \beta < \alpha \leq 1$, $f \in C^{0,1-}([0,T] \times W^\beta_{\mathcal{B}}, W^{\alpha-1}_{\mathcal{B}})$.

Assumption G_1. The control space U is a Banach space and

$$g(\bullet,\bullet,\bullet) : [0,T] \times W^\beta_{\mathcal{B}} \times U \to \partial_0 W^{-1+2\alpha}$$

is a map so that, for each $u \in U$,

$$g(\bullet,\bullet,u) \in C^{0,1-}([0,T] \times W^\beta_{\mathcal{B}}, \partial_0 W^{-1+2\alpha}).$$

We consider, for each $x_0 \in W^\beta_{\mathcal{B}}$ and $u \in L_\infty([0,T], U)$, the state equation given by the abstract semilinear initial boundary value problem

$$\begin{aligned} \dot{x} + \mathcal{A}(t)x &= f(t,x), \\ \mathcal{B}(t)x &= g(t,x,u), \quad t \in I, \\ x(0) &= x_0. \end{aligned} \tag{1.9}$$

By a solution x of (1.9) on $I \equiv [0,T]$ we mean a function $x \in C([0,T], W^\beta_{\mathcal{B}})$ such that

$$\begin{aligned} &\int_0^{T'} \{-\langle \dot{\varphi}, x\rangle + a(t)(\varphi, x)\}dt \\ &\quad = \int_0^{T'} \{-\langle \varphi, f(t,x)\rangle + \langle \ell^{\#}(t)(\varphi), g(t,x,u)\rangle_\partial\}dt + \langle \varphi(0), x_0\rangle \end{aligned} \tag{1.10}$$

for every $T' \in (0,T]$ and every $\varphi \in C([0,T'], W^{1-\beta}_{\#\mathcal{B}^\#}) \cap C^1([0,T'], W^{-\beta}_{\#\mathcal{B}^\#})$ satisfying $\varphi(T') = 0$.

LEMMA 1.1 (For proof see Theorems 9.1 and 12.1 of [8]). *Suppose $\mathcal{A}, \mathcal{B}, f, g$ satisfy all the assumptions stated above.*

(a) *Then, for each fixed* $u \in U$, *the mapping* $F^u_{\beta-1}$, *defined by*

$$F^u_{\beta-1}(\bullet,\bullet) = f(\bullet,\bullet) + (\sigma + A_{\beta-1}(\bullet))R_\beta(\bullet)g(\bullet,\bullet,u), \tag{1.11}$$

has the regularity property: $F^u_{\beta-1}(\bullet,\bullet) \in C^{0,1-}([0,T] \times W^\beta_{\mathcal{B}}, W^{\alpha-1}_{\mathcal{B}})$.

(b) *There exists a unique parabolic fundamental solution* $U_{\beta-1}$ *on* $E_{\beta-1}$ *for* $\{A_{\beta-1}(t): t \in I\}$ *and it possesses* E_β *as regularity subspace.*

(c) *For each* $u \in L_\infty([0,T],U)$, *an element* $x \in C([0,T],W^\beta_{\mathcal{B}})$ *is a* $W^\beta_{\mathcal{B}}$*-weak solution of* (1.9) *on* I *iff* x *is a solution of the following integral equation:*

$$x(t) = U_{\beta-1}(t,0)x_0 + \int_0^t U_{\beta-1}(t,\tau)F^u_{\beta-1}(\tau,x(\tau))d\tau \tag{1.12}$$

in $C([0,T],W^\beta_{\mathcal{B}})$.

The next theorem gives a useful sufficient condition that guarantees the existence of a solution of the state equation (1.9).

THEOREM 1.2 (For proof see Theorem 12.1 and Proposition 12.6 of [8]). *Suppose the assumptions of Lemma* 1.1 *hold and further there exists a constant* $C > 0$, *possibly dependent on* u, *such that* f *and* g *satisfy the following growth condition:*

$$\|f(t,y)\|_{W^{\alpha-1}_{\mathcal{B}}} + \|g(t,y,u)\|_{\partial W^{-1+2\alpha}} \leq C(1 + \|y\|_{W^\beta_{\mathcal{B}}}) \tag{1.13}$$

for all $(t,y) \in$ *graph* $x(\bullet,x_0,u)$, *which is the maximal solution of* (1.9). *Then* $x(\bullet,x_0,u)$ *is a global solution.*

2. Existence of optimal boundary controls. In this section we are concerned with the boundary control problem for the semilinear abstract evolution equation (1.9). Since our approach is based on the properties of multifunctions, we present below some basic definitions and facts. Let $\mathcal{Z}$ be any locally convex topological vector space and let $c(\mathcal{Z})$, $(cc(\mathcal{Z})$, $cbc(\mathcal{Z})$, $wkc(\mathcal{Z}))$ denote the class of nonempty closed (closed convex, closed bounded convex, weakly compact convex) subsets of $\mathcal{Z}$. A multifunction F mapping a Hausdorff topological space X to $c(Y)$, Y any locally convex topological vector space, is said to be upper (lower) semicontinuous with respect to inclusion if for every $x_0 \in X$ and every open set $V \subset Y$ satisfying $[F(x_0) \subset V]$ $(V \cap F(x_0) \neq \emptyset)$, there exists an open set $U \subset X$ containing x_0 such that $[F(x) \subset V]$ $(F(x) \cap V \neq \emptyset)$ for all $x \in U$. If Y is a metric space with metric d, then one can introduce a metric d_H, called the Hausdorff metric, on $c(Y)$ as follows:

$$d_H(C,D) \equiv \mathrm{Max}\{\mathrm{Sup}_{y\in D}d(C,y), \mathrm{Sup}_{z\in C}d(z,D)\}$$

for $C, D \in c(Y)$. If (Y,d) is complete, then so is $(c(Y),d_H)$. $F : X \mapsto c(Y)$ is said to be continuous in the Hausdorff metric if, whenever $x_n \longrightarrow x$ in the topology of X,

$$\mathrm{Lim}_{n\to\infty}d_H(F(x_n),F(x)) = 0.$$

It is said to be quasi upper semicontinuous if for each $x \in X$

$$d^*(F(x_n),F(x)) \equiv \mathrm{Sup}\{d(y,F(x)), y \in F(x_n)\} \longrightarrow 0,$$

whenever $x_n \longrightarrow x$. In [10] quasi upper semicontinuity is called mild upper semicontinuity. More precisely, if Y is a metric space the two notions are equivalent. For different types of continuity, see [2], [10], [12].

Now, we introduce the class of admissible controls. Let U be a Banach space and let $wkc(U)$ denote the class of nonempty weakly compact convex subsets of U.

Assumption U1. (a) U is a separable Banach space; (b) $V : I \to wkc(U)$ is an integrably bounded measurable multifunction, and

$$\mathcal{U}_{\text{ad}} = \{u : [0,T] \longrightarrow U \text{ weakly (strongly) measurable such that } u(t) \in V(t) \text{ a.e.}\}$$

We consider the following optimal (boundary) control problem which we shall denote by (P):

Minimize

$$J(u) = \int_0^T L(t, x(t), u(t))dt \tag{2.1}$$

over all controls $u \in \mathcal{U}_{\text{ad}}$ subject to the evolution equation (1.9).

We introduce the following assumptions for the function L.

Assumption L. $L : [0,T] \times E_\beta \times U \to R_\infty = R \cup \{+\infty\}$ be a mapping satisfying

(1) $(t,e,u) \to L(t,e,u)$ is Borel measurable,

(2) $(e,u) \to L(t,e,u)$ is lower semicontinuous for each $t \in I = [0,T]$,

(3) $u \to L(t,e,u)$ is convex for all $(t,e) \in I \times E_\beta$,

(4) $\varphi(t) - \lambda(\|e\|_{E_\beta} + \|u\|_U) \leq L(t,e,u)$ a.e. with $\varphi \in L_1(I), \lambda \geq 0$.

Now we are prepared to deal with the question of existence of optimal controls for the problem (P). The following theorem is our main result.

THEOREM 2.1. *Suppose the hypotheses on $\mathcal{A}, \mathcal{B}, f, g, L$, and* U1 *hold, $A^{-1}(t)$ is compact for each $t \in I$, $x_0 \in E_\alpha$, and $g : I \times E_\beta \times U \longrightarrow \partial W^{-1+2\alpha}$ is measurable in the first variable continuous with respect to the last two variables. Suppose also that the multifunction G given by $G(t,z) \equiv g(t,z,V(t))$ maps $I \times E_\beta$ to $cc(\partial_0 W^{-1+2\alpha})$. Then there exists an optimal control $u_0 \in \mathcal{U}_{\text{ad}}$ for problem* (P).

Proof. Note that by virtue of Assumptions U1 and L(4), $J(u) > -\infty$. Let $x(u)$ denote the solution of the initial boundary value problem (1.9) corresponding to an admissible control u and $\mathcal{X} \equiv \{x(u), u \in \mathcal{U}_{\text{ad}}\}$ denote the family of attainable trajectories of the corresponding control system. Define

$$\Xi \equiv \{(u,x) \in \mathcal{U}_{\text{ad}} \times C(I, E_\beta) : x = x(u)\}. \tag{2.2}$$

For $(u,x) \in \Xi$, define $\eta(u,x) \equiv J(u)$. Let $\{u_n, x_n\} \subset \Xi$ be a minimizing sequence, that is, $\lim_{n\to\infty} \eta(u_n, x_n) = m = \inf\{\eta(u,x) : (u,x) \in \Xi\}$.

We show that, through a subsequence if necessary, x_n converges to x^* and that there exists a control $u^* \in \mathcal{U}_{\text{ad}}$ such that $x^* = x(u^*)$ and that $\eta(u^*, x^*) = m$. With this in mind, first we show that the sequence $\{x_n\}$ is compact in $C([0,T], E_\beta)$. Theorem 1.2 shows that for every $u \in L_\infty([0,T], U)$, the controlled system (1.9) has at least one solution $x(\bullet, u) \in C([0,T], E_\beta)$. By virtue of Theorem 8.1 of [8] and a generalized version of the Gronwall inequality, we can prove that

$$\|x(\bullet, u)\|_{C([0,T],E_\beta)} \leq b < \infty,$$

where b is a constant dependent only on $\|x_0\|_{E_\beta}$ and $\|u\|_{L_\infty([0,T],U)}$. Thus it follows from growth condition (1.13), and Assumption U1, that there exists a constant $\tilde{b}$ such that

$$\text{Sup}\{\|x\|_{C([0,T],E_\beta)}, x \in \mathcal{X}\} \leq \tilde{b} < \infty.$$

In other words, the solution set $\mathcal{X}$ is a bounded subset of $C(I, E_\beta)$.

Take γ such that $\beta < \gamma < \alpha < 1 + \gamma$. Let $x_n \equiv x(u_n)$ be any solution of the following integral equation:

$$x_n(t) = U_{\beta-1}(t,0)x_0 + \int_0^t U_{\beta-1}(t,\tau)F_{\beta-1}^{u_n}(\tau, x_n(\tau))d\tau \tag{2.3}$$

in $C([0,T], E_\beta)$. Using the growth assumption on f, g as stated in Theorem 1.2, it follows from Theorem 8.1 of [8] that

$$\begin{aligned}
\|x_n(t)\|_{E_\gamma} &\le \|U_{\beta-1}(t,0)x_0\|_{E_\gamma} + \int_0^t \|U_{\beta-1}(t,s)F_{\beta-1}^{u_n}(s,x_n(s))\|_{E_\gamma} ds \\
&\le \|U_{\beta-1}(t,0)x_0\|_{E_\gamma} + C_1 \int_0^t (t-s)^{\alpha-1-\gamma} \|F_{\beta-1}^{u_n}(s,x_n(s))\|_{E_{\alpha-1}} ds \\
&\le C_2 e^{\sigma t}\|x_0\|_{E_\alpha} + C_3 \int_0^t (t-s)^{\alpha-1-\gamma}[1 + \|x_n(s)\|_{E_\beta}]ds \\
&\le C_4\|x_0\|_{E_\alpha} + C_5 \int_0^t (t-s)^{\alpha-1-\gamma}[1 + \|x_n(s)\|_{E_\gamma}]ds,
\end{aligned}$$

where C_1, C_2, C_3, C_4, C_5 are suitable constants depending only on $(\alpha, \beta, \gamma, \sigma, T, M_0, \mathcal{U}_{\text{ad}})$. Then it follows from a slight generalization of the Gronwall inequality that there exists a constant M^* such that

$$\|x_n(t)\|_{E_\gamma} \le M^*, \quad t \in [0,T],$$

for all positive integers n. Thus the set $\{x_n\}$ is bounded in $C([0,T], E_\gamma)$.

Further, for $0 \le t_2 < t_1 \le T$, we have

$$\begin{aligned}
\| x_n(t_1) - x_n(t_2) \|_{E_\beta} \le & \| (U_{\beta-1}(t_1,0) - U_{\beta-1}(t_2,0))x_0 \|_{E_\beta} \\
&+ \int_{t_2}^{t_1} \| U_{\beta-1}(t_1,s)F_{\beta-1}^{u_n}(s,x_n(s)) \|_{E_\beta} ds \\
&+ \int_0^{t_2} \| (U_{\beta-1}(t_1,s) - U_{\beta-1}(t_2,s))F_{\beta-1}^{u_n}(s,x_n(s)) \|_{E_\beta} ds \\
&\le C_6(t_1-t_2)^\sigma + C_7(t_1-t_2)^\sigma + C_8(t_1-t_2)^\delta,
\end{aligned}$$

where $0 < \sigma < \alpha - \beta, 0 < \delta \le \gamma - \beta$. The constant C_6 depends on M_0 and $\| x_0 \|_{E_\alpha}$, and the constants C_7 and C_8 depend on M_0 and ess-sup$\{\|F_{\beta-1}^{u_n}(s,x_n(s))\|_{\alpha-1}, s \in [0,T], n \in N\}$. From this one can easily verify that there exists a constant C_9 such that

$$\|x_n(t_1) - x_n(t_2)\|_{E_\beta} \le C_9(t_1-t_2)^\delta.$$

Since $E_\gamma \hookrightarrow\hookrightarrow E_\beta$ (that is, the injection is compact), for each $t \in I$, the set $X(t) \equiv \{x_n(t), n \in N\}$ is a compact subset of E_β. Summarizing, the family $\{x_n\}$ is a bounded and equicontinuous subset of $C(I, E_\beta)$ with each t-section, $X(t)$, being compact. Thus it follows from the Ascoli–Arzela theorem that the sequence $\{x_n\}$ is compact in $C([0,T], E_\beta)$. Therefore, there exists a convergent subsequence, relabeled $\{x_n\}$, and an $x^* \in C(I, E_\beta)$ such that $x_n \to x^*$ in $C([0,T], E_\beta)$. Denote by $\{h_n(\bullet)\}$ the corresponding sequence $\{g(\bullet, x_n(\bullet), u_n(\bullet))\}$. By virtue of the growth condition (see Theorem 1.2) and the boundedness of the sequence $\{x_n\}$ it follows that the sequence

$\{h_n\}$ is contained in a bounded subset of $L_\infty(I, \partial_0 W^{-1+2\alpha}) \subset L_p(I, \partial_0 W^{-1+2\beta})$ for any $p \geq 1$. Since for $1 < p < \infty$, $L_p(I, \partial_0 W^{-1+2\alpha})$ is a closed subspace of a reflexive Banach space, there exists a subsequence of $\{h_n\}$, relabeled $\{h_n\}$, and an element $h^* \in L_p(I, \partial_0 W^{-1+2\alpha})$ such that $h_n \xrightarrow{w} h^*$ in $L_p(I, \partial_0 W^{-1+2\alpha})$.

By the definition of E_β-weak solution, for all $t \in I$ and every $\varphi \in C([0,T), W^{1-\beta}_{\#\mathcal{B}^\#}) \cap C^1([0,T'], W^{\beta}_{\#\mathcal{B}^\#})$ satisfying $\varphi(T') = 0$, we have

$$\int_0^{T'} \{-\langle \varphi, x_n \rangle + a(t)\langle \varphi, x_n \rangle\} dt = \int_0^{T'} \{\langle \varphi, f(t, x_n) \rangle + \langle \ell^\#(t)\varphi, h_n(t) \rangle_\partial\} dt + \langle \varphi(0), x_0 \rangle.$$

Letting $n \to \infty$, through a subsequence if necessary, it follows from the facts that $x_n \xrightarrow{s} x^*$ in $C([0,T], E_\beta)$, the bilinear functional a is continuous, continuity of $x \longrightarrow f(t,x)$, and weak convergence of $\{h_n\}$ to h^* that

$$\int_0^{T'} \{-\langle \varphi, x^* \rangle + a(t)\langle \varphi, x^* \rangle\} dt = \int_0^{T'} \{\langle \varphi, f(t, x^*) \rangle + \langle \ell^\#(t)\varphi, h^*(t) \rangle_\partial\} dt + \langle \varphi(0), x_0 \rangle. \tag{2.4}$$

This implies that x^* is a weak solution of (1.9) with the boundary data g replaced by h^*. We must show that there exists an admissible control u^* such that $h^*(t) = g(t, x^*(t), u^*(t))$ a.e. and that $\eta(u^*, x^*) = m$. In view of this we note that by Mazur's theorem there exists a finite convex combination of $\{h_n\}$ that converges strongly to h^* in $L_p(I, \partial_0 W^{-1+2\alpha})$. In particular, for each integer k, there exists an integer n_k, a set of integers $\{i = 1, 2, \ldots, m(k)\}$, and $\{\alpha_{k,i} \geq 0, i = 1, 2, \ldots, m(k)\}$ such that

$$\begin{aligned} &\sum_{i=1}^{m(k)} \alpha_{k,i} = 1, \quad \text{for all integers } k, \\ &g_k(t) \equiv \sum_{i=1}^{m(k)} \alpha_{k,i}\, h_{n_k+i}(t), \quad t \in I, \end{aligned} \tag{2.5}$$

and

$$g_k \xrightarrow{s} h^* \text{ in } L_p(I, \partial_0 W^{-1+2\alpha}). \tag{2.6}$$

Corresponding to the above sequence, define the sequence $\{\ell_k\}$ as follows

$$\begin{aligned} &L_{n_k+i}(t) \equiv L(t, x_{n_k+i}(t), u_{n_k+i}(t)), \\ &\ell_k(t) \equiv \sum_{i=1}^{m(k)} \alpha_{k,i}\, L_{n_k+i}(t). \end{aligned} \tag{2.7}$$

Define

$$\ell^*(t) \equiv \operatorname{Lim\,inf}_{k\to\infty} \ell_k(t), \quad t \in I.$$

By virtue of Assumption L(4), it follows from boundedness of the set $\mathcal{X}$ that $\operatorname{Lim\,inf} \ell_k(t)$ is well defined on I. Hence by Fatou's lemma we have

$$\int_I \ell^*(t)dt \leq \operatorname{Lim\,inf}_{k\to\infty} \int_I \ell_k(t)dt. \tag{2.8}$$

Clearly

$$\operatorname{Lim}_{k\to\infty} \eta(u_{n_k+i}, x_{n_k+i}) \longrightarrow m,$$

and hence it follows from (2.7) that

$$\operatorname{Lim}_{k\to\infty} \int_I \ell_k(t)dt = m,$$

which in turn leads to the inequality

$$\int_I \ell^*(t)dt \leq m. \tag{2.9}$$

Again by virtue of Assumption L(4) and boundedness of the solution set $\mathcal{X}$, there exists a $\tilde{\phi} \in L_1(I)$ dependent on ϕ such that

$$\ell^*(t) \geq \tilde{\phi}(t) \text{ a.e. on } I.$$

This along with (2.9) implies that $\ell^* \in L_1(I)$. Define the set-valued map $\mathcal{Q}$ from $I \times E_\beta$ to $2^{R_\infty \times \partial_0 W^{-1+2\alpha}} \setminus \emptyset$ as follows:

$$\mathcal{Q}(t,z) \equiv \{(\gamma,\beta) \in R_\infty \times \partial_0 W^{-1+2\alpha} : \gamma \geq L(t,z,v), \beta = g(t,z,v), v \in V(t)\},$$

for $t \in I, z \in E_\beta$. We prove that

$$(\ell^*(t), h^*(t)) \in \mathcal{Q}(t, x^*(t)) \text{ a.e. on } I. \tag{2.10}$$

By following techniques similar to those in [12, Thm. 3.1, p. 225], we can find a set $I_0 \subset I$ with Lebesgue measure $\lambda(I \setminus I_0) = 0$ such that

$$(\ell^*(t), h^*(t)) \in \bigcap_{\epsilon>0} C\ell Co\mathcal{Q}(t, N_\epsilon(x^*(t))), \quad t \in I_0.$$

By virtue of convexity and lower semicontinuity of the map $v \longrightarrow L(t,e,v)$ and the assumption that $G(t,x) \in cc(\partial_0 W^{-1+2\alpha})$, it follows that the multifunction $\mathcal{Q}$ is closed convex valued. Further, it follows from lower semicontinuity Assumption L(2) and the continuity of the map $e \longrightarrow g(t,e,v)$ from E_β to $\partial_0 W^{-1+2\alpha}$, that $e \longrightarrow \mathcal{Q}(t,e)$ is quasi upper semicontinuous. A quasi upper semicontinuous multifunction with closed convex values satisfies the weak Cesari property [10, Thm. 5.5, p. 52]. Thus

$$\bigcap_{\epsilon>0} C\ell Co\mathcal{Q}(t, N_\epsilon(x^*(t))) \subset \mathcal{Q}(t, (x^*(t)), \quad t \in I_0. \tag{2.11}$$

Hence we have $(\ell^*(t), h^*(t)) \in \mathcal{Q}(t, (x^*(t)), \ t \in I_0$. Since I_0 has full Lebesgue measure, this proves (2.10). From (2.10) and the definition of $\mathcal{Q}$, it follows that, for almost all $t \in I$, there exists an element $\tilde{u}(t) \in V(t)$ such that

$$\begin{aligned} \ell^*(t) &\geq L(t, x^*(t), \tilde{u}(t)), \\ h^*(t) &= g(t, x^*(t), \tilde{u}(t)). \end{aligned} \tag{2.12}$$

In view of (2.9), (2.12), and the definition of admissible controls, it is sufficient to show that there exists a measurable substitute for $\tilde{u}$. Define for $t \in I_0$ the set-valued map

$$\Lambda(t) \equiv \{v \in V(t) : \ell^*(t) \geq L(t, x^*(t), v) \text{ and } h^*(t) = g(t, x^*(t), v)\}. \tag{2.13}$$

Clearly this set is nonempty. We prove that it has a measurable selection. A general result in this direction states that a (weakly) measurable multifunction with closed values, from an arbitrary measurable space to a Polish space, has measurable selections [9, Thm. 4.1, p. 867]. Since $V(t) \in wkc(U)$ and U is separable, the relative weak topology on $V(t)$ is metrizable [13, Thm. V.3, p. 434] and with respect to this metric topology, it is a separable complete metric space and hence a Polish space. Thus it is sufficient to verify that Λ is closed valued and measurable. The closedness of this set follows immediately from the lower semicontinuity of L and continuity of g in the control variable. Since G is closed convex valued, it follows from convexity of L (Assumption L(3)) that $\Lambda(t)$ is also convex and hence it is a closed convex-valued multifunction. For the proof of measurability we can follow the same technique as that in [12, Thm. 3.1, p. 228]. Here we give a simpler and direct proof. Define

$$\begin{aligned} \Lambda_1(t) &\equiv \{v \in U : L(t, x^*(t), v) - \ell^*(t) \leq 0\}, \quad t \in I, \\ \Lambda_2(t) &\equiv \{v \in U : h^*(t) - g(t, x^*(t), v) = 0\}. \end{aligned} \tag{2.14}$$

Then clearly

$$\Lambda(t) = \big(\Lambda_1(t) \cap V(t)\big) \bigcap \big(\Lambda_2(t) \cap V(t)\big).$$

We show that each component is measurable. First we show that for any closed subset $\Sigma \subset U$, $\Lambda_1^-(\Sigma) \equiv \{t \in I : \Lambda_1(t) \cap \Sigma \neq \emptyset\}$ is measurable. Since U is a separable Banach space, there exists a countable dense subset Σ_0 of the set Σ such that

$$\begin{aligned} \Lambda_1^-(\Sigma) &\equiv \{t \in I : \Lambda_1(t) \cap \Sigma \neq \emptyset\} \\ &= \bigcup_{v \in \Sigma_0} \{t \in I : L(t, x^*(t), v) \leq \ell^*(t)\}. \end{aligned}$$

Since ℓ^* is measurable and for each $v \in U$, $t \longrightarrow L(t, x^*(t), v)$ is measurable, the union is measurable. By assumption, V is measurable and hence $\Lambda_1 \cap V$ is measurable. Similarly we can write

$$\Lambda_2^-(\Sigma) \equiv \bigcup_{v \in \Sigma_0} \{t \in I : g(t, x^*(t), v) = h^*(t)\}.$$

Hence $\Lambda_2 \cap V$ is also measurable. Thus $t \longrightarrow \Lambda(t)$ is a measurable multifunction taking values from $cc(U)$. Hence by the selection theorem mentioned above, Λ has a measurable selection u^* which is a measurable substitute for $\tilde{u}$. This completes the proof.

The result of the above theorem can be extended to the case where the control constraint set is also state dependent (feedback) given by $V(t, x)$. We can prove the following result.

THEOREM 2.2. *Suppose the basic hypotheses on $\mathcal{A}, \mathcal{B}, f, g$ hold, $A^{-1}(t)$ is compact for each $t \in I$, $x_0 \in E_\alpha$, and L satisfies Assumptions* L(1)–L(3) *and* L(4*) *defined below.*

L(4*) *There exists* $\lambda \geq 0$ *such that* $\phi(t) - \lambda \parallel e \parallel_{E_\beta} \leq L(t,e,v), a.e.$ *for all* $v \in V(t,e)$. *The multifunction* $V : I \times E_\beta \longrightarrow wkc(U)$ *is graph measurable and the set-valued map*

$$\mathcal{Q}(t,e) \equiv \{(\gamma,\beta) \in R_\infty \times \partial_0 W^{-1+2\alpha} : \gamma \geq L(t,e,v), \beta = g(t,e,v), v \in V(t,e)\}$$

satisfies the weak Cesari property.

Then there exists an optimal control $u_0 \in \mathcal{U}_{\text{ad}}$ *for problem* (P).

Remark. Following the same procedure, the existence result presented here can be extended to relaxed control problems thereby relaxing the convexity assumptions on L and g. Further the result can be extended also to (boundary) control differential inclusions. We will provide the details in another paper. Here we present only a brief discussion.

Let Γ be a compact Polish space and $M(\Gamma)$ be the space of probability measures on Borel subsets of Γ. Let $\mathcal{U}_{\text{ad}}$ denote the class of w^*-measurable functions on $I \equiv [0,T]$ with values in $M(\Gamma)$ furnished with the Young topology (see [2], [3], [12]). For more general relaxed controls see [17]. Let

$$g : I \times E_\beta \times M(\Gamma) \longrightarrow \partial_0 W^{-1+2\alpha},$$
$$L : I \times E_\beta \times M(\Gamma) \longrightarrow R_\infty$$

be maps measurable in $t \in I$, continuous in $x \in E_\beta$, and w^*-continuous in $\mu \in M(\Gamma)$. In particular, as a function of μ, these maps may be given by

$$h(t,x,\mu) \equiv \int_\Gamma \tilde{h}(t,x,\xi)\mu(d\xi),$$

where $\xi \longrightarrow \tilde{h}(t,x,\xi)$ is continuous and bounded on Γ, with h denoting either of the maps g, L.

As in the preceding theorem, define the multifunction G on $I \times E_\beta$ with values

$$G(t,x) \equiv \{\zeta \in \partial_0 W^{-1+2\alpha} : \zeta = g(t,x,\mu),\ \mu \in M(\Gamma)\}.$$

Thus the relaxed control problem (P_r) can be stated as follows: Find $\nu \in \mathcal{U}_{\text{ad}}$ such that

$$J(\nu) \equiv \int_0^T L(t,x,\nu)dt \longrightarrow \text{Inf},$$
$$\dot{x}(t) + A_{\beta-1}(t)x(t) = \mathcal{F}^\nu_{\beta-1}(t,x(t)), \quad t \in I,$$

where $\mathcal{F}^\nu_{\beta-1}$ is defined accordingly.

Define the multifunction

$$Q(t,x) \equiv \{(\lambda,\xi) : (\lambda,\xi) \in R_\infty \times \partial_0 W^{-1+2\alpha}, \lambda \geq L(t,x,\mu), \xi = g(t,x,\mu), \mu \in M(\Gamma)\}.$$

Now using the weak Cesari property for the multifunction Q and the theory of measurable selections, we can prove, as in [2], [12], the existence of optimal relaxed controls under a much milder hypothesis on L and g.

THEOREM 2.3. *Suppose the basic hypotheses on* $\mathcal{A}, \mathcal{B}, f, g, L$ *hold,* $A^{-1}(t)$ *is compact for each* $t \in I$, $x_0 \in E_\alpha$, *and the multifunction* G *given by* $G(t,z) \equiv g(t,z,M(\Gamma))$ *mapping* $I \times E_\beta$ *to* $cc(\partial_0 W^{-1+2\alpha})$ *is quasi upper semicontinuous. Then there exists an optimal control* $u_0 \in \mathcal{U}_{\text{ad}}$ *for problem* (P_r).

Now we present a necessary condition of optimality. Let λ denote the Lebesgue measure and $M(I,U)$ denote the space of strongly measurable functions (equivalence classes) from I to U, furnished with the metric topology

$$\rho(u,v) \equiv \lambda\{t \in I : u(t) \neq v(t)\}.$$

Since U is a Banach space, (M,ρ) is a complete metric space. For admissible controls we choose

$$\mathcal{U}_{\text{ad}} \equiv \{u \in M : u(t) \in V(t) \text{ a.e.}\},$$

where V satisfies Assumption U1.

Assumption C. Let $\hat{F}(t) \equiv DF_{\beta-1}(t,x(t),u(t))$, $\hat{L}(t) \equiv DL(t,x(t),u(t))$ denote the Fréchet differentials of $F_{\beta-1}$ and L, respectively, along any admissible state control pair (u,x), satisfying $\hat{F} \in L_1(I,\mathcal{L}(E_\beta,E_{\alpha-1}))$, $\hat{L} \in L_1(I,E_\beta^*)$.

Following an approach similar to that in [15], [17], using Ekland's variational principle with respect to the metric topology ρ, we can prove the following necessary conditions of optimality.

THEOREM 2.4. *Suppose the assumptions of Theorem* 2.1 *hold and let* (u,x) *be an admissible pair. Suppose* f,g, *and* L *are continuously Fréchet differentiable in the state variable on* E_β *and continuous with respect to the control variable on* U *satisfying Assumption* C. *Then for the pair* $(u,x) \in \mathcal{U}_{\text{ad}} \times C(I,E_\beta)$ *to be optimal, it is necessary that there exists a* $\psi \in C(I,E_{1-\alpha}^{\#})$ *such that*

$$\begin{aligned} &\int_I \{\langle F_{\beta-1}(t,x(t),u(t)),\psi(t)\rangle + L(t,x(t),u(t))\}dt \\ &\quad \leq \int_I \langle F_{\beta-1}(t,x(t),v(t)),\psi(t)\rangle + L(t,x(t),v(t))dt \quad \textit{for all} \quad v \in \mathcal{U}_{\text{ad}}, \end{aligned} \tag{2.15}$$

where x *is the weak solution of equation* (1.9) *corresponding to* u *and* ψ *satisfies the adjoint equation*

$$-\dot{\psi} + A_{\beta-1}^*(t)\psi = \hat{F}^*(t)\psi + \hat{L}(t), \psi(T) = 0, \tag{2.16}$$

also in the weak sense.

Note that a pointwise necessary condition of optimality easily follows from (2.15).

3. Examples. In this section we give two examples to demonstrate applicability of our abstract results.

Example 1 (system of second-order PDEs). The system is governed by a coupled system of N second-order PDEs with nonlinear interactions both in the interior and on the boundary of a spatial domain in n-space. This is an appropriate model for reaction–diffusion processes. Let Ω be a bounded domain in R^n of class C^2, that is, Ω is an n-dimensional C^2-submanifold of R^n with boundary $\partial\Omega$.

For $1 < p < +\infty$ and $s \in R^1$ we let $L_p \equiv L_p(\Omega,C^N)$ and set $W_p^s \equiv W_p^s(\Omega,C^N)$, $W_p^s(\partial\Omega) \equiv W_p^s(\partial\Omega,C^N)$, where C^N is the N-dimensional complex Euclidean space.

We define the operators $-D\Delta$ and $-D\Delta^{\#}$ (in the sense of distributions) by

$$\begin{aligned} &-D\Delta: \quad W_p^2 \to L_p, \quad 1 < p < +\infty, \\ &-D\Delta^{\#} = -D\Delta: \quad W_{p'}^2 \to L_{p'}, \quad p' = p/(p-1), \end{aligned}$$

where $D = \operatorname{diag}(d_1, d_2, \ldots, d_N)(d_i > 0, i = 1, 2, \ldots, N)$, Δ is the Laplacian. Define the boundary operators B, $B^{\#}$ (in the sense of trace) by

$$By \equiv D(\partial y/\partial \nu) + b(x)y : \quad W_p^2 \to W_p^{1-1/p}(\partial\Omega), \quad 1 < p < +\infty,$$
$$B^{\#}y \equiv D(\partial y/\partial \nu) + b(x)y : \quad W_{p'}^2 \to W_{p'}^{1-1/p'}(\partial\Omega), \quad p' = p/(p-1),$$

where $b(x) = \operatorname{diag}(b_1(x), b_2(x), \ldots, b_N(x))$, $b_i(x) \in W_q^{1-1/q}(\partial\Omega, C^1)$ $(i = 1, 2, \ldots, N)$, $q > \max\{np, np'\}$. We set $W_B' \equiv \{y \in W_p^2 | By = 0\}$, $W_{B^{\#}}'^{\#} \equiv \{y \in W_{p'}^2 | B^{\#}y = 0\}$, and let $-D\Delta_B \equiv -D\Delta|_{W_B'}$, $-D\Delta_{B^{\#}}^{\#} \equiv -D\Delta^{\#}|_{W'^{\#}_{B^{\#}}}$.

We have the following important lemma (see [8]).

LEMMA 3.1. *$-D\Delta_B, -D\Delta_{B^{\#}}^{\#}$ are closed and densely defined linear operators in L_p and $L_{p'}$, respectively, and there exist constants $M_0 > 0$ and $c \in R$ with*

$$\rho(D\Delta_B) \supset c + \Sigma_0, \ \rho(D\Delta_{B^{\#}}^{\#}) \supset c + \Sigma_0,$$
$$\|(\lambda - D\Delta_B)^{-1}\| \le M_0/(1 + |\lambda - c|),$$
$$\|(\lambda - D\Delta_{B^{\#}}^{\#})^{-1}\| \le M_0/(1 + |\lambda - c|),$$

for $\lambda \in c + \Sigma_0$, where $\rho(\bullet)$ denotes the resolvent set, $\Sigma_0 \equiv \{z \in C^* | \ |\arg z| \le \pi/2\} \cup \{0\}$, $C^* \equiv C - \{0\}$.

Define $\mathcal{A} \equiv -D\Delta + c$, $\mathcal{A}^{\#} \equiv -D\Delta^{\#} + c$, $A \equiv -D\Delta_B + c$, and $A^{\#} \equiv -D\Delta_{B^{\#}}^{\#} + c$, then $A(A^{\#})$ is the infinitesimal generator of a strongly continuous analytic semigroup $\{e^{tA}\}$ $(\{e^{tA^{\#}}\})$ on L_p $(L_{p'})$ and there exist constants $M > 0$, $\omega > 0$ such that

$$\|e^{tA}\| \le Me^{-\omega t}, \quad t \ge 0,$$

$$\|e^{tA^{\#}}\| \le Me^{-\omega t}, \quad t \ge 0.$$

We write $A \in \mathcal{G}(L_p, M, -\omega) \cap \mathcal{H}(L_p)$, $A^{\#} \in \mathcal{G}(L_{p'}, M, -\omega) \cap \mathcal{H}(L_{p'})$.

Let $E \equiv L_p$, $E^{\#} = L_{p'}$, $1 < p < +\infty$, $p' = p/(p-1)$. Then $E^{\#} = (E)'$, $A^{\#} = (A)'$. Let $\|x\|_k = \|A^k x\|$, $x \in D(A^k)$, $k \in Z$. Put $E_k = (D(A^k), \| \bullet \|_k)$ if $k \ge 0$ and E_k is the completion of $(E, \| \bullet \|_k)$ if $k < 0$.

For $k < \beta < k+1$ and $k \in Z$, define the interpolation space $E_\beta \equiv (E_k, E_{k+1})_{\beta-k,p}$ as before and denote by A_β the E_β-realization of A_k.

LEMMA 3.2. *The "scale" $\{(E_\beta, A_\beta) : k < \beta < k+1\}$ is well defined, each E_β is a Banach space, and we have $A_\beta \in \mathcal{G}(E_\beta, M, -\omega) \cap \mathcal{H}(E_\beta)$, $A_\beta \in Isom\ (E_{\beta+1}, E_\beta)$. For $-\infty < \beta < \alpha < +\infty$, we have $E_\alpha \hookrightarrow\hookrightarrow E_\beta$, and for $t > 0, \sigma < \omega$,*

$$e^{-tA_\alpha} = e^{-tA_\beta}|_{E_\alpha}, \quad t \ge 0,$$
$$\|e^{-tA_\beta}\|_{\mathcal{L}(E_\beta, E_\alpha)} \le C(\alpha, \beta, \sigma, M)t^{\beta-1}e^{-\sigma t}.$$

Finally, let $\{(E_\beta^{\#}, A_\beta^{\#}) : \beta \in R\}$ denote the scale as constructed above starting with $E^{\#}$, $A^{\#}$. Then we have

$$(E_\beta)' = E_{-\beta}^{\#}, \ (A_\beta)' = A_{-\beta}^{\#};$$

$$E_0 = E = L_p, \ E_\beta = W_p^{2\beta} \ \text{ if } \ 1/p < 2\beta < 1 + 1/p, \ 1 < p < +\infty,$$

$$E_0^{\#} = E^{\#} = L_{p'},\ E_\beta^{\#} = W_{p'}^{2\beta} \text{ if } 1/p' < 2\beta < 1 + 1/p',\ p' = p/(p-1).$$

Let a denote the bilinear form on $E_{1-\beta}^{\#} \times E_\beta = W_{p'}^{2-2\beta} \times W_p^{2\beta}$ defined by

$$a(\varphi, y) \equiv \int_\Omega \left(\sum_{k=1}^{N} d_k (\nabla \varphi_k, \nabla y_k)_{R^n} + c(\varphi, y)_{R^N} \right) dx,$$

which satisfies

$$a(\varphi, y) = \langle \varphi, Ay \rangle, \quad \text{for } (\varphi, y) \in E_{1-\beta}^{\#} \times E_1,$$

$$a(\varphi, y) = \langle \varphi, A_{\beta-1} y \rangle, \quad \text{for } (\varphi, y) \in E_{1-\beta}^{\#} \times E_\beta.$$

LEMMA 3.3. *The operator* $(\mathcal{A}, B) \in Isom\ (W_p^2, L_p \times W_p^{1-(1/p)}(\partial\Omega))$, $1 < p < +\infty$, *and* $(\mathcal{A}, B)^{-1} \in \mathcal{L}(L_p \times W_p^{1-(1/p)}(\partial\Omega), W_p^2)$.

Further, for any θ $(0 \le \theta \le 1)$, $(\mathcal{A}, B)^{-1}$ *has a unique extension, which we denote also by* $(\mathcal{A}, B)^{-1} \in \mathcal{L}(L_p \times W_p^{2\theta-1-(1/p)}(\partial\Omega), W_p^{2\theta})$.

Defining $R_\theta = (\mathcal{A}, B)^{-1}|_{\{0\} \times W_p^{2\theta-1-(1/p)}(\partial\Omega)}$ we have $R_\theta \in \mathcal{L}(W_p^{2\theta-1-(1/p)}(\partial\Omega), W_p^{2\theta})$ and for $g \in W_p^{2\theta-1-(1/p)}(\partial\Omega)$, R_θ satisfies

$$\|R_\theta g\|_{W_p^{2\theta}} \le K(\theta) \|g\|_{W_p^{2\theta-1-(1/p)}(\partial\Omega)}.$$

We define the admissible controls $\mathcal{U}_{\text{ad}}$ as follows.

(U2) Let $U \equiv L_s(\partial\Omega), 1 < s < \infty$, $r \in L_1([0,T], L_s(\partial\Omega))$, and

$$V(t) \equiv \left\{ v \in U : |v|_U^s \le \int_{\partial\Omega} |r(t,\xi)|^s d\xi \right\}.$$

Take

$$\mathcal{U}_{\text{ad}} = \{u \in L_1(I, U) : u(t) \in V(t) \text{ a.e.}\}.$$

Clearly V is a measurable multifunction.

Define

$$f(t,\phi)(\xi) \equiv \hat{f}(t,\xi,\phi(\xi)), \quad \phi \in C((\bar{\Omega}, C^N)),\ t > 0,$$
$$g(t,\phi,v)(\xi) \equiv \hat{g}(t,\xi,\phi(\xi),v(\xi)), \quad \phi \in C(\partial\Omega, C^N), v \in U.$$

Define the operators $F(t,y) \equiv f(t,y) + cy$ and $G(t,y,u) = g(t,y,u)$, where c is the same constant as in Lemma 3.1. Suppose the operators F, G satisfy the following conditions.

(F,G) Let $p > n$, $1 < 2\beta < 1 + 1/p$, then there exists α with $2\beta < 2\alpha < 1 + 1/p$ such that

$$F \in C^{0,1-}([0,T] \times E_\beta, E_{\alpha-1})$$

and for each $v \in U$

$$G_v \equiv G(.,.,v) \in C^{0,1-}([0,T] \times E_\beta, W_p^{2\alpha-1-1/p}(\partial\Omega)),$$

where C^{1-} denotes local Lipschitz continuity and the Lip-constant for G_v depends only on $\|v\|_U$. Using the operators defined above, one can write the following controlled system:

$$\begin{aligned} y_t - D\,\triangle\, y &= f(t,\xi,y), \\ D(\partial y/\partial\nu) + b(\xi)y &= g(t,\xi,y,u), \\ y(0) &= y_0 \end{aligned} \tag{3.1}$$

in its abstract form

$$\begin{aligned} \dot{y} + \mathcal{A}y &= F(t,y), \\ By &= G(t,y,u), \\ y(0) &= y_0. \end{aligned} \tag{3.2}$$

As defined earlier, for each $y_0 \in E_\alpha = W_p^{2\alpha}$, the function $y \in C([0,T], E_\beta)$ is a E_β ($W_p^{2\beta}$)-weak solution of (3.2) if y satisfies

$$\begin{aligned} &\int_0^{T'} \{-\langle \dot{\varphi}, y\rangle + a(\varphi, y)\}dt \\ &\quad = \int_0^{T'} \{\langle \varphi, F(t,y)\rangle + \langle \varphi|_{\partial\Omega}, g(t,y,u)\rangle_\partial\}dt + \langle \varphi(0), y_0\rangle \end{aligned}$$

for every $T' \in (0,T)$ and every $\varphi \in C([0,T], E_{1-\beta}^{\#}) \cap C^1((0,T], E_{-\beta}^{\#})$ satisfying $\varphi(T') = 0$.

Here the duality pairings have the following specific meaning: $\langle \dot{\varphi}, y\rangle$ ($\langle \varphi, F(t,y)\rangle$, $\langle \varphi|_{\partial\Omega}$, $G_u(t,y)\rangle_\partial$, $\langle \varphi(0), y_0\rangle$) is the dual pairing of $E_{-\beta}^{\#}$ and $E_{\beta-1}$ ($E_{1-\beta}^{\#}$ and $E_{-\beta}$, $W_{p'}^{2-2\beta-1/p'}(\partial\Omega)$ and $W_p^{2\beta-1-1/p}(\partial\Omega)$, $E_{1-\beta}^{\#}$ and $E_{\beta-1}$, respectively).

Further we assume that for each $y \in E_\beta$,

$$\|F(t,y)\|_{E_{\alpha-1}} \le K_1(1 + \|y\|_{E_\beta}),$$

$$\|G(t,y(t),u)\|_{W_p^{2\alpha-1-1/p}(\partial\Omega)} \le K_2(1 + \|y\|_{E_\beta}),$$

where K_1 is constant, K_2 is only dependent on $\|u\|_{L_\infty([0,T],U)}$.

Combining Lemma 1.1 and Theorem 1.2, we have the following result for system (3.2).

THEOREM 3.4. *Suppose F, G satisfy all the assumptions mentioned above, $y_0 \in E_\beta \equiv W_p^{2\beta}$ $(1 < 2\beta < 1 + 1/p, p > n)$. Then we have*

(a) *for each $y \in C([0,T], E_\beta) = C([0,T], W_p^{2\beta})$, and $u \in \mathcal{U}_{\rm ad}$,*

$$t \longrightarrow F(t, y(t)) \in C([0,T], E_{\alpha-1})$$

$$\text{and } t \longrightarrow A_{\beta-1}R_\beta G(t,y(t),u) = A_{\alpha-1}R_\alpha G(t,y(t),u) \in L_\infty([0,T], E_{\alpha-1}),$$

where α is the number appearing in condition (F,G).

(b) *$y \in C([0,T], W_p^{2\beta})$ is a $W_p^{2\beta}$-weak solution of equation* (3.2) *on $[0,T]$, iff y is a solution of the following integral equation:*

$$y(t) = e^{-tA_{\beta-1}}y_0 + \int_0^t e^{-(t-s)A_{\beta-1}}[F(s,y(s)) + A_{\beta-1}R_\beta G(s,y(s),u(s))]ds$$

in $C([0,T],W_p^{2\beta})$ $(1<2\beta<1+1/p,\ p>n)$.

(c) *equation* (3.1) *has a unique global* $W_p^{2\beta}$*-weak solution.*

The basic assumptions on the cost integrand L are the same as those of Assumption L given for our main existence Theorem 2.1 with reference to $E_\beta \equiv W_p^{2\beta}, U \equiv L_s(\partial\Omega)$.

We consider the optimal boundary control problem $(\tilde{\mathrm{P}})$. Minimize

$$J(u)=\int_0^T L(t,x(t),u(t))dt \tag{3.3}$$

over all controls $u\in\mathcal{U}_{\mathrm{ad}}$ subject to the state equation (3.1) or, equivalently, (3.2).

THEOREM 3.5. *Under the assumptions of Theorem* 3.4, L, *and* U2, *there exists an optimal control for the problems* (3.2) *and* (3.3).

Proof. This is a special case of our general Theorem 2.1.

Example 2. In steel factories, ingots are raised to high temperature in a furnace and then stored in a ceramic kiln for a soaking process for a suitable period of time. The purpose of soaking is to allow time for the ingots to attain uniform temperature throughout the body before they are transported to the rolling mills. During this process heat loss by radiation and convection is controlled by maintaining the surrounding temperature in the kiln by an auxiliary heat source. Let Ω_o denote the interior of the kiln and $\Omega\subset\Omega_o$ denote the space occupied by the ingot. Loss of heat by radiation to the surrounding medium $\Omega_o\setminus\bar{\Omega}$ is governed by the Steffan–Boltzman law. The corresponding control system can then be described as follows:

$$\begin{aligned} y_t - K\,\triangle\, y &= 0, \quad \text{in } (0,T]\times\Omega,\\ K(\partial y/\partial\nu) &= -g(y,u), \quad \text{in } (0,T]\times\partial\Omega,\\ y(0) &= y_0, \quad \text{in } \Omega, \end{aligned} \tag{3.4}$$

where

(i) for purely radiative heat transfer g is given by

$$g(y,u)=\begin{cases}\sigma E(y^4-u^4)|_{\partial\Omega}, & \text{for } 0\le y\le\gamma_d,\ 0\le u\le\gamma_d,\\ \sigma E(\gamma_d^4-u^4)|_{\partial\Omega}, & \text{for } 0\le u\le\gamma_d,\ y\ge\gamma_d,\end{cases}$$

(ii) for a combination of radiative and convective heat transfer, g is given by

$$g(y,u)=\begin{cases}(\sigma E(y^4-u^4)+\alpha(y-u))|_{\partial\Omega}, & \text{for } 0\le y\le\gamma_d,\ 0\le u\le\gamma_d,\\ (\sigma E(\gamma_d^4-u^4)+\alpha(y-u))|_{\partial\Omega}, & \text{for } 0\le u\le\gamma_d,\ y\ge\gamma_d.\end{cases}$$

The parameters are as follows: K is the conductivity of the ingot material, σ is the Stefan–Boltzman constant, E is the emissivity of the ingot surface, α is the heat transfer coefficient due to convection, and γ_d is the maximum (attainable) temperature of the furnace.

(iii) In the case of hydrodynamics of liquid helium, Lin [18] has used for g the function

$$g(y,u)=\beta_1(y-u)|_{\partial\Omega}+\beta_2(y-u)^3|_{\partial\Omega},$$

where β_1 and β_2 are suitable constants determined by experiments.

Note that only case (i) can be transformed into a problem with control $v\equiv u^4$ appearing linearly; whereas cases (ii) and (iii) do not admit such simplification.

For the state space we choose $E_\beta \equiv W_p^{2\beta}$ so that $\beta > (3/p)$. Given that Ω has the cone property, by the Sobolev embedding theorem this last condition guarantees that $W_p^{2\beta}$ is an algebra (see [14, Thm. 5.23, p. 115]) and hence for $\phi \in W_p^{2\beta}, \phi^4 \in W_p^{2\beta}$, and its trace $\phi^4|_{\partial\Omega} \in W_p^{2\beta-1-1/p}(\partial\Omega)$ also. For admissible controls define

$$V \equiv \{v \in U \equiv W_p^{2\beta-1-1/p}(\partial\Omega) : v = \psi|_{\partial\Omega}, \psi \in W_p^{2\beta}(\Omega_o \setminus \bar{\Omega}) \text{ and } 0 \le v(\xi) \le \gamma_d \text{ a.e.}\}$$

and $\mathcal{U}_{\text{ad}} \equiv \{u \in L_\infty(I, U) : u(t) \in V \text{ a.e.}\}$. In particular we can choose $p = 4, \beta > 3/4$. This also implies that the embedding $W_p^{2\beta-1-1/p} \hookrightarrow L_p(\partial\Omega)$ is continuous and hence $V \subset L_p(\partial\Omega)$. Thus our boundary operator g is locally Lipschitz, satisfies the growth condition, and maps $E_\beta \times V$ to $W_p^{2\beta-1-1/p}$.

The cost integrand may be taken as

$$L(t, y(t), u(t)) \equiv \int_\Omega |y(t,\xi) - y^0 t, \xi)|^p d\xi + \int_{\partial\Omega} |u(t,\zeta)|^p d\zeta.$$

Thus all the assumptions of Theorem 3.5 are satisfied, and hence an optimal control exists.

Remark. We note that g is locally Lipschitz and that the (linear) growth condition is satisfied because of the physical limitation of the furnace temperature. Hence for arbitrary time interval I the equations have unique solutions and the optimal control is defined for the entire interval. If one has to deal with the polynomial growth our results will apply only for the maximal interval of existence of solutions of the evolution equations.

A SIMPLICIAL ALGORITHM FOR COMPUTING ROBUST STATIONARY POINTS OF A CONTINUOUS FUNCTION ON THE UNIT SIMPLEX*

ZAIFU YANG†

Abstract. A simplicial algorithm is proposed to compute a robust stationary point of a continuous function f from the $(n-1)$-dimensional unit simplex S^{n-1} into R^n. The concept of robust stationary point is a refinement of the concept of stationary point of f on S^{n-1}. Starting from an arbitrarily chosen interior point v in S^{n-1}, the algorithm generates a piecewise linear path of points in S^{n-1}. This path is followed by alternating linear programming pivot steps and replacement steps in a specific simplicial subdivision of the relative interior of S^{n-1}. In this way an approximate robust stationary point of any a priori chosen accuracy is reached within a finite number of steps. The algorithm leaves the starting point along one out of $n!$ rays. When the path approaches the boundary of S^{n-1}, the mesh size of the triangulation along the path automatically goes to zero. This makes the algorithm different from all simplicial restart algorithms and homotopy algorithms known so far. Roughly speaking, the algorithm is a blend of a restart and a homotopy algorithm and maintains the basic properties of both. However, the algorithm does not need an extra dimension as homotopy algorithms do. Some examples are discussed.

Key words. robust stationary point, variational inequality, simplicial algorithm, subdivision, piecewise linear approximation, stability

1. Introduction.

Let the $(n-1)$-dimensional unit simplex S^{n-1} be defined by

$$S^{n-1} = \left\{ x \in R^n_+ \mid \sum_{i=1}^{n} x_i = 1 \right\},$$

where R^n_+ is the nonnegative orthant of the n-dimensional Euclidean space. Let us assume that $f : S^{n-1} \mapsto R^n$ is a continuous function. Then the stationary point problem or variational inequality problem for f on S^{n-1} is to find a point $x^* \in S^{n-1}$ such that

$$(x^* - x)^\top f(x^*) \geq 0$$

for any point x in S^{n-1}. We call x^* a stationary point of f on S^{n-1}. It is well known that this problem is equivalent to the Brouwer fixed point problem on S^{n-1} (see, e.g., Eaves [6]).

To compute a fixed point or a stationary point of a continuous function on S^{n-1}, several simplicial algorithms have been developed (Scarf [17], [18], Kuhn [11], Eaves [7], Kuhn and MacKinnon [12], van der Laan and Talman [13], [14], Doup and Talman [4], and Doup, van der Laan, and Talman [5]). Todd [23] and Doup [3] presented excellent surveys on the development of simplicial algorithms. In a simplicial subdivision of S^{n-1} such algorithms search for a simplex which provides an approximate solution by generating a sequence of adjacent simplices. The simplex with which the algorithm terminates is found within a finite number of steps. The so-called variable dimension restart algorithm, originated in van der Laan and Talman [13], can be

* Received by the editors November 12, 1993; accepted for publication (in revised form) November 7, 1994. This research is part of the VF-program "Competition and Cooperation."

† Department of Econometrics and Center for Economic Research, Tilburg University, Postbox 90153, 5000 LE Tilburg, the Netherlands.

started in an arbitrarily chosen grid point of the subdivision and generates a sequence of adjacent simplices of varying dimension. When the end simplex does not yield an approximate solution with satisfactory accuracy, the algorithm can be restarted at the approximate solution with a finer triangulation in the hope of finding a better approximate solution within a small number of iterations.

The concept of robust stationary point is a refinement of the concept of stationary point on the unit simplex and is essentially motivated by economic equilibrium problems, noncooperative games, as well as biology and engineering applications (see, e.g., Myerson [16], Yamamoto [25], van Damme [2]). Because a continuous function from S^{n-1} into R^n may have multiple stationary points and some of them are undesirable from a point of view of stability, we need to refine the concept of stationary point.

In this paper we propose a simplicial algorithm to compute a robust stationary point. Starting from an arbitrarily chosen interior point v in S^{n-1}, the algorithm generates a piecewise linear path of points in S^{n-1}. This path is traced by alternating linear programming pivot steps, to follow a linear piece of the path and replacement steps in a simplicial subdivision of the relative interior of S^{n-1}. Within a finite number of function evaluations and linear programming pivot steps, the algorithm finds an approximate robust stationary point of any a priori, chosen accuracy. The path generated by the algorithm corresponds to a sequence of θ-robust stationary points of the piecewise linear approximation $\bar{f}$ of f with respect to the underlying simplicial subdivision, where $0 < \theta \leq 1$. This simplicial subdivision differs from other simplicial subdivisions of S^{n-1}. We call it the P-triangulation. When the path generated by the algorithm approaches the boundary of S^{n-1}, the mesh size of the triangulation along the path automatically converges to zero. This makes the algorithm different from all other simplicial algorithms. Roughly speaking, the algorithm is a blend of a simplicial restart algorithm and a homotopy algorithm and maintains the basic properties of both. This can be interpreted as follows. If the algorithm converges to a solution on the boundary of S^{n-1}, it shares the property with a homotopy algorithm that the variable θ can be considered as a homotopy parameter (see Eaves [7]), in the sense that when θ tends to zero, the mesh size of the triangulation also tends to zero. However it should be emphasized that the algorithm does not need an extra dimension which is required by homotopy algorithms. While the algorithm converges to a solution in the interior of S^{n-1}, it behaves exactly as a variable dimension algorithm does.

Although it may not be apparent from the arguments of this paper, the algorithm is implicitly related to the procedure proposed by Yamamoto [25] for the determination of a proper Nash equilibrium of finite-person games. Our algorithm can be seen as a constructive combinatorial analog of his continuous procedure when the starting point of our algorithm is chosen to be the barycenter of S^{n-1}.

This paper is organized as follows. In §2 we introduce the definition of a robust stationary point and prove the existence of a robust stationary point for a continuous function on the unit simplex. In §3 we specify the P-triangulation of the unit simplex. In §4 we give a detailed description of the algorithm. Section 5 is devoted to some numerical examples.

2. The concept of robust stationary point. In this section we first give the definition of a robust stationary point and then show the nonemptiness of the set of robust stationary points of a continuous function on the unit simplex. Let a function $f : S^{n-1} \mapsto R^n$ be given and N be the set of the integers $\{1, \ldots, n\}$.

DEFINITION 2.1. *For given $\theta > 0$ a point $x \in S^{n-1}$ is a θ-robust stationary point of f if*

(1) *x is a relative interior point of S^{n-1},*

(2) *$x_k \leq \theta x_l$ if $f_k(x) < f_l(x)$, for $k, l, 1 \leq k, l \leq n$.*

DEFINITION 2.2. *A point $x^* \in S^{n-1}$ is a robust stationary point of f on S^{n-1} if there exist sequences $\{\theta_t\}_1^\infty$ of positive numbers and $\{x(\theta_t)\}_1^\infty$ of θ_t-robust stationary points $x(\theta_t)$ of f such that*

$$\lim_{t\to\infty} \theta_t = 0 \quad \text{and} \quad \lim_{t\to\infty} x(\theta_t) = x^*.$$

We remark that if a stationary point x^* of f lies in the relative interior of S^{n-1}, then x^* must be a robust stationary point of f with equal values of the components. Some examples given in §5 will demonstrate that the concept of robust stationary point is a refinement of the concept of stationary point.

LEMMA 2.3. *Let $f : S^{n-1} \mapsto R^n$ be a continuous function. If $x^* \in S^{n-1}$ is a robust stationary point of f, then x^* is also a stationary point of f.*

Proof. We only need to consider two cases. If x^* lies in the relative interior of S^{n-1}, it implies that $f_i(x^*) = f_j(x^*)$ for $i, j \in N$. Hence we have

$$(x^* - x)^\top f(x^*) = \sum_{i=1}^{n} (x_i^* - x_i) f_i(x^*) = 0$$

for any $x \in S^{n-1}$, which means that x^* is a stationary point of f. On the other hand, if x^* is on the boundary of S^{n-1}, there exists a proper subset J of N such that $x_j^* = 0$ for $j \in J$. It follows from Definitions 2.1 and 2.2 that $f_i(x^*) = f_j(x^*)$ for $i, j \in N \backslash J$ and $f_i(x^*) \geq f_j(x^*)$ for $i \in N \backslash J$ and $j \in J$. Now for given $l \in N \backslash J$, we have

$$(x^* - x)^\top f(x^*) = \sum_{i \in N\backslash J} (x_i^* - x_i) f_i(x^*) - \sum_{j \in J} x_j f_j(x^*) \geq \sum_{i=1}^{n} (x_i^* - x_i) f_l(x^*) = 0$$

for any $x \in S^{n-1}$. This also implies that x^* is a stationary point of f. □

THEOREM 2.4. *Let $f : S^{n-1} \mapsto R^n$ be a continuous function. Then f has at least one robust stationary point in S^{n-1}.*

Proof. We first show that there exists at least one θ-robust stationary point, for any θ, $0 < \theta < 1$. Given such a θ, let $\delta = \frac{1}{n}\theta^{n-1}$ and define

$$S(\theta) = \{ x \in S^{n-1} \mid x_i \geq \delta,\ i = 1, \ldots, n \}.$$

It is clear that $S(\theta)$ is a nonempty, convex, compact subset of S^{n-1}. We further define a set-valued correspondence F on $S(\theta)$ by

$$F(x) = \{ y \in S(\theta) \mid \text{ if } f_i(x) < f_j(x) \text{ then } y_i \leq \theta y_j \text{ for any } i, j \},\ x \in S(\theta).$$

$F(x)$ is obviously a closed convex set for every $x \in S(\theta)$. Given $x \in S(\theta)$ and $i \in \{1, \ldots, n\}$, let $\Delta(i)$ be the number of j's such that $f_i(x) < f_j(x)$ and let

$$y_i^* = \theta^{\Delta(i)} \Big/ \sum_{l=1}^{n} \theta^{\Delta(l)}.$$

Then $y_i^* \geq \delta$ for $i = 1, \ldots, n$. Hence $y^* \in F(x)$ and therefore $F(x)$ is nonempty. Moreover the continuity of f guarantees that F is upper semicontinuous. Thus F

satisfies all conditions of the Kakutani fixed point theorem and so there exists a point $x(\theta) \in S(\theta)$ such that $x(\theta) \in F(x(\theta))$. It is easily seen that $x(\theta)$ is a θ-robust stationary point of f.

So for every $0 < \theta < 1$, f has a θ-robust stationary point $x(\theta)$. Now let us take a sequence $\{\theta_t\}_1^\infty$ of numbers between 0 and 1 converging to zero and a sequence of θ_t-robust stationary points of f. Since S^{n-1} is a compact set, there exists a subsequence converging to a cluster point $x^* \in S^{n-1}$. It is now clear that x^* is a robust stationary point of f. □

In the subsequent sections we will design an algorithm to compute a robust stationary point.

3. The P-triangulation of the unit simplex. We first introduce some notation to be used below. Z_+ and Z_0 represent the set of positive integers and the set of nonnegative integers, respectively. The ith unit vector in R^n is denoted by $e(i)$, $i \in N$. Moreover, $J \subset N$ denotes a proper subset J of N. Let v be a point in the relative interior of S^{n-1}. The point v will be the starting point of the algorithm. We rearrange the components of v in decreasing order to obtain a vector $p = (p_1, \ldots, p_n)^\top \in S^{n-1}$ represented by

$$p_i = v_{j_i}, \text{ for } i \in N$$
$$p_l \geq p_m, \text{ for } l \leq m, \text{ and } l, m \in N$$

where $(j_1, j_2, \ldots, j_n)$ is a permutation of $(1, 2, \ldots, n)$. For $t \in (0, 1]$, let

$$p_i(t) = p_i t^{i-1} \Big/ \sum_{j \in N} p_j t^{j-1}, \text{ for } i \in N,$$

and define

$$p_i(0) = \lim_{t \to 0^+} p_i(t) = \begin{cases} 1 & \text{for } i = 1, \\ 0 & \text{for } i \neq 1. \end{cases}$$

It is readily seen that $p_1(t) \geq p_2(t) \geq \cdots \geq p_n(t)$ for $t \in [0, 1]$.

DEFINITION 3.1. *For $t \in [0, 1]$, the set $A(t)$ is defined by*

$$A(t) = \left\{ x \in R^n \mid \sum_{i \in N} x_i = 1, \ \sum_{j \in J} x_j \leq \sum_{j=1}^{k} p_j(t) \text{ for any } J \subset N \text{ with } k = |J| \right\}.$$

It is easily seen that $A(0) = S^{n-1}$ and that if v is the barycenter of S^{n-1}, then $A(1) = \{v\}$. More generally, for every $t \in [0, 1]$ we have that $v \in A(t)$ and v is a vertex of $A(1)$. Moreover $A(t)$ is a polytope for every $t \in [0, 1]$.

For $J \subset N$ and $t \in [0, 1]$, we define $b(J)$ and $c_J(t)$ by

$$b(J) = \sum_{j \in J} e(j),$$
$$c_J(t) = \sum_{j=1}^{l} p_j(t) \text{ with } l = |J|.$$

Let $\mathcal{I} = \{ I = (I_1, I_2, \ldots, I_m) \mid \emptyset \neq I_1 \subset \cdots \subset I_m \subset N \}$. We say that $I \in \mathcal{I}$ conforms to $J \in \mathcal{I}$, if it holds that every component of I is also a component of J. For $I \in \mathcal{I}$ and a positive integer k, let

$$F(k, I) = \{ x \in A(2^{-k}) \mid b^\top(I_i)x = c_{I_i}(2^{-k}) \text{ for every } i \in \{1, 2, \ldots, m\} \}.$$

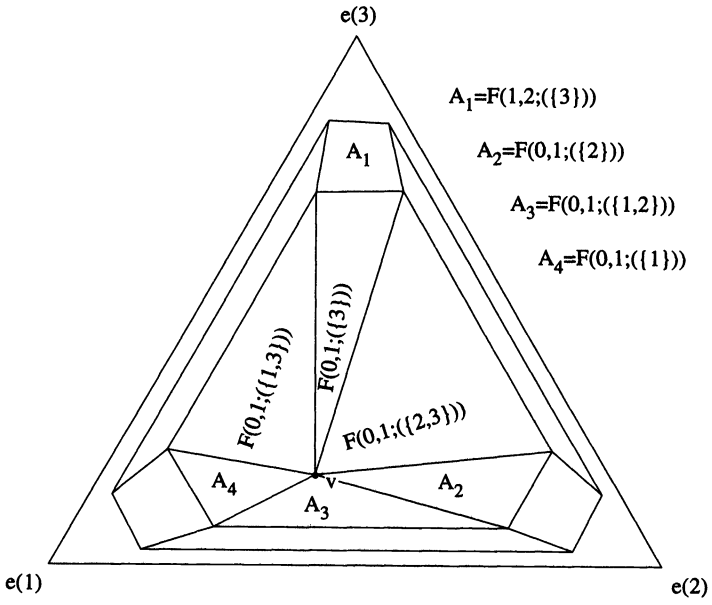

FIG. 1. *The subdivision of* S^{n-1} *for* $n = 3$ *and* $v = (1/2, 1/3, 1/6)^\top$.

Then $F(k, I)$ is a face of $A(2^{-k})$ with dimension equal to $n - 1 - m$. For $I \in \mathcal{I}$, let

$$F(0, 1; I) = \{ x \mid x = av + (1 - a)z \text{ for some } z \in F(1, I) \text{ and some } a \in [0, 1] \}$$

and for $k \in Z_+$

$$F(k, k+1; I) = \{ x \mid x = ay + (1 - a)z \text{ for some } y \in F(k, I), \text{ some } z \in F(k+1, I), \text{ and some } a \in [0, 1] \}.$$

Figure 1 shows the subdivision of S^{n-1} for $n = 3$ and $v = (1/2, 1/3, 1/6)^\top$.

For $I \in \mathcal{I}$ and $k \in Z_+$, we denote the union of $F(i-1, i; I)$ over $i = 1, 2, \ldots, k$ by $\mathcal{F}(k, I)$. We remark that $\mathcal{F}(k, I)$ is not necessarily a convex set. For $k \in Z_0$, we denote the union of $F(k, k+1; I)$ over all $I \in \mathcal{I}$ by $\mathcal{F}(k, k+1)$. For $I \in \mathcal{I}$, we denote the union of $F(k, k+1; I)$ over all $k = 0, 1, \ldots$ by $\mathcal{F}(I)$. Notice that the dimension of $\mathcal{F}(I)$ is equal to $t = n - m$ and that the union of $\mathcal{F}(I)$ over all $I \in \mathcal{I}$ is the relative interior of S^{n-1}. A simplicial subdivision underlying the algorithm must be such that every set $F(k, k+1; I)$ is subdivided into t-dimensional simplices. Such a triangulation can be described as follows. For $I \in \mathcal{I}$, we denote $v(0, I) = v$ and for $k \in Z_+$, let $v(k, I)$ be a relative interior point (e.g., the barycenter) of $F(k, I)$. For $I \in \mathcal{I}$, if I consists of $n-1$ components, then $F(k, I)$ is a vertex of $A(2^{-k})$. For general $I \in \mathcal{I}$, let $F(k, I(n-1))$ be a vertex of $F(k, I)$, i.e., $I(n-1)$ has $n-1$ components and I conforms to $I(n-1)$. Moreover let $(J_1, J_2, \ldots, J_t) = \gamma(I, I(n-1))$ be a conformation of I and $I(n-1)$, where $t = n - m$, i.e., $J_1 = I(n-1)$, $J_k \in \mathcal{I}$ for $k = 2, \ldots, t-1$, $J_t = I$, J_k conforms to J_{k-1} and has one component less than J_{k-1} for $k = 2, \ldots, t$. For given $k \in Z_0$, $I \in \mathcal{I}$, and $\gamma(I, I(n-1))$, the subset $F(k, k+1; I, \gamma(I, I(n-1)))$ of $F(k, k+1; I)$ is defined to be the convex hull of $v(k, J_1)$, $v(k, J_2), \ldots, v(k, J_t)$, $v(k+1, J_1)$, $v(k+1, J_2), \ldots$, and $v(k+1, J_t)$, so

$$F(k, k+1; I, \gamma(I, I(n-1))) = \left\{ x \in S^{n-1} \mid x = v(k, I(n-1)) + \alpha q_0 + \textstyle\sum_{j=1}^{t-1} \alpha_j q_j(\alpha), \right.$$

$$0 \le \alpha \le 1, \text{ and } 0 \le \alpha_{t-1} \le \cdots \le \alpha_1 \le 1 \Big\},$$

where $q_0 = (v(k+1, J_1) - v(k, J_1))$, and for $j = 1, \ldots, t-1$, $0 \le \alpha \le 1$,

$$q_j(\alpha) = \alpha(v(k+1, J_{j+1}) - v(k+1, J_j)) + (1-\alpha)(v(k, J_{j+1}) - v(k, J_j)).$$

The dimension of $F(k, k+1; I, \gamma(I, I(n-1)))$ is equal to t and $F(k, k+1; I)$ is the union of $F(k, k+1; I, \gamma(I, I(n-1)))$ over all conformations $\gamma(I, I(n-1))$ and over all index sets $I(n-1)$ conformed by I.

Let d be an arbitrary positive integer.

DEFINITION 3.2. *For given $k \in Z_0$, $I \in \mathcal{I}$, and $\gamma(I, I(n-1))$, the set $G^d(k, k+1; I, \gamma(I, I(n-1)))$ is the collection of t-simplices $\sigma(a, \pi)$ with vertices $y^1, \ldots, y^{t+1}$ in $F(k, k+1; I, \gamma(I, I(n-1)))$ such that*

(1) *$y^1 = v(k, I(n-1)) + a(0)d^{-1}q_0 + \sum_{j=1}^{t-1} a(j)q_j(a(0)/d)/(a(0)+kd)$, where $a = (a(0), a(1), \ldots, a(n-2))^\top$ is a vector of integers such that $0 \le a(0) \le d-1$ and $a(n-2) = \cdots = a(t) = 0 \le a(t-1) \le \cdots \le a(2) \le a(1) \le a(0) + kd$;*

(2) *$\pi = (\pi_1, \ldots, \pi_t)$ is a permutation of $(0, 1, \ldots, t-1)$ such that $s < s'$ if for some $q \in \{0, 1, \ldots, t-2\}$, it holds that $\pi_s = q$, $\pi_{s'} = q+1$, $a(q) = a(q+1)$ in the case where $q \ge 1$, and $a(0) + kd = a(1)$ in the case where $q = 0$;*

(3) *Let i be such that $\pi_i = 0$. Then*

$$\begin{aligned}
y^{j+1} &= y^j + q_{\pi_j}(a(0)/d)/(a(0)+kd), \ j = 1, \ldots, i-1, \\
y^{i+1} &= v(k, I(n-1)) + (a(0)+1)d^{-1}q_0 \\
&\quad + \sum_{j=1}^{t-1} a(j)q_j((a(0)+1)/d)/(a(0)+1+kd) \\
&\quad + \sum_{j=1}^{i-1} q_{\pi_j}((a(0)+1)/d)/(a(0)+1+kd), \\
y^{j+1} &= y^j + q_{\pi_j}((a(0)+1)/d)/(a(0)+1+kd), \ i < j \le t.
\end{aligned}$$

The set $G^d(k, k+1; I, \gamma(I, I(n-1)))$ is a simplicial subdivision of $F(k, k+1; I, \gamma(I, I(n-1)))$ with grid size d^{-1}. Moreover, the union $G^d(k, k+1; I)$ of $G^d(k, k+1; I, \gamma(I, I(n-1)))$ over all conformations $\gamma(I, I(n-1))$ and $I(n-1)$ conformed by I is a simplicial subdivision of $F(k, k+1; I)$, and the union $G^d(k, k+1)$ of $G^d(k, k+1; I)$ over all sets $I \in \mathcal{I}$ induces a triangulation of $\mathcal{F}(k, k+1)$. Taking the union $G^d(k)$ of $G^d(j, j+1)$ over $j = 0, 1, \ldots, k-1$, we obtain a simplicial subdivision of $A(2^{-k})$ with grid size d^{-1}. The union of $G^d(k)$ over all $k \in Z_0$ is a simplicial subdivision of the relative interior of S^{n-1} and is called the P-triangulation of S^{n-1} with grid size d^{-1}. Observe that for $I \in \mathcal{I}$ and $k \in Z_+$, the union $G^d(k, I)$ of $G^d(i-1, i; I)$ over $i = 1, 2, \ldots, k$, is a simplicial subdivision of the set $\mathcal{F}(I, k)$, and for $I \in \mathcal{I}$, the union $G^d(I)$ of $G^d(k, k+1; I)$ over $k = 0, 1, \ldots$, is a simplicial subdivision of the set $\mathcal{F}(I)$. The P-triangulation of S^{n-1} for $n = 3$, $d = 2$, and $v = (1/3, 1/3, 1/3)^\top$ is illustrated in Fig. 2.

As norm we use the Euclidean norm $||\cdot||$ in R^n. For a set B in R^n, we define the diameter of B by

$$diam(B) = \sup\{\, ||y^1 - y^2|| \,|\, y^1, y^2 \in B \,\}.$$

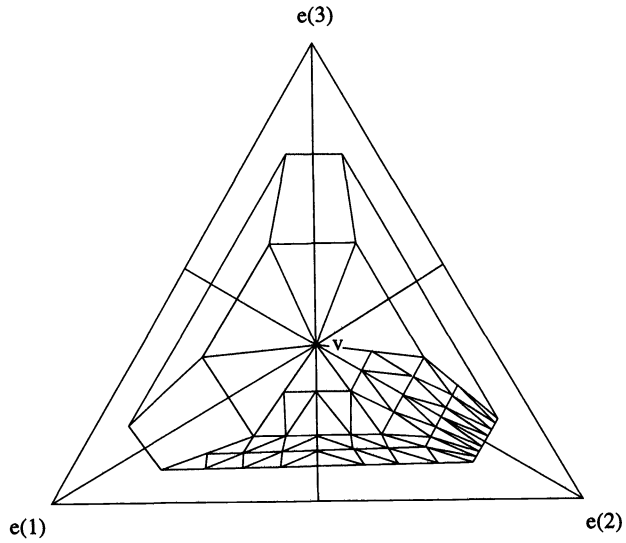

FIG. 2. *The P-triangulation of* S^{n-1} *for* $n = 3$, $d = 2$, *and* $v = (1/3, 1/3, 1/3)^\top$.

Then for given $k \in Z_0$ the mesh size of $G^d(k, k+1)$ is equal to

$$\delta_{k,d} = \sup\{\, diam(\sigma) \mid \sigma \in G^d(k, k+1) \,\}.$$

Now we have the following property.

LEMMA 3.3. *Let* d *be a given positive integer. For the P-triangulation of* S^{n-1} *with grid size* d^{-1}, *it holds that*

$$\lim_{k \to \infty} \delta_{k,d} = 0.$$

4. The algorithm. In this section we discuss how to operate the algorithm in the P-triangulation of S^{n-1} to approximate a robust stationary point of a continuous function on S^{n-1}. Starting at the point v, the algorithm will generate a sequence of adjacent simplices of the P-triangulation in the set $\mathcal{F}(I)$ having I-complete common facets, for varying $I \in \mathcal{I}$.

DEFINITION 4.1. *Let the function* $f : S^{n-1} \mapsto R^n$ *be given. For given* $I = (I_1, \ldots, I_m) \in \mathcal{I}$ *and* $s = t - 1$ *or* t, *where* $t = n - m$, *an* s*-simplex* σ *with vertices* $y^1, \ldots, y^{s+1}$ *is* I*-complete if the system of linear equations*

$$\sum_{i=1}^{s+1} \lambda_i \begin{pmatrix} f(y^i) \\ 1 \end{pmatrix} - \sum_{j=1}^{m} \mu_j \begin{pmatrix} b(I_j) \\ 0 \end{pmatrix} - \beta \begin{pmatrix} e \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \tag{4.1}$$

where e *is an* n*-vector of* 1*'s, has a solution* λ_i^*, $i = 1, \ldots, s+1$, μ_j^*, $j = 1, \ldots, m$, *and* β^* *with* $\lambda_i^* \geq 0$, $i = 1, \ldots, s+1$, *and* $\mu_j^* \geq 0$, $j = 1, \ldots, m$.

A solution λ_i^*, $i = 1, \ldots, s+1$, μ_j^*, $j = 1, \ldots, m$, and β^* will be denoted by $(\lambda^*, \mu^*, \beta^*)$. For $s = t - 1$ we assume that the system (4.1) has a unique solution with $\lambda_i^* > 0$, $i = 1, \ldots, t$, and $\mu_j^* > 0$, $j = 1, \ldots, m$, and that for $s = t$ at most one variable of (λ^*, μ^*) is equal to zero (nondegeneracy assumption). We remark that this assumption can be dropped if we use the lexicographic pivoting method in linear programming to solve system (4.1), see e.g., Todd [23].

The algorithm starts to leave the point v in one out of $n!$ directions. This direction is uniquely determined by $f(v)$. Because of the nondegeneracy assumption, all components of the vector $f(v)$ are different. Let $(i_1,\dots,i_n)$ be a permutation of the set $(1,\dots,n)$ such that $f_{i_1}(v) > \cdots > f_{i_n}(v)$. Then the 0-dimensional simplex $\{v\}$ is I^0-complete with $I^0 = (I^0_1,\dots,I^0_{n-1})$, where $I^0_j = \{i_1,\dots,i_j\}$ for $j = 1,\dots,n-1$. Moreover, $\{v\}$ is a facet of a unique 1-simplex σ^0 in $\mathcal{F}(I^0)$, where $\sigma^0 = \sigma(a,\pi)$ with $a = 0$ and $\pi = (0)$. Since for given $I \in \mathcal{I}$ an I-complete t-simplex has at most two I-complete facets and a facet of a t-simplex in $\mathcal{F}(I)$ is a facet of at most one other t-simplex in $\mathcal{F}(I)$, we obtain that the I-complete t-simplices $\sigma(a,\pi)$ in $\mathcal{F}(I)$ determine sequences of adjacent t-simplices in $\mathcal{F}(I)$ with I-complete common facets. As described below, the sequences of the I-complete t-simplices in $\mathcal{F}(I)$ can be uniquely linked together for varying $I \in \mathcal{I}$ to obtain sequences of adjacent simplices of varying dimension. Under the nondegeneracy assumption, one of these sequences starts with σ^0 in $\mathcal{F}(I^0)$ and is followed by the algorithm. Thus, starting at the point v, the algorithm generates a unique sequence of I-complete adjacent t-simplices in $\mathcal{F}(I)$ of varying dimension. In this way within a finite number of steps either the algorithm reaches a point $\bar{x}$ in an $(n-1)$-dimensional simplex for which $\bar{f}_i(\bar{x}) = \bar{f}_j(\bar{x})$ for every i and $j \in N$, where $\bar{f}$ is the piecewise linear (PL) approximation of f with respect to the P-triangulation, or for $k = 1,2,\dots$ the algorithm finds an I-complete $(t-1)$-simplex in $F(k,I)$ for some $I \in \mathcal{I}$. Suppose the latter case holds, then we have the following result.

LEMMA 4.2. *For $k \in Z_+$ and $I \in \mathcal{I}$, let σ with vertices $y^1,\dots,y^t$ be an I-complete $(t-1)$-simplex lying in $F(k,I)$. Let $(\lambda^*,\mu^*,\beta^*)$ be the corresponding unique solution of system (4.1). Then $x = \sum_{i=1}^t \lambda_i^* y^i$ is a 2^{-k}-robust stationary point of the PL approximation $\bar{f}$ of f with respect to the P-triangulation. Moreover, x is a stationary point of $\bar{f}$ on $A(2^{-k})$.*

Proof. Since $I = (I_1, I_2,\dots, I_m) \in \mathcal{I}$, there exist $l_1 < l_2 < \cdots < l_m$ such that

$$\begin{aligned} I_1 &= \{\, i_1,\dots,i_{l_1} \,\},\\ I_2 &= \{\, i_1,\dots,i_{l_1}, i_{l_1+1},\dots,i_{l_2} \,\},\\ &\vdots\\ I_m &= \{\, i_1,\dots,i_{l_m} \,\},\\ N\backslash I_m &= \{\, i_{l_m+1},\dots,i_n \,\}. \end{aligned}$$

Then it follows from equation (4.1) that

$$\begin{aligned} \bar{f}_{i_1}(x) = \cdots = \bar{f}_{i_{l_1}}(x) &= \mu_1^* + \cdots + \mu_m^* + \beta^*\\ > \bar{f}_{i_{l_1+1}}(x) = \cdots = \bar{f}_{i_{l_2}}(x) &= \mu_2^* + \cdots + \mu_m^* + \beta^*\\ &\vdots\\ > \bar{f}_{i_{l_{m-1}+1}}(x) = \cdots = \bar{f}_{i_{l_m}}(x) &= \mu_m^* + \beta^*\\ > \bar{f}_{i_{l_m+1}}(x) = \cdots = \bar{f}_{i_n}(x) &= \beta^*, \end{aligned}$$

where $\mu_i^* > 0$ for $i = 1,\dots,m$. Now it is not difficult to check that

$$x_i \le 2^{-k} x_j \quad \text{whenever } \bar{f}_i(x) < \bar{f}_j(x).$$

This means that x is a 2^{-k}-robust stationary point of the PL approximation $\bar{f}$ of f with respect to the P-triangulation.

Moreover, for each face $F(k, I)$, $I \in \mathcal{I}$, let $F^*(I)$ be the set of all n-dimensional vectors y such that every point of $F(k, I)$ is a solution of the linear programming problem

$$\max\ y^\top \hat{x} \quad \text{subject to } \hat{x} \in A(2^{-k}).$$

Then the stationary point problem for $\bar{f}$ on $A(2^{-k})$ is the problem of finding a point x in $A(2^{-k})$ such that $\bar{f}(x) \in F^*(I)$ for a minimum face $F(k, I)$ of $A(2^{-k})$ containing x. Duality theory implies that $F^*(I) = \{\, y \mid y = \sum_{i=1}^{m} \mu_i b(I_i) + \beta e,\ \mu_i \geq 0 \text{ for } i = 1, \ldots, m, \text{ and } \beta \in R \,\}$. It follows from equation (4.1) that $\bar{f}(x) \in F^*(I)$. Hence x is a stationary point of $\bar{f}$ on $A(2^{-k})$. □

To extend the domain of the PL approximation $\bar{f}$ of f, we recall that for a given positive integer d, the mesh size $\delta_{k,d}$ converges to zero as k goes to infinity. We can therefore take $\bar{f}(x)$ to be $f(x)$ if x lies on the boundary of S^{n-1}, since f is a continuous function. Hence $\bar{f}$ is also a continuous function from S^{n-1} into R^n.

For each $t \in [0, 1/2]$, let $V(t)$ denote the set of stationary points of f on $A(t)$. We summarize the following observations from the above discussions:

(P1) For each $t \in [0, 1/2]$, the set $V(t)$ is a nonempty closed set.

(P2) For each $t \in (0, 1/2]$, $x \in A(t)$ is a t-robust stationary point of f on S^{n-1} if and only if x belongs to the set $V(t)$.

(P3) For each $t \in [0, 1/2]$, if $x \in V(t)$ lies in the interior of $A(t)$, then all the components of $f(x)$ must be the same.

The next lemma shows that a 2^{-k}-robust stationary point of $\bar{f}$ on S^{n-1} is an approximate 2^{-k}-robust stationary point of f on S^{n-1}.

LEMMA 4.3. *Let* $\eta_{k,d} = \sup\{\, diam(f(\sigma)) \mid \sigma \in G^d(k-1, k) \,\}$. *Let* x *be a* 2^{-k}*-robust stationary point of the PL approximation* $\bar{f}$ *of* f *with respect to the P-triangulation obtained by the algorithm, so that* $x \in F(k, I_k)$ *for some* $I_k \in \mathcal{I}$. *Then* $f(x)$ *lies in the* $\eta_{k,d}$*-neighborhood of* $F^*(I_k)$, *i.e., there is a* $y \in F^*(I_k)$ *such that* $||y - f(x)|| \leq \eta_{k,d}$.

Proof. Let $y^1, \ldots, y^t$ be the vertices of a $(t-1)$-simplex of $G^d(k-1, k)$ in $F(k, I_k)$ containing x. Then $\bar{f}(x) = \sum_{j=1}^{t} \lambda_j^* f(y^j)$ lies in $F^*(I_k)$, where $\lambda_1^*, \ldots, \lambda_t^*$ are convex combination coefficients such that $x = \sum_{j=1}^{t} \lambda_j^* y^j$. Therefore

$$\begin{aligned} ||\bar{f}(x) - f(x)|| &= \left\| \sum_{j=1}^{t} \lambda_j^* f(y^j) - f(x) \right\| \\ &= \left\| \sum_{j=1}^{t} \lambda_j^* (f(y^j) - f(x)) \right\| \\ &\leq \sum_{j=1}^{t} \lambda_j^* ||f(y^j) - f(x)|| \\ &\leq \eta_{k,d}. \end{aligned}$$

Note that the following inequality also holds:

$$||\bar{f}(z) - f(z)|| \leq \eta_{k,d}, \text{ for any } z \in \mathcal{F}(k-1, k). \qquad \square$$

Next we discuss the case where the algorithm converges to a boundary point of S^{n-1}. Since S^{n-1} is compact and f is continuous on S^{n-1}, the error $\eta_{k,d}$ in Lemma

4.3 tends to zero as d is fixed and $\delta_{k,d}$ goes to zero when k goes to infinity. Let x^k be a 2^{-k}-robust stationary point of $\bar{f}$ and let $\eta_{k,d}$ be the error in Lemma 4.3. We can therefore consider x^k as an approximate 2^{-k}-robust stationary point of f. Then the algorithm generates a sequence $\{ x^k \mid k = 1, 2, \dots \}$ of approximate 2^{-k}-robust stationary points of f which therefore has a cluster point x^*. For simplicity of notation we can assume that this sequence itself converges to x^*. We are now ready to state the following result.

THEOREM 4.4. *Suppose that for a given positive integer d the vector x^k is an approximate 2^{-k}-robust stationary point generated by the algorithm, for $k = 1, 2, \dots$, i.e., for each $k \in Z_+$, $x^k \in F(k, I_k)$ with $I_k \in \mathcal{I}$ is a 2^{-k}-robust stationary point of $\bar{f}$. Then the sequence $\{ x^k \mid k = 1, 2, \dots \}$ has a cluster point x^* which is a robust stationary point of f on S^{n-1}.*

Proof. By definition, x^* is a robust stationary point of $\bar{f}$ on S^{n-1}. Notice that x^* lies on the boundary of S^{n-1}. We shall demonstrate that for any given $\epsilon > 0$, there exists a positive integer M, such that for $k \in Z_+$ with $k > M$, there is a 2^{-k}-robust stationary point $y^k \in A(2^{-k})$ of f on S^{n-1} which is in the ϵ-neighborhood of x^k.

Let

$$U(t) = \begin{cases} A(t) & \text{for } t \in [0, 1/2], \\ 2(1-t)A(2^{-1}) + (2t-1)\{ v \} & \text{for } t \in [1/2, 1], \end{cases}$$

and denote the set of stationary points of f on $U(t)$ by $Y(t)$ for $t \in [0, 1]$. Observe that $Y(t) = V(t)$ for $t \in [0, 1/2]$, and that $U(t)$ is contained in $A(2^{-1})$ for $t \in [1/2, 1]$. As t decreases from 1 to 0, $U(t)$ expands from the starting point v to the set $A(2^{-1})$ and then to the whole set S^{n-1}.

Now we define a function g_t (see, e.g., Doup [4] and Yamamoto [25]) from $U(t)$ into itself by

$$g_t(x) = \operatorname{argmin}\{ \| x + f(x) - y \| \mid y \in U(t) \}, x \in U(t).$$

Since $U(t)$ is a convex set and f is continuous, g_t is nonexpansive and hence is a Lipschitz continuous function. It is readily seen that $x \in Y(t)$ if and only if $x = g_t(x)$. Let

$$H(x, t) = x - g_t(x).$$

This is a Lipschitz continuous homotopy defined on $S^{n-1} \times [0, 1]$ between $H(x, 1) = x - v$ and $H(x, 0) = x - g_0(x)$. Now set

$$H^{-1}(0) = \{ (x, t) \in S^{n-1} \times [0, 1] \mid H(x, t) = 0 \}.$$

Let $W(t)$ denote the set of stationary points of $\bar{f}$ on $U(t)$ for $t \in [0, 1]$. Similarly, we can construct a Lipschitz continuous function with respect to $\bar{f}$, i.e.,

$$G : S^{n-1} \times [0, 1] \mapsto R^n,$$

such that

$$W(t) = \{ x \in S^{n-1} \mid G(x, t) = 0 \}, \ t \in [0, 1].$$

Set

$$G^{-1}(0) = \{ (x, t) \in S^{n-1} \times [0, 1] \mid G(x, t) = 0 \}.$$

For each $k \in Z_+$, let

$$\xi^k = (x^k, 2^{-k}).$$

It is clear that $\lim_{k\to\infty} \xi^k = \xi^* = (x^*, 0)$, since $\lim_{k\to\infty} x^k = x^*$. We define

$$N(\epsilon) = \{\, (x,t) \in S^{n-1} \times [0,1] \,|\, ||(x,t) - (z,s)|| < \epsilon \text{ for some } (z,s) \in H^{-1}(0) \,\}.$$

Clearly, it holds that

$$||H(\psi)|| > 0 \text{ for any } \psi \in S^{n-1} \times [0,1] \backslash N(\epsilon).$$

But $N(\epsilon)$ is open, so the set $S^{n-1} \times [0,1]\backslash N(\epsilon)$ is compact. The compactness means that the minimum can be attained and for some $\nu > 0$

$$\min\{\, ||H(\psi)|| \,|\, \psi \in S^{n-1} \times [0,1]\backslash N(\epsilon) \,\} > \nu.$$

Hence, if $\psi \in S^{n-1} \times [0,1]$ satisfies

$$||H(\psi)|| \leq \nu, \tag{4.2}$$

then ψ must be in $N(\epsilon)$. Because H is uniformly continuous on $S^{n-1} \times [0,1]$ and $\bar{f}$ is the PL approximation of f, it follows that

$$||H(\psi) - G(\psi)|| < \nu \tag{4.3}$$

for any $\psi = (x,t) \in S^{n-1} \times [0,1]$ under the condition that the diameter of simplices in which x lies is small enough, say, smaller than $\Delta > 0$.

Lemma 3.3 states that given a positive integer d, as k goes to infinity, the mesh size $\delta_{k,d}$ converges to zero. It implies that there exists a positive integer M such that for every $k \in Z_+$ with $k > M$, it holds that

$$\delta_{k,d} < \Delta.$$

Since for any $k \in Z_+$ with $k > M$, $\xi^k \in G^{-1}(0)$, i.e., $G(\xi^k) = 0$, it follows from (4.3) that

$$||H(\xi^k)|| < \nu.$$

By (4.2) ξ^k must be in $N(\epsilon)$. This implies that for any $k \in Z_+$ with $k > M$, there is $\psi^k \in H^{-1}(0)$ which is in the ϵ-neighborhood of ξ^k. Without loss of generality we may assume that $\psi^k = (y^k, 2^{-k})$. This is what we claimed.

On the other hand, since $\lim_{k\to\infty} x^k = x^*$, it immediately follows that

$$\lim_{k\to\infty} y^k = x^*.$$

Hence x^* is a robust stationary point of f on S^{n-1}. □

In the case where the algorithm terminates with an $(n-1)$-dimensional simplex σ with vertices $y^1, \ldots, y^n$, $\bar{x} = \sum_{i=1}^n \lambda_i^* y^i$ is a robust stationary point of $\bar{f}$. If the accuracy of approximation is not satisfactory, the algorithm can be restarted at the point $\bar{x}$ with a smaller grid size d^{-1} to find a better approximate robust stationary point, hopefully within a small number of steps. Without loss of generality we assume that the algorithm generates a sequence $\{\, \bar{x}^h \,|\, h = 1, 2, \ldots \}$, where $\bar{x}^h$ is the robust

stationary point of $\bar{f}$ corresponding to the grid size d_h^{-1} for an increasing sequence of positive integers $\{ d_h \mid h = 1, 2, \dots \}$. It is readily seen that for every $k \in Z_0$, the mesh size δ_{k,d_h} tends to zero as h goes to infinity. Therefore the sequence $\{ \bar{x}^h \mid h = 1, 2, \dots \}$ has a subsequence converging to a cluster point x^*. Clearly, x^* is a robust stationary point of f on S^{n-1}.

As described above, starting at the point v, the algorithm generates a unique sequence of adjacent t-simplices $\sigma(a, \pi)$ in $\mathcal{F}(I)$ for varying $I \in \mathcal{I}$ of varying dimension $t = n - m$. When, with respect to some $\sigma(a, \pi)$ with vertices $y^1, \dots, y^{t+1}$ in some $G^d(k, k+1; I, \gamma(I, I(n-1)))$ for some $k \in Z_0$ and $\gamma(I, I(n-1))$, the variable λ_q, for some q, $1 \leq q \leq t+1$, becomes zero through a linear programming (LP) pivot step in (4.1), then the replacement step determines the unique t-simplex $\bar{\sigma}(\bar{a}, \bar{\pi})$ in $F(k, k+1; I, \gamma(I, I(n-1)))$ sharing with σ the common facet τ opposite vertex y^q, unless this facet lies in the boundary of $F(k, k+1; I, \gamma(I, I(n-1)))$. If τ does not lie in the boundary of the set $F(k, k+1; I, \gamma(I, I(n-1)))$, then $\bar{\sigma}(\bar{a}, \bar{\pi})$ can be obtained from a and π as given in Table 1, where $E(j-1)$ is the jth unit vector in R^{n-1}, $j = 1, \dots, n-1$.

TABLE 1
Parameters of $\bar{\sigma}$ if the vertex y^q of $\sigma(a, \pi)$ is replaced.

	$\bar{\pi}$	$\bar{a}$
$q = 1$	$(\pi_2, \dots, \pi_t, \pi_1)$	$a + E(\pi_1)$
$1 < q < t+1$	$(\pi_1, \dots, \pi_{q-2}, \pi_q, \pi_{q-1}, \pi_{q+1}, \dots, \pi_t)$	a
$q = t+1$	$(\pi_t, \pi_1, \dots, \pi_{t-1})$	$a - E(\pi_t)$

The algorithm continues with $\bar{\sigma}$ by making an LP pivot step in (4.1) with $(f^\top(\bar{y}), 1)^\top$, where $\bar{y}$ is the vertex of $\bar{\sigma}$ opposite the facet τ. In the case where a facet τ of a simplex in $G^d(k, k+1; I, \gamma(I, I(n-1)))$ is not a facet of another simplex in $G^d(k, k+1; I, \gamma(I, I(n-1)))$, τ lies in the boundary of $F(k, k+1; I, \gamma(I, I(n-1)))$. According to Definition 3.2 we have the following lemma.

LEMMA 4.5. *Let $\sigma(a, \pi)$ be a t-simplex in $F(k, k+1; I, \gamma(I, I(n-1)))$. The facet τ of σ opposite the vertex y^q, $1 \leq q \leq t+1$, lies in the boundary of this set if and only if one of the following cases occurs:*

(i) *$1 < q < t+1$, $\pi_q = h+1$, $\pi_{q-1} = h$ for some $h \in \{0, 1, \dots, t-2\}$, and $a(h) = a(h+1)$ in the case where $h \geq 1$, and $a(0) + kd = a(1)$ in the case where $h = 0$;*

(ii) *$q = t+1$, $\pi_t = t-1$, and $a(t-1) = 0$;*

(iii) *$q = 1$, $\pi_1 = 0$, and $a(0) = d - 1$;*

(iv) *$q = t+1$, $\pi_t = 0$, and $a(0) = 0$.*

Suppose the algorithm generates the simplex $\sigma(a, \pi)$ as given in Lemma 4.5 and λ_q becomes zero after making an LP pivot step in (4.1). Then the facet τ of σ opposite the vertex y^q is I-complete. In case (iii) the facet τ lies in the face $F(k+1, I)$ of $A(2^{-k-1})$ and the algorithm reaches a 2^{-k-1}-robust stationary point $\bar{x} = \sum_{i=2}^{t+1} \lambda_i^* y^i$ of $\bar{f}$ lying in $F(k+1, I)$. If k is large enough, then $\bar{x}$ is an approximate robust stationary point of f. Otherwise, the algorithm proceeds with $\bar{\sigma}$ by making an LP pivot step in (4.1) with $(f^\top(\bar{y}), 1)^\top$, where $\bar{y}$ is the vertex of $\bar{\sigma}$ opposite the facet τ and $\bar{\sigma}$ in $F(k+1, k+2; I, \gamma(I, I(n-1)))$ is obtained according to Table 1.

In case (iv) the facet τ lies in the face $F(k, I)$ of $A(2^{-k})$ and the algorithm continues with $\bar{\sigma}$ by making an LP pivot step in (4.1) with $(f^\top(\bar{y}), 1)^\top$, where $\bar{y}$ is the vertex of $\bar{\sigma}$ opposite the facet τ and $\bar{\sigma}$ in $F(k-1, k; I, \gamma(I, I(n-1)))$ is also obtained from Table 1.

In case (i) and if $h \geq 1$, the facet τ is a facet of the t-simplex $\bar{\sigma} = \sigma(a, \pi)$ in $F(k, k+1; I)$ lying in the subset $F(k, k+1; I, \bar{\gamma}(I, I(n-1)))$ with

$$\bar{\gamma}(I, I(n-1)) = (J_1, \ldots, J_h, \bar{J}_{h+1}, J_{h+2}, \ldots, J_t),$$

where $\bar{J}_{h+1} \in \mathcal{I}$, $\bar{J}_{h+1} \neq J_{h+1}$, is uniquely determined by the properties that $\bar{J}_{h+1}$ conforms to J_h, has one component less than J_h, and is conformed by J_{h+2}. In case (i) and if $h = 0$, then τ is a facet of the t-simplex $\bar{\sigma} = \sigma(a, \pi)$ in $F(k, k+1; I, \bar{\gamma}(I, \bar{I}(n-1)))$ with $\bar{I}(n-1)$ and $\bar{\gamma}$ defined as follows. Let $J_1 = I(n-1) = (I_1, \ldots, I_{n-1})$. When $J_2 = (I_1, \ldots, I_{n-2})$, we have $\bar{I}(n-1) = (I_1, \ldots, I_{n-2}, \bar{I}_{n-1})$ with $\bar{I}_{n-1} = I_{n-2} \bigcup (N \backslash I_{n-1})$. When $J_2 = (I_2, \ldots, I_{n-1})$, let $\bar{I}(n-1) = (\bar{I}_1, I_2, \ldots, I_{n-1})$ with $\bar{I}_1 = I_2 \backslash I_1$. Finally if $J_2 = (I_1, \ldots, I_k, I_{k+2}, \ldots, I_{n-1})$ for some $k \in \{ 1, \ldots, n-3 \}$, we have $\bar{I}(n-1) = (I_1, \ldots, I_k, \bar{I}_{k+1}, I_{k+2}, \ldots, I_{n-1})$ with $\bar{I}_{k+1} = I_k \bigcup (I_{k+2} \backslash I_{k+1})$. Then $\bar{\gamma}(I, \bar{I}(n-1)) = (\bar{I}(n-1), J_2, \ldots, J_t)$. In both subcases of case (i) the algorithm continues by making a pivot step in (4.1) with $(f^\top(\bar{y}), 1)^\top$, where $\bar{y}$ is the vertex of the new t-simplex $\bar{\sigma}$ opposite the facet τ.

In case (ii) the facet lies in the set $F(k, k+1; J_{t-1})$ of $\mathcal{F}(I)$. More precisely, τ is the $(t-1)$-simplex $\sigma(a, \bar{\pi})$ in $F(k, k+1; \bar{I}, \bar{\gamma}(\bar{I}, I(n-1)))$, where $\bar{I} = J_{t-1}$, $\bar{\gamma}(\bar{I}, I(n-1)) = (J_1, \ldots, J_{t-1})$, and $\bar{\pi} = (\pi_1, \ldots, \pi_{t-1})$. The algorithm now proceeds by making a pivot step in (4.1) with $(-b^\top(I_h), 0)^\top$, where I_h is the unique component of J_{t-1} but not of J_t.

Finally, if through an LP pivot step in (4.1), the variable μ_h becomes 0 for some $h \in \{ 1, \ldots, m \}$, then the algorithm terminates with the approximate robust stationary point $\bar{x} = \sum_i \lambda_i^* y^i$ of f if $m = 1$ and restarts at the point $\bar{x}$ with a smaller grid size in case the accuracy is not satisfactory. Otherwise, the simplex $\sigma(a, \pi)$ is a facet of a unique $(t+1)$-simplex σ in $\mathcal{F}(\bar{I})$ with $\bar{I} = (I_1, \ldots, I_{h-1}, I_{h+1}, \ldots, I_m)$. More precisely, $\bar{\sigma} = \sigma(a, \bar{\pi})$ lies in $F(k, k+1; \bar{I}, \bar{\gamma}(\bar{I}, I(n-1)))$, where $\bar{\gamma}(\bar{I}, I(n-1)) = (\gamma, \bar{I})$, and $\bar{\pi} = (\pi_1, \ldots, \pi_t, t)$. The algorithm continues by making a pivot step in (4.1) with $(f^\top(\bar{y}), 1)^\top$, where $\bar{y}$ is the vertex of $\bar{\sigma}$ opposite the facet σ. This concludes the description of how the algorithm works in the P-triangulation of S^{n-1}.

5. Examples. Now we give some examples to show the power of the robust stationary point concept and the algorithm as well. Let us briefly review the standard model of a pure exchange economy. For details, we refer to Varian [24]. In such an economy there are, say, n commodities and a finite number of consumers, each having a vector of initial endowments. Exchange of commodities is based on relative prices. All consumers exchange goods in order to maximize their utility under their initial wealth constraints. This economy can be characterized by an excess demand function $z : R_+^n \backslash \{0\} \longrightarrow R^n$ which satifies the following standard conditions:

(i) z is a continuous function,

(ii) $z(\lambda p) = z(p)$ for any $\lambda > 0$ and $p \in R_+^n \backslash \{0\}$ (homogeneity),

(iii) $p^\top z(p) = 0$ for $p \in R_+^n \backslash \{0\}$ (Walras' law).

The element $p^* \in R_+^n \backslash \{0\}$ is an equilibrium price vector if $z(p^*) \leq 0$ (see Varian [24, p. 321]). Note that homogeneity permits us to normalize the price vectors to the $(n-1)$-dimensional unit simplex S^{n-1}. Now it is not hard to show that this problem is equivalent to the stationary point problem on S^{n-1}. We first present two examples of such an economic equilibrium model. To keep things simple and interesting, we shall focus on excess demand functions.

Example 1. There are two goods. The excess demand function is given by $z(p) = (p_1 p_2^2(1-p_1^2), -p_1^2 p_2(1-p_1^2))^\top$ for $p \in S^1$. There are two equilibria (i.e., stationary points) $x = (1,0)^\top$, $y = (0,1)^\top$. However only x is a robust stationary point. Further,

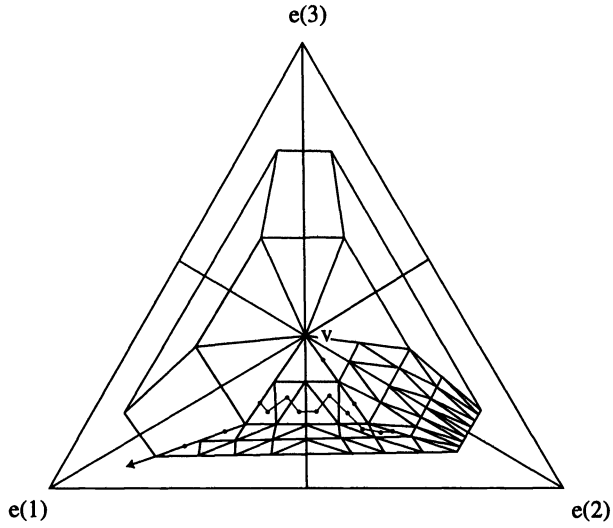

FIG. 3. *The path of the algorithm on* S^2 *for* $d = 2$ *and* $v = (1/3, 1/3, 1/3)^\top$.

x is more sensible than y in economic terms. We need to give some explanation. The basic idea of the Walrasian tatonnement process is as follows. Suppose that an economy is in disequilibrium. Then the Walrasian auctioneer would increase the price of a commodity if the excess demand of that commodity were positive, and decrease the price of a commodity if the excess demand of that commodity were negative. A sensible equilibrium should be stable against some data perturbation. In this example, suppose that the economy is slightly perturbed away from the equilibrium $(0, 1)^\top$. Then the tatonnement process would lead to another equilibrium $(1, 0)^\top$.

Example 2. There are three goods. The excess demand function is given by $z(p) = (p_2p_3, p_1p_3^2, -p_1p_2(1 + p_3))^\top$ for $p \in S^2$. The set of stationary points is $\{p \in S^2 | p_3 = 0\}$. But z only has one robust stationary point: $p^* = (1, 0, 0)^\top$. This fact is quite surprising. Moreover, the equilibrium price vector p^* is also most desirable from an economic point of view.

Finally, we conclude with two more examples.

Example 3. The function is defined by $f(x) = (x_1 + x_2, x_2 + x_3, x_3 + x_1)^\top$ for $x \in S^2$. The set of stationary points is

$$\{(1/3, 1/3, 1/3)^\top, (1, 0, 0)^\top, (0, 1, 0)^\top, (0, 0, 1)^\top\}.$$

However, f just has one robust stationary point: $(1/3, 1/3, 1/3)^\top$.

Example 4. The function is given by $f(x) = (x_1 - 9x_3, -7x_3, -9x_1 - 7x_2 - 7x_3)^\top$ for $x \in S^2$. This example is due to Myerson [16] and is often used in game theory literature. There are three stationary points: $(1, 0, 0)^\top$, $(0, 1, 0)^\top$, and $(0, 0, 1)^\top$. But f just has one robust stationary point: $(1, 0, 0)^\top$. The path followed by the algorithm is illustrated in Fig. 3 where the starting point is $(1/3, 1/3, 1/3)^\top$. The algorithm converges to the robust stationary point $(1, 0, 0)^\top$. At the $13 + 2(k - 1)$ step for $k \in Z_+$, we get the following approximate robust stationary point:

$$x^k = \left(\frac{1}{1 + 2^{-k} + 2^{-2k}}, \frac{2^{-k}}{1 + 2^{-k} + 2^{-2k}}, \frac{2^{-2k}}{1 + 2^{-k} + 2^{-2k}}\right)^\top.$$

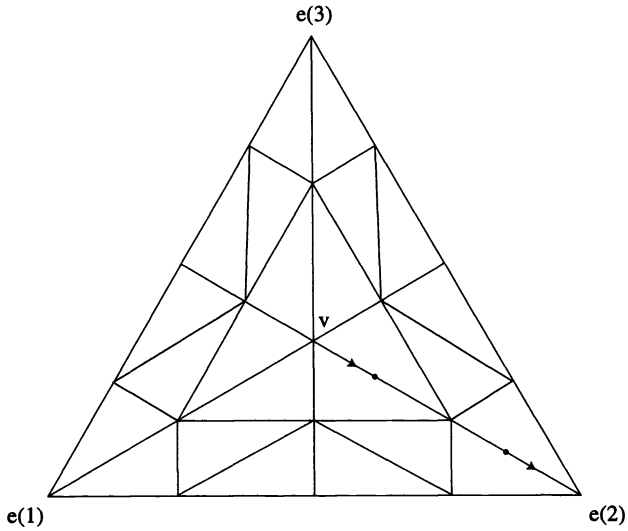

FIG. 4. *The path of the algorithm of van der Laan and Talman on* S^2 *for* $d = 2$ *and* $v = (1/3, 1/3, 1/3)^\top$.

It is easy to see that for each $k \in Z_+$, x^k is in fact a 2^{-k}-robust stationary point of f. By using this example and the same starting point, we also implement the well-known algorithm of van der Laan and Talman [13] (see also Doup and Talman [4]) based on the vector labelling and the V-triangulation [4]. No matter how fine triangulation is employed, their algorithm converges to the stationary point $(0, 1, 0)^\top$, which is not a robust stationary point. The path is shown in Fig. 4.

Acknowledgments. I would like to thank Gerard van der Laan, Dolf Talman, and Yoshi Yamamoto for their stimulating discussions, valuable comments, and constructive suggestions. The referees' helpful comments are gratefully acknowledged.

RECIPROCAL REALIZATIONS ON THE CIRCLE*

JAN-ÅKE SAND†

Abstract. Reciprocal realizations on a circle are defined. The concepts of minimality, interior observability, and exterior observability are introduced and related to each other, using geometric methods. In particular, the concept of a splitting subspace plays a central role.

Key words. reciprocal process, stochastic realization, splitting subspace

AMS subject classifications. 93E03, 94A12

1. Introduction.

Stochastic models of random phenomena that are spatially distributed are useful in applications such as image processing and computer vision; see, e.g., the paper by Levy [3] and references therein. It is often assumed then that the given object, a random process y, satisfies some strong assumptions about its dependency structure, e.g., that y is a Markov field. In order to relax these assumptions we may look for a model where y is the *output* of some underlying process x satisfying these stronger assumptions, i.e., a stochastic realization of y.

This is a natural generalization of the idea of state-space modeling of time series and leads naturally to the question whether it is possible to develop some stochastic realization theory for spatially indexed stochastic processes in the spirit of the geometric stochastic realization theory of Lindquist, Pavon, Picci and Ruckebusch [5]–[8].

Moreover, let us mention that the idea of realizing y as the output of a Markov field is present in the literaure on so-called hidden Markov models.

In this paper, as a prototype problem, we shall study stochastic processes defined on a discrete circle $\mathbb{T}$. The circle provides a parameter set that exhibits spatial properties but still has the advantage, from an analytical point of view, of being one dimensional.

More specifically, we shall study processes which are outputs of *reciprocal* state processes and define *reciprocal realizations.* Moreover, we shall define stochastic minimality, interior observability, and exterior observability for a reciprocal realization and relate these concepts to each other. Our approach will be geometric in the spirit of Lindquist and Picci, and the concept of a splitting subspace will play an important role when discussing minimality. For reciprocal realizations it turns out that the concept of minimality is quite subtle, since minimality of a reciprocal realization and minimality of its corresponding splitting subspaces do not coincide, as happens in stochastic realization theory for time series.

Reciprocal processes indexed by a discrete set were studied by Levy, Frezza, and Krener in [4], where they obtained finite-dimensional models for representing a certain class of Gaussian reciprocal processes. Such a model will be the basic ingredient in a reciprocal realization. Since our approach is geometric, we shall reformulate in a geometric language some of the results in [4] as well as add some new results on reciprocal processes.

† Division of Optimization and Systems Theory, Department of Mathematics, Royal Institute of Technology, 100 44 Stockholm, Sweden.

We shall briefly discuss the construction of reciprocal realizations. For example, it turns out that when using the models of [4] for representing the state process of a reciprocal realization, then the realization must be *external*; i.e., it cannot be constructed out of the given process y only. However, as will be pointed out, the theory on the construction of reciprocal realizations is far from complete.

Let us comment on the choice of a reciprocal state process for a realization on the circle. The reason that the state process x is reciprocal rather than Markovian is simply that the past and future of x with respect to a point in $\mathbb{T}$ coincide. Therefore, the Markov property is not very interesting on $\mathbb{T}$. A reciprocal process has the property that, for any interval, the values of the process in the interval are conditionally independent of those in the exterior, given the values of the process on the boundary of the interval. Hence, the reciprocal property is meaningful on $\mathbb{T}$, and it seems natural that a state process of a stochastic realization on $\mathbb{T}$ should be a reciprocal process.

The paper is organized as follows. In §2 we recall and reformulate in a geometric setting some of the results on reciprocal processes derived by Levy, Frezza, and Krener [4]. Moreover, we shall add some new results on reciprocal processes. In §3 we introduce reciprocal realizations and analyze minimality and observability with geometric tools. In §4 we discuss the construction of reciprocal realizations.

2. Reciprocal processes.

2.1. Preliminaries. In this paper we shall investigate random phenomena defined on a discrete circle $\mathbb{T}$. $\mathbb{T}$ has T elements and is indexed from 0 to $T-1$. All arithmetics on $\mathbb{T}$ is to be interpreted modulo T; e.g., we shall identify -1 with $T-1$. The closed interval $[s,t] \subseteq \mathbb{T}$ will denote the set $\{s, s+1, \dots, t-1, t\}$, and the open interval $(s,t) \subseteq \mathbb{T}$ will denote the set $\{s+1, s+2, \dots, t-1\}$.

Since we are interested in stationary processes on $\mathbb{T}$ which are outputs of systems with reciprocal state processes, we need first to review some of the theory of reciprocal processes on $\mathbb{T}$. We shall follow Levy, Frezza, and Krener [4] but also add some results. Moreover, the approach taken is geometric and in the spirit of Lindquist, Pavon, and Picci [6, 8].

Let H be a Hilbert space. If $M \subseteq H$ is a closed subspace, we write the orthogonal projection onto M as E^M. If η is an n-dimensional column vector with elements $\eta_i \in H$, we shall say that the vector itself belongs to H, i.e., $\eta \in H$. We write $E^M\eta$ for the vector $[E^M\eta_1, \dots, E^M\eta_n]'$ and say that the vectors $x = [\eta_1, \dots, \eta_n]'$ and $y = [\lambda_1, \dots, \lambda_m]'$ of elements in H are orthogonal if $(\eta_i, \lambda_j) = 0$ for all i, j.

If A and B are closed subspaces of H, $E^A B$ denotes the closure of the set $\{E^A b;\, b \in B\}$ and $A \vee B$ denotes the smallest closed vector space containing A and B. The following lemma will prove useful [5, p. 813].

LEMMA 2.1. *Let A and B be closed subspaces of H. Then $A = E^A B \oplus (A \cap B^\perp)$.*

The concept of conditionally orthogonal subspaces is of fundamental importance in stochastic systems theory. We say that the subspaces A and B are conditionally orthogonal given the space X, which we shall write as $A \perp B \,|\, X$, if for all $a \in A$ and $b \in B$ it holds that $(a - E^X a, b - E^X b) = 0$, which is equivalent to $E^{A \vee X} b = E^X b$ for $b \in B$ [5, p. 813]. The following lemma can be found in [5, p. 813].

LEMMA 2.2. *If $A \perp B \,|\, X$, then $A \cap B \subseteq X$.*

2.2. Reciprocal families of subspaces. In this paper all processes are zero-mean vector-valued Gaussian processes. Due to the Gaussian property, conditioning operations are linear projections onto relevant subspaces. Therefore, it is natural to analyze processes by means of the subspaces they generate. This way of handling

processes has the convenient property that any possible linear dependence between the components of $x(t)$ for a given vector process x is factored out of the analysis. To this end, we make the following definitions. Let x be an n-dimensional vector process on $\mathbb{T}$. The space X_t generated by x at t is defined as $X_t := \operatorname{span}\{x_i(t)\,; i = 1, \dots, n\}$. Moreover, let $[t_0, t_1]$ be an interval on $\mathbb{T}$. The spaces $X^i[t_0, t_1]$ and $X^e(t_0, t_1)$ are defined as $X^i[t_0, t_1] := X_{t_0} \vee X_{t_0+1} \vee \cdots \vee X_{t_1}$ and $X^e(t_0, t_1) := X_{t_1} \vee X_{t_1+1} \vee \cdots \vee X_{t_0-1} \vee X_{t_0}$. Finally, define $X_t^i := X^i[t-1, t+1]$ and $X_t^e := X^e(t-1, t+1)$.

Moreover, we notice that a family $\{X_t; t \in \mathbb{T}\}$ of subspaces generated by a stationary process with unitary shift U will have the property that $U^t X_s = X_{t+s}$ for all $t, s \in \mathbb{T}$. A family of subspaces having this shift property with unitary operator U is called a *stationary* family of subspaces.

A process x on $\mathbb{T}$ is *reciprocal* if, given an arbitrary interval $[t_0, t_1] \in \mathbb{T}$, the values of x in the interior and exterior of this interval are conditionally independent given $x(t_0)$ and $x(t_1)$; see [4, p. 1013]. In the Gaussian case it suffices to deal with conditional orthogonality, rather than conditional independence.

The family of subspaces generated by a Gaussian reciprocal process will possess a certain geometric structure.

DEFINITION 2.3. *A family* $\{X_t; t \in \mathbb{T}\}$ *of subspaces is* reciprocal *if for any given interval* $[t_0, t_1]$ *it holds that* $X^i[t_0, t_1]$ *and* $X^e(t_0, t_1)$ *are conditionally orthogonal given* $X_{t_0} \vee X_{t_1}$, *i.e.,*

$$X^i[t_0, t_1] \perp X^e(t_0, t_1) \mid X_{t_0} \vee X_{t_1}. \tag{2.1}$$

REMARK 2.4. *If specialized to the interval* $[t-1, t+1]$, *the condition* (2.1) *reduces to* $X_t^i \perp X_t^e \mid X_{t-1} \vee X_{t+1}$ *and especially for any* $\lambda \in X_t$ *it holds that* $E^{X_t^e}\lambda = E^{X_{t-1} \vee X_{t+1}}\lambda$.

Given a stationary reciprocal family of n-dimensional subspaces $\{X_t\}$ we can construct a vector process $\{x(t)\}$ such that the components of $x(t)$ form a basis for X_t in the following way. Let the set $\{\eta_1, \dots, \eta_n\}$ be a basis for X_0 and set $x(0) := [\eta_1, \dots, \eta_n]'$. Then the process $\{x(t)\}$ defined as $x(t) := [U^t\eta_1, \dots, U^t\eta_n]'$ is a basis process for $\{X_t\}$ in the sense that for every $\eta \in X_t$ there is a unique $a \in \mathbb{R}^n$ such that $\eta = a'x(t)$.

The process $\{x(t)\}$ is clearly reciprocal. In [4] it is shown that a stationary reciprocal process $\{x(t)\}$ satisfies the system

$$x(t) = F_- x(t-1) + F_+ x(t+1) + d(t), \tag{2.2}$$

where d is a certain noise process of which the covariance structure is entirely specified by the matrices F_- and F_+. The matrices F_- and F_+ are determined by the normal equations

$$\begin{bmatrix} \Gamma_1' & \Gamma_1 \end{bmatrix} = \begin{bmatrix} F_- & F_+ \end{bmatrix} \begin{bmatrix} \Gamma_0 & \Gamma_2 \\ \Gamma_2' & \Gamma_0 \end{bmatrix}, \tag{2.3}$$

where Γ_k is the covariance matrix $\Gamma_k := Ex(t)x(t+k)'$.

The system (2.3) always has a solution, but the solution need not be unique. The question of uniqueness is settled by the following lemma.

LEMMA 2.5. *The system* (2.3) *has a unique solution if and only if the vector sum* $X_{t-1} \vee X_{t+1}$ *is direct.*

Proof. Since the second matrix in the right-hand side of (2.3) is the Gram matrix of the set $\{x_1(t-1), \dots, x_n(t-1), x_1(t+1), \dots, x_n(t+1)\}$, the conclusion follows. □

The process d is constructed as $d(t) := E^{(X_t^e)^\perp} x(t)$ and therefore has the property that $d(t)$ is orthogonal to $x(s)$ when $t \neq s$. The process d is called the *two-sided innovation process.* The two-sided innovation process of a stationary reciprocal process is stationary. Moreover, in [4] it is shown that d is locally correlated, i.e., $d(t) \perp d(t+k)$ if $|k| > 1$.

The following lemma gives a necessary and sufficient condition for the two-sided innovation process of a reciprocal process to be identically zero.

LEMMA 2.6. *The two-sided innovation process d of a reciprocal process x is identically zero if and only if $X_t \subseteq (X_{t-1} \vee X_{t+1})$.*

Proof. The result follows from $d(t) = E^{(X_t^e)^\perp} x(t) = x(t) - E^{X_t^e} x(t) = x(t) - E^{X_{t-1} \vee X_{t+1}} x(t)$, where the last equality follows from reciprocity. □

If we identify the process x with a vector constructed by the random vectors $\{x(0), \dots, x(T-1)\}$, i.e., $x' = [x(0)', \dots, x(T-1)]'$, and make the corresponding identification for d, the system (2.2) can be written in matrix form as

$$Fx = d. \tag{2.4}$$

The matrix F is the block-circulant matrix $F = \operatorname{circ}(I, -F_+, 0, \dots, 0, -F_-)$. We say that the model (2.4) is *well posed* if F is invertible.

We shall now introduce a class of reciprocal processes having well-posed models. This is the class of *nonsingular* processes, essentially the class studied in [4]. The family $\{X_t\}$ of subspaces is *nonsingular* if the vector sum $X_0 \vee X_1 \vee \cdots \vee X_{T-1}$ is direct. We say that the vector process $\{x(t)\}$ is nonsingular if it generates a nonsingular family of subspaces. Nonsingularity means that for all $t \in \mathbb{T}$, X_t is linearly independent of X_t^e. Another way of characterizing nonsingularity is that for all $t \in \mathbb{T}$ the components of $d(t)$ form a basis for $(X_t^e)^\perp$, as stated in the following lemma. The proof is simple and omitted.

LEMMA 2.7. *A stationary reciprocal process x is nonsingular if and only if its two-sided innovation process satisfies $E\, d(t)d(t)' > 0$. Moreover, if x is nonsingular then x is uniquely determined by d.*

For reciprocal families nonsingularity is a "local" property, as shown in the following lemma.

LEMMA 2.8. *The reciprocal family is nonsingular if and only if $X_t \cap (X_{t-1} \vee X_{t+1}) = 0$ for all $t \in \mathbb{T}$.*

Proof. If the family is nonsingular it clearly holds that the intersection is trivial. Conversely, suppose that the intersection is trivial. Suppose, to get a contradiction, that the family is not nonsingular. Then there is a t such that $X_t \cap X_t^e \neq 0$; hence let $\lambda \in X_t \cap X_t^e$ and $\lambda \neq 0$. It now follows that $\lambda = E^{X_t^e} \lambda = E^{X_{t-1} \vee X_{t+1}} \lambda \neq \lambda$, which is a contradiction. □

EXAMPLE 2.9. *Let $\{x(t)\}$ be a nonsingular stationary reciprocal process on $\mathbb{T}$ such that $\dim X_t = n$ for all $t \in \mathbb{T}$. Since $\{X_t\}$ is nonsingular, it especially holds that $\dim(X_{t-1} \vee X_{t+1}) = 2n$. Hence, by Lemma 2.5 there is a unique model $x(t) = F_- x(t-1) + F_+ x(t+1) + d(t)$ satisfied by x. Moreover, x is uniquely determined from its two-sided innovation process d* [4].

Form another process $\{\tilde{x}(t)\}$ as $\tilde{x}(t) := [x(t)', x(t+1)']'$. It is easily verified that $\tilde{x}$ is reciprocal. Since $\dim(\tilde{X}_{t-1} \vee \tilde{X}_{t+1}) = 4n$, there is by Lemma 2.5 a unique model with matrices $\tilde{F}_-$ and $\tilde{F}_+$ However, the model is not well posed, since the inclusion

$$\tilde{X}_t = X_t \vee X_{t+1} \subseteq X_{t-1} \vee X_t \vee X_{t+1} \vee X_{t+2} = \tilde{X}_{t-1} \vee \tilde{X}_{t+1}$$

implies that $\tilde{d}(t) = 0$. *Hence, the process* $\tilde{x}$ *is not nonsingular and has a degenerated but unique model* $\tilde{F}\tilde{x} = 0$.

Necessary and sufficient conditions on $\{X_t\}$ for its corresponding model (2.2) to be well posed are not known.

From now on in this paper, we shall focus on *nonsingular* reciprocal processes. The reason for this is that this is a class of reciprocal processes for which we know that the model $Fx = d$ is well posed. Following Levy, Frezza, and Krener [4], we normalize the three-term difference equation (2.2) to obtain the symmetric descriptor model

$$Mx(t) = N'x(t-1) + Nx(t+1) + e(t), \tag{2.5}$$

where $M := D_0^{-1}$, $N := D_0^{-1}F_+$, and $e(t) := D_0^{-1}d(t)$.

Letting Λ be the block circulant $\Lambda := \operatorname{circ}(M, -N, 0, \ldots, -N')$, the normalized model can be written

$$\Lambda x = e. \tag{2.6}$$

It follows that the one-step covariance of the noise e is $Ee(t)e(t+1)' = -N$. Hence, the covariance matrix of e is $Eee' = \Lambda$, and multiplying (2.6) with e' from the right yields

$$Exe' = I. \tag{2.7}$$

From (2.7) it follows that e is the *conjugate process* of x.

In [4] it is shown that the solution x to the system $\Lambda x = e$ is a reciprocal process if Λ is positive definite and e is a stationary locally correlated process with $Ee(t)e(t)' = M$, $Ee(t)e(t+1)' = N$ and $Ee(t)e(t+k)' = 0$ if $|k-t| > 1$. The solution of the well-posed system $\Lambda x = e$ is also a stationary process. Thus we have the following theorem.

THEOREM 2.10. *The solution* x *of the well-posed system* $\Lambda x = e$ *on* $\mathbb{T}$ *is a stationary reciprocal process.*

Proof. The fact that x is a reciprocal process follows from [4]. To prove stationarity, it is enough to show that the covariance matrix of x is a block circulant. Since the model is well posed, we have that $x = \Lambda^{-1}e$ and the covariance of x can be written $Exx' = \Lambda^{-1}Edd'(\Lambda^{-1})' = \Lambda^{-1}$. The inverse of a block circulant is a block circulant [1, p. 181]. Hence, Λ^{-1} is a block circulant. □

We now summarize the results on reciprocal families of subspaces.

THEOREM 2.11. *Let* $\{X_t\}$ *be a family of finite-dimensional subspaces, with basis process* $\{x(t)\}$, *such that* $X_t \cap (X_{t-1} \vee X_{t+1}) = 0$. *Then* $\{X_t\}$ *is a stationary reciprocal family if and only the basis process* $\{x(t)\}$ *satisfies the system*

$$Mx(t) = N'x(t-1) + Nx(t+1) + e(t),$$

where e *is a stationary locally correlated process satisfying the necessary condition* $Eee' = \Lambda > 0$, *and* $\Lambda = \operatorname{circ}(M, -N, 0, \ldots, -N')$.

For a nonsingular stationary family of subspaces the reciprocal property has the following "local" characterization.

COROLLARY 2.12. *A stationary family of nonsingular subspaces* $\{X_t\}$ *is reciprocal if and only if* $X_0^i \perp X_0^e \mid X_{-1} \vee X_1$.

2.3. An abstract description of F_- and F_+. In this subsection we shall present abstract counterparts of the matrices F_- and F_+.

Let $\{X_t\}$ be a given nonsingular stationary reciprocal family and $\{x(t)\}$ be its basis process. For every $\lambda \in X_{-1}$ there is an $a \in \mathbb{R}^n$ such that $\lambda = a'x(-1)$.

We shall now show that F_- is the matrix representation of an operator acting on X_{-1} in this basis. By shifting, $U\lambda = a'x(0)$. Employing (2.2), we get $U\lambda = a'F_-x(-1) + a'F_+x(1) + a'd(0)$. The next step is to project orthogonally onto the subspace $X_{-1} \vee X_1$, which yields

$$E^{X_{-1}\vee X_1}U\lambda = a'F_-x(-1) + F_+a'x(1), \tag{2.8}$$

since $d(0) \perp X_0^e$. Finally, let Π_t be the projection onto X_t *along* X_t^e. By applying Π_{-1} to (2.8) we get $\Pi_{-1}E^{X_{-1}\vee X_1}U\lambda = a'F_-x(-1)$.

Motivated by the previous discussion we define the operator $A_- : X_{-1} \to X_{-1}$ as $A_-\lambda := \Pi_{-1}E^{X_{-1}\vee X_1}U\lambda$ for $\lambda \in X_{-1}$.

In particular, if we let $\lambda = x_k(-1)$, which corresponds to a being the kth unit vector in $\mathbb{R}^n$, we get that $A_-x_k(-1) = \sum_{j=1}^n (F_-)_{k,j}x_j(-1)$. Hence, $F_{-1} : X_- \to X_{-1}$ is the matrix representation of the operator A_- in the basis corresponding to $x(-1)$.

Analogously, we define $A_+ : X_1 \to X_1$ as $A_+\lambda := \Pi_1 E^{X_{-1}\vee X_1}U\lambda$ for $\lambda \in X_1$, and $F_+ : X_1 \to X_1$ is the matrix representation of A_+.

3. Reciprocal realizations. We shall now introduce the main objects of this paper, namely, reciprocal realizations on $\mathbb{T}$.

3.1. Geometric description of a realization. Given a nonsingular stationary reciprocal process x on $\mathbb{T}$ we can define a process y as $y(t) := Cx(t)$. This definition makes y a stationary, but not reciprocal, process on $\mathbb{T}$. If C is of full rank, then y will be nonsingular. However, the stationary process y has a very detailed structure as the output of a reciprocal process, and it makes sense to say that we have a reciprocal realization of y. The purpose of this chapter is to derive and discuss properties of reciprocal realizations. In the next chapter we shall discuss the construction of a realization, starting from the given process y.

DEFINITION 3.1. *The well-posed system*

$$\begin{cases} Mx(t) &= N'x(t-1) + Nx(t+1) + e(t), \\ y(t) &= Cx(t), \end{cases} \tag{3.1}$$

where M, N, and e satisfy the conditions of the preceding section, is a reciprocal realization *of y.*

We say that the process x is the *state process* of the realization and that X_t is the state space. As we will see, though, the relevant splitting subspaces are of the form $X_s \vee X_t$. This differs from Markovian realization theory, where the state space is the splitting subspace.

We shall now point out that the requirement that the state process x be nonsingular has advantages, as well as shortcomings. As advantages we regard the fact that nonsingular reciprocal processes are well studied and enjoy well-posed models of simple structure and that the condition for a stationary family of subspaces $\{X_t\}$ to be reciprocal reduces to the simple condition

$$X_0^i \perp X_0^e \,|\, X_{-1} \vee X_1.$$

As a shortcoming, we regard the result shown in the next section, that a reciprocal realization is necessarily external, which follows from the required nonsingularity of

x. This insight, gained by formulating the realization problem on $\mathbb{T}$ has motivated us to further investigate singular reciprocal processes, an investigation currently being done.

In order to analyze reciprocal realizations with geometric tools, we shall introduce some relevant subspaces. The space $H(y)$ is defined as the space spanned by y, i.e., $H(y) := \operatorname{span}\{y_i(t); \quad t \in \mathbb{T}, i = 1, \dots, m\}$.

The essence of a realization can now be expressed in a geometric and coordinate-free form. The state process x of (3.1) generates a stationary reciprocal family of subspaces $\{X_t\}$, and since the family is nonsingular, reciprocity is equivalent to

$$X_0^e \perp X_0^i \mid X_{-1} \vee X_1. \tag{3.2}$$

On the other hand, given a nonsingular family of subspaces satisfying (3.2) we can introduce a basis and get a three-term difference equation as

$$Mx(t) = N'x(t-1) + Nx(t+1) + e(t).$$

Furthermore, by stationarity, it is easily seen that $y(t) = Cx(t)$ for some matrix C is equivalent to $y(0) \in X_0$. Hence, an equivalent description of (3.1) is that we have a nonsingular stationary family of subspaces $\{X_t\}$ such that

1. $X_0^e \perp X_0^i \mid X_{-1} \vee X_1$,
2. $y(0) \in X_0$.

We shall now give an alternative equivalent geometric description of a reciprocal realization. This description employs the concept of splitting subspaces and opens the door to the geometric stochastic realization theory as developed in, e.g., [5]–[7].

Recall that, if H_1, H_2, and X are subspaces of some Hilbert space H, then X is a *splitting subspace* with respect to H_1 and H_2 if $H_1 \perp H_2 \mid X$. Moreover, a splitting subspace X is *minimal* if there is no proper subspace of X that is a splitting subspace with respect to H_1 and H_2.

We introduce the following subspaces of $H(y)$. Let $[s,t] \subseteq \mathbb{T}$. The subspaces $H^i[s,t]$ and $H^e(s,t)$ of $H(y)$ are defined as $H^i[s,t] := \operatorname{span}\{y_i(k); k \in [s,t], i = 1, \dots, m\}$ and $H^e(s,t) := \operatorname{span}\{y_i(k); k \in (s,t)^c, i = 1, \dots, m\}$. Note that the relation $H^i[s,t] = H^e(t,s)$ holds by symmetry properties of $\mathbb{T}$.

Note that we can write $H(y)$ as $H(y) = H^i[s,t] \vee H^e(s,t)$. For a given realization we see that the condition $y(t) \in X_t$ implies that $H^i[s,t] \subseteq X^i[s,t]$ and $H^e(s,t) \subseteq X^e(s,t)$. From this we get that

$$H^i[s,t] \perp H^e(s,t) \mid X_s \vee X_t. \tag{3.3}$$

Hence, the space $X_s \vee X_t$ is a splitting subspace with respect to $H^i[s,t]$ and $H^e(s,t)$. In contrast to Markovian realization theory on the real line or the integers, we notice that here the splitting subspace is not a space generated by the state process at a single point but instead the splitting subspace is the vector sum of the spaces generated by the state process at two different points in the index set $\mathbb{T}$.

We shall now show that the splitting relation (3.3) completely captures our idea of a realization.

THEOREM 3.2. *For a nonsingular reciprocal stationary family of subspaces $\{X_t\}$ the following are equivalent:*

1. $H_0^i \perp H_0^e \mid X_{-1} \vee X_1$,
2. $y(0) \in X_0$.

Proof. We have already shown that (2) $\Rightarrow$ (1). Suppose that (1) holds. Then by Lemma 2.2 it follows that $H_0^i \cap H_0^e \subseteq X_{-1} \vee X_1$, i.e.,

$$y(-1), y(1) \in X_{-1} \vee X_1. \tag{3.4}$$

By shifting (3.4) with U^2, we get $y(1), y(3) \in X_1 \vee X_3$. Hence, $y(1) \in (X_{-1} \vee X_1) \cap (X_1 \vee X_3)$. But since the family of subspaces is nonsingular, every sum of the type $X_s \vee X_t$ is *direct.* This implies that $(X_{-1} \vee X_1) \cap (X_1 \vee X_3) = X_1$, and we conclude that $y(1) \in X_1$, which, shifted, yields that $y(0) \in X_0$. □

In view of Theorem 3.2 we make the following equivalent definition of a reciprocal realization on $\mathbb{T}$.

DEFINITION 3.3. *Let* $\{y(t);\, t \in \mathbb{T}\}$ *be a stationary process. A nonsingular stationary family of finite-dimensional subspaces* $\{X_t\}$ *is a* reciprocal realization *of* $\{y(t);\, t \in \mathbb{T}\}$ *if*

1. $X_0^e \perp X_0^i \,|\, X_{-1} \vee X_1$,
2. $H_0^i \perp H_0^e \,|\, X_{-1} \vee X_1$.

3.2. Minimality and observability. The general goal of state-space modeling of some phenomena is to achieve data reduction for the behavior of the phenomena. In order to achieve *maximal* data reduction, the state space should be *minimal.*

DEFINITION 3.4. *A reciprocal realization of* $\{y(t);\, t \in \mathbb{T}\}$ *is* minimal *if the corresponding reciprocal family of subspaces* $\{X_k\}$ *has the property that there is no proper subspace* $\hat{X}_0 \subset X_0$ *such that* $\{\hat{X}_t\}$ *is a reciprocal realization of* $\{y(t);\, t \in \mathbb{T}\}$.

Due to stationarity, the inclusion $\hat{X}_0 \subset X_0$ holds if and only if $\hat{X}_t \subset X_t$ for all $t \in \mathbb{T}$.

Note that from this definition of minimality it does *not* follow that all minimal realizations of a given process y have the same dimension.

As previously seen, in realization theory on $\mathbb{T}$ the relevant splitting subspaces are of the form $X_s \vee X_t$, whereas the definition of minimality is given in terms of the state space X_t. Clearly, it is natural to try to relate these two concepts of minimality to each other. In the following theorem we give a sufficient condition for a reciprocal realization to be minimal.

THEOREM 3.5. *Let* $\{X_t\}$ *be a reciprocal realization. If there is a* τ *such that the splitting subspace* $X_0 \vee X_\tau$ *is a minimal splitting subspace, then the realization is minimal.*

Proof. Suppose there is a reciprocal realization $\{\hat{X}_t\}$ such that $\hat{X}_0 \subseteq X_0$. We have to show that $\hat{X}_0 = X_0$. Since $X_0 \vee X_\tau$ is a minimal splitting subspace, it follows that $\hat{X}_0 \vee \hat{X}_\tau = X_0 \vee X_\tau$. By directness of the vector sums it follows that $\hat{X}_\tau = X_\tau$ and stationarity implies that $\hat{X}_0 = X_0$. □

In order to analyze minimality further we shall introduce the concepts of interior and exterior observability. Fix any interval $[0, t]$ and suppose that y is given on $[0, t]$. Now let $\{X_t\}$ be a realization. Clearly, an element in the subspace $(X_0 \vee X_t) \cap H^i[0, t]^\perp$ cannot be distinguished from zero by observing y on $[0, t]$ and is therefore called *unobservable.* Note that this definition is a special case of a general definition of observability given in [7].

DEFINITION 3.6. *Let* $[0, t]$ *be an interval. The realization* $\{X_t\}$ *is* interiorly observable on $[0, t]$ *if* $(X_0 \vee X_t) \cap H^i[0, t]^\perp = 0$.

REMARK 3.7. *Due to stationarity, we can exploit the translation invariance and restrict the analysis to intervals of the type* $[0, t]$, *because on* $\mathbb{T}$ *any interval of the type* $[s, t]$ *can be shifted onto an interval of the type* $[0, t]$.

By Lemma 2.1 the space $X_0 \vee X_t$ can be decomposed as

$$X_0 \vee X_t = E^{X_0 \vee X_t} H^i[0,t] \oplus (X_0 \vee X_t) \cap H^i[0,t]^\perp. \tag{3.5}$$

From this decomposition we read that interior observability is equivalent to the equality

$$X_0 \vee X_t = E^{X_0 \vee X_t} H^i[0,t]. \tag{3.6}$$

DEFINITION 3.8. *Let $[0,t]$ be an interval. The realization $\{X_t\}$ is* exteriorly observable on $[0,t]$ *if* $(X_0 \vee X_t) \cap H^e(0,t)^\perp = 0$.

REMARK 3.9. *The situation here is analogous to that of Markovian realization theory, where it is necessary to introduce the two concepts observability and constructibility.*

The next theorem states that a splitting subspace $X_0 \vee X_t$ is minimal if and only if the realization is interiorly and exteriorly observable on the interval $[0,t]$. The theorem is a modification of Proposition 1 in [7, p. 273].

THEOREM 3.10. *Let $\{X_t\}$ be a reciprocal realization. The splitting subspace $X_0 \vee X_t$ is minimal if and only if the realization is interiorly and exteriorly observable on $[0,t]$.*

The next theorem states that for a given interval $[s,t]$, all minimal splitting subspaces $X_s \vee X_t$ with respect to $H^i[s,t]$ and $H^e(s,t)$ have the same dimension. The theorem follows directly from a general theorem by Lindquist and Picci [5, p. 822].

THEOREM 3.11. *Let $[s,t] \subseteq \mathbb{T}$. All minimal splitting subspaces of the form $X_0 \vee X_t$, with respect to $H^i[0,t]$ and $H^e(0,t)$, have the same dimension.*

3.3. An observability matrix. We shall now give an algebraic criterion for a realization defined by a triplet (M,N,C) and a noise process e to be interiorly observable on $[0,t]$. Recall that the block-circulant Λ is defined as $\Lambda = \operatorname{circ}(M, -N, 0, \dots, 0, -N')$. Since $x = \Lambda^{-1}e$ and $Eee' = \Lambda$, it follows that $Exx' = \Lambda^{-1}$. Let $\Gamma := \Lambda^{-1}$. In the case that T is even we have that

$$\Gamma = \operatorname{circ}(\Gamma_0, \Gamma_1, \dots, \Gamma_{\frac{T}{2}-1}, \Gamma_{\frac{T}{2}}, \Gamma'_{\frac{T}{2}-1}, \dots, \Gamma'_1).$$

The case of T odd is analogous.

Consider the relation (3.6); since the space on the right-hand side is included in the space on the left-hand side, the realization is interiorly observable on $[0,t]$ if and only if the inclusion $X_0 \vee X_t \subseteq E^{X_0 \vee X_t} H^i[0,t]$ holds. Equivalently, we require that

$$x_i(0), x_i(t) \in \operatorname{span}\{\hat{y}_j(s);\ s \in [0,t], j = 1, \dots, m\} \text{ for } i = 1, \dots, n, \tag{3.7}$$

where $\hat{y}_j(s) := E^{X_0 \vee X_t} y_j(s)$.

The condition (3.7) can be expressed as a rank condition on a certain observability matrix. To this end, let $s \in [0,t]$; since $y(s) = Cx(s)$, we get that $\hat{y}(s) = C\,E^{X_0 \vee X_t} x(s)$. The projection $E^{X_0 \vee X_t} x(s)$ can, with suitable matrices H_0 and H_t, be written as $E^{X_0 \vee X_t} x(s) = H_0 x(0) + H_t x(t)$. The normal equations for determining H_0 and H_t are $E\,[x(s) - H_0 x(0) - H_t x(t)]x(0)' = 0$ and $E\,[x(s) - H_0 x(0) - H_t x(t)]x(t)' = 0$. Taken together we get the following system of equations:

$$[E\,x(s)x(0)' \quad E\,x(s)x(t)'] = [H_0 \quad H_t] \begin{bmatrix} E\,x(0)x(0)' & E\,x(0)x(t)' \\ E\,x(t)x(0)' & E\,x(t)x(t)' \end{bmatrix}.$$

Recall that $Ex(s)x(s+k)' = \Gamma_k$, which yields $E\,x(s)x(0)' = \Gamma_s'$, $E\,x(s)x(t)' = \Gamma_{t-s}$ and $E\,x(0)x(t)' = \Gamma_t$. Since the process x is nonsingular, the normal equations have a unique solution for all $t \in \mathbb{T}$, and $\hat{y}(s)$ can be written as

$$\hat{y}(s) = C\begin{bmatrix}\Gamma_s' & \Gamma_{t-s}\end{bmatrix}\begin{bmatrix}\Gamma_0 & \Gamma_t \\ \Gamma_t' & \Gamma_0\end{bmatrix}^{-1}\begin{bmatrix}x(0) \\ x(t)\end{bmatrix}.$$

Stacking all $\hat{y}(s)$'s yields

$$\begin{bmatrix}\hat{y}(0) \\ \hat{y}(1) \\ \hat{y}(2) \\ \cdot \\ \cdot \\ \hat{y}(t)\end{bmatrix} = \begin{bmatrix}C\Gamma_0 & C\Gamma_t \\ C\Gamma_1' & C\Gamma_{t-1} \\ C\Gamma_2' & C\Gamma_{t-2} \\ \cdot & \cdot \\ \cdot & \cdot \\ C\Gamma_t' & C\Gamma_0\end{bmatrix}\begin{bmatrix}\Gamma_0 & \Gamma_t \\ \Gamma_t' & \Gamma_0\end{bmatrix}^{-1}\begin{bmatrix}x(0) \\ x(t)\end{bmatrix}.$$

By this calculation we are lead to define an observability matrix, which as shown can be calculated from the data (M, N, C), for which a rank criterion can be stated.

DEFINITION 3.12. *The observability matrix $\mathcal{O}(t)$ is defined as*

$$\mathcal{O}(t) := \begin{bmatrix}C\Gamma_0 & C\Gamma_t \\ C\Gamma_1' & C\Gamma_{t-1} \\ C\Gamma_2' & C\Gamma_{t-2} \\ \cdot & \cdot \\ \cdot & \cdot \\ C\Gamma_t' & C\Gamma_0\end{bmatrix}.$$

The condition (3.7) can now be expressed as $\ker \mathcal{O}(t) = 0$, and we get the following theorem on interior observability.

THEOREM 3.13. *The realization (M, N, C) is interiorly observable on $[0, t]$ if and only if* $\ker \mathcal{O}(t) = 0$, *i.e., if* $\operatorname{rank} \mathcal{O}(t) = 2n$.

We conclude this section with a numerical example.

EXAMPLE 3.14. *Let $T = 10$ be the length of $\mathbb{T}$ and let the matrices*

$$M = \begin{bmatrix}4 & 0 \\ 0 & 5\end{bmatrix}, N = \begin{bmatrix}-1 & 2 \\ -1 & 2\end{bmatrix}, \text{ and } C = \begin{bmatrix}1 & 0\end{bmatrix}$$

define a reciprocal realization of a process $\{y(t)\}$ as in Definition 3.1.

The covariance matrix $R = E\,yy'$ can be computed as

$$R = circ(0.41, -0.08, -0.02, -0.01, -0.002, -0.001, -0.002, -0.01, -0.02, -0.08),$$

and we conclude that $\{y(t)\}$ is stationary. It is easy to verify that R^{-1} is not a tridiagonal circulant, and consequently, $\{y(t)\}$ is not a reciprocal process. Hence, the dimension of a minimal realization is obviously 2.

The matrix $\mathcal{O}(2)$ is a 3×4 dimensional matrix and its rank cannot be 4, *as required for interior observability on $[0, 2]$. Hence, the splitting subspace $X_0 \vee X_2$ is not a minimal splitting subspace.*

The observability matrix $\mathcal{O}(3)$ is

$$\mathcal{O}(3) = \begin{bmatrix}0.4136 & 0.0322 & -0.0067 & 0.0182 \\ -0.0751 & -0.0894 & -0.0223 & 0.0615 \\ -0.0223 & -0.0265 & -0.0751 & 0.2074 \\ -0.0067 & -0.0077 & 0.4136 & 0.0322\end{bmatrix}$$

and has rank 4. *Consequently, the realization is interiorly observable on* $[0,3]$. *If the realization is also* exteriorly *observable on* $[0,3]$, *we can conclude by Theorem* 3.10 *that* $X_0 \vee X_3$ *is a minimal splitting subspace and by Theorem* 3.5 *that the realization is minimal. Since exterior observability on* $[0,3]$ *is equivalent to interior observability on* $[0,7]$, *we need only check that* rank $\mathcal{O}(7) = 2$, *which happens to be the case, as computations will show.*

4. Construction of reciprocal realizations. The realization problem amounts to the construction of a stochastic realization of a given process. In this paper the given process—y, say—is a stationary process defined on $\mathbb{T}$, and the objective is to produce a reciprocal realization of y, i.e., to find a triplet (M,N,C) and a locally correlated driving noise process e such that

$$\begin{cases} Mx(t) &= N'x(t-1) + Nx(t+1) + e(t), \\ y(t) &= Cx(t). \end{cases} \tag{4.1}$$

The reciprocal realization problem is equivalent to the following geometric problem. Given the stationary process y, find a minimal stationary nonsingular reciprocal family of subspaces $\{X_t\}$ such that $H_0^i \perp H_0^e \,|X_{-1} \vee X_1$.

In general, stochastic realization is a two-step procedure. First, we try to find a model for the process to be realized. In our setting this amounts to finding the matrices (M,N,C). Unfortunately, this problem, which we shall discuss in the next subsection, is still unsolved. Second, we must construct the state process x of the realization. In the following we show that the realization must be *external* and how to construct an external realization.

4.1. The covariance factorization problem. A realization (4.1) can be regarded as a mapping from the input noise e to the output y, which we can write as

$$y = We. \tag{4.2}$$

Since $y(t) = Cx(t)$, we get that $y = (I_T \otimes C)x$, where $\otimes$ denotes the Kronecker product. Furthermore, x satisfies $\Lambda x = e$, or equivalently, $x = \Lambda^{-1}e$. Recall that $Exe' = I$ and $Eee' = \Lambda$. Hence, $y = (I_T \otimes C)\Lambda^{-1}e$ and we define W as

$$W := (I_T \otimes C)\Lambda^{-1}.$$

Since the process y is given, its second-order properties are at hand and we let R_k be defined as $R_k := Ey(t)y(t+k)'$. Moreover, let R denote the covariance matrix

$$R := Eyy';$$

in the case of T even it follows that

$$R = \operatorname{circ}(R_0, R_1, \dots, R_{\frac{T}{2}-1}, R_{\frac{T}{2}}, R'_{\frac{T}{2}-1}, \dots, R'_1).$$

The case of T odd is analogous.

By straightforward calculations we get

$$R = Eyy' = WEee'W' = W\Lambda W'.$$

Inserting the expression for W, we get

$$R = (I_T \otimes C)\Lambda^{-1}(I_T \otimes C').$$

The procedure of going from the given matrix R to the triplet (M, N, C) is clearly a matrix-factorization problem. Moreover, we see that (M, N, C) are determined by the covariance data of y. Note that the smallest possible dimension of M is the minimal dimension of the realization. Necessary and sufficient conditions for a block-circulant R to admit such a factorization are not known.

Although covariance factorization is an inevitable step in constructing a realization we shall not investigate the factorization problem further in this paper but merely assume that the given process y is such that its corresponding R is factorizable and that the triplet (M, N, C) is at hand. Let us just remark that the problem, as it stands, does not seem elementary.

4.2. Nonexistence of internal realizations. If the state process x can be constructed using only the given process y we say that the realization is *internal*, which can be expressed as $X_t \subseteq H(y)$ for all $t \in \mathbb{T}$. Otherwise, the introduction of external random quantities is necessary in order to construct a realization and the state process will live in a larger space than $H(y)$, and we say that the realization is *external*. This larger space containing $H(y) \vee X_0 \vee X_1 \vee \cdots \vee X_{T-1}$ is called the *ambient space* of the realization.

For the case of nonsingular reciprocal realizations it turns out that internal realizations can never occur, except for the trivial case where y is already a reciprocal process itself. This is a consequence of the requirement that the state process be nonsingular and we give the following theorem.

THEOREM 4.1. *Suppose that is y is not reciprocal. Then there are no internal reciprocal realizations of y.*

Proof. To have an internal realization of y we must have a nonsingular reciprocal family of subspaces $\{X_t\}$ such that $X_t \subseteq H(y)$ and consequently, $X_0 \vee X_1 \vee \cdots \vee X_{T-1} \subseteq H(y)$. Moreover, the vector sum $X_0 \vee X_1 \vee \cdots \vee X_{T-1}$ must be direct.

Now if the given process y is an m-dimensional process, then $\dim H(y) \leq mT$. Since y is not reciprocal itself, for a realization it must hold that $\dim X_t > m$ and by the directness of the sum it necessarily follows that $\dim(X_0 \vee X_1 \vee \cdots \vee X_{T-1}) > mT$.

Hence, the existence of a nonsingular internal reciprocal realization would imply the contradiction

$$mT \geq \dim H(y) \geq \dim(X_0 \vee X_1 \vee \cdots \vee X_{T-1}) > mT. \qquad \square$$

4.3. External realizations. In this subsection we shall show how to construct *external* realizations by introducing random quantities that are orthogonal to $H(y)$, but that will help to span the state process in a realization.

Suppose that we are given the process y, such that its covariance matrix R can be factorized to give a minimal triplet (M, N, C). The problem is now to construct a driving noise e, which, fed into the system, gives exactly the process y. Since internal realizations are impossible, we cannot construct e out of y only but have to introduce some external random quantities. The explicit construction will now be given.

To make the calculations more transparent we will work with a white driving noise sequence u instead of e. Hence, let K be a square matrix solution to the equation $K'K = \Lambda^{-1}$. Observe that K is invertible. Define u as $u := Ke$; then it is easily seen that $Euu' = I$. The relation $y = We$ is now transformed to $y = WK^{-1}u$. By letting $S := WK^{-1}$ we have the relation

$$y = Su. \tag{4.3}$$

If we let $S^\sharp$ denote the pseudoinverse of S [9, Chap. 6.11] we can define an $nT \times nT$ matrix Π as

$$\Pi := I - S^\sharp S. \tag{4.4}$$

LEMMA 4.2. *Π is a projection matrix.*

Proof. We show that Π is symmetric and idempotent. $S^\sharp S$ is symmetric, which implies that Π is symmetric. Furthermore, $\Pi^2 = (I - S^\sharp S)(I - S^\sharp S) = I - 2S^\sharp S + S^\sharp S S^\sharp S = I - S^\sharp S = \Pi$, since $S^\sharp S S^\sharp = S^\sharp$. □

We notice that since Π is a projection matrix it is positive semidefinite and thus admissible as a covariance matrix. We can now characterize all possible white-noise solutions u to the equation $y = Su$, with y given. Suppose that u is a solution. Then we have $S^\sharp y = S^\sharp S u = (I - \Pi)u$, which gives that $u = S^\sharp y + \Pi u$. If we define z as $z := \Pi u$, we can write u as $u = S^\sharp y + z$. The covariance of z is Π and z is orthogonal to y, since $E\, yz' = SEuu'\Pi' = S\Pi = S - SS^\sharp S = 0$. This decomposition suggests how to construct the driving noise of an external realization.

THEOREM 4.3. *Let y be given as in* (4.3) *and let z be a process on $\mathbb{T}$ such that $H(z) \perp H(y)$ with covariance $Ezz' = \Pi$. Then the noise $\tilde{u}$ defined as*

$$\tilde{u} := S^\sharp y + \Pi z \tag{4.5}$$

will be white and satisfy (4.3) *and consequently, $\tilde{e}$ defined as $\tilde{e} := K^{-1}\tilde{u}$ will satisfy* (4.2).

Proof. Since y is in the range of S and $S\Pi = 0$, we have that $S\tilde{u} = SS^\sharp y + S\Pi z = y$. Furthermore, $E\tilde{u}\tilde{u}' = S^\sharp E yy' (S^\sharp)' + \Pi = S^\sharp S (S^\sharp S)' + \Pi = S^\sharp S S^\sharp S + \Pi = S^\sharp S + \Pi = I$. Hence, $\tilde{u}$ is white. □

Thus given any process z with the properties of Theorem 4.3, we may choose the basic ambient Hilbert space to be $H = H(y) \oplus H(z)$.

5. Conclusions. Results on reciprocal processes, originally obtained by Levy, Frezza, and Krener [4], are reformulated in a geometric framework. Some new results on reciprocal processes are added.

A nonsingular reciprocal realization is defined as a system of the following type:

$$\begin{cases} Mx(t) &= Nx(t-1) + N'x(t+1) + e(t), \\ y(t) &= Cx(t), \end{cases}$$

where the covariance structure of the driving noise $\{e(t)\}$ is entirely specified by the matrices M and N.

The nonsingularity of the state process, expressed as the vector sum $X_0 \vee X_1 \vee \cdots \vee X_{T-1}$ being direct, enables the characterization of a reciprocal realization in a coordinate-free form. With this geometric characterization at hand we can apply results from stochastic realization theory, as developed by Lindquist, Picci, and others, to define and analyze minimality and observability of a reciprocal realization.

As it turns out, the requirement that the state process be nonsingular implies that a reciprocal realization is necessarily external.

However, under the assumption that the model (M, N, C) is known, we show how to construct the driving noise of an external reciprocal realization.

The nonexistence of internal realizations, caused by the requirement that the state process be nonsingular, has initiated research on models for representing reciprocal processes that are not nonsingular. For example, consider the model

$$\begin{cases} x(t+1) &= Ax(t) + w(t), \\ x(T) &= x(0), \end{cases} \tag{5.1}$$

where w is a white noise defined on $\mathbb{T}$. It is straightforward to show that this model admits a well-posed solution if and only if A avoids certain eigenvalues on the unit circle. Moreover, if $Q := E\, w(t)w(t)' > 0$, it follows, using techniques from [4, pp. 1018–1019], that x is a nonsingular reciprocal process. Moreover, the two models (A, Q) and (M, N) are related by a certain algebraic Riccati equation. This algebraic Riccati equation is equivalent to a certain factorization of Λ in which the factors are circulants themselves. However, even if Q is only positive semidefinite, the solution of (5.1) is still a reciprocal process; this was shown in the continuous-time case by Krener [2]. Hence, this may be a way to bypass the problem of nonsingularity in reciprocal realization theory on $\mathbb{T}$.

It should be pointed out, though, that some results in the geometric analysis seem to depend on the directness of the sum $X_0 \vee X_1 \vee X_1 \vee \cdots \vee X_{T-1}$. Hence the geometric theory also may have to be extended to deal with the nonsingular case.

Acknowledgments. I would like to thank Professor Anders Lindquist, Royal Institute of Technology, for reading a preliminary version of this paper and giving many valuable suggestions for its improvement; Dr. Anders Rantzer, now at Lund Institute of Technology: during the time I worked on this paper, he was an invaluable discussion partner and provided many useful pieces of advice; Dr. Ruggero Frezza, University of Padova, for inviting me to Italy in February 1991 and for numerous discussions on reciprocal processes; and two anonymous referees for many helpful suggestions.

ON SPECTRUM AND RIESZ BASIS ASSIGNMENT OF INFINITE-DIMENSIONAL LINEAR SYSTEMS BY BOUNDED LINEAR FEEDBACKS*

CHENG-ZHONG XU† AND GAUTHIER SALLET†

Abstract. This paper deals with spectrum and Riesz basis assignability of infinite-dimensional linear systems via bounded linear feedbacks. The necessary and sufficient condition of Sun [*SIAM J. Control Optim.*, 19 (1981), pp. 730–743] is generalized to a large class of boundary control systems. Two typical examples are presented to illustrate the application of our results. The results obtained in this paper may have potential applications in nondissipative spectral systems.

Key words. distributed parameter systems, bounded linear feedback control perturbation, spectral determination, stability, flexible structures

AMS subject classifications. 93C20, 93D15, 93B60, 93B55

1. Introduction.

In this paper, we consider directly the following linear evolution systems on a separable Hilbert space H (the inner product and induced norm in H are denoted by $\langle\cdot,\cdot\rangle$ and $\|\cdot\|$, respectively):

$$(\Sigma_O)\ :\ \dot{X}(t) = AX(t) + bu(t),$$

where A is the infinitesimal generator of a C_0-semigroup on H and the input element b is not necessarily admissible in the sense of [7]. Throughout the paper, A and b are assumed to satisfy the conditions H1, H2, and H3.

Hypothesis H1. The operator A has compact resolvent. We suppose that the spectrum $\sigma(A) = \{\lambda_n, n \in \mathbb{N}\}$ is simple.

Hypothesis H2. The domain $\mathcal{D}(A^*)$ of the adjoint operator A^* is a Hilbert space with the graph norm. $\mathcal{D}'(A^*)$ is the topological dual of $\mathcal{D}(A^*)$. We suppose that b belongs to $\mathcal{D}'(A^*)$.

Hypothesis H3. The eigenvectors $\{\phi_k; k \in \mathbb{N}\}$ of A form a Riesz basis in H. The biorthogonal sequence corresponding to the eigenvectors of A^* is denoted by $\{\psi_k; k \in \mathbb{N}\}$ and is also a Riesz basis of H [5, p. 310]. We set $b_k = (\psi_k, b)$, where $(\cdot,\cdot)$ is the classical duality product on $\mathcal{D}(A^*) \times \mathcal{D}'(A^*)$. Here, it is defined as the continuous extension of the inner product on H (H is dense in $\mathcal{D}'(A^*)$). We suppose that $b_k \neq 0$ for all $k \in \mathbb{N}$. Let d_n be the distance of $\{\lambda_n\}$ to the rest of the spectrum $\sigma(A)$. We consider the set of disks $D_n, n \in \mathbb{N}$ centered at $\{\lambda_n\}$ with radius $\frac{1}{3}d_n$. Now suppose that there exists a positive constant M such that for all $\lambda \notin \bigcup_{j\in\mathbb{N}} D_j$ and all $m \in \mathbb{N}$,

$$\sum_{n=1}^{+\infty} \left| \frac{b_n}{\lambda - \lambda_n} \right|^2 \leq M < +\infty \tag{1}$$

and

$$\sum_{n=1, n\neq m}^{+\infty} \left| \frac{b_n}{\lambda_m - \lambda_n} \right|^2 \leq M < +\infty. \tag{2}$$

† Institut National de Recherche en Informatique et en Automatique–Lorraine (Projet CONGE), Centre National de la Recherche Scientifique Unité de Recherche Associée 399, CESCOM, 4 rue Marconi, 57070 Metz, France (xu@ilm.loria.fr, sallet@ilm.loria.fr).

The assumptions H2 and H3 allow us to take into account the cases of boundary control because many linear distributed parameter systems can be formulated in the form of (Σ_O) (see [7] and also [19], [15], [16]). In particular, the cases of [21], the cantilever beam equation with lateral force control [15], [24], or moment force control [15], heat conduction equations [7], and the wave equation [18] enter the class of the systems considered here. For each fixed $\lambda \in \rho(A^*)$, the resolvent set of the adjoint operator A^*, and all $r \in H$, it follows from the hypothesis H3 that

$$\left|\left((\lambda - A^*)^{-1} r, b\right)\right| \leq K_\lambda \|r\|_H.$$

The condition (1) forces the constant K_λ to be bounded uniformly with respect to $\lambda \notin \bigcup_{j\in\mathbb{N}} D_j$ (see §3). In certain cases, the condition (2) of H3 implies the condition (1). See the examples in §2.

A closed linear operator $A : \mathcal{D}(A) \to H$ is called regular spectral if its resolvent is compact and its eigenvectors form a Riesz basis of H [20]. Sun has proved in [21] that under the hypothesis H1, with $b \in H$, and a stronger hypothesis than H3, the following condition is necessary and sufficient for the operator $A + b\langle \cdot, h\rangle$ $(h \in H)$ to be regular spectral and to have the spectrum $\{v_k; k \in \mathbb{N}\}$ assigned:

$$\sum_{k\in\mathbb{N}} \left| \frac{v_k - \lambda_k}{b_k} \right|^2 < +\infty. \tag{3}$$

More results on spectrum assignment via linear feedback at the boundary have been obtained in [6], [12], [11], [15], and [16]. Notably, Rebarber has shown that for some cases, it is possible to assign uniformly an infinite number of eigenvalues by unbounded but admissible linear feedback at the boundary [16]. In [11], Lasiecka and Triggiani have given fine sufficient conditions on $\sigma(A)$ and b such that the operator $A + b\langle \cdot, h\rangle_H$ is regular spectral. In [12], Liu has generalized Sun's condition to the class of systems for which the hypotheses H1–H3 are satisfied, with the following condition replacing those of (1) and (2):

$$\inf_{n\neq m} |\lambda_n - \lambda_m| \geq \delta |\lambda_n|^\alpha \text{ and } \sum_{n=1}^{+\infty} \left(\frac{|b_n|}{|\lambda_n|^\alpha} \right)^2 < +\infty \tag{4}$$

for some $\alpha \in \mathbb{R}$ and $\delta > 0$. However the latter condition is restrictive in the sense that it singles out the one-dimensional wave equation and cantilever beam equation with moment control. The aim of this paper is to expand the result of Sun to a more general class of systems satisfying our conditions H1–H3. It is clear that the condition (4) implies the conditions (1) and (2) of the assumption H3.

In this paper, we do not restrict our study to the case of admissible input elements [6], but consider input elements in $\mathcal{D}'(A^*)$. However, we do restrict our study to the case of bounded linear feedbacks (BLF): $u(t) = \langle x(t), h\rangle$ with $h \in H$. We prove that under the hypotheses H1–H3, the condition (3) is also a necessary and sufficient condition for spectrum and Riesz basis assignment. On the one hand, after each BLF, the controlled operator $A + b\langle \cdot, h\rangle$ is still regular spectral. On the other hand, given a set of points satisfying the condition (3), we can compute explicitly the BLF which realizes the spectrum assignment. The main difference between the work of this paper and that of [6], [12], and [16] is that our condition (Theorem 1) is not only sufficient, but also necessary. The necessary part of the condition may find applications in controller design for infinite-dimensional linear systems (cf., [14] and [9]). Our results

also allow us to explain why the system (Σ_O) cannot be exponentially stabilized by the BLF laws when it has an infinite number of eigenvalues in $\Re e(s) \geq 0$ and its input vector b is admissible in the sense of [7]. However we prove that in some cases, the uniform assignment of the spectrum can be achieved by BLFs. We should point out that the construction of BLF laws is simple and systematic as illustrated by our examples.

The paper is organized as follows. In §2, we present our main result and two typical examples. Section 3 is devoted to the proof of our main theorem. The last section contains our conclusions.

2. Main results. As only BLF laws are considered in the paper, the closed-loop system is governed by the evolution equation (Σ_C) in the phase space H :

$$(\Sigma_C): \ \dot{X}(t) = AX(t) + b\langle X(t), h\rangle.$$

The linear operator $A : \mathcal{D}(A) \longrightarrow H \subset \mathcal{D}'(A^*)$ admits the unique extension

$$\hat{A} \in \mathcal{L}(H, \mathcal{D}'(A^*))$$

by continuity because $\mathcal{D}(A)$ is dense in H. Accordingly, the linear operator

$$A_h = A + b\langle \cdot, h\rangle : \mathcal{D}(A) \to \mathcal{D}'(A^*)$$

admits a unique extension from H to $\mathcal{D}'(A^*)$, still denoted by A_h, and for all $x \in H$, $A_h x = \hat{A}x + b\langle x, h\rangle$.

Define now $\mathcal{D}(A_h) = \{x \in H; \hat{A}x + b\langle x, h\rangle \in H\}$. We use here the same definition for the unbounded linear operator $A_h : \mathcal{D}(A_h) \longrightarrow H$ as that of [16]. In the following, instead of directly dealing with A_h, we study the unbounded linear operator $L_h = A^* + h(\cdot, b)$ because the infinitesimal generation property is equivalent between A_h and L_h if they are adjoint w.r.t. each other. It is easy to see that $\mathcal{D}(L_h) = \mathcal{D}(A^*)$ from the hypothesis H2 and that L_h is closed because $h(\cdot, b)$ is A^*-compact [8, p. 194].

LEMMA 1. *The unbounded linear operator $A_h : \mathcal{D}(A_h) \longrightarrow H$ is the adjoint operator of L_h with the inner product $\langle \cdot, \cdot \rangle$ on H.*

Proof. First, let us prove that for all $x \in H$ and $y \in \mathcal{D}(A^{*^2})$,

$$(y, \hat{A}x) = (A^*y, x). \tag{5}$$

Given all $x \in \mathcal{D}(A)$ and $y \in \mathcal{D}(A^{*^2})$, we have

$$(y, \hat{A}x) = (y, Ax) = \langle y, Ax\rangle = \langle A^*y, x\rangle = (A^*y, x).$$

Since the domain $\mathcal{D}(A)$ is dense in H and both the injection $H \to \mathcal{D}'(A^*)$ and the operator $\hat{A}$ are continuous from H to $\mathcal{D}'(A^*)$, the equality (5) is true for all $x \in H$ and $y \in \mathcal{D}(A^{*^2})$.

Now, for all $x \in \mathcal{D}(L_h^*)$ and $y \in \mathcal{D}(A^{*^2})$,

$$\begin{aligned}(y, A_h x) &= (y, \hat{A}x + b\langle x, h\rangle) = (y, \hat{A}x) + \langle h, x\rangle(y, b)\\ &= (y, \hat{A}x) + \langle h(y, b), x\rangle = (A^*y + h(y, b), x)\\ &= (L_h y, x) = \langle L_h y, x\rangle = \langle y, L_h^* x\rangle = (y, L_h^* x).\end{aligned} \tag{6}$$

With $\mathcal{D}(A^{*^2})$ dense in $\mathcal{D}(A^*)$, $A_h x = L_h^* x$. This means that $A_h \supset L_h^*$.

On the other hand, it follows from the equality (5) that for all $x \in \mathcal{D}(A_h)$ and all $y \in \mathcal{D}(A^{*^2})$, $\langle y, A_h x\rangle = (y, A_h x) = \langle L_h y, x\rangle$. Since A^* is the generator of a C_0-semigroup on H, for each $y \in \mathcal{D}(A^*)$, there is a sequence $y_n \in \mathcal{D}(A^{*^2})$ such that $y_n \to y$ and $L_h y_n \to L_h y$ in H as $n \to +\infty$. This means exactly that $x \in \mathcal{D}(L_h^*)$ and $A_h x = L_h^* x$. Hence $A_h \subset L_h^*$. Therefore $A_h = L_h^*$. □

THEOREM 1. *Assume that the hypotheses* H1–H3 *are satisfied. Then,*

1. *for every $h \in H$, the feedback controlled operator A_h is regular spectral and the spectrum $\sigma(A_h) = \{v_k, k \in \mathbb{N}\}$ satisfies the condition* (3);
2. *given a set $\Lambda = \{v_k, k \in \mathbb{N}\}$ such that $v_j \neq v_k$ for $j \neq k$, there exists an $h \in H$ for the operator A_h to have $\sigma(A_h) = \Lambda$ if and only if the set satisfies the condition* (3). *Moreover the feedback is given by*

$$h = \sum_{j=1}^{+\infty} h_j \psi_j \quad \text{and} \quad \overline{h}_j = \frac{v_j - \lambda_j}{\overline{b}_j} \prod_{n=1, n\neq j}^{+\infty} \frac{\lambda_j - v_n}{\lambda_j - \lambda_n}, \tag{7}$$

where $\overline{h}_j$ denotes the complex conjugate of h_j for $j \in \mathbb{N}$.

We should understand that the infinite product in the theorem is the limit of the sequence in l^2

$$h^N = \left\{ \frac{v_j - \lambda_j}{\overline{b}_j} \prod_{n=1, n\neq j}^{N} \frac{\lambda_j - v_n}{\lambda_j - \lambda_n} \right\}_{j=1,2,\ldots},$$

that is,

$$\lim_{N \to +\infty} \sum_{j=1}^{+\infty} |h_j^N - \overline{h}_j|^2 = 0.$$

We will remark that for any set $\Lambda = \{v_k, k \in \mathbb{N}\}$ assignable by bounded linear feedback, there exists necessarily some integer N such that for all k, $j > N$ and $k \neq j$, $v_k \neq v_j$. The detailed proof and discussion of this result will be given in the next section. The main idea is to prove that L_h, considered as perturbation of A^*, is regular spectral, and that from some rank, the eigenvalues of L_h can be located in the disks centered at the eigenvalues of A^* with radius $6|b_n h_n|$. Moreover we show that the corresponding eigenvectors of L_h form a Riesz basis in H. Then the same result is true for the adjoint operator A_h. It follows from [3] that the controlled operators A_h and L_h are the generators of C_0-semigroups on H. Here we give only two typical examples to illustrate the application of Theorem 1.

Example 1. The wave equation

$$u_{tt}(x,t) = u_{xx}(x,t), \quad u(0,t) = 0, \quad u_x(1,t) = \Gamma(t)$$

with the boundary control $\Gamma(t)$. Define the Hilbert spaces $H = W \times L^2[0,1]$ and $W = \{f; f, f_x \in L^2[0,1], f(0) = 0\}$ with the inner product

$$\left\langle \begin{bmatrix} f_1 \\ f_2 \end{bmatrix}, \begin{bmatrix} g_1 \\ g_2 \end{bmatrix} \right\rangle_H = \int_0^1 \left[f_{1x}(x)\overline{g_{1x}(x)} + f_2(x)\overline{g_2(x)} \right] dx.$$

Using the techniques of [7], we can formally write the control system on the Hilbert space H

$$\dot{\phi}(t) = A\phi(t) + b\Gamma(t).$$

The semigroup generator $A : \mathcal{D}(A) \to H$ is skew-adjoint with

$$A \begin{bmatrix} f_1 \\ f_2 \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ \frac{\partial^2}{\partial x^2} & 0 \end{bmatrix} \begin{bmatrix} f_1 \\ f_2 \end{bmatrix}$$

and

$$\mathcal{D}(A) = \{(f_1, f_2) \in L^2[0,1] \times L^2[0,1], f_1, f_{1x}, f_{1xx} \in L^2[0,1], f_2 \in W, \\ f_1(0) = f_{1x}(1) = 0\}$$

and $b(x) = [0, \delta(1-x)]'$. By direct computation one can find the following results :

- $L_h = A_h^* = -A + h(\cdot, b)$.
- The spectrum $\sigma(-A) = \{\lambda_{\pm k} = \pm i(k + 1/2)\pi, k = 0, 1, \ldots\}$ and the corresponding eigenvectors

$$\psi_{\pm k}(x) = \begin{bmatrix} 1 \\ -\lambda_{\pm k} \end{bmatrix} \frac{i \sin[(k+1/2)\pi x]}{2(k+1/2)\pi}, \quad k = 0, 1, \ldots.$$

Since the operator A is skew-adjoint and its resolvents are compact, the elements $\{\psi_{\pm k}\}$ form an orthogonal basis of H. It is evident that $b_{\pm k} = \pm(-1)^k/2$, $k = 0, 1, \ldots$. For all $j \geq 0$, we have

$$\sum_{n=0, n\neq j}^{+\infty} \left| \frac{1}{\lambda_j - \lambda_n} \right|^2 + \sum_{n=1}^{+\infty} \left| \frac{1}{\lambda_j - \lambda_{-n}} \right|^2 = \sum_{n=0, n\neq j}^{+\infty} \frac{1}{(j-n)^2\pi^2} + \sum_{n=1}^{+\infty} \frac{1}{(j+n+1)^2\pi^2}$$

$$= \sum_{n=j+1}^{+\infty} \frac{1}{(j-n)^2\pi^2} + \sum_{n=0}^{j-1} \frac{1}{(j-n)^2\pi^2} + \sum_{n=1}^{+\infty} \frac{1}{(j+n+1)^2\pi^2} \leq 3 \sum_{k=1}^{+\infty} \frac{1}{k^2\pi^2} = \frac{1}{2}.$$

The same result is true for $j \leq 0$. Hence the condition (2) is satisfied. We show that in this case the condition (2) does imply the condition (1). Indeed for each $\lambda \notin \bigcup_{j=0}^{+\infty} D_{\pm j}$, there is an integer m_0 such that

$$\Im m(\lambda) \in [\Im m(\lambda_{m_0}), \Im m(\lambda_{m_0+1})]$$

because the distance $d_j = |\Im m(\lambda_j) - \Im m(\lambda_{j+1})|$ is greater than some constant. Then for $j \geq m_0 + 2$,

$$|\lambda - \lambda_j|^2 = \Re e^2(\lambda) + [\Im m(\lambda) - (m_0 + 1 + 1/2)\pi + (m_0 + 1 + 1/2)\pi - (j + 1/2)\pi]^2 \\ \geq \Re e^2(\lambda) + (j - m_0 - 1)^2\pi^2 = \Re e^2(\lambda) + |\lambda_j - \lambda_{m_0+1}|^2.$$

For $j \leq m_0 - 1$,

$$|\lambda - \lambda_j|^2 = \Re e^2(\lambda) + [\Im m(\lambda) - (m_0 + 1/2)\pi + (m_0 + 1/2)\pi - (j + 1/2)\pi]^2 \\ \geq \Re e^2(\lambda) + (m_0 - j)^2\pi^2 = \Re e^2(\lambda) + |\lambda_{m_0} - \lambda_j|^2.$$

Moreover we have

$$|\lambda - \lambda_{m_0}|^2, \ |\lambda - \lambda_{m_0+1}|^2 \geq \pi^2/9.$$

Therefore for each $\lambda \notin \bigcup_{j=0}^{+\infty} D_{\pm j}$,

$$\sum_{j=0}^{+\infty} \left| \frac{1}{\lambda - \lambda_j} \right|^2 + \sum_{j=0}^{+\infty} \left| \frac{1}{\lambda - \lambda_{-j}} \right|^2 \leq \left| \frac{1}{\lambda - \lambda_{m_0}} \right|^2 + \left| \frac{1}{\lambda - \lambda_{m_0+1}} \right|^2 \\ + \sum_{j \geq m_0+2}^{+\infty} \left| \frac{1}{\lambda_j - \lambda_{m_0+1}} \right|^2 + \sum_{-\infty}^{m_0-1} \left| \frac{1}{\lambda_j - \lambda_{m_0}} \right|^2 \leq 1 + \frac{18}{\pi^2}.$$

According to Theorem 1, the spectrum assignable by continuous feedback must satisfy the condition

$$\sum_{n=0}^{+\infty} |v_n - i(n+1/2)\pi|^2 + \sum_{n=1}^{+\infty} |v_{-n} + i(n+1/2)\pi|^2 < +\infty.$$

Therefore the best stability result achievable by continuous feedback is strong stability. However we know that the unbounded feedback $\Gamma(t) = -\frac{1}{2}u_t(1,t)$ exponentially stabilizes the system [10], [18]. Moreover the resulting operator is still regular spectral [18].

Example 2. Consider the Hilbert space $H = W_0^2[0,1] \times L^2[0,1]$ with

$$W_0^n[0,1] = \left\{ f; f, f_x, \ldots, \frac{\partial^n}{\partial x^n} f \in L^2[0,1], f(0) = f_x(0) = 0 \right\}$$

and the inner product

$$\left\langle \begin{bmatrix} f_1 \\ f_2 \end{bmatrix}, \begin{bmatrix} g_1 \\ g_2 \end{bmatrix} \right\rangle_H = \int_0^1 \left[f_{1xx}(x)\overline{g_{1xx}(x)} + f_2(x)\overline{g_2(x)} \right] dx.$$

The cantilever beam equation with the moment force control can be formally written as follows [15] :

$$\dot{\phi}(t) = A\phi(t) + b\Gamma(t),$$

where the operator $A : \mathcal{D}(A) \to H$ is skew-adjoint with

$$A \begin{bmatrix} f_1 \\ f_2 \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ -\frac{\partial^4}{\partial x^4} & 0 \end{bmatrix} \begin{bmatrix} f_1 \\ f_2 \end{bmatrix}$$

and

$$\mathcal{D}(A) = \left\{ (f_1, f_2); f_1 \in W_0^4[0,1], f_2 \in W_0^2[0,1], f_{1xxx}(1) = f_{1xx}(1) = 0 \right\},$$

and $b(x) = [0, \delta'(1-x)]'$.

The spectrum of $-A$ is

$$\sigma(-A) = \left\{ \lambda_{\pm k} = \pm i[k\pi + \pi/2 + O(e^{-k\pi})]^2, k = 1, \ldots \right\}.$$

One may find two positive constants M_1 and M_2 such that $b_{\pm n} = \beta_{\pm n} n$ with $M_1 \leq |\beta_{\pm n}| \leq M_2$ for $n \in \mathbb{N}$ (see [15], [19], and also [24]). The eigenvectors of A form a Riesz basis of H. Without loss of generality, we consider only the case where $j \geq 1$. Then we have

$$|\lambda_j - \lambda_n|^2 = [(j-n)\pi + O(e^{-j\pi}) + O(e^{-n\pi})]^2 \times [(j+n)\pi + O(e^{-j\pi}) + O(e^{-n\pi})]^2$$

and

$$|\lambda_j - \lambda_{-n}|^2 = \left\{ [j\pi + \pi/2 + O(e^{-j\pi})]^2 + [n\pi + \pi/2 + O(e^{-n\pi})]^2 \right\}^2.$$

Then we get the following inequality for some fixed number $\tilde{M}_2$:

$$\sum_{n=1, n\neq j}^{+\infty} \left| \frac{b_n}{\lambda_j - \lambda_n} \right|^2 + \sum_{n=1}^{+\infty} \left| \frac{b_{-n}}{\lambda_j - \lambda_{-n}} \right|^2$$

$$\leq \tilde{M}_2 \left\{ \sum_{n=j+1}^{+\infty} \frac{n^2}{(j-n)^2(j+n)^2} + \sum_{n=1}^{j-1} \frac{n^2}{(j-n)^2(n+j)^2} + \sum_{n=1}^{+\infty} \frac{1}{n^2} \right\} \leq \frac{\tilde{M}_2 \pi^2}{2}.$$

As in Example 1, the reader can verify that in this case the condition (2) also implies the condition (1). Following Theorem 1, all set Λ satisfying

$$\sum_{n=-\infty,n\neq 0}^{+\infty}\left|\frac{v_n-\lambda_n}{n}\right|^2<+\infty$$

can be assigned for the spectrum of the operator A_h by continuous feedback. This is why it is possible to assign the spectrum uniformly by continuous feedback [15]. Here the feedback is simple as given in Theorem 1. For instance, the point set $\Lambda=\{v_{\pm n}=-n^p+\lambda_{\pm n}, p<1/2, n=1,2,\ldots\}$ can be assigned for the spectrum of the controlled operator A_h via the continuous feedback of Theorem 1. The resulting semigroup e^{tA_h} is exponentially stable. In particular, taking $\Lambda=\{v_{\pm n}=-\alpha^2+\lambda_{\pm n}, 0\neq\alpha\in\mathbb{R}, n=1,2,\ldots\}$, we get the controlled semigroup e^{tA_h} satisfying

$$\|e^{tA_h}\|_{\mathcal{L}(H)}\leq M_\alpha e^{-t\alpha^2}$$

for some positive constant M_α (depending on the constant α), where the decay rate is arbitrarily fast by increasing the number α^2. The feedback that realizes the spectrum assignment is

$$h=\sum_{j=-\infty,j\neq 0}^{+\infty}\frac{-\alpha^2}{b_j}\prod_{n=1,n\neq j}^{+\infty}\left(\frac{\overline{\lambda}_j-\overline{v}_n}{\overline{\lambda}_j-\overline{\lambda}_n}\right)\prod_{m=1,m\neq -j}^{+\infty}\left(\frac{\overline{\lambda}_j-\overline{v}_{-m}}{\overline{\lambda}_j-\overline{\lambda}_{-m}}\right)\psi_j.$$

3. Proof of Theorem 1. To simplify the presentation, we introduce the following notation. Define the bounded linear functional $\mathcal{F}\in\mathcal{D}'(A^*)$ such that for all $g\in\mathcal{D}(A^*)$, $\mathcal{F}(g)=(g,b)$. For all $\lambda\in\rho(A^*)$, the resolvent set of the operator A^*, define the characteristic function $F_h(\lambda)=1-\mathcal{F}(R(\lambda,A^*)h)$, where $h\in H$ and $R(\lambda,A^*)=(\lambda-A^*)^{-1}$. For each $\lambda_0\in\rho(A^*)$, the linear functional $\mathcal{F}\circ R(\lambda_0,A^*)\in\mathcal{L}(H,\mathbb{C})$. The complex function $F_h(\lambda)$ is analytic on the resolvent set $\rho(A^*)$ (see [6] for a proof). We set the perturbation operator $T=h\mathcal{F}$ which is A^* compact [8, p. 194]. Then the operator A^*+T is closed with $\mathcal{D}(A^*+T)=\mathcal{D}(A^*)$. The following result can be proved by direct computation.

LEMMA 2. *For all $\lambda\in\rho(A^*)$ such that $F_h(\lambda)\neq 0$, we have*

$$R(\lambda,A^*+T)=R(\lambda,A^*)+R(\lambda,A^*)TR(\lambda,A^*)/F_h(\lambda)$$

and $\lambda\in\rho(A^*+T)$. Moreover the perturbed operator A^*+T has compact resolvents.

From this lemma, we know that the spectrum $\sigma(A^*+T)$ consists entirely of isolated eigenvalues with finite multiplicity [8, p. 187]. Now consider the set of disks $\tilde{D}_j$, $j\in\mathbb{N}$, centered at $\{\overline{\lambda}_j\}$ with radius $\frac{1}{3}d_j$. It is evident that $\tilde{D}_j\bigcap\tilde{D}_l=\emptyset$ for $j\neq l$. *Technically we suppose that $\lambda\notin\bigcup_{j\in\mathbb{N}}\tilde{D}_j$ implies that its complex conjugate $\overline{\lambda}\notin\bigcup_{j\in\mathbb{N}}\tilde{D}_j$.* This assumption is minor because in applications the spectrum $\sigma(A)$ is usually symmetric with respect to the real axis in the complex plane. Otherwise it is sufficient to rewrite the condition (1).

LEMMA 3. *For each $h=\sum_{j=1}^{+\infty}h_j\psi_j$, there exists a positive number $R_1>0$ such that the subset in the complex plane*

$$S=\{\lambda;|\lambda|\leq R_1\}\bigcup\bigcup_{j=1}^{+\infty}\tilde{D}_j$$

contains all the spectrum points $\sigma(A^* + T)$.

Proof. To prove this lemma, it is sufficient to verify that $F_h(\lambda) \neq 0$ for all $\lambda \notin S$ (see Lemma 2). From the hypotheses H1 and H2, for each $h \in H$ and all $\lambda \notin \bigcup_{j=1}^{+\infty} \tilde{D}_j$,

$$\mathcal{F}(R(\lambda, A^*)h) = \sum_{n=1}^{+\infty} \frac{h_n b_n}{\lambda - \overline{\lambda}_n}. \tag{8}$$

Since $\{\psi_n\}_{n=1}^{+\infty}$ is a Riesz basis of H, the following is true for some numbers M_1, $M_2 > 0$:

$$M_1^2 \sum_{j \in \mathbb{N}} |h_j|^2 \leq \|h\|_H^2 \leq M_2^2 \sum_{j \in \mathbb{N}} |h_j|^2. \tag{9}$$

It follows directly from (8) that for all $\lambda \notin \bigcup_{j=1}^{+\infty} \tilde{D}_j$,

$$|\mathcal{F}(R(\lambda, A^*)h)| \leq \sum_{n=1}^{N_1} \frac{|h_n b_n|}{|\overline{\lambda} - \lambda_n|} + \left[\sum_{n \geq N_1 + 1} |h_n|^2 \sum_{n \geq N_1 + 1} \left| \frac{b_n}{\overline{\lambda} - \lambda_n} \right|^2 \right]^{\frac{1}{2}}. \tag{10}$$

Using the condition (1) of the hypothesis H3, we can choose a large integer N_1 such that

$$\sum_{n \geq N_1 + 1} |h_n|^2 \sum_{n \geq N_1 + 1} \left| \frac{b_n}{\overline{\lambda} - \lambda_n} \right|^2 \leq \sum_{n \geq N_1 + 1} |h_n|^2 M \leq \frac{1}{36}, \tag{11}$$

(where we have used the fact that $\lambda \notin \bigcup_{j \in \mathbb{N}} \tilde{D}_j$ implies that $\overline{\lambda} \notin \bigcup_{j \in \mathbb{N}} \tilde{D}_j$) and then choose a positive number R_1 large enough so that for all $|\lambda| \geq R_1$,

$$\sum_{n=1}^{N_1} \frac{|h_n b_n|}{|\overline{\lambda} - \lambda_n|} \leq \frac{1}{6}. \tag{12}$$

It follows from the conditions (10)–(12) that for all $\lambda \notin S$,

$$|\mathcal{F}(R(\lambda, A^*)h)| \leq \frac{1}{3},$$

that is, $|F_h(\lambda)| \geq \frac{2}{3}$. This proves that $\sigma(A^* + T) \subset S$. □

We let $\nu(\lambda, A^*)$ and $\nu(\lambda, A^* + T)$ denote the algebraic multiplicities of λ as eigenvalue of A^* and $A^* + T$, respectively, and $n(\lambda)$ denote the order of λ as zero of the characteristic function $F_h(\lambda)$. (The order of λ as pole of the characteristic function $F_h(\lambda)$ counts as negative and $\nu(\lambda, A^*)$ counts as zero if $\lambda \in \rho(A^*)$.) In [12], Liu has proved the following result.

PROPOSITION 1. *For all* λ *in the complex plane,*

$$\nu(\lambda, A^* + T) = \nu(\lambda, A^*) + n(\lambda). \tag{13}$$

LEMMA 4. *For each* $h \in H$, *there exists an integer* N_1 *such that the infinite part of the spectrum points* $\{\overline{v}_n, n \geq N_1\}$ *of* $A^* + T$ *are simple and the corresponding eigenvectors are given by*

$$\tilde{\psi}_n = \begin{cases} \psi_n + \dfrac{\overline{v}_n - \overline{\lambda}_n}{h_n} \displaystyle\sum_{j \neq n} \frac{h_j \psi_j}{\overline{v}_n - \overline{\lambda}_j}, & \text{if } h_n \neq 0, \\ \psi_n + \dfrac{b_n}{F_h(\overline{\lambda}_n)} \displaystyle\sum_{j \neq n} \frac{h_j \psi_j}{\overline{v}_n - \overline{\lambda}_j}, & \text{if } h_n = 0. \end{cases} \tag{14}$$

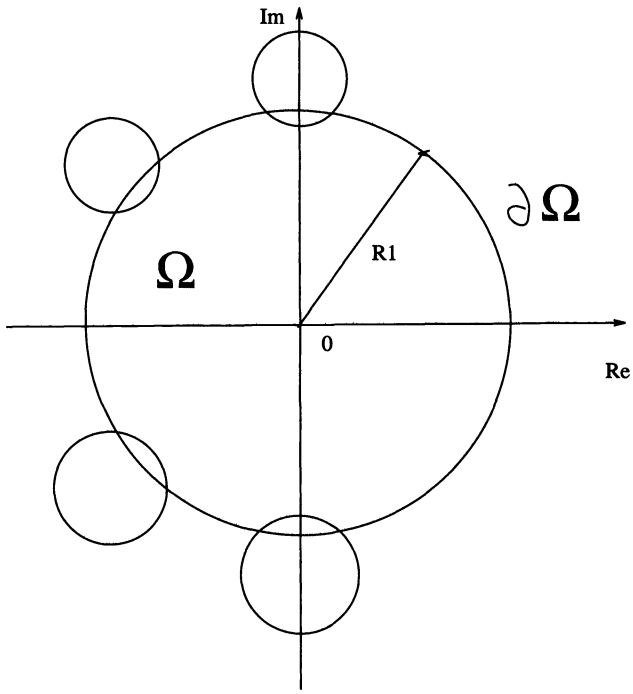

FIG. 1. *Illustrative distribution of the spectrum.*

Moreover the whole spectrum of $A^* + T$ *satisfies the condition*

$$\sum_{n=1}^{+\infty} \left| \frac{v_n - \lambda_n}{b_n} \right|^2 < +\infty.$$

Proof. Consider the disk $D(0, R_1)$ centered at zero with the radius R_1 defined in Lemma 3 such that $\overline{\lambda}_1 \in D(0, R_1)$. For all $\lambda \in \tilde{D}_j$,

$$|\lambda - \overline{\lambda}_1| \geq |\overline{\lambda}_j - \overline{\lambda}_1| - |\lambda - \overline{\lambda}_j| \geq \frac{2}{3}|\overline{\lambda}_j - \overline{\lambda}_1|$$

and

$$|\lambda| \geq |\lambda - \overline{\lambda}_1| - |\overline{\lambda}_1| \geq \frac{2}{3}|\overline{\lambda}_j - \overline{\lambda}_1| - |\overline{\lambda}_1| \geq \frac{2}{3}|\overline{\lambda}_j| - \frac{5}{3}|\overline{\lambda}_1|.$$

Since $\lim_{j \to +\infty} |\lambda_j| = +\infty$, only a finite number N_0 of disks $\tilde{D}_j$ intersect the disk $D(0, R_1)$. Take the boundary $\tilde{C}_j = \{\lambda; |\lambda - \overline{\lambda}_j| = d_j/3\}$ of the disk $\tilde{D}_j$. Define the closed curve $\partial\Omega$ by the boundary of the union

$$\Omega = D(0, R_1) \bigcup_{j=1}^{N_0} \tilde{D}_j$$

(as indicated in Fig. 1). From the proof of Lemma 3, we know that

$$\sup_{\lambda \in \partial\Omega} |\mathcal{F}(R(\lambda, A^*)h)| \leq \frac{1}{3}.$$

From the hypothesis H1, the function $F_h(\lambda)$ has at most N_0 poles in the domain Ω. Applying the Rouché theorem on the functions $g(\lambda) = 1$ and $F_h(\lambda)$ allows us to say that $F_h(\lambda)$ has the same number of zeros as poles in Ω, for $1 - F_h(\lambda) = \mathcal{F}(R(\lambda, A^*)h)$. Then from the identity (13),

$$\sum_{\lambda \in \Omega} \nu(\lambda, A^* + T) = N_0.$$

That means that the operator $A^* + T$ has N_0 eigenvalues (multiplicity counted) in the region Ω. By construction, it is also true that for all $j > N_0$,

$$\sup_{\lambda \in \tilde{C}_j} |\mathcal{F}(R(\lambda, A^*)h)| \leq \frac{1}{3}.$$

The function $F_h(\lambda)$ has either one pole $\overline{\lambda}_j$ or no pole in $\tilde{D}_j$. Applying the Rouché theorem on the functions $g(\lambda) = 1$ and $F_h(\lambda)$ allows us to say that $F_h(\lambda)$ has the same number of zeros as poles in the disk $\tilde{D}_j$. Then from the identity of Liu (13), the operator $A^* + T$ has a simple eigenvalue in $\tilde{D}_j$ for $j > N_0$. Moreover this eigenvalue is either $\{\overline{\lambda}_j\}$ or the unique zero $\overline{v}_j \neq \overline{\lambda}_j$ of $F_h(\lambda)$ in $\tilde{D}_j$.

Actually the simple eigenvalue $\overline{v}_j$ is situated in a smaller disk contained in $\tilde{D}_j$. Because

$$\lim_{\substack{j \to +\infty \\ j \neq n}} \frac{|h_j b_j|}{|\lambda_j - \lambda_n|} = 0,$$

we can take some $N_1 > N_0$ sufficiently large such that for any λ with $|\lambda - \overline{\lambda}_j| \leq 6|h_j b_j|$ and any integer n,

$$\sup_{j \geq N_1} \sup_{n \neq j} \left| \frac{\overline{\lambda}_n - \overline{\lambda}_j}{\lambda - \overline{\lambda}_n} \right| = \sup_{j \geq N_1} \sup_{n \neq j} \frac{1}{\left| 1 + \frac{\lambda - \overline{\lambda}_j}{\overline{\lambda}_j - \overline{\lambda}_n} \right|} \leq \sup_{j \geq N_1} \sup_{n \neq j} \frac{1}{1 - \frac{6|h_j b_j|}{|\lambda_j - \lambda_n|}} \leq \frac{3}{2}. \tag{15}$$

It follows from the definition (8) that for all $j \geq N_1$ and all $|\lambda - \overline{\lambda}_j| = 6|h_j b_j|$,

$$\begin{aligned}
|\mathcal{F}(R(\lambda, A^*)h)| &\leq \sum_{n=1, n \neq j}^{N_2} \frac{|h_n b_n|}{|\overline{\lambda} - \lambda_n|} + \sum_{n > N_2, n \neq j} \frac{|h_n b_n|}{|\overline{\lambda} - \lambda_n|} + \frac{1}{6} \\
&= \sum_{n=1, n \neq j}^{N_2} \frac{|h_n b_n|}{|\overline{\lambda}_j - \overline{\lambda}_n|} \left| \frac{\overline{\lambda}_n - \overline{\lambda}_j}{\lambda - \overline{\lambda}_n} \right| + \sum_{n > N_2, n \neq j} \frac{|h_n b_n|}{|\overline{\lambda}_n - \overline{\lambda}_j|} \left| \frac{\overline{\lambda}_n - \overline{\lambda}_j}{\lambda - \overline{\lambda}_n} \right| + \frac{1}{6} \\
&\leq \sum_{n=1, n \neq j}^{N_2} \frac{3|h_n b_n|}{2|\overline{\lambda}_j - \overline{\lambda}_n|} + \sum_{n > N_2, n \neq j} \frac{3|h_n b_n|}{2|\lambda_n - \lambda_j|} + \frac{1}{6}.
\end{aligned}$$

Take an integer N_2 so large that

$$\sum_{n > N_2, n \neq j} \frac{3|h_n b_n|}{2|\lambda_n - \lambda_j|} \leq \frac{1}{6}.$$

Then we can always choose the integer $N_1 > N_0$ so large that for all $j \geq N_1$,

$$\sum_{n=1, n \neq j}^{N_2} \frac{3|h_n b_n|}{2|\lambda_j - \lambda_n|} \leq \frac{1}{3}.$$

Therefore there is some integer N_1 such that for all $j \geq N_1$ and all $|\lambda - \overline{\lambda}_j| = 6|h_j b_j|$,

$$|\mathcal{F}(R(\lambda, A^*)h)| \leq \frac{2}{3}.$$

Applying again the Rouché theorem on the functions $g(\lambda) = 1$ and $F_h(\lambda)$ and reasoning with the identity (13) as above allows us to prove that $|v_j - \lambda_j| \leq 6|h_j b_j|$ for all $j \geq N_1$. It follows from the above that

$$\sum_{n=1}^{+\infty} \left| \frac{v_n - \lambda_n}{b_n} \right|^2 \leq \sum_{n=1}^{N_1 - 1} \left| \frac{v_n - \lambda_n}{b_n} \right|^2 + \sum_{n \geq N_1} 36|h_j|^2 < +\infty.$$

Now, we compute the corresponding eigenvectors of the operator $A^* + T$:

$$A^* \tilde{\psi}_j + h\mathcal{F}(\tilde{\psi}_j) = \overline{v}_j \tilde{\psi}_j. \tag{16}$$

Observe that for any eigenvector $\tilde{\psi}_j$, $\mathcal{F}(\tilde{\psi}_j) \neq 0$. Suppose that $\mathcal{F}(\tilde{\psi}_j) = 0$ for some j. The only solution of the above eigenvalue equation is $v_j = \lambda_j$ and $\tilde{\psi}_j = \psi_j$. This implies that $\mathcal{F}(\psi_j) = 0$, which contradicts the hypothesis H3. Setting

$$\begin{aligned} \tilde{\psi}_j &= \sum_{m=1}^{+\infty} \alpha_m \psi_m, \\ h &= \sum_{m=1}^{+\infty} h_m \psi_m, \end{aligned} \tag{17}$$

we prove that $v_j = \lambda_j$ in the eigenvalue equation, that is, $\overline{\lambda}_j \in \sigma(A^* + T)$ if and only if $h_j = 0$. Substituting the expression (17) into the equation (16) allows us to obtain the following:

$$(\overline{v}_j - \overline{\lambda}_m)\alpha_m = h_m \mathcal{F}(\tilde{\psi}_j), \quad m = 1, 2, \ldots. \tag{18}$$

It is evident that $h_j = 0$ if $v_j = \lambda_j$. Suppose that $h_j = 0$. Then the characteristic function

$$F_h(\lambda) = 1 - \sum_{n=1, n \neq j}^{+\infty} \frac{h_n b_n}{\lambda - \overline{\lambda}_n}$$

is analytic at the point $\lambda = \overline{\lambda}_j$. This implies that the order $n(\overline{\lambda}_j)$ of the point $\lambda = \overline{\lambda}_j$ as zero of the function $F_h(\lambda)$ is greater than or equal to zero. It follows from Proposition 1 that $\nu(\overline{\lambda}_j, A^* + T) \geq 1$, or $\overline{v}_j = \overline{\lambda}_j$. In particular, for all $j \geq N_1$, $\nu(\overline{\lambda}_j, A^* + T) = 1$. Now we are interested in the eigenvalue equation only for $j \geq N_1$. For $h_j \neq 0$, we know from the above that $v_j \neq \lambda_j$. Then direct computation from (18) leads to

$$\tilde{\psi}_j = \psi_j + \frac{\overline{v}_j - \overline{\lambda}_j}{h_j} \sum_{m \neq j} \frac{h_m \psi_m}{\overline{v}_j - \overline{\lambda}_m}.$$

For $h_j = 0$ and $j \geq N_1$, $v_j = \lambda_j$ and $F_h(\overline{\lambda}_j) \neq 0$ because $\nu(\overline{\lambda}_j, A^* + T) = 1$. One can find that

$$\tilde{\psi}_j = \sum_{m \neq j} \frac{h_m \mathcal{F}(\tilde{\psi}_j)}{\overline{v}_j - \overline{\lambda}_m} \psi_m + \frac{F_h(\overline{\lambda}_j)\mathcal{F}(\tilde{\psi}_j)}{b_j} \psi_j.$$

This finishes the proof of Lemma 4. □

LEMMA 5. *For some integer $N_2 \geq N_1$, the sequence $\{\psi_1, \ldots, \psi_{N_2}, \tilde{\psi}_{N_2+1}, \ldots\}$ forms a Riesz basis of H.*

Proof. Define the linear application $\Lambda : H \to H$ by $\Lambda(\psi_j) = \psi_j$ for $1 \leq j \leq N_2$ and $\Lambda(\psi_j) = \tilde{\psi}_j$ for $j \geq N_2 + 1$. We will prove that the application Λ as well as its inverse Λ^{-1} are bounded. Then the above sequence is also a Riesz basis because it is equivalent to the Riesz basis $\{\psi_j, j \in \mathbb{N}\}$ (see [5, p. 309]).

For all $g = \sum_{j=1}^{+\infty} \alpha_j \psi_j \in H$, using Lemma 4, we get

$$\begin{aligned}\Lambda(g) &= \sum_{j=1}^{+\infty} \alpha_j \psi_j + \sum_{j=N_2+1}^{+\infty} \alpha_j (\tilde{\psi}_j - \psi_j) = \sum_{j=1}^{+\infty} \alpha_j \psi_j + \sum_{j=N_2+1}^{+\infty} \alpha_j \beta_j \sum_{\substack{m \in \mathbb{N} \\ m \neq j}} \frac{h_m \psi_m}{\overline{v}_j - \overline{\lambda}_m} \\ &= g + \Delta\Lambda(g),\end{aligned}$$

where

$$\beta_j = \begin{cases} \dfrac{v_j - \lambda_j}{h_j} & \text{if } h_j \neq 0, \\ \dfrac{b_j}{F_h(\lambda_j)} & \text{if } h_j = 0, \end{cases} \tag{19}$$

and

$$\Delta\Lambda(g) = \sum_{j=N_2+1}^{+\infty} \alpha_j \beta_j \sum_{\substack{m \in \mathbb{N} \\ m \neq j}} \frac{h_m \psi_m}{\overline{v}_j - \overline{\lambda}_m}.$$

For $h_j = 0$, the function $\mathcal{F}(R(\lambda, A^*)h)$ is analytic in $\tilde{D}_j$. Then

$$\sup_{\lambda \in \tilde{D}_j} |\mathcal{F}(R(\lambda, A^*)h)| \leq \sup_{\lambda \in \tilde{C}_j} |\mathcal{F}(R(\lambda, A^*)h)| \leq \frac{1}{3}.$$

This implies that $|F_h(\lambda)| \geq 2/3$ for all $\lambda \in \tilde{D}_j$. In particular, $|F_h(\overline{\lambda}_j)| \geq 2/3$. From (19), for all $j \geq N_2$,

$$|\beta_j| \leq 6|b_j|. \tag{20}$$

Using the fact (9) that $\{\psi_j\}$ is a Riesz basis, we can obtain the following estimates:

$$\begin{aligned}\|\Delta\Lambda(g)\| &\leq \sum_{j=N_2+1}^{+\infty} |\alpha_j \beta_j| \left\| \sum_{m \neq j} \frac{h_m \psi_m}{\overline{v}_j - \overline{\lambda}_m} \right\| \leq M_2 \sum_{j=N_2+1}^{+\infty} |\alpha_j \beta_j| \left[\sum_{m \neq j} \left| \frac{h_m}{v_j - \lambda_m} \right|^2 \right]^{\frac{1}{2}} \\ &\leq M_2 \left[\sum_{j=N_2+1}^{+\infty} |\alpha_j|^2 \right]^{\frac{1}{2}} \left[\sum_{j=N_2+1}^{+\infty} |\beta_j|^2 \sum_{m \neq j} \left| \frac{h_m}{v_j - \lambda_m} \right|^2 \right]^{\frac{1}{2}} \\ &\leq \|g\| \frac{M_2}{M_1} \left[\sum_{j=N_2+1}^{+\infty} |\beta_j|^2 \sum_{m \neq j} \left| \frac{h_m}{v_j - \lambda_m} \right|^2 \right]^{\frac{1}{2}}. \end{aligned} \tag{21}$$

Let us prove that for some integer $N_2 \geq N_1$,

$$\frac{M_2^2}{M_1^2} \sum_{j=N_2+1}^{+\infty} |\beta_j|^2 \sum_{m \neq j} \left| \frac{h_m}{v_j - \lambda_m} \right|^2 \leq \left(\frac{2}{3}\right)^2.$$

From the conditions (20) and (15), choose an N_3 with $N_2 \geq N_1$ such that

$$\frac{M_2^2}{M_1^2} \sum_{j=N_2+1}^{+\infty} |\beta_j|^2 \sum_{m \neq j, m > N_3} \left| \frac{h_m}{v_j - \lambda_m} \right|^2 = \frac{M_2^2}{M_1^2} \sum_{m>N_3}^{+\infty} |h_m|^2 \sum_{j>N_2, j\neq m} \left| \frac{\beta_j}{\lambda_j - \lambda_m} \right|^2 \left| \frac{\lambda_j - \lambda_m}{v_j - \lambda_m} \right|^2$$

$$(22) \qquad \leq \frac{M_2^2}{M_1^2} \sum_{m \geq N_3+1}^{+\infty} |h_m|^2 \sum_{j>N_2, j\neq m} 36 \left| \frac{b_j}{\lambda_j - \lambda_m} \right|^2 \times \left(\frac{3}{2}\right)^2 \leq \left(\frac{1}{3}\right)^2.$$

Since from the hypothesis (2)

$$\lim_{N_2 \to +\infty} \sum_{m=1}^{N_3} |h_m|^2 \sum_{j>N_2, j\neq m} \left| \frac{b_j}{\lambda_j - \lambda_m} \right|^2 = 0,$$

we can always choose the $N_2 \geq N_1$ so large that

$$\frac{M_2^2}{M_1^2} \sum_{j=N_2+1}^{+\infty} |\beta_j|^2 \sum_{m \neq j, m=1}^{N_3} \left| \frac{h_m}{v_j - \lambda_m} \right|^2 = \frac{M_2^2}{M_1^2} \sum_{m=1}^{N_3} |h_m|^2 \sum_{j>N_2, j\neq m} \left| \frac{\beta_j}{\lambda_j - \lambda_m} \right|^2 \left| \frac{\lambda_j - \lambda_m}{v_j - \lambda_m} \right|^2$$

$$(23) \qquad \leq \frac{M_2^2}{M_1^2} \sum_{m=1}^{N_3} |h_m|^2 \sum_{j>N_2, j\neq m} 36 \left| \frac{b_j}{\lambda_j - \lambda_m} \right|^2 \times \left(\frac{3}{2}\right)^2 \leq \left(\frac{1}{3}\right)^2.$$

Substituting (22) and (23) into (21) proves that for some integer $N_2 \geq N_1$, $\|\Delta\Lambda\| \leq 2/3$. Therefore the linear operator Λ and its inverse are bounded. It follows from [5, p. 309] that the sequence $\{\psi_1, \ldots, \psi_{N_2}, \tilde{\psi}_j, j \geq N_2 + 1\}$ is a Riesz basis of H. □

Now let us prove Theorem 1.

Proof of Theorem 1. We take the linearly independent elements $\{\tilde{\psi}_1, \ldots, \tilde{\psi}_{N_2}\}$, which are the generalized eigenvectors of the operator $A^* + T$ corresponding to the finite set $\{\overline{v}_1, \ldots, \overline{v}_{N_2}\}$ of the spectrum $\sigma(A^* + T)$ in the following sense. Without loss of generality, we suppose that in the set $\{\overline{v}_1, \ldots, \overline{v}_{N_2}\}$ there are s distinct eigenvalues $\{\overline{v}_1, \ldots, \overline{v}_s\}$ with the respective algebraic multiplicities $\{\nu_1, \ldots, \nu_s\}$ such that $\sum_{j=1}^{s} \nu_j = N_2$. Then

$$\mathrm{Ker}(\overline{v}_1 - A^* - T)^{\nu_1} = \mathrm{Span}\{\tilde{\psi}_j, j = 1, 2, \ldots, \nu_1\}$$

$$\mathrm{Ker}(\overline{v}_2 - A^* - T)^{\nu_2} = \mathrm{Span}\{\tilde{\psi}_j, j = \nu_1 + 1, \ldots, \nu_1 + \nu_2\},$$

and so on. We want to prove that the sequence $\{\tilde{\psi}_j, j \in \mathbb{N}\}$ is still a Riesz basis of H. Two sequences of vectors $\{g_j, j \in \mathbb{N}\}$ and $\{f_j, j \in \mathbb{N}\}$ are said to be quadratically close if $\sum_{j \in \mathbb{N}} \|g_j - f_j\|^2 < +\infty$. It is obvious that the two sequences $\{\psi_1, \ldots, \psi_{N_2}, \tilde{\psi}_j, j >$

$N_2\}$ and $\{\tilde{\psi}_j, j \in \mathbb{N}\}$ are quadratically close to each other. A sequence of almost normalized vectors $\{g_j\}$ is said to be ω-linearily independent if the equality

$$\sum_{j=1}^{+\infty} c_j g_j = 0 \text{ for } \sum_{j=1}^{+\infty} |c_j|^2 < +\infty$$

implies that $c_j = 0$ for all $j \geq 1$. The Bari theorem [5, Thm. 2.3, p. 317] says that a sequence of ω-linearily independent vectors quadratically close to a Riesz basis is also a Riesz basis. Since we have already shown that the sequence $\{\psi_1, \ldots, \psi_{N_2}, \tilde{\psi}_j, j \geq N_2+1\}$ is a Riesz basis (Lemma 5), we now need only prove the ω-linear independence.

The Laurent series of the resolvent $R(\lambda, A^* + T)$ at $\{\overline{v}_1, \ldots, \overline{v}_s\}$ takes the form [8, p. 181]

$$R(\lambda, A^* + T) = \sum_{m=1}^{s} \left[\frac{P_m}{\lambda - \overline{v}_m} + \sum_{n=1}^{\nu_m - 1} \frac{D_m^n}{(\lambda - \overline{v}_m)^{n+1}} \right] + R_0(\lambda, A^* + T), \tag{24}$$

where the operator P_m is the projector on the subspace $\operatorname{Ker}(\overline{v}_m - A^* - T)^{\nu_m}$ and D_m is the nilpotent commuting with P_m for $m = 1, 2, \ldots, s$ and $R_0(\lambda, A^* + T)$ is analytic at $\overline{v}_j$, $j = 1, \ldots, s$ (see [4, p. 2292]). Let $\{\alpha_j\}_{j=1}^{+\infty} \in l^2$ and $\sum_{j=1}^{+\infty} \alpha_j \tilde{\psi}_j = 0$. Write

$$\sum_{j=1}^{N_2} \alpha_j \tilde{\psi}_j = - \sum_{j=N_2+1}^{+\infty} \alpha_j \tilde{\psi}_j. \tag{25}$$

Applying the resolvent operator on the two sides of the last identity, we obtain

$$R(\lambda, A^* + T) \sum_{j=1}^{N_2} \alpha_j \tilde{\psi}_j = - \sum_{j=N_2+1}^{+\infty} \frac{\alpha_j}{\lambda - \overline{v}_j} \tilde{\psi}_j. \tag{26}$$

Since $P_m P_n = \delta_{n,m} P_n$, $P_n D_n = D_n P_n = D_n$ and $R_0(\lambda, A^* + T) P_n = 0$ for all $\lambda \in \rho(A^* + T)$ [8, p. 181],

$$R(\lambda, A^* + T) \sum_{j=1}^{N_2} \alpha_j \tilde{\psi}_j = \sum_{m=1}^{s} \left\{ \left[\frac{P_m}{\lambda - \overline{v}_m} + \sum_{n=1}^{\nu_m - 1} \frac{D_m^n}{(\lambda - \overline{v}_m)^{n+1}} \right] \sum_{j=1}^{\nu_m} \alpha_j \tilde{\psi}_j \right\}. \tag{27}$$

Substituting (27) into (26) leads to

$$\begin{aligned} \left[\frac{P_1}{\lambda - \overline{v}_1} + \sum_{n=1}^{\nu_1 - 1} \frac{D_1^n}{(\lambda - \overline{v}_1)^{n+1}} \right] \sum_{j=1}^{\nu_1} \alpha_j \tilde{\psi}_j &= - \sum_{j=N_2+1}^{+\infty} \frac{\alpha_j}{\lambda - \overline{v}_j} \tilde{\psi}_j \\ &\quad - \sum_{m=2}^{s} \left\{ \left[\frac{P_m}{\lambda - \overline{v}_m} + \sum_{n=1}^{\nu_m - 1} \frac{D_m^n}{(\lambda - \overline{v}_m)^{n+1}} \right] \sum_{j=1}^{\nu_m} \alpha_j \tilde{\psi}_j \right\}. \end{aligned} \tag{28}$$

Since the controlled operator $A^* + T$ has compact resolvents, its spectrum has no accumulation point different from ∞, that is to say, $\lim_{j \to +\infty} |v_j| = +\infty$. So there is a positive integer δ such that for all $1 \leq k \leq s$ and all $j > N_2$,

$$|v_k - v_j| \geq \delta.$$

On the other hand, the sequence $\{\tilde{\psi}_j, j > N_2\}$ is a part of the Riesz basis in Lemma 5. This implies that for all $1 \leq k \leq s$,

$$\left\| \sum_{j>N_2}^{+\infty} \frac{\alpha_j}{\overline{v}_k - \overline{v}_j} \tilde{\psi}_j \right\|_H^2 \leq M_2^2 \sum_{j>N_2}^{+\infty} \left| \frac{\alpha_j}{\overline{v}_k - \overline{v}_j} \right|^2 \leq \frac{M_2^2}{\delta^2} \sum_{j>N_2}^{+\infty} |\alpha_j|^2.$$

Thus the right side of (28) is bounded on some domain containing $\overline{v}_1$. By multiplying the two sides by $(\lambda - \overline{v}_1)^j$, $j = \nu_1, \nu_1 - 1, \ldots, 1$ and taking the limit for $\lambda \to \overline{v}_1$, we get, successively,

$$D_1^m \sum_{j=1}^{\nu_1} \alpha_j \tilde{\psi}_j = 0, \quad m = \nu_1 - 1, \ldots, 1 \tag{29}$$

and

$$P_1 \left(\sum_{j=1}^{\nu_1} \alpha_j \tilde{\psi}_j \right) = \sum_{j=1}^{\nu_1} \alpha_j \tilde{\psi}_j = 0. \tag{30}$$

Since the elements $\{\tilde{\psi}_1, \ldots, \tilde{\psi}_{\nu_1}\}$ are linearly independent, the relation (30) implies that $\alpha_j = 0$, $j = 1, \ldots, \nu_1$. The relations (29) and (30) imply also that for all $\lambda \in \rho(A^* + T)$, the right side of (28) is identically zero. Repeating the same procedure for the other eigenvalues $\{\overline{v}_2, \overline{v}_3, \ldots, \overline{v}_s\}$ we can prove that $\alpha_j = 0$, $j = 1, \ldots, N_2$. Since the sequence $\{\tilde{\psi}_j, j \geq N_2 + 1\}$ is part of the Riesz basis, the relation (25) implies that $\alpha_j = 0$, $j \geq N_2 + 1$. Thus we have proved ω-linear independence of the sequence $\{\tilde{\psi}_j, j \in \mathbb{N}\}$. Therefore, it is a Riesz basis of H. So we have proved that for every $h \in H$, the contolled operator A_h is regular spectral. This result with Lemma 4 proves the assertion (1) of Theorem 1 and also the necessary part of the assertion (2).

Now let us prove the sufficient part of the assertion (2). Suppose that the given set satisfies the condition (3). Consider the Hilbert space l^2. We show that the element $\{\overline{h}_j\}_{j=1,2,\ldots}$ belongs to l^2, where the $\overline{h}_j$'s are given by the infinite products in (7). For this purpose, we consider the following sequence $h^N \in l^2$:

$$h_j^N = \frac{v_j - \lambda_j}{\overline{b}_j} \prod_{n \neq j}^{N} \left(\frac{\lambda_j - v_n}{\lambda_j - \lambda_n} \right).$$

This is a Cauchy sequence in l^2. In fact,

$$h^N - h^L = \left\{ \frac{v_j - \lambda_j}{\overline{b}_j} \left[\prod_{n \neq j}^{N} \left(\frac{\lambda_j - v_n}{\lambda_j - \lambda_n} \right) - \prod_{n \neq j}^{L} \left(\frac{\lambda_j - v_n}{\lambda_j - \lambda_n} \right) \right] \right\}_{j=1,2,\ldots}.$$

Since

$$\begin{aligned} \sum_{n \neq j} \left| 1 - \frac{\overline{\lambda}_j - \overline{v}_n}{\overline{\lambda}_j - \overline{\lambda}_n} \right| &= \sum_{n \neq j} \left| \frac{\lambda_n - v_n}{\lambda_j - \lambda_n} \right| = \sum_{n \neq j} \left| \frac{\lambda_n - v_n}{b_n} \right| \left| \frac{b_n}{\lambda_j - \lambda_n} \right| \\ &\leq \left[\sum_{n \neq j} \left| \frac{\lambda_n - v_n}{b_n} \right|^2 \sum_{n \neq j} \left| \frac{b_n}{\lambda_j - \lambda_n} \right|^2 \right]^{\frac{1}{2}} \leq M^2, \end{aligned} \tag{31}$$

we have (see [17, p. 291])

$$\prod_{n\neq j}\left|\frac{\lambda_j - v_n}{\lambda_j - \lambda_n}\right| \leq e^{M^2}.$$

Given an $\epsilon > 0$, there is an integer $\tilde{N}$ such that

$$\sum_{j>\tilde{N}}^{+\infty} |h_j^N - h_j^L|^2 < \frac{\epsilon}{2}.$$

Since the condition (31) is true, the infinite sum

$$\sum_{n\neq j}\left|1 - \frac{\overline{\lambda}_j - \overline{v}_n}{\overline{\lambda}_j - \overline{\lambda}_n}\right|$$

converges uniformally with respect to $j \leq \tilde{N}$. This implies that the infinite product

$$\prod_{n\neq j}^{N}\left(\frac{\lambda_j - v_n}{\lambda_j - \lambda_n}\right)$$

converges uniformally with respect to $j \leq \tilde{N}$. Hence for sufficiently large N and L, we have

$$\sum_{j=1}^{\tilde{N}} |h_j^N - h_j^L|^2 = \sum_{j=1}^{\tilde{N}}\left|\frac{v_j - \lambda_j}{\bar{b}_j}\right|^2\left|\prod_{n\neq j}^{N}\left(\frac{\lambda_j - v_n}{\lambda_j - \lambda_n}\right) - \prod_{n\neq j}^{L}\left(\frac{\lambda_j - v_n}{\lambda_j - \lambda_n}\right)\right|^2 \leq \frac{\epsilon}{2}.$$

Thus for sufficiently large N and L,

$$\|h^N - h^L\|_{l^2} < \epsilon.$$

This proves that the limit h, which is the feedback, belongs to the Hilbert space H. We must still prove that the controlled operator has the spectrum assigned $\sigma(A^* + T) = \{\overline{v}_j\}_{j=1}^{+\infty}$. With the feedback element h given in (7) and from the proof of Lemma 4, we know that the controlled operator A^*+T has N_0 eigenvalues (multiplicity counted) in the region Ω and the other eigenvalues are simple and each of them is situated in the corresponding disk. It is sufficient to verify that the finite part of the spectrum contained in Ω is equal to the subset $\{\overline{v}_j; j = 1, 2, \ldots, N_0\}$ and the only simple eigenvalue in the disk $\tilde{D}_j$ is equal to $\overline{v}_j$ for $j > N_0$. Reorder the elements $\overline{v}_1, \overline{v}_2, \ldots, \overline{v}_{N_0}$ such that $v_j = \lambda_j$ if some $\overline{v}_k \in \sigma(A^*)$ for $k \leq N_0$. From the expression of the feedback element, $h_j = 0$ if $v_j = \lambda_j$. So $\overline{\lambda}_j \in \sigma(A^* + T)$ with simple algebraic multiplicity (see Proposition 1). The rest of the spectrum $\sigma(A^* + T)$ is equal to the zero set of the function $F_h(\lambda)$. From Proposition 1 and the hypothesis that $v_j \neq v_n$ for $j \neq n$, it is easy to see that each eigenvalue $\{v_j\}$ is of simple algebraic multiplicity.

We claim that imposing the function $F_h(\lambda)$ to be zero on the point $\overline{v}_j \notin \sigma(A^*)$ gives the following unique solution (7) in l^2 :

$$F_h(\overline{v}_m) = 1 - \sum_{n=1}^{+\infty}\frac{b_n h_n}{\overline{v}_m - \overline{\lambda}_n} = 0.$$

Without loss of generality, the above equation is equivalent to

$$h_m + \sum_{n\neq m}^{+\infty} \frac{\overline{v}_m - \overline{\lambda}_m}{b_m} \frac{b_n h_n}{\overline{v}_m - \overline{\lambda}_n} = \frac{\overline{v}_m - \overline{\lambda}_m}{b_m}, \quad m \in \mathbb{N}. \tag{32}$$

Define the linear operator Θ, $T : l^2 \to l^2$ such that

$$\Theta h = \left\{ \sum_{n\neq m}^{+\infty} \frac{\overline{v}_m - \overline{\lambda}_m}{b_m} \frac{b_n h_n}{\overline{v}_m - \overline{\lambda}_n} \right\}_{m=1}^{+\infty},$$

and

$$T = I + \Theta.$$

We shall prove that the operator Θ is compact and that the operator T is one-to-one. Then the operator T has a bounded inverse. Set $g = \{(\overline{v}_m - \overline{\lambda}_m)/b_m\}_{m=1}^{+\infty}$. Then the above equation has a unique solution : $h = T^{-1}g$. Define also the sequence of operators $T_n : l^2 \to l^2$ by

$$T_n r = \begin{cases} r_m + \sum_{j\neq m}^{n} \frac{\overline{v}_m - \overline{\lambda}_m}{b_m} \frac{b_j r_j}{\overline{v}_m - \overline{\lambda}_j} & \text{for } m \leq n, \\ r_m & \text{for } m \geq n+1. \end{cases}$$

Using the same argument as that used to prove that Θ is compact, we can see that this sequence of operators is bounded. Direct matrix computations (tedious but elementary) allow us to show that T_n is invertible and that

$$T_n^{-1} g = \begin{cases} g_m \prod_{j\neq m}^{n} \frac{\overline{\lambda}_m - \overline{v}_j}{\overline{\lambda}_m - \overline{\lambda}_j} & \text{for } m \leq n, \\ g_m & \text{for } m \geq n+1. \end{cases}$$

As in the above we can show that

$$\lim_{n\to+\infty} T_n^{-1} g = \left\{ g_m \prod_{j\neq m}^{+\infty} \frac{\overline{\lambda}_m - \overline{v}_j}{\overline{\lambda}_m - \overline{\lambda}_j} \right\}_{m=1,2,\ldots}.$$

By direct matrix computations (which are also tedious) we can prove that the sequence of operators T_n^{-1} is bounded. Let us prove that

$$h = T^{-1}g = \lim_{n\to+\infty} T_n^{-1} g.$$

Since we have the identity

$$T_n^{-1} g - T^{-1} g = T_n^{-1}(T - T_n) T^{-1} g,$$

it is sufficient to prove that for any $r \in l^2$,

$$\lim_{n\to+\infty} (T - T_n) r = 0, \tag{33}$$

which will be evident in the following.

Now return to proving the compactness of the operator Θ and the one-to-one property of the operator T. Take any weakly convergent sequence $g^k \in l^2$. Then $\|g^k\|_{l^2} \leq M$ and

$$\Theta g^k = \left\{ \sum_{n \neq m}^{+\infty} \frac{\overline{v}_m - \overline{\lambda}_m}{b_m} \frac{b_n g_n^k}{\overline{v}_m - \overline{\lambda}_n} \right\}_{m=1}^{+\infty}.$$

We prove that for every $\epsilon > 0$, there is an $N > 0$ such that for all $k \geq N$,

$$\|\Theta g^k\|_{l^2}^2 < \epsilon. \tag{34}$$

In fact,

$$\|\Theta g^k\|_{l^2}^2 = \sum_{m=1}^{+\infty} \left| \frac{\overline{v}_m - \overline{\lambda}_m}{b_m} \right|^2 \left| \sum_{n \neq m}^{+\infty} \frac{b_n g_n^k}{\overline{v}_m - \overline{\lambda}_n} \right|^2.$$

Note that by hypothesis

$$\lim_{N_1 \to +\infty} \sum_{m \geq N_1, m \neq n} \left| \frac{\overline{v}_m - \overline{\lambda}_m}{b_m} \right| \left| \frac{b_m}{\lambda_m - \lambda_n} \right| = 0.$$

Therefore there is an integer N_1 such that for all $m \geq N_1$ and $n \neq m$,

$$|v_m - \lambda_m| \leq \frac{1}{3} |\lambda_m - \lambda_n|,$$

$$|v_m - \lambda_n| \geq |\lambda_m - \lambda_n| - |v_m - \lambda_m| \geq \frac{2}{3} |\lambda_m - \lambda_n|.$$

Then for all $m \geq N_1$ and $n \neq m$,

$$\frac{|\lambda_m - \lambda_n|}{|v_m - \lambda_n|} \leq \frac{3}{2}.$$

Since the conditions (3) and (1) are satisfied, we can choose an $\tilde{N} > N_1$ such that for all $m > \tilde{N}$,

$$\begin{aligned}
&\sum_{m=\tilde{N}}^{+\infty} \left| \frac{\overline{v}_m - \overline{\lambda}_m}{b_m} \right|^2 \left| \sum_{n \neq m}^{+\infty} \frac{b_n g_n^k}{\overline{v}_m - \overline{\lambda}_n} \right|^2 \\
&\quad \leq \sum_{m=\tilde{N}}^{+\infty} \left| \frac{v_m - \lambda_m}{b_m} \right|^2 \sum_{n \neq m}^{+\infty} \left| \frac{b_n}{v_m - \lambda_n} \right|^2 \sum_{l \neq m}^{+\infty} |g_l^k|^2 \\
&\quad \leq \sum_{m=\tilde{N}}^{+\infty} \left| \frac{v_m - \lambda_m}{b_m} \right|^2 \sum_{n \neq m}^{+\infty} \left| \frac{b_n}{\lambda_m - \lambda_n} \right|^2 \left| \frac{\lambda_m - \lambda_n}{v_m - \lambda_n} \right|^2 \sum_{l \neq m}^{+\infty} |g_l^k|^2 \\
&\quad \leq \sum_{m=\tilde{N}}^{+\infty} \left| \frac{v_m - \lambda_m}{b_m} \right|^2 \sum_{n \neq m}^{+\infty} \left| \frac{b_n}{\lambda_m - \lambda_n} \right|^2 \left(\frac{3}{2} \right)^2 \sum_{l \neq m}^{+\infty} |g_l^k|^2 \leq \frac{\epsilon}{2}.
\end{aligned} \tag{35}$$

Since the point $\overline{v}_j \in \rho(A^*)$, $\mathcal{F} \circ R(\overline{v}_j, A^*) \in \mathcal{L}(H, \mathbb{C})$. It is implied that the elements $r^m = \{b_n/(\overline{v}_m - \overline{\lambda}_n)\}_{n=1}^{+\infty}$ belong to the Hilbert space l^2. The weak convergence of the sequence g^k implies that there is an $N > 0$ such that for all $k > N$

$$\sum_{m=1}^{\tilde{N}-1} \left| \frac{\overline{v}_m - \overline{\lambda}_m}{b_m} \right|^2 \left| \sum_{n \neq m}^{+\infty} \frac{b_n g_n^k}{\overline{v}_m - \overline{\lambda}_n} \right|^2 < \frac{\epsilon}{2}. \tag{36}$$

The addition of the inequalities (35) and (36) implies that of (34). Therefore we have proved that

$$\lim_{k \to +\infty} \|\Theta g^k\|_{l^2}^2 = 0$$

and, as a result, the compactness of the operator Θ. Note that for all $r \in l^2$,

$$(T - T_n)r = \begin{cases} \dfrac{\overline{v}_m - \overline{\lambda}_m}{b_m} \displaystyle\sum_{j>n}^{+\infty} \frac{b_j r_j}{\overline{v}_m - \overline{\lambda}_j} & \text{for } m \leq n, \\ \dfrac{\overline{v}_m - \overline{\lambda}_m}{b_m} \displaystyle\sum_{j \neq m}^{+\infty} \frac{b_j r_j}{\overline{v}_m - \overline{\lambda}_j} & \text{for } m \geq n+1. \end{cases}$$

In fact, we have

$$\|(T - T_n)r\|_{l^2}^2 = \sum_{m=1}^{n} \left| \frac{\overline{v}_m - \overline{\lambda}_m}{b_m} \right|^2 \left| \sum_{j>n}^{+\infty} \frac{b_j r_j}{\overline{v}_m - \overline{\lambda}_j} \right|^2 + \sum_{m \geq n+1}^{+\infty} \left| \frac{\overline{v}_m - \overline{\lambda}_m}{b_m} \right|^2 \left| \sum_{j \neq m}^{+\infty} \frac{b_j r_j}{\overline{v}_m - \overline{\lambda}_j} \right|^2$$

$$\leq \sum_{m=1}^{n} \left| \frac{\overline{v}_m - \overline{\lambda}_m}{b_m} \right|^2 \sum_{j>n}^{+\infty} \left| \frac{b_j}{\overline{v}_m - \overline{\lambda}_j} \right|^2 \sum_{l>n}^{+\infty} |r_l|^2 + \sum_{m \geq n+1}^{+\infty} \left| \frac{\overline{v}_m - \overline{\lambda}_m}{b_m} \right|^2 \sum_{j \neq m}^{+\infty} \left| \frac{b_j}{\overline{v}_m - \overline{\lambda}_j} \right|^2 \sum_{l \neq m}^{+\infty} |r_l|^2,$$

which tends to zero for $n \to +\infty$, for the two terms

$$\sum_{l>n}^{+\infty} |r_l|^2, \quad \sum_{m \geq n+1}^{+\infty} \left| \frac{\overline{v}_m - \overline{\lambda}_m}{b_m} \right|^2$$

go to zero for $n \to +\infty$. Suppose that $Tr = 0$. Then $r = T_n^{-1}(T_n - T)r$. Taking the limit for $n \to +\infty$, we prove that $r = 0$. So the operator T is one-to-one. Finally the unique solution of (32) is

$$h = T^{-1} \left\{ \frac{\overline{v}_m - \overline{\lambda}_m}{b_m} \right\}_{m=1}^{+\infty} = \lim_{n \to +\infty} T_n^{-1} \left\{ \frac{\overline{v}_m - \overline{\lambda}_m}{b_m} \right\}_{m=1}^{+\infty}$$

$$= \left\{ \frac{\overline{v}_m - \overline{\lambda}_m}{b_m} \prod_{j \neq m}^{+\infty} \frac{\overline{\lambda}_m - \overline{v}_j}{\overline{\lambda}_m - \overline{\lambda}_j} \right\}_{m=1}^{+\infty}.$$

So we have finished the proof of Theorem 1. □

4. Conclusions. In this paper, the necessary and sufficient condition of Sun [21] has been generalized to a large class of distributed parameter systems with boundary controls, which allows us to exploit the limitations imposed by BLF. For example,

the input vector being admissible implies that $\{b_k\} \in l^\infty$ [22], [25]. In this case, BLF cannot uniformly assign the spectrum of the systems. We have proved that it is possible to achieve exponential stabilization of some systems by means of BLF only (Example 2). For an assignable spectrum set, we have given an explicit feedback law which realizes the spectrum assignment with the resulting controlled operator being regular spectral. The paper has also given a systematic method to assign a finite number of spectrum points. This method could find potential applications in damped flexible systems as illustrated by [24] (see [19] and [1] for other models). We should mention that the assumption that the eigenvectors of the operator A constitute a Riesz basis practically reduces the applications to evolution systems in space-dimension one.

Acknowledgments. The authors would like to thank the referees for their valuable suggestions and constructive comments on the paper.

SUPERIOR INFORMATION IS INSUFFICIENT TO WIN IN GAMES BETWEEN FINITE AUTOMATA*

VLADIMIR CHERNORUTSKII†, RAUF IZMAILOV‡, AND ALEXEI POKROVSKII§

Abstract. A game between two computers is considered: the first computer generates a binary sequence while the second one tries to predict the next element of this sequence using the previous elements. Both computers operate with the same pool of strategies, which is the set of all boolean functions of N arguments. Notwithstanding the asymmetry of the game, it turns out that the value of the game is zero. An algorithm for choosing an optimal superstrategy for the first computer is proposed, and several generalizations of the game are considered.

Key words. repeated games, finite automata, information, games on graphs

AMS subject classifications. 90D20, 90D43

1. Introduction.

Games with finite automata have been investigated for more than 30 years starting with the classical works by Tsetlin [8, 9]. The approach considered here is related to [1, 2, 4]. To describe the model, we start with the description of the motivating experiment.

In 1960s a group of researchers in Voronezh University (Russia) was carrying out the following experiments. Participating undergraduate students (later joined by postgraduate students and professors) were asked to generate sufficiently long (about several hundred digits) binary sequences. The only restriction was the request to generate these sequences without using coins, dice, or other devices—that was considered cheating. The elements of each sequence were transmitted one by one to the input of a computer program specially designed to predict the next element of the sequence using the already accumulated data on the previous ones. It turned out that humans could not generate "good" random sequences and a "smart" computer program predicted from 55% to 80% of elements of any human sequence.

So human intelligence proved to be unable to win against the computer in this game. But what can happen if two computers play against each other in such a game? Obviously, the answer depends on the relative "strength" or "complexity" of the computers and programs involved. But to keep matters simple, let us assume the game is fair and that both computers are of the same class—there is no advantage or disadvantage in complexity from either side. What would be the outcome of the game in this case, and what sort of strategies would be used?

To formalize the problem, consider two players **P** and **S** playing the matrix game with the payoff matrix, known to both players,

$$\mathbf{V} = \begin{pmatrix} +1 & -1 \\ -1 & +1 \end{pmatrix}.$$

Here **P**, being the minimizer, plays rows, whereas the maximizer **S** plays columns. In other words, **S** wins 1 if he guesses **P**'s decision correctly; otherwise **S** loses 1. For each player we are interested in the expected value of his gain during an infinite time. The key features of this game are the description of information accessible to the players and the extraction of a class of rules available to the players from which to choose their moves. Such situations are usually called *supergames* [11], and the permissible rules are called *superstrategies.*

Suppose in addition that **P** has no information about the previous performance of **S**, although **P** knows several of his own previous decisions. Moreover, we assume that exactly the same previous decisions of **P** are available to **S**, so both players make their choices based on the same amount of information. Similar assumptions about players' memory are typical for so-called games with inertia [10]. Thus every pure superstrategy of player **P** consists of choosing a rule for processing a sequence of his preceding decisions. We assume that all realizable rules are deterministic, while randomization is possible only before the beginning of a supergame, when each player chooses his superstrategy.

We consider only the case when every pure superstrategy of **S** consists of processing the available information about the previous moves of **P**, but not about **S**. In other words, **P** generates binary bits, where every bit is determined by N previous ones, and **S** tries to predict these bits, knowing N previous bits in **P**'s sequence. Both players can use the same set of programs for processing of previous bits.

Intuitively, the second player should not lose. After all, he has the advantage of knowing the history of **P**'s moves, whereas **P** has no information about the performance of **S**. On the other hand, **S** has the same complexity as **P**. Therefore the question is whether **S** can use his information edge without using more complex programs than **P**? In other words, *can an advantage in information be exploited without an accompanying advantage in intelligence?*

In the following sections we address this question and present several approaches. First, we describe the exact formulation of the game and present the basic result of this paper, Theorem 1, which gives a negative answer to the question posed above. Next, we present a geometric interpretation of the game which is used to describe an optimal algorithm for **P**, and for other generalizations of the game. Finally, we briefly outline several related problems which will be probably addressed in future research. All proofs are collected in the appendix.

2. Model and main result. To describe the game **G** formally, we fix a natural number N characterizing the "memory depth" of both **P** and **S**: **P** chooses his next move as a function of his N previous moves, while **S** predicts the move of **P** using N previous moves of **P**. The number N is called the *dimension* of the supergame. Let $\mathbb{B}$ be the set $\{0,1\}$; the elements of the set $\mathbb{B}^N$ are the binary representations of the numbers $0, 1, \ldots, 2^N - 1$. Denote by $\mathcal{F}$ the set of all pure superstrategies of the players. Then $\mathcal{F}$ is a set of boolean functions $F : \mathbb{B}^N \to \mathbb{B}$ such that if $F \in \mathcal{F}$, so also is the negation $1 - F \in \mathcal{F}$. Fix $\alpha_0 \in \mathbb{B}^N$ and superstrategies $P, S \in \mathcal{F}$ of players **P** and **S**, respectively. A realization of the supergame is a pair of binary sequences,

$$\{P(\alpha_0), P(\alpha_1), \ldots\} \quad \text{and} \quad \{S(\alpha_0), S(\alpha_1), \ldots\}, \tag{1}$$

of the players' moves, where

$$\alpha_k = P(\alpha_{k-1}) + (2\alpha_{k-1} \bmod 2^N), \quad k = 1, 2, \ldots. \tag{2}$$

Consider, for example, $N = 1$: both players "remember" only the last move. In this case $\mathbf{P}$ can use any of three functions P_1, P_2, and P_3 as a generator of his binary sequence:

$$\begin{cases} P_1(0) = 0, & P_1(1) = 0, \\ P_2(0) = 1, & P_2(1) = 0, \\ P_3(0) = 1, & P_3(1) = 1. \end{cases} \tag{3}$$

Actually, $\mathbf{P}$ can also use the function P_4, defined by

$$P_4(0) = 0, \ P_4(1) = 1,$$

but P_4 may be disregarded since the output sequence it generates is the same as one of the functions P_1 or P_3. The player $\mathbf{S}$ may use four functions $S_1, \ldots, S_4$ for his predictions:

$$\begin{cases} S_1(0) = 0, & S_1(1) = 1, \\ S_2(0) = 1, & S_2(1) = 0, \\ S_3(0) = 0, & S_3(1) = 0, \\ S_4(0) = 1, & S_4(1) = 1; \end{cases} \tag{4}$$

here function S_1 predicts that the next element of the sequence of $\mathbf{P}$ will be the same as the previous one, while the function S_2 predicts exactly the opposite. Each of the other functions S_3 and S_4 steadily predicts 0 or 1 without referring to the history of the game.

Given the superstrategies P and S, the mean payoff $V(P, S)$ of the supergame is determined by

$$V(P, S) = \lim_{k \to \infty} \frac{1}{k} \sum_{i=1}^{k} \eta(P(\alpha_i), S(\alpha_i)), \tag{5}$$

where the payoff function $\eta : \mathbb{B}^2 \to \mathbb{B}$ is defined as $\eta(a, b) = 1 - 2|a - b|$. Since the sequences (1) are periodic, the limit (5) exists.

Considering again the same example $N = 1$, the payoff V may be written in the matrix form

$$(V(P_i, S_j)) = \begin{pmatrix} 1 & -1 & 1 & -1 \\ -1 & 1 & 0 & 0 \\ 1 & -1 & -1 & 1 \end{pmatrix}. \tag{6}$$

For any fixed pure superstrategy $S_* \in \mathcal{F}$ of $\mathbf{S}$ the equality

$$\min_{P \in \mathcal{F}} \{V(P, S_*)\} = -1$$

holds (if $P = S_*$); also

$$\max_{S \in \mathcal{F}} \{V(P_*, S)\} = 1$$

holds (if $S = P_*$) for any fixed pure superstrategy P_* of $\mathbf{P}$. These two relations mean that the supergame $\mathbf{G}$ has no solutions in the class of pure superstrategies.

Therefore, mixed superstrategies (probability distributions $p(\cdot)$ on the finite set $\mathcal{F}$ of pure superstrategies) have to be considered. The choice of mixed superstrategy

is the choice of a random rule for using pure superstrategies. If mixed superstrategies $p_1(\cdot)$ and $p_2(\cdot)$ are chosen, the payoff $\overline{V}(p_1(\cdot), p_2(\cdot))$ of the supergame is determined as

$$\overline{V}(p_1(\cdot), p_2(\cdot)) = \sum_{P,S \in \mathcal{F}} p_1(P) p_2(S) V(P, S).$$

So the payoff of the supergame coincides with the payoff of the zero-sum two-person game [6] with the matrix $\mathbf{V} = \{\mathbf{v}_{ij}\}$, where $\mathbf{v}_{ij} = \overline{V}(F_i, F_j)$. The dimension of the matrix $\mathbf{V}$ is equal to the cardinality of the finite set $\mathcal{F}$. Therefore, we use the terms "games" and "strategy" instead of "supergame" and "superstrategy."

The payoff of the game $\mathbf{G}$ is nonnegative since the player $\mathbf{S}$ can guarantee the zero result using the mixed strategy of arbitrary pair of functions S and $1 - S$ with the weights $1/2$. For $\mathbf{P}$ there is no such simple strategy-provided nonnegative result. Nevertheless, the following theorem holds.

THEOREM 1. *The value of the game* $\mathbf{G}$ *is zero.*

Theorem 1 is the main result of this paper. As we can see from (5), the value $V(P, S)$ depends on the initial vector α_0. However, it will shown further that the price of the game does not depend on α_0. Theorem 1 provides the answer to the question formulated in the introduction: *an advantage in information cannot be exploited without an accompanying advantage in intelligence.*

3. Geometric interpretation. The following geometrical interpretation of the game $\mathbf{G}$ is convenient. We will follow the terminology in [3]. Denote by $\Gamma = \Gamma(N)$ the (directed) graph with 2^N vertices enumerated from 0 to $2^N - 1$ where each vertex α is the initial endpoint of exactly two arcs with the terminal endpoints $(2\alpha \bmod 2^N)$ and $(1+(2\alpha \bmod 2^N))$ (compare with the realization (2)).

Denote by $U = U(\Gamma)$ the set of all arcs of the graph Γ. The arc passing from the vertex α to the vertex β is denoted by $e_{\alpha\beta}$ (Figure 1). A subset $\mathcal{U} \subset U$ is called *proper* if for any vertex α the set $\mathcal{U}$ contains exactly 1 arc with the initial endpoint α.

We establish a one-to-one correspondence between the set $\mathcal{F}$ of strategies and the family of proper subsets of arcs. Let a strategy F belong to $\mathcal{F}$. Then for any vertex α choose $\beta = F(\alpha) + (2\alpha \bmod 2^N)$ and include the arc $e_{\alpha\beta}$ in $\mathcal{U}$. Conversely, if $e_{\alpha\beta} \in \mathcal{U}$, then put $F(\alpha) = \beta \bmod 2$. Now it is evident that a choice of the strategy F is equivalent to the choice of the proper subset $\mathcal{U} \in 2^{U(\Gamma)}$. If $\mathcal{U}$ is proper, write

$$\overline{\mathcal{U}} = \{e_{\alpha\gamma} : \gamma = \beta + 1 - 2(\beta \bmod 2),\ e_{\alpha\beta} \in \mathcal{U}\}.$$

Then the set $\mathcal{F}$ is that family of proper subsets $\mathcal{U}$ such that both $\mathcal{U}$ and $\overline{\mathcal{U}}$ belong to the family $\mathcal{F}$.

Fix strategies P, S of both players, and fix an initial point $\alpha_0 \in \mathbb{B}^N$. After an initial period the sequences (1) become periodic. The period of the first sequence corresponds to a elementary circuit in Γ. Denote this cycle by $C(P, \alpha_0)$ and the number of vertices in the cycle by $q(P, \alpha_0)$. Then (5) can be rewritten as

$$V(P, S) = [q(P, \alpha_0)]^{-1} \sum_{\alpha \in C(P, \alpha_0)} \eta(P(\alpha), S(\alpha)). \tag{7}$$

Note that $V(P, S)$ in (7) depends on α_0, but the value of the game does not: it follows from Theorem 1.

Consider an elementary q-cycle C. That is, a cycle with length q. All the arcs generating this cycle form the proper subset $\mathcal{U}(C) \in \mathcal{F}$. This defines the strategy $F(C)$

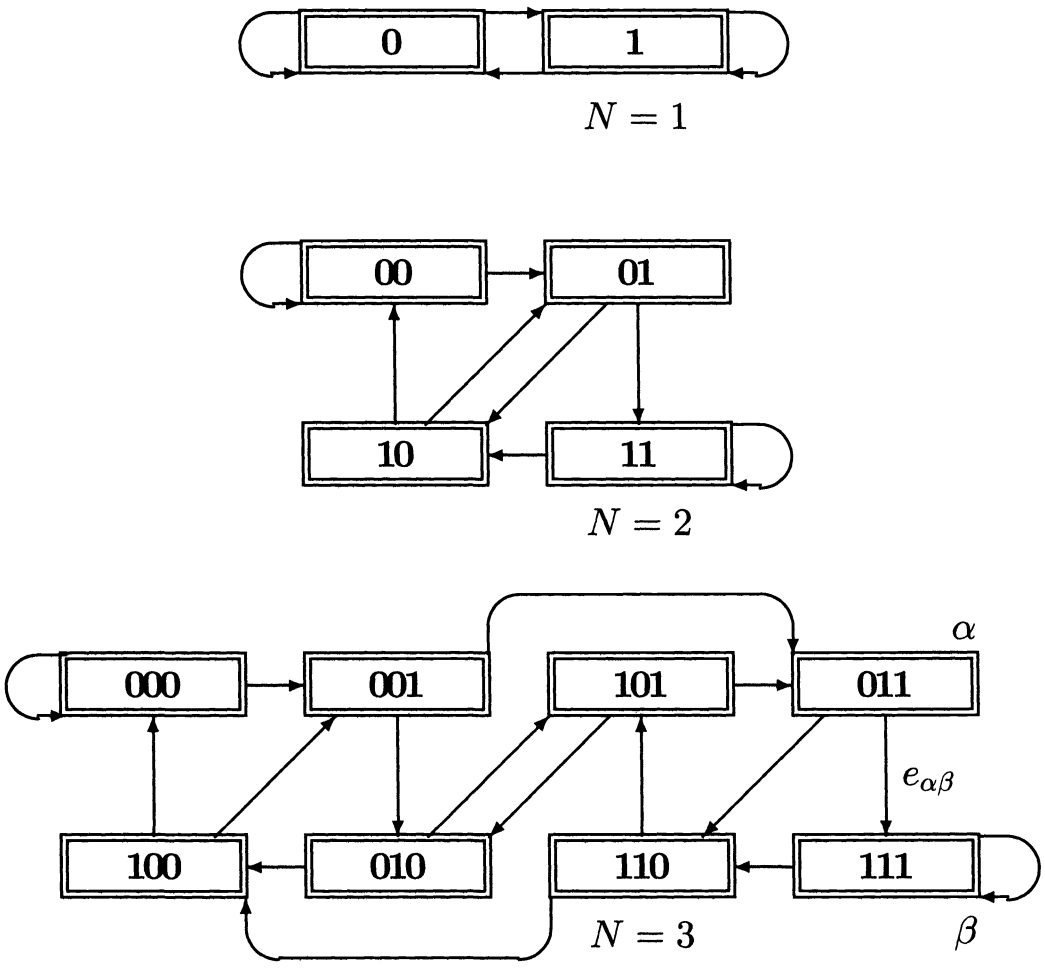

FIG. 1. *Graphs* $\Gamma(N)$.

that generates the cycle C. Denote by $\mathcal{C}(q,N)$ the set of all different elementary q-cycles in the graph $\Gamma(N)$, and let $\xi(q,N)$ be the number of elements in $\mathcal{C}(q,N)$. For example, Figure 2 shows all six elementary cycles for $N=2$. In this case $\xi(1,2) = \xi(3,2) = 2$ and $\xi(2,2) = \xi(4,2) = 1$.

4. Optimal strategies. Let the set $\mathcal{F}$ be the set of all boolean functions. Then an optimal strategy for **P** may be constructed effectively.

Denote by $\nu(N)$ the minimal number of active strategies in an optimal mixed strategy of the player **P**. As mentioned above, the minimal number of active strategies for **S** is 2.

THEOREM 2. *The minimum number* $\nu(N)$ *of active strategies in an optimal strategy of player* **P** *satisfies the upper bound*

$$\nu(N) \leq \sum_{q|(N+1)} \xi(q,N).$$

One of the optimal strategies of **P** *is the mixed strategy consisting of a weighted sum*

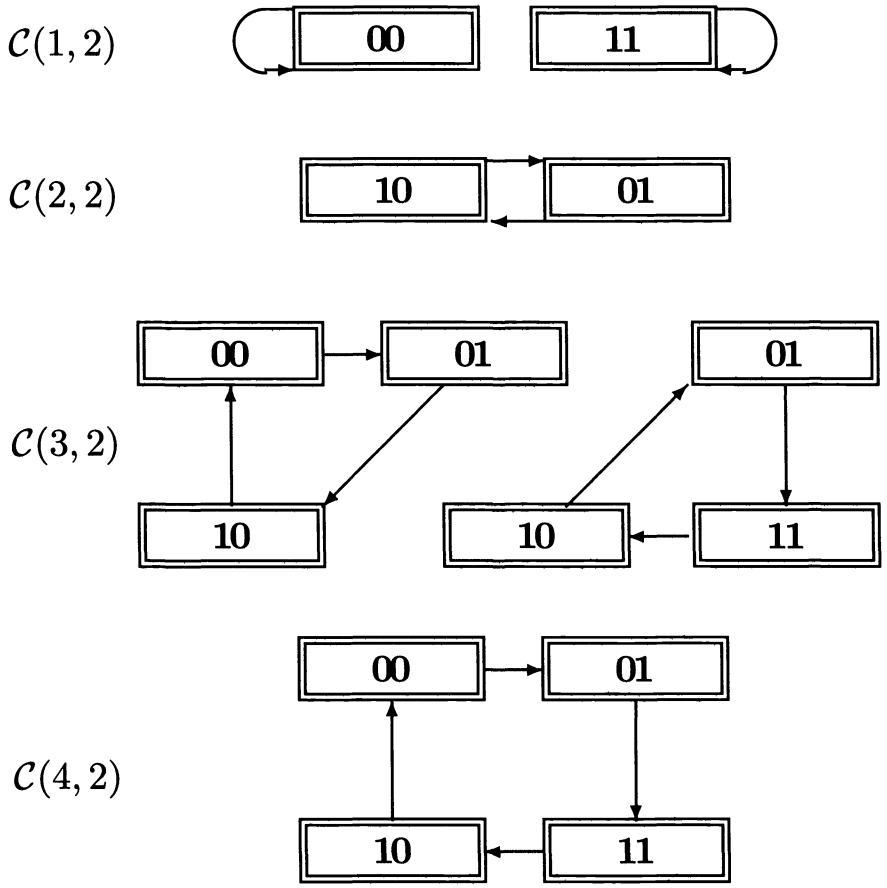

FIG. 2. *Elementary cycles in* $\Gamma(2)$.

of the functions $F(C)$ *generating all the cycles* $C \in \mathcal{C}(q,N)$, *where* $q|(N+1)$. *Every such function* $F(C)$ *has the weight* $2^{-(N+1)}q$ *in the mixed strategy.*

Therefore, the optimal mixture of strategies suggested in Theorem 2 prescribes the weights of the pure strategies to be chosen proportional to the periods of the binary sequences they generate.

For example, if $N = 3$, the optimal strategy may be constructed with 1-cycles, 2-cycles, and 4-cycles ($d = 1, 2, 4$ are the divisors of $N+1$). According to Figure 1, elementary cycles with the corresponding weights shown in Table 1 may be chosen.

For certain cases, an optimal strategy for **P** may be even simpler, as shown in the following statement.

COROLLARY 1. *If* $N+1$ *is prime, then* $\nu(N) \leq 2 + (2^{N+1} - 2)/(N+1)$.

For example, if $N = 2$, **P** may use only two kinds of cycles: 1-cycles and 3-cycles (see Figure 2). This is because 1 and 3 are the only divisors of $N+1$. Choosing them with the weights 1/8 and 3/8, respectively, we obtain the results in Table 2.

If $\mathcal{F}$ does not coincide with the set of all boolean functions, Theorem 2 is not applicable. However, **P** can always choose a "simple" optimal strategy (see [5] for

details).

LEMMA 1. *The set of optimal strategies of* $\mathbf{P}$ *contains a mixed strategy, all components of which have equal weight.*

5. Generalizations. The game $\mathbf{G}$ may be further generalized to the game $\mathbf{G}^*$. Maps $\Phi : I\!B^k \to I\!B^k$ will be called *filters* and positive functions $\Psi : I\!B^k \to I\!R_+$ will be called *factors*, where $I\!R_+$ denotes the set of nonnegative real numbers. The vectors of $I\!B^k$ will be called *strategies*.

Let the set of strategies $\mathcal{F}$ be a subset of $I\!B^k$, and suppose also that it contains along with any element $F = (f_1, \ldots, f_k) \in I\!B^k$ its boolean negation

$$1 - F = (1 - f_1, \ldots, 1 - f_k).$$

The number k is referred to as the *dimension* of the game $\mathbf{G}^*$. The game $\mathbf{G}^*$ is determined by its dimension k, filter Φ, and factor Ψ and the weight vector $M = (\mu_1, \ldots, \mu_k) \in I\!R^k_+$. Given the strategies $P = (p_1, \ldots, p_k)$ and $S = (s_1, \ldots, s_k)$, the payoff is determined by

$$W(P, S) = \Psi(P) \sum_{i=1}^{k} \mu_i \phi_i(P)(1 - 2|p_i - s_i|), \tag{8}$$

where $(\phi_1(P), \ldots, \phi_k(P))$ are the coordinates of the vector $\Phi(P)$. The values (8) form the matrix $\mathbf{W}$ of the game $\mathbf{G}^*$: $\mathbf{W} = (W(P_i, S_j))$.

The game $\mathbf{G}^*$ has the following interpretation. Let k cards be given, where each card i has its own value μ_i. Player **P** can write 0 or 1 on every card: that is, player **P** chooses a binary vector P. We assume that P can be chosen from the set $\mathcal{F}$ of admissible strategies. Then this vector P is filtered by the rule Φ. Only the cards with $\phi_i(P) = 1$ remain under consideration. Player **S** knows the rule Φ, although he does not know the vector P. He can also write 0 or 1 on every card trying to guess the vector P. Player **S** wins $\Psi(P)\mu_i$ if the ith card remains after filtration, $\phi_i(P) = 1$, and his prediction s_i coincides with p_i. Otherwise, if $p_i \neq s_i$, **S** loses $\Psi(P)\mu_i$. The game is repeated infinitely.

THEOREM 3. *For any filter and any factor the value of the game* $\mathbf{G}^*$ *is zero.*

Yet another generalization of the game **G** may be described in terms of the graphical interpretation of §3. Let Γ be an directed graph with exactly two arcs outgoing from every vertex. Denote by $\mathcal{C}(\Gamma)$ the set of all elementary cycles in Γ and by $\mathcal{D}(\Gamma)$ the set of all proper subsets of arcs. For every cycle $C \in \mathcal{C}(\Gamma)$ and for any set $D \in \mathcal{D}(\Gamma)$ define the number $V(C, D)$, which equals the fraction d/c, where d is the number of arcs of D belonging to cycle C and c is the length of this cycle. Enumerating the sets $\mathcal{C}(\Gamma)$ and $\mathcal{D}(\Gamma)$, one can obtain the matrix $\mathbf{V}$ with elements $\mathbf{v}_{ij} = V(C_i, D_j)$. Theorem 1 implies the following theorem.

THEOREM 4. *The value of the game with the matrix* $\mathbf{V}$ *equals* $1/2$.

6. Summary and conclusions. We considered a supergame between two computers, where the first computer generates a binary sequence while its opponent tries to predict the next element of this sequence using the previous elements. Both computers operate with the same pool of strategies, which is the set of boolean functions of N arguments. Despite asymmetry of the game, it is shown that the value of the game is zero. An algorithm for choosing an optimal superstrategy to generate the binary sequences is given.

We have addressed only several issues of this problem. It is interesting and important to address other open issues here. For example, suppose the players **P** and **S** have *different* memory capacities. What is the value of the game **G** in this case, and what would be the optimal strategies?

Another question is to gain an insight into the main reason for the superiority of the computer in the experiments described in the introduction: was it human predictability or the asymmetry of the game (the students were not aware of the computer predictions)? See [7] for other issues related to these experiments.

7. Appendix.

7.1. Proof of Theorem 3. We start with some notations and definitions. Nonzero vectors with nonnegative coordinates will be called *positive.*

Vectors $(1, 1, \ldots, 1)$ (of corresponding length) will be denoted by I. Denote by E_n^i the $2^n \times 2^n$-matrix with its ith row being equal to I and all other elements being zero. Let n-vector A (belonging to $\mathbb{B}^n$ or $\mathbb{R}^n$) be given, and $l < m \leq n$. We use the notations $A|_m$ for the mth coordinate of A and $A|_{l\,..\,m}$ for the vector $(A|_l, \ldots, A|_m)$. Given m-vector B, denote by $\langle A, B\rangle$ the concatenation of the A and B: the $(n+m)$-vector C such that $C|_{1,\ldots,n} = A$ and $C|_{n+1,\ldots,n+m} = B$.

It is sufficient to show (see, for example, [11]) that there exist positive vectors A and B (weights in the mixed strategies for the players **S** and **P**, correspondingly) such that

$$\mathbf{W}A = 0, \quad \mathbf{W}^T B = 0. \tag{9}$$

Moreover, further it will be proven that we may assume $A = I$.

Suppose that $\mathcal{F} = I\!B^k$ (the maximal set of functions). The relation (9) will be proved with induction on k. Let $k = 1$. Then the weight vector is $M = \mu_1$, the number of strategies equals to 2. Let the factor Ψ be determined by the relations

$$\Psi(0) = \psi_1, \ \Psi(1) = \psi_2.$$

Then four different filters Φ have to be considered:

$$\Phi\begin{pmatrix}0\\1\end{pmatrix} \in \left\{\begin{pmatrix}0\\0\end{pmatrix}, \begin{pmatrix}0\\1\end{pmatrix}, \begin{pmatrix}1\\0\end{pmatrix}, \begin{pmatrix}1\\1\end{pmatrix}\right\}.$$

Hence only four different matrices $\mathbf{W}$ may occur in this case:

$$\begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 0 \\ -\psi_2\mu_1 & \psi_2\mu_1 \end{pmatrix}, \begin{pmatrix} \psi_1\mu_1 & -\psi_1\mu_1 \\ 0 & 0 \end{pmatrix}, \begin{pmatrix} \psi_1\mu_1 & -\psi_1\mu_1 \\ -\psi_2\mu_1 & \psi_2\mu_1 \end{pmatrix}.$$

All these matrices satisfy (9) for appropriate pairs A and B. The sum of columns is zero, so we may assume $A = I$.

Suppose that (9) holds for all dimensions up to k inclusively. Fix a filter Φ in the game with the dimension $k+1$. Let $(\mu_1, \dots, \mu_{k+1})$ be the weight vector, $K = 2^{k+1}$, and let $(\psi_1, \dots, \psi_K)$ be the vector consisting of all values of factor Ψ, i.e., $\psi_i = \Psi(\alpha_i)$ (where $\alpha_i \in I\!B^{k+1}$). Split the strategy set into four nonintersecting subsets:

$$\begin{aligned} J_1 &= \{S : \ S|_{k+1} = 0, \ \Phi(S)|_{k+1} = 1\}, \\ J_2 &= \{S : \ S|_{k+1} = 0, \ \Phi(S)|_{k+1} = 0\}, \\ J_3 &= \{S : \ S|_{k+1} = 1, \ \Phi(S)|_{k+1} = 1\}, \\ J_4 &= \{S : \ S|_{k+1} = 1, \ \Phi(S)|_{k+1} = 0\}. \end{aligned}$$

Note that the set $J^0 = (J_1 \cup J_2)$ consists of all numbers from 0 to $K/2-1$ (in the sense of the one-to-one correspondence between natural numbers and elements of $I\!B^k$ stated above). In the same way, the set $J^1 = (J_3 \cup J_4)$ consists of all numbers from $K/2$ to $K-1$. Therefore, the sets J^0, J^1 can be considered as $I\!B^k$. Define two filters Φ^1 and Φ^2 as restrictions of Φ on J^0 and J^1, respectively:

$$\Phi^1(S) = \Phi(\langle S, 0\rangle)|_{1,\dots,k}, \quad \Phi^2(S) = \Phi(\langle S, 1\rangle)|_{1,\dots,k},$$

where $S \in I\!B^k$. Consider two games $\mathbf{G}^*$ of dimension k: the first game is determined by the filter Φ^1 and the factor $(\psi_1, \dots, \psi_{K/2})$, and the second game is determined by the filter Φ^2 and the factor $(\psi_{K/2+1}, \dots, \psi_K)$; the weight vector $(\mu_1, \dots, \mu_k)$ is the same for both games. Denote by $\mathbf{W}_1$ and $\mathbf{W}_2$ the matrices of these games. Denote

$$\mathbf{W}_1^{\pm} = \mathbf{W}_1 \pm \mu_{k+1} \sum_{i \in J_1} \psi_i E_k^i, \quad \mathbf{W}_2^{\pm} = \mathbf{W}_2 \pm \mu_{k+1} \sum_{i \in J_3} \psi_i E_k^i. \tag{10}$$

By definition, the matrix $\mathbf{W}$ has the form

$$\mathbf{W} = \begin{pmatrix} \mathbf{W}_1^+ & \mathbf{W}_1^- \\ \mathbf{W}_2^- & \mathbf{W}_2^+ \end{pmatrix}. \tag{11}$$

The induction assumption implies that the sum of all the columns of $\mathbf{W}$ is zero. That proves the first equality in (9) for $A = I$. Using the induction assumption

once again we conclude that there exist positive (2^k)-vectors $B^1 = (b_1^1, b_2^1, \ldots)$ and $B^2 = (b_1^2, b_2^2, \ldots)$ such that $\mathbf{W}_1^T B^1 = \mathbf{W}_2^T B^2 = 0$.

Suppose at least one of the numbers

$$p = \sum_{i \in J_1} \psi_i b_i^1, \quad q = \sum_{i \in J_3} \psi_i b_i^2 \tag{12}$$

is not equal to zero. Then (2^{k+1})-vector $B = \langle qB^1, pB^2 \rangle$ is positive. Therefore (10)–(12) imply

$$\mathbf{W}^T B = 0. \tag{13}$$

If, on the other hand, both numbers $p = q = 0$, then all the terms in (12) equal zero and (assuming $B = \langle B^1, B^2 \rangle$) we obtain (13). This proves the theorem for $\mathcal{F} = \mathbb{B}^k$.

Now let $\mathcal{F} \neq \mathbb{B}^k$. Since any element F belongs to $\mathcal{F}$ together with $I - F$, this is also true for the set $\mathbb{B}^k \setminus \mathcal{F}$. The numbers i and j are referred to as symmetrical if $i + j = 2^k$. The game matrix $\mathbf{W}$ can be obtained from the above construction by deleting some rows and columns with symmetrical numbers. It follows that $\mathbf{W}$ has the form of (10)–(11). Thus Theorem 3 remains valid.

7.2. Proof of Theorem 1. We will show that the game $\mathbf{G}$ is a special case of the game $\mathbf{G}^*$.

Let $k = 2^N$. (N and k are the dimensions of the games $\mathbf{G}$ and $\mathbf{G}^*$, respectively.) Consider the graph $\Gamma(\mathbf{G})$ corresponding to the game $\mathbf{G}$, and enumerate all its vertices with the numbers $0, \ldots, k-1$. Fix an initial vertex α_0. Now we establish a one-to-one correspondence between strategy sets $\mathcal{F}(\mathbf{G})$ and $\mathcal{F}(\mathbf{G}^*)$. As stated in §3, any strategy $P \in \mathcal{F}(\mathbf{G})$ may be considered as a proper subset of $U(\Gamma)$. Let the arc e_{ij} belong to P and denote $P^* = (p_0^*, \ldots, p_{k-1}^*) \in \mathbb{B}^k$, where $p_i^* = j \bmod 2$. Similarly, let $P^* \in \mathcal{F}(\mathbf{G}^*)$ and assume

$$P = \{e_{ij} : j = (2i \bmod k) + p_i^*;\ 0 \leq i \leq k-1\}.$$

The one-to-one correspondence is established.

As shown in §3, any strategy $P \in \mathcal{F}(\mathbf{G})$ defines the elementary cycle $C(P, \alpha_0)$ of length $q(P, \alpha_0)$. Choose the weight vector $M = I$, the factor $\Psi(P^*) = q^{-1}(P, \alpha_0)$, and the filter $\Phi(P^*) = (\phi_1(P^*), \ldots, \phi_k(P^*))$, where

$$\phi_i(P^*) = \begin{cases} 1 & \text{if the vertex } (i-1) \text{ belongs to the cycle } C(P, \alpha_0), \\ 0 & \text{otherwise.} \end{cases}$$

These definitions with (7) and (8) imply $\mathbf{V} = \mathbf{W}$; i.e., the games matrices are equal. Generally, different initial vertices α_0 define different games $\mathbf{G}^*$. Nevertheless, Theorem 3 implies that the price of any of these games is zero. This completes the proof of Theorem 1.

7.3. Proof of Theorem 2. The following *frequency* vectors are used further. Consider 2^{N+1}-dimensional vectors and enumerate their coordinates with the corresponding binary $(N+1)$-vectors. For example, if $N = 1$, then $2^{N+1} = 4$ and the components of 4-dimensional vectors are enumerated by (00), (01), (10), and (11), correspondingly. Each periodic binary sequence π defines the following relative frequencies of $(N+1)$-words in π. The relative frequency of a word $b = (b_1, \ldots, b_{N+1})$ is the limit

$$\lim_{M \to \infty} \left(\frac{1}{M} F(b, \pi_M) \right),$$

where π_M is the initial segment of π of length M and $F(b, \pi_M)$ is the number of the words b in π_M.

All the sequences π generated by $\mathbf{P}$ may be enumerated by corresponding 2^{N+1}-dimensional frequency vectors p. For example, for $N = 1$ the functions P_1, P_2, P_3 (see (3)) generate three different sequences π_i described by their frequency vectors p_i:

$$
\begin{array}{lll}
 & (00)\quad (01)\quad (10)\quad (11) \\
\pi_1 = 000000\ldots \Longrightarrow & p_1 = (1, \quad 0, \quad 0, \quad 0), \\
\pi_2 = 010101\ldots \Longrightarrow & p_2 = \left(0, \quad \frac{1}{2}, \quad \frac{1}{2}, \quad 0\right), \\
\pi_3 = 111111\ldots \Longrightarrow & p_3 = (0, \quad 0, \quad 0, \quad 1).
\end{array} \tag{14}
$$

The strategies of the player $\mathbf{S}$ are described by 2^{N+1}-dimensional payoff vectors s: if a strategy s predicts the $(N+1)$-th element d_{N+1} after a series $(d_1, \ldots, d_N)$, then the $(d_1, \ldots, d_N, d_{N+1})$-th coordinate of the vector s is equal to $+1$ and its $(d_1, \ldots, d_N, 1 - d_{N+1})$-th coordinate is equal to -1. For example, if $N = 1$, then the strategy S_1 repeating the last symbol generated by $\mathbf{P}$ is described by the vector $(+1, -1, -1, +1)$. Another available strategy S_2 in the case $N = 1$ is described by the vector $s_2 = (-1, +1, +1, -1)$ (see (4)). Other two functions s_3 and s_4 are described by the vectors $(+1, -1, +1, -1)$ and $(-1, +1, -1, +1)$.

In these notations the matrix of the game is the matrix of all pairwise vector products (p_i, s_j). In the case $N = 1$ this matrix has the same form as (6):

	s_1	s_2	s_3	s_4
π_1	1	−1	1	−1
π_2	−1	1	0	0
π_3	1	−1	−1	1.

The 2^{N+1}-dimensional vector I is orthogonal to any vector s_j (this fact follows from the definition of vectors s_j). If such nonnegative weights ζ_i are chosen that

$$
\sum_i \zeta_i p_i = I, \tag{15}
$$

then the mixed strategy of p_i with weights ζ_i (where $\zeta_1 + \zeta_2 + \cdots = 1$) has the zero price for player $\mathbf{P}$. For example, for $N = 1$ the coefficients

$$
\zeta_1 = \frac{1}{4}, \quad \zeta_2 = \frac{1}{2}, \quad \zeta_3 = \frac{1}{4}
$$

may be chosen; then the formulas (14) imply (15) for $N = 1$. Therefore it is sufficient to indicate an algorithm of choosing the base vectors p_i and the weights ζ_i so that (15) holds: in fact, this algorithm provides the way of choosing an optimal mixed strategy. This is what is to be done next, in the final part of the proof.

Consider a strategy F of $\mathbf{P}$ which generates a q-periodic binary sequence π. Then its frequency vector has $2^{N+1} - q$ zero components, and all its q nonzero components are equal to q^{-1}.

Let $q = N+1$. Consider a N-word b and both possible $(N+1)$-periodic extensions of this word:

$$
b0b0b0b0\ldots \quad \text{or} \quad b1b1b1b1\ldots.
$$

The next step is to demonstrate that each of these $(N+1)$-periodic extensions corresponds to some sequence generated by a boolean function of N arguments. The definition of such function F is straightforward: for any N-word $B = (b_k, \ldots, b_{k+N-1})$ in the infinite $(N+1)$-periodic sequence (b_i) we define $F(B) = b_{k+N}$. This way cannot lead to contradictions: if B_1 and B_2 are two $(N+1)$-words in the infinite $(N+1)$-periodic sequence (b_i) and the first N elements of both words B_1 and B_2 coincide, then their $(N+1)$-th elements also coincide (since the period of the sequence has fixed number of 0's and 1's).

Let $d|(N+1)$. Then *any* d-periodic sequence may be generated by some boolean function of N arguments. Denote by P_N the set of all boolean functions generating all d-periodic sequences. Consider two arbitrary strategies $F_1, F_2 \in P_N$ and denote the frequency vectors of these functions by p_1 and p_2. Then there are two possibilities:

1. The vectors p_1 and p_2 coincide.
2. The vectors p_1 and p_2 have no common nonzero components.

To prove it, suppose that there is a common nonzero component $(N+1)^{-1}$ of the vectors p_1 and p_2. Therefore two $(N+1)$-periodic sequences π_1 and π_2 share a $(N+1)$-word, which means they coincide. Now (15) holds for all *distinct* sequences p_i with periods d_i (where $d_i|(N+1)$) with the weights $\zeta_i = d_i^{-1}$.

7.4. Proof of Corollary 1. Using the approach of the proof of Theorem 2 and the fact $N+1$ is prime, the period d of a d-periodic subsequence of an $(N+1)$-periodic output sequence may be equal to either 1 or $(N+1)$. Hence there are two 1-periodical sequences (0000... and 1111...) which must be chosen with the weights $2^{-(N+1)}$, and other $(2^{N+1}-2)$ elements are covered by $(2^{N+1}-2)/(N+1)$ distinct $(N+1)$-periodic sequences; each of these $(N+1)$-periodic sequences has to be chosen with the weights $(N+1)2^{-(N+1)}$.

That gives the estimate of Corollary 1.

Acknowledgment. The authors would like to thank Phil Diamond for reading a draft of the manuscript and making many useful suggestions. We are also grateful to the anonymous reviewers for their helpful comments.

A NEW FORMULATION OF STATE CONSTRAINT PROBLEMS FOR FIRST-ORDER PDES *

HITOSHI ISHII† AND SHIGEAKI KOIKE‡

Abstract. The first-order Hamilton–Jacobi–Bellman equation associated with the state constraint problem for optimal control is studied. Instead of the boundary condition which Soner introduced, a new and appropriate boundary condition for the PDE is proposed. The uniqueness and Lipschitz continuity of viscosity solutions for the boundary value problem are obtained.

Key words. state constraint problem, viscosity solution, comparison principle

AMS subject classifications. 35B37, 35F30, 49L25

1. Introduction. In this paper we study state constraint (SC) problems for first-order PDEs. The name, state constraint problems, or state-space constraint problems, comes from optimal control. In [10] Soner first considered the problem of characterizing the value functions of state constraint problems in optimal control as the unique viscosity solutions of the associated Hamilton–Jacobi–Bellman equations.

Let us recall Soner's formulation. Consider the first-order PDE

$$H(x,u,Du)=0 \quad \text{in } \Omega, \tag{1}$$

where $H:\overline{\Omega}\times\mathbf{R}\times\mathbf{R}^n\to\mathbf{R}$ is given by

$$H(x,r,p)=\max_{a\in A}\{\lambda r-\langle g(x,a),p\rangle-f(x,a)\}. \tag{2}$$

Here Ω is a bounded open subset of $\mathbf{R}^n$, A is an index set, $\lambda>0$ is a constant, and $g:\overline{\Omega}\times A\to\mathbf{R}^n$ and $f:\overline{\Omega}\times A\to\mathbf{R}$ are given functions.

Equation (1) is the Hamilton–Jacobi–Bellman equation associated with the optimal control problem, where the sets $\overline{\Omega}$ and A, and the constant λ are the state space, the control set, and the discount factor, respectively, and where the functions g and f describe the dynamics and the running cost, respectively.

In Soner's formulation, a function $u\in C(\overline{\Omega})$ is a viscosity solution of the SC problem for (1) if

$$\begin{cases} H(x,u,Du)\le 0 \text{ in } \Omega, \\ H(x,u,Du)\ge 0 \text{ in } \overline{\Omega} \end{cases} \tag{3}$$

in the viscosity sense. We refer to [3] for the definition of viscosity solutions and for a general scope of the theory of viscosity solutions.

The above formulation (3) does not take into account the boundary behavior of u as a subsolution of (1), which reflects the fact that uniqueness results for (3) require

the continuity of the solution u of (3) near the boundary $\partial\Omega$. See for this [10], [2], and [6].

The primary purpose of this paper is to point out that the value function V of the SC problem in optimal control corresponding to the Hamiltonian H satisfies a condition on $\partial\Omega$ in addition to (3). If we take this boundary condition into account in the formulation of the SC problem for (1), then this new SC problem for (1) characterizes the value function as a unique solution among (not necessarily continuous) bounded functions on $\overline{\Omega}$ under natural hypotheses on Ω, g, and f. This will be done in §§2 and 3. It will turn out that the additional boundary condition behaves like an oblique boundary condition. In fact, to show our comparison theorem, we will employ some ideas from [4], [5], [7], and [8] that were useful to oblique boundary value problems. We refer to [1] and [11] for other ideas to show comparison theorems for oblique problems. We also refer to [11] for a general framework to boundary value problems for first-order PDEs.

In §5 we also take up the same subject for SC problems with state-space Ω (replacing $\overline{\Omega}$).

The secondary purpose is to show the Lipschitz continuity of the solution of the SC problem provided that λ is large enough. This result has been proved in [9] via a direct estimation of the value function and the method here gives a new approach to the result. This will be dealt with in §4.

Section 6 is devoted to the proof of certain lemmas.

2. New formulation. In this section we introduce and explain our new formulation of the SC problem for (1).

We assume throughout that A is a compact metric space and that

$$\text{(A1)} \qquad \begin{cases} g : \overline{\Omega} \times A \to \mathbf{R}^n,\ f : \overline{\Omega} \times A \to \mathbf{R} \text{ are continuous,} \\ \sup\limits_{a \in A} \|g(\cdot, a)\|_{C^{0,1}(\overline{\Omega})} < \infty. \end{cases}$$

Note that the function $f : \overline{\Omega} \times A \to \mathbf{R}$ is bounded and uniformly continuous. We may assume that g and f are defined on $\mathbf{R}^n \times A$ and moreover that $\sup_{a \in A} \|g(\cdot, a)\|_{C^{0,1}(\mathbf{R}^n)} < \infty$ and $f : \mathbf{R}^n \times A \to \mathbf{R}$ is bounded and uniformly continuous. We use this convention throughout this paper.

For a given Lipschitz function ξ on $\mathbf{R}^n$ and $x \in \mathbf{R}^n$, the unique solution $Y(t)$ of the initial value problem

$$\frac{dY}{dt}(t) = \xi(Y(t)) \quad \text{for } t > 0 \quad \text{and} \quad Y(0) = x$$

will be denoted by $Y(t; x, \xi)$. For any $z \in \overline{\Omega}$, let $A(z)$ denote the set

$$\{a \in A \mid \exists r > 0 \text{ such that } Y(t; x, g(\cdot, a)) \in \overline{\Omega} \text{ for } x \in \overline{\Omega} \cap B(z, r),\ t \in [0, r]\}.$$

Here and henceforth $B(z, r)$ denotes the closed ball with center z and radius r. It is clear that the multifunction $\overline{\Omega} \ni x \mapsto A(x)$ is lower semicontinuous and that $A(x) = A$ for all $x \in \Omega$.

In what follows we assume that

$$\text{(A2)} \qquad A(z) \neq \emptyset \quad \text{for all} \quad z \in \partial\Omega.$$

We define the inward Hamiltonian $H_{in} : \overline{\Omega} \times \mathbf{R} \times \mathbf{R}^n \to \mathbf{R}$ by

$$H_{in}(x,r,p) = \sup_{a \in A(x)} \{\lambda r - \langle g(x,a), p\rangle - f(x,a)\}.$$

Of course, $H_{in}(x,r,p) = H(x,r,p)$ for $(x,r,p) \in \Omega \times \mathbf{R} \times \mathbf{R}^n$. Moreover, by the semicontinuity of $x \mapsto A(x)$ and the uniform continuity of g, f we see that H_{in} is lower semicontinuous.

Our definition of solutions of the SC problem for (1) is as follows.

DEFINITION 2.1. *We call a bounded function $u : \overline{\Omega} \to \mathbf{R}$ a* viscosity subsolution (*respectively, a* viscosity supersolution) of the SC problem for (1) *if*

$$H_{in}(x, u^*, Du^*) \le 0 \quad \text{in } \overline{\Omega} \qquad (\text{respectively, } H(x, u_*, Du_*) \ge 0 \quad \text{in } \overline{\Omega})$$

in the viscosity sense. Here u^* and u_* denote the upper semicontinuous and the lower semicontinuous envelopes of u, respectively, i.e.,

$$u^*(x) = \lim_{r \downarrow 0} \sup\{u(y) \mid y \in \overline{\Omega} \cap B(x,r)\} \quad \text{for } x \in \overline{\Omega}$$

and $u_* = -(-u)^*$ on $\overline{\Omega}$. We call a bounded function $u : \overline{\Omega} \to \mathbf{R}$ a viscosity solution of the SC problem for (1) *if u is both a viscosity subsolution and a viscosity supersolution of the SC problem for* (1).

Now we consider the SC problem in optimal control associated with the Hamiltonian H given by (2). The value function $V : \overline{\Omega} \to \mathbf{R}$ of the problem is defined as follows: For $x \in \overline{\Omega}$ and a measurable function $\alpha : [0,\infty) \to A$ we consider the state equation

$$\frac{dX}{dt}(t) = g(X(t), \alpha(t)) \quad \text{for} \quad t > 0 \quad \text{and} \quad X(0) = x. \tag{4}$$

We write $X(t; x, \alpha)$ for the solution of (4) to indicate the dependence on x, α. For each $x \in \overline{\Omega}$ define the set $\mathcal{A}(x)$ as the set of all measurable functions $\alpha : [0,\infty) \to A$ such that the solution $X(t)$ of (4) stays in $\overline{\Omega}$ for all $t \in [0,\infty)$. It is easily seen that under assumption (A2), $\mathcal{A}(x) \neq \emptyset$.

Define the value function V on $\overline{\Omega}$ by

$$V(x) = \inf_{\alpha \in \mathcal{A}(x)} \int_0^\infty e^{-\lambda t} f(X(t; x, \alpha), \alpha(t)) dt. \tag{5}$$

THEOREM 2.2. *Under assumptions* (A1) *and* (A2), *V is a viscosity solution of the SC problem for* (1).

Proof. First of all, we observe that V is bounded on $\overline{\Omega}$. As in [10] we see that V satisfies (3) in the viscosity sense. (In [10] it is assumed that V is continuous on $\overline{\Omega}$ but this is not assumed here. Accordingly, we have to modify the argument in [10] a little.)

It remains to show that if $\varphi \in C^1(\overline{\Omega})$ and if $z \in \partial\Omega$ is a maximum point of $V^* - \varphi$, then

$$H_{in}(z, V^*(z), D\varphi(z)) \le 0. \tag{6}$$

To do this fix any $\varphi \in C^1(\overline{\Omega})$ and let $z \in \partial\Omega$ be a maximum point of $V^* - \varphi$. We may assume that $V^*(z) - \varphi(z) = 0$.

Fix any $a \in A(z)$. Set $\alpha(t) \equiv a$. By the definition of $A(z)$, there is $r > 0$ such that

$$X(t; x, \alpha) \in \overline{\Omega} \quad \text{for } x \in \overline{\Omega} \cap B(z, r) \text{ and } t \in [0, r].$$

It is obvious that if the choice of r is appropriate and if $x \in \overline{\Omega} \cap B(z, r)$, then the restriction $\alpha|_{[0,r]}$ can be extended to $[0, \infty)$ so that the resulting function which we denote by α_x belongs to $\mathcal{A}(x)$.

Fix $\varepsilon \in (0, r]$ and choose $x_\varepsilon \in \overline{\Omega} \cap B(z, \varepsilon)$ such that

$$V(x_\varepsilon) > \varphi(x_\varepsilon) - \varepsilon \int_0^\varepsilon e^{-\lambda t} dt. \tag{7}$$

The dynamic programming principle yields

$$V(x_\varepsilon) \leq \int_0^\varepsilon e^{-\lambda t} f(X(t; x_\varepsilon, \alpha_{x_\varepsilon}), a) dt + e^{-\lambda \varepsilon} V(X(\varepsilon; x_\varepsilon, \alpha_{x_\varepsilon})).$$

Hence, using (7) and observing that $V \leq \varphi$ on $\overline{\Omega}$, we get

$$\begin{aligned} 0 &< \int_0^\varepsilon e^{-\lambda t} \{ f(X(t; x_\varepsilon, \alpha_{x_\varepsilon}), a) + \varepsilon \} dt + e^{-\lambda \varepsilon} \varphi(X(\varepsilon; x_\varepsilon, \alpha_{x_\varepsilon})) - \varphi(x_\varepsilon) \\ &= \int_0^\varepsilon e^{-\lambda t} \{ f(X(t; x_\varepsilon, \alpha_{x_\varepsilon}), a) - \lambda \varphi(X(t; x_\varepsilon, \alpha_{x_\varepsilon})) \\ &\qquad + \langle g(X(t; x_\varepsilon, \alpha_{x_\varepsilon}), a), D\varphi(X(t; x_\varepsilon, \alpha_{x_\varepsilon})) \rangle + \varepsilon \} dt. \end{aligned}$$

Thus, there is $y_\varepsilon = X(t_\varepsilon; x_\varepsilon, \alpha_{x_\varepsilon})$ with $t_\varepsilon \in (0, \varepsilon)$ such that

$$-\varepsilon < f(y_\varepsilon, a) - \lambda \varphi(y_\varepsilon) + \langle g(y_\varepsilon, a), D\varphi(y_\varepsilon) \rangle.$$

Now, sending $\varepsilon \downarrow 0$, we conclude that (6) holds. □

3. Comparison of solutions. In what follows we use the condition introduced by Soner [10] which guarantees the continuity of value functions of SC problems in optimal control. Let $G(x)$ denote the set $\{g(x, a) \mid a \in A(x)\}$ for $x \in \overline{\Omega}$. For $B \subset \mathbf{R}^m$ let $\operatorname{co} B$ denote the convex hull of B. Soner's condition is stated as follows:

(A3) For each $z \in \partial\Omega$ there are $r > 0$ and $\xi \in \operatorname{co} G(z)$ such that

$$B(x + t\xi, rt) \subset \overline{\Omega} \quad \text{for all } x \in \overline{\Omega} \cap B(z, r) \text{ and } 0 \leq t \leq r. \tag{8}$$

Let us give a few remarks concerning condition (A3). First, it is obvious that if (A3) holds, then (A2) is satisfied. Second, if (8) holds for some $z \in \partial\Omega$, $r > 0$, and $\xi \in \mathbf{R}^n$, then we have

$$B(x - t\xi, rt) \subset \Omega^c \quad \text{for all } x \in \Omega^c \cap B(z, r) \text{ and } 0 \leq t \leq r.$$

(See the proof of Lemma 6.3 in §6.) That is, if (A3) holds, then the condition (A3) with Ω^c and $-G(z)$ replacing $\overline{\Omega}$ and $G(z)$, respectively, is satisfied. Condition (A3) thus implies that Ω is a Lipschitz domain.

Our main result in this section can now be stated.

THEOREM 3.1. *Let* (A1) *and* (A3) *hold. Let u and v be a viscosity subsolution and a viscosity supersolution of the SC problem for* (1), *respectively. Then $u \leq v$ on $\overline{\Omega}$.*

To prove this theorem, we need a few lemmas.

LEMMA 3.2. *Let* (A1) *and* (A3) *hold. Then there are* $\xi_0 \in C^{0,1}(\mathbf{R}^n, \mathbf{R}^n)$, $\eta_0 \in C(\mathbf{R}^n)$, *and* $r_0 > 0$ *such that*

$$(\xi_0(x), \eta_0(x)) \in \operatorname{co}\{(g(x,a), f(x,a)) \mid a \in A(x)\} \quad \text{for } x \in \partial\Omega$$

and

$$B(x + t\xi_0(x), r_0 t) \subset \overline{\Omega} \quad \text{for all } x \in \partial\Omega \text{ and } 0 \le t \le r_0.$$

Henceforth we assume that (A1) and (A3) are satisfied and fix ξ_0, η_0, and r_0 so that the above conditions are satisfied.

LEMMA 3.3. *There is a function* $\psi \in C^\infty(\overline{\Omega})$ *such that*

$$\langle \xi_0(x), D\psi(x) \rangle \ge 1 \quad \text{on } \partial\Omega.$$

LEMMA 3.4. *There are* $w \in C^1(\overline{\Omega} \times \overline{\Omega})$, *constants* $C_i > 0$, $i = 1, 2, 3$, *and* $r_1 > 0$ *such that*

$$\langle \xi_0(x), D_x w(x,y) \rangle \le 0 \quad \text{for all } x \in \partial\Omega \text{ and } y \in \overline{\Omega} \cap B(x, r_1),$$

and for all $x, y \in \overline{\Omega}$,

$$\begin{gathered} |x-y|^2 \le w(x,y) \le C_1 |x-y|^2, \\ \max\{|D_x w(x,y)|, |D_y w(x,y)|\} \le C_2 |x-y|, \\ |D_x w(x,y) + D_y w(x,y)| \le C_3 |x-y|^2. \end{gathered}$$

We postpone the proof of these lemmas until §6 and here complete the proof of Theorem 3.1, assuming the validity of these lemmas.

Proof. Let ψ be as in Lemma 3.3 and let μ be a constant to be fixed later. Define functions $\tilde{u}$ and $\tilde{v}$ on $\overline{\Omega}$ by

$$\tilde{u}(x) = u^*(x) + \mu\psi(x) \quad \text{and} \quad \tilde{v}(x) = v_*(x) + \mu\psi(x),$$

so that

$$\widetilde{H}_{in}(x, \tilde{u}, D\tilde{u}) \le 0 \quad \text{on } \overline{\Omega}$$

and

$$\widetilde{H}(x, \tilde{v}, D\tilde{v}) \ge 0 \quad \text{on } \overline{\Omega} \tag{9}$$

in the viscosity sense. Here $\widetilde{H}_{in}$ and $\widetilde{H}$ are defined by

$$\begin{aligned} &\widetilde{H}_{in}(x, r, p) \\ &\quad = \sup_{a \in A(x)} \{\lambda r - \langle g(x,a), p \rangle - f(x,a) - \lambda\mu\psi(x) + \mu\langle g(x,a), D\psi(x) \rangle\} \end{aligned}$$

and

$$\begin{aligned} &\widetilde{H}(x, r, p) \\ &\quad = \max_{a \in A}\{\lambda r - \langle g(x,a), p \rangle - f(x,a) - \lambda\mu\psi(x) + \mu\langle g(x,a), D\psi(x) \rangle\}. \end{aligned}$$

In particular, $\tilde{u}$ satisfies

$$\begin{cases} \widetilde{H}(x, \tilde{u}, D\tilde{u}) \leq 0 \ \text{ in } \Omega, \\ -\langle \xi_0(x), D\tilde{u} \rangle \leq -\lambda u^*(x) + \eta_0(x) - \mu \langle \xi_0(x), D\psi(x) \rangle \ \text{ on } \partial\Omega \end{cases}$$

in the viscosity sense (see Definition 7.4 in [3]). Now fix μ large enough so that

$$-\lambda u^*(x) + \eta_0(x) - \mu \langle \xi_0(x), D\psi(x) \rangle \leq -1 \ \text{ on } \partial\Omega.$$

Then $\tilde{u}$ satisfies

$$\begin{cases} \widetilde{H}(x, \tilde{u}, D\tilde{u}) \leq 0 \ \text{ in } \Omega, \\ -\langle \xi_0(x), D\tilde{u} \rangle \leq -1 \ \text{ on } \partial\Omega \end{cases} \tag{10}$$

in the viscosity sense.

It is enough to show that $\tilde{u} \leq \tilde{v}$ on $\overline{\Omega}$. To do this we argue by contradiction. Suppose that $\max_{\overline{\Omega}}(\tilde{u} - \tilde{v}) > 0$. Let $w \in C^1(\overline{\Omega} \times \overline{\Omega})$ be a function as in Lemma 3.4. Let $\varepsilon > 0$ and $(x_\varepsilon, y_\varepsilon)$ be a maximum point of the function

$$(x, y) \mapsto \tilde{u}(x) - \tilde{v}(y) - \frac{1}{\varepsilon} w(x, y) \ \text{ on } \overline{\Omega} \times \overline{\Omega}.$$

Standard arguments show that $(1/\varepsilon) w(x_\varepsilon, y_\varepsilon) \to 0$ as $\varepsilon \downarrow 0$. Choosing $\varepsilon > 0$ small enough, we may assume that $|x_\varepsilon - y_\varepsilon| \leq r_1$, where $r_1 > 0$ is from Lemma 3.4. If $x_\varepsilon \in \partial\Omega$, then in view of (10) we have either

$$-\frac{1}{\varepsilon} \langle \xi_0(x_\varepsilon), D_x w(x_\varepsilon, y_\varepsilon) \rangle \leq -1 \quad \text{or} \quad \widetilde{H}\left(x_\varepsilon, \tilde{u}(x_\varepsilon), \frac{1}{\varepsilon} D_x w(x_\varepsilon, y_\varepsilon) \right).$$

By our choice of w we have

$$\langle \xi_0(x_\varepsilon), D_x w(x_\varepsilon, y_\varepsilon) \rangle \leq 0.$$

This means that we always have

$$\widetilde{H}\left(x_\varepsilon, \tilde{u}(x_\varepsilon), \frac{1}{\varepsilon} D_x w(x_\varepsilon, y_\varepsilon) \right) \leq 0.$$

By (9) we have

$$\widetilde{H}\left(y_\varepsilon, \tilde{v}(y_\varepsilon), -\frac{1}{\varepsilon} D_y w(x_\varepsilon, y_\varepsilon) \right) \geq 0.$$

We proceed as in the standard comparison argument and get a contradiction. □

4. Lipschitz continuity. In this section we assume

$$\sup_{a \in A} \| f(\cdot, a) \|_{C^{0,1}(\overline{\Omega})} < \infty. \tag{A4}$$

In view of Theorems 2.2 and 3.1 there is a unique viscosity solution $u \in C(\overline{\Omega})$ of the SC problem for (1) under the hypotheses (A1) and (A3).

THEOREM 4.1. *Let* (A1), (A3), *and* (A4) *hold. Set*

$$L_1 = \sup_{a\in A} \|g(\cdot,a)\|_{C^{0,1}(\overline{\Omega})} \quad \text{and} \quad \lambda_0 = L_1(C_2+C_3)/2,$$

where C_2 and C_3 are constants from Lemma 3.4. *Let $\lambda > \lambda_0$. Then the viscosity solution $u \in C(\overline{\Omega})$ of the SC problem for* (1) *is Lipschitz continuous on $\overline{\Omega}$.*

Remark. Loreti and Tessitore [9] have already obtained the above result under a slightly stronger hypothesis on Ω. Their choice of λ_0 may differ from ours.

Proof. Let ξ_0, $\tilde{u}$, $\widetilde{H}$, w, r_1, μ, and ψ be as in the proof of Theorem 3.1. Let $C_i > 0$, $i = 2,3$, be constants from Lemma 3.4. We set

$$\tilde{f}(x,a) = f(x,a) + \lambda\mu\psi(x) - \mu\langle g(x,a), D\psi(x)\rangle.$$

Let $\lambda > \lambda_0$. We will prove that

$$\tilde{u}(x) - \tilde{u}(y) \le \alpha w(x,y)^{1/2} \quad \text{for all } x,y \in \overline{\Omega} \tag{11}$$

and for some $\alpha > 0$. Observe that the Lipschitz continuity of u is a direct consequence of (11).

To see that (11) holds, let $\alpha > 0$ be a constant to be fixed later and (x_α, y_α) be a maximum point of the function

$$\Phi(x,y) = \tilde{u}(x) - \tilde{u}(y) - \alpha w(x,y)^{1/2} \quad \text{on } \overline{\Omega}\times\overline{\Omega}.$$

Let $\alpha_0 = 2\|u\|_{C(\overline{\Omega})}/r_1$. Noting that $\Phi(x_\alpha, y_\alpha) \ge 0$, we see that if $\alpha \ge \alpha_0$, then $|x_\alpha - y_\alpha| \le r_1$. We assume henceforth that $\alpha \ge \alpha_0$. If $x_\alpha \ne y_\alpha$, then, as in the proof of Theorem 3.1, we have

$$\widetilde{H}\left(x_\alpha, \tilde{u}(x_\alpha), \frac{\alpha}{2} w(x_\alpha,y_\alpha)^{-1/2} D_x w(x_\alpha,y_\alpha)\right) \le 0,$$

and

$$\widetilde{H}\left(y_\alpha, \tilde{u}(y_\alpha), -\frac{\alpha}{2} w(x_\alpha,y_\alpha)^{-1/2} D_y w(x_\alpha,y_\alpha)\right) \ge 0.$$

Using these and still assuming that $x_\alpha \ne y_\alpha$, we compute that

$$\begin{aligned}
0 &\ge \min_{a\in A}\Big\{\lambda(\tilde{u}(x_\alpha) - \tilde{u}(y_\alpha)) - \frac{\alpha}{2} w(x_\alpha,y_\alpha)^{-1/2}(\langle g(x_\alpha,a) - g(y_\alpha,a), D_x w(x_\alpha,y_\alpha)\rangle \\
&\qquad + \langle g(y_\alpha,a), D_x w(x_\alpha,y_\alpha) + D_y w(x_\alpha,y_\alpha)\rangle) - \tilde{f}(x_\alpha,a) + \tilde{f}(y_\alpha,a)\Big\} \\
&\ge \alpha\lambda w(x_\alpha,y_\alpha)^{1/2} - \frac{\alpha}{2} w(x_\alpha,y_\alpha)^{-1/2} \\
&\quad \times \left(L_1|x_\alpha - y_\alpha| C_2 |x_\alpha - y_\alpha| + L_1 C_3 |x_\alpha - y_\alpha|^2\right) - L_2|x_\alpha - y_\alpha| \\
&\ge w(x_\alpha,y_\alpha)^{1/2}(\alpha(\lambda - \lambda_0) - L_2),
\end{aligned}$$

where

$$L_2 = \sup_{a\in A} \|\tilde{f}(\cdot,a)\|_{C^{0,1}(\overline{\Omega})}.$$

We now fix

$$\alpha = \max\{\alpha_0, (L_2+1)/(\lambda - \lambda_0)\}.$$

We see from the above computation that if $x_\alpha \ne y_\alpha$ then $w(x_\alpha, y_\alpha) \le 0$, which is impossible by our choice of w, and hence we conclude that $x_\alpha = y_\alpha$. This implies (11), and the proof is completed. □

5. The SC problem with state-space Ω. In this section we briefly discuss the SC problem with Ω as its state-space.

We define $\widehat{\mathcal{A}}(x)$ for each $x \in \Omega$ as the set of all measurable functions $\alpha : [0,\infty) \to A$ such that $X(t;x,\alpha) \in \Omega$ for all $t \geq 0$, and the value function $\widehat{V}$ on Ω by

$$\widehat{V}(x) = \inf_{\alpha \in \widehat{\mathcal{A}}(x)} \int_0^\infty e^{-\lambda t} f(X(t;x,\alpha),\alpha(t))dt.$$

Note that $\widehat{\mathcal{A}}(x) \subset \mathcal{A}(x)$ and $V(x) \leq \widehat{V}(x)$ for $x \in \Omega$. For $m = 1,2,\ldots$, we set

$$\Lambda_m = \left\{ (\gamma_1,\ldots,\gamma_m,a_1,\ldots,a_m) \mid \gamma_i \geq 0,\ a_i \in A,\ \sum_{i=1}^m \gamma_i = 1 \right\},$$

and define $\Lambda_m(z)$ for $z \in \overline{\Omega}$ as the set of those $(\gamma_1,\ldots,\gamma_m,a_1,\ldots,a_m) \in \Lambda_m$ which satisfy the following condition: there is $r > 0$ such that if $x,y \in \Omega \cap B(z,r)$ and $0 \leq t \leq r$, then $x + t\sum_{i=1}^m \gamma_i g(y,a_i) \in \Omega$. We set

$$\Lambda = \bigcup_{m\geq 1} \Lambda_m \quad \text{and} \quad \Lambda(z) = \bigcup_{m\geq 1} \Lambda_m(z) \quad \text{for } z \in \overline{\Omega}.$$

It is clear that $\Lambda(x) = \Lambda$ for $x \in \Omega$ under the assumption (A1). We define $\widehat{H}_{in} : \overline{\Omega} \times \mathbf{R} \times \mathbf{R}^n \to \mathbf{R}$ by

$$\widehat{H}_{in}(x,r,p) = \sup \sum_{i=1}^m \gamma_i \{\lambda r - \langle g(x,a_i),p\rangle - f(x,a_i)\},$$

where the supremum is taken over all $(\gamma_1,\ldots,\gamma_m,a_1,\ldots,a_m) \in \Lambda(x)$. We note that $\widehat{H}_{in}(x,r,p) = H(x,r,p)$ if $x \in \Omega$.

We have to modify the definition of viscosity solutions. To this end, we change the definition of upper and lower semicontinuous envelopes. For a bounded function $u : \Omega \to \mathbf{R}$ we define $u^*, u_* : \overline{\Omega} \to \mathbf{R}$ by

$$u^*(x) = \limsup_{r\downarrow 0} \{u(y) \mid y \in \Omega \cap B(x,r)\} \quad \text{and} \quad u_* = -(-u)^*.$$

DEFINITION 5.1. *A bounded function $u : \Omega \to \mathbf{R}$ is a* viscosity subsolution (*respectively, a* viscosity supersolution) of the SC problem for (1) with state-space Ω *if*

$$\widehat{H}_{in}(x,u^*,Du^*) \leq 0 \quad \text{in } \overline{\Omega} \qquad (\text{respectively, } H(x,u_*,Du_*) \geq 0 \quad \text{in } \overline{\Omega})$$

in the viscosity sense. Moreover, a bounded function $u : \Omega \to \mathbf{R}$ is a viscosity solution of the SC problem for (1) with state-space Ω *if it is both a viscosity subsolution and a viscosity supersolution of the SC problem for* (1) *with state-space* Ω.

The following conditions (A5) and (A6) play the roles of (A2) and (A3), respectively, in the current problem.

(A5) $$\Lambda(z) \neq \emptyset \quad \text{for all } z \in \partial\Omega.$$

(A6) For each $z \in \partial\Omega$ there are $r > 0$ and $(\gamma_1,\ldots,\gamma_m,a_1,\ldots,a_m) \in \Lambda$ such that if we set $\xi = \sum_{i=1}^m \gamma_i g(z,a_i)$, then

$$B(x + t\xi, tr) \subset \overline{\Omega} \quad \text{for all } x \in \overline{\Omega} \cap B(z,r) \text{ and } 0 \leq t \leq r.$$

We can now state the following theorems.

THEOREM 5.2. *Let* (A1) *and* (A5) *hold. Then the value function* $\widehat{V}$ *is a viscosity solution of the SC problem for* (1) *with state-space* Ω.

THEOREM 5.3. *Let* (A1) *and* (A6) *hold. Let* u *and* v *be a viscosity subsolution and a viscosity supersolution of the SC problem for* (1) *with state-space* Ω, *respectively. Then* $u \le v$ *on* Ω.

THEOREM 5.4. *Let* (A1), (A4), *and* (A6) *hold. Then there is* $\lambda_0 > 0$ *such that if* $\lambda > \lambda_0$ *and if* $u : \Omega \to \mathbf{R}$ *is a (unique) viscosity solution of the SC problem for* (1) *with state-space* Ω, *then* u *is Lipschitz continuous in* Ω.

We remark that conditions (A1) and (A6) together imply (A5).

LEMMA 5.5. *There are* $r_0 > 0$, $\zeta_i \in C^\infty(\mathbf{R}^n)$, *and* $a_i \in A$, *with* $i = 1, \dots, m$, *such that*

$$(\zeta_1(x), \dots, \zeta_m(x), a_1, \dots, a_m) \in \Lambda_m(x) \quad \text{for all } x \in \partial\Omega$$

and such that if we set $\xi_0(x) = \sum_{i=1}^m \zeta_i(x) g(x, a_i)$, *then*

$$B(x + t\xi_0(x), r_0 t) \subset \overline{\Omega} \quad \text{for } x \in \partial\Omega \text{ and } 0 \le t \le r_0.$$

The proof of this lemma parallels that of Lemma 6.2, so we omit giving it here.

Let $\zeta_i \in C^\infty(\mathbf{R}^n)$, $a_i \in A$, with $i = 1, \dots, m$, and ξ_0 be as in Lemma 5.5. Set

$$\eta_0(x) = \sum_{i=1}^m \zeta_i(x) f(x, a_i).$$

If u is a viscosity subsolution of the SC problem for (1) with state-space Ω, then it satisfies

$$\begin{cases} H(x, u^*, Du^*) \le 0 & \text{in } \Omega, \\ -\langle \xi_0(x), Du^* \rangle \le -\lambda u^*(x) + \eta_0(x) & \text{on } \partial\Omega \end{cases}$$

in the viscosity sense. Using this and proceeding as in the proof of Theorems 3.1 and 4.1, we can prove Theorems 5.3 and 5.4 without difficulty. We omit the details.

The proof of Theorem 5.2 is a little harder than that of Theorem 2.2. We may assume that $g \in C(\mathbf{R}^n \times A, \mathbf{R}^n)$ and $\sup_{a \in A} \|g(\cdot, a)\|_{C^{0,1}(\mathbf{R}^n)} < \infty$. The key observation is stated as Lemma 5.6.

LEMMA 5.6. *Let* $(\gamma_1, \dots, \gamma_m, a_1, \dots, a_m) \in \Lambda$. *Define* $\xi \in C^{0,1}(\mathbf{R}^n, \mathbf{R}^n)$ *by*

$$\xi(x) = \sum_{i=1}^m \gamma_i g(x, a_i).$$

(1) *Then there is a sequence of measurable* $\alpha_k : [0, \infty) \to \{a_1, \dots, a_m\}$ *such that for each* $T > 0$ *and* $h \in C([0, T] \times A)$,

$$\int_0^T h(t, \alpha_k(t)) dt \to \sum_{i=1}^m \gamma_i \int_0^T h(t, a_i) dt \quad \text{as } k \to \infty. \tag{12}$$

(2) *Fix such a sequence* $\{\alpha_k\}$. *Then*

$$X(t; x, \alpha_k) \to Y(t; x, \xi) \quad \text{as } k \to \infty,$$

uniformly on compact subsets of $[0,\infty)$.

Proof. We begin with (1). Set

$$I_1 = [0,\gamma_1),\ I_2 = [\gamma_1,\gamma_1+\gamma_2),\dots,I_m = [\gamma_1+\cdots+\gamma_{m-1},1).$$

Then, the interval $[0,1)$ is the direct sum of $I_1,\dots,I_m$. Define $\alpha_0 : [0,\infty) \to \{a_1,\dots,a_m\}$ by setting $\alpha_0(t) = a_i$ if $t \in I_i$, with $i = 1,\dots,m$, and $\alpha_0(t) = \alpha_0(t-k)$ if $t \in [k,k+1)$, with $k = 1,2,\dots$. Now, define $\alpha_k : [0,\infty) \to \{a_1,\dots,a_m\}$ for $k = 1,2,\dots$ by $\alpha_k(t) = \alpha_0(kt)$. It is not hard to see that for each $T > 0$ and $h \in C([0,T]\times A)$,

$$\int_0^T h(t,\alpha_k(t))dt \to \sum_{i=1}^m \gamma_i \int_0^T h(t,a_i)dt \ \text{ as } k\to\infty.$$

Next, we turn to (2). Fix $x \in \mathbf{R}^n$. By virtue of the Ascoli–Arzela theorem, we can extract a subsequence of $\{k\}$ along which $\{X(t;x,\alpha_k)\}$ converges to a function $Y \in C([0,\infty),\mathbf{R}^n)$ uniformly on compact subsets of $[0,\infty)$. Now, the sequence $\{\alpha_k\}$ satisfies (12). Therefore,

$$\int_0^T g(X(t;x,\alpha_k),\alpha_k(t))dt \to \int_0^T \xi(Y(t))dt \ \text{ as } k\to\infty$$

for each $T > 0$ along the subsequence. From this it is easily seen that $Y(t)$ is a solution of

$$\frac{dY}{dt}(t) = \xi(Y(t)) \ \text{ for } t>0 \ \text{ and } \ Y(0) = x.$$

That is, $Y(t;x,\xi) \equiv Y(t)$. This implies that

$$X(t;x,\alpha_k) \to Y(t;x,\xi) \ \text{ as } k\to\infty,$$

uniformly on compact subsets of $[0,\infty)$. □

As a consequence of Lemma 5.6, we deduce that under assumption (A5), $\widehat{\mathcal{A}}(x) \neq \emptyset$ for all $x \in \Omega$.

Outline of proof of Theorem 5.2. We write $u = \widehat{V}$. We shall prove only that if $\varphi \in C^1(\overline{\Omega})$ and if $z \in \partial\Omega$ is a maximum point of $u^* - \varphi$, then

$$\widehat{H}_{in}(z,u^*(z),D\varphi(z)) \le 0.$$

We may assume that $u^*(z) = \varphi(z)$.

Fix any $(\gamma_1,\dots,\gamma_m,a_1,\dots,a_m) \in \Lambda(z)$. Define ξ as in Lemma 5.6 and $\eta \in C(\overline{\Omega})$ by

$$\eta(x) = \sum_{i=1}^m \gamma_i f(x,a_i).$$

We write $Y(t;x)$ for $Y(t;x,\xi)$ for notational simplicity. We fix $r > 0$ so that $Y(t;x) \in \Omega$ for all $x \in \Omega\cap B(z,r)$ and $t \in [0,r]$.

Fix $\varepsilon \in (0,r]$ and choose $x_\varepsilon \in \Omega\cap B(z,\varepsilon)$ such that

$$u(x_\varepsilon) > \varphi(x_\varepsilon) - \varepsilon\int_0^\varepsilon e^{-\lambda t}dt.$$

By virtue of Lemma 5.6, there is $\alpha_\varepsilon \in \widehat{\mathcal{A}}(x_\varepsilon)$ such that

$$\left|\int_0^\varepsilon e^{-\lambda t}\{f(X(t;x_\varepsilon,\alpha_\varepsilon),\alpha_\varepsilon(t)) - \eta(Y(t;x_\varepsilon))\}dt\right| < \varepsilon\int_0^\varepsilon e^{-\lambda t}dt$$

and such that

$$\left|\int_0^\varepsilon e^{-\lambda t}\{\langle g(X(t;x_\varepsilon,\alpha_\varepsilon),\alpha_\varepsilon(t))D\varphi(X(t;x_\varepsilon,\alpha_\varepsilon))\rangle\right.$$

$$\left.-\langle \xi(Y(t;x_\varepsilon)), D\varphi(Y(t;x_\varepsilon))\rangle\}dt\right| < \varepsilon\int_0^\varepsilon e^{-\lambda t}dt.$$

By the dynamic programming principle, we have

$$u(x_\varepsilon) \le \int_0^\varepsilon e^{-\lambda t} f(X(t;x_\varepsilon,\alpha_\varepsilon),\alpha_\varepsilon(t))dt + e^{-\lambda\varepsilon}u(X(\varepsilon;x_\varepsilon,\alpha_\varepsilon)).$$

Combining these, we get

$$\begin{aligned} 0 &< \int_0^\varepsilon e^{-\lambda t}\{f(X(t;x_\varepsilon,\alpha_\varepsilon),\alpha_\varepsilon(t)) + \varepsilon\}dt + e^{-\lambda\varepsilon}\varphi(X(\varepsilon;x_\varepsilon,\alpha_\varepsilon)) - \varphi(x_\varepsilon) \\ &= \int_0^\varepsilon e^{-\lambda t}\{\eta(Y(t;x_\varepsilon)) - \lambda\varphi(X(t;x_\varepsilon,\alpha_\varepsilon)) + \langle\xi(Y(t;x_\varepsilon)), D\varphi(Y(t;x_\varepsilon))\rangle + 3\varepsilon\}dt. \end{aligned}$$

Thus, there is $y_\varepsilon = Y(t_\varepsilon;x_\varepsilon)$ and $z_\varepsilon = X(t_\varepsilon;x_\varepsilon,\alpha_\varepsilon)$ with $t_\varepsilon \in (0,\varepsilon)$ such that

$$-3\varepsilon < \eta(y_\varepsilon) - \lambda\varphi(z_\varepsilon) + \langle\xi(y_\varepsilon), D\varphi(y_\varepsilon)\rangle.$$

Now, sending $\varepsilon \downarrow 0$, we conclude that

$$\widehat{H}_{in}(z,u^*(z),D\varphi(z)) \le 0. \qquad \square$$

6. Proof of lemmas. Throughout this section we assume that (A1) and (A3) hold. We also assume that g is defined on $\mathbf{R}^n \times A$ and $\sup_{a\in A}\|g(\cdot,a)\|_{C^{0,1}(\mathbf{R}^n)} < \infty$.

The following constructions of ψ and w in Lemmas 3.3 and 3.4, respectively, are similar to those in Dupuis and Ishii [4]. We begin with the following lemma.

LEMMA 6.1. *Let $z \in \mathbf{R}^n$. Let $\xi,\eta \in \mathbf{R}^n$ and $r > 0$ satisfy*

$$B(x+t\xi,rt) \subset \overline{\Omega} \quad \text{for all } x \in \overline{\Omega}\cap B(z,r) \text{ and } 0 \le t \le r, \tag{13}$$

$$B(x+t\eta,rt) \subset \overline{\Omega} \quad \text{for all } x \in \overline{\Omega}\cap B(z,r) \text{ and } 0 \le t \le r. \tag{14}$$

Let $\zeta = \gamma\xi + (1-\gamma)\eta$ for some $\gamma \in [0,1]$. Then there is $s > 0$ such that

$$B(x+t\zeta,st) \subset \overline{\Omega} \quad \text{for all } x \in \overline{\Omega}\cap B(z,s) \text{ and } 0 \le t \le s. \tag{15}$$

Proof. We set

$$s = \min\left\{\frac{r}{2}, \frac{r}{2(r+|\xi|)}\right\},$$

and prove (15) for this s.

Let $0 < t \le s$ and $y \in B(x + t\zeta, st)$. For some $p \in B(0, s)$ we have

$$\begin{aligned} y &= x + t\zeta + tp \\ &= (x + t\gamma\xi + t\gamma p) + t(1-\gamma)\eta + t(1-\gamma)p. \end{aligned}$$

In view of (13) we see that $x + t\gamma\xi + t\gamma p \in \overline{\Omega}$. By our choice of s, it is easily checked that $x + t\gamma\xi + t\gamma p \in B(z, r)$. Hence, by using (14) we conclude that $y \in \overline{\Omega}$. □

LEMMA 6.2. *There are $r > 0$, $\zeta_i \in C^\infty(\mathbf{R}^n)$, and $a_i \in A$, with $i = 1, \dots, m$, satisfying $\zeta_i \ge 0$ and $\sum_{i=1}^m \zeta_i = 1$ on $\partial\Omega$ such that if we set $\xi(x) = \sum_{i=1}^m \zeta_i(x) g(x, a_i)$, then*

$$\xi(x) \in \operatorname{co} G(x) \quad \textit{for } x \in \partial\Omega,$$

and

$$B(x + t\xi(x), rt) \subset \overline{\Omega} \quad \textit{for } x \in \partial\Omega \textit{ and } 0 \le t \le r. \tag{16}$$

Proof. By the compactness of $\partial\Omega$, we deduce from (A3) that there are $r > 0$, $a_i \in A$, $z_j \in \partial\Omega$, and $\gamma_{ij} \ge 0$, with $i = 1, \dots, m$ and $j = 1, \dots, l$, such that

$$\sum_{i=1}^m \gamma_{ij} = 1 \text{ for all } j \quad \text{and} \quad \partial\Omega \subset \bigcup_{j=1}^l B(z_j, r/2),$$

and such that if we set $\xi_j(x) = \sum_{i=1}^m \gamma_{ij} g(x, a_i)$, then for all j,

$$\xi_j(x) \in \operatorname{co} G(x) \text{ for all } x \in B(z_j, r) \cap \overline{\Omega},$$

and

$$B(x + t\xi_j(x), rt) \subset \overline{\Omega} \text{ for all } x \in \overline{\Omega} \cap B(z_j, r) \text{ and } 0 \le t \le r.$$

By a standard argument, we find that there are $\zeta_j \in C_0^\infty(\mathbf{R}^n)$, with $j = 1, \dots, l$, such that $\zeta_j \ge 0$ and $\operatorname{supp} \zeta_j \subset \operatorname{Int} B(z_j, r)$ for all j and $\sum_{j=1}^l \zeta_j = 1$ on $\partial\Omega$. Using Lemma 6.1 and setting

$$\xi(x) = \sum_{i=1}^m \sum_{j=1}^l \zeta_j(x) \gamma_{ij} g(x, a_i),$$

we see that $\xi(x) \in \operatorname{co} G(x)$ for all $x \in \partial\Omega$ and that there is $s \in (0, r]$ such that (16) holds with s in place of r. □

Proof of Lemma 3.2. Lemma 3.2 follows immediately from Lemma 6.2. □

LEMMA 6.3. *Let $\xi \in C(\mathbf{R}^n, \mathbf{R}^n)$ and $r > 0$. Assume that* (16) *holds with these ξ and r. Then, for all $z \in \partial\Omega$, $x \in B(z, r)$ and $0 \le t \le r$,*

$$B(x + t\xi(x), rt) \subset \overline{\Omega} \quad \textit{if } x \in \overline{\Omega},$$

and

$$B(x - t\xi(x), rt) \subset \Omega^c \quad \textit{if } x \in \Omega^c. \tag{17}$$

Proof. Let $z \in \partial\Omega$, $x \in B(z, r)$, and $0 < t \le r$. First we suppose $x \in \overline{\Omega}$ and prove that

$$B(x + t\xi(x), rt) \cap B(z, r) \subset \overline{\Omega}. \tag{18}$$

Suppose that this is not true, and choose $p \in B(0,r)$ so that

$$x + t\xi(x) + tp \in B(z,r) \cap (\overline{\Omega})^c.$$

Then there is $\tau \in (0,t)$ such that $x+\tau\xi(x)+\tau p \in \partial\Omega$. It is obvious that $x+\tau\xi(x)+\tau p \in B(z,r)$. Hence, noting that

$$x + t\xi(x) + tp = (x + \tau\xi(x) + \tau p) + (t-\tau)\xi(x) + (t-\tau)p,$$

and using (16) we see that $x + t\xi(x) + tp \in \overline{\Omega}$. This is a contradiction, which implies that (18) holds.

Next we show that

$$B(x - t\xi(x), rt) \cap B(z,r) \subset \Omega^c \quad \text{if } x \in \Omega^c. \tag{19}$$

It is enough to prove (19) for the case when $x \in (\overline{\Omega})^c$. We thus assume that $x \in (\overline{\Omega})^c$. Again, we suppose that (19) is not true, and get a contradiction. Now, we have

$$x - t\xi(x) + tp \in B(z,r) \cap \Omega$$

for some $p \in B(0,r)$, and moreover,

$$x - \tau\xi(x) + \tau p \in \partial\Omega$$

for some $0 < \tau < t$. Since $x - \tau\xi(x) + \tau p \in B(z,r)$, noting that

$$x = (x - \tau\xi(x) + \tau p) + \tau\xi(x) + \tau(-p),$$

we see that $x \in \overline{\Omega}$, which is a contradiction. □

Proof of Lemma 3.3. Let $\xi_0 \in C^{0,1}(\mathbf{R}^n, \mathbf{R}^n)$ be from Lemma 3.2. By Lemma 6.3, there is $r > 0$ such that for all $z \in \partial\Omega$, $x \in B(z,r)$, and $0 \le t \le r$,

$$B(x + t\xi_0(x), 2rt) \subset \overline{\Omega} \quad \text{if } x \in \overline{\Omega}, \tag{20}$$

and

$$B(x - t\xi(x), 2rt) \subset \Omega^c \quad \text{if } x \in \Omega^c. \tag{21}$$

The following arguments are based on the idea of value functions in optimal control or the method of characteristics.

For $s > 0$ we write Γ_s for the open s-neighborhood of $\partial\Omega$, i.e.,

$$\Gamma_s = \{x \in \mathbf{R}^n \mid \operatorname{dist}(x, \partial\Omega) < s\}.$$

We may assume that $|\xi_0(x)| \le 1$ for $x \in \mathbf{R}^n$. We fix $\varepsilon > 0$ so that $\varepsilon(1/r + 1) \le r$ and so that if $x \in \Gamma_r$ and $y \in B(x, \varepsilon/r)$, then $|\xi_0(y) - \xi_0(x)| \le r$.

We write $Y(t;x)$ for $Y(t;x,-\xi_0)$ for notational simplicity. Now, we claim that

$$Y(t;x) \in (\Gamma_\varepsilon)^c \quad \text{for all } x \in \Gamma_\varepsilon \text{ and } t \ge 2\varepsilon/r. \tag{22}$$

To show this, we will prove that

$$x \in \Omega \cap \Gamma_\varepsilon \Longrightarrow \exists t \in (0, \varepsilon/r] \text{ such that } Y(t;x) \in \Omega^c, \tag{23}$$

$$x \in \Omega^c \cap \Gamma_\varepsilon \Longrightarrow \exists t \in (0, \varepsilon/r] \text{ such that } Y(t;x) \in (\Gamma_\varepsilon)^c \cap \Omega^c, \tag{24}$$

and

$$x \in \Omega^c \cap (\Gamma_\varepsilon)^c \Longrightarrow Y(t;x) \in (\Gamma_\varepsilon)^c \ \forall t > 0. \tag{25}$$

Once we have proved (23)–(25), we can easily conclude that (22) holds.

To prove (23), fix $x \in \Omega \cap \Gamma_\varepsilon$ and suppose that $Y(t;x) \in \Omega$ for all $t \in (0, \varepsilon/r]$. Fix $z \in \partial\Omega$ so that $|x - z| < \varepsilon$. Then, for all $t, \tau \in [0, \varepsilon/r]$,

$$|Y(t;x) - Y(\tau;x)| \leq \int_0^{\varepsilon/r} |\xi_0(Y(s;x))| ds \leq \varepsilon/r,$$

and hence,

$$|Y(t;x) - z| < \varepsilon/r + \varepsilon \leq r \quad \text{and} \quad |\xi_0(Y(t;x)) - \xi_0(Y(\tau,x))| \leq r.$$

Thus, setting $y = Y(\varepsilon/r;x)$, we have

$$\begin{aligned} x &= y + (\varepsilon/r)\xi_0(y) + \int_0^{\varepsilon/r} (\xi_0(Y(s;x)) - \xi_0(y)) ds \\ &\in B(y + (\varepsilon/r)\xi_0(y), \varepsilon). \end{aligned}$$

Hence, in view of (20) we see that $B(x,\varepsilon) \subset \overline{\Omega}$ and therefore that $\operatorname{dist}(x, \partial\Omega) \geq \varepsilon$. This is a contradiction, which proves (23).

To prove (24), let $x \in \Omega^c \cap \Gamma_\varepsilon$. As above, we find that for some $z \in \partial\Omega$, we have $x \in B(z,\varepsilon)$ and also $Y(t;x) \in B(z,r)$ and $|\xi_0(Y(t;x)) - \xi_0(x)| \leq r$ for all $0 \leq t \leq \varepsilon/r$. We have

$$\begin{aligned} Y(\varepsilon/r;x) &= x - (\varepsilon/r)\xi_0(x) - \int_0^{\varepsilon/r} (\xi_0(Y(s;x)) - \xi_0(x)) ds \\ &\in B(x - (\varepsilon/r)\xi_0(x), \varepsilon), \end{aligned}$$

and hence $B(Y(\varepsilon/r;x),\varepsilon) \subset \Omega^c$ by (21). Therefore we have $Y(\varepsilon/r;x) \in \Omega^c \cap (\Gamma_\varepsilon)^c$.

To prove (25), we let $x \in \Omega^c \cap (\Gamma_\varepsilon)^c$. Suppose that $Y(\tau;x) \in \Gamma_\varepsilon$ for some $\tau > 0$. We may assume that $Y(t;x) \in \Omega^c$ for all $0 \leq t \leq \tau$. Then there is $\sigma \in (0,\tau)$ such that $Y(\sigma;x) \in \partial(\Gamma_\varepsilon)$ and $Y(t;x) \in \Gamma_\varepsilon$ for $\sigma < \forall t < \tau$. We may assume that $\tau \leq \sigma + \varepsilon/r$. Then, for all $t \in [\sigma,\tau]$, $|Y(t;x) - Y(\sigma;x)| \leq \varepsilon/r$ and hence, $|\xi_0(Y(t;x)) - \xi_0(Y(\sigma;x) + p)| \leq r$ for all $p \in B(0,\varepsilon)$. Therefore, noting that for any $p \in \mathbf{R}^n$,

$$\begin{aligned} Y(\tau;x) + p = Y(\sigma;x) + p &- (\tau - \sigma)\xi_0(Y(\sigma;x) + p) \\ &+ \int_\sigma^\tau \{\xi_0(Y(\sigma;x) + p) - \xi_0(Y(t;x))\} dt, \end{aligned}$$

we find that for all $p \in B(0,\varepsilon)$,

$$Y(\tau;x) + p \in B(Y(\sigma;x) + p - (\tau - \sigma)\xi_0(Y(\sigma;x) + p), r(\tau - \sigma)).$$

Since $B(Y(\sigma;x),\varepsilon) \subset \Omega^c \cap \Gamma_r$, in view of (21) we have

$$B(Y(\tau;x) + p, r(\tau - \sigma)) \subset \Omega^c \quad \text{for all } p \in B(0,\varepsilon),$$

and, in particular, $B(Y(\tau;x),\varepsilon) \subset \Omega^c$. That is, $Y(\tau;x) \in (\Gamma_\varepsilon)^c$. This is a contradiction, from which (25) follows.

Now we choose $h \in C^\infty(\mathbf{R}^n)$ so that $h \geq 0$ on $\mathbf{R}^n$, $\operatorname{supp} h \subset \Gamma_\varepsilon$, and $h(x) \geq 2$ for $x \in \Gamma_{\varepsilon/2}$. Define $v : \Gamma_\varepsilon \to \mathbf{R}$ by

$$v(x) = \int_0^\infty h(Y(t;x))dt.$$

By virtue of (22) we see that

$$v(x) = \int_0^{2\varepsilon/r} h(Y(t;x))dt.$$

It is now easy to check that $v \in C^{0,1}(\Gamma_\varepsilon)$ and that v satisfies

$$\langle \xi_0(x), Dv \rangle = h(x) \quad \text{in } \Gamma_\varepsilon$$

in the viscosity sense, and as a result

$$\langle \xi_0(x), Dv \rangle = h(x) \quad \text{a.e. in } \Gamma_\varepsilon.$$

By mollifying both sides of this, we conclude that there is a function $\psi \in C^\infty(\mathbf{R}^n)$ such that $\langle \xi_0(x), D\psi(x) \rangle \geq 1$ on $\Gamma_{\varepsilon/2}$. □

We shall work in $\mathbf{R}^2$ for a while. Let e_1 denote the unit vector $(1,0) \in \mathbf{R}^2$. Fix $0 < \delta < \rho < 1$, and set

$$K = \bigcup_{t \geq 0} B(te_1, \delta t) \quad \text{and} \quad L = \bigcup_{t \geq 0} B(te_1, \rho t). \tag{26}$$

LEMMA 6.4. *There is a function $v \in C(\mathbf{R}^2) \cap C^{1,1}(\mathbf{R}^2 \setminus \{0\})$ such that v is convex and symmetric with respect to the x_1-axis,*

$$v(tx) = tv(x) \quad \textit{for } x \in \mathbf{R}^2 \textit{ and } t \geq 0,$$
$$v(x) > 0 \quad \textit{if } x \neq 0,$$

and

$$\langle q, Dv(x) \rangle \leq 0 \quad \textit{for all } q \in K \textit{ and } x \in L^c. \tag{27}$$

Proof. Set

$$\varepsilon = (\rho - \delta)\delta, \quad K_\varepsilon = \bigcup_{0 \leq t \leq \delta} B(te_1, \delta t + \varepsilon),$$

and

$$v(x) = \inf\{t > 0 \mid x \in tK_\varepsilon\} \quad \text{for } x \in \mathbf{R}^2.$$

We observe that K_ε contains the origin as its interior point; is convex, bounded, and symmetric with respect to the x_1-axis; and is the closed ε-neighborhood of the convex set

$$\bigcup_{0 \leq t \leq \delta} B(te_1, \delta t).$$

Then we have that v is convex and symmetric with respect to the axis $x_2 = 0$,

$$v(x) > 0 \text{ if } x \neq 0, \quad v(tx) = tv(x) \text{ for } x \in \mathbf{R}^2 \text{ and } t \geq 0,$$
$$v \in C(\mathbf{R}^2) \cap C^{1,1}(\mathbf{R}^2 \setminus \{0\}),$$
$$v(x) = 1 \iff x \in \partial(K_\varepsilon),$$
$$v(x) \leq 1 \iff x \in K_\varepsilon.$$

Next we must verify that (27) holds. Fix $x \in L^c$. We may assume without loss of generality that $x \in \partial(K_\varepsilon)$. Then $x = te_1 + p$ for some $0 \leq t \leq \delta$ and $p \in \partial B(0, \delta t + \varepsilon)$. Suppose for the moment that $t = \delta$. Then, $|p| \leq \delta^2 + \varepsilon = \rho\delta = \rho t$, and this implies that $x \in L$. This means that $t < \delta$. Therefore, there is $\eta > 0$ such that

$$x + K \cap B(0, \eta) \subset K_\varepsilon.$$

Fix any $q \in K$. If $s > 0$ is small enough, then we have

$$x + sq \in K_\varepsilon \text{ and hence } v(x + sq) \leq 1 = v(x).$$

Thus, differentiating $v(x + sq)$ with respect to s, we conclude that $\langle q, Dv(x) \rangle \leq 0$. □

Proof of Lemma 3.4. Let $\xi_0 \in C^{0,1}(\mathbf{R}^n, \mathbf{R}^n)$ and $0 < r < 1$ satisfy

$$B(x - t\xi_0(x), rt) \subset \Omega^c \text{ for all } x \in \partial\Omega \text{ and } 0 \leq t \leq r.$$

We shall build a function $w \in C^1(\overline{\Omega} \times \overline{\Omega})$ which satisfies the conditions of Lemma 3.4 concerning w with this ξ_0. To this end we may assume that $|\xi_0(x)| = 1$ for $x \in \Gamma_r \equiv \{y \mid \operatorname{dist}(y, \partial\Omega) < r\}$. Moreover, replacing r by a smaller number if necessary, we may assume that for some $\varepsilon > 0$,

$$B(x - t\xi_0(x), (r + \varepsilon)t) \subset \Omega^c \text{ for all } x \in \partial\Omega \text{ and } 0 \leq t \leq r.$$

We set $\rho = r/\sqrt{1 - r^2}$ and $\delta = \rho/2$, so that $r = \rho/\sqrt{1 + \rho^2}$ and $0 < \delta < \rho < 1$. In the above inclusion, we may assume that $\varepsilon/(1 - \varepsilon) \leq \delta/\sqrt{1 + \delta^2}$. Let K and L be the sets defined by (26) with the above δ and ρ. Observe that

$$K = \left\{(q_1, q_2) \mid |q_2| \leq \frac{\delta}{\sqrt{1 - \delta^2}} q_1\right\} \text{ and } L = \left\{(z_1, z_2) \mid |z_2| \leq \frac{\rho}{\sqrt{1 - \rho^2}} z_1\right\}.$$

By approximating ξ_0, we can choose a function $\xi \in C^\infty(\mathbf{R}^n, \mathbf{R}^n)$ and $s \in (0, r]$ so that $|\xi(y) - \xi_0(x)| \leq \varepsilon$ for all $x \in \partial\Omega$ and $y \in B(x, s)$ and $|\xi(x)| = 1$ for all $x \in \Gamma_r$. It follows that

$$B(x - t\xi(y), rt) \subset \Omega^c \text{ for all } x \in \partial\Omega, \ y \in B(x, s) \text{ and } 0 \leq t \leq r. \tag{28}$$

Let $v \in C(\mathbf{R}^2) \cap C^{1,1}(\mathbf{R}^2 \setminus \{0\})$ be from Lemma 6.4. We define $w \in C(\mathbf{R}^{2n})$ by

$$w(x, y) = v(\langle x - y, \xi(y) \rangle, |x - y - \langle x - y, \xi(y) \rangle \xi(y)|)^2.$$

It is convenient to introduce the following notation:

$$Q(y) = I - \xi(y) \otimes \xi(y) \equiv \Big(\delta_{ij} - \xi_i(y)\xi_j(y)\Big)_{1 \leq i,j \leq n}.$$

Note that

$$w(x,y) = v(\langle x-y, \xi(y)\rangle, |Q(y)(x-y)|)^2,$$

that if $|\xi(y)| = 1$ then $Q(y) : \mathbf{R}^n \to \mathbf{R}^n$ is the orthogonal projection onto the orthogonal complement to the space generated by $\xi(y)$, and that

$$x - y = \langle x-y, \xi(y)\rangle \xi(y) + Q(y)(x-y).$$

Noting that the function $v(z_1, z_2)$ is symmetric in the variable z_2, we see that $w \in C^1(\mathbf{R}^{2n})$.

For given $x, y \in \mathbf{R}^n$ we write

$$z_1 = \langle x-y, \xi(y)\rangle, \quad z_2 = |Q(y)(x-y)|, \quad \text{and} \quad z = (z_1, z_2).$$

Differentiation gives

$$D_x w(x,y) = 2v(z)\left\{ D_1 v(z)\xi(y) + D_2 v(z)\frac{Q(y)(x-y)}{|Q(y)(x-y)|}\right\},$$

and

$$D_y w(x,y) = 2v(z)\Big\{ D_1 v(z)(-\xi(y) + R_1(x,y)) + D_2 v(z)(-I + R_2(x,y))\frac{Q(y)(x-y)}{|Q(y)(x-y)|}\Big\},$$

provided $Q(y)(x-y) \neq 0$, where $R_1(x,y)$ and $R_2(x,y)$ are C^∞ functions on $\mathbf{R}^{2n}$ with values in $\mathbf{R}^n$ and in the space of real $n \times n$ matrices, respectively, and moreover, the estimate

$$|R_1(x,y)| + \|R_2(x,y)\| \leq C|x-y|$$

holds for all $x, y \in \mathbf{R}^n$ and for some $C > 0$. Here and later $D_1 v$ and $D_2 v$ denote the first and the second components of Dv, respectively. If, on the other hand, $Q(y)(x-y) = 0$, then we have

$$D_x w(x,y) = 2v(z)D_1 v(z)\xi(y), \quad D_y w(x,y) = 2v(z)D_1 v(z)(-\xi(y) + R_1(x,y)).$$

Now, we fix $x \in \partial\Omega$ and $y \in \overline{\Omega}$ so that $|x-y| \leq s$. We will show that $\langle \xi_0(x), D_x w(x,y)\rangle \leq 0$. If $x - y = 0$, then, trivially, the inequality holds. We shall assume that $x - y \neq 0$. We consider the case when $z_2 = |Q(y)(x-y)| = 0$. Observe that if $z_1 = \langle x-y, \xi(y)\rangle > 0$, then by (28) we have

$$B(x - z_1\xi(y), rz_1) = B(y, rz_1) \subset \Omega^c, \quad \text{which is a contradiction.}$$

Therefore, we have $z_1 \leq 0$ and hence $D_1 v(z) \leq 0$. We observe that

$$1 \geq \langle \xi_0(x), \xi(y)\rangle = 1 + \langle \xi_0(x), \xi(y) - \xi_0(x)\rangle \geq 1 - \varepsilon > 0.$$

Now, we see that $\langle \xi_0(x),\ D_x w(x,y)\rangle \leq 0$.

Next we consider the case when $z_2 = |Q(y)(x-y)| \neq 0$. We set

$$q_1 = \langle \xi_0(x), \xi(y)\rangle, \quad q_2 = \left\langle \xi_0(x), \frac{Q(y)(x-y)}{|Q(y)(x-y)|}\right\rangle \quad \text{and} \quad q = (q_1, q_2),$$

and note that

$$\langle \xi_0(x), D_x w(x,y)\rangle = 2v(z)\big(q_1 D_1 v(z) + q_2 D_2 v(z)\big) = 2v(z)\langle q, Dv(z)\rangle.$$

We now check that $q \in K$. To do this, we recall that $1-\varepsilon \le q_1 \le 1$, and observe that

$$\frac{|q_2|}{q_1} \le \frac{1}{1-\varepsilon}\left|\left\langle \xi_0(x) - \xi(y), \frac{Q(y)(x-y)}{|Q(y)(x-y)|}\right\rangle\right| \le \frac{\varepsilon}{1-\varepsilon}.$$

Thus, $|q_2| \le (\delta/\sqrt{1-\delta^2})q_1$ and hence $q \in K$. Next, we want to show that z is in the closure of L^c. If $z_1 \le 0$, we have immediately that $z \in L^c$. We thus assume that $z_1 > 0$. Observing that if $z_2/z_1 < r$, then

$$y = x - z_1\xi(y) + (Q(y)(y-x)) \in \operatorname{Int} B(x - z_1\xi(y), rz_1) \subset \Omega^c$$

by (28), we see that $z_2/z_1 \ge r = \rho/\sqrt{1+\rho^2}$ and hence that z is in the closure of L^c. Now we conclude in view of (27) that $\langle \xi_0(x), D_x w(x,y)\rangle \le 0$.

Multiplying w by an appropriate positive constant, we may assume that $w(x,y) \ge |x-y|^2$ for all $x, y \in \mathbf{R}^n$. It is easy to check that w satisfies the other requirements. □

Note Added in Proof. The authors recently learned that results similar to Theorem 4.1 are obtained in [8, Thm. X.2].

CONDITIONS FOR ROBUSTNESS AND NONROBUSTNESS OF THE STABILITY OF FEEDBACK SYSTEMS WITH RESPECT TO SMALL DELAYS IN THE FEEDBACK LOOP*

HARTMUT LOGEMANN†, RICHARD REBARBER‡, AND GEORGE WEISS§

Abstract. It has been observed that for many stable feedback control systems, the introduction of arbitrarily small time delays into the loop causes instability. In this paper we present a systematic frequency domain treatment of this phenomenon for distributed parameter systems. We consider the class of all matrix-valued transfer functions which are bounded on some right half-plane and which have a limit at $+\infty$ along the real axis. Such transfer functions are called regular. Under the assumption that a regular transfer function is stabilized by unity output feedback, we give sufficient conditions for the robustness and for the nonrobustness of the stability with respect to small time delays in the loop. These conditions are given in terms of the high-frequency behavior of the open-loop system. Moreover, we discuss robustness of stability with respect to small delays for feedback systems with dynamic compensators. In particular, we show that if a plant with infinitely many poles in the closed right half-plane is stabilized by a controller, then the stability is not robust with respect to delays. We show that the instability created by small delays is itself robust to small delays. Three examples are given to illustrate these results.

Key words. small time delays, robust stabilization, linear distributed parameter systems, regular transfer functions, dynamic stabilization

1. The main results.

Consider the linear feedback system shown in Fig. 1, where u is the input function and y is the output function, both $\mathbb{C}^m$-valued. $\mathbf{H}$ is the open-loop transfer function, with values in $\mathbb{C}^{m\times m}$, which we assume to be regular and in particular well posed. *Wellposedness* means that $\mathbf{H}$ is bounded on some right half-plane, and *regularity* means that, in addition, $\mathbf{H}$ has a limit at $+\infty$ along the real axis (see §2 for more detail on these concepts). The block with transfer function $e^{-\varepsilon s}$ represents a delay by ε, where $\varepsilon \geq 0$. The transfer function of the closed-loop system is given by

$$\mathbf{G}^\varepsilon(s) \;=\; \mathbf{H}(s)\left(I + e^{-\varepsilon s}\mathbf{H}(s)\right)^{-1}. \tag{1.1}$$

$\mathbf{G}^\varepsilon$ can be obtained from $\mathbf{G}^0$ by

$$\mathbf{G}^\varepsilon(s) \;=\; \mathbf{G}^0(s)\left[I - (1 - e^{-\varepsilon s})\mathbf{G}^0(s)\right]^{-1}. \tag{1.2}$$

To avoid possible complications with domains of transfer functions, we make the following convention: If a meromorphic function is defined on some right half-plane and can be extended meromorphically to a greater right half-plane, we will not make any distinction between the initial function and its extension. This will not lead to confusions.

We say that $\mathbf{G}^\varepsilon$ is *L^2-stable* if $\mathbf{G}^\varepsilon \in H^\infty(\mathbb{C}^{m\times m})$; i.e., $\mathbf{G}^\varepsilon$ is a bounded analytic function on the open right half-plane $\mathbb{C}_0 = \{s \in \mathbb{C} \mid \operatorname{Re} s > 0\}$. Indeed, as is well known, this property is equivalent to the one that $u \in L^2([0,\infty),\mathbb{C}^m)$ implies $y \in L^2([0,\infty),\mathbb{C}^m)$.

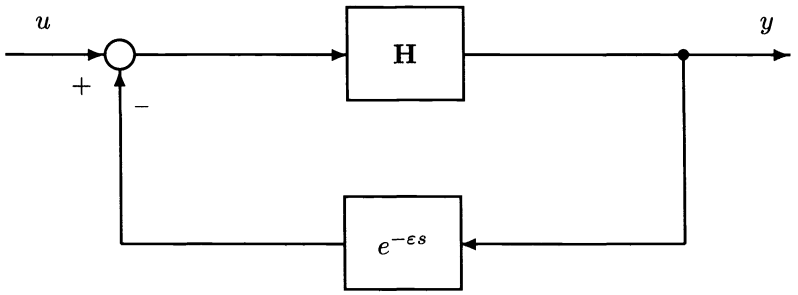

FIG. 1. *Feedback system with delay.*

In many engineering applications the aim is to stabilize a plant by a feedback controller. Here, stability may have various meanings—for example, exponential stability in the state space. We may think of $\mathbf{H}$ as the transfer function of the plant and the controller connected in cascade, and the stability of the corresponding closed-loop system implies that $\mathbf{G}^0$ is L^2-stable. However, stability might be lost if tiny (and often inevitable) delays are present in the feedback loop, leading to the feedback system shown in Fig. 1. Indeed, it might be that for arbitrarily small $\varepsilon > 0$, $\mathbf{G}^\varepsilon$ has poles in $\mathbb{C}_0$, which implies that the system cannot be stable in any reasonable state space sense either. Our aim in this paper is to find conditions on $\mathbf{H}$ (necessary and/or sufficient) for this phenomenon (observed by many authors) to happen.

We say that $\mathbf{G}^0$ is *robustly stable with respect to delays* if there is an $\varepsilon_0 > 0$ such that for any $\varepsilon \in [0,\varepsilon_0]$, $\mathbf{G}^\varepsilon$ is L^2-stable. The absence of this property means that arbitrarily small destabilizing delays can be found for $\mathbf{G}^0$.

If the transfer function $\mathbf{H}$ is meromorphic on the half-plane $\mathbb{C}_0$, then we denote by $\mathfrak{P}_\mathbf{H}$ the (discrete) set of its poles in $\mathbb{C}_0$. (We say that p is a pole of $\mathbf{H}$ if p is a pole of at least one entry of $\mathbf{H}$.) We define

$$\gamma = \limsup_{\substack{|s|\to\infty \\ s\in\mathbb{C}_0\setminus\mathfrak{P}_\mathbf{H}}} r(\mathbf{H}(s)), \tag{1.3}$$

where $r(\mathbf{H}(s))$ denotes the spectral radius of the matrix $\mathbf{H}(s)$. It might happen that $\gamma = \infty$—for example, if $\mathbf{H}$ is scalar and has an unbounded sequence of poles on the imaginary axis. If $\mathbf{G}^0$ is L^2-stable, then from the formula $\mathbf{H} = \mathbf{G}^0(I - \mathbf{G}^0)^{-1}$ it is not difficult to see that $\mathbf{H}$ is meromorphic on $\mathbb{C}_0$. Indeed, for s in the half-plane where $\mathbf{H}(s)$ was originally defined, $I - \mathbf{G}^0(s) = (I + \mathbf{H}(s))^{-1}$ so that $\det(I - \mathbf{G}^0(s))$ is not identically 0. Hence, if $\mathbf{G}^0$ is L^2-stable, then (1.3) makes sense. This fact is used implicitly in the statement of our main result, which is the following theorem.

THEOREM 1.1. *Let $\mathbf{H}$ be a $\mathbb{C}^{m\times m}$-valued regular transfer function and suppose that $\mathbf{G}^0 = \mathbf{H}(I + \mathbf{H})^{-1}$ is L^2-stable. Let γ be defined by* (1.3).

(i) *If $\gamma < 1$, then $\mathbf{G}^0$ is robustly stable with respect to delays.*

(ii) *If $\gamma > 1$, then $\mathbf{G}^0$ is not robustly stable with respect to delays.*

The proof of (i) is much easier than the proof of (ii) and is in §6. It is shown in the same section that (i) cannot be extended to multidelay perturbations. The proof of (ii) is very involved, so in order to present the ideas clearly, without multivariable

technicalities, we first give the proof for $m = 1$ in §§3 and 4. The multivariable case is treated in §5. We were not able to prove a general result for the case $\gamma = 1$. However, trivial examples (e.g., $\mathbf{H}(s) \equiv I$) show that $\mathbf{G}^0$ will in general not be robustly stable with respect to delays if $\gamma = 1$.

In §7 we show that the instability created by a small delay in the closed loop is itself robust to small delays.

In §8 we discuss destabilization and robustness with respect to delays for systems with dynamic feedback. Let $\mathbf{P}$ and $\mathbf{K}$ be meromorphic functions on $\mathbb{C}_0$ of appropriate dimensions such that the products $\mathbf{PK}$ and $\mathbf{KP}$ exist. We say that $\mathbf{K}$ *stabilizes* $\mathbf{P}$ if

$$\begin{bmatrix} I & \mathbf{P} \\ -\mathbf{K} & I \end{bmatrix}^{-1}$$

is L^2-stable. Intuitively, this means that if we connect the plant $\mathbf{P}$ and the controller $\mathbf{K}$ in a feedback loop with two external inputs, then all the possible transfer functions in the loop are L^2-stable (see §8 for details).

Let us denote $\mathbf{K}_\varepsilon(s) = e^{-\varepsilon s}\mathbf{K}(s)$. We say that $\mathbf{K}$ *stabilizes* $\mathbf{P}$ *robustly with respect to delays* if there is an $\varepsilon_0 > 0$ such that for any $\varepsilon \in [0, \varepsilon_0]$ $\mathbf{K}_\varepsilon$ stabilizes $\mathbf{P}$. Intuitively, this means that the introduction of sufficiently small delays into the feedback loop mentioned earlier does not destroy its stability. By a corollary of Theorem 1.1 stated in §8, if $\mathbf{H} = \mathbf{PK}$ is regular and γ is defined by (1.3), then $\gamma < 1$ implies that $\mathbf{K}$ stabilizes $\mathbf{P}$ robustly, while $\gamma > 1$ implies that the opposite is true. Let $\mathbb{C}_0^{\mathrm{cl}}$ denote the closure of $\mathbb{C}_0$. Using the above mentioned corollary and a lemma of independent interest, we prove (still in §8) the following theorem.

THEOREM 1.2. *Let* $\mathbf{P}$ *and* $\mathbf{K}$ *be matrix-valued meromorphic functions on a right open half-plane containing* $\mathbb{C}_0^{\mathrm{cl}}$. *Assume that* $\mathbf{PK}$ *is regular and* $\mathbf{K}$ *stabilizes* $\mathbf{P}$. *If* $\mathbf{P}$ *has infinitely many poles in* $\mathbb{C}_0^{\mathrm{cl}}$, *then* $\mathbf{K}$ *does not stabilize* $\mathbf{P}$ *robustly with respect to delays.*

Thus, roughly speaking, if a plant with infinitely many poles in $\mathbb{C}_0^{\mathrm{cl}}$ is given, we cannot find a controller such that the resulting feedback system is robustly stable with respect to small delays in the loop.

In §9 we give three simple examples.

2. Preliminaries and discussion of earlier results. There are many examples in the literature of systems described by partial differential equations which are exponentially stabilized by a feedback but are destabilized by arbitrarily small time delays in the feedback loop. The first example of this sort appeared in Datko, Lagnese, and Polis [9], where a one-dimensional wave equation with boundary feedback was studied. The same phenomenon has been subsequently described in many other examples; see Datko [10], Desch, Hannsgen, Renardy, and Wheeler [13], Hannsgen, Renardy, and Wheeler [20], Bontsema and deVries [3] and Grimmer, Lenczewski, and Schappacher [19]. In a more abstract framework, this destabilization by small delays was demonstrated for classes of distributed parameter feedback systems in Datko [10], [11] and Desch and Wheeler [12]. In these classes of systems the open loop semigroup is unitary, and only one stabilizing feedback is considered for each given plant, typically a type of co-located control.

In contrast with the works referred to above, we will take a frequency domain approach here, which is not tied to a specific form for the stabilizing feedback. Our approach is similar in spirit to that in the considerably older paper of Barman, Callier, and Desoer [1]. In that paper, necessary and sufficient conditions were given for a

class of single-input single-output (SISO) systems to be robustly stable with respect to delays. The results in [1] are limited by several restrictions, including the requirement that the open-loop transfer function has at most finitely many poles in the closed right half-plane. These results were applied to some systems described by partial differential equations in [3].

A more general class of perturbations of feedback systems, including small delays in the loop, were considered by Georgiou and Smith [17], [18] (see also Curtain [8]). Their concept of w-stability is considerably stronger than robust stability with respect to delays; it covers a large class of perturbations which represent high-frequency modelling uncertainties. The necessary and sufficient criterion for w-stability in [18] resembles our Corollaries 8.2 and 8.4, especially in the SISO case. For multiple-input multiple-output (MIMO) systems, there is a curious difference: the result for w-stability is in terms of the norms of the transfer functions, while our result for robustness with respect to delays is in terms of their spectral radius. The proof of destabilization results for w-stability is considerably easier than for robustness with respect to delays.

We will now recall some concepts and results needed in this paper. We will work with finite-dimensional input and output spaces, but we mention that these concepts and results have natural counterparts for Hilbert space-valued input/output functions, which means operator-valued transfer functions.

Let $\alpha \in \mathbb{R}$. We will use the notation

$$\mathbb{C}_\alpha = \{ s \in \mathbb{C} \mid \operatorname{Re} s > \alpha \},$$

and $H_\alpha^\infty(\mathbb{C}^{p\times m})$ will denote the space of all bounded analytic $\mathbb{C}^{p\times m}$-valued functions on $\mathbb{C}_\alpha$. We write H^∞ for H_0^∞. The norm $\|\mathbf{G}\|_\infty$ of a function $\mathbf{G} \in H_\alpha^\infty$ is the supremum of $\|\mathbf{G}(s)\|$ over $\mathbb{C}_\alpha$, the matrix norm being defined as the greatest singular value. After the identification of functions with their meromorphic extensions, which was mentioned in §1, we have that

$$H_\alpha^\infty \subset H_\beta^\infty \quad \text{if} \quad \alpha \le \beta.$$

DEFINITION 2.1. *A* well-posed $\mathbb{C}^{p\times m}$-valued transfer function *is an element of one of the spaces* $H_\alpha^\infty(\mathbb{C}^{p\times m})$.

Well-posed transfer functions correspond to shift invariant operators on $L^2_{loc}[0,\infty)$ with finite growth bound; see Weiss [32, §3]. In particular, the transfer function of any abstract linear system is well posed, as follows from [32, Prop. 4.1]. Conversely, for any well-posed transfer function $\mathbf{H}$ we can find an abstract linear system whose transfer function is $\mathbf{H}$, as follows from results in Salamon [29].

DEFINITION 2.2. *A well-posed matrix-valued transfer function* $\mathbf{H}$ *is* regular *if the limit* $\lim_{\lambda\to+\infty} \mathbf{H}(\lambda) = D$ *exists (where* λ *is real). Then* D *is the* feedthrough matrix *of* $\mathbf{H}$.

Practically all well-posed transfer functions of interest are regular. (In fact, it is a nontrivial exercise in complex analysis to construct an example of a well-posed and nonregular transfer function.) If the transfer function of an abstract linear system is regular (such systems are called regular), then the system has a simple and convenient state space representation, like finite-dimensional systems; see [32, §2].

For SISO systems, we will use the term *feedthrough value* instead of feedthrough matrix. We introduce a notation for angular domains in $\mathbb{C}$: for any number $\psi \in (0,\pi]$,

$$\mathcal{W}(\psi) = \left\{ re^{i\phi} \mid r \in (0,\infty),\ \phi \in (-\psi,\psi) \right\}.$$

We will need the following simple fact about regular transfer functions.

PROPOSITION 2.3. *Let* $\mathbf{H}$ *be a regular matrix-valued transfer function, with feedthrough matrix* D. *Then for any* $\psi \in (0, \frac{\pi}{2})$,

$$\lim_{\substack{|s|\to\infty \\ s\in\mathcal{W}(\psi)}} \mathbf{H}(s) = D.$$

This follows from Duren [14, Thm. 1.3], after mapping the half-plane onto the unit disk. It follows also from the results in [32, §5], where Laplace transform techniques are used.

Remark 2.4. If $\mathbf{H}$ and $\mathbf{G}^\varepsilon$ are related as in (1.1) and $\varepsilon > 0$, then it is easy to see that $\mathbf{H}$ is well posed (regular) if and only if $\mathbf{G}^\varepsilon$ is well posed (regular). If $\mathbf{H}$ and $\mathbf{G}^0$ are both well posed, then one of them is regular if and only if the other is. Similar statements are true for operator-valued transfer functions but are more difficult to prove; see Weiss [33].

3. Nonrobustness: The SISO case with $|D| \leq 1$. In this section we prove (ii) of Theorem 1.1 for SISO systems and under the additional assumption that D, the feedthrough value of $\mathbf{H}$, satisfies $|D| \leq 1$. This situation is fairly typical for transfer functions of unstable vibrating systems. Since we can say slightly more than what is written in (ii) of Theorem 1.1, we restate the result.

THEOREM 3.1. *Let* $\mathbf{H}$ *be a regular SISO transfer function and, for any* $\varepsilon \geq 0$, *the function* $\mathbf{G}^\varepsilon$ *be defined by* (1.1). *Let* D *denote the feedthrough value of* $\mathbf{H}$. *Assume that*

(1) $\mathbf{G}^0 \in H^\infty$, *so that* γ *can be defined by* (1.3),
(2) $\gamma > 1$,
(3) $|D| \leq 1$.

Then there exist sequences (ε_n) *and* (p_n) *with*

$$\varepsilon_n > 0, \quad \varepsilon_n \to 0, \quad p_n \in \mathbb{C}_0, \quad |\mathrm{Im}\, p_n| \to \infty$$

and such that for any $n \in \mathbb{N}$, p_n *is a pole of* $\mathbf{G}^{\varepsilon_n}$.

Proof. From condition (1), using (1.1) we can see that the point -1 has a neighborhood which does not intersect the range of $\mathbf{H}$ (regarded as a meromorphic function on $\mathbb{C}_0$). This implies that there exist $\eta > 0$ and $\gamma_1 > 1$ such that the set

$$S_1 = \left\{ re^{i\phi} \;\middle|\; r \in [1, \gamma_1],\ |\phi - \pi| < \eta \right\}$$

does not intersect the range of $\mathbf{H}$:

$$\mathbf{H}(s) \notin S_1 \qquad \forall\, s \in \mathbb{C}_0. \tag{3.1}$$

Since we may choose γ_1 arbitrarily close to 1, by condition (2) we may assume

$$1 < \gamma_1 < \gamma. \tag{3.2}$$

The definition of γ and (3.2) enable us to show that there exists a sequence (z_n) in $\mathbb{C}_0$ with the following properties:

(a) $|z_n| \to \infty$ as $n \to \infty$;
(b) for any $n \in \mathbb{N}$,

$$|\mathbf{H}(z_n)| \geq \gamma_1;$$

(c) for any $n \in \mathbb{N}$, $\mathbf{H}$ is analytic on the ray

$$\Gamma_n = \{z_n + a \mid a \in [0, \infty)\}$$

(i.e., there are no poles on these rays).

By Proposition 2.3, for any $\psi \in (0, \frac{\pi}{2})$ there exists an $r_\psi > 0$ such that for any $s \in \mathcal{W}(\psi)$ with $|s| > r_\psi$ we have $|\mathbf{H}(s) - D| < \gamma_1 - 1$. Using that $|\mathbf{H}(s)| \le |D| + |\mathbf{H}(s) - D|$ and condition (3), we get that, for s as above, $|\mathbf{H}(s)| < \gamma_1$. By property (b) it follows that the sequence (z_n) lies in the set $\{s \in \mathbb{C}_0 \mid |s| \le r_\psi \text{ or } |\arg s| \ge \psi\}$. Here and in the rest of this proof, the argument of a (nonzero) complex number s is defined such that $\arg s \in (-\pi, \pi]$. By property (a), for n sufficiently large, $|z_n| \le r_\psi$ is not possible, so that $|\arg z_n| \ge \psi$. Since the choice of $\psi \in (0, \frac{\pi}{2})$ was arbitrary, we conclude that

$$\lim_{n \to \infty} |\arg z_n| = \frac{\pi}{2}. \tag{3.3}$$

Together with property (a) this implies that

$$\lim_{n \to \infty} |\operatorname{Im} z_n| = \infty. \tag{3.4}$$

We may assume without loss of generality that for all $n \in \mathbb{N}$, $\operatorname{Im} z_n > 0$. Indeed, if such a subsequence does not exist, then a similar argument can be made assuming that $\operatorname{Im} z_n < 0$ for all $n \in \mathbb{N}$.

By property (c), $\mathbf{H}$ is continuous on each ray Γ_n, and by Proposition 2.3, $\mathbf{H}(s) \to D$ as $s \to \infty$ on Γ_n. Since $|D| \le 1$ (by condition (3)), the numbers

$$a_n' = \max\{a \in [0, \infty) \mid |\mathbf{H}(z_n + a)| \ge \gamma_1\},$$
$$a_n'' = \min\{a \in [a_n', \infty] \mid |\mathbf{H}(z_n + a)| \le 1\}$$

are well defined. (If $|D| = 1$, then it might happen that $a_n'' = \infty$.) Put

$$z_n' = z_n + a_n', \qquad z_n'' = z_n + a_n''.$$

(It might happen that $z_n'' = \infty$.) We will be looking for poles of $\mathbf{G}^\varepsilon$ in the open horizontal segments $(z_n', z_n'') \subset \Gamma_n$.

From the definition of z_n' and z_n'', using property (c) we see that the image of $[z_n', z_n'']$ through $\mathbf{H}$ is a curve Π_n contained in $\{s \in \mathbb{C} \mid 1 \le |s| \le \gamma_1\}$. The possibility that $z_n'' = \infty$ is not disturbing since (by Proposition 2.3) $\mathbf{H}$ is continuous at infinity along the ray Γ_n. By (3.1) Π_n cannot enter S_1, so it is confined to the set

$$S_2 = \{re^{i\phi} \mid r \in [1, \gamma_1],\ |\phi| \le \pi - \eta\};$$

see Fig. 2. Thus we have

$$\Pi_n \subset S_2 \qquad \forall\, n \in \mathbb{N}. \tag{3.5}$$

Using (1.1) we see that p is a pole of $\mathbf{G}^\varepsilon$ if and only if

$$e^{-\varepsilon p}\mathbf{H}(p) = -1.$$

A sufficient condition for this is

$$\log \mathbf{H}(p) - \varepsilon p = -i\pi, \tag{3.6}$$

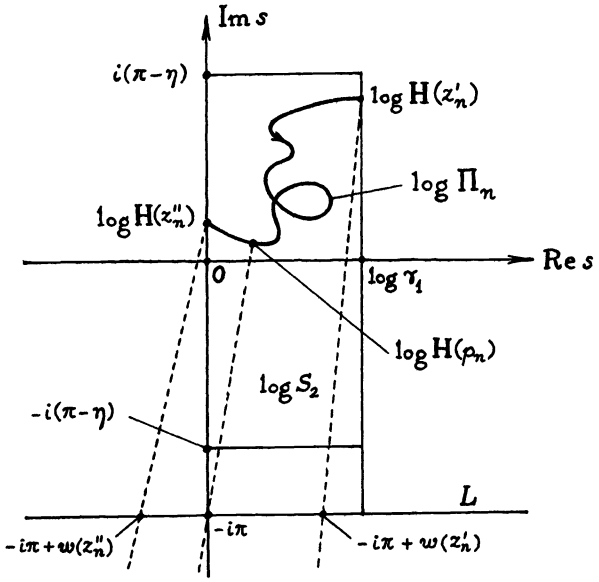

FIG. 2. *The sets S_1, S_2 and the curve Π_n.*

where we choose the branch of the logarithm to be $\log z = \log|z| + i \arg z$, with $\arg z \in (-\pi, \pi]$, as agreed earlier, and $\log|z| \in \mathbb{R}$.

For each $s \in \mathbb{C}_0$ with $\operatorname{Im} s > 0$, the ray $R(s) = \{\log \mathbf{H}(s) - \varepsilon s \mid \varepsilon \in [0, \infty)\}$ intersects the horizontal line $L = \{s \in \mathbb{C} \mid \operatorname{Im} s = -\pi\}$ in a point $w(s) - i\pi$. Indeed, for $\varepsilon = 0$ the corresponding point of $R(s)$ is above L, while for large $\varepsilon > 0$ the corresponding point of $R(s)$ is below L. Thus we can define the real-valued functions $w(s)$, $e(s)$ for each $s \in \mathbb{C}_0$ with $\operatorname{Im} s > 0$ such that $e(s) > 0$ and

$$\log \mathbf{H}(s) - e(s)s = w(s) - i\pi. \tag{3.7}$$

A simple computation shows that

$$e(s) = \frac{\arg \mathbf{H}(s) + \pi}{\operatorname{Im} s}, \tag{3.8}$$

$$w(s) = \log|\mathbf{H}(s)| - \frac{(\arg \mathbf{H}(s) + \pi)\operatorname{Re} s}{\operatorname{Im} s}. \tag{3.9}$$

CLAIM. *For all $n \in \mathbb{N}$ sufficiently large, there is a point $p_n \in (z'_n, z''_n)$ such that $w(p_n) = 0$.*

Figure 3 is intended to give an intuitive picture of this claim. In this figure we see the curve $\log \Pi_n$ which, according to (3.5), is contained in the rectangle $\log S_2$. It is assumed in the picture that z''_n is finite. The rays $R(z'_n)$, $R(z''_n)$, and $R(p_n)$ (dotted lines) and the horizontal line L are marked.

Proof of the claim. We define

$$w(\infty) = -\infty.$$

Then, as a $[-\infty, \infty)$-valued function, w is continuous on each segment $[z'_n, z''_n]$. Indeed, by (3.5) $\arg \mathbf{H}(s)$ has no jumps on such a segment. If z''_n is finite, then the continuity of w is clear from (3.9). If $z''_n = \infty$, then it is easy to see from (3.9) that $\lim_{s \to \infty} w(s) = -\infty$, where $s \in (z'_n, z''_n)$.

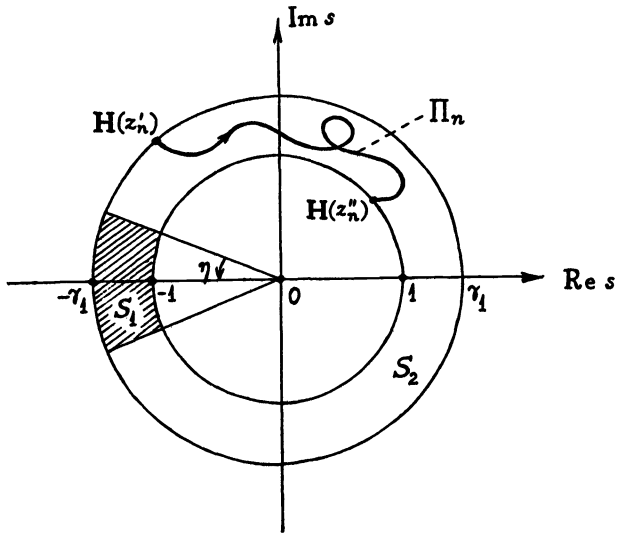

FIG. 3. *The claim (the existence of* p_n*).*

Next we show that for all $n \in \mathbb{N}$ sufficiently large,

$$w(z_n') > 0 \quad \text{and} \quad w(z_n'') < 0. \tag{3.10}$$

The sequence (z_n') shares with (z_n) properties (a) and (b) (also (c), but this is not needed now). By the exact same argument used to prove (3.3), and by the assumption $\operatorname{Im} z_n > 0$, we get that

$$\lim_{n\to\infty} \arg z_n' = \frac{\pi}{2}.$$

Hence

$$\lim_{n\to\infty} \frac{(\arg \mathbf{H}(z_n') + \pi)\operatorname{Re} z_n'}{\operatorname{Im} z_n'} = 0. \tag{3.11}$$

On the other hand, it is clear that

$$\frac{(\arg \mathbf{H}(z_n'') + \pi)\operatorname{Re} z_n''}{\operatorname{Im} z_n''} > 0. \tag{3.12}$$

By the definition of z_n' and z_n'', $|\mathbf{H}(z_n')| = \gamma_1 > 1$ and $|\mathbf{H}(z_n'')| = 1$. Therefore $\log|\mathbf{H}(z_n')| = \log\gamma_1 > 0$ and $\log|\mathbf{H}(z_n'')| = 0$. Combining this with (3.9), (3.11), and (3.12) we see that for all n sufficiently large, (3.10) holds.

Since $w(s)$ is continuous on $[z_n', z_n'']$, (3.10) implies that for all $n \in \mathbb{N}$ sufficiently large there exists $p_n \in (z_n', z_n'')$ such that $w(p_n) = 0$. (This is indicated in Fig. 3 by having the ray $R(p_n)$ go through $-i\pi$.) This completes the proof of the claim.

Returning to the main proof, we may now assume without loss of generality that for each $n \in \mathbb{N}$ there is a $p_n \in (z_n', z_n'')$ such that $w(p_n) = 0$. (If not, select an appropriate subsequence.) We denote $\varepsilon_n = e(p_n)$. By (3.7) (with $s = p_n$) we get that p_n and ε_n satisfy (3.6), so p_n is a pole of $\mathbf{G}^{\varepsilon_n}$. By (3.8), $\varepsilon_n > 0$. Since $\operatorname{Im} p_n = \operatorname{Im} z_n$, by (3.4) we have $|\operatorname{Im} p_n| \to \infty$. By (3.8) and (3.4) we have $\varepsilon_n \to 0$. □

4. Nonrobustness: The SISO case with $|D| > 1$. In this section we prove (ii) of Theorem 1.1 for SISO systems and under the additional assumption that D, the feedthrough value of $\mathbf{H}$, satisfies $|D| > 1$. Then obviously $\gamma > 1$, so that this does not have to be assumed. In fact, we will prove a stronger result, in which the assumption that $\mathbf{G}^0$ is L^2-stable is not needed. We do not even need that $\mathbf{H}$ should be meromorphic on $\mathbb{C}_0$.

THEOREM 4.1. *Let $\mathbf{H}$ be a regular SISO transfer function and, for any $\varepsilon \geq 0$, the function $\mathbf{G}^\varepsilon$ be defined by* (1.1). *Let D denote the feedthrough value of $\mathbf{H}$ and assume that*

$$|D| > 1.$$

Then there exist sequences (ε_n) and (p_n) with

$$\varepsilon_n > 0, \quad \varepsilon_n \to 0, \quad \operatorname{Re} p_n \to \infty, \quad \operatorname{Im} p_n \to \infty$$

and such that, for any $n \in \mathbb{N}$, p_n is a pole of $\mathbf{G}^{\varepsilon_n}$.

Proof. If D is not a negative real number, then we define the argument of any (nonzero) complex number s such that $\arg s \in (-\pi, \pi]$, as in the proof of Theorem 3.1. If D is negative then it is more convenient to change the definition such that $\arg s \in \left(-\frac{\pi}{2}, \frac{3\pi}{2}\right]$ (to avoid a jump discontinuity at D). The function log is defined by $\log s = \log|s| + i \arg s$ with $\log|s| \in \mathbb{R}$.

For any $r > 0$, B_r will denote the closed disk of radius r with center in D. Due to $|D| > 1$ and the way in which we have defined the function log, we can find a $\rho > 0$ such that (1) $|z| > 1$ for all $z \in B_\rho$ and (2) arg (and hence log) is continuous on B_ρ.

The simple inequalities

$$\min_{z \in B_\rho} (\arg z + \pi) > 0, \qquad \min_{z \in B_\rho} \log|z| > 0$$

enable us to find numbers $0 < \alpha < \beta$ such that for any $z \in B_\rho$

$$\log|z| - \frac{\arg z + \pi}{\alpha} < 0, \qquad \log|z| - \frac{\arg z + \pi}{\beta} > 0. \tag{4.1}$$

Let $\psi \in (0, \frac{\pi}{2})$ be such that $\beta < \operatorname{tg} \psi$. By Proposition 2.3, there exists a $\sigma > 0$ such that

$$\mathbf{H}(s) \in B_\rho \qquad \forall\, s \in \mathcal{W}(\psi) \cap \mathbb{C}_\sigma. \tag{4.2}$$

(The notation $\mathbb{C}_\sigma$ was introduced in §2.) Let (x_n) be a sequence of real numbers with $x_n > \sigma$ and such that $x_n \to \infty$. Define

$$z_n' = (1 + i\alpha)x_n, \qquad z_n'' = (1 + i\beta)x_n.$$

We will be looking for poles of $\mathbf{G}^\varepsilon$ in the open vertical segments (z_n', z_n'').

The remainder of this proof resembles the part of the proof of Theorem 3.1 which starts after (3.5), so we will be brief. Using (1.1) we see that p is a pole of $\mathbf{G}^\varepsilon$ if and only if $e^{-\varepsilon p}\mathbf{H}(p) = -1$. A sufficient condition for this is that (3.6) holds.

For each $s \in \mathbb{C}_0$ with $\operatorname{Im} s > 0$, the ray $R(s) = \{ \log \mathbf{H}(s) - \varepsilon s \mid \varepsilon \in [0, \infty) \}$ intersects the horizontal line $L = \{ s \in \mathbb{C} \mid \operatorname{Im} s = -\pi \}$ in a point $w(s) - i\pi$, as explained in

the previous proof. Thus we can define the functions $w(s)$, $e(s)$ for each $s \in \mathbb{C}_0$ with $\operatorname{Im} s > 0$ such that $e(s) > 0$ and (3.7) holds. These functions are given by (3.8) and (3.9). The following claim is almost identical to the one in the proof of Theorem 3.1.

CLAIM. *For all $n \in \mathbb{N}$ there exists $p_n \in (z_n', z_n'')$ such that $w(p_n) = 0$.*

The proof is simpler in this case: By (4.2) and property (2) it is clear that w is continuous on each segment $[z_n', z_n'']$. Moreover, (3.9), (4.1), and (4.2) imply (3.10), from which the claim follows.

We return to the proof of the theorem. We denote $\varepsilon_n = e(p_n)$. By (3.7) (with $s = p_n$) we get that p_n and ε_n satisfy (3.6), so p_n is a pole of $\mathbf{G}^{\varepsilon_n}$. By the definition of the function $e(\cdot)$, $\varepsilon_n > 0$. We have $\operatorname{Re} p_n = x_n$ so that $\operatorname{Re} p_n \to \infty$. Since $\operatorname{Im} p_n > \alpha x_n$, we also have $\operatorname{Im} p_n \to \infty$. Now by (3.8) we have $\varepsilon_n \to 0$. □

5. Nonrobustness: The MIMO case. In this section we show that the results in §§3 and 4 extend to the multivariable case. In particular, we prove part (ii) of Theorem 1.1 for $m > 1$. In order to do this, it is convenient to state some preliminary facts and results. If $V \subset U \subset \mathbb{C}$, we say that V is a *discrete* set in U if V has no accumulation points in U. Let $\mathcal{H}_\alpha$ denote the ring of holomorphic functions defined on $\mathbb{C}_\alpha$ and $\mathcal{M}_\alpha$ denote the field of meromorphic functions on $\mathbb{C}_\alpha$. The vector spaces of $\mathbb{C}^{p\times m}$-valued holomorphic functions and of $\mathbb{C}^{p\times m}$-valued meromorphic functions on $\mathbb{C}_\alpha$ will be denoted by $\mathcal{H}_\alpha(\mathbb{C}^{p\times m})$ and $\mathcal{M}_\alpha(\mathbb{C}^{p\times m})$, respectively. It is clear that $\mathcal{H}_\alpha(\mathbb{C}^{p\times m}) = {\mathcal{H}_\alpha}^{p\times m}$ and $\mathcal{M}_\alpha(\mathbb{C}^{p\times m}) = {\mathcal{M}_\alpha}^{p\times m}$. A complex number $s_0 \in \mathbb{C}_\alpha$ is a *pole* of $\mathbf{H} \in \mathcal{M}_\alpha(\mathbb{C}^{p\times m})$ if and only if s_0 is a pole of at least one of the entries of $\mathbf{H}$.

In the following let $\mathbf{H}$ be in $\mathcal{M}_\alpha(\mathbb{C}^{m\times m})$. The set of all poles of $\mathbf{H}$ is denoted by $\mathfrak{P}_\mathbf{H}$. Moreover, define

$$\psi(\cdot\,, \lambda) := \det(\lambda I - \mathbf{H}(\cdot)) \in \mathcal{M}_\alpha[\lambda]\,,$$

where $\mathcal{M}_\alpha[\lambda]$ denotes the ring of polynomials over $\mathcal{M}_\alpha$. Since $\mathcal{M}_\alpha$ is a field, there exist a unique $\ell \in \mathbb{N}$ and unique monic irreducible polynomials $\psi_i(\cdot\,, \lambda) \in \mathcal{M}_\alpha[\lambda]$ such that

$$\psi(s, \lambda) = \prod_{i=0}^{\ell} \psi_i(s, \lambda)\,.$$

Let $\Delta_i(\cdot) \in \mathcal{M}_\alpha$ denote the discriminant of $\psi_i(\cdot\,, \lambda) \in \mathcal{M}_\alpha[\lambda]$. If $s_0 \notin \mathfrak{P}_\mathbf{H}$, then it is not difficult to show that the coefficients of the polynomials $\psi_i(\cdot\,, \lambda)$ are holomorphic in a sufficiently small neighborhood of s_0 (cf. Baumgärtel [2, p. 397]) and hence $\Delta_i(s_0)$ is the discriminant of $\psi_i(s_0, \lambda) \in \mathbb{C}[\lambda]$. Thus $\psi_i(s_0, \lambda)$ has only simple zeros if and only if $\Delta_i(s_0) \neq 0$; see, for example, Cohn [7, p. 175]. Since $\psi_i(\cdot\,, \lambda)$ is irreducible, it follows that $\Delta_i(s) \not\equiv 0$ and hence the set $\mathfrak{C}_\mathbf{H}$ of *critical points* of $\mathbf{H}$ defined by

$$\mathfrak{C}_\mathbf{H} := \left\{ s \in \mathbb{C}_\alpha \mid \prod_{i=0}^{\ell} \Delta_i(s) = 0 \right\}$$

is a discrete set in $\mathbb{C}_\alpha$. We shall need the following lemma from Forster [15, p. 52].

LEMMA 5.1. *Let $s_0 \in \mathbb{C}$, let $U \subset \mathbb{C}$ be an open neighborhood of s_0, and suppose that $c_1(s), \ldots, c_n(s)$ are holomorphic functions on U. If $\lambda_0 \in \mathbb{C}$ is a simple zero of the polynomial*

$$\lambda^n + c_1(s_0)\lambda^{n-1} \ldots + c_n(s_0) \in \mathbb{C}[\lambda],$$

then there exists an open neighborhood $V \subset U$ of s_0 and a function ξ holomorphic on V such that $\xi(s_0) = \lambda_0$ and

$$\xi^n(s) + c_1(s)\xi^{n-1}(s) \ldots + c_n(s) = 0 \quad \forall\, s \in V.$$

For $s_0 \in \mathbb{C}_\alpha$, $\phi \in [0, 2\pi)$, and $0 < a \leq \infty$ set $\Gamma := \{s_0 + e^{i\phi}t \,|\, 0 \leq t < a\}$. Hence Γ is a half-line ($a = \infty$) or a line segment ($a \neq \infty$) with initial point s_0.

PROPOSITION 5.2. *Suppose that $\Gamma^{\mathrm{cl}} \subset \mathbb{C}_\alpha \setminus (\mathfrak{P}_{\mathbf{H}} \cup \mathfrak{C}_{\mathbf{H}})$. If $\lambda_0 \in \sigma(\mathbf{H}(s_0))$ (the spectrum of $\mathbf{H}(s_0)$), then there exists a region $V \subset \mathbb{C}_\alpha$ satisfying $\Gamma^{\mathrm{cl}} \subset V \subset \mathbb{C}_\alpha \setminus (\mathfrak{P}_{\mathbf{H}} \cup \mathfrak{C}_{\mathbf{H}})$ and a function ξ holomorphic on V such that $\xi(s_0) = \lambda_0$ and*

$$\psi(s, \xi(s)) = \det(\xi(s)I - \mathbf{H}(s)) = 0 \quad \forall\, s \in V.$$

Moreover, if $a = \infty$, then under the extra assumption that the limit

$$\lim_{|s| \to \infty,\, s \in \Gamma} \mathbf{H}(s) = D \in \mathbb{C}^{m \times m}$$

exists, it follows that

$$\lim_{|s| \to \infty,\, s \in \Gamma} \xi(s) =: \xi_\infty \in \sigma(D).$$

The above proposition remains true if Γ is replaced by more general curves. However, for our purposes Proposition 5.2 is sufficient.

Proof. Let $\lambda_0 \in \sigma(\mathbf{H}(s_0))$. After a suitable renumbering we may assume that $\psi_0(s_0, \lambda_0) = 0$. Let us first consider the case when $a \neq \infty$. Define $\gamma(t) := s_0 + e^{i\phi}t$ for $t \in [0, a]$. It follows from the assumption that for any $t \in [0, a]$ the polynomial $\psi_0(\gamma(t), \lambda) \in \mathbb{C}[\lambda]$ has no multiple zeros. Let n denote the degree of $\psi_0(\cdot\,, \lambda)$ and $\lambda_t^1, \ldots, \lambda_t^n$ denote the n different simple zeros of $\psi_0(\gamma(t), \lambda) \in \mathbb{C}[\lambda]$. Moreover, for $t \in [0, a]$ let $\mathfrak{B}_t$ denote the set of all open balls B_t with center in $\gamma(t)$ such that $B_t \subset \mathbb{C}_\alpha \setminus (\mathfrak{P}_{\mathbf{H}} \cup \mathfrak{C}_{\mathbf{H}})$ and such that there exist n functions ξ_t^i holomorphic on B_t satisfying $\xi_t^i(\gamma(t)) = \lambda_t^i$,

$$\xi_t^i(s) \neq \xi_t^j(s) \;\; \forall\, s \in B_t\,, \forall\, i, j \in \underline{n},\; i \neq j, \;\text{ and }\; \psi_0(s, \xi_t^i(s)) = 0 \;\; \forall\, s \in B_t\,, \forall\, i \in \underline{n}\,,$$

where $\underline{n}$ denotes the set $\{1, \ldots, n\}$. By Lemma 5.1 the set $\mathfrak{B}_t$ is nonempty, and by setting $\hat{B}_t := \bigcup_{B_t \in \mathfrak{B}_t} B_t$ we obtain the maximal element of $\mathfrak{B}_t$. Denoting the radius of $\hat{B}_t$ by ϱ_t we claim that

$$\varrho := \inf_{t \in [0,a]} \varrho_t > 0\,. \tag{5.1}$$

Assume that (5.1) is not true. Then there exist numbers $t_j \in [0, a]$ such that

$$\lim_{j \to \infty} \varrho_{t_j} = 0\,. \tag{5.2}$$

Since $a < \infty$, we may assume without loss of generality that $\lim_{j \to \infty} t_j =: t^* \in [0, a]$ exists. By assumption $\gamma(t^*) \in \mathbb{C}_\alpha \setminus (\mathfrak{P}_{\mathbf{H}} \cup \mathfrak{C}_{\mathbf{H}})$ and hence $\varrho_{t^*} > 0$. Using $\lim_{j \to \infty} \gamma(t_j) = \gamma(t^*)$, we conclude that there exist $j_0 \in \mathbb{N}$ and $\delta > 0$ such that $B(\gamma(t_j), \delta) \subset \hat{B}_{t^*}$ for all $j \geq j_0$, where $B(\gamma(t_j), \delta)$ denotes the open ball of radius δ with center in $\gamma(t_j)$. But this implies that $B(\gamma(t_j), \delta) \in \mathfrak{B}_{t_j}$ for all $j \geq j_0$ and therefore $B(\gamma(t_j), \delta) \subset \hat{B}_{t_j}$ for all $j \geq j_0$ (by the maximality of $\hat{B}_{t_j}$). Thus we obtain

that $\varrho_{t_j} \geq \delta$ for all $j \geq j_0$, which contradicts (5.2). It follows that (5.1) holds, and therefore there exists a largest number $m \in \mathbb{N}$ such that $m\varrho \leq a$. Setting $\tau_j := \varrho j$ it is clear that

$$B(\gamma(\tau_j), \varrho) \subset \hat{B}_{\tau_j} \text{ for } j = 0, \ldots, m \text{ and } \Gamma^{cl} \subset \bigcup_{j=0,\ldots,m} B(\gamma(\tau_j), \varrho).$$

Let $j_0 \in \underline{n}$ be such that $\lambda_{\tau_0}^{j_0} = \lambda_0^{j_0} = \lambda_0$, and set

$$\xi_0(s) := \xi_{\tau_0}^{j_0}(s) = \xi_0^{j_0}(s).$$

Now $S_0 := B(\gamma(0), \varrho) \cap B(\gamma(\tau_1), \varrho) \neq \emptyset$ is contained in $\mathbb{C}_\alpha \setminus (\mathfrak{P}_{\mathbf{H}} \cup \mathfrak{C}_{\mathbf{H}})$, and hence, for any $s \in S_0$, the polynomial $\psi_0(s, \lambda) \in \mathbb{C}[\lambda]$ has n different simple zeros, which are given by $\xi_{\tau_1}^1(s), \ldots, \xi_{\tau_1}^n(s)$. On the other hand we have

$$\psi_0(s, \xi_0(s)) = 0 \quad \forall s \in S_0,$$

and hence there must exist $j_1 \in \underline{n}$ such that

$$\xi_0(s) = \xi_{\tau_1}^{j_1}(s) \quad \forall s \in S_0.$$

Setting

$$\xi_1(s) := \xi_{\tau_1}^{j_1}(s) \ \forall s \in B(\gamma(\tau_1), \varrho) \text{ and } S_1 := B(\gamma(\tau_1), \varrho) \cap B(\gamma(\tau_2), \varrho) \neq \emptyset,$$

the same argument can be used to conclude that there exists $j_2 \in \underline{n}$ such that

$$\xi_1(s) = \xi_{\tau_2}^{j_2}(s) \quad \forall s \in S_1.$$

Repeating the above argument shows that there exist $m+1$ holomorphic functions $\xi_j : B(\gamma(\tau_j), \varrho) \to \mathbb{C}$ $(j = 0, \ldots, m)$ such that $\xi_{j+1}(s) = \xi_j(s)$ for all $s \in S_j := B(\gamma(\tau_j), \varrho) \cap B(\gamma(\tau_{j+1}), \varrho) \neq \emptyset$ $(j = 0, \ldots, m-1)$. On the region

$$V := \bigcup_{j=0,\ldots,m} B(\gamma(\tau_j), \varrho)$$

we define a function $\xi(s)$ by setting

$$\xi(s) := \xi_j(s) \text{ if } s \in B(\gamma(\tau_j), \varrho).$$

By construction ξ is a well-defined holomorphic function on V such that $\xi(s_0) = \lambda_0$ and $\det(\xi(s)I - \mathbf{H}(s)) = 0$ for all $s \in V$.

Let us now consider the case when $a = \infty$. For $j \in \mathbb{N}$ define $\Gamma_j := \{s_0 + e^{i\phi}t \,|\, 0 \leq t < j\}$. The above construction shows that there exist regions V_j satisfying $\Gamma_j^{\text{cl}} \subset V_j \subset \mathbb{C}_\alpha \setminus (\mathfrak{P}_{\mathbf{H}} \cup \mathfrak{C}_{\mathbf{H}})$ and $V_j \subset V_{j+1}$ and functions ξ_j holomorphic on V_j such that $\xi_j(s_0) = \lambda_0$, $\psi_0(s, \xi_j(s)) = 0$ for all $s \in V_j$ and $\xi_{j+1}|_{V_j} = \xi_j$. Hence on $V := \bigcup_{j=1}^{\infty} V_i$ we obtain a well-defined holomorphic function $\xi(s)$ with the desired properties by setting

$$\xi(s) := \xi_j(s) \text{ if } s \in V_j.$$

Finally, the last statement in the proposition is a consequence of the fact that the eigenvalues of $\mathbf{H}(\gamma(t))$ are continuous in t; see Kato [21, p. 106]. □

The next result extends Theorem 3.1 to the multivarable case.

THEOREM 5.3. *Let* $\mathbf{H}(s)$ *be a* $\mathbb{C}^{m\times m}$*-valued regular transfer function and define for any* $\varepsilon \geq 0$

$$\mathbf{G}^{\varepsilon}(s) := \mathbf{H}(s)(I + e^{-\varepsilon s}\mathbf{H}(s))^{-1}. \tag{5.3}$$

Let $D \in \mathbb{C}^{m\times m}$ *denote the feedthrough matrix of* $\mathbf{H}$ *and assume the following:*

(1) $\mathbf{G}^0 \in H^\infty(\mathbb{C}^{m\times m})$,

(2) $\limsup_{|s|\to\infty,\, s\in\mathbb{C}_0} r(\mathbf{H}(s)) =: \gamma > 1$,

(3) $r(D) \leq 1$.

Then there exist sequences (ε_n) *and* (p_n) *with*

$$\varepsilon_n > 0\,,\ \ \varepsilon_n \to 0\,,\ \ p_n \in \mathbb{C}_0\,,\ \ |\operatorname{Im} p_n| \to \infty$$

and such that for any $n \in \mathbb{N}$, p_n *is a pole of* $\mathbf{G}^{\varepsilon_n}$.

Remark 5.4. (i) Since $r(\mathbf{H}(s))$ is not defined, if s is a pole of $\mathbf{H}$, condition (2) in the previous theorem should be formulated more precisely as

$$\limsup_{|s|\to\infty,\, s\in\mathbb{C}_0\setminus\mathfrak{P}_{\mathbf{H}}} r(\mathbf{H}(s)) =: \gamma > 1.$$

To simplify the notation, we make the convention that if $s \in \mathfrak{P}_{\mathbf{H}}$, then $r(\mathbf{H}(s)) = 0$.

(ii) Suppose that $\lim_{\mu\downarrow 0} \mathbf{H}(\mu + i\omega) =: \mathbf{H}(i\omega)$ exists for almost all $\omega \in \mathbb{R}$. (For example, this is the case if $\mathbf{H} \in H^\infty(\mathbb{C}^{m\times m})$.) Then condition (2) in Theorem 5.3 is satisfied if

$$\lim_{\varrho\to\infty} \operatorname{ess\,sup}\{r(\mathbf{H}(i\omega)) \,|\, |\omega| > \varrho\} > 1. \tag{5.4}$$

Under the extra assumption that $\mathbf{H}(i\omega)$ is almost periodic, (5.4) holds if

$$\operatorname{ess\,sup}\{r(\mathbf{H}(i\omega) \,|\, \omega \in \mathbb{R}\} > 1.$$

For the proof of Theorem 5.3 we need the following simple lemma.

LEMMA 5.5. *Let the set* $A \subset \mathbb{C}_0$ *be discrete in* $\mathbb{C}_0$. *Then for any* $\varepsilon > 0$ *and* $\beta \in \mathbb{R}$, *there exists* $y_0 \in \mathbb{R}$ *such that*

$$|y_0 - \beta| \leq \varepsilon \quad \text{and} \quad \{x + iy_0 \,|\, x > 0\} \cap A = \emptyset\,.$$

Proof. It is easy to see that A is countable, so we can choose $y_0 \in (\beta - \varepsilon, \beta + \varepsilon)$ such that $y_0 \notin \operatorname{Im} A$. □

Proof of Theorem 5.3. As in the SISO case it follows from the assumptions (1) and (2) that there exist constants $\eta > 0$ and $\gamma_1 \in (1, \gamma)$ such that the set

$$S_1 = \{re^{i\phi} \mid r \in [1, \gamma_1]\,,\ |\phi - \pi| < \eta\}$$

does not intersect $\sigma(\mathbf{H}(s))$ for all $s \in \mathbb{C}_0 \setminus \mathfrak{P}_{\mathbf{H}}$:

$$\sigma(\mathbf{H}(s)) \cap S_1 = \emptyset \quad \forall\, s \in \mathbb{C}_0 \setminus \mathfrak{P}_{\mathbf{H}}. \tag{5.5}$$

Since $\gamma_1 < \gamma$, by assumption (2) there exists a sequence (s_n) in $\mathbb{C}_0 \setminus \mathfrak{P}_{\mathbf{H}}$ such that $|s_n| \to \infty$ and $r(\mathbf{H}(s_n)) > \gamma_1$ for all $n \in \mathbb{N}$. It is obvious that we can find numbers $\delta_n \in (0, 1)$ such that the vertical segment $J_n := [s_n - i\delta_n, s_n + i\delta_n]$ is contained in $\mathbb{C}_0 \setminus \mathfrak{P}_{\mathbf{H}}$ and

$$r(\mathbf{H}(s)) \geq \gamma_1 \ \ \forall\, s \in \bigcup_{n\in\mathbb{N}} J_n\,.$$

It follows from Lemma 5.5 that there exists $z_n \in J_n$ such that the ray

$$\Gamma_n = \{z_n + a \,|\, a \in [0, \infty)\}$$

does not intersect the set $\mathfrak{P}_{\mathbf{H}} \cup \mathfrak{C}_{\mathbf{H}}$:

$$\Gamma_n \cap (\mathfrak{P}_{\mathbf{H}} \cup \mathfrak{C}_{\mathbf{H}}) \neq \emptyset \quad \forall n \in \mathbb{N}. \tag{5.6}$$

Using assumption (3) it can be shown as in the SISO case that

$$\lim_{n \to \infty} |\mathrm{Im}\, z_n| = \infty. \tag{5.7}$$

Again, without loss of generality, we may assume that $\mathrm{Im}\, z_n > 0$ for all $n \in \mathbb{N}$. By construction we have that $r(\mathbf{H}(z_n)) \geq \gamma_1$ and hence there exists $\lambda_n \in \sigma(\mathbf{H}(z_n))$ such that $|\lambda_n| \geq \gamma_1 > 1$. Since (5.6) holds, an application of Proposition 5.2 shows that for all $n \in \mathbb{N}$ there exists a region V_n satisfying $\Gamma_n \subset V_n \subset \mathbb{C}_0 \setminus (\mathfrak{P}_{\mathbf{H}} \cup \mathfrak{C}_{\mathbf{H}})$ and a function ξ_n holomorphic on V_n such that $\xi_n(z_n) = \lambda_n$ and

$$\xi_n(s) \in \sigma(\mathbf{H}(s)) \quad \forall\, s \in V_n.$$

Moreover, by Proposition 2.3

$$\lim_{|s| \to \infty,\, s \in \Gamma_n} \mathbf{H}(s) = D,$$

and hence we obtain by Proposition 5.2 that

$$\lim_{|s| \to \infty,\, s \in \Gamma_n} \xi_n(s) =: \xi_n^{\infty} \in \mathbb{C}$$

exists and $\xi_n^{\infty} \in \sigma(D)$. As a consequence of assumption (3) we have that $|\xi_n^{\infty}| \leq 1$. Therefore the extended real numbers

$$\begin{aligned} a_n' &= \max\{a \in [0, \infty) \,|\, |\xi_n(z_n + a)| \geq \gamma_1\}, \\ a_n'' &= \min\{a \in [a_n', \infty] \,|\, |\xi_n(z_n + a)| \leq 1\} \end{aligned}$$

are well defined. (If $r(D) = 1$, it might happen that $a_n'' = \infty$.) Setting

$$z_n' = z_n + a_n' \quad \text{and} \quad z_n'' = z_n + a_n''$$

(where $z_n'' = \infty$ is possible), we will be looking for poles of $\mathbf{G}^{\varepsilon}$ in (z_n', z_n''). Notice that a sufficient condition for $p \in (z_n', z_n'')$ to be a pole of $\mathbf{G}^{\varepsilon}$ is that

$$\log \xi_n(p) - \varepsilon p = -i\pi.$$

By (5.5) it follows that for all $n \in \mathbb{N}$

$$\xi_n([z_n', z_n'']) \subset S_2 := \{re^{i\phi} \,|\, r \in [1, \gamma_1],\ |\phi| \leq \pi - \eta\}. \tag{5.8}$$

It follows that $\log \xi_n$ and $\arg \xi_n$ (where log and arg are defined as in §2) are continuous functions on $[z_n', z_n'']$. For $s \in [z_n', z_n'']$ define

$$R_n(s) := \{\log \xi_n(s) - \varepsilon s \,|\, \varepsilon \in [0, \infty)\}.$$

Then for each $n \in \mathbb{N}$ and $s \in [z_n', z_n'']$ the ray $R_n(s)$ intersects the line $L = \{s \in \mathbb{C} \mid \operatorname{Im} s = -\pi\}$ in a point $w_n(s) - i\pi$. Thus we can define functions $w_n, e_n : [z_n', z_n''] \to \mathbb{R}$ such that $e_n(s) > 0$ for all $s \in [z_n', z_n'']$ and

$$\log \xi_n(s) - e_n(s)s = w_n(s) - i\pi \quad \forall\, s \in [z_n', z_n''],\ \forall\, n \in \mathbb{N}. \tag{5.9}$$

As in the proof of Theorem 3.1 it follows that for all sufficiently large n there exists $p_n \in (z_n', z_n'')$ such that $w_n(p_n) = 0$. Thus, by (5.9)

$$\log \xi_n(p_n) - e_n(p_n)p_n = -i\pi\,.$$

Finally, it is clear that

$$e_n(p_n) = \frac{\arg \xi_n(p_n) + \pi}{\operatorname{Im} p_n}\,. \tag{5.10}$$

The sequence $(\arg \xi_n(p_n))$ is bounded, and by (5.7), we have that $\operatorname{Im} p_n = \operatorname{Im} z_n \to \infty$ as $n \to \infty$. Therefore we obtain from (5.10) that $\lim_{n\to\infty} e_n(p_n) = 0$. Setting $\varepsilon_n = e_n(p_n)$ it follows that $\mathbf{G}^{\varepsilon_n}$ has a pole in $p_n \in \mathbb{C}_0$. □

Along the same lines a multivariable extension of Theorem 4.1 can be obtained. We state this result without proof.

THEOREM 5.6. *Let* $\mathbf{H}$ *be a* $\mathbb{C}^{m\times m}$*-valued regular transfer function, and for any* $\varepsilon \geq 0$ *let* $\mathbf{G}^\varepsilon$ *be defined by* (5.3). *Let* D *denote the feedthrough matrix of* $\mathbf{H}$, *and assume that*

$$r(D) > 1.$$

Then there exist sequences (ε_n) *and* (p_n) *with*

$$\varepsilon_n > 0\,,\ \varepsilon_n \to 0\,,\ \operatorname{Re} p_n \to \infty\,,\ \operatorname{Im} p_n \to \infty$$

and such that for any $n \in \mathbb{N}$, p_n *is a pole of* $\mathbf{G}^{\varepsilon_n}$.

Combining Theorem 5.3 and Theorem 5.6 yields part (ii) of Theorem 1.1.

6. Robustness of stability. So far we have proved only part (ii) of Theorem 1.1. In this section we conclude the proof. In fact, since for part (i) of Theorem 1.1 the wellposedness and regularity assumptions are not needed and we obtain additionally uniform boundedness for the matrices $\mathbf{G}^\varepsilon$, we restate our result.

THEOREM 6.1. *Suppose* $\mathbf{G}^0 \in H^\infty(\mathbb{C}^{m\times m})$ *and denote* $\mathbf{H} = \mathbf{G}^0(I - \mathbf{G}^0)^{-1}$ (*so that* $\mathbf{H} \in \mathcal{M}_0(\mathbb{C}^{m\times m})$). *If*

$$\limsup_{|s|\to\infty,\, s\in\mathbb{C}_0} r(\mathbf{H}(s)) < 1, \tag{6.1}$$

then there exist numbers $\varepsilon_0 > 0$ *and* $M > 0$ *such that* $\mathbf{G}^\varepsilon(s) = \mathbf{H}(s)(I + e^{-\varepsilon s}\mathbf{H}(s))^{-1} \in H^\infty(\mathbb{C}^{m\times m})$ *and* $\|\mathbf{G}^\varepsilon\|_\infty \leq M$ *for all* $\varepsilon \in [0, \varepsilon_0]$.

Remark 6.2. Suppose that $\mathbf{H} \in H^\infty(\mathbb{C}^{m\times m})$. Then, as is well known,

$$\lim_{\mu\downarrow 0} \mathbf{H}(\mu + i\omega) =: \mathbf{H}(i\omega)$$

exists for almost all $\omega \in \mathbb{R}$. It is easy to show that $r(\mathbf{H}(s))$ is a subharmonic function on $\mathbb{C}_0$. Using standard results on subharmonic functions (see, for example, Narasimhan [25, p. 227]) it is not difficult to prove that

$$\sup\{r(\mathbf{H}(s)) \mid s \in \mathbb{C}_0\} = \operatorname{ess\,sup}\{r(\mathbf{H}(i\omega)) \mid \omega \in \mathbb{R}\}.$$

As a consequence, (6.1) will be satisfied if $\operatorname{ess\,sup}\{r(\mathbf{H}(i\omega)) \mid \omega \in \mathbb{R}\} < 1$.

The proof of Theorem 6.1 requires some preparation. If $\mathbf{H} \in \mathcal{M}_0(\mathbb{C}^{m\times m})$ and s_0 is a pole of $\mathbf{H}$, then trivial examples show that $r(\mathbf{H}(s))$ does not necessarily blow up as $s \to s_0$. However, the next lemma reveals that this phenomenon cannot occur if $\mathbf{H}(I+\mathbf{H})^{-1}$ is L^2-stable.

LEMMA 6.3. *Let $U \subset \mathbb{C}$, suppose $\mathbf{G}^0$ is bounded and holomorphic on U, and denote $\mathbf{H} = \mathbf{G}^0(I-\mathbf{G}^0)^{-1}$. If $\sup_{s\in U} r(\mathbf{H}(s)) < \infty$, then $\sup_{s\in U} \|\mathbf{H}(s)\| < \infty$.*

Proof. Assume the claim is not true; i.e., there exists a sequence (s_n) in U such that $\lim_{n\to\infty} \|\mathbf{H}(s_n)\| = \infty$. Using Cramer's rule and the boundedness of $\mathbf{G}^0$ on U, it follows that

$$\lim_{n\to\infty} \det(I - \mathbf{G}^0(s_n)) = 0. \tag{6.2}$$

Now $(\mathbf{G}^0(s_n))$ is a bounded sequence in $\mathbb{C}^{m\times m}$, and hence we may assume without loss of generality that $\lim_{n\to\infty} \mathbf{G}^0(s_n) =: D^0 \in \mathbb{C}^{m\times m}$ exists. From (6.2) it follows that $1 \in \sigma(D^0)$. This in turn implies that there exist eigenvalues $\lambda_n \in \sigma(\mathbf{H}(s_n))$ such that $\lim_{n\to\infty}[\lambda_n/(1+\lambda_n)] = 1$. But this leads to a contradiction, since the sequence (λ_n) is bounded by assumption. □

Proof of Theorem 6.1. *Step* 1: For $\varrho > 0$ set

$$\mathbb{C}_0^\varrho := \{s \in \mathbb{C}_0 \mid |s| \geq \varrho\}. \tag{6.3}$$

By (6.1) there exists $R > 0$ and $q \in (0,1)$ such that

$$r(\mathbf{H}(s)) \leq q < 1 \ \ \forall s \in \mathbb{C}_0^R. \tag{6.4}$$

Combining (6.4) and Lemma 6.3 shows that $\mathbf{H}(s)$ is bounded on $\mathbb{C}_0^R$.

Step 2: We claim that there exists a number $L > 0$ such that $\|\mathbf{G}^\varepsilon(s)\| \leq L$ for all $\varepsilon \geq 0$ and for all $s \in \mathbb{C}_0^R$. Suppose the claim is not true. Then, since by Step 1 $\mathbf{H}(s)$ is bounded on $\mathbb{C}_0^R$, it follows from Cramer's rule that there exists a sequence (s_n) in $\mathbb{C}_0^R$ and a sequence (ε_n) of nonnegative numbers such that

$$\lim_{n\to\infty} \det(I + e^{-\varepsilon_n s_n}\mathbf{H}(s_n)) = 0. \tag{6.5}$$

Now $(\mathbf{H}(s_n))$ is a bounded sequence in $\mathbb{C}^{m\times m}$ and $|e^{-\varepsilon_n s_n}| \leq 1$ for all $n \in \mathbb{N}$, and therefore (as in Step 1) we may assume without loss of generality that the limits $\lim_{n\to\infty} e^{-\varepsilon_n s_n} =: d$ and $\lim_{n\to\infty} \mathbf{H}(s_n) =: E$ exist. Using (6.4) and the fact that $|d| \leq 1$ we see that $r(dE) < 1$. On the other hand it follows from (6.5) that $-1 \in \sigma(dE)$, a contradiction.

Step 3: Choose $\varepsilon_0 > 0$ such that for any $s \in \mathbb{C}_0$ with $|s| \leq R$ and any $\varepsilon \in [0, \varepsilon_0]$

$$|1 - e^{-\varepsilon s}| \leq \frac{1}{2\|\mathbf{G}^0\|_\infty}.$$

The identity $\mathbf{G}^\varepsilon(s) = \mathbf{G}^0(s)(I - (1-e^{-\varepsilon s})\mathbf{G}^0(s))^{-1}$ shows that, for all s and ε as above, $\|\mathbf{G}^\varepsilon(s)\| \leq 2\|\mathbf{G}^0\|_\infty$.

Combining Steps 2 and 3, we obtain that $\mathbf{G}^\varepsilon \in H^\infty(\mathbb{C}^{m\times m})$ and $\|\mathbf{G}^\varepsilon\|_\infty \leq M$ for all $\varepsilon \in [0, \varepsilon_0]$, where $M := \max(L, 2\|\mathbf{G}^0\|_\infty)$. □

Theorem 6.1 deals with delay perturbations of the form $e^{-\varepsilon s}$. A natural question to ask is whether it remains true for *multidelay perturbations* of the form $\operatorname{diag}_{1\leq j\leq m}(e^{-\varepsilon^j s})$, where $\varepsilon^j \geq 0$, $j = 1, \ldots, n$. The answer is no, as the following example shows.

Example 6.4. Consider the transfer function $\mathbf{H}(s) \equiv D$, where D is given by

$$D = \begin{pmatrix} -1/2 & 1/4 \\ -1 & 1/2 \end{pmatrix}.$$

The matrix D is nilpotent; i.e., $\sigma(D) = \{0\}$ and hence $\mathbf{G}^0(s) = \mathbf{H}(s)(I + \mathbf{H}(s))^{-1} \equiv D(I + D)^{-1}$ belongs to $H^\infty(\mathbb{C}^{2\times 2})$. Moreover

$$\limsup_{|s|\to\infty, s\in\mathbb{C}_0} r(\mathbf{H}(s)) = r(D) = 0\,,$$

and thus, by Theorem 6.1, $\mathbf{G}^0$ is robustly stable with respect to delays. Setting $\Delta := \operatorname{diag}(1, -1)$, a trivial computation shows that $\sigma(\Delta D) = \{-1, 0\}$. Therefore, defining $\varepsilon_n^1 := 2\pi/n$ and $\varepsilon_n^2 := \pi/n$, it follows that

$$\det(I + \operatorname{diag}(e^{-in\varepsilon_n^1}, e^{-in\varepsilon_n^2})D) = \det(I + \Delta D) = 0 \quad \forall n \in \mathbb{N}\,.$$

As a consequence, for all $n \in \mathbb{N}$, $p_n = in$ is a pole of the closed-loop transfer function $\mathbf{G}^{\varepsilon_n}$ with multidelay $\varepsilon_n = (\varepsilon_n^1, \varepsilon_n^2)$, defined by

$$\mathbf{G}^{\varepsilon_n}(s) := \mathbf{H}(s)(I + \operatorname{diag}(e^{-\varepsilon_n^1 s}, e^{-\varepsilon_n^2 s})\mathbf{H}(s))^{-1}\,.$$

In order to give a sufficient condition for robust stability in the presence of multidelay perturbations, set

$$\mathbf{\Delta} := \{\operatorname{diag}_{1\le j\le m}(s_j) \mid s_j \in \mathbb{C}\} \subset \mathbb{C}^{m\times m}$$

and define the structured singular value $\mu_{\mathbf{\Delta}}(M)$ of $M \in \mathbb{C}^{m\times m}$ with respect to $\mathbf{\Delta}$ by

$$\mu_{\mathbf{\Delta}}(M) := \frac{1}{\min\{\|\Delta\| \mid \Delta \in \mathbf{\Delta},\ \det(I - M\Delta) = 0\}}\,,$$

unless no $\Delta \in \mathbf{\Delta}$ makes $I - M\Delta$ singular, in which case $\mu_{\mathbf{\Delta}}(M) := 0$ (cf. Packard and Doyle [26]).

THEOREM 6.5. *Suppose* $\mathbf{G}^0 \in H^\infty(\mathbb{C}^{m\times m})$ *and denote* $\mathbf{H} = \mathbf{G}^0(I - \mathbf{G}^0)^{-1}$ (*so that* $\mathbf{H} \in \mathcal{M}_0(\mathbb{C}^{m\times m})$). *If*

$$\limsup_{|s|\to\infty,\ s\in\mathbb{C}_0} \mu_{\mathbf{\Delta}}(\mathbf{H}(s)) < 1, \tag{6.6}$$

then there exist numbers $\delta > 0$ *and* $M > 0$ *such that*

$$\mathbf{G}^\varepsilon(s) := \mathbf{H}(s)(I + \operatorname{diag}_{1\le j\le m}(e^{-\varepsilon^j s})\mathbf{H}(s))^{-1} \in H^\infty(\mathbb{C}^{m\times m}) \tag{6.7}$$

and $\|\mathbf{G}^\varepsilon\|_\infty \le M$ *for all* $\varepsilon = (\varepsilon^1, \dots, \varepsilon^m) \in \mathbb{R}_+^m$ *satisfying* $\|\varepsilon\| < \delta$.

Using standard properties of structured singular values [26] the proof of Theorem 6.5 is a straightforward extension of the proof of Theorem 6.1 and is therefore left to the reader.

Condition (6.6) holds if

$$\limsup_{|s|\to\infty,\ s\in\mathbb{C}_0} \|\mathbf{H}(s)\| < 1 \tag{6.8}$$

is satisfied. Equation (6.8) is not necessary for robustness with respect to multidelay perturbations, as the following simple example shows.

Example 6.6. Let h_1, h_2, and h_3 be in H^∞ with $\|h_1\|_\infty < 1$, $\|h_3\|_\infty < 1$ and

$$\limsup_{|s|\to\infty,\, s\in\mathbb{C}_0} |h_2(s)| > 1\,.$$

If we define

$$\mathbf{H} = \begin{pmatrix} h_1 & h_2 \\ 0 & h_3 \end{pmatrix},$$

then it is clear that $\limsup_{|s|\to\infty,\, s\in\mathbb{C}_0} \|\mathbf{H}(s)\| > 1$, so (6.8) is not satisfied. Since

$$\det(I + \operatorname{diag}(e^{-\varepsilon^1 s}, e^{-\varepsilon^2 s})\mathbf{H}(s)) = (1 + e^{-\varepsilon^1 s}h_1(s))(1 + e^{-\varepsilon^2 s}h_2(s)) \;\forall\, (\varepsilon^1, \varepsilon^2) \in \mathbb{R}^2_+\,,$$

it follows that, denoting $\varepsilon = (\varepsilon^1, \varepsilon^2) \in \mathbb{R}^2_+$,

$$\inf_{\varepsilon\in\mathbb{R}^2_+} \inf_{s\in\mathbb{C}_0} |\det(I + \operatorname{diag}(e^{-\varepsilon^1 s}, e^{-\varepsilon^2 s})\mathbf{H}(s))| > 0\,.$$

Let $\mathbf{G}^\varepsilon$ be defined by (6.7). Using Cramer's rule we obtain that $\mathbf{G}^\varepsilon \in H^\infty(\mathbb{C}^{2\times 2})$ and $\sup_{\varepsilon\in\mathbb{R}^2_+} \|\mathbf{G}^\varepsilon\|_\infty < \infty$; in particular, we have robust stability with respect to multidelay perturbations.

It seems to be a difficult open problem whether the condition

$$\limsup_{|s|\to\infty,\, s\in\mathbb{C}_0} \mu_{\mathbf{\Delta}}(\mathbf{H}(s)) > 1$$

implies lack of robustness with respect to small multidelay perturbations.

7. Robustness of instability. Given a transfer function $\mathbf{H}$ of size $m \times m$, we have shown in the previous sections that, under certain conditions, there exists a positive sequence (ε_n) with $\varepsilon_n \to 0$ such that the closed-loop transfer function $\mathbf{G}^{\varepsilon_n}$ has at least one pole in $\mathbb{C}_0$ for all $n \in \mathbb{N}$. In this section we show that this property is robust in the following sense: For any $n \in \mathbb{N}$ there exists $\delta_n \in (0, \varepsilon_n)$ such that for any $\varepsilon \in \mathbb{R}^m_+$ with $\varepsilon = (\varepsilon^1, \ldots, \varepsilon^m) \in \bigcup_{n\in\mathbb{N}} (\varepsilon_n - \delta_n, \varepsilon_n + \delta_n)^m$, $\mathbf{G}^\varepsilon$ (defined by (6.7)) has a pole in $\mathbb{C}_0$.

In the following we shall need the notion of a right-coprime (or left-coprime) factorization of a matrix-valued meromorphic function.

LEMMA 7.1. *Suppose* $\mathbf{H} \in \mathcal{M}_\alpha(\mathbb{C}^{p\times m})$. *Then the following statements hold:*

(i) $\mathbf{H}$ *admits a right-coprime factorization over* $\mathcal{H}_\alpha$; *i.e., there exist matrices* $N \in \mathcal{H}_\alpha(\mathbb{C}^{p\times m})$, $D, Y \in \mathcal{H}_\alpha(\mathbb{C}^{m\times m})$, *and* $X \in \mathcal{H}_\alpha(\mathbb{C}^{m\times p})$ *such that*

$$\mathbf{H} = ND^{-1} \;\text{ and }\; XN + YD = I\,.$$

The matrices N *and* D *are unique up to multiplication from the right by a unimodular factor. A number* $s_0 \in \mathbb{C}_\alpha$ *is a pole of* $\mathbf{H}$ *if and only if* $\det D(s_0) = 0$.

(ii) $\mathbf{H}$ *admits a left-coprime factorization over* $\mathcal{H}_\alpha$; *i.e., there exist matrices* $\tilde{N} \in \mathcal{H}_\alpha(\mathbb{C}^{p\times m})$, $\tilde{D}, \tilde{Y} \in \mathcal{H}_\alpha(\mathbb{C}^{p\times p})$, *and* $\tilde{X} \in \mathcal{H}_\alpha(\mathbb{C}^{m\times p})$ *with*

$$\mathbf{H} = \tilde{D}^{-1}\tilde{N} \;\text{ and }\; \tilde{N}\tilde{X} + \tilde{D}\tilde{Y} = I\,.$$

The matrices $\tilde{N}$ *and* $\tilde{D}$ *are unique up to multiplication from the left by a unimodular factor. A number* $s_0 \in \mathbb{C}_\alpha$ *is a pole of* $\mathbf{H}$ *if and only if* $\det \tilde{D}(s_0) = 0$.

(iii) *If* $\mathbf{H} = ND^{-1}$ *is a right-coprime factorization over* $\mathcal{H}_\alpha$ *and* $\mathbf{H} = \tilde{D}^{-1}\tilde{N}$ *is a left-coprime factorization over* $\mathcal{H}_\alpha$*, then the zeros of* $\det D$ *and* $\det \tilde{D}$ *in* $\mathbb{C}_\alpha$ *coincide (counting multiplicities).*

Proof. It is well known that the ring $\mathcal{H}_\alpha$ is a Bézout domain; i.e., every finitely generated ideal is principal (see, for example, Narasimhan [25, p. 136]). Now $\mathcal{M}_\alpha$ is the quotient field of $\mathcal{H}_\alpha$, and statements (i) and (ii) follow from Vidyasagar [31, p. 330]. Statement (iii) is proved in [31, p. 76] for rational matrices. An inspection of the proof in [31] shows that it only utilizes the fact that the elementary divisor theorem holds for the ring of stable rational functions; i.e., any matrix with stable rational entries is equivalent to its Smith form. Since this is also true for the ring $\mathcal{H}_\alpha$ (see [25, p. 139]), it follows that the proof in [31] carries over to matrices with entries in $\mathcal{M}_\alpha$. □

If $f \in \mathcal{M}_0$ and $V \subset \mathbb{C}_0$ is compact, let $Z(f, V)$ denote the number of zeros of f in V, counting multiplicities. Moreover, if $\gamma : [0,1] \to \mathbb{C}$ is a closed curve and $a \in \mathbb{C} \setminus \gamma([0,1])$, we denote the winding number (index) of γ around a by $\operatorname{ind}(\gamma, a)$.

PROPOSITION 7.2. *Let* $\mathbf{H}$ *be in* $\mathcal{M}_0(\mathbb{C}^{m\times m})$ *and suppose that* $\mathbf{H}(s)(I + \mathbf{H}(s))^{-1}$ *has at least one pole in* $\mathbb{C}_0$*. Then there exists* $\delta > 0$ *such that* $\mathbf{G}^\eta$ *defined by*

$$\mathbf{G}^\eta(s) = \mathbf{H}(s)(I + \operatorname{diag}_{1\le j\le m}(e^{\eta^j s})\mathbf{H}(s))^{-1}$$

has at least one pole in $\mathbb{C}_0$ *for all* $\eta = (\eta^1, \dots, \eta^m) \in \mathbb{C}^m$ *satisfying* $\|\eta\| < \delta$.

Proof. Let $\mathbf{H} = ND^{-1}$ be a right-coprime factorization over $\mathcal{H}_0$ and $s_0 \in \mathbb{C}_0$ be a pole of $\mathbf{H}(I + \mathbf{H})^{-1}$. Set $V := \{s \in \mathbb{C} \mid |s_0 - s| \le \varrho\}$ and choose $\varrho > 0$ such that

$$V \subset \mathbb{C}_0 \quad \text{and} \quad Z(\det(D + N), \partial V) \neq 0 \quad \forall\, s \in \partial V. \tag{7.1}$$

Let $\gamma_V : [0,1] \to \mathbb{C}$ be the continuous parametrization of ∂V given by $t \mapsto s_0 + \varrho e^{2\pi i t}$. For $\eta = (\eta^1, \dots, \eta^m) \in \mathbb{C}^m$ set

$$\begin{aligned} N_\eta(s) &:= \operatorname{diag}_{1\le j\le m}(e^{\eta^j s})N(s)\,, \\ \Gamma_\eta(t) &:= \det[D(\gamma_V(t)) + N_\eta(\gamma_V(t))]\,. \end{aligned}$$

It is clear that

$$\lim_{\eta\to 0}\left(\sup_{t\in[0,1]} |\Gamma_0(t) - \Gamma_\eta(t)|\right) = 0. \tag{7.2}$$

Now it follows from (7.1) that

$$\inf_{t\in[0,1]} |\Gamma_0(t)| > 0,$$

and therefore we may conclude, using (7.2), that there exists $\delta > 0$ such that

$$\inf_{t\in[0,1]} |\Gamma_\eta(t)| > 0 \text{ for all } \eta \in \mathbb{C} \text{ such that } \|\eta\| < \delta\,. \tag{7.3}$$

Choose $\eta \in \mathbb{C}^m$ with $\|\eta\| < \delta$, and define the map

$$\Lambda : [0,1] \times [0,1] \to \mathbb{C}\,,\ (t,\tau) \mapsto \Gamma_{\tau\eta}(t)\,.$$

Then Λ is continuous and, by (7.3), $0 \notin \Lambda([0,1] \times [0,1])$. Trivially, it holds that

$$\begin{aligned} \Lambda(t,0) &= \Gamma_0(t) \ \ \forall\, t \in [0,1]\,, \\ \Lambda(t,1) &= \Gamma_\eta(t) \ \ \forall\, t \in [0,1], \end{aligned}$$

and furthermore we obtain for all $\tau \in [0,1]$ that

$$\Lambda(0,\tau) = \Gamma_{\tau\eta}(0) = \Gamma_{\tau\eta}(1) = \Lambda(1,\tau)\,.$$

Thus we have shown that Γ_0 and Γ_η are homotopic in $\mathbb{C} \setminus \{0\}$, and therefore (cf. Rudin [27, Thm. 10.40]) it follows that

$$\operatorname{ind}(\Gamma_0, 0) = \operatorname{ind}(\Gamma_\eta, 0)\,. \tag{7.4}$$

Using the principle of the argument we obtain

$$Z(\det(D+N_\eta), V) = \operatorname{ind}(\Gamma_\eta, 0) = \operatorname{ind}(\Gamma_0, 0) = Z(\det(D+N), V)\,. \tag{7.5}$$

Now, $s_0 \in V \subset \mathbb{C}_0$ is a pole of $\mathbf{H}(I+\mathbf{H})^{-1}$ or equivalently $\det(D(s_0)+N(s_0)) = 0$, and thus, by (7.5)

$$Z(\det(D+N_\eta), V) = Z(\det(D+N), V) \neq 0\,. \tag{7.6}$$

It is easy to see that $\mathbf{G}^\eta = N(D+N_\eta)^{-1}$ is a right-coprime factorization over $\mathcal{H}_0$, and thus it follows from (7.6) that $\mathbf{G}^\eta$ has a pole in $V \subset \mathbb{C}_0$. □

Combining Proposition 7.2 and Theorem 5.3 we obtain the main result of this section, a "robust" version of Theorem 5.3.

THEOREM 7.3. *Let $\mathbf{H}(s)$ be a $\mathbb{C}^{m\times m}$-valued regular transfer function and, for $\varepsilon = (\varepsilon^1, \dots, \varepsilon^m) \in \mathbb{R}_+^m$, $\mathbf{G}^\varepsilon$ be given by* (6.7). *If the conditions* (1)–(3) *of Theorem* 5.3 *are satisfied, then there exist sequences (ε_n) and (δ_n) with $\varepsilon_n > 0$, $\varepsilon_n \to 0$, $\delta_n \in (0, \varepsilon_n)$ and such that $\mathbf{G}^\varepsilon$ has poles in $\mathbb{C}_0$ for all $\varepsilon \in \bigcup_{n\in\mathbb{N}} (\varepsilon_n - \delta_n, \varepsilon_n + \delta_n)^m$.*

It is clear that Theorem 5.6 can be strengthened in a similar way.

8. Dynamic output feedback. In this section we apply our results to systems with dynamic output feedback. In particular we show that—roughly speaking—for a plant with infinitely many unstable poles there does *not* exist any stabilizing (dynamic) output feedback compensator such that the stability of the closed-loop system is robust with respect to small delays.

DEFINITION 8.1. *If $\mathbf{P} \in \mathcal{M}_\alpha(\mathbb{C}^{p\times m})$ and $\mathbf{K} \in \mathcal{M}_\alpha(\mathbb{C}^{m\times p})$ for some $\alpha \in \mathbb{R}$, we say that* $\mathbf{K}$ stabilizes $\mathbf{P}$ *if* $\det(I + \mathbf{P}(s)\mathbf{K}(s)) \not\equiv 0$ *and*

$$\begin{pmatrix} I & \mathbf{P} \\ -\mathbf{K} & I \end{pmatrix}^{-1} \in H^\infty(\mathbb{C}^{(m+p)\times(m+p)}). \tag{8.1}$$

It follows from a well-known formula of Frobenius (see Gantmacher [16, p. 73]) that $\mathbf{K}$ stabilizes $\mathbf{P}$ if and only if $\det(I + \mathbf{P}(s)\mathbf{K}(s)) \not\equiv 0$ and the transfer function

$$F(\mathbf{P},\mathbf{K}) = \begin{pmatrix} \mathbf{K}(I+\mathbf{P}\mathbf{K})^{-1} & -\mathbf{K}\mathbf{P}(I+\mathbf{K}\mathbf{P})^{-1} \\ \mathbf{P}\mathbf{K}(I+\mathbf{P}\mathbf{K})^{-1} & \mathbf{P}(I+\mathbf{K}\mathbf{P})^{-1} \end{pmatrix} \tag{8.2}$$

is in $H^\infty(\mathbb{C}^{(m+p)\times(m+p)})$. Note that $F(\mathbf{P},\mathbf{K})$ is the transfer function from (u_1,u_2) to (y_1,y_2) of the feedback system shown in Fig. 4, if we take there $\varepsilon = 0$. If $\mathbf{K} \in H^\infty(\mathbb{C}^{m\times p})$, then $\mathbf{K}$ stablizes $\mathbf{P}$ if and only if $\mathbf{P}(I+\mathbf{K}\mathbf{P})^{-1} \in H^\infty(\mathbb{C}^{p\times m})$. The next result follows trivially from Theorems 5.3 and 5.6.

COROLLARY 8.2. *Let $\mathbf{P}$ and $\mathbf{K}$ be matrix-valued transfer functions of size $p \times m$ and $m \times p$, respectively. Suppose that $\mathbf{P}\mathbf{K}$ is regular, and for $\varepsilon \geq 0$ set $\mathbf{K}_\varepsilon(s) := e^{-\varepsilon s}\mathbf{K}(s)$ and define*

$$F^\varepsilon(\mathbf{P},\mathbf{K}) := \begin{pmatrix} \mathbf{K}(I+\mathbf{P}\mathbf{K}_\varepsilon)^{-1} & -\mathbf{K}_\varepsilon\mathbf{P}(I+\mathbf{K}_\varepsilon\mathbf{P})^{-1} \\ \mathbf{P}\mathbf{K}(I+\mathbf{P}\mathbf{K}_\varepsilon)^{-1} & \mathbf{P}(I+\mathbf{K}_\varepsilon\mathbf{P})^{-1} \end{pmatrix}. \tag{8.3}$$

Then, if $\mathbf{K}$ *stabilizes* $\mathbf{P}$ *(i.e.,* $F^0(\mathbf{P},\mathbf{K}) \in H^\infty(\mathbb{C}^{(m+p)\times(m+p)})$*) and*

$$\limsup_{|s|\to\infty,\, s\in\mathbb{C}_0} r(\mathbf{P}(s)\mathbf{K}(s)) = \limsup_{|s|\to\infty,\, s\in\mathbb{C}_0} r(\mathbf{K}(s)\mathbf{P}(s)) > 1,$$

there exist sequences (ε_n) *and* (p_n) *with*

$$\varepsilon_n > 0\,,\ \varepsilon_n \to 0\,,\ p_n \in \mathbb{C}_0\,,\ |\mathrm{Im}\, p_n| \to \infty$$

and such that for any $n \in \mathbb{N}$, p_n *is a pole of* $\mathbf{PK}(I+\mathbf{PK}_{\varepsilon_n})^{-1}$ *and hence of the overall closed-loop transfer function* $F^{\varepsilon_n}(\mathbf{P},\mathbf{K})$.

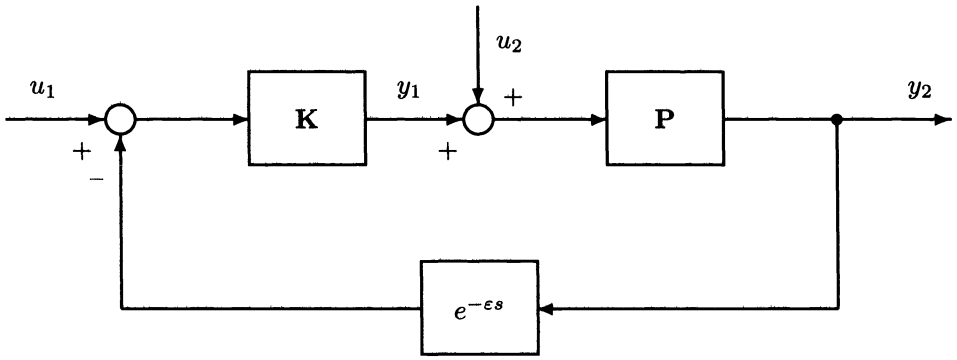

FIG. 4. *Feedback system with plant, compensator, and delay.*

The feedback system corresponding to $F^\varepsilon(\mathbf{P},\mathbf{K})$ is shown in Fig. 4; in particular we have that $(y_1,y_2)^T = F^\varepsilon(\mathbf{P},\mathbf{K})(u_1,u_2)^T$. It is clear that $F(\mathbf{P},\mathbf{K}_\varepsilon)$ is L^2-stable if $F^\varepsilon(\mathbf{P},\mathbf{K})$ is. Conversely, under the assumptions that $\mathbf{P}$ and $\mathbf{K}$ are well posed and $\mathbf{P}$ stabilizes $\mathbf{K}$,[1] it is easy to show that $F^\varepsilon(\mathbf{P},\mathbf{K})$ is L^2-stable if $F(\mathbf{P},\mathbf{K}_\varepsilon)$ is.

In order to apply Theorem 6.1 to systems with dynamic output feedback we need the following lemma.

LEMMA 8.3. *For some* $\alpha \in \mathbb{R}$ *let* $\mathbf{P}$ *and* $\mathbf{K}$ *be in* $\mathcal{M}_\alpha(\mathbb{C}^{p\times m})$ *and* $\mathcal{M}_\alpha(\mathbb{C}^{m\times p})$*, respectively, and suppose that* $\mathbf{K}$ *stabilizes* $\mathbf{P}$. *If* $U \subset \mathbb{C}_0$ *and*

$$\sup_{s\in U} \|\mathbf{P}(s)\| = \infty \ \text{ or } \ \sup_{s\in U} \|\mathbf{K}(s)\| = \infty\,,$$

then it follows that $\sup_{s\in U} \|\mathbf{P}(s)\mathbf{K}(s)\| = \infty$.

Proof. From the assumption that $\mathbf{K}$ stabilizes $\mathbf{P}$ it follows that the entries of $\mathbf{P}$ and $\mathbf{K}$ belong to the the quotient field of H^∞; i.e., they can be written as the fraction of two H^∞-functions. Moreover, it follows from Smith [30] that $\mathbf{P}$ and $\mathbf{K}$ both have right- and left-coprime factorizations over H^∞. This means in particular that there exist matrices $\tilde{N}_\mathbf{P}$, $\tilde{D}_\mathbf{P}$, $\tilde{X}_\mathbf{P}$, $\tilde{Y}_\mathbf{P}$, $N_\mathbf{K}$, $D_\mathbf{K}$, $X_\mathbf{K}$, and $Y_\mathbf{K}$ with entries in H^∞ satisfying

$$\begin{aligned} \mathbf{P} &= \tilde{D}_\mathbf{P}^{-1}\tilde{N}_\mathbf{P}\,, & \tilde{N}_\mathbf{P}\tilde{X}_\mathbf{P} + \tilde{D}_\mathbf{P}\tilde{Y}_\mathbf{P} &= I,\\ \mathbf{K} &= N_\mathbf{K}D_\mathbf{K}^{-1}\,, & X_\mathbf{K}N_\mathbf{K} + Y_\mathbf{K}D_\mathbf{K} &= I. \end{aligned}$$

Moreover, since by assumption the closed-loop system is stable, it follows trivially that I stabilizes $\mathbf{PK}$. Therefore, using again the result in Smith [30], we conclude that

[1] If $\mathbf{PK}$ is well posed and $\mathbf{P}$ stabilizes $\mathbf{K}$, then Lemma 8.3 shows that $\mathbf{P}$ and $\mathbf{K}$ are well posed.

$\mathbf{PK}$ admits a right-coprime factorization over H^∞; i.e., there exist matrices N, D, X, and Y with entries in H^∞ such that

$$\mathbf{PK} = ND^{-1}, \quad XN + YD = I. \tag{8.4}$$

It is well known (see Vidyasagar [31, p. 364]) that closed-loop stability is equivalent to

$$\inf_{s\in\mathbb{C}_0} |\det(\tilde{D}_{\mathbf{P}}(s)D_{\mathbf{K}}(s) + \tilde{N}_{\mathbf{P}}(s)N_{\mathbf{K}}(s))| > 0. \tag{8.5}$$

Let us assume that $\sup_{s\in U} \|\mathbf{P}(s)\| = \infty$. Then there exists a sequence (s_n) in U such that $\lim_{n\to\infty} \|\mathbf{P}(s_n)\| = \infty$, and hence, using the boundedness of $\tilde{D}_{\mathbf{P}}(s)$ and $\tilde{N}_{\mathbf{P}}(s)$, we obtain

$$\lim_{n\to\infty} \det(\tilde{D}_{\mathbf{P}}(s_n)) = 0. \tag{8.6}$$

Realizing that

$$\begin{aligned} \det(\tilde{D}_{\mathbf{P}}D_{\mathbf{K}} + \tilde{N}_{\mathbf{P}}N_{\mathbf{K}}) &= \det(\tilde{D}_{\mathbf{P}})\det(D_{\mathbf{K}})\det(I + \mathbf{PK}) \\ &= \frac{\det(\tilde{D}_{\mathbf{P}})\det(D_{\mathbf{K}})}{\det(D)}\det(D + N) \end{aligned} \tag{8.7}$$

and combining (8.5)–(8.7) we see that

$$\lim_{n\to\infty} \det(D(s_n)) = 0. \tag{8.8}$$

Moreover, using (8.4), it follows that

$$\det(X\mathbf{PK} + Y) = \frac{1}{\det(D)}. \tag{8.9}$$

Finally, (8.8), (8.9), and the boundedness of the matrices $X(s)$ and $Y(s)$ imply that $\lim_{n\to\infty} \|\mathbf{P}(s_n)\mathbf{K}(s_n)\| = \infty$ and thus $\sup_{s\in U} \|\mathbf{P}(s)\mathbf{K}(s)\| = \infty$. With a similar argument we can prove the claim if we assume that $\sup_{s\in U} \|\mathbf{K}(s)\| = \infty$. □

COROLLARY 8.4. *Let* $\mathbf{P} \in \mathcal{M}_\alpha(\mathbb{C}^{p\times m})$ *and* $\mathbf{K} \in \mathcal{M}_\alpha(\mathbb{C}^{m\times p})$ *for some* $\alpha \in \mathbb{R}$. *If* $F^0(\mathbf{P},\mathbf{K}) \in H^\infty(\mathbb{C}^{(m+p)\times(m+p)})$ *and*

$$\limsup_{|s|\to\infty,\, s\in\mathbb{C}_0} r(\mathbf{P}(s)\mathbf{K}(s)) < 1, \tag{8.10}$$

then there exist numbers $\varepsilon_0 > 0$ *and* $M > 0$ *such that* $F^\varepsilon(\mathbf{P},\mathbf{K}) \in H^\infty(\mathbb{C}^{(m+p)\times(m+p)})$ *and* $\|F^\varepsilon(\mathbf{P},\mathbf{K})\|_\infty \le M$ *for all* $\varepsilon \in [0,\varepsilon_0]$.

Proof. For $\varrho > 0$ let $\mathbb{C}_0^\varrho$ be defined by (6.3). Combining (8.10), the fact that $\mathbf{PK}(I + \mathbf{PK})^{-1} \in H^\infty(\mathbb{C}^{p\times p})$, and Lemma 6.3, we see that there exists numbers $R_1 > 0$ and $L_1 > 0$ such that

$$\|\mathbf{P}(s)\mathbf{K}(s)\| \le L_1 \ \forall\, s \in \mathbb{C}_0^{R_1}.$$

Hence we obtain using Lemma 8.3 that

$$\|\mathbf{P}(s)\| \le L_2 \text{ and } \|\mathbf{K}(s)\| \le L_2 \ \forall\, s \in \mathbb{C}_0^{R_2}, \tag{8.11}$$

where L_2 and R_2 are suitable positive constants. By Theorem 6.1 there exist numbers $\varepsilon_1 > 0$ and $M_1 > 0$ such that

$$\|\mathbf{PK}(I + \mathbf{PK}_\varepsilon)^{-1}\|_\infty \leq M_1 \quad \forall \varepsilon \in [0, \varepsilon_1] \tag{8.12}$$

and so

$$\|(I + \mathbf{PK}_\varepsilon)^{-1}\|_\infty \leq 1 + M_1 \quad \forall \varepsilon \in [0, \varepsilon_1]\,.$$

Therefore, and by (8.11), there exists $\tilde{M}_2 > 0$ such that

$$\|\mathbf{K}(s)(I + \mathbf{P}(s)\mathbf{K}_\varepsilon(s))^{-1}\| \leq \tilde{M}_2 \quad \forall s \in \mathbb{C}_0^{R_2}\,,\ \forall \varepsilon \in [0, \varepsilon_1]\,. \tag{8.13}$$

Setting $\mathbf{L}_\varepsilon := \mathbf{K}(I + \mathbf{PK}_\varepsilon)^{-1}$, we have $\mathbf{L}_0 \in H^\infty(\mathbb{C}^{m\times p})$ and $\mathbf{PL}_0 \in H^\infty(\mathbb{C}^{p\times p})$. Choosing $\varepsilon_2 \in (0, \varepsilon_1]$ such that for any $s \in \mathbb{C}_0$ with $|s| \leq R_2$ and any $\varepsilon \in [0, \varepsilon_2]$

$$|1 - e^{-\varepsilon s}| \leq \frac{1}{2\|\mathbf{PL}_0\|_\infty}$$

and realizing that

$$\mathbf{L}_\varepsilon(s) = \mathbf{L}_0(s)[I - (1 - e^{-\varepsilon s})\mathbf{P}(s)\mathbf{L}_0(s)]^{-1},$$

we obtain that for all s and ε as above

$$\|\mathbf{L}_\varepsilon(s)\| \leq 2\|\mathbf{L}_0\|_\infty\,. \tag{8.14}$$

Combining (8.13) and (8.14) shows that

$$\|\mathbf{K}(I + \mathbf{PK}_\varepsilon)^{-1}\|_\infty \leq M_2 \quad \forall \varepsilon \in [0, \varepsilon_2]\,, \tag{8.15}$$

where $M_2 := \max(\tilde{M}_2, 2\|\mathbf{L}_0\|_\infty)$. Finally, using similar arguments, it can be shown that

$$\|\mathbf{K}_\varepsilon\mathbf{P}(I + \mathbf{K}_\varepsilon\mathbf{P})^{-1}\|_\infty \leq M_3 \quad \forall \varepsilon \in [0, \varepsilon_3] \tag{8.16}$$

and

$$\|\mathbf{P}(I + \mathbf{K}_\varepsilon\mathbf{P})^{-1}\|_\infty \leq M_4 \quad \forall \varepsilon \in [0, \varepsilon_4]\,, \tag{8.17}$$

where M_3, M_4, ε_3, and ε_4 are suitable positive numbers. The claim now follows from (8.12) and (8.15)–(8.17). □

Using Corollary 8.2 and Lemma 8.3 it is easy to give the proof of Theorem 1.2. More precisely, we prove the following result which is slightly stronger than Theorem 1.2.

THEOREM 8.5. *Let* $\mathbf{P} \in \mathcal{M}_\alpha(\mathbb{C}^{p\times m})$ *and* $\mathbf{K} \in \mathcal{M}_\alpha(\mathbb{C}^{m\times p})$ *for some* $\alpha \in \mathbb{R}$, *and suppose that* $\mathbf{PK}$ *is regular. Then, if* $\mathbf{K}$ *stabilizes* $\mathbf{P}$ *and* $\limsup_{|s|\to\infty,\, s\in\mathbb{C}_0} \|\mathbf{P}(s)\| = \infty$, *there exist sequences* (ε_n) *and* (p_n) *with*

$$\varepsilon_n > 0\,,\ \varepsilon_n \to 0\,,\ p_n \in \mathbb{C}_0\,,\ |\mathrm{Im}\, p_n| \to \infty$$

and such that, for any $n \in \mathbb{N}$, p_n *is a pole of* $\mathbf{PK}(I + \mathbf{PK}_{\varepsilon_n})^{-1}$ *and hence of the overall closed-loop transfer function* $F^{\varepsilon_n}(\mathbf{P}, \mathbf{K})$ *given by* (8.3).

Proof. Since $\limsup_{|s|\to\infty,\, s\in\mathbb{C}_0} \|\mathbf{P}(s)\| = \infty$ and $\mathbf{K}$ stabilizes $\mathbf{P}$, it follows from Lemma 8.3 that $\limsup_{|s|\to\infty,\, s\in\mathbb{C}_0} \|\mathbf{P}(s)\mathbf{K}(s)\| = \infty$. Now, by assumption, $\mathbf{PK}(I +$

$\mathbf{PK})^{-1} \in H^\infty(\mathbb{C}^{p\times p})$, and hence an application of Lemma 6.3 and Corollary 8.2 yields the claim. □

The following remark shows that for a large class of transfer functions which are bounded at high frequencies there always exists a stabilizing compensator such that the stability of the closed loop is robust with respect to small delays.

Remark 8.6. Define $\mathcal{T} := \bigcup_{\alpha<0} H_\alpha^\infty + \mathcal{R}_{spu}$, where $\mathcal{R}_{spu}$ denotes the ring of strictly proper totally unstable rational functions, i.e., $\mathcal{R}_{spu} := \{f \in \mathbb{C}(s) \mid f(\infty) = 0 \text{ and } f(s) \neq \infty \text{ for all } s \in \mathbb{C} \setminus \mathbb{C}_0^{cl}\}$. Note that if $\mathbf{P} \in \mathcal{T}^{p\times m}$, then

$$\limsup_{|s|\to\infty,\, s\in\mathbb{C}_0} \|\mathbf{P}(s)\| < \infty,$$

which implies in particular that $\mathbf{P}$ has at most finitely many poles in $\mathbb{C}_0^{cl}$. The ring $\mathcal{T}$ contains the so-called Callier–Desoer ring of transfer functions (cf. Callier and Desoer [4],[5]). It is known that for any $\mathbf{P} \in \mathcal{T}^{p\times m}$ there exists a *strictly proper rational* compensator $\mathbf{K}$ such that $F(\mathbf{P},\mathbf{K}) \in H^\infty(\mathbb{C}^{(m+p)\times(m+p)})$; see Logemann [24] and the references therein. Combining this result with Corollary 8.4, it follows that for any $\mathbf{P} \in \mathcal{T}^{p\times m}$ there exists a compensator $\mathbf{K} \in \mathcal{T}^{m\times p}$ and a number $\varepsilon_0 > 0$ such that $F^\varepsilon(\mathbf{P},\mathbf{K}) \in H^\infty(\mathbb{C}^{(m+p)\times(m+p)})$ for all $\varepsilon \in [0,\varepsilon_0]$.

Remark 8.7. We claim that the conclusions of Theorem 8.5 do not remain true if the assumption $\limsup_{|s|\to\infty,\, s\in\mathbb{C}_0} \|\mathbf{P}(s)\| = \infty$ is replaced by the weaker assumption that there exist a sequence of poles of $\mathbf{P}$ in the open left half-plane going to ∞ tangentially along the imaginary axis. To this end let $\mathbf{P}$ be the transfer function of the following neutral system:

$$\begin{pmatrix} \dot{x}_1(t) \\ \dot{x}_2(t) - \dot{x}_2(t-h) \end{pmatrix} = \begin{pmatrix} -1 & 0 \\ 1 & -a \end{pmatrix} \begin{pmatrix} x_1(t) \\ x_2(t) \end{pmatrix} + \begin{pmatrix} 1 \\ 0 \end{pmatrix} u(t)$$
$$y(t) = x_2(t)\,,$$

i.e.,

$$\mathbf{P}(s) = \frac{1}{s+1}\,\frac{1}{s(1-e^{-hs})+a}\,,$$

where $a, h > 0$. It is shown in Logemann [23] that $\mathbf{P} \in H^\infty$. Trivially, for any compensator $\mathbf{K} \in H^\infty$ satisfying $\|\mathbf{PK}\|_\infty < 1$ the closed-loop transfer function $F^\varepsilon(\mathbf{P},\mathbf{K})$ is in $H^\infty(\mathbb{C}^{2\times 2})$ for all $\varepsilon \geq 0$. However, using Rouché's theorem, it is not difficult to show that there exist a sequence of poles $p_n \in \mathbb{C} \setminus \mathbb{C}_0^{cl}$ of $\mathbf{P}$ and numbers $\ell_n \in \mathbb{N}$ with $\ell_n \to \infty$ as $n \to \infty$ such that

$$\lim_{n\to\infty} |p_n - i\frac{2\pi}{h}\ell_n| = 0\,.$$

9. Examples. In this section we illustrate Theorem 1.1 with three examples.

Example 9.1. In this example we analyze the robustness with respect to delays for a damped wave equation. For $x \in (0,1)$ and $t > 0$ we consider the following system:

$$w_{tt}(x,t) - w_{xx}(x,t) + 2aw_t(x,t) + a^2 w(x,t) = 0\,, \tag{9.1}$$

$$w(0,t) = 0\,, \qquad w_x(1,t) = u(t)\,, \tag{9.2}$$

$$y(t) = kw_t(1,t)\,. \tag{9.3}$$

We assume here that the viscous damping parameter a is nonnegative and the boundary damping parameter k is positive. It is known that the feedback control

$$u(t) = -y(t) \tag{9.4}$$

exponentially stabilizes the system (see, for instance, Chen [6]). Hence, if the transfer function of (9.1)–(9.3) is denoted by $\mathbf{H}$, then it follows that $\mathbf{H}(I+\mathbf{H})^{-1} \in H^\infty$. An easy computuation shows that $\mathbf{H}$ is given by

$$\mathbf{H}(s) = \frac{ks}{s+a}\left(\frac{1-e^{-2(s+a)}}{1+e^{-2(s+a)}}\right).$$

In Datko, Lagnese, and Polis [9] the robustness of the closed loop system (9.1)–(9.4) with respect to small delays was analyzed. We will obtain frequency domain versions of their results, using Theorem 1.1. We need to compute γ as defined by (1.3) for this system.

CLAIM.

$$\gamma = \limsup_{|s|\to\infty, s\in\mathbb{C}_0} |\mathbf{H}(s)| = k\frac{e^{2a}+1}{e^{2a}-1}\,.$$

Proof. The following simple estimates are clear for Re $s > 0$:

$$|1-e^{-2(s+a)}| \le 1+e^{-2a}\,, \qquad |1+e^{-2(s+a)}| \ge 1-e^{-2a}\,, \qquad \left|\frac{s}{s+a}\right| \le 1\,.$$

These estimates show that $\gamma \le k(e^{2a}+1)/(e^{2a}-1)$. To obtain the opposite inequality, let $s_n = (1/n) + i(2n+1)\pi/2$ for $n \in \mathbb{N}$. Then

$$\lim_{n\to\infty} \mathbf{H}(s_n) = \lim_{n\to\infty} \frac{ks_n}{s_n+a}\frac{1+e^{-2/n}e^{-2a}}{1-e^{-2/n}e^{-2a}} = k\frac{e^{2a}+1}{e^{2a}-1}\,.$$

This shows that $\gamma \ge k(e^{2a}+1)/(e^{2a}-1)$, completing the proof of the claim. □

Let us apply Theorem 1.1 to this system. We consider two cases.

Case 1: $k \ge 1$. In this case $\gamma > 1$ for any $a \ge 0$, so the transfer function $\mathbf{H}(s)(I+e^{-\varepsilon s}\mathbf{H}(s))^{-1}$ has poles in $\mathbb{C}_0$ for arbitrarily small $\varepsilon > 0$.

Case 2: $k < 1$. In this case $\gamma > 1$ if and only if

$$a < \frac{1}{2}\ln\frac{1+k}{1-k}\,.$$

If a satisfies this estimate, then the same conclusion as in case 1 holds. When

$$a > \frac{1}{2}\ln\frac{1+k}{1-k}\,,$$

the delayed feedback system is L^2-stable for all sufficiently small delays.

Example 9.2. We consider the following first-order neutral system:

$$\dot{x}(t) - a\dot{x}(t-h) = -bx(t) + u(t)\,,$$
$$y(t) = c\dot{x}(t-h)\,.$$

Here $a \geq 1$, $b > 0$, $c \in \mathbb{R}$, and $h > 0$. We consider the feedback $u(t) = -y(t)$, so the free dynamics of the closed loop are described by

$$\dot{x}(t) + (c-a)\dot{x}(t-h) = -bx(t)\,.$$

This system is exponentially stable if $|c-a| < 1$. The open-loop transfer function is

$$\mathbf{H}(s) = \frac{sce^{-hs}}{s(1-ae^{-sh})+b}.$$

$\mathbf{H}$ is clearly well posed and regular with feedthrough 0. If $a > 1$, then the equation $1-ae^{-sh} = 0$ has a zero at $s = \log(a)/h$, which is in $\mathbb{C}_0$. Hence, by a result in Salamon [28, p. 160], the characteristic equation $s(1-ae^{-sh})+b = 0$ has infinitely many zeros in $\mathbb{C}_0$. (This follows also directly from the periodicity of $1-ae^{-hs}$ and an application of Rouché's theorem.) As a consequence $\gamma = \infty > 1$, so the closed-loop stability is destroyed by arbitrarily small delays. If $a = 1$, then the equation $1-e^{-sh} = 0$ has a zero at $s = 0$. It is easy to see that $\mathbf{H}(s)$ has no poles in $\mathbb{C}_0^{\mathrm{cl}}$. However, as shown in Logemann [23], we have that $\limsup_{\omega\to\infty} |\mathbf{H}(i\omega)| = \infty$. Hence $\gamma = \infty > 1$, and so the closed-loop system is not robustly stable with respect to delays.

Example 9.3. In this example the input space and the output space are $\mathbb{R}^2$. We consider two coupled vibrating strings, one with spatial extent $0 \leq x \leq 1$ and the other with spatial extent $1 \leq x \leq 2$. Each string satisfies the damped wave equation

$$w_{tt}(x,t) - w_{xx}(x,t) + 2aw_t(x,t) + a^2 w(x,t) = 0\,, \quad x \in (0,1)\cup(1,2)\,,$$

where the viscous damping parameter $a \geq 0$. At the linkage we assume the displacement is continuous, so

$$w(1^-,t) = w(1^+,t)\,,$$

and we set the discontinuity of the vertical tension force equal to a control variable:

$$w_x(1^-,t) - w_x(1^+,t) = u_1(t)\,.$$

We take the right endpoint fixed, and at the left endpoint we set the vertical tension force equal to another control variable, leading to

$$w(2,t) = 0\,, \qquad w_x(0,t) = u_2(t)\,.$$

We take one observation proportional to the velocity at the linkage, and the other observation negatively proportional to the velocity at the left endpoint, leading to

$$y_1(t) = k_1 w_t(1,t)\,, \qquad y_2(t) = -k_2 w_t(0,t)\,,$$

for $k_1, k_2 \geq 0$. Let $u(t) = [u_1(t), u_2(t)]^T$ and $y(t) = [y_1(t), y_2(t)]^T$. The transfer function $\mathbf{H}$ for this system can be computed to be

$$\mathbf{H}(s) = \frac{s}{s+a}\begin{pmatrix} -\dfrac{k_1}{2}\dfrac{e^{-4(s+a)}-1}{e^{-4(s+a)}+1} & k_1\dfrac{e^{-(s+a)}(e^{-2(s+a)}-1)}{e^{-4(s+a)}+1} \\ k_2\left(\dfrac{e^{-(s+a)}(e^{-2(s+a)}-1)}{e^{-4(s+a)}+1}\right) & k_2\left(\dfrac{1-e^{-4(s+a)}}{e^{-4(s+a)}+1}\right) \end{pmatrix}.$$

TABLE 1
Values of γ for given values of a, k_1, and k_2.

(k_1, k_2)	$a = .1$	$a = .25$	$a = .5$	$a = 3$	$a = 10$
(.1, .1)	.7562	.3146	.1755	.1005	.1
(.1, .5)	2.7790	1.1714	.6881	.5003	.5

(1, 1)	7.5621	3.1461	1.7553	1.0049	1

Clearly, $\mathbf{H}$ is regular with feedthrough matrix

$$D = \begin{pmatrix} k_1/2 & 0 \\ 0 & k_2 \end{pmatrix}.$$

It is not hard to show that for any values of $a \geq 0$, $k_1 \geq 0$, $k_2 \geq 0$, $a + k_1 + k_2 > 0$ the closed-loop transfer function $\mathbf{H}(I+\mathbf{H})^{-1}$ is in $H^\infty(\mathbb{C}^{2\times 2})$. In the case when $a = 0$ this follows also from the fact that the closed-loop semigroup is shown in Liu, Huang, and Chen [22] to be exponentially stable.

There are some values of k_1, k_2, and a where no further computation needs to be done in order to apply the results in the preceeding sections. If $k_1 > 2$ or $k_2 > 1$, the spectral radius of D is greater than 1, so Theorem 5.6 implies that there exists $\varepsilon_n \downarrow 0$ such that $\mathbf{G}^{\varepsilon_n}(s) = \mathbf{H}(s)(I + e^{-\varepsilon_n s}\mathbf{H}(s))^{-1}$ has poles $p_n \in \mathbb{C}_0$ such that the real and imaginary parts of p_n go to infinity as n goes to infinity. Another simple case is when $a = 0$ and $k_1 + k_2 > 0$. In this case $\mathbf{G}^0$ is stable and $\mathbf{H}$ has poles at $s = \pi i(1 + 2n)/4$ for all integers n. Thus we obtain from Lemma 6.3 that $\gamma = \limsup_{|s|\to\infty,\, s\in\mathbb{C}_0} r(\mathbf{H}(s)) = \infty$, and hence, by Theorem 1.1, $\mathbf{G}^0$ is not robustly stable with respect to delays.

In the case where $a > 0$, $0 < k_1 < 2$, $0 < k_2 < 1$ we need to compute γ. First note that γ is the same for $\tilde{\mathbf{H}}(s) := ((s + a)/s)\mathbf{H}(s)$ as it is for $\mathbf{H}(s)$. To compute the spectral radius of $\tilde{\mathbf{H}}(s)$, we need to compute the eigenvalues of $\tilde{\mathbf{H}}(s)$. These are found to be

$$\eta_\pm(k_1, k_2, s, a) = -\frac{k_1 + 2k_2}{4}\frac{1 - e^{4(s+a)}}{1 + e^{4(s+a)}} \pm \frac{1}{4(1 + e^{4(s+a)})}\sqrt{g(k_1, k_2, s, a)},$$

where

$$g(k_1, k_2, s, a) = (k_1 - 2k_2)^2 + 16k_1k_2e^{2(s+a)} - 2e^{4(s+a)}(k_1^2 + 12k_1k_2 + 4k_2^2) \\ +16k_1k_2e^{6(s+a)} + e^{8(s+a)}(k_1 - 2k_2)^2.$$

Since $\eta_\pm(k_1, k_2, s + \pi i, a) = \eta_\pm(k_1, k_2, s, a)$ and $\tilde{\mathbf{H}}$ is in $H^\infty(\mathbb{C}^{2\times 2})$, we obtain, using Remark 6.2, that

$$\gamma = \limsup_{|s|\to\infty, s\in\mathbb{C}_0} r(\tilde{\mathbf{H}}(s)) = \sup_{s\in\mathbb{C}_0} r(\tilde{\mathbf{H}}(s)) = \sup_{\omega\in\mathbb{R}} r(\tilde{\mathbf{H}}(i\omega)) = \sup_{0\leq\omega\leq\pi} r(\tilde{\mathbf{H}}(i\omega)).$$

Thus, computing γ is a fairly straightfoward numerical problem. Using Mathematica, we obtain Table 1, giving values of γ for some values of k_1, k_2, and a. As we see from the table, the possibility of robustness increases as a increases and decreases as

k_1 and k_2 increase. Note that the last column, with $a = 10$, is almost the same as that obtained by taking the limit of γ as $a \to \infty$, which is easily computed to be $\max\{k_2, k_1/2\}$. Thus, for large values of the viscous damping coefficient a, robustness is determined in a simple way by k_1 and k_2.

Acknowledgments. We would like to thank Bengt Mårtensson (Bremen) for a helpful discussion on Example 6.4 and Fabian Wirth (Bremen) for some useful remarks which led to an improvement of an earlier version of Theorem 6.5.

GENERALIZED DISCRETE-TIME RICCATI THEORY*

VLAD IONESCU† AND CRISTIAN OARĂ‡

Abstract. A Riccati-like equation, termed the generalized (discrete-time) algebraic Riccati equation, which incorporates as special cases both the standard and the constrained discrete-time algebraic Riccati equations, is introduced and investigated under the weakest possible assumptions imposed on the initial data. A complete characterization of the conditions under which such an equation of general form has a stabilizing solution is presented in terms of the so-called proper deflating subspace of the extended Hamiltonian pencil. An evaluation of an associated quadratic index along constrained stable trajectories is given in terms of the stabilizing solution to the generalized Riccati equation. Possible applications of the developed theory range from nonstandard spectral and inner-outer factorizations to H^2 and H^∞ control in singular cases. The results exposed in the present paper are the discrete-time counterpart of those stated in the authors' previous paper concerning the generalized (singular) continuous-time Riccati theory. The results could be also seen as an extension to singular cases of the usual discrete-time algebraic Riccati equation theory (of indefinite sign).

Key words. generalized Riccati equation, extended Hamiltonian pencil, proper deflating subspace, Kronecker canonical form, constrained dynamics with quadratic cost

1. Introduction.

In the past decade the topics on the Riccati equation theory have been continuously enlarged. Thus the usual field consisting of standard Riccati equations (control and estimation) encountered in the linear quadratic theory [5], [19] has been considerably increased by considering those Riccati equations which are typically used for game theoretic situations (see, for instance, [3], [5], [25]). The unorthodox cases, such as those regarding the constrained Riccati equation used for nonstandard inner-outer factorization (see [6], [14], [15], [26]), must be also seen as significant factors that prove the progress in the field.

Among the paths that have been explored in this area, a relevant one is that based on the Popov–Yakubovich–type approach in conjunction with the matrix pencil theory (see [11], [12], [13], [16], [17]). The present paper contains the discrete counterpart of the theory developed in [17] and presents a unified approach of the various cases in which discrete-time Riccati-like equations are involved. As we shall see, the results obtained in the continuous case [17] cannot be entirely transferred to the discrete case and there are many situations when significant differences occur.

The main tool used in the paper is based on the notion of the so-called *proper deflating subspace* of the extended Hamiltonian pencil (EHP) (for EHP see, for instance, [16]). In fact the significant differences between the continuous and the discrete cases have their origin in the differences that occur in the intimate structure of the corresponding EHPs.

Subsequently the following notations will be used. The open unit disk and its closure in the complex plane will be denoted by $\mathbf{D}_1(0)$ and $\overline{\mathbf{D}}_1(0)$, respectively. $\mathbf{R}^n$ and $\mathbf{R}^{m\times n}$ will be used to denote the real n-dimensional Euclidean space and the ring of real $m \times n$ matrices, respectively. $\mathbf{R}(\lambda)$ will stand for the field of rational functions over $\mathbf{R}$. Any matrix of full column (row) rank will be called monic (epic).

‡ Faculty of Automatic Control and Computers, University Politehnica Bucharest, 34 Austrului, 73115, Bucharest, Romania.

The spectrum of a square matrix A will be denoted by $\Lambda(A)$. For the transpose and the Moore–Penrose pseudo inverse of a matrix A we shall use the notations A^T and $A^{\#}$, respectively. By A^{-T} we denote $(A^{-1})^T$, if A^{-1} exists. Script capital letters will be used for subspaces in $\mathbf{R}^n$. If $\mathcal{V} \subset \mathbf{R}^n$ and $A\mathcal{V} \subset \mathcal{V}$, write $A|\mathcal{V}$ for the restriction of A to $\mathcal{V}$. The image and the null space of a matrix A will be denoted by $\mathrm{Im}A$ and $\ker A$, respectively. Strict equivalence of two matrix pencils $\lambda M - N$ and $\lambda\tilde{M} - \tilde{N}$ will be denoted by $\lambda M - N \sim \lambda\tilde{M} - \tilde{N}$ and means the existence of two constant nonsingular matrices H and Z of appropriate dimensions such that $H(\lambda M - N)Z = \lambda\tilde{M} - \tilde{N}$. By $l^2(\mathbf{N}; \mathbf{R}^r)$ we shall denote the Hilbert space of norm-square-summable $\mathbf{R}^r$-valued sequences. Here $\mathbf{N}$ stands for the set of positive integers. The inner product in $l^2(\mathbf{N}; \mathbf{R}^r)$ will be denoted by $\langle , \rangle$. Irrelevant block entries of a matrix are denoted by x.

2. Definitions and basic notions. Any triplet $\Sigma = (A, B, P)$, where $A \in \mathbf{R}^{n\times n}$, $B \in \mathbf{R}^{n\times m}$, and $P \in \mathbf{R}^{(n+m)\times(n+m)}$, with

$$P = \begin{bmatrix} Q & L \\ L^T & R \end{bmatrix} = P^T,$$

will be called a *Popov triplet.* Such a triplet expresses synthetically a tandem which consists of a linear (discrete-time) system $\sigma x = Ax + Bu$ and an associated quadratic cost criterion $\sum_{k=0}^{\infty} w_k^T P w_k$, $w_k := [x_k^T u_k^T]^T$. Here σ stands for the unit shift operator, i.e., $(\sigma x)_k = x_{k+1}$.

DEFINITION 1. *Let Σ be a Popov triplet. The algebraic equation*

$$\begin{bmatrix} A^TXA - X + Q & A^TXB + L \\ L^T + B^TXA & R + B^TXB \end{bmatrix} \begin{bmatrix} I \\ F \end{bmatrix} V = 0, \tag{1}$$

where $X \in \mathbf{R}^{n\times n}, V \in \mathbf{R}^{n\times r}$ is monic with $r \leq n$, r unfixed, and F such that $(A+BF)V = VS$ for an appropriate matrix $S \in \mathbf{R}^{r\times r}$ will be termed the generalized discrete-time algebraic Riccati equation (GDTARE).

A quadruple (r, X, V, F) for which (1) holds and $V^TXV = V^TX^TV$ will be called a solution to GDTARE. A solution to GDTARE will be called stabilizing if, in addition, $\Lambda(S) \subset \mathbf{D}_1(0)$.

Remark 1. If (r, X, V, F) is a stabilizing solution to the GDTARE, then $\mathcal{V} = \mathrm{Im}V$ is a stable (A, B) invariant subspace. Indeed, we have directly from Definition 1 that $(A + BF)\mathcal{V} \subset \mathcal{V}$ and $\Lambda((A + BF)|\mathcal{V}) \subset \mathbf{D}_1(0)$. □

Remark 2. If V is invertible, we may assume that $V = I$ and (1) becomes

$$\begin{aligned} A^TXA - X + Q + (A^TXB + L)F = 0, \\ L^T + B^TXA + (R + B^TXB)F = 0. \end{aligned} \tag{2}$$

In this case a stabilizing solution reduces to a pair (X, F) satisfying (2) with $X = X^T$ and $A + BF$ stable. For $X = X^T$ the system (2) can be rewritten

$$\begin{aligned} A^TXA - X - F^T(R + B^TXB)F + Q = 0, \\ L^T + B^TXA + (R + B^TXB)F = 0 \end{aligned} \tag{3}$$

or as

$$\begin{aligned} A^TXA - X - (A^TXB + L)(R + B^TXB)^{\#}(B^TXA + L^T) + Q = 0, \\ \ker(R + B^TXB) \subset \ker(A^TXB + L). \end{aligned} \tag{4}$$

The form (3) is the discrete counterpart of the form encountered in [1] and [20], while the form (4) is known as the *constrained discrete-time algebraic Riccati equation* (CDTARE). (See [14] for the continuous-time case and [15] for the discrete-time case.) If, in addition, $R + B^T X B$ is invertible, (2) reduces to the well-known discrete-time algebraic Riccati equation:

$$A^T X A - X - (A^T X B + L)(R + B^T X B)^{-1}(B^T X A + L^T) + Q = 0. \tag{5}$$

Note that no assumption on the inertia of the symmetric matrix R or on the invertibility of A are made. □

For earlier works on existence, convergence, and numerical solution of Riccati equations in such standard cases as, for example, the control and estimation Riccati equations, refer to [2], [19], [21]. A very good survey of the progress in the field of the Riccati equation, including the indefinite-sign case, can be also found in [5].

With the above definitions we can now state the following proposition.

PROPOSITION 2.1. *If* (r, X, V, F) *and* $(r, \tilde{X}, V, \tilde{F})$ *are two stabilizing solutions to* (1), *then* $V^T X V = V^T \tilde{X} V$.

Proof. We may write $(A + BF)V = VS$ and $(A + B\tilde{F})V = V\tilde{S}$ with both $\Lambda(S)$ and $\Lambda(\tilde{S})$ in $\mathbf{D}_1(0)$. From (1) we have $A^T X A V - XV + QV + LFV + A^T X B F V = A^T X (A + BF)V - XV + QV + LFV = A^T X V S - XV + QV + LFV = 0$ and thus

$$V^T A^T X V S - V^T X V + V^T Q V + V^T L F V = 0. \tag{6}$$

Again using (1) we also have

$$V^T \tilde{F}^T (L^T + B^T X A)V + V^T \tilde{F}^T (R + B^T X B) F V$$

$$= V^T \tilde{F}^T B^T X (A + BF)V + V^T \tilde{F}^T L^T V + V^T \tilde{F}^T R F V = 0,$$

that is,

$$V^T \tilde{F}^T B^T X V S + V^T \tilde{F}^T L^T V + V^T \tilde{F}^T R F V = 0. \tag{7}$$

Adding (6) and (7) yields

$$\tilde{S}^T V^T X V S - V^T X V + V^T (LF + \tilde{F}^T L^T)V + V^T \tilde{F}^T R F V + V^T Q V = 0. \tag{8}$$

A similar procedure applied to (1) for $\tilde{X}$ and $\tilde{F}$ instead of X and F, respectively, yields

$$S^T V^T \tilde{X} V \tilde{S} - V^T \tilde{X} V + V^T (L\tilde{F} + F^T L^T)V + V^T F^T R \tilde{F} V + V^T Q V = 0. \tag{9}$$

As $V^T \tilde{X} V = V^T \tilde{X}^T V$, we get, by transposing (9),

$$\tilde{S}^T V^T \tilde{X} V S - V^T \tilde{X} V + V^T (\tilde{F}^T L^T + LF)V + V^T \tilde{F}^T R F V + V^T Q V = 0, \tag{10}$$

and subtracting (10) from (8) we have

$$\tilde{S}^T (V^T X V - V^T \tilde{X} V) S - (V^T X V - V^T \tilde{X} V) = 0. \tag{11}$$

Hence, as both $\Lambda(\tilde{S})$ and $\Lambda(S)$ are in $\mathbf{D}_1(0)$, the Stein equation (11) has a unique zero solution, and consequently $V^T X V = V^T \tilde{X} V$. □

Let Σ be a Popov triplet and associate with it the discrete-time linear system

$$\begin{aligned} \sigma x &= Ax + Bu, \\ \lambda &= Qx + A^T\sigma\lambda + Lu, \\ v &= L^Tx + B^T\sigma\lambda + Ru. \end{aligned} \tag{12}$$

Let $w = [x^T\ \lambda^T\ u^T]^T \in \mathbf{R}^n \times \mathbf{R}^n \times \mathbf{R}^m$. Then for $v = 0$, (12) can be written in the descriptor form $M\sigma w = Nw$, where

$$M = \begin{bmatrix} I & 0 & 0 \\ 0 & -A^T & 0 \\ 0 & -B^T & 0 \end{bmatrix}, \qquad N = \begin{bmatrix} A & 0 & B \\ Q & -I & L \\ L^T & 0 & R \end{bmatrix}; \tag{13}$$

$M, N \in \mathbf{R}^{(2n+m)\times(2n+m)}$.

DEFINITION 2 (see [13], [15]). *The matrix pencil $\lambda M - N$ with M and N defined via* (13) *is called the EHP associated with Σ.*

As we shall see in §3, the EHP introduced by Definition 2 will play a crucial role in studying the GDTARE. In order to investigate the EHP let us briefly recall some geometric notions intimately related to the general matrix pencil theory, which have been introduced and studied in [13], [17], [22], [26].

DEFINITION 3. *Let $\lambda M - N$ with $M, N \in \mathbf{R}^{p\times q}$ be an arbitrary matrix pencil. A subspace $\mathcal{V} \subset \mathbf{R}^q$ of dimension ρ will be called a proper deflating subspace to the right if*

$$NV = MVS \tag{14}$$

and

$$MV \text{ is monic,}$$

where $V \in \mathbf{R}^{q\times\rho}$ is any basis matrix for $\mathcal{V}$ and S is an appropriate $\rho \times \rho$ matrix. A subspace $\mathcal{W} \subset \mathbf{R}^p$ of dimension σ is a proper deflating subspace to the left if

$$WN = TWM \tag{15}$$

and

$$WM \text{ is epic,}$$

where $W^T \in \mathbf{R}^{p\times\sigma}$ is any basis matrix for $\mathcal{W}$, and T is an appropriate $\sigma \times \sigma$ matrix. A proper deflating subspace to the right is said to be stable (antistable) if $\Lambda(S) \subset \mathbf{D}_1(0)(\Lambda(S) \subset \mathbf{C} - \overline{\mathbf{D}}_1(0))$. A proper deflating subspace to the left is said to be stable (antistable) if $\Lambda(T) \subset \mathbf{D}_1(0)(\Lambda(T) \subset \mathbf{C} - \overline{\mathbf{D}}_1(0))$. A proper deflating subspace to the right (left) is said strictly stable if $\Lambda(S)(\Lambda(T))$ is in $\overline{\mathbf{D}}_1(0) - \{0\}$.

For deflating and reducing subspaces of a matrix pencil see also [4], [7], [8], [10], [24].

Recall from [9] that any matrix pencil is strictly equivalent to the Kronecker

canonical form

$$\lambda M - N \sim \begin{bmatrix} L_{\epsilon_1} & & & & & & & \\ & \ddots & & & & & & \\ & & L_{\epsilon_{\nu_r}} & & & & & \\ & & & {L_{\eta_1}}^T & & & & \\ & & & & \ddots & & & \\ & & & & & {L_{\eta_{\nu_l}}}^T & & \\ & & & & & & \lambda I - J & \\ & & & & & & & \lambda E - I \end{bmatrix},$$

where $L_{\epsilon_i} \in \mathbf{R}^{\epsilon_i \times (\epsilon_i+1)}, i = 1, \ldots, \nu_r$ (${L_{\eta_j}}^T \in \mathbf{R}^{(\eta_j+1)\times\eta_j}, j = 1, \ldots, \nu_l$) are the right (left) Kronecker blocks with $\epsilon_i \geq 0 (\eta_j \geq 0)$ the right (left) Kronecker indices and $\nu_r(\nu_l)$ the number of right (left) Kronecker blocks, respectively; J is in the real Jordan canonical form; and E is block diagonal, each block consisting of units placed on the first upper diagonal and zeros in the rest.

Let $n_r := \Sigma_{i=1}^{\nu_r} \epsilon_i$, $n_l := \Sigma_{j=1}^{\nu_l} \eta_j$ and let n_f and n_∞ be the sizes of J and E, respectively. Then n_f equals the number of finite generalized eigenvalues and n_∞ equals the number of infinite generalized eigenvalues. Clearly

$$\operatorname{rank}_{\mathbf{R}(\lambda)}(\lambda M - N) = n_r + n_l + n_f + n_\infty \leq \min(p, q).$$

Now write $n_f = n_f^- + n_f^+ + n_f^0$, where $n_f^-(n_f^+)$ is the number of finite generalized eigenvalues inside the unit disk (outside the closed unit disk) and n_f^0 is the number of finite generalized eigenvalues placed on the unit circle. Also write $n_f^- = \tilde{n}_f^- + \pi_0$, where π_0 is the multiplicity of the generalized eigenvalues located in the origin and $\tilde{n}_f^-$ is the number of nonzero generalized eigenvalues in $\mathbf{D}_1(0)$.

THEOREM 2.2. 1. *A matrix pencil has a stable (antistable) proper deflating subspace to the right if and only if* $n_r + n_f^- > 0$ $(n_r + n_f^+ > 0)$. *Moreover the maximal dimension of a stable (antistable) proper deflating subspace is* $n_r + n_f^-$ $(n_r + n_f^+)$, *and such a dimension can be effectively attained.*

2. *A matrix pencil has a stable (antistable) proper deflating subspace to the left if and only if* $n_l + n_f^- > 0$ $(n_l + n_f^+ > 0)$. *Moreover the maximal dimension of a stable (antistable) proper deflating subspace is* $n_l + n_f^-$ $(n_l + n_f^+)$, *and such a dimension can be effectively attained.*

3. *A matrix pencil has a strictly stable proper deflating subspace to the right (left) if and only if* $n_r + \tilde{n}_f^- > 0$ $(n_l + \tilde{n}_f^- > 0)$. *Moreover the maximal dimension of a strictly stable proper deflating subspace to the right (left) is* $n_r + \tilde{n}_f^-$ $(n_l + \tilde{n}_f^-)$, *and such a dimension can be effectively attained.*

The proof runs similarly to that given for Theorem 1 in [17] by changing the role of $\mathbf{C}^-$ and $\mathbf{C}^+$ with $\mathbf{D}_1(0)$ and $\mathbf{C} - \overline{\mathbf{D}}_1(0)$. Here $\mathbf{C}^-(\mathbf{C}^+)$ stands for the open left (right) half of the complex plane.

3. The EHP. Using Theorem 2.2 some remarkable properties of the EHP will be emphasized.

PROPOSITION 3.1. *If the EHP has a strictly stable (antistable) proper deflating subspace to the right, then it has an antistable (strictly stable) proper deflating subspace to the left of the same dimension.*

Proof. Let

$$V = [\underbrace{V_1^T}_{n} \quad \underbrace{V_2^T}_{n} \quad \underbrace{V_3^T}_{m}]^T$$

be monic and such that (14) holds, with $\Lambda(S) \subset \mathbf{D}_1(0) - \{0\}$ and MV monic. Then making (14) explicit, we have

$$AV_1 + BV_3 = V_1 S,$$

$$QV_1 - V_2 + LV_3 = -A^T V_2 S, \tag{16}$$

$$L^T V_1 + RV_3 = -B^T V_2 S$$

with

$$MV = \begin{bmatrix} V_1 \\ -A^T V_2 \\ -B^T V_2 \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & -A^T \\ 0 & -B^T \end{bmatrix} \begin{bmatrix} V_1 \\ V_2 \end{bmatrix} \tag{17}$$

monic. By transposing (16) and then interchanging the first two equations, one obtains

$$S^T V_2^T A + V_1^T Q + V_3^T L^T = S^{-T}(S^T V_2^T),$$

$$-V_1^T = S^{-T}(-V_1^T A^T - V_3^T B^T), \tag{18}$$

$$S^T V_2^T B + V_1^T L + V_3^T R = 0,$$

where S is clearly nonsingular. Thus if we define

$$W := [S^T V_2^T \quad V_1^T \quad V_3^T], \tag{19}$$

then (15) is fulfilled with $T = S^{-T}$. Moreover from (17) it follows that $[V_1^T V_2^T]^T$ must be also monic; otherwise the left-hand side of (17) is not monic, which yields a contradiction. Hence

$$\begin{aligned} WM &= [S^T V_2^T \quad -V_1^T A^T - V_3^T B^T \quad 0] = [S^T V_2^T \quad -S^T V_1^T \quad 0] \\ &= S^T [V_2^T \quad -V_1^T \quad 0], \end{aligned} \tag{20}$$

where (19) and the second equation in (18) have been used. But the rightmost term in (20) is clearly epic (as $[V_1^T V_2^T]$ is epic and S nonsingular), and consequently WM and W are epic. Thus (19) defines, via $\mathcal{W} = \mathrm{Im} W^T$, an antistable proper deflating subspace to the left of the same dimension as $\mathcal{V}$. For the parenthesized text the same scheme of proof works. □

Remark 3. It has been shown in [17] that in the continuous-time case Proposition 3.1 can be stated in the "if and only if" form; that is, the proposition is also true if in its statement the order of the words *right* and *left* is changed. In the discrete-time case such a scheme does not work. To be more specific, assume that for $W = [W_1 \; W_2 \; W_3]$

epic, (15) is fulfilled, with $\Lambda(T) \subset \mathbf{C} - \mathbf{D}_1(0)$, and WM is epic. Then it can be easily checked that

$$V = \begin{bmatrix} W_2^T \\ W_1^T T^T \\ W_3^T \end{bmatrix}$$

is monic and (14) is fulfilled for such V with $S = T^{-T}$. Hence $\Lambda(S) \subset \mathbf{D}_1(0)$ and S is nonsingular. Moreover, since WM is epic, it follows that $[W_1 \quad -T^{-1}W_2 \quad 0]$ is epic. Thus

$$MV = \begin{bmatrix} I & 0 \\ 0 & -A^T \\ 0 & -B^T \end{bmatrix} \begin{bmatrix} W_2^T T^{-T} \\ W_1^T \end{bmatrix} T^T, \tag{21}$$

where the last two matrices in the right-hand side of (21) are clearly both monic. Hence the whole right-hand side of (21) is monic, provided that

$$\begin{bmatrix} I & 0 \\ 0 & -A^T \\ 0 & -B^T \end{bmatrix}$$

is also monic. But this clearly happens if the pair (A, B) has no uncontrollable modes in the origin. Thus we can conclude that the converse of Proposition 3.1 is also true if the minor hypothesis on the pair (A, B) is in addition assumed to be true. Notice also that if the EHP is regular, then the converse of Proposition 3.1 is true (see Remark 4 in [17]). □

Now introduce the discrete-time Popov function

$$\Pi(\lambda) = [B^T(\frac{1}{\lambda}I - A^T)^{-1} \; I] \begin{bmatrix} Q & L \\ L^T & R \end{bmatrix} \begin{bmatrix} (\lambda I - A)^{-1}B \\ I \end{bmatrix} \tag{22}$$

associated with Σ (see [16]). Let $\rho = \operatorname{rank}_{\mathbf{R}(\lambda)}\Pi(\lambda)$. Then we have the main result of this section.

THEOREM 3.2. *For the EHP the following hold:*

1. $n_r \leq n_l$.
2. $\tilde{n}_f^- = n_f^+$.
3. $\operatorname{rank}_{\mathbf{R}(\lambda)}(\lambda M - N) = 2n + \rho$.
4. $n_\infty \geq \rho + \pi_0$.
5. $n_r + n_f^- \leq n$, *and the equality holds if and only if* $n_f^0 = 0$, $n_r = n_l$, *and* $n_\infty = \rho + \pi_0$.

Proof. 1. Using 3. of Theorem 2.2 followed by Proposition 3.1 and then 2. of Theorem 2.2, we get $n_r + \tilde{n}_f^- \leq n_l + n_f^+$. Using 1. of Theorem 2.2 followed by Proposition 3.1 and then 3. of Theorem 2.2, we have that $n_r + n_f^+ \leq n_l + \tilde{n}_f^-$. By adding the above two inequalities, 1. follows.

2. The following identity can be easily checked:

$$\frac{1}{\lambda}M - N = \begin{bmatrix} 0 & \frac{1}{\lambda}I_n & 0 \\ I_n & 0 & 0 \\ 0 & 0 & I_m \end{bmatrix} (\lambda M - N)^T \begin{bmatrix} 0 & \frac{1}{\lambda}I_n & 0 \\ I_n & 0 & 0 \\ 0 & 0 & I_m \end{bmatrix}. \tag{23}$$

This shows that λ is a nonzero generalized eigenvalue for the EHP if and only if $\frac{1}{\lambda}$ is a generalized eigenvalue for the EHP.

3. By simple computation we may write the identity

$$\lambda M - N = \begin{bmatrix} I_n & 0 & 0 \\ -Q(\lambda I - A)^{-1} & I_n & 0 \\ -L^T(\lambda I - A)^{-1} & -\lambda B^T(I - \lambda A^T)^{-1} & I_m \end{bmatrix}$$

$$\times \begin{bmatrix} \lambda I - A & 0 & 0 \\ 0 & I - \lambda A^T & 0 \\ 0 & 0 & \Pi(\lambda) \end{bmatrix} \begin{bmatrix} I_n & 0 & -(\lambda I - A)^{-1}B \\ 0 & I_n & -(I - \lambda A^T)^{-1}(L + Q(\lambda I - A)^{-1}B) \\ 0 & 0 & I_m \end{bmatrix},$$

which proves assertion 3.

4. The following identity can be directly checked:

$$(M - \lambda N)\Xi(\lambda) = G(\lambda)\lambda(\lambda M - N)^T H(\lambda), \tag{24}$$

where

$$\Xi(\lambda) := \begin{bmatrix} \lambda I_n & 0 & 0 \\ 0 & \lambda I_n & 0 \\ 0 & 0 & I_m \end{bmatrix}, \qquad G(\lambda) := \begin{bmatrix} 0 & I_n & 0 \\ I_n & (1-\lambda)Q(I - \lambda A)^{-1} & 0 \\ 0 & (1-\lambda)L^T(I - \lambda A)^{-1} & I_m \end{bmatrix},$$

$$H(\lambda) := \begin{bmatrix} 0 & I_n & 0 \\ I_n & 0 & (\lambda - 1)(I - \lambda A)^{-1}B \\ 0 & 0 & I_m \end{bmatrix}.$$

Clearly $G(\lambda)$ and $H(\lambda)$ are regular at 0 (i.e., without null poles and zeroes). Denote by $n_{K(\lambda)}$ the number of null zeroes of the rational matrix $K(\lambda)$. Using the Smith–McMillan form of a rational matrix it can be easily seen (see also [26]) that

$$n_{\lambda(\lambda M - N)^T} = \pi_0 + \operatorname{rank}_{\mathbf{R}(\lambda)}(\lambda M - N) = \pi_0 + 2n + \rho, \tag{25}$$

where assertion 3. has been used. As both $G(\lambda)$ and $H(\lambda)$ are regular at 0, with (24) we get that

$$n_{\lambda(\lambda M - N)^T} \leq n_{M - \lambda N} + n_{\Xi(\lambda)},$$

and since $n_{\Xi(\lambda)} = 2n$ and $n_\infty = n_{M-\lambda N}$, we obtain with (25)

$$\pi_0 + 2n + \rho \leq n_\infty + 2n. \tag{26}$$

From (26) the conclusion follows immediately.

5. Since $\operatorname{rank}_{R(\lambda)}(\lambda M - N) = n_r + n_l + n_f^- + n_f^+ + n_f^0 + n_\infty = n_r + n_l + \tilde{n}_f^- + \pi_0 + n_f^+ + n_f^0 + n_\infty$ always, it follows from 1., 2., and 3. just proved above that $2n + \rho \geq 2n_r + 2n_f^- + \pi_0 + \rho + n_f^0$, from where $n \geq n_r + n_f^-$ and the equality holds if and only if $n_f^0 = 0$, $n_r = n_l$ and $n_\infty = \pi_0 + \rho$. □

COROLLARY 3.3. *The maximal dimension of a stable proper deflating subspace to the right of the EHP does not exceed n.*

Proof. This follows directly from assertion 4. of Theorem 3.2 combined with 1. of Theorem 2.2. □

Remark 4. If the EHP is regular, then assertion 4. of Theorem 3.2 reads $n_\infty = \pi_0 + m$, and thus the result stated in Proposition 3 in [13] is recovered. Indeed, (24) can be rewritten as

$$M - \lambda N = G(\lambda)(\lambda M - N)^T H(\lambda)\tilde{\Xi}(\lambda),$$

where

$$\tilde{\Xi}(\lambda) := \begin{bmatrix} I_n & 0 & 0 \\ 0 & I_n & 0 \\ 0 & 0 & \lambda I_m \end{bmatrix}.$$

Using arguments similar to those for assertion 4. in Theorem 3.2 we get

$$n_\infty \leq \pi_0 + n_{\tilde{\Xi}(\lambda)} = \pi_0 + m.$$

Since the EHP is regular, $\operatorname{rank}(\lambda M - N) = 2n + m = 2n + \rho$ and consequently $m = \rho$. Hence the conclusion follows by using assertion 4. in Theorem 3.2 in conjunction with the above inequality. □

Remark 5. Unlike the continuous case, where the corresponding assertions 1. and 4. stated in Theorem 3.2 are always expressed via equalities (see Theorem 2 in [17]), the discrete case is quite different. This is emphasized by the fact that sometimes 1. and 4. become strict inequalities, as is shown below.

Example. Let the Popov triplet be defined as $n = m = 1$, $A = 0, B = 0, Q = 0, L = 1, R = 0$. Then (see (13))

$$M = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \qquad N = \begin{bmatrix} 0 & 0 & 0 \\ 0 & -1 & 1 \\ 1 & 0 & 0 \end{bmatrix},$$

and by elementary row and column operations we get

$$\lambda M - N \sim \begin{bmatrix} \lambda & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

So $n_r = 0, n_l = 1, n_\infty = 1, \pi_0 = 0$ (in fact $n_f = 0$), and $\rho = 0$ because of $\Pi(\lambda) = 0$ (see (22)). Hence $n_l > n_r$ and $n_\infty > \rho + \pi_0$. □

Now a remarkable property of the stable proper deflating subspaces will be pointed out.

PROPOSITION 3.4. *Let $\mathcal{V}$ be any stable proper deflating subspace to the right for the EHP and*

$$V = [\underbrace{V_1^T}_{n} \; \underbrace{V_2^T}_{n} \; \underbrace{V_3^T}_{m}]^T$$

be any basis matrix for it. Then

$$V_1^T V_2 = V_2^T V_1. \tag{27}$$

Proof. The proof runs similarly to that in [13]. □

Suppose temporarily that the pair (A, B) has no null uncontrollable modes. Then we are in the position to formulate the following unicity result.

PROPOSITION 3.5. *Let $\mathcal{V}$ be a stable proper deflating subspace to the right of maximal dimension, i.e., $\dim \mathcal{V} = n_r + n_f^- > 0$, and let*

$$V = [\underbrace{V_1^T}_{n} \quad \underbrace{V_2^T}_{n} \quad \underbrace{V_3^T}_{m}]^T$$

be any basis matrix for $\mathcal{V}$. Then

$$\bar{\mathcal{V}} := \operatorname{Im} \begin{bmatrix} V_1 \\ V_2 \end{bmatrix} \subset \mathbf{R}^{2n} \tag{28}$$

does not depend on the choice of the maximal stable proper deflating subspace $\mathcal{V}$, i.e., it is uniquely determined.

Proof. Let

$$\begin{gathered} \bar{V} = \begin{bmatrix} V_1 \\ V_2 \end{bmatrix}, \quad \bar{A} = \begin{bmatrix} A & 0 \\ -Q & -I \end{bmatrix}, \quad \bar{B} = \begin{bmatrix} B \\ L \end{bmatrix}, \quad \bar{C} = \begin{bmatrix} L^T & 0 \end{bmatrix}, \quad \bar{D} = R, \\ \bar{E} = \begin{bmatrix} I & 0 \\ 0 & -A^T \end{bmatrix}, \quad \bar{G} = \begin{bmatrix} 0 & -B^T \end{bmatrix}, \end{gathered} \tag{29}$$

where $\bar{V}$ is clearly monic, as has been shown in the proof of Proposition 3.1 (see (17)). Then the EHP (13) can be written as

$$M = \begin{bmatrix} \bar{E} & 0 \\ \bar{G} & 0 \end{bmatrix}, \qquad N = \begin{bmatrix} \bar{A} & \bar{B} \\ \bar{C} & \bar{D} \end{bmatrix}, \tag{30}$$

and $[\frac{\bar{E}}{\bar{G}}]$ is monic. From (14) we get

$$\begin{bmatrix} \bar{A} \\ \bar{C} \end{bmatrix} \bar{V} + \begin{bmatrix} \bar{B} \\ \bar{D} \end{bmatrix} V_3 = \begin{bmatrix} \bar{E} \\ \bar{G} \end{bmatrix} \bar{V} S, \tag{31}$$

where obviously (see Definition 3)

$$\begin{bmatrix} \bar{E} \\ \bar{G} \end{bmatrix} \bar{V} \tag{32}$$

is monic and

$$\Lambda(S) \subset \mathbf{D}_1(0). \tag{33}$$

If $\bar{F} := V_3 \bar{V}^{\#}$, where $\bar{V}^{\#}$ is any left inverse of $\bar{V}$ ($\bar{V}$ is monic), then (31) finally yields

$$\begin{bmatrix} \bar{A} + \bar{B}\bar{F} \\ \bar{C} + \bar{D}\bar{F} \end{bmatrix} \bar{V} = \begin{bmatrix} E \\ G \end{bmatrix} \bar{V} S. \tag{34}$$

Note now that if $\bar{E} = I$ and $\bar{G} = 0$, then (34) with (33) expresses the usual condition that $\bar{\mathcal{V}}$ (defined by (28)) is a stable null output $(\bar{A}, \bar{B})$ invariant subspace of the system $(\bar{A}, \bar{B}, \bar{C}, \bar{D})$. Clearly $\bar{\mathcal{V}} \subset \mathbf{R}^{2n}$ is of maximal dimension since otherwise (34) would hold for a monic $\bar{V}$ with the rank greater than $n_f + n_f^-$, which contradicts the maximality of $\mathcal{V} \subset \mathbf{R}^{2n+m}$. As is well known, such a subspace is unique (see [27], [23]). Generalizing the above notion, we shall say that $\bar{\mathcal{V}}$, satisfying (34) with

(33), is a stable null output invariant subspace of the generalized descriptor system representation (M, N), with M and N written as in (30). Based on similar arguments as above, $\bar{\mathcal{V}}$ is of maximal dimension. As in the usual case, mentioned above, such a subspace is the supremal one of the family of subspaces with the properties (32), (33), (34) and consequently is unique (see Appendix A). □

DEFINITION 4. *The EHP is said to be dichotomic if* $n_f^0 = 0, n_r = n_l$, *and* $n_\infty = \rho + \pi_0$.

We have immediately the following proposition.

PROPOSITION 3.6. *The EHP is dichotomic if and only if it has a stable proper deflating subspace to the right of dimension* n.

Proof. Only if: According to 5. of Theorem 3.2 we have $n_r + n_f^- = n$. Following 1. of Theorem 2.2 a stable proper deflating subspace of dimension n for the EHP exists.

If: Following 1. of Theorem 2.2 we have $n \leq n_r + n_f^-$. Hence by 5. of Theorem 3.2 the equality holds, and $n_f^0 = 0$, $n_r = n_l$, and $n_\infty = \rho + \pi_0$. □

DEFINITION 5. *Let* $\mathcal{V}$ *be any stable proper deflating subspace to the right of dimension* σ *and*

$$V = [\underbrace{V_1^T}_{n} \quad \underbrace{V_2^T}_{n} \quad \underbrace{V_3^T}_{m}]^T$$

be any basis matrix for it. We call $\mathcal{V}$ *disconjugate if* V_1 *is monic.*

Note that

a) The notion of disconjugacy is well defined since Corollary 3.3 asserts that the number of columns of V_1 does not exceed n.

b) The notion of disconjugacy is independent of the choice of the basis matrix V for the (stable) proper deflating subspace. Indeed, if $\hat{V} = [\hat{V}_1^T \ \hat{V}_2^T \ \hat{V}_3^T]^T$ is another basis matrix, then clearly $\hat{V} = VG$ for an appropriate nonsingular $\sigma \times \sigma$ matrix G. Hence $\hat{V}_1 = V_1 G$ and the conclusion follows. Based on Proposition 3.6 we can introduce the following definition.

DEFINITION 6. *A dichotomic EHP is said to be disconjugate if it has a disconjugate (stable) proper deflating subspace to the right of dimension* n.

Remark 6. According to Proposition 3.6 the dichotomy of the EHP implies the existence of a stable proper deflating subspace to the right $\mathcal{V}$ of dimension n. Hence in accordance with Corollary 3.3 such a subspace is of maximal dimension. If

$$V = [\underbrace{V_1^T}_{n} \quad \underbrace{V_2^T}_{n} \quad \underbrace{V_3^T}_{m}]^T$$

is any basis matrix for $\mathcal{V}$, then, following Proposition 3.5, $\bar{\mathcal{V}} = \mathrm{Im}[V_1^T V_2^T]^T$ is unique. Consequently the disconjugacy is checked by checking the invertibility of V_1. If V_1 is singular, there is no other basis matrix V with V_1 nonsingular because of the uniqueness of $\bar{\mathcal{V}}$. Thus we can effectively check the disconjugacy of a dichotomic EHP. □

4. Main result. Now we are ready to state and prove our main result.

THEOREM 4.1. *The GDTRE* (1) *has a stabilizing solution* (r, X, V, F) *if and only if the EHP has a disconjugate proper deflating subspace.*

Proof. If: Let $\mathcal{V}$ be any disconjugate proper deflating subspace of dimension r with basis matrix

$$V = [\underbrace{V_1^T}_{n} \quad \underbrace{V_2^T}_{n} \quad \underbrace{V_3^T}_{m}]^T.$$

Then equations (16) are fulfilled for $S \in \mathbf{R}^{r\times r}$ stable since disconjugacy *pre*supposes the proper deflating subspace to be stable (see Definition 5). Let $X := V_2V_1^{\#}$ and $F := V_3V_1^{\#}$, where V_1 is any left inverse of V_1, which is monic because of disconjugacy. Then (16) provides

$$\begin{aligned} (A+BF)V_1 &= V_1S, \\ (Q-X+LF)V_1 &= -A^TXV_1S, \\ (L^T+RF)V_1 &= -B^TXV_1S. \end{aligned} \tag{35}$$

By eliminating V_1S in the first two equations (35), equation (1) with $V = V_1$ is easily obtained. This, together with the first equation in (35) and Proposition 3.4, which implies (see (27)) $V_1^TXV_1 = V_1^TV_2V_1^{\#}V_1 = V_1^TV_2 = V_2^TV_1 = V_1^T(V_1^T)^{\#}V_2^TV_1 = V_1^TX^TV_1$, prove the if part.

Only if: Let (r, X, V_1, F) be a stabilizing solution to (1). Then by taking

$$\begin{bmatrix} V_1 \\ V_2 \\ V_3 \end{bmatrix} = \begin{bmatrix} V_1 \\ XV_1 \\ FV_1 \end{bmatrix}$$

it can be easily checked that (16) holds, i.e., (14) holds and MV is monic since V_1 is monic as follows from

$$MV = \begin{bmatrix} V_1 \\ -A^TV_2 \\ -B^TV_2 \end{bmatrix}. \qquad \square$$

From Theorem 4.1 we immediately derive the following corollary.

COROLLARY 4.2. *The CDTARE* (3) (*or* (4)) *has a stabilizing solution if and only if the EHP is disconjugate.*

5. Constrained dynamics with quadratic cost. Let Σ be a Popov triplet and associate with it the following:

1) the linear (discrete) system

$$\sigma x = Ax + Bu \tag{36}$$

and the quadratic cost

$$J = \sum_{k=0}^{\infty} \begin{bmatrix} x_k \\ u_k \end{bmatrix}^T \begin{bmatrix} Q & L \\ L^T & R \end{bmatrix} \begin{bmatrix} x_k \\ u_k \end{bmatrix} \tag{37}$$

with x_k and u_k linked by (36);

2) the GDTARE (1) written in explicit form, for $V = V_1$:

$$(A^TXA - X + Q)V_1 + (A^TXB + L)FV_1 = 0, \tag{38}$$

$$(L^T + B^TXA)V_1 + (R + B^TXB)FV_1 = 0. \tag{39}$$

Assume that the GDTARE has a stabilizing solution (r, X, V_1, F); that is, (38) and (39) both hold

$$X_1 := V_1^T X V_1 = V_1^T X^T V_1 = X_1^T \tag{40}$$

and

$$(A + BF)V_1 = V_1 S \tag{41}$$

with $S \in \mathbf{R}^{r\times r}$ stable. Following Remark 1, $\mathcal{V}_1 = \mathrm{Im}V_1$ is a stable (A, B) invariant subspace of dimension r. Hence, for any initial condition placed in $\mathcal{V}_1$ and an appropriate control input $u \in l^2(\mathbf{N}; \mathbf{R}^m)$ we can force the system (36) to have its evolution entirely contained in $\mathcal{V}_1$ and exponentially approaching zero as k approaches infinity. Thus we can write

$$V_1\sigma\xi = AV_1\xi + Bu. \tag{42}$$

In this section, we shall evaluate, in terms of the GDTARE (1), the quadratic cost (37) along the trajectories described by (42) with $u \in l^2(\mathbf{N}, \mathbf{R}^m)$, i.e., along those trajectories located in $\mathcal{V}_1$ and which exponentially approach the origin. To this end, let us introduce the following notations:

$$Q_1 = V_1^T Q V_1, \quad L_1 = V_1^T L, \quad F_1 = FV_1. \tag{43}$$

With (43) and (41), (38) and (39) become

$$A^T X V_1 S - X V_1 + Q V_1 + L F_1 = 0, \tag{44}$$

$$L_1^T + B^T X V_1 S + R F_1 = 0. \tag{45}$$

Premultiplying (44) by V_1^T and taking into account the transpose of (41) we get

$$S^T X_1 S - F_1^T B^T X V_1 S - X_1 + Q_1 + L_1 F_1 = 0. \tag{46}$$

Premultiplying (45) by F_1^T one obtains

$$F_1^T L_1^T + F_1^T B^T X V_1 S + F_1^T R F_1 = 0. \tag{47}$$

With $F_1^T B^T X V_1 S$ substituted from (47) in (46) we have further

$$S^T X_1 S - X_1 + Q_1 + L_1 F_1 + F_1^T L_1^T + F_1^T R F_1 = 0. \tag{48}$$

Remark 7. Let V_1 be nonsingular. Then without loss of generality we may take $V_1 = I_n$ in (38), (39), and (41), and (48) becomes

$$(A + BF)^T X (A + BF) - X + Q + LF + F^T L^T + F^T R F = 0 \tag{49}$$

with $A + BF$ stable. But (49) is exactly the "closed loop" form of the (constrained) Riccati equation. □

Now we are ready to state the main result of this section.

PROPOSITION 5.1. *Suppose that the GDTARE has a stabilizing solution. Then the quadratic cost* (37) *evaluated for those pairs* $(\xi, u) \in l^2(\mathbf{N}; \mathbf{R}^r) \times l^2(\mathbf{N}; \mathbf{R}^m)$ *linked by* (42) *has the expression*

$$J = \xi_0^T X_1 \xi_0 + \langle u - F_1\xi, (R + B^T X B)(u - F_1\xi)\rangle, \tag{50}$$

where $\xi_0 := \xi(0)$. *If the "positivity condition"* $R + B^T X B \geq 0$ *holds, then the minimum of* J *over* u *is attained (nonuniquely) for* $u = F_1\xi$. *Such a feedback provides also stabilization with respect to the stable* (A, B) *invariant subspace* $\mathcal{V}_1$.

Proof. See Appendix B for the proof. □

6. Conclusions. Necessary and sufficient conditions for the existence of the stabilizing solution to the GDTARE have been given. These conditions are expressed in terms of the disconjugacy of proper (stable) deflating subspaces associated with the EHP. The basic results concerning the CDTARE, intensively used in nonstandard factorizations, are easily recovered and enlarged. An evaluation of the quadratic index along constrained stable trajectories was also given in terms of the stabilizing solution of the associated GDTARE. Based on the above results, a numerically reliable method for computing the stabilizing solution of the GDTARE and CDTARE is proposed in [22]. The method uses the algorithms for computing the generalized Schur form of a singular pencil developed in [7], [8] and the refinements in [4]. Applications of the developed theory can be found in [18] and in a forthcoming paper dealing with singular H^2 optimal control.

Appendix A. Supremal stable null output invariant subspace of the generalized descriptor system representation. Let (M, N) be a matrix pair defined by

$$M = \begin{bmatrix} E & 0 \\ G & 0 \end{bmatrix}, \qquad N = \begin{bmatrix} A & B \\ C & D \end{bmatrix} \tag{A.1}$$

and termed a *generalized descriptor system representation.* Assume that $\left[\begin{smallmatrix} E \\ G \end{smallmatrix}\right]$ is monic.

DEFINITION A1. *A subspace $\mathcal{V} \subset \mathbf{R}^n$ is called a null output invariant subspace of the system pair (M, N), represented by* (A.1), *if*

$$\begin{bmatrix} A \\ C \end{bmatrix} \mathcal{V} \subset \begin{bmatrix} E \\ G \end{bmatrix} \mathcal{V} + \operatorname{Im} \begin{bmatrix} B \\ D \end{bmatrix}. \tag{A.2}$$

The family of all such subspaces will be denoted by $\mathbf{I}(M, N)$.

Clearly

$$\begin{bmatrix} E \\ G \end{bmatrix} V \text{ is monic} \tag{A.3}$$

for any basis matrix V of $\mathcal{V}$ and $\mathbf{I}(M, N) \neq \emptyset$ because it contains $\mathbf{R}^n$.

Note that

a) If $E = I$ and $G = 0$, then the usual definition of the null output (A, B) invariant subspace encountered in [23] and [27] is recovered. It corresponds to the usual system representation $\sigma x = Ax + Bu, y = Cx + Du$.

b) If $G = 0$, then the above notion is adapted to the usual descriptor system representation $E\sigma x = Ax + Bu, y = Cx + Du$.

As has been noted in the previous sections, the notion introduced by Definition A1 is associated with the (discrete) Hamiltonian systems (12) (with $v = 0$), which simultaneously incorporates both forward and backward time evolutions.

Let $\mathcal{V} \subset \mathbf{I}(M, N)$, with $\dim \mathcal{V} = \rho$, and $V \in \mathbf{R}^{n \times \rho}$ be any basis matrix of $\mathcal{V}$. Then (A.2) is equivalent to

$$\begin{bmatrix} A \\ C \end{bmatrix} V = \begin{bmatrix} E \\ G \end{bmatrix} VS - \begin{bmatrix} B \\ D \end{bmatrix} H \tag{A.4}$$

for adequate $S \in \mathbf{R}^{\rho \times \rho}$ and $H \in \mathbf{R}^{m \times \rho}$. Since V is monic, let

$$F = HV^{\#}, \tag{A.5}$$

where $V^{\#}$ is any left inverse of V. Then (A.4) reduces to

$$\begin{bmatrix} A+BF \\ C+DF \end{bmatrix} V = \begin{bmatrix} EV \\ GV \end{bmatrix} S, \tag{A.6}$$

which is also equivalent to

$$\begin{bmatrix} A+BF \\ C+DF \end{bmatrix} \mathcal{V} \subset \begin{bmatrix} E \\ G \end{bmatrix} \mathcal{V} \tag{A.7}$$

and where (A.3) automatically holds.

Let $\mathbf{F}(M,N,\mathcal{V}) = \{ F : \text{(A.7) is true} \}$. Clearly $\mathcal{V} \subset \mathbf{I}(M,N)$ if and only if $\mathbf{F}(M,N,\mathcal{V}) \neq \emptyset$.

In order to emphasize the structural aspects related to Definition A1, we have to perform several strict equivalence operations on the (singular) matrix pencil $\lambda M - N$. Let $F_1 \in F(M,N,\mathcal{V})$, define the nonsingular matrix

$$Z_1 = \begin{bmatrix} I_n & 0 \\ F_1 & I_m \end{bmatrix}, \tag{A.8}$$

and consider the strict equivalent pencil $\lambda M_1 - N_1 \sim \lambda M - N$ defined via

$$M_1 = MZ_1 = \begin{bmatrix} E & 0 \\ G & 0 \end{bmatrix}, \qquad N_1 = NZ_1 = \begin{bmatrix} A+BF_1 & B \\ C+DF_1 & D \end{bmatrix}. \tag{A.9}$$

Introduce now the nonsingular matrix

$$Z_2 = \begin{bmatrix} V & W & 0 \\ 0 & 0 & I_m \end{bmatrix} = \begin{bmatrix} \tilde{V} & 0 \\ 0 & I_m \end{bmatrix}, \tag{A.10}$$

where W is any completion of V (which is monic) up to a nonsingular matrix $\tilde{V} = [V\ W]$. Consider the decomposition

$$\operatorname{Im} \begin{bmatrix} B \\ D \end{bmatrix} = \operatorname{Im} \begin{bmatrix} B \\ D \end{bmatrix} \cap \operatorname{Im} \begin{bmatrix} EV \\ GV \end{bmatrix} \oplus \operatorname{Im} \begin{bmatrix} \tilde{B} \\ \tilde{D} \end{bmatrix}, \tag{A.11}$$

and introduce the nonsingular matrix

$$Q_2 = \begin{bmatrix} EV & E_1 \\ GV & G_1 \end{bmatrix}, \tag{A.12}$$

where the completion $\left[\begin{smallmatrix} E_1 \\ G_1 \end{smallmatrix}\right]$ of the monic matrix $\left[\begin{smallmatrix} EV \\ GV \end{smallmatrix}\right]$ (see (A.3)) is chosen such that

$$\operatorname{Im} \begin{bmatrix} \tilde{B} \\ \tilde{D} \end{bmatrix} \subset \operatorname{Im} \begin{bmatrix} E_1 \\ G_1 \end{bmatrix}. \tag{A.13}$$

Let now $\lambda M_2 - N_2 \sim \lambda M_1 - N_1$ be defined as $M_2 = Q_2 M_1 Z_2$ and $N_2 = Q_2 N_1 Z_2$. Then according to (A.6), where $F = F_1$, (A.11) and (A.13), we get

$$M_2 = \begin{bmatrix} & \overbrace{}^{n-\rho} & \overbrace{}^{m} \\ I_\rho & x & 0 \\ 0 & x & 0 \end{bmatrix}, \qquad N_2 = \begin{bmatrix} \overbrace{}^{\rho} & \overbrace{}^{n-\rho} & \overbrace{}^{m_1} & \overbrace{}^{m_2} \\ S & x & B_1 & 0 \\ 0 & T & 0 & D_1 \end{bmatrix}, \tag{A.14}$$

where D_1 can be chosen to be monic as easily can be remarked. It can be also easily checked that for

$$\hat{Z}_3 = \begin{bmatrix} I_n & 0 \\ F_3 & I_m \end{bmatrix} \tag{A.15}$$

the strict equivalence $\lambda M_2 - N_2 \sim \lambda M_2 \hat{Z}_3 - N_2 \hat{Z}_3$ preserves the structure of (A.14) if and only if

$$F_3 = \begin{bmatrix} F_{3,11} & F_{3,12} \\ 0 & F_{3,22} \end{bmatrix}, \tag{A.16}$$

as follows from the fact that $D_1 F_{3,21} = 0 \Leftrightarrow F_{3,21} = 0$ since D_1 is monic. Note now that with (A.8), (A.10), and (A.15) we have

$$Z_1 Z_2 \hat{Z}_3 = \begin{bmatrix} I & 0 \\ F_1 & I_m \end{bmatrix} \begin{bmatrix} \tilde{V} & 0 \\ 0 & I_m \end{bmatrix} \begin{bmatrix} I & 0 \\ F_3 & I \end{bmatrix} = \begin{bmatrix} \tilde{V} & 0 \\ F_1 \tilde{V} + F_3 & I_m \end{bmatrix}$$

$$= \begin{bmatrix} I_n & 0 \\ F & I_m \end{bmatrix} \begin{bmatrix} \tilde{V} & 0 \\ 0 & I_m \end{bmatrix}, \tag{A.17}$$

where $F\tilde{V} = F_1 \tilde{V} + F_3$, i.e., $F = F_1 + F_3 \tilde{V}^{-1}$. Thus $\mathbf{F} = \{F_1 + F_3 \tilde{V}^{-1} : F_3$ of the form (A.16) $\}$ and for any F_1 for which (A.6) holds, i.e., determined via (A.5).

Remark A1. Equality (A.17) shows that any successive product of matrices of type (A.8) and (A.10) reduces to the product of *two* matrices of type (A.8) and (A.10). In the usual cases this expresses the well-known feedback and coordinate changing operations. □

Since $\lambda M_2 - N_2 \sim \lambda M - N$, (A.14) shows that $\Lambda(S)$ is a subset of the set of finite generalized eigenvalues of the pencil $\lambda M - N$, and we shall write $\Lambda(S) = \Lambda((M, N)|\mathcal{V})$.

DEFINITION A2. *$\mathcal{V} \in \mathbf{I}(M, N)$ is said to be stable if $\Lambda((M, N)|\mathcal{V})$ is located in $\mathbf{D}_1(0)$.*

Let $\mathbf{I}_s = \{\mathcal{V} : \mathcal{V} \in \mathbf{I}$ and stable$\}$. Since if $\mathcal{V}_1, \mathcal{V}_2 \in \mathbf{I}(M, N)$, then $\mathcal{V}_1 + \mathcal{V}_2 \in \mathbf{I}(M, N)$, as directly follows from (A.2), we conclude that $\mathbf{I}(M, N)$ has a (unique) supremal element denoted $\mathcal{V}^* = \sup \mathbf{I}(M, N)$. Following a scheme of proof similar to that in [27] we have that $\lim \mathcal{V}_k = \mathcal{V}^*$ for the sequence $\mathcal{V}_k$ defined by

$$\mathcal{V}_{k+1} = \begin{bmatrix} A \\ C \end{bmatrix}^{-1} \left(\begin{bmatrix} E \\ G \end{bmatrix} \mathcal{V}_k + \operatorname{Im} \begin{bmatrix} B \\ D \end{bmatrix} \right), \quad \mathcal{V}_0 = \mathbf{R}^n, \quad k \geq 0. \tag{A.18}$$

We are now interested in finding $\mathcal{V}_s^* := \sup \mathbf{I}_s(M, N)$. To this end consider the structure (A.14), where $\rho = \dim \mathcal{V}^*$. For the pair (S, B_1) apply the controllable decomposition, that is,

$$TST^{-1} = \begin{bmatrix} S_{11} & S_{12} \\ 0 & S_{22} \end{bmatrix}, \qquad TB_1 = \begin{bmatrix} B_{11} \\ 0 \end{bmatrix}, \tag{A.19}$$

where (S_{11}, B_{11}) is controllable. Let

$$Q_3 = \begin{bmatrix} T & 0 \\ 0 & I_{n+p-\rho} \end{bmatrix}, \qquad Z_3 = \begin{bmatrix} T & 0 \\ 0 & I_{n+m-\rho} \end{bmatrix}, \tag{A.20}$$

and consider $\lambda M_3 - N_3 \sim \lambda M_2 - N_2$ with $M_3 = Q_3 M_2 Z_3$ and $N_3 = Q_3 N_2 Z_3$. Then

$$\text{(A.21)}\quad M_3 = \begin{bmatrix} I_{\rho_1} & 0 & x & 0 \\ 0 & I_{\rho_2} & x & 0 \\ 0 & 0 & x & 0 \end{bmatrix}, \qquad N_3 = \begin{bmatrix} S_{11} & S_{12} & x & B_{11} & 0 \\ 0 & S_{22} & x & 0 & 0 \\ 0 & 0 & x & 0 & D_1 \end{bmatrix}.$$

Now, following the same argument as in [27], we have

$$\text{(A.22)}\qquad \mathcal{V}^* \supset V_s^* = \langle S_{11} | \mathrm{Im} B_{11} \rangle \oplus \chi^-(S_{22}),$$

where $\langle S_{11} | \mathrm{Im} B_{11} \rangle$ is the controllable subspace of the pair (S_{11}, B_{11}) and $\chi^-(S_{22})$ is the stable subspace of S_{22}, i.e., $\chi^-(S_{22}) = \ker \mu^-(\lambda)$, where $\mu(\lambda) = \mu^-(\lambda)\mu^+(\lambda)$ is the factorization of the minimal polynomial $\mu(\lambda)$ of S_{22} with respect to the unit circle. Here the roots of $\mu^-(\lambda)$ are in $\mathbf{D}_1(0)$.

Appendix B. Proof of Proposition 5.1. Suppose the GDTARE (1) (or equivalently the system (38)–(39)) has a stabilizing solution (r, X, V_1, F). Then using (41), (42) becomes

$$\text{(B.1)}\qquad V_1 \sigma\xi = V_1 S\xi - BF_1\xi + Bu,$$

and premultiplying both sides of the above equation by $V_1^T X^T$ we get (see (40))

$$\text{(B.2)}\qquad X_1 \sigma\xi = X_1 S\xi - V_1^T X^T BF_1\xi + V_1^T X^T Bu.$$

Now we are ready to evaluate the quadratic cost (37) for those pairs $(\xi, u) \in l^2(\mathbf{N}; \mathbf{R}^r) \times l^2(\mathbf{N}; \mathbf{R}^m)$ linked by (42) (or equivalently (B.2)). First we can write

$$J = \sum_{k=0}^{\infty} \begin{bmatrix} \xi_k \\ u_k \end{bmatrix}^T \begin{bmatrix} Q_1 & L_1 \\ L_1^T & R \end{bmatrix} \begin{bmatrix} \xi_k \\ u_k \end{bmatrix} = \left\langle \begin{bmatrix} \xi \\ u \end{bmatrix}, \begin{bmatrix} Q_1 & L_1 \\ L_1^T & R \end{bmatrix} \begin{bmatrix} \xi \\ u \end{bmatrix} \right\rangle,$$

where $x = V_1\xi$ and (43) have been used. Then with (48) and (45), we have the evaluation

$$\begin{bmatrix} \xi \\ u \end{bmatrix}^T \begin{bmatrix} Q_1 & L_1 \\ L_1^T & R \end{bmatrix} \begin{bmatrix} \xi \\ u \end{bmatrix} = \xi^T Q_1 \xi + 2u^T L_1^T \xi + u^T Ru$$

$$= \xi^T(-S^T X_1 S + X_1 - L_1 F_1 - F_1^T L_1^T - F_1^T R F_1)\xi + 2u^T(-B^T X V_1 S - RF_1)\xi + u^T Ru$$

$$= -\xi^T S^T X_1 S\xi + \xi^T X_1 \xi + \xi^T (F_1^T R + S^T V_1^T X^T B) F_1 \xi + \xi^T F_1^T (B^T X V_1 S + RF_1)\xi$$

$$-2u^T(B^T X V_1 S + RF_1)\xi + u^T Ru - \xi^T F_1^T R F_1 \xi$$

$$= -\xi^T S^T X_1 S\xi + \xi^T X_1 \xi + 2\xi^T S^T V_1^T X^T B F_1 \xi - 2u^T B^T X V_1 S\xi + (u - F_1\xi)^T R(u - F_1\xi)$$

$$\overset{(B2)}{=} (-(\sigma\xi)^T X_1 - \xi^T F_1^T B^T X V_1 + u^T B^T X V_1) S\xi + \xi^T X_1 \xi + 2\xi^T S^T V_1^T X^T B F_1 \xi$$

$$-2u^T B^T X V_1 S\xi + (u - F_1\xi)^T R(u - F_1\xi)$$

$$= -(\sigma\xi)^T X_1 S\xi + \xi^T F_1^T B^T X V_1 S\xi - u^T B^T X V_1 S\xi + \xi^T X_1 \xi + (u - F_1\xi)^T R(u - F_1\xi)$$

$$\overset{(B2)}{=} -(\sigma\xi)^T (X_1\sigma\xi + V_1^T X^T B F_1\xi - V_1^T X^T B u) + \xi^T F_1^T B^T X V_1 S\xi - u^T B^T X V_1 S\xi$$

$$+\xi^T X_1 \xi + (u - F_1\xi)^T R(u - F_1\xi)$$

$$= -(\sigma\xi)^T X_1\sigma\xi + \xi^T X_1\xi + \xi^T F_1^T B^T X(-V_1\sigma\xi + V_1 S\xi) + u^T B^T X(V_1\sigma\xi - V_1 S\xi)$$

$$+(u - F_1\xi)^T R(u - F_1\xi)$$

$$\overset{(B1)}{=} -(\sigma\xi)^T X_1\sigma\xi + \xi^T X_1\xi + \xi^T F_1^T B^T X(BF_1\xi - Bu) + u^T B^T X(Bu - BF_1\xi)$$

$$+(u - F_1\xi)^T R(u - F_1\xi)$$

$$= -(\sigma\xi)^T X_1\sigma\xi + \xi^T X_1\xi + \xi^T F_1^T B^T X B F_1\xi - \xi^T F_1^T B^T X B u - u^T B^T X B F_1\xi$$

$$+u^T B^T X B u + (u - F_1\xi)^T R(u - F_1\xi)$$

$$= -(\sigma\xi)^T X_1\sigma\xi + \xi^T X_1\xi + (u - F_1\xi)^T R(u - F_1\xi) + (u - F_1\xi)^T (B^T X B)(u - F_1\xi)$$

$$= -(\sigma\xi)^T X_1\sigma\xi + \xi^T X_1\xi + (u - F_1\xi)^T (R + B^T X B)(u - F_1\xi). \tag{B.3}$$

As $\xi \in l^2(\mathbf{N}; \mathbf{R}^r)$, then $\langle \xi, X_1\xi\rangle - \langle \sigma\xi, X_1\sigma\xi\rangle = \xi_0^T X_1 \xi_0$. Hence it follows from (B.3) that

$$J = \xi_0^T X_1 \xi_0 + \langle u - F_1\xi, (R + B^T X B)(u - F_1\xi)\rangle. \tag{B.4}$$

From (B.4) the conclusion follows immediately.

Acknowledgments. After the review process was completed, Dr. Martin Weiss drew our attention to the fact that the absence of null uncontrollable modes for the pair (A, B) is in fact not necessary for proving that the disconjugacy of a maximal proper deflating subspace to the EHP does not depend on the particular choice of the maximal proper deflating subspace. Moreover, the proof of Proposition 3.5 can be considerably simplified.

APPROXIMATION OF THE ZAKAI EQUATION FOR NONLINEAR FILTERING*

KAZUFUMI ITO†

Abstract. In this paper we consider numerical approximations of solutions to the Zakai equation. Time discretization based on the implicit Milshtein and Euler methods and Galerkin approximation in the spatial coordinates are investigated. Convergence and rate of convergence of approximation methods are established.

Key words. Zakai equation, numerical approximations

AMS subject classifications. 60H15, 65M10, 93E11

1. Introduction.

In this paper we consider approximations of solutions to the Zakai equation of the form

$$dp(t) + A(y(t))p(t)\,dt = B(y(t))p(t)\,dy(t), \quad p(0) = p_0 \in L^2(R^d), \tag{1.1}$$

where $p(t) = p(t,x)$ is the nonnormalized conditional probability density function appearing in nonlinear filtering problem as follows. A signal process $x(t) \in R^d$ satisfies the Ito stochastic differential equation

$$dx(t) = g(x(t), y(t))\,dt + \sigma(x(t))\,dw_1(t), \quad x(0) = x, \tag{1.2}$$

and the observation process $y(t) \in R^p$ is given by

$$dy(t) = h(x(t))\,dt + b(y(t))\,dw_1(t) + dw_2(t), \quad y(0) = 0. \tag{1.3}$$

The dependency of the drift term g on y accounts for output feedback of the observation $y(t)$. Let $(\Omega, \mathcal{F}, P)$ be the probability space with an increasing family of sub-σ-algebras $\{\mathcal{F}_t\}$ of $\mathcal{F}$ is right continuous and complete with respect to the probability measure P. Assume that $w_1(t)$, $w_2(t)$ are $\mathcal{F}_t$-adapted independent Wiener processes with covariance I and R, respectively. The initial condition x is a R^d-valued, $\mathcal{F}_0$-measurable random variable with probability density $p_0(x)$. Suppose $b(y) = 0$; then the signal process and the observation process are uncorrelated. Assume that the functions g, σ, h, and b are bounded and that g, σ, and b are Lipschtz. A core of the Zakai theory (e.g., see [Be], [Pa], [Ro]) is that the conditional expectation of $\phi(x(t))$ based on the observations $\{y(s),\ 0 \le s \le T\}$ is given by

$$E\left[\phi(x(t))|y(s),\ 0 \le s \le t\right] = \frac{\int \phi(x)p(t,x)\,dx}{\int p(t,x)\,dx}. \tag{1.4}$$

The Zakai theory is based on the change of probability measure [Be], [Ro]. Let $\eta(t)$ be a stochastic process defined by

$$\eta(t) = \exp\left(-\int_0^t h^*(x)D(y)^{-1}(b(y)\,dw_1(s) + dw_2(s)) \right.$$
$$\left. -\frac{1}{2}\int_0^t h^*(x)D(y)^{-1}h(x)\,ds\right),$$

where $D(y) = R + b(y)b(y)^*$. Define a probability measure $\tilde{P}$ on $(\Omega, \mathcal{F})$ by

$$\left.\frac{d\tilde{P}}{dP}\right|_{\mathcal{F}_t} = \eta(t).$$

Then the observation process $y(t)$ becomes an $\mathcal{F}_t$-adapted Wiener process with covariance D on $(\Omega, \mathcal{F}, \tilde{P})$. Henceforth, $\tilde{E}$ denotes the expectation with respect to $\tilde{P}$. The linear operators $A = A(y)$ and $B = B(y)$ appearing in (1.1) are defined by

$$-A\phi = \frac{\partial}{\partial x_i}\left(a_{i,j}\frac{\partial}{\partial x_j}\phi\right) - \frac{\partial}{\partial x_i}(a_i\phi) \tag{1.5}$$

and

$$B\phi = hD^{-1}\phi - \frac{\partial}{\partial x_i}(c_i\phi),$$

where

$$c = \sigma b^* D^{-1}, \quad a = \frac{1}{2}\sigma\sigma^* + \frac{1}{2}cDc^*, \quad \text{and} \quad a_i = g_i - \frac{\partial}{\partial x_j}a_{i,j}.$$

As in [Be], [Pa], [Ro] we employ the variational formulation of (1.1). Let $H = L^2(R^d)$ and $V = H^1(R^d)$, and V^* denotes the strong dual space of V. H^* is identified with H so that $V \subset H = H^* \subset V^*$. We define the inner product $(\cdot, \cdot)$ of H by

$$(\phi, \psi) = \int_{R^d} \phi(x)\psi(x)\,dx.$$

The dual product of $V^* \times V$ is denoted by $\langle \cdot, \cdot \rangle$. Let $H_k(x)$, $k \geq 0$, be the Hermite polynomials on R. Then a family of functions

$$e_k(x) = \prod_{i=0}^{d} \exp(-x_i^2/2)H_{k_i}(x_i), \quad k = (k_1, \ldots, k_d) \in N^d \tag{1.6}$$

forms the orthogonal basis of $L^2(R^d)$. If for $\phi \in V$ we define

$$\phi^n(x) = \sum_{k \in J} (\phi, e_k)\, e_k(x),$$

where $J = [0, n]^d \in N^d$, then $|\phi^n - \phi|_V \to 0$ as $n \to \infty$. Then we have that for $\phi, \psi \in V$

$$\langle A\phi, \psi \rangle = \lim (A\phi^n, \psi) = \lim (A_0\nabla\phi^n - a\phi^n, \nabla\psi) = \langle A_0\nabla\phi - a\phi, \nabla\psi \rangle, \tag{1.7}$$

where A_0 denotes the symmetric matrix $\{a_{i,j}\}$ on R^d. We assume that there exists a constant $\alpha > 0$ such that

$$x^* A_0 x \geq \alpha |x|^2 \quad \text{for all } x \in R^d,\ y \in R^p. \tag{1.8}$$

Hence $A = A(y) \in \mathcal{L}(V, V^*)$, and if $\sigma\sigma^*$ is coercive uniformly in x and y, then there exist positive constants ρ and β such that

(1.9)

$$\langle A(y)\phi, \phi \rangle - \frac{1}{2}|B(y)\phi|_D^2 + \rho|\phi|_H^2 \geq \frac{1}{2}\beta|\phi|_V^2 \quad \text{for all } \phi \in V \text{ and uniformly in } y,$$

where $|\phi|_V^2 = (\nabla\phi, \nabla\phi) + |\phi|_H^2$ and $|B\phi|_D^2 = \int (B\phi)D(y)(B\phi)^* \, dx$.

An outline of our paper is as follows. In §2 we consider an approximation scheme (2.1) in which the backward Euler scheme is used to discretize (1.1) in time and the operators A, B are approximated by a sequence of stable and consistent approximations (see (A1)–(A3)), and its convergence properties are established. For the uncorrelated case a higher-order approximation based on the Milshtein scheme [Mi] is discussed in §3. The convergence rate of both schemes is established in §4. In §3 we also consider the robust form of the Zakai equation for the uncorrelated case. Finally, we apply our results to the spectral method based on the Hermite polynomials.

We refer to [BGR], [FL], [Pi] for time-discretization schemes for the Zakai equation. In [BGR], [FL] the operator splitting method is used to split up the deterministic and stochastic evolutions (see also §3). Numerical experiments based on the methods described in this paper will be reported in a forthcoming paper.

2. Implicit Euler approximation. In this section we consider the following approximation method of (1.1); for $n, m \in N$ the sequence $\{p_{m,n}^k\}$ is generated by

$$p^k - p^{k-1} + \lambda (A^n(y_{k-1}) + \rho I)p^k = \lambda\rho\, p^{k-1} + B^n(y_{k-1})p^{k-1}(y_k - y_{k-1}), \tag{2.1}$$

where $\lambda = T/m$, $y_k = y(k\lambda)$, and the pair of linear operators $(A^n(y), B^n(y))$ satisfies the approximation conditions:

$$\text{(A1)} \quad |A^n(y)\phi|_{V^*} \le \gamma\,|\phi|_V \quad \text{and} \quad |B^n(y)\phi|_H \le \gamma\,|\phi|_V \quad \text{uniformly in } n \text{ and } y \in R^p,$$

$$\text{(A2)} \quad \langle A^n(y)\phi, \phi\rangle - \frac{1}{2}|B^n(y)\phi|_D^2 + \rho\,|\phi|_H^2 \ge \frac{1}{2}\beta\,|\phi|_V^2 \quad \text{for all } \phi \in V \text{ and } y \in R^p,$$

$$\text{(A3)} \quad |A^n(y)\phi - A(y)\phi|_{V^*} + |B^n(y)\phi - B(y)\phi|_H \to 0 \text{ as } n \to \infty \text{ for all } \phi \in V \text{ and } y \in R^p.$$

For ease of presentation $A(y_{k-1})$ and $B(y_{k-1})$ will be denoted simply by A and B, respectively, throughout the paper. Similarly, the dependency of (A^n, B^n) on $y(\cdot)$ will be suppressed and understood from the context of our discussions. Let $S = (\Omega \times [0,T], \mathcal{F} \times \mathcal{B}, d\tilde{P} \times dt)$. Then we have the convergence theory.

THEOREM 2.1. *Assume that a family of linear operators (A^n, B^n) and initial conditions p_0^n satisfy the conditions* (A1)–(A3) *and $|p_0^n - p_0|_H \to 0$ as $n \to \infty$, respectively. Then the sequence $\{p_{m,n}^k\}$ generated by* (2.1) *with initial condition p_0^n converges to the unique solution $p(t)$ of* (1.1) *as $m,\ n \to \infty$ in the sense that the function $p_{m,n}(t)$ defined by*

$$p_{m,n}(t) = p_{m,n}^k \quad \text{on } [k\lambda, (k+1)\lambda)$$

converges to $p(t)$ strongly in $L^2(S;V)$ and weakly star in $L^\infty(0,T;L^2(\Omega,H,d\tilde{P}))$.

Proof. We prove the theorem in two steps. First we show convergence of the sequence $\{p^k\}$ generated by

$$p^k - p^{k-1} + \lambda (A + \rho I)p^k = \lambda\rho\, p^{k-1} + Bp^{k-1}(y_k - y_{k-1}) \tag{2.2}$$

to the unique solution $p(t)$ of (1.1) provided that (1.9) holds. Define a linear operator A_ρ by $A + \rho I$. Then from (1.9) $J_\lambda = (I + \lambda A_\rho)^{-1} \in \mathcal{L}(V^*, V)$. Thus, given V-valued random variable x, the equation

$$\hat{x} - x + \lambda A_\rho \hat{x} = \lambda\rho\, x + Bx\,\Delta y \tag{2.3}$$

has a unique solution $\hat{x} = J_\lambda((1+\lambda\rho)x + Bx\,\Delta y))$, where $\Delta y = y_k - y_{k-1}$ is a R^p-valued random variable with mean 0 and covariance λD that is independent of x. Multiplying (2.3) by $\hat{x}$,

$$(\hat{x} - (1+\lambda\rho)x,\, \hat{x}) + \lambda\,\langle A_\rho \hat{x},\, \hat{x}\rangle = (Bx\,\Delta y,\, \hat{x}).$$

Completing the square,

$$\frac{1}{2}(\,|\hat{x}|_H^2 - (1+\lambda\rho)^2\,|x|_H^2 + |\hat{x} - (1+\lambda\rho)x|_H^2\,) + \lambda\,\langle A_\rho\hat{x},\, \hat{x}\rangle = (Bx\,\Delta y,\, \hat{x}).$$

Let $z = (1+\lambda\rho)x + Bx\,\Delta y$. Then $\hat{x} = J_\lambda z$ and

$$\begin{aligned} |J_\lambda z - z|_H^2 &= |\hat{x} - (1+\lambda\rho)x - Bx\,\Delta y|_H^2 \\ &= |\hat{x} - (1+\lambda\rho)x|_H^2 - 2\,(Bx\,\Delta y,\, \hat{x} - (1+\lambda\rho)x) + |Bx\,\Delta y|_H^2. \end{aligned}$$

Note that $\tilde{E}\,(Bx\,\Delta y,\, x) = 0$ since x and Δy are independent. Hence, combining the above equalities, we obtain

$$\frac{1}{2}\,(\tilde{E}|\hat{x}|_H^2 - (1+\lambda\rho)^2\,\tilde{E}|x|_H^2) + \lambda\,\tilde{E}\left(\langle A_\rho\hat{x},\, \hat{x}\rangle - \frac{1}{2}|Bx|_D^2\right) \le 0. \tag{2.4}$$

Setting $\hat{x} = p^k$ and $x = p^{k-1}$ in (2.4) and multiplying it by $(1+\lambda\rho)^{-2k}$, it follows from (1.9) that for $k \ge 1$

$$c^{-k}\,\tilde{E}\,(|p^k|_H^2 + \lambda\,|Bp^k|_D^2) + \lambda\beta c^{-k}\,\tilde{E}\,|p^k|_V^2 \le c^{-(k-1)}\,(\tilde{E}\,(|p^{k-1}|_H^2 + \lambda\,|Bp^{k-1}|_D^2)),$$

where $c = (1+\lambda\rho)^2$. Summing up this in k, we obtain

$$c^{-m}\,\tilde{E}\,(|p^m|_H^2 + \lambda\,|Bp^m|_D^2) + \beta\,\tilde{E}\sum_{k=1}^{m}\lambda c^{-k}\,|p^k|_V^2 \le \tilde{E}(|p^0|_H^2 + \lambda\,|Bp^0|_D^2).$$

Thus, for $\lambda\rho$ sufficiently small,

$$\tilde{E}|p^m|_H^2 + \beta\,\tilde{E}\sum_{k=1}^{m}\lambda c^{m-k}\,|p^k|_V^2 \le e^{2\rho T}\,\tilde{E}\,(|p^0|_H^2 + \lambda\,|Bp^0|_D^2). \tag{2.5}$$

Let Δ be the Laplacian and $p^0 = (I - \lambda\,\Delta)^{-1}p_0$. Here, for $x \in H$, we have

$$|(I - \lambda\,\Delta)^{-1}x - x|_H \to 0 \quad \text{and} \quad \lambda\,|B(I - \lambda\,\Delta)^{-1}x|_D^2 \to 0$$

as $\lambda \to 0$. Define a function $p_\lambda(t)$ by

$$p_\lambda(t) = p^k \quad \text{if} \quad t \in [k\lambda, (k+1)\lambda),\ k \ge 0.$$

Then from (2.5) we obtain

$$\sup_{t\in[0,T]}\tilde{E}\,|p_\lambda(t)|_H^2 + \int_0^T \tilde{E}\,|p_\lambda(t)|_V^2\,dt \le e^{2\rho T}\,\tilde{E}\,(|p^0|_H^2 + \lambda\,|Bp^0|_D^2), \tag{2.6}$$

and thus $p_\lambda(t) \in L^2(S;V) \cap L^\infty(0,T;L^2(\Omega;H))$ uniformly in $\lambda > 0$. Consequently, there exists a subsequence of $\{p_\lambda\}$, which will be denoted by the same symbol, such

that $p_\lambda \to p$ weakly in $L^2(S;V)$ and weakly star in $L^\infty(0,T;L^2(\Omega;H))$, where $p(t) \in L^2(S;V) \cap L^\infty(0,T;L^2(\Omega,H))$ can be chosen to be progressively measurable. Note that

$$\tilde{E}\,|\,(A_\rho(y(k\lambda+s)) - A_\rho(y(k\lambda)))\,p_\lambda(k\lambda)|_{V^*}^2$$

$$\le M\tilde{E}\,|y(k\lambda+s)-y(k\lambda)|^2\,\tilde{E}\,|p_\lambda(k\lambda)|_V^2 \le M\lambda\tilde{E}\,|p_\lambda(k\lambda)|_V^2$$

for $s \in (0,\lambda)$ and some constant $M > 0$. Similarly, we have

$$\tilde{E}\,|\,(B(y(k\lambda+s)) - B(y(k\lambda)))\,p_\lambda(k\lambda)|_H^2 \le M\lambda\tilde{E}\,|p_\lambda(k\lambda)|_V^2.$$

Thus we have

(2.7)

$A_\rho p_\lambda(t) \to A_\rho p(t)$ weakly in $L^2(S;V^*)$ and $Bp_\lambda(t) \to Bp(t)$ weakly in $L^2(S;\mathcal{L}(R^p,H))$.

From (2.2) we have

$$p_\lambda(t) = p^0 - \int_0^{[t/\lambda]\lambda} (A_\rho p_\lambda(s+\lambda) - \rho\, p_\lambda(s))\,ds + \int_0^{[t/\lambda]\lambda} Bp_\lambda(s)\,dy(s).$$

Thus, for almost all (t,ω), a continuous modification of $p(t)$ in H (see [KR, Thm. 3.2]) satisfies

$$p(t) = p_0 - \int_0^t (A_\rho p(s) - \rho\, p(s))\,ds + \int_0^t Bp(s)\,dy(s). \tag{2.8}$$

Define

$$S_\lambda = \int_0^T e_\lambda(t)\tilde{E}\left(2\langle A_\rho p_\lambda(t+\lambda) - A_\rho p(t),\, p_\lambda(t+\lambda) - p(t)\rangle - |Bp_\lambda(t+\lambda) - Bp(t)|_D^2\right)\,dt,$$

where $e_\lambda(t) = c^{-k}$ on $[(k-1)\lambda, k\lambda)$, $k \ge 1$. It then follows from (1.9) that

$$S_\lambda \ge \beta \int_0^T e_\lambda(t)\,\tilde{E}\,|p_\lambda(t+\lambda) - p(t)|_V^2\,dt. \tag{2.9}$$

Setting $\hat{x} = p^k$ and $x = p^{k-1}$ in (2.4) and multiplying it by $c^{-k} = (1+\lambda\rho)^{-2k}$, we obtain for $k \ge 1$

$$c^{-k}\tilde{E}(|p^k|_H^2 + \lambda\,|Bp^k|^2) - c^{k-1}\tilde{E}(|p^{k-1}|_H^2 + \lambda\,|Bp^{k-1}|^2) + \lambda c^{-k}\,\tilde{E}(2\langle A_\rho p^k, p^k\rangle - |Bp^k|_D^2) \le 0.$$

Summing up this in k, we obtain

$$c^{-m}\tilde{E}\,|p_\lambda(T)|_H^2 - \tilde{E}\,(|p^0|_H^2 + \lambda\,|Bp^0|_D^2) + T_\lambda \;\le\; 0, \tag{2.10}$$

where T_λ is defined by

$$T_\lambda = \int_0^T e_\lambda(t)\,\tilde{E}\,(2\langle A_\rho p_\lambda(t+\lambda),\, p_\lambda(t+\lambda)\rangle - |Bp_\lambda(t+\lambda)|_D^2)\,dt.$$

On the other hand, it follows from (2.8) and the Ito lemma (Thm. I.3.2 in [KR]) that

$$e^{-2\rho T}\,\tilde{E}\,|p(T)|_H^2 - \tilde{E}\,|p_0|_H^2 + \int_0^T e^{-2\rho t}\tilde{E}\,(\,2\langle A_\rho p(t),\, p(t)\rangle - |Bp(t)|_D^2\,)\,dt = 0. \tag{2.11}$$

Note that $|e_\lambda(t) - e^{-2\rho t}| \to 0$ as $\lambda \to 0$, uniformly on $[0,T]$. Hence, since from (2.7)

$$\liminf\ S_\lambda = \int_0^T e^{-2\rho t}\tilde{E}\left(-2\langle A_\rho p(t),\, p(t)\rangle + |Bp(t)|_D^2\right) dt + \liminf\ T_\lambda \geq 0,$$

it follows from (2.10) that

(2.12)

$$\int_0^T e^{2\rho(t-s)}\tilde{E}(-2\langle A_\rho p(t),\, p(t)\rangle + |Bp(t)|_D^2)\, dt + \tilde{E}|p_0|_H^2 - e^{-2\rho T}\ \limsup\ \tilde{E}|p_\lambda(T)|_H^2 \geq 0.$$

Combining (2.11) – (2.12), we obtain

$$e^{-2\rho T}\left(\tilde{E}\,|p(T)|_H^2 - \limsup\ \tilde{E}\,|p_\lambda(T)|_H^2\right) \geq 0.$$

Since $p_\lambda(T)$ converges weakly to $p(T)$ (without loss of generality),

$$\tilde{E}\,|p(T)|_H^2 - \liminf\ \tilde{E}\,|p_\lambda(T)|_H^2 \leq 0,$$

and thus we have

$$\tilde{E}\,|p_\lambda(T) - p(T)|_H^2 \to 0 \quad \text{as } \lambda \to 0.$$

Moreover, from (2.9)

$$\tilde{E}\,|p_\lambda(t) - p(t)|_{L^2(0,T;V)} \to 0 \quad \text{as } \lambda \to 0.$$

Suppose there exist two solutions $p(t)$, $\hat{p}(t) \in L^2(S;V)$ to (2.8) satisfying $p(0) = \hat{p}(0) = p_0$. It then follows from the Ito lemma that

$$\tilde{E}\,|p(t) - \hat{p}(t)|_H^2 + \int_0^t e^{-2\rho s}\tilde{E}\left(2\langle A_\rho(p(s) - \hat{p}(s)),\, p(s) - \hat{p}(s)\rangle - |B(p(s) - \hat{p}(s))|_D^2\right) ds = 0$$

for $t \in [0,T]$. Hence from (1.9) $\tilde{E}\,|p(t) - \hat{p}(t)|_H^2 = 0$ on $[0,T]$, and thus (2.8) has a unique solution. Since the above arguments do not depend on $T > 0$, $p_\lambda(t)$ converges strongly to $p(t)$, a unique solution of (2.8) in $L^2(\Omega;H)$ everywhere on $[0,T]$. Hence $p_\lambda(t)$ converges to $p(t)$ in $L^2(S;V)$ and strongly in $L^2(\Omega,H)$ everywhere on $[0,T]$.

Next we show that if for each n, $p_n(t)$ is the solution to

$$p_n(t) = p_0^n - \int_0^t A^n p_n(s)\, ds + \int_0^t B^n p_n(s)\, dy(s) \quad \text{in } V^*,$$

then $p_n(t)$ converges to $p(t)$ strongly in $L^2(S;V)$ and $L^\infty(0,T;L^2(\Omega;H,d\tilde{P}))$ as $n \to \infty$. It follows from the Ito lemma that

$$\tilde{E}\,|p_n(t) - p(t)|_H^2 + \int_0^t e^{2\rho(t-s)}\tilde{E}\left(2\langle A_\rho^n(p_n(s) - p(s)) + A_\rho^n p(s) - A_\rho p(s),\, p_n(s) - p(s)\rangle\right.$$

$$\left. - |B^n(p_n(s) - p(s)) + B^n p(s) - Bp(s)|_D^2\right) ds = e^{2\rho t}\,\tilde{E}\,|p_0^n - p_0|_H^2.$$

From (A1) we have

$$\langle A_\rho^n p_n(s) - A_\rho p(s),\, p_n(s) - p(s)\rangle \leq \frac{\beta}{4}\,|p_n(s) - p(s)|_V^2 + \frac{1}{\beta}\,|A_\rho^n p_n(s) - A_\rho p(s)|_{V^*}^2$$

and

$$(B^n(p_n(s)-p(s)),\, B^n p(s)-Bp(s))_D \le \frac{\beta}{4}\,|p_n(s)-p(s)|_V^2 + \frac{\gamma^2}{\beta}|B^n p_n(s)-Bp(s)|_D^2.$$

It thus follows from (A2) that

(2.13)

$$\tilde{E}\,|p_n(t)-p(t)|_H^2 + \frac{\beta}{4}\int_0^t e^{2\rho(t-s)}\tilde{E}\,|p_n(s)-p(s)|_V^2\,ds \le e^{2\rho t}\,\tilde{E}\,|p_0^n-p_0|_H^2$$

$$+\int_0^t e^{2\rho(t-s)}\tilde{E}\left(\frac{2}{\beta}\,|A_\rho^n p(s)-A_\rho p(s)|_{V^*}^2\,ds + \left(\frac{\gamma^2}{\beta}+1\right)|B^n p(s)-Bp(s)|_D^2\right)ds.$$

It then follows from (A1) and (A3) that $|A_\rho^n p(s)-A_\rho p(s)|_{V^*}^2$ and $|B^n p(s)-Bp(s)|_D^2$ converge to zero as $n\to\infty$, almost all (t,ω) and are uniformly integrable. By Lebesgue-dominated convergence theory,

$$\int_0^T e^{2\rho(T-t)}\tilde{E}\,(|A_\rho^n p(t)-A_\rho p(t)|_{V^*}^2 + |B^n p(t)-Bp(t)|_D^2)\,dt$$

converges to zero as $n\to\infty$. Thus it follows from (2.13) that $p_n(t)$ converges to $p(t)$ strongly in $L^2(S;V)$ and $L^\infty(0,T;L^2(\Omega;H,d\tilde{P}))$ as $n\to\infty$. Hence, combining the two steps we obtain the desired convergence. □

3. Uncorrelated case: Milshtein approximation and robust form. In this section we consider the case when $b(y)=0$. Then $B\in\mathcal{L}(H)$ is given by $(B\phi)(x)=h(x)\phi(x)$. Here, without loss of generality, one can assume that $R=I$ and thus $D=I$ on R^p. First, we consider the time discretization of (1.1) based on the Milshtein approximation of the Ito stochastic integral:

$$p^k-p^{k-1}+\lambda\,(A+\rho\,I)p^k = \lambda\rho\,p^{k-1}+Bp^{k-1}\,\Delta y_k+\frac{1}{2}\,BBp^{k-1}(\Delta y_k^2-\lambda), \tag{3.1}$$

where $A=A(y_{k-1})$, $B=B(y_{k-1})$, and $\Delta y_k = y(k\lambda)-y((k-1)\lambda)$. The last term in (3.1) is understood as

$$\sum_{i=1}^p B_iB_i\phi(\,(\Delta y_k^i)^2-\lambda) \quad \text{for } \phi\in H,$$

where $(B_i\phi)(x)=h_i(x)\phi(x)$. Note that B_i is self-adjoint and commutes with B_j for all i, j. As shown in the next section, the Milshtein scheme (3.1) provides a higher-order approximation than the Euler scheme (2.2). Assume that x is a V-valued random variable and x and $\Delta y\in R^p$ are independent. Then the equation for $\hat{x}\in V$

$$\hat{x}-x+\lambda\,(A+\rho\,I)\hat{x} = \lambda\rho\,x+Bx\,\Delta y+\frac{1}{2}BBx\,(\Delta y^2-\lambda) \tag{3.2}$$

has a unique solution $\hat{x}=J_\lambda z$, where $z=(1+\lambda\rho)\,x+Bx\,\Delta y+\frac{1}{2}BBx\,(\Delta y^2-\lambda)$. Multiplying (3.2) by $\hat{x}$ and completing the square, we obtain

$$\frac{1}{2}\,(\,|\hat{x}|_H^2-(1+\lambda\rho)^2\,|x|_H^2+|\hat{x}-(1+\lambda\rho)\,x|_H^2\,)+\lambda\,\langle A_\rho\hat{x},\,\hat{x}\rangle = (\xi,\hat{x}),$$

where $\xi = Bx\,\Delta y + \frac{1}{2}BBx\,(\Delta y^2 - \lambda)$. Then

$$|J_\lambda z - z|_H^2 = |\hat{x} - (1+\lambda\rho)\,x - \xi|_H^2$$
$$= |\hat{x} - (1+\lambda\rho)\,x|_H^2 - 2\,(\xi,\ \hat{x} - (1+\lambda\rho)\,x) + |\xi|_H^2.$$

Note that $\tilde{E}\,(\xi,\ x) = 0$ since x and Δy are independent and that

$$\tilde{E}\,|\xi|_H^2 = \tilde{E}\,|Bx\,\Delta y|_H^2 + \tilde{E}\,\left|\frac{1}{2}BBx\,(\Delta y^2 - \lambda)\right|_H^2$$
$$= \lambda\left(\tilde{E}\,|Bx|_H^2 + \frac{1}{2}\lambda\,\tilde{E}\,|BBx|_H^2\right).$$

Hence, combining the above equalities, we obtain

$$\frac{1}{2}\,(\tilde{E}\,|\hat{x}|_H^2 - (1+\lambda\rho)^2\,\tilde{E}\,|x|_H^2) + \lambda\,\tilde{E}\left(\langle A_\rho\hat{x},\ \hat{x}\rangle - \frac{1}{2}\,|Bx|_H^2\right) \le \frac{1}{4}\lambda^2\,\tilde{E}\,|BBx|_H^2. \tag{3.3}$$

Setting $\hat{x} = p^k$ and $x = p^{k-1}$ in (3.3) and multiplying it by $(1+\lambda\rho)^{-2k}$, it follows from (3.1) and (1.9) that, for $k \ge 1$,

$$c^{-k}\,\tilde{E}\,(|p^k|_H^2 + \lambda\,|Bp^k|_H^2) - c^{k-1}\,\tilde{E}\,(|p^{k-1}|_H^2 + \lambda\,|Bp^{k-1}|_H^2)$$
$$+\lambda\beta c^{-k}\,\tilde{E}\,|p^k|_V^2 \le \frac{1}{2}\lambda^2 c^{-k}\,\tilde{E}\,|BBp^{k-1}|_H^2, \tag{3.4}$$

where $c = (1+\lambda\rho)^2$. Summing up this in k, we have

$$c^{-m}\,\tilde{E}\,(|p^m|_H^2 + \lambda\,|Bp^m|_H^2) + \beta\,\tilde{E}\sum_{k=1}^{m}\lambda c^{-k}\,|p^k|_V^2$$
$$\le \tilde{E}\,(|p_0|_H^2 + \lambda\,|Bp_0|_H^2) + \frac{1}{2}\lambda|B|^2\,\tilde{E}\sum_{k=1}^{m}\lambda c^{-k}\,|p^{k-1}|_H^2.$$

Thus, for $\lambda\rho$ sufficiently small,

$$\tilde{E}\,|p^m|_H^2 + \frac{\beta}{2}\,\tilde{E}\sum_{k=1}^{m}\lambda c^{m-k}\,|p^k|_V^2 \le e^{2\rho T}\,\tilde{E}\,(|p_0|_H^2 + \lambda\,|Bp_0|_H^2),$$

where we assume that $\beta \le 2\lambda|B|^2$. Define a function $p_\lambda(t)$ by

$$p_\lambda(t) = p^k \quad \text{if } t \in [k\lambda, (k+1)\lambda),\ k \ge 0.$$

Then from (3.4) instead of (2.10) we have

$$c^{-m}\,\tilde{E}\,|p_\lambda(T)|_H^2 - \tilde{E}\,(|p_0|_H^2 + \lambda\,|Bp_0|_H^2) + T_\lambda \le \frac{1}{2}\lambda|B|^2\,\tilde{E}\sum_{k=1}^{m}\lambda c^{-k}\,|p^{k-1}|_H^2,$$

where the right-hand side converges to zero as $\lambda \to 0$. Thus, using the same arguments as in the proof of Theorem 2.1, one can show that $p_\lambda(t)$ converges to $p(t)$ strongly

in $L^2(S;V)$ and weakly star in $L^\infty(0,T;L^2(\Omega,H))$. Hence we obtain the following theorem.

THEOREM 3.1. *Assume that* $b(y) = 0$ *and that a family of linear operators* (A^n, B^n) *and initial conditions* p_0^n *satisfy the conditions* (A1)–(A3) *and* $|p_0^n - p_0|_H \to 0$ *as* $n \to \infty$, *respectively. Then the sequence* $\{p_{m,n}^k\}$ *generated by*

$$(3.5)\quad p^k - p^{k-1} + \lambda(A^n + \rho I)p^k = \lambda\rho p^{k-1} + B^n p^{k-1}\,\Delta y_k + \frac{1}{2}B^n B^n p^{k-1}(\Delta y_k^2 - \lambda)$$

converges to the unique solution $p(t)$ *of* (1.1) *as* $m,\ n \to \infty$ *in the sense that the function* $p_{m,n}(t)$ *defined by*

$$p_{m,n}(t) = p_{m,n}^k \quad \text{on } [k\lambda, (k+1)\lambda),\ k \geq 0,$$

converges $p(t)$ *strongly in* $L^2(S;V)$ *and weakly star in* $L^\infty(0,T;L^2(\Omega;H,d\tilde{P}))$.

Remark 3.2. Consider the approximation scheme based on the Trotter product formula (e.g., [BGR], [FL], [Pi]):

$$(3.6)\quad p^k - p^{k-1} + \lambda(A + \rho I)p^k = \lambda\rho p^{k-1} + \left(\exp\left(B\,\Delta y_k - \frac{\lambda}{2}BB\right) - I\right)p^{k-1},$$

where $\hat{p}(t) = (\exp(B\,\Delta y_k - \frac{\lambda}{2}BB) - I)p^{k-1}$ satisfies

$$\hat{p}(t) - p^{k-1} = \int_{k-1\lambda}^{t} B\hat{p}(s)dy(s), \quad t \geq (k-1)\lambda.$$

For the scheme (3.6), in steps (3.1)–(3.3) ξ is defined by

$$\xi = \left(\exp\left(B\,\Delta y_k - \frac{\lambda}{2}BB\right) - I\right)p^{k-1}.$$

Note that

$$\hat{p}(t) - p^{k-1} = Bp^{k-1}\Delta y_k + \int_{k-1\lambda}^{t} B(\hat{\rho}(s) - p^{k-1})dy(s),$$

where $x = p^{k-1}$ in (3.2). Hence

$$\tilde{E}\,|\xi|_H^2 \leq \lambda(1 + M\lambda)\,\tilde{E}\,|Bx|^2$$

for some $M > 0$ independent of $\lambda > 0$ and $x \in L^2(\Omega;H)$. Thus exactly the same arguments as above are applied to show that Theorem 3.1 also holds for the sequence generated by (3.6)

Next we consider the robust form of (1.1) in which the Ito stochastic differential equation is transformed into an ordinary partial differential equation with random coefficients [Cl], [Da], [Be], [Ro]. Define a function $\eta(t)$ by

$$\eta(t,x) = \exp(-h(x)^* y(t)).$$

Then $\eta(t)$ satisfies

$$d\eta(t,x) = \frac{1}{2}|h(x)|^2\eta(t,x)\,dt - h(x)\eta(t,x)\,dy(t).$$

If we define a function $q(t)$ by $q(t,x) = \eta(t,x)p(t,x)$, then it follows from the Ito stochastic differential rule (e.g., see [KR]) that $q(t)$ satisfies

$$\frac{d}{dt}q(t) + \eta A(\eta^{-1}q(t)) + \frac{1}{2}|h|^2 q(t) = 0, \quad q(0) = p_0 \in H. \tag{3.7}$$

The weak or variational form of (3.7) is given by

$$\left\langle \frac{d}{dt}q(t), \psi \right\rangle + \langle A_0(\nabla q(t) + q(t)\nabla\chi) - aq(t), \nabla\psi - \psi\nabla\chi\rangle + \frac{1}{2}(|h|^2 q(t), \psi) = 0$$

for all $\psi \in V$, where $\chi(t,x) = h(x)^* y(t)$ is a pathwise continuous random function. Define a sesquilinear form μ on $V \times V$ by

$$\mu(t,\phi,\psi) = \langle A_0(\nabla\phi + \phi\nabla\chi) - a\phi, \nabla\psi - \psi\nabla\chi\rangle + \frac{1}{2}(|h|^2\phi, \psi)_H.$$

Then there exist functions $M(t,\omega)$ and $\rho(t,\omega)$ such that

$$|\mu(t,\phi,\psi)| \le M\,|\phi|_V|\psi|_V, \quad \phi, \psi \in V,$$

and

$$\operatorname{Re}\mu(t,\phi) + \rho\,|\phi|_H^2 \ge \frac{1}{2}\alpha\,|\phi|_V^2, \quad \phi \in V,$$

for almost all (t,ω). Hence the standard theory of the parabolic equation in [Li], [KR] shows that there exists a pathwise unique solution $q(t) \in L^2(0,T;V) \cap H^1(0,T;V^*) \cap C(0,T;H)$. Let us consider a full approximation scheme of (3.7); i.e., a sequence of functions $\{q^k\}$ that takes values in a finite dimensional subspace V^n of V is defined by

$$\left(\frac{q^k - q^{k-1}}{\lambda}, \psi\right) + (A_0(\nabla q^k + q^k\nabla\chi^k) - a\,q^k, \nabla\psi - \psi\nabla\chi^k) + \frac{1}{2}(|h|^2 q^k, \psi) = 0$$

for all $\psi \in V^n$, where $\lambda = T/m$ and $\chi^k = \chi(k\lambda)$. Assume the approximation condition:

for each ϕ in V there exists a sequence of function ϕ^n in V^n such that $|\phi^n - \phi|_V \to 0$ as $n \to \infty$.

Then it is easy to prove (e.g, see [Li] and Theorem 2.1) that the function $q_\lambda^n(t)$ defined by

$$q_\lambda^n(t) = q^k + \frac{q^{k+1} - q^k}{\lambda}(t - k\lambda) \quad \text{on } [k\lambda, (k+1)\lambda]$$

converges to $q(t)$ almost surely in $L^2(0,T;V) \cap H^1(0,T;V^*) \cap C(0,T;H)$ as $m,\ n \to \infty$.

4. Convergence rate. In this section we establish convergence rate of the time discretization schemes (2.1) and (3.1). Assume that $g = g(x)$ does not depend on y. First we consider the scheme (2.1). For $k \ge 0$ define the approximation error $\epsilon_k = \epsilon_k^{(1)} - \epsilon_k^{(2)}$ by

$$\begin{aligned} \epsilon_k^{(1)} &= \int_{t_{k-1}}^{t_k} A(p(t) - p(t_k))\,dt + \lambda\rho\,(p(t_k)) - p(t_{k-1})), \\ \epsilon_k^{(2)} &= \int_{t_{k-1}}^{t_k} B(p(t) - p(t_{k-1}))\,dy(t), \end{aligned} \tag{4.1}$$

where $p(t)$ is the unique solution to (1.1) and $t_k = k\lambda$. Then since (1.1) is equivalently written as

$$p(t_k) - p(t_{k-1}) + \int_{t_{k-1}}^{t_k} Ap(t)\,dt = \int_{t_{k-1}}^{t_k} Bp(t)\,dy(t), \tag{4.2}$$

the error function $\delta p_k = p^k - p(t_k)$ satisfies

$$\delta p_k - \delta p_{k-1} + \lambda(A + \rho I)\delta p_k = \lambda\rho\,\delta p_{k-1} + B\delta p_{k-1}\,\Delta y_k + \epsilon_k, \tag{4.3}$$

where $\lambda = T/m$, $\Delta y_k = y(t_k) - y(t_{k-1})$, and $\{p^k\}$ is the approximate sequence generated by (2.2). Note that $\tilde{E}(\delta p_{k-1}, \epsilon_k^{(2)}) = 0$. Thus, multiplying (4.2) by δp_k and using exactly the same arguments as in the proof of Theorem 2.1, we obtain

$$\tilde{E}\,|\delta p_k|_H^2 - c\,\tilde{E}\,|\delta p_{k-1}|_H^2 + 2\,\tilde{E}\langle\lambda A_\rho \delta p_k - \epsilon_k^{(1)},\, \delta p_k\rangle \le \tilde{E}\,|B\delta p_{k-1}\,\Delta y_k - \epsilon_k^{(2)}|_H^2,$$

where $c = (1+\lambda\rho)^2$. Since $B_i \in \mathcal{L}(V,H)$ it follows from (1.9) that there exists an $\varepsilon > 0$ such that

$$2\,\langle A_\rho\phi,\,\phi\rangle - (1+\varepsilon)\,|B\phi|_D^2 \ge \frac{3\beta}{4}\,|\phi|_V^2 \quad \text{for all } \phi \in V.$$

Note that

$$\tilde{E}\,|B\delta p_{k-1}\,\Delta y_k - \epsilon_k^{(2)}|_H^2 \le (1+\varepsilon)\,\tilde{E}\,|B\delta p_{k-1}|_D^2 + \left(1 + \frac{1}{\varepsilon}\right)\tilde{E}\,|\epsilon_k^{(2)}|_H^2.$$

Since $2\,(\delta p_k, \epsilon_k^{(1)}) \le \frac{\lambda\beta}{4}\,|\delta p_k|_V^2 + \frac{4}{\lambda\beta}|\epsilon_k^{(1)}|_{V^*}^2$ we have

$$\begin{aligned}
&\tilde{E}\,(|\delta p_k|_H^2 + \lambda\,|B\delta p_k|_D^2) + \frac{\lambda\beta}{2}\,\tilde{E}|\delta p_k|_V^2 \\
&\le c\,\tilde{E}\,(|\delta p_{k-1}|_H^2 + \lambda\,|B\delta p_{k-1}|_D^2) + \frac{4\lambda}{\beta}\,\tilde{E}\left|\frac{\epsilon_k^{(1)}}{\lambda}\right|_{V^*}^2 + \left(1 + \frac{1}{\varepsilon}\right)\tilde{E}\,|\epsilon_k^{(2)}|_H^2.
\end{aligned}$$

Multiplying this by c^{-k} and summing it up in k,

$$c^{-k}\,\tilde{E}\,|\delta p_k|_H^2 + \frac{\beta}{2}\,\tilde{E}\sum_{j=1}^{k}\lambda c^{-j}\,|\delta p_j|_V^2 \le \tilde{E}\sum_{j=1}^{k}\lambda c^{-j}\left(\frac{4}{\beta}\left|\frac{\epsilon_j^{(1)}}{\lambda}\right|_{V^*}^2 + \frac{1+\frac{1}{\varepsilon}}{\lambda}\,\tilde{E}\,|\epsilon_j^{(2)}|_H^2\right) \tag{4.4}$$

for $1 \le k \le m$.

THEOREM 4.1. *Assume that the solution $p(t)$ of (1.1) satisfies the following regularity:*

$$\tilde{E}\,|Bp(t)|_V^2 \le M_1 \quad \textit{and} \quad \int_0^T \tilde{E}\,|Ap(t)|_V^2\,dt \le M_1 \tag{4.5}$$

for some $M_1 > 0$, independent of $t \in [0,T]$. Then

$$\tilde{E}\,|\delta p_k|_H^2 + \frac{\beta}{2}\,\tilde{E}\sum_{j=1}^{k}\lambda c^{k-j}\,|\delta p_j|_V^2 \le M_2\,\frac{1 - e^{-2\rho T}}{2\rho}\lambda$$

for $1 \le k \le m$ *and some* $M_2 > 0$.

Proof. Note that $p(\cdot)$ satisfies

$$p(t) - p(s) + \int_s^t Ap(\tau)\, d\tau = \int_s^t Bp(\tau)\, dy(\tau) \tag{4.6}$$

for $s \le t$. Thus,

$$\tilde{E}\,|p(t_k) - p(t)|_V^2 \le 2|t - t_k| \int_t^{t_k} \tilde{E}\,|Ap(\tau)|_V^2\, d\tau + 2|D| \int_t^{t_k} \tilde{E}\,|Bp(\tau)|_V^2\, d\tau$$

for $t \le t_k$. From (4.5) we have $\tilde{E}\,|p(t_k) - p(t)|_V^2 \le 2M_1(1+|D|)\,|t - t_k|$. It then follows from (4.1) that there exists a constant $M_2 > 0$ such that

$$\frac{4}{\beta}\,\tilde{E}\left|\frac{\epsilon_k^{(1)}}{\lambda}\right|_{V^*}^2 + \frac{1+\frac{1}{\varepsilon}}{\lambda}\,\tilde{E}\,|\epsilon_k^{(2)}|_H^2 \le M_2\lambda$$

for $1 \le k \le m$. Hence the theorem follows from (4.4). □

Next we discuss the convergence rate of the Milshtein scheme (3.1) for the uncorrelated case. In this case the approximation error $\epsilon_k^{(2)}$ is defined by

$$\epsilon_k^{(2)} = \int_{t_{k-1}}^{t_k} B(\, p(t) - p(t_{k-1}) - Bp(t_{k-1})(y(t) - y(t_{k-1}))\,)\, dy(t). \tag{4.7}$$

Note that

$$\int_{t_{k-1}}^{t_k} (y^i(t) - y^i(t_{k-1}))\, dy^j(t) = \frac{1}{2}\delta_{i,j}\,((\Delta y^i)^2 - \lambda)$$

since we assumed that $R = I$. Thus, the error function $\delta p_k = p^k - p(t_k)$ satisfies

$$\delta p_k - \delta p_{k-1} + \lambda\,(A + \rho\, I)\delta p_k = \lambda\rho\,\delta p_{k-1} + B\delta p_{k-1}\,\Delta y_k + \frac{1}{2}\,BB\delta p_{k-1}\,((\Delta y_k)^2 - \lambda) + \epsilon_k, \tag{4.8}$$

where $\{p^k\}$ is generated by (3.1). Note that $\tilde{E}\,(\delta p_{k-1},\, \epsilon_k^{(2)}) = 0$. Multiplying (4.8) by δp_k and using exactly the same arguments as in §3, we obtain

$$\begin{aligned} &\tilde{E}\,|\delta p_k|_H^2 - c\,\tilde{E}\,|\delta p_{k-1}|_H^2 + 2\lambda\,\tilde{E}\,\langle A_\rho \delta p_k,\, \delta p_k\rangle \\ &\quad -2(1+\lambda\rho)\,\tilde{E}\,(\delta p_{k-1},\, \epsilon_k^{(1)}) \le \tilde{E}\,|\xi_k - \epsilon_k^{(2))}|_H^2, \end{aligned} \tag{4.9}$$

where $\xi_k = B\delta p_{k-1}\,\Delta y_k + \frac{1}{2}BB\delta p_{k-1}\,((\Delta y_k)^2 - \lambda)$. Here

$$\begin{aligned} \tilde{E}\,(\delta p_{k-1},\, \epsilon_k^{(1)}) = \tilde{E}\,\Bigg(&\delta p_{k-1},\, \int_{t_{k-1}}^{t_k} A(p(t_k) - p(t)) - Bp(t)\,(y(t_k) - y(t))\, dt \\ &+\lambda\rho\,(p(t_k) - p(t_{k-1})) - Bp(t_{k-1})\,\Delta y_k\Bigg). \end{aligned} \tag{4.10}$$

Assume that the solution $p(t)$ of (1.1) satisfies the following regularity:

$$\tilde{E}\,|Bp(t)|_V^2 \le M_3 \quad \text{and} \quad \tilde{E}\,|Ap(t)|_V^2 \le M_3 \tag{4.11}$$

for some $M_3 > 0$ and all $t \in [0, T]$. It then follows from the proof of Theorem 4.1 that $\tilde{E}\,|p(t) - p(s)|^2 \leq M_3\,|t - s|$ for $t \geq s$. From (4.6) we have that for $t \geq s$

(4.12)
$$\tilde{E}\,|p(t) - p(s) - Bp(s)\,(y(t) - y(s))|_V^2 \leq 2M_3\,|t - s|^2 + \int_s^t |B(p(\tau) - p(s))|_V^2\,d\tau$$
$$\leq M\,|t - s|^2$$

for some $M > 0$. Hence it follows from (4.10)–(4.12) that

$$2(1 + \lambda\rho)\,\tilde{E}\,(\delta p_{k-1},\, \epsilon_k^{(1)}) \leq \frac{\beta\lambda}{4}\,|\delta p_{k-1}|_V^2 + \frac{4c\lambda^3}{\beta}\,(|A|_{\mathcal{L}(V,V^*)} + \rho)^2 M^2. \tag{4.13}$$

It follows from (1.9) that there exists an $\varepsilon > 0$ such that for λ sufficiently small

$$2\,\langle A_\rho\phi,\, \phi\rangle - (1 + \varepsilon)|B\phi|_H^2 \geq \frac{3\beta}{4}\,|\phi|_V^2 \quad \text{for all } \phi \in V.$$

Note that

$$\tilde{E}\,|\xi_k - \epsilon_k^{(2)}|_H^2 \leq (1 + \varepsilon)\,\tilde{E}\,|\xi_k|_H^2 + \left(1 + \frac{1}{\varepsilon}\right)\,\tilde{E}\,|\epsilon_k^{(2)}|_H^2.$$

From (4.7) and (4.12) we have

$$\tilde{E}\,|\epsilon_k^{(2)}|_H^2 \leq M^2|B|^2\lambda^3. \tag{4.14}$$

Since

$$|\xi_k|_H^2 = \lambda\left(|B\delta p_{k-1}|_H^2 + \frac{\lambda}{2}\,|BB\delta p_{k-1}|_H^2\right),$$

it follows from (4.9), (4.13), and (4.14) that

$$\tilde{E}\,(|\delta p_k|_H^2 + \lambda(1 + \varepsilon)\,|B\delta p_k|_H^2) + \frac{\lambda\beta}{2}\,\tilde{E}\,|\delta p_k|_V^2$$
$$\leq c\,\tilde{E}\,(|\delta p_{k-1}|_H^2 + \lambda(1 + \varepsilon)\,|B\delta p_{k-1}|_H^2) + \frac{1 + \varepsilon}{2}\lambda^2|B|^2\,\tilde{E}\,|\delta p_{k-1}|_H^2 + M_4\lambda^3$$

for some $M_4 > 0$. Multiplying this by c^{-k} and summing it up in k, we obtain

$$\tilde{E}\,|\delta p_k|_H^2 + \frac{\beta}{4}\,\tilde{E}\sum_{j=1}^{k}\lambda c^{k-j}|\delta p_k|_V^2 \leq M_4\frac{1 - e^{-2\rho T}}{2\rho}\lambda^2 \tag{4.15}$$

for $1 \leq k \leq m$, where we assumed that $2(1 + \varepsilon)\lambda|B|^2 \leq \beta$. Hence one obtains the error estimate.

THEOREM 4.2. *Assume that the solution $p(t)$ of* (1.1) *satisfies the regularity* (4.11). *Then rate of convergence of the Milshtein scheme* (3.1) *applied to the uncorrelated case is the first order in the sense of* (4.15).

Remark 4.3. The regularity assumptions (4.5) and (4.11) of the solution to (1.1) can be verified under certain smoothness assumptions on the function g, σ, h, and b and the initial condition p_0 (e.g., see [Ro]).

5. Hermite polynomial–based spectral method. In this section we discuss the so-called spectral method [GO] based on the Hermite polynomial to approximate the solution to (1.1). Consider the orthogonal functions $e_k(x)$, $k \geq 0$, of $L^2(R)$:

$$e_k(x) = \exp(-x^2/2)H_k(x),$$

where $H_k(x)$ is the normalized Hermite polynomial of degree k, i.e., the original Hermite polynomial divided by $\sqrt{k!}$. A family of functions $\{e_k\}$ has the orthogonality

$$(e_k, e_j)_H = \sqrt{\pi}\,\delta_{k,j}$$

and satisfies the recursive formula

$$\sqrt{k+1}\,e_{k+1}(x) = \sqrt{2}x\,e_k(x) - \sqrt{k}e_{k-1}(x).$$

The differential rule is given by

$$e_k'(x) = \frac{1}{\sqrt{2}}\left(\sqrt{k}\,e_{k-1}(x) - \sqrt{k+1}\,e_{k+1}(x)\right)$$

since $H_k'(x) = \sqrt{2k}\,H_{k-1}(x)$. The Gauss quadrature rule is given by

$$\int_R f(x)e^{-x^2}\,dx = \sum_{i=1}^{m} w_i f(x_i),$$

where the equality holds for all polynomials of degree up to $2m+1$ and the quadrature points x_i and the weights w_i are determined (e.g., see [G]) as follows. Let J be the symmetric tridiagonal matrix with zero diagonals and $J_{i,i+1} = \sqrt{i/2}$, $1 \leq i \leq m-1$. Then $\{x_i\}$ are eigenvalues of J and w_i equal to $(v_i)_1^2$, where $(v_i)_1$ is the first element of the ith normalized eigenvector of J.

For $\sigma > 0$ let $\phi_k(x) = \prod_{i=1}^n e_{k_i}(x_i/\sigma)$ for $k = (k_1, \ldots, k_d) \in N^d$ and $K = [0, n]^d \subset N^d$. The Galerkin approximation of (1.1) involves representing the approximate solution $p_n(t, x)$ by

$$p_n(t, x) = \sum_{k \in K} \alpha_k(t)\phi_k(x), \quad \alpha_k \in R,$$

and projecting the equation (1.1) onto $V^n = \text{span}\{\phi_k,\ k \in K\}$ in the sense that

$$(p_n(t) - p_0,\, \psi) + \int_0^t \langle Ap_n(s),\, \psi\rangle\, ds = \int_0^t (Bp_n(s),\, \psi)\, dy(s),$$

for all $\psi \in V^n$. Define a pair of linear operators (A^n, B^n) by

$$\langle A^n\phi,\, \psi\rangle = \langle A_0\phi - a\,\phi,\, \psi\rangle,$$

$$(B^n\phi,\, \psi) = (c\phi,\, \nabla\psi) + (h\phi,\, \psi)$$

for all $\phi,\ \psi \in V^n$, where $A_0 = a_{i,j}$, a_i and c_i are defined in (1.6). Then $p_n(t, \cdot)$ satisfies

$$dp_n(t) + A^n p_n(t)\,dt = B^n p_n(t)\,dy(t), \quad p_n(0) = p_0^n,$$

where p_0^n is the orthogonal projection of p_0 onto V^n of H. Condition (A2) follows from (1.9) since the left-hand side of (A2) is the restriction of (1.9) onto V^n. Condition (A3) follows from the fact that $|P_V^n\phi - \phi|_V \to 0$ as $n \to \infty$, where P_V^n is the orthogonal projection of V onto V^n. Hence Theorems 2.1 and 3.1 are applied to the Galerkin approximation based on the Hermite polynomials.

Acknowledgment. The author thanks Professor B. Rozovskii for many helpful discussions and the referees for careful reviews and useful suggestions.

OPTIMALITY CONDITIONS FOR A CONSTRAINED CONTROL PROBLEM*

GIANNA STEFANI† AND PIERLUIGI ZEZZA‡

Abstract. This paper is devoted to the study of necessary or sufficient second-order conditions for a weak local minimum in an optimal control problem. The problem is stated in the Mayer form and includes equality constraints both on the endpoints and on the state-control trajectory. The second-order conditions are stated through an associated linear–quadratic problem.

Key words. optimal control, second-order conditions, necessary and sufficient conditions, state-control constraints

AMS subject classifications. 49K15, 49K27, 93C10, 93C50

1. Introduction. This paper is devoted to obtaining necessary or sufficient optimality conditions for an optimal control problem in the Mayer form which is characterized by the presence of two types of equality constraints. The first one concerns the endpoints of the trajectory, and it is a finite-dimensional constraint, while the second one is a time-dependent state-control constraint and it can be regarded as being infinite dimensional. We look for necessary or sufficient second-order conditions for a weak local minimum in the framework of extremal problems, that is, our approach is to transform the original optimal control problem into an abstract constrained optimization problem in the Banach space $E = \mathbf{R}^n \times L^\infty$, which is the space of the couples (*initial condition*, *control*). The transformed problem is the following:

$$\text{Minimize} \quad \phi_0(e)$$

subject to

$$\chi(e) = 0,$$

where $\chi \equiv (\phi_1, \dots, \phi_p) + \psi$, the ϕ_i's are scalar functions, and ψ has range in an infinite-dimensional space F. The optimality conditions are obtained by studying the range of the map $\tilde{\chi} \equiv (\phi_0, \dots, \phi_p) + \psi : E \to \mathbf{R}^{p+1} \oplus F$ locally around a reference admissible point $\hat{e}$. In fact $\hat{e}$ is a local constrained minimizer if and only if locally the range of $\tilde{\chi}$ does not intersect the vertical line below $\phi_0(\hat{e})$. These results (Lemma 4.3 and Lemma 4.5) are expressed by the first and second derivatives of $\tilde{\chi}$ and χ. In particular in the *normal* case, when the multiplier λ_0 corresponding to the cost ϕ_0 is positive, the second-order conditions depend on the *hessian* of $\tilde{\chi}$ while in the abnormal one they depend only on the hessian of χ (see Remark 4.6). Recall that the hessian is the restriction of the second derivative to the kernel of the first one modulo the range of the first derivative.

A crucial role will be played by the assumptions on the constraints. We assume that the reference point is a *regular* point for the infinite-dimensional constraint ψ, i.e., $D\psi(\hat{e})$ is onto (Assumption 2.4 and Lemma 5.2). This assumption allows us to reduce

the constraint to a finite-dimensional one (see Lemma 4.2) and it ensures that the multiplier associated with the state-control constraint belongs to L^∞. This is the only rank assumption we make and unlike many authors we do not make any controllability assumption on the linearized problem. We prove that the controllability assumption is equivalent to the regularity of the constraint χ at the reference point (Lemma 5.4).

In our approach the regularity assumptions on the data (Assumption 2.2) are in some sense minimal to obtain the C^2 dependence of the flow of the differential equation from the control in the appropriate function spaces. This is needed to prove the smoothness of the function $\tilde{\chi}$. In this setting we determine that the multiplier belongs to L^∞ for a problem whose data have a t-dependence that is only locally bounded and measurable while other authors [9] assume a continuous t-dependence. We should mention that in [9] a maximum principle is derived, while we are interested in second-order necessary or sufficient conditions and we obtain only the weak version of the maximum principle.

In stating the second-order necessary conditions (Theorem 2.5), we assume that the dimension of the space of the multipliers which satisfies the first-order conditions is 1. The case when there are independent multipliers satisfying the first-order conditions has been addressed by some authors [4], [18] while studying the case of inequality finite-dimensional constraints. In the case studied here we show (Corollary 4.4) that the second-order necessary conditions are trivial when there exist independent multipliers, in the sense that they are satisfied for every cost. Also in the case when the space of multipliers has dimension 1 we have to distinguish between the so-called normal case when the reference point is regular for the constraint χ and the abnormal one. In this last case, although the cost does not appear in the necessary conditions we still have some information on the constraints (see Remark 2.7).

To derive the sufficient conditions it is crucial to consider different norms on L^∞, because a coerciveness condition on the second derivative is needed but it cannot be imposed on L^∞ endowed with its norm because it is not isomorphic to a Hilbert space (see, e.g., [3]). The possibility of considering the L^p norms is suggested by Volterra expansions which give us the ith derivative of the flow of the system in an integral form which is defined on L^i (Theorem 3.3). The regularity Assumption 2.2 needs to be strengthened to achieve the needed regularity with respect to the required norms (Theorem 3.5), it cannot be weakened as is shown by Example 3.6. In the statement of the second-order sufficient conditions (Theorem 2.6), we need not assume that the space of multipliers has dimension 1. Also for the sufficient conditions the abnormal case has a special meaning: it means that the reference point is an isolated admissible one (Remark 4.8). Theorem 2.6 gives full information in the normal case and also when there are independent multipliers. Many authors, see, e.g., [3], assume controllability of the linearized system, which implies normality but which is not equivalent to it.

Most of the literature addressing state-control constraints considers the case of equality and inequality constraints, so that it is difficult to compare those results with ours because of the constraint qualification assumptions. For example, some authors impose a constraint qualification assumption that cannot be satisfied by pure equality constraints [10].

The Russian school uses a different approach which obtains powerful abstract results (for a survey see [8], and also the recent book [1] in Russian). An application of this theory to control problems with mixed equality and inequality constraints is stated but not proved in [11]. The same results are quoted in the survey paper [8] where, in the supplement to Chapter VI, it is said that "the derivation of the conditions

is very special and difficult." This survey paper does not contain the proofs and it again quotes [11] and Osmolovskiĭ's thesis [12]. In any case the methods used should be completely different from ours because the results for the equality case are derived from those in the case of mixed equality and inequality by adding an extra inequality constraint. It is our opinion that it is interesting to have a clear and readable proof of the results which also gives an explicit expression of the infinite-dimensional multiplier.

Other authors have addressed the same problem, i.e., to obtain stability results for the numerical solution of optimal control problems. In [3], sufficient conditions for weak local optimality are stated in a problem with equality and inequality constraints on the control but mixed state-control constraints are not considered. Moreover they assume that the reference trajectory satisfies the maximum principle.

Riccati-type techniques are used in [19] to prove sufficient conditions for weak and strong local minima for a problem in the calculus of variations with separate constraints on the endpoints but without other restrictions on the control. While preparing this revised version, a further paper by Zeidan has been published [20], where Riccati-type techniques are used for control problems with fixed initial point equality constraint on the final one and mixed state-control inequality constraints. The specific constraint qualification assumption used does not allow the inclusion of equality constraints.

We have studied separately the reduction to the accessory problem and the nonnegativity (coercivity) of the corresponding quadratic form. Preliminary results concerning second-order conditions have been presented in [14], [15], while an extension of the conjugate point theory which applies to the accessory problem is in progress [17] and it has been presented in [16].

This paper is organized as follows. In §2 we state our main results. In §3 we derive the regularity properties of the flow of the control system. In §4 we prove the abstract lemmata from which, in §5, we derive the proofs of the main results.

2. An optimal control problem. Let us first introduce some notation and definitions needed to properly describe the problem, the assumptions, and the main results.

X, Y, Z are Banach spaces with norm $\|\cdot\|$. Let $\phi : X \to Y$ be a C^2 map; we write $D^i\phi(x)$ for the ith Fréchet derivative of the map ϕ evaluated at the point $x \in X$. By definition $D^0\phi \equiv \phi$, $D\phi(x) \in \mathcal{L}(X,Y)$, and $D^2\phi(x) \in \mathcal{L}^2(X,Y)$. For $\Gamma \in \mathcal{L}^2(X,Y)$ and $\Phi \in \mathcal{L}(Z,X)$ we write

$$\Gamma(x)^2 \equiv \Gamma(x,x), \ (\Gamma \otimes \Phi)(z)^2 \equiv \Gamma(\Phi z)^2.$$

If $X \equiv X_1 \times \cdots \times X_s$, with $X_1, \ldots, X_s$ normed spaces, we denote by $D_i\phi(x)$ the Fréchet derivative of ϕ with respect to the ith variable and by $D^2_{ij}\phi(x) \equiv D_i \circ D_j\phi(x) \in \mathcal{L}^2(X_i \times X_j, Y)$.

The next definition describes the main regularity assumption which is a strengthening of the usual Carathéodory-type assumption. This hypothesis will be used to ensure that the solution of the system (1) depends regularly on the control. Its role is explained in §3.

DEFINITION 2.1 (see [5]). *Assume that X, Y are finite-dimensional vector spaces. We will say that the map $G : \mathbf{R} \times X \to Y$ is quasi-C^k if it satisfies the following:*

(i) *for each $t \in \mathbf{R}$ the map $x \mapsto G(t,x)$ is C^k,*

(ii) *the maps $D^i_2 G$ are locally essentially bounded and measurable in their variables, for $i = 0, \ldots, k$.*

Moreover we will say that the map G is uniformly quasi-C^k if

(iii) *the map $D_2^k G$ is continuous in x uniformly with respect to t in any compact interval J, i.e., for all $x_0 \in X$, $\epsilon > 0$, there exists $\delta > 0$ such that*

$$\|x - x_0\| \leq \delta \Longrightarrow \|D_2^k G(t,x) - D_2^k G(t,x_0)\| \leq \epsilon, \text{ a.e. } t \in J.$$

Property (ii) implies that for any compact interval J and any point $x_0 \in X$ there is a neighborhood $\mathcal{U}$ of x_0 and a constant $h > 0$ such that

$$\|D_2^k G(t,x)\| \leq h, \ x \in \mathcal{U}, \text{ a.e. } t \in J.$$

Therefore, from the intermediate value theorem it is easy to prove that if a function is quasi-C^k then it is uniformly quasi-C^{k-1}.

Since we are interested in local properties, we could assume that the domains of all the maps are not the whole space but just open sets; we prefer the above notation to emphasize the space where we are working.

On a given interval $J = [t_0, t_1]$, let us consider the following optimal control problem:

$$\text{Minimize } a_0(\xi(t_0), \xi(t_1))$$

over all ξ satisfying the following control problem with constraints:

$$\begin{aligned} \dot{\xi}(t) &= F(t, \xi(t), u(t)), \quad \text{a.e. } t \in J, \\ a_i(\xi(t_0), \xi(t_1)) &= 0, \ i = 1, \ldots, p, \\ \alpha(t, \xi(t), u(t)) &= 0, \quad \text{a.e. } t \in J, \end{aligned} \tag{1}$$

where the data satisfy the following regularity assumptions.

Assumption 2.2. The map $F : \mathbf{R} \times \mathbf{R}^n \times \mathbf{R}^m \to \mathbf{R}^n$ is quasi-C^2, the map $\alpha : \mathbf{R} \times \mathbf{R}^n \times \mathbf{R}^m \to \mathbf{R}^r$ is uniformly quasi-C^2, and the maps $a_i : \mathbf{R}^n \times \mathbf{R}^n \to \mathbf{R}$, $i = 0, \ldots, p$, are C^2.

By Assumption 2.2, equation (1) has uniqueness of solutions so that we can identify a couple (ξ, u), satisfying equation (1), with the couple (x, u) given by the initial condition and the control which will always be our control variable. Hence, we will minimize on the space

$$\mathbf{R}^n \times L^\infty(J, \mathbf{R}^m),$$

which is a Banach space with the topology τ_∞ induced by the norm

$$\|(x,u)\|_\infty \equiv \|x\| + \|u\|_\infty.$$

On this space we will also consider other topologies, namely τ_p, $p \geq 1$, will be the topologies induced by the norm $\|(x,u)\|_p \equiv \|x\| + \|u\|_p$, where $\|\cdot\|_p$ denotes the L^p norm. Pointwise equalities between functions in L^p spaces are always assumed to hold almost everywhere.

We are now interested in necessary or sufficient conditions for a weak local minimum.

DEFINITION 2.3. *A reference couple $(x_0, \hat{u})$, satisfying the above constrained control system, is a weak local minimizer for the optimal control problem if it is a local constrained minimizer in $\mathbf{R}^n \times L^\infty(J, \mathbf{R}^m)$ with respect to the τ_∞ topology.*

In the following we will consider a given $(x_0, \hat{u})$ which satisfies the constraints and we denote by $\hat{\xi}$ the corresponding solution of (1) and by x_1 the endpoint value $\hat{\xi}(t_1)$. We denote by $\hat{}$ the evaluation along the reference objects and by $^\top$ the transpose.

An assumption which will play a crucial role concerns the infinite-dimensional constraint α, and it corresponds to the regularity of this constraint at $(x_0, \hat{u})$; see Lemma 5.2.

Assumption 2.4. The constraint α satisfies the following rank condition at $(x_0, \hat{u})$

$$\det\left(D_3\hat{\alpha}(t)D_3\hat{\alpha}(t)^{\top}\right) \geq k > 0,$$

for some positive $k \in \mathbf{R}$.

This assumption allows us to reduce the set of constraints to a finite-dimensional one so that we can give an explicit (through the data) expression of the modified Hamiltonian associated to the constrained problem. Let

$$A(t) \equiv D_2\hat{F}(t),\ B(t) \equiv D_3\hat{F}(t),\ C(t) \equiv D_2\hat{\alpha}(t),\ D(t) \equiv D_3\hat{\alpha}(t). \tag{2}$$

For the sake of simplicity we will denote by ∇ the derivative with respect to the coupled variables $(x, w) \in \mathbf{R}^n \times \mathbf{R}^m$, so that, for example, $\nabla\hat{\alpha}(t) = (C(t), D(t))$.

The second-order conditions will hold on the space of *critical directions*, i.e., the space of couples (x, u) which satisfies the following system obtained by linearizing (1) and the constraints along the reference trajectory:

$$\dot{\xi}_L(t) = A(t)\xi_L(t) + B(t)u(t),\ \xi_L(t_0) = x, \tag{3}$$

$$C(t)\xi_L(t) + D(t)u(t) = 0, \tag{4}$$

$$Da_i(x_0, x_1)(x, \xi_L(t_1)) = 0,\ i = 1, \ldots, p. \tag{5}$$

We denote the solutions of equation (3) by $\xi_L(\cdot, x, u)$. Assumption 2.4 ensures the existence of a right inverse of $D(t)$ which can be taken as

$$D^{\sharp}(t) \equiv D^{\top}(t)\left(D(t)D^{\top}(t)\right)^{-1}.$$

The next theorems are our main results and give first- and second-order necessary or sufficient weak optimality conditions for this kind of constraint. The results are expressed through the Hamiltonian $\mathcal{H} : J \times (\mathbf{R}^n)^* \times \mathbf{R}^n \times \mathbf{R}^m \to \mathbf{R}$ modified to take into account the infinite-dimensional constraint and defined by

$$\mathcal{H}(t, \omega, x, w) = \omega(F(t, x, w) - B(t)D^{\sharp}(t)\alpha(t, x, w)). \tag{6}$$

The first result concerns necessary optimality conditions which are derived under two main assumptions. The infinite-dimensional constraint is regular (the rank condition) and the multiplier associated with the finite-dimensional part (cost and endpoint constraints) is unique up to a positive constant.

THEOREM 2.5. *Assume that*

(i) *F is quasi-C^2, α is uniformly quasi-C^2, and the a_i, $i = 0, \ldots, p$, are C^2;*

(ii) *the rank condition* $\det\left(D(t)D^{\top}(t)\right) \geq k > 0$ *is satisfied.*

Assume that $(x_0, \hat{u})$ is a weak local minimizer for the optimal control problem; then there exist $\lambda = (\lambda_0, \ldots, \lambda_p) \neq 0$ with $\lambda_0 \geq 0$ and a solution $\hat{p}$ of the adjoint equation (7) *satisfying the transversality conditions* (8)*:*

$$-\dot{p}(t) = D_3\mathcal{H}(t, p(t), \hat{\xi}(t), \hat{u}(t)), \tag{7}$$

$$(-p(t_0), p(t_1)) = \sum_{i=0}^{p} \lambda_i Da_i(x_0, x_1) \tag{8}$$

such that

$$D_4\hat{\mathcal{H}}(t) = D_4\mathcal{H}(t, \hat{p}(t), \hat{\xi}(t), \hat{u}(t)) = 0. \tag{9}$$

Assume moreover that

(iii) *the above multiplier* λ *is unique up to a positive constant. Then for each* (x, u) *satisfying the linearized system* (3)–(5) *we have*

$$\sum_{i=0}^{p} \lambda_i D^2 a_i(x_0, x_1)((x, \xi_L(t_1, x, u)))^2 + \int_{t_0}^{t_1} \nabla^2 \hat{\mathcal{H}}(s)((\xi_L(s, x, u), u(s)))^2 ds \geq 0. \tag{10}$$

In the literature the case when the assumption (iii) is dropped has also been considered [4], [18]. Their results specialized to our case give trivial conditions in the following sense. They would say that for each critical direction (x, u) there is a multiplier λ such that (9) and (10) hold. It is a consequence of Corollary 4.4 that this is true independently from the cost and it depends only on the existence of independent multipliers.

The second result concerns second-order sufficient conditions and it does not require the uniqueness of the multiplier. It is stated under stronger regularity assumptions on F.

THEOREM 2.6. *Assume that*

(i) F *and* α *are uniformly quasi-*C^2 *and the* a_i, $i = 0, \dots, p$, *are* C^2,

(ii) *the rank condition* $\det(D(t)D^{\top}(t)) \geq k > 0$ *is satisfied,*

(iii) *there exist* $\lambda = (\lambda_0, \dots, \lambda_p) \neq 0$ *with* $\lambda_0 \geq 0$ *and a solution* $\hat{p}$ *of the adjoint equation* (7) *satisfying the transversality conditions* (8) *for which the first-order conditions* (9) *hold true,*

(iv) *there is* $K > 0$ *such that for each* (x, u) *satisfying the linearized system* (3)–(5) *one has*

$$\sum_{i=0}^{p} \lambda_i D^2 a_i(x_0, x_1)((x, \xi_L(t_1, x, u)))^2 + \int_{t_0}^{t_1} \nabla^2 \hat{\mathcal{H}}(s)((\xi_L(s, x, u), u(s)))^2 ds \geq K\|(x, u)\|_2^2;$$

hence, as a result, $(x_0, \hat{u})$ *is a weak local minimizer for the optimal control problem.*

Remark 2.7. Although Theorems 2.5 and 2.6 are stated without any normality assumption, the abnormal case, i.e., $\lambda_0 = 0$, has a particular meaning. Let us first remark that the multiplier is normal and unique if and only if the point $(x_0, \hat{u})$ is regular for the constraints and if and only if the input–output system

$$\dot{\eta}(t) = (A(t) - B(t)D^{\sharp}(t)C(t))\eta(t) + B(t)(Id - D^{\sharp}(t)D(t))u(t), \ \eta(t_0) = x,$$
$$y_i(t) = Da_i(x_0, x_1)(x, \eta(t, x, u)), \ i = 1, \dots, p,$$

is controllable at time t_1 (see Lemma 5.4), that is, the input–output map $(x, u) \mapsto (y_1(t_1), \dots, y_p(t_1))$ is surjective. The second-order necessary conditions are stated under the assumption that there are not independent multipliers λ. Hence, if the point $(x_0, \hat{u})$ is not regular for the constraints, the multiplier is abnormal and the

statements do not involve the cost a_0 so that they concern mainly the constraints. Nevertheless if (10) is not satisfied then, for the reference point to be an extremum for a cost a_0, it is necessary to have independent multipliers λ satisfying the first-order conditions.

The codimension assumption does not play any role in the sufficient conditions but if Theorem 2.6 holds for an abnormal multiplier, then the reference point $(x_0, \hat{u})$ is an isolated admissible point (Remark 4.8).

Finally let us remark that from the proof of Lemma 3.1 in [15] it follows that if Assumption 2.4 is not satisfied then the codimension of the closure of the range of $\tilde{\chi}'$ is infinite. Consequently, by using the Hahn–Banach theorem, we can prove that the space of multipliers is infinite dimensional and they belong to the dual of L^∞.

3. Properties of the flow. This section is devoted to the study of some local properties of the flow of (1). We denote by $\xi(t, s, x, u)$ the solution of system (1) at time t with initial condition $\xi(s) = x$ and control u. For a fixed reference initial point x_0 and reference control function $\hat{u}$, let the corresponding solution of (1), $\hat{\xi}(\cdot) \equiv \xi(\cdot, t_0, x_0, \hat{u})$, be defined on the compact interval J.

For more details on the properties of the flow described below we refer to [5] where complete proofs are given. If we assume that F is quasi-C^2 then there is an open set $\mathcal{D}(\xi) \subset \mathbf{R} \times \mathbf{R} \times \mathbf{R}^n \times L^\infty(J, \mathbf{R}^m)$ where the flow of system (1) is defined, namely

$$\xi : \mathcal{D}(\xi) \to \mathbf{R}^n, \ (t, s, x, u) \mapsto \xi(t, s, x, u).$$

$\xi(\cdot, s, x, u)$ is a locally Lipschitz map and we look at its restriction to any compact interval J as an element of the Banach space $L^\infty(J, \mathbf{R}^n)$. There is a neighborhood $\mathcal{V}$ of $(x_0, \hat{u}) \in \mathbf{R}^n \times L^\infty(J, \mathbf{R}^m)$ such that $J \times \{t_0\} \times \mathcal{V} \subseteq \mathcal{D}(\xi)$ and the flow of the system, which can be seen as the map

$$\Xi : \mathcal{V} \subset \mathbf{R}^n \times L^\infty(J, \mathbf{R}^m) \to L^\infty(J, \mathbf{R}^n) \ , \ (x, u) \mapsto \xi(\cdot, t_0, x, u), \tag{11}$$

is C^2. When it is clear from the context, we will drop the variable denoting the initial time and we will write $\xi(t, x, u)$ instead of $\xi(t, t_0, x, u)$.

In [15] we describe the second-order Taylor approximation of the map Ξ with respect to u. The results therein are based on [6], [7], [13]. Here we are going to give the approximation with respect to both variables and a sharper estimate of the remainder.

To simplify the computations, we consider the system pulled back by the reference flow which is suitable for studying the system in a neighborhood of the reference trajectory. Let $\gamma : \mathcal{D}(\gamma) \to \Omega$ be the flow of the reference time–dependent vector field $(t, x) \mapsto F(t, x, \hat{u}(t))$. If we define

$$\sigma(t, t_0, x, u) = \gamma(t_0, t, \xi(t, t_0, x, \hat{u} + u)),$$
$$\Phi(t, x, w) = D_3\gamma(t_0, t, \gamma(t, t_0, x))[F(t, \gamma(t, t_0, x), \hat{u}(t) + w) - F(t, \gamma(t, t_0, x), \hat{u}(t))],$$

then $\sigma(\cdot, t_0, x, u)$ is the solution of

$$\dot{\sigma}(t) = \Phi(t, \sigma(t), u(t)), \ \sigma(t_0) = x. \tag{12}$$

Although this pull-back system is easier to handle, we have lost some regularity. If F is (uniformly) quasi-C^2 then Φ is not necessarily (uniformly) quasi-C^2 in both variables. Nevertheless it is (uniformly) quasi-C^1, and the second derivatives with respect to w are (uniformly) quasi-C.

Notice that $\Phi(t,x,w)$ is defined for $t \in J$ and (x,w) in a suitable neighborhood of $(x_0,0) \in \mathbf{R}^n \times \mathbf{R}^m$. For this new system the reference control function is zero, and the reference control vector field $(t,x) \mapsto \Phi(t,x,0)$ is identically zero, so that the reference trajectory $t \mapsto \hat{\sigma}(t)$ is constant, equal to x_0. Moreover by taking a suitable neighborhood $\mathcal{W}$ of $(x_0,0)$ in $\mathbf{R}^n \times L^\infty(J,\mathbf{R}^m)$ as the set of admissible couples, all the trajectories remain close to the reference constant trajectory x_0. The corresponding flow will be denoted by

$$\Sigma : \mathcal{W} \subset \mathbf{R}^n \times L^\infty(J,\mathbf{R}^m) \to L^\infty(J,\mathbf{R}^n).$$

We are now going to define a linear–quadratic system which gives the second-order approximation of the flow of (12):

$$\begin{aligned} \dot{\sigma}_L(t) &= D_3\hat{\Phi}(t)u(t),\ \sigma_L(t_0) = x, \\ \dot{\sigma}_Q(t) &= \nabla^2\hat{\Phi}(t)((\sigma_L(t),u(t)))^2,\ \sigma_Q(t_0) = 0. \end{aligned} \tag{13}$$

The above system is a cascade of integrators whose solution has components $\sigma_L(t,x,u)$ and $\sigma_Q(t,x,u)$. We write x in the second argument of σ_Q because we want to recall that the initial condition of σ_L is x, while the initial condition of σ_Q will always be zero.

We are now going to express the second derivative of the flow of (12) by means of the solutions of the above linear–quadratic system (13).

THEOREM 3.1. *Let F be quasi-C^2 then the second-order expansion of the flow of* (12) *at $(x_0,0)$ can be written as*

$$\sigma(t,t_0,x_0+x,u) = x_0 + \sigma_L(t,x,u) + \frac{1}{2}\sigma_Q(t,x,u) + \mathcal{R}_2(x,u)(t),$$

where

$$\left\|\mathcal{R}_2(x,u)(t)\right\| \le o(\|(x,u)\|_\infty^2).$$

Proof. Let us first take the second-order approximation of Φ with respect to $w \in \mathbf{R}^m$,

$$\Phi_2(t,y,w) = D_3\Phi(t,y,0)w + \frac{1}{2}D_{33}^2\Phi(t,y,0)(w)^2,$$

and consider the corresponding differential equation

$$\dot{\sigma}_2(t) = \Phi_2(t,\sigma_2(t),u(t)). \tag{14}$$

By taking the approximate flow we may lose some properties of the original flow; for example, the new flow may not be uniquely defined, as is shown by Example 3.2. We want to prove that

$$\|\sigma(\cdot,x_0+x,u) - \sigma_2(\cdot,x_0+x,u)\|_\infty = o(\|(x,u)\|_\infty^2), \tag{15}$$

for any solution σ_2 of (14) with initial condition x_0+x. Let us prove that (15) holds for any sequence $(x_i,u_i) \in \mathbf{R}^n \times L^\infty(J,\mathbf{R}^m)$ converging to zero. Using the notation $\sigma^i(t) = \sigma(t,x_0+x_i,u_i)$, $\sigma_2^i(t) = \sigma_2(t,x_0+x_i,u_i)$, we have

$$\|\sigma^i(t) - \sigma_2^i(t)\| \le \int_{t_0}^t \|\Phi(s,\sigma^i(s),u_i(s)) - \Phi_2(s,\sigma_2^i(s),u_i(s))\|ds$$

$$\leq \int_{t_0}^{t} \|\Phi(s,\sigma^i(s),u_i(s)) - \Phi(s,\sigma_2^i(s),u_i(s))\|ds$$
$$+ \int_{t_0}^{t} \|\Phi(s,\sigma_2^i(s),u_i(s)) - \Phi_2(s,\sigma_2^i(s),u_i(s))\|ds.$$

Set $h_i(s) = \|\Phi(s,\sigma_2^i(s),u_i(s)) - \Phi_2(s,\sigma_2^i(s),u_i(s))\|/\|(x_i,u_i)\|_\infty^2$, then there are $\theta_i(s) \in [0,1]$ such that

$$h_i(s) \leq \frac{1}{2}\|D_{33}^2\Phi(s,\sigma_2^i(s),\theta_i(s)u_i(s)) - D_{33}^2\Phi(s,\sigma_2^i(s),0)\|. \tag{16}$$

Thanks to their definition, the h_i's are integrable. Moreover from (16), since $D_{33}^2\Phi$ is quasi-C, then $\{h_i\}$ is a bounded sequence converging pointwise to zero. Therefore the L^∞ norm of the integral of h_i tends to zero by the Lebesgue theorem on dominated convergence. From the above estimate, since Φ is quasi-C^1, we deduce

$$\frac{\|\sigma^i(t) - \sigma_2^i(t)\|}{\|(x_i,u_i)\|_\infty^2} \leq H_1 \int_{t_0}^{t} \frac{\|\sigma^i(s) - \sigma_2^i(s)\|}{\|(x_i,u_i)\|_\infty^2}ds + \int_{t_0}^{t} h_i(s)ds.$$

By the Gronwall inequality we obtain (15).

Volterra expansions will give us the approximation of σ_2. For any scalar C^2 map ρ and any vector field h we define the new function $h \cdot \rho : y \mapsto D\rho(y)h(y)$. Let us denote the derivatives of Φ as time-dependent vector fields by

$$D_3\Phi(t,y,0) = (g_1(t)(y),\ldots,g_m(t)(y)),\ D_{33}^2\Phi(t,y,0) = (g_{ij}(t)(y))_{i,j=1,\ldots,m}.$$

The g_i's are quasi-C^1 and the g_{ij}'s are quasi-C. We will first take the expansion of the flow of σ_2 with respect to u and then take the expansion with respect to x. Set $y = x_0 + x$ and let ρ be a coordinate function. Then

$$\rho(\sigma_2(t)) = \rho(y) + \int_{t_0}^{t} \sum_{i=1}^{m} u_i(s)(g_i(s)\cdot\rho)(\sigma_2(s))ds$$
$$+ \frac{1}{2}\int_{t_0}^{t} \sum_{i,j=1}^{m} u_i(s)u_j(s)(g_{ij}(s)\cdot\rho)(\sigma_2(s))ds$$
$$= \rho(y) + \int_{t_0}^{t} \sum_{i=1}^{m} u_i(s)(g_i(s)\cdot\rho)(y)ds$$
$$+ \frac{1}{2}\int_{t_0}^{t} \sum_{i,j=1}^{m} u_i(s)u_j(s)(g_{ij}(s)\cdot\rho)(\sigma_2(s))ds$$
$$+ \int_{t_0}^{t}\int_{t_0}^{s} \sum_{i,j=1}^{m} u_i(s)u_j(\tau)(g_j(\tau)\cdot g_i(s)\cdot\rho)(\sigma_2(s))d\tau ds.$$

If we proceed as before, we can estimate the remainder in the expansion to obtain

$$\rho(\sigma_2(t)) = \rho(y) + \int_{t_0}^{t} \sum_{i=1}^{m} u_i(s)(g_i(s)\cdot\rho)(y)ds + \frac{1}{2}\int_{t_0}^{t} \sum_{i,j=1}^{m} u_i(s)u_j(s)(g_{ij}(s)\cdot\rho)(y)ds$$
$$+ \int_{t_0}^{t}\int_{t_0}^{s} \sum_{i,j=1}^{m} u_i(s)u_j(\tau)(g_j(\tau)\cdot g_i(s)\cdot\rho)(y)d\tau ds + R(t,x,u),$$

where $|R(t,x,u)| \le o(\|(x,u)\|_\infty^2)$. Let us now take the expansion with respect to x:

$$\rho(x_0+x) = \rho(x_0) + D\rho(x_0)x + S(x) \text{ with } |S(x)| = o(\|x\|^2),$$
$$g_i(s)\cdot\rho(x_0+x) = g_i(s)\cdot\rho(x_0) + D(g_i(s)\cdot\rho)(x_0)x + T(s,x)$$

with $|T(s,x)| \le o(\|x\|)$. Then

$$\int_{t_0}^t \sum_{i=1}^m u_i(s)(g_i(s)\cdot\rho)(x_0+x)ds$$
$$= \int_{t_0}^t \sum_{i=1}^m u_i(s)\left(g_i(s)\cdot\rho(x_0) + (x\cdot g_i(s)\cdot\rho)(x_0)\right)ds + W(t,x,u),$$

with $|W(t,x,u)| \le o(\|(x,u)\|_\infty^2)$. Combining all the previous estimates we obtain for the second derivative

$$\sigma(t,x_0+x,u) = x_0 + x + \int_{t_0}^t \left(\sum_{i=1}^m u_i(s)g_i(s,x_0)\right)ds$$
$$+ \int_{t_0}^t \left(\sum_{i=1}^m u_i(s)D_2g_i(s,x_0)x\right)ds + \frac{1}{2}\int_{t_0}^t \left(\sum_{i,j=1}^m u_i(s)u_j(s)g_{ij}(s,x_0)\right)ds$$
$$+ \int_{t_0}^t\int_{t_0}^s \left(\sum_{i,j=1}^m u_i(s)u_j(\tau)D_2g_i(s,x_0)g_j(\tau,x_0)\right)d\tau ds + \mathcal{R}_2(x,u)(t)$$
$$= x_0 + \sigma_L(t,x,u) + \int_{t_0}^t D^2_{23}\hat\Phi(s)(x,u(s))ds$$
$$+ \frac{1}{2}\int_{t_0}^t D^2_{33}\hat\Phi(s)(u(s))^2ds + \int_{t_0}^t D^2_{23}\hat\Phi(s)(\sigma_L(s,0,u),u(s))ds + \mathcal{R}_2(x,u)(t)$$
$$= x_0 + \sigma_L(t,x,u) + \frac{1}{2}\int_{t_0}^t D^2_{33}\hat\Phi(s)(u(s))^2ds$$
$$+ \int_{t_0}^t D^2_{23}\hat\Phi(s)(\sigma_L(s,x,u),u(s))ds + \mathcal{R}_2(x,u)(t)$$
$$= x_0 + \sigma_L(t,x,u) + \frac{1}{2}\sigma_Q(t,x,u) + \mathcal{R}_2(x,u)(t). \qquad \square$$

The next example shows that the approximating flow may not have uniqueness of solutions.

Example 3.2. Let us consider

$$\Phi(y,w) = (y+w)^{\frac{7}{3}} - y^{\frac{7}{3}};$$

Φ is quasi-C^2. For the reference control $u \equiv 0$, the reference vector field is also zero and the second-order approximation is

$$\Phi_2(y,w) = D_2\Phi(y,0)w + \frac{1}{2}D^2_{22}\Phi(y,0)w^2 = \frac{7}{3}y^{\frac{4}{3}}w + \frac{14}{9}y^{\frac{1}{3}}w^2,$$

which is not Lipschitz continuous with respect to y at $y=0$, and the corresponding flow, defined through

$$\dot\sigma_2(t) = \frac{7}{3}\sigma_2^{\frac{4}{3}}(t)u(t) + \frac{14}{9}\sigma_2^{\frac{1}{3}}(t)u^2(t)\ ,\ \sigma_2(t_0) = x,$$

does not have a unique solution at $x = 0$.

Let us now express the results of Theorem 3.1 for the original system (1). Let A, B be the matrices describing the linearized system introduced in §2 and consider the following system:

$$\begin{aligned} \dot{\xi}_L(t) &= A(t)\xi_L(t) + B(t)u(t),\ \xi_L(t_0) = x, \\ \dot{\xi}_Q(t) &= A(t)\xi_Q(t) + \nabla^2\hat{F}(t)((\xi_L(t), u(t)))^2,\ \xi_Q(t_0) = 0. \end{aligned} \tag{17}$$

We denote by $\xi_L(t, x, u)$ and by $\xi_Q(t, x, u)$ the solutions of the above system, following the notation used for the solutions of (13).

Theorem 3.1 is equivalent to the following theorem.

THEOREM 3.3. *Let F be quasi-C^2, then the second-order expansion of the flow of* (1) *at $(x_0, \hat{u})$ can be written as*

$$\xi(t, x_0 + x, \hat{u} + u) = \hat{\xi}(t) + \xi_L(t, x, u) + \frac{1}{2}\xi_Q(t, x, u) + \mathcal{R}_2(x, u)(t),$$

where

$$\|\mathcal{R}_2(x, u)(t)\| \leq o(\|(x, u)\|_\infty^2).$$

Proof. Since $\xi(t, x, \hat{u} + u) = \gamma(t, t_0, \sigma(t, t_0, x, u))$ then

$$\begin{aligned} D\Xi(x_0, \hat{u})(x, u)(t) &= D_3\gamma(t, t_0, x_0)D\Sigma(x_0, 0)(x, u)(t), \\ D^2\Xi(x_0, \hat{u})((x, u))^2(t) &= D_{33}^2\gamma(t, t_0, x_0)(D\Sigma(x_0, 0)(x, u)(t))^2 \\ &\quad + D_3\gamma(t, t_0, x_0)D^2\Sigma(x_0, 0)((x, u))^2(t). \end{aligned}$$

The maps $\Gamma_L(t) \equiv D_3\gamma(t, t_0, x_0)$, $\Gamma_Q(t) \equiv D_{33}^2\gamma(t, t_0, x_0)$ satisfy the following differential system:

$$\begin{aligned} \dot{\Gamma}_L(t) &= A(t)\Gamma_L(t),\ \Gamma_L(t_0) = Id, \\ \dot{\Gamma}_Q(t) &= A(t)\Gamma_Q(t) + D_{22}^2\hat{F}(t) \otimes \Gamma_L(t),\ \Gamma_Q(t_0) = 0. \end{aligned}$$

Moreover from $\gamma(t_0, t, \gamma(t, t_0, x_0)) = x_0$ one can derive

$$\begin{aligned} D_3\gamma(t_0, t, \gamma(t, t_0, x_0)) &= \Gamma_L^{-1}(t), \\ D_{33}^2\gamma(t_0, t, \gamma(t, t_0, x_0)) \otimes \Gamma_L(t) &= -\Gamma_L^{-1}(t)\Gamma_Q(t). \end{aligned}$$

Hence $D\Xi(x_0, \hat{u})(x, u)$ is the solution of the system

$$\dot{\xi}_L(t) = \dot{\Gamma}_L(t)\sigma_L(t) + \Gamma_L(t)\dot{\sigma}_L(t) = A(t)\xi_L(t) + \Gamma_L D_3\hat{\Phi}(t)u(t).$$

Taking into account that $D_3\hat{\Phi}(t) = \Gamma_L^{-1}(t)D_3F(t, \gamma(t, t_0, x_0), \hat{u}(t))$, we determine that the first derivative of Ξ is ξ_L as expressed in (17). $D^2\Xi(x_0, \hat{u})(x, u)$ is the solution of the system

$$\begin{aligned} \dot{\xi}_Q(t) &= \dot{\Gamma}_Q(t)(\sigma_L(t))^2 + 2\Gamma_Q(t)(\dot{\sigma}_L(t), \sigma_L(t)) + \dot{\Gamma}_L(t)\sigma_Q(t) + \Gamma_L(t)\dot{\sigma}_Q(t) \\ &= A(t)\Gamma_Q(t)(\sigma_L(t))^2 + D_{22}^2\hat{F}(t)(\Gamma_L(t)\sigma_L(t))^2 + 2\Gamma_Q(t)(\dot{\sigma}_L(t), \sigma_L(t)) \\ &\quad + A(t)\Gamma_L(t)\sigma_Q(t) + \Gamma_L(t)\dot{\sigma}_Q(t) \\ &= A(t)\xi_Q(t) + D_{22}^2\hat{F}(t)(\xi_L(t))^2 + 2\Gamma_Q(t)(\dot{\sigma}_L(t), \sigma_L(t)) + \Gamma_L(t)\dot{\sigma}_Q(t). \end{aligned}$$

Since

$$D^2_{33}\hat{\Phi}(t) = \Gamma_L^{-1}(t) D^2_{33} F(t, \gamma(t, t_0, x_0), \hat{u}(t))$$

and

$$\begin{aligned} &D^2_{23}\hat{\Phi}(t)(\sigma_L(t), u(t)) \\ &\quad = -\Gamma_L^{-1}(t)\Gamma_Q(t)(\sigma_L(t), \Gamma_L^{-1}(t) D_3\hat{F}(t)u(t)) + \Gamma_L^{-1}(t) D^2_{33}\hat{F}(t)(\Gamma_L(t)\sigma_L(t), u(t)), \end{aligned}$$

then

$$\begin{aligned} &2\Gamma_Q(t)(\dot{\sigma}_L(t), \sigma_L(t)) + \Gamma_L(t)\dot{\sigma}_Q(t) \\ &\quad = 2\Gamma_Q(t)(D_3\hat{\Phi}(t)u(t), \sigma_L(t)) - 2\Gamma_Q(t)(\sigma_L(t), \Gamma_L^{-1}(t) D_3\hat{F}(t)(u(t))) \\ &\qquad + D^2_{23}\hat{F}(t)(\Gamma_L(t)\sigma_L(t), u(t)) + D^2_{33}\hat{F}(t)(u(t))^2 \\ &\quad = 2D^2_{23}\hat{F}(t)(\xi_L(t), u(t)) + D^2_{33}\hat{F}(t)(u(t))^2. \end{aligned}$$

Thus we obtain the second derivative of Ξ:

$$\dot{\xi}_Q(t) = A(t)\xi_Q(t) + D^2_{22}\hat{F}(t)(\xi_L(t))^2 + 2D^2_{23}\hat{F}(t)\,(\xi_L(t), u(t)) + D^2_{33}\hat{F}(t)(u(t))^2,$$

which is equivalent to the expression in (17). □

Remark 3.4. It is important to notice that the first and second derivatives of the flow of (12), at a given point, are defined and continuous also on the larger spaces $\mathbf{R}^n \times L^1(J, \mathbf{R}^m)$ and $\mathbf{R}^n \times L^2(J, \mathbf{R}^m)$, respectively.

The next theorem states the smooth dependence of the derivatives of the flow of (12) with respect to the point (x, u).

THEOREM 3.5. *Assume that the map F is uniformly quasi-C^2; then the maps*

$$\begin{aligned} D\Xi &: \mathbf{R}^n \times L^\infty(J, \mathbf{R}^m) \to \mathcal{L}\left(\mathbf{R}^n \times L^1(J, \mathbf{R}^m), L^\infty(J, \mathbf{R}^n)\right), \\ D^2\Xi &: \mathbf{R}^n \times L^\infty(J, \mathbf{R}^m) \to \mathcal{L}^2\left(\mathbf{R}^n \times L^2(J, \mathbf{R}^m), L^\infty(J, \mathbf{R}^m)\right) \end{aligned}$$

are continuous on a neighborhood of $(x_0, \hat{u})$.

Proof. We notice that for the solution of a linear system

$$\dot{\varphi}(t) = A(t)\varphi(t) + f(t), \ \varphi(t_0) = y$$

if $\|A\|_\infty \le L$ then there is $M > 0$ such that

$$\|\varphi\|_\infty \le M\|(y, f)\|_1. \tag{18}$$

Let (x, u) and $(\bar{x}, \bar{u}) = (x + \Delta x, u + \Delta u)$ be two points in a neighborhood of $(x_0, \hat{u})$ and let $\xi_i \equiv D^i\Xi(x, u)\big((y, v)\big)^i$ and $\eta_i \equiv D^i\Xi(\bar{x}, \bar{u})\big((y, v)\big)^i$ for $i = 1, 2$.

By the previous results we have

$$\begin{aligned} \dot{\xi}_1(t) &= A(t)\xi_1(t) + B(t)v(t), \ \xi_1(t_0) = y, \\ \dot{\xi}_2(t) &= A(t)\xi_2(t) + H(t)(\xi_1(t), v(t))^2, \ \xi_2(t_0) = 0, \\ \dot{\eta}_1(t) &= \bar{A}(t)\eta_1(t) + \bar{B}(t)v(t), \ \eta_1(t_0) = y, \\ \dot{\eta}_2(t) &= \bar{A}(t)\eta_2(t) + \bar{H}(t)(\eta_1(t), v(t))^2, \ \eta_2(t_0) = 0, \end{aligned}$$

where $H, \bar{H}$ are the second derivatives of F evaluated along the corresponding solutions of (1). We investigate the behavior of $\epsilon_i \equiv \xi_i - \eta_i$, $i = 1, 2$, as follows:

$$\dot{\epsilon}_1(t) = A(t)\epsilon_1(t) + (A(t) - \bar{A}(t))\eta_1(t) + (B(t) - \bar{B}(t))v(t), \ \epsilon_1(t_0) = 0.$$

Applying (18) first to η_1 and then to ϵ_1 we obtain

$$\|\epsilon_1\|_\infty \le \left(h_1\|A-\bar{A}\|_\infty + h_2\|B-\bar{B}\|_\infty\right)\|(y,v)\|_1 = \phi_1(\Delta x,\Delta u)\|(y,v)\|_1, \tag{19}$$

where $\phi_1(\Delta x,\Delta u)\to 0$ as $\|(\Delta x,\Delta u)\|_\infty \to 0$ thanks to the regularity assumptions on the data.

With

$$\begin{aligned}\dot{\epsilon}_2(t) = {} & A(t)\epsilon_2(t) + (A(t)-\bar{A}(t))\eta_2(t) + H(t)(\xi_1(t),v(t))^2 \\ & - \bar{H}(t)(\xi_1(t)-\epsilon_1(t),v(t))^2, \quad \epsilon_2(t_0)=0,\end{aligned}$$

let us estimate ϵ_2. By (18) we have

$$\|(\xi_1,v)\|_2^2 \le M(\|\xi_1\|_\infty^2 + \|v\|_2^2) \le M_1\|(y,v)\|_2^2. \tag{20}$$

Since an analogous estimate holds for η_1, we can estimate the forcing term involving η_2. For the other terms

$$\begin{aligned}&\left\|H(t)(\xi_1(t),v(t))^2 - \bar{H}(t)(\xi_1(t)-\epsilon_1(t),v(t))^2\right\| \\ &\quad \le \left\|H(t)-\bar{H}(t)\right\|\|(\xi_1(t),v(t))\|^2 + \left\|\bar{H}(t)\right\|\|(\epsilon_1(t),0)\|^2 \\ &\qquad + 2\left\|\bar{H}(t)\right\|\|(\xi_1(t),v(t))\|\,\|(\epsilon_1(t),0)\|,\end{aligned}$$

from estimates (19) and (20) and taking into account the uniform continuity of $\|\nabla^2 F\|$ with respect to t. Applying (18) we obtain

$$\|\epsilon_2\|_\infty \le \phi_2(\Delta x,\Delta u)\|(y,v)\|_2^2,$$

where $\phi_2(\Delta x,\Delta u)\to 0$ as $\|(\Delta x,\Delta u)\|_\infty \to 0$. This ends the proof. □

The assumption that the vector field is uniformly quasi-C^2 is essential to obtaining the smoothness of Theorem 3.5. For the sake of simplicity we give a first-order example where a flow whose first derivative does not have the required continuity properties corresponds to a quasi-C^1 vector field.

Example 3.6. For $t\in[0,T]$, let us consider the following control system:

$$\dot{\xi}(t) = -t\cos\left(\frac{u(t)}{t}\right), \quad \xi(0)=x.$$

Take $(x_0,\hat{u})\equiv(0,0)$ to obtain $\hat{\xi}=-\frac{1}{2}t^2$ as a reference trajectory. By taking the sequence $\{w_n\equiv 1/n\}$ it is easy to check that the nonlinear function $(t,w)\mapsto -t\cos(w/t)$ is quasi-C^1 but not uniformly quasi-C^1. The first derivative of the flow of this system at $(x_0,\hat{u})$ is clearly $\xi_L(t,x,u)\equiv x$, and if we take the derivative at a δ-neighboring point $(0,u_\delta)$ we obtain

$$\dot{\eta}(t) = \sin\left(\frac{u_\delta(t)}{t}\right)v(t), \quad \eta(0)=0.$$

Let us compute the error

$$\epsilon_1(t) = \int_0^t \sin\left(\frac{u_\delta(s)}{s}\right)v(s)ds.$$

Choosing $u_\delta(t) = t\rho_{[0,\delta]}(t)$, where ρ_I is the characteristic function of the set I, we obtain

$$\epsilon_1(t) = \begin{cases} \sin(1)\displaystyle\int_0^t v(s)ds, & \text{if } t \le \delta, \\ \sin(1)\displaystyle\int_0^\delta v(s)ds, & \text{if } t \ge \delta. \end{cases}$$

We want to show that

$$\lim_{\delta\to 0}\sup_v \frac{\|\epsilon_1\|_\infty}{\|v\|_1} \neq 0.$$

To do this let us take

$$v_\delta = \frac{1}{\delta}\rho_{[0,\delta]}$$

to obtain

$$\epsilon_1(t) = \begin{cases} \frac{t}{\delta}\sin(1), & \text{if } t \le \delta, \\ \sin(1), & \text{if } t \ge \delta, \end{cases}$$

so that

$$\lim_{\delta\to 0} \frac{\|\epsilon_1\|_\infty}{\|v_\delta\|_1} = \sin(1) \neq 0.$$

4. Abstract optimization results. In this section we state some abstract results which will be applied to obtain necessary or sufficient conditions for our original optimization problem. Let us first transform the control problem described in §2 into an abstract problem on the Banach space $E = \mathbf{R}^n \times L^\infty(J, \mathbf{R}^m)$. Define $\phi \equiv (\phi_0, \dots, \phi_p) : E \to \mathbf{R}^{p+1}$ as

$$\phi_i(x,u) = a_i(x, \xi(t_1, x, u)),\ i = 0, \dots, p,$$

and $\psi : E \to F \equiv L^\infty(J, \mathbf{R}^r)$ as

$$\psi(x,u)(t) = \alpha(t, \xi(t,x,u), u(t)).$$

The study of the problem will be pursued through the analysis of the range of the map

$$\tilde{\chi} \equiv (\phi + \psi) : E \to Z \equiv \mathbf{R}^{p+1} \oplus F.$$

The first component of $\tilde{\chi}$ is the cost and it has a special role. For this reason we decompose $\tilde{\chi}$ in the direct sum of two components: the cost ϕ_0 and the constraint $\chi \equiv (\phi_1, \dots, \phi_p) + \psi$. We indicate with $\mathbf{z_0}$ the unit vector of the cost axis, i.e., the vector in Z which has the first component equal to one and all the others equal to zero. A point $e = (x,u) \in E$ satisfies the constraints if and only if it has an image on the straight line through the origin, parallel to $\mathbf{z_0}$. These points will be called admissible. The point e is said to be *regular* for the constraints χ if and only if $D\chi(e)$ is onto. An element $\Lambda \in Z^*$, called *multiplier*, is said to be *normal* if and only if $\Lambda \mathbf{z_0} \neq 0$, that is, its cost component λ_0 is not zero.

An admissible reference couple $\hat{e} \equiv (x_0, \hat{u})$ is a weak local minimizer for the original problem if and only if there exists a neighborhood Θ of $\hat{e}$ in E such that

$$\tilde{\chi}(\Theta) \bigcap \{\tilde{\chi}(\hat{e}) - a\mathbf{z_0} : a > 0\} = \emptyset. \tag{21}$$

The properties of the range of $\tilde{\chi}$ will be described by the first and second derivatives at the reference point $\hat{e} \in E$, which will be denoted by

$$\tilde{\chi}' \equiv D\tilde{\chi}(\hat{e}),\ \tilde{\chi}'' \equiv D^2\tilde{\chi}(\hat{e}).$$

The same notation will also be used for other maps. The main assumption we will make on the function $\tilde{\chi}$ is as follows.

Assumption 4.1. The map $\tilde{\chi}$ satisfies

(i) $\tilde{\chi}$ is a C^2 map,

(ii) ψ' is onto and it has a continuous right inverse $\psi^\sharp : F \to E$.

Let us consider a complement Z_2 of $\operatorname{Im} \phi'_{|\operatorname{Ker}\psi'} = Y$ in $\mathbf{R}^{p+1}$. When $\mathbf{z_0} \notin Y$, Z_2 will be chosen so that $\mathbf{z_0} \in Z_2$. We denote by p_1, p_2 the projections from $\mathbf{R}^{p+1}$ onto Y and Z_2, respectively. There exists a continuous right inverse of ϕ' defined on Y with values in $\operatorname{Ker}\psi'$. Let $\phi^\sharp : \mathbf{R}^{p+1} \to \operatorname{Ker}\psi'$ be such an inverse extended zero to Z_2 so that $\phi'\phi^\sharp = p_1$ and $\phi^\sharp_{|Z_2} = 0$. The choice of Z_2 implies that

$$\text{either } \mathbf{z_0} \in Y \text{ or } \phi^\sharp \mathbf{z_0} = 0. \tag{22}$$

Notice that if $Z = X \oplus Y$ then we consider X, Y as subspaces of Z. From this point of view we consider $\mathbf{z_0}$ as an element of $\mathbf{R}, \mathbf{R}^{p+1}$ or Z.

In the following lemma we describe some properties of $\tilde{\chi}'$.

LEMMA 4.2. *If Assumption* 4.1 *is satisfied, then*

(i) $\operatorname{Im}\tilde{\chi}'$ *is closed in* Z *and it has* Z_2 *as a finite-dimensional complement,*

(ii) *the map* $\tilde{\chi}^\sharp : Z \to E$ *defined as*

$$\tilde{\chi}^\sharp(y + \omega) = \phi^\sharp(y - \phi'\psi^\sharp\omega) + \psi^\sharp\omega$$

is such that $\tilde{\chi}^\sharp_{|\operatorname{Im}\tilde{\chi}'}$ *is a continuous right inverse of* $\tilde{\chi}'$ *and* $\tilde{\chi}^\sharp_{|Z_2} = 0$,

(iii) *for* $\Lambda \in Z^*$ *let* $\lambda = \Lambda_{|\mathbf{R}^{p+1}}$. *Then* $\Lambda\tilde{\chi}' \equiv 0$ *if and only if*

$$\lambda\phi'_{|\operatorname{Ker}\psi'} = 0,\ \Lambda(y + \omega) = \lambda(y - \phi'\psi^\sharp\omega).$$

Proof. If we define $P_2 : Z \to Z_2$ as

$$P_2 : (y + \omega) \mapsto p_2\left(y - \phi'\psi^\sharp\omega\right),$$

then P_2 is a continuous projection.

Let us show that $\operatorname{Im}\tilde{\chi}' = \operatorname{Ker} P_2$. By definition $P_2\tilde{\chi}' = p_2\left(\phi' - \phi'\psi^\sharp\psi'\right)$. Part (ii) of Assumption 4.1 implies that $E = \operatorname{Ker}\psi' \oplus \operatorname{Im}\psi^\sharp$, hence $Id - \psi^\sharp\psi'$ is the projection onto $\operatorname{Ker}\psi'$ and we obtain

$$P_2\tilde{\chi}' = p_2\phi'_{|\operatorname{Ker}\psi'} = 0.$$

On the other hand if $P_2(y+\omega) = p_2\left(y - \phi'\psi^\sharp\omega\right) = 0$, then there exists $e \in \operatorname{Ker}\tilde{\chi}'$ such that $\phi' e = y - \phi'\psi^\sharp\omega$. Hence $\tilde{\chi}'(e + \psi^\sharp\omega) = \phi' e + \phi'\psi^\sharp\omega + \psi'\psi^\sharp\omega = y + \omega$, and statement (i) is proved.

Since $\phi^\sharp p_2 = 0$, from the definitions of P_2 and of $\tilde{\chi}^\sharp$ it follows that $\tilde{\chi}^\sharp P_2 = 0$. Moreover

$$\tilde{\chi}'\tilde{\chi}^\sharp\tilde{\chi}' = \tilde{\chi}'(\phi^\sharp\phi'(Id - \psi^\sharp\psi') + \psi^\sharp\psi').$$

Recalling that $\psi'\phi^\sharp = 0$, we obtain that $\tilde{\chi}'\tilde{\chi}^\sharp\tilde{\chi}' = \tilde{\chi}'$, which is equivalent to (ii).

Set $\Lambda = \lambda + \Theta$,

$$\Lambda\tilde{\chi}' = 0 \iff \Lambda = \Lambda P_2 \iff \lambda y + \Theta\omega = \lambda p_2(y - \phi'\psi^\sharp\omega).$$

The last equivalence implies that $\lambda = \lambda p_2$ and statement (iii) is easily verified. □

Let $P_2 : Z \to Z_2$ be defined as in Lemma 4.2 and define $Z_1 = \operatorname{Im}\tilde{\chi}'$, $P_1 = Id - P_2$. With this notation

$$\tilde{\chi}'\tilde{\chi}^\sharp = P_1,\ \tilde{\chi}^\sharp P_1 \equiv \tilde{\chi}^\sharp.$$

If we set $\operatorname{Ker}\tilde{\chi}' \equiv E_0$, then $E_1 \equiv \operatorname{Im}\tilde{\chi}^\sharp$ is a topological complement of E_0, and $E = E_0 \oplus E_1$. For $i = 0, 1$, denote by Π_i the canonical projections onto E_i so that $\Pi_1 \equiv \tilde{\chi}^\sharp\tilde{\chi}'$.

The next lemma gives necessary conditions for (21) to hold under the assumption that *codim* $\operatorname{Im}\tilde{\chi}' = 1$, hence this lemma gives necessary optimality conditions for our problem.

LEMMA 4.3. *Assume that the map $\tilde{\chi}$ satisfies Assumption* 4.1 *and that*

1. *there exists a neighborhood Θ of $\hat{e}$ such that* (21) *holds,*
2. *codim* $\operatorname{Im}\tilde{\chi}' = 1$;

then there exists a nonzero multiplier $\Lambda \in Z^*$ such that

(i) $\Lambda\tilde{\chi}' = 0$,

(ii) $\Lambda\mathbf{z_0} \geq 0$,

(iii) $\Lambda\tilde{\chi}''(e)^2 \geq 0$ *for all* $e \in \operatorname{Ker}\chi' = \operatorname{Ker}\tilde{\chi}' \oplus \mathbf{R}\chi^\sharp\mathbf{z_0}$.

Proof. (21) can be written as $\phi(\psi^{-1}(0)\bigcap\Theta)\bigcap\{\phi(\hat{e}) - a\mathbf{z_0} : a > 0\} = \emptyset$. The implicit function theorem applied to ψ yields that there is a neighborhood $\mathcal{V}$ of 0 in E_0 and a C^2 map $\nu : \mathcal{V} \to E$ such that, for a possibly smaller Θ, $\psi^{-1}(0)\bigcap\Theta = \{\hat{e} + v + \nu(v) : v \in \mathcal{V}\}$. Moreover $D\nu(0) = 0$, $D^2\nu(0) = -\psi^\sharp\psi''$. If we let $\Phi(v) = \phi(\hat{e} + v + \nu(v))$ then (21) is equivalent to

$$\Phi(\mathcal{V})\bigcap\{\phi(\hat{e}) - a\mathbf{z_0} : a > 0\} = \emptyset. \tag{23}$$

Notice that $\Phi' \equiv D\Phi(0) = \phi'_{|E_0}$ and without loss of generality we may assume that

$$\Phi'' \equiv D^2\Phi(0) = p_2\Phi''. \tag{24}$$

In fact on E_0 we can make the local change of coordinates given by $\beta \equiv Id - \frac{1}{2}\phi^\sharp\Phi''$ to obtain

$$(\Phi \circ \beta)' = \Phi',\ (\Phi \circ \beta)'' = p_2(\Phi \circ \beta)'' = p_2\Phi''.$$

By Assumption 2 and Lemma 4.2 there is a nonzero $\lambda \in (\mathbf{R}^{p+1})^*$, unique up to a nonzero factor, such that

$$\lambda\phi'_{|\operatorname{Ker}\psi'} = 0.$$

Without loss of generality we may assume that $\lambda\mathbf{z_0}$ is either one or zero. If we define $\Lambda = \lambda P_2$, we have that $\Lambda\tilde{\chi}' = 0$ and $\Lambda\tilde{\chi}'' = \lambda(\phi'' - \phi'\psi^\sharp\psi'') = \lambda\Phi''$, moreover $\Lambda\mathbf{z_0}$ is either one or zero. Let us consider these two cases separately.

Case I: $\lambda \mathbf{z_0} = \Lambda \mathbf{z_0} = 1$. In this case $\mathbf{z_0} \notin \operatorname{Im} \tilde{\chi}'$. Hence by (22), $p_2 = \mathbf{z_0}\lambda$ and $\operatorname{Ker} \chi' = \operatorname{Ker} \tilde{\chi}'$. By contradiction assume that there is $e_0 \in \operatorname{Ker} \tilde{\chi}' = \operatorname{Ker} \psi' \bigcap \operatorname{Ker} \phi'$ such that

$$\Lambda \tilde{\chi}''(e_0)^2 = \lambda \Phi''(e_0)^2 = -2.$$

We want to show that this contradicts (23). Let $H = \phi^\sharp(\mathbf{R}^{p+1}) \subset E_0$ and, locally around zero, define $\rho : \mathbf{R} \times H \times \mathbf{R} \to \mathbf{R}^{p+1}$ by

$$\rho(\epsilon, e, c) \equiv \rho_\epsilon(e, c) = \begin{cases} \dfrac{1}{\epsilon^2}\left[\Phi(\epsilon c e_0 + \epsilon^2 e) - \phi(\hat{e})\right], & \text{if } \epsilon \neq 0, \\ \phi' e + \dfrac{1}{2} c^2 \Phi''(e_0)^2, & \text{if } \epsilon = 0. \end{cases}$$

For $\epsilon \neq 0$ we obtain $\rho_\epsilon(e, c) = \rho_0(e, c) + \frac{1}{\epsilon^2} o(\epsilon^2)$, so ρ is continuous with respect to ϵ. By (24) $\rho_0(0, 1) = -\mathbf{z_0}$. It is easy to check that $D\rho_0(0, 1)$ is an isomorphism so that by standard arguments of degree theory, we determine that, for ϵ sufficiently small, $\operatorname{Im} \rho_\epsilon$ contains a ball with center at $-\mathbf{z_0}$ and radius r. As a consequence $\Phi(\mathcal{V})$ contains $\phi(\hat{e}) - \epsilon^2 \mathbf{z_0}$, which is a contradiction.

Case II: $\lambda \mathbf{z_0} = \Lambda \mathbf{z_0} = 0$. In this case $\phi^\sharp \mathbf{z_0} \neq 0$. Let $\bar{z}$ be such that $p_2 = \bar{z}\lambda$. If $\lambda \Phi''(\tilde{\chi}^\sharp \mathbf{z_0})^2 \neq 0$ then we may assume that it is negative. Assume by contradiction that there is $e_0 \in E_0$ such that

$$\lambda \Phi''(e_0)^2 > 0.$$

Decompose H as $H = K \oplus \mathbf{R}\phi^\sharp \mathbf{z_0}$ and define, for $\epsilon > 0$, $\rho_\epsilon : K \times \mathbf{R}^2 \to \mathbf{R}^{p+1}$ by

$$\rho_\epsilon(e, a, b) = \Phi' e + a \mathbf{z_0} + \frac{1}{2} \epsilon \lambda \Phi''(e + a\phi^\sharp \mathbf{z_0} + b e_0)^2 \bar{z}.$$

We have

$$\frac{1}{\epsilon}[\Phi(\epsilon(e + a\phi^\sharp \mathbf{z_0} + b e_0)) - \phi(\hat{e})] = \rho_\epsilon(e, a, b) + o(\epsilon).$$

For ϵ sufficiently small let us now define the homotopy $h_\epsilon : [0, 1] \times K \times \mathbf{R}^2 \to \mathbf{R}^{p+1} = \Phi' K \oplus \mathbf{R}\mathbf{z_0} \oplus \mathbf{R}\bar{z}$ by

$$h_\epsilon(t, e, a, b) = \rho_\epsilon(e, a, b) + t\, o(\epsilon).$$

By the assumptions there is $\bar{b}$ such that $\lambda \Phi''(-\phi^\sharp \mathbf{z_0} + \bar{b} e_0)^2 = 0$, so $\rho_\epsilon(0, -1, \bar{b}) = -\mathbf{z_0}$. Moreover we obtain

$$D\rho_\epsilon(0, -1, \bar{b}) = \begin{pmatrix} \Phi' & 0 & 0 \\ 0 & 1 & 0 \\ * & * & \epsilon \lambda \Phi''(-\phi^\sharp \mathbf{z_0} + \bar{b} e_0, e_0) \end{pmatrix}.$$

Since the quadratic form $\lambda \Phi''$ is not degenerate on $Span\{e_0, \phi^\sharp \mathbf{z_0}\}$ then $\lambda \Phi''(-\phi^\sharp \mathbf{z_0} + \bar{b} e_0, e_0) = \kappa \neq 0$. Hence there is $\bar{\epsilon}$, such that for $\epsilon < \bar{\epsilon}$

$$\left\| D\rho_\epsilon(0, -1, \bar{b}) x \right\| \geq \epsilon \kappa \|x\|$$

and there is $r > 0$ such that if $\|f\| \leq r$, then

$$\|\rho_\epsilon((0, -1, \bar{b}) + f) + \mathbf{z_0}\| \geq \frac{\epsilon \kappa}{2} \|f\|.$$

For $\|f\| = \|(e,a,b)\| = r$ we obtain the following estimate:

$$\|h_\epsilon(t,e,-1+a,\bar{b}+b)) + \mathbf{z_0}\| = \|\rho_\epsilon(e,-1+a,\bar{b}+b)) + t\,o(\epsilon) + \mathbf{z_0}\|$$
$$\geq \epsilon\Big(\frac{\kappa r}{2} - \frac{\|o(\epsilon)\|}{\epsilon}\Big) > 0$$

for ϵ sufficiently small. Using the homotopy invariance property of the Brower degree (see [2]), the above inequality implies that the degree of the maps $h_\epsilon(1,\cdot)$ and $h_\epsilon(0,\cdot)$ on the ball $B(r,(0,-1,\bar{b}))$ with respect to $\mathbf{z_0}$ is the same. Since the second map is a local homeomorphism these degrees are not zero; therefore $\phi(\hat{e}) - \epsilon\mathbf{z_0} \in \Phi(\mathcal{V})$, which contradicts (23).

To end the analysis of this case let $\lambda\Phi''(\phi^\sharp\mathbf{z_0})^2 = 0$ and assume by contradiction that there are $e_0,\ f_0 \in E_0$ such that

$$\lambda\Phi''(e_0)^2 > 0,\ \lambda\Phi''(f_0)^2 < 0.$$

Let us prove that this contradicts (23). With the same notation as in Case I define, locally around zero, $\rho : \mathbf{R}\times H\times\mathbf{R}\to\mathbf{R}^{p+1}$ by

$$\rho(\epsilon,e,c) \equiv \rho_\epsilon(e,c) = \begin{cases} \dfrac{1}{\epsilon^2}\left[\Phi(\epsilon c e_0 + \epsilon f_0 + \epsilon^2 e) - \phi(\hat{e})\right], & \text{if } \epsilon \neq 0, \\ \phi' e + \dfrac{1}{2}\Phi''(ce_0+f_0)^2, & \text{if } \epsilon = 0. \end{cases}$$

By (24) ρ is continuous with respect to ϵ and $\rho_0(e,c) = \phi' e + \frac{1}{2}\lambda\Phi''(ce_0+f_0)^2\bar{z}$. By the assumptions, there exists $\bar{c}$ such that $\lambda\Phi''(\bar{c}e_0+f_0)^2 = 0$. Moreover for the same reasons as before $\lambda\Phi''(\bar{c}e_0+f_0,e_0) \neq 0$. We have that $\rho_0(0,\bar{c}) = 0$ and

$$D\rho_0(0,\bar{c}) = \begin{pmatrix} \phi' & 0 \\ 0 & \lambda\Phi''(\bar{c}e_0+f_0,e_0) \end{pmatrix}.$$

Reasoning as in Case I we obtain a contradiction to (23). □

If we drop the assumption *codim* $\operatorname{Im}\tilde{\chi}' = 1$, the statement of Lemma 4.3 could be false but one can obtain the following trivial corollary.

COROLLARY 4.4. *Assume that the map $\tilde{\chi}$ satisfies Assumption* 4.1 *and that there exists a neighborhood Θ of $\hat{e}$ such that* (21) *holds. Then for all $e \in \operatorname{Ker}\chi' = \operatorname{Ker}\tilde{\chi}' \oplus \mathbf{R}\chi^\sharp\mathbf{z_0}$ there exists a nonzero multiplier $\Lambda \in Z^*$ such that*

(i) $\Lambda\tilde{\chi}' = 0$,
(ii) $\Lambda\mathbf{z_0} \geq 0$,
(iii) $\Lambda\tilde{\chi}''(e)^2 \geq 0$

Proof. If *codim* $\operatorname{Im}\tilde{\chi}' = 1$ we can apply the previous Lemma 4.3. If it is greater than one then we can consider the space $\bar{Z}$ spanned by $\operatorname{Im}\tilde{\chi}'$ and $\tilde{\chi}''(e)^2$. Take a nonzero multiplier $\bar{\Lambda}$ which is zero on $\bar{Z}$ to obtain the statement. □

To state conditions sufficient for (21) to hold, we now consider the Banach space E endowed also with another, possibly different, norm $\|\cdot\|_2$. We denote by τ the topology under which E is a Banach space and by τ_2, the other.

The next lemma provides an abstract framework to prove sufficient conditions for weak local optimality for our optimization problem. Let us emphasize that it is necessary that the completion of E_0 under τ_2 be a Hilbert space, otherwise no continuous positive quadratic form on (E_0,τ_2) could be coercive.

LEMMA 4.5. *Assume that $\tilde{\chi} : E \to Z$ satisfies Assumption* 4.1 *and*

1. $\tilde{\chi}^\sharp D\tilde{\chi} : (E,\tau) \to \mathcal{L}((E,\tau_2),(E,\tau_2))$ *is continuous.*

Assume moreover that there exists a multiplier $\Lambda \in Z^*$ *and* $K > 0$ *such that*

2. $\Lambda D^2\tilde{\chi} : (E,\tau) \to \mathcal{L}^2((E,\tau_2),\mathbf{R})$ *is continuous,*
3. $\Lambda\tilde{\chi}' = 0$,
4. $\Lambda\mathbf{z_0} \geq 0$,
5. $\Lambda\tilde{\chi}''(e)^2 \geq K\|e\|_2^2$ *for every* $e \in \operatorname{Ker}\chi' = \operatorname{Ker}\tilde{\chi}' \oplus \mathbf{R}\tilde{\chi}^\sharp\mathbf{z_0}$.

Then there exists a neighborhood Θ *of* $\hat{e}$ *in* (E,τ) *such that*

$$\tilde{\chi}(\Theta) \cap \{\tilde{\chi}(\hat{e}) - a\mathbf{z_0} : a > 0\} = \emptyset.$$

Proof. Let us prove the statement by contradiction. Assume that there exist sequences $\{a_i\} \subset \mathbf{R}_+$ and $\{e_i\} \subset E$ such that

$$\|e_i\| \to 0 \text{ and } \tilde{\chi}(\hat{e} + e_i) = \tilde{\chi}(\hat{e}) - a_i\mathbf{z_0}.$$

There are $\theta_i \in [0,1]$ such that

$$P_1(\tilde{\chi}(\hat{e} + e_i) - \tilde{\chi}(\hat{e})) = \tilde{\chi}'e_i + P_1\big(D\tilde{\chi}(\hat{e} + \theta_i e_i) - \tilde{\chi}'\big)e_i = -a_i P_1\mathbf{z_0}.$$

Hence applying $\tilde{\chi}^\sharp$ we obtain

$$\tilde{\chi}^\sharp\tilde{\chi}'e_i = \Pi_1 e_i = -a_i\tilde{\chi}^\sharp\mathbf{z_0} - \tilde{\chi}^\sharp(D\tilde{\chi}(\hat{e} + \theta_i e_i) - D\tilde{\chi}(\hat{e}))e_i.$$

Let us consider two different cases. If $\Lambda\mathbf{z_0} \neq 0$, then by assumption 4 we can assume that $\Lambda\mathbf{z_0} = 1$ and by (22) $\tilde{\chi}^\sharp\mathbf{z_0} = 0$. Then assumption 1 yields

$$\frac{\|\Pi_1 e_i\|_2}{\|e_i\|_2} \to 0. \tag{25}$$

Moreover, using assumptions 3 and 5, for suitable $\theta_i \in [0,1]$, we obtain

$$\begin{aligned} -\frac{1}{\|e_i\|_2^2}a_i &= \frac{1}{\|e_i\|_2^2}\Lambda\big(\tilde{\chi}(\hat{e} + e_i) - \tilde{\chi}(\hat{e})\big) \\ &= \frac{1}{2}\Lambda\tilde{\chi}''\left(\frac{e_i}{\|e_i\|_2}\right)^2 + \frac{1}{2}\Lambda\big(D^2\tilde{\chi}(\hat{e} + \theta_i e_i) - D^2\tilde{\chi}(\hat{e})\big)\left(\frac{e_i}{\|e_i\|_2}\right)^2 \\ &\geq K\frac{\|\Pi_0 e_i\|_2^2}{\|e_i\|_2^2} - \frac{1}{2}\frac{2\|\Pi_0 e_i\|_2\|\Pi_1 e_i\|_2 + \|\Pi_1 e_i\|_2^2}{\|e_i\|_2^2}\|\Lambda\tilde{\chi}''\|_2 \\ &\quad - \frac{1}{2}|\Lambda(D^2\tilde{\chi}(\hat{e} + \theta_i e_i) - D^2\tilde{\chi}(\hat{e}))|. \end{aligned} \tag{26}$$

Let us examine the three addends in (26). From assumption 1 evaluated at $\hat{e}$ we also have that Π_0 is continuous with respect to τ_2. By (25) and assumption 2 the second and the third addend tend to zero. Since K and a_i have the same sign it follows that

$$\frac{\|\Pi_0 e_i\|_2}{\|e_i\|_2} \to 0,$$

which together with (25) yields a contradiction.

If $\Lambda\mathbf{z_0} = 0$, then assumption 1 yields

$$\Pi_1 e_i = -a_i\tilde{\chi}^\sharp\mathbf{z_0} + o_i$$

with

$$\frac{\|o_i\|_2}{\|e_i\|_2} \to 0. \tag{27}$$

From this equation one can deduce that $f_i = -a_i\tilde{\chi}^\sharp \mathbf{z_0} + \Pi_2 e_i = e_i - o_i \in \operatorname{Ker}\chi'$ is such that

$$\frac{\|f_i\|_2}{\|e_i\|_2} \text{ is bounded.} \tag{28}$$

Moreover, using assumptions 3 and 5, for suitable $\theta_i \in [0,1]$, we obtain

$$\begin{aligned} 0 &= \Lambda\tilde{\chi}''\left(\frac{e_i}{\|e_i\|_2}\right)^2 + \Lambda\big(D^2\tilde{\chi}(\hat{e}+\theta_i e_i) - D^2\tilde{\chi}(\hat{e})\big)\left(\frac{e_i}{\|e_i\|_2}\right)^2 \\ &\geq K\frac{\|f_i\|_2^2}{\|e_i\|_2^2} - \frac{2\|f_i\|_2\|o_i\|_2 + \|o_i\|_2^2}{\|e_i\|_2^2}\|\Lambda\tilde{\chi}''\|_2 - |\Lambda(D^2\tilde{\chi}(\hat{e}+\theta_i e_i) - D^2\tilde{\chi}(\hat{e}))|. \end{aligned} \tag{29}$$

By (27), (28), and assumption 2 the second and the third addend in (29) tend to zero, so

$$\frac{\|f_i\|_2}{\|e_i\|_2} \to 0,$$

which together with (27) yields a contradiction. □

Remark 4.6. It is important to emphasize the difference between the normal case ($\Lambda\mathbf{z_0} \neq 0$) and the abnormal one ($\Lambda\mathbf{z_0} = 0$). In the normal case $\operatorname{Ker}\tilde{\chi}' = \operatorname{Ker}\chi'$ and the second order optimality conditions concern the quadratic form $\Lambda\tilde{\chi}''_{|\operatorname{Ker}\tilde{\chi}'}$ which depends only on the *hessian* of $\tilde{\chi}$. In the abnormal case $\Lambda \in (\mathbf{R}^p \oplus F)^*$ and the quadratic form is $\Lambda\chi''_{|\operatorname{Ker}\chi'}$ which depends only on the hessian of the constraints χ. In this last case the optimality conditions essentially give information on the constraints.

The next remarks explain the difference between these two cases.

Remark 4.7. Lemma 4.3 is stated under the assumption that $codim\,\operatorname{Im}\tilde{\chi}' = 1$ so that in this case a normal multiplier corresponds to a regular point $\hat{e}$ and the optimality conditions directly involve both the cost ϕ_0 and the constraints χ. When the multiplier Λ is abnormal the cost does not appear in the optimality conditions. The information we have is that if $\Lambda\chi''_{|\operatorname{Ker}\chi'}$ is indefinite, then $\hat{e}$ cannot be an extremum for any cost satisfying $codim\,\operatorname{Im}\tilde{\chi}' = codim\,\operatorname{Im}\chi' = 1$.

Remark 4.8. If the multiplier in Lemma 4.5 is abnormal then the sufficient conditions hold true for any cost so that the point $\hat{e}$ is isolated among the admissible points.

In the normal case the coerciveness of $\Lambda\tilde{\chi}''$ is assumed on $\operatorname{Ker}\tilde{\chi}' = \operatorname{Ker}\chi'$. We have seen in Remark 4.8 that, in the abnormal case, if one imposes the coerciveness on $\operatorname{Ker}\chi'$ the sufficient conditions hold only at isolated points. One could think that, in this case, the coerciveness has to be imposed on $\operatorname{Ker}\tilde{\chi}'$, which is smaller, but this is not sufficient for optimality as is shown by the following example.

Example 4.9. Let us consider the following function $\tilde{\chi} : \mathbf{R}^2 \to \mathbf{R}^2$, defined as

$$\tilde{\chi}(x,y) = \begin{pmatrix} x \\ \frac{1}{2}(y^2 - x^2) \end{pmatrix}.$$

All the smoothness assumptions are verified and we have $\tilde{\chi}' = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$ so that

$$E_0 = Z_2 = span\left\{\begin{pmatrix} 0 \\ 1 \end{pmatrix}\right\}, \quad E_1 = Z_1 = span\left\{\begin{pmatrix} 1 \\ 0 \end{pmatrix}\right\}.$$

By taking $\Lambda = (0,1) \in (\mathbf{R}^2)^*$ we obtain $\operatorname{Im}\tilde{\chi}' = \operatorname{Ker}\Lambda$. Since $\Lambda\tilde{\chi}'' \otimes \Pi_0$ is the restriction to E_0 of the quadratic form $\left(\begin{smallmatrix} -2 & 0 \\ 0 & 2 \end{smallmatrix}\right)$ then $\Lambda\tilde{\chi}''_{|\operatorname{Ker}\tilde{\chi}'}$ is coercive, while studying the image of $\tilde{\chi}$ by the image of straight lines through the origin we have

$$\operatorname{Im}\tilde{\chi} = \left\{\begin{pmatrix} x \\ y \end{pmatrix} \in \mathbf{R}^2 : x \geq -y^2\right\},$$

and the image contains the whole y-axis.

5. Proof of the main results. In this section we suppose that our main Assumptions 2.2 and 2.4 are satisfied. Necessary or sufficient conditions which characterize a weak local minimum of the optimal control problem will be deduced from the abstract results described in §4.

For the derivatives at our reference point $\hat{e} \in E$, we will use the same notation as in §4. Moreover let $a \equiv (a_0, \ldots, a_p)$, $a' = Da(x_0, x_1)$, and $a'' = D^2a(x_0, x_1)$.

Since in the definition of ψ a Nemytskii-type operator is involved, we introduce a specific notation for the *superposition operator* and we state some of its properties. Let X, Y be finite-dimensional vector spaces. If $\mu : J \times X \to Y$, we denote by $\tilde{\mu} : L^\infty(J,X) \to L^\infty(J,Y)$ the superposition operator

$$\tilde{\mu}(\xi)(t) = \mu(t, \xi(t))$$

so, for example, $\psi(x,u) \equiv \tilde{\alpha} \circ (\Xi(x,u), u)$.

LEMMA 5.1. *Assume that the map μ is uniformly quasi-C^2, then the operator $\tilde{\mu}$ is C^2. Moreover the operator*

$$D\tilde{\mu} : L^\infty(J,X) \to \mathcal{L}((L^\infty(J,X), \tau_p), (L^\infty(J,Y), \tau_p))$$

is continuous for $1 \leq p \leq \infty$ and

$$D^2\tilde{\mu} : L^\infty(J,X) \to \mathcal{L}^2((L^\infty(J,X), \tau_2), (L^\infty(J,Y), \tau_1))$$

is continuous.

The proof of the above lemma is a straightforward consequence of the regularity assumption on the map μ.

Let us describe some properties of the infinite-dimensional constraint ψ that are needed to apply the results obtained in §4. Under our assumptions the map ψ' admits a continuous right inverse and we can apply Lemma 4.2.

LEMMA 5.2. *If the smoothness Assumption 2.2 is satisfied then ψ is a C^2 map and $\psi' : E \to L^\infty(J, \mathbf{R}^r)$ is given by*

$$\psi'(x,u)(t) = C(t)\xi_L(t,x,u) + D(t)u(t), \tag{30}$$

where ξ_L is the solution of the linearized system (3) *and C, D are defined in* (2).

Moreover ψ' is onto and it admits a continuous right inverse $\psi^\sharp$ if and only if Assumption 2.4 *holds. For $\omega \in L^\infty(J, \mathbf{R}^r)$, $\psi^\sharp\omega$ is given by the output of the system*

$$\begin{aligned} \dot{\zeta}(t) &= (A(t) - K(t))\zeta(t) + B(t)D^\sharp(t)\omega(t), \quad \zeta(t_0) = 0 \\ \psi^\sharp\omega(t) &= (0, D^\sharp(t)(\omega(t) - C(t)\zeta(t))), \end{aligned} \tag{31}$$

where $D^\sharp = D^\top(DD^\top)^{-1}$ *and* $K = BD^\sharp C$.

Proof. The smoothness of ψ follows from the properties of the flow and of the superposition operator described in Lemma 5.1. The proof of the other statements of this lemma is not significantly different from that of Lemma 3.1 in [15]. □

LEMMA 5.3. *If the smoothness Assumption* 2.2 *is satisfied, then the map* $\tilde{\chi}$ *satisfies Assumption* 4.1 *and*

$$\tilde{\chi}'(x,u) = a'(x,\xi_L(t_1,x,u)) + C(\cdot)\xi_L(\cdot,x,u) + D(\cdot)u(\cdot). \tag{32}$$

Proof. The smoothness of ϕ is a consequence of the properties of the flow and the chain rule so the statement is a consequence of Lemma 5.2. □

LEMMA 5.4. *If the smoothness Assumption* 2.2 *and the rank Assumption* 2.4 *are satisfied then the following statements are equivalent:*

(i) $(x_0,\hat{u})$ *is a regular point for the constraint* χ,

(ii) *the input–output system*

$$\begin{aligned} \dot{\eta}(t) &= (A(t) - B(t)D^\sharp(t)C(t))\eta(t) + B(t)(Id - D^\sharp(t)D(t))u(t),\ \eta(t_0) = x \\ y_i(t) &= Da_i(x_0,x_1)(x,\eta(t,x,u)),\ i = 1,\dots,p, \end{aligned} \tag{33}$$

is controllable at time t_1, *i.e.,* $(x,u) \mapsto (y_1(t_1),\dots,y_p(t_1))$ *is surjective.*

Proof. Applying (iii) of Lemma 4.2 to χ we determine that $(x_0,\hat{u})$ is regular for the constraints if and only if the map $(\phi_1',\dots,\phi_p')_{|Ker\,\psi'}$ is onto. The properties of the right inverse give that $Id - \psi^\sharp\psi'$ is the projection onto $\operatorname{Ker}\psi'$ so

$$\operatorname{Im}\phi'_{i|\operatorname{Ker}\psi'} = \operatorname{Im}\ \phi_i'(Id - \psi^\sharp\psi').$$

Let us first compute $\phi_i'\psi^\sharp$. By Lemma 5.2 and by (32) we have that, for $\omega \in L^\infty(J,\mathbf{R}^r)$, $\phi_i'\psi^\sharp\omega$ is given by

$$\begin{aligned} \dot{\zeta}(t) &= (A(t) - K(t))\zeta(t) + B(t)D^\sharp(t)\omega(t),\ \zeta(t_0) = 0, \\ \dot{\xi}_L(t) &= A(t)\xi_L(t) + B(t)D^\sharp(t)(\omega(t) - C(t)\zeta(t)),\ \xi_L(t_0) = 0, \\ \phi_i'\psi^\sharp\omega &= a_i'(x,\xi_L(t_1)). \end{aligned}$$

Taking the difference between the two above differential equations we can immediately verify that $\zeta - \xi_L$ is a solution of a linear differential equation with zero initial condition and hence it is zero itself. Thus

$$\phi_i'\psi^\sharp\omega = a_i'(x,\zeta(t_1,0,\omega)), \tag{34}$$

where ζ is defined in (31). Let us set $\rho_i(x,u) \equiv (\phi_i'(x,u) - \phi_i'\psi^\sharp\psi'(x,u))$, for $i = 1,\dots,p$. Then from (30) it follows that we can define ρ_i through the following cascade of systems:

$$\begin{aligned} \dot{\xi}_L(t) &= A(t)\xi_L(t) + B(t)u(t),\ \xi_L(t_0) = x, \\ \dot{\zeta}(t) &= (A(t) - K(t))\zeta(t) + B(t)D^\sharp(t)(C(t)\xi_L(t) + D(t)u(t)),\ \zeta(t_0) = 0, \\ \rho_i(x,u) &= a_i'(x,\xi_L(t_1) - \zeta(t_1)). \end{aligned}$$

Setting $\eta = \xi_L - \zeta$ one can readily verify that $\rho_i(x,u) = a_i'(x,\eta(t_1,x,u))$, where η is defined in (33). □

In the following lemma we describe some relations linking the adjoint covector, the Hamiltonian, and the ranges of $\tilde{\chi}'$ and $\tilde{\chi}''$.

LEMMA 5.5. *For* $\lambda \equiv (\lambda_0, \dots, \lambda_p) \in (\mathbf{R}^{p+1})^*$ *we have that* $\lambda \phi'_{|\operatorname{Ker} \psi'} = 0$ *if and only if there exists a solution* $\hat{p} : J \to (\mathbf{R}^n)^*$ *of the adjoint equation* (7) *satisfying the transversality conditions* (8) *such that*

$$D_4 \mathcal{H}(t, \hat{p}(t), \hat{\xi}(t), \hat{u}(t)) = 0,$$

where the Hamiltonian $\mathcal{H}$ *is defined in* (6).

If we define $\Lambda \in Z^*$ *as* $\Lambda(y + \omega) = \lambda(y - \phi' \psi^\sharp \omega)$, *then*

$$\begin{aligned} \Lambda \tilde{\chi}''((x,u))^2 &= \lambda a''((x, \xi_L(t_1, x, u)))^2 \\ &\quad + \int_{t_0}^{t_1} \nabla^2 \hat{\mathcal{H}}(s)((\xi_L(s, x, u), u(s)))^2 ds. \end{aligned} \tag{35}$$

Proof. Using the same arguments as in Lemma 5.4, one can show that $\lambda \phi'_{|\operatorname{Ker} \psi'} = 0$ if and only if $\lambda \phi'(Id - \psi^\sharp \psi') = 0$. From the proof of Lemma 5.4 it follows that

$$\lambda \phi'(Id - \psi^\sharp \psi')(x,u) = \lambda a'(x, \eta(t_1, x, u)),$$

where η is defined in (33). Therefore we have

$$\lambda \phi'_{|\operatorname{Ker} \psi'} = 0 \iff \lambda D_1 a(x_0, x_1) x + \lambda D_2 a(x_0, x_1) \eta(t_1, x, u) = 0, \ \forall (x,u) \in E. \tag{36}$$

To express the above relations by means of the appropriate Hamiltonian let us denote by Ω the solution of the matrix equation

$$\dot{\Omega}(t) = (A(t) - K(t))\Omega(t), \ \Omega(t_0) = Id.$$

Then $\eta(t_1, x, u) = \Omega(t_1)(x + \int_{t_0}^{t_1} \Omega^{-1}(t) B(t)(Id - D^\sharp(t) D(t)) u(t) dt)$, so that equation (36) is equivalent to the system

$$\lambda D_1 a(x_0, x_1) = -\lambda D_2 a(x_0, x_1) \Omega(t_1), \tag{37}$$

$$\lambda D_2 a(x_0, x_1) \Omega(t_1) \Omega^{-1}(t) B(t)(Id - D^\sharp(t) C(t)) = 0. \tag{38}$$

If $\hat{p}(t)$ is the solution of $\dot{p}(t) = -D_3 \mathcal{H}(t, p(t), \hat{\xi}(t), \hat{u}(t)) = -p(t)(A(t) - K(t))$, which satisfies $p(t_1) = \lambda D_2 a(x_0, x_1)$, then (37) is equivalent to the transversality condition (8). Taking into account the definitions of B, C, D, and the Hamiltonian $\mathcal{H}$, it follows that condition (38) can be expressed as

$$\hat{p}(t) D_3 \hat{F}(t) - \hat{p}(t) B(t) D^\sharp(t) D_3 \hat{\alpha}(t) = D_4 \hat{\mathcal{H}}(t) = 0.$$

This ends the first part of the proof.

From the definition of Λ it follows that $\Lambda \tilde{\chi}'' = \lambda(\phi'' - \phi' \psi^\sharp \psi'')$. Since

$$\begin{aligned} \phi''(x,u) &= a''((x, \xi_L(t_1, x, u)))^2 + D_2 a(x_0, x_1) \ \xi_Q(t_1, x, u), \\ \psi''(x,u)(t) &= \nabla^2 \hat{\alpha}(t)(\xi_L(t, x, u), u(t))^2 + D_2 \hat{\alpha}(t) \xi_Q(t, x, u), \end{aligned}$$

then by (34), $\Lambda \tilde{\chi}''$ an be written as the output of the following cascade of systems:

$$\begin{aligned} \dot{\xi}_L(t) &= A(t) \xi_L(t) + B(t) u(t), \ \xi_L(t_0) = x, \\ \dot{\xi}_Q(t) &= A(t) \xi_Q(t) + \nabla^2 \hat{F}(t)((\xi_L(t), u(t)))^2, \ \xi_Q(t_0) = 0, \\ \dot{\zeta}(t) &= (A(t) - K(t)) \zeta(t) \\ &\quad + B(t) D^\sharp(t)[\nabla^2 \hat{\alpha}(t)((\xi_L(t), u(t)))^2 + C(t) \xi_Q(t)], \ \zeta(t_0) = 0, \\ \lambda(\phi'' - \phi' \psi^\sharp \psi'')(x,u) &= \lambda \, a''((x, \xi_L(t_1)))^2 + \lambda \, D_2 a(x_0, x_1) \, [\xi_Q(t_1) - \zeta(t_1)]. \end{aligned}$$

If we define $z_Q(t) = \xi_Q(t) - \zeta(t)$, then one can readily verify that it is the solution of

$$\dot{z}_Q(t) = (A(t) - K(t))z_Q(t) + H(t)((\xi_L(t), u(t)))^2, \ z_Q(t_0) = 0,$$

where $H(t) = \nabla^2 \hat{F}(t) - B(t)D^\sharp(t)\nabla^2\hat{\alpha}(t)$. Therefore we obtain

$$\Lambda\tilde{\chi}''((x,u))^2 = \lambda a''((x, \xi_L(t_1, x, u)))^2 + \lambda\, D_2 a(x_0, x_1) z_Q(t_1, x, u).$$

Writing z_Q explicitly by means of the fundamental matrix Ω, substituting $\hat{p}$, and taking into account the expressions of H and $\mathcal{H}$, we easily obtain the second statement. □

Proof of Theorem 2.5. If $\hat{e} \equiv (x_0, \hat{u})$ is a weak local minimizer, then $\tilde{\chi}$ is not locally onto at that point and the same holds for $\tilde{\chi}'$. Lemma 4.2 (i) yields that *codim* $\operatorname{Im}\tilde{\chi}' = \dim Z_2$. Since Z_2 is a complement of $\operatorname{Im}\phi'_{|\operatorname{Ker}\psi'}$, then there exists $\lambda \equiv (\lambda_0, \ldots, \lambda_p) \neq 0$ such that $\lambda\,\phi'_{|\operatorname{Ker}\psi'} = 0$ and we can always take $\lambda_0 \geq 0$. Lemma 5.5 proves the first-order conditions (9).

The uniqueness of λ up to a positive constant and Lemma 4.2 imply that the codimension of $\operatorname{Im}\tilde{\chi}'$ is one. Therefore Lemma 4.3 applies and $\Lambda\tilde{\chi}''_{|\operatorname{Ker}\chi'} \geq 0$. Since $(x,u) \in \operatorname{Ker}\chi'$ if and only if (x,u) satisfies the linearized problem (3), (4), (5), then from (35) we obtain the second-order conditions. □

Proof of Theorem 2.6. To prove the theorem we only have to verify that the map $\tilde{\chi}$ satisfies the assumptions of Lemma 4.5. Let λ be the one given in (ii) of Theorem 2.6 and define $\Lambda \in Z^*$ as in Lemma 5.5. Then $\Lambda\tilde{\chi}' = \lambda\phi'(Id - \psi^\sharp\psi') = 0$, so assumption (3) in Lemma 4.5 holds. From Lemma 4.2 we obtain

$$\tilde{\chi}^\sharp(y + \omega) = \phi^\sharp(y - \phi'\psi^\sharp\omega) + \psi^\sharp\omega.$$

By (31) the map $\psi^\sharp$ belongs to $\mathcal{L}(L^q(J, \mathbf{R}^r), (E, \tau_q))$, for all $q \geq 1$. Since $\phi' \in \mathcal{L}((E, \tau_q), \mathbf{R}^{p+1})$ and $\phi^\sharp$ is a linear map between finite-dimensional vector spaces, $\tilde{\chi}^\sharp \in \mathcal{L}((E, \tau_q), (E, \tau_q))$, for all $q \geq 1$. Denoting by $\pi_2 : E \to L^\infty(J, \mathbf{R}^m)$ the projection on the second factor, we can write $D\tilde{\chi} = D\phi + D\tilde{\alpha} \circ (D\Xi, \pi_2)$; therefore by (i) in Theorem 2.6, Theorem 3.5, and Lemma 5.1, we can deduce that $\tilde{\chi}^\sharp D\tilde{\chi} : (E, \tau_\infty) \to \mathcal{L}((E, \tau_2), (E, \tau_2))$ is continuous. Assumption (1) of Lemma 4.5 is verified.

By definition $\Lambda D^2\tilde{\chi} = \lambda(D^2\phi - \phi'\psi^\sharp D^2\psi)$. $\lambda D^2\phi : (E, \tau_\infty) \to \mathcal{L}^2((E, \tau_2), \mathbf{R})$ is continuous by Theorem 3.5. Again using the results in Theorem 3.5 and in Lemma 5.1 it is not difficult to prove that $D^2\psi = D^2\tilde{\alpha} \otimes (D\Xi, \pi_2) + D\tilde{\alpha}(D^2\Xi, 0)$ is a continuous map from (E, τ_∞) to $\mathcal{L}^2((E, \tau_2), L^1(J, \mathbf{R}^r)$. From the regularity properties of $\psi^\sharp$ and ϕ' discussed above, we obtain assumption (2) of Lemma 4.5. Finally (iii) of Theorem 2.6 and Lemma 5.5 imply assumption (5) of Lemma 4.5, which now yields the desired result. □

THE EFFICIENCY OF SUBGRADIENT PROJECTION METHODS FOR CONVEX OPTIMIZATION, PART I: GENERAL LEVEL METHODS*

KRZYSZTOF C. KIWIEL†

Abstract. We study subgradient methods for convex optimization that use projections onto successive approximations of level sets of the objective corresponding to estimates of the optimal value. We present several variants and show that they enjoy almost optimal efficiency estimates. In another paper we discuss possible implementations of such methods. In particular, their projection subproblems may be solved inexactly via relaxation methods, thus opening the way for parallel implementations. They can also exploit accelerations of relaxation methods based on simultaneous projections, surrogate constraints, and conjugate and projected (conditional) subgradient techniques.

Key words. nondifferentiable (nonsmooth) optimization, convex programming, relaxation methods, subgradient optimization, successive projections, linear inequalities, parallel computing

AMS subject classifications. 65K05, 90C25

1. Introduction.

This is the first of two papers in which we study various modifications of Polyak's [Pol69] subgradient projection algorithm (SPA) and the recently proposed level method of [LNN95, LNN91] for solving the convex program

$$f^* = \min\{ f(x) : x \in S \} \tag{1.1}$$

under the following assumptions. S is a nonempty compact convex subset of $\mathbb{R}^N$; f is a convex function Lipschitz continuous on S with Lipschitz constant L_f; for each $x \in S$ we can compute $f(x)$ and a subgradient $g_f(x) \in \partial f(x)$ of f at x such that $|g_f(x)| \le L_f$; and for each $x \in \mathbb{R}^N$ we can find $P_S(x) = \arg\min\{|x - y| : y \in S\}$, its orthogonal projection on S, where $|\cdot|$ denotes the Euclidean norm.

If f^* is known, the simplest version of the SPA generates successive iterates

$$x^{k+1} = P_S(x^k - t_k(f(x^k) - f^*)g_f(x^k)/|g_f(x^k)|^2) \quad \text{for } k = 1, 2, \ldots, \tag{1.2}$$

until $g_f(x^k) = 0$, where $x^1 \in S$ and t_k are scalars in the set of *admissible stepsizes*

$$T = [\, t_{\min}, t_{\max} \,] \quad \text{for some fixed} \quad 0 < t_{\min} \le t_{\max} < 2. \tag{1.3}$$

It has the following *efficiency estimate* for any (absolute) accuracy $\epsilon > 0$:

$$\begin{aligned} &k > c_{\mathrm{SPA}}(t_{\min}, t_{\max})(\operatorname{diam}(S)L_f/\epsilon)^2 \quad \Rightarrow \quad \min\{ f(x^j) : j = 1{:}k \} - f^* < \epsilon, \\ &c_{\mathrm{SPA}}(t_{\min}, t_{\max}) = 1/[t_{\min}(2 - t_{\max})] \quad \text{and} \quad \min c_{\mathrm{SPA}}(\cdot,\cdot) = c_{\mathrm{SPA}}(1,1) = 1, \end{aligned} \tag{1.4}$$

where $\operatorname{diam}(S) = \sup_{x,y \in S} |x - y|$ denotes the diameter of S. This estimate (see §5) seems to be a folklore result, but it is less well known that it is optimal in a certain sense [LNN95, NeY79]: if S is a ball and $N \ge (\operatorname{diam}(S)L_f/\epsilon)^2/4$, then for any method that uses at most $(\operatorname{diam}(S)L_f/\epsilon)^2/4$ objective and subgradient evaluations, there exists a function for which this method does not obtain an accuracy better than ϵ.

We present three schemes for estimating f^* in (1.2) that extend the ideas in [KAC91, KuF90, LNN95]. Two of them employ an overestimate $\bar{D} \geq \operatorname{diam}(S)$, which replaces $\operatorname{diam}(S)$ in (1.4); the third does not involve $\bar{D}$ but is much more difficult to implement.

To enable faster convergence, we give algorithms that use projections onto successive approximations of level sets of f derived from *several accumulated subgradient linearizations* of f or their *aggregates* (convex combinations) as in descent bundle methods for nondifferentiable optimization [HUL93, Kiw85, Lem89]. Such algorithms provide freedom to trade off storage requirements and work per iteration for speed of convergence.

In the accompanying paper [Kiw96] we discuss implementations of such algorithms, based on accelerations of the relaxation method for linear inequalities [Agm54, MoS54], and provide a unified perspective on various modifications proposed in the literature.

In effect, we show that several versions of subgradient projection methods share efficiency estimates similar to (1.4). Since this estimate cannot, in general, be improved uniformly with respect to the dimension N by more than an absolute constant factor, all these methods are optimal in the sense of [NeY79]. We note, however, that this estimate can be attained only for really large N. We may also expect that for "most" functions encountered in applications, the methods should be much more efficient than the worst-case estimates suggest. Indeed, preliminary numerical experience with the level method of [LNN95] has been very encouraging. Yet this method is not readily implementable because it requires unbounded storage (at least of order $k(N+1)$ at iteration k). Thus the main aim of our work has been to derive methods which have comparable efficiency but are more easily implementable.

We may add that the alternative extension [Kiw95] of the level methods of [LNN95, LNN91] is less suitable for parallel computing.

The paper is organized as follows. In §2 we introduce a general relaxation level algorithm. Its efficiency is analyzed in §3. In §4 we extend the nested ball principle of [Dre83]. Some useful modifications are given in §§5 and 6. Two alternative techniques for generating lower bounds f^k_{low} via fixed level gaps and full model minimizations are described in §7 and §8, respectively. Dual level methods are the subject of §9.

We use the following notation. We denote by $\langle \cdot, \cdot \rangle$ and $|\cdot|$, respectively, the usual inner product and norm in $\mathbb{R}^N$. $B(x,r) = \{y : |y-x| \leq r\}$ denotes the ball with center x and radius $r \geq 0$. For $\epsilon \geq 0$, the ϵ-subdifferential of f at x is defined by $\partial_\epsilon f(x) = \{p \in \mathbb{R}^N : f(y) \geq f(x) + \langle p, y-x \rangle - \epsilon \quad \forall y \in \mathbb{R}^N\}$. We denote by ∂f the ordinary subdifferential $\partial_0 f$. The natural logarithm with base e is denoted by $\ln(\cdot)$. We let $1{:}k$ denote $1, 2, \ldots, k$. For brevity, we let $a/bc = a/(bc)$. The convex hull is denoted by co.

2. The relaxation level algorithm. In this section we describe our first modification of the SPA. As in [BaS81, KAC91, LNN95], when the optimal value f^* is unknown, it may be replaced in (1.2) by a *variable target (level) value*

$$f^k_{\text{lev}} = f^k_{\text{up}} - \kappa(f^k_{\text{up}} - f^k_{\text{low}}) = \kappa f^k_{\text{low}} + (1-\kappa) f^k_{\text{up}}, \tag{2.1}$$

where $0 < \kappa < 1$ is fixed, $f^k_{\text{up}} = \min_{j=1:k} f(x^j)$ is an *upper bound* on f^*, and the *lower bound* $f^k_{\text{low}} \leq f^*$ is chosen to ensure $f^k_{\text{lev}} \to f^*$ as $k \to \infty$. Thus we obtain the subgradient projection level algorithm (SPLA):

$$x^{k+1} = P_S(x^k - t_k(f(x^k) - f^k_{\text{lev}}) g_f(x^k)/|g_f(x^k)|^2), \; t_k \in T, \; k = 1, 2, \ldots; \tag{2.2}$$

if $g_f(x^k) = 0$, then, of course, the method stops with an optimal x^k in $S^* = \operatorname{Arg\,min}_S f$. To get some feeling about possible updates of f^k_{low}, it is instructive to consider first the following ideal bisection method (cf. [MTA81]). Let $\mathcal{L}(f, f^k_{\text{lev}}) = \{x : f(x) \le f^k_{\text{lev}}\}$.

ALGORITHM 2.1 (*ideal level method for* (1.1)).

Step 0. Choose $0 < \kappa < 1$, $z^1 \in S$, and $f^1_{\text{low}} \le f^*$. Set $k = 1$.

Step 1. Set $f^k_{\text{up}} = f(z^k)$, f^k_{lev} by (2.1), and the optimality gap $\Delta^k = f^k_{\text{up}} - f^k_{\text{low}}$.

Step 2. If $\mathcal{L}(f, f^k_{\text{lev}}) \cap S = \emptyset$, go to step 4.

Step 3. Find $z^{k+1} \in \mathcal{L}(f, f^k_{\text{lev}}) \cap S$, set $f^{k+1}_{\text{low}} = f^k_{\text{low}}$, increase k by 1, and go to step 1.

Step 4. Set $z^{k+1} = z^k$, $f^{k+1}_{\text{low}} = f^k_{\text{lev}}$, increase k by 1, and go to step 1.

Clearly, the method produces $f^k_{\text{low}} \le f^*$, $f^k_{\text{up}} - f^* \le \Delta^k$, and $\Delta^{k+1} \le \max\{\kappa, (1-\kappa)\}\Delta^k$ for all k. The crucial property is that $\mathcal{L}(f, f^k_{\text{lev}}) \cap S = \emptyset$ implies $f^k_{\text{lev}} < f^*$.

To make Algorithm 2.1 implementable, we need a submethod for finding a point in $\mathcal{L}(f, f^k_{\text{lev}}) \cap S$ or detecting that $\mathcal{L}(f, f^k_{\text{lev}}) \cap S = \emptyset$. For this kth *set intersection problem*, an iteration of the successive projections method [GPR67] of the form $\hat{x}^{k+1} = P_S(P_{\mathcal{L}(f, f^k_{\text{lev}})}(x^k))$ can be implemented approximately as follows: letting $\bar{f}(\cdot; y) = f(y) + \langle g_f(y), \cdot - y\rangle$ denote the *linearization* of f at any $y \in S$, with $\bar{f}(\cdot; y) \le f(\cdot)$ and $\bar{f}(y; y) = f(y)$ by convexity, we have

$$S^* = \{ x : \bar{f}(x; y) \le f^* \ \forall y \in S \} \cap S \tag{2.3}$$

and

$$\mathcal{L}(f, f^k_{\text{lev}}) = \{ x : \bar{f}(x; y) \le f^k_{\text{lev}} \ \forall y \in S \}. \tag{2.4}$$

We may use some accumulated linearizations $f^j(\cdot) = \bar{f}(\cdot; x^j)$, $j \le k$, in the kth model of f,

$$\hat{f}^k(x) = \max\{ f^j(x) : j \in J^k \} \quad \text{with} \quad k \in J^k \subset \{1{:}\,k\}, \tag{2.5}$$

and let

$$x^{k+1} = P_S(x^k + t_k[P_{\mathcal{L}(\hat{f}^k, f^k_{\text{lev}})}(x^k) - x^k]), \tag{2.6}$$

where we have *underprojection* if $t_k < 1$ or *overprojection* if $t_k > 1$. For instance, (2.6) gives (1.2) when $f^k_{\text{lev}} = f^*$, $J^k = \{k\}$, and $\mathcal{L}(\hat{f}^k, f^k_{\text{lev}})$ is the halfspace $H^k = \{x : f^k(x) \le f^k_{\text{lev}}\}$ given by the inequality of (2.3) most violated at x^k; of course, $P_{H^k}(x^k) = x^k - (f(x^k) - f^k_{\text{lev}}) g_f(x^k)/|g_f(x^k)|^2$. This is just an iteration of a relaxation method for solving the inequalities of (2.4), followed by a projection on S. As for (2.2), *f^k_{low} may be increased to f^k_{lev} when it is discovered that these inequalities do not have a solution in S.* Hence we shall exploit the fact that certain versions of successive projections methods can detect in finite time that a given set intersection problem is unsolvable (although they need not find a solution in finite time when it exists). As will be seen below, the main idea of such methods is to reduce the distance of the iterates from S^*. They may be painfully slow, even in the most favorable case of $f^k_{\text{lev}} = f^*$, when only one inequality of (2.3) is considered at a time. To accelerate convergence, we may use a larger J^k, i.e., a tighter approximation $\hat{f}^k$ of f.

To illustrate these facts we need a result of Agmon [Agm54]. Given a closed convex set $C \subset \mathbb{R}^N$ and an admissible stepsize $t \in T$, we define the *relaxation operator*

$$\mathcal{R}_{C,t}(x) = x + t(P_C(x) - x) \tag{2.7}$$

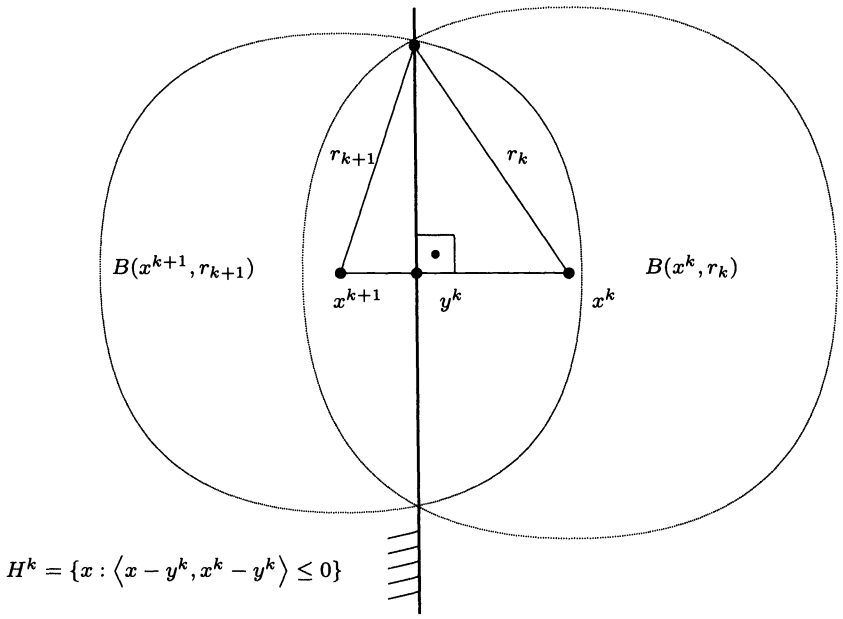

FIG. 2.1. *Illustration of the Fejér property of* $x^{k+1} = x^k + t_k(y^k - x^k)$ *with* $y^k = P_{H^k}(x^k)$ *when* $x^{k+1} \in S$. *By Pythagoras' theorem,* $r_{k+1}^2 - |x^{k+1} - y^k|^2 = r_k^2 - |y^k - x^k|^2$, *where* $x^{k+1} - y^k = (t_k - 1)(y^k - x^k)$, *so* $r_{k+1}^2 = r_k^2 - t_k(2 - t_k)|y^k - x^k|^2$. *Clearly,* $B(x^k, r_k) \cap H^k \subset B(x^{k+1}, r_{k+1}) \cap H^k$.

(where $P_C(x) = x$ if $C = \emptyset$) that has the Fejér contraction property

$$
\begin{aligned}
|y - \mathcal{R}_{C,t}(x)|^2 &\leq |y - x|^2 - t(2 - t)|x - P_C(x)|^2 \\
&\leq |y - x|^2 - t_{\min}(2 - t_{\max}) d_C^2(x) \quad \forall y \in C, x \in \mathbb{R}^N,
\end{aligned} \tag{2.8}
$$

where $d_C(x) = \inf_{y \in C} |x - y|$. Indeed, if $y \in C$, $P = P_C$, and $z = x + t(P(x) - x)$, then

$$
\begin{aligned}
|y - z|^2 &= |y - x|^2 + (t|P(x) - x|)^2 - 2t \langle y - x, P(x) - x \rangle \\
&= |y - x|^2 + (t|P(x) - x|)^2 - 2t \langle P(x) - x, P(x) - x \rangle \\
&\qquad - 2t \langle y - P(x), P(x) - x \rangle \\
&\leq |y - x|^2 - t(2 - t)|P(x) - x|^2 \leq |y - x|^2 - t_{\min}(2 - t_{\max})|P(x) - x|^2
\end{aligned}
$$

from the projection property $\langle y - P(x), P(x) - x \rangle \geq 0$ and (1.3). Note that $t_{\min}(2 - t_{\max})$ in (2.8) can be replaced by $\min_{t \in T} t(2 - t)$.

Figure 2.1 illustrates the Fejér property of (2.2) with $H^k = \mathcal{L}(f^k, f_{\text{lev}}^k)$. For motivation, we now state some facts that will be proved later. Suppose we have generated some $r_k \geq d_{S^*}(x^k)$ (starting, e.g., from $r_1 = \bar{D} \geq \text{diam}(S)$) so that $B(x^k, r_k) \cap S^* \neq \emptyset$. If $f_{\text{lev}}^k \geq f^*$, then $S^* \subset H^k$, so setting $y^k = P_{H^k}(x^k)$, finding r_{k+1} from

$$
r_{k+1}^2 = r_k^2 - t_k(2 - t_k)|y^k - x^k|^2, \tag{2.9}
$$

and applying (2.8) twice, as in the proof of Lemma 3.2 below, we deduce that $S^* \cap B(x^k, r_k) \subset S^* \cap B(x^{k+1}, r_{k+1})$. Thus we improve our localization of the solution (since $r_{k+1} < r_k$ due to $x^k \notin H^k$ from $f(x^k) > f_{\text{lev}}^k$). On the other hand, if $t_k(2 -$

$t_k)d^2_{H^k}(x^k) > r_k^2$, then $f^k_{\text{lev}} < f^*$ (by contradiction), so we may increase f^k_{low} to f^k_{lev} and reset r_{k+1} to $\bar{D}$. To sum up, if $f^k_{\text{lev}} \geq f^*$, then progress towards the solution is measured by the magnitude of $d_{H^k}(x^k)$, otherwise $d_{H^k}(x^k)$ may be used to shrink r_k until $f^k_{\text{lev}} < f^*$ is discovered; thus $d_{H^k}(x^k)$ should be as large as possible in both cases. Hence the algorithm may be accelerated by choosing a smaller $\mathcal{L}(\hat{f}^k, f^k_{\text{lev}})$ to produce $d_{\mathcal{L}(\hat{f}^k, f^k_{\text{lev}})}(x^k) > d_{H^k}(x^k)$. However, a large J^k in (2.5) would create difficulties with storage and work per iteration. This raises the following basic questions. Is it possible to select J^k so that $\hat{f}^k$ approximates f tightly in the region of interest without J^k becoming inordinately large? Can we reduce J^k by replacing some f^j with their convex combinations, i.e., by aggregating some constraints in $\mathcal{L}(\hat{f}^k, f^k_{\text{lev}})$? Should not $\mathcal{L}(\hat{f}^k, f^k_{\text{lev}})$ be augmented with some inequalities related to S? Instead of finding $P_{\mathcal{L}(\hat{f}^k, f^k_{\text{lev}})}(x^k)$, can we perform several "simpler" projections (possibly inexactly and in parallel) and combine their solutions? Our partial answers to these questions will involve a combination of some quite technical properties of relaxation methods. For instance, note that, in view of the outer projection in (2.2), r^2_{k+1} in (2.9) could be further reduced by $d^2_S(z^k)$, where $z^k = x^k + t_k(y^k - x^k)$. In fact more than two successive projections could be employed to reduce r_{k+1}. We shall need rather abstract notation to make such concepts precise.

Let δ_S denote the indicator of S ($\delta_S(x) = 0$ if $x \in S$, ∞ otherwise) and $f_S = f + \delta_S$ the extended objective. Let $\check{f}^k = \max_{j=1:k} f^j$ denote the kth "best" model of f (which we would *not* like to store). Note that $\check{f}^k_S = \check{f}^k + \delta_S$ is the largest convex minorant of f_S compatible with the accumulated information about f. Clearly, f^k, $\hat{f}^k$, $\check{f}^k$, and $\check{f}^k_S$ belong to the following *set of admissible models of* f_S:

$$\Phi = \{\, \phi\colon \mathbb{R}^N \to (-\infty, \infty] : \phi \text{ is closed convex and } \phi(x) \leq f^* \ \forall x \in S^* \,\}. \tag{2.10}$$

At iteration k, we may choose a model $\phi^k \in \Phi$ such that $\phi^k \geq f^k$ (to exploit the latest subgradient information) and a stepsize $t_k \in T$. Then the iteration

$$x^{k+1} = P_S(\mathcal{R}_{\mathcal{L}(\phi^k, f^k_{\text{lev}}), t_k}(x^k)) \tag{2.11}$$

is a generalization of (2.2) and (2.6), which have $\phi^k = f^k$ and $\phi^k = \hat{f}^k$, respectively. This notation is convenient for the implementations discussed later, in which each ϕ^k may be the maximum of several accumulated linearizations f^j, $j \leq k$, or their convex combinations, possibly augmented with δ_S or its convex minorants. It will also prepare ground for extensions which use several models from Φ at each iteration for successive or parallel relaxations. (For the first reading, one may assume $\phi^k = f^k$.) We should, of course, ensure that $\mathcal{L}(\phi^k, f^k_{\text{lev}}) \neq \emptyset$ in (2.11). (Detecting this may require calculating $\inf \phi^k$ approximately.) Since, by (2.10),

$$\emptyset \neq S^* \subset \mathcal{L}(\phi, f^k_{\text{lev}}) \quad \text{if} \quad \phi \in \Phi \text{ and } f^k_{\text{lev}} \geq f^*, \tag{2.12}$$

$\mathcal{L}(\phi^k, f^k_{\text{lev}}) = \emptyset$ means that we may repeat (2.11) with f^k_{lev} increased to a new value by increasing f^k_{low} to the old value of f^k_{lev}. Note that $\mathcal{L}(\phi^k, f^k_{\text{lev}}) = \emptyset$ cannot occur in the simplest method (2.2), for which the test based on r_k must be employed.

We may now state the first general subgradient projection algorithm with relaxation and target level updating. Its notation is slightly redundant, being geared toward subsequent convergence proofs and modifications.

ALGORITHM 2.2.

Step 0 (Initialization). Select an initial point $x^1 \in S$, a final optimality tolerance

$\epsilon_{\text{opt}} \geq 0$, a level parameter $0 < \kappa < 1$, and stepsize parameters $0 < t_{\min} \leq t_{\max} < 2$. Choose $\bar{D} \geq \operatorname{diam}(S)$ and $f^1_{\text{low}} \leq f^*$. Set $\rho_1 = 0$ and $f^0_{\text{up}} = \infty$. Set the counters $k = 1$, $l = 0$, and $k(0) = 0$. ($k(l)$ will denote the iteration number of the lth increase of f^k_{low}.)

Step 1 (Objective evaluation). Calculate $f(x^k)$ and $g_f(x^k)$.

Step 2 (Level update). Set $f^k_{\text{up}} = \min\{f(x^k), f^{k-1}_{\text{up}}\}$, f^k_{lev} by (2.1), and the *gap* $\Delta^k = f^k_{\text{up}} - f^k_{\text{low}}$.

Step 3 (Stopping criterion). If $\min\{\Delta^k, |g_f(x^k)|/\bar{D}\} \leq \epsilon_{\text{opt}}$, terminate.

Step 4 (Projections). Perform (2.11), checking if it is well defined, as follows:

(i) Choose an admissible model $\phi^k \in \Phi$ such that $\phi^k \geq f^k$ and a stepsize $t_k \in T$.

(ii) If $\mathcal{L}(\phi^k, f^k_{\text{lev}}) = \emptyset$, go to step 5. Otherwise, set $y^k = P_{\mathcal{L}(\phi^k, f^k_{\text{lev}})}(x^k)$, $z^k = x^k + t_k(y^k - x^k)$, $x^{k+1} = P_S(z^k)$, $\rho^k_\phi = t_k(2 - t_k)|y^k - x^k|^2$, and $\rho^k_S = |x^{k+1} - z^k|^2$.

(iii) If $\rho_k + \rho^k_\phi + \rho^k_S > \bar{D}^2$, go to step 5; otherwise, go to step 6.

Step 5 (Update lower bound).

(i) Choose a lower bound $\hat{f}^k_{\text{low}} \in [\max\{f^k_{\text{low}}, f^k_{\text{lev}}\}, f^*]$ (e.g., $\hat{f}^k_{\text{low}} = \max\{f^k_{\text{low}}, f^k_{\text{lev}}\}$). Set $f^{k+1}_{\text{low}} = \hat{f}^k_{\text{low}}$, $\rho_{k+1} = 0$, and $\hat{\Delta}^k = f^k_{\text{up}} - \hat{f}^k_{\text{low}}$.

(ii) If $\hat{\Delta}^k \leq \epsilon_{\text{opt}}$, terminate; otherwise, continue.

(iii) Set $x^{k+1} = x^k$ (*null step*), $k(l+1) = k$, and increase k and l by 1. Go to step 2.

Step 6 (Serious step). Set $f^{k+1}_{\text{low}} = f^k_{\text{low}}$, $\hat{f}^k_{\text{low}} = f^k_{\text{low}}$, $\hat{\Delta}^k = \Delta^k$, and $\rho_{k+1} = \rho_k + \rho^k_\phi + \rho^k_S$. Increase k by 1 and go to step 1.

A few comments on the method are in order.

At step 0, f^1_{low} may be obtained, e.g., from a relaxation of (1.1) or from the relations

$$f^* \geq \min_S f^1 \geq f(x^1) - |g_f(x^1)| \operatorname{diam}(S) \geq f(x^1) - |g_f(x^1)|\bar{D}, \tag{2.13}$$

since $f(\cdot) \geq f^1(\cdot) = f(x^1) + \langle g_f(x^1), \cdot - x^1 \rangle \geq f(x^1) - |g_f(x^1)||\cdot - x^1|$ by the Cauchy–Schwarz inequality. In many applications one may find a "simple" set (e.g., a box or a ball) that contains S; the diameter of this set may serve as $\bar{D}$. (Choosing f^1_{low} and $\bar{D}$ when f is strongly convex on S is discussed in [KAC91]; see also [KuF90].) In general, the algorithm should perform better the closer f^1_{low} and $\bar{D}$ are to f^* and $\operatorname{diam}(S)$, respectively.

Note that the f-evaluation at step 1 is skipped if $x^k = x^{k-1}$ after a null step at step 5, i.e., if $k = k(l) + 1$. The current number of f-evaluations is $k - l$.

Step 3 is justified by the optimality estimates (2.14) and and the fact that $f^* \geq f(x^k) - |g_f(x^k)| \operatorname{diam}(S)$.

Step 4 performs the two successive relaxations of (2.11), unless an exit to step 5 occurs with $f^k_{\text{lev}} < f^*$. (The empty intersection test of step 2 in Algorithm 2.1 is done in two separate tests in step 4 of Algorithm 2.2.) The exit from step 4(ii) is justified by (2.12) and from step 4(iii) by Lemma 3.3, which formalizes our argument concerning (2.9). Specifically, with $r^2_k = \bar{D}^2 - \rho_k$, step 6 replaces (2.9) by $r^2_{k+1} = r^2_k - \rho^k_\phi - \rho^k_S$, whereas steps 0 and 5 ensure $r_{k(l)+1} = \bar{D}$.

Let us split the iterations into groups $K_0 = \{1 : k(1) - 1\}$ and $K_l = \{k(l) : k(l+1) - 1\}$ if $l \geq 1$. Each group K_l ends by discovering that the target level is unattainable. Then an increase of the lower bound reduces the gap between the bounds by at least a fraction of $\kappa < 1$. The remaining level and gap decreases within each group occur only when the objective improves, with the lower bound staying fixed. These simple

properties of the method may by derived inductively from the following observations. By construction, $f^k_{\rm up} \ge f^{k+1}_{\rm up} \ge f^* \ge f^{k+1}_{\rm low} = \hat f^k_{\rm low} \ge f^k_{\rm low}$, $\hat\Delta^k = f^k_{\rm up} - \hat f^k_{\rm low}$, and $\Delta^k = f^k_{\rm up} - f^k_{\rm low}$, so the gaps $\hat\Delta^k \le \Delta^k$ overestimate the optimality gap

$$f^k_{\rm up} - f^* = \min\{ f(x^j) : j = 1{:}k \} - f^* \le \hat\Delta^k \le \Delta^k \tag{2.14}$$

and $\Delta^{k+1} \le \hat\Delta^k \le \Delta^k$ for all k. In fact, if $k(l) < k < k(l+1)$, then $f^k_{\rm low} = \hat f^{k(l)}_{\rm low}$ $(= f^1_{\rm low}$ if $l = 0)$; therefore, the level $f^k_{\rm lev} = f^k_{\rm low} + (1-\kappa)\Delta^k$ cannot increase:

$$f^{k(l)+1}_{\rm lev} \ge f^j_{\rm lev} \ge f^k_{\rm lev} \quad \text{if} \quad k(l) < j \le k \le k(l+1) \tag{2.15}$$

and $\Delta^k = \hat\Delta^k$ if $k(l) < k < k(l+1)$. Hence $\hat f^k_{\rm low}$ and $\hat\Delta^k$ only reflect the improvement in $f^k_{\rm low}$ and Δ^k at iterations $k = k(l+1)$, $l \ge 0$. Then at step 5, $\hat f^k_{\rm low} \ge f^k_{\rm lev} = f^k_{\rm up} - \kappa\Delta^k$ implies $\hat\Delta^k = f^k_{\rm up} - \hat f^k_{\rm low} \le \kappa\Delta^k$. Thus we have the useful relations

$$\Delta^k \ge \hat\Delta^k \ge \hat\Delta^{k(l+1)}/\kappa \quad \text{if} \quad k \in K_l \text{ and } l \ge 0, \tag{2.16}$$

$$\hat\Delta^{k(l)} \le \kappa^l \Delta^1 \quad \text{if} \quad l \ge 1. \tag{2.17}$$

3. Efficiency. Our aim is to show that the SPLA of (2.2) has the following efficiency estimate for any $\epsilon > 0$:

$$k > c_{\rm SPLA}(t_{\min}, t_{\max}, \kappa)(\bar D L_f/\epsilon)^2 \quad \Rightarrow \quad \min\{ f(x^j) : j = 1{:}k \} - f^* < \epsilon, \tag{3.1a}$$

$$c_{\rm SPLA}(t_{\min}, t_{\max}, \kappa) = 1/t_{\min}(2 - t_{\max})\kappa^2(1-\kappa^2), \tag{3.1b}$$

$$\min c_{\rm SPLA}(\cdot,\cdot,\cdot) = c_{\rm SPLA}(1, 1, 1/\sqrt{2}) = 4, \tag{3.1c}$$

and to establish a modified form of this estimate for Algorithm 2.2. We assume, with no loss of generality, that the tolerance $\epsilon_{\rm opt} = 0$ and that the algorithm does not terminate, i.e., $\Delta^k \ge \hat\Delta^k > 0$ for all k.

We start by showing that each first relaxation at step 4 provides a significant growth of ρ_k related to Fejér contractions. Note that with $H^k = \{x : f^k(x) \le f^k_{\rm lev}\}$ we have

$$d_C(x^k) \ge d_{H^k}(x^k) = (f(x^k) - f^k_{\rm lev})/|g_f(x^k)| \quad \text{if} \quad C \subset H^k. \tag{3.2}$$

LEMMA 3.1. *If $\mathcal{L}(\phi^k, f^k_{\rm lev}) \ne \emptyset$ at step 4, then $\rho^k_\phi \ge t_{\min}(2 - t_{\max})(\kappa\Delta^k/L_f)^2$.*

Proof. Use (3.2) with $\mathcal{L}(\phi^k, f^k_{\rm lev}) \subset H^k$ (from $\phi^k \ge f^k$), $|g_f(x^k)| \le L_f$, and $f(x^k) - f^k_{\rm lev} \ge f^k_{\rm up} - (f^k_{\rm up} - \kappa\Delta^k) = \kappa\Delta^k$ (from $f(x^k) \ge f^k_{\rm up}$); recall step 4 and (1.3). □

LEMMA 3.2. *Suppose $y \in \mathcal{L}(\phi^k, f^k_{\rm lev}) \cap S$ for iterations $k = k_1{:}k_2$ that do not execute step 5 (i.e., y is a common point of all the sets involved in the successive relaxations (2.11) at step 4 for such k). Then*

$$\begin{aligned} \rho_{k_2+1} - \rho_{k_1} &= \sum_{k=k_1}^{k_2} [t_k(2-t_k)|y^k - x^k|^2 + |x^{k+1} - z^k|^2] \\ &\le |y - x^{k_1}|^2 - |y - x^{k_2+1}|^2. \end{aligned} \tag{3.3}$$

Proof. Fix $k \in [k_1, k_2]$. Use (2.8) with $C = \mathcal{L}(\phi^k, f^k_{\text{lev}})$, $t = t_k$, and $x = x^k$ and next with $C = S$, $t = 1$, and $x = z^k$ to get

$$\rho^k_\phi = t_k(2 - t_k)|y^k - x^k|^2 \le |y - x^k|^2 - |y - z^k|^2, \tag{3.4a}$$

$$\rho^k_S = |x^{k+1} - z^k|^2 \le |y - z^k|^2 - |y - x^{k+1}|^2. \tag{3.4b}$$

Add the inequalities above to get $\rho_{k+1} - \rho_k = \rho^k_\phi + \rho^k_S \le |y - x^k|^2 - |y - x^{k+1}|^2$. Adding these inequalities for $k = k_1 : k_2$ yields (3.3). □

The next result validates the test at step 4(iii) for increasing f^k_{low} at step 5. Recall that $k(l)$ is the iteration number of the lth increase of f^k_{low}; these quantities change only at step 5, and we *always* have $k(l) < k$ (cf. step 0). Note that Lemma 3.2 assumes that step 5 is not executed, but this is to be proved for the lemma below.

LEMMA 3.3. *If $f^k_{\text{lev}} \ge f^*$ at step 4, then step 5 is not entered and*

$$\begin{aligned} \rho_{k+1} = \rho_k + \rho^k_\phi + \rho^k_S &\le |y - x^{k(l)+1}|^2 - |y - x^{k+1}|^2 \\ &\le \operatorname{diam}(S)^2 \le \bar{D}^2 \quad \forall y \in S^*. \end{aligned} \tag{3.5}$$

Proof. First, suppose $k > k(l) + 1$. Since $f^k_{\text{lev}} \ge f^*$, (2.12) and (2.15) imply that the assumptions of Lemma 3.2 hold for any fixed $y \in S^*$, $k_1 = k(l)+1$, and $k_2 = k-1$. Then, due to the rules of steps 5 and 6, (3.3) becomes

$$\rho_k \le |y - x^{k(l)+1}|^2 - |y - x^k|^2. \tag{3.6}$$

Adding (3.6) to (3.4) we get (3.5), noting that $\rho_k + \rho^k_\phi + \rho^k_S \le |y - x^{k(l)+1}|^2 \le \bar{D}^2$; i.e., no null step occurs. Next, if $k = k(l) + 1$, then $\rho_k = 0$ (cf. steps 0 and 5), so (3.6) holds again and the conclusion follows as before. □

We may now estimate the rate of decrease of the gap Δ^k within each group K_l.

LEMMA 3.4. *If $k(l) < k < k(l+1)$ and $\Delta^k > 0$, then*

$$k - k(l) \le (\bar{D}L_f/\kappa\Delta^k)^2/t_{\min}(2 - t_{\max}). \tag{3.7}$$

Proof. Note that $\Delta^j \ge \Delta^k$ for $j = 1 : k$ because Δ^j never increases. By the rules of steps 4 and 5, we have $\rho_{k+1} \le \bar{D}^2$ (otherwise $k(l+1) = k$ would occur, a contradiction) and

$$\begin{aligned} \bar{D}^2 \ge \rho_{k+1} &\ge \sum_{j=k(l)+1}^{k} \rho^j_\phi \ge t_{\min}(2 - t_{\max}) \sum_{j=k(l)+1}^{k} (\kappa\Delta^j/L_f)^2 \\ &\ge t_{\min}(2 - t_{\max})(\kappa\Delta^k/L_f)^2(k - k(l)) \end{aligned}$$

from Lemma 3.1. Rearranging, we get (3.7). □

At step 2, let $n^k_f = k - l$ and $l^k = l$ denote the total numbers of f-evaluations and lower bound increases, respectively. In (3.8) below we in fact relate n^k_f to the gap $\hat{\Delta}^k$.

LEMMA 3.5. *If $\hat{\Delta}^{k_\epsilon} \ge \epsilon > 0$ for some $k_\epsilon \in K_m$ and $m \ge 0$, then $n^{k_\epsilon}_f = k_\epsilon - m$ and*

$$k_\epsilon \le m + (\bar{D}L_f/\epsilon)^2/\kappa^2(1 - \kappa^2)t_{\min}(2 - t_{\max}). \tag{3.8}$$

If additionally $\Delta^1 \le \bar{D}L_f$, then $m \le -\ln(\bar{D}L_f/\epsilon)/\ln(\kappa)$ and

$$k_\epsilon \le (\bar{D}L_f/\epsilon)^2[1/\kappa^2(1 - \kappa^2)t_{\min}(2 - t_{\max}) - 1/2e\ln(\kappa)]. \tag{3.9}$$

Proof. (i) Let $K(\epsilon) = \{1{:}\, k_\epsilon\}$. Since $\hat{\Delta}^{k_\epsilon} \geq \epsilon > 0$ and $\Delta^{k+1} \leq \hat{\Delta}^k \leq \Delta^k$ for all k, use (2.16) and induction to obtain $\Delta^k \geq \epsilon/\kappa^{m-l}$ for all $k \in K_l \cap K(\epsilon)$ and $l = 0{:}\, m$.

(ii) Let $c = (\bar{D}L_f/\kappa)^2/t_{\min}(2 - t_{\max})$. By (i) and Lemma 3.4, $|K_l \cap K(\epsilon)| \leq 1 + c\kappa^{2(m-l)}/\epsilon^2$ for $l = 1{:}\, m$ and $|K_0 \cap K(\epsilon)| \leq c\kappa^{2m}/\epsilon^2$. Since $0 < \kappa < 1$, we get (3.8) from

$$k_\epsilon = \sum_{l=0}^{m} |K_l \cap K(\epsilon)| \leq m + \sum_{l=0}^{m} (c/\epsilon^2)\kappa^{2(m-l)} \leq m + c/\epsilon^2(1 - \kappa^2).$$

(iii) If $\Delta^1 \leq \bar{D}L_f$ and $m > 0$, then (2.17) yields $\epsilon \leq \hat{\Delta}^{k(m)} \leq \kappa^m \bar{D}L_f$, so $m \leq -\ln(\bar{D}L_f/\epsilon)/\ln(\kappa)$ in (3.8). Thus, to get (3.9), it suffices to prove that $-\ln(t)/\ln(\kappa) \leq -t^2/2e\ln(\kappa)$ for all $t > 0$. Indeed, $t^2 - 2e\ln(t) \geq 0$ for all $t > 0$ (minimize it!). □

We may now state our principal result. Notice that, in view of (2.13), we may always ensure that $\Delta^1 \leq \bar{D}L_f$ by taking $f^1_{\text{low}} \geq f(x^1) - |g_f(x^1)|\bar{D}$, and recall (2.14).

THEOREM 3.6. *If $\Delta^1 \leq \bar{D}L_f$, then the following efficiency estimate holds for each $\epsilon > 0$:*

$$k > c_{\text{RLA}}(t_{\min}, t_{\max}, \kappa)(\bar{D}L_f/\epsilon)^2 \quad \Rightarrow \quad f^k_{\text{up}} - f^* \leq \hat{\Delta}^k < \epsilon, \tag{3.10a}$$

$$c_{\text{RLA}}(t_{\min}, t_{\max}, \kappa) = 1/t_{\min}(2 - t_{\max})\kappa^2(1 - \kappa^2) - 1/2e\ln(\kappa), \tag{3.10b}$$

$$\min c_{\text{RLA}}(\cdot,\cdot,\cdot) = c_{\text{RLA}}(1, 1, 0.677653\ldots) \approx 4.49950. \tag{3.10c}$$

Proof. This is an immediate consequence of Lemma 3.5. □

Let $x^k_{\text{rec}} \in \{x^j\}_{j=1}^k$ be such that $f(x^k_{\text{rec}}) = f^k_{\text{up}}$ $(= \min_{j=1:k} f(x^j))$, for all k.

COROLLARY 3.7. *If $\epsilon_{\text{opt}} = \epsilon > 0$ and $\Delta^1 \leq \bar{D}L_f$, then the algorithm will terminate with $f(x^k_{\text{rec}}) \leq f^* + \epsilon$ in $k = 1 + k_\epsilon$ iterations after $n^k_f = 1 + n^{k_\epsilon}_f$ f-evaluations, where k_ϵ and $n^{k_\epsilon}_f = k_\epsilon - m$ satisfy the bounds of Lemma 3.5.* □

For completeness, we include an asymptotic result.

THEOREM 3.8. *If the algorithm does not terminate, then f^k_{up}, f^k_{low}, and f^k_{lev} converge to f^*, and Δ^k and $\hat{\Delta}^k$ converge to zero as $k \to \infty$. Moreover, $\{x^k_{\text{rec}}\}$ converges to S^*.*

Proof. Since $\hat{\Delta}^k > 0$ never increases, $\hat{\Delta}^k \downarrow 0$ either by (2.17) if $l \to \infty$ or by Lemma 3.5 otherwise. (Then m would be bounded in (3.8).) Hence the facts that $\Delta^{k+1} \leq \hat{\Delta}^k \leq \Delta^k$ and $\max\{|f^k_{\text{low}} - f^*|, |f^k_{\text{up}} - f^*|, |f^k_{\text{lev}} - f^*|\} \leq \Delta^k$ for all k imply the first assertion. The second one follows from $f(x^k_{\text{rec}}) \to f^*$, the continuity of f, and the compactness of S. □

Remark 3.9. In view of the preceding results, we again emphasize the crucial role of $\rho^k_\phi = t_k(2 - t_k)d^2_{\mathcal{L}(\phi^k, f^k_{\text{lev}})}(x^k)$ in our efficiency analysis. The algorithm may be accelerated (locally) by choosing ϕ^k and t_k to generate a large ρ^k_ϕ. (In fact we should try to increase the less easily manageable quantity $\rho^k_\phi + \rho^k_S$ instead of just ρ^k_ϕ.) Our efficiency estimates are best when $t_{\min} = t_{\max} = 1$; also $t_k = 1$ maximizes each ρ^k_ϕ. However, as in other relaxation methods, other choices of t_k may be preferable in practice.

4. The nested ball principle. We shall need the following reformulation of Lemma 3.3 in terms of $r^2_k = \bar{D}^2 - \rho_k$. It generalizes similar results of [Gof81, Tel82] obtained for classical relaxation methods.

LEMMA 4.1 (the ball induction principle). *If $f^k_{\text{lev}} \geq f^*$ at step 4, then $\emptyset \neq S^* \cap B(x^k, r_k) \subset S^* \cap B(z^k, (r^2_k - \rho^k_\phi)^{1/2}) \subset S^* \cap B(x^{k+1}, r_{k+1})$.*

Proof. Letting $y \in S^*$, use (3.4) and (3.6). □

The following result extends one of Drezner [Dre83] (and simplifies its proof).

LEMMA 4.2 (the nested ball principle). *If* $(\bar{D} - |z^k - x^{k(l)+1}|)^2 > r_k^2 - \rho_\phi^k$ *or* $(\bar{D} - |x^{k+1} - x^{k(l)+1}|)^2 > r_k^2 - \rho_\phi^k - \rho_S^k$ *at step* 4, *then* $f_{\text{lev}}^k < f^*$.

Proof. For contradiction suppose $f_{\text{lev}}^k \geq f^*$. Let $x = x^{k(l)+1}$, $z = z^k$, $\hat{r} = (r_k^2 - \rho_\phi^k)^{1/2}$, and $y \in S^* \cap B(x, \bar{D}) \cap B(z, \hat{r})$ (cf. Lemma 4.1). Suppose $\bar{D} > \hat{r} + |z - x|$. By construction, (3.4a) and (3.6), $|y-z|^2 \leq |y-x|^2 + \hat{r}^2 - \bar{D}^2 \leq (|y-z| + |z-x|)^2 + \hat{r}^2 - \bar{D}^2$ with $|z-x| \neq 0$ due to $\hat{r} < \bar{D}$, so $|y-z| \geq (\bar{D}^2 - \hat{r}^2 - |z-x|^2)/2|z-x| > \hat{r}$ contradicts $y \in B(z, \hat{r})$. Hence $\bar{D} \leq \hat{r} + |z - x|$ and, since $|z - x| \leq |z - y| + |y - x| \leq \hat{r} + \bar{D}$, we have $\left|\bar{D} - |z - x|\right| \leq \hat{r}$. Next, obtain the same inequality with $z = x^{k+1}$ and $\hat{r} = (r_k^2 - \rho_\phi^k - \rho_S^k)^{1/2}$ to get a contradiction. □

Lemma 4.2 says that for each group there is a growing ball $B(x^{k(l)+1}, \bar{D} - r_k)$ such that if x^k enters this ball then $f_{\text{lev}}^k < f^*$. Hence Lemma 4.2 may be used at step 4(iii) to detect $f_{\text{lev}}^k < f^*$. Following [Dre83], one may argue that the conditions of Lemma 4.2 will be activated earlier than the usual condition $r_k^2 < \rho_\phi^k + \rho_S^k$. Indeed, r_k decreases from $\bar{D}$ to zero, whereas usually $|x^{k+1} - x^{k(l)+1}| \ll \bar{D}$, e.g., if $\bar{D}$ is a generous overestimate of diam(S).

5. Simple modifications. We shall now describe some simple modifications of Algorithm 2.2.

At step 5(iii) one may set $x^{k+1} = x_{\text{rec}}^k$; i.e., each group K_l may start from the best point found so far (if $g_f(x_{\text{rec}}^k)$ is stored). Alternatively, as in [KAC91], x^{k+1} could be chosen arbitrarily in S, but then step 1 would have to evaluate f and g_f at this point, leading to a slight deterioration in efficiency estimates such as Lemma 3.5 and Corollary 3.7 (where we would have $n_f^{k_\epsilon} = k_\epsilon$).

By suppressing null steps in our notation we may express the efficiency estimates in terms of the number of f-evaluations alone (as is customary in, e.g., [NeY79]).

THEOREM 5.1. *Suppose step* 5(iii) *sets* $f_{\text{low}}^k = \hat{f}_{\text{low}}^k$ *and* $\rho_k = 0$ *without increasing* k. *Then the total number of* f*-evaluations always equals* k, *and the efficiency estimate* (3.1) *holds.*

Proof. For contradiction, consider the *unmodified* algorithm. At step 0 set $n = 1$ and $\hat{z}^1 = x^1$. At step 6 set $\hat{z}^{n+1} = x^{k+1}$ and $\Delta_z^n = \hat{\Delta}^k$, and increase n by 1. Then at steps 2 and 6 we always have $n = k - l$ for the current values of k, l and n, and at step 2 $n_f^k = n$. Suppose $\Delta_z^{n_\epsilon} \geq \epsilon > 0$ for some $n_\epsilon = k_\epsilon - l^{k_\epsilon}$ at step 6. By Lemma 3.5 and (3.1b), we have $n_\epsilon \leq c_{\text{SPLA}}(t_{\min}, t_{\max}, \kappa)(\bar{D}L_f/\epsilon)^2$. Hence, for any $\epsilon > 0$, (3.1a) holds with k and $\{x^j\}_{j=1}^k$ replaced by n and $\{\hat{z}^j\}_{j=1}^n$, respectively. It remains to identify $\{\hat{z}^n\}$ with the sequence $\{x^k\}$ generated when step 5 does not increase k. □

We conclude, in particular, that by letting $\phi^k \equiv f^k$ at step 4, we obtain the simple SPLA of (2.2) that enjoys the efficiency estimate (3.1). One must, however, be cautious in interpreting such results, because Algorithm 2.2 could loop infinitely between steps 2 and 5.

COROLLARY 5.2. *Suppose* $\epsilon_{\text{opt}} > 0$ *and step* 5(iii) *sets* $f_{\text{low}}^k = \hat{f}_{\text{low}}^k$ *and* $\rho_k = 0$ *without increasing* k. *Then the algorithm will terminate with* $f(x_{\text{rec}}^k) \leq f^* + \epsilon_{\text{opt}}$ *after* $k = 1 + k_{\epsilon_{\text{opt}}}$ *iterations and* f*-evaluations, where*

$$k_{\epsilon_{\text{opt}}} \leq c_{\text{SPLA}}(t_{\min}, t_{\max}, \kappa)(\bar{D}L_f/\epsilon_{\text{opt}})^2$$

with c_{SPLA} *given by* (3.1b). *Moreover,* (3.1) *holds for any* $\epsilon > \epsilon_{\text{opt}}$.

Proof. Arguing by contradiction, use Theorem 3.8 to deduce that any loop between steps 2 and 5 must be finite when $\epsilon_{\text{opt}} > 0$, and then apply Theorem 5.1. □

As in [KAC91], let us consider setting $f^k_{\text{lev}} = f^k_{\text{up}} - \kappa_k \Delta^k$ at step 2, where $\kappa_k \in [\kappa_{\min}, \kappa_{\max}]$ for some fixed $0 < \kappa_{\min} \le \kappa_{\max} < 1$. We only require κ_k to produce $f^k_{\text{lev}} \le f^{k-1}_{\text{lev}}$ if $k > k(l) + 1$ (e.g., let $\kappa_k \in [\kappa_{k-1}, \kappa_{\max}]$ for such k). Then, as before, the level can increase only after the lower bound increases (i.e., (2.15) holds). Clearly, we must replace κ by $\kappa_{\max}$ in (2.16) and (2.17), and by $\kappa_{\min}$ in Lemmas 3.1 and 3.4. Similar replacements should be made in the remaining efficiency results. For instance, (3.10b) becomes

$$\hat{c}_{\text{RLA}}(t_{\min}, t_{\max}, \kappa_{\min}, \kappa_{\max}) = 1/t_{\min}(2 - t_{\max})\kappa^2_{\min}(1 - \kappa^2_{\max}) - 1/2e \ln(\kappa_{\max}),$$

where again the "best" $\kappa_{\min} = \kappa_{\max} \approx 0.677653$. We conclude that this modification cannot improve the preceding efficiency estimates. It may, however, be useful in practice to choose small κ_k at initial iterations in order to reduce the dependence on f^k_{low} until it is improved.

6. Using the known optimal value. Let us now consider the case when f^* is known.

THEOREM 6.1. *If $f^1_{\text{low}} = f^*$, then $l \equiv 0$ and the following efficiency estimate holds*:

$$\text{(6.1a)} \qquad k > c^*_{\text{RLA}}(t_{\min}, t_{\max}, \kappa)(\text{diam}(S) L_f/\epsilon)^2 \quad \Rightarrow \quad f^k_{\text{up}} - f^* \le \hat{\Delta}^k < \epsilon,$$

$$\text{(6.1b)} \qquad c^*_{\text{RLA}}(t_{\min}, t_{\max}, \kappa) = 1/t_{\min}(2 - t_{\max})\kappa^2,$$

$$\text{(6.1c)} \qquad \min c^*_{\text{RLA}}(\cdot, \cdot, \kappa) = c^*_{\text{RLA}}(1, 1, \kappa) = 1/\kappa^2.$$

Moreover, one may use $\kappa = 1$ and $f^k_{\text{lev}} \equiv f^*$, in which case (6.1) *reduces to* (1.4).

Proof. Use (2.1), (2.12), and Lemma 3.3 to deduce that step 5 cannot be entered (i.e., $l \equiv 0$) and $f^k_{\text{lev}} \ge f^k_{\text{low}} = f^*$ for all k. Next, invoke (3.5) in the proof of Lemma 3.4 in order to replace $\bar{D}$ by $\text{diam}(S)$ in Lemmas 3.4 and 3.5. Finally, observe that m and $(1 - \kappa^2)$ may be dropped from (3.8) to give (6.1), since $m = 0$ and $k_\epsilon \le c/\epsilon^2$ in part (ii) of the proof of Lemma 3.5, which remains valid even if $\kappa = 1$ because no summation is required. □

We conclude that if f^* is known then step 5 and the tests of step 4 may be omitted, so that $\bar{D}$ is not required. Moreover, setting $f^k_{\text{lev}} \equiv f^*$ ($\kappa = 1$ in (6.1)) gives the "best" efficiency estimate (1.4). In particular, (1.4) holds for for the simplest method of (1.2) (using $\phi^k \equiv f^k$ at step 4), as well as for Polyak's accelerated method from [Pol69] (with $\phi^k \equiv \hat{f}^k$; cf. (2.5)).

Remark 6.2. Note that, by Lemma 3.3, $f^k_{\text{low}} \equiv f^*$ ensures Fejér monotonicity $|x^* - x^{k+1}| \le |x^* - x^k|$ for all k and $x^* \in S^*$. Hence one easily checks that $\text{diam}(S)$ and L_f in (6.1) may be replaced by $D^* = |x^* - x^1|$ and $L^*_f = \sup\{|g_f(x)| : |x^* - x| \le D^*\}$ for any $x^* \in S^*$. Thus one may get an efficiency estimate even for *unbounded* S if S^* is nonempty! Also Fejér monotonicity and Theorem 3.8 imply that $\{x^k\}$ *converges* to an optimal point. (Let x^* be a cluster point of $\{x^k_{\text{rec}}\}$.) The question whether $\{x^k\}$ converges for other level controls is left open for future research.

The same argument also shows that if we chose $f^1_{\text{low}} > f^*$, then either termination would occur with $f^k_{\text{up}} \le f^1_{\text{low}} + \epsilon_{\text{opt}}$ or (6.1) would hold with f^* replaced by f^1_{low} (as if f were replaced by $\max\{f, f^1_{\text{low}}\}$).

7. Level control via frozen level gaps. In Algorithm 2.2 we have $f^k_{\rm up} - f^k_{\rm lev} = \kappa\Delta^k$; i.e., the desired objective reduction is a fraction of the current gap. An alternative technique consists in freezing the level gap $\Delta^k_{\rm lev} = f^k_{\rm up} - f^k_{\rm lev}$ at $\kappa\Delta^{k(l)}$ between iterations $k(l)$ and $k(l+1)$ that increase the lower bound.

Thus we modify Algorithm 2.2 as follows. Step 2 sets $f^k_{\rm lev} = f^k_{\rm up} - \Delta^k_{\rm lev}$, with $\Delta^1_{\rm lev} = \kappa\Delta^1$; step 5 sets $\Delta^{k+1}_{\rm lev} = \kappa\hat\Delta^k$, whereas step 6 sets $\Delta^{k+1}_{\rm lev} = \Delta^k_{\rm lev}$.

It is easy to check that the relations that ensure (2.14) continue to hold, whereas (2.15) follows from the fact that $f^{k+1}_{\rm up} \le f^k_{\rm up}$, while $\Delta^k_{\rm lev} = \kappa\hat\Delta^{k(l)}$ if $k(l) < k \le k(l+1)$ and $l \ge 0$, where $\hat\Delta^0 = \Delta^1$. Next, for $k = k(l+1)$ at step 5 we have $\hat f^k_{\rm low} \ge f^k_{\rm lev} = f^k_{\rm up} - \Delta^k_{\rm lev}$, so

$$\hat\Delta^{k(l+1)} \le \Delta^k_{\rm lev} = \kappa\hat\Delta^{k(l)} \quad \text{if} \quad k(l) < k \le k(l+1) \text{ and } l \ge 0 \tag{7.1}$$

and (2.17) follow by induction. Notice that the algorithm may also go to step 5 from step 2 if $f^k_{\rm lev} \le f^k_{\rm low}$. In other words: each group K_l ends by discovering that the target level is unattainable (and possibly that the lower bound may be increased). Then the level is raised by setting the level gap to a fraction of the "true" gap (between the bounds). The remaining level reductions within each group occur only when the objective improves, with the level gap and the lower bound staying fixed.

The efficiency analysis for the modified algorithm is similar to that for Algorithm 2.2, so we shall only indicate changes. Lemmas 3.2 and 3.3 remain valid. In Lemma 3.1 we may replace $\kappa\Delta^k$ by $\Delta^k_{\rm lev}$ (using $f(x^k) - f^k_{\rm lev} \ge f^k_{\rm up} - f^k_{\rm up} + \Delta^k_{\rm lev} = \Delta^k_{\rm lev}$), so (3.7) is replaced by

$$k - k(l) \le (\bar D L_f/\Delta^k_{\rm lev})^2/t_{\min}(2 - t_{\max}) \text{ if } k(l) < k < k(l+1) \text{ and } \Delta^k_{\rm lev} > 0. \tag{7.2}$$

In part (i) of the proof of Lemma 3.5 refer to (7.1) (instead of (2.16)) to get $\Delta^k_{\rm lev} \ge \epsilon/\kappa^{m-l-1}$ for all $k \in K_l \cap K(\epsilon)$ and $l = 0{:}m$, and use this relation and (7.2) in part (ii) to get the previous bounds. The remaining convergence results of §3 are easy to verify.

Another interesting modification is described in the following theorem.

THEOREM 7.1. *If we set $\epsilon_{\rm opt} = \epsilon$ and $\Delta^1_{\rm lev} = \epsilon$ for a given $\epsilon > 0$ (and possibly $f^1_{\rm low} = -\infty$), then the modified algorithm will terminate with $f^k_{\rm up} - f^* \le \epsilon$ and $l = 0$ at iteration $k = 1 + k_\epsilon$, where*

$$k_\epsilon \le (\bar D L_f/\epsilon)^2/t_{\min}(2 - t_{\max}). \tag{7.3}$$

Proof. If step 5 is not entered for $k = 1{:}k_\epsilon$ then (7.2) with $\Delta^k_{\rm lev} = \epsilon$ and $l = 0$ implies (7.3). Iteration $k = k_\epsilon + 1$ terminates at step 2, or at step 5 with $\hat\Delta^k \le \Delta^1_{\rm lev} = \epsilon$ (cf. (7.1)). □

A result essentially equivalent to the above theorem is given in [KuF90] for the simplest case of $\phi^k \equiv f^k$ at step 4. A comparison with all the preceding efficiency estimates (especially Corollary 5.2) suggests that, for a given accuracy $\epsilon_{\rm opt} > 0$, the strategy of Theorem 7.1 yields the best estimate. We believe, however, that in practice a "small" $\Delta^1_{\rm lev} = \epsilon_{\rm opt}$ might result in a slow "short-step" method, whose behavior would be close to the worst-case estimate even for "well-behaved" objectives. On the other hand, one may set $\Delta^1_{\rm lev}$ to an estimate of $f(x^1) - f^*$ (if any), so as to exploit any extra information at initial iterations; once a "reasonable" $f^k_{\rm low}$ is obtained then a switch to the original level strategy of Algorithm 2.2 may occur. (A similar idea is used in [LNN95].)

8. Level control via full model minimization. As in [LNN95], the *best underestimate* of f^* at iteration k is given by $\check{f}^k_{\min} = \min_S \check{f}^k$ with $\check{f}^k = \max_{j=1:k} f^j$. Let us, therefore, consider a version of Algorithm 2.2 in which step 2 sets $f^k_{\rm low} = \check{f}^k_{\min}$, step 4(i) chooses $\phi^k \le \check{f}^k$, and steps 4(iii) and 5 are deleted because $\bar{D}$ is no longer required for updating $f^k_{\rm low}$. (Note that $\mathcal{L}(\phi^k, f^k_{\rm lev}) \neq \emptyset$ at step 4(ii) due to $f^k_{\rm lev} > \check{f}^k_{\min} \ge \inf \phi^k$ by (2.1).)

Since $\check{f}^k \le \max\{\check{f}^k, f^{k+1}\} = \check{f}^{k+1} \le f$, we still have $f^{k+1}_{\rm low} \ge f^k_{\rm low}$, $\Delta^{k+1} \le \Delta^k$ and (2.14) for all k. Next,

$$\Delta^k < \kappa\Delta^j \quad \text{if} \quad \check{f}^k_{\min} > f^j_{\rm lev} \text{ and } j < k, \tag{8.1}$$

since then $\check{f}^k_{\min} > f^j_{\rm up} - \kappa\Delta^j \ge f^k_{\rm up} - \kappa\Delta^j$ by (2.1) with $\Delta^k = f^k_{\rm up} - \check{f}^k_{\min}$.

THEOREM 8.1. *The following efficiency estimate holds for each $\epsilon > 0$:*

$$k > c_{\rm LNN}(t_{\min}, t_{\max}, \kappa)(\operatorname{diam}(S)L_f/\epsilon)^2 \quad \Rightarrow \quad f^k_{\rm up} - f^* \le \Delta^k < \epsilon, \tag{8.2a}$$

$$c_{\rm LNN}(t_{\min}, t_{\max}, \kappa) = 1/t_{\min}(2 - t_{\max})\kappa^2(1 - \kappa^2), \tag{8.2b}$$

$$\min c_{\rm LNN}(\cdot,\cdot,\cdot) = c_{\rm LNN}(1, 1, 1/\sqrt{2}) = 4. \tag{8.2c}$$

Proof. (i) Suppose $\Delta^{k_\epsilon} \ge \epsilon > 0$ for some k_ϵ. Let us split $K(\epsilon) = \{1{:}\,k_\epsilon\}$ into groups $\check{K}_l$, $l = 1{:}\,m$ as follows. Let $\check{k}(1) = k_\epsilon$. For $l = 1, 2, \ldots$, set $\check{K}_l = \{k \le \check{k}(l) : \Delta^k \le \Delta^{\check{k}(l)}/\kappa\}$ and $\check{k}(l+1) = \min\{k : k \in \check{K}_l\} - 1$ until $\check{k}(l+1) = 0$, and then set $m = l$. By construction, $\Delta^k \ge \epsilon/\kappa^{l-1}$ for all $k \in \check{K}_l = \{\check{k}(l+1)+1{:}\,\check{k}(l)\}$ and $l = 1{:}\,m$.

(ii) Fix $1 \le l \le m$ and let $\check{y}^l \in \operatorname{Arg\,min}_S \check{f}^{\check{k}(l)}$. By (i) and (8.1), $\check{f}^{\check{k}(l)}_{\min} \le f^k_{\rm lev}$ for all $k \in \check{K}_l$. Hence, since $\check{f}^k$ are nondecreasing and $\phi^k \le \check{f}^k$, we have $\check{y}^l \in \mathcal{L}(\phi^k, f^k_{\rm lev})$ at step 4 for all $k \in \check{K}_l$. Therefore, $|\check{K}_l| \le (\operatorname{diam}(S)L_f/\kappa\Delta^{\check{k}(l)})^2/t_{\min}(2 - t_{\max})$ by Lemmas 3.1 and 3.2, as in the proof of Lemma 3.4, with $k_1 = \check{k}(l+1) + 1$, $k_2 = \check{k}(l)$ and $y = \check{y}^l \in S$.

(iii) Let $c = (\operatorname{diam}(S)L_f/\kappa)^2/t_{\min}(2 - t_{\max})$. By (i) and (ii),

$$k_\epsilon = \sum_{l=1}^{m} |\check{K}_l| \le \sum_{l=1}^{m} (c/\epsilon^2)\kappa^{2(l-1)} \le c/\epsilon^2(1 - \kappa^2). \qquad \square$$

Theorem 8.1 subsumes a result in [LNN95] obtained for $\phi^k \equiv \check{f}^k + \delta_S$ and $t_k \equiv 1$. Thus it shows that the good efficiency estimate for the level method of [LNN95] comes from level control, rather than from full projection subproblems.

It is easy to verify Theorem 3.8 and Corollary 5.2 (with $\bar{D} = \operatorname{diam}(S)$) for the modified method. Moreover, we may consider setting $f^k_{\rm lev} = f^k_{\rm up} - \kappa_k\Delta^k$, where $\kappa_k \in [\kappa_{\min}, \kappa_{\max}] \subset (0, 1)$. Then (8.2) involves $\hat{c}_{\rm LNN}(t_{\min}, t_{\max}, \kappa_{\min}, \kappa_{\max}) = 1/t_{\min}(2 - t_{\max})\kappa^2_{\min}(1 - \kappa^2_{\max})$, where again the "best" $\kappa_{\min} = \kappa_{\max} = 1/\sqrt{2}$. To check this, replace κ with $\kappa_{\max}$ in (8.1) and part (i) of the proof of Theorem 8.1 and with $\kappa_{\min}$ in part (ii).

Although it eliminates the need for $\bar{D}$, finding $\check{f}^k_{\min} = \min_S \max_{j=1:k} f^j$ may require too much storage and work per iteration when k is large. Let us therefore consider the following *partial model minimization strategy.* At step 2 find $\hat{f}^k_{\min} \le \min_S \hat{f}^k$ (cf. (2.5)) and set $f^k_{\min} = \max\{\hat{f}^k_{\min}, f^{k-1}_{\min}\}$ (with $f^0_{\min} = f^1_{\rm low}$). If $f^k_{\rm lev} \le f^k_{\min}$, go to step 5, choosing $\hat{f}^k_{\rm low} \ge f^k_{\min}$. Clearly, the efficiency results of the preceding sections remain true. Although this technique does not eliminate the dependence on $\bar{D}$ in theory, we believe that when $\hat{f}^k$ are chosen "rich enough," it will ensure better performance in practice. Also note that, to save work, $\min_S \hat{f}^k$ need not be found exactly.

9. Dual level methods. We shall now show how to use dual (ϵ-subgradient) techniques for constructing models of f that generalize those in [KuF90, LNN95]. In the simplest case such models are aggregate linearizations of f that are convex combinations of the ordinary linearizations f^j. We shall later relate them to surrogate inequalities used in relaxation methods. We start with an abstract framework that will cover several examples motivated by the the following representation:

$$\partial_\epsilon \hat{f}^k(x^k) = \left\{ \sum_{j\in J^k} \lambda_j g_f(x^j) : \lambda_j \geq 0, j \in J^k, \sum_{j\in J^k} \lambda_j = 1, \right. \tag{9.1}$$
$$\left. \sum_{j\in J^k} \lambda_j [\hat{f}^k(x^k) - f^j(x^k)] \leq \epsilon \right\}.$$

DEFINITION 9.1. *Let $\mu > 0$ be an additional fixed parameter associated with Algorithm 2.2. At step 4 let Φ^k_μ denote the set of all closed proper convex functions $\phi^k\colon \mathbb{R}^N \to (-\infty, \infty]$ that satisfy*

$$S^* \subset \mathcal{L}(\phi^k, f^k_{\text{lev}}) \quad \text{and} \quad d_{\mathcal{L}(\phi^k, f^k_{\text{lev}})}(x^k) \geq \mu\kappa\Delta^k/L_f \quad \text{if} \quad f^k_{\text{lev}} \geq f^*. \tag{9.2}$$

LEMMA 9.2. *Let $0 < \mu_\epsilon \leq 1$ and $\mu_g > 0$ be additional fixed parameters associated with Algorithm 2.2. At step 4 let $\Phi^k_{\mu_\epsilon,\mu_g}$ denote the set of all functions of the form $\phi^k(\cdot) = \hat{\phi}^k(x^k) - \epsilon_k + \langle p^k, \cdot - x^k\rangle$, where $\hat{\phi}^k\colon \mathbb{R}^N \to (-\infty, \infty]$ is closed, proper and convex, $\hat{\phi}^k \in \Phi$ if $f^k_{\text{lev}} \geq f^*$, $p^k \in \partial_{\epsilon_k}\hat{\phi}^k(x^k)$ satisfies $|p^k| \leq L_f/\mu_g$, and $\epsilon_k \in [0, \epsilon^k_{\max}]$ with*

$$\epsilon^k_{\max} = \hat{\phi}^k(x^k) - f^k_{\text{up}} + (1-\mu_\epsilon)(f^k_{\text{up}} - f^k_{\text{lev}}) = \hat{\phi}^k(x^k) - f^k_{\text{lev}} - \mu_\epsilon\kappa\Delta^k. \tag{9.3}$$

Suppose step 4(ii) uses such a ϕ^k (although it need not majorize f^k). If $f^k_{\text{lev}} \geq f^*$ then $S^* \subset \mathcal{L}(\phi^k, f^k_{\text{lev}})$, $y^k = P_{\mathcal{L}(\phi^k, f^k_{\text{lev}})}(x^k) = x^k - (\hat{\phi}^k(x^k) - \epsilon_k - f^k_{\text{lev}})p^k/|p^k|^2$ and

$$\begin{aligned} \rho^k_\phi/t_{\min}(2 - t_{\max}) &\geq d^2_{\mathcal{L}(\phi^k, f^k_{\text{lev}})}(x^k) = (\hat{\phi}^k(x^k) - \epsilon_k - f^k_{\text{lev}})^2/|p^k|^2 \\ &\geq (\mu_\epsilon\mu_g\kappa\Delta^k/L_f)^2, \end{aligned} \tag{9.4}$$

whereas if $\mathcal{L}(\phi^k, f^k_{\text{lev}}) = \emptyset$, then $f^k_{\text{lev}} < f^*$. Moreover, $\Phi^k_{\mu_\epsilon,\mu_g} \subset \Phi^k_\mu$ if $\mu = \mu_\epsilon\mu_g$.

Proof. Suppose $f^k_{\text{lev}} \geq f^*$. Let $x \in S^*$. By construction and (2.10), $\phi^k(x) \leq \hat{\phi}^k(x) \leq f^*$ yield $S^* \subset \mathcal{L}(\phi^k, f^k_{\text{lev}}) \neq \emptyset$. By (9.3), $p^k = 0$ would imply $f^* \geq \phi^k(\cdot) = \hat{\phi}^k(x^k) - \epsilon_k \geq f^k_{\text{lev}} + \mu_\epsilon\kappa\Delta^k > f^k_{\text{lev}}$, a contradiction. Thus $y^k - x^k = -(\phi^k(x^k) - f^k_{\text{lev}})p^k/|p^k|^2$. Since $\phi^k(x^k) - f^k_{\text{lev}} = \hat{\phi}^k(x^k) - \epsilon_k - f^k_{\text{lev}} \geq \mu_\epsilon\kappa\Delta^k$ from (9.3) and $|p^k| \leq L_f/\mu_g$ by the choice of p^k, we have (9.4), which yields (9.2) if $\mu = \mu_\epsilon\mu_g$. □

Let us consider efficiency before examples. The preceding proofs hinge on $\phi^k \in \Phi^k_1$ *only* (cf. (2.15) and the proof of Lemma 3.3), so $\phi^k \notin \Phi$ is admissible if $f^k_{\text{lev}} < f^*$. (This is used in [Kiw96, §6].) Hence step 4 may use any $\phi^k \in \Phi^k_{\mu_\epsilon,\mu_g} \cup \Phi^k_\mu$ with $\mu = \mu_\epsilon\mu_g > 0$. Then, comparing (9.2) and (9.4) with Lemma 3.1, we see that *only the first terms* of the constants in all the preceding efficiency estimates and the right side of (7.3) need be *divided by* μ^2; of course, Δ^k_{lev} replaces $\kappa\Delta^k$ in (9.2), (9.3) and (9.4) for the frozen level gaps of §7.

As in §8, suppose $f^k_{\text{low}} \equiv \check{f}^k_{\min}$ at step 2, step 5 is deleted, and step 4 chooses $\hat{\phi}^k \le \check{f}^k$ and ϕ^k as in Lemma 9.2. Then Theorem 8.1 holds with c_{LNN} divided by $\mu^2 = \mu_\epsilon^2$, since $\mu_g = 1$. (In part (ii) of its proof use (9.4) to replace κ by $\mu\kappa$.)

It should be clear that, as in §§5 and 8, we may use variable $\kappa_k \in [\kappa_{\min}, \kappa_{\max}]$ and $\mu_{\epsilon,k} \in [\mu_{\min}, 1] \subset (0,1]$ in (9.3). Then the efficiency constants are divided by $(\mu_{\min}\mu_g)^2$.

For choosing $\hat{\phi}^k$ in Lemma 9.2, note that any $\hat{\phi}^k \in \Phi$ such that $f^k \le \hat{\phi}^k \le \check{f}^k$ is admissible. Indeed, $f^k(x^k) = \check{f}^k(x^k) = f(x^k)$ yield $\epsilon^k_{\max} \ge 0$ in (9.3), and we may always ensure $|p^k| \le L_f$ because $g_f(x^k) \in \partial\hat{\phi}^k(x^k)$ has $|g_f(x^k)| \le L_f$. In view of Remark 3.9, to enlarge ρ^k_ϕ in (9.4), we may let

$$p^k = \arg\min\{\, |p|^2/2 : p \in \partial_{\epsilon_k}\hat{\phi}^k(x^k)\,\}. \tag{9.5}$$

For example, if we use $\hat{\phi}^k = \hat{f}^k$ and (9.1), then p^k may by found by quadratic programming (QP). Since there is no need to solve (9.5) exactly, iterative QP methods (e.g., parallel relaxation-type methods) and various heuristics may by employed to save work. Note that (9.5) minimizes the denominator in (9.4) with a fixed numerator. An alternative construction is described in the following lemma (in which one may assume $\hat{\phi}^k = \hat{f}^k$ for the first reading). It implies that we may use convex combinations of linearizations with quite arbitrary weights without destroying the preceding efficiency estimates. Possible advantages of such combinations are discussed later.

LEMMA 9.3. *Let $\hat{\phi}^k = \max_{i\in I^k}\phi^k_i$, where $|I^k| < \infty$, each ϕ^k_i is an affine function of the form $\phi^k_i(x) = \phi^k_i(x^k) + \langle p^k_{\phi_i}, x - x^k\rangle$ with $|p^k_{\phi_i}| \le L_f/\mu_g$, and $\phi^k_i \in \Phi$ if $f^k_{\text{lev}} \ge f^*$. Suppose $\hat{\phi}^k(x^k) > f^k_{\text{lev}}$, $\hat{I}^k \subset \{i \in I^k : \phi^k_i(x^k) \ge f^k_{\text{lev}}\}$, $\bar{I}^k = \{i \in \hat{I}^k : \phi^k_i(x^k) = \hat{\phi}^k(x^k)\} \ne \emptyset$, $\lambda_i > 0$ for $i \in \hat{I}^k$, $\lambda_i = 0$ for $i \in I^k \setminus \hat{I}^k$, $\sum_{i\in\hat{I}^k}\lambda_i = 1$, $(p^k, \epsilon_k) = \sum_{i\in\hat{I}^k}\lambda_i(p^k_{\phi_i}, \hat{\phi}^k(x^k) - \phi^k_i(x^k))$, and $\phi^k(\cdot) = \hat{\phi}^k(x^k) - \epsilon_k + \langle p^k, \cdot - x^k\rangle$. If $f^k_{\text{lev}} \ge f^*$, then $d_{\mathcal{L}(\phi^k, f^k_{\text{lev}})}(x^k) \ge \sum_{i\in\bar{I}^k}\lambda_i(\hat{\phi}^k(x^k) - f^k_{\text{lev}})\mu_g/L_f$, whereas if $p^k = 0$, then $f^k_{\text{lev}} < f^*$. In particular, $\phi^k \in \Phi^k_{\mu_\epsilon,\mu_g}$ if $\lambda_j \ge \mu_\epsilon\kappa\Delta^k/(\hat{\phi}^k(x^k) - f^k_{\text{lev}})$ for some $j \in \bar{I}^k$, e.g., if $\lambda_j \ge \mu_\epsilon$ and $\hat{\phi}^k(x^k) \ge f^k_{\text{up}}$.*

Proof. Suppose $f^k_{\text{lev}} \ge f^*$, $x \in S^*$, and $j \in \bar{I}^k$. By construction, $\hat{\phi}^k(x^k) - \epsilon_k - f^k_{\text{lev}} = \sum_{i\in\hat{I}^k}\lambda_i(\phi^k_i(x^k) - f^k_{\text{lev}}) \ge \sum_{i\in\bar{I}^k}\lambda_i(\hat{\phi}^k(x^k) - f^k_{\text{lev}}) > 0$. Hence with $\phi^k(x^k) = \hat{\phi}^k(x^k) - \epsilon_k$, $p^k = 0$ would give $f^* \ge \sum_{i\in\hat{I}^k}\lambda_i\phi^k_i(x) = \phi^k(x) = \phi^k(x^k) > f^k_{\text{lev}}$, a contradiction. Thus $d_{\mathcal{L}(\phi^k, f^k_{\text{lev}})}(x^k) = (\phi^k(x^k) - f^k_{\text{lev}})/|p^k| \ge \sum_{i\in\bar{I}^k}\lambda_i(\hat{\phi}^k(x^k) - f^k_{\text{lev}})/|p^k|$, where $|p^k| \le \sum_{i\in\hat{I}^k}\lambda_i|p^k_{\phi_i}| \le L_f/\mu_g$. Recall Lemma 9.2 and (2.1) to complete the proof. □

Supposing $f^k_{\text{lev}} \ge f^*$, let us now compare the dual approach based on (9.4) (and possibly (9.5)) using $y^k = P_{\mathcal{L}(\phi^k, f^k_{\text{lev}})}(x^k)$ with a primal one that employs $\hat{\phi}^k$ directly to find

$$\hat{y}^k = P_{\mathcal{L}(\hat{\phi}^k, f^k_{\text{lev}})}(x^k) = \arg\min\{\, |x - x^k|^2/2 : \hat{\phi}^k(x) \le f^k_{\text{lev}}\,\}. \tag{9.6}$$

LEMMA 9.4. *We have $|y - \hat{y}^k|^2 \le |y - x^k|^2 - |\hat{y}^k - x^k|^2$ and $|y - y^k|^2 \le |y - x^k|^2 - |y^k - x^k|^2$ for all $y \in \mathcal{L}(\hat{\phi}^k, f^k_{\text{lev}})$, where $|y^k - x^k|^2 \le |\hat{y}^k - x^k|^2 - |\hat{y}^k - y^k|^2$. Moreover,*

$$\begin{aligned}\sup\{\, (\hat{\phi}^k(x^k) - \epsilon - f^k_{\text{lev}})/|p| : \epsilon \in [0, \hat{\phi}^k(x^k) - f^k_{\text{lev}}),\ p \in \partial_\epsilon\hat{\phi}^k(x^k)\,\} \\ = |\hat{y}^k - x^k|,\end{aligned} \tag{9.7}$$

with the supremum attained at some $\hat{\epsilon}_k$ *and* $\hat{p}^k$ *if* $\hat{\phi}^k$ *is polyhedral or* $\inf \hat{\phi}^k < f^k_{\text{lev}}$.

Proof. The first assertion follows from (2.8) and $\phi^k \le \hat{\phi}^k$. Hence, recalling (9.4), $|\hat{y}^k - x^k|$ majorizes the left side of (9.7). To establish equality, suppose initially that $\hat{\phi}^k$ is polyhedral or $\inf \hat{\phi}^k < f^k_{\text{lev}}$. Then, by the Karush–Kuhn–Tucker conditions for (9.6), there exist $\hat{p}^k \in \partial\hat{\phi}^k(\hat{y}^k)$ and a multiplier $\hat{\lambda} \ge 0$ such that $\hat{y}^k - x^k = -\hat{\lambda}\hat{p}^k$. Clearly, $\hat{\phi}^k(\hat{y}^k) = f^k_{\text{lev}}$ and $\hat{\lambda} > 0$ because $x^k \notin \mathcal{L}(\phi^k, f^k_{\text{lev}}) \supset \mathcal{L}(\hat{\phi}^k, f^k_{\text{lev}})$ $(\phi^k \le \hat{\phi}^k)$. Letting $\tilde{\phi}^k(\cdot) = \hat{\phi}^k(\hat{y}^k) + \langle \hat{p}^k, \cdot - \hat{y}^k \rangle$ and $\hat{\epsilon}_k = \hat{\phi}^k(x^k) - \tilde{\phi}^k(x^k) = \hat{\phi}^k(x^k) - f^k_{\text{lev}} - \hat{\lambda}|\hat{p}^k|^2$, we get (9.7). In the general case, replace f^k_{lev} in (9.6) by $t > f^k_{\text{lev}}$ so that the Slater condition holds, define $\hat{y}(t)$, $\hat{p}(t)$, and $\hat{\epsilon}(t)$, as above, and let $t \downarrow f^k_{\text{lev}}$ with $\hat{y}(t) \to \hat{y}^k$. □

In view of Remark 3.9, the first bound of Lemma 9.4 is, in general, better than the second one. On the other hand, (9.7) says that the dual approach can, in principle, be as good as the primal one if (9.5) is used with a carefully chosen ϵ_k. Thus such bounds seem to favor the primal approach. However, they are local and the dual one may employ inexact QP solvers, so it may be easier to implement.

Choosing $(\epsilon_k, p^k) = (\hat{\epsilon}_k, \hat{p}^k)$ to solve (9.7) gives an *"optimal" dual method* that does not need $\mu_\epsilon > 0$ in (9.3) if $\hat{\phi}^k \ge f^k$ and $\hat{\phi}^k \in \Phi$. It is, however, more difficult to implement than the equivalent primal method that may solve (9.6) via QP when $\hat{\phi}^k$ is polyhedral.

We may add that [LNN95] employs $\hat{\phi}^k = \check{f}^k$, $t_k = 1$, $f^k_{\text{lev}} = \check{f}^k_{\min}$ and constant κ, $\mu_\epsilon \in (0,1)$ and $\mu_g = 1$, whereas [KuF90] proceeds as in Theorem 6.1 with $\mu_\epsilon = 1$ and $\hat{\phi}^k = f$ without specifying any models of f (but $\mu_\epsilon = 1$ may severely restrict the choice of p^k; cf. (9.3)).

Acknowledgments. This work was started during my six-month stay at INRIA, Rocquencourt, in 1992, owing to the kind invitation by C. Lemaréchal and the French Ministry for Research and Technology, whose financial support is gratefully acknowledged. I would also like to thank the two anonymous referees for their valuable comments.

THE EFFICIENCY OF SUBGRADIENT PROJECTION METHODS FOR CONVEX OPTIMIZATION, PART II: IMPLEMENTATIONS AND EXTENSIONS*

KRZYSZTOF C. KIWIEL†

Abstract. In the first part of this paper we studied subgradient methods for convex optimization that use projections onto successive approximations of level sets of the objective corresponding to estimates of the optimal value. We presented several variants and showed that they enjoy almost optimal efficiency estimates. In this part of the paper we discuss possible implementations of such methods. In particular, their projection subproblems may be solved inexactly via relaxation methods, thus opening the way for parallel implementations. We discuss accelerations of relaxation methods based on simultaneous projections, surrogate constraints, and conjugate and projected (conditional) subgradient techniques.

Key words. nondifferentiable (nonsmooth) optimization, convex programming, relaxation methods, subgradient optimization, successive projections, linear inequalities, parallel computing

AMS subject classifications. 65K05, 90C25

1. Introduction.

This is the second of two papers in which we study variants of Polyak's [Pol69] subgradient projection algorithm (SPA) and the level method of [LNN95] for solving the convex program

$$f^* = \min\{ f(x) : x \in S \} \tag{1.1}$$

under the following assumptions. S is a nonempty compact convex subset of $\mathbb{R}^N$; f is a convex function Lipschitz continuous on S with Lipschitz constant L_f; for each $x \in S$ we can compute $f(x)$ and a subgradient $g_f(x) \in \partial f(x)$ of f at x such that $|g_f(x)| \leq L_f$; and for each $x \in \mathbb{R}^N$ we can find $P_S(x) = \arg\min\{|x - y| : y \in S\}$, its orthogonal projection on S, where $|\cdot|$ denotes the Euclidean norm. The SPA generates successive iterates

$$x^{k+1} = P_S(x^k - t_k(f(x^k) - f^*)g_f(x^k)/|g_f(x^k)|^2) \quad \text{for } k = 1, 2, \ldots, \tag{1.2}$$

where $x^1 \in S$ and t_k are stepsizes in $T = [t_{\min}, t_{\max}]$ with $0 < t_{\min} \leq t_{\max} < 2$.

In part I [Kiw96] we gave efficiency estimates for three schemes for estimating f^* in (1.2), stemming from [KAC91, KuF90, LNN95]. Moreover, to enable faster convergence, we studied algorithms that use projections onto successive approximations of level sets of f derived from *several accumulated subgradient linearizations* of f or their *aggregates* as in descent bundle methods for nondifferentiable optimization (NDO) [HUL93, Kiw85, Lem89].

In this paper we discuss possible implementations of such algorithms that provide freedom to trade off storage requirements and work per iteration for speed of convergence. Their projection subproblems can be solved efficiently even in the large-scale case by a variety of methods, especially those that can benefit from parallel computation; see, e.g., [AhC89, BeT89, IDP91, Kiw95, LoH88, Oko92, Spi87, Tse90a, Tse90b, YaM92] and the references therein. The ability to use *inexact* projections makes such

† Systems Research Institute, Newelska 6, 01–447 Warsaw, Poland (kiwiel@ibspan.waw.pl).

algorithms very attractive in large-scale applications. In contrast, the existing bundle methods (cf. [Kiw89, ScZ92]) employ nonstrictly convex quadratic programming (QP) subproblems, and it is not clear how to solve such QP subproblems exactly via parallel computation.

It is fruitful to view subgradient methods as extensions of relaxation methods for linear inequalities [Agm54, Gof78, MoS54]. Motivated by possible applications to the subgradient methods of this paper, we have introduced in [Kiw95] several parallelizable relaxation methods. Here we provide a unified perspective on acceleration techniques for such methods, including simultaneous projections [Tod79], surrogate cuts [BGT81, GoT82, Oko92], surrogate constraints [YaM92], conjugate subgradients (CSs) [CFM75, KKA87, Shc92, ShU89, Sho79], and projected (conditional) subgradients [BaG79, KiU89]. In contrast to their usual interpretations, we show that such methods hinge on *implicitly* generated affine (or polyhedral) models of f. *Explicit* use of such models allows various modifications and extensions that seem more efficient. It turns out that some of these methods are simplified versions of others that trade speed of convergence for ease of implementation. Further, our framework shows how to modify their models to account for the constraint $x \in S$. For instance, it suggests the following simple modification of (1.2) (proposed independently in [KiU93, Kiw93]):

$$x^{k+1} = \arg\min\{\, |x - x^k|^2/2 : f(x^k) + \langle g_f(x^k), x - x^k \rangle \le f^*, x \in S \,\}, \tag{1.3}$$

which seems to be more efficient in general [KiU93].

The paper is organized as follows. In §2 we extend the level algorithm of [Kiw96] and give conditions that allow efficient implementations via general relaxation and QP methods discussed in §§3 and 4, as well as "cheap" surrogate projection methods developed in §5. Extensions of conjugate subgradient implementations are given in §6. In §7 we argue that subgradient relaxation should also include inequalities related to S. Finally, we have a concluding section.

We use the following notation. We denote by $\langle \cdot, \cdot \rangle$ the usual inner product in $\mathbb{R}^N$. For $\epsilon \ge 0$, the ϵ-subdifferential of f at x is defined by $\partial_\epsilon f(x) = \{p \in \mathbb{R}^N : f(y) \ge f(x) + \langle p, y - x \rangle - \epsilon \quad \forall y \in \mathbb{R}^N\}$. $\mathcal{L}(f, \alpha) = \{x : f(x) \le \alpha\}$ is the α-level set of f, and $\operatorname{diam}(S) = \sup_{x,y \in S} |x - y|$ is the diameter of S. Given a closed convex set $C \subset \mathbb{R}^N$ and a stepsize $t \in T$, the *relaxation operator* $\mathcal{R}_{C,t}(x) = x + t(P_C(x) - x)$ has the Fejér contraction property [Agm54, Kiw96]

$$|y - \mathcal{R}_{C,t}(x)|^2 \le |y - x|^2 - t(2 - t)d_C^2(x) \quad \forall y \in C, x \in \mathbb{R}^N, \tag{1.4}$$

where $d_C(x) = |x - P_C(x)|$. We let $1{:}k$ denote $1, 2, \ldots, k$. For brevity, we let $a/bc = a/(bc)$. The convex hull is denoted by co.

2. The generalized relaxation level algorithm. We start by presenting an extension of Algorithm 2.2 from [Kiw96].

ALGORITHM 2.1.

Step 0 (Initialization). Select an initial point $x^1 \in S$, a final optimality tolerance $\epsilon_{\text{opt}} \ge 0$, a level parameter $0 < \kappa < 1$, and stepsize parameters $0 < t_{\min} \le t_{\max} < 2$. Choose $\bar{D} \ge \operatorname{diam}(S)$ and $f_{\text{low}}^1 \le f^*$. Set $\rho_1 = 0$ and $f_{\text{up}}^0 = \infty$. Set the counters $k = 1$, $l = 0$, and $k(0) = 0$. ($k(l)$ will denote the iteration number of the lth increase of f_{low}^k.)

Step 1 (Objective evaluation). Calculate $f(x^k)$ and $g_f(x^k)$.

Step 2 (Level update). Using the current *lower bound* f_{low}^k on f^*, update the *upper bound* $f_{\text{up}}^k = \min\{f(x^k), f_{\text{up}}^{k-1}\}$, the *gap* $\Delta^k = f_{\text{up}}^k - f_{\text{low}}^k$, and the *target* (*level*) $f_{\text{lev}}^k = f_{\text{up}}^k - \kappa\Delta^k$.

Step 3 (Stopping criterion). If $\min\{\Delta^k, |g_f(x^k)|/\bar{D}\} \le \epsilon_{\text{opt}}$, terminate.

Step 4 (Relaxations). Let $f^k(\cdot) = f(x^k) + \langle g_f(x^k), \cdot - x^k\rangle$.

(i) Find $z^k \in \mathbb{R}^N$ and $\rho_\phi^k \ge 0$ such that $\rho_\phi^k \ge t_{\min}(2 - t_{\max})d^2_{\mathcal{L}(f^k, f_{\text{lev}}^k)}(x^k)$ and

$$|y - z^k|^2 \le |y - x^k|^2 - \rho_\phi^k \quad \forall y \in S^* \quad \text{if} \quad f_{\text{lev}}^k \ge f^*; \tag{2.1}$$

if $f_{\text{lev}}^k < f^*$, then z^k and ρ_ϕ^k are arbitrary (even $\rho_\phi^k = \infty$ is admissible). If $\rho_k + \rho_\phi^k > \bar{D}^2$ or it is discovered by another test that $f_{\text{lev}}^k < f^*$, go to step 5.

(ii) Find $x^{k+1} \in S$ and $\rho_S^k \ge 0$ such that $|y - x^{k+1}|^2 \le |y - z^k|^2 - \rho_S^k$ for all $y \in S$. If $\rho_k + \rho_\phi^k + \rho_S^k > \bar{D}^2$, go to step 5; otherwise, go to step 6.

Step 5 (Update lower bound).

(i) Choose a lower bound $\hat{f}_{\text{low}}^k \in [\max\{f_{\text{low}}^k, f_{\text{lev}}^k\}, f^*]$ (e.g., $\hat{f}_{\text{low}}^k = \max\{f_{\text{low}}^k, f_{\text{lev}}^k\}$). Set $f_{\text{low}}^{k+1} = \hat{f}_{\text{low}}^k$, $\rho_{k+1} = 0$ and $\hat{\Delta}^k = f_{\text{up}}^k - \hat{f}_{\text{low}}^k$.

(ii) If $\hat{\Delta}^k \le \epsilon_{\text{opt}}$, terminate; otherwise, continue.

(iii) Set $x^{k+1} = x^k$ (*null step*), $k(l+1) = k$, and increase k and l by 1. Go to step 2.

Step 6 (Serious step). Set $f_{\text{low}}^{k+1} = f_{\text{low}}^k$, $\hat{f}_{\text{low}}^k = f_{\text{low}}^k$, $\hat{\Delta}^k = \Delta^k$ and $\rho_{k+1} = \rho_k + \rho_\phi^k + \rho_S^k$. Increase k by 1 and go to step 1.

We need only discuss possible implementations of step 4. First, as in [Kiw96], we may choose a stepsize $t_k \in T$ and an *admissible model* ϕ^k of f in the set

$$\Phi = \{\, \phi\colon \mathbb{R}^N \to (-\infty, \infty] : \phi \text{ is closed convex and } \phi(x) \le f^* \ \forall x \in S^* \,\}$$

such that $\phi^k \ge f^k$, discover that $f_{\text{lev}}^k < f^*$ if $\mathcal{L}(\phi^k, f_{\text{lev}}^k) = \emptyset$, and otherwise set $y^k = P_{\mathcal{L}(\phi^k, f_{\text{lev}}^k)}(x^k)$, $z^k = x^k + t_k(y^k - x^k)$, $x^{k+1} = P_S(z^k)$, $\rho_\phi^k = t_k(2 - t_k)|y^k - x^k|^2$, and $\rho_S^k = |x^{k+1} - z^k|^2$. (Then $x^{k+1} = P_S(\mathcal{R}_{\mathcal{L}(\phi^k, f_{\text{lev}}^k), t_k}(x^k))$, and ρ_ϕ^k and ρ_S^k stem from Fejér estimates; cf. (1.4).) For instance, we may let ϕ^k be the kth polyhedral model of f

$$\hat{f}^k(x) = \max\{\, f^j(x) : j \in J^k \,\} \quad \text{with} \quad k \in J^k \subset \{1\colon k\};$$

e.g., $J^k \equiv \{k\}$ yields the subgradient projection level algorithm (SPLA):

$$x^{k+1} = P_S(x^k - t_k(f(x^k) - f_{\text{lev}}^k)g_f(x^k)/|g_f(x^k)|^2) \quad \text{for } k = 1, 2, \ldots. \tag{2.2}$$

Alternatively, for the *dual level methods* of [Kiw96, §9], we may choose $\phi^k \in \Phi_\mu^k \cup \Phi_{\mu_\epsilon, \mu_g}^k$ and replace f^k with ϕ^k at step 4(i), where $\mu > 0$, $0 < \mu_\epsilon \le 1$, and $\mu_g > 0$ are additional fixed parameters, and Φ_μ^k and $\Phi_{\mu_\epsilon, \mu_g}^k$ are defined as follows. Φ_μ^k denotes the set of all closed proper convex functions $\phi^k\colon \mathbb{R}^N \to (-\infty, \infty]$ that satisfy

$$S^* \subset \mathcal{L}(\phi^k, f_{\text{lev}}^k) \quad \text{and} \quad d_{\mathcal{L}(\phi^k, f_{\text{lev}}^k)}(x^k) \ge \mu\kappa\Delta^k/L_f \quad \text{if} \quad f_{\text{lev}}^k \ge f^*. \tag{2.3}$$

$\Phi_{\mu_\epsilon, \mu_g}^k$ denotes the set of all functions of the form $\phi^k(\cdot) = \hat{\phi}^k(x^k) - \epsilon_k + \langle p^k, \cdot - x^k\rangle$, where $\hat{\phi}^k\colon \mathbb{R}^N \to (-\infty, \infty]$ is closed, proper and convex, $\hat{\phi}^k \in \Phi$ if $f_{\text{lev}}^k \ge f^*$, $p^k \in$

$\partial_{\epsilon_k}\hat{\phi}^k(x^k)$ satisfies $|p^k| \le L_f/\mu_g$, and $\epsilon_k \in [0, \epsilon^k_{\max}]$ with $\epsilon^k_{\max} = \hat{\phi}^k(x^k) - f^k_{\text{lev}} - \mu_\epsilon \kappa \Delta^k$. In particular, we may choose $\hat{\phi}^k = \hat{f}^k$, $\epsilon_k \in [0, \epsilon^k_{\max}]$ and

$$p^k = \arg\min\{\, |p|^2/2 : p \in \partial_{\epsilon_k}\hat{\phi}^k(x^k)\,\}, \tag{2.4}$$

using

$$\partial_\epsilon \hat{f}^k(x^k) = \left\{ \sum_{j\in J^k} \lambda_j g_f(x^j) : \lambda_j \ge 0, j \in J^k, \sum_{j\in J^k} \lambda_j = 1, \right. \tag{2.5}$$
$$\left. \sum_{j\in J^k} \lambda_j [\hat{f}^k(x^k) - f^j(x^k)] \le \epsilon \right\}.$$

Remark 2.2. For the methods from [Kiw96, §8], which use $f^k_{\text{lev}} \equiv \min_S \check{f}^k$ with $\check{f}^k = \max_{j=1:k} f^j$, S^* in (2.1) should be replaced by $\{y \in S : \check{f}^k(y) \le f^k_{\text{lev}}\}$. It is easy to verify all the efficiency results of [Kiw96] for such modifications. (Hint: let $y \in S^*$ in [Kiw96, Lem. 3.2], with S^* replaced by $\mathcal{L}(\check{f}^k, f^k_{\text{lev}})$ in [Kiw96, §8].)

3. Using general relaxation methods. We now show how to implement step 4 via general relaxation methods for linear inequalities; see, e.g., [AhC89, Kiw95] and the references therein.

Suppose ϕ^k is polyhedral, so that $\mathcal{L}(\phi^k, f^k_{\text{lev}})$ has the form $\{x : \langle a^i, x\rangle \le b_i, i \in I\}$. Let $C_i = \{x : \langle a^i, x\rangle \le b_i\}$, $i \in I$. Given a starting point $\tilde{x}^1 \notin \cap_{i\in I} C_i$, many relaxation methods attempt to find a point in $\cap_i C_i$ via the iteration $\tilde{x}^{n+1} = \sum_{i\in I} \tilde{\lambda}^n_i \mathcal{R}_{C_i,\tilde{t}_n}(\tilde{x}^n)$, $n = 1, 2, \ldots$, where the weights $\tilde{\lambda}^n_i \ge 0$, $i \in I$, satisfy $\sum_i \tilde{\lambda}^n_i = 1$, and $0 < \tilde{t}_n \le 2$. By (1.4),

$$|y - \mathcal{R}_{C_i,\tilde{t}_n}(\tilde{x}^n)|^2 \le |y - \tilde{x}^n|^2 - \tilde{t}_n(2 - \tilde{t}_n) d^2_{C_i}(\tilde{x}^n) \quad \forall y \in C_i;$$

multiply this by $\tilde{\lambda}^n_i$, sum over i, and use $\sum_i \tilde{\lambda}^n_i = 1$ and the convexity of $|\cdot|^2$ to get

$$\left| y - \sum_i \tilde{\lambda}^n_i \mathcal{R}_{C_i,\tilde{t}_n}(\tilde{x}^n) \right|^2 \le |y - \tilde{x}^n|^2 - \tilde{t}_n(2 - \tilde{t}_n) \sum_i \tilde{\lambda}^n_i d^2_{C_i}(\tilde{x}^n) \quad \forall y \in \cap_i C_i.$$

In other words, letting $\tilde{\rho}_n = \tilde{t}_n(2 - \tilde{t}_n) \sum_i \tilde{\lambda}^n_i d^2_{C_i}(\tilde{x}^n)$, we have the Fejér estimates $|y - \tilde{x}^1|^2 - |y - \tilde{x}^n|^2 \ge \sum_{j=1}^{n-1} \tilde{\rho}_j$ $\forall y \in \cap_i C_i$. Therefore, if we start from $\tilde{x}^1 = P_{\mathcal{L}(f^k, f^k_{\text{lev}})}(x^k)$ and terminate *for any* $n \ge 1$, then $z^k = \tilde{x}^n$ and $\rho^k_\phi = d^2_{\mathcal{L}(f^k, f^k_{\text{lev}})}(x^k) + \sum_{j=1}^{n-1} \tilde{\rho}_j$ will satisfy the requirements of step 4. (In particular we may stop if $\rho_k + \rho^k_\phi > \bar{D}^2$ for such ρ^k_ϕ.) Moreover, ρ^k_ϕ may be increased by using more refined Fejér estimates to replace $\tilde{\rho}_j$ with some larger quantities [Kiw95]. In fact [Kiw95] shows that other relaxation methods have much better Fejér estimates; hence they could provide more efficient implementations of step 4(i).

Similar ideas may be used for implementing step 4(ii) via finite iterative methods that do not necessarily compute x^{k+1} as the projection of z^k onto S; see [KuF90] for details.

It is worth observing that many relaxation methods are highly amenable to parallel computation; see [AhC89, Kiw95]. Since we do not require exact projections, various heuristics may limit the work spent on relaxations.

4. QP-based implementations. We shall now discuss possible implementations of our methods that employ subgradient selection and aggregation. These two techniques have proved to be highly useful in implementations of other NDO bundle methods; see, e.g., [Kiw85, Kiw89, Kiw90] for details.

First, we describe *subgradient selection*. If $\phi^k = \hat{f}^k$ and $\mathcal{L}(\phi^k, f^k_{\text{lev}}) \neq \emptyset$ then

$$y^k = \arg\min\{\, |x - x^k|^2/2 : f^j(x) \leq f^k_{\text{lev}}, j \in J^k \,\}. \tag{4.1}$$

Denote the Lagrange multipliers of (4.1) by λ^k_j, $j \in J^k$. Let $\hat{J}^k = \{j \in J^k : \lambda^k_j > 0\}$. By the Karush–Kuhn–Tucker (KKT) conditions, if we select $J^k_s \subset J^k$ such that $\hat{J}^k \subset J^k_s$, then J^k_s may replace J^k in (4.1) without changing its solution. This suggests that only the linearizations f^j, $j \in J^k_s$, that have contributed to y^k should be retained for the next iteration. Moreover, many QP methods will automatically produce $|\hat{J}^k| \leq N$. Hence we may choose $J^{k+1} = J^k_s \cup \{k+1\}$ such that $|J^{k+1}| \leq N+1$. Storing the subgradients $g^j = g_f(x^j)$ for the representation $f^j = f^j(x^k) + \langle g^j, \cdot - x^k \rangle$, we do not need x^j to update $f^j(x^{k+1}) = f^j(x^k) + \langle g^j, x^{k+1} - x^k \rangle$ for $j \in J^k_s$. Thus the required storage is of order $(N+1)^2$ (plus the QP workspace).

Since subgradient selection may require excessive storage for large N, we now turn to *subgradient aggregation*, in which aggregate linearizations are produced recursively by taking convex combinations of the "ordinary" linearizations. Suppose $\phi^k = \max\{\hat{f}^k, \psi^{k-1}\}$ for some affine $\psi^{k-1} \in \text{co}\{f^j\}_{j=1}^{k-1}$ of the form $\psi^{k-1}(\cdot) = \psi^{k-1}(x^k) + \langle g^{k-1}_\psi, \cdot - x^k \rangle$ ($\psi^0 = f^1$). Let us add to (4.1) the constraint $\psi^{k-1}(x) \leq f^k_{\text{lev}}$ with Lagrange multiplier λ^k_ψ. Equivalently, in terms of $d^k = y^k - x^k$, $\alpha^k_j = f^k_{\text{lev}} - f^j(x^k)$, $j \in J^k$, and $\alpha^k_\psi = f^k_{\text{lev}} - \psi^{k-1}(x^k)$, we must find

$$d^k = \arg\min\{\, |d|^2/2 : \langle g^j, d \rangle \leq \alpha^k_j, j \in J^k, \langle g^{k-1}_\psi, d \rangle \leq \alpha^k_\psi \,\}. \tag{4.2}$$

Letting $\lambda^k_s = \sum_{j \in J^k} \lambda^k_j + \lambda^k_\psi$, we define "normalized" multipliers $\hat{\lambda}^k_j = \lambda^k_j / \lambda^k_s$, $j \in J^k$, $\hat{\lambda}^k_\psi = \lambda^k_\psi / \lambda^k_s$ that form a convex combination. Then, by the KKT conditions, $d^k = -\lambda^k_s g^k_\psi$, where $g^k_\psi = \sum_{j \in J^k} \hat{\lambda}^k_j g^j + \hat{\lambda}^k_\psi g^{k-1}_\psi \in \partial \phi^k(y^k)$. (Incidentally, $\lambda^k_s > 0$ because $y^k \neq x^k$ due to $f(x^k) > f^k_{\text{lev}}$.) Defining the next *aggregate linearization* $\psi^k(\cdot) = \phi^k(y^k) + \langle g^k_\psi, \cdot - y^k \rangle$, we observe that $\psi^k = \sum_{j \in J^k} \hat{\lambda}^k_j f^j + \hat{\lambda}^k_\psi \psi^{k-1} \in \text{co}\{f^j\}_{j=1}^k$ and $y^k = P_{\mathcal{L}(\psi^k, f^k_{\text{lev}})}(x^k)$. In effect, ψ^k embodies all the past subgradient information that determined y^k. (Equivalently, this amounts to replacing the constraints of (4.2) by their convex combination with normalized multipliers.) With such motivation, the next iteration may use $\phi^{k+1} = \max\{\hat{f}^{k+1}, \psi^k\}$ with J^{k+1} containing $k+1$ and, e.g., all but one of the elements of J^k to ensure bounded storage.

An alternative *selective aggregation* consists in aggregating just two linearizations. Specifically, if we pick $i, j \in J^k$ with $\lambda^k_i, \lambda^k_j > 0$, replace f^j with $(\lambda^k_i f^i + \lambda^k_j f^j)/(\lambda^k_i + \lambda^k_j)$, and drop i from J^k, then the solution of (4.1) is unchanged and the new $f^j \in \Phi$ ($f^j \leq \hat{f}^k$). In other words, we may replace f^j with the aggregate of f^i and f^j and destroy f^i to make room for the next f^{k+1}. (Here aggregation limits only the loss of information necessary to ensure bounded storage. In other bundle methods [Kiw85], it is crucial for convergence.)

Remark 4.1. The simplest case of aggregating just two linearizations, i.e., $J^k = \{k\}$ in (4.2), may be handled analytically. Suppose g^k and g^{k-1}_ψ are independent (the other case involves projecting on one halfspace only). Then one of the following three

cases may arise: $\lambda_k^k = -\alpha_k^k/|g^k|^2$ and $\lambda_\psi^k = 0$ (if $\alpha_k^k\langle g^k, g_\psi^{k-1}\rangle \le \alpha_\psi^k|g^k|^2$); $\lambda_k^k = 0$ and $\lambda_\psi^k = -\alpha_\psi^k/|g_\psi^{k-1}|^2$; or

$$\lambda_k^k = (\langle g^k, g_\psi^{k-1}\rangle\alpha_\psi^k - |g_\psi^{k-1}|^2\alpha_k^k)/(|g^k|^2|g_\psi^{k-1}|^2 - \langle g^k, g_\psi^{k-1}\rangle^2), \tag{4.3a}$$

$$\lambda_\psi^k = (\langle g^k, g_\psi^{k-1}\rangle\alpha_k^k - |g^k|^2\alpha_\psi^k)/(|g^k|^2|g_\psi^{k-1}|^2 - \langle g^k, g_\psi^{k-1}\rangle^2). \tag{4.3b}$$

In particular, if $\alpha_\psi^k = 0$, then either $d^k = -\alpha_k^k g^k/|g^k|^2$ if $\langle g^k, g_\psi^{k-1}\rangle \ge 0$ or

$$-d^k/\lambda_k^k = g^k - \langle g^k, g_\psi^{k-1}\rangle g_\psi^{k-1}/|g_\psi^{k-1}|^2 \quad \text{and} \quad \langle d^k, g_\psi^{k-1}\rangle = 0 \quad \text{if} \quad \langle g^k, g_\psi^{k-1}\rangle < 0, \tag{4.4}$$

where $g_\psi^{k-1} = -d^{k-1}/\lambda_s^{k-1}$ if $k > 1$, so that $-d^k/\lambda_k^k = g^k - \langle g^k, d^{k-1}\rangle d^{k-1}/|d^{k-1}|^2$ and $\langle d^k, d^{k-1}\rangle = 0$ if $\langle g^k, d^{k-1}\rangle > 0$. Hence subgradient aggregation is related to the CS techniques of [CFM75, ShU89]; see §6.

Let us now describe subgradient selection for the dual methods of [Kiw96, §9]. Let λ_j^k, $j \in J^k$, denote a solution to (2.4) using (2.5) for $\hat\phi^k = \hat f^k$. As in the primal case, if $\hat J^k \equiv \{j \in J^k : \lambda_j^k > 0\} \subset J_s^k \subset J^k$, then J_s^k may replace J^k in (2.5) without changing p^k, and we may select $J^{k+1} = J_s^k \cup \{k+1\}$. Again, many QP methods will ensure $|\hat J^k| \le N+1$, and the required storage is of order $(N+2)^2$.

Aggregation is natural in the dual methods, since they produce an aggregate linearization ϕ^k (from $\hat\phi^k$) that determines y^k. Specifically, employing $\hat\phi^k = \max\{\hat f^k, \phi^{k-1}\}$ in (2.4) to find ϕ^k, we may choose $\hat\phi^{k+1} = \max\{\hat f^{k+1}, \phi^k\}$ with J^{k+1} containing $k+1$ and all but one of the elements of J^k to ensure bounded storage.

The following (primal) *pairwise projections* strategy generalizes one in [KKA87]. Having several f^j, $j \in J^k$, let $\phi^k = \max\{f^k, f^{\hat\jmath}\}$ for $\hat\jmath \in J^k$ chosen to maximize the resulting $|y^k - x^k|$ when $\{k, \hat\jmath\}$ replaces J^k in (4.1). For example, use the formula (cf. (4.3))

$$|d^k|^2 = [(|g^k|\alpha_{\hat\jmath}^k)^2 - 2\langle g^k, g^{\hat\jmath}\rangle\alpha_{\hat\jmath}^k\alpha_k^k + (|g^{\hat\jmath}|\alpha_k^k)^2]/(|g^k|^2|g^{\hat\jmath}|^2 - \langle g^k, g^{\hat\jmath}\rangle^2) \quad \text{if} \quad \lambda_{\hat\jmath}^k, \lambda_k^k > 0.$$

Such $\hat\jmath$ may be included in J^{k+1}. Alternatively, if $\hat f^k(y^k) > f_{\text{lev}}^k$, we may replace f^k by the aggregate linearization of f^k and $f^{\hat\jmath}$, pick $\hat\jmath$ such that $f^{\hat\jmath}(y^k) > f_{\text{lev}}^k$, and recompute y^k. Of course, more than two constraints can be used at a time, and projections may continue until y^k becomes almost feasible in (4.1). Moreover, if $N \gg |J^k|$, then maintaining a matrix of inner products between g^j, $j \in J^k$, allows us to compute pairwise projections without additional expensive inner products; cf. (4.3). One may use Lemma 9.4 in [Kiw96] to show that pairwise projections are essentially equivalent to the surrogate method $S2$ of [Oko92] applied to the inequalities $f^j(x) \le f_{\text{lev}}^k$, $j \in J^k$, starting from x^k. (The remaining surrogate methods of [Oko92] are obtained by using triples of inequalities and successive aggregation.)

Remark 4.2. It is worth observing that step 4 may perform *several relaxations* using the accumulated linearizations. Specifically, at step 4(iii), instead of going to step 6, we may return to step 4(i) to choose *any* $\phi^k \in \Phi$ for the next relaxation with ρ_k replaced by $\rho_k + \rho_\phi^k + \rho_S^k$ and x^k by x^{k+1} (the replacement being justified by Remark 2.2); any number of such returns can occur, and all but the final one may skip the projection on S by setting $x^{k+1} = z^k$. For example, suppose J^k is so large that we do not want to solve (4.1). Then, until y^k becomes almost feasible in (4.1), each execution of step 4 may use $\phi^k = \max\{f^{\hat\jmath}, \phi^{k-1}\}$, where $\hat\jmath \in \operatorname{Arg\,max}_{j\in J^k} f^j(x^k)$ and ϕ^{k-1} is

the current aggregate linearization; i.e., it may solve (4.2) with J^k replaced by $\{\hat{\jmath}\}$. Alternatively, $\{\hat{\jmath}\}$ may be replaced by some larger set for which the solution of (4.2) is "cheap"; cf. §5. The dual methods can be used iteratively in the same way. In other words, we may attempt to *accelerate* our algorithm by performing *extra iterations on models* of f to exploit more fully the accumulated information about f and hence to reduce the number of f-evaluations at the cost of more work per iteration.

5. Relaxation with surrogate inequalities. This section introduces "cheap" QP-based implementations by extending the framework of deep surrogate cuts of relaxation methods for linear inequalities [BGT81, GoT82, Tod79].

We need additional notation. For any set $\mathcal{A} \subset \mathbb{R}^N$, $\operatorname{lin}\mathcal{A}$ denotes its linear span and $\operatorname{cone}\mathcal{A} = \{a : a = \sum_{i=1}^n \lambda_i a^i, a^i \in \mathcal{A}, \lambda_i \geq 0, n < \infty\}$ denotes its convex conical hull. We let $\mathcal{A}^- = \{x : \langle x, y\rangle \leq 0 \ \forall y \in \mathcal{A}\}$ and $\mathcal{A}^+ = -\mathcal{A}^-$ denote its negative and positive polar cones, respectively. For a matrix $A \in \mathbb{R}^{n\times n}$, a_{ij} and a^i denote its ijth element and ith column, respectively. Given a set $\mathcal{I} \subset \{1{:}\,n\}$, $A_{\mathcal{I}}$ denotes the matrix with columns a^i, $i \in \mathcal{I}$. For a given $b \in \mathbb{R}^n$, $b_{\mathcal{I}}$ denotes the vector with elements b_i, $i \in \mathcal{I}$. Matrix inequalities hold componentwise. A is called a *Stieltjes* matrix if $a_{ij} = a_{ji} \leq 0 \ \forall i \neq j$, $i, j = 1{:}\,n$, and $A^{-1} \geq 0$.

Given $A \in \mathbb{R}^{N\times m}$ and $b \in \mathbb{R}^m$, consider the system of linear inequalities $\langle a^i, x\rangle \leq b_i$, $i = 1{:}\,m$, having a (possibly empty) solution set $\mathcal{P} = \{x : A^T x \leq b\}$. Suppose $a^i \neq 0$ for $i = 1{:}\,m$. Then each inequality defines a closed halfspace $H_i = \{x : \langle a^i, x\rangle \leq b_i\}$, and $\mathcal{P} = \bigcap_{i=1}^m H_i$ is a convex polyhedron.

Remark 5.1. We are mainly interested in the case where $\mathcal{P} = \mathcal{L}(\hat{f}^k, f^k_{\text{lev}})$, but to compare the convergence results of [Kiw96] with those for relaxation methods [Gof81, Tel82] one may observe the following. If $\mathcal{P} \neq \emptyset$, then $\mathcal{P} = \operatorname{Arg\,min} f$, where $f = \max_{i=1:m}(\langle a^i, \cdot\rangle - b_i)_+$ has a subgradient $g_f(x) = a^i$ if $\langle a^i, x\rangle - b_i = f(x) > 0$, $g_f(x) = 0$ if $f(x) = 0$, satisfying $|g_f(x)| \leq L_f := \max_{i=1:m} |a^i|$. In this case we may let $f^k_{\text{lev}} \equiv f^* = 0$ in Algorithm 2.1 and proceed as if S were $\mathbb{R}^N$, replacing $\operatorname{diam}(S)$ in [Kiw96, Eq. (1.4)] by $|x^* - x^1|$ for any $x^* \in \mathcal{P}$; cf. [Kiw96, §6]. Then the SPA of (1.2) describes the *maximal residual* version of the relaxation method; the *maximal distance* version corresponds to dividing each a^i and b_i by $|a^i|$ initially.

In classical versions of relaxation and ellipsoid methods for finding a point in $\mathcal{P}$, given a current point $\tilde{x} \notin \mathcal{P}$, one finds the next point $\bar{x}$ by projecting $\tilde{x}$ on the halfspace H_i that is furthest from $\tilde{x}$, since for faster convergence one wishes to maximize $|\bar{x} - \tilde{x}|$. By combining inequalities one can sometimes obtain halfspaces that are further from $\tilde{x}$.

If $\lambda \in \mathbb{R}^m_+$, $a^\lambda = A\lambda$, and $b_\lambda = b^T\lambda$, then the *surrogate inequality* $\langle a^\lambda, x\rangle \leq b_\lambda$ is valid ($A^T x \leq b \Rightarrow \lambda^T A^T x \leq \lambda^T b$). The *deepest* surrogate inequality that maximizes the distance $(\langle a^\lambda, \tilde{x}\rangle - b_\lambda)_+/|a^\lambda|$ from $\tilde{x}$ to $H_\lambda = \{x : \langle a^\lambda, x\rangle \leq b_\lambda\}$ corresponds to

$$\tilde{\lambda} \in \operatorname{Arg\,max}\{\, \tilde{s}^T\lambda/|A\lambda| : \lambda \geq 0\,\}, \tag{5.1}$$

where $\tilde{s} := A^T\tilde{x} - b \not\leq 0$ ($\tilde{x} \notin \mathcal{P}$). Clearly, if $\mathcal{P} \neq \emptyset$, then $H_{\tilde{\lambda}}$ is the unique halfspace containing $\mathcal{P}$ that is furthest from $\tilde{x}$, and $H_{\tilde{\lambda}} = \{x : \langle \tilde{d}, x - \tilde{x}\rangle \geq |\tilde{d}|^2\}$, where $\tilde{d} = P_{\mathcal{P}}(\tilde{x}) - \tilde{x}$ (since for any halfspace $H \ni P_{\mathcal{P}}(\tilde{x})$, $d_H(\tilde{x}) < d_{\mathcal{P}}(\tilde{x})$ unless $P_H(\tilde{x}) = P_{\mathcal{P}}(\tilde{x})$). Of course, $\tilde{d}$ solves the QP problem

$$\tilde{d} = \arg\min\{\, |d|^2/2 : A^T d \leq -\tilde{s}\,\}. \tag{5.2}$$

By duality, we may equivalently find its (possibly nonunique) Lagrange multiplier

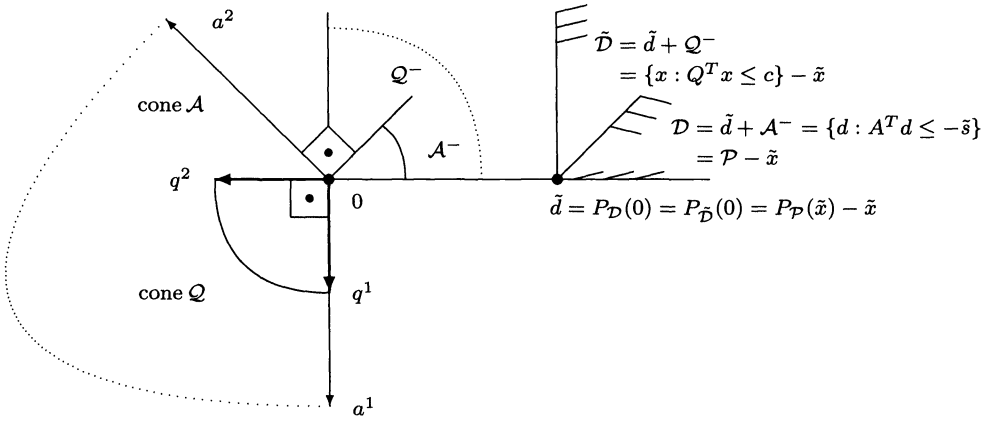

FIG. 5.1. *Illustration of orthogonal surrogates.*

vector

$$\tilde{\lambda} \in \operatorname{Arg\,min}\{\, |A\lambda|^2/2 - \tilde{s}^T\lambda : \lambda \ge 0 \,\}. \tag{5.3}$$

Indeed, by the KKT conditions, $\tilde{d}$ and $\tilde{\lambda}$ satisfy (5.2)–(5.3) iff $\tilde{d} = -A\tilde{\lambda}$, $A^T\tilde{d} \le -\tilde{s}$, $\tilde{\lambda} \ge 0$, and $\tilde{\lambda}^T(A^T\tilde{d} + \tilde{s}) = 0$. Hence $\tilde{s}^T\tilde{\lambda} = |\tilde{d}|^2$ and $\langle a^{\tilde{\lambda}}, \tilde{x}\rangle - |\tilde{d}|^2 = \tilde{\lambda}^T A^T\tilde{x} - \tilde{x}^T A\tilde{\lambda} + b^T\tilde{\lambda} = b_{\tilde{\lambda}}$, so $\langle a^{\tilde{\lambda}}, x\rangle \le b_{\tilde{\lambda}}$ iff $\langle \tilde{d}, x - \tilde{x}\rangle \ge |\tilde{d}|^2$, and $P_{H_{\tilde{\lambda}}}(\tilde{x}) = P_{\mathcal{P}}(\tilde{x})$. (We may add that the optimal values in (5.1) and (5.3) are infinite iff $\mathcal{P} = \emptyset$. Since the objective of (5.1) is positively homogeneous, the deepest cut can also be found by solving $\min\{|A\lambda| : \tilde{s}^T\lambda = 1, \lambda \ge 0\}$, $\max\{\tilde{s}^T\lambda : |A\lambda| = 1, \lambda \ge 0\}$ or $\min\{|A\lambda|/\tilde{s}^T\lambda : \sum_i \lambda_i = 1, \lambda \ge 0\}$. We note that (5.1) is a special case of [Kiw96, Eq. (9.7)], whereas the restricted variant (2.4) does not seem to have been considered explicitly in the context of linear inequalities.)

Of course, finding the deepest surrogate inequality via (5.1)–(5.3) may be too expensive, *except when A is orthonormal and $\tilde{s} \ge 0$*, in which case $\tilde{d} = -A\tilde{\lambda}$ and $\tilde{\lambda} = \tilde{s}$ by (5.3). In the general case, we may project on a surrogate $\tilde{\mathcal{P}} = \{x : Q^T x \le c\}$ of $\mathcal{P}$, where $Q^T x \le c$ is a surrogate of $A^T x \le b$ (so that $\mathcal{P} \subset \tilde{\mathcal{P}}$) and Q is orthonormal. As in [BGT81, GoT82, Tod79], it is convenient to work with a subset of inequalities, indexed by $\mathcal{I} \subset \{1{:}m\}$, say, that satisfy the *obtuse angles condition* $\langle a^i, a^j\rangle \le 0$ $\forall i \ne j$, $i, j \in \mathcal{I}$. Taking $\mathcal{I} = \{1{:}m\}$ first for simplicity, we now show how to construct suitable surrogates via orthogonalization (see Figure 5.1).

LEMMA 5.2. *Let $\mathcal{A} = \{a^i\}_{i=1}^m$, $C = \operatorname{cone}\mathcal{A}$, $\hat{m} = \operatorname{rank} A$, and $\mathcal{G} = A^T A$. If $\langle a^i, a^j\rangle \le 0$ $\forall i \ne j$, $i, j = 1{:}m$, then*

(i) *C contains an orthonormal system $\mathcal{Q} = \{q^i\}_{i=1}^{\hat{m}}$ such that $\operatorname{lin} C = \operatorname{lin}\mathcal{Q}$ and $A = QR$, where $Q \in \mathbb{R}^{N\times\hat{m}}$ is orthonormal and $R \in \mathbb{R}^{\hat{m}\times m}$ is upper triangular, with $r_{ii} \ge 0$ and $r_{ij} \le 0$ for $i = 1{:}\hat{m}$, $j = i+1{:}m$. Q and R can be found via the Gram–Schmidt orthogonalization: set $m_1 = 0$, and for $j = 1{:}m$ set $\tilde{q}^j = a^j - \sum_{i=1}^{m_j}\langle a^j, q^i\rangle q^i$, $r_{jj} = |\tilde{q}^j|$, $r_{ij} = \langle a^j, q^i\rangle$ for $i = 1{:}m_j$, $r_{ij} = 0$ for $i > m_j$, $i \ne j$, $q^j = \tilde{q}^j/|\tilde{q}^j|$ and $m_{j+1} = m_j + 1$ if $\tilde{q}^j \ne 0$, $m_{j+1} = m_j$ otherwise. (The final $m_{m+1} = \hat{m}$.)*

(ii) *$C^+ \cap \operatorname{lin} C \subset \mathcal{Q}^+ \cap \operatorname{lin}\mathcal{Q} = \mathcal{Q}^+ \cap \operatorname{cone}\mathcal{Q} \subset C$.*

(iii) *If $\operatorname{rank} A = m$, then $R^{-1} \ge 0$ and $\mathcal{G}^{-1} \ge 0$; i.e., $\mathcal{G}$ is a Stjelties matrix.*

(iv) *If $\operatorname{rank} A = m$, then R is the unique Cholesky factor of $\mathcal{G}$ having a positive diagonal, $Q = AR^{-1}$ and $\mathcal{P} \subset \{x : Q^T x \le c\}$, where $c = R^{-T}b$. In particular,*

each inequality $\langle q^j, x\rangle \le c_j$ *is a surrogate of the system* $\langle q^i, x\rangle \le c_i$, $i = 1{:}\, j-1$, $\langle a^j, x\rangle \le b_j$, *and hence a surrogate of the (possibly stronger) system* $\langle a^i, x\rangle \le b_i$, $i = 1{:}\, j$.

Proof. (i) If $\mathcal{Q}_j = \{q^i\}_{i=1}^{m_j} \subset C_j = \operatorname{cone}\{a^i\}_{i=1}^{j-1}$, then $a^j \in C_j^-$ yields $\langle a^j, q^i\rangle \le 0$ for $i = 1{:}\, m_j$, so $\tilde{q}^j \in \operatorname{cone}(\{a^j\} \cup \mathcal{Q}_j) \subset C_{j+1}$ and $\mathcal{Q}_{j+1} \subset C_{j+1}$. The rest follows by induction.

(ii) $a \in \mathcal{Q}^+ \cap \operatorname{lin}\mathcal{Q} \iff a = \sum_{i=1}^{\hat{m}} \langle a, q^i\rangle q^i$ with $\langle a, q^i\rangle \ge 0$ for $i = 1{:}\, \hat{m} \iff a \in \operatorname{cone}\mathcal{Q}$, since $a = \sum_{i=1}^{\hat{m}} \lambda_i q^i$ iff $\lambda_i = \langle a, q^i\rangle$ for $i = 1{:}\, \hat{m}$. Clearly, $\mathcal{Q} \subset \operatorname{cone}\mathcal{Q} \subset C$ and $C^+ \subset \mathcal{Q}^+$.

(iii) If $\hat{m} = m$, then $r_{ii} > 0$ for $i = 1{:}\, m$, so R and $\mathcal{G} = R^T R$ are nonsingular. Since $r_{ij} \le 0$ for $i < j$, if $Ru = v \ge 0$, then $u \ge 0$ from $u_i = (v_i - \sum_{j=i+1}^{m} r_{ij}u_j)/r_{ii}$, $i = m, \ldots, 1$. Hence $R^{-1} \ge 0$ and $\mathcal{G}^{-1} = R^{-1}R^{-T} \ge 0$.

(iv) The uniqueness of R is well known. Use $(Q^T, c) = R^{-T}(A^T, b)$ and $(q^j, c_j) = [(a^j, b_j) - \sum_{i=1}^{j-1} r_{ij}(q^i, c_i)]/r_{jj}$, $j = 1, \ldots, m$, with $R^{-T} \ge 0$ and $r_{ij} \le 0$ by (i) and (iii), to get the desired conclusion, noting that $A^T x \le b \Rightarrow R^{-T}A^T x = Q^T x \le R^{-T} b = c$. □

The next result helps in selecting subsets of inequalities for which the projections are "easy." For any $\mathcal{I} \subset \{1{:}\, m\}$, let $\mathcal{A}_\mathcal{I} = \{a^i\}_{i\in\mathcal{I}}$, $\mathcal{P}_\mathcal{I} = \{x : A_\mathcal{I}^T x \le b_\mathcal{I}\}$, $\mathcal{D}_\mathcal{I} = \{d : A_\mathcal{I}^T d \le -\tilde{s}_\mathcal{I}\}$, and $\mathcal{G}_{\mathcal{I}\mathcal{I}} = A_\mathcal{I}^T A_\mathcal{I}$. If $\mathcal{P}_\mathcal{I} \ne \emptyset$, let $\tilde{d}_{(\mathcal{I})} = P_{\mathcal{D}_\mathcal{I}}(0)$, so that $\tilde{d}_{(\mathcal{I})} = P_{\mathcal{P}_\mathcal{I}}(\tilde{x}) - \tilde{x}$ from $\tilde{s}_\mathcal{I} = A_\mathcal{I}^T \tilde{x} - b_\mathcal{I}$.

LEMMA 5.3. *Suppose* $\mathcal{I} \subset \{1{:}\, m\}$, $\langle a^i, a^j\rangle \le 0$ $\forall i \ne j$, $i, j \in \mathcal{I}$, *and* $\tilde{s}_\mathcal{I} \ge 0$. *Then*

(i) *If* $\operatorname{rank} A_\mathcal{I} = |\mathcal{I}|$, *then* $\tilde{d}_{(\mathcal{I})} = -A_\mathcal{I}\tilde{\lambda}_\mathcal{I}$, *where* $\tilde{\lambda}_\mathcal{I} = \mathcal{G}_{\mathcal{I}\mathcal{I}}^{-1}\tilde{s}_\mathcal{I} \ge 0$, *and*

$$\tilde{d}_{(\mathcal{I})} = \arg\min\{\, |d|^2/2 : A_\mathcal{I}^T d = -\tilde{s}_\mathcal{I}\,\}. \tag{5.4}$$

Moreover, for $\hat{\mathcal{I}} = \{i : \tilde{\lambda}_i > 0\}$ *and each* $j \in \mathcal{I}$, $\tilde{\lambda}_j > 0$ *if* $\tilde{s}_j > 0$; *if* $\tilde{s}_j = \tilde{\lambda}_j = 0$, *then* $a^j \perp \mathcal{A}_{\hat{\mathcal{I}}}$; *and* $\tilde{\lambda}_j = 0$ *if* $\tilde{s}_j = 0$ *and* $a^j \perp \mathcal{A}_{\mathcal{I}\setminus\{j\}}$.

(ii) *If* $\operatorname{rank} A_\mathcal{I} = |\mathcal{I}|$, $j \in \{1{:}\, m\} \setminus \mathcal{I}$, $A_\mathcal{I}^T a^j \le 0$, $\mathcal{J} = \mathcal{I} \cup \{j\}$, *and either* $\tilde{s}_j > 0$ *or* $\tilde{s}_j = 0$ *and* $\tilde{s}_\mathcal{I} > 0$, *then* $\operatorname{rank} A_\mathcal{J} = |\mathcal{J}| \iff \mathcal{D}_\mathcal{J} \ne \emptyset \iff \mathcal{P}_\mathcal{J} \ne \emptyset$.

(iii) $\operatorname{rank} A_\mathcal{I} = |\mathcal{I}| \iff A_\mathcal{I}^T \check{d} < 0$ *for some* $\check{d}$.

(iv) *If* $\tilde{s}_\mathcal{I} > 0$ *and* $\mathcal{P}_\mathcal{I} \ne \emptyset$, *then* $\operatorname{rank} A_\mathcal{I} = |\mathcal{I}|$ *and* $\tilde{\lambda}_\mathcal{I} = \mathcal{G}_{\mathcal{I}\mathcal{I}}^{-1}\tilde{s}_\mathcal{I} > 0$.

(v) *If* $\mathcal{G}_{\mathcal{I}\mathcal{I}} = R^T R$ *is nonsingular, where* $R \in \mathbb{R}^{|\mathcal{I}|\times|\mathcal{I}|}$ *is upper triangular,* $Q = A_\mathcal{I} R^{-1}$, *and* $\sigma = R^{-T}\tilde{s}_\mathcal{I}$, *then* $\tilde{d}_{(\mathcal{I})} = -Q\sigma$ *and* $\tilde{\lambda}_\mathcal{I} = R^{-1}\sigma$ *in* (i). *Moreover, if* $r_{ii} > 0$ *for* $i = 1{:}\, |\mathcal{I}|$ *and* $\tilde{\mathcal{D}} = \{d : Q^T d \le -\sigma\}$, *then* $\tilde{\mathcal{D}} \supset \mathcal{D}_\mathcal{I}$, $\tilde{d}_{(\mathcal{I})} = P_{\tilde{\mathcal{D}}}(0)$ *and* $Q^T \tilde{d}_{(\mathcal{I})} = -\sigma$.

Proof. (i) Replace $\{1{:}\, m\}$ with $\mathcal{I}$ in Lemma 5.2 to get $\mathcal{G}_{\mathcal{I}\mathcal{I}}^{-1} \ge 0$. Hence $\tilde{\lambda}_\mathcal{I} = \mathcal{G}_{\mathcal{I}\mathcal{I}}^{-1}\tilde{s}_\mathcal{I} \ge 0$, and letting $\bar{d} = -A_\mathcal{I}\tilde{\lambda}_\mathcal{I}$ we have $A_\mathcal{I}^T \bar{d} = -\tilde{s}_\mathcal{I}$, so (5.4) holds with $\bar{d} = \tilde{d}_{(\mathcal{I})}$ by the KKT conditions. Since $\mathcal{G}_{\mathcal{I}\mathcal{I}}^{-1} \ge 0$ is positive definite, it has a positive diagonal, so $\tilde{\lambda}_j > 0$ if $\tilde{s}_j > 0$. Next, suppose $\tilde{s}_j = 0$ and let $\mathcal{J} = \mathcal{I} \setminus \{j\}$. If $\tilde{\lambda}_j = 0$, then $0 = -\tilde{s}_j = \langle a^j, \bar{d}\rangle = -\sum_{i\in\hat{\mathcal{I}}} \tilde{\lambda}_i \langle a^j, a^i\rangle$ with $\tilde{\lambda}_i > 0$ and $\langle a^j, a^i\rangle \le 0$ imply $a^j \perp \mathcal{A}_{\hat{\mathcal{I}}}$. Conversely, if $a^j \perp \mathcal{A}_\mathcal{J}$, then after symmetric permutations we have

$$\mathcal{G}_{\mathcal{I}\mathcal{I}} = \begin{bmatrix} \mathcal{G}_{\mathcal{J}\mathcal{J}} & 0 \\ 0 & |a^j|^2 \end{bmatrix} \text{ and } \mathcal{G}_{\mathcal{I}\mathcal{I}}^{-1} = \begin{bmatrix} \mathcal{G}_{\mathcal{J}\mathcal{J}}^{-1} & 0 \\ 0 & |a^j|^{-2} \end{bmatrix},$$

so $\tilde{\lambda}_j = \tilde{s}_j/|a^j|^2 = 0$.

(ii) If $\operatorname{rank} A_\mathcal{J} = |\mathcal{J}|$, then $-A_\mathcal{J}\mathcal{G}_{\mathcal{J}\mathcal{J}}^{-1}\tilde{s}_\mathcal{J} \in \mathcal{D}_\mathcal{J}$. If $\operatorname{rank} A_\mathcal{J} = |\mathcal{I}|$, then $a^j \in \operatorname{lin}\mathcal{A}_\mathcal{I}$. Since $a^j \in (\operatorname{cone}\mathcal{A}_\mathcal{I})^-$, Lemma 5.2(ii) applied to $\mathcal{A}_\mathcal{I}$ yields $-a^j \in \operatorname{cone}\mathcal{A}_\mathcal{I}$; i.e.,

there exists $\lambda_{\mathcal{I}} \geq 0$ such that $-a^j = A_{\mathcal{I}}\lambda_{\mathcal{I}}$. Thus if $A_{\mathcal{I}}^T d \leq -\tilde{s}_{\mathcal{I}}$ for some d, then $\langle a^j, d\rangle = -\lambda_{\mathcal{I}}^T A_{\mathcal{I}}^T d \geq \lambda_{\mathcal{I}}^T \tilde{s}_{\mathcal{I}} \geq 0$ from $\tilde{s} \geq 0$, so $D_{\mathcal{J}} = \emptyset$ because $\lambda_{\mathcal{I}}^T \tilde{s}_{\mathcal{I}} \geq 0 > -\tilde{s}_j$ if $\tilde{s}_j > 0$, whereas $\lambda_{\mathcal{I}}^T \tilde{s}_{\mathcal{I}} > 0 = -\tilde{s}_j$ if $\tilde{s}_j = 0$ and $\tilde{s}_{\mathcal{I}} > 0$, with $\lambda_{\mathcal{I}} \neq 0$ due to $a^j \neq 0$.

(iii) For "$\Rightarrow$," choose $s_{\mathcal{I}} > 0$ and $\check{d} = -A_{\mathcal{I}}\mathcal{G}_{\mathcal{I}\mathcal{I}}^{-1} s_{\mathcal{I}}$ to get $A_{\mathcal{I}}^T \check{d} = -s_{\mathcal{I}} < 0$. For "$\Leftarrow$," suppose $A_{\mathcal{I}}^T \check{d} < 0$. Replacing $\tilde{x}$ by $\tilde{x} - \check{d}$ if necessary, we may assume $\tilde{s}_{\mathcal{I}} > 0$. Since $t\check{d} \in \mathcal{D}_{\mathcal{I}}$ for large $t > 0$, $\mathcal{D}_{\mathcal{I}} \neq \emptyset$. For any $i \in \mathcal{I}$, $\operatorname{rank} A_{\{i\}} = 1$, since $a^i \neq 0$. If $\tilde{\mathcal{I}} \subset \mathcal{I}$, $\operatorname{rank} A_{\tilde{\mathcal{I}}} = |\tilde{\mathcal{I}}|$, $j \in \mathcal{I} \setminus \tilde{\mathcal{I}}$, and $\tilde{\mathcal{J}} = \tilde{\mathcal{I}} \cup \{j\}$, then $\operatorname{rank} A_{\tilde{\mathcal{J}}} = |\tilde{\mathcal{J}}|$ by (ii) with $\mathcal{I}$ replaced by $\tilde{\mathcal{I}}$, since $\tilde{s}_j > 0$ and $\mathcal{D}_{\tilde{\mathcal{J}}} \supset \mathcal{D}_{\tilde{\mathcal{I}}} \neq \emptyset$. Hence, by induction, $\operatorname{rank} A_{\mathcal{I}} = |\mathcal{I}|$.

(iv) Combine (iii) and (i), noting that $\tilde{\lambda}_{\mathcal{I}} > 0$ if $\tilde{s}_{\mathcal{I}} > 0$.

(v) Clearly, $\tilde{d}_{(\mathcal{I})} = -A_{\mathcal{I}}\tilde{\lambda}_{\mathcal{I}} = -QR(R^TR)^{-1}\tilde{s}_{\mathcal{I}} = -Q\sigma$. Suppose $r_{ii} > 0$ for $i = 1{:}|\mathcal{I}|$. Apply Lemma 5.2(iii,iv) to $A_{\mathcal{I}}$ and $c = R^{-T}b_{\mathcal{I}}$ to get $\mathcal{D}_{\mathcal{I}} \subset \tilde{\mathcal{D}}$ from $\sigma = R^{-T}(A_{\mathcal{I}}^T\tilde{x} - b_{\mathcal{I}}) = Q^T\tilde{x} - c$, with $\sigma = R^{-T}\tilde{s}_{\mathcal{I}} \geq 0$ since $R^{-1} \geq 0$ and $\tilde{s}_{\mathcal{I}} \geq 0$. Hence, replacing $(A_{\mathcal{I}}, \tilde{s}_{\mathcal{I}})$ by (Q, σ) in (i), we have $P_{\tilde{\mathcal{D}}}(0) = -Q(Q^TQ)^{-1}\sigma = -Q\sigma = \tilde{d}_{(\mathcal{I})}$ and $Q^T\tilde{d}_{(\mathcal{I})} = -\sigma$. □

Lemmas 5.2–5.3 extend some results of [Tod79] in a way that is useful for algorithmic developments. For example, consider the following extension of the simultaneous projections method of [Tod79] for solving a possibly inconsistent system $A^Tx \leq b$.

PROCEDURE 5.4 (for finding a point in $\mathcal{P} = \{x : A^Tx \leq b\}$).

Step 0 (*Initialization*). Select $\tilde{x}^1 \in \mathbb{R}^N$, a feasibility tolerance $\epsilon_{\text{tol}} \geq 0$ and $\tilde{D} < \infty$ such that $d_{\mathcal{P}}(\tilde{x}^1) \leq \tilde{D}$ if $\mathcal{P} \neq \emptyset$. Choose $I^0 \subset \{1{:}m\}$ such that $\operatorname{rank} A_{I^0} = |I^0|$ and $\langle a^i, a^j\rangle \leq 0\ \forall i \neq j$, $i, j \in I^0$, e.g., $I^0 = \emptyset$. Set $\tilde{\rho}_1 = 0$ and $n = 1$.

Step 1 (*Constraint evaluation*). Calculate $s^n = A^T\tilde{x}^n - b$ and i_n such that $s_{i_n}^n = \max_i s_i^n$.

Step 2 (*Stopping criterion*). If $s_{i_n}^n \leq \epsilon_{\text{tol}}$, terminate.

Step 3 (*Selection*). Set $\tilde{I}^{n-1} = \{i \in I^{n-1} : \langle a^{i_n}, a^i\rangle \leq 0, s_i^n \geq 0\}$ and $I^n = \tilde{I}^{n-1} \cup \{i_n\}$. If desired, repeat the following for some $i \in \{1{:}m\} \setminus I^n$: if $A_{I^n}^T a^i \leq 0$ and either $s_i^n > 0$ or $s_i^n = 0$, and $A_{I^n}^T a^i \neq 0$ and either $s_{I^n}^n > 0$ or $\operatorname{rank} A_{I^n \cup \{i\}} = |I^n| + 1$, then augment I^n with i.

Step 4 (*Relaxation*). Print "$\mathcal{P} = \emptyset$" and terminate if $\operatorname{rank} A_{I^n} < |I^n|$. Otherwise set $\tilde{y}^n = P_{\mathcal{P}_{I^n}}(\tilde{x}^n) = \tilde{x}^n - A_{I^n}\lambda_{I^n}^n$ with $\lambda_{I^n}^n = \mathcal{G}_{I^nI^n}^{-1} s_{I^n}^n$. Choose a stepsize $\tilde{t}_n \in T$ and set $\tilde{x}^{n+1} = \tilde{x}^n + \tilde{t}_n(\tilde{y}^n - \tilde{x}^n)$ and $\tilde{\rho}_{n+1} = \tilde{\rho}_n + \tilde{t}_n(2 - \tilde{t}_n)|\tilde{y}^n - \tilde{x}^n|^2$.

Step 5 (*Infeasibility detection*). If $\tilde{\rho}_{n+1} > \tilde{D}^2$ or $(\tilde{D} - |\tilde{x}^{n+1} - \tilde{x}^1|)^2 > \tilde{D}^2 - \tilde{\rho}_{n+1}$, print "$\mathcal{P} = \emptyset$" and terminate.

Step 6. Increase n by 1 and go to step 1.

If $\mathcal{P} \neq \emptyset$, we may identify Procedure 5.4 with a version of Algorithm 2.1 that minimizes $f = \max_{i=1:m}(\langle a^i, \cdot\rangle - b_i)_+$ using $f_{\text{lev}}^k \equiv f^* = 0$; cf. [Kiw96, §6] and Remark 5.1. In particular $\mathcal{P} \subset \mathcal{P}_{I^n} \subset \{x : \langle a^{i_n}, x\rangle \leq b_{i_n}\}$ corresponds to $\phi^k \in \Phi_1^k$, and step 4 may be validated by applying Lemma 5.3 inductively at step 3 to get $\operatorname{rank} A_{I^n} = |I^n|$ if $\mathcal{P} \neq \emptyset$. Hence if $\mathcal{P} \neq \emptyset$, then Procedure 5.4 shares the convergence properties of Algorithm 2.1 from [Kiw96, §6], as well as those of classical relaxation methods [Agm54, Gof81, MoS54, Tel82, Tod79], such as linear rate of convergence and possible finite termination. The infeasibility test of step 5 is justified similarly as for Algorithm 2.1; cf. [Kiw96, §4]. Note that step 3 may include in I^n several i with $s_i^n = 0$; e.g., $i \in I^{n-1}$ if $\tilde{t}_{n-1} = 1$ and $s_{I^{n-1}}^n = 0$ from $\tilde{x}^n = \tilde{y}^{n-1}$. It is natural to choose I^n as large as possible, although one need not insist on maximality. Of course, in practice detecting $\operatorname{rank} A_{I^n} < |I^n|$ will require tolerances tuned to the factorization of A_{I^n}.

Remark 5.5. By using the Gram matrix $\mathcal{G} = A^TA$ one may avoid expensive

scalar products in updating s^n without forming $\tilde{x}^n$; cf. [Tod79]. Specifically, let $s^1 = A^T\tilde{x}^1 - b$, $\nu^1 = 0 \in \mathbb{R}^m$, $s^{n+1}_{I^n} = (1-\tilde{t}_n)s^n_{I^n}$, $s^{n+1}_{I^n_c} = s^n_{I^n_c} - \tilde{t}_n \mathcal{G}_{I^n_c I^n}\lambda^n_{I^n}$, and $\nu^{n+1} = \nu^n + \tilde{t}_n\lambda^n$ with $\lambda^n_{I^n_c} = 0$ and $I^n_c = \{1{:}\,m\} \setminus I^n$ for all n, so that $\tilde{x}^n = \tilde{x}^1 - A\nu^n$ and $\nu^n = \sum_{j=1}^n \tilde{t}_j\lambda^j$ for all n.

Remark 5.6. If we compute the Cholesky factorization $A^T_{I^n}A_{I^n} = R^TR$, then λ^n can be found by solving the two systems $R^T\sigma = s^n_{I^n}$ and $R\lambda^n_{I^n} = \sigma$; cf. Lemma 5.3(v). To save work, R and σ may be updated when I^n changes. However, as with normal equations for least-squares problems, one may need to employ iterative refinement to improve accuracy in the presence of rounding errors. Alternatively, one may use any stable method for computing the "skinny" QR-factorization $A_{I^n} = QR$, where Q is orthonormal, so that $A^T_{I^n}A_{I^n} = R^TR$. The classical Gram–Schmidt process may fail due to rounding errors, but reorthogonalization can ensure higher accuracy. Moreover, by Lemma 5.3, $\tilde{d}^n = \tilde{y}^n - \tilde{x}^n$ satisfies

$$\tilde{d}^n = \arg\min\{\, |d|^2/2 : A^T_{I^n}d = -s^n_{I^n}\,\}, \tag{5.5}$$

and this equality QP problem can be solved via many well-known methods. All these aspects are treated in depth in, e.g., [Bjö90, Fle87, GMW91, GVL89].

Remark 5.7. Suppose step 3 of Procedure 5.4 chooses $I^n = \tilde{I}^{n-1} \cup \{i_n\}$ with $s^n_{\tilde{I}^{n-1}} = 0$. (Recall that $s^n_{I^{n-1}} = 0$ if $\tilde{t}_{n-1} = 1$ and $\tilde{x}^n = \tilde{y}^{n-1}$.) Let $\hat{m} = |I^n|$ and let $e^{\hat{m}}$ denote column $\hat{m}$ of the $\hat{m} \times \hat{m}$ identity matrix, so that $s^n_{I^n} = s^n_{i_n}e^{\hat{m}}$. Then, using $R^T\sigma = s^n_{I^n}$ and $R\lambda^n_{I^n} = \sigma$ as in Remark 5.6, we have $\sigma = s^n_{i_n}e^{\hat{m}}/r_{\hat{m}\hat{m}}$ and only the system $R\lambda^n_{I^n} = s^n_{i_n}e^{\hat{m}}/r_{\hat{m}\hat{m}}$ must be solved. This system may be used even if $s^n_{\tilde{I}^{n-1}} \neq 0$. Specifically, decreasing $s^n_{I^n}$ to $\tilde{s}^n_{I^n}$ with $\tilde{s}^n_{\tilde{I}^{n-1}} = 0$ and $\tilde{s}^n_{i_n} = s^n_{i_n}$ corresponds to setting $\tilde{y}^n = P_{\mathcal{P}^n}(\tilde{x}^n)$, where $\mathcal{P}^n = \{x : A^T_{I^n}x \le b_{I^n} + s^n_{I^n} - \tilde{s}^n_{I^n}\}$ satisfies $\mathcal{P}_{I^n} \subset \mathcal{P}^n \subset \{x : \langle a^{i_n}, x\rangle \le b_{i_n}\}$, so the efficiency results remain true. This simplification is used in [Ceg92] when $\tilde{t}^{n-1} < 1$. It may, however, result in slower convergence, since $\mathcal{P}^n$ can be much bigger than $\mathcal{P}_{I^n}$. (The method of [Ceg92] scales the constraints of (5.5) before computing R, but $\tilde{d}^n$ is not affected.)

Remark 5.8. Using $\tilde{d}^n = -A_{I^n}\lambda^n_{I^n}$ and $R\lambda^n_{I^n} = s^n_{i_n}e^{\hat{m}}/r_{\hat{m}\hat{m}}$ as above, for the QR-factorization $A_{I^n} = QR$ we have $\tilde{d}^n = -s^n_{i_n}q^{\hat{m}}/r_{\hat{m}\hat{m}}$, where we may take $r_{\hat{m}\hat{m}} = |q|$ and $q^{\hat{m}} = q/|q|$ for $q = a^{i_n} - \sum_{i=1}^{\hat{m}-1}\langle a^{i_n}, q^i\rangle q^i$ as in Lemma 5.2. Thus only Q could be updated by computing some elements of $R = Q^TA_{I^n}$. However, using Q instead of R would require more storage and work if $\hat{m} \le N$, and could be less accurate without reorthogonalization.

We may add that the idea of using the obtuse angle property to identify cheap projections has wider implications. (A *cheap* projection requires only the solution of one or two linear systems in contrast to combinatorial QP.) For instance, it may be employed to accelerate general projection methods for convex feasibility problems; see [Kiw95].

Let us now show how to employ Procedure 5.4 as a subroutine for implementing step 4 of Algorithm 2.1; cf. §§2 and 3. Suppose Procedure 5.4 is called to find a point in $\mathcal{P} = \mathcal{L}(\hat{f}^k, f^k_{\text{lev}})$, starting from $\tilde{x}^1 = x^k$ (with $\epsilon_{\text{tol}} = 0$). Then it may be exited at any iteration $\bar{n} \ge 1$ also at step 6. Specifically, in view of [Kiw96, §4], we may take $\tilde{D} = r_k = (\bar{D}^2 - \rho_k)^{1/2}$, and step 5 may use the additional test $(\bar{D} - |\tilde{x}^{n+1} - x^{k(l)+1}|)^2 > r_k^2 - \tilde{\rho}_{n+1}$. Upon termination at step j, say, set $z^k = \tilde{x}^{\bar{n}}$, $\rho^k_\phi = \tilde{\rho}_{\bar{n}}$ if $j = 2$, $\rho^k_\phi = \infty$ if $j = 4$ or 5, and $z^k = \tilde{x}^{\bar{n}+1}$ and $\rho^k_\phi = \tilde{\rho}_{\bar{n}+1}$ if $j = 6$. Then z^k and ρ^k_ϕ satisfy (2.1) (cf. [Kiw96, §4]). The easiest way to ensure

that $\rho_\phi^k \geq t_{\min}(2-t_{\max})d^2_{\mathcal{L}(f^k,f^k_{\rm lev})}(x^k)$ consists of taking $i_1 \in \operatorname{Arg\,max}_i s_i^1/|a^i|$ at step 1, since then $|\tilde{y}^1 - \tilde{x}^1| = d_{\mathcal{P}_{I^1}}(\tilde{x}^1) \geq d_{\mathcal{L}(f^k,f^k_{\rm lev})}(x^k)$. (In fact the usual choice yields $|\tilde{y}^1-\tilde{x}^1| \geq (f(x^k)-f^k_{\rm lev})/\max_{j\in J^k}|g^j|$, and this suffices; cf. [Kiw96, Lem. 3.1].) Thus, if desired, *only one* iteration of Procedure 5.4 may be executed, but more iterations will yield better z^k and ρ_ϕ^k for Algorithm 2.1. Note that *if step* 6 *always exits*, then we may set $n=k$ and $\tilde{x}^n = x^k$ at step 0, terminating with $x^{k+1} = \tilde{x}^{k+1}$ at steps 4 or 5 or $z^k = \tilde{x}^{k+1}$ and $y^k = \tilde{y}^k$ at step 6.

Remark 5.9. As in §4, the final $\lambda^{\bar{n}}$ may be used for subgradient selection or aggregation. Note that selective aggregation corresponds to dropping from $A_{I^{\bar{n}}}$ one column aggregated into another, thus retaining the crucial property $\langle a^i, a^j\rangle \leq 0\ \forall i \neq j$ in the new $I^{\bar{n}}$ (in contrast to total aggregation that replaces one column by a convex combination of all columns). Of course, the final $I^{\bar{n}}$ may become the initial I^0 on the next call to Procedure 5.4, and the final matrix factorization should be used in a hot start, e.g., if only $f^k_{\rm lev}$ has changed. We may add that most matrix factorizations can be updated to reflect selective aggregation.

Remark 5.10. The following modification is useful when $\mathcal{P} = \mathcal{L}(\hat{f}^k, f^k_{\rm lev})$. Unless $f^k_{\rm lev} \equiv f^*$ is employed, it suffices to discover that $f^k_{\rm lev} \leq f^*$, since then $f^{k+1}_{\rm low} = f^k_{\rm lev}$ can be used without impairing the preceding efficiency results. To this end, step 3 may choose *any* I^n such that $i_n \in I^n$, $s_i^n \geq 0$, and $\langle a^i, a^j\rangle \leq 0\ \forall i \neq j$, $i,j \in I^n$. Indeed, suppose $f^k_{\rm lev} > f^*$. By [Kiw96, Eq. (2.1)], $\hat{f}^k(x^*) \leq f^*$ for any $x^* \in S^*$, and since $\hat{f}^k = \max_{j\in J^k} f^j$ and $\langle a^i, \cdot\rangle - b_i = f^j(\cdot) - f^k_{\rm lev}$ for suitable i and j, we have $\langle a^i, x^*\rangle - b_i \leq \hat{f}^k(x^*) - f^k_{\rm lev} < 0 \leq s_i^n = \langle a^i, \tilde{x}^n\rangle - b_i\ \forall i \in I^n$, so $A^T_{I^n}(x^* - \tilde{x}^n) < 0$ and $\operatorname{rank} A_{I^n} = |I^n|$ by Lemma 5.3(iii). Therefore, if $\operatorname{rank} A_{I^n} < |I^n|$ is revealed by any factorization then $f^k_{\rm lev} \leq f^*$ and Algorithm 2.1 may set $f^{k+1}_{\rm low} = f^k_{\rm lev}$.
