LIMITS OF SINGULARLY PERTURBED CONTROL PROBLEMS WITH STATISTICAL DYNAMICS OF FAST MOTIONS*

ALEXANDER VIGODNER†

Abstract. We describe the limit behavior of admissible trajectories in a singularly perturbed control system as the small parameter tends to zero. A general case is considered where, in the limit, the fast motion may infinitely rapidly oscillate in time. Invariant measures of the parameterized fast flow are employed to describe the limit behavior and construct the limit control problem. The notion of relatively slow controls is introduced. Approximating properties of the limit problem within the families of relatively slow controls are verified. The results are illustrated by examples.

Key words. singular perturbations, invariant measure, statistical convergence, relaxed control, relatively slow control

1. Introduction.

In this paper we consider a singularly perturbed control system which consists of two differential equations,

$$\begin{aligned} \dot{x} &= f(u,x,y), \\ \varepsilon\dot{y} &= g(u,x,y), \end{aligned} \tag{1.1}$$

together with initial conditions

$$x(0) = x^0,\ y(0) = y^0. \tag{1.2}$$

Here $x \in \mathbb{R}^m, y \in \mathbb{R}^n$, and ε is a positive small parameter. A dot denotes a derivative with respect to time t. The controls $u(t)$ are functions satisfying the inclusion $u(t) \in U$, where U is a prescribed compact metric space. As is customary, we refer to the first equation in (1.1) as generating the slow x-trajectory, while the second one generates the fast y-trajectory. This terminology may be justified by orders of magnitude of the derivatives $\dot{x}, \dot{y}$ which are $|f|$ and $|g|/\varepsilon$, respectively.

The control problem associated with these equations consists of minimizing the integral $J_\varepsilon(u)$ given by

$$J_\varepsilon(u) = \int_0^1 Q(u(t), x_\varepsilon(t), y_\varepsilon(t))dt, \tag{1.3}$$

where $(x_\varepsilon(t), y_\varepsilon(t))$ is the assumed unique solution of (1.1)–(1.2) for $t \in [0,1]$, induced by $u(\cdot)$.

The problems that we are interested in are as follows:

— to study the limit behavior of the trajectories of this control system and the cost as ε tends to zero,

— to construct a limit system which could in some sense approximate the behavior of the original ε-system for ε small.

†Department of Theoretical Mathematics, Weizmann Institute of Science, 76100 Rehovot, Israel. Present address: Intel Israel, M.T.M., Haifa 31015, Israel (vigod@wisdom.weizmann.ac.il or vigodner@iil.intel.com).

Such problems were examined by many authors. See for instance the works of Bensoussan [Be1, Be2]; O'Malley [O'M]; Kokotovic [Ko1]; Kokotovic, O'Malley, and Sannuti [KOS]; Bensoussan and Blankenship [BB]; and Donchev and Veliov [DV1, DV2]. These papers consider the case where it is possible to identify a limit system for $\varepsilon \to 0$ in the form of a reduced system which is obtained by setting $\varepsilon = 0$ in (1.1), namely,

$$\begin{aligned} &\dot{x} = f(u, x, y),\ x(0) = x^0; \\ &0 = g(u, x, y). \end{aligned} \tag{1.4}$$

This reduced order scheme was suggested by Tichonov [Ti] for uncontrolled singularly perturbed differential equations and has been developed, among many others, by Vasil'eva [Va], Vasil'eva and Butuzov [VB], O'Malley [O'M2], and Campbell [Ca].

Under appropriate conditions the algebraic equation can be inverted with respect to y, resulting in a manifold $y = q(u, x)$. This manifold is then inserted into the dynamic part of (1.4) as follows:

$$\begin{aligned} &\dot{x} = f(u, x, q(u, x)),\ x(0) = x^0; \\ &y = q(u, x). \end{aligned} \tag{1.5}$$

The limit control problem is then to minimize the cost

$$J_0(u) = \int_0^1 Q(u(t), x_0(t), y_0(t))\, dt,$$

where $(x_0(t), y_0(t))$ is the trajectory of (1.5) induced by the control $u(t)$. Under appropriate conditions $x_\varepsilon(t) \to x_0(t)$ uniformly for $t \in [0, 1]$, $y_\varepsilon(t) \to y_0(t)$ uniformly for $t \in [\delta, 1]$, where $\delta > 0$ is arbitrary, and $J_\varepsilon(u) \to J_0(u)$. Moreover under additional conditions the value of the original problem converges to the value of the reduced problem. Namely $\inf_u J_\varepsilon(u) \to \inf_u J_0(u)$. A main condition for this scheme to be valid is that the point $q(u, x)$ (u, x are fixed) be a (locally) asymptotically stable equilibrium point for the (u, x)-parameterized time-invariant differential equation

$$\frac{dy}{d\tau} = g(u, x, y). \tag{1.6}$$

The problem of Mayer's type, that is, $J_\varepsilon(u) = Q(y_\varepsilon(1))$, was considered in [DV1]. Some related recent results are given in the works of Kabanov and Pergamenshchikov [KaP] and Tuan [Tu]. In the latter works the well-posedness of Mayer's problems is considered. The well-posedness is connected with the convergence as $\varepsilon \to 0$ of the reachable set of the original system to the reachable set of the limit problem. One can easily extend the results of this paper for Mayer's problems too.

In many works (see, e.g., Gaitsgory [G1, G2, G3]) it was noted that the reduced model approximates the original problem (1.1)–(1.3) only if the optimal control $u_\varepsilon(t)$ does not change rapidly as $\varepsilon \to 0$. If, for instance, in the optimal regime the control u and the fast variable y oscillate rapidly and the oscillation rate grows to infinity as ε tends to zero, then the reduced model cannot describe the limit behavior of the optimal trajectories of the original system. To define the limit control system in this case, Gaitsgory [G1, G2, G3] suggests another approach which is an extension of the averaging method described for uncontrolled motions in Volosov [Vo]. The limit problem in [G1, G2, G3] has the following form of a differential inclusion for the slow variable x:

$$\dot{x} \in V(x), \tag{1.7}$$

where $V(x)$ is a convex compact set-valued function, constructed by the special scheme of averaging of the function $f(u,x,y)$ over solutions of (1.6) on the infinite time interval. For a more recent result concerning topological dynamics and other properties of the differential inclusion in (1.7) see Grammel [Gr].

In this paper we consider a more general case where, even for constant in time controls $u \in U$, the reduced order system (1.4) may not be an appropriate nominal limit for (1.1)–(1.3) as $\varepsilon \to 0$. More specifically, the solutions of (1.6) for x, u fixed may not converge to an equilibrium. We establish conditions on the asymptotic topological dynamics of these trajectories and build a limit control system for (1.1)–(1.2). We develop here an approach suggested in [AV] for uncontrolled singularly perturbed dynamical systems.

We use *invariant measures* of (1.6) for x, u fixed instead of considering a root $y = q(u,x)$ of $0 = g(u,x,y)$. If there is a (locally) unique invariant measure of (1.6) (depending on parameters u, x), say $\nu(u,x)$, we suggest the following limit control system instead of (1.4):

$$\begin{aligned} \dot{x} &= \int_{\mathbb{R}^m} f(u,x,y)\,\nu(u,x)(dy),\ x(0) = x^0; \\ \mu(t) &= \nu(u(t),x(t)). \end{aligned} \tag{1.8}$$

The limit control problem is then to minimize over u the integral

$$J_0(u) = \int_0^1 Q(u(t),x_0(t),y)\,\mu_0(t)(dy), \tag{1.9}$$

where $(x_0(t),\mu_0(t))$ is the trajectory of (1.8) generated by a control $u(t)$. $\mu_0(t) = \nu(u(t),x_0(t))$ is a function which takes values in the space of probability measures on $\mathbb{R}^n$. The limit control problem (1.8)–(1.9) is similar to the chattering control problem as developed in [A1, A2, A3, A4]. The only complication is that in our model the measure-valued function $\mu_0(t)$ is a function of $x(t)$ and $u(t)$ rather than a parametric function. We then verify that this limit control problem approximates the original (1.1)–(1.3) problem on the special families of *relatively slow controls*. By relatively slow control we mean a function $u_\varepsilon(t)$ which may be "fast" in time t as ε tends to zero, but in time $\tau = \varepsilon^{-1}t$ the control $\tilde{u}_\varepsilon(\tau) = u_\varepsilon(\varepsilon\tau)$ is "slow." The families of relatively slow controls are deeply connected with the so-called *ergodic families of controls* with respect to the fast system (1.6) defined in [G1]. Note also that the average technique suggested in [G1, G2, G3] is applicable in our case too. However, our approach has two advantages. First, in the average technique, attention is paid only to the asymptotic behavior of the slow variable $x_\varepsilon(t)$. Asymptotic behavior of the fast variable $y_\varepsilon(t)$ is studied only in the reduced order case. Our approach employs the theory of measure-valued functions and determines completely the statistical asymptotic behavior of the fast variable $y_\varepsilon(t)$ in the general case. And second, we have in the limit, an explicit form of the control problem rather than the form of the differential inclusion (1.7).

The paper is organized as follows. Section 2 is devoted to the properties of invariant measures of dynamical system (flows) and their invariant measures depending on parameters. The results of this section are not new but presented in a convenient form. In section 3 we give a formal description of the singularly perturbed control problem and the technical conditions. We construct the limit control problem (1.8)–(1.9) and verify when this problem is well posed. In section 4 we employ *relaxed controls* and construct the limit relaxed control problem which guarantees existence

of the optimal solutions. We use the standard technique originally introduced by Warga [Wa]. In section 5 we define the notion of relatively slow controls and give two preliminary estimates on convergence for the trajectories of the original system. The main result is presented in section 6. It consists of four convergence theorems. The first three theorems state the same convergence result of the trajectories and the cost of the original system when, respectively, continuous, piecewise continuous, and measurable controls are applied. The difference between these theorems is only in appropriate assumptions. The fourth theorem determines the convergence result for the value of the original control problem to the value of the limit problem on the families of relatively slow controls. The proof of Theorems I–III is given in section 7. In the closing section we comment on the results obtained.

2. Dynamical systems, invariant measures, and convergence of motions. In this section we recall some properties of dynamical systems and invariant measures which depend on parameters. We establish the properties of asymptotic convergence of motions to invariant measure and prescribed sets. Consult with Nemytskii and Stepanov [NS] and Sell [Se] as a general reference and with Billingsley [Bi] as our reference on probability measures.

Consider a dynamical system (semiflow) $\phi(\tau, y)$ which is a continuous mapping

$$\phi(\tau, y) : \mathbb{R}_+ \times \mathbb{R}^n \to \mathbb{R}^n; \quad \phi(0, y) = y; \quad \phi(\tau_1, \phi(\tau_2, y)) = \phi(\tau_1 + \tau_2, y) \quad \forall \tau_{1,2} \in \mathbb{R}_+.$$

In what follows we shall often use the term flow instead of semiflow if no difference between properties of flows and semiflows appears.

The ω-limit set $\Omega(y)$ of a point y consists of all the points $z = \lim \phi(\tau_k, y)$ for some sequence $\tau_k \to +\infty$. A set A is *positively invariant* with respect to ϕ if $y \in A$ implies $\phi(\tau, y) \in A$ for $\tau \geq 0$.

We shall need also in the sequel the notion of *a prolongation of a set*; see, e.g., Bhatia and Szegö [BS]. Let K be a subset of R^n. The prolongation of K with respect to ϕ consists of all limit points $z = \lim \phi(\tau_i, y_i)$ with $r(y_i, K) \to 0$ as $i \to \infty$ and $\tau_i \geq 0$ for all i. Here r is a distance on $\mathbb{R}^n$.

Let Γ be a complete separable metric space, endowed with its Borel structure. We need some properties of measures defined on Γ. (We let Γ be an abstract space rather than, say $\mathbb{R}^n$, since in this paper we shall use measures on different spaces.)

Let Σ be a Borel σ-algebra on Γ. We denote the space of Borel probability measures on (Γ, Σ) by $\mathcal{P}(\Gamma)$. The space $\mathcal{P}(\Gamma)$ is endowed with the weak convergence of measures defined as follows. The sequence μ_k converges to μ if for every continuous bounded function $h(y) : \Gamma \to \mathbb{R}$

$$\int_{\leqq} h(y)\, \mu_k(dy) \to \int_{\Gamma} h(y)\, \mu(dy). \tag{2.1}$$

$\mathcal{P}(\Gamma)$ is metrizable. For definiteness we choose the Prohorov metric ρ defined as follows (see [Bi, p. 238]):

$$\rho(\mu_1, \mu_2) = \inf\{\eta : \mu_1(A) \leq \mu_2(A^\eta) + \eta,\ \mu_2(A) \leq \mu_1(A^\eta) + \eta\ \forall A \in \Sigma\}, \tag{2.2}$$

where A^η denotes the η-neighborhood of A in Γ.

A measure ν in $\mathcal{P}(\mathbb{R}^n)$ is said to be an *invariant measure* with respect to ϕ if for every $\tau \in \mathbb{R}_+$ and for every bounded and continuous function $h(\cdot)$

$$\int_{\mathbb{R}^n} h(\phi(\tau, y))\, \nu(dy) = \int_{\mathbb{R}^n} h(y)\, \nu(dy). \tag{2.3}$$

(2.3) is thus equivalent to the relation $\nu(A) = \nu(\phi(-\tau, A))$ for any Borel A in Γ.

In what follows we shall denote the Lebesgue measure on $\mathbb{R}$ by λ.

DEFINITION 2.1. *Let $w(\tau) : \mathbb{R}_+ \to \mathbb{R}^n$ be continuous, and let ν be a probability measure on R^n. We say that $w(\cdot)$ converges asymptotically in distribution to ν if the probability measures μ_s, given by*

$$\mu_s(A) = \frac{1}{s}\lambda(\{\tau : \tau \in [0, s],\ w(\tau) \in A\}),\ A \in \Sigma,$$

converge weakly to ν as $s \to \infty$.

Parameterized flows. Consider now the following differential equation depending on the parameter $p \in P$ where P is a metric space:

$$\frac{dy}{d\tau} = g(p, y) \tag{2.4}$$

with $y \in \mathbb{R}^n$. We assume that $g(\cdot, \cdot)$ is continuous on $P \times \mathbb{R}^n$ and that with any initial condition $y(0) = y$ the equation has a unique solution $\phi(\tau, p, y)$ for $\tau \in \mathbb{R}_+$ such that $\phi(0, p, y) = y$. Thus the mapping ϕ is continuous on $\mathbb{R}_+ \times P \times \mathbb{R}^n$, and for p fixed, ϕ is a continuous semiflow. For $\phi(\cdot, p, \cdot)$ we shall often use the notations ϕ_p or $\phi_p(\tau, y)$.

We state now an assumption under which we work throughout.

Assumption 2.2. For each p let $G(p)$ be an open subset of R^n and such that

(i) $G(p)$ is positively invariant with respect to ϕ_p;

(ii) for open $P' \subset P$, the set $\{(p, y) : p \in P',\ y \in G(p)\}$ is an open subset of $P \times \mathbb{R}^n$;

(iii) a compact $K(p) \subset G(p)$ exists such that the ω-limit set of $\phi_p(\tau, y)$ for p fixed, is in $K(p)$ for all $y \in G(p)$, and for compact $P' \subset P$ the set $\{(p, y) : p \in P',\ y \in K(p)\}$ is compact in $P \times R^n$.

Let $L(p)$ be the prolongation of the set $K(p)$ with respect to ϕ_p for p fixed. It is clear that $L(p) \supset K(p)$.

PROPOSITION 2.3. *Under Assumption* 2.2 *the set-valued function $L(p)$ has compact values included in $G(p)$ and $L(\cdot)$ is upper semicontinuous.*

Proof. See [AV, Proposition 8.2]. □

Note that by the Krilov–Bogolubov theorem (see, e.g., [NS, p. 493] the parameterized flow $\phi(\tau, p, y)$ for each p has at least one invariant measure supported in $G(p)$ if $G(p)$ is bounded. In our case $G(p)$ may not be bounded (actually $G(p)$ can coincide with $\mathbb{R}^n$). Nevertheless the existence of the compact subset $K(p)$ with properties (iii) of the latter assumption implies (see [AV, Proposition 3.2]) that the set of all ϕ_p-invariant measures in $G(p)$ is not empty, compact, and convex. Moreover, all these measures are supported on $K(p)$.

PROPOSITION 2.4. *Suppose that Assumption* 2.2 *is fulfilled. Then for $(p, y) \in$ graph G*

(i) *the average integral*

$$\frac{1}{s}\int_0^s d((p, \phi(\tau, p, y)), \mathit{graph}\, K)\, d\tau$$

tends to zero as $s \to \infty$. (Here d is a distance on $P \times \mathbb{R}^n$.)

(ii) *the pair $(p, \phi(\tau, p, y))$ converges to graph L as $\tau \to \infty$. Namely, $d((p, \phi(\tau, p, y)),$ graph $L) \to 0$ as $\tau \to \infty$.*

(iii) *the convergences in* (i) *and* (ii) *are uniform on compact subsets of pairs (p, y) in graph G.*

If additionally $\nu(p)$ for each p is the unique invariant measure of (2.4) *supported on $G(p)$, then*

(iv) *$\nu(p)$ is supported on $K(p)$ and continuous on P (in topology on $\mathcal{P}(\mathbb{R}^n)$).*

(v) *the parameterized flow $\phi(\tau, p, y)$ converges asymptotically in distribution to $\nu(p)$ uniformly on compact subsets of pairs (p, y) in graph G.*

Proof. (i) follows from [AV, Lemma 3.1 and Proposition 3.2] and properties of the weak convergence of measures. (ii) follows from (i) and the definition of a prolongation of a set. Uniformity of these convergences follows from [AV, Proposition 3.5]. (iv) and (v) follow also from [AV, Proposition 3.7]. The full proof of the results can be found in [Vi, Proposition 2.4.9]. □

Remark 2.5. The openness of *graph* G is essential for further considerations. However it can be easily proved that all latter results hold true if the graph $\{(p, y) : p \in P', y \in G(p)\}$ is closed for closed P'. Then, in particular, $G(p)$ can be compact and $K(p)$ may coincide with $G(p)$. For the details see [Vi, Chapter II].

It may seem that the stronger continuity property (for instance the Lipschitz continuity) of function g with respect to p implies the Lipschitz continuity of the invariant measure $\nu(p)$ in the sense of the Prohorov metric (2.2). But in general this is not true. As an example consider the one-dimensional system $\dot{y} = y(p - r(y))$, $p \in [1/2, 2]$; $r(y) = \sin(y)$ if $y \le \pi/2$ and $r(y) = (y - \pi/2)^2 + 1$ if $y > \pi/2$. This system is C^1 in p, y. For any p there exists then the equilibrium point $y(p) = \arcsin(p)$ if $p \le 1$ and $y(p) = \sqrt{(p-1)} + \pi/2$ if $p > 1$ which is locally asymptotically stable. The set is $G(p) = (0, \pi)$ and $K(p) = \{y(p)\}$. The invariant measure is concentrated on the point $y(p)$. It is clear that for $p^* = 1$ we have $\rho(\nu(p^*), \nu(p))/|p - p^*| \to \infty$ as $p \to 1$. Then $\nu(p)$ is not Lipschitz continuous in p on the interval $[1/2, 2]$.

The next result is concerned with time-varying perturbation of the variable p.

PROPOSITION 2.6. *Suppose that Assumption* 2.2 *is fulfilled. Let E be a compact subset of graph G. Then for any $\eta > 0$, there exist an $s_0 > 0$ and a $\theta > 0$ such that whenever $|p(\tau) - p_0| < \theta$ for $\tau \in [0, 2s_0]$ and $w(\tau)$ is a solution of $\dot{y} = g(p(\tau), y)$, with $(p_0, w(0)) \in E$, then for $s \in [s_0, 2s_0]$ the following inequalities hold:*

$$\frac{1}{s}\lambda(\{\tau : \tau \in [0, s], d((p(\tau), w(\tau)), graph\, K) > \eta\}) < \eta,$$
$$d((p(s), w(s)), graph\, L) < \eta.$$

Proof. It follows from Proposition 2.4 and the continuous dependence results in ordinary differential equations. □

The next proposition states a correspondence of the Prohorov metric between two measures and the difference between the corresponding integrals. This is a general property of the Prohorov metric without any connection to dynamical systems and invariant measures.

PROPOSITION 2.7. *Let $h : \Gamma \to \mathbb{R}$ be a bounded uniformly continuous function; namely, there exist constants a, b and a nondecreasing function $\omega(s) \to 0$ as $s \to 0$ such that*

$$a \le h(x) \le b;\ |h(x) - h(y)| \le \omega(|x - y|)\ \forall x, y \in \Gamma.$$

Assume that $\mu_1, \mu_2 \in \mathcal{P}(\Gamma)$. Let $\delta = \rho(\mu_1, \mu_2)$.

Then

$$\left| \int_\Gamma h(s)\mu_2(ds) - \int_\Gamma h(s)\mu_1(ds) \right| \le \omega(\delta) + (b - a)\delta. \tag{2.5}$$

Proof. We can write the following representation of the integrals for $i = 1, 2$:

$$\begin{aligned}\int_\Gamma h(s)\mu_i(ds) &= \int_{\{x:h(x)\geq a\}} h(s)\mu_i(ds)\\ &= a + \int_a^\infty \mu_i\{x : h(x) \geq s\}ds = a + \int_a^b \mu_i\{x : h(x) \geq s\}ds\end{aligned} \tag{2.6}$$

(see [Bi, p. 222]). We denote the set $A_s = \{x : h(x) \geq s\}$. Take the sequence $\delta_k > \delta$, $\delta_k \to \delta$. From the continuous property of h it follows that $A_s^{\delta_k} \subset A'_s$ where $A'_s = \{x : h(x) > s - w(\delta_k)\}$. Then $\mu_i(A'_s) \geq \mu_i(A_s^{\delta_k})$. Therefore from (2.6) we can make the following estimate:

$$\begin{aligned}&\int_\Gamma h(s)\mu_2(ds) - \int_\Gamma h(s)\mu_1(ds) = \int_a^b \mu_2(A_s) - \mu_1(A_s)ds\\ &= \int_a^b \mu_2(A_s) - \mu_1(A'_s)ds + \int_{a-\omega(\delta_k)}^a \mu_1(A_s)ds - \int_{b-\omega(\delta_k)}^b \mu_1(A_s)ds\\ &\leq \int_a^b \mu_2(A_s) - \mu_1(A_s^{\delta_k})ds + \omega(\delta_k) \leq \omega(\delta_k) + (b-a)\delta_k.\end{aligned} \tag{2.7}$$

Passing to the limit as $k \to \infty$ and according to the symmetry in (2.7), we obtain estimate (2.5). This completes the proof. □

In what follows we shall denote the metric on the abstract metric space, say Γ, by d_Γ.

3. The setting. In this section we give a formal description of the singularly perturbed control problem (we refer to this problem as the ε-problem) and introduce the conditions under which we work.

The control problem (1.1–1.3) is identified by the following data functions:

$$\begin{aligned}f(u, x, y) &: U \times \mathbb{R}^m \times \mathbb{R}^n \to \mathbb{R}^m,\\ g(u, x, y) &: U \times \mathbb{R}^m \times \mathbb{R}^n \to \mathbb{R}^n,\\ Q(u, x, y) &: U \times \mathbb{R}^m \times \mathbb{R}^n \to \mathbb{R}.\end{aligned}$$

The trajectories $x_\varepsilon(t), y_\varepsilon(t)$ of the system (1.1)–(1.2) generated by some admissible control function $u(t)$ induce the cost $J_\varepsilon(u)$ given by (1.3). We define the value of the ε-problem as follows:

$$\mathrm{val}_\varepsilon(\mathcal{U}) = \inf_{u(\cdot)\in\mathcal{U}} J_\varepsilon(u).$$

Here $\mathcal{U}$ is the family of admissible control functions $u(\cdot)$:

$$u(t) : [0, 1] \to U.$$

In this paper we consider three classes of admissible controls:

(1) $\mathcal{U}^c$ is a family of all continuous functions.

(2) $\mathcal{U}^p$ is a family of all piecewise continuous functions. By piecewise continuous functions we mean the functions which are continuous on $[0, 1]$ except possibly at a finite number of points and these points are discontinuities of the first type.

(3) $\mathcal{U}^m$ is a family of all measurable functions.

Let us introduce now the technical conditions assumed throughout the paper. We construct these conditions in order to study just a phenomenon of singular perturbations and to avoid other pathologies.

Remark. In the various estimates we shall often use the value of the function $u(t+z)$ where $t \in [0,1]$ and z is some number. Since $t+z$ may not be included in $[0,1]$ we shall suppose that $u(t)$ is extended for $t \in \mathbb{R}$ such that $u(t) = u(0)$ for $t < 0$ and $u(t) = u(1)$ for $t > 1$. No confusion should arise.

Assumption 3.1 (continuity of the data).

(i) The functions f, g, Q are continuous on $U \times \mathbb{R}^m \times \mathbb{R}^n$.

(ii) For any (u, x, y^0) fixed, the system $\dot{y} = g(u, x, y), \quad y(0) = y^0$ has a unique solution $\phi(\tau, u, x, y^0)$ defined for all $\tau \geq 0$.

Note that the pair $(u, x) \in U \times \mathbb{R}^m$ can be denoted as the parameter $p \in P$ from the previous section. Here $P = U \times \mathbb{R}^m$. With this notation the parameterized flow $\phi(\tau, p, y)$ (or $\phi(\tau, u, x, y)$) is a solution of (1.6). The following assumption copies the assumptions under which the results of section 2 were obtained.

Assumption 3.2. For any $p = (u, x)$ there exist sets $G(u, x)$ and $K(u, x)$ such that the corresponding set-valued maps $G(p)$ and $K(p)$ satisfy Assumption 2.2.

The following growth condition is there to ensure that for ε small, the trajectories $x_\varepsilon(t)$ stay bounded over $[0, 1]$.

Assumption 3.3 (growth condition). For some $c > 0$ the function $f(u, x, y)$ satisfies

$$\sup_{y \in G(u,x)} |f(u, x, y)| \leq c(1 + |x|) \quad \forall u \in U.$$

Assumption 3.4 (unique ergodicity). For each (u, x), the (u, x)-parameterized flow $\phi(\tau, u, x, y)$ has a unique invariant measure in $G(u, x)$; we denote this by $\nu(u, x)$.

Note that by Proposition 2.4 the mapping $\nu(u, x) : U \times \mathbb{R}^m \to \mathcal{P}(\mathbb{R}^n)$ is continuous on $U \times \mathbb{R}^m$.

Assumption 3.5 (Lipschitz continuity).

(i) The function $\nu(\cdot, \cdot)$ is Lipschitz continuous in x on every compact subset of $\mathbb{R}^m$ in the sense of the Prohorov metric and uniformly with respect to $u \in U$. Namely, for any compact D from $\mathbb{R}^m$ there exists a number $L > 0$ such that for any $u \in U$ and $x_1, x_2 \in D$

$$\rho(\nu(u, x_1), \nu(u, x_2)) \leq L|x_1 - x_2|.$$

(ii) On each compact subset of $\mathbb{R}^m \times \mathbb{R}^n$ the function f is Lipschitz continuous in x, y uniformly with respect to $u \in U$.

The limit control problem. Under Assumptions 3.1–3.4 we can formally build the limit control problem for $\varepsilon = 0$ in the following form:

$$\begin{aligned} &\underset{u(\cdot) \in \mathcal{U}}{\text{minimize}} \int_0^1 \int_{\mathbb{R}^n} Q(u(t), x(t), y)\, \mu(t)(dy)\, dt \\ &\text{subject to } \dot{x} = \int_{\mathbb{R}^n} f(u(t), x, y)\, \mu(t)(dy), \ x(0) = x^0, \\ &\mu(t) = \ \nu(u(t), x(t)). \end{aligned} \tag{3.1}$$

Here $\mu(t) \in \mathcal{P}(\mathbb{R}^n)$ for each t.

We do not specify here the family of admissible controls $\mathcal{U}$. For $u(\cdot) \in \mathcal{U}$ fixed we denote by $(x_0(t), \mu_0(t))$ $(\mu_0(t) = \nu(u(t), x_0(t)))$ an admissible trajectory of (3.1).

We define also the value of the limit problem

$$\mathrm{val}_0(\mathcal{U}) = \inf_{u(\cdot)\in\mathcal{U}} J_0(u).$$

In the next sections we shall show that this limit problem actually approximates in some sense the ε-problem (1.1)–(1.3). But in order to verify the approximating properties of the limit problem we need that the equations in (3.1) be uniquely solvable for $t \in [0,1]$ with respect to $x(t), \mu(t)$ for any given control $u(\cdot) \in \mathcal{U}$. To do that it is enough to assume that for the right-hand side of the differential equation

$$\dot{x} = \int_{\mathbb{R}^n} f(u,x,y)\,\nu(u,x)(dy) \tag{3.2}$$

is Lipschitz continuous in x on any compact subset of $\mathbb{R}^m$ uniformly with respect to $u \in U$. Assumptions 3.3–3.5 imply this property.

LEMMA 3.6. *Under Assumptions* 3.3–3.5 *the right-hand side of* (3.2) *is Lipschitz continuous in x on any compact subset of $\mathbb{R}^m$ uniformly with respect to $u \in U$.*

Proof. It follows directly from Proposition 2.7 and that by Assumption 3.2 for any compact D from $\mathbb{R}^m$ all measures $\{\nu(u,x) : u \in U, x \in D\}$ are supported in the compact set $\{y : u \in U, x \in D, y \in K(u,x)\}$. □

Therefore by Lemma 3.6 and under all assumptions in this section the system in (3.1) is uniquely solvable on the interval $t \in [0,1]$ for any given $u(\cdot) \in \mathcal{U}$.

Comments on the assumptions. Assumption 3.1 is standard. Without this assumption we could get various deviations which are not connected with singular perturbations.

Assumption 3.2 is crucial. Openness of the set $G(u,x)$ is essential for the proof that the triple $(u_\varepsilon(t), x_\varepsilon(t), y_\varepsilon(t))$ is defined for all $t \in [0,1]$, and it is included in *graph* G for ε small enough. On the other hand, without any additional requirements we can define (1.1) on the metric space $X \times Y$ where X is homeomorphic to $\mathbb{R}^m$ and Y is a closed subset of $\mathbb{R}^n$. Then the triple $(u_\varepsilon(t), x_\varepsilon(t), y_\varepsilon(t))$ is automatically included in the set $U \times X \times Y$. Hence G can be taken as Y and by Remark 2.5 the main results of this paper can be extended to the case where G is not open.

Assumption 3.3 implies that if the fast trajectory $y_\varepsilon(t)$ induced by a control $u_\varepsilon(t)$ exists uniquely on the time interval $[0,1]$ and $y_\varepsilon(t) \in G(u_\varepsilon(t), x_\varepsilon(t))$ (we shall prove this), then the slow trajectory $x_\varepsilon(t)$ is also defined for $t \in [0,1]$. This assumption can be omitted if it is known a priori that $x_\varepsilon(t)$ can be defined for all $t \in [0,1]$. We could assume that the function g satisfies the same growth condition too. But then we would rule out interesting examples.

Assumption 3.5 is needed only to prove the uniqueness of the solutions of (3.2). Thus instead of these assumptions we could assume the uniqueness directly. The similar condition is introduced in the steady state approach (Assumption (E) in Wasow [Was, p. 253]), but certainly in the steady state approach this condition can be checked easier.

Assumption 3.4 is crucial. Without this assumption the limit differential equation in (3.2) makes no sense, since the measure $\nu(u,x)$ is not uniquely defined. Instead, in this equation a limit differential inclusion must be defined; see [AV, Theorem I]. On the other hand, the local (in G) uniqueness of the invariant measure is equivalent to that for all continuous f of the following convergence:

$$\frac{1}{S}\int_0^S f(u,x,\phi(\tau,u,x,y))\,d\tau \to \int_{\mathbb{R}^n} f(u,x,y)\,\nu(u,x)(dy)$$

holds for $S \to \infty$ uniformly with respect to y, x, u (Proposition 2.4 (v)). This property reflects the deep connection between our technique and the averaging approach; see [Vo] and [G1, G2, G3]. In some sense the unique ergodicity is the weakest possible condition which guarantees applicability of the averaging technique for an arbitrary f. The simplest cases of the unique (local) ergodicity are where $\dot{y} = g(u, x, y)$ has an asymptotic stable equilibrium $q(u, x)$ or it has a stable limit cycle. In the first case $\nu(u, x)$ is the Dirac measure concentrated at the point $q(u, x)$ and in the second case $\nu(u, x)$ is distributed on the corresponding periodic curve. In a more general case the verification of the unique ergodicity is more difficult.

Measure-valued functions. Note that the trajectory $\mu_0(t) = \nu(u(t), x_0(t))$ of (3.1) is a measure-valued function. We want to display how this function approximates the fast trajectory $y_\varepsilon(t)$ of the ε-system. But $y_\varepsilon(t)$ and $\mu_0(t)$ take values in different spaces. Thus we need to define the type of convergence.

Let us describe briefly the properties of measure-valued functions. We use here the description of *chattering parametric functions* given in [A3]. By measure-valued functions we mean the family $\mathcal{M}$ of measurable mapping

$$\mu(t) : [0, 1] \to \mathcal{P}(\Gamma).$$

Here Γ is a separable complete metric space. A measure-valued function is assumed measurable if for every measurable $A \subset \Gamma$ the real-valued map $\mu(t)(A) : [0, 1] \to [0, 1]$ is measurable (see [A3, section 3]). Here $\mu(t)(A)$ is the weight the measure assigns to A. Any measurable function $r(t)$ with values in Γ can be presented as an element of $\mathcal{M}$ which for each $t \in [0, 1]$ is the measure concentrated on the point $\{r(t)\}$. We denote this measure-valued function by $\delta_r(t)$. Each measure-valued function $\mu(\cdot)$ can be identified with the measure $\boldsymbol{\mu}$ on the product $[0, 1] \times \Gamma$ which is the direct integral

$$\boldsymbol{\mu} = (D) \int_0^1 \mu(t)\, dt \tag{3.3}$$

defined as follows. On a Borel set $E \subset [0, 1] \times \Gamma$ it is given by

$$\boldsymbol{\mu}(E) = \int_0^1 \mu(t)(E_t)\, dt,$$

where $E_t = \{y : (t, y) \in E\}$ is a t-section of the set E.

Convergence on $\mathcal{M}$ is taken to be the weak convergence defined in (2.1)–(2.2) of the corresponding probability measures on $[0, 1] \times \Gamma$. (See also [A3, section 4].)

Note that since Γ, hence $[0, 1] \times \Gamma$, is complete and separable, it follows (see, e.g., Artstein [A3]) that $\mathcal{M}$ itself is a complete metric space. If Γ is compact, then $\mathcal{M}$ is also compact.

The distance on $\mathcal{M}$ between $\mu_1(\cdot)$ and $\mu_2(\cdot)$ is denoted by $\boldsymbol{\rho}(\mu_1, \mu_2)$ and equal to the Prohorov distance between the corresponding measures $\boldsymbol{\mu}_1$ and $\boldsymbol{\mu}_2$, namely $\boldsymbol{\rho}(\mu_1, \mu_2) = \rho(\boldsymbol{\mu}_1, \boldsymbol{\mu}_2)$. No confusion should arise with the distance $\boldsymbol{\rho}$ on $\mathcal{M}$ between two functions $\mu_1(\cdot)$ and $\mu_2(\cdot)$ and the distance on $\mathcal{P}(M)$ between two measures $\mu_1(t)$ and $\mu_2(t)$ for the t fixed.

Remark 3.7. For the sake of convenience we consider the problem on the unit interval of time $t \in [0, 1]$. Hence all measures $\boldsymbol{\mu}$ defined by (3.3) are probability measures namely $\boldsymbol{\mu}([0, 1] \times \Gamma) = 1$. If we take an interval $[0, T]$ instead of $[0, 1]$ then $\boldsymbol{\mu}([0, T] \times \Gamma) = T$ and T is common for all $\boldsymbol{\mu}$. Therefore the weak convergence of

measures on $\tilde{\Gamma} = [0,T] \times \Gamma$ is also defined by (2.1). The distance $\rho_T(\boldsymbol{\mu}_1, \boldsymbol{\mu}_2)$ can be taken as $T\rho(\boldsymbol{\mu}_1/T, \boldsymbol{\mu}_2/T)$. Thus all further results hold true for the general finite time interval case.

DEFINITION 3.8. *Let $\mu(t)$ be an element of $\mathcal{M}$. Let $y_k(t)$ be a sequence of measurable functions defined on* [0,1] *with values in* Γ. *We say that* $y_k(\cdot)$ statistically *converges to $\mu(\cdot)$ if the corresponding measure-valued functions $\delta_{y_k}(\cdot)$ converge to $\mu(\cdot)$ on $\mathcal{M}$.*

4. Relaxed controls. Optimal solutions of the limit control problem. We want the limit problem (3.1) to be an approximation of the ε-problem in some sense. In particular we need the optimal trajectories of the limit problem to be ε-close to some admissible trajectories of the ε-system. But it is well known that the solution of the optimal control problem may fail to exist; see Warga [Wa]. In this section we recall the notion of relaxed controls to provide (generalized) solutions to the limit optimal control problem (3.1). We apply the standard technique originally introduced by Warga [Wa] and developed by Artstein [A1, A2, A3, A4].

Following the ideas of Warga we introduce the relaxed controls as follows. We allow the control function to assign to each t a probability measure on U. Namely, the relaxed control $v(\cdot)$ is a measure-valued function:

$$v(t) : [0,1] \to \mathcal{P}(U). \tag{4.1}$$

Denote the family of all measurable relaxed controls (4.1) by $\mathcal{V}$. Convergence on $\mathcal{V}$ is taken to be the convergence of measure-valued functions.

Relaxed limit control problem. A relaxed control $v(\cdot)$ affects (3.1) by integration with respect to the measure $v(t)$, for each t, the effects of the points $u \in U$. To employ another integral notation in (3.1) could complicate the formulas. Thus we use here the standard notation. If $h(u)$ is a function of the variable u on U and if v is a measure on U, then $\bar{h}(v))$ is a function of v on $\mathcal{P}(U)$, which is the average $\int_U h(u)v(du)$. Define now the new data functions $\boldsymbol{Q}$ and $\boldsymbol{f}$:

$$\begin{aligned} \boldsymbol{Q}(u,x) &= \int_{\mathbb{R}^n} Q(u,x,y)\, \nu(u,x)(dy), \\ \boldsymbol{f}(u,x) &= \int_{\mathbb{R}^n} f(u,x,y)\, \nu(u,x)(dy). \end{aligned} \tag{4.2}$$

With this notation, the limit optimal control problem (3.1) with the availability of relaxed controls has the following form:

$$\begin{aligned} &\underset{v(\cdot)\in V}{\text{minimize}} \int_0^1 \bar{\boldsymbol{Q}}(v(t),x(t))\, dt \\ &\text{subject to } \dot{x} = \bar{\boldsymbol{f}}(v(t),x); \quad x(0) = x^0, \\ &\mu(t) = \bar{\nu}(v(t),x(t)). \end{aligned} \tag{4.3}$$

Here $\mu(t) \in \mathcal{P}(\mathbb{R}^n)$ and by $\bar{\nu}(v,x)$ we understand the following integration for every measurable set $A \subset \mathbb{R}^n$:

$$\bar{\nu}(v,x)(A) = \int_U \nu(u,x)(A)\, v(du);$$

namely, $\mu(t)$ for each t is an average of the measures $\nu(u, x(t))$ on U with the measure $v(t)$ on U.

We shall denote the cost of the relaxed problem by $\bar{J}_0(v)$, namely,

$$\bar{J}_0(v) = \int_0^1 \bar{\boldsymbol{Q}}(v(t), x_0(t))\, dt.$$

It is clear that if $v(t)$ for each t is a Dirac measure concentrated on the point $u(t)$, then $\bar{J}_0(v) = J_0(u)$.

The limit optimal control problem (3.1) with ordinary controls can be rewritten as follows:

$$\begin{gathered} \underset{u(\cdot)\in\mathcal{U}}{\text{minimize}} \int_0^1 \boldsymbol{Q}(u(t), x(t))\, dt \\ \text{subject to } \dot{x} = \boldsymbol{f}(u(t), x); \quad x(0) = x^0, \\ \mu(t) = \nu(u(t), x(t)). \end{gathered} \tag{4.4}$$

Approximation of relaxed controls.

PROPOSITION 4.1. *$\mathcal{V}$ is compact. The family of ordinary measurable controls $\mathcal{U}^m$ is dense in $\mathcal{V}$.*

Proof. The space of measures supported on a common compact set with the weak convergence of measures is compact. Since the convergence on $\mathcal{V}$ is taken to be the weak convergence of measures on $[0, 1] \times U$, the first claim follows. The approximation by ordinary controls follows from [A3, Proposition 4.5]. □

Suppose now that U can be included in a separable Banach space—say, Z. Then the Lebesgue integral $\int_0^t u(t)\, dt$ is well defined. If U is convex, then any measurable function $u(\cdot)$ can be approximated by a continuous function $u_\delta(t) \in U$ such that $u_\delta(t) \to u(t)$ as $\delta \to 0$ for almost every $t \in [0, 1]$ and defined as follows:

$$u_\delta(t) = \frac{1}{2\delta} \int_{t-\delta}^{t+\delta} u(s)\, ds. \tag{4.5}$$

COROLLARY 4.2. *If U is a convex subset of a separable Banach space, then the family $\mathcal{U}^c$ is dense in $\mathcal{V}$. Moreover, for any $u^0 \in U$ and $v_0(\cdot) \in \mathcal{V}$ there exists a sequence $u_k(\cdot) \in \mathcal{U}^c$ statistically converging to $v_0(\cdot)$ and such that $u_k(0) = u^0$ for any k.*

Proof. The first statement directly follows from Proposition 4.1 and (4.5). Suppose now that $\tilde{u}_k(\cdot)$ statistically converges to $v_0(\cdot)$, and take a $u^0 \in U$. Construct a new sequence $u_k(\cdot)$ such that $u_k(0) = u_0$, $u_k(t) = \tilde{u}_k(t)$ for $t \geq 1/k$, and affine otherwise. Then clearly $u_k(\cdot)$ statistically converges to $v_0(\cdot)$. This completes the proof. □

COROLLARY 4.3. *The family of piecewise constant functions $u(t) : [0, 1] \to U$ is dense in $\mathcal{V}$.*

Proof. By Proposition 4.1 it is enough to show that piecewise constant functions are dense in $\mathcal{U}^m$ in some strong topology, say L^1. Since U is compact, we can just show that for any *simple* function $u^0(t) : [0, 1] \to U$ with a finite number of different values u^i, $i = 1, k + 1$, there exists a sequence u_j of piecewise constant functions converging *in measure* to u. The proof is standard. It follows from the property that for any measurable subset $T \subset [0, 1]$ and any $\delta > 0$ there exists a subset $E \subset [0, 1]$ which is a union of a finite number of disjoint intervals of $[0, 1]$ and such that $\lambda(T \Delta E) < \delta$; see Halmos [Ha, p. 56]. □

Existence of optimal solutions to (4.3) and their approximation follow from the general theory of Warga [Wa, Chapter 4]. We formulate these results in the following lemma.

LEMMA 4.4. *Under Assumptions* 3.1–3.5 *the optimization problem* (4.3) *has an optimal relaxed control—say,* $v(\cdot)$. *There is a sequence of ordinary measurable controls* $u_k(\cdot) \in \mathcal{U}^m$ *which statistically converges to* $v(\cdot)$. *In particular the cost* $J_0(u_k)$ *converges to the value* $\mathrm{val}_0(\mathcal{U}^m) = \mathrm{val}_0(\mathcal{V})$.

5. Relatively slow controls. Preliminary convergence estimates. In this section we present the results on the limit behavior of the admissible trajectories $(x_\varepsilon(t), y_\varepsilon(t))$, with respect to prescribed sets. We establish also a preliminary result on the statistical convergence of the fast variable $y_\varepsilon(t)$.

The trajectories $(x_\varepsilon(t), y_\varepsilon(t))$ are induced by special families of *relatively slow controls*.

Relatively slow controls. We introduce now the special families of continuous, piecewise continuous, and measurable controls, depending additionally on the parameter ε. We call these families *relatively slow controls* since the control $u_\varepsilon(t)$ may change rapidly in time $t \in [0,1]$ as $\varepsilon \to \infty$, but for $\tau = \varepsilon^{-1}t$ the function $\tilde{u}_\varepsilon(\tau) = u_\varepsilon(\varepsilon\tau)$ converges to constant as $\varepsilon \to 0$ while τ is fixed. For instance if $u_\varepsilon(t) = \cos(t/\sqrt{\varepsilon})$, then $\tilde{u}_\varepsilon(\tau) = \cos(\sqrt{\varepsilon}\tau) \to 1$ as $\varepsilon \to 0$.

Let $F > 0$ be the diameter of the set U. Define two special positive real-valued functions $M(z)$ and Δ_ε of variables $z \in [0,1]$, $\varepsilon > 0$ such that for some $L > 0$

$$\begin{gathered} Lz \le M(z) \le F, \\ M(z) \to 0, \text{ as } z \to 0 \text{ and } \Delta_\varepsilon \to 0, \quad \varepsilon\Delta_\varepsilon^{-1} \to 0, \text{ as } \varepsilon \to 0. \end{gathered} \tag{5.1}$$

DEFINITION 5.1. *Let* $z \in [0, \Delta_\varepsilon]$. *A control function* $u_\varepsilon(\cdot)$ *is said to be a* relatively slow continuous control *with respect to the functions* $M(\cdot)$ *and* Δ_ε *if for any* $t \in [0,1]$

$$d_U(u_\varepsilon(t+z), u_\varepsilon(t)) \le M(\Delta_\varepsilon^{-1}z). \tag{5.2}$$

A control function $u_\varepsilon(\cdot)$ *is said to be a* relatively slow piecewise continuous control *if*

(i) *the minimal length of interval of continuity is not less than* Δ_ε,

(ii) *for* $t, t+z$ *from every common interval of continuity,* (5.2) *is satisfied.*

A control function $u_\varepsilon(\cdot)$ *is said to be a* relatively slow measurable control *if*

$$\int_0^1 d_U(u_\varepsilon(t+z), u_\varepsilon(t))\, dt \le M(\Delta_\varepsilon^{-1}z).$$

We denote by $\mathcal{U}_\varepsilon^c$,$\mathcal{U}_\varepsilon^p$, and $\mathcal{U}_\varepsilon^m$, respectively, the families of all relatively slow continuous, piecewise continuous, and measurable controls with respect to the fixed functions $M(\cdot)$ and Δ_ε.

In what follows we assume that the functions $M(z)$ and Δ_ε are given, and therefore the families $\mathcal{U}_\varepsilon^c$, $\mathcal{U}_\varepsilon^p$, $\mathcal{U}_\varepsilon^m$ are completely determined.

Remark 5.2. Let $M(\cdot)$ and Δ_ε be fixed functions. Note then that if $u(\cdot)$ is *piecewise constant* (with a finite number of discontinuities), then for small ε, $u(\cdot) \in \mathcal{U}_\varepsilon^p$ and $u(\cdot) \in \mathcal{U}_\varepsilon^m$. If $u(\cdot)$ is continuous and *piecewise linear* (if U is certainly included in a vector space), then for sufficiently small ε, $u(\cdot) \in \mathcal{U}_\varepsilon^c$. These inclusions obviously follow from Definition 5.1 and the properties of the latter functions. On the other

hand, by the standard approximation arguments, any continuous function can be uniformly approximated by a continuous piecewise linear function. Besides, by the proof of Corollary 4.3, any measurable function with values in a compact space can be approximated in L^1-metric by a piecewise constant function.

Therefore, for $\varepsilon \to 0$

(i) for an arbitrary measurable function $u(\cdot) \in \mathcal{U}^m$ there exists a function $u_\varepsilon(\cdot) \in \mathcal{U}^m_\varepsilon$ such that

$$\int_0^1 d_U(u(t), u_\varepsilon(t))\, dt \to 0 \text{ as } \varepsilon \to 0, \tag{5.3}$$

(ii) for an arbitrary piecewise continuous function $u(\cdot) \in \mathcal{U}^p$ there exists a function $u_\varepsilon(\cdot) \in \mathcal{U}^p_\varepsilon$ satisfying (5.3),

(iii) for an arbitrary continuous function $u(\cdot) \in \mathcal{U}^c$ (if U is convex) there exists a function $u_\varepsilon(\cdot) \in \mathcal{U}^c_\varepsilon$ satisfying

$$\sup_{t\in[0,1]} d_U(u(t), u_\varepsilon(t)) \to 0 \text{ as } \varepsilon \to 0.$$

In this sense the families $\mathcal{U}^c_\varepsilon$, $\mathcal{U}^p_\varepsilon$, $\mathcal{U}^m_\varepsilon$ converge as $\varepsilon \to 0$ to the basic families $\mathcal{U}^c$, $\mathcal{U}^p$, $\mathcal{U}^m$, respectively.

Preliminary estimates. We now establish two important lemmas which will be useful in what follows. The first lemma states convergence of the trajectory $(x_\varepsilon(t), y_\varepsilon(t))$ to prescribed sets. The second lemma determines statistical convergence of $y_\varepsilon(t)$ to the corresponding measure-valued function.

Suppose that $u_\varepsilon(\cdot)$ is a relatively slow control, and consider the fast equation from the system (1.1) separately:

$$\varepsilon \dot{y} = g(u_\varepsilon(t), x_\varepsilon(t), y). \tag{5.4}$$

LEMMA 5.3. *Suppose that Assumptions* 3.1–3.3 *are satisfied. Let D be a compact subset of $\operatorname{graph} G$.*

Then for any $\eta_0 > 0$ there exists an $\varepsilon_0 > 0$ such that if $\varepsilon < \varepsilon_0$, then for $(u_\varepsilon(0), x_\varepsilon(0), y_\varepsilon(0)) \in D$ and $u_\varepsilon(\cdot) \in \mathcal{U}^c_\varepsilon$

(i) *the pair $(x_\varepsilon(t), y_\varepsilon(t))$ can be extended to $t \in [0,1]$, and $(u_\varepsilon(t), x_\varepsilon(t), y_\varepsilon(t)) \in \operatorname{graph} G$. Moreover there exists a compact $X \subset \mathbb{R}^m$ such that $x_\varepsilon(t) \in X$;*

(ii) $\lambda\{t : t \in [0,1], d((u_\varepsilon(t), x_\varepsilon(t), y_\varepsilon(t)), \boldsymbol{K}) > \eta_0\} < \eta_0$;

(iii) $d((u_\varepsilon(t), x_\varepsilon(t), y_\varepsilon(t)), \boldsymbol{L}) < \eta_0$ *for* $t \in [\Delta_\varepsilon, 1]$.

Here $\boldsymbol{K}$, $\boldsymbol{L}$ are compact subsets of $\operatorname{graph} G$ defined as follows:

$$\begin{aligned} \boldsymbol{K} &= \{(u,x,y) : u \in U, x \in X, y \in K(u,x)\}, \\ \boldsymbol{L} &= \{(u,x,y) : u \in U, x \in X, y \in L(u,x)\}. \end{aligned} \tag{5.5}$$

Proof. (i). The result follows directly from [AV, Lemma 4.7]. (ii) and (iii). Denote $p = (u,x)$ and $p_\varepsilon(t) = (u_\varepsilon(t), x_\varepsilon(t))$. Take $\eta < \eta_0$ such that $\boldsymbol{L}^\eta \subset \operatorname{graph} G$. Such an η exists by Assumption 3.2 and Proposition 2.3. Denote $C = \operatorname{cl} L^\eta$. Choose $s_0 > 0$ and $\theta > 0$ provided by Proposition 2.6 with $E = C \cup D$. Take $\varepsilon_0 > 0$ such that for $\varepsilon < \varepsilon_0$ we have $\varepsilon s_0 < \eta$, $2\varepsilon s_0 < \Delta_\varepsilon$ and the following inequality holds for $s \in [s_0, 2s_0]$ and $t \in [0, 1 - \varepsilon s]$:

$$M(\varepsilon \Delta_\varepsilon^{-1} s) + |x_\varepsilon(t + \varepsilon s) - x_\varepsilon(t)| < \theta.$$

Such an ε_0 exists by property (5.1) of the functions $M(z)$, Δ_ε. Then since $u_\varepsilon(\cdot)$ satisfies (5.2) we obtain that for $s \in [s_0, 2s_0]$ and $t \in [0, 1-\varepsilon s]$:

$$d_P(p_\varepsilon(t+\varepsilon s), p_\varepsilon(t)) < \theta.$$

Define a subset of $[0,1]$:

$$R_\varepsilon = \{t : (p_\varepsilon(t), y_\varepsilon(t)) \in E\}.$$

Then Proposition 2.6 implies that for $t' \in R_\varepsilon$ and $s \in [s_0, 2s_0]$

$$\begin{gathered} \frac{1}{\varepsilon s}\lambda(\{t : t \in [t', t'+\varepsilon s], d((p_\varepsilon(t), y_\varepsilon(t)), \boldsymbol{K}) > \eta\}) < \eta, \\ d((p_\varepsilon(t'+\varepsilon s), y_\varepsilon(t'+\varepsilon s)), \boldsymbol{L}) < \eta. \end{gathered} \tag{5.6}$$

Construct a sequence $t_{i+1} = t_i + \varepsilon s_0$, $i = 0, k-1$, $t_0 = 0, t_{k+1} = 1$ such that $1 - t_k < \varepsilon s_0$. Then since $t_0 \in R_\varepsilon$ we obtain from (5.6) that $t_i \in R_\varepsilon$ for $i = 1, k-1$. Then from (5.6) it follows that for $i = 0, k$,

$$\begin{gathered} \lambda(\{t : t \in [t_i, t_{i+1}], d((p_\varepsilon(t), y_\varepsilon(t)), \boldsymbol{K}) > \eta\}) < \eta(t_{i+1} - t_i), \\ d((p_\varepsilon(t), y_\varepsilon(t)), \boldsymbol{L}) < \eta \quad \forall t \in [t_{i+1}, t_{i+2}]. \end{gathered} \tag{5.7}$$

By an extension of (5.7) to the interval $[0,1]$ and as $\varepsilon s_0 < \Delta_\varepsilon$ we obtain the desired result. This completes the proof. □

LEMMA 5.4. *Suppose that Assumptions* 3.1–3.5 *are fulfilled and the function $u_\varepsilon(\cdot)$ is a relatively slow measurable control. Furthermore, assume that $(x_\varepsilon(t), y_\varepsilon(t))$ for small ε can be extended to $t \in [0,1]$ and there exists a compact set C, $C \subset \operatorname{graph} G$, such that*

$$\lambda\{t : (u_\varepsilon(t), x_\varepsilon(t), y_\varepsilon(t)) \notin C\} \to 0 \text{ as } \varepsilon \to 0. \tag{5.8}$$

Then the distance $\boldsymbol{\rho}(\delta_{y_\varepsilon}, \mu_\varepsilon)$ tends to 0 as $\varepsilon \to 0$. Here $\mu_\varepsilon(t) = \nu(u_\varepsilon(t), x_\varepsilon(t))$ is invariant for the flow $\phi(\tau, u_\varepsilon(t), x_\varepsilon(t), y)$ for any t fixed.

Proof. Denote $p_\varepsilon(t) = (u_\varepsilon(t), x_\varepsilon(t))$. Take any bounded uniformly continuous function $h(t,y) : [0,1] \times \mathbb{R}^n$ and an arbitrary $\eta > 0$. Define the set

$$I_\varepsilon = \{t : (p_\varepsilon(t), y_\varepsilon(t)) \notin C\}.$$

From Propositions 2.4 and 2.7 it follows that there exists an $s_0 > 0$ such that for $t \in [0,1] \setminus I_\varepsilon$

$$\left| \int_{\mathbb{R}^n} h(t,y)\nu(p_\varepsilon(t))(dy) - \frac{1}{s_0}\int_0^{s_0} h(t, \phi(\tau, p_\varepsilon(t), y_\varepsilon(t)))\, d\tau \right| < \frac{\eta}{4}. \tag{5.9}$$

Note that

$$\int_0^1 h(t, y_\varepsilon(t))\, dt = \int_{-\varepsilon\tau}^{1-\varepsilon\tau} h(t+\varepsilon\tau, y_\varepsilon(t+\varepsilon\tau))\, d\tau.$$

Since h is bounded and uniformly continuous, we can find a positive $\varepsilon_1 > 0$ such that for $\varepsilon < \varepsilon_1$ and $\tau \in [0, s_0]$

$$\left| \int_0^1 h(t, y_\varepsilon(t))\, dt - \int_0^{1-\varepsilon_1 s} h(t, y_\varepsilon(t+\varepsilon\tau))\, dt \right| < \frac{\eta}{4}. \tag{5.10}$$

A change of time scale t to $\tau = (t-t')/\varepsilon$ yields that $y_\varepsilon(t'+\varepsilon\tau)$ solves the equation

$$\frac{dy}{d\tau} = g(p_\varepsilon(t'+\varepsilon\tau), y), \qquad y(0) = y_\varepsilon(t'). \tag{5.11}$$

The flow $\phi(\tau, p_\varepsilon(t'), y_\varepsilon(t'))$ for t' fixed solves the following equation:

$$\frac{dy}{d\tau} = g(p_\varepsilon(t'), y), \qquad y(0) = y_\varepsilon(t'). \tag{5.12}$$

Denote

$$n(\varepsilon, t') = \frac{1}{s_0}\int_0^{s_0} d_P(p_\varepsilon(t'+\varepsilon\tau), p_\varepsilon(t'))\, d\tau.$$

Take $\theta > 0$ such that if $n(\varepsilon, t') < \theta$, then for $\tau \in [0, s_0]$ the solutions of (5.11) and (5.12) satisfy

$$w(|y_\varepsilon(t'+\varepsilon\tau) - \phi(\tau, p_\varepsilon(t'), y_\varepsilon(t'))|) < \frac{\eta}{4}. \tag{5.13}$$

Here the function $w(s)$ is the modulus of continuity of the function $h(t, y)$. Such a θ exists by standard continuous dependence arguments.

Define the set T_ε:

$$T_\varepsilon = \{t' : n(\varepsilon, t') \geq \theta\}.$$

By property $x_\varepsilon(t)$ and $u_\varepsilon(t)$ (Definition 5.1) $\lambda(T_\varepsilon) \to 0$ as $\varepsilon \to 0$. This implies that there exists an $\varepsilon_2 > 0$ (and $\varepsilon_2 \leq \varepsilon_1$) such that for $\varepsilon < \varepsilon_2$ we get

$$\int_{I_\varepsilon} h(t, y_\varepsilon(t))\, dt + \int_{T_\varepsilon} h(t, y_\varepsilon(t+\varepsilon\tau))\, dt < \frac{\eta}{4}. \tag{5.14}$$

Then from (5.9), (5.10), (5.13), and (5.14) we obtain that for $\varepsilon < \varepsilon_2$

$$\left| \int_0^1 h(t, y_\varepsilon(t))\, dt - \int_0^1 \left(\int_{\mathbb{R}^n} h(t, y)\nu(p_\varepsilon(t))(dy) \right) dt \right| < \eta.$$

This implies that $\boldsymbol{\rho}(\delta_{y_\varepsilon}(t), \nu(p_\varepsilon(t))) \to 0$, which completes the proof. □

6. Approximating properties of the limit problem: The main results. In this section we present the main approximating properties of the limit control problem (3.1) and the relaxed limit problem (4.3).

Approximation of relaxed controls by relatively slow controls.

Claim 6.1. Let $v_0(\cdot) \in \mathcal{V}$ be an arbitrary relaxed control. Then

(i) there exists a relatively slow *measurable* control $u_\varepsilon(\cdot)$ statistically converging to $v_0(\cdot)$ as $\varepsilon \to 0$;

(ii) there exists a relatively slow *piecewise continuous* control $u_\varepsilon(\cdot)$ statistically converging to $v_0(\cdot)$ as $\varepsilon \to 0$;

(iii) if U is a convex subset of a separable Banach space, there exists a relatively slow continuous control $u_\varepsilon(\cdot)$ statistically converging to $v_0(\cdot)$ as $\varepsilon \to 0$. Moreover, for any $u^0 \in U$ there exists a relatively slow continuous control $u_\varepsilon(\cdot)$ statistically converging to $v_0(\cdot)$ and such that $u_\varepsilon(0) = u_0$ for any ε.

Proof. The result directly follows from Proposition 4.1, Corollaries 4.2 and 4.3, and Remark 5.2. □

Convergence result with continuous control. We establish now the first convergence result. We refer to the original ε-problem, the limit problem, and the limit relaxed problem. Let $v_0(\cdot)$ be an arbitrary admissible relaxed control defined in (4.1). Let the pair $(x_0(t), \mu_0(t))$ be the trajectory of (4.3) induced by $v_0(t)$. Let the pair $(x_\varepsilon(t), y_\varepsilon(t))$ be the trajectory of (1.1)–(1.2) induced by the control $u_\varepsilon(t)$ and an initial data $x^0_\varepsilon \to x^0$ and $y^0_\varepsilon \to y^0$. Note that if $u_\varepsilon(\cdot)$ is a relatively slow continuous control, then by Lemma 5.3 this trajectory indeed exists on $[0,1]$ and the triple $(u_\varepsilon(t), x_\varepsilon(t), y_\varepsilon(t))$ is included in $graph\, G$ if $(u_\varepsilon(0), x_\varepsilon(0), y_\varepsilon(0))$ is in a compact set E of $graph\, G$ for all $\varepsilon > 0$ small enough.

THEOREM I. *Under Assumptions* 3.1–3.5*, suppose that there exists a relatively slow continuous control $u_\varepsilon(\cdot)$ converging to $v_0(\cdot)$, and a compact set $E \subset graph\, G$ such that $(u_\varepsilon(0), x_\varepsilon(0), y_\varepsilon(0)) \in E$ for all $\varepsilon > 0$ small enough. Then*

(i) $\sup_{t\in[0,1]} |x_\varepsilon(t) - x_0(t)| \to 0$ *as* $\varepsilon \to 0$*;*

(ii) $y_\varepsilon(t)$ *statistically converges to the measure-valued function* $\mu_0(t)$*, where* $\mu_0(t) = \bar\nu(v_0(t), x_0(t))$*;*

(iii) $J_\varepsilon(u_\varepsilon) \to \bar J_0(v_0)$ *as* $\varepsilon \to 0$*.*

COROLLARY 6.2. *Suppose that $v_0(t) = \delta_{u_0}(t)$ where $u_0(\cdot) \in \mathcal{U}^c$. Then under Assumptions* 3.1–3.5 *if $y^0 \in G(u_0(0), x^0)$, then the trajectory $(x_\varepsilon(t), y_\varepsilon(t))$ and the cost $J_\varepsilon(u)$ of the ε-system induced by the control $u_0(t)$ converge, respectively, to the trajectory $(x_0(t), \mu_0(t))$ and the cost $J_0(u_0)$ of the limit system* (3.1)*. This convergence is uniform for (x^0, y^0) in compact sets of the graph $G(u_0(0), \cdot)$.*

Proof. It follows immediately from Theorem I. □

Remark 6.3. Corollary 6.2 coincides with [AV, Theorem II], where the result has been proved for uncontrolled systems.

Remark 6.4. For some $u^0 \in U$ take a compact set $H \subset graph\, G(u^0, \cdot)$. If U is a convex subset of a separable Banach space, then Claim 6.1 implies that there exists a relatively slow continuous control $u_\varepsilon(\cdot)$ converging to $v_0(\cdot)$ and such that $u_\varepsilon(0) = u^0$. In this case if $(x^0, y^0) \in H$, then the ε-system can always approximate any trajectories and the cost (in particular, the value) of the limit relaxed problem. But if U is not convex, then, in general, this approximation does not work.

Example 6.5. We provide now an example illustrating the convergence result in Theorem I. (Compare with [AV, Example 7.4].)

Consider the system with $U = [2,4]$, $x \in \mathbb{R}$, and $y = (y_1, y_2) \in \mathbb{R}^2$:

$$\begin{aligned} \dot x &= 2\frac{y_1^2}{|y|} - 3x, \\ \varepsilon \dot y_1 &= y_1\left(1 - \frac{|y|}{xu}\right) - y_2, \\ \varepsilon \dot y_2 &= y_2\left(1 - \frac{|y|}{xu}\right) + y_1, \\ x(0) &= x^0, \quad y(0) = y^0. \end{aligned}$$

Here by $|y|$ we denote the Euclidean norm of the vector y. Define

$$Q(u,x,y) = (x-1)^2 + (u-2)^2(u-4)^2 + y_1.$$

Then

$$J_\varepsilon(u) = \int_0^1 (x_\varepsilon(t) - 1)^2 + (u(t) - 2)^2(u(t) - 4)^2 + y_{1,\varepsilon}(t)\, dt.$$

The fast system for $u > 0, x > 0$ fixed, converges to the limit cycle $|y| = ux$ if $|y(0)| \neq 0$. The sets $G(u,x)$ and $K(u,x)$ can be chosen as follows: $G(u,x) = \{y : 3ux > |y| > 0\}$ and $K(u,x) = \{(y : |y| = xu\}$. The prolongation $L(u,x)$ of $K(u,x)$ coincides with $K(u,x)$. It is easily checked that all conditions of Theorem I are satisfied. The invariant measure $\nu(u,x)$ is equally distributed on the circle $|y| = xu$, namely,

$$\nu(u,x)(A) = \frac{1}{2\pi}\int_0^{2\pi} \chi_A(ux\cos\theta, ux\sin\theta)\,d\theta,$$

where $A \subset \mathbb{R}^2$ and χ_A is the indicator function of the set A. Then it is easy to see that the limit problem has the following form:

$$\begin{aligned} &\text{minimize} \int_0^1 (x(t)-1)^2 + (u(t)-4)^2(u(t)-2)^2\,dt \\ &\text{subject to } \dot{x} = x(u(t)-3); \quad x(0) = x^0, \\ &\mu(t) = \nu(u(t), x(t)). \end{aligned} \tag{6.1}$$

Thus the slow solution $x_\varepsilon(t)$ tends to $x_0(t) = x^0\exp(\int_0^t (u(t)-3)\,dt)$, while the fast solution tends to the measure-valued function $\nu(u(t), x_0(t))$. Suppose that $x^0 = 1$. It is easy to see that the optimization problem (6.1) does not have an optimal solution. The infimal cost in this problem is zero, but clearly it cannot be achieved with an ordinary control. But we can construct a sequence of controls u_k such that $J_0(u_k) \to 0$. To do this we define the relaxed limit problem in the following form:

$$\begin{aligned} &\text{minimize} \int_0^1 (x(t)-1)^2 + \int_U (u-4)^2(u-2)^2\,v(t)(du)dt \\ &\text{subject to } \dot{x} = x\int_U (u-3)\,v(t)(du), \\ &\mu(t) = \int_U \nu(u, x(t)\,v(t)(du). \end{aligned}$$

The optimal relaxed control $v_0(\cdot)$ assigns to each t the values 2 and 4 with equal probability. Then $\dot{x}_0(t) = 0$ and $x_0(t) = x^0 = 1$, and $\mu(t) = 1/2\nu(2,1) + 1/2\nu(4,1)$. The relaxed control can certainly be approximated by the sequence of continuous controls $\tilde{u}_k$ which can be defined as follows. The interval $[0,1]$ can be divided on $2k$ intervals of length $1/k - 1/k^2$ and $1/k^2$ where the small and large intervals alternate. Then $\tilde{u}_k(t)$ is chosen equal to 2 or 4 on the large alternate intervals and affine on the small intervals.

We now have to find a relatively slow continuous control $u_\varepsilon(t)$ statistically converging to $v_0(t)$ and such that $y^0 \in G(u_\varepsilon(0), 1)$. Suppose that $y^0 = (1,0)$. Then $(1,0) \in G(u,1)$ for $u \in [2,4]$ and we can take any initial values of $u_\varepsilon(0)$. To find u_ε we should define the functions $M(z)$ and Δ_ε. Take $\Delta_\varepsilon = \sqrt{\varepsilon}$ and $M(z) = z$. Define an integer-valued function $k(\varepsilon)$ such that $k(\varepsilon) < \varepsilon^{-1/4}$. Then it is easy to verify that $u_\varepsilon(t) = \tilde{u}_{k(\varepsilon)}$ is a relatively slow continuous control with respect to the given $M(z)$ and Δ_ε.

Suppose now that the set U is not convex and consists only of two points 2 and 4. Namely, $U = \{2,4\}$. Then we have only two admissible continuous functions $u(t) \equiv 2$

or 4 which certainly cannot approximate the relaxed control v_0. We should take a piecewise continuous control to approximate the optimal solution of the limit relaxed problem.

However, if $u(\cdot)$ is a piecewise continuous function, then the assumptions of Theorem I are not enough to provide the convergence result even in the case when the invariant measure is a Dirac measure; namely, the reduced order system (1.4) can be defined.

Example 6.6. Consider only the fast equation with $u(t) \in U = [1/2, 1]$,

$$\varepsilon \dot{y} = y\left(1 - \frac{y}{2u}\right)\left(1 - \frac{y}{u}\right);\ y(0) = y^0 > 0.$$

Then we can define the open set $G(u) = (0, 2u)$ and the corresponding compact $K(u) = \{u\}$. All conditions of Theorem I are satisfied. Suppose now that $u(t)$ is the piecewise constant function $u(t) = 1$ if $t \in [0, 1/2]$ and $u(t) = 1/2$ if $t \in [1/2, 1]$. Then if $y^0 > 1$, at time $t = 1/2$, set $G(u(t)) = G(1)$ switches to $G(1/2) = (0, 1)$ and the fast solution $y_\varepsilon(1/2) > 1$, and therefore $y_\varepsilon(t) \notin G(1/2)$. Thus $y_\varepsilon(t)$ goes to infinity as $\varepsilon \to 0$ and the desired convergence does not hold.

Convergence result with piecewise continuous controls.

Assumption 6.7. There exists a set $G(u, x)$ such that for any $u \in U, u' \in U$, and x, the following inclusion is valid: $G(u, x) \supset L(u', x)$.

Note that in Example 6.6 there is no $G(u, x)$ satisfying Assumption 6.7.

Remark 6.8. Assumption 6.7 is satisfied automatically if $G(u, x)$ can be found not depending on u.

The following theorem extends Theorem I to the case where $u_\varepsilon(\cdot)$ is a relatively slow piecewise continuous control. Notice that if Assumption 6.7 is satisfied then there exists a compact set H such that $H \subset G(u, \cdot)$ for any $u \in U$.

THEOREM II. *Suppose that Assumptions* 3.1–3.5*, Lemma* 3.6*, Remark* 3.7*, and Assumption* 6.7 *are fulfilled. Let $u_\varepsilon(\cdot)$ be a relatively slow piecewise continuous control statistically converging to $v_0(\cdot)$. Let H be a compact subset of graph $G(u_\varepsilon(0), \cdot)$ for any ε and $(x^0_\varepsilon, y^0_\varepsilon) \in H$. Then all statements of Theorem* I *hold.*

COROLLARY 6.9. *Suppose that $v_0(t) = \delta_{u_0}(t)$, where $u_0(\cdot) \in \mathcal{U}^p$. Then under Assumptions* 3.1–3.5 *and* 6.7 *and Lemma* 3.6 *if $(x^0, y^0) \in H$, the trajectory $(x_\varepsilon(t), y_\varepsilon(t))$ and the cost $J_\varepsilon(u)$ of the ε-system induced by the control $u_0(t)$ converge, respectively, to the trajectory $(x_0(t), \mu_0(t))$ and the cost $J_0(u_0)$ of the limit system* (3.1)*. This convergence is uniform for $(x^0, y^0) \in H$.*

Proof. It follows directly from Theorem II. □

Remark 6.10. Take a compact set $H \subset graph\, G(w, \cdot)$ for all $w \in U$. By Assumption 6.7 such an H exists. Therefore if $(x^0, y^0) \in H$, then the ε-system can always approximate any trajectories and the cost (in particular the value) of the limit relaxed problem if the family $\mathcal{U}^p_\varepsilon$ is applied.

Example 6.11. Consider the system from Example 6.5 and suppose that $U = \{2, 4\}$. Note that the prolongation of the set $K(u, x)$ coincides in this example with $K(u, x)$, namely $L(u, x) = K(u, x) = \{y : |y| = xu\}$. Recall that we take $G(u, x) = \{y : 3ux > |y| > 0\}$. Since $6x > 4x$ we see that Assumption 6.7 is fulfilled. Then if we define $\Delta_\varepsilon = \sqrt{\varepsilon}$, we can take a relatively slow piecewise continuous control which is equal to 2 or to 4 on alternative intervals with the same length equal to $\delta(\varepsilon)$ converging to zero and such that $\delta(\varepsilon) \geq \sqrt(\varepsilon)$.

Remark 6.12. We emphasize that piecewise continuous functions considered by us have only discontinuities of the first type. The next example illustrates the case

when discontinuity of a control $u_\varepsilon(\cdot)$, even at a single point (say, $t=0$), may falsify the consequences of Theorem II and even Corollary 6.9 if the right limit $u(0^+)$ does not exist.

Example 6.13. This example employs the same idea of resonance as in [AV, Example 9.2]. We could use the example from [AV], but let us show that the same phenomenon arises in control systems which are linear with respect to control. We shall show that even the convergence result in Corollary 6.9 does not hold in general if we deal with measurable controls. We consider the case when $u_0(t)$ has only the discontinuity of the second type in 0.

Define a nonlinear two-dimensional controlled oscillator with $U=[-1,1]$ as follows:

$$\begin{aligned} \frac{dy_1}{d\tau} &= y_2, \\ \frac{dy_2}{d\tau} &= -k\left(1-\frac{|y|}{4}\right)y_2 - y_1 + \beta(y)u. \end{aligned} \tag{6.2}$$

Here $k>0$ is small and

$$\beta(y)=\begin{cases} 1, & |y|<4, \\ 2(1-\frac{|y|}{8}), & 8>|y|\geq 4, \\ 0, & |y|\geq 8. \end{cases}$$

The corresponding fast system for $t\in[0,1]$ has the following form:

$$\varepsilon\dot{y}=g(u,y); \qquad g(u,y)=\begin{pmatrix} y_2 \\ -k(1-\frac{|y|}{4})y_2 - y_1 + \beta(y)u \end{pmatrix}. \tag{6.3}$$

For u fixed, the point $(u,0)$ is asymptotically stable for (6.2) if $|y(0)|<4$. For any u fixed, the sets $K(u)$ and $G(u)$ can be defined as follows: $K(u)=\{(u,0)\}$ and $G(u): G(u)=\{(y_1,y_2):(y_1-u)^2+y_2^2<9\}$. It is clear that for any $u\in[-1,1]$

$$\{y:|y|<2\}\subset G(u)\subset\{y:|y|<4\}.$$

The prolongation $L(u)$ of $K(u)$ coincides with $K(u)$ in this example. Namely $L(u)=K(u)$ and then $L(u)\subset G(v)$ for any $u,v\in[-1,1]$. All assumptions of Theorem II are satisfied, and we can guarantee the statistical convergence of the solution $y_\varepsilon(t)$ of (6.3) to the measure $\delta_{(u(t),0)}$ if any piecewise continuous control $u(\cdot)$ is applied and if $|y_\varepsilon(0)|<4$. In this example the statistical convergence of $y_\varepsilon(t)$ is reduced to the L^1 convergence to the function $(u(t),0)$ (see [A3, Remark 4.4]). Besides for small ε: $y_\varepsilon(t)\in G(u(t))$ and therefore $|y_\varepsilon(t)|<4$.

Suppose now that in (6.2) $u=\sin(\tau)$. Then it can be proved that for small k because of the resonance, the solution tends to infinity for any initial condition. This convergence is uniform with respect to $y(0)$ in compact sets of the set $\{y:|y|<8\}$. Since for $|y(0)|\geq 8$ the solution $y(\tau)$ never comes back in the ball $\{y:|y|<8\}$ we conclude that there exists a number $T>0$ such that for any initial data $y(0)$ we have $y(T)>8$.

Now we are ready to construct a control $u_0(t)$ which is continuous on $(0,1]$ and such that for any $y^0\in G(u(0))$, $y_\varepsilon(t)$ does not converge to the function $(u_0(t),0)$. As in [AV, Example 9.2] we identify a sequence of disjoint intervals $[a_j,b_j]$ with $a_j>0$ and $a_j,b_j\to 0$ as $j\to\infty$. Next we denote $\varepsilon_j=(b_j-a_j)T^{-1}$.

Define $u_0(t)$ as follows:
(1) $u_0(0) = 0$.
(2) For $t \in [a_j, b_j]$ let $u_0(t) = \sin(\varepsilon_j^{-1}(t - a_j))$.
(3) For $t \in (b_j, a_{j-1})$ define $u_0(t)$ such that $u_0(t)$ becomes continuous on $[b_j, a_{j-1}]$.
Note that $u_0(0^+)$ does not exist.

Consider now the solution $y_\varepsilon(t)$ with $|y_\varepsilon(0)| < 2$ (namely, $y_\varepsilon(0) \in G(u)$ for all $u \in [-1, 1]$) and take a sequence $\varepsilon_j \to 0$. Then by the properties of the sequence a_j, b_j for any j large, we have $|y_{\varepsilon_j}(b_j)| > 8$ and therefore $|y_{\varepsilon_j}(t)| > 8$ for all $t \in [b_j, 1]$. So $y_{\varepsilon_j}(t)$ stays away from the set $\{(y_1, y_2) : y_1 \in [-1, 1], y_2 = 0\}$ for $t \in [b_j, 1]$ and cannot converge to the function $(u(t), 0)$. The counterexample is complete.

Convergence result with measurable controls. We present now a similar result as in Theorems I and II but in the general case when the relatively slow measurable control is applied. An additional condition of the following theorem may not seem constructive since it is difficult to check it in the general case. However we shall display an assumption and the corresponding example when these conditions are fulfilled automatically.

THEOREM III. *Suppose that Assumptions* 3.1–3.5 *are satisfied. Let $v_0(\cdot)$ be a relaxed control and $u_\varepsilon(t)$ be a relatively slow measurable control statistically converging to $v_0(t)$. Let H be a compact subset of $\mathbb{R}^m \times \mathbb{R}^n$, $(x_\varepsilon^0, y_\varepsilon^0) \in H$, and $(x_\varepsilon^0, y_\varepsilon^0) \to (x^0, y^0)$. Assume, additionally, that there exists a compact set $\boldsymbol{C} \subset \mathit{graph}\, G$ such that*

$$\lambda(\{t : (u_\varepsilon(t), x_\varepsilon(t), y_\varepsilon(t)) \notin \boldsymbol{C}\}) \to 0 \text{ as } \varepsilon \to 0. \tag{6.4}$$

Then all convergence statements of Theorem I *hold.*

Remark 6.14. It is easy to show that condition (6.4) (which is identical to (5.8) in Lemma 5.4) actually is a necessary condition for the desired convergence in Theorems I and II. We omit the details. Notice just that in Example 6.13 the fast motion $y_\varepsilon(t)$ goes to infinity as $\varepsilon \to 0$ for $t \in [\delta, 1]$, where $\delta > 0$ is an arbitrary fixed positive number. Thus the desired convergence cannot hold.

The following assumption implies condition (6.4) of Theorem III. Recall that by Remark 2.5, the set $G(u, x)$ may be taken closed and upper semicontinuous in (u, x) if the existence of the triple $(u_\varepsilon(t), x_\varepsilon(t), y_\varepsilon(t)) \in \mathit{graph}\, G$ for $t \in [0, 1]$ is known a priori.

Assumption 6.15. Suppose that G is compact and does not depend on u, x. Assume additionally that for any measurable function $u(\tau) : \mathbb{R}_+ \to U$, x fixed and $y^0 \in G$, the solution of the system

$$\frac{dy}{d\tau} = g(u(\tau), y, x), \quad y(0) = y^0, \quad x\text{-fixed}, \tag{6.5}$$

is unique and is included in the set G for any $\tau \geq 0$. We denote this by $\pi(\tau, u, x, y)$.

LEMMA 6.16. *Assume that $y^0 \in G$ and $x^0 \in X_0$, where X_0 is a compact subset of $\mathbb{R}^m$. Then under Assumptions* 3.1, 3.3–3.5, *and* 6.15 *there exists a compact $X \subset \mathbb{R}^m$ such that for any $\varepsilon > 0$ and any measurable $u_\varepsilon(t)$, the solution of the ε-system exists uniquely for $t \in [0, 1]$ and $x_\varepsilon(t) \in X$, $y_\varepsilon(t) \in G$.*

Proof. From Assumption 6.15 we immediately see that the solution of (6.5) exists uniquely for any $\tau \geq 0$ if x is a piecewise constant function. Take an arbitrary $\varepsilon > 0$ and let $\tau' = \varepsilon^{-1}$. Then since any continuous function on $[0, \tau']$ can be approximated uniformly by a sequence of piecewise constant functions, we see by the continuous dependence and compactness arguments that for $\tau \in [0, \tau']$ the solution of (6.5) exists uniquely and is included in G for any continuous function $x(\tau)$. After changing

the time scale from τ to $t = \varepsilon\tau$ and from Assumption 3.3, we obtain the desired result. □

Lemma 6.16 immediately implies that under Assumption 6.15 the conditions of Theorem III are fulfilled. Indeed the set C can be defined then as the product $C = U \times X \times G$. Moreover $(u_\varepsilon(t), x_\varepsilon(t), y_\varepsilon(t)) \in C$ for every $t \in [0,1]$. In the following example we consider a case in which Assumption 6.15 is satisfied.

Example 6.17. This example displays the convergence result if any measurable function $u(\cdot)$ is applied. The fast subsystem is defined on $\mathbb{R}^2$ and is presented in polar coordinates (r, θ):

$$\begin{aligned} \dot{x} &= f(x, r, \theta, u); x(0) = x^0, \\ \varepsilon\dot{r} &= r(1-r);\ r(0) = r^0, \\ \varepsilon\dot{\theta} &= \sin^2(\theta/2) + ux^2;\ \theta(0) = \theta^0. \end{aligned}$$

Here $u(t) \in [0,1]$. The associated system has the following form:

$$\begin{aligned} \frac{dr}{d\tau} &= r(1-r), \\ \frac{d\theta}{d\tau} &= \sin^2\left(\frac{\theta}{2}\right) + ux^2. \end{aligned}$$

It is clear that the sets $G = \{(r,\theta)) : a \le |r| \le b\}$ are positively invariant for $0 < a < 1 < b$ if any measurable $u(\tau)$ is used. We can also define $K = L = G$. Hence all conditions of Lemma 6.16, and thus of Theorem III, are satisfied.

For $ux^2 > 0$ the system has a stable limit cycle and the unique invariant measure $\nu(u,x)$ which is supported on the circle $\{y : |y| = 1\}$ with density $\beta(u,x,\theta)$ for $\theta \in [0, 2\pi]$ given by

$$\beta(u,x,\theta) = \left((\sin^2\left(\frac{\theta}{2}\right) + ux^2) \int_0^{2\pi} \frac{ds}{\sin^2(\frac{s}{2}) + ux^2} \right)^{-1}.$$

If $ux^2 = 0$ then the system has an attracting point $r = 1, \theta = 0$ and the unique invariant measure is a Dirac measure concentrated at the point $(1,0)$.

Thus for all measurable $u(\cdot)$ the solutions of the original system converge to the solution of the limit system:

$$\begin{aligned} \dot{x} &= \int_0^{2\pi} f(x,1,\theta)\nu(u,x)(d\theta);\ x(0) = x^0, \\ \nu(u,x)(d\theta) &= \begin{cases} \beta(u,x,\theta)d\theta, & ux^2 > 0, \\ \delta(\theta)d\theta, & ux^2 = 0. \end{cases} \end{aligned}$$

(Here $\delta(\cdot)$ is the delta-function.)

If we take a relaxed control $v(t)$, we can find a relatively slow measurable control $u_\varepsilon(t)$ statistically converging to $v(t)$ and such that the corresponding trajectory $(x_\varepsilon(t), y_\varepsilon(t))$ converges to the trajectory of the relaxed limit problem

$$\begin{aligned} \dot{x} &= \int_U \left(\int_0^{2\pi} f(x,1,\theta)\nu(u,x)(d\theta) \right) v(\tau)(du);\ x(0) = x^0, \\ \bar{\nu}(v(\tau),x) &= \int_U \nu(u,x)v(\tau)(du). \end{aligned}$$

Continuity of the value. The last result of this paper deals with continuity of the value of the ε-problem with respect to ε on the families of relatively slow controls, namely, $\mathrm{val}_\varepsilon(\mathcal{U}_\varepsilon) \to \mathrm{val}_0(\mathcal{U})$. Note that in general the convergence $\mathrm{val}_\varepsilon(\mathcal{U})$ to $\mathrm{val}_0(\mathcal{U})$ does not hold. Sometimes we can find a control $u_\varepsilon(t)$ such that the cost $J_\varepsilon(u_\varepsilon)$ may be much less than $\mathrm{val}_0(\mathcal{U})$. Usually a phenomenon of resonance and nonconvexity of the cost function Q is employed. We refer to Gaitsgory [G1, G2] for various examples.

Example 6.18. Consider the fast system of Example 6.13. Define $Q(u,y) = u^2 - |y|^2$. The limit system is defined only by the algebraic equation $y_1 = u, y_2 = 0$. Then $Q(u,y)$ is equal to zero on admissible trajectories and thus $\mathrm{val}_0(\mathcal{U}) = 0$. On the other hand if we apply a control $u = \sin(t/\varepsilon)$ to the fast system we obtain $|y_\varepsilon(t)| \to \infty$ as $\varepsilon \to 0$ for $t \in (0,1]$. Therefore $\mathrm{val}_\varepsilon(\mathcal{U}) \to -\infty$ as $\varepsilon \to 0$ and the limit control problem cannot approximate optimal or near optimal trajectories of the ε-system.

Remark 6.19. In the classic case where the invariant measure $\nu(u,x)$ is concentrated on the point $q(u,x)$ (the reduced system (1.4),(1.5) is well defined) the conditions under which $\mathrm{val}_\varepsilon(\mathcal{U}) \to \mathrm{val}_0(\mathcal{U})$ can be found for instance in Bensoussan [Be] and Gaitsgory [G1, G2]. However, for the general model, to the best of the author's knowledge, the conditions for the validity of this approximation still have not been provided.

THEOREM IV. *Suppose that Assumptions* 3.1–3.5 *and Lemma* 3.6 *are satisfied. Let $v_0(\cdot)$ be the optimal relaxed control for the limit problem. Then*

(i) *if U is convex, then* $\mathrm{val}_\varepsilon(\mathcal{U}^c_\varepsilon) \to \mathrm{val}_0(\mathcal{U}^c) = \mathrm{val}_0(\mathcal{U}^m)$*;*

(ii) *if Assumption* 6.7 *is fulfilled, then* $\mathrm{val}_\varepsilon(\mathcal{U}^p_\varepsilon) \to \mathrm{val}_0(\mathcal{U}^p) = \mathrm{val}_0(\mathcal{U}^m)$*;*

(iii) *if there exists a compact $C \subset \mathit{graph}\, G$ such that* (5.8) *is satisfied for any $u_\varepsilon(\cdot) \in \mathcal{U}^m_\varepsilon$, then* $\mathrm{val}_\varepsilon(\mathcal{U}^m_\varepsilon) \to \mathrm{val}_0(\mathcal{U}^m)$*;*

(iv) *if in* (i)–(iii) *$u_\varepsilon(\cdot)$ statistically converges to $v_0(\cdot)$, then $|J_\varepsilon(u_\varepsilon) - \mathrm{val}_\varepsilon(\mathcal{U}_\varepsilon)| \to 0$ for the corresponding family of relatively slow controls.*

Proof. Theorems I–III with Claim 6.1 imply upper semicontinuity of $\mathrm{val}_\varepsilon(\mathcal{U}_\varepsilon)$ where $\mathcal{U}_\varepsilon$ is a corresponding family of relatively slow controls. Indeed, for $u_\varepsilon(\cdot) \to v_0(\cdot)$ we have that

$$\mathrm{val}_\varepsilon(\mathcal{U}_\varepsilon) \le J_\varepsilon(u_\varepsilon) \quad \text{and} \quad J_\varepsilon(u_\varepsilon) \to \mathrm{val}_0(\mathcal{U}^m).$$

This implies that $\limsup \mathrm{val}_\varepsilon(\mathcal{U}_\varepsilon) \le \mathrm{val}_0(\mathcal{U}^m)$.

Lower semicontinuity follows from the compactness of the family $\mathcal{V}$ (Proposition 4.1). The pair $(x_\varepsilon(t), y_\varepsilon(t))$ for each ε takes value in a compact set. Then by continuity properties of the function Q, the value $\mathrm{val}_\varepsilon(\mathcal{U}_\varepsilon)$ is finite for each ε. Take $u_\varepsilon(\cdot) \in \mathcal{U}_\varepsilon$ such that $J_\varepsilon(u_\varepsilon) - \mathrm{val}_\varepsilon(\mathcal{U}_\varepsilon)$ tends to zero. Take any sequence $\varepsilon_k \to 0$ as $k \to \infty$ and find a subsequence $\varepsilon_{k(j)}$ such that $u_{\varepsilon_{k(j)}}$ tends to some $v(\cdot) \in \mathcal{V}$. Then from Theorems I–III we have that $J_{\varepsilon_{k(j)}}(u_{\varepsilon_{k(j)}}) \to J_0(v) \ge \mathrm{val}_0(\mathcal{U}^m)$ and therefore as the sequence ε_j is arbitrary, we have

$$\liminf \mathrm{val}_\varepsilon(\mathcal{U}_\varepsilon) \ge \mathrm{val}_0(\mathcal{U}^m).$$

Then $\lim \mathrm{val}_\varepsilon(\mathcal{U}_\varepsilon) = \mathrm{val}_0(\mathcal{U}^m)$, and this completes the proof of (i)–(iii). The proof of (iv) follows immediately from Theorems I–III and (i)–(iii). □

7. Proof of Theorems I–III. Let $E \subset \mathit{graph}\, G$ be a compact set. The first part of the proof verifies that the trajectories $x_\varepsilon(t)$ of the solution $(x_\varepsilon(t), y_\varepsilon(t))$ of (1.1), induced by a control function $u_\varepsilon(\cdot)$ and initial conditions $(u_\varepsilon(0), x^0_\varepsilon, y^0_\varepsilon)$ in E, indeed converge to the x-trajectory $x_0(t)$ of (3.1).

Note that $x_\varepsilon(t)$ solves the differential equation

$$\dot{x} = f(u_\varepsilon(t), x, y_\varepsilon(t)), \quad x(0) = x^0_\varepsilon, \tag{7.1}$$

which is a time-varying equation. Our method now is to modify (7.1) and construct a differential equation

$$\dot{x} = f_\varepsilon(t,x) \tag{7.2}$$

which, on the one hand has $x_\varepsilon(t)$ as a solution and on the other hand will converge to the equation (3.2) as $\varepsilon \to 0$ in a sense that guarantees the continuous dependence of solutions. The function $f_\varepsilon(t,x)$ is constructed as follows:

$$\begin{aligned} f_\varepsilon(t,x) = \alpha(\varepsilon,x,t)\int_{\mathbb{R}^n} f(u_\varepsilon(t),x,y)\nu(u_\varepsilon(t),x)(dy) \\ +(1-\alpha(\varepsilon,x,t))f(u_\varepsilon(t),x,y_\varepsilon(t)) \end{aligned} \tag{7.3}$$

with $\alpha(\varepsilon,x,t)$ given by

$$\alpha(\varepsilon,x,t) = \begin{cases} 0, & |x-x_\varepsilon(t)| \le \varepsilon, \\ |x-x_\varepsilon(t)|/\varepsilon - 1, & \varepsilon < |x-x_\varepsilon(t)| \le 2\varepsilon, \\ 1, & |x-x_\varepsilon(t)| > 2\varepsilon. \end{cases} \tag{7.4}$$

Note that $\alpha(\varepsilon,x_\varepsilon(t),t) \equiv 0$ and hence $x_\varepsilon(t)$ solves (7.2) as well.

The function $f_0(t,x)$ is defined as follows:

$$f_0(t,x) = \bar{\boldsymbol{f}}(v_0(t),x), \tag{7.5}$$

where we recall that $\bar{\boldsymbol{f}}$ is defined by (4.2) as

$$\bar{\boldsymbol{f}}(v_0,x) = \int_U \left(\int_{\mathbb{R}^n} f(u,x,y)\,\nu(u,x)(dy)\right) v_0(du).$$

We now explain in what sense we claim that $f_\varepsilon(t,x)$ converges to $f_0(t,x)$.

LEMMA 7.1. *Suppose that $\zeta_\varepsilon(t) : [0,1] \to R^n$ are continuous functions, uniformly converging to $\zeta_0(t)$. Then for every $s \in [0,1]$*

$$\int_0^s f_\varepsilon(t,\zeta_\varepsilon(t))dt \to \int_0^s f_0(t,\zeta_0(t))dt, \tag{7.6}$$

if $\boldsymbol{\rho}(\delta_{y_\varepsilon},\mu_\varepsilon) \to 0$ as $\varepsilon \to 0$. Here $\mu_\varepsilon(t) = \nu(u_\varepsilon(t),x_\varepsilon(t))$.

Proof. We interpret the right-hand side of (7.6) as an integral,

$$\int_0^s \bar{\boldsymbol{f}}(v_0(t),\zeta_0(t))\,dt,$$

which by the definition of $\bar{\boldsymbol{f}}$ is given by

$$\int_0^s \int_U \left(\int_{\mathbb{R}^n} f(u,\zeta_0(t),y)\,\nu(u,\zeta_0(t))(dy)\right) v_0(t)(du)\,dt. \tag{7.7}$$

We interpret the left-hand side of (7.6) as an integral,

$$\int_0^s \left(\int_{\mathbb{R}^n} f(u_\varepsilon(t),\zeta_\varepsilon(t),y)\,\beta_\varepsilon(t)(dy)\right) dt, \tag{7.8}$$

with $\beta_\varepsilon(t) : [0,1] \to \mathcal{P}(\mathbb{R}^n)$ a measure-valued function given by

$$\beta_\varepsilon(t) = \alpha(\varepsilon,\zeta_\varepsilon(t),t)\nu_\varepsilon(t) + (1-\alpha(\varepsilon,\zeta_\varepsilon(t),t))\delta_{y_\varepsilon}(t),$$

where

$$\nu_\varepsilon(t) = \nu(u_\varepsilon(t), \zeta_\varepsilon(t)). \tag{7.9}$$

We also define another function $\tilde{\beta}_\varepsilon(t)$ given by

$$\tilde{\beta}_\varepsilon(t) = \alpha(\varepsilon, \zeta_\varepsilon(t), t)\nu_\varepsilon(t) + (1 - \alpha(\varepsilon, \zeta_\varepsilon(t), t))\mu_\varepsilon(t).$$

By definition (7.4) of the function $\alpha(\varepsilon, x, t)$ and continuity of the function $\nu(u, x)$ it follows that $\boldsymbol{\rho}(\tilde{\beta}_\varepsilon, \nu_\varepsilon) \to 0$. By an assumption of the lemma, $\boldsymbol{\rho}(\delta_{y_\varepsilon}, \mu_\varepsilon) \to 0$. Therefore $\boldsymbol{\rho}(\tilde{\beta}_\varepsilon, \beta_\varepsilon) \to 0$ and then $\boldsymbol{\rho}(\beta_\varepsilon, \nu_\varepsilon) \to 0$. Thus from (7.8) we have that for every $s \in [0, 1]$

$$\left| \int_0^s f_\varepsilon(t, \zeta_\varepsilon(t))\, dt - \int_0^s \left(\int_{\mathbb{R}^n} f(u_\varepsilon(t), \zeta_\varepsilon(t), y)\, \nu_\varepsilon(t)(dy) \right) dt \right| \to 0,$$

and hence we have just to prove that

$$\int_0^s \left(\int_{\mathbb{R}^n} f(u_\varepsilon(t), \zeta_\varepsilon(t), y)\, \nu_\varepsilon(t)(dy) \right) dt \to \int_0^s \bar{\boldsymbol{f}}_0(v_0(t), \zeta_0(t))\, dt, \tag{7.10}$$

where the right-hand side is defined in (7.7) But from (7.9) we can interpret the left-hand side of (7.10) as an integral

$$\int_0^s \bar{\boldsymbol{f}}(v_\varepsilon(t), \zeta_\varepsilon(t))\, dt,$$

where $v_\varepsilon(t) = \delta_{u_\varepsilon}(t)$ is a measure-valued interpretation of the ordinary function $u_\varepsilon(t)$. Since $v_\varepsilon(\cdot)$ statistically converges to $v_0(\cdot)$ and $\zeta_\varepsilon(\cdot)$ uniformly converges to $\zeta_0(\cdot)$ and from the uniform continuity of $\bar{\boldsymbol{f}}(v, x)$ on compact sets we conclude that

$$\int_0^s \bar{\boldsymbol{f}}(v_\varepsilon(t), \zeta_\varepsilon(t))\, dt \to \int_0^s \bar{\boldsymbol{f}}(v_0(t), \zeta_0(t))\, dt.$$

This completes the proof. □

LEMMA 7.2. *Under the assumptions of Theorems* I–III, $\boldsymbol{\rho}(\delta_{y_\varepsilon}, \mu_\varepsilon) \to 0$, *where* $\mu_\varepsilon(t) = \nu(u_\varepsilon(t), x_\varepsilon(t))$.

Proof. For Theorem III the result immediately follows from Lemma 5.4. Now define set C as follows:

$$C = \lambda(\{t : d((u_\varepsilon(t), x_\varepsilon(t), y_\varepsilon(t)), \boldsymbol{K}) \le \eta\}), \tag{7.11}$$

where K is defined in (5.5) and η is chosen such that $\boldsymbol{C} \subset \mathit{graph}\, G$. Then under assumptions of Lemma 5.3 (and hence of Theorem I) conditions of Lemma 5.4 are satisfied. Therefore the result follows for Theorem I also. Thus we have to prove the claim of the lemma only for Theorem II, namely, for the case where relatively slow piecewise continuous controls are employed.

We just have to show that statements of Lemma 5.3 hold true. Indeed, let t_ε^i, $i = 1, k(\varepsilon)$ be the points of discontinuity of the function $u_\varepsilon(\cdot)$. Then $t_\varepsilon^{i+1} - t_\varepsilon^i \ge \Delta_\varepsilon$. On each interval $[t_\varepsilon^i, t_\varepsilon^{i+1})$ the function $u_\varepsilon(\cdot)$ is relatively slow continuous with the common modulus of continuity $M(\Delta_\varepsilon^{-1} z)$, and then on each interval of continuity we can use Lemma 5.3 if we prove that the pairs $(x_\varepsilon(t_\varepsilon^i), y_\varepsilon(t_\varepsilon^i))$ stay in a common compact set and the triples $(u_\varepsilon(t), x_\varepsilon(t), y_\varepsilon(t))$ are included in $\mathit{graph}\, G$. Let $E = U \times H$ be a compact subset of $\mathit{graph}\, G$ and $(x_\varepsilon(0), y_\varepsilon(0)) \in H$. Let X be a compact subset

of $\mathbb{R}^m$ such that if $(u_\varepsilon(t), x_\varepsilon(t), y_\varepsilon(t)) \in \mathit{graph}\, G$ for $t \in [0,s]$ then $x_\varepsilon(t) \in X$ for $t \in [0,s]$. Such a set exists by Assumption 3.3. Define the set $\tilde{L}(x) = \cup_{u\in U} L(u,x)$. By the upper semicontinuity of L the mapping $\tilde{L}(\cdot)$ is compact for each x and upper semicontinuous. Thus by Assumption 6.7 $\mathit{graph}\, G$ contains the compact set

$$\tilde{\boldsymbol{L}} = \{(u,x,y) : u \in U, x \in X, y \in \tilde{L}(x)\}$$

(with, say, an η-neighborhood small enough).

We denote now a new compact set

$$\tilde{E} = E \cup \{(u,x,y) : u \in U, x \in X, d((u,x,y), \tilde{\boldsymbol{L}}) \le \eta\}.$$

Since by the definition the set $\tilde{\boldsymbol{L}}$ contains the set $\mathbf{L}$ defined in (5.5), we can employ estimates (5.6) and (5.7) of Lemma 5.3 to conclude that the triples $(u_\varepsilon(t), x_\varepsilon(t), y_\varepsilon(t))$ are included in $\mathit{graph}\, G$ for $t \in [0,1]$. Moreover for $(u_\varepsilon(t^i_\varepsilon), x_\varepsilon(t^i_\varepsilon), y_\varepsilon(t^i_\varepsilon)) \in \tilde{E}$ the triples $(u_\varepsilon(t^{i+1}_\varepsilon), x_\varepsilon(t^{i+1}_\varepsilon), y_\varepsilon(t^{i+1}_\varepsilon))$ are also included in $\tilde{E}$ for ε small enough. Hence the first inequality in (5.7) can be extended for $t \in [0,1]$, and we obtain the convergence in (5.8) (or (6.4)) if the set C is defined by (7.11). Therefore by Lemma 5.4 the result follows from the conditions of Theorem II too. □

Now we can proceed with the proof of Theorems I–III.

From Lemmas 7.1 and 7.2 it follows by the standard continuous dependence arguments (see, e.g., [AV, Lemma 4.1]) that $x_\varepsilon(t) \to x_0(t)$. Since by Lemma 7.2 $\boldsymbol{\rho}(\delta_{y_\varepsilon}, \mu_\varepsilon) \to 0$ where $\mu_\varepsilon(t) = \nu(u_\varepsilon(t), x_\varepsilon(t))$ and $\nu(u,x)$ is continuous in (u,x), we obtain $\boldsymbol{\rho}(\delta_{y_\varepsilon}, \nu_\varepsilon) \to 0$, where $\nu_\varepsilon(t) = \nu(u_\varepsilon(t), x_0(t))$. By an assumption $u_\varepsilon(\cdot)$ statistically converges to $v_0(\cdot)$, and then for any continuous function $h(t,u)$

$$\int_0^1 h(t, u_\varepsilon(t))\, dt \to \int_0^1 \int_U h(t,y)\, v_0(t)(du)\, dt. \tag{7.12}$$

For an arbitrary continuous function $\tilde{h}(t,y)$ define

$$h(t,u) = \int_{\mathbb{R}^n} \tilde{h}(t,y)\, \nu(u, x_0(t))(dy). \tag{7.13}$$

Then from (7.12) and (7.13) it follows that for any continuous $\tilde{h}(t,y)$

$$\int_0^1 \left(\int_{\mathbb{R}^n} \tilde{h}(t,y) \nu(u_\varepsilon(t), x_0(t))(dy) \right) dt \to \int_0^1 \left(\int_{\mathbb{R}^n} \tilde{h}(t,y)\, \bar{\nu}(v_0(t), x_0(t))(dy) \right) dt.$$

Therefore $\nu_\varepsilon(t)$ statistically converges to $\bar{\nu}(v_0(t), x_0(t))$, and since $\boldsymbol{\rho}(\delta_{y_\varepsilon}, \nu_\varepsilon) \to 0$ we get that $y_\varepsilon(t)$ statistically converges to $\bar{\nu}(v_0(t), x_0(t))$. Since the function $Q(u,x,y)$ is continuous, the convergence of the cost $J_\varepsilon \to J_0$ follows. This completes the proof of Theorems I–III.

8. Concluding remarks. Note that in our consideration U is an abstract metric compact space. This means that U itself may be a space of probability measures—say, on a compact set W of $\mathbb{R}^k$. Then the controls $u(t) \in U$ are themselves relaxed controls. In this case the relaxed controls $v(t) \in \mathcal{P}(U)$ are relaxed with respect to the controls $u(t)$.

Our convergence results may have another interpretation. Suppose we have an original control problem in the limit form (3.1). This type of problem arises for

instance in systems with uncertainty when we make appropriate averaging of the data functions. Then if we can find a function g such that the flow induced by the corresponding differential equation has an invariant measure ν from the model (3.1), we can construct the ε-system (1.1)–(1.3) which approximates (3.1).

We emphasize that our limit model completely approximates only the ε-problem on the families of relatively slow controls. We do not consider the fast controls $u(\tau) = u(t/\varepsilon)$. If, for instance, $u(\tau)$ is a periodic function, then the limit of $\mathrm{val}_\varepsilon(\mathcal{U})$ may be much less than $\mathrm{val}_0(\mathcal{U})$, as was mentioned in Example 6.18. (Consult also Gaitsgory [G1, G2, G3].) However, periodic controls induce the *discrete time* dynamical systems which are Poincaré maps. This gives an opportunity to apply the dynamical system approach to construct an extension of the limit control problem (3.1) when the fast periodic control is allowed.

Acknowledgment. This work is a part of a Ph.D. dissertation carried out under the supervision of Professor Zvi Artstein. The author would like to express his gratitude to Prof. Artstein for very useful discussions of these results.

ON POSITIVE ORTHANT CONTROLLABILITY OF BILINEAR SYSTEMS IN SMALL CODIMENSIONS*

YURI L. SACHKOV†

Abstract. For the bilinear control system of the form $\dot{x} = (A + \sum_{i=1}^{m} u_i B_i)x$, $x \in \mathbf{R}^n$, $u_i \in \mathbf{R}$, with A essentially nonnegative and B_i constant diagonal matrices, the following global controllability question is studied: when can any two points in $\mathbf{R}^n$ with positive coordinates be connected by a trajectory of this system? The answers for $m = n - 1$ and $m = n - 2$ for any $n > 2$ are given; some necessary conditions for other cases are proven.

Key words. bilinear system, global controllability, positive orthant

AMS subject classifications. 93B05, 93B27

PII. S0363012994270898

1. Introduction. The bilinear systems proved to be an interesting class of nonlinear control systems, both in theory and for applications. This class is one of the rare ones for which global controllability questions can be answered rather completely. This paper is devoted to one of such questions proposed by Boothby in [1].

Consider the bilinear control system

$$\dot{x} = \left(A + \sum_{i=1}^{m} u_i B_i \right) x, \tag{1}$$

where $x \in \mathbf{R}^n$; $u_1, \dots, u_m$ are the piecewise continuous scalar unbounded inputs; and A, $B_1, \dots, B_m$ are the constant $n \times n$ matrices.

The attainability set for system (1) from a point $x \in \mathbf{R}^n$ for all nonnegative times will be denoted by $\mathbf{A}(x)$.

We will denote *the open positive orthant* $\{x \in \mathbf{R}^n : x > 0\}$ by $\overset{\circ}{\mathbf{R}}{}^n_+$.

System (1) is called *controllable in* $\overset{\circ}{\mathbf{R}}{}^n_+$ if for any $x \in \overset{\circ}{\mathbf{R}}{}^n_+$ we have $\mathbf{A}(x) = \overset{\circ}{\mathbf{R}}{}^n_+$.

In what follows we will suppose that all trajectories of system (1) starting in $\overset{\circ}{\mathbf{R}}{}^n_+$ do not leave $\overset{\circ}{\mathbf{R}}{}^n_+$, i.e.,

(1) the matrix A is essentially nonnegative: $A = (a_{ij})$, $a_{ij} \geq 0$ for all $i \neq j$;

(2) the matrices $B_1, \dots, B_m$ are diagonal: $B_i = \operatorname{diag}(b_i)$, $b_i \in \mathbf{R}^n$, $i = 1, \dots, m$.

We will also suppose that the matrices B_i (or, equivalently, the vectors b_i) are linearly independent: for the linear hull $l = \operatorname{span}(b_1, \dots, b_m)$ we have $\dim l = m$. This can be achieved, if necessary, by eliminating some B_i and decreasing m.

The problem of controllability of system (1) in $\overset{\circ}{\mathbf{R}}{}^n_+$ under the conditions (1) and (2) was studied first by Boothby in [1]; he obtained some results for $m = 1$ and showed that for $m = n$ system (1) is controllable in $\overset{\circ}{\mathbf{R}}{}^n_+$. A complete solution for $m = 1$, $n = 2$ was obtained by Bacciotti in [2]. In [3] it was proven that for $m = 1$, $n > 2$, system (1) is, generically, noncontrollable in $\overset{\circ}{\mathbf{R}}{}^n_+$. So the problem was solved for the extreme codimensions 0 and $n - 1$.

In this paper we propose a solution of the problem for the systems of codimension 1 and 2 (i.e., for $m = n - 1$ and $m = n - 2$) and give some conditions sufficient for noncontrollability for $m \leq n - 2$.

The main idea is natural: if a simply connected state space is stratified into the integral manifolds of codimension one of the fields $B_i x$, then system (1) is globally

controllable iff all these manifolds are intersected by the field Ax in both directions. The corresponding general result was obtained by Bacciotti and Stefani in [4].

The structure of this paper is as follows. In section 2 we introduce a function determining the direction of intersection of the integral manifolds of the fields $B_i x$ by the field Ax and obtain conditions of change of sign of this function. In section 3 these conditions are applied to obtain the controllability conditions for $m = n-1$. In section 4 we give a test of controllability in $\overset{\circ}{\mathbf{R}}{}^n_+$ in terms of the notion of directional controllability. Finally, in sections 5 and 6 we apply the above results and give the conditions of controllability for other cases.

2. Conditions of change of sign. For every vector $h = (h_1, \dots, h_n) \in \mathbf{R}^n$ we will consider the corresponding function H defined on $\overset{\circ}{\mathbf{R}}{}^n_+$ by the equality

$$H(x) = x_1^{h_1} x_2^{h_2} \cdots x_n^{h_n}.$$

LEMMA 2.1. *Let $B = diag(b)$ be an $n \times n$ diagonal matrix and let $h \in \mathbf{R}^n$. The corresponding function H is an integral of the field Bx iff vectors h and b are orthogonal.*

Here and below we use the scalar product in $\mathbf{R}^n$: $\langle x, y \rangle = \sum_{i=1}^n x_i y_i$.

Proof. $\langle \operatorname{grad} H(x), Bx \rangle = \langle h, b \rangle H(x)$. □

Consider the function

$$\phi(x) = \langle \operatorname{grad} H(x), Ax \rangle / H(x),$$

which determines the direction of intersection of the level surfaces $\{H(x) = C\}$ by the field Ax. In the further part of this section we obtain, in terms of the vector h and matrix A, conditions that

$$\forall C > 0 \quad \text{the function } \phi(x)|_{\{H(x)=C\}} \text{ changes its sign.} \tag{2}$$

These conditions (Theorems 2.2 and 2.3) will be applied in the following sections to obtain the conditions of controllability of system (1) in $\overset{\circ}{\mathbf{R}}{}^n_+$.

Let us recall that an $n \times n$ matrix A is called *permutations irreducible* if the corresponding linear operator A has no k-dimensional invariant coordinate subspaces in $\mathbf{R}^n$ with $0 < k < n$; $A = (a_{ij})$ is called *essentially positive* if $a_{ij} > 0$ for all $i \neq j$.

THEOREM 2.2. *Let $h = (h_1, \dots, h_n) \in \mathbf{R}^n$ and let $\sum_{i=1}^n h_i \neq 0$.*

(1) *If the matrix A is permutations irreducible and the vector h has a pair of components with the mutually opposite signs, then condition* (2) *is satisfied.*

(2) *If $h_i \geq 0$ for all $i = 1, \dots, n$ and $\sum_{i=1}^n h_i a_{ii} \geq 0$, then condition* (2) *is not satisfied.*

Proof. Statement (1). Without loss of generality we can assume that $h_1 > 0$ and $h_n < 0$. H is a homogeneous function of order $\sum_{i=1}^n h_i \neq 0$, and every ray through x with the vertex in the origin intersects all hypersurfaces $\{H(x) = C\}$. So condition (2) holds iff $\phi(x)$ changes its sign in $\overset{\circ}{\mathbf{R}}{}^n_+$.

For $x_2 = x_3 = \cdots = x_n = 1$ and small $x_1 > 0$ the sign of the function $\phi(x) = \sum_{i,j=1}^n a_{ij} h_i x_j / x_i$ is determined by the large positive term $h_1 \sum_{j=2}^n a_{1j} x_j / x_1$. For $x_1 = x_2 = \cdots = x_{n-1} = 1$ and small $x_n > 0$ the function $\phi(x)$ is negative because of the term $h_n \sum_{j=1}^{n-1} a_{nj} x_j / x_n$. That is why $\phi(x)$ changes its sign in $\overset{\circ}{\mathbf{R}}{}^n_+$. Statement (1) is proven.

Statement (2) follows directly from the expansion

$$\phi(x) = \sum_{i \neq j} a_{ij} h_i x_j / x_i + \sum_{i=1}^n a_{ii} h_i. \qquad \square$$

THEOREM 2.3. *Let the matrix A be essentially positive, $h = (h_1, \dots, h_n) \in \mathbf{R}^n$, and $\sum_{i=1}^n h_i = 0$. Then condition (2) holds iff vector h has at least two positive and at least two negative components.*

This theorem follows from Lemmas 2.4–2.6.

LEMMA 2.4. *Let $n = 4$ and let the matrix A be essentially positive; suppose that $\sum_{i=1}^4 h_i = 0$; $h_1 > 0$, $h_2 > 0$, $h_3 < 0$, $h_4 < 0$. Then condition (2) is satisfied.*

Proof. Suppose that there exists $C > 0$ such that $\phi(x)$ does not change its sign on $\{H(x) = C\}$. We can assume that $\phi(x) \geq 0$ on $\{H(x) = C\}$.

In the homogeneous coordinates $u_i = x_i/x_4$, $i = 1, 2, 3$, $u_4 \equiv 1$, we have $H(u) = u_1^{h_1} u_2^{h_2} u_3^{h_3}$, $\phi(u) = \sum_{i,j=1}^4 h_i a_{ij} u_j / u_i$, and $\phi(u) \geq 0$ on $\{H(u) = C\}$.

On the surface $\{H(u) = C\}$ we have $u_3 = C^{1/h_3} u_1^{p_1} u_2^{p_2}$, where

$$p_1 = -h_1/h_3 > 0, \quad p_2 = -h_2/h_3 > 0.$$

(A) First we show that $p_2 \leq 1$.

Introduce the following family of curves parametrized by α:

$$\gamma_\alpha(s) = (s, s^\alpha, C^{1/h_3} s^{p_1 + \alpha p_2}). \tag{3}$$

Note that for any $\alpha \in \mathbf{R}$ and $s > 0$ we have $H(\gamma_\alpha(s)) \equiv C$.

Let $\alpha < 0$. On the curve $\gamma_\alpha(s)$ for $s \to +\infty$ we have $u_1 \to \infty$, $u_2 \to 0$. Then the largest positive terms in $\phi(u)$ are $h_2 a_{21} u_1/u_2$ and $h_2 a_{23} u_3/u_2$. Let us show that if $p_2 > 1$, then the parameter α can be chosen such that these positive terms have absolute value less than the negative term $h_3 a_{31} u_1/u_3 = h_3 a_{31} C^{-1/h_3} s^{1 - p_1 - \alpha p_2}$. Actually, on the curve $\gamma_\alpha(s)$ we have $u_1/u_2 = s^{1-\alpha}$, $u_3/u_2 = C^{1/h_3} s^{p_1 + \alpha p_2 - \alpha}$, and existence of the indicated α follows from compatibility of the system of inequalities

$$\begin{cases} 1 - p_1 - \alpha p_2 > 1 - \alpha \\ 1 - p_1 - \alpha p_2 > p_1 + \alpha p_2 - \alpha \\ \alpha < 0 \end{cases} \quad \underset{(\text{if } p_2 > 1)}{\Longleftrightarrow} \quad \begin{cases} \alpha < p_1/(1 - p_2) \\ \alpha < (2p_1 - 1)/(1 - 2p_2) \\ \alpha < 0. \end{cases}$$

So the indicated α exists, and the contradiction with $(\phi(u)|_{H(u)=C}) \geq 0$ shows that statement (A) is proven.

(B) Then we show, in the same way, that $p_1 \leq 1$.

(C) Then we show that $p_1 + p_2 \leq 1$. We consider family (3) for $\alpha > 0$ and $s \to 0$ and show, analogously to (A), that $p_1 + p_2 > 1$, $p_1 \leq 1$, $p_2 \leq 1$ imply that $\phi(\gamma_\alpha(s)) < 0$ for these α and s.

But inequality $p_1 + p_2 \leq 1$ is equivalent to $h_1 + h_2 + h_3 \leq 0$, which contradicts the conditions $h_1 + h_2 + h_3 + h_4 = 0$ and $h_4 < 0$. This contradiction shows that $\phi(x)$ changes its sign on the surface $\{H(x) = C\}$. □

Then we generalize Lemma 2.4 for any $n > 4$.

LEMMA 2.5. *Let $n > 4$ and let the matrix A be essentially positive; $h = (h_1, \dots, h_n)$ $\in \mathbf{R}^n$, $\sum_{i=1}^n h_i = 0$; $h_1 > 0$, $h_2 > 0$, $h_3 < 0$, $h_4 < 0$. Then condition (2) is satisfied.*

Proof. The general case is reduced to the case $n = 4$ by "freezing" the superfluous coordinates.

In the homogeneous coordinates $u_i = x_i/x_4$, $i \neq 4$, $u_4 \equiv 1$, we consider for any $K > 0$ the plane

$$\Pi_K = \{u = (u_1, \dots, u_n) : u_5 = \dots = u_n = K\}.$$

$H(u)|_{\Pi_K} = u_1^{h_1} u_2^{h_2} u_3^{h_3} K^{h_5 + \dots + h_n}$, and the plane Π_K intersects with the surface $\{H(u) = C\}$ for any $C > 0$, $K > 0$. So to prove this lemma it is sufficient to show that

$$\forall C > 0 \quad \exists K > 0 \text{ such that } \phi(u)|_{\{H(u)=C\} \cap \Pi_K} \text{ changes its sign.} \tag{4}$$

The direct calculations show that

$$\phi(u)|_{\Pi_K} = \sum_{i,j=1}^{4} h_i \tilde{a}_{ij}(K) u_j/u_i,$$

where

$$\tilde{a}_{ij}(K) \equiv a_{ij} \quad \text{for } i,j = 1,2,3,$$
$$\tilde{a}_{i4}(K) = a_{i4} + K\sum_{j=5}^{n} a_{ij} \quad \text{for } i = 1,2,3,$$
$$\tilde{a}_{4j}(K) = a_{4j} + 1/K\sum_{i=5}^{n} h_i/h_4 a_{ij} \quad \text{for } j = 1,2,3,$$
$$\tilde{a}_{44}(K) = a_{44} + K\sum_{j=5}^{n} a_{4j} + 1/K\sum_{i=5}^{n} h_i/h_4 a_{i4} + \sum_{i,j=5}^{n} h_i/h_4 a_{ij}.$$

So the function $\phi(u)|_{\Pi_K}$ coincides with the function of change of sign $\tilde{\phi}_K(x) = \langle \operatorname{grad} \tilde{H}(x), \tilde{A}(K)x\rangle/\tilde{H}(x)$ with $x \in \mathbf{R}^4$, $\tilde{H}(x) = x_1^{h_1}x_2^{h_2}x_3^{h_3}x_4^{h_4}$, $\tilde{A}(K) = (\tilde{a}_{ij}(K))$, $i,j = 1,\dots,4$ (after $\tilde{\phi}_K(x)$ is expressed in the usual homogeneous coordinates u_i). For a sufficiently large K the matrix $\tilde{A}(K)$ is essentially positive, so we can use conditions of change of sign for $n = 4$ obtained before. If $h_1 + h_2 + h_3 + h_4 \neq 0$, then it follows from statement (1) of Theorem 2.2 that $\tilde{\phi}_K(x)|_{H(x)=C}$ changes sign for any $C > 0$. And if $h_1 + h_2 + h_3 + h_4 = 0$, the same result follows from Lemma 2.4. So statement (4) is proven, as is Lemma 2.5. □

Now we will consider the case when h has only one component with the sign opposite to the signs of all other components. (There always exists at least one such component under the assumption $\sum_{i=1}^{n} h_i = 0$, $h \neq 0$.)

LEMMA 2.6. *Let the matrix A be essentially positive, $h \in \mathbf{R}^n$, $\sum_{i=1}^{n} h_i = 0$; $h_1 \geq 0$, $h_2 \geq 0, \dots, h_{n-1} \geq 0$, $h_n < 0$. Then condition (2) is not satisfied.*

Proof. In the coordinates $u_i = x_i/x_n$, $i = 1,\dots,n-1$, $u_n \equiv 1$, we have $H(u) = u_1^{h_1}u_2^{h_2}\dots u_{n-1}^{h_{n-1}}$. It follows from the inequalities $h_1 \geq 0$, $h_2 \geq 0$, …, $h_{n-1} \geq 0$ that

$$\lim_{C\to 0} \sup_{H(u)=C} \min_{h_i>0} \{u_i\} = 0;$$

i.e., for small $C > 0$ at least one of those components u_i of vector u, for which $h_i > 0$, becomes small on the surface $\{H(u) = C\}$. Choose sufficiently small $C > 0$, and let u_k be the small component in some neighborhood of u, $H(u) = C$, with $h_k > 0$.

In expansion $\phi(u) = \sum_{i,j=1}^{n} h_i a_{ij} u_j/u_i$ the negative terms are $h_n \sum_{j=1}^{n-1} a_{nj}u_j$ and, maybe, $\sum_{i=1}^{n} h_i a_{ii}$. But for small u_k the absolute values of all these terms are less than the large positive term $h_k \sum_{j\neq k} a_{kj}u_j/u_k$. Actually, we decompose the negative terms in the form

$$h_n\left(\sum_{j=1}^{k-1} a_{nj}u_j + a_{nk}u_k + \sum_{j=k+1}^{n-1} a_{nj}u_j\right) + \sum_{i=1}^{n} h_i a_{ii}$$

and the positive terms in the form

$$h_k\left(\sum_{j=1}^{k-1} a_{kj}u_j/u_k + \sum_{j=k+1}^{n-1} a_{kj}u_j/u_k + a_{kn}/u_k\right).$$

For sufficiently small u_k we have

$$h_k \sum_{j=1}^{k-1} a_{kj}u_j/u_k > \left| h_n \sum_{j=1}^{k-1} a_{nj}u_j \right|,$$

$$h_k \sum_{j=k+1}^{n-1} a_{kj}u_j/u_k > \left| h_n \sum_{j=k+1}^{n-1} a_{nj}u_j \right|,$$

$$h_k a_{kn}/u_k > |h_n a_{nk} u_k| + \left| \sum_{i=1}^{n} h_i a_{ii} \right|.$$

So the positive terms dominate all negative terms, and ϕ is positive in the neighborhood of the chosen u. Since u is arbitrary, $\phi(u)|_{H(u)=C} > 0$ for small $C > 0$. □

3. Systems of codimension one. In this section we suppose that $m = n - 1$ and obtain conditions of controllability of system (1) in $\overset{\circ}{\mathbf{R}}{}^n_+$ for this case.

There exists a unique (up to a scalar factor) nonzero vector $h \in \mathbf{R}^n$ orthogonal to the hyperplane $l = \operatorname{span}(b_1, \ldots, b_{n-1})$. We fix such vector $h = (h_1, \ldots, h_n)$ and the corresponding function $H(x) = x_1^{h_1} \ldots x_n^{h_n}$.

LEMMA 3.1. *System* (1) *is controllable in* $\overset{\circ}{\mathbf{R}}{}^n_+$ *iff the field* Ax *intersects any level surface* $\{H(x) = C\}$ *in both directions.*

Proof. We use the theory of global controllability of systems with $n - 1$ inputs on a manifold of dimension n, developed by Bacciotti and Stefani in [4]. It follows from Theorem 5.1 in [4] that system (1) is controllable in $\overset{\circ}{\mathbf{R}}{}^n_+$ iff for any $x \in \overset{\circ}{\mathbf{R}}{}^n_+$ the maximal integral manifold of the fields B_1x, …, $B_{n-1}x$ through the point x is intersected by the field Ax in both directions. But the family of fields B_1x, …, $B_{n-1}x$ is involutive (as all Lie brackets $[B_ix, B_jx] = [B_i, B_j]x$ vanish), so this integral manifold has dimension $n - 1$. On the other hand, the function H is an integral of the fields B_1x, …, $B_{n-1}x$ (see Lemma 2.1). The level surfaces of H are connected, so they coincide with the maximal integral manifolds of these fields. □

The direction of intersection of a level surface of H by the field Ax is determined by the sign of the function $\phi(x) = \langle \operatorname{grad} H(x), Ax \rangle / H(x)$, so Lemma 3.1 gives the following theorem.

THEOREM 3.2. *Let* $m = n - 1$, $h \perp l$, $h \neq 0$. *System* (1) *is controllable in* $\overset{\circ}{\mathbf{R}}{}^n_+$ *iff for any* $C > 0$ *the function* $\phi(x)|_{H(x)=C}$ *changes its sign.*

Now we apply the conditions of change of sign of ϕ obtained before (Theorems 2.2 and 2.3) and get the controllability conditions in the following form.

THEOREM 3.3. *Let* $m = n - 1$, $h \perp l$, $\sum_{i=1}^n h_i \neq 0$.

(1) *If the matrix* A *is permutations irreducible and the vector* h *has a pair of components with the mutually opposite signs, then system* (1) *is controllable in* $\overset{\circ}{\mathbf{R}}{}^n_+$.

(2) *If* $h_i \geq 0$ *for all* $i = 1, \ldots, n$ *and* $\sum_{i=1}^n h_i a_{ii} \geq 0$, *then system* (1) *is not controllable in* $\overset{\circ}{\mathbf{R}}{}^n_+$.

THEOREM 3.4. *Let* $m = n - 1$, $h \perp l$, $h \neq 0$, $\sum_{i=1}^n h_i = 0$. *Suppose that the matrix* A *is essentially positive. System* (1) *is controllable in* $\overset{\circ}{\mathbf{R}}{}^n_+$ *iff the vector* h *has at least two positive and two negative components.*

4. Directional controllability. In this section we apply the notion of directional controllability of system (1) and obtain controllability test in $\overset{\circ}{\mathbf{R}}{}^n_+$.

System (1) is *directionally controllable in* $\overset{\circ}{\mathbf{R}}{}^n_+$ if for any $x, y \in \overset{\circ}{\mathbf{R}}{}^n_+$ there exists $r \in \mathbf{R}_+$ such that $ry \in \mathbf{A}(x)$.

We will say that a point $x \in \mathbf{R}^n \setminus \{0\}$ determines *the direction entering (leaving) origin* for system (1) if $rx \in \mathbf{A}(x)$ for all $r \in (0;1)$ (respectively, $rx \in \mathbf{A}(x)$ for all $r \in (1;+\infty)$).

THEOREM 4.1. *System* (1) *is controllable in* $\overset{\circ}{\mathbf{R}}{}^n_+$ *iff*

(1) *it is directionally controllable in* $\overset{\circ}{\mathbf{R}}{}^n_+$*;*

(2) *there exist the vectors in* $\overset{\circ}{\mathbf{R}}{}^n_+$ *determining a direction entering the origin and a direction leaving the origin.*

Proof. Necessity is obvious.

Sufficiency. Let x determine an entering direction and y determine a leaving direction; $x, y \in \overset{\circ}{\mathbf{R}}{}^n_+$. Then we can move along the interval $\{rx : r \in (0;1)\}$ toward origin and along the ray $\{ry : r \in (1;+\infty)\}$ away from origin. But directional controllability of system (1) in $\overset{\circ}{\mathbf{R}}{}^n_+$ means that $\mathbf{A}(z)$ meets every ray of the form $\{rw : r \in \mathbf{R}_+\}$ in $\overset{\circ}{\mathbf{R}}{}^n_+$. So for any $z \in \overset{\circ}{\mathbf{R}}{}^n_+$ the attainable set $\mathbf{A}(z)$ is invariant under homotheties with respect to the origin, and that is why $\mathbf{A}(z) = \overset{\circ}{\mathbf{R}}{}^n_+$. □

5. Systems of codimension two. In this section we consider the case $m = n-2$. We use the controllability test from the previous section and reduce this case to the case of codimension one.

Let the $(n-2)$-dimensional plane $l = \operatorname{span}(b_1, \ldots, b_{n-2})$ not contain the vector $e = (1, 1, \ldots, 1)$. Then we fix a nonzero vector $h = (h_1, \ldots, h_n) \in \mathbf{R}^n$, orthogonal to the hyperplane $\operatorname{span}(e, l)$, and the corresponding functions $H(x) = x_1^{h_1} x_2^{h_2} \cdots x_n^{h_n}$ and $\phi(x) = \langle \operatorname{grad} H(x), Ax \rangle / H(x)$.

Note that $\sum_{i=1}^n h_i = 0$ for the chosen vector h.

LEMMA 5.1. *Let the matrix A be essentially positive. System* (1) *is directionally controllable in* $\overset{\circ}{\mathbf{R}}{}^n_+$ *iff the vector h has at least two positive and at least two negative components.*

Proof. Consider the auxiliary system

$$\dot{x} = \left(A + \sum_{i=1}^{m} u_i B_i + u_{m+1} E \right) x, \tag{5}$$

where A, B_i, u_i, $i = 1, \ldots, m$, are the same as in system (1), E is the identity $n \times n$ matrix, and u_{m+1} is an unbounded scalar input. It may easily be seen that system (1) is directionally controllable in $\overset{\circ}{\mathbf{R}}{}^n_+$ iff system (5) is controllable in $\overset{\circ}{\mathbf{R}}{}^n_+$. But system (5) has codimension 1, and we can apply Theorem 3.4 to obtain the conditions of controllability of system (5) $\overset{\circ}{\mathbf{R}}{}^n_+$. □

LEMMA 5.2. *Let the matrix A be permutations irreducible. If there exists a vector $b \in l \cap \overset{\circ}{\mathbf{R}}{}^n_+$ with pairwise distinct components, then system* (1) *has a direction entering origin and a direction leaving origin in* $\overset{\circ}{\mathbf{R}}{}^n_+$.

Proof. We apply Proposition 4.3 of [1] to the matrix $B = \operatorname{diag}(b)$ and obtain that for sufficiently large u (respectively, sufficiently negative u) all eigenvalues of the matrix $A + uB$ are positive (respectively, all negative). But the matrix $A + uB$ is essentially nonnegative and permutations irreducible. So we apply Frobenius's theorem on spectral properties of the nonnegative irreducible matrices [5] and the argument of Boothby from section 4 of [1] and obtain that the corresponding eigenvectors x with positive eigenvalue and y with negative eigenvalue belong to $\overset{\circ}{\mathbf{R}}{}^n_+$. But then x and y determine the direction leaving the origin and the direction entering the origin in $\overset{\circ}{\mathbf{R}}{}^n_+$, respectively. □

Now we apply Theorem 4.1 and Lemmas 5.1 and 5.2 and obtain the following controllability conditions for the systems of codimension 2.

THEOREM 5.3. *Let $m = n-2$, $e \notin l$, $h \perp span\,(e,l)$. Let the following conditions additionally hold:*

(1) *the vector h has at least two positive and at least two negative components;*
(2) *the matrix A is essentially positive;*
(3) *there exists a vector $b \in l \cap \overset{\circ}{\mathbf{R}}{}^n_+$ with pairwise distinct components.*

Then system (1) *is controllable in $\overset{\circ}{\mathbf{R}}{}^n_+$.*

THEOREM 5.4. *Let $m = n-2$, the matrix A be essentially positive, $e \notin l$, $h \perp span\,(e,l)$. Suppose that for some $i = 1,\dots,n$ we have $h_i > 0$ and $h_j \le 0$ for all $j \ne i$. Then system* (1) *is not controllable in $\overset{\circ}{\mathbf{R}}{}^n_+$.*

6. Systems of arbitrary codimensions. For the systems not covered by controllability conditions of sections 3 and 5 we can give some conditions sufficient for noncontrollability (i.e., in fact, necessary for controllability) due to the following simple consideration: if system (1) can be complemented to a system

$$\dot{x} = \left(A + \sum_{i=1}^{m} u_i B_i + \sum_{i=m+1}^{m+k} u_i B_i \right) x$$

for some $k > 0$ in such a way that the above system is noncontrollable in $\overset{\circ}{\mathbf{R}}{}^n_+$, then the initial system (1) is noncontrollable in $\overset{\circ}{\mathbf{R}}{}^n_+$ too.

THEOREM 6.1. *Let $m < n-1$, and let there exist a vector $h \in \mathbf{R}^n$, $h \perp l$, such that $h_i \ge 0$ for all $i = 1,\dots,n$ and $\sum_{i=1}^n a_{ii} h_i \ge 0$. Then system* (1) *is not controllable in $\overset{\circ}{\mathbf{R}}{}^n_+$.*

Proof. Let L be the hyperplane in $\mathbf{R}^n$ orthogonal to the vector h. We have $L \supset l = \operatorname{span}(b_1,\dots,b_m)$, so we can choose vectors $b_{m+1}, \dots, b_{n-1}$ complementing $b_1, \dots, b_m$ to a basis of L. Let us introduce the diagonal matrices $B_i = \operatorname{diag}(b_i)$ for $i = m+1,\dots,n-1$. Then the system $\dot{x} = (A + \sum_{i=1}^{n-1} u_i B_i)x$ has codimension one and is not controllable by statement 2. of Theorem 3.3. That is why system (1) is not controllable too. □

THEOREM 6.2. *Let $m < n-2$, the matrix A be essentially positive, and there exists a vector $h \in \mathbf{R}^n$, $h \perp span\,(e,l)$, such that for some $i = 1,\dots,n$ we have $h_i > 0$ and $h_j \le 0$ for $j \ne i$. Then system* (1) *is not controllable in $\overset{\circ}{\mathbf{R}}{}^n_+$.*

Proof. With the help of the same argument as in Theorem 6.1 we complement system (1) to a system of codimension two and obtain noncontrollability by Theorem 5.4. □

Acknowledgments. The author thanks Professor A. F. Filippov for his kind attention to this work. The author is also grateful to the anonymous referees for their helpful suggestions on correction of some statements and language of the paper.

LYAPUNOV EXPONENTS FOR FINITE STATE NONLINEAR FILTERING*

RAMI ATAR† AND OFER ZEITOUNI†

Abstract. Consider the Wonham optimal filtering problem for a finite state ergodic Markov process in both discrete and continuous time, and let σ be the noise intensity for the observation. We examine the sensitivity of the solution with respect to the filter's initial conditions in terms of the gap between the first two Lyapunov exponents of the Zakai equation for the unnormalized conditional probability. This gap is studied in the limit as $\sigma \to 0$ by techniques involving considerations of nonlinear filtering and the stochastic Feynman–Kac formula. Conditions are given for the limit to be either negative or $-\infty$. Asymptotic bounds are derived in the latter case.

Key words. Lyapunov exponents, nonlinear filtering, Wonham's equation, Feynman–Kac formula

1. Introduction and statement of results.

Let $\{X_n\}_{n=0}^{\infty}$ denote a finite state space, discrete time homogeneous Markov chain, with transition matrix G and initial distribution p_0. Without loss of generality, we take the state space of the Markov chain to consist of the set $\{1,\dots,d\}$. Denote the law of the chain X_n on $\{1,\dots,d\}^{\mathbb{Z}}$ by P. Throughout this paper, we assume that G leads to an ergodic noncyclic chain. That is, we assume

(A1) there exists a $k \geq 1$ such that $G^k(i,j) > 0$ for all $i,j \in \{1,\dots,d\}$.

We denote by E_s expectations under the unique stationary measure of $\{X_n\}$.

We assume that the Markov chain X_n is observed through the sequence $\{Y_n\}_{n=1}^{\infty}$, where

$$Y_n = \delta h_{X_n} + \sqrt{\delta}\sigma\nu_n\,.$$

Here, $h : \{1,\dots,d\} \to \mathbb{R}$ is the observation function, $\delta > 0$ is a parameter (which, for as long as one deals only with discrete time, may be taken as $\delta = 1$), σ is an observation noise parameter related to the signal-to-noise ratio (SNR), and $\{\nu_n\}_{n=1}^{\infty}$ is a sequence of i.i.d., standard Gaussian random variables.

Let $\mathcal{Y}_n$ denote the σ-algebra generated by the observations $Y_1,\dots,Y_n$. The nonlinear filtering problem consists of computing the conditional law $p_j(n) = P(X_n = j|\mathcal{Y}_n)$. Let D_n denote the diagonal matrix with $D_n(i,i) = \exp[\sigma^{-2}(h_i Y_n - h_i^2\delta/2)]$, and define

$$\rho(n) = D_n G^* \rho(n-1)\,, \tag{1}$$

where G^* denotes the transpose of G, and $\rho(0) = p_0$. It is a straightforward consequence from Bayes's rule (see, e.g., [1, p. 460] and also the continuous time case in [9]) that the vector $p(n) = (p_1(n),\dots,p_d(n))^*$ satisfies $p(n) = \rho(n)/\langle\rho(n),\mathbf{1}\rangle$, where

†Department of Electrical Engineering, Technion-Israel Institute of Technology, Haifa 32000, Israel (rami@aluf.technion.ac.il, zeitouni@ee.technion.ac.il).

$\rho(n) = (\rho_1(n), \ldots, \rho_d(n))^*$, $\mathbf{1} = (1, \ldots, 1)^*$, and $\langle \cdot, \cdot \rangle$ denotes the standard inner product in $\mathbb{R}^d$.

Often, one has no access to the initial distribution p_0. A common procedure is then to initialize (1) with some initial condition $q_0 \in S^{d-1}$, where S^{d-1} denotes the $(d-1)$-dimensional simplex. Denote by $\rho^{q_0}(n)$ the solution to (1) initialized this way, and denote by $p^{q_0}(n)$ the corresponding normalized (random) probability vector. Natural questions are then, how far is $p^{q_0}(n)$ from $p^{p_0}(n)$, what are the conditions for stability in the sense that $\|p^{q_0}(n) - p^{p_0}(n)\| \to_{n\to\infty} 0$, and under these conditions what is the rate of convergence? We emphasize that we deal here with the dependence of the optimal filter on *its* initial conditions and not with its dependence on perturbations of the initial distribution of the state process $\{X_n\}$. The latter is a different problem which we do not deal with here.

Motivated by the approach taken in [4] (see [6] for a related computation in the continuous time, linear case), we couch the question in terms of Lyapunov exponents. That is, for any two $q_0 \neq q_0' \in S^{d-1}$, define

$$\gamma_\sigma^\delta(q_0, q_0', \omega) = \limsup_{n\to\infty} \frac{1}{n\delta} \log ||p^{q_0}(n) - p^{q_0'}(n)|| \,.$$

Although here and in what follows we take $||\cdot||$ to denote the Euclidean norm, note that the definition does not depend on the precise norm used and, in particular, one could use the variation (ℓ^1) norm here.

We will see that, under mild conditions, $\gamma_\sigma^\delta(q_0, q_0', \omega)$ is almost surely deterministic and $\gamma_\sigma^\delta = \gamma_\sigma^\delta(q_0, q_0', \omega)$ is independent of q_0, q_0' for a.e. q_0, q_0' (when q_0, q_0' are distributed uniformly over the simplex) and is related to the gap between the top two Lyapunov exponents associated with the Zakai equation for the unnormalized conditional probability. The deterministic quantity $-1/\gamma_\sigma^\delta$ can then be interpreted as the "memory length" of the filter. Obviously, this approach is meaningful only if $\gamma_\sigma^\delta < 0$. We will identify below sufficient conditions for this to happen. An analogous continuous time question is examined as well.

We remark that in order to deal with the filter's memory length, we introduce and use tools borrowed from the theory of products of random matrices. Especially, we formulate the (qualitative) question of stability and the (quantitative) question of memory length in terms of Lyapunov exponents of the solution of Zakai's equation. While the question of computing Lyapunov exponents is, in general, difficult, we study the above-mentioned gap in the limiting cases, i.e., the regimes $\sigma \to \infty$ and $\sigma \to 0$. Under appropriate conditions, we obtain the exact order of the memory length as a function of σ in the latter case.

A natural guess is that γ_σ^δ becomes more negative as the SNR increases (i.e., as $\sigma \to 0$). As pointed out in [4] for the continuous time setup, this is not always the case, and one may even have situations where $\lim_{\sigma\to 0} \gamma_\sigma^\delta = 0$ though $\gamma_\sigma^\delta < 0$ for all positive σ. We identify below conditions for the memory length $-1/\gamma_\sigma^\delta$ to remain bounded as a function of σ and conditions for it to decay to zero as $\sigma \to 0$.

The structure of the paper is as follows. In the rest of this section, we describe the results for the memory length in both discrete and continuous time. In particular, in both cases we provide the uniform bounds on γ_σ^δ alluded to above and determine under appropriate conditions the limits of γ_σ^δ under both high and low SNR. Sections 2 and 3, respectively, are devoted to proofs of the discrete and continuous time results.

We begin with the following rather straightforward consequence of Oseledec's theorem (see [2, p. 181] and [3]).

THEOREM 1.1. *Assume* (A1). *Then there exists a deterministic function of* σ *and* δ, γ_σ^δ *which admits the following:*

(1) *Let* q_0, q_0' *be random, uniformly distributed (U) on the simplex* S^{d-1}, *independent of each other, and of the chain* $X_0, \{X_n, Y_n\}_{n=1}^\infty$. *Then*

$$\gamma_\sigma^\delta(q_0, q_0', \omega) = \gamma_\sigma^\delta\,, \quad U \times U \times P - a.s.$$

(2) *For any deterministic* $q_0 \neq q_0'$ *with all entries strictly positive, one has*

$$\gamma_\sigma^\delta(q_0, q_0', \omega) \leq \gamma_\sigma^\delta\,, \quad P - a.s.$$

As is seen in section 2, γ_σ^δ is just δ^{-1} times the difference between the two top Lyapunov exponents of solutions of (1).

We turn to study γ_σ^δ quantitatively. First is a bound which is uniform with respect to σ.

THEOREM 1.2. *Assume that all entries of* G *are strictly positive. Then*

$$\gamma_\sigma^\delta \leq \frac{c}{\delta} < 0$$

for some constant c *independent of* h, σ, δ.

Remark. Actually, one may somewhat relax the condition that all entries of G are positive and still have the conclusion of the theorem. See Theorem 2.3 in section 2 for such a statement and its proof there (which also serves as a proof of Theorem 1.2) for the explicit dependence of c on the matrix G.

While the above bound relies on the nature of the law of $\{X_n\}$ and *its* mixing properties, the next bound relies on the quality of the observation. In fact, it is shown that under a condition on h, the decay rate tends to infinity as the noise parameter tends to zero. The condition required on h is that it possesses one coordinate which differs from the rest (h one to one suffices). For each $i \in \{1, \ldots, d\}$, define the set

$$\mathrm{nbr}(i) = \{j \neq i : |h_i - h_j| = \min_{k \neq i} |h_i - h_k|\}$$

and define $h_{\mathrm{nbr}(i)} = h_j$, where j is one of the members in the set $\mathrm{nbr}(i)$.

THEOREM 1.3. *Assume* (A1). *Then*

$$\limsup_{\sigma \to 0} \sigma^2 \gamma_\sigma^\delta \leq -\frac{1}{2} E_s [h_{X_1} - h_{\mathrm{nbr}(X_1)}]^2\ . \tag{2}$$

If, in addition, $\det(G) \neq 0$, *then*

$$\liminf_{\sigma \to 0} \sigma^2 \gamma_\sigma^\delta \geq -\frac{1}{2} E_s \sum_{i=1}^d [h_{X_1} - h_i]^2\ . \tag{3}$$

Note that while the gap between the upper and the lower bounds increases with the dimension d (and is nonzero as soon as $d > 2$), one may conclude from Theorem 1.3 that $\gamma_\sigma^\delta = \Omega(\sigma^{-2})$ as soon as there exists an i such that the set $\{j : h_j = h_i\}$ consists of a single point. The memory length is thus of the order of σ^2.

In continuous time, the behavior at low SNR ($\sigma \to \infty$) is completely determined by the top, nonzero eigenvalue of G (see [4]). An analogous result is shown here to hold for the discrete time case.

Let τ be the Birkhoff contraction coefficient (see (11) for a definition).

THEOREM 1.4. *Assume* (A1). *Then*

$$\limsup_{\sigma\to\infty}\gamma_\sigma^\delta \le \inf_{m\ge 1}\frac{1}{m\delta}\log\tau(P^m) < 0.$$

In continuous time we prove results analogous to Theorems 1.1, 1.2, and 1.3. Though the statements are similar, the proofs are harder and involve different techniques; in particular, a naive discretization approach fails. Let $\{x_t\}$ denote a Markov chain, with state space $\{1,\dots,d\}$ and transition matrix $\hat{G}$. We assume that $\hat{G}$ leads to an ergodic chain; that is,

(A2) for every $\delta > 0$, $(\exp(\hat{G}\delta))(i,j) > 0$ for all $i,j \in \{1,\dots,d\}$.

The above holds iff all states are communicating. Next, assume that $\{x_t\}$ is observed via

$$dy_t = h_{x_t}dt + \sigma d\nu_t,$$

where ν_t is a standard Wiener process independent of $\{x_t\}$ and h is as in the discrete time case. Let H denote the diagonal matrix with elements $H(i,i) = h_i$; then the Zakai equation for the problem is

$$d\rho_t = \hat{G}^*\rho_t dt + \sigma^{-2}H\rho_t dy_t \tag{4}$$

with $p_t = \rho_t/\langle\rho_t,\mathbf{1}\rangle$. Now define for every $q_0 \ne q_0' \in S^{d-1}$

$$\gamma_\sigma(q_0,q_0',\omega) = \limsup_{t\to\infty}\frac{1}{t}\log\|p_t^{q_0} - p_t^{q_0'}\|;$$

then a result similar to Theorem 1.1 holds.

THEOREM 1.5. *Assume* (A2). *Then there exists a deterministic function of* σ, γ_σ, *which admits the following:*

(1) *Let* q_0, q_0' *be random, uniformly distributed (U) on the simplex* S^{d-1}, *independent of each other and of the chain* $\{x_t,y_t\}_{t=0}^\infty$. *Then*

$$\gamma_\sigma(q_0,q_0',\omega) = \gamma_\sigma\,, \quad U\times U\times P - a.s.$$

(2) *For any deterministic* $q_0 \ne q_0'$, *one has*

$$\gamma_\sigma(q_0,q_0',\omega) \le \gamma_\sigma\,, \quad P - a.s.$$

A result analogous to Theorem 1.2 holds also.

THEOREM 1.6. *Assume* (A2). *Then*

$$\gamma_\sigma \le -2\min_{1\le i,j\le d\,:\,i\ne j}(g_{ij}g_{ji})^{1/2},$$

where $g_{ij} = \hat{G}(i,j)$.

Remark. In [4] it is already proven that $\gamma_\sigma < 0$ under certain conditions, although not uniformly in σ.

Finally, a result analogous to Theorem 1.3 holds.

THEOREM 1.7. *Assume* (A2). *Then*

$$\limsup_{\sigma\to 0}\sigma^2\gamma_\sigma \le -\frac{1}{2}E_s[h_{x_0} - h_{\mathrm{nbr}(x_0)}]^2\,. \tag{5}$$

Moreover,

$$\liminf_{\sigma\to 0}\sigma^2\gamma_\sigma \ge -\frac{1}{2}E_s\sum_{i=1}^d[h_{x_0} - h_i]^2\,. \tag{6}$$

2. Proofs—discrete time. Throughout, we let $T_n = D_n G^*$ and $M_n^\sigma = T_n \cdots T_1$. We denote by $a \wedge b$ the exterior product of two vectors in $\mathbb{R}^d$ and by $A \wedge B$ the exterior product of two subspaces of $\mathbb{R}^d$ (see [2] for definitions of exterior products). For a $d \times d$ matrix A, $||A||$ denotes the operator norm (with respect to the Euclidean norm on $\mathbb{R}^d$). Finally, we use c throughout to denote a constant whose value may change from line to line which is independent of n, σ, δ.

Proof of Theorem 1.1. Note first that it is enough to prove the theorem in the case in which X_0 is distributed according to the stationary distribution of $\{X_n\}$. Indeed, due to (A1), the stationary distribution has all entries strictly positive, and thus all almost sure statements, once proved for X_0 distributed according to the stationary law, must translate to the case where $X_0 = j$ for any $j = 1, \ldots, d$. The case of general initial distributions follows immediately.

We may thus assume that X_0 is distributed according to its stationary law. In that case, the sequence of matrices $\{D_n G^*\}_{n=1}^\infty$ possesses a stationary law, which is also ergodic by (A1). Moreover,

$$E \log^+ ||D_n G^*|| \le cE \max_{i=1}^d \sigma^{-2} \left(Y(n) h_i - \frac{1}{2} h_i^2 \delta \right)^+ < \infty .$$

Hence, we may apply Oseledec's theorem (see, e.g., [2, p. 181]) to conclude that there exists a (random) strict subspace $S_\omega^1 \subset \mathbb{R}^d$ such that if $q_0 \notin S_\omega^1$ then

$$\frac{1}{n} \log ||\rho^{q_0}(n)|| \to \lambda_1^\sigma , \quad P - \text{a.s.} \tag{7}$$

Here and in what follows, λ_i^σ denotes the ith (nonrandom) Lyapunov exponent associated with the product of matrices M_n^σ. As is well known (see [3]), the matrix sequence $((M_n^\sigma)^* M_n^\sigma)^{1/2n}$ has a (random) limit a.s., the eigenvalues of which are $e^{\lambda_i^\sigma}$. Note that $(M_n^\sigma)^* M_n^\sigma$ is a nonnegative matrix, thus by the Perron–Frobenius theorem the eigenvector associated with the highest eigenvalue of $(M_n^\sigma)^* M_n^\sigma$ has all coordinates real and nonnegative. The last property thus holds for $((M_n^\sigma)^* M_n^\sigma)^{1/2n}$, too, and hence also for $\lim_{n\to\infty} (M_n^* M_n)^{1/2n}$. Since S_ω^1 must be orthogonal to the eigenvector associated with the highest eigenvalue of $\lim_{n\to\infty} (M_n^* M_n)^{1/2n}$, it follows that S_ω^1 cannot include any probability vector with all entries strictly positive. As for the case where q_0 does not have all its entries strictly positive, notice that $p^{q_0}(k)$ does (where k is such that $G^k(i,j) > 0$ for all $i, j \in \{1, \ldots, d\}$). Thus (7) really holds for any $q_0 \in S^{d-1}$.

Using again Oseledec's theorem, this time for the $\mathbb{R}^d \wedge \mathbb{R}^d$-valued process $\rho^{q_0}(n) \wedge \rho^{q_0'}(n)$, there exists a (random) strict subspace $S_\omega^2 \subset \mathbb{R}^d \wedge \mathbb{R}^d$ such that if $q_0 \wedge q_0' \notin S_\omega^2$ then

$$\frac{1}{n} \log ||\rho^{q_0}(n) \wedge \rho^{q_0'}(n)|| \to_{n\to\infty} \lambda_1^\sigma + \lambda_2^\sigma , \quad P - \text{a.s.} \tag{8}$$

Furthermore, for $q_0 \wedge q_0' \in S_\omega^2$, Oseledec's theorem implies

$$\limsup_{n\to\infty} \frac{1}{n} \log ||\rho^{q_0}(n) \wedge \rho^{q_0'}(n)|| \le \lambda_1^\sigma + \lambda_2^\sigma , \quad P - \text{a.s.} \tag{9}$$

Next, note that there exists a dimensional constant c_d such that if a, b are two probability vectors in S^{d-1} then

$$\frac{1}{c_d} |\sin(a,b)| \le ||a - b|| \le c_d |\sin(a,b)| ,$$

where (a,b) denotes the angle between the vectors a,b. Since for any two nonzero vectors c,d (not necessarily normalized) one has that $|\sin(c,d)| = ||c \wedge d||/(||c|| \cdot ||d||)$, one may conclude that

$$\limsup_{n\to\infty} \frac{1}{n} \log ||p^{q_0}(n) - p^{q_0'}(n)||$$

$$= \limsup_{n\to\infty} \frac{1}{n} [\log ||\rho^{q_0}(n) \wedge \rho^{q_0'}(n)|| - \log ||\rho^{q_0}(n)|| - \log ||\rho^{q_0'}(n)||] .$$

Combining this and the fact that (7) holds for any probability vectors q_0, q_0' with either (8) or (9) yields both parts of the theorem, with $\gamma_\sigma^\delta = \delta^{-1}(\lambda_2^\sigma - \lambda_1^\sigma)$. □

It is useful to state the last sentence of the proof of Theorem 1.1 as the following.

COROLLARY 2.1.

$$\gamma_\sigma^\delta = \delta^{-1}(\lambda_2^\sigma - \lambda_1^\sigma) . \tag{10}$$

As is clear from [4] (and is evident also in the course of the proof of Theorem 1.1), the gap between the first and the second Lyapunov exponents will play a crucial role in our study of the stability of the nonlinear filter. Before providing the proof of Theorem 1.2, it is useful to recall some definitions and a result of Peres concerning this gap. We follow the notations of [7], [8].

We say that a matrix A possessing nonnegative entries is *allowable* if it contains no columns or rows whose entries are all zero. Let S_+^{d-1} denote those elements of S^{d-1} whose entries are all strictly positive. *Hilbert's projective metric* is the metric $\bar{h}(\cdot,\cdot)$ on $S_+^{d-1} \times S_+^{d-1}$ defined by

$$\bar{h}(x,y) = \log \max_{1\le i,j\le d} \frac{x_i y_j}{x_j y_i} .$$

Every allowable matrix A can be seen, by normalization of the linear action of A, as an operator $A : S_+^{d-1} \to S_+^{d-1}$. We denote by $A.x$ its action on $x \in S_+^{d-1}$. Define now the *Birkhoff contraction coefficient* of an allowable matrix A by

$$\tau(A) = \sup \left\{ \frac{\bar{h}(A.x, A.y)}{\bar{h}(x,y)} \,\middle|\, x,y \in S_+^{d-1}, x \neq y \right\} . \tag{11}$$

LEMMA 2.2 (see Peres [7]). *Let $\{T_n\}_{n\ge1}$ be an ergodic stationary sequence of nonnegative, allowable matrices, such that $E\log^+||T_1|| < \infty$. Let λ_1, λ_2 denote the top two Lyapunov exponents for the random product of the T_i. Then*

$$\lambda_1 - \lambda_2 \ge -E \log \tau(T_1) ,$$

where $\lambda_2 = -\infty$ if the right-hand side is infinite.

Proof. See [7, Prop. 5]. □

We recall from [7] and [8] the following useful properties of the contraction coefficient $\tau(\cdot)$:

Property 1. $\tau(AD) = \tau(DA) = \tau(A)$ for any diagonal matrix D with strictly positive diagonal terms.

Property 2. For any matrix A with strictly positive entries, $\tau(A) < 1$.

Property 3. Let A be allowable and define

$$\psi(A) = \min_{i,j,k,l} \left\{ \frac{a_{ik}a_{jl}}{a_{il}a_{jk}} \middle| a_{il}a_{jk} \neq 0 \right\} . \tag{12}$$

Then

$$\tau(A) = \frac{1-\sqrt{\psi(A)}}{1+\sqrt{\psi(A)}}\,. \tag{13}$$

We are now in a position to state the extension of Theorem 1.2 alluded to in the introduction.

THEOREM 2.3. *Assume that $\tau(G) < 1$. Then*

$$\gamma_\sigma^\delta \le \frac{\log \tau(G)}{\delta} < 0\,.$$

Note that Theorem 1.2 follows at once from Theorem 2.3 by using Property 2 for $\tau(G)$. Moreover, it follows that c may be taken as $c = \log(1-\Psi)/(1+\Psi)$ with $\Psi = \min_{i,j} G_{ij}/\max_{i,j} G_{ij}$.

Proof of Theorem 2.3. Applying Theorem 1.1 and Corollary 2.1 in combination with Lemma 2.2 to the recursion (1), one sees that

$$\gamma_\sigma^\delta \le \delta^{-1} E \log \tau(D_1 G^*) = \delta^{-1} \log \tau(G^*) = \delta^{-1} \log \tau(G) < 0\,,$$

where the first equality follows from Property 1 for $\tau(\cdot)$, the second from Property 3, and the last inequality from the assumption $\tau(G) < 1$. □

Proof of Theorem 1.3. Suppose equation (1) is given two initial conditions q_0, q_0'; denote

$$q_n = p_n^{q_0}, \quad q_n' = p_n^{q_0'}, \quad r_n = q_n - q_n'.$$

Now, $q_n = T_n q_{n-1}/\langle T_n q_{n-1}, \mathbf{1}\rangle$, and subtracting $\langle T_n q_{n-1}', \mathbf{1}\rangle q_n' = T_n q_{n-1}'$ from $\langle T_n q_{n-1}, \mathbf{1}\rangle q_n = T_n q_{n-1}$ one gets

$$\langle T_n q_{n-1}, \mathbf{1}\rangle r_n + \langle T_n r_{n-1}, \mathbf{1}\rangle q_n' = T_n r_{n-1}.$$

Denoting $a_n = \langle T_n q_{n-1}, \mathbf{1}\rangle$ and noticing $a_n > 0$ one obtains

$$\begin{aligned} r_n &= a_n^{-1} T_n r_{n-1} - a_n^{-1} q_n' \langle T_n r_{n-1}, \mathbf{1}\rangle = a_n^{-1}(I - q_n' \mathbf{1}^*) T_n r_{n-1} \\ &= a_n^{-1}(I - q_n' \mathbf{1}^*) D_n G^* r_{n-1}. \end{aligned}$$

The following recursion for r_n then holds:

$$\begin{aligned} r_0 &= q_0 - q_0', \\ r_n &= a_n^{-1} T_n' G^* r_{n-1}, \end{aligned} \tag{14}$$

where we denote

$$T_n' = (I - q_n' \mathbf{1}^*) D_n.$$

In order to estimate the growth rate of r_n one notices

$$\frac{1}{n}\log\|r_n\| \le \frac{1}{n}\sum_{i=1}^n \log a_i^{-1} + \frac{1}{n}\sum_{i=1}^n \log\|T_i'\| + \frac{1}{n}\sum_{i=1}^n \log\|G^*\| + \frac{1}{n}\log\|r_0\|. \tag{15}$$

Since the third term is bounded by zero and the fourth tends to zero, we turn to bound the two first terms. The first term tends for any q_0, a.s., to $-\lambda_1^\sigma$, since

$$\frac{1}{n}\sum_{i=1}^{n}\log a_i^{-1} = -\frac{1}{n}\log\langle T_n T_{n-1}\cdots T_1 q_0, \mathbf{1}\rangle$$

(cf. the discussion following (7) above). Hence, it suffices to compute the limit of the last quantity for $q_0 = p_0$. Denoting the density of $(Y_1,\dots,Y_n)$ by $f_{Y_1^n}(\beta_1^n)$ and the distribution of $(X_1,\dots,X_n)$ by $P((X_1,\dots,X_n)=(\alpha_1,\dots,\alpha_n)) = p_{X_1^n}(\alpha_1^n)$ it follows from Bayes' rule that

$$\begin{aligned}
\frac{1}{n}\sum_{i=1}^{n}\log a_i^{-1} &= -\frac{1}{n}\log\left[f_{Y_1^n}(Y_1^n)(2\pi\sigma^2\delta)^{n/2}\exp\frac{1}{2\sigma^2\delta}\sum_i Y_i^2\right]\\
&= -\frac{1}{n}\log\left[\sum_{\alpha_1^n} p_{X_1^n}(\alpha_1^n)(2\pi\sigma^2\delta)^{-n/2}\exp-\frac{1}{2\sigma^2\delta}\sum_i (Y_i - h_{\alpha_i}\delta)^2\right]\\
&\quad -\frac{1}{2}\log 2\pi\sigma^2\delta - \frac{1}{2n\sigma^2\delta}\sum_i Y_i^2\\
&\le -\frac{1}{n}\log\left[p_{X_1^n}(X_1^n)\exp-\sum_i\frac{1}{2\sigma^2}(\sigma\nu_i)^2\right] - \frac{1}{2\sigma^2\delta}\frac{1}{n}\sum_i Y_i^2\\
&= -\frac{1}{n}\log p_{X_1^n}(X_1^n) - \frac{1}{2\sigma^2}\frac{1}{n}\sum_i[h_{X_i}^2\delta + 2\sqrt{\delta}\sigma\nu_i h_{X_i}]. \qquad (16)
\end{aligned}$$

Next we turn to the second term in the right-hand side of (15). Writing the diagonal terms of D_n as $\Delta_n^i = D_n(i,i)$ we have the following expression for T_n':

$$T_n' = \begin{pmatrix}
\Delta_n^1(1-q_n'^1) & \Delta_n^2(-q_n'^1) & \cdots & \Delta_n^d(-q_n'^1)\\
\Delta_n^1(-q_n'^2) & \Delta_n^2(1-q_n'^2) & \cdots & \Delta_n^d(-q_n'^2)\\
\vdots & \vdots & \ddots & \vdots\\
\Delta_n^1(-q_n'^d) & \Delta_n^2(-q_n'^d) & \cdots & \Delta_n^d(1-q_n'^d)
\end{pmatrix}.$$

It is useful to consider here the operator norm of $T_n' : \ell^1 \to \ell^1$, namely, $\|T_n'\|_1 = \max_k \sum_i |(T_n')_{ik}|$. Fix n and suppose $X_n = j$; then $Y_n = h_j\delta + \sigma\nu_n\sqrt{\delta}$, and

$$\|T_n'\|_1 = \max_i\left\{\Delta_n^i\left[1 - q_n'^i + \sum_{l\ne i} q_n'^l\right]\right\} = 2\max_i \Delta_n^i(1-q_n'^i).$$

Denoting the vector $b_n = (b_n^1,\dots,b_n^d)^* := G^* q_{n-1}'$ it follows that

$$q_n'^j = \frac{b_n^j\Delta_n^j}{\sum_{l=1}^d b_n^l\Delta_n^l},$$

and thus

$$1 - q_n'^j = \frac{\sum_{k\ne j} b_n^k\Delta_n^k}{\sum_{l=1}^d b_n^l\Delta_n^l} \le \min\left(1, \frac{\max_{k\ne j}\Delta_n^k}{b_n^j\Delta_n^j}\right) \le 1_{\{b_n^j<\alpha\}} + 1_{\{b_n^j\ge\alpha\}}\frac{\max_{k\ne j}\Delta_n^k}{\alpha\Delta_n^j}$$

for every fixed $0 < \alpha < 1$. Therefore,

$$2\Delta_n^j(1-q_n'^j) \le 2\Delta_n^j 1_{\{b_n^j<\alpha\}} + \frac{2}{\alpha} 1_{\{b_n^j \ge \alpha\}} \max_{k\neq j} \Delta_n^k$$

and, clearly,

$$\forall i, i \neq j \quad 2\Delta_n^i(1-q_n'^i) \le \frac{2}{\alpha} \max_{k\neq j} \Delta_n^k.$$

Using the equivalence of the norms $||\cdot||$ and $||\cdot||_1$, it follows that there exists a constant c, independent of n such that

$$\|T_n'\| \le \frac{2c}{\alpha}\left[1_{\{b_n^j<\alpha\}} \max_k \Delta_n^k + 1_{\{b_n^j\ge\alpha\}} \max_{k\neq j} \Delta_n^k\right]$$

and thus, defining $h_{\max} = \max_i\{|h_i|\}$,

$$\begin{aligned}
&\frac{1}{n}\sum_{i=1}^n \log\|T_i'\| \\
&\le \log\frac{2c}{\alpha} + \frac{1}{n}\sum_{i=1}^n 1_{\{b_i^{X_i}<\alpha\}}\, \sigma^{-2} \max_k \left(h_k h_{X_i}\delta + h_k\sigma\sqrt{\delta}\nu_i - \frac{1}{2}\, h_k^2\delta\right) \\
&\quad + \frac{1}{n}\sum_{i=1}^n 1_{\{b_i^{X_i}\ge\alpha\}} \sigma^{-2} \max_{k\neq X_i} \left(h_k h_{X_i}\delta + h_k\sigma\sqrt{\delta}\nu_i - \frac{1}{2}\, h_k^2\delta\right) \\
&\le \log\frac{2c}{\alpha} + \frac{1}{n}\sum_{i=1}^n 1_{\{b_i^{X_i}<\alpha\}} (\sigma^{-2}\delta {h_{\max}}^2 + \sigma^{-1}\sqrt{\delta} h_{\max}|\nu_i|) \\
&\quad + \frac{1}{n}\sum_{i=1}^n \sigma^{-2}\delta\left(h_{\mathrm{nbr}(X_i)} h_{X_i} - \frac{1}{2}\, h_{\mathrm{nbr}(X_i)}^2\right) + \sigma^{-1}\sqrt{\delta} h_{\max}|\nu_i|.
\end{aligned}$$

Now, $b_i^{X_i} \ge (G)_{X_{i-1}X_i} q_{i-1}'^{X_{i-1}}$ so choosing $\alpha = \frac{1}{2}\min_{u,v:(G)_{uv}>0}(G)_{uv}$ it follows that $1_{\{b_i^{X_i}<\alpha\}} \le 1_{\{q_{i-1}^{X_{i-1}}<\frac{1}{2}\}}$. Combining this with inequalities (15) and (16) one arrives, after taking expectation and limit, at

$$\begin{aligned}
\lim_{n\to\infty}\frac{1}{n} E\,\log\|r_n\| \le c_1 + c_2\sqrt{\delta}/\sigma - \frac{\delta}{2\sigma^2} E_s\left(h_{X_i} - h_{\mathrm{nbr}(X_i)}\right)^2 \\
+ c_3\sigma^{-2}\lim_{n\to\infty}\frac{1}{n}\sum_{i=1}^n P\left(q_{i-1}^{X_{i-1}} < \frac{1}{2}\right).
\end{aligned}$$

Since $P\left(q_n'^{X_n} < \frac{1}{2}\right) \longrightarrow_{\sigma\to 0} 0$ uniformly in n and since again by Oseledec's theorem (see, e.g., [2, p. 181])

$$\lim\frac{1}{n}\log\|\wedge^r T_n\cdots T_1\| = \lim\frac{1}{n} E\,\log\|\wedge^r T_n\cdots T_1\| \quad \text{a.s.},$$

the first part of the theorem is proved.

The second part easily follows from the following facts. First, the spectrum of the matrix process certainly satisfies

$$\lambda_2^\sigma - \lambda_1^\sigma \ge \lambda_2^\sigma - \lambda_1^\sigma + 2\lambda_1^\sigma + \lambda_3^\sigma + \cdots + \lambda_d^\sigma - d\lambda_1^\sigma = \sum_{i=1}^d \lambda_i^\sigma - d\lambda_1^\sigma.$$

Second, since $\det T_n \cdots T_1 = \det T_n \cdots \det T_1$, the sum of the exponents can be explicitly expressed as

$$\sum_{i=1}^{d} \lambda_i^\sigma = \lim_{n\to\infty} \frac{1}{n} \log |\det T_n \cdots T_1| = E_s \frac{1}{\sigma^2} \left(Y_1 \sum_{i=1}^{d} h_i - \frac{1}{2} \sum_{i=1}^{d} h_i^2 \delta \right) + \log |\det G|$$
$$= \frac{\delta}{\sigma^2} E_s \left(h_{X_1} \sum_{i=1}^{d} h_i - \frac{1}{2} \sum_{i=1}^{d} h_i^2 \right) + \log |\det G| ,$$

while

$$\lambda_1^\sigma \le E \log \| \operatorname{diag}(\Delta_1^i)_{i=1}^d \|_1 + \log \|G\|_1$$
$$\le E \max_i \left[-\frac{\delta}{2\sigma^2} (h_{X_1} - h_i)^2 + \frac{\delta h_{X_1}^2}{2\sigma^2} + h_i \frac{\sqrt{\delta}\nu_1}{\sigma} \right] \le \frac{\delta}{2\sigma^2} E_s\, h_{X_1}^2 + \frac{c\sqrt{\delta}}{\sigma}.$$

Thus we conclude that

$$\liminf_{\sigma\to 0} \sigma^2 \gamma_\sigma^\delta \ge E_s \left[h_{X_1} \sum_{i=1}^{d} h_i - \frac{1}{2} \sum_{i=1}^{d} h_i^2 - \frac{d}{2} h_{X_1}^2 \right] = E_s \left[-\frac{1}{2} \sum_i (h_{X_1} - h_i)^2 \right]. \qquad \square$$

Proof of Theorem 1.4. The last inequality holds, since by the assumption there exists an m_0 such that for all $m \ge m_0$, $G^{m_0} > 0$. As for the first inequality, as in the proof of Theorem 1.1, it suffices to work under the assumption that X_0 is distributed according to the stationary distribution. One may apply Lemma 2.2 for the process of matrices that are derived from $\{T_n\}$ by taking products of blocks at length m, where $m \ge m_0$:

$$T_m T_{m-1} \cdots T_1, \quad T_{2m} T_{2m-1} \cdots T_{m+1}, \quad \ldots.$$

Ergodicity, stationarity, and integrability follow from those of $\{T_n\}$. Since $(G^*)^m$ is positive, that is,

$$\sum_{i_2,\ldots,i_{m-1}} (G^*)_{i_1 i_2} \cdots (G^*)_{i_{m-1} i_m} > 0,$$

it follows that

$$(T_m \cdots T_1)_{i_1 i_m} = \sum_{i_2,\ldots,i_{m-1}} \Delta_i^{i_1} (G^*)_{i_1 i_2} \cdots \Delta_m^{i_m} (G^*)_{i_{m-1} i_m} > 0$$

and allowability follows. The Lyapunov spectrum for this sequence is $\{m\lambda_i^\sigma\}_{i=1}^d$, thus

$$\gamma_\sigma^\delta \le \frac{1}{m\delta} E \log \tau(T_m T_{m-1} \cdots T_1). \tag{17}$$

The diagonal terms Δ_j^i for which $T_j = \operatorname{diag}(\Delta_j^i)_{i=1}^d G^*$ may be expressed as

$$\Delta_j^i = \exp \sigma^{-2} \left(h_i Y_j - \frac{1}{2} h_i^2 \delta \right) = \exp \left[\delta \sigma^{-2} \left(h_i h_{X_j} - \frac{1}{2} h_i^2 \right) + \sqrt{\delta} \sigma^{-1} h_i \nu_j \right] = 1 + \alpha_j^i.$$

Thus

$$T_m T_{m-1} \cdots T_1 = (I + \operatorname{diag}(\alpha_m^i)_{i=1}^d) G^* \cdots (I + \operatorname{diag}(\alpha_1^i)_{i=1}^d) G^* = (G^*)^m + M,$$

where M is a matrix satisfying

$$\|M\| \le \|G\|^m[(1+\|\operatorname{diag}(\alpha_m^i)_{i=1}^d\|)\cdots(1+\|\operatorname{diag}(\alpha_1^i)_{i=1}^d\|) \ -1].$$

Now,

$$\|\operatorname{diag}(\alpha_j^i)_{i=1}^d\| = \max_i \left|\exp\left[\delta\sigma^{-2}\left(h_i h_{X_j} - \frac{1}{2}\,h_i^2\right) + \sqrt{\delta}\sigma^{-1}h_i\nu_j\right] - 1\right| \longrightarrow_{\sigma\to\infty} 0 \quad \text{a.s.;}$$

therefore

$$T_m T_{m-1}\cdots T_1 \longrightarrow_{\sigma\to\infty} (G^*)^m \quad \text{a.s.}$$

Since $(G^*)^m$ is positive, ψ is continuous at $(G^*)^m$ and so is τ; hence,

$$\tau(T_m T_{m-1}\cdots T_1) \longrightarrow_{\sigma\to\infty} \tau((G^*)^m) = \tau(G^m) \quad \text{a.s.}$$

Since $\log(\tau(\cdot)) \le 0$, Fatou's lemma may be applied to get

$$\limsup_{\sigma\to\infty} E\log\tau(T_m T_{m-1}\cdots T_1) \le E\ \limsup_{\sigma\to\infty}\log\tau(T_m T_{m-1}\cdots T_1)$$

$$= E\ \log\tau(G^m) = \log\tau(G^m),$$

and the result follows from inequality (17). □

3. Proofs—continuous time. Throughout this section, c denotes a t-independent deterministic constant (whose value may change from line to line). p^x_{stat} denotes the (unique, by (A2)) stationary law corresponding to $\hat{G}$. We use the notations x_0^t and y_0^t to denote the sub σ-fields generated, respectively, by $\{x_s, 0 \le s \le t\}$ and $\{y_s, 0 \le s \le t\}$. E_0 denotes expectations under the product measure $\mathcal{P}_x \times \mathcal{P}_y$, where $\mathcal{P}_x$ denotes the law of the Markov chain x (under the stationary measure) and $\mathcal{P}_y$ denotes the law of the observation process $\{y_t, 0 \le t < \infty\}$.

Proof of Theorem 1.5. Aside from the conditions needed to meet the assumptions of Oseledec's theorem that are proved below, the proof is identical to that of Theorem 1.1. Notice that equation (4) is bilinear, thus there exists a multiplicative process denoted $U = \{U_t\}_{t\in\mathbb{R}_+}$ such that $\rho_t = U_t\rho_0$. Assuming x_0 is distributed according to its stationary law, the shift transformation θ_t is measure preserving with respect to $\{x, \nu\}$ and thus with respect to U. Ergodicity of U follows from that of $\{x, \nu\}$, and separability follows from continuity. It follows from Theorem 2.1 in [5] that $U_t : \mathbb{R}^d \to \mathbb{R}^d$ is a homeomorphism and thus is invertible for any $t \ge 0$. For Oseledec's theorem to hold, one needs to show also the integrability of (see [2, p. 181])

$$u_1 = \sup_{0\le t\le 1} \log^+\|U_t\|, \quad u_2 = \sup_{0\le t\le 1}\log^+\|U_t^{-1}\|.$$

To show u_1 is integrable, it suffices to show that $\sup_{0\le t\le 1}\|U_t\|$ is. Note that by the Kallianpur–Striebel formula, U_t is a nonnegative matrix for any $t \ge 0$, and hence the unit vector w maximizing $\|U_t w\|$ has nonnegative entries. Thus, it suffices, by considering the projection on w, to show integrability of $\sup_{0\le t\le 1}\|U_t v\|$ for some v, all of whose entries are positive. Under (A2) all entries of p^x_{stat} are positive, so v may be chosen to be p^x_{stat}. Since this vector is also the initial distribution of x, it follows that $\|U_t p^x_{\text{stat}}\|_1 = \langle\rho_t, \mathbf{1}\rangle$. By the Kallianpur–Striebel formula,

$$\langle\rho_t, \mathbf{1}\rangle = E_0\left[\exp\int_0^t\left(h_{x_s}dy_s - \frac{1}{2}\,h_{x_s}^2 ds\right)\Big| y_0^t\right] \le E_0\left[\exp h_{\max}\sum_i|\Delta y_i|\right],$$

where $\Delta y_i = y_{\tau_{i+1}} - y_{\tau_i}, \tau_0 = 0, \tau_i = \min\{t > \tau_{i-1} : x_t \neq x_{\tau_{i-1}}\} \wedge 1$, and integrability follows from the existence of exponential moments of the normal distribution and the exponential law of $\tau_i - \tau_{i-1}$. As for u_2, denote, for a symmetric matrix A, by $\lambda_i(A)$ the ith largest eigenvalue of A, then

$$\begin{aligned}\log^+ \|U_t^{-1}\| \leq \|U_t^{-1}\| &= [\lambda_1(U_t^{-1*}U_t^{-1})]^{1/2} = [\lambda_d(U_tU_t^*)]^{-1/2} \\ &\leq \frac{[\lambda_1(U_tU_t^*)]^{(d-1)/2}}{(|\det U_tU_t^*|)^{1/2}} \leq \frac{\|(U_tU_t^*)\|^{(d-1)/2}}{|\det U_t|} \leq \frac{\|U_t\|^{d-1}}{|\det U_t|}. \end{aligned} \tag{18}$$

Now, U_t solves the Stratonovich equation

$$dU_t = \left(\hat{G}^* - \frac{1}{2}\,\sigma^{-2}H^2\right)U_t dt + \sigma^{-2}HU_t \circ dy_t\,;$$

thus

$$|\det U_t| = \exp\left[\int_0^t \operatorname{trace}\left(\hat{G}^* - \frac{1}{2}\,\sigma^{-2}H^2\right)ds + \int_0^t \operatorname{trace}(\sigma^{-2}H)\circ dy_s\right],$$

and combining this with inequality (18) and the Cauchy–Schwartz inequality, the integrability of u_2 follows. □

A corollary analogous to Corollary 2.1 follows.

COROLLARY 3.1. *Let $\lambda_1^\sigma \geq \lambda_2^\sigma \geq \cdots \geq \lambda_d^\sigma$ denote the Lyapunov exponents associated with the multiplicative process U_t. Then,*

$$\gamma_\sigma = \lambda_2^\sigma - \lambda_1^\sigma\ . \tag{19}$$

Proof of Theorem 1.6. By Oseledec's theorem,

$$\lim_t \frac{1}{t}\log\|\wedge^r U_t\| = \lambda_1^\sigma + \cdots + \lambda_r^\sigma \quad \text{a.s.}$$

This limit equals the limit on the discrete time sequence $\{n\delta\}$ for some $\delta > 0$, so if one looks at the sequence of linear operators $\{\hat{A}_n^\delta\}$ for which

$$\rho^{p_0}(n\delta) = \hat{A}_n^\delta \rho^{p_0}((n-1)\delta)\,, \quad \rho^{p_0}(0) = p_0\,, \tag{20}$$

then

$$\lim_n \frac{1}{n\delta}\log\|\wedge^r \hat{A}_n^\delta \cdots \hat{A}_1^\delta\| = \lambda_1^\sigma + \cdots + \lambda_r^\sigma \quad \text{a.s.}$$

Stationarity, ergodicity, and integrability of $\{\hat{A}_n^\delta\}$ follow from those of the continuous time process, so the assumptions of Oseledec's theorem hold, and there exists a Lyapunov spectrum for (20) denoted $\{\lambda_i^{\sigma,\delta}\}_{i=1}^d$. The relation between the spectra is $\frac{1}{\delta}\lambda_i^{\sigma,\delta} = \lambda_i^\sigma$ and thus by (19),

$$\gamma_\sigma = \frac{1}{\delta}(\lambda_2^{\sigma,\delta} - \lambda_1^{\sigma,\delta}).$$

It is useful to consider here the well-known representation of the solution to the Zakai equation as

$$\rho^{p_0}(t) = L_t f_t,$$

where

$$L_t = \operatorname{diag}\left\{\exp \sigma^{-2}\left(h_i y_t - \frac{1}{2}\, h_i^2 t\right)\right\}_{i=1}^{d}$$

and $f : \mathbb{R}^+ \mapsto \mathbb{R}^d$ is the solution of

$$\begin{cases} \dot{f}_t = L_t^{-1}\hat{G}^* L_t f_t, \\ f_0 = p_0. \end{cases}$$

Denote by $\{A_i^\delta\}$ the matrices for which $f_{n\delta} = A_n^\delta f_{(n-1)\delta}$. Now, by Property 1, $\tau(\hat{A}_1^\delta) = \tau(L_\delta A_1^\delta) = \tau(A_1^\delta)$. As U_t is a homeomorphism, $\hat{A}_1^\delta$ is invertible. Therefore, A_1^δ is invertible and thus also allowable. One therefore has by Lemma 2.2 and Fatou's lemma

$$\gamma_\sigma \le \limsup_{\delta\to 0} \frac{1}{\delta} E \log \tau(A_1^\delta) \le E \limsup_{\delta\to 0} \frac{1}{\delta} \log \tau(A_1^\delta). \tag{21}$$

Since f_t belongs to $C^1[0,\infty)$, it follows that

$$f_\delta = (I + L_0^{-1}\hat{G}^* L_0 \delta + M^\delta) f_0,$$

where M^δ is a $d \times d$ matrix with $\|M^\delta\| = o(\delta)$. It suffices to prove the theorem for $\hat{G}$, for which $\forall i, j,\ i \ne j,\ g_{ij} > 0$. Under this condition, ψ may be expressed as

$$\psi(A_1^\delta) = \psi(I + \hat{G}^*\delta + M^\delta) = \min_{1\le i,j,k,l\le d} \frac{(1_{\{i=j\}} + g_{ji}\delta + m_{ij}^\delta)(1_{\{l=k\}} + g_{kl}\delta + m_{lk}^\delta)}{(1_{\{i=k\}} + g_{ki}\delta + m_{ik}^\delta)(1_{\{l=j\}} + g_{jl}\delta + m_{lj}^\delta)},$$

where $m_{ij}^\delta = (M^\delta)_{ij}$. There exists a δ_0 such that for every $0 < \delta < \delta_0$, the minimum is achieved on $i = k \ne l = j$; thus

$$\psi(A_1^\delta) = \min_{i,j:i\ne j} g_{ij} g_{ji}\delta^2 + o(\delta^2),$$
$$\psi^{1/2}(A_1^\delta) = \min_{i,j:i\ne j} (g_{ij} g_{ji})^{1/2}\delta + o(\delta),$$

and

$$\frac{1}{\delta}\log \tau(A_1^\delta) = \frac{1}{\delta}\log\frac{1-\psi^{1/2}(A_1^\delta)}{1+\psi^{1/2}(A_1^\delta)} = \frac{1}{\delta}\left[-2\min_{i,j:i\ne j}(g_{ij}g_{ji})^{1/2}\delta + o(\delta)\right]$$
$$\longrightarrow_{\delta\to 0} -2\min_{i,j:i\ne j}(g_{ij}g_{ji})^{1/2},$$

and the result follows from inequality (21). □

Proof of Theorem 1.7. It seems natural to approach the continuous time case as a limit of the discrete time problem. Note, however, that a change in the order of limits is needed to carry out this approach, and justifying this change of order seems challenging. We thus take below a different route. Although the general idea is similar to the discrete time case, extra care is needed due to the fact that the trajectories of the x process do not possess positive probability, and an appropriate version of the Feynman–Kac formula is needed.

The first part of the theorem is a direct consequence of the following three lemmas, whose proof is deferred.

LEMMA 3.2. *Assume* (A2) *holds. Then* $\limsup_{\sigma\to 0} \sigma^2 \lambda_1^\sigma \le \frac{1}{2} E h_{x_0}^2$.

LEMMA 3.3. *Assume* (A2) *holds. Then*

$$\limsup_{\sigma\to 0}\sigma^2(\lambda_1^\sigma+\lambda_2^\sigma)\le \frac{1}{2}\,Eh_{x_0}^2+Eh_{x_0}h_{\mathrm{nbr}(x_0)}-\frac{1}{2}\,Eh_{\mathrm{nbr}(x_0)}^2.$$

LEMMA 3.4. *Assume* (A2) *holds. Then* $\liminf_{\sigma\to 0}\sigma^2\lambda_1^\sigma\ge \frac{1}{2}\,Eh_{x_0}^2$.

Given Lemma 3.2 above, the proof of (6) is similar to the proof of (3) in the discrete time setup, with trace $\hat{G}$ playing the role of $\log|\det G|$ there. □

Proof of Lemma 3.2. Using (A2), and denoting by e_i the unit vectors in $\mathbb{R}^d$, it holds that $\cos(e_i,p^x_{\mathrm{stat}})\ge c>0$ for some c independent of t. Therefore, since U_t is nonnegative, and using c_1 to denote another positive deterministic constant independent of t, $\parallel U_tp^x_{\mathrm{stat}}\parallel\ge \min_i\cos(e_i,p^x_{\mathrm{stat}})\max_i\parallel U_te_i\parallel\ge c_1\parallel U_t\parallel$ and

$$\lambda_1^\sigma=\lim_{t\to\infty}\frac{1}{t}E\log\parallel U_t\parallel\le\lim_{t\to\infty}\frac{1}{t}E\log\parallel U_tp^x_{\mathrm{stat}}\parallel\ .$$

Let $\tilde{x}$ denote the realization of the x process under E_0, initialized at the stationary measure. Then, by the Kallianpur–Striebel formula and Oseledec's theorem,

$$\lambda_1^\sigma\le\lim_{t\to\infty}\frac{1}{t}E\log E_0\left[\exp\left(\sigma^{-2}\left(\int_0^t h(\tilde{x}_s)dy_s-\frac{1}{2}\,h^2(\tilde{x}_s)ds\right)\right)\,\middle|\,y_0^t\right]. \tag{22}$$

Fix $\delta>0$ and define $\Delta_iy=y_{(i+1)\delta}-y_{i\delta}$, $|\Delta y|^{i,\delta}_{\max}=\max\{|y_t-y_{t'}|\,:\,t,t'\in[i\delta,(i+1)\delta)\}$. Let $\{\tau_i\}$ be the jumping times of $\{\tilde{x}_t\}$, and let $|\Delta y|^{\tau_i,\delta}_{\max}=\max\{|y_t-y_{t'}|\,:\,t,t'\in[\tau_i-\delta,\tau_i+\delta)\}$. Define similarly $\Delta_i\nu$, $|\Delta\nu|^{i,\delta}_{\max}$, $|\Delta\nu|^{\tau_i,\delta}_{\max}$ and let $h_{\max}=\max_i|h_i|$. Let $i_t=[t/\delta]$ and $N_t=\max\{i:\tau_i\le t\}=\#\{\tau_i\le t\}$. We control the integral in (22) by its discrete time skeleton, with errors occurring only around jump times. That is,

$$\begin{aligned}
&\int_0^t\left(h(\tilde{x}_s)dy_s-\frac{1}{2}\,h^2(\tilde{x}_s)ds\right)\\
&\le\sum_{i=0}^{i_t}\left(h(\tilde{x}_{i\delta})\Delta_iy-\frac{1}{2}\,h^2(\tilde{x}_{i\delta})\delta\right)+\sum_{i=1}^{N_t}(2h_{\max}|\Delta y|^{\tau_i,\delta}_{\max}+{h_{\max}}^2\delta)\\
&\le\frac{1}{2}\sum_{i=0}^{i_t}\frac{(\Delta_iy)^2}{\delta}+\sum_{i=1}^{N_t}\left[2h_{\max}\left(2h_{\max}\delta+\sigma|\Delta\nu|^{\tau_i,\delta}_{\max}\right)+h_m^2\delta\right]\ .
\end{aligned} \tag{23}$$

Thus, by Jensen's inequality,

$$\begin{aligned}
&\frac{1}{t}E\log E_0\left[\exp\left(\sigma^{-2}\int_0^t h(\tilde{x}_s)dy_s-\frac{1}{2}\,h^2(\tilde{x}_s)ds\right)\,\middle|\,y_0^t\right]\\
&\le\frac{1}{t}\frac{1}{2\sigma^2\delta}E\sum_{i=0}^{i_t}(\Delta_iy)^2+\frac{1}{t}\log E_0\left[\exp\left(\sigma^{-2}\sum_{i=1}^{N_t}(5{h_{\max}}^2\delta+2h_{\max}\sigma|\Delta\nu|^{\tau_i,\delta}_{\max})\right)\right].
\end{aligned} \tag{24}$$

On the other hand, using stationarity,

$$\begin{aligned}
E(\Delta_iy)^2&=E\left(\int_0^\delta h(x_s)ds+\sigma\nu_\delta\right)^2=E\left(\int_0^\delta h(x_s)ds\right)^2+\sigma^2\delta\\
&\le E_sh^2(x_0)\delta^2+\sigma^2\delta+E\left[1_{\{x_t\ \text{jumps in}\ [0,\delta)\}}(2h_{\max}\delta)^2\right]\\
&=E_sh^2(x_0)\delta^2+\sigma^2\delta+\delta^2C'_\delta\,,
\end{aligned} \tag{25}$$

with $C'_\delta\underset{\delta\to 0}{\longrightarrow}0$.

Conditioning on N_t, one has

$$\begin{aligned}
&\frac{1}{t}\log E_0 \exp\left(\sigma^{-2}\sum_{i=1}^{N_t}\left(5{h_{\max}}^2\delta + 2h_{\max}\sigma|\Delta\nu|^{\tau_i,\delta}_{\max}\right)\right)\\
\leq&\frac{1}{t}\log E_0 \exp(N_t c\sigma^{-2}\delta)\\
\leq&\frac{1}{t}\log\sum_{n=0}^{\infty}\exp(nc\sigma^{-2}\delta)c\frac{(\mu t)^n}{n!}e^{-\mu t}\\
=&\frac{1}{t}\log c + \mu(e^{c\delta/\sigma^2}-1)\,, \qquad (26)
\end{aligned}$$

where $\mu = \max_i \sum_{j\neq i}\hat{G}_{ij}$. Combining (22), (24), (25), and (26),

$$\sigma^2\lambda_1^\sigma \leq \frac{1}{2}\,E_s h^2(x_0) + \frac{\sigma^2}{2\delta} + \frac{C'_\delta}{2} + \sigma^2\mu\left(e^{c\delta/\sigma^2}-1\right)\,. \qquad (27)$$

Now take $\sigma^2/\delta = \epsilon$ and $\delta, \sigma \to 0$, then take infimum over $\{\epsilon > 0\}$ to get

$$\limsup_{\sigma\to 0}\sigma^2\lambda_1^\sigma \leq \frac{1}{2}\,E_s h^2(x_0)\,. \qquad \square$$

Proof of Lemma 3.3. We use the same notations as in Lemma 3.2. Let $d\rho_t = \hat{G}^*\rho_t dt + \sigma^{-2}H\rho_t dy_t$, $d\eta_t = \hat{G}^*\eta_t dt + \sigma^{-2}H\eta_t dy_t$ (the difference between ρ_t and η_t lies in possibly different initial conditions). In what follows, we suppress the index t. Write $\rho\wedge\eta = \frac{1}{2}(\rho\eta^* - \eta\rho^*)$, then

$$\begin{aligned}
d\rho\eta^* &= \hat{G}^*\rho\eta^* dt + \sigma^{-2}H\rho\eta^* dy_t + \rho\eta^*\hat{G}dt + \sigma^{-2}\rho\eta^* H dy_t + \sigma^{-2}H\rho\eta^* H dt\,, \qquad (28)\\
d(\rho\wedge\eta) &= \left[\hat{G}^*(\rho\wedge\eta) - \left(\hat{G}^*(\rho\wedge\eta)\right)^*\right]dt + \sigma^{-2}\left[H(\rho\wedge\eta) - (H(\rho\wedge\eta))^*\right]dy_t\\
&\quad + \sigma^{-2}H(\rho\wedge\eta)H dt\,.
\end{aligned}$$

Let the $(d-1)d$-dimensional vector $\underline{\alpha} = (\alpha_{12}\ \alpha_{13}\cdots\alpha_{1d}\ \alpha_{21}\ \alpha_{23}\cdots\alpha_{d(d-1)})^*$ be defined by

$$\rho\wedge\eta = \begin{pmatrix} 0 & \alpha_{12}\ \alpha_{13} & \cdots & \alpha_{1d}\\ \alpha_{21} & 0\ \alpha_{23} & \cdots & \alpha_{2d}\\ \vdots & \ddots & & \\ \alpha_{d1} & & & 0 \end{pmatrix}.$$

Then (28) can be written as

$$d\underline{\alpha} = \bar{G}^*\,\underline{\alpha}\,dt + \sigma^{-2}\bar{H}_1\,\underline{\alpha}\,dt + \sigma^{-2}\bar{H}_2\,\underline{\alpha}\,dy_t \qquad (29)$$

with $\bar{G}(i,j) \geq 0$ for all $i \neq j$,

$$\bar{H}_1 = \begin{pmatrix} h_1h_2 & & & \\ & h_1h_3 & & \\ & & \ddots & \\ & & & h_dh_{d-1} \end{pmatrix},$$

$$\bar{H}_2 = \begin{pmatrix} h_1+h_2 & & & \\ & h_1+h_3 & & \\ & & \ddots & \\ & & & h_d+h_{d-1} \end{pmatrix}.$$

We may now regard $\underline{\alpha}$ as a $d(d-1)$-dimensional vector indexed by ij with $i \neq j$. Viewed this way, the matrix $\bar{G}$ has off-diagonal entries

$$\bar{G}_{ij,\ell m} = \begin{cases} \hat{G}_{\ell i} & j = m \neq \ell, \\ \hat{G}_{mj} & i = \ell \neq m, \\ 0 & j \neq m \,\text{and}\, i \neq \ell. \end{cases}$$

The matrix $\bar{G}$ is not necessarily a transition-rate matrix. However, there exists a transition-rate matrix $\tilde{G}$ which is equal to $\bar{G}$ off the diagonal. Thus (29) may be written

$$d\underline{\alpha} = \tilde{G}^* \,\underline{\alpha}\, dt + \sigma^{-2}\tilde{H}_1 \,\underline{\alpha}\, dt + \sigma^{-2}\tilde{H}_2 \,\underline{\alpha}\, dy_t\,, \tag{30}$$

with $\tilde{G}^* + \sigma^{-2}\tilde{H}_1 = \bar{G}^* + \sigma^{-2}\bar{H}_1$, $\tilde{H}_2 = \bar{H}_2$. It follows that

$$\tilde{H}_1 = \begin{pmatrix} h_1h_2+\sigma^2\Delta g_{12} & & & \\ & h_1h_3+\sigma^2\Delta g_{13} & & \\ & & \ddots & \\ & & & h_dh_{d-1}+\sigma^2\Delta g_{d(d-1)} \end{pmatrix}.$$

Note that while we are primarily interested in solutions to (30) which are in the anti-symmetric subspace $\underline{\alpha}_{ij} = -\underline{\alpha}_{ji}$, (30) makes perfect sense for arbitrary vectors in $\mathbb{R}^{d(d-1)}$. This point of view is particularly useful when computing upper bounds on Lyapunov exponents.

We now use $\tilde{h}_i(j\,k)$ ($\bar{h}_i(j\,k)$) to denote the jkth element on the diagonal of $\tilde{H}_i$ (respectively, $\bar{H}_i$), $i = 1, 2$. Let $S = \{jk : j,k \in \{1,\ldots,d\}, j \neq k\}$. Associate to the Markovian generator $\tilde{G}$ the S-valued process $\{\tilde{x}_t\}$, independent of $\{x_0^t\}$ and of $\{y_0^t\}$. We now introduce an auxiliary assumption on $\tilde{G}$, which will later be proved to be implied by (A2).

(A3) Let (A2) hold. In addition, assume that $\tilde{x}$ has no transient states.

Note that (A3) implies that $\tilde{x}$ possesses a stationary distribution (not necessarily unique) with strictly positive components.

By the stochastic Feynman–Kac formula of nonlinear filtering (using, e.g., an argument similar to Lemma 2.1 of [10]), if $\underline{\alpha}_{ij}(t=0) = P(\tilde{x}_0 = (ij))$, then

$$\langle \underline{\alpha}, \mathbf{1} \rangle = \sum_{i,j} \underline{\alpha}_{ij} = E_0\left[\exp\left(\sigma^{-2}\left(\int_0^t \tilde{h}_2(\tilde{x}_s)dy_s - \frac{1}{2}\,\tilde{h}_2^2(\tilde{x}_s)ds + \tilde{h}_1(\tilde{x}_s)ds\right)\right)\,\middle|\, y_0^t\right].$$

Let A_t denote the linear map $\underline{\alpha}_0 \to \underline{\alpha}_t$. Let $p^{\tilde{x}}_{\rm stat}$ denote the stationary distribution of $\tilde{x}$, which by (A3) has all entries strictly positive. Mimicking the argument used in the proof of Lemma 3.2, one has by positivity and Oseledec's theorem that

(31)
$$\begin{aligned}
&\lambda_1^\sigma + \lambda_2^\sigma \\
&= \lim_{t\to\infty} \frac{1}{t} \log \sup_{\{\rho_0,\eta_0:\|\rho_0\wedge\eta_0\|=1\}} \| \rho_t \wedge \eta_t \| \leq \lim_{t\to\infty} \frac{1}{t} E \log \|A_t\| \\
&\leq \lim_{t\to\infty} \frac{1}{t} E \log \| A_t p^{\tilde{x}}_{\rm stat} \| \\
&= \lim_{t\to\infty} \frac{1}{t} E \log E_0 \Big[\exp\Big(\sigma^{-2} \Big(\int_0^t \tilde{h}_2(\tilde{x}_s) dy_s - \frac{1}{2} \int_0^t \tilde{h}^2(\tilde{x}_s) ds + \int_0^t \tilde{h}_1(x_s) ds \Big) \Big) | y_0^t \Big].
\end{aligned}$$

Define $\hat{n} : \mathbb{R} \to \{1,\dots,d\}$ by $\hat{n}(a) = \mathrm{argmin}_i |h_i - a|$. Then there exists a constant $r_0 > 0$ such that if $|h_i - a| \leq r_0$ then $\mathrm{argmin}_{i\neq\hat{n}(a)} |h_i - a| = \mathrm{nbr}(\hat{n}(a))$. Now, denoting $g_m = \max |\Delta g(\cdot)|$,

(32)
$$\begin{aligned}
J_t :=& \int_0^t \tilde{h}_2(\tilde{x}_s) dy_s - \frac{1}{2} \int_0^t \tilde{h}_2^2(\tilde{x}_s) ds + \int_0^t \tilde{h}_1(\tilde{x}_s) ds \\
=& \int_0^t \bar{h}_2(\tilde{x}_s) dy_s + \int_0^t \sigma^2 \Delta g(\tilde{x}_s) dy_s - \int_0^t \frac{1}{2} \bar{h}_2^2(\tilde{x}_s) ds \\
&+ \int_0^t \bar{h}_2(\tilde{x}_s) \sigma^2 \Delta g(\tilde{x}_s) ds - \int_0^t \frac{1}{2} \sigma^4 \Delta g^2(\tilde{x}_s) ds + \int_0^t \bar{h}_1(\tilde{x}_s) ds \\
\leq& \sum_{i=0}^{i_t} \Big\{ \bar{h}_2(\tilde{x}_{i\delta}) \Delta_i y - \frac{1}{2} \bar{h}_2^2(\tilde{x}_{i\delta}) \delta + \bar{h}_1(\tilde{x}_{i\delta}) + \sigma^2 g_m |\Delta y|^{i,\delta}_{\max} + 2 h_{\max} \sigma^2 g_m \delta \Big\} \\
&+ \sum_{i=1}^{N_t} (2 h_{\max} |\Delta y|^{\tau_i,\delta}_{\max} + 2 {h_{\max}}^2 \delta) \\
\leq& J_t^1 + J_t^2,
\end{aligned}$$

where

$$\begin{aligned}
J_t^1 =& \sum_{i=0}^{i_t} \delta \Big\{ \Big[h\Big(\hat{n}\Big(\frac{\Delta_i y}{\delta} \Big) \Big) + h\Big(\mathrm{nbr}\Big(\hat{n}\Big(\frac{\Delta_i y}{\delta} \Big) \Big) \Big) \Big] \frac{\Delta_i y}{\delta} \\
&- \frac{1}{2} h^2\Big(\hat{n}\Big(\frac{\Delta_i y}{\delta} \Big) \Big) - \frac{1}{2} h^2\Big(\mathrm{nbr}\Big(\hat{n}\Big(\frac{\Delta_i y}{\delta} \Big) \Big) \Big) \Big\} \\
&+ \sum_{\{i\leq i_t : |\frac{\Delta_i y}{\delta} - h_j| > r_0 \ \forall j\}} \big\{ 4 h_{\max} |\Delta_i y|^{i,\delta}_{\max} + h_m^2 \delta \big\}
\end{aligned}$$

and

$$\begin{aligned}
J_t^2 =& \sum_{i=1}^{i_t} \big\{ \sigma^2 g_m (2 h_{\max} \delta + \sigma |\Delta \nu|^{i,\delta}_{\max}) + 2 h_{\max} g_m \sigma^2 \delta \big\} \\
&+ \sum_{i=1}^{N_t} \big\{ 2 h_{\max} \big(2 h_{\max} \delta + \sigma |\Delta \nu|^{\tau_i,\delta}_{\max} \big) + 2 {h_{\max}}^2 \delta \big\} \ .
\end{aligned}$$

Having J_t^1 measurable with respect to y_0^t, it follows using Jensen's inequality that

$$\frac{1}{t} E \log E_0 \left[\exp\left(\sigma^{-2} J_t\right) | y_0^t \right] \leq \frac{1}{t} \frac{1}{\sigma^2} E J_t^1 + \frac{1}{t} \log E_0 \exp\left(\sigma^{-2} J_t^2\right). \tag{33}$$

Now,

$$\begin{aligned} \frac{1}{t} E J_t^1 \leq & \frac{1}{\delta} E_s \left\{ (h(x_0) + h(\mathrm{nbr}(x_0)))(\delta h(x_0) + \sigma \Delta\nu) - \frac{\delta}{2} h^2(x_0) - \frac{\delta}{2} h^2(\mathrm{nbr}(x_0)) \right\} \\ & + c\delta + c e^{-r_0^2 \delta / 2\sigma^2}, \end{aligned} \tag{34}$$

where the second term is due to the fact that the probability of having a jump in the x process on any δ-interval is of order δ, and the last term is due to the Gaussian law of ν. Next,

$$\begin{aligned} & \frac{1}{t} \log E_0 \left(\exp \sigma^{-2} J_t^2 \right) \leq \frac{1}{t} \log E_0 \, E_0 \left[\exp(\sigma^{-2} J_t^2) | N_t \right] \\ & \leq \frac{1}{t} \log E_0 \, E_0 \left[\exp \left\{ \sum_{i=1}^{N_t} \left(c\delta + c\sigma |\Delta\nu|_{\max}^{i,\delta} \right) + \sum_{i=1}^{N_t} c\delta\sigma^{-2} + c\sigma^{-1} |\Delta\nu|_{\max}^{\tau_i \delta} \right\} \, | N_t \right] \\ & = \frac{1}{t} \log E_0 \exp \left(\frac{t}{\delta} c\delta + \frac{t}{\delta} c^2\sigma^2\delta + N_t c\delta\sigma^{-2} + N_t c^2 \sigma^{-2} \delta \right) \\ & = c + c^2\sigma^2 + \frac{1}{t} \log E \, \exp c N_t \delta \sigma^{-2} \\ & \leq c + c^2\sigma^2 + \lambda(e^{c\delta/\sigma^2} - 1). \end{aligned} \tag{35}$$

Finally, combining (33), (34), and (35),

$$\begin{aligned} \sigma^2(\lambda_1^\sigma + \lambda_2^\sigma) \leq E_s & \left[(h(x_0) + h(\mathrm{nbr}(x_0)))h(x_0) - \frac{1}{2} h^2(x_0) - \frac{1}{2} h^2(\mathrm{nbr}(x_0)) \right] + c\delta \\ & + c e^{-r_0^2 \delta / 2\sigma^2} + \sigma^2 c + \sigma^4 c^2 + \sigma^2 c (e^{c\delta/\sigma^2} - 1). \end{aligned}$$

Take now $\sigma^2/\delta = \epsilon$, $\delta, \sigma \to 0$, then take $\epsilon \to 0$ to conclude the lemma under (A3).

Although (A2) does not imply that all states of $\tilde{x}$ are communicating (as the example $d = 3, \hat{G}_{13} = \hat{G}_{31} = 0$ shows), we now show that it does imply (A3). It suffices to show that for every two states $ij,\ kl \in S$, if $(\tilde{G}^m)_{ij,\,kl} > 0$ for some m, then there exists an n such that $(\tilde{G}^n)_{kl,\,ij} > 0$, or, in the terminology we use in what follows, if the path $ij \to kl$ exists then the path $kl \to ij$ exists, too. Note next that it suffices to show the above for $j = l$ and for $i, k \neq j$ such that $\hat{G}_{i\,k} > 0$ (that is $i \to k$ in one step). Suppose, then, that $ij \to kj$ in one step. It needs to be shown that $kj \to ij$. If there exists a path $k \to i$ that does not contain j, then the claim is proved. Otherwise, since $\hat{G}$ is communicating, there exists a path $k \to j \to i$ such that $k \to j$ does not contain i and $j \to i$ does not contain k. Thus the following path exists too:

$$kj \to ki \to ji \to jk \to ik \to ij,$$

and it follows that $\tilde{x}$ has no transient states. This concludes the proof. □

Proof of Lemma 3.4. The top Lyapunov exponent satisfies

$$\lambda_1^\sigma = \lim_{t\to\infty} \frac{1}{t} E \log \|U_t\| \geq \lim_{t\to\infty} \frac{1}{t} E \log \|U_t p_{\mathrm{stat}}^x\|.$$

Again, we compute $\|U_t p^x_{\rm stat}\|$ using the Kallianpur–Striebel formula. Fix $\delta > 0$ and let I_i be the interval $[\delta j, \delta(j+1))$ such that $\tau_i \in I_i$. Then denoting, as above, by $\tilde{x}$ a copy of the process x which is independent of y_0^t under E_0,

$$\begin{aligned}
&\frac{1}{t} E \log E_0 \left[\exp\left(\sigma^{-2} \left(\int_0^t h(\tilde{x}_s) dy_s - \frac{1}{2} \int_0^t h^2(\tilde{x}_s) ds \right) \right) | y_0^t \right] \\
&\geq \frac{1}{t} E \log E_0 \left[E_0 \left[1_{\{\tilde{x}_s = x_s \, \forall s \notin \bigcup_i I_i, \, s<t\}} \right. \right. \\
&\qquad \left. \left. \exp\left(\sigma^{-2} \left(\int_0^t h(\tilde{x}_s) dy_s - \frac{1}{2} \int_0^t h^2(\tilde{x}_s) ds \right) \right) | x_0^t, y_0^t \right] | y_0^t \right] \\
&\geq \frac{1}{t} E \log E_0 \left[E_0 \left[1_{\{\tilde{x}_s = x_s \, \forall s \notin \bigcup_i I_i, \, s<t\}} \exp\left(\sigma^{-2} \, B_t(x,y) \right) | x_0^t, y_0^t \right] | y_0^t \right],
\end{aligned}$$

where

$$B_t(x,y) = \int_0^t h(x_s) dy_s - \frac{1}{2} \int_0^t h^2(x_s) ds - \sum_i (c |\Delta y|^{\tau_i, \delta}_{\max} + c\delta).$$

Thus, by Jensen's inequality,

$$\begin{aligned}
\frac{1}{t} E \log \|U_t p^x_{\rm stat}\| &\geq \frac{1}{t} E \log E_0 \left[1_{\{\tilde{x}_s = x_s \, \forall s \notin \bigcup_i I_i, \, s<t\}} \exp\left(\sigma^{-2} B_t(x,y) \right) | x_0^t, y_0^t \right] \\
&= \frac{1}{t} \log E \left[1_{\{\tilde{x}_s = x_s \, \forall s \notin \bigcup_i I_i, \, s<t\}} | x_0^t \right] + \frac{1}{t} E \sigma^{-2} B_t(x,y).
\end{aligned}$$

Now,

$$\begin{aligned}
&\frac{1}{t} E \log E \left[1_{\{\tilde{x}_s = x_s \, \forall s \notin \bigcup_i I_i, \, s<t\}} | x_0^t \right] \\
&= \frac{1}{t} E \log E \left[1_{\{\tilde{x}_{j\delta} = x_{j\delta} \, \forall j < t/\delta \text{ s.t. } j\delta \notin \bigcup_i I_i\}} | x_0^t \right] \\
&\geq \frac{1}{t} E \log E \left[1_{\{\tilde{x}_{j\delta} = x_{j\delta} \, \forall j < t/\delta\}} | x_0^t \right].
\end{aligned}$$

The last quantity tends to $-\frac{1}{\delta} \mathcal{H}(\{x_{j\delta}\})$, where $\mathcal{H}(\{x_{j\delta}\})$ is the entropy rate for $\{x_{j\delta}\}$. Moreover,

$$\lim_{t \to \infty} \frac{1}{t} E B_t(x,y) = \frac{1}{2} E h^2(x_0) - c\delta,$$

and thus we have shown

$$\sigma^2 \lambda_1^\sigma \geq \frac{1}{2} E h^2(x_0) - c\delta - \frac{\sigma^2}{\delta} \log d.$$

Now taking $\sigma \to 0$ and then $\delta \to 0$ yields the result. □

Remark. The vector $\rho \wedge \eta$ has only $(d-1)d/2$ degrees of freedom, the same as the vector $\underline{\alpha}$. We have used a $(d-1)d$ dimensional vector $\underline{\alpha}$ in order to write (29) as a matrix with nonnegative off-diagonal entries. For general (nonfiltering) situations, this might not be possible.

Acknowledgment. We thank P. Bougerol for bringing [7] to our attention.

THE EXTENDED EULER–LAGRANGE CONDITION FOR NONCONVEX VARIATIONAL PROBLEMS*

RICHARD VINTER† AND HARRY ZHENG†

Abstract. This paper provides necessary conditions of optimality for a general variational problem for which the dynamic constraint is a differential inclusion with a possibly nonconvex right side. They take the form of an Euler–Lagrange inclusion involving convexification in only one coordinate, supplemented by the transversality and Weierstrass conditions. It is also shown that for time-invariant, free time problems, the adjoint arc can be chosen so that the Hamiltonian function is constant along the minimizing state arc. The methods used here, based on simple "finite dimensional" nonsmooth calculus, Clarke decoupling, and a rudimentary version of the maximum principle, offer an alternative, and somewhat simpler, derivation of such results to those used by Ioffe and Rockafellar in concurrent research.

Key words. Euler–Lagrange condition, calculus of variations, nonconvex differential inclusion, nonsmooth analysis, limiting subdifferential

1. Introduction.

We consider nonsmooth variational problems of the form (P):

$$\text{(P)}\qquad \begin{aligned} &\text{minimize } l(x(0),x(1)) + \int_0^1 L(t,x(t),\dot{x}(t))dt \\ &\text{over arcs } x \in W^{1,1}([0,1];R^n) \text{ which satisfy} \\ &\dot{x}(t) \in F(t,x(t)) \quad \text{a.e. on } [0,1]. \end{aligned}$$

Here $l : R^n \times R^n \to R \cup \{+\infty\}$ and $L : [0,1] \times R^n \times R^n \to R$ are given functions and $F : [0,1] \times R^n \rightrightarrows R^n$ is a given multifunction.

The minimization is performed over arcs x in $W^{1,1}([0,1];R^n)$ (the space of absolutely continuous R^n-valued functions on $[0,1]$) which satisfy the differential inclusion constraint and for which $L(t,x(t),\dot{x}(t))$ is an integrable function. Let $\bar{x}$ be a minimizer.

Problem (P) provides a framework for dynamic optimization which emphasizes the constraints on allowable velocities $\dot{x}$ for a given time and state (t,x). It covers the formulation traditionally adopted in optimal control theory involving a differential equation parameterized by a control function u

$$\dot{x}(t) = f(t,x(t),u(t)) \quad \text{a.e.}$$

and

$$u(t) \in U(t) \quad \text{a.e.}$$

Here we choose the multifunction to be $F(t,x) \equiv f(t,x(t),U(t))$. (A differential inclusion arising in this way is said to have a "parameterization" (f,U).) But problem

†Department of Electrical and Electronic Engineering and Centre for Process Systems Engineering, Imperial College, Exhibition Road, London SW7 2BT, UK (r.vinter@ic.ac.uk, h.zheng@ic.ac.uk).

(P) is a convenient description of dynamic systems incorporating feedback loops, state-dependent control constraints, and other such features for purposes of deriving optimality conditions.

In the case of no dynamical constraints ($F \equiv R^n$), smooth l, and L and when the Lipschitz rank of $(x,u) \to L(t,x,u)$ is suitably bounded, the following classical first-order necessary conditions are satisfied by the minimizer $\bar{x}$: there exists $p \in W^{1,1}$ such that

$$(\dot{p}(t), p(t)) = \nabla L(t, \bar{x}(t), \dot{\bar{x}}(t)) \tag{1}$$

(the Euler–Lagrange condition),

$$p(t)\dot{\bar{x}}(t) - L(t, \bar{x}(t), \dot{\bar{x}}(t)) \geq p(t)v - L(t, \bar{x}(t), v) \quad \forall\ v \in R^n \text{ a.e.} \tag{2}$$

(the Weierstrass condition), and

$$(p(0), -p(1)) \in \nabla l(\bar{x}(0), \bar{x}(1)) \tag{3}$$

(the transversality condition).

Modern developments provide necessary conditions when a dynamic constraint is present ($F \not\equiv R^n$) and when the functions l and L are possibly nonsmooth. There are three main strands to this research. The first is the maximum principle (for parameterized problems) and its nonsmooth counterparts. The second is to replace (1) and (2) with Clarke's Hamiltonian inclusion [2]:

$$(-\dot{p}(t), \dot{\bar{x}}(t)) \in \text{co}\partial H_\lambda(t, \bar{x}(t), p(t)) \tag{4}$$

$$(p(0), -p(1)) \in \partial l(\bar{x}(0), \bar{x}(1)),$$

in which H_λ is the Hamiltonian

$$H_\lambda(t,x,p) := \sup\{pv - \lambda L(t,x,v) : v \in F(t,x)\}.$$

Here ∂H_λ denotes the limiting subdifferential of $H_\lambda(t,\cdot,\cdot)$, defined below (its convex hull $\text{co}\partial H_\lambda$ is the Clarke generalized gradient). The presence of constraints necessitates the introduction of a cost multiplier λ ($\lambda \geq 0$, λ and $p(\cdot)$ not both zero).

We focus attention on the third type of conditions, namely conditions which are nonsmooth analogues of the classical conditions (1)–(3). What form should they take? Notice that $\bar{x}$ is a minimizer for a variational problem in which the dynamic constraint is absorbed into the cost integrand, namely

$$\text{minimize } \int_0^1 (L(t,x,\dot{x}) + \Psi_{\text{Gr}\{F(t,\cdot)\}}(x,\dot{x}))dt.$$

(Here Ψ_A is the indicator function for the set A, which takes value 0 on A and $+\infty$ elsewhere.) This would suggest a nonsmooth version of (1) "$(\dot{p}(t), p(t)) \in \lambda\text{co}\partial(L(t,\cdot,\cdot) + \Psi_{\text{Gr}\{F(t,\cdot)\}})(\bar{x}(t), \dot{\bar{x}}(t))$," from which we might expect to deduce, via a sum rule and a subdifferential calculus for indicator functions

$$(\dot{p}(t), p(t)) \in \lambda\text{co}\partial L(t, \bar{x}(t), \dot{\bar{x}}(t)) + \overline{\text{co}}N_{\text{Gr}\{F(t,\cdot)\}}(\bar{x}(t), \dot{\bar{x}}(t)) \quad \text{a.e.}$$

Here $N_{\text{Gr}\{F(t,\cdot)\}}$ is the limiting normal cone, defined below. (Its closed convex hull $\overline{\text{co}}N_{\text{Gr}F(t,\cdot)}$, featured here, is the Clarke normal cone.) See Clarke's paper [1] for results in this spirit, which we refer to as the Euler–Lagrange inclusion.

The weak convergence techniques used in the proof of necessary conditions of this type make it almost inevitable that the conditions take the form of a convex set inclusion. Nonetheless a research theme of recent years has been to reduce the extent of convexification involved. Under the convexity hypothesis Mordukhovich [11, 12] derived, via discrete approximations, a form of the Euler–Lagrange inclusion which involves convexification with respect to only one coordinate

$$\dot{p}(t) \in \text{co}\{\eta : (\eta, p(t)) \in \lambda \partial L(t, \bar{x}(t), v) + N_{\text{Gr}\{F(t,\cdot)\}}(\bar{x}(t), v) \text{ for some } v \in F(t, \bar{x}(t))$$

$$\text{such that } p(t)v - \lambda L(t, \bar{x}(t), v) = H_\lambda(t, \bar{x}(t), p(t))\} \quad \text{a.e.}$$

The sharpest available conditions along these lines, in which the convex hull is taken just with respect to $v = \dot{\bar{x}}(t)$ rather than all v's achieving the maximum in the Hamiltonian, were obtained by Loewen and Rockafellar [9] with an analysis based on Hamiltonian inclusions and a subdifferential calculus of perturbed Hamiltonian functions for convex differential inclusions. Under the convexity hypothesis they showed that there exists $\lambda \geq 0$ and $p \in W^{1,1}$ (not all zero) such that

$$\dot{p}(t) \in \text{co}\{\eta : (\eta, p(t)) \in \lambda \partial L(t, \bar{x}(t), \dot{\bar{x}}(t)) + N_{\text{Gr}\{F(t,\cdot)\}}(\bar{x}(t), \dot{\bar{x}}(t))\} \tag{5}$$

$$(p(0), -p(1)) \in \lambda \partial l(\bar{x}(0), \bar{x}(1)).$$

(We have been informed that similar results were derived by Smirnov [16] for a narrower class of problems using discrete approximation methods.) We refer to (5) as the extended Euler–Lagrange condition.

Interest in these conditions has been heightened by recent findings of Rockafellar [15] that under the convexity assumption and other mild hypotheses this last condition is equivalent to

$$\dot{p}(t) \in \text{co}\{\eta : (-\eta, \dot{\bar{x}}(t)) \in \partial H_\lambda(t, \bar{x}(t), p(t))\} \quad \text{a.e.},$$

which will be recognized as a sharpened version of the Hamiltonian inclusion (4) involving convexification with respect to only one coordinate. Thus sharpened forms of the Hamiltonian inclusion and extended Euler–Lagrange inclusion coalesce under the convexity hypothesis.

We mention that in addition to the three types of necessary conditions for (P) outlined above there are hybrid conditions due to Kaśkosz and Lojasiewicz [6, 7] and refined by Zhu [18]. These conditions, expressed in terms of a family of "Lipschitz selectors" of the multifunction co$F$, are applicable to variational problems involving general, unparameterized, differential inclusions, yet have the character of the maximum principle.

What necessary conditions are valid for variational problems (P) with general endpoint constraints when the convexity hypothesis is dropped? The maximum principle remains valid and also the maximum principle–like conditions of Kaśkosz, Lojasiewicz, and Zhu. Whether the Hamiltonian inclusion is valid in this situation is a long-standing open question in dynamic optimization.

What about nonsmooth analogues of the classical first-order conditions for nonsmooth, nonconvex problems? The expected conditions are as follows: there exist λ (≥ 0) and $p \in W^{1,1}$, not both zero, such that

$$\dot{p}(t) \in \text{co}\{\eta : (\eta, p(t)) \in \lambda \partial L(t, \bar{x}(t), \dot{\bar{x}}(t)) + N_{\text{Gr}\{F(t,\cdot)\}}(\bar{x}(t), \dot{\bar{x}}(t))\}, \tag{6}$$

$$p(t)\dot{\bar{x}}(t) - \lambda L(t, \bar{x}(t), \dot{\bar{x}}(t)) \geq p(t)v - \lambda L(t, \bar{x}(t), v) \quad \text{for all } v \in F(t, \bar{x}(t)) \text{ a.e.}, \tag{7}$$

and

$$(p(0), -p(1)) \in \lambda \partial l(\bar{x}(0), \bar{x}(1)). \tag{8}$$

Notice that the extended Euler–Lagrange inclusion (6) and transversality conditions (8) have been supplemented by a form of the Weierstrass condition (7) appropriate to problems with dynamic constraints. The Weierstrass condition is superfluous for convex problems (it is implied by the extended Euler–Lagrange inclusion (6)), but for nonconvex problems it is a genuinely independent condition on minimizers which introduces an important global dimension into the optimality conditions regarding treatment of the velocity variable. The methods of Loewen and Rockafellar [9], which depend critically on the convexity of the differential inclusion concerned, give little indication of how such conditions might be derived.

Mordukhovich [14], using a discrete approximation approach, derived the extended Euler–Lagrange inclusion and transversality condition (but not the Weierstrass condition) for the costate arc p in the nonconvex case. However, the dropping of the convexity hypothesis was counterbalanced by imposition of hypotheses stronger than those of Loewen and Rockafellar regarding regularity and boundedness of F and its associated subdifferentials.

In a recent paper [5] Ioffe and Rockafellar established validity of the extended Euler–Lagrange, Weierstrass, and transversality conditions for nonconvex problems in the case $F \equiv R^n$ (no dynamic constraints). For the class of problems considered, the regularity and boundedness hypotheses imposed on the data are considerably weaker than those of [14]. The analysis is based on an analysis of integral functionals and is a showcase of new constructs of infinite dimensional nonsmooth analysis (those associated with fuzzy calculus of approximate subdifferential, etc.).

We come now to the contributions of this paper. These are partly improvements on earlier results concerning extended Euler–Lagrange and related conditions for nonconvex problems with a dynamic constraint and partly methodology. A relatively straightforward derivation of Ioffe and Rockafellar's necessary conditions for nonconvex problems is first given, when $F \equiv R^n$, which just uses the "elementary" finite dimensional calculus of limiting subdifferentials, a simple version of the maximum principle and the most traditional of nonsmooth variational principles, Ekeland's theorem. These results are a stepping stone to our subsequent derivation of related necessary conditions (via an exact penalization technique akin to that used by Clarke [2]) when a (nonconvex) differential inclusion is added to the constraints. The necessary conditions provided here go beyond those for $W^{1,1}$ minimizers in [14], both because they incorporate the Weierstrass condition and because they are derived under boundedness and regularity hypotheses akin to those adopted by Loewen and Rockafellar (in the convex case), which are significantly weaker than those invoked in [14]. In particular the hypotheses concerning a.e. continuity of $F(\cdot, x)$, upper semicontinuous dependence of certain subdifferentials, and uniform boundedness of F are dispensed with. Finally, we examine free time, autonomous problems (problems where neither L nor F depend on t). It is shown here that the earlier conditions can be augmented by a constancy condition on the Hamiltonian and a modified transversality condition.

A word about methodology. This borrows ideas from Clarke's "decoupling" technique [3], whereby a variational problem involving a state-dependent velocity constraint is approximated by one for which the velocity constraint is state-free. The Pontryagin maximum principle provides very precise optimality conditions for this

latter category of variational problems; these are applied to the approximate problems and we then pass to the limit. However, our approximations procedure is based on use of Ekeland's theorem rather than on density properties of proximal subgradients (as with Clarke), which allows us to conclude strong L^1 convergence of velocities. (It would appear that weak L^1 convergence provided by the proximal analysis approach is inadequate for the derivation of optimality conditions in the nonconvex case.)

Consider the $F = R^n$ case. Our simple idea is to replace the variational problem (P) with the "decoupled" problem

$$\text{minimize } l(x(0), x(1)) + \int_0^1 L(t, w(t), v(t))dt + \epsilon^{-1} \int_0^1 k(t)|x(t) - w(t)|^2 dt$$

over $(x, (w, v))$ which satisfies $\dot{x}(t) = v(t)$ for some arbitrarily small $\epsilon > 0$. (Here $k(t)$ is a Lipschitz constant for the data.) (v, w) are treated as control functions. Because of the third (penalty) term in the cost, which forces w to approximate a state trajectory corresponding to v, $\bar{x}$ is an approximate minimizer for this new problem. We then can perturb the approximating problem, with the help of Ekeland's theorem, to guarantee it has a local minimizer converging to $\bar{x}$ as $\epsilon \downarrow 0$, in some sense. Applying the Pontryagin maximum principle to the perturbed problem and passing to the limit as $\epsilon \downarrow 0$ give the desired necessary conditions when $F = R^n$. From this everything follows.

We claim our methods provide a simple derivation of the extended Euler–Lagrange and related conditions. Some readers might object that we call upon the Pontryagin maximum principle, which, in its full generality, has a lengthy proof. However, the special case of it required for application to the decoupled approximation problem, a case treated by Mordukhovich in [10], admits a simple, direct proof because the dynamics and cost integrand are smooth in the state variable and nonsmoothness is confined to the description of the endpoint constraints.

Concurrently, Ioffe [4] too has derived extended Euler–Lagrange and related conditions for nonconvex problems of type (P) with a dynamic constraint. Ioffe improves on the necessary conditions reported in this paper, regarding fixed time problems, by weakening the Lipschitz continuity hypotheses on F under which they apply. Again, the starting point is the necessary conditions of Ioffe and Rockafellar for the case $F \equiv R^n$, but then a more refined penalty function argument than that employed here is used to introduce the dynamic constraint. It would appear, however, that a combination of the proof techniques of this paper based on application of a simple version of the maximum principle to treat the case $F \equiv R^n$ and the penalization arguments of Ioffe to allow for dynamic constraints provides the most straightforward but general derivation of the Euler–Lagrange and related conditions currently available.

The picture that emerges of necessary conditions for optimal control problems involving differential inclusions is one in which the extended Euler–Lagrange condition (coupled with the Weierstrass and transversality conditions) has a pivotal position. As we have noted, under the convexity hypothesis, it is more or less equivalent to the latest refinements of the Hamiltonian inclusion condition, but it also applies to nonconvex problems. Besides, as Ioffe has recently shown [4], the extended Euler–Lagrange condition (with its associated conditions) provides general versions of the Pontryagin-type necessary conditions of a kind previously derived by Kaśkosz and Lojasiewicz [7] as straightforward corollaries. Simple derivations of the extended Euler–Lagrange inclusion, etc., such as we provide have a valuable role then in making more accessible latest developments in the theory of necessary conditions.

The norm on $W^{1,1}$ is taken to be

$$\|x\|_{W^{1,1}} := |x(0)| + \|\dot{x}\|_{L^1}.$$

$|\cdot|$ denotes the Euclidean norm throughout. The Euclidian closed unit ball is written B. $d_C(x)$ denotes the Euclidian distance of the point $x \in R^n$ from the set $C \subset R^n$. $d_{\text{Haus}}(F_1, F_2)$ denotes the Hausdorff distance between two sets. epi$\{f\}$ is the epigraph set of the function f.

The following two constructs from nonsmooth analysis are required.

DEFINITION 1. *Take a closed set $A \subseteq R^k$ and points $x \in A$, $p \in R^k$. We say that p is a* limiting normal *to A at x if and only if there exists $p_i \to p$ and $x_i \to x$ in A such that, for each i, $p_i \cdot (x - x_i) \le o(|x - x_i|)$ for all $x \in A$, in which $o(\alpha)/\alpha \to 0$ as $\alpha \downarrow 0$ (i.e., limiting normals are limits of vectors which support A at points near x to first order). The limiting normal cone to A at x, written $N_A(x)$, is the set of all limiting normals to A at x.*

DEFINITION 2. *Given a lower semicontinuous function $f : R^k \to R \cup \{+\infty\}$ and a point $x \in R^k$ such that $f(x) < +\infty$, the* limiting subdifferential *of f at x, written $\partial f(x)$, is*

$$\partial f(x) := \{\xi : (\xi, -1) \in N_{\text{epi}\{f\}}(x, f(x))\},$$

in which epi$\{f\}$ *denotes the epigraph set $\{(x, \alpha) \in R^k \times R : \alpha \ge f(x)\}$.*

We refer to [8, 13] for expository accounts of the properties of limiting normal cones, limiting subdifferentials, and associated calculus rules.

Finally we mention that necessary conditions are derived throughout this paper for an arc $\bar{x}$ to be a $W^{1,1}$ local minimizer for (P) (or special cases of this general problem). This means that there exists $\eta > 0$ such that $\bar{x}$ is a minimizer with respect to all arcs $x \in W^{1,1}$ which satisfy the constraints of (P) and also

$$\|x - \bar{x}\|_{W^{1,1}} < \eta. \tag{9}$$

The concept of a $W^{1,1}$ local minimizer is less restrictive than that of strong local minimizer (where (9) is replaced by $\|x - \bar{x}\|_{L^\infty} < \eta$). See [14] and [17] for a discussion of this point.

2. The Bolza problem with finite Lagrangian. We begin by deriving necessary conditions for the special case of problem (P) in which $F = R^n$, namely,

$$\text{minimize } J(x) := l(x(0), x(1)) + \int_0^1 L(t, x(t), \dot{x}(t))dt \text{ over arcs } x \in W^{1,1}. \tag{2.1}$$

(This is described as the "finite Lagrangian" case because the extended Lagrangian $L_e(t, x, v)$ which coincides with $L(t, x, v)$ on $F(t, x)$ and takes value $+\infty$ off $F(t, x)$ is finite valued.) The primary role of these necessary conditions is to provide a stepping stone to treat problems with a dynamic constraint. But necessary conditions for finite Lagrangian problems are of independent interest because of the unrestrictive nature of the hypotheses under which they are valid (apart of course from the assumption that $F = R^n$!). These hypotheses, which relate to the local minimizer $\bar{x}$ of interest, are as follows:

(H1) l is lower semicontinuous.

(H2) $L(\cdot, x, \cdot)$ is measurable for each x with respect to the product σ-algebra $\mathcal{L} \times \mathcal{B}$. ($\mathcal{L}$ denotes the Lebesgue subsets of $[0, 1]$ and $\mathcal{B}$ the Borel sets of R^n.) $L(t, \cdot, \cdot)$ is lower semicontinuous for a.e. t.

(H3) For every $K > 0$ there exist $\delta > 0$ and $k \in L^1$ such that

$$|L(t, x', v) - L(t, x, v)| \leq k(t)|x' - x|, \quad L(t, \bar{x}(t), v) \geq -k(t)$$

for all $x', x \in \bar{x}(t) + \delta B$, and $v \in \dot{\bar{x}}(t) + KB$ a.e. $t \in [0, 1]$.

THEOREM 3. *Let $\bar{x}$ be a $W^{1,1}$ local minimizer for (2.1), for which $J(\bar{x}) < \infty$. Then there exists an arc $p \in W^{1,1}$ which satisfies*

(i) *the Euler condition: $\dot{p}(t) \in co\{\eta : (\eta, p(t)) \in \partial L(t, \bar{x}(t), \dot{\bar{x}}(t))\}$ a.e.;*
(ii) *the transversality condition: $(p(0), -p(1)) \in \partial l(\bar{x}(0), \bar{x}(1))$;*
(iii) *the Weierstrass condition: $p(t)\dot{\bar{x}}(t) - L(t, \bar{x}(t), \dot{\bar{x}}(t)) \geq p(t)v - L(t, \bar{x}(t), v)$ for all $v \in R^n$ a.e.*

Remark. If $L(t, x, v)$ is continuous in x, v, then the measurability condition in (H2) can be replaced by the requirement that $L(\cdot, x, v)$ is Lebesgue measurable for each x, v. We make use of this fact later.

Proof. Fix $K > 0$ and let $k(\cdot)$ and δ be the corresponding bounds and constant of (H3). We may of course assume that $k(t) \geq 1$ a.e. Let $\eta > 0$ be a constant such that $\bar{x}$ is a minimizer with respect to all competing arcs which satisfy $\|x - \bar{x}\|_{W^{1,1}} \leq \eta$ and also such that $\|x - \bar{x}\|_{W^{1,1}} \leq \eta$ implies $\|x - \bar{x}\|_{L^\infty} \leq \delta$.

The first step of the proof is to find $p \in W^{1,1}$ which satisfies the conditions of the theorem statement, except that (iii) is replaced by a weaker local version of the condition:

(iii′) $p(t)\dot{\bar{x}}(t) - L(t, \bar{x}(t), \dot{\bar{x}}(t)) \geq p(t)v - L(t, \bar{x}(t), v)$ for all $v \in \dot{\bar{x}}(t) + KB$.

We can assume without loss of generality that (H3) has been strengthened to

(H3′) $|L(t, x', v) - L(t, x, v)| \leq k(t)|x' - x|$ and $L(t, \bar{x}(t), v) \geq -k(t)$ for all $x', x \in R^n$ and $v \in \dot{\bar{x}}(t) + KB$ a.e.

This is because, if (H3′) were not satisfied, we could replace it with

$$L'(t, x, v) := \begin{cases} L(t, x, v) & \text{if } |x - \bar{x}(t)| \leq \delta, \\ L(t, \bar{x}(t) + \delta \frac{x - \bar{x}(t)}{|x - \bar{x}(t)|}, v) & \text{otherwise.} \end{cases}$$

The data (L', l) satisfy (H3′) (in addition to (H1) and (H2)). $\bar{x}$ remains a $W^{1,1}$ local minimizer. If some p satisfies (i), (ii), and (iii′) for data (L', l) at $\bar{x}$, it also satisfies these same conditions for data (L, l) because of their "local" nature. So we may assume that (H3′) is satisfied. Define

$$\tilde{L}(t, w, v) := L(t, \bar{x}(t) + w, \dot{\bar{x}}(t) + v),$$
$$\tilde{l}(x, y) := l(\bar{x}(0) + x, \bar{x}(1) + y).$$

Choose a positive sequence $\epsilon_i \to 0$. Define

$$W := \{(\xi, w, v) \in R^n \times L^1 \times L^1 : |v(t)| \leq K \text{ a.e.}, \|x_{\xi,v}\|_{W^{1,1}} \leq \eta\},$$

where $x_{\xi,v}(t) = \xi + \int_0^t v(s)ds$,

$$\|(\xi, w, v)\|_k := |\xi| + \|kw\|_{L^1} + \|kv\|_{L^1}$$

and, for each i,

$$\tilde{J}_i(\xi, w, v) := \tilde{l}(x_{\xi,v}(0), x_{\xi,v}(1)) + \int_0^1 \tilde{L}(t, w(t), v(t))dt + \epsilon_i^{-1} \int_0^1 k(t)|x_{\xi,v}(t) - w(t)|^2 dt.$$

LEMMA 4. *For each i, $(W, \|\cdot\|_k)$ is a complete metric space and $\tilde{J}_i$ is lower semicontinuous on $(W, \|\cdot\|_k)$. There exists a positive sequence $\alpha_i \to 0$ such that, for each i, $\tilde{J}_i(0,0,0) \le \inf_W \tilde{J}_i(\xi, w, v) + \alpha_i^2$.*

Proof. Obviously, W is a subset of the Banach space $\{(\xi, w, v) \in R^n \times L^1 \times L^1 : \|(\xi, w, v)\|_k < \infty\}$ with norm $\|\cdot\|_k$. We show that it is strongly closed and, for each i, $\tilde{J}_i$ is lower semicontinuous on W. Take an arbitrary sequence $(\xi_j, w_j, v_i) \to (\xi, w, v)$ in $(W, \|\cdot\|_k)$. Write $x_j = x_{\xi_j, v_j}$. Then $x_j \to x_{\xi,v}$ in $W^{1,1}$. Restricting attention to a subsequence, we have $w_j(t) \to w(t)$ and $v_j(t) \to v(t)$ a.e. So $|v(t)| \le K$ and $\|x_{\xi,v}\|_{W^{1,1}} \le \eta$. The limit point (ξ, w, v) then satisfies the conditions confirming membership of W, so W is strongly closed. This establishes that $(W, \|\cdot\|_k)$ is complete.

Next we show that $\tilde{J}_i$ is lower semicontinuous. Again take an arbitrary sequence $(\xi_j, w_j, v_j) \to (\xi, w, v)$ in $(W, \|\cdot\|_k)$. By hypothesis (H3′), the sequence $\tilde{L}(t, w_j(t), v_j(t)) + k(t)|w_j(t) - w(t)|$ is bounded below by the integrable function $-k(t) - k(t)|w(t)|$. We may therefore deduce from the lower semicontinuity of $\tilde{L}$ and Fatou's lemma that

$$\begin{aligned}\liminf_{j\to\infty} \int_0^1 \tilde{L}(t, w_j(t), v_j(t))dt &= \liminf_{j\to\infty} \int_0^1 (\tilde{L}(t, w_j(t), v_j(t)) + k(t)|w_j(t) - w(t)|)dt \\ &\ge \int_0^1 \liminf_{j\to\infty} (\tilde{L}(t, w_j(t), v_j(t)) + k(t)|w_j(t) - w(t)|)dt \\ &\ge \int_0^1 \tilde{L}(t, w(t), v(t))dt.\end{aligned}$$

Since $x_j \to x_{\xi,v}$ uniformly, lower semicontinuity of $\tilde{l}$ gives

$$\liminf_{j\to\infty} \tilde{l}(x_j(0), x_j(1)) \ge \tilde{l}(x_{\xi,v}(0), x_{\xi,v}(1)).$$

It follows that

$$\begin{aligned}\liminf_{j\to\infty} \tilde{J}_i(\xi_j, w_j, v_j) &\ge \liminf_{j\to\infty} \tilde{l}(x_j(0), x_j(1)) + \liminf_{j\to\infty} \int_0^1 \tilde{L}(t, w_j(t), v_j(t))dt \\ &\quad + \liminf_{j\to\infty} \int_0^1 \epsilon_i^{-1} k(t)|x_j(t) - w_j(t)|^2 dt \\ &\ge \tilde{l}(x_{\xi,v}(0), x_{\xi,v}(1)) + \int_0^1 \tilde{L}(t, w(t), v(t))dt \\ &\quad + \int_0^1 \epsilon_i^{-1} k(t)|x_{\xi,v}(t) - w(t)|^2 dt \\ &= \tilde{J}_i(\xi, w, v).\end{aligned}$$

We conclude that $\tilde{J}_i$ is lower semicontinuous.

Define

$$\alpha_i^2 := \tilde{J}_i(0,0,0) - \inf_W \tilde{J}_i(\xi, w, v).$$

Since $(0,0,0) \in W$, $\alpha_i^2 \ge 0$. For arbitrary $(\xi, w, v) \in W$,

$$\begin{aligned}\tilde{J}_i(\xi, w, v) &= \tilde{J}_i(\xi, x_{\xi,v}, v) + \int (\tilde{L}(t, w(t), v(t)) - \tilde{L}(t, x_{\xi,v}(t), v(t)))dt + \epsilon_i^{-1} c^2 \\ &\ge \tilde{J}_i(0,0,0) - \int k(t)|x_{\xi,v}(t) - w(t)|dt + \epsilon_i^{-1} c^2\end{aligned}$$

(by the minimizing properties of $(0,0,0)$)

$$\begin{aligned}
&\geq \tilde{J}_i(0,0,0) - cd + \epsilon_i^{-1}c^2 \\
&= \tilde{J}_i(0,0,0) + \epsilon_i^{-1}(c - \epsilon_i d/2)^2 - \epsilon_i d^2/4 \\
&\geq \tilde{J}_i(0,0,0) - \epsilon_i d^2/4,
\end{aligned}$$

where $c^2 := \int_0^1 k(t)|w(t) - x_{\xi,v}(t)|^2 dt$ and $d^2 := \int_0^1 k(t)dt$. So we have

$$0 \leq \alpha_i^2 \leq \epsilon_i \int_0^1 k(t)dt/4.$$

Since the right side converges to 0 as $i \to \infty$, the lemma is proved. □

We have shown that for each i, $(0,0,0)$ is an "α_i^2 minimizer" for $\tilde{J}_i$ over W. By Ekeland's variational principle there exists $(\xi_i, w_i, v_i) \in W$ which minimizes

$$J_i(\xi, w, v) := \tilde{J}_i(\xi, w, v) + \alpha_i \|(\xi, w, v) - (\xi_i, w_i, v_i)\|_k$$

over W. Also

$$\|(\xi_i, w_i, v_i)\|_k \leq \alpha_i.$$

Write $x_i = x_{\xi_i, v_i}$. This last property implies that, for some subsequence, $(w_i, v_i) \to 0$ in L^1 and a.e. and $x_i \to 0$ uniformly.

Since $\tilde{J}_i(0,0,0) + \alpha_i\|(\xi_i, w_i, v_i)\|_k \geq \tilde{J}_i(\xi_i, w_i, v_i)$, we have

$$\begin{aligned}
\tilde{J}_i(0,0,0) &= \tilde{l}(0,0) + \int_0^1 \tilde{L}(t,0,0)dt \\
&\geq \limsup_{i\to\infty} \tilde{J}_i(\xi_i, w_i, v_i) \\
&\geq \limsup_{i\to\infty} \tilde{l}(x_i(0), x_i(1)) + \liminf_{i\to\infty} \int_0^1 \tilde{L}(t, w_i(t), v_i(t))dt
\end{aligned}$$

But $\liminf_{i\to\infty} \tilde{l}(x_i(0), x_i(1)) \geq \tilde{l}(0,0)$ and $\liminf_{i\to\infty} \int_0^1 \tilde{L}(t, w_i(t), v_i(t))dt \geq \int_0^1 \tilde{L}(t,0,0)dt$. It follows from these relationships that

$$\lim_{i\to\infty} \tilde{l}(x_i(0), x_i(1)) = \tilde{l}(0,0)$$

and

$$\liminf_{i\to\infty} \int_0^1 (\tilde{L}(t, w_i(t), v_i(t)) - \tilde{L}(t,0,0))dt = 0.$$

But as before we can use Fatou's lemma to deduce that

$$\int_0^1 (\liminf_{i\to\infty} \tilde{L}(t, w_i(t), v_i(t)) - \tilde{L}(t,0,0))dt \leq \liminf_{i\to\infty} \int_0^1 (\tilde{L}(t, w_i(t), v_i(t)) - \tilde{L}(t,0,0))dt = 0.$$

Since $\liminf_{i\to\infty} \tilde{L}(t, w_i(t), v_i(t)) \geq \tilde{L}(t,0,0)$ a.e. We conclude that

$$\liminf_{i\to\infty} \tilde{L}(t, w_i(t), v_i(t)) = \tilde{L}(t,0,0) \quad \text{a.e.}$$

We pause to sharpen this last relationship.

LEMMA 5. *We may arrange by subsequence extraction that*

$$\lim_{i\to\infty} \tilde{L}(t, w_i(t), v_i(t)) = \tilde{L}(t,0,0) \quad a.e.$$

Proof. Write $\Delta_i(t) := \tilde{L}(t, w_i(t), v_i(t)) - \tilde{L}(t, 0, 0) + k(t)|w_i(t)|$. Note that the functions $\Delta_i(t)$ are bounded below by an integral function $k_1(t) := -k(t) - \tilde{L}(t, 0, 0)$. This fact is required for application of Fatou's lemma below. Since $kw_i \to 0$ in L^1 and a.e., we have from the preceding analysis that $\liminf_{i\to\infty} \Delta_i(t) \to 0$ a.e. After extracting a subsequence we also have

$$\lim_{i\to\infty} \int_0^1 (\tilde{L}(t, w_i(t), v_i(t)) - \tilde{L}(t, 0, 0))dt = 0.$$

This implies that $\int_0^1 \Delta_i(t)dt \to 0$ as $i \to \infty$.

We show $\Delta_i \to 0$ in measure. This will imply that, for a subsequence, $\Delta_i(t) \to 0$ a.e.

Suppose that it is not true; then there exist two positive numbers ϵ and δ and a subsequence of $\{\Delta_i\}$ such that

$$m(\{t : |\Delta_i(t)| > \epsilon\}) > \delta, \tag{10}$$

where m is Lebesgue measure on $[0, 1]$. Write $A_i^\epsilon = \{t : \Delta_i(t) > \epsilon\}$ and $B_i^r = \{t : \Delta_i(t) < -r\}$. Here r is a positive number whose value will be set presently. Note that

$$\liminf_{i\to\infty} \Delta_i(t)\chi_{B_i^r}(t) = 0,$$

where $\chi_{B_i^r}(t)$ equals 1 if $t \in B_i^r$ and 0 otherwise. We have that

$$\begin{aligned}\liminf_{i\to\infty}(-rm(B_i^r)) &\geq \liminf_{i\to\infty} \int_0^1 \Delta_i(t)\chi_{B_i^r}(t)dt \\ &\geq \int_0^1 \liminf_{i\to\infty} \Delta_i(t)\chi_{B_i^r}(t)dt = 0.\end{aligned}$$

Hence $\limsup_{i\to\infty} m(B_i^r) = 0$. By (10) however, $m(A_i^\epsilon) > \delta$ for i sufficiently large. Now choose $r > 0$ and an integer N such that

$$r + \int_{B_i^r} k_1(t)dt < \epsilon\delta/2 \quad \text{for} \quad i \geq N.$$

We have

$$\begin{aligned}\int_0^1 \Delta_i(t)dt &= \int_{A_i^\epsilon} \Delta_i(t)dt + \int_{B_i^r} \Delta_i(t)dt + \int_{\{-r\leq\Delta_i(t)\leq\epsilon\}} \Delta_i(t)dt \\ &\geq \epsilon\delta - \int_{B_i^r} k_1(t)dt - r > \epsilon\delta/2 \quad \text{for} \quad i \geq N.\end{aligned}$$

This contradicts $\int_0^1 \Delta_i(t)dt \to 0$ as $i \to \infty$. So $\Delta_i \to 0$ in measure. It follows that $\Delta_i(t) \to 0$ a.e. along a subsequence. □

We can summarize the above discussion in control theoretic terms. Define

$$\begin{aligned}\tilde{L}_i(t, x, w, v) &:= \tilde{L}(t, w, v) + \alpha_i k(t)|w - w_i(t)| + \alpha_i k(t)|v - v_i(t)| + \epsilon_i^{-1} k(t)|x - w|^2, \\ \tilde{l}_i(x, y) &:= \tilde{l}(x, y) + \alpha_i|x - x_i(0)|.\end{aligned}$$

The minimizing property of (ξ_i, v_i, w_i) can be expressed as follows: $((x_i, y_i, z_i), (v_i, w_i))$ is a minimizer for the problem

$$\text{minimize } z(1) + \int_0^1 \tilde{L}_i(t, x(t), w(t), v(t))dt$$

subject to

$$\begin{cases} \dot{x}(t) = v(t), \dot{z}(t) = 0, \\ w(t) \in R^n, v(t) \in KB, \\ (x(0), x(1), z(1)) \in \text{epi}\{\tilde{l}_i\} \end{cases}$$

and

$$\begin{cases} \dot{y}(t) = |v(t)|, \\ y(0) = 0,\ |x(0)| + y(1) \le \eta. \end{cases}$$

Here $x_i(t) := x_{\xi_i, v_i}(t)$, $y_i(t) := \int_0^t |v_i(s)|ds$, and $z_i(t) := \tilde{l}_i(x_i(0), x_i(1))$. We have shown $v_i, w_i \to 0$ in L^1 and a.e., $x_i, y_i \to 0$ uniformly and

$$\tilde{L}(t, w_i(t), v_i(t)) \to \tilde{L}(t, 0, 0),$$
$$\tilde{l}(x_i(0), x_i(1)) \to \tilde{l}(0, 0).$$

This is an optimal control problem to which the maximum principle in [2, Thm. 5.2.1] is applicable, with transversality conditions refined as indicated in [9]. We observe that the differential equation constraint has a right side which is independent of the state variable. Also, since $k(t)|x_i(t) - w_i(t)|^2$ is an L^1 function there exist a function $c : [0, 1] \times R^n \times R^n \to R^+$ and $\eta > 0$ such that (a) the cost integrand $x \to \tilde{L}_i(t, x, v, w)$ is Lipschitz continuous on $x_i(t) + \eta B$ with rank $c(t, v, w)$ for all $v \in KB$, $w \in R^n$ and a.e. t and (b) $c(t, x_i(t), v_i(t), w_i(t))$ is integrable in accordance with the Lipschitz continuity hypotheses which must be checked for application of [2, Thm. 5.2.1] with modified transversality condition. We take advantage then of the unrestrictive nature of the hypotheses under which this version of the maximum principle applies. (The hypothesis that $c(t, x, v, w) = \tilde{c}(t)$ for some integrable function $\tilde{c}$, invoked elsewhere in the necessary conditions literature, is violated.)

Notice that because the right endpoint constraint on y is inactive at $y \equiv y_i$ and because of the "decoupled" structure of the cost and dynamics in y and (x, z), the costate arc component associated with y must be zero; we therefore drop it from the relationships. The optimality conditions tell us that there exist $p_i \in W^{1,1}$ and $\lambda_i \ge 0$ such that

(A) $-\dot{p}_i(t) = -2\lambda_i \epsilon_i^{-1} k(t)(x_i(t) - w_i(t))$,
(B) $(p_i(0), -p_i(1), -\lambda_i) \in N_{\text{epi}\{\tilde{l}_i\}}(x_i(0), x_i(1), \tilde{l}_i(x_i(0), x_i(1)))$,
(C) $(w, v) \mapsto p_i(t)v - \lambda_i \tilde{L}_i(t, x_i(t), w, v)$ achieves its maximum at $(w_i(t), v_i(t))$ over all $(w, v) \in R^n \times KB$ for almost every t,
(D) $\|p_i\|_\infty + \lambda_i = 1$.

Condition (C) implies

$$(\dot{p}_i(t), p_i(t)) \in \lambda_i \partial[\tilde{L}(t, w_i(t), v_i(t)) + \Psi_{KB}(v_i(t))] + \lambda_i \alpha_i k(t)(B \times B). \tag{11}$$

Fix $v = v_i(t)$, then $w \mapsto p_i(t)v_i(t) - \lambda_i \tilde{L}_i(t, x_i(t), w, v_i(t))$ achieves its maximum at $w_i(t)$ over all $w \in R^n$. This implies

$$\dot{p}_i(t) \in \lambda_i \partial_w \tilde{L}(t, w_i(t), v_i(t)) + \lambda_i \alpha_i k(t) B. \tag{12}$$

Fix $w = w_i(t)$, then $v \mapsto p_i(t)v - \lambda_i \tilde{L}_i(t, x_i(t), w_i(t), v)$ achieves its maximum at $v_i(t)$ over $v \in KB$. This implies

(13)
$$p_i(t)(v - v_i(t)) \le \lambda_i \tilde{L}(t, w_i(t), v) - \lambda_i \tilde{L}(t, w_i(t), v_i(t)) + \lambda_i \alpha_i k(t)|v - v_i(t)| \quad \forall v \in KB \text{ a.e.}$$

Since $\tilde{L}(t, \cdot, v)$ is Lipschitz with rank $k(t)$ for all $v \in KB$, (12) implies $|\dot{p}_i(t)| \le 2k(t)$. Since the p_i's are uniformly bounded (see (D)), we can arrange, by limiting attention to a subsequence, that $p_i \to p$ uniformly and $\dot{p}_i \to \dot{p}$ weakly in L^1 for some $p \in W^{1,1}$. We can also ensure that $\lambda_i \to \lambda$ for some $\lambda \ge 0$ such that

$$\|p\|_{L^\infty} + \lambda = 1. \tag{14}$$

(13) implies in the limit that

$$p(t)v \le \lambda \tilde{L}(t, 0, v) - \lambda \tilde{L}(0, 0, 0) \text{ a.e. for } v \in KB.$$

Observe now that $\lambda > 0$, since otherwise this last relation implies $p(t) \equiv 0$, which contradicts (D). Since $\lambda > 0$, (B) implies

$$(p_i(0), -p_i(1)) \in \lambda_i \partial \tilde{l}_i(x_i(0), x_i(1)),$$

and we conclude that

$$(p(0), -p(1)) \in \lambda \partial \tilde{l}(0, 0).$$

We next verify the Euler–Lagrange inclusion in the limit.

By Mazur's theorem there exists for each i an integer $N_i \ge i$ and a convex combination $\{\lambda_{i1}, \ldots, \lambda_{iN_i}\}$ such that if we write

$$q_i(t) = \sum_{j=i}^{N_i} \lambda_{ij} \dot{p}_j(t),$$

then

$$q_i(t) \to \dot{p}(t) \quad \text{strongly in } L^1.$$

Appealing to Carathéodory's theorem, we deduce that for each i and t there exists a convex combination $\{\alpha_{i0}(t), \ldots, \alpha_{in}(t)\}$ and integers $0 \le k_{i0}(t) < \cdots < k_{in}(t)$ such that

$$q_i(t) = \sum_{j=0}^{n} \alpha_{ij}(t) \dot{p}_{i+k_{ij}(t)}(t).$$

A subsequence $\{q_i\}_{i \in S}$ can be chosen (S denotes the index values which are retained) such that

$$q_i(t) \xrightarrow{S} \dot{p}(t) \quad \text{a.e.}$$

Write $A \subset [0,1]$ for the set of full measure:

$$A := \{t : q_i(t) \overset{S}{\to} \dot{p}(t), |\dot{p}_i(t)| \leq 2k(t) \forall i, k(t) < \infty \text{ and } (w_i(t), v_i(t)) \to (0,0)\}.$$

Fix $t \in A$. For any $j \in \{0, \ldots, n\}$ we note that $\{\alpha_{ij}(t)\}_{i=1,2,\ldots}$ and $\{\dot{p}_{i+k_{ij}(t)}(t)\}_{i=1,2,\ldots}$ are bounded sequences. Consequently we may choose subsequences with index values the set $S' \subset S$ such that as $i \overset{S'}{\to} \infty$,

$$\alpha_{ij}(t) \to \alpha_j(t) \text{ and } \dot{p}_{i+k_{ij}}(t) \to q_j(t) \text{ for } j = 0, \ldots, n$$

for some convex combination $\{\alpha_j(t) : j = 0, \ldots, n\}$ and $q_j(t) \in R^n$. Since $(w_i(t), v_i(t)) \to (0,0)$, $\tilde{L}_i(t, w_i(t), v_i(t)) + \Psi_{KB}(v_i(t)) \to \tilde{L}(t,0,0)$ and $p_i(t) \to p(t)$ as $i \to \infty$, we deduce from (11) that

$$(q_j(t), p(t)) \in \lambda \partial \tilde{L}(t,0,0) \text{ for } j = 0, \ldots, n.$$

It follows that

$$\dot{p}(t) = \sum_{j=0}^{n} \alpha_j q_j(t) \in \text{co}\{\eta : (\eta, p(t)) \in \lambda \partial \tilde{L}(t,0,0)\} \quad \text{a.e.}$$

These are precisely the assertions of Theorem 3, except that they are expressed in terms of a cost multiplier λ which is possibly not equal to 1 and that, in the last condition, the inequality holds only for $v \in \dot{\bar{x}}(t) + KB$.

Take $K_i \to \infty$. Let p_i denote the adjoint arc and $\lambda_i > 0$ the cost multiplier when $K = K_i$. We deduce from the Euler condition that the $\dot{p}_i$'s are uniformly integrably bounded. Of course the p_i's are uniformly bounded. Now extract subsequences to arrange that p_i converges uniformly to some limit p, $\dot{p}_i$ converges weakly to $\dot{p}$, and $\lambda_i \to \lambda$ for some λ such that $\|p\|_{L^\infty} + \lambda = 1$. Arguing as before, we arrive at our earlier conclusions, but the Weierstrass condition is now satisfied globally. From the Weierstrass condition, however, $\lambda = 0$ implies $p(t) \equiv 0$, which is not possible. So $\lambda > 0$. The final touch is to scale p and λ so that $\lambda = 1$. The theorem is proved. □

3. Problems with dynamic and endpoint constraints. We now derive necessary conditions for a version of (P) which allow for dynamic constraints $\dot{x} \in F$, with possibly $F \neq R^n$, and endpoint constraints. The problem (which is labeled (Q)) is

$$\text{(Q)} \qquad \begin{aligned} &\text{minimize } l(x(0), x(1)) + \int_0^1 L(t, x(t), \dot{x}(t)) dt \\ &\text{over arcs } x \in W^{1,1} \text{ which satisfy} \\ &\dot{x}(t) \in F(t, x(t)), \quad (x(0), x(1)) \in C. \end{aligned}$$

$l : R^n \times R^n \to R$ and $L : [0,1] \times R^n \times R^n \to R$ are given functions. $F : [0,1] \times R^n \to R^n$ is a given multifunction. $C \subset R^n \times R^n$ is a given closed set.

Notice that in this formulation l is everywhere finite. Endpoint constraints are specified directly via the constraint set C rather than implicitly in terms of the effective domain of l.

The hypotheses which will be invoked are now listed. They involve $\delta \in (0, \infty)$ and $k_l \in (0, \infty)$ (for convenience we assume $k_l \geq 1$) and nonnegative, measurable functions k_F and k_L which satisfy

$$k_F \in L^1, \quad k_L \in L^1, \quad k_F k_L \in L^1.$$

(G1) $|l(x,y)-l(x',y')| \le k_l|(x,y)-(x',y')| \forall (x,y),(x',y') \in (\bar{x}(0),\bar{x}(1))+\delta(B\times B)$.

(G2) $F(t,x)$ is nonempty and closed for each (t,x). $F(t,x)$ is measurable in t for fixed x and

$$F(t,x') \subset F(t,x) + k_F(t)|x'-x|B \quad \forall x,x' \in \bar{x}(t)+\delta B \text{ a.e.}$$

(G3) $L(t,x,v)$ is measurable in t for fixed (x,v) and $|L(t,x,v) - L(t,x',v')| \le k_L(t)|(x,v)-(x',v')| \forall (x,v),(x',v') \in (\bar{x}(t)+\delta B)\times R^n$.

THEOREM 6. *Let $\bar{x}$ be a local minimizer for* (Q)*, for which hypotheses* (G1)–(G3) *above are satisfied for some $\delta > 0$. Then there exist $p \in W^{1,1}$ and $\lambda \ge 0$, not both zero, satisfying*

(i) *the Euler condition:*

$$\dot{p}(t) \in co\{\eta : (\eta, p(t)) \in \lambda \partial L(t,\bar{x}(t),\dot{\bar{x}}(t)) + N_{\mathrm{Gr}\{F(t,\cdot)\}}(\bar{x}(t),\dot{\bar{x}}(t))\} \quad a.e.;$$

(ii) *the transversality condition:*

$$(p(0),-p(1)) \in \lambda \partial l(\bar{x}(0),\bar{x}(1)) + N_C(\bar{x}(0),\bar{x}(1));$$

(iii) *the Weierstrass condition:*

$$p(t)\dot{\bar{x}}(t) - \lambda L(t,\bar{x}(t),\dot{\bar{x}}(t)) \ge p(t)v - \lambda L(t,\bar{x}(t),v) \forall v \in F(t,\bar{x}(t)) \quad a.e.$$

We begin by proving the theorem under the condition $L = 0$. We may assume without loss of generality that F is globally Lipschitz continuous in x (i.e., the first condition in hypothesis (G2) is satisfied for all $x,x' \in R^n \times R^n$.) This is because we can derive necessary conditions for the "truncated" differential inclusion

$$\tilde{F}(t,x) := \begin{cases} F(t,x) & \text{if } x \in \bar{x}(t)+\delta B, \\ F\left(t, \bar{x}(t) + \delta \frac{x-\bar{x}(t)}{|x-\bar{x}(t)|}\right) & \text{otherwise,} \end{cases}$$

which is globally Lipschitz continuous, and the necessary conditions are the same.

We may arrange, by reducing δ if necessary, that $\bar{x}$ is a minimizer with respect to competing arcs which satisfy $\|x-\bar{x}\|_{W^{1,1}} \le \delta/2$.

Denote by W the subset of $R^n \times W^{1,1}$:

$$W = \{(e,x) \in R^n \times W^{1,1} : (x(0),e) \in C, \dot{x}(t) \in F(t,x(t)), \|x-\bar{x}\|_{W^{1,1}} \le \delta/2\}.$$

Here W is equipped with norm

$$\|(e,x)\|_W := |e| + |x(0)| + \|\dot{x}\|_{L^1}.$$

We must show that $(W, \|\cdot\|_W)$ is complete. Consider a Cauchy sequence (e_j,x_j) in $(W,\|\cdot\|_W)$. Then $e_j \to e$, $x_j(0) \to \eta$, and $\dot{x}_j \to \xi$ in L^1 for some $e \in R^n$, $\eta \in R^n$, and $\xi \in L^1$. We see that $x_j(t) - \int_0^t \xi(s)ds - \eta = \int_0^t (\dot{x}_j(s) - \xi(s))ds + (x_j(0)-\eta)$ tends to zero uniformly in t. So in fact $x_j(t)$ converges in $W^{1,1}$ to the absolutely continuous function $x(t) := \eta + \int_0^t \xi(s)ds$. It follows we can identify $\xi(t)$ with $\dot{x}(t)$ and $(e,x(0)) \in C$ since C is closed. Along a subsequence then $\dot{x}_j \to \dot{x}$ a.e. By the continuity of F in x, $\dot{x}(t) \in F(t,x(t))$ a.e. we see that $(e,x) \in W$, so $(W,\|\cdot\|_W)$ is complete.

For each i define

$$l_i(x,y,x',y') := \max\{l(x,y) - l(\bar{x}(0),\bar{x}(1)) + \epsilon_i^2, |x'-y'|\}.$$

Notice that l_i is Lipschitz continuous with rank at most k_l on $\delta(B \times B) \times \delta(B \times B)$. (We use here $k_l \geq 1$.)

Now consider the minimization problem

$$\text{minimize } \{l_i(x(0), e, x(1), e) : (e, x) \in W\}.$$

The functional $(e, x) \to l_i(x(0), e, x(1), e)$ is continuous on $(W, \|\cdot\|_W)$. Notice also that l_i is nonnegative valued and

$$l_i(\bar{x}(0), \bar{x}(1), \bar{x}(1), \bar{x}(1)) = \epsilon_i^2.$$

So $(\bar{x}(1), \bar{x})$ is an "ϵ_i^2 minimizer." According to Ekeland's principle, there exists $(e_i, x_i) \in W$ such that

$$l_i(x_i(0), e_i, x_i(1), e_i) \leq l_i(x(0), e, x(1), e) + \epsilon_i \|(e, x) - (e_i, x_i)\|_W \tag{15}$$

for all $(e, x) \in W$ and

$$\|(e_i, x_i) - (\bar{x}(1), \bar{x})\|_W \leq \epsilon_i \tag{16}$$

for all i. Take y_i to be the constant arc

$$y_i(t) \equiv e_i.$$

(16) implies that $y_i(1) \to \bar{x}(1)$, $x_i(0) \to \bar{x}(0)$, and also (following extraction of subsequences) $\dot{x}_i \to \dot{\bar{x}}$ both in L^1 and a.e. We have then that $x_i \to \bar{x}$. We can arrange, by eliminating initial terms of the sequence, that $\|x_i - \bar{x}\|_{W^{1,1}} < \delta/2$ for all i; i.e., the state constraint $\|x - \bar{x}\|_{W^{1,1}} \leq \delta/2$ implicit in the definition of W is nonactive and can be disregarded since we are interested only in local minimizing properties of (e_i, x_i).

Define

$$\tilde{l}_i(x, y, x', y') := l_i(x, y, x', y') + \epsilon_i |x - x_i(0)| + \epsilon_i |y - y_i(0)|.$$

(15) implies that for each i the arc (x_i, y_i) is a local minimizer for the variational problem:

$$\begin{aligned} &\text{minimize } J_i(x, y) := \tilde{l}_i(x(0), y(0), x(1), y(1)) + \epsilon_i \int_0^1 |\dot{x}(t) - \dot{x}_i(t)| dt \\ &\text{over arcs } (x, y) \in W^{1,1} \text{ which satisfy} \\ &(\dot{x}(t), \dot{y}(t)) \in F(t, x(t)) \times \{0\} \quad \text{a.e.}, \quad (x(0), y(0)) \in C. \end{aligned} \tag{17}$$

The following lemma justifies replacing (17) by another variational problem in which the dynamic constraint is represented by a term in the cost function ("exact penalization," cf. [2, Chap. 3]). This involves the function

$$\rho(t, x, y, v, w) := d_{F(t,x) \times \{0\}}(v, w) = d_{F(t,x)}(v) + |w|.$$

LEMMA 7. *For each i, (x_i, y_i) is a local minimizer for*

$$\begin{aligned} &\textit{minimize } J_i(x, y) + M \int_0^1 \rho(t, x(t), y(t), \dot{x}(t), \dot{y}(t)) dt \\ &\textit{over arcs } (x, y) \textit{ which satisfy } (x(0), y(0)) \in C. \end{aligned}$$

Here M is any constant satisfying $M > (k_l + 3)K$, where $K = \exp(\int_0^1 k_F(t) dt)$.

Proof. Suppose that the assertions of Lemma 7 are false. Then there must exist a sequence $\{(\tilde{x}_j, \tilde{y}_j)\}$ in $W^{1,1}$ such that $\|(\tilde{x}_j, \tilde{y}_j) - (x_i, y_i)\|_{W^{1,1}} \to 0$ and, for each j, $(\tilde{x}_j(0), \tilde{y}_j(0)) \in C$ and

$$J_i(\tilde{x}_j, \tilde{y}_j) + M \int_0^1 \rho(t, \tilde{x}_j(t), \tilde{y}_j(t), \dot{\tilde{x}}_j(t), \dot{\tilde{y}}_j(t))dt < J_i(x_i, y_i).$$

Since $J_i(\tilde{x}_j, \tilde{y}_j) \geq l_i(\tilde{x}_j(0), \tilde{y}_j(0), \tilde{x}_j(1), \tilde{y}_j(1))$ for each j and the right side of this inequality tends to $J_i(x_i, y_i)$ as $j \to \infty$, we deduce that

$$\int_0^1 \rho(t, \tilde{x}_j(t), \tilde{y}_j(t), \dot{\tilde{x}}_j(t), \dot{\tilde{y}}_j(t))dt \to 0.$$

For sufficiently large j, the successive approximations theorem [2, Thm. 3.1.6] yields an arc $(\hat{x}_j, \hat{y}_j)$ satisfying the differential inclusion and endpoint constraints of problem (17) and for which

$$(\hat{x}_j(0), \hat{y}_j(0)) = (\tilde{x}_j(0), \tilde{y}_j(0))$$

and

$$\begin{aligned}\|(\hat{x}_j, \hat{y}_j) - (\tilde{x}_j, \tilde{y}_j)\|_{W^{1,1}} &\leq \int_0^1 |(\dot{\hat{x}}_j(t), \dot{\hat{y}}_j(t)) - (\dot{\tilde{x}}_j(t), \dot{\tilde{y}}_j(t)|dt \\ &\leq K \int_0^1 \rho(t, \tilde{x}_j(t), \tilde{y}_j(t), \dot{\tilde{x}}_j(t), \dot{\tilde{y}}_j(t))dt.\end{aligned}$$

Since $(\tilde{x}_j, \tilde{y}_j) \to (x_i, y_i)$ uniformly, those relationships tell us that $(\hat{x}_j, \hat{y}_j) \to (x_i, y_i)$ uniformly. For sufficiently large j therefore we have from the fact that (x_i, y_i) is a local minimizer for (17),

$$J_i(x_i, y_i) \leq J_i(\hat{x}_j, \hat{y}_j).$$

Also, we can deduce from the Lipschitz continuity properties of the data that

$$\begin{aligned}J_i(\hat{x}_j, \hat{y}_j) &\leq J_i(\tilde{x}_j, \tilde{y}_j) + (k_l + 3\epsilon_i)K \int_0^1 \rho(t, \tilde{x}_j(t), \tilde{y}_j(t), \dot{\tilde{x}}_j(t), \dot{\tilde{y}}_j(t))dt \\ &\leq J_i(\tilde{x}_j, \tilde{y}_j) + M \int_0^1 \rho(t, \tilde{x}_j(t), \tilde{y}_j(t), \dot{\tilde{x}}_j(t), \dot{\tilde{y}}_j(t))dt \\ &< J_i(x_i, y_i).\end{aligned}$$

This contradicts the preceding inequality, and Lemma 7 is proved. □

LEMMA 8. *For any $x, v \in R^n \times R^n$ and $t \in [0, 1]$*

$$d_{F(t,x)}(v) \leq (1 + k_F(t))d_{\mathrm{Gr}\{F(t,\cdot)\}}(x, v).$$

Proof. Because $F(t, \cdot)$ has closed values and is assumed to be globally Lipschitz continuous, $\mathrm{Gr}\{F(t, \cdot)\}$ is closed and there exists $(y, w) \in \mathrm{Gr}\{F(t, \cdot)\}$ such that $d_{\mathrm{Gr}\{F(t,\cdot)\}}(x, v) = |(x, v) - (y, w)|$. By the Lipschitz continuity of $F(t, \cdot)$, however,

$$\begin{aligned}d_{F(t,x)}(v) &\leq d_{F(t,y)}(v) + d_{\mathrm{Haus}}(F(t, x), F(t, y)) \\ &\leq |v - w| + k_F(t)|x - y| \\ &\leq (1 + k_F(t))|(x, v) - (y, w)| \\ &\leq (1 + k_F(t))d_{\mathrm{Gr}\{F(t,\cdot)\}}(x, v).\end{aligned}$$

(Here $d_{\text{Haus}}(F_1, F_2)$ is the Hausdorff distance function.) This result is the desired inequality. □

Lemma 8 tells us that the penalty term $M\int_0^1 \rho(t,x,y,\dot{x},\dot{y})dt$ satisfies

$$M\int_0^1 \rho(t,x,y,\dot{x},\dot{y})dt \le M\int_0^1 ((1+k_F)d_{\mathrm{Gr}\{F(t,\cdot)\}}(x,\dot{x}) + |\dot{y}|)dt$$

for all $(x,y) \in W^{1,1}$. Of course, because $(\dot{x}_i, \dot{y}_i) \in F(t,x_i) \times \{0\}$,

$$0 = M\int_0^1 \rho(t,x_i,y_i,\dot{x}_i,\dot{y}_i)dt = M\int_0^1 (1+k_F)d_{\mathrm{Gr}\{F(t,\cdot)\}}(x_i,\dot{x}_i)dt.$$

These relationships combine with the assertions of the lemma to give the following: for each i, (x_i, y_i) is a local minimizer for

$$\text{minimize } J_i(x,y) + M\int_0^1 ((1+k_F)d_{\mathrm{Gr}\{F(t,\cdot)\}}(x,\dot{x}) + |\dot{y}|)dt$$
$$\text{over arcs } (x,y) \in W^{1,1} \text{ which satisfy } (x(0),y(0)) \in C.$$

Our findings up to this point can be expressed as follows: for each i, (x_i, y_i) is a minimizer for

$$\text{minimize } \tilde{l}_i(x(0),y(0),x(1),y(1)) + \int_0^1 \tilde{L}_i(t,x(t),y(t),\dot{x}(t),\dot{y}(t))dt$$
$$\text{over arcs } (x,y) \text{ which satisfy } (x(0),y(0)) \in C.$$

Here, we recall

$$\tilde{l}_i(x,y,x',y') := \max\{l(x,y) - l(\bar{x}(0),\bar{x}(1)) + \epsilon_i^2, |x'-y'|\} + \epsilon_i|x - x_i(0)| + \epsilon_i|y - y_i(0)|,$$

and $\tilde{L}_i$ is taken to be the function

$$\tilde{L}_i(t,x,y,v,w) := \epsilon_i|v - \dot{x}_i(t)| + M(1+k_F(t))d_{\mathrm{Gr}\{F(t,\cdot)\}}(x,v) + M|w|.$$

The hypotheses under which Theorem 3 applies are satisfied, to give the following information about the minimizer (x_i, y_i). (See Remark after Theorem 3.) There exist arcs p_i and q_i such that

(A′) $(\dot{p}_i(t), \dot{q}_i(t)) \in \mathrm{co}\{(\eta,\xi) : (\eta,\xi,p_i(t),q_i(t)) \in \partial\tilde{L}_i(t,x_i(t),y_i(t),\dot{x}_i(t),0)\}$;

(B′) $(p_i(0),q_i(0),-p_i(1),-q_i(1)) \in \partial\tilde{l}_i(x_i(0),y_i(0),x_i(1),y_i(1)) + N_C(x_i(0),y_i(0)) \times \{(0,0)\}$;

(C′) $p_i(t)\dot{x}_i(t) \ge p_i(t)v + q_i(t)w - \tilde{L}_i(t,x_i(t),y_i(t),v,w) \quad \forall v,w \in R^n$ a.e.

Condition (A′) implies that $q_i(t)$ is a constant (we write it q_i); $|q_i| \le M$, $|\dot{p}_i(t)| \le M(1+k_F(t))$; and

$$\begin{aligned}\dot{p}_i(t) &\in \mathrm{co}\{\eta : (\eta,p_i(t)) \in \{0\} \times \epsilon_i B + M(1+k_F(t))\partial d_{\mathrm{Gr}\{F(t,\cdot)\}}(x_i(t),\dot{x}_i(t))\} \\ &\subseteq \mathrm{co}\{\eta : (\eta,p_i(t)) \in \{0\} \times \epsilon_i B + N_{\mathrm{Gr}\{F(t,\cdot)\}}(x_i(t),\dot{x}_i(t))\}.\end{aligned} \tag{18}$$

From (B′),

$$\begin{aligned}(p_i(0),q_i,-p_i(1),-q_i) \in \partial l_i(x_i(0),y_i(0),x_i(1),y_i(1)) \\ + \epsilon_i(B\times B)\times\{(0,0)\} + N_C(x_i(0),y_i(0))\times\{(0,0)\}.\end{aligned} \tag{19}$$

We observe that $l_i(x_i(0), y_i(0), x_i(1), y_i(1)) > 0$ for all i. Otherwise it is zero for some i which implies $y_i(1) = x_i(1)$, $(x_i(0), x_i(1)) \in C$ and $l(x_i(0), x_i(1)) \le l(\bar{x}(0), \bar{x}(1)) - \epsilon_i^2$. But then x_i would satisfy the constraints of (Q) and also $\|x_i - \bar{x}\|_{W^{1,1}} \le \delta/2$ and have lower cost than $\bar{x}$; this contradicts the optimality properties of $\bar{x}$.

It is now claimed that there exist $\lambda_i \ge 0$ and $e_i \in R^n$ such that $\lambda_i + |e_i| = 1$ and

$$\partial l_i(x_i(0), y_i(0), x_i(1), y_i(1)) \subseteq \lambda_i \partial l(x_i(0), y_i(0)) \times \{(0,0)\} + \{(0, 0, e_i, -e_i)\}. \tag{20}$$

Fix i. There are two cases to consider:

(i) $x_i(1) = y_i(1)$. In this case $l_i(x, y, x', y') = l(x, y) - l(\bar{x}(0), \bar{x}(1)) + \epsilon_i^2$ on a neighborhood of $(x_i(0), y_i(0), x_i(1), y_i(1))$, so

$$\partial l_i(x_i(0), y_i(0), x_i(1), y_i(1)) = \partial l(x_i(0), y_i(0)) \times \{(0,0)\}.$$

This implies (20) with $\lambda_i = 1$ and $e_i = 0$.

(ii) $x_i(1) \ne y_i(1)$. In this case the chain rule gives $\partial\{(x, y) \to |x - y|\}|_{x_i(1), y_i(1)} = (\tilde{e}_i, -\tilde{e}_i)$ for some unit vector $\tilde{e}_i$. We may therefore deduce from the calculus rules concerning function defined by the pointwise-maximum operation (see, e.g., [13, Thm. 6.9]) that, for some $\lambda_i \in [0, 1]$,

$$\partial l_i(x_i(0), y_i(0), x_i(1), y_i(1)) \subseteq \lambda_i \partial l(x_i(0), y_i(0)) \times \{(0,0)\} + (1 - \lambda_i)\{(0, 0, \tilde{e}_i, -\tilde{e}_i)\}.$$

Now set $e_i = (1 - \lambda_i)\tilde{e}_i$. We see that $\lambda_i + |e_i| = 1$ and (20) is satisfied.

We may now deduce from (19) that $-p_i(1) = e_i = q_i$, and

$$|p_i(1)| + \lambda_i = 1, \tag{21}$$

$$(p_i(0), -p_i(1)) \in \lambda_i \partial l(x_i(0), y_i(0)) + \epsilon_i(B \times B) + N_C(x_i(0), y_i(0)). \tag{22}$$

Condition (C′) implies

$$p_i(t)\dot{x}_i(t) \ge p_i(t)v - \epsilon_i|v - \dot{x}_i(t)| \quad \forall v \in F(t, x_i(t)). \tag{23}$$

Recall that $|\dot{p}_i(t)| \le M(1 + k_F(t))$ and $|p_i(1)| \le 1$. We may therefore arrange by subsequence extraction that $\dot{p}_i \to \dot{p}$ weakly in L^1 and $p_i \to p$ uniformly for some arc p. We have shown also that $\dot{x}_i \to \dot{\bar{x}}$ strongly in L^1 and a.e., $y_i(0) \to \bar{x}(1)$, and $x_i \to \bar{x}$ uniformly. Straightforward limit-taking arguments permit us now to deduce all the assertions of Theorem 6 from (18), (21)–(23). (Analysis of (18) in the limit is based on the upper semicontinuous properties of the limiting normal cone and an appeal to Carathéodory's theorem.)

This completes the proof in the case $L = 0$.

Suppose now the integral term is present in the cost of (Q). We reformulate (Q) as

$$\begin{aligned} &\text{minimize } l(x(0), x(1)) + z(1) \\ &\text{over arcs } (x, z) \text{ which satisfy} \\ &(\dot{x}(t), \dot{z}(t)) \in E(t, x(t)) \\ &(x(0), x(1)) \in C, z(0) = 0. \end{aligned} \tag{24}$$

Here

$$E(t, x) := \{(v, w) : v \in F(t, x), w \ge L(t, x, v)\}.$$

For reasons similar to those previously given, we may assume that the multifunctions $F(t,\cdot)$ and the functions $L(t,\cdot,\cdot)$ are Lipschitz continuous on R^n and $R^n \times (\dot{\bar{x}}(t) + rB)$ with Lipschitz ranks at most $k_F(t)$ and $k_L(t)$, respectively. We claim that

$$E(t,x) \subset E(t,x') + k(t)|x - x'|B \quad \forall x, x' \in R^n \text{ a.e.},$$

where $k(t) := k_F(t) + k_L(t) + k_F(t)k_L(t)$ which, under the hypotheses, is an integrable function. To verify this take any $x', x \in R^n$ and $(v', w') \in E(t,x')$. Then $v' \in F(t,x')$ and $w' \geq L(t,x',v')$. The Lipschitz continuity of $F(t,\cdot)$ implies the existence of some $v \in F(t,x)$ such that $|v' - v| \leq k_F(t)|x' - x|$. Define $w := L(t,x,v) - L(t,x',v') + w'$. Obviously, $(v,w) \in E(t,x)$. We have by the Lipschitz continuity properties of L

$$|w' - w| = |L(t,x',v') - L(t,x,v)| \leq k_L(t)|(x',v') - (x,v)|.$$

But then

$$\begin{aligned} |(v',w') - (v,w)| &\leq (k_F^2|x' - x|^2 + k_L^2(|x' - x|^2 + k_F^2|x' - x|^2))^{1/2} \\ &\leq (k_F + k_L + k_L k_F)|x' - x| = k(t)|x' - x|. \end{aligned}$$

Set $\bar{z}(t) = \int_0^t L(s,\bar{x}(s),\bar{x}'(s))ds$. Then, since $\bar{x}$ is a minimizer for (Q), $(\bar{x},\bar{z})$ is a minimizer for (24), a problem of the special kind ("$L \equiv 0$") for which necessary conditions have already been derived. We have already checked that $E(t,\cdot)$ satisfies the Lipschitz continuity hypothesis for application of Theorem 4, the other hypotheses on the data for (24) are easily verified. From Theorem 6 we know that there exist $p \in W^{1,1}$, $q \in R^n$, and $\lambda \geq 0$, not all zero, such that

(A″) $\dot{p}(t) \in \text{co}\{\eta : (\eta, p(t), q) \in N_{\text{Gr}\{E(t,\cdot)\}}(\bar{x}(t), \dot{\bar{x}}(t), L(t,\bar{x}(t),\dot{\bar{x}}(t)))\}$,

(B″) $(p(0), -p(1), q, -q) \in \lambda[\partial l(\bar{x}(0),\bar{x}(1)) \times \{(0,1)\}] + N_C(\bar{x}(0),\bar{x}(1)) \times R \times \{0\}$,

(C″) $p(t)\dot{\bar{x}}(t) + q\dot{\bar{z}}(t) \geq p(t)v + qw \quad \forall (v,w) \in E(t,\bar{x}(t))$.

Condition (B″) implies $q = -\lambda$, so in particular p and λ are not both zero, and

$$(p(0), -p(1)) \in \lambda \partial l(\bar{x}(0),\bar{x}(1)) + N_C(\bar{x}(0),\bar{x}(1)).$$

Now $\text{Gr}\{E(t,\cdot)\} = \text{epi}\{(x,v) \to \Psi_{\text{Gr}E(t,\cdot)}(x,v) + L(t,x,v)\}$. Furthermore, since $\text{Gr}\{E(t,\cdot)\}$ is closed, the normal cone of this epigraph set at $(\bar{x}(t), \dot{\bar{x}}(t), L(t,\bar{x}(t),\dot{\bar{x}}(t)))$ is known to be contained in

$$\{(\xi, -\alpha) : \alpha \geq 0, \xi \in \alpha \partial_{x,v} L(t,\bar{x}(t),\dot{\bar{x}}(t)) + N_{\text{Gr}\{F(t,\cdot)\}}(\bar{x}(t),\dot{\bar{x}}(t))\}.$$

It follows therefore from (A″) that we must choose $\alpha = -q = \lambda$ and

$$\dot{p}(t) \in \text{co}\{\eta : (\eta, p(t)) \in \lambda \partial L(t,\bar{x}(t),\dot{\bar{x}}(t)) + N_{\text{Gr}\{F(t,\cdot)\}}(\bar{x}(t),\dot{\bar{x}}(t))\}.$$

Finally from condition (C″), since $(v, L(t,\bar{x}(t),v)) \in E(t,\bar{x}(t))$ for any $v \in F(t,\bar{x}(t))$, we get

$$p(t)\dot{\bar{x}}(t) - \lambda L(t,\bar{x}(t),\dot{\bar{x}}(t)) \geq p(t)v - \lambda L(t,\bar{x}(t),v) \quad \forall v \in F(t,\bar{x}(t)).$$

Proof of the theorem is complete. □

4. Autonomous problems. Consider a modification of problem (Q), in which the dynamics and the cost integrand are independent of time, the terminal time is a choice variable, and the terminal time, together with the end states, are constrained to lie in a specified set:

$$\text{minimize } l(x(0),x(T),T)+\int_0^T L(x(t),\dot{x}(t))dt$$

over terminal times $T>0$ and arcs $x\in W^{1,1}$ satisfying

$$\dot{x}(t)\in F(x(t)),\quad (x(0),x(T),T)\in D.$$

The data here are functions $l: R^n\times R^n\times R\to R$, $L: R^n\times R^n\to R$, a multifunction $F: R^n\rightrightarrows R^n$, and a closed set $D\subset R^n\times R^n\times R$.

A pair $(\bar{T},\bar{x})$ is said to be a local minimizer for the free time problem with autonomous dynamics if there exists $\epsilon>0$ such that it is minimizing over all (T,x)'s such that

$$\mathrm{Gr}\{x\}\subset \mathrm{Gr}\{\bar{x}\}+\epsilon B. \tag{25}$$

Necessary conditions are now derived with the help of transformation of the independent variable techniques previously used, for example, in [2, p. 151 et seq.].

THEOREM 9. *Let $(\bar{T},\bar{x})$ be a local minimizer for the free time problem with autonomous dynamics, with $\bar{T}>0$. Assume that for some $\delta\in(0,\infty)$ and some nonnegative measurable functions k_F and k_L such that $k_F\in L^1$, $k_L\in L^1$, and $k_Fk_L\in L^1$, we have the following:*

(GF1) *l is Lipschitz continuous on a neighborhood of $(\bar{x}(0),\bar{x}(\bar{T}),\bar{T})$.*

(GF2) *$F(x)$ is nonempty and closed for each x,*

$$F(x')\subset F(x)+k_F(t)|x'-x|B\quad \forall x,x'\in\bar{x}(t)+\delta B\quad a.e.$$

(GF3) $|L(x,v)-L(x',v')|\le k_L(t)|(x,v)-(x',v')|\forall (x,v),(x',v')\in(\bar{x}(t)+\delta)\times R^n$.

Then there exist $p\in W^{1,1}([0,\bar{T}];R^n)$ and $\lambda\ge 0$, not both zero, such that

$$\dot{p}(t)\in \mathrm{co}\{\eta:(\eta,p(t))\in\lambda\partial L(\bar{x}(t),\dot{\bar{x}}(t))+N_{\mathrm{Gr}\{F(\cdot)\}}(\bar{x}(t),\dot{\bar{x}}(t))\},$$

$$p(t)\dot{\bar{x}}(t)-\lambda L(\bar{x}(t),\dot{\bar{x}}(t))\ge p(t)v-\lambda L(\bar{x}(t),v)\forall v\in F(\bar{x}(t)),$$

$$p(t)\dot{\bar{x}}(t)-\lambda L(\bar{x}(t),\dot{\bar{x}}(t))=h\quad \text{a.e. for some constant } h, \text{ and}$$

$$(p(0),-p(1),h)\in\lambda\partial l(\bar{x}(0),\bar{x}(\bar{T}),\bar{T})+N_D(\bar{x}(0),\bar{x}(\bar{T}),\bar{T}).$$

Proof. We deal first with the case $L\equiv 0$. Consider the fixed time problem:

$$\text{minimize } l(x(0),x(\bar{T}),y(\bar{T}))$$

subject to

$$(\dot{x}(t),\dot{y}(t))\in\tilde{F}(x(t))$$

$$(x(0),x(\bar{T}),y(\bar{T}))\in D, y(0)=0$$

in which $\tilde{F}(x):=\{(\alpha v,\alpha):\alpha\in[0.5,1.5],v\in F(x)\}$.

Take any $\epsilon'>0$ and any feasible arc (x,y) for this problem satisfying $|(x(s),y(s))-(\bar{x}(s),\bar{y}(s)=s)|\le\epsilon'$ for all $s\in[0,\bar{T}]$. Then there exist measurable function α :

$[0,\bar{T}] \to [0.5, 1.5]$ and an integrable function $\phi(s)$ such that $\dot{x}(s) = \alpha(s)\phi(s)$, $\phi(s) \in F(x(s))$, and $\dot{y}(s) = \alpha(s)$ a.e. Now consider the strictly increasing function $\theta(s) = \int_0^s \alpha(\sigma)d\sigma$. We can use this to define a change of variables $t = \theta(s)$. Write $\tilde{x}(t) = x(\theta^{-1}(t)), 0 \le t \le T$, where $T = \theta(\bar{T})$. We can show, with the help of Fabini's theorem, that $\tilde{x}$ is absolutely continuous, $\dot{\tilde{x}}(t) = \phi(\theta^{-1}(t)) \in F(\tilde{x}(t))$ a.e. We note also that

$$(\tilde{x}(0), \tilde{x}(T), T) = (x(0), x(\bar{T}), y(\bar{T})).$$

Hence $l(\tilde{x}(0), \tilde{x}(T), T) = l(x(0), x(\bar{T}), y(\bar{T}))$, and $(\tilde{x}(0), \tilde{x}(T), T) \in D$. We see that $(T, \tilde{x})$ is feasible for the original free time problem and has the same cost as that of (x, y) for the fixed time problem. It is also the case that we can arrange, by choosing ϵ' sufficiently small that $\mathrm{Gr}\{x\} \subset \mathrm{Gr}\{\bar{x}\} + \epsilon B$, where ϵ is the parameter in (25) associated with $(\bar{T}, \bar{x})$ as local minimizer. Since $(\bar{x}(s), \bar{y}(s) = s)$ is feasible for the fixed time problem and has cost $l(\bar{x}(0), \bar{x}(\bar{T}), \bar{T})$ we conclude that $(\bar{x}, \bar{y})$ is a local minimizer. The hypotheses are satisfied under which Theorem 6 is available to give information about the local minimizer $(\bar{x}, \bar{y})$: there exist $p \in W^{1,1}$, $q \in R$, and $\lambda \ge 0$, not all zero, such that

$$\dot{p}(s) \in \mathrm{co}\{\eta : (\eta, p(s), q) \in N_{\mathrm{Gr}\{\tilde{F}\}}(\bar{x}(s), \dot{\bar{x}}(s), 1)\},$$

$$(p(0), -p(\bar{T}), -q) \in \lambda \partial l(\bar{x}(0), \bar{x}(\bar{T}), \bar{T}) + N_D(\bar{x}(0), \bar{x}(\bar{T}), \bar{T}),$$

$$p(s)\dot{\bar{x}}(s) + q \ge (p(s)v + q)\alpha \quad \forall \alpha \in [0.5, 1.5], v \in F(\bar{x}(s)).$$

This last relation tells us that

$$-q = p(s)\dot{\bar{x}}(s) \quad \text{a.e.} \quad s \in [0, \bar{T}],$$

$$p(s)\dot{\bar{x}}(s) \ge p(s)v \quad \forall v \in F(\bar{x}(s)).$$

To analyze the implications of the costate equation above, note that neighboring points to $(\bar{x}(s), \dot{\bar{x}}(s), 1)$ in the graph of $\tilde{F}$ can be expressed as $(x', \alpha' v', \alpha')$ for some x', v', α' close to $(\bar{x}(s), \dot{\bar{x}}(s), 1)$ and that, if (η', p', q') is a proximate normal to $\mathrm{Gr}\{\tilde{F}\}$ for some such $(x', \alpha' v', \alpha')$, then

$$\eta'(x - x') + p'(\alpha v - \alpha' v') + q'(\alpha - \alpha') \le M(|(x, \alpha v, \alpha) - (x', \alpha' v', \alpha')|^2)$$

for all $x \in R^n$, $v \in F(x)$, and α near (x', v', α'). Setting $\alpha = \alpha'$, we deduce from the inequality that $(\eta', \alpha' p') \in N_{\mathrm{Gr}F}(x', v')$. The usual limit-taking procedure now permits us to deduce from $(\eta, p(s), q) \in N_{\mathrm{Gr}\{\tilde{F}\}}(\bar{x}(s), \dot{\bar{x}}(s), 1)$ that

$$(\eta, p(s)) \in N_{\mathrm{Gr}\{F\}}(\bar{x}(s), \dot{\bar{x}}(s)).$$

Assembling all the above relationships and defining $h = -q$ we arrive at the theorem statement. (Note that $q = 0$ if $p = 0$, so that p and λ cannot both be zero.)

To conclude, we allow an integral cost term. The free time problem is reformulated as an integral cost free problem by state augmentation (the dynamics remain autonomous). The desired necessary conditions for the original problem are now obtained by applying the special case of the necessary conditions (already proved) to the "augmented" problem. (The arguments required to show that the relevant hypotheses are satisfied for application of the special case of the necessary conditions are in essential respects the same as those appearing in the proof of Theorem 6.) □

LOW-GAIN CONTROL OF UNCERTAIN REGULAR LINEAR SYSTEMS*

HARTMUT LOGEMANN† AND STUART TOWNLEY‡

Abstract. It is well known that closing the loop around an exponentially stable, finite-dimensional, linear, time-invariant plant with square transfer-function matrix $\mathbf{G}(s)$ compensated by a controller of the form $(k/s)\Gamma_0$, where $k \in \mathbb{R}$ and $\Gamma_0 \in \mathbb{R}^{m\times m}$, will result in an exponentially stable closed-loop system which achieves tracking of arbitrary constant reference signals, provided that (i) all the eigenvalues of $\mathbf{G}(0)\Gamma_0$ have positive real parts and (ii) the gain parameter k is positive and sufficiently small.

In this paper we consider a rather general class of infinite-dimensional linear systems, called regular systems, for which convenient representations are known to exist, both in time and in frequency domain. The purpose of the paper is twofold: (i) we extend the above result to the class of exponentially stable regular systems and (ii) we show how the parameters k and Γ_0 can be tuned adaptively. The resulting adaptive tracking controllers are not based on system identification or parameter estimation algorithms, nor is the injection of probing signals required.

Key words. regular infinite-dimensional systems, integral controllability, robust tracking, adaptive tracking, state-space methods, frequency-domain methods

1. Introduction.

The synthesis of low-gain I and PI-controllers for uncertain stable plants has received considerable attention in the past 20 years. Let $\mathbf{G}$ be a stable proper rational transfer function matrix. The main existence result on robust low-gain I-control says that for any matrix Γ_0 satisfying

$$\text{spectrum}(\mathbf{G}(0)\Gamma_0) \subset \{s \in \mathbb{C} \mid \operatorname{Re} s > 0\}, \tag{1.1}$$

there exists $k^* > 0$ such that for all $k \in (0, k^*)$ the controller $(1/s)k\Gamma_0$ stabilizes $\mathbf{G}$ and the resulting closed-loop system asymptotically tracks arbitrary constant reference signals. This result has been proved by Davison [4][1] and Lunze [18] using state-space methods and by Grosdidier, Morari, and Holt [5] and Morari [25] using frequency-domain methods (see also the book by Lunze [20, Chapter 10], and the textbook by Morari and Zafiriou [26, p. 362]). There are consequently two parts to the design of low-gain tracking controllers: choosing Γ_0 and tuning k. Such a controller design approach, called "tuning regulator theory" [4], has been successfully applied to industrial control problems; see Coppus, Sha, and Wood [2] and Lunze [19].

In the case that $\mathbf{G}$ is square, $\mathbf{G}^{-1}(0)$ would be a natural choice for Γ_0, but in the presence of uncertainty, $\mathbf{G}(0)$ might not be known exactly. However, an estimate

[1] In [4] the result is proven for the special choice $\Gamma_0 = \mathbf{G}^{-1}(0)$. However, an inspection of the Lyapunov argument in the proof of lemma 3 in [4] shows that it can be easily extended to the more general case when Γ_0 satisfies (1.1) (simply replace the identity I in equation (28) in [4] by N, where N is the positive definite solution of the Lyapunov equation $(\mathbf{G}(0)\Gamma_0)^T N + N(\mathbf{G}(0)\Gamma_0) = -I$).

G_0 of $\mathbf{G}(0)$ can be obtained, in principle, by performing step response experiments on the plant. In this case the matrix Γ_0 is then chosen such that (1.1) holds with $\mathbf{G}(0)$ replaced by G_0. Although Mustafa [28] has recently derived a formula for the maximal k^* in terms of a minimal realization (A, B, C, D) of $\mathbf{G}$, in the presence of uncertainty there are only crude methods available for determining a number $k^* > 0$ such that all gain parameters $k \in (0, k^*)$ will lead to a stable closed-loop system; see, e.g., Lunze [18] and Owens and Chotai [29]. Methods for tuning Γ_0 and k by means of experiments and simulation have been developed and discussed in many places; we mention only [4], [18], [20], [29], and the paper by Penttinen and Koivo [31].

The above-mentioned tuning regulator result has been extended by Pohjolainen [32], [33], Pohjolainen and Lätti [34], Logemann and Owens [15] and Logemann, Bontsema, and Owens [11] to various classes of (abstract) infinite-dimensional systems and by Koivo and Pohjolainen [9] and Jussila and Koivo [8] to differential delay systems.

If the plant uncertainty is large and/or if reliable plant step data are not available, then the parameters k and Γ_0 need to be tuned adaptively. It turns out that, once the tuning problem for k is solved, the tuning of Γ_0 can be achieved by applying the spectrum unmixing techniques used in multivariable high-gain adaptive stabilization, Mårtensson [21], [22]. Low-gain universal adaptive controllers which achieve asymptotic tracking of constant reference signals for finite-dimensional linear stable plants have been presented by Cook [1] and Miller and Davison [23], [24].[2] By "universal" we mean that the controllers are not based on system identification or parameter estimation algorithms. The controller given in [1] is smooth, while the control laws derived in [23], [24] are "piecewise constant." The controller given in [24] satisfies a control input constraint.

In this paper we consider the problem of low-gain I-control for the class of exponentially stable, linear, regular infinite-dimensional systems introduced and studied by Weiss; see [44], [45], [46], [47], [48], [49]. This class is rather general and includes all distributed parameter systems and all time-delay systems (retarded and neutral) which are of interest in applications. In particular, it includes the classes of infinite-dimensional systems considered in the references [8], [9], [15], [11], [32], [33], [34] mentioned earlier and the well-known class of Pritchard–Salamon systems; see Pritchard and Salamon [35], [36] and Curtain et al. [3]. Although there exist well-posed infinite-dimensional systems which are not regular, the authors believe that any physically motivated well-posed linear time-invariant control system is regular.

In section 2 we provide the necessary background on regular systems which will be needed in sections 3–5. With one exception, all the results in section 2 are due to Weiss [44], [45], [46], [47], [48], [49], the exception being a nonlinear existence result which is required for adaptive low-gain control. The proof of this result is relegated to an appendix.

Section 3 is devoted to nonadaptive low-gain control of regular systems. We first prove a frequency-domain result on the existence of low-gain tuning regulators of the form $(1/s)k\Gamma_0$ for all square transfer function matrices $\mathbf{G}$ which are holomorphic and bounded on some right-half plane $\operatorname{Re} s > \alpha$ for some $\alpha = \alpha(\mathbf{G}) < 0$ and satisfy $\det \mathbf{G}(0) \neq 0$. This result is then applied to regular state-space systems, and it is shown that for all sufficiently small k the closed-loop system will achieve asymptotic

[2] Surprisingly, the low-gain adaptive tracking problem has received less attention than its high-gain counterpart; see Ilchmann [7], Logemann and Ilchmann [12], Ryan [38], and the references therein.

tracking of constant reference signals, provided that the initial state of the open-loop system is sufficiently "smooth."

In sections 4 and 5 we consider the adaptive low-gain tracking problem for regular infinite-dimensional systems. While the problem of universal adaptive stabilization for infinite-dimensional systems has received some attention in recent years (see Logemann [10], Logemann and Mårtensson [13], Logemann and Owens [14], Logemann and Zwart [17], and Townley [41]), very little work has been done on adaptive tracking (see, however, the paper by Logemann and Ilchmann [12] on a high-gain adaptive servomechanism for a class of infinite-dimensional systems). In particular, it seems that so far no research has been carried out on the adaptive low-gain control problem in an infinite-dimensional setting. We mention that the main result in Cook [1] (at least as we understand it) relies on the Kalman–Yakubovich lemma. A straightforward extension of the approach in [1] to regular infinite-dimensional systems is not possible, since the existence of an appropriate infinite-dimensional version of the Kalman–Yakubovich lemma is a difficult open problem. The (discontinuous) piecewise constant controllers presented in Miller and Davison [23], [24] seem unnecessarily complicated and would not generalize to the infinite-dimensional case either. Section 4 is restricted to the case when the steady-state gain matrix $\mathbf{G}(0)$ is sign definite; i.e., $\mathbf{G}(0)$ is either positive or negative definite. We first give an alternative proof of the finite-dimensional result obtained by Cook [1]. Our proof illustrates certain special system theoretic properties of the low-gain problem, properties which can even be exploited in the infinite-dimensional case. The basic idea in [1] is to set the integrator gain k equal to $\mathcal{K}(\gamma)$, where $\mathcal{K}$ is a function, the so-called tuning function, and γ is a parameter which is adjusted by a suitable adaptation law. The class of tuning functions $\mathcal{K}$ given in [1] exploits the low-gain nature of the problem in the sense that $\mathcal{K}(\gamma) \to 0$ as $\gamma \to \infty$. We then prove the main result in section 4, a low-gain adaptive tuning regulator result for infinite-dimensional regular systems. The choice of tuning functions is more constrained than in the finite-dimensional case, although we can still work with functions $\mathcal{K}$ satisfying that $\mathcal{K}(\gamma) \to 0$ as $\gamma \to \infty$. In the sign-indefinite case, which is treated in section 5, we have to resort to tuning functions which oscillate smoothly between 0 and an arbitary positive number.

We illustrate our results by a number of examples and simulations in section 6.

Notation.

- For $\alpha \in \mathbb{R}$ set $\mathbb{C}_\alpha := \{s \in \mathbb{C} \,|\, \operatorname{Re} s > \alpha\}$.
- For $\alpha \in \mathbb{R}$ and H a Hilbert space we define the exponentially weighted L^2-space $L^2_\alpha(\mathbb{R}_+, H) := \{f \in L^2_{loc}(\mathbb{R}_+, H) \,|\, f(\cdot)\exp(-\alpha\,\cdot) \in L^2(\mathbb{R}_+, H)\}$.
- If A is a linear operator, then the domain, spectrum, and resolvent set of A are denoted by $D(A)$, $\sigma(A)$, and $\varrho(A)$, respectively.
- The Laplace transform is denoted by $\mathbb{L}$.

2. Preliminaries on abstract linear systems. In this section we give some background on abstract linear systems. Apart from Proposition 2.4 almost all the results are due to Weiss [44], [45], [46], [47], [48], [49].

First we introduce some notation. For any Hilbert space H and any $\tau \geq 0$, $\mathbf{R}_\tau$ and $\mathbf{L}_\tau$ will denote the right-shift by τ and the left-shift by τ on $L^2_{loc}(\mathbb{R}_+, H)$, respectively. The truncation operator $\mathbf{P}_\tau : L^2_{loc}(\mathbb{R}_+, H) \to L^2(\mathbb{R}_+, H)$ is given by

$$(\mathbf{P}_\tau u)(t) = \begin{cases} u(t) & \text{if} \quad t \in [0, \tau], \\ 0 & \text{if} \quad t > \tau. \end{cases}$$

For $u, v \in L^2_{loc}(\mathbb{R}_+, H)$ and $\tau \geq 0$, the *τ-concatenation* $u \overset{\tau}{\diamondsuit} v$ is defined by

$$u \overset{\tau}{\diamondsuit} v = \mathbf{P}_\tau u + \mathbf{R}_\tau v\,.$$

The following concept was introduced by Weiss [46]. An equivalent definition can be found in Salamon [39].

DEFINITION 2.1. *Let U, X, and Y be real Hilbert spaces. An* abstract linear system *with* state-space X, input-space U, *and* output-space Y *is a quadruple* $\mathbf{\Sigma} = (\mathbf{T}, \mathbf{\Phi}, \mathbf{\Psi}, \mathbf{F})$, *where*

(i) $\mathbf{T} = (\mathbf{T}_t)_{t\geq 0}$ *is a C_0-semigroup of bounded linear operators on X;*

(ii) $\mathbf{\Phi} = (\mathbf{\Phi}_t)_{t\geq 0}$ *is a family of bounded linear operators from $L^2(\mathbb{R}_+, U)$ to X such that*

$$\mathbf{\Phi}_{\tau+t}(u \overset{\tau}{\diamondsuit} v) = \mathbf{T}_t \mathbf{\Phi}_\tau u + \mathbf{\Phi}_t v$$

for all $u, v \in L^2(\mathbb{R}_+, U)$ and all $\tau, t \geq 0$;

(iii) $\mathbf{\Psi} = (\mathbf{\Psi}_t)_{t\geq 0}$ *is a family of bounded linear operators from X to $L^2(\mathbb{R}_+, Y)$ such that*

$$\mathbf{\Psi}_{\tau+t} x_0 = \mathbf{\Psi}_\tau x_0 \overset{\tau}{\diamondsuit} \mathbf{\Psi}_t \mathbf{T}_\tau x_0$$

for all $x_0 \in X$ and all $\tau, t \geq 0$, and $\mathbf{\Psi}_0 = 0$;

(iv) $\mathbf{F} = (\mathbf{F}_t)_{t\geq 0}$ *is a family of bounded linear operators from $L^2(\mathbb{R}_+, U)$ to $L^2(\mathbb{R}_+, Y)$ such that*

$$\mathbf{F}_{\tau+t}(u \overset{\tau}{\diamondsuit} v) = \mathbf{F}_\tau u \overset{\tau}{\diamondsuit} (\mathbf{\Psi}_t \mathbf{\Phi}_\tau u + \mathbf{F}_t v)\,,$$

$u, v \in L^2(\mathbb{R}_+, U)$ and all $\tau, t \geq 0$, and $\mathbf{F}_0 = 0$.

It follows easily from the definition that $\mathbf{\Phi}_0 = 0$ and that for any $\tau \geq 0$, $x_0 \in X$, and $u \in L^2_{loc}(\mathbb{R}_+, U)$

$$(\mathbf{\Psi}_\tau x_0)(t) = (\mathbf{F}_\tau u)(t) = 0 \quad \text{for a.e. } t \geq \tau\,.$$

Let an input $u \in L^2_{loc}(\mathbb{R}_+, U)$ and an initial state $x_0 \in X$ be given. The state $x(t) = x(t; x_0, u)$ of $\mathbf{\Sigma}$ at time $t \geq 0$ and the output $y(\cdot) = y(\cdot\,; x_0, u)$ of $\mathbf{\Sigma}$ are defined by

$$x(t) = \mathbf{T}_t x_0 + \mathbf{\Phi}_t \mathbf{P}_t u\,, \tag{2.1a}$$

$$\mathbf{P}_t y = \mathbf{\Psi}_t x_0 + \mathbf{F}_t \mathbf{P}_t u\,. \tag{2.1b}$$

The state trajectory $x(\cdot)$ is continuous from $\mathbb{R}_+ \to X$, and the output $y(\cdot)$ is in $L^2_{loc}(\mathbb{R}_+, Y)$. Furthermore, if $t \geq \tau \geq 0$, then the functions $x(\cdot)$ and $y(\cdot)$ defined by (2.1) satisfy

$$x(t) = \mathbf{T}_{t-\tau} x(\tau) + \mathbf{\Phi}_{t-\tau} \mathbf{L}_\tau \mathbf{P}_t u\,, \tag{2.2a}$$

$$\mathbf{L}_\tau \mathbf{P}_t y = \mathbf{\Psi}_{t-\tau} x(\tau) + \mathbf{F}_{t-\tau} \mathbf{L}_\tau \mathbf{P}_t u\,. \tag{2.2b}$$

The equations (2.2) express the *time-invariance* of $\mathbf{\Sigma}$. They follow in a straightforward way from Definition 2.1. We say that $\mathbf{\Sigma}$ is *exponentially stable* if the semigroup $\mathbf{T}$ is exponentially stable, i.e.,

$$\omega(\mathbf{T}) := \lim_{t\to\infty} \frac{1}{t} \log \|\mathbf{T}_t\| < 0\,.$$

It is clear that there exist unique operators $\mathbf{\Psi}_\infty : X \to L^2_{loc}(\mathbb{R}_+, Y)$ and $\mathbf{F}_\infty : L^2_{loc}(\mathbb{R}_+, U) \to L^2_{loc}(\mathbb{R}_+, Y)$ such that for all $\tau \geq 0$

$$\mathbf{\Psi}_\tau = \mathbf{P}_\tau \mathbf{\Psi}_\infty \,, \quad \mathbf{F}_\tau = \mathbf{P}_\tau \mathbf{F}_\infty \,.$$

The generator of $\mathbf{T}$ is denoted by A. Let X_1 be the space $D(A)$ endowed with the graph norm, and let X_{-1} be the completion of X with respect to the norm $\|x\|_{-1} = \|(\lambda I - A)^{-1}x\|$, where $\lambda \in \varrho(A)$ is fixed. We have $X_1 \subset X \subset X_{-1}$ and the canonical injections are bounded and dense. The semigroup $\mathbf{T}$ can be restricted to a C_0-semigroup on X_1 and extended to a C_0-semigroup on X_{-1}. The exponential growth constant is the same on all three spaces. The generator on X_1 is the restriction of A to $D(A^2)$, and the generator on X_{-1} is an extension of A to X (which is bounded as an operator from X to X_{-1}). We shall use the same symbols for the original semigroup and its generator and the corresponding restrictions and extensions.

By a representation theorem due to Salamon [39] (see also Weiss [44], [45]) there exist unique operators $B \in \mathcal{L}(U, X_{-1})$ and $C \in \mathcal{L}(X_1, Y)$ (the *control operator* and the *observation operator* of $\mathbf{\Sigma}$, respectively) such that for all $t \geq 0$, all $u \in L^2_{loc}(\mathbb{R}_+, U)$, and all $x_0 \in X_1$

$$\mathbf{\Phi}_t \mathbf{P}_t u = \int_0^t \mathbf{T}_{t-\xi} B u(\xi)\, d\xi \quad \text{and} \quad (\mathbf{\Psi}_\infty x_0)(t) = C\mathbf{T}_t x_0 \ .$$

B is called *bounded* if $B \in \mathcal{L}(U, X)$ (and *unbounded* otherwise), whereas C is called *bounded* if it can be extended continuously to X (and *unbounded* otherwise).

The *Lebesgue extension* of C was introduced in [45] and is defined by

$$C_L x_0 = \lim_{t \to 0} C \frac{1}{t} \int_0^t \mathbf{T}_\xi x_0 \, d\xi \,,$$

where $D(C_L)$ is equal to the set of all those $x_0 \in X$ for which the above limit exists. Clearly $X_1 \subset D(C_L) \subset X$, and for any $x_0 \in X$ we have that $\mathbf{T}_t x_0 \in D(C_L)$ for almost every $t \geq 0$. Furthermore,

$$(\mathbf{\Psi}_\infty x_0)(t) = C_L \mathbf{T}_t x_0 \quad \text{for a.e. } t \geq 0 \,.$$

Let Ω be a subset of $\mathbb{C}$. A function $\mathbf{H} : \Omega \to \mathcal{L}(U, Y)$ is called *well posed* if there exists $\alpha \in \mathbb{R}$ such that $\mathbb{C}_\alpha \subset \Omega$ and $\mathbf{H}$ is holomorphic and bounded on $\mathbb{C}_\alpha$. It can be shown (see Weiss [47]) that if $\alpha > \omega(\mathbf{T})$ and if $u \in L^2_\alpha(\mathbb{R}_+, U)$, then $\mathbf{F}_\infty u \in L^2_\alpha(\mathbb{R}_+, Y)$ and there exists a unique well-posed function $\mathbf{G} : \mathbb{C}_{\omega(\mathbf{T})} \to \mathcal{L}(U, Y)$ such that

$$\mathbf{G}(s)(\mathbb{L}u)(s) = [\mathbb{L}(\mathbf{F}_\infty u)](s) \quad \forall\, s \in \mathbb{C}_\alpha \,.$$

In particular, $\mathbf{G}$ is holomorphic on $\mathbb{C}_{\omega(\mathbf{T})}$ and bounded on $\mathbb{C}_\alpha$ for all $\alpha > \omega(\mathbf{T})$. The function $\mathbf{G}$ is called the *transfer function* of $\mathbf{\Sigma}$. Conversely, due to a result by Salamon [39], any well-posed function can be realized by an abstract linear system in the sense of Definition 2.1.

The following lemma will be needed in section 3. Certainly, it should be well known. However, since we could not find it in the literature, we include the proof.

LEMMA 2.2. *Suppose that* $\mathbf{\Sigma} = (\mathbf{T}, \mathbf{\Phi}, \mathbf{\Psi}, \mathbf{F})$ *is exponentially stable. For any* $x_0 \in X$ *and any* $u \in L^2(\mathbb{R}_+, U)$, *the functions* $x(\cdot)$ *and* $y(\cdot)$ *defined by* (2.1) *satisfy*

$$x \in L^2(\mathbb{R}_+, X) \,, \quad y \in L^2(\mathbb{R}_+, Y) \,.$$

Proof. Since $x(t) = \mathbf{T}_t x_0 + \int_0^t \mathbf{T}_{t-\xi} B u(\xi)\, d\xi$, it follows from the exponential stability of $\mathbf{T}$ that $x \in L^2(\mathbb{R}_+, X)$ if and only if the function $\bar{x} : t \mapsto \int_0^t \mathbf{T}_{t-\xi} B u(\xi)\, d\xi$ is in $L^2(\mathbb{R}_+, X)$. Let $H^2(\mathbb{C}_0, X)$ denote the usual Hardy space of holomorphic functions defined on $\mathbb{C}_0$ with values in X. Appealing to the Paley–Wiener theorem, it follows that $\bar{x} \in L^2(\mathbb{R}_+, X)$ if we can show that $\mathbb{L}\bar{x} \in H^2(\mathbb{C}_0, X)$. To this end set $\omega_0 := \omega(\mathbf{T})$ and recall from [48] that for any $\omega > \omega_0$ there exists $M_\omega > 0$ such that

$$\|(sI - A)^{-1} B\|_{\mathcal{L}(U,X)} \leq \frac{M_\omega}{\sqrt{\operatorname{Re} s - \omega}} \quad \forall\, s \in \mathbb{C}_\omega\,. \tag{2.3}$$

(In particular, $(sI - A)^{-1} B \in \mathcal{L}(U, X)$ for all $s \in \mathbb{C}_\omega$.) Moreover, it is routine to show that the function

$$\mathbb{C}_{\omega_0} \to \mathcal{L}(U, Y)\,, \quad s \mapsto (sI - A)^{-1} B$$

is holomorphic. Finally, the Laplace transform of $\bar{x}$ is given by

$$(\mathbb{L}\bar{x})(s) = (sI - A)^{-1} B (\mathbb{L}u)(s) \quad \forall\, s \in \mathbb{C}_{\omega_0}\,, \tag{2.4}$$

and by hypothesis, $\omega_0 < 0$ and $\mathbb{L}u \in H^2(\mathbb{C}_0, X)$. Therefore, combining (2.3) and (2.4) we obtain that $\mathbb{L}\bar{x} \in H^2(\mathbb{C}_0, X)$.

In order to prove that $y \in L^2(\mathbb{R}_+, Y)$, write y in the form

$$y = \mathbf{\Psi}_\infty x_0 + \mathbf{F}_\infty u.$$

Using the remarks preceding the lemma, it follows from the hypothesis that $\mathbf{F}_\infty u \in L^2(\mathbb{R}_+, Y)$. It remains to show that $\mathbf{\Psi}_\infty x_0 \in L^2(\mathbb{R}_+, Y)$. By the exponential stability of $\mathbf{T}$ it follows in a straightforward way from condition (iii) in Definition 2.1 that there exists a constant $\gamma > 0$ such that

$$\|\mathbf{\Psi}_\tau x_0\|_{L^2(\mathbb{R}_+, Y)} \leq \gamma \|x_0\| \quad \forall\, \tau \geq 0 \;\; \forall\, x_0 \in X\,.$$

Hence

$$\|\mathbf{P}_\tau \mathbf{\Psi}_\infty x_0\|_{L^2(\mathbb{R}_+, Y)} = \|\mathbf{\Psi}_\tau x_0\|_{L^2(\mathbb{R}_+, Y)} \leq \gamma \|x_0\| \quad \forall\, \tau \geq 0\,,\; \forall\, x_0 \in X\,,$$

which implies that $\mathbf{\Psi}_\infty x_0 \in L^2(\mathbb{R}_+, Y)$. □

$\mathbf{\Sigma}$ and its transfer function $\mathbf{G}$ are called *regular* if for any $u \in U$ the limit

$$\lim_{s \to \infty,\, s \in \mathbb{R}} \mathbf{G}(s) u = Du$$

exists. It follows from the principle of uniform boundedness that $D \in \mathcal{L}(U, Y)$. The operator D is called the *feedthrough operator* of $\mathbf{\Sigma}$. If $\mathbf{\Sigma}$ is regular, then for any $x_0 \in X$ and $u \in L^2_{loc}(\mathbb{R}_+, U)$, the functions $x(\cdot)$ and $y(\cdot)$, defined by (2.1), satisfy the equations

$$\dot{x}(t) = Ax(t) + Bu(t)\,, \tag{2.5a}$$

$$y(t) = C_L x(t) + Du(t) \tag{2.5b}$$

for a.e. $t \geq 0$ (in particular $x(t) \in D(C_L)$ for a.e. $t \geq 0$). The derivative on the left-hand side of (2.5a) has of course to be understood in X_{-1}. Moreover, as has been shown in [47], if $\mathbf{\Sigma}$ is regular, then $(sI - A)^{-1} BU \subset D(C_L)$ for all $s \in \varrho(A)$ and the transfer function $\mathbf{G}$ can be expressed in the following way:

$$\mathbf{G}(s) = C_L (sI - A)^{-1} B + D \quad \forall\, s \in \mathbb{C}_{\omega(\mathbf{T})}\,,$$

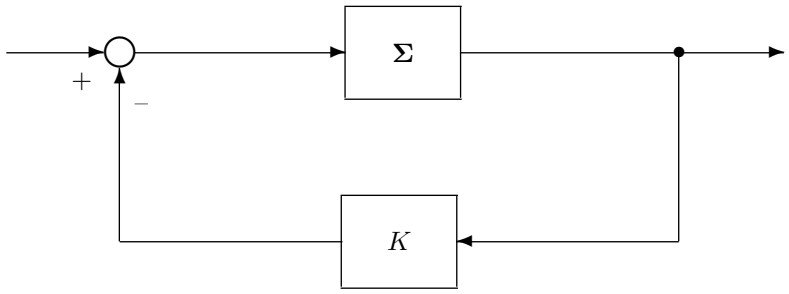

FIG. 2.1. *Static output feedback.*

which is familiar from finite-dimensional systems theory. The operators A, B, C, and D are called the *generating operators* of $\mathbf{\Sigma}$.

Finally, we review some of the results on static output feedback for abstract linear systems which have been recently obtained by Weiss [49]. Consider the feedback system shown in Figure 2.1.

An operator $K \in \mathcal{L}(Y,U)$ is called an *admissible feedback operator* for $\mathbf{\Sigma}$ if $I + K\mathbf{G}$ has a well-posed inverse, i.e., if there exists a well-posed transfer function $\mathbf{J}$ such that

$$\mathbf{J}(s)(I + K\mathbf{G}(s)) = (I + K\mathbf{G}(s))\mathbf{J}(s) = I \quad \forall\, s \in \mathbb{C}_\alpha$$

for some $\alpha \in \mathbb{R}$. It is easy to see that $I + K\mathbf{G}$ has a well-posed inverse if and only if $I + \mathbf{G}K$ has. If $\mathbf{\Sigma}$ is regular and if $K \in \mathcal{L}(Y,U)$ is an admissible feedback operator for $\mathbf{\Sigma}$, then $I + DK$ (and hence also $I + KD$) is left invertible. In particular, if U or Y is finite-dimensional, then $I + DK$ (and hence also $I + KD$) is invertible.

The next result shows that if K is an admissible feedback operator for $\mathbf{\Sigma}$, then there exists a unique abstract linear system $\mathbf{\Sigma}^K$ representing the feedback system shown in Figure 2.1.

THEOREM 2.3. *Let $\mathbf{\Sigma} = (\mathbf{T}, \mathbf{\Phi}, \mathbf{\Psi}, \mathbf{F})$ be an abstract linear system, let $\mathbf{G}$ denote its transfer function and let $K \in \mathcal{L}(Y,U)$ be an admissible feedback operator for $\mathbf{\Sigma}$. Then the following statements are true:*

(i) *There exists a unique abstract linear system $\mathbf{\Sigma}^K = (\mathbf{T}^K, \mathbf{\Phi}^K, \mathbf{\Psi}^K, \mathbf{F}^K)$ such that, when we denote*

$$\mathbf{\Sigma}_\tau = \begin{pmatrix} \mathbf{T}_\tau & \mathbf{\Phi}_\tau \\ \mathbf{\Psi}_\tau & \mathbf{F}_\tau \end{pmatrix}, \quad \mathbf{\Sigma}^K_\tau = \begin{pmatrix} \mathbf{T}^K_\tau & \mathbf{\Phi}^K_\tau \\ \mathbf{\Psi}^K_\tau & \mathbf{F}^K_\tau \end{pmatrix}$$

($\tau \geq 0$), we have

$$\mathbf{\Sigma}^K_\tau = \mathbf{\Sigma}_\tau - \mathbf{\Sigma}_\tau \begin{pmatrix} 0 & 0 \\ 0 & K \end{pmatrix} \mathbf{\Sigma}^K_\tau \quad \textit{and} \quad \mathbf{\Sigma}_\tau = \mathbf{\Sigma}^K_\tau + \mathbf{\Sigma}^K_\tau \begin{pmatrix} 0 & 0 \\ 0 & K \end{pmatrix} \mathbf{\Sigma}_\tau \quad \forall\, \tau \geq 0\,. \tag{2.6}$$

The transfer function $\mathbf{G}^K$ of $\mathbf{\Sigma}^K$ is given by $\mathbf{G}^K = \mathbf{G}(I + K\mathbf{G})^{-1}$. Moreover, $L \in \mathcal{L}(Y,U)$ is an admissible feedback operator for $\mathbf{\Sigma}^K$ if and only if $K+L$ is an admissible feedback operator for $\mathbf{\Sigma}$. If this is the case, then

$$(\mathbf{\Sigma}^K)^L = \mathbf{\Sigma}^{K+L}\,. \tag{2.7}$$

(ii) *Under the extra assumptions that* $\mathbf{\Sigma}$ *is regular and that* $I + DK$ *is invertible, it follows that* $\mathbf{\Sigma}^K$ *is regular, and the generating operators* A^K, B^K, C^K, *and* D^K *of* $\mathbf{\Sigma}^K$ *are given by*

$$A^K = A - BK(I + DK)^{-1}C_L\,,\ C^K = (I + DK)^{-1}C_L\,,\ B^K = B(I + KD)^{-1}\,,$$
$$\text{and}\quad D^K = (I + DK)^{-1}D\,,$$

where $D(A^K) = \{x \in D(C_L) \mid (A - BK(I + DK)^{-1}C_L)x \in X\}$.

For $x_0 \in X$ and $u \in L^2_{loc}(\mathbb{R}_+, U)$ define the functions $x(\cdot)$ and $y(\cdot)$ by (2.1). The second equation in (2.6) then implies for $t \geq 0$

$$x(t) = \mathbf{T}^K_t x_0 + \mathbf{\Phi}^K_t \mathbf{P}_t(Ky + u), \tag{2.8a}$$

$$\mathbf{P}_t y = \mathbf{\Psi}^K_t x_0 + \mathbf{F}^K_t \mathbf{P}_t(Ky + u)\,. \tag{2.8b}$$

Moreover, for $t \geq \tau \geq 0$ we have that

$$x(t) = \mathbf{T}^K_{t-\tau} x(\tau) + \mathbf{\Phi}^K_{t-\tau} \mathbf{L}_\tau \mathbf{P}_t(Ky + u), \tag{2.9a}$$

$$\mathbf{L}_\tau \mathbf{P}_t y = \mathbf{\Psi}^K_{t-\tau} x(\tau) + \mathbf{F}^K_{t-\tau} \mathbf{L}_\tau \mathbf{P}_t(Ky + u)\,. \tag{2.9b}$$

The above formulas (2.8) and (2.9) will turn out to be very useful in sections 4 and 5.

Finally, consider the nonlinear system given by

$$\dot\gamma(t) = \|v(t)\|^2\,, \quad k(0) = k_0 \in \mathbb{R}, \tag{2.10a}$$

$$w(t) = \mathcal{K}(\gamma(t))v(t)\,, \quad t \geq 0\,, \tag{2.10b}$$

where $v \in L^2_{loc}(\mathbb{R}_+, \mathbb{R}^m)$ is the input and w denotes the output. The function $\mathcal{K} : \mathbb{R} \to \mathbb{R}$ is assumed to be locally Lipschitz.

For sections 4 and 5 we need a well-posedness result for the feedback interconnection of $\mathbf{\Sigma}$ and (2.10). More precisely, consider the feedback system given by (2.1), (2.10), and the interconnection equations

$$v = y\,, \quad u = -w$$

(where, of course, we assume that $U = Y = \mathbb{R}^m$). The closed-loop equations for y and γ then take the following form:

$$y(t) = (\mathbf{\Psi}_\infty x_0)(t) - (\mathbf{F}_\infty \mathcal{K}(\gamma) y)(t)\,, \tag{2.11a}$$

$$\gamma(t) = \gamma_0 + \int_0^t \|y(\xi)\|^2\, d\xi\,. \tag{2.11b}$$

Let $\tau \in (0, \infty]$. A function $(y, \gamma) : [0, \tau) \to \mathbb{R}^m \times \mathbb{R}$ is called a *solution* of (2.11) on $[0, \tau)$ if

(i) $(y, \gamma) \in L^2([0, \tau'], \mathbb{R}^m) \times AC([0, \tau'], \mathbb{R})$ for all $\tau' \in [0, \tau)$, where $AC([0, \tau'], \mathbb{R})$ denotes the real-valued absolutely continuous functions defined on $[0, \tau']$.

(ii) (y, γ) satisfies (2.11) almost everywhere on $[0, \tau)$.

If (2.11) has a solution (y, γ) on $[0, \tau)$, then the corresponding state trajectory of $\mathbf{\Sigma}$ is given by

$$x(t) = \mathbf{T}_t x_0 - \mathbf{\Phi}_t(\mathbf{P}_t \mathcal{K}(\gamma) y) \quad \forall\, t \in [0, \tau)\,.$$

PROPOSITION 2.4. *Suppose that* $U = Y = \mathbb{R}^m$ *and that* $\mathbb{L}^{-1}\mathbf{G} \in L^1_{loc}(\mathbb{R}_+, \mathbb{R}^{m\times m})$. *Then for any* $(x_0, \gamma_0) \in X \times \mathbb{R}$ *there exists a maximal solution of* (2.11). *To be more*

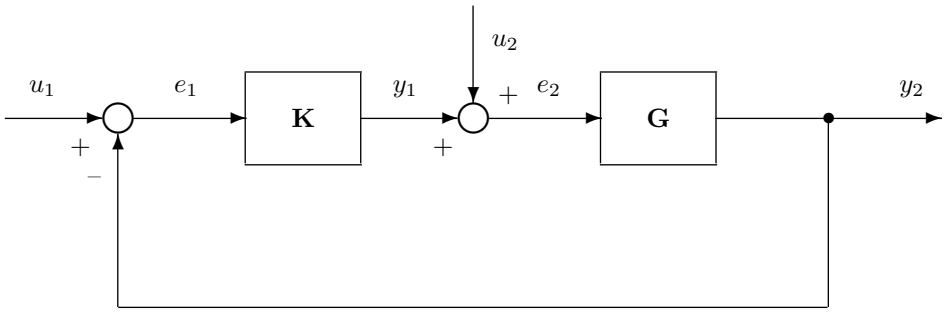

FIG. 3.1. *Closed-loop system* $\mathcal{F}(\mathbf{G},\mathbf{K})$.

precise, there exists $\tau_{max} \in (0,\infty]$ *such that* (2.11) *has a unique solution* (y_{max},γ_{max}) *on* $[0,\tau_{max})$*, and moreover*

$$\tau_{max} < \infty \quad \Longrightarrow \quad \int_0^{\tau_{max}} \|y_{max}(t)\|^2\, dt = \infty\ .$$

The proof of Proposition 2.4 is given in the appendix.

3. Nonadaptive low-gain control. For $\alpha \in \mathbb{R}$ let $\mathcal{M}_\alpha$ denote the field of all meromorphic functions defined on $\mathbb{C}_\alpha$. The algebra of all bounded holomorphic functions defined on $\mathbb{C}_\alpha$ will be denoted by H_α^∞. The symbol H_α^2 stands for the vector space of all holomorphic functions $f : \mathbb{C}_\alpha \to \mathbb{C}$ such that $\sup_{\xi>\alpha} \int_{-\infty}^{\infty} |f(\xi+\imath\omega)|^2\, d\omega < \infty$. Moreover, we define

$$\mathcal{M}_- := \bigcup_{\alpha<0} \mathcal{M}_\alpha\,, \quad H_-^\infty := \bigcup_{\alpha<0} H_\alpha^\infty\,, \quad H_-^2 := \bigcup_{\alpha<0} H_\alpha^2\,.$$

Let $\mathbf{G} \in \mathcal{M}_-^{m\times m}$ and $\mathbf{K} \in \mathcal{M}_-^{m\times m}$ be square transfer-function matrices, and consider the feedback system shown in Figure 3.1, which will be denoted by $\mathcal{F}(\mathbf{G},\mathbf{K})$. We shall call the feedback system $\mathcal{F}(\mathbf{G},\mathbf{K})$ input-output stable if every transfer function $u_i \mapsto y_j$ that occurs around the loop has all its entries in H_-^∞. More precisely, we make the following definition.

DEFINITION 3.1. *Let* $\mathbf{G} \in \mathcal{M}_-^{m\times m}$ *and* $\mathbf{K} \in \mathcal{M}_-^{m\times m}$*. The feedback system* $\mathcal{F}(\mathbf{G},\mathbf{K})$ *is called* input-output stable *if* $\det(I+\mathbf{G}(s)\mathbf{K}(s)) \not\equiv 0$ *and*

$$F(\mathbf{G},\mathbf{K}) := \begin{pmatrix} \mathbf{K}(I+\mathbf{G}\mathbf{K})^{-1} & -\mathbf{K}\mathbf{G}(I+\mathbf{K}\mathbf{G})^{-1} \\ \mathbf{G}\mathbf{K}(I+\mathbf{G}\mathbf{K})^{-1} & \mathbf{G}(I+\mathbf{K}\mathbf{G})^{-1} \end{pmatrix} \in H_-^{\infty\ 2m\times 2m}\ .$$

We say that $\mathbf{K}$ stabilizes $\mathbf{G}$ *if* $\mathcal{F}(\mathbf{G},\mathbf{K})$ *is input-output stable.*

Note that the above concept of input-output stability is stronger than L^2-stability, which is equivalent to $F(\mathbf{G},\mathbf{K}) \in H_0^{\infty\ 2m\times 2m}$. However, Definition 3.1 has the advantage that it guarantees the analyticity of the closed-loop transfer function on $\mathbb{C}_\alpha$ for some $\alpha < 0$, a property which will be needed in the following.

Remark 3.2. (i) It is trivial that $\mathbf{K}$ stabilizes $\mathbf{G}$ if and only if $\mathbf{G}$ stabilizes $\mathbf{K}$.

(ii) Let $\mathcal{Q}(H_-^\infty)$ denote the quotient field of H_-^∞, i.e., $\mathcal{Q}(H_-^\infty) = \{n/d \,|\, n,d \in H_-^\infty,\ d(s) \not\equiv 0\}$. If $\mathcal{F}(\mathbf{G},\mathbf{K})$ is input-output stable, then $\mathbf{G} \in \mathcal{Q}(H_-^\infty)^{m\times m}$ and $\mathbf{K} \in \mathcal{Q}(H_-^\infty)^{m\times m}$.

(iii) If $\mathbf{G} \in H_-^{\infty\ m\times m}$, then $\mathcal{F}(\mathbf{G},\mathbf{K})$ is input-output stable if and only if $\det(I+\mathbf{G}(s)\mathbf{K}(s)) \not\equiv 0$ and $\mathbf{K}(I+\mathbf{G}\mathbf{K})^{-1}$ is in $H_-^{\infty\ m\times m}$.

(iv) A *left coprime factorization* of $\mathbf{G}$ over H_-^∞ is a pair $(\mathbf{D},\mathbf{N}) \in {H_-^\infty}^{m\times m} \times {H_-^\infty}^{m\times m}$ such that $\det \mathbf{D} \not\equiv 0$, $\mathbf{G} = \mathbf{D}^{-1}\mathbf{N}$ and there exist $\mathbf{X}, \mathbf{Y} \in {H_-^\infty}^{m\times m}$ satisfying $\mathbf{DX}+\mathbf{NY} = I$. *Right coprime factorizations* over H_-^∞ are defined in an analogous way. It follows from Smith [40] that $\mathbf{G}$ and $\mathbf{K}$ admit left and right coprime factorizations over H_-^∞ if $\mathcal{F}(\mathbf{G},\mathbf{K})$ is input-output stable.

PROPOSITION 3.3. *Let* $\mathbf{G} \in \mathcal{M}_-^{m\times m}$ *and* $\mathbf{K} \in \mathcal{M}_-^{m\times m}$. *If* $\mathbf{K}$ *stabilizes* $\mathbf{G}$ *and if*

$$\lim_{\operatorname{Re} s\to\infty} \mathbf{K}(s) = 0\,,$$

then $\mathbf{G}$ *is well posed.*

Proof. By Remark 3.2 (ii) we have that $\mathbf{G},\mathbf{K} \in \mathcal{Q}(H_-^\infty)^{m\times m}$, and hence, by Remark 3.2 (iv), there exists a right coprime factorization $(\mathbf{N_G},\mathbf{D_G})$ of $\mathbf{G}$ over H_-^∞ and a left coprime factorization $(\mathbf{D_K},\mathbf{N_K})$ of $\mathbf{K}$ over H_-^∞. By a standard result in fractional representation theory (cf. Vidyasagar, Schneider, and Francis [42]) the input-output stability of the closed-loop system is equivalent to

$$\inf_{s\in\mathbb{C}_0^{cl}} |\det[\mathbf{N_K}(s)\mathbf{N_G}(s) + \mathbf{D_K}(s)\mathbf{D_G}(s)]| > 0\,. \tag{3.1}$$

Seeking a contradiction, suppose that $\mathbf{G}$ is not well posed. Then there exists a sequence $(s_n)_{n\in\mathbb{N}} \subset \mathbb{C}_0^{cl}$ with $\lim_{n\to\infty} \operatorname{Re} s_n = \infty$ and such that $\lim_{n\to\infty} \|\mathbf{G}(s_n)\| = \infty$. As a consequence

$$\lim_{n\to\infty} \det \mathbf{D_G}(s_n) = 0\,. \tag{3.2}$$

On the other hand $\lim_{n\to\infty} \mathbf{K}(s_n) = 0$, and hence

$$\lim_{n\to\infty} \mathbf{N_K}(s_n) = 0\,. \tag{3.3}$$

Combining (3.2) and (3.3) shows that

$$\lim_{n\to\infty} \det[\mathbf{N_K}(s_n)\mathbf{N_G}(s_n) + \mathbf{D_K}(s_n)\mathbf{D_G}(s_n)] = 0\,,$$

contradicting (3.1). □

Since in this paper we will be mainly concerned with controllers of the form $\mathbf{K}(s) = (1/s)\Gamma$, where $\Gamma \in \mathbb{R}^{m\times m}$, the following definition will turn out to be useful.

DEFINITION 3.4. *A transfer function matrix* $\mathbf{G} \in \mathcal{M}_-^{m\times m}$ *is called* integral stabilizable *if there exists* $\Gamma \in \mathbb{R}^{m\times m}$ *such that the controller* $\mathbf{K}(s) = (1/s)\Gamma$ *stabilizes* $\mathbf{G}$. *If the extra condition*

$$[\mathbf{GK}(I+\mathbf{GK})^{-1}](0) = I \tag{3.4}$$

is satisfied, then $\mathbf{G}$ *is called* integral controllable.

A controller of the form $(1/s)\Gamma$ is called an *integrator*. It is a trivial consequence of Proposition 3.3 that if a transfer-function matrix in $\mathcal{M}_-^{m\times m}$ is integral stabilizable, then necessarily it is well posed.

In the following let $\theta(\cdot)$ denote the Heaviside step function, i.e.,

$$\theta(t) = \begin{cases} 1 & \text{if} \quad t > 0, \\ 0 & \text{if} \quad t \le 0, \end{cases}$$

As usual, convolution will be denoted by $\star$. The next result shows that condition (3.4) is closely related to the asymptotic tracking of constant reference signals.

PROPOSITION 3.5. *Suppose that* $\mathbf{G} \in \mathcal{M}_-^{m\times m}$ *is integral stabilizable, and let* $\mathbf{K}(s) = (1/s)\Gamma$, *where* $\Gamma \in \mathbb{R}^{m\times m}$, *be a stabilizing integrator. Then*

$$\lim_{t\to\infty}[\mathbb{L}^{-1}(\mathbf{GK}(I+\mathbf{GK})^{-1}) \star \theta r](t) = r$$

for all $r \in \mathbb{R}^m$ *if and only if* (3.4) *holds.*

For the proof of the above proposition we need the following lemma, which is a special case of the main result in Mossaheb [27].

LEMMA 3.6. *Suppose that* h *is a holomorphic function defined on* $\mathbb{C}_\alpha$ *such that the function* $s \mapsto sh(s)$ *is in* H_α^∞. *Then there exists a measurable function* $f : \mathbb{R}_+ \to \mathbb{C}$ *with* $f(\cdot)\exp(-\beta\,\cdot) \in L^1(\mathbb{R}_+, \mathbb{C})$ *for all* $\beta > \alpha$ *and such that*

$$(\mathbb{L}f)(s) = h(s) \quad \forall\, s \in \mathbb{C}_\alpha\,.$$

Proof of Proposition 3.5. By assumption we have that

$$\mathbf{H} := (I+\mathbf{GK})^{-1}\mathbf{G} = \mathbf{G}(I+\mathbf{KG})^{-1} \in H_-^{\infty\,m\times m}\,,$$

and hence

$$s[\mathbf{GK}(I+\mathbf{GK})^{-1}](s) = s[(I+\mathbf{GK})^{-1}\mathbf{GK}](s) = \mathbf{H}(s)\Gamma \in H_-^{\infty\,m\times m}\,.$$

Thus, by Lemma 3.6

$$\mathbb{L}^{-1}[\mathbf{GK}(I+\mathbf{GK})^{-1}] \in L^1(\mathbb{R}_+, \mathbb{C}^{m\times m})\,.$$

Therefore

$$\begin{aligned}\lim_{t\to\infty}[\mathbb{L}^{-1}(\mathbf{GK}(I+\mathbf{GK})^{-1}) \star \theta r](t) &= \lim_{t\to\infty}\left(\int_0^t [\mathbb{L}^{-1}(\mathbf{GK}(I+\mathbf{GK})^{-1})](\tau)\,d\tau\right) r \\ &= [\mathbf{GK}(I+\mathbf{GK})^{-1}](0)r\,,\end{aligned}$$

which yields the claim. □

The next result gives a necessary condition for integral controllability. It shows that an integral controllable transfer function does not have any transmission zeros at 0.

PROPOSITION 3.7. *Suppose that* $\mathbf{G} \in \mathcal{M}_-^{m\times m}$ *is integral controllable. Then there exists a left coprime factorization* $(\mathbf{D}, \mathbf{N})$ *of* $\mathbf{G}$ *over* H_-^∞, *and the numerator* $\mathbf{N}$ *in any such factorization satisfies*

$$\det \mathbf{N}(0) \neq 0\,.$$

Proof. It follows from Remark 3.2 (iv) that there exists a left coprime factorization $(\mathbf{D}, \mathbf{N})$ of $\mathbf{G}$ over H_-^∞. Let $\Gamma \in \mathbb{R}^{m\times m}$ be such that $\mathbf{K}(s) = (1/s)\Gamma$ stabilizes $\mathbf{G}$ and (3.4) is satisfied. Define

$$\mathbf{H} := \mathbf{GK}(I+\mathbf{GK})^{-1}\,, \quad \Delta := \lim_{s\to 0}[\mathbf{K}(I+\mathbf{GK})^{-1}](s)\,.$$

Then $\mathbf{DH} = \mathbf{NK}(I+\mathbf{GK})^{-1}$. Moreover, letting $s \to 0$ and using (3.4) yield $\mathbf{D}(0) = \mathbf{N}(0)\Delta$. Since $\mathbf{D}$ and $\mathbf{N}$ are left coprime over H_-^∞, it follows that

$$\operatorname{rank} \mathbf{N}(0)(\Delta, I) = \operatorname{rank}[\mathbf{D}(0), \mathbf{N}(0)] = m\,.$$

Therefore $\operatorname{rank} \mathbf{N}(0) = m$, and hence $\det \mathbf{N}(0) \neq 0$. □

The following theorem is the main input-output result of this section.

THEOREM 3.8. *Suppose that* $\mathbf{G} \in H_-^{\infty\, m\times m}$ *and that* $\mathbf{G}(0)$ *is real. Then* $\mathbf{G}$ *is integral controllable if and only if*

$$\det \mathbf{G}(0) \neq 0\,. \tag{3.5}$$

If (3.5) *holds, then there exists* $\Gamma_0 \in \mathbb{R}^{m\times m}$ *such that*

$$\sigma(\mathbf{G}(0)\Gamma_0) \subset \mathbb{C}_0\,, \tag{3.6}$$

and for any $\Gamma_0 \in \mathbb{R}^{m\times m}$ *satisfying* (3.6)*, there exists* $k^* > 0$ *such that for all* $k \in (0, k^*)$

$$F(\mathbf{G}, \mathbf{K}_k) \in H_-^{\infty\, 2m\times 2m} \quad \textit{and} \quad [\mathbf{G}\mathbf{K}_k(I + \mathbf{G}\mathbf{K}_k)^{-1}](0) = I\,, \tag{3.7}$$

where $\mathbf{K}_k(s) := (1/s)k\Gamma_0$*. Moreover, setting* $\mathbf{E}_k(s) = (1/s)(I + \mathbf{G}\mathbf{K}_k)^{-1}(s)$*, we have that* $\mathbf{E}_k \in H_-^{2\ m\times m}$ *for all* $k \in (0, k^*)$*.*

The result shows in particular that there exist low-gain integral controllers which achieve stability and asymptotic tracking of constant reference signals. Since for constant reference signals $r\theta(t)$, the error signal $e(t)$ of the feedback system is given by $(\mathbb{L}e)(s) = \mathbf{E}_k(s)r$, it follows from the last statement of Theorem 3.8 via the Paley–Wiener theorem that $e \in L^2(\mathbb{R}_+, \mathbb{R}^m)$ for all $k \in (0, k^*)$. In order to apply Theorem 3.8, we have to know only that the plant is stable and that (3.5) holds. Estimates of G_0 of $\mathbf{G}(0)$ can be obtained from step response data. An obvious choice for the gain matrix Γ_0 is $\Gamma_0 = G_0^{-1}$. Once a Γ_0 satisfying (3.6) has been found, the solution of the tracking problem reduces to the tuning of the gain parameter k.

Proof of Theorem 3.8. The necessity of (3.5) for integral controllability follows from Proposition 3.7 and from the hypothesis that $\mathbf{G} \in H_-^{\infty\, m\times m}$. In order to prove sufficiency, define $\Gamma_0 := \mathbf{G}^{-1}(0)$. Then, trivially, (3.6) is satisfied. Moreover, as in Logemann and Owens [15, pp. 17, 18], it can be shown that there exists a number $k^* > 0$ such that for all $k \in (0, k^*)$ the controller $\mathbf{K}_k$ stabilizes $\mathbf{G}$, i.e.,

$$F(\mathbf{G}, \mathbf{K}_k) \in H_-^{\infty\, 2m\times 2m}\,.$$

Next observe that by the invertibility of $k\mathbf{G}(0)\Gamma_0$

$$\lim_{s\to 0}[\mathbf{G}\mathbf{K}_k(I + \mathbf{G}\mathbf{K}_k)^{-1}](s) = \lim_{s\to 0} \mathbf{G}(s)k\Gamma_0(sI + k\mathbf{G}(s)\Gamma_0)^{-1} = I\,,$$

which yields the second equation in (3.7). Finally, $\mathbf{E}_k = k^{-1}\Gamma_0^{-1}\mathbf{K}_k(I + \mathbf{G}\mathbf{K}_k)^{-1}$, and therefore $\mathbf{E}_k \in H_-^{\infty\, m\times m}$ for all $k \in (0, k^*)$. Since for all such k the transfer function matrix $(I + \mathbf{G}\mathbf{K}_k)^{-1}$ is in $H_-^{\infty\, m\times m}$ as well, we see that $\mathbf{E}_k \in H_-^{2\ m\times m}$ for all $k \in (0, k^*)$. □

For Hermitian matrices $M, N \in \mathbb{C}^{m\times m}$, in the following we write $M \prec N$ if $N - M$ is positive definite and $M \succ N$ if $N - M$ is negative definite. Similarly, we write $M \preceq N$ if $N - M$ is positive semidefinite and $M \succeq N$ if $N - M$ is negative semidefinite. Moreover, for a complex matrix M let M^H denote the conjugate transpose of M.

The next result will be an important tool in section 4, although it is interesting in its own right.

PROPOSITION 3.9. *Let* $\mathbf{G} \in H_-^{\infty\, m\times m}$ *and suppose that* $\det \mathbf{G}(0) \neq 0$*. Setting* $\tilde{\mathbf{G}}(s) := (1/s)\mathbf{G}(s)$ *and using the notation of Theorem* 2.3 *we write*

$$\tilde{\mathbf{G}}^k(s) = \tilde{\mathbf{G}}(s)(I + k\tilde{\mathbf{G}}(s))^{-1} = \frac{1}{s}\mathbf{G}(s)\left(I + \frac{k}{s}\mathbf{G}(s)\right)^{-1}\,,$$ [3]

[3] By slight abuse of notation we write $\tilde{\mathbf{G}}^k$ instead of $\tilde{\mathbf{G}}^{kI}$.

where $k \in \mathbb{R}$. Under these conditions there exists $k^* > 0$ such that for all $k \in (0, k^*)$

$$\|\tilde{\mathbf{G}}^k\|_\infty = \frac{1}{k} \tag{3.8}$$

if and only if $\mathbf{G}(0) \succ 0$. Moreover, the claim remains true if we replace k with $-k$ in (3.8) *and $\mathbf{G}(0) \succ 0$ by $\mathbf{G}(0) \prec 0$.*

As usual, the H^∞-norm in (3.8) is defined to be the supremum over $\mathbb{C}_0$ of $\sigma_{max}(\tilde{\mathbf{G}}^k(s))$, the largest singular value of $\tilde{\mathbf{G}}^k(s)$. For the single-input single-output case it follows that if $\mathbf{G}(0) \neq 0$ and if $\mathbf{G}(0) \in \mathbb{R}$, then there exists $k^* > 0$ such that $\|\tilde{\mathbf{G}}^k\|_\infty = 1/|k|$ for all $k \in \mathbb{R}$ satisfying $|k| \in (0, k^*)$ and $k\mathbf{G}(0) > 0$.

Proposition 3.9 is an immediate consequence of the following lemma.

LEMMA 3.10. *Let $\mathbf{G} \in H_-^{\infty\, m\times m}$. Using the notation of Proposition* 3.9*, the following statements hold:*

(i) *Suppose that $\det \mathbf{G}(0) \neq 0$ and $k \neq 0$. Then* (3.8) (*with k replaced by $|k|$*) *is true if and only if $I + k\tilde{\mathbf{G}}(s) + k\tilde{\mathbf{G}}^H(s) \succeq 0$ for all $s \in \mathbb{C}_0$.*

(ii) *There exists $k^* > 0$ such that $I + k\tilde{\mathbf{G}}(s) + k\tilde{\mathbf{G}}^H(s) \succeq 0$ for all $s \in \mathbb{C}_0$ and for all $k \in (0, k^*)$ if and only if $\mathbf{G}(0) \succeq 0$.*

Note that if $\mathbf{G}(s) \in \mathbb{R}^{\,m\times m}$ for all $s \in (0, \infty)$, then $I + k\tilde{\mathbf{G}}(s) + k\tilde{\mathbf{G}}^H(s) \succeq 0$ for all $s \in \mathbb{C}_0$ if and only if $(1/2)I + k\tilde{\mathbf{G}}(s)$ is positive real.

Proof of Lemma 3.10. (i) By assumption, $\mathbf{G}^{-1}(0)$ exists, and thus $\sigma_{max}(\tilde{\mathbf{G}}^k(0)) = 1/k$. Therefore (3.8) holds if and only if

$$\sigma_{max}(\tilde{\mathbf{G}}^k(s)) \leq \frac{1}{k} \quad \forall\, s \in \mathbb{C}_0\,,$$

or equivalently

$$(I + k\tilde{\mathbf{G}}(s))^{-1}\tilde{\mathbf{G}}(s)\tilde{\mathbf{G}}^H(s)(I + k\tilde{\mathbf{G}}^H(s))^{-1} \preceq \frac{1}{k^2} I \quad \forall\, s \in \mathbb{C}_0\,,$$

or equivalently

$$k^2\tilde{\mathbf{G}}(s)\tilde{\mathbf{G}}^H(s) \preceq (I + k\tilde{\mathbf{G}}(s))(I + k\tilde{\mathbf{G}}^H(s)) \quad \forall\, s \in \mathbb{C}_0\,,$$

which in turn is equivalent to the positive semidefiniteness of $I + k\tilde{\mathbf{G}}(s) + k\tilde{\mathbf{G}}^H(s)$ for all $s \in \mathbb{C}_0$.

(ii) Since $\mathbf{G}$ is holomorphic at 0, we can write

$$\mathbf{G}(s) = \mathbf{G}(0) + \sum_{i=1}^{\infty} G_i s^i\,, \tag{3.9}$$

where $G_i \in \mathbb{C}^{\,m\times m}$ and the power series in (3.9) converges in some disc Δ_ε centred at 0 and with radius $\varepsilon > 0$. Consequently,

$$I + k\tilde{\mathbf{G}}(s) + k\tilde{\mathbf{G}}^H(s) = I + \frac{k}{s}\mathbf{G}(0) + \frac{k}{\bar{s}}\mathbf{G}^H(0) + k\mathbf{H}(s) \quad \forall\, s \in \Delta_\varepsilon\,, \tag{3.10}$$

where

$$\mathbf{H}(s) := \sum_{i=1}^{\infty} G_i s^{i-1} + \sum_{i=1}^{\infty} G_i^H \bar{s}^{\,i-1}\,.$$

Moreover, since $\tilde{\mathbf{G}}(s)$ is bounded on $\mathbb{C}_0 \setminus \Delta_\varepsilon$, there exists $k_1 > 0$ such that

$$I + k\tilde{\mathbf{G}}(s) + k\tilde{\mathbf{G}}^H(s) \succeq 0 \quad \forall\, s \in \mathbb{C}_0 \setminus \Delta_\varepsilon\,,\ \forall\, k \in (0, k_1)\,. \tag{3.11}$$

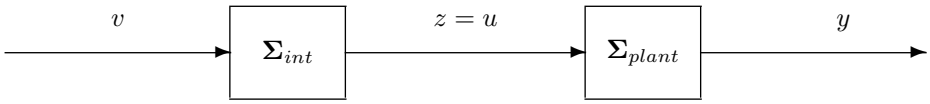

FIG. 3.2. *Cascade $\tilde{\mathbf{\Sigma}}$ with input v and output y.*

Suppose first that $\mathbf{G}(0) \succeq 0$. Then, using (3.10) and the boundedness of $\mathbf{H}(s)$ on Δ_ε, it follows that there exists $k_2 > 0$ such that

$$I + k\tilde{\mathbf{G}}(s) + k\tilde{\mathbf{G}}^H(s) \succeq 0 \quad \forall\, s \in \mathbb{C}_0 \cap \Delta_\varepsilon\,,\ \forall\, k \in (0, k_2)\,. \tag{3.12}$$

Setting $k^* := \min(k_1, k_2)$ we obtain from (3.11) and (3.12) that

$$I + k\tilde{\mathbf{G}}(s) + k\tilde{\mathbf{G}}^H(s) \succeq 0 \quad \forall\, s \in \mathbb{C}_0\,,\ \forall\, k \in (0, k^*)\,. \tag{3.13}$$

Conversely, suppose that (3.13) holds. Then, by (3.10), we obtain for any $\xi \in \mathbb{C}^m$ that

$$2\mathrm{Re}\left\langle \xi, \frac{k}{s}\mathbf{G}(0)\xi \right\rangle + \|\xi\|^2 + k\langle \xi, \mathbf{H}(s)\xi\rangle \geq 0 \quad \forall\, s \in \mathbb{C}_0 \cap \Delta_\varepsilon\,,\ \forall\, k \in (0, k^*)\,,$$

and hence it follows that for all $s \in \mathbb{C}_0 \cap \Delta_\varepsilon$ and all $k \in (0, k^*)$

$$\frac{2k}{|s|^2}\left(\mathrm{Re}\, s\, \mathrm{Re}\,\langle \xi, \mathbf{G}(0)\xi\rangle - \mathrm{Im}\, s\, \mathrm{Im}\,\langle \xi, \mathbf{G}(0)\xi\rangle\right) + \|\xi\|^2 + k\langle \xi, \mathbf{H}(s)\xi\rangle \geq 0\,.$$

Therefore, using the boundedness of $\mathbf{H}(s)$ on Δ_ε, we may conclude that for all $\xi \in \mathbb{C}^m$, $\mathrm{Im}\,\langle \xi, \mathbf{G}(0)\xi\rangle = 0$ and $\mathrm{Re}\,\langle \xi, \mathbf{G}(0)\xi\rangle \geq 0$, which in turn implies that $\mathbf{G}(0) \succeq 0$. □

In the following we will apply Theorem 3.8 to regular linear state space-systems. Since this additional assumption of regularity does not exclude any physically motivated well-posed system, the following results are as general as can be expected. For the rest of the section let $\mathbf{\Sigma}_{plant} = (\mathbf{T}, \mathbf{\Phi}, \mathbf{\Psi}, \mathbf{F})$ be an exponentially stable abstract linear regular system with generating operators (A, B, C, D), state space X, input space $U = \mathbb{R}^m$, output space $Y = \mathbb{R}^m$, and transfer function $\mathbf{G}$. Clearly, by exponential stability, $\mathbf{G} \in H_-^{\infty\, m\times m}$. If $u \in L^2_{loc}(\mathbb{R}_+, \mathbb{R}^m)$ denotes the input and $x_0 \in X$ denotes the initial state, then the state $x(\cdot)$ and the output $y(\cdot)$ are given by (2.1). Moreover, let $\mathbf{\Sigma}_{int}$ denote the integrator described by

$$z(t) = z_0 + \int_0^t v(\tau)\, d\tau\,, \quad z_0 \in \mathbb{R}^m\,,$$

where $v \in L^2_{loc}(\mathbb{R}_+, \mathbb{R}^m)$ is the integrator input.

We will consider the series connection $\tilde{\mathbf{\Sigma}}$ of $\mathbf{\Sigma}_{int}$ followed by $\mathbf{\Sigma}_{plant}$ with input v and output y (cf. Figure 3.2).

In order to show that $\tilde{\mathbf{\Sigma}}$ is again an abstract linear regular system, we introduce an extra external input $w \in L^2_{loc}(\mathbb{R}_+, \mathbb{R}^m)$ and consider the cascade interconnection $\hat{\mathbf{\Sigma}}$ with input (w, v) and output (y, z) obtained by setting $u = z + w$ (cf. Figure 3.3).

We claim that $\hat{\mathbf{\Sigma}}$ is an abstract linear regular system. To this end consider the parallel interconnection $\mathbf{\Sigma}_{par}$ of $\mathbf{\Sigma}_{int}$ and $\mathbf{\Sigma}_{plant}$ shown in Figure 3.4.

Clearly, $\mathbf{\Sigma}_{par}$ is an abstract linear regular system, and the matrix J given by

$$J = \begin{pmatrix} 0 & -I \\ 0 & 0 \end{pmatrix}$$

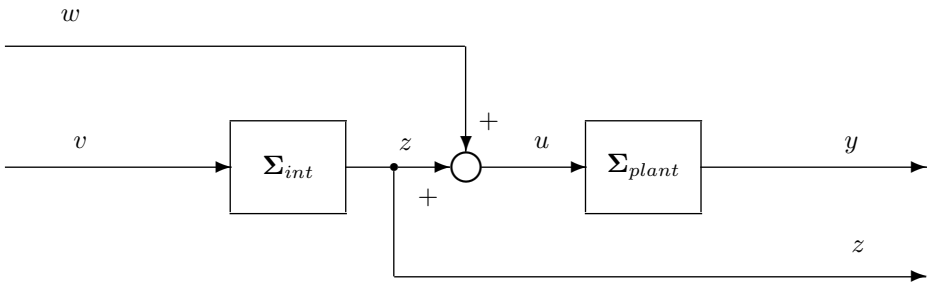

FIG. 3.3. *Cascade* $\hat{\mathbf{\Sigma}}$ *with input* (w, v) *and output* (y, z).

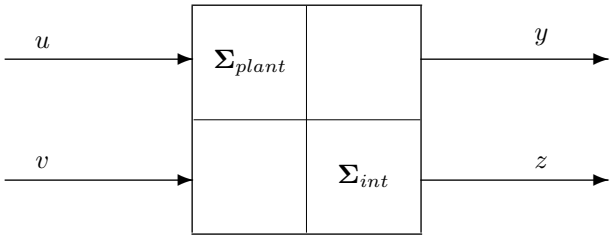

FIG. 3.4. *Parallel interconnection* $\mathbf{\Sigma}_{par}$.

is an admissible feedback operator for $\mathbf{\Sigma}_{par}$. Using the notation of section 2, we have that $\hat{\mathbf{\Sigma}} = (\mathbf{\Sigma}_{par})^J$, and hence it follows from Theorem 2.3 that $\hat{\mathbf{\Sigma}}$ is an abstract linear regular system. Writing $\hat{\mathbf{\Sigma}} = (\hat{\mathbf{T}}, \hat{\mathbf{\Phi}}, \hat{\mathbf{\Psi}}, \hat{\mathbf{F}})$, we see that $\tilde{\mathbf{\Sigma}} = (\tilde{\mathbf{T}}, \tilde{\mathbf{\Phi}}, \tilde{\mathbf{\Psi}}, \tilde{\mathbf{F}})$, where

$$\tilde{\mathbf{T}} = \hat{\mathbf{T}}\,, \quad \tilde{\mathbf{\Phi}} = \hat{\mathbf{\Phi}}\begin{pmatrix} 0 \\ I \end{pmatrix}, \quad \tilde{\mathbf{\Psi}} = (I, 0)\hat{\mathbf{\Psi}}\,, \quad \tilde{\mathbf{F}} = (I, 0)\hat{\mathbf{F}}\begin{pmatrix} 0 \\ I \end{pmatrix}.$$

Therefore $\tilde{\mathbf{\Sigma}}$ is an abstract linear regular system whose state, input, and output spaces are given by $X \times \mathbb{R}^m$, $U = \mathbb{R}^m$, and $Y = \mathbb{R}^m$, respectively. Denoting the generating operators of $\tilde{\mathbf{\Sigma}}$ by $\tilde{A}$, $\tilde{B}$, $\tilde{C}$, and $\tilde{D}$ it follows from Theorem 2.3 (ii) that

$$\tilde{A} = \begin{pmatrix} A & B \\ 0 & 0 \end{pmatrix}, \quad \tilde{B} = \begin{pmatrix} 0 \\ I \end{pmatrix}, \quad \tilde{C} = (C_L, D), \quad \tilde{D} = 0, \tag{3.14}$$

where the domain $D(\tilde{A})$ of $\tilde{A}$ is given by

$$D(\tilde{A}) = \{(x, u) \in D(C_L) \times \mathbb{R}^m \,|\, Ax + Bu \in X\}\,.$$

If B is bounded, then it follows easily that $D(\tilde{A}) = D(A) \times \mathbb{R}^m$. Note that any unboundedness of B is absorbed into the unboundedness of $\tilde{A}$ and hence the control operator $\tilde{B}$ of $\tilde{\mathbf{\Sigma}}$ is bounded. Trivially, the function $\tilde{\mathbf{G}}(s) := (1/s)\mathbf{G}(s)$ is the transfer function of $\tilde{\mathbf{\Sigma}}$.

LEMMA 3.11. *Every* $\Gamma \in \mathbb{R}^{m \times m}$ *is an admissible feedback operator for* $\tilde{\mathbf{\Sigma}}$ *and* (*using the notation of section* 2) *we have that for all* $\Gamma \in \mathbb{R}^{m \times m}$

$$D(\tilde{A}^\Gamma) = D(\tilde{A}) = \{(x, u) \in X \times \mathbb{R}^m \,|\, Ax + Bu \in X\}\,. \tag{3.15}$$

Proof. Since $\tilde{\mathbf{G}}(s) = (1/s)\mathbf{G}(s)$ and $\mathbf{G} \in H_\alpha^\infty$ for some $\alpha < 0$, it follows from section 2 that any $\Gamma \in \mathbb{R}^{m \times m}$ is an admissible feedback operator for $\tilde{\mathbf{\Sigma}}$.

We show first that the second equality in (3.15) holds. It is clear that

$$D(\tilde{A}) \subset \{(x,u) \in X \times \mathbb{R}^m \,|\, Ax + Bu \in X\} =: \mathcal{D}\,,$$

and it only remains to prove that $\mathcal{D} \subset D(\tilde{A})$. To this end define

$$W := D(A) + (\lambda I - A)^{-1} B\mathbb{R}^m\,,$$

where $\lambda \in \varrho(A)$. Since $D(A) \subset D(C_L)$ and, by regularity, $(\lambda I - A)^{-1}B\mathbb{R}^m \subset D(C_L)$, it follows that $W \subset D(C_L)$.

Let $(x,u) \in \mathcal{D}$. Then $\xi := (\lambda I - A)x - Bu \in X$, and hence

$$x = (\lambda I - A)^{-1}\xi + (\lambda I - A)^{-1}Bu \in W\,.$$

It follows that $x \in D(C_L)$ and therefore $(x,u) \in D(\tilde{A})$.

In order to show that the first equality in (3.15) is true, recall from section 2 that

$$\tilde{A}^\Gamma(x,u) = (\tilde{A} - \tilde{B}\Gamma\tilde{C}_L)(x,u)$$

for all $(x,u) \in D(\tilde{A}^\Gamma)$, where $D(\tilde{A}^\Gamma)$ is given by

$$D(\tilde{A}^\Gamma) = \{(x,u) \in D(\tilde{C}_L) \,|\, (\tilde{A} - \tilde{B}\Gamma\tilde{C}_L)(x,u) \in X \times \mathbb{R}^m\}\,.$$

Moreover, using (3.14), we see that for all $(x,u) \in D(\tilde{A}^\Gamma)$

$$\tilde{A}^\Gamma(x,u) = (Ax + Bu, -\Gamma\tilde{C}_L(x,u))\,.$$

This shows that

$$D(\tilde{A}^\Gamma) = \{(x,u) \in D(\tilde{C}_L) \,|\, Ax + Bu \in X\}\,. \tag{3.16}$$

Since $D(\tilde{C}_L) \subset X \times \mathbb{R}^m$, it follows from (3.16) that $D(\tilde{A}^\Gamma) \subset \mathcal{D} = D(\tilde{A})$.

To prove that $D(\tilde{A}) \subset D(\tilde{A}^\Gamma)$, let $(x,u) \in D(\tilde{A})$. Then $(x,u) \in D(\tilde{C}_L)$ and $Ax + Bu \in X$, and hence, by (3.16), $(x,u) \in D(\tilde{A}^\Gamma)$. □

In the following we endow $D(\tilde{A}^\Gamma)$ with its graph norm. The resulting complete space will be denoted by $\tilde{X}_1^\Gamma$.

PROPOSITION 3.12. *Let $\Gamma \in \mathbb{R}^{m\times m}$ and suppose that $\det\Gamma \neq 0$. If the integrator $\mathbf{K}(s) = (1/s)\Gamma$ stabilizes $\mathbf{G}$ (in the sense of Definition 3.1), then the following statements hold:*

(i) *The closed-loop semigroup $\tilde{\mathbf{T}}^\Gamma$ is exponentially stable.*

(ii) *$\tilde{C}^\Gamma = \tilde{C}$ and there exist $M > 0$ and $\omega > 0$ such that for all $(x_0,u_0) \in D(\tilde{A})$*

$$\|\tilde{C}\tilde{\mathbf{T}}_t^\Gamma(x_0,u_0)\| \le Me^{-\omega t}\|(x_0,u_0)\|_{\tilde{X}_1^\Gamma} \quad \forall\, t \ge 0\,.$$

If the observation operator C is bounded, then for any $(x_0,u_0) \in X \times \mathbb{R}^m$

$$\|\tilde{C}\tilde{\mathbf{T}}_t^\Gamma(x_0,u_0)\| \le Me^{-\omega t}\|(x_0,u_0)\|_{X\times\mathbb{R}^m} \quad \forall\, t \ge 0\,.$$

Proof. (i) The semigroup $\tilde{\mathbf{T}}^\Gamma$ describes the dynamics of the feedback system shown in Figure 3.5. Note that the state of $\mathbf{\Sigma}_{int}$ and the input of $\mathbf{\Sigma}_{plant}$ are identical. Therefore we denote both by the same symbol $u(\cdot)$.

The state $(x(t),u(t)) \in X \times \mathbb{R}^m$ at time $t \ge 0$ is given by

$$(x(t),u(t)) = \tilde{\mathbf{T}}_t^\Gamma(x_0,u_0)\,,$$

where $(x_0,u_0) := (x(0),u(0)) \in X \times \mathbb{R}^m$. Defining

$$y_0(t) := C_L\mathbf{T}_t x_0\,, \quad t \ge 0\,,$$

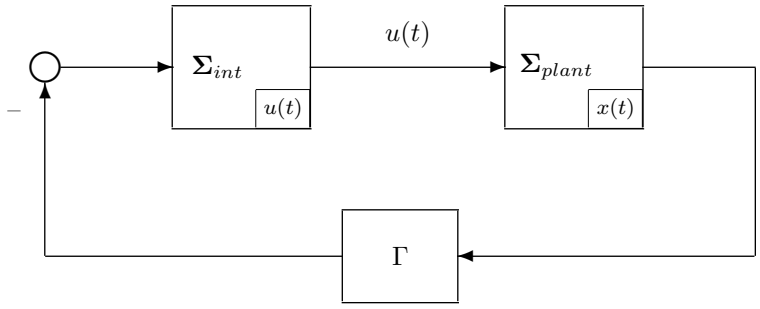

FIG. 3.5. *Internal dynamics of the closed loop.*

it follows from the exponential stability of $\mathbf{T}$ that $y_0 \in L^2(\mathbb{R}_+, \mathbb{R}^m)$. The Laplace transform of $u(\cdot)$ is then given by

$$(\mathbb{L}u)(s) = \frac{1}{s}u_0 - \mathbf{K}(s)[(\mathbb{L}y_0)(s) + \mathbf{G}(s)(\mathbb{L}u)(s)];$$

cf. Figure 3.5. It follows that

$$\mathbb{L}u = (I + \mathbf{KG})^{-1}\mathbf{K}\Gamma^{-1}u_0 - (I + \mathbf{KG})^{-1}\mathbf{K}\mathbb{L}y_0\,. \tag{3.17}$$

By assumption the closed-loop system is input-output stable, and so $(I + \mathbf{KG})^{-1}\mathbf{K}$, $(I + \mathbf{KG})^{-1} \in H_-^{\infty\ m\times m}$. Using the fact that $\mathbf{K}(s) = (1/s)\Gamma$ we see that

$$(I + \mathbf{KG})^{-1}\mathbf{K} \in H_-^{2\ m\times m}\,,$$

and thus, since $\mathbb{L}y_0 \in H_0^{2\ m}$, we obtain from (3.17) that $\mathbb{L}u \in H_0^{2\ m}$. Hence, by the Paley–Wiener theorem, $u \in L^2(\mathbb{R}_+, \mathbb{R}^m)$. Moreover, $\mathbf{\Sigma}_{plant}$ is exponentially stable and driven by u, and therefore by Lemma 2.2, $x \in L^2(\mathbb{R}_+, X)$. Thus, we see that for all $(x_0, u_0) \in X \times \mathbb{R}^m$

$$t \mapsto \tilde{\mathbf{T}}_t^{\Gamma}(x_0, u_0) \in L^2(\mathbb{R}_+, X \times \mathbb{R}^m)\,.$$

By a well-known result on the stability of C_0-semigroups (cf. Pazy [30, p. 116]) it follows that the semigroup $\tilde{\mathbf{T}}^{\Gamma}$ is exponentially stable.

(ii) Since $\tilde{D} = 0$, it follows from Theorem 2.3 (ii) that

$$\tilde{C}^{\Gamma}(x, u) = \tilde{C}_L(x, u) \qquad \forall\,(x, u) \in D(\tilde{A}^{\Gamma})\,.$$

An application of Lemma 3.11 shows that $\tilde{C}^{\Gamma} = \tilde{C}$.

Let $(x_0, u_0) \in D(\tilde{A})$. Then, by Lemma 3.11, $(x_0, u_0) \in \tilde{X}_1^{\Gamma}$. By part (i) the semigroup $\tilde{\mathbf{T}}^{\Gamma}$ is exponentially stable on $\tilde{X} = X \times \mathbb{R}^m$, and hence it is also exponentially stable on $\tilde{X}_1^{\Gamma}$. Since $\tilde{C}^{\Gamma} \in \mathcal{L}(\tilde{X}_1^{\Gamma}, \mathbb{R}^m)$, it follows from the above that $\tilde{C} \in \mathcal{L}(\tilde{X}_1^{\Gamma}, \mathbb{R}^m)$ as well. As a consequence there exist $M, \omega > 0$ such that

$$\|\tilde{C}\tilde{\mathbf{T}}_t^{\Gamma}(x_0, u_0)\| \le Me^{-\omega t}\|(x_0, u_0)\|_{\tilde{X}_1^{\Gamma}} \qquad \forall\, t \ge 0\,.$$

The last statement of part (ii) follows from the fact that the boundedness of the observation operator C implies the boundedness of the observation operator $\tilde{C}$. ∎

Remark 3.13. Part (i) of Proposition 3.12 shows that in our special situation (i.e., the plant is exponentially stable and the controller is an integrator) input-output stability implies exponential stability. Using a result by Rebarber [37], it can be

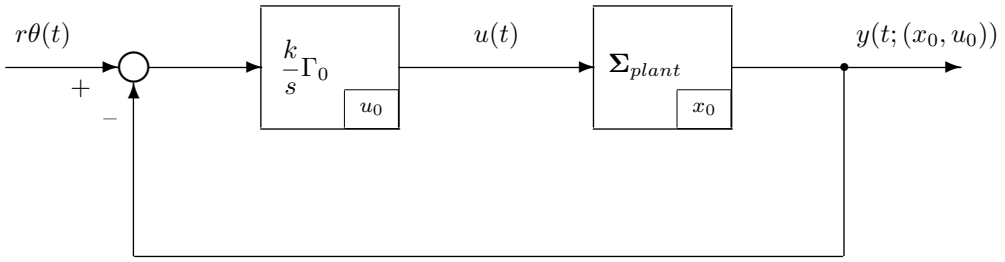

FIG. 3.6. *Low-gain control system.*

shown (Weiss [50]) that under suitable stabilizability and detectability assumptions the feedback interconnection of any two linear regular systems is exponentially stable if it is input-output stable. Since this result is not yet available in the literature (not even in form of a preprint), we have included a proof of Proposition 3.12 (i).

We are now in the position to prove the main result of this section, an internal version of Theorem 3.8 which applies to abstract linear regular state-space systems. Consider the feedback system in Figure 3.6, where $r \in \mathbb{R}^m$, $\Gamma_0 \in \mathbb{R}^{m\times m}$, $k > 0$, and $(x_0, u_0) \in X \times \mathbb{R}^m$. The output $y(\cdot\,;(x_0,u_0))$ can be written in the form

$$y(t;(x_0,u_0)) = \tilde{C}_L^{k\Gamma_0}\tilde{\mathbf{T}}_t^{k\Gamma_0}(x_0,u_0) + y(t;(0,0))\,. \tag{3.18}$$

Moreover, we define the corresponding error by

$$e(t;(x_0,u_0)) = r\theta(t) - y(t;(x_0,u_0))\,.$$

THEOREM 3.14. *Let $r \in \mathbb{R}^m$. Suppose that $\det \mathbf{G}(0) \neq 0$ and let $\Gamma_0 \in \mathbb{R}^{m\times m}$ be such that $\sigma(\mathbf{G}(0)\Gamma) \subset \mathbb{C}_0$. Then there exists $k^* > 0$ such that for any $k \in (0,k^*)$ the closed-loop semigroup $\tilde{\mathbf{T}}^{k\Gamma_0}$ is exponentially stable and $e(\cdot\,;(x_0,u_0)) \in L^2(\mathbb{R}_+,\mathbb{R}^m)$ for all $(x_0,u_0) \in X \times \mathbb{R}^m$. Furthermore,*

$$\lim_{t\to\infty} e(t;(x_0,u_0)) = 0 \quad \forall\,(x_0,u_0) \in D(\tilde{A})\,.$$

If the observation operator C is bounded, then the above equation holds for all $(x_0,u_0) \in X \times \mathbb{R}^m$.

Remark 3.15. If $(x_0,u_0) \notin D(\tilde{A})$, then in general $e(t) := e(t;(x_0,u_0))$ will not converge to 0 as $t \to \infty$. (In fact $e(\cdot)$ does not even make sense pointwise.) However, by Theorem 3.14, we still have that $e \in L^2(\mathbb{R}_+,\mathbb{R}^m)$, which implies that $e(t)$ *converges to* 0 *in measure* as $t \to \infty$ in the sense that for any $\varepsilon > 0$ and any $\delta > 0$ there exists $T = T(\varepsilon,\delta) > 0$ such that

$$\boldsymbol{\lambda}(\{t \in [\tau,\infty)\,|\,|e(t)| > \delta\} < \varepsilon \quad \forall\,\tau \geq T\,,$$

where $\boldsymbol{\lambda}$ denotes the Lebesgue measure.

Proof of Theorem 3.14. As in Theorem 3.8 we set $\mathbf{E}_k(s) = (1/s)(I+\mathbf{G}\mathbf{K}_k)^{-1}(s)$. By Theorem 3.8 there exists a $k^* > 0$ such that for all $k \in (0,k^*)$ the compensator $\mathbf{K}_k(s) = (1/s)k\Gamma_0$ stabilizes $\mathbf{G}$, and furthermore

$$\mathbf{E}_k \in H_-^{2\ m\times m} \quad \text{and} \quad [\mathbf{G}\mathbf{K}_k(I+\mathbf{G}\mathbf{K}_k)^{-1}](0) = I \qquad \forall\,k \in (0,k^*)\,. \tag{3.19}$$

In particular it follows from Proposition 3.12(i) that the semigroup $\tilde{\mathbf{T}}^{k\Gamma_0}$ is exponentially stable for all $k \in (0,k^*)$. Moreover, we have that

$$e(\cdot\,;(0,0)) = \mathbb{L}^{-1}(\mathbf{E}_k r)\,, \quad y(\cdot\,;(0,0)) = \mathbb{L}^{-1}[\mathbf{G}\mathbf{K}_k(I+\mathbf{G}\mathbf{K}_k)^{-1} \star \theta r]\,,$$

and therefore we obtain, using (3.19) and Proposition 3.5,

$$e(\cdot\,;(0,0)) \in L^2(\mathbb{R}_+,\mathbb{R}^m) \quad \text{and} \quad \lim_{t\to\infty} e(t;(0,0)) = 0\,, \tag{3.20}$$

provided that $k \in (0,k^*)$. Since the function

$$y_0(t;(x_0,u_0)) := \tilde{C}_L^{k\Gamma_0}\tilde{\mathbf{T}}_t^{k\Gamma_0}(x_0,u_0)$$

is the output of an exponentially stable regular system, it follows from Lemma 2.2 that $y_0(\cdot\,;(x_0,u_0)) \in L^2(\mathbb{R}_+,\mathbb{R}^m)$ for all $(x_0,u_0) \in X \times \mathbb{R}^m$ and all $k \in (0,k^*)$. Now, by (3.18),

$$e(t;(x_0,u_0)) = e(t;(0,0)) - y_0(t;(x_0,u_0))\,,$$

and thus, using (3.20), we obtain

$$e(\cdot\,;(x_0,u_0)) \in L^2(\mathbb{R}_+,\mathbb{R}^m) \quad \forall\,(x_0,u_0) \in X \times \mathbb{R}^m\,,$$

provided that $k \in (0,k^*)$. Finally, let $(x_0,u_0) \in D(\tilde{A})$. Then, by Proposition 3.12(ii), we may conclude that

$$\lim_{t\to\infty} y_0(t;(x_0,u_0)) = \lim_{t\to\infty} \tilde{C}_L^{k\Gamma_0}\tilde{\mathbf{T}}_t^{k\Gamma_0}(x_0,u_0) = \lim_{t\to\infty} \tilde{C}\tilde{\mathbf{T}}_t^{k\Gamma_0}(x_0,u_0) = 0\,. \tag{3.21}$$

Using (3.18), (3.20), and (3.21) we obtain that

$$\lim_{t\to\infty} e(t;(x_0,u_0)) = 0\,. \tag{3.22}$$

It follows from Proposition 3.12 (ii) that (3.22) holds for all $(x_0,u_0) \in X \times \mathbb{R}^m$ if the observation operator C is bounded. □

We close this section with a lemma which will be needed in section 4 in order to reformulate adaptive tracking problems as adaptive stabilization problems.

LEMMA 3.16. *For any $r \in \mathbb{R}^m$ there exists $(x_r,u_r) \in D(\tilde{A})$ such that*

$$\tilde{C}\tilde{\mathbf{T}}_t(x_r,u_r) = r \quad \forall\, t \geq 0\,.$$

Proof. For given $r \in \mathbb{R}^m$ define

$$x_r := -A^{-1}B\mathbf{G}^{-1}(0)r\,, \quad u_r := \mathbf{G}^{-1}(0)r\,.$$

Then $(x_r,u_r) \in X \times \mathbb{R}^m$, and moreover $Ax_r + Bu_r = 0$. It follows that $(x_r,u_r) \in \{(x,u) \in X \times \mathbb{R}^m \,|\, Ax + Bu \in X\} = D(\tilde{A})$, and by (3.14), $\tilde{A}(x_r,u_r) = 0$. We therefore easily conclude that $\tilde{\mathbf{T}}_t(x_r,u_r) = (x_r,u_r)$ for all $t \geq 0$. Finally, since $\mathbf{G}(0) = D - C_LA^{-1}B$, we see that for all $t \geq 0$

$$\tilde{C}\tilde{\mathbf{T}}_t(x_r,u_r) = C_Lx_r + Du_r = (\mathbf{G}(0) - D)\mathbf{G}^{-1}(0)r + D\mathbf{G}^{-1}(0)r = r\,. \qquad \square$$

4. Adaptive low-gain control of multivariable systems with sign-definite steady-state gain. In this section we consider the adaptive low-gain control of systems with *sign-definite* steady-state gains $\mathbf{G}(0)$, that is where either $\mathbf{G}(0) \succ 0$ or $\mathbf{G}(0) \prec 0$. This situation arises most naturally in the single-input single-output case where we need to assume only that the steady-state gain is nonzero.[4] In the multivariable case the situation of significance is when the steady-state gain is positive definite (see Propositions 4.4 and 4.6).

[4] Of course, we also need that $\mathbf{G}(0)$ is real. This will always be the case if $\mathbf{G}$ is the transfer function of a regular system, which is real by definition.

Consider the control law given by

$$\dot{u}(t) = \mathcal{K}(\gamma(t))e(t)\,, \quad u(0) = u_0\,, \tag{4.1a}$$

$$\dot{\gamma}(t) = \|e(t)\|^2\,, \quad \gamma(0) = \gamma_0 > a \geq -\infty\,, \tag{4.1b}$$

where $\mathcal{K} : (a, \infty) \to \mathbb{R}$ is locally Lipschitz. In the following $\mathcal{K}$ will be called a *tuning function*. Choosing $a = 0$ and

$$\mathcal{K}(\gamma) = \sin(\gamma^q)/\gamma^p\,, \quad 0 < q < p < 1 - q, \tag{4.2}$$

Cook [1] has shown that (4.1) is a universal adaptive, low-gain tracking controller for the class of single-input single-output, exponentially stable, finite-dimensional, linear systems with transfer function $\mathbf{G}$, input function $u(\cdot)$, output function $y(\cdot)$, and constant reference signal $r\theta(t), r \in \mathbb{R}$, in the sense that (i) $e(t) = (r - y(t)) \to 0$ as $t \to \infty$ and (ii) state and input functions remain bounded, independently of initial data, provided that $\mathbf{G}(0) \neq 0$. It is also shown in [1] that if $\mathbf{G}(0) > 0$, then $\mathcal{K}$ in (4.2) can be replaced by $\mathcal{K}(\gamma) = \gamma^{-p}$, $0 < p < 1$. The main tool in [1] is the fact that the return difference function is positive real for all k small enough and of the correct sign. It is clear, using Lemma 3.10, that these results extend to the multivariable case provided that $\mathbf{G}(0)$ is sign-definite.

In this section we prove that with different, suitably chosen tuning functions $\mathcal{K}$, these results extend to the case when the system is infinite-dimensional, regular, and exponentially stable. However, first we give alternative proofs of the finite-dimensional results in [1].

The finite-dimensional case. Our approach is based on Proposition 3.9, i.e., the fact that the H^∞-norm of the closed-loop transfer function $\tilde{\mathbf{G}}^k$ equals $1/|k|$ for all small enough k of the correct sign, and on the connection between this result and the existence of solutions to certain algebraic Riccati equations which arise in the characterization of the complex stability radius given in Hinrichsen and Pritchard [6]. We note that whilst neither this approach based on the algebraic Riccati equation nor the approach based on positive realness of the return difference equation and associated Lur'e equations extends to general regular systems, Proposition 3.9 will remain a crucial tool in the infinite-dimensional case.

LEMMA 4.1. *There exists $k^* > 0$ such that for any k with $|k| < k^*$ and $k\mathbf{G}(0) \succ 0$ the Riccati equation*

$$(\tilde{A} - k\tilde{B}\tilde{C})^T Z + Z(\tilde{A} - k\tilde{B}\tilde{C}) - k^2\tilde{C}^T\tilde{C} - Z\tilde{B}\tilde{B}^T Z = 0, \tag{4.3}$$

where $\tilde{A}, \tilde{B}$, and $\tilde{C}$ are given by (3.14)*, has a unique solution $\tilde{P}_k = \tilde{P}_k^T \preceq 0$.*

Proof. An application of Theorem 3.8 and Proposition 3.9 shows the existence of a constant $k^* > 0$ such that for any k with $|k| < k^*$ and $k\mathbf{G}(0) \succ 0$ the matrix $\tilde{A} - k\tilde{B}\tilde{C}$ is exponentially stable and $\|\tilde{\mathbf{G}}^k\|_\infty = 1/|k|$. Therefore the existence of a unique $\tilde{P}_k = \tilde{P}_k^T \preceq 0$ satisfying (4.3) is guaranteed by Hinrichsen and Pritchard [6, pp. 107–109]. □

The above lemma can now be used to give an alternative proof of the main result in [1].

THEOREM 4.2. *Let*

$$\dot{x}(t) = Ax(t) + Bu(t)\,, \quad x(0) = x_0 \in \mathbb{R}^n\,, \tag{4.4a}$$

$$y(t) = Cx(t) + Du(t) \tag{4.4b}$$

be any finite-dimensional, m-input m-output, exponentially stable system with sign-definite steady-state gain $\mathbf{G}(0)$. *Moreover, let* $\mathcal{K} : (a, \infty) \to \mathbb{R}$, *where* $a \geq -\infty$, *be locally Lipschitz and bounded with* $\mathcal{K} \in L^2(b, \infty; \mathbb{R})$ *for some* $b > a$ *and such that*

$$\liminf_{\gamma\to\infty} \int_b^\gamma \mathcal{K}(\xi)\, d\xi = -\infty\,, \quad \limsup_{\gamma\to\infty} \int_b^\gamma \mathcal{K}(\xi)\, d\xi = +\infty\,. \tag{4.5}$$

If $r\theta(t)$, $r \in \mathbb{R}^m$, *is any constant reference signal and* $u(t)$ *is defined by* (4.1), *with* $e(t) = r - y(t)$, *then for each* $\gamma_0 > a$, $x_0 \in \mathbb{R}^n$, *and* $u_0 \in \mathbb{R}^m$ *the following statements hold:*

(i) $\lim_{t\to\infty} \gamma(t) = \gamma_\infty < \infty$;
(ii) $\|x(t)\|$ *and* $\|u(t)\|$ *remain bounded as* $t \to \infty$;
(iii) $\lim_{t\to\infty} y(t) = r$.

Proof. The first step is to realize the reference signal $r\theta$ as an unforced motion of the series connection of the integrator $1/s$ followed by (4.4). By Lemma 3.16, applied in this simple finite-dimensional context, there exists $(x_r, u_r) \in \mathbb{R}^n \times \mathbb{R}^m$ such that $r = \tilde{C}e^{\tilde{A}t}(x_r, u_r)$ for all $t \geq 0$. It follows that

$$e(t) = r - y(t) = \tilde{C}\tilde{x}(t)\,, \tag{4.6}$$

where $\tilde{x}(t)$ is given by

$$\tilde{x}(t) = e^{\tilde{A}t}(x_r, u_r) - (x(t), u(t))\,. \tag{4.7}$$

Clearly, $\tilde{x}(\cdot)$ satisfies

$$\dot{\tilde{x}}(t) = \tilde{A}\tilde{x}(t) - \mathcal{K}(\gamma(t))\tilde{B}\tilde{C}\tilde{x}(t) \tag{4.8}$$

$$= (\tilde{A} - k\tilde{B}\tilde{C})\tilde{x}(t) - (\mathcal{K}(\gamma(t) - k)\tilde{B}e(t)\,, \tag{4.9}$$

where $k \in \mathbb{R}$ is arbitrary. Now the right-hand sides of (4.1b) and (4.8) are locally Lipschitz in $\tilde{x}$ and γ so that $\tilde{x}(t)$ and $\gamma(t)$ are uniquely determined on a maximal interval of existence—say, $[0, \tau)$. We now invoke Lemma 4.1 and define

$$V(t) = -\langle \tilde{x}(t), \tilde{P}_k\tilde{x}(t)\rangle,$$

where $\tilde{P}_k = \tilde{P}_k^T \preceq 0$ is the unique solution of (4.3), with $|k|$ small enough and $k\mathbf{G}(0) \succ 0$. Differentiating V along solutions of (4.1b) and (4.8) gives

$$\begin{aligned}
\dot{V} &= -k^2\|\tilde{C}\tilde{x}\|^2 - \|\tilde{B}^T\tilde{P}_k\tilde{x}\|^2 - 2(\mathcal{K}(\gamma) - k)\langle\tilde{C}\tilde{x}, \tilde{B}^T\tilde{P}_k\tilde{x}\rangle \\
&= -(k^2 - (\mathcal{K}(\gamma) - k)^2)\|\tilde{C}\tilde{x}\|^2 - \|(\mathcal{K}(\gamma) - k)\tilde{C}\tilde{x} + \tilde{B}^T\tilde{P}_k\tilde{x}\|^2 \\
&\leq \mathcal{K}(\gamma)(\mathcal{K}(\gamma) - 2k)\|\tilde{C}\tilde{x}\|^2\,.
\end{aligned}$$

Integrating this inequality from t_0 to t, where $0 \leq t_0 < t < \tau$, and using (4.1b) and (4.6) yield

$$-\infty < -V(t_0) \leq V(t) - V(t_0) \leq \int_{\gamma(t_0)}^{\gamma(t)} \mathcal{K}(\xi)(\mathcal{K}(\xi) - 2k)\, d\xi\,. \tag{4.10}$$

Seeking a contradiction, assume that $\lim_{t\to\tau} \gamma(t) = \infty$. Then, using (4.5) and exploiting the assumption that $\mathcal{K} \in L^2(b, \infty; \mathbb{R})$ we obtain

$$\lim_{n\to\infty} \int_{\gamma(t_0)}^{\gamma(t_n)} \mathcal{K}(\xi)(\mathcal{K}(\xi) - 2k)\, d\xi = -\infty$$

for some sequence $(t_n)_{n\in\mathbb{N}}$ with $\gamma(t_0) = b$ and $\lim_{n\to\infty} t_n = \tau$. Since this contradicts (4.10), it follows that $\gamma(t)$ is bounded on $[0,\tau)$ and consequently $\tau = \infty$, which establishes (i).

In order to prove statements (ii) and (iii), choose k in (4.9) such that $\tilde{A} - k\tilde{B}\tilde{C}$ is exponentially stable (this is possible by Theorem 3.8). Trivially, by (i), $e \in L^2(\mathbb{R}_+, \mathbb{R}^m)$, and so it follows from the boundedness of $\mathcal{K}$ that the forcing term on the right-hand side of (4.9) is in $L^2(\mathbb{R}_+, \mathbb{R}^m)$. Therefore $\tilde{x}(t)$ is the state of an exponentially stable system driven by an L^2-input, and consequently $\lim_{t\to\infty} \tilde{x}(t) = 0$. Statements (ii) and (iii) follow now from (4.7) and (4.6), respectively. □

Remark 4.3. Whilst the property of symmetry for a general $m \times m$ matrix is non-generic in that symmetry is destroyed by arbitrarily small perturbations, symmetry of $\mathbf{G}(0)$ is a direct consequence of, for example,

$$A = A^T\,, \quad B = C^T, \quad \text{and} \quad D = D^T\,.$$

If additionally, $D \succeq 0$, then positive definiteness of $\mathbf{G}(0)$ follows, since A is exponentially stable and $\mathbf{G}(0)$ is invertible.

It is not difficult to show that the function given in (4.2) satisfies the conditions imposed on $\mathcal{K}$ in Theorem 4.2. Notice that in general these conditions do not imply that $\lim_{\gamma\to\infty} \mathcal{K}(\gamma) = 0$.

PROPOSITION 4.4. *Suppose* $\mathbf{G}(0) \succ 0$. *With the tuning function* $\mathcal{K}(\gamma) = \gamma^{-p}$, $0 < p < 1$, *and* $\gamma_0 > 0$ *statements* (i)–(iii) *of Theorem* 4.2 *hold.*

Proof. The proof is the same as that of Theorem 4.2 up to (4.10). By the special choice of $\mathcal{K}$, (4.10) implies that $\gamma(\cdot)$ is bounded. The remainder of the proof is the same as that of Theorem 4.2. □

In Proposition 4.4 we may replace γ^{-p} by any function $\mathcal{K}$ which satisfies

$$\int_{\gamma_0}^{\infty} \mathcal{K}(\xi)(\mathcal{K}(\xi) - 2k)d\xi = -\infty$$

for some stabilizing gain $k > 0$.

The infinite-dimensional case. For the rest of this paper we will let $\mathbf{\Sigma}_{plant} = (\mathbf{T}, \mathbf{\Phi}, \mathbf{\Psi}, \mathbf{F})$ be an exponentially stable regular system with transfer function $\mathbf{G}$. Let A, B, C, and D denote the generating operators of $\mathbf{\Sigma}_{plant}$. As in section 3 we denote the series connection of the integrator $1/s$ followed by $\mathbf{\Sigma}_{plant}$ by $\tilde{\mathbf{\Sigma}} = (\tilde{\mathbf{T}}, \tilde{\mathbf{\Phi}}, \tilde{\mathbf{\Psi}}, \tilde{\mathbf{F}})$. It was shown in section 3 that the system $\tilde{\mathbf{\Sigma}}$ is regular. Let $\tilde{A}$, $\tilde{B}$, and $\tilde{C}$ denote the corresponding generating operators (trivially, $\tilde{D} = 0$), and let $\tilde{\mathbf{G}}(s) = (1/s)\mathbf{G}(s)$ denote the transfer function of $\tilde{\mathbf{\Sigma}}$.

We were not able to extend the proofs of Theorem 4.2 and Proposition 4.4 to the infinite-dimensional setting outlined in section 2. The problem is caused by the fact that Lemma 4.1 does not hold in the infinite-dimensional case, unless very strong and unnatural controllability assumptions are imposed. As already mentioned in the introduction, the approach in Cook [1] does not carry over to infinite-dimensional systems either. Nevertheless, it will turn out that in the infinite-dimensional situation we can still use tuning functions $\mathcal{K}$ satisfying $\mathcal{K}(\gamma) \to 0$ as $\gamma \to \infty$.

THEOREM 4.5. *Let* $\mathbf{\Sigma}_{plant}$ *be a* m*-input* m*-output exponentially stable regular system given by* (2.1). *Suppose that the transfer function* $\mathbf{G}$ *of* $\mathbf{\Sigma}_{plant}$ *is such that* $\mathbf{G}(0)$ *is sign definite. Let* $r\,\theta(t)$, $r \in \mathbb{R}^m$, *be an arbitrary constant vector-valued reference signal, and consider the control law*

$$u(t) = u_0 + \int_0^t \log^{-p}\gamma(\xi)\cos(\log^q\gamma(\xi))e(\xi)\,d\xi\,, \tag{4.11}$$

$$\dot{\gamma}(t) = \|e(t)\|^2\,, \quad \gamma(0) = \gamma_0\,, \tag{4.12}$$

where $e(t) = r - y(t)$ *and* $p \geq 0$, $q > 0$, *and* $q + 2p < 1$. *Then for all* $(x_0, u_0) \in X \times \mathbb{R}^m$ *and* $\gamma_0 > 1$, *where* X *denotes the state space of* $\mathbf{\Sigma}_{plant}$, *the following statements hold true:*

(i) $\lim_{t\to\infty} \gamma(t) = \gamma_\infty < \infty$;
(ii) $\|x(t)\|$ *and* $\|u(t)\|$ *remain bounded as* $t \to \infty$;
(iii) $e(\cdot) \in L^2(\mathbb{R}_+, \mathbb{R}^m)$.

Moreover, if $(x_0, u_0) \in D(\tilde{A})$, *then*

$$\lim_{t\to\infty} y(t) = r\,. \tag{4.13}$$

If the observation operator C *of* $\mathbf{\Sigma}_{plant}$ *is bounded, then* (4.13) *is true for all* $(x_0, u_0) \in X \times \mathbb{R}^m$.

Proof. We assume throughout the proof that $p > 0$. The case $p = 0$ can be proven using the techniques in the proof of Theorem 5.1. The first step is to convert the tracking problem ($r \neq 0$) into a stabilization problem ($r = 0$). By Lemma 3.16 there exists $(x_r, u_r) \in D(\tilde{A})$ so that $r = \tilde{C}\tilde{\mathbf{T}}_t(x_r, u_r)$ for all $t \geq 0$. Therefore, setting $\mathcal{K}(\gamma) = \log^{-p}\gamma \cos(\log^q \gamma)$ and using (4.11), it follows that

$$e = r\theta - y = \tilde{\mathbf{\Psi}}_\infty(x_r - x_0, u_r - u_0) - \tilde{\mathbf{F}}_\infty(\mathcal{K}(\gamma)e)\,. \tag{4.14}$$

The nonlinear closed-loop system given by (4.14) and (4.12) is in a form so that Proposition 2.4 is applicable. Let $[0, \tau)$ be the maximal interval of existence for solutions (e, γ) of (4.14) and (4.12) as guaranteed by Proposition 2.4. We know that $\tau < \infty$ only if $\lim_{t\to\tau} \gamma(t) = \infty$. We will prove that $\gamma(t)$ is bounded on $[0, \tau)$.

Let $(\rho_i)_{i\in\mathbb{N}}$, with $\rho_0 \geq \gamma_0$, be a strictly increasing sequence converging to ∞ and satisfying

$$\operatorname{sign}(\mathbf{G}(0)) \cos(\log^q \rho_{2i}) = 1 \quad \text{and} \quad \mathcal{K}(\rho_{2i+1}) = \mathcal{K}(\rho_{2i})/2\,, \quad i = 0, 1, 2, \ldots\,,$$

where $\operatorname{sign}(\mathbf{G}(0)) = \pm 1$, depending on whether $\mathbf{G}(0)$ is positive or negative definite. Choosing ρ_0 sufficiently large, it follows from Theorem 3.8 that the numbers

$$k_i := \mathcal{K}(\rho_{2i})$$

are stabilizing gains for $\tilde{\mathbf{G}}(s) = (1/s)\mathbf{G}(s)$; i.e., the integrators k_i/s stabilize $\mathbf{G}$ in the sense of Definition 3.1. Note that $(\rho_i)_{i\in\mathbb{N}}$ can be chosen so that

$$|\mathcal{K}(\gamma)| \in (|k_i|/2, |k_i|) \quad \text{and} \quad k_i\mathcal{K}(\gamma) > 0 \qquad \forall\, \gamma \in (\rho_{2i}, \rho_{2i+1})$$

and that $|k_i| \searrow 0$ as $i \to \infty$. Moreover, by applying Proposition 3.9 we can always choose ρ_0 sufficiently large so that

$$\|\tilde{\mathbf{G}}^{k_i}\|_\infty = \frac{1}{|k_i|} \tag{4.15}$$

for all i.

Seeking a contradiction, suppose that $\gamma(t)$ is unbounded on $[0, \tau)$. Then we can find a sequence of times $t_0 < t_1 < \cdots < \tau$ with

$$\gamma(t_i) = \rho_i.$$

We now use these observations combined with estimates we obtain from contraction-mapping–type arguments. Using (2.9b) on each interval $[t_{2i}, t_{2i+1}]$ we can write the error $e(\cdot)$ as

$$\mathbf{L}_{t_{2i}}\mathbf{P}_{t_{2i+1}}e = \tilde{\mathbf{\Psi}}^{k_i}_{t_{2i+1}-t_{2i}}(\tilde{x}(t_{2i})) - \tilde{\mathbf{F}}^{k_i}_{t_{2i+1}-t_{2i}}(\mathbf{L}_{t_{2i}}\mathbf{P}_{t_{2i+1}}(\mathcal{K}(\gamma) - k_i)e)\,, \tag{4.16}$$

[5]

[5] By slight abuse of notation we write $\tilde{\mathbf{\Psi}}^{k_i}_{t_{2i+1}-t_{2i}}$ instead of $\tilde{\mathbf{\Psi}}^{k_i I}_{t_{2i+1}-t_{2i}}$, etc.

where

$$\tilde{x}(t) = \tilde{\mathbf{T}}_t(x_r - x_0, u_r - u_0) - \tilde{\mathbf{\Phi}}_t(\mathbf{P}_t\mathcal{K}(\gamma)e)\,.$$

By using (2.8a) we can express $\tilde{x}(t)$ as

$$\tilde{x}(t) = \tilde{\mathbf{T}}^{k_0}_t(x_r - x_0, u_r - u_0) - \tilde{\mathbf{\Phi}}^{k_0}_t(\mathbf{P}_t(\mathcal{K}(\gamma) - k_0)e)\,. \tag{4.17}$$

Using (2.7) and (2.8b), with $u = 0$ and $K = k_0 - k_i$, we obtain

$$\tilde{\mathbf{\Psi}}^{k_i}_t z = \tilde{\mathbf{\Psi}}^{k_0}_t z - \tilde{\mathbf{F}}^{k_0}_t((k_i - k_0)\tilde{\mathbf{\Psi}}^{k_i}_t z) \quad \forall\, t \geq 0\,,\ \forall\, z \in X \times \mathbb{R}^m\,. \tag{4.18}$$

Now for all $t \in [t_{2i}, t_{2i+1}]$ we have

$$|\mathcal{K}(\gamma(t)) - k_i| \leq \frac{|k_i|}{2}.$$

Moreover, $\|\tilde{\mathbf{F}}^{k_i}_\infty\| = \|\tilde{\mathbf{G}}^{k_i}\|_\infty$, and hence it follows from (4.15) that

$$\|\tilde{\mathbf{F}}^{k_i}_{t_{2i+1}-t_{2i}}\| \leq \|\tilde{\mathbf{F}}^{k_i}_\infty\| = \frac{1}{|k_i|}\,, \quad \text{whilst} \quad \|\tilde{\mathbf{F}}^{k_0}_t\| \leq \|\tilde{\mathbf{F}}^{k_0}_\infty\| = \frac{1}{|k_0|}\,.$$

Therefore integrating (4.16) from 0 to $t_{2i+1} - t_{2i}$ and taking estimates we have

$$\|e\|_{L^2(t_{2i},t_{2i+1})} \leq \frac{1}{1 - \|\tilde{\mathbf{F}}^{k_i}_\infty\|\,\|\mathcal{K}(\gamma) - k_i\|_{L^\infty(t_{2i},t_{2i+1})}}\|\tilde{\mathbf{\Psi}}^{k_i}_{t_{2i+1}-t_{2i}}(\tilde{x}(t_{2i}))\|_{L^2(0,t_{2i+1}-t_{2i})}$$

$$\leq 2\|\tilde{\mathbf{\Psi}}^{k_i}_{t_{2i+1}-t_{2i}}(\tilde{x}(t_{2i}))\|_{L^2(0,t_{2i+1}-t_{2i})}\,. \tag{4.19}$$

Since $\tilde{\mathbf{G}}^{k_i} \in H^{\infty\ m\times m}_-$, an application of Theorem 3.14 yields that the closed-loop semigroup $\tilde{\mathbf{T}}^{k_i}$ is exponentially stable. It follows that $\tilde{\mathbf{\Psi}}^{k_i}_\infty z \in L^2(\mathbb{R}_+, \mathbb{R}^m)$ for all $z \in X \times \mathbb{R}^m$. As a consequence, integrating in (4.18) from 0 to ∞ and taking estimates gives

$$\|\tilde{\mathbf{\Psi}}^{k_i}_\infty(\tilde{x}(t_{2i}))\|_{L^2(0,\infty)} \leq \frac{1}{1 - \|\tilde{\mathbf{F}}^{k_0}_\infty\||k_0 - k_i|}\|\tilde{\mathbf{\Psi}}^{k_0}_\infty(\tilde{x}(t_{2i}))\|_{L^2(0,\infty)}$$

$$= \frac{k_0}{k_i}\|\tilde{\mathbf{\Psi}}^{k_0}_\infty(\tilde{x}(t_{2i}))\|_{L^2(0,\infty)}\,. \tag{4.20}$$

Combining (4.19) and (4.20) and using the definition of $\gamma(t)$, we obtain

$$\sqrt{\rho_{2i+1} - \rho_{2i}} = \|e\|_{L^2(t_{2i},t_{2i+1})} \leq 2\frac{k_0}{k_i}\|\tilde{\mathbf{\Psi}}^{k_0}_\infty\tilde{x}(t_{2i})\|_{L^2(0,\infty)} \leq \frac{c_0}{|k_i|}\|\tilde{x}(t_{2i})\|\,, \tag{4.21}$$

where $c_0 > 0$ is a constant obtained from the exponential stability of the semigroup $\tilde{\mathbf{T}}^{k_0}$. Setting $t = t_{2i}$ in (4.17) and taking estimates yield

$$\|\tilde{x}(t_{2i})\| \leq c_1 + c_2\sqrt{\rho_{2i} - \gamma_0} \tag{4.22}$$

for suitable constants $c_1 > 0$ and $c_2 > 0$. Combining (4.21) and (4.22) and using the fact that $k_i = \mathcal{K}(\rho_{2i})$, we have

$$\sqrt{\rho_{2i+1} - \rho_{2i}} \leq \frac{c_0}{|\mathcal{K}(\rho_{2i})|}(c_1 + c_2\sqrt{\rho_{2i} - \gamma_0})\,. \tag{4.23}$$

Now, by the mean value theorem, there exists $\xi_{2i} \in (\rho_{2i}, \rho_{2i+1})$ such that

$$-\frac{1}{\mathcal{K}'(\xi_{2i})} = \frac{\rho_{2i+1} - \rho_{2i}}{\mathcal{K}(\rho_{2i}) - \mathcal{K}(\rho_{2i+1})} = 2\,\frac{\rho_{2i+1} - \rho_{2i}}{\mathcal{K}(\rho_{2i})}$$

so that (4.23) becomes

$$\sqrt{\frac{-\mathcal{K}^3(\rho_{2i})}{2\mathcal{K}'(\xi)}} \le c_0(c_1 + c_2\sqrt{\rho_{2i} - \gamma_0})\,. \tag{4.24}$$

Using the specific form of $\mathcal{K}$ we have

$$\mathcal{K}'(\xi) = -\frac{p\cos(\log^q \xi) + q\log^q \xi \sin(\log^q \xi)}{\xi \log^{1+p} \xi}\,,$$

which on substituting in (4.24) and rearranging yields

$$1 \le 2\,\left[c_0(c_1 + c_2\sqrt{\rho_{2i} - \gamma_0})\right]^2 \frac{1}{|\mathcal{K}(\rho_{2i})|^3}\,\frac{|p\cos(\log^q \xi_{2i}) + q\log^q \xi_{2i}\sin(\log^q \xi_{2i})|}{\xi_{2i}\log^{1+p}\xi_{2i}}\,. \tag{4.25}$$

Using the fact that $\mathcal{K}(\rho_{2i}) = |\log^{-p} \rho_{2i}|$ and gathering dominant terms in (4.25) lead to

$$1 \le c_3\left(p(\log \rho_{2i})^{2p-1} + q(\log \rho_{2i})^{2p+q-1}\right) \tag{4.26}$$

for some constant $c_3 > 0$. But $p, q > 0$ and $q + 2p < 1$ so that the right-hand side of (4.26) approaches zero for $\rho_{2i} \to \infty$, which is in contradiction to (4.26). Hence $\gamma(\cdot)$ is bounded, which establishes statements (i) and (iii). Boundedness of $\tilde{x}(t)$ and therefore part (ii) follows directly from (4.17), the exponential stability of $\tilde{\mathbf{T}}^{k_0}$, and statements (i) and (iii).

To prove the last statement in the theorem let $(x_0, u_0) \in D(\tilde{A})$. Then $\tilde{x}_0 := (x_r - x_0, u_r - u_0) \in D(\tilde{A})$, and from (4.14) and (2.8b) we obtain

$$e(t) = \tilde{C}^{k_0}\tilde{\mathbf{T}}_t^{k_0}\tilde{x}_0 - (\tilde{\mathbf{F}}_\infty^{k_0}[(\mathcal{K}(\gamma) - k_0)e])(t) \quad \forall\, t \ge 0\,. \tag{4.27}$$

By Lemma 3.11, $\tilde{x}_0 \in D(\tilde{A}^{k_0})$, and hence it follows from the exponential stability of the semigroup $\tilde{\mathbf{T}}^{k_0}$ that the first term on the right-hand side of (4.27) tends exponentially to 0 as $t \to \infty$. In order to show that the second term converges to 0 as $t \to \infty$ set $v(t) = (\mathcal{K}(\gamma(t)) - k_0)e(t)$, and realize that, by statements (i) and (iii), $v \in L^2(\mathbb{R}_+, \mathbb{R}^m)$. Clearly,

$$(\mathbb{L}(\tilde{\mathbf{F}}_\infty^{k_0} v))(s) = \tilde{\mathbf{G}}(s)(1 + k_0\tilde{\mathbf{G}}(s))^{-1}(\mathbb{L}v)(s) = \tilde{\mathbf{G}}^{k_0}(s)(\mathbb{L}v)(s)\,.$$

Since $|k_0|$ is sufficiently small, it follows from Theorem 3.8 that $\tilde{\mathbf{G}}^{k_0} \in H_-^{2\ m\times m}$. (Note that using the notation in Theorem 3.8 we have $\tilde{\mathbf{G}}^{k_0} = \mathbf{G}\mathbf{E}_{k_0}$.) Therefore, by the Paley–Wiener theorem, $\tilde{\mathbf{F}}_\infty^{k_0}$ is a convolution operator with a matrix-valued kernel whose entries are L^2-functions. Now it is well known that the convolution of two functions belonging to $L^2(\mathbb{R}_+, \mathbb{R})$ converges to 0 as $t \to \infty$, and hence $\lim_{t\to\infty}(\tilde{\mathbf{F}}_\infty^{k_0} v)(t) = 0$. Finally, if C is bounded, then $\tilde{C}$ is bounded, i.e., $\tilde{C} \in \mathcal{L}(X \times \mathbb{R}^m, \mathbb{R}^m)$. Furthermore, by Proposition 3.12, $\tilde{C}^{k_0} = \tilde{C}$, and therefore the first term on the right-hand side of (4.27) converges (exponentially) to 0 as $t \to \infty$ for all $(x_0, u_0) \in X \times \mathbb{R}^m$. □

Note that the condition $(x_0, u_0) \in D(\tilde{A})$ in statement (iv) of Theorem 4.5 required in proving that $\lim_{t\to 0} e(t) = 0$ is system dependent. This is a little disturbing

since, from the outset, we assume that the specific system to be controlled is unknown. However, in most cases, the initial states will be sufficiently smooth so that the condition $(x_0, u_0) \in D(\tilde{A})$ is satisfied. Note that if $(x_0, u_0) \notin D(\tilde{A})$, then $e(\cdot)$ will in general not make sense pointwise and cannot be expected to converge to 0 in the usual sense (see, however, Remark 3.15).

Note that in the infinite-dimensional case the tuning function $\mathcal{K}(\gamma)$ decays to 0 like a fractional power of $\log \gamma$ as $\gamma \to \infty$, whereas in the finite-dimensional case it decays to 0 like a fractional power of γ. However, in the case when it is known that $\mathbf{G}(0) \succ 0$, we can use tuning functions which decay to 0 like a fractional power, although more slowly than in the finite-dimensional case.

PROPOSITION 4.6. *Suppose that the conditions of Theorem* 4.5 *hold and that additionally* $\mathbf{G}(0) \succ 0$. *If*

$$u(t) = u_0 + \int_0^t \gamma^{-p}(\xi) e(\xi)\, d\xi\,, \tag{4.28}$$

$$\dot{\gamma}(t) = \|e(t)\|^2\,, \quad \gamma(0) = \gamma_0 > 0\,, \tag{4.29}$$

and $0 < p < \frac{1}{2}$, *then the conclusions of Theorem* 4.5 *hold.*

Proof. It is sufficient to show that $\gamma(\cdot)$ is bounded. Let $[0, \tau)$ be the maximal interval of existence. If $\gamma(\cdot)$ is unbounded on $[0, \tau)$, then there exists $t_1 \geq 0$ such that with $\gamma_1 = \gamma(t_1)$, $k_1 = \gamma_1^{-p}$ is a stabilizing gain. For any $t \in (t_1, \tau)$ we have, as in the proof of Theorem 4.5, that on $[t_1, t]$

$$\mathbf{L}_{t_1} \mathbf{P}_t e = \tilde{\mathbf{\Psi}}^{k_1}_{t-t_1}(\tilde{x}(t_1)) - \tilde{\mathbf{F}}^{k_1}_{t-t_1}(\mathbf{L}_{t_1} \mathbf{P}_t (\mathcal{K}(\gamma) - k_1) e)\,. \tag{4.30}$$

We can assume that k_1 is small enough so that, using Proposition 3.9 and estimating, we obtain

$$\sqrt{\gamma(t) - \gamma_1} \leq c \gamma^p(t)$$

for some $c > 0$ and all $t \in [t_1, \tau)$. This inequality clearly contradicts the unboundedness of $\gamma(\cdot)$ and the assumption that $p < 1/2$. ∎

The condition $\mathbf{G}(0) \succ 0$ is satisfied for a large class of exponentially stable infinite-dimensional systems with self-adjoint generator A, co-located control and observation and positive semidefinite feedthrough (cf. Remark 4.3).

5. Adaptive low-gain control of multivariable systems with sign-indefinite steady-state gain. In this section we consider the adaptive low-gain tracking problem, for stable regular systems with square $m \times m$ transfer functions $\mathbf{G}(s)$ and invertible steady-state gain. In section 4, under the assumption that $\mathbf{G}(0)$ is sign definite, we could exploit the fact that for all gains k having the "correct" sign and with $|k|$ sufficiently small, $\|\tilde{\mathbf{G}}^k\|_\infty = 1/|k|$ (see Proposition 3.9). If $\mathbf{G}(0)$ is sign indefinite or even nonsymmetric, then, again by Proposition 3.9, we no longer have this result. To overcome this problem we do not use a tuning function $\mathcal{K}$ reflecting the low-gain nature of the problem in the sense that $\lim_{\gamma \to \infty} \mathcal{K}(\gamma) = 0$ but instead resort to a gain which oscillates smoothly between 0 and 2. (In fact, 2 could be replaced by any positive number δ.)

As in the previous sections let $u(\cdot)$ and $y(\cdot)$ denote the plant input and plant output, respectively, and set $e(\cdot) = r - y(\cdot)$, where $r \in \mathbb{R}^m$ is a demand vector. Modulo certain technicalities involving "spectrum unmixing" of $\mathbf{G}(0)$ (to be made precise) we show that

$$u(t) = u_0 + \int_0^t [1 + \cos(\log^q \gamma(\xi))] e(\xi)\, d\xi\,, \quad \text{where } 0 < q < 1\,, \tag{5.1}$$

$$\dot{\gamma}(t) = \|e(t)\|^2\,, \quad \gamma(0) = \gamma_0, \tag{5.2}$$

is a universal adaptive tracking controller.

We assume throughout that $\mathbf{\Sigma}_{plant}$ is an m-input m-output, exponentially stable, regular system given by (2.1). We will consider two cases. In the first one we assume that the spectrum of $\mathbf{G}(0)$ is unmixed in the sense that $\sigma(\mathbf{G}(0)) \subset \mathbb{C}_0$. In the second case the a priori knowledge about $\mathbf{G}(0)$ guarantees only that $\mathbf{G}(0)$ is invertible.

THEOREM 5.1. *Assume that $\sigma(\mathbf{G}(0)) \subset \mathbb{C}_0$. Let $r \in \mathbb{R}^m$ be an arbitrary demand vector. If $u(t)$ is given by* (5.1)*, with gain adaptation* (5.2)*, then for each $(x_0, u_0) \in X \times \mathbb{R}^m$ and $\gamma_0 > 1$ we have*

(i) $\lim_{t\to\infty} \gamma(t) = \gamma_\infty < \infty$;

(ii) *$\|x(t)\|$ and $\|u(t)\|$ remain bounded as $t \to \infty$;*

(iii) $e(\cdot) \in L^2(\mathbb{R}_+, \mathbb{R}^m)$.

Moreover, if $(x_0, u_0) \in D(\tilde{A})$, then

$$\lim_{t\to\infty} y(t) = r\,. \tag{5.3}$$

If the observation operator C is bounded, then (5.3) *holds for all $(x_0, u_0) \in X \times \mathbb{R}^m$.*

In the proof of this result we do not have to be so careful with the estimates, since we need only to work in a neighborhood of a stabilizing integral gain and do not need to account for the possibility of the feedback gain approaching 0.

Proof. The first step is to convert the tracking problem ($r \neq 0$) into a stabilization problem ($r = 0$). Let $r \in \mathbb{R}^m$, $(x_0, u_0) \in X \times \mathbb{R}^m$ be given and set $\mathcal{K}(\gamma) := 1 + \cos(\log^q \gamma(t))$. By Lemma 3.16 there exists $\tilde{x}_0 \in X \times \mathbb{R}^m$ such that

$$e = \tilde{\mathbf{\Psi}}_\infty \tilde{x}_0 - \tilde{\mathbf{F}}_\infty(\mathcal{K}(\gamma)e)\,. \tag{5.4}$$

Moreover, if $(x_0, u_0) \in D(\tilde{A})$, then $\tilde{x}_0 \in D(\tilde{A})$. The closed-loop system given by (5.4) and (5.2) is in a form so that Proposition 2.4 is applicable.

By Theorem 3.8 there exists $k \in (0, 1)$ for which $\tilde{\mathbf{G}}^k \in H_-^{\infty\, m\times m}$. Consequently, by Theorem 3.14, $\tilde{\mathbf{T}}^k$ is an exponentially stable semigroup on $X \times \mathbb{R}^m$. As in the sign-definite case, seeking a contradiction, suppose that $\gamma(t)$ is unbounded on the maximal interval of existence $[0, \tau)$. To this end choose $\varepsilon \in (0, k)$ such that $k + \varepsilon < 1$ and let $(\rho_i)_{i\in\mathbb{N}}$ be a sequence with

$$\rho_i \nearrow \infty\,, \quad \rho_0 \geq \gamma_0\,, \quad \mathcal{K}(\rho_{2i}) = k - \varepsilon\,, \quad \mathcal{K}(\rho_{2i+1}) = k + \varepsilon$$

and such that

$$\mathcal{K}(\gamma) \in (k - \varepsilon, k + \varepsilon) \quad \forall\, \gamma \in (\rho_{2i}, \rho_{2i+1})\,.$$

Exploiting the unboundedness of $\gamma(t)$ we can find a sequence of times $t_0 < t_1 < \cdots < \tau$ so that $\gamma(t_i) = \rho_i$. Using (2.9b) we obtain

$$\mathbf{L}_{t_{2i}}\mathbf{P}_{t_{2i+1}} e = \tilde{\mathbf{\Psi}}^k_{t_{2i+1}-t_{2i}} \tilde{x}(t_{2i}) - \tilde{\mathbf{F}}^k_{t_{2i+1}-t_{2i}}(\mathbf{L}_{t_{2i}}\mathbf{P}_{t_{2i+1}}(\mathcal{K}(\gamma) - k)e)\,, \tag{5.5}$$

where

$$\tilde{x}(t) = \tilde{\mathbf{T}}_t \tilde{x}_0 - \tilde{\mathbf{\Phi}}_t \mathbf{P}_t \mathcal{K}(\gamma) e\,.$$

Integrating from 0 to $t_{2i+1} - t_{2i}$ in (5.5) and taking estimates yield

$$\|e\|_{L^2(t_{2i},t_{2i+1})} \leq \frac{1}{1 - \|\tilde{\mathbf{F}}^k_\infty\| \|\mathcal{K}(\gamma) - k\|_{L^\infty(t_{2i},t_{2i+1})}} \|\tilde{\mathbf{\Psi}}^k_\infty \tilde{x}(t_{2i})\|_{L^2(0,\infty)}$$

$$\leq c_0 \|\tilde{x}(t_{2i})\| \tag{5.6}$$

for some suitable $c_0 > 0$, provided that ε is small enough (for example, $\|\tilde{\mathbf{F}}^k_\infty\|\varepsilon = 1/2$).

Applying the input-state variation of parameters formula (2.8a) to $\tilde{\mathbf{\Sigma}}$ with $K = kI$ and $u = \mathcal{K}(\gamma)e$ it follows from the exponential stability of $\tilde{\mathbf{T}}^k$ and (5.2) that

$$\|\tilde{x}(t_{2i})\| \le c_1 + c_2\sqrt{\rho_{2i} - \gamma_0} \tag{5.7}$$

for some constants $c_1 > 0$ and $c_2 > 0$. Combining (5.6) and (5.7) we have

$$\sqrt{\rho_{2i+1} - \rho_{2i}} \le c_0(c_1 + c_2\sqrt{\rho_{2i} - \gamma_0})\,. \tag{5.8}$$

Clearly,

$$\rho_{2i+1} - \rho_{2i} = 2\varepsilon/\mathcal{K}'(\xi_{2i})$$

for some $\xi_{2i} \in (\rho_{2i}, \rho_{2i+1})$. Combining this with (5.8) leads to

$$1 \le \frac{1}{2\varepsilon}[c_0(c_1 + c_2\sqrt{\rho_{2i} - \gamma_0})]^2\mathcal{K}'(\xi_{2i})\,. \tag{5.9}$$

Now

$$\mathcal{K}'(\xi) = -q\sin(\log^q \xi)(\log^{q-1} \xi)/\xi,$$

and $0 < q < 1$, and we see that the right-hand side of (5.9) converges to 0 as $i \to \infty$, which yields a contradiction. It follows that $\gamma(\cdot)$ is bounded, showing that (i) and (iii) hold true. The remaining claims follow readily, using the same techniques as in the proof of Theorem 4.5. □

Specialized to the case when $\mathbf{G}(0) \succ 0$, it is natural to compare the control law in Theorem 5.1 to the one in Proposition 4.6. Intuitively it should be advantageous to use the controller in Proposition 4.6, since in this case the gain passes rapidly into the "correct" parameter region once and remains there, whereas the gain in the controller in Theorem 5.1 oscillates slowly and may pass in and out of the "correct" region several times before converging. Moreover, small output disturbances could lead to further cycles in the gain adaptation.

In Theorem 5.1 we assumed that $\sigma(\mathbf{G}(0)) \subset \mathbb{C}_0$. We now consider the case when we know only that $\det \mathbf{G}(0) \neq 0$. In the context of high-gain adaptive stabilization Mårtensson [21], [22] has shown that there exists a finite set $\{\Gamma_1, \dots, \Gamma_\ell\}$ so that given any invertible $m \times m$ matrix M there exists $\nu \in \{1, 2, \dots, \ell\}$ such that $\sigma(M\Gamma_\nu) \subset \mathbb{C}_0$. We now use this result in order to unmix the spectrum of $\mathbf{G}(0)$. Consider the feedback law

$$u(t) = u_0 + \int_0^t [1 + \cos(\log^q \gamma(\xi))]\Gamma_{S(\gamma(\xi))}e(\xi)\,d\xi\,, \tag{5.10}$$

where $0 < q < 1$ and

$$S(\gamma) = j \quad \text{if} \quad (2\pi)^{-1}\log^q \gamma \in [p\ell + j, p\ell + j + 1) \quad \text{for some} \quad p \in \mathbb{N}.$$

Note that the feedback gain matrix in (5.10) is piecewise smooth but discontinuous whenever $(2\pi)^{-1}\log^q \gamma$ takes on integer values, so Proposition 2.4 is no longer valid. However, these discontinuities in the gain are easily handled by a minor modification to the proof of Proposition 2.4.

THEOREM 5.2. *Assume that* $\det \mathbf{G}(0) \neq 0$. *Let* $r \in \mathbb{R}^m$ *be an arbitrary demand vector. If* $u(t)$ *is given by* (5.10), *with adaptation* (5.2), *then for each* $(x_0, u_0) \in X \times \mathbb{R}^m$ *and* $\gamma_0 > \exp(\sqrt[q]{2\pi})$ *we have*[6]

[6]Note that $S(\gamma)$ is defined only for $\gamma \ge \exp(\sqrt[q]{2\pi})$.

(i) $\lim_{t\to\infty}\gamma(t)=\gamma_\infty<\infty$;
(ii) $\|x(t)\|$ *and* $\|u(t)\|$ *remain bounded as* $t\to\infty$;
(iii) $e(\cdot)\in L^2(\mathbb{R}_+,\mathbb{R}^m)$.

Moreover, if $(x_0,u_0)\in D(\tilde{A})$, *then* (5.3) *holds. If the observation operator* C *is bounded, then* (5.3) *holds for all* $(x_0,u_0)\in X\times\mathbb{R}^m$.

Proof. Let $\nu\in\{1,2,\dots,\ell\}$ be such that $\sigma(\mathbf{G}(0)\Gamma_\nu)\in\mathbb{C}_0$. By Theorem 3.8 there exists $k\in(0,1)$ such that the integrator $(k/s)\Gamma_\nu$ stabilizes $\mathbf{G}$. Consequently, by Theorem 3.14, the semigroup $\tilde{\mathbf{T}}^{k\Gamma_\nu}$ is exponentially stable. As in the proof of Theorem 5.1 set $\mathcal{K}(\gamma)=1+\cos(\log^q\gamma)$. By Lemma 3.16 there exists $\tilde{x}_0\in X\times\mathbb{R}^m$ such that

$$e=\tilde{\mathbf{\Psi}}_\infty\tilde{x}_0-\tilde{\mathbf{F}}_\infty(\mathcal{K}(\gamma)\Gamma_{S(\gamma)}e)\,. \tag{5.11}$$

Let $[0,\tau)$ be the maximal interval of existence for the solution (e,γ) of the closed-loop system given by (5.11) and (5.2). Seeking a contradiction, suppose that $\lim_{t\to\tau}\gamma(t)=\infty$. Choose $\varepsilon\in(0,k)$ such that $\varepsilon+k<1$. Then there exists a sequence $0\le t_0<t_1<\cdots<\tau$ with

$$\mathcal{K}(\gamma(t_{2i}))=k-\varepsilon\,,\quad \mathcal{K}(\gamma(t_{2i+1}))=k+\varepsilon$$

and such that

$$\mathcal{K}(\gamma(t))\in(k-\varepsilon,k+\varepsilon)\quad\text{and}\quad S(\gamma(t))=\nu\qquad\forall\,t\in[t_{2i},t_{2i+1}]\,.$$

As in the proof of Theorem 5.1, we can use (2.9b) to obtain

$$\mathbf{L}_{t_{2i}}\mathbf{P}_{t_{2i+1}}e=\tilde{\mathbf{\Psi}}^{k\Gamma_\nu}_{t_{2i+1}-t_{2i}}\tilde{x}(t_{2i})-\tilde{\mathbf{F}}^{k\Gamma_\nu}_{t_{2i+1}-t_{2i}}(\mathbf{L}_{t_{2i}}\mathbf{P}_{t_{2i+1}}(\mathcal{K}(\gamma)-k)\Gamma_\nu e)\,.$$

The remainder of the proof follows closely that of Theorem 5.1 and is omitted. ∎

The control law given by (5.10) and (5.2) depends crucially on the unmixing set $\{\Gamma_1,\Gamma_2,\dots,\Gamma_\ell\}$. Clearly, if $m=1$, then $\{1,-1\}$ is an unmixing set. For the case $m=2$ an unmixing set of cardinality 6 is given in Mårtensson [21], [22]. Zhu [51] has constructed an unmixing set having cardinality 32 for the case $m=3$. Unfortunately, the cardinality of the unmixing sets given by the general construction in [22] is far too large than would be convenient for applications.

6. Examples and simulations. The results of sections 3–5 apply to the general class of regular linear systems. For the purpose of illustration we consider two simple examples: finite-dimensional systems with output delays and a damped wave equation in a single spatial variable with boundary control and observation. In all of the simulations we used Simulink in Matlab. Note that the reference signals to be tracked are stepped, with nonzero step time.

Example 6.1. Systems with output delays:

We consider a class

$$\dot{x}(t)=Ax(t)+Bu(t)\,,\quad y(t)=Cx(t-h) \tag{6.1}$$

of systems with output delay, where $A\in\mathbb{R}^{n\times n}$, $B\in\mathbb{R}^{n\times m}$, $C\in\mathbb{R}^{m\times n}$, and $h>0$. The system (6.1) can be represented as a so-called Pritchard–Salamon system with state space $\mathbb{R}^n\times L^2(-h,0;\mathbb{R}^n)$; see, e.g., Pritchard and Salamon [35, 36]. Since Pritchard–Salamon systems are regular in the sense of section 2, it follows that the results of sections 3–5 can be applied to (6.1), provided that $\sigma(A)\subset\mathbb{C}_0$ and $\det CA^{-1}B\neq0$. We consider three particular cases.

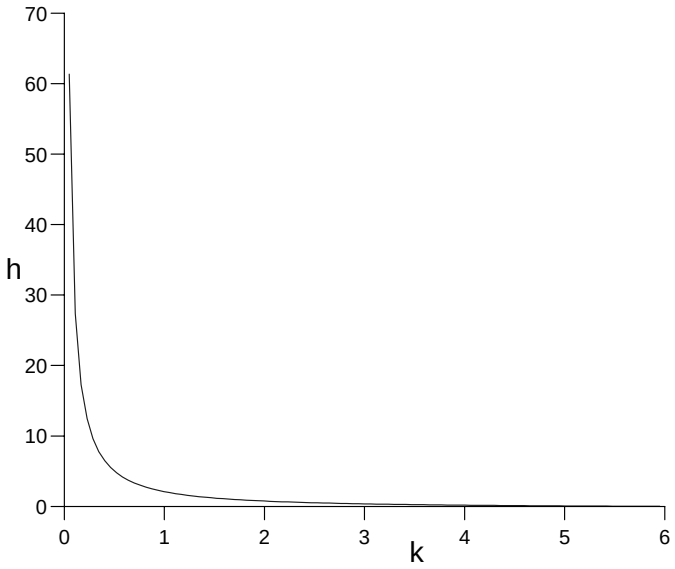

FIG. 6.1. *Tolerable delay as a function of k.*

(a) $m = 1$, $n = 2$, and

$$A = \begin{pmatrix} 0 & 1 \\ -2 & -3 \end{pmatrix}, \quad B = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad C = (1, 0)\,.$$

If $h = 0$, then $\dot{u} = -ky$ stabilizes (6.1) for all $k \in (0, 6)$. Using a stability window analysis (Walton and Marshall [43]), we can compute for each $k \in (0, 6)$ the range of $h \in (0, h(k))$ for which $\dot{u} = -ky$ stabilizes (6.1). In Figure 6.1, $h(k)$ is plotted against k for k in the range $(0, 6)$. Figure 6.2 shows a plot of $y(t)$, $r(t)$, and $\mathcal{K}(\gamma(t))$ against t for (4.28) with $p = 0.4$ when $h = 4$, $x(0) = (-1 \;\; 3)^T$, $u(0) = -1$, and $y(t) = -4$ for $t < 0$. Note in this case that the integrator gain can take values in $(0, 0.6)$ and that $\mathcal{K}(\gamma(\infty)) = 0.07$.

(b) We now consider two cases with $m = 2$, $n = 3$. In the first case $\mathbf{G}(0)$ is sign definite and in the second $\mathbf{G}(0)$ is sign indefinite.

(i) In this example we take

$$A = \begin{pmatrix} -1 & 0 & -2 \\ 0 & -1 & -3 \\ -2 & -3 & -14 \end{pmatrix}, \quad B = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad C = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}$$

so that

$$\mathbf{G}(0) = \begin{pmatrix} 7 & 6 \\ 6 & 11 \end{pmatrix} \succ 0\,.$$

We assume that this knowledge of the sign of the steady-state gain is available and use (4.28) with $p = 0.15$.

Figure 6.3 shows plots of $y(t)$, $r(t)$, and $\mathcal{K}(\gamma(t))$ for the case $h = 1$ with $y(\cdot) = 0$ on $[-1, 0)$, $x(0) = (0.4, 0.3, 0.25)^T$, and $u(0) = (1.5, 1)^T$, with the reference signal $r(t) = \theta(t)(5, 0)^T + \theta(t - 20)(5, 3)^T$.

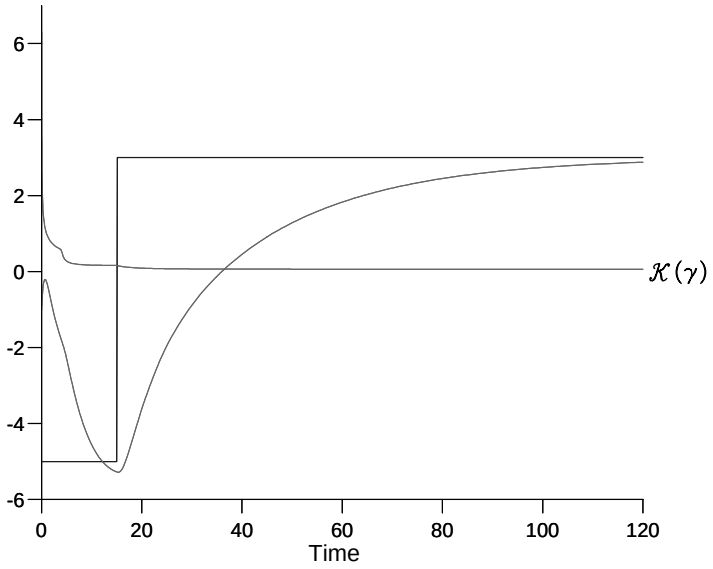

FIG. 6.2. *Simulation with* $\mathcal{K}(\gamma) = \gamma^{-0.4}$.

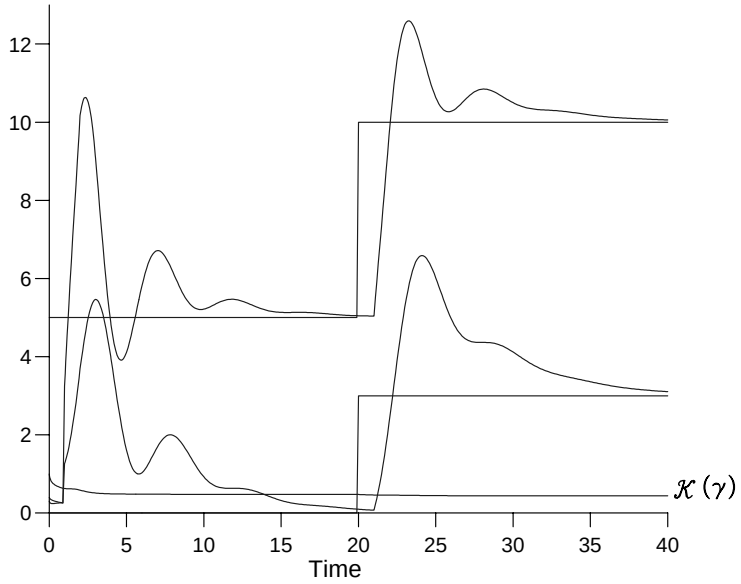

FIG. 6.3. *Simulation with* $\mathcal{K}(\gamma) = \gamma^{-0.15}$.

(ii) In this example we take

$$A = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -6 & -11 & -6 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 0 \\ 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad C = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}$$

so that

$$\mathbf{G}(0) = \begin{bmatrix} 3 & 0.1667 \\ 0 & 1 \end{bmatrix}.$$

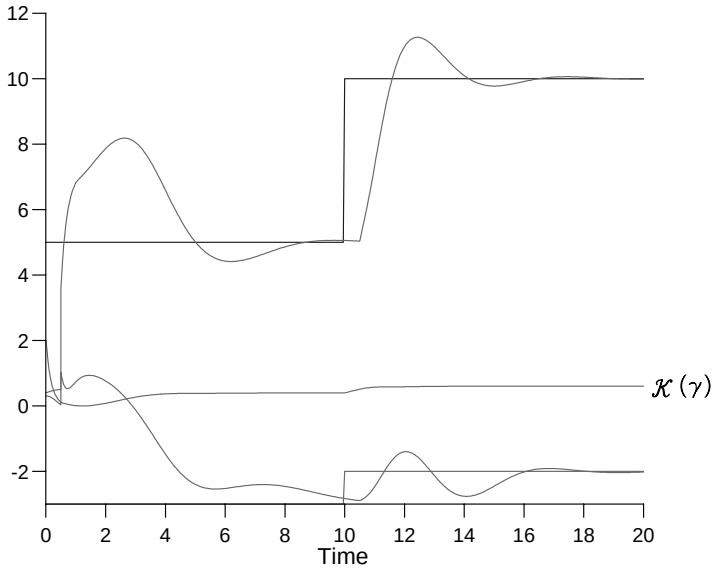

FIG. 6.4. *Simulation with* $\mathcal{K}(\gamma) = 1 + \cos(\log^{0.95}\gamma)$.

Clearly $\sigma(\mathbf{G}(0)) \subset \mathbb{C}_0$. We assume that this knowledge is available and use (5.1) with $q = 0.95$.

Figure 6.4 shows plots of $y(t)$, $r(t)$, and $\mathcal{K}(\gamma(t))$ for the case $h = 0.5$ with $y(\cdot) = 0$ on $[-0.5, 0)$, $x(0) = (0.4, 0.3, 0.25)^T$ and $u(0) = (1.5, 1)^T$ with the reference signal $r(t) = \theta(t)(5, -3)^T + \theta(t-10)(5, 1)^T$.

Example 6.2. A wave equation with boundary control and observation: We consider the damped wave equation

$$\frac{\partial^2 w}{\partial t^2}(z,t) = \frac{\partial^2 w}{\partial z^2}(z,t) - 2a\frac{\partial w}{\partial t}(z,t) - a^2 w(z,t)\,, \qquad t > 0\,,\ z \in (0,1)\,, \tag{6.2}$$

with boundary conditions

$$w(0,t) = 0\,, \quad \frac{\partial w}{\partial z}(1,t) = u(t)$$

and boundary observation

$$y(t) = \frac{\partial w}{\partial t}(1,t) + bw(1,t)\,,$$

where $a > 0$ and $b \neq 0$. This system has a regular, exponentially stable realization on the state space

$$X = \{x = [x_1, x_2]^T \in H^1[0,1] \oplus L^2[0,1] \mid x_1(0) = 0\}.$$

Moreover, $\mathbf{G}(s) = \frac{s+b}{s+a}\frac{\sinh(s+a)}{\cosh(s+a)}$ so that $\mathbf{G}(0) = \frac{b\sinh(a)}{a\cosh(a)} \neq 0$. We assume that $a = \frac{1}{2}\log 0.3$ and $b = 0.3$. For purposes of illustration we assume that $\operatorname{sign}(\mathbf{G}(0))$ is unknown so that we use (4.11) with $p = 0$ and $q = 0.9$ and the initial conditions are equal to zero.

Figure 6.5 shows $y(t)$, $r(t)$, and $\mathcal{K}(\gamma(t))$, whilst Figure 6.6 shows $y(t)$, $r(t)$, and $\mathcal{K}(\gamma(t))$ when the sign of $\mathbf{G}(0)$ is switched. Note that whilst (6.2) gives a partial differential equation realization of $\mathbf{G}(s)$, for the simulations we exploited the fact

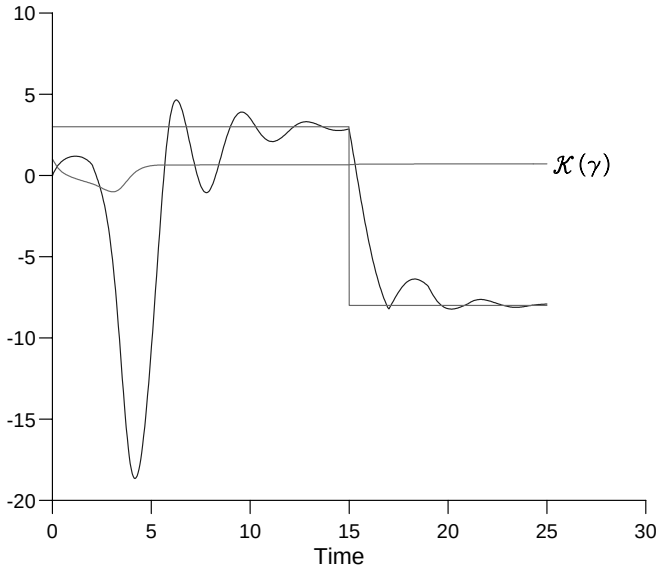

FIG. 6.5. *Simulation with* $\mathcal{K}(\gamma) = \cos(\log^{0.9}\gamma)$ *and* $\mathbf{G}(0) > 0$.

that the input-ouput behavior of (6.2), with zero initial conditions, is the same as that for the series connection of $\frac{s+b}{s+a}$ with the functional difference equation

$$y(t) = -e^{-2a}y(t-2) + u(t) - e^{-2a}u(t-2)\,. \tag{6.3}$$

The system given by (6.3) is easily realized using Simulink in Matlab.

In comparing Figures 6.5 and 6.6, we note that in the former, the gain function $\mathcal{K}(\gamma)$ undergoes two switches in sign before reaching a positive limit and in the latter switches sign only once before reaching a negative limit. The simulations are consistent with the fact that $\mathbf{G}(0) > 0$ in Figure 6.5 and $\mathbf{G}(0) < 0$ in Figure 6.6.

7. Concluding remarks. In this paper we have obtained results on nonadaptive and adaptive low-gain control of square regular systems for tracking step reference signals. It is possible to extend some of the results to nonsquare systems and sinusoidal reference signals. Finally, in [16] we have obtained discrete-time versions of the results in sections 3 and 4, with applications to sampled-data control of regular systems.

Appendix.

Proof of Proposition 2.4. For $a < b \le \infty$ we define $L(a,b) := L^2(a,b;\mathbb{R}^m) \times L^\infty(a,b;\mathbb{R})$ and $L_{loc}(a,\infty) := L^2_{loc}(a,\infty;\mathbb{R}^m) \times L^\infty_{loc}(a,\infty;\mathbb{R})$. We define a norm on $L(a,b)$ by setting $\|(f_1,f_2)\|_{(a,b)} := \|f_1\|_{L^2(a,b)} + \|f_2\|_{L^\infty(a,b)}$. In order to prove Proposition 2.4 we shall first consider an initial value problem which contains (2.11) as a special case.

Let $T \ge 0$, $(y^0,\gamma^0) \in L_{loc}(T,\infty)$ and $(f,g) \in L(0,T)$ be given, and suppose that $F \in L^1_{loc}(\mathbb{R}_+, \mathbb{R}^{m\times m})$ and $\mathcal{K} : \mathbb{R} \to \mathbb{R}$ is a locally Lipschitz function. For $\tau > T$ define the operator $\mathbf{N}_\tau : L(0,\tau) \to L(0,\tau)$ by

$$\text{(A.1a)}\quad \mathbf{N}_\tau \begin{pmatrix} y \\ \gamma \end{pmatrix}(t) = \begin{pmatrix} f(t) \\ g(t) \end{pmatrix}, \quad t \in [0,T]\,,$$

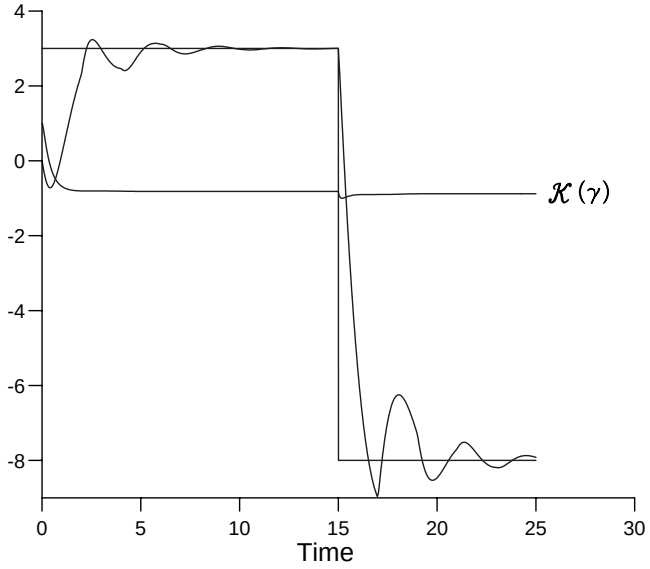

FIG. 6.6. *Simulation with* $\mathcal{K}(\gamma) = \cos(\log^{0.9}\gamma)$ *and* $\mathbf{G}(0) < 0$.

$$\text{(A.1b)}\quad \mathbf{N}_\tau \begin{pmatrix} y \\ \gamma \end{pmatrix}(t) = \begin{pmatrix} y^0(t) \\ \gamma^0(t) \end{pmatrix} + \int_0^t \begin{pmatrix} F(t-\xi) & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \mathcal{K}(\gamma(\xi))y(\xi) \\ \|y(\xi)\|^2 \end{pmatrix} d\xi\,, \quad t \geq T\,.$$

For $\rho > 0$ and $\tau > T$, let $B_{\rho,\tau}$ denote the closed ball in $L(T,\tau)$ of radius ρ with center in $(y^0|_{[T,\tau]}, \gamma^0|_{[T,\tau]} + \|f\|^2_{L^2(0,T)})$. Finally define

$$\mathfrak{M}_{\rho,\tau} := \{(y,\gamma) \in L(0,\tau) \,|\, (y,\gamma)|_{[T,\tau]} \in B_{\rho,\tau},\ (y,\gamma)|_{[0,T]} = (f,g)\}\,.$$

Endowed with the metric

$$d[(y_1,\gamma_1),(y_2,\gamma_2)] = \|(y_1 - y_2, \gamma_1 - \gamma_2)\|_{(T,\tau)} = \|(y_1 - y_2, \gamma_1 - \gamma_2)\|_{(0,\tau)}\,,$$

$\mathfrak{M}_{\rho,\tau}$ becomes a complete metric space.

The following lemma will be the key tool for the proof of Proposition 2.4.

LEMMA A.1. *Let* $\rho \in (0, 1/2)$. *Then there exists a* $T^* > T$ *such that for all* $\tau \in (T, T^*)$ *the operator* $\mathbf{N}_\tau$ *is a contraction on* $\mathfrak{M}_{\rho,\tau}$, *i.e.,* (i) $\mathbf{N}_\tau \mathfrak{M}_{\rho,\tau} \subset \mathfrak{M}_{\rho,\tau}$ *and* (ii) *there exists* $\delta_\tau \in (0,1)$ *such that for all* $(y_1,\gamma_1), (y_2,\gamma_2) \in \mathfrak{M}_{\rho,\tau}$

$$\|\mathbf{N}_\tau(y_1,\gamma_1) - \mathbf{N}_\tau(y_2,\gamma_2)\|_{(T,\tau)} \leq \delta_\tau \|(y_1,\gamma_1) - (y_2,\gamma_2)\|_{(T,\tau)}\,.$$

In particular, for all τ *as above,* $\mathbf{N}_\tau$ *has a unique fixed point in* $\mathfrak{M}_{\rho,\tau}$.

Proof. Let $\mathbf{\Pi}_i$, $i = 1, 2$, denote the operator on $L(0,\tau)$ defined by $\mathbf{\Pi}_i(f_1, f_2) = f_i$, and let $\tau^* > T$ be fixed.

(i) Setting $\eta(t) := \int_0^T F(t-\xi)\mathcal{K}(g(\xi))f(\xi)\,d\xi$, it is clear that $\eta \in L^2_{loc}(\mathbb{R}_+, \mathbb{R}^m)$. For all $\tau \in (T, \tau^*)$ and all $(y,\gamma) \in \mathfrak{M}_{\rho,\tau}$ it follows that

$$\begin{aligned}
&\|\mathbf{\Pi}_1 \mathbf{N}_\tau(y,\gamma) - y^0\|^2_{L^2(T,\tau)} \\
&= \int_T^\tau \|\eta(t) + \int_0^t (\mathbf{P}_{\tau-T}F)(t-\xi)[(I - \mathbf{P}_T)\mathcal{K}(\gamma)y](\xi)\,d\xi\|^2\,dt \\
&\leq 2\left(\|\eta\|^2_{L^2(T,\tau)} + \left(\int_0^\tau \|(\mathbf{P}_{\tau-T}F)(\xi)\|\,d\xi\right)^2 \int_T^\tau \|\mathcal{K}(\gamma(\xi))y(\xi)\|^2\,d\xi\right)
\end{aligned}$$

$$\leq 2\left(\|\eta\|^2_{L^2(T,\tau)} + K^2\left(\int_0^{\tau-T}\|F(\xi)\|\,d\xi\right)^2\left(\rho^2+\int_T^\tau\|y^0(\xi)\|^2\,d\xi\right)\right), \tag{A.2}$$

where $K>0$ is such that $|\mathcal{K}(\kappa)|\leq K$ for all $\kappa\in\mathbb{R}$ with $|\kappa|\leq\rho+\|\gamma^0\|_{L^\infty(T,\tau^*)}+\|f\|^2_{L^2(0,T)}$. It follows from (A.2) that there exists $T_1\in(T,\tau^*)$ such that for all $(y,\gamma)\in\mathfrak{M}_{\rho,\tau}$ and for all $\tau\in(T,T_1)$

$$\|\mathbf{\Pi}_1\mathbf{N}_\tau(y,\gamma)-y^0\|^2_{L^2(T,\tau)}\leq\frac{\rho^2}{4}\,. \tag{A.3}$$

Moreover, we have that for $(y,\gamma)\in\mathfrak{M}_{\rho,\tau}$

$$\|\mathbf{\Pi}_2\mathbf{N}_\tau(y,\gamma)-\gamma^0(\cdot)-\|f\|^2_{L^2(0,T)}\|_{L^\infty(T,\tau)}=\int_T^\tau\|y(\xi)\|^2\,d\xi\leq\rho^2+\|y^0\|^2_{L^2(T,\tau)}\,. \tag{A.4}$$

Since $\rho<\frac{1}{2}$, it follows that $\rho^2<\rho/2$, and hence we obtain by using (A.4) that there exists $T_2>T$ such that for all $(y,\gamma)\in\mathfrak{M}_{\rho,\tau}$ and for all $\tau\in(T,T_2)$

$$\|\mathbf{\Pi}_2\mathbf{N}_\tau(y,\gamma)-\gamma^0(\cdot)-\|f\|^2_{L^2(0,T)}\|_{L^\infty(T,\tau)}<\frac{\rho}{2}\,. \tag{A.5}$$

Combining (A.3) and (A.5), we see that

$$\mathbf{N}_\tau\mathfrak{M}_{\rho,\tau}\subset\mathfrak{M}_{\rho,\tau}\quad\forall\,\tau\in(T,\min(T_1,T_2))\,. \tag{A.6}$$

(ii) For any $\tau\in(T,\tau^*)$ and any $(y_1,\gamma_1),(y_2,\gamma_2)\in\mathfrak{M}_{\rho,\tau}$ the following estimates hold:

$$\begin{aligned}
&\|\mathbf{\Pi}_1\mathbf{N}_\tau(y_1,\gamma_1)-\mathbf{\Pi}_1\mathbf{N}_\tau(y_2,\gamma_2)\|^2_{L^2(T,\tau)}\\
&\quad=\int_0^\tau\left(\int_0^t(\mathbf{P}_{T-\tau}F)(t-\xi)(\mathcal{K}(\gamma_1(\xi))y_1(\xi)-\mathcal{K}(\gamma_2(\xi))y_2(\xi))\,d\xi\right)^2dt\\
&\quad\leq\left(\int_0^\tau\|(\mathbf{P}_{\tau-T}F)(\xi)\|\,d\xi\right)^2\int_0^\tau\|\mathcal{K}(\gamma_1(\xi))y_1(\xi)-\mathcal{K}(\gamma_1(\xi))y_2(\xi)\\
&\qquad\qquad+\mathcal{K}(\gamma_1(\xi))y_2(\xi)-\mathcal{K}(\gamma_2(\xi))y_2(\xi)\|^2\,d\xi\\
&\quad\leq 2\left(\int_0^{\tau-T}\|F(\xi)\|\,d\xi\right)^2\left(K^2\int_T^\tau\|y_1(\xi)-y_2(\xi)\|^2\,d\xi\right.\\
&\qquad\qquad\left.+\;L^2\left(\int_0^\tau\|y_2(\xi)\|^2\,d\xi\right)\|\gamma_1-\gamma_2\|^2_{L^\infty(T,\tau)}\right),
\end{aligned} \tag{A.7}$$

where we have chosen $K>0$ and $L>0$ in such a way that for all real numbers κ, κ_1 and κ_2 with $|\kappa|,|\kappa_1|,|\kappa_2|\leq\max(\|g\|_{L^\infty(0,T)},\rho+\|\gamma^0\|_{L^\infty(T,\tau^*)}+\|f\|^2_{L^2(0,T)})$

$$\mathcal{K}(\kappa)\leq K\quad\text{and}\quad|\mathcal{K}(\kappa_1)-\mathcal{K}(\kappa_2)|\leq L|\kappa_1-\kappa_2|\,.$$

Realizing that

$$\int_0^\tau\|y_2(\xi)\|^2\,d\xi\leq\|f\|^2_{L^2(0,T)}+\|y^0\|^2_{L^2(T,\tau)}+\rho^2\,,$$

it follows from (A.7) that there exists $M > 0$ such that for all $\tau \in (T, \tau^*)$ and all $(y_1, \gamma_1), (y_2, \gamma_2) \in \mathfrak{M}_{\rho,\tau}$

$$\|\mathbf{\Pi}_1 \mathbf{N}_\tau(y_1, \gamma_1) - \mathbf{\Pi}_1 \mathbf{N}_\tau(y_2, \gamma_2)\|^2_{L^2(T,\tau)} \\ \leq M \left(\int_0^{\tau - T} \|F(\xi)\| \, d\xi \right)^2 (\|y_1 - y_2\|^2_{L^2(T,\tau)} + \|\gamma_1 - \gamma_2\|^2_{L^\infty(T,\tau)}).$$

Defining

$$\delta'_\tau := \sqrt{M} \int_0^{\tau - T} \|F(\xi)\| \, d\xi \,, \tag{A.8}$$

we obtain that for all $\tau \in (T, \tau^*)$ and all $(y_1, \gamma_1), (y_2, \gamma_2) \in \mathfrak{M}_{\rho,\tau}$

$$\|\mathbf{\Pi}_1 \mathbf{N}_\tau(y_1, \gamma_1) - \mathbf{\Pi}_1 \mathbf{N}_\tau(y_2, \gamma_2)\|_{L^2(T,\tau)} \leq \delta'_\tau (\|y_1 - y_2\|_{L^2(T,\tau)} + \|\gamma_1 - \gamma_2\|_{L^\infty(T,\tau)}) \,. \tag{A.9}$$

Furthermore, we have that for all $(y_1, \gamma_1), (y_2, \gamma_2) \in \mathfrak{M}_{\rho,\tau}$

$$\begin{aligned} &\|\mathbf{\Pi}_2 \mathbf{N}_\tau(y_1, \gamma_1) - \mathbf{\Pi}_2 \mathbf{N}_\tau(y_2, \gamma_2)\|_{L^\infty(T,\tau)} \\ &\qquad = \sup_{t \in [T,\tau]} \left| \int_T^t \|y_1(\xi)\|^2 \, d\xi - \int_T^t \|y_2(\xi)\|^2 \, d\xi \right| \\ &\qquad \leq \int_T^\tau (\|y_1(\xi)\| + \|y_2(\xi)\|) \|y_1(\xi) - y_2(\xi)\| \, d\xi \\ &\qquad \leq (\|y_1\|_{L^2(T,\tau)} + \|y_2\|_{L^2(T,\tau)}) \|y_1 - y_2\|_{L^2(T,\tau)} \\ &\qquad \leq 2(\rho + \|y^0\|_{L^2(T,\tau)}) \|y_1 - y_2\|_{L^2(T,\tau)} \,. \end{aligned} \tag{A.10}$$

Setting

$$\delta''_\tau := 2(\rho + \|y^0\|_{L^2(T,\tau)}) \,, \tag{A.11}$$

it follows from (A.10) that for all $(y_1, \gamma_1), (y_2, \gamma_2) \in \mathfrak{M}_{\rho,\tau}$

$$\|\mathbf{\Pi}_2 \mathbf{N}_\tau(y_1, \gamma_1) - \mathbf{\Pi}_2 \mathbf{N}_\tau(y_2, \gamma_2)\|_{L^\infty(T,\tau)} \leq \delta''_\tau \|y_1 - y_2\|_{L^2(T,\tau)} \,. \tag{A.12}$$

Clearly, since $\rho < \frac{1}{2}$ and by (A.8) and (A.11), there exists $T_3 \in (T, \tau^*)$ such that $\delta_\tau := \max(\delta'_\tau, \delta''_\tau) < 1$ for all $\tau \in (T, T_3)$. Setting $T^* = \min(T_1, T_2, T_3)$, we see that $T^* > T$, $\delta_\tau < 1$ for all $\tau \in (T, T^*)$, and moreover, by (A.6), (A.9), and (A.12), we have that for all $\tau \in (T, T^*)$ and all $(y_1, \gamma_1), (y_2, \gamma_2) \in \mathfrak{M}_{\rho,\tau}$

$$\mathbf{N}_\tau \mathfrak{M}_{\rho,\tau} \subset \mathfrak{M}_{\rho,\tau} \,, \quad \|\mathbf{N}_\tau(y_1, \gamma_1) - \mathbf{N}_\tau(y_2, \gamma_2)\|_{(T,\tau)} \leq \delta_\tau \|(y_1, \gamma_1) - (y_2, \gamma_2)\|_{(T,\tau)} \,.$$

Finally, it follows from Banach's contraction mapping theorem that for all τ as above $\mathbf{N}_\tau$ has a unique fixed point in $\mathfrak{M}_{\rho,\tau}$. □

Proof of Proposition 2.4. We proceed in several steps.

Step 1 (existence and uniqueness on a small interval). An application of Lemma A.1 to the case where $T = 0$, $y^0 = \mathbf{\Psi}_\infty x_0$, $\gamma^0(t) \equiv \gamma_0$ and $F = -\mathbb{L}^{-1}\mathbf{G}$ shows that for all sufficiently small $\tau > 0$ the operator $\mathbf{N}_\tau$ has a unique fixed point in $\mathfrak{M}_{\rho,\tau}$ and hence there exists $\tau^* > 0$ such that (2.11) has a unique solution (y^*, γ^*) on $[0, \tau^*)$.

Step 2 (continuation of solutions). If $\|y^*\|_{L^2(0,\tau^*)} = \infty$, then $\tau_{max} = \tau^*$ and $(y_{max}, \gamma_{max}) = (y^*, \gamma^*)$, and we are finished. Thus, let us suppose that $\|y^*\|_{L^2(0,\tau^*)} <$

∞. We claim that then the solution (y^*, γ^*) can be extended beyond τ^*. To this end we apply Lemma A.1 to the case where $T = \tau^*$, $(f, g) = (y^*, \gamma^*)$, $y^0 = (\mathbf{\Psi}_\infty x_0)|_{[\tau^*,\infty)}$, $\gamma^0(t) \equiv \gamma_0$, and $F = -\mathbb{L}^{-1}\mathbf{G}$. It follows that there exist $\tau^{**} > \tau^*$ and $(y^{**}, \gamma^{**}) \in L_{(0,\tau^{**})}$ such that $(y^{**}, \gamma^{**})|_{[0,\tau^*]} = (y^*, \gamma^*)$, and moreover (y^{**}, γ^{**}) solves (2.11) on $[0, \tau^{**})$.

Step 3 (extended uniqueness). Let (y_1, γ_1) and (y_2, γ_2) be two solutions of (2.11) on $[0, \tau_1)$ and $[0, \tau_2)$, respectively, where $\tau_2 \geq \tau_1 > 0$. We claim that

$$(y_2(t), \gamma_2(t)) = (y_1(t), \gamma_1(t)) \quad \text{for a.e. } t \in [0, \tau_1)\,. \tag{A.13}$$

For $\tau \in [0, \tau_1)$ define

$$\Omega_\tau := \{t \in [0, \tau] \,|\, (y_1(t), \gamma_1(t)) \neq (y_2(t), \gamma_2(t))\}\,,$$

and set

$$\hat{\tau} := \inf\{\tau \in [0, \tau_1) \,|\, \boldsymbol{\lambda}(\Omega_\tau) > 0\}\,,$$

where $\boldsymbol{\lambda}$ denotes the Lebesgue measure. It is clear that (A.13) is equivalent to $\hat{\tau} = \tau_1$. Seeking a contradiction, assume that $\hat{\tau} < \tau_1$. Let $t_n \in (0, \hat{\tau})$ with $\lim_{n\to\infty} t_n = \hat{\tau}$. (Recall that by Step 1, $\hat{\tau} > 0$.) Obviously,

$$\Omega_{\hat{\tau}} \setminus \{\hat{\tau}\} = \bigcup_{n\in\mathbb{N}} \Omega_{t_n}\,.$$

Now $\boldsymbol{\lambda}(\Omega_{t_n}) = 0$ for all $n \in \mathbb{N}$, and thus $\boldsymbol{\lambda}(\Omega_{\hat{\tau}}) = 0$, which in turn implies that for a.e. $t \in [0, \hat{\tau}]$

$$(y_1(t), \gamma_1(t)) = (y_2(t), \gamma_2(t)) =: (\hat{y}(t), \hat{\gamma}(t))\,.$$

An application of Lemma A.1 to the case where $T = \hat{\tau}$, $(f, g) = (\hat{y}, \hat{\gamma})$, $y^0 = (\mathbf{\Psi}_\infty x_0)|_{[\hat{\tau},\infty)}$, $\gamma^0(t) \equiv \gamma_0$, and $F = -\mathbb{L}^{-1}\mathbf{G}$ shows that there exists $t^* \in (\hat{\tau}, \tau_1)$ such that the operator $\mathbf{N}_{t^*}$ has a unique fixed point in $\mathfrak{M}_{\rho,t^*}$. Since the restrictions of (y_1, γ_1) and of (y_2, γ_2) to $[0, t^*]$ are both fixed points of $\mathbf{N}_{t^*}$, we see that $(y_1, \gamma_1)|_{[0,t^*]} = (y_2, \gamma_2)|_{[0,t^*]}$, which is in contradiction to the definition of $\hat{\tau}$.

Step 4 (existence of a maximal solution). Define

$$\mathfrak{T} := \{\tau > 0 \,|\, (2.11) \text{ has a solution on } [0, \tau)\}\,.$$

Set $\tau_{max} := \sup \mathfrak{T}$ and let $\tau_n \in \mathfrak{T}$ be such that $\tau_n \nearrow \tau_{max}$ as $n \to \infty$. Let (y_n, γ_n) denote the unique (by Step 3) solution of (2.11) on $[0, \tau_n)$. Using Step 3 again it is clear that $(y_n, \gamma_n)_{[0,\tau_m]} = (y_m, \gamma_m)$ for all $m, n \in \mathbb{N}$ with $n > m$. Therefore, we obtain a well-defined function (y_{max}, γ_{max}) on $[0, \tau_{max})$ by setting

$$(y_{max}(t), \gamma_{max}(t)) = (y_n(t), \gamma_n(t)) \quad \text{if } t \in [0, \tau_n)\,.$$

By construction (y_{max}, γ_{max}) is a solution of (2.11) on $[0, \tau_{max})$, which, by Step 3, is unique. Finally, it follows from Step 2 and the definition of τ_{max} that

$$\tau_{max} < \infty \quad \Longrightarrow \quad \int_0^{\tau_{max}} \|y_{max}(\xi)\|^2\, d\xi = \infty\,. \qquad \square$$

REGULARIZATION OF LINEAR DESCRIPTOR SYSTEMS WITH VARIABLE COEFFICIENTS*

RALPH BYERS†, PETER KUNKEL‡, AND VOLKER MEHRMANN§

Abstract. We study linear descriptor control systems with rectangular variable coefficient matrices. We introduce condensed forms for such systems under equivalence transformations and use these forms to detect whether the system can be transformed to a uniquely solvable closed loop system via state or derivative feedback. We show that under some mild assumptions every such system consists of an underlying square subsystem that behaves essentially like a standard state space system, plus some solution components that are constrained to be zero.

Key words. Descriptor systems, differential algebraic equations, condensed forms, smooth singular value decomposition, strangeness index, regularization, linear feedback

1. Introduction.

In this paper we study linear variable coefficient descriptor systems

$$E(t)\dot{x}(t) = A(t)x(t) + B(t)u(t) \tag{1}$$

in the interval $[t_0, t_1] \subset \mathcal{R}$ together with an initial condition

$$x(t_0) = x_0. \tag{2}$$

If we denote by $C^r([t_0, t_1], \mathcal{C}^{n,\ell})$ the set of r-times continuously differentiable functions from the interval $[t_0, t_1]$ to the vector space $\mathcal{C}^{n,\ell}$ of complex $n \times \ell$ matrices, then we assume that

$$\begin{array}{ll} E(t), A(t) \in C([t_0, t_1], \mathcal{C}^{n,\ell}), & \\ B(t) \in C([t_0, t_1], \mathcal{C}^{n,m}), & \\ x(t) \in C([t_0, t_1], \mathcal{C}^{\ell}) & \text{is the state of the system,} \\ u(t) \in C([t_0, t_1], \mathcal{C}^{m}) & \text{is the control of the system.} \end{array} \tag{3}$$

Descriptor systems of the form (1) are used in modeling control problems for mechanical multibody systems [32, 30, 31] or electrical circuits [16]. They are also obtained as linearizations of general nonlinear systems along trajectories [6].

In order to study the properties of such systems one needs an understanding of the behavior of the corresponding differential algebraic equations (DAEs). However,

fundamentally different definitions of solvability, index, etc., appear in the literature. See, for example, [1, 18]. These different definitions lead to different results, although only a few have been achieved so far [7, 8]. In particular, the latter results use the solvability concepts for differential algebraic equations as described in [1, 9, 10, 6].

In recent papers, Kunkel and Mehrmann have discussed a more general solvability concept and developed canonical forms [18, 20], existence and uniqueness theorems [18, 21], and numerical methods [22, 23] for linear variable coefficient DAEs. Extensions to this approach have recently been given by Rabier and Rheinboldt [27].

Several generalizations of the concept of index have also been discussed in the literature. The approach in [7, 8] is based on the solvability concept in [9]. Another approach based on generic solvability is discussed in [14].

It is our ultimate goal to develop numerical methods that allow the computation of the invariants in finite precision arithmetic. We do not discuss the generic approach here, because it is better suited for computer algebra computation. Instead, we will briefly discuss the two different solvability concepts of [9] and [18] in section 2 and give some extensions of solvability results discussed in [18, 20, 27].

We then show in section 3 that analogous methods can be used to study the properties of linear descriptor systems with variable coefficients. We obtain condensed forms for linear systems which display properties of the system.

In section 4 we show that under some mild assumptions every rectangular variable coefficient descriptor system has an underlying square system which in principle behaves like a standard linear state space system, together with some purely algebraic equations and some solution components which are constrained to be zero.

In section 5 we study the question whether the solvability properties of descriptor systems can be improved by different types of feedback, i.e., whether appropriate linear time-varying feedbacks can be chosen, so that the closed loop system is uniquely solvable for all consistent initial conditions. This topic has been discussed for linear, constant coefficient descriptor systems in [5]. There, it is shown (in the square case $n = \ell$) that uncontrollable higher index modes are constrained to be zero. Thus, regularizable descriptor systems consist of a subsystem that can be made index one via feedback together with some zero components of the state. In this paper we come to essentially the same conclusion for time-varying descriptor systems despite the fact that the transformations are more complex.

2. Existence and uniqueness of solutions of linear time-varying DAEs. We begin our analysis of the descriptor system (1), (2) with the following definition from [18, 20] on the solvability of linear variable coefficient DAEs of the form

$$E(t)\dot{x}(t) = A(t)x(t) + f(t), \quad t \in [t_0, t_1] \subset \mathcal{R} \tag{4}$$

with initial condition (2), E, A as in (3), and $f \in C([t_0, t_1], \mathcal{C}^n)$.

DEFINITION 2.1. *A function $x : [t_0, t_1] \to \mathcal{C}^\ell$ is a* solution *of* (4) *if $x \in C^1([t_0, t_1], \mathcal{C}^\ell)$ and x satisfies* (4) *pointwise. It is a* solution of the initial value problem (4), (2) *if x is solution of* (4) *and x satisfies* (2). *An initial condition* (2) *is called* consistent *if the corresponding initial value problem is solvable, i.e., has at least one solution.*

The definition of solvability is still a subject of discussion in the literature. Often it is required that a solution exists for all sufficiently differentiable inhomogeneities [1, p. 22]. Alternatively, only a well-behaved manifold of solutions is required [28]. Also, unique dependence on initial conditions is sometimes incorporated in the definition of solvability [1, 7].

The difficulty is illustrated by the following examples.

Example 1. Consider the DAE

$$\begin{bmatrix} -t & t^2 \\ -1 & t \end{bmatrix} \dot{x}(t) = \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix} x(t), \qquad t \in [-1, 1].$$

By Definition 2.1

$$x(t) = c(t) \begin{bmatrix} t \\ 1 \end{bmatrix}$$

is a solution for all $c \in C^1([-1, 1], \mathcal{C})$. Nevertheless, this DAE is not solvable in the sense of [1].

Example 2. The linear DAE

$$\begin{bmatrix} 0 & t \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \dot{x}_1(t) \\ \dot{x}_2(t) \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x_1(t) \\ x_2(t) \end{bmatrix} + \begin{bmatrix} f_1(t) \\ f_2(t) \end{bmatrix}$$

has the solution $x_1(t) = -t\dot{f}_2(t) - f_1(t)$ and $x_2(t) = -f_2(t)$. Although the matrix E changes rank, no singularity appears in the solution. This DAE does not satisfy the hypothesis of the solvability theorem in [18], but as shown in [27], the requirement of constant rank for E can be relaxed in this case and an extension of the solvability theorem under weaker assumptions is true. This system also satisfies the hypothesis of the solvability theorem in [1, p. 30].

Example 3. A special case of (4) is the purely algebraic equation $0 = A(t)x(t) + f(t)$. If $A(t)$ is nonsingular, then there is a unique solution $x(t) = -A(t)^{-1}f(t)$ regardless of the smoothness of $f(t)$. However, this DAE is not solvable in the sense of [1] unless $f(t)$ is differentiable, because the equivalent ODE is $A(t)\dot{x}(t) = -\dot{A}(t)x(t) + \dot{f}(t)$. Although this system is also not solvable in the sense of [18], the normal form given in [18] exists and suggests the introduction of a weaker solution concept; see also [15]. If $A(t)$ drops rank for some t, then one has to apply the extension of the theory in [18, 20] given in [27] to show solvability. The weakness in [1], which is used in the context of control problems in [7, 8], is that it requires differentiability of all components of the inhomogeneity which is usually not the case in the applications from control. Another weakness of this concept is that it does not apply to rectangular systems. The concept introduced in [18] with the extensions given in [20, 27] is more general, is better suited to control problems, and applies to rectangular systems and distributional solutions. This is the reason why we prefer [18] to [1]. In this paper we will, however, discuss only classical solutions in the sense of Definition 2.1.

Remark 1. A simple but useful trick that removes some but not all of the discussed difficulties with the solvability concept is the following. If we add the term $\dot{E}(t)x(t)$ on both sides of (4), we obtain

$$\frac{d}{dt}(E(t)x(t)) = (A(t) + \dot{E}(t))x(t) + f(t). \tag{5}$$

In this form we would have to require sufficient smoothness of $x(t)$ only in the range of $E(t)^T$. This would allow weaker differentiability assumptions for x at the cost of smoothness assumptions for E. Such an approach would be more suitable for index one problems in particular, since exactly the differentiability that is needed is displayed. But as is shown in [18] for higher index problems, it is still not possible to identify the exact differentiability conditions without going to a canonical form. In

order to avoid confusion with the existing literature we therefore use the solvability condition introduced in Definition 2.1.

Another modification of the solvability concept that has been used frequently with constant coefficient systems is to restrict the initial conditions to the range of E by requiring

$$E(t_0)x(t_0) = E(t_0)x_0. \tag{6}$$

This would be in line with (5). We will determine in general what the exact consistency conditions for the initial values are in the following. Since these include not only modifications like (6) but also others, we will use the more general condition in Definition 2.1.

The standard variable coefficient transformations that can be applied to linear DAEs are changes of bases, i.e., $x(t) = Q(t)y(t)$, and premultiplication of (1) by $P(t)$. Under these transformations (4) transforms to

$$P(t)E(t)Q(t)\dot{y}(t) = (P(t)A(t)Q(t) - P(t)E(t)\dot{Q}(t))y(t) + P(t)f(t). \tag{7}$$

DEFINITION 2.2. *Two pairs of matrix functions* $(E_i(t),\ A_i(t))$, $E_i,\ A_i \in C([t_0, t_1], \mathcal{C}^{n,\ell})$, $i = 1, 2$ *are* equivalent *if there exist* $P \in C([t_0, t_1], \mathcal{C}^{n,n})$ *and* $Q \in C^1([t_0, t_1], \mathcal{C}^{\ell,\ell})$ *with* $P(t)$, $Q(t)$ *nonsingular for all* $t \in [t_0, t_1]$ *such that*

$$(E_2(t), A_2(t)) = P(t)(E_1(t), A_1(t)) \begin{bmatrix} Q(t) & -\dot{Q}(t) \\ 0 & Q(t) \end{bmatrix}. \tag{8}$$

Based on suitable equivalence transformations we will now extend the solvability theorems of [18, 20, 27].

To simplify the notation in the condensed forms, we denote in the following by $\Sigma_j(t)$ a square diagonal matrix valued function of dimension $j \times j$ which is invertible for all but finitely many $t \in [t_0, t_1]$. We also denote blocks of a matrix which are not specifically needed but which are not necessarily identically zero by $*$ and zero blocks of all dimensions by 0.

We construct the condensed form via smooth unitary equivalence transformations. This displays the invariants of the system but does not produce a canonical form but rather a condensed staircase form in the sense of Van Dooren [33] from which invariants can be read off. To do the transformations we use smooth singular value decompositions as they were introduced in [2] and for which several numerical methods are available [2, 25, 34]. To apply these transformations, we need derivatives of the right transformations. These can be obtained numerically from the original matrix function $E(t)$ and its derivatives using the method described in [17]. Note, however, that the following theorem and the construction procedure in the proof cannot be applied as a practical numerical algorithm. Nevertheless, it gives an indication how the computation of the invariants can be carried out locally. (For a discussion of this topic for DAEs see [18]. The extension to descriptor systems is currently being investigated.) One step of the construction given in the proof of the following theorem can be carried out locally. If more steps are needed, then local computation is not applicable in the given form. For the use of determining the required information on the global invariants via local computation see [22].

THEOREM 2.3. *Given analytic matrix-valued functions* $E(t)$, $A(t)$ *as in* (3) *there exist unitary analytic matrix-valued functions* $P(t)$, $Q(t)$, *as in* (8) *such that the*

matrices $P(t)E(t)Q(t)$, $P(t)A(t)Q(t) - P(t)E(t)\dot{Q}(t)$ have the following form:

$$\begin{array}{c} d_\mu \\ a_\mu \\ u^l_\mu \end{array} \begin{bmatrix} E_{11}(t) & E_{12}(t) & 0 \\ 0 & E_{22}(t) & 0 \\ 0 & E_{32}(t) & 0 \end{bmatrix}, \begin{bmatrix} A_{11}(t) & A_{12}(t) & A_{13}(t) \\ 0 & A_{22}(t) & 0 \\ 0 & A_{32}(t) & 0 \end{bmatrix}, \tag{9}$$

where $E_{11}(t)$ is diagonal and nonsingular except for isolated points, $E_{22}(t)$, $E_{32}(t)$, and $A_{32}(t)$ are block upper triangular with zero diagonal blocks, and $A_{22}(t)$ is block upper triangular with diagonal blocks which are nonsingular except for isolated points. The block columns have sizes d_μ, a_μ, u^r_μ. (Note that 0×0 matrices are diagonal and invertible, e.g., [11].*)*

Proof. The proof is constructive using a sequence of analytic singular value decompositions (ASVDs); see [2]. In the following we drop the dependence on t in the formulas. Consider the following recursive procedure:

Begin: Let $E_0 = E$, $A_0 = A$ and set $j = 0$, $n_j = n$, $\ell_j = \ell$.

(1) Let P_1, Q_1 be unitary matrices of appropriate dimensions that produce an ASVD of E_0 such that

$$E_1 := P_1^* E_0 Q_1 = \begin{bmatrix} \Sigma_{r_j} & 0 \\ 0 & 0 \end{bmatrix}.$$

Set

$$A_1 := P_1^* A_0 Q_1 - P_1^* E_0 \dot{Q}_1 = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}.$$

If $r_j = n_j$, i.e., E_1 has full row rank except for isolated points, then we **STOP** the process here.

(2) Let $\tilde{P}_2, Q_2$ be unitary matrices that produce a permuted ASVD of $\begin{bmatrix} A_{21} & A_{22} \end{bmatrix}$:

$$\tilde{P}_2^* \begin{bmatrix} A_{21} & A_{22} \end{bmatrix} Q_2 = \begin{bmatrix} 0 & \Sigma_{t_j} \\ 0 & 0 \end{bmatrix}.$$

Set

$$P_2 := \begin{bmatrix} I_{r_j} & 0 \\ 0 & \tilde{P}_2 \end{bmatrix},$$

and set

$$E_2 := P_2^* E_1 Q_2 = \left[\begin{array}{c|c} \tilde{E}_{11} & \tilde{E}_{12} \\ \hline 0 & 0 \\ 0 & 0 \end{array}\right], \; A_2 := P_2^* A_1 Q_2 - P_2^* E_1 \dot{Q}_2 = \left[\begin{array}{c|c} \tilde{A}_{11} & \tilde{A}_{12} \\ \hline 0 & \Sigma_{t_j} \\ 0 & 0 \end{array}\right].$$

The row dimensions are now $r_j, t_j, p_j = n_j - r_j - t_j$ and the column dimensions are $\ell_j - t_j, t_j$.

We then set $n_{j+1} := r_j$, $\ell_{j+1} := \ell_j - t_j$, $E_0 := \tilde{E}_{11}$, $A_0 := \tilde{A}_{11}$, and $j = j + 1$ and repeat the process from step (1) by applying transformations always to the complete system via an appropriate embedding of the transformation matrices.

end

It is clear that the procedure is finite, since n_j decreases in each step. At the end of this recursion we have the form

$$P(t)E(t)Q(t) = \left[\begin{array}{c|c|c|c|c|c} \Sigma_{n_\mu}(t) & 0 & * & * & \dots & * \\ \hline 0 & 0 & 0 & * & \dots & * \\ 0 & 0 & 0 & * & \dots & * \\ \hline & & & 0 & \ddots & \vdots \\ & & & & & \\ & & & 0 & & \vdots \\ \hline & & & & \ddots & \vdots \\ \hline & & & & & 0 \\ & & & & & 0 \end{array}\right] \begin{array}{l} n_\mu \\ \hline t_{\mu-1} \\ p_{\mu-1} \\ \hline t_{\mu-2} \\ \\ p_{\mu-2} \\ \hline \vdots \\ \hline t_0 \\ p_0 \end{array}, \tag{10}$$

$$P(t)A(t)Q(t) - P(t)E(t)\dot{Q}(t)$$

$$= \left[\begin{array}{c|c|c|c|c|c} \hat{A}_{11}(t) & \hat{A}_{12}(t) & * & * & \dots & * \\ \hline 0 & 0 & \Sigma_{t_{\mu-1}}(t) & * & \dots & * \\ 0 & 0 & 0 & * & \dots & * \\ \hline & & & \Sigma_{t_{\mu-2}}(t) & \dots & * \\ & & & 0 & \dots & * \\ \hline & & & & \ddots & \vdots \\ \hline & & & & & \Sigma_{t_0}(t) \\ & & & & & 0 \end{array}\right] \begin{array}{l} n_\mu \\ \hline t_{\mu-1} \\ p_{\mu-1} \\ \hline t_{\mu-2} \\ p_{\mu-2} \\ \hline \vdots \\ \hline t_0 \\ p_0 \end{array}. \tag{11}$$

We then set $E_{11}(t) = \Sigma_{n_\mu}(t)$ and permute the second block column to the end and the block rows in the order $1, 2, 4, 6, \dots, 3, 5, 7, \dots$ to obtain the final form with $d_\mu = n_\mu$, $a_\mu = t_0 + \cdots + t_\mu$, $u_\mu^l = n - a_\mu - d_\mu$, and $u_\mu^r = \ell - a_\mu - d_\mu$. □

Remark 2. Note that the analyticity assumption on the coefficient matrices can be relaxed to the condition that all smooth singular value decompositions exist and that rank changes in the factored matrices occur only at isolated points. This property is hard to quantify, however, since already infinite differentiability of the coefficient matrices may not be enough to guarantee the existence of such a decomposition with once-differentiable unitary factors; see [2]. The construction given in the proof of Theorem 2.3 is similar to the construction given in [18], but it needs fewer assumptions; in particular, no constant rank assumptions are needed.

Remark 3. The block sizes $t_{\mu-1}, \dots, t_0, p_{\mu-1}, \dots, p_0$ can be combined to determine the invariants of the equivalence transformation. However, (10) does not display all invariants, so it is a condensed form—not a canonical form. The quantities d_μ, a_μ, u_μ^ℓ, u_μ^r are invariants (see [18]), and they determine existence and uniqueness, as is shown in the following corollary. The condensed form is analogous to the staircase form of Van Dooren [33], which is a condensed form for constant matrix pencils that displays some of the invariants of the Kronecker canonical. Such condensed forms are useful, because they allow one to compute the relevant information via unitary transformations, which can be implemented in a numerically stable way. The quantity μ is called the *strangeness index* of the DAE, and it is a generalization of the differentiation index, e.g., [1, 18, 27, 21]. A variant of the solvability theorem of [20] is then as follows.

COROLLARY 2.4. *Let $(E(t), A(t))$ be analytic matrix-valued functions as in* (3) *and $f \in C^\mu([t_0, t_1], \mathcal{C}^n)$. Then,* (4) *is equivalent to a DAE of the form*

$$
\begin{aligned}
&\text{(a)} \quad \Sigma_{d_\mu}(t)\dot{x}_1(t) + E_{12}(t)\dot{x}_2(t) \\
&\qquad\qquad = A_{11}(t)x_1(t) + A_{12}(t)x_2(t) + A_{13}(t)x_3(t) + f_1(t), \\
&\text{(b)} \quad E_{22}(t)\dot{x}_2(t) = A_{22}(t)x_2(t) + f_2(t), \\
&\text{(c)} \quad E_{32}(t)\dot{x}_2(t) = A_{32}(t)x_2(t) + f_3(t),
\end{aligned} \tag{12}
$$

where the inhomogeneity is determined by $f^{(0)}, \ldots, f^{(\mu)}$ *and* $E_{22}(t)$, $E_{32}(t)$, $A_{22}(t)$, *and* $A_{32}(t)$ *are as in* (9). *In particular,* d_μ, a_μ, u_μ^r *are the numbers of differential, algebraic, and undetermined components of the unknown* x *in* (a), (b), *while* u_μ^l *is the number of conditions in* (c). *In particular, if in addition* $f \in C^{\mu+1}([t_0, t_1], \mathcal{C}^n)$, *then equation* (4) *is solvable if and only if the following properties hold:*

(i) *At isolated points where the diagonal matrix* $\Sigma_{d_\mu}(t)$ *or the diagonal blocks of* $A_{22}(t)$ *are singular, the components in* $x_3(t)$ *(if they occur) can be chosen so that the solution can be completed in a continuously differentiable way.*

(ii) *The conditions in* (12(b)) *are satisfied at the initial point.*

(iii) *The* u_μ^l *functional consistency conditions in* (12(c)) *are satisfied for* $x_2(t)$, *which is fixed by* (12(b)). (*Observe that* (12(b)) *fixes* $x_2(t)$ *by recursive insertion and differentiation except for points where the diagonal blocks of* $A_{22}(t)$ *are singular, using the nilpotency structure of* $E_{22}(t)$.)

An initial condition (2) *is consistent if and only if the* a_μ *conditions*

$$
E_{22}(t_0)\dot{x}_2(t_0) = A_{22}(t_0)x_2(t_0) + f_2(t_0) \tag{13}
$$

yield an $x_2(t_0)$ *which coincides with solution of* (12(b)) *at* t_0.

The initial value problem (1), (2) *is uniquely solvable if we also have*

$$
u_\mu^r = 0. \tag{14}
$$

Otherwise, we can choose $x_3(t) \in C^1([t_0, t_1], \mathcal{C}^{u_\mu^r})$ *arbitrarily.*

Proof. The proof follows directly from Theorem 2.3. Considering the second block equation, we obtain from the form of $E_{22}(t), A_{22}(t)$ that we can recursively solve for the solution components. The diagonal blocks of $A_{22}(t)$ are diagonal matrices which are invertible except possibly at isolated points. In these points we have to be able to complete the solution in a smooth way, since these components then have to be differentiated to continue the solution process. There are μ differentiations necessary to completely solve for the second block. Inserting $\dot{x}_2$ and x_2 and choosing x_3 we can solve equation (12(a)) except at points where the matrix $\Sigma_{d_\mu}(t)$ is singular. The same argument as above applies in these points. The remaining assertions are straightforward. □

In this section we have given a generalization of the condensed form and the solvability results of [18, 20, 27]. We do not need to apply constant rank assumptions, but we need assumptions that guarantee the existence of all ASVDs according to Remark 2. Here we could generalize the construction to weak solvability, which would allow us to drop some further smoothness assumptions; see [27]. In the next section we perform the corresponding construction for linear systems.

3. Condensed forms for linear descriptor systems. In this section we discuss the set of equivalence transformations that we will apply to variable coefficient descriptor systems and canonical forms under these transformations. Using these forms, we obtain information about the system properties. For constant coefficient systems such forms have been studied for general transformations in [24] and for unitary transformations in [3, 4, 5]. The results that we give here generalize the results for the unitary case even for constant coefficient systems.

Observe that we cannot apply directly the solvability result of section 2, since *usually we cannot assume* that the input functions $u(t)$ are sufficiently differentiable. In principle we can apply differentiation of components only in the uncontrollable subspace, i.e., the part of the system operating in the left nullspace of $B(t)$. Note that this is a major difference to the approach in [7, 8], where it is assumed that the input functions are sufficiently smooth.

We use the following global equivalence transformations for the triple of matrix valued functions $(E(t), A(t), B(t))$.

DEFINITION 3.1. *Two triples of matrix functions* $(E_i(t), A_i(t), B_i(t))$, $E_i, A_i \in C([t_0, t_1], \mathcal{C}^{n,\ell})$, $B_i \in C([t_0, t_1], \mathcal{C}^{n,m}), i = 1, 2$ *are called* equivalent *if there exist* $P \in C([t_0, t_1], \mathcal{C}^{n,n})$, $Q \in C^1([t_0, t_1], \mathcal{C}^{\ell,\ell})$ *and* $W \in C([t_0, t_1], \mathcal{C}^{m,m})$ *with* $P(t), Q(t), W(t)$ *nonsingular for all* $t \in [t_0, t_1]$ *such that*

$$(E_2(t), A_2(t), B_2(t)) = P(t)(E_1(t), A_1(t), B_1(t)) \begin{bmatrix} Q(t) & -\dot{Q}(t) & 0 \\ 0 & Q(t) & 0 \\ 0 & 0 & W(t) \end{bmatrix}. \tag{15}$$

It is easily checked that the above transformations describe equivalence transformations.

We obtain the following condensed form.

THEOREM 3.2. *Given analytic matrix-valued functions* $E(t)$, $A(t)$, $B(t)$ *as in* (3) *there exist unitary analytic matrix-valued functions* $P(t)$, $Q(t)$, $W(t)$ *as in* (15) *such that the three matrices* $P(t)E(t)Q(t)$, $P(t)A(t)Q(t) - P(t)E(t)\dot{Q}(t)$, *and* $P(t)B(t)W(t)$ *have the following form:*

$$\begin{array}{c} \begin{array}{c} d_\nu \\ v_\nu \\ \hline s_\nu \\ \hline \tilde{u}_\nu^l \\ \hline u_\nu^l \end{array} \left[\begin{array}{cc|c|c} \Sigma_{d_\nu}(t) & 0 & E_{13}(t) & 0 \\ 0 & 0 & E_{23}(t) & 0 \\ \hline 0 & 0 & E_{33}(t) & 0 \\ \hline 0 & 0 & E_{43}(t) & 0 \\ \hline 0 & 0 & E_{53}(t) & 0 \end{array}\right], \\ \left[\begin{array}{cc|c|c} A_{11}(t) & A_{12}(t) & A_{13}(t) & A_{14}(t) \\ A_{21}(t) & A_{22}(t) & A_{23}(t) & A_{24}(t) \\ \hline 0 & 0 & A_{33}(t) & 0 \\ \hline A_{41}(t) & A_{42}(t) & A_{43}(t) & A_{44}(t) \\ \hline 0 & 0 & A_{53}(t) & 0 \end{array}\right], \quad \left[\begin{array}{ccc} B_{11}(t) & B_{12}(t) & B_{13}(t) \\ \Sigma_{v_\nu}(t) & 0 & 0 \\ \hline 0 & 0 & 0 \\ \hline 0 & \Sigma_{\tilde{u}_\nu^l}(t) & 0 \\ \hline 0 & 0 & 0 \end{array}\right] \end{array} \tag{16}$$

with $E_{33}(t)$ *block upper triangular with zero diagonal blocks, and* $A_{33}(t)$ *block upper triangular with diagonal blocks which are diagonal matrices that are nonsingular except for isolated points. The block columns in* E, A *have sizes* d_ν, v_ν, s_ν, u_ν^r.

Proof. The proof is constructive using again a sequence of analytic singular value decompositions (ASVDs). We again drop the dependence on t in the formulas. Consider the following recursive procedure:

Begin:

Let $E_0 = E$, $A_0 = A$, $B_0 = B$ and set $j = 0$, $n_j = n$, $\ell_j = \ell$.

(1) Let P_1, Q_1 be unitary matrices of appropriate dimensions that produce an ASVD of E_0 such that

$$E_1 := P_1^* E_0 Q_1 = \begin{bmatrix} \Sigma_{d_j} & 0 \\ 0 & 0 \end{bmatrix}.$$

Set

$$A_1 := P_1^* A_0 Q_1 - P_1^* E_0 \dot{Q}_1 = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}, \qquad B_1 := P_1 B_0 = \begin{bmatrix} B_{11} \\ B_{21} \end{bmatrix}.$$

(2) Let $\tilde{P}_2, W_2$ be unitary matrices of appropriate dimensions that produce an ASVD of B_{21}. Set

$$\tilde{P}_2^* B_{21} W_2 = \begin{bmatrix} \Sigma_{c_j} & 0 \\ 0 & 0 \end{bmatrix}, \; P_2 := \begin{bmatrix} I_{d_j} & 0 \\ 0 & \tilde{P}_2 \end{bmatrix},$$

and

$$E_2 := P_2^* E_1 = \begin{bmatrix} \Sigma_{d_j} & 0 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}, \; A_2 := P_2^* A_1 = \begin{bmatrix} \tilde{A}_{11} & \tilde{A}_{12} \\ \tilde{A}_{21} & \tilde{A}_{22} \\ \tilde{A}_{31} & \tilde{A}_{32} \end{bmatrix},$$
$$B_2 := P_2^* B_1 W_2 = \begin{bmatrix} \tilde{B}_{11} & \tilde{B}_{12} \\ \Sigma_{c_j} & 0 \\ 0 & 0 \end{bmatrix}.$$

If B_{21} has full row rank except at isolated points, then we **STOP** the process here.

(3) Let $\tilde{P}_3, Q_3$ be unitary matrices that produce a permuted ASVD of $\begin{bmatrix} \tilde{A}_{31} & \tilde{A}_{32} \end{bmatrix}$. Set

$$\tilde{P}_3^* \begin{bmatrix} \tilde{A}_{31} & \tilde{A}_{32} \end{bmatrix} Q_3 = \begin{bmatrix} 0 & \Sigma_{k_j} \\ 0 & 0 \end{bmatrix}, \qquad P_3 := \begin{bmatrix} I_{d_j} & 0 & 0 \\ 0 & I_{c_j} & 0 \\ 0 & 0 & \tilde{P}_3 \end{bmatrix}$$

and

$$E_3 := P_3^* E_2 Q_3 = \left[\begin{array}{c|c} \hat{E}_{11} & \hat{E}_{12} \\ 0 & 0 \\ \hline 0 & 0 \\ 0 & 0 \end{array}\right], \qquad A_3 := P_3^* A_2 Q_3 - P_3^* E \dot{Q}_3 = \left[\begin{array}{c|c} \hat{A}_{11} & \hat{A}_{12} \\ \hat{A}_{21} & \hat{A}_{22} \\ \hline 0 & \Sigma_{k_j} \\ 0 & 0 \end{array}\right],$$
$$B_3 := P_3^* B_2 = \left[\begin{array}{c|c} \hat{B}_{11} & \hat{B}_{12} \\ \Sigma_{c_j} & 0 \\ \hline 0 & 0 \\ 0 & 0 \end{array}\right].$$

(17)

with block rows of sizes $d_j, c_j, k_j, q_j = n_j - d_j - c_j - k_j$ and block columns of sizes $\ell_j - k_j, k_j$ in E_3, A_3, and $c_j, m - c_j$ in B_3.

Now we set $n_{j+1} = d_j + c_j$, $\ell_{j+1} = \ell_j - k_j$, and we set E_0, A_0 to be the $n_{j+1} \times \ell_{j+1}$ upper left submatrices of E_3, A_3 and B_0 to be the upper $n_{j+1} \times m$ submatrix of B_3. Set $j = j + 1$, and repeat the process from step (1) by applying transformations always to the complete system via an appropriate embedding of the transformation matrices.

end

It is clear that the procedure is finite, since n_j decreases in each step. At the end of this recursion we have the following forms for the transformed E, A, B:

$$\left[\begin{array}{cc|c|c|c|c}
\Sigma_{d_\nu}(t) & 0 & * & * & \dots & * \\
0 & 0 & * & * & \dots & * \\
\hline
 & & 0 & * & \dots & * \\
 & & 0 & * & \dots & * \\
\hline
 & & & \ddots & \vdots & \\
\hline
 & & & & 0 & * \\
 & & & & 0 & * \\
\hline
 & & & & & 0 \\
 & & & & & 0
\end{array}\right]
\begin{array}{l}
d_\nu \\ c_\nu \\ \hline k_{\nu-1} \\ q_{\nu-1} \\ \hline \vdots \\ \hline k_1 \\ q_1 \\ \hline k_0 \\ q_0
\end{array},$$

$$\left[\begin{array}{cc|c|c|c|c}
A_{11}(t) & A_{12}(t) & * & * & \dots & * \\
A_{21}(t) & A_{22}(t) & * & * & \dots & * \\
\hline
 & & \Sigma_{k_{\nu-1}}(t) & * & \ddots & \vdots \\
 & & 0 & * & & \vdots \\
\hline
 & & & \ddots & \ddots & \vdots \\
\hline
 & & & & \Sigma_{k_1}(t) & * \\
 & & & & 0 & * \\
\hline
 & & & & & \Sigma_{k_0}(t) \\
 & & & & & 0
\end{array}\right]
\begin{array}{l}
d_\nu \\ c_\nu \\ \hline k_{\nu-1} \\ q_{\nu-1} \\ \hline \vdots \\ \hline k_1 \\ q_1 \\ \hline k_0 \\ q_0
\end{array},$$

$$\left[\begin{array}{cc}
B_{11}(t) & B_{12}(t) \\
\Sigma_{c_\nu}(t) & 0 \\
\hline
0 & 0 \\
0 & 0 \\
\hline
\vdots & \vdots \\
\hline
0 & 0 \\
0 & 0 \\
\hline
0 & 0 \\
0 & 0
\end{array}\right]
\begin{array}{l}
d_\nu \\ c_\nu \\ \hline k_{\nu-1} \\ q_{\nu-1} \\ \hline \vdots \\ \hline k_1 \\ q_1 \\ \hline k_0 \\ q_0
\end{array}.$$

The columns of E, A have sizes $d_\nu, \ell - k_{\nu-1} - \cdots - k_0, k_{\nu-1}, \dots, k_0$.

We now split the second block row and column further so that we obtain a square diagonal block of size $v_\nu = \min(c_\nu, \ell - k_{\nu-1} - \cdots - k_0)$ in the (2,2) position. Set $u_\nu^r := \ell - k_{\nu-1} - \cdots - k_0 - v_\nu$, and $u_\nu^l := c_\nu - v_\nu$. The final form is then obtained by a block permutation which moves the new third block column to the end and permutes

the block rows in the order $1, 2, 3, 5, \ldots, 4, 6, \ldots$. It is as follows:

$$P(t)E(t)Q(t) = \left[\begin{array}{cc|cccc|c} \Sigma_{d_\nu} & 0 & * & * & \ldots & * & 0 \\ 0 & 0 & 0 & * & \ldots & * & 0 \\ \hline & & 0 & * & \ldots & * & 0 \\ & & & 0 & \ddots & \vdots & 0 \\ & & & & \ddots & * & 0 \\ & & & & & 0 & 0 \\ \hline & & * & * & \ldots & * & 0 \\ \hline & & 0 & * & \ldots & * & 0 \\ & & & 0 & \ddots & \vdots & 0 \\ & & & & \ddots & * & 0 \\ & & & & & 0 & 0 \end{array}\right] \begin{array}{l} d_\nu \\ v_\nu \\ \hline k_{\nu-1} \\ k_{\nu-2} \\ \vdots \\ k_0 \\ \hline \tilde{u}_\nu^l \\ \hline q_{\nu-1} \\ \vdots \\ q_1 \\ q_0 \end{array},$$

$$P(t)A(t)Q(t) - P(t)E(t)\dot{Q}(t)$$

$$= \left[\begin{array}{cc|cccc|c} A_{11}(t) & A_{12}(t) & * & * & \ldots & * & * \\ A_{21}(t) & A_{22}(t) & * & * & \ldots & * & 0 \\ \hline & & \Sigma_{k_{\nu-1}}(t) & * & \ddots & * & 0 \\ & & & \ddots & \ddots & \vdots & \vdots \\ & & & & \Sigma_{k_1}(t) & * & 0 \\ & & & & & \Sigma_{k_0}(t) & 0 \\ \hline * & * & * & \ldots & \ldots & * & * \\ \hline & & 0 & * & \ldots & * & 0 \\ & & & 0 & \ddots & \vdots & \vdots \\ & & & & 0 & * & 0 \\ & & & & & 0 & 0 \end{array}\right] \begin{array}{l} d_\nu \\ v_\nu \\ \hline k_{\nu-1} \\ k_{\nu-2} \\ \vdots \\ k_0 \\ \hline \tilde{u}_\nu^l \\ \hline q_{\nu-1} \\ \vdots \\ q_1 \\ q_0 \end{array},$$

$$P(t)B(t)W(t) = \left[\begin{array}{ccc} * & * & * \\ \Sigma_{v_\nu}(t) & 0 & 0 \\ \hline 0 & 0 & 0 \\ \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots \\ 0 & 0 & 0 \\ \hline 0 & \Sigma_{\tilde{u}_\nu^l} & 0 \\ \hline 0 & 0 & 0 \\ \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots \\ 0 & 0 & 0 \end{array}\right] \begin{array}{l} d_\nu \\ v_\nu \\ \hline k_{\nu-1} \\ k_{\nu-2} \\ \vdots \\ k_0 \\ \hline \tilde{u}_\nu^l \\ \hline q_{\nu-1} \\ \vdots \\ q_1 \\ q_0 \end{array},$$

where the widths of the block columns in the transformed E, A are d_ν, v_ν, $k_{\nu-1}$, $\ldots$, k_0, u_ν^r and v_ν, $\tilde{u}_\nu^l$, $m - v_\nu - \tilde{u}_\nu^l$ in the transformed B. We then combine all the

k_j-blocks and the q_j-blocks to make blocks of sizes $s_\nu = \sum_{j=0}^{\nu} k_j$, $u_\nu^r = \sum_{j=0}^{\nu} q_j$, respectively. □

Note again that the analyticity assumption on the coefficient matrices can be relaxed to the condition that all smooth singular value decompositions exist and that rank changes in the factored matrices occur only at isolated points; see Remark 2. If only one step of the procedure given in the proof of Theorem 3.2 needs to be performed, i.e., $\nu = 0$, then the invariant quantities can be obtain via local rank computations.

Remark 4. Like Theorem 2.3, the condensed form of Theorem 3.2 is not a canonical form, but it does display the relevant information. The corresponding canonical form, using nonunitary transformations has subsequently been developed by Rath [29].

In this section we have determined invariants of the system under global equivalence transformations. We will apply these results in the next section to analyze system properties.

4. The square subsystem. We will now analyze the system (1) after transformation to the condensed form (16).

$$\begin{array}{c} d_\nu \\ v_\nu \\ \hline s_\nu \\ \hline \tilde{u}_\nu^l \\ \hline u_\nu^l \end{array} \left[\begin{array}{cc|c|c} \Sigma_{d_\nu}(t) & 0 & E_{13}(t) & 0 \\ 0 & 0 & E_{23}(t) & 0 \\ \hline 0 & 0 & E_{33}(t) & 0 \\ \hline 0 & 0 & E_{43}(t) & 0 \\ \hline 0 & 0 & E_{54}(t) & 0 \end{array}\right] \left[\begin{array}{c} \dot{x}_1 \\ x_2 \\ \hline x_3 \\ \hline x_4 \end{array}\right]$$

$$= \left[\begin{array}{cc|c|c} A_{11}(t) & A_{12}(t) & A_{13}(t) & A_{14}(t) \\ A_{21}(t) & A_{22}(t) & A_{23}(t) & A_{24}(t) \\ \hline 0 & 0 & A_{33}(t) & 0 \\ \hline A_{41}(t) & A_{42}(t) & A_{43}(t) & A_{44}(t) \\ \hline 0 & 0 & A_{53}(t) & 0 \end{array}\right] \left[\begin{array}{c} x_1 \\ x_2 \\ \hline x_3 \\ \hline x_4 \end{array}\right] + \left[\begin{array}{ccc} B_{11}(t) & B_{12}(t) & B_{13}(t) \\ \Sigma_{v_\nu}(t) & 0 & 0 \\ \hline 0 & 0 & 0 \\ \hline 0 & \Sigma_{\tilde{u}_\nu^l}(t) & 0 \\ \hline 0 & 0 & 0 \end{array}\right] \left[\begin{array}{c} u_1 \\ u_2 \\ u_3 \end{array}\right], \tag{18}$$

with columns of sizes d_ν, v_ν, s_ν, u_r^ν in E, A and columns of sizes v_ν, $\tilde{u}_\nu^l$, $m - u_\nu - \tilde{u}_\nu^l$ in B. We immediately make the following observations:

(1) From the third block equation we obtain by recursive substitution that $x_3(t) = 0$ almost everywhere, and since we want a smooth solution, we obtain $x_3(t) \equiv 0$.

(2) Since $x_3(t) \equiv 0$, the equations given by the last block row are fulfilled trivially. So we might leave these equations off altogether.

Thus we may consider the subsystem

$$\begin{array}{c} d_\nu \\ v_\nu \\ \hline \tilde{u}_\nu^l \end{array} \left[\begin{array}{cc|c} \Sigma_{d_\nu}(t) & 0 & 0 \\ 0 & 0 & 0 \\ \hline 0 & 0 & 0 \end{array}\right] \left[\begin{array}{c} \dot{x}_1 \\ x_2 \\ \hline x_4 \end{array}\right]$$

$$= \left[\begin{array}{cc|c} A_{11}(t) & A_{12}(t) & A_{14}(t) \\ A_{21}(t) & A_{22}(t) & A_{24}(t) \\ \hline A_{41}(t) & A_{42}(t) & A_{44}(t) \end{array}\right] \left[\begin{array}{c} x_1 \\ x_2 \\ \hline x_4 \end{array}\right] + \left[\begin{array}{ccc} B_{11}(t) & B_{12}(t) & B_{13}(t) \\ \Sigma_{v_\nu}(t) & 0 & 0 \\ \hline 0 & \Sigma_{\tilde{u}_\nu^l}(t) & 0 \end{array}\right] \left[\begin{array}{c} u_1 \\ u_2 \\ u_3 \end{array}\right], \tag{19}$$

with columns of sizes d_ν, v_ν, u_r^ν in E, A and columns of sizes v_ν, $\tilde{u}_\nu^l$, $m - u_\nu - \tilde{u}_\nu^l$ in B.

If in this reduced form $u_r^\nu = \tilde{u}_{\nu^l}$ then this pencil is square and if we would compute the condensed form for this subsystem via Theorem 3.2, we would obtain $\nu = 0$, $s_0 = 0$, $\tilde{u}_\nu^l = u_\nu^l$.

If $u_r^\nu \neq \tilde{u}_{\nu^l}$, then we have many possibilities to reconsider this system. Solution component $x_4(t)$ can be chosen arbitrarily and hence could be viewed as an *extra input* to the system. Compare this with the results concerning generalized inverses of differential algebraic operators in [19]. Also, if $\Sigma_{\tilde{u}_\nu^l}$ is pointwise nonsingular, we could use a nonunitary equivalence transformation to eliminate the block $B_{12}(t)$ in B. If we do this and choose some x_4, u_1, u_3, then the first two equations form a subsystem independent from the rest and if its solution is computed, then u_2 is fixed. Thus we could interpret u_2 as an *extra state variable* rather than a control variable. Combining these ideas we could replace (18) with the system

$$
\begin{array}{l} d_\nu \\ v_\nu \\ s_\nu \\ \tilde{u}_\nu^l \end{array}
\begin{bmatrix} \Sigma_{d_\nu} & 0 & E_{13} & 0 \\ 0 & 0 & E_{23} & 0 \\ 0 & 0 & E_{33} & 0 \\ 0 & 0 & E_{43} & 0 \end{bmatrix}
\begin{bmatrix} \dot{x}_1 \\ x_2 \\ x_3 \\ u_2 \end{bmatrix}
\tag{20}
$$

$$
= \begin{bmatrix} A_{11} & A_{12} & A_{13} & B_{12} \\ A_{21} & A_{22} & A_{23} & 0 \\ 0 & 0 & A_{33} & 0 \\ A_{41} & A_{42} & A_{43} & \Sigma_{\tilde{u}_\nu^l} \end{bmatrix}
\begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ u_2 \end{bmatrix}
+ \begin{bmatrix} B_{11} & A_{14} & B_{13} \\ \Sigma_{v_\nu} & A_{24} & 0 \\ 0 & 0 & 0 \\ 0 & A_{44} & 0 \end{bmatrix}
\begin{bmatrix} u_1 \\ x_4 \\ u_3 \end{bmatrix},
$$

where we have left out the dependence on t for convenience. This is now a square system.

But it is clear that we can extract a square subsystem in many different ways by reinterpreting states as inputs or vice versa. A suitable choice will certainly depend on the application. In any case we wish to have a unique solution for suitably chosen inputs, thus we cannot allow the pencil to have more columns than rows. On the other hand, if there are more rows than columns, then the set of controls that will lead to continuous solutions is restricted by these extra algebraic equations.

The previous observations suggest that the design of a practical control problem should be done in such a way, that components which are identically zero should be left off already in the model and the reinterpretation of components as states or controls should be done beforehand.

Thus we will assume in the following that the system has been reordered so that it has square matrices $E(t), A(t)$ with $\nu = 0$, $s_0 = 0$, $\tilde{u}_\nu^l = u_\nu^l$ if we transform it to the condensed form of Theorem 3.2. We call such a subsystem *an underlying square subsystem.*

Observe that although all the transformations that we used are unitary transformations which can in principle be carried out in a numerically stable way, the rank decisions are still an ill-conditioned problem and small perturbations can change the picture completely. See the remarks for constant coefficient systems in [5], which hold here, too.

5. Regularization by feedback. For constant coefficient systems regularizability, i.e., the question whether there exist proportional and/or derivative feedbacks such that the closed loop system has a regular pencil, i.e. is solvable for all consistent initial vectors, has been studied by several authors; see, for example, [13, 26, 3, 5]. We now generalize these results to the variable coefficient case. We introduce the following concepts.

DEFINITION 5.1.

(a) *The descriptor system* (1) *is called* regularizable by proportional feedback *if there exists a (proportional state) feedback* $u(t) = F(t)x(t) + w(t)$ *such that the closed*

loop system

$$E(t)\dot{x}(t) = (A(t) + B(t)F(t))x(t) + B(t)w(t), \qquad x(t_0) = x_0, \tag{21}$$

is uniquely solvable for every consistent initial vector x_0 and any given control $w(t)$.

(b) *The descriptor system* (1) *is called* regularizable by derivative feedback *if there exists a (derivative) feedback $u(t) = G(t)\dot{x}(t) + w(t)$ such that the closed loop system*

$$(E(t) + B(t)G(t))\dot{x}(t) = A(t)x(t) + B(t)w(t), \qquad x(t_0) = x_0, \tag{22}$$

is uniquely solvable for all consistent initial vectors x_0 and any given control $w(t)$.

It is clear from the discussion in the previous section that we need $\tilde{u}_\nu^l = u_\nu^r$ in order to obtain regularizability, otherwise we cannot expect a unique solution or we have to reinterpret certain variables. If $\tilde{u}_\nu^l > u_\nu^r$, then we cannot apply arbitrary controls, and if $u_\nu^r > \tilde{u}_\nu^l$, then the solution will not be unique.

As the following theorem shows, this gives a necessary and sufficient condition if the matrices Σ_{d_ν}, Σ_{v_ν} occurring in the condensed form are invertible everywhere in the given interval; i.e., no rank drops occur, not even at isolated points.

THEOREM 5.2. *Consider system* (1) *in the condensed form* (16)*, and assume that the diagonal matrices $\Sigma_{d_\nu}(t)$, $\Sigma_{v_\nu}(t)$, $\Sigma_{\tilde{u}_\nu^l}(t)$ are pointwise nonsingular in the whole interval $[t_0, t_1]$.*

System (1) *can be regularized by proportional state feedback if and only if $\tilde{u}_\nu^l = u_\nu^r$.*

System (1) *can be regularized by derivative feedback if and only if $\tilde{u}_\nu^l = u_\nu^r$.*

Proof. We have already observed that $\tilde{u}_\nu^l = u_\nu^r$ is a necessary condition. In order to show that this is also sufficient observe that in this case the system can be permuted (by exchanging the last two block rows and columns) to the form

$$\begin{array}{c} d_\nu \\ v_\nu \\ \tilde{u}_\nu^l = u_\nu^r \\ s_\nu \end{array} \begin{bmatrix} \Sigma_{d_\nu} & 0 & 0 & E_{13} \\ 0 & 0 & 0 & E_{23} \\ 0 & 0 & 0 & E_{43} \\ 0 & 0 & 0 & E_{33} \end{bmatrix} \begin{bmatrix} \dot{x}_1 \\ x_2 \\ x_4 \\ x_3 \end{bmatrix}$$

$$= \begin{bmatrix} A_{11} & A_{12} & A_{14} & A_{13} \\ A_{21} & A_{22} & A_{24} & A_{23} \\ A_{41} & A_{42} & A_{44} & A_{43} \\ 0 & 0 & 0 & A_{33} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_4 \\ x_3 \end{bmatrix} + \begin{bmatrix} B_{11} & B_{12} & B_{13} \\ \Sigma_{v_\nu} & 0 & 0 \\ 0 & \Sigma_{\tilde{u}_\nu^l} & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \\ u_3 \end{bmatrix}.$$

Since Σ_{d_ν} and $\Sigma_{\tilde{u}_\nu^l}$ are nonsingular in the whole interval, we can choose the proportional feedback

$$\begin{bmatrix} u_1(t) \\ u_2(t) \\ u_3(t) \end{bmatrix} = \begin{bmatrix} F_{11}(t) & F_{12}(t) & 0 & 0 \\ F_{21}(t) & F_{22}(t) & F_{23}(t) & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} x_1(t) \\ x_2(t) \\ x_4(t) \\ x_3(t) \end{bmatrix} + w(t)$$

such that

$$\Sigma_{v_\nu}(t) \begin{bmatrix} F_{11}(t) & F_{12}(t) \end{bmatrix} = \begin{bmatrix} -A_{21}(t) & I - A_{22}(t) \end{bmatrix}$$

and

$$\Sigma_{\tilde{u}_\nu^l}(t) \begin{bmatrix} F_{21}(t) & F_{22}(t) & F_{23}(t) \end{bmatrix} = \begin{bmatrix} -A_{41}(t) & -A_{42}(t) & I - A_{44}(t) \end{bmatrix}.$$

This choice gives a closed loop system

$$\begin{matrix} d_\nu \\ v_\nu \\ \tilde{u}_\nu^l = u_\nu^r \\ s_\nu \end{matrix} \begin{bmatrix} \Sigma_{d_\nu} & 0 & 0 & E_{13} \\ 0 & 0 & 0 & E_{23} \\ 0 & 0 & 0 & E_{43} \\ 0 & 0 & 0 & E_{33} \end{bmatrix} \begin{bmatrix} \dot{x}_1 \\ x_2 \\ x_4 \\ x_3 \end{bmatrix}$$

$$= \begin{bmatrix} A_{11} & A_{12} & A_{14} & A_{13} \\ 0 & I & A_{24} & A_{23} \\ 0 & 0 & I & A_{43} \\ 0 & 0 & 0 & A_{33} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_4 \\ x_3 \end{bmatrix} + \begin{bmatrix} B_{11} & B_{12} & B_{13} \\ \Sigma_{v_\nu} & 0 & 0 \\ 0 & \Sigma_{\tilde{u}_\nu^l} & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} w_1 \\ w_2 \\ w_3 \end{bmatrix}.$$

Recall that the solutions components x_3 are constrained to be zero. If we remove these equations, then the remaining system has strangeness index $\mu = 0$, i.e., is uniquely solvable for all consistent initial values.

Similarly, in the case of derivative feedback we choose the derivative feedback

$$\begin{bmatrix} u_1(t) \\ u_2(t) \\ u_3(t) \end{bmatrix} = \begin{bmatrix} 0 & F_{12}(t) & 0 & 0 \\ 0 & 0 & F_{13}(t) & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} \dot{x}_1(t) \\ x_2(t) \\ x_4(t) \\ x_3(t) \end{bmatrix} + w(t)$$

such that $\Sigma_{v_\nu} F_{12} = -I$ and $\Sigma_{\tilde{u}_\nu^l} F_{23} = -I$.

This choice gives a closed loop system

$$\begin{matrix} d_\nu \\ v_\nu \\ \tilde{u}_\nu^l = u_\nu^r \\ s_\nu \end{matrix} \begin{bmatrix} \Sigma_{d_\nu} & 0 & 0 & E_{13} \\ 0 & I & 0 & E_{23} \\ 0 & 0 & I & E_{43} \\ 0 & 0 & 0 & E_{33} \end{bmatrix} \begin{bmatrix} \dot{x}_1 \\ x_2 \\ x_4 \\ x_3 \end{bmatrix}$$

$$= \begin{bmatrix} A_{11} & A_{12} & A_{14} & A_{13} \\ A_{21} & A_{22} & A_{24} & A_{23} \\ A_{43} & A_{42} & A_{44} & A_{43} \\ 0 & 0 & 0 & A_{33} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_4 \\ x_3 \end{bmatrix} + \begin{bmatrix} B_{11} & B_{12} & B_{13} \\ \Sigma_{v_\nu} & 0 & 0 \\ 0 & \Sigma_{\tilde{u}_\nu^l} & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} w_1 \\ w_2 \\ w_3 \end{bmatrix},$$

which is as required. □

It is clear that weaker assumptions can be considered in Theorem 5.2 by allowing rank jumps in the matrices Σ_{d_ν}, Σ_{v_ν} at isolated points and using a weak solvability concept. This topic is currently under investigation.

Note further that there is still quite a lot of freedom in the choice of the feedback, and the freedom may be used to improve the robustness of the system as was done for constant coefficient systems in [3, 4, 12]. Unfortunately, so far it is not really clear what robustness means for variable coefficient systems of the type considered.

6. Conclusion. We have shown that under some smoothness assumptions every linear time-varying descriptor system can be transformed to a condensed form which displays free state components which can be interpreted as inputs, fixed controls which can be interpreted as states and form a regularizable subsystem, solution components which are constrained to be zero coming from higher index components that are unchanged by feedback, plus equations which hold trivially. In principle this structure can be obtained from a sequence of smooth singular value decompositions for which numerical methods are available. From a practical point of view, however,

the uncontrollable higher index part and the other removable parts are very sensitive to perturbations which may change the whole system structure. In view of this, modeling or linearization which leads to such components should be avoided.

Acknowledgment. We thank Werner Rath for helpful comments.

ON CONVERGENCE OF ATTAINABILITY SETS FOR CONTROLLED TWO-SCALE STOCHASTIC LINEAR SYSTEMS*

YURI KABANOV† AND SERGEI PERGAMENSHCHIKOV‡

Abstract. A limit of attainability sets is found for a linear two-scale stochastic system for the case when the diffusion coefficient of the fast variable is of order $\varepsilon^{1/2}$. The attainability set is defined as the set of distributions of attainable terminal values of solutions of stochastic differential equations. As a corollary we calculate a limit of the optimal value of the terminal cost in the stochastic Mayer problem.

Key words. controlled stochastic differential equations, two-scale system, singular perturbations, attainability sets, Mayer problem, Hausdorff metric

Introduction. In mathematical modeling of complex systems with processes having two essentially different "velocities," fast variables are usually described by singularly perturbed differential equations, i.e., by equations having a small parameter ε on the left-hand side. In general, there is a hope that the reduced limiting model (when the parameter is equal to zero) is more simple and can be used as an approximation of the original one which may be rather complicated. This idea seems to be fruitful also in the set-up of controlled systems. However, here an additional difficulty arises since the optimal value of the cost function which depends smoothly on $\varepsilon \in]0,1]$ may have a discontinuity at the most interesting point $\varepsilon = 0$.

To overcome this difficulty in the deterministic setting, an approach based on a study of the convergence of the attainability sets in the Hausdorff metric has been developed; see, e.g., recent work [10]. In the linear case it is possible to find a limit of the attainability sets in a rather explicit way which has been done by Dontchev and Veliov [8]; see also the book [7]. Their result is as follows.

Let us consider the controlled system

$$\dot{x}_t = A_1(t)x_t + A_2(t)y_t + B_1(t)u_t, \quad x_0 = 0, \tag{0.1}$$

$$\varepsilon\dot{y}_t = A_3(t)x_t + A_4(t)y_t + B_2(t)u_t, \quad y_0 = 0, \tag{0.2}$$

where ε is a small positive number; u is any measurable function with values in a convex compact subset of $\mathbf{R}^d$; matrix-valued functions A_i, B_i are continuous; and the eigenvalues of $A_4(t)$ have strictly negative real parts.

Let $K_\varepsilon(t)$ be the attainability set of the system (0.1), (0.2), i.e., the set of all end points (x_T, y_T) corresponding to various admissible controls, and let $K_0^x(T)$ be the attainability set of the reduced system

$$\dot{x}_t = A_0(t)x_t + B_0(t)u_t, \quad x_0 = 0,$$

with the coefficients $A_0 := A_1 - A_2A_4^{-1}A_3$, $B_0 := B_1 - A_2A_4^{-1}B_2$.

Let us define the set $K_0(T) := \{(x,y) : \ x \in K_0^x(T),\ y \in R(T,x)\}$, where $R(T,x) := -A_4^{-1}(T)A_3(T)x + Y$,

$$Y := \int_0^\infty \exp\{A_4(T)s\}B_2(T)U ds = \left\{y : y = \int_0^\infty \exp\{A_4(T)s\}B_2(T)v_s ds,\ v_s \in V_U\right\}.$$

V_U is the set of all U-valued Borel functions. In other words, if we put $F(x,y) = (x, -A_4^{-1}(T)A_3(T)x + y)$, then $K_0(T)$ is the image of $K_0^x(T) \times Y$ under the mapping F.

THEOREM (see [8], [7]). *The sets $K_\varepsilon(T)$ tend to $K_0(T)$ in the Hausdorff metric as $\varepsilon \to 0$.*

Let us consider for the system (0.1), (0.2) the Mayer problem

$$g(x_T, y_T) \to \min,$$

where g is a continuous function. Then the optimal value for the perturbed problem is

$$J_\varepsilon^* = \min_{K_\varepsilon(T)} g(x,y).$$

From the above theorem it follows immediately that

$$\lim_{\varepsilon \to 0} J_\varepsilon^* = \min_{K_0(T)} g(x,y).$$

In the paper [13] the authors extended the theorem on the convergence of the attainability sets to stochastic differential equations of the form

$$dx_t = (A_1(t)x_t + A_2(t)y_t + B_1(t)u_t)dt + dw_t^x, \quad x_0 = 0, \tag{0.3}$$

$$\varepsilon dy_t = (A_3(t)x_t + A_4(t)y_t + B_2(t)u_t)dt + \sigma(\varepsilon)dw_t^y, \quad y_0 = 0, \tag{0.4}$$

where w^x, w^y are independent Wiener processes and $\sigma(\varepsilon) = O(\varepsilon^{1/2+\delta})$, $\delta > 0$. In the stochastic setting it is natural to define the attainability set as the set of distributions of all terminal random variables (x_T, y_T) when u runs through the set of admissible controls. There are several possible choices for the latter. It seems that the most adequate one is to consider all nonanticipating functions of the trajectories as admissible controls. This implies the need to understand the system (0.3), (0.4) in the weak sense; i.e., the Wiener processes are not given in advance and the solution is actually a probability measure $P^{\varepsilon,u}$ in the space of continuous functions $C[0,T]$. Such a solution can be constructed by the Girsanov theorem. In this case the attainability set $\mathcal{K}_\varepsilon(T)$ is a compact convex set in the space of probability measures equipped with the Prohorov metric. In [13] it was shown that $\mathcal{K}_\varepsilon(T) \to \mathcal{K}_0(T)$ in the Hausdorff metric, where $\mathcal{K}_0(T)$ is the set of probability measures μF^{-1} where $\mu = \mu(dx, dy)$ is such that $\mu(dx, \mathbf{R}^n)$ belongs to the attainable set $\mathcal{K}_0^x(T)$ of the reduced system and $\mu(\mathbf{R}^k, dy)$ belongs to the set $\mathbf{P}(Y)$ of probability measures on Y. The reduced system is given by

$$dx_t = (A_0(t)x_t + B_0(t)u_t)dt + dw_t^x, \quad x_0 = 0, \tag{0.5}$$

where, as in the deterministic case, the coefficients A_0 and B_0 can be obtained if we substitute in (0.3) the expression for y_t which is a formal solution of (0.4) with $\varepsilon = 0$.

Notice that the condition $\delta > 0$ provides a limiting degeneracy of the stochastic equation (0.4) (with a fixed control) to an algebraic one.

In the present paper we prove the convergence result for $\sigma(\varepsilon) = \varepsilon^{1/2}$. In this case $\mathcal{K}_0(T)$ is the set of all measures μF^{-1} such that $\mu(dx, \mathbf{R}^n) \in \mathcal{K}_0^x(T)$ and $\mu(x, dy)$ belong to the convex closure of the set of probability distributions of random variables

$$\xi_0 + \int_0^\infty \exp\{A_4(T)s\} B_2(T) v_s ds,$$

where ξ is the stationary Gaussian Markov process (called also Ornstein–Uhlenbeck) with the zero mean and covariance

$$K(s,t) := \Xi \exp\{A_4'(T)(t-s)\}, \quad s \le t,$$
$$\Xi := \int_0^\infty \exp\{A_4(T)s\} \exp\{A_4'(T)s\} ds,$$

v is any measurable process with values in U such that for any t the random variable v_t is measurable with respect to the σ-algebra $\mathcal{F}^\xi_{\ge t} := \sigma\{\xi_s,\ s \ge t\}$, and prime denotes the matrix transpose. As a corollary of the theorem on convergence of the attainability sets we calculate a limit of the optimal value in the Mayer problem $Eg(x_T^{\varepsilon,u}, y_T^{\varepsilon,u}) \to \min$ when ε tends to zero.

In the last few years singularly perturbed controlled stochastic differential equations have been intensively studied by various methods, mainly based on the theory of weak convergence in the functional spaces or the Bellman–Hamilton–Jacobi equation; see monographs [3], [4], [20] and papers [2], [5] (and the collection [17] for early results). However, almost all studies concern models where the controlled fast variable does not affect the terminal cost. Harold Kushner wrote in his book [20, p. 64]:

> It is hard to deal in any general way with the case where the fast system is also controlled. The main difficulty is due to the fact that the 'stationary measures' which are used to average out the fast variable depend on the control which is used in the fast system. This makes it hard to define the 'averaged problem.'... Similar problems occur in the deterministic case, and it is commonly dealt with there by supposing that the choice of control for the fast system does not alter the steady state value of that system, for each value of the fast variable, i.e., that the fast system is asymptotically stable and the control chosen in a class such that the limit point of that fast system does not depend on the control *when x is fixed*. This assumption essentially 'decouples' the fast and slow system. The assumption seems reasonable and yields good results. Unfortunately, it does not seem possible to find a stochastic analog of this approach which works in any generality.

It worth noticing that the result presented here is nontrivial even for a system with only fast variables. In this case it is clear that the limit of the attainability sets shows to what extent optimal controls (acting on the drift of the process) can follow the change in the scale parameter near the point zero.

The structure of the paper is the following. In section 1 we give the formal description of the problem. Section 2 contains some preliminary explanations and the proof of the result for the simplest one-dimensional model with the fast variable only. The proof of Theorem 1.1 is given in sections 3 and 4. Section 5 is devoted to measure-theoretical aspects which may have some independent interest.

1. Formulations of the results. We consider here the linear stochastic controlled system given by

$$dx_t = (A_1(t)x_t + A_2(t)y_t + B_1(t)u_t)dt + dw_t^x, \quad x_0 = 0, \tag{1.1}$$

$$\varepsilon dy_t = (A_3(t)x_t + A_4(t)y_t + B_2(t)u_t)dt + \sqrt{\varepsilon}dw_t^y, \quad y_0 = 0, \tag{1.2}$$

where w^x and w^y are standard independent Wiener processes with values in $\mathbf{R}^k$ and $\mathbf{R}^n,\ 0 \le t \le T < \infty,\ \varepsilon \in]0,1]$.

We shall understand (1.1), (1.2) as a symbolic notation for the stochastic differential equation in a weak sense when a Wiener process $W = (w^x, w^y)$ is not given in advance and u is a feedback control. Actually, in the following rigorous formulation we could avoid the above representation (which is, in fact, a bit ambiguous) altogether.

We consider as a phase space $\mathbf{R}^m = \mathbf{R}^k \times \mathbf{R}^n$. ($\mathbf{R}^k$ corresponds to the slow and $\mathbf{R}^n$ to the fast variables.) The phase space of control will be a compact convex set $U \subseteq \mathbf{R}^d$. In our matrix notations vectors are column vectors.

The path space of the system is the space $C[0,T]$ of continuous functions $W : [0,T] \to \mathbf{R}^m$. Let $\mathcal{C}_T$ be the Borel σ-algebra on $C[0,T]$, $\mathcal{C}_t^o := \sigma\{W_s,\ s \le t\}$, $\mathcal{C}_t := \mathcal{C}_{t+}^o$. Let $\mathcal{P}$ be the predictable σ-algebra in $C[0,T] \times [0,T]$ corresponding to the filtration $\mathbf{C} = (\mathcal{C}_t)$.

The class of admissible controls $\mathcal{U}$ is defined as the set of all predictable processes $u = (u_t)_{t\in[0,T]}$ with values in U.

Let $A_i = A_i(t),\ B_i = B_i(t)$ be matrix-valued continuous functions of dimensions compatible with (1.1), (1.2); i.e., $A_1(t)$ is a $k \times k$ matrix, $A_4(t)$ is $n \times n$, etc.

We introduce the following notation:

$$f_\varepsilon(W,t,u) = \begin{pmatrix} A_1(t) & A_2(t) \\ \varepsilon^{-1}A_3(t) & \varepsilon^{-1/2}A_4(t) \end{pmatrix} W_t + \begin{pmatrix} B_1(t) \\ \varepsilon^{-1}B_2(t) \end{pmatrix} u_t, \tag{1.3}$$

$$D_\varepsilon := \begin{pmatrix} I_k & 0 \\ 0 & \varepsilon^{-1}I_n(t) \end{pmatrix}, \tag{1.4}$$

where $I_k,\ I_n$ are the identity matrices of corresponding dimensions.

Consider on $(C[0,T], \mathcal{C}_T)$ the probability measure P^ε such that with respect to P^ε the coordinate process W is the Wiener process with the correlation matrix $D_\varepsilon D_\varepsilon'$.

For any admissible control u we define the measure $P^{\varepsilon,u} := \rho_T^\varepsilon(u)P^\varepsilon$ with

$$\rho_T^\varepsilon(u) = \exp\left\{\int_0^T f_\varepsilon(W,s,u_s)' dW_s - \frac{1}{2}\int_0^T |f_\varepsilon(W,s,u_s)' D_\varepsilon|^2 ds\right\}. \tag{1.5}$$

It is well known (see [1] or [16]) that $P^{\varepsilon,u}$ is a probability measure. By the Girsanov theorem the process

$$W_t - \int_0^t f_\varepsilon(W,s,u_s)ds$$

with respect to $P^{\varepsilon,u}$ is the Wiener process with the correlation matrix $D_\varepsilon D_\varepsilon'$. Thus, we can write that

$$dW_t = f_\varepsilon(W,t,u_t)dt + D_\varepsilon dB_t, \quad W_0 = 0,$$

where B is the standard Wiener process.

If we denote the first k components of W and B by x and w^x and the remaining n components by y and w^y, the above representation formally coincides with the system (1.1), (1.2) and the control u will be a nonanticipating functional of the phase trajectory. This explains the terminology where $P^{\varepsilon,u}$ is called a weak solution of (1.1), (1.2) and the model itself usually is referred to as the model with the feedback control.

Let $\mathcal{K}_\varepsilon := \{P^{\varepsilon,u} : \ u \in \mathcal{U}\}$, where $\varepsilon > 0$ is fixed. The set $\mathcal{K}_\varepsilon$ is an analog of the "tube" of trajectories for deterministic systems. Correspondingly, the attainability set $\mathcal{K}_\varepsilon(T) := \{P^{\varepsilon,u}W_T^{-1} : \ u \in \mathcal{U}\}$ is the set of all probability measures on $\mathbf{R}^m$ which are the images of elements of $\mathcal{K}_\varepsilon$ under the mapping $W \mapsto W_T$. It was proved in [1] that $\mathcal{K}_\varepsilon$ is a convex set, hence $\mathcal{K}_\varepsilon(T)$ is also convex. In [1] it was also shown that the set $\{\rho_T^\varepsilon(u) : \ u \in \mathcal{U}\}$ of the attainable densities is sequentially compact in the weak topology of $L^1(P^\varepsilon)$. It follows immediately that $\mathcal{K}_\varepsilon$ and $\mathcal{K}_\varepsilon(T)$ are compact subsets of the corresponding spaces of probability measures $\mathbf{P}(C[0,T])$ and $\mathbf{P}(\mathbf{R}^m)$ equipped with the Prohorov metric.

To formulate the convergence result we need the following assumption.

(A) For all t the real parts of the eigenvalues of $A_4(t)$ have strictly negative real parts:

$$\operatorname{Re}\lambda(A_4(t)) \le -2\kappa < 0. \tag{1.6}$$

Let $\mathcal{K}_0^x(T)$ be the attainability set of the stochastic differential equation

$$dx_t = (A_0(t)x_t + B_0(t)u_t)dt + dw_t^x, \quad x_0 = 0, \tag{1.7}$$

where $A_0 := A_1 - A_2A_4^{-1}A_3, \ B_0 := B_1 - A_2A_4^{-1}B_2$.

Let ξ be the (strong) solution of the following stochastic differential equation with constant coefficients on some filtered probability space $(\Omega, \mathcal{F}, \mathbf{F} = (\mathcal{F}_t), P)$:

$$d\xi_t = A_4(T)\xi_t dt + db_t, \quad \xi_0 = \xi^o, \tag{1.8}$$

where b is a standard Wiener process in $\mathbf{R}^n$ and ξ^o is an independent Gaussian random variable with the zero mean and covariance matrix

$$\Xi := \int_0^\infty \exp\{A_4(T)s\}\exp\{A_4^{'}(T)s\}ds. \tag{1.9}$$

In other words, ξ is the stationary Gaussian Markov process with zero mean and covariance function

$$K(s,t) := E\xi_s x i_t^{'} = \Xi\exp\{A_4^{'}(T)(t-s)\}; \tag{1.10}$$

see, e.g., [16].

Let $\mathcal{V}_U$ be the set of all U-valued processes $v = (v_t)_{t\ge 0}$ such that $v_{1/t}$ is a predictable process with respect to the filtration generated by the process $\xi_{1/t}$, $S_Y^o := \{\mathcal{L}(\xi_0 + I(v)) : \ v \in \mathcal{V}_U\}$, where

$$I(v) := \int_0^\infty \exp\{A_4(T)s\}B_2(T)v_s ds. \tag{1.11}$$

Here and in what follows we use the notation $\mathcal{L}(\eta) := P\eta^{-1}$ for the distribution of the random variable η. The set S_Y^o is compact in $\mathbf{P}(\mathbf{R}^n)$; see Lemma 5.5.

Put $S_Y := \overline{\text{conv}}\ S_Y^o$, the convex closure of S_Y^o in $\mathbf{P}(\mathbf{R}^n)$.

Let S be the set of all probability measures $\mu = \mu(dx, dy)$ on $\mathbf{R}^m = \mathbf{R}^k \times \mathbf{R}^n$ such that

(1) $\mu(x, dy) \in S_Y$;

(2) $\mu(dx, \mathbf{R}^n) \in \mathcal{K}_0^x(T)$.

From the Proposition 5.2 it follows that S is compact in $\mathbf{P}(\mathbf{R}^m)$.

Define a linear mapping $F(x, y) := (x, -A_4^{-1}(T)A_3(T)x + y)$ of $\mathbf{R}^m$ into itself. Put $\mathcal{K}_0(T) := \{\mu F^{-1} : \ \mu \in S\}$.

Our main result is the following theorem.

THEOREM 1.1. *The set $\cup_{\varepsilon\in]0,1]}\mathcal{K}_\varepsilon(T)$ is compact, and as $\varepsilon \to 0$, $\mathcal{K}_\varepsilon(T)$ tend to $\mathcal{K}_0(T)$ in the Hausdorff metric in the space of compact subsets of $\mathbf{P}(\mathbf{R}^m)$.*

For the model (1.1), (1.2) we consider now the Mayer problem, which can be rigorously formulated as the problem to determine the minimal value of the functional

$$J_\varepsilon^* := \inf_{u\in\mathcal{U}} E^{\varepsilon,u} g(W_T) = \inf_{\mu\in\mathcal{K}_\varepsilon(T)} \int g(x, y)\mu(dx, dy), \tag{1.12}$$

where g is a function on $\mathbf{R}^m$ which is integrable with respect to the measures μ from $\mathcal{K}_\varepsilon(T)$.

COROLLARY 1.1. *Assume that g is continuous and bounded. Then*

$$\lim_{\varepsilon\to 0} J_\varepsilon^* = \inf_{\mu\in\mathcal{K}_0(T)} \int g(x, y)\mu(dx, dy). \tag{1.13}$$

Remark 1.1. The definition of the set $\mathcal{V}_U$ seems rather complicated. Essentially, $\mathcal{V}_U$ contains measurable processes v such that for any t the random variable v_t is measurable with respect to the σ-algebra $\mathcal{F}_{\geq t}^{\xi} := \sigma\{\xi_s, \ s \geq t\}$. To avoid a discussion of the measurable structures related to a decreasing family of σ-algebras we prefer to consider the processes in reversed time.

Remark 1.2. There is an alternative description of the set S_Y. Let α be a random variable independent of ξ with values in some Polish space and with a nonatomic distribution. Define the set $\mathcal{V}_U^\alpha$ as the set of all U-valued processes $v = (v_t)_{t\geq 0}$ such that $v_{1/t}$ is a predictable process with respect to the filtration generated by the process $\xi_{1/t}$ and the random variable α. Then $S_Y = \{\mathcal{L}(\xi_0 + I(v)) : \ v \in \mathcal{V}_U^\alpha\}$; see section 5.

Remark 1.3. Evidently, Theorem 1.1 can be applied to the more general optimization problem $J^\varepsilon(u) = F(P^{\varepsilon,u}) \to \min$, where F is any continuous function on $\mathbf{P}(\mathbf{R}^m)$.

We also use in our proof another possible model based on a different (and more traditional) interpretation of the equations (1.1), (1.2). To describe this alternative approach we consider the standard Wiener measure P on $(C[0, T], \mathcal{C}_T)$. Let w^x be the notation for the first k coordinates of the function W and w^y be the notation for the remaining n coordinates. Then for any $u \in \mathcal{U}$ we can find the strong solution $X^{\varepsilon,u} = (x^{\varepsilon,u}, y^{\varepsilon,u})$ of (1.1), (1.2). This model is referred to as the model with the open loop controls (since in this case u is a nonanticipating functional of the "noise").

Let $P_X^{\varepsilon,u} := P(X^{\varepsilon,u})^{-1}$ be the distribution in $C[0, T]$ of the process $X^{\varepsilon,u}$. Certainly, the measure $P_X^{\varepsilon,u}$ need not be equal to $P^{\varepsilon,u}$. Let us consider the sets $\tilde{\mathcal{K}}_\varepsilon := \{P_X^{\varepsilon,u} : \ u \in \mathcal{U}\} \subseteq \mathbf{P}(C[0, T])$ and $\tilde{\mathcal{K}}_\varepsilon(T) := \{P(X_T^{\varepsilon,u})^{-1} : \ u \in \mathcal{U}\} \subseteq \mathbf{P}(\mathbf{R}^m)$. We do not know whether the attainability set $\tilde{\mathcal{K}}_\varepsilon(T)$ coincides with the attainability set $\mathcal{K}_\varepsilon(T)$. However, in our paper [13] it has been shown that there are dense embeddings $\tilde{\mathcal{K}}_\varepsilon \subseteq \mathcal{K}_\varepsilon$ and $\tilde{\mathcal{K}}_\varepsilon(T) \subseteq \mathcal{K}_\varepsilon(T)$ in the sense of total variation convergence (thus, in the weak topology) and that the inclusion $\tilde{\mathcal{K}}_\varepsilon \subseteq \mathcal{K}_\varepsilon$ is strict even in the simplest cases.

This fact, certainly, does not exclude the coincidence of $\tilde{\mathcal{K}}_\varepsilon(T)$ and $\mathcal{K}_\varepsilon(T)$. Nevertheless, the result that there is a dense embedding $\tilde{\mathcal{K}}_\varepsilon(T) \subseteq \mathcal{K}_\varepsilon(T)$ is very helpful since it permits us to apply pathwise techniques similar to that of the deterministic theory.

2. Main ideas and the proof of Theorem 1.1 in the simplest case. We recall some basic facts concerning the Hausdorff metric and convergence of compact sets (for details see, e.g., [11]).

Let (X, d) be a metric space and let $\mathbf{K}_X$ be the class of all its nonempty compact subsets. For $A,\ B \in \mathbf{K}_X$ put $l(A, B) := \sup_{z\in A} d(z, B)$. The Hausdorff distance between A and B is defined by the equality

$$d_H(A, B) := l(A, B) \vee l(B, A).$$

If $A_m \in \mathbf{K}_X$, $m \in \mathbf{Z}_+$, and all A_m are contained in some compact set, then $\lim d_H(A_m, A_0) = 0$ if and only if the following two much more tractable conditions are satisfied for any subsequences of indices (n):

(1) For any convergent sequence $z_n \in A_n$ its limit is a point in A_0.

(2) For any point $z \in A_0$ there exists a subsequence $z_{n_k} \in A_{n_k}$ converging to z.

Notice that if A_n are not subsets of some compact set, the above equivalence fails in general. For the subsets of the real line $A_n := [0, 1] \cup \{n\}$, conditions (1) and (2) are satisfied but A_n do not tend to A_0 in the Hausdorff metric.

The strategy of the proof of Theorem 1.1 is the following. In the first stage we show that for any $\mu_\varepsilon \in \mathcal{K}_\varepsilon(T),\ \varepsilon \in]0, 1]$, there exists $\bar{\mu}_\varepsilon \in \mathcal{K}_0(T)$ such that $d(\bar{\mu}_\varepsilon, \mu_\varepsilon) \to 0$ (d here is the Prohorov metric). Since all $\mathcal{K}_\varepsilon(T)$ are compact this implies that $\cup_{\varepsilon\geq 0}\mathcal{K}_\varepsilon(T)$ is compact and all limit points of $\{\mu_\varepsilon\}$ belongs to $\mathcal{K}_0(T)$; i.e., (1) is fulfilled. Since $\tilde{\mathcal{K}}_\varepsilon(T)$ is dense in $\mathcal{K}_\varepsilon(T)$ it is sufficient to consider only the case when $\mu_\varepsilon \in \tilde{\mathcal{K}}_\varepsilon(T)$. Thus, we can argue with terminal random variables $(x_T^{\varepsilon,u}, y_T^{\varepsilon,u})$ with the distributions μ_ε and approximate them in probability (or in L^p) by random variables $(\bar{x}_T^{\varepsilon,u}, \bar{y}_T^{\varepsilon,u})$ with distributions from $\mathcal{K}_0(T)$.

In the second step of the proof we should find for a given measure $\mu \in \mathcal{K}_0(T)$ the sequence of measures μ_n which are elements of $\tilde{\mathcal{K}}_{\varepsilon_n}(T)$ converging to μ. Again we shall argue with suitably chosen random variables with distributions corresponding to the measures for which we are looking.

Since the proof for the general multidimensional two-scale system requires rather long arguments, we clarify main ideas on the example of a one-dimensional model with constant coefficients and containing only the fast variable.

Let us consider the controlled stochastic differential equation

$$\varepsilon dy_t^{\varepsilon,u} = (-\gamma y_t^{\varepsilon,u} + u_t)dt + \varepsilon^{1/2} dw_t^y, \quad y_0 = 0, \tag{2.1}$$

where u is a predictable process which takes values in $U = [0, 1]$. In this case the set $\mathcal{K}_0(T)$ is the convex closure of the set $\{\mathcal{L}(\xi_0 + I(v)),\ v \in \mathcal{V}_U\}$, where

$$I(v) := \int_0^\infty e^{-\gamma s} v_s ds,$$

ξ is an Ornstein–Uhlenbeck process on some probability space $(\Omega, \mathcal{F}, P)$ with correlation function $K(s, t) = (2\gamma)^{-1} e^{-\gamma|t-s|}$, and $\mathcal{V}_U$ is the set of all U-valued processes v such that $v_{1/t}$ is a predictable process with respect to the filtration generated by the process $\xi_{1/t}$. For our purpose it is more convenient to use the alternative description of $\mathcal{K}_0(T)$ as the set $\{\mathcal{L}(\xi_0 + I(v)),\ v \in \mathcal{V}_U^\alpha\}$, where α is a random variable independent of ξ with values in a Polish space and nonatomic distribution and $\mathcal{V}_U^\alpha$ is the set of

all U-valued processes v such that $v_{1/t}$ is a predictable process with respect to the filtration generated by the process $\xi_{1/t}$ and the random variable α. We understand the equation (2.1) in the strong sense. Its solution can be represented in the following way:

$$y_t^{\varepsilon,u} = \varepsilon^{-1} \int_0^t e^{-\gamma(t-s)/\varepsilon} u_s ds + \eta_t^\varepsilon, \tag{2.2}$$

where

$$\eta_t^\varepsilon := \varepsilon^{-1/2} \int_0^t e^{-\gamma(t-s)/\varepsilon} dw_s^y. \tag{2.3}$$

Put $T_\varepsilon := T(1-\varepsilon^{1/2})$. Let us consider on the interval $[T_\varepsilon, T]$ the Gaussian stationary process

$$\tilde{\xi}_t^\varepsilon := (2\gamma)^{-1/2} \exp\{-\gamma(t-T_\varepsilon)/\varepsilon\}\beta + \varepsilon^{-1/2} \int_{T_\varepsilon}^t e^{-\gamma(t-s)/\varepsilon} dw_s^y,$$

where β is a standard normal random variable independent of the Wiener process w^y (to define β we can extend our canonical coordinate probability space). The process $\tilde{\xi}^\varepsilon$ is the solution of the linear equation

$$\varepsilon d\tilde{\xi}_t^\varepsilon = -\gamma \tilde{\xi}_t^\varepsilon dt + \varepsilon^{1/2} dw_t^y, \quad \tilde{\xi}_{T_\varepsilon}^\varepsilon = (2\gamma)^{-1/2}\beta.$$

Let us consider the Ornstein–Uhlenbeck process $\xi_t^\varepsilon = \tilde{\xi}_{T-\varepsilon t}^\varepsilon,\ t \in [0, T/\sqrt{\varepsilon}]$.

Evidently, $\eta_T^\varepsilon - \xi_0^\varepsilon = \eta_T^\varepsilon - \tilde{\xi}_T^\varepsilon \to 0$ in L^2 as $\varepsilon \to 0$.

For $u \in \mathcal{U}$ we define the process $v_s = v_s^\varepsilon := u_{T-\varepsilon s} I_{[0,T/\sqrt{\varepsilon}[}$.

Now we can write that

$$y_T^{\varepsilon,u} = \eta_T^\varepsilon + \int_0^{T/\sqrt{\varepsilon}} e^{-\gamma s} u_{T-\varepsilon s} ds + \int_{T/\sqrt{\varepsilon}}^{T/\varepsilon} e^{-\gamma s} u_{T-\varepsilon s} ds = \bar{y}_T^{\varepsilon,u} + R^\varepsilon(u),$$

where $\bar{y}_T^{\varepsilon,u} = \xi_0^\varepsilon + I(v)$,

$$R^\varepsilon(u) := \int_{T/\sqrt{\varepsilon}}^{T/\varepsilon} e^{-\gamma s} u_{T-\varepsilon s} ds + \eta_T^\varepsilon - \xi_0^\varepsilon.$$

Since $\sup_{u\in\mathcal{U}} |R^\varepsilon(u)| \to 0$ in probability, to accomplish the first step we need to check only that $\mathcal{L}(\xi_0^\varepsilon + I(v)) \in \mathcal{K}_0(T)$. Indeed, let us take for ξ the process ξ^ε defined above. For any $s \le T/\sqrt{\varepsilon}$ the random variable v_s is measurable with respect to the σ-algebra $\mathcal{C}_{T-\varepsilon s}$. But

$$\begin{aligned}\mathcal{C}_{T-\varepsilon s} &= \sigma\{w_r,\ r \le T_\varepsilon\} \vee \sigma\{w_r,\ T_\varepsilon \le r \le s\} \subseteq \sigma\{w_r,\ r \le T_\varepsilon\} \vee \sigma\{\tilde{\xi}_r^\varepsilon,\ T_\varepsilon \le r \le s\} \\ &= \sigma\{w_r,\ r \le T_\varepsilon\} \vee \sigma\{\xi_r^\varepsilon,\ s \le r \le T/\sqrt{\varepsilon}\},\end{aligned}$$

and we see that $v \in \mathcal{V}_U^\alpha$ where the random variable α is defined as the projection mapping of $C[0,T]$ onto $C[0,T_\varepsilon]$. The above considerations show that the limit of any convergent sequence $\mu^n \in \tilde{\mathcal{K}}_{\varepsilon_n}(T)$ is an element of $\mathcal{K}_0(T)$.

Now we introduce the set $\mathcal{V}_U^{\alpha\prime}$ consisting of all processes

$$v_s = \sum_{i=1}^N \varphi_i I_{]s_i, s_{i+1}]}(s) + u^0 I_{]s_{N+1},\infty[}(s), \tag{2.4}$$

where $0 = s_1 < \cdots < s_{N+1},\ u^0 \in U$, and the U-valued random variables φ_i have the form

$$\varphi_i = f_i(\alpha, \xi(r_1^i), \dots, \xi(r_{M_i}^i)), \quad s_{i+1} < r_j^i \le s_N. \tag{2.5}$$

Let $\mathcal{K}_0'(T) := \{\mathcal{L}(\xi_0 + I(v)),\ v \in \mathcal{V}_U^{\alpha'}\}$. It is easy to show that the set $\{I(v),\ v \in \mathcal{V}_U^{\alpha'}\}$ is dense in $\{I(v),\ v \in \mathcal{V}_U\}$ in probability. Thus, $\mathcal{K}'(T)$ is dense in $\mathcal{K}_0(T)$ in $\mathbf{P}(\mathbf{R})$.

Let $\mu \in \mathcal{K}'(T)$. This means that μ is the distribution of a random variable $\chi := \xi_0 + I(v)$ where v is of the form (2.4). The result will be proved if we construct a random variable χ^ε and a control u^ε such that $\mathcal{L}(\chi^\varepsilon) = \mathcal{L}(\chi)$ and $\chi^\varepsilon - y_T^{u^\varepsilon,\varepsilon} \to 0$ in probability. To this aim it is enough to find on the coordinate probability space $(C[0,T], \mathcal{C}, P)$ a stationary Gaussian Markov process ξ^ε with correlation function $K(s,t)$, a standard normal random variable α^ε independent on ξ^ε, and an admissible control $u^\varepsilon \in \mathcal{U}$ such that $\xi_0^\varepsilon - \eta_T^\varepsilon \to 0$ in probability (η_T^ε is defined by (2.3)), and

$$\int_0^\infty e^{-\gamma s} v_s^\varepsilon ds - \varepsilon^{-1} \int_0^T e^{-\gamma(T-s)/\varepsilon} u_s^\varepsilon ds \to 0,$$

where v^ε is the process given by the formula (2.4) if we substitute ξ^ε, φ^ε, and α^ε for ξ, φ, and α. Indeed, in this case the random variable $\chi^\varepsilon := \xi_0^\varepsilon + I(v^\varepsilon)$ meets the required properties.

The process ξ^ε can be constructed in the following way. For sufficiently small ε let $T_\varepsilon^k := T(1 - k\varepsilon^{1/2}),\ k = 1,2,3$. Put

$$\alpha^\varepsilon := (w_{T_\varepsilon^2} - w_{T_\varepsilon^3})/(T_\varepsilon^2 - T_\varepsilon^3)^{1/2},$$

$$\beta^\varepsilon := (2\gamma)^{-1/2}(w_{T_\varepsilon^1} - w_{T_\varepsilon^2})/(T_\varepsilon^1 - T_\varepsilon^2)^{1/2},$$

$$\tilde{\xi}_t^\varepsilon := \exp\{(t - T_\varepsilon^1)/\varepsilon\}\beta^\varepsilon + \varepsilon^{-1/2} \int_{T_\varepsilon^1}^t e^{-\gamma(t-s)/\varepsilon} dw_s, \quad t \ge T_\varepsilon^1.$$

Define the process ξ^ε on $[0, \varepsilon^{-1/2}T]$ by the equality $\xi_t^\varepsilon := \tilde{\xi}_{T-\varepsilon t}^\varepsilon$.

Evidently,

$$\xi_0^\varepsilon - \eta_T^\varepsilon = \exp\{(T - T_\varepsilon^1)/\varepsilon\}\beta^\varepsilon - \varepsilon^{-1/2} \int_0^{T_\varepsilon^1} e^{-\gamma(T-s)/\varepsilon} dw_s \to 0 \text{ in } L^2.$$

For sufficiently small ε we put

$$u^\varepsilon := u^0 I_{[0, t_{N+1}[} + \sum_{i=1}^{N+1} \varphi_i^\varepsilon I_{[t_{i+1}, t_i[},$$

where $t_i := T - \varepsilon s_i,\ i \le N+1$.

The random variables φ_i^ε are $\mathcal{C}_{t_{i+1}}$-measurable. Thus, $u^\varepsilon \in \mathcal{U}$. It follows that

$$\begin{aligned}\int_0^\infty e^{-\gamma s} v_s^\varepsilon ds - \varepsilon^{-1} \int_0^T e^{-\gamma(T-s)/\varepsilon} u_s^\varepsilon ds &= \int_0^\infty e^{-\gamma s} v_s^\varepsilon ds - \int_0^{T/\varepsilon} e^{-\gamma s} u_{T-\varepsilon s}^\varepsilon ds \\ &= \int_{T/\varepsilon}^\infty e^{-\gamma s} v_s^\varepsilon ds \to 0.\end{aligned}$$

The proof of the result for this particular case is finished.

3. Proof of Theorem 1.1. Part 1. We use the notation $\| f \|_t := \sup_{s\le t} |f_s|$ (omitting the subscript $t = T$) and denote by C different constants which do not depend on ε and u.

In the following statements the solution of (1.1), (1.2) (as well as that of (3.1)) is understood in the strong sense as given on the probability space $(C[0,T], \mathcal{C}_T, P)$.

PROPOSITION 3.1. *Let $(x_T^{\varepsilon,u}, y_T^{\varepsilon,u})$ be the solution of* (1.1), (1.2) *corresponding to some $u \in \mathcal{U}$, and let $\bar{x}^u$ be the solution of the reduced equation*

$$d\bar{x}_t^u = (A_0(t)\bar{x}_t^u + B_0(t)u_t)dt + dw_t^x, \quad \bar{x}_0^u = 0. \tag{3.1}$$

Then for any $p \in [1, \infty[$

$$\sup_\varepsilon \sup_{u\in\mathcal{U}} E \| x^{\varepsilon,u} \|^p < \infty, \tag{3.2}$$

$$\lim_{\varepsilon\to 0} \sup_{u\in\mathcal{U}} E \| x^{\varepsilon,u} - \bar{x}^u \|^p = 0, \tag{3.3}$$

$$\sup_\varepsilon \sup_{u\in\mathcal{U}} \sup_{t\le T} E|y_t^{\varepsilon,u}|^p < \infty. \tag{3.4}$$

Proof. Let us introduce for $\varepsilon^{-1}A_4(t)$ the fundamental matrix $\Psi^\varepsilon(t,s)$, which is the solution of the linear matrix equation

$$\frac{\partial \Psi^\varepsilon(t,s)}{\partial t} = \varepsilon^{-1}A_4(t)\Psi^\varepsilon(t,s), \quad \Psi^\varepsilon(s,s) = I_n. \tag{3.5}.$$

Since A_4 is continuous and the eigenvalues satisfy (1.6), there exists a constant L such that

$$|\Psi^\varepsilon(t,s)| \le Le^{-\kappa(t-s)/\varepsilon} \tag{3.6}$$

for all $s \le t \le T$ and $\varepsilon \in]0,1]$; see, e.g., [18]. In particular, from the above bound it follows that for all $t \le T$ and $\varepsilon \in]0,1]$

$$\frac{1}{\varepsilon}\int_0^t |\Psi^\varepsilon(t,s)|ds \le L/\kappa. \tag{3.7}$$

Using the fundamental matrix, the equation (1.2) can be solved with respect to $y = y^{\varepsilon,u}$ and we get the representation

$$y_t^{\varepsilon,u} = \frac{1}{\varepsilon}\int_0^t \Psi^\varepsilon(t,s)[A_3(s)x_s^{\varepsilon,u} + B_2(s)u_s]ds + \eta_t^\varepsilon, \tag{3.8}$$

where

$$\eta_t^\varepsilon := \frac{1}{\sqrt{\varepsilon}}\int_0^t \Psi^\varepsilon(t,s)dw_s^y. \tag{3.9}$$

The process η^ε is the solution of the linear stochastic equation

$$d\eta_t^\varepsilon = \varepsilon^{-1}A_4(t)\eta_t^\varepsilon dt + \varepsilon^{-1/2}dw_t^y, \quad \eta_0^\varepsilon = 0. \tag{3.10}$$

We shall use the following properties of η^ε following, e.g., from Theorem 3.1 in [14]: there exists a constant C_p such that

$$\sup_{t\ge 0} E|\eta_t^\varepsilon|^p \le C_p \tag{3.11}$$

for any $p \in [1, \infty[$ and

$$E \parallel \eta^\varepsilon \parallel^p \leq C_p \varepsilon^{-1/4} \tag{3.12}$$

for any $p \in [4, \infty[$.

Substituting (3.8) in the equation (1.1) written in the integral form we come to the following representation for the slow variable:

$$x_t^{\varepsilon,u} = \int_0^t [A_1(s) x_s^{\varepsilon,u} + B_1(s) u_s] ds$$
$$+ \int_0^t \left\{ A_2(s) \frac{1}{\varepsilon} \int_0^s \Psi^\varepsilon(s,r) [A_3(r) x_r^{\varepsilon,u} + B_2(r) u_r] dr \right\} ds + \zeta_t^\varepsilon + w_t^x, \tag{3.13}$$

where

$$\zeta_t^\varepsilon := \int_0^t A_2(s) \eta_s^\varepsilon ds. \tag{3.14}$$

LEMMA 3.1. *For any $p \in [1, \infty[$ there exists a constant c_p such that for all $\varepsilon \in]0, 1]$ it holds that*

$$E \parallel \zeta^\varepsilon \parallel^p \leq c_p, \tag{3.15}$$

$$\lim_{\varepsilon \to 0} E \parallel \zeta^\varepsilon \parallel^p = 0. \tag{3.16}$$

Proof. Since A_2 is bounded, (3.15) follows immediately from the Jensen inequality and (3.11). To prove (3.16) we consider the approximation of $D := A_2 A_4^{-1}$ by the step functions

$$D^N := \sum_{i=1}^N D_{t_i} I_{]t_{i-1}, t_i]},$$

where $t_i := iT/N$. Using (3.10) we have

$$\zeta_t^\varepsilon = \int_0^t D_s^N A_4(s) \eta_s^\varepsilon ds + \int_0^t (D_s - D_s^N) A_4(s) \eta_s^\varepsilon ds$$
$$= \varepsilon \sum_{i=1}^N D_{t_i} [\eta_{t_i \wedge t}^\varepsilon - \eta_{t_{i-1} \wedge t}^\varepsilon - \varepsilon^{1/2} (w_{t_i \wedge t}^y - w_{t_{i-1} \wedge t}^y)] + \int_0^t (D_s - D_s^N) A_4(s) \eta_s^\varepsilon ds.$$

This implies the bound

$$\parallel \zeta^\varepsilon \parallel \leq 2\varepsilon^{1/2} (\varepsilon^{1/2} \parallel \eta^\varepsilon \parallel + \parallel w^y \parallel) + C \delta_N \int_0^T |\eta_s^\varepsilon| ds, \tag{3.17}$$

where $\delta_N := \parallel D - D^N \parallel \to 0$ as $N \to \infty$ due to continuity of α.

Notice that (3.12) implies that the family of random variables $\{\varepsilon^{1/2} \parallel \eta^\varepsilon \parallel,\ \varepsilon \in]0, 1]\}$ is bounded in L^p (for any finite p). It follows from (3.11) that the family of integrals on the right-hand side of (3.17) is also bounded in L^p. Thus,

$$\limsup_{\varepsilon \to 0} \parallel \zeta^\varepsilon \parallel \leq C \delta_N$$

and (3.16) holds.

From the representation (3.13) and bounds (3.6), (3.15) it is easy to deduce that

$$E \parallel x^{\varepsilon,u} \parallel_t^{2p} \leq C \left(1 + \int_0^t E \parallel x^{\varepsilon,u} \parallel_s^{2p} ds\right),$$

and the standard application of the Gronwall–Bellman lemma gives (3.2).

Put $\bar{\Delta}_t^{x,\varepsilon,u} := x_t^{\varepsilon,u} - \bar{x}_t^u$. The relations (3.1), (3.13) imply that

$$\bar{\Delta}_t^{x,\varepsilon,u} = \int_0^t A_0(s)\bar{\Delta}_t^{x,\varepsilon,u} ds + R_t^{\varepsilon,u}, \tag{3.18}$$

where

$$\begin{aligned} R_t^{\varepsilon,u} &:= \int_0^t A_2(s) \left[\frac{1}{\varepsilon}\int_0^s \Psi^\varepsilon(s,r)A_3(r)x_r^{\varepsilon,u} dr + A_4^{-1}(r)A_3(r)x_r^{\varepsilon,u}\right] ds \\ &+ \int_0^t A_2(s) \left[\frac{1}{\varepsilon}\int_0^s \Psi^\varepsilon(s,r)B_2(r)u_r dr + A_4^{-1}(r)B_2(r)u_r\right] ds + \zeta_t^\varepsilon. \end{aligned} \tag{3.19}$$

It follows from (3.18) that

$$E \parallel \bar{\Delta}^{x,\varepsilon,u} \parallel_t^p \leq C \left(\int_0^t E \parallel \bar{\Delta}^{x,\varepsilon,u} \parallel_s^p ds + E \parallel R^{\varepsilon,u} \parallel^p\right),$$

and by the Gronwall–Bellman lemma we have

$$E \parallel \bar{\Delta}^{x,\varepsilon,u} \parallel_t^p \leq CE \parallel R^{\varepsilon,u} \parallel^p e^{CT}.$$

Thus, to prove (3.3) we need to show that

$$\lim_{\varepsilon\to 0} \sup_{u\in\mathcal{U}} E \parallel R^{\varepsilon,u} \parallel^p = 0.$$

But this relation follows from (3.2), (3.16) and the following statement (see [15, Lemma 3.1] or [13, Lemma 3.2]).

LEMMA 3.2. *For any $\varepsilon \in]0,1]$, $\eta > 0$, and bounded measurable function h the following holds:*

$$\begin{aligned} &\left\| \int_0^\cdot A_2(s) \left[\frac{1}{\varepsilon}\int_0^s \Psi^\varepsilon(s,r)h_r dr + A_2(s)A_4^{-1}(s)h_s\right] ds \right\| \\ &\qquad \leq \parallel h \parallel T(C_1\eta + \varepsilon C_2(\eta)), \end{aligned} \tag{3.20}$$

where C_1, $C_2(\eta)$ depend on A_2 and A_4.

At last, the property (3.4) of uniform boundedness in L^p of values of the fast variables for the fixed time follows from the representation (3.8) and (3.2), (3.7), and (3.11).

PROPOSITION 3.2. *Let $(x^{\varepsilon,u}, y^{\varepsilon,u})$ be the solution of* (1.1), (1.2) *corresponding to some $u \in \mathcal{U}$, and let $\bar{x}^u$ be the solution of the reduced equation* (3.1). *Let the random variable $\bar{y}_T^{\varepsilon,u}$ be defined by*

$$\bar{y}_T^{\varepsilon,u} := -A_4^{-1}(T)A_3(T)\bar{x}_T^u + \int_0^\infty \exp\{A_4(T)r\}B_2(T)v_r^\varepsilon dr + \tilde{\xi}_T^\varepsilon, \tag{3.21}$$

where $v^\varepsilon_r := u_{T-r\varepsilon} I_{[0,T/\sqrt{\varepsilon}]}(r) + u^0 I_{]T/\sqrt{\varepsilon},\infty[}(r)$, u^0 *is an arbitrary point in* U,

$$\tilde{\xi}^\varepsilon_T := \exp\{\varepsilon^{-1}A_4(T)(T-T^\varepsilon\}\beta + \frac{1}{\sqrt{\varepsilon}}\int_{T_\varepsilon}^T \exp\{\varepsilon^{-1}A_4(T)(T-s)\}dw^y_s, \tag{3.22}$$

$T_\varepsilon := (1-\sqrt{\varepsilon})T$, β *is a Gaussian random variable with the zero mean and covariance* Ξ, *and the matrix* Ξ *is defined in* (1.9).

Then for any $p \in [1,\infty[$

$$\lim_{\varepsilon\to 0}\sup_{u\in\mathcal{U}} E|y^{\varepsilon,u}_T - \bar{y}^{\varepsilon,u}_T|^p = 0. \tag{3.23}$$

Proof. Let $\tilde{y}^{\varepsilon,u}$ be the solution of the stochastic differential equation

$$\varepsilon d\tilde{y}^{\varepsilon,u}_t = (A_3(T)\bar{x}^u_T + A_4(T)\tilde{y}^{\varepsilon,u}_t + B_2(T)u_t)dt + \sqrt{\varepsilon}dw^y_t \quad \tilde{y}^{\varepsilon,u}_0 = 0. \tag{3.24}$$

Put

$$\tilde{\Delta}^{y,\varepsilon,u}_t := y^{\varepsilon,u}_t - \tilde{y}^{\varepsilon,u}_t, \quad \widehat{x}^{\varepsilon,u}_t := x^{\varepsilon,u}_t - x^{\varepsilon,u}_T,$$

$\widehat{A}_i(t) := A_i(t) - A_i(T)$, $\quad \widehat{B}_i(t) := B_i(t) - B_i(T)$.

The process $\tilde{\Delta}^{y,\varepsilon,u}$ is the solution of the ordinary differential equation

$$d\tilde{\Delta}^{y,\varepsilon,u}_t = (A_4(T)\tilde{\Delta}^{y,\varepsilon,u}_t + \varphi^{\varepsilon,u}_t)dt, \quad \tilde{\Delta}^{y,\varepsilon,u}_0 = 0,$$

where

$$\varphi^{\varepsilon,u}_t := \widehat{A}_4(t)y^{\varepsilon,u}_t + \widehat{A}_3(t)x^{\varepsilon,u}_t + A_3(T)\widehat{x}^{\varepsilon,u}_t + A_3(T)\bar{\Delta}^{x,\varepsilon,u}_T + \widehat{B}_2(t)u_t.$$

Thus,

$$\tilde{\Delta}^{y,\varepsilon,u}_T = \frac{1}{\varepsilon}\int_0^T \exp\{\varepsilon^{-1}A_4(T)(T-s)\}\varphi^{\varepsilon,u}_s ds. \tag{3.25}$$

By virtue of (1.6) for all $t \geq 0$ we have that

$$|\exp\{\varepsilon^{-1}A_4(T)t\}| \leq Ce^{-2\kappa t/\varepsilon}. \tag{3.26}$$

Taking into account (3.2), (3.4) and the boundedness of U, we get from (3.25) that the L^p-norm of $\tilde{\Delta}^{y,\varepsilon,u}_T$ is bounded by

$$C\frac{1}{\varepsilon}\int_0^T e^{-2\kappa(T-s)/\varepsilon}(|\widehat{A}_4(s)| + |\widehat{A}_3(s)| + f^\varepsilon_s + \bar{g}^\varepsilon + |\widehat{B}_2(s)|)ds, \tag{3.27}$$

where

$$f^\varepsilon_s := \sup_{u\in\mathcal{U}}(E|x^{\varepsilon,u}_s - x^{\varepsilon,u}_T|^p)^{1/p}, \quad \bar{g}^\varepsilon := \sup_{u\in\mathcal{U}}(E|\bar{\Delta}^{x,\varepsilon,u}_T|^p)^{1/p}.$$

Let $\bar{f}_s$ be the function similar to f^ε_s but defined for $\bar{x}^u$. It follows from (3.3) that for any $\delta > 0$ we have $f^\varepsilon_s \leq \bar{f}_s + \delta$ for all sufficiently small ε. But it is clear from the equation (3.1) that $\lim_{s\to T}\bar{f}_s = 0$. Taking into account the above remarks we check easily that the expression (3.27) tends to zero as $\varepsilon \to 0$ and, hence,

$$\lim_{\varepsilon\to 0}\sup_{u\in\mathcal{U}} E|y^{\varepsilon,u}_T - \tilde{y}^{\varepsilon,u}_T|^p = 0. \tag{3.28}$$

Now we show that

$$\lim_{\varepsilon\to 0}\sup_{u\in\mathcal{U}} E|\bar{y}_T^{\varepsilon,u}-\tilde{y}_T^{\varepsilon,u}|^p=0. \tag{3.29}$$

Indeed,

$$\bar{y}_T^{\varepsilon,u}-\tilde{y}_T^{\varepsilon,u}=\left(-A_4^{-1}(T)-\frac{1}{\varepsilon}\int_0^T \exp\{\varepsilon^{-1}A_4(T)(T-s)\}ds\right)A_3(T)\bar{x}_T^u$$
$$+\int_{T/\varepsilon}^{\infty}\exp\{A_4(T)r\}B_2(T)u_r^0dr-\int_{T/\sqrt{\varepsilon}}^{T/\varepsilon}\exp\{A_4(T)r\}B_2(T)u_{T-\varepsilon r}dr$$
$$+\exp\{\varepsilon^{-1/2}A_4(T)T\}\beta-\frac{1}{\sqrt{\varepsilon}}\int_0^{T_\varepsilon}\exp\{\varepsilon^{-1}A_4(T)(T-s)\}dw_s^y.$$

Evidently, L^p-norms of all terms on the right-hand side of this identity tend to zero and the convergence of the first one is uniform in $u\in\mathcal{U}$ by virtue of (3.2) and (3.3). Thus, (3.29) holds. The relations (3.28), (3.29) imply (3.23).

Proposition 3.2 is proved.

Assume that sequence $\mathcal{L}(x_T^{\varepsilon_n,u_n},y_T^{\varepsilon_n,u_n})$ converges in $\mathbf{P}(\mathbf{R}^m)$ to some μ. Choose in the representation (3.22) the random variable β independent of W. It follows from Propositions 3.1, 3.2 that the sequence $\mathcal{L}(\bar{x}_T^{u_n},\bar{y}_T^{\varepsilon_n,u_n})$ converges to the same limit. Let us introduce the modified controls $\hat{u}_n=u_nI_{[0,T_{\varepsilon_n}]}+u^0I_{]T_{\varepsilon_n},T]}$, where u^0 is a fixed point from U. Since $\bar{x}_T^{u_n}-\bar{x}_T^{\hat{u}_n}$ tends to zero in probability, the sequence $\mathcal{L}(\bar{x}_T^{\hat{u}_n},\bar{y}_T^{\varepsilon_n,u_n})$ converges to μ and we need to check only that $\mathcal{L}(\bar{x}_T^{\hat{u}_n},\bar{y}_T^{\varepsilon_n,u_n})\in\mathcal{K}_0(T)$. To show this notice that $\bar{x}_T^{\hat{u}_n}$ is a function of the natural projection

$$i^{\varepsilon_n}:\{w_t^x,w_t^y,\ t\in[0,T]\}\mapsto(\{w_t^x,\ t\in[0,T]\},\{w_t^y,\ t\in[0,T_{\varepsilon_n}]\}).$$

As in section 2 it can be shown that the regular conditional distribution of the random variable $\xi_0^{\varepsilon_n}+I(v^{\varepsilon_n})$ for a fixed value i^{ε_n} belongs to S. Since S is a convex closed set and $\bar{x}_T^{\hat{u}_n}$ is a measurable function on i^{ε_n}, it follows from Lemma 5.6 that the regular conditional distribution of $\xi_0^{\varepsilon_n}+I(v^{\varepsilon_n})$ for a fixed value $\bar{x}_T^{\hat{u}_n}$ also belongs to S, implying the result.

4. Proof of Theorem 1.1. Part 2. Now we must show that for any measure $\mu F^{-1}\in\mathcal{K}_0(T)$ there exists a sequence $\mu_n\in\mathcal{K}_{\varepsilon_n}(T)$ which converges to μF^{-1} in $\mathbf{P}(\mathbf{R}^n)$. It is sufficient to find such a sequence for an arbitrary μF^{-1} from the set $\tilde{\mathcal{K}}_0(T)$ which is dense in $\mathcal{K}_0(T)$ in the total variation topology. The latter property holds since the attainability set $\tilde{\mathcal{K}}_0^x$ corresponding to the strong solutions of (2.1) is dense in $\mathcal{K}_0^x$ in the total variation topology. Thus, there are dense embeddings $\tilde{\mathcal{K}}_0\subseteq\mathcal{K}_0$ and $\tilde{\mathcal{K}}_0(T)\subseteq\mathcal{K}_0(T)$.

Let us fix $\delta>0$ and a measure $\mu=m(x,dy)\nu(dx)$ such that $\mu F^{-1}\mathcal{K}_0(T)$. By definition $\nu=\mathcal{L}(\bar{x}_T^u)$, where $\bar{x}^u$ is a solution of the reduced equation (2.1) corresponding to some admissible control u. Let $\nu_h:=\mathcal{L}(\bar{x}_{T-h}^u),\ \mu_h(dx,dy):=m(x,dy)\nu_h(dx),\ h\in[0,T]$. Then there exists $h_0>0$ such that

$$d(\mu F^{-1},\mu_hF^{-1})\le\delta \tag{4.1}$$

for all $h\in]0,h_0]$.

To prove (4.1) we use the following.

LEMMA 4.1. *Let $\bar{x}^u$ be the solution of* (3.1). *Then*

$$\lim_{s\to 0}\sup_{u\in\mathcal{U}} \mathrm{Var}(\mathcal{L}(\bar{x}^u_{T-s}) - \mathcal{L}(\bar{x}^u_T)) = 0. \tag{4.2}$$

Proof. For any $u \in \mathcal{U}$ let $u^r := uI_{[0,T-r]} + u^0 I_{]T-r,T]}$, where u^0 is an arbitrary point in $\mathcal{U}$. It follows from the bound for the total variation distance in terms of the Hellinger process h_t (see [12, Theorems 2.2 and 5.1]) that

$$\mathrm{Var}(\mathcal{L}(\bar{x}^u) - \mathcal{L}(\bar{x}^{u^r})) \le Cr^{1/2}. \tag{4.3}$$

(Notice that in the considered situation the Hellinger process for the pair $(\mathcal{L}(\bar{x}^u), \mathcal{L}(\bar{x}^{u^r}))$ has the form

$$h_t = \int_0^t I_{[r,T]}(\tau)|B_0(\tau)(\widehat{u}_\tau - u^0)|^2 d\tau,$$

where $\widehat{u}_s$ takes values in U.)

Fix $\gamma > 0$ and $r > 0$ such that $Cr^{1/2} \le \gamma$. For any $s \in [0, r]$ we have

$$\mathcal{L}(\bar{x}^{u^r}_{T-s}) = \mathcal{L}(\bar{x}^u_{T-r}) * \mathcal{N}(a_s, K_s),$$

where $*$ denotes the convolution, $\mathcal{N}(a_s, K_s)$ is the nondegenerate Gaussian distribution with the mean

$$a_s := \int_{T-r}^{T-s} B_0(\tau)u^0 d\tau$$

and covariance

$$K_s := \int_{T-r}^{T-s} \Phi_0(T-s,\tau)\Phi_0'(T-s,\tau)d\tau,$$

and $\Phi_0(T-s,\tau)$ is the fundamental matrix corresponding to $A_0(t)$. In particular,

$$\mathcal{L}(\bar{x}^{u^r}_T) = \mathcal{L}(\bar{x}^u_{T-r}) * \mathcal{N}(a_0, K_0).$$

The well-known inequality

$$\mathrm{Var}(F * G - F * \tilde{G}) \le \mathrm{Var}(G - \tilde{G})$$

implies that

$$\mathrm{Var}(\mathcal{L}(\bar{x}^{u^r}_{T-s}) - \mathcal{L}(\bar{x}^{u^r}_T)) \le \mathrm{Var}(\mathcal{N}(a_s, K_s) - \mathcal{N}(a_0, K_0)),$$

where the right-hand side tends to zero as $s \to 0$.

Thus, for sufficiently small s we have

$$\sup_{u\in\mathcal{U}} \mathrm{Var}(\mathcal{L}(\bar{x}^{u^r}_{T-s}) - \mathcal{L}(\bar{x}^{u^r}_T)) \le \gamma. \tag{4.4}$$

It follows from (4.3) and (4.4) that

$$\sup_{u\in\mathcal{U}} \mathrm{Var}(\mathcal{L}(\bar{x}^u_{T-s}) - \mathcal{L}(\bar{x}^u_T)) \le 3\gamma$$

and the lemma is proved.

Since

$$\mathrm{Var}(\mu F^{-1} - \mu_h F^{-1}) = \mathrm{Var}(\mu - \mu_h) = \mathrm{Var}(\nu - \nu_h) \to 0$$

by virtue of the above lemma, the relation (4.1) holds.

Furthermore, there exists $h_1 > 0$

$$\sup_{\varepsilon} \sup_{z \in \mathcal{U}_h(u)} d(\mathcal{L}(x^{\varepsilon,z}_{T-h}, y^{\varepsilon,z}_T), \mathcal{L}(x^{\varepsilon,z}_T, y^{\varepsilon,z}_T)) \le \delta, \tag{4.5}$$

where $\mathcal{U}_h(u)$ is the set consisting of all $z \in \mathcal{U}$ such that

$$zI_{[0,T-h]} = uI_{[0,T-h]}. \tag{4.6}$$

The relation (4.5) is an evident corollary of Proposition 3.1 and the following.

LEMMA 4.2. *Let $(\xi^{(i)}_{\iota,h})$, $\iota \in I(h)$, $h \in [0,T]$, $i = 1,\ 2$, be two families of random variables with values in $\mathbf{R}^m$ such that*

$$\sup_h \sup_{\iota \in I(h)} E|\xi^{(i)}_{\iota,h}|^p < \infty, \quad i = 1,\ 2,$$

$$\lim_{h \to 0} \sup_{\iota \in I(h)} E|\xi^{(1)}_{\iota,h} - \xi^{(2)}_{\iota,h}|^p = 0$$

for some $p > 0$. Then for any bounded continuous function f on $\mathbf{R}^m$

$$\lim_{h \to 0} \sup_{\iota \in I(h)} |Ef(\xi^{(1)}_{\iota,h}) - f(\xi^{(2)}_{\iota,h})| = 0.$$

The proof of Lemma 4.2 is easy and is omitted.

Lemma 4.2 implies also the existence of $h_2 > 0$ such that

$$\sup_{\iota} d(\mathcal{L}(\bar{x}^u_{T-h}, -A_4(T)A_3(T)\bar{x}^u_{T-h} + \eta_\iota), \mathcal{L}(\bar{x}^u_{T-h}, -A_4(T)A_3(T)\bar{x}^u_T + \eta_\iota)) \le \delta, \tag{4.7}$$

where the family (η_ι) consists of all random variables with distribution from S_Y.

Let us consider some $h \le h_0 \wedge h_1 \wedge h_2$. The desired result will be proved if we find for any sufficiently small ε an admissible control $z = z^\varepsilon$ satisfying (4.6) such that

$$d(\mathcal{L}(x^{\varepsilon,z}_{T-h}, y^{\varepsilon,z}_T), \mu_h F^{-1}) \le 2\delta. \tag{4.8}$$

Indeed, it follows from (4.1), (4.5), and (4.8) that

$$d(\mathcal{L}(x^{\varepsilon,z}_T, y^{\varepsilon,z}_T), \mu_h F^{-1}) \le 4\delta,$$

and this means that any point in $\mathcal{K}_0(T)$ can be approximated by points from $\mathcal{K}_\varepsilon(T)$.

Let $(\Omega, \mathcal{F}, P)$ be a probability space with a countably generated σ-algebra. Assume that on this space we have independent random elements $\zeta,\ \alpha,\ \xi$, where ζ has the distribution ν_h, i.e., the same distribution as $\bar{x}^u_{T-h}$; α has the standard normal distribution; ξ is a stationary Gaussian Markov process with zero mean and covariance function given by (1.8), (1.9). Let us consider the set $\mathcal{V}^\alpha_U$ of all U-valued processes which are predictable with respect to the filtration generated by $\xi_{1/t}$ and α (we denote by $\mathcal{P}$ the corresponding predictable σ-algebra in $\Omega \times \mathbf{R}_+$).

LEMMA 4.3. *There is a function $v : \Omega \times \mathbf{R}_+ \times \mathbf{R}^m \to U$ which is measurable with respect to $\mathcal{P} \otimes \mathcal{B}(\mathbf{R}^m)$ such that $v(.,x) \in \mathcal{V}^\alpha$ for all $x \in \mathbf{R}^m$ and $\mathcal{L}(\xi_0 + I(v(.,x)))$ is equal to $\mu(x, dy)$ for ν_h almost all $x \in \mathbf{R}^m$.*

Proof. Evidently, $v \mapsto \mathcal{L}(\xi_0 + I(v))$ is a continuous, hence measurable, mapping from the space $\mathbf{V} := L^1(\Omega \times \mathbf{R}_+, \mathcal{P}, \rho)^d$ into $\mathbf{P}(\mathbf{R}^n)$, where $\rho(d\omega, dt) = e^{-2\kappa t} P(d\omega)dt$. Thus, the multivalued mapping

$$\Gamma : x \mapsto \{v \in \mathbf{V} : \ v(\omega, t) \in U \ \rho \text{ a.e.}, \ \mathcal{L}(\xi_0 + I(v)) = \mu(x, .)\}$$

has a measurable graph. Hence, it admits a measurable selector $x \mapsto V(x)$. Notice that $V(x)$ as an element of $\mathbf{V}$ is a class of ρ-equivalent functions. To choose from $V(x)$ a representative in a measurable way we proceed as follows. Let (v^i) be a sequence of elements from $\mathcal{V}_U^\alpha$ which is dense in $\mathcal{V}_U^\alpha \cap \mathbf{V}$, $j(x, l) := \min\{i : \| v(x) - v^i \| \leq 1/l\}$. Then $v^{j(l)} = v^{j(x,l)}(\omega, t)$ is a $\mathcal{P} \otimes \mathcal{B}(\mathbf{R}^m)$-measurable function with values in U. The sequence $v^{j(x,l)}$ converges to $V(x)$ in $\mathbf{V}$. Since U is bounded, the sequence $v^{j(l)}$ converges to V in $L^1(\Omega \times \mathbf{R}_+ \times \mathbf{R}^m, \mathcal{P} \otimes \mathcal{B}(\mathbf{R}^m), \rho \times \nu_h)^d$. Hence, there exists a subsequence which converges $\rho \times \nu_h$ a.e. to some $\mathcal{P} \otimes \mathcal{B}(\mathbf{R}^m)$-measurable function $v = v(\omega, t, x)$. For ν_h almost all x we have the inclusion $v(., x) \in V(x)$ implying that $\mathcal{L}(\xi_0 + I(v(., x))) = \mu(x, dy)$ for such x.

It follows from the above lemma that the measure μ_h is the distribution of the random variable $(\zeta, \xi_0 + I(v(., \zeta)))$, i.e.,

$$\mu_h = \mathcal{L}(\zeta, \xi_0 + I(v(., \zeta))). \tag{4.9}$$

Generalizing the arguments of section 2 we introduce a set $\mathcal{V}_U^{(\alpha,\zeta)\prime}$ consisting of all functions

$$v(s, x) = \sum_{i=1}^{N} \varphi_i(x) I_{]s_i, s_{i+1}]}(s) + u^0 I_{]s_{N+1}, \infty[}(s), \tag{4.10}$$

where $0 = s_1 < \cdots < s_{N+1}$, $u^0 \in U$, and $\varphi_i(x)$ have the form

$$\varphi_i(x) = f_i(\alpha, \xi(r_1^i), \ldots, \xi(r_{M_i}^i), x), \quad s_{i+1} < r_j^i \leq s_N, \tag{4.11}$$

and the functions f_i are measurable with respect to their arguments and take values in U.

Assume that the representation (4.9) holds with $v \in \mathcal{V}_U^{(\alpha,\zeta)\prime}$. There is a freedom in the choice of ζ, α, and ξ which we use in the following constructions.

Put $T_\varepsilon^k := T(1 - k\varepsilon^{1/2})$, $k = 1, 2, 3$, $\zeta := \bar{x}_{T-h}^u$.

Define

$$\alpha^\varepsilon := (w_{T_\varepsilon^2}^{y,1} - w_{T_\varepsilon^3}^{y,1})/(T_\varepsilon^2 - T_\varepsilon^3)^{1/2},$$

where $w^{y,1}$ is the first component of the vector process w^y,

$$\beta^\varepsilon := \Xi^{1/2}(w_{T_\varepsilon^1}^y - w_{T_\varepsilon^2}^y)/(T_\varepsilon^1 - T_\varepsilon^2)^{1/2}.$$

Let us consider on $[T_\varepsilon^1, T]$ the linear stochastic differential equation

$$\varepsilon d\tilde{\xi}_t^\varepsilon = A_4(T)\tilde{\xi}_t^\varepsilon dt + \varepsilon^{1/2} dw_t^y, \quad \tilde{\xi}_{T_\varepsilon^1}^\varepsilon = \beta^\varepsilon.$$

Put $\xi_t^\varepsilon := \tilde{\xi}_{T-\varepsilon t}^\varepsilon$, $t \in [0, \varepsilon^{-1/2}T]$. For sufficiently small ε we define the admissible control

$$z^\varepsilon := uI_{[0,t_{N+1}[} + \sum_{i=1}^{N+1} \varphi_i^\varepsilon(\bar{x}_{T-h}^u) I_{[t_{i+1}, t_i[},$$

where $t_i := T - \varepsilon s_i$, $i \leq N + 1$, and φ_i^ε is constructed in accordance with (4.11).

It follows from Propositions 3.1 and 3.2 that

$$(x^{\varepsilon,z^\varepsilon}_{T-h}, y^{\varepsilon,z^\varepsilon}_T) - (\bar{x}^u_{T-h}, -A_4(T)A_3(T)\bar{x}^u_T + \xi^\varepsilon_0 + I(v(.,\bar{x}^u_{T-h}))) \to 0$$

in probability as $\varepsilon \to 0$. Thus,

$$d(\mathcal{L}(x^{\varepsilon,z^\varepsilon}_{T-h}, y^{\varepsilon,z^\varepsilon}_T), \mathcal{L}(\bar{x}^u_{T-h}, -A_4(T)A_3(T)\bar{x}^u_T + \xi^\varepsilon_0 + I(v(.,\bar{x}^u_{T-h})))) \le \delta \tag{4.12}$$

for all sufficiently small ε. Taking into account (4.7) we get from here the desired inequality (4.8).

Part 2 of Theorem 1.1 is proved now for the case when μ_h is given by (4.9) with $v \in \mathcal{V}_U^{(\alpha,\zeta)\prime}$. Since the set $\{I(v) : \ v \in \mathcal{V}_U^{(\alpha,\zeta}\prime\}$ is dense in probability in the set $\{I(v) : \ v \in \mathcal{V}_U^{\alpha,\zeta}\}$, the result holds for the general case as well.

5. On a compactness of some subsets in the space of probability measures.

5.1. Notations and preliminaries. Let X be a Polish space with the Borel σ-algebra $\mathcal{X}$ and $\mathbf{P}(X)$ be a space of all probability measures on X with the topology of weak convergence. It is well known that $\mathbf{P}(X)$ equipped by the Prohorov metric is again a Polish space. The relative compactness of a subset $A \subseteq \mathbf{P}(X)$ is equivalent to its tightness. The last means that for any $\varepsilon > 0$ there exists a compact set $K \subseteq X$ such that $m(K) \ge 1 - \varepsilon$ for all $m \in A$.

We shall use the notation $m(f) = \int_X f(x)m(dx)$. We denote by $\mathcal{L}(\xi)$ the distribution of a random variable ξ.

Let $(X, \mathcal{X})$ and $(Y, \mathcal{Y})$ be two Polish spaces. We denote by $\mathcal{M}(X, Y)$ the set of stochastic kernels from $(X, \mathcal{X})$ to $(Y, \mathcal{Y})$ that is mappings $\mu : X \times \mathcal{Y} \to ([0,1], \mathcal{B}[0,1])$ such that $x \mapsto \mu(x, \Gamma)$ is $\mathcal{X}$-measurable for any $\Gamma \in \mathcal{Y}$ and $\mu(x, .) \in \mathbf{P}(Y)$ for any $x \in X$.

It is easy to check that the mapping $\mu : X \times \mathcal{Y} \to ([0,1], \mathcal{B}[0,1])$ is in $\mathcal{M}(X, Y)$ if and only if one of the following equivalent conditions is satisfied:

(1) The mapping $x \mapsto \mu(x, .)$ is $\mathcal{X}$-measurable (i.e., $\mu(x, .)$ is a $\mathbf{P}(Y)$-valued random variable).

(2) For any $f \in C_b(Y)$ (the set of all bounded continuous functions on Y) the mapping $x \mapsto \mu(x, f)$ is $\mathcal{X}$-measurable (i.e., $\mu(x, f)$ is a real-valued random variable).

The Skorohod Representation Theorem. *Let Y be a Polish space and $m_n \in \mathbf{P}(Y)$ be a sequence converging in $\mathbf{P}(Y)$ to some m. Then on the probability space $([0,1], \mathcal{B}[0,1], dx)$ there exist Y-valued random variables $\tilde{\xi}_n$ and $\tilde{\xi}$ such that $\mathcal{L}(\tilde{\xi}_n) = m_n$, $\mathcal{L}(\tilde{\xi}) = m$, and $\tilde{\xi}_n \to \tilde{\xi}$ pointwise.*

The Measurable Isomorphism Theorem. *Let $(X, \mathcal{X}$ be an uncountable Polish space. Then there is a one-to-one mapping $i : X \to [0,1]$ such that $i(\Gamma) \in \mathcal{B}[0,1]$ for any $\Gamma \in \mathcal{X}$ and $i^{-1}(A) \in \mathcal{X}$ for any $A \in \mathcal{B}[0,1]$.*

Another useful result is that any Polish space X is homeomorphic to a G_δ-subset of the Hilbert cube $[0,1]^{\mathbf{N}}$. For further information see, e.g., [6], [9].

5.2. For $\mu \in \mathcal{M}(X, Y)$, $m \in \mathbf{P}(X)$, and $\Gamma \in \mathcal{Y}$, the integral $\int_X \mu(x, \Gamma)m(dx)$ defines a probability measure on $(Y, \mathcal{Y})$ which we shall denote by $\int_X \mu(x, .)m(dx)$.

Lemma 5.1. *Let $(X, \mathcal{X})$ be a Polish space with nonatomic measure ν on it, let S be a compact set in $\mathbf{P}(Y)$, and let $\mathcal{M})$ be the set consisting of all stochastic kernels μ from $(X, \mathcal{X}$ to $(Y, \mathcal{Y})$ such that $\mu(x, .) \in S$ for all $x \in X$. Then the set*

$$K = \left\{ m \in \mathbf{P}(Y) : \ m(.) = \int_X \mu(x, .)\nu(dx), \ \mu \in \mathcal{M} \right\}$$

is a convex compact subset in $\mathbf{P}(Y)$ coinciding with $\overline{\text{conv}}S$.

Proof. By virtue of the measurable isomorphism theorem we can consider only the case when $(X, \mathcal{X}) = ([0,1], \mathcal{B}[0,1])$. Assume at first that $\nu(dx) = dx$, i.e., ν is the Lebesgue measure. Convexity of $\mathcal{M}$ is clear: if measures $m_i(.) = \int_X \mu_i(x,.)dx,\ i = 1,\ 2$, belong to K, $\alpha > 0,\ \beta > 0,\ \alpha + \beta = 1$, then the measure $\alpha m_1(.) + \beta m_2(.) = \int_X \mu(x,.)dx$ with

$$\mu(x,.) = I_{[0,\alpha]}(x)\mu_1(\alpha^{-1}x,.) + I_{]1-\beta,1]}(x)m_2(\beta^{-1}(x-1+\beta),.)$$

also belonging to K. The tightness of K follows easily from the tightness of S. To prove that K is closed, let us consider the sequence $m_n(.) = \int \mu_n(x,.)dx \in K$ converging to some $m(.)$ in $\mathbf{P}(Y)$. Notice that elements of $\mathcal{M}$ are random variables with values in the compact subset S of a Polish space. Thus, the set of distributions of these random variables $\{\mathcal{L}(\mu) :\ \mu \in \mathcal{M}\}$ is relatively compact in $\mathbf{P}(\mathbf{P}(Y))$. Taking, if necessary, a subsequence we can assume that $\mathcal{L}(\mu_n)$ tend to some $\mathcal{L}$ in $\mathbf{P}(\mathbf{P}(Y))$. By the Skorohod representation theorem on the probability space $([0,1], \mathcal{B}[0,1], dx)$ there exist S-valued random variables $\tilde{\mu}_n$ and $\tilde{\mu}$ such that $\tilde{\mu}_n(x,.) \to \tilde{\mu}(x,.)$ for all x when $n \to \infty$ and $\mathcal{L}(\tilde{\mu}) = m,\ \mathcal{L}(\tilde{\mu}_n) = \mathcal{L}(\mu_n)$ for all n.

The last equality means that for any $f \in C_b(Y)$ the distribution of the random variable $\tilde{\mu}_n(f)$ coincides with the distribution of $\mu_n(f)$. It follows that for any $f \in C_b(Y)$

$$m(f) = \lim_{n\to\infty} m_n(f) = \lim_{n\to\infty} \int \mu_n(x,f)dx = \lim_{n\to\infty} \int \tilde{\mu}_n(x,f)dx = \int \tilde{\mu}(x,f)dx.$$

Thus, $m(.) = \int \tilde{\mu}(x,.)dx \in K$.

The general case when ν is any nonatomic measure on $[0,1], \mathcal{B}[0,1]$ is easily reduced to the considered one by the quantile transformation. Indeed, let $F(t) := \nu([0,t],\ C(t) := \inf\{s :\ F(s) > t\}$. Then we have the identities

$$\int \mu(x,.)dx = \int \mu(F(x),.)\nu(dx), \qquad \int \mu(x,.)\nu(dx) = \int \mu(C(x),.)dx$$

which show that K does not depend on the measure ν.

Evidently, $S \subseteq K$. Hence, $\overline{\text{conv}}\, S \subseteq K$. Let $m_0(.) = \int \mu(t,.)dt$ be a point in K which does not belong to $\overline{\text{conv}}\, S$. By the separation theorem a convex compact set and a point outside it can be strictly separated by a continuous linear functional. This means that there exists $f \in C_b(Y)$ such that $\inf_{m \in \overline{\text{conv}}\, S} m(f) < m_0(f)$. It follows that $\int \mu(t,f)dt < m_0(f)$ in contradiction with the assumption that $m_0 \in K$.

Remark 5.1. If ν has atoms, then we can assert only that K is a subset of $\overline{\text{conv}}\, S$, even when S is compact.

5.3. Convergence of measure-valued martingales.

PROPOSITION 5.1. *Let $(\Omega, \mathcal{F}, P)$ be a probability space with an increasing family of σ-algebras $(\mathcal{F}_n)$ such that $\mathcal{F} = \sigma\{\mathcal{F}_n,\ n \in \mathbf{N}\}$. Let $\mu_n(\omega,.)$ be a stochastic kernel from $(\Omega, \mathcal{F}_n)$ to $(Y, \mathcal{Y})$ such that for any $f \in C_b(Y)$ the sequence $(\mu_n(f), \mathcal{F}_n)$ is a martingale. Assume that for almost all ω the sequence $\mu_n(\omega,.)$ is tight. Then for almost all ω there exists a limit $\mu(.)$ of $\mu_n(\omega,.)$ in $\mathbf{P}(Y)$ and $E(\mu(f) \mid \mathcal{F}_n) = \mu_n(f)$ for all $f \in C_b(Y)$ and $n \in \mathbf{N}$.*

Proof. To clarify ideas we start from the case when $Y = \mathbf{R}$. Let $M_n(\omega, y) = \mu_n(\omega,]-\infty, y])$ be the distribution function of $\mu_n(\omega,.)$. Evidently, $(M_n(y), \mathcal{F}_n)$ is a bounded martingale for all $y \in \mathbf{R}$ and by the Doob theorem it converges almost surely (a.s.) to $M^0(y)$. There is a set Ω_1 with $P(\Omega_1) = 1$ such that for all $\omega \in \Omega_1$

and all rationals r we have convergence of $M_n(\omega, r)$ to $M^0(\omega, r)$. Put $M(\omega, y) = \inf\{M^0(\omega, r) :\ r \in \mathbf{Q},\ r > y\}$ for $\omega \in \Omega_1$. Let $M(\omega, .)$ be equal to any distribution function outside Ω_1. The assumption on tightness implies that $M(\omega, .)$ is a probability distribution function and for any $\omega \in \Omega_1$ we have that $M_n(\omega, y)$ tends to $M(\omega, y)$ at any point y where the function $M(\omega, .)$ is continuous.

As any Polish space is homeomorphic to a G_δ-subset of $H = [0,1]^{\mathbf{N}}$ we can assume in general case that Y is the intersection of open subsets G_n in H. The closure $\bar{Y}$ of Y is a compact subset of H. Thus, $C_b(\bar{Y})$ is separable. Let A be a countable dense subset of $C_b(\bar{Y})$ closed under finite sums and multiplication by rationals. For any $f \in A$ the sequence $\mu_n(\omega, f)$ converges to some $\mu_f(\omega)$ for all ω from a set Ω_f with $P(\Omega_f) = 1$. It is possible to find a set Ω_1 with $P(\Omega_1) = 1$ such that for all $\omega \in \Omega_1,\ f,\ g \in A$, and rational a and b

$$\mu_{af+bg}(\omega) = a\mu_f(\omega) + b\mu_g(\omega).$$

Evidently,

$$\mid \mu_f(\omega) - \mu_g(\omega) \mid \leq \parallel f - g \parallel,\ \omega \in \Omega_1,$$

where $\parallel . \parallel$ is a uniform norm in $C_b(\bar{Y})$, and the function $f \mapsto \mu_f(\omega)$ can be extended uniquely to the continuous positive linear functional on $C_b(\bar{Y})$ which by the Riesz theorem has the form $\mu_f(\omega) = \mu(\omega, f)$ for some measure $\mu(\omega, .)$ on $\bar{Y}$. For $\omega \in \Omega_1$ we put $\mu(\omega, .)$ equal to any fixed probability measure on Y. We show that μ is the kernel we are seeking. Notice that $\mu(\omega, Y) = 1$. Fix $\omega \in \Omega_1$. By the assumption there exists a subsequence $\mu_{n'}(\omega, .)$ which converges in $\mathbf{P}(Y)$ to a measure $\mu'(\omega, .)$ on Y. We can extend $\mu_{n'}(\omega, .)$ and $\mu'(\omega, .)$ to $\bar{Y}$ in a trivial way. Then for $f \in A$ we have

$$\int_{\bar{Y}} f(y)\mu'(\omega, dy) = \int_Y f(y)\mu'(\omega, dy) = \lim_{n\to\infty} \int_Y f(y)\mu_{n'}(\omega, dy)$$
$$= \lim_{n\to\infty} \int_{\bar{Y}} f(y)\mu_{n'}(\omega, dy) = \int_{\bar{Y}} f(y)\mu(\omega, dy).$$

It follows that the probability measures $\mu'(\omega, .)$ and $\mu(\omega, .)$ coincide, and, since any convergent subsequence has the same limit, the whole sequence $\mu_n(\omega, .)$ converges in $\mathbf{P}(Y)$ to $\mu_n(\omega, .)$.

The result is proved.

5.4. Let X and Y be Polish spaces. Any measure $m \in \mathbf{P}(X \times Y)$ can be desintegrated, that is, can be represented as $m(dx, dy) = \mu(x, dy)\nu(dx)$, where ν is the image of m under the projection mapping $X \times Y$ onto X and μ is an element of $\mathcal{M}(X, Y)$ (regular conditional probability) defined ν a.s. uniquely.

LEMMA 5.2. *Let S_Y be a convex compact subset in $\mathbf{P}(Y)$, and let S be the set of all $m \in \mathbf{P}([0,1] \times Y)$ such that $m(dx, dy) = \mu(x, dy)dx$ with $\mu(x, .) \in S_Y$ for all $t \in [0,1]$. Then S is a convex compact set.*

Proof. The problem is to prove that S is closed. Let us consider for any $\Delta = [a, b] \subseteq [0,1],\ b > a$, the set

$$K_\Delta = \left\{ m \in \mathbf{P}(Y) :\ m(.) = \frac{1}{b-a} \int_\Delta \mu(x, .)dx,\ \mu(x, .) \in S_Y \text{ for all } x \in \Delta \right\},$$

which is, by Lemma 5.1, a convex compact set in $\mathbf{P}(Y)$. Let L be the set of all $m \in \mathbf{P}([0,1] \times Y)$ such that the image of m under the projection mapping $X \times Y$

onto X is the Lebesgue measure (this means that $m(dx,dy)=\mu(x,dy)dx$ without any restriction on μ). Evidently, L is a closed convex set in $\mathbf{P}([0,1]\times Y)$.

Define the continuous affine mapping $f_\Delta : L \to \mathbf{P}(Y)$ by the formula $f_\Delta : m \mapsto m_\Delta$ where $m_\Delta(\Gamma) = m(\Delta\times\Gamma)/(b-a)$. The result will be proved if we show that $S = \cap_\Delta f_\Delta^{-1}(K_\Delta)$. The inclusion $S \subseteq \cap_\Delta f_\Delta^{-1}(K_\Delta)$ is evident. To prove the opposite inclusion let us consider the measure m from L which belongs to $\cap_\Delta f_\Delta^{-1}(K_\Delta)$. Let us define the dyadic σ-algebras $\mathcal{F}_l = \sigma\{\Delta_{k,l},\ k=1,\dots,\ 2^l\}$, where $\Delta_{0,l}=[0,2^{-l}]$, $\Delta_{k,l}=](k-1)2^{-l},k2^{-l}]$, $k\ge 1$. Using Lemma 5.1 it is easy to show that for any l there exists a stochastic kernel μ_l such that $\mu_l(x,.)\in S_Y$ for all $t\in[0,1]$ and

$$m(A\times .) = \int_A \mu_l(x,.)dx$$

for all $A\in\mathcal{F}_l$. Put

$$m_l(t,.) = \sum_{k=1}^{2^l} I_{\Delta_{k,l}}(t) m_{l,k}(.)$$

where

$$m_{l,k}(.) = 2^l \int_{\Delta_l} \mu_l(x,.)dx \in S$$

according to Lemma 5.1. By Proposition 5.1 on convergence of measure-valued martingales, the sequence $\mu_l(x,.)$ tends to $\mu(x,.)$ in $\mathbf{P}(Y)$ for almost all x and

$$\int_A \mu_l(x,.)dx = \int_A \mu(x,.)dx$$

for all $A\in\mathcal{F}_l$. Thus, we find a stochastic kernel μ such that $\mu(x,.)\in S_Y$ for all $x\in[0,1]$ and $m(A\times\Gamma)=\int_A\mu(x,\Gamma)dx$ for all $A\in\mathcal{B}_l,\ l\in\mathbf{N}$, and $\Gamma\in\mathcal{Y}$. It follows that $m(dx,dy)=\mu(x,dy)dt$. Hence, $m\in S$ and the lemma is proved.

5.5.

LEMMA 5.3. *Let $(X,\mathcal{X})$ be any uncountable Polish space with a probability measure ν on it. Then there exists an increasing family of σ-algebras $(\mathcal{X}_l)$, $l\in\mathbf{N}$, such that*

(1) *$\mathcal{X}_l$ is generated by a finite partition of X to the sets $A_{k,l}$, $k=1,\dots,\ r_l$;*

(2) *$\mathcal{X}=\sigma\{\mathcal{X}_l,\ l\in\mathbf{N}\}$;*

(3) *$\nu(\partial A_{k,l})=0$ for any k and l (∂A denotes the boundary of A).*

Proof. Since a Polish space is homeomorphic to G_δ-subsets of $H=[0,1]^{\mathbf{N}}$, we can assume without loss of generality that X is a Borel subset of H. Moreover, it is sufficient to construct the family $(\mathcal{X}_l)$ for the space H (then the σ-algebras $\mathcal{X}_l\cap X=\{A\cap X,\ X\in\mathcal{X}_l\}$ will have the desired properties for X). Let $\varepsilon\in[0,1/2[$. Let us define the partitions of the interval $[0,1]$ by points $a^\varepsilon_{k2^{-l}}$, $k=0,\ \dots,\ 2^l$, in the following recurrent way. Let $a^\varepsilon_0=0$, $a^\varepsilon_1=1$, $a^\varepsilon_{2^{-l}}=2^{-1}+\varepsilon$. Starting from the lth partition we define for k even the point $a^\varepsilon_{k2^{-l-1}}=(a^\varepsilon_{k2^{-l}}+a^\varepsilon_{(k+1)2^{-l}})/2$; i.e., we construct the ordinary dyadic partitions on both intervals $[0,2^{-1}+\varepsilon]$ and $]2^{-1}+\varepsilon,1]$.

Evidently, diameters of the partitions tend to zero as $l\to\infty$.

Put

$$\Delta^\varepsilon_{1,l}=[0,a^\varepsilon_{2^{-l}}],\ \Delta^\varepsilon_{k,l}=]a^\varepsilon_{(k-1)2^{-l}},a^\varepsilon_{k2^{-l}}],\ k=1,\dots,\ 2^l,$$
$$\Gamma^\varepsilon=\{a^\varepsilon_{k2^{-l}},\ k=1,\ \dots,\ 2^l,\ l\in\mathbf{N}\}.$$

Let $\Delta^{\varepsilon}_{k_1,\dots,k_l,l} = \{x : x_1 \in \Delta^{\varepsilon}_{k_l,l}, \dots, x_l \in \Delta^{\varepsilon}_{k_1,1}\}$, $\mathcal{X}^{\varepsilon}_l = \sigma\{\Delta^{\varepsilon}_{k_1,\dots k_l,l},\ k_i \le 2^l\}$. Notice that the set N_d of superscripts $\varepsilon \in [0, 1/2[$ such that Γ^{ε} are disjoint is uncountable (this follows from the observation that $\Gamma^{\varepsilon} \cap \Gamma^{\eta} = \oslash$ if $\mathbf{Q}\varepsilon + \mathbf{Q} \ne \mathbf{Q}\eta + \mathbf{Q}$ and there are uncountably many different sets $\mathbf{Q}\varepsilon + \mathbf{Q}$). Let's consider the countable subset N_p of N_d containing all superscripts ε such that at least one of the probabilities $\nu(x :\ x_k \in \Gamma^{\varepsilon}),\ k \in \mathbf{N}$, is positive. Thus, $N_d \setminus N_p$ is uncountable. It is clear that for any $\varepsilon \in N_d \setminus N_p$ the sequence of σ-algebras $\mathcal{X}^{\varepsilon}_l$ has the needed properties.

5.6. The following assertion is a generalization of Lemma 5.2.

PROPOSITION 5.2. *Let S_X be a compact subset in $\mathbf{P}(X)$, and let S_Y be a convex compact subset in $\mathbf{P}(Y)$. Assume that all elements of S_X are nonatomic. Let S be the set of all $m \in \mathbf{P}(X \times Y)$ such that $m(dx, dy) = \mu(x, dy)\nu(dx)$ with $\mu(x, .) \in S_Y$ for all x and $\nu(.) \in S_X$. Then S is a compact set.*

Proof. Since the relative compactness is evident, we need to show only that S is closed. Let us consider the sequence $m_n \in S$ with $m_n(dx, dy) = \mu_n(x, dy)\nu_n(dx)$ which tends in $\mathbf{P}(X \times Y)$ to $m(dx, dy) = \mu(x, dy)\nu(dx)$. As ν_n tends to ν in $\mathbf{P}(X)$ and S_X is a compact, $\nu \in S$.

To prove that $m \in S$ for all x, we construct a sequence of stochastic kernels $\tilde{\mu}_l$ such that $\tilde{\mu}_l(x, .) \in S_Y$ for any x, $\tilde{\mu}_l(x, .)$ converges ν-a.s. to some $\tilde{\mu}(x, .)$, and $\tilde{\mu}(x, dy)\nu(dx) = \mu(x, dy)\nu(dx)$.

Let us consider the σ-algebras $\mathcal{X}_l = \sigma\{A_{k,l},\ k = 1, \dots,\ r_l\}$, $l \in \mathbf{N}$, defined in Lemma 5.3. Since $\nu(\partial A_{k,l}) = 0$, the sequence of measures $m_n(A_{k,l} \times .)$ converges in $\mathbf{P}(Y)$ to the measure $m(A_{k,l} \times .)$ for any set $A_{k,l}$. From Lemma 5.1 it follows that for any $l \in \mathbf{N}$ there exists a stochastic kernel μ_l such that $\mu_l(t, .) \in S_Y$ for all $t \in [0, 1]$ and

$$m(A \times .) = \int_A \mu_l(x, .)\nu(dx)$$

for all $A \in \mathcal{X}_l$. Let

$$\tilde{\mu}_l(x, .) = \sum_{k=1}^{2^l} I_{A_{k,l}}(x) m_{l,k}(.),$$

where

$$m_{l,k}(.) = \frac{1}{\nu(A_{k,l})} \int_{A_{k,l}} \mu_l(x, .)\nu(dx) \in S_Y$$

according to Lemma 5.1 (if $\nu(A_{k,l}) = 0$ we can put $m_{l,k}(.)$ to be equal to any point of S_Y). By Proposition 5.1 on the convergence of measure-valued martingales the sequence $\tilde{\mu}_l(x, .)$ tends to $\tilde{\mu}(x,)$ in $\mathbf{P}(Y)$ for almost all x and

$$\int_A \tilde{\mu}_l(x, .)\nu(dx) = \int_A \tilde{\mu}(x, .)\nu(dx)$$

for all $A \in \mathcal{X}_l$. Thus, we found a stochastic kernel μ such that $\tilde{\mu}(x, .) \in S_Y$ for all $x \in [0, 1]$ and $m(A \times \Gamma) = \int_A \tilde{\mu}(x, \Gamma)\nu(dx)$ for all $A \in \mathcal{X}_l$, $l \in \mathbf{N}$, and $\Gamma \in \mathcal{Y}$. It follows that $m(dx, dy) = \tilde{\mu}(x, dy)\nu(dx)$. Hence, $m \in S$.

Remark 5.2. Walter Schachermayer suggested the following simpler proof of the above result without the assumption that measures from S_X are nonatomic. At first, notice that $S_Y = \cup_{j=1}^{n} \Gamma_j$, where $\Gamma_j := \{\mu :\ \mu(f_j) \le \beta_j\}$, $f_j \in C_b(Y)$, $\beta_j \in \mathbf{R}$.

Indeed, from the Hahn–Banach theorem it follows that S_Y is an intersection of sets of this type. Their complements form an open covering of the open set $\mathbf{P}(Y)\setminus S_Y$. Since a Polish space is Lindelöf it contains a countable covering $\bar{\Gamma}_j,\ j\in\mathbf{N}$. Assume now that for the limiting measure $m(dx,dy)=\mu(x,dy)\nu(dx)$ there exists a set of positive ν-measure where $\mu(x,.)\notin S_Y$. The above representation for S_Y implies that there exists a set $B=\{x:\ \mu(x,f)>\beta\}$ with $\nu(B)>0$. Let $g_k\in C_b(X)$ be a sequence converging in $L^1(\nu)$ to I_B. Since $\mu_n(x,.)\in S_Y$ we have that $\mu_n(x,f)\le\beta$. Thus,

$$\lim_{k\to\infty}\lim_{n\to\infty}\int\int g_k(x)f(y)m_n(dx,dy)=\lim_{k\to\infty}\lim_{n\to\infty}\int g_k(x)\mu_n(x,f)\nu_n(dx)$$
$$\le\lim_{k\to\infty}\beta\int g_k(x)\nu(dx)=\beta\nu(B).$$

From the other side,

$$\lim_{k\to\infty}\lim_{n\to\infty}\int\int g_k(x)f(y)m_n(dx,dy)=\lim_{k\to\infty}\lim_{n\to\infty}\int\int g_k(x)f(y)m(dx,dy)$$
$$=\lim_{k\to\infty}\int g_k(x)\mu(dx,f)\nu(dx)=\int_B\mu(dx,f)\nu(dx)>\beta\nu(B),$$

and we get a contradiction to the assumption that $\mu(x,.)$ does not belong to S_Y ν-a.s.

5.7. Now we consider the following problem.

Let $(\Omega,\mathcal{F},P)$ be a probability space, $\mathcal{P}$ be a σ-algebra in the product $\Omega\times\mathbf{R}_+$ such that $\mathcal{P}\subseteq\mathcal{F}\otimes\mathcal{B}(\mathbf{R}_+)$, Γ is a measurable set-valued mapping from $(\mathbf{R}_+,\mathcal{B}(\mathbf{R}_+))$ to $\mathbf{R}^q$. Measurability means that the graph $\operatorname{Gr}\Gamma=\{(t,x):\ x\in\Gamma(t)\}$ is a $\mathcal{B}(\mathbf{R}_+)\otimes\mathcal{B}(\mathbf{R}^q)$-measurable set. We shall assume that $\Gamma(t)$ are closed sets and there exists a function $r\in L^1(\mathbf{R}_+,dt)$ such that $|\Gamma(t)|\le r_t$ for all t. Let $\mathcal{V}$ be a set of all $\mathcal{P}$-measurable functions f on $\Omega\times\mathbf{R}_+$ such that $f(\omega,t)\in\Gamma(t)$. Define the set K in $\mathbf{P}(\mathbf{R}^q)$ as

$$K:=\left\{\mathcal{L}(\phi):\ \phi=\int_0^\infty f(t)dt,\ f\in\mathcal{V}\right\}.$$

The question is if K is a compact set. We give here only a partial answer to this question imposing some specific assumption on the structure of the σ-algebra $\mathcal{P}$.

Let $w=(w_t)$ be a d-dimensional Wiener process on $(\Omega,\mathcal{F},P)$, $\mathcal{F}_t^{o,w}=\sigma\{w_s,\ s\le t\}$, $\mathcal{F}_t^w=\mathcal{F}_{t+}^{o,w}\vee\mathcal{N}$, where $\mathcal{N}$ is a family of all sets from $\mathcal{F}$ of zero probability. In other words, $\mathbf{F}^w=(\mathcal{F}_t^w)$ is the minimal filtration generated by the Wiener process and satisfying the usual assumptions.

LEMMA 5.4. *Assume that $\mathcal{P}$ is the predictable σ-algebra generated by $\mathbf{F}^w$ and $\Gamma(t)$ is a convex set for all t. Then K is a compact set.*

Proof. Since random variables ϕ are bounded by some constant, K is relatively compact and it remains to show that K is closed.

Let us consider the sequence $f^n\in\mathcal{V}$ such that the corresponding sequence of distribution $\mathcal{L}(\phi^n)$ converges in $\mathbf{P}(\mathbf{R}^q)$. Define the random processes

$$\phi_t^n=\int_0^t f^n(\omega,s)ds.$$

Using the criteria of relative compactness in $\mathbf{P}(C^{q+d}(\mathbf{R}_+))$ (the space $C^{q+d}(\mathbf{R}_+)$ is equipped with the metric $\sum_j 2^{-j}\parallel x\parallel_j(1+\parallel x\parallel_j)^{-1}$), we can assume without loss

of generality that the sequence $\mathcal{L}((\phi^n, w))$ converges to some $\mathcal{L}$ in $\mathbf{P}(C^{q+d}(\mathbf{R}_+))$. The Skorohod theorem asserts that on some probability space $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{P})$ (actually, on the standard unit interval) there are processes $(\tilde{\phi}^n, \tilde{w}^n),\ n \in \mathbf{N}$, and $(\tilde{\phi}, \tilde{w})$ such that $\mathcal{L}(\tilde{\phi}^n, \tilde{w}^n) = \mathcal{L}(\phi^n, w),\ \mathcal{L}(\tilde{\phi}, \tilde{w}) = \mathcal{L}$, and $(\tilde{\phi}^n, \tilde{w}^n)$ converges to $(\tilde{\phi}, \tilde{w})$ in $C^{q+d}(\mathbf{R}_+)$ pointwise.

It is easy to show that the following properties hold:

(1) The process $\tilde{\phi}^n$ is adapted with respect to $(\tilde{\mathcal{F}}_t^n)$, where $\tilde{\mathcal{F}}_t^n := \sigma\{\tilde{w}_s^n,\ s \le t\}$ and

$$\tilde{\phi}_t^n(\tilde{\omega}) = \int_0^t \tilde{f}^n(\tilde{\omega}, s)ds \tag{5.1}$$

with $\tilde{\mathcal{P}}^n$-measurable $\tilde{f}^n$ such that $\tilde{f}^n(\tilde{\omega}, s) \in \Gamma(s)$ for $(\tilde{\omega}, s)$ (where $\tilde{\mathcal{P}}^n$ is the predictable σ-algebra generated by $(\tilde{\mathcal{F}}_t^n)$).

(2) The process $\tilde{\phi}$ is adapted with respect to $(\tilde{\mathcal{F}}_t)$, where $\tilde{\mathcal{F}}_t := \sigma\{\tilde{w}_s,\ s \le t\}$ and

$$\tilde{\phi}_t(\tilde{\omega}) = \int_0^t \tilde{f}(\tilde{\omega}, s)ds \tag{5.2}$$

with $\tilde{\mathcal{P}}$-measurable $\tilde{f}$ such that $\tilde{f}(\tilde{\omega}, s) \in \Gamma(s)$ for $(\tilde{\omega}, s)$ (where $\tilde{\mathcal{P}}$ is the predictable σ-algebra generated by the minimal filtration with the usual assumptions for $\tilde{w}$).

Let us prove that $\tilde{\phi}^n$ is adapted with respect to $(\tilde{\mathcal{F}}_t^n)$. Fix $t \in \mathbf{R}_+$ and define the Wiener process $\widehat{w}_s^n = \tilde{w}_{s+t}^n - \tilde{w}_t^n,\ s \in \mathbf{R}_+$, which is independent of $\tilde{\mathcal{F}}_t^n$. It is sufficient to show that $\tilde{E}(\tilde{\phi}_t^n \mid \tilde{\mathcal{F}}_t^n) = \tilde{\phi}_t^n$ ($\tilde{P}$-a.s.) or, equivalently, that

$$\tilde{E}\tilde{E}(\tilde{\phi}_t^n \mid \tilde{\mathcal{F}}_t^n)h(\tilde{w}^n)g(\widehat{w}^n) = \tilde{E}\tilde{\phi}_t h(\tilde{w}^n)g(\widehat{w}^n)$$

for any bounded continuous functions $h : C^d[0,t] \to \mathbf{R}$ and $g : C^d(\mathbf{R}_+) \to \mathbf{R}$ (the argument of h, in fact, is the restriction of $\tilde{w}^n$ to $[0,t]$). Since $h(\tilde{w}^n)$ is $\tilde{\mathcal{F}}_t^n$-measurable, it follows from properties of the conditional expectations that the above equality holds if and only if

$$\tilde{E}\tilde{\phi}_t^n h(\tilde{w}^n)\tilde{E}g(\widehat{w}^n) = \tilde{E}\tilde{\phi}_t^n h(\tilde{w}^n)g(\widehat{w}^n). \tag{5.3}$$

But $\mathcal{L}(\tilde{\phi}^n, \tilde{w}^n) = \mathcal{L}(\phi^n, w)$, and the last identity is equivalent to the following one:

$$E\phi_t^n h(w)Eg(w) = E\phi_t^n h(w)g(w'),$$

where $w'_s = w_{s+t} - w_t,\ s \in \mathbf{R}_+$, which holds because ϕ^n is adapted with respect to $(\mathcal{F}_t^n)$.

Taking a limit in (5.3) we get that

$$\tilde{E}\tilde{\phi}_t h(\tilde{w})\tilde{E}g(\tilde{w}) = \tilde{E}\tilde{\phi}_t h(\tilde{w})g(\widehat{w}),$$

where $\widehat{w}_s = \tilde{w}_{s+t} - \tilde{w}_t,\ s \in \mathbf{R}_+$. As above, this means that $\tilde{\phi}_t = \tilde{E}(\tilde{\phi}_t \mid \tilde{\mathcal{F}}_t)$; i.e., $\tilde{\phi}$ is adapted with respect to $(\tilde{\mathcal{F}}_t)$. The representation (5.1) follows from the definition of ϕ^n and coincidence of $\mathcal{L}(\tilde{\phi}^n, \tilde{w}^n)$ and $\mathcal{L}(\phi^n, w)$. To obtain the representation (5.2) we notice that by the Komloś theorem [19] for the bounded sequence $\tilde{f}^n$, there exists a subsequence (n_j) such that $(\tilde{f}^{n_1} + \cdots + \tilde{f}^{n_k})/k$ converge to some function $\tilde{f}^0$ for almost all $(\tilde{\omega}, t)$. It follows that

$$\tilde{\phi}_t(\tilde{\omega}) = \int_0^t \tilde{f}^0(\tilde{\omega}, s)ds. \tag{5.4}$$

The convexity assumption implies that $\tilde{f}^0(\tilde{\omega},s)\in\Gamma(s)$ for almost all $(\tilde{\omega},s)$, and we can assume without loss of generality that $\tilde{f}^0(\tilde{\omega},s)\in\Gamma(s)$ for all $(\tilde{\omega},s)$. This means that the trajectories of $\tilde{\phi}$ are absolutely continuous functions. Let

$$\tilde{f}'(\tilde{\omega},s)=\limsup_{m\to\infty}\sum_{i=2}^{m}I_{\Delta_i}(s)2^m(\tilde{\phi}_{t_{i-1}}(\tilde{\omega})-\tilde{\phi}_{t_{i-2}}(\tilde{\omega})),$$

where $t_i=i2^{-m}$, $\Delta_i=t_i-t_{i-1}$. Clearly, $\tilde{f}'(\tilde{\omega},s)$ is a $\tilde{\mathcal{P}}$-measurable function, and for all $\tilde{\omega}$ and almost all s it coincides with $\tilde{f}^0(\tilde{\omega},s)\in\Gamma(s)$. Thus, the following function gives the representation (5.2) with the required properties:

$$\tilde{f}(\tilde{\omega},s)=\tilde{f}'(\tilde{\omega},s)I_A+x(s)I_{\bar{A}},$$

where $A=\{(\tilde{\omega},s):\ \tilde{f}'(\tilde{\omega},s)\in\Gamma(s)\}$, $x(s)$ is any Borel function such that $x(s)\in\Gamma(s)$.

Properties (1) and (2) imply the result. Indeed, it follows from (2) and Lemma 2.1 in [13] that there exists a predictable function $a(x,s):C^d(\mathbf{R}_+)\times\mathbf{R}_+\to\mathbf{R}^q$ such that $\tilde{f}(\tilde{\omega},s)=a(\tilde{w}(\tilde{\omega}),s)$. Evidently, we can modify $a(x,s)$ in such a way that $a(x,s)\in\Gamma(s)$ for all (x,s). Let us define on the original probability space $(\Omega,\mathcal{F},P)$ the process

$$\phi_t(\omega)=\int_0^t f(\omega,s)ds$$

with $f(\omega,s)=a(w(\omega),s)$. Since $f\in\mathcal{V}$ and $\mathcal{L}(\phi)=\mathcal{L}(\tilde{\phi})=\mathcal{L}$ it follows that the limit of $\mathcal{L}(\phi^n)$ belongs to K and the lemma is proved.

5.8. Now we apply the previous result to our specific setting.

LEMMA 5.5. *The set* $S_Y^0:=\{\mathcal{L}(\xi_0+I(v):\ v\in\mathcal{V}_U)\}$ *is compact in* $\mathbf{P}(\mathbf{R}^n)$.

Proof. Reversing the time and taking into account the notations of the previous subsection we can reduce the problem to the question of whether the set

$$K:=\left\{\mathcal{L}(\phi):\ \phi=\int_0^\infty f(t)dt,\ f\in\mathcal{V}\right\}$$

is compact. Here $\Gamma(t)=-s^{-2}\exp\{A_4(T)/s\}B_2(T)U$ and the σ-algebra $\mathcal{P}$ is generated by the time reverse of the Ornstein–Uhlenbeck process $\xi_{1/t}$, or, equivalently, by the process $\eta_t:=t\xi_{1/t}$. The process η (as well as ξ) is defined in the present context only up to the distribution. For example, we can take as η the process defined by the stochastic differential equations

$$d\eta_t=t^{-2}(tI-A)\eta_t dt+dw_t,\quad \eta_0=0, \tag{5.5}$$

where I is the unit matrix and w is the Wiener process. This representation can be deduced from the differential equation for the Ornstein–Uhlenbeck process by the Ito formula. But from equation (5.5) it follows that $\mathcal{F}_t^{o,w}=\sigma\{\eta_s,s\le t\}$ and the needed result is a corollary of Lemma 5.4.

5.9. Let η_i be random variables with values in Polish spaces $(X_i,\mathcal{X}_i)$, $i=1,\ 2,\ 3$, let ν_i be the distribution of η_i, and let $\mu_{ij}(x_j,dx_i)$ be the regular conditional distribution of η_i given η_j.

LEMMA 5.6. *Let* $\eta_3=f(\eta_2)$ *for some measurable function* $f:X_2\to X_3$, *and let* S_1 *be a compact convex set in* $\mathbf{P}(X_1)$. *Assume that* $\mu_{12}(x_2,dx_1)\in S_1$ *for all* x_2. *Then* $\mu_{13}(x_3,dx_1)\in S_1$ *for* ν_3*-almost all* x_3.

Proof. The assertion follows from the relation

$$\mu_{13}(x_3, dx_1) = \int_{X_2} \mu_{12}(x_2, dx_1)\mu_{23}(x_3, dx_2) \quad (\nu_3\text{-a.e.})$$

and Remark 5.1.

Acknowledgment. The authors express their thanks to Walter Schachermayer for helpful discussions of functional-analytic aspects of the problem.

ANALYSIS OF ROBUST $\mathbf{H}_2$ PERFORMANCE USING MULTIPLIER THEORY*

ERIC FERON†

Abstract. In this paper, the problem of determining the worst-case $\mathbf{H}_2$ performance of a control system subject to linear time-invariant uncertainties is considered. A set of upper bounds on the performance is derived, based on the theory of stability multipliers and the solution of an original optimal control problem. The numerical issues raised by the resulting computational problems are discussed; in particular, newly developed interior-point convex optimization methods, combined with linear matrix inequalities, apply very well to the fast and accurate solution of these problems. The new results compare favorably with prior ones. The method can be extended to other types of perturbations.

Key words. $\mathbf{H}_2$ performance, stability multipliers, convex optimization, linear matrix inequalities

1. Introduction.

Among all performance indices known to control engineering, the $\mathbf{H}_2$ performance index holds a special place for historical and practical reasons. The historical reasons are that minimizing the $\mathbf{H}_2$ norm of a linear control system via feedback, better known as the LQG problem, is among the first optimal control problems to have been solved analytically. (For an extensive presentation and bibliography, see [1].) The practical reason is that this problem can be solved using reliable and fast computational procedures [2, 20, 39].

It is, however, well known that the performance of the LQG-optimal controller can be very sensitive to perturbations on the nominal system [11]. In view of this fact, devising analysis and synthesis tools that will respectively evaluate and minimize worst-case $\mathbf{H}_2$ norms of control systems is especially relevant.

In this paper, we consider the following specific problem: given a linear control system perturbed by linear time-invariant (LTI) perturbations, what is its worst-case $\mathbf{H}_2$ norm? This question has remained open until recently when some attempts have been made at its solution. Packard and Doyle [26] and Bernstein and Haddad [4, 5, 6] are among the first to consider the problem of robust $\mathbf{H}_2$ performance in the face of dynamic and parametric uncertainty. Stoorvogel [37, 38], Petersen, Rotea, and McFarlane [30, 31] find bounds on the worst-case $\mathbf{H}_2$ norm of a system subject to norm-bounded, noncausal, possibly nonlinear, and time-varying uncertainties. Peres, Geromel, and Souza [28, 29] find upper bounds on the $\mathbf{H}_2$ norm of linear time-varying and uncertain LTI systems based on quadratic Lyapunov functions. The book and papers by Boyd, El Ghaoui, Feron, and Balakrishnan [9, 14, 7, 13] show that the computation of all these bounds on $\mathbf{H}_2$ performance can be reduced to convex optimization problems involving linear matrix inequalities, which can be solved via efficient convex optimization techniques. In [9, 13], attempts are made to refine the upper bounds

on $\mathbf{H}_2$ performance when dealing with particular classes of perturbations such as static nonlinearities and parametric uncertainties, using Lur'e Lyapunov functions and causal multipliers. Other attempts at obtaining reliable upper bounds on robust $\mathbf{H}_2$ performance include the recent paper by Paganini, Doyle, and D'Andrea [27].

In this paper, we propose to extend the results presented in [9, 13] by using noncausal multipliers to evaluate the worst-case $\mathbf{H}_2$ norm of linear systems perturbed by LTI perturbations. Using noncausal multipliers is a well-known technique to determine the stability of uncertain systems (see [10, 40] and references therein) and has proved to yield effective computational procedures [36, 34]. We believe this paper is the first attempt to use them to determine robust $\mathbf{H}_2$-performance of linear systems subject to linear perturbations. It is organized as follows.

The first part is devoted to a few definitions and notations. In particular, we recall the notions of boundedness, positivity, and passivity of operators.

In the second part, we formulate the robust $\mathbf{H}_2$ analysis problem and sketch our line of attack to get upper bounds on worst-case $\mathbf{H}_2$ performance. We present a new upper bound on robust $\mathbf{H}_2$ performance, based on the use of certain dynamic Lagrange multipliers.

In the third part of this paper, we present a way to compute the upper bound on robust performance using convex optimization and linear matrix inequalities. In particular, we exhibit convenient linear families of finite-dimensional multipliers to perform this computation.

In the fourth part, we discuss the obtained results: in particular, we study conditions for the obtained upper bound to be finite. We also study special cases and show they correspond to results having already appeared in the literature. A numerical example that illustrates the usefulness of dynamic multipliers to determine accurate upper bounds on robust performance is provided.

2. Notation. In this paper, $\mathbf{R}$ (resp., $\mathbf{C}$) denotes the set of real (resp., complex) numbers. $\mathbf{R}_+$ denotes the set of nonnegative real numbers. $\mathbf{R}^{n\times p}$ (resp., $\mathbf{C}^{n\times p}$) is the vector space of $n \times p$ real (resp., complex) matrices. $\mathbf{R}^{n\times 1}$ ($\mathbf{C}^{n\times 1}$) is abbreviated $\mathbf{R}^n$ ($\mathbf{C}^n$). For the random variable x, $\mathbf{E}\, x$ denotes the expected value of x. For any matrix X, X^T denotes its transpose and X^* denotes its complex conjugate transposed. The identity matrix is noted I. If X is invertible, then its inverse is noted X^{-1}. When X is not invertible, its Moore–Penrose inverse is noted $X^\dagger$. When $X \in \mathbf{R}^{n\times n}$, $\mathbf{Tr}\, X$ denotes the trace of X. A square matrix X is said stable if all its eigenvalues lie in the open left complex half-plane. Given a set of matrices $X_1 \in \mathbf{R}^{n_1\times p_1}, \ldots, X_N \in \mathbf{R}^{n_N\times p_N}$ and defining $n = \sum_{i=1}^N n_i$, $p = \sum_{i=1}^N p_i$, $\mathbf{diag}(X_1, \ldots, X_N)$ denotes the $n \times p$ matrix

$$\begin{bmatrix} X_1 & 0 & \cdots & 0 \\ 0 & X_2 & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \cdots & 0 & X_N \end{bmatrix}.$$

Note that the X_is need not be square. From time to time, when no ambiguity is possible, $\mathbf{diag}(X_1, \ldots, X_N)$ is noted $\mathbf{diag}_{i=1}^L(X_i)$, or $\mathbf{diag}_i(X_i)$.

For any two matrices X and $Y \in \mathbf{R}^{n\times n}$, the inequality $X \le Y$ means that X and Y are symmetric and that the difference $Y - X$ is positive. The inequality $X < Y$ means that X and Y are symmetric and that the difference $Y - X$ is positive definite.

$\mathbf{L}_2(\mathbf{R})$ denotes the Hilbert space of functions h mapping $\mathbf{R}$ into $\mathbf{R}^{n\times p}$ which satisfy

$$\int_{-\infty}^{\infty} \mathbf{Tr}\, h(t)^T h(t) dt < \infty.$$

It is equipped with the standard scalar product

$$\forall g, h \in \mathbf{L}_2(\mathbf{R}), \quad \langle g, h\rangle \triangleq \int_{-\infty}^{\infty} \mathbf{Tr}\, g(t)^T h(t) dt,$$

and for all $h \in \mathbf{L}_2(\mathbf{R})$, the Euclidean norm $\langle h, h\rangle^{1/2}$ of h is denoted $\|h\|_2$. $\mathbf{L}_2(\mathbf{R}_+)$ denotes the subspace of $\mathbf{L}_2(\mathbf{R})$ made of the functions h satisfying $h(t) = 0$ when $t < 0$. $\mathbf{L}_{2e}$ denotes the space of functions h mapping $\mathbf{R}$ into $\mathbf{R}^{n\times p}$ satisfying $h(t) = 0$ for $t < 0$ and

$$\forall t \geq 0, \quad \int_{-\infty}^{t} \mathbf{Tr}\, h(t)^T h(t) dt < \infty.$$

Following the usage of Francis [16], we suppress the dependence of these spaces on the integers n and p.

For a given operator Δ and a function p mapping $\mathbf{R}$ into $\mathbf{R}^n$, $(\Delta p)(t)$ denotes the value taken by the image function Δp at time t. An operator Δ is said to be *causal* if for any function p and any time t, $(\Delta p)(t)$ depends only on the past values of p up to time t. It is said *anticausal* if $(\Delta p)(t)$ depends only on the future values of p from time t. In any other case, Δ is said *noncausal*.

Given a set of operators $\Delta_1, \ldots, \Delta_L$, $\mathbf{diag}(\Delta_1, \ldots \Delta_L)$ stands for the operator which maps the function taking the value $\begin{bmatrix} u_1(t)^T & \ldots & u_L(t)^T \end{bmatrix}^T$ at time t to the function taking the value $\begin{bmatrix} (\Delta_1 u_1)(t)^T & \ldots & (\Delta_L u_L)(t)^T \end{bmatrix}^T$ at time t.

Let H map $\mathbf{L}_2(\mathbf{R})$ into $\mathbf{L}_2(\mathbf{R})$ and be linear. The *adjoint* of H, denoted H^*, is the unique linear operator satisfying

$$\langle x, Hy\rangle = \langle H^* x, y\rangle \quad \forall x, y \in \mathbf{L}_2(\mathbf{R}).$$

Defining s as the usual Laplace variable, the transfer function of H is denoted $H(s)$ whenever it exists.

Let us now introduce the notions of finite gain, positivity, and passivity that we will use throughout this paper.

DEFINITION 2.1 (see [32]). *An operator F mapping $\mathbf{L}_2(\mathbf{R})$ into $\mathbf{L}_2(\mathbf{R})$ has finite gain (or, equivalently, is bounded) if there exists a positive δ such that for any $u \in \mathbf{L}_2$*

$$\|Fu\|_2 \leq \delta \|u\|_2 .$$

The smallest such δ is called the gain of F and denoted $\|F\|_\infty$.

DEFINITION 2.2 (see [10]). *A linear operator G mapping $\mathbf{L}_2(\mathbf{R})$ into $\mathbf{L}_2(\mathbf{R})$ is said to be positive if for any $u \in \mathbf{L}_2(\mathbf{R})$*

$$\langle Gu, u\rangle \geq 0.$$

G is said to be strictly positive if there exists $\delta > 0$ such that for any $u \in \mathbf{L}_2(\mathbf{R})$

$$\langle Gu, u\rangle \geq \delta \|u\|_2^2 .$$

DEFINITION 2.3 (see [10]). *A linear, causal operator G mapping $\mathbf{L}_{2e}$ into $\mathbf{L}_{2e}$ is said to be passive if for any $u \in \mathbf{L}_{2e}$ and $T \geq 0$*

$$\int_0^T (Gu)^T u \, dt \geq 0.$$

3. Problem statement and line of attack. Consider the system

$$\begin{aligned} \frac{d}{dt}x(t) &= Ax(t) + B_p p(t) + B_w w(t), \quad x(0) = x_0, \\ q(t) &= C_q x(t) + D_{qp} p(t), \\ z(t) &= C_z x(t), \\ p(t) &= (\Delta q)(t), \end{aligned} \tag{1}$$

where $x : \mathbf{R} \to \mathbf{R}^n$, $p : \mathbf{R} \to \mathbf{R}^{n_p}$, $q : \mathbf{R} \to \mathbf{R}^{n_p}$, $z : \mathbf{R} \to \mathbf{R}^{n_z}$, and $w : \mathbf{R} \to \mathbf{R}^{n_w}$ and all quantities are equal to 0 for $t < 0$. Assume that the matrix A is stable. Δ is a perturbation that satisfies the following set of assumptions:

$$\begin{aligned} &\Delta = \mathbf{diag}(\Delta_1, \ldots, \Delta_{n_p}), \\ &\forall u \in \mathbf{L}_2(\mathbf{R}), \quad (\Delta_i u)(t) = \int_0^\infty \delta_i(\tau) u(t-\tau) \, d\tau, \\ &\int_0^\infty |\delta_i(\tau)| \, d\tau < \infty, \\ &\Delta_i \text{ is passive}, \quad i = 1, \ldots, n_p. \end{aligned} \tag{2}$$

In the literature, the passivity assumption on Δ is often replaced by a finite-gain assumption [12]. Standard loop-transformations allow us to move almost freely from one framework to the other (see [10, p. 215] and the end of this paper for a more detailed discussion).

Much of the existing literature is devoted to studying the robust stability of the system (1) against the uncertainty Δ in the following sense: Assume $w = 0$ and any initial condition x_0; then the signals x, p, q, and z belong to $\mathbf{L}_2(\mathbf{R}_+)$.

In this paper, we assume the system (1) to be robustly stable, and we are interested in evaluating its worst-case $\mathbf{H}_2$ performance against the uncertainty Δ: Let

$$H_\Delta(s) = H_{zw}(s) + H_{zp}(s)\Delta(s)(I - H_{qp}(s)\Delta(s))^{-1} H_{qw}(s),$$

where

$$\begin{aligned} H_{zw}(s) &= C_z(sI - A)^{-1} B_w, \\ H_{zp}(s) &= C_z(sI - A)^{-1} B_p, \\ H_{qp}(s) &= C_q(sI - A)^{-1} B_p + D_{qp}, \\ H_{qw}(s) &= C_q(sI - A)^{-1} B_w. \end{aligned} \tag{3}$$

The $\mathbf{H}_2$ norm of the system (1) is defined as

$$\|H_\Delta\|_2 = \left(\frac{1}{2\pi} \int_{-\infty}^{\infty} \mathbf{Tr} \, H_\Delta(j\omega)^* H_\Delta(j\omega) \, d\omega \right)^{1/2}.$$

Equivalently, using Parseval's theorem, $\|H_\Delta\|_2$ may also be expressed as $\|h_\Delta\|_2$, where h_Δ is the impulse matrix of H_Δ. In the subsequent developments of this paper, it will also be very convenient to express it as

$$\|H_\Delta\|_2 = \left(\mathbf{E}\,\|z\|_2^2\right)^{1/2}, \tag{4}$$

where z is the output of the system (1) with the following assumptions: the input w is identically 0 and the initial condition x_0 is equal to $B_w u$, where u is a random variable satisfying $\mathbf{E}\,uu^T = I$. (The expectation appearing in (4) is therefore to be taken with respect to u.)

The robust $\mathbf{H}_2$ analysis problem is to compute the worst-case $\mathbf{H}_2$ norm of the system (1) over all possible values of Δ that satisfy (2). This computation is in general quite a complicated problem. Thus, we propose to replace it by the computation of upper bounds on robust $\mathbf{H}_2$ norm, using a technique similar to the classical technique of Lagrange multipliers: Consider any family $\mathcal{M}$ of operators M mapping $\mathbf{L}_2(\mathbf{R})$ into $\mathbf{L}_2(\mathbf{R})$ such that the operator $M^*\Delta$ is positive for any Δ satisfying (2). The following lemma gives us an *upper bound* on the worst-case $\mathbf{H}_2$ norm of the system (1).

LEMMA 3.1. *We have the inequality*

$$\max_{\Delta} \mathbf{E}\,\|z\|_2^2 \le \min_{M\in\mathcal{M}} \mathbf{E} \max_{\tilde{p}\in\mathbf{L}_2(\mathbf{R}_+)} \|\tilde{z}\|_2^2 + 2\langle \tilde{p}, M\tilde{q}\rangle, \tag{5}$$

where $\tilde{p}$, $\tilde{q}$, and $\tilde{z}$ are the inputs and outputs of the system

$$\begin{aligned} \frac{d}{dt}\tilde{x}(t) &= A\tilde{x}(t) + B_p\tilde{p}(t), \;\; \tilde{x}(0) = B_w u, \\ \tilde{q}(t) &= C_q\tilde{x}(t) + D_{qp}\tilde{p}(t), \\ \tilde{z}(t) &= C_z\tilde{x}(t), \end{aligned} \tag{6}$$

where all variables belong to $\mathbf{L}_2(\mathbf{R}_+)$, and u is a random variable satisfying $\mathbf{E}\,uu^T = I$.

Proof. Consider the system (1). For any $M \in \mathcal{M}$, we have $\langle p, Mq\rangle = \langle \Delta q, Mq\rangle = \langle M^*\Delta q, q\rangle \ge 0$, since $M^*\Delta$ is positive. Therefore, for any Δ satisfying (2), any initial condition x_0, and any $M \in \mathcal{M}$, we have $\|z\|_2^2 \le \|z\|_2^2 + 2\langle p, Mq\rangle$. Since $p \in \mathbf{L}_2(\mathbf{R}_+)$, we furthermore have

$$\|z\|_2^2 + 2\langle p, Mq\rangle \le \max_{\tilde{p}\in\mathbf{L}_2(\mathbf{R}_+)} \|\tilde{z}\|_2^2 + 2\langle \tilde{p}, M\tilde{q}\rangle,$$

where the right-hand side of the inequality may be infinite. Taking expected values (with respect to the random variable u) on both sides of these inequalities, we conclude that

$$\mathbf{E}\,\|z\|_2^2 \le \mathbf{E} \max_{\tilde{p}\in\mathbf{L}_2(\mathbf{R}_+)} \|\tilde{z}\|_2^2 + 2\langle \tilde{p}, M\tilde{q}\rangle.$$

This ends the proof of our lemma. □

Note that the multiplier M can indeed be seen as a *Lagrange multiplier*. Such an approach is not unlike the one encountered in the papers by Yakubovich [43, 15, 44] and Megretsky [21, 22, 23], where it is named the $\mathcal{S}$-procedure. In the remainder of this paper, we will show that a suitable choice of the family of multipliers $\mathcal{M}$ allows the right-hand side of (5) to be easily computed.

4. Upper bound computation via linear families of finite-dimensional multipliers.

4.1. Linear families of finite-dimensional operators. Following an idea arising in [8, 33, 9], we consider finite-dimensional, noncausal operators $M \in \mathcal{M}$, where

$$\mathcal{M} = \left\{ \begin{array}{l} M = \mathbf{diag}(M_1, \ldots, M_{n_p}), \\ M_i(s) = m_{i0} + \displaystyle\sum_{j=1}^{N} \frac{m_{ij}}{(s+1)^j} + \frac{m_{ij}}{(-s+1)^j}, \\ M_i(j\omega) \geq 0 \ \ \forall \omega \in \mathbf{R}, \\ m_{i,j} \in \mathbf{R}, \ \ 1 \leq i \leq n_p, \ \ 0 \leq j \leq N \end{array} \right\}.$$

(We refer the reader to [16] for a complete discussion of the representation of noncausal operators via transfer functions with unstable poles.) Thus, the set $\mathcal{M}$ is parameterized by the real numbers m_{ij}, $i = 1, \ldots, n_p$, $j = 0, \ldots, N$. Each transfer function $M_i(s)$ may alternatively be written as $M_i(s) = C_{M_i}(sI - A_{M_i})^{-1}B_{M_i} + D_{M_i}$, where

$$\begin{aligned} A_{Mi} &= \left[\begin{array}{cc} A_{\mathrm{ca}i} & 0 \\ 0 & -A_{\mathrm{ac}i} \end{array} \right], \quad B_{Mi} = \left[\begin{array}{c} B_{\mathrm{ca}i} \\ -B_{\mathrm{ac}i} \end{array} \right], \\ C_{Mi} &= \left[\begin{array}{cc} C_{\mathrm{ca}i} & C_{\mathrm{ac}i} \end{array} \right], \qquad D_{Mi} = m_{i0}, \end{aligned} \tag{7}$$

and

$$\begin{aligned} A_{\mathrm{ca}i} &= \left[\begin{array}{ccccc} -1 & 1 & 0 & \cdots & 0 \\ 0 & -1 & 1 & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & 0 \\ \vdots & & \ddots & -1 & 1 \\ 0 & \cdots & \cdots & 0 & -1 \end{array} \right], \quad A_{\mathrm{ac}i} = A_{\mathrm{ca}i}, \ \ A_{\mathrm{ca}i} \in \mathbf{R}^{N \times N}, \\ B_{\mathrm{ca}i} &= \left[\begin{array}{cccc} 0 & \cdots & 0 & 1 \end{array} \right]^T, \qquad B_{\mathrm{ac}i} = B_{\mathrm{ca}i}, \\ C_{\mathrm{ca}i} &= \left[\begin{array}{ccc} m_{iN} & \cdots & m_{i1} \end{array} \right], \qquad C_{\mathrm{ac}i} = C_{\mathrm{ca}i}, \quad i = 1, \ldots, n_p. \end{aligned} \tag{8}$$

Likewise, the transfer function $M(s)$ may also be written as $M(s) = C_M(sI - A_M)^{-1}B_M + D_M$, with

$$\begin{aligned} A_M &= \left[\begin{array}{cc} A_{\mathrm{ca}} & 0 \\ 0 & -A_{\mathrm{ac}} \end{array} \right], \quad B_M = \left[\begin{array}{c} B_{\mathrm{ca}} \\ -B_{\mathrm{ac}} \end{array} \right], \\ C_M &= \left[\begin{array}{cc} C_{\mathrm{ca}} & C_{\mathrm{ac}} \end{array} \right], \qquad D_M = \mathbf{diag}_i(m_{i0}), \end{aligned} \tag{9}$$

and

$$\begin{aligned} A_{\mathrm{ca}} &= \mathbf{diag}_i(A_{\mathrm{ca}i}), \quad A_{\mathrm{ac}} = \mathbf{diag}_i(A_{\mathrm{ac}i}), \\ B_{\mathrm{ca}} &= \mathbf{diag}_i(B_{\mathrm{ca}i}), \quad B_{\mathrm{ac}} = \mathbf{diag}_i(B_{\mathrm{ac}i}), \\ C_{\mathrm{ca}} &= \mathbf{diag}_i(C_{\mathrm{ca}i}), \quad C_{\mathrm{ac}} = \mathbf{diag}_i(C_{\mathrm{ac}i}), \\ & i = 1, \ldots, n_p. \end{aligned} \tag{10}$$

To check that $\mathcal{M}$ is indeed an admissible set, we must check that for any $M \in \mathcal{M}$ and any Δ satisfying (2), $M^*\Delta$ is positive. Since $M^*\Delta$ is a diagonal operator, we just need to check that $M_i^*\Delta_i$ is positive for $i = 1, \ldots, n_p$. From [10, p. 174], passivity of Δ_i is equivalent to the inequality

$$\Delta_i(j\omega)^* + \Delta_i(j\omega) \geq 0 \ \ \forall \omega \in \mathbf{R}. \tag{11}$$

By hypothesis, $M_i(j\omega)$ is real and nonnegative. Thus, the inequality (11) implies

$$\Delta_i(j\omega)^* M_i(j\omega) + M_i(j\omega)\Delta_i(j\omega) \geq 0. \tag{12}$$

Thus, positivity of $M_i^*\Delta_i$ holds, since by Parseval's theorem, we have

$$\begin{aligned}&\langle u, M^*\Delta_i u\rangle \\ &\quad = \frac{1}{2\pi}\int_{-\infty}^{\infty} u(j\omega)^*(\Delta_i(j\omega)^* M_i(j\omega) + M_i(j\omega)\Delta_i(j\omega))u(j\omega)d\omega \quad \forall u \in \mathbf{L}_2(\mathbf{R}).\end{aligned}$$

The inequality $M_i(j\omega) + M_i(j\omega)^* \geq 0$ for all $\omega \in \mathbf{R}$ can be expressed in a convenient form via a straightforward application of Theorems 3 and 4 of Willems [41], subsequently corrected in [42].

LEMMA 4.1. *The inequality*

$$M_i(j\omega) + M_i(j\omega)^* \geq 0 \ \ \forall \omega \in \mathbf{R}$$

is satisfied if and only if there exists a symmetric matrix P_i satisfying

$$\begin{bmatrix} A_{M_i}^T P_i + P_i A_{Mi} & P_i B_{Mi} - C_{M_i}^T \\ B_{M_i}^T P_i - C_{Mi} & -(D_{Mi} + D_{M_i}^T) \end{bmatrix} \leq 0. \tag{13}$$

Note that this lemma requires controllability of (A_{M_i}, B_{M_i}) to hold and that this assumption is indeed satisfied.

When $\tilde{q} \in \mathbf{L}_2(\mathbf{R}_+)$, a simple state-space representation of $M\tilde{q}$ can be given that will be useful in the subsequent developments in this paper.

LEMMA 4.2. *For any $\tilde{q} \in \mathbf{L}_2(\mathbf{R}_+)$, we can write $M\tilde{q}$ as the output of the system*

$$\begin{aligned}\frac{d}{dt}x_M &= A_M x_M + B_M \tilde{q}, \qquad x_M(0) = \begin{bmatrix} 0 \ x_{\mathrm{ac}0}^T \end{bmatrix}^T, \\ M\tilde{q} &= C_M x_M + D_M \tilde{q},\end{aligned} \tag{14}$$

where $x_{\mathrm{ac}0}$ is the unique initial condition such that $\lim_{t\to\infty} x_M = 0$, given by

$$x_{\mathrm{ac}0} = \int_0^{\infty} e^{A_{\mathrm{ac}}\tau} B_{\mathrm{ac}} \tilde{q}(\tau) d\tau. \tag{15}$$

A proof of this lemma may be found in Appendix A.

4.2. Upper bound computation. Having identified an appropriate family of multipliers $\mathcal{M}$, we can now describe a numerical implementation of the upper bound on worst-case $\mathbf{H}_2$ norm given in Lemma 3.1.

We first proceed to compute $\mathbf{E}\max_{\tilde{p}\in\mathbf{L}_2(\mathbf{R}_+)} \|\tilde{z}\|^2 + \langle \tilde{p}, M\tilde{q}\rangle$ for a given operator M, where $\tilde{p}$, $\tilde{q}$, and $\tilde{z}$ satisfy (6) and $\tilde{x}(0) = B_w u$, where $\mathbf{E}\, uu^T = I$. Introduce the augmented system

$$
\begin{aligned}
&\frac{d}{dt}\bar{x}(t) = A_{MH}\bar{x}(t) + B_{MH}\tilde{p}(t), \qquad \bar{x}(0) = \begin{bmatrix} \tilde{x}(0)^T & 0 & x_{\mathrm{ac}0}^T \end{bmatrix}^T,\\
&(M\tilde{q})(t) = C_{MH}\bar{x}(t) + D_{MH}\tilde{p}(t),\\
&\tilde{z}(t) = C_{MHz}\bar{x}(t),
\end{aligned} \tag{16}
$$

where $A_{MH},\ B_{MH},\ C_{MH},\ D_{MH}$, and C_{MHz} are given by

$$
\begin{aligned}
&A_{MH} = \begin{bmatrix} A & 0 \\ B_M C_q & A_M \end{bmatrix}, \quad B_{MH} = \begin{bmatrix} B_p \\ B_M D_{qp} \end{bmatrix},\\
&C_{MH} = \begin{bmatrix} D_M C_q & C_M \end{bmatrix}, \quad D_{MH} = D_M D_{qp},\\
&C_{MHz} = \begin{bmatrix} C_z & 0 & 0 \end{bmatrix},
\end{aligned}
$$

and $x_{\mathrm{ac}0}$ is given by (15). From Lemma 4.2, computing $\max_{\tilde{p}\in\mathbf{L}_2(\mathbf{R}_+)} \|\tilde{z}\|_2^2 + 2\langle \tilde{p}, M\tilde{q}\rangle$ is equivalent to computing

$$
\max_{\tilde{p}\in\mathbf{L}_2(\mathbf{R}_+)} \int_0^\infty \begin{bmatrix} \bar{x}(t) \\ \tilde{p}(t) \end{bmatrix}^T \begin{bmatrix} C_{MHz}^T C_{MHz} & C_{MH}^T \\ C_{MH} & D_{MH} + D_{MH}^T \end{bmatrix} \begin{bmatrix} \bar{x}(t) \\ \tilde{p}(t) \end{bmatrix} dt, \tag{17}
$$

where $\tilde{p}$ and $\bar{x}$ satisfy (16). If the initial condition $\bar{x}(0)$ was constant, the solution to this quadratic optimal control problem could be obtained by standard methods such as the ones described in [41]. Unfortunately, this is not the case, because the noncausal multiplier M is involved, which makes $\bar{x}(0)$ depend on $\tilde{p}$ through the relation (15). In fact, assuming that (A_{MH}, B_{MH}) is controllable (we will make this technical assumption from now on), $x_{\mathrm{ac}0}$ spans all of $\mathbf{R}^{Nn_p}$ as $\tilde{p}$ spans all of $\mathbf{L}_2(\mathbf{R}_+)$. Therefore, in order to compute (17) subject to the constraints (16) and (15), we propose the following two-step strategy:

(i) Fix $x_{\mathrm{ac}0}$. Compute (17) subject to the constraints (16) and

$$
\int_0^\infty e^{A_{\mathrm{ac}}\tau} B_{\mathrm{ac}} \tilde{q}(\tau) d\tau = x_{\mathrm{ac}0}.
$$

(ii) Maximize the resulting solution over $x_{\mathrm{ac}0} \in \mathbf{R}^{Nn_p}$.

From Lemma 4.2, step (i) is equivalent to computing (17) subject to the constraints (16) and $\lim_{t\to\infty} \bar{x}(t) = 0$. This is a well-known problem whose solution is given by Willems or Yakubovich, for example.

LEMMA 4.3 (see [41, Theorem 3]; [44, Theorem 3]). *Assume that (A_{MH}, B_{MH}) is controllable. The value of* (17) *subject to the constraints* (16) *and $\lim_{t\to\infty} \bar{x}(t) = 0$ is finite if and only if there exists a symmetric matrix P satisfying the matrix inequality*

$$
\begin{bmatrix} A_{MH}^T P + P A_{MH} + C_{MHz}^T C_{MHz} & P B_{MH} + C_{MH}^T \\ B_{MH}^T P + C_{MH} & D_{MH} + D_{MH}^T \end{bmatrix} \le 0. \tag{18}
$$

It is then given by $\bar{x}(0)^T P^- \bar{x}(0)$, where P^- is the smallest (in the sense of the partial ordering of symmetric matrices) among all matrices P satisfying (18).

A proof of this lemma may be found in Appendix B.

In particular, we see that P^- is independent from the initial condition $\bar{x}(0)$. Therefore, step (ii) is simply done by maximizing

$$
\begin{bmatrix} x_0^T & 0 & x_{\mathrm{ac}0}^T \end{bmatrix} P^- \begin{bmatrix} x_0^T & 0 & x_{\mathrm{ac}0}^T \end{bmatrix}^T
$$

over $x_{\mathrm{ac}0}$. Partitioning P^- as

$$P^- = \begin{bmatrix} P_{11}^- & P_{12}^- & P_{13}^- \\ P_{12}^{-T} & P_{22}^- & P_{23}^- \\ P_{13}^{-T} & P_{23}^{-T} & P_{33}^- \end{bmatrix},$$

this problem is equivalent to maximizing

$$\phi(x_{\mathrm{ac}0}) = x_0^T P_{11}^- x_0 + 2x_0^T P_{13}^- x_{\mathrm{ac}0} + x_{\mathrm{ac}0}^T P_{33}^- x_{\mathrm{ac}0}.$$

The function ϕ is quadratic in $x_{\mathrm{ac}0}$. Thus, it has a maximum if and only if $P_{33}^- \leq 0$ and it has a stationary point $x_{\mathrm{ac}0}$, solution to the equation $P_{13}^{-T} x_0 = -P_{33}^- x_{\mathrm{ac}0}$. In this case, the maximum value of ϕ is given by

$$x_0^T (P_{11}^- - P_{13}^- P_{33}^{-\dagger} P_{13}^{-T}) x_0. \tag{19}$$

Assume now that $x_0 = B_w u$, where u is a random variable satisfying $\mathbf{E}\, uu^T = I$. Then

$$\mathbf{E} \max_{\tilde{p} \in \mathbf{L}_2(\mathbf{R}_+)} \|\tilde{z}\|_2^2 + 2\langle \tilde{p}, M\tilde{q} \rangle \tag{20}$$

is finite if and only if

$$\begin{aligned} &P_{33}^- \leq 0, \\ &\forall u \in \mathbf{R}^{n_w}, \ \ \exists x_{\mathrm{ac}0} \text{ such that } P_{13}^{-T} B_w u = -P_{33}^- x_{\mathrm{ac}0}. \end{aligned} \tag{21}$$

Then, from (19), the value of (20) is

$$\begin{aligned} &\mathbf{E}\, u^T B_w^T (P_{11}^- - P_{13}^- P_{33}^{-\dagger} P_{13}^{-T}) B_w u \\ &\qquad = \mathbf{Tr}\, B_w^T (P_{11}^- - P_{13}^- P_{33}^{-\dagger} P_{13}^{-T}) B_w. \end{aligned} \tag{22}$$

It is possible to write the second condition in (21) in a more compact manner by remarking that it is equivalent to the requirement that $P_{13}^{-T} B_w$ lie in the range of P_{33}^- or, equivalently, in the nullspace of $I - P_{33}^- P_{33}^{-\dagger} = I - P_{33}^{-\dagger} P_{33}^-$. Thus, this condition may also be written $(I - P_{33}^{-\dagger} P_{33}^-) P_{13}^{-T} B_w = 0$.

Introducing the symmetric matrix $\Gamma \in \mathbf{R}^{n_w \times n_w}$ as a slack variable, we can also write the value of (22) together with the condition (21) as the minimum value of $\mathbf{Tr}\, \Gamma$ subject to the conditions

$$\begin{aligned} &B_w^T (P_{11}^- - P_{13}^- P_{33}^{-\dagger} P_{13}^{-T}) B_w \leq \Gamma, \\ &P_{33}^- \leq 0, \\ &(I - P_{33}^{-\dagger} P_{33}^-) P_{13}^{-T} B_w = 0. \end{aligned} \tag{23}$$

Using Schur complements (see [9, p. 28] for details), it is also the minimum value of $\mathbf{Tr}\, \Gamma$ subject to the single constraint

$$\begin{bmatrix} B_w^T P_{11}^- B_w - \Gamma & B_w^T P_{13}^- \\ P_{13}^{-T} B_w & P_{33}^- \end{bmatrix} \leq 0.$$

We now remark that for a general symmetric matrix P partitioned as

$$P = \begin{bmatrix} P_{11} & P_{12} & P_{13} \\ P_{12}^T & P_{22} & P_{23} \\ P_{13}^T & P_{23}^T & P_{33} \end{bmatrix},$$

the matrix

$$X(P) = \begin{bmatrix} B_w^T P_{11} B_w & B_w^T P_{13} \\ P_{13}^T B_w & P_{33} \end{bmatrix}$$

varies monotonically with P, meaning that if $P_1 \le P_2$, then $X(P_1) \le X(P_2)$. Thus, given P^- as defined in Lemma 4.3, we compute the value of $\mathbf{E} \max_{\tilde{p} \in \mathbf{L}_2(\mathbf{R}_+)} \|\tilde{z}\|_2^2 + 2\langle \tilde{p}, M\tilde{q} \rangle$ by minimizing $\mathbf{Tr}\,\Gamma$ over the variables P and Γ subject to the matrix constraints (18) and

$$\begin{bmatrix} B_w^T P B_w - \Gamma & B_w^T P_{13} \\ P_{13}^T B_w & P_{33} \end{bmatrix} \le 0. \tag{24}$$

Thus the value of $\min_{M \in \mathcal{M}} \mathbf{E} \max_{\tilde{p} \in \mathbf{L}_2} \|\tilde{z}\|_2^2 + 2\langle \tilde{p}, M\tilde{q} \rangle$ is obtained by minimizing $\mathbf{Tr}\,\Gamma$ over the variables P, Γ, and $M \in \mathcal{M}$ subject to the matrix constraints (18) and (24). Remarking that $M \in \mathcal{M}$ if and only if the inequality (13) holds, we can now summarize the computation of the upper bound on robust $\mathbf{H}_2$ performance in the following theorem.

THEOREM 4.4. *Consider system* (6). *The quantity*

$$\min_{M \in \mathcal{M}} \mathbf{E} \max_{\tilde{p} \in \mathbf{L}_2(\mathbf{R}_+)} \|\tilde{z}\|_2^2 + 2\langle \tilde{p}, M\tilde{q} \rangle,$$

where $\tilde{z}$, $\tilde{p}$, *and* $\tilde{q}$ *satisfy* (6), *is computed as the minimum of* $\mathbf{Tr}\,\Gamma$ *over the variables* Γ, P, $P_1, \ldots, P_{n_p}$, m_{ij}, $i = 1, \ldots, n_p$, $j = 0, \ldots, N$, *satisfying the constraints*

$$\begin{bmatrix} A_{Mi}^T P_i + P_i A_{Mi} & P_i B_{Mi} - C_{Mi}^T \\ B_{Mi}^T P_i - C_{Mi} & -(D_{Mi} + D_{Mi}^T) \end{bmatrix} \le 0, \quad i = 1, \ldots, n_p, \tag{25}$$

$$\begin{bmatrix} A_{MH}^T P + P A_{MH} + C_{MHz}^T C_{MHz} & P B_{MH} + C_{MH}^T \\ B_{MH}^T P + C_{MH} & D_{MH} + D_{MH}^T \end{bmatrix} \le 0, \tag{26}$$

and

$$\begin{bmatrix} B_w^T P_{11} B_w - \Gamma & B_w^T P_{13} \\ P_{13}^T B_w & P_{33} \end{bmatrix} \le 0, \tag{27}$$

where

$$P = \begin{bmatrix} P_{11} & P_{12} & P_{13} \\ P_{12}^T & P_{22} & P_{23} \\ P_{13}^T & P_{23}^T & P_{33} \end{bmatrix} \tag{28}$$

has been partitioned conformally with the dimensions of A, A_{ca}, *and* A_{ac} (*where* A_{ca} *and* A_{ac} *are given by* (10)).

5. Discussion. In this section, we discuss the main result of this paper and compare it with some previous approaches.

5.1. Computational issues. We see that Theorem 4.4 gives us *effective means* to compute the upper bound on the worst-case $\mathbf{H}_2$ norm of the system (1): indeed, we have to minimize the linear objective $\mathbf{Tr}\,\Gamma$ over the variables Γ, P, $P_1, \ldots, P_{n_0}$, m_{ij}, $i = 1, \ldots, n_p$, $j = 0, \ldots, N$, which appear *linearly* in the matrix constraints (25)–(27). In particular, new interior-point convex optimization algorithms will solve this problem very efficiently [25, 9]. Note also that the size of the optimization problem grows with the dimension N of the family of multipliers used. Note finally that the solution of the optimization problem in Theorem 4.4 via interior-point methods requires that all soft inequality signs of the form $\leq$ appearing in the constraints (25)–(27) be replaced by strict inequality signs. This does not present significant problems in most practical cases. (For a detailed discussion, we refer the reader to [9, section 2.5]).

5.2. When the obtained bound is finite. Theorem 4.4 provides an upper bound for the worst-case $\mathbf{H}_2$ norm of the system (1). However, it does not guarantee that this upper bounds is finite. Thus, it is interesting to examine cases for which this bound is guaranteed to be finite.

One such case arises when there exists $M \in \mathcal{M}$ such that $-MH_{qp}$ is strictly positive, where H_{qp} is the operator whose transfer function is given in (3). Then there exists a positive δ such that

$$\forall p \in \mathbf{L}_2(\mathbf{R}), \quad \langle p, MH_{qp}p\rangle \leq -\delta\langle p, p\rangle.$$

Define the impulse matrices

$$h_{zw}(t) = \begin{cases} C_z e^{At} B_w \text{ for } t \geq 0, \\ 0 \text{ otherwise} \end{cases}$$

and

$$h_{qw}(t) = \begin{cases} C_q e^{At} B_w \text{ for } t \geq 0, \\ 0 \text{ otherwise.} \end{cases}$$

Then, for any $\lambda > 0$, any initial condition $\tilde{x}(0) = B_w u$ and any $\tilde{p} \in \mathbf{L}_2(\mathbf{R}_+)$ in the system (6), we have

$$\begin{aligned} &\|\tilde{z}\|_2^2 + 2\lambda\langle\tilde{p}, M\tilde{q}\rangle \\ &= \|h_{zw}u + H_{zp}\tilde{p}\|_2^2 + 2\lambda\langle\tilde{p}, MH_{qp}\tilde{p} + Mh_{qw}u\rangle \\ &\leq \|h_{zw}u\|_2^2 + 2(\|h_{zw}u\|_2 \|H_{zp}\|_\infty + \lambda \|h_{qw}u\|_2 \|M\|_\infty) \|\tilde{p}\|_2 + (\|H_{zp}\|_\infty^2 - 2\lambda\delta) \|\tilde{p}\|_2^2 . \end{aligned}$$

Choosing $\lambda = (\|H_{zp}\|_\infty^2 + 1)/2\delta$, we therefore have

$$\begin{aligned} &\|\tilde{z}\|_2^2 + 2\lambda\langle\tilde{p}, M\tilde{q}\rangle \\ &\quad \leq \|h_{zw}u\|_2^2 + 2(\|h_{zw}u\|_2 \|H_{zp}\|_\infty + \lambda \|h_{qw}u\|_2 \|M\|_\infty) \|\tilde{p}\|_2 - \|\tilde{p}\|_2^2 \\ &\quad \leq \|h_{zw}u\|_2^2 + (\|h_{zw}u\|_2 \|H_{zp}\|_\infty + \lambda \|h_{qw}u\|_2 \|M\|_\infty)^2 \\ &\quad \leq \|h_{zw}u\|_2^2 + 2(\|h_{zw}u\|_2^2 \|H_{zp}\|_\infty^2 + \lambda^2 \|h_{qw}u\|_2^2 \|M\|_\infty^2). \end{aligned}$$

(Note that the quantities $\|M\|_\infty$ and $\|H_{zp}\|_\infty$ are well defined, since the corresponding transfer functions have no poles on the imaginary axis.) Taking expected values with respect to the random variable u, we have

$$\begin{aligned}&\mathbf{E}\max_{\tilde{p}\in\mathbf{L}_2(\mathbf{R}_+)} \|\tilde{z}\|_2^2 + 2\lambda\langle\tilde{p}, M\tilde{q}\rangle \\ &\qquad \le \|h_{zw}\|_2^2 + 2(\|h_{zw}\|_2^2 \|H_{zp}\|_\infty^2 + \lambda^2 \|h_{qw}\|_2^2 \|M\|_\infty^2).\end{aligned}$$

Noting that $M \in \mathcal{M}$ implies $\lambda M \in \mathcal{M}$, we conclude our upper bound is finite.

It is interesting to remark that the strict positivity of $-MH_{qp}$ is one of the conditions used in the classical theory of stability multipliers to prove stability of the system (1) as described in [10, p. 203]. Thus, whenever stability of the system (1) can be proven via stability multipliers, then we can provide finite bounds on its worst-case $\mathbf{H}_2$ performance. Note that numerical methods involving linear matrix inequalities to prove robust stability of the system (1) using linear families of finite-dimensional multipliers may be found in [3, 35].

5.3. Special cases and comparison with earlier results. In this section, we investigate what happens when considering special cases of the system (1) and of the multiplier M.

Consider first the case when the system (1) is perfectly known, that is, $B_p = 0, C_q = 0, D_{qp} = 0$. The optimization problem in Theorem 4.4 is solved by choosing $m_{ij} = 0$ for all i and j; $P_i = 0$ for all i;

$$P = \begin{bmatrix} P_{11} & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix},$$

where P_{11} satisfies $A^T P_{11} + P_{11} A + C_z^T C_z = 0$; and $\Gamma = B_w^T P B_w$. P_{11} is the *observability Gramian*, and the obtained bound is then exact.

Second, consider the case when $N = 0$ and $n_p = 1$, that is, when the multiplier $M = m_{10} = m$ is simply a nonnegative scalar. Then, applying Theorem 4.4 leads to the computation of

$$\min_{m\ge 0} \mathbf{E} \max_{p\in\mathbf{L}_2(\mathbf{R}_+)} \|\tilde{z}\|^2 + 2m\langle\tilde{p}, \tilde{q}\rangle \tag{29}$$

via convex programming and linear matrix inequalities.

This special case in which scalar, memoryless multipliers are used has already appeared in the literature—for example, in the papers by Stoorvogel [37, 38], although in a different format: in these papers, the problem under consideration is to compute the worst-case $\mathbf{H}_2$ norm of the system

$$\begin{aligned}\frac{d}{dt}x(t) &= \hat{A}x(t) + \hat{B}_p\hat{p}(t) + B_w w(t), \quad x(0) = x_0, \\ \hat{q}(t) &= \hat{C}_q x(t) + \hat{D}_{qp}\hat{p}(t), \\ z(t) &= C_z x(t),\end{aligned} \tag{30}$$

when $\hat{p}$ and $\hat{q} \in \mathbf{L}_2(\mathbf{R}_+)$ are subject to the constraint

$$\|\hat{p}\|_2^2 \le \|\hat{q}\|_2^2. \tag{31}$$

Stoorvogel obtains an upper bound on the worst-case $\mathbf{H}_2$ norm for this system by relaxing the constraint (31) and by computing

$$\min_{m\geq 0} \mathbf{E} \max_{\hat{p}\in \mathbf{L}_2(\mathbf{R}_+)} \|z\|_2^2 + 2m(\|\hat{q}\|_2^2 - \|\hat{p}\|_2^2), \tag{32}$$

where z, $\hat{p}$, and $\hat{q}$ satisfy (30), subject to the boundary conditions $x(0) = B_w u$, $w(t) = 0$, and u is a random variable satisfying $\mathbf{E}\, uu^T = I$. This formulation can be cast in our framework the following way: Introduce the scattering variables $q = (\hat{p}+\hat{q})/2$ and $p = -(\hat{p}-\hat{q})/2$. Then, following the same reasoning as in [10, p. 215], the system (30) and the constraint (31) can also be written as

$$\begin{aligned} \frac{d}{dt}x(t) &= Ax(t) + B_p p(t) + B_w w(t), \quad x(0) = x_0, \\ q(t) &= C_q x(t) + D_{qp} p(t), \\ z(t) &= C_z x(t), \end{aligned} \tag{33}$$

and

$$\langle p, q\rangle \geq 0, \tag{34}$$

where A, B_p, C_q, and D_{qp} are determined from $\hat{A}$, $\hat{B}_p$, $\hat{C}_q$, and $\hat{D}_{qp}$ via the relations

$$\begin{aligned} A &= \hat{A} + \hat{B}_p(I - \hat{D}_{qp})^{-1}\hat{C}_q, \quad & B_p &= -2\hat{B}_p(I - \hat{D}_{qp})^{-1}, \\ C_q &= (I - \hat{D}_{qp})^{-1}\hat{C}_q, & D_{qp} &= -(I + \hat{D}_{qp})(I - \hat{D}_{qp})^{-1}. \end{aligned} \tag{35}$$

(These relations are valid if and only if $I - \hat{D}_{qp}$ is invertible.) The upper bound (32) can then be written as

$$\min_{m\geq 0} \mathbf{E} \max_{p\in \mathbf{L}_2(\mathbf{R}_+)} \|z\|_2^2 + 2m\langle p, q\rangle, \tag{36}$$

where z, p, and q satisfy (33), subject to the boundary conditions $x(0) = B_w u$, $w(t) = 0$, and u is a random variable satisfying $\mathbf{E}\, uu^T = I$. But then the quantity (36) is the same as the special case (29). Note that the only difference between Stoorvogel's system as given by (33) and (34) and the system (1) is that the uncertainty relationship $p(t) = (\Delta q)(t)$, where Δ is a passive, LTI operator, has been replaced by the uncertainty relationship $\langle p, q\rangle \geq 0$. The latter relationship describes a larger class of uncertainties than the former relationship, since whenever $p = \Delta q$ for Δ LTI and passive, then $\langle p, q\rangle \geq 0$. Similar comments may be made about the results presented in [30, 9, 13, 19].

6. Example. In this section, we present an example to illustrate the developed method, and compare it with earlier results. We consider the system (1) with

$$A = \begin{bmatrix} -0.1 & -0.1 & 0 & 0 & 0 \\ 0.1 & 0 & 0 & 0 & 0 \\ 0 & 0 & -0.2 & -0.2 & 0 \\ 0 & 0 & 0.1 & 0 & 0 \\ 0 & 0 & 0 & 0 & -2 \end{bmatrix}, \quad B_p = \begin{bmatrix} 0.1 \\ 0 \\ 0.1 \\ 0 \\ 0.001 \end{bmatrix}, \quad B_w = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 1 \end{bmatrix},$$

$$C_q = \begin{bmatrix} 11.98 & 0 & 0.01 & 0 & 20 \end{bmatrix}, \qquad D_{qp} = -12,$$

$$C_z = \begin{bmatrix} 0 & 0 & 0 & 2 & 0 \end{bmatrix},$$

TABLE 1
Upper bound on square of $\mathbf{H}_2$ *performance as a function of multiplier order.*

N	0	1	2	3	4	5	6
Upper bound	341.17	137.87	99.03	83.59	75.81	71.39	68.69

and the perturbation Δ is any passive, LTI, and single-input, single-output system. It is easy to check (via a Nyquist plot, for example) that the transfer function $-H(s) = -C_q(sI - A)^{-1}B_p - D_{qp}$ has positive dissipation such that by application of the passivity theorem [10], the system (1) is stable. Using the software described in [18, 24, 17], we have recorded in Table 1 the obtained bounds on the square of its worst-case $\mathbf{H}_2$ norm as a function of N. ($2N$ is the order of the noncausal multiplier which is used.) Thus, $N = 0$ corresponds to the use of simple constant-gain, memoryless multipliers. As can be seen, the use of dynamic, noncausal multipliers improves the estimate on the square of the worst-case $\mathbf{H}_2$ norm by a factor of 5. Note also that the best upper bound converges to a steady state value quite fast with the size of the multiplier. This result is indeed obtained at the expense of increased computations.

7. Conclusion and extensions. In this paper, we have considered the problem of determining an upper bound for the worst-case $\mathbf{H}_2$ norm of linear systems subject to LTI uncertainties, by extending the theory of stability multipliers to handle $\mathbf{H}_2$ performance.

We have shown this bound appears as the solution of a convex optimization problem involving linear matrix inequalities. Thus there exist algorithms that will compute it fast and accurately.

We have shown this bound is always sharper than the ones devised earlier for larger classes of uncertainties. One example shows that this improvement can be significant.

This work can be extended in many directions. For example, the theory of stability multipliers has proved to be effective not only on LTI perturbations but also on other classes of uncertainties, including memoryless, sector-bounded, and monotonic nonlinearities and constant, unknown linear gains (parametric uncertainties). Thus, this paper could be easily extended to these cases (with the restriction that $\mathbf{H}_2$ norms of nonlinear systems require careful definition). The set of allowable multipliers $\mathcal{M}$ would then be different.

Appendix A: Proof of Lemma 4.2. Using inverse Fourier transforms, it is easy to show that for any $\tilde{q} \in \mathbf{L}_2(\mathbf{R})$, we have

$$(37)\quad (M\tilde{q})(t) = \int_{-\infty}^{t} C_{\mathrm{ca}} e^{A_{\mathrm{ca}}(t-\tau)} B_{\mathrm{ca}} \tilde{q}(\tau) d\tau + D_M \tilde{q}(t) + \int_{t}^{\infty} C_{\mathrm{ac}} e^{A_{\mathrm{ac}}(\tau-t)} B_{\mathrm{ac}} \tilde{q}(\tau) d\tau.$$

Thus, $(M\tilde{q})(t)$ is the sum of three parts: the first integral accounts for the causal part of H, the midterm represents a possible feedthrough term, and the second integral accounts for the anticausal part of M. (This is the reason for using the subscripts "ca" and "ac," which stand for "causal" and "anticausal," respectively.)

When $\tilde{q} \in \mathbf{L}_2(\mathbf{R}_+)$, the first integral in (37) is easily computed as $r_{\mathrm{ca}}(t)$, the output of the system

$$\begin{aligned} \frac{d}{dt} x_{\mathrm{ca}}(t) &= A_{\mathrm{ca}} x_{\mathrm{ca}}(t) + B_{\mathrm{ca}} \tilde{q}(t), \quad x_{\mathrm{ca}}(0) = 0, \\ r_{\mathrm{ca}}(t) &= C_{\mathrm{ca}} x_{\mathrm{ca}}(t). \end{aligned}$$

The second integral can be transformed the following way:

$$\begin{aligned}\int_t^\infty & C_{\rm ac}e^{A_{\rm ac}(\tau-t)}B_{\rm ac}\tilde q(\tau)d\tau \\ &= \int_0^\infty C_{\rm ac}e^{A_{\rm ac}(\tau-t)}B_{\rm ac}\tilde q(\tau)d\tau - \int_0^t C_{\rm ac}e^{A_{\rm ac}(\tau-t)}B_{\rm ac}\tilde q(\tau)d\tau \\ &= C_{\rm ac}\left[e^{-A_{\rm ac}t}\int_0^\infty e^{A_{\rm ac}\tau}B_{\rm ac}\tilde q(\tau)d\tau - \int_0^t e^{-A_{\rm ac}(t-\tau)}B_{\rm ac}\tilde q(\tau)d\tau\right].\end{aligned}$$

Therefore, defining

$$x_{\rm ac0} = \int_0^\infty e^{A_{\rm ac}\tau}B_{\rm ac}\tilde q(\tau)d\tau$$

($x_{\rm ac0}$ is always defined and finite, since $\tilde q \in \mathbf{L}_2(\mathbf{R}_+)$ and $A_{\rm ac}$ is stable), the second integral term in (37) can be written as $r_{\rm ac}(t)$, the output of the system

$$\begin{aligned}\frac{d}{dt}x_{\rm ac}(t) &= -A_{\rm ac}x_{\rm ac}(t) - B_{\rm ac}\tilde q(t), \quad x_{\rm ac}(0) = x_{\rm ac0}, \\ r_{\rm ac}(t) &= C_{\rm ac}x_{\rm ac}(t).\end{aligned}$$

Thus we obtain the expression (14) for $(M\tilde q)(t)$. The fact that $\lim_{t\to\infty} x_{\rm ca}(t) = 0$ is a direct consequence of the fact that $A_{\rm ca}$ is stable; the fact that $\lim_{t\to\infty} x_{\rm ac}(t) = 0$ follows from the identity

$$x_{\rm ac}(t) = \int_t^\infty e^{A_{\rm ac}(\tau-t)}B_{\rm ac}\tilde q(\tau)d\tau.$$

Conversely, consider the system (14), and let $x_{\rm ac0}$ be such that $\lim_{t\to\infty} x_{\rm ac}(t) = 0$. Then

$$x_{\rm ac}(t) = e^{-A_{\rm ac}t}x_{\rm ac0} - \int_0^t e^{-A_{\rm ac}(t-\tau)}\tilde q(\tau)d\tau.$$

If $\lim_{t\to\infty} x_{\rm ac}(t) = 0$, then $\lim_{t\to\infty} e^{A_{\rm ac}t}x_{\rm ac}(t) = 0$. Therefore, from the above equality, we must have

$$\lim_{t\to\infty}\int_0^t e^{A_{\rm ac}\tau}\tilde q(\tau)d\tau = x_{\rm ac0},$$

which proves that $x_{\rm ac0}$ is indeed unique. □

Appendix B: Proof of Lemma 4.3. From the literature on linear quadratic control, it is well known that the value of (17) subject to the constraint $\lim_{t\to\infty}\bar x = 0$ is a quadratic function of $\bar x(0)$ whenever it is finite. See for example [1, p. 21]. Denote this quadratic form as $\bar x(0)^T P^-\bar x(0)$. We first prove that P^- must satisfy the inequality (18). This is done by first noting that for any input $\tilde p$ and corresponding trajectory $\bar x$, the dissipation inequality

$$\frac{d}{dt}(\bar x(t)^T P^-\bar x(t)) \le -w(\bar x(t),\tilde p(t)) \tag{38}$$

must be satisfied, where

$$w(\bar x(t),\tilde p(t)) = \begin{bmatrix}\bar x(t)\\ \tilde p(t)\end{bmatrix}^T \begin{bmatrix} C_{MHz}^T C_{MHz} & C_{MH}^T \\ C_{MH} & D_{MH}+D_{MH}^T\end{bmatrix}\begin{bmatrix}\bar x(t)\\ \tilde p(t)\end{bmatrix}.$$

Indeed, for any initial condition $\bar{x}(t)$ and any input $\tilde{p}_1$ defined over the time interval $[t \;\; t+dt]$, standard dynamic programming arguments yield the inequality

$$\int_t^{t+dt} w(\bar{x},\tilde{p}_1)dt + \max_{\tilde{p}\in\mathbf{L}_2}\int_{t+dt}^{\infty} w(\bar{x},\tilde{p})dt \le \max_{\tilde{p}\in\mathbf{L}_2}\int_t^{\infty} w(\bar{x},\tilde{p})dt.$$

Letting dt tend toward 0 yields the equivalent differential form

$$w(\bar{x}(t),\tilde{p}(t)) \le -\frac{d}{dt}\max_{\tilde{p}\in\mathbf{L}_2}\int_t^{\infty} w(\bar{x},\tilde{p})dt,$$

which yields (38). Noting that this quadratic inequality must hold for any $\bar{x}$ and $\tilde{p}$ and that

$$\frac{d}{dt}\bar{x}(t)^T P^- \bar{x}(t) = 2\bar{x}(t)^T P^-(A_{MH}\bar{x}(t) + B_{MH}\tilde{p}(t))$$

yields the equivalent inequality (18).

Conversely, consider any feasible solution P to the matrix inequality (18). Then, the inequality (38) is automatically satisfied. Integrating this inequality from zero to infinity with any $\tilde{p} \in \mathbf{L}_2$ such that $\lim_{t\to\infty}\bar{x}(t) = 0$ implies

$$\bar{x}(0)^T P\bar{x}(0) \ge \int_0^{\infty} w(\bar{x},\tilde{p})dt.$$

Thus, whenever P^- exists, we have

P^- satisfies (18) and
$\bar{x}(0)^T P^- \bar{x}(0) \le \bar{x}(0)^T P\bar{x}(0) \;\; \forall(\bar{x}(0), P)$,
where P satisfies (18).

Thus, P^- must be the smallest feasible solution to the inequality (18). □

A NEW NONSMOOTH EQUATIONS APPROACH TO NONLINEAR COMPLEMENTARITY PROBLEMS*

HOUYUAN JIANG† AND LIQUN QI†

Abstract. Based on Fischer's function, a new nonsmooth equations approach is presented for solving nonlinear complementarity problems. Under some suitable assumptions, a local and Q-quadratic convergence result is established for the generalized Newton method applied to the system of nonsmooth equations, which is a reformulation of nonlinear complementarity problems. To globalize the generalized Newton method, a hybrid method combining the generalized Newton method with the steepest descent method is proposed. Global and Q-quadratic convergence is established for this hybrid method. Some numerical results are also reported.

Key words. nonlinear complementarity problems, nonsmooth equations, semismoothness, uniform P-functions

1. Introduction.

Consider the following nonlinear complementarity problem (denoted the NCP):

$$\text{find } x \in \mathcal{R}^n \text{ such that } x \geq 0, \quad F(x) \geq 0, \quad \text{and } x^T F(x) = 0, \tag{1}$$

where $F : \mathcal{R}^n \to \mathcal{R}^n$ is continuously differentiable and the superscript T denotes the transpose operator.

The NCP has been used as a general framework for quadratic programming, linear complementarity problems, mathematical programming and some equilibrium problems. Designing algorithms for solving the NCP became extremely popular in the last decade, although it has a relatively long history. Many different approaches such as fixed point, homotopy, projection, Newton, smooth or nonsmooth optimization, smooth or nonsmooth equations, and many other methods have appeared. For an extensive survey of the NCP, we refer the reader to [34] and references therein; see also [13].

Josephy [17] presented a generalized Newton method for solving variational inequalities which contain the NCP as a special case. The Josephy–Newton method was shown to be convergent locally as well as Q-quadratically. However, this method does not converge globally. Therefore, the design of good global methods for solving the NCP becomes a challenging endeavor.

Based on the above motivation, Pang [33] reformulated the NCP as a system of nonsmooth equations. This makes it possible to extend the classical damped Newton method for solving smooth equations to the nonsmooth case. Harker and Xiao [14] also converted the NCP into a system of nonsmooth equations in a different way. Pang and Gabriel [35] further combined the nonsmooth equations reformulation with sequential quadratic programming, resulting in a so-called NE/SQP method. They established that the NE/SQP method converges both globally and locally Q-quadratically. The

idea of reformulating the NCP as a system of equations is not new. Actually, Mangasarian [25] reformulated the NCP as a system of smooth equations (see also [41]). But the singularity of the system confines the application of Mangasarian's method. Kanzow [19] further established many ways for reformulating the NCP. Chen and Mangasarian [4] proposed smoothing methods where a class of smooth functions approximate certain nonsmooth functions arising in the reformulations of the NCP. The further study of those methods has been done by Chen and Harker [3].

Another approach is to reformulate the NCP as a smooth unconstrained minimization problem. Mangasarian and Solodov [26] introduced a smooth function in such a way that any global minimizer of the unconstrained minimization problem with this function as the objective function is a solution of the NCP. Yamashita and Fukushima [43] proved that any stationary point of the unconstrained minimization problem proposed by Mangasarian and Solodov is a solution of the NCP if F is continuously differentiable and strongly monotone in $\mathcal{R}^n$. This shows that any method for solving unconstrained minimization problems is applicable for the NCP in this special case. Kanzow [18] gave some more approaches to characterize the NCP as unconstrained minimization problems. Geiger and Kanzow [12] proved that one of these approaches has a good property as Yamashita and Fukushima observed for the Mangasarian–Solodov function, but with a weaker assumption. Reformulating the NCP as a smooth constrained minimization problem is also a direction to follow. This approach is due to Fukushima's [11] and Auchmuty's [1] remarkable work; see [11, 1] for more details. Recently, Moré [30] formulated the NCP as a bound-constrained nonlinear least squares problem which may be classified as part of the smooth constrained minimization reformulation approach. For nonsmooth constrained minimization reformulations of the NCP, we refer the reader to [27].

Other methods for solving the NCP include homotopy or continuation methods. The idea is also based on the equivalence between the NCP and a system of equations; see [2, 20, 21, 22, 42].

The discussion above shows that the approaches of reformulating the NCP into smooth or nonsmooth equations, smooth or nonsmooth minimization problems are very promising. It generates a new future for the designing of computational methods for solving the NCP.

In this paper, we shall propose a new nonsmooth equations–based method for the NCP. This work is more related to nonsmooth equations and smooth unconstrained minimization based methods. We first transform the NCP into a system of nonsmooth equations in the next section by employing a function introduced by Fischer [8]. In section 3, we establish locally Q-quadratic convergence of the generalized Newton method for solving the NCP under some suitable conditions. Unlike other nonsmooth equations–based methods, we solve a system of linear equations instead of a mixed complementarity problem or a quadratic programming problem for each inner iteration. To globalize the generalized Newton method, we propose in section 4 a hybrid method by combining the generalized Newton method with a minimization technique. This hybrid method enjoys not only global convergence but also locally Q-quadratic convergence under some assumptions. In section 5, some numerical results are reported for both the generalized Newton and the hybrid methods.

2. The nonsmooth equations reformulation. Let $\phi : R^2 \to R$ be defined by

$$\phi(a, b) = \sqrt{a^2 + b^2} - a - b. \tag{2}$$

Fischer [8] first introduced this function to reformulate the Karush–Kuhn–Tucker (KKT) optimality conditions of nonlinear programming problems as systems of nonsmooth equations. Kanzow [18, 19] used this same function to reformulate linear and nonlinear complementarity problems as smooth nonlinear programs or systems of smooth equations. Jiang [16] studied sensitivity properties of nonsmooth variational inequalities by employing nonsmooth analysis to the function ϕ.

One basic property of this function is that

$$\phi(a,b)=0 \Longleftrightarrow a\geq 0, \quad b\geq 0, \quad ab=0. \tag{3}$$

From the above characterization, (1) can be recast as a system of nonsmooth equations defined by

$$H(x)=\begin{pmatrix} H_1(x) \\ \vdots \\ H_n(x) \end{pmatrix}=\begin{pmatrix} \phi(x_1,F_1(x)) \\ \vdots \\ \phi(x_n,F_n(x)) \end{pmatrix}=0 \tag{4}$$

in the sense that x solves (1) if and only if x solves (4).

Note that H is locally Lipschitz on $\mathcal{R}^n$ and Fréchet differentiable only on the set Ω, where

$$\Omega=\{x\in\mathcal{R}^n | x_i^2+(F_i(x))^2>0, i=1,...,n\}.$$

Let $G:\mathcal{R}^n\to\mathcal{R}^n$ be locally Lipschitz on $\mathcal{R}^n$. Then Clarke's generalized Jacobian of G at x, denoted by $\partial G(x)$, can be defined as the convex hull of the set

$$\{\lim_{x^k\to x} \bigtriangledown G(x^k) \mid G \text{ is differentiable at } x^k\in\mathcal{R}^n\}.$$

As an analogue to Fischer's analysis [8], we study Clarke's generalized Jacobian of H at all points on $\mathcal{R}^n$. For $x\in\Omega$, we have

$$\bigtriangledown H(x)=\mathrm{diag}(\gamma_i(x))\bigtriangledown F(x)+\mathrm{diag}(\mu_i(x)),$$

where $\mathrm{diag}(\alpha_i)$ denotes a diagonal matrix with diagonal elements $\alpha_1,\alpha_2,...,\alpha_n$, and

$$\gamma_i(x)=F_i(x)((F_i(x))^2+x_i^2)^{-1/2}-1,$$

$$\mu_i(x)=x_i((F_i(x))^2+x_i^2)^{-1/2}-1.$$

Clearly, for $i=1,...,n$,

$$(\gamma_i(x)+1)^2+(\mu_i(x)+1)^2=1. \tag{5}$$

It also follows that

$$\mu_i(x)=-1, \quad \gamma_i(x)=0 \Longleftrightarrow F_i(x)>0, \quad x_i=0,$$

$$\mu_i(x)=0, \quad \gamma_i(x)=-1 \Longleftrightarrow F_i(x)=0, \quad x_i>0.$$

For $x\notin\Omega$, by the definition of Clarke's generalized Jacobian and some simple calculations, any $V\in\partial H(x)$ can be represented as follows

$$V=\mathrm{diag}(\gamma_i)\bigtriangledown F(x)+\mathrm{diag}(\mu_i), \tag{6}$$

where

$$(\gamma_i + 1)^2 + (\mu_i + 1)^2 \leq 1, \quad i = 1, 2, ..., n. \tag{7}$$

Remark. The reverse of the above assertion is not true in general. However, one can find a matrix $V \in \partial H(x)$ for any $x \in \mathcal{R}^n$. For any given $x \in \mathcal{R}^n$, let $\mathcal{I} = \{i | x_i = F_i(x) = 0\}$ and u be a vector of $\mathcal{R}^n$ with $u_i \neq 0$ for $i \in \mathcal{I}$. Define

$$\gamma_i = \begin{cases} F_i(x)((F_i(x))^2 + x_i^2)^{-1/2} - 1, & i \notin \mathcal{I}, \\ \nabla F_i(x)^T u((\nabla F_i(x)^T u)^2 + u_i^2)^{-1/2} - 1, & i \in \mathcal{I}, \end{cases}$$

and

$$\mu_i = \begin{cases} x_i((F_i(x))^2 + x_i^2)^{-1/2} - 1, & i \notin \mathcal{I}, \\ u_i((\nabla F_i(x)^T u)^2 + u_i^2)^{-1/2} - 1, & i \in \mathcal{I}. \end{cases}$$

It is not hard to prove that $\mathrm{diag}(\gamma_i)\nabla F(x) + \mathrm{diag}(\mu_i)$ is a Clarke generalized Jacobian of H at x. This technique is also used by De Luca, Facchinei, and Kanzow [5].

3. The algorithm and its local convergence. Since Robinson's and Pang's pioneering works [40], [32], numerical methods for solving nonsmooth equations have been developed quite extensively. In particular, the generalized Newton method was proved to be convergent locally and superlinearly under the key assumption that the considered function is semismooth at solution points; see Qi and Sun [38] and Qi [37] for more details. Kojima and Shindo [23], Kummer [24], Pang [33], Pang and Qi [36], Ralph [39], and many more studied nonsmooth equations from different perspectives. Our goal here is to establish a local and superlinear convergence result when the generalized Newton method is applied to (4).

We now present our generalized Newton method for solving the system (4).

ALGORITHM A.

Step 1. Choose initial point $x^0 \in \mathcal{R}^n$ and Let $k = 0$.

Step 2. Choose $V^k \in \partial H(x^k)$ and solve the following Newton equations for the direction $d^k \in \mathcal{R}^n$:

$$H(x^k) + V^k d^k = 0. \tag{8}$$

Step 3. Set $x^{k+1} = x^k + d^k$. If x^{k+1} solves $H(x) = 0$, stop. Otherwise, let $k := k + 1$ and go to Step 2.

Note that d^k is not unique in (8) if V^k is not nonsingular. Moreover, it is not known if (8) is solvable or not. We shall provide conditions to ensure the solvability of (8).

Recall that a function $G : \mathcal{R}^n \to \mathcal{R}^n$ is said to be monotone if

$$(y - x)^T(G(y) - G(x)) \geq 0 \quad \text{for all } x, y \in \mathcal{R}^n.$$

Furthermore, G is called a uniform P-function [29] if there is $\alpha > 0$ such that

$$\max_{1 \leq i \leq n} (y_i - x_i)(G_i(y) - G_i(x)) \geq \alpha ||y - x||^2 \text{ for all } x, y \in \mathcal{R}^n.$$

Both monotone functions and uniform P-functions are very broad and have very fine properties. It is known [31] that a smooth function is monotone on $\mathcal{R}^n$ if and only

if its Jacobian function is positive semidefinite on $\mathcal{R}^n$. The following lemma shows a similar relation to the above characterization for uniform P-functions.

LEMMA 3.1. *Suppose that $G : \mathcal{R}^n \to \mathcal{R}^n$ is a smooth uniform P-function with modulus $\alpha > 0$. Then for any $x \in \mathcal{R}^n$ and $0 \neq d \in \mathcal{R}^n$*

$$\max_{1\leq i\leq n} \; d_i \bigtriangledown G_i(x)^T d \geq \alpha ||d||^2.$$

Proof. Let $y = x + td$ for $t > 0$. Then the result follows from the mean value theorem. □

PROPOSITION 3.2. *Suppose $F : \mathcal{R}^n \to \mathcal{R}^n$ is continuously differentiable. If F is a uniform P-function, then V is nonsingular for any $V \in \partial H(x)$ and $x \in \mathcal{R}^n$.*

Proof. Let $V \in \partial H(x)$ for $x \in \mathcal{R}^n$. Let d solve the equations $Vd = 0$. By (6), there exist constants $\gamma_1, \ldots, \gamma_n, \mu_1, \ldots, \mu_n$ satisfying (7) such that

$$\mathrm{diag}(\gamma_i) \bigtriangledown F(x)d + \mathrm{diag}(\mu_i)d = 0,$$

namely,

$$\begin{cases} \mu_1 d_1 + \gamma_1 \bigtriangledown F_1(x)d = 0, \\ \qquad\qquad \vdots \\ \mu_n d_n + \gamma_n \bigtriangledown F_n(x)d = 0. \end{cases}$$

Multiplying the ith equation by d_i, we have

$$\begin{cases} \mu_1 d_1^2 + d_1\gamma_1 \bigtriangledown F_1(x)d = 0, \\ \qquad\qquad \vdots \\ \mu_n d_n^2 + d_n\gamma_n \bigtriangledown F_n(x)d = 0. \end{cases}$$

By (7), if $\gamma_i = 0$ then $d_i = 0$. Consequently,

$$\max_{1\leq i\leq n} d_i \bigtriangledown F_i(x)d \leq \max_{1\leq i\leq n, \gamma_i\neq 0} \{0, -\mu_i/\gamma_i d_i^2\} \leq 0.$$

But the uniform P-function property of F implies that $d = 0$. Thus the nonsingularity of V follows. □

By a similar argument with some minor modifications, one can prove the following result.

PROPOSITION 3.3. *Suppose $F : \mathcal{R}^n \to \mathcal{R}^n$ is continuously differentiable. If $\bigtriangledown F(x)$ is positive definite for all $x \in \mathcal{R}^n$, then V is nonsingular for any $V \in \partial H(x)$ and $x \in \mathcal{R}^n$.*

Remarks. (1) The positive definiteness assumption of Proposition 3.3 cannot be weakened to the condition that F is strictly monotone on $\mathcal{R}^n$. This is shown by the following example. Let $F(x) = x^3$. Then F is strictly monotone on $\mathcal{R}$ and $H(x) = \sqrt{x^2 + x^6} - x - x^3$. An easy calculation shows that $\partial H(0) = [-2, 0]$. Therefore, $0 \in \partial H(0)$ is singular. (2) Clearly, for the nonsingularity of the generalized Jacobian of H at a given point, say x in Propositions 3.2 and 3.3, it is sufficient to impose the uniform P-function property or the positive definiteness of the Jacobian of the function F only in an open neighborhood of x.

It is known [37] that the semismooth condition imposed on the function at the solution point plays a key role in establishing the superlinear convergence of the generalized Newton method for nonsmooth equations. We now verify this property

for H. Denote $y \to_d x$ if $y \to x$, $y \neq x$ and $(y-x)/||y-x|| \to d/||d||$ for some $d \in \mathcal{R}^n \setminus \{0\}$. A function $G : \mathcal{R}^n \to \mathcal{R}^n$ is said to be semismooth at $x \in \mathcal{R}^n$ if G is Lipschitz continuous in an open neighborhood of x and the following limit exists:

$$\lim_{V \in \partial G(y), y \to_d x} Vd.$$

Furthermore, the function G is said to be semismooth in a given domain if it is semismooth at each point of the domain. A semismooth function has many fine properties. We introduce some of them in the following lemma taken from [37, 38].

LEMMA 3.4. *If G is semismooth at x, then it is directionally differentiable at x; i.e., $G'(x,d)$ exists for any $d \in \mathcal{R}^n$ and*

$$\lim_{\|d\| \to 0} \frac{G(x+d) - G(x) - G'(x,d)}{\| d \|} = 0, \tag{9}$$

$$\lim_{V \in \partial G(x+d), \|d\| \to 0} \frac{Vd - G'(x,d)}{\| d \|} = 0. \tag{10}$$

Qi and Sun [38] also introduced 1-order semismoothness. A function G is called 1-order semismooth at x if G is semismooth at x and for any $d \in \mathcal{R}^n$:

$$G(x+d) - G(x) - G'(x,d) = O(\| d \|^2). \tag{11}$$

We are now ready to establish the semismooth property for H.

PROPOSITION 3.5. *Suppose that $F : \mathcal{R}^n \to \mathcal{R}^n$ is twice continuously differentiable. Then H defined by* (4) *is* 1*-order semismooth on $\mathcal{R}^n$.*

Proof. Clearly, we only need to prove that H is 1-order semismooth at points on which H is not differentiable, i.e., $x \notin \Omega$. Note that H is 1-order semismooth at a point x if and only if H_i is 1-order semismooth at x for all i. Without loss of generality, we prove only H_1 is 1-order semismooth at the point x such that $x_1 = 0$ and $F_1(x) = 0$. A quick calculation yields for any $d \in \mathcal{R}^n$

$$H_1'(x,d) = \sqrt{d_1^2 + (\bigtriangledown F_1(x)^T d)^2} - d_1 - \bigtriangledown F_1(x)^T d.$$

Similarly, if $d_1^2 + (\bigtriangledown F_1(x)^T d)^2 > 0$, then

$$\begin{aligned}
&H_1(x+d) - H_1(x) - H_1'(x,d) \\
&= \sqrt{d_1^2 + (\bigtriangledown F_1(x)^T d + O(||d||^2))^2} - \sqrt{d_1^2 + (\bigtriangledown F_1(x)^T d)^2} + O(||d||^2) \\
&= \frac{O(||d||^2)(2 \bigtriangledown F_1(x)^T d + O(||d||^2))}{\sqrt{d_1^2 + (\bigtriangledown F_1(x)^T d)^2 + O(||d||^2)} + \sqrt{d_1^2 + (\bigtriangledown F_1(x)^T d)^2}} + O(||d||^2) \\
&= O(||d||^2),
\end{aligned}$$

which shows the 1-order semismoothness of H_1 at x. If $d_1^2 + (\bigtriangledown F_1(x)^T d)^2 = 0$, then $d_1 = 0 = \bigtriangledown F_1(x)^T d$. Hence the above estimate still holds:

$$H_1(x+d) - H_1(x) - H_1'(x,d) = O(||d||^2).$$

The desired result follows. ∎

THEOREM 3.6. *Let $F : \mathcal{R}^n \to \mathcal{R}^n$ be twice continuously differentiable. Suppose that F is a uniform P-function on $\mathcal{R}^n$. Suppose that x^* is a solution of* (1). *Then the sequence $\{x^k\}$ generated by Algorithm* A *is Q-quadratically convergent to x^* if x^0 is sufficiently to x^*.*

Proof. The result follows from the application of Theorem 3.2 of [38]. □

Remark. The above convergence result still holds if we only assume that any $V \in \partial H(x^*)$ is nonsingular where x^* is the solution point. The latter is guaranteed by a condition presented in the remark after Proposition 3.3.

4. A globally convergent algorithm. It is well known that the Newton method for solving a system of smooth equations does not necessarily converge if the initial point is chosen arbitrarily. Traditionally, the Gauss–Newton method is a remedy to achieve both global and local superlinear convergence; namely, a globalization convergence strategy is applied to the merit function defined by the 2-norm operator. Unfortunately, this method cannot be applied directly to the nonsmooth case, although some special Gauss–Newton methods do work; see [33, 14]. These methods solve either a mixed linear complementarity problem or a quadratic programming problem at each inner iteration. Therefore, it is highly desirable to solve some simpler problems rather than mixed linear complementarity problems or quadratic programming problems in some cases. This is our goal in this section.

Define a merit function $\theta : \mathcal{R}^n \to \mathcal{R}$ by

$$\theta(x) = \frac{1}{2}\sum_{i=1}^{n} \phi(x_i, F_i(x))^2 = \frac{1}{2}||H(x)||^2.$$

Geiger and Kanzow [12] used this function to reformulate nonlinear complementarity problems. They showed that solving (1) is equivalent to finding stationary points of the unconstrained optimization problem

$$\min_{x\in\mathcal{R}^n} \theta(x), \tag{12}$$

whenever the continuously differentiable function F is monotone and (1) is solvable.

Note that θ is continuously differentiable on the whole space $\mathcal{R}^n$. This suggests that it is possible to invoke any global convergence algorithm for solving (12). Clearly, the Newton method combined with a line search or a trust region strategy is one option. However, the singularity of the second-order derivative of θ at the solution point makes it doubtful to obtain superlinear convergence. Moreover, much computational work is needed to get the second-order derivative of θ. For this reason, using the Newton method combined with a line search or a trust region strategy is not recommended for solving (12). It is known that the steepest descent method can guarantee the global convergence of (12). But one of the disadvantages of this method is that it usually performs poorly, particularly when the solution point is close.

Based on the above discussion, we propose a hybrid method which combines the steepest descent method for solving (12) and the generalized Newton method for solving (4). The idea is simple. We first check if the Newton step gives a sufficient decrease to θ. If it does, another point is obtained. Otherwise, the steepest descent method is applied to the minimization (12). It also provides a new iteration point. Moreover, when the iterated point is close enough to the solution point of (1), the algorithm never requires any steepest descent step. Then the superlinear convergence result follows directly, provided that the generalized Newton method possesses this property locally.

Define a function $\Phi : \mathcal{R}^2 \to \mathcal{R}$,

$$\Phi(a,b) = \frac{1}{2}(\phi(a,b))^2.$$

Geiger and Kanzow [12] have established the following lemma.

LEMMA 4.1.

(1) Φ *is continuously differentiable for all* $a, b \in \mathcal{R}$, *in particular* $\bigtriangledown\Phi(0,0) = (0,0)^T$.

(2) $\bigtriangledown_a\Phi(a,b) \bigtriangledown_b \Phi(a,b) \geq 0$ *for* $a, b \in \mathcal{R}$.

(3) $\bigtriangledown_a\Phi(a,b) \bigtriangledown_b \Phi(a,b) = 0$ *implies* $\Phi(a,b) = 0$.

Remark. The inverse of (3) in Lemma 4.1 is also true by a simple argument.

We are now ready to present the hybrid algorithm.

ALGORITHM B.

Step 1. Choose initial point $x^0 \in \mathcal{R}^n$, parameters $\sigma \in (0, 1/2), \rho \in (0,1)$, and $\beta \in (0,1)$. Let $k = 0$.

Step 2. Choose $V^k \in \partial H(x^k)$ and solve the following Newton equations for the direction $d^k \in \mathcal{R}^n$:

$$H(x^k) + V^k d^k = 0. \tag{13}$$

Step 3. If (13) is solvable and $\theta(x^k + d^k) \leq \beta\theta(x^k)$, go to Step 5. Otherwise, go to Step 4.

Step 4. Let $\bar{d^k} = - \bigtriangledown \theta(x^k)$. Find a minimum nonnegative integer, say m, such that

$$\theta(x^k + \rho^m \bar{d^k}) \leq \theta(x^k) + \sigma\rho^m \bigtriangledown \theta(x^k)^T \bar{d^k}. \tag{14}$$

Let $d^k = \rho^m \bar{d^k}$, and go to Step 5.

Step 5. Set $x^{k+1} = x^k + d^k$. If x^{k+1} solves $H(x) = 0$, stop. Otherwise, let $k := k + 1$ and go to Step 2.

To prove the existence of a cluster point of the sequence $\{x^k\}$ generated by Algorithm B, we need the following result. It is a generalization of Theorem 3.2 of Geiger and Kanzow [12]. The technique of the proof is also due to [12].

PROPOSITION 4.2. *Suppose that* $F : \mathcal{R}^n \to \mathcal{R}^n$ *is a continuous and uniform P-function. Let* $L(x^0) = \{x \in \mathcal{R}^n | \theta(x) \leq \theta(x^0)\}$, *where* $x^0 \in \mathcal{R}^n$. *Then* $L(x^0)$ *is compact.*

Proof. Clearly, $L(x^0)$ is closed. Suppose that $L(x^0)$ is not compact for a given $x^0 \in \mathcal{R}^n$; namely, there exists a sequence of $\{x^k\} \subseteq L(x^0)$ such that $\lim_{k\to\infty} ||x^k|| = \infty$. Let

$$I = \{1 \leq i \leq n \mid \{x_i^k\} \text{ is unbounded}\}.$$

Clearly, $I \neq \emptyset$ due to our assumption. Define a new sequence $\{y^k\}$ associated with $\{x^k\}$ by

$$y_i^k = \begin{cases} 0 & \text{if } i \in I, \\ x_i^k & \text{otherwise.} \end{cases}$$

Since F is a uniform P-function, there exists $\alpha > 0$ such that

$$\begin{aligned}
\alpha \textstyle\sum_{i\in I}(x_i^k)^2 &= \alpha||x^k - y^k||^2 \\
&\leq \max_{1\leq i\leq n}(x_i^k - y_i^k)(F_i(x^k) - F_i(y^k)) \\
&= \max\{0, \max_{i\in I} x_i^k(F_i(x^k) - F_i(y^k))\} \\
&\leq \sqrt{\textstyle\sum_{i\in I}(x_i^k)^2}\, \max_{i\in I}|F_i(x^k) - F_i(y^k)| \\
&\leq \sqrt{\textstyle\sum_{i\in I}(x_i^k)^2}\, \textstyle\sum_{i\in I}|F_i(x^k) - F_i(y^k)|.
\end{aligned}$$

Consequently, by the definition of I there exists a subset K such that for $k \in K$

$$\alpha\sqrt{\sum_{i\in I}(x_i^k)^2} \leq \sum_{i\in I}|F_i(x^k) - F_i(y^k)|.$$

From the continuity of F, the boundedness of $\{y^k\}$, the definition of I, and the fact that I contains only a finite number of elements, the above inequality implies that there exists $i_0 \in I$ such that $\{|F_{i_0}(x^k)|, k \in K\}$ is unbounded. Since $i_0 \in I$, it follows from the definition of I that $\{x_{i_0}^k\}$ is also unbounded. By Lemma 3.1 of [12], $\{\phi(x_{i_0}^k, F_{i_0}(x^k)), k \in K\}$ is unbounded. Thus, $\{\theta(x^k)\}$ is unbounded, which is a contradiction. □

It is well known that some local minimum points of an unconstrained optimization problem are not global minimum points in general. This shows that some cluster points generated by the above algorithm are not solutions of (12) in general. Fortunately, under some assumptions, the local minimum points of (12) coincide with its global minimum points. We present this in the following proposition.

PROPOSITION 4.3. *Suppose that $F : \mathcal{R}^n \to \mathcal{R}^n$ is continuously differentiable, that F is a uniform P-function. Then x^* is a global minimum point of* (12) *if and only if x^* is a stationary point of* (12)*, i.e., $\bigtriangledown\theta(x^*) = 0$; moreover, such a point x^* must be a solution of* (1)*.*

Proof. The "only if" part is obvious. Now we suppose x^* is a stationary point of (12), namely, $\bigtriangledown\theta(x^*) = 0$. Some simple calculations show that

$$\bigtriangledown\theta(x) = \begin{pmatrix} \bigtriangledown_a\Phi(x_1, F_1(x)) \\ \vdots \\ \bigtriangledown_a\Phi(x_n, F_n(x)) \end{pmatrix} + \bigtriangledown F(x)^T \begin{pmatrix} \bigtriangledown_b\Phi(x_1, F_1(x)) \\ \vdots \\ \bigtriangledown_b\Phi(x_n, F_n(x)) \end{pmatrix}.$$

Denote $\Phi_a = (\bigtriangledown_a\Phi(x_1^*, F_1(x^*)), \ldots, \bigtriangledown_a\Phi(x_n^*, F_n(x^*)))^T$, and $\Phi_b = (\bigtriangledown_b\Phi(x_1^*, F_1(x^*)), \ldots, \bigtriangledown_b\Phi(x_n^*, F_n(x^*)))^T$. Hence,

$$0 = \bigtriangledown\theta(x^*) = \begin{pmatrix} \bigtriangledown_a\Phi(x_1^*, F_1(x^*)) + (\bigtriangledown F(x^*)^T\Phi_b)_1 \\ \vdots \\ \bigtriangledown_a\Phi(x_n^*, F_n(x^*)) + (\bigtriangledown F(x^*)^T\Phi_b)_n \end{pmatrix},$$

where $(\nabla F(x^*)^T\Phi_b)_i$ denotes the ith element of the column vector $\nabla F(x^*)^T\Phi_b$. Multiplying the ith equation above by $\bigtriangledown_b\Phi(x_i^*, F_i(x^*))$, we have for $i = 1, 2, \ldots, n$,

$$\bigtriangledown_b\Phi(x_i^*, F_i(x^*))\, \bigtriangledown_a \Phi(x_i^*, F_i(x^*)) + \bigtriangledown_b\Phi(x_i^*, F_i(x^*))(\bigtriangledown F(x^*)^T\Phi_b)_i = 0.$$

This implies

$$\max_{1\le i\le n} \bigtriangledown_b\Phi(x_i^*, F_i(x^*))(\bigtriangledown F(x^*)^T\Phi_b)_i = -\min_{1\le i\le n} \bigtriangledown_b\Phi(x_i^*, F_i(x^*))\bigtriangledown_a\Phi(x_i^*, F_i(x^*)) \le 0,$$

where the inequality is due to (2) of Lemma 4.1. By the uniform P-function property of F, both $\nabla F(x^*)$ and $\nabla F(x^*)^T$ are P-matrices. It follows from the definition of P-matrix that $\Phi_b = 0$, which shows that x^* is a global solution of (12) by (3) of Lemma 4.1. This completes the proof. □

It is clear that if Algorithm B stops after a finite number of steps, then a solution to (1) is obtained. In what follows, we assume that Algorithm B generates a sequence $\{x^k\}$. We now establish global convergence for Algorithm B.

THEOREM 4.4. *Suppose that $F : \mathcal{R}^n \to \mathcal{R}^n$ is twice continuously differentiable, and $\{x^k\}$ is a sequence generated by Algorithm* B. *Then*

(1) *$\{x^k\}$ converges to the unique solution x^* of* (1) *if F is a uniform P-function on $\mathcal{R}^n$. Furthermore, $\{x^k\}$ converges quadratically to x^*.*

(2) *x^* is a solution of* (1) *if F is monotone on $\mathcal{R}^n$ and if x^* is an accumulation point of $\{x^k\}$. Moreover, $\{x^k\}$ converges quadratically to x^* if $\bigtriangledown F(x^*)$ is positive definite.*

Proof. (1) Suppose that there are an infinite number of Newton steps, say $k \in K$ in Algorithm B. Then $\lim_{k\to\infty, k\in K} ||H(x^k)|| = 0$. Since F is a uniform P-function on $\mathcal{R}^n$, Proposition 4.2 shows that $\{x^k, k \in K\}$ is bounded. Assume that x^{**} is an accumulation point of $\{x^k, k \in K\}$. Then x^{**} is a solution to (1). But x^{**} should be the unique solution x^* of (1) by the uniform P-function property of F.

Suppose that there are only a finite number of Newton steps taken in Algorithm B. Then Algorithm B eventually reduces to the steepest descent algorithm for solving the unconstrained optimization problem (12). Proposition 4.2 shows that $\{x^k\}$ is bounded. Assuming that x^{**} is an accumulation point of $\{x^k\}$, we have that x^{**} is a stationary point of (12) by the optimization literature of [10]. By Proposition 4.3, x^{**} is a solution of (1). Clearly, it follows that $x^* = x^{**}$ by the uniform P-function property of F.

Thus we have proved that x^k converges to x^*. Next we show that Step 3 of Algorithm B is always successful eventually. Suppose x^k is sufficiently close to the solution point x^*. Then the generalized Newton method gives

$$||H(x^k)|| = ||V^k d^k||, \tag{15}$$

$$||x^k + d^k - x^*|| = o(||x^k - x^*||) = o(||d^k||). \tag{16}$$

By the semismoothness of H, (15), and (16), we have

$$\begin{aligned} ||H(x^k + d^k)|| &= ||H(x^*) + \bar{V}(x^k + d^k - x^*) + o(||x^k + d^k - x^*||)|| \\ &= ||\bar{V}(x^k + d^k - x^*) + o(||x^k + d^k - x^*||)||, \end{aligned}$$

where $\bar{V} \in \partial H(x^k + d^k)$. By Proposition 3.2, any generalized Jacobian of H at x^* is nonsingular. Moreover, there exists a constant $c > 0$ such that for any $V \in \partial H(x)$, $d \in \mathcal{R}^n$, and x sufficiently close to x^* we have

$$||Vd||/||d|| \ge c.$$

Consequently,

$$\frac{||H(x^k + d^k)||}{||H(x^k)||} = \frac{||\bar{V}(x^k + d^k - x^*) + o(||x^k + d^k - x^*||)||}{||V^k d^k||} = o(1).$$

TABLE 1
Number of iterations for Example 1.

n	8	16	32	64	128	256
Algorithm A	4	4	4	4	4	4
Algorithm B	4	4	4	4	4	4
Steepest descent method	37	31	30	32	32	31

The above argument means that Algorithm B always implements the Newton step after a finite number of iterations. The remaining results follow from Theorem 3.6.

(2) The proof is analogous to that of (1). We omit the detail. □

Remarks. (1) Algorithm B does not use the second-order derivative of the merit function but still achieves the second-order convergence results. (2) From a numerical point of view, the steepest descent method is not a good option. One may propose other algorithms for solving the NCP by combining the generalized Newton method and other global methods of unconstrained optimization.

5. Numerical results. In this section, we present some numerical experiments for three algorithms, i.e., the generalized Newton method (Algorithm A), the hybrid algorithm (Algorithm B), and the steepest descent method to $\theta(x)$. For Algorithm A we used $\theta(x) < \epsilon$ as the stopping criteria. Algorithm B stops if either $\theta(x) < \epsilon$ or $|| \bigtriangledown \theta(x)|| < \epsilon_1$. When F is not a uniform P-function, the stationary point of θ may not be a solution of the NCP. In this case, Algorithm B may converge to a stationary point of θ but which is not a solution of the NCP. Thus, the second stopping rule $|| \bigtriangledown \theta(x)|| < \epsilon_1$ can be necessary for some cases.

Throughout the computational experiments, the parameters used in the algorithms were set as $\epsilon = 10^{-6}$, $\epsilon_1 = 10^{-5}$, $\sigma = 10^{-4}$, $\rho = 0.5$, $\beta = 0.95$. All computational results were undertaken on a DEC 5000 workstation by MATLAB.

Example 1. This example was used by Geiger and Kanzow [12]. Let $F(x) = Mx + q$, where

$$M = \begin{pmatrix} 4 & -1 & 0 & \cdots & 0 \\ -1 & 4 & -1 & \cdots & 0 \\ 0 & -1 & 4 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & -1 \\ 0 & 0 & 0 & \cdots & 4 \end{pmatrix}, \quad q = (-1, \ldots, -1)^T.$$

Since F is strongly monotone on $\mathcal{R}^n$, the corresponding NCP has a unique solution. Table 1 lists the results for this example with initial point $x = (0, \ldots, 0)$ for different dimensions n.

Example 2. This example is also taken from Geiger and Kanzow [12]. Define $F(x) = Mx + q$, where

$$M = \text{diag}(1/n, 2/n, \ldots, 1), \qquad q = (-1, \ldots, -1)^T.$$

Again F is strongly monotone on $\mathcal{R}^n$. The corresponding strong monotonicity modulus depends on the dimension n and approaches zero when n tends to infinity. Table 2 gives the results for this example with starting point $x = (0, \ldots, 0)$ for different dimensions n.

From Tables 1 and 2, one observes that both the generalized Newton and the hybrid methods work quite well for Examples 1 and 2, respectively. However, the

(-10^5, -10^5, -10^5, -10^5)	11*	7*
(1234, 2345, 3456, 4567)	17*	53*

steepest descent method demonstrates very poor performance, especially for Example 2, in which the problem becomes ill conditioned as n increases. For this reason, we choose not to test the steepest descent method for the remaining examples.

Example 3. This example was used by Pang and Gabriel [35], Mangasarian and Solodov [26], and Kanzow [19] with four variables. Let

$$\begin{aligned} F_1(x) &= 3x_1^2 + 2x_1x_2 + 2x_2^2 + x_3 + 3x_4 - 6, \\ F_2(x) &= 2x_1^2 + x_1 + x_2^2 + 10x_3 + 2x_4 - 2, \\ F_3(x) &= 3x_1^2 + x_1x_2 + 2x_2^2 + 2x_3 + 9x_4 - 9, \\ F_4(x) &= x_1^2 + 3x_2^2 + 2x_3 + 3x_4 - 3. \end{aligned}$$

This example has one degenerate solution $(\frac{\sqrt{6}}{2}, 0, 0, \frac{1}{2})$ and one nondegenerate solution $(1, 0, 3, 0)$. This result is summarized in Table 3 using different starting points. The asterisk (*) denotes that the limit point generated by the algorithms is the degenerate solution, otherwise it is the nondegenerate solution.

Example 4. This example was tested by Kanzow [19] with five variables defined by

$$F_i(x) = 2\exp\left(\sum_{i=1}^{5}(x_i - i + 2)^2\right)(x_i - i + 2), \qquad 1 \le i \le 5.$$

This example has one degenerate solution, namely, $(0, 0, 1, 2, 3)$. The results are listed in Table 4 using different starting points. The asterisk denotes that the algorithm does not converge due to the inability of the computer to deal with very large number overflow.

Example 5. This example is a modification of Mathiesen [28] tested in [19]. Let

$$\begin{aligned} F_1(x) &= -x_2 + x_3 + x_4, \\ F_2(x) &= x_1 - (4.5x_3 + 2.7x_4)/(x_2 + 1), \\ F_3(x) &= 5 - x_1 - (0.5x_3 + 0.3x_4)/(x_3 + 1), \\ F_4(x) &= 3 - x_1. \end{aligned}$$

TABLE 4
Number of iterations for Example 4.

Starting point	Algorithm A	Algorithm B
(0, 0, 0, 0, 0)	20	20
(1, 1, 1, 1, 1)	18	*
(−1, −1, −1, −1, −1)	37	37
(2, 2, 2, 2, 2)	85	*
(−2, −2, −2, −2, −2)	61	61

(3, 2, 1, 2, 3)	1	1
(1, 0, 1, 3, 5)	20	6

TABLE 5
Number of iterations for Example 5.

Starting point	Algorithm A	Algorithm B
(1, 1, 1, 1)	3	3
(2, 2, 2, 2)	4	6
(−2 , −2, −2, −2)	4	4
(10, 10, 10, 10)	5	5
(− 10, −10, −10, −10)	6	*
(1234, 2345, 3456, 4567)	6	6

This example has infinitely many solutions $(\lambda, 0, 0, 0)$, where $\lambda \in [0, 3]$. For $\lambda = 1, 3$, the solutions are degenerate, and for $\lambda \in (0, 3)$ nondegenerate. The test results for Example 5 are listed in Table 5 using different starting points. For all starting points, the limit points generated by both the generalized Newton method and the hybrid method are the degenerate solutions if the algorithms converge. The asterisk denotes the algorithm fails due to discontinuity of F when $x_2 = -1$ or $x_3 = -1$.

Example 6. This example is problem 35 of Hock and Schittkowski [15] and was tested by Geiger and Kanzow [12]. The problem is defined by

$$\begin{aligned} \min \quad & f(x) = 9 - 8x_1 - 6x_2 - 4x_3 + 2x_1^2 + 2x_2^2 + x_3^2 + 2x_1x_2 + 2x_1x_3 \\ \text{s.t.} \quad & 3 - x_1 - x_2 - x_3 \geq 0, \\ & 0 \leq x_i, \quad i = 1, 2, 3. \end{aligned}$$

The original problem is a convex programming problem. Its KKT optimality conditions lead to a monotone complementarity problem with four variables. This example has one optimal solution $x = (4/3, 7/9, 4/9)$. The test results for Example 6 are listed in Table 6 using different initial starting points.

We next test some economic equilibrium problems with larger sizes, but with only standard starting points.

Example 7. This is a problem arising in a spatial equilibrium model with dimension 42; see [4, 5, 35] for more details. The numerical results for Example 7 are listed in Table 7 using the starting point $(0, \ldots, 0)$.

Example 8. This is a 50-variable traffic equilibrium problem with elastic demand; see [4, 5, 35] for more details. The numerical results for Example 8 are listed in Table 7 using the standard starting point defined below. $x_1, x_2, x_3, x_{10}, x_{11}, x_{20}, x_{21}, x_{22}, x_{29}, x_{30}, x_{40}, x_{45}$ are all ones; $x_{39}, x_{42}, x_{43}, x_{46}$ are equal to 7; $x_{41}, x_{47}, x_{48}, x_{50}$ are equal to 6; x_{44} and x_{49} are equal to 10; and all other elements are zeros.

6. Conclusions. In this paper, we have presented an equivalent reformulation of the NCP as a system of nonsmooth equations. The generalized Newton method applied to the system of nonsmooth equations has been shown to be locally and Q-quadratically convergent. The hybrid method, which is a combination of the generalized Newton method and a minimization technique for solving the NCP, enjoys both global convergence and local Q-quadratic convergence under some conditions. From a numerical point of view, the steepest descent direction method used in the hybrid method is not a good option. However, the numerical results reported still show that the approaches presented in this paper are promising. Therefore, for global methods, numerical results should appear better than those in this paper if a better unconstrained minimization method is used combining with the generalized Newton method.

Very recently, De Luca, Facchinei, and Kanzow [5] proposed a global convergent algorithm for solving the NCP. They use the same local approach as our generalized Newton method. However, their global approach is quite different from ours. It appears that their global strategy is better than ours from the robustness point of view. In particular, it was pointed out [5] that the solution d^k of (8) is always a descent direction of the merit function θ if x^k is not a solution of the NCP. Regarding the nonsingularity of the generalized Jacobians of H, De Luca, Facchinei, and Kanzow [5] provided more general conditions which are weaker than uniform P-functions. As for the equivalence between the stationary point set of the merit function θ and the solution set of the NCP, the condition presented in Proposition 4.3 can be weakened substantially; see [5, 6, 7, 9] for more details. Tseng [42] proved that the R_0-function property, which is weaker than the uniform P-function property, of F is a sufficient condition for ensuring the compactness of the level set in Proposition 4.2. For some further refinements and more discussions, we refer the reader to [5, 9]. All those improvements show that the combination of nonsmooth equation and unconstrained optimization approaches for the solution of the NCP is very encouraging.

Acknowledgments. The authors are grateful to F. Facchinei, A. Fischer, C. Kanzow, and two anonymous referees for their helpful and detailed comments.

FAMILIES OF SOLUTIONS OF MATRIX RICCATI DIFFERENTIAL EQUATIONS*

M. PAVON† AND D. D'ALESSANDRO‡

Abstract. The J. C. Willems–Coppel–Shayman geometric characterization of solutions of the algebraic Riccati equation (ARE) is extended to *asymmetric* Riccati *differential* equations with *time-varying coefficients*. The coefficients do not need to satisfy any *definiteness*, *periodicity*, or *system-theoretic condition*. More precisely, given any two solutions $X_1(t)$ and $X_2(t)$ of such equation on a given interval $[t_0, t_1]$, we show how to construct a family of solutions of the same equation of the form $X(t) = (I - \pi(t))X_1(t) + \pi(t)X_2(t)$, where π is a suitable matrix-valued function. Even when specialized to the case of X_1 and X_2 equilibrium solutions of a symmetric equation with constant coefficients, our results considerably extend the classical ones, as no further assumption is made on the pair X_1, X_2 and on the coefficient matrices.

Key words. asymmetric Riccati differential equation, families of solutions, geometric characterization, invariant subspaces, projection-preserving differential equation

1. Families of solutions of the RDE.

Consider the asymmetric Riccati differential equation (RDE)

$$\dot{X} = AX + XB + XPX + Q, \tag{1.1}$$

where X is $m \times n$ and A, B, P, Q are continuous, matrix-valued functions with real entries on $[t_0, t_1]$ of dimension $m \times m, n \times n, n \times m$, and $m \times n$, respectively. As is well known, the symmetric version of (1.1), i.e., when $n = m$, $B = A^T$, $P = P^T$, $Q = Q^T$, plays a central role in many fields of applied mathematics, including optimal control and estimation, and has therefore been intensively studied. General Riccati equations such as (1.1) arise in the theory of differential games [3], in state-space solutions to H^∞ problems [10], in polynomial factorization [5], in problems of feedback control [1], and in the singular perturbation of boundary value problems [4]; see the introductions of [17, 3, 12] for further information. A further example is provided by equation (1.7) below, which is asymmetric even when (1.1) is symmetric.

All through this paper, X_1 and X_2 denote two fixed but arbitrary solutions of (1.1) on the time interval $[t_0, t_1]$. Moreover, let $\Delta_{12} := X_2 - X_1$. There exists a one-to-one correspondence between solutions of (1.1) and solutions of the homogeneous Riccati equation

$$\dot{\Delta} = A_{X_1}\Delta + \Delta B_{X_1} + \Delta P \Delta, \tag{1.2}$$

where $A_{X_1} := A + X_1 P$ and $B_{X_1} := B + PX_1$, given by $X \leftrightarrow \Delta = X - X_1$. Thus, all results below concerning solutions of (1.1) may also be viewed as results concerning

solutions of (1.2), where the roles of X_1 and X_2 are played by the zero solution and Δ_{12}, respectively.

Jan Willems' classification of solutions of the ARE [23] was used in [14] to classify all output-induced minimal stochastic realizations of a given process. In [2, Theorem 8.3], this classification was extended to the nonstationary case. Its implications for the RDE, however, were not pursued there. Jan Willems' original derivation of the geometric parametrization of solutions of the ARE relied on first establishing a similarity relation involving two "extreme" closed-loop matrices [23, Lemma 8]. The latter result was generalized to the symmetric, nonsingular (i.e., Δ_{12} invertible), time-varying situation in [18, Theorem 5.5]. It can indeed be extended to our very general setting, and its consequences are far reaching.

LEMMA 1.1. *Let X be any solution of* (1.1) *on* $[t_0, t_1]$ *and let* $\Delta_i := X - X_i$, $i = 1, 2$. *Let* $\phi(\cdot,\cdot)$ *and* $\psi(\cdot,\cdot)$ *be the transition matrices corresponding to* $A_X := A + XP$ *and* $-B_X := -(B + PX)$, *respectively. Let* $\phi_i(\cdot,\cdot)$ *and* $\psi_i(\cdot,\cdot)$, $i = 1, 2$, *be the transition matrices corresponding to* $A_{X_i} := A + X_iP$ *and* $-B_{X_i} := -(B + PX_i)$, *respectively. Then, for* $i = 1, 2$ *and for all* s *and* t *in* $[t_0, t_1]$, *we have*

$$\Delta_i(t)\psi_i(t,s) = \phi(t,s)\Delta_i(s), \tag{1.3}$$

$$\Delta_i(t)\psi(t,s) = \phi_i(t,s)\Delta_i(s). \tag{1.4}$$

Proof. Notice that Δ_i satisfies

$$\begin{aligned}\dot{\Delta}_i &= A_{X_i}\Delta_i + \Delta_i B_{X_i} + \Delta_i P\Delta_i \\ &= A_X\Delta_i + \Delta_i B_{X_i} = A_{X_i}\Delta_i + \Delta_i B_X.\end{aligned} \tag{1.5}$$

From (1.5) it follows that

$$\begin{aligned}\frac{\partial(\Delta_i(t)\psi_i(t,s))}{\partial t} &= \dot{\Delta}_i(t)\psi_i(t,s) + \Delta_i(t)\frac{\partial\psi_i(t,s)}{\partial t} \\ = \dot{\Delta}_i(t)\psi_i(t,s) - \Delta_i(t)B_{X_i}\psi_i(t,s) &= A_X(t)\Delta_i(t)\psi_i(t,s).\end{aligned}$$

Hence, both sides of (1.3) satisfy

$$\frac{\partial W(t,s)}{\partial t} = A_X(t)W(t,s).$$

Since they coincide for $s = t$, they coincide everywhere. Exchanging the roles of X and X_i, we get (1.4) from (1.3). □

COROLLARY 1.2. $\Delta_i(t), i = 1, 2$, *has constant rank on* $[t_0, t_1]$.

Proof. By (1.3), $\Delta_i(t) = \phi(t, t_0)\Delta_i(t_0)\psi_i(t_0, t)$. □

COROLLARY 1.3. *Let X be any solution of* (1.1) *on* $[t_0, t_1]$, *and let* $i = 1, 2$. *Suppose that* $\ker\Delta_{12}(t_0) \subseteq \ker\Delta_i(t_0)$. *Then* $\ker\Delta_{12}(t) \subseteq \ker\Delta_i(t)$ *for all* $t \in [t_0, t_1]$.

Proof. Let $x \in R^n$ be such that $\Delta_{12}(t)x = 0$. By (1.3), we get $\Delta_{12}(t_0)\psi_i(t_0, t)x = 0$. Thus, $\psi_i(t_0, t)x$ is in the kernel of $\Delta_{12}(t_0)$. By hypothesis, $\Delta_i(t_0)\psi_i(t_0, t)x = 0$. The latter implies $\phi(t, t_0)\Delta_i(t_0)\psi_i(t_0, t)x = 0$. Using equation (1.3) again, we get $\Delta_i(t)x = 0$. □

Obviously, the above result holds true if t_0 is replaced by any other time s in $[t_0, t_1]$. Let us agree that all through the paper $\pi(t)$ denotes an $m \times m$ matrix function on $[t_0, t_1]$.

THEOREM 1.4. *The matrix function* $X(t) = (I - \pi(t))X_1(t) + \pi(t)X_2(t)$ *is a solution of* (1.1) *on* $[t_0, t_1]$ *if and only if* $\pi(t)$ *is a* C^1 *function satisfying*

$$\dot{\pi}\Delta_{12} = [A_{X_1}\pi - \pi A_{X_1} - \pi\Delta_{12}P(I - \pi)]\Delta_{12}. \tag{1.6}$$

Conversely, let $X(t)$ *be a solution of* (1.1) *on* $[t_0, t_1]$ *with* $\ker \Delta_{12}(t_0) \subseteq \ker \Delta_1(t_0)$ *where* $\Delta_1 = X - X_1$. *Then there exists a* C^1 *function* $\pi(t)$ *satisfying* (1.6) *such that* $X(t) = (I - \pi(t))X_1(t) + \pi(t)X_2(t)$. *Moreover, if* $\mathrm{Rank}\Delta_{12}(t_0) = m$, (1.6) *may be replaced by the* auxiliary Riccati differential equation (ARDE)

$$\dot{\pi} = A_{X_1}\pi - \pi A_{X_1} - \pi\Delta_{12}P(I - \pi), \tag{1.7}$$

and there is a one-to-one correspondence between solutions of (1.1) *and solutions of* (1.7).

Proof. Let $\mathcal{R}(X) := AX + XB + XPX + Q$. If $X(t) = (I - \pi(t))X_1(t) + \pi(t)X_2(t)$, we get

$$\begin{aligned}
\mathcal{R}(X) &= A[(I-\pi)X_1 + \pi X_2] + [(I-\pi)X_1 + \pi X_2]B \\
&\quad + [(I-\pi)X_1 + \pi X_2]P[(I-\pi)X_1 + \pi X_2] + Q \\
&= (I-\pi)\mathcal{R}(X_1) + \pi\mathcal{R}(X_2) - (I-\pi)AX_1 - (I-\pi)X_1PX_1 - \pi AX_2 \\
&\quad - \pi X_2PX_2 + A(I-\pi)X_1 + A\pi X_2 + [(I-\pi)X_1 + \pi X_2]P[(I-\pi)X_1 + \pi X_2] \\
&= (I-\pi)\mathcal{R}(X_1) + \pi\mathcal{R}(X_2) - \pi A\Delta_{12} + A\pi\Delta_{12} \\
&\quad - (I-\pi)X_1P\pi X_1 - \pi X_2P(I-\pi)X_2 + \pi X_2P(I-\pi)X_1 + (I-\pi)X_1P\pi X_2 \\
&= (I-\pi)\mathcal{R}(X_1) + \pi\mathcal{R}(X_2) + [-\pi A + A\pi + (I-\pi)X_1P\pi - \pi X_2P(I-\pi)]\Delta_{12} \\
&= (I-\pi)\mathcal{R}(X_1) + \pi\mathcal{R}(X_2) \\
&\quad + [-\pi A + A\pi + (I-\pi)X_1P\pi - \pi\Delta_{12}P(I-\pi) - \pi X_1P(I-\pi)]\Delta_{12} \\
&= (I-\pi)\mathcal{R}(X_1) + \pi\mathcal{R}(X_2) + [A_{X_1}\pi - \pi A_{X_1} - \pi\Delta_{12}P(I-\pi)]\Delta_{12}.
\end{aligned}$$

If π is of class C^1, it then follows that X is a solution of (1.1) if and only if (1.6) holds. Conversely, suppose that X is a solution of (1.1) on $[t_0, t_1]$ such that $\ker \Delta_{12}(t_0) \subseteq \ker \Delta_1(t_0)$. By Corollary 1.3, the inclusion $\ker \Delta_{12}(t) \subseteq \ker \Delta_i(t)$ holds for all $t \in [t_0, t_1]$. Then there exist $m \times m$-valued matrix functions $Z(t)$ such that

$$\Delta_1(t) = Z(t)\Delta_{12}(t) \tag{1.8}$$

for all $t \in [t_0, t_1]$. Notice that (1.8) already implies that $X(t) = (I - Z(t))X_1(t) + Z(t)X_2(t)$. Thus, the proof of the converse will be complete if we can show that among the functions Z satisfying (1.8) there is at least one $\tilde{Z}$ of class C^1. In that case, we can take $\pi = \tilde{Z}$. To this end, notice that, in view of Lemma 1.1, any function Z satisfying (1.8) also satisfies

$$\Delta_1(t)\psi_2(t, t_0) = Z(t)\phi_1(t, t_0)\Delta_{12}(t_0). \tag{1.9}$$

This leads us to introduce the function $\tilde{Z}$ defined by

$$\tilde{Z}(t) = \Delta_1(t)\psi_2(t, t_0)\Delta_{12}^{\#}(t_0)\phi_1(t_0, t),$$

where $\Delta_{12}^{\#}(t_0)$ denotes the Moore–Penrose pseudoinverse of $\Delta_{12}(t_0)$. The function $\tilde{Z}$ is clearly continuously differentiable. We show next that indeed $\tilde{Z}$ satisfies $\Delta_1(t) = \tilde{Z}(t)\Delta_{12}(t)$. Observe that the latter is equivalent to

$$\Delta_1(t)[I - \psi_2(t, t_0)\Delta_{12}^{\#}(t_0)\phi_1(t_0, t)\Delta_{12}(t)] = 0. \tag{1.10}$$

Now let Z be any function satisfying (1.8). Using (1.9) in (1.10), we see that the latter is equivalent to

$$Z(t)\phi_1(t, t_0)\Delta_{12}(t_0)\psi_2(t_0, t)[I - \psi_2(t, t_0)\Delta_{12}^{\#}(t_0)\phi_1(t_0, t)\Delta_{12}(t)] = 0.$$

Obtaining $\Delta_{12}(t)$ from Lemma 1.1 and using properties of transition matrices, it can be verified that the latter equation is in turn equivalent to

$$Z(t)\phi_1(t,t_0)\Delta_{12}(t_0)[I-\Delta_{12}^{\#}(t_0)\Delta_{12}(t_0)]\psi_2(t_0,t)=0. \tag{1.11}$$

Because of $\Delta(I-\Delta^{\#}\Delta)=0$, the preceding identity (1.11) is valid. Finally, suppose that $\mathrm{Rank}\Delta_{12}(t_0)=m$. By Corollary 1.2 the same is true for $\Delta_{12}(t)$, $t\in[t_0,t_1]$. The one-to-one map between the solution sets of (1.1) and (1.7) is then given by $\pi(t):=[X(t)-X_1(t)]\Delta_{12}^{-R}(t)$, where Δ_{12}^{-R} denotes any right inverse of Δ_{12}. □

Remark 1.5. Obviously, in Theorem 1.4 (and in the following), we could have considered combinations of the form $X(t)=X_1(t)(I-\sigma(t))+X_2(t)\sigma(t)$. The assumption for the converse part would then read $\ker\Delta_{12}(t_0)^T\subseteq\ker\Delta_1(t_0)^T$. Equation (1.6) would be replaced by the equation

$$\Delta_{12}\dot{\sigma}=\Delta_{12}[\sigma B_{X_1}-B_{X_1}\sigma-(I-\sigma)P\Delta_{12}\sigma].$$

Remark 1.6. Notice that if π_1 and π_2 are two C^1 functions generating the same solution X of (1.1) on $[t_0,t_1]$, i.e., $X(t)=X_1(t)+\pi_1(t)\Delta_{12}(t)=X_1(t)+\pi_2(t)\Delta_{12}(t)$, then necessarily $[\pi_1(t)-\pi_2(t)]\Delta_{12}(t)=0$ for all t in $[t_0,t_1]$. If $\Delta_{12}(t_0)$ admits a right inverse, then $\pi_1=\pi_2$.

At first sight, the correspondence between solutions of (1.1) and solutions of (1.6) or (1.7) established by Theorem 1.4 appears rather disappointing. Indeed, in the best case, we still have to deal with an asymmetric Riccati equation, the ARDE, with the only apparent advantage that π, A_{X_1}, and $\Delta_{12}P$ are all square $m\times m$-dimensional. Notice that solutions X_1 and X_2 of (1.1) correspond to the equilibrium solutions zero and identity, respectively, of (1.6) and (1.7). Nevertheless, the power of this connection will shortly be apparent. Indeed, (1.6) and (1.7) lend themselves naturally to a geometric characterization of a subclass of their solutions; see Theorems 2.3 and 2.5 below.

We conclude this section with a result relating different ϕ transition matrices. This result, which will not be needed in what follows, appears to be of interest for nonstationary stochastic realization [2]. Indeed, it extends a result for feedback matrices corresponding to different solutions of the symmetric ARE that was applied to stationary stochastic realization in [11, Lemma 4.1].

PROPOSITION 1.7. *Let X be any solution of* (1.1) *on* $[t_0,t_1]$. *If* $X(t)-X_1(t)=\Delta_1(t)=\pi(t)\Delta_{12}(t)$ *on* $[t_0,t_1]$ *for some function* π, *we have, in the notation of Lemma* 1.1,

$$\{\phi(t,s)\pi(s)-\pi(t)\phi_2(t,s)\}\Delta_{12}(s)=0, \tag{1.12}$$

$$\{\phi(t,s)(I-\pi(s))-(I-\pi(t))\phi_1(t,s)\}\Delta_{12}(s)=0. \tag{1.13}$$

If π *is projection valued, it follows that*

$$(I-\pi(t))\phi(t,s)\pi(s)\Delta_{12}(s)=0, \tag{1.14}$$

$$\pi(t)\phi(t,s)(I-\pi(s))\Delta_{12}(s)=0. \tag{1.15}$$

If, moreover, π *is* C^1, *the latter gives*

$$(I-\pi)(\dot{\pi}-A_X\pi)\Delta_{12}=0, \tag{1.16}$$

$$\pi(\dot{\pi}+A_X(I-\pi))\Delta_{12}=0. \tag{1.17}$$

Proof. Employing (1.3) twice, once for X and once for X_2, we get

$$\phi(t,s)\pi(s)\Delta_{12}(s) = \phi(t,s)\Delta_1(s) = \Delta_1(t)\psi_1(t,s)$$
$$= \pi(t)\Delta_{12}(t)\psi_1(t,s) = \pi(t)\phi_2(t,s)\Delta_{12}(s),$$

which is (1.12). Similarly, (1.13) is established. If π is a C^1, projection-valued function, differentiating (1.14) and the equation $\pi(t) = \pi(t)^2$ with respect to t, we get $[(I-\pi(t))A_X - \dot{\pi}(t)]\phi(t,s)\pi(s)\Delta_{12}(s) = 0$ and $\dot{\pi}(t)\pi(t) = (I-\pi(t))\dot{\pi}(t)$, respectively. Evaluating the first at $s = t$ and then using the second, we get (1.16). Similarly, we get (1.17) from (1.15). □

2. Geometric results. The first step in establishing a geometric characterization of certain families of solutions of (1.1) consists of rewriting (1.6) and (1.7). Simply rearranging terms, we get that these equations are equivalent to

$$[\dot{\pi} - (I-\pi)A_{X_1}\pi + \pi A_{X_2}(I-\pi)]\Delta_{12} = 0, \tag{2.1}$$
$$\dot{\pi} - (I-\pi)A_{X_1}\pi + \pi A_{X_2}(I-\pi) = 0, \tag{2.2}$$

where $A_{X_2} := A + X_2P = A_{X_1} + \Delta_{12}P$.

LEMMA 2.1. *If π is a projection for all times, i.e., $\pi(t) = \pi(t)^2$ for t in $[t_0,t_1]$, then it satisfies* (2.1) *if and only if it satisfies the system of equations*

$$(I-\pi)[\dot{\pi} - A_{X_1}\pi]\Delta_{12} = 0, \tag{2.3}$$
$$\pi[(I-\dot{\pi}) - A_{X_2}(I-\pi)]\Delta_{12} = 0. \tag{2.4}$$

Proof. Multiplying (2.1) on the left first by $(I-\pi)$ and then by π, we get (2.3) and (2.4), respectively. Conversely, obtaining $\pi\dot{\pi}\Delta_{12}$ from (2.4) and plugging it into (2.3), we get (2.1). □

Remark 2.2. Equations (2.3), (2.4) can be obtained from (1.16), (1.17), observing that

$$(I-\pi)A_{X_1} = (I-\pi)A_X,$$
$$\pi A_{X_2} = \pi A_X.$$

Equations (2.1), (2.2), (2.3), (2.4) enjoy a certain symmetry. Indeed, they are invariant under the permutation $\pi \leftrightarrow (I-\pi)$, $X_1 \leftrightarrow X_2$. Lemma 2.1 above singles out a subclass of solutions of (2.1) and, by Theorem 1.4, of (1.1). This subclass may also be described as the solutions on $[t_0,t_1]$ of the following *implicit system*:

$$[0, I-\pi, \pi]\dot{\pi}\Delta_{12} = [\pi - \pi^2, (I-\pi)A_{X_1}\pi\Delta_{12}, -\pi A_{X_2}(I-\pi)\Delta_{12}]. \tag{2.5}$$

The following result provides a geometric characterization of the *projection-valued* solutions of (2.1). The question of *existence* of such solutions will be addressed in Theorem 2.7 below.

THEOREM 2.3. *Let $X(t) = (I-\pi(t))X_1(t) + \pi(t)X_2(t)$ be a solution of* (1.1) *on $[t_0,t_1]$. Let $M(t) := \pi(t)\Delta_{12}(t)R^n$ and $N(t) := (I-\pi(t))\Delta_{12}(t)R^n$. Then, for s and t in $[t_0,t_1]$, we have*

$$M(t) = \phi_1(t,s)M(s), \tag{2.6}$$
$$N(t) = \phi_2(t,s)N(s). \tag{2.7}$$

Moreover, we also have

$$M(t) = \phi(t,s)M(s), \tag{2.8}$$

$$N(t) = \phi(t,s)N(s). \tag{2.9}$$

Conversely, Let $\{M(t)\}$ *and* $\{N(t)\}$, $t \in [t_0, t_1]$, *be two families of subspaces of* R^m *providing a direct sum decomposition of* $\Delta_{12}(t)R^n$. *Let* π *be a* C^1 *function such that* $\pi(t)x = x\ \forall x \in M(t)$ *and* $\pi(t)y = 0\ \forall y \in N(t)$. *If* (2.6), (2.7) *hold for all* s *and* t *in* $[t_0, t_1]$, *then* $X(t) = (I - \pi(t))X_1(t) + \pi(t)X_2(t)$ *is a solution of the* RDE (1.1) *on* $[t_0, t_1]$.

Proof. By Lemma 1.1, $\Delta_1(t) = \phi_1(t,s)\Delta_1(s)\psi(s,t)$. Replacing $\Delta_1(t)$ with $\pi(t)\Delta_{12}(t)$, we get $\pi(t)\Delta_{12}(t)R^n = \phi_1(t,s)\pi(s)\Delta_{12}(s)R^n$, namely (2.6) holds. Formula (2.7) is proven similarly. Lemma 1.1 also gives $\Delta_1(t) = \phi(t,s)\Delta_1(s)\psi_1(s,t)$. The same argument as above then gives (2.8). Similarly, (2.9) is established. To prove the converse, notice that (2.6), (2.7) imply

$$[I - \pi(t)]\phi_1(t,s)\pi(s)\Delta_{12}(s) = 0, \tag{2.10}$$

$$\pi(t)\phi_2(t,s)[I - \pi(s)]\Delta_{12}(s) = 0. \tag{2.11}$$

Evaluating the derivatives of (2.10) and (2.11) with respect to t on the diagonal $t = s$, we get (2.3) and (2.4). The latter imply that (1.6) holds, and consequently X is a solution of (1.1). □

Remark 2.4. Notice that the first half of the theorem holds for *any* solution X of (1.1) of the form $X(t) = (I - \pi(t))X_1(t) + \pi(t)X_2(t)$, namely even when π is not projection valued. In that case, however, the spaces $M(t)$ and $N(t)$ do not need to form a direct sum. Observing once more that $X - X_1 = \pi\Delta_{12}$ and $X_2 - X = (I - \pi)\Delta_{12}$, we also see that the spaces $M(t)$ and $N(t)$ are *uniquely determined* by the solution X and do not depend on the particular projection π used in the definition.

In the important case where Δ_{12} has full row rank, Theorem 2.3 reads as follows.

THEOREM 2.5. *Assume that* $\Delta_{12}(t_0)$ *has full row rank. Let* $X(t) = (I - \pi(t))X_1(t) + \pi(t)X_2(t)$ *be a solution of* (1.1) *on* $[t_0, t_1]$. *Let* $M(t)$ *and* $N(t)$ *denote the range of* $\pi(t)$ *and the range of* $(I - \pi(t))$, *respectively. Then, for* s *and* t *in* $[t_0, t_1]$, *relations* (2.6), (2.7), (2.8) *and* (2.9) *hold true. Conversely, let* $\pi(\cdot)$ *be a* C^1, *projection-valued function on* $[t_0, t_1]$, *and let* $M(t)$ *and* $N(t)$ *denote the range of* $\pi(t)$ *and the range of* $(I - \pi(t))$, *respectively. If the propagation relations* (2.6) *and* (2.7) *hold for all* s *and* t *in* $[t_0, t_1]$, *then* $X(t) = (I - \pi(t))X_1(t) + \pi(t)X_2(t)$ *is a solution of the* RDE (1.1) *on the same time interval.*

Theorems 2.3 and 2.5 provide the desired geometric characterization of a subclass of solutions of the ARDE (2.2) and, consequently, of the RDE (1.1). Notice that, in the case $m = n$, Remark 2.4 gives that the first half of Theorem 2.5 applies to *any* solution of (1.1) on $[t_0, t_1]$. Indeed, in this case, $\Delta_{12}(t)$ is invertible at all times, and $\ker \Delta_{12}(t) \subseteq \ker \Delta_1(t)$ is trivially satisfied. Hence, any solution X of (1.1) can be expressed as $X(t) = (I - \pi(t))X_1(t) + \pi(t)X_2(t)$. For the purpose of immediate comparison, we state below Jan Willems' classical result; cf. also [6, 19, 20, 21, 13] (the latter should also be compared with Theorems 3.3 and 4.2 below).

THEOREM 2.6. *In equation* (1.1), *let* $n = m$, $B = A^T$, $P = P^T$, $Q = Q^T$. *Suppose moreover that* P *is negative semidefinite and that the pair* (A, P) *is reachable. Let* X_- *and* X_+ *denote two symmetric equilibrium solutions of* (1.1) *such that the corresponding closed-loop matrices* $A_- := A + X_-P$ *and* $A_+ := A + X_+P$ *have all their eigenvalues in the closed right and left half-planes, respectively. Suppose that*

$\Delta := X_+ - X_-$ is positive definite. Then X is another symmetric equilibrium solution of (1.1) *if and only if it can be expressed as*

$$X = (I - \pi)X_- + \pi X_+$$

where π projects onto an A_--invariant subspace and $I - \pi$ projects onto an A_+-invariant subspace.

We now turn to the question of *existence of projection-valued solutions* of (2.2) ((1.7)) (equivalently, of solutions of the implicit system (2.5) if $\Delta_{12}(t_0)$ has full row rank). The following remarkable result basically says that (2.2) is a *projection-preserving differential equation.*

THEOREM 2.7. *Let π be a solution of* (2.2) *on $[t_0, t_1]$. Suppose that $\pi(t_0)$ is a projection. Then $\pi(t)$ is a projection for all t in $[t_0, t_1]$.*

Proof. Let us rewrite (2.2) as

$$\dot{\pi} = A_{X_1}\pi - \pi A_{X_2} + \pi\Delta_{12}P\pi.$$

Then

$$\begin{aligned}\frac{d\pi^2}{dt} = \dot{\pi}\pi + \pi\dot{\pi} &= [A_{X_1}\pi - \pi A_{X_2} + \pi\Delta_{12}P\pi]\pi + \pi[A_{X_1}\pi - \pi A_{X_2} + \pi\Delta_{12}P\pi] \\ &= A_{X_1}\pi^2 - \pi A_{X_2}\pi + \pi\Delta_{12}P\pi^2 + \pi A_{X_1}\pi - \pi^2 A_{X_2} + \pi^2\Delta_{12}P\pi.\end{aligned}$$

Hence,

$$\frac{d(\pi^2 - \pi)}{dt} = A_{X_1}(\pi^2-\pi)-(\pi^2-\pi)A_{X_2}-(\pi^2-\pi)\Delta_{12}P(\pi^2-\pi)+\pi^2\Delta_{12}P\pi^2-\pi\Delta_{12}P\pi.$$

Adding and subtracting the quantity $\pi^2\Delta_{12}P\pi$ in the right-hand side and rearranging terms, we finally get

$$\frac{d(\pi^2 - \pi)}{dt} = (A_{X_1}+\pi^2\Delta_{12}P)(\pi^2-\pi)-(\pi^2-\pi)(A_{X_2}-\Delta_{12}P\pi)-(\pi^2-\pi)\Delta_{12}P(\pi^2-\pi).$$

Let $F_1 := A_{X_1} + \pi^2\Delta_{12}P$ and $F_2 := A_{X_2} - \Delta_{12}P\pi$. It follows that, if $\pi(t)$ is a solution of (2.2), then, on the same time interval, $\pi^2 - \pi$ is a solution of the homogeneous Riccati equation

$$\dot{X} = F_1X - XF_2 - X\Delta_{12}PX, \tag{2.12}$$

and F_1 and F_2 are there bounded. Since $\pi^2(t_0) - \pi(t_0) = 0$, by uniqueness of the solution of equation (2.12) starting at zero, it follows that $\pi^2(t) - \pi(t) = 0$ on all of $[t_0, t_1]$. □

The above proof actually establishes an amplification of Theorem 2.7. We record it below because it is of interest on its own.

PROPOSITION 2.8. *Let A_1 and A_2 be $m \times m$ continuous matrix functions on $[t_0, t_1]$. Let Y be an $m \times m$ matrix function solving the homogeneous Riccati equation*

$$\dot{Y} = A_1Y - YA_2 + Y(A_2 - A_1)Y \tag{2.13}$$

on $[t_0, t_1]$. If there exists a time $\bar{t} \in [t_0, t_1]$ such that $Y(\bar{t}) = Y(\bar{t})^2$, then $Y(t) = Y(t)^2$ on all of $[t_0, t_1]$.

Remark 2.9. Notice that $Y_1 \equiv 0$ and $Y_2 \equiv I$ are two equilibrium solutions of (2.13). Also notice that the corresponding closed-loop matrices are $A_1 + 0(A_2 - A_1) = A_1$

and $A_1 + I(A_2 - A_1) = A_2$. Now let Y be as in the proposition above—namely, a projection-valued solution of (2.13)—and let $M(t)$ and $N(t)$ be the range spaces of $Y(t)$ and $I - Y(t)$, respectively. Then, by Theorem 2.5, the propagation properties (2.6) and (2.7) hold true, where ϕ_1 and ϕ_2 are the transition matrices corresponding to A_1 and A_2, respectively. Finally, if A_1 and A_2 are constant and $Y = Y^2$ is an equilibrium solution of (2.13), Y projects onto a subspace invariant for A_1 along a subspace invariant for A_2.

Remark 2.10. The geometric results of this section provide a procedure to produce new solutions of (1.1). For instance, in the full-rank case, let π_0 be any projection, and let M_0 and N_0 be the ranges of π_0 and $I-\pi_0$, respectively. Define $M(t) := \phi_1(t, t_0)M_0$ and $N(t) := \phi_2(t, t_0)N_0$. Let $\bar{t}$ be the largest time such that for $t_0 \le t < \bar{t}$, $M(t)$ and $N(t)$ give a direct sum decomposition of R^m (by continuity, $\bar{t} > 0$). Let $\pi(t)$ be the projection such that $M(t)$ and $N(t)$ are the ranges of $\pi(t)$ and $I - \pi(t)$, respectively. Then π solves (2.2) and $X = (I-\pi)X_1 + \pi X_2$ solves (1.1) on $[t_0, \bar{t})$. Using an explicit expression for π in terms of bases for its range and the range of $I - \pi$, it is easily seen that $\pi(t)$ becomes unbounded as t tends to $\bar{t}$. If $\Delta_{12}(t_0)$ has full row rank, it follows that the corresponding solution $X(\cdot)$ has a finite escape time (see, e.g., [16, 7, 8]) at $t = \bar{t}$.

We conclude the section with an example that illustrates Remark 2.10 as well as Proposition 2.8 and Remark 2.9.

Example 2.11. Consider equation (2.13) with $m = 2$ and

$$A_1 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \quad A_2 = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

Choose as reference solutions $Y_1 = 0$ and $Y_2 = I$, and let π_0 be given by

$$\pi_0 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}.$$

Clearly π_0 is a projection, in fact an orthogonal projection. We have that $M_0 = \binom{R}{0}$ and $N_0 = \binom{0}{R}$. Next notice that the transition matrices $\phi_1(t, s)$ and $\phi_2(t, s)$ are given here by

$$\phi_1(t,s) = e^{A_1(t-s)} = \begin{pmatrix} e^{t-s} & 0 \\ 0 & 1 \end{pmatrix}, \quad \phi_2(t,s) = e^{A_2(t-s)} = \begin{pmatrix} 1 & t-s \\ 0 & 1 \end{pmatrix}.$$

Hence, $M(t) = \phi_1(t, t_0)M_0$ is the span of the vector $\binom{1}{0}$ and $N(t) = \phi_2(t, t_0)N_0$ is the span of the vector $\binom{t-t_0}{1}$. Notice that $M(t)$ and $N(t)$ provide a direct sum decomposition of R^2 for all $t \ge t_0$. The projection $\pi(t)$ with range $M(t)$ and kernel $N(t)$ is given by

$$\pi(t) = \begin{pmatrix} 1 & t_0 - t \\ 0 & 0 \end{pmatrix}.$$

The corresponding solution of (2.13) is $Y(t) = 0 + \pi(t)(I - 0) = \pi(t)$, namely $\pi(t)$ itself. This is no surprise. Since $Y(t_0) = 0 + \pi_0(I - 0) = \pi_0$ is a projection, Theorem 2.7 implies that $Y(t)$ has to be a projection for all t. Notice that $\pi(t)$ is unbounded as t tends to infinity. This is possible because $\pi(t)$ for $t > 0$ is not an *orthogonal* projection, although π_0 is orthogonal.

3. Geometric results: The case where X_1 and X_2 are equilibrium solutions. All through this section we assume that X_1 and X_2 are equilibrium solutions of (1.1). The coefficients A, B, P, and Q may still be time varying.

PROPOSITION 3.1. *Let X be an equilibrium solution of* (1.1) *and let $\Delta_i = X - X_i$, $i = 1, 2$. Then for all t in $[t_0, t_1]$,*

$$A_X(t)\Delta_i = -\Delta_i B_{X_i}(t), \tag{3.1}$$

$$A_{X_i}\Delta_i = -\Delta_i B_X(t). \tag{3.2}$$

It follows that if $(\xi(t), \lambda(t))$ is an eigenvector-eigenvalue pair for $B_{X_i}(t)$ so that $B_{X_i}(t)\xi(t) = \lambda(t)\xi(t)$, then either $\Delta_i\xi(t) = 0$ or $(\Delta_i\xi(t), -\lambda(t))$ is an eigenvector-eigenvalue pair for $A_X(t)$. Similarly, it follows for $A_{X_i}(t)$ and $B_X(t)$. If Δ_i admits a right inverse, we get the relations

$$A_X(t) = -\Delta_i B_{X_i}(t)\Delta_i^{-R},$$
$$A_{X_i}(t) = -\Delta_i B_X(t)\Delta_i^{-R}.$$

In particular, if $m = n$ and Δ_{12} is invertible, we have

$$A_{X_2}(t) = -\Delta_{12} B_{X_1}(t)\Delta_{12}^{-1}. \tag{3.3}$$

Proof. Relations (3.1) and (3.2) are a consequence of (1.5). □

Once more, we compare (3.3) with the corresponding classical result. In the notation of Theorem 2.6, let $X_1 = X_-$ and $X_2 = X_+$. Then (3.3) reads $A_+ = -\Delta A_-^T \Delta^{-1}$ which is precisely [23, Lemma 8]. Let us now assume that the coefficients of (1.1) are constant. Theorems 1.4 and 2.3 yield the following result.

THEOREM 3.2. *Let $X = (I - \pi)X_1 + \pi X_2$ be an equilibrium solution of the RDE* (1.1). *Let $M := \pi\Delta_{12}R^n$ and $N := (I - \pi)\Delta_{12}R^n$. Then M is an invariant subspace for A_{X_1} and N is an invariant subspace for A_{X_2}. Moreover, M and N are both invariant for A_X. Conversely, let M and N be two subspaces of R^m providing a direct sum decomposition of $\Delta_{12}R^n$. Let π be an $m \times m$ matrix such that $\pi x = x$ for any x in M and $\pi y = 0$ for any y in N. If M is an invariant subspace for A_{X_1} and N is an invariant subspace for A_{X_2}, then $X = (I - \pi)X_1 + \pi X_2$ is an equilibrium solution of the RDE* (1.1).

Once more, we state independently the result in the case when Δ_{12} has full row rank.

THEOREM 3.3. *Suppose Δ_{12} has full row rank and let X be an equilibrium solution of* (1.1). *Assume that* $\ker \Delta_{12} \subseteq \ker \Delta_1$. *Then there exists an $m \times m$ matrix π such that $X = (I - \pi)X_1 + \pi X_2$. Moreover, the range M of π is invariant for A_{X_1} and for A_X, and the range N of $I - \pi$ is invariant for A_{X_2} and for A_X. Conversely, if π is any oblique projection onto a subspace invariant for A_{X_1} along a subspace invariant for A_{X_2}, then $X = (I - \pi)X_1 + \pi X_2$ satisfies* (1.1).

In order to compare this result with Theorem 2.6, notice that if $m = n$ and Δ_{12} has full rank, the condition $\ker \Delta_{12} \subseteq \ker \Delta_1$ is always satisfied. The additional assumptions of Theorem 2.6 permit us to conclude that if $X = (I - \pi)X_1 + \pi X_2$ is an equilibrium solution of (1.1), π is always a projection.

4. The symmetric Riccati equation. We finally consider the symmetric case where $n = m$, $B = A^T$, $P = P^T$, $Q = Q^T$ but return to the nonequilibrium situation. Equation (1.1) is now

$$\dot{X} = AX + XA^T + XPX + Q. \tag{4.1}$$

We also assume that the two reference solutions X_1 and X_2 take values in the symmetric matrices. Hence, $\Delta_{12}(t)$ is also symmetric at all times. It is then natural to restrict our attention to *symmetric* solutions of (4.1).

LEMMA 4.1. $\phi_2(t,s)\Delta_{12}(s) = \Delta_{12}(t)\phi_1(s,t)^T$.

Proof. By Lemma 1.1, $\phi_2(t,s)\Delta_{12}(s) = \Delta_{12}(t)\psi_1(t,s)$. The conclusion now follows observing that $B_{X_1} = A_{X_1}^T$ implies that $\psi_1(t,s) = \phi_1(s,t)^T$. □

For the sake of simplicity, we only give the main result in the case where Δ_{12} is nonsingular.

THEOREM 4.2. *Let X_1 and X_2 be any two symmetric solutions of* (4.1) *on $[t_0,t_1]$ such that $\Delta_{12}(t_0)$ is invertible. Let $X(t) = (I-\pi(t))X_1(t)+\pi(t)X_2(t)$ be a symmetric solution of* (4.1) *on $[t_0,t_1]$. Let $M(t)$ and $N(t)$ denote the range of $\pi(t)$ and the range of $(I-\pi(t))$, respectively. Then for s and t in $[t_0,t_1]$ the following relations hold true:*

$$\pi(t)\Delta_{12}(t) = \Delta_{12}(t)\pi(t)^T, \tag{4.2}$$

$$(I-\pi(t))\phi_1(t,s)\pi(s) = 0. \tag{4.3}$$

Conversely, let π be a C^1, projection-valued function satisfying for all s and t in $[t_0,t_1]$ (4.2), (4.3). *Then $X(t) = (I-\pi(t))X_1(t)+\pi(t)X_2(t)$ is also a symmetric solution of the RDE* (4.1) *on $[t_0,t_1]$.*

Proof. Let $X(t) = (I-\pi(t))X_1(t)+\pi(t)X_2(t) = X_1(t)+\pi(t)\Delta_{12}(t)$ be a symmetric solution of (4.1) on $[t_0,t_1]$. The symmetry of $X(t)$ implies that (4.2) must hold. Let $M(t)$ and $N(t)$ denote the range of $\pi(t)$ and of $I-\pi(t)$, respectively. By Theorem 2.5, we have $M(t) = \phi_1(t,s)M(s)$ from which (4.3) follows. Conversely, suppose that (4.2) and (4.3) are verified. From (4.3) we get $\phi_1(t,s)M(s) \subseteq M(t)$. Exchanging the roles of s and t, we see that equality, i.e., equation (2.6), must hold. Now, multiplying equation (4.3) (with s and t exchanged) by $\Delta_{12}(s)^{-1}$ on the left and by $\Delta_{12}(t)$ on the right we get

$$\Delta_{12}(s)^{-1}(I-\pi(s))\phi_1(s,t)\pi(t)\Delta_{12}(t) = 0. \tag{4.4}$$

Transposing (4.4) and using (4.2) twice, we get

$$\pi(t)\Delta_{12}(t)\phi_1(s,t)^T\Delta_{12}(s)^{-1}(I-\pi(s)) = 0.$$

The latter equation, together with Lemma 4.1, now gives equation (2.7). The conclusion now follows from Theorem 2.5. □

5. Closing comments. As is well known, the Riccati differential equation may be viewed as the description in local coordinates of the restriction to a subset of the Lagrangian Grassmannian manifold $\mathcal{L}$ of a vector field on $\mathcal{L}$; see [15, 19]. Our results may then be readily interpreted in that setting. In fact, some may be also directly derived in that setting; see [8], where the case of $l \geq 2$ reference solutions $X_1, X_2, \ldots, X_l$, is also considered (see also [17, Theorem 4]). Similar results may also be derived in the discrete-time setting [9]. Alternative representation formulas for solutions of (1.1) have been proposed in [22] and references therein.

The classification of the solutions of the ARE via invariant subspaces of the Hamiltonian matrix has the disadvantage, when compared with the J. C. Willems classification, that the invariant subspaces need to be J-neutral and complementary to the subspace Span $\binom{0}{I}$; see [13, pp. 67–68]. In [19] it was observed that the disadvantages of Jan Willems method are that, contrary to the Hamiltonian matrix method, it does not lead naturally to a concept of solution at infinity (phenomenon of

the finite escape time; see, e.g., [16, 7]) and it does not have an obvious generalization to the nonsymmetric Riccati equation. Whereas the first disadvantage persists, we observe that this paper has completely removed the second.

Acknowledgment. This paper has considerably profited from the detailed comments of an anonymous reviewer who went so far as to produce a more elegant proof of Theorem 1.4. His or her help is gratefully acknowledged.

SUFFICIENT OPTIMALITY CONDITIONS FOR OPTIMAL CONTROL SUBJECT TO STATE CONSTRAINTS*

K. MALANOWSKI†

Abstract. Strong second-order sufficient optimality conditions (SSC) are derived for optimal control problems of systems described by nonlinear ODEs subject to mixed control-state and pure state constraints. The obtained SSC are expressed in terms of a modified Legendre–Clebsch condition and the associated Riccati equation. The role of SSC in stability analysis of solutions to parametric optimal control problems is briefly discussed.

Key words. optimal control, nonlinear ordinary differential equations, control and state constraints, second-order sufficient optimality conditions, Riccati equation, parametric optimal control, stability analysis

1. Introduction.

The concept of *second-order sufficient optimality conditions* in mathematical programming has been developed for many years. The well-known condition in finite-dimensional programs requires that the Hessian of Lagrangian is positive definite on the critical cone.

However, it was shown by Maurer and Zowe [18] that, in general, this condition is no longer sufficient in infinite-dimensional situations. Instead, Maurer and Zowe derived a stronger coercivity condition (cf. Theorem 5.6 in [18]), which provides some "margin of freedom" and ensures sufficiency of optimality. This concept has been extended by Maurer in [16] to optimization problems with the so-called *two-norm discrepancy* typical for nonlinear optimal control.

Recently, in Dontchev and Hager [1] and in Dontchev et al. [2] this approach has been further developed using three different norms and applied to control constrained optimal control problems.

Along with the second-order sufficient optimality conditions, the concept of *strong second-order sufficient optimality conditions* (SSC) has been introduced and analyzed. For finite-dimensional mathematical programs, SSC require that the Hessian of Lagrangian is positive definite on the affine hull of the critical cone (cf. [26]). It turnes out that SSC play an important role in stability analysis of solutions to parametric programming problems (cf. [8, 9, 25, 26]).

Also in optimal control problems, SSC require that the Hessian of Lagrangian is coercive on the subspace orthogonal to the gradients of some active constraints. Certainly, it is desirable that this subspace is narrow, so in its construction we would like to include as many constraints as possible.

Attempts have been made to express the coercivity condition in the form similar to that known in calculus of variations, which involves the so-called *strengthened Legendre–Clebsch condition* and *strengthened Jacobi condition* (cf., e.g., [4]). This last condition can be expressed in terms of the existence of a bounded solution to a

*Received by the editors May 13, 1994; accepted for publication (in revised form) November 14, 1995. This research was supported by grant 3 P403 002 05 from the Polish State Committee of Scientific Research (Komitet Badań Naukowych).

†Systems Research Institute, Polish Academy of Sciences, ul. Newelska 6, 01–447 Warsaw, Poland (kmalan@ibspan.waw.pl).

certain *Riccati equation* (cf. [24]). The difficulties with extending these conditions to optimal control problems are connected to the presence of inequality-type constraints and the associated lack of smoothness of the solutions.

The first result in this direction was obtained by Maurer in [16], where only equality-type constraints (the state equation) were used in the construction of the relevant subspace.

Later, some attempts have been made to weaken this condition by including active inequality constraints (cf. [17, 20, 22, 23, 28, 29, 30]). In the last paper by Zeidan [30] she considers both necessary and sufficient second-order optimality conditions for optimal control problems subject to mixed control-state constraints and gives a weak version of SSC.

The main contributions of the present paper is the *derivation of weak SSC for optimal control problems, where, along with the mixed, pure state constraints of first order also are present and used in the construction of the relevant subspace.* That can be viewed as a direct generalization of Zeidan's result.

It should be stressed that the presence of pure state-space constraints complicates the analysis very much since it necessitates the additional discussion of regularity of the solutions and Lagrange multipliers, which is not needed if these constraints are void.

The organization of the paper is as follows: In section 2 we derive SSC for cone-constrained optimization problems in Banach spaces, using the same formalism as in [12]. This result is only a slight reformulation of that due to Dontchev et al. [2].

In sections 3 and 4 the abstract SSC are used to obtain SSC for nonlinear optimal control problems subject to both mixed control-state and pure state constraints. In these conditions active constraints of both types are taken into account.

One of the important applications of SSC is stability analysis of solutions to parametric optimization problems (cf. [1, 2, 3, 8, 9, 10, 11, 12, 13, 14, 25, 26]). In section 5 the possibility of application of the derived SSC to stability analysis of the solutions to parametric optimal control problems is briefly discussed. It turns out that SSC involving active state constraints are too weak to repeat the proof of stability of the solutions given in [13].

Some notation used: $X, Y, Z, \ldots$ denote Banach spaces and $\widehat{X}, \widehat{Y}, \widehat{Z}, \ldots$, Hilbert spaces. Asterisks denote dual spaces. $L(X, Y)$ is the Banach space of linear continuous operators from X into Y.

The norms in Banach and Hilbert spaces are denoted by $[\![\cdot]\!]$ and $\|\cdot\|$, respectively, with a subscript refering to the space.

For $f : X \times Y \mapsto Z$, $D_x f(x, y), D_y f(x, y), D^2_{xy} f(x, y), \ldots$ denote the respective Fréchet derivatives in the corresponding arguments.

$\mathbb{R}^n$ is the n-dimensional Euclidean space with the inner product denoted by $\langle x, y\rangle$ and the norm $|x| = \langle x, x\rangle^{\frac{1}{2}}$.

$L^2(0, T; \mathbb{R}^n)$ is the Hilbert space of square integrable vector functions, with the inner product

$$(x, y) = \int_0^T \langle x(t), y(t)\rangle dt \quad \text{and the norm } \|x\|_2 = (x, x)^{\frac{1}{2}}.$$

$L^\infty(0, T; \mathbb{R}^n)$ is the Banach space of essentially bounded vector functions with the norm

$$\|x\|_\infty = \max_i \operatorname*{ess\,sup}_{t\in[0,T]} |x^i(t)|.$$

$C^0(0,T;\mathbb{R}^n)$ and $C^1(0,T;\mathbb{R}^n)$ are the spaces of continuous and continuously differentiable vector functions, respectively, equipped with the usual norms.

$$W^{1,p}(0,T;\mathbb{R}^n) = \{x \in L^p(0,T;\mathbb{R}^n) \mid \dot{x} \in L^p(0,T;\mathbb{R}^n)\}, \qquad p = 2, \infty,$$

denote Sobolev spaces of absolutely continuous functions with the norms $\|x\|_{1,2} = \{|x(0)|^2 + \|\dot{x}\|_2^2\}^{\frac{1}{2}}$ and $\|x\|_{1,\infty} = \max\{|x(0)|, \|\dot{x}\|_\infty\}$, respectively.

2. SSC for abstract optimization problems. In this section we discuss SSC for cone-constrained optimization problems with two-norm discrepancy in Banach spaces.

Let Z and Y be two Banach spaces, the space of arguments and constraints, respectively. Moreover, two Hilbert spaces $\widehat{Z}$ and $\widehat{Y}$ are given such that $Z \subset \widehat{Z}$ and $Y \subset \widehat{Y}$ with dense and continuous embeddings. The duality pairing between $\widehat{Z}^*$ and $\widehat{Z}$ or Z^* and Z is denoted by $(\cdot,\cdot)_{\widehat{Z}}$. We put $\widehat{Y}^* = \widehat{Y}$, and by $(\cdot,\cdot)_{\widehat{Y}}$ we denote the inner product in $\widehat{Y}$, extended by continuity to $Y^* \times Y$. We denote

$$X = Z \times Y, \qquad \widehat{X} = \widehat{Z} \times \widehat{Y}.$$

In Y there is given a closed convex cone K with vertex at the origin, which induces a partial order in Y. By $\widehat{K}$ we denote the closure of K in $\widehat{Y}$, and by

$$K^+ = \{\lambda \in Y^* \mid (\lambda, y)_{\widehat{Y}} \geq 0 \quad \text{for all } y \in K\}, \tag{2.1}$$

the positive polar cone to K.

We consider the following optimization problem:

$$\min_{z \in Z} F(z) \qquad \text{subject to} \qquad \varphi(z) \in K. \tag{P}$$

We assume the following.

(I.1) The functions $F : Z \mapsto \mathbb{R}^1$ and $\varphi : Z \mapsto Y$ are twice Fréchet differentiable, and the following compatibility conditions are satisfied:

$$\begin{array}{lll} D_z F(z) \in \widehat{Z}^*, & D^2_{zz} F(z) \in L(\widehat{Z}, \widehat{Z}^*), & \\ D_z \varphi(z) \in L(\widehat{Z}, \widehat{Y}), & D_z \varphi^*(z)\lambda \in \widehat{Z}^*, & D^2_{zz} \varphi^*(z)\lambda \in L(\widehat{Z}, \widehat{Z}^*) \end{array} \tag{2.2}$$

for all $z \in Z$ and $\lambda \in Y$.
Moreover

$$\begin{aligned} &\lim \|D^2_{zz} F(z_1) - D^2_{zz} F(z_2)\|_{\widehat{Z} \mapsto \widehat{Z}^*} = 0, \\ &\lim \|D_z \varphi(z_1) - D_z \varphi(z_2)\|_{\widehat{Z} \mapsto \widehat{Y}} = 0, \\ &\lim \|D^2_{zz} \varphi^*(z_1)\lambda_1 - D^2_{zz} \varphi^*(z_2)\lambda_2\|_{\widehat{Z} \mapsto \widehat{Z}^*} = 0 \end{aligned} \tag{2.3}$$

for $[\![z_1 - z_2]\!]_Z \to 0$ and $[\![\lambda_1 - \lambda_2]\!]_Y \to 0$.

Let $z_0 \in Z$ be a given point feasible for (P). We will find sufficient conditions under which z_0 is a locally unique minimizer of (P).

Let us start with the constraint qualifications, which will be formulated in the same way as in [12]. To this end, for any $y \in K$ we define the following subspace of Y:

$$M_y = (K + [y]) \cap (-K + [y]), \tag{2.4}$$

and denote $M_0 := M_{y_0}$, where $y_0 = \varphi(z_0)$ and $[y]$ is the one-dimensional subspace generated by the element y. We assume that

(I.2) there exists a subspace $M \subset M_0$, closed in Y-topology, and a linear continuous mapping

$$\Pi \in L(Y,Y) \cup L(\widehat{Y},\widehat{Y}), \qquad \Pi : Y \mapsto M$$

such that

$$D_z\varphi(z_0)Z + \Pi Y = Y, \qquad D_z\varphi(z_0)\widehat{Z} + \Pi\widehat{Y} = \widehat{Y}. \tag{2.5}$$

Moreover, there exists a neighborhood $\mathcal{Y}_0 \subset Y$ of $y_0 = \varphi(z_0)$ such that

$$M \subset M_y \quad \text{for all } y \in \mathcal{Y}_0 \cap K. \tag{2.6}$$

If we define

$$S_0 \in L(X,Y) \cap L(\widehat{X},\widehat{Y}), \qquad S_0 \begin{pmatrix} z \\ y \end{pmatrix} := D_z\varphi(z_0)z + \Pi y, \tag{2.7}$$

then condition (2.5) amounts to that $S_0 \in L(X,Y) \cup L(\widehat{X},\widehat{Y})$ is surjective.

Let us introduce the following Lagrangian associated with (P):

$$\mathcal{L} : Z \times Y^* \mapsto \mathbb{R}^1, \qquad \mathcal{L}(z,\lambda) = F(z) - \varphi^*(z)\lambda. \tag{2.8}$$

We assume that

(I.3) there exists a Lagrange multiplier $\lambda_0 \in Y^*$ associated with z_0 such that the following Kuhn–Tucker conditions hold:

$$\begin{aligned} &D_z\mathcal{L}(z_0,\lambda_0) := D_zF(z_0) - D_z\varphi^*(z_0)\lambda_0 = 0, \\ &(\lambda_0, \varphi(z_0))_{\widehat{Y}} = 0, \qquad \lambda_0 \in K^+. \end{aligned} \tag{2.9}$$

It follows from (I.2) (cf. Lemma 3.1 and Theorem 4.8 in [12]) that λ_0 is defined uniquely and it belongs to $\widehat{Y}$. We assume that λ_0 is more regular. Namely,

(I.4) $\lambda_0 \in Y$.

By (I.2) and (I.4) we have $D^2_{zz}\mathcal{L}(z_0,\lambda_0) \in L(\widehat{Z},\widehat{Z}^*)$ and

$$|(D^2_{ZZ}\mathcal{L}(z_0,\lambda_0)x,z)_{\widehat{Z}}| \le c\|x\|_{\widehat{Z}}\|z\|_{\widehat{Z}} \quad \text{for all } x,z \in \widehat{Z}. \tag{2.10}$$

In a way similar to (2.4), for $\lambda \in K^+$ we define

$$N_\lambda = (K^+ + [\lambda]) \cap (-K^+ + [\lambda]), \tag{2.11}$$

denote $N_0 := N_{\lambda_0}$, and assume that

(I.5) there exist a subspace $N \subset N_0 \subset Y^*$ and a constant $\gamma > 0$ such that

$$\begin{aligned} &(D^2_{zz}\mathcal{L}(z_0,\lambda_0)z,z)_{\widehat{Z}} \ge \gamma\|z\|^2_{\widehat{Z}} \\ &\text{for all } z \in E_0 := \{z \in \widehat{Z} \mid D_z\varphi(z_0)z \in \widehat{N}^\perp\}, \end{aligned} \tag{2.12}$$

where $\widehat{N}^\perp$ is the closure in $\widehat{Y}$ of the subspace $\{y \in Y \mid (\lambda,y)_{\widehat{Y}} = 0 \quad \text{for all } \lambda \in N\}$. Moreover, there exists $\sigma > 0$ such that

$$\Lambda_0 \cap (K^+ + N) \subset K^+, \tag{2.13}$$

where $\Lambda_0 = \{\lambda \in Y \mid [\![\lambda - \lambda_0]\!]_Y \le \sigma\}$. We also require that

$$[\![y^\perp]\!]_Y \le c[\![y]\!]_Y \qquad \text{for all } y \in Y, \tag{2.14}$$

where $y^{\perp}$ denotes the projection of y onto $\widehat{N}^{\perp}$ orthogonal in $\widehat{Y}$. Note that it follows from (2.9) that

$$M \subset \widehat{N}^{\perp}. \tag{2.15}$$

Remark 2.1. Condition (I.5) is a counterpart of the SSC in finite-dimensional mathematical programs (cf., e.g., [8, 9, 26]), since we require that coercivity is satisfied on a whole subspace. We are interested in this type of condition, having in mind further applications in stability analysis. A counterpart of the *second-order sufficient optimality condition* for finite-dimensional mathematical programs (cf., e.g., [3]) is used in [2], where in our terminology it is assumed that coercivity condition (2.12) is satisfied on the more narrow set

$$\{z \in Z \mid \varphi(z_0) + D_z\varphi(z_0)z \in \widehat{N}^{\perp} \cap K,\ \|z - z_0\|_Z \le \beta \quad \text{for some } \beta > 0\}.$$

In this context we should mention another similar but not identical sufficient optimality condition, which was introduced in pioneering papers by Maurer and Zowe [18] and Maurer [16] and later used in [27]. In [16] it is assumed that the coercivity condition (2.12) is satisfied on the set

$$\{z \in Z \mid D_z\varphi(z_0)z \in K + [\varphi(z_0)],\ (D_z\varphi^*(z_0)\lambda_0, z)_{\widehat{Z}} \le \beta\|z\|_{\widehat{Z}} \quad \text{for some } \beta > 0\}.$$

Remark 2.2. A condition similar to (2.12) was introduced in [11]. However, in that case only the one-norm situation was considered, whereas (2.12) constitutes the essence of the so called *two-norm discrepancy* for (P). Namely, the problem is well defined and differentiable in the stronger topology of space Y, whereas the coercivity condition (2.12) is satisfied only in the weaker norm $\widehat{Y}$, in which problem (P) is not differentiable.

In assumption (I.5) the additional condition (I.4) on regularity of the Lagrange multiplier is crucial. It allows us to formulate stability condition (2.13) for a neighborhood Λ_0 in the stronger topology of Y, rather than in the topology of the dual space Y^*, as was done in [11].

The following theorem is actually a weakened version of Theorem 1 in [2]. For the sake of completeness, the proof of the theorem based on that in [2] is given in Appendix A. Later, some elements of this proof will be used in the proof of Proposition 4.5.

THEOREM 2.3. *If assumptions* (I.1)–(I.5) *hold, then there exist constants* $\rho_1 > 0$ *and* $\gamma_1 > 0$ *such that*

$$\begin{aligned} &F(z) \ge F(z_0) + \gamma_1\|z - z_0\|^2_{\widehat{Z}} \\ &\text{for all feasible } z \in \mathcal{O}_0^{\rho_1} := \{z \in Z \mid \|z - z_0\|_Z < \rho_1\}; \end{aligned} \tag{2.16}$$

i.e., z_0 is a locally unique minimizer of (P).

To illustrate the nature of the abstract assumptions (I.1)–(I.5), let us consider the following simple example:

$$\min_{z \in L^\infty(0,1)} F(z) := \int_0^1 f(z(t))dt \quad \text{subject to } \varphi(z(t)) \ge 0 \text{ for all } t \in [0,1], \tag{E}$$

where $f(\cdot)$ and $\varphi(\cdot)$ are twice continuously differentiable.

To put (E) in the framework of (P) we define $Z = Y = L^\infty(0,1)$, $\widehat{Z} = \widehat{Y} = L^2(0,1)$, and $K = \{y \in L^\infty(0,1) \mid y(t) \ge 0 \text{ for all } t \in [0,1]\}$. It is easy to see that conditions (I.1) are satisfied.

Let $z_0 \in L^\infty(0,1)$ be a feasible element. For $\alpha \geq 0$ introduce the set $\Omega_\alpha = \{t \in [0,1] \mid z_0(t) < \alpha\}$ and define the set M in (I.2) as

$$M = \{y \in L^\infty(0,1) \mid y(t) = 0 \text{ for all } t \in [0,1] \setminus \Omega_{\bar\alpha}\},$$

where $\bar\alpha > 0$ is an arbitrary number.

It is easy to see that condition (I.2) is satisfied if

$$D_z\varphi(z_0(t)) \neq 0 \quad \text{for all } t \in \Omega_{\bar\alpha}. \tag{2.17}$$

Let us introduce the following Lagrangian:

$$\mathcal{L}(z,\lambda) = \int_0^1 \ell(z(t),\lambda(t))dt = \int_0^1 [f(z(t)) - \lambda(t)\varphi(z(t))]\,dt.$$

Conditions (I.3) and (I.4) amounts to the existence of a Lagrange multiplier $\lambda_0 \in L^\infty(0,1)$ such that the Kuhn–Tucker conditions are satisfied:

$$\begin{aligned} &D_z\mathcal{L}(z_0,\lambda_0) = 0,\\ &\lambda_0(t)z_0(t) = 0, \qquad \lambda_0(0) \geq 0 \quad \text{for all } t \in [0,1]. \end{aligned}$$

By (2.17) the Lagrange multiplier λ_0 is defined uniquely.

For $\sigma \geq 0$ introduce the set $\Xi_\sigma = \{t \in [0,1] \mid \lambda_0(t) > \sigma\}$, and define the set N in (I.5) as

$$N = \{\lambda \in L^\infty(0,1) \mid \lambda(t) = 0 \text{ for all } t \in [0,1] \setminus \Xi_{\bar\sigma}\},$$

where $\bar\sigma > 0$ is an arbitrary number.

Condition (I.5) is satisfied if $\gamma > 0$ exists such that

$$(D_{zz}\mathcal{L}(z_0,\lambda_0)z,z) \geq \gamma \text{ for all } z \in \{z \in L^2(0,1) \mid (\lambda,z) = 0 \text{ for all } \lambda \in N\}, \quad \text{i.e.,}$$

$$D_{zz}\ell(z_0(t),\lambda_0(t)) \geq \gamma > 0 \quad \text{for all } t \in [0,1] \setminus \Xi_{\bar\sigma}. \tag{2.18}$$

It should be stressed that, except some technicalities, the nature of assumptions (I.2) and (I.5) for optimal control problems is the same as (2.17) and (2.18).

3. Optimal control problems: Constraint qualifications. In this section we consider a class of optimal control problems for nonlinear ordinary differential equations and discuss conditions under which constraint qualifications (I.2) of the abstract problem (P) are satisfied. The problems considered are quite general. They are subject to mixed initial-terminal constraints as well as to pointwise inequality constraints, both mixed control-state and pure state. Hence they include problems considered in [1, 2, 12] (pure control constraints), in [15, 17, 22, 30] (mixed constraints), and in [11, 13, 23] (state constraints).

Our model optimal control problem is the following:

(O) Find $(x_0,u_0) \in W^{1,\infty}(0,T;\mathbb{R}^n) \times L^\infty(0,T;\mathbb{R}^m)$ such that

$$F(x_0,u_0) = \min\left\{F(x,u) := \int_0^T f^0(x(t),u(t))dt + g(x(T))\right\} \tag{3.1}$$

subject to

$$\dot x(t) - f(x(t),u(t)) = 0 \qquad \text{for a.a. } t \in [0,T], \tag{3.2}$$

$$\xi(x(0),x(T)) = 0, \tag{3.3}$$

$$\theta(x(t),u(t)) \leq 0 \qquad \text{for a.a. } t \in [0,T], \tag{3.4}$$

$$\vartheta(x(t)) \leq 0 \qquad \text{for all } t \in [0,T], \tag{3.5}$$

where $\xi : \mathbb{R}^n \times \mathbb{R}^n \mapsto \mathbb{R}^d$, $\theta : \mathbb{R}^n \times \mathbb{R}^m \mapsto \mathbb{R}^k$, $\vartheta : \mathbb{R}^n \mapsto \mathbb{R}^l$.

Denote by $I = \{1, ..., k\}$ and $J = \{1, ..., l\}$ the sets of indices of constraints.

It is assumed that

(II.1) functions $f^0(\cdot,\cdot), g(\cdot), f(\cdot,\cdot), \xi(\cdot,\cdot), \theta(\cdot,\cdot), \vartheta(\cdot)$ and $D_x\vartheta(\cdot)$ are twice Fréchet differentiable in all arguments, and the respective derivatives are locally Lipschitz continuous.

We assume that for a fixed feasible point (x_0, u_0), at which we will find sufficient optimality conditions, the following regularity condition is satisfied:

(II.2) u_0 is a piecewise continuous function with finite number of discontinuity points t_k.

In order to represent (O) in form (P) we put

$$Z = W^{1,\infty}(0,T;\mathbb{R}^n) \times L^\infty(0,T;\mathbb{R}^m), \quad \widehat{Z} = W^{1,2}(0,T;\mathbb{R}^n) \times L^2(0,T;\mathbb{R}^m).$$

For $z = (x,u)$ belonging to Z or $\widehat{Z}$ we define the norms

$$[\![z]\!]_Z = \max\{\|x\|_{1,\infty}, \|u\|_\infty\} \text{ and } \|z\|_{\widehat{Z}} = \{\|x\|_{1,2}^2 + \|u\|_2^2\}^{\frac{1}{2}}.$$

Moreover we put

$$F(z) = F(x,u), \qquad \varphi(z) = (\dot{x} - f(x,u), \xi(x(0),x(T)), -\theta(x,u), -\vartheta(x)).$$

Hence it is natural to choose

$$Y = L^\infty(0,T;\mathbb{R}^n) \times \mathbb{R}^d \times L^\infty(0,T;\mathbb{R}^k) \times W^{1,\infty}(0,T;\mathbb{R}^l),$$
$$\widehat{Y} = L^2(0,T;\mathbb{R}^n) \times \mathbb{R}^d \times L^2(0,T;\mathbb{R}^k) \times W^{1,2}(0,T;\mathbb{R}^l),$$

with

$$K = K_1 \times K_2 \times K_3 \times K_4, \tag{3.6}$$

where

$$K_1 = \{0\}, \qquad K_2 = \{0\},$$
$$K_3 = \{u \in L^\infty(0,T;\mathbb{R}^k) \mid u^i(t) \geq 0, \quad i = 1,\dots,k, \quad \text{for a.a. } t \in [0,T]\},$$
$$K_4 = \{x \in W^{1,\infty}(0,T;\mathbb{R}^l) \mid x^j(t) \geq 0, \quad j = 1,\dots,l, \quad \text{for all } t \in [0,T]\}.$$

The cone $\widehat{K}$ is defined as in (3.6) but with Y substituted by $\widehat{Y}$.

For $y = (p,q,r,s)$ belonging to Y or $\widehat{Y}$ we define the norms

$$[\![y]\!]_Y = \max\{\|p\|_\infty, |q|, \|r\|_\infty, \|s\|_{1,\infty}\} \text{ and } \|y\|_{\widehat{Y}} = \{\|p\|_2^2 + |q|^2 + \|r\|_2^2 + \|s\|_{1,2}^2\}^{\frac{1}{2}}.$$

As in section 2, we denote $X = Z \times Y$ and $\widehat{X} = \widehat{Z} \times \widehat{Y}$.

Note that by (II.1) conditions (I.1) are satisfied. Now we will formulate conditions under which (I.2) holds.

To simplify notation we put

$$\begin{aligned}
&A(t) := D_x f(x_0(t), u_0(t)), && B(t) := D_u f(x_0(t), u_0(t)),\\
&\Xi_0 := D_{x(0)}\xi(x_0(0), x_0(T)), && \Xi_T := D_{x(T)}\xi(x(0), x_0(T)),\\
&\Theta_x(t) := D_x\theta(x_0(t), u_0(t)), && \Theta_u(t) := D_u\theta(x_0(t), u_0(t)),\\
&\Upsilon(t) := D_x\vartheta(x_0(t)).
\end{aligned} \tag{3.7}$$

Moreover denote by

$$I^a(t) = \{i \in I \mid \theta^i(x_0(t), u_0(t)) = 0\}, \qquad J^a(t) = \{j \in J \mid \vartheta^j(x_0(t)) = 0\}$$

the sets of indices of active constraints.

For $\alpha \geq 0$ we introduce the sets

$$\begin{aligned} \Psi^i_\alpha &:= \left\{t \in [0,T] \mid \theta^i(x_0(t), u_0(t)) < -\alpha\right\}, \quad i = 1, ..., k, \\ \Omega^j_\alpha &:= \left\{t \in [0,T] \mid \vartheta^j(x_0(t)) < -\alpha\right\}, \quad j = 1, ..., l, \end{aligned} \tag{3.8}$$

and define the following functions

$$\psi^i_\alpha(t) = \begin{cases} \theta^i(x_0(t), u_0(t)) + \alpha & \text{if} \quad t \in \Psi^i_\alpha, \\ 0 & \text{if} \quad t \notin \Psi^i_\alpha \end{cases} \tag{3.9}$$

and

$$\omega^j_\alpha(t) = \begin{cases} \vartheta^j(x_0(t)) + \alpha & \text{if} \quad t \in \Omega^j_\alpha, \\ 0 & \text{if} \quad t \notin \Omega^j_\alpha. \end{cases} \tag{3.10}$$

We introduce the $(k \times k)$ and $(l \times\ l)$ diagonal matrices

$$U_\alpha(t) = \operatorname{diag} \psi^i_\alpha(t), \qquad T_\alpha(t) = \operatorname{diag} \omega^j_\alpha(t) \tag{3.11}$$

and define $(k+l) \times (m+k+l)$ matrices

$$V_\alpha(t) = \begin{bmatrix} \Theta_u(t) & U_\alpha(t) & 0 \\ \Upsilon(t)B(t) & 0 & T_\alpha(t) \end{bmatrix}. \tag{3.12}$$

Let us choose any $\alpha \geq 0$ and define the subspace $M^\alpha \subset Y$ by

$$M^\alpha = M^\alpha_1 \times M^\alpha_2 \times M^\alpha_3 \times M^\alpha_4, \tag{3.13}$$

where

$$\begin{aligned} &M^\alpha_1 = 0, \qquad M^\alpha_2 = 0, \\ &M^\alpha_3 = \left\{u \in L^\infty(0,T;\mathbb{R}^k) \mid u^i(t) = 0 \text{ for all } t \in [0,T] \setminus \Psi^i_\alpha, \quad i = 1, ..., k\right\}, \\ &M^\alpha_4 = \left\{x \in W^{1,\infty}(0,T;\mathbb{R}^l) \mid x^j(t) = 0 \text{ for all } t \in [0,T] \setminus \Omega^j_\alpha, \quad j = 1, ..., l\right\}. \end{aligned}$$

It is easy to see that for any $\alpha > 0$, $M^\alpha \subset M_0$, where M_0 is defined in (2.4). Moreover, if we choose as $\mathcal{Y}^\alpha_0 \subset Y$ the open ball of radius $\alpha/2$ about $y_0 = \varphi(z_0)$, then (2.6) is satisfied.

Define the mapping $\Pi^\alpha := (\Pi^\alpha_1, \Pi^\alpha_2, \Pi^\alpha_3, \Pi^\alpha_4) : Y \mapsto M^\alpha$ by

$$\begin{aligned} &\Pi^\alpha_1 = 0, && \Pi^\alpha_2 = 0, \\ &(\Pi^\alpha_3 y)(t) = U_\alpha(t) y(t), && (\Pi^\alpha_4 y)(t) = T_\alpha(t) y(t). \end{aligned} \tag{3.14}$$

Condition (I.2) will be fully satisfied if we are able to show that there exists $\alpha > 0$ such that for $\Pi := \Pi^\alpha$ surjectivity conditions (2.5) hold. We assume that

(II.3) there exists $\beta > 0$ such that

$$|V_0(t) V_0(t)^* \chi| \geq \beta |\chi| \tag{3.15}$$

for all $\chi \in \mathbb{R}^{k+l}$ and all $t \in [0,T]$.

(II.4) For any $\widetilde{q} \in \mathbb{R}^{d+l}$ an element $(\eta, \upsilon) \in W^{1,\infty}(0,T;\mathbb{R}^{n+l}) \times L^{\infty}(0,T;\mathbb{R}^{m+k+l})$ exists such that the following equations hold (the complete controllability condition is satisfied):

$$\begin{aligned} &\dot{\eta}(t) - \widetilde{A}(t)\eta(t) - \widetilde{B}(t)\upsilon(t) = 0, \\ &\widetilde{P}_0\eta(0) + \widetilde{P}_T\eta(T) = \widetilde{q}, \end{aligned} \tag{3.16}$$

where

$$\widetilde{A}(t) = \begin{bmatrix} \widetilde{A}_{11}(t) & \widetilde{A}_{12}(t) \\ \widetilde{A}_{21}(t) & \widetilde{A}_{22}(t) \end{bmatrix},$$

$$\widetilde{A}_{11}(t) = A(t) - B(t) \begin{bmatrix} \Theta_u(t)^* & B(t)^*\Upsilon(t)^* \end{bmatrix} [V_0(t)V_0(t)^*]^{-1} \times \begin{bmatrix} \Theta_x(t) \\ \Upsilon(t)A(t) + \dot{\Upsilon}(t) \end{bmatrix},$$

$$\widetilde{A}_{12}(t) = -B(t) \begin{bmatrix} \Theta_u(t)^* & B(t)^*\Upsilon(t)^* \end{bmatrix} [V_0(t)V_0(t)^*]^{-1} \begin{bmatrix} 0 \\ \dot{T}_0(t) \end{bmatrix},$$

$$\widetilde{A}_{21}(t) = \begin{bmatrix} 0 & T_0(t)^* \end{bmatrix} [V_0(t)V_0(t)^*]^{-1} \begin{bmatrix} \Theta_x(t) \\ \Upsilon(t)A(t) + \dot{\Upsilon}(t) \end{bmatrix},$$

$$\widetilde{A}_{22}(t) = \begin{bmatrix} 0 & T_0(t)^* \end{bmatrix} [V_0(t)V_0(t)^*]^{-1} \begin{bmatrix} 0 \\ \dot{T}_0(t) \end{bmatrix},$$

$$\widetilde{B}(t) = \begin{bmatrix} B(t) & 0 & 0 \\ 0 & 0 & I \end{bmatrix} - \begin{bmatrix} B(t)\Theta_u(t)^* & B(t)B(t)^*\Upsilon(t)^* \\ 0 & T_0(t)^* \end{bmatrix} \times [V_0(t)V_0(t)^*]^{-1} V_0(t),$$

$$\widetilde{P}_0 = \begin{bmatrix} \Xi_0 & 0 \\ \Upsilon(0) & T_0(0) \end{bmatrix}, \qquad \widetilde{P}_T = \begin{bmatrix} \Xi_T & 0 \\ 0 & 0 \end{bmatrix}.$$

Remark 3.1. Condition (II.3) means that all gradients $D_u\theta^i(x_0(t), u_0(t))$, $i \in I^a(t)$, of the active mixed constraints and all gradients $D_x\vartheta^j(x_0(t))$, $j \in J^a(t)$, of the active state constraints, transformed into the space $\mathbb{R}^m$ by means of the mapping $B^*(t) : \mathbb{R}^n \mapsto \mathbb{R}^m$, are jointly linearly independent, uniformly on $[0,T]$. This condition implies that we restrict ourselves to the *first-order* state constraints (cf. [6]).

Remark 3.2. By a standard argument we find that system (3.16) is completely controllable if and only if the following rank condition is satisfied:

$$\operatorname{rank}\left\{ [\widetilde{P}_0 + \widetilde{P}_T\Phi(T)][\widetilde{P}_0 + \widetilde{P}_T\Phi(T)]^* + \int_0^T G(t)G(t)^* dt \right\} = d + l, \tag{3.17}$$

where Φ is the solution of the homogeneous matrix equation

$$\dot{\Phi}(t) = \widetilde{A}(t)\Phi(t), \qquad \Phi(0) = I,$$

and $G(t) = \widetilde{P}_T\Phi(T)\Phi(t)^{-1}\widetilde{B}(t)$.

LEMMA 3.3. *If assumptions* (II.3) *and* (II.4) *are satisfied, then there exists* $\alpha > 0$ *such that the mapping* $\Pi := \Pi_\alpha$ *defined by* (3.14) *satisfies conditions* (I.2).

Proof. Condition (2.6) is satisfied by construction of Π_α, so it remains to check (2.5). We will prove the first equation in (2.5). The proof of the second one is the same.

We have to show that there exist $\alpha > 0$ such that, for any

$$\begin{aligned} &p \in L^\infty(0,T;\mathbb{R}^n), && q \in \mathbb{R}^d, \\ &r \in L^\infty(0,T;\mathbb{R}^k), && s \in W^{1,\infty}(0,T;\mathbb{R}^l), \end{aligned}$$

there exists a solution

$$\begin{aligned} &\sigma \in L^\infty(0,T;\mathbb{R}^m), && \zeta \in W^{1,\infty}(0,T;\mathbb{R}^n), \\ &\rho \in L^\infty(0,T;\mathbb{R}^k), && \tau \in W^{1,\infty}(0,T;\mathbb{R}^l) \end{aligned}$$

of the following system of equations:

$$\dot\zeta(t) - A(t)\zeta(t) - B(t)\sigma(t) = p(t), \tag{3.18}$$

$$\Xi_0\zeta(0) + \Xi_T\zeta(T) = q, \tag{3.19}$$

$$\Theta_x(t)\zeta(t) + \Theta_u(t)\sigma(t) + U_\alpha(t)\rho(t) = r(t), \tag{3.20}$$

$$\Upsilon(t)\zeta(t) + T_\alpha(t)\tau(t) = s(t). \tag{3.21}$$

First we will show that (3.18)–(3.21) have a solution for $\alpha = 0$. From the proof it will follow that it also has a solution for a sufficiently small $\alpha > 0$.

Note that (3.21) is equivalent to

$$\Upsilon(0)\zeta(0) + T_0\tau(0) = s(0), \tag{3.22}$$

$$\dot\Upsilon(t)\zeta(t) + \Upsilon(t)\dot\zeta(t) + \dot T_0(t)\tau(t) + T_0(t)\dot\tau(t) = \dot s(t). \tag{3.23}$$

Multiplying (3.18) by $\Upsilon(t)$ and using (3.23) we obtain

$$\begin{aligned} &\Upsilon(t)B(t)\sigma(t) + T_0(t)\dot\tau(t) \\ &\qquad = (\dot s(t) - \Upsilon(t)p(t)) - (\Upsilon(t)A(t) + \dot\Upsilon(t))\zeta(t) - \dot T_0(t)\tau(t). \end{aligned} \tag{3.24}$$

Combining (3.20) and (3.24) yields

$$\begin{aligned} &V_0 \begin{bmatrix} \sigma(t) \\ \rho(t) \\ \dot\tau(t) \end{bmatrix} := \begin{bmatrix} \Theta_u(t)\sigma(t) + U_0(t)\rho(t) \\ \Upsilon(t)B(t)\sigma(t) + T_0(t)\dot\tau(t) \end{bmatrix} \\ &= \begin{bmatrix} r(t) - \Theta_x(t)\zeta(t) \\ (\dot s(t) - \Upsilon(t)p(t)) - (\Upsilon(t)A(t) + \dot\Upsilon(t))\zeta(t) - \dot T_0(t)\tau(t) \end{bmatrix}. \end{aligned} \tag{3.25}$$

By (II.3), any solution of (3.25) can be expressed in the form

$$\begin{aligned} &\begin{bmatrix} \sigma(t) \\ \rho(t) \\ \dot\tau(t) \end{bmatrix} = V_0(t)^*[V_0(t)V_0(t)^*]^{-1} \\ &\times \begin{bmatrix} r(t) - \Theta_x(t)\zeta(t) \\ (\dot s(t) - \Upsilon(t)p(t)) - (\Upsilon(t)A(t) + \dot\Upsilon(t))\zeta(t) - \dot T_0(t)\tau(t) \end{bmatrix} \\ &+ \big(I - V_0(t)^*[V_0(t)V_0(t)^*]^{-1}V_0(t)\big)\,\upsilon(t), \end{aligned} \tag{3.26}$$

where $\upsilon(t) \in \mathbb{R}^{m+k+l}$ is an arbitrary vector.

Combining (3.18) with the first and the third row of (3.26) we obtain

$$\begin{bmatrix} \dot\zeta(t) \\ \dot\tau(t) \end{bmatrix} - \begin{bmatrix} \widetilde A_{11}(t) & \widetilde A_{12}(t) \\ \widetilde A_{21}(t) & \widetilde A_{22}(t) \end{bmatrix} \begin{bmatrix} \zeta(t) \\ \tau(t) \end{bmatrix} - \begin{bmatrix} \widetilde B_1(t) \\ \widetilde B_2(t) \end{bmatrix} \upsilon(t) = \begin{bmatrix} \widetilde C_1(t) \\ \widetilde C_2(t) \end{bmatrix}, \tag{3.27}$$

where $\widetilde A_{ij}$ and $\widetilde B(t) = \left[\begin{smallmatrix} \widetilde B_1(t) \\ \widetilde B_2(t) \end{smallmatrix}\right]$ are given in (3.16) and

$$\begin{bmatrix} \widetilde C_1(t) \\ \widetilde C_2(t) \end{bmatrix} = \begin{bmatrix} B(t)\Theta_u(t)^* & B(t)B(t)^*\Upsilon(t)^* \\ 0 & T_0(t)^* \end{bmatrix} \times [V_0(t)V_0(t)^*]^{-1} \begin{bmatrix} r(t) \\ \dot s(t) - \Upsilon(t)p(t) \end{bmatrix} + \begin{bmatrix} p(t) \\ 0 \end{bmatrix}.$$

On the other hand from (3.19) and (3.22) we obtain

$$\widetilde P_0 \begin{bmatrix} \zeta(0) \\ \tau(0) \end{bmatrix} + \widetilde P_T \begin{bmatrix} \zeta(T) \\ \tau(T) \end{bmatrix} = \begin{bmatrix} q \\ s(0) \end{bmatrix}. \tag{3.28}$$

It is easy to see that for any (p, q, r, s) there exists a control function υ as well as functions ζ and τ such that (3.27) along with (3.28) is satisfied if and only if (II.4) holds. Having (ζ, τ, υ) we find σ and ρ from the first two rows of (3.26).

Thus, we have proved that (3.18)–(3.21) are satisfied for $\alpha = 0$. Now we will briefly show that these equations are also satisfied for sufficiently small $\alpha > 0$.

By (II.2), (II.3), and slight modification of Lemma 7.2 in [12], we find that for $\alpha > 0$ sufficiently small

$$|V_\alpha(t)V_\alpha(t)^*\chi| \ge \frac{1}{2}\beta|\chi|$$

for all $\chi \in \mathbb{R}^{k+l}$ and all $t \in [0, T]$.

Hence we can repeat the above argument with 0 substituted by $\alpha > 0$ to obtain (3.27) and (3.28), where all data are functions of α. The matrix on the left-hand side of (3.17) becomes a continuous function of α, so shrinking α, if necessary, we find that the rank condition is satisfied. This completes the proof of the lemma. □

Remark 3.4. Note that Lemma 3.3 assures that conditions (II.3) and (II.4), originally assumed at $\alpha = 0$, actually are satisfied with some "margin of freedom" $\alpha > 0$. This result was proven using the assumption (II.2) of piecewise continuity of u_0. It allows us to verify the abstract assumption (I.2), and in section 5 it will play a crucial role in stability analysis.

4. SSC for optimal control problems. This section is devoted to deriving SSC.

Let us introduce the following Lagrangian associated with (O):

$$\begin{aligned} &\mathcal{L} : W^{1,\infty}(0,T;\mathbb{R}^n) \times L^\infty(0,T;\mathbb{R}^m) \times (L^\infty(0,T;\mathbb{R}^n))^* \times \mathbb{R}^d \\ &\qquad \times \left(L^\infty(0,T;\mathbb{R}^k)\right)^* \times \left(W^{1,\infty}(0,T;\mathbb{R}^l)\right)^* \mapsto \mathbb{R}^1, \\ &\mathcal{L}(x,u,q,\rho,\kappa,\mu) = F(x,u) + (q, \dot x - f(x,u)) + \langle \rho, \xi(x(0),x(T))\rangle \\ &\qquad\qquad + (\kappa, \theta(x,u)) + \langle \mu(0), \vartheta(x(0))\rangle + (\dot\mu, D_x\vartheta(x)f(x,u)). \end{aligned} \tag{4.1}$$

Note that the Lagrangian is in the so-called *Pontryagin form* with absolutely continuous adjoint function q (cf. section 7 in [6] as well as [5] and [19]). The state constraints are considered in $W^{1,\infty}(0,T;\mathbb{R}^l)$, where the general form of a linear functional is given by $\langle \mu(0), y(0)\rangle + (\dot\mu, \dot y)$. Accordingly, the terms of Lagrangian (4.1) corresponding to the state constraints (3.5) are obtained as follows:

$$\begin{aligned}\langle \mu(0), \vartheta(x(0))\rangle + \left(\dot\mu_0, \frac{d}{dt}\vartheta(x)\right) &= \langle \mu(0), \vartheta(x(0))\rangle + (\dot\mu_0, D_x\vartheta(x)\dot x)\\ &= \langle \mu(0), \vartheta(x(0))\rangle + (\dot\mu_0, D_x\vartheta(x)f(x,u)).\end{aligned}$$

As in (I.3) we assume that

(II.5) there exist Lagrange multipliers $(q_0, \rho_0, \kappa_0, \mu_0) \in Y^*$ associated with (x_0, u_0) such that the following Kuhn–Tucker conditions are satisfied:

$$D_x\mathcal{L}(x_0, u_0, q_0, \kappa_0, \rho_0, \mu_0) = 0, \tag{4.2}$$

$$D_u\mathcal{L}(x_0, u_0, q_0, \kappa_0, \rho_0, \mu_0) = 0, \tag{4.3}$$

$$(\kappa_0, \theta(x_0, u_0)) = 0, \quad \kappa_0 \in K_3^+, \tag{4.4}$$

$$\langle \mu_0(0), \vartheta(x_0(0))\rangle + (\dot\mu_0, D_x\vartheta(x_0)f(x_0, u_0)) = 0, \quad \mu_0 \in K_4^+. \tag{4.5}$$

By Lemma 3.3 the multipliers $(q_0, \rho_0, \kappa_0, \mu_0)$ are defined uniquely and belong to $\widehat Y$.

Recall (cf. [21]) that

$$\begin{aligned}\widehat K_4^+ = \{\mu \in W^{1,2}(0,T:\mathbb{R}^n) \mid \mu^j(t) \ge 0, \dot\mu^j(t) \text{ is nonincreasing}\\ \text{and } 0 \le \dot\mu^j(t) \le \mu^j(t), \quad j \in J\}.\end{aligned} \tag{4.6}$$

Let us introduce the following augmented Hamiltonian:

$$\begin{aligned}\mathcal{H}(t) = f^0(x_0(t), u_0(t)) - \langle q_0(t), f(x_0(t), u_0(t))\rangle\\ +\langle \kappa_0(t), \theta(x_0(t), u_0(t))\rangle + \langle \dot\mu_0(t), D_x\vartheta(x_0(t))f(x_0(t), u_0(t))\rangle.\end{aligned} \tag{4.7}$$

Condition (4.2) takes on the form of the adjoint equation

$$\dot q_0(t) - D_x\mathcal{H}(t) = 0,$$

along with the boundary conditions

$$-q_0(0) + D_{x(0)}\xi(x_0(0), x_0(T))^*\rho_0 + D_x\vartheta(x_0(0))^*\mu_0(0) = 0,$$

$$q_0(T) + D_{x(T)}\xi(x_0(0), x_0(T))^*\rho_0 + D_x g(x_0(T)) = 0,$$

while (4.3) can be expressed as

$$D_u\mathcal{H}(t) = 0 \qquad \text{for a.a. } t \in [0,T].$$

The Hessian of Lagrangian (4.1), evaluated at the reference point, can be expressed in terms of Hamiltonian (4.7) as follows:

$$\begin{aligned}&\left((y,v), \begin{pmatrix} D^2_{xx}\mathcal{L}_0 & D^2_{xu}\mathcal{L}_0 \\ D^2_{ux}\mathcal{L}_0 & D^2_{uu}\mathcal{L}_0 \end{pmatrix}(y,v)\right)\\ &\quad = \int_0^T \begin{bmatrix} y(t) \\ v(t) \end{bmatrix}^* \begin{bmatrix} D^2_{xx}\mathcal{H}(t) & D^2_{xu}\mathcal{H}(t) \\ D^2_{ux}\mathcal{H}(t) & D^2_{uu}\mathcal{H}(t) \end{bmatrix} \begin{bmatrix} y(t) \\ v(t) \end{bmatrix} dt\\ &\qquad + \begin{bmatrix} y(0) \\ y(T) \end{bmatrix}^* \begin{bmatrix} \mathcal{R}_{11} & \mathcal{R}_{12} \\ \mathcal{R}_{21} & \mathcal{R}_{22} \end{bmatrix} \begin{bmatrix} y(0) \\ y(T) \end{bmatrix},\end{aligned} \tag{4.8}$$

where $\mathcal{L}_0 := \mathcal{L}(x_0, u_0, q_0, \rho_0, \kappa_0, \mu_0)$ and

$$\mathcal{R}_{11} = D^2_{x(0)x(0)}\xi(x_0(0), x_0(T))\rho_0 + D^2_{xx}\vartheta(x_0(0))^*\mu_0(0),$$
$$\mathcal{R}_{12} = \mathcal{R}^*_{21} = D^2_{x(0)x(T)}\xi(x_0(0), x_0(T))\rho_0,$$
$$\mathcal{R}_{22} = D^2_{x(T)x(T)}\xi(x_0(0), x_0(T))\rho_0 + D^2_{xx}g(x_0(T)).$$

We have to show that (4.8) is positive definite on the subspace defined in (I.5). We are going to construct this subspace. To this end we need several technical results. Let us start with the discussion of the regularity of primal and dual optimal variables. Using the same argument as in [5] we obtain the following regularity of the multipliers.

LEMMA 4.1. *If* (II.1)–(II.5) *are satisfied, then* $\dot q_0, \kappa_0$, *and* $\dot\mu_0$ *are continuous and uniformly bounded on all subintervals* $(t_k, t_{k+1}) \subset [0, T]$.

Assume that the following modified Legendre–Clebsch condition is satisfied:

$$\langle u, D^2_{uu}\mathcal{H}(t)u\rangle \geq \gamma|u|^2, \qquad \gamma > 0, \tag{4.9}$$

for all

$$u \in \{u \in \mathbb{R}^m \quad |\langle D_u\theta^i(x_0(t), u_0(t), h_0), u\rangle = 0 \qquad \text{for all } i \in I^0(t),$$
$$\langle D_x\vartheta^j(x_0(t), h_0)D_uf(x_0(t), u_0(t), h_0), u\rangle = 0 \quad \text{for all } j \in J^0(t)\}$$

and for all $t \in [0, T]$.

Using the same argument as in [5] (cf. also [13]) we obtain the following regularity result.

LEMMA 4.2. *If* (II.1)–(II.5) *and* (4.9) *are satisfied, then* $(u_0, \dot q_0, \kappa_0, \dot\mu_0)$ *are uniformly Lipschitz continuous functions on all subintervals* $(t_k, t_{k+1}) \subset [0, T]$.

Note that strict complementarity condition for state constraints at some t amounts to $-\ddot\mu_0(t) > 0$. In order to construct the subspace N needed in (I.5) we introduce the sets of indices $I^+_\alpha(t)$ and $J^+_\alpha(t)$ of those constraints active at t for which strict complementarity condition is satisfied with the margin $\alpha \geq 0$:

$$I^+_\alpha(t) = \{i \in I^a(t) \mid \kappa^i_0(t) > \alpha\}, \quad J^+_\alpha(t) = \{j \in J^a(t) \mid -\ddot\mu^j_0(t) > \alpha\}. \tag{4.10}$$

Let us define the following subspaces of $\mathbb{R}^m$:

$$\begin{aligned}
&\mathcal{D}_\alpha(t) = \{u \in \mathbb{R}^m \mid \langle D_u\theta^i(x_0(t), u_0(t)), u\rangle = 0 \quad \text{for } i \in I^+_\alpha(t)\},\\
&\mathcal{E}_\alpha(t) = \{u \in \mathbb{R}^m \mid \langle D_x\vartheta^j(x_0(t))D_uf(x_0(t), u_0(t)), u\rangle = 0\\
&\qquad\qquad \text{for } j \in J^+_\alpha(t)\},\\
&\mathcal{G}_\alpha(t) = \mathcal{D}_\alpha(t) \cap \mathcal{E}_\alpha(t).
\end{aligned} \tag{4.11}$$

Now we are in a position to introduce subspace N needed in (I.5). We put

$$\begin{aligned}
&N = N_1 \times N_2 \times N_3 \times N_4,\\
&N_1 = L^\infty(0, T; \mathbb{R}^n), \qquad N_2 = \mathbb{R}^d,\\
&N_3 = \{\theta \in L^\infty(0, T; \mathbb{R}^k) \mid \theta^i(t) = 0 \ \text{ for } i \notin I^+_\alpha(t)\},\\
&N_4 = \{\mu \in W^{2,\infty}(t_k, t_{k+1}; \mathbb{R}^l) \mid \ddot\mu^j(t) = 0 \ \text{ for } j \notin J^+_\alpha(t)\},
\end{aligned} \tag{4.12}$$

where $\alpha > 0$, and $W^{2,\infty}(t_k, t_{k+1}; \mathbb{R}^l)$ is the space of absolutely continuous functions that are of class $W^{2,\infty}$ on each subinterval (t_k, t_{k+1}), supplied with the norm

$$\|x\|_{2,\infty} = \max\{|x(0)|, |\dot x(0)|, |\dot x(t_k)|, \|\ddot x\|_\infty\}.$$

The subspace N defined in (4.12) does not fully correspond to that defined in (I.5), since N_4 is a closed subspace in $W^{2,\infty}(t_k, t_{k+1}; \mathbb{R}^l)$ rather than in $W^{1,\infty}(0, T; \mathbb{R}^l)$. Accordingly, Λ_0 in (2.13) is the ball of radius $\alpha/2$ in the space

$$\widetilde{Y} = L^\infty(0, T; \mathbb{R}^n) \times \mathbb{R}^d \times L^\infty(0, T; \mathbb{R}^k) \times W^{2,\infty}(t_k, t_{k+1}; \mathbb{R}^l).$$

Note that for $j \in J_0^+(t)$ we have

$$\frac{d}{dt}\vartheta^j(x_0(t)) = D_x\vartheta^j(x_0(t))\dot{x}_0(t) = D_x\vartheta^j(x_0(t))f(x_0(t), u_0(t)) = 0. \tag{4.13}$$

Hence we can use the mixed constraints (4.13), rather than the pure state constraints (3.5), to define the subspace E_0 in (2.12). Namely E_0 is defined as the set of all pairs $(y, v) \in W^{1,2}(0, T; \mathbb{R}^n) \times L^2(0, T; \mathbb{R}^m)$ such that

$$\dot{y}(t) - A(t)y(t) - B(t)v(t) = 0, \tag{4.14}$$

$$\Xi_0 y(0) + \Xi_T y(T) = 0, \tag{4.15}$$

$$\Theta_x^\alpha(t)y(t) + \Theta_u^\alpha(t)v(t) = 0, \tag{4.16}$$

$$C^\alpha(t)y(t) + \Upsilon^\alpha(t)B(t)v(t) = 0, \tag{4.17}$$

where $\Theta_x^\alpha(t)$ (respectively, $\Theta_u^\alpha(t)$) is the matrix whose rows are the functions $D_x\theta^i(x_0(t), u_0(t))$ (respectively, $D_u\theta^i(x_0(t), u_0(t))$) for $i \in I_\alpha^+(t)$. The rows of matrices $C^\alpha(t)$ and $\Upsilon^\alpha(t)$ are given by

$$C^j(t) = D_{xx}^2\vartheta^j(x_0(t))f(x_0(t), u_0(t)) + D_x\vartheta^j(x_0(t))D_x f(x_0(t), u_0(t))$$

and $D_x\vartheta^j(x_0(t))$, respectively, for $j \in J_\alpha^+(t)$.

We have to find conditions under which the quadratic form (4.8) is positive definite on the subspace of pairs satisfying (4.14)–(4.17).

We will need a coercivity condition stronger than (4.9), satisfied with some "margin of freedom." Namely, we assume that

(II.6) there exists a constant $\bar{\alpha} > 0$ such that

$$\langle u, D_{uu}^2\mathcal{H}(t)u\rangle \geq \gamma|u|^2 \quad \text{for all } u \in \mathcal{G}_{\bar{\alpha}}(t) \text{ and all } t \in [0, T]. \tag{4.18}$$

Remark 4.3. We are not going to discuss here conditions under which (4.18) satisfied for $\bar{\alpha} = 0$ is satisfied also for some $\bar{\alpha} > 0$. The reader can find such a discussion in section 4 of [2].

For any $\alpha > 0$, let us define the matrix

$$\mathcal{K}^\alpha(t) = \begin{bmatrix} D_{uu}^2\mathcal{H}(t) & \Theta_u^\alpha(t)^* & B(t)^*\Upsilon^\alpha(t)^* \\ \Theta_u^\alpha(t) & 0 & 0 \\ \Upsilon^\alpha(t)B(t) & 0 & 0 \end{bmatrix}. \tag{4.19}$$

By (II.3) matrix $[\ \Theta_u^\alpha(t)^* \quad B(t)^*\Upsilon^\alpha(t)^*\ ]$ has the full row rank, whereas by (II.6) matrix $D_{uu}^2\mathcal{H}(t)$ is positive definite on the subspace generated by the columns of $[\ \Theta_u^\alpha(t)^* \quad B(t)^*\Upsilon^\alpha(t)^*\ ]$ for any $\alpha \leq \bar{\alpha}$. Hence for any $\alpha \leq \bar{\alpha}$, matrix $\mathcal{K}^\alpha(t)$ is non-singular (cf., e.g., Lemma 3.2 in [5]).

Let us introduce the following *matrix Riccati equation* for a symmetric $(n \times n)$-matrix function Q (cf. [15]):

$$\begin{aligned}\dot{Q}(t) = R^{\bar\alpha}(Q(t)) := &-Q(t)A(t) - A(t)^*Q(t) - D^2_{xx}\mathcal{H}(t)\\ &+\left\{\begin{bmatrix} D^2_{ux}\mathcal{H}(t)\\ \Theta^{\bar\alpha}_x(t)\\ C^{\bar\alpha}(t)\end{bmatrix}^* + Q(t)\begin{bmatrix} B(t)^*\\ 0\\ 0\end{bmatrix}^*\right\}\\ &\times \mathcal{K}^{\bar\alpha}(t)^{-1}\left\{\begin{bmatrix} B(t)^*\\ 0\\ 0\end{bmatrix}Q(t) + \begin{bmatrix} D^2_{ux}\mathcal{H}(t)\\ \Theta^{\bar\alpha}_x(t)\\ C^{\bar\alpha}(t)\end{bmatrix}\right\}.\end{aligned} \tag{4.20}$$

The following assumption is crucial for obtaining coercivity of (4.8).

(II.7) The Riccati equation (4.20) has a solution Q bounded on $[0,T]$, which satisfies the following boundary condition:

$$\begin{aligned}&\begin{bmatrix} y(0)\\ y(T)\end{bmatrix}^*\begin{bmatrix} \mathcal{R}_{11}+Q(0) & \mathcal{R}_{12}\\ \mathcal{R}_{21} & \mathcal{R}_{22}-Q(T)\end{bmatrix}\begin{bmatrix} y(0)\\ y(T)\end{bmatrix} > 0\\ &\text{for all } (y(0),y(T)) \text{ such that } \Xi_0 y(0) + \Xi_T y(T) = 0.\end{aligned} \tag{4.21}$$

LEMMA 4.4. *If* (II.1)–(II.7) *are satisfied, then there exists* $\bar\gamma > 0$ *such that*

$$\left((y,v), \begin{pmatrix} D^2_{xx}\mathcal{L}_0 & D^2_{xu}\mathcal{L}_0\\ D^2_{ux}\mathcal{L}_0 & D^2_{uu}\mathcal{L}_0\end{pmatrix}(y,v)\right) \ge \bar\gamma(\|y\|^2_2 + \|v\|^2_2) \tag{4.22}$$

for all (y,v) *satisfying* (4.14)–(4.17) *with* $\alpha = \bar\alpha$.

Proof. We will follow the idea of the proof of Lemma 4.2 in [15].

Let $Q : [0,T] \mapsto \mathbb{R}^{n\times n}$ be any Lipschitz continuous symmetric matrix function. By a direct computation, using integration by parts, we find that for any pair (y,v) satisfying (4.14) we have

$$\begin{aligned}&\int_0^T \begin{bmatrix} y(t)\\ v(t)\end{bmatrix}^*\begin{bmatrix} D^2_{xx}\mathcal{H}(t) & D^2_{xu}\mathcal{H}(t)\\ D^2_{ux}\mathcal{H}(t) & D^2_{uu}\mathcal{H}(t)\end{bmatrix}\begin{bmatrix} y(t)\\ v(t)\end{bmatrix} dt\\ &= \int_0^T \begin{bmatrix} y(t)\\ v(t)\end{bmatrix}^*\\ &\times \begin{bmatrix} \dot{Q}(t) + Q(t)A(t) + A(t)^*Q(t) + D^2_{xx}\mathcal{H}(t) & D^2_{xu}\mathcal{H}(t) + Q(t)B(t)\\ D^2_{ux}\mathcal{H}(t) + B(t)^*Q(t) & D^2_{uu}\mathcal{H}(t)\end{bmatrix}\\ &\times \begin{bmatrix} y(t)\\ v(t)\end{bmatrix} dt + y(0)^*Q(0)y(0) - y(T)^*Q(T)y(T).\end{aligned}$$

Hence, using (4.8) we obtain

$$
\begin{aligned}
&\left((y,v),\begin{pmatrix} D^2_{xx}\mathcal{L}_0 & D^2_{xu}\mathcal{L}_0 \\ D^2_{ux}\mathcal{L}_0 & D^2_{uu}\mathcal{L}_0 \end{pmatrix}(y,v)\right) \\
&= \int_0^T \begin{bmatrix} y(t) \\ v(t) \end{bmatrix}^* \\
&\times \begin{bmatrix} \dot{Q}(t)+Q(t)A(t)+A(t)^*Q(t)+D^2_{xx}\mathcal{H}(t) & D^2_{xu}\mathcal{H}(t)+Q(t)B(t) \\ D^2_{ux}\mathcal{H}(t)+B(t)^*Q(t) & D^2_{uu}\mathcal{H}(t) \end{bmatrix} \\
&\times \begin{bmatrix} y(t) \\ v(t) \end{bmatrix} dt + \begin{bmatrix} y(0) \\ y(T) \end{bmatrix}^* \begin{bmatrix} \mathcal{R}_{11}+Q(0) & \mathcal{R}_{12} \\ \mathcal{R}_{21} & \mathcal{R}_{22}-Q(T) \end{bmatrix} \begin{bmatrix} y(0) \\ y(T) \end{bmatrix},
\end{aligned}
\tag{4.23}
$$

and if Q is such that (4.21) is satisfied, then to show (4.22) it is enough to prove that the integral term in (4.23) is coercive for (y,v) satisfying (4.14)–(4.17).

To this end, let us introduce slack variables $w \in \mathbb{R}^{i(t)}$ and $z \in \mathbb{R}^{j(t)}$, where $i(t) = \operatorname{card} I^+_{\bar\alpha}(t), j(t) = \operatorname{card} J^+_{\bar\alpha}(t)$. Define the following quadratic form, which is the augmented integrant in (4.23):

$$
\begin{aligned}
&\begin{bmatrix} y \\ v \\ w \\ z \end{bmatrix}^* \mathcal{P}^{\bar\alpha}(t) \begin{bmatrix} y \\ v \\ w \\ z \end{bmatrix} \\
&= \begin{bmatrix} y \\ v \end{bmatrix}^* \begin{bmatrix} \dot{Q}(t)+Q(t)A(t)+A(t)^*Q(t)+D^2_{xx}\mathcal{H}(t) & D^2_{xu}\mathcal{H}(t)+Q(t)B(t) \\ D^2_{ux}\mathcal{H}(t)+B(t)^*Q(t) & D^2_{uu}\mathcal{H}(t) \end{bmatrix} \\
&\times \begin{bmatrix} y \\ v \end{bmatrix} + 2w^*[\Theta^{\bar\alpha}_x(t)y + \Theta^{\bar\alpha}_u(t)v] + 2z^*[C^{\bar\alpha}(t)y + \Upsilon^{\bar\alpha}(t)B(t)v)],
\end{aligned}
\tag{4.24}
$$

where $\mathcal{P}^{\bar\alpha}(t)$ is $(n+m+i(t)+j(t))$-dimensional square matrix given by

$$
\mathcal{P}^{\bar\alpha}(t) = \begin{bmatrix} \mathcal{M}(t) & \mathcal{N}^{\bar\alpha}(t)^* \\ \mathcal{N}^{\bar\alpha}(t) & \mathcal{K}^{\bar\alpha}(t) \end{bmatrix},
$$

with

$$
\mathcal{M}(t) = \dot{Q}(t) + Q(t)A(t) + A(t)^*Q(t) + D^2_{xx}\mathcal{H}(t),
$$

$$
\mathcal{N}^{\bar\alpha}(t) = \begin{bmatrix} B(t)^* \\ 0 \\ 0 \end{bmatrix} Q(t) + \begin{bmatrix} D^2_{ux}\mathcal{H}(t) \\ \Theta^{\bar\alpha}_x(t) \\ C^{\bar\alpha}(t) \end{bmatrix}.
$$

Consider the subspace $\mathcal{V}(t) \subset \mathbb{R}^{n+m+i(t)+j(t)}$ on which $\mathcal{P}^{\bar\alpha}(t)$ is *positive definite*. Let $\pi(S)$ denote the number of positive eigenvalues of a symmetric matrix S. By Theorem 1 in [7], it follows that

$$
\pi(\mathcal{P}^{\bar\alpha}(t)) = \pi(\mathcal{K}^{\bar\alpha}(t)) + \pi(\mathcal{M}(t) - \mathcal{N}^{\bar\alpha}(t)^*\mathcal{K}^{\bar\alpha}(t)^{-1}\mathcal{N}^{\bar\alpha}(t)).
$$

If (II.7) holds, then by stability results for ODEs there exist $\epsilon > 0$ and a Lipschitz continuous matrix function $\widetilde{Q}$ such that the Riccati equation

$$
\dot{\widetilde{Q}}(t) = R^{\bar\alpha}(\widetilde{Q}(t)) + \epsilon I_n
$$

is satisfied along with (4.21), where $R^{\bar\alpha}(\cdot)$ is given by the right-hand side of the Riccati equation (4.20). Putting the matrix $\widetilde{Q}(t)$ into (4.24) we obtain

$$\mathcal{M}(t)-\mathcal{N}^{\bar\alpha}(t)^*\mathcal{K}^{\bar\alpha}(t)^{-1}\mathcal{N}^{\bar\alpha}(t)=\epsilon I_n,\ \text{i.e.,}\ \ \pi(\mathcal{M}(t)-\mathcal{N}^{\bar\alpha}(t)^*\mathcal{K}^{\bar\alpha}(t)^{-1}\mathcal{N}^{\bar\alpha}(t))=n.$$

On the other hand, (II.3) and (II.6) yield

$$\pi(\mathcal{K}^{\bar\alpha}(t))\ge m-i(t)-j(t).$$

Hence we get

$$\pi(\mathcal{P}^{\bar\alpha}(t))\ge n+m-i(t)-j(t); \tag{4.25}$$

i.e., there exists a subspace

$$\mathcal{V}(t)\subset\mathbb{R}^{n+m+i(t)+j(t)},\quad \dim\mathcal{V}(t)\ge n+m-i(t)-j(t),$$

which is generated by appropriate eigenvectors of $\mathcal{P}^{\bar\alpha}(t)$, such that the quadratic form (4.24) is positive definite on $\mathcal{V}(t)$. The right-hand side of (4.24) shows that on $\mathcal{V}(t)$ we must have

$$\begin{array}{lll} & \text{either } w^i=0 \ \text{ or } \ \Theta^i_x(t)y+\Theta^i_u(t)v=0 & \text{for all } i\in I^+_{\bar\alpha}(t)\\ \text{and} & \text{either } z^j=0 \ \text{ or } \ C^j(t)y+\Upsilon^j(t)B(t)v)=0 & \text{for all } j\in J^+_{\bar\alpha}(t).\end{array} \tag{4.26}$$

Let $\bar\lambda\ne0$ be any nonzero eigenvalue of $\mathcal{P}^{\bar\alpha}(t)$ and $(\bar y^*,\bar v^*,\bar w^*,\bar z^*)$ be the corresponding eigenvector, i.e.,

$$\mathcal{P}^{\bar\alpha}(t)\begin{bmatrix}\bar y\\ \bar v\\ \bar w\\ \bar z\end{bmatrix}=\bar\lambda\begin{bmatrix}\bar y\\ \bar v\\ \bar w\\ \bar z\end{bmatrix}.$$

By definition of $\mathcal{P}^{\bar\alpha}(t)$, the last $i(t)+j(t)$ rows of this equation take on the form

$$\Theta^{\bar\alpha}_x(t)\bar y+\Theta^{\bar\alpha}_u(t)\bar v=\bar\lambda\bar w,\qquad C^{\bar\alpha}(t)\bar y+\Upsilon^{\bar\alpha}(t)B(t)\bar v=\bar\lambda\bar z.$$

In view of (4.26), it implies

$$\begin{array}{ll}\Theta^{\bar\alpha}_x(t)\bar y+\Theta^{\bar\alpha}_u(t)\bar v=0 & \text{and } \bar w=0,\\ C^{\bar\alpha}(t)\bar y+\Upsilon^{\bar\alpha}(t)B(t)\bar v=0 & \text{and } \bar z=0.\end{array} \tag{4.27}$$

Therefore, all eigenvectors corresponding to nonzero eigenvalues belong to $(n+m-i(t)-j(t))$-dimensional subspace of $(n+m+i(t)+j(t))$-dimensional vectors satisfying (4.27). In view of (4.25), this subspace coincides with $\mathcal{V}(t)$, which means that all $(n+m-i(t)-j(t))$ nonzero eigenvalues $\bar\lambda\ne0$ of $\mathcal{P}^{\bar\alpha}(t)$ are positive. Moreover, since the lower bounds in (II.3) and (II.6) are uniform with respect to $t\in[0,T]$, we can find a uniform on $[0,T]$ lower bound $\bar\gamma>0$ for all positive eigenvalues of $\mathcal{P}^{\bar\alpha}(t)$. Hence, using (4.21), (4.24), and (4.27) we obtain (4.22) from (4.23). □

PROPOSITION 4.5. *If assumptions* (II.1)–(II.7) *hold, then there exist constants* $\rho_1>0$ *and* $\gamma_1>0$ *such that*

$$F(x,u)\ge F(x,u)+\gamma_1(\|x-x_0\|_2^2+\|u-u_0\|_2^2) \tag{4.28}$$

for all (x,u) *satisfying* (3.2)–(3.5) *and such that*

$$\max\{\|x-x_0\|_\infty, \|u-u_0\|_\infty\} \le \rho_1.$$

Proof. We will follow the idea of the proof of Theorem 2.3.

Note that, for feasible (x,u) the components of the term $(\kappa_0, \theta(x,u))$ in Lagrangian (4.1) can be estimated as follows:

$$\begin{aligned} -\int_0^T \kappa_0^i(t)\theta^i(x(t),u(t))dt &\ge -\int_{L_{\bar\alpha}^i} \kappa_0^i(t)\theta^i(x(t),u(t))dt \\ &\ge \bar\alpha \int_{L_{\bar\alpha}^i} |\theta^i(x(t),u(t))|dt, \end{aligned} \tag{4.29}$$

where

$$L_\alpha^i = \{t\in[0,T] \mid i\in I_\alpha^+(t)\} := \{t\in[0,T] \mid \kappa_0^i(t) > \alpha\}.$$

Similarly, by the regularity of μ_0 (cf. Lemma 4.2) and by (4.6), for any feasible (x,u) and for any component of the last two terms in (4.1) we have

$$\begin{aligned} &-\mu_0^j(0)\vartheta^j(x(0)) - \int_0^T \dot\mu_0^j(t) D_x\vartheta^j(x(t))f(x(t)),u(t))dt \\ &= -\mu_0^j(0)\vartheta^j(x(0)) - \int_0^T \dot\mu_0^j(t)\frac{d}{dt}\vartheta^j(x(t))dt \\ &= -(\mu_0^j(0)-\dot\mu_0^j(0))\vartheta^j(x(0)) + \Sigma_k(\dot\mu(t_k+)-\dot\mu(t_{k+1}-))\vartheta(x(t_k) \\ &-\dot\mu_0^j(T)\vartheta^j(x(T)) + \int_0^T \ddot\mu_0^j(t)\vartheta^j(x(t))dt \\ &\ge \int_{P_{\bar\alpha}^j} \ddot\mu_0^j(t)\vartheta^j(x(t))dt \ge \bar\alpha\int_{P_{\bar\alpha}^j} |\vartheta^j(x(t))|dt, \end{aligned} \tag{4.30}$$

where

$$P_\alpha^j = \{t\in[0,T] \mid j\in J_\alpha^+(t)\} := \{t\in[0,T] \mid -\ddot\mu_0^j(t) > \alpha\}.$$

Estimates (4.29) and (4.30) show that condition (A.2) in the proof of Theorem 2.3 is satisfied with the norm of Y^* substituted by that of $L^1(0,T;\mathbb{R}^k)\times L^1(0,T;\mathbb{R}^l)$. Hence, using (4.22) we can repeat the further steps of that proof and arrive at (4.28). □

Note that it follows from (3.2) that for any feasible (x,u) we have

$$\|\dot x-\dot x_0\|_2 \le c(\|x-x_0\|_2 + \|u-u_0\|_2), \qquad \|\dot x-\dot x_0\|_\infty \le c(\|x-x_0\|_\infty + \|u-u_0\|_\infty).$$

Hence, from Proposition 4.5 we obtain the following SSC result for (O).

THEOREM 4.6. *If assumptions* (II.1)–(II.7) *hold, then there exist constants* $\rho>0$ *and* $\gamma>0$ *such that*

$$F(x,u) \ge F(x_0,u_0) + \gamma(\|x-x_0\|_{1,2}^2 + \|u-u_0\|_2^2) \tag{4.31}$$

for all (x,u) *satisfying* (3.2)–(3.5) *and such that*

$$\max\{\|x-x_0\|_{1,\infty}, \|u-u_0\|_\infty\} \le \rho.$$

Remark 4.7 Theorem 4.6 can be viewed as a generalization of the results due to Dontchev et al. [2], Maurer and Pickenhain [17], and Zeidan [30] to the optimal control problems involving pure state-space constraints of order 1. This generalization is not trivial, since it requires the analysis of regularity of the solutions and Lagrange multipliers, which is not needed if these constraints are not present.

Without state-space constraints, Theorem 4.6 reduces to the SSC derived in [30], where a Riccati equation in the form different from but equivalent to (4.20) was used. In case with pure control constraints only, the result stronger than Theorem 4.6 was obtained in [2], but without characterization of the coercivity condition (4.22) by a Riccati equation.

5. Application to stability analysis. In this section the role of second-order sufficient optimality conditions in stability analysis of solutions to parametric optimal control problems is briefly discussed. Only the main results are presented. For the relevant proofs, the reader is refered to the technical report [14].

Let us introduce a Banach space H of parameters and an open set $G \subset H$ of feasible parameters.

Problem (O) is embedded in a family of parametric problems (O_h) depending upon $h \in G$:

$$
\begin{aligned}
(\mathrm{O}_h) \qquad & \text{Find} (x_h, u_h) \in W^{1,\infty}(0,T;\mathbb{R}^n) \times L^\infty(0,T;\mathbb{R}^m) \text{ such that} \\
& F(x_h, u_h, h) = \min\{F(x,u,h) \\
& \qquad\qquad := \int_0^T f^0(x(t),u(t),h)dt + g(x(T),h)\} \\
& \text{subject to} \\
& \dot{x}(t) - f(x(t),u(t),h) = 0 \qquad \text{for a.a. } t \in [0,T], \\
& \xi(x(0),x(T),h) = 0, \\
& \theta(x(t),u(t),h) \le 0 \qquad \text{for a.a. } t \in [0,T], \\
& \vartheta(x(t),h) \le 0 \qquad \text{for all } t \in [0,T].
\end{aligned}
$$

We assume that

(III.1) functions $f^0(\cdot,\cdot,\cdot), g(\cdot,\cdot), f(\cdot,\cdot,\cdot), \xi(\cdot,\cdot,\cdot), \theta(\cdot,\cdot,\cdot), \vartheta(\cdot,\cdot)$, and $D_x\vartheta(\cdot,\cdot)$ are twice Fréchet differentiable in all arguments, and the respective derivatives are locally Lipschitz continuous in u, x.

(III.2) The space H is independent of t.

(III.3) There exists a possibly local solution $(x_{h_0}, u_{h_0}) := (x_0, u_0)$ of the reference problem (P_{h_0}), where u_0 is a piecewise continuous function with the finite set of discontinuity points denoted by $\{t_k\}$.

In stability analysis we are interested in sufficient conditions under which a neighborhood $G_0 \subset G$ of h_0 exists such that for each $h \in G_0$ there is a locally unique solution (x_h, u_h) of (P_h), which is a Lipschitz continuous function of h.

Such an analysis for a class of optimal control problems very similar to (O_h) was performed in [13]. The main tool of this analysis was a modification of Robinson's implicit function theorem for generalized equations [25] developed in [12]. In this modification additional information on regularity of the solutions and the Lagrange multipliers, as functions of time, is used to overcome the difficulty connected with *two-norm discrepancy.*

In Theorem 7.1 of [13] conditions are formulated under which the solutions to (O_h) are locally Lipschitz continuous functions of h. These conditions consist of con-

straint qualifications, virtually identical to (II.3) and (II.4), and second-order sufficient optimality conditions.

The second-order sufficient optimality condition used therein is much stronger than the SSC derived in section 4. Namely, it is required that the coercivity condition (4.22) is satisfied on the subspace of all pairs $(y,v) \in W^{1,2}(0,T;\mathbb{R}^n) \times L^2(0,T;\mathbb{R}^m)$ satisfying equations (4.14) and (4.15). This is the subspace orthogonal to linearization of equality-type constraints only, and the active inequality type constraints are not taken into account.

It is natural to ask the question, *can the same stability results be obtained under the weaker coercivity condition given in* (4.22)?

This problem is analyzed in part II of [14], where it is shown that (4.22) is *too weak* to repeat the proof of the local stability of the solutions to (P_h) given in [13]. More precisely, equation (4.16) corresponding to the active mixed control-state constraints can be included in the needed coercivity condition; however, it is not possible for equality (4.17) corresponding to the active pure state-space constraints.

This phenomenon is connected with different properties of the Lagrange multipliers associated with those two types of constraints.

Thus, the second-order sufficient optimality condition needed in stability analysis based on Robinson's implicit function theorem takes on the following form:

($\widetilde{\mathrm{SSC}}$) There exist constants $\bar\alpha > 0$ and $\bar\gamma > 0$ such that

$$\left((y,v), \begin{pmatrix} D^2_{xx}\mathcal{L}_0 & D^2_{xu}\mathcal{L}_0 \\ D^2_{ux}\mathcal{L}_0 & D^2_{uu}\mathcal{L}_0 \end{pmatrix}(y,v)\right) \ge \bar\gamma(\|y\|_2^2 + \|v\|_2^2)$$

for all $(y,v) \in W^{1,2}(0,T;\mathbb{R}^n) \times L^2(0,T;\mathbb{R}^m)$ satisfying

$$\begin{aligned} &\dot y(t) - A(t)y(t) - B(t)v(t) = 0,\\ &\Xi_0 y(0) + \Xi_T y(T) = 0,\\ &\Theta^{\bar\alpha}_x(t)y(t) + \Theta^{\bar\alpha}_u(t)v(t) = 0, \end{aligned} \tag{5.1}$$

where the notation is the same as in section 4.

Remark 5.1. Condition ($\widetilde{\mathrm{SSC}}$) is *stronger* than (4.22), but it is *weaker* than the condition used in [13], where the last equation in (5.1) was void.

Note that in the same way as in section 4, condition ($\widetilde{\mathrm{SSC}}$) can be expressed in terms of the modified Legendre–Clebsch condition analogous to (II.6) as well as the Riccati equation analogous to (II.7). The main stability result of [14] (Theorem 3.7 in part II) can be formulated as follows.

THEOREM 5.2. *If* (III.1)–(III.3), (II.4), (II.5)*, and* ($\widetilde{\mathrm{SSC}}$) *are satisfied, then there exist a neighborhood $G_0 \subset G$ of h_0 and a neighborhood $\mathcal{Z}_0 \subset Z$ of z_0 such that for all $h \in G_0$ there exist a unique in $\mathcal{Z}_0$ solution (x_h, u_h) of (O_h) and unique associated Lagrange multipliers $(q_h, \rho_h, \kappa_h, \mu_h)$.*

Moreover, there exists a constant $c > 0$ such that

$$\|z_{h_1} - z_{h_2}\|_{1,2}, \|u_{h_1} - u_{h_2}\|_2, \|q_{h_1} - q_{h_2}\|_{1,2}, |\rho_{h_1} - \rho_{h_2}|,$$

$$\|\kappa_{h_1} - \kappa_{h_2}\|_2, \|\mu_{h_1} - \mu_{h_2}\|_{1,2} \le c\, [\![h_1 - h_2]\!]_H \qquad \textit{for all } h_1, h_2 \in G_0.$$

Appendix A. Proof of Theorem 2.3. Let z be feasible for (P), i.e., $\varphi(z) \in K$. Expanding $\mathcal{L}(\cdot,\lambda_0)$ into Taylor's series at z_0 and using (I.1) and (2.9) we obtain

$$F(z) - F(z_0) = (\lambda_0, \varphi(z))_{\widehat Y} + \frac{1}{2}(D^2_{zz}\mathcal{L}(z_0,\lambda_0)(z-z_0),(z-z_0))_{\widehat Z} + \xi(z,z_0), \tag{A.1}$$

where $\frac{|\xi(z,z_0)|}{\|z-z_0\|^2_{\widehat Z}} \to 0$ as $[\![z - z_0]\!]_Z \to 0$.

To estimate the term $(\lambda_0, \varphi(z))_{\widehat{Y}}$ let us represent any $y \in K$ in the form $y = y^{\perp} + y^{\parallel}$, where $y^{\perp}$ and $y^{\parallel}$ are orthogonal projections onto $\widehat{N}^{\perp}$ and onto its orthogonal complement $\widehat{N} \in \widehat{Y}$, respectively.

By (2.13) we have

$$(\lambda_0 - k, y)_{\widehat{Y}} \geq 0 \qquad \text{for all } k \in (\Lambda_0 - \lambda_0) \cap N.$$

Hence

$$(\lambda_0, y)_{\widehat{Y}} \geq \sup_{k \in (\Lambda_0 - \lambda_0) \cap N} (k, y^{\perp} + y^{\parallel})_{\widehat{Y}} = \sup_{k \in (\Lambda_0 - \lambda_0) \cap N} (k, y^{\parallel})_{\widehat{Y}} = \sigma [\![y^{\parallel}]\!]_{Y^*}.$$

Thus we obtain

$$(\lambda_0, \varphi(z))_{\widehat{Y}} \geq \sigma [\![\varphi(z)^{\parallel}]\!]_{Y^*}. \tag{A.2}$$

Note that by (2.9) and (A.2), we get

$$\varphi(z_0)^{\parallel} = 0. \tag{A.3}$$

On the other hand, by (I.1) we have

$$\varphi(z) = \varphi(z_0) + D_z \varphi(z_0)(z - z_0) + \zeta(z, z_0), \tag{A.4}$$

where $\frac{\|\zeta(z,z_0)\|_Y}{\|z - z_0\|_{\widehat{Z}}} \to 0$ as $[\![z - z_0]\!]_Z \to 0$.

By (2.5) and (2.13) there exists a solution $(z - z_0)^{\parallel}$ of the equation

$$D_z \varphi(z_0)(z - z_0)^{\parallel} = (\varphi(z) - \varphi(z_0) - \zeta(z, z_0))^{\parallel} = \varphi(z)^{\parallel} - \zeta(z, z_0)^{\parallel} \tag{A.5}$$

such that

$$\begin{aligned} \|(z - z_0)^{\parallel}\|_{\widehat{Y}} &\leq c \left(\|\varphi(z)^{\parallel}\|_{\widehat{Y}} + \|\zeta(z, z_0)^{\parallel}\|_{\widehat{Y}} \right) \\ &\leq c \left(\|\varphi(z)^{\parallel}\|_{\widehat{Y}} + \|\zeta(z, z_0)\|_{\widehat{Y}} \right). \end{aligned} \tag{A.6}$$

Let us define

$$(z - z_0)^{\perp} = (z - z_0) - (z - z_0)^{\parallel}.$$

In view of (A.3), (A.4), and (A.5) we have

$$D_z \varphi(z_0)(z - z_0)^{\perp} \in \widehat{N}^{\perp}. \tag{A.7}$$

By (I.5), (2.10), and (A.2) we obtain from (A.1)

$$\begin{aligned} F(z) - F(z_0) \geq{}& \sigma [\![\varphi(z)^{\parallel}]\!]_{Y^*} + \tfrac{\gamma}{2} \|(z - z_0)^{\perp}\|^2_{\widehat{Z}} \\ &- c \|(z - z_0)^{\perp}\|_{\widehat{Z}} \|(z - z_0)^{\parallel}\|_{\widehat{Z}} - \tfrac{c}{2} \|(z - z_0)^{\parallel}\|^2_{\widehat{Z}} - |\xi(z, z_0)|. \end{aligned} \tag{A.8}$$

It follows from (A.1), (A.4), and (A.6) that for each $\epsilon > 0$ there exists $\rho(\epsilon) > 0$ such that for all $[\![z - z_0]\!]_Z \leq \rho(\epsilon)$ we have

$$\begin{aligned} &|\xi(z, z_0)| \leq \epsilon \|z - z_0\|^2_{\widehat{Z}}, \\ &\|(z - z_0)^{\parallel}\|_{\widehat{Z}} \leq c \left(\|\varphi(z)^{\parallel}\|_{\widehat{Y}} + \epsilon \|(z - z_0)^{\perp}\|_{\widehat{Z}} \right). \end{aligned} \tag{A.9}$$

Substituting these estimates into (A.8), using Young's inequality, and performing some elementary calculations, for sufficiently small $\rho(\epsilon)$ we obtain

$$F(z) - F(z_0) \geq \sigma [\![\varphi(z)^{\|}]\!]_{Y^*} + \gamma' \|(z - z_0)^{\perp}\|_{\widehat{Z}}^2 - c' \|\varphi(z)^{\|}\|_{\widehat{Y}}^2. \tag{A.10}$$

On the other hand, for any $y \in Y$ we have

$$\|y\|_{\widehat{Y}}^2 = (y, y)_{\widehat{Y}} \leq [\![y]\!]_{Y^*} [\![y]\!]_Y, \quad \text{i.e., } \frac{\|y\|_{\widehat{Y}}^2}{[\![y]\!]_{Y^*}} \leq [\![y]\!]_Y.$$

Note that by (2.14), (A.3), and continuity of $\varphi(z)$ we have $[\![\varphi(z)^{\|}]\!]_Y \to 0$ as $[\![z - z_0]\!]_Z \to 0$. Hence, shrinking $\rho(\epsilon)$ if necessary, we obtain from (A.10)

$$F(z) - F(z_0) \geq \sigma' [\![\varphi(z)^{\|}]\!]_{Y^*} + \gamma'' \|(z - z_0)^{\perp}\|_{\widehat{Z}}^2.$$

Using (A.9) again we arrive at (2.16).

Acknowledgments. The author would like to express his gratitude to Professor Helmut Maurer for helpful discussions and suggestions.

OVERLAPPING BLOCK-BALANCED CANONICAL FORMS AND PARAMETRIZATIONS: THE STABLE SISO CASE*

BERNARD HANZON† AND RAIMUND J. OBER‡

Abstract. The balanced canonical form and parametrization of Ober for the case of SISO stable systems are extended to block-balanced canonical forms and related input-normal forms and parametrizations. They form an overlapping atlas of parametrizations of the manifold of stable SISO systems of given order. This extends the usefulness of these parametrizations, e.g., in gradient algorithms for system identification. As an implication of our construction it follows that each of the subsets of the parametrization of [R. Ober, *Internat. J. Control*, 46 (1987), pp. 643–670] corresponding to a choice for the structural indices is in fact an imbedded submanifold of the manifold of stable SISO systems of fixed order.

Key words. linear dynamical systems, differentiable manifolds, stable systems, canonical forms, atlas, system identification

1. Introduction.

In [18], [19] a canonical state-space form was presented for the set of asymptotically stable linear systems, with the property that it is balanced; i.e., for each system represented in canonical form, the corresponding observability and controllability Gramians are equal and diagonal (and positive definite). One motivation for studying balanced realizations and balanced canonical forms is their close relation to model reduction (see [19] and the references given there), which is in turn closely related to robust control theory (see, e.g., [20], [3]). Another motivation mentioned in [19] is the potential usefulness of balanced realizations for system identification, as indicated by [15]. In many cases, in system identification as well as in related areas, one can reduce the problem at hand to an optimization problem in which some criterion function is optimized over a set of systems. Very often one cannot solve the optimization problem analytically and has to use search algorithms (e.g., gradient algorithms), in which an initial point in the set of systems is adapted iteratively to give, ideally, a good approximation of the optimal system. In such search algorithms one often uses a parametrization of the set of relevant systems. The balanced parametrization of [19] has the advantage that by construction, problems of identifiability are to a large extent avoided in such a search algorithm. The parametrization has the property that it contains structural indices (i.e., discrete-valued parameters), and to each possible choice of values for these indices corresponds a particular subset of systems, for which a parametrization in terms of real-valued parameters is given. (In fact it will be shown in section 6 that these subsets are in fact submanifolds.) To each system corresponds a unique set of structural indices. Since the structural indices can take a large number of values, even for rather low order systems (the number of possibilities increases fast with increasing order of the system), this means that in a search algorithm one has either to identify the structural indices by other means

or to apply the search algorithm to a large number of parametrized submanifolds of systems. This is due to the fact that the parametrizations are disjoint.

Several authors (e.g. [4, 2, 10, 11, 20, 5, 6, 21, 22]) have investigated the possibility of using so-called overlapping parametrizations (in differential geometric terms: an atlas of coordinate charts). If one uses overlapping parametrizations, one does not have to search through each and every of the submanifolds but instead can search through the manifold as a whole, using the parametrizations to describe the manifold locally and changing from one parametrization to another when required. In case the search algorithm is of the gradient type, one can make sure that the decision rule for changing from one parametrization to another has little effect on the search algorithm by using a Riemannian gradient with respect to some suitable Riemannian metric on the manifold (cf. [7, 6, 8, 22, 9, 21]).

In view of this it would be very desirable if the balanced parametrization of [19] could be extended to give a set of overlapping parametrizations. In this paper such an extension, will be presented for the case of SISO stable systems. In the extension, balancedness of the realization no longer holds for all realizations. Instead block-balanced realizations and the corresponding input-normal realizations are used. A block-balanced canonical form is a canonical form for which the observability and controllability Gramians are equal and block-diagonal (and of course positive definite).

In section 2 some basic definitions are presented, including the concept of block-balanced realizations. In section 3 we present a Schwarz-like canonical form which will be a building block in the block-balanced canonical forms and the corresponding input-normal canonical forms that are treated in section 4. In section 5 it is shown how this leads to a set of overlapping block-balanced canonical forms and a corresponding atlas for the manifold of stable SISO input-output systems of a fixed order, and remarks are made as to how this atlas can be used if one wants to work with balanced and "almost balanced" realizations in search algorithms in system identification, for example. In section 6 the imbedded submanifolds structure of the original balanced parametrization is analyzed, using the atlas of the previous section.

2. Canonical forms, balanced realizations, and block-balanced realizations. In this section to a large extent the setup of [19] is followed. Let us consider continuous-time SISO systems of the form

$$\dot{x}_t = Ax_t + bu_t, \tag{1}$$

$$y_t = cx_t, \tag{2}$$

with $t \in \mathbf{R}, u_t \in \mathbf{R}, x_t \in \mathbf{R}^n, y_t \in \mathbf{R}, A \in \mathbf{R}^{n\times n}, b \in \mathbf{R}^{1\times n}, c \in \mathbf{R}^{n\times 1}$, and (A, b, c) a minimal triple.

For each $n \in \{1, 2, 3, \ldots\}$ let the set C_n be given by $C_n = \{(A, b, c) \in \mathbf{R}^{n\times n} \times \mathbf{R}^{n\times 1} \times \mathbf{R}^{1\times n} | (A, b, c)$ minimal and the spectrum of A is contained in the open left half plane$\}$.

As is well known, two minimal system representations (A_1, b_1, c_1) and (A_2, b_2, c_2) have the same transfer function, $g(s) = c_1(sI - A_1)^{-1}b_1 = c_2(sI - A_2)^{-1}b_2$, and therefore describe the same input-output behavior iff there exists an $n \times n$ matrix $T \in Gl_n(\mathbf{R})$ such that $A_1 = TA_2T^{-1}, b_1 = Tb_2, c_1 = c_2T^{-1}$. In that case we say that (A_1, b_1, c_1) and (A_2, b_2, c_2) are i/o-equivalent. This is clearly an equivalence relation; write $(A_1, b_1, c_1) \sim (A_2, b_2, c_2)$. A unique representation of a linear system can be obtained by deriving a canonical form.

DEFINITION 2.1. *A canonical form for an equivalence relation $\sim$ on a set X is a map*

$$\Gamma : X \to X$$

which satisfies, for all $x, y \in X$,

(i) $\Gamma(x) \sim x$;

(ii) $x \sim y \Longrightarrow \Gamma(x) = \Gamma(y)$.

Equivalently a canonical form can be given by the image set $\Gamma(X)$; a subset $B \subseteq X$ describes a canonical form if for each $x \in X$ there is precisely one element $b \in B$ such that $b \sim x$. The mapping $X \to B, x \mapsto b$ then describes a canonical form.

Let $(A, b, c) \in C_n$. The controllability Gramian W_c is the positive definite matrix that is given by the integral

$$W_c = \int_0^\infty \exp(At) b b^T \exp(A^T t) \mathrm{d}t.$$

As is well known, W_c can be obtained as the unique solution of the following Lyapunov equation:

$$AW_c + W_c A^T = -bb^T. \tag{3}$$

In a dual fashion, the observability Gramian W_o is the positive definite matrix that is given by the integral

$$W_o = \int_0^\infty \exp(A^T t) c^T c \exp(At) \mathrm{d}t.$$

This matrix is the unique solution of the following Lyapunov equation:

$$A^T W_o + W_o A = -c^T c. \tag{4}$$

DEFINITION 2.2. *Let $(A, b, c) \in C_n$. Then (A, b, c) is called* balanced *if the corresponding observability and controllability Gramians are equal and diagonal; i.e., there exist positive numbers $\sigma_1, \sigma_2, \ldots, \sigma_n$ such that*

$$W_o = W_c = \mathrm{diag}(\sigma_1, \ldots, \sigma_n) =: \Sigma. \tag{5}$$

The numbers $\sigma_1, \ldots, \sigma_n$ are called the (Hankel) singular values of the system.

The singular values are known to be uniquely determined by the input-output behavior of the system.

THEOREM 2.3 (see [17]). *Let $(A, b, c) \in C_n$ with*

$$\Sigma = \mathrm{diag}(\sigma_1 I_{n(1)}, \ldots, \sigma_k I_{n(k)}), \quad \sigma_1 > \sigma_2 > \ldots \sigma_k > 0, \quad \text{and} \quad \sum_{i=1}^{k} n(i) = n.$$

Then (A, b, c) is unique within its i/o-equivalence class up to an orthogonal state-space transformation of the form

$$Q = \mathrm{diag}(Q_1, Q_2, \ldots, Q_k)$$

with orthogonal $Q_i \in \mathbf{R}^{n(i) \times n(i)}, i = 1, \ldots, k$.

DEFINITION 2.4. *Let* $(A,b,c) \in C_n$. *Then* (A,b,c) *is called* input-normal *if* $W_c = I_n$ *and will be called* σ-input-normal *if* $W_c = \sigma I_n$.

Similarly (A,b,c) *is called* output-normal *if* $W_o = I_n$ *and* σ-output-normal *if* $W_o = \sigma I_n$.

It is not difficult to show that an input-normal realization is unique up to an arbitrary orthogonal state-space transformation.

The following definition is basic to our considerations in this paper.

DEFINITION 2.5. *Let* $(A,b,c) \in C_n$. *Then* (A,b,c) *will be called* block-balanced, *with indices* $n(i) \in \mathbf{N}, i = 1,\dots,k$, *adding up to* n, *if the observability Gramian and the controllability Gramian are equal and block-diagonal; i.e., there exist* $n(i) \times n(i)$ *positive definite matrices* $\Sigma_i, i = 1,\dots,k$, *such that*

$$W_o = W_c = \operatorname{diag}(\Sigma_1,\dots,\Sigma_k).$$

It will be convenient to call an arbitrary system representation $(A,b,c) \in \mathbf{R}^{n\times n} \times \mathbf{R}^{n\times 1} \times \mathbf{R}^{1\times n}$ *block-balanced if the pair of Lyapunov equations* $A\Sigma + \Sigma A^T = -bb^T$, $A^T\Sigma + \Sigma A = -c^Tc$ *has a positive definite solution of the form* $\Sigma = \operatorname{diag}(\Sigma_1,\dots,\Sigma_k)$ *(assuming neither asymptotic stability nor minimality).*

Remark. The matrices $\Sigma_i, i = 1,\dots,k$, are in general *not* uniquely determined by the input-output behavior of the system. However, the eigenvalues $\lambda_1(\Sigma_i) \geq \lambda_2(\Sigma_i) \geq \cdots \geq \lambda_{n(i)}(\Sigma_i)$ of the matrices $\Sigma_i, i = 1,\dots,k$, together form the set of Hankel singular values of the system, which are uniquely determined by the input-output behavior of the system, as remarked before.

THEOREM 2.6. *Suppose that* $(A,b,c) \in C_n$ *is block-balanced with indices* $n(j) \in \mathbf{N}, j = 1,\dots,k, \sum_{j=1}^{k} n(j) = n$, *and the additional property* $\lambda_1(\Sigma_1) \geq \lambda_{n(1)}(\Sigma_1) > \lambda_1(\Sigma_2) \geq \lambda_{n(2)}(\Sigma_2) > \cdots > \lambda_1(\Sigma_k) \geq \lambda_{n(k)}(\Sigma_k) > 0$.

This uniquely determines (A,b,c) *within its i/o-equivalence class up to an orthogonal state-space transformation of the form*

$$Q = \operatorname{diag}(Q_1,\dots,Q_k)$$

with orthogonal $Q_i \in \mathbf{R}^{n(i)\times n(i)}, i = 1,\dots,k$.

Proof. First note that if an *orthogonal* state-space transformation Q is applied to the system representation, then both Gramians transform in the same way, and therefore if they were equal before the orthogonal state-space transformation, then they will also be equal after the transformation.

Now consider two i/o-equivalent systems $(A_1,b_1,c_1), (A_2,b_2,c_2)$, which are both block-balanced with the same indices $n(j), j = 1,\dots,k$, and with Gramians $W_o^{(i)} = W_c^{(i)} = \operatorname{diag}(\Sigma_1^{(i)},\dots,\Sigma_k^{(i)}), i = 1,2$, with the property that $\lambda_1(\Sigma_1^{(i)}) \geq \lambda_{n(1)}(\Sigma_1^{(i)}) > \lambda_1(\Sigma_2^{(i)}) \geq \lambda_{n(2)}(\Sigma_2^{(i)}) > \cdots > \lambda_1(\Sigma_k^{(i)}) \geq \lambda_{n(k)}(\Sigma_k^{(i)}) > 0, i = 1,2$.

Because $\Sigma_j^{(i)}$ is symmetric positive definite for any $i = 1,2, j = 1,\dots,k$, there exists an orthogonal matrix $Q_j^{(i)}$ such that $Q_j^{(i)}\Sigma_j^{(i)}(Q_j^{(i)})^T = \operatorname{diag}(\lambda_1(\Sigma_j^{(i)}), \lambda_2(\Sigma_j^{(i)}), \dots, \lambda_{n(j)}(\Sigma_j^{(i)}))$. Therefore, the state-space transformation $Q^{(i)} := \operatorname{diag}(Q_1^{(i)},\dots,Q_k^{(i)})$ applied to the system representation (A_i,b_i,c_i) brings it into *balanced form with non-increasing singular values*, $i = 1,2$. We can therefore apply Theorem 2.3 to the transformed system representations, and it follows that there exists an orthogonal state-space transformation of the form $Q = \operatorname{diag}(Q_1,\dots,Q_k)$ with $Q_i \in \mathbb{R}^{n(i)\times n(i)}, i = 1,2,\dots,k$, that transforms (A_1,b_1,c_1) into (A_2,b_2,c_2) (and vice versa). □

The following theorem will be fundamental for our results.

THEOREM 2.7 (Pernebo and Silverman [24], Kabamba [12]). *Let* $(A,b,c) \in \mathbf{R}^{n\times n} \times \mathbf{R}^{n\times 1} \times \mathbf{R}^{1\times n}$ *be conformally partitioned as*

$$A = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix}, \quad b = \begin{pmatrix} b_1 \\ b_2 \end{pmatrix}, \quad c = \begin{pmatrix} c_1 & c_2 \end{pmatrix},$$

with $A_{ii} \in \mathbf{R}^{n(i)\times n(i)}, i = 1,2$, *and let* (A,b,c) *be block-balanced with indices* $n(1), n(2)$ *such that* $\Sigma_1, \Sigma_2 > 0$ *have no eigenvalues in common.*

Then $(A,b,c) \in C_n \Leftrightarrow (A_{ii}, b_i, c_i) \in C_{n(i)}, i = 1,2.$

3. The case *k*=1: A Schwarz-like canonical form for stable SISO systems in continuous time.

THEOREM 3.1. *Consider the set* B_n *of all* $(A,b,c) \in C_n$ *of the following form:*

$$A = \begin{pmatrix} a_{11} & -\alpha_1 & & 0 \\ \alpha_1 & 0 & \ddots & \\ & \ddots & \ddots & -\alpha_{n-1} \\ 0 & & \alpha_{n-1} & 0 \end{pmatrix}, \qquad a_{11} = -\frac{b_1^2}{2} < 0,$$

$$\alpha_i > 0, \qquad i = 1, \ldots, n-1,$$

$$b = \begin{pmatrix} b_1 \\ 0 \\ \vdots \\ 0 \end{pmatrix}, \qquad b_1 > 0,$$

$$c = \begin{pmatrix} c_1 & \gamma_1 & \ldots & \gamma_{n-1} \end{pmatrix}, \qquad c_1 \in \mathbf{R},\ \gamma_j \in \mathbf{R},\ j = 1, \ldots, n-1.$$

Each triple $(A,b,c) \in B_n$ *is input-normal.*

Let S_n *be the set of values of the vector of parameters* $(b_1, \alpha_1, \ldots, \alpha_{n-1}, c_1, \gamma_1, \ldots, \gamma_{n-1})$ *such that the corresponding triple* $(A,b,c) \in B_n$, *i.e., such that* $b_1 > 0, \alpha_i > 0, i = 1, \ldots, n$, *and* $c_1, \gamma_1, \ldots, \gamma_{n-1}$ *such that the pair* (c,A) *is observable.*

The set B_n *describes a real analytic (hence continuous) canonical form, and the parametrization mapping* $S_n \longrightarrow B_n$, *which maps each parameter vector to the corresponding triple* (A,b,c), *is a real analytic diffeomorphism (hence a homeomorphism).*

If $(\gamma_1, \ldots, \gamma_{n-1}) \neq 0 \in \mathbf{R}^{n-1}, n \geq 2$, *then the system has several different singular values.*

Proof. The requirement that a realization is input-normal reduces the freedom of choosing a basis of the state space to the freedom of choosing an *orthonormal* basis, i.e., to the freedom of choosing an element from the orthogonal group.

Now consider the controllability matrix of a triple $(A,b,c) \in B_n$. It is easily seen to be positive upper triangular. According to [19] there is a unique element in the orthogonal group that transforms a controllability matrix to a positive upper triangular matrix. Therefore the form presented here is canonical indeed.

Next let us show the smoothness properties. The mapping $S_n \longrightarrow B_n$, which maps a parameter vector from S_n to its corresponding triple (A,b,c), is polynomial, hence real analytic.

Now consider the mapping $C_n \longrightarrow S_n$, which maps *any* triple $(\tilde{A}, \tilde{b}, \tilde{c}) \in C_n$ to the corresponding parameter vector describing the *canonical form* of the system. Clearly the coefficients of the characteristic polynomial of $\tilde{A}$ depend polynomially on $\tilde{A}$, and therefore the parameters $a_{11}, \alpha_1, \ldots, \alpha_{n-1}$ depend real analytically on $\tilde{A}$, as they are rational functions of these characteristic polynomial coefficients (cf. [18]).

It remains to show that the parameter vector $c = (c_1, \gamma_1, \ldots, \gamma_{n-1})$ depends real analytically on the entries of $(\tilde{A}, \tilde{b}, \tilde{c})$. Let (A, b, c) denote the canonical form of the system and $g(z) := \frac{p(z)}{q(z)} := c(zI - A)^{-1}b = \tilde{c}(zI - \tilde{A})^{-1}\tilde{b}$ denote the (rational) transfer function of the system, with monic polynomial denominator $q(z) := \det(zI - A) = \det(zI - \tilde{A})$ and polynomial numerator $p(z)$. It is easy to see that the coefficients of $p(z)$ depend real analytically on the entries of $(\tilde{A}, \tilde{b}, \tilde{c})$. Let $M(z)$ denote the polynomial matrix of cofactors of $(zI - A)$. Then one has

$$p(z) = cM(z)^T b. \tag{6}$$

Consider $m_{1i}(z)$, which is $(-1)^{1+i}$ times the determinant of the matrix that is obtained from $zI - A$ by leaving out the first row and ith column, $i \in \{1, \ldots, n\}$:

$$m_{1i}(z) = (-1)^{1+i} \times \left|\begin{array}{cccc|cccccc} \alpha_1 & * & \ldots & * & * & \ldots & \ldots & \ldots & \ldots & * \\ 0 & \ddots & & \vdots & \vdots & & & & & \vdots \\ \vdots & & \ddots & * & \vdots & & & & & \vdots \\ 0 & \ldots & 0 & \alpha_{i-1} & * & \ldots & \ldots & \ldots & \ldots & * \\ \hline 0 & \ldots & \ldots & 0 & z & -\alpha_{i+1} & 0 & \ldots & \ldots & 0 \\ \vdots & & & \vdots & \alpha_{i+1} & z & -\alpha_{i+2} & 0 & \ldots & 0 \\ \vdots & & & \vdots & 0 & \ddots & \ddots & \ddots & \ddots & \vdots \\ \vdots & & & \vdots & \vdots & \ddots & \ddots & \ddots & \ddots & 0 \\ \vdots & & & \vdots & \vdots & & \ddots & \ddots & \ddots & -\alpha_{n-1} \\ 0 & \ldots & \ldots & 0 & 0 & 0 & \ldots & 0 & \alpha_{n-1} & z \end{array}\right|$$

$$= (-1)^{1+i} \times \left(\prod_{j=1}^{i-1} \alpha_j\right) z^{n-i} + \text{terms of lower degree in } z,$$

where $i \in \{1, \ldots, n\}$; if $i = 1$, the product $\prod_{j=1}^{i-1} \alpha_j$ is taken to be equal to one by convention. Because $\prod_{j=1}^{i-1} \alpha_j$ is unequal to zero (and in fact positive) for each $i \in \{1, \ldots, n\}$ the polynomials $m_{11}(z), \ldots, m_{1n}(z)$ form a basis of the linear vector space of polynomials of degree $< n$ over $\mathbf{R}$. Therefore (6), which can be rewritten as

$$c_1 m_{11}(z) + \gamma_1 m_{12}(z) + \cdots + \gamma_{n-1} m_{1n}(z) = \frac{p(z)}{b_1}, \tag{7}$$

has a unique solution $c = (c_1, \gamma_1, \gamma_2, \ldots, \gamma_{n-1})$, which depends real analytically on the entries of $(\tilde{A}, \tilde{b}, \tilde{c})$ and the parameters $b_1, \alpha_1, \ldots, \alpha_{n-1}$. Since these parameters themselves depend real analytically on the entries of $(\tilde{A}, \tilde{b}, \tilde{c})$, the real analyticity of all parameters on the entries of $(\tilde{A}, \tilde{b}, \tilde{c})$ follows. This completes the proof of the smoothness properties.

The remaining statements follow from the fact that for $\gamma = 0$, the form is a canonical form for systems with only *one* positive Hankel singular value (i.e., all nonzero Hankel singular values coincide); cf. [19], [18]. □

Remarks. (i) The fact that *if* the asymptotically stable matrix A can be brought into the presented form by a basis change of the state space, then the resulting matrix

is unique, also follows from the fact mentioned in the proof that for $\gamma = 0, c_1 \neq 0$ the form is a canonical form for systems with only one positive Hankel singular value; cf. [19], [18]. Note that here we use a different sign convention for the off-diagonal elements of the matrix A than in those papers. This corresponds to consideration of the dual state-space representation.

(ii) If $c_1 \neq 0$, we define $\sigma := |\frac{c_1}{b_1}| > 0$, which we will call a pseudosingular value. If the vector $\gamma = (\gamma_1, \ldots, \gamma_{n-1})$ is close enough to zero, the pseudosingular value will be close to the true singular values of the system, because of continuity of the singular values as a function of γ and the fact that if $\gamma = 0$, the system has only one singular value and its value is σ. If $c_1 \neq 0$, the system can be brought simply into σ-input-normal form by multiplying c by $\sigma^{-\frac{1}{2}}$ and b by $\sigma^{\frac{1}{2}}$. The resulting σ-input-normal form is a *canonical* form locally around $\gamma = 0$, but not globally because the systems which have $c_1 = 0$ in the previous canonical form cannot be represented in this way. (It would lead to $\sigma = 0$, and therefore one cannot transform back to the input-normal case, etc.) Locally around $\gamma = 0$ it takes the following form:

$$A = \begin{pmatrix} a_{11} & -\alpha_1 & & 0 \\ \alpha_1 & 0 & \ddots & \\ & \ddots & \ddots & -\alpha_{n-1} \\ 0 & & \alpha_{n-1} & 0 \end{pmatrix},$$

$$a_{11} = -\frac{b_1^2}{2\sigma} < 0,$$

$$\alpha_i > 0, \qquad i = 1, \ldots, n-1,$$

$$b = \begin{pmatrix} b_1 \\ 0 \\ \vdots \\ 0 \end{pmatrix}, \qquad b_1 > 0$$

$$c = \begin{pmatrix} sb_1 & \gamma_1 & \ldots & \gamma_{n-1} \end{pmatrix}, \qquad s \in \{-1, 1\},\ \gamma_j \in \mathbf{R},\ j = 1, \ldots, n-1.$$

(iii) Because the canonical form is input-normal, if one starts with an arbitrary input-normal realization $(\tilde{A}, \tilde{b}, \tilde{c})$ of the system, it takes an orthogonal state-space transformation Q in order to obtain the canonical form of the system involved. The same holds for the (local) σ-input-normal canonical form.

(iv) Clearly the canonical forms presented are controllable (because they are input-normal; resp., σ-input-normal), but observability will fail for certain choices of c; the observability Gramian will be singular for such a choice of c. If $\gamma = 0, c_1 \neq 0$, the system is observable, because the observability Gramian will be $\sigma^2 I$ (resp., σI). (In that case the system representation is σ^2-output-normal; resp., σ-output-normal.) Therefore, also in some open neighborhood around such a system, observability will still hold. (This follows from the continuity of the determinant of the observability Gramian as a function of the parameters.)

(v) This canonical form is closely related to the so-called Schwarz canonical form; cf. [13], [14], [25].

(vi) A canonical form can be interpreted as a choice of basis of the state space for each system. In this case the basis can be obtained as follows. Define an inner product on the state space by the inverse of the reachability Gramian. Take the first n columns of the reachability matrix, and apply the Gram–Schmidt orthogonalization procedure to it, with respect to the inner product. With respect to the resulting

set of n vectors as the basis of the state space the system has the canonical form. This observation can in fact be used to obtain an alternative proof of the smoothness properties stated in the theorem.

4. An input-normal and a block-balanced canonical form. Let $n(1), \dots, n(k) \in \{1, 2, \dots, n\}, \sum_{j=1}^{k} n(j) = n$, denote a partition of n as before. Let $C_{n(1),n(2),\dots,n(k)}$ denote the subset of all systems in C_n, with the property that their n Hankel singular values (multiplicities *included*) $\sigma(1) \geq \sigma(2) \geq \cdots \geq \sigma(n) > 0$ can be partitioned into k disjoint sets of singular values (again with multiplicities included) in the following way:

$$\begin{aligned}\sigma(1) &\geq \cdots \geq \sigma(n(1)) > \sigma(n(1)+1)\\ &\geq \cdots \geq \sigma(n(1)+n(2)) > \sigma(n(1)+n(2)+1)\\ &\geq \cdots \geq \sigma\left(\sum_{j=1}^{l} n(j)\right) > \sigma\left(\left(\sum_{j=1}^{l} n(j)\right)+1\right)\\ &\geq \cdots > 0. \qquad (8)\end{aligned}$$

So we require that $\sigma(\sum_{j=1}^{l} n(j)) > \sigma((\sum_{j=1}^{l} n(j)) + 1)$ for $l = 1, 2, \dots, k-1$ and $\sigma(n) > 0$, of course. Note that the notation is consistent with the fact that C_n denotes the set of stable systems which have as their only "restriction" that there are n positive singular values (multiplicities included), i.e., that the order of the system is n.

The other extreme is $C_{1,1,\dots,1}$, which denotes the set of nth-order stable systems with n *distinct* singular values. For this set of systems a balanced canonical form was derived in [12].

Remark. The set $C_{n(1),\dots,n(k)}$ should not be confused with the subset of C_n consisting of the systems which have k distinct singular values $\sigma_1 > \cdots > \sigma_k > 0$ with multiplicities $n(1), \dots, n(k)$. Of course these systems are included in $C_{n(1),\dots,n(k)}$, but they generally form only a (thin) subset.

Next we will present a canonical form on $C_{n(1),\dots,n(k)}$.

THEOREM 4.1. *Consider the set $B_{n(1),\dots,n(k)}$ of triples (A, b, c) of the following form:*

$$\begin{aligned}A &= (A(i,j))_{1\leq i,j\leq k},\\ A(i,j) &\in \mathbf{R}^{n(i)\times n(j)}, \qquad i,j \in \{1,\dots,k\},\\ b &= \begin{pmatrix} b(1)\\ b(2)\\ \vdots\\ b(k)\end{pmatrix}, \qquad b(i) \in \mathbf{R}^{n(i)},\ i = 1,\dots,k,\\ c &= (c(1),\dots,c(k)), \qquad c(j)^T \in \mathbf{R}^{n(j)},\ j = 1,\dots,k,\\ A(i,i) &= \begin{pmatrix} a(i,i)_{11} & -\alpha(i)_1 & 0 & \dots & 0\\ \alpha(i)_1 & 0 & -\alpha(i)_2 & \ddots & \vdots\\ 0 & \alpha(i)_2 & & \ddots & 0\\ \vdots & \ddots & \ddots & & -\alpha(i)_{n(i)-1}\\ 0 & \dots & 0 & \alpha(i)_{n(i)-1} & 0\end{pmatrix},\end{aligned}$$

$$
\begin{aligned}
a(i,i)_{11} &= -\frac{b_i^2}{2}, \\
\alpha(i)_j &> 0, \qquad j = 1, \ldots, n(i)-1, \\
b(i) &= \begin{pmatrix} b_i \\ 0 \\ \vdots \\ 0 \end{pmatrix}, \qquad b_i > 0, \\
c(i) &= \left(c_i, \gamma(i)_1, \ldots, \gamma(i)_{n(i)-1}\right), \qquad i = 1, \ldots, k,
\end{aligned}
$$

where the parameters are to be taken such that the corresponding observability Gramians $\Sigma_i^2, i = 1, \ldots, k$, *which satisfy the observability Lyapunov equations*

$$
\Sigma_i^2 A(i,i) + A(i,i)^T \Sigma_i^2 = -c(i)^T c(i) \tag{9}
$$

are fulfilling the following inequalities:

$$
\lambda_1(\Sigma_1^2) \geq \lambda_{n(1)}(\Sigma_1^2) > \lambda_1(\Sigma_2^2) \geq \lambda_{n(2)}(\Sigma_2^2) > \cdots > \lambda_1(\Sigma_k^2) \geq \lambda_{n(k)}(\Sigma_k^2) > 0. \tag{10}
$$

For each pair $(i,j), i \neq j$, *the matrices* $A(i,j), A(j,i)$ *are determined (uniquely!) from the following pair of linear matrix equations:*

$$
\begin{aligned}
A(i,j) + A(j,i)^T &= -b(i)b(j)^T, \\
\Sigma_i^2 A(i,j) + A(j,i)^T \Sigma_j^2 &= -c(i)^T c(j).
\end{aligned} \tag{11}
$$

The set $B_{n(1),\ldots,n(k)}$ *describes a real analytic (hence continuous) canonical form on* $C_{n(1),\ldots,n(k)}$. *The* $2n$ *"free" parameters of the canonical form are*

$$
b_i, \alpha(i)_1, \ldots, \alpha(i)_{n(i)-1}, c_i, \gamma(i)_1, \ldots, \gamma(i)_{n(i)-1}, \qquad i = 1, \ldots, k.
$$

Let $S_{n(1),\ldots,n(k)} \subset \mathbf{R}^{2n}$ *be the set of all values of the parameter vector for which the corresponding triple* $(A,b,c) \in B_{n(1),\ldots,n(k)}$, *i.e., for all* $i \in \{1, \ldots, k\}$ $b_i > 0$, $\alpha(i)_j > 0$, $j = 1, \ldots, n(i)-1$, *and* $c_i, \gamma(i)_1, \ldots, \gamma(i)_{n(i)-1}$ *such that the matrices* $\Sigma_i, i = 1, \ldots, k$, *found in* (9) *satisfy the inequalities* (10). *The mapping* $S_{n(1),\ldots,n(k)} \longrightarrow B_{n(1),\ldots,n(k)}$ *which maps a parameter vector to the corresponding triple* (A,b,c) *is a real analytic diffeomorphism.*

The form is input-normal, i.e.,

$$
A + A^T = -bb^T, \tag{12}
$$

and has block-diagonal observability Gramian $\Sigma^2 := \operatorname{diag}(\Sigma_1^2, \ldots, \Sigma_k^2) > 0$.

Let $\sigma(1) \geq \sigma(2) \geq \cdots \geq \sigma(n) > 0$ *denote the* n *positive Hankel singular values of the system (with their multiplicities). If for some* $i \in \{1, \ldots, k\}$ *the vector* $\gamma(i) = 0$, *then* Σ_i^2 *is a scalar matrix*

$$
\Sigma_i^2 = \sigma^2 \left(1 + \sum_{j=1}^{i-1} n(j)\right) \times I_{n(i)}, \tag{13}
$$

and

$$\sigma\left(\sum_{j=1}^{i-1} n(j)\right) > \sigma\left(1+\sum_{j=1}^{i-1} n(j)\right) = \sigma\left(2+\sum_{j=1}^{i-1} n(j)\right) = \cdots = \sigma\left(\sum_{j=1}^{i} n(j)\right) > \sigma\left(1+\sum_{j=1}^{i} n(j)\right).$$

The observability Gramian is diagonal if and only if for all $i \in \{1,\ldots,k\}, \gamma(i) = 0$.

Remark. A block-balanced realization can be obtained from the presented canonical form by applying a state-space transformation

$$T := \Sigma^{\frac{1}{2}} = \operatorname{diag}\left(\Sigma_1^{\frac{1}{2}},\ldots,\Sigma_k^{\frac{1}{2}}\right) > 0. \tag{14}$$

The corresponding controllability and observability Gramians will both be equal to

$$\Sigma = \operatorname{diag}(\Sigma_1,\ldots,\Sigma_k) > 0.$$

Proof. (i) To start we will show that the form presented is canonical on $C_{n(1),\ldots,n(k)}$. Consider a system which can be represented by a triple in $C_{n(1),\ldots,n(k)}$. A balanced realization of the system is also in block-balanced form with partitioning indices $n(1),\ldots,n(k)$. So one can find a block-balanced realization (A,b,c) of the system with these partitioning indices. It follows from Theorem 2.6 that the requirement that (A,b,c) is block-balanced with these partitioning indices uniquely determines (A,b,c) up to an orthogonal state-space transformation of the form $Q = \operatorname{diag}(Q_1,Q_2,\ldots,Q_k)$, with orthogonal matrices $Q_i \in \mathbf{R}^{n(i)\times n(i)}$. If (A,b,c) is in block-balanced form, it can be brought into input-normal form with block-diagonal observability Gramian by the state-space transformation T^{-1}, where T is as defined in (14). It follows easily that if (A,b,c) is in input-normal form with block-diagonal controllability Gramian $\Sigma^2 = \operatorname{diag}\left(\Sigma_1^2,\ldots,\Sigma_k^2\right)$, with $\lambda_1(\Sigma_1^2) \geq \lambda_{n(1)}(\Sigma_1^2) > \lambda_1(\Sigma_2^2) \geq \lambda_{n(2)}(\Sigma_2^2) > \cdots > \lambda_1(\Sigma_k^2) \geq \lambda_{n(k)}(\Sigma_k^2) > 0$, $\Sigma_i^2 \in \mathbf{R}^{n(i)\times n(i)}$, then (A,b,c) is uniquely determined up to an orthogonal state-space transformation of the form $Q = \operatorname{diag}(Q_1,Q_2,\ldots,Q_k)$. If such a transformation is applied, then $(A(i,i),b(i),c(i))$ is transformed to $\left(Q_iA(i,i)Q_i^T, Q_ib(i), c(i)Q_i^T\right)$. Note that $(A(i,i),b(i),c(i)) \in C_{n(i)}$ because of Theorem 2.7, and therefore it follows from Theorem 3.1 that there is a unique choice for Q_i which brings $\left(Q_iA(i,i)Q_i^T, Q_ib(i), c(i)Q_i^T\right)$ into the required canonical form.

We need only to check that by using the solutions $A(i,j), A(j,i)$ of (11) the Gramians indeed have the required block structure, which is straightforward and left to the reader.

(ii) Second, we will show the smoothness properties. Clearly the mapping $S_{n(1),\ldots,n(k)} \longrightarrow B_{n(1),\ldots,n(k)}$, which maps any parameter vector in $S_{n(1),\ldots,n(k)}$ to the corresponding triple $(A,b,c) \in B_{n(1),\ldots,n(k)}$, is real analytic.

Now consider the mapping $C_{n(1),\ldots,n(k)} \longrightarrow S_{n(1),\ldots,n(k)}$, which maps a triple $(\tilde{A},\tilde{b},\tilde{c})$ to the parameter vector of the corresponding canonical form.

The map which assigns to $(\tilde{A},\tilde{b},\tilde{c})$ the coefficients of the characteristic polynomial of the product of the Gramians is real analytic. The zeroes of this polynomial are the

squared singular values. Now consider the polynomial

$$a(z) = \prod_{j=n(1)+1}^{n} (z - \sigma(j)^2).$$

Because on $C_{n(1),\ldots,n(k)}$ the inequality $\sigma(n(1)) > \sigma(n(1)+1)$ holds, the coefficients of $a(z)$ depend real analytically on those of the characteristic polynomial of the product of the Gramians (see, e.g., [16]).

Let $\Sigma^2 = W_c^{\frac{1}{2}} W_o W_c^{\frac{1}{2}}$, where W_c and W_o are the controllability and observability Gramians, respectively, of $(\tilde{A}, \tilde{b}, \tilde{c})$; W_c and W_o depend real analytically on $(\tilde{A}, \tilde{b}, \tilde{c})$. The matrix $a(\Sigma^2)$ has as its range space an $n(1)$-dimensional linear subspace of $\mathbf{R}^n$ which clearly depends real analytically on $(\tilde{A}, \tilde{b}, \tilde{c})$. The corresponding orthogonal projection matrix Π_1, which maps an arbitrary vector $x \in \mathbf{R}^n$ to its orthogonal projection in the linear subspace spanned by the columns of $a(\Sigma^2)$ (i.e., the linear subspace which is obtained by taking the direct sum of the eigenspaces of the largest $n(1)$ eigenvalues $\sigma(1)^2, \ldots, \sigma(n(1))^2$ of Σ^2), depends real analytically on $a(\Sigma^2)$.

Now consider $(\Pi_1 W_c^{-\frac{1}{2}} \tilde{A} W_c^{\frac{1}{2}} \Pi_1, \Pi_1 W_c^{-\frac{1}{2}} \tilde{b}, \tilde{c} W_c^{\frac{1}{2}} \Pi_1)$ with corresponding controllability Gramian Π_1 and observability Gramian $\Pi_1 \Sigma^2 \Pi_1 = \Pi_1 \Sigma^2 = \Sigma^2 \Pi_1$. (Because of the way Π_1 is constructed, it commutes with Σ^2.) We can now apply the canonical form of Theorem 3.1 to find a basis for the range space of Π_1 (which corresponds to the state space there) depending real analytically on $(\tilde{A}, \tilde{b}, \tilde{c})$. The first basis vector is

$$\frac{\Pi_1 W_c^{-\frac{1}{2}} \tilde{b}}{\| \Pi_1 W_c^{-\frac{1}{2}} \tilde{b} \|};$$

the second one (Gram–Schmidt orthonormalization) is obtained by normalization of the vector

$$\begin{aligned} &\Pi_1 W_c^{-\frac{1}{2}} \tilde{A} W_c^{\frac{1}{2}} \Pi_1 W_c^{-\frac{1}{2}} \tilde{b} \\ &\quad - \frac{\left(\tilde{b}^T W_c^{-\frac{1}{2}} \Pi_1 W_c^{\frac{1}{2}} \tilde{A}^T W_c^{-\frac{1}{2}} \Pi_1 W_c^{-\frac{1}{2}} \tilde{b} \right)}{\left(\tilde{b}^T W_c^{-\frac{1}{2}} \Pi_1 W_c^{-\frac{1}{2}} \tilde{b} \right)} \times \Pi_1 W_c^{-\frac{1}{2}} \tilde{b}; \end{aligned}$$

and so on. Clearly this choice of basis of the range space of Π_1 is real analytic. With respect to the resulting basis of the $n(1)$-dimensional state space the triple

$$\left(\Pi_1 W_c^{-\frac{1}{2}} \tilde{A} W_c^{\frac{1}{2}} \Pi_1, \Pi_1 W_c^{-\frac{1}{2}} \tilde{b}, \tilde{c} W_c^{\frac{1}{2}} \Pi_1 \right)$$

takes the form $(\tilde{A}(1,1), \tilde{b}(1), \tilde{c}(1))$, as described in Theorem 3.1:

$$\tilde{A}(1,1) = \begin{pmatrix} a(1,1)_{11} & -\alpha(1)_1 & 0 & \ldots & 0 \\ \alpha(1)_1 & 0 & -\alpha(1)_2 & \ddots & \vdots \\ 0 & \alpha(1)_2 & & \ddots & 0 \\ \vdots & \ddots & \ddots & & -\alpha(1)_{n(1)-1} \\ 0 & \ldots & 0 & \alpha(1)_{n(1)-1} & 0 \end{pmatrix},$$

$$a(1,1)_{11} = -\frac{b_1^2}{2},$$
$$\alpha(1)_j > 0, \qquad j = 1, \ldots, n(1)-1,$$
$$\tilde{b}(1) = \begin{pmatrix} b_1 \\ 0 \\ \vdots \\ 0 \end{pmatrix}, \qquad b_1 > 0,$$
$$\tilde{c}(1) = \left(c_1, \gamma(1)_1, \ldots, \gamma(1)_{n(1)-1}\right),$$

and therefore this triple and the parameters describing it depend real analytically on $(\tilde{A}, \tilde{b}, \tilde{c})$. Similarly for any $i \in \{1, \ldots, k\}$ the matrix triple and the parameters describing it depend real analytically on $(\tilde{A}, \tilde{b}, \tilde{c})$. This proves the real analyticity of the mapping which maps $(\tilde{A}, \tilde{b}, \tilde{c})$ to the parameters of the canonical form.

(iii) The remaining statements follow from the results in [19]. □

5. An atlas of overlapping block-balanced canonical forms.

THEOREM 5.1. *Let the state-space dimension n be fixed. The canonical forms $C_{n(1),\ldots,n(k)} \longrightarrow B_{n(1),\ldots,n(k)}$, $n(j) \in \{1, \ldots, n\}, j = 1, \ldots, k$, $\sum_{j=1}^{k} n(j) = n$, $k \in \{1, \ldots, n\}$, form an overlapping set of real analytic (hence continuous) canonical forms covering C_n. Each of the sets $C_{n(1),\ldots,n(k)}$, $\sum_{j=1}^{k} n(j) = n$, is an open subset of C_n, and together they cover C_n.*

Proof. Let $P(n;k) := \{(n(1), \ldots, n(k)) | n(j) \in \{1, \ldots, n\}; j = 1, \ldots, k; \sum_{j=1}^{k} n(j) = n\}$, the set of partitions of n into k parts. It is trivial to show that

$$\bigcup_{k=1}^{n} \bigcup_{(n(1),\ldots,n(k)) \in P(n;k)} C_{n(1),\ldots,n(k)} = C_n, \tag{15}$$

because $C_{n(1),\ldots,n(k)} \subset C_n$ for each partition $(n(1), \ldots, n(k))$ of n and for $k = 1$ one has $n(1) = n$ and $C_{n(1)} = C_n$. Clearly for each partition $(n(1), \ldots, n(k))$ of n the set $C_{n(1),\ldots,n(k)}$ is an open subset of C_n. The remaining properties follow from Theorem 4.1. □

COROLLARY 5.2. *The set of mappings*

$$\phi : C_{n(1),\ldots,n(k)}/\sim \longrightarrow S_{n(1),\ldots,n(k)} \subset \mathbf{R}^{2n},$$
$$(n(1), \ldots, n(k)) \in P(n;k), \qquad k = 1, \ldots, n,$$

which map each equivalence class of triples to the corresponding parameter vector in the canonical form, forms an atlas for the real analytic manifold of stable SISO input-output systems of order n.

Proof. Any input-output system has a minimal state-space realization which is unique up to choice of basis of the state space. Therefore, the equivalence classes of (minimal!) triples in C_n can be identified with stable SISO input-output systems, and the result follows from the theorem. □

Remark. A motivation for using this atlas rather than, for example, just the Schwarz-like canonical form B_n is the following. Suppose one wants to use *balanced realizations.* Then one can use the balanced parametrization of [19]. However, this parametrization is discontinuous at all points of $C_n \setminus C_{1,\ldots,1}$, i.e., in all triples $(\tilde{A}, \tilde{b}, \tilde{c})$ which have two or more coinciding singular values. Also, the complement $C_{1,\ldots,1}$, of the set of discontinuity points consists of 2^n topological components, one component

for each sign pattern of the vector c (which cannot have zero components in this case; cf. (9), (10) with $n(i) = 1, i = 1, 2, \ldots, k$); this should be compared to C_n, which has only $n + 1$ topological components (the Brockett components). It appears that this is a serious disadvantage if one wants to use balanced realizations and balanced parametrizations in, for example, search algorithms for system identification, because one has to find out first which is the right "cell" of the parametrization. Another difficulty is that the balanced parametrization will tend to become numerically ill behaved if two or more of the Hankel singular values of the system are close to each other. For example, for the class of second-order systems, the determinant of the L_2-induced Riemannian metric tensor of the balanced parametrization can be calculated (e.g., using a computer algebra package) to be

$$b_1^2 b_2^2 \left(\frac{s_1\sigma_1 - s_2\sigma_2}{s_1\sigma_1 + s_2\sigma_2} \right)^2$$

in the notation of [19]. Here the s_1 and s_2 are the sign parameters, which are either $+1$ or -1. It follows that if two Hankel singular values come close, for given values of b_1 and b_2, then the parametrization becomes *ill conditioned* in the sense that a small parameter change may lead to a large change in the system (in the L_2-sense) and/or a large parameter change may lead to only a small change in the system (again in the L_2-sense).

In order to overcome these difficulties one could use the overlapping block-balanced canonical forms as follows. If $(\tilde{A}, \tilde{b}, \tilde{c})$ has k distinct Hankel singular values $\sigma_1 > \sigma_2 > \cdots > \sigma_k > 0$ with respective multiplicities $n(1), \ldots, n(k)$, then one can use the block-balanced continuous canonical form on $C_{n(1),\ldots,n(k)}$ *locally around* $(\tilde{A}, \tilde{b}, \tilde{c})$. If one is moving away from $(\tilde{A}, \tilde{b}, \tilde{c})$ in a search algorithm, for example, one has to decide whether the canonical form corresponding to a different partition should be used: if the largest $n(1)$ singular values differ sufficiently from each other, one could use, e.g., $C_{1,\ldots,1,n(2),\ldots,n(k)}$ (where there are $n(1)$ ones in the subindex before $n(2)$), etc. In this way one would use balanced realizations and "almost-balanced" realizations while moving around in the set of nth-order systems, without encountering discontinuity points.

6. On the imbedded submanifolds structure of the balanced canonical form. Consider the balanced canonical form for C_n of [19]. For each $k \in \{1, \ldots, n\}$ and each partition $(n_1, n_2, \ldots, n_k) \in P(n; k)$ let $K_{n_1,\ldots,n_k}$ denote the subset of C_n of systems with k distinct singular values $\sigma_1 > \sigma_2 > \cdots > \sigma_k$, which have multiplicities $n_1, n_2, \ldots, n_k$, respectively. Clearly $K_{n_1,\ldots,n_k} \subset C_{n_1,\ldots,n_k}$ and equality holds only if $k = n,\ n_i = 1,\ i = 1, \ldots, n$. The mapping $K_{n_1,\ldots,n_k} \longrightarrow B_{n_1,\ldots,n_k} \cap K_{n_1,\ldots,n_k}$ is a canonical form on $K_{n_1,\ldots,n_k}$, the restriction of the canonical form $C_{n_1,\ldots,n_k} \longrightarrow B_{n_1,\ldots,n_k}$ to $K_{n_1,\ldots,n_k}$. This canonical form on $K_{n_1,\ldots,n_k}$ is input-normal with diagonal observability Gramian W_o. If one applies the state-space transformation (14) (which is diagonal here), then one obtains the balanced canonical form of [19] restricted to $K_{n_1,\ldots,n_k}$. Clearly on $K_{n_1,\ldots,n_k}$ the balanced canonical form is smooth (real analytic), while it is of course not even continuous on C_n. Both the balanced canonical form and the corresponding input-normal form parametrize $K_{n_1,\ldots,n_k}/\sim$ by the parameters $b_i > 0, \alpha(i)_j > 0, j = 1, \ldots, n_i - 1, c_i \neq 0, i = 1, \ldots, k$. Because $(c_1, \ldots, c_k)$ has 2^k possible sign patterns, it follows that $K_{n_1,\ldots,n_k}/\sim$ has 2^k topological components, each real analytically diffeomorphic to $\mathbf{R}^{n+k}$. It follows clearly that $K_{n_1,\ldots,n_k}/\sim$ is a real analytic manifold. The question arises whether it is a *regular* submanifold of $C_n/\sim$ in the sense of [1] and therefore an imbedded submanifold (cf. [1], esp. Lemma 5.2).

The answer is affirmative and is a direct consequence of the construction developed in the previous sections.

THEOREM 6.1. *For each $k \in \{1, \dots, n\}$ and each partition $(n_1, \dots, n_k) \in P(n; k)$ the subset $K_{n_1,\dots,n_k}/\sim$ is a regular submanifold of $C_n/\sim$ and therefore an imbedded submanifold with the inclusion as the imbedding map.*

Proof. It follows from [1, Chapter III, section 5] that it suffices to show the socalled *$n+k$-submanifold property* for $K_{n_1,\dots,n_k}/\sim$. This property is said to hold if for each point $p \in K_{n_1,\dots,n_k}/\sim$ there exists a coordinate neighborhood U, φ on $C_n/\sim$ with local coordinates $\xi_1, \dots, \xi_{2n}$ such that (i) $\varphi(p) = (0, \dots, 0)$, (ii) $\varphi(U) = \{(\xi_1, \dots, \xi_{2n}) | -\epsilon < \xi_i < \epsilon, i = 1, \dots, 2n\}$, and (iii) $\varphi(U \cap K_{n_1,\dots,n_k}/\sim) = \{\xi \in \varphi(U) | \xi_{n+k+1} = \cdots = \xi_{2n} = 0\}$. The $n+k$-submanifold property can be shown to hold as follows. Suppose that the parameter values of point $p \in K_{n_1,\dots,n_k}/\sim$ are $b_i^0, \alpha(i)_j^0 > 0, j = 1, \dots, n_i - 1, c_i^0 \neq 0$; of course at p, $\gamma(i)_1 = \cdots = \gamma(i)_{n_i-1} = 0$. Now choose the local coordinates $\xi_1, \dots, \xi_{2n}$, as follows: $(\xi_1, \dots, \xi_{n+k}) = (b_1 - b_1^0, \alpha(1)_1 - \alpha(1)_1^0, \dots, \alpha(1)_{n_1-1} - \alpha(1)_{n_1-1}^0, c_1 - c_1^0; b_2 - b_2^0, \alpha(2)_1 - \alpha(2)_1^0, \dots, \alpha(2)_{n_2-1} - \alpha(2)_{n_2-1}^0, c_2 - c_2^0; \dots; b_k - b_k^0, \alpha(k)_1 - \alpha(k)_1^0, \dots, \alpha(k)_{n_k-1} - \alpha(k)_{n_k-1}^0, c_k - c_k^0)$, $(\xi_{n+k+1}, \dots, \xi_{2n}) = (\gamma(1)_1, \dots, \gamma(1)_{n_1-1}, \dots, \gamma(k)_1, \dots, \gamma(k)_{n_k-1})$. Clearly (i) holds. It follows from Theorem 4.1 that there exists a neighborhood U of p such that (ii) holds, and from Theorem 4.1, (iii) follows. ∎

Acknowledgment. Discussions with Dr. J. M. Maciejowski are gratefully acknowledged.

Note added in proof. In a forthcoming article by the present authors in *Linear Algebra and its Applications*, the results presented here are extended to various classes of SISO and multivariable systems.

STOCHASTIC VERIFICATION THEOREMS WITHIN THE FRAMEWORK OF VISCOSITY SOLUTIONS*

XUN YU ZHOU†, JIONGMIN YONG‡, AND XUNJING LI‡

Abstract. This paper studies controlled systems governed by Ito's stochastic differential equations in which control variables are allowed to enter both drift and diffusion terms. A new verification theorem is derived within the framework of viscosity solutions without involving any derivatives of the value functions. This theorem is shown to have wider applicability than the restrictive classical verification theorems, which require the associated dynamic programming equations to have smooth solutions. Based on the new verification result, optimal stochastic feedback controls are obtained by maximizing the generalized Hamiltonians over *both* the control regions and the superdifferentials of the value functions.

Key words. stochastic optimal control, verification theorem, Hamilton–Jacobi–Bellman equation, viscosity solution, superdifferential, feedback control

1. Introduction.

We consider in this paper stochastic optimal control problems of the following kind. For a given $s \in [0,1]$, by the set of admissible controls $U_{ad}[s,1]$ we mean the collection of (i) standard probability spaces $(\Omega, \mathcal{F}, P)$ along with l-dimensional Brownian motions $B = \{B(t) : s \le t \le 1\}$ with $B(s) = 0$ and (ii) Γ-valued $\mathcal{F}_t^s$-adapted measurable processes $u(\cdot) = \{u(t) : s \le t \le 1\}$, where $\mathcal{F}_t^s = \sigma\{B(r) : s \le r \le t\}$ and Γ is a given closed set in some Euclidean space R^m. We denote $(\Omega, \mathcal{F}, P, B; u(\cdot)) \in U_{ad}[s,1]$, but occasionally we will write only $u(\cdot) \in U_{ad}[s,1]$ if no ambiguity arises. Let $(s,y) \in [0,1) \times R^d$ be given. For each $(\Omega, \mathcal{F}, P, B; u(\cdot)) \in U_{ad}[s,1]$, the corresponding cost is

$$J(s,y;u(\cdot)) = E\left[\int_s^1 L(t,x(t),u(t))dt + h(x(1))\right], \tag{1.1}$$

where $x(\cdot) = \{x(t) : s \le t \le 1\}$ is the solution of the following Ito stochastic differential equation (SDE) on the filtered space $(\Omega, \mathcal{F}, P; \mathcal{F}_t^s)$:

$$\begin{cases} dx(t) = f(t,x(t),u(t))dt + \sigma(t,x(t),u(t))dB(t), \\ x(s) = y. \end{cases} \tag{1.2}$$

The solution $x(\cdot)$ of the above SDE is called the response of the control $u(\cdot) \in U_{ad}[s,1]$, and $(x(\cdot), u(\cdot))$ is called an admissible pair. The objective of the optimal control problem is to minimize the cost function $J(s,y;u(\cdot))$, for a given $(s,y) \in [0,1) \times R^d$, over all $u(\cdot) \in U_{ad}[s,1]$. We denote the above problem by $C_{s,y}$ to recall the dependence

on the initial time s and the initial state y. The value function is defined as

$$V(s,y) = \inf_{u(\cdot)\in U_{ad}[s,1]} J(s,y;u(\cdot)). \tag{1.3}$$

An admissible pair $(x^*(\cdot), u^*(\cdot))$ is called *optimal* for $C_{s,y}$ if $u^*(\cdot)$ achieves the minimum of $J(s,y;u(\cdot))$ over $U_{ad}[s,1]$.

As a part of the dynamic programming approach, the so-called verification technique plays an important role in testing for optimality of a given admissible pair and (more importantly) in constructing optimal feedback controls. The classical verification theorem is as follows (see Fleming and Rishel [5, Theorem VI.4.1]):

THEOREM 1.1. *Let $W \in C^{1,2}([0,1]\times R^d)$ be a solution of the following Hamilton–Jacobi–Bellman (HJB) equation:*

$$\begin{cases} -v_t(t,x) + \sup_{u\in\Gamma} G(t,x,u,v_x(t,x),v_{xx}(t,x)) = 0,\ (t,x)\in[0,1)\times R^d, \\ v(1,x) = h(x) \end{cases} \tag{1.4}$$

where the function G is defined as

$$G(t,x,u,q,Q) = -\frac{1}{2}\mathrm{tr}(\sigma^T(t,x,u)Q\sigma(t,x,u)) - q\cdot f(t,x,u) - L(t,x,u) \tag{1.5}$$

for $(t,x,u,q,Q)\in[0,1]\times R^d\times\Gamma\times R^d\times R^{d\times d}$. Then

(a) *$W(s,y)\le J(s,y;u(\cdot))$ for any $(s,y)\in[0,1)\times R^d$ and any $u(\cdot)\in U_{ad}[s,1]$.*

(b) *Suppose that a given admissible pair $(x^*(\cdot),u^*(\cdot))$ for the problem $C_{s,y}$ satisfies*

$$-W_t(t,x^*(t)) + G(t,x^*(t),u^*(t),W_x(t,x^*(t)),W_{xx}(t,x^*(t))) = 0, P\text{-a.s., a.e.}t\in[s,1]; \tag{1.6}$$

then $(x^*(\cdot),u^*(\cdot))$ is an optimal pair for the problem $C_{s,y}$.

Remark 1.1. The function G is called the *generalized Hamiltonian* [17]. By the HJB equation, (1.6) is equivalent to a more familiar form:

$$\begin{aligned} & G(t,x^*(t),u^*(t),W_x(t,x^*(t)),W_{xx}(t,x^*(t))) \\ = \ & \max_{u\in\Gamma} G(t,x^*(t),u,W_x(t,x^*(t)),W_{xx}(t,x^*(t))). \end{aligned}$$

Then, an optimal feedback control $u^*(t,x)$ can be constructed by minimizing $G(t,x,u,W_x(t,x),W_{xx}(t,x))$ over $u\in\Gamma$. For details, see [5].

When practically applying Theorem 1.1, one usually takes the verification function W to be the value function V, as V satisfies the HJB equation if $V\in C^{1,2}([0,1]\times R^d)$. Unfortunately, it is well known that the HJB equation (1.4) does not necessarily admit smooth solutions in general. This makes the applicability of the classical verification theorems very restrictive and is a major deficiency in dynamic programming theory. In recent years, the viscosity solution theory of general nonlinear PDEs, which was launched by Crandall and Lions [4], has been significantly developed. In this theory, all the derivatives involved are replaced by the so-called superdifferentials and subdifferentials, and the solutions in the viscosity sense can be merely continuous functions. The existence and uniqueness of viscosity solutions of the HJB can be guaranteed under very mild and reasonable assumptions, which are satisfied in the great majority of cases arising in optimal control problems. For example, the value function turns out to be the unique viscosity solution of the HJB equation [14]. Since the verification theorems have been playing primary roles in constructing optimal feedback controls, and in many practical problems HJB equations do not have smooth solutions

at all, a natural question arises: do verification theorems still hold, with the solutions of the HJB equation in the classical sense replaced by the ones in the viscosity sense and the derivatives involved replaced by the superdifferentials and/or subdifferentials? For the deterministic case ($\sigma = 0$), the answer to the above question is "yes" [18]. Moreover, based on the new, nonsmooth versions of the verification theorems obtained, a scheme of obtaining feedback controls is proposed in [18], which does not involve any derivative of the value function. For some related works, see [2], [6], and [15].

The present paper proceeds to answer the above question for *stochastic* systems. It should be noted that verification technique is particularly important for stochastic systems because only feedback controls perform well in the uncertain environment. However, the approach for the deterministic case [18] relies heavily on the value function being Lipschitz continuous in both time and spatial variables, which is no longer true for stochastic systems of Ito's type. Indeed, since $\int_0^t \sigma dB$ is only of order $t^{\frac{1}{2}}$, the value function in the stochastic case is Hölder continuous of order $\frac{1}{2}$. This causes a great difficulty in the analysis. In this paper, we shall overcome the difficulty by delicate stochastic analysis.

The paper is organized as follows. In section 2, some preliminary results about viscosity solutions and the associated superdifferentials and subdifferentials will be introduced. In section 3, a new verification theorem in terms of viscosity solutions and the superdifferentials is established. In addition, an example is presented showing that the obtained theorem can test for the optimality of a given control while the classical verification theorems cannot. Section 4 discusses the construction of optimal stochastic feedback controls based on the new verification theorem. Finally, section 5 gives some concluding remarks.

2. Superdifferentials, subdifferentials, and viscosity solutions. We shall use the following basic notation throughout the paper:

A^T : the transpose of any vector or matrix A,

$|A|$: the maximum of the elements of any vector or matrix A,

$R^{n\times k}$: the set of all $n \times k$ matrices,

$S^{n\times n}$: the set of all $n \times n$ symmetric matrices.

Given a probability space $(\Omega, \mathcal{F}, P)$ with a filtration $\{\mathcal{F}_t : a \le t \le b\}$ $(-\infty \le a < b \le +\infty)$, a Hilbert space X with the norm $\|\cdot\|_X$, and $p, 1 \le p \le +\infty$, define the set $L^p_{\mathcal{F}}(a, b; X) = \{\phi(\cdot) = \{\phi(t,\omega) : a \le t \le b\}|\ \phi(\cdot)$ is an $\mathcal{F}_t$-adapted, X-valued measurable process on $[a, b]$, and $E\int_a^b \|\phi(t,\omega)\|_X^p\, dt < +\infty\}$.

DEFINITION 2.1. *Let $v \in C([0,1]\times R^n)$. The right superdifferential (resp., subdifferential) of v at $(t_0, x_0) \in [0,1)\times R^n$, denoted by $D^+_{t+,x}v(t_0,x_0)$ (resp., $D^-_{t+,x}v(t_0,x_0)$), is a set defined by*

$$D^+_{t+,x}v(t_0,x_0) = \{(p,q,Q) \in R^1 \times R^n \times S^{n\times n}| \ \overline{\lim}_{t\to t_0+, x\to x_0} \frac{v(t,x)-v(t_0,x_0)-p(t-t_0)-q\cdot(x-x_0)-\frac{1}{2}(x-x_0)^T Q(x-x_0)}{|t-t_0|+|x-x_0|^2} \le 0\}$$

(*resp.*,

$$D^-_{t+,x}v(t_0,x_0) = \{(p,q,Q) \in R^1 \times R^n \times S^{n\times n}| \ \underline{\lim}\{\cdots\} \ge 0\}).$$

Remark 2.1. To study stochastic control problems, many authors make use of the superdifferential $D^+_{t,x}v(t_0,x_0)$ and subdifferential $D^-_{t,x}v(t_0,x_0)$ obtained by replacing the right-sided limit $t \to t_0+$ in the above definition by the two-sided limit $t \to t_0$ (e.g., [13, 14, 3]). The right-sided differentials have been studied extensively in [17] and proved to be more useful than the two-sided differential in treating some stochastic

control problems (see, e.g., [17, Remark 4.1] and [7]). On the other hand, the following inclusions are clear:

$$D^+_{t,x}v(t_0,x_0) \subseteq D^+_{t+,x}v(t_0,x_0),\ D^-_{t,x}v(t_0,x_0) \subseteq D^-_{t+,x}v(t_0,x_0).$$

DEFINITION 2.2. *A function $v \in C([0,1]\times R^n)$ is called a viscosity solution of the HJB equation* (1.4) *if*

$$\begin{aligned} &-p+\sup_{u\in\Gamma} G(t,x,u,q,Q) \le 0 \quad \forall (p,q,Q)\in D^+_{t+,x}v(t,x)\ \ \forall (t,x)\in[0,1)\times R^d,\\ &-p+\sup_{u\in\Gamma} G(t,x,u,q,Q) \ge 0 \quad \forall (p,q,Q)\in D^-_{t+,x}v(t,x)\ \ \forall (t,x)\in[0,1)\times R^d, \end{aligned}$$

and $v(1,x)=h(x)$.

Remark 2.2. The notion of a viscosity solution in the sense specified in Definition 2.2 is more general than those which involve two-sided differentials in t (cf. [3, 13, 14]) in view of the set inclusions in Remark 2.1. Moreover, the uniqueness of viscosity solutions in our sense holds if the uniqueness holds in the "two-sided" sense.

Now let us turn to the control problem formulated in section 1. We impose the following assumptions throughout this paper.

(A1) f, σ, and L are continuous mappings from $[0,1]\times R^d\times\Gamma$ to R^d, $R^{d\times l}$, and R^1, respectively; moreover, they are continuous with respect to (t,x), uniformly in $u\in\Gamma$.

(A2) There exists a constant $K>0$ which is independent of (t,u) such that

$$\begin{aligned} &|f(t,x,u)-f(t,y,u)|+|\sigma(t,x,u)-\sigma(t,y,u)|\\ +\ &|L(t,x,u)-L(t,y,u)|+|h(x)-h(y)|\le K|x-y| \quad \forall x,y\in R^d,\\ &|f(t,x,u)|+|\sigma(t,x,u)|+|L(t,x,u)|+|h(x)|\le K(1+|x|)\ \ \forall x\in R^d. \end{aligned}$$

The following result can be found in [16, 17].

LEMMA 2.1. *The value function V satisfies*

$$|V(t,x)-V(t',x')|\le C(|t-t'|^{\frac12}+|x-x'|).$$

Moreover, V is a unique viscosity solution of the HJB equation (1.4).

An immediate consequence of Lemma 2.1 is the following.

COROLLARY 2.1. *We have*

$$\inf_{(p,q,Q,u)\in D^+_{t+,x}V(t,x)\times\Gamma}[p-G(t,x,u,q,Q)]\ge 0\ \ \forall (t,x)\in[0,1)\times R^d.$$

We need some technical lemmas.

LEMMA 2.2. *Let $v\in C([0,1]\times R^n)$ be a given function that satisfies*

$$|v(t,x)-v(t',x')|\le C_1(|t-t'|^{\frac12}+|x-x'|).$$

For any $(t_0,x_0)\in[0,1)\times R^n$, if $(p,q,Q)\in D^+_{t+,x}v(t_0,x_0)$ (resp., $(p,q,Q)\in D^-_{t+,x}v(t_0,x_0)$), then there exists a function $\phi:[t_0,1]\times R^n\to R^1$ satisfying

(i) $\phi\in C([t_0,1]\times R^n)\cap C^{1,2}((t_0,1]\times R^n)$,

(ii) $\phi(t_0,x_0)=v(t_0,x_0)$ *and* $\phi(t,x)>v(t,x)$ (*resp.,* $\phi(t,x)<v(t,x)$) *for any* $(t,x)\ne(t_0,x_0)$,

(iii) $\lim_{t\to t_0+,x\to x_0,|x-x_0|\le N|t-t_0|^{\frac12}}\phi_t(t,x)=p$ *for any fixed* $N>0$, $\phi_x(t_0,x_0)=q$ *and* $\phi_{xx}(t_0,x_0)=Q$,

(iv)

$$|\phi_t(t,x)| \le C_2(1+\tfrac{|x-x_0|}{|t-t_0|^{\frac{1}{2}}}) \ \ \forall (t,x)\in (t_0,1]\times R^n,$$
$$|\phi_x(t,x)|+|\phi_{xx}(t,x)| \le C_2(1+|x|+|x|^2+|x|^3) \ \ \forall (t,x)\in [t_0,1]\times R^n.$$

Proof. This lemma was presented and proved in Zhou [17] except that for (iii) the statement there was

$$\lim_{t\to t_0+,x\to x_0}\phi_x(t,x)=q, \qquad \lim_{t\to t_0+,x\to x_0}\phi_{xx}(t,x)=Q.$$

However, it is easily seen by the proof in [17] that

$$\phi_x(t_0,x_0)=q \text{ and } \phi_{xx}(t_0,x_0)=Q$$

hold as well. □

LEMMA 2.3. *Let $g\in C[0,1]$. Suppose that there is $\rho\in L^1[0,1]$ such that for sufficiently small $h>0$,*

$$\frac{g(t+h)-g(t)}{h}\le \rho(t), \ \text{a.e. } t\in[0,1]. \tag{2.1}$$

Then

$$g(t)-g(0)\le \int_0^t \overline{\lim_{h\to 0+}}\frac{g(r+h)-g(r)}{h}dr \ \ \forall t\in[0,1]. \tag{2.2}$$

Proof. First fix $t\in[0,1)$. By (2.1), we can apply Fatou's lemma to get

$$\begin{aligned}\textstyle\int_0^t \overline{\lim}_{h\to 0+}\frac{g(r+h)-g(r)}{h}dr &\ge \textstyle\overline{\lim}_{h\to 0+}\int_0^t \frac{g(r+h)-g(r)}{h}dr\\ &= \textstyle\overline{\lim}_{h\to 0+}\frac{\int_h^{t+h} g(r)dr-\int_0^t g(r)dr}{h}\\ &= \textstyle\overline{\lim}_{h\to 0+}\frac{\int_t^{t+h} g(r)dr-\int_0^h g(r)dr}{h}\\ &= g(t)-g(0).\end{aligned}$$

This proves (2.2) $\forall t\in[0,1)$. Finally, the $t=1$ case is obtained by continuity. □

3. Verification theorems.

THEOREM 3.1. *Let $W\in C([0,1]\times R^d)$ be a viscosity solution of the HJB equation (1.4). Then*

(a) *$W(s,y)\le J(s,y;u(\cdot))$ for any $(s,y)\in[0,1)\times R^d$ and any $u(\cdot)\in U_{ad}[s,1]$.*

(b) *Let $(x^*(\cdot),u^*(\cdot))$ be a given admissible pair for the problem $C_{s,y}$. Suppose that there exists $(p^*,q^*,Q^*)\in L^2_{\mathcal{F}}(s,1;R^1)\times L^2_{\mathcal{F}}(s,1;R^d)\times L^2_{\mathcal{F}}(s,1;S^{d\times d})$ (where the filtration $\mathcal{F}_t=\mathcal{F}_t^s$) such that for a.e. $t\in[s,1]$,*

$$(p^*(t),q^*(t),Q^*(t))\in D^+_{t+,x}W(t,x^*(t)), \ P\text{-a.s.} \tag{3.1}$$

and

$$-p^*(t)+G(t,x^*(t),u^*(t),q^*(t),Q^*(t))=0, \ P\text{-a.s.}; \tag{3.2}$$

then $(x^*(\cdot),u^*(\cdot))$ is an optimal pair for the problem $C_{s,y}$.

Proof. Part (a) is trivial since $W=V$ in view of the uniqueness of the viscosity solutions. (Note that we state our results in the present form purposely in order to

compare with the classical verification theorem.) We prove only part (b) of the theorem. Set $f^*(t) = f(t, x^*(t), u^*(t))$, etc., to simplify the notation. Fix $t \in [s, 1)$ such that (3.1) and (3.2) hold. Choose a test function $\phi \in C([t,1] \times R^d) \cap C^{1,2}((t,1] \times R^d)$ as determined by $(p^*(t), q^*(t), Q^*(t)) \in D^+_{t+,x} W(t, x^*(t))$ and Lemma 2.2. Applying Ito's formula to ϕ, we have for any $h > 0$,

$$\begin{aligned} & W(t+h, x^*(t+h)) - W(t, x^*(t)) \\ \leq\ & \phi(t+h, x^*(t+h)) - \phi(t, x^*(t)) \\ =\ & \textstyle\int_t^{t+h} [\phi_t(r, x^*(r)) + \phi_x(r, x^*(r)) \cdot f^*(r) + \frac{1}{2}\mathrm{tr}(\sigma^{*T}(r)\phi_{xx}(r, x^*(r))\sigma^*(r))]dr. \end{aligned} \tag{3.3}$$

It is well known by the martingale property of stochastic integrals that there are constants $C_3, C_4(\alpha) > 0$, independent of t, such that

$$\begin{aligned} & E|x^*(r) - x^*(t)|^2 \leq C_3|r-t| \ \ \forall r \geq t, \\ & E \sup_{s \leq r \leq 1} |x^*(r)|^\alpha \leq C_4(\alpha) \ \ \forall \alpha \geq 1. \end{aligned} \tag{3.4}$$

Hence, in view of Lemma 2.2 (iv), we have

$$\sup_{t<r\leq 1} E|\phi_t(r, x^*(r))|^2 \leq C_2^2 \sup_{t<r\leq 1} E\left[1 + \frac{|x^*(r) - x^*(t)|^2}{r-t}\right] \leq C_5, \tag{3.5}$$

or

$$\sup_{t<r\leq 1} E|\phi_t(r, x^*(r))| \leq \sqrt{C_5}.$$

Moreover, by Lemma 2.2 (iv) and assumption (A2), one can show that

$$\sup_{t\leq r\leq 1} E|\phi_x(r, x^*(r)) \cdot f^*(r) + \frac{1}{2}\mathrm{tr}(\sigma^{*T}(r)\phi_{xx}(r, x^*(r))\sigma^*(r))| \leq C_6.$$

It then follows from (3.3) that for sufficiently small $h > 0$,

$$\frac{EW(t+h, x^*(t+h)) - EW(t, x^*(t))}{h} \leq \sqrt{C_5} + C_6. \tag{3.6}$$

Now we calculate, for any fixed $N > 0$,

$$\begin{aligned} & \tfrac{1}{h}\textstyle\int_t^{t+h} E[\phi_t(r, x^*(r)) - p^*(t)]dr \\ =\ & \tfrac{1}{h}\textstyle\int_t^{t+h} E[(\phi_t(r, x^*(r)) - p^*(t))\chi_{|x^*(r)-x^*(t)|>N|r-t|^{\frac{1}{2}}}]dr \\ & + \tfrac{1}{h}\textstyle\int_t^{t+h} E[(\phi_t(r, x^*(r)) - p^*(t))\chi_{|x^*(r)-x^*(t)|\leq N|r-t|^{\frac{1}{2}}}]dr \\ =\ & I_1(N,h) + I_2(N,h). \end{aligned}$$

By virtue of (3.4) and (3.5), we have

$$\begin{aligned} I_1(N,h) & \leq \tfrac{1}{h}\textstyle\int_t^{t+h} [E|\phi_t(r, x^*(r)) - p^*(t)|^2]^{\frac{1}{2}} [P(|x^*(r) - x^*(t)| > N|r-t|^{\frac{1}{2}})]^{\frac{1}{2}} dr \\ & \leq \tfrac{C}{N} \to 0 \text{ uniformly in } h > 0 \text{ as } N \to \infty. \end{aligned}$$

On the other hand, for fixed $N > 0$, we apply Lemma 2.2 (iii) to get

$$\sup_{t<r\leq t+h} \left[(\phi_t(r, x^*(r)) - p^*(t))\chi_{|x^*(r)-x^*(t)|\leq N|r-t|^{\frac{1}{2}}}\right] \to 0 \text{ as } h \to 0+, P\text{-a.s.}$$

Thus we conclude by the dominated convergence theorem that

$$I_2(N,h) \to 0 \text{ as } h \to 0+ \text{ for each fixed } N.$$

Therefore, we have proved that $\frac{1}{h}\int_t^{t+h} E\phi_t(r, x^*(r))dr \to Ep^*(t)$ as $h \to 0+$. Similarly (in fact, more easily), we can show that

$$\frac{1}{h}\int_t^{t+h} E[\phi_x(r, x^*(r)) \cdot f^*(r)]dr \to E[\phi_x(t, x^*(t)) \cdot f^*(t)] = E[q^*(t) \cdot f^*(t)]$$

and

$$\frac{1}{h}\int_t^{t+h} E[\frac{1}{2}\mathrm{tr}(\sigma^{*T}(r)\phi_{xx}(r, x^*(r))\sigma^*(r))]dr \to E[\frac{1}{2}\mathrm{tr}(\sigma^{*T}(t)\phi_{xx}(t, x^*(t))\sigma^*(t))]$$

$$= E[\frac{1}{2}\mathrm{tr}(\sigma^{*T}(t)Q^*(t)\sigma^*(t))]$$

as $h \to 0+$. Consequently, (3.3) gives

$$\begin{aligned} & \overline{\lim}_{h\to 0+} \frac{EW(t+h, x^*(t+h)) - EW(t, x^*(t))}{h} \\ \leq\ & E[p^*(t) + q^*(t) \cdot f^*(t) + \frac{1}{2}\mathrm{tr}(\sigma^{*T}(t)Q^*(t)\sigma^*(t))] \\ =\ & -EL^*(t), \end{aligned}$$

where the last equality is due to (3.2). Noting (3.6) and applying Lemma 2.3 to $g(t) = EW(t, x^*(t))$, we arrive at

$$EW(1, x^*(1)) - EW(s, y) \leq \int_s^1 -EL^*(t)dt,$$

which leads to $W(s, y) \geq J(s, y; u^*(\cdot))$. It follows from (a) that $(x^*(\cdot), u^*(\cdot))$ is an optimal pair for $C_{s,y}$. □

Remark 3.1. In view of Corollary 2.1, the condition (3.2) implies that $(p^*(t), q^*(t), Q^*(t), u^*(t))$ achieves the infimum of $p - G(t, x^*(t), u, q, Q)$ over $D^+_{t+,x}V(t, x^*(t)) \times \Gamma$. Meanwhile, it also shows that (3.2) is equivalent to

$$p^*(t) \leq G(t, x^*(t), u^*(t), q^*(t), Q^*(t)).$$

Remark 3.2. The condition (3.2) implies that

$$\max_{u\in\Gamma} G(t, x^*(t), u, q^*(t), Q^*(t)) = G(t, x^*(t), u^*(t), q^*(t), Q^*(t)). \tag{3.7}$$

This is easily seen by recalling the fact that V is the viscosity solution of (1.4):

$$-p^*(t) + \sup_{u\in\Gamma} G(t, x^*(t), u, q^*(t), Q^*(t)) \leq 0,$$

which yields (3.7) under (3.2).

Remark 3.3. By Remark 2.1, the new verification theorem holds if the right superdifferential $D^+_{t+,x}W(t, x^*(t))$ is replaced by the (smaller) two-sided superdifferential $D^+_{t,x}W(t, x^*(t))$.

Theorem 3.1 is a generalization of the classical verification theorem (Theorem 1.1). On the other hand, we do have examples showing that the classical verification theorem may not be able to verify the optimality of a given control, whereas Theorem 3.1 can.

Example 3.1. Consider the following optimal control problem:

$$\begin{aligned} \text{minimize} \quad & E[-x(1)], \\ \text{subject to} \quad & \begin{cases} dx(t) = [x(t)(u(t)+1) - e^t u(t)]dt + |x(t) - e^t|dB(t), \\ x(s) = y \in R^1, \end{cases} \\ \text{control} \quad & u(\cdot) : [0,1] \to \{r \in R^1 | 0 \leq r \leq 1\}. \end{aligned}$$

The HJB equation is

$$\begin{cases} -v_t(t,x) + \sup_{0\le u\le 1}[v_x(t,x)(e^t - x)u] - \frac{1}{2}(x-e^t)^2 v_{xx}(t,x) - xv_x(t,x) = 0, \\ v(1,x) = -x. \end{cases}$$

It is not difficult to verify that the following function is a viscosity solution of the HJB equation

$$V(t,x) = \begin{cases} -e^{1-t}x & \text{if } x \le e^t, \\ (e^{1-t} - e^{1-2t}x - 1)e & \text{if } x > e^t, \end{cases}$$

which, by the uniqueness of the viscosity solutions, turns out to be the value function of the control problem. Let us consider an admissible control $u^*(\cdot) \equiv 0$ for initial time $s = 0$ and initial state $y = 1$. The trajectory under $u^*(\cdot)$ is easily seen to be $x^*(t) = e^t$. Now we want to see if the pair $(x^*(\cdot), u^*(\cdot))$ is optimal. Theorem 1.1 cannot tell us anything, because $V_x(t, x^*(t))$ does not exist on the *whole* trajectory $x^*(\cdot)$. However, we have $D^+_{t+,x}V(t,x^*(t)) = [e,+\infty) \times [-e^{2-2t}, -e^{1-t}] \times \{Q \in S^{d\times d} : Q \ge 0\}$. Now if we take $(p^*(t), q^*(t), Q^*(t)) = (e, -e^{1-t}, 0) \in D^+_{t+,x}V(t,x^*(t))$ for each t, then (3.2) is satisfied. This implies that the pair $(x^*(\cdot), u^*(\cdot))$ is indeed optimal by virtue of Theorem 3.1.

4. Optimal feedback controls. This section describes how to construct optimal feedback controls by the verification theorem obtained. First we recall the definition of admissible feedback controls.

DEFINITION 4.1. *A measurable function* $\mathbf{u}$ *from* $[0,1] \times R^d$ *to* Γ *is called an admissible feedback control if for any* $(s,y) \in [0,1) \times R^d$ *there is a weak solution* $x(\cdot; s, y)$ *of the following equation:*

$$\begin{cases} dx(t) = f(t, x(t), \mathbf{u}(t, x(t)))dt + \sigma(t, x(t), \mathbf{u}(t, x(t)))dB(t), \\ x(s) = y. \end{cases} \tag{4.1}$$

An admissible feedback control $\mathbf{u}^*$ *is called optimal if* $(x^*(\cdot; s, y), \mathbf{u}^*(\cdot, x^*(\cdot; s, y)))$ *is optimal for the problem* $C_{s,y}$ *for* each (s,y)*, where* $x^*(\cdot; s, y)$ *is a solution of* (4.1) *corresponding to* $\mathbf{u}^*$*.*

THEOREM 4.1. *Let* $\mathbf{u}^*$ *be an admissible feedback control and* $\mathbf{p}^*$*,* $\mathbf{q}^*$*, and* $\mathbf{Q}^*$ *be measurable functions satisfying* $(\mathbf{p}^*(t,x), \mathbf{q}^*(t,x), \mathbf{Q}^*(t,x)) \in D^+_{t+,x}V(t,x)$ *for all* (t,x)*. If*

$$\begin{aligned} & \mathbf{p}^*(t,x) - G(t,x,\mathbf{u}^*(t,x), \mathbf{q}^*(t,x), \mathbf{Q}^*(t,x)) \\ = \ & \inf_{(p,q,Q,u)\in D^+_{t+,x}V(t,x)\times\Gamma}[p - G(t,x,u,q,Q)] \\ = \ & 0 \end{aligned} \tag{4.2}$$

for all $(t,x) \in [0,1] \times R^d$*, then* $\mathbf{u}^*$ *is optimal.*

Proof. The result follows readily from (b) of Theorem 3.1. □

By Theorem 4.1, we see that under proper conditions, one can obtain an optimal feedback control by minimizing $p - G(t,x,u,q,Q)$ over $(p,q,Q,u) \in D^+_{t+,x}V(t,x) \times \Gamma$ for each (t,x). Let us investigate the conditions imposed in Theorem 4.1. First of all, (4.2) requires that

$$\inf_{(p,q,Q,u)\in D^+_{t+,x}V(t,x)\times\Gamma}[p - G(t,x,u,q,Q)] = 0, \tag{4.3}$$

and in addition the infimum can be achieved. This condition in fact partially characterizes the existence of an optimal feedback control, although rather implicitly in the sense that the value function is involved. In particular, this condition is satisfied *automatically* if V is smooth. Next, in order to apply Filippov's lemma to obtain a *measurable selector* of $(\mathbf{p}^*(t,x), \mathbf{q}^*(t,x), \mathbf{Q}^*(t,x), \mathbf{u}^*(t,x))$ which achieves the infimum in (4.2), we must study the measurability of the multifunction $(t,x) \mapsto D^+_{t+,x}V(t,x)$. To do this, let us first recall the measurability of the multifunctions (see, e.g., [12], [1], and [8] for details).

DEFINITION 4.2. *Let $X \subset R^n$ be a Lebesgue measurable set, Y be a metric space, and $\Lambda : X \to 2^Y$ be a multifunction. We say that Λ is measurable if for any closed set $F \subset Y$ the set*

$$\Lambda^{-1}(F) \triangleq \Big\{ x \in X \mid \Lambda(x) \bigcap F \neq \emptyset \Big\}$$

is Lebesgue measurable.

Note that in the above we do not need Λ to be closed set valued. It is clear that when Y is a Polish space (i.e., a separable complete metric space), the closed set F in the above definition can be replaced by any open set. Consequently, we have the following simple result.

LEMMA 4.1. *Let $X \subset R^n$ be a Lebesgue measurable set, Y be a Polish space, and $\Lambda : X \to 2^Y$ be a multifunction. Then, Λ is measurable if and only if the multifunction $x \mapsto \overline{\Lambda}(x) \triangleq \overline{\Lambda(x)}$ is measurable.*

Proof. We note that for any open set $U \subset Y$ and $x \in X$,

$$\Lambda(x) \bigcap U \neq \phi \quad \Longleftrightarrow \quad \overline{\Lambda(x)} \bigcap U \neq \phi.$$

Hence,

$$\Lambda^{-1}(U) = \overline{\Lambda}^{-1}(U) \qquad \forall \text{ open set } U \subset Y.$$

Then, by the above observation, we obtain our conclusion. □

PROPOSITION 4.1. *Both the multifunctions $(t,x) \mapsto D^+_{t+,x}V(t,x)$ and $(t,x) \mapsto \overline{D^+_{t+,x}V(t,x)}$ are convex set valued and are measurable.*

Proof. For any $(s,y) \in (0,1] \times R^d$, we define

$$W(t,x,p,q,Q;s,y) = \begin{cases} \frac{V(s,y)-V(t,x)-p(s-t)-q\cdot(y-x)-\frac{1}{2}(y-x)^T Q(y-x)}{|s-t|+|y-x|^2} & \text{if } t \in [0,s), \\ 0 & \text{if } t \in [s,1]. \end{cases}$$

Then, (s,y) being regarded as parameters, the function $(t,x,p,q,Q) \mapsto W(t,x,p,q,Q;s,y)$ is Borel measurable. Hence, the function

$$\overline{\lim_{s \to t+, y \to x}} W(t,x,p,q,Q;s,y) \triangleq \widetilde{W}(t,x,p,q,Q)$$

is also Borel measurable. Then, by [12, Theorem III.2.20], we know that the multifunction

$$D^+_{t+,x}V(t,x) \equiv \{(p,q,Q) \mid \widetilde{W}(t,x,p,q,Q) \leq 0\}$$

is measurable. By Lemma 4.1, we obtain the measurability of the multifunction $(t,x) \mapsto \overline{D^+_{t+,x}V(t,x)}$. The convexity of these two multifunctions is obvious. □

Filippov's lemma (see, e.g., [12], [1], and [8]) says that if Λ is a measurable multifunction defined on some Lebesgue measurable set taking closed set values in a Polish space, then it admits a measurable selection. Therefore, if we assume that $D^+_{t+,x}V(t,x)$ is closed and that the infimum in (4.2) can be achieved, then by Proposition 4.1 and Filippov's lemma, we can find a measurable selection $(\mathbf{p}^*(t,x), \mathbf{q}^*(t,x), \mathbf{Q}^*(t,x), \mathbf{u}^*(t,x)) \in D^+_{t+,x}V(t,x)$ that minimizes $p - G(t,x,u,q,Q)$.

Suppose now we have selected a measurable function $\mathbf{u}^*(t,x)$. It may not be an admissible feedback control. The reason is because the coefficients $\tilde{f}(t,x) \stackrel{\Delta}{=} f(t,x,\mathbf{u}^*(t,x))$ and $\tilde{\sigma}(t,x) \stackrel{\Delta}{=} \sigma(t,x,\mathbf{u}^*(t,x))$ of the SDE (4.1) are only measurable in (t,x), which does not guarantee the existence of a solution. This difficulty occurs in the deterministic case as well. However, for the stochastic case, there are some elegant existence and uniqueness results for SDEs with measurable coefficients. Let us briefly discuss two situations.

Case 1. Assume that $\sigma(t,x,u)$ is a $d \times d$ matrix and is uniformly elliptic, i.e.,

$$\lambda^T \sigma(t,x,u)\lambda \geq \delta|\lambda|^2 \tag{4.4}$$

for some constant $\delta > 0$ for all (t,x,u). Then by Krylov [10, Theorem II.6.1], there exists a solution to SDE (4.1) under $\mathbf{u}^*(t,x)$. By Theorem 4.1, $\mathbf{u}^*(t,x)$ is an optimal feedback control.

Case 2. Assume that σ is a nonsingular $d \times d$ matrix and does not depend on u. Moreover,

$$\sup_{t,x} |\sigma^{-1}(t,x)| < +\infty. \tag{4.5}$$

Then under $\mathbf{u}^*(t,x)$, the existence and uniqueness (in law) of the solutions to (4.1) are obtained by Girsanov's transformation (see, e.g., [9, Theorem IV.4.2]). Once again, $\mathbf{u}^*(t,x)$ is an optimal feedback control by Theorem 4.1.

To summarize the above discussion, we have the following theorem.

THEOREM 4.2. *Assume that*

(i) $\inf_{(p,q,Q,u)\in D^+_{t+,x}V(t,x)\times\Gamma}[p - G(t,x,u,q,Q)] = 0$.

(ii) $D^+_{t+,x}V(t,x)$ *is closed and the infimum above can be achieved.*

(iii) *Either* (4.4) *or* (4.5) *holds.*

Then, there is a measurable selector $(\mathbf{p}^*(t,x), \mathbf{q}^*(t,x), \mathbf{Q}^*(t,x), \mathbf{u}^*(t,x))$ *that minimizes* $p - G(t,x,u,q,Q)$. *Moreover, the fourth component* $\mathbf{u}^*(t,x)$ *is an optimal feedback control.*

Remark 4.1. In the presence of the uniform ellipticity of $\sigma\sigma^T$, Krylov proved the existence of classical solutions to the HJB equation under additional regularity and strong boundness assumptions on the coefficients f, σ, L, h (see [11, Chapter 6, p. 301]). Under the mild assumptions in this paper, one does not know the existence of classical solutions to the HJB equation even with (4.4).

5. Concluding remarks. In this paper we have derived a new verification theorem in the language of viscosity solutions and the associated superdifferentials. The conditions under which the theorem is valid are very mild and reasonable, compared with the restrictive classical verification theorem. We have also discussed the construction of optimal feedback controls based on the verification theorem obtained in this paper. Basically, the verification theorem reduces the original stochastic control problem into a two-phase problem. In the first phase, one has to solve the HJB equations which are fully nonlinear second-order PDEs. In most cases one has to

rely on numerical methods to solve the equations, whereas only in some exceptional cases one may obtain analytical solutions (like the one in Example 3.1). In the second phase, one finds the optimal feedback $\mathbf{u}^*$ by minimizing $p - G(t, x, u, q, Q)$ over *both* superdifferential of V and the control region. The second phase is relatively easy because the superdifferential of V is explicitly known once V is known. However, if V is approximated by numerical solutions V_n, then a natural problem is under what conditions the feedback controls obtained by applying our verification theorem to V_n are good enough. We then need to study the asymptotic behavior of the superdifferentials/subdifferentials of the approximating solutions V_n. These remain very challenging problems.

It should be noted that the results of this paper were derived when there was no state constraint in the optimal control problem. We do not know how to treat the state constraint problems. Indeed, the presence of state constraints causes great difficulty to the analysis; they bring some particular boundary conditions (depending on the particular features of the state constraints imposed) to the associated HJB equations, while the existing viscosity solutions theory on nonlinear PDEs with boundary conditions is far from satisfactory and complete.

BEHAVIORAL CONTROLLABILITY OF DELAY-DIFFERENTIAL SYSTEMS*

PAULA ROCHA† AND JAN C. WILLEMS‡

Abstract. In this paper we will prove that the system described by the delay-differential equation $R(d/dt, \Delta)w = 0$ (with Δ the unit delay operator) is controllable if and only if the rank of $R(\lambda, e^{-\lambda})$ is constant for all $\lambda \in \mathbb{C}$. This condition is compared with the existing results obtained both by the analytic approach and by the algebraic approach to delay-differential systems.

Key words. behavioral systems, controllability, delay-differential systems, polynomial matrices

AMS subject classification. 93B05

1. Introduction. The aim of this paper is to analyze controllability for delay-differential (d-d) systems. We will derive a concrete necessary and sufficient condition for controllability of d-d systems in kernel representation. We will use the behavioral approach to dynamical systems [12]. Thus a continuous-time dynamical system is a triple $\Sigma = (\mathbb{R}, \mathbb{R}^q, \mathcal{B})$ with *behavior* $\mathcal{B}$ being a set of trajectories $w : \mathbb{R} \to \mathbb{R}^q$. We will assume that $\mathcal{B}$ is shift invariant, i.e., that $(w(.) \in \mathcal{B}) \Rightarrow (w(t + .) \in \mathcal{B} \ \ \forall t \in \mathbb{R})$. Since the behavior is the most intrinsic feature of a system, it is logical to define the system properties in terms of the set $\mathcal{B}$, i.e., at an external level. This applies in particular for the notion of controllability.

DEFINITION 1.1. *The system Σ is said to be* controllable *if for all $w_1, w_2 \in \mathcal{B}$ there exist a $w \in \mathcal{B}$ and a $T \geq 0$ such that*

$$w(t) = \begin{cases} w_1(t) & for \quad t < 0, \\ w_2(t - T) & for \quad t \geq T. \end{cases}$$

Note that for shift-invariant behaviors the controllability condition of Definition 1.1 is equivalent to the following property. For all $w_1, w_2 \in \mathcal{B}$, w_1 is $\mathcal{B}$-*compatible* with w_2, i.e., for all $t_1 \in \mathbb{R}$ there exist $t_2 \geq t_1$ and $w \in \mathcal{B}$ such that $w^* = w_1 \wedge_{t_1} w \wedge_{t_2} w_2 \in \mathcal{B}$. Here $w^* = w_1 \wedge_{t_1} w \wedge_{t_2} w_2$ stands for the successive concatenation of w_1, w, and w_2, respectively, at times t_1 and t_2 and is defined as follows: $w^*(t) = w_1(t)$ for $t < t_1$, $w^*(t) = w(t)$ for $t_1 \leq t < t_2$, and $w^*(t) = w_2(t)$ for $t \geq t_2$. In other words, controllability requires that every past trajectory can be transferred to any future trajectory. In order to distinguish this property from the classical state controllability and to emphasize the fact that it concerns the system behavior we will refer to it as behavioral controllability.

Behavioral controllability has been widely studied for both continuous- and discrete-time systems, respectively, described by differential and difference equations, see [12, 8]. In this paper we consider continuous-time systems described by differential

equations with delays, i.e., d-d systems. More concretely, we will be concerned with systems whose behavior $\mathcal{B}$ can be described as the kernel of a d-d operator $R(d/dt, \Delta)$ (where $R(z_1, z_2)$ is a two-dimensional (2D) polynomial matrix in z_1 and z_2 and Δ is the delay). This is a very general description which can comprise both the polynomial input-output equations and the pseudostate representations considered in the literature [11], [3]. We will show that $\mathcal{B} = \ker R(d/dt, \Delta)$ is controllable if and only if (iff) $R(\lambda, e^{-\lambda})$ has constant rank for all $\lambda \in \mathbb{C}$. It turns out that this condition reduces to spectral controllability if one considers pseudostate representations as in [3], [6], and [9].

This characterization of behavioral controllability has also been independently obtained in [1], where the author develops an elegant theory for d-d systems in a behavioral framework based on the properties of a suitable ring of entire functions. Here we follow a different approach based on the analysis of the exponential-polynomial trajectories in the system.

2. Delay-differential systems. Let $R(z_1, z_2)$ be a 2D polynomial matrix having g rows and q columns. Now consider the equation

$$R\left(\frac{d}{dt}, \Delta\right) w = 0, \tag{1}$$

where Δ denotes the unit delay operator: $(\Delta f)(t) := f(t-1)$. Equation (1) defines the dynamical system $(\mathbb{R}, \mathbb{R}^q, \mathcal{B})$ with $\mathcal{B} = \ker(R(d/dt, \Delta))$ and $R(d/dt, \Delta)$ viewed as a map from $\mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^q)$ into $\mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^g)$. In other words, the behavior consists of the $\mathcal{C}^\infty$-solutions of (1). We will call (1) a d-d system (even though it would be more appropriate to refer to it as a d-d system in kernel representation).

Note that this kernel representation is more general than the polynomial input-output descriptions considered in [11], as well as than the pseudostate descriptions of [3]. Indeed, any polynomial input-output d-d equation $Py = Qu$ can be regarded as a kernel representation with $R(d/dt, \Delta) = [P(d/dt, \Delta) \mid -Q(d/dt, \Delta)]$ and with $w = col(y, u)$. In turn, the pseudostate description $\{dx/dt = A(\Delta)x + Bu \;\; y = Cx\}$ can also be viewed as a kernel representation with $w = col(x, y, u)$ and $R(d/dt, \Delta) = col([d/dt - A(\Delta) \mid 0 \mid -B], [-C \mid I \mid 0])$. Observe, however, that (1) is a broader class of systems than those mentioned. For example, both the systems defined by

$$w_1 = \frac{d}{dt}\Delta w_2$$

and by

$$\Delta w_1 = (1 + \Delta^2) w_2$$

fit (1) but not the classical input/state/output frameworks.

3. Behavioral controllability of d-d systems. Our problem is to find conditions on the 2D polynomial matrix $R(z_1, z_2)$ such that (1) defines a system which is controllable in the sense of Definition 1.1. The following is the main result of this paper.

THEOREM 3.1. (1) *defines a controllable d-d system iff the rank of the complex matrix* $R(\lambda, e^{-\lambda})$ *is constant for* $\lambda \in \mathbb{C}$.

The above theorem is a natural generalization of the well-known identical result for differential systems $R(d/dt)w = 0$. However, the proof will show that from a mathematical point of view Theorem 3.1 is a much deeper result.

As an alternative to systems (1), consider the following d-d systems. Let $M(z_1, z_2)$ be a 2D polynomial matrix with q rows and l columns. Consider the equation

$$w = M\left(\frac{d}{dt}, \Delta\right) a, \tag{2}$$

where $a \in C^\infty(\mathbb{R}, \mathbb{R}^l)$ corresponds to an auxiliary variable. Equation (2) defines a dynamical system $(\mathbb{R}, \mathbb{R}^q, \mathrm{im}(M(d/dt, \Delta)))$ with $M(d/dt, \Delta)$ viewed as an operator from $\mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^l)$ into $\mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^q)$. We will call (2) a d-d system in image representation. It is easy to prove that (2) defines a dynamical system which is automatically controllable. For differential systems, a system is controllable if and *only if* it admits an image representation. This is, in fact, also the case for d-d systems (1).

THEOREM 3.2. *A d-d system* (1) *is a controllable system iff there exists a* 2*D polynomial matrix* $M(z_1, z_2)$ *such that*

$$\ker R\left(\frac{d}{dt}, \Delta\right) = \mathrm{im} M\left(\frac{d}{dt}, \Delta\right). \tag{3}$$

In order to give a further insight, it is useful to compare our result with the existing results on state controllability for d-d systems. We will first focus on the class of retarded d-d systems Σ considered in [3] which have a pseudostate description of the form

$$\begin{cases} dx/dt &= A(\Delta)x + Bu, \\ y &= Cx, \end{cases}$$

where x is the (n-dimensional) pseudostate, u is the input, y is the output, and $A(z) = A_N z^N + \cdots + A_1 z + A_0$ is a polynomial matrix in z. For the system Σ, the state at time t is defined in [3] as being $z(t) = col(x(t), x_t)$, where $x_t \in L_2[(-N, 0], \mathbb{R}^n]$ is given by $x_t(\tau) = x(t + \tau)$ for all $\tau \in (-N, 0]$. This yields the infinite-dimensional state space $Z = \mathbb{R}^n \times L_2[(-N, 0), \mathbb{R}^n]$. Define, in this state space, the set K_t of all attainable states in time t, and let $K_\infty := \cup_{t>0} K_t$. Then Σ is said to be approximately controllable if K_∞ is dense in Z. The next theorem, providing a characterization of approximate controllability, has been derived in [3].

THEOREM 3.3. Σ *is approximately controllable iff* (1) $\mathrm{rank}[(\lambda I - A(e^{-\lambda}) \mid B] = n \ \ \forall \lambda \in \mathbb{C}$ *and* (2) $\mathrm{rank}[A_N \mid B] = n$.

The first condition of the theorem is known as *spectral controllability*.

Note that the pseudostate description that we have considered here can be regarded as a kernel representation with $R(d/dt, \Delta) = col([d/dt - A(\Delta) \mid 0 \mid -B], [-C \mid I \mid 0])$ if Σ is viewed as a system with external variable vector $w = col(x, y, u)$ and with smooth signals. It turns out from Theorem 3.1 that the behavior of Σ is controllable iff $\mathrm{rank}[(\lambda I - A(e^{-\lambda}) \mid B] = n$ for all $\lambda \in \mathbb{C}$. So behavioral controllability seems to correspond to spectral rather than to approximate controllability. The situation can be illustrated by the following example.

EXAMPLE 3.4. Let $A(z) = A_0 + A_1 z$ with $A_0 = col([0 \mid 1], [0 \mid 0])$, $A_1 = col([0 \mid 0], [-1 \mid 0])$, and $B = col(0, -1)$. Then the corresponding system Σ is not approximately controllable since $\mathrm{rank}[A_1 \mid B] = 1 < 2$. However, it is easy to check that $[\lambda I - A(e^{-\lambda}) \mid B]$ has rank 2 $\forall \lambda \in \mathbb{C}$ and hence the behavior of Σ is controllable. What happens in this case is that the pseudostate components x_1 and x_2 are related by $dx_1/dt = x_2$. This holds in particular in the interval $[-1, 0)$; therefore, not all the

elements in the state space $\mathbb{R}^2 \times L_2([-1,0),\mathbb{R}^2)$ are feasible, which prevents approximate controllability. This obstacle does not arise for behavioral controllability since this property exclusively regards admissible system signals (and hence one does not take into account the signals which do not satisfy $dx_1/dt = x_2$).

The characterization of approximate controllability has been extended to neutral d-d systems in [6] and [9] and later generalized in [13] to the case of (possibly) noncommensurable delays. For systems with a pseudostate description of the form

$$\left\{ \begin{array}{lcl} dx/dt & = & A(\Delta_1,\ldots,\Delta_N,D)x + Bu, \\ y & = & Cx \end{array} \right. \tag{4}$$

(where $A(z_1,\ldots,z_N,z_{N+1}) = A_0 + \sum_{i=1}^{N} A_i(z_{N+1})z_i$, $A_i(z_{N+1})z_i = E_i + F_i z_{N+1}$, and Δ_i represents the delay by h_i units of time, $i = 1,\ldots,N$), the following result has been derived (and formulated in slightly different terms).

THEOREM 3.5 (see [13]). *The system described by* (4) *is approximately controllable iff* (a) $\operatorname{rank}[A(e^{h_1\lambda},\ldots,e^{h_N\lambda},\lambda),B] = n \ \ \forall\lambda \in \mathbb{C}$ *and* (b) $\operatorname{rank}[A_N(\lambda),B] = n$ *for some* $\lambda \in \mathbb{C}$.

As before, the first condition corresponds to spectral controllability and coincides with our characterization of behavioral controllability if the delays are commensurable.

Another interesting issue is the comparison of our notion of controllability with the ones which have been studied in [5] and [2] within an algebraic approach. Here the authors consider systems Σ with pseudostate-space representations of the form

$$\left\{ \begin{array}{lcl} dx/dt & = & A(\Delta)x + B(\Delta)u, \\ y & = & C(\Delta)x + D(\Delta)u, \end{array} \right. \tag{5}$$

where $A(z_2), B(z_2), C(z_2), D(z_2)$ are polynomial matrices in z_2. For such systems the following two notions of controllability are introduced. Let $\mathcal{R}(z_2) := [B(z_2) \mid A(z_2)B(z_2) \mid \ldots \mid (A(z_2))^{n-1}B(z_2)]$, where n is the size of $A(z_2)$. Σ is said to be *weakly controllable* if $\mathcal{R}(z_2)$ has full row rank over the field of fractions $\mathbb{R}(z_2)$. If $\mathcal{R}(\lambda_2)$ has full row rank $\forall\lambda_2 \in \mathbb{C}$, Σ is said to be *strictly controllable*. Theorem 3.6 is shown in [2].

THEOREM 3.6. *With the previous notation,* (1) Σ *is weakly controllable iff* $[z_1 - A(z_2) \mid B(z_2)]$ *is left prime, and* (2) Σ *is strictly controllable iff* $\operatorname{rank}[\lambda_1 - A(\lambda_2) \mid B(\lambda_2)] = n \ \forall(\lambda_1,\lambda_2) \in \mathbb{C}\times\mathbb{C}$.

Regarding the pseudostate representation (5) as a kernel representation, it follows from Theorem 3.1 that the behavior of Σ is controllable iff $\operatorname{rank}[\lambda - A(e^{-\lambda}) \mid B(e^{-\lambda})] = n \ \forall\lambda \in \mathbb{C}$. Thus strict controllability implies behavioral controllability. On the other hand, if $[z_1 - A(z_2) \mid B(z_2)]$ has a left factor $\Phi(z_1,z_2)$ with nontrivial determinant $f(z_1,z_2)$, then $\Phi(\lambda,e^{-\lambda})$ will be a left factor of $[\lambda - A(e^{-\lambda}) \mid B(e^{-\lambda})]$, implying that this matrix drops in rank when λ is a zero of $f(\lambda,e^{-\lambda})$. Therefore we can conclude that behavioral controllability implies weak controllability.

Summarizing the preceding considerations, we have that strict controllability implies behavioral controllability, which in its turn implies weak controllability. The next examples show that the converse implications do not hold true.

EXAMPLE 3.7. Consider the delay-differential system Σ described by

$$\left\{ \begin{array}{lcl} dx/dt & = & (-\Delta + 1)x + (2 - \Delta)u, \\ y & = & x. \end{array} \right.$$

Letting $w := col(u,y,x)$ and $R(z_1,z_2) := col([z_2 - 2 \mid 0 \mid z_1 + (z_2 - 1)],[0 \mid 1 \mid -1])$ this description becomes $R(d/dt,\Delta)w = 0$. Since $R(\lambda,e^{-\lambda}) = col([e^{-\lambda} - 2 \mid 0 \mid$

$\lambda + (e^{-\lambda} - 1)], [0 \mid 1 \mid -1])$ has rank 2 $\forall \lambda \in \mathbb{C}$, the behavior of Σ is controllable. However, $[\lambda_1 - (1-\lambda_2) \mid 2 - \lambda_2]$ clearly drops in rank for $(\lambda_1, \lambda_2) = (-1, 2)$, and hence Σ is not strictly controllable.

EXAMPLE 3.8. Let Σ be described by the following equations:

$$\begin{cases} dx/dt &= (-\Delta + 1)u, \\ y &= x. \end{cases}$$

Proceeding as in the previous example, we have that $R(\lambda, e^{-\lambda}) = col([1 - e^{-\lambda} \mid 0 \mid \lambda], [0 \mid 1 \mid -1])$, which drops in rank for $\lambda = 0$. So the behavior of Σ is not controllable. However $[z_1 \mid z_2 - 1]$ is left prime and hence Σ is weakly controllable.

EXAMPLE 3.9. Consider the system described in image representation by

$$\begin{bmatrix} w_1 \\ w_2 \end{bmatrix} = \begin{bmatrix} 1 - \Delta \\ \frac{d}{dt} \end{bmatrix} a. \tag{6}$$

This is a system with transfer function $w_2 \to w_1$:

$$\frac{\hat{w}_1}{\hat{w}_2} = \frac{1 - e^{-s}}{s}. \tag{7}$$

Obviously, since it is an image representation, it defines a controllable system. The logical candidate for the kernel representation is

$$\frac{d}{dt} w_1 = (1 - \Delta) w_2. \tag{8}$$

However, (8) is not controllable and hence not a faithful representation of (6). This shows that the d-d system (6) *cannot*, in fact, be represented as a kernel representation (1). In particular, this implies that what we call the latent variable elimination theorem [12] does not hold for d-d systems!

4. Proofs. We will show Theorems 3.1 and 3.2 in three main steps, respectively, corresponding to Propositions 4.1, 4.5, and 4.6 below. In the first step we prove that the rank constancy of $R(\lambda, e^{-\lambda})$ implies that (1) has an image representation. In the second step we prove that the existence of an image representation implies controllability. Finally, in the third step we show that if (1) defines a controllable system then $R(\lambda, e^{-\lambda})$ must have constant rank over $\mathbb{C}$. For a question of simplicity in the notation, in this section we will write $D = d/dt$ for the differentiator.

PROPOSITION 4.1. *With the previous notation, if* $\operatorname{rank} R(\lambda, e^{-\lambda}) = r \ \forall \lambda \in \mathbb{C}$ *then there exists a* $2D$ *polynomial matrix* $M(z_1, z_2)$ *such that* $\mathcal{B} := \ker R(D, \Delta) = \operatorname{im} M(D, \Delta)$*, with the operator* $M(D, \Delta)$ *acting on* $\mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^l)$ *for a certain integer* l*.*

Proof. Under the hypothesis, the 2D polynomial matrix $R(z_1, z_2)$ has rank r (over the field of fractions $\mathbb{R}(z_1, z_2)$). Suppose first that $R(z_1, z_2)$ has $q = r$ columns. Then $R(\lambda, e^{-\lambda})$ has full column rank $\forall \lambda \in \mathbb{C}$, and hence $\ker R(D, \Delta)$ does not contain any element with components of the form $t^k e^{\lambda t}$. By [10, Theorem 5] this implies that $\ker R(D, \Delta) = \{0\}$, and the equality $\ker R(D, \Delta) = \operatorname{im} M(D, \Delta)$ is trivially satisfied with $M(z_1, z_2)$ being the $q \times 1$ zero matrix. Suppose now that $R(z_1, z_2)$ has $q > r$ columns. Then Lemma 4.2 follows.

LEMMA 4.2. $R(z_1, z_2)$ *can be factored as* $F(z_1, z_2)\bar{R}(z_1, z_2)$*, where* F *and* $\bar{R}$ *are* $2D$ *polynomial matrices of sizes* $g \times r$ *and* $r \times q$*, respectively, such that* $F(z_1, z_2)$ *has full column rank (over* $\mathbb{R}(z_1, z_2)$*) and* $\mathbb{R}(z_1, z_2)$ *is left prime (i.e.,* $\bar{R}$ *has full row rank and all its left factors are invertible in* $\mathbb{R}^{r \times r}[z_1, z_2]$*).*

Proof. Without loss of generality we may assume that $R(z_1, z_2) = [-Q(z_1, z_2) \mid P(z_1, z_2)]$, where $P(z_1, z_2)$ is a full rank matrix with r columns. Moreover, there exists a rational matrix $G(z_1, z_2)$ such that $PG = Q$. Let $G = \hat{Q}\hat{P}^{-1}$ and $G = \bar{P}^{-1}\bar{Q}$ be, respectively, a right coprime and a left coprime factorization of G [4]. Then the matrix $\bar{R} = [-\bar{Q} \mid \bar{P}]$ is a minimal left annihilator of $H := col(\hat{P}, \hat{Q})$ (cf. [7]); i.e., $\bar{R}H = 0$ and for every 2D polynomial matrix $S(z_1, z_2)$ such that $SH = 0$ there exists a 2D polynomial matrix $L(z_1, z_2)$ satisfying $S = L\bar{R}$. Since, obviously, also $RH = 0$, there exists a polynomial matrix $F(z_1, z_2)$ such that $R = F\bar{R}$. Further, since $\bar{R}$ is a full rank polynomial matrix with r rows, F must have column rank. □

Let then F and $\bar{R}$ be as in the previous lemma. Note that due to the fact that $\text{rank}R(\lambda, e^{-\lambda}) = r \ \forall \lambda \in \mathbb{C}$ neither $F(z_1, z_2)$ nor $\bar{R}(z_1, z_2)$ can have zeros of the form $(z_1, z_2) = (\lambda, e^{-\lambda})$. Now, since $\bar{R}$ is left prime, there exists a polynomial matrix W such that

$$\bar{R}(z_1, z_2)W(z_1, z_2) = N(z_1),$$

with $N(z_1) = \text{diag}(d(z_1), \ldots, d(z_1))$ for a suitable (nonzero) 1D polynomial $d(z_1)$. Let $M(z_1, z_2)$ be a right-prime 2D polynomial matrix such that $\bar{R}M = 0$ (we can take $M = H$ as in Lemma 4.2) and define the matrix $U(z_1, z_2) := [W(z_1, z_2) \mid M(z_1, z_2)]$.

LEMMA 4.3. *The operator $U(D, \Delta) : C^\infty(\mathbb{R}, \mathbb{R}^q) \to C^\infty(\mathbb{R}, \mathbb{R}^q)$ is surjective.*

Proof. We start by showing that $\det U = \det N = d^r(z_1) =: n(z_1)$. Without loss of generality we may assume that $\bar{R}(z_1, z_2)$ can be partitioned as $\bar{R}(z_1, z_2) = [P(z_1, z_2) \mid -Q(z_1, z_2)]$, with $P(z_1, z_2)$ square and nonsingular. Consider the corresponding partitions $\left[\begin{smallmatrix} X \\ Y \end{smallmatrix}\right] =: W$ and $\left[\begin{smallmatrix} \bar{Q} \\ \bar{P} \end{smallmatrix}\right] =: M$ of W and M. It is well known (see [4]) that $\det \bar{P}(z_1, z_2) = \det P(z_1, z_2)$. Now,

$$\det U = \det \begin{bmatrix} X & \bar{Q} \\ Y & \bar{P} \end{bmatrix} = \det \left(\begin{bmatrix} X & \bar{Q} \\ Y & \bar{P} \end{bmatrix} \begin{bmatrix} I & 0 \\ -\bar{P}^{-1}Y & I \end{bmatrix} \right)$$

$$= \det \begin{bmatrix} X - \bar{Q}\bar{P}^{-1}Y & \bar{Q} \\ 0 & \bar{P} \end{bmatrix} = \det \bar{P} \cdot \det(X - \bar{Q}\bar{P}^{-1}Y)$$

$$= \det \bar{P} \cdot \det(X - P^{-1}QY),$$

since $\bar{Q}\bar{P}^{-1} = P^{-1}Q$ (due to the fact that M is a dual basis of $\bar{R}$). Thus,

$$\begin{aligned} \det U &= \det \bar{P} \cdot \det(P^{-1}(PX - QY) \\ &= \det \bar{P}. \det P^{-1} \cdot \det(PX - QY) \\ &= \det \bar{P}.(\det P)^{-1} \cdot \det(PX - QY) \\ &= \det(PX - QY), \end{aligned}$$

and as $N = PX - QY$, we conclude that

$$\det U = \det N = \det(\text{diag}(d(z_1), \ldots, d(z_1))) = d^r(z_1) =: n(z_1).$$

Consider now the equation

$$U(D, \Delta)\alpha = \beta.$$

Given $\beta \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^q)$, define $\bar{\alpha}$ such that

$$\bar{N}(D)\bar{\alpha} = \beta,$$

with $\bar{N}(z_1) := \mathrm{diag}(n(z_1), \ldots, n(z_1))$. Note that $\bar{N}(D)$ is a surjective operator in $\mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^q)$. Define $\alpha := \bar{V}(D, \Delta)\bar{\alpha} \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^q)$, where $\bar{V}(z_1, z_2)$ is such that

$$U(z_1, z_2)\bar{V}(z_1, z_2) = \bar{N}(z_1).$$

Then

$$U(D, \Delta)\alpha = U(D, \Delta)\bar{V}(D, \Delta)\bar{\alpha} = \bar{N}(D)\bar{\alpha} = \beta,$$

showing that $U(D, \Delta)$ is a surjective operator in $\mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^q)$. □

This implies that $\forall w \in \mathcal{B} = \ker R(D, \Delta)$ there exists $\bar{w}$ such that $w = U(D, \Delta)\bar{w}$ and hence $R(D, \Delta)U(D, \Delta)\bar{w} = 0$, i.e., $\bar{w} \in \ker R(D, \Delta)U(D, \Delta)$. So,

$$\mathcal{B} \subseteq U(D, \Delta) \ker(R(D, \Delta)U(D, \Delta)).$$

On the other hand, if $w = U(D, \Delta)\bar{w}$ and $R(D, \Delta)U(D, \Delta)\bar{w} = 0$, then $R(D, \Delta)w = 0$, i.e.,

$$\mathcal{B} \supseteq U(D, \Delta) \ker(R(D, \Delta)U(D, \Delta)).$$

Therefore $\mathcal{B} = U(D, \Delta) \ker(R(D, \Delta)U(D, \Delta))$. Taking into account that $U = [W \mid M]$ and that $RU = [FN \mid 0]$, this yields $\mathcal{B} = [W(D, \Delta) \mid M(D, \Delta)](\ker[F(D, \Delta)N(D, \Delta) \mid 0])$. Thus

$$\mathcal{B} = W(D, \Delta) \ker(F(D, \Delta)N(D, \Delta)) + \mathrm{im}M(D, \Delta).$$

Finally, it turns out that Lemma 4.4 follows.

LEMMA 4.4. $W(\ker FN) \subseteq \mathrm{im}M$.

Proof. Recall that $F(\lambda, e^{-\lambda})$ has full column rank $\forall \lambda \in \mathbb{C}$. This implies that $\ker F(D, \Delta) = \{0\}$, and hence $\ker FN = \ker N$. Therefore, in order to prove the lemma we will show that $W(\ker N) \subseteq \mathrm{im}M$. As is well known,

$$\ker N(D) = \mathrm{span}\{t^j e^{\lambda_i t} e_k : i = 1, \ldots, p, j = 0, \ldots, \mu(\lambda_i) - 1, k = 1, \ldots, r\},$$

where $\lambda_1, \ldots, \lambda_p$ are the distinct roots of $d(z_1)$, $\mu(\lambda_i)(i = 1, \ldots, p)$ are the corresponding multiplicities, and e_k is the kth vector in the canonical basis of $\mathbb{R}^r$. So, $W(\ker N) \subseteq \mathrm{im}M$ iff for every root λ of $d(z_1)$, for every m subject to $0 \leq m \leq \mu(\lambda) - 1$, and for every $k \in \{1, \ldots, r\}$, $W(t^m e^{\lambda t} e_k) \in \mathrm{im}M$; i.e., there is a $\mathcal{C}^\infty$ trajectory x such that

$$Mx(t) = W(t^m e^{\lambda t} e_k). \tag{9}$$

Let then λ be a root of $d(z_1)$ and let m be a positive integer not greater than $\mu(\lambda) - 1$. Without loss of generality we may assume that $\bar{R} = [P \mid -Q]$ with $P(\lambda, e^{-\lambda})$ invertible. Consider the corresponding partitions of M and W as defined in the proof of Lemma 4.3. Note that in this case, $\bar{P}(\lambda, e^{-\lambda})$ is also invertible. Now, (9) can be rewritten as

$$\bar{Q}\, x = X(t^m e^{\lambda t} e_k), \tag{10}$$

$$\bar{P}\, x = Y(t^m e^{\lambda t} e_k). \tag{11}$$

It is not difficult to see that

$$Y(D, \Delta)(t^m e^{\lambda t} e_k) \;=\; Y(\lambda, e^{-\lambda}) e_k t^m e^{\lambda t} + (Y_{m-1} t^{m-1} + \cdots + Y_0) e_k e^{\lambda t}$$

for some suitable matrices $Y_{m-1},\dots,Y_0$. Take x to be of the form $x(t)=(\xi_m t^m+\cdots+\xi_0)e^{\lambda t}$. Then

$$\begin{aligned}(\bar{P}(D,\Delta)x)(t)=\{&\bar{P}(\lambda,e^{-\lambda})\xi_m t^m+[\bar{P}(\lambda,e^{-\lambda})\xi_{m-1}+G_m^{m-1}\xi_m]t^{m-1}\\&+\cdots+[\bar{P}(\lambda,e^{-\lambda})\xi_0+G_1^0\xi_1+\cdots+G_m^0\xi_m]\}e^{\lambda t},\end{aligned}$$

and x satisfies (11) iff

$$\text{(12)}\qquad\begin{cases}\bar{P}(\lambda,e^{-\lambda})\xi_m &= Y(\lambda,e^{-\lambda})e_k,\\ \bar{P}(\lambda,e^{-\lambda})\xi_{m-1}&=Y_{m-1}e_k-G_m^{m-1},\\ \vdots&\\ \bar{P}(\lambda,e^{-\lambda})\xi_0 &= Y_0e_k-(G_1^0\xi_1+\cdots+G_1^0\xi_1).\end{cases}$$

As $\bar{P}(\lambda,e^{-\lambda})$ is invertible, there is a (unique) solution $(\xi_m,\dots,\xi_0)$ to (12), showing that (11) has a $\mathcal{C}^\infty$ solution $x(t)=(\xi_m t^m+\cdots+\xi_0)e^{\lambda t}$. It remains to prove that this solution $x(t)$ also satisfies (10). It follows from (11) that

$$\begin{aligned}Q\bar{P}x&=QY(t^me^{\lambda t}e_k)\ \Leftrightarrow\\ P\bar{Q}x&=QY(t^me^{\lambda t}e_k)\ \Leftrightarrow\\ P\bar{Q}x&=(PX-N)(t^me^{\lambda t}e_k)\ \Leftrightarrow\\ 0&=P(\bar{Q}x-Xt^me^{\lambda t}e_k),\end{aligned}\qquad\text{(13)}$$

since $Q\bar{P}=P\bar{Q}$, $PX+QY=N$, and $t^me^{\lambda t}e_k\in\ker N$. Note that $\bar{Q}(D,\Delta)x-X(D,\Delta)t^me^{\lambda t}e_k=E(t)e^{\lambda t}$, where $E(t)$ is a polynomial column in t containing powers of t of order not greater than m. Assume that $E(t)=E_{\bar{m}}t^{\bar{m}}+\cdots+E_0$, where $E_{\bar{m}}$ is a nonzero column and $\bar{m}\le m$. Then (13) becomes

$$[P(\lambda,e^{-\lambda})E_{\bar{m}}t^{\bar{m}}+(G_{\bar{m}-1}t^{m-1}+\cdots+G_0)]e^{\lambda t}=0,$$

which implies that $P(\lambda,e^{-\lambda})E_{\bar{m}}=0$. This is absurd, since $P(\lambda,e^{-\lambda})$ is an invertible matrix and $E_{\bar{m}}$ is assumed to be nonzero. Thus, $E(t)$ must be zero, i.e.,

$$\bar{Q}x-Xt^me^{\lambda t}e_k=0,$$

which shows that x satisfies equation (10) and hence also (9). □

As a consequence of this lemma we have that $\mathcal{B}=\mathrm{im}M(D,\Delta)$, i.e., (1) has an image representation, proving the proposition. □

Now, it is not difficult to come to the following conclusion.

PROPOSITION 4.5. *If* (1) *has an image representation, then it defines a controllable system.*

Proof. Suppose that (1) has an image representation, i.e., $\mathcal{B}=\mathrm{im}M(D,\Delta)$, and let w_1 and w_2 be two arbitrary signals in $\mathcal{B}$. Then, there exist a_1 and a_2 in $\mathcal{C}^\infty(\mathbb{R},\mathbb{R}^l)$ such that $w_i=Ma_i,(i=1,2)$. Now, it is possible to construct a smooth signal a^* which coincides with a_1 in the past and with a_2 in the (sufficiently far) future. Such signal yields an element $w^*=Ma^*$ in $\mathcal{B}$ which coincides with w_1 in the past and with w_2 in the future. Thus w_1 is $\mathcal{B}$-compatible, with w_2 showing that $\mathcal{B}$ is controllable. □

Finally, if $R(z_1,z_2)$ is a 2D polynomial matrix of rank r and $\mathrm{rank}R(\lambda,e^{-\lambda})<r$ for some $\lambda_0\in\mathbb{C}$ we can show that there exists a signal associated with the frequency λ_0 which is not $\mathcal{B}$-compatible with the identical zero signal and hence $\mathcal{B}$ is not controllable.

PROPOSITION 4.6. *Let $\mathcal{B} := \ker R(D, \Delta)$, where $R(z_1, z_2)$ is a 2D polynomial matrix of rank r. If $\mathcal{B}$ is controllable then* $\text{rank}R(\lambda, e^{-\lambda}) = r \ \forall \lambda \in \mathbb{C}$.

Proof. We start by noting that, formally, $e^{-z_1} = \sum_{k=0}^{+\infty} \frac{(-1)^k}{k!} z_1^k$. Thus, if $z_2 = e^{-z_1}$, $R(z_1, z_2) = \tilde{\Pi}(z_1)$, where $\tilde{\Pi}(z_1)$ is a matrix over the ring $\mathbb{R}[[z_1]]$ of formal power series in z_1. Suppose now that $\text{rank}R(\lambda, e^{-\lambda}) < \text{rank}R(z_1, z_2) = \text{rank}R(z_1, e^{-z_1}) = r$ for a certain $\lambda_0 \in \mathbb{C}$. We consider first the case where $\lambda_0 = 0$; so $\text{rank}R(0, 1) < \text{rank}R(z_1, e^{-z_1})$. This means that $\text{rank}\tilde{\Pi}(0) < \text{rank}\tilde{\Pi}(z_1) = r$, and therefore we may assume without loss of generality that

$$\tilde{\Pi}(z_1) = \text{diag}(z_1^{k_1}, \ldots, z_1^{k_r}, z_1^{k_{r+1}}, \ldots, z_1^{k_s})\tilde{\Gamma}(z_1),$$

where $k_1, \ldots, k_s$ are integers, $k_1 \geq 1$, and

$$\tilde{\Gamma}(0) = \begin{bmatrix} I_{r\times r} & 0 \\ 0 & 0 \end{bmatrix}$$

(with the zero rows possibly void).

Let

$$\Gamma(z_1) = \begin{bmatrix} I_{r\times r} & 0 \\ 0 & 0 \end{bmatrix} + z_1\Gamma_1 + z_1^2\Gamma_2 + \cdots + z_1^{k_1-1}\Gamma_{k_1-1}$$

be such that

$$\tilde{\Gamma}(z_1) = \Gamma(z_1) + \text{higher-order terms.}$$

Then, using the same kind of arguments as in the proof of Lemma 4.4, it is possible to show that there exists a trajectory $w^*(t) = \alpha_{k_1-1}t^{k_1-1} + \cdots + \alpha_0$ such that

$$\Gamma(D)w^*(t) = \begin{bmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \frac{t^{k_1-1}}{(k_1-1)!}.$$

Now, this trajectory w^* is clearly such that

$$R(D, \Delta)w^* = \text{diag}(D^{k_1}, \ldots, D^{k_s})\Gamma(D)w = D^{k_1}t^{k_1-1} = 0,$$

and hence it belongs to $\mathcal{B}$.

LEMMA 4.7. *With the previous notation, w^* is not $\mathcal{B}$-compatible with the zero trajectory.*

Proof. Suppose that w^* is $\mathcal{B}$-compatible with the zero trajectory, yielding a trajectory $v^* \in \mathcal{B}$ such that $v^*|_{(-\infty,\tau_1)} = w^*|_{(-\infty,\tau_1)}$ and $v^*|_{[\tau_2,+\infty)} = 0|_{[\tau_2,+\infty)}$ for some $\tau_1 < \tau_2$. Since $v^* \in \mathcal{B}$, $R(D, \Delta)v^* = 0$ and therefore also

$$\int_{T_1}^{T_2+1} [R(D, \Delta)v^*]dt = 0.$$

In particular, if $r(z_1, z_2)$ denotes the first row of $R(z_1, z_2)$, we have that

$$\int_{T_1}^{T_2+1} [r(D, \Delta)v^*]dt = 0. \tag{14}$$

Note further that $r(\lambda, e^{-\lambda})$ becomes zero for $\lambda = 0$, and hence $r(z_1, z_2) = r(z_1, e^{-z_1})$ must be of the form

$$r(z_1, z_2) = r(z_1, e^{-z_1}) = z_1 r_0(z_1) + (e^{-z_1} - 1) r_1(z_1, e^{-z_1}),$$

where $r_0(z_1)$ and $r_1(z_1, z_2)$, respectively, are 1D and 2D polynomial rows. So equation (14) is of the form

$$\int_{T_1}^{T_2+1} [(\Delta - 1) r_1(D, \Delta) + D r_0(D)] v^* dt = 0.$$

This is equivalent to

$$\int_{T_1-1}^{T_1} r_1(D, \Delta) v^* dt + \int_{T_2}^{T_2+1} r_1(D, \Delta) v^* dt + [r_0(D) v^*] \Big|_{T_1}^{T_2+1} = 0,$$

which is still equivalent to

$$\int_{T_1-1}^{T_1} r_1(D, \Delta) w^* dt + \int_{T_2}^{T_2+1} r_1(D, \Delta) 0 dt + (r_0(D)0)(T_2 + 1) - (r_0(D) w^*)(T_1) = 0$$

if $T_2 + 1 \gg \tau_2$ and $T_1 \ll \tau_1$ so that in a sufficiently big interval around $T_2 + 1$, v^* coincides with the zero trajectory, and in a sufficiently big interval around T_1, it coincides with w^*. This yields

$$\int_{T_1-1}^{T_1} r_1(D, \Delta) w^* dt - (r_0(D) w^*)(T_1) = 0. \tag{15}$$

Let $\eta = col(\eta_1, \ldots, \eta_q)$ be a trajectory such that $\eta(t) = \frac{\alpha_{k_1-1}}{k_1} t^{k_1} + \cdots + \alpha_0 t$; then $D\eta = w^*$ and we may write (15) as

$$\int_{T_1-1}^{T_1} r_1(D, \Delta) D\eta \, dt - (r_0(D) D\eta)(T_1) = 0,$$

which is equivalent to having

$$[((\Delta - 1) r_1(D, \Delta) + r_0(D) D)\eta](T_1) = 0$$

or still

$$(r(D, \Delta)\eta)(T_1) = 0.$$

Now, it follows from our previous considerations that

$$r(D, \Delta)\eta)(T_1) = (D^{k_1}[1 \;\; 0 \;\; \ldots \;\; 0]\eta)(T_1) = [1 \;\; 0 \;\; \ldots \;\; 0]\alpha_{k_1-1}(k_1 - 1)! = 1,$$

since $[1 \quad 0 \quad \ldots \quad 0]\Gamma(D) w^* = \frac{t^{k_1-1}}{(k_1-1)!}$. In this way we obtain that $0 = 1$, which is absurd. Consequently the hypothesis that w^* is $\mathcal{B}$-concatenable with the zero trajectory cannot hold true. □

It follows from this result that if $R(\lambda, e^{-\lambda})$ drops in rank for $\lambda = 0$, then $\mathcal{B}$ is not controllable. It remains to show that if $\text{rank} R(\lambda, e^{-\lambda}) < \text{rank} R(z_1, z_2)$ for $\lambda = \lambda^* \neq 0$ then $\mathcal{B}$ is not controllable.

Assume now that $R(\lambda, e^{-\lambda})$ drops in rank for $\lambda = \lambda^* \neq 0$, and consider the system Σ^* with behavior $\mathcal{B}^* := \exp_{\lambda^*} \mathcal{B}$, where $\exp_{\lambda^*}$ is defined by $\exp_{\lambda^*}(t) = e^{-\lambda^* t}\ \forall t \in \mathbb{R}$. Then $\mathcal{B}^*$ is described by a polynomial matrix $R^*(z_1, z_2)$ such that $R^*(\lambda, e^{-\lambda}) = R(\lambda + \lambda^*, e^{-(\lambda+\lambda^*)})$. As $\text{rank} R(\lambda, e^{-\lambda})$ drops for $\lambda = \lambda^*$, $R^*(\lambda, e^{-\lambda})$ drops for $\lambda = 0$. Thus, by the foregoing arguments, $\mathcal{B}^*$ is not controllable. This implies that $\mathcal{B}$ is also not controllable, completing the proof of the proposition. □

5. Conclusion. We have presented a necessary and sufficient condition for the controllability of the behavior of d-d systems with kernel representations. Moreover, we have compared the notion of behavioral controllability with the notions of approximate and spectral controllability considered in [3] as well as with other controllability properties (namely, weak and strict controllability) that have been introduced within an algebraic approach to d-d systems [5]. Contrary to what happens with the results of [3], [6], [9], and [5], our results hold for all types of systems with commensurable delays and not only for retarded or neutral systems in pseudostate form.

A FARKAS LEMMA WITHOUT A STANDARD CLOSURE CONDITION*

JEAN B. LASSERRE†

Abstract. We present a setting in which we derive a new Farkas lemma for the system $\{Ax = b,\ x \in S\}$ without the standard closure condition on $A(S)$. Further characterization in Hilbert spaces is also presented.

Key words. Farkas lemma, duality, convex cones, Banach spaces, locally convex topological vector spaces, Hilbert spaces

1. Introduction.

The celebrated Farkas lemma is a fundamental tool in optimization to characterize existence of solutions for a system $\{Ax = b,\ x \in S\}$, where A is a linear mapping and S a positive convex cone. It is also the basis of many duality results such as first-order optimality conditions. There have been a great number of papers devoted to various *asymptotic* and *nonasymptotic*, linear and nonlinear versions of Farkas' lemma. The asymptotic version is a weaker notion that replaces feasibility with versions of asymptotic feasibility. For instance, the interested reader is referred to [10] for various Farkas lemmas in arbitrary dual pairs of vector spaces, using weak topologies [4], [3], [12], [13], [14], [16], [18], [19] for linear and nonlinear versions with various applications; the discussion in [11]; and all the references in the above papers as well as the references in [1].

In this paper we are concerned with the linear nonasymptotic version. In this case, Farkas' lemma holds only under a crucial *closure* assumption in some appropriate topology. The closure assumption is concerned with $A(S)$, the image of the positive cone S, and holds for example when the cone S is a *polyhedral* cone in some finite-dimensional space. In general, this closure assumption is very restrictive, and some specific properties of A and S must be invoked. (For example, sufficient conditions are given in [15].) The reader is referred to [3] for simple examples in finite-dimensional spaces where this closure assumption does not hold and only an *asymptotic* version of Farkas' lemma holds.

The purpose of this paper is to provide a setting in which, by introducing another appropriate convex cone (indexed by a scalar parameter and some vector), one may derive a (nonasymptotic) Farkas lemma without this (strong) closure assumption. The underlying idea is that if a solution exists, it must be in this cone for some sufficiently large value of the parameter and also must satisfy some linear constraint related to the vector used in the definition of the new cone. Doing so permits us to use a weak* sequential compactness argument and yields the desired result. The Farkas lemma is stated in terms of the dual of the cone introduced. A more precise characterization is given in Hilbert spaces. This new Farkas lemma is also illustrated for linear systems of matrix equalities involving the cone of positive semidefinite matrices.

*Received by the editors February 7, 1995; accepted for publication (in revised form) November 24, 1995.

Finally, thanks to an anonymous referee, we also give a different Farkas lemma that reveals what lies behind the previous one, namely, the existence of an appropriate, compactly generated, convex cone.

2. Notation and definitions. We use notation similar to [10]. Let X and Y be two real vector spaces with a bilinear form $\langle , \rangle$ defined on $X \times Y$. We also assume that

(i) for each $x \neq 0$ in X, $\exists y \in Y$ with $\langle x, y\rangle \neq 0$,

(ii) for each $y \neq 0$ in Y, $\exists x \in X$ with $\langle x, y\rangle \neq 0$,

so that (X, Y) is a *dual* pair. We also equip X with the *weak topology* $\sigma(X, Y)$ so that all the elements of Y are continuous when regarded as linear forms on X. We are also given a convex cone $S \subset X$. Similarly, Y is equipped with the $\sigma(Y, X)$ weak topology and $S^+ \subset Y$ denotes the anticone of S, i.e.,

$$S^+ := \{y \in Y |\ \langle y, x\rangle \geq 0 \ \ \forall x \in S\}.$$

When $Y \equiv X^*$, where X^* is the topological dual of X, S^+ is called the dual cone of S and is denoted by S^*.

Let (Z, W) be some other real dual pair where Z (resp., W) is also equipped with the $\sigma(Z, W)$ (resp., $\sigma(W, Z)$) weak topology. Let A be a linear mapping $A : X \to Z$. A necessary and sufficient condition for A to be weakly continuous is $A^*(W) \subset Y$. The restriction A^+ of A^* to W is then weakly continuous and is called the *adjoint* of A with respect to the dual pairs (X, Y) and (Z, W) (see [10]).

Weak convergence of x_n to x will be denoted by $x_n \overset{w}{\to} x$. Note that with the weak topology, all the vector spaces are *locally convex* [17].

We are interested in existence of solutions to the system

$$Ax = b, \quad x \in S,$$

where b is some vector in Z. We first briefly recall a standard Farkas lemma [10] that addresses this issue.

THEOREM 2.1 (see [10, p. 987]). *Let (X, Y), (Z, W) be real dual pairs, S be a convex cone in X, and $A : X \to Z$ be a weakly continuous linear mapping. If $A(S)$ is weakly closed, then the following are equivalent:*

(a) *The system $Ax = b$ has a solution $x \in S$.*

(b) $A^+w \in S^+ \Rightarrow \langle b, w\rangle \geq 0$.

Conversely, the equivalence of (a) *and* (b) *implies that $A(S)$ is weakly closed.*

As may be noted from the last assertion, the condition "$A(S)$ weakly closed" is crucial. Indeed, without such a condition, only *asymptotic existence* can sometimes be asserted when (b) holds (see [3]). However, in many practical examples, the closure assumption on $A(S)$ is not satisfied.

The purpose of this paper is to provide a setting in which a Farkas lemma holds with no closure assumption on $A(S)$.

3. The main result. In the following discussion, the spaces X, Y, Z, and W are all assumed to be Banach spaces. In addition, we make the following assumption.

Assumption H.

(i) $(X, \| \cdot \|)$ is the topological dual of a separable Banach space Y.

(ii) $\exists y_0 \in S^+$ such that $x \in S$, $\langle y_0, x\rangle = 0, \ \Rightarrow x = 0$.

Remark. H (ii) obviously implies that the cone S is pointed, i.e., $S \cap -S = \{0\}$. Actually, H (ii) merely asserts that the cone S admits a *positive* linear functional $y_0 \in S^+$ (which implies that S has a base). When $Y = X^*$, in which case $S^+ = S^*$,

the dual cone of S, then it is equivalent to assuming that S has a *base* (see, e.g., [5]). In some cases (e.g., when X is a normed separable space and $Y = X^*$), pointedness and existence of a positive functional are equivalent for closed convex cones.

Examples where H holds:

• X is the vector space of (n, n) real symmetric matrices with y_0 the identity matrix, S the cone of positive semidefinite matrices, and $\langle x, y\rangle := \text{trace}(x.y)$.

• Let $(K, \mathcal{B}, \mu)$ be a σ-finite measure space. $X := L^p(K, \mathcal{B}, \mu)$ with $1 < p \leq \infty$. S is the usual positive cone in X. y_0 is any strictly positive function in $Y := L^q(K, \mathcal{B}, \mu)$ with $1/p + 1/q = 1$ and $q = 1$ if $p = \infty$.

• $X := \mathcal{M}(K)$, the Banach space of bounded Borel signed measures on K, with K a locally compact separable metric space. S is again the usual positive cone in X, and $Y := C_0(K)$ the space of continuous functions that vanish at infinity. y_0 is any strictly positive function in $C_0(K)$.

• $X := l^p,\ 1 < p \leq \infty$, with S the usual positive cone in X and y_0 any strictly positive sequence in $Y := l^q$, with $1/p + 1/q = 1$.

• $X := l^1$ with S the usual positive cone and $Y := c_0$ the space of sequences that vanish at infinity. y_0 is any strictly positive sequence in c_0.

For $\lambda > 0$, let $S_{\lambda y_0}$ be the set $\{x \in S|\ \parallel x \parallel \leq \lambda\langle y_0, x\rangle\}$. Obviously, $S_{\lambda y_0}$ is a convex cone. We then have the following result.

THEOREM 3.1. *Let (X, Y), (Z, W) be real dual pairs, S be a weakly closed convex cone in X, and $A: X \to Z$ be a weakly continuous linear mapping. Assume also that* H *holds for some given $y_0 \in Y$. Then the following are equivalent:*

(i) *The system $Ax = b$ has a solution $x \in S$*

(ii) *There exists some positive (λ, δ) such that*

$$A^+w + \gamma y_0 \in S^+_{\lambda y_0}, \qquad \gamma \geq 0 \Rightarrow \langle b, w\rangle + \gamma\delta \geq 0.$$

(iii) *There exists some positive (λ, δ) such that*

$$A^+w \in S^+_{\lambda y_0} \Rightarrow \langle b, w\rangle \geq 0 \quad \textit{and } A^+w + y_0 \in S^+_{\lambda y_0} \Rightarrow \langle b, w\rangle \geq -\delta.$$

Proof. Consider the linear mapping

$$T:\ X \times R \to Z \times R,\ T(x, z) := \begin{bmatrix} Ax \\ \langle y_0, x\rangle + z \end{bmatrix}.$$

Its adjoint $T^+:\ W \times R \to Y \times R$ is given by $T^+(w, \gamma) := (A^+w + \gamma y_0, \gamma)$. Let R^+ denote the nonnegative real numbers. We first prove that $T(S_{\lambda y_0} \times R^+)$ is weakly closed.

For some directed set $\{D,\ \succeq\}$, let $\{(x_\alpha, z_\alpha)\}$ (where $\alpha \in D$) be a net in $S_{\lambda y_0} \times R^+$ such that w-lim $T(x_\alpha, z_\alpha) = (a_1, a_2)$, where w-lim denotes the $(\sigma(Z \times R, W \times R))$ weak limit. In particular, lim $\langle y_0, x_\alpha\rangle + z_\alpha = a_2$ and $a_2 \geq 0$.

If $a_2 = 0$, then lim $\langle y_0, x_\alpha\rangle = 0$ and lim $z_\alpha = 0$ so that since $x_\alpha \in S_{\lambda y_0}$, lim $||x_\alpha|| = 0$, which in turn implies w-lim $x_\alpha = 0$, where the latter w-lim denotes the $\sigma(X, Y)$ weak limit. Thus by continuity of A, we must have $a_1 = 0$. Hence, $T(0, 0) = (0, 0) = (a_1, a_2)$.

If $a_2 \neq 0$, then for some $\alpha_0 \in D$ and all $\alpha \succeq \alpha_0$, $z_\alpha \leq 2a_2$, and $\langle y_0, x_\alpha\rangle \leq 2a_2$, which in turn implies $\parallel x_\alpha \parallel \leq 2\lambda a_2$. Let $\xi_\alpha := \frac{x_\alpha}{2\lambda a_2}$. Then, $\xi_\alpha \in S \cap B(0, 1)$, where $B(0, 1)$ is the unit ball in $(X, \parallel . \parallel)$, compact in the *weak* topology*, which in our setting is precisely the $\sigma(X, Y)$ (weak) topology. (See Alaoglu's theorem in, e.g., [17].) From H (i), $B(0, 1)$ is also weakly sequentially compact (see [17]) so that from

the net $\{(x_\alpha, z_\alpha)\}$ we can extract a countable family and therefore a sequence $\{z_n\}$ that converges to some $z \geq 0$ and a sequence $\{\xi_n\}$ that converges weakly to some $\xi \in S$ ($\xi_n \stackrel{w}{\to} \xi$) since S is weakly closed.

The weak convergence yields

$$\langle y_0, \xi_n \rangle + \frac{z_n}{2\lambda a_2} \to \langle y_0, \xi \rangle + \frac{z}{2\lambda a_2} = \frac{1}{2\lambda} \quad \text{as} \quad n \uparrow \infty$$

so that $\langle y_0, 2\lambda a_2 \xi \rangle + z = a_2$. By weak continuity of A, $A\xi_n \stackrel{w}{\to} a_1/2\lambda a_2 = A\xi$ or equivalently $A(2\lambda a_2 \xi) = a_1$. Hence, $T(2\lambda a_2 \xi, z) = (a_1, a_2)$.

It remains to prove that $x := 2\lambda a_2 \xi \in S_{\lambda y_0}$. Observe that $x \in S$ since $\xi \in S$. Moreover, as $x_n \stackrel{w}{\to} x$ we have $\liminf_{n\uparrow\infty} \| x_n \| \geq \| x \|$ (see, e.g., [9]). Therefore, from $\| x_n \| \leq \lambda \langle y_0, x_n \rangle$ and $x_n \stackrel{w}{\to} x$ we conclude that $\| x \| \leq \lambda \langle y_0, x \rangle$, i.e., $x \in S_{\lambda y_0}$, which in turn implies $(x, z) \in S_{\lambda y_0} \times R^+$ so that, finally, $T(S_{\lambda y_0} \times R^+)$ is weakly closed.

Now the system $Ax = b$ has a solution in S if and only if the system $T(x, z) = (b, \delta)$ has a solution in $S_{\lambda y_0}$ for some λ sufficiently large and some $\delta > 0$. Indeed, by H (ii), given any $x \in S$, $x \in S_{\lambda y_0}$ for all λ sufficiently large.

Therefore, we now can apply the generalized Farkas lemma (cf. Theorem 2.1) to the latter system since $T(S_{\lambda y_0} \times R^+)$ is weakly closed. (Indeed, the weak continuity of T follows easily from the weak continuity of A.) Thus, $T(x, z)$ has a solution in $S_{\lambda y_0} \times R^+$ if and only if

$$T^+(w, \gamma) \in S^+_{\lambda y_0} \times R^+ \Rightarrow \langle b, w \rangle + \gamma\delta \geq 0$$

or equivalently

$$A^+ w + \gamma y_0 \in S^+_{\lambda y_0}, \qquad \gamma \geq 0 \Rightarrow \langle b, w \rangle + \gamma\delta \geq 0,$$

which is the desired result.

(ii) $\Leftrightarrow$ (iii) is trivial. □

We have stated (iii) to express the two cases $\gamma > 0$ and $\gamma = 0$. Indeed, the case $\gamma = 0$ covers the standard Farkas lemma so that the case $\gamma > 0$ (eliminated by dividing w by γ) describes the additional condition required in Farkas' lemma when $A(S)$ is not weakly closed.

Also note that if X is a reflexive Banach space, the weak topology $\sigma(X, Y)$ is also the standard weak topology so that the assumption S *weakly closed* can be replaced by S *closed* since strongly closed and weakly closed convex sets coincide in locally convex topological vector spaces.

Particular case. It may happen that when $x \in S$, $\langle y_0, x \rangle = \| x \|_1$ for some norm $\| \cdot \|_1$ and some appropriate y_0. If this norm is equivalent to $\| \cdot \|$, then $S \equiv S_{\lambda y_0}$ for all λ sufficiently large so that one may replace $S^+_{\lambda y_0}$ by S^+ in Theorem 3.1. An example is the space of (n, n) symmetric matrices with norm $||x||_1 := \sum_i |\sigma_i(x)|$, where the $\{\sigma_i(x)\}$ are the eigenvalues of x. If S is the cone of positive semidefinite matrices, then $\sigma_i(x) \geq 0 \ \forall i$ when $x \in S$ so that $||x||_1 = \langle I, x \rangle$, where I is the identity matrix.

Actually, the same conclusion holds if $\langle y_0, x \rangle \geq ||x||$ when $x \in S$, for some well-chosen y_0.

Similarly to [10] we also can derive a *dual* version of Theorem 3.1 for a linear system $\{Cy = b, \ y \in S^*\}$, where now C is a linear mapping X^* $(:= Y^{**}) :\to Z$ and $S^* \subset X^*$ is the dual cone of $S \subset X$. The $\sigma(X^*, X)$ topology on X^* is the weak* topology. Moreover, if S is a convex cone in X, then S^* is $(\sigma(X^*, X))$ weakly closed,

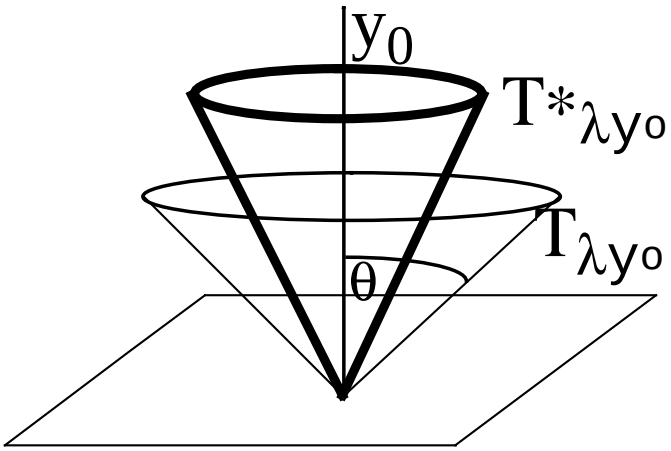

FIG. 1. *Cones* $T_{\lambda y_0}$ *and* $T^*_{\lambda y_0}$.

i.e., weak* closed. Hence it is also closed, and with the natural embedding of X in the bidual X^{**}, $(S^*)^+ = S^{**} \cap X = S$ (see [10]). We also define $S_{\lambda x_0} := \{y \in S^* |\ ||y|| \leq \lambda \langle y, x_0\rangle\}$ for some given $x_0 \in S$ such that $y \in S^*$ and $\langle y, x_0\rangle = 0 \Rightarrow y = 0$. $S^+_{\lambda x_0} = S^*_{\lambda x_0} \cap X$. The dual version of Theorem 3.1 now reads as follows.

THEOREM 3.2. *Let* (X^*, X), (Z, W) *be real dual pairs,* S *be a convex cone in* X*, and* $C : X^* \to Z$ *be a weakly continuous linear mapping. Assume also that* X *is separable and there is some* $x_0 \in S$ *such that* $y \in S^*$ *and* $\langle y, x_0\rangle = 0 \Rightarrow y = 0$*. Then the following are equivalent:*

(i) *The system* $Cy = b$ *has a solution* $y \in S^*$.

(ii) *There exists some positive* (λ, δ) *such that*

$$C^+ w + \gamma x_0 \in S^+_{\lambda x_0}, \qquad \gamma \geq 0 \Rightarrow \langle b, w\rangle + \gamma\delta \geq 0.$$

(iii) *There exists some positive* (λ, δ) *such that*

$$C^+ w \in S^+_{\lambda x_0} \Rightarrow \langle b, w\rangle \geq 0 \quad \textit{and} \quad C^+ x + x_0 \in S^+_{\lambda x_0} \Rightarrow \langle b, w\rangle \geq -\delta.$$

The proof is along the same lines as for Theorem 3.1.

Hilbert spaces. In the case where $(X, \|\ .\ \|)$ is a Hilbert space, the assumption that S is weakly closed is equivalent to S (strongly) closed and one may further characterize the cone $S^+_{\lambda y_0}$.

S^+ and $S^+_{\lambda y_0}$ coincide with the *dual* cones S^* and $S^*_{\lambda y_0}$. We can write $S_{\lambda y_0} = S \cap T_{\lambda y_0}$ with $T_{\lambda y_0} := \{x \in X |\ \|\ x\ \| \leq \lambda \langle y_0, x\rangle\}$ and $T_{\lambda y_0}$ a convex cone. As soon as $\|\ \lambda y_0\ \| > 1$, $T_{\lambda y_0}$ may be interpreted as the cone of vectors x such that their angle θ with y_0 satisfies $\tan(\theta) \leq (\|\ \lambda y_0\ \|^2 - 1)^{1/2}$, i.e., $\theta \leq \theta_0$ (see Figure 1).

LEMMA 3.3. *Assume that* S *is closed and* $0 \in \text{int}\,(S - T_{\lambda y_0})$ *(for the strong topology). Then,* $S^*_{\lambda y_0} = S^* + T^*_{\lambda y_0}$. *In addition, if* $y_0 \in \text{int}\,(S^*)$ *(for the strong topology), then* $S^*_{\lambda y_0} = S^*$ *for* λ *sufficiently large.*

Proof. First note that $T_{\lambda y_0}$ is (strongly) closed and so is S by hypothesis. Therefore, as $0 \in \text{int}\,(S - T_{\lambda y_0})$, then from, e.g., [2],

$$S^*_{\lambda y_0} = (S \cap T_{\lambda y_0})^* = S^* + T^*_{\lambda y_0}.$$

Thus, under the assumptions of the above lemma, one may replace $S^*_{\lambda y_0}$ with $S^* + T^*_{\lambda y_0}$ in Theorem 3.1. In addition,

$$T^*_{\lambda y_0} = \left\{ p \in X \mid \| p \| \leq \frac{\lambda}{\sqrt{\| \lambda y_0 \|^2 - 1}} \langle p, y_0 \rangle \right\}.$$

$T^*_{\lambda y_0}$ is the cone of vectors whose angle θ with y_0 satisfies $\tan(\theta) \leq (\| \lambda y_0 \|^2 - 1)^{-1/2}$, i.e., $\theta \leq \pi/2 - \theta_0$. Therefore, if $y_0 \in \text{int}(S^*)$, then for λ sufficiently large, $T^*_{\lambda y_0} \subset S^*$ so that $S^*_{\lambda y_0} = S^*$. □

4. Illustrative example. As a simple illustrative example, consider the case of a linear system involving positive semidefinite matrices (see [4], [3]).

In this case, $X \equiv Y$ is the vector space R^n of (N, N) real symmetric matrices identified as a vector in R^n with $n = N(N+1)/2$. X is a finite-dimensional Hilbert space with norm induced from the bracket $\langle x, y \rangle := \text{trace}(x.y)$, where $x.y$ denotes the standard (N, N)-matrix product. S is the closed convex cone of positive semidefinite matrices. We want to check existence of solutions to the system $\{Ax = b;\ x \in S\}$, where A is a linear mapping $A : X \to Z$ and $Z \equiv R^m$ with the usual scalar product.

Choose $y_0 := I$ the identity matrix in X. Assumption H trivially holds. Then, if $\{\sigma_i(x)\}$ denotes the eigenvalues of x, all nonnegative when $x \in S$,

$$0 = \langle I, x \rangle = \text{trace}(x) = \sum_{i=1}^{N} \sigma_i(x) \Rightarrow \sigma_i(x) = 0 \quad \forall i \ \Rightarrow x = 0.$$

Moreover (see last paragraph in the previous section), $S \equiv S_{\lambda I}$ for all $\lambda \geq 1$. Indeed, when $x \in S$,

$$\langle I, x \rangle := \sum_{i=1}^{N} \sigma_i(x) \geq \sqrt{\sum_{i=1}^{N} \sigma_i^2(x)} = ||x||.$$

Thus, one may derive a Farkas lemma for existence of solutions to systems of matrix equalities with no closure assumption on $A(S)$. In general, without very specific properties of the mapping A, $A(S)$ is not closed and the standard Farkas lemma states only a property of *asymptotic consistency* (see [3], [4]). In this context, our theorem specializes to the following.

THEOREM 4.1. *Consider X, the Hilbert space of (n, n) symmetric real matrices with norm $||x||^2 := \langle x, x \rangle := \text{trace}(x^2)$. Let Z be R^m and $A : X \to Z$ be a linear mapping.*

The system $Ax = b$ has a solution $x \in S$ if and only if there is some $\delta > 0$ such that

$$A^*u \in S^* \Rightarrow \langle b, u \rangle \geq 0 \text{ and } A^*u + I \in S^* \Rightarrow \langle b, u \rangle \geq -\delta.$$

In the example given in [3, p. 378] the system $\{Ax = b,\ x \in S\}$ is inconsistent whereas $A^*u \in S^* \Rightarrow \langle b, u \rangle \geq 0$. However, as indicated in the theorem, one may check that $A^*u + y_0 \in S^* \Rightarrow \langle b, u \rangle \geq -\delta$ does not hold for any positive δ.

5. Another approach. In this section we present another Farkas theorem with a short proof kindly provided by a referee. This theorem (Theorem 5.1 below) reveals what lies behind Theorem 3.1, which appears as a simple corollary.

THEOREM 5.1. *Let X, Y, Z, W, S, and A be as in Theorem* 3.1. *Then the following are equivalent:*

(1) *The system* $Ax = b$ *has a solution* $x \in S$.

(2) *There exists a compact, convex set* $0 \notin B \subset S$ *and a* $\delta > 0$ *such that for* $K := \text{cone } B$, $y_0 \in \text{int } K^+$, *we have*

$$A^+ w + y_0 \in K^+ \Rightarrow \langle b, w \rangle \geq -\delta.$$

Proof. (1) $\Rightarrow$ (2). Suppose that $x \in S$ and $Ax = b$, $x \neq 0$. (The case $b = 0$ is trivial.) Choose an appropriate B such that it is convex and compact and $0 \notin B \subset S$, with $x \in B$ (e.g., $B := \{x\}$). Therefore, the generated dual cone K^+ has nonempty interior. Choose any $y_0 \in \text{int } K^+$. Then, the program

$$(P) \quad \mu = \{\inf \langle b, w \rangle \mid A^+ w + y_0 \in K^+\}$$

satisfies Slater's condition with $w := 0$. The dual program

$$(D) \quad \nu = \{\sup \langle y_0, x \rangle \mid Ax = b,\ x \in K\}$$

is consistent. Therefore, by weak duality, $\mu \geq \nu > -\infty$; i.e., we can choose $\delta = -\mu$. Therefore, (2) holds.

(2) $\Rightarrow$ (1). Conversely, if (2) holds, then Slater's condition holds for (P) and $\mu > -\infty$. Therefore, by strong duality, (D) must be consistent. □

This theorem can also be derived from closely related results in [6], [7], [8]. Theorem 3.1 is a corollary of Theorem 5.1. This follows from the Banach–Alaoglu theorem; i.e., we can choose λ in the definition of $S_{\lambda y_0}$ so that this cone contains the x from the consistent system. A compact and convex base for the cone is obtained by taking the intersection with the set $\{x|\ \langle y_0, x \rangle = 1\}$. The definition of the cone implies that this set is norm bounded and thus $w*$-compact.

Finally, note that Theorem 4.1 can be proved directly and trivially, since Slater's condition holds for (P) with $y_0 = I$ and $K = S$.

6. Conclusion. We have presented a new nonasymptotic Farkas lemma in Banach spaces for a linear system $Ax = b,\ x \in S$, where S is some positive cone. Under some assumptions on the spaces involved, this Farkas lemma holds without the usual restrictive closure assumption on $A(S)$. The assumptions are rather weak and concern many examples. Theorem 5.1 reveals what lies behind Theorem 3.1, i.e., the existence of an appropriate, compactly generated, convex cone. Using this new Farkas lemma to develop first-order optimality conditions in mathematical programming is a topic for further research.

Acknowledgment. The author wishes to thank the anonymous referees for very helpful comments and suggestions to improve the original version. In particular, Theorem 5.1 and its short and elegant proof were kindly provided by one of them.

EQUIVALENT UNCONSTRAINED MINIMIZATION AND GLOBAL ERROR BOUNDS FOR VARIATIONAL INEQUALITY PROBLEMS*

NOBUO YAMASHITA† AND MASAO FUKUSHIMA†

Abstract. New merit functions for variational inequality problems are constructed through the Moreau–Yosida regularization of some gap functions. The proposed merit functions constitute *unconstrained* optimization problems equivalent to the original variational inequality problem under suitable assumptions. Conditions are studied for those merit functions to be differentiable and for any stationary point of those functions to be a solution of the original variational inequality problem. Moreover, those functions are shown to provide global error bounds for general variational inequality problems under the strong monotonicity assumption only.

Key words. variational inequality problem, merit function, unconstrained optimization problem, global error bounds

1. Introduction.

Merit functions for variational inequality and complementarity problems have recently drawn much attention (see [8] for a survey). Such a function naturally constitutes an equivalent optimization formulation and has turned out to be very useful in designing new globally convergent algorithms and analyzing the rate of convergence of some algorithms [2, 6, 7, 9, 10, 12, 13, 14, 15, 16, 17, 20, 21, 22, 19, 28, 26, 27, 31, 29, 30, 32, 33]. For nonlinear complementarity problems, both constrained and unconstrained differentiable optimization formulations are already known and various interesting results on iterative methods and error bounds have been established [9, 12, 17, 19, 31, 30, 33]. For variational inequality problems, constrained differentiable optimization formulations have been proposed [6, 7, 13, 20, 28, 32]. To the authors' knowledge, however, an unconstrained differentiable optimization formulation has yet to be discussed in the literature. (During the review of this paper, Peng proposed an unconstrained optimization formulation in a technical report [23], which is based on the regularized gap function [7] and the implicit Lagrangian [19]. His approach is, however, quite different from the one adopted in this paper.) The purpose of this paper is to present unconstrained differentiable optimization formulations for general variational inequality problems and to give some error bound results based on them.

The variational inequality problem (VIP) is to find a vector x in a closed convex subset S of R^n such that

$$\langle F(x), y - x\rangle \geq 0 \quad \text{for all } y \in S,$$

where F is a mapping from R^n into itself and $\langle \cdot, \cdot \rangle$ denotes the inner product in R^n. Throughout the paper, we shall assume that the mapping F is continuous.

†Department of Applied Mathematics and Physics, Graduate School of Engineering, Kyoto University, Kyoto 606-01, Japan (nobuo@kuamp.kyoto-u.ac.jp, fuku@kuamp.kyoto-u.ac.jp).

First, we review some well-known merit functions for VIP. Let $\Psi : R^n \times R^n \to R$ be defined by

$$\Psi(x, y) = \langle F(x), x - y \rangle. \tag{1}$$

Using Ψ, define the class of functions $f(\,\cdot\,;\alpha) : R^n \to R \cup \{+\infty\}$ by

$$f(x;\alpha) = \sup_{y \in S} \left\{ \Psi(x, y) - \alpha \|x - y\|^2 \right\}, \tag{2}$$

where α is a nonnegative parameter. This function was first introduced by Auslender [2] for $\alpha = 0$ (see also [11]) and by Fukushima [7] for $\alpha > 0$. The latter case was also considered by Auchmuty [1] independently in a general form (see also [13]). The function $f(\,\cdot\,;0)$ is commonly called the gap function, while the function $f(\,\cdot\,;\alpha)$ with $\alpha > 0$ is called the regularized gap function. For each $\alpha \geq 0$, the function $f(\,\cdot\,;\alpha)$ is nonnegative on S and becomes zero at any solution of VIP [11, 7]. Hence, VIP is equivalent to finding a global minimizer of $f(\,\cdot\,;\alpha)$ on S. If F is a continuous mapping, then $f(\,\cdot\,;\alpha)$ is lower semicontinuous for $\alpha = 0$ [5, Lemma 4.1] and continuous for $\alpha > 0$ [7, Theorem 3.1]. The gap function $f(\,\cdot\,;0)$ has the serious drawback, however, that it is in general nondifferentiable even if F is differentiable, and, even worse, it may not be finite valued. On the other hand, the regularized gap function $f(\,\cdot\,;\alpha)$ with $\alpha > 0$ has such desirable properties that it is finite valued everywhere and is differentiable whenever F is differentiable [7, Theorem 3.1]. (See [7, 13] for further properties of the regularized gap function.) A modification of the regularized gap function has recently been proposed in [26, 27].

Closely related to the functions $f(\,\cdot\,;\alpha)$ is the class of functions $h(\,\cdot\,;\beta) : R^n \to R \cup \{+\infty\}$ given by

$$h(x;\beta) = \sup_{y \in S} \left\{ -\Psi(y, x) + \beta \|x - y\|^2 \right\}, \tag{3}$$

where β is a nonnegative parameter. This function has been studied in [20] for the case $\beta = 0$. In particular, if F is pseudomonotone on S [4, 25], i.e.,

$$\langle F(y), x - y \rangle \geq 0 \Longrightarrow \langle F(x), x - y \rangle \geq 0 \quad \text{for all } x, y \in S,$$

then the function $h(\,\cdot\,;0)$ is nonnegative on S and vanishes at any solution of VIP, implying that VIP is equivalent to minimizing $h(\,\cdot\,;0)$ over S [20, Proposition 1]. We will see that this property is extended to the case $\beta > 0$. It is easily seen that, for any $\beta \geq 0$, the function $h(\,\cdot\,;\beta)$ is convex. Moreover, if F is continuous, then $h(\,\cdot\,;\beta)$ is lower semicontinuous, as shown in the next section.

It should be noted that the above-mentioned merit functions all constitute constrained optimization problems equivalent to VIP. In this paper, we explore the possibility of constructing unconstrained differentiable optimization problems equivalent to VIP. Specifically, we consider the following functions derived from the Moreau–Yosida regularization:

$$\phi_f(x;\alpha,\lambda) = \inf_{z \in S} \left\{ f(z;\alpha) + \lambda \|x - z\|^2 \right\} \tag{4}$$

and

$$\phi_h(x;\beta,\lambda) = \inf_{z \in S} \left\{ h(z;\beta) + \lambda \|x - z\|^2 \right\}, \tag{5}$$

where λ is a positive parameter and $f(\,\cdot\,;\alpha)$ and $h(\,\cdot\,;\beta)$ are defined by (2) and (3), respectively. In general, the functions $\phi_f(\,\cdot\,;\alpha,\lambda)$ and $\phi_h(\,\cdot\,;\beta,\lambda)$ may not be easy to

evaluate in practice unless VIP has a certain special structure. (In section 3, we show that the function $\phi_f(\,\cdot\,;\alpha,\lambda)$ is actually computable for monotone affine VIP with polyhedral convex set S.) Nevertheless these functions enjoy some nice theoretical properties that existing merit functions for VIP do not have. Under some assumptions, the functions $\phi_f(\,\cdot\,;\alpha,\lambda)$ and $\phi_h(\,\cdot\,;\beta,\lambda)$ are shown to be differentiable even if F is not differentiable. We shall investigate conditions under which any stationary point of these functions solves the original VIP. We also discuss how the foregoing results are specialized to affine VIP and illustrate how the function $\phi_f(\,\cdot\,;\alpha,\lambda)$ is calculated for the monotone affine VIP with linear constraints. Finally, we will show that $\phi_f(\,\cdot\,;\alpha,\lambda)$ and $\phi_h(\,\cdot\,;\beta,\lambda)$ provide global error bounds for the strongly monotone VIP. We remark that those results are valid for problems with general convex constraints S and do not rely on the Lipschitz continuity of F, while the well-known error bound for VIP obtained by Pang [21] assumes that the set S is polyhedral and F is both strongly monotone and Lipschitz continuous.

2. VIP as unconstrained minimization. In this section, we show that the unconstrained minimization of the function $\phi_f(\,\cdot\,;\alpha,\lambda)$ defined by (4) is equivalent to VIP, and that, under some additional assumptions, the unconstrained minimization of the function $\phi_h(\,\cdot\,;\beta,\lambda)$ defined by (5) is also equivalent to VIP. Further, we shall investigate the differentiability and the convexity of these functions. Recall that the mapping $F : R^n \to R^n$ is said to be monotone on S if

$$\langle F(x) - F(y), x - y\rangle \geq 0 \quad \text{for all } x, y \in S,$$

and strongly monotone with modulus $\mu > 0$ on S if

$$\langle F(x) - F(y), x - y\rangle \geq \mu\|x - y\|^2 \quad \text{for all } x, y \in S.$$

First, we state some lemmas which will be useful in proving the subsequent theorems.

LEMMA 2.1. *For any $\alpha \geq 0$, $f(\,\cdot\,;\alpha)$ is nonnegative on S. Moreover, $f(x;\alpha) = 0$ if and only if x is a solution of VIP.*

Proof. See [11] for the case $\alpha = 0$ and [7, Theorem 3.1] for the case $\alpha > 0$. □

LEMMA 2.2. *For any $\beta \geq 0$, the function $h(\,\cdot\,;\beta)$ is a closed convex function.*

Proof. The convexity of $h(\,\cdot\,;\beta)$ follows from the definition (3) directly, since $-\Psi(y,\,\cdot\,)+\beta\|\,\cdot\,-y\|^2$ is convex for every y. The closedness of $h(\,\cdot\,;\beta)$ follows from the fact that a pointwise supremum of continuous functions yields a lower semicontinuous function. □

LEMMA 2.3.

(a) *For any $\beta \geq 0$, $h(\,\cdot\,;\beta)$ is nonnegative on S.*

(b) *Suppose that F is pseudomonotone on S. Then x is a solution of VIP if and only if $h(x;0) = 0$ and $x \in S$.*

(c) *Suppose that F is strongly monotone on S with modulus μ and that β is chosen to satisfy $0 \leq \beta \leq \mu$. Then x is a solution of VIP if and only if $h(x;\beta) = 0$ and $x \in S$.*

Proof. (a) This is obvious from the definition (3) of $h(\,\cdot\,;\beta)$. (b) See [20, Proposition 1].

(c) By the definition (1) of Ψ, we have

$$\begin{aligned}\Psi(x,y) &\geq -\Psi(y,x) + \mu\|x-y\|^2\\ &\geq -\Psi(y,x) + \beta\|x-y\|^2\\ &\geq -\Psi(y,x) \qquad \text{for all } x, y \in S,\end{aligned}$$

implying that

$$f(x;0) \geq h(x;\beta) \geq h(x;0) \quad \text{for all } x \in S. \tag{6}$$

Let x^* be a solution of VIP. Then, since $f(x^*;0) = 0$ by Lemma 2.1 and $h(x^*;0) = 0$ by part (b) of this lemma, we have $h(x^*;\beta) = 0$ by (6). Conversely, let $h(x;\beta) = 0$. Then, since $h(\,\cdot\,;0)$ is nonnegative on S by part (a), it follows from (6) that $h(x;0) = 0$. Thus, x is a solution of VIP by part (b). □

Using these lemmas, we establish the equivalence between VIP and the unconstrained minimization of $\phi_f(\,\cdot\,;\alpha,\lambda)$ and $\phi_h(\,\cdot\,;\beta,\lambda)$. The next theorem shows that these functions are nonnegative on R^n and that, under suitable conditions, the sets of unconstrained minima of these functions coincide with the set of solutions of VIP.

THEOREM 2.4.

(a) *For any $\alpha \geq 0$, $\beta \geq 0$, and $\lambda > 0$, the functions $\phi_f(\,\cdot\,;\alpha,\lambda)$ and $\phi_h(\,\cdot\,;\beta,\lambda)$ are nonnegative on R^n.*

(b) *For any $\alpha \geq 0$ and $\lambda > 0$, x^* is a solution of VIP if and only if $\phi_f(\,\cdot\,;\alpha,\lambda)$ attains its global minimum at x^* and the minimum value is zero.*

(c) *Suppose that F is pseudomonotone on S. Then, for any $\lambda > 0$, x^* is a solution of VIP if and only if $\phi_h(\,\cdot\,;0,\lambda)$ attains its global minimum at x^* and the minimum value is zero.*

(d) *Suppose that F is strongly monotone on S with modulus μ and that β is chosen to satisfy $0 \leq \beta \leq \mu$. Then, for any $\lambda > 0$, x^* is a solution of VIP if and only if $\phi_h(\,\cdot\,;\beta,\lambda)$ attains its global minimum at x^* and the minimum value is zero.*

Proof. We consider the function $\phi_f(\,\cdot\,;\alpha,\lambda)$. (a) Since $f(\,\cdot\,;\alpha)$ is nonnegative on S by Lemma 2.1, we can easily deduce from the definition (4) of $\phi_f(\,\cdot\,;\alpha,\lambda)$ that $\phi_f(x;\alpha,\lambda)$ is nonnegative for all $x \in R^n$. (b) Suppose that x^* is a solution of VIP. Then, we have

$$\begin{aligned}\phi_f(x^*;\alpha,\lambda) &= \inf_{z\in S}\left\{f(z;\alpha) + \lambda\|x^* - z\|^2\right\} \\ &\leq f(x^*;\alpha) + \lambda\|x^* - x^*\|^2 \\ &= 0,\end{aligned}$$

where the last equality follows from $f(x^*;\alpha) = 0$. Since $\phi_f(x;\alpha,\lambda) \geq 0$ for all x as shown above, we obtain $\phi_f(x^*;\alpha,\lambda) = 0$. Conversely, suppose $\phi_f(x^*;\alpha,\lambda) = 0$. Then since $f(z;\alpha) \geq 0$ for all $z \in S$, it follows from the definition (4) of $\phi_f(\,\cdot\,;\alpha,\lambda)$ that there exists a sequence $\{z^k\}$ in S such that $f(z^k;\alpha) \to 0$ and $\|z^k - x^*\| \to 0$. Since S is closed, $z^k \to x^*$ and $z^k \in S$ imply $x^* \in S$. Moreover, since $f(\,\cdot\,;\alpha)$ is lower semicontinuous for $\alpha = 0$ [5, 13] and continuous for $\alpha > 0$ [7], we have

$$0 \leq f(x^*;\alpha) \leq \lim_{k\to\infty} f(z^k;\alpha) = 0.$$

Thus, x^* must be a solution of VIP.

By using Lemmas 2.2 and 2.3, the proof for the function $\phi_h(\,\cdot\,;\beta,\lambda)$ can be done analogously. □

By this theorem, the unconstrained minimization problem

$$\min_{x\in R^n} \quad \phi_f(x;\alpha,\lambda) \tag{7}$$

is equivalent to VIP, and the unconstrained minimization problem

$$\min_{x\in R^n} \quad \phi_h(x;\beta,\lambda) \tag{8}$$

is equivalent to VIP under suitable assumptions on F and the parameters involved.

In order for these minimization problems to be practically useful, it is desirable that the objective functions $\phi_f(\,\cdot\,;\alpha,\lambda)$ and $\phi_h(\,\cdot\,;\beta,\lambda)$ are everywhere differentiable. For the discussions to follow, it will be convenient to define the functions $\Phi_f(\,\cdot\,,\,\cdot\,;\alpha,\lambda) : R^{2n} \to R \cup \{+\infty\}$ and $\Phi_h(\,\cdot\,,\,\cdot\,;\beta,\lambda) : R^{2n} \to R \cup \{+\infty\}$ by

$$\Phi_f(x,z;\alpha,\lambda) = f(z;\alpha) + \lambda\|x-z\|^2$$

and

$$\Phi_h(x,z;\beta,\lambda) = h(z;\beta) + \lambda\|x-z\|^2,$$

respectively. By (4) and (5), we have

$$\phi_f(x;\alpha,\lambda) = \inf_{z\in S} \Phi_f(x,z;\alpha,\lambda)$$

and

$$\phi_h(x;\beta,\lambda) = \inf_{z\in S} \Phi_h(x,z;\beta,\lambda).$$

Whenever the functions $\Phi_f(x,\,\cdot\,;\alpha,\lambda)$ and $\Phi_h(x,\,\cdot\,;\beta,\lambda)$ are assumed to attain their minima uniquely in the set S, we shall denote those minima by $z_f(x;\alpha,\lambda)$ and $z_h(x;\beta,\lambda)$, respectively. The following propositions are consequences of [2, Chapter 4, Theorem 1.7]. Note that these propositions do not rely upon the differentiability of F.

PROPOSITION 2.5. *Let $\alpha \geq 0$ and $\lambda > 0$. If the function $\Phi_f(x,\,\cdot\,;\alpha,\lambda)$ attains its unique minimum $z_f(x;\alpha,\lambda)$ on S for each $x \in R^n$, then $\phi_f(\,\cdot\,;\alpha,\lambda)$ is differentiable on R^n and*

$$\nabla\phi_f(x;\alpha,\lambda) = 2\lambda\left(x - z_f(x;\alpha,\lambda)\right).$$

Proof. This follows immediately from Theorem 1.7 in [2, Chapter 4]. □

PROPOSITION 2.6. *For any $\beta \geq 0$ and $\lambda > 0$, the function $\Phi_h(x,\,\cdot\,;\beta,\lambda)$ attains its minimum $z_h(x;\beta,\lambda)$ uniquely. Moreover, $\phi_h(\,\cdot\,;\beta,\lambda)$ is a differentiable convex function on R^n and*

$$\nabla\phi_h(x;\beta,\lambda) = 2\lambda\left(x - z_h(x;\beta,\lambda)\right).$$

Proof. By Lemma 2.2, $h(\,\cdot\,;\beta)$ is a closed convex function. Thus, by Theorem 31.5 in [24], $\Phi_h(x,\,\cdot\,;\beta,\lambda)$ uniquely attains its minimum on S for any x and hence, by Theorem 1.7 in [2, Chapter 4], $\phi_h(\,\cdot\,;\beta,\lambda)$ is differentiable and its gradient is represented as indicated in the proposition. Moreover, it follows from the convexity of $h(\,\cdot\,;\beta)$ that $\phi_h(\,\cdot\,;\beta,\lambda)$ is also convex (see the proof of Proposition 4.1 in [3]). □

Theorem 2.4 is concerned with the equivalence between VIP and global minimization of $\phi_f(\,\cdot\,;\alpha,\lambda)$ and $\phi_h(\,\cdot\,;\beta,\lambda)$. In general, however, there may exist local minima or stationary points which do not solve VIP. In the remainder of the section, we study conditions under which any stationary point of problems (7) and (8) is a solution of VIP.

The following proposition gives a condition for $\phi_f(\,\cdot\,;\alpha,\lambda)$ to be convex.

PROPOSITION 2.7. *Suppose that $\Psi(\,\cdot\,,y)$ is convex for each fixed $y \in S$. Then, for any $\lambda > 0$, $\phi_f(\,\cdot\,;0,\lambda)$ is a differentiable convex function on R^n. Moreover, suppose*

that $\Psi(\,\cdot\,, y)$ is strongly convex with modulus μ for each fixed $y \in S$. Then, for any $\lambda > 0$ and any α such that $0 \le \alpha \le \mu$, $\phi_f(\,\cdot\,; \alpha, \lambda)$ is a differentiable convex function on R^n.

Proof. We prove the first half only; the latter half can be proved by a similar argument. Since $\Psi(\,\cdot\,, y)$ is finite valued and convex for each fixed $y \in S$, $f(\,\cdot\,; 0)$ is a closed proper convex function. So we can prove the convexity of $\phi_f(\,\cdot\,; 0, \lambda)$ in a way similar to the proof of Proposition 4.1 in [3]. Moreover, since $\Phi_f(x, \,\cdot\,; 0, \lambda)$ uniquely attains its minimum on S for any x by Theorem 31.5 in [24], $\phi_f(\,\cdot\,; 0, \lambda)$ is differentiable by Proposition 2.5. □

Note that, as shown in [11], if S is polyhedral convex, $\langle F(x), x\rangle$ is convex on S and each component of F is concave on S, then $f(\,\cdot\,; 0)$ is convex. Thus it follows that, under these assumptions, $\phi_f(\,\cdot\,; 0, \lambda)$ is a differentiable convex function.

The following result is a consequence of Proposition 2.7.

THEOREM 2.8. *Assume that VIP has a solution. If $\Psi(\,\cdot\,, y)$ is convex for each fixed $y \in S$, then for each $\lambda > 0$ any stationary point of $\phi_f(\,\cdot\,; 0, \lambda)$ is a solution of VIP. Moreover, if $\Psi(\,\cdot\,, y)$ is strongly convex with modulus μ for each fixed $y \in S$, then for each $\lambda > 0$ and α such that $0 \le \alpha \le \mu$ any stationary point of $\phi_f(\,\cdot\,; \alpha, \lambda)$ is a solution of VIP.*

Proof. Under given assumptions, $\phi_f(\,\cdot\,; \alpha, \lambda)$ is a differentiable convex function for each $\alpha \ge 0$ by Proposition 2.5. Therefore $\nabla\phi_f(x; \alpha, \lambda) = 0$ if and only if $\phi_f(\,\cdot\,; \alpha, \lambda)$ attains its global minimum at x. The desired results then follow from Theorem 2.4. □

Next we restrict our attention to the function $\phi_f(\,\cdot\,; \alpha, \lambda)$ with $\alpha > 0$. The following theorem gives conditions under which any stationary point of $\phi_f(\,\cdot\,; \alpha, \lambda)$ is a solution of VIP.

THEOREM 2.9. *Assume that VIP has a solution. Let $\alpha > 0$ and $\lambda > 0$. Suppose that the function $\Phi_f(x, \,\cdot\,; \alpha, \lambda)$ attains its unique minimum $z_f(x; \alpha, \lambda)$ on S for any fixed $x \in R^n$. If F is differentiable and $\nabla F(x)$ is positive definite on S, then any stationary point of $\phi_f(\,\cdot\,; \alpha, \lambda)$ is a solution of VIP.*

Proof. Let $\hat{x}$ be an arbitrary stationary point of $\phi_f(\,\cdot\,; \alpha, \lambda)$. Then by Proposition 2.5 it satisfies

$$\nabla\phi_f(\hat{x}; \alpha, \lambda) = 2\lambda\,(\hat{x} - z_f(\hat{x}; \alpha, \lambda)) = 0.$$

Hence, we have $\hat{x} = z_f(\hat{x}; \alpha, \lambda) \in S$. On the other hand, since $z_f(x; \alpha, \lambda)$ is the minimizer of $\Phi_f(x, \,\cdot\,; \alpha, \lambda)$ on S and since $f(\,\cdot\,; \alpha)$ is differentiable [7], the first-order optimality condition yields

$$\langle \nabla_z \Phi_f(x, z_f(x; \alpha, \lambda); \alpha, \lambda), y - z_f(x; \alpha, \lambda)\rangle \ge 0 \quad \text{for all } y \in S;$$

that is,

$$\langle \nabla f(z_f(x; \alpha, \lambda); \alpha) + 2\lambda(z_f(x; \alpha, \lambda) - x), y - z_f(x; \alpha, \lambda)\rangle \ge 0 \quad \text{for all } y \in S. \tag{9}$$

Substituting $\hat{x}$ for x in (9) and using $\hat{x} = z_f(\hat{x}; \alpha, \lambda)$, we have

$$\langle \nabla f(\hat{x}; \alpha), y - \hat{x}\rangle \ge 0 \quad \text{for all } y \in S.$$

Namely, $\hat{x}$ is a stationary point of $f(\,\cdot\,; \alpha)$ on S. Then, by Theorem 3.3 in [7], the positive definiteness of $\nabla F(x)$ ensures that $\hat{x}$ is a solution of VIP. □

Finally, we consider the function $\phi_h(\,\cdot\,; \beta, \lambda)$. Proposition 2.6 and Theorem 2.4 immediately yield the following theorem.

THEOREM 2.10. *Assume that VIP has a solution. Let $\lambda > 0$. If F is pseudomonotone on S, then any stationary point of $\phi_h(\,\cdot\,;0,\lambda)$ is a solution of VIP. Moreover, if F is strongly monotone on S with modulus μ and if β is chosen to satisfy $0 \le \beta \le \mu$, then any stationary point of $\phi_h(\,\cdot\,;\beta,\lambda)$ is a solution of VIP.*

Proof. First note that for each $\beta \ge 0$ and $\lambda > 0$, $\phi_h(\,\cdot\,;\beta,\lambda)$ is a differentiable convex function by Proposition 2.6. Thus, $\nabla\phi_h(x;\beta,\lambda) = 0$ if and only if $\phi_h(\,\cdot\,;\beta,\lambda)$ attains its global minimum at x. The theorem then follows from Theorem 2.4 (c) and (d). □

3. Monotone affine VIP. In this section, we consider the special case of VIP where F is the affine mapping

$$F(x) = Mx + a.$$

Here the $n \times n$ matrix M is assumed to be positive semidefinite, that is, the mapping F is monotone. The next two theorems show some properties of $\phi_f(\,\cdot\,;\alpha,\lambda)$ and $\phi_h(\,\cdot\,;\beta,\lambda)$ for the monotone affine VIP.

THEOREM 3.1. *Let μ be a nonnegative constant such that*

$$\langle x, Mx\rangle \ge \mu\|x\|^2 \quad \text{for all } x \in R^n.$$

Then for any $\lambda > 0$ and $\alpha \ge 0$ such that $\alpha \le \mu$, $\phi_f(\,\cdot\,;\alpha,\lambda)$ is a differentiable convex function. Moreover, any stationary point of $\phi_f(\,\cdot\,;\alpha,\lambda)$ is a solution of the affine VIP.

Proof. If $0 \le \alpha \le \mu$, then the function

$$\Psi(z,y) - \alpha\|z-y\|^2 = \langle Mz + a, z - y\rangle - \alpha\|z-y\|^2$$

is convex in z for each fixed y. Hence, by the definition (2), $f(\,\cdot\,;\alpha)$ is a closed convex function. So it follows from the proof of Proposition 4.1 in [3] that $\phi_f(\,\cdot\,;\alpha,\lambda)$ is a closed convex function. Moreover, by Theorem 31.5 in [24], $\Phi_f(x,\,\cdot\,;\alpha,\lambda)$ uniquely attains its minimum on S for any x. Hence, by Proposition 2.5, $\phi_f(\,\cdot\,;\alpha,\lambda)$ is differentiable. This proves the first half of the theorem. Since $\nabla\phi_f(x;\alpha,\lambda) = 0$ if and only if x is a global minimizer of $\phi_f(\,\cdot\,;\alpha,\lambda)$, the last half of the theorem follows from Theorem 2.4 (b). □

THEOREM 3.2. *Let μ be a nonnegative constant such that*

$$\langle x, Mx\rangle \ge \mu\|x\|^2 \quad \text{for all } x \in R^n.$$

Then, for any $\lambda > 0$ and $\beta \ge 0$ such that $\beta \le \mu$, $\phi_h(\,\cdot\,;\beta,\lambda)$ is a differentiable convex function and any stationary point of $\phi_h(\,\cdot\,;\beta,\lambda)$ is a solution of the affine VIP.

Proof. By Proposition 2.6 and Theorem 2.10, we get the desired results using a similar argument to the proof of Theorem 3.1. □

Note that if M is not positive definite but simply positive semidefinite, then the constant μ in Theorems 3.1 and 3.2 is zero, and hence α and β must be zero, too. Namely, the theorems then apply to the functions $\phi_f(\,\cdot\,;0,\lambda)$ and $\phi_h(\,\cdot\,;0,\lambda)$.

In the rest of this section, we show that the function $\phi_f(\,\cdot\,;\alpha,\lambda)$ can be practically computed for the monotone affine VIP with linear constraints: Find $x \in S$ such that

$$\langle Mx + a, y - x\rangle \ge 0 \quad \text{for all } y \in S, \tag{10}$$

where $S = \{x \in R^n \mid x \ge 0, Ax \ge b\}$ with $m \times n$ matrix A and m-vector b.

To evaluate the function $\phi_f(\,\cdot\,;\alpha,\lambda)$, we need to solve the minimization problem

$$\min_{z\in S} f(z;\alpha)+\lambda\|x-z\|^2, \tag{11}$$

where $f(z;\alpha)$ is given by

$$f(z;\alpha)=\sup_{y\in S}\left\{\langle Mz+a,z-y\rangle-\alpha\|z-y\|^2\right\}.$$

Since

$$\nabla f(z;\alpha)=Mz+a+(M^T-2\alpha I)(z-[z-\tfrac{1}{2\alpha}(Mz+a)]_S^+),$$

where $[\,\cdot\,]_S^+$ denotes the orthogonal projection onto S, the Karush–Kuhn–Tucker conditions for the minimization problem (11) are written as

$$\begin{gathered} Mz+a+(M^T-2\alpha I)(z-[z-\tfrac{1}{2\alpha}(Mz+a)]_S^+)+2\lambda(z-x)-u-A^Tv=0,\\ s=Az-b,\\ z\ge 0,\ \ s\ge 0,\ \ u\ge 0,\ \ v\ge 0,\\ \langle z,u\rangle=0,\ \ \langle s,v\rangle=0, \end{gathered} \tag{12}$$

where $u\in R^n$ and $v\in R^m$ are the vectors of Lagrange multipliers and $s\in R^m$ is the vector of slack variables. Moreover, the vector $[z-\frac{1}{2\alpha}(Mz+a)]_S^+$ is a solution of the linear complementarity problem (LCP) of finding $y\in R^n$ such that

$$\begin{gathered} y-z+\tfrac{1}{2\alpha}(Mz+a)-p-A^Tq=0,\\ t=Ay-b,\\ y\ge 0,\ \ t\ge 0,\ \ p\ge 0,\ \ q\ge 0,\\ \langle y,p\rangle=0,\ \ \langle t,q\rangle=0. \end{gathered}$$

Hence, the Karush–Kuhn–Tucker conditions (12) can be rewritten as the following LCP: find $(z,v,y,q)\in R^{2m+2n}$ such that

$$\begin{gathered} \begin{pmatrix} u\\ s\\ p\\ t \end{pmatrix}=\begin{pmatrix} Mz+a+(M^T-2\alpha I)(z-y)+2\lambda(z-x)-A^Tv\\ Az-b\\ y-z+\frac{1}{2\alpha}(Mz+a)-A^Tq\\ Ay-b \end{pmatrix},\\ z\ge 0,\ \ s\ge 0,\ \ y\ge 0,\ \ t\ge 0,\ \ u\ge 0,\ \ v\ge 0,\ \ p\ge 0,\ \ q\ge 0,\\ \langle z,u\rangle=0,\ \ \langle s,v\rangle=0,\ \ \langle y,p\rangle=0,\ \ \langle t,q\rangle=0. \end{gathered} \tag{13}$$

Now let us put $\alpha=\frac{1}{2}$. Then the LCP (13) becomes

$$\begin{gathered} \begin{pmatrix} u\\ s\\ p\\ t \end{pmatrix}=\begin{pmatrix} N & -A^T & -M^T+I & 0\\ A & 0 & 0 & 0\\ M-I & 0 & I & -A^T\\ 0 & 0 & A & 0 \end{pmatrix}\begin{pmatrix} z\\ v\\ y\\ q \end{pmatrix}+\begin{pmatrix} a-2\lambda x\\ -b\\ a\\ -b \end{pmatrix},\\ z\ge 0,\ \ s\ge 0,\ \ y\ge 0,\ \ t\ge 0,\ \ u\ge 0,\ \ v\ge 0,\ \ p\ge 0,\ \ q\ge 0,\\ \langle z,u\rangle=0,\ \ \langle s,v\rangle=0,\ \ \langle y,p\rangle=0,\ \ \langle t,q\rangle=0, \end{gathered} \tag{14}$$

where $N=M+M^T+(2\lambda-1)I$. If $2\lambda\ge 1$, then the positive semidefiniteness of M ensures that (14) is a monotone LCP. Thus, the function $\phi_f(x;\alpha,\lambda)$ for the monotone affine VIP (10) can be computed by solving the monotone LCP (14), provided that α and λ are chosen such that $\alpha=\frac{1}{2}$ and $\lambda\ge\frac{1}{2}$.

4. Global error bounds. Error bounds play an important role in analyzing the convergence rate of iterative algorithms [16, 29]. In particular, the natural residual $r : R^n \to R$, which is defined by

$$r(x) = \|x - [x - F(x)]_S^+\|, \tag{15}$$

is known to provide a global error bound for linearly constrained VIP under the Lipschitz continuity and strong monotonicity of F [21]. In this section, we show that $\phi_f(\,\cdot\,;\alpha,\lambda)$ and $\phi_h(\,\cdot\,;\beta,\lambda)$ provide global error bounds for VIP under the strong monotonicity of F.

To begin with, we point out that, when F is strongly monotone, the functions $f(\,\cdot\,;\alpha)$ and $h(\,\cdot\,;\beta)$ provide error bounds on S, provided that the parameters α and β are small enough. Note that the strong monotonicity of F guarantees the existence of a unique solution to VIP.

LEMMA 4.1. *If F is strongly monotone on S with modulus μ and if α is chosen to satisfy $0 \le \alpha < \mu$, then we have $f(x^*;\alpha) = 0$ and*

$$f(x;\alpha) \ge (\mu - \alpha)\,\|x - x^*\|^2 \qquad \text{for all } x \in S,$$

where x^* is the unique solution of VIP.

Proof. For this proof see Proposition 3.4 in [28] and Theorem 4.5 in [13]. □

LEMMA 4.2. *If F is strongly monotone on S with modulus μ and if β is chosen to satisfy $0 < \beta \le \mu$, then we have $h(x^*;\beta) = 0$ and*

$$h(x;\beta) \ge \beta\|x - x^*\|^2 \qquad \text{for all } x \in S,$$

where x^* is the unique solution of VIP.

Proof. By Lemma 2.3, we have $h(x^*,\beta) = 0$. Let $x \in S$ be arbitrary. Then, we have

$$\begin{aligned} h(x;\beta) &= \sup_{y\in S}\left\{\langle F(y), x - y\rangle + \beta\|x - y\|^2\right\} \\ &\ge \langle F(x^*), x - x^*\rangle + \beta\|x - x^*\|^2 \\ &\ge \beta\|x - x^*\|^2, \end{aligned}$$

where the last inequality follows from the fact that x^* is a solution of VIP. □

Note that the error bounds given in the above lemmas are valid on the constraint set S. Using these lemmas, we prove below that $\phi_f(\,\cdot\,;\alpha,\lambda)$ and $\phi_h(\,\cdot\,;\beta,\lambda)$ provide global error bounds for VIP on the whole space R^n, whenever F is strongly monotone.

The next theorem shows that the growth rate of $\phi_f(\,\cdot\,;\alpha,\lambda)$ is in the order of the squared distance to the unique solution of VIP, provided that the parameter α is chosen sufficiently small.

THEOREM 4.3. *If F is strongly monotone on S with modulus μ and if α is chosen to satisfy $0 \le \alpha < \mu$, then for each $\lambda > 0$,*

$$\frac{1}{2}\min\{\mu - \alpha, \lambda\}\,\|x - x^*\|^2 \le \phi_f(x;\alpha,\lambda) \le \lambda\|x - x^*\|^2 \qquad \text{for all } x \in R^n,$$

where x^* is the unique solution of VIP.

Proof. First we consider the right-hand inequality. Since $x^* \in S$ and $f(x^*;\alpha) = 0$ by Lemma 2.1, we have

$$\begin{aligned} \phi_f(x;\alpha,\lambda) &= \inf_{z\in S}\left\{f(z;\alpha) + \lambda\|z - x\|^2\right\} \\ &\le f(x^*;\alpha) + \lambda\|x - x^*\|^2 \\ &= \lambda\|x - x^*\|^2. \end{aligned}$$

Next, we prove the left-hand inequality. It follows from Lemma 4.1 that

$$\begin{aligned}
\phi_f(x;\alpha,\lambda) &= \inf_{z\in S}\left\{f(z;\alpha)+\lambda\|z-x\|^2\right\}\\
&\geq \inf_{z\in S}\left\{(\mu-\alpha)\|z-x^*\|^2+\lambda\|z-x\|^2\right\}\\
&\geq \min\{\mu-\alpha,\lambda\}\inf_{z\in S}\left\{\|z-x^*\|^2+\|z-x\|^2\right\}\\
&= \min\{\mu-\alpha,\lambda\}\left(\left\|\left[\frac{x+x^*}{2}\right]_S^+-x^*\right\|^2+\left\|\left[\frac{x+x^*}{2}\right]_S^+-x\right\|^2\right)\\
&\geq \frac{1}{2}\min\{\mu-\alpha,\lambda\}\|x-x^*\|^2,
\end{aligned}$$

where the last inequality follows from the inequality

$$\|a\|^2+\|b\|^2\geq\frac{\|a-b\|^2}{2}\qquad\text{for all } a,b\in R^n. \qquad \square$$

Now we turn our attention to the function $\phi_h(\,\cdot\,;\beta,\lambda)$. The next theorem shows that the quadratic growth rate of $\phi_h(\,\cdot\,;\beta,\lambda)$ is ensured, provided that the parameter β is chosen sufficiently small.

THEOREM 4.4. *If F is strongly monotone on S with modulus μ and if β is chosen to satisfy $0<\beta\leq\mu$, then for each $\lambda>0$,*

$$\frac{1}{2}\min\{\beta,\lambda\}\|x-x^*\|^2\leq\phi_h(x;\beta,\lambda)\leq\lambda\|x-x^*\|^2\quad\text{for all } x\in R^n,$$

where x^* is the unique solution of VIP.

Proof. Noting that $x^*\in S$ and $h(x^*;\beta)=0$, the right-hand inequality can be proved in a way similar to the first part of the proof of Theorem 4.3. Moreover, by using Lemma 4.2, we can prove the left-hand inequality analogously to the last part of the proof of Theorem 4.3. $\square$

Theorems 4.3 and 4.4 demonstrate that $\phi_f(\,\cdot\,;\alpha,\lambda)$ and $\phi_h(\,\cdot\,;\beta,\lambda)$ provide global error bounds for VIP without the Lipschitz continuity of F. Recall that for the natural residual r defined by (15) to provide a global error bound not only the strong monotonicity but also the Lipschitz continuity of F is required [21]. In this respect, $\phi_f(\,\cdot\,;\alpha,\lambda)$ and $\phi_h(\,\cdot\,;\beta,\lambda)$ are more favorable than the natural residual r.

5. Concluding remarks. When S is given by

$$S=\{x\in R^n_+\mid g_i(x)\leq 0,\ \ i=1,\ldots,m\},\tag{16}$$

where R^n_+ denotes the nonnegative orthant in R^n and $g_i: R^n\to R$ are twice differentiable convex functions, the Karush–Kuhn–Tucker conditions for VIP yield the nonlinear complementarity problem: find $(x,\nu)\in R^n_+\times R^m_+$ such that

$$\langle(x,\nu),H(x,\nu)\rangle=0,\quad H(x,\nu)\geq 0,\tag{17}$$

where

$$H(x,\nu)=\begin{bmatrix}F(x)+\nabla g(x)\nu\\ -g(x)\end{bmatrix}$$

with $g(x)=(g_1(x),g_2(x),\ldots,g_m(x))^T$. For nonlinear complementarity problems various equivalent formulations as a system of equations or an unconstrained optimization

problem have been proposed and studied extensively [9, 12, 18, 19, 31, 29, 33]. So we might first reformulate VIP with the inequality constraints (16) as the nonlinear complementarity problem (17) and then convert it into one of the known equivalent unconstrained optimization problems. However, such a transformation into the nonlinear complementarity problem (17) is not necessarily a panacea for dealing with the inequality-constrained VIP. For instance, global error bounds for nonlinear complementarity problems are obtained under the strong monotonicity of the mapping involved [21, 33]. Unfortunately, it is unlikely that the nonlinear complementarity problem (17) satisfies the strong monotonicity condition, because the Jacobian

$$\nabla H(x,\nu) = \begin{bmatrix} \nabla F(x) + \sum_{i=1}^{m} \nu_i \nabla^2 g_i(x) & \nabla g(x) \\ -\nabla g(x)^T & 0 \end{bmatrix}$$

is never positive definite for any (x,ν), even if F is strongly monotone. On the other hand, as shown in the preceding sections, the functions $\phi_f(\,\cdot\,;\alpha,\lambda)$ and $\phi_h(\,\cdot\,;\beta,\lambda)$ enjoy various favorable properties, particularly when F is strongly monotone.

Acknowledgments. The authors would like to thank the associate editor and the referees for their constructive comments. They also thank Professor Paul Tseng for his helpful comment.

STABLITY OF SET-VALUED MAPPINGS IN INFINITE DIMENSIONS: POINT CRITERIA AND APPLICATIONS*

BORIS S. MORDUKHOVICH† AND YONGHENG SHAO†

Abstract. This paper deals with effective characterizations of stability and regularity properties of set-valued mappings in infinite dimensions, which are of great importance for applications to many aspects in optimization and control. The main purpose is to obtain verifiable necessary and sufficient conditions for these properties that are expressed in terms of constructive generalized differential structures at reference points and are convenient for applications. Based on advanced techniques in nonsmooth analysis, new dual criteria are proven in this direction under minimal assumptions. Applications of such point conditions are given to sensitivity analysis for parametric constraint and variational systems which describe sets of feasible and optimal solutions to various optimization and related problems.

Key words. infinite-dimensional systems, stability, metric regularity, optimization, nonsmooth analysis, set-valued solution maps, generalized differentiation, sensitivity

1. Introduction.

It has long been recognized that many principal aspects in optimization and control (e.g., optimality conditions, controllability, sensitivity, numerical methods, and so on) are related to studying stability/regularity properties of corresponding set-valued mappings (multifunctions). Such properties are known under different names (metric regularity, openness, covering, surjection, Lipschitzian stability, etc.), which are often equivalent to each other. We refer the reader to [1, 2, 3, 6, 7, 8, 9, 10, 11, 13, 14, 15, 17, 18, 19, 20, 25, 26, 27, 28, 29, 30, 31, 32, 37, 38, 40, 41, 42] and bibliographies therein for various results in this direction as well as for applications of the mentioned properties to optimization and control.

The main goal of the paper is to obtain effective characteristics and applications of such stability properties by means of appropriate generalized derivatives in nonsmooth analysis. In finite dimensions, complete *dual* characterizations of openness, metric regularity, and Lipschitzian behavior for closed-graph multifunctions were established by Mordukhovich [25, 26] on the basis of nonconvex generalized derivativelike objects developed in [24, 25]. Various applications of those results to optimization, sensitivity, and optimal control can be found in [27, 28, 29, 30, 31]. However, using only finite-dimensional characteristics, one cannot cover a broad range of significant problems arising, e.g., in optimization and sensitivity analysis of constrained control systems governed by ordinary and partial differential equations/inclusions as well as variational inequalities. This is one of our primary motivations: to develop proper infinite-dimensional extensions of the previous theory.

We have been already concerned with this topic in [32], where dual differential characterizations of stability and associated properties of multifunctions have been obtained in Banach spaces. In contrast to [26], corresponding criteria and constants in [32] are expressed not in terms of generalized differential constructions at reference

points but in terms of their perturbations in neigborhoods. Some results in this direction are related to those in Ioffe [15] and Kruger [20]; see [32] for more details. Note that such *neighborhood conditions* are rather complicated and generally are not very convenient for applications.

In this paper we establish effective differential *point conditions* for the fundamental properties considered under appropriate assumptions on multifunctions and spaces in question. For this purpose we use generalized differential constructions introduced by Kruger and Mordukhovich on the base of *sequential limits* of the so-called *Fréchet ε-normals* [21]. These simply defined *nonconvex* objects are infinite-dimensional extensions of the corresponding constructions [24] in finite dimensions and possess some useful properties in general Banach space settings; see [33]. However, full calculus (at the same level of perfection as in finite dimensions) is available for them in the class of *Asplund spaces*; see [34, 35, 36] and section 2 below for more details. The latter subclass of Banach spaces is sufficiently broad and includes, in particular, all spaces with Fréchet differentiable renorms (therefore, all reflexive spaces) as well as those with separable duals; see, e.g., [39].

We employ the sequential differential constructions to obtain effective point criteria for openness, stability, and related properties of infinite dimensional multifunctions under *partial normal compactness* (p.n.c.) assumptions on their graphs introduced in this paper. These assumptions support the limiting procedure to prove point criteria in terms of the sequential constructions in general settings when the latter may not even be closed. In section 3 we discuss the p.n.c. assumptions in detail and compare them with previous results in this direction.

Employing the p.n.c. assumptions, we establish a number of *sufficient* point conditions for openness, metric regularity, and stability properties of nonsmooth mappings and multifunctions between Asplund spaces with *point estimates* of the exact bounds for corresponding moduli. Moreover, those conditions are proven to be also *necessary* for the fundamental properties under consideration even without p.n.c. and Asplundity assumptions. The conditions obtained completely cover the finite-dimensional case in [26] and turn out to be useful in many infinite-dimensional settings important for applications to optimization, sensitivity, control, etc. In particular, in the last section we provide some effective applications of the main point criteria to *sensitivity analysis* of constraint and variational systems.

One of the principal results in the paper is a sufficient point condition for both openness and metric regularity properties of p.n.c. multifunctions $\Phi : X \rightrightarrows Y$ between Asplund spaces, which is obtained in the form

$$[(0, y^\star) \in N((\bar{x}, \bar{y}); \operatorname{gph} \Phi)] \Longrightarrow y^\star = 0, \tag{1.1}$$

where $N((\bar{x}, \bar{y}); \operatorname{gph} \Phi)$ is our basic sequential normal cone in Definition 2.1(ii) to the graph

$$\operatorname{gph} \Phi := \{(x, y) \in X \times Y |\ y \in \Phi(x)\}$$

at $(\bar{x}, \bar{y})$; see Theorem 4.2. We also establish the necessity of (1.1) for the mentioned properties and provide two-sided point estimates for corresponding moduli.

These results were first obtained and presented at the workshop "Convexity, Monotonicity, and Differentiability" (Waterloo, Ontario, Canada, March 1993) under the assumption that the graph of Φ is compactly epi-Lipschitzian [5]. Then we received the paper [18] by Jourani and Thibault, which contains another proof of the fact that an analogue of (1.1) is a sufficient condition for metric regularity of Φ in

general Banach spaces under the less restrictive "partial compact epi-Lipschitzian" assumption. The latter one implies the p.n.c. assumption imposed here and actually has a different nature: primal vs. dual; see section 3.

Note that, in contrast to (1.1), the point condition in [18] is expressed in terms of an approximate normal cone defined by Ioffe, who proved a similar sufficient condition for the case of $\dim Y < \infty$ [15]. The latter construction is also an infinite-dimensional generalization of that in [24], which is well defined in any Banach space [16]. On the other hand, it is more complicated and may be bigger (but never smaller) than the Kruger–Mordukhovich sequential extension in infinite dimensions (see [35, section 9] for more details). Moreover, in the case of Asplund spaces, approximate normals used in [16, 18] can be obtained by adding points of the weak-star *topological closure* to the sequential normal cone in (1.1). One can observe that such a procedure may substantially enlarge the set in the left-hand side of (1.1).

The rest of the paper is organized as follows. Section 2 contains basic definitions and preliminaries in nonsmooth analysis needed in later discussion. Section 3 is concerned with normal compactness conditions important for limiting procedures. In section 4 we obtain the main point characterizations of openness properties for set-valued mappings with corresponding modulus estimates. Section 5 is devoted to point criteria for metric regularity and Lipschitzian stability. In section 6 we present some applications of the main criteria to sensitivity analysis of constraint and variational systems.

Throughout the paper we use standard notation, with some special symbols introduced where they are defined. Unless otherwise stated, all spaces considered are *Banach* whose norms are always denoted by $\|\cdot\|$. For any space X we consider its dual space $X^\star$ equipped with the weak-star topology $w^\star$, where $\langle\cdot,\cdot\rangle$ means the canonical pairing. Recall that cl Ω stands for the closure of $\Omega \subset X$, while cl* is used for the weak-star topological closure in $X^\star$. The *distance function* to the set Ω is denoted by

$$\operatorname{dist}(x,\Omega) := \inf\{\|x-\omega\| \ \text{ s.t. } \ \omega \in \Omega\}.$$

In contrast to the case of *single-valued mappings* $f : X \to Y$, the symbol $\Phi : X \rightrightarrows Y$ stands for a *multifunction* from X into Y with the *domain* and *kernel* denoted, respectively, by

$$\operatorname{Dom}\Phi := \{x \in X |\ \Phi(x) \neq \emptyset\} \ \text{ and } \ \operatorname{Ker}\Phi := \{x \in X |\ 0 \in \Phi(x)\}.$$

The *inverse* multifunction $\Phi^{-1} : Y \rightrightarrows X$ to Φ satisfies the relationships

$$x \in \Phi^{-1}(y) \Longleftrightarrow y \in \Phi(x) \Longleftrightarrow (x,y) \in \operatorname{gph}\Phi,$$

and the *norm* of any positive homogeneous multifunction is defined by

$$\|\Phi\| := \sup\{\|y\| \ \text{ s.t. } \ y \in \Phi(x) \ \text{ and } \ \|x\| \le 1\}. \tag{1.2}$$

For multifunctions $\Phi : X \rightrightarrows X^\star$, the expression

$$\limsup_{x\to\bar{x}} \Phi(x) := \{x^\star \in X^\star |\ \exists \text{ sequences } \ x_k \to \bar{x} \ \text{ and } \ x_k^\star \overset{w^\star}{\to} x^\star \ \text{ with } \ x_k^\star \in \Phi(x_k) \ \text{ for all } \ k = 1,2,\ldots\}$$

always means the *sequential* Kuratowski–Painlevé upper limit with respect to the norm topology in X and the weak-star topology in $X^\star$.

As usual, we denote by B and $B^\star$ the unit closed balls in the space and dual space in question; $A^\star$ stands for the adjoint operator to a linear bounded operator $A : X \to Y$. The symbol $B_r(x)$ means the closed ball with center x and radius r, while

$$B_r(\Phi(x)) := \bigcup_{y\in\Phi(x)} B_r(y) \ \text{ and } \ \Phi(B_r(x)) := \bigcup_{z\in B_r(x)} \Phi(z)$$

for any multifunction $\Phi : X \rightrightarrows Y$.

If $\varphi : X \to \bar{\mathbf{R}} := [-\infty, \infty]$ is an *extended-real-valued function*, then

$$\operatorname{dom}\varphi := \{x \in X \ \text{ with } \ |\varphi(x)| < \infty\} \ \text{ and } \ \operatorname{epi}\varphi := \{(x,\mu) \in X \times \mathbf{R} |\ \mu \ge \varphi(x)\}.$$

In this case, limsup $\varphi(x)$ and liminf $\varphi(x)$ denote the upper and lower limits in the classical (scalar) sense. Depending on context, the symbols $x \overset{\varphi}{\to} \bar{x}$ and $x \overset{\Omega}{\to} \bar{x}$ mean, respectively, that $x \to \bar{x}$ with $\varphi(x) \to \varphi(\bar{x})$ and $x \to \bar{x}$ with $x \in \Omega$. Thoughout the paper we use the convention that $\inf\emptyset = \infty$, $\sup\emptyset = -\infty$, $\|\emptyset\| = \infty$, and $a + \emptyset = \emptyset + b = \emptyset$ for any elements a and b.

2. Basic definitions and preliminaries. This section is mostly concerned with preliminary material on the basic generalized differential constructions used in the paper. Let us begin with the definitions of normal elements to arbitrary sets in Banach spaces, as appeared in [21].

DEFINITION 2.1. (i) *Let $\Omega \subset X$ and $\varepsilon \ge 0$. Given $x \in \operatorname{cl}\Omega$, the nonempty set*

$$\hat{N}_\varepsilon(x;\Omega) := \left\{ x^\star \in X^\star |\ \limsup_{u \overset{\Omega}{\to} x} \frac{\langle x^\star, u - x\rangle}{\|u - x\|} \le \varepsilon \right\} \tag{2.1}$$

is called the set of (Fréchet) ε-normals *to Ω at x. When $\varepsilon = 0$, the set* (2.1) *is a cone which is called the* prenormal cone *or* Fréchet normal cone *to Ω at x and is denoted by $\hat{N}(x;\Omega)$. If $x \notin \operatorname{cl}\Omega$, we set $\hat{N}_\varepsilon(x;\Omega) = \emptyset$ for all $\varepsilon \ge 0$.*

(ii) *Let $\bar{x} \in \operatorname{cl}\Omega$. The nonempty cone*

$$N(\bar{x};\Omega) := \limsup_{x\to\bar{x},\ \varepsilon\downarrow 0} \hat{N}_\varepsilon(x;\Omega) \tag{2.2}$$

is called the normal cone *to Ω at $\bar{x}$. We set $N(\bar{x};\Omega) = \emptyset$ for $\bar{x} \notin cl\,\Omega$.*

(iii) *The set Ω is called* regular *at $\bar{x}$ if $N(\bar{x};\Omega) = \hat{N}(\bar{x};\Omega)$.*

The reader may consult with the recent papers [33, 35] and their references for basic properties of the normal cone (2.2) and related subdifferential constructions. It is shown in [35] that for Asplund spaces X one can always let $\varepsilon = 0$ in (2.2); i.e., the normal cone is represented by

$$N(\bar{x};\Omega) = \limsup_{x\to\bar{x}} \hat{N}(x;\Omega). \tag{2.3}$$

Let us mention [35] that, for the case of Asplund spaces, the weak-star *topological closure* in $X^\star$ of the sequential normal cone (2.2) coincides with the G-normal cone in Ioffe [16], while the weak-star closure of its *convexification* gives Clarke's normal cone [9]. Note also that the normal cone (2.2) coincides with the cone of "limiting proximal normals" when X is Hilbert; cf. [23].

Now we consider a derivativelike object for *multifunctions* which is used for formulations and proofs of the main results in the paper.

DEFINITION 2.2. *Let $\Phi : X \rightrightarrows Y$ be a multifunction between Banach spaces and $(\bar{x}, \bar{y}) \in \text{cl gph } \Phi$. The multifunction $D^\star\Phi(\bar{x}, \bar{y})$ from $Y^\star$ into $X^\star$ defined by*

$$D^\star\Phi(\bar{x}, \bar{y})(y^\star) := \{x^\star \in X^\star | \ (x^\star, -y^\star) \in N((\bar{x}, \bar{y}); \text{gph } \Phi)\} \tag{2.4}$$

is called the coderivative *of Φ at $(\bar{x}, \bar{y})$. We let $D^\star\Phi(\bar{x}, \bar{y})(y^\star) := \emptyset$ if $(\bar{x}, \bar{y}) \notin \text{cl gph } \Phi$. The symbol $D^\star\Phi(\bar{x})(y^\star)$ is used in* (2.4) *when Φ is single valued at $\bar{x}$ and $\bar{y} = \Phi(\bar{x})$.*

The coderivative introduced can be treated as a generalized concept of *adjoint mapping* that coincides with the adjoint operator to the derivative in the classical framework. Indeed, let $\Phi = f : X \to Y$ be *strictly differentiable* at $\bar{x}$ with the derivative $f'(\bar{x})$, i.e.,

$$\lim_{x \to \bar{x}, u \to \bar{x}} \frac{f(x) - f(u) - f'(\bar{x})(x - u)}{\|x - u\|} = 0.$$

Then it is easy to show (see [36]) that for any Banach spaces X and Y one has

$$D^\star f(\bar{x})(y^\star) = (f'(\bar{x}))^\star y^\star. \tag{2.5}$$

In general, the coderivative (2.4) is a positive homogeneous multifunction with respect to $y^\star$ whose values may be nonconvex and even not closed in $X^\star$. Nevertheless, this construction possesses a rich calculus, especially in the Asplund space setting. We refer the reader to our paper [36], which contains complete infinite-dimensional extensions of the previous finite-dimensional results in [28].

Now let us consider subdifferential constructions for *extended-real-valued functions* related to the normal and prenormal cones in Definition 2.1.

DEFINITION 2.3. *Let $\varphi : X \to \bar{\mathbf{R}}$ and $\bar{x} \in \text{dom } \varphi$. The set*

$$\partial\varphi(\bar{x}) := \{x^\star \in X^\star | \ (x^\star, -1) \in N((\bar{x}, \varphi(\bar{x})); \text{epi } \varphi)\} \tag{2.6}$$

is called the subdifferential *of φ at $\bar{x}$, while the set*

$$\hat{\partial}\varphi(\bar{x}) := \{x^\star \in X^\star | \ (x^\star, -1) \in \hat{N}(\bar{x}, \varphi(\bar{x})); \text{epi } \varphi)\} \tag{2.7}$$

is called the presubdifferential *or* Fréchet subdifferential *of φ at this point. We let $\partial\varphi(\bar{x}) = \hat{\partial}\varphi(\bar{x}) := \emptyset$ when $\bar{x} \notin \text{dom } \varphi$.*

When φ is convex, both the subdifferential and the presubdifferential coincide with the subdifferential of convex analysis. In general, the set (2.7) is always convex but is frequently empty (as, e.g., for $\varphi(x) = -|x|$ at $0 \in \mathbf{R}$), while the subdifferential (2.6) is nonempty at least for locally Lipschitzian functions but may be nonconvex in common situations (as in the example above). Note that when φ is *lower semicontinuous* (l.s.c.) around $\bar{x} \in \text{dom } \varphi$, one has

$$\hat{\partial}\varphi(\bar{x}) = \left\{x^\star \in X^\star | \ \liminf_{x \to \bar{x}} \frac{\varphi(x) - \varphi(\bar{x}) - \langle x^\star, x - \bar{x}\rangle}{\|x - \bar{x}\|} \geq 0\right\}$$

for any Banach space X and

$$\partial\varphi(\bar{x}) = \limsup_{x \xrightarrow{\varphi} \bar{x}} \hat{\partial}\varphi(x) \tag{2.8}$$

if X is Asplund; see [35]. One can easily check that

$$\hat{\partial}\delta(\bar{x}, \Omega) = \hat{N}(\bar{x}; \Omega) \quad \text{and} \quad \partial\delta(\bar{x}, \Omega) = N(\bar{x}; \Omega) \tag{2.9}$$

for $\bar{x} \in \Omega$, where $\delta(\cdot, \Omega)$ is the *indicator function* of Ω.

The next "zero fuzzy calculus" result for Fréchet subdifferentials in Asplund spaces follows from Fabian [12]. We prove in [34] that such a calculus rule is equivalent to the *extremal principle* (generalized Euler equation for extremal points) [21, 25].

PROPOSITION 2.4. *Let X be an Asplund space and $\varphi_i : X \to \bar{\mathbf{R}}$, $i = 1, \ldots, n$ ($n \geq 2$), be a collection of l.s.c. functions, all but one of which are Lipschitz continuous around $\bar{x}$. Assume that $\bar{x}$ is a local minimum point for the sum $\varphi_1 + \cdots + \varphi_n$. Then for any positive numbers ε and γ one has*

$$0 \in \bigcup\{\hat{\partial}\varphi_1(x_1) + \cdots + \hat{\partial}\varphi_n(x_n) |\ x_i \in B_\gamma(\bar{x}),\ |\varphi_i(x_i) - \varphi_i(\bar{x})| \leq \gamma,\ i = 1, \ldots, n\} + \varepsilon B^\star.$$

In conclusion of this section we discuss relations between the coderivative (2.4) and the subdifferential (2.6). It follows from the definitions that

$$\partial\varphi(\bar{x}) = D^\star E_\varphi(\bar{x}, \varphi(\bar{x}))(1), \quad \text{where} \quad E_\varphi(x) := \{\mu \in \mathbf{R} |\ \mu \geq \varphi(x)\} \tag{2.10}$$

for any $\varphi : X \to \bar{\mathbf{R}}$ and $\bar{x} \in \operatorname{dom}\varphi$. Moreover, $\partial\varphi(\bar{x}) = D^\star\varphi(\bar{x})(1)$ if φ is continuous around $\bar{x}$. On the other hand, for some classes of single-valued mappings f between Banach spaces, the coderivative of f can be expressed in terms of the subdifferential of its *Lagrange scalarization* $\langle y^\star, f\rangle(x) := \langle y^\star, f(x)\rangle$.

Recall that a mapping $f : X \to Y$ Lipschitz continuous around $\bar{x}$ is said to be *strictly Lipschitzian* at $\bar{x}$ [35] if there exists a neighborhood V of the origin in X such that the sequence

$$[f(x_k + t_k v) - f(x_k)]/t_k, \quad k = 1, 2, \ldots,$$

has a convergent subsequence in the norm topology of Y for each $v \in V$, $x_k \to \bar{x}$, and $t_k \downarrow 0$ as $k \to \infty$. (As we were recently informed by Lionel Thibault, this definition is equivalent to a variant of his concept of compactly Lipschitzian mappings [43].)

Obviously, every mapping strictly differentiable at $\bar{x}$ is strictly Lipschitzian at this point. When $\dim Y < \infty$, there is no difference between locally Lipschitzian and strictly Lipschitzian mappings. Furthermore, any locally Lipschitzian mapping between Banach spaces is strictly Lipschitzian at $\bar{x}$ if it has a norm-compact-valued "strict prederivative" in the sense of Ioffe [16] that includes many important applications, particularly in optimal control [13]. The following scalarization result is proven in [35].

PROPOSITION 2.5. *Let X and Y be Asplund and Banach spaces, respectively, and let $f : X \to Y$ be strictly Lipschitzian at $\bar{x}$. Then one has*

$$D^\star f(\bar{x})(y^\star) = \partial\langle y^\star, f\rangle(\bar{x}) \neq \emptyset \ \ \forall y^\star \in Y^\star.$$

3. Normal compactness conditions. In this section we study effective conditions on sets and multifunctions that are widely used to justify limiting procedures in proving the main results of the paper.

Let us start with arbitrary closed sets Ω in a Banach space Z, which will be mainly considered in the form $X \times Y$ later on. When Z is finite dimensional, the normal cone (2.2) at $\bar{z} \in \Omega$ has closed values, and moreover, its graph is closed. (It is the so-called *robustness* or upper semicontinuity property.) In infinite dimensions, these facts are no longer true both in topological and in sequential senses. This appears because the normal cone is defined *sequentially*, while the weak-star topology of $Z^\star$ is not always sequential; see [4, 22, 23] for more discussions. To overcome these difficulties, Loewen introduced in [22] a local compactness condition of the following kind, which we call here *normal compactness* of a set around a given point.

DEFINITION 3.1. *A closed set $\Omega \subset Z$ is said to be* normally compact *around $\bar{z} \in \Omega$ if there exist positive numbers γ, σ, and a compact subset C of Z such that*

$$\hat{N}(z;\Omega) \subset K_\sigma(C) := \left\{ z^\star \in Z^\star \ \ s.t. \ \ \sigma\|z^\star\| \le \max_{c\in C} |\langle z^\star, c\rangle| \right\} \ \ \forall z \in B_\gamma(\bar{z}) \cap \Omega. \tag{3.1}$$

Note that condition (3.1) is always valid if Z is finite dimensional. When Z is Asplund, the prenormal cone $\hat{N}(z;\Omega)$ in Definition 3.1 can be equivalently replaced by the normal cone (2.2). This follows from (2.3) and the fact that the cone $K_\sigma(C)$ in (3.1) is weak-star closed in $Z^\star$; see the proof of Proposition 3.4 below.

Let us observe that condition (3.1) is *dual* in the sense that it is expressed in the dual space setting. Loewen shows [22] that (3.1) always holds when Ω is *compactly epi-Lipschitzian* around $\bar{x}$ in the sense of Borwein and Strojwas [5]. The latter is a primal condition on the set Ω that generalizes Rockafellar's original concept of epi-Lipschitzian sets; see [5, 22].

In [22], Loewen demonstrates that the graph of the normal-cone multifunction $N(\cdot;\Omega)$ is closed near $\bar{z}$ in the norm$\times$weak-star topology of $Z \times Z^\star$ if Ω satisfies the normal compactness condition (3.1) around $\bar{z}$. He establishes this fact for the case of reflexive spaces Z that is essential in his proof. Let us obtain this robustness property of (2.2) in a more general setting based on recent developments in Borwein and Fitzpatrick [4].

Recall that a Banach space Z is *weakly compactly generated* (WCG), provided that there is a weakly compact set K such that $Z = \mathrm{cl}(\mathrm{span}\, K)$. This class of spaces includes, in particular, all reflexive spaces as well as all separable Banach spaces; see [39]. We will use the following result proven in [4].

PROPOSITION 3.2. *Let Z be a WCG space and $\{A_k\}$ be a sequence of subsets of $Z^\star$ such that $A_{k+1} \subset A_k$ for all $k = 1, 2, \ldots$. Then one has*

$$\bigcup_{m=1}^{\infty} \bigcap_{k=1}^{\infty} \mathrm{cl}^\star(A_k \cap mB^\star) = \left\{ \lim_{k\to\infty} z_k^\star |\ z_k^\star \in A_k \ \text{ for all } \ k \right\}, \tag{3.2}$$

where $\lim z_k^\star$ is taken in the weak-star topology of $Z^\star$.

Now we can establish extensions of Loewen's main results in [22]. Say that a set $K \subset Z^\star$ is *weak-star locally bounded*, provided that each point of K has a weak-star neighborhood U such that $U \cap K$ is norm bounded in $Z^\star$.

PROPOSITION 3.3. *Let $(M,\ \rho)$ be a metric space, Z be a WCG space, and $\Phi : M \rightrightarrows Z^\star$ be an arbitrary multifunction. Equip $M \times Z^\star$ with the $\rho\times$weak-star topology, and assume that there exists a weak-star locally bounded, weak-star closed subset K of $Z^\star$ such that*

$$\Phi(z) \subset K \ \ \text{for any} \ \ z \in M. \tag{3.3}$$

Then $(\bar{z}, z^\star) \in \mathrm{cl\ gph}\ \Phi$ if and only if $z^\star = \lim_{k\to\infty} z_k^\star$ for some sequence $z_k^\star \in \Phi(z_k)$ with $z_k \to \bar{z}$ as $k \to \infty$.

Proof. Let $\{(z_\alpha, z_\alpha^\star)\}_{\alpha\in\Lambda} \subset M \times Z^\star$ be a net such that $z_\alpha \to \bar{z}$ and $z_\alpha^\star \overset{w^\star}{\to} z^\star$ with $z_\alpha^\star \in \Phi(z_\alpha)$ for all $\alpha \in \Lambda$. The weak-star closedness of K and condition (3.3) ensure $z^\star \in K$. Now taking into account the weak-star local boundedness of K, we find a natural number m and a subnet $\{(z_\beta, z_\beta^\star)\}_{\beta\in\tilde{\Lambda}}$ ($\tilde{\Lambda} \subset \Lambda$) of $\{(z_\alpha, z_\alpha^\star)\}_{\alpha\in\Lambda}$ such that $\|z_\beta^\star\| \le m$ for all $\beta \in \tilde{\Lambda}$. Letting

$$A_k = \bigcup \{\Phi(z) |\ \rho(z,\bar{z}) \le 1/k\}, \ \ k = 1, 2, \ldots,$$

one concludes that $z^\star$ belongs to the left-hand side set in (3.2). Finally employing Proposition 3.2, we finish the proof. □

The result obtained ensures the following *robustness property* of the normal cone (2.2).

PROPOSITION 3.4. *Let Z be a WCG Asplund space and Ω be a closed subset of Z satisfying the normal compactness condition* (3.1) *around $\bar{z} \in \Omega$. Then the multifunction $N(\cdot;\Omega)$ has closed graph near $\bar{z}$; i.e., for some $\gamma > 0$ the set*

$$(\text{gph } N(\cdot;\Omega)) \cap ((\bar{z} + \gamma B) \times Z^\star) \tag{3.4}$$

is closed in the norm×weak-star topology of $Z \times Z^\star$. In particular, for any sequences $z_k \to \bar{z}$ and $z_k^\star \overset{w^\star}{\to} z^\star$ with $z_k^\star \in N(z_k;\Omega)$, $k = 1, 2, \ldots$, one has $z^\star \in N(\bar{z};\Omega)$.

Proof. Following the proof in [22, Proposition 3.5], one can conclude that the cone $K_\sigma(C)$ in (3.1) is both weak-star closed and weak-star locally bounded in $Z^\star$. The only change we need to do is to observe that the set

$$\{z^\star \in Z^\star |\ \sigma\|z^\star\| - |\langle z^\star, c\rangle| \le 0\}$$

is weak-star closed in $Z^\star$ for any $c \in Z$. The latter follows directly from the well-known lower semicontinuity of the norm function $\|z^\star\|$ and continuity of the function $|\langle z^\star, c\rangle|$ in the weak-star topology of $Z^\star$.

Now applying Proposition 3.3 with $(M,\rho) = (\Omega \cap B_\gamma(\bar{z}), \|\cdot\|_Z)$ and $\Phi(\cdot) = \hat{N}(\cdot;\Omega)$, we conclude that the topological closure of gph $\hat{N}(\cdot;\Omega)$ in $M \times Z^\star$ coinsides with its sequential closure. Due to (2.3) the latter set is equal to the graph of $N(\cdot;\Omega)$ near $\bar{z}$. This proves the closedness of the set (3.4) in the norm×weak-star topology of $Z \times Z^\star$. □

Remarks 3.5. (i) The robustness property in Proposition 3.4 does not hold, and moreover, values of the normal cone $N(\cdot;\Omega)$ may *not* be closed in the weak-star topology of $Z^\star$ if one has all the assumptions of the theorem except that Z is a WCG space. This happens, in particular, for epigraphical sets $\Omega = \text{epi}\,\varphi \subset X \times \mathbf{R}$ generated by *Lipschitz* continuous functions φ on spaces X with Fréchet differentiable renorms; see examples in Borwein and Fitzpatrick [4].

(ii) Recently Fitzpatrick showed (personal communication) that the normal cone (2.2) may not be closed even in the *norm* topology of the *Hilbert* space l^2.

(iii) It is worth mentioning that the normal compactness assumption (3.1) has been employed in [35] to establish important calculus results for the normal cone (2.2) to general closed sets in arbitrary Asplund (not just WCG) spaces. What turns out to be essential for those purposes is *not* robustness of (2.2) but the following *limiting property*, which is easily implied by (3.1): for any sequences

$$z_k^\star \in \hat{N}(z_k;\Omega) \ \text{ with } \ z_k \to \bar{z} \ \text{ and } \ z_k^\star \overset{w^\star}{\to} 0 \ \text{ as } \ k \to \infty$$

one has $z_k^\star \to 0$ in the norm topology of $Z^\star$.

Now let us consider normal compactness conditions for *multifunctions* $\Phi : X \rightrightarrows Y$ between Banach spaces. It is clear that the case of multifunctions can be reduced to the case of sets in the space $Z = X \times Y$ taking $\Omega = \text{gph}\,\Phi$. According to Definition 3.1, a closed-graph multifunction Φ is said to be *normally compact* around $(\bar{x},\bar{y}) \in \text{gph}\,\Phi$ if there are positive numbers γ and σ as well as compact sets $P \subset X$ and $S \subset Y$ such that

$$\sigma(\|x^\star\| + \|y^\star\|) \le \max_{p\in P} |\langle x^\star, p\rangle| + \max_{s\in S} |\langle y^\star, s\rangle| \tag{3.5}$$

for any $(x^\star, y^\star) \in X^\star \times Y^\star$ satisfying

$$(x^\star, y^\star) \in \hat{N}((x,y); \operatorname{gph} \Phi) \text{ with } (x,y) \in [B_\gamma(\bar{x}) \times B_\gamma(\bar{y})] \cap \operatorname{gph} \Phi. \tag{3.6}$$

It follows from the previous discussions that the normal compactness of Φ around $(\bar{x}, \bar{y})$ implies that for any sequence $(x_k, y_k, x_k^\star, y_k^\star)$ with

$$(x_k^\star, y_k^\star) \in \hat{N}((x_k, y_k); \operatorname{gph} \Phi), \ (x_k, y_k) \to (\bar{x}, \bar{y}), \text{ and } (x_k^\star, y_k^\star) \overset{w^\star}{\to} (0,0) \tag{3.7}$$

one has $\|x_k^\star\| \to 0$ and $\|y_k^\star\| \to 0$ as $k \to \infty$.

One can observe that for many applications including those in this paper, it is sufficient that (3.7) implies the norm convergence of only *one* component (depending on the context). This allows us to weaken the normal compactness condition (3.5) in the following way (considering for definiteness the case of the y-component): there exist positive numbers γ, σ and compact sets $P \subset X$, $S \subset Y$ such that

$$\sigma \|y^\star\| \le \max_{p \in P} |\langle x^\star, p \rangle| + \max_{s \in S} |\langle y^\star, s \rangle| \tag{3.8}$$

for any $(x^\star, y^\star)$ satisfying (3.6). Moreover, requirement (3.7) can be also relaxed to achieve our purposes in this paper. Namely, we need $\|y_k^\star\| \to 0$ not for all $(x_k^\star, y_k^\star) \overset{w^\star}{\to} (0,0)$ satisfying the inclusion in (3.7) but only for those with $\|x_k^\star\| \to 0$. Let us introduce an *intrinsic* dual condition on Φ that generalizes the above normal compactness and ensures the required limiting behavior (see Proposition 3.8).

DEFINITION 3.6. (i) *A multifunction $\Phi : X \rightrightarrows Y$ of closed graph is called* partially normally compact (p.n.c.) with respect to y (image) *around $(\bar{x}, \bar{y}) \in \operatorname{gph} \Phi$ if there exist a weak-star closed subspace $L^\star \subset Y^\star$ of finite codimension, positive numbers γ and σ, and a compact set $S \subset Y$ such that*

$$\|x^\star\| + \max_{s \in S} |\langle y^\star, s \rangle| \ge \sigma \tag{3.9}$$

for any $(x^\star, y^\star)$ satisfying (3.6) *with*

$$\|y^\star\| = 1 \text{ and } \operatorname{dist}(y^\star, L^\star) \le \gamma. \tag{3.10}$$

(ii) *Φ is said to be* p.n.c. with respect to x (domain) *around $(\bar{x}, \bar{y})$ if the inverse multifunction $\Phi^{-1} : Y \rightrightarrows X$ is p.n.c. with respect to its image.*

Remark 3.7. In contrast of the normal compactness conditions discussed previously, the p.n.c. conditions in Definition 3.6 may become stronger (even in the case of Asplund spaces) if the prenormal cone in (3.6) is replaced by the basic normal cone $N((x,y); \operatorname{gph} \Phi)$ related to the coderivative (2.4). However, an important advantage of the latter modification is a *rich calculus* available for this coderivative in infinite dimensions; see [36]. Based on such a calculus, one can employ the p.n.c. conditions for various combinations of nonsmooth mappings and multifunctions.

In the rest of this section we deal with the p.n.c. condition for Φ with respect to its image. The next proposition establishes the mentioned *sequential limiting property* of p.n.c. multifunctions, which is what we need to prove the main results of the paper.

PROPOSITION 3.8. *Let $\Phi : X \rightrightarrows Y$ be p.n.c. with respect to y around $(\bar{x}, \bar{y})$. Then any sequence $(x_k, y_k, x_k^\star, y_k^\star)$ satisfying*

$$(x_k^\star, y_k^\star) \in \hat{N}((x_k, y_k); \operatorname{gph} \Phi), \ (x_k, y_k) \to (\bar{x}, \bar{y}), \ \|x_k^\star\| \to 0, \text{ and } y_k^\star \overset{w^\star}{\to} 0 \tag{3.11}$$

as $k \to \infty$ contains a subsequence with $\|y_{k_m}^\star\| \to 0$ as $m \to \infty$.

Proof. Let $E^\star \subset Y^\star$ be a finite-dimensional subspace complementary to $L^\star$ from Definition 3.6(i). Taking $y_k^\star$ in (3.11), we have the unique representation

$$y_k^\star = l_k^\star + e_k^\star \ \text{ with } \ l_k^\star \in L^\star \ \text{ and } \ e_k^\star \in E^\star \ \ \forall k = 1, 2, \ldots.$$

Since $y_k^\star \overset{w^\star}{\to} 0$ and $\dim E^\star < \infty$, one gets $l_k^\star \overset{w^\star}{\to} 0$ and $\|e_k^\star\| \to 0$ as $k \to \infty$.

Proving by contradiction, we assume that the result of the proposition does not hold. In this case there is $\alpha > 0$ such that $\|y_k^\star\| \ge \alpha$ for all k. Then taking $\gamma > 0$ in Definition 3.6(i), one derives from the inclusion in (3.11) that

$$(\tilde{x}_k^\star, \tilde{y}_k^\star) \in \hat{N}((x_k, y_k); \operatorname{gph} \Phi) \ \text{ with } \ \|\tilde{y}_k^\star\| = 1 \ \text{ and } \ (x_k, y_k) \in [B_\gamma(\bar{x}) \times B_\gamma(\bar{y})] \cap \operatorname{gph} \Phi,$$

where $\tilde{x}_k^\star := x_k^\star / \|y_k^\star\|$ and $\tilde{y}_k^\star := y_k^\star / \|y_k^\star\|$ for all k. It follows from

$$\operatorname{dist}(\tilde{y}_k^\star, L^\star) \le \|y_k^\star\|^{-1} \|e_k^\star\| \le \|e_k^\star\| / \alpha \to 0 \ \text{ as } \ k \to \infty$$

that $\operatorname{dist}(\tilde{y}_k^\star, L^\star) \le \gamma$ for k sufficiently large. Employing (3.9), we arrive at

$$\|\tilde{x}_k^\star\| + \max_{s \in S} |\langle \tilde{y}_k^\star, s \rangle| \ge \sigma,$$

which implies the estimate

$$\|y_k^\star\| \le \sigma^{-1} \left(\|x_k^\star\| + \max_{s \in S} |\langle y_k^\star, s \rangle| \right). \tag{3.12}$$

Using the compactness of the set S in (3.12), we conclude that $\langle y_k^\star, s \rangle \to 0$ *uniformly* in $s \in S$. Therefore, (3.12) implies that $\|y_k^\star\| \to 0$ as $k \to \infty$. The contradiction obtained ends the proof of the proposition. □

Now we present some sufficient conditions ensuring the p.n.c. property of Φ in Definition 3.6(i). First let us observe that this property always holds (with $L^\star = \{0\}$) when Y is *finite dimensional*. One can also check that the previously discussed condition (3.8) implies the p.n.c. property with $L^\star = Y^\star$.

Next let us consider an important class of multifunctions generated by a single-valued mapping $f : X \to Y$ and closed sets $\Lambda,\ \Omega$ in the form

$$\Phi(x) := \begin{cases} f(x) + \Lambda & \text{if } x \in \Omega, \\ \emptyset & \text{otherwise,} \end{cases} \tag{3.13}$$

which frequently appears in applications to optimization and related problems. The following result provides the p.n.c. condition for (3.13) in the general case of Banach spaces X and Y.

PROPOSITION 3.9. *Let $f : X \to Y$ be Lipschitz continuous around $\bar{x} \in \Omega$ and $\Lambda \subset Y$ be normally compact around $\bar{y} := -f(\bar{x}) \in \Lambda$. Then multifunction* (3.13) *is p.n.c. with respect to the image around $(\bar{x}, 0)$.*

Proof. According to Definition 3.1 we can find positive numbers $\sigma,\ \gamma$ and a compact set $S \subset Y$ such that

$$\sigma \|y^\star\| \le \max_{s \in S} |\langle y^\star, s \rangle| \ \ \forall y^\star \in \hat{N}(v; \Lambda) \ \text{ with } \ v \in B_\gamma(\bar{y}) \cap \Lambda. \tag{3.14}$$

Let $l \ge 0$ be a Lipschitz modulus of f in some (fixed) neighborhood of $\bar{x}$. Consider any pair $(x^\star, y^\star)$ satisfying

$$(x^\star, y^\star) \in \hat{N}((x, y); \operatorname{gph} \Phi) \ \text{ with } \ \|x - \bar{x}\| \le \gamma/(l+1), \ \|y\| \le \gamma/(l+1) \tag{3.15}$$

for Φ defined in (3.13). We are going to show that (3.15) implies the existence of $v \in B_\gamma(y) \cap \Lambda$ such that $y^\star \in \hat{N}(v;\Lambda)$. In this way we obtain condition (3.8) for multifunction (3.13) around $(\bar{x},0)$ with the given compact set $S \subset Y$ and $P = \{0\}$. The latter automatically ensures the p.n.c. property of Φ under consideration.

To justify the mentioned fact, let us employ the definition of the prenormal cone in (3.15). For any $\varepsilon > 0$ we find $\eta > 0$ such that $B_{2\eta}(\bar{x})$ lies in the given neighborhood of $\bar{x}$ where f is locally Lipschitzian, and moreover,

$$\langle x^\star, u - x\rangle + \langle y^\star, w - y\rangle \le \varepsilon(\|u - x\| + \|w - y\|)$$

when $\|u - x\| \le \eta$ and $\|w - y\| \le \eta$ with $w \in \Phi(u)$ and $u \in \Omega$. Letting $u = x$ in the latter formula and taking (3.13) into account, one has

$$\langle y^\star, w - y\rangle \le \varepsilon\|w - y\| \ \ \forall w \in B_\eta(y) \cap [f(x) + \Lambda] \tag{3.16}$$

with $x \in B_{\gamma/(l+1)}(\bar{x}) \cap \Omega$ and $\|y\| \le \gamma/(l+1)$. Now for any such (x,y) we consider $v := y - f(x) \in \Lambda$ which satisfies

$$\|v - \bar{y}\| \le \|y\| + l\|x - \bar{x}\| \le \gamma,$$

i.e., $v \in B_\gamma(\bar{y}) \cap \Lambda$. Letting $w = f(x) + \vartheta$ in (3.16), we get from here that

$$\langle y^\star, \vartheta - v\rangle \le \varepsilon\|\vartheta - v\| \ \ \forall \vartheta \in B_\eta(v) \cap \Lambda.$$

The latter implies that $y^\star \in \hat{N}(v;\Lambda)$ and $\sigma\|y^\star\| \le \max_{s\in S}\langle y^\star, s\rangle$ due to (3.14). This completes the proof of the proposition. □

An important special case of multifunctions (3.13) occurs when $\Lambda = \{0\}$; i.e., one considers in fact a single-valued mapping defined on a closed set. It turns out that Proposition 3.9 cannot be employed in this case for $\dim Y = \infty$ since the set $\Lambda = \{0\}$ is *not* normally compact in infinite dimensions. The case of (3.13) with $\Lambda = \{0\}$ was studied in Ioffe [15] and Ginsburg and Ioffe [13] on the base of the so-called *finite codimension property* for f with respect to Ω. Such a property provides sufficient amounts of compactness to obtain point criteria in the case considered. Moreover, it appears to be inherent in a broad class of *Fredholm operators* important for applications in optimal control; see [13, 15] for more details and discussions.

Two versions of the finite codimension property were introduced in [13, 15] in terms of topologically closed approximate subdifferentials and normal cones. Now we consider a *sequential* version of this property in terms of the basic constructions in section 2.

DEFINITION 3.10. *Let Ω be a closed subset of X with $\bar{x} \in \Omega$ and $f : X \to Y$ be a single-valued mapping continuous around $\bar{x}$. We say that f has the* finite codimension property *with respect to Ω around $\bar{x}$ if there exist a weak-star closed subspace $L^\star \subset Y^\star$ of finite codimension and positive numbers γ, σ such that for any $x \in B_\gamma(\bar{x})$, $u^\star \in N(x;\Omega)$, and $x^\star \in D^\star f(x)(y^\star)$ with $y^\star$ satisfying (3.10), one has $\|x^\star + u^\star\| \ge \sigma$.*

Let us show that, in the case of Asplund spaces X and Y, this finite codimension property implies the p.n.c. condition in Definition 3.6(i) for multifunctions defined in (3.13) when $\Lambda = \{0\}$. Moreover, in this case one always has $S = \{0\}$ in (3.9).

PROPOSITION 3.11. *Let both X and Y be Asplund and $f : X \to Y$ be Lipschitz continuous around $\bar{x} \in \Omega$. If f has the finite codimension property with respect to Ω around $\bar{x}$ and $\Lambda = \{0\}$ in (3.13), then the latter multifunction is p.n.c. with respect to y around $(\bar{x}, f(\bar{x}))$ when $S = \{0\}$ in (3.9).*

Proof. According to Thibault [44, Proposition 2.7], for any closed-graph multifunction $\Phi : X \rightrightarrows Y$ between Banach spaces and any point $(\bar{x}, \bar{y}) \in \text{gph } \Phi$ one has

$$N(\bar{x}, \bar{y}); \text{gph } \Phi) = \bigcup_{\lambda>0} \lambda \partial \text{dist}(\cdot, \Phi(\cdot))(\bar{x}, \bar{y}). \tag{3.17}$$

For the multifunction Φ defined in (3.13) with $\Lambda = \{0\}$, we easily get the representation

$$\text{dist}(v, \Phi(u)) = \|v - f(u)\| + \delta((u, v), \Omega \times Y) \ \ \forall (u, v) \in X \times Y, \tag{3.18}$$

where the first function is Lipschitz continuous. Then employing in (3.17), (3.18) the subdifferential sum and chain rules in Asplund spaces [35], we arrive at the inclusion

$$N(x, f(x)); \text{gph } \Phi) \subset \bigcup_{\lambda>0} \bigcup_{v^\star \in B^\star} [D^\star f(x)(\lambda v^\star) \times \{-\lambda v^\star\}] + N((x; \Omega) \times \{0\} \ \ \forall x \in \Omega.$$

The latter yields

$$D^\star \Phi(x, f(x))(y^\star) \subset D^\star f(x)(y^\star) + N(x; \Omega) \ \ \forall x \in \Omega \ \text{ and } \ y^\star \in Y^\star. \tag{3.19}$$

According to (3.19), for any $(x^\star, y^\star) \in N((x, f(x)); \text{gph } \Phi)$ with $x \in \Omega$ there exist $x_1^\star \in D^\star f(x)(-y^\star)$ and $x_2^\star \in N(x; \Omega)$ such that $x^\star = x_1^\star + x_2^\star$. Therefore, the finite codimension property in Definition 3.10 implies the p.n.c. condition in Definition 3.6(i) with $S = \{0\}$ in (3.9). □

Now let us compare the (dual) p.n.c. property of multifunctions with their (primal) epi-Lipschitzian kind of behavior discussed in the beginning of this section. Note that the notion of compactly epi-Lipschitzian sets mentioned above immediately induces the corresponding notion for multifunctions being applied to their graphs. In [18], Jourani and Thibault introduce a useful generalization of the latter property in the following way: A closed-graph multifunction $\Phi : X \rightrightarrows Y$ is said to be *partially compactly epi-Lipschitzian* (with respect to y) around $(\bar{x}, \bar{y}) \in \text{gph } \Phi$ if there exist neighborhoods U of $\bar{x}$, V of $\bar{y}$, and O of the origin in Y as well as a number $r > 0$ and compact sets $P \subset X$ and $S \subset Y$ such that

$$(\text{gph}) \cap (U \times V) + \lambda(\{0\} \times O) \subset \text{gph } \Phi + \lambda(P \times S) \ \ \forall \lambda \in (0, r). \tag{3.20}$$

When $P = \{0\}$ and S is a singleton in (3.20), this property corresponds to that considered by Kruger [20] under the name "uniformly epi-Lipschitzian" multifunctions. In [18, 20] one can find useful examples of multifunctions with such a behavior. Let us show that (3.20) always implies estimate (3.8) and, therefore, the p.n.c. property in Definition 3.6(i). One may observe that this result can be derived from [18, Proposition 3.5], taking into account that the normal cone (2.2) is always included in the so-called nucleus of the G-normal cone [16].

PROPOSITION 3.12. *Let $\Phi : X \rightrightarrows Y$ be a multifunction between Banach spaces that is partially compactly epi-Lipschitzian around $(\bar{x}, \bar{y})$. Then Φ is p.n.c. with respect to y around this point.*

Proof. Let us use (3.20) with $B_\gamma(\bar{x}) \subset U$, $B_\gamma(\bar{y}) \subset V$, and $\sigma B \subset O$ for some positive numbers γ and σ. Then for any $(x, y) \in (\text{gph } \Phi) \cap [B_\gamma(\bar{x}) \times B_\gamma(\bar{y})]$, $e \in B$, and a sequence $\lambda_k \in (0, r)$ with $\lambda_k \downarrow 0$ as $k \to \infty$, there are $p_k \in P$ and $s_k \in S$ such that

$$(x, y) + \lambda_k \sigma(0, e) - \lambda_k(p_k, s_k) \in \text{gph } \Phi \ \ \forall k = 1, 2, \ldots.$$

Due to compactness of P and S one can select a subsequence of $\{(p_k, s_k)\}$ which converges to some $(p, s) \in P \times S$. This implies that the difference $\sigma(0, e) - (p, s)$ belongs to the (Bouligand) *contingent cone* $K((x, y); \text{gph } \Phi)$; see [2]. It is well known that the Fréchet normal cone is always contained in the polar to the contingent cone. Therefore,

$$\min_{(p,s)\in P\times S} \langle (x^\star, y^\star), \sigma(0, e) - (p, s)\rangle \le 0 \ \ \forall (x^\star, y^\star) \in \hat{N}((x, y); \text{gph } \Phi)$$

with $(x, y) \in (\text{gph } \Phi) \cap [B_\gamma(\bar{x}) \times B_\gamma(\bar{y})]$. The latter implies (3.8) and completes the proof of the proposition. □

4. Point criteria and estimates for openness properties of multifunctions. In the rest of the paper $\Phi : X \rightrightarrows Y$ is a *closed-graph* multifunction between Banach spaces. In this section we pay the most attention to the following *openness property* of Φ in a *neighborhood* of a given point from its graph.

DEFINITION 4.1. *A multifunction Φ is said to be* open at a linear rate *around $(\bar{x}, \bar{y}) \in \text{gph } \Phi$ if there exist neighborhoods U of $\bar{x}$ and V of $\bar{y}$ as well as a positive number a such that*

$$B_{ar}(\Phi(x) \cap V) \subset \Phi(B_r(x)) \ \text{ for any } \ (x, r) \ \text{ with } \ B_r(x) \subset U.$$

Each of such numbers a (corresponding to different neighborhoods) is called an openness modulus *for Φ around $(\bar{x}, \bar{y})$. The supremum of all openness moduli is called the* openness bound *for Φ around $(\bar{x}, \bar{y})$ and is denoted by* $(\text{ope } \Phi)(\bar{x}, \bar{y})$.

Note that, for the case of linear bounded operators, this property goes back to the classical (Banach) open mapping principle. Let us emphasize two essential features of the given definition: *linear rate* of openness and *uniformity* of the openness property around the point under consideration; see [26, 32] for more discussion and references.

Using the coderivative (2.4) of Φ at $(\bar{x}, \bar{y})$, we introduce the main *openness constant* in the general setting,

$$a(\Phi, \bar{x}, \bar{y}) := \inf\{\|x^\star\| \ \text{ s.t. } \ x^\star \in D^\star\Phi(\bar{x}, \bar{y})(y^\star) \ \text{ and } \ \|y^\star\| = 1\}, \tag{4.1}$$

and formulate the principal result of the paper.

THEOREM 4.2. *For any multifunction $\Phi : X \rightrightarrows Y$ and point $(\bar{x}, \bar{y}) \in \text{gph } \Phi$, let us consider the properties:*

(a) *Φ is open at a linear rate around $(\bar{x}, \bar{y})$;*

(b) *$a(\Phi, \bar{x}, \bar{y}) > 0$ for the openness constant* (4.1)*;*

(c) *the coderivative* (2.4) *is injective at $(\bar{x}, \bar{y})$, i.e.,*

$$\text{Ker } D^\star\Phi(\bar{x}, \bar{y}) = \{0\}.$$

Then (b)$\Longrightarrow$(c) *and the following results hold.*

(I) *When Φ is p.n.c. with respect to y around $(\bar{x}, \bar{y})$ and both spaces X and Y are Asplund, one has*

$$\text{(c)} \Longrightarrow \text{(a)}; \tag{4.2}$$

i.e., each of the conditions (b) *and* (c) *is sufficient for Φ to be open at a linear rate around $(\bar{x}, \bar{y})$. Moreover,*

$$(\text{ope } \Phi)(\bar{x}, \bar{y}) \ge a(\Phi, \bar{x}, \bar{y}) \tag{4.3}$$

if Y is finite dimensional.

(II) *When Φ is an arbitrary multifunction from a finite-dimensional space X into a Banach space Y, one has*

$$\text{(a)} \Longrightarrow \text{(b)}; \tag{4.4}$$

i.e., both conditions (b) *and* (c) *are necessary for Φ to be open at a linear rate around $(\bar{x},\bar{y})$. Moreover, in this case*

$$(\text{ope}\,\Phi)(\bar{x},\bar{y}) \le a(\Phi,\bar{x},\bar{y}). \tag{4.5}$$

Proof. Implication (b)$\Longrightarrow$(c) is obvious. Let us establish assertion (I) and first justify (4.2) under the assumptions made. Proving by contradiction, we suppose that Φ is *not* open at a linear rate around $(\bar{x},\bar{y})$. Therefore, for any $a_k \downarrow 0$ one can find sequences $\{x_k\}$, $\{y_k\}$, $\{r_k\}$, and $\{z_k\}$ such that

$$x_k \to \bar{x},\ y_k \to \bar{y},\ r_k \downarrow 0 \ \text{ as } \ k \to \infty \ \text{ with } \ y_k \in \Phi(x_k) \cap B_{a_k}(\bar{y}), \tag{4.6}$$

$$\|z_k - y_k\| \le a_k r_k, \ \text{ and } \ z_k \notin \Phi(x) \ \ \forall x \in B_{r_k}(x_k), \ \ k = 1,2,\ldots. \tag{4.7}$$

Now let us employ the Ekeland variational principle that has become a conventional tool for this kind of study; see, e.g., [3, 14, 18, 20, 25]. For each k we consider an l.s.c. function $f_k : E_k \to \mathbf{R}$ defined by

$$f_k(x,y) := \|y - z_k\| \ \text{ on } \ E_k := (\text{gph}\,\Phi) \cap B_{r_k}((x_k,y_k)) \tag{4.8}$$

with the metric on E_k induced by the norm $\|(x,y)\| := \|x\| + \|y\|$ on $X \times Y$. Due to (4.6) and (4.7) one has

$$f_k(x_k,y_k) \le a_k r_k \ \text{ and } \ f_k(x,y) > 0 \ \ \forall (x,y) \in E_k.$$

Applying Ekeland's principle to the function f_k on the metric space E_k, we obtain the following: for the given numbers $\epsilon_k := a_k r_k$, $\lambda_k := (1/2)r_k$ and point (x_k,y_k) there exists $(\tilde{x}_k,\tilde{y}_k) \in \text{gph}\,\Phi \cap B_{(1/2)r_k}((x_k,y_k))$ such that

$$0 < \|\tilde{y}_k - z_k\| \le \|y_k - z_k\| \le \epsilon_k \ \text{ and}$$
$$\|\tilde{y}_k - z_k\| \le \|y - z_k\| + (\epsilon_k/\lambda_k)\|(x,y) - (\tilde{x}_k,\tilde{y}_k)\| \ \ \forall (x,y) \in E_k.$$

The latter means that $(\tilde{x}_k,\tilde{y}_k)$ is a local minimizer of the function

$$\varphi_k(x,y) := \|y - z_k\| + 2a_k\|(x,y) - (\tilde{x}_k,\tilde{y}_k)\| + \delta((x,y),\text{gph}\,\Phi) \tag{4.9}$$

defined on $X \times Y$. It is well known that the Cartesian product of two Asplund spaces is also Asplund, so one can apply Proposition 2.4 to the sum of three functions in (4.9) at $(\tilde{x}_k,\tilde{y}_k)$. Using this result with $\varepsilon = \gamma < \min\{a_k,\ \|z_k - \tilde{y}_k\|\}$ and taking into account the first formula in (2.9), we find $(x_{ik},y_{ik}) \in \text{gph}\,\Phi$ such that $\|x_{ik} - \tilde{x}_k\| \le a_k$, $\|y_{ik} - \tilde{y}_k\| \le a_k$, $y_{ik} \ne z_k$, $i = 1,2,3$, and

$$0 \in \hat{\partial}(\|\cdot - z_k\|)(x_{1k},y_{1k}) + \hat{\partial}(2a_k\|(\cdot,\cdot) - (\tilde{x}_k,\tilde{y}_k)\|)(x_{2k},y_{2k})$$
$$+ \hat{N}((x_{3k},y_{3k});\text{gph}\,\Phi) + a_k(B^\star \times B^\star).$$

Employing the well-known convex subdifferential formula for the norm function and taking into account that $y_{ik} \ne z_k$, we obtain a triple $(\tilde{x}_k^\star,\tilde{y}_k^\star,\tilde{z}_k^\star) \in X^\star \times Y^\star \times Y^\star$ with

$$(\tilde{x}_k^\star,-\tilde{y}_k^\star) \in \hat{N}((x_{3k},y_{3k});\text{gph}\,\Phi), \ \ \|\tilde{z}_k^\star\| = 1, \ \text{ and } \ \|\tilde{z}_k^\star - \tilde{y}_k^\star\| \le 3a_k.$$

The latter yields $\|\tilde{y}_k^\star\| \ge 1 - 3a_k > 1/2$ for all big k. Then letting $x_k := x_{3k}$, $y_k := y_{3k}$, $x_k^\star := \tilde{x}_k^\star/\|\tilde{y}_k^\star\|$, and $y_k^\star := \tilde{y}_k^\star/\|\tilde{y}_k^\star\|$, we conclude that $x_k \to \bar{x}$ and $y_k \to \bar{y}$ as $k \to \infty$ while

$$(x_k^\star, -y_k^\star) \in \hat{N}((x_k, y_k); \operatorname{gph}\Phi) \ \text{ with } \ \|y_k^\star\| = 1 \ \text{ and } \ \|x_k^\star\| \le 6a_k. \tag{4.10}$$

Since Y is Asplund, the unit ball of the dual space $Y^\star$ is sequentially weak-star compact. Taking into account the boundedness of $\{y_k^\star\}$, one may assume that $y_k^\star \xrightarrow{w^\star} \tilde{y}^\star$ as $k \to \infty$ for some $\tilde{y}^\star \in Y^\star$. On the other hand, relationships (4.10) imply that $x_k^\star \to 0$ as $k \to \infty$ in the norm topology of $X^\star$ and $0 \in D^\star\Phi(\bar{x}, \bar{y})(\tilde{y}^\star)$ by virtue of Definition 2.2. Moreover, due to the p.n.c. property of Φ with respect to y around $(\bar{x}, \bar{y})$ one can conclude that $\tilde{y}^\star \ne 0$. Indeed, otherwise we employ Proposition 3.8 and arrive at the contradiction with $\|y_k^\star\| = 1$ for all k. Finally letting $y^\star := \tilde{y}^\star/\|\tilde{y}^\star\|$, one has

$$0 \in D^\star\Phi(\bar{x}, \bar{y})(y^\star) \ \text{ with } \ \|y^\star\| = 1.$$

This contradicts condition (c) in the theorem and completes the proof of implication (4.2).

Now let us establish estimate (4.3) assuming that Y is finite dimensional. To furnish this, we make some changes in the previous procedure similarly to the related proof of [32, Theorem 3.2] in a somewhat different situation.

Suppose that (4.3) is not true; i.e., there exist a positive number $a < a(\Phi, \bar{x}, \bar{y})$ as well as sequences $\{x_k\}$, $\{y_k\}$, $\{r_k\}$, and $\{z_k\}$ such that

$$\begin{gathered} x_k \to \bar{x}, \ \ y_k \to \bar{y}, \ \ r_k \downarrow 0 \ \text{ as } \ k \to \infty, \ \text{ and} \\ y_k \in \Phi(x_k), \ \ \|z_k - y_k\| \le ar_k, \ \ z_k \notin \Phi(x) \ \ \forall x \in B_{r_k}(x_k). \end{gathered} \tag{4.11}$$

For any $\varepsilon > a$ we take some $\alpha \in (a/\varepsilon, 1)$ and pick a sequence $\{\eta_k\}$ with

$$0 < \eta_k < \min\left\{ r_k, \ \frac{1}{2(\varepsilon\alpha + 1)}, \ \frac{\varepsilon(1-\alpha)}{1 + \varepsilon(\varepsilon\alpha + 1)} \right\} \ \ \forall k = 1, 2, \ldots. \tag{4.12}$$

For each fixed k, let us consider function (4.8) on the space E_k whose metric is induced by the norm $\|(x, y)\|_{\eta_k} := \|x\| + \eta_k\|y\|$ on $X \times Y$, in contrast to the proof of (4.2). Now we again apply the Ekeland variational principle to this function f_k at the point (x_k, y_k), but with different parameters, namely, $\epsilon_k := ar_k$ and $\lambda_k := ar_k/\varepsilon\alpha$. Noting that $f_k(x_k, y_k) \le \epsilon_k$ due to (4.11), we find a point $(\tilde{x}_k, \tilde{y}_k) \in E_k$ such that the function

$$\psi_k(x, y) := \|y - z_k\| + \varepsilon\alpha\|(x, y) - (\tilde{x}_k, \tilde{y}_k)\|_{\eta_k} + \delta((x, y), \operatorname{gph}\Phi) \tag{4.13}$$

attains its unconditional local minimum on $X \times Y$ at the point $(\tilde{x}_k, \tilde{y}_k)$.

Letting $\rho_k := \|\tilde{y}_k - z_k\|$, we apply Proposition 2.4 with $\varepsilon = \eta_k$ and $\gamma = \rho_k\eta_k/2$ to the sum of three functions in (4.13) at $(\tilde{x}_k, \tilde{y}_k)$. In this way we find three pairs (x_{ik}, y_{ik}) such that

$$\begin{gathered} \|(x_{ik}, y_{ik}) - (\tilde{x}_k, \tilde{y}_k)\| \le \rho_k\eta_k/2 \ \text{ with } \ y_{ik} \ne z_k \ \text{ for } \ i = 1, 2, 3 \ \text{ and} \\ 0 \in \hat{\partial}(\|\cdot - z_k\|)(x_{1k}, y_{1k}) + \hat{\partial}(\varepsilon\alpha\|(\cdot, \cdot) - (\tilde{x}_k, \tilde{y}_k)\|_{\eta_k})(x_{2k}, y_{2k}) \\ + \hat{N}((x_{3k}, y_{3k}); \operatorname{gph}\Phi) + \eta_k(B^\star \times B^\star). \end{gathered} \tag{4.14}$$

Now computing subdifferentials of the norm functions in (4.14) and taking into account (4.12), we get a pair $(x_k^\star, y_k^\star) \in X^\star \times Y^\star$ satisfying

$$(x_k^\star, -y_k^\star) \in \hat{N}((x_{3k}, y_{3k});\ \text{gph}\ \Phi),\ \ \|y_k^\star\| = 1,\ \ \|x_k^\star\| \le \frac{\varepsilon\alpha + \eta_k}{1 - \eta_k(\varepsilon\alpha + 1)} < \varepsilon. \tag{4.15}$$

By the constructions above we have $x_{3k} \to \bar{x}$ and $y_{3k} \to \bar{y}$ as $k \to \infty$. Moreover, due to Asplundity of X and dim $Y < \infty$ one can select a subsequence of $\{k\}$ along which $x_k^\star \overset{w^\star}{\to} x^\star \in X^\star$ and $y_k^\star \to y^\star$ with $\|y^\star\| = 1$. Finally passing to the limit in (4.15) when $k \to \infty$ and using (2.3), (2.4), (4.1) as well as the l.s.c. of the norm function in the weak-star topology of $X^\star$, we conclude that $a(\Phi, \bar{x}, \bar{y}) \le \varepsilon$. Since $\varepsilon > a$ was chosen arbitrary, the latter yields $a(\Phi, \bar{x}, \bar{y}) \le a$ that contradicts the choice of a. Therefore, one arrives at (4.3), which completes the proof of assertion (I).

Let us prove assertion (II) under the assumptions made therein. We are going to show that if Φ possesses the openness property with a modulus $a > 0$, then one always has $a \le a(\Phi, \bar{x}, \bar{y})$. The latter implies both (4.4) and (4.5).

Proving by contradiction, we assume that $a > a(\Phi, \bar{x}, \bar{y})$. Then there is a number $\alpha > 0$ such that $a(\Phi, \bar{x}, \bar{y}) < a - \alpha$, i.e.,

$$\|x^\star\| < a - \alpha \ \text{ for some } \ x^\star \in D^\star\Phi(\bar{x}, \bar{y})(y^\star) \ \text{ and } \ y^\star \in Y^\star \ \text{ with } \ \|y^\star\| = 1.$$

Now using the basic definitions (2.4) and (2.2) as well as dim $X < \infty$, one gets sequences $\{(x_k, y_k)\} \subset \text{gph}\ \Phi$, $\{x_k^\star\} \subset X^\star$, $\{y_k^\star\} \subset Y^\star$, and $\{\varepsilon_k\} \subset \mathbf{R}_+$ such that

$$\|x_k^\star\| < a - \alpha \ \text{ and } \ (x_k^\star, -y_k^\star) \in \hat{N}_{\varepsilon_k}((x_k, y_k); \text{gph}\ \Phi) \ \ \forall k = 1, 2, \ldots, \tag{4.16}$$

where $x_k \to \bar{x}$, $y_k \to \bar{y}$, $\varepsilon_k \downarrow 0$, $x_k^\star \to x^\star$ and $y_k^\star \overset{w^\star}{\to} y^\star$ as $k \to \infty$. Due to (2.1) and the inclusion in (4.16), we find a sequence $\gamma_k \downarrow 0$ with

$$\langle y_k^\star, y - y_k\rangle + 2\varepsilon_k(\|x - x_k\| + \|y - y_k\|) \ge \langle x_k^\star, x - x_k\rangle \tag{4.17}$$

for all $(x, y) \in \text{gph}\ \Phi$ satisfying $\|x - x_k\| \le \gamma_k$ and $\|y - y_k\| \le \gamma_k$ as $k = 1, 2, \ldots$.

Next let us choose a positive number β, a sequence of positive numbers $\{r_k\}$, and the sequence $\{\varepsilon_k\}$ in (4.17) such that

$$\beta \le \min\{a, \alpha/2\},\ \ r_k \le \min\{\gamma_k, \gamma_k/a\},\ \text{ and } \ \varepsilon_k \le (\alpha - \beta)/2(1 + a) \tag{4.18}$$

for all k. Due to $y_k^\star \overset{w^\star}{\to} y^\star$ with $\|y^\star\| = 1$ and the l.s.c. of $\|\cdot\|$ in the weak-star topology of $Y^\star$, one can assume that

$$\|y_k^\star\| > 1 - \beta/a \ \ \forall k = 1, 2, \ldots.$$

Therefore, there is $v_k \in Y$ such that

$$\|v_k\| = 1 \ \text{ and } \ \langle y_k^\star, v_k\rangle > 1 - \beta/a \ \ \forall k = 1, 2, \ldots. \tag{4.19}$$

Let us define $z_k := y_k - ar_kv_k$ for each $k = 1, 2, \ldots$. Using (4.18) and (4.19), we have $\|z_k - y_k\| = ar_k \le \gamma_k$ and the chain of estimates

$$\begin{aligned}
&\langle y_k^\star, z_k - y_k\rangle + 2\varepsilon_k(\|x - x_k\| + \|z_k - y_k\|)\\
&< -ar_k + \beta r_k + \frac{\alpha - \beta}{1 + a}(\|x - x_k\| + ar_k) \le -(a - \alpha)r_k < \langle x_k^\star, x - x_k\rangle,
\end{aligned}$$

which are valid for any $x \in B_{r_k}(x_k)$. By virtue of (4.17) the latter means that $z_k \notin \Phi(x)$ whatever $x \in B_{r_k}(x_k)$. Therefore, we have sequences $x_k \to \bar{x},\ y_k \to \bar{y},\ z_k \to \bar{y}$, and $r_k \downarrow 0$ as $k \to \infty$ such that (4.11) holds. Due to Definition 4.1 this contradicts the assumption that the number a is an openness modulus for Φ around $(\bar{x}, \bar{y})$. The contradiction obtained shows that $a \le a(\Phi, \bar{x}, \bar{y})$ and completes the proof of the theorem. □

COROLLARY 4.3. *Let $\Phi : X \rightrightarrows Y$ be a multifunction from a finite-dimensional space X into an Asplund space Y. Assume that Φ is p.n.c. with respect to y around $(\bar{x}, \bar{y}) \in \operatorname{gph} \Phi$. Then each of the conditions (b) and (c) in Theorem* 4.2 *is necessary and sufficient for Φ to be open at a linear rate around $(\bar{x}, \bar{y})$.*

Proof. This follows directly from the comparison of assertions (I) and (II) in Theorem 4.2. □

Remark 4.4. Another approach to prove the results in Theorem 4.2 consists of directly using neighborhood criteria established in our paper [32] in terms of the Fréchet coderivative of Φ and then employing the limiting arguments developed above. Following these arguments, one can observe that *when Y is finite dimensional*, a sufficient condition for the openness property of Φ around $(\bar{x}, \bar{y})$ can be expressed in the form

$$\operatorname{Ker} D^\star_s \Phi(\bar{x}, \bar{y}) = \{0\}, \tag{4.20}$$

where $D^\star_s \Phi(\bar{x}, \bar{y})$ is an analogue of the coderivative (2.4) corresponding to the *strong* upper limit (with respect to the norm topology on $X^\star \times Y^\star$) in the normal cone definition (2.2); cf. Penot [38, section 5]. Although the coderivative object in (4.20) may be smaller than the basic construction (2.4), no useful calculus rules are available for the former one in contrast to (2.4). Note also that the necessity of condition (4.20) for the openness of Φ is a weaker result in comparison with (II) in Theorem 4.2, but it does not need the assumption about $\dim X < \infty$; see [38, Remark 4.5].

Now employing Theorem 4.2 and the robustness property in Proposition 3.4, we obtain a useful *neighborhood criterion* for openness of multifunctions that is expressed in terms of the coderivative (2.4). Note that this criterion and its inverse counterpart (d) in Theorem 5.4 are important for applications in optimal control; cf. [25, 31].

COROLLARY 4.5. *Let both X and Y be WCG Asplund spaces and $\Phi : X \rightrightarrows Y$ be a multifunction normally compact around $(\bar{x}, \bar{y}) \in \operatorname{gph} \Phi$. Then each of the conditions* (b) *and* (c) *in Theorem* 4.2 *is equivalent to the following one:*

(d) *There exist positive numbers μ, γ, and η such that*

$$\|y^\star\| \le \mu \|x^\star\| \ \ \forall x^\star \in D^\star \Phi(x, y)(y^\star),\ x \in B_\gamma(\bar{x}),\ y \in \Phi(x) \cap B_\eta(\bar{y}).$$

Therefore, condition (d) *is sufficient for the openness property of Φ around $(\bar{x}, \bar{y})$ and is also necessary for this property when* $\dim X < \infty$.

Proof. Since implications (d)$\Longrightarrow$(b)$\Longrightarrow$(c) are always true, it remains to establish that (c)$\Longrightarrow$(d).

Proving by contradiction, let us assume that (d) fails. Then one has sequences $\{(x_k, y_k)\} \subset \operatorname{gph} \Phi$ and $\{(x_k^\star, y_k^\star)\} \subset X^\star \times Y^\star$ such that

$$x_k^\star \in D^\star \Phi(x_k, y_k)(y_k^\star), \ \ \|y_k^\star\| > k \|x_k^\star\| \ \ \forall k = 1, 2, \ldots$$

and $(x_k, y_k) \to (\bar{x}, \bar{y})$ as $k \to \infty$. Since $\|y_k^\star\| > 0$, we set $\tilde{y}_k^\star := y_k^\star / \|y_k^\star\|,\ \tilde{x}_k^\star := x_k^\star / \|y_k^\star\|$ and get

$$\tilde{x}_k^\star \in D^\star \Phi(x_k, y_k)(\tilde{y}_k^\star), \ \text{ with } \ \|\tilde{y}_k^\star\| = 1 \ \text{ and } \ \|\tilde{x}_k^\star\| < 1/k \ \ \forall k = 1, 2, \ldots. \tag{4.21}$$

Taking into account the sequential weak-star compactness of the unit ball in $Y^\star$ (since Y is Asplund), one may assume that $\tilde{y}_k^\star \xrightarrow{w^\star} \tilde{y}^\star$ as $k \to \infty$ for some $\tilde{y}^\star \in Y^\star$. On the other hand, (4.21) implies that $\tilde{x}_k^\star \to 0$ as $k \to \infty$ in the norm topology of $X^\star$. Since Φ is normally compact around $(\bar{x}, \bar{y})$ and both X and Y are Asplund, we can use the limiting property (3.7) with the normal cone $N((x,y); \operatorname{gph}\Phi)$ replacing the prenormal one. This yields $\tilde{y}^\star \neq 0$. Moreover, Proposition 3.4 ensures that $0 \in D^\star\Phi(\bar{x}, \bar{y})(\tilde{y}^\star)$. Denoting $y^\star := \tilde{y}^\star/\|\tilde{y}^\star\|$, we arrive at

$$0 \in D^\star\Phi(\bar{x}, \bar{y})(y^\star) \ \text{ with } \ \|y^\star\| = 1. \tag{4.22}$$

This contradicts condition (c) in Theorem 4.2 and completes the proof of the corollary. □

The next corollary contains effective characteristics for the openness property of multifunctions belonging to class (3.13), which is important for applications in optimization and optimal control. In particular, results in this vein directly induce necessary optimality conditions in various problems of scalar and/or vector optimization; cf. [17, 18, 25].

COROLLARY 4.6. *Assume that both spaces X and Y are Asplund, the sets $\Omega \subset X$ and $\Lambda \subset Y$ are closed, and the function $f : X \to Y$ is strictly Lipschitzian around $\bar{x} \in X$ with $\bar{y} := -f(\bar{x}) \in \Lambda$. In addition, let Λ be normally compact around $\bar{y}$. Then the multifunction Φ defined by* (3.13) *is open at a linear rate around $(\bar{x}, 0)$ if*

$$[y^\star \in \partial\operatorname{dist}(\cdot, \Lambda)(\bar{y}) \ \text{ and } \ 0 \in \partial\langle y^\star, f\rangle(\bar{x}) + N(\bar{x}; \Omega)] \Longrightarrow y^\star = 0. \tag{4.23}$$

Proof. Following the proof of Proposition 3.11, we get the respresentation

$$N((\bar{x}, 0); \operatorname{gph}\Phi) = \bigcup_{\lambda > 0} \lambda\partial\varphi(\bar{x}, 0), \tag{4.24}$$

where the distance function $\varphi(x, y) := \operatorname{dist}(y, \Phi(x))$ is expressed in the form

$$\varphi(x, y) = \operatorname{dist}(y - f(x), \Lambda) + \delta((x, y), \Omega \times Y) \ \ \forall (x, y) \in X \times Y. \tag{4.25}$$

One can easily observe that the mapping $(x, y) \to y - f(x)$ is strictly Lipschitzian around $(\bar{x}, 0)$. Now employing subdifferential calculus rules [35] and Proposition 2.5 in (4.24) and (4.25), we find a number $\lambda > 0$ such that

$$N((\bar{x}, 0); \operatorname{gph}\Phi) \subset \bigcup_{\lambda > 0} \bigcup_{y^\star \in \partial dist(\cdot, \Lambda)(\bar{y})} [\partial\langle \lambda y^\star, f\rangle(\bar{x}) \times \{-\lambda y^\star\}] + N(\bar{x}; \Omega) \times \{0\}. \tag{4.26}$$

Therefore, condition (4.23) implies criterion (c) in Theorem 4.2 due to (4.26) and the coderivative construction (2.4). Moreover, Proposition 3.9 ensures that the multifunction Φ in (3.13) is p.n.c. with respect to y around $(\bar{x}, 0)$ under the assumptions made. In this way we deduce the corollary from assertion (I) of Theorem 4.2. □

In conclusion of this section let us consider a *global* (relative to the image) counterpart of the openness property for closed-graph multifunctions.

DEFINITION 4.7. *We say that Φ enjoys the* covering property *around $\bar{x} \in \operatorname{Dom}\Phi$ if there exist a number $a > 0$ and a neighborhood U of $\bar{x}$ such that for any (x, r) with $B_r(x) \subset U$ one has*

$$B_{ar}(\Phi(x)) \subset \Phi(B_r(x)).$$

Each of such numbers a is called the covering modulus *for Φ around $\bar{x}$. The supremum of all covering moduli is called the* covering bound *for Φ around $\bar{x}$ and is denoted by* $(\operatorname{cov}\Phi)(\bar{x})$.

Let us consider the *covering constant*

$$a(\Phi,\bar{x}) := \inf\{\|x^\star\| \text{ s.t. } x^\star \in D^\star\Phi(\bar{x},\bar{y})(y^\star),\ \ \|y^\star\|=1, \quad \text{and } \ \bar{y}\in\Phi(\bar{x})\} \tag{4.27}$$

related to (4.1) and formulate the covering characterization result that follows from Theorem 4.2 and Corollary 4.5. Recall that a multifunction $\Phi : X \rightrightarrows Y$ between Banach spaces is said to be *locally compact* around $\bar{x}$ if there are a neighborhood U of $\bar{x}$ and a compact set $V \subset Y$ such that $\Phi(U) \subset V$.

THEOREM 4.8. *Let the multifunction $\Phi : X \rightrightarrows Y$ be locally compact around $\bar{x} \in \operatorname{Dom}\Phi$. Consider the following statements:*

(a) *Φ enjoys the covering property around $\bar{x}$;*

(b) *$a(\Phi,\bar{x}) > 0$ for the covering constant* (4.27)*;*

(c) *the coderivative* (2.4) *at $(\bar{x},\bar{y})$ is injective for all $\bar{y}\in\Phi(\bar{x})$, i.e.,*

$$\operatorname{Ker} D^\star\Phi(\bar{x},\bar{y}) = \{0\} \ \ \forall \bar{y}\in\Phi(\bar{x});$$

(d) *there exist positive numbers μ and γ such that*

$$\|y^\star\| \le \mu\|x^\star\| \ \ \forall x^\star \in D^\star\Phi(x,y)(y^\star),\ \ x\in B_\gamma(\bar{x}),\ \ y\in\Phi(x).$$

Then (d) $\Longrightarrow$ (b) $\Longrightarrow$ (c) *and the following results hold:*

(I) *When Φ is p.n.c. with respect to y around $(\bar{x},\bar{y})$ for any $\bar{y}\in\Phi(\bar{x})$ and both spaces X and Y are Asplund, one has* (c)$\Longrightarrow$(a)*; i.e., each of the conditions* (b), (c), *and* (d) *is sufficient for Φ to enjoy the covering property around $\bar{x}$. Moreover,*

$$(\operatorname{cov}\Phi)(\bar{x}) \ge a(\Phi,\bar{x})$$

when Y is finite dimensional.

(II) *When Φ is an arbitrary multifunction from a finite-dimensional space X into a Banach space Y, one has* (a)$\Longrightarrow$(b)*; i.e., both conditions* (b) *and* (c) *are necessary for Φ to enjoy the covering property around $\bar{x}$. Moreover, in this case*

$$(\operatorname{cov}\Phi)(\bar{x}) \le a(\Phi,\bar{x}).$$

(III) *Each of the conditions* (b) *and* (c) *is equivalent to* (d) *when both spaces X and Y are WCG Asplund and the multifunction Φ is normally compact around $\bar{x}$ for any $\bar{y}\in\Phi(\bar{x})$.*

Proof. Using the local compactness of Φ around $\bar{x}$ and the compactness arguments in [26, Theorem 3.9] (cf. also [42, Theorem 2.2]), one can establish that the covering property of Φ around $\bar{x}$ is *equivalent* in this case to the openness property of Φ around $(\bar{x},\bar{y})$ for *every* $\bar{y}\in\Phi(\bar{x})$. Moreover,

$$a(\Phi,\bar{x}) = \inf\{a(\Phi,\bar{x},\bar{y})|\ \bar{y}\in\Phi(\bar{x})\} \ \text{ and } \ (\operatorname{cov}\Phi)(\bar{x}) = \inf\{(\operatorname{ope}\Phi)(\bar{x},\bar{y})|\ \bar{y}\in\Phi(\bar{x})\}.$$

In this way one can also check that properties (b)–(d) in the theorem are equivalent to the fulfilment of the corresponding properties in Theorem 4.2 and Corollary 4.5 for all $\bar{y}\in\Phi(\bar{x})$ (respectively, all $y\in\Phi(x)$ in (d)). Therefore, the results formulated follow from the corresponding results of Theorem 4.2 and Corollary 4.5. □

5. Point characterizations of metric regularity and Lipschitzian stability. This section is concerned with other significant properties of closed-graph multifunctions $\Phi : X \rightrightarrows Y$ related to the openness and covering considered above. We start with definitions of the (local) metric regularity and pseudo-Lipschitzian properties initiated, respectively, by Robinson [40] and Aubin [1].

DEFINITION 5.1. (i) Φ *is said to be* local-metrically regular *around* $(\bar{x},\bar{y}) \in \operatorname{gph}\Phi$ *with modulus* $c > 0$ *if there exist a neighborhood* U *of* $\bar{x}$*, a neighborhood* V *of* $\bar{y}$*, and a number* $\alpha > 0$ *such that*

$$\operatorname{dist}(x, \Phi^{-1}(y)) \;\le\; c\operatorname{dist}(y, \Phi(x))$$

for any $x \in U$ *and* $y \in V$ *satisfying* $\operatorname{dist}(y,\Phi(x)) \le \alpha$*. The infimum of all regularity moduli* c *is called the* bound of local-metric regularity *for* Φ *around* $(\bar{x},\bar{y})$ *and is denoted by* $(\operatorname{lreg}\Phi)(\bar{x},\bar{y})$.

(ii) Φ *is said to be* pseudo-Lipschitzian *around* $(\bar{x},\bar{y}) \in \operatorname{gph}\Phi$ *with modulus* $l > 0$ *if there exist a neighborhood* U *of* $\bar{x}$ *and a neighborhood* V *of* $\bar{y}$ *such that*

$$\Phi(x_1) \cap V \subset \Phi(x_2) + l\|x_1 - x_2\|B \;\; \forall x_1, x_2 \in U. \tag{5.1}$$

The infimum of all such moduli l *is called the* bound of pseudo-Lipschitzness *for* Φ *around* $(\bar{x},\bar{y})$ *and is denoted by* $(\operatorname{plip}\Phi)(\bar{x},\bar{y})$.

The interrelations between the properties in Definitions 4.1 and 5.1 can be obtained from Borwein and Zhuang [7] and Penot [37]; cf. also [26].

PROPOSITION 5.2. (I) Φ *is local-metrically regular around* $(\bar{x},\bar{y})$ *if and only if* Φ *is open at a linear rate around* $(\bar{x},\bar{y})$*. Moreover,* $(\operatorname{lreg}\Phi)(\bar{x},\bar{y}) = 1/(\operatorname{ope}\Phi)(\bar{x},\bar{y})$.

(II) Φ *is pseudo-Lipschitzian around* $(\bar{x},\bar{y}) \in \operatorname{gph}\Phi$ *with modulus* l *if and only if* Φ^{-1} *is local-metrically regular around* $(\bar{y},\bar{x})$ *with the same modulus* $c = l$.

Following [26], let us introduce the *regularity constant*

$$c(\Phi,\bar{x},\bar{y}) := \inf\{c > 0 \;\text{ s.t. }\; \|y^\star\| \le c\|x^\star\| \;\text{ when }\; x^\star \in D^\star\Phi(\bar{x},\bar{y})(y^\star)\} \tag{5.2}$$

and observe the relationships between constants (5.2), (4.1), and the norm (1.2) of the coderivative (2.4):

$$c(\Phi,\bar{x},\bar{y}) = 1/a(\Phi,\bar{x},\bar{y}) \;\text{ when }\; a(\Phi,\bar{x},\bar{y}) > 0; \tag{5.3}$$

$$c(\Phi^{-1},\bar{y},\bar{x}) = \|D^\star\Phi(\bar{x},\bar{y})\|. \tag{5.4}$$

Now using Proposition 5.2 and relationships (5.3) and (5.4), one can deduce effective characterizations of the metric regularity and Lipschitzian behavior of multifunctions from our main results in Theorem 4.2 and Corollary 4.5.

THEOREM 5.3. (I) *Let both spaces* X *and* Y *be Asplund and the multifunction* $\Phi : X \rightrightarrows Y$ *be p.n.c. with respect to* y *around* $(\bar{x},\bar{y}) \in \operatorname{gph}\Phi$*. Then each of the conditions*

$$c(\Phi,\bar{x},\bar{y}) < \infty \tag{5.5}$$

and (c) *in Theorem* 4.2 *is sufficient for* Φ *to be local-metrically regular around* $(\bar{x},\bar{y})$*. Moreover, one has*

$$(\operatorname{lreg}\Phi)(\bar{x},\bar{y}) \le c(\Phi,\bar{x},\bar{y})$$

when Y *is finite dimensional.*

(II) *Let Φ be an arbitrary closed-graph multifunction from a finite-dimensional space X into a Banach space Y. Then both conditions* (5.5) *and* (c) *in Theorem* 4.2 *are necessary for Φ to be local-metrically regular around $(\bar{x},\bar{y})$. In this case one has*

$$(\operatorname{lreg}\Phi)(\bar{x},\bar{y})\geq c(\Phi,\bar{x},\bar{y}).$$

One can observe that in the classical cases where Φ either is strictly differentiable at $\bar{x}$ or has convex graph, the coderivative criteria of Theorems 4.2 and 5.3 are reduced to the corresponding surjectivity and interiority conditions of the celebrated Ljusternik–Graves and Robinson–Ursescu theorems; see, e.g., [2] and references therein. Note that those conditions turn out to be *necessary and sufficient* for the metric regularity/openness (at a linear rate) properties under the assumptions made. The latter fact holds in more general infinite-dimensional settings; cf. [10, 11, 32]. Let us emphasize that we also get effective modulus estimates.

Next we formulate results on the pseudo-Lipschitzian property that are *inverse* to criteria in Theorem 4.2 and Corollary 4.5. One can easily observe from the definitions that

$$D^\star\Phi^{-1}(\bar{y},\bar{x})(x^\star)=\{y^\star\in Y^\star|\ x^\star\in -D^\star\Phi(\bar{x},\bar{y})(-y^\star)\} \tag{5.6}$$

for any multifunction $\Phi: X\Rightarrow Y$ between Banach spaces.

THEOREM 5.4. *Let $\Phi: X\Rightarrow Y$ be a closed-graph multifunction with $(\bar{x},\bar{y})\in \operatorname{gph}\Phi$. Consider the following properties:*

(a) *Φ is pseudo-Lipschitzian around $(\bar{x},\bar{y})$;*

(b) *the coderivative $D^\star\Phi(\bar{x},\bar{y})(\cdot)$ is bounded, i.e., $\|D^\star\Phi(\bar{x},\bar{y})\|<\infty$;*

(c) *the coderivative satisfies the null-condition at $(\bar{x},\bar{y})$:*

$$D^\star\Phi(\bar{x},\bar{y})(0)=\{0\}; \tag{5.7}$$

(d) *there are numbers $\gamma>0$, $\eta>0$, and $l>0$ such that the coderivative satisfies the uniform linear estimate around $(\bar{x},\bar{y})$:*

$$\sup\{\|x^\star\|\ s.t.\ x^\star\in D^\star\Phi(x,y)(y^\star)\}\leq l\|y^\star\|\ \ \forall x\in B_\gamma(\bar{x}),\ y\in\Phi(x)\cap B_\eta(\bar{y}),\ \text{and}\ y^\star\in Y^\star.$$

Then (d)$\Longrightarrow$(b)$\Longrightarrow$ (c) *and the following assertions hold:*

(I) *One has* (c)$\Longrightarrow$(a) *when Φ is p.n.c. with respect to x around $(\bar{x},\bar{y})$ and both spaces X and Y are Asplund. Thus in this case each of the conditions* (b), (c), *and* (d) *is sufficient for Φ to be pseudo-Lipschitzian around $(\bar{x},\bar{y})$. Moreover,*

$$(\operatorname{plip}\Phi)(\bar{x},\bar{y})\leq\|D^\star\Phi(\bar{x},\bar{y})\| \tag{5.8}$$

when X is finite dimensional.

(II) *One has* (a)$\Longrightarrow$(b) *when Φ is an arbitrary multifunction from a Banach space X into a finite-dimensional space Y. Thus in this case both conditions* (b) *and* (c) *are necessary for Φ to be pseudo-Lipschitzian around $(\bar{x},\bar{y})$ and, in addition,*

$$(\operatorname{plip}\Phi)(\bar{x},\bar{y})\geq\|D^\star\Phi(\bar{x},\bar{y})\|.$$

(III) *Conditions* (b), (c), *and* (d) *are equivalent when both X and Y are WCG Asplund spaces and Φ is normally compact around $(\bar{x},\bar{y})$.*

COROLLARY 5.5. *Let X be Asplund, let* $\dim Y<\infty$, *and let $\Phi: X\Rightarrow Y$ be p.n.c. with respect to x around $(\bar{x},\bar{y})$. Then each of the conditions* (b) *and* (c) *in Theorem* 5.4 *is necessary and sufficient for Φ to be pseudo-Lipschitzian around $(\bar{x},\bar{y})$.*

In the next section we present some applications of Theorem 5.4 to Lipschitzian stability of parametric constraint and variational systems. Now let us show how the results obtained allow one to characterize Lipschitzian behavior of an extended-real-valued function $\varphi : X \to \bar{\mathbf{R}}$ in terms of its *singular subdifferential*

$$\partial^\infty \varphi(\bar{x}) := \{x^\star \in X^\star |\ (x^\star, 0) \in N((\bar{x}, \varphi(\bar{x})); \operatorname{epi} \varphi)\} \tag{5.9}$$

at $\bar{x} \in \operatorname{dom} \varphi$. Along with φ we consider the *epigraphical multifunction* E_φ associated with φ by virtue of (2.10). We say that φ is *normally epi-compact* around $\bar{x}$ if the set $\Omega := \operatorname{epi} \varphi$ (or the multifunction E_φ) is normally compact around $(\bar{x}, \varphi(\bar{x}))$. The latter property always holds if φ is compactly epi-Lipschitzian (in particular, Lipschitz continuous or directionally Lipschitzian) around $\bar{x}$; see [22, 35] for more details.

COROLLARY 5.6. *Let X be a Banach space and $\varphi : X \to \bar{\mathbf{R}}$ be l.s.c. around $\bar{x} \in \operatorname{dom} \varphi$. Consider the following properties:*

(a) *φ is Lipschitz continuous around $\bar{x}$;*

(b) *E_φ is pseudo-Lipschitzian around $(\bar{x}, \varphi(\bar{x}))$;*

(c) $\partial^\infty \varphi(\bar{x}) = \{0\}$.

Then one always has (a)$\Longleftrightarrow$(b)$\Longrightarrow$(c). *Moreover,* (c) *is equivalent to* (a) *and* (b) *when X is Asplund and φ is normally epi-compact around $\bar{x}$.*

Proof. It follows directly from the definitions that (a)$\Longrightarrow$(b) and, conversely, (b)$\Longrightarrow$(a) if φ is continuous around $\bar{x}$. On the other hand, it is easy to show by contradiction that the pseudo-Lipschitzian property of E_φ around $(\bar{x}, \varphi(\bar{x}))$ automatically implies the upper semicontinuity of φ around $\bar{x}$. This yields the equivalence between (a) and (b) in general Banach spaces. Further taking (2.4), (2.10), and (5.9) into account, we observe that

$$D^\star E_\varphi(\bar{x}, \varphi(\bar{x}))(0) = \partial^\infty \varphi(\bar{x}).$$

Therefore, the implication (b)$\Longrightarrow$(c) follows from Theorem 5.4(II) with $\Phi = E_\varphi$.

It remains to prove that (c)$\Longrightarrow$(b) when X is Asplund and φ is normally epi-compact around $\bar{x}$. But this is a direct corollary of Theorem 5.4(I) since the normal epi-compactness of φ around $\bar{x}$ obviously implies the partial normal compactness of the multifunction E_φ with respect to x around $(\bar{x}, \varphi(\bar{x}))$. □

Remark 5.7. Following the line of [26], one may consider the so-called *global-metric regularity* property of a multifunction Φ around $\bar{x} \in \operatorname{Dom} \Phi$ that is a global counterpart of the regularity property in Definition 5.1. (A local condition $y \in V$ for a neighborhood V of $\bar{y}$ is replaced by $y \in Y$.) Similarly to Theorem 4.8 we can derive the corresponding characteristics of global-metric regularity from their local analogues in Theorem 5.3. Moreover, these results follow directly from Theorem 4.8 due to the equivalence between the covering and global-metric regularity properties established in [32, Proposition 5.2] for the case of general Banach spaces.

In the same way we get effective characteristics for the *(Hausdorff) local Lipschitz continuity* of Φ around $\bar{x}$ which corresponds to $V = Y$ in (5.1). Indeed, when Φ is locally compact around $\bar{x}$, its local Lipschitz continuity around this point is equivalent to the pseudo-Lipschitzian property of Φ around $(\bar{x}, \bar{y})$ for every $\bar{y} \in \Phi(\bar{x})$. This allows us to obtain analogues of the results in Theorem 5.4 for such a local Lipschitz continuity where one should take *every* $\bar{y} \in \Phi(\bar{x})$ in all the criteria and replace $B_\eta(\bar{y})$ with Y in (d); cf. the proof of Theorem 4.8 above and [27, Theorem 3.5]. When Φ happens to be locally *single valued* around $\bar{x}$, the results obtained provide dual criteria for the *classical local Lipschitzian property* of continuous mappings with effective modulus estimates.

Remark 5.8. It immediately follows from the proofs given above that the p.n.c. property in Theorems 4.2, 4.8, 5.3, and 5.4 and their corollaries can be replaced with the weaker sequential limiting property established in Proposition 3.8 and called *partial sequential normal compactness* in [36].

6. Applications to sensitivity analysis for constraint and variational systems. In this section we consider a class of multifunctions $\Phi : X \rightrightarrows Y$ given in the form

$$\Phi(x) = \{y \in Y |\ g(x,y) \in \Lambda,\ (x,y) \in \Omega\}, \tag{6.1}$$

where $g : X \times Y \to Z$ is a mapping between Banach spaces and Λ and Ω are subsets of the spaces Z and $X \times Y$, respectively. Following Rockafellar [42], we call (6.1) *constraint systems* depending on a parameter $x \in X$. One can treat (6.1) as, e.g., a natural generalization of the *feasible solution sets* to perturbed problems in nonlinear programming with equality and inequality constraints described by

$$\Phi(x) = \{y |\ \varphi_i(x,y) \le 0 \text{ for } i = 1,\dots,r \text{ and } \varphi_i(x,y) = 0 \text{ for } i = r+1,\dots,q\}, \tag{6.2}$$

which corresponds to (6.1) when $g = (\varphi_1,\dots,\varphi_q)$, $\Omega = X \times Y$, $Z = \mathbf{R}^q$, and

$$\Lambda = \{(\mu_1,\dots,\mu_q) |\ \mu_i \le 0 \text{ for } i = 1,\dots,r \text{ and } \mu_i = 0 \text{ for } i = r+1,\dots,q\}. \tag{6.3}$$

A special case of (6.1) with $\Lambda = \{0\}$ and $\Omega = X \times Y$ is addressed by the classical implicit function theorem when the mapping (6.1) is single valued and smooth. In general we have an *implicit multifunction* in this case and are interested in properties of *Lipschitz continuity*.

Another important class of multifunctions described by (6.1) is related to solution sets for parametrized *generalized equations*

$$\Phi(x) = \{y \in Y |\ 0 \in f(x,y) + Q(y)\}, \tag{6.4}$$

where $f : X \times Y \to W$ and $Q : Y \rightrightarrows W$. One can see that (6.4) corresponds to (6.1) with

$$g(x,y) = (y, -f(x,y)),\ \ \Lambda = \operatorname{gph} Q,\ \ \Omega = X \times Y,\ \ Z = Y \times W. \tag{6.5}$$

Generalized equations were introduced by Robinson [41] and turned out to be a very convenient model for developing sensitivity analysis and numerical methods in problems of optimization, control, complementarity, mathematical economics, equilibrium, etc.; see, e.g., [11, 19, 30, 41] and references therein. When $Q(y) = N(y;\Omega)$ is the normal-cone operator for a convex set Ω, the generalized equation in (6.4) is reduced to the parametric *variational inequality*

$$\text{find } \ y \in \Omega \ \text{ s.t. } \ \langle f(x,y), \omega - y\rangle \ge 0 \ \ \forall \omega \in \Omega,$$

which is of particular interest for applications. As an important special case, generalized equations/variational inequalities include sets of all *optimal solutions* with associated Lagrange multipliers satisfying first-order necessary optimality conditions in nonlinear programming and optimal control.

In what follows we obtain point conditions ensuring the pseudo-Lipschitzian property for parametric constraint systems (6.1) and generalized equations (6.4) in infinite dimensions. To furnish this, we develop the approach and results in Mordukhovich

[27, 30] where such conditions were obtained in the case of finite dimensional spaces X, Y, Z, and W. This approach is based on using the null-condition (5.7) in Theorem 5.4 valid for arbitrary closed-graph multifunctions and then on effective calculus rules available for our basic generalized differential constructions. In this way we are able to express *sufficient* as well as *necessary and sufficient* conditions for Lipschitzian stability of parametric systems under consideration in terms of their initial data. Moreover, we provide lower and upper estimates for the *exact bounds* of associated Lipschitz moduli that appears to be even more practical in some situations.

THEOREM 6.1. *Let Φ be defined by (6.1), where $g : X \times Y \to Z$ is a continuous function and $\Lambda \subset Z$ and $\Omega \subset X \times Y$ are closed sets with $\bar{z} := g(\bar{x}, \bar{y}) \in \Lambda$ and $(\bar{x}, \bar{y}) \in \Omega$. Then one has the following results:*

(I) *Assume that* $\dim X < \infty$, *Ω is normally compact around $(\bar{x}, \bar{y})$, and either*

(h1) *both Y and Z are Asplund while Λ is normally compact around $\bar{z}$, or*

(h2) *both Y and Z are Banach while g is strictly differentiable at $(\bar{x}, \bar{y})$ with $g'(\bar{x}, \bar{y})$ invertible.*

Then Φ is pseudo-Lipschitzian around $\bar{x}$ if the following three conditions are fulfilled simultaneously:

$$[(x^\star, 0) \in D^\star g(\bar{x}, \bar{y})(z^\star) + N((\bar{x}, \bar{y}); \Omega) \ \text{ and } \ z^\star \in N(\bar{z}; \Lambda)] \Longrightarrow x^\star = 0, \tag{6.6}$$

$$D^\star g(\bar{x}, \bar{y})(z^\star) \cap (-N((\bar{x}, \bar{y}); \Omega)) = \{0\} \ \ \forall z^\star \in N(\bar{z}; \Lambda), \tag{6.7}$$

$$\text{Ker } D^\star g(\bar{x}, \bar{y}) \cap N(g(\bar{x}, \bar{y}); \Lambda) = \{0\}. \tag{6.8}$$

Moreover, under these assumptions one has the upper estimate

$$\begin{aligned}(\text{plip } \Phi)(\bar{x}, \bar{y}) \le \bar{l} := \sup \Big\{ \|x^\star\| \ s.t. \ (x^\star, -y^\star) \in \bigcup [D^\star g(\bar{x}, \bar{y})(z^\star) \ \ with \\ z^\star \in N(\bar{z}; \Lambda)] + N((\bar{x}, \bar{y}); \Omega), \ \ \|y^\star\| \le 1 \Big\}.\end{aligned} \tag{6.9}$$

(II) *Let* $\dim Y < \infty$, *and let one of the following groups of hypotheses hold:*

(h3) *the spaces X and Z are Asplund; the sets Ω and Λ are regular at the points $(\bar{x}, \bar{y})$ and $\bar{z}$, respectively; the qualification conditions* (6.7) *and* (6.8) *are fulfilled; and either g is strictly differentiable at $(\bar{x}, \bar{y})$ or* $\dim Z < \infty$ *and g is Lipschitz continuous at this point with* gph g *regular at $(\bar{x}, \bar{y}, \bar{z})$;*

(h4) *both X and Z are Banach, $\Omega = X \times Y$, and g is strictly differentiable at $(\bar{x}, \bar{y})$ with $g'(\bar{x}, \bar{y})$ invertible.*

Then condition (6.6) *is necessary for the pseudo-Lipschitzian property of Φ around $(\bar{x}, \bar{y})$. Moreover, under these assumptions one has the lower estimate (*$\text{plip } \Phi)(\bar{x}, \bar{y}) \ge \bar{l}$, *where the number $\bar{l}$ is defined in* (6.9).

Proof. Let us observe that gph $\Phi = g^{-1}(\Lambda) \cap \Omega$ for the multifunction Φ in (6.1). Therefore, its coderivative (2.4) is represented in the form

$$D^\star \Phi(\bar{x}, \bar{y})(y^\star) = \{x^\star \in X^\star | \ (x^\star, -y^\star) \in N((\bar{x}, \bar{y}); g^{-1}(\Lambda) \cap \Omega)\}. \tag{6.10}$$

Using the calculus of normal cones [35, Corollary 4.5], we obtain the inclusion

$$N((\bar{x}, \bar{y}); g^{-1}(\Lambda) \cap \Omega) \subset N((\bar{x}, \bar{y}); g^{-1}(\Lambda)) + N((\bar{x}, \bar{y}); \Omega), \tag{6.11}$$

provided that Ω is normally compact around $(\bar{x}, \bar{y})$ and the qualification condition

$$N((\bar{x}, \bar{y}); g^{-1}(\Lambda)) \cap (-N((\bar{x}, \bar{y}); \Omega)) = \{0\} \tag{6.12}$$

is fulfilled. Moreover, equality holds in (6.11) when either $\Omega = X \times Y$ or both sets Ω and $g^{-1}(\Lambda)$ are regular at $(\bar{x}, \bar{y})$.

Next let us use [35, Corollary 6.9] for representing the normal cone to $g^{-1}(\Lambda)$ at $(\bar{x}, \bar{y})$. According to this result the qualification condition (6.8), Asplundity of X, and assumptions (h1) in the theorem ensure the inclusion

$$N((\bar{x}, \bar{y}); g^{-1}(\Lambda)) \subset \bigcup [D^\star g(\bar{x}, \bar{y})(z^\star) |\ z^\star \in N(\bar{z}; \Lambda)], \tag{6.13}$$

where, in addition, equality holds and $g^{-1}(\Lambda)$ is regular at $(\bar{x}, \bar{y})$ under assumptions (h3) concerning g, Λ, and Z. Moreover, equality also holds in (6.13) (but no regularity of $g^{-1}(\Lambda)$ is guaranteed) under assumptions (h2) with a Banach space X; see [33, Corollary 4.4]. Thus (6.12) follows from (6.7) under the assumptions made in (I).

Now substituting (6.13) into (6.10)–(6.12), we arrive at the inclusion

$$D^\star \Phi(\bar{x}, \bar{y})(y^\star) \subset \Big\{ x^\star \in X^\star |\ (x^\star, -y^\star) \in \bigcup [D^\star g(\bar{x}, \bar{y})(z^\star) \ \text{ with } \ z^\star \in N(\bar{z}; \Lambda)] + N((\bar{x}, \bar{y}); \Omega) \Big\}, \tag{6.14}$$

which is valid when Ω is normally compact around $(\bar{x}, \bar{y})$, the qualification conditions (6.7) and (6.8) are fulfilled, and either X is Asplund and assumptions (h1) hold or X is Banach and one has assumptions (h2). (Note that (6.8) is automatic in the latter case.) Therefore, (6.6) implies the null-condition (5.7) in Theorem 5.4(I), while the upper estimate (6.9) follows from (5.8) and (1.2). This proves the sufficiency assertion (I) of the theorem.

To establish the necessity part (II), we use the assumptions above ensuring equality in the coderivative formula (6.14). Finally employing Theorem 5.4(II), we come to all the conclusions (II) of the theorem under the assumptions made therein. □

COROLLARY 6.2. *Let Φ be defined in* (6.1)*, where* $\dim X < \infty$*, Y and Z are Asplund, g is strictly Lipschitzian at $(\bar{x}, \bar{y})$, and the sets Ω and Λ are normally compact around $(\bar{x}, \bar{y})$ and $\bar{z}$, respectively. Then the condition*

$$[(x^\star, 0) \in \partial \langle z^\star, g \rangle (\bar{x}, \bar{y}) + N((\bar{x}, \bar{y}); \Omega) \text{ and } z^\star \in N(\bar{z}; \Lambda)] \Longrightarrow z^\star = 0, \quad x^\star = 0, \tag{6.15}$$

is sufficient for Φ to be pseudo-Lipschitzian around $(\bar{x}, \bar{y})$, and one can replace $D^\star g(\bar{x}, \bar{y})(z^\star)$ with $\partial \langle z^\star, g \rangle (\bar{x}, \bar{y})$ in the upper estimate (6.9).

Proof. First we observe that Proposition 2.5 allows us to replace $D^\star g(\bar{x}, \bar{y})(z^\star)$ with $\partial \langle z^\star, g \rangle (\bar{x}, \bar{y})$ in all conditions (6.6)–(6.9) when g is strictly Lipschitzian at $(\bar{x}, \bar{y})$ and both X and Y are Asplund. Then following [27, Corollary 4.2], one can show that in this case the simultaneous fulfillment of conditions (6.6)–(6.8) is *equivalent* to (6.15). Thus we obtain all the conclusions of the corollary from Theorem 6.1(I). □

Following [27, 30], one can derive various consequences of Theorem 6.1 and Corollary 6.2 for special parametric constraint systems. Let us present effective results for the classical constraint system (6.2) in *nonlinear programming* that seem to be new in infinite dimensions.

COROLLARY 6.3. *Let Φ be given by* (6.2)*, where real-valued functions φ_i are strictly differentiable at $(\bar{x}, \bar{y})$ for all $i = 1, \ldots, q$. Then the following hold:*

(I) *The Mangasarian–Fromovitz condition*

$$[\lambda_1 (\varphi_1)'_y(\bar{x}, \bar{y}) + \cdots + \lambda_q (\varphi_q)'_y(\bar{x}, \bar{y}) = 0] \Longrightarrow \lambda_i = 0 \ \text{ for } \ i = 1, \ldots, q$$
$$\text{if } \ \lambda_i \ge 0 \ \text{ and } \ \lambda_i \varphi_i(\bar{x}, \bar{y}) = 0 \ \text{ for } \ i = 1, \ldots, r$$

is sufficient for Φ *to be pseudo-Lipschitzian around* $(\bar{x},\bar{y})$ *when* $\dim X<\infty$ *and* Y *is Asplund. Moreover, in this case one has the upper modulus estimate*

$$(\text{plip }\Phi)(\bar{x},\bar{y})\le\sup\left\{\left|\sum_{i=1}^q\lambda_i(\varphi_i)'_x(\bar{x},\bar{y})\right|\ \ s.t.\ \ \left|\sum_{i=1}^q\lambda_i(\varphi_i)'_y(\bar{x},\bar{y})\right|\le 1,\right.$$
$$\left.\lambda_i\ge 0,\ \ and\ \ \lambda_i\varphi_i(\bar{x},\bar{y})=0\ \ for\ \ i=1,\dots,r\right\}.$$

(II) *Let* X *be Asplund and let* $\dim Y<\infty$. *Then the condition*

$$\left[\sum_{i=1}^q\lambda_i(\varphi_i)'_y(\bar{x},\bar{y})=0\right]\Longrightarrow\left[\sum_{i=1}^q\lambda_i(\varphi_i)'_x(\bar{x},\bar{y})=0\right]$$
$$if\ \ \lambda_i\ge 0\ \ and\ \ \lambda_i\varphi_i(\bar{x},\bar{y})=0\ \ for\ \ i=1,\dots,r$$

is necessary for the pseudo-Lipschitzian property of Φ *around* $(\bar{x},\bar{y})$ *provided that*

$$[\lambda_1\varphi_1'(\bar{x},\bar{y})+\cdots+\lambda_q\varphi_q'(\bar{x},\bar{y})]\Longrightarrow\lambda_i=0\ \ for\ \ i=1,\dots,q$$
$$if\ \ \lambda_i\ge 0\ \ and\ \ \lambda_i\varphi_i(\bar{x},\bar{y})=0\ \ for\ \ i=1,\dots,r.$$

Proof. This follows from Theorem 6.1 with $g=(\varphi_1,\dots,\varphi_q):X\times Y\to\mathbf{R}^q$, $\Omega=X\times Y$, and Λ defined in (6.3) by taking into account representations (2.5) and

$$N(g(\bar{x},\bar{y});\Lambda)=\{(\lambda_1,\dots,\lambda_q)\in\mathbf{R}^q|\ \lambda_i\ge 0\ \text{ with }\ \lambda_i\varphi_i(\bar{x},\bar{y})=0\ \text{ for }\ i=1,\dots,r\}.\quad\square$$

Next we provide a local sensitivity analysis for *generalized equations* and find effective conditions ensuring the pseudo-Lipschitzian property of the parametric solution sets (6.4).

THEOREM 6.4. *Let* Φ *be defined by* (6.4), *where* $f:X\times Y\to W$ *is continuous around* $(\bar{x},\bar{y})\in\text{gph }\Phi$ *and where* $Q:Y\rightrightarrows W$ *has closed graph around* $(\bar{y},\bar{w})$ *with* $\bar{w}:=-f(\bar{x},\bar{y})$. *Assume that both* Y *and* W *are Asplund, that* $\dim X<\infty$, *and that* Q *is normally compact around* $(\bar{y},\bar{w})$. *Then the condition*

$$[(x^\star,-y^\star)\in D^\star f(\bar{x},\bar{y})(w^\star)\ \ and\ \ y^\star\in D^\star Q(\bar{y},\bar{w})(w^\star)]\Longrightarrow x^\star=0,\ y^\star=0,\ w^\star=0\tag{6.16}$$

is sufficient for Φ *to be pseudo-Lipschitzian around* $(\bar{x},\bar{y})$. *Moreover, in this case one has the upper modulus estimate*

$$(\text{plip }\Phi)(\bar{x},\bar{y})\le\sup\{\|x^\star\|\ \ s.t.\ \ (x^\star,-y^\star)\in D^\star f(\bar{x},\bar{y})(y^\star)+(0,D^\star Q(\bar{y},\bar{w})(w^\star))\ \ with\ \ (y^\star,w^\star)\in Y^\star\times W^\star,\ \|y^\star\|\le 1\}.\tag{6.17}$$

Proof. Let us represent (6.4) in form (6.1) with data (6.5) and evaluate the coderivative of this Φ using inclusion (6.14). In order to do it, we first compute the coderivative of g in (6.5). For this g one obviously has

$$g(x,y)=g_1(x,y)+g_2(x,y),\tag{6.18}$$

where $g_1(x,y):=(y,0)$ and $g_2(x,y):=(0,-f(x,y))$. It is easy to see that

$$D^\star g_1(\bar{x},\bar{y})(u^\star,-w^\star)=(0,u^\star)\ \text{ and }\ D^\star g_2(\bar{x},\bar{y})(u^\star,-w^\star)=D^\star f(\bar{x},\bar{y})(w^\star)$$

for all $(u^\star, w^\star) \in Y^\star \times W^\star$. Now applying the coderivative sum rule [36, Theorem 3.6] in (6.18), we get

$$D^\star g(\bar{x}, \bar{y})(u^\star, -w^\star) = (0, u^\star) + D^\star f(\bar{x}, \bar{y})(w^\star).$$

According to (6.14) this yields the inclusion

$$D^\star \Phi(\bar{x}, \bar{y})(y^\star) \subset \{x^\star \in X^\star |\ (x^\star, -y^\star) \in D^\star f(\bar{x}, \bar{y})(w^\star) + (0, D^\star Q(\bar{y}, \bar{w})(w^\star))\} \tag{6.19}$$

for the coderivative of (6.4). Finally substituting (6.19) into (5.7) and (5.8), we derive conclusions (6.16) and (6.17) of the theorem from the corresponding results of Theorem 5.4(I). □

COROLLARY 6.5. *Let f be strictly Lipschitzian at $(\bar{x}, \bar{y})$, in addition to the other assumptions in Theorem* 6.4. *Then the solution map* (6.4) *is pseudo-Lipschitzian around $(\bar{x}, \bar{y})$ if one has*

$$[0 \in \mathrm{proj}_y \partial\langle w^\star, f\rangle(\bar{x}, \bar{y}) + D^\star Q(\bar{y}, \bar{w})(w^\star)] \Longrightarrow w^\star = 0, \tag{6.20}$$

where $\mathrm{proj}_y \partial\langle w^\star, f\rangle(\bar{x}, \bar{y})$ *denotes the projection of the set* $\partial\langle w^\star, f\rangle(\bar{x}, \bar{y}) \subset X^\star \times Y^\star$ *on the space* $Y^\star$.

Proof. When f is strictly Lipschitzian at $(\bar{x}, \bar{y})$, condition (6.20) is equivalent to (6.16) due to Proposition 2.5. □

Finally let us consider the generalized equation in (6.4), where f is *strictly differentiable* at $(\bar{x}, \bar{y})$. In this case we introduce the adjoint relationship of the same (but linearized/homogenized and unperturbed) form

$$0 \in (f'_y(\bar{x}, \bar{y}))^\star w^\star + D^\star Q(\bar{y}, \bar{w})(w^\star), \tag{6.21}$$

which is called the *adjoint generalized equation* to (6.4) at $(\bar{x}, \bar{y})$. Now we are able to obtain *sufficient* as well as *necessary* conditions for the pseudo-Lipschitzian property of the original solution map (6.4) in the form of *Fredholm's alternative*.

THEOREM 6.6. *Let Φ be given by* (6.4), *where f is strictly differentiable at $(\bar{x}, \bar{y})$ in the framework of Theorem* 6.4. *Then the following hold:*

(I) *Assume that* $\dim X < \infty$ *and either*

(h1) *both Y and W are Asplund while Q is normally compact around $(\bar{y}, \bar{w})$, or*

(h2) *Y is Banach and the operator $f'_x(\bar{x}, \bar{y}) : X \to W$ is invertible (hence* $\dim W < \infty$).

Then Φ is pseudo-Lipschitzian around $(\bar{x}, \bar{y})$ if the adjoint generalized equation (6.21) *has only the trivial solution, i.e.,*

$$[0 \in (f'_y(\bar{x}, \bar{y}))^\star w^\star + D^\star Q(\bar{y}, \bar{w})(w^\star)] \Longrightarrow w^\star = 0. \tag{6.22}$$

Moreover, under these assumptions one has the upper modulus estimate

$$\begin{aligned}(\mathrm{plip}\ \Phi)(\bar{x}, \bar{y}) \le \sup\{\|(f'_x(\bar{x}, \bar{y}))^\star w^\star\| \ \ &s.t.\ \exists y^\star \in D^\star Q(\bar{y}, \bar{w})(w^\star)\\ &with\ \ \|(f'_y(\bar{x}, \bar{y}))^\star w^\star + y^\star\| \le 1\}.\end{aligned} \tag{6.23}$$

(II) *Assume that* $\dim Y < \infty$ *and either*

(h3) *both X and W are Asplund,* $\mathrm{Ker}(f'_x(\bar{x}, \bar{y}))^\star = \{0\}$ *while the graph of Q is regular at $(\bar{y}, \bar{w})$, or*

(h4) *both X and W are Banach while the operator $f'_x(\bar{x}, \bar{y})$ is invertible.*

Then condition (6.22) *is necessary for* Φ *to be pseudo-Lipschitzian around* $(\bar{x},\bar{y})$*, and one has the opposite inequality in* (6.23)*.*

Proof. It is easy to see that the sufficiency part (I) of the theorem follows from Corollary 6.5 under assumptions (h1). To establish (I) under assumptions (h2), we observe that the operator $g : X \times Y \to Y \times W$ defined in (6.5) has the invertible strict derivative at $(\bar{x},\bar{y})$ if the linear operator $f'_x(\bar{x},\bar{y}) : X \times Y \to W$ is invertible. In this case conditions (6.7) and (6.8) are automatic while (6.6) is equivalent to (6.22) and yields the pseudo-Lipschitzian property of (6.4) due to Theorem 6.1(I). The upper estimate (6.23) follows from (6.17) due to formula (2.5). This ends the proof of (I).

The necessity part (II) of the theorem follows from Theorem 6.1(II) for the special structure (6.5). □

COROLLARY 6.7. *Condition* (6.22) *is necessary and sufficient for the pseudo-Lipschitzian property of the solution map* (6.4) *around* $(\bar{x},\bar{y})$ *when spaces* X *and* Y *are finite dimensional and one of the following groups of hypotheses is fulfilled:*

(h1) W *is Asplund,* $\mathrm{Ker}(f'_x(\bar{x},\bar{y}))^\star = \{0\}$*,* Q *is normally compact around* $(\bar{y},\bar{w})$ *while the graph of* Q *is regular at this point;*

(h2) $\dim W < \infty$ *and* $f'_x(\bar{x},\bar{y})$ *is invertible.*

In both cases (h1) *and* (h2) *equality holds in* (6.23)*, where the supremum is attained.*

Proof. This follows directly from Theorem 6.6, combining assertions (I) and (II) therein. We can conclude that the supremum is attained in (6.23) because both spaces X and Y are finite dimensional; cf. [30]. □

Remark 6.8. Similarly to [27, 29, 30] in the finite-dimensional case, we can consider various concretizations and refinements of the results obtained when the multifunction Q admits some special representations. In particular, let $Q : Y \rightrightarrows Y^\star$ be a *subdifferential mapping*, i.e.,

$$Q(y) = \begin{cases} \partial\varphi(y) & \text{if } |\varphi(y)| < \infty, \\ \emptyset & \text{otherwise,} \end{cases} \tag{6.24}$$

in terms of the subdifferential (2.6) of an extended-real-valued function. Then the pseudo-Lipschitzian property of the solution map (6.4) generated by (6.24) can be characterized by the *second-order subdifferential* of φ at $(\bar{y},\bar{w}) \in \mathrm{gph}\,\partial\varphi$ defined as

$$\partial^2\varphi(\bar{y},\bar{w})(w^\star) := (D^\star\partial\varphi)(\bar{y},\bar{w})(w^\star).$$

Note that subdifferential mappings (6.24) cover the case of *variational inequalities and complementarity problems* in (6.4) when φ is the indicator function of a convex set. Note also that another approach [29] can be developed to obtain refined sufficient conditions for Lipschitzian stability of infinite-dimensional variational systems like (6.4).

Remark 6.9. Results of this paper related to *sufficient* conditions for openness, metric regularity, and Lipschitzian stability of set-valued mappings as well as their applications to sensitivity analysis can be obtained in broader classes of Banach spaces using different subdifferential structures. Indeed, one can observe that the proof of the main Theorem 4.2(I) holds true for *sequential* limits of any subdifferentials satisfying the "zero fuzzy calculus" rule of Proposition 2.4 in appropriate Banach spaces. Such a rule appears to be important for all reasonable subdifferentials, and now it is known for most subdifferential constructions used in applications; see, e.g., the recent paper [6] and its references. In this connection let us note that, for an arbitrary Banach space, our basic subdifferential (2.6) is included in the sequential closure of *any* subdifferential satisfying the "zero fuzzy calculus" rule mentioned above; see [35, Theorem 9.7].

FIRST- AND SECOND-ORDER SUFFICIENT OPTIMALITY CONDITIONS FOR BANG-BANG CONTROLS*

ANDREI V. SARYCHEV†

Abstract. We study L_1-local optimality of a given control $\tilde{u}(\cdot)$ in the time-optimal control problem for an affine control system. We start with the necessary optimality condition—the Pontryagin maximum principle, which selects the candidates for minimizers, the extremal controls. Generally the corresponding Pontryagin extremals consist of bang-bang and singular subarcs, separated by switching points. In the present paper we treat only pure bang-bang extremals. We introduce extended first and second variations along a bang-bang extremal and establish first- and second-order sufficient optimality conditions for the bang-bang extremal controls.

Key words. optimal control problem, Pontryagin maximum principle, bang-bang extremals, sufficient optimality conditions

AMS subject classifications. 49K30, 93C10

1. Introduction.

We consider a nonlinear time-optimal control problem:

$$t \to \min, \tag{1.1}$$

$$\dot{q} = f(q) + G(q)u(\tau),\ q(0) = q_0,\ q \in M,\ u \in U, \tag{1.2}$$

$$q(t) = q_1, \tag{1.3}$$

for an affine control system (1.2) with end-point condition (1.3) on a C^∞-smooth n-dimensional manifold M. Here $G(q) = (g^1(q), \dots, g^r(q))$ and $f(q), g^1(q), \dots, g^r(q)$ are C^∞-smooth vector fields on M; admissible controls $u(\tau) = (u_1(\tau), \dots, u_r(\tau))$ are measurable and take their values in a convex compact polyhedron $U \subset R^r$.

We set the problem of L_1-*local optimality* according to the following definition.

DEFINITION 1.1. *A pair* $(\tilde{u}(\cdot), \tilde{q}(\cdot))$ *meeting* (1.2)–(1.3) *for* $t = T$ *is called* L_1 *locally optimal if there exist* $\Delta > 0$ *and a ball* $\mathcal{U} \supset \tilde{u}(\cdot)$ *in* $L_1^r[0, T]$ *such that no admissible control from* $\mathcal{U}$ *can steer the system* (1.2) *from* q_0 *to* q_1 *in time* $T' \in [T - \Delta, T)$.

A first-order optimality condition for the problem (1.1)–(1.3) is provided by the *Pontryagin maximum principle* (see [7]). If a pair $(\tilde{u}(\cdot), \tilde{q}(\cdot))$ meets this principle for some covector function (Hamiltonian multiplier) $\tilde{\zeta}(\cdot)$, then the triple $(\tilde{u}(\cdot), \tilde{q}(\cdot), \tilde{\zeta}(\cdot))$ is called a *Pontryagin extremal* and $\tilde{u}(\cdot)$ is called the *extremal control.* There can exist different Pontryagin extremals with different $\tilde{\zeta}(\cdot)$ corresponding to the same extremal control $\tilde{u}(\cdot)$.

In what follows we assume that the extremal control $\tilde{u}(\cdot)$ is a piecewise C^1-smooth function of τ. Then due to the Pontryagin maximum principle the domain $[0, T]$ of $\tilde{u}(\cdot)$ can be subdivided into subintervals $0 = \tau_0 < \tau_1 < \cdots < \tau_m < \tau_{m+1} = T$ in such way that for each $\tau \in (\tau_i, \tau_{i+1})$ the maximality condition of the Pontryagin maximum principle is fulfilled on a k_i-dimensional ($k_i \geq 0$) face W_i of the polyhedron U. The

†Department of Mathematics, University of Aveiro, 3810, Aveiro, Portugal (ansar@mat.ua.pt).

subinterval (τ_i, τ_{i+1}) is called *bang-bang* if $k_i = 0$; i.e., the maximum is achieved at a vertex of U and is called *singular* if k_i is positive. The points τ_i $(i = 1, \dots, m)$ are called *switching points*.

As is well known, the extremality of control $\tilde{u}(\cdot)$ does not imply its optimality. To ascertain optimality one should at least investigate the *second variation* of the control system (1.2) on singular subintervals. But even *bang-bang Pontryagin extremals*, which have no singular arcs, may happen to be nonoptimal. Corresponding examples, as well as some high-order necessary optimality conditions for bang-bang extremals, can be found in [4, 15, 16, 17].

One should note a characteristic feature of bang-bang Pontryagin extremals: the first variation of the system (1.2) along these extremals cannot be nontrivially nullified. Due to this fact the traditional approach of the calculus of variations and optimal control theory is no longer valid in the bang-bang case, since the first-order conditions do not guarantee optimality, while high-order variations, which according to this approach are to be defined on the kernel of the first variation, simply do not exist because this kernel is trivial.

To overcome the difficulties we shall introduce below an extension of the first variation by adding to the space of admissible variations of the extremal control $\tilde{u}(\cdot)$ some finite-dimensional space of Dirac measures, located at the switching points of the extremal. This extension gives new addends for the first and the second variations, which are called *first* and *second variations of the system at switching points of extremal*.

Studying the first variation at switching points we derive a *first-order sufficient condition of L_1-local optimality* for bang-bang Pontryagin extremals (Theorem 6.1). When this condition is not met for a bang-bang extremal, we bring into consideration a corresponding *second variation at switching points*. It is a finite-dimensional quadratic form and its *negative definiteness* is the crucial point for setting *second-order sufficient conditions of optimality* for bang-bang Pontryagin extremals (Theorems 7.1 and 7.2).

In a forthcoming paper we are going to present a Legendre–Jacobi–Morse-type theory of the second variation for Pontryagin extremals, containing both bang-bang and singular arcs, and establish for these extremals second-order sufficient optimality conditions. Most of these results has been published in the preprint [13]; part of the formulations have been presented in [12, 14].

2. Preliminaries. Below we introduce some notation of *chronological calculus* developed by Agrachev and Gamkrelidze. The details are to be found in [1, 3].

Let $C^\infty(M)$ be an algebra of infinitely differentiable or smooth functions on M. The value of $\varphi \in C^\infty(M)$ at a point $q \in M$ is denoted by $q \circ \varphi$. The correspondence $\varphi \mapsto q \circ \varphi$ defines a multiplicative functional on M. A diffeomorphism $P : M \to M$ is identified with the corresponding automorphism of $C^\infty(M)$: $\varphi(\cdot) \mapsto P \circ \varphi(\cdot) = \varphi(P(\cdot))$. The group of diffeomorphisms $P : M \to M$ is denoted by $\mathrm{Diff}M$. The value of $P \in \mathrm{Diff}M$ at a point $q \in M$ is denoted $q \circ P$. Smooth vector fields on M are arbitrary derivations of the algebra $C^\infty(M)$, or R-linear mappings $Y : C^\infty(M) \to C^\infty(M)$ satisfying the Leibnitz rule: $Y(\varphi\psi) = (Y\varphi)\psi + \varphi(Y\psi)$. The value of a vector field Y at a point $q \in M$ is denoted $q \circ Y$; it belongs to the tangent space T_qM to M at point q. We denote by $[Y, Z]$ the *commutator* or *Lie bracket* of vector fields Y, Z. In local coordinates on M this Lie bracket is calculated as

$$[Y, Z] = \left[\sum_{i=1}^{m} Y_i \partial/\partial x_i, \sum_{i=1}^{m} Z_i \partial/\partial x_i\right] = \sum_{i=1}^{m} (\partial Z_i/\partial x Y - \partial Y_i/\partial x Z)\partial/\partial x_i.$$

The Lie algebra of smooth vector fields on M is denoted by $\mathrm{Vect}M$. Let us note that defining diffeomorphisms and vector fields as operators of $C^\infty(M)$ we embed them in some *linear* space of linear operators $\mathcal{L}(C^\infty(M), C^\infty(M))$.

For $P \in \mathrm{Diff}M$ the symbol $\mathrm{Ad}P$ denotes the following inner automorphism of the Lie algebra. $\mathrm{Vect}M$: $\mathrm{Ad}PY = P \circ Y \circ P^{-1} = (\partial P^{-1}/\partial x Y)(P(\cdot)) = P_*^{-1}Y$. (We denote by $P_*^{-1}Y$ the result of translation of the vector field Y by the diffeomorphism P^{-1}.) For $Y \in \mathrm{Vect}M$ the inner derivation $\mathrm{ad}Y$ of $\mathrm{Vect}M$ is defined as $(\mathrm{ad}Y)Z = [Y, Z]$ $\forall Z \in \mathrm{Vect}M$.

The *Whitney topology* in $C^\infty(M)$ is introduced by means of a family of seminorms $\|\cdot\|_{s,K}$, where $s \geq 0$, K is a compact set ($K \subset M$), and the seminorm $\|\cdot\|_{s,K}$ introduces the topology of uniform convergence of all derivatives of order $\leq s$ on the compact set K. The Whitney topology in the space of vector fields is defined by means of the family of seminorms

$$\|Y\|_{s,K} = \sup\{\|Y\varphi\|_{s,K} : \ \|\varphi\|_{s+1,K} = 1\} \ \forall Y \in \mathrm{Vect}M.$$

The Whitney topology introduces the structure of a Frechet space in $\mathrm{Vect}M$.

A *flow* on M is an absolutely continuous curve $\tau \mapsto P_\tau$ in $\mathrm{Diff}\, M$ ($P_0 = I$—the identical isomorphism) such that $\varphi(P_\tau(\cdot))$ is absolutely continuous with respect to τ for every $\varphi \in C^\infty(M)$. A *time-dependent vector field* on M is a locally integrable curve $\tau \mapsto Y_\tau$ in $\mathrm{Vect}M$ such that $\forall \varphi \in C^\infty(M)$, the function $(Y_\tau \varphi)(q)$ is measurable with respect to τ for every $q \in M$ and

$$\int_{t_1}^{t_2} \|Y_\tau \varphi\|_{s,K} d\tau < +\infty \ \forall t_1 \leq t_2, \ \forall s, K.$$

A time-dependent vector field $\tau \mapsto Y_\tau$ defines the ordinary differential equation $\dot{q}(\tau) = q(\tau) \circ Y_\tau$ on the manifold M; if every solution of the differential equation is defined $\forall \tau \in R$, then the vector field Y_τ is called complete. A complete vector field Y_τ defines a flow P_τ ($\tau \in R$) on M, the unique solution of the operator differential equation

$$dP_\tau/d\tau = P_\tau \circ Y_\tau, \ P_0 = I. \tag{2.1}$$

This solution can be represented (see [1, 3]) as *right chronological exponential* in Y_τ, denoted by $P_t = \overrightarrow{\exp} \int_0^t Y_\tau d\tau$. If the vector field Y_τ is time independent, i.e., $Y_\tau \equiv Y$, then the corresponding flow is denoted by $P_t = e^{tY}$.

Let us also introduce the *Volterra expansion*, or *Volterra series*, for the chronological exponential $\overrightarrow{\exp} \int_0^t Y_\tau d\tau$. It is expressed as follows (see [1, 3]):

$$\overrightarrow{\exp} \int_0^t Y_\tau d\tau \asymp I + \sum_{i=1}^{\infty} \int_0^t d\tau_1 \int_0^{\tau_1} d\tau_2 \ldots \int_0^{\tau_{i-1}} d\tau_i (Y_{\tau_i} \circ \cdots \circ Y_{\tau_1}) = I + \int_0^t Y_{\tau_1} d\tau_1$$
$$+ \int_0^t \int_0^{\tau_1} (Y_{\tau_2} \circ Y_{\tau_1}) d\tau_2 d\tau_1 + \int_0^t \int_0^{\tau_1} \int_0^{\tau_2} (Y_{\tau_3} \circ Y_{\tau_2} \circ Y_{\tau_1}) d\tau_3 d\tau_2 d\tau_1 + \cdots. \tag{2.2}$$

One can prove that the Volterra series (2.2) provides an asymptotic approximation for $\overrightarrow{\exp} \int_0^t Y_\tau d\tau$. Namely, according to [1], $\forall \varphi \in C^\infty(M)$

$$\left\| \overrightarrow{\exp} \int_0^t Y_\tau d\tau - \left(I + \sum_{i=1}^{\ell-1} \int_0^t d\tau_1 \int_0^{\tau_1} d\tau_2 \ldots \int_0^{\tau_{i-1}} d\tau_i (Y_{\tau_i} \circ \cdots \circ Y_{\tau_1}) \right) \varphi \right\|_{s,K}$$
$$\leq C e^{(c_2 \int_0^t \|Y_\tau\|_{s,\tilde{K}} d\tau)} \left(\int_0^t \|Y_\tau\|_{s+\ell-1,\tilde{K}} d\tau \right)^\ell \|\varphi\|_{s+\ell,\tilde{K}}, \tag{2.3}$$

where $\tilde{K}$ is some compact neighborhood of the compact set K. Since further on we deal with some neighborhood of a continuous curve $\tilde{q}(\cdot) : [0,T] \to M$, then without lack of generality we may assume M to be compact or, all the same, ignore dependence of $\|\cdot\|_{s,K}$ on K.

It follows also from the results of [1] that

$$\left\|\left(\int_0^t d\tau_1 \int_0^{\tau_1} d\tau_2 \ldots \int_0^{\tau_{\ell-1}} d\tau_\ell (Y_{\tau_\ell} \circ \cdots \circ Y_{\tau_1})\right)\varphi\right\|_s \le C\left(\int_0^t \|Y_\tau\|_{s+\ell-1} d\tau\right)^\ell \|\varphi\|_{s+\ell}.$$

We put

$$\left\|\left(\int_0^t d\tau_1 \int_0^{\tau_1} d\tau_2 \ldots \int_0^{\tau_{\ell-1}} d\tau_\ell (Y_{\tau_\ell} \circ \cdots \circ Y_{\tau_1})\right)\right\|$$
$$= \sup\left\{\left\|\int_0^t d\tau_1 \int_0^{\tau_1} d\tau_2 \ldots \int_0^{\tau_{\ell-1}} d\tau_\ell (Y_{\tau_\ell} \circ \cdots \circ Y_{\tau_1})\varphi\right\|_0 \ : \ \|\varphi\|_\ell = 1\right\}$$

and

$$\left\|q_0 \circ \left(\int_0^t d\tau_1 \int_0^{\tau_1} d\tau_2 \ldots \int_0^{\tau_{\ell-1}} d\tau_\ell (Y_{\tau_\ell} \circ \cdots \circ Y_{\tau_1})\right)\right\|$$
$$= \inf_{\mathcal{V}} \sup\left\{\left\|\int_0^t d\tau_1 \int_0^{\tau_1} d\tau_2 \ldots \int_0^{\tau_{\ell-1}} d\tau_\ell (Y_{\tau_\ell} \circ \cdots \circ Y_{\tau_1})\varphi\right\|_0 \ | \right.$$
$$\left. \operatorname{supp}\varphi \subset \mathcal{V},\ \|\varphi\|_\ell = 1\right\} \tag{2.4}$$

with the infimum taken over the set of all neighborhoods $\mathcal{V}$ of the point $q_0 \in M$.

Finally, if $\zeta \in \mathcal{T}^*_{q_0}M$ is a covector, then we put

$$\left\|\left\langle \zeta, q_0 \circ \left(\int_0^t d\tau_1 \int_0^{\tau_1} d\tau_2 \ldots \int_0^{\tau_{\ell-1}} d\tau_\ell (Y_{\tau_\ell} \circ \cdots \circ Y_{\tau_1})\right)\right\rangle\right\|$$
$$= \inf_{\mathcal{V}} \sup\left\{\left\|\int_0^t d\tau_1 \int_0^{\tau_1} d\tau_2 \ldots \int_0^{\tau_{\ell-1}} d\tau_\ell (Y_{\tau_\ell} \circ \cdots \circ Y_{\tau_1})\varphi\right\|_0 \ | \right.$$
$$\left. \operatorname{supp}\varphi \subset \mathcal{V},\ d\varphi|_{q_0} = \zeta,\ \|\varphi\|_\ell = 1\right\}. \tag{2.5}$$

If one considers a family of operators $\mathrm{Ad}P_t$ produced by a flow $\overrightarrow{\exp}\int_0^t Y_\tau d\tau$, then differentiating $\mathrm{Ad}P_t Z = P_t \circ Z \circ P_t^{-1}$ with respect to t, one obtains

$$d(\mathrm{Ad}P_t Z)/dt = \mathrm{Ad}P_t \circ \mathrm{ad}Y_t Z \ \forall Z \in \mathrm{Vect}M,$$

or after omission of Z : $d(\mathrm{Ad}P_t)/dt = \mathrm{Ad}P_t \circ \mathrm{ad}Y_t$. This means, that $\mathrm{Ad}P_t$ satisfies an operator differential equation similar to (2.1) and justifies the notation

$$\mathrm{Ad}\left(\overrightarrow{\exp}\int_0^t Y_\tau d\tau\right) = \overrightarrow{\exp}\int_0^t \mathrm{ad}Y_\tau d\tau.$$

This last chronological exponential also admits the Volterra expansion

$$\overrightarrow{\exp}\int_0^t \mathrm{ad}Y_\tau d\tau \asymp I + \sum_{i=1}^\infty \int_0^t d\tau_1 \int_0^{\tau_1} d\tau_2 \ldots \int_0^{\tau_{i-1}} d\tau_i (\mathrm{ad}Y_{\tau_i} \circ \cdots \circ \mathrm{ad}Y_{\tau_1}).$$

Let us assume for the moment that time-dependent vector fields Y_τ and $Y_\tau + Z_\tau$ are complete. The following variant of the variation of constants formula appeared in [1]; it represents the flow $\overrightarrow{\exp}\int_0^t (Y_\tau + Z_\tau)d\tau$ as a perturbation of the flow $\overrightarrow{\exp}\int_0^t Y_\tau d\tau$:

$$\overrightarrow{\exp}\int_0^t (Y_\tau + Z_\tau)d\tau = \overrightarrow{\exp}\int_0^t \mathrm{Ad}\left(\overrightarrow{\exp}\int_0^\tau Y_\theta d\theta\right) Z_\tau d\tau \circ \overrightarrow{\exp}\int_0^t Y_\tau d\tau.$$

By virtue of the aforesaid one may also write

$$\overrightarrow{\exp}\int_0^t (Y_\tau + Z_\tau)d\tau = \overrightarrow{\exp}\int_0^t \overrightarrow{\exp}\int_0^\tau \mathrm{ad}Y_\theta d\theta Z_\tau d\tau \circ \overrightarrow{\exp}\int_0^t Y_\tau d\tau. \tag{2.6}$$

3. Local properties of end-point mapping and optimality. Let $\tilde{u}(\tau)$ be an admissible control which steers the system (1.2) from q_0 to q_1 in time T. In what follows we always assume that the final moment T is a generic (Lebesgue) point of $\tau \mapsto \tilde{u}(\tau)$ (a non-Lebesgue point would require minor modifications to the transversality condition of the Pontryagin maximum principle and of the high-order conditions which are presented below).

Let us put $\tilde{f}_\tau(q) = f(q) + G(q)\tilde{u}(\tau)$ and denote by $\tilde{P}_t = \overrightarrow{\exp}\int_0^t \tilde{f}_\tau d\tau$ $(t \in [0,T])$ the solution of ordinary differential equation

$$\partial P_\tau / d\tau = P_\tau \circ \tilde{f}_\tau,\ \tau \in [0,T],\ P_0 = I.$$

Let $u(\cdot)$ be an admissible variation of $\tilde{u}(\cdot)$, i.e., $\tilde{u}(\tau)+u(\tau) \in U$ for every $\tau \in [0,T]$. We consider a family of mappings $F_t : L^r_\infty \to M$ defined on the space of admissible variations. For a given t the mapping F_t maps $u(\cdot)|_{[0,t]}$ into the point

$$q(t) = q_0 \circ \overrightarrow{\exp}\int_0^t (\tilde{f}_\tau + Gu(\tau))d\tau$$

of the trajectory $q(\cdot)$ of the system (1.2) driven by $\tilde{u}(\cdot) + u(\cdot)$. When $t = T$ we will call F_T an *end-point mapping*.

It is known (see [1, 3]) that F_t is C^∞-smooth with respect to $u(\cdot)$ in some neighborhood of the origin of $L^r_\infty[0,T]$. By virtue of the variation of constants formula (2.6) one can represent F_t as

$$\begin{aligned} F_t(u(\cdot)) &= q_0 \circ \overrightarrow{\exp}\int_0^t (\tilde{f}_\tau + Gu(\tau))d\tau \\ &= q_0 \circ \overrightarrow{\exp}\int_0^t \left(\overrightarrow{\exp}\int_0^\tau \mathrm{ad}\tilde{f}_\theta d\theta\right) Gu(\tau)d\tau \circ \overrightarrow{\exp}\int_0^t \tilde{f}_\tau d\tau. \end{aligned} \tag{3.1}$$

It is often more suitable to use a family of mappings $\Phi(u(\cdot)) = F_t(u(\cdot)) \circ \tilde{P}_t^{-1}$ in place of F_t. To calculate Φ_t one should map $u(\cdot)$ into $q(t)$ by means of F_t and then pull the result back by $\tilde{P}_t^{-1} = (\overrightarrow{\exp}\int_0^t \tilde{f}_\tau d\tau)^{-1}$. It follows from (3.1) that Φ_t can be represented as

$$\Phi_t(u(\cdot)) = q_0 \circ \overrightarrow{\exp}\int_0^t X_\tau u_\tau d\tau, \tag{3.2}$$

where

$$X_\tau = (X^1_\tau, \ldots, X^r_\tau),\ X^i_\tau = \overrightarrow{\exp}\int_0^\tau \mathrm{ad}\tilde{f}_\theta d\theta g^i\ (i = 1, \ldots, r). \tag{3.3}$$

This means that Φ_t is determined by a time-dependent differential equation

$$\dot{q}(\tau) = q(\tau) \circ X_\tau u(\tau),\ q(0) = q_0, \tag{3.4}$$

which is linear (homogeneous) with respect to the control u.

Obviously $\Phi_t(0) = q_0$ for any t. We call Φ_T the *pulled-back end-point mapping* (below the words pulled-back are omitted for the sake of brevity).

Taking the Volterra expansion (see (2.2) for the chronological exponential (3.2) (with $t = T$), we obtain Taylor expansion for Φ_T:

$$\begin{aligned}\Phi_T(u(\cdot)) = q_0 + q_0 \circ \int_0^T X_\tau d\tau + q_0 \circ \int_0^T \int_0^\tau X_\xi u(\xi) d\xi \circ X_\tau u(\tau) d\tau \\ + q_0 \circ \int_0^T \int_0^\tau \int_0^\xi X_\theta u(\theta) d\theta \circ X_\xi u(\xi) d\xi \circ X_\tau u(\tau) d\tau + \cdots .\end{aligned} \tag{3.5}$$

(Let us recall that the vector fields and their compositions, appearing in this formula, belong to the *linear* space of operators over $C^\infty(M)$.)

We are going to establish the relations between the optimality of $\tilde{u}(\cdot)$ and the properties of the end-point mappings F_T and Φ_T. We shall present some (almost trivial) results which provide *sufficient optimality conditions* for $\tilde{u}(\cdot)$ in terms of local properties of F_T and Φ_T. In fact one can hardly apply these results directly, but they are useful as auxiliary tools. To prove optimality we shall verify the conditions of one of these auxiliary propositions.

Let us for a moment consider $F_t(u(\cdot))$ as the mapping defined on the pairs $(t, u(\cdot))$. Define a small (semi)neighborhood W_Δ of $(T, \tilde{u}(\cdot))$ as $W \times (T-\Delta, T]$, where W is small in terms of the L_1-metric neighborhood of $\tilde{u}(\cdot)$ in the space of admissible controls.

For a subset $A \subset M$ let us define a *set of tangent vectors to A at a point $a \in \bar{A}$* as a set of tangent vectors to the C^1-curves $\gamma : [0, \varepsilon) \to M$, starting at $\gamma(0) = a$ and such that $\gamma(\tau) \in A$ for $\tau \in (0, \varepsilon)$.

PROPOSITION 3.1. *Let $F_T(\tilde{u}(\cdot)) = q_1$. If for some small (in terms of the metric of $R \times L_1^r[0, T]$) neighborhood W_Δ of $(T, \tilde{u}(\cdot))$ the vector $q_1 \circ \tilde{f}_T$ does not belong to the set of tangent vectors (at the point q_1) to the image $F_\cdot(W_\Delta)$, then the control $\tilde{u}(\cdot)$ is optimal for the problem* (1.1)–(1.3).

Proof. Indeed, if $\tilde{u}(\cdot)$ is nonoptimal, this means that for some $\varepsilon \in (0, \Delta]$,

$$q_1 \in F_{T-\varepsilon}(W) \subseteq F_\cdot(W_\varepsilon) \subseteq F_\cdot(W_\Delta).$$

Let us consider the trajectory of the control system (1.2), starting at q_1, which is driven by the constant control $u = \tilde{u}(T)$ (or, equivalently, the trajectory of the vector field $\tilde{f}_T$). It follows from the definition of F_t that $q_1 \circ e^{\eta \tilde{f}_T} \in F_{T-\varepsilon+\eta}(W) \subseteq F_\cdot(W_\Delta)$ for $\eta \in [0, \varepsilon]$. Therefore the tangent vector $q_1 \circ \tilde{f}_T$ to the curve $q_1 \circ e^{\eta \tilde{f}_T}$ at q_1 belongs to the set of tangent vectors, and we get a contradiction. □

In what follows we proceed from a stronger hypothesis than that of Proposition 3.1. Namely we will assume the existence of a nonzero covector $\zeta_1 \in \mathcal{T}_{q_1}^* M$, such that the tangent vectors to the image $F_\cdot(W_\Delta)$ belong to the semispace $\{y :\ \langle \zeta_1, y \rangle \le 0\}$ of $\mathcal{T}_{q_1} M$, while $\langle \zeta_1, q_1 \circ \tilde{f}_T \rangle > 0$. When the first-order (with respect to the variation of the final moment T) tangent vector $dF_{T-\varepsilon}(\tilde{u}(\cdot))/d\varepsilon|_{\varepsilon=0} = -q_1 \circ \tilde{f}_T$ belongs to the *open* semispace $\{y :\ \langle \zeta_1, y \rangle < 0\}$, one can easily prove that whenever the tangent vectors to the image $F_T(W)$ (with fixed T!) belong to the semispace $\{y :\ \langle \zeta_1, y \rangle \le 0\}$, then the same holds for the tangent vectors to $F_\cdot(W_\Delta)$. So in this case one can dispense with the variation of the final moment T. This gives the following.

PROPOSITION 3.2. *If there exists a neighborhood (in terms of L_1-metric) W of the control $\tilde{u}(\cdot)$ in the space of admissible controls such that the vector $q_1 \circ \tilde{f}_T$ can be strictly separated by a nonzero covector $\zeta_1 \in \mathcal{T}^*_{q_1}M$ from the set of tangent vectors to the image $F_T(W)$ at the point q_1, then $\tilde{u}(\cdot)$ is optimal for the problem* (1.1)–(1.3).

Finally we will reformulate the Proposition 3.2 by passing from F_T to Φ_T and pulling back the whole consideration from q_1 to q_0.

PROPOSITION 3.3 (auxiliary lemma on optimality). *If there exists a neighborhood (in terms of the L_1-metric) W of the control $\tilde{u}(\cdot)$ in the space of admissible controls such that the vector $Y_T = q_0 \circ Ad(\overrightarrow{\exp} \int_0^T \tilde{f}_\tau d\tau)\tilde{f}_T$ can be strictly separated by a nonzero covector $\zeta_0 \in \mathcal{T}^*_{q_0}M$ from the set of tangent vectors to the image $\Phi_T(W)$ at the point q_0, then $\tilde{u}(\cdot)$ is optimal for the problem* (1.1)–(1.3).

4. First and second variations of control system. Pontryagin maximum principle. In the previous section we have established the relation between optimality of $\tilde{u}(\cdot)$ and local properties of the end-point mappings F_T and Φ_T. These local properties are essentially determined by Taylor expansions of F_T and Φ_T. In this section we define first and second variations of the control system (1.2) which correspond to the first and second differentials of Φ_T. We also formulate the Pontryagin maximum principle, which provides *first-order necessary optimality condition* for $\tilde{u}(\cdot)$.

From the Volterra expansion (3.5) of Φ_T one derives an expression

$$\Phi'_T u(\cdot) = \int_0^T q_0 \circ X_\tau u(\tau) d\tau \tag{4.1}$$

for the (first) differential of Φ_T at the origin of $L^r_\infty[0,T]$; here X_τ is defined according to (3.3). Obviously (4.1) defines linear mapping from $L^r_\infty[0,T]$ into $\mathcal{T}_{q_0}M$.

Let $\tilde{u}(\cdot) \in \mathcal{U}$, where $\mathcal{U}$ is the set of admissible controls of the system (1.2). A *cone of admissible variations* of $\tilde{u}(\cdot)$ is by definition the (convex) conic hull of the set $\mathcal{U} - \tilde{u}(\cdot)$. We denote this cone by $K_{\tilde{u}}\mathcal{U}$.

DEFINITION 4.1. *The restriction of the first differential Φ'_T to the cone $K_{\tilde{u}}\mathcal{U}$ is called the first variation of the system* (1.2) *on $[0,T]$ along the control $\tilde{u}(\cdot)$. The image $\Phi'_T(K_{\tilde{u}}\mathcal{U})$ is called the first variational cone along $\tilde{u}(\cdot)$.*

It is clear, that (for any $\varepsilon > 0$) the first variational cone along $\tilde{u}(\cdot)$ is a subset of the set of tangent vectors to the image $\Phi_T(\mathcal{U}_\varepsilon)$, where $\mathcal{U}_\varepsilon = \{u(\cdot) \in \mathcal{U} : \ \|u - \tilde{u}\|_{L_1} < \varepsilon\}$. The auxiliary lemma on optimality implies that the strict separability of the vector $Y_T = q_0 \circ \mathrm{Ad}(\overrightarrow{\exp} \int_0^T \tilde{f}_\tau d\tau)\tilde{f}_T$ from the set of tangent vectors is sufficient for optimality of $\tilde{u}(\cdot)$. The Pontryagin maximum principle implies (see [7]) that separability of Y_T from the first variational cone along $\tilde{u}(\cdot)$ is necessary for optimality of $\tilde{u}(\cdot)$.

DEFINITION 4.2. *A control $\tilde{u}(\cdot)$ is called an extremal control for the problem* (1.1)–(1.3) *if the vector $Y_T = q_0 \circ Ad(\overrightarrow{\exp} \int_0^T (f + G\tilde{u}(\tau))d\tau)(f + G\tilde{u}(T))$ can be separated from the first variational cone along $\tilde{u}(\cdot)$.*

According to the definition and the Pontryagin maximum principle, any optimal control for the problem (1.1)–(1.3) must be an extremal one.

The separability of the vector Y_T from the first variational cone means the existence of a (possibly nonunique) covector $\zeta_0 \in \mathcal{T}^*_{q_0}M$ such that $\forall u(\cdot) \in K_{\tilde{u}}\mathcal{U}$ the following inequalities hold:

$$\int_0^T \langle \zeta_0, q_0 \circ X_\tau u(\tau)\rangle d\tau \le 0, \tag{4.2}$$

$$\langle \zeta_0, Y_T \rangle \ge 0. \tag{4.3}$$

The last inequality is the so called *transversality condition of Pontryagin maximum principle*. We call its strengthened form,

$$\langle \zeta_0, Y_T \rangle > 0, \tag{4.4}$$

the *strong transversality condition*.

The inequality (4.2) implies the inequalities

$$\langle \zeta_0, q_0 \circ X_\tau(u - \tilde{u}(\tau)) \rangle \le 0 \ \forall u \in U \text{ for almost every } \tau \in [0, T],$$

so that for almost every $\tau \in [0, T]$ we have

$$\tilde{u}(\tau) \in \mathrm{Argmax}_{u \in U} \langle \zeta_0, q_0 \circ X_\tau u \rangle. \tag{4.5}$$

Introducing linear operator $\Xi_\tau : R^r \to \mathcal{T}_{q_0} M$, which maps $u \in R^r$ to $q_0 \circ X_\tau u$, we consider its adjoint operator $\Xi_\tau^* : \mathcal{T}_{q_0}^* M \to R^{r^*}$, and denoting by $\chi_\tau = \Xi_\tau^* \zeta_0$, we transform (4.5) into

$$\tilde{u}(\tau) \in \mathrm{Argmax}_{u \in U} \langle \chi_\tau, u \rangle. \tag{4.6}$$

The covector function χ_τ is called the *switching function*.

The conditions (4.3) and (4.6) can be easily transformed into a standard form of Pontryagin maximum principle. Indeed by the definition of X_τ, the switching function χ_τ can be represented as $\chi_\tau = \tilde{\zeta}(\tau) G(\tilde{q}(\tau))$, where the covector function $\tilde{\zeta}(\cdot)$ is a solution of the *adjoint equation of the Hamiltonian system* with the Hamiltonian

$$H(q, \zeta, u) = \langle \zeta, f(q) + G(q)u \rangle. \tag{4.7}$$

In local coordinates this (linear) adjoint equation has the form

$$\dot{\zeta} = -\partial H / \partial q(\tilde{q}(\tau), \zeta, \tilde{u}(\tau)). \tag{4.8}$$

The initial condition for $\tilde{\zeta}(\cdot)$ is $\zeta(0) = \zeta_0$.

Now we formulate the following.

THEOREM 4.1 (Pontryagin maximum principle [5, 7]). *If $(\tilde{q}(\cdot), \tilde{u}(\cdot), T)$ is a solution of the optimal control problem* (1.1)–(1.3)*, then there exists a nonzero absolutely continuous covector function $\tilde{\zeta} : R \to \mathcal{T}^* M$ meeting the condition $\tilde{\zeta}(t) \in \mathcal{T}_{\tilde{q}(t)} M$ and satisfying in local coordinates the adjoint equation* (4.8) *with the Hamiltonian* (4.7) *such that for $(\tilde{q}(\cdot), \tilde{u}(\cdot), \tilde{\zeta}(\cdot), T)$ the following conditions hold:*

(i) *maximality condition* (*equivalent to* (4.6))*:*

$$H(\tilde{q}(t), \tilde{\zeta}(t), \tilde{u}(t)) = \max\{H(\tilde{q}(t), \tilde{\zeta}(t), u) : \ u \in U\} \ \textit{a.e. on } [0, T]; \tag{4.9}$$

(ii) *transversality condition* (*equivalent to* (4.3))*:*

$$H(\tilde{q}(T), \tilde{\zeta}(T), \tilde{u}(T)) \ge 0. \qquad \square \tag{4.10}$$

We shall call the strong transversality condition the strengthened version of (4.10):

$$H(\tilde{q}(T), \tilde{\zeta}(T), \tilde{u}(T)) > 0. \tag{4.11}$$

Remark 4.1. Since variations of $\tilde{u}(\cdot)$ on subsets $\Omega \subset [0, T]$ of zero measure have no effect, then without loss of generality we may assume that the maximality condition (4.9) is satisfied at *all* points of $[0, T]$.

It is evident that for any $\tau \in [0,T]$ maximum is attained at some (perhaps 0-dimensional) face W_τ of the polyhedron U. We will denote by V_τ a directing subspace of this face; $V_\tau = \operatorname{span}\{W_\tau - w\}$, where $w \in W$ can be chosen arbitrarily. Evidently $\forall v \in V_\tau,\ \tau \in [0,T]:\ \langle \chi_\tau, v\rangle = 0$.

In what follows we assume the mapping $\tau \to V_\tau$ to be piecewise constant with $0 = \tau_0 < \tau_1 < \cdots < \tau_m < \tau_{m+1} = T$ determining the intervals of constancy. We will call $(\tau_i, \tau_{i+1}]$ a *bang-bang interval of the extremal control* $\tilde{u}(\cdot)$ if $\dim V_\tau = 0$, or equivalently W_τ is a vertex of U for $\tau \in (\tau_i, \tau_{i+1})$, and a *singular interval* if $\dim V_\tau > 0$ on (τ_i, τ_{i+1}). The points τ_i are called *switching points*; if τ_i separates two bang-bang intervals, then we shall call it a *bang-bang switching point*. It is obvious that $W_{\tau_i \pm 0} \subseteq W_{\tau_i}$ for any τ_i and $\dim W_{\tau_i} \geq 1$. The face W_{τ_i} is called *face of switching at* τ_i.

In what follows the extremal $(\tilde{u}(\cdot), \tilde{q}(\cdot), \tilde{\zeta}(\cdot))$ (with its switching points) is fixed and we will simplify the notation, putting $X_i, W_i, V_i, X_{i\pm 0}, W_{i\pm 0}, V_{i\pm 0}$ instead of $X_{\tau_i}, W_{\tau_i}, V_{\tau_i},\ X_{\tau_i \pm 0}, W_{\tau_i \pm 0}, V_{\tau_i \pm 0}$.

Let us consider two faces $W \subseteq W'$ of the polyhedron $U \subset R^r$. Obviously, for all points $w \in \operatorname{relint} W$ the conic hulls of the sets $W' - w$ coincide. We shall call any of them the *tangent cone* to W' at W and denote this cone by $\mathcal{K}_W W'$. These tangent cones are closed.

Any of these cones is naturally imbedded into the directing linear space V' of the face W'. The cone $\mathcal{K}_W W'$ is pointed if and only if W is a vertex of U; otherwise the directing space V of the face W is the maximal linear subspace of $\mathcal{K}_W W':\ V = \mathcal{K}_W W' \cap (-\mathcal{K}_W W')$.

Now we introduce certain *genericity assumptions*, which will be involved in the optimality conditions.

Strong genericity assumption for bang-bang switchings. For every bang-bang switching point τ_i the maximum $\max\{H(\tilde{q}(t), \tilde{\zeta}(t), u) :\ u \in U\}$ is achieved on an edge (= 1-dimensional face) of U; the left and right derivatives $\dot{\chi}_{\tau_j \pm 0}$ of the switching function χ_τ are not orthogonal to this edge of switching.

The nonorthogonality of $\dot{\chi}_{\tau_i \pm 0}$ to the edge of switching means that the Pontryagin maximum principle definitely forces the switching. It can be better visualized in the case of scalar u's, when the segment U (for example, $U = [-1,1]$) is the edge itself. Then by virtue of the Pontryagin maximum principle the sign of extremal control $\tilde{u}(\tau)$ must coincide with the sign of the (scalar-valued) function χ_τ. The nonorthogonality turns out in this case to be $\dot{\chi}_{\tau_i \pm 0} \neq 0$, and it implies the transversality of the graph $\tau \mapsto \chi_\tau$ to the τ-axis at the point $(\tau_i, 0)$.

Weak genericity assumption for bang-bang switchings. For every switching point τ_i the maximum $\max\{H(\tilde{q}(t), \tilde{\zeta}(t), u) :\ u \in U\}$ is achieved on a face W_i of U. For the cones $K_i^- = \mathcal{K}_{W_{i-0}} W_i,\ K_i^+ = \mathcal{K}_{W_{i+0}} W_i$ and the switching function χ_τ we have

$$\dot{\chi}_{\tau_i - 0}\xi \neq 0 \quad \forall \xi \in K_i^-; \quad \dot{\chi}_{\tau_i + 0}\xi \neq 0 \quad \forall \xi \in K_i^+. \tag{4.12}$$

Remark 4.2. Actually the inequalities (4.12) together with the maximality condition (4.9) imply more

$$\dot{\chi}_{\tau_i - 0}\xi > 0 \quad \forall \xi \in K_i^-; \quad \dot{\chi}_{\tau_i + 0}\xi < 0 \quad \forall \xi \in K_i^+. \tag{4.13}$$

Remark 4.3. For a bang-bang switching point τ_i the cones K_i^-, K_i^+ are the tangent cones to the face W_j at the vertices $\tilde{u}(\tau_i - 0)$ and $\tilde{u}(\tau_i + 0)$, correspondingly.

Remark 4.4. It is clear that for bang-bang switchings the strong genericity assumption is a particular case of the weak one.

In what follows we assume both the weak genericity assumption and the strong transversality condition to hold for any extremal under consideration.

To introduce the second variation of the system (1.2) along an extremal $(\tilde{u}(\cdot), \tilde{q}(\cdot), \tilde{\zeta}(\cdot))$ on $[0,T]$ we denote by $\ker \Phi'_T$ the kernel of the first variation along $\tilde{u}(\cdot)$, i.e., the set of $u(\cdot) \in K_{\tilde{u}}\mathcal{U}$ such that

$$\int_0^T q_0 \circ X_\tau u(\tau) d\tau = 0. \tag{4.14}$$

Note that the conditions (4.2) and (4.14) imply an inclusion

$$u(\tau) \in V_\tau \text{ a.e. on } [0,T]$$

for any control $u(\cdot) \in \ker \Phi'_T$; in particular, $u(\tau)$ must vanish on the bang-bang intervals of $\tilde{u}(\cdot)$. Obviously $\ker \Phi'_T$ is linear subspace of L^r_∞, which is trivial if $\tilde{u}(\cdot)$ is a bang-bang extremal control.

Returning to the Taylor expansion (3.5) of the mapping Φ_T let us consider its quadratic term. We denote by Φ''_T the restriction of this vector-valued quadratic form to $\ker \Phi'_T$. It is known (see [1, 3, 8]) that Φ''_T can be represented as

$$\Phi''_T(u(\cdot)) = \int_0^T q_0 \circ \left[\int_0^\tau X_\theta u(\theta) d\theta, X_\tau u(\tau) \right] d\tau, \ u(\cdot) \in \ker \Phi'_T.$$

Definition 4.3. *The second variation of the system* (1.2) *along the extremal* $(\tilde{u}(\cdot), \tilde{q}(\cdot), \tilde{\zeta}(\cdot))$ *on* $[0,T]$ *is the projection of* Φ''_T *on the covector* $\zeta_0 = \tilde{\zeta}(0)$*, i.e., the scalar valued quadratic form*

$$\zeta_0 \Phi''_T(u(\cdot)) = \int_0^T \left\langle \zeta_0, q_0 \circ \left[\int_0^\tau X_\theta u(\theta) d\theta, X_\tau u(\tau) \right] \right\rangle d\tau, \ u(\cdot) \in \ker \Phi'_T. \tag{4.15}$$

5. Extended first and second variations of the control system. From now on we deal with a fixed bang-bang Pontryagin extremal $(\tilde{u}(\cdot), \tilde{q}(\cdot), \tilde{\zeta}(\cdot))$. As was already shown, the first variation of the system (1.2) along the bang-bang control $\tilde{u}(\cdot)$ has trivial kernel. This fact on one hand obstructs the construction of high-order variations while on the other hand does not guarantee optimality of $\tilde{u}(\cdot)$. Our idea is to define first variation with extended domain in such a way that the triviality of the kernel of the extended first variation along the bang-bang extremal control $\tilde{u}(\cdot)$ implies L_1-local optimality of $\tilde{u}(\cdot)$. If the extended first variation can be nullified, then we will define on its kernel an extended second variation and formulate second-order sufficient conditions of L_1-local optimality for the bang-bang extremal control $\tilde{u}(\cdot)$.

The extended first and second variations are to be defined via the end-point mapping Φ_T. Let us recall that Φ_T can be represented via chronological exponential $\Phi_T(u(\cdot) = q_0 \circ \overrightarrow{\exp} \int_0^t X_\tau u(\tau) d\tau$, which is in turn defined by the control system

$$\dot{q} = q(\tau) \circ X_\tau u(\tau), \ q(0) = q_0, \tag{5.1}$$

$$X_\tau = (X^1_\tau, \dots, X^r_\tau), \ X^i_\tau = \overrightarrow{\exp} \int_0^\tau \operatorname{ad} \tilde{f}_\theta d\theta g^i \ (i = 1, \dots, r),$$

with admissible controls being admissible variations of $\tilde{u}(\cdot)$.

Let us extend the domain of Φ_T by adding some Dirac measures located at the switching points of the bang-bang extremal. To introduce them let us consider the

directing subspaces $V_j = V_{\tau_j}$ of the switching faces $W_j = W_{\tau_j}$ $(j = 1, \dots, m)$ and consider the generalized functions of the form

$$\omega = \sum_{j=1}^{m} \omega_j \delta(\tau - \tau_j),\ \omega_j \in V_j\ (j = 1, \dots, m), \tag{5.2}$$

where τ_j $(j = 1, \dots, m)$ are the switching points of the extremal. We will denote by $\Delta\{\tau_j, V_j\}$ the set of the generalized controls (5.2).

A natural way to construct extended first and second variations would be by extending the end-point mapping Φ_T onto the extended domain, which includes the Dirac measures (5.2), and then calculating first and second differentials of the extension. To realize this scheme one has to define the generalized trajectories of the control system (5.1), driven by the generalized controls (5.2). These trajectories cannot be constructed in the classical way. Indeed, it is evident that the trajectories should have discontinuities at the points τ_j $(j = 1, \dots, m)$. Therefore when substituting (5.2) into (5.1) and transforming the differential equation into an integral one, we obtain an integral of a discontinous function with respect to the measure (5.2), which has atoms just at the points of discontinuity.

An approach to constructing generalized trajectories for a class of generalized controls, which is much wider than (5.2), has been developed in [9, 10, 11]. (See especially [9, Section 4] and [10, Section 5], where the trajectory of the control system (5.1), driven by a generalized control (5.2), has been calculated explicitly.) Here we do not go into details of the topic, only introducing the definitions of extended first and second variations along the extremal.

DEFINITION 5.1. *Let $\Delta\{\tau_j, V_j\}$ be the set of Dirac measures* (5.2). *The linear operator $\Phi_T^{e'} : \mathcal{K}_{\tilde{u}}\mathcal{U} \oplus \Delta\{\tau_j, V_j\} \to \mathcal{T}_{q_0}M$, defined by*

$$\Phi_T^{e'}(u(\cdot) \oplus \omega) = q_0 \circ \left(\int_0^T X_\tau u(\tau) d\tau + \sum_{j=1}^{m} X_j \omega_j \right), \tag{5.3}$$

is called an extended first variation along the extremal. The summand $q_0 \circ \sum_{j=1}^{m} X_j \omega_j$ is called the first variation at the switching points of the extremal.

This definition is justified by the following proposition.

LEMMA 5.1. *For every $j = 1, \dots, m$ let a δ-sequence of controls $w_k^j(\cdot)$ $(k = 1, \dots)$ tend weakly to the Dirac measure $\omega_j \delta(\tau - \tau_j)$. Put $w_k(\cdot) = \sum_{j=1}^{m} w_k^j(\cdot)$. Then as $k \to \infty$ the values of the first variation*

$$\Phi'_T(u(\cdot) + w_k(\cdot)) = q_0 \circ \left(\int_0^T X_\tau (u(\tau) + w_k(\tau)) \right) d\tau$$

tend to the value of the extended first variation (5.3). □

(Note that we are not able to approximate Dirac measures by *admissible* controls, since the latter are bounded.)

In the next section we will prove that if the extended first variation along the bang-bang extremal has trivial kernel, then the bang-bang extremal control $\tilde{u}(\cdot)$ is optimal.

If the extended first variation along $\tilde{u}(\cdot)$ can be nullified, then we define on its kernel an extended second variation along the extremal.

DEFINITION 5.2. *The extended second variation of the system* (1.2) *along the Pontryagin extremal* $(\tilde{u}(\cdot), \tilde{q}(\cdot), \tilde{\zeta}(\cdot))$ *is the quadratic form*

$$\zeta_0 \Phi_T^{e''} = \frac{1}{2}\left\langle \zeta_0, \int_0^T q_0 \circ \left[\int_0^\tau X_\xi u(\xi)d\xi + \sum_{\tau_j \le \tau} X_j\omega_j, X_\tau u(\tau)\right] d\tau \right.$$

$$\left. + \sum_{i=1}^m q_0 \circ \left[\int_0^{\tau_i} X_\xi u(\xi)d\xi + \sum_{j=1}^i X_j\omega_j, X_i\omega_i\right]\right\rangle, \tag{5.4}$$

where $u(\cdot) \oplus \omega \in \ker \Phi_T^{e'}$, *i.e.,* $u(\cdot) \oplus \omega \in \mathcal{K}_{\tilde{u}}\mathcal{U} \oplus \Delta\{\tau_j, V_j\}$ *and*

$$q_0 \circ \left(\int_0^T X_\tau u(\tau)d\tau + \sum_{j=1}^m X_j\omega_j\right) = 0. \tag{5.5}$$

Putting $u(\cdot) \equiv 0$ in (5.4) and (5.5), one obtains the quadratic form

$$\frac{1}{2}\left\langle \zeta_0, q_0 \circ \left[\sum_{j=1}^i X_j\omega_j, X_i\omega_i\right]\right\rangle \tag{5.6}$$

defined on the kernel of the first variation at the switching points, which is a finite-dimensional subspace:

$$\left\{\omega = (\omega_1, \dots, \omega_m) \in \oplus_{j=1}^m V_j : \ q_0 \circ \sum_{j=1}^m X_j\omega_j = 0\right\}. \tag{5.7}$$

DEFINITION 5.3. *The quadratic form* (5.6) *defined on the subspace* (5.7) *is called the second variation of the system* (1.2) *at the switching points of the extremal* $(\tilde{u}(\cdot), \tilde{q}(\cdot), \tilde{\zeta}(\cdot))$.

Agrachev and Gamkrelidze introduced in [2] a different type of second variation which corresponds to the variation of the moments of switchings. Using this form they established necessary second-order optimality condition for a bang-bang extremal.

6. First-order sufficient optimality condition for bang-bang Pontryagin extremals. As has been already established, the first variation along a bang-bang Pontryagin extremal has trivial kernel; at the same time a bang-bang Pontryagin extremal is not necessarily optimal. We have introduced above the extended first and second variations along a Pontryagin extremal. In this section we shall establish that if the kernel of the extended first variation is also trivial or, equivalently, if the kernel of the first variation at the switching points is trivial, then the Pontryagin extremal is optimal (under few additional assumptions).

DEFINITION 6.1. *We say that second-order horizontality conditions for switchings of the Pontryagin extremal* $(\tilde{u}(\cdot), \tilde{q}(\cdot), \tilde{\zeta}(\cdot))$ *hold if*

$$\langle \tilde{\zeta}(\tau_j), \tilde{q}(\tau_j) \circ [Gv, Gv']\rangle = 0 \ \forall v, v' \in V_j, \ \forall j = 1, \dots, m, \tag{6.1}$$

or, equivalently,

$$\langle \zeta_0, q_0 \circ [X_j v, X_j v']\rangle = 0 \ \forall v, v' \in V_j, \ \forall j = 1, \dots, m \tag{6.2}$$

for all its switching points τ_j $(j = 1, \dots, m)$.

Remark 6.1. If the equality $\langle\tilde{\zeta}(\tau_j), y\rangle = 0$ defines a "horizontal hyperplane" in $T_{\tilde{q}(\tau_j)}M$ (correspondingly, $\langle\tilde{\zeta}_0, y\rangle = 0$ defines a horizontal hyperplane in $T_{q_0}M$), then the equalities (6.1), (6.2) mean that for those controlled vector fields whose values are horizontal, their second-order Lie brackets also have horizontal values. Everywhere below we assume this condition to hold.

Remark 6.2. Goh has established [6] that the fulfillment of the second-order horizontality condition along a singular subarc of extremal is necessary for optimality of this subarc. We require this condition to hold along the degenerate singular subarcs, which are the switching points.

Remark 6.3. If the strong genericity assumption holds, then $\dim V_j = 1$ $(j = 1, \ldots, m)$, and the second-order horizontality condition (6.1) for switchings holds automatically.

THEOREM 6.1 (first-order sufficient optimality condition for bang-bang extremals). *Let the bang-bang Pontryagin extremal* $(\tilde{u}(\cdot), \tilde{q}(\cdot), \tilde{\zeta}(\cdot))$ *meet the strong transversality condition* (4.11)*, the weak genericity assumption* (4.12)*, and the second-order horizontality condition for switchings* (6.1)*. If the first variation at the switching points of the bang-bang extremal has a trivial kernel, i.e.,*

$$q_0 \circ \sum_{i=1}^{m} X_i v_i = 0,\ v_i \in V_i\ (i = 1, \ldots, m) \Rightarrow v_i = 0\ (i = 1, \ldots, m), \tag{6.3}$$

then the bang-bang extremal control $\tilde{u}(\cdot)$ *is optimal for the problem* (1.1)–(1.3). □

Remark 6.4. The triviality of the kernel of the first variation at switching points can be better visualized when the controls u are scalar. Then it amounts to the linear independence of the values of the vector fields $q_0 \circ X_{\tau_j}$ computed for the switching points τ_j $(j = 1, \ldots, m)$. Recall that $q_0 \circ X_{\tau_j}$ (see (5.1) and (3.3)) is the result of pulling back the value of the (unique) controlled vector field g from $\tilde{q}(\tau_j)$ to q_0 by means of $\tilde{P}^{-1}_{\tau_j}$. Obviously the triviality of the kernel limits the number of switchings by $n = \dim M$.

Proof of Theorem 6.1. To establish optimality of $\tilde{u}(\cdot)$ we shall verify the conditions of the auxiliary lemma on optimality (section 4).

Let us choose some positive $\Delta < 1$ in such a way that the intervals $[\tau_j - \Delta, \tau_j + \Delta]$ $(j = 1, \ldots, m)$ are mutually nonintersecting. Consider an arbitrary admissible variation $u(\cdot)$ of the bang-bang control $\tilde{u}(\cdot)$, and take the restriction of $u(\cdot)$ to a subinterval $[\tau_j - \Delta, \tau_j)$. Since $\tilde{u}(\cdot)$ is constant on $[\tau_j - \Delta, \tau_j)$ and takes its value at some vertex η_j^- of the polyhedron U, the admissible variations of $\tilde{u}(\cdot)$ on this interval must take their values in the polyhedral tangent cone $K_{\eta_j^-}$ to U at η_j^- (the convex conic hull of the set $U - \eta_j^-$). Let us consider the tangent cone K_j^- to the face of switching W_j at the point $\tilde{u}(\tau_j - 0) = \eta_j^-$ (see (4.12)). Obviously K_j^- is one of the faces of the cone $K_{\eta_j^-}$. Let us denote by $K_j^{-\natural}$ the convex conic hull of those edges of $K_{\eta_j^-}$ which do not belong to K_j^-. The admissible variation $u(\cdot)|_{[\tau_j - \Delta, \tau_j)}$ can be represented (nonuniquely!) as a sum $u(\tau) = \bar{u}(\tau) + v(\tau)$, with $v(\tau) \in K_j^-$ and $\bar{u}(\tau) \in K_j^{-\natural}$. We can repeat a similar procedure for $u(\cdot)|_{(\tau_j, \tau_j + \Delta]}$ and for all $j = 1, \ldots, m$. Taking the concatenation of all $\bar{u}(\cdot)$'s and $v(\cdot)$'s constructed on the intervals $[\tau_j - \Delta, \tau_j + \Delta]$, we obtain the functions $\bar{u}(\cdot), v(\cdot)$, whose support is located in the set $I^\Delta = \cup_{j=1}^m [\tau_j - \Delta, \tau_j + \Delta]$; $u(\tau) = \bar{u}(\tau) + v(\tau)\ \forall \tau \in I^\Delta$. Finally we will put $\bar{u}(\tau) = u(\tau)$, $v(\tau) = 0$ on $[0, T] \setminus I^\Delta$. Then $u(\tau) = \bar{u}(\tau) + v(\tau)\ \forall \tau \in [0, T]$.

Setting $v_j = \int_{\tau_j-\Delta}^{\tau_j+\Delta} v(\tau)d\tau$ for $j = 1, \dots, m$, we put $v = (v_1, \dots, v_m)$ and denote by $v^s(t)$ the piecewise constant function which equals $v_j/2\Delta$ on $[\tau_j - \Delta, \tau_j + \Delta]$ and vanishes outside I^Δ. We put $|v| = \sum_{j=1}^m |v_j|$. Obviously $|v| = \|v^s(\cdot)\|_{L_1}$. Finally define the function $w(\cdot) = v(\cdot) - v^s(\cdot)$. Evidently $w(\cdot)$ vanishes outside I^Δ and $\int_{\tau_j-\Delta}^{\tau_j+\Delta} w(\tau)d\tau = 0$. We put the triple $(\bar{u}(\cdot), v, w(\cdot))$ into correspondence with an admissible variation $u(\cdot)$ and consider it as a (nonuniquely defined) "coordinatization" of $u(\cdot)$.

Let us introduce the vertical direction in $T_{q_0}M$, a vector $z \in T_{q_0}M$ such that $\langle \zeta_0, z\rangle = 1$. Let us put $\mathcal{V}^1(u(\cdot)) = q_0 \circ \int_0^T X_\tau u(\tau)d\tau$ and denote by $\mathcal{V}^1_v(u(\cdot))$ its vertical projection $\langle \zeta_0, \mathcal{V}^1(u(\cdot))\rangle z$ and by $\mathcal{V}^1_h(u(\cdot)) = \mathcal{V}^1(u(\cdot)) - \mathcal{V}^1_v(u(\cdot))$ its projection onto the horizontal hyperplane $\{y \mid \langle \zeta_0, y\rangle = 0\}$. Let us denote by $\mathcal{V}^2(u(\cdot)) = \Phi_T(u(\cdot)) - \mathcal{V}^1(u(\cdot))$ the first-order remainder term of the Taylor expansion for Φ_T and introduce by analogy its vertical and horizontal components $\mathcal{V}^2_v(u(\cdot))$ and $\mathcal{V}^2_h(u(\cdot))$.

Now we shall derive a lower estimate for the length of $\mathcal{V}^1(u(\cdot)) + \mathcal{V}^2_h(u(\cdot)) \in T_{q_0}M$.

LEMMA 6.2. *If the weak genericity assumption holds for the bang-bang Pontryagin extremal $(\tilde{u}(\cdot), \tilde{q}(\cdot), \tilde{\zeta}(\cdot))$, then there exists a positive constant α and for any sufficiently small $\Delta > 0$ there exists a neighborhood $\mathcal{U}^\Delta$ of the origin by the L_1-norm, such that for all admissible variations $u(\cdot) \in \mathcal{U}^\Delta \cap L^r_\infty[0, T]$ and all possible coordinatizations the inequality*

$$|\mathcal{V}^1(u(\cdot)) + \mathcal{V}^2_h(u(\cdot))| \geq \alpha(\|\bar{u}(\cdot)\|_{L_1} + \Delta^{-2}|v|^2 + \|w(\cdot)\|^2_{L_1}) \tag{6.4}$$

holds. □

The proof of this lemma will be presented below together with the proof of another technical lemma, which provides an upper estimate for the vertical component $|\mathcal{V}^2_v(u(\cdot))|$ of the first-order remainder term.

LEMMA 6.3. *Provided that the second-order horizontality condition for switchings holds, there exists a positive constant A and for any sufficiently small $\Delta > 0$ there exists a neighborhood $\mathcal{U}^\Delta$ of the origin by the L_1-norm such that for any admissible variation $u(\cdot) \in \mathcal{U}^\Delta \cap L^r_\infty[0, T]$ and all possible coordinatizations the inequality*

$$|\mathcal{V}^2_v(u(\cdot))| \leq A\Delta(\|\bar{u}(\cdot)\|_{L_1} + \Delta^{-2}|v|^2 + \|w(\cdot)\|^2_{L_1}) \tag{6.5}$$

holds. □

On the basis of these lemmas one can prove Theorem 6.1 easily. First let us fix some $\Delta_0 > 0$ meeting the condition $1 - \Delta_0 A/\alpha > 0$ and denote by $\mathcal{U}^{\Delta_0}$ the neighborhood of the origin by L_1-metric for which the conclusions of the Lemmas 6.2 and 6.3 hold. Let us denote A/α by κ; $0 < \kappa\Delta_0 < 1$. Then (6.4)–(6.5) imply $\forall u(\cdot) \in \mathcal{U}^{\Delta_0}$

$$\|\mathcal{V}^2_v(u(\cdot))\| \leq \kappa\Delta_0\|\mathcal{V}^1(u(\cdot)) + \mathcal{V}^2_h(u(\cdot))\|$$

and

$$\begin{aligned}\|\Phi_T(u(\cdot))\| &= \|\mathcal{V}^1(u(\cdot)) + \mathcal{V}^2_h(u(\cdot)) + \mathcal{V}^2_v(u(\cdot))\| \\ &\geq (1 - \kappa\Delta_0)\alpha(\|\bar{u}(\cdot)\|_{L_1} + \Delta_0^{-2}|v|^2 + \|w(\cdot)\|^2_{L_1}).\end{aligned}$$

This means that

$$\{u^m(\cdot)\} \in \mathcal{U}^{\Delta_0},\ \Phi_T(u^m(\cdot)) \overset{m\to+\infty}{\longrightarrow} 0 \Longrightarrow \|u^m(\cdot)\|_{L_1} \overset{m\to+\infty}{\longrightarrow} 0 \tag{6.6}$$

and also

$$\Phi_T(u(\cdot)) = 0, u(\cdot) \in \mathcal{U}^{\Delta_0} \Longrightarrow u(\cdot) = 0.$$

The bang-bang extremality of $\tilde{u}(\cdot)$ (see the Pontryagin maximum principle) implies that the vector $\mathcal{V}^1(u(\cdot))$, and hence also the vector $\mathcal{V}^1(u(\cdot)) + \mathcal{V}^2_h(u(\cdot))$, belongs to the open "lower" semispace of $T_{q_0}M$, defined by the inequality $\langle \zeta_0, y\rangle < 0$.

Therefore for any $\Delta < \Delta_0$ $\forall u(\cdot) \in \mathcal{U}^{\Delta}$:

$$|\langle \zeta_0, (\mathcal{V}^1+\mathcal{V}^2)(u(\cdot))\rangle| = |\langle \zeta_0, \Phi_T(u)\rangle| \le |\mathcal{V}^2_v(u(\cdot))| \le A(\Delta\|\bar{u}(\cdot)\|_{L_1}+\Delta^{-1}|v|^2+\Delta\|w(\cdot)\|^2_{L_1})$$

and

$$\|\Phi_T(u(\cdot))\| \ge (1-\kappa\Delta)\alpha(\|\bar{u}(\cdot)\|_{L_1} + \Delta^{-2}|v|^2 + \|w(\cdot)\|^2_{L_1}).$$

Hence

$$\langle \zeta_0, \Phi_T(u)\rangle / \|\Phi_T(u(\cdot))\| \le A\Delta/(1-\kappa\Delta)\alpha = \kappa\Delta/(1-\kappa\Delta) \tag{6.7}$$

for $u(\cdot)$ which are sufficiently close to the origin in the L_1-metric.

Let us consider an arbitrary C^1-smooth curve $\tau \to \gamma(\tau)$ ($\tau \in [0,t]$) starting at $q_0 = \gamma(0)$ and belonging to $\Phi_T(\mathcal{U}^{\Delta_0})$. By virtue of (6.6)–(6.7) its tangent vector at $q_0 = \gamma(0)$ belongs to the nonconvex subcone of $T_{q_0}M$ defined by the inequality

$$\langle \zeta_0, y\rangle \le \frac{\kappa\Delta}{1-\kappa\Delta}\|y\|. \tag{6.8}$$

Recall that $\Delta > 0$ in (6.8) can be chosen arbitrarily small. When $\Delta \to +0$, the right-hand side of this inequality tends to $+0$ and we may conclude that the tangent vectors to the set $\Phi_T(\mathcal{U}^{\Delta_0})$ belong to the closed lower semispace of $T_{q_0}M$ determined by the inequality $\langle \zeta_0, y\rangle \le 0$. Applying the auxiliary lemma on optimality we establish L_1-local optimality of $\tilde{u}(\cdot)$. □

Proof of Lemma 6.2. Using the coordinatization $(\bar{u}(\cdot), v, w(\cdot))$ of the arbitrary admissible variation $u(\cdot)$ of the extremal control $\tilde{u}(\cdot)$ we represent the first variation $\int_0^T q_0 \circ X_\tau u(\tau)d\tau$ as

$$\begin{aligned} q_0 \circ \int_0^T X_\tau u(\tau)d\tau &= q_0 \circ \left(\int_0^T X_\tau \bar{u}(\tau)d\tau \right. \\ &\left. + \sum_{i=1}^m \left(\int_{\tau_i-\Delta}^{\tau_i+\Delta} X_\tau d\tau \right) v_i/2\Delta + \sum_{i=1}^m \int_{\tau_i-\Delta}^{\tau_i+\Delta} X_\tau w(\tau)d\tau \right) \\ = q_0 \circ \left(\int_0^T X_\tau \bar{u}(\tau)d\tau + \sum_{i=1}^m X_i v_i + \sum_{i=1}^m \int_{\tau_i-\Delta}^{\tau_i+\Delta} (X_\tau - X_i)(v_i/2\Delta + w(\tau))d\tau \right). \end{aligned} \tag{6.9}$$

Recall that the notation X_i is for X_{τ_i} $(i = 1, \dots, m)$.

The first and the third summands in the right-hand side of (6.9) belong to the open lower semispace, while the second summand belongs to the horizontal hyperplane.

In accordance with the definition of the coordinatization $u(\cdot) \mapsto (\bar{u}(\cdot), v, w(\cdot))$ of the admissible variations of $\tilde{u}(\cdot)$, the values $\bar{u}(\tau)$ belong to $K^{\natural}_{\tilde{u}(\tau)}U$. By virtue of the maximality condition (4.2) of the Pontryagin maximum principle there exists $a_1 > 0$ such that

$$\max_{u \in K^{\natural}_{\tilde{u}(\tau)}U} \langle \zeta_0, q_0 \circ X_\tau \bar{u}(\tau)\rangle \le -a_1|\bar{u}(\tau)| \ \forall \tau \in [0,T].$$

This gives the estimate for the projection on ζ_0 of the first summand in the right-hand side of (6.9):

$$\left\langle \zeta_0, q_0 \circ \int_0^T X_\tau \bar{u}(\tau) d\tau \right\rangle \leq -a_1 \|\bar{u}(\cdot)\|_{L_1}. \tag{6.10}$$

Since the first variation at the switching points of the extremal control $\tilde{u}(\cdot)$ has a trivial kernel, then the second addend of (6.9) admits a lower estimate:

$$\left| \sum_{i=1}^m q_0 \circ X_i v_i \right| \geq b_3 |v|. \tag{6.11}$$

Since $\dot{X}_\tau$ is continuous with regard to τ on $[\tau_i - \Delta, \tau_i)$ and on $(\tau_i, \tau_i + \Delta]$, then we may assume by virtue of the weak genericity assumption (and decreasing Δ, if necessary), that for some $c_1 > 0$,

$$\begin{aligned} &\langle \zeta_0, q_0 \circ \dot{X}_\tau v \rangle \geq c_1 |v| \ \forall \tau \in [\tau_i - \Delta, \tau_i), \ \forall v \in K_i^-, \ \forall i = 1, \ldots, m, \\ &\langle \zeta_0, q_0 \circ \dot{X}_\tau v \rangle \leq -c_1 |v| \ \forall \tau \in (\tau_i, \tau_i + \Delta], \ \forall v \in K_i^+, \ \forall i = 1, \ldots, m. \end{aligned} \tag{6.12}$$

Therefore, since $v(\tau) \in K_i^-$ for $\tau \in [\tau_i - \Delta, \tau_i)$, $v(\tau) \in K_i^+$ for $\tau \in (\tau_i, \tau_i + \Delta]$, then

$$\left\langle \zeta_0, q_0 \circ \sum_{i=1}^m \int_{\tau_i - \Delta}^{\tau_i + \Delta} (X_\tau - X_i) v(\tau) d\tau \right\rangle \leq -c_1 \sum_{i=1}^m \int_{\tau_i - \Delta}^{\tau_i + \Delta} |\tau - \tau_i| |v(\tau)| d\tau. \tag{6.13}$$

To estimate the integral $\int_{\tau_i}^{\tau_i + \Delta} (\tau - \tau_i) |v(\tau)| d\tau$ we integrate it by parts obtaining

$$\int_{\tau_i}^{\tau_i + \Delta} (V(\tau_i + \Delta) - V(\tau)) d\tau, \text{ where } V(\tau) = \int_{\tau_i}^{\tau} |v(\xi)| d\xi.$$

As long as $|v(\tau)| \leq M$, $V(\tau_i) = 0$, and $dV(\tau) = |v(\tau)| d\tau$, we have

$$\begin{aligned} \int_{\tau_i}^{\tau_i + \Delta} (V(\tau_i + \Delta) - V(\tau)) d\tau &\geq (1/M) \int_{\tau_i}^{\tau_i + \Delta} (V(\tau_i + \Delta) - V(\tau)) |v(\tau)| d\tau \\ &= (-1/2M)(V(\tau_i + \Delta) - V(\tau))^2 |_{\tau_i}^{\tau_i + \Delta} \\ &= (V(\tau_i + \Delta))^2 / 2M = \|v(\cdot)|_{[\tau_i, \tau_i + \Delta]}\|_{L_1}^2 / 2M. \end{aligned} \tag{6.14}$$

Deriving a similar estimate for $\int_{\tau_i - \Delta}^{\tau_i} |\tau - \tau_i| |v(\tau)| d\tau$ and repeating it for all $i \in \{1, \ldots, m\}$ we may conclude that for some $c_2 > 0$,

$$\left\langle \zeta_0, q_0 \circ \sum_{i=1}^m \int_{\tau_i - \Delta}^{\tau_i + \Delta} (X_\tau - X_i) v(\tau) d\tau \right\rangle \leq -c_2 \|v(\cdot)\|_{L_1}^2. \tag{6.15}$$

Obviously $\|v^s(\cdot)\|_{L_1} = |v| = \sum_{i=1}^m |\int_{\tau_i - \Delta}^{\tau_i + \Delta} v(\tau) d\tau| \leq \|v(\cdot)\|_{L_1}$. Since $w(\cdot) = v(\cdot) - v^s(\cdot)$, we conclude that

$$\|w(\cdot)\|_{L_1} \leq \|v(\cdot)\|_{L_1} + \|v^s(\cdot)\|_{L_1} \leq 2 \|v(\cdot)\|_{L_1}.$$

Therefore $\|v(\cdot)\|_{L_1}^2 \geq (|v|^2 + \|w(\cdot)\|_{L_1}^2)/5$, and we may change the estimate (6.15) to

$$\left\langle \zeta_0, q_0 \circ \sum_{i=1}^{m} \int_{\tau_i-\Delta}^{\tau_i+\Delta} (X_\tau - X_i)v(\tau)d\tau \right\rangle \leq -c_3(|v|^2 + \|w(\cdot)\|_{L_1}^2). \tag{6.16}$$

The projections of the first and the third summands in the right-hand side of (6.9) on the horizontal hyperplane admit *upper* estimates $\beta\|\bar{u}(\cdot)\|_{L_1}$ and $k\Delta(|v|+\|w(\cdot)\|_{L_1})$ correspondingly.

We shall prove now that $|\mathcal{V}^2(u(\cdot))| = O(\|u(\cdot)\|_{L_1}^2)$. To this end let us introduce the notation $P_t = \overrightarrow{\exp} \int_0^t X_\tau u(\tau)d\tau$ and recall that $\frac{d}{dt}P_t = P_t \circ X_t u(t)$, $P_0 = I$, and $\Phi_T(u(\cdot)) = q_0 \circ P_T$. Then

$$\Phi_T(u(\cdot)) - \mathcal{V}^1(u(\cdot)) = q_0 \circ \int_0^T (P_t - I)X_t u(t)dt = q_0 \circ \int_0^T \int_0^t P_\tau \circ X_\tau u(\tau)d\tau \circ X_t u(t)dt,$$

and the required estimate is now obvious.

This implies an upper estimate $|\mathcal{V}_h^2(u(\cdot))| \leq C(\|\bar{u}(\cdot)\|_{L_1}^2 + |v|^2 + \|w(\cdot)\|_{L_1}^2)$. Assuming the neighborhood $\mathcal{U}^\Delta$ to be such that $\max(\|u(\cdot)\|_{L_1}, |v|, \Delta^{-1}\|w(\cdot)\|_{L_1}) \leq \varepsilon < b_3/2C$ we may change this estimate to

$$|\mathcal{V}_h^2(u(\cdot))| \leq C\varepsilon(\|\bar{u}(\cdot)\|_{L_1} + |v| + \Delta\|w(\cdot)\|_{L_1}). \tag{6.17}$$

The estimates for the summands of the right-hand side of (6.9) imply a lower estimate for the vector $\mathcal{V}^1(u(\cdot))$:

$$\begin{aligned} &|\mathcal{V}^1(u(\cdot))| \\ &\geq a_1\|\bar{u}(\cdot)\|_{L_1} + c_3(|v|^2 + \|w(\cdot)\|_{L_1}^2) + \max(0, b_3|v| - \beta_3\|\bar{u}(\cdot)\|_{L_1} - k\Delta\|w(\cdot)\|_{L_1}). \end{aligned}$$

By virtue of the upper estimate (6.17) a similar lower estimate (possibly with different constants $b_3, \beta_3, k > 0$) holds for $|\mathcal{V}^1(u(\cdot)) + \mathcal{V}_h^2(u(\cdot))|$:

$$\begin{aligned} &|\mathcal{V}^1(u(\cdot)) + \mathcal{V}_h^2(u(\cdot))| \geq a_1\|\bar{u}(\cdot)\|_{L_1} + c_3(|v|^2 + \|w(\cdot)\|_{L_1}^2) \\ &+ \max(0, b_3|v| - \beta_3\|\bar{u}(\cdot)\|_{L_1} - k\Delta\|w(\cdot)\|_{L_1}) \\ &\geq a_1\|\bar{u}(\cdot)\|_{L_1} + c_3\|w(\cdot)\|_{L_1}^2 + \max(0, b_3|v| - \beta_3\|\bar{u}(\cdot)\|_{L_1} - k\Delta\|w(\cdot)\|_{L_1}). \end{aligned} \tag{6.18}$$

To establish the estimate (6.4) let us assume first that

$$b_3|v|/2 \geq \beta_3\|\bar{u}(\cdot)\|_{L_1} + k\Delta\|w\|_{L_1}.$$

Then $\max(0, b_3|v| - \beta_3\|\bar{u}(\cdot)\|_{L_1} - k\Delta\|w\|_{L_1}) \geq b_3|v|/2$ and we come to a lower estimate

$$|\mathcal{V}^1(u(\cdot)) + \mathcal{V}_h^2(u(\cdot))| \geq a_1\|\bar{u}\|_{L_1} + b_3|v|/2 + c_3\|w\|_{L_1}^2.$$

Evidently $b_3|v|/2 \geq \gamma\Delta^{-2}|v|^2$ for all small enough $|v| > 0$, and we derive the lower estimate (6.4).

Assume now, on the contrary, that

$$b_3|v|/2 \leq \beta_3\|\bar{u}(\cdot)\|_{L_1} + k\Delta\|w\|_{L_1}. \tag{6.19}$$

If $\beta_3\|\bar{u}(\cdot)\|_{L_1} \geq k\Delta\|w\|_{L_1}$, then $b_3|v|/2 \leq 2\beta_3\|\bar{u}(\cdot)\|_{L_1}$, and we derive

$$a_1\|\bar{u}(\cdot)\|_{L_1} \geq \frac{a_1}{2}\|\bar{u}(\cdot)\|_{L_1} + a_1k\Delta\|w\|_{L_1}/4\beta_3 + a_1b_3|v|/16\beta_3.$$

The sum of the last two terms is bounded below by $\gamma\Delta^{-2}|v|^2+\mu\|w\|_{L_1}^2$ for sufficiently small $|v|, \|w\|_{L_1} > 0$.

If $\beta_3\|\bar u(\cdot)\|_{L_1} \le k\Delta\|w\|_{L_1}$, then (6.19) implies $b_3|v| \le 4k\Delta\|w\|_{L_1}$ and hence in (6.18)

$$c_3\|w\|_{L_1}^2 \ge \frac{c_3}{2}\|w\|_{L_1}^2 + \frac{c_3 b_3^2}{32k^2}\Delta^{-2}|v|^2. \qquad \square$$

Proof of Lemma 6.3. As has been already established,

$$\Phi_T(u(\cdot)) - \mathcal{V}^1(u(\cdot)) = q_0 \circ \int_0^T (P_t - I)X_t u(t)dt = q_0 \circ \int_0^T \int_0^t P_\tau X_\tau u(\tau)d\tau \circ X_t u(t)dt.$$

Substituting $P_\tau = I + (P_\tau - I)$ into the last expression we transform it into

$$\begin{aligned}\Phi_T(u(\cdot)) - \mathcal{V}^1(u(\cdot)) &= q_0 \circ \int_0^T \int_0^t X_\tau u(\tau)d\tau \circ X_t u(t)dt \\ &+ q_0 \circ \int_0^T \int_0^t (P_\tau - I)X_\tau u(\tau)d\tau \circ X_t u(t)dt. \end{aligned} \tag{6.20}$$

Since $P_\tau - I = \int_0^\tau X_\xi u(\xi)d\xi$, then (see [7]) $\|P_\tau - I\|_{s,K} \le c(s,K)\|u(\cdot)\|_{L_1}$ and therefore the second summand at the right-hand side of (6.20) admits an estimate $O(\|u(\cdot)\|_{L_1}^3)$ which implies the upper estimate (6.5), if $\|u(\cdot)\|_{L_1}$ is sufficiently small. Obviously the same estimate holds for the vertical component of this summand.

To estimate the term $q_0 \circ \int_0^T \int_0^t X_\tau u(\tau)d\tau \circ X_t u(t)dt$ we represent it as a sum

$$\begin{aligned} q_0 \circ \Bigg(&\int_0^T \int_0^t X_\tau u(\tau)d\tau \circ X_t \bar u(t)dt + \sum_{i=1}^m \int_{\tau_i-\Delta}^{\tau_i+\Delta} \int_0^t X_\tau u(\tau)d\tau \circ X_t(v_i/2\Delta)dt \\ &+ \sum_{i=1}^m \int_{\tau_i-\Delta}^{\tau_i+\Delta} \int_0^t X_\tau u(\tau)d\tau \circ X_t w(t)dt \Bigg). \end{aligned} \tag{6.21}$$

The first summand of the right-hand side admits an upper estimate $c\|u(\cdot)\|_{L_1}\|\bar u(\cdot)\|_{L_1}$, which is majorized by $A\Delta\|\bar u(\cdot)\|_{L_1}$, if $\|u(\cdot)\|_{L_1}$ is small enough. The second summand admits an upper estimate

$$c(|v|^2 + \|\bar u(\cdot)\|_{L_1}^2 + \|w(\cdot)\|_{L_1}|v|) \le A(\Delta^{-1}|v|^2 + \Delta\|w(\cdot)\|_{L_1}^2 + \|\bar u(\cdot)\|_{L_1}^2),$$

which implies the estimate (6.5) if $\|u(\cdot)\|_{L_1}$ is small enough.

Now we shall transform the third summand of (6.21) by representing it as a sum:

$$\begin{aligned} &\sum_{i=1}^m \int_{\tau_i-\Delta}^{\tau_i+\Delta} \int_0^t X_\tau \bar u(\tau)d\tau \circ X_t w(t)dt + \sum_{i=1}^m \int_{\tau_i-\Delta}^{\tau_i+\Delta} \int_0^t X_\tau v^s(\tau)d\tau \circ X_t w(t)dt \\ &+ \sum_{i=1}^m \int_{\tau_i-\Delta}^{\tau_i+\Delta} \int_0^t X_\tau w(\tau)d\tau \circ X_t w(t)dt. \end{aligned} \tag{6.22}$$

The first summand admits an upper estimate $c\|\bar u(\cdot)\|_{L_1}\|w(\cdot)\|_{L_1}$, which can be substituted by $A\Delta\|\bar u(\cdot)\|_{L_1}$, if $\|u(\cdot)\|_{L_1}$ is small enough. The second summand admits an upper estimate

$$c|v|\|w(\cdot)\|_{L_1} \le (c/2)(\Delta^{-1}|v|^2 + \Delta\|w(\cdot)\|_{L_1}^2).$$

To estimate the third summand let us represent it as

$$\sum_{i=1}^{m}\int_{\tau_i-\Delta}^{\tau_i+\Delta} X_t w(t)\circ\left(\sum_{j=1}^{i-1}\int_{\tau_j-\Delta}^{\tau_j+\Delta} X_\tau w(\tau)d\tau+\int_{\tau_i-\Delta}^{t} X_\tau w(\tau)d\tau\right)dt.$$

Taking into account that $\int_{\tau_j-\Delta}^{\tau_j+\Delta} w(\tau)d\tau=0$ $(j=0,\dots,m)$, we may rewrite it as

$$\sum_{i=1}^{m}\int_{\tau_i-\Delta}^{\tau_i+\Delta} X_t w(t)\circ\left(\sum_{j=1}^{i-1}\int_{\tau_j-\Delta}^{\tau_j+\Delta} (X_\tau-X_j) w(\tau)d\tau+\int_{\tau_i-\Delta}^{t} X_\tau w(\tau)d\tau\right)dt.$$

Since for any i,j,

$$\Delta^{-1}\left|\int_{\tau_i-\Delta}^{\tau_i+\Delta} X_t w(t)\circ\int_{\tau_j-\Delta}^{\tau_j+\Delta}(X_\tau-X_j)w(\tau)d\tau\,dt\right|=O(\|w(\cdot)\|_{L_1}^2),$$

then we only have to estimate $\int_{\tau_i-\Delta}^{\tau_i+\Delta} X_t w(t)\circ\int_{\tau_i-\Delta}^{t} X_\tau w(\tau)d\tau dt$ $(i=1,\dots,m)$.

Substituting X_i in place of X_t and X_τ $(t,\tau\in[\tau_i-\Delta,\tau_i+\Delta])$ in this integral, we change its value by $O(1)\Delta\|w(\cdot)\|_{L_1}^2$. Integrating by parts we derive

$$\int_{\tau_i-\Delta}^{\tau_i+\Delta} X_i w(t)\circ X_i\int_{\tau_i-\Delta}^{t} w(\tau)d\tau dt$$
$$=X_i\int_{\tau_i-\Delta}^{\tau_i+\Delta} w(t)dt\circ X_i\int_{\tau_i-\Delta}^{\tau_i+\Delta} w(\tau)d\tau-\int_{\tau_i-\Delta}^{\tau_i+\Delta} X_i\int_{\tau_i-\Delta}^{t} w(\tau)d\tau\circ X_i w(t)dt.$$

The first summand vanishes and hence

$$\int_{\tau_i-\Delta}^{\tau_i+\Delta} X_i w(t)\circ X_i\int_{\tau_i-\Delta}^{t} w(\tau)d\tau dt=\frac{1}{2}\int_{\tau_i-\Delta}^{\tau_i+\Delta}\left[X_i w(t), X_i\int_{\tau_i-\Delta}^{t} w(\tau)d\tau\right]dt.$$

The projection of the last term on ζ_0 vanishes, provided that the second-order horizontality condition for switchings holds. Therefore

$$\Delta^{-1}\left\langle\zeta_0,\int_{\tau_i-\Delta}^{\tau_i+\Delta} X_t w(t)\circ\int_{\tau_i-\Delta}^{t} X_\tau w(\tau)d\tau dt\right\rangle=O(\|w(\cdot)\|_{L_1}^2).\qquad\square$$

7. Second-order sufficient optimality conditions for bang-bang Pontryagin extremals. It has been established (Theorem 6.1) that the triviality of the kernel of the first variation at switching points of the bang-bang Pontryagin extremal $(\tilde u(\cdot),\tilde q(\cdot),\tilde\zeta(\cdot))$ implies optimality of the extremal control $\tilde u(\cdot)$. In this section we study what happens if the first variation at the switching points possesses a nontrivial kernel. We establish in this case the second-order sufficient optimality condition (Theorem 7.1) involving the second variation at switching points. Regrettably this condition is not as sharp as one could wish. Below we shall provide some comments and also a *sharper* form of the sufficient condition for the case where the strong generecity assumption holds (Theorem 7.2).

THEOREM 7.1 (second-order sufficient optimality condition for bang-bang extremals). *Let the strong transversality condition* (4.11)*, the weak genericity assumption*

and the second-order horizontality condition for switchings (6.2) *hold for the bang-bang Pontryagin extremal* $(\tilde{u}(\cdot), \tilde{q}(\cdot), \tilde{\zeta}(\cdot))$. *If the second variation at the switching points* τ_j $(j = 1, \dots, m)$ *of the Pontryagin extremal, i.e., the quadratic form*

$$Q(v) = \sum_{i=1}^{m} \left\langle \zeta_0, q_0 \circ \left[\sum_{j<i} X_j v_j, X_i v_i \right] \right\rangle, \tag{7.1}$$

is nonpositive (negative semidefinite) on the kernel of the first variation at switching points

$$\left\{ v = (v_1, \dots, v_m) \in \oplus_{i=1}^{m} V_i \mid \sum_{i=1}^{m} q_0 \circ X_i v_i = 0 \right\}, \tag{7.2}$$

then $\tilde{u}(\cdot)$ *is optimal for the problem* (1.1)–(1.3). □

As one can see, the formulation of the *sufficient* condition is somewhat unusual, since it involves negative semidefiniteness of the second variation, while usually second-order sufficient optimality conditions involve strict definiteness of the second variation. We should also emphasize that negative semidefiniteness of the second variation at the switching points *is not necessary* for the optimality of $\tilde{u}(\cdot)$. The reason is that the first and the second variations at switching points have been constructed on the basis of Dirac measures (located at swiching points) used as generalized variations of $\tilde{u}(\cdot)$. Were it possible to approximate these Dirac measures by ordinary controls, this construction would be quite adequate. Since the admissible controls are bounded we cannot arrange such approximations, and this is why asking for negative definiteness of the second variation at switching points means asking too much; i.e., it provides stronger optimality than the one we investigate. Technically speaking it results in the following phenomenon: provided that the weak genericity assumption holds, there is some term of the first variation, which has the same order of smallness as the second variation. Due to the Pontryagin maximum principle the vertical component of this term takes negative values for any admissible variation of $\tilde{u}(\cdot)$. Therefore a more adequate sufficient condition would be the negative definiteness of the sum of this part of the first variation with the second variation at switching points. Unfortunately this part of the first variation does not admit reasonable representation. The case where one can achieve more progress is the one where the strong genericity assumption holds. In this case the faces V_i of switching are one-dimensional edges and the above-mentioned term of the first variation admits a rather simple quadratic upper estimate which, when added to the second variation, provides us with a sharper sufficient optimality condition. The second-order horizontality condition for switchings holds in this case automatically.

To introduce this additional term let us consider the unit directing vectors ℓ_i $(i = 1, \dots, m)$ of the switching edges V_i $(i = 1, \dots, m)$; $\ell_i = (\eta_i^+ - \eta_i^-)/|\eta_i^+ - \eta_i^-|$, where $\eta_i^- = \tilde{u}(\tau_i - 0), \eta_i^+ = \tilde{u}(\tau_i + 0)$. Let $M_i = |\eta_i^+ - \eta_i^-|$ $(i = 1, \dots, m)$ be the lengths of the switching edges. The variables v_i $(i = 1, \dots, m)$ involved in the expression for the second variation are in this case *scalar*. Let us introduce the quadratic form[1] $\frac{1}{2}\sum_{i=1}^{m} \langle \zeta_0, \dot{X}_i \ell_i \rangle v_i^2 / 2M_i$ (by virtue of the Pontryagin maximum principle $\langle \zeta_0, \dot{X}_i \ell_i \rangle > 0,\ i = 1, \dots, m$). Subtracting this quadratic form from the second variation at the

[1] Under the strong genericity assumption $\dot{X}_\tau \ell_i$ is continuous at the switching point τ_i.

switching points we obtain the quadratic form

$$-\frac{1}{2}\sum_{i=1}^{m}\langle\zeta_0, q_0\circ\dot{X}_i\ell_i\rangle v_i^2/2M_i+\sum_{i=1}^{m}\left\langle\zeta_0, q_0\circ\left[\sum_{j<i}X_jv_j, X_iv_i\right]\right\rangle \tag{7.3}$$

with the domain (7.2); obviously its values are less than the values of the quadratic form (7.1)–(7.2).

THEOREM 7.2 (second-order sufficient optimality condition under the strong genericity assumption). *Let the strong transversality condition* (4.11) *and the strong genericity assumption hold for the bang-bang Pontryagin extremal* $(\tilde{u}(\cdot),\tilde{q}(\cdot),\tilde{\zeta}(\cdot))$. *If the quadratic form* (7.3) *with the domain* (7.2) *is negative definite, then* $\tilde{u}(\cdot)$ *is optimal for the problem* (1.1)–(1.3). □

Proof of Theorem 7.1. We are going to verify the conditions of the auxiliary lemma on optimality and to this end will derive estimates similar to (6.4)–(6.5).

First we slightly modify the coordinatization $u(\cdot)\mapsto(\bar{u}(\cdot),v,w(\cdot))$, splitting $\oplus_{i=1}^{m}V_i$ into the sum of the subspace (7.2) and a complementary linear subspace. Therefore any $v\in\oplus_{i=1}^{m}V_i$ can now be represented as $v=v_0+v^\sharp$ with v_0 coordinatizing the subspace (7.2) and $v^\sharp$ coordinatizing the complementary subspace. The new coordinatization is $u(\cdot)\mapsto(\bar{u}(\cdot),v^\sharp,v^0,w(\cdot))$. The formula (6.9) changes to

$$\begin{aligned}
&q_0\circ\int_0^T X_\tau u(\tau)d\tau\\
&=q_0\circ\left(\int_0^T X_\tau\bar{u}(\tau)d\tau+\sum_{i=1}^{m}\left(\int_{\tau_i-\Delta}^{\tau_i+\Delta}X_\tau d\tau\right)v_i/2\Delta+\sum_{i=1}^{m}\int_{\tau_i-\Delta}^{\tau_i+\Delta}X_\tau w(\tau)d\tau\right)\\
&=q_0\circ\left(\int_0^T X_\tau\bar{u}(\tau)d\tau+\sum_{i=1}^{m}X_iv_i^\sharp+\sum_{i=1}^{m}\int_{\tau_i-\Delta}^{\tau_i+\Delta}(X_\tau-X_i)(v_i/2\Delta+w(\tau))d\tau\right).
\end{aligned}\tag{7.4}$$

The estimate (6.11) changes to

$$\left|\sum_{i=1}^{m}q_0\circ X_iv_i^\sharp\right|\geq b_3|v^\sharp|. \tag{7.5}$$

The estimate (6.18) changes to

$$\begin{aligned}
&|\mathcal{V}^1(u(\cdot))+\mathcal{V}_h^2(u(\cdot))|\geq a_1\|\bar{u}(\cdot)\|_{L_1}+c_3(|v^\sharp|^2+|v^0|^2+\|w(\cdot)\|_{L_1}^2)\\
&+\max(0,b_3|v^\sharp|-\beta_3\|\bar{u}(\cdot)\|_{L_1}-k\Delta\|w(\cdot)\|_{L_1}-k\Delta|v^0|)\geq a_1\|\bar{u}(\cdot)\|_{L_1}\\
&+c_3(|v^0|^2+\|w(\cdot)\|_{L_1}^2)+\max(0,b_3|v^\sharp|-\beta_3\|\bar{u}(\cdot)\|_{L_1}-k\Delta\|w(\cdot)\|_{L_1}-k\Delta|v^0|),
\end{aligned}\tag{7.6}$$

from which one derives as in the previous section

$$|\mathcal{V}^1(u(\cdot))+\mathcal{V}_h^2(u(\cdot))|\geq\alpha(\|\bar{u}(\cdot)\|_{L_1}+\Delta^{-2}|v^\sharp|^2+|v^0|^2+\|w(\cdot)\|_{L_1}^2). \tag{7.7}$$

For the estimate of the vertical component of the remainder term we formulate the following lemma, which is the analogue of Lemma 6.3.

LEMMA 7.3. *Provided that the second-order horizontality condition for switchings holds, there exists a positive constant* A *and for any sufficiently small* $\Delta>0$ *there exists a neighborhood* $\mathcal{U}^\Delta$ *of the origin in the* L_1*-metric, such that for any admissible*

variation $u(\cdot) \in \mathcal{U}^\Delta \cap L_\infty^r[0,T]$ *and all possible coordinatizations the inequality*

$$\langle \zeta_0, \mathcal{V}^2(u(\cdot))\rangle \le \frac{1}{2}\sum_{i=1}^m \left\langle \zeta_0, q_0 \circ \left[\sum_{j<i} X_j v_j^0, X_i^0 v_i^0\right]\right\rangle$$
$$+A(\Delta\|\bar u(\cdot)\|_{L_1} + \Delta^{-1}|v^\sharp|^2 + \Delta(|v^0|^2 + \|w(\cdot)\|_{L_1}^2)) \tag{7.8}$$

holds. □

Providing the proof of the lemma below we finish now the proof of Theorem 7.1.

If the second variation (7.1)–(7.2) at the switching points of the extremal is non-positive, then the estimate (7.8) implies the estimate

$$\langle \zeta_0, \mathcal{V}^2(u(\cdot))\rangle \le A(\Delta\|\bar u(\cdot)\|_{L_1} + \Delta^{-1}|v^\sharp|^2 + \Delta(|v^0|^2 + \|w(\cdot)\|_{L_1}^2)). \tag{7.9}$$

The conditions of the auxiliary lemma on optimality are then derived from the estimates (7.7)–(7.9) in the same way as in the proof of Theorem 6.1. Theorem 7.1 is proved. □

Proof of Theorem 7.2. To prove the theorem we shall slightly modify the estimates (7.6), (7.7), and (7.9). First, we shall add to $\mathcal{V}^1 + \mathcal{V}_h^2$ the vector-valued quadratic form

$$\mathcal{V}_v^2(v^0) = \frac{1}{2}\left(\sum_{i=1}^m \left\langle \zeta_0, q_0 \circ \left[\sum_{j<i} X_j v_j^0, X_i v_i^0\right]\right\rangle\right) z.$$

Evidently the projection of this form onto the covector ζ_0 coincides with the second variation at the switching points. The proof of the theorem can be completed by invoking the following technical lemma.

LEMMA 7.4. *If the strong genericity assumption holds for the bang-bang Pontryagin extremal* $(\tilde u(\cdot), \tilde q(\cdot), \tilde\zeta(\cdot))$*, and the quadratic form* (7.3) *is negative definite on its domain* (7.2)*, then the values of* $\mathcal{V}^1(u(\cdot)) + \mathcal{V}_h^2(u(\cdot)) + \mathcal{V}_v^2(v^0)$ *belong to the lower semispace and there exists both a positive constant* α *and for any sufficiently small* $\Delta > 0$ *a neighborhood* $\mathcal{U}^\Delta$ *of the origin in the* L_1*-norm such that for all admissible variations* $u(\cdot) \in \mathcal{U}^\Delta \cap L_\infty^r[0,T]$ *and all possible coordinatizations the inequality*

$$|\mathcal{V}^1(u(\cdot)) + \mathcal{V}_h^2(u(\cdot)) + \mathcal{V}_v^2(v^0)| \ge \alpha(\|\bar u(\cdot)\|_{L_1} + |v^0|^2 + \Delta^{-2}|v^\sharp|^2 + \|w(\cdot)\|_{L_1}^2) \tag{7.10}$$

holds. □

Postponing the proof of this lemma we finish the proof of the Theorem 7.2. It follows from (7.8) that

$$|\mathcal{V}_v^2(u(\cdot)) - \mathcal{V}_v^2(v^0)| \le A(\Delta\|\bar u(\cdot)\|_{L_1} + \Delta^{-1}|v^\sharp|^2 + \Delta(|v^0|^2 + \|w(\cdot)\|_{L_1}^2)). \tag{7.11}$$

The conditions of the auxiliary lemma on optimality are to be derived from the estimates (7.10)–(7.11) in the same way as in the proof of the Theorem 6.1. Theorem 7.2 is proved. □

Proof of Lemma 7.3. As in the proof of the Lemma 6.5 we may restrict our consideration to the vertical component of the term $q_0 \circ \int_0^T \int_0^t X_\tau u(\tau)d\tau \circ X_t u(t)dt$ of the Volterra expansion. First we represent this term as a sum:

$$\int_0^T \int_0^t X_\tau u(\tau)d\tau \circ X_t \bar u(t)dt + \sum_{i=1}^m \int_{\tau_i-\Delta}^{\tau_i+\Delta} \int_0^t X_\tau u(\tau)d\tau \circ X_t(w(t) + v_i/2\Delta)dt.$$

The first summand of the right-hand side admits an upper estimate $c\|u(\cdot)\|_{L_1}\|\bar u(\cdot)\|_{L_1}$, which is majorized by $A\Delta\|\bar u(\cdot)\|_{L_1}$, provided that $\|u(\cdot)\|_{L_1}$ is small enough. Substituting $\bar u(t)+v^s(t)+w(t)$ in place of $u(t)$ in the second summand we transform it into

$$\sum_{i=1}^m\int_{\tau_i-\Delta}^{\tau_i+\Delta}\int_0^t X_\tau\bar u(\tau)d\tau\circ X_t(w(t)+v_i/2\Delta)dt$$
$$+\sum_{i=1}^m\int_{\tau_i-\Delta}^{\tau_i+\Delta}\int_0^t X_\tau(v^s(\tau)+w(\tau))d\tau\circ X_t(w(t)+v_i/2\Delta)dt.$$

Again the first summand admits an upper estimate $c\|u(\cdot)\|_{L_1}\|\bar u(\cdot)\|_{L_1}$, majorized by $A\Delta\|\bar u(\cdot)\|_{L_1}$, provided that $\|u(\cdot)\|_{L_1}$ is small enough. The second summand can be represented as

$$\sum_{i=1}^m\int_{\tau_i-\Delta}^{\tau_i+\Delta}\sum_{j=1}^{i-1}\int_{\tau_j-\Delta}^{\tau_j+\Delta}X_\tau(w(\tau)+v_j/2\Delta)d\tau\circ X_t(w(t)+v_i/2\Delta)dt$$
$$+\sum_{i=1}^m\int_{\tau_i-\Delta}^{\tau_i+\Delta}\int_{\tau_i-\Delta}^t X_\tau(w(\tau)+v_i/2\Delta)d\tau\circ X_t(w(t)+v_i/2\Delta)dt.$$

Changing X_τ to X_i on an interval $[\tau_i-\Delta,\tau_i+\Delta]$ in this last formula we change it by $O(1)\Delta(|v^0|^2+|v^\sharp|^2+\|w(\cdot)\|_{L_1}^2)$, obtaining

$$\sum_{i=1}^m\left(\sum_{j=1}^{i-1}X_jv_j\circ X_iv_i+\frac12X_iv_i\circ X_iv_i\right)$$
$$+\sum_{i=1}^m\int_{\tau_i-\Delta}^{\tau_i+\Delta}X_i\int_{\tau_i-\Delta}^t w(\tau)d\tau\circ X_i(w(t)+v_i/2\Delta)dt \tag{7.12}$$
$$+\int_{\tau_i-\Delta}^{\tau_i+\Delta}X_i\int_{\tau_i-\Delta}^t(v_i/2\Delta)d\tau\circ X_iw(t)dt.$$

Splitting $v=(v_1,\dots,v_m)$ into the sum $v^\sharp+v^0$, where $v^\sharp=(v_1^\sharp,\dots,v_m^\sharp)$, $v^0=(v_1^0,\dots,v_m^0)$, we represent the first summand as

$$\sum_{i=1}^m\sum_{j=1}^{i-1}X_jv_j^0\circ X_iv_i^0+O(1)(|v^\sharp||v^0|+|v^\sharp|^2).$$

Obviously $O(1)(|v^\sharp||v^0|+|v^\sharp|^2)$ is $O(1)(\Delta|v^0|^2+\Delta^{-1}|v^\sharp|^2)$, as $(|v^\sharp||v^0|+|v^\sharp|^2)\to0$.

Since $\sum_{j=1}^m q_0\circ X_jv_j^0=0$, then

$$0=\sum_{i=1}^m\sum_{j=1}^m q_0\circ X_jv_j^0\circ X_iv_i^0$$
$$=\sum_{i=1}^m\left(\left(\sum_{j<i}+\frac12\sum_{j=i}^i\right)q_0\circ X_jv_j^0\circ X_iv_i^0\right)+\sum_{i=1}^m\left(\left(\sum_{j<i}+\frac12\sum_{i=j}^j\right)q_0\circ X_iv_i^0\circ X_jv_j^0\right)$$

and hence

$$\sum_{i=1}^m\left(\sum_{j=1}^{i-1}X_jv_j^0\circ X_iv_i^0+\frac12X_iv_i^0\circ X_iv_i^0\right)=\frac12\sum_{i=1}^m\sum_{j<i}q_0\circ[X_jv_j^0,X_iv_i^0].$$

Let us estimate other terms of (7.12), i.e., the sum

$$\sum_{i=1}^{m}\int_{\tau_i-\Delta}^{\tau_i+\Delta}X_i\int_{\tau_i-\Delta}^{t}w(\tau)d\tau\circ X_iw(t)dt+\sum_{i=1}^{m}\int_{\tau_i-\Delta}^{\tau_i+\Delta}X_i\int_{\tau_i-\Delta}^{t}w(\tau)d\tau\circ X_iv_i/2\Delta dt$$
$$+\int_{\tau_i-\Delta}^{\tau_i+\Delta}X_i\int_{\tau_i-\Delta}^{t}(v_i/2\Delta)d\tau\circ X_iw(t)dt.$$

Integration by parts gives us

$$\int_{\tau_i-\Delta}^{\tau_i+\Delta}X_i\int_{\tau_i-\Delta}^{t}w(\tau)d\tau\circ X_iw(t)dt$$
$$=\int_{\tau_i-\Delta}^{\tau_i+\Delta}X_i\int_{\tau_i-\Delta}^{\tau_i+\Delta}w(\tau)d\tau\circ X_iw(t)dt-\int_{\tau_i-\Delta}^{\tau_i+\Delta}X_iw(t)\circ X_i\int_{\tau_i-\Delta}^{t}w(\tau)d\tau dt.$$

Since the first summand of this last formula vanishes, we derive

$$\int_{\tau_i-\Delta}^{\tau_i+\Delta}X_i\int_{\tau_i-\Delta}^{t}w(\tau)d\tau\circ X_iw(t)dt=\frac{1}{2}\int_{\tau_i-\Delta}^{\tau_i+\Delta}\left[X_i\int_{\tau_i-\Delta}^{t}w(\tau)d\tau,X_iw(t)\right]dt;$$

its projection onto ζ_0 vanishes by virtue of the second-order horizontality condition for switchings.

Similarly

$$\int_{\tau_i-\Delta}^{\tau_i+\Delta}X_i\int_{\tau_i-\Delta}^{t}w(\tau)d\tau\circ X_i(v_i/2\Delta)dt$$
$$=\int_{\tau_i-\Delta}^{\tau_i+\Delta}X_i\int_{\tau_i-\Delta}^{\tau_i+\Delta}w(\tau)d\tau\circ X_i(v_i/2\Delta)dt-\int_{\tau_i-\Delta}^{\tau_i+\Delta}X_iw(t)\circ X_i\int_{\tau_i-\Delta}^{t}(v_i/2\Delta)d\tau dt.$$

The first summand in the right-hand side vanishes, and we obtain

$$\int_{\tau_i-\Delta}^{\tau_i+\Delta}X_i\int_{\tau_i-\Delta}^{t}w(\tau)d\tau\circ X_i(v_i/2\Delta)dt+\int_{\tau_i-\Delta}^{\tau_i+\Delta}X_i\int_{\tau_i-\Delta}^{t}(v_i/2\Delta)d\tau\circ X_iw(t)dt$$
$$=\int_{\tau_i-\Delta}^{\tau_i+\Delta}\left[X_i\int_{\tau_i-\Delta}^{t}(v_i/2\Delta)d\tau,X_iw(t)\right]dt.$$

The projection of this last expression onto ζ_0 vanishes by virtue of the second-order horizontality condition for switchings, and therefore the Lemma 7.3 is proved. □

Proof of Lemma 7.4. The estimate (7.10) is derived from the estimate

$$|\mathcal{V}^1(u(\cdot))+\mathcal{V}_h^2(u(\cdot))+\mathcal{V}_v^2(v^0)|\geq a_1\|\bar{u}(\cdot)\|_{L_1}+c_3(|v^\sharp|^2+|v^0|^2+\|w(\cdot)\|_{L_1}^2)$$
$$+\max(0,b_3|v^\sharp|-\beta_3\|\bar{u}(\cdot)\|_{L_1}-k\Delta\|w(\cdot)\|_{L_1}-k\Delta|v^0|), \tag{7.13}$$

which is a modification of the estimate (7.6). To establish (7.13) and to prove that $\mathcal{V}^1(u(\cdot))+\mathcal{V}_h^2(u(\cdot))+\mathcal{V}_v^2(v^0)$ belongs to the lower semispace we return to the estimates (6.12) and note that under the strong genericity assumption $K_i^-=R_+\ell_i$, $K_i^+=R_-\ell_i$ $\forall i=1,\dots,m$, and there exists a constant $B>0$ such that

$$|\langle\zeta_0,q_0\circ((X_\tau-X_i)v-\dot{X}_i\ell_i(\tau-\tau_i)|v|)\rangle|\leq B\Delta|\tau-\tau_i||v| \tag{7.14}$$

$\forall(\tau,v)\in([\tau_i-\Delta,\tau_i)\times K_i^-)\cup((\tau_i,\tau_i+\Delta]\times K_i^+)$.

Repeating the computation (6.14) we derive

$$\sum_{i=1}^{m}\langle\zeta_0, q_0\circ\dot X_i\ell_i\rangle\left(\int_{\tau_i-\Delta}^{\tau_i}(\tau-\tau_i)|v(\tau)|d\tau-\int_{\tau_i}^{\tau_i+\Delta}(\tau-\tau_i)|v(\tau)|d\tau\right)$$

$$\leq-\sum_{i=1}^{m}\langle\zeta_0, q_0\circ\dot X_i\ell_i\rangle\left(\left(\int_{\tau_i-\Delta}^{\tau_i}v(\tau)d\tau\right)^2+\left(\int_{\tau_i}^{\tau_i+\Delta}v(\tau)d\tau\right)^2\right)/2M_i. \tag{7.15}$$

Denoting $v_i^-=\int_{\tau_i-\Delta}^{\tau_i}|v(\tau)|d\tau,\ v_i^+=-\int_{\tau_i}^{\tau_i+\Delta}|v(\tau)|d\tau$ we note that

$$\langle\zeta_0, q_0\circ\dot X_i\ell_i\rangle>0,\ v_i^-\geq 0,\ v_i^+\leq 0,\ \text{and } v_i=v_i^-+v_i^+.$$

To derive an upper estimate for the negative definite quadratic form (7.15) in terms of v_i we have to solve an elementary extremal problem

$$((v_i^-)^2+(v_i^+)^2)/2M_i\to\min,\ v_i^-+v_i^+=v_i, v_i^-\geq 0,\ v_i^+\leq 0.$$

Using the Kuhn–Tucker theorem we obtain the value $v_i^2/2M_i$ for the minimum. Therefore the negative definite quadratic form $-\sum_{i=1}^m\langle\zeta_0, q_0\circ\dot X_i\ell_i\rangle v_i^2/2M$ provides the upper estimate for (7.15). By virtue of (7.14) the negative definite quadratic form

$$-(1-B\Delta)\sum_{i=1}^{m}\langle\zeta_0, q_0\circ\dot X_i\ell_i\rangle v_i^2/2M$$

provides the upper estimate for $\langle\zeta_0, q_0\circ\sum_{i=1}^m\int_{\tau_i-\Delta}^{\tau_i+\Delta}(X_\tau-X_i)v(\tau)d\tau\rangle$.

Extracting the terms which are quadratic in v_0 we represent it as

$$-(1-B\Delta)\left(\sum_{i=1}^{m}\langle\zeta_0, q_0\circ\dot X_i\ell_i\rangle(v_i^0)^2/2M_i+\sum_{i=1}^{m}\langle\zeta_0, q_0\circ\dot X_i\ell_i\rangle(2v_i^\sharp v_i^0+(v_i^\sharp)^2)\right).$$

The second summand admits an estimate

$$\left|\sum_{i=1}^{m}\langle\zeta_0, q_0\circ\dot X_i\ell_i\rangle(2v_i^\sharp v_i^0+(v_i^\sharp)^2)\right|=O(1)(\Delta^{-1}|v^\sharp|^2+\Delta|v^0|^2).$$

Since

$$-\frac{1}{2}\sum_{i=1}^{m}\langle\zeta_0, q_0\circ\dot X_i\ell_i\rangle(v_i^0)^2/2M_i+\sum_{i=1}^{m}\left\langle\zeta_0, q_0\circ\left[\sum_{j<i}X_jv_j^0, X_iv_i^0\right]\right\rangle$$

is a negative definite quadratic form in v^0, then for sufficiently small $\Delta>0$ the quadratic form

$$-\frac{1}{2}(1-B\Delta)\sum_{i=1}^{m}\langle\zeta_0, q_0\circ\dot X_i\ell_i\rangle(v_i^0)^2/2M_i+\sum_{i=1}^{m}\left\langle\zeta_0, q_0\circ\left[\sum_{j<i}X_jv_j^0, X_iv_i^0\right]\right\rangle$$

admits an upper estimate $-\gamma|v^0|^2$ and we derive that $\mathcal{V}^1(u(\cdot))+\mathcal{V}_h^2(u(\cdot))+\mathcal{V}_v^2(v^0)$ belongs to the lower semispace and satisfies the estimate (7.13), which implies the estimate (7.10). □

A CONVERGENT ALGORITHM FOR THE OUTPUT COVARIANCE CONSTRAINT CONTROL PROBLEM*

G. ZHU†, M. A. ROTEA‡, AND R. SKELTON§

Abstract. This paper considers the optimal control problem of minimizing control effort subject to multiple performance constraints on output covariance matrices Y_i of the form $Y_i \leq \overline{Y}_i$, where $\overline{Y}_i$ is given. The contributions of this paper are a set of conditions that characterize global optimality, and an iterative algorithm for finding a solution to the optimality conditions. This iterative algorithm is completely described up to a user-specified parameter. We show that, under suitable assumptions on problem data, the iterative algorithm converges to a solution of the optimality conditions, provided that this parameter is properly chosen. Both discrete- and continuous-time problems are considered.

Key words. covariance control, convergent algorithm

1. Introduction.

Consider the following linear time-invariant system:

$$\begin{aligned} \dot{x}_p(t) &= A_p x_p(t) + B_p u(t) + D_p w_p(t), \\ y_p(t) &= C_p x_p(t), \\ z(t) &= M_p x_p(t) + v(t), \end{aligned} \tag{1.1}$$

where x_p is the state, u the control, w_p represents process noise, and v is the measurement noise. The vector y_p contains all variables whose dynamic responses are of interest. The vector z is a vector of noisy measurements.

Suppose that we apply to the plant (1.1) a full state feedback stabilizing control law of the form

$$u(t) = G x_p(t) \tag{1.2}$$

or a strictly proper output feedback stabilizing control law given by

$$\begin{aligned} \dot{x}_c(t) &= A_c x_c(t) + F z(t), \\ u(t) &= G x_c(t). \end{aligned} \tag{1.3}$$

Then the resulting closed-loop system is

$$\begin{aligned} \dot{x}(t) &= Ax(t) + Dw(t), \\ y(t) &= \begin{bmatrix} y_p(t) \\ u(t) \end{bmatrix} = \begin{bmatrix} C_y \\ C_u \end{bmatrix} x(t) = Cx(t), \end{aligned} \tag{1.4}$$

where for the state feedback case we have $x = x_p$ and $w = w_p$, while for the output feedback case we have $x = [x_p^T \ x_c^T]^T$ and $w = [w_p^T \ v^T]^T$. Moreover, formulas for A, C, and D are easy to obtain from (1.1) and (1.2) or (1.3).

Consider the closed-loop system (1.4). Let W_p and V denote positive definite symmetric matrices with dimensions equal to the process noise w_p and measurement vector z, respectively. Define $W = W_p$, if the state feedback controller (1.2) is used in (1.4) or $W =$ block diag $[W_p, \ V]$ if (1.3) is used in (1.4). Let X denote the closed-loop controllability Gramian from the (weighted) disturbance input $W^{-1/2}w$. Since A is stable, X satisfies

$$0 = AX + XA^T + DWD^T. \tag{1.5}$$

Partition the performance output y_p in (1.4) into $y_p := [y_1^T, y_2^T, \ldots, y_m^T]^T$, where $y_i = C_i x \in \mathcal{R}^{m_i}$ for $i = 1, 2, \ldots, m$. In this paper we are interested in finding controllers of the form (1.2) or (1.3) that minimize the (weighted) control energy *trace* $RC_uXC_u^T$ with $R > 0$, and satisfy the constraints

$$Y_i = C_iXC_i^T \le \overline{Y}_i, \quad i = 1, 2, \ldots, m, \tag{1.6}$$

where $\overline{Y}_i > 0$ $(i = 1, 2, \ldots, m)$ are given and X solves (1.5). This problem, which we call the the output covariance constraint (OCC) problem, is defined as follows.

The OCC Problem. Find a static state feedback or full-order dynamic output feedback controller for system (1.1) to minimize the OCC cost

$$J_{OCC} = \text{trace } RC_uXC_u^T, \qquad R > 0, \tag{1.7}$$

subject to (1.5) and (1.6). □

The OCC problem may be given several interesting interpretations. For instance, assume first that w_p and v are uncorrelated zero-mean white noises with intensity matrices $W_p > 0$ and $V > 0$. That is, let $\mathcal{E}$ be an expectation operator, and

$$\begin{aligned} \mathcal{E}[w_p(t)] = 0, \qquad & \mathcal{E}[w_p(t)w_p^T(t-\tau)] = W_p\delta(\tau), \\ \mathcal{E}[v(t)] = 0, \qquad & \mathcal{E}[v(t)v^T(t-\tau)] = V\delta(\tau). \end{aligned} \tag{1.8}$$

Letting $\mathcal{E}_\infty[\cdot] := \lim_{t\to\infty} \mathcal{E}[\cdot]$ and $W = W_p$ for the case of state feedback or $W =$ block diag $[W_p, \ V]$ for the output feedback case, it is easy to see that the OCC is the problem of minimizing $\mathcal{E}_\infty u^T Ru$ subject to the OCCs $Y_i := \mathcal{E}_\infty y_i(t)y_i^T(t) \le \overline{Y}_i$. As is well known, these constraints may be interpreted as constraints on the variance of the performance variables or lower bounds on the residence time (in a given ball around the origin of the output space) of the performance variables [10].

The OCC problem may also be interpreted from a deterministic point of view. To see this, define the $\mathcal{L}_\infty$ and $\mathcal{L}_2$ norms

$$\begin{aligned} \| \ y_i\|_\infty^2 &:= \sup_{t\ge 0} \ y_i^T(t)y_i(t), \\ \| \ w\|_2^2 &:= \int_0^\infty w^T(t)w(t)dt, \end{aligned} \tag{1.9}$$

and define the (weighted) $\mathcal{L}_2$ disturbance set

$$\mathcal{W} := \{w : R \to R^{n_w} \text{ and } \| \ W^{-1/2}w\|_2^2 \le 1\}, \tag{1.10}$$

where $W > 0$ is a real symmetric matrix. Then, for any $w \in \mathcal{W}$, we have [17, 18]

$$\| \ y_i\|_\infty^2 \le \overline{\sigma}[Y_i], \qquad i = 1, 2, \ldots, m, \tag{1.11}$$

and

$$\|u_i\|_\infty^2 \le [C_u X C_u^T]_{ii}, \qquad i = 1, 2, \ldots, n_u, \tag{1.12}$$

where n_u is the dimension of u. (Here, $\overline{\sigma}[\cdot]$ denotes the maximum singular value and $[\,]_{ii}$ is the ith diagonal entry.) Moreover, [17, 18] show that the bounds in (1.11) and (1.12) are the least upper bounds that hold for an arbitrary signal $w \in \mathcal{W}$.

Thus, if we define $\overline{Y}_i := I_{m_i}\epsilon_i^2$ in (1.6) and $R :=$ diag $[r_1, r_2, \ldots, r_{n_u}]$ in (1.7), the OCC problem is the problem of minimizing the (weighted) sum of worst-case peak values on the control signals given by

$$J_{OCC} = \sum_{i=1}^{n_u} r_i \left\{ \sup_{w \in \mathcal{W}} \|u_i\|_\infty^2 \right\} \tag{1.13}$$

subject to constraints on the worst-case peak values of the performance variables of the form

$$\sup_{w \in \mathcal{W}} \|y_i\|_\infty^2 \le \epsilon_i^2, \qquad i = 1, 2, \ldots, m. \tag{1.14}$$

This interpretation is important in applications where hard constraints on responses or actuator signals cannot be ignored, such as space telescope pointing and machine tool control.

Control problems related to the OCC problem defined here have been considered before by several authors. See, for example, [6, 9, 5, 1, 3, 15, 16] for work in multiobjective optimal control with quadratic cost functionals, [13, 14, 4, 19] for the so-called variance constraint control problems, and [12] for the so-called generalized $\mathcal{H}_2$ control problem.

In the above references, one may find two different approaches for solving this class of optimal control problems: the approach based on solving the optimality conditions corresponding to the optimization problem at hand [4, 16, 19] and the approach based on reducing the given problem to a finite dimensional convex optimization problem [1, 3, 12].

In this paper, we follow the approach initiated in [4, 19]. Here, we consider a more general and realistic problem, i.e., the OCC problem, than the one studied in [4, 16, 19], and provide an iterative algorithm for solving the optimality conditions corresponding to this problem. Our main contribution is in the algorithm itself. This iterative algorithm is completely described up to a user-specified parameter. We show that the algorithm converges to a solution of the optimality conditions (assuming that one exists), provided that the user-specified parameter is properly chosen. Both discrete- and continuous-time problems are considered.

The paper is organized as follows. Section 2 provides optimality conditions for the continuous-time OCC problem in the case of state feedback. These conditions comprise one algebraic Riccati equation and one Lyapunov equation. The Riccati equation has a forcing term depending on a matrix Q (which represents the Kuhn–Tucker multipliers) that must be determined. An algorithm for finding this matrix Q is given, and its convergence analyzed. Section 2 concludes with the extension of the state feedback results to the output feedback case. Section 3 is the discrete-time version of section 2. An example is presented in section 4 to illustrate the performance of the algorithm. Section 5 gives the conclusions of this work.

The notation used in this paper is fairly standard. Given the continuous-time algebraic Riccati equation

$$0 = A_p^T K + K A_p - K B_p R^{-1} B_p^T K + C_p^T Q C_p,$$

we say that K is the stabilizing solution if $K = K^T$ satisfies the Riccati equation and $A_p - B_p R^{-1} B_p^T K$ has all eigenvalues in the open left half plane. Similarly, given the discrete-time algebraic Riccati equation

$$K = A_p^T K A_p - A_p^T K B_p (R + B^T K B_p^T)^{-1} B_p^T K A_p + C_p^T Q C_p,$$

we say that K is the stabilizing solution if $K = K^T$ satisfies the Riccati equation and $A_p - B_p(R + B_p K B_p^T)^{-1} B_p^T K A_p$ has all eigenvalues in the open unit disk. Note that when the continuous (or discrete) stabilizing solution exists it is unique. Moreover, if $Q = Q^T \geq 0$, the stabilizing solution is positive semidefinite.

2. The OCC algorithm for continuous systems.

2.1. The OCC algorithm for state feedback. In this section we consider the case of state feedback. With the state feedback controller (1.2) the closed-loop system matrices in (1.4) are given by

$$A = A_p + B_p G, \quad D = D_p, \quad C_y = C_p, \quad C_u = G. \tag{2.1}$$

The following theorem provides conditions for optimality in the state feedback case.

THEOREM 2.1. *Suppose there exists a matrix*

$$Q^* = \text{ block diag } [Q_1^*, Q_2^*, \ldots, Q_m^*] \geq 0, \quad Q_i^* = Q_i^{*T} \in R^{m_i \times m_i}, \quad i = 1, 2, \ldots, m, \tag{2.2}$$

such that the algebraic Riccati equation

$$0 = A_p^T K + K A_p - K B_p R^{-1} B_p^T K + C_p^T Q^* C_p \tag{2.3}$$

has the (unique) stabilizing solution K^*. Define

$$G^* = -R^{-1} B_p^T K^*, \tag{2.4}$$

and let X^* denote the unique solution of the Lyapunov equation

$$0 = (A_p + B_p G^*) X + X (A_p + B_p G^*)^T + D_p W_p D_p^T, \tag{2.5}$$

and define $Y_i = C_i X^* C_i^T$ $(i = 1, 2, \ldots, m)$. Then if

$$0 = (Y_i - \overline{Y}_i) Q_i^* \text{ and } Y_i \leq \overline{Y}_i \tag{2.6}$$

for all $i = 1, 2, \ldots, m$, we have that G^* given by (2.4) *is an optimal solution to the OCC problem defined in* (1.7).

Proof. Let Q^* be given by (2.1) and define the following LQ problem:

$$\min_{(G,X)} J(G, X) = \text{ trace } RGXG^T + \sum_{i=1}^{m} \text{ trace } (C_i X C_i^T - \overline{Y}_i) Q_i^* \tag{2.7}$$

subject to $A_p + B_p G$ stable and

$$0 = (A_p + B_p G) X + X (A_p + B_p G)^T + D_p W_p D_p^T. \tag{2.8}$$

Using a simple completion of square argument, it is easy to see from (2.3), (2.4), and (2.5) that (G^*, X^*) solves (2.7).

Now let G denote a feasible controller (arbitrary but fixed) for the OCC problem. That is, $(A_p + B_pG)$ is stable and $C_iXC_i^T \leq \overline{Y}_i$ (for all $i = 1, 2, \ldots, m$), where X is the closed-loop Gramian corresponding to G. From the previous paragraph, we get that

$$\begin{aligned} J_{OCC}(G^*, X^*) = &\text{ trace } RG^*X^*(G^*)^T + \sum_{i=1}^{m} \text{ trace } (C_iX^*C_i^T - \overline{Y}_i)Q_i^* \\ \leq &\text{ trace } RGXG^T + \sum_{i=1}^{m} \text{ trace } (C_iXC_i^T - \overline{Y}_i)Q_i^* \\ \leq &\text{ trace } RGXG^T. \end{aligned} \tag{2.9}$$

Using the fact that $0 = (C_iX^*C_i^T - \overline{Y}_i)Q_i^*$, from (2.9) we obtain

$$\text{trace } RG^*X^*(G^*)^T \leq \text{ trace } RGXG^T. \tag{2.10}$$

This last inequality, together with the fact that G^* is also feasible for the OCC problem because $C_iX^*C_i^T \leq \overline{Y}_i$ (for all $i = 1, 2, \ldots, m$), implies that G^* is a solution to the OCC problem. □

From (2.3) and (2.4), it follows that the solution of the OCC problem with static state feedback is an LQ controller with a special choice of output-weighting matrix Q. Therefore, our algorithm for solving the conditions in Theorem 2.1 needs only to iterate on Q.

Before giving the algorithm we would like to mention that the existence of Q^* satisfying the conditions of Theorem 2.1 is necessary in certain cases. For example, from Theorem 5.8 of [5], it follows that, when the constraints in (1.6) are scalar and (for example) the pairs (C_1, A_p), ..., (C_m, A_p) do not have imaginary axis unobservable modes, then a diagonal Q^* exists if a solution to the OCC problem exists. See also [3]. The case of block diagonal matrices Q does not seem to appear in the published literature. It should be noted that the emphasis of the present paper is an algorithm for computing Q^* (and thus a controller that solves the OCC problem) under the assumption that a matrix Q^* satisfying the conditions of Theorem 2.1 exists. This algorithm is given next.

To give this algorithm we need to introduce the following operator. Let M denote a real symmetric matrix, and suppose that

$$M = [U_1\ U_2] \text{ block diag } [E_p,\ E_n]\ [U_1\ U_2]^T \tag{2.11}$$

is the (real) Schur decomposition of M, where E_p and E_n are diagonal matrices containing the strictly positive and nonpositive eigenvalues of M in decreasing order, respectively, and $[U_1\ U_2]$ is an orthogonal matrix. Define

$$\mathcal{P}[M] = \begin{cases} 0 & \text{if } M \leq 0, \\ U_1E_pU_1^T & \text{otherwise.} \end{cases} \tag{2.12}$$

Note that if M is a symmetric matrix with block diagonal structure, the operator $\mathcal{P}[\cdot]$ preserves the block structure; i.e., $\mathcal{P}[M]$ has the block structure of M.

The following algorithm for solving the conditions in Theorem 2.1 is the main contribution of this paper.

THE OCC ALGORITHM.

(1) Given A_p, B_p, D_p, C_p, W_p, R, $\overline{Y}^b =$ block diag $[\overline{Y}_1, \overline{Y}_2, \ldots, \overline{Y}_m]$, an initial point $Q(0) =$ block diag $[Q_1(0), Q_2(0), \ldots, Q_m(0)] > 0$, and constants $\alpha > 0$, $0 < \beta < 1$, let $j = 0$ and go to 2).

(2) Compute $K(j) \geq 0$ and $G(j)$ by solving

$$\begin{aligned} 0 &= A_p^T K(j) + K(j) A_p - K(j) B_p R^{-1} B_p^T K(j) + C_p^T Q(j) C_p, \\ G(j) &= -R^{-1} B_p^T K(j). \end{aligned} \tag{2.13}$$

(3) Compute $X(j)$ by solving

$$0 = [A_p + B_p G(j)] X(j) + X(j) [A_p + B_p G(j)]^T + D_p W_p D_p^T. \tag{2.14}$$

(4) Set $Y_i(j) = C_i X(j) C_i^T$ for $i = 1, 2, \ldots, m$.

(5) Let $Y^b(j) =$ block diag $[Y_1(Q(j)), Y_2(Q(j)), \ldots, Y_m(Q(j))]$, and

$$Q(j+1) = \beta Q(j) + (1-\beta) \mathcal{P}[Q(j) + \alpha \{Y^b(j) - \overline{Y}^b\}] , \tag{2.15}$$

$j = j + 1$, go to 2). □

Several stopping criteria may be used to guarantee that the OCC algorithm terminates in a finite number of steps. In this paper, we propose stopping the algorithm whenever the first equation in condition (2.6) is satisfied to a given numerical accuracy. This can be achieved by checking if the inequality

$$\sum_{i=1}^{m} ||(Y_i(j) - \overline{Y}_i) Q_i(j)|| < \epsilon \tag{2.16}$$

holds, where $\epsilon > 0$ is the specified tolerance. Inequality (2.16) must be tested after step 4). If (2.16) holds, we stop the algorithm and declare $G(j)$, $Q_1(j)$, $Q_2(j)$, and $Q_m(j)$ to be a numerical solution to the OCC problem; if (2.16) does not hold, the algorithm continues.

The rest of this section is devoted to showing that, under the assumption

(A1) (A_p, B_p) is stabilizable and A_p has no eigenvalues on the imaginary axis,

if there exists Q^* satisfying the conditions in Theorem 2.1, then the OCC algorithm will find it, provided that α is properly chosen. More specifically, under the assumptions mentioned, we will show that the sequence of matrices $\{Q(j)\}_{j=0}^{\infty}$ generated by the OCC algorithm (see (2.15)) has a limit $\hat{Q}$ which satisfies all the conditions of Theorem 2.1. Thus, the OCC algorithm converges to a globally optimal solution to the OCC problem. Note that the existence of the limit $\hat{Q}$ implies that, given any $\epsilon > 0$, there exists an integer j such that inequality (2.16) holds.

Note that the OCC algorithm is well posed in the sense that the unique positive semidefinite solution $K(j)$ to the Riccati equation (2.13) and the solution $X(j)$ to the Lyapunov equation (2.14) exist at each iteration. This follows from assumption (A1) and the fact that, at each iteration, $Q(j) \geq 0$. As is well known [7], since (A_p, B_p) is stabilizable and the pair $(Q(j)^{1/2} C_p, A_p)$ has no imaginary axis unobservable modes, $K(j) \geq 0$ exists, is unique, and renders $A_p - B_p R^{-1} B_p^T K(j)$ asymptotically stable.

To establish our results we need to introduce the following operators:

$$\begin{aligned} \mathcal{T}_\beta[Q] &:= \beta Q + (1-\beta) \mathcal{T}[Q], \\ \mathcal{T}[Q] &:= \mathcal{P}[Q + \alpha \{Y^b(Q) - \overline{Y}^b\}], \end{aligned} \tag{2.17}$$

where $\alpha > 0$ and $\beta \in (0,1)$ are parameters of the OCC algorithm. Note that, with this notation, the sequence of matrices $Q(j)$ generated by the OCC algorithm is $\{\mathcal{T}_\beta^j[Q(0)]\}_{j=0}^\infty$, where $Q(0) \geq 0$ is block diagonal.

THEOREM 2.2. *Consider the OCC algorithm, and suppose that $\alpha > 0$, $0 < \beta < 1$, and assumption* (A1) *holds. Suppose that the algorithm converges; that is, the sequence $\{\mathcal{T}_\beta^j[Q(0)]\}_{j=0}^\infty$ converges to Q^*. Then $Q^* :=$ block diag $[Q_1^*, Q_2^*, \ldots, Q_m^*]$ satisfies the sufficient conditions in Theorem* 2.1 *for optimality. In other words, if the OCC algorithm converges, the resulting controller $u{=}-R^{-1}B_p^T K^* x$, where K^* solves* (2.3)*, is a global optimal solution to the given OCC problem, where Q^* is the limit of the convergent sequence $\{\mathcal{T}_\beta^j[Q(0)]\}_{j=0}^\infty$.*

The proof of Theorem 2.2 requires the following lemma.

LEMMA 2.3. *For any symmetric matrices $M = M^T$ and $N = N^T$ of the same dimensions, the following statements hold:*

1. *$\mathcal{P}[M+N] = M$ if and only if $M \geq 0$, $N \leq 0$, and $MN = 0$.*
2. *$\|\mathcal{P}[M] - \mathcal{P}[N]\| \leq \|M - N\|$, where $\|\cdot\|$ denotes the Frobenius norm.*

Proof. First, we shall show the necessity part of 1. The property $M \geq 0$ is a direct consequence of the definition of $\mathcal{P}[\cdot]$ in (2.12). Next, we show that $N \leq 0$ and $MN = 0$. Let $M + N$ have the Schur decomposition

$$\begin{aligned} M + N &= [U_1\ U_2]\ \text{block diag}\ [E_p\ ,\ E_n][U_1\ U_2]^T \\ &= U_1 E_p U_1^T + U_2 E_n U_2^T, \end{aligned} \tag{2.18}$$

where $E_p > 0$ and $E_n \leq 0$. Thus, from (2.12) and $\mathcal{P}[M+N] = M$ we obtain

$$\mathcal{P}[M+N] = U_1 E_p U_1^T = M. \tag{2.19}$$

Subtracting this last equation from (2.18) we obtain

$$N = U_2 E_n U_2^T \leq 0. \tag{2.20}$$

Since $U_1^T U_2 = 0$, from (2.19) and (2.20) it follows that

$$MN = U_1 E_p U_1^T U_2 E_n U_2^T = 0.$$

Second, we shall show the sufficiency part of 1. Let $M \geq 0$ and $N \leq 0$ be given and suppose that $MN = 0$. Note that if either M or N is zero, the sufficiency of property 1) is trivial. Now suppose that $M \neq 0$ and $N \neq 0$. The real Schur decompositions of M and N are

$$M = U_1 E_p U_1^T, \qquad N = U_2 E_n U_2^T,$$

where $E_p > 0$, $E_n < 0$, $U_1^T U_1 = I$, $U_2^T U_2 = I$, and $U_1^T U_2 = 0$. Then

$$\mathcal{P}[M+N] = \mathcal{P}[U_1 E_p U_1^T + U_2 E_n U_2^T] = U_1 E_p U_1^T = M. \tag{2.21}$$

Finally, we show property 2. Let M and N have the following Schur decompositions:

$$\begin{aligned} M &= [U_1\ U_2]\ \text{block diag}\ [E_p\ ,\ E_n][U_1\ U_2]^T, \quad E_p > 0, \quad E_n \leq 0, \\ N &= [\hat{U}_1\ \hat{U}_2]\ \text{block diag}\ [\hat{E}_p\ ,\ \hat{E}_n][\hat{U}_1\ \hat{U}_2]^T, \quad \hat{E}_p > 0, \quad \hat{E}_n \leq 0. \end{aligned} \tag{2.22}$$

Let

$$\begin{aligned} M^+ &:= \mathcal{P}[M] = U_1 E_p U_1^T > 0, \\ M^- &:= U_2 E_n U_2^T \le 0, \\ N^+ &:= \mathcal{P}[N] = \hat{U}_1 \hat{E}_p \hat{U}_1^T > 0, \\ N^- &:= \hat{U}_2 \hat{E}_n \hat{U}_2^T \le 0. \end{aligned}$$

Note that $M = M^+ + M^-$, $N = N^+ + N^-$, $M^+M^- = 0$, and $N^+N^- = 0$. Then

$$\begin{aligned} \|M - N\|^2 &= \|(M^+ - N^+) + (M^- - N^-)\|^2 \\ &= \|M^+ - N^+\|^2 + \|M^- - N^-\|^2 \\ &\quad -2\text{trace}M^-N^+ - 2\text{trace}M^+N^-. \end{aligned} \tag{2.23}$$

Since $-\text{trace}M^-N^+ \ge 0$ and $-\text{trace}M^+N^- \ge 0$, we obtain

$$\|M - N\|^2 \ge \|M^+ - N^+\|^2 = \|\mathcal{P}[M] - \mathcal{P}[N]\|^2, \tag{2.24}$$

which completes the proof. □

The following lemma, essentially due to [2], is also required for the proof of Theorem 2.2.

LEMMA 2.4. *Consider the plant defined in* (1.1) *and suppose that assumption* (A1) *holds. Let K denote the unique stabilizing solution to the Riccati equation* (2.3) *with $Q = Q^T \ge 0$. Then $K(Q)$ is a real analytic function of $Q = Q^T \ge 0$.*

Proof of Theorem 2.2. By Lemma 2.4, the state feedback control gain $G(Q)$ in (2.4) is a continuous function of $Q = Q^T \ge 0$. Hence, the block output covariance matrix $Y^b(Q)$ is continuous with respect to $Q = Q^T \ge 0$. Since the operator $\mathcal{P}[\cdot]$ is continuous, we obtain that $\mathcal{T}[\cdot]$ and $\mathcal{T}_\beta[\cdot]$ are well defined and continuous for any $Q = Q^T \ge 0$. Suppose that $\{\mathcal{T}_\beta^j[Q(0)]\}_{j=0}^\infty$ converges to Q^*, i.e.,

$$\lim_{j\to\infty} \mathcal{T}_\beta^j[Q(0)] = Q^*. \tag{2.25}$$

Since $\beta \in (0,1)$ and $\mathcal{P}[\cdot]$ preserves the block structure, we may conclude that, for each j, $\mathcal{T}_\beta^j[Q(0)]$ has the correct block diagonal structure and is positive semidefinite. Thus, $Q^* = \text{block diag}\,[Q_1^*, Q_2^*, \ldots, Q_m^*]$ and $Q^* \ge 0$.

From the continuity properties of $\mathcal{T}_\beta$, we obtain

$$\mathcal{T}_\beta[Q^*] = \mathcal{T}_\beta\left\{\lim_{j\to\infty} \mathcal{T}_\beta^j[Q(0)]\right\} = \lim_{j\to\infty} \mathcal{T}_\beta^{j+1}[Q(0)] = Q^*. \tag{2.26}$$

That is, Q^* is a fixed point of $\mathcal{T}_\beta[\cdot]$. Since $\beta \ne 1$, from (2.17), we get

$$Q^* = \mathcal{T}[Q^*] = \mathcal{P}[Q^* + \alpha\{Y^b(Q^*) - \overline{Y}^b\}]\,. \tag{2.27}$$

Let $M = Q^*$ and $N = \alpha[Y^b(Q^*) - \overline{Y}^b]$. From Lemma 2.3, we conclude that

$$\alpha[Y^b(Q^*) - \overline{Y}^b] \le 0 \;\text{ and }\; \alpha Q^*[Y^b(Q^*) - \overline{Y}^b] = 0\,.$$

Since $\alpha > 0$, the above inequalities imply that Q^* satisfies (2.6). Hence, Q^* satisfies the conditions in Theorem 2.1. This completes the proof. □

The following result shows that there is always a choice for the parameter α in the OCC algorithm that will guarantee its convergence, provided that the conditions in Theorem 2.1 admit one solution.

THEOREM 2.5. *Suppose that assumption* (A1) *holds. Assume also that there exists* Q^* *satisfying the conditions in Theorem* 2.1. *Then, given any* $Q(0) \geq 0 \in \mathcal{R}^{n_y \times n_y}$ *with the appropriate block diagonal structure, there exists an* $\alpha^* > 0$ *such that if* $0 < \alpha \leq \alpha^*$, *the sequence* $\{\mathcal{T}_\beta^n[Q(0)]\}_{n=0}^\infty$ *will converge to some* $\hat{Q} \geq 0$ *satisfying the conditions in Theorem* 2.1. *That is, the OCC algorithm will converge to a global optimal solution of the given OCC problem.*

In order to prove Theorem 2.5, we need a few intermediate results and definitions. Let $Q = Q^T \geq 0$ be given and K denote the (unique) stabilizing solution to

$$0 = A_p^T K + K A_p - K B_p R^{-1} B_p^T K + C_p^T Q C_p. \tag{2.28}$$

Then, with the state feedback gain $G = -R^{-1} B_p^T K$, the lth output covariance of the closed-loop system Y_l $(l = 1, 2, \cdots, m)$ is given by

$$Y_l = C_l X C_l^T,$$

where X is the unique solution to

$$0 = (A_p + B_p G)X + X(A_p + B_p G)^T + D_p W_p D_p^T. \tag{2.29}$$

Now, let

$$Q = \text{block diag}[Q_1, Q_2, \ldots, Q_m], \qquad Q_l := [q_{ij}^l] \in \mathcal{R}^{m_l \times m_l}, \tag{2.30}$$

and

$$Y^b = \text{block diag}[Y_1, Y_2, \ldots, Y_m]\ . \tag{2.31}$$

Below, we compute the derivative of Y^b with respect to the weighting matrix Q given in (2.30). We do this using vector notation. Let Q be given by (2.30) and define the operator *svec* by

$$svec[Q] = \begin{bmatrix} q^1 \\ q^2 \\ \vdots \\ q^m \end{bmatrix} \in \mathcal{R}^n\ , \tag{2.32}$$

where

$$q^i := \sqrt{2}\ \left[\frac{q_{11}^i}{\sqrt{2}}, q_{12}^i, \ldots, q_{1m_i}^i, \frac{q_{22}^i}{\sqrt{2}}, q_{23}^i, \ldots, q_{2m_i}^i, \ldots, \frac{q_{m_i m_i}^i}{\sqrt{2}}\right]^T\ . \tag{2.33}$$

Note also that the operator *svec* defined in (2.32) preserves the Frobenius norm; i.e., if Q is given by (2.30), we have

$$||Q|| = ||svec[Q]||\ . \tag{2.34}$$

Moreover, $svec[\cdot]$ is a linear operator.

Let

$$y = svec[Y^b] \,, \tag{2.35}$$

where Y^b is given by (2.31). Define also the symmetric matrix

$$E_i = svec^{-1}[e_i] \,, \tag{2.36}$$

where $e_i \in \mathcal{R}^n$ has a one in the ith row and zeros elsewhere, and $svec^{-1}$ is the inverse of the operator *svec*.

LEMMA 2.6. *Consider the system defined in* (1.1)*, and suppose that assumption* (A1) *holds. Let* $Q = Q^T \geq 0$ *be given by* (2.30)*, and define* $q = svec[Q]$*. Let* y *be given by* (2.35)*. Then the partial derivative of* $y \in \mathcal{R}^n$ *with respect to* $q \in \mathcal{R}^n$ *is*

$$\frac{\partial y}{\partial q} = -[H_{ij}] = -[2\text{trace}(P_i B_p R^{-1} B_p^T P_j X)], \qquad i,j = 1,2,\ldots,n, \tag{2.37}$$

where P_i *is the unique solution to*

$$0 = P_i(A_p + B_p G) + (A_p + B_p G)^T P_i + C_p^T E_i C_p \tag{2.38}$$

with E_i *given by* (2.36)*. Moreover, if* $Q = Q^T \geq 0$*, the matrix-valued function* $H(Q) = [H_{ij}]$ *is continuous and it satisfies* $H(Q) \geq 0$*.*

Proof. Let y_i denote the ith component of y. From the definition of the operator *svec* (see, for example, (2.32)) it follows that

$$y_i = \text{trace}(E_i C_p X C_p^T). \tag{2.39}$$

Using the Lyapunov equations (2.29) and (2.38) it follows from (2.39) that

$$y_i = \text{trace}(P_i D_p W_p D_p^T), \tag{2.40}$$

where P_i is the solution to (2.38). Hence, from (2.40), we get

$$\frac{\partial y_i}{\partial q_j} = \text{trace}(P_{ij} D_p W_p D_p^T), \tag{2.41}$$

where q_j is the jth component of q and $P_{ij} = \frac{\partial P_i}{\partial q_j}$.

Now to generate P_{ij}, differentiate equation (2.38) with respect to q_j to obtain

$$\begin{aligned} 0 &= P_{ij}(A_p + B_p G) + (A_p + B_p G)^T P_{ij} \\ &\quad - P_i B_p R^{-1} B_p^T \frac{\partial K}{\partial q_j} - \frac{\partial K}{\partial q_j} B_p R^{-1} B_p^T P_i. \end{aligned} \tag{2.42}$$

From the Riccati equation (2.28) and the Lyapunov equation (2.38) we get

$$P_j = \frac{\partial K}{\partial q_j},$$

where P_j solves (2.38) with the "E-matrix" equal to E_j. Hence, from (2.42), we obtain

$$\begin{aligned} P_{ij} = -\int_0^\infty \exp[(A_p + B_p G)^T t][P_i B_p R^{-1} B_p^T P_j \\ + P_j B_p R^{-1} B_p^T P_i] \exp[(A_p + B_p G)t] dt. \end{aligned} \tag{2.43}$$

Finally, from (2.29), (2.41), and (2.43) we obtain

$$\frac{\partial y}{\partial q} = -[H_{ij}] = -[2\text{trace}(P_i B_p R^{-1} B_p^T P_j X)] \,, \tag{2.44}$$

which gives (2.37).

The continuity of $H(Q)$ follows from the fact that, on the set of positive semidefinite matrices Q, the matrix-valued functions P_i, P_j, and X are all continuous. Note also that

$$\begin{aligned} H_{ij} &= \text{trace}\,(P_i B_p R^{-1} B_p^T P_j X) \\ &= \langle X^{1/2} P_i B_p R^{-1/2}, X^{1/2} P_j B_p R^{-1/2} \rangle, \end{aligned}$$

where $\langle M, N \rangle = \text{trace} MN^T$ is the standard inner product on the space of matrices $\mathcal{R}^{n_x \times n_u}$, where n_x and n_u are dimensions of the plant states and controls. Thus, H is of the form

$$H = [\langle X^{1/2} P_i B_p R^{-1/2}, X^{1/2} P_j B_p R^{-1/2} \rangle], \tag{2.45}$$

which shows that $H \geq 0$. □

The following results may be found in [11]; see Propositions 3.2.3 and 12.3.7.

LEMMA 2.7. *Assume that $\mathcal{F} : \mathcal{R}^n \to \mathcal{R}^n$ is Fréchet differentiable on a convex set $\mathcal{D}'_0 \subset \mathcal{R}^n$. Then for any x and $y \in \mathcal{D}'_0$,*

$$\|\mathcal{F}(y) - \mathcal{F}(x)\| \leq \sup_{0 \leq t \leq 1} \overline{\sigma}\{\mathcal{F}'[x + t(y - x)]\} \|x - y\| \,, \tag{2.46}$$

where $\mathcal{F}'(\cdot)$ denotes the Fréchet derivative of $\mathcal{F}(\cdot)$ and $\overline{\sigma}[\cdot]$ denotes the maximum singular value of $[\cdot]$.

LEMMA 2.8. *Suppose that $\mathcal{T} : \mathcal{R}^{n_y \times n_y} \to \mathcal{R}^{n_y \times n_y}$ is nonexpansive on the closed, convex set $\mathcal{D}_0$. That is, for any $x, y \in \mathcal{D}_0$, we have*

$$\|\mathcal{T}(y) - \mathcal{T}(x)\| \leq \|y - x\| \,. \tag{2.47}$$

Assume, further, that $\mathcal{T}\mathcal{D}_0 \subset \mathcal{D}_0$ and that $\mathcal{D}_0$ contains a fixed point of $\mathcal{T}$. Then for any $\beta \in (0, 1)$ and $x^0 \in \mathcal{D}_0$ the iteration

$$x^{k+1} = \beta x^k + (1 - \beta)\mathcal{T}(x^k), \qquad k = 0, 1, \ldots, \tag{2.48}$$

converges to a fixed point of $\mathcal{T}$ in $\mathcal{D}_0$.

Proof of Theorem 2.5. The proof of Theorem 2.5 consists of two steps. First, we show the nonexpansive property of operator $\mathcal{T}$ defined in (2.17). By assumption, there exists Q^* satisfying the conditions in Theorem 2.1. Define a subset of $\mathcal{R}^{n_y \times n_y}$ as follows:

$$\begin{aligned} \mathcal{D}_0 := \{ & Q \geq 0 \in \mathcal{R}^{n_y \times n_y} : Q = \text{block diag}[Q_1, Q_2, \ldots, Q_m] \\ & \text{and } \|Q - Q^*\| \leq \|Q(0) - Q^*\| \}, \end{aligned} \tag{2.49}$$

where n_y is the dimension of y_p, and $Q(0)$ is the initial output-weighting matrix for the OCC algorithm. It is obvious that the set $\mathcal{D}_0$ is compact (i.e., closed and bounded) and convex. Let $\mathcal{D}'_0$ be a set defined by

$$\mathcal{D}'_0 := \{ q = svec[Q] \in \mathcal{R}^n : Q \in \mathcal{D}_0 \} \,. \tag{2.50}$$

It is clear that $\mathcal{D'}_0$ is convex, because $svec[\cdot]$ is a linear operator and $\mathcal{D}_0$ is convex. Let $q \in \mathcal{D}'_0$ and define $y(q) = svec[Y^b(Q)]$, and

$$\mathcal{F}[q] = q + \alpha y(q). \tag{2.51}$$

Note that $\mathcal{F}[\cdot]$ is well defined and Fréchet differentiable, with respect to q, in $\mathcal{D'}_0$. In fact, from Lemma 2.6, it follows that the Frechet derivative of $\mathcal{F}[\cdot]$ is

$$\mathcal{F}'[q] = I - \alpha H(q), \tag{2.52}$$

where $H(q)$ is defined in (2.37). (Here, we think of H as a function of $q = svec[Q]$ instead of a function Q.)

Now, let Q^ν and Q^μ in $\mathcal{D}_0$ be given. Define $q^\nu = svec[Q^\nu]$ and $q^\mu = svec[Q^\mu]$. Then, since $svec[\cdot]$ preserves the Frobenius norm, we have

$$\begin{aligned} \|\mathcal{T}[Q^\nu] - \mathcal{T}[Q^\mu]\| &= \|\mathcal{P}[Q^\nu - \alpha\{Y^b(Q^\nu) - \overline{Y}^b\}] - \mathcal{P}[Q^\mu - \alpha\{Y^b(Q^\mu) - \overline{Y}^b\}]\| \\ &\le \|Q^\nu - Q^\mu - \alpha[Y^b(Q^\nu) - Y^b(Q^\mu)]\| \\ &= \|q^\nu - q^\mu - \alpha[y^\nu - y^\mu]\|, \end{aligned} \tag{2.53}$$

where $y^\nu := svec[Y^b(Q^\nu)]$ and $y^\mu := svec[Y^b(Q^\mu)]$. Since q^ν and q^μ belong to $\mathcal{D'}_0$, using Lemma 2.7, we have

$$\begin{aligned} \|q^\nu - q^\mu - \alpha[y^\nu - y^\mu]\| &= \|\mathcal{F}[q^\nu] - \mathcal{F}[q^\mu]\| \\ &\le \sup_{0\le t\le 1} \overline{\sigma}[\mathcal{F}'[tq^\nu + (1-t)q^\mu]]\|q^\nu - q^\mu\| \\ &= \sup_{0\le t\le 1} \overline{\sigma}[I - \alpha H\{[tq^\nu + (1-t)q^\mu]\}]\|q^\nu - q^\mu\|. \end{aligned} \tag{2.54}$$

Since H is a continuous function over the compact set $\mathcal{D'}_0$, there exists an $\alpha^* > 0$ such that for any $q^\nu \in \mathcal{D'}_0$, $q^\mu \in \mathcal{D}'_0$, and $0 \le t \le 1$, we have

$$\overline{\sigma}\{H[tq^\nu + (1-t)q^\mu]\} \le 2/\alpha^*. \tag{2.55}$$

Thus, since for any q^ν and $q^\mu \in \mathcal{D'}_0$ and any $t \in [0,1]$, $H[tq^\nu + (1-t)q^\mu] \ge 0$, we have

$$\sup_{0\le t\le 1} \overline{\sigma}\{I - \alpha H[tq^\nu + (1-t)q^\mu]\} \le 1 \tag{2.56}$$

for any $\alpha \le \alpha^*$. Therefore, using (2.53) and (2.54), for any $\alpha \le \alpha^*$ we obtain

$$\|\mathcal{T}[Q^\nu] - \mathcal{T}[Q^\mu]\| \le \|q^\nu - q^\mu\| = \|Q^\nu - Q^\mu\|. \tag{2.57}$$

Hence, for any $\alpha \le \alpha^*$, the operator $\mathcal{T}$ is nonexpansive on $\mathcal{D}_0$. Replacing Q^μ by Q^* proves that for any $Q \in \mathcal{D}_0$

$$\|\mathcal{T}[Q] - \mathcal{T}[Q^*]\| \le \|Q - Q^*\| \le \|Q(0) - Q^*\|. \tag{2.58}$$

Now, using Lemma 2.3 and the fact that Q^* satisfies the conditions of Theorem 2.1, we conclude that $\mathcal{T}[Q^*] = Q^*$. This equation and (2.58) imply

$$\|\mathcal{T}[Q] - Q^*\| \le \|Q(0) - Q^*\|; \tag{2.59}$$

therefore, $\mathcal{T}[Q] \in \mathcal{D}_0$.

Second, we shall show the convergence of the OCC algorithm, that is, the convergence of the sequence $\{\mathcal{T}_\beta^j[Q(0)]\}_{j=0}^\infty$. Since $\mathcal{T}\mathcal{D}_0 \subset \mathcal{D}_0$, $\mathcal{D}_0$ is convex and contains a fixed point of $\mathcal{T}$, from Lemma 2.8 we obtain that the sequence $\{\mathcal{T}_\beta^j[Q(0)]\}_{j=0}^\infty$ generated by the iteration

$$Q(j+1) = \mathcal{T}_\beta[Q(j)] = \beta Q(j) + (1-\beta)\mathcal{T}[Q(j)] \tag{2.60}$$

converges to a fixed point of $\mathcal{T}$ in $\mathcal{D}_0$—say, $\hat{Q}$. The fact that $\hat{Q}$ satisfies the sufficient conditions in Theorem 2.1 is the direct consequence of Theorem 2.2. □

2.2. The OCC algorithm for full-order dynamic feedback. The extension of the state feedback case to the full-order dynamic feedback case is straightforward. In fact, the state feedback OCC algorithm can be applied to solve the full-order dynamic feedback OCC problem. Here, for system (1.1), we assume that assumption (A1) holds and that

(A2) (M_p, A_p) is detectable.

As is well known [7], under assumption (A2), there exists a unique matrix $\tilde{X}$ that satisfies the Riccati equation

$$0 = A_p\tilde{X} + \tilde{X}A_p^T - \tilde{X}M_p^T V^{-1} M_p \tilde{X} + D_p W_p D_p^T \tag{2.61}$$

and $A_p - \tilde{X}M_p^T V^{-1}$ is asymptotically stable. Moreover, $\tilde{X} \geq 0$. With this matrix $\tilde{X}$, we define

$$F = \tilde{X}M_p^T V^{-1}\ . \tag{2.62}$$

THEOREM 2.9. *Consider the plant defined in* (1.1). *Let* $\tilde{X}$ *and* F *denote the matrices in* (2.61) *and* (2.62). *Suppose that there exists a matrix*

$$Q^* = \text{ block diag}[Q_1^*, Q_2^*, \ldots, Q_m^*] \geq 0, \quad Q_i^* = {Q_i^*}^T \in \mathcal{R}^{m_i \times m_i}, \quad i = 1, 2, \ldots, m, \tag{2.63}$$

such that the algebraic Riccati equation

$$0 = A_p^T K + K A_p - K B_p R^{-1} B_p^T K + C_p^T Q^* C_p \tag{2.64}$$

has the (unique) stabilizing solution K^*. *Define*

$$G = -R^{-1}B_p^T K^*, \tag{2.65}$$

and let X^* *denote the unique solution to the Lyapunov equation*

$$0 = (A_p + B_p G)X + X(A_p + B_p G)^T + FVF^T, \tag{2.66}$$

and define $Y_i = C_i(\tilde{X} + X^*)C_i^T$ $(i = 1, 2, \ldots, m)$. *Then if*

$$0 = (Y_i - \overline{Y}_i)Q_i^* \text{ and } Y_i \leq \overline{Y}_i \tag{2.67}$$

for all $i = 1, 2, \ldots, m$, *the dynamic controller*

$$\begin{aligned} \dot{x}_c(t) &= (A_p + B_p G - FM_p)x_c(t) + Fz(t), \\ u(t) &= Gx_c(t) \end{aligned} \tag{2.68}$$

is an optimal solution to the OCC problem defined in (1.7).

A proof of this theorem may be obtained by combining Theorem 2.1 in this paper and Lemma 4.2 and Theorem 4.1 in [12]. The result in [12] shows how to reduce the OCC problem (and other $\mathcal{H}_2$-like problems) with output feedback to an equivalent problem with state feedback.

Note that the matrices $\tilde{X}$ and F in (2.61) and (2.62) do not depend on the weighting matrix Q^*. To find a matrix Q^* satisfying the conditions in Theorem 2.9, we can use the OCC algorithm given in section 2. This requires that we replace D_p, W_p, and $\overline{Y}_i$ in the OCC algorithm F, V, and $\overline{Y}_i - C_i\tilde{X}C_i^T$, respectively.

3. Discrete-time version. The discrete-time version of the OCC problem is very much like the continuous-time case. Here, we give the definition of the OCC problem and the main results.

Consider the following discrete system:

$$\begin{aligned} x_p(k+1) &= A_p x_p(k) + B_p u(k) + D_p w_p(k), \\ y_p(k) &= C_p x_p(k), \\ z(k) &= M_p x_p(k) + v(k). \end{aligned} \tag{3.1}$$

Suppose that we apply to the plant (3.1) a full state feedback stabilizing control, i.e.,

$$u(k) = Gx(k), \tag{3.2}$$

or a strictly proper stabilizing control

$$\begin{aligned} x_c(k+1) &= A_c x_c(k) + Fz(k), \\ u(k) &= Gx_c(k). \end{aligned} \tag{3.3}$$

Then the closed-loop system has the following form:

$$\begin{aligned} x(k+1) &= Ax(k) + Dw(k), \\ y(k) &= \begin{bmatrix} y_p(k) \\ u(k) \end{bmatrix} = \begin{bmatrix} C_y \\ C_u \end{bmatrix} x(k) = Cx(k), \end{aligned} \tag{3.4}$$

where the definitions of matrices A, B, and C and vectors x, w, and y are as in the continuous-time case.

As in section 1, let $W_p > 0$ and $V > 0$ denote symmetric matrices with dimensions equal to the dimensions of w_p and z, respectively. Define $W = W_p$ if (3.2) is used in (3.4) or $W =$ block diag$[W_p,\ V]$ if (3.3) is used. Let X denote the closed-loop controllability Gramian from the input $W^{-1/2}w$. Since A is stable, X is given by

$$X = AXA^T + DWD^T. \tag{3.5}$$

As in the continuous-time case, we seek a solution to the following optimal control problem.

The Discrete-Time OCC Problem. Find a state feedback stabilizing controller (3.2) or a strictly proper output feedback stabilizing controller (3.3) for the system (3.1) to minimize the OCC cost

$$J_{OCC} = \text{trace}RC_uXC_u^T, \qquad R > 0, \tag{3.6}$$

subject to

$$Y_i = C_iXC_i^T \le \overline{Y}_i, \qquad i = 1, 2, \ldots, m, \tag{3.7}$$

where X is given by (3.5). □

The discrete-time OCC problem has interpretations similar to the ones of the continuous-time case. For example, the discrete-time OCC problem may be interpreted as the problem of minimizing a weighted sum of the worst-case peak values of the control signals u_i subject to constraints on the worst-case peak values of the response y_i, when the disturbance w is unknown but has bounded energy. This is because, as in the continuous-time case, discrete-time gains from ℓ_2 to ℓ_∞ may also be computed using controllability Gramians [18].

3.1. State feedback case. In this section we consider the case of state feedback. The following theorem provides conditions for global optimality. Its proof is similar to that of Theorem 2.1 and is omitted.

THEOREM 3.1. *Suppose there exists a matrix*

$$Q^* = \text{ block diag}[Q_1^*, Q_2^*, \dots, Q_m^*] \geq 0, \quad Q_i^* = {Q_i^*}^T \in R^{m_i \times m_i}, \qquad i = 1, 2, \dots, m, \tag{3.8}$$

such that the algebraic Riccati equation

$$K = A_p^T K A_p - A_p^T K B_p (R + B_p^T K B_p)^{-1} B_p^T K A_p + C_p^T Q^* C_p \tag{3.9}$$

has the (unique) stabilizing solution K^*. Define

$$G^* = -(R + B_p^T K^* B_p)^{-1} B_p^T K^* A_p, \tag{3.10}$$

let X^* denote the unique solution of the Lyapunov equation

$$X = (A_p + B_p G^*) X (A_p + B_p G^*)^T + D_p W_p D_p^T, \tag{3.11}$$

and define $Y_i = C_i X^* C_i^T$ $(i = 1, 2, \dots, m)$. Then, if

$$0 = (Y_i - \overline{Y}_i) Q_i^* \text{ and } Y_i \leq \overline{Y}_i \tag{3.12}$$

for all $i = 1, 2, \dots, m$, we have that G^* given by (3.10) *is an optimal solution to the OCC problem defined in* (3.6).

The following algorithm may be used to find a matrix Q^* and consequently a matrix G^* for the OCC problem satisfying the conditions in Theorem 3.1.

THE DISCRETE-TIME OCC ALGORITHM.

(1) Given A_p, B_p, D_p, C_p, W_p, R, $\overline{Y}_i = \text{block diag}[\overline{Y}_1, \overline{Y}_2, \dots, \overline{Y}_m]$, an initial point $Q(0) = \text{block diag}[Q_1(0), Q_2(0), \dots, Q_m(0)] > 0$, and constants $\alpha > 0$, $0 < \beta < 1$, let $j = 0$ and go to 2).

(2) Compute $K(j) \geq 0$ and $G(j)$ by solving

$$\begin{aligned} K(j) &= A_p^T K(j) A_p + C_p^T Q(j) C_p \\ &\quad - A_p^T K(j) B_p [R + B_p^T K(j) B_p]^{-1} B_p^T K(j) A_p, \\ G(j) &= -[R + B_p^T K(j) B_p]^{-1} B_p^T K(j) A_p. \end{aligned} \tag{3.13}$$

(3) Compute $X(j)$ by solving

$$X(j) = [A_p + B_p G(j)] X(j) [A_p + B_p G(j)]^T + D_p W_p D_p^T. \tag{3.14}$$

(4) Set $Y_i(j) = C_i X(j) C_i^T$ for $i = 1, 2, \dots, m$.

(5) Let $Y^b(j) = \text{block diag}[Y_1(Q(j)), Y_2(Q(j)), \ldots, Y_m(Q(j))]$, and

$$Q(j+1) = \beta Q(j) + (1-\beta)\mathcal{P}[Q(j) + \alpha\{Y^b(j) - \overline{Y}^b\}], \tag{3.15}$$

$j = j+1$, go to 2).

In (3.15), the operator $\mathcal{P}[\cdot]$ is as defined in (2.12).

The same stop criterion as the continuous-time case is proposed for the discrete-time OCC algorithm. That is, (2.16) needs to be tested after step 4) for a given tolerance $\epsilon > 0$. If (2.16) holds, $G(j)$, $Q_1(j)$, $Q_2(j)$, and $Q_m(j)$ are numerical solutions for the given OCC problem; otherwise, the algorithm continues.

In the rest of this section, we will assume the following:

(A3) (A_p, B_p) is stabilizable and A_p has no eigenvalues on the unit circle.

Note that the discrete-time OCC algorithm is well posed in the sense that the unique positive semidefinite solution $K(j)$ to the Riccati equation (3.13) and the solution $X(j)$ to the Lyapunov equation (3.14) exist at each iteration. This follows from assumption (A3) and the fact that, at each iteration, $Q(j) \geq 0$. As is well known [8], since (A_p, B_p) is stabilizable and the pair $(Q(j)^{1/2}C_p, A_p)$ has no unobservable modes on the unit circle, $K(j) \geq 0$ exists, is unique, and renders $A_p - B_p(R + B_p^T K(j) B_p)^{-1} B_p^T K(j) A_p$ asymptotically stable.

A close examination of the proofs of the continuous-time results given in Theorems 2.2 and 2.5 reveals that the convergence property of the continuous-time algorithm follows from

(i) the properties of the operator $\mathcal{P}[\cdot]$ given in Lemma 2.3,

(ii) the properties of the stabilizing solution to the continuous-time Riccati equation given in Lemma 2.4,

(iii) the formula for the derivatives of the output covariance matrices $Y_1(Q)$, $Y_2(Q)$, ..., $Y_m(Q)$, with respect to Q, given in Lemma 2.6.

Certainly, property (i) above holds in the discrete-time case because the operator $\mathcal{P}[\cdot]$ is the same. Also, it is relatively easy to show that, under assumption (A3), property (ii) extends to the discrete-time setting. Finally, property (iii) above also holds in the discrete-time case, provided that the Lyapunov equation (2.38) is replaced by its discrete-time counterpart and the matrices R and X in (2.37) are replaced by $R + B_p^T K B_p$ and $X - D_p W_p D_p^T$, respectively. Thus, we may now conclude the following result.

THEOREM 3.2. *Suppose that the assumption* (A3) *holds. Assume also that there exists Q^* satisfying the conditions in Theorem* 3.1. *Then, given any $Q(0) \geq 0 \in \mathcal{R}^{n_y \times n_y}$ with the appropriate block diagonal structure, there exists an $\alpha^* > 0$ such that if $0 < \alpha \leq \alpha^*$, the sequence $\{\mathcal{T}_\beta^j[Q(0)]\}_{j=0}^\infty$ will converge to some $\hat{Q} \geq 0$ satisfying the conditions in Theorem* 3.1. *That is, the discrete-time OCC algorithm will converge to a global optimal solution of the given OCC problem.*

3.2. Full-order dynamic feedback. As in the continuous-time case, the discrete-time state feedback results can be readily extended to solve the discrete-time OCC problem with output feedback.

Consider the system (3.1) and suppose that

(A4) (M_p, A_p) is detectable.

Then there exists a unique matrix $\tilde{X}$ that satisfies the Riccati equation

$$\tilde{X} = A_p \tilde{X} A_p^T - A_p \tilde{X} M_p^T (V + M_p \tilde{X} M_p^T)^{-1} M_p \tilde{X} A_p^T + D_p W_p D_p^T \tag{3.16}$$

and $A_p - A_p\tilde{X}M_p^T(V + M_p\tilde{X}M_p^T)^{-1}M_p$ is asymptotically stable; see, for example, [8]. Moreover, $\tilde{X} \geq 0$. With this matrix $\tilde{X}$, we define

$$F = A_p\tilde{X}M_p^T(V + M_p\tilde{X}M_p^T)^{-1}. \tag{3.17}$$

The next result gives a solution to the OCC problem with strictly proper output feedback controllers. The proof follows the continuous-time case and is omitted.

THEOREM 3.3. *Consider the plant defined in* (3.1). *Let* $\tilde{X}$ *and* F *denote the matrices in* (3.16) *and* (3.17). *Suppose that there exists a matrix*

$$Q^* = \text{ block diag}[Q_1^*, Q_2^*, \ldots, Q_m^*] \geq 0, \quad Q_i^* = Q_i^{*T} \in \mathcal{R}^{m_i \times m_i}, \quad i = 1, 2, \ldots, m, \tag{3.18}$$

such that the algebraic Riccati equation

$$K = A_p^T K A_p - A_p^T K B_p(R + B_p^T K B_p)^{-1} B_p^T K A_p + C_p^T Q^* C_p \tag{3.19}$$

has the (unique) stabilizing solution K^*. *Define*

$$G = -(R + B_p^T K^* B_p)^{-1} B_p^T K^* A_p, \tag{3.20}$$

let X^* *denote the unique solution to the Lyapunov equation*

$$X = (A_p + B_pG)X(A_p + B_pG)^T + F(V + M_p\tilde{X}M_p^T)F^T, \tag{3.21}$$

and define $Y_i = C_i(\tilde{X} + X^*)C_i^T$ $(i = 1, 2, \ldots, m)$. *Then, if*

$$0 = (Y_i - \overline{Y}_i)Q_i^* \text{ and } Y_i \leq \overline{Y}_i \tag{3.22}$$

for all $i = 1, 2, \ldots, m$, *the dynamic controller*

$$\begin{aligned} x_c(k+1) &= (A_p + B_pG - FM_p)x_c(k) + Fz(k), \\ u(k) &= Gx_c(k) \end{aligned} \tag{3.23}$$

is an optimal solution to the OCC problem defined in (3.6).

Note that, as in the continuous-time case, the computation of $\tilde{X}$ and F are independent of the selection of the output-weighting matrix Q. Hence, we can apply the discrete-time OCC algorithm with state feedback to solve the discrete-time full-order output feedback OCC problem under the assumption that the optimal solutions are strictly proper. This requires that in the algorithm given in section 3.1, we replace D_p, W_p, and $\overline{Y}_i$ with F, $V + M_p\tilde{X}M_p^T$, and $\overline{Y}_i - C_i\tilde{X}C_i^T$, respectively.

4. An example. We consider the continuous-time OCC problem defined in (1.7) for the plant (1.1) with the following system matrices:

$$A_p = \begin{bmatrix} 0 & 1 & 0 \\ -1 & -0.1 & 1 \\ 0 & 0 & -10 \end{bmatrix}, \quad B_p = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}, \quad D_p = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}, \tag{4.1a}$$

$$M_p = \begin{bmatrix} 1 & 1 & 0 \end{bmatrix}, \tag{4.1b}$$

$$C_p = \begin{bmatrix} 1 & 0.5 & 0 \\ 0 & 0 & 0.5 \\ 1 & 1 & 0 \end{bmatrix}. \tag{4.1c}$$

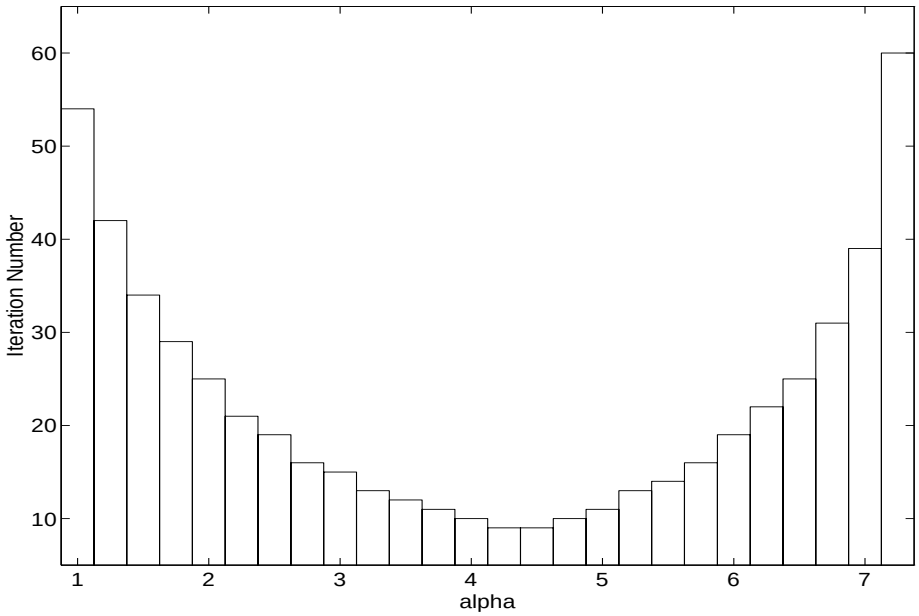

FIG. 4.1. *Iteration number versus* α.

Both the process noise w_p and the measurement noise v are scalar variables, while the performance variable y_p has three components. The weighting matrices required to define the OCC problem (1.7) are taken to be

$$W_p = 1, \quad V = 0.01, \quad \text{and} \quad R = 1. \tag{4.2}$$

Below, we consider two different OCC problems. These two problems differ in the grouping of the performance variables y_i used to define the constraints (1.6). For each problem, we consider both state feedback and dynamic output feedback.

4.1. Problem 1. Here, the OCC problem has the performance constraints

$$Y_1 \leq 0.035, \quad Y_2 \leq 0.050, \quad Y_3 \leq 0.050, \tag{4.3}$$

where Y_1, Y_2, and Y_3 denote the output covariance (1×1) matrices introduced in (1.6), corresponding to the first, second, and third performance variables, respectively. Note that this OCC problem can be also solved by the ellipsoid algorithms given in [1, 3, 12] or the quadratically convergent algorithms given in [16].

First, we consider the case of state feedback. We use the algorithm described in section 2.1 with the following parameters:

$$Q(0) = I_3, \quad \beta = 0.1, \quad \epsilon = 10^{-6}. \tag{4.4}$$

To assess the effect of the user-specified parameter α, we ran the the algorithm with $1.0 \leq \alpha \leq 7.25$. Figure 4.1 shows the number of iterations required to meet the stopping criteria of the algorithm versus α. Clearly, as α approaches 1 or 7.25, the iteration number increases. From Figure 4.1, it follows that there exists an optimal α which uses the least number of iterations. Finding such an optimal α in terms of the system and specification matrices remains an open problem.

TABLE 4.1
Solution to Problem 1 with $\alpha = 4.5$.

number	Spec. ($\overline{Y}_i$)	Actual (Y_i)	J_{OCC}	Q_i	G^T
22	0.0350	0.0314	0.0340	0.0000	0.0193
	0.0500	0.0126		0.0000	−1.3839
	0.0500	0.0500		2.3765	−0.1374

Table 4.1 shows the results of running the algorithm with $\alpha = 4.5$. Both state and output feedback cases are computed. In the state feedback case, G denotes the state feedback gain. In the output feedback case, G denotes the controller output matrix; see (2.65) and (2.68). The controller input matrix F is precomputed according to (2.62). In this case we have

$$F = [\ 0.4412\ \ 0.7633\ \ 0.4796\ ]^T. \tag{4.5}$$

From Table 4.1, we can see that both controllers are feasible, since Y_i satisfies the bound $Y_i \leq \overline{Y}_i$. The only active constraint is the third one, i.e., $Y_3 = \overline{Y}_3$; hence, the corresponding output weight Q_3 is nonzero. As expected, the optimal cost J_{OCC} with output feedback is bigger than that with state feedback.

4.2. Problem 2. Now, the OCC problem has the performance constraints

$$Y_1 \leq 0.035, \qquad Y_2 \leq 0.050 \times I_2, \tag{4.6}$$

where Y_1 denotes the (1×1) output covariance matrix corresponding to the first performance output and Y_2 denotes the (2×2) output covariance matrix of the second and third performance outputs grouped together.

Table 4.2 shows the results of running the algorithm with $\alpha = 30$ for both state and output feedback cases. The other parameters required by the algorithm are those in (4.4). For the output feedback case the input gain matrix F of the controller given in (4.5).

From Table 4.2, we can see that both controllers are feasible. As expected, the optimal cost J_{OCC} with output feedback is bigger than that with state feedback. Also, note that the constraint on the second output group $Y_2 \leq 0.05 \times I_2$ is sufficient for the output covariance constraints of Problem 1 in (4.3), that is, $Y_2 \leq 0.05$ and $Y_3 \leq 0.05$. As expected, the costs of Problem 2 for both state and output feedback cases are bigger than those of Problem 1.

5. Conclusion. In this paper we have considered the so-called output covariance constraint (OCC) control problem. This is the problem of minimizing control effort subject to matrix inequality constraints on several closed-loop covariance matrices. Optimality conditions for characterizing a global solution are provided. In the state feedback case, these conditions comprise one algebraic Riccati equation, one Lyapunov equation, and a coupling condition. The unknown in this system of equations is a

matrix Q which may be interpreted as a matrix of Kuhn–Tucker multipliers. We have given an iterative algorithm to find such a matrix Q. Under the assumption that the optimality conditions admit a solution Q, we have shown that the iterative algorithm converges to one such solution, provided that the step size parameter α is properly chosen. Using the separation property of a closed-loop covariance matrix given in [12], we have shown how to modify the state feedback algorithm to solve the OCC problem with output feedback. Both discrete- and continuous-time problems have been solved. Finally, an example is presented to demonstrate the applicability of our results.

CENTRALIZED AND DECENTRALIZED SUPERVISORY CONTROL OF NONDETERMINISTIC SYSTEMS UNDER PARTIAL OBSERVATION*

RATNESH KUMAR† AND MARK A. SHAYMAN‡

Abstract. In this paper we extend our earlier work on supervisory control of nondeterministic systems using prioritized synchronization as the mechanism of control and trajectory model as the modeling formalism by considering design of supervisors under partial observation. We introduce the notion of *observation-compatible* systems and show that prioritized synchronous composition (PSC) of observation-compatible systems can be used as a mechanism of control of nondeterministic systems under partial observation in presence of driven events. Necessary and sufficient conditions that depend on the trajectory model as opposed to the language model of the plant are obtained for the existence of *centralized* as well as *decentralized* supervision. Our work on centralized control shows that the results of the traditional supervisory control can be "extended" to the above setting, provided that the supervisor is deterministic and the observation mask is projection type. On the other hand, our work on decentralized control is based on a new relation between controllability, observability, co-observability, and PSC that we derive in this paper.

Key words. discrete event systems, supervisory control, partial observation, nondeterministic automata, driven events, prioritized synchronization, trajectory models, controllability, observability, co-observability

1. Introduction.

Discrete event systems (DESs) are systems which involve quantities that take a discrete set of values and which evolve according to occurrence of certain discrete qualitative changes, called *events*, such as arrival of a customer in a queue, termination of an algorithm in a computer program, loss of a message packet in a communication network, breakdown of a machine in a manufacturing system, and the like. The theory of supervisory control of DESs was introduced by Ramadge and Wonham [26, 27] for designing controllers so that the controlled system satisfies certain desired *qualitative* constraints, such as that a buffer in a manufacturing system should never overflow, a message sequence in a communication network must be received in the same order as it was transmitted, and so on.

Such qualitative behavior of a *deterministic*[1] DES can be described by the set of all possible event *traces*, called a *language* model, that the system can execute starting from its initial state. However, due to partial observation and/or unmodeled dynamics, it is too restrictive to require determinism of a system. If a DES is nondeterministic, then its language model may not adequately describe its qualita-

[1] A DES is said to be deterministic if, given the current state and an event that occurs in that state, the next state is uniquely determined.

tive behavior, and more detailed models are needed. Several models such as *failures model* [10], *refusal-trace model* [25], *ready-trace model* [1], *bisimulation model* [23, 24], etc. have been proposed in the literature for representing qualitative behavior of nondeterministic DESs. A nice comparative study of such modeling formalisms can be found in [2, 31]. As a designer, it is desirable to choose the *least detailed* modeling formalism that is adequate for the design task at hand. As is argued below, this is the reason for us to choose the *trajectory model* proposed by Heymann [8], also known as *refusal-trace model*, for representing nondeterministic DESs.

Most of the prior work on supervisory control of DESs, such as [26, 16, 4], essentially use *strict synchronous composition* (SSC) of *plant* DES and *supervisor* DES as the mechanism of control. In SSC of systems, it is required that the common events must occur synchronously. This is restrictive, because due to nondeterminism the plant state is not uniquely known after the execution of a certain observed trace, and the set of executable events in each such state may differ. If we require strict synchronization, then the supervisor is restricted to enable those events that are executable in each of those states, which imposes a severe restriction on the supervisor. Moreover, there is no a priori reason for a supervisor to synchronously execute all the *uncontrollable* events that the plant can execute. Similarly, it is restrictive to require that the plant synchronously executes the so-called *forcible* [7] or *command* [4] or *driven* [8] events that are initiated by the supervisor. The motivating example in [30, section 2, Example 5] describes a nondeterministic plant that can be controlled only when the requirement of strict synchronization is relaxed.

In this paper we study the control of qualitative behavior of nondeterministic DESs using *prioritized synchronous composition* (PSC) as the mechanism of control. PSC was originally proposed by Heymann [8, 9] and was later applied to supervisory control in the deterministic setting by Balemi [3] and in the nondeterministic setting by Shayman and Kumar [30]. PSC is a generalization of the SSC. The parallel operator considered by Inan [12, 13], an extension of the parallel operator defined in [14, 15], can be viewed as a generalization of PSC when applied to the so-called *improper* systems. However, while studying supervisory control only proper systems are considered; consequently the resulting operation is that of strict synchronization.

In PSC each system is associated with a certain priority set of events, and for an event to occur in the composition of a pair of systems operating in prioritized synchrony, each system having the priority over the event must participate. So if an event belongs to the common priority set, then it occurs synchronously. On the other hand, if a certain event belongs to the priority set of a single system, then it can occur asynchronously without the participation of the second system. However, the second system will participate whenever possible; such synchronization is called *broadcast synchronization*. Thus PSC does not impose the unnecessarily restrictive requirement of SSC that common events must always occur in synchrony. For supervisory control, the priority set of a plant consists of the uncontrollable and the controllable events, while the priority set of a supervisor consists of the controllable and the driven events. Since controllable events are in the priority sets of plant as well as supervisor, they always occur in synchrony in the controlled system, whereas the uncontrollable and the driven events may occur asynchronously.

Heymann showed via an example [8, Example 7] that if PSC is *admitted* as a mechanism of interconnection, then a modeling formalism which is more detailed than the failures model (and consequently, more detailed than the language model) is needed to adequately describe the behavior of nondeterministic DESs. For this reason,

Heymann proposed the modeling formalism called *trajectory model*. A trajectory model consists of *generated* and *recognized* trajectories, also called *refusal-traces*, of a system. A refusal-trace is a sequence of alternating refusal sets and events, where a refusal set consists of those events that the system "refuses" to execute when offered at a certain execution point. The trajectory model is quite similar to the refusal-testing model of Phillips [25] but differs in its treatment of *silent* or epsilon transitions.

In our previous work [30, 19] we showed that the trajectory model can be used for adequately describing behaviors of nondeterministic DESs that may be interconnected using PSC, and also that the operation of PSC is associative. Since an event that belongs to the priority set of a single system can occur asynchronously if we *augment* the other system by adding *self-loops* on such events, then the operation of PSC can be reduced to the operation of SSC, provided that the priority sets of the two systems exhaust the entire event set. Under this condition, we proved in [30, 19] that the PSC of a pair of systems is equivalent to SSC of appropriately augmented systems. In particular, if the plant is augmented with driven events and the supervisor is augmented with uncontrollable events, then the PSC of plant and supervisor is equivalent to SSC of augmented plant and augmented supervisor. Using these results we obtained necessary and sufficient conditions for the existence of a supervisor so that the language of the controlled plant equals a desired language.

In this paper we extend our earlier work on supervisory control of nondeterministic systems using prioritized synchronization as the mechanism of control and trajectory model as the modeling formalism by considering design of supervisors under partial observation. Partial observation in the setting of supervisory control arises due to lack of sufficient number of sensors. As in the work of Lin and Wonham [21], we use a projection function, also called an *observation mask*, to represent such partial observation. A supervisor under partial observation must take identical control action following indistinguishable traces. We call this property of a supervisor *observation-compatibility*, which captures physically realizable supervisors. Such supervisors make control decisions based on *only* the observed event trace of the system and do not require any "special" internal knowledge of the system.

We define the notion of observation-compatibility of a trajectory model and prove that this property is preserved under augmentation whenever the system is deterministic. Using this result we obtain a necessary and sufficient condition for the existence of an observation-compatible supervisor so that the language of the plant operating in prioritized synchrony with the supervisor equals the desired one. This result is then applied to obtain a supervisor which achieves mutually exclusive usage of a shared channel in a communication system. We also obtain conditions for the existence of *nonblocking* supervisors [27, 5].

Finally, we study the problem of decentralized supervision [29, 20, 22, 6, 32]. Decentralized supervision is inevitable when the plant is physically distributed for example as in communication networks and manufacturing systems. A supervisor is installed at each location of the "subplant." In such a situation, a supervisor is able to control a certain set of events, called *local* events, and is able to observe a partial set of events. The problem of decentralized supervision requires design of supervisors that are observation-compatible with respect to their own observation function, and control events in their own priority sets. This problem is naturally formulated in our framework. We show that the condition of controllability together with the condition of *co-observability* is necessary and sufficient for decentralized supervision. Our constructive proof is novel and is based on a nice relationship between control-

lability, observability, co-observability, and PSC that we derive in this paper. These conditions, however, are significantly different from the standard ones [21, 29], as they depend on the trajectory model (rather than language model) of the plant.

The remainder of the paper is organized as follows: In section 2 we introduce the relevant notation. In section 3, we define the notion of observation-compatibility and study some of its properties. In section 4 we study the supervisory control problem under partial observation in the proposed framework and apply it to achievement of mutually exclusive usage of a shared communication channel in a communication system. In section 5 we study the problem of decentralized supervision. Finally, section 6 concludes the work presented here.

2. Notation and preliminaries. Given a finite event set Σ, Σ^* is used to denote the collection of all *traces*, i.e., finite sequences of events, including the zero-length sequence, denoted ϵ. A subset of Σ^* is called a language. Symbols H, K, etc. are used to denote languages. For a language $K \subseteq \Sigma^*$, the notation $\mathrm{pr}(K) \subseteq \Sigma^*$, called the *prefix-closure* of K, is the set of all prefixes of traces from K. K is said to be prefix-closed if $K = \mathrm{pr}(K)$.

The set $2^\Sigma(\Sigma \times 2^\Sigma)^*$ is used to denote the collection of all *refusal-traces*, i.e., finite sequences of alternating *refusals* and events [9, 30] of the type

$$\Sigma_0(\sigma_1, \Sigma_1) \dots (\sigma_n, \Sigma_n),$$

where $n \in \mathcal{N}$. The sequence $\sigma_1 \dots \sigma_n \in \Sigma^*$ is the trace, and for each $i \leq n$, $\Sigma_i \subseteq \Sigma$ is a set of events refused (if offered) at the indicated point. Symbols P, Q, R, S, etc., are used to denote sets of refusal-traces. Refusal-traces are also referred to as *trajectories*.

Given $e \in 2^\Sigma(\Sigma \times 2^\Sigma)^*$, we use $|e|$ to denote the length of e, and for each $k \leq |e|$, $\Sigma_k(e) \subseteq \Sigma$ is used to denote the kth refusal in e and $\sigma_k(e) \in \Sigma$ is used to denote the kth event in e, i.e.,

$$e = \Sigma_0(e)(\sigma_1(e), \Sigma_1(e)) \dots (\sigma_k(e), \Sigma_k(e)) \dots (\sigma_{|e|}(e), \Sigma_{|e|}(e)).$$

The *trace* of e, denoted $\mathrm{tr}(e) \in \Sigma^*$, is defined as $\mathrm{tr}(e) := \sigma_1(e) \dots \sigma_{|e|}(e)$. Given a set of refusal-traces $P \subseteq 2^\Sigma(\Sigma \times 2^\Sigma)^*$, we use $L(P) := \mathrm{tr}(P)$ to denote its set of traces.

If $f \in 2^\Sigma(\Sigma \times 2^\Sigma)^*$ is another refusal-trace such that $|f| \leq |e|$ and for each $k \leq |f|$, $\Sigma_k(f) = \Sigma_k(e)$ and $\sigma_k(f) = \sigma_k(e)$, then f is said to be a prefix of e, denoted by $f \leq e$. For each $k \leq |e|$, the notation $e^k \leq e$ is used to denote the prefix of length k of e. The prefix-closure of e, denoted $\mathrm{pr}(e) \subseteq 2^\Sigma(\Sigma \times 2^\Sigma)^*$, is the set of all prefixes of e. If $f \in 2^\Sigma(\Sigma \times 2^\Sigma)^*$ is such that $|f| = |e|$ and for each $k \leq |f|$, $\Sigma_k(f) \subseteq \Sigma_k(e)$ and $\sigma_k(f) = \sigma_k(e)$, then f is said to be *dominated* by e, denoted by $f \sqsubseteq e$. The *dominance-closure* of e, denoted $\mathrm{dom}(e) \subseteq 2^\Sigma(\Sigma \times 2^\Sigma)^*$, is the set of all refusal-traces dominated by e.

Symbols $\mathcal{P}, \mathcal{Q}, \mathcal{R}$, etc., are used to denote nondeterministic state machines (NSMs) (with ϵ-moves). Let the 5-tuple

$$\mathcal{P} := (X_\mathcal{P}, \Sigma, \delta_\mathcal{P}, x^0_\mathcal{P}, X^m_\mathcal{P})$$

represent a DES modeled as an NSM, where $X_\mathcal{P}$ is the state set, Σ is the finite event set, $\delta_\mathcal{P} : X_\mathcal{P} \times (\Sigma \cup \{\epsilon\}) \to 2^{X_\mathcal{P}}$ denotes the nondeterministic transition function,[2] $x^0_\mathcal{P} \in X_\mathcal{P}$ is the initial state, and $X^m_\mathcal{P} \subseteq X_\mathcal{P}$ is the set of accepting or marked states.

[2] ϵ represents both an *internal* or *unobservable* event and an *internal* or *nondeterministic* choice [10, 23].

A triple $(x_1, \sigma, x_2) \in X_{\mathcal{P}} \times (\Sigma \cup \{\epsilon\}) \times X_{\mathcal{P}}$ is said to be a transition if $x_2 \in \delta_{\mathcal{P}}(x_1, \sigma)$. A transition (x_1, ϵ, x_2) is referred to as a *silent* or *hidden* transition. We assume that the plant cannot undergo an unbounded sequence of silent transitions.

The ϵ-*closure* of $x \in X_{\mathcal{P}}$, denoted $\epsilon^*_{\mathcal{P}}(x) \subseteq X_{\mathcal{P}}$, is defined inductively as

$$x \in \epsilon^*_{\mathcal{P}}(x) \text{ and } x' \in \epsilon^*_{\mathcal{P}}(x) \Rightarrow \delta_{\mathcal{P}}(x', \epsilon) \subseteq \epsilon^*_{\mathcal{P}}(x),$$

and the set of *refusal events* at $x \in X_{\mathcal{P}}$, denoted $\Re_{\mathcal{P}}(x) \subseteq \Sigma$, is defined as

$$\Re_{\mathcal{P}}(x) := \{\sigma \in \Sigma \mid \delta_{\mathcal{P}}(x', \sigma) = \emptyset, \forall x' \in \epsilon^*_{\mathcal{P}}(x)\}.$$

In other words, given $x \in X_{\mathcal{P}}$, $\epsilon^*_{\mathcal{P}}(x)$ is the set of states that can be reached from x on zero or more ϵ-moves, and $\Re_{\mathcal{P}}(x)$ is the set of events that are undefined at each state in the ϵ-closure of x. Using the definitions of the ϵ-closure and refusal maps, the transition function $\delta_{\mathcal{P}} : X_{\mathcal{P}} \times (\Sigma \cup \{\epsilon\}) \to 2^{X_{\mathcal{P}}}$ is extended (i) to the set of *traces*, denoted $\delta^*_{\mathcal{P}} : X_{\mathcal{P}} \times \Sigma^* \to 2^{X_{\mathcal{P}}}$, which is defined in the usual way [11], and (ii) to the set of *refusal-traces*, denoted $\delta^T_{\mathcal{P}} : X \times (2^{\Sigma}(\Sigma \times 2^{\Sigma})^*) \to 2^{X_{\mathcal{P}}}$, which is defined inductively as

$$\forall x \in X_{\mathcal{P}} : \begin{cases} \forall \Sigma' \subseteq \Sigma : \delta^T_{\mathcal{P}}(x, \Sigma') := \{x' \in \epsilon^*_{\mathcal{P}}(x) \mid \Sigma' \subseteq \Re_{\mathcal{P}}(x')\}, \\ \forall e \in 2^{\Sigma}(\Sigma \times 2^{\Sigma})^*,\ \sigma \in \Sigma, \Sigma' \subseteq \Sigma : \\ \delta^T_{\mathcal{P}}(x, e(\sigma, \Sigma')) := \{x' \in \epsilon^*_{\mathcal{P}}(\delta_{\mathcal{P}}(\delta^T_{\mathcal{P}}(x, e), \sigma)) \mid \Sigma' \subseteq \Re_{\mathcal{P}}(x')\}. \end{cases}$$

These maps are then used to obtain the language models and the trajectory models of $\mathcal{P}$ as follows:

$$L(\mathcal{P}) := \{s \in \Sigma^* \mid \delta^*_{\mathcal{P}}(x^0_{\mathcal{P}}, s) \neq \emptyset\},\ \ L^m(\mathcal{P}) := \{s \in L(\mathcal{P}) \mid \delta^*_{\mathcal{P}}(x^0_{\mathcal{P}}, s) \cap X^m_{\mathcal{P}} \neq \emptyset\},$$

$$T(\mathcal{P}) := \{e \in 2^{\Sigma}(\Sigma \times 2^{\Sigma})^* \mid \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e) \neq \emptyset\}, T^m(\mathcal{P}) := \{e \in T(\mathcal{P}) \mid \delta^T_{\mathcal{P}}(x^0_{\mathcal{P}}, e) \cap X^m_{\mathcal{P}} \neq \emptyset\}.$$

$L(\mathcal{P}), L^m(\mathcal{P}), T(\mathcal{P})$, and $T^m(\mathcal{P})$ are called the *generated language, recognized language, generated trajectory set, and recognized trajectory set,* respectively, of $\mathcal{P}$. The pairs $(L^m(\mathcal{P}), L(\mathcal{P}))$ and $(T^m(\mathcal{P}), T(\mathcal{P}))$ are called the language model and the trajectory model, respectively, of $\mathcal{P}$. Two language models, (K^m_1, K_1) and (K^m_2, K_2), are said to be equal, written $(K^m_1, K_1) = (K^m_2, K_2)$, if $K^m_1 = K^m_2$ and $K_1 = K_2$; equality of two trajectory models is defined analogously.

Given a trajectory model, the trace map can be used to obtain the associated language model. On the other hand, given a language model (K^m, K), the *trajectory* map, $\mathrm{tr}j_K : K \to 2^{\Sigma}(\Sigma \times 2^{\Sigma})^*$ can be used to obtain the *deterministic* trajectory model[3] having the language model (K^m, K), which is defined as follows:

$$\mathrm{tr}j_K(s) := \Sigma_0(s)(\sigma_1(s), \Sigma_1(s)) \ldots (\sigma_{|s|}(s), \Sigma_{|s|}(s)) \in 2^{\Sigma}(\Sigma \times 2^{\Sigma})^*, \text{ where}$$

$$\Sigma_k(s) := \{\sigma \in \Sigma \mid s^k\sigma \notin K\} \quad \forall k \leq |s|.$$

Define $(\det^m(K^m, K),\ \det(K)) := (\mathrm{dom}(\mathrm{tr}j_K(K^m)),\ \mathrm{dom}(\mathrm{tr}j_K(K)))$. Then it is shown in [19, Proposition 1] that it is the unique deterministic trajectory model that has the language model (K^m, K).

[3] A trajectory model (P^m, P) is said to be deterministic if there exists a deterministic state machine $\mathcal{P}$ such that $(T^m(\mathcal{P}), T(P)) = (P^m, P)$.

In [8, 9, 30, 19] PSC of systems is used as the mechanism of control. In this setting, associated with each system is a priority set of events, which endows the system with the ability to prevent the occurrence of events belonging to its priority set; a system must participate in the execution of an event belonging to its priority set for that event to occur in the PSC with other system(s). Letting $\mathcal{P}\ {}_A\|_B\ \mathcal{Q}$ denote the PSC of NSMs $\mathcal{P}$ and $\mathcal{Q}$ with priority sets $A, B \subseteq \Sigma$, respectively, and $T^m(\mathcal{P})\ {}_A\|_B\ T^m(\mathcal{Q})$, $T(\mathcal{P})\ {}_A\|_B\ T(\mathcal{Q})$ denote the PSC of corresponding trajectory models, it was proven in [30, Theorem 2] and [19, Theorem 2] that

$$T^m(\mathcal{P})\ {}_A\|_B\ T^m(\mathcal{Q}) = T^m(\mathcal{P}\ {}_A\|_B\ \mathcal{Q}); \quad T(\mathcal{P})\ {}_A\|_B\ T(\mathcal{Q}) = T(\mathcal{P}\ {}_A\|_B\ \mathcal{Q}).$$

Various properties of PSC of trajectory models were studied in [30, 19]. In particular, associativity of PSC was proven [19, Proposition 2, Corollary 6], a language intersection result for the case when $A = B = \Sigma$ was obtained [19, Corollary 4, Corollary 5], and the notion of *augmentation* and its properties were studied.

We recall from [30, 19] that the *augmentation* of an NSM $\mathcal{P}$ by an event set $D \subset \Sigma$ is the NSM $\mathcal{P}^D := \mathcal{P}\ {}_\emptyset\|_\emptyset\ \mathcal{D}$, where $\mathcal{D}$ denotes the deterministic state machine with one state, which is marked, and has self-loops labeled by every event in D. Thus the augmented NSM $\mathcal{P}^D$ can also be obtained by adding self-loops on each state of $\mathcal{P}$ on those events in D that are refused at that state, i.e., $\mathcal{P}^D := (X_\mathcal{P}, \Sigma, \delta_{\mathcal{P}^D}, x^0_\mathcal{P}, X_m)$, where the transition function is defined as

$$\forall x \in X_\mathcal{P}, \sigma \in \Sigma : \delta_{\mathcal{P}^D}(x,\sigma) := \begin{cases} \{x\} & \text{if } \sigma \in D \cap \Re_\mathcal{P}(x), \\ \delta_\mathcal{P}(x,\sigma) & \text{otherwise.} \end{cases}$$

Refer to Example 1 for illustration. Since the trajectory model of $\mathcal{D}$ is $(\det(D^*), \det(D^*))$, the augmented trajectory model is given by

$$((T^m(\mathcal{P}))^D, (T(\mathcal{P}))^D) := (T^m(\mathcal{P}^D), T(\mathcal{P}^D)) = (T^m(\mathcal{P})\ {}_\emptyset\|_\emptyset\ \det(D^*), T(\mathcal{P})\ {}_\emptyset\|_\emptyset\ \det(D^*)).$$

It was shown in [30, Proposition 4] and [19, Proposition 3] that whenever the priority sets of a given pair of systems exhaust the entire event set, then the operation of PSC can be reduced to that of SSC of appropriately augmented systems. Specifically, given a pair of trajectory models (P^m, P) and (Q^m, Q) with priority sets $A, B \subseteq \Sigma$, respectively, if $A \cup B = \Sigma$, then

$$P^m\ {}_A\|_B\ Q^m = (P^m)^{\Sigma - A}\ {}_\Sigma\|_\Sigma\ (Q^m)^{\Sigma - B}; \quad P\ {}_A\|_B\ Q = P^{\Sigma - A}\ {}_\Sigma\|_\Sigma\ Q^{\Sigma - B}.$$

Consequently we have the following identities:

$$L(P^m\ {}_A\|_B\ Q^m) = L((P^m)^{\Sigma-A}) \cap L((Q^m)^{\Sigma-B}); \quad L(P\ {}_A\|_B\ Q) = L(P^{\Sigma-A}) \cap L(Q^{\Sigma-B}).$$

Thus the technique of augmentation is useful in studying the behavior of a pair of systems operating in prioritized synchrony if their priority sets jointly exhaust the entire event set. In particular, we can apply the technique of augmentation in supervisory control, as the event set Σ can be written as the union of the priority set of plant, which is the set of uncontrollable and controllable events, and the priority set of supervisor, which is the set of controllable and driven events.

3. Observation-compatible systems. In many control designs, it is not possible to completely observe the behavior of the uncontrolled plant due to lack of sufficient number of sensors. Thus, certain events executed by the uncontrolled plant

may be *unobservable*. In the setting of supervisory control, an observation mask—a projection map defined from the set of events to the set of observable events—is used to describe such partial observation. In such situations it is natural to require that the control actions taken by a supervisor following indistinguishable traces be identical. We call this property of a supervisor *observation-compatibility*. In this section, we formally define the notion of observation-compatibility of the trajectory model of a nondeterministic DES and study some of its properties.

Let $\Sigma^o \subseteq \Sigma$ be the set of *observable* events, i.e., the events that can be sensed by a supervisor. A projection function $M : \Sigma \to \Sigma^o \cup \{\epsilon\}$, called an *observation mask* [21, 6], is used to represent such a partial observation; it is defined as

$$\forall \sigma \in \Sigma : M(\sigma) := \begin{cases} \sigma & \text{if } \sigma \in \Sigma^o, \\ \epsilon & \text{otherwise.} \end{cases}$$

Note that we assume that the observation mask is a projection function.

Recall from [26] that a language $K \subseteq \Sigma^*$ is said to be controllable with respect to a given prefix-closed language H and the set of uncontrollable events $\Sigma - B$, called $(H, \Sigma - B)$-*controllable*, if

$$\mathrm{pr}(K)(\Sigma - B) \cap H \subseteq \mathrm{pr}(K),$$

i.e., if the extension of a certain prefix of K by an uncontrollable event results in a trace of H, then this extended trace should also be a prefix of K. Also, recall from [21] that K is said to be observable with respect to H and a given observation mask $M(\cdot)$, called (H, M)-*observable*, if

$$\forall s, t \in \mathrm{pr}(K), \sigma \in \Sigma : \quad M(s) = M(t), \quad s\sigma \in \mathrm{pr}(K), \quad t\sigma \in H \Rightarrow t\sigma \in \mathrm{pr}(K).$$

In other words, K is said to be (H, M)-observable if given an indistinguishable pair of traces in $\mathrm{pr}(K)$, the pair of traces resulting from appending a common event to the given pair has identical membership in $\mathrm{pr}(K)$ whenever they have identical membership in H. It was shown in [21] that the observability of prefix-closed languages is preserved under intersection so that the *infimal prefix-closed and observable superlanguage* of a given language exists. Using the above notion of observability we next define the concept of observation-compatibility.

DEFINITION 1. *Given a trajectory model (S^m, S) and an observation mask $M(\cdot)$, (S^m, S) is said to be* observation compatible with respect to $M(\cdot)$ *or simply* M-compatible *if*

$$\forall s, t \in L(S), \sigma \in \Sigma : \quad M(s) = M(t), \quad s\sigma \in L(S) \Rightarrow t\sigma \in L(S).$$

An NSM is said to be M-compatible if its associated trajectory model is M-compatible. Thus a trajectory model is M-compatible if and only if its generated language is (Σ^*, M)-observable. Note that the property of *observation-compatibility* captures physically realizable supervisors. Such supervisors make control decisions based on *only* the observed event trace of the system and do not require any "special" internal knowledge of the system. Next we show that M-compatibility of a *deterministic* trajectory model is preserved under augmentation. We first need to establish two lemmas.

DEFINITION 2. *Given a nonempty prefix-closed language K, the* projection of Σ^* onto K *is defined inductively by*

$$\pi_K(\epsilon) := \epsilon; \quad \forall s \in \Sigma^*, \sigma \in \Sigma : \pi_K(s\sigma) := \begin{cases} \pi_K(s)\sigma & \text{if } \pi_K(s)\sigma \in K, \\ \pi_K(s) & \text{otherwise.} \end{cases}$$

When the choice of K is clear, we use the abbreviated notation s' for $\pi_K(s)$.

The first lemma asserts that the state reached by the execution of a certain trace in an augmented deterministic state machine is the same as that reached in the unaugmented state machine by the execution of the trace projected onto its language.

LEMMA 1. *Let $\mathcal{P} := (X_{\mathcal{P}}, \Sigma, \delta_{\mathcal{P}}, x^0_{\mathcal{P}}, X^m_{\mathcal{P}})$ be a deterministic state machine and $D \subseteq \Sigma$. Then for each $s \in L(\mathcal{P}^D)$, $\delta^*_{\mathcal{P}^D}(x^0_{\mathcal{P}}, s) = \delta^*_{\mathcal{P}}(x^0_{\mathcal{P}}, \pi_{L(\mathcal{P})}(s))$.*

Proof. We use induction on length of s for proving the assertion. For notational simplicity, define $\pi_{L(\mathcal{P})}(s) := s'$. If $|s| = 0$, then $s = s' = \epsilon$. Hence $\delta^*_{\mathcal{P}^D}(x^0_{\mathcal{P}}, s) = \delta^*_{\mathcal{P}}(x^0_{\mathcal{P}}, s') = x^0_{\mathcal{P}}$, since $\mathcal{P}$, and thus $\mathcal{P}^D$, are deterministic. Thus the base step trivially holds. In order to prove the induction step, suppose $s = \bar{s}\sigma$, where $\sigma \in \Sigma$. Define $\bar{s}' := \pi_{L(\mathcal{P})}(\bar{s})$. Then it follows from induction hypothesis that $\delta^*_{\mathcal{P}^D}(x^0_{\mathcal{P}}, \bar{s}) = \delta^*_{\mathcal{P}}(x^0_{\mathcal{P}}, \bar{s}') := x_{\bar{s}}$. If $\sigma \notin \Re_{\mathcal{P}}(x_{\bar{s}})$, then $\delta^*_{\mathcal{P}^D}(x^0_{\mathcal{P}}, s) = \delta^*_{\mathcal{P}}(x_{\bar{s}}, \sigma) = \delta^*_{\mathcal{P}}(x^0_{\mathcal{P}}, s')$. On the other hand, if $\sigma \in D \cap \Re_{\mathcal{P}}(x_{\bar{s}})$, then $s' = \bar{s}'$, and $\delta^*_{\mathcal{P}^D}(x^0_{\mathcal{P}}, s) = x_{\bar{s}}$, so $\delta^*_{\mathcal{P}}(x^0_{\mathcal{P}}, s') = \delta^*_{\mathcal{P}}(x^0_{\mathcal{P}}, \bar{s}') = x_{\bar{s}} = \delta^*_{\mathcal{P}^D}(x^0_{\mathcal{P}}, s)$. This proves the induction step and completes the proof. ∎

The next lemma asserts that if a certain language is (Σ^*, M)-observable, then the indistinguishability of a pair of traces implies indistinguishability of their projections onto the language.

LEMMA 2. *Consider an observation mask $M(\cdot)$, and a nonempty prefix-closed language $K \subseteq \Sigma^*$. If K is (Σ^*, M)-observable, then*

$$\forall s, t \in \Sigma^* : M(s) = M(t) \Rightarrow M(\pi_K(s)) = M(\pi_K(t)).$$

Proof. For notational simplicity, define $s' := \pi_K(s)$ and $t' := \pi_K(t)$. We prove the assertion by induction on $|s| + |t|$. For the base step, if $|s| = 0$ or $|t| = 0$, then $M(s) = M(t) = \epsilon$, so $M(s') = M(t') = \epsilon$. For the induction step, consider $s = \bar{s}\sigma_s$ and $t = \bar{t}\sigma_t$ with $\bar{s}, \bar{t} \in \Sigma^*$ and $\sigma_s, \sigma_t \in \Sigma$. Define $\bar{s}' := \pi_K(\bar{s})$ and $\bar{t}' := \pi_K(\bar{t})$. We have three possibilities: (i) $M(\sigma_s) = \epsilon$, which implies that $M(\bar{s}) = M(t)$. Then, $M(s') = M(\bar{s}') = M(t')$, where the first equality follows trivially from the unobservability of σ_s and the second equality follows by induction hypothesis. (ii) $M(\sigma_t) = \epsilon$. Then it follows from symmetry and case (i) above that $M(s') = M(t')$. (iii) $M(\sigma_s) \neq \epsilon$, $M(\sigma_t) \neq \epsilon$, which implies that $\sigma_s = \sigma_t := \sigma$ and $M(\bar{s}) = M(\bar{t})$. By the induction hypothesis, $M(\bar{s}') = M(\bar{t}')$. Since K is (Σ^*, M)-observable, either $\bar{s}'\sigma, \bar{t}'\sigma \in K$ or $\bar{s}'\sigma, \bar{t}'\sigma \notin K$. In the first case, $M(s') = M(\bar{s}'\sigma) = M(\bar{s}')\sigma = M(\bar{t}')\sigma = M(\bar{t}'\sigma) = M(t')$. In the second case, $M(s') = M(\bar{s}') = M(\bar{t}') = M(t')$. ∎

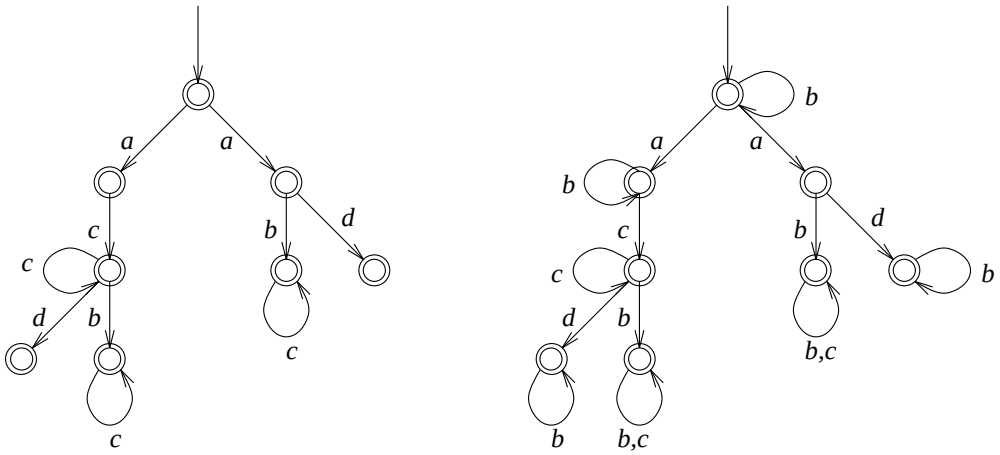
The results of Lemma 1 and 2 are now used to prove that the observation-compatibility of a deterministic system is preserved under augmentation.

THEOREM 1. *Let (S^m, S) be a deterministic trajectory model, $M(\cdot)$ be an observation mask, and $D \subseteq \Sigma$. Suppose that (S^m, S) is M-compatible. Then $((S^m)^D, S^D)$ is also M-compatible (and deterministic).*

Proof. It suffices to show that $L(S^D)$ is (Σ^*, M)-observable. Pick $s, t \in L(S^D), \sigma \in \Sigma$ such that $M(s) = M(t)$ and $s\sigma \in L(S^D)$. Then we need to show that $t\sigma \in L(S^D)$. Since (S^m, S) is a deterministic trajectory model, there exists a deterministic state machine $\mathcal{S} := (X_{\mathcal{S}}, \Sigma, \delta_{\mathcal{S}}, x^0_{\mathcal{S}}, X^m_{\mathcal{S}})$ with trajectory model (S^m, S). Then $((S^m)^D, S^D) = (T^m(\mathcal{S}^D), T(\mathcal{S}^D))$. Define $s' := \pi_{L(\mathcal{S})}(s)$ and $t' := \pi_{L(\mathcal{S})}(t)$. Then it follows from Lemma 1 that

$$\delta^*_{\mathcal{S}^D}(x^0_{\mathcal{S}}, s) = \delta^*_{\mathcal{S}}(x^0_{\mathcal{S}}, s'); \quad \delta^*_{\mathcal{S}^D}(x^0_{\mathcal{S}}, t) = \delta^*_{\mathcal{S}}(x^0_{\mathcal{S}}, t'). \tag{1}$$

Also, since $M(s) = M(t)$, it follows from Lemma 2 that $M(s') = M(t')$. Hence if $s'\sigma \in L(S)$, then it follows from (Σ^*, M)-observability of $L(S)$ that $t'\sigma \in L(S)$. Hence



(a) NSM P (b) Augmented NSM $P^{\{b\}}$

FIG. 1. *Diagram illustrating Example* 1.

(1) implies $t\sigma \in L(S^D)$. On the other hand, if $s'\sigma \notin L(S)$, then $\sigma \in D$, so $t\sigma \in L(S^D)$ trivially. □

We show via the following example that the requirement of determinism cannot be relaxed in Theorem 1.

Example 1. In order to see that the determinism is a necessary condition for Theorem 1 to hold, consider the NSM $\mathcal{P}$ shown in Figure 1(a) with $\Sigma = \{a, b, c, d\}$ and $M(\cdot)$ such that $M(a) = a, M(b) = b, M(c) = \epsilon, M(d) = d$. Then (i) $ac^* \in L(\mathcal{P})$, and each trace in ac^* has identical mask value. It can be checked that the set of events enabled after each trace in ac^* equals $\{b, c, d\}$. (ii) $ac^*bc^* \in L(\mathcal{P})$, and each trace in ac^*bc^* has identical mask value. It can also be checked that the set of events enabled after each trace in ac^*bc^* equals $\{c\}$. (iii) Finally, $ac^*d \in L(\mathcal{P})$, and each trace in ac^*d has identical mask value. One can verify that no event is enabled after each such trace. Thus $L(\mathcal{P})$ is (Σ^*, M)-observable, so the associated trajectory model $(T^m(\mathcal{P}), T(\mathcal{P}))$ is M-compatible.

The augmented NSM $\mathcal{P}^{\{b\}}$ is shown in Figure 1(b). Then $ab, abc \in L(\mathcal{P}^{\{b\}})$ with $M(ab) = M(abc)$. However, the set of events enabled after ab equals $\{b, c\}$, whereas the set of events enabled after abc equals $\{b, c, d\}$. Thus $L(\mathcal{P}^{\{b\}})$ is not (Σ^*, M)-observable, and so the associated trajectory model $(T^m(\mathcal{P}^{\{b\}}), T(\mathcal{P}^{\{b\}})$ is not M-compatible. □

4. Centralized control under partial observation. In a previous paper [30], we showed that PSC can be used as a mechanism of control under the restriction that all controllable events are observable to the supervisor. We show in this section that PSC can be used as a mechanism of control without imposing this restriction on the observation mask. As discussed in the previous section, whenever the observations of a supervisor are filtered through a mask, the supervisor must be observation-compatible with respect to its observation mask; i.e., a supervisor under partial observation must satisfy the constraint that following each pair of traces that look alike under the observation mask, it must take identical control action.

Prior to establishing the main result of this section, we prove the following preliminary result.

LEMMA 3. *Let $H \subseteq \Sigma^*$ be prefix-closed, $K \subseteq H$, and $M(\cdot)$ be an observation mask. If $K^M \subseteq \Sigma^*$ denotes the infimal prefix-closed and (Σ^*, M)-observable superlanguage of K, then $K^M \cap H$ equals the infimal prefix-closed and (H, M)-observable superlanguage of K.*

Proof. For simplicity of notation define $K' := K^M \cap H$. Let $\hat{K} \subseteq \Sigma^*$ denote the infimal prefix-closed and (H, M)-observable superlanguage of K. We need to show that $K' = \hat{K}$. In order to show that $\hat{K} \subseteq K'$, it suffices to show that K' is a prefix-closed (H, M)-observable superlanguage of K. Since $K \subseteq H$, it follows that $K' = K^M \cap H$ is a superlanguage of K. Also, from the fact that prefix-closure is preserved under intersection, it follows that K' is prefix-closed. Finally, since K^M is (Σ^*, M)-observable, clearly, it is (H, M)-observable. Then it follows from the fact that observability of prefix-closed languages is preserved under intersection [21, 28] that $K' = K^M \cap H$ is also (H, M)-observable.

It remains to show that $K' \subseteq \hat{K}$. Suppose for contradiction that $\hat{K}$ is a proper sublanguage of K'. Then there exists $s \in \hat{K}$ and $\sigma \in \Sigma$ such that $s\sigma \in K' - \hat{K}$. Since $K' \subseteq K^M$, it follows that $s\sigma \in K^M$. Also, since $K \subseteq \hat{K} \subset K' \subseteq K^M$, and K^M is the infimal prefix-closed and (Σ^*, M)-observable superlanguage of K, it follows that K^M is also the infimal prefix-closed and (Σ^*, M)-observable superlanguage of $\hat{K}$. Finally, since $s \in \hat{K}$, $s\sigma \notin \hat{K}$, and $s\sigma \in K^M$, it follows from the fact that K^M is the infimal prefix-closed and (Σ^*, M)-observable superlanguage of $\hat{K}$ that there exists $t \in \hat{K}$ such that $M(t) = M(s)$ and $t\sigma \in \hat{K}$. We also have that $s \in \hat{K}$, and $s\sigma \in K' - \hat{K} \subseteq H - \hat{K}$. Thus we arrive at a contradiction to the fact that $\hat{K}$ is (H, M)-observable. ∎

The following corollary is immediate from Lemma 3.

COROLLARY 1. *Let $H \subseteq \Sigma^*$ be prefix-closed, $M(\cdot)$ be an observation function, and $K \subseteq H$ be prefix-closed and (H, M)-observable. If $K^M \subseteq \Sigma^*$ denotes the infimal prefix-closed and (Σ^*, M)-observable superlanguage of K, then $K^M \cap H = K$.*

Recall from [19] that a supervisor with trajectory model (S^m, S) is said to be *nonmarking* if $S^m = S$. In the following theorem we obtain a necessary and sufficient condition for the existence of a nonmarking and observation-compatible deterministic supervisor. We need the following result from [30, Remark 11]: Given a plant trajectory model (P^m, P) with priority set A, if a language K satisfies the controllability condition of Theorem 2 below and H is any prefix-closed language satisfying $L(P^{\Sigma-A}) \cap H = K$, then the nonmarking deterministic supervisor $(S, S) := (\det(H), \det(H))$ with priority set B such that $A \cup B = \Sigma$ yields K as the closed-loop behavior $L(P\ {}_A\|_B\ S)$.

THEOREM 2. *Let (P^m, P) be the trajectory model of a plant, $A, B \subseteq \Sigma$, with $A \cup B = \Sigma$; $M(\cdot)$ be an observation mask; and $K \subseteq L(P^{\Sigma-A})$ be a nonempty language. Then there exists a deterministic, nonmarking, and M-compatible supervisor with trajectory model (S, S) such that $L(P\ {}_A\|_B\ S) = K$ if and only if all of the following conditions are met:*

Prefix-closure: $\mathrm{pr}(K) = K$,

Controllability: $\mathrm{pr}(K)(\Sigma - B) \cap L(P^{\Sigma-A}) \subseteq \mathrm{pr}(K)$,

Observability: $\forall s, t \in \mathrm{pr}(K), \sigma \in \Sigma : M(s) = M(t), s\sigma \in \mathrm{pr}(K), t\sigma \in L(P^{\Sigma-A}) \Rightarrow t\sigma \in \mathrm{pr}(K)$.

In this case S can be chosen to be $\det(K^M)$, where K^M is the infimal prefix-closed and (Σ^*, M)-observable superlanguage of K.

Proof. In order to see the sufficiency part, consider the supervisor with $S := \det(K^M)$. Then $L(S) = K^M$, so that S is M-compatible. Also, it follows from Corollary 1 that $K^M \cap L(P^{\Sigma-A}) = K$. Using [30, Remark 11], we obtain $L(P\ {}_A\|_B\ S) = K$.

In order to see the necessity part, suppose that (S, S) is the trajectory model of a deterministic nonmarking and M-compatible supervisor such that $L(P\ {}_A\|_B\ S) = K$. Then it follows from the necessity part of [30, Theorem 4] that K is prefix-closed and controllable. It remains to show that K is $(L(P^{\Sigma-A}), M)$-observable. Since $K = L(P\ {}_A\|_B\ S) = L(P^{\Sigma-A}) \cap L(S^{\Sigma-B})$, it suffices to show that $L(S^{\Sigma-B})$ is (Σ^*, M)-observable. This follows from the fact that (S, S) is a deterministic and M-compatible trajectory model, and as shown in Theorem 1, M-compatibility of deterministic trajectory models is preserved under augmentation. □

Remark 1. In contrast to the standard controllability and observability condition of the Ramadge–Wonham setting, the conditions of Theorem 2 refer to the language of the *augmented* plant. This language depends on the *trajectory model* of the plant and in general cannot be deduced from the language model of the plant. Readers are referred to [30, Remark 9, Example 3] for further elaboration on this point.

Also, since the necessity part of Theorem 2 uses the result of Theorem 1, it follows from Example 3 that the necessity part of Theorem 2 may not hold if the supervisor is not required to be deterministic. In a recent paper Inan has studied the design of nondeterministic supervisors under partial observation [13], where he has introduced the notion of *co-closure* (a condition weaker than controllability and observability combined) and has proved its necessity and sufficiency.

Finally, it may seem that the result of Theorem 2 is an immediate consequence of our prior work on nondeterministic systems and the standard supervisory control results. However, this is not true as it is not clear at the outset whether our results on nondeterministic systems under *complete* observations will immediately "carry over" to the case of *partial* observations (with appropriate extensions as in the standard supervisory control). In fact the result of Theorem 2 fails to hold if more general *nonprojection* type observation masks are considered. This is because the observation-compatibility of a deterministic system is not preserved under augmentation if the observation mask is no longer the projection type. To see this consider an observation mask that identifies the only events a and b of a deterministic system which executes the event a in its initial state and deadlocks. Clearly, the system is observation-compatible. However, its augmentation with the event b has a self-loop on b in both its states. So, in the augmented system a as well as b can occur after the occurrence of the initial b, whereas only b can occur after the occurrence of the initial a, which violates the observation-compatibility since a and b are indistinguishable.

We next apply the result of Theorem 2 to the design of a supervisor that achieves mutually exclusive usage of a shared communication channel in a communication system.

Example 2. Consider the nondeterministic plant P depicted in Figure 2(a). In this example, the plant represents a partial model of a multiuser communication system. Only the portions of the model needed to illustrate the main result are included. The communication system has two channels. The first user can transmit messages using either channel and switches between the channels in a manner that is unmodeled and hence nondeterministic. The second user can transmit only on channel 2. The event a represents the commencement of transmission by user 1 and results in a nondeterministic transition to one of two successor states depending on which channel is used. The event b represents the commencement of transmission by user 2. Both the commencement events are controllable but are unobservable to the supervisor to be constructed. If both users are able to transmit their messages without collision, then an uncontrollable completion event c occurs which returns the plant to its initial state.

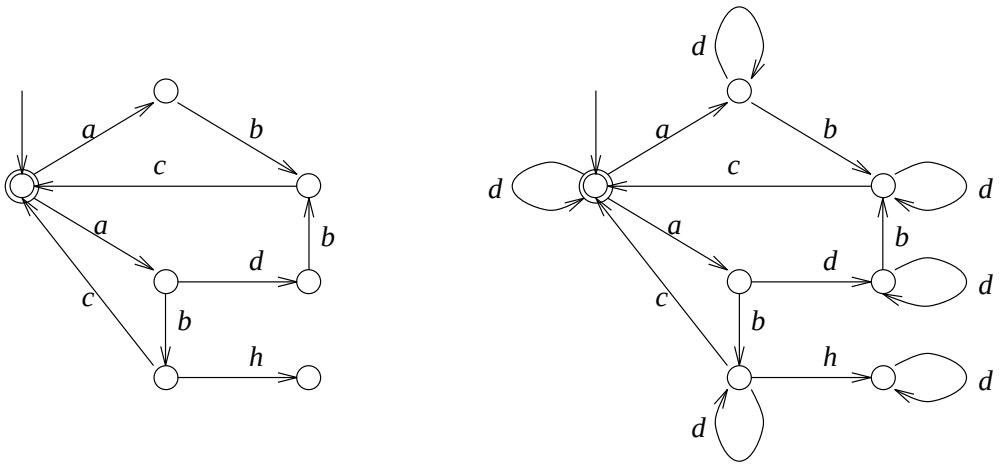


FIG. 2. *Plant P and augmented plant $P^{\Sigma-A} = P^{\{d\}}$.*

In order to avoid collision of messages, user 1 may receive a signal that causes it to vacate channel 2, provided that it has in fact chosen channel 2. This is represented by the event d. It is a driven event because it must be initiated by a supervisor and is executed synchronously by the plant only if able to do so, i.e., only if user 1 is transmitting on channel 2. If user 1 has been transmitting on channel 2 and user 2 commences transmission without it being preceded by d, then there are two possibilities: If user 1 has happened to finish before user 2 starts, then b is followed by the completion event c; otherwise b is followed by the collision event h, an uncontrollable event.

Thus, in this example,

$$\Sigma = \{a, b, c, d, h\}, \quad A = \{a, b, c, h\}, \quad B = \{a, b, d\},$$

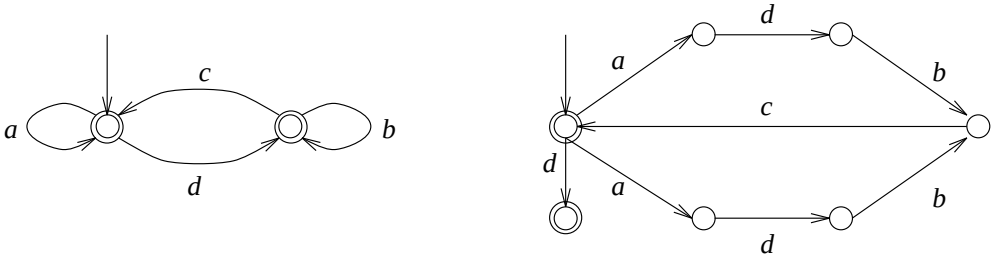
since a and b are controllable, c and h are uncontrollable, and d is a driven event. Note that a and b are the only events that are unobservable to the supervisor to be constructed. The basic performance specification is that a collision-free service should be provided. This can be represented by the prefix-closed sublanguage of the augmented plant (shown in Figure 2(b)) given by

$$K_0 := \{s \in L(P^{\Sigma-A}) \mid s \text{ does not contain } h\} = \text{ pr}[(d^*ad^*bd^*c)^*].$$

However, since user 1 cannot vacate channel 2 unless it is using it, it is reasonable to consider the desired behavior to be the sublanguage of K_0 consisting of those traces that do not contain any occurrence of d that is not immediately preceded by a. This is given by

$$K_1 := \text{ pr}[(abc + adbc)^*].$$

Since the uncontrollable event h can occur following the trace $ab \in K_1$, it is not controllable. The supremal prefix-closed and controllable sublanguage of K_1 is given



(a) Supervisor 1 (b) Closed-loop system 1

FIG. 3. *Supervisor S_1 and closed-loop system $P\ {}_A\|_B\ S_1$.*

by

$$K_1^{\uparrow} = \ \mathrm{pr}[(adbc)^*].$$

However, this is not $L(P^{\Sigma-A}, M)$-observable. In fact since $\epsilon, a \in K_1^{\uparrow}$ with $M(\epsilon) = M(a)$ and $d \in L(P^{\Sigma-A}) - K_1^{\uparrow}$, it follows that any prefix-closed sublanguage of $K_1^{\uparrow}$ that is $(L(P^{\Sigma-A}), M)$-observable cannot contain ad. Thus, a prefix-closed $(L(P^{\Sigma-A}), M)$-observable sublanguage of $K_1^{\uparrow}$ is contained in $\mathrm{pr}(a)$. By Theorem 2, it follows any M-compatible supervisor that results in a closed-loop generated language contained in the specification language K_1 gives a closed-loop generated language contained in $\mathrm{pr}(a)$. This is clearly unsatisfactory.

Thus, we must relax the specification given by K_1 keeping in mind that the constraint given by K_0 must be satisfied. The infimal prefix-closed and $(L(P^{\Sigma-A}), M)$-observable superlanguage of $K_1^{\uparrow}$ is $\mathrm{pr}[(adbc)^*d]$, which is a sublanguage of K_0. Since $\mathrm{pr}[(adbc)^*d]$ is also controllable, and since its infimal prefix-closed and (Σ^*, M)-observable superlanguage is $\mathrm{pr}[(a^*db^*c)^*d]$, it follows from Theorem 2 that the nonmarking supervisor

$$S_1 := \ \det[(pr(a^*db^*c)^*d)] = \ \det[(pr(a^*db^*c)^*)]$$

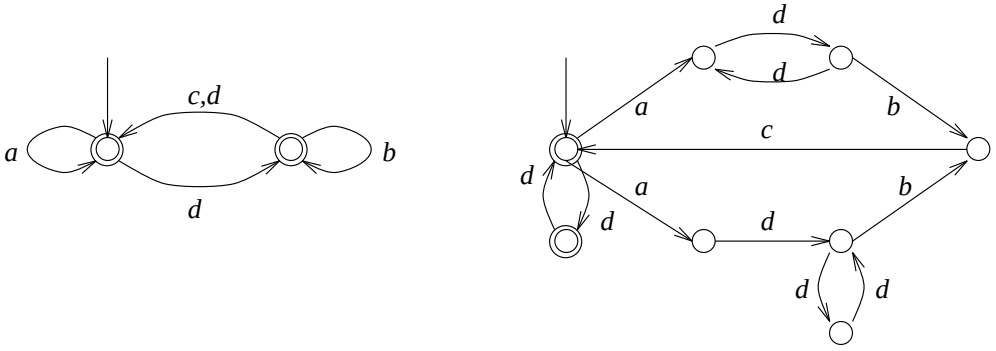
depicted in Figure 3(a) is M-compatible and yields $\mathrm{pr}[(adbc)^*d]$ as the closed-loop generated language. The closed-loop system is shown in Figure 3(b).

The supervisor implements the following simple control strategy: Initially it allows only user 1 to transmit. Before enabling transmission by user 2, it signals user 1 to vacate channel 2. This command is synchronously executed in the plant only when user 1 is transmitting on channel 2; otherwise, it is "refused" by the plant and occurs asynchronously in the supervisor. The supervisor then allows user 2 to communicate and returns to its initial state when the completion event c occurs. The ability of the plant to refuse a driven event initiated by the supervisor is essential to our control and is available because of the PSC-based control design. (Such a feature is certainly unavailable in an SSC-based control design.)

This design is not entirely satisfactory since, as can be seen from Figure 3(b), the closed-loop system deadlocks following the execution of any trace in $(adbc)^*d$.[4] This is because we did not require that the closed-loop behavior be *live* [17].[5] So the next

[4]Note that although the closed-loop system is nonblocking in the sense that the prefix-closure of the recognized refusal-traces is the same as the generated refusal-traces, it may deadlock.

[5]Informally, a language is said to be live if each of its trace has an extension in the language.



(a) Supervisor 2 (b) Closed-loop system 2

FIG. 4. *Supervisor S_2 and closed-loop system $P\ {}_A\|_B\ S_2$.*

alternative is to consider a live superlanguage of the "nonlive" language $\mathrm{pr}[(adbc)^*d]$ that is also controllable and observable and is contained in K_0. Although controllability and observability of prefix-closed languages are preserved under intersection, liveness is not. Similarly, although controllability and liveness of languages is preserved under union, observability is not. Hence, no unique solution can be identified. So a "semiautomatic" design involving some human reasoning is unavoidable.

With a little insight into the problem, it is easy to see that a simple modification of the supervisor in which a transition is added to permit the supervisor to return to its initial state by execution of d achieves liveness of the closed-loop behavior. The new supervisor, denoted S_2, and the resulting closed-loop system are shown in Figure 4. The closed-loop system can no longer deadlock. The language of the closed-loop system equals $\mathrm{pr}[(dd + ad(dd)^*bd^*c)^*]$, which is a sublanguage of K_0 as desired.

Note that both S_1 and S_2 do not change their state when either a or b occur, showing that they are compatible with the unobservability of these events.

We conclude this section by extending the result of Theorem 2 to obtain conditions for the existence of *nonblocking* supervisors. Recall from [19, Definition 6] that given a plant (P^m, P) with priority set A, a supervisor (S^m, S) with priority set B is said to be *language model nonblocking* if $\mathrm{pr}(L(P^m\ {}_A\|_B\ S^m)) = L(P\ {}_A\|_B\ S)$; it is said to be *trajectory model nonblocking* if $\mathrm{pr}(P^m\ {}_A\|_B\ S^m) = P\ {}_A\|_B\ S$. In the following corollary we provide a necessary and sufficient condition for the existence of an observation-compatible and language model nonblocking supervisor.

COROLLARY 2. *Let (P^m, P) be the trajectory model of a plant, $A, B \subseteq \Sigma$, with $A \cup B = \Sigma$; $M(\cdot)$ be an observation mask; and $K^m \subseteq L((P^m)^{\Sigma - A})$ be a nonempty language. Then there exists a deterministic, nonmarking, language model nonblocking, and M-compatible supervisor with trajectory model (S, S) such that $L(P^m\ {}_A\|_B\ S^m) = K^m$ if and only if all of the following conditions are met:*

Relative-closure: $\mathrm{pr}(K^m) \cap L((P^m)^{\Sigma - A}) = K^m$,

Controllability: $\mathrm{pr}(K^m)(\Sigma - B) \cap L(P^{\Sigma - A}) \subseteq \mathrm{pr}(K^m)$,

Observability: $\forall s, t \in \mathrm{pr}(K^m), \sigma \in \Sigma : M(s) = M(t), s\sigma \in \mathrm{pr}(K^m), t\sigma \in L(P^{\Sigma - A}) \Rightarrow t\sigma \in \mathrm{pr}(K^m)$.

In this case S can be chosen to be $\det((K^m)^M)$, *where $(K^m)^M$ denotes the infimal prefix-closed and (Σ^*, M)-observable superlanguage of K^m.*

Proof. First consider sufficiency. Since $\mathrm{pr}(K^m)$ is nonempty, prefix-closed, controllable, and $(L(P^{\Sigma - A}), M)$-observable, it follows from the sufficiency part of

Theorem 2 that the nonmarking supervisor with $S := \det((\mathrm{pr}(K^m))^M) = \det((K^m)^M)$ is M-compatible, and $L(P\ {}_A\|_B\ S) = \mathrm{pr}(K^m)$. Hence, using the relative closure condition we obtain the following series of equalities:

$$\begin{aligned} K^m &= \mathrm{pr}(K^m) \cap L((P^m)^{\Sigma-A}) \\ &= L(P\ {}_A\|_B\ S) \cap L((P^m)^{\Sigma-A}) \\ &= [L(P^{\Sigma-A}) \cap L(S^{\Sigma-B})] \cap L((P^m)^{\Sigma-A}) \\ &= L((P^m)^{\Sigma-A}) \cap L(S^{\Sigma-B}) \\ &= L(P^m\ {}_A\|_B\ S). \end{aligned}$$

Since $\mathrm{pr}(K^m) = L(P\ {}_A\|_B\ S)$ and $K^m = L(P^m\ {}_A\|_B\ S)$, the supervisor is language model nonblocking.

The necessity part follows from the necessity parts of Theorem 2 and [19, Theorem 5]. □

The result of Corollary 2 can be extended to obtain a necessary and sufficient condition for the existence of an observation-compatible and trajectory model nonblocking supervisor. We need the following result from [19, Proposition 4]: Given a plant (P^m, P) with priority set A and a nonempty language $K^m \subseteq L((P^m)^{\Sigma-A})$, if there exists a deterministic, nonmarking, and language model nonblocking supervisor (S, S) with priority set B such that $A \cup B = \Sigma$ and $L(P^m\ {}_A\|_B\ S) = K^m$, then

$$P^m\ {}_A\|_B\ \det(\mathrm{pr}(K^m)) = P^m\ {}_A\|_B\ S; \quad P\ {}_A\|_B\ \det(\mathrm{pr}(K^m)) = P\ {}_A\|_B\ S.$$

COROLLARY 3. *Let (P^m, P) be the trajectory model of a plant, $A, B \subseteq \Sigma$, with $A \cup B = \Sigma$; $M(\cdot)$ be an observation mask; and $K^m \subseteq L((P^m)^{\Sigma-A})$ be a nonempty language. Then there exists a deterministic, nonmarking, trajectory model nonblocking, and M-compatible supervisor with trajectory model (S, S) such that $L(P^m\ {}_A\|_B\ S^m) = K^m$ if and only if all of the following conditions are met:*

Relative-closure: $\mathrm{pr}(K^m) \cap L((P^m)^{\Sigma-A}) = K^m$,

Controllability: $\mathrm{pr}(K^m)(\Sigma - B) \cap L(P^{\Sigma-A}) \subseteq \mathrm{pr}(K^m)$,

Observability: $\forall s, t \in \mathrm{pr}(K^m), \sigma \in \Sigma : M(s) = M(t),\ s\sigma \in \mathrm{pr}(K^m), t\sigma \in L(P^{\Sigma-A}) \Rightarrow t\sigma \in \mathrm{pr}(K^m)$,

Trajectory-closure: $P\ {}_A\|_B \det(\mathrm{pr}(K^m)) = \mathrm{pr}[P^m\ {}_A\|_B \det(\mathrm{pr}(K^m))]$.

In this case S can be chosen to be $\det((K^m)^M)$, where $(K^m)^M$ denotes the infimal prefix-closed and (Σ^*, M)-observable superlanguage of K^m.

Proof. The necessity part follows from the necessity part of Corollary 2 and that of [19, Theorem 6]; the sufficiency part follows from the sufficiency part of Corollary 2 and [19, Proposition 4]. □

5. Decentralized control. So far we have restricted our attention to the problem of *centralized* control under partial observation. However, in many applications, such as manufacturing systems, communication networks, and so on, the plant is physically distributed and it is desirable to have decentralized controllers [6, 20, 22, 29, 32], where each controller is able to control a certain set of events and is able to observe certain other events. The problem of decentralized control can be studied quite elegantly in our PSC-based approach.

Without any loss of generality we consider the case of "two-decentralization"; i.e., given a discrete event plant P with priority set A we consider synthesis of two supervisors S_1 and S_2 with priority sets B_1 and B_2, respectively, which are compatible with their own observation masks $M_1(\cdot)$ and $M_2(\cdot)$, respectively, such that the

controlled plant $P\ {}_A\|_{B_1\cup B_2}\ (S_1\ {}_{B_1}\|_{B_2}\ S_2)$ satisfies a desired behavior constraint. The priority set of supervisor $S_i (i = 1, 2)$ is B_i, and its observations are filtered through the mask function $M_i(\cdot)$. Thus the events in the set $A \cap B_i$ are the controllable events for S_i, those in the set $A - B_i$ are the uncontrollable events for S_i, and finally those in $B_i - A$ are the driven events for S_i. Also, S_i must be compatible with $M_i(\cdot)$; i.e., its generated language must be (Σ^*, M_i)-observable. Since an event must belong to at least one of the priority sets we have that $A \cup B_1 \cup B_2 = \Sigma$.

For notational simplicity we define $B := B_1 \cup B_2$ and $S := S_1\ {}_{B_1}\|_{B_2}\ S_2$. Since the events in the set $A - B$ are in the priority set of neither of the supervisors, these represent the uncontrollable events. Thus for decentralized supervision it is expected that the desired behavior be controllable with respect to these uncontrollable events. The remaining events are in the priority set(s) of one or both of the supervisors; however, their enablement/disablement must satisfy the restriction that results from the partial observability of the supervisors. This is captured by the following condition of co-observability, which is similar to that given by Rudie and Wonham [29].

DEFINITION 3. *Given the priority sets B_1 and B_2 of two supervisors, and their observation masks $M_1(\cdot)$ and $M_2(\cdot)$, respectively, a language $K \subseteq \Sigma^*$ is said to be* co-observable *with respect to a prefix-closed language $H \subseteq \Sigma^*$, called* (H, B_1, B_2, M_1, M_2)–co-observable*, if*

$\forall s_1, s_2, t \in \mathrm{pr}(K), \sigma \in B_1 \cup B_2$*:*

(1) $[\sigma \in B_1 - B_2, M_1(s_1) = M_1(t), s_1\sigma \in \mathrm{pr}(K), t\sigma \in H] \Rightarrow [t\sigma \in \mathrm{pr}(K)]$

(2) $[\sigma \in B_2 - B_1, M_2(s_2) = M_2(t), s_2\sigma \in \mathrm{pr}(K), t\sigma \in H] \Rightarrow [t\sigma \in \mathrm{pr}(K)]$

(3) $[\sigma \in B_1 \cap B_2, M_1(s_1) = M_1(t), M_2(s_2) = M_2(t), s_1\sigma, s_2\sigma \in \mathrm{pr}(K), t\sigma \in H] \Rightarrow [t\sigma \in \mathrm{pr}(K)]$.

Thus if an event belongs solely to priority set of one of the supervisors and it is enabled following a trace, then it must be enabled following any other trace that is indistinguishable to that supervisor (provided it can occur in the plant). On the other hand, if the event belongs to the common priority set of the supervisors and it can occur in the plant following a trace which is indistinguishable from a certain trace to the first supervisor, and from another trace to the second supervisor, and the event is enabled following these latter pair of traces, then the event must also be enabled following the former trace. It is clear that K is co-observable if and only if $\mathrm{pr}(K)$ is co-observable. Also, as is the case with observability, co-observability of prefix-closed languages is preserved under intersection [29]; consequently, the infimal prefix-closed and co-observable superlanguage of a given language exists.

We show below that controllability together with co-observability is necessary and sufficient for decentralized supervision. It is clear that observability with respect to each of the masks implies co-observability. Thus a weaker condition than observability with respect to each of the masks is needed for decentralized supervision; this is because the events in the common priority set of the two supervisors can be disabled by either of them. However, if the common priority set is empty, then under the condition of controllability, co-observability is equivalent to observability with respect to each of the masks.

We saw above that the operation of PSC of a pair of systems can be reduced to that of SSC when the priority sets of the two systems exhaust the entire event set. We next prove that this is also the case when more than two systems are involved. We need the following lemma.

LEMMA 4. *Consider NSMs $\mathcal{S}_1$ and $\mathcal{S}_2$ with priority sets B_1 and B_2, respectively. Then*

$$(\mathcal{S}_1\ {}_{B_1}\|_{B_2}\ \mathcal{S}_2)^{\Sigma - B} = \mathcal{S}_1^{\Sigma - B_1}\ {}_{\Sigma}\|_{\Sigma}\ \mathcal{S}_2^{\Sigma - B_2},$$

where $B := B_1 \cup B_2$.

Proof. The above lemma follows from the following series of equalities:

$$\begin{aligned}
\mathcal{S}_1^{\Sigma-B_1}\ {}_{\Sigma}\|_{\Sigma}\ \mathcal{S}_2^{\Sigma-B_2} &= (\mathcal{S}_1^{B-B_1})^{\Sigma-B}\ {}_{\Sigma}\|_{\Sigma}\ (\mathcal{S}_2^{B-B_2})^{\Sigma-B} \\
&= [\mathcal{S}_1^{B-B_1}{}_B\|_{\Sigma-B}\ \det((\Sigma-B)^*)]_{\Sigma}\|_{\Sigma} \\
&\quad \times[\mathcal{S}_2^{B-B_2}{}_B\|_{\Sigma-B}\ \det((\Sigma-B)^*)] \\
&= [\mathcal{S}_1^{B-B_1}{}_B\|_B\mathcal{S}_2^{B-B_2}]\ {}_B\|_{\Sigma-B} \\
&\quad \times[\det((\Sigma-B)^*)\ {}_{\Sigma-B}\|_{\Sigma-B}\ \det((\Sigma-B)^*)] \\
&= [\mathcal{S}_1^{B-B_1}\ {}_B\|_B\ \mathcal{S}_2^{B-B_2}]\ {}_B\|_{\Sigma-B}\ \det((\Sigma-B)^*) \\
&= [\mathcal{S}_1\ {}_{B_1}\|_{B_2}\ \mathcal{S}_2]^{\Sigma-B},
\end{aligned}$$

where the first, second, and final equalities follow from definition of augmentation and the third equality follows from associativity of PSC. ∎

The following corollary is immediate from the above lemma.

COROLLARY 4. *Consider NSMs $\mathcal{P}$, $\mathcal{S}_1$, and $\mathcal{S}_2$ with priority sets A, B_1, and B_2, respectively, such that $A \cup B_1 \cup B_2 = \Sigma$. Then*

$$\mathcal{P}\ {}_A\|_B\ \mathcal{S} = P^{\Sigma-A}\ {}_{\Sigma}\|_{\Sigma}\ [\mathcal{S}_1^{\Sigma-B_1}\ {}_{\Sigma}\|_{\Sigma}\ \mathcal{S}_2^{\Sigma-B_2}],$$

where $B := B_1 \cup B_2$ and $\mathcal{S} := \mathcal{S}_1\ {}_{B_1}\|_{B_2}\ \mathcal{S}_2$.

Proof. Since $A \cup B = \Sigma$, it follows from a PSC property [9, 30, 19] that

$$\mathcal{P}\ {}_A\|_B\ \mathcal{S} = \mathcal{P}^{\Sigma-A}\ {}_{\Sigma}\|_{\Sigma}\ \mathcal{S}^{\Sigma-B}.$$

Thus the result follows from Lemma 4. ∎

Remark 2. Corollary 4 shows that the operation of PSC of two or more systems can be reduced to that of SSC whenever the priority sets of all the systems jointly exhaust the entire event set. It also follows that under the hypothesis of Corollary 4

$$L(\mathcal{P}\ {}_A\|_B\ \mathcal{S}) = L(\mathcal{P}^{\Sigma-A}) \cap L(\mathcal{S}_1^{\Sigma-B_1}) \cap L(\mathcal{S}_2^{\Sigma-B_2}). \tag{2}$$

Next we establish a relationship between controllability, observability, co-observability, and PSC. In the following lemma we prove that if supervisors $\mathcal{S}_1$ and $\mathcal{S}_2$ are M_1-compatible and M_2-compatible, respectively, and both generate $(\Sigma^*, \Sigma - B)$ controllable languages, then the language of $\mathcal{S}_1\ {}_{B_1}\|_{B_2}\ \mathcal{S}_2$ is $(\Sigma^*, \Sigma - B)$-controllable and $(\Sigma^*, B_1, B_2, M_1, M_2)$–co-observable.

LEMMA 5. *Consider deterministic state machines $\mathcal{S}_1$ and $\mathcal{S}_2$ with priority sets B_1 and B_2, respectively. Suppose that $\mathcal{S}_1$ and $\mathcal{S}_2$ are observation-compatible with respect to masks M_1 and M_2, respectively, and $L(\mathcal{S}_1)$ as well as $L(\mathcal{S}_2)$ are $(\Sigma^*, \Sigma - B)$ controllable, where $B := B_1 \cup B_2$. Then $L(\mathcal{S})$, where $\mathcal{S} := \mathcal{S}_1\ {}_{B_1}\|_{B_2}\ \mathcal{S}_2$, is $(\Sigma^*, B_1, B_2, M_1, M_2)$–co-observable and $(\Sigma^*, \Sigma - B)$ controllable.*

Proof. In order to see co-observability, pick $s_1, s_2, t \in L(\mathcal{S})$, and $\sigma \in B$. Since $\mathcal{S}_1$ and $\mathcal{S}_2$ are deterministic, $\mathcal{S}$ is also deterministic. Let $(x^1_{s_1}, x^2_{s_1})$, $(x^1_{s_2}, x^2_{s_2})$, and (x^1_t, x^2_t) denote the states reached in $\mathcal{S}$ after execution of s_1, s_2, and t, respectively, where the first coordinate denotes the state reached in $\mathcal{S}_1$ and the second coordinate denotes the state reached in $\mathcal{S}_2$.

In order to prove co-observability of $L(\mathcal{S})$ we must consider the three different cases of the definition of co-observability. First suppose $\sigma \in B_1 - B_2$, $M_1(s_1) = M_1(t)$, and $s_1\sigma \in L(\mathcal{S})$; we need to show that $t\sigma \in L(\mathcal{S})$. Since $\sigma \in B_1 - B_2$ and $s_1\sigma \in L(\mathcal{S})$, it follows that σ is defined at the state $x^1_{s_1}$ of $\mathcal{S}_1$. Then using the result of Lemma 2 and the fact that $\mathcal{S}_1$ is M_1-compatible, we obtain that σ is also defined at the state x^1_t of $\mathcal{S}_1$, which implies that $t\sigma \in L(\mathcal{S})$. It can be argued in a similar manner that the second and third cases of the definition of co-observability also hold.

In order to see controllability, consider $s \in L(\mathcal{S})$ and $\sigma \in \Sigma - B$. Let (x_s^1, x_s^2) be the state reached in $\mathcal{S}$ by execution of s. Then it follows from the controllability of $L(\mathcal{S}_1)$ that σ is defined at state x_s^1 of $\mathcal{S}_1$. Hence $s\sigma \in L(\mathcal{S})$. □

Given a language K, we use K^{BM_i} $(i = 1, 2)$ to denote the infimal prefix-closed, $(\Sigma^*, \Sigma - B)$-controllable, and (Σ^*, M_i)-observable superlanguage of K, which exists as the controllability and observability of prefix-closed languages is preserved under intersection. The notation $K^{BM_{12}}$ is used to denote the infimal prefix-closed, $(\Sigma^*, \Sigma - B)$-controllable, and $(\Sigma^*, M_1, M_2, B_1, B_2)$–co-observable superlanguage of K. The result of Lemma 5 can be used to show that if $\mathcal{S}_1$ generates K^{BM_1} and $\mathcal{S}_2$ generates K^{BM_2}, then $\mathcal{S}$ generates $K^{BM_{12}}$. This we state in the following theorem.

THEOREM 3. *Let $M_1, M_2, B_1, B_2, K^{BM_1}, K^{BM_2}$, and $K^{BM_{12}}$ be as defined above. Suppose that $\mathcal{S}_1$ and $\mathcal{S}_2$ are deterministic state machines with $L(\mathcal{S}_1) = K^{BM_1}$ and $L(\mathcal{S}_2) = K^{BM_2}$. Then $L(\mathcal{S}) = K^{BM_{12}}$, where $\mathcal{S} := \mathcal{S}_1 \,{}_{B_1}\|_{B_2}\, \mathcal{S}_2$ and $B := B_1 \cup B_2$.*

Proof. Since $K \subseteq L(\mathcal{S}_1)$ and $K \subseteq L(\mathcal{S}_2)$, it follows that $K \subseteq L(\mathcal{S})$. Also, it follows from Lemma 5 that $L(\mathcal{S})$ is controllable and co-observable. Thus $L(\mathcal{S})$ is a prefix-closed, controllable, and co-observable superlanguage of K. Hence we have that $K^{BM_{12}} \subseteq L(\mathcal{S})$. In order to see the reverse containment, it suffices to show that non–zero-length strings of $L(\mathcal{S})$ are also in $K^{BM_{12}}$, as the zero-length string ϵ does belong to $K^{BM_{12}}$. Thus we need to show that for any string $t \in K^{BM_{12}}$ and an event σ such that $t\sigma \in L(\mathcal{S})$, $t\sigma \in K^{BM_{12}}$. If $\sigma \in \Sigma - B$, then it follows from the prefix-closure and $(\Sigma^*, \Sigma - B)$-controllability of $K^{BM_{12}}$ that $t\sigma \in K^{BM_{12}}$. On the other hand, if $\sigma \in B$, then we show that the following hold:

(1) $[\sigma \in B_1 - B_2] \Rightarrow [\exists s_1 : M_1(s_1) = M_1(t), s_1\sigma \in \mathrm{pr}(K)]$,

(2) $[\sigma \in B_2 - B_1] \Rightarrow [\exists s_2 : M_2(s_2) = M_2(t), s_2\sigma \in \mathrm{pr}(K)]$,

(3) $[\sigma \in B_1 \cap B_2] \Rightarrow [\exists s_1, s_2 : M_1(s_1) = M_1(t), M_2(s_2) = M_2(t), s_1\sigma, s_2\sigma \in \mathrm{pr}(K)]$,

as this together with $(\Sigma^*, B_1, B_2, M_1, M_2)$–co-observability of $K^{BM_{12}}$ clearly implies that $t\sigma \in K^{BM_{12}}$.

We prove this using induction on length of t. We only prove that the case (1) holds, as the proof for the other two cases is similar. In order to see the base step, set $t = \epsilon$ (note that we do have $\epsilon \in K^{BM_{12}}$) and pick $\sigma \in B_1 - B_2$. Since $t\sigma = \sigma \in L(\mathcal{S})$ and $\sigma \in B_1 - B_2$, it follows from construction of $\mathcal{S}$ that $\sigma \in L(\mathcal{S}_1) = K^{BM_1}$. Since K^{BM_1} is the infimal prefix-closed, $(\Sigma^*, \Sigma - B)$-controllable, and (Σ^*, M_1)-observable superlanguage of K, and σ is not an uncontrollable event, it follows that there exists a string s_1 such that $s_1\sigma \in \mathrm{pr}(K)$ and $M_1(s_1) = M_1(t) = \epsilon$. The other two cases of the base step can be proved analogously.

In order to see the induction step set $t = \bar{t}\bar{\sigma}$ and pick $\sigma \in B_1 - B_2$. Suppose $\bar{\sigma} \in B_1 - B_2$. Then it follows from induction hypothesis that there exists $\bar{s}_1$ such that $s_1' := \bar{s}_1\bar{\sigma} \in \mathrm{pr}(K)$ and $M_1(\bar{s}_1) = M_1(\bar{t})$. Let (x_t^1, x_t^2) and $(x_{s_1'}^1, x_{s_1'}^2)$ denote the states reached in $\mathcal{S}$ after execution of t and s_1', respectively, where the first coordinate denotes the state reached in $\mathcal{S}_1$ and the second coordinate denotes the state reached in $\mathcal{S}_2$. Since $\sigma \in B_1 - B_2$, we have that σ is defined at state x_t^1. Hence it follows from Lemma 2 and M_1-compatibility of $\mathcal{S}_1$ that σ is also defined at state $x_{s_1'}^1$, which implies that $s_1'\sigma \in L(\mathcal{S})$. Since $s_1' \in \mathrm{pr}(K) \subseteq L(\mathcal{S}_1)$ and $\sigma \in B_1 - B_2$, we must have $s_1'\sigma \in L(\mathcal{S}_1) = K^{BM_1}$. Since K^{BM_1} is the infimal prefix-closed controllable and observable superlanguage of K, and σ is not an uncontrollable event, this implies that there exists s_1 such that $s_1\sigma \in \mathrm{pr}(K)$ and $M_1(s_1) = M_1(s_1')$. Thus s_1 is the desired string, as $M_1(s_1) = M_1(s_1') = M_1(t)$. □

Using the results derived in this section, we are now ready to present a necessary and sufficient condition for decentralized supervision.

THEOREM 4. *Consider A, B_1, B_2, M_1, and M_2 as defined above with $A \cup B_1 \cup B_2 = \Sigma$. Let (P^m, P) be the trajectory model of a plant and $K \subseteq L(P^{\Sigma-A})$ be a nonempty language. Then there exist deterministic, nonmarking, and M_1-compatible supervisor with trajectory model (S_1, S_1) and M_2-compatible supervisor with trajectory model (S_2, S_2) such that $L(P\ {}_A\|_B\ S) = K$, where $S := S_1\ {}_{B_1}\|_{B_2}\ S_2$ and $B := B_1 \cup B_2$ if and only if all of the following hold:*

Prefix-closure: $\mathrm{pr}(K) = K$,

Controllability: $\mathrm{pr}(K)(\Sigma - B) \cap L(P^{\Sigma-A}) \subseteq \mathrm{pr}(K)$,

Co-observability: K is $(L(P^{\Sigma-A}), B_1, B_2, M_1, M_2)$–co-observable.

In this case S_i $(i = 1, 2)$ can be chosen to be $\det(K^{BM_i})$, where K^{BM_i} is the infimal prefix-closed, $(\Sigma^*, \Sigma - B)$-controllable, and (Σ^*, M_i)-observable superlanguage of K.

Proof. We begin by proving the necessity. Prefix-closure and controllability conditions follow from the necessity part of [30, Theorem 4]. We need to show that the co-observability condition also holds. It follows from hypothesis and Corollary 4 that $K = L(P\ {}_A\|_B\ S) = L(P^{\Sigma-A}) \cap L(S_1^{\Sigma-B_1}) \cap L(S_2^{\Sigma-B_2})$. Hence it suffices to show that $H := L(S_1^{\Sigma-B_1}) \cap L(S_2^{\Sigma-B_2})$ is $(\Sigma^*, B_1, B_2, M_1, M_2)$–co-observable. Pick $s_1, s_2, t \in H$ and $\sigma \in \Sigma$. We must consider the three different cases of the definition of co-observability. We consider only the first case, as the other cases can be proven in a similar manner. Suppose $\sigma \in B_1 - B_2$, $s_1\sigma \in H$, and $M_1(s_1) = M_1(t)$. We need to show that $t\sigma \in H$. Since $t \in L(S_2^{\Sigma-B_2})$ and $\sigma \in B_1 - B_2 \subseteq \Sigma - B_2$, $t\sigma \in L(S_2^{\Sigma-B_2})$ trivially. It remains to show that $t\sigma \in L(S_1^{\Sigma-B_1})$. This follows from the fact that $S_1^{\Sigma-B_1}$ is M_1-compatible (as S_1 is M_1-compatible and deterministic, and observation-compatibility of deterministic systems is preserved under augmentation). This completes the proof of the necessity part.

In order to see the sufficiency part, select $S_1 := \det(K^{BM_1})$ and $S_2 := \det(K^{BM_2})$. Then S_1 and S_2 are deterministic, S_1 is M_1-compatible, and S_2 is M_2-compatible. It remains to show that the controlled plant language equals K. From Theorem 3 we have that $L(S) = K^{BM_{12}}$, where $K^{BM_{12}}$ is the infimal prefix-closed, $(\Sigma^*, \Sigma - B)$-controllable, and $(\Sigma^*, B_1, B_2, M_1, M_2)$–co-observable superlanguage of K. Using arguments similar to those in Lemma 3 we can readily conclude that $L(P^{\Sigma-A}) \cap L(S)$ is the infimal prefix-closed, $(L(P^{\Sigma-A}), \Sigma - B)$-controllable, and $(L(P^{\Sigma-A}), B_1, B_2, M_1, M_2)$–co-observable superlanguage of K. Hence it follows from the prefix-closure, controllability, and co-observability conditions that

$$L(P^{\Sigma-A}) \cap L(S) = K. \tag{3}$$

We need to show that we also have the following equality: $H := L(P^{\Sigma-A}) \cap L(S^{\Sigma-B}) = K$. This follows from (3) and the fact that K is controllable as is shown next.

Since $L(S) \subseteq L(S^{\Sigma-B})$, clearly $K \subseteq H$. Suppose for contradiction that there exists a string s such that $s \in H - K$. Let s be a minimal-length such string. Since $\epsilon \in K$, we have $s \neq \epsilon$, which implies $s = \bar{s}\sigma$, where $\bar{s} \in K$ and $\sigma \in \Sigma$. Since $\bar{s} \in K$ and $\bar{s}\sigma \notin K$, it must be the case that $\sigma \in \Sigma - B$. This is contradictory to the fact that K is controllable, as we have $\bar{s} \in K$, $\sigma \in \Sigma - B$, $\bar{s}\sigma \in H$, which implies $\bar{s}\sigma \in L(P^{\Sigma-A})$; however, $\bar{s}\sigma \notin K$. This completes the proof. ∎

Remark 3. Note that the conditions of controllability and co-observability in Theorem 4 are with regard to the language of the *augmented* plant, which depends on the trajectory model of the plant and cannot be inferred from the language model of the plant. Also, as is the case of the necessity part of Theorem 2, the necessity part of Theorem 4 may not hold if the supervisors are nondeterministic.

Finally, the result of Theorem 4 can be easily extended to obtain conditions for either language model nonblocking or trajectory model nonblocking supervisors. In

fact arguments similar to those given in Corollaries 2 and 3 can be used to show that language model nonblocking supervision would require the condition of relative-closure instead of that of prefix-closure, and a trajectory model nonblocking supervision would require the additional trajectory-closure condition.

6. Conclusion. In this paper we have extended our earlier work on supervisory control of nondeterministic systems using prioritized synchronization as the mechanism of control and trajectory model as the modeling formalism to control under partial observation. The notion of observation-compatibility of trajectory models has been introduced, and necessary and sufficient conditions for the existence of observation-compatible supervisors have been obtained for centralized as well as decentralized supervision. Although these conditions are similar to the standard conditions of controllability, observability, and co-observability found in literature, they are different, as they depend on the trajectory model as opposed to the language model of the plant. Also, our work demonstrates the suitability of PSC-based supervisor design for nondeterministic systems under centralized as well as decentralized setting. These results have been applied to the design of a supervisor that achieves a mutually exclusive usage of a communication channel in a communication system.

ON CONTROLLABILITY CONCEPTION FOR STOCHASTIC SYSTEMS*

AGAMIRZA E. BASHIROV† AND KERIM R. KERIMOV‡

Abstract. The controllability notions for partially observed stochastic systems are defined. Their relation with complete and approximate controllabilities is shown. In particular, it is proven that the approximate controllability condition is necessary and the complete controllability condition is sufficient for the partially observed linear Gaussian control system to attain the arbitrarily small neighborhood of each point in the state space with probability arbitrarily closely to one.

Key words. controllability, stochastic system, separation principle

AMS subject classifications. Primary, 93B, 93E; Secondary, 60G, 49N

1. Introduction. A quite complete theory of the controllability for the deterministic linear systems exists (see, for example, Curtain and Pritchard [1]). At the same time there have been only several attempts to introduce a controllability notion for stochastic systems, which do not agree in general with either complete or approximate controllabilities when a deterministic system is considered as a stochastic system with zero noise, and to obtain the conditions of its contents. For example, the stochastic ε-controllability with probability p, defined in Sunahara et al. [2], cannot be reduced to the known controllability notions for the deterministic systems.

In Bashirov and Hajiyev [3, 4] the approximate and complete controllability notions for the deterministic systems and the stochastic controllability from [2] were combined. In this paper, using the approach from [3, 4]—that is, based on the separation principle—we introduce the controllability notions for partially observed stochastic systems, show their relation with complete and approximate controllabilities, and study them for the linear systems. In particular, in this paper it is proven that the approximate controllability condition is necessary and the complete controllability condition is sufficient for the partially observed linear Gaussian control system to attain the arbitrarily small neighborhood of each point in the state space with probability arbitrarily closely to one.

2. Notations. In this paper X and Y are the real separable Hilbert spaces. R^n denotes the n-dimensional real Euclidean space. The closure of the set D is denoted by $\overline{D}$.

The space of all linear bounded operators on X to Y is denoted by $\mathcal{L}(X,Y)$. The brief notation $\mathcal{L}(X)=\mathcal{L}(X,X)$ is used as well. A^* denotes the adjoint to the operator A. The trace of the operator A is denoted by $\mathrm{tr}A$. If $A\in\mathcal{L}(X)$ is self-adjoint and $\langle h,Ah\rangle\geq 0$ (respectively, $\langle h,Ah\rangle\geq c\|h\|^2$, where $c=\text{const.}>0$) for all $h\in X$,

then we write $A \geq 0$ (respectively, $A > 0$), where $\langle \cdot\,, \cdot \rangle$ is an inner product and $\| \cdot \|$ is a norm.

Always it is supposed that $(\Omega, \mathcal{F}, \mathbf{P})$ is a complete probability space, and two time moments are given. The initial time moment is identified with zero. The terminal moment is denoted by T. The notation $\mathbf{T} = [0, T]$ is used for the finite time interval on which all random and nonrandom processes will be considered. $L_2(\mathbf{T}, X)$ (respectively, $L_2(\Omega, X)$) denotes the space of equivalence classes of all functions on $\mathbf{T}$ (respectively, Ω) to X that are Lebesgue measurable (respectively, $\mathcal{F}$-measurable) and square integrable with respect to the Lebesgue measure (respectively, measure $\mathbf{P}$).

The notation $\Delta = \{(t, s) : \ 0 \leq s \leq t \leq T\}$ is used for the triangular set over $\mathbf{T}$. $B_2(\Delta, \mathcal{L}(X, Y))$ denotes the class of all $\mathcal{L}(X, Y)$-valued functions on Δ that are strongly measurable and square integrable with respect to the Lebesgue measure on Δ (see Curtain and Ichikawa [5]).

All integrals of the abstract functions are in Bochner sense. For the expectation and the conditional expectation the notations $\mathbf{E}$ and $\mathbf{E}(\cdot\,|\,\cdot)$ are used, respectively. $\operatorname{cov}(x, y)$ is the covariance operator of the random variables x and y. The brief notation $\operatorname{cov} x = \operatorname{cov}(x, x)$ is used as well. The integrals of the operator valued functions (except the stochastic integrals) are in strong Bochner sense.

3. Main definitions. Consider a control system on $\mathbf{T}$. Let x_t^u be its (random or not) state value at time $t \in \mathbf{T}$ corresponding to the control u taken from the set of the admissible controls U. If the considered control system is stochastic, then by $\mathcal{F}^u$ we denote the smallest σ-algebra generated by the observations on the time interval $\mathbf{T}$ corresponding to the control u. Suppose that X is the state space. Introduce the following sets:

$$D = \{x_T^u : u \in U\}, \tag{1}$$

$$S(\varepsilon, p) = \{h \in X : \exists u \in U \ \mathbf{P}\{\|\mathbf{E}(x_T^u|\mathcal{F}^u) - h\|^2 > \varepsilon\} \leq 1 - p\}, \tag{2}$$

$$C(\varepsilon, p) = \{h \in X : \exists u \in U \ h = \mathbf{E}x_T^u, \ \mathbf{P}\{\|\mathbf{E}(x_T^u|\mathcal{F}^u) - h\|^2 > \varepsilon\} \leq 1 - p\}, \tag{3}$$

where $0 \leq \varepsilon < \infty$ and $0 \leq p \leq 1$ are the parameters.

DEFINITION 1. *If $D = X$ (respectively, $\overline{D} = X$), then the corresponding deterministic control system will be called* D^c-controllable (*respectively,* D^a-controllable).

DEFINITION 2. *If $0 \in S(\varepsilon, p)$, then the corresponding stochastic control system will be called* $S^0_{\varepsilon,p}$-controllable.

DEFINITION 3. *If $S(\varepsilon, p) = X$ (respectively, $\overline{S(\varepsilon, p)} = X$), then the corresponding stochastic control system will be called* $S^c_{\varepsilon,p}$-controllable (*respectively,* $S^a_{\varepsilon,p}$-controllable).

It is clear that D^c- and D^a-controllabilities are the well-known complete and approximate controllabilities for the deterministic systems, respectively. The $S^0_{\varepsilon,p}$-controllability is a generalization of the ε-controllability with probability p, defined in Sunahara et al. [2], to the partially observed stochastic systems.

The geometric interpretation of the $S^c_{\varepsilon,p}$ (respectively, $S^a_{\varepsilon,p}$)-controllability is as follows. If a stochastic system with the initial (random or not) state x_0 is $S^c_{\varepsilon,p}$ (respectively, $S^a_{\varepsilon,p}$)-controllable, then with probability not less than p it can pass from x_0 for the time T into the $\sqrt{\varepsilon}$-neighborhood of the arbitrary point of the state space

(respectively, the set that is dense in the state space). The $S^0_{\varepsilon,p}$-controllability means that the hitting probability into the $\sqrt{\varepsilon}$-neighborhood of zero is not less than p. The smaller ε is and the larger p is for the stochastic system, the more controllable it is; i.e., it is possible to hit into the smaller neighborhood with higher probability. In particular, if a D^c (respectively, D^a)-controllable deterministic system is considered as stochastic with zero noise, then this system is $S^c_{0,1}$ (respectively, $S^a_{0,1}$)-controllable (with parameters $\varepsilon = 0$ and $p = 1$). At the same time it is clear that all stochastic systems are $S^c_{\varepsilon,p}$- and $S^a_{\varepsilon,p}$-controllable with $\varepsilon \geq 0$ and $p = 0$ or $\varepsilon = \infty$ and $0 \leq p \leq 1$ if we admit ∞ as a value for ε.

It is also to be noted that if a given stochastic system is $S^c_{\varepsilon,p}$ (respectively, $S^a_{\varepsilon,p}$)-controllable, then it is also $S^c_{\varepsilon_1,p_1}$ (respectively, $S^a_{\varepsilon_1,p_1}$)-controllable, where $\varepsilon \leq \varepsilon_1 < \infty$ and $0 \leq p_1 \leq p$. So, if ε is given for some system, it becomes important to find the largest value of p with which the system is $S^c_{\varepsilon,p}$ (respectively, $S^a_{\varepsilon,p}$)-controllable. Similarly, if there is given p, then it is worth finding the smallest ε.

We also introduce the following stronger controllability notions.

DEFINITION 4. *If $C(\varepsilon,p) = X$ (respectively, $\overline{C(\varepsilon,p)} = X$), then the corresponding stochastic control system will be called* $C^c_{\varepsilon,p}$-controllable (*respectively,* $C^a_{\varepsilon,p}$-controllable).

It is clear that $C^c_{\varepsilon,p}$ (respectively, $C^a_{\varepsilon,p}$)-controllability implies $S^c_{\varepsilon,p}$ (respectively, $S^a_{\varepsilon,p}$) -controllability, but the converses are not true in general. The geometric interpretation of the $C^c_{\varepsilon,p}$- and $C^a_{\varepsilon,p}$-controllabilities differs from that of $S^c_{\varepsilon,p}$- and $S^a_{\varepsilon,p}$-controllabilities since among the controls, with the help of which the $\sqrt{\varepsilon}$-neighborhood of any point h is achieved, there exists one with property that the expectation of the target state, corresponding to this control, coincides with h.

To introduce the next controllability notion we need the following lemma.

LEMMA 1. *A stochastic system is $S^a_{\varepsilon,p}$-controllable for all $\varepsilon > 0$ and $0 \leq p < 1$ if and only if it is $S^c_{\varepsilon,p}$-controllable for all $\varepsilon > 0$ and $0 \leq p < 1$.*

Proof. The sufficiency is obvious. Let us prove the necessity. Suppose that a given stochastic control system is $S^a_{\varepsilon,p}$-controllable for all $\varepsilon > 0$ and $0 \leq p < 1$. Let $S(\varepsilon,p)$ be the set (2) corresponding to this system. We have $\overline{S(\varepsilon,p)} = X$ for all $\varepsilon > 0$ and $0 \leq p < 1$, where X is the state space. We should show that the stronger condition $S(\varepsilon,p) = X$ for all $\varepsilon > 0$ and $0 \leq p < 1$ holds. Fix arbitrary $\varepsilon_0 > 0$, $0 \leq p_0 < 1$ and $h \in X$. Since $\overline{S(\varepsilon,p)} = X$ for all $\varepsilon > 0$ and $0 \leq p < 1$, there is $h_0 \in S(\varepsilon_0/4, p_0)$ such that $\|h_0 - h\|^2 \leq \varepsilon_0/4$. At the same time, since $h_0 \in S(\varepsilon_0/4, p_0)$, there exists $u \in U$ with

$$\mathbf{P}\{\|\mathbf{E}(x^u_T|\mathcal{F}^u) - h_0\|^2 > \varepsilon_0/4\} \leq 1 - p_0.$$

Hence, for this $u \in U$, we have

$$\mathbf{P}\{\|\mathbf{E}(x^u_T|\mathcal{F}^u) - h\|^2 > \varepsilon_0\} \leq \mathbf{P}\{\|\mathbf{E}(x^u_T|\mathcal{F}^u) - h_0\| + \|h_0 - h\| > \sqrt{\varepsilon_0}\}$$

$$\leq \mathbf{P}\{\|\mathbf{E}(x^u_T|\mathcal{F}^u) - h_0\| + \sqrt{\varepsilon_0}/2 > \sqrt{\varepsilon_0}\} = \mathbf{P}\{\|\mathbf{E}(x^u_T|\mathcal{F}^u) - h_0\|^2 > \varepsilon_0/4\} \leq 1 - p_0.$$

Thus, $h \in S(\varepsilon_0, p_0)$. Since $\varepsilon_0 > 0$, $0 \leq p_0 < 1$ and $h \in X$ are arbitrary, we have $S(\varepsilon,p) = X$ for all $\varepsilon > 0$ and $0 \leq p < 1$. The lemma is proven.

DEFINITION 5. *A stochastic control system will be called* S-controllable *if it is $S^c_{\varepsilon,p}$-controllable (or, equivalently, $S^a_{\varepsilon,p}$-controllable) for all $\varepsilon > 0$ and $0 \leq p < 1$.*

Obviously, S-controllability is independent on parameters ε and p. Moreover, by Lemma 1, the complete and approximate versions of this controllability are equivalent.

S-controllability is the main object of our consideration. The geometric interpretation of S-controllability is as follows: an S-controllable stochastic control system can attain the arbitrarily small neighborhood of each point in the state space with probability arbitrarily closely to one.

Finally, it is to be noted that in the previously introduced controllability notions the abbreviations D, S, and C mean deterministic, stochastic, and combined, respectively.

4. Separation theorem. In this section we shall prove that in the case of linear systems the $C^c_{\varepsilon,p}$ (respectively, $C^a_{\varepsilon,p}$)-controllability is equivalent to the $S^0_{\varepsilon,p}$- and D^c (respectively, D^a)-controllabilities combined.

Suppose that A is the infinitesimal generator of a strongly continuous semigroup $\mathcal{U}$; $B \in \mathcal{L}(Y,X)$; $C \in \mathcal{L}(X,R^k)$; $f \in L_2(\mathbf{T},X)$; $x_0 \in L_2(\Omega,X)$ is a Gaussian random variable with $\mathrm{cov}x_0 = P_0$; m and n are X- and R^k-valued Wiener processes, respectively; $n_0 = 0$; $m_0 = 0$; $\mathbf{E}n_t = 0$; $\mathbf{E}m_t = 0$; $\mathrm{cov}n_t = It$; I is the unit $(k \times k)$-matrix, $\mathrm{cov}m_t = Mt$; M is a nuclear operator on X; and x_0, n, m are mutually independent. Consider the linear partially observed stochastic system

$$\left\{ \begin{array}{ll} dx^u_t = (Ax^u_t + Bu_t + f_t)dt + dm_t, & 0 < t \le T, \quad x^u_0 = x_0, \\ d\xi^u_t = Cx^u_t dt + dn_t, & 0 < t \le T, \quad \xi^u_0 = 0, \end{array} \right. \tag{4}$$

where x, u, and ξ are the state, control, and observation processes. Under a set U of the admissible controls we consider the set of all controls in the linear form

$$u_t = \bar{u}_t + \int_0^t K_{t,s} d\xi^u_s, \tag{5}$$

where $K \in B_2(\Delta, \mathcal{L}(R^k,Y))$, $\bar{u} \in L_2(\mathbf{T},Y)$.

Note that under the above and some additional conditions the random function x, defined by

$$x_t = \mathcal{U}_t x_0 + \int_0^t \mathcal{U}_{t-s}(B_s u_s + f_s)ds + \int_0^t \mathcal{U}_{t-s} dm_s, \qquad 0 \le t \le T,$$

satisfies the equation in (4) and stands for its unique solution (see Curtain and Pritchard [1]). On the other hand, the function x_t, $0 \le t \le T$, is well defined even if these additional conditions do not hold. According to the theory of the differential equations in Banach spaces the function x_t, $0 \le t \le T$, is called the mild solution of the equation in (4) that becomes the solution (in the ordinary sense) when the abovementioned additional conditions hold. Below under the solution of the equation in (4) we shall keep in mind its mild solution.

One can associate two systems with the system (4). The first of them is the deterministic system

$$\frac{d}{dt} y^v_t = Ay^v_t + Bv_t + f_t, \qquad 0 < t \le T, \ y^v_0 = y_0 = \mathbf{E}x_0, \tag{6}$$

where v is a control from $V = \{v : v_t = \mathbf{E}u_t, \ u \in U\}$. The second one is the partially observed stochastic system

$$\left\{ \begin{array}{ll} dz^w_t = (Az^w_t + Bw_t)dt + dm_t, & 0 < t \le T, \quad z^w_0 = z_0 = x_0 - \mathbf{E}x_0, \\ d\eta^w_t = Cz^w_t dt + dn_t, & 0 < t \le T, \quad \eta^w_0 = 0, \end{array} \right. \tag{7}$$

where w is a control from $W = \{w : w_t = u_t - \mathbf{E}u_t, \ u \in U\}$.

Note that under the solution of the equations in (6) and (7) we shall also mean their mild solution.

LEMMA 2. *Under the above conditions and notation the following equalities hold:*
(a) $V = L_2(\mathbf{T}, Y)$;
(b) $W = \{w : w_t = \int_0^t K_{t,s} d\eta_s^w,\ K \in B_2(\Delta, \mathcal{L}(R^k, Y))\}$.

Proof. Item (a) can be proven by easy verification. To prove item (b) let $w \in W$. Then there exists such $u \in U$ that $w = u - \mathbf{E}u$. Let u be in the form (5) with $K \in B_2(\Delta, \mathcal{L}(R^k, Y))$ and $\bar{u} \in L_2(\mathbf{T}, Y)$. Then

$$\begin{aligned} w_t = u_t - \mathbf{E}u_t &= \int_0^t K_{t,s} C(x_s^u - \mathbf{E}x_s^u) ds + \int_0^t K_{t,s} dn_s \\ &= \int_0^t K_{t,s} C z_s^w ds + \int_0^t K_{t,s} dn_s = \int_0^t K_{t,s} d\eta_s^w. \end{aligned}$$

On the other hand, if

$$w_t = \int_0^t K_{t,s} d\eta_s^w, \tag{8}$$

then for u, which has the representation (5), we have $w = u - \mathbf{E}u$. So item (b) is true.

LEMMA 3. *Under the above conditions and notation the equality $U = V + W$ holds, where $+$ is the sign of the sum of the sets.*

Proof. Suppose $v \in V$, $w \in W$, and w has the form (8). Let $u = v + w$. Then

$$\begin{aligned} u_t &= v_t + \int_0^t K_{t,s} C z_s^w ds + \int_0^t K_{t,s} dn_s \\ &= v_t - \int_0^t K_{t,s} C y_s^v ds + \int_0^t K_{t,s} C x_s^u ds + \int_0^t K_{t,s} dn_s. \end{aligned}$$

Denote

$$\bar{u}_t = v_t - \int_0^t K_{t,s} C y_s^v ds. \tag{9}$$

Then u has the form of (5) with $\bar{u}$ as in (9), i.e., $u \in U$. On the other hand, each element of U can be shown as a sum of some elements taken from V and W. So $U = V + W$.

LEMMA 4. *Under the above conditions and notation, if $u = v + w$, $v \in V$, $w \in W$, then the σ-algebras $\mathcal{F}^{u,\xi}$ and $\mathcal{F}^{w,\eta}$, generated by ξ_s^u, $0 \le s \le T$, and η_s^w, $0 \le s \le T$, respectively, are equal.*

Proof. Using $u = v + w$ with $v = \mathbf{E}u$ it is easy to show that

$$\xi_t^u = \eta_t^w + C \int_0^t y_s^v ds, \qquad 0 \le t \le T. \tag{10}$$

Since the second term in the right-hand side of (10) is nonrandom, we conclude that ξ_s^u, $0 \le s \le T$, and η_s^w, $0 \le s \le T$, generate the same σ-algebra.

THEOREM 1. *Under the above conditions and notation the system* (4) *is $C^c_{\varepsilon,p}$ (respectively, $C^a_{\varepsilon,p}$)-controllable if and only if the system* (6) *is D^c (respectively, D^a)-controllable and the system* (7) *is $S^0_{\varepsilon,p}$-controllable.*

Proof. Let $C(\varepsilon, p)$ be the set (3) corresponding to the system (4). Similarly, let D be the set (1) corresponding to the system (6). Suppose that the system (4) is

$C^c_{\varepsilon,p}$ (respectively, $C^a_{\varepsilon,p}$)-controllable. Then, from the inclusion $C(\varepsilon,p)\subset D$, it follows that the system (6) is D^c (respectively, D^a)-controllable. Let $h\in C(\varepsilon,p)$. Then there exists $u\in U$ such that $h=\mathbf{E}x^u_T$ and

$$\mathbf{P}\{\|\mathbf{E}(x^u_T|\mathcal{F}^{u,\xi})-h\|^2>\varepsilon\}\le 1-p.$$

Consider $w=u-\mathbf{E}u\in W$. By Lemma 4, we have $\mathcal{F}^{u,\xi}=\mathcal{F}^{w,\eta}$. Therefore,

$$\mathbf{P}\{\|\mathbf{E}(z^w_T|\mathcal{F}^{w,\eta})\|^2>\varepsilon\}=\mathbf{P}\{\|\mathbf{E}(x^u_T|\mathcal{F}^{u,\xi})-\mathbf{E}x^u_T\|^2>\varepsilon\}\le 1-p;$$

i.e., the system (7) is $S^0_{\varepsilon,p}$-controllable. So the necessity is proven. To prove the sufficiency let $h\in D$. Then there exists $v\in V$ such that $h=y^v_T$. From the $S^0_{\varepsilon,p}$-controllability of the system (7), we conclude that there exists $w\in W$ with

$$\mathbf{P}\{\|\mathbf{E}(z^w_T|\mathcal{F}^{w,\eta})\|^2>\varepsilon\}\le 1-p.$$

Consider $u=v+w$. By Lemma 3, $u\in U=V+W$. Moreover,

$$\mathbf{P}\{\|\mathbf{E}(x^u_T|\mathcal{F}^{u,\xi})-h\|^2>\varepsilon\}=\mathbf{P}\{\|\mathbf{E}(z^w_T|\mathcal{F}^{w,\eta})\|^2>\varepsilon\}\le 1-p,$$

i.e., $h\in C(\varepsilon,p)$. Therefore, $D\subset C(\varepsilon,p)$. As $D=X$ (respectively, $\overline{D}=X$), then $C(\varepsilon,p)=X$ (respectively, $\overline{C(\varepsilon,p)}=X$). Thus, the system (4) is $C^c_{\varepsilon,p}$ (respectively, $C^a_{\varepsilon,p}$)-controllable.

Theorem 1 separates the study of the $C^c_{\varepsilon,p}$ (respectively, $C^a_{\varepsilon,p}$)-controllability of the general system (4) into the study of the D^c (respectively, D^a)-controllability and the $S^0_{\varepsilon,p}$-controllability of the systems (6) and (7), respectively. The D^c- and D^a-controllabilities of the linear system (6) on the set $L_2(\mathbf{T},Y)$ of admissible controls are investigated in a number of papers. Therefore, we mention only the following results from Curtain and Pritchard [1, pp. 56, 60] that will be used later.

THEOREM 2. *Under the above conditions and notation the following statements hold:*

(a) *the system* (6) *is D^c-controllable if and only if*

$$\int_t^T \mathcal{U}_{T-s}BB^*\mathcal{U}^*_{T-s}ds>0,\qquad 0\le t<T;$$

(b) *the system* (6) *is D^a-controllable if and only if $B^*\mathcal{U}^*_t x=0$ implies $x=0$ for all $t\in\mathbf{T}$.*

5. Sufficient condition for $S^0_{\varepsilon,p}$-controllability. Consider the system (7) under the above conditions and notation. Let Q^i and P be the solutions of the following operator Riccati equations, respectively:

$$\frac{d}{dt}Q_t+Q_tA+A^*Q_t-iQ_tBB^*Q_t=0,\qquad 0\le t<T,\ Q_T=I,\ i=1,2,\dots, \tag{11}$$

$$\frac{d}{dt}P_t-AP_t-P_tA^*-M+P_tC^*CP_t=0,\qquad 0<t\le T,\ P_0=\operatorname{cov}z_0, \tag{12}$$

where I is the identity operator. Note that under the solution of (11) we mean the operator-valued function Q that for all $x,y\in D(A)$ satisfies

$$\frac{d}{dt}\langle Q_tx,y\rangle+\langle Q_tAx,y\rangle+\langle Q_tx,Ay\rangle-i\langle Q_tBB^*Q_tx,y\rangle=0,\qquad 0\le t<T,$$

where $D(A)$ is the domain of A. The same sense is applied to the solution of (12). It follows from Curtain and Pritchard [1] that these equations have the unique strongly continuous solutions Q^i and P with $Q_t^i \geq 0$ and $P_t \geq 0$ for all $t \in \mathbf{T}$.

LEMMA 5. *Under the above conditions and notation the equality*

$$\inf_W \mathbf{E}\|\mathbf{E}(z_T^w|\mathcal{F}^{w,\eta})\|^2 = \lim_{i\to\infty} \int_0^T \text{tr } CP_sQ_s^iP_sC^*ds \tag{13}$$

holds, where Q^i and P are the solutions of (11) *and* (12)*, respectively, and there exists a finite limit in the right-hand side of* (13)*.*

Proof. First we shall prove the existence of the finite limit. Consider the family of the stochastic optimal control problems on W with the state and observation systems defined by (7) and the functional

$$J^i(w) = \mathbf{E}\left(\|z_T^w\|^2 + i^{-1}\int_0^T \|w_t\|^2 dt\right), \qquad i = 1, 2, \dots,$$

to be minimized. It is known (see Curtain and Ichikawa [5]) that there exists the unique optimal control $w^i \in W$ in the considered optimal control problem and

$$J^i(w^i) = \text{tr}P_T + \int_0^T \text{tr } CP_sQ_s^iP_sC^*ds.$$

Since P_T is the covariance of the error $z_T^w - \mathbf{E}(z_T^w|\mathcal{F}^{w,\eta})$ (see Curtain [6]) independently on w,

$$\mathbf{E}\|z_T^w\|^2 - \mathbf{E}\|\mathbf{E}(z_T^w|\mathcal{F}^{w,\eta})\|^2 = \mathbf{E}\|z_T^w - \mathbf{E}(z_T^w|\mathcal{F}^{w,\eta})\|^2 = \text{tr}P_T.$$

Therefore, if we denote

$$\tilde{J}^i(w) = \mathbf{E}\left(\|\mathbf{E}(z_T^w|\mathcal{F}^{w,\eta})\|^2 + i^{-1}\int_0^T \|w_t\|^2 dt\right),$$

then

$$\tilde{J}^i(w^i) = J^i(w^i) - \text{tr}P_T = \int_0^T \text{tr } CP_sQ_s^iP_sC^*ds. \tag{14}$$

Let us show that $\tilde{J}^i(w^i)$ does not increase as $i \to \infty$. Let $j \geq i$. Then

$$\begin{aligned}
\tilde{J}^j(w^j) &= \mathbf{E}\left(\|z_T^{w^j}\|^2 + j^{-1}\int_0^T \|w_t^j\|^2 dt\right) - \text{tr}P_T \\
&\leq \mathbf{E}\left(\|z_T^{w^i}\|^2 + j^{-1}\int_0^T \|w_t^i\|^2 dt\right) - \text{tr}P_T \\
&\leq \mathbf{E}\left(\|z_T^{w^i}\|^2 + i^{-1}\int_0^T \|w_t^i\|^2 dt\right) - \text{tr}P_T = \tilde{J}^i(w^i).
\end{aligned}$$

We conclude that $\tilde{J}^i(w^i)$, $i = 1, 2, \dots$, is a nonnegative and nonincreasing sequence. Therefore, there exists a finite limit of $\tilde{J}^i(w^i)$ as $i \to \infty$. From (14), it follows that there exists a finite limit in the right-hand side of (13). Now let us show that (13) is true. Indeed

$$\inf_W \mathbf{E}\|\mathbf{E}(z_T^w|\mathcal{F}^{w,\eta})\|^2 \leq \tilde{J}^i(w^i) \leq \mathbf{E}\left(\|\mathbf{E}(z_T^{\tilde{w}^r}|\mathcal{F}^{\tilde{w}^r,\eta})\|^2 + i^{-1}\int_0^T \|\tilde{w}_t^r\|^2 dt\right), \tag{15}$$

where $\tilde{w}^r$, $r = 1, 2, \ldots$, is a minimizing sequence of the functional

$$J_0(w) = \mathbf{E}\|\mathbf{E}(z_T^w|\mathcal{F}^{w,\eta})\|^2. \tag{16}$$

Consequently, taking the limit in (15) as $i \to \infty$ and $r \to \infty$, we obtain the equality (13). The lemma is proven.

Denote

$$a = \lim_{i\to\infty} \int_0^T \operatorname{tr} CP_sQ_s^iP_sC^*ds. \tag{17}$$

THEOREM 3. *Under the above conditions and notation the system* (7) *is* $S^0_{\varepsilon,p}$*-controllable if*

$$a < \varepsilon(1-p), \tag{18}$$

where a *is defined by* (17).

Proof. By Lemma 5, we have

$$\inf_W \mathbf{E}\|\mathbf{E}(z_T^w|\mathcal{F}^{w,\eta})\|^2 = a < \varepsilon(1-p).$$

Therefore, there exists $w^0 \in W$ such that

$$\mathbf{E}\|\mathbf{E}(z_T^{w^0}|\mathcal{F}^{w^0,\eta})\|^2 < \varepsilon(1-p).$$

Using Chebyshev's inequality, we obtain

$$\mathbf{P}\{\|\mathbf{E}(z_T^{w^0}|\mathcal{F}^{w^0,\eta})\|^2 > \varepsilon\} \le \frac{1}{\varepsilon}\mathbf{E}\|\mathbf{E}(z_T^{w^0}|\mathcal{F}^{w^0,\eta})\|^2 \le 1-p.$$

Hence, the theorem is proven.

It should be noted that the condition (18) that is the sufficient condition for $S^0_{\varepsilon,p}$-controllability is not necessary in general. In view of this we present the following arguments. Define the following functions for a given system:

$$\varphi_p = \inf \Phi_p,\ \Phi_p = \{\varepsilon :\ \text{the system is } S^0_{\varepsilon,p}\text{-controllable}\}, \tag{19}$$

$$\psi_\varepsilon = \sup \Psi_\varepsilon,\ \Psi_\varepsilon = \{p :\ \text{the system is } S^0_{\varepsilon,p}\text{-controllable}\}. \tag{20}$$

Obviously, φ and ψ are the nondecreasing functions and $\varphi_0 = 0$, $\lim_{\varepsilon\to\infty} \psi_\varepsilon = 1$. It follows from the definitions that the necessary and sufficient condition for the system to be $S^0_{\varepsilon,p}$-controllable is

$$\begin{cases} \varphi_p < \varepsilon & \text{if } \inf \Phi_p \text{ is not achieved,} \\ \varphi_p \le \varepsilon & \text{if } \inf \Phi_p \text{ is achieved,} \end{cases} \tag{21}$$

which can be written in the following equivalent form:

$$\begin{cases} \psi_\varepsilon > p & \text{if } \sup \Psi_\varepsilon \text{ is not achieved,} \\ \psi_\varepsilon \ge p & \text{if } \sup \Psi_\varepsilon \text{ is achieved.} \end{cases} \tag{22}$$

Using (18), define the functions

$$\tilde{\varphi}_p = \begin{cases} a(1-p)^{-1}, & 0 \le p < 1, \\ \infty, & p = 1, \end{cases} \qquad \tilde{\psi}_\varepsilon = \begin{cases} 1 - a\varepsilon^{-1}, & a < \varepsilon < \infty, \\ 0, & 0 \le \varepsilon \le a. \end{cases}$$

By (21), (22), and Theorem 3, it follows that

$$\varphi_p \le \tilde{\varphi}_p,\ 0 \le p \le 1,\ \text{and}\ \psi_\varepsilon \ge \tilde{\psi}_\varepsilon,\ 0 \le \varepsilon < \infty;$$

i.e., in the case of the system (7) the functions $\tilde{\varphi}$ and $\tilde{\psi}$, defined with the help of (18), give only approximations of the functions φ and ψ and may not be equal to them. In the case $\varphi_p < \tilde{\varphi}_p$ or $\psi_\varepsilon > \tilde{\psi}_\varepsilon$ the condition (18) cannot be necessary for $S^0_{\varepsilon,p}$-controllability. But it turns out that the condition (18), being sufficient for $S^0_{\varepsilon,p}$-controllability of the system (7), is weaker than the D^c-controllability of the system (6). We shall prove this result in the next section.

6. Necessary and sufficient condition for $C^c_{\varepsilon,p}$-controllability. Using the special form of the Riccati equation (11), we can present its solution in the following explicit form.

LEMMA 6. *Under the above conditions and notation the Riccati equation* (11) *has a solution in the form*

$$Q^i_t = \mathcal{U}^*_{T-t}\left(I + i\int_t^T \mathcal{U}_{T-s}BB^*\mathcal{U}^*_{T-s}ds\right)^{-1}\mathcal{U}_{T-t}, \qquad 0 \le t \le T,\ i = 1, 2, \dots . \tag{23}$$

Proof. First note that the right-hand side of (23) is a composition of three operators, each depending on time t. The first and third of them satisfy

$$\frac{d}{dt}\mathcal{U}_{T-t}x = -A\mathcal{U}_{T-t}x = -\mathcal{U}_{T-t}Ax, \qquad x \in D(A). \tag{24}$$

But the middle one is the inverse of the operator that is strongly differentiable in t. According to the rule for the derivative of the inverse operator, we have

$$\frac{d}{dt}\left(I + i\int_t^T \mathcal{U}_{T-s}BB^*\mathcal{U}^*_{T-s}ds\right)^{-1}$$

$$= i\left(I + i\int_t^T \mathcal{U}_{T-s}BB^*\mathcal{U}^*_{T-s}ds\right)^{-1}\mathcal{U}_{T-t}BB^*\mathcal{U}^*_{T-t}\left(I + i\int_t^T \mathcal{U}_{T-s}BB^*\mathcal{U}^*_{T-s}ds\right)^{-1}. \tag{25}$$

Thus, for all $x, y \in D(A)$, from (23), we have

$$\begin{aligned}
\frac{d}{dt}\langle Q^i_t x, y\rangle &= \frac{d}{dt}\left\langle \left(I + i\int_t^T \mathcal{U}_{T-s}BB^*\mathcal{U}^*_{T-s}ds\right)^{-1}\mathcal{U}_{T-t}x, \mathcal{U}_{T-t}y\right\rangle \\
&= \left\langle \left(\frac{d}{dt}\left(I + i\int_t^T \mathcal{U}_{T-s}BB^*\mathcal{U}^*_{T-s}ds\right)^{-1}\right)\mathcal{U}_{T-t}x \right. \\
&\quad + \left(I + i\int_t^T \mathcal{U}_{T-s}BB^*\mathcal{U}^*_{T-s}ds\right)^{-1}\frac{d}{dt}\mathcal{U}_{T-t}x, \mathcal{U}_{T-t}y\Big\rangle \\
&\quad \left. + \left\langle \left(I + i\int_t^T \mathcal{U}_{T-s}BB^*\mathcal{U}^*_{T-s}ds\right)^{-1}\mathcal{U}_{T-t}x, \frac{d}{dt}\mathcal{U}_{T-t}y\right\rangle\right.
\end{aligned} \tag{26}$$

Substituting (24) and (25) in (26) and using (23), one can easily show that Q^i, defined by (23), is a solution of (11).

LEMMA 7. *Under the above conditions and notation the D^c-controllability condition for the system* (6) *from Theorem* 2(a) *implies*

$$a = \lim_{i\to\infty} \int_0^T \operatorname{tr}\, CP_sQ_s^iP_sC^*ds = 0.$$

Proof. By D^c-controllability condition, for all $0 \le t < T$ we have

$$\left\langle x, \left(I + i\int_t^T \mathcal{U}_{T-s}BB^*\mathcal{U}_{T-s}^*ds\right)x\right\rangle$$

$$= \|x\|^2 + i\left\langle x, \int_t^T \mathcal{U}_{T-s}BB^*\mathcal{U}_{T-s}^*xds\right\rangle \ge (1+ib_t)\|x\|^2,$$

where $b_t > 0$ for all $0 \le t < T$. Therefore,

$$\left\|\left(I + i\int_t^T \mathcal{U}_{T-s}BB^*\mathcal{U}_{T-s}^*ds\right)^{-1}\right\| \le (1+ib_t)^{-1},$$

and by (23),

$$\|Q_t^i\| \le \|\mathcal{U}_{T-t}\|^2(1+ib_t)^{-1}.$$

The last inequality implies

$$\|Q_t^i\| \le \|\mathcal{U}_{T-t}\|^2,\ i = 1,2,\dots,\ 0\le t\le T; \qquad \|Q_t^i\| \to 0,\ i\to\infty,\ 0\le t<T. \tag{27}$$

Thus, applying majorized convergence theorem, we obtain

$$a = \lim_{i\to\infty}\int_0^T \operatorname{tr}\, CP_sQ_s^iP_sC^*ds \le \lim_{i\to\infty}\int_0^T (\operatorname{tr}P_s)^2\|C\|^2\|Q_s^i\|ds$$

$$= \int_0^T (\operatorname{tr}P_s)^2\|C\|^2 \lim_{i\to\infty}\|Q_s^i\|ds = 0.$$

THEOREM 4. *Under the above conditions and notation the system* (4) *is $C^c_{\varepsilon,p}$-controllable for all $\varepsilon > 0$ and $0 \le p < 1$ if and only if the system* (6) *is D^c-controllable.*

Proof. The necessity follows from Theorem 1. Suppose that the system (6) is D^c-controllable. Using Theorem 2(a), we obtain that the condition of Lemma 7 holds. Therefore, $a = 0$, and, applying Theorem 3, we get the $S^0_{\varepsilon,p}$-controllability for all ε and p satisfying $\varepsilon(1-p) > 0$ for the system (7). Note that the condition $\varepsilon(1-p) > 0$ includes all pairs (ε, p) with $\varepsilon > 0$ and $0 \le p < 1$. Finally, by Theorem 1, we obtain $C^c_{\varepsilon,p}$-controllability of the system (4) for all $\varepsilon > 0$ and $0 \le p < 1$. The theorem is proven.

Remark. One may ask, is the analogue of Theorem 4 true in the approximate controllability case; i.e., is $C^a_{\varepsilon,p}$-controllability of the system (4) for all $\varepsilon > 0$ and $0 \le p < 1$ equivalent to D^a-controllability of the system (6)? The necessity part again holds in view of Theorem 1. Problems arise in proving the sufficiency. The sufficiency part of Theorem 4 is based on Lemma 7, in the proof of which the uniform operator convergence (27) under the D^c-controllability condition from Theorem 2(a)

was used. There is an example (see section 7) constructed by the reviewer of this article which shows that, if the exact controllability condition in Lemma 7 is replaced with the approximate controllability condition (see Theorem 2(b)), then the uniform operator convergence (27) is not true. Nevertheless, it might be possible to prove the convergence $Q_t^i \to 0,\ i \to \infty$, in the strong (or weak) operator topology. This problem needs further investigation.

7. Necessary and sufficient conditions for *S*-controllability. Now we can consider the main controllability notion for the stochastic systems that was defined in Definition 5.

LEMMA 8. *Under the above conditions and notation let w be the random process defined by* (8)*, where $K \in B_2(\Delta, \mathcal{L}(R^k, Y))$ and η^w is defined by* (7)*. Then there exists $M \in B_2(\Delta, \mathcal{L}(R^k, Y))$ such that*

$$w_t = \int_0^t M_{t,s} d\eta_s^0, \tag{28}$$

where η^0 is the observation process of the system (7) *corresponding to the zero-control. Conversely, if w is defined by* (28) *with $M \in B_2(\Delta, \mathcal{L}(R^k, Y))$, then there exists $K \in B_2(\Delta, \mathcal{L}(R^k, Y))$ such that w has the representation* (8)*.*

Proof. The direct statement is proven in Curtain [6]. The converse will be proven in the same way as in Curtain [6]. Suppose w has the form (28). It is easy to observe that there exists the following relation between η^w and η^0:

$$d\eta_s^0 = d\eta_s^w - \int_0^s C\mathcal{U}_{s-r} B w_r dr ds. \tag{29}$$

Substituting (29) in (28) we have

$$w_t = \int_0^t M_{t,s} d\eta_s^w - \int_0^t \int_0^s M_{t,s} C\mathcal{U}_{s-r} B w_r dr ds. \tag{30}$$

Equation (30) is a Volterra integral equation with respect to w which has the kernel

$$L_{t,r} = -\int_r^t M_{t,s} C\mathcal{U}_{s-r} B ds.$$

It is known that (30) has a solution in the form

$$w_t = \int_0^t M_{t,s} d\eta_s^w + \int_0^t N_{t,s} \int_0^s M_{s,r} d\eta_r^w ds$$

for some $N \in B_2(\Delta, \mathcal{L}(Y))$. Applying the stochastic analogue of the Fubini theorem (see Curtain and Pritchard [1]) we obtain that w has the form (8) with

$$K_{t,s} = M_{t,s} + \int_s^t N_{t,r} M_{r,s} dr.$$

So $w \in W$. The lemma is proven.

LEMMA 9. *Under the above conditions and notation the set U of admissible controls of the system* (4) *is convex.*

Proof. Suppose $u^1, u^2 \in U$ and $\lambda_1 > 0, \lambda_2 > 0$ with $\lambda_1 + \lambda_2 = 1$. Consider $u = \lambda_1 u^1 + \lambda_2 u^2$. We have

$$u_t^i = v_t^i + \int_0^t M_{t,s}^i d\eta_s^0, \qquad i = 1, 2,$$

for some $v^1, v^2 \in L_2(\mathbf{T}, Y)$ and $M^1, M^2 \in B_2(\Delta, \mathcal{L}(R^k, Y))$. Denoting $v = \lambda_1 v^1 + \lambda_2 v^2$ and $M = \lambda_1 M^1 + \lambda_2 M^2$, we have

$$u_t = v_t + \int_0^t M_{t,s} d\eta_s^0$$

for $v \in L_2(\mathbf{T}, Y)$ and $M \in B_2(\Delta, \mathcal{L}(R^k, Y))$. It means that $u \in U$ and, therefore, U is convex. The lemma is proven.

THEOREM 5. *Under the above conditions and notation,*

(a) D^c*-controllability of the system* (6) *is sufficient for the* S*-controllability of the system* (4)*;*

(b) D^a*-controllability of the system* (6) *is necessary for the* S*-controllability of the system* (4)*.*

Proof. By Theorem 4, we obtain that the D^c-controllability of the system (6) implies $C^c_{\varepsilon,p}$-controllability of the system (4) for all $\varepsilon > 0$ and $0 \le p < 1$. Since $C(\varepsilon, p) \subset S(\varepsilon, p)$ for an arbitrary system, where $C(\varepsilon, p)$ and $S(\varepsilon, p)$ are defined by (3) and (2), then $C(\varepsilon, p) = X$ implies $S(\varepsilon, p) = X$. Therefore, the system (4) is $S^c_{\varepsilon,p}$-controllable for all $\varepsilon > 0$ and $0 \le p < 1$, which means the S-controllability of the system (4). This proves item (a). Let us prove item (b). Suppose that the system (4) is S-controllable, i.e., $S^a_{\varepsilon,p}$-controllable for all $\varepsilon > 0$ and $0 \le p < 1$. To prove the D^a-controllability of the system (6) let us consider arbitrary $h \in X$. We shall show that there exists a sequence $\{\tilde{u}^n\}$ in U such that $\|\mathbf{E}x_T^{\tilde{u}^n} - h\| \to 0$ as $n \to \infty$, where x_t^u is the state of the system (4) at time t corresponding to control $u \in U$. Consider the sequences $\{\varepsilon_n\}$ and $\{p_n\}$ with $\varepsilon_n > 0$, $0 \le p_n < 1$ and $\varepsilon_n \to 0$, $p_n \to 1$ as $n \to \infty$. Then from $S^a_{\varepsilon_n,p_n}$-controllability of the system (4) we obtain the existence of the sequence $\{u^n\}$ in U such that

$$\mathbf{P}\{\|\mathbf{E}(x_T^{u^n} | \mathcal{F}^{u^n,\xi}) - h\|^2 > \varepsilon_n\} \le 1 - p_n. \tag{31}$$

Inequality (31) implies the convergence in probability of $\|\mathbf{E}(x_T^{u^n} | \mathcal{F}^{u^n,\xi}) - h\|$ to zero. Indeed, for any $\varepsilon > 0$ we can find a number N such that $0 < \varepsilon_n < \varepsilon^2$ for all $n > N$. Therefore, for $n > N$ we have

$$\mathbf{P}\{\|\mathbf{E}(x_T^{u^n} | \mathcal{F}^{u^n,\xi}) - h\| > \varepsilon\} \le \mathbf{P}\{\|\mathbf{E}(x_T^{u^n} | \mathcal{F}^{u^n,\xi}) - h\|^2 > \varepsilon_n\} \le 1 - p_n \to 0, \qquad n \to \infty.$$

Hence, $\mathbf{E}(x_T^{u^n} | \mathcal{F}^{u^n,\xi})$ converges to h in probability. Since $\mathbf{E}(x_T^{u^n} | \mathcal{F}^{u^n,\xi})$ is a Gaussian random variable for all n, the characteristic functions of these random variables have the form (see Vakhania [7])

$$\chi_n(x) = \exp\left(i\langle m_n, x\rangle - \frac{1}{2}\langle \Lambda_n x, x\rangle\right), \qquad x \in X, \tag{32}$$

where $m_n = \mathbf{E}(\mathbf{E}(x_T^{u^n} | \mathcal{F}^{u^n,\xi})) = \mathbf{E}x_T^{u^n}$ and $\Lambda_n = \mathrm{cov}\mathbf{E}(x_T^{u^n} | \mathcal{F}^{u^n,\xi})$. Also, the vector $h \in X$ is considered as a degenerate Gaussian random variable with characteristic function

$$\chi(x) = \exp\Big(i\langle h, x\rangle\Big), \qquad x \in X. \tag{33}$$

The convergence of $\mathbf{E}(x_T^{u^n}|\mathcal{F}^{u^n,\xi})$ to h in probability implies $\chi_n(x) \to \chi(x)$ for all $x \in X$. The last convergence is possible when

$$\langle m_n, x\rangle = \langle \mathbf{E}x_T^{u^n}, x\rangle \to \langle h, x\rangle, \quad \langle \Lambda_n x, x\rangle \to 0, \quad n \to \infty.$$

First of these convergences means the convergence of $\mathbf{E}x_T^{u^n}$ to h in the weak topology of the Hilbert space X. By Mazur's theorem (see Balakrishnan [8]) we can construct a sequence

$$h_n = \sum_{i=1}^{n} c_i^n \mathbf{E}x_T^{u^i}, \quad c_i^n \geq 0, \quad \sum_{i=1}^{n} c_i^n = 1, \quad i = 1, 2, \dots, n, \quad n = 1, 2, \dots,$$

of convex combinations of $\mathbf{E}x_T^{u^n}$ such that h_n converges to h in the strong topology of X. Denote $\tilde{u}_n = \sum_{i=1}^{n} c_i^n u^i$, $n = 1, 2, \dots$. By Lemma 9, $\tilde{u}_n \in U$ for all n. Moreover, in view of the affineness of the system (4), $h_n = \mathbf{E}x_T^{\tilde{u}^n}$. In terms of the system (6) it means that, for the sequence of controls $\tilde{v}_n = \mathbf{E}\tilde{u}_n$ in V, the sequence of vectors $h_n = \mathbf{E}x_T^{\tilde{u}^n} = y_T^{\tilde{v}^n}$ converges to h in the strong topology of X. Since h is an arbitrary point of X, we conclude that the set D defined by (1) for the system (6) is dense in X. The theorem is proven.

8. Discussion. One can call the stochastic system (4) D^c (respectively, D^a)-controllable if the associated deterministic system (6) has the same property. Theorem 5 indicates the following implications between D^c-, D^a-, and S-controllability properties for the system (4):

$$D^c \;\Rightarrow\; S \;\Rightarrow\; D^a, \tag{34}$$

in which S-controllability has the middle position between the stronger D^c and weaker D^a-controllabilities. The following example shows that in general the reverse implication $D^c \Leftarrow S$ does not hold. Note that this example was constructed by the reviewer of this article to show that if D^c-controllability in Lemma 7 is replaced with the D^a-controllability condition, then the uniform operator convergence (27) does not hold.

Let $X = Y = l_2$ (the Hilbert space of numerical sequences $\{x_n\}$ satisfying $\sum_{n=1}^{\infty} x_n^2 < \infty$ with scalar product $\langle\{x_n\}, \{y_n\}\rangle = \sum_{n=1}^{\infty} x_n y_n$), $\mathcal{U}_t \equiv I$ (the identity operator) and

$$B = \begin{pmatrix} 1 & 0 & 0 & \cdots \\ 0 & \frac{1}{2} & 0 & \cdots \\ 0 & 0 & \frac{1}{3} & \cdots \\ \cdot & \cdot & \cdot & \cdots \end{pmatrix}.$$

Consider the basis $e_1 = (1, 0, 0, \dots)$, $e_2 = (0, 1, 0, \dots)$, $e_3 = (0, 0, 1, \dots), \dots$ in l_2. Since

$$\sum_{n=1}^{\infty} \langle Be_n, Be_n\rangle = \sum_{n=1}^{\infty} \frac{1}{n^2} < \infty,$$

then B is a Hilbert–Schmidt operator on l_2 (the notation is $B \in \mathcal{L}_2(l_2)$) and, therefore, $B \in \mathcal{L}(l_2)$. Obviously, $B = B^*$. Also, $B^*\mathcal{U}_t^* x = 0$ implies $Bx = 0$ and, hence, $x = 0$. So the system (4) with $\mathcal{U}$ and B defined as above is D^a-controllable (see Theorem

2(b)). But it is not D^c-controllable since $\|B^2 e_n\|_{l_2} = n^{-2} \to 0$ as $n \to \infty$, and, therefore, the operator

$$\int_t^T \mathcal{U}_{T-s} B B^* \mathcal{U}_{T-s}^* ds = (T-t)B^2$$

is not positive (see Theorem 2(a)).

Let us show that the system (4) with $\mathcal{U}$ and B defined as above is S-controllable. Consider Q^i defined by (23). For above $\mathcal{U}$ and B, we have

$$Q_t^i x = (I + i(T-t)B^2)^{-1} x = \left\{ \frac{n^2 x_n}{n^2 + i(T-t)} \right\}, \qquad x = \{x_n\} \in l_2.$$

Therefore,

$$\|Q_t^i x\|^2 = \sum_{i=1}^{\infty} \frac{n^4 x_n^2}{(n^2 + i(T-t))^2}.$$

The last series is majorized by the convergent series $\sum_{n=1}^{\infty} x_n^2$. Hence, for $0 \le t < T$, we have

$$\lim_{i\to\infty} \|Q_t^i x\|^2 = \lim_{i\to\infty} \sum_{i=1}^{\infty} \frac{n^4 x_n^2}{(n^2 + i(T-t))^2} = \sum_{i=1}^{\infty} \lim_{i\to\infty} \frac{n^4 x_n^2}{(n^2 + i(T-t))^2} = 0.$$

We obtain that $Q_t^i \to 0$ as $i \to \infty$ for all $0 \le t < T$ in the strong operator topology. Now consider a defined by (17):

$$a = \lim_{i\to\infty} \int_0^T \operatorname{tr}\, C P_s Q_s^i P_s C^* ds = \lim_{i\to\infty} \int_0^T \sum_{i=1}^{\infty} \langle Q_s^i P_s C^* e_n, P_s C^* e_n \rangle ds. \tag{35}$$

In (35) we can change the places of the limit, integration, and summation operations since $Q_s^i \le I$ for all i and for all $0 \le s \le T$. Therefore,

$$\sum_{i=1}^{\infty} \langle Q_s^i P_s C^* e_n, P_s C^* e_n \rangle \le \sum_{i=1}^{\infty} \|P_s C^* e_n\|^2 = \operatorname{tr}\, C P_s P_s C^* \le (\operatorname{tr} P_s)^2 \|C\|^2 < \infty.$$

Hence, from (35), by strong operator convergence $Q_t^i \to 0$ as $i \to \infty$, for all $0 \le t < T$, we obtain

$$a = \int_0^T \sum_{i=1}^{\infty} \langle \lim_{i\to\infty} Q_s^i P_s C^* e_n, P_s C^* e_n \rangle ds = 0.$$

Finally, having $a = 0$ and following the proof of Theorem 4 (sufficiency part) and Theorem 5(a), the S-controllability of the system (4) can be obtained.

This example indicates that in (34) there is the middle case of $a = 0$ between D^c- and S-controllability conditions; i.e., (34) could be completed as

$$D^c \;\Rightarrow\; a = 0 \;\Rightarrow\; S \;\Rightarrow\; D^a.$$

For completeness a counterexample showing the nonvalidity of the implication $D^a \Rightarrow S$ would be also presented. We do not present such an example for two reasons. First, it is not easy to construct such an example even if it exists. Second, the authors tend to think that in the case of the system (4) the equivalence $S \Leftrightarrow D^a$ takes place. Of course, this subject needs further study.

Acknowledgments. The authors would like to thank the reviewers of this paper for their useful recommendations. In particular, the results of section 6 were predicted by them.

DETERMINISTIC EXIT TIME CONTROL PROBLEMS WITH DISCONTINUOUS EXIT COSTS*

ALAIN-PHILIPPE BLANC†

Abstract. We study deterministic exit time control problems with discontinuous exit costs. When the exit cost φ is upper semicontinuous and there is an outer field on the boundary, we show that all the value functions have the same lower semicontinuous envelope which is the unique lower semicontinuous viscosity solution of the associated Dirichlet problem. We also prove uniqueness results for the generalized Dirichlet problem for first-order Hamilton–Jacobi equations with convex Hamiltonians and with discontinuous boundary conditions, under some nondegeneracy conditions on the Hamiltonians on the boundary.

Key words. exit time problems, Hamilton–Jacobi equations, Dirichlet problems, discontinuous data, viscosity solutions

1. Introduction.

This paper is concerned with deterministic exit time control problems with discontinuous exit costs. We want to characterize the value functions of this type of control problems as the unique viscosity solutions of the corresponding Hamilton–Jacobi–Bellman problem. We obtain, under some suitable conditions, the uniqueness of the lower semicontinuous (l.s.c.) envelope of the value function.

In order to be more specific, we now describe the optimal control problem. Let Ω be a smooth bounded domain of $\mathbb{R}^N$. We consider a system whose state is given by the solution of the ordinary differential equation

$$\begin{cases} dy_x(t) &= b(y_x(t), \alpha(t))dt, \\ y_x(0) &= x \in \overline{\Omega}, \end{cases}$$

where b is a Lipschitz continuous function from $\overline{\Omega} \times \mathcal{A}$ into $\mathbb{R}^N$ and $\alpha(.) \in L^\infty(\mathbb{R}^+, \mathcal{A})$ is the control; $\mathcal{A}$, the control space, is a compact metric space. We denote by τ the first exit time of the trajectory y_x from Ω, i.e.,

$$\tau \;=\; \inf\{t \geq 0,\; y_x(t) \notin \Omega\}.$$

In this framework, it is well known that the value function can be defined in several ways: the first value function that we want to consider is given by

$$u(x) \;=\; \inf_{\alpha(.) \in L^\infty(\mathbb{R}^+, \mathcal{A})} \left\{ \int_0^\tau f(y_x(t), \alpha(t)) e^{-\lambda t} dt + \varphi(y_x(\tau)) e^{-\lambda \tau} \right\},$$

where f is a given continuous real-valued function and λ is a positive constant, the discount factor. Precise assumptions on f and b are detailed in the first part. The main point is that we assume only that φ, the exit cost, is a bounded function on $\partial\Omega$ defined pointwise; in particular, it may present discontinuities.

It is well known that when the value function is continuous, it is a viscosity solution of the corresponding Hamilton–Jacobi–Bellman equation

$$H(x,u,Du) \;=\; 0 \quad \text{in } \Omega,$$

where

$$H(x,t,p) \;=\; \sup_{\alpha\in\mathcal{A}}\{-b(x,\alpha)\cdot p + \lambda t - f(x,\alpha)\}. \tag{1}$$

This is a consequence of the so-called dynamic programming principle (cf. [17]). We recall that the notion of viscosity solutions was introduced in [11] by M. G. Crandall and P. L. Lions (see also [10]). We refer the reader to [12, 17], where the applications of viscosity solutions to deterministic and stochastic control problems are described.

But the value function u may be discontinuous even when the exit cost φ is continuous. Therefore, we have to use the notion of discontinuous viscosity solution, which was introduced by H. Ishii [13, 14] and requires the concepts of l.s.c. and upper semicontinuous (u.s.c.) envelopes of functions. In all the following discussion, ξ_* (resp., ξ^*) will denote the l.s.c. (resp., u.s.c.) envelope of the locally bounded function ξ, which is defined by

$$\xi_*(x) \;=\; \liminf_{y\to x}\, \xi(y) \quad (\text{resp.,} \quad \xi^*(x) \;=\; \limsup_{y\to x}\, \xi(y)).$$

G. Barles and B. Perthame [5] first considered the connections of such discontinuous solutions with optimal control problems.

Moreover, the concept of viscosity solutions is used to identify the appropriate boundary conditions satisfied by the value function. In the case of a continuous exit cost, H. Ishii [15] and G. Barles and B. Perthame [6] show the connections between the above control problem and the following Hamilton–Jacobi–type problem:

$$\begin{cases} H(x,u,Du) \;=\; 0 & \text{in } \Omega, \\ \min\{H(x,u,Du), u-\varphi\} \;\le\; 0 & \text{on } \partial\Omega, \\ \max\{H(x,u,Du), u-\varphi\} \;\ge\; 0 & \text{on } \partial\Omega. \end{cases} \tag{2}$$

When the function φ is discontinuous, the definition of viscosity solutions deals with the l.s.c. and the u.s.c. envelope of φ. For illustration, we say that the bounded function u is a viscosity subsolution of (2) on the boundary $\partial\Omega$ if

$$\text{for every function } \phi\in C^1(\overline{\Omega}), \quad \text{if } x\in\partial\Omega \;\text{ is a maximum point of } u^*-\phi, \quad \text{we have}$$
$$H(x,u^*(x),D\phi(x)) \;\le\; 0 \qquad \text{or} \qquad u^*(x) \;\le\; \varphi^*(x).$$

Our first aim is to prove that the value function u is a viscosity solution of (2).

Then we have to look at "uniqueness" (or characterization) properties for the viscosity solution u. In general, the discontinuous viscosity solution is not unique. One reason is that the Hamilton–Jacobi–Bellman equation is the same for the control problem and for the relaxed control problem. But the value function can be different for these two problems. Moreover, it is quite natural to consider different stopping times on the boundary: for example, the first exit time from the closed set $\overline{\Omega}$, i.e.,

$$\bar{\tau} \;=\; \inf\{t\ge 0,\; y_x(t)\notin\overline{\Omega}\}.$$

In this paper, since the exit cost φ is discontinuous, an additional choice is to use φ_* or φ^*, instead of taking φ, in the definition of u.

We first prove the existence of a minimum and of a maximum solution, which are given respectively by

$$u_-(x) \;=\; \inf\left\{\int_0^\theta \int_{\mathcal{A}} f(\hat{y}_x(t),\alpha)e^{-\lambda t}d\mu_t(\alpha)dt + \varphi_*(\hat{y}_x(\theta))e^{-\lambda\theta},\ \hat{\tau}\le\theta\le\hat{\bar{\tau}},\right.$$
$$\left.\hat{y}_x(\theta)\in\partial\Omega,\ \text{and } \mu\in L^\infty(\mathbb{R}^+,P(\mathcal{A}))\right\},$$

and

$$u^+(x) \;=\; \inf_{\alpha(.)\in L^\infty(\mathbb{R}^+,\mathcal{A})}\left\{\sup\left\{\int_0^\theta f(y_x(t),\alpha(t))e^{-\lambda t}dt + \varphi^*(y_x(\theta))e^{-\lambda\theta},\ \tau\le\theta\le\bar{\tau},\right.\right.$$
$$\left.\left.\text{and}\quad y_x(\theta)\in\partial\Omega\right\}\right\}.$$

It is clear from these definitions that one has

$$u_- \;\le\; u \;\le\; u^+ \quad \text{in } \Omega.$$

But these functions may be very different, in particular because of the trajectories which remain on $\overline{\Omega}$ but which touch the boundary several times ($\tau\neq\bar{\tau}$).

Nevertheless, in the case when the function φ is continuous, G. Barles and B. Perthame [7] showed that, essentially, if there exist outer and inner fields at each point of $\partial\Omega$, the value function u is continuous and is the unique solution of (2); hence, we get

$$u_- \;=\; u \;=\; u^+ \quad \text{in } \Omega. \tag{3}$$

The underlying idea is that, with these outer and inner fields, one can control a trajectory close to the boundary to make it stay in Ω or to leave $\overline{\Omega}$.

An other aim of this article is to give a similar uniqueness result when φ is discontinuous. But since the value functions may be discontinuous, we first have to explain how to interpret uniqueness of the solution in this case. We want the equalities (3) to hold again in a weaker sense, namely,

$$u_- \;=\; u_* \;=\; (u^+)_* \quad \text{in } \Omega,$$

since u_- is l.s.c. on $\overline{\Omega}$. Therefore uniqueness means in this context that all the solutions have the same l.s.c. envelope.

In the case when the exit cost φ satisfies

$$(\varphi^*)_* \;=\; \varphi_* \quad \text{on } \partial\Omega, \tag{4}$$

and when there is an outer field on the boundary, we show that

$$u_- \;=\; (u^+)_* \quad \text{in } \Omega$$

by working directly on the control formulas. And therefore, all the solutions of (2) have the same l.s.c. envelope since u_- and u^+ are, respectively, the minimum and the maximum solution of (2).

But we want also an uniqueness result without the condition (4) on φ since, for control problems, it is quite natural to consider exit costs φ which are only l.s.c. In fact, one of our motivations for this work is the exit problem from a part Γ of the boundary $\partial\Omega$. If, for instance, Γ is reduced to a point $\{x_0\}$, then φ is equal to 0 at x_0 and 1 elsewhere; therefore it does not satisfy (4). To solve this difficulty, we adapt PDE arguments introduced by E. N. Barron and R. Jensen [8, 9] for convex Hamiltonians.

Under a nondegeneracy condition on the Hamiltonian which we interpret as the existence of an outer field on the boundary for control problems, we prove that there exists a unique l.s.c. viscosity solution in the sense of Barron and Jensen in Ω which is a classical viscosity supersolution on the boundary and which satisfies, for every $x \in \partial\Omega$,

$$\liminf_{y\to x, y\in\Omega} u(y) \;\leq\; \varphi_*(x). \tag{5}$$

We emphasize that this uniqueness result is obtained by PDE arguments.

The application of this result to the control problem is the following: since P. Soravia [19] showed that all the value functions are viscosity solutions in the sense of Barron and Jensen, we have the uniqueness of the l.s.c. envelope of the value functions which satisfy the condition (5). Besides, when the condition (4) holds, we recover the uniqueness result obtained by working directly on the representation formulas of the value functions.

We also refer the reader interested in the discontinuous viscosity solution approach to Dirichlet problems to the work of A. I. Subbotin [20], M. Bardi and P. Soravia [1], P. Soravia [19], and G. Barles [3]. These authors consider mainly continuous Dirichlet function on the boundary. In the case of discontinuous data, the pioneering paper of Barron and Jensen [8] was concerned with the Cauchy problem in $\mathbb{R}^N$. G. Barles [2] extended their ideas to stationary optimal stopping time in $\mathbb{R}^N$. To the best of our knowledge, the exit time problems with discontinuous exit costs have not yet been considered in the literature with such a generality.

This paper is organized as follows: the first section is devoted to the study of the exit time problems and its connections with (2). We also introduce the condition on the behavior of the controlled vector field at the boundary to obtain an uniqueness result. In the second section, we describe the new idea for discontinuous viscosity solutions for convex Hamiltonians and prove uniqueness results in the case when φ is discontinuous by PDE arguments. The third section is devoted to applications of the uniqueness results. The two first parts are nearly independent.

2. The exit time control problems with discontinuous exit costs. We recall that Ω is a smooth bounded domain of $\mathbb{R}^N$ and that the state of the system is described by the solution of

$$\begin{cases} dy_x(t) &= b(y_x(t), \alpha(t))dt, \\ y_x(0) &= x \in \overline{\Omega} \end{cases}$$

or, in the case of relaxed controls, by

$$\begin{cases} d\hat{y}_x(t) &= \displaystyle\int_{\mathcal{A}} b(\hat{y}_x(t), \alpha) d\mu_t(\alpha)dt, \\ \hat{y}_x(0) &= x \in \overline{\Omega}, \end{cases}$$

where $\alpha(.) \in L^\infty(\mathbb{R}^+, \mathcal{A})$ and $\mu_. \in L^\infty(\mathbb{R}^+, P(\mathcal{A}))$; $\mathcal{A}$ is a compact metric space and $P(\mathcal{A})$ is the set of probability measures on $\mathcal{A}$. The function b is continuous from $\overline{\Omega}\times\mathcal{A}$

into $\mathbb{R}^N$ and satisfies

$$\text{(6)} \qquad \begin{cases} |b(x,\alpha)| \le C, \quad \forall x \in \overline{\Omega},\ \forall \alpha \in \mathcal{A}; \\ |b(x,\alpha) - b(y,\alpha)| \le C|x-y|, \quad \forall x,y \in \overline{\Omega},\ \forall \alpha \in \mathcal{A}. \end{cases}$$

These assumptions imply the existence and the uniqueness of the solution y_x for all $t > 0$.

In the same way as for τ and $\bar{\tau}$, we define $\hat{\tau}$ and $\hat{\bar{\tau}}$ for a relaxed trajectory $\hat{y}_x$ respectively by

$$\hat{\tau} = \inf\{t \ge 0,\ \hat{y}_x(t) \notin \Omega\} \quad \text{and} \quad \hat{\bar{\tau}} = \inf\{t \ge 0,\ \hat{y}_x(t) \notin \overline{\Omega}\}.$$

The associated cost functions are

$$J(x,\alpha,\theta,\varphi) = \int_0^\theta f(y_x(t),\alpha(t))e^{-\lambda t}dt + \varphi(y_x(\theta))e^{-\lambda\theta}$$

and

$$\hat{J}(x,\mu,\theta,\varphi) = \int_0^\theta \int_{\mathcal{A}} f(\hat{y}_x(t),\alpha)e^{-\lambda t}d\mu_t(\alpha)dt + \varphi(\hat{y}_x(\theta))e^{-\lambda\theta},$$

where λ is some positive constant and f is a continuous function from $\overline{\Omega} \times \mathcal{A}$ into $\mathbb{R}$ satisfying

$$\text{(7)} \qquad \begin{cases} |f(x,\alpha)| \le C \quad \forall x \in \overline{\Omega},\ \forall \alpha \in \mathcal{A}; \\ |f(x,\alpha) - f(y,\alpha)| \le C|x-y| \quad \forall x,y \in \overline{\Omega},\ \forall \alpha \in \mathcal{A}. \end{cases}$$

We use particularly the following three value functions:

$$u_-(x) = \inf_{\mu \in L^\infty(\mathbb{R}^+, P(\mathcal{A}))} \{\hat{J}(x,\mu,\theta,\varphi_*),\ \hat{\tau} \le \theta \le \hat{\bar{\tau}} \text{ and } \hat{y}_x(\theta) \in \partial\Omega\},$$

which is l.s.c. on $\overline{\Omega}$;

$$u^+(x) = \inf_{\alpha(.) \in L^\infty(\mathbb{R}^+, \mathcal{A})} \{\sup\{J(x,\alpha,\theta,\varphi^*),\ \tau \le \theta \le \bar{\tau} \text{ and } y_x(\theta) \in \partial\Omega\}\},$$

which is u.s.c. on $\overline{\Omega}$; and the value function already introduced in the introduction,

$$u[\varphi](x) = \inf_{\alpha(.) \in L^\infty(\mathbb{R}^+, \mathcal{A})} \{J(x,\alpha,\tau,\varphi)\}.$$

These three types of value functions have already been studied in [6, 13] when the function φ is continuous. In the case of a discontinuous exit cost, we introduce different exit cost functions, namely, φ_* and φ^*. Our main results are the following. First, we prove that the function u_- is the minimum supersolution of (2) with the Hamiltonian given by (1) and the function u^+ is the maximum subsolution. We show that the value functions $u[\varphi_*]$, $u[\varphi]$, and $u[\varphi^*]$ are viscosity solutions of (2), and an example shows that all these value functions may be very different.

In order to obtain the uniqueness of the l.s.c. envelope of the value functions, we are going to prove that

$$(u^+)_* = u_- \quad \text{on } \overline{\Omega}.$$

Therefore we have to show the following series of equalities:

$$(u^+)_* \;=\; (u[\varphi^*])_* \;=\; (u[\varphi_*])_* \;=\; u_- \quad \text{on } \overline{\Omega}.$$

The first equality is proven without additional assumptions; it already holds in the continuous case (see [6]). For the second, since we minimize, "interesting values" may be lost by taking the exit cost φ^* instead of φ_*: for instance, if φ is equal to 0 at one point and 1 elsewhere, then φ^* is equal to 1 everywhere. To avoid this difficulty in this section, we consider only "regular" exit costs, i.e., satisfying the property (4). Finally, the difficulty with the trajectories which touch the boundary several times is solved by assuming that there exists an outer field at every point on the boundary or that the boundary is such that there are only inner fields on $\partial\Omega$.

This section is divided in three subsections. In the first, we study the value functions u_- and u^+. The second is devoted to the properties of the function $u[\varphi]$. And, in the last one, we prove the uniqueness result.

2.1. The value functions u_- and u^+. In this subsection, we characterize u_- and u^+ as the minimal and maximal solutions of (2). We also prove the connection between u^+ and $u[\varphi^*]$.

THEOREM 2.1. *We assume that φ is a bounded function defined pointwise, the constant λ is positive, and the assumptions* (6) *and* (7) *hold.*

1. *The function u_- is l.s.c. and the function u^+ is u.s.c. on $\overline{\Omega}$.*
2. *The functions u^+ and u_- are viscosity solutions of* (2).
3. *The functions u^+ and u_- are, respectively, the maximal subsolution and the minimal supersolution of* (2).

Proof. We first consider the case of u^+. We introduce a nonincreasing sequence $(\varphi^n)_n$ of continuous functions such that

$$\inf_n \varphi^n \;=\; \varphi^*.$$

We note $u^+[\varphi^n]$, the value function defined by the same formula as u^+ except that the exit cost function φ^* is replaced by φ^n (in particular, $u^+[\varphi^*]$ is equal to u^+). Then we need the following lemma.

LEMMA 2.2. *We have*

$$\inf_n u^+[\varphi^n] \;=\; u^+[\varphi^*] \quad \textit{on } \overline{\Omega}.$$

Proof. It is clear enough that

$$u^+[\varphi^n] \;\geq\; u^+[\varphi^{n+1}] \;\geq\; u^+[\varphi^*] \quad \text{on } \overline{\Omega}, \tag{8}$$

and thus $\inf_n u^+[\varphi^n] \geq u^+[\varphi^*]$ on $\overline{\Omega}$.

To prove the opposite inequality, we use the definition of $u^+[\varphi^n]$. For any control $\alpha(.)$ and any point $x \in \overline{\Omega}$, we have

$$u^+[\varphi^n](x) \;\leq\; \sup\{J(x,\alpha,\theta,\varphi^n), \tau \leq \theta \leq \bar{\tau} \text{ and } y_x(\theta) \in \partial\Omega\}.$$

Now, for a fixed control $\alpha(.)$, we pick a sequence $(\theta_n)_n$ such that

$$u^+[\varphi^n](x) \;\leq\; \frac{1}{n} + \int_0^{\theta_n} f(y_x(t),\alpha(t))e^{-\lambda t}dt + \varphi^n(y_x(\theta_n))e^{-\lambda\theta_n}. \tag{9}$$

First case. If the sequence $(\theta_n)_n$ is bounded, considering a subsequence if necessary, we may assume that $\theta_n \to \bar{\theta}$. Taking the limit superior as $n \to \infty$ in the inequality (9), we get

$$\limsup_n\ u^+[\varphi^n](x)\ \le\ \int_0^{\bar{\theta}} f(y_x(t),\alpha(t))e^{-\lambda t}dt + \limsup_n\ \varphi^n(y_x(\theta_n))e^{-\lambda\bar{\theta}}. \tag{10}$$

But since $y_x(\theta_n) \to y_x(\bar{\theta})$, since the function φ^n is continuous and since $\inf_n\ \varphi^n = \varphi^*$, we easily deduce

$$\limsup_n\ \varphi^n(y_x(\theta_n))\ \le\ \varphi^*(y_x(\bar{\theta})).$$

Moreover, using (8), we obtain

$$\limsup_n\ u^+[\varphi^n](x)\ =\ \inf_n\ u^+[\varphi^n](x).$$

Combining these two results with (10), we get

$$\inf_n\ u^+[\varphi^n](x)\ \le\ \int_0^{\bar{\theta}} f(y_x(t),\alpha(t))e^{-\lambda t}dt + \varphi^*(y_x(\bar{\theta}))e^{-\lambda\bar{\theta}}\ =\ J(x,\alpha,\bar{\theta},\varphi^*),$$

and taking the supremum in $\bar{\theta}$ in the right-hand side, we have

$$\inf_n\ u^+[\varphi^n](x)\ \le\ \sup\{J(x,\alpha,\theta,\varphi^*), \tau \le \theta \le \bar{\tau},\ \text{and}\ y_x(\theta) \in \partial\Omega\}. \tag{11}$$

Second case. If the sequence $(\theta_n)_n$ is not bounded, then there exists a subsequence, still denoted $(\theta_n)_n$, such that $\theta_n \to +\infty$. The inequality (9) implies

$$\begin{aligned} u^+[\varphi^n](x) &\le \frac{1}{n} + \int_0^{\theta_n} f(y_x(t),\alpha(t))e^{-\lambda t}dt + \varphi^*(y_x(\theta_n))e^{-\lambda\theta_n} \\ &\quad + \varphi^n(y_x(\theta_n))e^{-\lambda\theta_n} - \varphi^*(y_x(\theta_n))e^{-\lambda\theta_n} \\ &\le \frac{1}{n} + J(x,\alpha,\theta_n,\varphi^*) + (\varphi^n(y_x(\theta_n)) - \varphi^*(y_x(\theta_n)))e^{-\lambda\theta_n}. \end{aligned}$$

Since φ^n and φ^* are bounded, the last term tends to zero and we conclude as before.

Hence, finally, since the inequality (11) holds for any control $\alpha(.)$ and for any point $x \in \overline{\Omega}$, we conclude

$$\inf_n\ u^+[\varphi^n](x)\ \le\ u^+[\varphi^*](x). \qquad \square$$

Now we deduce the properties of u^+ from this lemma. By using the results of [6], the function $u^+[\varphi^n]$ is u.s.c. Then the function u^+ is u.s.c. too since u^+ is equal to the limit of the nonincreasing sequence of function $u^+[\varphi^n]$. Moreover, again by the results of [6], $u^+[\varphi^n]$ is the maximal subsolution (and solution) of

$$\begin{cases} H(x,u,Du) &= 0 \quad \text{in } \Omega, \\ \min\{H(x,u,Du), u-\varphi^n\} &\le 0 \quad \text{on } \partial\Omega, \\ \max\{H(x,u,Du), u-\varphi^n\} &\ge 0 \quad \text{on } \partial\Omega. \end{cases} \tag{12}$$

Then, using standard stability results (cf. [5]), $u^+[\varphi^*]$ is a subsolution of (2) because, for every $x \in \overline{\Omega}$, we have

$$\limsup_{n\to\infty, y\to x} u^+[\varphi^n](y) \;=\; \inf_n u^+[\varphi^n](x) \;=\; u^+[\varphi^*](x)$$

and

$$\limsup_{n\to\infty, y\to x} \varphi^n(y) \;=\; \inf_n \varphi^n(x) \;=\; \varphi^*(x).$$

It is also a supersolution of (2) since we have, for every $x \in \overline{\Omega}$,

$$\liminf_{n\to\infty, y\to x} u^+[\varphi^n](y) \;=\; \liminf_{y\to x} u^+[\varphi^*](y) \;=\; (u^+[\varphi^*])_*(x)$$

and since

$$\begin{aligned}\liminf_{n\to\infty, y\to x} \varphi^n(y) \;&=\; (\inf_n \varphi^n)_*(x) = (\varphi^*)_*(x)\\ &\geq \varphi_*(x).\end{aligned}$$

Moreover, if w is a subsolution of (2), w is also a subsolution of (12) since $\varphi^n \geq \varphi^*$ on $\partial\Omega$. This implies, for every n, that

$$w \;\leq\; u^+[\varphi^n] \quad \text{on } \overline{\Omega},$$

because $u^+[\varphi^n]$ is the maximal subsolution of (12). Therefore, by Lemma 2.2, taking the infimum over n yields

$$w \;\leq\; u^+[\varphi^*] \quad \text{on } \overline{\Omega},$$

which implies that the function $u^+[\varphi^*]$ is a maximal subsolution of (2).

For the function u_-, we proceed exactly as for the value function u^+ . Let $(\varphi_n)_n$ be a nondecreasing sequence of continuous functions such that

$$\sup_n \varphi_n \;=\; \varphi_*.$$

Again we introduce the notation $u_-[\varphi_n]$ to denote the value function defined as u_- but with the exit cost φ_n instead of φ_*. Then we consider the following lemma, which corresponds to Lemma 2.2 for u^+.

LEMMA 2.3. *We have*

$$\sup_n u^+[\varphi_n] \;=\; u_-[\varphi_*] \quad \textit{on } \overline{\Omega}.$$

With this lemma, we conclude the proof by deducing the properties of $u_-[\varphi_*]$ from the properties of $u_-[\varphi_n]$ as before. □

Proof of Lemma 2.3. It is clear enough that

$$\sup_n u_-[\varphi_n] \;\leq\; u_-[\varphi_*] \quad \text{on } \overline{\Omega}.$$

It remains to prove the opposite inequality. For every $x \in \overline{\Omega}$, we consider a minimizing sequence $(\mu_n, \theta_n)_n$ for $u_-[\varphi_n]$ such that

$$u_-[\varphi_n](x) + \frac{1}{n} \;\geq\; \int_0^{\theta_n} \int_{\mathcal{A}} f(\hat{y}_x^n(t), \alpha) e^{-\lambda t} d\mu_n(\alpha) dt + \varphi_n(\hat{y}_x^n(\theta_n)) e^{-\lambda\theta_n}. \tag{13}$$

First case. If the sequence $(\theta_n)_n$ is bounded, considering a subsequence if necessary, we may assume that there exists a stopping time $\bar{\theta}$ such that $\theta_n \to \bar{\theta}$ as $n \to \infty$. Moreover, using classical arguments relying on the compactness of relaxed controls, we may also assume that $\mu_n \to \bar{\mu}$ weakly in $L^\infty(\mathbb{R}^+, P(\mathcal{A}))$ for some relaxed control $\bar{\mu}$. Let $\hat{y}_x$ be the relaxed trajectory associated with $\bar{\mu}$. Since $\hat{y}^n_x$ converges locally uniformly to $\hat{y}_x$, we can check that $\hat{y}_x(\bar{\theta}) \in \partial\Omega$ and $\hat{y}^n_x(\theta_n) \to \hat{y}_x(\bar{\theta})$.

Then, again using the local uniform convergence of $\hat{y}^n_x$ to $\hat{y}_x$ together with the fact that f is Lipschitz continuous, we replace the trajectory $\hat{y}^n_x$ by $\hat{y}_x$ in the integral of (13), i.e.,

$$u_-[\varphi_n](x) + \frac{1}{n} \;\geq\; \int_0^{\bar{\theta}} \int_{\mathcal{A}} f(\hat{y}_x(t), \alpha) e^{-\lambda t} d\bar{\mu}(\alpha) dt + \varphi_n(\hat{y}^n_x(\theta_n)) e^{-\lambda\bar{\theta}} + \varepsilon_n,$$

with a sequence of numbers ε_n such that $\varepsilon_n \to 0$ when $n \to \infty$. From the above inequality, we deduce

$$u_-[\varphi_n](x) + \frac{1}{n} \;\geq\; u_-[\varphi_*](x) + (\varphi_n(\hat{y}^n_x(\theta_n)) - \varphi_*(\hat{y}_x(\bar{\theta}))) e^{-\lambda\bar{\theta}} + \varepsilon_n.$$

Then, taking the limit inferior, we get

$$\liminf_n\, u_-[\varphi_n](x) \;\geq\; u_-[\varphi_*](x) + \liminf_n \{\varphi_n(\hat{y}^n_x(\theta_n)) - \varphi_*(\hat{y}_x(\bar{\theta}))\} e^{-\lambda\bar{\theta}}. \tag{14}$$

But since $\hat{y}^n_x(\theta_n) \to \hat{y}_x(\bar{\theta})$, since the function φ_n is continuous, and since $\sup_n \varphi_n = \varphi_*$, we easily deduce

$$\liminf_n\, \varphi_n(\hat{y}^n_x(\theta_n)) \;\geq\; \varphi_*(\hat{y}_x(\bar{\theta}));$$

thus, combining this with (14), we obtain

$$\begin{aligned} \liminf_n\, u_-[\varphi_n](x) &= \sup_n\, u_-[\varphi_n](x) \\ &\geq u_-[\varphi_*](x). \end{aligned}$$

Second case. If the sequence $(\theta_n)_n$ is not bounded, we may assume without loss of generality that $\theta_n \to \infty$, and then the inequality (13) implies

$$u_-[\varphi_n](x) + \frac{1}{n} \;\geq\; u_-[\varphi_*](x) + (\varphi_n(\hat{y}^n_x(\theta_n)) - \varphi_*(\hat{y}^n_x(\theta_n))) e^{-\lambda\theta_n}.$$

Since φ_* is bounded and since $(\varphi_n)_n$ is uniformly bounded, letting $n \to \infty$, we have the desired result. □

The following theorem shows that u^+ and $u[\varphi^*]$ are not very different.

THEOREM 2.4. *Under the same assumptions of Theorem* 2.1*, we have*

$$(u^+)_* \;=\; (u[\varphi^*])_* \qquad \text{in } \Omega.$$

Proof. We first remark that the proof is inspired from the corresponding one in [6].

It is clear that $(u^+)_* \geq (u[\varphi^*])_*$ in Ω since $u^+ \geq u[\varphi^*]$ on $\overline{\Omega}$.

It remains to prove the opposite inequality. For any point x of Ω, there exists a sequence $(x_n)_n$ of points of Ω such that $x_n \to x$ and

$$\lim_n u[\varphi^*](x_n) \;=\; (u[\varphi^*])_*(x).$$

For each x_n, we consider a control $\alpha_n(.)$ such that

$$u[\varphi^*](x_n) + \frac{1}{n} \ \geq \ J(x_n, \alpha_n, \tau_n, \varphi^*). \tag{15}$$

Then we need the following lemma.

LEMMA 2.5. *For every $x \in \Omega$ and $\alpha \in L^\infty(\mathbb{R}^+, \mathcal{A})$, there exists a sequence $(x_p)_p$ of points of Ω such that*

$$\liminf_p u^+(x_p) \ \leq \ J(x, \alpha, \tau, \varphi^*),$$

where τ is the first exit time of the trajectory y_x associated with the control α.

For every n, we apply this lemma to the point x_n and to the control α_n. Thus there exists a sequence $(x_n^p)_p$ such that $x_n^p \to x_n$ as $p \to \infty$ and

$$J(x_n, \alpha_n, \tau_n, \varphi^*) \ \geq \ u^+(x_n^p) - \frac{1}{p}.$$

Combining this with (15), we pass to the limit, and by a diagonal procedure, we get

$$\begin{aligned}(u[\varphi^*])_*(x) &= \lim_n u[\varphi^*](x_n) \\ &\geq (u^+)_*(x),\end{aligned}$$

which is the desired result. □

Proof of Lemma 2.5. If $\tau = \infty$, then $u^+(x) \leq J(x, \alpha, \tau, \varphi^*)$, and therefore it suffices to take $x_p := x$ for all p.

If $\tau \neq \infty$, we consider the map $Y_\tau : z \mapsto y_z(\tau)$, which is an homeomorphism from a neighborhood of x onto some neighborhood of $y_x(\tau)$. We introduce the domain D defined by $D := Y^{-1}(\mathcal{B}(y_x(\tau), \varepsilon) \cap \overline{\Omega}^c)$, where $\mathcal{B}(z, r)$ is the open ball centered at z and of radius r and $\overline{\Omega}^c$ is the complementary set of $\overline{\Omega}$ in $\mathbb{R}^N$. For ε small enough, the domain D is a nonempty open subset of $\mathbb{R}^N$ and the point x is in its closure $\overline{D}$.

Moreover, since the function b is Lipschitz continuous, classical ODE estimates yield

$$|y_z(s) - y_x(s)| \ \leq \ |z - x| e^{Cs} \quad \text{for every } s \in [0, \tau].$$

And, for every p, since we have

$$\inf \left\{ \operatorname{dist}(y_x(s), \partial\Omega), 0 \leq s \leq \tau - \frac{1}{p} \right\} \ = \ \delta \ > \ 0,$$

we consider the constant η equal to

$$\eta \ := \ \max \left\{ \frac{1}{p}, \delta \right\} e^{-C\tau},$$

and therefore we have, for $|z - x| < \eta$,

$$|y_z(s) - y_x(s)| \ < \ \frac{1}{p} \quad \text{for every } s \in [0, \tau], \tag{16}$$

and

$$y_z(s) \in \Omega \quad \text{for every } s \in \left[0, \tau - \frac{1}{p}\right].$$

Then we choose a point $x_p \in \mathcal{B}(x,\eta) \cap D$. We first remark that the first exit time τ_p of the trajectory y_{x_p} from Ω satisfies $\tau - \frac{1}{p} \le \tau_p$ since $x_p \in \mathcal{B}(x,\eta)$. The exit time $\bar{\tau}_p$ satisfies $\bar{\tau}_p \le \tau$ since $x_p \in D$. We may write

$$u^+(x_p) \ \le \ \sup\{J(x_p,\alpha,\theta,\varphi^*), \theta \in [\tau_p, \bar{\tau}_p] \text{ and } y_{x_p}(\theta) \in \partial\Omega\}.$$

Using the Lipschitz continuity of f and the inequality (16), we compute, for every $\theta \in [\tau_p, \bar{\tau}_p]$,

$$\begin{aligned} J(x_p,\alpha,\theta,\varphi^*) &\le J(x,\alpha,\tau,\varphi^*) - \varphi^*(y_x(\tau))e^{-\lambda\tau} + \varphi^*(y_{x_p}(\theta))e^{-\lambda\tau} \\ &\quad + \|\varphi\|_\infty |e^{-\lambda\theta} - e^{-\lambda\tau}| + \|f\|_\infty |\tau - \theta| + \frac{C\tau}{p} \\ &\le J(x,\alpha,\tau,\varphi^*) + \rho_{\varphi^*}(|y_x(\tau) - y_{x_p}(\theta)|) + \tilde{C}\left(|\theta - \tau| + \frac{1}{p}\right), \end{aligned} \tag{17}$$

where ρ_{φ^*} is a continuous function such that $\rho_{\varphi^*}(t) \to 0$ as $t \to 0^+$ and, for every $y \in \partial\Omega$,

$$\varphi^*(y) - \varphi^*(y_x(\tau)) \ \le \ \rho_{\varphi^*}(|y_x(\tau) - y|).$$

We pass to the limit inferior in (17), and again using (16) and the fact that

$$\tau - \frac{1}{p} \ \le \ \tau_p \ \le \ \theta \ \le \ \bar{\tau}_p \ \le \ \tau,$$

we get

$$\begin{aligned} J(x,\alpha,\tau,\varphi^*) &\ge \liminf_p J(x_p,\alpha,\theta,\varphi^*) \\ &\ge \liminf_p u^+(x_p). \end{aligned}$$

Thus the proof is complete. □

2.2. The properties of the value function $u[\varphi]$. In this section, we prove that the value functions $u[\varphi_*]$, $u[\varphi]$, and $u[\varphi^*]$ are viscosity solutions. Then we give an example which shows that these functions may be very different.

Let us begin by a result concerning the values of the solutions of (2) on the boundary.

PROPOSITION 2.6. *Let u be a bounded function from Ω into $\mathbb{R}$.*

We define

$$\check{u} \ = \ \begin{cases} u & \text{in } \Omega, \\ \varphi & \text{on } \partial\Omega, \end{cases} \qquad \text{and} \qquad \tilde{u} \ = \ \begin{cases} u & \text{in } \Omega, \\ \xi & \text{on } \partial\Omega, \end{cases}$$

where ξ is a real-valued function such that

$$\varphi_* \ \le \ \xi \ \le \ \varphi^* \quad \text{on } \partial\Omega.$$

Then $\check{u}$ is a subsolution (resp., supersolution) of (2) *if and only if $\tilde{u}$ is a subsolution (resp., supersolution) of* (2).

REMARK 2.7. *This proposition shows that the values of the solutions of* (2) *are not prescribed by the viscosity condition on the boundary. Thus the uniqueness results cannot be extended up to the boundary.*

Proof. We prove only the proposition in the subsolutions case. The other case may be obtained by the same method. Let us first remark that, for every $x \in \partial\Omega$, we have

$$\tilde{u}^*(x) \;=\; \sup\{u^*(x), \xi^*(x)\} \;\leq\; \check{u}^*(x) \;=\; \sup\{u^*(x), \varphi^*(x)\}. \tag{18}$$

We first assume that $\check{u}$ is a subsolution, and therefore we have to prove that $\tilde{u}$ is a subsolution too. Let $\phi \in C^1(\overline{\Omega})$ be a test function and $x_0 \in \partial\Omega$ be a maximum point of $\tilde{u}^* - \phi$. Changing ϕ in $\phi + (\tilde{u}^*(x_0) - \phi(x_0))$, we may assume without loss of generality that $\tilde{u}^*(x_0) = \phi(x_0)$ and thus $\tilde{u}^* \leq \phi$.

• If $\tilde{u}^*(x_0) \leq \varphi^*(x_0)$, there is nothing to prove.

• If $\tilde{u}^*(x_0) > \varphi^*(x_0)$, then by definition of $\tilde{u}$ and since we have $\xi \leq \varphi^*$ on $\partial\Omega$, this implies $u^*(x_0) > \varphi^*(x_0)$. Hence, using the inequality (18), we deduce that $\check{u}^*(x_0) = \tilde{u}^*(x_0)$.

We introduce the positive constant $\delta := \tilde{u}^*(x_0) - \varphi^*(x_0)$. Then, since $\tilde{u}^*(x_0) = \phi(x_0)$, we get

$$\varphi^*(x_0) + \frac{\delta}{2} \;=\; \phi(x_0) - \frac{\delta}{2}. \tag{19}$$

Since ϕ is continuous, there exists some constant $\varepsilon_1 > 0$ such that, for all $y \in \overline{\Omega}$ and $|x_0 - y| < \varepsilon_1$, we have

$$|\phi(x_0) - \phi(y)| \;<\; \frac{\delta}{2}.$$

And since φ^* is u.s.c., there exists some constant $\varepsilon_2 > 0$ such that, for all $y \in \partial\Omega$ and $|x_0 - y| < \varepsilon_2$, we have

$$\varphi^*(y) - \varphi^*(x_0) \;<\; \frac{\delta}{2}.$$

Hence, combining these two preceding estimates with the equality (19), we deduce

$$\varphi^*(y) \;<\; \varphi^*(x_0) + \frac{\delta}{2} \;=\; \phi(x_0) - \frac{\delta}{2} \;<\; \phi(y) \quad \text{for } y \in \partial\Omega \cap \mathcal{B}(x_0, \varepsilon_1 \wedge \varepsilon_2),$$

where $a \wedge b := \inf\{a, b\}$ for $a, b \in \mathbb{R}$. Combining this with the fact that

$$\check{u}^* \;\leq\; \phi \quad \text{for } y \in \Omega \cap \mathcal{B}(x_0, \varepsilon_1 \wedge \varepsilon_2),$$

since $u^* \leq \phi$ in Ω, we deduce that x_0 is also a maximum point of $\check{u}^* - \phi$. And thus $\tilde{u}^*$ is a subsolution.

Conversely, if $\tilde{u}$ is a subsolution, let $x_0 \in \partial\Omega$ be a maximum point of $\check{u}^* - \phi$ with $\phi \in C^1(\overline{\Omega})$. As before, we choose $\check{u}^*(x_0) = \phi(x_0)$.

• If $\check{u}^*(x_0) \leq \varphi^*(x_0)$, $\check{u}^*$ is a subsolution.

• If $\check{u}^*(x_0) > \varphi^*(x_0)$, then using the inequality (18) and the fact that $\xi^* \leq \varphi^*$ on $\partial\Omega$, we get

$$\check{u}^*(x_0) \;=\; u^*(x_0) \;=\; \tilde{u}^*(x_0).$$

Since $\check{u}^* \geq \tilde{u}^*$ on $\overline{\Omega}$, it is easy to show that $\check{u}^*$ is a subsolution. ∎

Now, we recall a general result in control theory which is the dynamic programming principle.

THEOREM 2.8. *Under the same assumptions of Theorem* 2.1*, for any* $T > 0$ *and for any* $x \in \overline{\Omega}$*, we have*

$$u[\varphi](x) = \inf_{\alpha(.)\in L^\infty(\mathbb{R}^+,\mathcal{A})} \left\{ \int_0^{\tau\wedge T} f(y_x(t),\alpha(t))e^{-\lambda t}dt \right.$$
$$\left. +\mathbb{1}_{\{\tau\le T\}}\varphi(y_x(\tau))e^{-\lambda\tau} + \mathbb{1}_{\{\tau>T\}}u[\varphi](y_x(T))e^{-\lambda T} \right\}.$$

Proof. To prove the theorem, we just remark that the continuity of the exit cost is no used in the classical proof (see [17], for instance). □

THEOREM 2.9. *Under the assumptions of Theorem* 2.1*, the value functions* $u[\varphi_*]$*,* $u[\varphi]$ *and* $u[\varphi^*]$ *are viscosity solutions of* (2).

Proof. Since the proof is inspired from the corresponding one in the continuous case, we point out only the modifications that we need. Let us denote by $\bar{\varphi}$ the functions φ_*, φ, or φ^*. We prove only that $u[\bar{\varphi}]$ is a supersolution of (2) on $\partial\Omega$. The other properties may be obtained by the same method. We consider some point $x_0 \in \partial\Omega$.

• If $(u[\bar{\varphi}])_*(x_0) \ge \varphi_*(x_0)$, we have nothing to prove.

• If $(u[\bar{\varphi}])_*(x_0) < \varphi_*(x_0)$, we have to show that the function u satisfies the equation $H(x,u,Du) = 0$ in viscosity sense.

There exists a sequence $(x_n)_n$ of points of $\overline{\Omega}$ such that $x_n \to x_0$ and

$$\lim_n u[\bar{\varphi}](x_n) \;=\; (u[\bar{\varphi}])_*(x_0).$$

We may assume without loss of generality that $x_n \in \Omega$ for all n. Indeed, if there exists a subsequence $(x_p)_p$ of $(x_n)_n$ such that $x_p \in \partial\Omega$ for all p, then, by definition of the value function $u[\bar{\varphi}]$,

$$u[\bar{\varphi}](x_p) \;=\; \bar{\varphi}(x_p).$$

And since $\bar{\varphi}$ is equal to φ_*, φ, or φ^*, passing to the limit, we obtain

$$\liminf_p \bar{\varphi}[x_p] \;\ge\; \varphi_*(x_0).$$

Hence we get a contradiction.

Now we choose a constant T such that

$$T\|f\|_\infty + \rho_{\varphi_*}(\|b\|_\infty T) + \|\varphi\|_\infty|1-e^{-\lambda T}| \;\le\; \frac{\varphi_*(x_0)-(u[\bar{\varphi}])_*(x_0)}{2}, \tag{20}$$

where ρ_{φ_*} is a nondecreasing continuous function satisfying $\rho_{\varphi_*}(t) \to 0$ as $t \to 0^+$ and, for every $y \in \partial\Omega$,

$$\varphi_*(x_0) - \varphi_*(y) \;\le\; \rho_{\varphi_*}(|x_0-y|).$$

(Such a function ρ_{φ_*} exists because φ_* is l.s.c.)

For every x_n, we introduce a control $\alpha_n(.)$ such that

$$u[\bar{\varphi}](x_n) + \frac{1}{n} \geq \int_0^{\tau_n \wedge T} f(y_{x_n}(t), \alpha_n(t)) e^{-\lambda t} dt + \mathbb{1}_{\{\tau_n \leq T\}} \bar{\varphi}(y_{x_n}(\tau_n)) e^{-\lambda \tau_n}$$

$$+ \mathbb{1}_{\{\tau_n > T\}} u[\bar{\varphi}](y_{x_n}(T)) e^{-\lambda T}. \tag{21}$$

If, for n large enough, we have $\tau_n > T$, then the inequality (21) implies

$$u[\bar{\varphi}](x_n) + \frac{1}{n} \ \geq \ \int_0^T f(y_{x_n}(t), \alpha_n(t)) e^{-\lambda t} dt + u[\bar{\varphi}](y_{x_n}(T)) e^{-\lambda T}.$$

And, since this inequality does not deal with the discontinuous exit cost $\bar{\varphi}$, we may apply classical arguments (see [3], for instance).

Otherwise, we may assume that, for all n, there exists p_n such that $\tau_{p_n} \leq T$. Then the inequality (21) implies, for the index p_n, that

$$u[\bar{\varphi}](x_{p_n}) + \frac{1}{p_n} \ \geq \ \int_0^{\tau_{p_n}} f(y_{x_{p_n}}(t), \alpha_{p_n}(t)) e^{-\lambda t} dt + \bar{\varphi}(y_{x_{p_n}}(\tau_{p_n})) e^{-\lambda \tau_{p_n}}.$$

Then we compute

$$\begin{aligned}
\varphi_*(x_0) - u[\bar{\varphi}](x_{p_n}) - \frac{1}{p_n} & \\
&\leq \int_0^{\tau_{p_n}} \|f\|_\infty dt + \varphi_*(x_0) - \bar{\varphi}(y_{x_{p_n}}(\tau_{p_n})) + \|\varphi\|_\infty |1 - e^{-\lambda \tau_{p_n}}| \\
&\leq \int_0^T \|f\|_\infty dt + \rho_{\varphi_*(x_0)}(|x_0 - y_{x_{p_n}}(\tau_{p_n})|) + \|\varphi\|_\infty |1 - e^{-\lambda T}| \\
&\leq T\|f\|_\infty + \rho_{\varphi_*(x_0)}(|x_0 - x_{p_n}| + \|b\|_\infty T) + \|\varphi\|_\infty |1 - e^{-\lambda T}|.
\end{aligned}$$

We pass to the limit, and we get a contradiction with the choice of T in (20). □

Example 2.10. We are going to show in this example that the value functions $u[\varphi_*]$, $u[\varphi]$, and $u[\varphi^*]$ may be not equal.

We take in $\mathbb{R}^2$

$$\Omega \ := \ \{(x, y) \in [-1, 1]^2, \ y \ > \ 0 \text{ or } x \ < \ 0\},$$

$$f \equiv 0, \ \lambda \ = \ 0$$

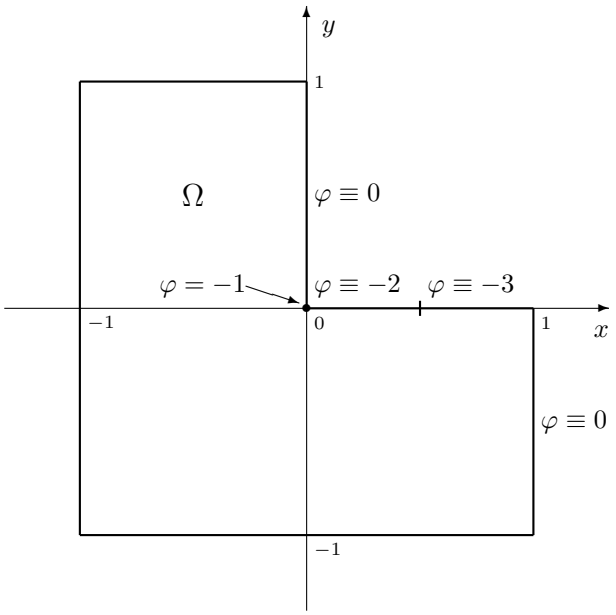
(λ is null for the sake of simplicity but this is not relevant here), and

$$b(x, \alpha) \ := \ \alpha \in \mathcal{A},$$

with $\mathcal{A} := \mathcal{B}(0, 1) \cap (\mathbb{R}^+ \times \mathbb{R}^-)$, i.e., $\{(\alpha_1, \alpha_2) \in \mathbb{R}^2, \ \alpha_1^2 + \alpha_2^2 \leq 1, \alpha_1 \geq 0, \alpha_2 \leq 0\}$.

The exit cost φ is equal to 0 except on $[0, 1] \times \{0\}$, where

$$\varphi(0, 0) \ = \ -1, \quad \varphi(x, 0) \ = \ -2 \ \text{ for } x \in \left]0, \frac{1}{2}\right[, \quad \varphi(x, 0) \ = \ -3 \ \text{ for } x \in \left[\frac{1}{2}, 1\right].$$



In the region $]-1,0[\times]0,1[$, it is easy to show that the best strategy is to reach the point $(0,0)$. To do so, we may, for example, use the control $(0,-1)$ until we touch the line $y=0$, and then we take the control $(1,0)$. Hence we compute that $u[\varphi_*] \equiv -2$, $u[\varphi] \equiv -1$, $u[\varphi^*] \equiv 0$, and $u_- \equiv -3$ in $]-1,0[\times]0,1[$.

The value functions $u[\varphi_*]$, $u[\varphi]$, and $u[\varphi^*]$ are very different because at the point $(0,0)$, the exit costs φ_*, φ, and φ^* take different values. Moreover, the functions u_- and $u[\varphi_*]$ are not equal because the trajectories which reach $[\frac{1}{2},1]\times\{0\}$ must be tangent to the boundary.

The open set Ω is not regular for the sake of simplicity. But we can easily change it. With φ continuous, a similar example was used to show that u_- and $u[\varphi]$ are not necessarily equal (cf. [6]).

This example shows that the discontinuous viscosity solutions may be very different even if we consider only their l.s.c. or u.s.c. envelopes.

2.3. Partial controllability on the boundary. We introduce now new assumptions which allow us to prove that all the value functions have the same l.s.c. envelope, namely, u_-.

We denote by $d(.)$ the distance function to the boundary $\partial\Omega$. We are given a smooth bounded domain; more precisely, we assume that

$$d \text{ is a } C^{1,1} \text{ function in the neighborhood } \mathcal{V} \text{ of } \partial\Omega. \tag{22}$$

Then we set $n(x) := -Dd(x)$ for $x \in \mathcal{V}$.

We assume that $\partial\Omega = \partial\Omega_1 \cup \partial\Omega_2$, where $\partial\Omega_1$ and $\partial\Omega_2$ are unions of connected components of $\partial\Omega$, and, at every point of $\partial\Omega_1$, there exists an outer field, i.e.,

$$\forall x \in \partial\Omega_1,\ \exists \alpha \in \mathcal{A},\ b(x,\alpha)\cdot n(x) \ \geq\ \beta \ >\ 0, \tag{23}$$

and, on $\partial\Omega_2$, there are only inner fields, i.e.,

$$\forall x \in \partial\Omega_2,\ \forall \alpha \in \mathcal{A}, \quad b(x,\alpha)\cdot n(x) \ \leq\ -\beta \ <\ 0. \tag{24}$$

Note that in (23) and (24), β can be chosen independent of x since $\partial\Omega_1$ and $\partial\Omega_2$ are compact subsets of $\mathbb{R}^N$ and since the functions b and n are continuous on $\partial\Omega$.

THEOREM 2.11. *We assume that φ is a bounded function defined pointwise satisfying* (4)*, that the constant λ is positive, and that the assumptions* (6), (7)*, and* (22)–(24) *hold.*

Then we have

$$u_- \;=\; (u^+)_* \quad \text{in } \Omega \cup \partial\Omega_1.$$

Using the representation formula, one easily build special examples where the equality may be wrong on $\partial\Omega_2$. For example, if the exit cost φ is equal to 0 on $\partial\Omega_2$ and to 1 on $\partial\Omega_1$, the value function u_- is null on the boundary $\partial\Omega_2$ but not the function u^+ since the trajectories cannot exit through $\partial\Omega_2$, i.e., $\bar{\tau} > \tau$.

Since u^+ and u_- are the maximum and minimum solutions of (2), this result characterizes the discontinuous solutions of (2) in $\Omega \cup \partial\Omega_1$. Indeed, if w is a solution of (2), then

$$u_- \;\le\; w_* \;\le\; w^* \;\le\; u^+ \quad \text{in } \Omega \cup \partial\Omega_1,$$

and therefore, taking the l.s.c. envelope of these inequalities and using Theorem 2.11 yield

$$u_- \;=\; w_* \;=\; (w^*)_* \quad \text{in } \Omega \cup \partial\Omega_1.$$

When the exit cost is continuous (cf. [6]), to get the uniqueness result, it is enough to know that the first exit time τ is equal to the "best exit time," i.e., which gives the minimal value for the value function or that $u_- = \varphi$ on $\partial\Omega$. But this is not the case with discontinuous exit cost since we deal with φ_* and φ^*.

Example 2.12. We show that the assumption (23) is necessary to prove Theorem 2.11. In fact, we take up the above Example 2.10, but we change φ to satisfy (4). Precisely,

$$\varphi(x) \;=\; \begin{cases} -2 & \text{on } [0,1]\times\{0\}, \\ \\ 0 & \text{otherwise.} \end{cases}$$

Then we can easily compute $u[\varphi_*] \equiv -2$ and $u[\varphi^*] \equiv 0$ in the region $]-1,0[\times]0,1[$.

REMARK 2.13. *The assumption* (24) *was introduced and used by H. M. Soner* [18] *for control problems with state-space constraints to prove the continuity and the uniqueness of the value function.*

Proof of Theorem 2.11. It is easy to see that the trajectories cannot exit through the boundary $\partial\Omega_2$ because of (24). And since the result holds only in $\Omega \cup \partial\Omega_1$, we do not need to take care of the value of the exit cost on the boundary $\partial\Omega_2$.

First, we prove that

$$(u^+)_* \;=\; (u[\varphi^*])_* \;=\; (u[\varphi_*])_* \;=\; u_- \quad \text{in } \Omega.$$

First equality: $(u^+)_* = (u[\varphi^*])_*$.

This is nothing but Theorem 2.4.

Second equality: $(u[\varphi^*])_* = (u[\varphi_*])_*$.

It is clear that $(u[\varphi_*])_* \le (u[\varphi^*])_*$ in the domain Ω, since $u[\varphi_*] \le u[\varphi^*]$ on $\overline{\Omega}$.

To prove the opposite inequality, let x be a point of Ω. Then there exists a sequence $(x_n)_n$ of points of Ω such that $x_n \to x$ and

$$\lim_n u[\varphi_*](x_n) \;=\; (u[\varphi_*])_*(x).$$

For each x_n, we consider a control $\alpha_n(.)$ such that

$$u[\varphi_*](x_n) + \frac{1}{n} \;\geq\; J(x_n, \alpha_n, \tau_n, \varphi_*). \tag{25}$$

We denote by $y^n_{x_n}$ the trajectory associated with α_n and by z_n its first exit point from Ω, i.e., $z_n := y^n_{x_n}(\tau_n) \in \partial\Omega_1$.

By using the assumption (4), we take a sequence $(z^p_n)_p$ of points of the boundary such that $z^p_n \to z_n$ and

$$\lim_p \varphi^*(z^p_n) \;=\; \varphi_*(z_n). \tag{26}$$

Now we need the following lemma.

LEMMA 2.14. *Let y_x be a trajectory such that its first exit time τ from Ω is positive and bounded. Then, for ε small enough and for $\tilde{z} \in \partial\Omega_1$ such that $|y_x(\tau) - \tilde{z}| < \varepsilon$, there exists a trajectory $\tilde{y}_{\tilde{x}}$ such that $\tilde{z} = \tilde{y}_{\tilde{x}}(\tilde{\tau})$ and*

$$|y_x(t) - \tilde{y}_{\tilde{x}}(t)| \;<\; D\varepsilon \quad \text{for } t \in [0, \tau]$$

with some constant D independent of ε.

For each trajectory $y^n_{x_n}$ and for p large enough, using (26), we apply Lemma 2.14 to the point z^p_n. Then, using again (26) and the Lipschitz continuity of the function f, we obtain after tedious but straightforward computations

$$J(x_n, \alpha_n, \tau_n, \varphi_*) \;\geq\; J(x^p_n, \alpha^p_n, \tau^p_n, \varphi^*) - \varepsilon^p_n,$$

with a sequence $(\varepsilon^p_n)_p$ of numbers such that $\varepsilon^p_n \to 0$ as $p \to \infty$. Combining this with (25), we get

$$\begin{aligned} u[\varphi_*](x_n) + \frac{1}{n} &\geq J(x^p_n, \alpha^p_n, \tau^p_n, \varphi^*) - \varepsilon^p_n \\ &\geq u[\varphi^*](x^p_n) - \varepsilon^p_n. \end{aligned}$$

Hence, passing to the limit, by a diagonal procedure, we obtain

$$\begin{aligned} (u[\varphi_*])_*(x) &= \lim_n u[\varphi_*](x_n) \\ &\geq (u[\varphi^*])_*(x). \end{aligned}$$

Since it is true for every $x \in \Omega$, the result is complete.

Third equality: $(u[\varphi_*])_* = u_-$.

By their definitions, $u_- \leq u[\varphi_*]$ in Ω. And since the value function u_- is l.s.c., we deduce $u_- \leq (u[\varphi_*])_*$ in Ω.

It remains to prove the opposite inequality. Let x_0 be a point of Ω. By the compactness of the set of relaxed controls, using classical arguments, there exist $\bar{\mu} \in L^\infty(\mathbb{R}^+, P(\mathcal{A}))$ and $\bar{\theta} \in [0, \infty]$ such that

$$u_-(x_0) \;=\; \hat{J}(x_0, \bar{\mu}, \bar{\theta}, \varphi_*).$$

Then we need the following lemma.

LEMMA 2.15. *Let $\hat{y}_x$ be a trajectory associated with a relaxed control μ and with a point $x \in \Omega$.*

Then, for any bounded exit time θ of $\hat{y}_x$, there exists a classical trajectory $\tilde{y}_{\tilde{x}}$ arbitrarily close to $\hat{y}_x$ and such that

$$\tilde{y}_{\tilde{x}}(\tilde{\tau}) \;=\; \hat{y}_x(\theta),$$

where $\tilde{\tau}$ is the first exit time of $\tilde{y}_{\tilde{x}}$ from Ω.

If $\bar{\theta}$ is bounded, using Lemma 2.15, there exists a sequence of points x_n and of controls $\alpha_n(.)$ such that $x_n \to x_0$ and

$$\hat{J}(x_0, \bar{\mu}, \bar{\theta}, \varphi_*) \;=\; J(x_n, \alpha_n, \tau_n, \varphi_*) - \varepsilon_n,$$

where $\varepsilon_n \to 0$ when $n \to \infty$ using the Lipschitz continuity of f. Then this implies

$$u_-(x_0) \;\geq\; u[\varphi_*](x_n) - \varepsilon_n.$$

Passing to the limit, we get

$$u_-(x_0) \;\geq\; (u[\varphi_*])_*(x_0).$$

It remains the cases when $\bar{\theta}$ is not bounded. We have several cases to consider. The easier is when the trajectory $\hat{y}_{x_0}$ stays far to the boundary, i.e.,

$$\inf_{t \,\geq\, 0} d(\hat{y}_{x_0}(t)) \;=\; \delta \;>\; 0;$$

then classical arguments imply that $\hat{y}_{x_0}$ can be approximated by classical trajectories. A connected case is when it is true but only after some finite time T, i.e.,

$$\inf_{t \,\geq\, T} d(\hat{y}_{x_0}(t)) \;=\; \delta \;>\; 0;$$

then we mix the preceding arguments with those of Lemma 2.14. The last case is when, for any $T > 0$, we get

$$\inf_{t \,\geq\, T} d(\hat{y}_{x_0}(t)) \;=\; 0.$$

Then we may assume that there exists a sequence of trajectories y_n such that their exit times τ_n tend to ∞ as $n \to \infty$, by using Lemma 2.14 for exit times of $\hat{y}_{x_0}$ large enough, or after modifying $\hat{y}_{x_0}$ when $\hat{y}_{x_0}$ is near the boundary, in order that it touches the boundary by using (23). Therefore, using the term $e^{-\lambda t}$ which tends to zero as $t \to \infty$ and the boundedness of f and φ, there exists a sequence $(\varepsilon_n)_n$ of numbers such that $\varepsilon_n \to 0$ as $n \to \infty$ and

$$\begin{aligned}\hat{J}(x_0, \bar{\mu}, \bar{\theta}, \varphi_*) &= \int_0^\infty \int_{\mathcal{A}} f(\hat{y}_{x_0}(t), \alpha) e^{-\lambda t} d\bar{\mu}(\alpha) dt \\ &\geq J(x_n, \alpha_n, \tau_n, \varphi_*) - \varepsilon_n.\end{aligned}$$

Then we conclude as before.

It remains to prove that $u_- = (u[\varphi_*])_*$ on the boundary $\partial\Omega_1$. Then we need the following lemma.

LEMMA 2.16. *The function u_- satisfies*

$$u_-(x) \;=\; \liminf_{y \to x, y \in \Omega} u_-(y) \quad \textit{for every } x \in \partial\Omega_1.$$

We postpone the proof of this lemma.

Moreover, since the function u^+ is u.s.c., for every $x \in \partial\Omega_1$, we have

$$(u^+)_*(x) \;=\; \liminf_{y\to x, y\in\Omega} u^+(y).$$

Therefore, since $u_- = (u^+)_*$ in Ω, we deduce that $u_- = (u^+)_*$ on $\partial\Omega$. □

Now we turn to the proof of the lemmas.

Proof of Lemma 2.14. In order to simplify the notation, we denote $z := y_x(\tau)$, by $\alpha(.)$ the control associated with the trajectory y_x, and by $\tilde{\alpha}(.)$ the control associated with $\tilde{y}_{\tilde{x}}$, which is the unknown.

We first remark that since the map $Y_\tau : x \mapsto y_x(\tau)$ is locally an homeomorphism, we may always find a point $\tilde{x}$ such that $y_{\tilde{x}}(\tau) = \tilde{z}$. Then a possible candidate for $\tilde{\alpha}$ may directly be α (and thus the constant D is equal to $e^{C\tau}$ by standard ODE estimates). But the difficulty is that the trajectory $y_{\tilde{x}}$ may cross the complementary set of Ω to reach $\tilde{z}$. In order to avoid this difficulty, we use the assumption (23) of a partial controllability on the boundary. Briefly speaking, we consider a backward trajectory which comes from the point $\tilde{z}$ and which goes in the interior of Ω for a short time. Afterward, the trajectory is again associated with α in order to reach a neighborhood of x.

First, using the assumption (23), we consider the control $\bar{\alpha} \in \mathcal{A}$ such that $b(z,\bar{\alpha}) \cdot n(z) > 0$. Thus we define the control $\tilde{\alpha}$ by

$$\tilde{\alpha}(t) \;=\; \begin{cases} \alpha(t) & \text{for } t \in [0,\tau[, \\ \bar{\alpha} & \text{for } t \in [\tau, \tau+\varepsilon]. \end{cases}$$

Then the trajectory $\tilde{y}_{\tilde{x}}$ is the solution of

$$\begin{cases} d\tilde{y}_{\tilde{x}}(s) &= b(\tilde{y}_{\tilde{x}}(s), \tilde{\alpha}(s))ds \quad \text{for } s \in [0, \tau+\varepsilon[, \\ \tilde{y}_{\tilde{x}}(\tau+\varepsilon) &= \tilde{z}. \end{cases}$$

Using the assumptions (22) on n and (6) on b, there exists a constant $\delta > 0$ such that

$$b(\xi,\bar{\alpha}) \cdot n(\xi) \;>\; \frac{\beta}{2} \quad \text{for } \xi \in \mathcal{B}(z,\delta) \cap \overline{\Omega}.$$

Moreover, using the boundedness of b, standard ODE estimates yield, for $t \in [\tau, \tau+\varepsilon]$,

$$\begin{aligned} |z - \tilde{y}_{\tilde{x}}(t)| &\le |z - \tilde{z}| + |\tilde{z} - \tilde{y}_{\tilde{x}}(t)| \\ &\le \varepsilon + C\varepsilon. \end{aligned}$$

Therefore, for ε small enough, the trajectory $\tilde{y}_{\tilde{x}}$ stays in $\mathcal{B}(z,\delta)$, and then we compute, for $t \in [\tau, \tau+\varepsilon]$,

$$\begin{aligned} d(\tilde{y}_{\tilde{x}}(t)) &= d(\tilde{z}) + \int_t^{\tau+\varepsilon} n(\tilde{y}_{\tilde{x}}(s)) \cdot b(\tilde{y}_{\tilde{x}}(s), \bar{\alpha}) ds \\ &\ge \frac{\beta}{2}(\tau + \varepsilon - t). \end{aligned} \tag{27}$$

Next, we prove that the trajectory $\tilde{y}_{\tilde{x}}$ does not touch the boundary during $[\tau-\eta, \tau]$, where η is a positive constant to determine. In order to simplify the notation, we set $z_\varepsilon := \tilde{y}_{\tilde{x}}(\tau)$ and $\tilde{y}_{z_\varepsilon}(.) := \tilde{y}_{\tilde{x}}(.)$. To prove the claim, it suffices to show that $d(\tilde{y}_{z_\varepsilon}(t))$

is positive for $t \in [\tau - \eta, \tau]$. Since the functions b and n are Lipschitz continuous, at least, in the neighborhood $\mathcal{V}$ of the boundary, for η small enough, we compute

$$\begin{aligned} d(\tilde{y}_{z_\varepsilon}(t)) - d(y_x(t)) &= d(z_\varepsilon) - d(z) \\ &\quad + \int_t^\tau (n(\tilde{y}_{z_\varepsilon}(s)) \cdot b(\tilde{y}_{z_\varepsilon}(s), \alpha(s)) - n(y_x(s)) \cdot b(y_x(s), \alpha(s)))ds \\ &\geq d(z_\varepsilon) - CK \int_t^\tau |\tilde{y}_{z_\varepsilon}(s) - y_x(s)|ds. \end{aligned}$$

Using standard ODE estimates, we obtain

$$\begin{aligned} d(\tilde{y}_{z_\varepsilon}(t)) - d(y_x(t)) &\geq d(z_\varepsilon) - CK \int_t^\tau |z_\varepsilon - z| e^{C(\tau - s)} ds \\ &\geq d(z_\varepsilon) - K|z_\varepsilon - z|(e^{C(\tau - t)} - 1) \\ &\geq d(z_\varepsilon) - K(|z_\varepsilon - \tilde{z}| + |\tilde{z} - z|)(e^{C\eta} - 1). \end{aligned} \tag{28}$$

We need an estimate for $|z_\varepsilon - \tilde{z}|$. But, since b is bounded and since $z_\varepsilon = \tilde{y}_{z_\varepsilon}(\tau)$, we have

$$\begin{aligned} |z_\varepsilon - \tilde{z}| &= \left| \int_\tau^{\tau + \varepsilon} b(\tilde{y}_{z_\varepsilon}(s), \bar{\alpha}) ds \right| \\ &\leq C\varepsilon. \end{aligned} \tag{29}$$

Combining this and (27) with (28), we get

$$d(\tilde{y}_{z_\varepsilon}(t)) - d(y_x(t)) \ \geq \ \frac{\beta\varepsilon}{2} - K(C\varepsilon + |\tilde{z} - z|)(e^{C\eta} - 1).$$

But, since $\tilde{z}$ is such that $|\tilde{z} - z| < \varepsilon$, this implies

$$d(\tilde{y}_{z_\varepsilon}(t)) - d(y_x(t)) \ \geq \ \varepsilon \left(\frac{\beta}{2} - K(1 + C)(e^{C\eta} - 1) \right). \tag{30}$$

Then we take η such that the right-hand side of this inequality is null, i.e.,

$$\eta \ := \ \frac{1}{C} \ln \left(1 + \frac{\beta}{2K(1 + C)} \right).$$

Hence we conclude that

$$d(\tilde{y}_{z_\varepsilon}(t)) \ \geq \ 0 \quad \text{for every } t \in [\tau - \eta, \tau],$$

and the inequality is strict because of the term $d(y_x(t))$. We may remark that the constant η depends only on the functions b and n.

Finally, since τ is the first exit time of y_x, we have

$$\inf\{d(y_x(t)), t \in [0, \tau - \eta]\} \ = \ \rho \ > \ 0.$$

We compute, for $t \in [0, \tau - \eta]$,

$$\begin{aligned} d(\tilde{y}_{z_\varepsilon}(t)) &\geq d(y_x(t)) - |(\tilde{y}_{z_\varepsilon} - y_x)(t)| \\ &\geq \rho - |z_\varepsilon - z|(e^{C\tau} - 1) \\ &\geq \rho - (C + 1)(e^{C\tau} - 1)\varepsilon. \end{aligned}$$

Therefore, for ε small enough, we obtain the result with a constant D equal to $(C+1)(e^{C\tau}-1)$. □

Proof of Lemma 2.15. First we approximate $\hat{y}_x$ by a relaxed trajectory whose first exit point is $\tilde{z} := \hat{y}_x(\theta)$. We use backward trajectories. We recall that a backward trajectory $\check{y}_z$ is a solution of the ODE

$$\begin{cases} d\check{y}_z(t) = -b(\check{y}_z(t), \alpha(t))dt, \\ \check{y}_z(0) = z. \end{cases}$$

We begin by choosing a control $\bar{\alpha} \in \mathcal{A}$ such that $b(\tilde{z}, \bar{\alpha}) \cdot n(\tilde{z}) > 0$. Then we consider the backward trajectory $\check{y}_1$ with $\check{y}_1(0) = \tilde{z}$ and associated with the relaxed control μ_1 defined by

$$\mu_1(t) \;=\; \begin{cases} \bar{\alpha} & \text{if } t \in [0, \varepsilon_1[, \\ \mu(t) & \text{elsewhere,} \end{cases}$$

with a parameter $\varepsilon_1 > 0$ to be chosen later. Using the estimate (27), which can be extended to backward relaxed trajectories, we know that the new trajectory $\check{y}_1$ does not touch the boundary during $]0, \varepsilon_1[$, for ε_1 small enough. Now, if the new trajectory $\check{y}_1$ touches the boundary at the time τ_1, we set $z_1 := \check{y}_1(\tau_1)$ and choose $\alpha_1 \in \mathcal{A}$ such that $b(z_1, \alpha_1) \cdot n(z_1) > 0$. Then we change the control μ_1 for μ_2 given by

$$\mu_2(t) \;=\; \begin{cases} \alpha_1 & \text{if } t \in [\tau_1 - \varepsilon_2, \tau_1], \\ \mu_1(t) & \text{elsewhere.} \end{cases}$$

Therefore the trajectory associated with μ_2 does not touch $\partial\Omega$, at least during $[\tau_1 - \varepsilon_2, \tau_1]$. In fact, by using the arguments of the proof of Lemma 2.14, we know that the trajectory lies in the open set Ω during the fixed time η.

Next, we do the same thing as many times as the trajectory touches the boundary. Finally, since after each modification, we know that the trajectory does not touch $\partial\Omega$ during η, we change the control only a finite number of time.

In order to be close to the trajectory $\hat{y}_x$, it suffices to choose the parameters ε_i small enough since the relaxed control of the new trajectory is equal to μ except during the times ε_i where μ is replaced by α_i.

Finally, it remains to approximate the new relaxed trajectory by a classical trajectory. But it is standard since the relaxed trajectory lies in Ω during $[\varepsilon_1, \theta]$. □

Proof of Lemma 2.16. We consider a point z of $\partial\Omega_1$. Using the assumption (23), there exists a control $\bar{\alpha} \in \mathcal{A}$ such that $b(z, \bar{\alpha}) \cdot n(z) > 0$. As in Lemma 2.14, we consider the solution $\tilde{y}_z$ of

$$\begin{cases} d\tilde{y}_z(s) &=& b(\tilde{y}_z(s), \bar{\alpha})ds \quad \text{for } s \in [0, 1[, \\ \tilde{y}_z(1) &=& z. \end{cases}$$

Then we consider the points

$$x_n \;:=\; \tilde{y}_z\left(1 - \frac{1}{n}\right)$$

and the trajectories

$$\tilde{y}_{x_n}(.) \;:=\; \tilde{y}_z\left(. + 1 - \frac{1}{n}\right).$$

It is clear enough that, for n large enough, $x_n \in \Omega$ and $x_n \to z$ as $n \to \infty$. Note also that the first exit time of $\tilde{y}_{x_n}$ is equal to $\frac{1}{n}$. Thus the cost function associated with the trajectory $\tilde{y}_{x_n}$ is

$$J\left(x_n, \bar{\alpha}, \frac{1}{n}, \varphi_*\right) \;=\; \int_0^{\frac{1}{n}} f(\tilde{y}_{x_n}(t), \bar{\alpha}) e^{-\lambda t} dt + \varphi_*(z) e^{-\lambda \frac{1}{n}}.$$

Therefore this implies

$$u_-(x_n) \;\leq\; J\left(x_n, \bar{\alpha}, \frac{1}{n}, \varphi_*\right).$$

Then we pass to the limit

$$\begin{aligned} \liminf_n \; u_-(x_n) &\leq \liminf_n \; J\left(y_n, \alpha_1, \frac{1}{n}, \varphi_*\right) \\ &\leq \varphi_*(x_0). \end{aligned}$$

Finally, by definition of the limit inferior, we deduce

$$\begin{aligned} \liminf_{y \to z, y \in \Omega} u_-(y) &\leq \liminf_n \; u_-(x_n) \\ &\leq \varphi_*(x_0), \end{aligned}$$

and the proof is complete. □

Example 2.17. We will show that the assumption (23) is necessary to prove Lemma 2.15. More precisely, we give a relaxed trajectory which cannot be approximated by classical trajectories in a closed set. To this end, we consider in $\mathbb{R}^3$ the field b given, for $x = (x_1, x_2, x_3) \in \mathbb{R}^3$, by

$$b(x, \alpha) \;=\; \begin{bmatrix} 1 \\ \alpha \\ \frac{1}{1+\alpha^2} + |x_2| \end{bmatrix}$$

with $\alpha \in \mathcal{A} := [-1, 1]$. (This field was already considered in [5].)

Around the point $O = (0, 0, 0)$, the domain Ω is reduced by two cylinders, C_1 and C_2:

$$\begin{aligned} C_1 &= \left\{(x_1, x_2, x_3) \in \mathbb{R}^3,\; (x_1 - 5)^2 + (x_3)^2 \;\leq\; 5\right\}, \\ C_2 &= \left\{(x_1, x_2, x_3) \in \mathbb{R}^3,\; (x_1 - 9)^2 + (x_3 - 7)^2 \;\leq\; 5\right\}. \end{aligned}$$

We can define a relaxed trajectory $\hat{y}_O$ satisfying $(\hat{y}_O)_3(t) = \frac{t}{2}$ which is tangent to the two cylinders. We can easily prove that classical trajectories cannot approximate the trajectory $\hat{y}_O$ when $t \geq 10$ because, since the classical trajectories are such that

$$(\dot{y}(t))_3 \;>\; \frac{1}{2} \quad \text{for } t > 0$$

(see [5]), at the time $t = 5$ they have to be above the cylinder C_1 and then they cannot pass below C_2 for $t = 10$.

3. The uniqueness results. In this part, we prove uniqueness results for Hamilton–Jacobi equations in the case when the Dirichlet boundary data φ is assumed only to be defined pointwise, by using PDE methods. We recall that uniqueness means in this context that all the solutions have the same l.s.c. envelope.

For simplicity in what follows, we assume henceforth that $H(x,t,p) = H(x,p) + t$ and that $(x,p) \to H(x,p)$ is a continuous function from $\overline{\Omega} \times \mathbb{R}^N$ into $\mathbb{R}$ which satisfies

$$H(x,p) \text{ is convex in } p \text{ for every } x \in \overline{\Omega} \tag{31}$$

and

$$\left|\frac{\partial H}{\partial p}\right| \le C, \quad \left|\frac{\partial H}{\partial x}\right| \le C(1+|p|) \quad \text{on } \overline{\Omega} \times \mathbb{R}^N \text{ for some constant } C > 0. \tag{32}$$

To explain the problems coming from the discontinuity of the Dirichlet condition, we consider the function φ being equal to 0 at some point $x_0 \in \partial\Omega$ and 1 elsewhere, as in the introduction. Then the viscosity subsolution condition on the boundary is satisfied by the function u if

$$u^* \le \varphi^* \equiv 1 \quad \text{on } \partial\Omega.$$

It is clear that this condition is not restrictive enough because the fact that $\varphi(x_0) = 0$ is not seen by this boundary condition.

Indeed, for illustration, we consider the exit time problem from the point x_0. To this end, we even assume that the controllability is complete; i.e., the field b is given by $b(x,\alpha) := \alpha$ with α in the unit ball $\mathcal{B}(0,1)$ of $\mathbb{R}^N$. Then, if we assume that the domain Ω is convex, any point $x \in \Omega$ may reach the point x_0 by following the straight line $[x, x_0]$. Finally, we take $f \equiv 1$ and $\lambda = 1$. With the notation of the introduction, the value function $u[\varphi]$ is defined, for every $x \in \overline{\Omega}$, by

$$\begin{aligned} u[\varphi](x) &= \inf_{\alpha(.) \in L^\infty(\mathbb{R}^+, \mathcal{B}(0,1))} \left\{ \int_0^\tau 1 e^{-t} dt + \varphi(y_x(\tau)) e^{-\tau} \right\} \\ &= \inf_{\alpha(.) \in L^\infty(\mathbb{R}^+, \mathcal{B}(0,1))} \{1 - e^{-\tau} + \mathbb{1}_{\partial\Omega \setminus \{x_0\}}(y_x(\tau)) e^{-\tau}\}. \end{aligned}$$

It is easy to show that the best strategy is to reach the point x_0. Then, the value function is equal to

$$u[\varphi](x) = 1 - e^{-|x - x_0|}.$$

But by the result of the first part, all the functions $u_\zeta(x) := 1 - \zeta e^{-|x-x_0|}$ with $\zeta \in [0,1]$ are also solutions of (2) since $\varphi_* \le \zeta \mathbb{1}_{\partial\Omega\setminus\{x_0\}} \le \varphi^*$. In particular, the maximal subsolution u^+, which is equal to $u[\varphi^*] \equiv 1$, appears to be a pathological solution for this exit time problem.

We consider two ways to avoid this difficulty: the first one is to consider only "regular" boundary data φ, i.e., functions satisfying the condition (4) as we did in the first section. The second one is to impose additional conditions on the solution u: since the viscosity subsolution condition on the boundary turns out to be not restrictive enough, we replace it by the condition (5), i.e., for any $x \in \partial\Omega$,

$$\liminf_{y \to x, y \in \Omega} u(y) \le \varphi_*(x),$$

and moreover, we need that the function u is a viscosity solution in the sense of Barron and Jensen inside the domain Ω. For the sake of completeness, we recall the following definition.

DEFINITION 3.1. *Let u be a bounded function. We say that u is a Barron–Jensen solution of*

$$H(x, Du) + u \;=\; 0 \quad \text{in } \Omega \tag{33}$$

if it satisfies

$$\begin{cases} \forall\, \phi \in C^1(\Omega) \text{ at each minimum point } x_0 \in \Omega \text{ of } u_* - \phi, \text{ we have} \\ H(x_0, D\phi(x_0)) + u_*(x_0) \;=\; 0. \end{cases} \tag{34}$$

In the case of continuous solutions, we have an equivalence between (34) and the definition of viscosity solutions of (33): if the function u satisfies (34), then u is a viscosity solution of (33) and vice versa.

For discontinuous solutions, the connections are far less simple (cf. [2]).

• If u is a bounded viscosity solution of (33) satisfying $(u^*)_* = u_*$ in Ω, then the property (34) holds for u_*. (In particular, it holds if u is u.s.c.)

• If u is a l.s.c. bounded function satisfying the property (34), then u is a viscosity solution of (33).

To prove the uniqueness result, we need to add nondegeneracy conditions on the Hamiltonian on the boundary. To do so, we recall that we assume that the distance function d satisfies (22). We assume that $\partial\Omega = \partial\Omega_1 \cup \partial\Omega_2$, where $\partial\Omega_1$ and $\partial\Omega_2$ are unions of connected components of $\partial\Omega$ and

$$\begin{cases} \forall x \in \partial\Omega_1,\ \forall R \;>\; 0,\ \exists C^R \;>\; 0 \text{ such that} \\ \text{if } |y - x| \;\le\; \dfrac{1}{C^R},\ y \in \overline{\Omega}, \text{ and } \lambda \;\ge\; C^R(1 + |p|),\ \lambda \in \mathbb{R}^+,\ p \in \mathbb{R}^N, \\ \text{then} \quad H(y, p - \lambda n(y)) \;\ge\; R, \end{cases} \tag{35}$$

and

$$\begin{cases} \forall x \in \partial\Omega_2,\ \forall R \;>\; 0,\ \exists C^R \;>\; 0 \text{ such that} \\ \text{if } |y - x| \;\le\; \dfrac{1}{C^R},\ y \in \overline{\Omega}, \text{ and } \lambda \;\ge\; C^R(1 + |p|),\ \lambda \in \mathbb{R}^+,\ p \in \mathbb{R}^N, \\ \text{then} \quad H(y, p - \lambda n(y)) \;\le\; -R. \end{cases} \tag{36}$$

We recall that $n(x) := -Dd(x)$ for every x in the neighborhood $\mathcal{V}$ of $\partial\Omega$. We also assume that

$$\begin{cases} \text{in a neighborhood of } \partial\Omega_2, \text{ for every } p \in \mathbb{R}^N, \\ \text{the map } \lambda \to H(x, p + \lambda n(x)) \text{ is a nondecreasing function.} \end{cases} \tag{37}$$

In the case of control problems when the Hamiltonian is given by (1), the assumption (35) is equivalent to (23), i.e., the existence of an outer field on $\partial\Omega_1$ and the assumptions (36) and (37) are equivalent to (24), which implies that there are only inner fields on $\partial\Omega_2$.

The assumption (36) is used in the comparison result of [7].

Our result is the following theorem.

THEOREM 3.2. *We assume that φ is a bounded function defined pointwise and that the assumptions* (22), (31), (32), *and* (35)–(37) *hold.*

(1) *If the condition* (4) *holds on $\partial\Omega_1$ and if the functions u and v are viscosity solutions of* (2), *then*

$$u_* \;=\; v_* \quad \text{in } \Omega.$$

(2) *If the functions u and v are Barron–Jensen solutions of* (33) *which are supersolutions of* (2) *on the boundary and which satisfy the condition* (5) *on $\partial\Omega_1$, then*

$$u_* \;=\; v_* \quad \text{in } \Omega.$$

In the first point, we recover the uniqueness result of the first section in the case of control problems. We will detail in the part on applications the adaptation of the second point. In particular, we will show that all the value functions are Barron–Jensen solutions of the associated Bellman equation.

Finally, let us come back to the example of the beginning of the section. The function u^+, which is equal to 1, and the functions u_ζ with $\zeta \in]0,1[$ are Barron–Jensen solutions of the associated Bellman equation in Ω, but they do not satisfy the condition (5) on $\partial\Omega$. Only the function $u[\varphi]$ satisfies both properties.

A viscosity solution u is a Barron–Jensen solution in particular if u satisfies the property $(u^*)_* = u_*$ in Ω which is a criterion for uniqueness in [6] or if the function u is continuous. We recall that the solution u is continuous if $H(x,p) \to \infty$ when $|p| \to \infty$.

This result is similar to that obtained in the case of optimal stopping time problems with discontinuous stopping costs (cf. [2]).

The following comparison principle is the keystone of the proof of the uniqueness results.

THEOREM 3.3. *Under the assumptions of Theorem* 3.2, *if the function u is a Barron–Jensen solution of* (33) *satisfying* (5) *on $\partial\Omega_1$ and if the function v is a bounded supersolution of* (2), *then*

$$u_* \;\le\; v_* \quad \text{in } \Omega.$$

Proof of Theorem 3.2. (1) First, we remark that all the subsolutions of equation (2) satisfy condition (5): indeed, using a classical result when the assumption (35) holds, we have

$$u^* \;\le\; \varphi^* \quad \text{on } \partial\Omega_1.$$

Taking the limit inferior, we find that

$$(u^*)_* \;\le\; (\varphi^*)_* \;=\; \varphi_* \quad \text{on } \partial\Omega_1, \tag{38}$$

since the function φ satisfies the assumption (4). Finally, since we have, for every $x \in \partial\Omega$,

$$\liminf_{y\to x, y\in\Omega} u^*(y) \;=\; (u^*)_*(x),$$

we deduce from (38) that the solution u^* satisfies, for every $x \in \partial\Omega_1$,

$$\liminf_{y\to x, y\in\Omega} u^*(y) \;\le\; \varphi_*(x).$$

Now since the function u^* is not necessarily a Barron–Jensen solution of (33), we are not able to use directly Theorem 3.3 with u. Then we introduce the maximal subsolution u^+ of equation (2). The function u^+ may be obtained by considering the following standard approximate Dirichlet problem:

$$\left\{ \begin{array}{ll} -\dfrac{1}{n}|Du^n|^2 + H(x, Du^n) + u^n = 0 & \text{in } \Omega, \\ u^n = \varphi^n & \text{on } \partial\Omega, \end{array} \right. \tag{39}$$

where $(\varphi^n)_n$ is a nonincreasing sequence of continuous functions such that

$$\inf_n \varphi^n \;=\; \varphi^*.$$

The existence of solutions of the problem (39) is a classical consequence of Perron's method (cf. [14]) since the constants

$$M_n \;:=\; \max\{\|H(x,0)\|_\infty, \|\varphi_n\|_\infty\}$$

and $-M_n$ are, respectively, a supersolution and a subsolution of this problem. Moreover, the new Hamiltonian satisfies the property

$$-\frac{1}{n}|p|^2 + H(x,p) \to -\infty \quad \text{as} \quad |p| \to \infty,$$

which corresponds to the opposite of the classical coercivity property. Nevertheless, we recover the results of [6], but for supersolutions instead of subsolutions: the supersolutions of (39) are uniformly Lipschitz continuous in Ω and we have a comparison result for this equation. Thus we get that the function u^n is continuous and unique. Thanks to the formulation of the approximate problem, a subsolution w of the equation (2) is still a subsolution of the new equation (39). Then this implies that $w \le u^n$ in Ω. Hence, the maximal subsolution u^+ is defined, for $x \in \overline{\Omega}$, by

$$u^+(x) \;:=\; \limsup_{n\to\infty, y\to x} u^n(y) \;=\; \inf_n u^n(x).$$

Therefore the function u^+ is u.s.c.; hence it satisfies the property (34) and the condition (5) by the first remark. Using the comparison principle of Theorem 3.3, we get

$$(u^+)_* \;\le\; v_* \quad \text{in } \Omega.$$

But since u^+ is the maximal subsolution, we have $u^+ \ge u^*$ in Ω. Hence

$$\begin{aligned} v_* &\ge (u^+)_* \\ &\ge (u^*)_* \;\ge\; u_* \quad \text{in } \Omega. \end{aligned}$$

Finally, we exchange the roles of the functions u and v, and the proof is complete.

(2) The second point is a direct consequence of Theorem 3.3. □

Now we turn to the proof of the comparison principle.

Proof of Theorem 3.3. We first recall that the distance function to the boundary d is assumed to be $C^{1,1}$ in the neighborhood $\mathcal{V}$ of $\partial\Omega$ by the assumption (22). We still denote by d a nondecreasing $C^{1,1}$ function on $\overline{\Omega}$ which is equal to the distance

function to $\partial\Omega$ in a neighborhood $\mathcal{V}'$ of $\partial\Omega$ included in $\mathcal{V}$. And we set $n(x) := -Dd(x)$ for $x \in \overline{\Omega}$, even if, for $x \notin \mathcal{V}'$, $n(x)$ is not necessarily unitary.

For every $\alpha > 0$, we introduce the function u^α defined, for every $(x,t) \in \Omega \times \mathbb{R}^+$, by

$$u^\alpha(x,t) \;=\; \inf_{y\in\overline{\Omega}} \{u_*(y) + e^{-Kt}\phi_\alpha(x,y) + \bar{C}(d(x) - d(y))\},$$

with

$$\phi_\alpha(x,y) \;:=\; \frac{|x-y|^4}{\alpha} + L\frac{|x-y|^3}{\alpha}(d(x)-d(y)) + M\frac{|d(x)-d(y)|^4}{\alpha},$$

where $\bar{C}$, K, L, and M are some positive constants to be chosen later.

The properties of u^α are described in the following lemma.

LEMMA 3.4. *There exist constants $\bar{C}$, K, L, and M such that, for every $T > 0$ and for α small enough, the following properties hold:*

(1) *the function u^α is Lipschitz continuous in $\Omega \times [0,T]$. (Thus we may extend it by continuity to the boundary $\partial\Omega \times [0,T]$.)*

(2) *The function u^α is a viscosity subsolution of*

$$\frac{\partial w}{\partial t} + H(x,Dw) + w - B\sqrt[4]{\alpha} \;=\; 0 \qquad \text{in } (\Omega \cup \partial\Omega_2)\times]0,T] \tag{40}$$

for some constant $B > 0$, independent of α.

(3) *We have $u^\alpha \le \varphi^\alpha$ on $\partial\Omega_1 \times [0,T]$, where the function φ^α is defined, for every $x \in \partial\Omega_1$ and $t \ge 0$, by*

$$\varphi^\alpha(x,t) \;=\; \inf_{y\in\partial\Omega_1} \left\{ \varphi_*(y) + e^{-Kt}\frac{|x-y|^4}{\alpha} \right\}.$$

We postpone the proof of the lemma.

REMARK 3.5. *The inf-convolution procedure, which usually leads a supersolution in the viscosity solution theory, allows us to obtain a subsolution following new ideas introduced by Barron and Jensen* [8] *for convex Hamiltonians. The time-dependent formulation of u^α is a technical point which permits to treat discontinuous solutions for stationary problems* (*cf.* [2]).

The terms with the distance function is a trick to obtain the classical property of the inf-convolution procedure despite the presence of the boundary, thanks to the assumptions (35) *and* (36). *The distance function to $\partial\Omega$ plays here essentially the same role as the time variable in the classical Barron–Jensen approach for the Cauchy problem.*

To conclude the proof of Theorem 3.3, we compare the functions u^α and v. Since $\varphi_* \ge \varphi^\alpha$ on Ω and since the function v_* does not depend on t, v_* is a supersolution of

$$\begin{cases} \dfrac{\partial w}{\partial t} + H(x,Dw) + w = 0 & \text{in } \Omega\times]0,T], \\ w = \varphi^\alpha & \text{on } \partial\Omega\times]0,T]. \end{cases} \tag{41}$$

Because of the Lipschitz continuity of u^α and φ^α, an easy adaptation of the comparison result of [6] for the Cauchy problem (41) (see also [17] and [18]) yields

$$u^\alpha(x,T) - v_*(x) \;\le\; e^{-T}\|(u^\alpha(.,0) - v_*(.))^+\|_\infty + B\sqrt[4]{\alpha}.$$

We first let $\alpha \to 0$ in this inequality and then $T \to \infty$. Since the functions u and v are bounded, we obtain

$$u_* \ \leq \ v_* \quad \text{in } \Omega,$$

which is the inequality that we wanted to prove. □

Now we turn to the proofs of the lemmas.

Proof of Lemma 3.4. (1) Regularity and elementary properties of u^α.

For every x, $z \in \Omega$, and $t \geq 0$, we have

$$\begin{aligned} u^\alpha(x,t) - u^\alpha(z,t) &\leq \sup_{y\in\overline{\Omega}}\{(e^{-Kt}\phi_\alpha(x,y) + \bar{C}(d(x) - d(y))) \\ &\qquad -(e^{-Kt}\phi_\alpha(z,y) + \bar{C}(d(z) - d(y)))\} \\ &\leq e^{-Kt}\sup_{y\in\overline{\Omega}}\{\phi_\alpha(x,y) - \phi_\alpha(z,y)\} + \bar{C}(d(x) - d(z)). \end{aligned}$$

By the compactness of the domain $\overline{\Omega}$ and by Lipschitz regularity of the distance function, we obtain

$$u^\alpha(x,t) - u^\alpha(z,t) \ \leq \ \frac{C}{\alpha}|x - z|.$$

Therefore the function u^α is Lipschitz continuous in the space variable. It is easy to check the same property in the time variable.

Then, by Rademacher's theorem, u^α is differentiable almost everywhere, and then, by classical result in optimization theory, if y_α is a point such that $u^\alpha(x,t) = u_*(y_\alpha) + e^{-Kt}\phi_\alpha(x,y_\alpha) + \bar{C}(d(x) - d(y_\alpha))$, we have

$$Du^\alpha(x,t) \ = \ e^{-Kt}D_x\phi_\alpha(x,y_\alpha) - \bar{C}n(x)$$

and

$$\frac{\partial u^\alpha}{\partial t}(x,t) \ = \ -Ke^{-Kt}\phi_\alpha(x,y_\alpha).$$

Let us check some elementary properties of the function u^α. First, using the fact that the functions u and v are bounded, we fix the constant $\bar{C}$ to the largest of the constants C^R which appear in the assumptions (35) and (36) for $R = \max\{\|u\|_\infty, \|v\|_\infty\}$.

LEMMA 3.6. *For L large enough and $M \gg L$ and for every $(x,t) \in \Omega \times [0,T]$, the following properties hold:*

(1) $u^\alpha(x,t) \leq u_*(x)$.

(2) *If y_α is a point such that $u^\alpha(x,t) = u_*(y_\alpha) + e^{-Kt}\phi_\alpha(x,y_\alpha) + \bar{C}(d(x) - d(y_\alpha))$, there exists a constant E independent of α such that*

$$|x - y_\alpha| \ \leq \ E\sqrt[4]{\alpha}.$$

(3) *For x in a neighborhood of the boundary, if we write $Du^\alpha(x,t) = p_\alpha - \lambda_\alpha n(x)$ and if we have $d(x) \geq d(y_\alpha)$, then*

$$\lambda_\alpha \ \geq \ \bar{C}(1 + |p_\alpha|).$$

(4) *There exists a constant $\bar{K}$ independent of α and of K such that*

$$|Du^\alpha(x,t)||x - y_\alpha| \ \leq \ \bar{K}(|x - y_\alpha| + e^{-Kt}\phi_\alpha(x,y_\alpha)).$$

We postpone the proof of this lemma.

(2) Equation satisfied by u^α.

Since the Hamiltonian is convex, in order to prove that the function u^α is a viscosity subsolution of (40) in $\Omega\times]0,T[$, it is enough to show that u^α satisfies (40) in the almost everywhere sense (cf. [17]). Let (x_0,t_0) be a point of $\Omega\times]0,T[$ where u^α is differentiable.

We consider a point $y_\alpha\in\overline{\Omega}$ such that

$$u^\alpha(x_0,t_0) \;=\; u_*(y_\alpha)+e^{-Kt_0}\phi_\alpha(x_0,y_\alpha)+\bar{C}(d(x_0)-d(y_\alpha)).$$

By the definition of u^α, the point y_α is a minimum point of $u_*-\psi$ with

$$\psi(y) \;:=\; -e^{-Kt_0}\phi_\alpha(x_0,y)-\bar{C}(d(x_0)-d(y)).$$

In order to use the equation on u, we have to show that $y_\alpha\in\Omega$. We first remark that the assumptions (22), (35), and (36) are satisfied in the neighborhood of $\partial\Omega$ included in $\mathcal{V}'$,

$$\Omega_\delta \;:=\; \{x\in\overline{\Omega} \text{ such that } \; d(x)<\delta\},$$

for some positive constant δ small enough.

• If $x_0\notin\Omega_\delta$, then $d(x_0)\geq\delta$ and, by using the second point of Lemma 3.6, we obtain

$$\begin{aligned} d(y_\alpha) &\geq d(x_0)-|x_0-y_\alpha| \\ &\geq \delta - E\sqrt[4]{\alpha}. \end{aligned}$$

Hence, for α small enough, we find that $d(y_\alpha)>0$.

• If $x_0\in\Omega_\delta$, we need the following lemma.

LEMMA 3.7. *If $x_0\in\Omega_\delta$, then we have*

$$d(x_0) \;\leq\; d(y_\alpha).$$

Using Lemma 3.7, we deduce that $d(y_\alpha)>0$ since $x_0\in\Omega$.

Hence, we get

$$H(y_\alpha,D\psi(y_\alpha))+u_*(y_\alpha) \;=\; 0, \tag{42}$$

where

$$D\psi(y_\alpha) \;=\; -e^{-Kt}D_y\phi_\alpha(x,y_\alpha)-\bar{C}n(y_\alpha).$$

We want to replace y_α by x_0 and $u_*(y_\alpha)$ by $u^\alpha(x_0,t_0)$ in the equality (42). By using the assumption (32) and the definition of u^α, we get

$$\begin{aligned} H(x_0,Du^\alpha(x_0,t_0))+u^\alpha(x_0,t_0) \leq\; & C(1+|Du^\alpha(x_0,t_0)|)|x_0-y_\alpha| \\ & +C|Du^\alpha(x_0,t_0)-D\psi(y_\alpha)| \\ & +e^{-Kt_0}\phi_\alpha(x_0,y_\alpha)+\bar{C}(d(x_0)-d(y_\alpha)). \end{aligned} \tag{43}$$

To estimate the right side of this inequality, we use Lemma 3.6 and we compute

$$\begin{aligned} |Du^\alpha(x_0,t_0)-D\psi(y_\alpha)| &\leq |\lambda_\alpha||n(x_0)-n(y_\alpha)| \\ &\leq \|Dn\|_\infty|Du^\alpha(x_0,t_0)||x_0-y_\alpha|. \end{aligned}$$

Therefore we deduce from the inequality (43) that

$$H(x_0, Du^\alpha(x_0,t_0)) + u^\alpha(x_0,t_0) \;\le\; B\sqrt[4]{\alpha} + Ke^{-Kt_0}\phi_\alpha(x_0,y_\alpha),$$

with $B := (C(1+\bar{K}+\bar{K}\|Dn\|_\infty)+\bar{C})E$ and $K := C\bar{K}(1+\|Dn\|_\infty)+1$.

It remains to introduce the time derivative of u^α, i.e.,

$$\frac{\partial u^\alpha}{\partial t}(x_0,t_0) \;=\; -Ke^{-Kt_0}\phi_\alpha(x_0,y_\alpha).$$

Then, we obtain

$$\frac{\partial u^\alpha}{\partial t}(x_0,t_0) + H(x_0, Du^\alpha(x_0,t_0)) + u^\alpha(x_0,t_0) \;\le\; B\sqrt[4]{\alpha}.$$

Hence, the function u^α satisfies the equation (40) in the almost everywhere sense.

Finally, since u^α is a viscosity subsolution of (40) in $\Omega\times]0,T[$, u^α is also a subsolution of (40) on the boundary $\Omega\times\{T\}$ by classical properties of Cauchy problems (cf. [7]).

Moreover, on the boundary $\partial\Omega_2\times]0,T]$, the assumption (37) implies the following.

LEMMA 3.8. *The function u^α is a viscosity subsolution of* (40) *on $\partial\Omega_2\times]0,T]$.*

We again postpone the proof of this lemma.

(3) Boundary properties of u^α.

By the definition of φ^α, for any $x_0\in\partial\Omega_1$ and any $t\ge 0$, there exists a point y_0 of $\partial\Omega_1$ such that

$$\varphi^\alpha(x_0,t) \;=\; \varphi_*(y_0) + e^{-Kt}\frac{|x_0-y_0|^4}{\alpha}.$$

We take a sequence $(y_n)_n$ of points of Ω such that $y_n\to y_0$ and

$$\liminf_{y\to y_0, y\in\Omega} u(y) \;=\; \lim_n u(y_n).$$

By the property (5), we know that

$$\lim_n u(y_n) \;\le\; \varphi_*(y_0).$$

Now we introduce the sequence $(x_n)_n$ defined by $x_n := x_0 - d(y_n)n(x_0)$ for every n. Since we have $d(y_n)\to 0$ as $n\to\infty$, the sequence $(x_n)_n$ converges to x_0. Note also that $d(x_n)=d(y_n)$ for n large enough.

By the definition of u^α, we may write

$$\begin{aligned}
u^\alpha(x_n,t) &\le u_*(y_n) + e^{-Kt}\phi_\alpha(x_n,y_n) + \bar{C}(d(x_n)-d(y_n))\\
&\le u_*(y_n) + e^{-Kt}\left[\frac{|x_n-y_n|^4}{\alpha} + L\frac{|x_n-y_n|^3}{\alpha}(d(x_n)-d(y_n))\right.\\
&\qquad\left. + M\frac{|d(x_n)-d(y_n)|^4}{\alpha}\right] + \bar{C}(d(x_n)-d(y_n))\\
&\le u_*(y_n) + e^{-Kt}\frac{|x_n-y_n|^4}{\alpha} \qquad \text{for } n \text{ large enough.}
\end{aligned}$$

Then, letting $n\to\infty$, we obtain

$$u^\alpha(x_0,t) \;=\; \lim_n u^\alpha(x_n,t) \;\le\; \varphi_*(y_0) + e^{-Kt}\frac{|x_0-y_0|^4}{\alpha} \;=\; \varphi^\alpha(x_0,t).$$

Since it is true for every $x_0\in\partial\Omega_1$ and $t\ge 0$, the result is proven. □

Proof of Lemma 3.6. (1) Since $\phi_\alpha(x,x)=0$ for any $x\in\overline{\Omega}$, we have $u_*\geq u^\alpha$ in $\Omega\times[0,T]$.

(2) Since the function u_* is l.s.c., for any α, there exists a point $y_\alpha\in\overline{\Omega}$ such that

$$u^\alpha(x,t) \;=\; u_*(y_\alpha)+e^{-Kt}\phi_\alpha(x,y_\alpha)+\bar{C}(d(x)-d(y_\alpha)),$$

and since $u^\alpha \;\leq\; u_*$ in $\Omega\times[0,T]$, we have

$$u_*(y_\alpha)+e^{-Kt}\phi_\alpha(x,y_\alpha)+\bar{C}(d(x)-d(y_\alpha)) \;\leq\; u_*(x).$$

Then we deduce

$$e^{-Kt}\phi_\alpha(x,y_\alpha) \;\leq\; 2\|u\|_\infty+2\bar{C}\|d\|_\infty. \tag{44}$$

By using the Young inequality

$$L\frac{|x-y|^3}{\alpha}(d(x)-d(y)) \;\leq\; \frac{3}{4}\frac{|x-y|^4}{\alpha}+\frac{1}{4}L^4\frac{|d(x)-d(y)|^4}{\alpha},$$

we get

$$\phi_\alpha(x,y_\alpha)\geq\frac{1}{4}\frac{|x-y|^4}{\alpha}+(M-\frac{1}{4}L^4)\frac{|d(y)-d(x)|^4}{\alpha} \tag{45}$$

$$\geq\frac{1}{4}\frac{|x-y|^4}{\alpha} \tag{46}$$

for $M\geq\frac{1}{2}L^4$. Combining it with (44), this implies

$$|x-y_\alpha| \;\leq\; e^{\frac{Kt}{4}}\sqrt[4]{2(\|u\|_\infty+\bar{C}\|d\|_\infty)\alpha}.$$

(3) If the function u^α is differentiable at (x,t), we may write $Du^\alpha(x,t)=p_\alpha-\lambda_\alpha n(x)$ with

$$p_\alpha \;:=\; e^{-Kt}\left[4(x-y_\alpha)\frac{|x-y_\alpha|^2}{\alpha}+3L(x-y_\alpha)\frac{|x-y_\alpha|}{\alpha}(d(x)-d(y_\alpha))\right]$$

and

$$\lambda_\alpha \;:=\; e^{-Kt}\left[L\frac{|x-y_\alpha|^3}{\alpha}+4M(d(x)-d(y_\alpha))\frac{|d(x)-d(y_\alpha)|^2}{\alpha}\right]+\bar{C}.$$

Again, we use the Young inequality to get

$$3L\frac{|x-y_\alpha|^2}{\alpha}|d(x)-d(y_\alpha)| \;\leq\; 2\frac{|x-y_\alpha|^3}{\alpha}+L^3\frac{|d(x)-d(y_\alpha)|^3}{\alpha}.$$

If we have $d(x)\geq d(y_\alpha)$, then we deduce

$$\bar{C}(1+|p_\alpha|)-\lambda_\alpha \;\leq\; e^{-Kt}\left[(6\bar{C}-L)\frac{|x-y_\alpha|^3}{\alpha}+(\bar{C}L^3-4M)\frac{|d(x)-d(y_\alpha)|^3}{\alpha}\right].$$

The right-hand side of this inequality is negative for $L\geq 6\bar{C}$ since we already know that $M\geq\frac{1}{2}L^4$.

(4) We compute

$$|Du^\alpha(x,t)||x-y_\alpha| \le e^{-Kt}\left[4\frac{|x-y_\alpha|^4}{\alpha} + 3L\frac{|x-y_\alpha|^3}{\alpha}|d(x)-d(y_\alpha)| + L\frac{|x-y_\alpha|^4}{\alpha}\right.$$

$$\left. + 4M\frac{|d(x)-d(y_\alpha)|^3}{\alpha}|x-y_\alpha|\right] + \bar{C}|x-y_\alpha|. \tag{47}$$

Then, using again Young inequalities, we obtain after straightforward computations

$$|Du^\alpha(x,t)||x-y_\alpha| \le e^{-Kt}\left[\left((4+\frac{13}{4}L+M\right)\frac{|x-y_\alpha|^4}{\alpha}\right.$$

$$\left. + \left(\frac{3}{4}L+3M\right)\frac{|d(x)-d(y_\alpha)|^4}{\alpha}\right] + \bar{C}|x-y_\alpha|.$$

Finally, we use the inequality (45) to fix the constant $\bar{K}$. □

Proof of Lemma 3.7. We argue by contradiction assuming that

$$d(x_0) \;>\; d(y_\alpha). \tag{48}$$

We first consider the case when the point y_α is in the domain Ω. Hence, we use the equation on u and we get

$$H(y_\alpha, D\psi(y_\alpha)) + u_*(y_\alpha) \;=\; 0, \tag{49}$$

where

$$D\psi(y_\alpha) \;=\; p_\alpha - \lambda_\alpha n(y_\alpha)$$

with the notation of Lemma 3.6.

But, since $d(x_0) < \delta$, we get that $y_\alpha \in \Omega_\delta$ using the inequality (48). Then, we may apply the assumptions (35) or (36) to the equality (49), and thus we get a contradiction since, by Lemma 3.6, we have

$$\lambda_\alpha \;\ge\; \bar{C}(1+|p_\alpha|).$$

It remains the case when the minimum point y_α is on the boundary $\partial\Omega$. We set

$$\chi_\varepsilon(y) \;:=\; u_*(y) - \psi(y) + |y-y_\alpha|^2 + \frac{\varepsilon}{d(y)}$$

for $y \in \Omega$ and $\varepsilon > 0$. We add the term $|.-y_\alpha|^2$ to be sure that the point y_α is a strict local minimum point of $u_*(.) - \psi(.) + |.-y_\alpha|^2$. Then there exists a sequence $(y_\varepsilon)_\varepsilon$ of local minimum points of χ_ε such that

$$\lim_{\varepsilon\to 0} y_\varepsilon \;=\; y_\alpha \quad \text{and} \quad \lim_{\varepsilon\to 0} \chi_\varepsilon(y_\varepsilon) \;=\; u_*(y_\alpha) - \psi(y_\alpha).$$

Since $y_\varepsilon \in \Omega$, we may use the equation on u:

$$H\left(y_\varepsilon, D\psi(y_\alpha) - 2(y_\varepsilon - y_\alpha) - \frac{\varepsilon}{d(y_\varepsilon)^2}n(y_\varepsilon)\right) + u_*(y_\varepsilon) \;=\; 0. \tag{50}$$

But since $d(y_\varepsilon) \to 0$ as $\varepsilon \to 0$, we have $d(y_\varepsilon) < d(x_0)$ for ε small enough. Then, using the same arguments as in preceding case, we get a contradiction with (50) since the term $|y_\varepsilon - y_\alpha|$ tends to 0 and the additional term with the normal is negative.

Hence, we have $d(x_0) \le d(y_\alpha)$. □

Proof of Lemma 3.8. Let ϕ be a C^1 function on $\overline{\Omega} \times [0,T]$ and let $(x_0,t_0) \in \partial\Omega_2 \times]0,T]$ be a maximum point of $u^\alpha - \phi$. We may assume (x_0,t_0) to be a strict local maximum point of $u^\alpha - \phi$ by changing, if needed, ϕ in $\phi + |.-x_0|^2 + |.-t_0|^2$. Following an idea of [4], for $\varepsilon > 0$ and for every $(x,t) \in \Omega \times]0,T]$, we set

$$\chi_\varepsilon(x,t) \;=\; u^\alpha(x,t) - \phi(x,t) - \frac{\varepsilon}{d(x)}.$$

As in Lemma 3.7, since the point (x_0,t_0) is a strict local maximum point of $u^\alpha - \phi$, there exists a sequence $(x_\varepsilon,t_\varepsilon)_\varepsilon$ of local maximum points of χ_ε such that

$$(x_\varepsilon,t_\varepsilon) \to (x_0,t_0) \quad \text{ and } \quad u^\alpha(x_\varepsilon,t_\varepsilon) \to u^\alpha(x_0,t_0) \quad \text{ as } \varepsilon \to 0.$$

Since $x_\varepsilon \in \Omega$, (40) holds for u^α and we get

$$\frac{\partial\phi}{\partial t}(x_\varepsilon,t_\varepsilon) + H\left(x_\varepsilon, D\phi(x_\varepsilon,t_\varepsilon) + \frac{\varepsilon}{d(x_\varepsilon)^2} n(x_\varepsilon)\right) + u^\alpha(x_\varepsilon,t_\varepsilon) - B\sqrt[4]{\alpha} \;\le\; 0. \tag{51}$$

Using the assumption (37), we get

$$H(x_\varepsilon, D\phi(x_\varepsilon,t_\varepsilon)) \;\le\; H\left(x_\varepsilon, D\phi(x_\varepsilon,t_\varepsilon) + \frac{\varepsilon}{d(x_\varepsilon)^2} n(x_\varepsilon)\right).$$

Combining this with (51), we obtain

$$\frac{\partial\phi}{\partial t}(x_\varepsilon,t_\varepsilon) + H(x_\varepsilon, D\phi(x_\varepsilon,t_\varepsilon)) + u^\alpha(x_\varepsilon,t_\varepsilon) - B\sqrt[4]{\alpha} \;\le\; 0.$$

We conclude by letting ε go to zero. □

4. Applications. In this section, we apply the uniqueness results of Theorem 3.2 to exit time control problems.

We use the notations of the first section; in particular, the Hamiltonian is given by (1).

THEOREM 4.1. *We assume that φ is a bounded function defined pointwise, that the constant λ is positive, and that the assumptions* (6), (7), *and* (22)–(24) *hold. Then*

(1) *if the property* (4) *holds for φ on $\partial\Omega_1$, the l.s.c. envelope of the solutions of* (2) *is equal to the value function u_-.*

(2) *all the Barron–Jensen solutions of* (33) *in Ω which are supersolutions of* (2) *on the boundary and which satisfy the condition* (5) *on $\partial\Omega_1$ have the same l.s.c. envelope, u_-.*

In the second point, the only value functions satisfying the condition (5) are, in general, u_- and $u[\varphi_*]$. It is clear enough in the example of the introduction where $\varphi := \mathbb{1}_{\partial\Omega\setminus\{x_0\}}$. Besides, we can directly show that $(u[\varphi_*])_* = u_-$ by Lemma 2.15.

P. Soravia [19] showed that all the value functions are Barron–Jensen solutions of (33) in Ω, using their explicit representation formulas. We have the following theorem.

THEOREM 4.2. *Assume* (6) *and* (7). *The value functions $u[\varphi_*]$, $u[\varphi]$, $u[\varphi^*]$, u_-, and u^+ are Barron–Jensen solutions of* (33) *in Ω.*

It is an open problem to know under which assumptions the other solutions of (2) are Barron–Jensen solutions.

Now we turn to the proofs.

Proof of Theorem 4.1. This result is an easy adaptation of Theorem 3.2. We just have to verify the assumptions of this theorem. The Hamiltonian satisfies (32)

because of the conditions (6) and (7) on b and f. Also, the assumptions (23) and (24) lead to (35), (36), and (37).

We prove only the claim for (35) since the other cases use the same kind of arguments. For any $x \in \partial\Omega_1$, using (23), we choose a control $\bar{\alpha}$ such that $b(x,\bar{\alpha}) \cdot n(x) \geq \beta$. Then, by definition of the Hamiltonian, for $R > 0$, $\lambda \in \mathbb{R}^+$ and $p \in \mathbb{R}^N$, and for $y \in \mathcal{V}$, we have

$$\begin{aligned} H(y, p - \lambda n(y)) - R &= \sup_{\alpha \in \mathcal{A}} \{-b(y,\alpha) \cdot (p - \lambda n(y)) - f(y,\alpha)\} - R \\ &\geq -b(y,\bar{\alpha}) \cdot (p - \lambda n(y)) - f(y,\bar{\alpha}) - R, \\ H(y, p - \lambda n(y)) - R &\geq \lambda\beta - \lambda(b(x,\bar{\alpha}) \cdot n(x) - b(y,\bar{\alpha}) \cdot n(y)) \\ &\quad - \|b\|_\infty |p| - \|f\|_\infty - R. \end{aligned}$$

Using the Lipschitz continuity of the functions b and n, we get

$$H(y, p - \lambda n(y)) - R \ \geq \ \lambda(\beta - K|x-y|) - \max\{\|b\|_\infty,\ \|f\|_\infty + R\}(1 + |p|).$$

Then, if we take

$$C^R \ := \ \frac{2}{\beta} \max\{K,\ \|b\|_\infty,\ \|f\|_\infty + R\},$$

the right side of the preceding inequality is negative and therefore the assumption (35) is satisfied.

Now, by Theorem 4.2, we already know that u_- satisfies (34). And Lemma 2.16 implies that u_- satisfies (5). Then the proof is complete. □

Proof of Theorem 4.2. We have already proved that all these value functions are supersolutions of (2) in the first part. In order to prove the opposite viscosity inequality, we need the following lemma introduced by P. Soravia [19] as the backward dynamic programming principle.

LEMMA 4.3. *Let x be a point of Ω and $\alpha(.)$ be a control, i.e., $\alpha \in L^\infty(\mathbb{R}^+, \mathcal{A})$. We consider the backward trajectory $\check{y}_x$ solution of the dynamical system*

$$\begin{cases} d\check{y}_x(t) = -b(\check{y}_x(t), \alpha(t))dt, \\ \check{y}_x(0) = x \in \overline{\Omega}, \end{cases}$$

We denote by τ_x the first exit time of the backward trajectory $\check{y}_x$ from Ω.

Then, for all T such that $0 < T < \tau_x$, we have

$$u(x) \ \geq \ -\int_0^T f(\check{y}_x(t), \alpha(t)) e^{\lambda t} dt + u(\check{y}_x(T)) e^{\lambda T}.$$

To prove Theorem 4.2, we just have to use the classical arguments as in Theorem 2.9, but using the inequality of Lemma 4.3 instead of the usual dynamic programming principle. □

Now we explain how use the uniqueness result to pass to the limit. We consider an exit time problem satisfying the assumption (23) on $\partial\Omega$ with a exit cost satisfying (5). Let $(\varphi_n)_n$ be a nondecreasing sequence of continuous functions such that

$$\sup_n \varphi_n \ = \ \varphi_* \ = \ (\varphi^*)_*.$$

We note u_n, a viscosity solution of problem (2) where φ is replaced by φ_n.

By the second part, $((u_n)^*)_*$ satisfies the property (34). Using (23) and since φ_n is continuous, we get

$$((u_n)^*)_* \ \leq \ \varphi_n \quad (\leq \ \varphi_{n+1}) \quad \text{ on } \partial\Omega.$$

Therefore $((u_n)^*)_*$ satisfies also the property (5). Then we apply Theorem 4.1 to get

$$\begin{aligned}(u_{n+1})_* &\geq ((u_n)^*)_* \\ &\geq (u_n)_* \quad \text{ in } \Omega.\end{aligned}$$

Thus, for $x \in \Omega$, we have

$$\liminf_{n\to\infty, y\to x} (u_n)_*(y) \ = \ \sup_n (u_n)_*(x).$$

Finally, by classical stability results, the function

$$\underline{u}(x) \ := \ \liminf_{n\to\infty, y\to x} (u_n)_*(y) \ = \ \sup_n (u_n)_*(x)$$

is a supersolution of (2). Moreover it easy to check that $\underline{u}$ satisfies the properties (5) and (34). Hence, by using again the preceding uniqueness result, we conclude

$$\lim_n (u_n)_* \ = \ \sup_n (u_n)_* \ = \ \underline{u} \ = \ u_- \quad \text{ in } \Omega.$$

NONLINEAR FILTERING REVISITED: A SPECTRAL APPROACH*

SERGEY LOTOTSKY†, REMIGIJUS MIKULEVICIUS‡, AND BORIS L. ROZOVSKII†

Abstract. The objective of this paper is to develop an approach to nonlinear filtering based on the Cameron–Martin version of Wiener chaos expansion. This approach gives rise to a new numerical scheme for nonlinear filtering. The main feature of this algorithm is that it allows one to separate the computations involving the observations from those dealing only with the system parameters and to shift the latter off-line.

Key words. Cameron–Martin development, Wick polynomials, Wiener chaos, Zakai equation

AMS subject classifications. 60G35, 60H15, 62M20

1. Introduction.

Nonlinear filtering is a classic problem of applied stochastic analysis (see, e.g., Kallianpur [19], Kunita [23], Kushner [24], Liptser and Shiryayev [27], etc.). It is of notable theoretical and practical importance by itself and also as a part of control theory for partially observable stochastic systems (see, e.g., Fleming and Pardoux [11]).

In this paper we consider the filtering scheme where the signal process $x(t)$ is a Markov diffusion process and the observation process is of the form

$$y(t) = y_0 + \int_0^t h(x(s))ds + w(t),$$

where $w(t)$ is a Brownian motion independent of the process $x(t)$.

Let f be a given bounded function on $\mathbf{R}^d$ and $\hat{f}(x(t))$ be the optimal filter (the best in the mean-square estimate for $f(x(t))$ based on observations $y(s)$, $s \le t$). A fundamental result of filtering theory says that the optimal filter is given by the formula

$$\hat{f}(x(t)) = \frac{\int_{\mathbf{R}^d} f(x)u(t,x)dx}{\int_{\mathbf{R}^d} u(t,x)dx}, \tag{1.1}$$

where $u(t,x)$ is the so-called unnormalized filtering density (UFD); of course, some regularity assumptions are needed to ensure the existence of the density.

A standard way to study the UFD (analytically or numerically) is to treat it as a solution of the Zakai equation

$$du(t,x) = \mathcal{L}^* u(t,x)dt + h(x)u(t,x)dy(t), \tag{1.2}$$

where $\mathcal{L}^*$ is the formally adjoint operator to the generator of the Markov process $x(t)$ (see, e.g., Baras [2]; Benesh [3]; Bensoussan, Glowinski, and Rascanu [4]; Clark [8];

Another comparatively recent approach is based on the Wiener chaos expansion (WCE) (see references below). In this paper we further develop a version of this approach based on the Cameron–Martin orthogonal decomposition of L_2-functionals of a Gaussian process (see Cameron and Martin [7]). We prove that the UFD can be written in the form

$$u(t,x) = \sum_{\alpha} \frac{1}{\sqrt{\alpha!}} \varphi_\alpha(t,x)\xi_\alpha(y), \tag{1.3}$$

where $\xi_\alpha(y)$ are Wick polynomials (certain products of Hermite polynomials; see, e.g., [14]) of Wiener integrals $\int_0^t m_i(s)dy(s)$, where $\{m_k\}$ is a complete orthonormal system in $L_2([0,t])$, and $\varphi_\alpha(t,x)$ are deterministic Hermite–Fourier coefficients in the Cameron–Martin orthogonal decomposition of $u(t,x)$ (see Mikulevicius and Rozovskii [30, 31]). The Wick series expansion (1.3) converges in L_2-sense on the reference probability space.

We prove that the set of functions $\{\varphi_\alpha(t,x)\}$ is a solution to a simple recursive system of Kolmogorov-like equations (see (2.6)). Below it will be referred to as the S-system.

Our interest in the WCE was motivated mainly by computational purposes. One important feature of the expansion (1.3) is that it separates observations and parameters in that the Wick polynomials are completely defined by the observation process $y(t)$ but the Hermite–Fourier coefficients $\varphi_\alpha(t,x)$ are determined only by the coefficients of the signal process $x(t)$, its initial distribution, and the observation function h.

Unfortunately, direct application of the above expansion for numerical computations is impractical, limited, at best, to short time intervals. The main reason is possible exponential growth of the errors inflicted by truncation of the infinite series (1.3) as the time interval $[0,t]$ increases (Theorem 2.2).

One important objective of the paper is to develop a numerical approximation scheme for the UFD which retains the separation of observations and parameters but is not subject to the aforementioned limitations (Theorem 2.5 and the accompanying algorithm).

This recursive scheme splits into two parts: deterministic and stochastic. The deterministic part (solving the S-system) might be time consuming but can be performed off-line since in many applications the coefficients of the processes $x(t), y(t)$ and also of the S-system are known a priori. The stochastic part (determining the Wick polynomials $\xi_\alpha(y)$) is computationally simple and can be performed in real time. In this paper this scheme is referred to as the spectral separating scheme (S^3).

We prove the strong convergence of S^3 both in L_2 and $\mathbf{C}$ spaces and demonstrate that the overall rate of convergence (on- and off-line) is of order $O(\Delta)$, where Δ is the time step (Theorems 2.2 and 2.4).

S^3 can be also viewed as a time-discretization scheme for a solution of the Zakai equation. In section 4 we demostrate that some well-known discretization algorithms for this equation (e.g., explicit Euler scheme, splitting-up method (see [4, 26])) can be derived from a multistep version of (1.3). In this section we also discuss the computational complexity of S^3, compare it with the complexity of the splitting-up method, and present some results of numerical simulations.

We conclude the introduction with some historical remarks. The idea of obtaining an "explicit" WCE solution of a stochastic (ordinary) differential equation can be

traced back to the paper [21] by Krylov and Veretennikov (see also Zvonkin and Krylov [38]). Kunita [22] applied this idea to prove uniqueness of the Zakai equation. Wong [35] obtained the solution of a special class of nonlinear filtering problems in the form of the WCE. Ocone [32] pioneered finite-order WCEs of normalized nonlinear filters (see also references therein).

In these works the multiple Wiener integral version of the WCE was used. The Cameron–Martin development is analytically equivalent to this version of the WCE (see, e.g., Ito [17]). However, it has some computational advantage since only ordinary Wiener integrals are required in this approach. Lo and Ng [28] were the first ones to utilize the above fact. They modified Ocone's approximation using the Cameron–Martin expansion. Unfortunately, the equations for the deterministic coefficients of the finite-order approximations in [28] are quite complex. To solve them one needs to know the Hermite–Fourier coefficients for the corresponding unnormalized filters. Computation of the latter was not discussed in [28].

The S-system (2.6) was introduced by Mikulevicius and Rozovskii [30, 31]. The upper bound $ce^{ct}t^{N+1}/(N+1)!$ on the error of the Nth-order approximation to (1.3) was obtained in [30]. Recently, Budhiraja and Kallianpur [5] developed a different WCE-type approximation of the unnormalized filtering density using the Haar-type basis. They also established an upper bound on the error of truncation with respect to the stochastic and deterministic bases.

2. Main results. Let $(\Omega, \mathcal{F}, \mathrm{P})$ be a probability space and $w(t)$ be an r-dimensional Brownian motion on the space. Let $x(t)$ be a d-dimensional (unobservable) signal process and $y(t)$ be the r-dimensional observation process given by

$$y(t) = \int_0^t h(x(s))ds + w(t), \quad 0 \le t \le T, \tag{2.1}$$

where $h = (h^l)_{1\le l\le r}$ is an r-dimensional vector function on $\mathbf{R}^d$. We assume in addition that the signal $x(t)$ is a diffusion Markov process of the form[1]

$$\begin{aligned} dx^i(t) &= b^i(x(t))dt + \sigma^{ij}(x(t))d\tilde{w}^j(t), \quad 0 < t \le T, \\ x(0) &= x_0, \end{aligned} \tag{2.2}$$

where $b = (b^i)_{1\le i\le d}$ is a d-dimensional vector function on $\mathbf{R}^d$, $\sigma = (\sigma^{ij})_{1\le i\le d,\ 1\le j\le d_1}$ is a $d\times d_1$ dimensional matrix function on $\mathbf{R}^d$, and $\tilde{w} = (\tilde{w}^i)_{1\le i\le d_1}$ is a d_1-dimensional Brownian motion on $(\Omega, \mathcal{F}, \mathrm{P})$.

The following is assumed about the model (2.1), (2.2):

(A1) the functions b, σ, and h are infinitely differentiable and bounded with all derivatives;

(A2) the processes w and $\tilde{w}$ are independent;

(A3) the random vector x_0 is independent of both w and $\tilde{w}$ and has density[2] $p(x) \in \mathbf{H}^n$ for $n = 0, 1, 2, \ldots$.

(Then by the Sobolev embedding theorem, $p(x)$ is also in $\mathbf{C}_b^n$ for any n.) Some of these assumptions can be weakened, and we will discuss them at the end of this section.

Let $\mathcal{F}_t^y$ be the σ-algebra generated by $y(s)$, $s \le t$. Denote

$$\rho(t) = \exp\Big\{ -\int_0^t h^l(x(s))dw^l(s) - \frac{1}{2}\sum_{l=1}^r \int_0^t |h^l(x(s))|^2 ds\Big\}.$$

[1] When the sum is finite, we assume summation over repeated indices and omit the $\sum$ sign.

[2] Here and below $\mathbf{H}^n$ is the Sobolev space $W_2^n(\mathbf{R}^d)$ (see, e.g., [25]), and $\mathbf{C}_b^n$ is the space of n times continuously differentiable on $\mathbf{R}^d$ functions bounded with all the derivatives.

It is well known (see, e.g., [27] or [19]) that the measure $\tilde{\mathrm{P}}$ defined by $d\tilde{\mathrm{P}} = \rho(T)d\mathrm{P}$ is a probability measure on $(\Omega, \mathcal{F})$ with the following properties:

(i) on the reference probability space $(\Omega, \mathcal{F}, \tilde{\mathrm{P}})$, $y(\cdot)$ is a Brownian motion independent of $x(\cdot)$;

(ii) the optimal filter $\hat{f}(x(t)) = \mathbf{E}[f(x(t))|\mathcal{F}_t^y]$ is given by

$$\hat{f}(x(t)) = \frac{\tilde{\mathbf{E}}[f(x(t))\rho(t)^{-1}|\mathcal{F}_t^y]}{\tilde{\mathbf{E}}[\rho(t)^{-1}|\mathcal{F}_t^y]}, \tag{2.3}$$

where $\tilde{\mathbf{E}}$ is the expectation with respect to measure $\tilde{\mathrm{P}}$. If assumptions (A1)–(A3) hold, the unnormalized filtering measure $\Phi_t(dx) = \tilde{\mathbf{E}}[1_{\{x(t)\in dx\}}\rho(t)^{-1}|\mathcal{F}_t^y]$ admits the density $u(t,x) = \Phi_t(dx)/dx$, called the UFD, which is a solution of the Zakai equation

$$du(t,x) = \mathcal{L}^* u(t,x)dt + h^l(x)u(t,x)dy^l(t), \tag{2.4}$$

where $\mathcal{L}^* u := \frac{1}{2}\frac{\partial^2}{\partial x_i \partial x_j}((\sigma\sigma^*)^{ij}u) - \frac{\partial}{\partial x_i}(b^i u)$ and such that for every $n \in N$

$$\tilde{\mathbf{E}}\sup_{t\le T}||u(t,\cdot)||^2_{\mathbf{C}_b^n} < \infty,$$
$$\tilde{\mathbf{E}}\sup_{t\le T}||u(t,\cdot)||^2_{\mathbf{H}^n} < \infty.$$

Using the UFD $u(t,x)$, one can rewrite (2.3) in the form (1.1).

DEFINITION. *A collection $\alpha = (\alpha_k^l)_{1\le l\le r,\ k\ge 1}$ of nonnegative integers is called an r-dimensional multiindex if only finitely many of α_k^l are different from zero.*

The set of all r-dimensional multiindices will be denoted by J. For $\alpha \in J$ we use the following definitions:

$|\alpha| := \sum_{l,k}\alpha_l^k$, length of α;

$d(\alpha) := \max\{k \ge 1 :\ \alpha_k^l > 0 \text{ for some } 1 \le l \le r\}$, order of α.

We also write $\alpha! = \prod_{k,l}(\alpha_k^l!)$.

Let us fix an arbitrary orthonormal system $\{m_k\} = \{m_k(s)\}_{k\ge 1}$ in the space $L_2([0,t])$ of square integrable functions on $[0,t]$ and set

$$\xi_{k,l} = \int_0^t m_k(s)dy^l(s).$$

Note that due to property (i) of the measure $\tilde{\mathrm{P}}$, $\xi_{k,l}$ are independent Gaussian random variables with zero mean and unit variance.

Let H_n be the nth Hermite polynomial defined by

$$H_n(x) = (-1)^n e^{x^2/2}\frac{d^n}{dx^n}e^{-x^2/2}. \tag{2.5}$$

It is well known (see, e.g., [7] or Theorem A.1) that the collection

$$\left\{\xi_\alpha := \prod_{k,l}\left(\frac{H_{\alpha_k^l}(\xi_{k,l})}{\sqrt{\alpha_k^l!}}\right),\quad \alpha \in J\right\}$$

is a complete orthonormal system (CONS) in $L_2(\Omega, \mathcal{F}_t^y, \tilde{\mathrm{P}})$.

To illustrate how the system is constructed, consider the case $r = 1$. Then α is a multiindex of the form $(\alpha_1, \alpha_2, \dots)$. If $|\alpha| = 0$ (i.e., $\alpha = (0, 0, \dots)$), then obviously $\xi_\alpha \equiv 1$.

If $|\alpha| = 1$, then the multiindex α is of the form $(0, \dots, 0, 1, 0, \dots)$ (i.e., $\alpha_i = 1$, $\alpha_k = 0$, $k \neq i$). In this case, $\xi_\alpha = \int_0^t m_i(s)dy(s)$.

Similarly, if $|\alpha| = 2$, then α is of either the form

$$(0, \dots, 0, 1, 0, \dots, 0, 1, 0, \dots)$$

(if $i < j$ and $\alpha_i = \alpha_j = 1$, $\alpha_k = 0, k \neq i, j$) or the form $(0, \dots, 0, 2, 0, \dots)$ (if $i = j$). For such α we have

$$\xi_\alpha = \Big(\int_0^t m_i(s)dy(s) \Big) \Big(\int_0^t m_j(s)dy(s) \Big)$$

in the first case,

$$\xi_\alpha = \frac{1}{\sqrt{2}} \Big[\Big(\int_0^t m_i(s)dy(s) \Big)^2 - 1 \Big]$$

in the second case, and so on. See also Remark A.2.

First, we will focus on the expansion of the UFD in the Wick polynomials ξ_α. To determine the coefficients of the expansion we consider the following system of deterministic PDEs:

$$\begin{aligned} \frac{\partial \varphi_\alpha(s,x)}{\partial s} &= \mathcal{L}^* \varphi_\alpha(s,x) + \textstyle\sum_{k,l} \alpha_k^l m_k(s) h^l(x) \varphi_{\alpha(k,l)}(s,x), \quad 0 < s \leq t, \\ \varphi_\alpha(0,x) &= p(x) 1_{\{|\alpha|=0\}}, \end{aligned} \tag{2.6}$$

where $\alpha = (\alpha_k^l)_{1 \leq l \leq r,\ k \geq 1} \in J$ and $\alpha(i,j)$ stands for the multiindex $\tilde{\alpha} = (\tilde{\alpha}_k^l)_{1 \leq l \leq r,\ k \geq 1}$ with

$$\tilde{\alpha}_k^l = \begin{cases} \alpha_k^l & \text{if } k \neq i \text{ or } l \neq j \text{ or both}, \\ \max(0, \alpha_i^j - 1) & \text{if } k = i \text{ and } l = j. \end{cases} \tag{2.7}$$

This system is recursive in $|\alpha|$: once we know the functions φ_α for all α of length $|\alpha| = k$, we can compute all φ_α for $|\alpha| = k + 1$. To illustrate the idea, again consider the case $r = 1$. Let us write φ_0 for the φ_α with $\alpha = (0, 0, \dots, 0, \dots)$ ($|\alpha| = 0$). Then $\varphi_0(s,x)$ satisfies the forward Kolmogorov equation corresponding to the state process:

$$\begin{aligned} \frac{\partial \varphi_0(s,x)}{\partial s} &= \mathcal{L}^* \varphi_0(s,x), \\ \varphi_0(0,x) &= p(x). \end{aligned}$$

If $|\alpha| = 1$ with $\alpha_i = 1$ and we write φ_i for φ_α with this α, then the corresponding equation in (2.6) becomes

$$\begin{aligned} \frac{\partial \varphi_i(s,x)}{\partial s} &= \mathcal{L}^* \varphi_i(s,x) + m_i(s) h(x) \varphi_0(s,x), \\ \varphi_i(0,x) &= 0. \end{aligned}$$

For $|\alpha| = 2$, the corresponding function $\varphi_{ij},\ i \leq j$, satisfies the equation

$$\begin{aligned} \frac{\partial \varphi_{ij}(s,x)}{\partial s} &= \mathcal{L}^* \varphi_{ij}(s,x) + m_i(s) h(x) \varphi_j(s,x) + m_j(s) h(x) \varphi_i(s,x), \\ \varphi_{ij}(0,x) &= 0, \end{aligned}$$

and so on.

Under assumptions (A1) and (A3), system (2.6) has a unique smooth solution (see Proposition A.1 for details).

Our approach is based on the following expansion of the UFD.

THEOREM 2.1 (Mikulevicius and Rozovskii [30, 31]). *Assume* (A1)–(A3). *Then for each* $x \in \mathbf{R}^d$ *the UFD is given by*

$$u(t,x) = \sum_{\alpha \in J} \frac{1}{\sqrt{\alpha!}} \varphi_\alpha(t,x)\xi_\alpha \quad (\mathrm{P}-\text{a.s.}). \tag{2.8}$$

This series converges in $L_2(\Omega, \tilde{\mathrm{P}})$, *and* $L_1(\Omega, \mathrm{P})$, *and the following Parseval's equality holds:*

$$\tilde{\mathbf{E}}|u(t,x)|^2 = \sum_{\alpha \in J} \frac{1}{\alpha!} |\varphi_\alpha(t,x)|^2. \tag{2.9}$$

Proof of this theorem is given in the appendix.

For the computational purposes one needs to truncate the sum in the expansion of u. This sum is "double infinite." Writing

$$u(t,x) = \sum_{k=0}^{\infty} \sum_{|\alpha|=k} \frac{1}{\sqrt{\alpha!}} \varphi_\alpha(t,x)\xi_\alpha, \tag{2.10}$$

one can see that for $k \geq 1$ there are infinitely many multiindices α with $|\alpha| = k$. To make it finite, we have to bound the length $|\alpha|$ of α and also the order $d(\alpha)$ of α: if $d(\alpha) \leq n$, then there are at most $(nr)^k$ multiindices α with $|\alpha| = k$.

Recall that if $\alpha = (\alpha_k^l)_{1 \leq l \leq r,\ k \geq 1}$, then α_k^l defines the degree of the Hermite polynomial of $\int_0^t m_k(s)dy^l(s)$ used in the construction of ξ_α. If $d(\alpha) \leq n$, then $\alpha_k^l = 0$ for all $k > n$, so the truncation of the order of α is equivalent to keeping only the first n elements of the (deterministic) basis $\{m_k(s)\}_{k \geq 1}$.

On the other hand, by restricting the length of α, we eliminate a number of elements of the stochastic basis $\{\xi_\alpha\}$, which are otherwise available with the retained collection of $\{m_k\}$.

Thus, restriction of the order of α makes the inner sum in (2.10) finite and is equivalent to the truncation of the deterministic basis $\{m_k\}$, while restriction of the length of α makes the outer sum in (2.10) finite and is equivalent to the truncation of the stochastic basis ξ_α.

The following theorem gives the upper bound on the error that one makes by doing both truncations for a particular choice of the basis $\{m_k\}$.

THEOREM 2.2. *Suppose that assumptions* (A1)–(A3) *hold and the deterministic basis* $\{m_k\}$ *is chosen as follows:*

$$m_1(s) = \frac{1}{\sqrt{t}}, \quad m_k(s) = \sqrt{\frac{2}{t}} \cos\Big(\frac{\pi(k-1)s}{t}\Big),\ k > 1,\ 0 \leq s \leq t.$$

Write $J_N^n = \{\alpha \in J : |\alpha| \leq N,\ d(\alpha) \leq n\}$ *and define*

$$u_N^n(t,x) := \sum_{\alpha \in J_N^n} \frac{1}{\sqrt{\alpha!}} \varphi_\alpha(t,x)\xi_\alpha. \tag{2.11}$$

Then

$$\tilde{\mathbf{E}}||u_N^n(t,\cdot) - u(t,\cdot)||_{L_2}^2 \leq Be^{Bt}\Big(\frac{(h_0 t)^{N+1}}{(N+1)!}||p||_{L_2}^2 + \frac{t^3}{n}||p||_{\mathbf{H}^2}^2\Big), \tag{2.12}$$

$$\sup_{x\in\mathbf{R}^d}\tilde{\mathbf{E}}|u_N^n(t,x)-u(t,x)|^2\le Ce^{Ct}\Big(\frac{(h_0t)^{N+1}}{(N+1)!}||p||^2_{\mathbf{C}_b^0}+\frac{t^3}{n}||p||^2_{\mathbf{C}_b^2}\Big). \tag{2.13}$$

Constants B and C depend only on the coefficients b, σ, and h of the model and $h_0:=\sum_{l=1}^r\sup_{x\in\mathbf{R}^d}|h^l(x)|^2$.

This and the following theorems will be proven in section 3.

REMARK 2.1. *For different k and l, random variables $\int_0^t m_k(s)dy^l(s)$, which make the stochastic basis ξ_α, are idependent and identically distributed $\mathcal{N}(0,1)$ under measure $\tilde{\mathrm{P}}$ for any CONS $\{m_k\}$. This suggests that the part of the error due to the truncation in the length of α should be independent of the choice of $\{m_k\}$, and the analysis of the proof shows that this is indeed the case. On the other hand, the error due to the truncation of the order of α crucially depends on the choice of $\{m_k\}$ (see also Remark* 3.1).

Truncations in the order and in the length can be done independently of each other. If $n=\infty$, we have truncation in length only; this case was studied by Mikulevicius and Rozovskii [30].

The Hermite–Fourier coefficients φ_α in (2.10) and (2.11) can be computed off-line, since system (2.6) does not involve the observation process y. In spite of this important property, approximation (2.11) does not yet provide an effective numerical algorithm for computing the UFD. The major reason for this is that the error of truncation may grow exponentially with t, so we can expect (2.11) to give a good approximation only for sufficiently small t. The above is a typical problem for approximations of solutions of parabolic equations (both deterministic and stochastic). One can try to offset this effect by choosing a higher-order approximation (in our case by taking larger N and n). However, higher-order numerical schemes are slower and often numerically unstable. A standard way to overcome the exponential growth of the truncation errors is to develop a recursive procedure by iterating the one-step approximation.

REMARK 2.2. *Of course, for the recursive approximation to converge, it is necessary that the error of the one-step approximation converges to zero fast enough as $t\downarrow 0$. By Theorem* 2.2*, the short time asymptotics of the error of approximation* (2.11) *are of order t if $N=1$ and of order $t^{3/2}$ if $N>1$, so it is possible to use* (2.11) *to costruct a multistep approximation* (*Theorem* 2.4).

In what follows, we present a recursive version of the expansion (2.8). It will allow us to modify the corresponding numerical scheme and eliminate the possible error growth.

Let $0=t_0<t_1<\cdots<t_M=T$ be a uniform partition of the interval $[0,T]$ with step Δ (so that $t_i=i\Delta$, $i=0,\dots,M$). Let $\{m_k^i\}=\{m_k^i(s)\}_{k\ge1}$ be a CONS in $L_2([t_{i-1},t_i])$. We also define random variables

$$\left\{\xi_\alpha^i:=\prod_{k,l}\left(\frac{H_{\alpha_k^l}(\xi_{k,l}^i)}{\sqrt{\alpha_k^l!}}\right),\quad \alpha\in J\right\}, \tag{2.14}$$

where $\xi_{k,l}^i=\int_{t_{i-1}}^{t_i}m_k^i(s)dy^l(s)$ and H_n is the nth Hermite polynomial (2.5).

Consider the following system of equations:

$$\begin{aligned}\frac{\partial\varphi_\alpha^i(s,x,g)}{\partial s}&=\mathcal{L}^*\varphi_\alpha^i(s,x,g)+\sum_{k,l}\alpha_k^lm_k^i(s)h^l(x)\varphi_{\alpha(k,l)}^i(s,x,g),\qquad t_{i-1}<s\le t_i,\\ \varphi_\alpha^i(t_{i-1},x,g)&=g(x)1_{\{|\alpha|=0\}},\end{aligned} \tag{2.15}$$

where $g(x)$ is a function to be determined. For each $i = 1, \dots, M$ this system is similar to (2.6). The main new feature is that the initial time moment is no longer zero and we now allow *that an arbitrary initial condition g may be different for different i*; this dependence on g is indicated explicitly in the arguments of φ.

The following is the recursive version of Theorem 2.1.

THEOREM 2.3. *Define $u(t_0, x) := p(x)$. Then for each $x \in \mathbf{R}^d$ and each t_i, $i = 1, \dots, M$, the UFD is given by*

$$u(t_i, x) = \sum_{\alpha \in J} \frac{1}{\sqrt{\alpha!}} \varphi_\alpha^i(t_i, x, u(t_{i-1}, \cdot)) \xi_\alpha^i, \quad i = 1, \dots, M \ (P - \ a.s.). \tag{2.16}$$

This series converges in $L_2(\Omega, \tilde{\mathrm{P}})$ and $L_1(\Omega, \mathrm{P})$, and the following Parseval's equality holds:

$$\tilde{\mathbf{E}} |u(t_i, x)|^2 = \sum_{\alpha \in J} \frac{1}{\alpha!} \tilde{\mathbf{E}} |\varphi_\alpha(t, x, u(t_{i-1}, \cdot))|^2, \qquad i = 1, \dots, M.$$

This result follows easily from Theorem 2.1, since (2.4) is linear with a unique solution, and random variables $u(t_{i-1}, x)$ and ξ_α^i are independent under measure $\tilde{\mathrm{P}}$.

Again, for computational purposes, we need to perform truncations in (2.16). For that purpose, as in Theorem 2.2, we will use the special basis $\{m_k^i\}$:

$$\begin{aligned} &m_k^i(s) = m_k(s - t_{i-1}), \qquad t_{i-1} \le s \le t_i, \\ &m_1(s) = \frac{1}{\sqrt{\Delta}}, \quad m_k(s) = \sqrt{\frac{2}{\Delta}} \cos\Big(\frac{\pi(k-1)s}{\Delta}\Big), \ k > 1, \quad 0 \le s \le \Delta, \\ &m_k(s) = 0, \qquad k \ge 1, \ s \notin [0, \Delta]. \end{aligned} \tag{2.17}$$

THEOREM 2.4. *Suppose that basis $\{m_k^i\}$ is given by* (2.17) *and assumptions* (A1)–(A3) *hold. Define $u_N^n(t_0, x) := p(x)$ and by induction*

$$u_N^n(t_i, x) := \sum_{\alpha \in J_N^n} \frac{1}{\sqrt{\alpha!}} \varphi_\alpha^i(\Delta, x) \xi_\alpha^i, \tag{2.18}$$

where $J_N^n = \{\alpha \in J : |\alpha| \le N, \ d(\alpha) \le n\}$ and φ_α^i are solutions of the system

$$\begin{aligned} &\frac{\partial \varphi_\alpha^i(s, x)}{\partial s} = \mathcal{L}^* \varphi_\alpha^i(s, x) + \textstyle\sum_{k,l} \alpha_k^l m_k(s) h^l(x) \varphi_{\alpha(k,l)}^i(s, x), \quad 0 < s \le \Delta, \\ &\varphi_\alpha^i(0, x) = u_N^n(t_{i-1}, x) 1_{\{|\alpha| = 0\}}. \end{aligned} \tag{2.19}$$

Then

$$\max_{1 \le i \le M} \tilde{\mathbf{E}} ||u_N^n(t_i, \cdot) - u(t_i, \cdot)||_{L_2}^2 \le B e^{BT} \Big(\frac{(h_0 \Delta)^N}{(N+1)!} ||p||_{L_2}^2 + \frac{\Delta^2}{n} ||p||_{\mathbf{H}^2}^2 \Big), \tag{2.20}$$

$$\max_{1 \le i \le M} \sup_{x \in \mathbf{R}^d} \tilde{\mathbf{E}} |u_N^n(t_i, x) - u(t_i, x)|^2 \le C e^{CT} \Big(\frac{(h_0 \Delta)^N}{(N+1)!} ||p||_{\mathbf{C}_b^0}^2 + \frac{\Delta^2}{n} ||p||_{\mathbf{C}_b^2}^2 \Big). \tag{2.21}$$

Constants B and C depend only on the coefficients b, σ, and h of the model and $h_0 := \sum_{l=1}^r \sup_{x \in \mathbf{R}^d} |h^l(x)|^2$.[3]

[3] Of course, B and C here are, in general, different from constants B and C in Theorem 2.2.

The sequence $\{u_N^n(t_i,x)\}_{1\le i\le M}$ gives an approximation to the UFD at all points of the time grid. This is a flexible and comparatively universal approximation. Many well-known numerical schemes for the Zakai equation can be obtained as particular cases of (2.18). In section 4 we will demonstrate this for two well-known algorithms: the explicit Euler scheme and the splitting-up method.

REMARK 2.3. *Analysis of the proofs of Theorems* 2.2–2.4 *shows that the wavelet type structure of our "global" basis* $\mathcal{M}=\cup_{i=1}^M\cup_{k=1}^\infty\{m_k^i\}$ *is of central importance.*

Specifically the following two properties of the basis are crucial:

(1) *The global basis* $\mathcal{M}$ *is a direct sum of "local" bases* $\mathcal{M}^i=\cup_{k=1}^\infty\{m_k^i\}$ *with nonoverlapping supports* (*Theorems* 2.3–2.5).

(2) *The functions* $m_k^i(s)$ *are smooth and* $\int_{t_{i-1}}^{t_i} m_k^i(s)ds=0$ *for* $k\ge 2$, $i=1,\dots,M$ (*see Theorem* 2.4).

The recursive version (2.18) of the spectral approximation of the unnormalized filtering density has one important disadvantage as compared to the one-step approximation (2.11). Indeed, to compute $u_N^n(t_i,x)$ we have to solve a certain number of equations from system (2.19). Although these equations are the same on every time interval and their coefficients do not involve the observation process y, the initial condition for the first equation of the system, $u_N^n(t_{i-1},x)$, does. This fact of course rules out off-line computation of the Fourier–Hermite coefficients $\varphi_\alpha(t,x)$, which is one of the important objectives of our study. For this reason, we present below a modification of the expansion (2.18) which admits off-line computations. Loosely speaking, the idea is to expand the initial condition for the first equation of (2.19) in a Fourier series as a function of spatial variable x, $u_N^n(t_{i-1},x)=\sum_l c_l e_l(x)$, and to exploit the obvious relation

$$\varphi_\alpha(t_i,x,u(t_{i-1},x))=\sum_l c_l\varphi_\alpha(t_i,x,e_l).$$

Note that the functions $\varphi_\alpha(t_i,x,e_l)$ can be computed off-line.

THEOREM 2.5. *Let* $\{e_l\}=\{e_l(x)\}_{l\ge1}$, $e_l\in\cap_n\mathbf{H}^n$, *be a CONS in* $L_2(\mathbf{R}^d)$ *and* $(\cdot,\cdot)$ *be the inner product in that space. Suppose that assumptions* (A1)–(A3) *hold and* $\{m_k^i\}$ *are given by* (2.17). *Consider the following system of equations:*

(2.22)
$$\frac{\partial\varphi_\alpha(s,x,g)}{\partial s}=\mathcal{L}^*\varphi_\alpha(s,x,g)+\sum_{k,l}\alpha_k^l m_k(s)h^l(x)\varphi_{\alpha(k,l)}(s,x,g),\qquad 0<s\le\Delta,$$
$$\varphi_\alpha(0,x,g)=g(x)1_{\{|\alpha|=0\}}.$$

Define $q_{\alpha k}^l:=(\varphi_\alpha(\Delta,\cdot,e_k),e_l)$ *and then by induction*

(2.23)
$$\psi_l(0,N,n):=(p,e_l),$$
$$\psi_l(i,N,n):=\sum_{\alpha\in J_N^n}\sum_k\frac{1}{\sqrt{\alpha!}}\psi_k(i-1,N,n)q_{\alpha k}^l\xi_\alpha^i.$$

Then

(2.24)
$$u_N^n(t_i,x)=\sum_l\psi_l(i,N,n)e_l(x),\ 0\le i\le M\quad(P-\ a.s.).$$

Now we can describe an approximation algorithm which stems from Theorem 2.5.

(1) Before the observations become available, (a) choose a finite collection $\{e_l\}_{1\le l\le\kappa}$;

(b) compute $\psi_l(0,N,n,\kappa) := (p,e_l),\ 1 \le l \le \kappa$, where p is the initial density;
(c) for all $\alpha \in J_N^n$ and $l = 1,\dots,\kappa$ compute $\varphi_\alpha(\Delta,x,e_l)$;
(d) compute $q_{\alpha k}^l = (\varphi_\alpha(\Delta,\cdot,e_k),e_l)$.
(2) On the ith step, when the observations become available,
(a) compute ξ_α^i;
(b) compute $\psi_l(i,N,n,\kappa) := \sum_{\alpha\in J_N^n}\sum_{k=1}^{\kappa}(1/\sqrt{\alpha!})\psi_k(i-1,N,n,\kappa)q_{\alpha k}^l\xi_\alpha^i$ for $l = 1,\dots,\kappa$;
(c) compute

$$u_N^{n,\kappa}(t_i,x) := \sum_{l=1}^{\kappa}\psi_l(i,N,n,\kappa)e_l(x). \tag{2.25}$$

.

We refer to this algorithm as the spectral separating scheme (S^3).

REMARK 2.4. *The amount of on-line operations and the amount of information that has to be stored in each step of* S^3 *do not depend on the number of steps to be performed. Also in contrast to the standard time-discretization schemes for the Zakai equation,* S^3 *does not require computing of the UFD at all the grid points* t_i, $i = 1,\dots,M$. *Specifically, step* 2(c) *of the algorithm can be omitted on any subset of time grid points (e.g., everywhere except the final point* t_M*). Note that computing of* (2.25) *is time consuming since it has to be done at all points of the space mesh.*

The truncation of the basis $\{e_l\}$ assumed in the above algorithm is necessary for computational reasons. Obviously it adds an extra error to (2.20). It is also clear that the error depends on the choice of the basis $\{e_l\}$ and is very much related to the particular numerical scheme used to solve (2.22).

It is beyond the scope of this work to study the above questions in detail, so we restrict ourselves to one particular case.

THEOREM 2.6. *Suppose that* $\{e_l\}$ *is the Hermite basis in* $L_2(\mathbf{R}^d)$ [16].

Let $0 = t_0 < \cdots < t_M = T$ *be a uniform partition of* $[0,T]$ *and* $u_N^n(t_i,x)$ *and* $u_N^{n,\kappa}(t_i,x)$ *be defined by* (2.18) *and* (2.25)*, respectively. Assume that* (A1)–(A3) *hold and in addition the initial density* p *and all its derivatives decay faster than any negative power of* $|x|$ *as* $|x| \to \infty$.

Then for any positive integer γ *there is a real number* $C_\gamma > 0$ *depending only on* γ *and the parameters* σ, b, p, *and* d *of the model such that*

$$\max_{1\le i\le M}\sqrt{\tilde{\mathbf{E}}||u_N^n(t_i,\cdot) - u_N^{n,\kappa}(t_i,\cdot)||_{L_2}^2} \le \frac{MC_\gamma(e^{C_\gamma T}-1)}{T\kappa^{\gamma-1/2}}. \tag{2.26}$$

This theorem shows that for sufficiently smooth initial condition p and with appropriate choice of the basis $\{e_l\}$, the error due to the truncation of the basis decays faster than any power of κ; i.e., our approximation is of a "spectral quality" (see, e.g., [15]).

REMARK 2.5. *The overall error of approximation for the spectral separating scheme follows from* (2.20) *and* (2.26) *and is given by*

$$\max_{1\le i\le M}\tilde{\mathbf{E}}||u(t_i,\cdot) - u_N^{n,\kappa}(t_i,\cdot)||_{L_2}^2 \le C\Big(\frac{(h_0\Delta)^N}{(N+1)!} + \frac{\Delta^2}{n} + \frac{C(\gamma)}{\Delta^2\kappa^{2\gamma-1}}\Big), \tag{2.27}$$

where C *is a constant depending on the parameters of the model (including the initial density* p *and the length of the time interval* T*) and it is assumed that the Wiener integrals* $\int_{t_{i-1}}^{t_i} m_k(t)dy^l(t)$ *are computed exactly. If* $n = 1$, *then only increments of the*

observation process are needed at each step and the computation of the integrals does not introduce any additional error. For $n > 1$, the integrals $\int_{t_{i-1}}^{t_i} m_k(t)dy^l(t),\ k > 1$, can be reduced to Riemann integrals and then approximated by subdividing the interval $[t_{i-1}, t_i]$ with some step $\delta << \Delta$. The error of the corresponding approximation will depend on the new asymptotic parameter δ. Still, formula (2.27) *implies that, in the limit $\lim_{\Delta\to 0}\lim_{\kappa\to\infty}$, the schemes with $n = 1$ and $n > 1$ have the same rate of convergence.*

REMARK 2.6. *Another approximation based on the Haar basis was proposed by Budhiraja and Kallianpur* [5]. *The approximation in* [5] *converges when $N \uparrow \infty$ and $\Delta \downarrow 0$. For computational purposes, though, it can be difficult to take arbitrarily large values of N because of the growing complexity and possible numerical instability. On the other hand, it follows from* (2.27) *that the spectral separating scheme converges in the limit $\lim_{\Delta\to 0}\lim_{\kappa\to\infty}$ for every $N \geq 1$ and the rate of convergence is the same for all $N \geq 2$.*

We remark that Theorems 2.1–2.6 can be extended to the case of time-dependent coefficients. Theorems 2.1–2.6 hold if the coefficients belong to the Hölder space $\mathbf{C}^{2+\alpha}(\mathbf{R}^d)$ for each t. The generalization is straightforward yet a bit cumbersome. Theorems 2.1–2.2 can be carried over to the case of correlated noises without many changes in the proofs [29, 31]. On the other hand the error estimates in the latter case are more delicate.

By no means is our approach a universal one. For example, it requires advanced knowledge of the parameters of the system, which are not always readily available. Also, it is not clear if it could be extended to the case of a non-Markov state process.

3. Proofs. In this section we will prove Theorems 2.2, 2.4, and 2.5. Everywhere C stands for a positive constant depending only on the parameters of the system; its actual value may be different in different places.

We introduce the following notation:

$\{T_s\}_{s\geq 0}$, the semigroup generated by the operator $\mathcal{L}^*$;

s^k, the the ordered set $(s_1, \dots, s_k)$; $ds^k := ds_1 \dots ds_k$;

$F(t; s^k; x) := T_{t-s_k} h T_{s_k - s_{k-1}} \dots h T_{s_1} p(x),\ k \geq 1$;

$\int^{(k)}(\cdots)ds^k := \int_0^t \int_0^{s_k} \dots \int_0^{s_2} (\cdots) ds_1 \dots ds_k$.

When $r = 1$, each multiindex $\alpha = (\alpha_1, \alpha_2, \dots)$ of length $|\alpha| = k$ can be identified with a vector $K_\alpha = (i_1^\alpha, \dots, i_k^\alpha)$, where $i_1^\alpha \leq i_2^\alpha \leq \dots \leq i_k^\alpha$. The first entry i_1^α of K_α is the number of the first nonzero element of α. The second entry i_2^α is equal to i_1^α if that first nonzero element $\alpha_{i_1^\alpha}$ is greater than 1; otherwise i_2^α is the number of the second nonzero element and so on. As a result, if $\alpha_j > 0$, then exactly α_j entries of the vector K_α are equal to j. We will call this vector the *characteristic set* of multiindex α. For example, if $\alpha = (0, 1, 0, 2, 3, 0, \dots)$, then nonzero elements are $\alpha_2 = 1,\ \alpha_4 = 2,\ \alpha_5 = 3$, and the characteristic set is $(2, 4, 4, 5, 5, 5)$. A similar construction is possible for general $r > 1$. In the future, when there is no danger of confusion, we will omit the upper index in i (i.e., write i_j rather than i_j^α).

Let $\mathcal{P}^k$ be the permutation group of the set $\{1, \dots, k\}$. For a given $\alpha \in J$ with $|\alpha| = k$ and the characteristic set $(i_1, \dots, i_k)$ $(r = 1)$ define

$$E_\alpha(s^k) := \sum_{\sigma\in\mathcal{P}^k} m_{i_1}(s_{\sigma(1)}) \cdots m_{i_k}(s_{\sigma(k)}).$$

Proof of Theorem 2.2. We will prove inequality (2.12); the other can be proven in a similar way.

Set

$$u_N(t,x) := \sum_{|\alpha|\le N} \frac{\varphi_\alpha(t,x)\xi_\alpha}{\sqrt{\alpha!}}.$$

Suppose that we know that

$$\tilde{\mathbf{E}}||u(t,\cdot) - u_N(t,\cdot)||^2_{L_2} \le \frac{(h_0 t)^{N+1}}{(N+1)!} e^{Ct} ||p||^2_{L_2} \tag{3.1}$$

and

$$\tilde{\mathbf{E}}||u_N(t,\cdot) - u^n_N(t,\cdot)||^2_{L_2} \le C\frac{t^3}{n} e^{Ct} ||p||^2_{\mathbf{H}^2}. \tag{3.2}$$

Then (2.12) will follow immediately from the inequality $(a+b)^2 \le 2(a^2+b^2)$.

The problem is thus to prove (3.1) and (3.2). To simplify the presentation, we assume that $r = 1$.

Proof of (3.1). We will use the following results:

$$\sum_{|\alpha|=k} \frac{\varphi^2_\alpha(t,x)}{\alpha!} = \int^{(k)} |F(t;s^k;x)|^2 ds^k, \tag{3.3}$$

where φ_α is the solution of (2.6) with any CONS $\{m_k\}$, and

$$||T_s f||^2_{L_2} \le e^{Cs} ||f||^2_{L_2}. \tag{3.4}$$

The first equality is established in the appendix, Proposition A.1 (see also [30]); inequality (3.4) is a standard fact (see [25]).

Since ξ_α are uncorrelated under $\tilde{\mathrm{P}}$, we have

$$\tilde{\mathbf{E}}|u(t,x) - u_N(t,x)|^2 = \sum_{k>N} \sum_{|\alpha|=k} \frac{\varphi^2_\alpha(t,x)}{\alpha!} = \sum_{k>N} \int^{(k)} |F(t;s^k;x)|^2 ds^k.$$

Then by the Fubini theorem

$$\begin{aligned}\tilde{\mathbf{E}}||u(t,\cdot) - u_N(t,\cdot)||^2_{L_2} &= \sum_{k>N} \int^{(k)} \Big(\int_{\mathbf{R}^d} |F(t;s^k;x)|^2 dx \Big) ds^k \\ &= \sum_{k>N} \int^{(k)} ||F(t,s^k,\cdot)||^2_{L_2} ds^k.\end{aligned}$$

Since h is bounded, it follows from the definition of F and (3.4) that

$$\begin{aligned}||F(t;s^k;\cdot)||^2_{L_2} &\le h_0 e^{C(t-s_k)} ||T_{s_k - s_{k-1}} h \dots h T_{s_1} p||^2_{L_2} \\ &\le \dots \le h_0^k e^{t - s_k + s_k - \dots + s_2 - s_1 + s_1} ||p||^2_{L_2} = h_0^k e^{Ct} ||p||^2_{L_2}.\end{aligned}$$

Finally, from $\int^{(k)} ds^k = t^k/k!$, we conclude that

$$\begin{aligned}\tilde{\mathbf{E}}||u(t,\cdot) - u_N(t,\cdot)||^2_{L_2} &\le e^{Ct} \sum_{k>N} \frac{(th_0)^k}{k!} \\ &\le \frac{(th_0)^{N+1}}{(N+1)!} e^{(C+h_0)t},\end{aligned}$$

and (3.1) follows. Note that it holds for any CONS $\{m_k\}$.

Proof of (3.2). If α is a multiindex with $|\alpha| = k$ and the characteristic set $(i_1^\alpha, \dots, i_k^\alpha)$, then $i_k^\alpha = d(\alpha)$, the order of α, and so the set J_N^n can be described as $\{\alpha \in J : |\alpha| \le N;\ i_{|\alpha|}^\alpha \le n\}$. Thus

$$\tilde{\mathbf{E}}|u_N^n(t,x) - u_N(t,x)|^2 = \sum_{l=n+1}^{\infty} \sum_{k=1}^{N} \sum_{|\alpha|=k; i_k^\alpha = l} \frac{\varphi_\alpha^2(t,x)}{\alpha!}.$$

The problem is thus to estimate $\sum_{l=n+1}^{\infty} \sum_{k=1}^{N} \sum_{|\alpha|=k; i_k^\alpha=l} \frac{\varphi_\alpha^2(t,x)}{\alpha!}$.

By Proposition A.1 (see also [30]) the corresponding solution φ_α of (2.6) can be written as

$$\varphi_\alpha(t,x) = \int^{(k)} F(t; s^k; x) E_\alpha(s^k) ds^k. \tag{3.5}$$

Note that we can also write

$$E_\alpha(s^k) = \sum_{j=1}^{k} m_{i_k}(s_j) E_{\alpha(i_k)}(s_j^k),$$

where s_j^k denotes the same set $(s_1, \dots, s_k)$ with omitted s_j (e.g., $s_1^k = (s_2, \dots, s_k)$) and $\alpha(i_k)$ is the multiindex with this characteristic set $(i_1, \dots, i_{k-1})$ (cf. (2.7); recall that $r = 1$).

This allows us to write (3.5) as

$$\varphi_\alpha(t,x) = \sum_{j=1}^{k} \int^{(k-1)} \Big(\int_{s_{j-1}}^{s_{j+1}} F(t; s^k; x) m_{i_k}(s_j) ds_j \Big) E_{\alpha(i_k)}(s_j^k) ds_j^k, \tag{3.6}$$

where $s_0 := 0;\ s_{k+1} := t$. (We just change the order of integration in the multiple integral.)

Denote

$$M_k(s) := \frac{\sqrt{2t}}{\pi(k-1)} \sin\Big(\frac{\pi(k-1)}{t} s\Big), \qquad k > 1,\ 0 \le s \le t,$$

and also $F_j := \frac{\partial F(t; s^k; x)}{\partial s_j}$. Then, as long as $i_k = l > 1$, we can integrate by parts the inner integral on the right of (3.6) to get

$$\begin{aligned} &\int_{s_{j-1}}^{s_{j+1}} F(t; s^k; x) m_l(s_j) ds_j \\ &\quad = F(t; s^k; x) M_l(s_j) \Big|_{s_j = s_{j-1}}^{s_j = s_{j+1}} - \int_{s_{j-1}}^{s_{j+1}} F_j(t, s^k, x) M_l(s_j) ds_j. \end{aligned}$$

For each j, let us rename the remaining variables s_j^k in (3.6) as follows: $t_i := s_i, i \le j-1;\ t_i := s_{i+1}, i > j-1$, or, symbolically, $t^{k-1} := s_j^k$. We will set $t_0 := 0$, $t_k := t$ and denote by $t^{k-1,j}, j = 1, \dots, k-1$, the set t^{k-1} in which t_j is repeated twice (e.g., $t^{k-1,1} = (t_1, t_1, \dots, t_{k-1})$, etc.); also $t^{k-1,0} := (t_0, t_1, t_2, \dots, t_{k-1})$, $t^{k-1,k} := (t_1, \dots, t_{k-1}, t_k)$.

Then

$$F(t;s^k;x)M_l(s_j)\Big|_{s_j=s_{j-1}}^{s_j=s_{j+1}}$$
$$= F(t;t^{k-1,j};x)M_l(t_j) - F(t;t^{k-1,j-1};x)M_l(t_{j-1}), \qquad j=1,\dots,k.$$

As a result, since $M_l(t_0)=M_l(t_k)=0$ (and this is the only place where the choice of $\{m_k\}$ really makes the difference), all these terms will cancel out as we sum over j. What remains can be written as

$$\int^{(k-1)} f_l(t;t^{k-1};x)E_{\alpha(l)}(t^{k-1})dt^{k-1},$$

where

$$f_l(t;t^{k-1};x) = -\int_0^{t_1} F_1(t;\tau,t^{k-1};x)M_l(\tau)d\tau$$
$$-\sum_{j=2}^{k-1}\int_{t_{j-1}}^{t_j} F_j(t;\dots,t_{j-1},\tau,t_j,\dots;x)M_l(\tau)d\tau$$
$$-\int_{t_{k-1}}^{t_k} F_k(t;t^{k-1},\tau;x)M_l(\tau)d\tau.$$

Then, since $|\alpha(i_{|\alpha|})| = |\alpha|-1$, $\alpha! \geq \alpha(i_{|\alpha|})!$, we get

$$\sum_{|\alpha|=k;i_k^\alpha=l} \frac{\varphi_\alpha^2(t,x)}{\alpha!}$$
$$= \sum_{|\alpha|=k;i_k^\alpha=l} \Big(\frac{1}{\sqrt{\alpha!}}\int^{(k-1)} f_l(t;t^{k-1};x)E_{\alpha(l)}(t^{k-1})dt^{k-1}\Big)^2$$
$$\leq \sum_{|\beta|=k-1} \Big(\frac{1}{\sqrt{\beta!}}\int^{(k-1)} f_l(t;t^{k-1};x)E_{\beta}(t^{k-1})dt^{k-1}\Big)^2,$$

and arguments similar to those used in the proof of Proposition A.1 show that the last expression is equal to

$$\int^{(k-1)} |f_l(t;t^{k-1};x)|^2 dt^{k-1}. \tag{3.7}$$

Direct computations yield

$$F_j(t,s^k,x) = T_{t-s_k}h\dots T_{s_{j+1}-s_j}h\mathcal{L}^*T_{s_j-s_{j-1}}\dots T_{s_1}p(x)$$
$$-T_{t-s_k}h\dots\mathcal{L}^*T_{s_{j+1}-s_j}hT_{s_j-s_{j-1}}\dots T_{s_1}p(x).$$

Since $\mathcal{L}^*$ is a continuous operator from $\mathbf{H}^2$ to L_2, it follows from (3.4) and a similar inequality for $\mathbf{H}^2$-norms that

$$||F_j(t;s^k;\cdot)||_{L_2}^2 \leq e^{Ct}C^k||p||_{\mathbf{H}^2}^2.$$

Then the definition of f_l and obvious inequalities

$$(a_1+\dots+a_k)^2 \leq k(a_1^2+\dots+a_k^2)$$

and

$$\left(\int_0^x f(y)dy\right)^2 \le x\int_0^x (f(y))^2 dy$$

imply

$$\begin{aligned}||f_l(t;t^{k-1};\cdot)||_{L_2}^2 &\le kC^k e^{Ct}||p||_{\mathbf{H}^2}^2 t\int_0^t (M_l(s))^2 ds\\ &\le \frac{kC^k t^3 e^{Ct}}{(l-1)^2}||p||_{\mathbf{H}^2}^2;\end{aligned}$$

so, since $\int^{(k-1)} dt^{k-1} = t^{k-1}/(k-1)!$, (3.7) and the last inequality yield

$$\sum_{|\alpha|=k, i_k^\alpha = l} \frac{||\varphi_\alpha^2(t,\cdot)||_{L_2}^2}{\alpha!} \le e^{Ct}||p||_{\mathbf{H}^2}^2 t^3 \frac{kC^k}{(l-1)^2(k-1)!}.$$

Now we collect everything to get

$$\begin{aligned}\tilde{\mathbf{E}}||u_N(t,\cdot) - u_N^n(t,\cdot)||_{L_2}^2 &= \sum_{l\ge n+1}\sum_{k=1}^N \sum_{|\alpha|=k; i_k^\alpha = l} \frac{\varphi_\alpha^2(t,x)}{\alpha!}\\ &\le Ct^3 e^{Ct}\Big(\sum_{k\ge 1}\frac{k(Ct)^{k-1}}{(k-1)!}\Big)\sum_{l\ge n}\frac{1}{l^2} \le C\frac{t^3}{n}e^{Ct}||p||_{\mathbf{H}^2}^2.\end{aligned}$$

This completes the proof of (3.2) and the theorem as a whole. □

Proof of Theorem 2.4. We again prove only the first inequality.

First of all notice that time homogeneity of (2.15) and the special choice of $\{m_k^i\}$ as $m_k^i(s) = m_k(s - t_{i-1})$ imply

$$\varphi_\alpha^i(\Delta, x) = \varphi_\alpha^i(t_i, x, u(t_{i-1},\cdot))$$

(see (2.15) and (2.19)). Then by Fubini's theorem and Theorem 2.3 and due to linearity of system (2.15),

$$\begin{aligned}\tilde{\mathbf{E}}||u_N^n(t_i,\cdot) - u(t_i,\cdot)||_{L_2}^2 &= \sum_{\alpha\in J_N^n}\frac{1}{\alpha!}\tilde{\mathbf{E}}||\varphi_\alpha^i(t_i,\cdot,u_N^n(t_{i-1},\cdot) - u(t_{i-1},\cdot))||_{L_2}^2\\ &\quad + \sum_{\alpha\notin J_N^n}\frac{1}{\alpha!}\tilde{\mathbf{E}}||\varphi_\alpha^i(t_i,\cdot,u(t_{i-1},\cdot))||_{L_2}^2\\ &\le \sum_{\alpha\in J}\frac{1}{\alpha!}\tilde{\mathbf{E}}||\varphi_\alpha^i(t_i,\cdot,u_N^n(t_{i-1},\cdot) - u(t_{i-1},\cdot))||_{L_2}^2\\ &\quad + \sum_{\alpha\notin J_N^n}\frac{1}{\alpha!}\tilde{\mathbf{E}}||\varphi_\alpha^i(t_i,\cdot,u(t_{i-1},\cdot))||_{L_2}^2.\end{aligned} \tag{3.8}$$

By Theorem 2.3 and linearity of equation (2.4), we have

$$\begin{aligned}&\sum_{\alpha\in J}\frac{1}{\alpha!}\tilde{\mathbf{E}}||\varphi_\alpha^i(t_i,\cdot,u_N^n(t_{i-1},\cdot) - u(t_{i-1},\cdot))||_{L_2}^2\\ &\qquad = \tilde{\mathbf{E}}||U(t_i,x;u_N^n(t_{i-1},\cdot) - u(t_{i-1},\cdot))||_{L_2}^2,\end{aligned} \tag{3.9}$$

where $U(t,x;u_N^n(t_{i-1},\cdot)-u(t_{i-1},\cdot))$ is the solution of

$$\begin{aligned} dv(t,x) &= \mathcal{L}^* v(t,x)dt + h^l(x)v(t,x)dy^l(t), \quad t\in(t_{i-1},t_i],\\ v(t_{i-1},x) &= u_N^n(t_{i-1},x)-u(t_{i-1},x). \end{aligned}$$

It is a standard fact that under assumptions (A1) and (A3),

$$\tilde{\mathbf{E}}||U(t_i,\cdot;u_N^n(t_{i-1},\cdot)-u(t_{i-1},\cdot))||_{L_2}^2 \le e^{C\Delta}\tilde{\mathbf{E}}||u_N^n(t_{i-1},\cdot)-u(t_{i-1},\cdot)||_{L_2}^2 \tag{3.10}$$

(see, e.g., [34]).

Repeating the same arguments as in the proof of Theorem 2.2, one can check that

$$\begin{aligned} &\sum_{\alpha\notin J_N^n}\frac{1}{\alpha!}\tilde{\mathbf{E}}||\varphi_\alpha^i(t_i,\cdot,u(t_{i-1},\cdot))||_{L_2}^2\\ &\qquad \le Ce^{C\Delta}\Big(\frac{(h_0\Delta)^{N+1}}{(N+1)!}\tilde{\mathbf{E}}||u(t_{i-1},\cdot)||_{L_2}^2+\frac{\Delta^3}{n}\tilde{\mathbf{E}}||u(t_{i-1},\cdot)||_{\mathbf{H}^2}^2\Big). \end{aligned} \tag{3.11}$$

Finally, we use the inequalities

$$\tilde{\mathbf{E}}||u(t_{i-1},\cdot)||_{L_2}^2 \le e^{CT}||p||_{L_2}^2 \tag{3.12}$$

and

$$\tilde{\mathbf{E}}||u(t_{i-1},\cdot)||_{\mathbf{H}^2}^2 \le e^{CT}||p||_{\mathbf{H}^2}^2. \tag{3.13}$$

These inequalities are similar to (3.10) and can also be found in [34].

If we now denote $\tilde{\mathbf{E}}||u_N^n(t_i,\cdot)-u(t_i,\cdot)||_{L_2}^2$ by ε_i, then, combining (3.8)–(3.13), we arrive at

$$\varepsilon_i \le \left(\varepsilon_{i-1}+Ce^{CT}\Big(\frac{(h_0\Delta)^{N+1}}{(N+1)!}||p||_{L_2}^2+\frac{\Delta^3}{n}\tilde{\mathbf{E}}||p||_{\mathbf{H}^2}^2\Big)\right)e^{C\Delta},$$

and since $\varepsilon_0=0$, the statement of the theorem follows from the discrete Gronwall lemma. □

Proof of Theorem 2.5. By construction, $u_N^n(t_i,\cdot)\in L_2(\mathbf{R}^d)$ (P − a.s.), so

$$u_N^n(t_i,x)=\sum_{l\ge1}\psi_l(i,N,n)e_l(x) \quad (\mathrm{P}-\text{a.s.})$$

with some $\psi_l(i,N,n)$. Then all we have to do is to establish (2.23), which means

$$\sum_{\alpha\in J_N^n}\sum_k\frac{1}{\sqrt{\alpha!}}\psi_k(i-1,N,n)q_{\alpha k}^l\xi_\alpha^i=(u_N^n(t_i,\cdot),e_l). \tag{3.14}$$

We will prove this by induction. For $i=0$, $\psi_l(0,N,n)=(u_N^n(t_0,\cdot),e_l)$ by definition. Assume that $u_N^n(t_{i-1},x)=\sum_l\psi_l(i-1,N,n)e_l(x)$ for some $i\ge1$.

The proof of Theorem 2.2 shows that operator $g\mapsto\varphi_\alpha(t_i,\cdot,g)$ is continuous and linear from $L_2(\mathbf{R}^d)$ to $L_2(\mathbf{R}^d)$ for all $\alpha\in J$, where $\varphi_\alpha(t_i,\cdot,g)$ is the solution of (2.22). Then

$$\begin{aligned} \sum_k\psi_k(i-1,N,n)q_{\alpha k}^l &= \sum_k\psi_k(i-1,N,n)(\varphi_\alpha(\Delta,\cdot,e_k),e_l)\\ &= \Big(\varphi_\alpha\Big(\Delta,\cdot,\sum_k\psi_k(i-1,N,n)e_k\Big),e_l\Big), \end{aligned}$$

and by an induction assumption the right-hand side of the above formula is equal to

$$(\varphi_\alpha(\Delta, \cdot, u_N^n(t_{i-1}, \cdot)), e_l).$$

On the other hand, comparing (2.19) and (2.22) we conclude that

$$\varphi_\alpha(\Delta, x, u_N^n(t_{i-1}, \cdot)) = \varphi_\alpha^i(\Delta, x).$$

As a result,

$$\sum_{\alpha \in J_N^n} \sum_k \frac{1}{\sqrt{\alpha!}} \psi_k(i-1, N, n) q_{\alpha k}^l \xi_\alpha^i = \Big(\sum_{\alpha \in J_N^n} \frac{1}{\sqrt{\alpha!}} \varphi_\alpha^i(t_i, \cdot, u_N^n(t_{i-1}, \cdot)) \xi_\alpha^i, e_l \Big),$$

and by (2.18) this is equal to $(u_N^n(t_i, \cdot), e_l)$. This completes the proof of (3.14) and the theorem as a whole. □

REMARK 3.1. *Analysis of the proof shows that the result (with obvious modifications) is also true for the exact solution $u(t_i, x)$.*

Proof of Theorem 2.6. In what follows, C_γ denotes a constant depending on γ and (maybe) the parameters of the model. As before, C is a constant depending only on the parametes of the model. Values of C and C_γ may be different in different places.

If $d = 1$, then

$$e_l(x) = \frac{1}{\sqrt{(2\pi)^{1/2} l!}} e^{-x^2/4} H_l(x), \tag{3.15}$$

where H_l is the lth Hermite polynomial (2.5) [15, 16].

For $d > 1$, the elements of the basis are

$$e_l(x_1, \dots, x_d) = e_{l_1}(x_1) \dots e_{l_d}(x_d),$$

where $l_i \geq 0$ and e_{l_i} are given by (3.15), $i = 1, \dots, d$ [16]. The system $\{e_l\}$ is thus indexed by the set of d-dimensional multiindices $l = (l_1, \dots, l_d)$ ordered in some natural way. We will say that $l \leq \kappa$ if $\max_{1 \leq i \leq d} l_i \leq \kappa$.

To simplify the presentation, we assume from now on that $d = 2$. Then $l = (l_1, l_2)$.

Direct computations show that e_{l_i} satisfies

$$\mathcal{A}_i e_{l_i} = (l_i + 1) e_{l_i}, \quad i = 1, 2,$$

where operator $\mathcal{A}_i$ is defined by

$$\mathcal{A}_i f(x) = -\frac{\partial^2 f(x)}{\partial x_i^2} + \frac{2 + x_i^2}{4} f(x).$$

As a result, $\mathcal{A}_2 \mathcal{A}_1 e_l(x_1, x_2) = (l_1 + 1) \mathcal{A}_2 (e_{l_1}(x_1) e_{l_2}(x_2)) = (l_1 + 1)(l_2 + 1) e_l(x_1, x_2)$. This means that if f and all its derivative decay fast enough, then

$$|(f, e_l)| \leq \frac{||\mathcal{A}_1 \mathcal{A}_2 f||_{L_2}}{(l_1 + 1)(l_2 + 1)} \leq \dots \leq \frac{||(\mathcal{A}_1 \mathcal{A}_2)^\gamma f||_{L_2}}{(l_1 + 1)^\gamma (l_2 + 1)^\gamma}. \tag{3.16}$$

If $\mathbf{H}^s(r)$, $s, r \in \mathbf{R}$, is the weighted Sobolev space $W_2^s(r, \mathbf{R}^2)$ ([34]; see also [16]), then definition of $\mathcal{A}_i$ implies that

$$||(\mathcal{A}_1 \mathcal{A}_2)^\gamma f||_{L_2} \leq C_\gamma ||f||_{\mathbf{H}^{4\gamma}(4\gamma)},$$

and (3.16) becomes

$$|(f,e_k)| \le \frac{C_\gamma ||f||_{\mathbf{H}^{4\gamma}(4\gamma)}}{(l_1+1)^\gamma (l_2+1)^\gamma}. \tag{3.17}$$

Introduce the following notation:
$|||f||| := \sqrt{\tilde{\mathbf{E}}||f||^2_{L_2}}$,
$\varepsilon_i := |||u^n_N(t_i,\cdot) - u^{n,\kappa}_N(t_i,\cdot)|||$,
Π^κ, the L_2-orthogonal projection on the subspace generated by $e_l,\ l \le \kappa$,
$V^{n,i}_N(f)$, the operator $f \mapsto \sum_{\alpha\in J^n_N} \varphi_\alpha(\Delta,\cdot,f)\xi^i_\alpha;\ f \in L_2(\Omega,\mathcal{F}^y_{t_{i-1}},\tilde{\mathrm{P}})$ and $U^i(f) := V^{\infty,i}_\infty$. Since $V^{n,i}_N(f)$ is the $L_2(\Omega,\tilde{\mathrm{P}})$-orthogonal projection of $U^i(f)$ on the subspace generated by $\{\xi_\alpha,\ \alpha \in J^n_N\}$,

$$|||V^{n,i}_N(f)||| \le |||U^i(f)|||. \tag{3.18}$$

Below we will be dealing with a fixed set (n,i,N) and to simplify notation will write V instead of $V^{n,i}_N$. We also omit the dot in $u^n_N(t_i,\cdot)$, etc.

Since the coefficients of the model are time independent,

$$u^n_N(t_i) = V(u^n_N(t_{i-1})), \qquad u^{n,\kappa}_N(t_i) = \Pi^\kappa V(u^{n,\kappa}_N(t_{i-1})).$$

The second equality follows from (2.25), the definition of $\psi_l(i,N,n,\kappa)$, and the linearity of the map $f \mapsto \varphi_\alpha(\Delta,f)$. Then by the triangle inequality

$$\begin{aligned}\varepsilon_i \le {} & |||\Pi^\kappa V(u^n_N(t_{i-1})) - \Pi^\kappa V(u^{n,\kappa}_N(t_{i-1}))||| \\ & + |||u^n_N(t_i) - \Pi^\kappa u^n_N(t_i)|||.\end{aligned} \tag{3.19}$$

By the definition of Π^κ,

$$\begin{aligned}&|||\Pi^\kappa V(u^n_N(t_{i-1})) - \Pi^\kappa V(u^{n,\kappa}_N(t_{i-1}))||| \\ &\quad \le |||V(u^n_N(t_{i-1})) - V(u^{n,\kappa}_N(t_{i-1}))||| \le e^{C\Delta}\varepsilon_{i-1},\end{aligned} \tag{3.20}$$

$\Delta = t_i - t_{i-1}$, where the last inequality follows from (3.18) and (3.10).

Under the assumptions of the theorem it is easy to show, using the standard estimates from [25] or [34], that for any $i = 1,\dots,M$, $u^n_N(t_i) \in \cap_s \mathbf{H}^s(r)$ $(\mathrm{P}-\text{a.s.})$ for any $r \in \mathbf{R}$. In addition,

$$\sum_{\alpha\in J^n_N} \frac{\tilde{\mathbf{E}}||\varphi^i_\alpha(\Delta)||^2_{\mathbf{H}^\gamma(\gamma)}}{\alpha!} \le e^{C_\gamma T}||p||^2_{\mathbf{H}^\gamma(\gamma)} \tag{3.21}$$

for any positive integer γ, where $\varphi^i_\alpha(\Delta) = \varphi_\alpha(\Delta,u(t_{i-1}))$. As a result, from (2.18), (3.17), (3.21), and the obvious estimates $\sum_{j>\kappa} 1/(j+1)^\gamma \le C_\gamma/(\kappa+1)^{\gamma-1} \le C_\gamma/\kappa^{\gamma-1}$ (valid for $\gamma > 1$), we conclude that

$$\begin{aligned}|||u^n_N(t_{i-1}) - \Pi^\kappa u^n_N(t_{i-1})|||^2 &= \sum_{\alpha\in J^n_N}\sum_{l>\kappa} \frac{\tilde{\mathbf{E}}(\varphi^i_\alpha(\Delta),e_l)^2}{\alpha!} \\ &\le 2\sum_{\alpha\in J^n_N}\Big(\sum_{l_1>\kappa,l_2\ge 0}\frac{1}{(l_1+1)^{2\gamma}(l_2+1)^{2\gamma}}\Big)\frac{\tilde{\mathbf{E}}||\varphi^i_\alpha(\Delta)||^2_{\mathbf{H}^{4\gamma}(4\gamma)}}{\alpha!} \\ &\le \frac{C_\gamma e^{C_\gamma T}}{\kappa^{2\gamma-1}}||p||^2_{\mathbf{H}^{4\gamma}(4\gamma)}.\end{aligned} \tag{3.22}$$

Combining (3.19), (3.20), and (3.22), we arrive at

$$\varepsilon_i \le e^{C\Delta}\varepsilon_{i-1} + \frac{C_\gamma e^{C_\gamma T}}{\kappa^{\gamma-1/2}}||p||_{\mathbf{H}^{4\gamma}(4\gamma)},$$

which by the discrete Gronwall lemma implies

$$\varepsilon_i \le \frac{C_\gamma(e^{C_\gamma T}-1)}{\Delta\ \kappa^{\gamma-1/2}}||p||_{\mathbf{H}^{4\gamma}(4\gamma)}.$$

Since $\Delta = T/M$ and by assumption $||p||_{\mathbf{H}^{4\gamma}(4\gamma)} \le C_\gamma$, (2.26) follows. □

4. Comparison with other algorithms and numerical simulations. The Wiener chaos approximations (2.8), (2.16) can be viewed as higher-order time-discretization schemes for the Zakai equation.

For $N \ge 2$, the rate of convergence of the Wiener chaos approximation u_N^n is $O(\Delta)$, where Δ is the time step (Theorem 2.4). This is similar to the rates of convergence of the splitting-up algorithm (see [26]) and the implicit Euler–Milstein scheme (see [18]) for the Zakai equation.

In fact, many well-known time-discretization schemes can be obtained as particular cases of the Wiener chaos approximation.

One of the simplest is the explicit Euler scheme. Take a uniform partition of the interval $[0,T]$ with step Δ. Then the explicit Euler approximation $u_i(x)$ to the Zakai equation is obtained from

(4.1)
$$u_0(x) = p(x), \quad u_i(x) = (1+\Delta\cdot\mathcal{L}^*)u_{i-1}(x) + \sum_{l=1}^{r} h^l(x)u_{i-1}(x)(y^l(t_i)-y^l(t_{i-1})).$$

Now we will derive the same result from Theorem 2.4. Take $n = N = 1$. Then set J_1^1 contains $r+1$ elements, and on each step we need to solve $r+1$ equations from (2.19):

$$\frac{\partial\varphi_0^i(s,x)}{\partial s} = \mathcal{L}^*\varphi_0^i(s,x), \quad 0 < s \le \Delta,$$
$$\varphi_0^i(0,x) = u_1^1(t_{i-1},x)$$

(for $|\alpha| = 0$);

$$\frac{\partial\varphi_l^i(s,x)}{\partial s} = \mathcal{L}^*\varphi_l^i(s,x) + \textstyle\sum_l \frac{h^l(x)}{\sqrt{\Delta}}\varphi_0^i(s,x), \quad 0 < s \le \Delta,$$
$$\varphi_l^i(0,x) = 0, \qquad l = 1,\dots,r$$

(for $|\alpha| = 1$ with $\alpha_1^l = 1$) and $u_1^1(t_0,x) = p(x)$.

We solve these equations using the explicit Euler scheme; the (approximate) solutions are then given by

$$\varphi_0^i(\Delta,x) = (1+\Delta\cdot\mathcal{L}^*)u_1^1(t_{i-1},x),$$

$$\varphi_l^i(\Delta,x) = h^l(x)\sqrt{\Delta}u_1^1(t_{i-1},x).$$

By definition,

$$\xi_l^i = \int_{t_{i-1}}^{t_i} m_1(s)dy^l(s) = \frac{y^l(t_i)-y^l(t_{i-1})}{\sqrt{\Delta}},$$

and by Theorem 2.4,

$$u_1^1(t_i,x)=\varphi_0^i(\Delta,x)+\sum_{l=1}^{r}\varphi_l^i(\Delta,x)\xi_l^i,$$

and this, due to the above relations, coincides with (4.1).

Another well-known algorithm for solving the Zakai equation (2.4) is the splitting-up approximation (see Bensoussan, Glowinski, and Rascanu [4]; Florchinger and LeGland [12]; etc.). For simplicity, we consider the case $r=1$. Take a uniform partition of $[0,T]$ with step Δ and let $\{T_t\}$ be the semigroup generated by operator $\mathcal{L}^*$ (or some approximation of that semigroup). Then the splitting-up approximation $u_i(x)$ to $u(t_i,x)$ is computed from the recursion

$$u_0(x)=p(x),\qquad u_i(x)=T_\Delta\exp([y(t_i)-y(t_{i-1})]h-0.5h^2\Delta)u_{i-1}(x). \tag{4.2}$$

Let us see how the same result can be obtained from Theorem 2.4. Set $n=1$, $N=\infty$. Then the set J_N^n consists of multiindices $\alpha=(k,0,0,\dots)$; the corresponding φ_α will be denoted by φ_k. We need to solve the following system:

$$\frac{\partial\varphi_0^i(s,x)}{\partial s}=\mathcal{L}^*\varphi_0^i(s,x),\quad 0<s\le\Delta,$$
$$\varphi_0^i(0,x)=u_\infty^1(t_{i-1},x)$$

(for $|\alpha|=0$);

$$\frac{\partial\varphi_k^i(s,x)}{\partial s}=\mathcal{L}^*\varphi_k^i(s,x)+k\tfrac{h(x)}{\sqrt{\Delta}}\varphi_{k-1}^i(s,x),\quad 0<s\le\Delta,$$
$$\varphi_k^i(0,x)=0,\quad k\ge1$$

(for $|\alpha|=k$) and $u_\infty^1(t_0,x)=p(x)$. An approximate solution to this system is given by

$$\varphi_k^i(t,x)=T_t\Big(\frac{th}{\sqrt{\Delta}}\Big)^k u_\infty^1(t_{i-1},\cdot)\ (x),\qquad k\ge0. \tag{4.3}$$

Indeed, for $k=0$, this is the exact solution (if T_t is exact); assuming (4.3) for some $k=n-1\ge0$, we get for $k=n$

$$\begin{aligned}\varphi_n^i(t,x)&=n\int_0^t T_{t-s}\frac{h}{\sqrt{\Delta}}\varphi_{n-1}^i(s,\cdot)(x)ds\\&=\frac{n}{\Delta^{n/2}}\int_0^t T_{t-s}h^nT_su_\infty^1(t_{i-1},\cdot)(x)s^{n-1}ds\\&\approx\frac{n}{\Delta^{n/2}}T_th^nu_\infty^1(t_{i-1},\cdot)(x)\int_0^t s^{n-1}ds\\&=T_t\Big(\frac{th}{\sqrt{\Delta}}\Big)^n u_\infty^1(t_{i-1},\cdot)\ (x),\end{aligned}$$

so (4.3) follows by induction. Note that, if $T_t(hf)(x)=hT_t(f)$ for all $f(x)$, it would be an exact solution.

Clearly, (4.3) implies that

$$\varphi_k^i(\Delta,x)=T_\Delta(h\sqrt{\Delta})^ku_\infty^1(t_{i-1},\cdot)\ (x),\qquad k\ge0.$$

It is also clear that

$$\xi_k^i = \frac{1}{\sqrt{k!}} H_k\Big(\frac{y(t_i) - y(t_{i-1})}{\sqrt{\Delta}}\Big), \tag{4.4}$$

and then by Theorem 2.4

$$\begin{aligned} u_\infty^1(t_i, x) &= T_\Delta u_\infty^1(t_{i-1}, \cdot)(x) + T_\Delta \sum_{k\geq 1} \frac{1}{k!} (h\sqrt{\Delta})^k H_k\Big(\frac{y(t_i) - y(t_{i-1})}{\sqrt{\Delta}}\Big) \\ &= T_\Delta \exp([y(t_i) - y(t_{i-1})]h - 0.5h^2\Delta) u_\infty^1(t_i, \cdot)(x). \end{aligned}$$

(The last equality follows from the well-known expansion

$$\exp(ax - 0.5x^2) = \sum_{k\geq 0} \frac{1}{k!} H_k(a) x^k$$

if we set $a = (y(t_i) - y(t_{i-1}))/\sqrt{\Delta},\ x = h\sqrt{\Delta}$.)

An alternative form of the splitting-up approximation, namely,

$$u_o(x) = p(x), \qquad u_i(x) = \exp((y(t_i) - y(t_{i-1}))h(x) - 0.5|h(x)|^2\Delta) T_\Delta u_{i-1}(\cdot)(x)\ , \tag{4.5}$$

can be obtained by Theorem 2.4 in the same way.

Next, we present an estimate on the number of on-line operations required by S^3 and compare it with a corresponding estimate for the splitting-up method.

We introduce the following parameters: N_s, the number of grid points in the spatial domain; N_J, the number of elements in J_N^n; κ, the number of basis functions e_l.

Assume that one needs to compute an approximation to the solution of (2.4) at moment $t = N_\tau \Delta$.

To do this using S^3, one has to find $\psi_l(i, N, n, \kappa)$, $i = 1, \dots, N_\tau$, for every $l = 1, \dots, \kappa$, which requires about $2\kappa^2 N_J N_\tau$ flops, and then compute the sum in (2.25)—κN_s more flops. The Wiener integral $\xi_{k,l} = \int_0^\Delta m_k(s) dy^l(s)$ reduces to a one-dimensional Riemann integral by integrating by parts. In addition, computations of the integrals $\xi_{k,l}$ for different k and l can be performed in parallel. As a result, computational complexity of the Wick polynomials ξ_α is negligible as compared to other procedures of S^3.

The total number of flops N_{S^3} is then $N_{S^3} = 2\kappa^2 N_J N_\tau + N_s \kappa$. Given the precision of the approximation, the number κ^2 will grow with d as C^d, where C is some constant depending on the type of the basis (but not on d), so $N_{S^3} \leq C^d(2N_J N_\tau + N_s)$.

If the splitting-up algorithm is used, one has to perform N_τ steps of the type (4.2). Each step requires solving a parabolic equation. To estimate the corresponding number of operations, assume that a finite element method is used and the resulting linear system is solved using an iterative procedure without preconditioning. The matrix of the system is of dimension $N_s \times N_s$, sparse and nonsymmetric (since operator $\mathcal{L}^*$ is not self-adjoint). Then one iteration requires about $C_d N_s$ flops, where C_d is a constant depending on d and on the particular numerical algorithm (see [1]), and the total number of iterations is proportional to the condition number of the matrix [36]. For nonsymmetric matrices, the condition number is proportional to at least $(\ln N_s)^{d-1}$ [1, 6]. Thus the total number of operations required to solve the equation on one step is $C_d N_s (\ln N_s)^{d-1}$. One also has to compute a certain number of exponential

TABLE 4.1
Comparison of the splitting-up approximation and the S^3.

	$t = 1$ (Step 100)		$t = 2$ (Step 200)	
	Splitting-up	S^3	Splitting-up	S^3
Flops	8161001	397431	16321601	788431
N_{50}	32	27	20	16
N_{75}	61	55	47	36
N_{95}	93	90	85	81

functions, but this can be done much faster and we disregard it. The total number of on-line operations is then $N_{sp-up} = N_\tau C_d N_s (\ln N_s)^{d-1}$.

As a result,

$$\frac{N_{\mathrm{S}^3}}{N_{sp-up}} \le \frac{C}{C_d}\Big(\frac{C}{\ln N_s}\Big)^{d-1}\Big[\frac{2N_J}{N_s} + \frac{1}{N_\tau}\Big].$$

Theorem 2.4 shows that for any d the splitting-up algorithm and S^3 have errors of the same order in Δ already for $N = 2,\ n = 1$, so we can take $1 + 2r + r(r-1)/2$ as the lower bound on N_J, where r is the dimension of the observation process. Since N_s usually grows with d, we can expect S^3 to have an advantage over the splitting-up algorithm in the following situations:

(1) when the estimation of u is required at one time moment after a long observation period ($N_\tau \gg 1$). This is characteristic for some tracking problems.

(2) when the dimension d of the state process is large.

To conclude this section we compare (numerically) the on-line performance of S^3 and the splitting-up method for one simple example.

For the test model, both signal and observation processes were chosen one-dimensional with the signal

$$dx(t) = 0.1\cos(2x(t))dt + 0.14 d\tilde{w}(t), \quad x(0) \sim \mathcal{N}(0, 0.1),$$

and the observations

$$y(t) = \int_0^t \arctan(x(s))ds + 0.04 w(t);$$

obvious modifications were made to reduce the last equation to the standard form (2.1). We took $T = 2$ and $\Delta = 0.01$.

The interval $[-1, 1]$ was taken as the spatial domain; it was discretized uniformly with step 0.01. Functions $\sin(\pi l(x-1)/2),\ 1 \le l \le 15$, sampled at the points of the spatial grid served as the basis $\{e_l\}$.

For the S^3, multiindices α with $|\alpha| \le 8,\ d(\alpha) \le 1$ were used. (This corresponds to the set J_8^1 in Theorem 2.4.)

Given the trajectory of the signal process, 100 independent observation trajectories were simulated; for each trajectory, the filtering density was computed at moments $25\Delta,\ 50\Delta, \dots, 200\Delta$, using both the S^3 and the splitting-up method.

The results are presented in Table 4.1. They are borrowed from [13]. In the table, "flops" stands for the total number of the *on-line* floating point operations (additions and multiplications) that it took to compute the filtering density at the given time moment; N_{50} (resp., N_{75}, N_{95}) is the number of times the value of the signal process was in the 50% (resp., 75%, 95%) confidence interval defined by the *computed* density.

We see that S^3 results in substantial reduction (up to 20 times) in the number of on-line computations without significant loss of accuracy. The decrease in the number of on-line computations should be even more conspicuous as the dimension of the observation process grows.

Appendix. To make the exposition as self-contained as possible, we will prove Theorem 2.1 and give some other results used in the proof of Theorem 2.2. Most of the results come from [30].

The summation over repeated indices convention is still in force. We also use the notations introduced at the beginning of section 3.

To begin with we recall the celebrated Cameron–Martin development (see, e.g., [7] and also [16, 19]).

THEOREM A.1 (Cameron–Martin development). *Let $B_s = (B_s^1, \dots, B_s^r)$, $0 \le s \le T$, be an r-dimensional Brownian motion and η be a measurable functional of the path $\{B_s, s \le T\}$ such that $\mathbf{E}\eta^2 < \infty$. Let $\{c_i(t)\}_{i\ge 1}$ be an arbitrary complete orthonormal system in $L_2([0,T])$. For $\alpha = \{\alpha_k^l\} \in J$ set*

$$\xi_\alpha(B) = \prod_{k,l} \frac{H_{\alpha_k^l}\Big(\int_0^T c_k(s)dB^l(s)\Big)}{\sqrt{\alpha_k^l!}}.$$

Then $(\xi_\alpha)_{\alpha\in J}$ is a CONS in $L_2(\Omega, \mathcal{F}_T^B, \mathrm{P})$, where $\mathcal{F}_T^B = \sigma(B_s,\ s \le T)$, and

$$\eta = \sum_{\alpha\in J} \mathbf{E}[\eta\xi_\alpha(B)]\xi_\alpha(B), \tag{A.1}$$

$$\mathbf{E}\eta^2 = \sum_{\alpha\in J} (\mathbf{E}[\eta\xi_\alpha(B)])^2. \tag{A.2}$$

The series (A.1) *converges in $L_2(\Omega, \mathrm{P})$.*

Let $\{z_k^l\},\ l = 1, \dots, r,\ k = 1, 2, \dots$, be a sequence of real numbers such that $\sum_{k,l} |z_k^l|^2 < \infty$. Set $m_z^l = m_k(s)z_k^l$, where $\{m_k\}$ is a CONS in $L_2([0,t])$. We also define

$$P_s(z) = \exp\Big\{ \int_o^s m_z^l(\tau)dy^l(\tau) - 0.5 \int_0^s \sum_{l=1}^r |m_z^l(\tau)|^2 d\tau \Big\}$$

and denote

$$\frac{\partial^\alpha}{\partial z^\alpha} := \prod_{k,l} \frac{\partial^{\alpha_k^l}}{(\partial z_k^l)^{\alpha_k^l}}.$$

Proof of Theorem 2.1. It is known (see, e.g., [34]) that for every t, x the UFD $u(t,x)$ is a measurable functional of the observation process $y(s),\ s \le t$. By Girsanov's theorem $y(s)$ is a Brownian motion on the new probability space $(\Omega, \mathcal{F}, \tilde{\mathrm{P}})$ (recall that $d\tilde{\mathrm{P}} = \rho(T)d\mathrm{P}$). Then by Theorem A.1 we have

$$u(t,x) = \sum_{\alpha\in J} \tilde{\mathbf{E}}[u(t,x)\xi_\alpha(y)]\xi_\alpha(y), \tag{A.3}$$

$$\tilde{\mathbf{E}}|u(t,x)|^2 = \sum_{\alpha\in J} (\tilde{\mathbf{E}}[u(t,x)\xi_\alpha(y)])^2, \tag{A.4}$$

where $\tilde{\mathbf{E}}$ stands for the expectation symbol with respect to measure $\tilde{\mathrm{P}}$, and the right-hand side of (A.3) converges in $L_2(\Omega, \tilde{\mathrm{P}})$.

Let us denote

$$\varphi_\alpha(s,x) := \sqrt{\alpha!}\tilde{\mathbf{E}}[u(s,x)\xi_\alpha(y)].$$

It is a standard fact (see, e.g., [16]) that

$$\xi_\alpha(y) = \frac{1}{\sqrt{\alpha!}}\frac{\partial^\alpha}{\partial z^\alpha}P_t(z)|_{z=0},$$

and so for every $s \le t$

$$\varphi_\alpha(s,x) = \frac{\partial^\alpha}{\partial z^\alpha}\tilde{\mathbf{E}}[u(s,x)P_t(z)]|_{z=0} = \frac{\partial^\alpha}{\partial z^\alpha}\tilde{\mathbf{E}}[u(s,x)P_s(z)]|_{z=0},$$

where the second equality follows from the martingale property of $P_s(z)$ on $(\Omega, \tilde{\mathrm{P}})$. Now to prove (2.8) and (2.9) it remains to show that the system of functions $\{\varphi_\alpha\}$, $\alpha \in J$, is a solution to the S-system (2.6). For this purpose it will be convenient to treat the UFD $u(t,x)$ as the solution of the Zakai equation (2.4). Since $P_s(z)$ satisfies the Ito stochastic differential equation

$$dP_s(z) = m_z^l(s)P_s(z)dy^l(s), \quad s \le t;\ P_0(z) = 1, \tag{A.5}$$

by the Ito chain rule

$$\begin{aligned} u(t,x)P_t(z) = p(x) &+ \int_0^t (\mathcal{L}^* u(s,x)P_s(z) + h^l(x)m_z^l(z)u(s,x)P_s(z))ds \\ &+ \int_0^t (h^l(x)u(s,x)P_s(z) + u(s,x)m_z^l(s)P_s(z))dy^l(s). \end{aligned}$$

Taking expectation $\tilde{\mathbf{E}}$ on both sides of the last equality and setting $\varphi(s,x,z) := \tilde{\mathbf{E}}u(s.x)P_s(z)$ we obtain

$$\begin{aligned} &\frac{\partial\varphi(s,x,z)}{\partial s} = \mathcal{L}^*\varphi(s,x,z) + m_z^l(s)h^l(x)\varphi(s,x,z), \quad 0 < s \le t, \\ &\varphi(0,x,z) = p(x)1_{\{|\alpha|=0\}}. \end{aligned} \tag{A.6}$$

Applying the operator $\frac{1}{\sqrt{\alpha!}}\frac{\partial^\alpha}{\partial z^\alpha}$ on both sides of (A.6) and setting $z = 0$ we get (2.6).

To complete the proof of Theorem 2.1 one needs to prove that the right-hand side of (2.8) converges also in $L_1(\Omega, \mathrm{P})$. This follows in a simple way from the convergence in $L_2(\Omega, \tilde{\mathrm{P}})$ and Cauchy–Schwartz inequality [30]. □

In what follows we give some additional properties of the solution of (2.6) in the case $r = 1$; these properties are used in the proof of Theorem 2.2. Generalizations to the general case $r > 1$ are straightforward.

PROPOSITION A.1 (see [30]). *Let $\{\varphi_\alpha(t,x)\}_{\alpha\in J}$ be a solution of* (2.6). *Then for each α with $|\alpha| = k$*

$$\begin{aligned} &\varphi_\alpha(t,x) = \sum_{\sigma\in\mathcal{P}^k}\int^{(k)} F(t;s^k;x)m_{i_{\sigma(k)}}(s_k)\dots m_{i_{\sigma(1)}}(s_1)ds^k, \qquad k > 1, \\ &\varphi_\alpha(t,x) = \int_0^t T_{t-s_1}hT_{s_1}p(x)m_i(s_1)ds_1, \qquad k = 1, \\ &\varphi_\alpha(t,x) = T_t p(x), \qquad k = 0, \end{aligned} \tag{A.7}$$

where $(i_1, \dots, i_k)$ *is the characteristic set of* α *(see the beginning of section* 3 *for notation).*

In addition,

$$\sum_{|\alpha|=k} \frac{\varphi_\alpha^2(t,x)}{\alpha!} = \int^{(k)} |F(t;s^k;x)|^2 ds^k. \tag{A.8}$$

Proof. Representation (A.7) is obviously true for $|\alpha| = 0$. Then the general case $|\alpha| \geq 1$ follows by induction from the variation of parameters formula.

To prove (A.8), first of all note that

$$\sum_{\sigma\in\mathcal{P}^k} m_{i_{\sigma(k)}}(s_k) \dots m_{i_{\sigma(1)}}(s_1) = \sum_{\sigma\in\mathcal{P}^k} m_{i_k}(s_{\sigma(k)}) \dots m_{i_1}(s_{\sigma(1)}).$$

Indeed, any term on the left corresponding to a given $\sigma_0 \in \mathcal{P}^k$ is equal to the term on the right corresponding to $\sigma_0^{-1} \in \mathcal{P}^k$.

Then we can write (A.7) as

$$\varphi_\alpha(t,x) = \int^{(k)} F(t;s^k;x) E_\alpha(s^k) ds^k.$$

Introducing

$$G(s^k;x) := \sum_{\sigma\in\mathcal{P}^k} T_{t-s_{\sigma(k)}} h \dots T_{s_{\sigma(2)}-s_{\sigma(1)}} h T_{s_{\sigma(1)}} p(x) 1_{s_{\sigma(1)}<\dots<s_{\sigma(k)}},$$

we can rewrite it further as

$$\varphi_\alpha(t,x) = \frac{1}{k!} \int\limits_{[0,t]^k} G(s^k) E_\alpha(s^k) ds^k. \tag{A.9}$$

Since for each x G is a symmetric function from $L_2([0,t]^k)$ and $\{E_\alpha/\sqrt{\alpha!k!}, |\alpha| = k\}$ form a CONS for the symmetric part of the space, we have

$$G = \sum_{|\alpha|=k} \frac{c_\alpha E_\alpha}{\sqrt{\alpha!k!}}$$

with some $c_\alpha \in \mathbf{R}$. Then from (A.9) $\varphi_\alpha^2/\alpha! = c_\alpha^2/k!$ and so

$$\sum_{|\alpha|=k} \frac{\varphi_\alpha^2(t,x)}{\alpha!} = \frac{1}{k!} \sum_{|\alpha|=k} c_\alpha^2 = \frac{1}{k!} \int\limits_{[0,t]^k} |G(s^k;x)|^2 ds^k$$

$$= \frac{1}{k!} \int\limits_{[0,t]^k} \Big| \sum_{\sigma\in\mathcal{P}^k} T_{t-s_{\sigma(k)}} h \dots T_{s_{\sigma(2)}-s_{\sigma(1)}} h T_{s_{\sigma(1)}} p(x) 1_{s_{\sigma(1)}<\dots<s_{\sigma(k)}} \Big|^2 ds^k$$

$$= \int^{(k)} |F(t;s^k;x)|^2 ds^k,$$

which proves (A.6). □

REMARK A.1. *In this article we needed WCE* (2.8) *only at the final point of the time interval. However, it is readily checked that, due to* $\mathcal{F}_t^y$*-measurability of UFD*

$u(s,x)$ for all $s \le t$, the statement and the proof of Theorem 2.1 *remain virtually unchanged if, in* (2.8) *and* (2.9)*, we replace t by any $s \le t$. This implies in particular that equality* (2.16) *holds not only for grid points t_i but for every $s \in [t_{i-1}, t_i]$.*

REMARK A.2. *If $r = 1$ and $|\alpha| = k$, then, by* [17, *Theorem* 3.1],

$$\xi_\alpha = \frac{1}{\sqrt{\alpha!}} \int_0^t \int_0^{s_k} \dots \int_0^{s_2} E_\alpha(s^k) dy(s_1) \dots dy(s_k).$$

This gives an alternative (but equivalent) form of WCE (2.8) *in terms of multiple Wiener integrals. A similar expansion holds for an arbitrary r.*

Acknowledgments. Very helpful comments and suggestions from Drs. K. Ito and J. Dym and from the reviewers are acknowledged.

DESCRIPTOR SYSTEMS WITHOUT CONTROLLABILITY AT INFINITY*

RALPH BYERS†, TON GEERTS‡, AND VOLKER MEHRMANN§

Abstract. This paper concerns the structure that can be achieved by feedback in descriptor systems that lack controllability at infinity. Staircase and double staircase condensed forms obtained through a sequence of orthogonal state transformations display when and how feedback can be used to achieve minimal index. Furthermore, they reveal that the modes that are uncontrollable at infinity have a fixed minimal index that cannot be reduced by feedback. However, this fixed higher index part of the control system is constrained to be zero in an appropriate coordinate system, provided the initial conditions are consistent. The remainder is a reduced order system that is controllable at infinity that can be made to have index one by feedback.

Key words. descriptor system, controllability, numerical methods, impulse

1. Introduction.

Consider the linear, time-invariant descriptor system

$$\begin{aligned} E\dot{x} &= Ax + Bu, \qquad Ex(0) = Ex^0, \\ y &= Cx, \end{aligned} \tag{1}$$

with system matrices $E \in \mathbf{C}^{n\times n}$, $A \in \mathbf{C}^{n\times n}$, $B \in \mathbf{C}^{n\times m}$, $C \in \mathbf{C}^{p\times n}$, state $x = x(t) \in \mathbf{C}^n$, input $u = u(t) \in \mathbf{C}^m$, and output $y = y(t) \in \mathbf{C}^p$. Descriptor systems arise naturally in circuit design, mechanical multibody systems, and a variety of other applications [25, 32, 33]. They have recently attracted the attention of many authors to all aspects of control, including pole placement, filtering, stabilization, controllability, observability, optimal control problems, invertibility, duality, realization, etc. See, for example, [6, 14, 13, 27] and the references therein.

In contrast to standard systems in which $E = I$, continuous inputs to a descriptor system can give rise to discontinuities or impulsive modes in the state trajectories. A detailed analysis of solvability aspects of the distributional version of (1) is given in [14]. A simple example is the single input system determined by

$$E = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}, \quad A = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ -1 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}. \tag{2}$$

The input $u(t)$ induces the state $x(t)$:

$$x(t) = \begin{bmatrix} x_1(t) \\ x_2(t) \end{bmatrix} = \begin{bmatrix} \dot{u}(t) \\ u(t) \end{bmatrix}.$$

If $x^0 = x(0^-) = \left[\begin{smallmatrix} x_1^0 \\ x_2^0 \end{smallmatrix}\right]$ and u is smooth but $x_2^0 \neq u(0^+)$, then x_1 will still exhibit a pulse $[u(0^+) - x_2^0]\delta$, where δ is the Dirac delta distribution [14]. (If $u(0^+) = x_2^0$ but $\dot{u}(0^+) \neq x_1^0$, i.e., $x_1(0^+) \neq x_1(0^-)$, then x_1 will still be impulse free [14, 40].)

If (1) is controllable and observable at infinity, i.e., $\operatorname{rank}[E,\, AS_\infty,\, B] = n$, where

$$\operatorname{Im}(S_\infty) = \ker(E) \quad \text{and} \quad \operatorname{rank} \begin{bmatrix} E \\ T_\infty^H A \\ C \end{bmatrix} = n,$$

where $\operatorname{Im}(T_\infty) = \ker(E^H)$, then the problem of impulses can be avoided (or at least disguised) by using an appropriate feedback [4, 3]. Here, $\operatorname{Im}(\cdot)$ denotes the image (or range) and $\ker(\cdot)$ is the kernel (or null space).

For example, using the feedback control $u = FCx + v$, where $F = \begin{bmatrix} -1 & 0 \end{bmatrix}$ in (2) gives the closed loop system matrices

$$E = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}, \quad A = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ -1 \end{bmatrix}, \quad C = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}. \tag{3}$$

Here the inputs $v(t)$ and the resulting state trajectories exhibit the same impulsive behavior, and thus x will be impulse free if v is. In addition if v is q-times continuously differentiable for $t > 0$, then x is as well.

Notice that the closed loop system matrices (3) have a stronger robustness property than the ones in (2). If the closed loop system is perturbed by some unmodeled dynamic forcing function $f(t)$ giving

$$E\dot{x} = (A + BFC)x + Bv + f(t),$$

then the resulting state $x(t)$ still has as many derivatives as $\left[\begin{smallmatrix} f(t) \\ v(t) \end{smallmatrix}\right]$, even if $x(0^-) = x^0$ is not consistent. Using distributions, we get

$$\begin{aligned} x_1 &= -x_2 + v - f_2, \\ x_2 &= (\delta^{(1)} + \delta)^{*^{-1}}[x_2(0^-)\delta + v + f_1 - f_2]. \end{aligned}$$

In time domain, if v and f are functions, we have

$$\begin{aligned} x_1(t) &= -x_2(t) + v(t) - f_2(t), \\ x_2(t) &= e^{-t}x_2(0^-) + \int_0^t e^{-(t-s)}[v(s) + f_1(s) - f_2(s)]ds. \end{aligned}$$

Hence, $x = \left[\begin{smallmatrix} x_1(t) \\ x_2(t) \end{smallmatrix}\right]$ has indeed as many derivatives for $t > 0$ as $\left[\begin{smallmatrix} f \\ v \end{smallmatrix}\right]$, even if $x(0^-) \neq x(0^+)$.

We call this property *index-one robustness* because it is shared by regular descriptor systems of index at most one. (Regularity and index are defined in the next

section.) Even smooth perturbations f in (2) will in general give rise to extra pulses in the solution, whereas this cannot happen in systems that are index-one robust. It is implicit in the results of [4, 3] that systems that are controllable and observable at infinity can be made to be index-one robust by feedback.

In several applications including mechanical multibody systems [19, 29, 28, 33, 34] the assumptions of controllability and/or observability at infinity do not hold. Consider for example the planar model of a three-link manipulator introduced in [19],

$$E = \begin{bmatrix} I & 0 & 0 \\ 0 & M_0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \; A = \begin{bmatrix} 0 & I & 0 \\ -K_0 & -D_0 & F_0^T \\ F_0 & 0 & 0 \end{bmatrix}, \; B = \begin{bmatrix} 0 \\ S_0 \\ 0 \end{bmatrix}.$$

This system is not controllable at infinity. With output $y = \begin{bmatrix} C_1 & C_2 & 0 \end{bmatrix}$ it is not observable at infinity either. Due to the special structure of this mechanical multibody system, however, the part of the system that is characterized by the uncontrollable modes at infinity can be neglected. The remaining system can be made index-one robust [28]. If this simplification is not carried out, then undesired phenomena as in the following example may occur. Let

$$E = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \quad A = I, \quad B = \begin{bmatrix} 0 \\ -1 \\ 0 \\ 0 \end{bmatrix}, \quad C = I. \tag{4}$$

In this case, the first two components of the state obey (2), while the second two components of the state are confined to be zero (assuming consistent initial conditions). Choosing an appropriate feedback causes the first two components of the state to obey (3) while the second two remain zero. However, regardless of what feedback is chosen, the closed loop system does not have index-one robustness. If the forcing function $f(t) = \begin{bmatrix} f_1(t), & f_2(t), & f_3(t), & f_4(t) \end{bmatrix}^T$ were added to the closed loop system, then the third state component is $x_3(t) = -f_3(t) - \dot{f}_4$. In the third component of the state, we will obtain an impulse of the form $(-f_4(0^+) - x_{04})\delta$, where $x_{04} = x_4(0^-)$. Lack of differentiability in $f_4(t)$ may translate into lack of continuity in x_3. A jump discontinuity in $f(t)$ may cause an impulse.

This paper concerns the properties that can be achieved without controllability and observability at infinity, including when and how feedback can be used to achieve minimal index by numerically stable methods. All these properties are displayed by the Kronecker-like feedback canonical form introduced in [24]. Extracting this canonical form may, however, require ill-conditioned transformations which are sensitive to rounding errors. For this reason, following the approaches of [4, 3, 37, 36], we derive condensed staircase and double staircase forms through a sequence of unitary state space transformations. They display when and how feedback can be used to achieve minimal index. They also reveal that (4) is typical of systems which lack controllability at infinity. The parts of the state which are uncontrollable at infinity are constrained to be zero in an appropriate coordinate system, provided the initial conditions are consistent and may be decoupled from the rest of the system. This leaves a reduced order system that is controllable at infinity to which the work of [4, 3] applies. A similar argument applies to parts of the state which are not observable at infinity. By choosing an appropriate basis, these parts can be decoupled from the rest, and since they cannot be observed, they can be removed without changing the dynamics of the system.

2. Definitions and lemmas. The control system (1) and the associated matrix pencil $\lambda E - A$ are said to be *regular* if the characteristic polynomial $\det(\lambda E - A)$ is not identically zero. If the pencil $\lambda E - A$ is not regular, then the system of differential algebraic equations

$$E\dot{x} = Ax + f(t) \tag{5}$$

is underdetermined in the sense that consistent initial conditions do not uniquely determine solutions [12]. If the pencil $\lambda E - A$ is regular, then the roots of the characteristic polynomial are the finite eigenvalues of the pencil and include the poles of the transfer function of (1). In addition, if E is singular, the pencil is said to have infinite eigenvalues which may be identified as the zero eigenvalues of the inverse pencil $E - \lambda A$.

The eigenstructure of regular pencils is displayed by the Weierstraß canonical form (WCF).

THEOREM 2.1 (Weierstraß canonical form [12]). *If $\lambda E - A$ is regular, then there exist nonsingular matrices $X = [X_r, X_\infty] \in \mathbf{C}^{n\times n}$ and $Y = [Y_r, Y_\infty] \in \mathbf{C}^{n\times n}$ for which*

$$Y^H E X = \begin{bmatrix} Y_r^H \\ Y_\infty^H \end{bmatrix} E \begin{bmatrix} X_r & X_\infty \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & N \end{bmatrix} \tag{6}$$

and

$$Y^H A X = \begin{bmatrix} Y_r^H \\ Y_\infty^H \end{bmatrix} A \begin{bmatrix} X_r & X_\infty \end{bmatrix} = \begin{bmatrix} J & 0 \\ 0 & I \end{bmatrix}, \tag{7}$$

where J is a matrix in Jordan form whose diagonal elements are the finite eigenvalues and N is a nilpotent matrix also in Jordan form. J and N are unique up to permutation of Jordan blocks. □

The *index* of the pencil $\lambda E - A$ and of the descriptor system (1) is the index of nilpotency of the nilpotent block N in the WCF; i.e., the index of the pencil is μ if and only if $N^{\mu-1} \neq 0$ and $N^\mu = 0$. By convention, if E is nonsingular, then the pencil is said to have index zero. We denote the index of the pencil $\lambda E - A$ by $\operatorname{index}(\lambda E - A)$. If E is a nilpotent matrix and A nonsingular, then we write $\operatorname{index}(E)$ instead of $\operatorname{index}(\lambda E - A)$.

Most of the information displayed by the WCF is also easily obtained from triangular pencils or block triangular pencils. It often simplifies derivations to use triangular or block triangular pencils. Furthermore, numerical algorithms that transform pencils to triangular form are usually more reliable than those that reduce to the WCF (6)–(7) [7, 8, 20].

LEMMA 2.2. *The eigenvalues of the block triangular pencil*

$$\lambda \begin{bmatrix} E_{11} & E_{12} \\ 0 & E_{22} \end{bmatrix} - \begin{bmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{bmatrix} \tag{8}$$

are the union of the eigenvalues of the diagonal blocks

$$\lambda E_{11} - A_{11}, \tag{9}$$

$$\lambda E_{22} - A_{22}. \tag{10}$$

In particular, (8) *is regular if and only if* (9) *and* (10) *are regular.*

Moreover, if (9) *and* (10) *have disjoint eigenvalues, then the Jordan and nilpotent parts of the WCF of* (8) *are the union of the Jordan and nilpotent parts of the WCFs of* (9) *and* (10). □

The next lemma gives a useful characterization of regular, index-one pencils.

LEMMA 2.3 (see [21]). *The pencil $\lambda E - A$ is regular and has index at most one if and only if*

$$\operatorname{rank}\left(\begin{bmatrix} E \\ T_\infty^H A \end{bmatrix}\right) = \operatorname{rank}\left(E + T_\infty T_\infty^H A\right) = n,$$

where the columns of T_∞ span the null space of E^H. Equivalently, the pencil $\lambda E - A$ is regular and of index less than or equal to one if and only if

$$\operatorname{rank}\left([E,\ AS_\infty]\right) = \operatorname{rank}\left(E + AS_\infty S_\infty^H\right) = n,$$

where the columns of S_∞ span the null space of E. □

Similar statements for arbitrary linear systems are given in [14].

If $\lambda E - A$ is regular, then in terms of the WCF (6)–(7), the solutions of (5) take the form

$$x(t) = X_r z_1(t) + X_\infty z_2(t),$$

where

$$z_1(t) = e^{tJ} z_1(0) + \int_0^t e^{(t-s)J} Y_r^H f(s)\, ds,$$

$$z_2(t) = -\sum_{i=0}^{\mu-1} \frac{d^i}{dt^i}(N^i Y_\infty^H f(t)). \tag{11}$$

From this we see that in order to have a smooth solution $x(t)$, the initial condition $x(0^-)$ must be a member of the set of *admissible* initial conditions

$$\left\{ X_r z_1 + X_\infty z_2 \;\middle|\; z_1 \in \mathbf{C}^r,\ z_2 = -\sum_{i=0}^{\mu-1} (N^i Y_\infty^H f^{(i)}(0)) \right\}.$$

It may be worthwhile to use feedback to minimize the index of a control system even when it cannot be reduced to index one in order to minimize the effect of discontinuities in the derivatives of unmodeled or perturbing forcing functions. One of the goals of this study is to determine what is the minimal index that can be achieved and to determine a feedback that achieves it. It turns out that according to the linear model (1), the modes that cannot be made to be index one by feedback are constrained to be zero in an appropriate coordinate system, provided the initial conditions are consistent. The remaining active modes may be made to have index one.

We now introduce some further definitions and notation. A system of the form (1) is *regularizable by state feedback*, if there exists a feedback $F \in \mathbf{C}^{m\times n}$ such that the pencil $\lambda E - (A + BF)$ is regular [3, 31]. Similarly, it is *regularizable by output feedback* if there exists $G \in \mathbf{C}^{m\times p}$ such that the pencil $\lambda E - (A + BGC)$ is regular. A system (1) is *controllable at infinity or impulse controllable* if $\operatorname{rank}[E,\ AS_\infty,\ B] = n$, where $\operatorname{Im}(S_\infty) = \ker(E)$. It is called *observable at infinity or impulse observable* if

$$\operatorname{rank}\begin{bmatrix} E \\ T_\infty^H A \\ C \end{bmatrix} = n,$$

where $\mathrm{Im}(T_\infty) = \ker(E^H)$ [5, 40]. In geometric terms, controllability at infinity is equivalent to

$$\mathrm{Im}(E) + A\ker(E) + \mathrm{Im}(B) = \mathbf{C}^n.$$

(See [5, 14, 17, 40].)

A regular descriptor system with index of at most one is a fortiori controllable at infinity. Systems that are controllable at infinity admit a state feedback control which makes the closed loop system be regular and have index of at most one [4, 3]. Moreover, the system transformations may be chosen to minimize the effects of rounding error [3, 10].

Let $P \in \mathbf{C}^{n\times n}$, $Q \in \mathbf{C}^{n\times n}$, $R \in \mathbf{C}^{m\times m}$, and $S \in \mathbf{C}^{p\times p}$ be nonsingular. If

$$\begin{aligned} \tilde{E} = PEQ\tilde{A} = PAQ\tilde{B} = PBR, \\ \tilde{C} = SCQ, \end{aligned} \tag{12}$$

then the descriptor system

$$\begin{aligned} \tilde{E}\dot{\tilde{x}} &= \tilde{A}\tilde{x} + \tilde{B}\tilde{u}, \\ \tilde{y} &= \tilde{C}\tilde{x} \end{aligned}$$

is equivalent to (1) in the sense that

$$\begin{aligned} x &= Q\tilde{x}, \\ u &= R\tilde{u}, \\ y &= S\tilde{y}. \end{aligned}$$

The transformation (12) is a *generalized state transformation*. Such transformations establish an equivalence relation among descriptor systems. Controllability at infinity, observability at infinity, regularity, eigenvalues, and index are preserved by generalized state transformations. Canonical forms under these and other state transformations are discussed in [24, 31]. However, these canonical forms are not easily computed, because modeling errors, measurement errors, or rounding errors may sometimes change them completely. In the next section we use a sequence of state transformations via unitary matrices to bring $\tilde{E}$, $\tilde{A}$, $\tilde{B}$, and $\tilde{C}$ into a staircase-like form in the style of [4, 3, 37, 36]. Although our canonical forms display less information than those of [24, 31], they are less sensitive to data perturbations and rounding errors.

The proofs of the staircase-like form in this paper are constructive and form the basis of a numerically stable algorithm for computing the factorization. The basic operations are *row compressions* and *column compressions*. A row compression of a matrix $M \in \mathbf{C}^{h\times k}$ of rank r is the factorization

$$UM = \begin{matrix} \\ r \\ h-r \end{matrix} \begin{matrix} \begin{matrix} r & k-r \end{matrix} \\ \begin{bmatrix} M_1 & M_2 \\ 0 & 0 \end{bmatrix} \end{matrix},$$

where $U \in \mathbf{C}^{h\times h}$ is unitary and $\begin{bmatrix} M_1, & M_2 \end{bmatrix}$ has full row rank r. The unitary matrix U may be obtained from a QR factorization or the singular value decomposition (SVD) of M or a combination of both [18]. If necessary, U may be chosen so that M_1 is upper triangular. Excellent software for computing the SVD and QR factorizations is widely available [1, 9, 35]. A column compression is a row compression of M^H.

3. Reduction to condensed form. In this section we construct a unitary state transformation that reduces the system matrices of (1) to a staircase and double staircase form similar to those constructed in [2, 4, 3, 37, 36, 38, 39]. A feedback that minimizes the index can be constructed from this staircase form. In addition, the staircase form reveals which modes are uncontrollable at infinity and cannot be reduced to index one by feedback. According to the linear model (1) these modes are not excited and play no role in the system dynamics.

In what follows, it is convenient to allow partitioned matrices which in some special cases may have submatrices with no rows or no columns. In this case, of course, those submatrices are vacuous and simply do not appear. By convention, "0−by−0 matrices" are nonsingular.

LEMMA 3.1. *There exists a state transformation of* (1) *by unitary matrices* $P \in \mathbf{C}^{n\times n}$ *and* $Q \in \mathbf{C}^{n\times n}$ *such that*

$$PEQ = \begin{array}{c} \\ r \\ s \\ q \end{array}\!\!\begin{array}{c} \begin{array}{ccc} r & s & q \end{array} \\ \begin{bmatrix} E_{11} & 0 & E_{13} \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \end{array}, \tag{13}$$

$$PAQ = \begin{array}{c} \\ r \\ s \\ q \end{array}\!\!\begin{array}{c} \begin{array}{ccc} r & s & q \end{array} \\ \begin{bmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{23} \\ 0 & 0 & A_{33} \end{bmatrix} \end{array}, \tag{14}$$

$$PB = \begin{array}{c} \\ r \\ s \\ q \end{array}\!\!\begin{array}{c} \begin{array}{c} m \end{array} \\ \begin{bmatrix} B_1 \\ B_2 \\ 0 \end{bmatrix} \end{array}, \tag{15}$$

$$CQ = \begin{array}{c} \\ p \end{array}\!\!\begin{array}{c} \begin{array}{ccc} r & s & q \end{array} \\ \begin{bmatrix} C_1 & C_2 & C_3 \end{bmatrix} \end{array}, \tag{16}$$

where $r = \operatorname{rank}(E)$, $s = \operatorname{rank}(B_2)$, *and* $q = n - r - s$.

Proof. The proof is by construction. First choose a row compression of the augmented matrix $\begin{bmatrix} E, B, A \end{bmatrix}$,

$$P\begin{bmatrix} E, B, A \end{bmatrix} = \begin{array}{c} \\ r \\ s \\ q \end{array}\!\!\begin{array}{c} \begin{array}{ccccccc} r & s & q & m & r & s & q \end{array} \\ \begin{bmatrix} \tilde{E}_{11} & \tilde{E}_{12} & \tilde{E}_{13} & B_1 & \tilde{A}_{11} & \tilde{A}_{12} & \tilde{A}_{13} \\ 0 & 0 & 0 & B_2 & \tilde{A}_{21} & \tilde{A}_{22} & \tilde{A}_{23} \\ 0 & 0 & 0 & 0 & \tilde{A}_{31} & \tilde{A}_{32} & \tilde{A}_{33} \end{bmatrix} \end{array}, \tag{17}$$

where $r = \operatorname{rank}(E)$, $s = \operatorname{rank}(B_2)$, and $q = n - r - s$. If the column space of B is contained in the column space of E, then B_2 is vacuous and $s = 0$. Now, choose a column compression of the permuted submatrix

$$\begin{array}{c} \\ q \\ r \end{array}\!\!\begin{array}{c} \begin{array}{ccc} q & r & s \end{array} \\ \begin{bmatrix} \tilde{A}_{33} & \tilde{A}_{31} & \tilde{A}_{32} \\ \tilde{E}_{13} & \tilde{E}_{11} & \tilde{E}_{12} \end{bmatrix} \end{array}$$

to get

$$\begin{array}{c} \\ q \\ r \end{array}\!\!\begin{array}{c} \begin{array}{ccc} q & r & s \end{array} \\ \begin{bmatrix} \tilde{A}_{33} & \tilde{A}_{31} & \tilde{A}_{32} \\ \tilde{E}_{13} & \tilde{E}_{11} & \tilde{E}_{12} \end{bmatrix} \end{array}\tilde{Q} = \begin{array}{c} \\ q \\ r \end{array}\!\!\begin{array}{c} \begin{array}{ccc} q & r & s \end{array} \\ \begin{bmatrix} A_{33} & 0 & 0 \\ E_{13} & E_{11} & 0 \end{bmatrix} \end{array}.$$

If $K \in \mathbf{C}^{n\times n}$ is the permutation matrix

$$K = \begin{array}{c} \\ r \\ s \\ q \end{array} \begin{array}{c} \begin{array}{ccc} q & r & s \end{array} \\ \begin{bmatrix} 0 & I & 0 \\ 0 & 0 & I \\ I & 0 & 0 \end{bmatrix} \end{array},$$

then P as in (17) and $Q = K\tilde{Q}K^T$ satisfy the statement of the lemma. □

Note that E_{11} in (13) is not necessarily of full row rank. To achieve this we apply the lemma recursively to construct the following staircase-like condensed form, which generalizes the staircase form in [37] to three and four matrices.

THEOREM 3.2. *There exists a state transformation of* (1) *by unitary matrices* $P \in \mathbf{C}^{n\times n}$ *and* $Q \in \mathbf{C}^{n\times n}$ *which puts the system pencil in the form*

$$PEQ = \begin{array}{c} \\ t_1 \\ t_2 \\ t_3 \end{array} \begin{array}{c} \begin{array}{ccc} t_1 & t_2 & t_3 \end{array} \\ \begin{bmatrix} E_{11} & 0 & E_{13} \\ 0 & 0 & E_{23} \\ 0 & 0 & E_{33} \end{bmatrix} \end{array}, \tag{18}$$

$$PAQ = \begin{array}{c} \\ t_1 \\ t_2 \\ t_3 \end{array} \begin{array}{c} \begin{array}{ccc} t_1 & t_2 & t_3 \end{array} \\ \begin{bmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{23} \\ 0 & 0 & A_{33} \end{bmatrix} \end{array}, \tag{19}$$

$$PB = \begin{array}{c} \\ t_1 \\ t_2 \\ t_3 \end{array} \begin{array}{c} \begin{array}{c} m \end{array} \\ \begin{bmatrix} B_1 \\ B_2 \\ 0 \end{bmatrix} \end{array}, \tag{20}$$

$$CQ = \begin{array}{c} \\ p \end{array} \begin{array}{c} \begin{array}{ccc} t_1 & t_2 & t_3 \end{array} \\ \begin{bmatrix} C_1 & C_2 & C_3 \end{bmatrix} \end{array}, \tag{21}$$

where

(1) $\operatorname{rank}(E_{11}) = t_1$,

(2) $\operatorname{rank}(B_2) = t_2$,

(3) A_{33} *is block upper triangular, and*

(4) E_{33} *is block upper triangular, has zero diagonal blocks, and is partitioned conformally with* A_{33}.

Proof. The proof uses Lemma 3.1 inductively. Initially, apply Lemma 3.1 to get unitary matrices $P^{(1)}$ and $Q^{(1)}$ such that

$$P^{(1)}EQ^{(1)} = \begin{bmatrix} E_{11}^{(1)} & 0 & E_{13}^{(1)} \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix},$$

$$P^{(1)}AQ^{(1)} = \begin{bmatrix} A_{11}^{(1)} & A_{12}^{(1)} & A_{13}^{(1)} \\ A_{21}^{(1)} & A_{22}^{(1)} & A_{23}^{(1)} \\ 0 & 0 & A_{33}^{(1)} \end{bmatrix},$$

$$P^{(1)}B = \begin{bmatrix} B_1^{(1)} \\ B_2^{(1)} \\ 0 \end{bmatrix},$$

$$CQ^{(1)} = \begin{bmatrix} C_1^{(1)} & C_2^{(1)} & C_3^{(1)} \end{bmatrix}.$$

For the inductive step, assume that we have constructed a unitary state transformation $P^{(k)}$ and $Q^{(k)}$ such that the transformed system is in the form of (18)–(21) with the exception that $\operatorname{rank}(E_{11}^{(k)}) < t_1$. Apply Lemma 3.1 to the subsystem

$$\tilde{E} = \begin{bmatrix} E_{11}^{(k)} & 0 \\ 0 & 0 \end{bmatrix}, \quad \tilde{A} = \begin{bmatrix} A_{11}^{(k)} & A_{12}^{(k)} \\ A_{21}^{(k)} & A_{22}^{(k)} \end{bmatrix}, \quad \tilde{B} = \begin{bmatrix} B_1^{(k)} \\ B_2^{(k)} \end{bmatrix},$$
$$\tilde{C} = \begin{bmatrix} C_1^{(k)} & C_2^{(k)} \end{bmatrix}$$

to obtain a state transformation of the subsystem $\tilde{P}$ and $\tilde{Q}$ which brings the subsystem into the form of (13)–(16). Embed this transformation by defining

$$P^{(k+1)} = \begin{bmatrix} \tilde{P} & 0 \\ 0 & I \end{bmatrix} P^{(k)},$$
$$Q^{(k+1)} = Q^{(k)} \begin{bmatrix} \tilde{Q} & 0 \\ 0 & I \end{bmatrix}.$$

If the $(1,1)$ block of $P^{(k+1)}EQ^{(k+1)}$ is nonsingular, then the pencil is in the required form. Otherwise, Lemma 3.1 may be applied again to further refine the block structure. Each application of Lemma 3.1 reduces t_1 by at least one. After at most n steps either the $(1,1)$ block of the transformed E is nonsingular or $t_1 = 0$. In either case, the pencil reaches the required form in at most n steps. ∎

Theorem 3.2 essentially separates the uncontrollable infinite modes from the others. We have the following corollary.

COROLLARY 3.3. *In Theorem* 3.2*, the subsystem obtained from the first two block rows and columns of* (18)–(21)*,*

$$\begin{bmatrix} E_{11} & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \begin{bmatrix} B_1 \\ B_2 \end{bmatrix} u,$$

is controllable at infinity.

Proof. The proof follows directly from the definition. ∎

To understand the output feedback case, it is helpful to condense (18)–(21) somewhat further to a double staircase form that decouples both the uncontrollable at infinity modes and the unobservable at infinity modes. (See also [6].)

THEOREM 3.4. *There exists a state transformation of* (1) *by unitary matrices* $\tilde{P} \in \mathbf{C}^{n\times n}$ *and* $\tilde{Q} \in \mathbf{C}^{n\times n}$ *which puts the system pencil in the form*

$$\tilde{P}E\tilde{Q} = \begin{array}{c} \\ \tilde{t}_1 \\ \tilde{t}_2 \\ \tilde{t}_3 \\ \tilde{t}_4 \end{array} \begin{array}{c} \begin{array}{cccc} \tilde{t}_1 & \tilde{t}_2 & \tilde{t}_3 & \tilde{t}_4 \end{array} \\ \begin{bmatrix} \tilde{E}_{11} & 0 & 0 & \tilde{E}_{14} \\ 0 & 0 & 0 & \tilde{E}_{24} \\ \tilde{E}_{31} & \tilde{E}_{32} & \tilde{E}_{33} & \tilde{E}_{34} \\ 0 & 0 & 0 & \tilde{E}_{44} \end{bmatrix} \end{array}, \tag{22}$$

$$\tilde{P}A\tilde{Q} = \begin{array}{c} \\ \tilde{t}_1 \\ \tilde{t}_2 \\ \tilde{t}_3 \\ \tilde{t}_4 \end{array} \begin{array}{c} \begin{array}{cccc} \tilde{t}_1 & \tilde{t}_2 & \tilde{t}_3 & \tilde{t}_4 \end{array} \\ \begin{bmatrix} \tilde{A}_{11} & \tilde{A}_{12} & 0 & \tilde{A}_{14} \\ \tilde{A}_{21} & \tilde{A}_{22} & 0 & \tilde{A}_{24} \\ \tilde{A}_{31} & \tilde{A}_{32} & \tilde{A}_{33} & \tilde{A}_{34} \\ 0 & 0 & 0 & \tilde{A}_{44} \end{bmatrix} \end{array}, \tag{23}$$

$$\tilde{P}B = \begin{matrix} \\ \tilde{t}_1 \\ \tilde{t}_2 \\ \tilde{t}_3 \\ \tilde{t}_4 \end{matrix} \begin{matrix} m \\ \left[\begin{matrix} \tilde{B}_1 \\ \tilde{B}_2 \\ \tilde{B}_3 \\ 0 \end{matrix}\right] \end{matrix}, \tag{24}$$

$$C\tilde{Q} = \begin{matrix} \\ p \end{matrix} \begin{matrix} \tilde{t}_1 & \tilde{t}_2 & \tilde{t}_3 & \tilde{t}_4 \\ \left[\begin{matrix} \tilde{C}_1 & \tilde{C}_2 & 0 & \tilde{C}_4 \end{matrix}\right] \end{matrix}, \tag{25}$$

with the following properties.

(1) $\operatorname{rank}(\tilde{E}_{11}) = \tilde{t}_1$*;*

(2) $\operatorname{rank}(\tilde{C}_2) = \tilde{t}_2$*;*

(3) $\tilde{A}_{33}$ *is block lower triangular;*

(4) $\tilde{E}_{33}$ *is block lower triangular with zero diagonal blocks, partitioned conformally with* $\tilde{A}_{33}$*;*

(5) $\tilde{A}_{44}$ *is block upper triangular;*

(6) $\tilde{E}_{44}$ *is block upper triangular with zero diagonal blocks, partitioned conformally with* $\tilde{A}_{44}$*;*

(7) *the subsystem obtained by deleting the last block row and column in* (22)–(25) *is controllable at infinity.*

Proof. Apply Theorem 3.2 to system (1) to get the state transformations P_1 and Q_1 and partitioning of (18)–(21). Apply Theorem 3.2 again to the transposed subsystem given by

$$\hat{E} = \begin{pmatrix} & t_1 & t_2 \\ t_1 & \left[\begin{matrix} E_{11} & 0 \end{matrix}\right] \\ t_2 & \left[\begin{matrix} 0 & 0 \end{matrix}\right] \end{pmatrix}^H,$$

$$\hat{A} = \begin{pmatrix} & t_1 & t_2 \\ t_1 & \left[\begin{matrix} A_{11} & A_{12} \end{matrix}\right] \\ t_2 & \left[\begin{matrix} A_{21} & A_{22} \end{matrix}\right] \end{pmatrix}^H,$$

$$\hat{B} = \begin{pmatrix} & t_1 & t_2 \\ p & \left[\begin{matrix} C_1 & C_2 \end{matrix}\right] \end{pmatrix}^H,$$

$$\hat{C} = \begin{pmatrix} & m \\ t_1 & \left[\begin{matrix} B_1 \end{matrix}\right] \\ t_2 & \left[\begin{matrix} B_2 \end{matrix}\right] \end{pmatrix}^H$$

to get orthogonal matrices $\hat{P}$, $\hat{Q} \in \mathbf{C}^{(t_1+t_2)\times(t_1+t_2)}$ that reduce the subsystem to the form of (18)–(21). Define P_2 and Q_2 by

$$P_2 = \begin{bmatrix} \hat{Q}^H & 0 \\ 0 & I_{t_3} \end{bmatrix},$$

$$Q_2 = \begin{bmatrix} \hat{P}^H & 0 \\ 0 & I_{t_3} \end{bmatrix}.$$

The state transformation given by $\tilde{P} = P_2 P_1$ and $\tilde{Q} = Q_1 Q_2$ achieves the condensed form of (22)–(25).

Properties (1)–(4) come directly from Theorem 3.2 applied to the subsystem. Properties (5) and (6) also follow from Theorem 3.2 because when the second state transformation P_2, Q_2 is applied to (18)–(21), E_{33} and A_{33} are unchanged; i.e., $\tilde{A}_{44}$ in (23) is just A_{33} in (19) and $\tilde{E}_{44}$ in (22) is just E_{33} in (19). Property (7) follows because the first three block rows and columns in (22)–(25) are a state transformation by $\hat{P}$ and $\hat{Q}$ of the first two block rows and columns of (18)–(21). ∎

We have the following corollary.

COROLLARY 3.5. *The subsystem obtained by deleting the last two block rows and columns from* (22)–(25) *is controllable and observable at infinity.*

Proof. It is clear that the subsystem is observable at infinity by construction. By Theorem 3.4, we have that the subsystem given by

$$\begin{array}{c} \\ \tilde{t}_1 \\ \tilde{t}_2 \\ \tilde{t}_3 \end{array} \begin{array}{c} \begin{array}{ccc} \tilde{t}_1 & \tilde{t}_2 & \tilde{t}_3 \end{array} \\ \begin{bmatrix} \tilde{E}_{11} & 0 & 0 \\ 0 & 0 & 0 \\ \tilde{E}_{31} & \tilde{E}_{32} & \tilde{E}_{33} \end{bmatrix} \end{array}, \quad \begin{array}{c} \\ \tilde{t}_1 \\ \tilde{t}_2 \\ \tilde{t}_3 \end{array} \begin{array}{c} \begin{array}{ccc} \tilde{t}_1 & \tilde{t}_2 & \tilde{t}_3 \end{array} \\ \begin{bmatrix} \tilde{A}_{11} & \tilde{A}_{12} & 0 \\ \tilde{A}_{21} & \tilde{A}_{22} & 0 \\ \tilde{A}_{31} & \tilde{A}_{32} & \tilde{A}_{33} \end{bmatrix} \end{array}, \quad \begin{array}{c} \\ \tilde{t}_1 \\ \tilde{t}_2 \\ \tilde{t}_3 \end{array} \begin{array}{c} \begin{array}{c} m \end{array} \\ \begin{bmatrix} \tilde{B}_1 \\ \tilde{B}_2 \\ \tilde{B}_3 \end{bmatrix} \end{array},$$

$$\begin{array}{c} \\ p \end{array} \begin{array}{c} \begin{array}{ccc} \tilde{t}_1 & \tilde{t}_2 & \tilde{t}_3 \end{array} \\ \begin{bmatrix} \tilde{C}_1 & \tilde{C}_2 & 0 \end{bmatrix} \end{array}$$

is controllable at infinity. This directly implies that the subsystem given by

$$\begin{array}{c} \\ \tilde{t}_1 \\ \tilde{t}_2 \end{array} \begin{array}{c} \begin{array}{cc} \tilde{t}_1 & \tilde{t}_2 \end{array} \\ \begin{bmatrix} \tilde{E}_{11} & 0 \\ 0 & 0 \end{bmatrix} \end{array}, \quad \begin{array}{c} \\ \tilde{t}_1 \\ \tilde{t}_2 \end{array} \begin{array}{c} \begin{array}{cc} \tilde{t}_1 & \tilde{t}_2 \end{array} \\ \begin{bmatrix} \tilde{A}_{11} & \tilde{A}_{12} \\ \tilde{A}_{21} & \tilde{A}_{22} \end{bmatrix} \end{array}, \quad \begin{array}{c} \\ \tilde{t}_1 \\ \tilde{t}_2 \end{array} \begin{array}{c} \begin{array}{c} m \end{array} \\ \begin{bmatrix} \tilde{B}_1 \\ \tilde{B}_2 \end{bmatrix} \end{array},$$

$$\begin{array}{c} \\ p \end{array} \begin{array}{c} \begin{array}{cc} \tilde{t}_1 & \tilde{t}_2 \end{array} \\ \begin{bmatrix} \tilde{C}_1 & \tilde{C}_2 \end{bmatrix} \end{array}$$

is also controllable at infinity. ∎

4. Regularization and index minimization by state feedback. The following theorem answers the question of when state feedback may be used to make a descriptor system regular.

THEOREM 4.1. *If system* (1) *is in the form of Theorem* 3.2*, then the system is regularizable by state feedback; i.e., there exists a state feedback gain matrix* $F \in \mathbf{C}^{m\times n}$ *such that the pencil* $\lambda E - (A + BF)$ *is regular if and only if* A_{33} *is nonsingular.*

Proof. Let $F \in \mathbf{C}^{m\times n}$ be partitioned as

$$\begin{array}{c} \\ F = m \end{array} \begin{array}{c} \begin{array}{ccc} t_1 & t_2 & t_3 \end{array} \\ \begin{bmatrix} F_1 & F_2 & F_3 \end{bmatrix} \end{array}.$$

The pencil $\lambda E - (A + BF)$ is block upper triangular, so its characteristic polynomial is

$$\begin{aligned} &\det(\lambda E - (A + BF)) \\ &\quad = \det\left(\lambda \begin{bmatrix} E_{11} & 0 \\ 0 & 0 \end{bmatrix} - \left(\begin{bmatrix} A_{11} + B_1F_1 & A_{12} + B_1F_2 \\ A_{21} + B_2F_1 & A_{22} + B_2F_2 \end{bmatrix}\right)\right) \det(\lambda E_{33} - A_{33}) \\ &\quad = \det\left(\lambda \begin{bmatrix} E_{11} & 0 \\ 0 & 0 \end{bmatrix} - \left(\begin{bmatrix} A_{11} + B_1F_1 & A_{12} + B_1F_2 \\ A_{21} + B_2F_1 & A_{22} + B_2F_2 \end{bmatrix}\right)\right) \det(-A_{33}). \end{aligned} \tag{26}$$

The last equality follows because $\lambda E_{33} - A_{33}$ is block triangular with diagonal blocks that are independent of λE_{33}.

If A_{33} is singular, then (26) is zero independent of λ, and the pencil is not regular.

Suppose that A_{33} is nonsingular. Because B_2 has full row rank, there exists a matrix $F_2 \in \mathbf{C}^{m\times t_2}$ such that $A_{22} + B_2F_2$ is nonsingular. Let

$$F = \begin{matrix} \\ m \end{matrix} \begin{matrix} \begin{matrix} t_1 & t_2 & t_3 \end{matrix} \\ \begin{bmatrix} 0 & F_2 & 0 \end{bmatrix} \end{matrix}.$$

The first factor on the right-hand side of (26) is the characteristic polynomial of the subpencil

$$\lambda \begin{bmatrix} E_{11} & 0 \\ 0 & 0 \end{bmatrix} - \left(\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} + \begin{bmatrix} B_1 \\ B_2 \end{bmatrix} \begin{bmatrix} 0 & F_2 \end{bmatrix} \right). \tag{27}$$

Since $A_{22} + B_2F_2$ is nonsingular, the pencil in (27) is equivalent to a pencil of the form

$$\lambda \begin{bmatrix} E_{11} & 0 \\ 0 & 0 \end{bmatrix} - \begin{bmatrix} \tilde{A}_{11} & \tilde{A}_{12} \\ 0 & A_{22} + B_2F_2 \end{bmatrix}. \tag{28}$$

It then follows from the nonsingularity of E_{11} and Lemma 2.3 that (28) is regular and has index one. Hence, neither factor in (26) is identically zero and the pencil is regular. ∎

The next theorem shows what index can be achieved by state feedback.

THEOREM 4.2. *If system* (1) *is in the form of Theorem* 3.2 *and* A_{33} *is nonsingular, then there exists a state feedback gain matrix* $F \in \mathbf{C}^{m\times n}$ *such that* $\lambda E - (A + BF)$ *is regular and*

$$\operatorname{index}(\lambda E - (A + BF)) = \operatorname{index} \begin{pmatrix} & \begin{matrix} t_2 & t_3 \end{matrix} \\ \begin{matrix} t_2 \\ t_3 \end{matrix} & \begin{bmatrix} 0 & E_{23} \\ 0 & E_{33} \end{bmatrix} \end{pmatrix}.$$

Proof. Choose $F_1 \in \mathbf{C}^{m\times t_1}$ so that $A_{21} + B_2F_1 = 0$ and choose $F_2 \in \mathbf{C}^{m\times t_2}$ so that $A_{22} + B_2F_2$ is nonsingular. Both F_1 and F_2 exist, because B_2 has full row rank. Define $F \in \mathbf{C}^{m\times n}$ by

$$F = \begin{matrix} \\ m \end{matrix} \begin{matrix} \begin{matrix} t_1 & t_2 & t_3 \end{matrix} \\ \begin{bmatrix} F_1 & F_2 & 0 \end{bmatrix} \end{matrix}.$$

The pencil $\lambda E - (A + BF)$ is block upper triangular with diagonal blocks

$$\lambda E_{11} - (A_{11} + B_1F_1), \tag{29}$$

$$\lambda \begin{bmatrix} 0 & E_{23} \\ 0 & E_{33} \end{bmatrix} - \begin{bmatrix} A_{22} + B_2F_2 & A_{32} \\ 0 & A_{33} \end{bmatrix}. \tag{30}$$

Pencil (29) has only finite eigenvalues because E_{11} is nonsingular. Pencil (30) has only infinite eigenvalues, because the left-hand side is nilpotent and the right-hand side is nonsingular. Lemma 2.2 implies that

$$\begin{aligned} \operatorname{index}(\lambda E - (A + BF)) &= \operatorname{index} \left(\lambda \begin{bmatrix} 0 & E_{23} \\ 0 & E_{33} \end{bmatrix} - \begin{bmatrix} A_{22} + B_2F_2 & A_{32} \\ 0 & A_{33} \end{bmatrix} \right) \\ &= \operatorname{index} \left(\begin{bmatrix} 0 & E_{23} \\ 0 & E_{33} \end{bmatrix} \right). \end{aligned}$$

Here we have used properties 3 and 4 of Theorem 3.2. ∎

The index of nilpotency of $\left(\begin{bmatrix} 0 & E_{23} \\ 0 & E_{33} \end{bmatrix}\right)$ can be displayed by applying another staircase algorithm.

The Kronecker-like feedback canonical form of [24] also displays this minimal index, but this canonical form is not suitable for numerical computation.

An obvious consequence of Theorem 4.2 is that the index of nilpotency of E_{33} differs from the minimal obtainable index by at most one.

THEOREM 4.3. *Suppose that system* (1) *is in the form of Theorem* 3.2. *If* $F \in \mathbf{C}^{m\times n}$ *is a state feedback gain matrix for which* $\lambda E - (A + BF)$ *is regular, then*

$$\operatorname{index}(E_{33}) + 1 \geq \operatorname{index}(\lambda E - (A + BF)) \geq \operatorname{index}(E_{33}).$$

Proof. The proof is an immediate consequence of Theorem 4.2. ∎

If (1) is in the form of Theorem 3.2, then the subsystem $E_{33}\dot{z} = A_{33}z$ represents the uncontrollable infinite eigenvalue modes. Being uncontrollable, as Theorem 4.3 shows, there is nothing that feedback can do to lower $\operatorname{index}(\lambda E_{33} - A_{33})$. However, the next theorem shows that, regardless of initial condition, $z(t) = 0$ for $t > 0$ and $z(0^+) = 0$.

If $z(0^-) = 0$, then z is impulse free and constrained to be zero. Hence, the uncontrollable, infinite modes are not involved in the dynamics! To prove this result we use the trivial fact that if $N \in \mathbf{C}^{n\times n}$ is nilpotent, then the only smooth function $x = x(t) \in \mathbf{C}^n$ satisfying $N\dot{x} = x$ is $x = 0$. It follows that any distributional solution of $N\dot{x} = x$ is purely impulsive and for $t > 0$, $x(t) = 0$. The distributional solution is impulse free if and only if $Nx(0^-) = 0$. Moreover, $x(0^-) = x(0^+)$ if and only if $x(0^-) = x(0^+) = 0$.

THEOREM 4.4. *If the descriptor system in the form of Theorem* 3.2,

$$\begin{bmatrix} E_{11} & 0 & E_{13} \\ 0 & 0 & E_{23} \\ 0 & 0 & E_{33} \end{bmatrix} \begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \dot{x}_3 \end{bmatrix} = \begin{bmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{23} \\ 0 & 0 & A_{33} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} + \begin{bmatrix} B_1 \\ B_2 \\ 0 \end{bmatrix} u, \tag{31}$$

is regularizable, then for $t > 0$, $x_3(t) = 0$ *independent of the control* u. *If* $E_{33}x_3(0^-) = 0$, *then* x_3 *is impulse free.*

Proof. The third equation of (31) is $E_{33}\dot{x}_3 = A_{33}x_3$. Theorem 4.1 implies that A_{33} is nonsingular, so this is equivalent to $A_{33}^{-1}E_{33}\dot{x}_3 = x_3$ and $A_{33}^{-1}E_{33}x_3(0^-) = 0$. By hypothesis, properties 3 and 4 of Theorem 3.2 hold, so A_{33} and E_{33} are block upper triangular and $A_{33}^{-1}E_{33}$ is nilpotent. The theorem follows. ∎

It follows from Theorems 4.1, 4.2, and 4.4 that a regularizable system decouples into the uncontrollable infinite modes and the subsystem

$$\begin{bmatrix} E_{11} & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \begin{bmatrix} B_1 \\ B_2 \end{bmatrix} u. \tag{32}$$

The infinite uncontrollable modes play no role in the system dynamics. With consistent initial conditions, they are constrained to be zero. Only the modes involved in (32) are active. The subsystem (32) is controllable at infinity, so the results of [4, 3] apply. It follows that those modes constrained to be zero may be eliminated from the system. In this way, all regularizable descriptor systems may be made to be controllable at infinity. Hence, the methods designed for linear quadratic control, pole assignment, stabilization, etc., under the assumption of controllability at infinity, may be used [27].

A similar result in the context of linear quadratic control of a particular mechanical multibody system was obtained by explicit transformation in [28].

5. Geometric proofs. In this section we will provide *geometric* proofs for the results in the previous sections.

Let $\mathcal{I}_s$ denote the *largest* subspace $\mathcal{L}$ that satisfies

$$\mathcal{L} \subset A^{(-1)}(E\mathcal{L} + \mathrm{Im}(B)).$$

For a discussion of this space see [13, 23, 26]. The subspace $\mathcal{I}_s = A^{(-1)}(E\mathcal{L}+\mathrm{Im}(B))$ is called the *consistent* subspace, since every point in $\mathcal{I}_s$ is consistent; i.e., for every point $x_0 \in \mathcal{I}_s$ there exists a smooth input $u(t)$ and an associated smooth state trajectory $x(t)$ of system (1) satisfying $x(0) = x_0$ [13].

Let $\mathcal{X}_1$ be such that $\mathcal{X}_1 \oplus (\mathcal{I}_s \cap \ker(E)) = \mathcal{I}_s$; let $\mathcal{X}_3$ be such that $\mathcal{I}_s \oplus \mathcal{X}_3 = \mathbf{C}^n$; and let $\mathcal{Y}_2, \mathcal{Y}_3, \mathcal{Y}_4$ be spaces chosen such that $E\mathcal{I}_s \oplus \mathcal{Y}_2 = E\mathcal{I}_s + \mathrm{Im}(B)$, $(E\mathcal{I}_s + \mathrm{Im}(B)) \oplus \mathcal{Y}_3 = E\mathcal{I}_s + \mathrm{Im}(B) + \mathrm{Im}(A)$, and $(E\mathcal{I}_s + \mathrm{Im}(B) + \mathrm{Im}(A)) \oplus \mathcal{Y}_4 = \mathbf{C}^n$. Choose $\mathcal{U}_2$ so that $B^{(-1)}(E\mathcal{I}_s) \oplus \mathcal{U}_2 = \mathbf{C}^m$. With respect to suitably chosen bases, (1) transforms to

$$\begin{bmatrix} E_{11} & 0 & E_{13} \\ 0 & 0 & E_{23} \\ 0 & 0 & E_{33} \\ 0 & 0 & E_{43} \end{bmatrix} \dot{x}(t) = \begin{bmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{23} \\ 0 & 0 & A_{33} \\ 0 & 0 & 0 \end{bmatrix} x(t) + \begin{bmatrix} B_{11} & B_{12} \\ 0 & B_{22} \\ 0 & 0 \\ 0 & 0 \end{bmatrix} u(t). \tag{33}$$

By construction, $\ker(B_{22}) = 0$, B_{22} is right invertible, E_{11} is invertible, and

$$M(\lambda) = \left[\lambda \begin{bmatrix} E_{23} \\ E_{33} \\ E_{43} \end{bmatrix} - \begin{bmatrix} A_{23} \\ A_{33} \\ 0 \end{bmatrix}, \quad \begin{bmatrix} B_{22} \\ 0 \\ 0 \end{bmatrix} \right]$$

has full column rank for all $\lambda \in \mathbf{C}$ [15, Appendix, Lemma 1]. In addition, we can show that A_{33} is square and therefore nonsingular.

LEMMA 5.1. *If the system* (1) *is in the form* (33)*, then* A_{33} *is invertible.*

Proof. We have that $A\mathcal{I}_s = (E\mathcal{I}_s + \mathrm{Im}(B)) \cap \mathrm{Im}(A)$. (See, for example, [16].) In addition [30]

$$\begin{aligned} \dim(A\mathcal{I}_s) &= \dim(\mathcal{I}_s) - \dim(\mathcal{I}_s \cap \ker(A)) \\ &= \dim(\mathcal{I}_s) - \dim(\ker(A)) \\ &= \dim(\mathcal{I}_s) - n + \mathrm{rank}(A). \end{aligned}$$

Thus,

$$\begin{aligned} &\dim(E\mathcal{I}_s + \mathrm{Im}(B)) + \dim(\mathrm{Im}(A)) \\ &= \dim(E\mathcal{I}_s + \mathrm{Im}(B) + \mathrm{Im}(A)) + \dim(E\mathcal{I}_s + \mathrm{Im}(B)) \cap \mathrm{Im}(A)) \\ &= \dim(E\mathcal{I}_s + \mathrm{Im}(B) + \mathrm{Im}(A)) + \dim(\mathcal{I}_s) - n + \dim(\mathrm{Im}(A)) \end{aligned}$$

and $\dim(E\mathcal{I}_s + \mathrm{Im}(B) + \mathrm{Im}(A)) = n - \dim(\mathcal{I}_s)$. Therefore, A_{33} is square and hence invertible. ∎

The next step is to relate the condensed form (33) to the regularizability of the system. We have the following well-known result [11, 31].

THEOREM 5.2. *The following are equivalent.*

(i) $E\mathcal{I}_s + \mathrm{Im}(B) + \mathrm{Im}(A) = \mathbf{C}^n$.

(ii) $\begin{bmatrix} \lambda E - A, & B \end{bmatrix}$ *is right invertible as a rational matrix.*

(iii) *The system* (1) *is regularizable by proportional state feedback.*

Proof. For completeness we give a short proof of this result. Statement (i) implies that $\mathcal{Y}_4 = \{0\}$. Hence, the last block row in (33) does not occur. From Lemma 5.1, it follows that A_{33} is invertible. By choosing feedback $u = Fx + v$ with

$$F = \begin{bmatrix} 0 & 0 & 0 \\ -B_{22}^{-1}A_{21} & B_{22}^{-1}(I - A_{22}) & 0 \end{bmatrix}, \tag{34}$$

we obtain the closed loop system

$$E\dot{x} = (A + BF)x + Bv \tag{35}$$

for which $\begin{bmatrix} \lambda E - (A + BF), & B \end{bmatrix}$ is right invertible. This implies (ii).

Conversely (ii) implies that $M(\lambda)$ is right invertible. Hence, $\mathcal{Y}_4 = \{0\}$ and we have (i).

Statement (i) implies statement (iii) because the feedback (34) makes the pencil (35) regular. The converse is clear. If (i) did not hold, then for every feedback F, the pencil of the closed loop system would be singular, which contradicts (iii). ∎

From this we see that for regularizable systems the condensed form (18)–(21), which is constructible in a numerically stable way, coincides with the form (33).

6. Derivative and output feedback. In this section we give a few results about derivative and output feedback.

If we use state derivative feedback, the minimal attainable index is index(E_{33}) in (18).

THEOREM 6.1. *If* (1) *is in the form of Theorem* 3.2 *and* A_{33} *is nonsingular, then then there exists a derivative feedback gain matrix* $G \in \mathbf{C}^{m\times n}$ *such that the pencil* $\lambda(E + BG) - A$ *is regular with* $t_1 + t_2$ *finite eigenvalues and* index$(\lambda(E + BG) - A =$ index(E_{33}).

Proof. Let $G_2 \in \mathbf{C}^{m\times t_2}$ be chosen so that B_2G_2 is nonsingular. Define G by

$$G = \begin{matrix} \\ m \end{matrix} \begin{matrix} \begin{matrix} t_1 & t_2 & t_3 \end{matrix} \\ \begin{bmatrix} 0 & G_2 & 0 \end{bmatrix} \end{matrix}.$$

Then

$$\lambda(E + BG) - A = \lambda \begin{bmatrix} E_{11} & B_1G_2 & E_{13} \\ 0 & B_2G_2 & E_{23} \\ 0 & 0 & E_{33} \end{bmatrix} - \begin{bmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{23} \\ 0 & 0 & A_{33} \end{bmatrix}.$$

This is a block triangular pencil with diagonal blocks

$$\lambda \begin{bmatrix} E_{11} & B_1G_2 \\ 0 & B_2G_2 \end{bmatrix} - \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}, \qquad \lambda E_{33} - A_{33}.$$

By Lemma 2.2, the infinite eigenvalues are the eigenvalues of $\lambda E_{33} - A_{33}$ and

$$\begin{aligned} \text{index}(\lambda(E + BG) - A) &= \text{index}(\lambda E_{33} - A_{33}) \\ &= \text{index}(E_{33}). \end{aligned}$$ ∎

The conclusion of Theorem 6.1 also holds if both state and derivative feedback are used.

An extra hypothesis is needed to obtain the same results in the output feedback case.

THEOREM 6.2. *If equation* (1) *is in the form of Theorem* 3.2*, then the system is regularizable by output feedback; i.e., there exists an output feedback gain matrix* F *such that* $\lambda E - (A + BFC)$ *is regular and*

$$\operatorname{index}(\lambda E - (A + BFC)) = \operatorname{index} \begin{pmatrix} & t_2 & t_3 \\ t_2 & \begin{bmatrix} 0 & E_{23} \end{bmatrix} \\ t_3 & \begin{bmatrix} 0 & E_{33} \end{bmatrix} \end{pmatrix}$$

if and only if A_{33} *is nonsingular and* $\begin{bmatrix} A_{22} \\ C_2 \end{bmatrix}$ *has full column rank.*

Proof. Since B_2 has full row rank there is a matrix F such that $A_{22} + B_2FC_2$ is nonsingular if and only if $\begin{bmatrix} A_{22} \\ C_2 \end{bmatrix}$ has full column rank. Applying the argument in the proof of Theorem 4.1, the result follows. ∎

It follows immediately from Theorem 3.4 that the part of the system which is unobservable at infinity can be completely decoupled from the rest of the system. This part of the system can be removed because, according to the linear model, it does not influence the dynamics of the system and the possible impulsive behavior cannot be observed.

7. Discrete time systems and linear quadratic control. So far, we have discussed continuous time systems only. It should be noted that Lemma 3.1, Corollary 3.5, and Theorems 3.2, 3.4, 4.1, 4.2, 4.3, and 6.1 are independent of the origin of the matrices and thus also hold for discrete time systems. There exists an easily formulated, analogous discrete time version of Theorem 4.4.

The results apply to linear quadratic optimal control problems of the following form:

minimize the cost functional

$$J(x, u) := \int_{t_0}^{t_1} (x^T Q x + u^T R u)\, dt$$

subject to the descriptor system (1).

After transforming to the reduced form of Theorem 3.2, we may just omit the components which are uncontrollable at infinity from the cost functional and the constraint to obtain a reduced order problem which is controllable at infinity. For such systems, the methods described in [27] apply. For a detailed analysis of general linear quadratic optimal control problems for descriptor systems see [15].

8. Conclusions. According to the linear model (1), problems associated with uncontrollable infinite modes in a regularizable system do not occur. With consistent initial conditions, they are constrained to be zero. The only active dynamics in (1) are controllable at infinity. The active dynamics may be made to be index one by state feedback and the entire system may be treated as if it were controllable at infinity as in [4, 3]. However, the resulting system is not index-one robust. If there is an unmodeled forcing function that excites modes that are uncontrollable at infinity, then it may generate impulses.[1]

[1] The situation is similar to one described in a nonsense verse [22]:

Yesterday, upon the stair
I saw a man who wasn't there.
He wasn't there again today.
Gee, I wish he'd go away!

The uncontrollable high-index infinite modes are the man upon the stair. He is not there, but he is disturbing nevertheless.

Acknowledgment. We thank P.C. Müller for bringing the systems that are not controllable at infinity to our attention and A. Bunse-Gerstner, J. Demmel, and P. Van Dooren for helpful discussions in an early stage of this paper. We also thank an anonymous referee for many helpful comments in preparing a revised version of the paper.

A BEHAVIORAL APPROACH TO DELAY-DIFFERENTIAL SYSTEMS*

HEIDE GLÜSING-LÜERSSEN†

Abstract. We will study linear time-invariant delay-differential systems from the behavioral point of view as it was introduced for dynamical systems by Willems [*Dynam. Report.*, 2 (1989), pp. 171–269]. A ring $\mathcal{H}$ which lies between $\mathbb{R}[s, z, z^{-1}]$ and $\mathbb{R}(s)[z, z^{-1}]$ will be presented, whose elements can be interpreted as a generalized version of delay-differential operators on $\mathcal{C}^\infty(\mathbb{R}, \mathbb{R})$. In this framework, a behavior is the kernel of such an operator. Using the ring $\mathcal{H}$, an algebraic characterization of inclusion, respectively, equality of the behaviors under consideration, is given. Finally, controllability of the behaviors is characterized in terms of the rank of the associated matrices. In the case of time-delay state-space systems this criterion becomes the known Hautus criterion for spectral controllability.

Key words. time-delay systems, behaviors, polynomial matrices

1. Introduction.

The purpose of this paper is an approach to linear time-invariant delay-differential systems with algebraic methods. In contrast to the work of, e.g., Morse [16], Sontag [21], and more recently Habets [8], we will not consider these systems as systems over (polynomial) rings. Instead we will use the behavioral viewpoint for dynamical systems as it was introduced by Willems [22]: our objects will be behaviors, which are defined by linear time-invariant delay-differential equations over the time axis $\mathbb{R}$ (for the definition of a behavior, see [22]). In the scalar case such equations are given by

$$\sum_{j=0}^{L}\sum_{i=0}^{N} p_{ij} w^{(i)}(t-j) = 0, \qquad t \in \mathbb{R}, \tag{1.1}$$

where $p_{ij} \in \mathbb{R}$ and $w^{(i)}$ denotes the ith derivative of the function w. In our approach only functions w in $\mathcal{C}^\infty(\mathbb{R}, \mathbb{R})$ will be considered. In the multivariable case, linear subspaces $\mathcal{B}$ of $\mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^m)$ are investigated that are the solution space of a system of delay-differential equations, i.e., for which there exist n, L, $N \in \mathbb{N}$, and matrices $P_{ij} \in \mathbb{R}^{n\times m}$ so that

$$\mathcal{B} = \left\{ w \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^m) \middle| \sum_{j=0}^{L}\sum_{i=0}^{N} P_{ij} w^{(i)}(t-j) = 0,\ t \in \mathbb{R} \right\}. \tag{1.2}$$

The behavior in (1.2) can be written as $\mathcal{B} = \ker \widetilde{P}$, where $P = \sum_{j=0}^{L}\sum_{i=0}^{N} P_{ij} s^i z^j \in \mathbb{R}[s, z]^{n\times m}$ and $\widetilde{P}$ denotes the associated delay-differential operator from $\mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^m)$ to $\mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^n)$; i.e., $\widetilde{P}w(t) = \sum_{j=0}^{L}\sum_{i=0}^{N} P_{ij} w^{(i)}(t-j)$. Note that (1.2) includes ordinary differential equations ($P \in \mathbb{R}[s]$) as well as the case of a pure delay equation

($P \in \mathbb{R}[z]$). Since the shift yields an isomorphism on $\mathcal{C}^\infty(\mathbb{R},\mathbb{R})$, it is algebraically more adequate to consider the polynomial ring $\mathbb{R}[s,z,z^{-1}]$ instead of $\mathbb{R}[s,z]$.

Although the space $\mathcal{B}$ is in general infinite dimensional, via polynomial matrices it is given a description with finitely many parameters. This leads to the possibility of studying special aspects of this type of equations with mainly algebraic methods.

The polynomial approach to time-delay systems was already introduced by Kamen [10]. He considered delay-differential operators as special convolution operators in the distributional sense and presented, within this set-up, procedures for the solution of input/output equations and for the internal description (state-space realizations) of such equations.

In the present paper our starting point will be the solution spaces (or behaviors) $\ker \widetilde{P}$ as given in (1.2). We will not investigate the question as to which subspaces of $\mathcal{C}^\infty(\mathbb{R},\mathbb{R}^m)$ occur as such behaviors. The main ideas for an answer to this question are contained in the thesis of Soethoudt [20]. He characterizes behaviors which have an AR-representation (that is, a representation via autoregressive equations) in the purely differential sense. Instead of attacking this (nevertheless interesting) problem of the existence of polynomial representations, we will consider the question of uniqueness: for what pairs of matrices P, Q over $\mathbb{R}[s,z,z^{-1}]$ does $\ker \widetilde{P} = \ker \widetilde{Q}$ hold? It should be obvious that an answer to this question is necessary for the development of a "behavioral theory" using polynomial (AR-) representations for time-delay systems. Simple examples show that the above problem cannot be satisfactorily solved with the help of the ring $\mathbb{R}[s,z,z^{-1}]$ or even $\mathbb{R}(s)[z,z^{-1}]$. The appropriate domain in order to translate relations between behaviors into relations between the associated polynomial matrices lies between these two rings and turns out to be

$$\mathcal{H} = \{p \in \mathbb{R}(s)[z,z^{-1}] \,|\, p(s,e^{-s}) \text{ is an entire function}\}.$$

In the preliminaries an interpretation of the elements of $\mathcal{H}$ as operators on $\mathcal{C}^\infty(\mathbb{R},\mathbb{R})$ is given. It generalizes the interpretation of polynomials in $\mathbb{R}[s,z,z^{-1}]$ as delay-differential operators. Therefore we will refer to these associated operators as delay-differential operators as well.

A similar construction occurred already in the work of Kamen, Khargonekar, and Tannenbaum [11], where the ring Θ generated by the entire functions $(1-e^{-s}e^{\sigma})(s-\sigma)^{-1}$, $\sigma \in \mathbb{C}$, and their derivatives is considered. One can easily see that the ring $\Theta[s,z]$ in [11, p. 841] is contained in $\mathcal{H}$. Kamen, Khargonekar, and Tannenbaum also gave an interpretation of the functions $(1-e^{-s}e^{\sigma})(s-\sigma)^{-1}$ as transfer functions of distributed-delay systems.

One main tool in the present approach is the fact that the division properties in the ring $\mathcal{H}$ correspond to the division properties in the ring of entire functions, i.e., for p, $q \in \mathcal{H}$ it holds: p divides q in $\mathcal{H}$ iff $q(s,e^{-s})p(s,e^{-s})^{-1}$ is an entire function. For the associated delay-differential equations this has as a consequence that it suffices to consider *fundamental solutions*, i.e., functions of the type $w(t) = t^k e^{\lambda t}$ instead of the full solution space. This fits with a result of Malgrange [14, p. 318], who proved that the space of all linear combinations of fundamental solutions of a delay-differential equation lies dense in the full space of smooth solutions (with respect to the topology of uniform convergence of all derivatives on all compact subsets in $\mathbb{R}$).

Another important result in our framework is the fact that $\mathcal{H}$ is a so-called elementary divisor ring. This means first that $\mathcal{H}$ is a Bézout domain, i.e., every finitely generated ideal in $\mathcal{H}$ is principal. Second, every matrix over $\mathcal{H}$ can be brought into diagonal form via multiplication with unimodular matrices from the left and from the right. With this type of normal form (which cannot be achieved, e.g., over the

ring $\mathbb{R}[s, z, z^{-1}]$), the results for multivariable delay-differential equations can easily be derived from the scalar case.

With this information about the ring $\mathcal{H}$, which is derived in section 3, we will show in the fourth section how the relations between behaviors as given in (1.2) can be put into correspondence with the division relations of the associated matrices over $\mathcal{H}$. In particular, we prove for $P \in \mathcal{H}^{n\times m}$, $Q \in \mathcal{H}^{r\times m}$: $\ker \widetilde{P} \subseteq \ker \widetilde{Q}$ iff $Q = AP$ for some $A \in \mathcal{H}^{n\times r}$, which yields $\ker \widetilde{P} = \ker \widetilde{Q}$ iff A is unimodular over $\mathcal{H}$.

Finally, in section 5, controllability of delay-differential systems is considered. In this set-up it is natural to use the notion of controllability for behaviors as introduced by Willems [22]. Using a diagonal form for matrices $P \in \mathcal{H}^{n\times m}$, it will be proven that $\ker \widetilde{P}$ is controllable iff $\mathrm{rk}_{\mathbb{C}} P(s, e^{-s}) = \mathrm{rk}_{\mathcal{H}} P$ for all $s \in \mathbb{C}$. Recently, this characterization has been obtained independently for the same situation of delay-differential equations by Rocha and Willems [19]. The given criterion is a generalization of the Hautus test for time-delay state-space systems which characterizes the so-called *spectral controllability*; see, e.g., Pandolfi [18], Bhat and Koivo [2], Manitius and Triggiani [15], and Kamen, Kargonekar, and Tannenbaum [11].

2. Preliminaries. In this section we present the framework for our study of delay-differential equations and introduce the notations. Starting with the interpretation of polynomials in $\mathbb{R}[s, z, z^{-1}]$ as delay-differential operators on $\mathcal{C}^\infty(\mathbb{R}, \mathbb{R})$, we first have a glance at the fundamental solutions of the associated equations. This leads us to the corresponding characteristic function and its zeros. Simple examples suggest the introduction of a larger space $\mathcal{H}$ of operators which are closely related to the delay-differential operators. Finally we state the surjectivity of the operators under consideration.

DEFINITION 2.1.

(1) *Put* $\mathcal{R} := \mathbb{R}[s, z, z^{-1}]$ *and let* $\mathcal{C}^\infty(\mathbb{R}^m) := \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^m)$ *for* $m \geq 1$.

(2) *For* $m \geq 1$ *and* $t_0 \in \mathbb{R}$ *define the shift* $\sigma^{t_0} : \mathcal{C}^\infty(\mathbb{R}^m) \to \mathcal{C}^\infty(\mathbb{R}^m)$ *by* $(\sigma^{t_0} w)(t) = w(t - t_0)$ *for* $w \in \mathcal{C}^\infty(\mathbb{R}^m)$. *In particular, let* $\sigma := \sigma^1$.

(3) *With* $P = \sum_{j=l}^{L} \sum_{i=0}^{N} P_{ij} s^i z^j \in \mathcal{R}^{n\times m}$ *associate the following delay-differential operator:*

$$\begin{aligned} \widetilde{P} : \mathcal{C}^\infty(\mathbb{R}^m) &\longrightarrow \mathcal{C}^\infty(\mathbb{R}^n), \\ w &\longmapsto \sum_{j=l}^{L} \sum_{i=0}^{N} P_{ij} \sigma^j w^{(i)}, \end{aligned} \tag{2.1}$$

where $w^{(i)} = \frac{d^i}{dt^i} w$.

(4) *For* $p = \sum_{i=0}^{N} p_i s^i \in \mathbb{R}[s]$ *and* $w \in \mathcal{C}^\infty([a, b], \mathbb{R}) =: \mathcal{C}^\infty[a, b]$ *we use analogously the notion* $\widetilde{p}(w)(t) = \sum_{i=0}^{N} p_i w^{(i)}(t)$, *hence* $\widetilde{p}(w) \in \mathcal{C}^\infty[a, b]$.

Note that part (3) indeed makes sense, since on $\mathcal{C}^\infty(\mathbb{R})$ the operators σ and $\frac{d}{dt}$ commute.

In this context, the solution space in $\mathcal{C}^\infty(\mathbb{R})$ of the scalar equation (1.1) is just $\ker \widetilde{p}$, a linear *shift-invariant* subspace of $\mathcal{C}^\infty(\mathbb{R})$; i.e., $\sigma^t(\ker \widetilde{p}) = \ker \widetilde{p}$ for all $t \in \mathbb{R}$. In this section we will only study the scalar equation (1.1). We will come to the multivariable situation in section 4.

Remark 2.2. The map

$$\begin{aligned} T : \mathcal{R} &\longrightarrow \mathrm{End}_{\mathbb{R}}(\mathcal{C}^\infty(\mathbb{R})), \\ p &\longmapsto \widetilde{p} \end{aligned}$$

is an injective algebra homomorphism. The homomorphism properties $\widetilde{p+q} = \widetilde{p} + \widetilde{q}$, $\widetilde{pq} = \widetilde{p} \circ \widetilde{q}$ can easily be verified. To prove injectivity of T, let $p = \sum_{i,j} p_{ij} s^i z^j \in \mathcal{R}$ and assume that $\widetilde{p} = 0$. Then for arbitrary $\lambda \in \mathbb{C}$ and $w \in \mathcal{C}^\infty(\mathbb{R})$ with $w(t) = e^{\lambda t}$ we obtain $0 = \widetilde{p}(w)(t) = \sum_{i,j} p_{ij} \lambda^i e^{\lambda(t-j)} = \sum_{i,j} p_{ij} \lambda^i e^{-\lambda j} e^{\lambda t}$ for all $t \in \mathbb{R}$, hence $\sum_{i,j} p_{ij} \lambda^i e^{-\lambda j} = 0$. Since this holds true for all $\lambda \in \mathbb{C}$, the linear independence of the functions $\lambda \mapsto \lambda^i e^{\lambda j}$ yields in fact $p_{ij} = 0$ for all i, j.

One question we want to attack in this paper is how to characterize the inclusion $\ker \widetilde{p} \subseteq \ker \widetilde{q}$ in terms of the elements p, $q \in \mathcal{R}$. Let us first have a look at a simple example.

Example 2.3.

(1) For p, $q \in \mathbb{R}[s] \subset \mathcal{R}$ the theory of ordinary differential equations leads to $\ker \widetilde{p} \subseteq \ker \widetilde{q}$ iff p divides q in $\mathbb{R}[s]$, hence iff p divides q in $\mathcal{R}$.

(2) It is easily seen that

$$\ker \widetilde{s} = \{\text{constants}\} \subset \ker \widetilde{z-1} = \{w \in \mathcal{C}^\infty(\mathbb{R}) | w \text{ is of period } 1\}.$$

But s does not divide $z - 1$ in $\mathcal{R}$. Of course, s divides $z - 1$ in $\mathbb{R}(s)[z, z^{-1}]$.

The above shows that the division properties of the two rings $\mathcal{R}$ and $\mathbb{R}(s)[z, z^{-1}]$ are not useful in the algebraic description of $\ker \widetilde{p} \subseteq \ker \widetilde{q}$.

As with ordinary differential equations, more information about the solution space of (1.1) is obtainable by studying fundamental solutions $w(t) = t^k e^{\lambda t}$, where $k \in \mathbb{N}_0$ and $\lambda \in \mathbb{C}$. In the present case this leads to the characteristic function of (1.1), which will be an entire function. We will need the concept of a characteristic function in a slightly more general situation, which is handled in the next definition. In the special case of part (2) of the definition, these functions are often called quasi polynomials (see, e.g., [7, p. 63]) or exponential polynomials (see [1, Chap. 12]). In parts (3) and (4) we introduce some notations useful for what follows.

DEFINITION 2.4.

(1) *For* $p = \sum_{j=l}^{L} p_j z^j \in \mathbb{R}(s)[z, z^{-1}]$ *with* $p_j \in \mathbb{R}(s)$ *and* $p_l \neq 0 \neq p_L$ *define the degree of* p *to be* $\deg_z p := L - l$. *Further, let*

$$p^*(s) := \sum_{j=l}^{L} p_j(s) e^{-js} \text{ for all } s \in \mathbb{C} \text{ not being a pole of } p_j,\ j = l, \ldots, L.$$

Then $p^* \in M(\mathbb{C})$, *the set of all meromorphic functions on* $\mathbb{C}$.

(2) *If* $p = \sum_{j=l}^{L} \sum_{i=0}^{N} p_{ij} s^i z^j \in \mathcal{R}$, *then* $p^* \in H(\mathbb{C})$, *the set of entire functions.* p^* *is called the* characteristic function of the delay-differential equation

$$\sum_{j=l}^{L} \sum_{i=0}^{N} p_{ij} w^{(i)}(t-j) = 0, \qquad t \in \mathbb{R}.$$

(3) *For* $f \in M(\mathbb{C})$ *and* $\alpha \in \mathbb{C}$ *denote the* order of the zero *(resp.,* pole*)* α *of* f *by*

$$\mu_\alpha(f) := \min\{k \in \mathbb{Z} \,|\, (s-\alpha)^{-k} f \text{ holomorphic and not zero around } \alpha\}.$$

(4) *For* $f_1, \ldots, f_r \in M(\mathbb{C})$ *let*

$$\mathcal{V}(f_1, \ldots, f_r) = \{\alpha \in \mathbb{C} \,|\, \mu_\alpha(f_i) \geq 1,\ i = 1, \ldots, r\}$$

be the set of common zeros of $f_1, \ldots, f_r$.

Note that we interpret here s as an algebraic indeterminate over $\mathbb{R}$ as well as a complex variable.

Remark 2.5. The map $\mathbb{R}(s)[z, z^{-1}] \to M(\mathbb{C})$, $p \mapsto p^*$ is an injective ring homomorphism. The injectivity follows, as in Remark 2.2, from the linear independence of the functions $s \mapsto s^k e^{js}$.

With this notation, we get from the theory of delay-differential equations for $p \in \mathcal{R}$ and for the function $w \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{C})$, $w(t) = t^k e^{\lambda t}$,

$$w \in \ker \widetilde{p} \iff \mu_\lambda(p^*) > k \tag{2.2}$$

(see [1, pp. 54–55] for a special case). This can also be proven directly by showing that $\widetilde{p}w(t) = \frac{d^k}{ds^k}(p^*(s)e^{st})|_{s=\lambda}$. As with ordinary differential equations it is true that with $w \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{C})$ also $\operatorname{Re} w$, $\operatorname{Im} w \in \mathcal{C}^\infty(\mathbb{R})$ are in $\ker \widetilde{p}$.

The foregoing consideration indicates that a first knowledge about the dimension of $\ker \widetilde{p}$ can be obtained by calculating the number of zeros of the associated characteristic function p^*. Using the theory of entire functions this can be done in the following sense.

PROPOSITION 2.6. *Let $p \in \mathcal{R}$. Then*

$$\#\mathcal{V}(p^*) < \infty \iff p = z^k \phi \text{ for some } k \in \mathbb{Z} \text{ and } \phi \in \mathbb{R}[s]\backslash\{0\}.$$

This result can be proven by use of some facts about the order of entire functions, as they can be found, e.g., in [9]. Since we are not aware of an explicit proof in the literature, we present here a short sketch of how to establish the result with the help of [9].

Proof. "$\Leftarrow$" is obvious.

"$\Rightarrow$" Let $p = \sum_{j=l}^{L} p_j z^j \in \mathcal{R}$ with $p_j \in \mathbb{R}[s]$. If $\#\mathcal{V}(p^*) < \infty$, then $p^* = ae^g$ with $a \in \mathbb{C}[s]$ and $g \in H(\mathbb{C})$. Suppose that g is not a constant. From [9, Lemmas 2.7.3 and 2.7.4 and Theorem 4.2.1] it follows that $\operatorname{ord}(p^*) = \operatorname{ord}(\sum_{j=l}^{L} p_j e^{-j\cdot}) \leq 1$, where the order $\operatorname{ord}(f)$ of an entire function f is defined as in [9, Definition 1.11.1]. But then [9, Lemmas 2.7.3 and 2.7.5] implies $g \in \mathbb{C}[s]$, and moreover $g(s) = \alpha s + \beta$ with some $\alpha, \beta \in \mathbb{C}$. Hence $p^*(s) = \sum_{j=l}^{L} p_j(s) e^{-js} = a(s)e^{\beta} e^{\alpha s}$. Now, from the independence of the functions $s^k e^{\alpha s}$, we get $\alpha \in \{-L, \ldots, -l\}$ and $p_j = 0$ for $j \neq -\alpha$. Thus $p = p_{-\alpha} z^\alpha$. ∎

Note the simple fact that for $p = z^k \phi \in \mathcal{R}$ with $\phi \in \mathbb{R}[s]$ and $k \in \mathbb{Z}$ one has $\ker \widetilde{p} = \ker \widetilde{\phi}$, which is just the solution space of an ordinary linear homogeneous differential equation with constant coefficients over $\mathbb{R}$. Hence, as an immediate consequence of (2.2) and Proposition 2.6 we get

$$\#\mathcal{V}(p^*) = \infty \iff \dim \ker \widetilde{p} = \infty$$

for arbitrary $p \in \mathcal{R}$. In other words, $\ker \widetilde{p}$ is finite dimensional iff $\widetilde{p}$ is a (shifted) ordinary differential operator. Moreover, for $q \in \mathcal{R}$ and $\phi \in \mathbb{R}[s]\backslash\{0\}$ the finite dimensionality of $\ker \widetilde{\phi}$ together with (2.2) implies the crucial fact that

$$\frac{q^*}{\phi} \in H(\mathbb{C}) \iff \ker \widetilde{\phi} \subseteq \ker \widetilde{q}. \tag{2.3}$$

This easy equivalence is central for our framework, as it allows us to introduce a bigger class $\mathcal{H}$ of linear operators on $\mathcal{C}^\infty(\mathbb{R})$ which are closely related to delay-differential operators. More precisely, for $p = q\phi^{-1} \in \mathbb{R}(s)[z, z^{-1}]$, where $p^* = q^* \phi^{-1} \in H(\mathbb{C})$, it is possible to define $\widetilde{p} = \widetilde{q} \circ \widetilde{\phi}^{-1}$.

We introduce precisely these objects in the following definition and show their well-definedness as well as some elementary properties in Remark 2.8.

DEFINITION 2.7.

(1) *Put* $\mathcal{H} := \{p \in \mathbb{R}(s)[z, z^{-1}] \mid p^* \in H(\mathbb{C})\}$.

(2) *For* $p = q\phi^{-1} \in \mathcal{H}$ *with* $q \in \mathcal{R}$ *and* $\phi \in \mathbb{R}[s]\backslash\{0\}$ *define the operator*

$$\widetilde{p}: \mathcal{C}^\infty(\mathbb{R}) \longrightarrow \mathcal{C}^\infty(\mathbb{R}),$$
$$w \longmapsto \widetilde{p}(w) := \widetilde{q}(v), \quad \text{where } v \in \mathcal{C}^\infty(\mathbb{R}) \text{ with } \widetilde{\phi}(v) = w.$$

We call $\widetilde{p}$ *a* delay-differential operator *also if* $p \in \mathcal{H}$.

Remark 2.8.

(1) From Remark 2.5 it follows that $\mathcal{H}$ is a commutative domain.

(2) One has to establish the well-definedness of the map $\widetilde{p}$. First, for fixed $q \in \mathcal{R}$ and $\phi \in \mathbb{R}[s]$ with $q\phi^{-1} \in \mathcal{H}$ the well-definedness of the map $w \mapsto \widetilde{q}(v)$, where $v \in \mathcal{C}^\infty(\mathbb{R})$ satisfies $\widetilde{\phi}(v) = w$, is a consequence of (2.3). Next, to see that the map $\widetilde{p}$ does not depend on the special representation of p, let $p = q\phi^{-1} = q'\psi^{-1} \in \mathcal{H}$. For $w \in \mathcal{C}^\infty(\mathbb{R})$ put $\widetilde{\phi}(v) = w = \widetilde{\psi}(v')$ and $\widetilde{\phi}(h) = v'$ with suitable v, v', $h \in \mathcal{C}^\infty(\mathbb{R})$. Then $\widetilde{\psi}(h) - v \in \ker\widetilde{\phi} \subseteq \ker\widetilde{q}$ and therefore $\widetilde{q}(v) = \widetilde{q}(\widetilde{\psi}(h)) = \widetilde{q'}(\widetilde{\phi}(h)) = \widetilde{q'}(v')$.

(3) It can easily be verified that $\widetilde{p}$ is an endomorphism on $\mathcal{C}^\infty(\mathbb{R})$. Moreover, the ring $\mathcal{H}$ can be viewed as a subring of $\mathrm{End}_{\mathbb{R}}(\mathcal{C}^\infty(\mathbb{R}))$. To see this, we need to prove that the map $p \mapsto \widetilde{p}$ is an injective ring homomorphism. For this, let $p = a\phi^{-1}$, $q = b\psi^{-1} \in \mathcal{H}$ with a, $b \in \mathcal{R}$, and ϕ, $\psi \in \mathbb{R}[s]$. For $w \in \mathcal{C}^\infty(\mathbb{R})$ define $v \in \mathcal{C}^\infty(\mathbb{R})$ such that $\widetilde{\phi\psi}(v) = w$. Then $\widetilde{p+q}(w) = (\widetilde{a\psi + b\phi})(v) = \widetilde{a\psi}(v) + \widetilde{b\phi}(v) = \widetilde{p}(w) + \widetilde{q}(w)$ and from $\widetilde{\psi}(\widetilde{\phi}(v)) = w$ it follows $\widetilde{p} \circ \widetilde{q}(w) = \widetilde{p}(\widetilde{b}(\widetilde{\phi}(v))) = \widetilde{p} \circ \widetilde{\phi}(\widetilde{b}(v)) = \widetilde{a} \circ \widetilde{b}(v) = \widetilde{ab}(v) = \widetilde{pq}(w)$, where we used the homomorphism properties of T as defined in Remark 2.2. The injectivity of $p \mapsto \widetilde{p}$ follows from the same remark.

(4) A special case of the homomorphism property of $p \mapsto \widetilde{p}$ is the following: from $p = q\phi^{-1} \in \mathcal{H}$ one has obviously $p\phi = q = \phi p$ in the ring $\mathcal{H}$. The definition of $\widetilde{p}$ tells us that $\widetilde{q}(v) = \widetilde{p} \circ \widetilde{\phi}(v)$ for all $v \in \mathcal{C}^\infty(\mathbb{R})$ and $\widetilde{q}(w) = \widetilde{q}(\widetilde{\phi}(v)) = \widetilde{\phi}(\widetilde{q}(v)) = \widetilde{\phi} \circ \widetilde{p}(w)$ for v, $w \in \mathcal{C}^\infty(\mathbb{R})$ satisfying $\widetilde{\phi}(v) = w$. Hence it is indeed $\widetilde{q} = \widetilde{p} \circ \widetilde{\phi} = \widetilde{\phi} \circ \widetilde{p}$.

This shows that Definition 2.7(2) represents the unique extension of the algebra homomorphism T given in Remark 2.2 from $\mathcal{R}$ to the larger ring $\mathcal{H}$.

Let us illustrate the general delay-differential operator by the following example, which is in some sense the simplest nonordinary delay-differential operator.

Example 2.9. Let $p := (z-1)s^{-1} \in \mathbb{R}(s)[z]$. Then $p^*(s) = (e^{-s} - 1)s^{-1}$ is an entire function; thus $p \in \mathcal{H}$. The associated operator is given by

$$\widetilde{p}: \mathcal{C}^\infty(\mathbb{R}) \longrightarrow \mathcal{C}^\infty(\mathbb{R}),$$
$$w \longmapsto \sigma(v) - v, \text{ where } v^{(1)} = w.$$

Obviously, $\ker(\widetilde{z-1}) = \{v \in \mathcal{C}^\infty(\mathbb{R}) | v \text{ is of period } 1\}$; therefore,

$$\ker\widetilde{p} = \{w \in \mathcal{C}^\infty(\mathbb{R}) | \exists v \in \mathcal{C}^\infty(\mathbb{R}) \text{ of period 1 and with } v^{(1)} = w\},$$

which is a proper subspace of $\ker(\widetilde{z-1})$. Note that in the above case we have $\widetilde{p}(w) = \int_t^{t-1} w(\tau)d\tau$, which indicates that $\mathcal{H}$ includes not only point-delay operators but also distributed-delay operators.

As we will see in section 4, it is just the ring $\mathcal{H}$ which gives an algebraic description of the relation between behaviors of the type $\ker\widetilde{p} \subset \mathcal{C}^\infty(\mathbb{R})$: the lattice of kernels of operators $\widetilde{p}$ corresponds to the lattice of principal ideals in $\mathcal{H}$. Therefore, for the development of this correspondence it makes sense to consider also delay-differential operators in the generalized version of Definition 2.7. The ring $\mathcal{H}$ will be investigated in the next section.

We close the preliminaries with the following proposition.

PROPOSITION 2.10. *Let $p \in \mathcal{H}\backslash\{0\}$. Then*

(1) *The map $\widetilde{p} \in \mathrm{End}_{\mathbb{R}}(\mathcal{C}^\infty(\mathbb{R}))$ is surjective.*

(2) *Let $\deg_z p = L > 0$. If $w \in \mathcal{C}^\infty(\mathbb{R})$ satisfies $\widetilde{p}(w) = 0$ and $w|_{[k,k+L]} = 0$ for some $k \in \mathbb{Z}$, then $w = 0$.*

The result of part (1) can be found in [6, p. 697]. Since [6] uses rather difficult methods to also prove surjectivity for other (more general) operators, we present a complete and elementary proof of both parts of the proposition in the appendix. Of course, the surjectivity of $\widetilde{p}$ is well known if $p \in \mathbb{R}[s]$.

3. Properties of the ring $\mathcal{H}$. Two facts about the ring $\mathcal{H}$ will be important for what follows. One is that the division structure of $\mathcal{H}$ corresponds to the division properties of the associated entire functions in the full ring $H(\mathbb{C})$. This is made precise in Proposition 3.1(5). The other main fact about $\mathcal{H}$ is its advantageous ring structure. In Theorem 3.2 we will show that $\mathcal{H}$ is a *Bézout ring*, i.e., that every finitely generated ideal is principal. Stated in other words, finitely many elements $p_1, \dots, p_r \in \mathcal{H}$ have a greatest common divisor $d \in \mathcal{H}$ which fulfills a Bézout equation $d = \sum_{i=1}^r a_i p_i$ over $\mathcal{H}$. Furthermore, with Lemma 3.4 it will be proven that $\mathcal{H}$ is an *elementary divisor ring*, which means that matrices over $\mathcal{H}$ can be brought into diagonal form via multiplication with unimodular matrices from both sides. This is a very useful fact in order to handle the matrix case of delay-differential equations. One should note that both properties hold true also for the ring $H(\mathbb{C})$ (see, e.g., [17, Thm. 5, p. 136 and Thm. 8, p. 141]), but not for $\mathcal{R}$.

PROPOSITION 3.1.

(1) *If $p \in \mathcal{H}$ and $\alpha \in \mathbb{C}$, then $p^*(\bar{\alpha}) = \overline{p^*(\alpha)}$, where $^-$ denotes complex conjugation.*

(2) *Define $\mathcal{H}^\times := \{p \in \mathcal{H} \,|\, p \text{ is a unit}\}$. Then $\mathcal{H}^\times = \{az^k \,|\, a \in \mathbb{R}\backslash\{0\},\, k \in \mathbb{Z}\} = \{p \in \mathcal{H} \,|\, \mathcal{V}(p^*) = \emptyset\}$.*

(3) *$\mathcal{H}$ is not a unique factorization domain and not a Noetherian ring.*

(4) *For $p \in \mathcal{H}$ the following statements are equivalent:* (i) *p is irreducible,* (ii) *$p = \phi z^k$ for some irreducible $\phi \in \mathbb{R}[s]$ and $k \in \mathbb{Z}$, and* (iii) *p is prime.*

(5) *Let $p, q \in \mathcal{H}$. Then $p^* \,|\, q^*$ in $H(\mathbb{C}) \Longleftrightarrow p \,|\, q$ in $\mathcal{H}$.*

(6) *For $p, q \in \mathcal{H}$, not both zero, there exists a greatest common divisor (gcd) $d \in \mathcal{H}\backslash\{0\}$ of p, q which is unique up to multiplication by units in $\mathcal{H}$. Moreover, $\mathcal{V}(d^*) = \mathcal{V}(p^*, q^*)$. In particular, p and q are coprime in $\mathcal{H}$ iff $\mathcal{V}(p^*, q^*) = \emptyset$.*

(7) *Let $p = ad$, $q = bd \in \mathcal{H}\backslash\{0\}$, with d being a gcd of p, q and with $a, b \in \mathcal{H}$. Then $c := abd \in \mathcal{H}$ is a least common multiple (lcm) of p, q. An lcm is unique up to multiplication by units in $\mathcal{H}$.*

Proof. (1) This is obvious.

(2) Let $p \in \mathcal{H}^\times$. Then p is also a unit in $\mathbb{R}(s)[z, z^{-1}]$. Thus $p = az^k$ for some $a \in \mathbb{R}(s)$ and $k \in \mathbb{Z}$. Since $p^*(s) = a(s)e^{-ks}$ and $(p^{-1})^*(s) = a(s)^{-1}e^{ks}$ are both entire functions, it follows that $a \in \mathbb{R}\backslash\{0\}$. The last equality holds with Proposition 2.6.

(3) Consider $z - 1 \in \mathcal{H}$. Let $(\alpha_i)_{i\in\mathbb{N}} \subset \mathbb{C}\backslash\{0\}$ so that $e^{-\alpha_i} - 1 = 0$, $\alpha_i \neq \alpha_j$ for $i \neq j$ and $\alpha_{2i+1} = \overline{\alpha_{2i}}$ for $i \in \mathbb{N}$. Then $p_i := (s - \alpha_{2i})(s - \alpha_{2i+1}) \in \mathbb{R}[s]$ satisfies $z - 1 = \frac{z-1}{p_i} p_i = \frac{z-1}{\Pi_{i=1}^n p_i} \prod_{i=1}^n p_i$, and these are factorizations of $z - 1$ in $\mathcal{H}$. Moreover, the chain

$$\tfrac{z-1}{p_1}\mathcal{H} \subseteq \tfrac{z-1}{p_1 p_2}\mathcal{H} \subseteq \tfrac{z-1}{p_1 p_2 p_3}\mathcal{H} \subseteq \cdots$$

of ideals in $\mathcal{H}$ will not become stationary.

(4) "(i) $\Rightarrow$ (ii)" Let $p \in \mathcal{H}$ be irreducible. According to part (2) there exists $\alpha \in \mathbb{C}$ with $p^*(\alpha) = 0$. If $\alpha \in \mathbb{R}$, then $p = \frac{p}{s-\alpha}(s-\alpha)$ is a factorization in $\mathcal{H}$; thus $\frac{p}{s-\alpha}$ has to be a unit in $\mathcal{H}$. By (2) this yields $p = az^k(s-\alpha)$ for some nonzero $a \in \mathbb{R}$ and $k \in \mathbb{Z}$, which gives (ii). If $\alpha \notin \mathbb{R}$, then with part (1) one gets analogously $p = az^k(s-\alpha)(s-\bar{\alpha})$.

"(ii) $\Rightarrow$ (iii)" Let $\phi \in \mathbb{R}[s]$ be irreducible. Then ϕ is prime in $\mathbb{R}[s]$ and of the form $\phi = s-\alpha$ or $\phi = (s-\alpha)(s-\bar{\alpha})$. Suppose $p = \phi z^k$ and $p \,|\, fg$ in $\mathcal{H}$ for some $f, g \in \mathcal{H}$. Then $(fg)^* p^{*^{-1}} = (f^* g^*) p^{*^{-1}} \in H(\mathbb{C})$ and both cases for ϕ imply by use of (1): $p \,|\, f$ or $p \,|\, g$.

"(iii) $\Rightarrow$ (i)" holds true in every commutative domain.

(5) The direction "$\Leftarrow$" holds since $p \mapsto p^*$ is a ring homomorphism. "$\Rightarrow$" Let $q^*(p^*)^{-1} \in H(\mathbb{C})$. In the field $\mathbb{R}(s,z)$ we can write $qp^{-1} = ab^{-1}$ with coprime $a, b \in \mathbb{R}[s,z]$. The theorem of Bézout for algebraic curves implies

$$\#\{(\lambda,\mu) \in \mathbb{C}^2 \,|\, a(\lambda,\mu) = 0 = b(\lambda,\mu)\} < \infty.$$

Since $a^*(b^*)^{-1} = q^*(p^*)^{-1} \in H(\mathbb{C})$ yields $\mathcal{V}(b^*) \subseteq \mathcal{V}(a^*)$, we get $\#\mathcal{V}(b^*) < \infty$. By use of Proposition 2.6, this leads to $b = \phi z^k$ for some $\phi \in \mathbb{R}[s]\backslash\{0\}$ and $k \in \mathbb{Z}$. Hence $qp^{-1} = az^{-k}\phi^{-1} \in \mathcal{H}$.

(6) Since $\mathcal{H} \subset \mathbb{R}(s)[z,z^{-1}]$, there exists a gcd $d \in \mathbb{R}(s)[z,z^{-1}]$ of p, q. Thus $p = fd$, $q = gd$ with coprime f, $g \in \mathbb{R}(s)[z,z^{-1}]$.

In order to derive from this suitable factorizations in $\mathcal{H}$, we shall shift the poles of f^* or g^* and the common zeros of f^* and g^* within multiplicities into the factor d. To do so, let

$$\mathcal{P} = \{\alpha \in \mathbb{C} | \mu_\alpha(f^*) < 0 \text{ or } \mu_\alpha(g^*) < 0\}$$

be the set of poles of f or g. Then we have $\#\mathcal{P} < \infty$ as well as $\#\mathcal{V}(f^*, g^*) < \infty$ and $\mathcal{P} \cap \mathcal{V}(f^*, g^*) = \emptyset$. Put

$$\phi := \prod_{\alpha \in \mathcal{P}} (s-\alpha)^{\max\{-\mu_\alpha(f^*), -\mu_\alpha(g^*)\}} \in \mathbb{R}[s],$$
$$\psi := \prod_{\alpha \in \mathcal{V}(f^*,g^*)} (s-\alpha)^{\min\{\mu_\alpha(f^*), \mu_\alpha(g^*)\}} \in \mathbb{R}[s].$$

This leads to

$$(3.1)\quad p = \frac{f\phi}{\psi}\frac{\psi}{\phi}d,\ q = \frac{g\phi}{\psi}\frac{\psi}{\phi}d \ \text{ where } \frac{f\phi}{\psi},\ \frac{g\phi}{\psi} \in \mathcal{H} \ \text{ and } \mathcal{V}\left(\left(\frac{f\phi}{\psi}\right)^*, \left(\frac{g\phi}{\psi}\right)^*\right) = \emptyset.$$

Moreover, $\frac{\psi}{\phi}d \in \mathcal{H}$, for if $\alpha \in \mathbb{C}$ was a pole of $(\frac{\psi}{\phi}d)^*$, then it would follow that $\alpha \in \mathcal{V}((\frac{f\phi}{\psi})^*, (\frac{g\phi}{\psi})^*)$ since $p^*, q^* \in H(\mathbb{C})$. Hence we have a factorization $p = f'd'$, $q = g'd'$ in $\mathcal{H}$, and $\mathcal{V}((f')^*, (g')^*) = \emptyset$ implies that $(d')^*$ is a gcd of p^*, q^* in $H(\mathbb{C})$.

To show that d' is a gcd of p, q in $\mathcal{H}$, let $p = f''d''$, $q = g''d''$ with f'', g'', $d'' \in \mathcal{H}$. Then $p^* = (f'')^*(d'')^*$, $q^* = (g'')^*(d'')^*$, and thus $(d'')^* \,|\, (d')^*$ in $H(\mathbb{C})$. By part (5) this yields $ad'' = d'$ for some $a \in \mathcal{H}$ and therefore d' is a gcd of p, q in $\mathcal{H}$. This argument also implies the uniqueness property claimed for a gcd in $\mathcal{H}$.

The equality $\mathcal{V}(d^*) = \mathcal{V}(p^*, q^*)$ follows from (3.1), and the last claim of part (6) is an easy consequence of (2).

(7) Obviously $p \,|\, c$ and $q \,|\, c$ in $\mathcal{H}$. Let $c' \in \mathcal{H}$ be another common multiple of p and q; i.e., let there exist v, $w \in \mathcal{H}$ with $adv = c' = bdw$. Therefore $av = bw$

and $a^*v^* = b^*w^*$ in $H(\mathbb{C})$. This yields $w^* = (a^*v^*)(b^*)^{-1} \in H(\mathbb{C})$, and moreover $v^*(b^*)^{-1} \in H(\mathbb{C})$, since by (6) a^* and b^* have no common zeros. From (5) we get the existence of $b' \in \mathcal{H}$ with $bb' = v$ and thus $c' = adbb' = cb'$. □

Now we can prove the following.

THEOREM 3.2. *$\mathcal{H}$ is a* Bézout ring*, i.e., every finitely generated ideal is a principal ideal.*

Proof. We need to show that for $p, q \in \mathcal{H}$ and a gcd $d \in \mathcal{H}$ of p, q there exist $a, b \in \mathcal{H}$ so that $d = ap+bq$, for this implies $p\mathcal{H}+q\mathcal{H} = d\mathcal{H}$. Without loss of generality we can assume $d = 1$; hence by Proposition 3.1(6) we see that $\mathcal{V}(p^*, q^*) = \emptyset$.

Step 1. The elements p, q are coprime also in $\mathbb{R}(s)[z, z^{-1}]$. To see this, let $uv = p$, $uw = q$ with $u, v, w \in \mathbb{R}(s)[z, z^{-1}]$; then let $u = \widetilde{u}\phi^{-1}$, $v = \widetilde{v}\phi^{-1}, p = \tilde{p}\phi^{-1}, q = \tilde{q}\phi^{-1}$ with $\widetilde{u}, \widetilde{v}, \widetilde{p}, \widetilde{q} \in \mathcal{R}$, $\phi \in \mathbb{R}[s]$. Then $\widetilde{u}\widetilde{v} = p\phi$ and $\deg_z \widetilde{u} \geq 1$ would imply that all irreducible factors u_i of $\widetilde{u}$ with $\deg_z u_i \geq 1$ divide $\widetilde{p}$ in $\mathcal{R}$. Similarly $u_i \mid \widetilde{q}$ in $\mathcal{R}$ and thus u would be a nontrivial common factor of p, q in $\mathcal{H}$, which contradicts the coprimeness of p, q in $\mathcal{H}$. Thus $u \in \mathbb{R}(s)$ and is therefore a unit in $\mathbb{R}(s)[z, z^{-1}]$.

Hence there exists a Bézout equation in $\mathbb{R}(s)[z, z^{-1}]$; i.e.,

$$1 = ap + bq \text{ with suitable } a, b \in \mathbb{R}(s)[z, z^{-1}]. \tag{3.2}$$

Step 2. Next we will vary the coefficients a, b of (3.2) in such a way that we get a Bézout equation for p and q with coefficients in $\mathcal{H}$. More precisely, we will construct a rational function $v \in \mathbb{R}(s)$ so that

$$b + vp,\ a - vq \in \mathcal{H}. \tag{3.3}$$

Then (3.2) will imply the Bézout equation $1 = (a - vq)p + (b + vp)q$ in $\mathcal{H}$.

Step 2a. In order to achieve (3.3) we have to get rid of the poles of a^* and b^*. Therefore, write

$$a = \frac{\widetilde{a}}{\psi},\ b = \frac{\widetilde{b}}{\phi} \text{ with } \widetilde{a}, \widetilde{b} \in \mathcal{H},\ \psi, \phi \in \mathbb{R}[s] \text{ and } \mathcal{V}(\widetilde{a}^*, \psi) = \mathcal{V}(\widetilde{b}^*, \phi) = \emptyset. \tag{3.4}$$

Let $h \in \mathbb{R}[s]$ be a gcd of ψ, ϕ and $\psi = h\psi_1$, $\phi = h\phi_1$ with ψ_1, $\phi_1 \in \mathbb{R}[s]$. Then (3.2) becomes

$$h\psi_1\phi_1 = \phi_1\widetilde{a}p + \psi_1\widetilde{b}q, \tag{3.5}$$

where all elements are in $\mathcal{H}$. From $\psi_1(h\phi_1 - \widetilde{b}q) = \phi_1\widetilde{a}p$ and $\mathcal{V}(\psi_1, \phi_1) = \emptyset = \mathcal{V}(\widetilde{a}^*, \psi_1)$ it results with Proposition 3.1(5) $\psi_1 \mid p$ in $\mathcal{H}$. So let $p = p_1\psi_1$ with $p_1 \in \mathcal{H}$. Similarly, it is $q = q_1\phi_1$ with $q_1 \in \mathcal{H}$. Thus after cancellation of $\psi_1\phi_1$, (3.5) reads

$$h = \widetilde{a}p_1 + \widetilde{b}q_1. \tag{3.6}$$

Step 2b. Put $v = \frac{f}{h\psi_1\phi_1} \in \mathbb{R}(s)$, where $f \in \mathbb{R}[s]$ still has to be specified. Then (3.3) implies that we have to find $f \in \mathbb{R}[s]$ such that

$$\begin{cases} (b+vp)^* &= \big(\dfrac{\widetilde{b}}{h\phi_1} + \dfrac{f}{h\phi_1\psi_1}p_1\psi_1\big)^* = \dfrac{(\widetilde{b}+fp_1)^*}{h\phi_1} \in H(\mathbb{C}), \\ (a-vq)^* &= \big(\frac{\widetilde{a}}{h\psi_1} - \frac{f}{h\phi_1\psi_1}q_1\phi_1\big)^* = \frac{(\widetilde{a}-fq_1)^*}{h\psi_1} \in H(\mathbb{C}). \end{cases} \tag{3.7}$$

Hence we have to look for a polynomial $f \in \mathbb{R}[s]$ which places the zeros of $\widetilde{b}^* + fp_1^*$ and $\widetilde{a}^* - fq_1^*$ appropriately at the same time. In the rest of the proof we will show

that these are two interpolation problems for f which can in fact be solved with the same polynomial $f \in \mathbb{R}[s]$.

First, for $\alpha \in \mathcal{V}(\phi_1 h)$ one has $p_1^*(\alpha) \neq 0$, since (i) If $\alpha \in \mathcal{V}(\phi_1) \subset \mathcal{V}(q^*)$, then $\alpha \notin \mathcal{V}(p^*)$; hence $\alpha \notin \mathcal{V}(p_1^*)$. (ii) If $h(\alpha) = 0$, then by (3.6) and (3.4) it follows that $0 = \widetilde{a}^*(\alpha)p_1^*(\alpha) + \widetilde{b}^*(\alpha)q_1^*(\alpha)$ and $\widetilde{a}^*(\alpha) \neq 0 \neq \widetilde{b}^*(\alpha)$. Therefore, $\mathcal{V}(p^*, q^*) = \emptyset$ yields $p_1^*(\alpha) \neq 0 \neq q_1^*(\alpha)$.

For $\alpha \in \mathcal{V}(\phi_1 h)$ this leads to

$$\begin{aligned}
\mu_\alpha(\widetilde{b}^* + fp_1^*) \geq k &\iff (\widetilde{b}^* + fp_1^*)^{(\nu)}(\alpha) = 0,\ \nu = 0, \dots, k-1 \\
&\iff \widetilde{b}^{*^{(\nu)}}(\alpha) + \sum_{\mu=0}^{\nu} \tbinom{\nu}{\mu} f^{(\mu)}(\alpha) p_1^{*^{(\nu-\mu)}}(\alpha) = 0,\ \nu = 0, \dots, k-1 \\
&\iff f^{(\nu)}(\alpha) = -\frac{1}{p_1^*(\alpha)} \left[\widetilde{b}^{*^{(\nu)}}(\alpha) + \sum_{\mu=0}^{\nu-1} \tbinom{\nu}{\mu} p_1^{*^{(\nu-\mu)}}(\alpha) f^{(\mu)}(\alpha) \right] \\
&\qquad \text{for } \nu = 0, \dots, k-1.
\end{aligned}$$

A similar result holds for $\alpha \in \mathcal{V}(\psi_1 h)$. As a consequence $f \in \mathbb{R}[s]$ satisfies (3.7) iff

$$f^{(\nu)}(\alpha) = \begin{cases}
-\dfrac{1}{p_1^*(\alpha)} \left[\widetilde{b}^{*^{(\nu)}}(\alpha) + \displaystyle\sum_{\mu=0}^{\nu-1} \tbinom{\nu}{\mu} p_1^{*^{(\nu-\mu)}}(\alpha) f^{(\mu)}(\alpha) \right] & \\
\text{for } \nu = 0, \dots, \mu_\alpha(\phi_1 h) - 1 \qquad \text{if } \alpha \in \mathcal{V}(\phi_1 h) & \\
\dfrac{1}{q_1^*(\alpha)} \left[\widetilde{a}^{*^{(\nu)}}(\alpha) - \displaystyle\sum_{\mu=0}^{\nu-1} \tbinom{\nu}{\mu} q_1^{*^{(\nu-\mu)}}(\alpha) f^{(\mu)}(\alpha) \right] & \\
\text{for } \nu = 0, \dots, \mu_\alpha(\psi_1 h) - 1 \qquad \text{if } \alpha \in \mathcal{V}(\psi_1 h). &
\end{cases} \tag{3.8}$$

In particular, for $\alpha \in \mathcal{V}(\phi_1 h) \cap \mathcal{V}(\psi_1 h) = \mathcal{V}(h)$ and $\nu = 0, \dots, \mu_\alpha(h) - 1$ the derivative $f^{(\nu)}(\alpha)$ has to be equal to both expressions given in (3.8). Thus we can find such an f only if for those α and ν it is true that

$$\begin{aligned}
&-\frac{1}{p_1^*(\alpha)} \left[\widetilde{b}^{*^{(\nu)}}(\alpha) + \sum_{\mu=0}^{\nu-1} \tbinom{\nu}{\mu} p_1^{*^{(\nu-\mu)}}(\alpha) f^{(\mu)}(\alpha) \right] \\
&\qquad = \frac{1}{q_1^*(\alpha)} \left[\widetilde{a}^{*^{(\nu)}}(\alpha) - \sum_{\mu=0}^{\nu-1} \tbinom{\nu}{\mu} q_1^{*^{(\nu-\mu)}}(\alpha) f^{(\mu)}(\alpha) \right].
\end{aligned}$$

But this is indeed valid, since from (3.6) it follows that

$$\begin{aligned}
0 = h^{(\nu)}(\alpha) &= (\widetilde{a}^* p_1^* + \widetilde{b}^* q_1^*)^{(\nu)}(\alpha) \\
&= \sum_{\mu=0}^{\nu} \tbinom{\nu}{\mu} \widetilde{a}^{*^{(\mu)}}(\alpha) p_1^{*^{(\nu-\mu)}}(\alpha) + \sum_{\mu=0}^{\nu} \tbinom{\nu}{\mu} \widetilde{b}^{*^{(\mu)}}(\alpha) q_1^{*^{(\nu-\mu)}}(\alpha)
\end{aligned}$$

for $\nu = 0, \dots, \mu_\alpha(h) - 1$ and therefore one can apply Lemma A.2.

As $\mathcal{V}(\phi_1 \psi_1 h) \subseteq \mathbb{C}$ is symmetric with respect to complex conjugation, Proposition 3.1(1) and Lemma A.1 imply the existence of $f \in \mathbb{R}[s]$ with the properties required in (3.8). ∎

Example 3.3. Let $p = s^2$, $q = z - 1 \in \mathcal{H}$. Then $s \,|\, q^*$ but $s^2 \not| \, q^*$ in $H(\mathbb{C})$, thus $d = s$ is a gcd of p, q. A Bézout equation is given by

$$s = \frac{(1-s)z + 2s - 1}{s^2} s^2 + (s-1)(z-1).$$

Note also that $\ker \widetilde{p} = \{w \in \mathcal{C}^\infty(\mathbb{R}) \,|\, \exists\, \alpha, \beta \in \mathbb{R} \text{ for all } t \in \mathbb{R} : w(t) = \alpha + \beta t\}$ and $\ker \widetilde{q} = \{w \in \mathcal{C}^\infty(\mathbb{R}) \,|\, w \text{ is of period } 1\}$; hence $\ker \widetilde{p} \cap \ker \widetilde{q} = \{w \in \mathcal{C}^\infty(\mathbb{R}) \,|\, w \text{ constant}\} = \ker \widetilde{d}$.

It is a standing conjecture that every commutative Bézout domain is an *elementary divisor domain*, which means that matrices can be brought into diagonal form via left–right equivalence; see, e.g., [3, p. 92]. In the present case, one can in fact prove the elementary divisor property. To do so, we will show the following lemma, which states that $\mathcal{H}$ is a so-called *adequate ring*; see, e.g., [12, p. 473].

LEMMA 3.4. *Let $p, q \in \mathcal{H}$, $p \neq 0$. There exists a factorization $p = ab$ with $a, b \in \mathcal{H}$ such that a and q are coprime, whereas $\hat{b}$ and q are not coprime whenever $\hat{b} \in \mathcal{H} \backslash \mathcal{H}^\times$ is a divisor of b.*

Proof. The idea for the factorization is as follows: factorize $p = ab$ such that $\mathcal{V}(b^*) = \mathcal{V}(p^*, q^*)$ and $\mu_\lambda(b^*) = \mu_\lambda(p^*)$ for all $\lambda \in \mathcal{V}(b^*)$. This can easily be done if $\#\mathcal{V}(p^*, q^*) < \infty$. In the infinite case it needs an iterative procedure as described below.

Let $b_1 \in \mathcal{H}$ be a gcd of p and q and put $a_1 = \frac{p}{b_1}$ so that $p = a_1 b_1$. Define successively the following elements:

$$\text{let } c_i \in \mathcal{H} \text{ be a gcd of } a_i \text{ and } b_i; \text{ define } a_{i+1} = \frac{a_i}{c_i} \text{ and } b_{i+1} = c_i b_i. \tag{3.9}$$

Hence $p = a_i b_i = a_{i+1} c_i b_i = a_{i+1} b_{i+1}$. This gives a sequence of elements $a_i \in \mathcal{H}$ with the property that a_{i+1} divides a_i in $\mathcal{H}$. But then a_{i+1} divides a_i also in the principal ideal ring $\mathbb{R}(s)[z, z^{-1}]$ with the consequence that for some $k \in \mathbb{N}$ there exist $l \in \mathbb{Z}$ and $\phi \in \mathbb{R}[s] \backslash \{0\}$ such that $c_k = \phi z^l$ is a unit in $\mathbb{R}(s)[z, z^{-1}]$. Thus the procedure (3.9) yields the existence of a factorization:

$$p = a_k b_k \text{ with } \phi \in \mathbb{R}[s] \text{ as a gcd of } a_k \text{ and } b_k \text{ in } \mathcal{H}.$$

This implies that $\mathcal{V}(a_k^*, b_k^*)$ is finite, say $\mathcal{V}(a_k^*, b_k^*) = \{\lambda_1, \ldots, \lambda_n\}$, and we can define

$$f := \prod_{i=1}^{n} (s - \lambda_i)^{l_i} \in \mathbb{R}[s], \text{ where } l_i = \mu_{\lambda_i}(a_k^*).$$

With $a := a_k f^{-1} \in \mathcal{H}$ and $b := f b_k \in \mathcal{H}$ we get the factorization $p = ab$, which in fact satisfies the requirements of the lemma: (1) To establish the coprimeness of a and q, suppose $\mathcal{V}(a^*, q^*) \neq \emptyset$. Thus let $\lambda \in \mathcal{V}(a^*, q^*) \subseteq \mathcal{V}(p^*, q^*) = \mathcal{V}(b_1^*)$. Then $\lambda \in \mathcal{V}(b_1^*, a_k^*) \subseteq \mathcal{V}(a_k^*, b_k^*) = \{\lambda_1, \ldots, \lambda_n\}$. But for $\lambda = \lambda_j$ it is $\mu_\lambda(a^*) = \mu_{\lambda_j}(a_k^*) - \mu_{\lambda_j}(f) = 0$. Hence $\mathcal{V}(a^*, q^*) = \emptyset$ and from Proposition 3.1(6) we conclude the coprimeness of a and q.

(2) Let $\hat{b} \in \mathcal{H} \backslash \mathcal{H}^\times$ be a divisor of b and fix some $\lambda \in \mathcal{V}(b^*)$ with $\hat{b}^*(\lambda) = 0$. The construction (3.9) of the sequences (c_i) and (b_i) leads to the following equality of zero sets (note that we count zeros in $\mathcal{V}$ not with multiplicity):

$$\mathcal{V}(b^*) = \mathcal{V}(f^* b_k^*) = \mathcal{V}(b_k^*) = \mathcal{V}(c_{k-1}^* b_{k-1}^*) = \mathcal{V}(b_{k-1}^*) = \cdots = \mathcal{V}(b_1^*) = \mathcal{V}(p^*, q^*).$$

Thus $\lambda \in \mathcal{V}(q^*, \hat{b}^*)$ and therefore $\hat{b}$ and q are not coprime.

Note that when $\mathcal{V}(p^*, q^*) = \{\lambda_1, \ldots, \lambda_n\}$ is finite, the above construction leads to the factorization $p = \frac{p}{b} b$ with $b = \prod_{i=1}^{n} (s - \lambda_i)^{l_i}$ and $l_i = \mu_{\lambda_i}(p^*)$. □

Now we can summarize the properties for matrices over $\mathcal{H}$ as they follow from the above ring theory results.

THEOREM 3.5.

(1) *Let $a_1, \ldots, a_n \in \mathcal{H}$ and $d \in \mathcal{H}$ be a gcd of $a_1, \ldots, a_n$. Then there exists a matrix $A \in \mathcal{H}^{n \times n}$ with $[a_1, \ldots, a_n]$ as its first row and* $\det A = d$.

(2) *For $P \in \mathcal{H}^{n \times m}$ there exists $U \in Gl_n(\mathcal{H})$ so that $UP \in \mathcal{H}^{n \times m}$ has upper triangular form.*

(3) *Let $P \in \mathcal{H}^{n \times m}$ and $Q \in \mathcal{H}^{l \times m}$. There exists a greatest common right divisor (gcrd) $D \in \mathcal{H}^{m \times m}$ of P and Q and matrices $A \in \mathcal{H}^{m \times n}$, $B \in \mathcal{H}^{m \times l}$ with $D = AP + BQ$. If* $\mathrm{rk} D = m$, *then D is unique modulo multiplication from the left by unimodular matrices.*

(4) *Let $P, Q \in \mathcal{H}^{m \times m}$ with* $\mathrm{rk} P = \mathrm{rk} Q = m$. *Then there exists a least common left multiple (lclm) $M \in \mathcal{H}^{m \times m}$ of P and Q which is uniquely determined up to unimodular factors from the left.*

(5) *$\mathcal{H}$ is an* elementary divisor ring*; that is, for $P \in \mathcal{H}^{n \times m}$ with* $\mathrm{rk} P = r$ *there exist $U \in Gl_n(\mathcal{H})$ and $V \in Gl_m(\mathcal{H})$ such that*

$$UPV = \begin{bmatrix} P_1 & 0 \\ 0 & 0 \end{bmatrix} \in \mathcal{H}^{n \times m} \quad \text{with} \quad P_1 = \begin{bmatrix} p_1 & 0 & \cdots & 0 \\ 0 & \ddots & & \vdots \\ \vdots & & \ddots & 0 \\ 0 & \cdots & 0 & p_r \end{bmatrix} \in \mathcal{H}^{r \times r}, \tag{3.10}$$

where $p_i \neq 0$ for all i and $p_i \,|\, p_{i+1}$ for $i = 1, \ldots, r-1$.

Proof. Parts (1)–(4) hold in general for matrices over commutative Bézout domains. The proof of these parts is identical with that given for principal ideal domains in [13, pp. 31–36]. Part (5) follows from Lemma 3.4, as shown in [12, p. 473] for arbitrary adequate rings. □

The existence of an lcm for elements $p, q \in \mathcal{H}$ as we proved in Proposition 3.1(7) can also be concluded from part (1) of the above theorem (see, e.g., [4, Cor. 2, p. 126]).

4. Correspondence between behaviors and ideals in $\mathcal{H}$. The results in section 3 enable us to show a correspondence between the lattice of behaviors associated with delay-differential equations of the type (1.1) and the lattice of finitely generated ideals in $\mathcal{H}$. After introducing multivariable delay-differential operators, an analogous version of this correspondence will be shown also in that case.

Remember that, as outlined in Definition 2.7 and Remark 2.8, for $p \in \mathcal{H}$ the operator $\widetilde{p} \in \mathrm{End}_{\mathbb{R}}(\mathcal{C}^\infty(\mathbb{R}))$ exists. In particular, for $p \in \mathbb{R}[s, z] \subset \mathcal{H}$ this includes the classical case as in equation (1.1).

PROPOSITION 4.1. *For $p, q \in \mathcal{H} \backslash \{0\}$ let $d \in \mathcal{H}$ be a gcd of p, q, and $c \in \mathcal{H}$ be an lcm of p, q. Then*

(1) $\ker \widetilde{p} \subseteq \ker \widetilde{q} \iff p \,|\, q$;

(2) $\ker \widetilde{d} = \ker \widetilde{p} \cap \ker \widetilde{q}$;

(3) $\ker \widetilde{c} = \ker \widetilde{p} + \ker \widetilde{q}$;

(4) *if $d \in \mathcal{H}^\times$, then* $\ker \widetilde{p} + \ker \widetilde{q} = \ker \widetilde{pq} = \ker \widetilde{qp}$;

(5) *let $a \in \mathcal{H}$ be such that* $\ker \widetilde{p} \cap \ker \widetilde{q} \subseteq \ker \widetilde{a}$. *Then $a \in p\mathcal{H} + q\mathcal{H}$.*

Proof. (1)"⇒" Let $p = a\phi^{-1}$, $q = b\phi^{-1}$ with $a, b \in \mathcal{R}$ and $\phi \in \mathbb{R}[s]$. Then it is easy to see that $\ker \widetilde{p} \subseteq \ker \widetilde{q}$ implies $\ker \widetilde{a} \subseteq \ker \widetilde{b}$. Thus by (2.2) one has $b^*(a^*)^{-1} = q^*(p^*)^{-1} \in H(\mathbb{C})$ and with Proposition 3.1(5) it follows that $p \,|\, q$ in $\mathcal{H}$.

"$\Leftarrow$" If $q = ap$ with some $a \in \mathcal{H}$, then Remark 2.8(3) yields $\widetilde{q} = \widetilde{a} \circ \widetilde{p}$, and therefore $\ker \widetilde{p} \subseteq \ker \widetilde{q}$.

(2) This is a consequence of (1) and the existence of a Bézout equation $d = ap + bq$ in $\mathcal{H}$ together with Remark 2.8(3).

(3) "$\supseteq$" follows from (1).

"$\subseteq$" Let $p = ad$, $q = bd$ with $a, b \in \mathcal{H}$. Then, by Proposition 3.1(7) we can take $c = abd$ as an lcm of p, q. By coprimeness of a, b there exists $f, g \in \mathcal{H}$ with $1 = af + bg$. Hence $w \in \ker \widetilde{c}$ satisfies $w = \widetilde{fa}(w) + \widetilde{gb}(w) \in \ker \widetilde{q} + \ker \widetilde{p}$.

(4) If $d \in \mathcal{H}^\times$, then pq is an lcm of p, q; hence the claim holds by (3).

(5) This follows from (1) and (2) and the equality $d\mathcal{H} = p\mathcal{H} + q\mathcal{H}$. □

Notice that the Examples 2.9 and 3.3 correspond to the situation given in (1) and (2) of the above proposition.

Now we will come to the multivariable case. From Remark 2.8 we conclude that for a matrix $P = (p_{ij}) \in \mathcal{H}^{n\times m}$ the operator

$$\begin{aligned} \widetilde{P} : \quad & \mathcal{C}^\infty(\mathbb{R}^m) \longrightarrow \mathcal{C}^\infty(\mathbb{R}^n), \\ & (w_1, \dots, w_m)^{\mathtt{t}} \longmapsto \left(\sum_{j=1}^m \widetilde{p_{1j}}(w_j), \dots, \sum_{j=1}^m \widetilde{p_{nj}}(w_j) \right)^{\mathtt{t}} \end{aligned}$$

is well defined. Thus the behavior, defined by a system of delay-differential equations, can be described as $\ker \widetilde{P}$ with some $P \in \mathcal{R}^{n\times m}$, or in the more general case $P \in \mathcal{H}^{n\times m}$.

Remark 4.2.

(1) The map

$$\begin{aligned} \mathcal{H}^{n\times m} &\longrightarrow \mathrm{Hom}_{\mathbb{R}}(\mathcal{C}^\infty(\mathbb{R}^m), \mathcal{C}^\infty(\mathbb{R}^n)), \\ P &\longmapsto \widetilde{P} \end{aligned}$$

is $\mathbb{R}$ linear and injective and satisfies $\widetilde{PQ} = \widetilde{P} \circ \widetilde{Q}$ for $P \in \mathcal{H}^{n\times m}$, $Q \in \mathcal{H}^{m\times l}$.

(2) Analogous to the scalar case in Definition 2.4(1) the map

$$\begin{aligned} \mathcal{H}^{n\times m} &\longrightarrow H(\mathbb{C})^{n\times m}, \\ P &\longmapsto P^*(s) := P(s, e^{-s}) \end{aligned}$$

is a well-defined $\mathbb{R}$-linear map and fulfills $(PQ)^*(s) = P^*(s)Q^*(s)$ for $P \in \mathcal{H}^{n\times m}$, $Q \in \mathcal{H}^{m\times l}$.

Let us first list some properties of the operator $\widetilde{P}$.

PROPOSITION 4.3. *Let $P \in \mathcal{H}^{n\times m}$. Then*

(1) *if $n = m$ and $P \in Gl_n(\mathcal{H})$, then $\widetilde{P}$ is bijective and $P^*(s) \in Gl_n(\mathbb{C})$ for all $s \in \mathbb{C}$;*

(2) *$\widetilde{P}$ is surjective iff* $\mathrm{rk}P = n$;

(3) *the following properties are equivalent:*

(i) *$\widetilde{P}$ is injective,*

(ii) $\mathrm{rk}P^*(s) = m$ *for all $s \in \mathbb{C}$,*

(iii) *there exists $Q \in \mathcal{H}^{m\times n}$ with $QP = I_m$.*

Proof. (1) This follows from the existence of $Q \in \mathcal{H}^{n\times n}$ with $PQ = QP = I_n$ together with Remark 4.2.

(2) Let $\mathrm{rk}P = r \leq n$. By Theorem 3.5(5) there exist $U \in Gl_n(\mathcal{H})$ and $V \in Gl_m(\mathcal{H})$ so that UPV is as in (3.10). By (1) $\widetilde{P}$ is surjective iff $\widetilde{UPV}$ is surjective, and together with Proposition 2.10 this holds iff $r = n$.

(3) All three properties are invariant under multiplication with unimodular matrices from the left or from the right. Thus, using again Theorem 3.5(5), we can restrict ourselves to diagonal P. Since all three properties imply $\mathrm{rk}P = m$, we can assume

$$P = \begin{bmatrix} P_1 \\ 0 \end{bmatrix} \in \mathcal{H}^{n\times m} \text{ with } P_1 = \mathrm{diag}(p_1, \ldots, p_m) \in \mathcal{H}^{m\times m}.$$

Now (i) implies the injectivity of $\widetilde{p_i}$; thus, with (2.2) and Proposition 3.1(2), $p_i \in \mathcal{H}^\times$. This yields (ii). In the same way, (ii) leads to $p_i \in \mathcal{H}^\times$ for all i, and (iii) can be concluded. The implication "(iii) $\Rightarrow$ (i)" follows from Remark 4.2(1). □

Now we can generalize part of the results in Proposition 4.1 to the multivariable case.

PROPOSITION 4.4. *Let $P \in \mathcal{H}^{n\times m}$, $Q \in \mathcal{H}^{l\times m}$, and $D \in \mathcal{H}^{m\times m}$ be a gcrd of P, Q. Then*

(1) $\ker \widetilde{P} \cap \ker \widetilde{Q} = \ker \widetilde{D}$;

(2) *P is a right divisor of Q iff* $\ker \widetilde{P} \subseteq \ker \widetilde{Q}$;

(3) *under the condition* $\mathrm{rk}P = n$, $\mathrm{rk}Q = l$ *the following holds true:* $\ker \widetilde{P} = \ker \widetilde{Q}$ *iff $n = l$ and $P = UQ$ for some $U \in Gl_n(\mathcal{H})$.*

Proof. (1) Since "$\Rightarrow$" of (2) holds by Remark 4.2(1), part (1) follows from the existence of a Bézout equation for D (see Theorem 3.5(3)).

(2) It remains to prove "$\Leftarrow$." Let $r = \mathrm{rk}P$ and $U \in Gl_n(\mathcal{H})$, $V \in Gl_m(\mathcal{H})$ be such that $P' = UPV$ is as in (3.10). Denoting $Q' = UQV$, Proposition 4.3(1) implies $\ker \widetilde{P'} \subseteq \ker \widetilde{Q'}$. This yields $Q' = [R, 0]$ with $R \in \mathcal{H}^{l\times r}$, and, moreover, $\ker \widetilde{p_j} \subseteq \ker \widetilde{R_{ij}}$ for all $j = 1, \ldots, r$ and $i = 1, \ldots, l$. Hence, using Proposition 4.1(1) we get the existence of $A \in \mathcal{H}^{l\times n}$ such that $AP' = Q'$ and therefore $U^{-1}AUP = Q$.

(3) "$\Leftarrow$" is obvious.

"$\Rightarrow$" By (2) there exist $P = UQ$ and $Q = VP$ for some $U \in \mathcal{H}^{n\times l}$, $V \in \mathcal{H}^{l\times n}$. Then the full rank assumption implies $VU = I_l$ and $UV = I_n$, which leads to the desired result. □

5. Controllability. In this section we will generalize the well-known Hautus criterion for controllability to delay-differential systems. For time-delay state-space systems this criterion characterizes spectral controllability as it is known from, e.g., [18] and [2]. In the behavioral context this criterion is established for finite-dimensional discrete- or continuous-time AR-systems (see, e.g., [22, Prop. 4.3]) and, very recently, in [19] for exactly the same situation of delay-differential equations as presented in the paper at hand. However, the proof in [19] uses quite different methods than those developed in this paper.

Whereas controllability for state-space systems is formulated, of course, in terms of control functions and state trajectories, we do not have this possibility for behaviors. Hence we will use the notion of controllability as defined in [22]. For this we have to introduce first the concatenation of two functions.

DEFINITION 5.1. *Let $-\infty \le a_1 < a_2 \le b_1 < b_2 \le \infty$, and let $w_1 \colon (a_1, b_1) \to \mathbb{R}^m$ and $w_2 : [a_2, b_2) \to \mathbb{R}^m$ be two functions. For $t_0 \in [a_2, b_1]$ denote by $w_1 \wedge_{t_0} w_2 : (a_1, b_2) \to \mathbb{R}^m$ the following* concatenation of w_1 and w_2 at t_0*:*

$$(w_1 \wedge_{t_0} w_2)(t) := \begin{cases} w_1(t) & \text{for } a_1 < t < t_0, \\ w_2(t) & \text{for } t_0 \le t < b_2. \end{cases}$$

Using this definition, a behavior is called controllable if it is closed under concatenation in the sense given below. In [22, p. 186] one can find the system theory justification of this notion.

DEFINITION 5.2. *Let $\mathcal{B}$ be a shift-invariant subspace of $\mathcal{C}^\infty(\mathbb{R}^m)$. Then $\mathcal{B}$ is called* controllable *if it satisfies the following: for all w, $w' \in \mathcal{B}$ there exists $t_0 \geq 0$ and $c \in \mathcal{C}^\infty([0,t_0),\mathbb{R}^m)$ with $w\wedge_0 c\wedge_{t_0}\sigma^{t_0}w' \in \mathcal{B}$.*

The requirement $w\wedge_0 c\wedge_{t_0}\sigma^{t_0}w' \in \mathcal{B}$ yields in particular that the concatenation is in $\mathcal{C}^\infty(\mathbb{R}^m)$.

Note that $\mathcal{C}^\infty(\mathbb{R}^m)$ is controllable; even more, $\mathcal{C}^\infty(\mathbb{R}^m)$ is controllable in arbitrary short time: for all w, $w' \in \mathcal{C}^\infty(\mathbb{R}^m)$ and all $t_0 > 0$ there exists $c \in \mathcal{C}^\infty([0,t_0),\mathbb{R}^m)$ with $w\wedge_0 c\wedge_{t_0}\sigma^{t_0}w' \in \mathcal{C}^\infty(\mathbb{R}^m)$.

Since we introduce the concept of controllability only for shift-invariant subspaces, it makes sense to consider only controllability at time zero.

Whereas it is obvious that for $U \in \mathbb{R}[s]^{n\times m}$ and w, $w' \in \mathcal{C}^\infty(\mathbb{R}^m)$ it is $\widetilde{U}(w\wedge_0 w') = \widetilde{U}(w)\wedge_0\widetilde{U}(w')$ if $w\wedge_0 w'$ is sufficiently differentiable at $t_0 = 0$, it is a priori not clear that $\widetilde{U}(w\wedge_0 w')$ is a sort of concatenation of $\widetilde{U}(w)$ and $\widetilde{U}(w')$ if $U \in \mathbb{R}[s,z]^{n\times m}$ or even $U \in \mathcal{H}^{n\times m}$.

LEMMA 5.3. *Let $U = \sum_{j=0}^L U_j z^j \in \mathbb{R}[s,z]^{n\times m}$ with $U_j \in \mathbb{R}[s]^{n\times m}$. Further, let w, $w' \in \mathcal{C}^\infty(\mathbb{R}^m)$, $t_0 \in \mathbb{R}$ with $w\wedge_{t_0} w' \in \mathcal{C}^\infty(\mathbb{R}^m)$. Then there exists $c \in \mathcal{C}^\infty([t_0,t_0+L),\mathbb{R}^n)$ so that $\widetilde{U}(w\wedge_{t_0}w') = \widetilde{U}(w)\wedge_{t_0}c\wedge_{t_0+L}\widetilde{U}(w')$.*

Proof. A direct calculation shows

$$\begin{aligned}\widetilde{U}(w\wedge_{t_0}w')(t) &= \sum_{j=0}^L \widetilde{U}_j(w\wedge_{t_0}w')(t-j) = \sum_{j=0}^L (\widetilde{U}_j(w)\wedge_{t_0}\widetilde{U}_j(w'))(t-j)\\ &= \begin{cases} \sum_{j=0}^L \widetilde{U}_j(w')(t-j) = \widetilde{U}(w')(t) & \text{if } t \geq t_0+L,\\ c(t) & \text{if } t_0 \leq t < t_0+L,\\ \sum_{j=0}^L \widetilde{U}_j(w)(t-j) = \widetilde{U}(w)(t) & \text{if } t < t_0 \end{cases}\end{aligned}$$

for some function $c : [t_0, t_0+L) \to \mathbb{R}^n$. Hence $\widetilde{U}(w\wedge_{t_0}w') = \widetilde{U}(w)\wedge_{t_0}c\wedge_{t_0+L}\widetilde{U}(w')$. Since $\widetilde{U}(w\wedge_{t_0}w') \in \mathcal{C}^\infty(\mathbb{R}^n)$, we also get $c \in \mathcal{C}^\infty([t_0,t_0+L),\mathbb{R}^n)$. □

With this knowledge we can prove the following.

LEMMA 5.4. *Let $\mathcal{B}$ be a shift-invariant linear controllable subspace of $\mathcal{C}^\infty(\mathbb{R}^m)$ and let $U \in \mathcal{H}^{n\times m}$. Then $\widetilde{U}(\mathcal{B})$ is a shift-invariant linear controllable subspace of $\mathcal{C}^\infty(\mathbb{R}^n)$.*

Proof. Since $\mathcal{B}$ is shift invariant, it is enough to consider $U = \sum_{j=0}^L U_j z^j \in \mathbb{R}(s)[z]^{n\times m}$ with $U_j \in \mathbb{R}(s)^{n\times m}$.

Let w, $w' \in \mathcal{B}$. Then $\sigma^L w' \in \mathcal{B}$ and there exist $t_0 \geq 0$ and $c \in \mathcal{C}^\infty([0,t_0),\mathbb{R}^m)$ so that $\bar{w} := w\wedge_0 c\wedge_{t_0}\sigma^{t_0+L}w' \in \mathcal{B}$.

Case 1. Let $U_j \in \mathbb{R}[s]^{n\times m}$ for all j, thus $U \in \mathbb{R}[s,z]^{n\times m}$. Then by Lemma 5.3 we get the existence of $c' \in \mathcal{C}^\infty([0,t_0+L),\mathbb{R}^n)$, so that

$$\begin{aligned}\widetilde{U}(\bar{w}) &= \widetilde{U}(w\wedge_0 c\wedge_{t_0}\sigma^{t_0+L}w')\\ &= \widetilde{U}(w)\wedge_0 c'\wedge_{t_0+L}\widetilde{U}(\sigma^{t_0+L}w')\\ &= \widetilde{U}(w)\wedge_0 c'\wedge_{t_0+L}\sigma^{t_0+L}\widetilde{U}(w') \in \widetilde{U}(\mathcal{B}).\end{aligned}$$

Since w, $w' \in \mathcal{B}$ were arbitrary, this yields the controllability of $\widetilde{U}(\mathcal{B})$.

Case 2. Let $U_j = V_j\phi^{-1}$ with $V_j \in \mathbb{R}[s]^{n\times m}$. Put $V = \sum_{j=0}^L V_j z^j \in \mathbb{R}[s,z]^{n\times m}$. Then $U = V\phi^{-1}$ and by definition $\widetilde{U}(\bar{w}) = \widetilde{V}(v)$, if $v \in \mathcal{C}^\infty(\mathbb{R}^m)$ fulfills $\widetilde{\phi}(v) = \bar{w}$.

As in the first case, we shall show that $\widetilde{U}(\bar{w})$ is a concatenation of $\widetilde{U}(w)$ and $\sigma^{t_0+L}\widetilde{U}(w')$ so that $\widetilde{U}(\bar{w}) \in \widetilde{U}(\mathcal{B})$ implies the controllability of $\widetilde{U}(\mathcal{B})$. In order to do

so, we will construct a solution of $\widetilde{\phi}(v) = \bar{w}$ which corresponds to the special form of $\bar{w} = w \wedge_0 c \wedge_{t_0} \sigma^{t_0+L} w'$. For this let $c' \in \mathcal{C}^\infty([0, t_0), \mathbb{R}^m)$ be so that $\widetilde{\phi}(c') = c$. Then the solutions $v_i \in \mathcal{C}^\infty(\mathbb{R}^m)$, $i = 1, 2$, of

$$\begin{aligned} &\widetilde{\phi}(v_1) = w, && v_1^{(\nu)}(0) = c'^{(\nu)}(0) \text{ for } \nu = 0, \dots, \deg \phi - 1, \\ &\widetilde{\phi}(v_2) = \sigma^{t_0+L} w', && v_2^{(\nu)}(t_0) = c'^{(\nu)}(t_0) \text{ for } \nu = 0, \dots, \deg \phi - 1 \end{aligned}$$

satisfy $v := v_1 \wedge_0 c' \wedge_{t_0} v_2 \in \mathcal{C}^\infty(\mathbb{R}^m)$ and $\widetilde{\phi}(v) = \bar{w}$. Moreover, $\widetilde{V}(v_1) = \widetilde{U}(w)$, $\widetilde{V}(v_2) = \widetilde{U}(\sigma^{t_0+L} w')$. Now, by the first case of this proof there exists $c'' \in \mathcal{C}^\infty([0, t_0 + L), \mathbb{R}^n)$ so that

$$\begin{aligned} \widetilde{U}(\bar{w}) = \widetilde{V}(v) &= \widetilde{V}(v_1 \wedge_0 c' \wedge_{t_0} v_2) = \widetilde{V}(v_1) \wedge_0 c'' \wedge_{t_0+L} \widetilde{V}(v_2) \\ &= \widetilde{U}(w) \wedge_0 c'' \wedge_{t_0+L} \widetilde{U}(\sigma^{t_0+L} w') \\ &= \widetilde{U}(w) \wedge_0 c'' \wedge_{t_0+L} \sigma^{t_0+L} \widetilde{U}(w') \in \widetilde{U}(\mathcal{B}). \qquad \square \end{aligned}$$

Now we can prove the main part of this section

THEOREM 5.5. *Let $P \in \mathcal{H}^{n \times m}$. Then* $\ker \widetilde{P}$ *is controllable iff* $\mathrm{rk} P^*(s) = \mathrm{rk} P$ *for all $s \in \mathbb{C}$.*

Proof. (a) We first prove the scalar case $p \in \mathcal{H}$. If $p = 0$ then obviously $\ker \widetilde{p} = \mathcal{C}^\infty(\mathbb{R})$ is controllable. Let $p \neq 0$.

"$\Leftarrow$" This holds, since $\ker \widetilde{p} = \{0\}$ if $p \in \mathcal{H}^\times$.

"$\Rightarrow$" Let $w_1 \in \ker \widetilde{p}$. Then there exist $t_0 > 0$ and some $c \in \mathcal{C}^\infty([0, t_0), \mathbb{R})$ with $v := w_1 \wedge_0 c \wedge_{t_0} 0 \in \ker \widetilde{p}$ and Proposition 2.10(2) implies $v = 0$; hence, again by Proposition 2.10(2), $w_1 = 0$. Therefore controllability of $\ker \widetilde{p}$ implies $\ker \widetilde{p} = \{0\}$ and from Proposition 3.1(2) it follows that $p \in \mathcal{H}^\times$.

(b) Let $P \in \mathcal{H}^{n \times m}$. Using Theorem 3.5(5) and Lemma 5.4 we can restrict ourselves to the case of P being as in (3.10).

"$\Leftarrow$" The assumption on the rank implies that $p_j \in \mathcal{H}^\times$ for $j = 1, \dots, r$, and therefore $\ker \widetilde{P} = \{(0, \dots, 0, w_{r+1}, \dots, w_m)^\mathrm{t} \mid w_i \in \mathcal{C}^\infty(\mathbb{R}),\ i = r+1, \dots, m\}$, which is indeed controllable.

"$\Rightarrow$" The controllability of $\ker \widetilde{P}$ yields the controllability of $\ker \widetilde{p_j}$ for $j = 1, \dots, r$. Hence by the scalar case $p_j \in \mathcal{H}^\times$ and the desired conclusion follows. $\square$

Conclusions. As can be seen from sections 4 and 5, the ring $\mathcal{H}$ seems to be the adequate object for an algebraic treatment of delay-differential equations as (1.1) and (1.2). Once the algebraic properties of $\mathcal{H}$ are established, the translation into properties of the solution spaces are nearly straightforward.

In a forthcoming paper it will be shown how the existence of image representations for the systems under investigation can be characterized with the help of this algebraic framework. Moreover, the analytical meaning of the operators in $\mathcal{H}$ has to be clarified.

Appendix. We start with the following.

Proof of Proposition 2.10.

(1) Let $p \in \mathcal{H} \backslash \{0\}$ and $v \in \mathcal{C}^\infty(\mathbb{R})$. We have to find $w \in \mathcal{C}^\infty(\mathbb{R})$ fulfilling $\widetilde{p}(w) = v$.

First, it suffices to assume $p \in \mathcal{R}$ for let $p = q\phi^{-1}$ with $q \in \mathcal{R}$, $\phi \in \mathbb{R}[s]$. If we find $f \in \mathcal{C}^\infty(\mathbb{R})$ with $\widetilde{q}(f) = v$ and put $\widetilde{\phi}(f) = w$, then we have $\widetilde{p}(w) = v$. Hence we need to show the surjectivity of $\widetilde{q}$.

Thus let $p \in \mathcal{R}$ and, more precisely,

$$p = \sum_{j=0}^{L} p_j z^j \in \mathbb{R}[s,z] \text{ with } p_j \in \mathbb{R}[s] \text{ and } L \geq 1.$$

Put $p_0 = \sum_{i=0}^{l} a_i s^i$, $a_l = 1$, and $p_L = \sum_{i=0}^{r} b_i s^i$, $b_r \neq 0$.

We will construct piecewise a function $w \in \mathcal{C}^\infty(\mathbb{R})$ which fulfills for all $t \in \mathbb{R}$

$$\widetilde{p}(w)(t) = \sum_{j=0}^{L} \widetilde{p_j}(w)(t-j) = v(t). \tag{A.1}$$

The idea of the construction is as follows: start with a function $w_0 \in \mathcal{C}^\infty[0,L]$. In order to extend w_0 via concatenation (see Definition 5.1) to a solution of $\widetilde{p}(w) = v$ one has to solve successively ordinary inhomogeneous differential equations of the type

$$\widetilde{p_0}(\bar{w}_{k+1}) = v - \widetilde{(p-p_0)}(w_k) \text{ on the time interval } [L+k, L+k+1] \text{ for } k \geq 0,$$
$$\widetilde{p_L}(\bar{w}_k) = \sigma^{-L}\Big(v - \widetilde{(p-p_L)}(w_{k+1})\Big) \text{ on the time interval } [k, k+1] \text{ for } k \leq -1,$$

where the right-hand sides are determined successively by

$$w_k = w_0 \wedge_L \bar{w}_1 \wedge_{L+1} \ldots \wedge_{L+k-1} \bar{w}_k \text{ on } [0, L+k] \text{ for } k \geq 1,$$
$$w_{k+1} = \bar{w}_{k+1} \wedge_{k+2} \ldots \wedge_{-1} \bar{w}_{-1} \wedge_0 w_0 \text{ on } [k+1, L] \text{ for } k < -1.$$

The initial conditions at the points $L+k$ (for $k \geq 0$) and $k+1$ (for $k \leq -1$) have, of course, to be prescribed such that the concatenations are as smooth as possible. If one chooses the initial function $w_0 \in \mathcal{C}^\infty[0,L]$ appropriately, this procedure leads indeed to infinitely smooth concatenations and thus to a solution $w \in \mathcal{C}^\infty(\mathbb{R})$ of $\widetilde{p}(w) = v$.

The choice of the function w_0 is carried out in step (i) of the following elaboration. Steps (ii) and (iii) give the details of the extension of w_0 to a solution of $\widetilde{p}(w) = v$ on the positive real line, whereas step (iv) extends w_0 for negative time.

(i) Let $f \in \mathcal{C}^\infty[0,L]$ satisfy

$$\sum_{i=0}^{l} a_i f^{(i)}(t) = v(t), \qquad t \in [0,L],\ f^{(\nu)}(L) = 0 \text{ for } \nu = 0, \ldots, l-1.$$

(In the case $l = 0$, one has no freedom for the initial conditions. In this case the rest of the proof in (ii) and (iii) works analogously.) Let $g \in \mathcal{C}^\infty[0,L]$ be such that $g|_{[0,L-1]} = 0$ and $g|_{[L-0.5,L]} = 1$. Put $w_0 := fg \in \mathcal{C}^\infty[0,L]$. Then $w_0|_{[0,L-1]} = 0$ and

$$w_0^{(\nu)}(L) = f^{(\nu)}(L) = \begin{cases} 0 & \text{for } \nu = 0, \ldots, l-1, \\ v^{(\nu-l)}(L) - \sum_{i=0}^{l-1} a_i w_0^{(\nu-l+i)}(L) & \text{for } \nu \geq l. \end{cases}$$

(ii) Let $\bar{w}_1 \in \mathcal{C}^\infty[L, L+1]$ fulfill

$$\sum_{i=0}^{l} a_i \bar{w}_1^{(i)}(t) = v(t) - \sum_{j=1}^{L} \widetilde{p_j}(w_0)(t-j),\ t \in [L, L+1],$$

with initial conditions $\bar{w}_1^{(\nu)}(L) = 0$ for $\nu = 0, \ldots, l-1$. By differentiation one checks that $\bar{w}_1^{(\nu)}(L) = w_0^{(\nu)}(L)$ for all $\nu \in \mathbb{N}_0$ and thus $w_1 := w_0 \wedge_L \bar{w}_1 \in \mathcal{C}^\infty[0, L+1]$ fulfills $\sum_{j=0}^{L} \widetilde{p_j}(w_1)(t-j) = v(t)$ for $t \in [L, L+1]$.

(iii) Inductively, if $w_k \in \mathcal{C}^\infty[0, L+k]$ satisfies

$$\sum_{i=0}^{l} a_i w_k^{(i)}(t) = v(t) - \sum_{j=1}^{L} \widetilde{p_j}(w_k)(t-j)$$

for $t \in [L, L+k]$, then take the solution $\bar{w}_{k+1} \in \mathcal{C}^\infty[L+k, L+k+1]$ of the ODE

$$\sum_{i=0}^{l} a_i \bar{w}_{k+1}^{(i)}(t) = v(t) - \sum_{j=1}^{L} \widetilde{p_j}(w_k)(t-j),\ t \in [L+k, L+k+1],$$

with initial conditions $\bar{w}_{k+1}^{(\nu)}(L+k) = w_k^{(\nu)}(L+k)$ for $\nu = 0, \dots, l-1$. From this we obtain again by differentiation $\bar{w}_{k+1}^{(\nu)}(L+k) = w_k^{(\nu)}(L+k)$ for all $\nu \in \mathbb{N}_0$, and therefore we get a solution $w_{k+1} := w_k \wedge_{L+k} \bar{w}_{k+1} \in \mathcal{C}^\infty[0, L+k+1]$. Hence we can construct a function $w_+ \in \mathcal{C}^\infty[0, \infty)$ which satisfies (A.1) for $t \geq L$.

(iv) Let $\bar{w}_{-1} \in \mathcal{C}^\infty[-1, 0]$ satisfy

$$\sum_{i=0}^{r} b_i \bar{w}_{-1}^{(i)}(t) = v(t+L) - \sum_{j=0}^{L-1} \widetilde{p_j}(w_+)(t+L-j),\ t \in [-1, 0],$$

with the initial conditions $\bar{w}_{-1}^{(\nu)}(0) = 0$ for $\nu = 0, \dots, r-1$. Then $\bar{w}_{-1}^{(\nu)}(0) = 0$ for all $\nu \in \mathbb{N}_0$ and the function $w_{-1} := \bar{w}_{-1} \wedge_0 w_+ \in \mathcal{C}^\infty[-1, \infty)$ satisfies (A.1) for $t \geq L-1$. In a way analogous to (iii) we can proceed inductively and finally find a solution $w \in \mathcal{C}^\infty(\mathbb{R})$ for $\widetilde{p}(w) = v$.

(2) Put $p = q\phi^{-1}$ with $q \in \mathcal{R}$ and $\phi \in \mathbb{R}[s]$ and let $w \in \mathcal{C}^\infty(\mathbb{R})$ be given as in Proposition 2.10(2). It is easy to see that there exists $v \in \mathcal{C}^\infty(\mathbb{R})$ with $\widetilde{\phi}(v) = w$ and $v|_{[k, k+L]} = 0$. But then $0 = \widetilde{p}(w) = \widetilde{q}(v)$ and the proof of (1) shows by proceeding step by step on the intervals $[j, j+1]$ that $v = 0$ and thus $w = 0$. ∎

The following two lemmas are used in the proof of Theorem 3.2. The first one states the interpolation property for polynomials: given a finite set of points in the complex plane, there exists a polynomial $f \in \mathbb{C}[s]$, such that a specified number of derivatives $f^{(\nu)}$ take prescribed values at those points. If the required situation is symmetric with respect to complex conjugation, one can find a real interpolation polynomial.

LEMMA A.1. *Let $\alpha_1, \dots, \alpha_r \in \mathbb{C}\backslash\mathbb{R}$, $\alpha_{r+1}, \dots, \alpha_{r+t} \in \mathbb{R}$, $k_1, \dots, k_{r+t} \in \mathbb{N}_0$, $c_{j\nu} \in \mathbb{C}$ for $j = 1, \dots, r$ and $\nu = 0, \dots, k_j$, and $c_{j\nu} \in \mathbb{R}$ for $j = r+1, \dots, r+t$ and $\nu = 0, \dots, k_j$. Then there exists a unique $f \in \mathbb{R}[s]$ satisfying*

$$\begin{aligned}
&\deg f \leq N := 2\sum_{j=1}^{r}(k_j+1) + \sum_{j=r+1}^{r+t}(k_j+1) - 1,\\
&f^{(\nu)}(\alpha_j) = c_{j\nu} \text{ for } j = 1, \dots, r+t,\ \nu = 0, \dots, k_j,\\
&f^{(\nu)}(\overline{\alpha_j}) = \overline{c_{j\nu}} \text{ for } j = 1, \dots, r,\ \nu = 0, \dots, k_j.
\end{aligned}$$

Proof. The existence and uniqueness of $f \in \mathbb{C}[s]$ with the desired properties can be found, e.g., in [5, p. 37]. But this already implies $f \in \mathbb{R}[s]$, since with $f = \sum_{j=0}^{N} f_j s^j \in \mathbb{C}[s]$, $\bar{f} = \sum_{j=0}^{N} \bar{f}_j s^j$ also fulfills the above requirements. ∎

The second lemma is just a rather specific calculation. It is used to show that the interpolation requirements given in (3.8) can be satisfied by one polynomial, $f \in \mathbb{R}[s]$.

LEMMA A.2. *Let $K \in \mathbb{N}_0$ and a_j, b_j, p_j, $q_j \in \mathbb{C}$ for $j = 0, \dots, K$. Let $p_0 \neq 0 \neq q_0$ and*

$$\sum_{m=0}^{n} \binom{n}{m} b_m q_{n-m} = -\sum_{m=0}^{n} \binom{n}{m} a_m p_{n-m} \text{ for } n = 0, \dots, K. \tag{A.2}$$

Put $f_n := q_0^{-1}[a_n - \sum_{m=0}^{n-1} \binom{n}{m} q_{n-m} f_m]$ for $n = 0, \dots, K$. Then the recursion $f_n = -p_0^{-1}[b_n + \sum_{m=0}^{n-1} \binom{n}{m} p_{n-m} f_m]$ is also valid for $n = 0, \dots, K$.

Proof. For $n = 0$ it is $b_0 q_0 = -a_0 p_0$; hence $f_0 = \frac{a_0}{q_0} = -\frac{b_0}{p_0}$.

Suppose the claim holds true for $f_0, \dots, f_n$, $n < K$. Then one calculates

$$\begin{aligned}
q_0 f_{n+1} &= a_{n+1} - \sum_{m=0}^{n} \tbinom{n+1}{m} q_{n+1-m} f_m \\
&= a_{n+1} + \sum_{m=0}^{n} \tbinom{n+1}{m} q_{n+1-m} \left[\frac{1}{p_0} \left(b_m + \sum_{k=0}^{m-1} \tbinom{m}{k} p_{m-k} f_k \right) \right] \\
&= a_{n+1} + \frac{1}{p_0} \left[\sum_{m=0}^{n} \tbinom{n+1}{m} q_{n+1-m} b_m \right. \\
&\qquad \left. + \sum_{m=1}^{n} \sum_{k=0}^{m-1} \tbinom{n+1}{m} \tbinom{m}{k} q_{n+1-m} p_{m-k} f_k \right] \\
&= \frac{1}{p_0} \left[-b_{n+1} q_0 - \sum_{m=0}^{n} \tbinom{n+1}{m} a_m p_{n+1-m} \right. \\
&\qquad \left. + \sum_{k=0}^{n-1} \sum_{m=k+1}^{n} \tbinom{n+1}{m} \tbinom{m}{k} q_{n+1-m} p_{m-k} f_k \right] \\
&= -\frac{1}{p_0} \left[b_{n+1} q_0 + \sum_{m=0}^{n} \tbinom{n+1}{m} a_m p_{n+1-m} \right. \\
&\qquad \left. - \sum_{m=1}^{n} \sum_{k=0}^{m-1} \tbinom{n+1}{m} \tbinom{m}{k} p_{n+1-m} q_{m-k} f_k \right] \\
&= -\frac{1}{p_0} \left[b_{n+1} q_0 + q_0 \sum_{m=0}^{n} \tbinom{n+1}{m} p_{n+1-m} \frac{1}{q_0} \left(a_m - \sum_{k=0}^{m-1} \tbinom{m}{k} q_{m-k} f_k \right) \right] \\
&= -\frac{q_0}{p_0} \left[b_{n+1} + \sum_{m=0}^{n} \tbinom{n+1}{m} p_{n+1-m} f_m \right],
\end{aligned}$$

where the fourth equation follows from (A.2) and the fifth one from

$$\begin{aligned}
\sum_{m=k+1}^{n} \tbinom{n+1}{m} \tbinom{m}{k} q_{n+1-m} p_{m-k} &= \sum_{l=k+1}^{n} \tbinom{n+1}{n+1+k-l} \tbinom{n+1+k-l}{k} q_{l-k} p_{n+1-l} \\
&= \sum_{l=k+1}^{n} \tbinom{n+1}{l} \tbinom{l}{k} q_{l-k} p_{n+1-l}. \qquad \square
\end{aligned}$$

FEEDBACK STABILIZATION OF AFFINE IN THE CONTROL STOCHASTIC DIFFERENTIAL SYSTEMS BY THE CONTROL LYAPUNOV FUNCTION METHOD*

PATRICK FLORCHINGER†

Abstract. The purpose of this paper is to study the asymptotic stability in probability of affine in the control stochastic differential systems. Sufficient conditions for the existence of control Lyapunov functions leading to the existence of stabilizing feedback laws which are smooth, except possibly at the equilibrium point of the system, are provided.

Key words. stochastic stability, control stochastic differential equation, control Lyapunov function, feedback law

Introduction. The stabilization of nonlinear stochastic differential systems by means of state feedback laws is an important problem in control theory. The stochastic version of the Lyapunov theorem has been used to derive necessary and sufficient conditions for stabilization of stochastic differential systems at their equilibrium state. The stabilizability of various types of nonlinear stochastic differential systems has been studied for different notions of stochastic stability in the last past years (see, for instance, [8], [3], [4], [5], [7], or [6]).

The procedure used by Gao and Ahmed [8] relies on the stochastic Lyapunov theory and on the properties of the solution of a stochastic algebraic Riccati equation introduced by Wonham [16].

In [3], [4], and [6] the necessary and sufficient conditions for the asymptotic feedback stability in probability of the stochastic differential systems at their equilibrium state are of Lyapunov type, the stabilizers computed in these papers are smooth except possibly at the equilibrium state, and their construction is based on the knowledge of an appropriate control Lyapunov function. The aim of this paper is to study the asymptotic stability in probability for a wider class of affine in the control nonlinear stochastic differential systems than the one considered in [6]. This class of stochastic differential systems can be characterized in terms of *computable* control Lyapunov functions which depend on the system coefficients.

Note that a wide class of stochastic bilinear differential systems (like those used to model biological processes) as well as the equation of the angular velocity of a rigid body corrupted by noise (see [13] for the deterministic case) can be stabilized by using the results proved in the following. The main tools used in this paper are the stochastic Lyapunov theorem proved by Khasminskii [9] and the converse stability theorems of Kushner [10], Khasminskii [9], and Wilson [15]. In this paper, we extend some results proved by Tsinias [14] for deterministic control systems to control stochastic differential systems driven by a Wiener process. The analysis used in this paper is

closely related to that of [14], taking into account that one needs differentiability of higher order than the one needed in the deterministic case. Furthermore, in order to use converse stochastic Lyapunov theorems, more restrictive assumptions on the system coefficients than those stated in [14] have to be assumed. This paper is divided in three sections organized as follows. In section 1, we introduce the class of affine in the control stochastic differential systems that we are dealing with in this paper, and we recall the stochastic version of Artstein's theorem proved in [6]. In section 2, we state and prove the main results of the paper on the existence of control Lyapunov functions (for the class of systems introduced in section 1) leading to the existence of stabilizing feedback laws which are smooth, except possibly at the equilibrium points of the systems. In section 3, we provide some numerical examples, for which the results proved in the previous sections allow, to compute stabilizing feedback laws. For a brief review of the Lyapunov machinery that we need in what follows to study the stochastic stability of the equilibrium solution of a stochastic differential equation, we refer the reader to [6], and for a detailed exposition of the stochastic stability theory we refer the reader to Khasminskii [9] or Arnold [1], for example.

1. Problem statement. The purpose of this section is to introduce the class of affine in the control stochastic differential systems that we are dealing with in this paper and to recall the stochastic version of Artstein's theorem proved in [6]. Denote by $(\Omega, \mathcal{F}, P)$ a complete probability space and by $w = \{w_t, t \in \mathbb{R}_+\}$ a standard $\mathbb{R}^m$-valued Wiener process defined on this space. Consider the multi-input stochastic differential system in $\mathbb{R}^n$ written in the Itô form,

$$x_t = x_0 + \int_0^t (f(x_s) + h(x_s)u)ds + \int_0^t g(x_s)dw_s, \tag{1}$$

where

1. x_0 is given in $\mathbb{R}^n$;
2. u is an $\mathbb{R}^p$-valued control law;
3. f, g, and h are C^∞ functionals mapping $\mathbb{R}^n$ into $\mathbb{R}^n$, $\mathbb{R}^{n\times m}$, and $\mathbb{R}^{n\times p}$, respectively, vanishing in the origin and such that there exists a nonnegative constant K such that for any $x \in \mathbb{R}^n$,

$$|f(x)| + |g(x)| + |h(x)| \leq K(1 + |x|).$$

The stochastic differential system (1) is said to be *asymptotically stabilizable in probability* (at the origin) if there exist a neighborhood D of the origin in $\mathbb{R}^n$ and a function k mapping D in $\mathbb{R}^p$, vanishing in the origin, such that

1. for every $x \in D$, the solution x_t of the closed-loop system

$$x_t = x + \int_0^t (f(x_s) + h(x_s)k(x_s))ds + \int_0^t g(x_s)dw_s \tag{2}$$

is uniquely defined;

2. the equilibrium solution $x_t \equiv 0$ of the resulting closed-loop system (2) is asymptotically stable in probability.

Denoting by L the infinitesimal generator of the stochastic process solution of the uncontrolled part of the stochastic differential system (1), that is, L is the second-order differential operator defined for any function Ψ in $C^2(\mathbb{R}^n; \mathbb{R})$ by

$$L\Psi(x) = \sum_{i=1}^n f_i(x)\frac{\partial \Psi}{\partial x_i}(x) + \frac{1}{2}\sum_{i,j=1}^n a_{ij}(x)\frac{\partial^2 \Psi}{\partial x_i \partial x_j}(x),$$

where $a_{ij}(x) = \sum_{k=1}^m g_k^i(x) g_k^j(x)$, $1 \le i, j \le n$, one can introduce the notion of *control Lyapunov function* as follows.

DEFINITION 1.1. *The stochastic differential system* (1) *satisfies a* stochastic Lyapunov condition *at the origin if there exist a neighborhood D of the origin in $\mathbb{R}^n$ and a Lyapunov function V defined on D such that for every $x \in D \setminus \{0\}$ the following condition holds:*

$$\sum_{j=0}^n h_i^j(x) \frac{\partial V}{\partial x_j}(x) = 0,\ i = 1, ..., p \ \Rightarrow\ LV(x) < 0.$$

A Lyapunov function V satisfying the above condition is called a control Lyapunov function for the stochastic differential system (1).

The control Lyapunov function V defined above is said to satisfy the *bounded control property* if there exists a positive real function d mapping D in $\mathbb{R}$ such that d is bounded on D and for every $x \in D \setminus \{0\}$ there exists a control $u \in \mathbb{R}^p$ such that

$$||u|| < d(x) \tag{3}$$

and

$$LV(x) + \sum_{i=1}^p \sum_{j=1}^n h_i^j(x) \frac{\partial V}{\partial x_j}(x) u^i < 0. \tag{4}$$

If in addition $\lim_{x \to 0} d(x) = 0$, then we say that the control Lyapunov function V satisfies the *small control property*. The following theorem, established in [6], is an extension of Artstein's theorem [2] to the feedback stabilization of stochastic differential systems. Another version of this result can be found in [3].

THEOREM 1.2. 1. *The stochastic differential system* (1) *satisfies a stochastic Lyapunov condition at the origin if and only if it is asymptotically stabilizable by means of a feedback law $u = k(x)$ which is smooth in a neighborhood of the origin except possibly in zero.*

2. *The corresponding control Lyapunov function V satisfies the bounded control property if and only if there exists a stabilizing feedback law $u = k(x)$ which is smooth in a neighborhood D of the origin, except possibly in zero, and such that*

$$||k(x)|| < d(x)$$

for every $x \in D \setminus \{0\}$ where d is defined in (3).

Furthermore, the function k is bounded in a neighborhood of the origin in $\mathbb{R}^n$, and if in addition the control Lyapunov function V satisfies the small control property, then $k(x)$ tends to zero as x tends to zero.

In the following section, we consider stochastic differential systems (1) of the form

$$\begin{aligned} d \begin{pmatrix} x_{1,t} \\ x_{2,t} \end{pmatrix} = \begin{pmatrix} f_1(x_{1,t}, x_{2,t}) \\ f_2(x_{1,t}, x_{2,t}) \end{pmatrix} dt + \begin{pmatrix} 0 \\ h_2(x_{1,t}, x_{2,t}) \end{pmatrix} u dt \\ + \begin{pmatrix} g_1(x_{1,t}) \\ g_2(x_{1,t}, x_{2,t}) \end{pmatrix} dw_t, \end{aligned} \tag{5}$$

where $x_t = \binom{x_{1,t}}{x_{2,t}} \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}$, $n = n_1 + n_2$, and we derive sufficient conditions for the existence of control Lyapunov functions guaranteeing the existence of stabilizing feedback laws. A similar decomposition for the stochastic differential system (1) has

been considered by Mao [11], but his methodology is quite different from the one used in this work. To illustrate the method used in the following section, consider a single-input stochastic differential system in the form (5) with $n_2 = 1$. Assume that there exists a C^2 function ϕ mapping $\mathbb{R}^{n_1}$ into $\mathbb{R}$, vanishing in the origin, which is the unique solution of the equation $h_2(x_1, \nu) = 0$ and such that $\nu = \phi(x_1)$ is a stabilizing feedback law for the single-input stochastic differential system in $\mathbb{R}^{n_1}$,

$$dx_{1,t} = f_1(x_{1,t}, \nu)dt + g_1(x_{1,t})dw_t \tag{6}$$

(see Example 1). Then, the stochastic differential system (5) satisfies a stochastic Lyapunov condition at the origin, and so by application of Theorem 1.2 it is asymptotically stabilizable in probability. Indeed, if V is a Lyapunov function for the closed-loop system

$$dx_{1,t} = f_1(x_{1,t}, \phi(x_{1,t}))dt + g_1(x_{1,t})dw_t \tag{7}$$

deduced from (6) when the control law ν is given by $\nu = \phi(x_1)$, then the function Φ defined on $\mathbb{R}^n$ by

$$\Phi(x_1, x_2) = V(x_1) + \frac{1}{4}(x_2 - \phi(x_1))^4$$

is a control Lyapunov function for the stochastic differential system (5). It is obvious that the function Φ is twice continuously differentiable on $\mathbb{R}^n$ and positive definite, and for any $x \neq 0$ with

$$h_2(x)\frac{\partial \Phi}{\partial x_2}(x) = h_2(x_1, x_2)(x_2 - \phi(x_1))^3 = 0$$

one has $x_2 = \phi(x_1)$, and therefore, denoting by $\mathcal{L}_1$ the infinitesimal generator of the stochastic process solution of the stochastic differential equation (7), it yields

$$L\Phi(x_1, x_2)|_{x_2=\phi(x_1)} = \mathcal{L}_1 V(x_1) < 0.$$

Hence, the stochastic differential system (5) satisfies a stochastic Lyapunov condition at the origin, and, according to Theorem 1.2, it is asymptotically stabilizable in probability by means of a feedback law which is smooth in a neighborhood of the origin except possibly in zero. The method described above is applicable to stochastic differential systems in the form

$$d\begin{pmatrix} x_1 \\ . \\ . \\ . \\ x_n \end{pmatrix} = \begin{pmatrix} x_2 \\ . \\ . \\ x_n \\ f(x) \end{pmatrix} dt + u\begin{pmatrix} 0 \\ . \\ . \\ 0 \\ h(x) \end{pmatrix} dt + \begin{pmatrix} x_1 \\ . \\ . \\ x_{n-1} \\ g(x) \end{pmatrix} dw_t, \tag{8}$$

where f, g, and h are C^∞ functionals vanishing in the origin. The stochastic differential system (8) satisfies a stochastic Lyapunov condition at the origin provided that there exists a function ϕ mapping $\mathbb{R}^{n-1}$ into $\mathbb{R}$, vanishing in the origin, such that $x_n = \phi(x_1, ..., x_{n-1})$ is the unique solution of the equation $h(x) = 0$ and the equilibrium solution $x_t \equiv 0$ of the lower-dimensional stochastic differential system

$$d\begin{pmatrix} x_1 \\ . \\ . \\ . \\ x_{n-1} \end{pmatrix} = \begin{pmatrix} x_2 \\ . \\ . \\ x_{n-1} \\ \phi(x_1, ..., x_{n-1}) \end{pmatrix} dt + \begin{pmatrix} x_1 \\ . \\ . \\ . \\ x_{n-1} \end{pmatrix} dw_t$$

is asymptotically stable in probability. In the following section, we extend the above results to more general stochastic differential systems. A special emphasis is given to the asymptotic stabilization in probability of stochastic differential systems (5) in which the function h is constant and they are of the form

$$d\begin{pmatrix} x_{1,t} \\ x_{2,t} \end{pmatrix} = \begin{pmatrix} f_1(x_{1,t}, x_{2,t}) \\ f_2(x_{1,t}, x_{2,t}) \end{pmatrix} dt + \begin{pmatrix} 0 \\ u \end{pmatrix} dt + \begin{pmatrix} g_1(x_{1,t}) \\ g_2(x_{1,t}, x_{2,t}) \end{pmatrix} dw_t, \tag{9}$$

where $(x_1, x_2) \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}$ and u is an $\mathbb{R}^{n_2}$-valued control law.

2. Main results. Consider the lower-dimensional subsystems of the stochastic differential system (5):

$$dx_{1,t} = f_1(x_{1,t}, \nu)dt + g_1(x_{1,t})dw_t, \tag{10}$$

$$dx_{2,t} = h_2(x_{1,t}, x_{2,t})udt, \tag{11}$$

where $\nu \in \mathbb{R}^{n_2}$ and u is an $\mathbb{R}^p$-valued control law. Then, one can prove the following result, where the stochastic Lyapunov condition for the stochastic differential system (5) is characterized in terms of suitable positive functions for the stochastic differential systems (10)–(11).

THEOREM 2.1. *Assume that there exist neighborhoods D and D_1 of the origin in $\mathbb{R}^n$ and $\mathbb{R}^{n_1}$, respectively, and mappings $r : D \to \mathbb{R}^p$, $\phi : D_1 \to \mathbb{R}^{n_2}$, and $W : D \to \mathbb{R}$ such that $\phi(0) = 0$, ϕ is continuous, and W is twice continuously differentiable.*

Denote by M, S_1, and S_2 the subsets of $\mathbb{R}^n$ defined by

$$M = \{x \in D \ / \ x_2 = \phi(x_1)\}, \quad S_1 = \{x \in D \ / \ \nabla^\alpha W(x) = 0, \ \alpha = 0, 1, 2\}$$

and

$$S_2 = \left\{ x \in D \ / \ \left(\frac{\partial W}{\partial x_2} h_2 r \right)(x) = 0 \right\},$$

and suppose that

1. *for any x in a neighborhood of the origin in $\mathbb{R}^n$, $W(x) \geq 0$ and $S_2 \subset S_1 = M$;*
2. *the stochastic differential system (10) is asymptotically stabilizable in probability by means of the feedback law $\nu = \phi(x_1)$.*

Then, the stochastic differential system (5) satisfies a stochastic Lyapunov condition at the origin. Furthermore, if Φ denotes the corresponding control Lyapunov function and if one assumes further that

3. *the function r is bounded, and the functions ϕ and $\frac{\partial W}{\partial x_2}$ are continuously differentiable;*
4. *there exist positive constants c and $a \leq 2$ such that*

$$\left(\frac{\partial W}{\partial x_2} h_2 r \right)(x) \leq -c||x_2 - \phi(x_1)||^a \tag{12}$$

for x in a neighborhood of the origin in $\mathbb{R}^n$,
then if $a \leq 1$ the function Φ satisfies the small control property, and if $1 < a \leq 2$ and the equilibrium solution $x_{1,t} \equiv 0$ of the stochastic differential system

$$dx_{1,t} = f_1(x_{1,t}, \phi(x_{1,t}))dt + g_1(x_{1,t})dw_t,$$

the coefficients of which are assumed to be C_b^2, is exponentially stable in mean square, the stochastic control Lyapunov function Φ satisfies the bounded control property.

Proof of Theorem 2.1. Since the equilibrium solution $x_{1,t} \equiv 0$ of the closed-loop system

$$dx_{1,t} = f_1(x_{1,t}, \phi(x_{1,t}))dt + g_1(x_{1,t})dw_t, \tag{13}$$

deduced from the stochastic differential system (10) when the control law ν is given by $\nu = \phi(x_1)$, is asymptotically stable in probability, the converse Lyapunov theorem for asymptotic stability in probability proved by Kushner [10] asserts that there exist a neighborhood $\mathcal{D}$ of the origin in $\mathbb{R}^{n_1}$ and a Lyapunov function V defined on $\mathcal{D}$ such that

$$L_1 V(x_1) < 0$$

for any $x_1 \in \mathcal{D}$, $x_1 \neq 0$, where L_1 denotes the infinitesimal generator of the stochastic process solution of the closed-loop system (13). On the other hand, the function Φ defined on $\mathbb{R}^n$ by

$$\Phi(x) = V(x_1) + W(x) \tag{14}$$

is positive definite, and for any $x \in (\mathcal{D} \times \mathbb{R}^{n_2}) \cap D$,

$$\nabla\Phi(x).\begin{pmatrix} 0 \\ h_2(x) \end{pmatrix} = \frac{\partial W}{\partial x_2}(x)h_2(x).$$

Hence for any $x \neq 0$ such that $\nabla\Phi(x).\binom{0}{h_2(x)} = 0$ one has, according to assumption 1 of Theorem 2.1, $x_2 = \phi(x_1)$, which implies that

$$\nabla W(x_1, \phi(x_1)) = 0 \text{ and } \nabla^2 W((x_1, \phi(x_1)) = 0.$$

Then, denoting by $\mathcal{L}$ the infinitesimal generator of the stochastic process solution of the uncontrolled part of the stochastic differential system (5) yields

$$\mathcal{L}\Phi(x)|_{x_2=\phi(x_1)} = L_1 V(x_1) < 0.$$

Therefore, the stochastic differential system (5) satisfies a stochastic Lyapunov condition at the origin, and the function Φ defined by (14) is a control Lyapunov function. Now, assume that (12) holds, and let $a \leq 1$. Since the function f is continuously differentiable, W is twice differentiable and for any $x_1 \in \mathcal{D}$, $\nabla W(x_1, \phi(x_1)) = 0$ and $\nabla^2 W(x_1, \phi(x_1)) = 0$, one can prove easily that there exist nonnegative constants c_1, c_2, and c_3 such that

$$||\nabla f(x)|| \leq c_1, \tag{15}$$

$$||\nabla W(x)|| \leq c_2||x_2 - \phi(x_1)||, \tag{16}$$

and

$$||\nabla^2 W(x)|| \leq c_3||x_2 - \phi(x_1)|| \tag{17}$$

for x in a neighborhood of the origin in $\mathbb{R}^n$. On the other hand, denoting by q the positive definite functional defined by

$$q(x) = -L_1 V(x_1) + ||x_2 - \phi(x_1)||^2$$

and denoting by b the functional defined by

$$b(x) = c_1||\nabla V(x_1)|| + c_2||f(x)|| + \frac{c_3}{2}||(gg^\star)(x)||$$

yield

$$\begin{aligned}|\mathcal{L}\Phi(x) + q(x)| &\leq b(x)||x_2 - \phi(x_1)|| \\ &\leq b(x)||x_2 - \phi(x_1)||^a.\end{aligned}$$

Then, taking into account inequality (12) one gets

$$\mathcal{L}\Phi(x) + \left(\frac{\partial \Phi}{\partial x_2} h_2\right)(x) \frac{b(x) r(x)}{c} \leq -q(x) < 0$$

for x in a neighborhood of the origin $x \neq 0$. Therefore, since r is bounded and b is continuous with $b(0) = 0$, it follows that the control Lyapunov function Φ satisfies the small control property. Finally, assume that (12) holds with $1 < a \leq 2$ and that the function ϕ is continuously differentiable. Since the function g is continuously differentiable there exists a nonnegative constant c_4 such that

$$||\nabla(gg^\star)(x)|| \leq c_4 \tag{18}$$

for x in a neighborhood of the origin. On the other hand, since $\phi(0) = 0$, there exists a nonnegative constant c_5 such that

$$||\phi(x_1)|| \leq c_5||x_1|| \tag{19}$$

for x_1 in a neighborhood of the origin in $\mathbb{R}^{n_1}$, and since $f(0) = 0$ and $g(0) = 0$, one can deduce from (15), (18), and (19) that

$$||f(x)|| \leq c_1\left((c_5 + 1)||x_1|| + ||x_2 - \phi(x_1)||\right)$$

and

$$||(gg^\star)(x)|| \leq c_4\left((c_5 + 1)||x_1|| + ||x_2 - \phi(x_1)||\right)$$

for all x in a neighborhood of the origin in $\mathbb{R}^n$. Furthermore, since the equilibrium solution $x_t \equiv 0$ of the stochastic differential equation (13) is exponentially stable in mean square, the converse Lyapunov theorem proved by Khasminskii [9] asserts that there exists a Lyapunov function V and positive constants β_1 and β_2 such that

$$L_1 V(x_1) \leq -\beta_1||x_1||^2$$

and

$$||\nabla V(x_1)|| \leq \beta_2||x_1||^2$$

for all x_1 in a neighborhood of the origin in $\mathbb{R}^{n_1}$. Then, defining the function q on $\mathbb{R}^n$ by

$$\begin{aligned}q(x) = -L_1 V(x_1) - \left(\nabla V \frac{\partial f_1}{\partial x_2}\right)(x_1, \phi(x_1))(x_2 - \phi(x_1)) - \mathcal{L}W(x) \\ + k||x_2 - \phi(x_1)||^2,\end{aligned}$$

where k is nonnegative, one can prove that there exist nonnegative constants M_1 and M_2 such that

$$q(x) \geq \beta_1 ||x_1||^2 - M_1 ||x_1||.||x_2 - \phi(x_1)|| + (k - M_2)||x_2 - \phi(x_1)||^2,$$

and so q is positive definite provided that k is large enough. On the other hand, denoting by K a nonnegative constant such that

$$||f_1(x) - f_1(x_1, \phi(x_1)) - \frac{\partial f_1}{\partial x_2}(x_1, \phi(x_1))(x_2 - \phi(x_1))|| \leq K||x_2 - \phi(x_1)||,$$

one can prove that there exists a constant $s > 0$ such that for all x in a neighborhood of the origin in $\mathbb{R}^n$,

$$\begin{aligned} |\mathcal{L}\Phi(x) + q(x)| &\leq s||x_2 - \phi(x_1)||^a \\ &\leq -\frac{s}{c}\left(\frac{\partial W}{\partial x_2} h_2 r\right)(x). \end{aligned}$$

Therefore,

$$\mathcal{L}\Phi(x) + \left(\frac{\partial \Phi}{\partial x_2} h_2\right)(x)\frac{rs}{c} \leq -q(x)$$

for all x in a neighborhood of the origin in $\mathbb{R}^n$, $x \neq 0$, and since $\frac{rs}{c}$ is bounded, the control Lyapunov function Φ satisfies the bounded control property. This concludes the proof of Theorem 2.1.

The following result, which is an immediate consequence of the previous theorem, provides a control Lyapunov function for the stochastic differential system (5) that depends directly on the dynamics of the stochastic differential systems (10) and (11).

THEOREM 2.2. *Assume that there exist neighborhoods D and D_1 of the origin in $\mathbb{R}^n$ and $\mathbb{R}^{n_1}$, respectively, and mappings $r : D \to \mathbb{R}^p$ and $\phi : D_1 \to \mathbb{R}^{n_2}$ such that r is Lipschitz continuous, $\phi(0) = 0$, ϕ is continuous, the equilibrium solution $x_{1,t} \equiv 0$ of the stochastic differential system*

$$dx_{1,t} = f_1(x_{1,t}, \phi(x_{1,t}))dt + g_1(x_{1,t})dw_t \tag{20}$$

is asymptotically stable in probability, and the set

$$M = \{x \in D \ / \ x_2 = \phi(x_1), \ x_1 \in D_1\}$$

is asymptotically stable with respect to the differential system

$$\dot{x} = \begin{pmatrix} 0 \\ (h_2 r)(x) \end{pmatrix}. \tag{21}$$

Then, the stochastic differential system (5) *satisfies a stochastic Lyapunov condition at the origin.*

Proof of Theorem 2.2. Let N be the subset of $\mathbb{R}^n$ defined by

$$N = \{x \in \mathbb{R}^n \ / \ x_1 \in D_1\}.$$

Then the region N is positively invariant for the ordinary differential system (21) (cf. [12]), and since $M \subset N$ is asymptotically stable with respect to (21), one can

deduce from [15] that there exists a smooth Lyapunov function W defined on N such that $W(x) > 0$ and $(\frac{\partial W}{\partial x_2} h_2 r)(x) < 0$ for $x \notin M$, whereas $W(x) = 0$ for $x \in M$. Therefore, $(\frac{\partial W}{\partial x_2} h_2 r)(x) \leq 0$ in a neighborhood of the origin and $(\frac{\partial W}{\partial x_2} h_2 r)(x) = 0$ if and only if $x_2 = \phi(x_1)$. Then, assumptions 1 and 2 of Theorem 2.1 are satisfied, and so the stochastic differential system (5) satisfies a stochastic Lyapunov condition at the origin. This concludes the proof of Theorem 2.2.

In the following, we study the particular case of stochastic differential systems in the form (9). Note that one can assume without loss of generality that $f_2 \equiv 0$. Otherwise, it suffices to apply in (9) the smooth feedback law $u \to -f_2 + u$, and the stochastic differential system becomes

$$d \begin{pmatrix} x_{1,t} \\ x_{2,t} \end{pmatrix} = \begin{pmatrix} f_1(x_{1,t}, x_{2,t}) \\ 0 \end{pmatrix} dt + \begin{pmatrix} 0 \\ u \end{pmatrix} dt + \begin{pmatrix} g_1(x_{1,t}) \\ g_2(x_{1,t}, x_{2,t}) \end{pmatrix} dw_t. \tag{22}$$

The stabilizability of such stochastic differential systems has already been studied in [6]; however, the following result asserts that the existence of stabilizing feedback laws for the stochastic differential system (22) is a consequence of Theorem 2.1.

PROPOSITION 2.3. *Assume that the stochastic differential system* (10) *is asymptotically stabilizable in probability by means of a feedback law* $\nu = \phi(x_1)$ *which is continuously differentiable in a neighborhood of the origin in* $\mathbb{R}^{n_1}$. *Then, the stochastic differential system* (22) *satisfies a stochastic Lyapunov condition at the origin, and the corresponding control Lyapunov function satisfies the small control property.*

Proof of Proposition 2.3. Since the equilibrium solution $x_{1,t} \equiv 0$ of the stochastic differential equation

$$dx_{1,t} = f_1(x_{1,t}, \phi(x_{1,t}))dt + g_1(x_{1,t})dw_t$$

is asymptotically stable in probability, the converse Lyapunov theorem proved by Kushner [10] asserts that there exists a Lyapunov function V defined in a neighborhood $\mathcal{D}$ of the origin in $\mathbb{R}^{n_1}$ such that

$$L_1 V(x_1) < 0$$

for any $x_1 \in \mathcal{D}$, $x_1 \neq 0$. On the other hand, let W be the functional defined on $\mathbb{R}^n$ by

$$W(x) = \frac{1}{2} ||x_2 - \phi(x_1)||^2.$$

Then, W is semipositive definite and $\frac{\partial W}{\partial x_2}$ is continuously differentiable in a neighborhood of the origin. Furthermore, if r denotes the functional defined on $\mathbb{R}^n$ by

$$r_i(x) = -\operatorname{sgn}\left((x_2 - \phi(x_1))_i\right), \qquad 1 \leq i \leq n_2,$$

it is obvious that r is uniformly bounded on $\mathbb{R}^n$ and so W satisfies the hypotheses of Theorem 2.1.

In particular, note that (12) is fulfilled with $a = 1$, which implies that the control Lyapunov function Φ defined on $\mathbb{R}^n$ by

$$\Phi(x) = V(x_1) + W(x)$$

satisfies the small control property. This completes the proof of Proposition 2.3.

3. Numerical examples.

Example 1. Let x_0 be given in $\mathbb{R}^2$, and denote by $x_t \in \mathbb{R}^2$, the solution of the stochastic differential system

$$d\begin{pmatrix} x_{1,t} \\ x_{2,t} \end{pmatrix} = \begin{pmatrix} -\frac{1}{2}x_{1,t} + x_{2,t} \\ \phi_1(x_{1,t}, x_{2,t}) \end{pmatrix} dt + u \begin{pmatrix} 0 \\ x_{2,t} + \phi_2(x_{1,t}) \end{pmatrix} dt + \begin{pmatrix} x_{1,t} \\ x_{2,t} \end{pmatrix} dw_t, \tag{23}$$

where ϕ_2 is a C^2 functional on $\mathbb{R}$ such that

$$-2x_1\phi_2(x_1) + (x_1\nabla\phi_2(x_1) - \phi_2(x_1))^2 < 0 \tag{24}$$

for any x_1 in a neighborhood of the origin in $\mathbb{R}$, $x_1 \neq 0$. (Note that $\phi_2(x_1) = x_1$ satisfies inequality (24).) Then one can prove easily that

- the function Φ defined on $\mathbb{R}^2$ by

$$\Phi(x) = x_1^2 + (x_2 + \phi_2(x_1))^2$$

is a control Lyapunov function for the stochastic differential system (23);

- the feedback law $\nu = -\phi_2(x_1)$ renders the control stochastic differential system

$$dx_{1,t} = -\frac{1}{2}x_{1,t}dt + \nu dt + x_{1,t}dw_t$$

asymptotically stable in probability.

Therefore, according to Theorems 1.2 and 2.1 the stochastic differential system (23) is asymptotically stabilizable in probability by means of a feedback law which is smooth in a neighborhood of the origin in $\mathbb{R}^2$, except possibly at the origin. On the other hand, if W denotes the function defined on $\mathbb{R}^2$ by

$$W(x) = (x_2 + \phi(x_1))^2,$$

one can prove that inequality (12) is fulfilled with $a = 2$ and $r = -1$; therefore, the function Φ satisfies the bounded control property provided that $\nabla\phi_2(0) = 0$.

Furthermore, in this case the equilibrium solution $x_{1,t} \equiv 0$ of the stochastic differential equation

$$dx_{1,t} = \left(-\frac{1}{2}x_{1,t} - \phi_2(x_{1,t})\right) dt + x_{1,t}dw_t$$

is exponentially stable in mean square, which implies, according to Theorem 2.1, that the stochastic differential system (23) is asymptotically stabilizable in probability by a bounded feedback law.

Example 2. Consider the stochastic differential system in $\mathbb{R}^3$ defined by

$$dy_t = \begin{pmatrix} y_{1,t}^3 - y_{1,t}^2(y_{2,t} + y_{3,t}) \\ y_{2,t} \\ 0 \end{pmatrix} dt + \begin{pmatrix} 0 \\ (y_{1,t} - y_{2,t})^3 \\ 0 \end{pmatrix} u_1 dt + \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} u_2 dt + \begin{pmatrix} y_{1,t}^2 \\ y_{2,t} \\ y_{3,t} \end{pmatrix} dw_t, \tag{25}$$

where y_0 is given in $\mathbb{R}^3$. The stochastic differential system (25) has the form (5), where

$$x_{1,t} = y_{1,t}, x_{2,t} = \begin{pmatrix} y_{2,t} \\ y_{3,t} \end{pmatrix}, \qquad x_t = \begin{pmatrix} x_{1,t} \\ x_{2,t} \end{pmatrix},$$
$$f_1(x) = y_{1,t}^3 - y_{1,t}^2(y_{2,t} + y_{3,t}), \qquad f_2(x) = \begin{pmatrix} y_{2,t} \\ 0 \end{pmatrix},$$
$$g_1(x_{1,t}) = x_{1,t}^2, \qquad g_2(x) = x_{2,t},$$
$$u = \begin{pmatrix} u_1 \\ u_2 \end{pmatrix},$$

and

$$h_2(x) = \begin{pmatrix} (y_{1,t} - y_{2,t})^3 & 0 \\ 0 & 1 \end{pmatrix}.$$

Furthermore, if r denotes the functional defined on $\mathbb{R}^3$ by

$$r(x) = \begin{pmatrix} 1 \\ y_{1,t} - y_{3,t} \end{pmatrix}$$

and if ϕ denotes the functional defined on $\mathbb{R}$ by

$$\phi(x_1) = \begin{pmatrix} x_1 \\ x_1 \end{pmatrix}, \tag{26}$$

then the set

$$M = \left\{ x \in \mathbb{R}^3 \ / \ x_2 = \phi(x_1) \right\}$$

is asymptotically stable with respect to the ordinary differential system (21). This result is easily proved by evaluating the derivative of the Lyapunov function W defined on $\mathbb{R}^3$ by

$$W(x) = \frac{1}{2} ||x_2 - \phi(x_1)||^2$$

along the trajectories of (21). On the other hand, the feedback law ν defined on $\mathbb{R}$ by

$$\nu = \phi(x_1)$$

asymptotically stabilizes in probability the stochastic differential system (10). Indeed, if V denotes the Lyapunov function defined on $\mathbb{R}$ by

$$V(x_1) = \frac{1}{2} x_1^2,$$

one has

$$L_1 V(x_1) = -\frac{1}{2} x_1^4,$$

which implies, according to the stochastic Lyapunov theorem (Theorem 1.3 in [6]), that the equilibrium solution $x_{1,t} \equiv 0$ of the stochastic differential system (20) is asymptotically stable in probability. Therefore, the stochastic differential system (25) satisfies the hypotheses of Theorem 2.2 and so is asymptotically stabilizable in probability.

OPTIMAL STRATEGIES FOR BILEVEL DYNAMIC PROBLEMS*

JANE J. YE†

Abstract. In this paper we study the bilevel dynamic problem, which is a hierarchy of two dynamic optimization problems, where the constraint region of the upper level problem is determined implicitly by the solutions to the lower level optimal control problem. To obtain optimality conditions, we reformulate the bilevel dynamic problem as a single level optimal control problem that involves the value function of the lower-level problem. Sensitivity analysis of the lower-level problem with respect to the perturbation in the upper-level decision variable is given and first-order necessary optimality conditions are derived by using nonsmooth analysis. A constraint qualification of calmness type and a sufficient condition for the calmness are also given.

Key words. necessary conditions, bilevel dynamic problems, sensitivity analysis, nonsmooth analysis, value function, constraint qualification, calmness condition

1. Introduction.

Let us consider a two-level hierarchical system where two decision makers try to find best decisions with respect to certain, but generally different, goals. Moreover, assume that these decision makers cannot act independently of each other but only according to a certain hierarchy whereby the optimal strategy chosen by the lower level (hereafter the "follower") depends on the strategy selected by the upper level (hereafter the "leader"). On the other hand, let the objective function of the leader depend not only on his own decision but also on the reaction of the follower. Then while having the first choice, the leader is able to evaluate the true value of his own selection only after knowing the follower's possible reactions. Assume that the game is cooperative; i.e., if the follower's problem has several optimal decisions for a given leader's decision, then the follower allows the leader to choose which of them is actually used. Thus the leader will choose his optimal decision among all decisions available and the follower's optimal decision to minimize his objective. In particular, we consider a hierarchical dynamical system, where the state $x(t) \in R^d$ is influenced by the decisions of both leader and follower $u(\cdot)$ and $v(\cdot)$. The state $x(t) \in R^d$ is described by

$$\begin{aligned} &\dot{x}(t) = \phi(t, x(t), u(t), v(t)) \qquad \text{almost everywhere (a.e.) } t \in [t_0, t_1], \\ &x(t_0) = x_0, \end{aligned}$$

where $u(t) \in U$, a closed subset of R^n and $v(t) \in W(t) \subset R^m$ for almost all $t \in [t_0, t_1]$. In mathematical terms, given any control function $u(\cdot)$ selected by the leader, the follower faces the ordinary (single-level) optimal control problem involving a parameter u,

$$P_2(u) \qquad \min J_2(x, u, v) = \int_{t_0}^{t_1} G(t, x(t), u(t), v(t))dt + g(x(t_1))$$

$$\begin{aligned} \text{subject to (s.t.) } & \dot{x}(t) = \phi(t, x(t), u(t), v(t)) \qquad \text{a.e.}, \\ & x(t_0) = x_0, \\ & v(t) \in W(t) \qquad \text{a.e.}, \end{aligned}$$

while the leader faces the *bilevel dynamic problem*,

$$\begin{aligned} P_1 \qquad & \min\ J_1(x,u,v) = \int_{t_0}^{t_1} F(t, x(t), u(t), v(t))dt + f(x(t_1)) \\ & \text{over } u \in L^2([t_0,t_1], U) \text{ and all solutions } (x,v) \text{ of } P_2(u). \end{aligned}$$

The bilevel static problem, where both the leader's and the follower's decisions are vectors instead of control functions, was first introduced by von Stackelberg [14] for an economic model. The bilevel dynamic problems were first considered by Chen and Cruz in [2]. Most of the bilevel (static or dynamic) problems are attacked by reducing the bilevel problem to a single-level problem with the first-order necessary optimality conditions for the lower-level problem as additional constraints (cf. Bard and Falk [1] and Zhang [20], [21] for bilevel static problems, Chen and Cruz [2] and Zhang [20] for bilevel dynamic problems). The reduction is equivalent provided the lower-level optimal control problem is convex, since in this case the first-order necessary optimality condition is also sufficient. Apart from the strong convexity assumption, the resulting optimality conditions of the above approach involve second-order derivatives and a larger system, since the reduced problem minimizes over the set of original decision variables as well as the set of multipliers of the lower-level problem.

To our knowledge, there is no optimality condition for a general bilevel dynamic problem to date. The necessary condition obtained by Chen and Cruz in [2] holds in the case where Pontryagin's maximum principle for the lower-level optimal control problem is sufficient for optimality and no bounds are allowed for the control functions. The necessary condition was stated in a normal form (i.e., the multiplier for the objective function of the upper-level problem is 1) that holds only when the reduced single-level optimal control problem is calm (see [3] for definition). The necessary condition obtained by Zhang in [20] is only for a bilevel dynamic problem in which the dynamics are linear in the state and control variables and require convexity assumptions on the objective function of the lower-level problem. The purpose of this paper is to provide first-order necessary optimality conditions for problem P_1 under *very general* assumptions (in particular, without convexity assumptions and with bounds on the control functions).

Define the *value function of the lower-level optimal control problem* as an extended-valued functional $V(u) : L^2([t_0,t_1], U) \to \bar{R}$ defined by

$$V(u) := \inf \left\{ \int_{t_0}^{t_1} G(t, x(t), u(t), v(t))dt + g(x(t_1)) : \begin{array}{ll} \dot{x}(t) = \phi(t, x(t), u(t), v(t)) & \text{a.e.} \\ v(t) \in W(t) \qquad \text{a.e.} & \\ x(t_0) = x_0 & \end{array} \right\},$$

where $\bar{R} := R \cup \{-\infty\} \cup \{+\infty\}$ is the extended real line and $\inf \emptyset = +\infty$ by convention. Our approach is to reformulate P_1 as the following single-level optimal control problem:

$$\widetilde{P}_1 \qquad \min\ J_1(u,v) = \int_{t_0}^{t_1} F(t, x(t), u(t), v(t))dt + f(x(t_1))$$

$$\begin{aligned} \text{s.t. } & \dot{x}(t) = \phi(t, x(t), u(t), v(t)) \qquad \text{a.e.}, \\ & x(t_0) = x_0, \\ & u(\cdot) \in L^2([t_0, t_1], U), v(t) \in W(t) \qquad \text{a.e.}, \\ & \int_{t_0}^{t_1} G(t, x(t), u(t), v(t))dt + g(x(t_1)) - V(u) = 0. \end{aligned} \tag{1}$$

The above problem is obviously equivalent to the original bilevel dynamic problem P_1 and is a *nonstandard optimal control problem* since the constraint (1) involves a functional defined by the value function $V(u)$ of the lower-level optimal control problem. In general $V(u)$ is not an explicit function of the problem data and is nonsmooth even in the case where all problem data are smooth functions. To derive a necessary condition for optimality for problem P_1, one needs to study Lipschitz continuity and generalized gradients of the value function $V(u)$ and develop a necessary optimality condition for the nonstandard optimal control problem with functional constraints (1). Recent developments in nonsmooth analysis allow us to study Lipschitz continuity and generalized gradients of the value function $V(u)$ with respect to a *nonadditive* infinite-dimensional perturbation u. We then reformulate the nonstandard optimal control problem as an infinite-dimensional optimization problem and use a result due to Ioffe [8] to derive a necessary optimality condition for the nonstandard optimal control problem with functional constraints.

The approach of reducing a bilevel problem to a single-level problem using the value function was used in the literature (see [11], [12]) for numerical purposes and for deriving first-order necessary conditions for the static bilevel optimization problem [17], [18]. The essential issue in the static case is the constraint qualification since the generalized differentiability of the value function in the finite-dimensional case is well known and the resulting equivalent single-level problem is an ordinary mathematical programming problem. It was shown in [17] and [18] that bilevel problems always have abnormal multipliers, and the right constraint qualification for ensuring the existence of a normal multiplier is the calmness condition. In Ye [16], a bilevel dynamic optimization problem where the lower level is an optimal control problem while the upper-level decision variable is a vector is considered. Although the bilevel dynamic optimization problem considered in [16] is a special case of the problem we study in this paper, it deserves special attention since it reduces to a single-level optimal control problem with end point constraints involving a value function that is a function of the upper-level decision vector. Fritz John–type necessary optimality conditions were derived under more general assumptions.

The following basic assumptions are in force throughout this paper:

(A1) $W(t) : [t_0, t_1] \to R^m$ is a nonempty, compact-valued, set-valued map. The graph of $W(t)$ (i.e., the set $\{(s, r) : s \in [t_0, t_1], r \in W(s)\}$), denoted by Gr$W$, is $\mathcal{L} \times \mathcal{B}$ measurable, where $\mathcal{L} \times \mathcal{B}$ denotes the σ-algebra of subsets of $[t_0, t_1] \times R^m$ generated by product sets $M \times N$ where M is a Lebesgue measurable subset of $[t_0, t_1]$ and N is a Borel subset of R^m.

(A2) The function $F(t, x, u, v) : [t_0, t_1] \times R^d \times R^n \times R^m \to R$ is $\mathcal{L} \times \mathcal{B}$ measurable in (t, v) and continuously differentiable in x and u. The functions $\phi(t, x, u, v) : [t_0, t_1] \times R^d \times R^n \times R^m \to R^d$, $G(t, x, u, v) : [t_0, t_1] \times R^d \times R^n \times R^m \to R$ are measurable in t, continuously differentiable in x and u, and lower semicontinuous in v.

(A3) There exists an integrable function $\psi : [t_0, t_1] \to R$ such that

$$|\nabla_{(x,u)} F| + |\nabla_{(x,u)} G| + |\nabla_{(x,u)} \phi| \le \psi(t) \quad \forall (t, x, u, v) \in [t_0, t_1] \times R^d \times U \times W(t).$$

(A4) The function $f(x) : \mathbb{R}^d \to R$ is locally Lipschitz continuous, and the function $g(x) : R^d \to R$ is Lipschitz continuous of rank $L_g \geq 0$.

(A5) For any $u \in L^2([t_0, t_1], U)$, $P_2(u)$ has an admissible pair (whose definition is given below).

A *control function* for $P_2(u)$ is a (Lebesgue) measurable selection $v(\cdot)$ for $W(\cdot)$, that is, a measurable function satisfying $v(t) \in W(t)$ a.e. $t \in [t_0, t_1]$. An *arc* is an absolutely continuous function. An *admissible pair* for $P_2(u)$ is a pair of functions $(x(\cdot), v(\cdot))$ on $[t_0, t_1]$ of which $v(\cdot)$ is a control function for $P_2(u)$ and $x(\cdot) : [t_0, t_1] \to R^d$ is an arc that satisfies the differential equation $\dot{x}(t) = \phi(t, x(t), u(t), v(t))$ a.e., together with the initial condition $x(t_0) = x_0$. The first and the second components of an admissible pair are called an *admissible trajectory* and *admissible control*, respectively. A *solution* to problem $P_2(u)$ is an admissible pair for $P_2(u)$ that minimizes the value of the cost functional $J_2(x, u, v)$ over all admissible pairs for $P_2(u)$. An *admissible strategy* for P_1 includes $u \in L^2([t_0, t_1], U)$ and an optimal control v for $P_2(u)$. The strategy (u, v) and the corresponding trajectory x are *optimal* for the bilevel dynamic problem P_1 if (x, u, v) minimizes the value of the cost functional $J_1(x, u, v)$ among all admissible strategies and the corresponding trajectories for P_1.

The plan of the paper is as follows. In section 2, we study generalized differentiability of the value function $V(u)$. In section 3, under a calmness-type constraint qualification, we derive a Kuhn–Tucker–type necessary optimality condition for the bilevel dynamic problem. It is also shown that the existence of a uniformly weak sharp minimum is a sufficient condition for the calmness, and a sufficient condition for existence of a weak sharp minimum is given. Finally, three examples are given in section 3 to illustrate applications of the constraint qualification and the necessary optimality conditions.

2. Differentiability of the value function. Let X be a Hilbert space. Consider a lower semicontinuous functional $\phi : X \to R \cup \{+\infty\}$ and a point $\bar{x} \in X$, where ϕ is finite. A vector $\zeta \in X$ is called a *proximal subgradient* of $\phi(\cdot)$ at $\bar{x}$ provided that there exist $M > 0, \delta > 0$ such that

$$\phi(x') - \phi(\bar{x}) + M\|x' - \bar{x}\|^2 \geq \langle \zeta, x' - \bar{x} \rangle, \qquad x' \in \bar{x} + \delta B.$$

The set of all proximal subgradients of $\phi(\cdot)$ at $\bar{x}$ is denoted $\partial^\pi \phi(\bar{x})$. A *limiting subgradient* of ϕ at $\bar{x}$ is the set

$$\hat{\partial}\phi(\bar{x}) := \{\text{weak} \lim_{k \to \infty} \zeta_k : \zeta_k \in \partial^\pi \phi(x_k), x_k \to \bar{x}, \phi(x_k) \to \phi(\bar{x})\}.$$

The limiting subgradient is a smaller object than the *Clarke generalized gradient* (see Clarke [3] for definition). In fact, if ϕ is Lipschitz continuous near $\bar{x}$, we have $\partial\phi(\bar{x}) = \text{clco}\hat{\partial}\phi(\bar{x})$, where ∂ and clcoA denote the Clarke generalized gradient and closed convex hull of set A, respectively. For the definition and more details of the precise relation between the limiting subgradient and the Clarke generalized gradient, the reader is referred to Clarke [4] and Rockafellar [13].

The following result concerning the compactness of trajectories of a differential inclusion is slightly different from [3, Theorem 3.1.7] and will be used repeatedly. We omit the proof here since it can be proved similarly to [3, Theorem 3.1.7].

PROPOSITION 2.1. *Let $\Gamma : [t_0, t_1] \times R^d \times R^n \to R^n \times R^n$ be a set-valued map. We suppose that Γ is integrably bounded (i.e., there exists an integrable function $k(t)$ such that $|v| \leq k(t) \forall v \in \Gamma(t, x, u)$) and that Γ is nonempty, compact, and convex. We suppose that for every $(t, x, u) \in [t_0, t_1] \times R^d \times R^n$ the set-valued map $t' \to \Gamma(t', x, u)$*

is measurable and $\forall [t_0,t_1]\times R^d\times R^n$*, the set-valued map* $(x',u')\to\Gamma(t,x',u')$ *is upper semicontinuous. Let* Γ *be* $\mathcal{L}\times\mathcal{B}$ *measurable, where* $\mathcal{L}\times\mathcal{B}$ *denotes the* σ*-algebra of subsets of* $[t_0,t_1]\times R^d\times R^n$ *generated by product sets* $M\times N$*, where* M *is a Lebesque measurable subset of* $[t_0,t_1]$ *and* N *is a Borel subset of* $R^d\times R^n$*.*

Let $\{x_i\}$ *be a sequence of arcs on* $[t_0,t_1]$ *and* $\{\zeta_i\}$ *be a sequence of functions in* $L^2([t_0,t_1],R^n)$ *satisfying*

(i) $(\dot{x}_i(t),\zeta_i(t))\in\Gamma(t,x_i(t),u_i(t))$ *a.e.* $t\in[t_0,t_1]$,

(ii) $\zeta_i\to\zeta$ *weakly in* L^2,

(iii) $u_i\to u$ *in* L^2,

(iv) $\{x_i(t_0)\}$ *is bounded.*

Then there exists a subsequence of $\{x_i\}$ *that converges uniformly to an arc* x *such that*

$$(\dot{x}(t),\zeta(t))\in\Gamma(t,x(t),u(t))\qquad \text{a.e. } t\in[t_0,t_1].$$

To discuss generalized differentiability of the value function $V(u)$, we will need the following assumptions:

(A6) There exists $k(t)\in L^2([t_0,t_1],R)$ such that

$$|\phi|+|\nabla_{(x,u)}\phi|+|G|+|\nabla_{(x,u)}G|\le k(t)\quad\forall(t,x,u,v)\in[t_0,t_1]\times R^d\times U\times W(t).$$

(A7) For any $(t,x,u)\in[t_0,t_1]\times R^d\times R^n$ the set

$$\{(\phi(t,x,u,v),G(t,x,u,v)+r):v\in W(t),r\ge 0\}$$

is convex.

(A8) $|\nabla_u\phi|\le M\quad\forall(t,x,u,v)\in[t_0,t_1]\times R^d\times U\times W(t)$, where $M>0$ is a constant.

Remark 2.2. Assumption (A7) is standard in control theory to ensure the existence of an optimal control for the lower-level problem. In the case where this assumption is not satisfied, the standard procedure is to go for the relaxed control (see, e.g., [19] and [22]).

Let the Hamiltonian for $P_2(u)$ be the function defined by

$$H_2(t,x,u,p_2):=\sup\{p_2\cdot\phi(t,x,u,v)-G(t,x,u,v):v\in W(t)\}$$

and Y_u be the set of all optimal trajectories x to problem $P_2(u)$.

The following result gives the Lipschitz continuity of the value function and characterizes the generalized gradient of the value function. It extends the result of Clarke [5] to allow general *nonadditive* perturbations in both the dynamics and the objective function.

THEOREM 2.3. *Suppose that assumptions* (A1)–(A8) *hold. Then* V *is Lipschitz continuous near* u *and*

$$\partial V(u)\subset clco\cup_{x\in Y_u}\{\zeta:\exists\ arc\ p_2\ s.t.\ (-\dot{p_2},-\zeta,\dot{x})\in\partial H_2(t,x,u,p_2)\ a.e.\ -p_2(t_1)\in\hat{\partial}g(x(t_1))\},$$

where ∂H_2 *denotes the Clarke generalized gradient with respect to* (x,u,p_2)*.*

Before proving Theorem 2.3, we first give the following result.

LEMMA 2.4. *Let* u_i *be a sequence converging (in* L^2*) to* u *and let* (x_i,v_i) *be an admissible pair for* $P_2(u_i)$*. Then there exist a subsequence of* $\{x_i\}$ *converging*

uniformly to an arc x and a control v with (x, v) being an admissible pair for $P_2(u)$ such that

$$J_2(x, u, v) \le \liminf J_2(x_i, u_i, v_i).$$

Proof. Let

$$\dot{y}_i(t) := G(t, x_i(t), u_i(t), v_i(t)).$$

Then

$$(\dot{x}_i(t), \dot{y}_i(t)) \in \Gamma(t, x_i(t), y_i(t), u_i(t)), \tag{2}$$

where

$$\Gamma(t, x, y, u) := \{(\phi(t, x, u, v), r) : G(t, x, u, v) \le r \le k(t) + 1, v \in V(t)\}.$$

The proof can be reduced to an application of Proposition 2.1 by studying the differential inclusion (2). The essential fact in the reduction is Fillipov's lemma: an (extended) arc (x, y) satisfies the differential inclusion iff there is a control function v for x such that (x, v) is feasible for $P_2(u)$ and y satisfies $G(t, x, u, v) \le \dot{y} \le k(t) + 1$. □

We now turn to the proof of the theorem. By (A5), $P_2(u)$ has an admissible pair. So $V(u)$ is finite. By Lemma 2.4, V is (strongly) lower semicontinuous.

Step 1. Let $u \in L^2([t_0, t_1], U)$ and $\zeta \in \partial^\pi V(u)$. Let (x, v) be a solution of $P_2(u)$ that exists by virtue of Lemma 2.4. Then by definition, for some $M > 0$ and $\forall\ u'$ near u (in the L^2 norm), we have

$$\begin{aligned} V(u') - \langle \zeta, u' \rangle + M\|u' - u\|_2^2 &\ge V(u) - \langle \zeta, u \rangle \\ &= \int_{t_0}^{t_1} G(t, x(t), u(t), v(t))dt + g(x(t_1)) - \int_{t_0}^{t_1} \langle \zeta(t), u(t) \rangle dt. \end{aligned}$$

Let (x', v') be an admissible pair for $P_2(u')$. Then

$$\begin{aligned} &\int_{t_0}^{t_1} G(t, x'(t), u'(t), v'(t))dt + g(x'(t_1)) - \int_{t_0}^{t_1} \langle \zeta(t), u'(t) \rangle dt + M\|u' - u\|_2^2 \\ &\qquad \ge \int_{t_0}^{t_1} G(t, x(t), u(t), v(t))dt + g(x(t_1)) - \int_{t_0}^{t_1} \langle \zeta(t), u(t) \rangle dt. \end{aligned}$$

Hence (x, u, v) is a solution of the following optimal control problem:

$$\begin{aligned} \min & \int_{t_0}^{t_1} [G(t, x'(t), u'(t), v'(t)) - \langle \zeta(t), u'(t) \rangle]dt + g(x'(t_1)) + M\|u' - u\|_2^2 \\ \text{s.t. } & \dot{x'}(t) = \phi(t, x'(t), u'(t), v'(t)) \qquad \text{a.e.}, \\ & x'(t_0) = x_0, \\ & v'(t) \in W(t) \qquad \text{a.e.}, \\ & u'(t) \in U(t) := \{u' \in R^n : |u' - u(t)| \le \epsilon\}. \end{aligned}$$

Applying Theorem 5.2.1 of Clarke [3] with the Clarke generalized gradient replaced by the limiting subgradient in the transversality conditions (cf. [4, 10, 9]) to the above

optimal control problem with free end points leads to the existence of an arc p_2 such that

$$-\dot{p_2}(t) = \nabla_x \phi(t, x(t), u(t), v(t))^\top p_2(t) - \nabla_x G(t, x(t), u(t), v(t)) \quad \text{a.e.,} \tag{3}$$
$$\max_{u \in U(t), v \in W(t)} \{p_2(t) \cdot \phi(t, x(t), u, v) - G(t, x(t), u, v) + \langle \zeta(t), u \rangle\}$$

$$= p_2(t) \cdot \phi(t, x(t), u(t), v(t)) - G(t, x(t), u(t), v(t)) + \langle \zeta(t), u(t) \rangle \text{ a.e.,} \tag{4}$$

$$-p_2(t_1) \in \hat{\partial} g(x(t_1)), \tag{5}$$

where $^\top$ denotes the transpose. Equation (4) implies that

$$\max_{v \in W(t)} \{p_2(t) \cdot \phi(t, x(t), u(t), v) - G(t, x(t), u(t), v)\}$$
$$= p_2(t) \cdot \phi(t, x(t), u(t), v(t)) - G(t, x(t), u(t), v(t)) \text{ a.e.}$$

and

$$-\zeta(t) = \nabla_u \phi(t, x(t), u(t), v(t))^\top p_2(t) - \nabla_u G(t, x(t), u(t), v(t)). \tag{6}$$

Step 2. For any $\zeta \in \hat{\partial} V(u)$ by definition $\zeta = \text{weak} \lim_{i \to \infty} \zeta_i$, where $\zeta_i \in \partial^\pi V(u_i)$, $u_i \to u$ in L^2 and $V(u_i) \to V(u)$. By Step 1, for each u_i there exists an arc p_2^i and an arc x_i that solves $P_2(u_i)$ (along with v_i) such that

$$-\dot{p_2}^i(t) = \nabla_x \phi(t, x_i(t), u_i(t), v_i(t))^\top p_2^i(t) - \nabla_x G(t, x_i(t), u_i(t), v_i(t)) \quad \text{a.e.,} \tag{7}$$
$$\max_{v \in W(t)} \{p_2^i(t) \cdot \phi(t, x_i(t), u_i(t), v) - G(t, x_i(t), u_i(t), v)\}$$

$$= p_2^i(t) \cdot \phi(t, x_i(t), u_i(t), v_i(t)) - G(t, x_i(t), u_i(t), v_i(t)) \text{ a.e.,} \tag{8}$$

$$-\zeta_i(t) = \nabla_u \phi(t, x_i(t), u_i(t), v_i(t))^\top p_2^i(t) - \nabla_u G(t, x_i(t), u_i(t), v_i(t)), \tag{9}$$

$$-p_2^i(t_1) \in \hat{\partial} g(x_i(t_1)). \tag{10}$$

By [3, Theorem 2.8.2], (7), (8), and (9) imply that

$$(-\dot{p_2^i}(t), -\zeta_i(t), \dot{x_i}(t)) \in \partial H_2(t, x_i(t), u_i(t), p_2^i(t)) \quad \text{a.e.} \tag{11}$$

From (7)

$$p_2^i(t) = p_2^i(t_1) - \int_{t_1}^{t} [\nabla_x \phi(s, x_i(s), u_i(s), v_i(s))^\top p_2^i(s) - \nabla_x G(s, x_i(s), u_i(s), v_i(s))] ds.$$

By assumption (A4) and inclusion (10), the norm of $p_2^i(t_1)$ is bounded by L_g. Assumption (A3) implies that the norms of $\nabla_x \phi$ and $\nabla_x G$ are bounded by the integrable function ψ. Thus

$$|p_2^i(t)| \le (L_g + \int_{t_0}^{t_1} \psi(s) ds) + \int_t^{t_1} \psi(s) |p_2^i(s)| ds$$
$$= K + \int_t^{t_1} \psi(s) |p_2^i(s)| ds,$$

where $K := L_g + \int_{t_0}^{t_1} \psi(s)ds$. Invoking Gronwall's inequality, we conclude that

$$|p_2^i(t)| \le Ke^{\int_t^{t_1} \psi(s)ds},$$

which implies that $\|p_2^i\|_\infty$ is bounded. It follows that the set-valued map ∂H_2 is integrably bounded. Applying Proposition 2.1 to differential inclusion (11) with boundary condition (10), we conclude that there exists a convergent subsequence of $\{x_i, p_2^i\}$ that converges to the arcs x, p_2 such that

$$(-\dot{p_2}(t), -\zeta(t), \dot{x}(t)) \in \partial H_2(t, x(t), u(t), p_2(t)) \qquad \text{a.e.}$$

Note that by Lemma 2.4 we may suppose $x \in Y_u$ since x_i is an optimal trajectory of $P_2(u_i)$. From the upper semicontinuity of the limiting subgradients

$$-p_2(t_1) \in \hat{\partial} g(x(t_1)).$$

Therefore we conclude that

$$\hat{\partial} V(u) \subset \cup_{x \in Y_u} \{\zeta : \exists \text{ arc } p_2 \text{ s.t. } (-\dot{p_2}, -\zeta, \dot{x}) \in \partial H_2(t, x, u, p_2) \text{ a.e.}, -p_2(t_1) \in \hat{\partial} g(x(t_1))\}.$$

Step 3. To complete the proof of the theorem, we only have to show that V is Lipschitz near u. By [6, Theorem 3.6], V is Lipschitz near u of rank C iff

$$\sup\{\|\zeta\|_2 : \zeta \in \partial^\pi V(u')\} \le C \qquad \forall u' \text{ in a neighborhood of } u.$$

Indeed, by Step 1, for any u and any $\zeta \in \partial^\pi V(u)$ there exists an arc p_2 along with a solution (x, v) of $P_2(u)$ such that (3), (5), and (6) hold. Therefore

$$|\zeta(t)| \le M(|p_2(t)| + |\nabla_u G|). \tag{12}$$

Since $\forall$ such p_2, $\|p_2\|_\infty \le Ke^{\int_{t_0}^{t_1} \psi(s)ds}$, it then follows from (12) that all $\zeta \in \partial^\pi V(u), \forall u \in L^2([t_0, t_1], U)$ are bounded in L^2. Hence V is Lipschitz continuous, and the proof of Theorem 2.3 is now complete. □

3. Necessary conditions for optimality. As in the static case (cf. [17, 18]), it is easy to show that the equivalent single-level optimal control problem $\widetilde{P}_1$ always has a nontrivial abnormal multiplier; i.e., there always exists (λ, r, p_1) not all equal to zero with $\lambda = 0$ satisfying (13), (14), (15), and (16). Hence the traditional technique of concluding the existence of a normal multiplier from the nonexistence of a nontrivial abnormal multiplier will not work for the bilevel dynamic problem, and the calmness is the right constraint qualification (see more discussion in [17, 18]). The purpose of this section is to derive a Kuhn–Tucker–type necessary optimality condition for the bilevel dynamic problem under a *calmness*-type constraint qualification. Our approach is to reformulate the original problem as an infinite-dimensional optimization problem and derive the desired result from the necessary optimality condition for this infinite-dimensional optimization problem. Formulation as an infinite-dimensional optimization problem takes care of the functional constraints. However, the usual Lagrange multiplier rule for infinite-dimensional optimization problems cannot be used here since the problem data are not Lipschitz in the control variable in the lower-level optimal control problem. Ioffe [8] derived a very general maximum principle for the standard optimal control problem by reduction to an infinite-dimensional optimization problem. We will use the result and approach of Ioffe to derive the necessary optimality condition of the maximum principle type for the bilevel dynamic problem.

DEFINITION 3.1. *Let (u^*, v^*) be an optimal strategy of P_1 (equivalently $\widetilde{P}_1$) and x^* the corresponding trajectory. $\widetilde{P}_1$ is said to be* partially calm *at (x^*, u^*, v^*) with modulus $\mu \geq 0$ if $\forall (x, u, v)$ satisfying*

$$\begin{aligned} &\dot{x}(t) = \phi(t, x(t), u(t), v(t)) \quad \text{a.e.}, \\ &x(t_0) = x_0, \\ &u(\cdot) \in L^2([t_0, t_1], U), v(\cdot) \in \mathcal{V}, \end{aligned}$$

we have

$$J_1(x, u, v) - J_1(x^*, u^*, v^*) + \mu(J_2(x, u, v) - V(u)) \geq 0,$$

where $\mathcal{V}$ denotes the collection of all admissible control functions for $P_2(u)$.

Define the *pseudo Hamiltonian* for problem $(\widetilde{P}_1)$ as

$$H_1(t, x, u, v, p_1; \lambda, r) := p_1 \cdot \phi(t, x, u, v) - rG(t, x, u, v) - \lambda F(t, x, u, v),$$

for $t \in [t_0, t_1]$, $x, p_1 \in \mathbb{R}^d$, $u \in R^n$, $v \in R^m$, $\lambda, r \in \mathbb{R}$.

THEOREM 3.2. *Assume that* (A1)–(A5) *hold. Let (x^*, u^*, v^*) be an optimal solution of P_1. Suppose that $\widetilde{P}_1$ is* partially calm *at (x^*, u^*, v^*) with modulus $\mu \geq 0$. Assume that the value function for the lower-level problem V is locally Lipschitz continuous near u^*. Then there exist $\lambda > 0, r = \lambda\mu$, and an arc p_1 such that*

$$\begin{aligned} -\dot{p_1}(t) &= \nabla_x H_1(t, x^*(t), u^*(t), v^*(t), p_1(t); \lambda, r) \qquad \text{a.e.}, \\ &\max_{v \in W(t)} H_1(t, x^*(t), u^*(t), v, p_1(t); \lambda, r) \end{aligned} \tag{13}$$

$$= H_1(t, x^*(t), u^*(t), v^*(t), p_1(t); \lambda, r) \quad \text{a.e.}, \tag{14}$$

$$-p_1(t_1) \in \lambda \partial f(x^*(t_1)) + r\partial g(x^*(t_1)), \tag{15}$$

$$\nabla_u H_1(\cdot, x^*(\cdot), u^*(\cdot), v^*(\cdot), p_1(\cdot); \lambda, r) \in -r\partial V(u^*) + N_{L^2([t_0, t_1], U)}(u^*). \tag{16}$$

Proof. Since $\widetilde{P}_1$ is partially calm at (x^*, u^*, v^*) with modulus μ, it is easy to see that (x^*, u^*, v^*) is also optimal for the following penalized problem:

$$\begin{aligned} P(\mu) \qquad \min \;& J_1(x, u, v) + \mu(J_2(x, u, v) - V(u)) \\ \text{s.t.} \;& \dot{x}(t) = \phi(t, x(t), u(t), v(t)) \qquad \text{a.e.}, \\ & x(t_0) = x_0, \\ & u(\cdot) \in L^2([t_0, t_1], U), \quad v(t) \in W(t) \qquad \text{a.e.}, \end{aligned}$$

which can be equivalently posed as the following problem:

$$\begin{aligned} \widehat{P}_1 \qquad \min \;& f(x(t_1)) + z(t_1) + \mu(g(x(t_1)) + y(t_1) - V(u)) \\ \text{s.t.} \;& \dot{x}(t) = \phi(t, x(t), u(t), v(t)) \qquad \text{a.e.}, \\ & \dot{y}(t) = G(t, x(t), u(t), v(t)) \qquad \text{a.e.}, \\ & \dot{z}(t) = F(t, x(t), u(t), v(t)) \qquad \text{a.e.}, \\ & v(t) \in W(t) \qquad \text{a.e.}, \\ & (x, y, z)(t_0) \in \{x_0\} \times \{0\} \times \{0\}. \end{aligned}$$

We now reformulate the above problem as an infinite-dimensional optimization problem. Let $C([t_0,t_1],R^n)$ be the space of continuous mappings from $[t_0,t_1]$ into R^n with the usual supremum norm. Set

$$\widetilde{x} := (x,y,z), \qquad \widetilde{\phi} := (\phi,G,F).$$

For $v(\cdot)\in\mathcal{V}$, the mapping $(\widetilde{x}(\cdot),u(\cdot))\to F_0(\widetilde{x}(\cdot),u(\cdot),v(\cdot))$ from $X := C([t_0,t_1],R^{d+2})$ $\times L^2([t_0,t_1],U)$ into $Y := C([t_0,t_1],R^{d+2})$:

$$F_0(\widetilde{x}(\cdot),u(\cdot),v(\cdot))(t) := \widetilde{x}(t)-\widetilde{x}(t_0)+\int_{t_0}^{t}\widetilde{\phi}(s,\widetilde{x}(s),u(s),v(s))ds$$

is well defined, continuously differentiable in $\widetilde{x}(\cdot)$, and Lipschitz continuous in $u(\cdot)$. Finally, let

$$f_0(\widetilde{x}(\cdot)) := f(x(t_1))+z(t_1), \tag{17}$$

$$G_0(\widetilde{x}(\cdot),u(\cdot)) := y(t_1)+g(x(t_1))-V(u), \tag{18}$$

$$S := \{\widetilde{x}\subset Y : x(t_0)=x_0, y(t_0)=0, z(t_0)=0\}.$$

Then problem $\widehat{P}_1$ is equivalent to the following infinite-dimensional optimization problem:

$$\begin{aligned} P_1{}' \qquad \min\ & f_0(\widetilde{x})+\mu G_0(\widetilde{x},u)\\ \text{s.t.}\ & F_0(\widetilde{x},u,v)=0,\\ & (\widetilde{x},u)\in S\times L^2([t_0,t_1],U),\\ & v\in\mathcal{V}. \end{aligned}$$

The above problem is in the form of a very general problem in section 4 of Ioffe [8]. Let the Lagrangian of the above problem be

$$L(\lambda,\alpha,\widetilde{x},u,v) := \lambda(f_0(\widetilde{x})+\mu G_0(\widetilde{x},u))+\langle\alpha,F_0(\widetilde{x},u,v)\rangle.$$

As in section 5 of Ioffe [8], the assumptions for [8, Theorem 2] can be verified. By [8, Theorem 2], if (x^*,u^*,v^*) is a local solution to $P_1{}'$, then there exist Lagrange multipliers $\lambda\ge 0$, $\alpha\in Y^*$ not all equal to zero such that

$$0\in\partial_{(\widetilde{x},u)}L(\lambda,\alpha,\widetilde{x}^*,u^*,v^*)+N_S(\widetilde{x}^*)\times N_{L^2([t_0,t_1],U)}(u^*), \tag{19}$$

$$L(\lambda,\alpha,\widetilde{x}^*,u^*,v^*)=\min_{v\in\mathcal{V}}L(\lambda,\alpha,\widetilde{x}^*,u^*,v), \tag{20}$$

where Y^* denotes the space of continuous linear functions on Y. Since f_0,G_0 are separable functions of $(\widetilde{x},u)$ (f_0 is independent of u and G_0 is the sum of a function independent of $\widetilde{x}$ and a function independent of u), by [15, Proposition 1.8], (19) implies that

$$\begin{aligned} 0\in{}&\lambda\partial f_0(\widetilde{x}^*)\times\{0\}+(\lambda\mu\partial_{\widetilde{x}}G_0(\widetilde{x}^*,u^*))\times(-\lambda\mu\partial V(u^*))\\ &+\partial_{(\widetilde{x},u)}\langle\alpha,F_0(\widetilde{x}^*,u^*,v^*)\rangle+N_S(\widetilde{x}^*)\times N_{L^2([t_0,t_1],U)}(u^*). \end{aligned} \tag{21}$$

Notice that $\langle \alpha, F_0(\widetilde{x}, u, v)\rangle$ can be represented as an integral functional on $X \times L^2$ by

$$\begin{aligned}&\langle \alpha, F_0(\widetilde{x}, u, v)\rangle\\ &= \int_{t_0}^{t_1} \langle \widetilde{x}(s) - \widetilde{x}(t_0), \xi(s)\rangle d\mu - \int_{t_0}^{t_1} \left\langle \int_t^{t_1} \xi(\tau) d\mu, \widetilde{\phi}(t, \widetilde{x}(t), u(t), v(t))\right\rangle dt,\end{aligned}$$

where the pair $(\mu, \xi(\cdot))$ represents the functional $\alpha \in Y^*$ (μ being a nonnegative Radon measure on $[t_0, t_1]$ and $\xi(\cdot) : [t_0, t_1] \to R^{d+2}$, μ-integrable); i.e.,

$$\int_{t_0}^{t_1} \langle \xi(t), y(t)\rangle d\mu = \langle \alpha, y(\cdot)\rangle \qquad \forall y(\cdot) \in Y.$$

Hence by Theorems 2.7.4 and 2.7.5 of [3] it is regular. Therefore, by [3, Proposition 2.3.15], (21) implies that

$$0 \in \lambda \partial f_0(\widetilde{x}^*) + \lambda\mu \partial_{\widetilde{x}} G_0(\widetilde{x}^*, u^*) + D_{\widetilde{x}} \langle \alpha, F_0(\widetilde{x}^*, u^*, v^*)\rangle + N_S(\widetilde{x}^*), \tag{22}$$

$$0 \in -\lambda\mu \partial V(u^*) + \partial_u \langle \alpha, F_0(\widetilde{x}^*, u^*, v^*)\rangle + N_{L^2([t_0,t_1],U)}(u^*), \tag{23}$$

where $D_{\widetilde{x}} \langle \alpha, F_0(\widetilde{x}, u, v)\rangle$ denotes the Gâteaux derivative of the functional $\langle \alpha, F_0(\widetilde{x}, u, v)\rangle$ with respect to $\widetilde{x}$.

Now let us analyze (22). We have that $\partial f_0(\widetilde{x}(\cdot))$ contains those $\beta \in Y^*$ that can be represented in the form

$$\langle \beta, h(\cdot)\rangle = \langle a, h(t_1)\rangle$$

for some $a \in \partial f(x(t_1)) \times \{0\} \times \{1\}$.

Similarly, $\partial_{\widetilde{x}} G_0(\widetilde{x}, u)$ contains those $\beta \in Y^*$ that can be represented in the form

$$\langle \beta, h(\cdot)\rangle = \langle b, h(t_1)\rangle$$

for some $b \in \partial g(x(t_1)) \times \{1\} \times \{0\}$.

Let $p(t) := \int_t^{t_1} \xi(\tau) d\mu$. Then p is an arc. For any $h \in X$,

$$\begin{aligned}\langle D_{\widetilde{x}} \langle \alpha, F_0(\widetilde{x}, u, v)\rangle, h(\cdot)\rangle &= \int_{t_0}^{t_1} \langle h(t) - h(t_0), \xi(t)\rangle d\mu\\ &\quad - \int_{t_0}^{t_1} \langle \nabla_{\widetilde{x}} \widetilde{\phi}(t, \widetilde{x}(t), u(t), v(t))^\top p(t), h(t)\rangle dt.\end{aligned}$$

$N_S(\widetilde{x})$ contains those $\beta \in Y^*$ that can be represented in the form

$$\langle \beta, h(\cdot)\rangle = \langle c, h(t_0)\rangle$$

for some $c \in N_{\{x_0\}\times\{0\}\times\{0\}}(\widetilde{x}(t_0))$.

Inclusion (22) yields the existence of

$$a \in \partial f(x^*(t_1)) \times \{0\} \times \{1\}, b \in \partial g(x^*(t_1)) \times \{1\} \times \{0\}, c \in N_{\{x_0\}\times\{0\}\times\{0\}}(\widetilde{x}^*(t_0))$$

such that

$$\begin{aligned}0 &= \lambda \langle a, h(t_1)\rangle + \lambda\mu \langle b, h(t_1)\rangle + \int_{t_0}^{t_1} \langle h(t) - h(t_0), \xi(t)\rangle d\mu\\ &\quad - \int_{t_0}^{t_1} \langle \nabla_{\widetilde{x}} \widetilde{\phi}(t, \widetilde{x}^*(t), u^*(t), v^*(t))^\top p(t), h(t)\rangle dt + \langle c, h(t_0)\rangle \qquad \forall h \in X.\end{aligned}$$

Let us denote $h = (h_1, h_2, h_3)$, $\xi = (\xi_1, \xi_2, \xi_3)$, $p = (p_1, p_2, p_3)$, where subscript 1 corresponds to vectors in R^d and subscripts $2, 3$ to vectors in R. In particular, if we choose $h(\cdot)$ that are absolutely continuous with $h(t_0) = 0, h_i(\cdot) = 0$ for $i = 1, 3$, we have

$$0 = \lambda\mu h_2(t_1) + \int_{t_0}^{t_1} h_2(t)\xi_2(t)d\mu,$$

which is equal to

$$0 = \int_{t_0}^{t_1} \left(\int_t^{t_1} \xi_2(s)d\mu + \lambda\mu \right) dh_2(t),$$

which implies that $p_2(t) = -\lambda\mu$.

Similarly, if we choose $h(\cdot)$ that are absolutely continuous with $h(t_0) = 0, h_i(\cdot) = 0$ for $i = 1, 2$, we have

$$0 = \lambda h_3(t_1) + \int_{t_0}^{t_1} h_3(t)\xi_3(t)d\mu,$$

which implies that $p_3(t) = -\lambda$.

If we choose $h(\cdot)$ that are absolutely continuous with $h(t_0) = 0, h_i(\cdot) = 0$ for $i = 2, 3$, we have

$$\begin{aligned} 0 = \lambda\langle a_1, h_1(t_1)\rangle + \lambda\mu\langle b_1, h_1(t_1)\rangle + \int_{t_0}^{t_1} \langle h_1(t), \xi_1(t)\rangle d\mu \\ - \int_{t_0}^{t_1} \langle \nabla_x \widetilde{\phi}(t, \widetilde{x}^*(t), u^*(t), v^*(t))^\top p(t), h_1(t)\rangle dt. \end{aligned}$$

Setting $-q = \lambda a_1 + \lambda\mu b_1$ and changing the order of integration, we obtain

$$\begin{aligned} 0 = \int_{t_0}^{t_1} \Big\langle \int_t^{t_1} \xi_1(t)d\mu + \nabla_x \phi(t, x^*(t), u^*(t), v^*(t))^\top p_1(t) \\ - \lambda\mu\nabla_x G(t, x^*(t), u^*(t), v^*(t)) - \lambda\nabla_x F(t, x^*(t), u^*(t), v^*(t)) - q, k(t) \Big\rangle dt, \end{aligned}$$

where $k(t) = \dot{h}(t)$ is an arbitrary integrable mapping. In view of the definition of $p_1(t)$, this implies

$$\begin{aligned} p_1(t) - q = -\int_t^{t_1} (\nabla_x \phi(s, x^*(s), u^*(s), v^*(s))^\top p_1(s) \\ + \lambda\mu\nabla_x G(s, x^*(s), u^*(s), v^*(s)) + \lambda\nabla_x F(s, x^*(s), u^*(s), v^*(s)))ds, \end{aligned}$$

from which we derive (13).

Let us now analyze (23). Since $\langle \alpha, F_0(\widetilde{x}, u, v)\rangle$ is an integral functional of u on L^2, it is not Gâteaux differentiable. However, under our assumptions, [3, Theorem 2.7.5] applies. Therefore, for $\beta \in \partial_u \langle \alpha, F_0(\widetilde{x}^*, u^*, v^*)\rangle$,

$$\langle \beta, h(\cdot)\rangle = -\int_{t_0}^{t_1} \langle \nabla_u \widetilde{\phi}(t, \widetilde{x}^*(t), u^*(t), v^*(t))^\top p(t), h(t)\rangle dt$$

for any $h \in L^2([t_0, t_1], R^n)$. Hence (23) implies (16).

We also have

$$p(t_1) = q \in -\lambda \partial f(x^*(t_1)) - \lambda\mu \partial g(x^*(t_1)).$$

That is (15).

Equation (20) implies that

$$-\int_{t_0}^{t_1} \langle p(t), \widetilde{\phi}(t, \widetilde{x}^*(t), u^*(t), v^*(t))\rangle dt \le -\int_{t_0}^{t_1} \langle p(t), \widetilde{\phi}(t, \widetilde{x}^*(t), u^*(t), v(t))\rangle dt.$$

Since $-\lambda = p_2(t), \lambda\mu = -p_3(t)$, the above inequality implies that

$$\int_{t_0}^{t_1} H_1(t, x^*(t), u^*(t), v^*(t), p_1(t); \lambda, \lambda\mu)dt \ge \int_{t_0}^{t_1} H_1(t, x^*(t), u^*(t), v(t), p_1(t); \lambda, \lambda\mu)dt$$

for any $v(\cdot) \in \mathcal{V}$. Since for any measurable set $E \subset [t_0, t_1]$,

$$v(\cdot) = \chi_E(\cdot)v(\cdot) + (1 - \chi_E(\cdot))v^*(\cdot),$$

where χ_E denotes the characteristic function of E, and belongs to $\mathcal{V}$ whenever $v(\cdot) \in \mathcal{V}$, it follows that

$$H_1(t, x^*(t), u^*(t), v^*(t), p_1(t); \lambda, \lambda\mu) \ge H_1(t, x^*(t), u^*(t), v(t), p_1(t); \lambda, \lambda\mu) \text{ a.e.}$$

for any $v(\cdot) \in \mathcal{V}$. From measurable selection theory, (14) follows.

Now we need to show that $\lambda \ne 0$. From the fact that λ and α are not all equal to zero, it follows easily that

$$\|p_1\|_\infty + \lambda > 0. \tag{24}$$

This condition prevents λ becoming zero. Indeed if $\lambda = 0$, then the transversality condition (15) would imply that $p_1(t_1) = 0$. This in turn implies that $p_1 \equiv 0$, which contradicts (24). The proof of the theorem is now complete. □

Combining Theorems 3.2 and 2.3, the following Kuhn–Tucker–type necessary optimality condition for the general bilevel dynamic problem is obtained.

THEOREM 3.3. *Assume* (A1)–(A8) *hold. Let* $(u^*(t), v^*(t))$ *be an optimal strategy of the bilevel dynamic problem* P_1 *and* $x^*(t)$ *the corresponding optimal trajectory. Suppose that* $\widetilde{P}_1$ *is partially calm at* (x^*, u^*, v^*) *with modulus* $\mu \ge 0$. *Then there exists arc* p_1 *such that*

$$-\dot{p_1}(t) = \nabla_x H_1(t, x^*(t), u^*(t), v^*(t), p_1(t); 1, \mu), \tag{25}$$

$$\max_{v \in W(t)} H_1(t, x^*(t), u^*(t), v, p_1(t); 1, \mu)$$

$$= H_1(t, x^*(t), u^*(t), v^*(t), p_1(t); 1, \mu) \text{ a.e.}, \tag{26}$$

$$-p_1(t_1) \in \partial f(x^*(t_1)) + \mu \partial g(x^*(t_1)), \tag{27}$$

$$\nabla_u H_1(\cdot, x^*(\cdot), u^*(\cdot), v^*(\cdot), p_1(\cdot); 1, \mu)$$

$$\in \mu \, clco \cup_{x \in Y_{u^*}} \{\zeta : \exists \text{ arc } p_2 \text{ s.t. } (-\dot{p_2}, \zeta, \dot{x}) \in \partial H_2(t, x, u^*, p_2) \quad \text{a.e.},$$

$$-p_2(t_1) \in \hat{\partial} g(x(t_1))\}$$

$$+ N_{L^2([t_0,t_1],U)}(u^*). \tag{28}$$

It is clear that in the minimax case (i.e., when $J_1 = -J_2$) and the trivial case (i.e., when $J_1 = J_2$), the calmness condition always holds with $\mu = 1$ and $\mu = 0$, respectively. We now give an example that satisfies the partial calmness condition.

Example 1. Consider the following bilevel dynamic problem:

$$\begin{aligned} &\min\ (x_1(1))^2 + (x_2(1))^2 \\ &\text{s.t. } u(t) \geq 0, (x, v) \in S(u), \end{aligned}$$

where $S(u)$ is the solution set of

$$\begin{aligned} &\min\ (x_1(1) + x_2(1))^3 \\ &\text{s.t. } \dot{x}_1(t) = u(t), \\ &\qquad \dot{x}_2(t) = v(t),\ v(t) \geq 0, \\ &\qquad x_1(0) = x_2(0) = 0. \end{aligned}$$

The solution of the above problem is $x^* = 0, u^* = 0, v^* = 0$. Since $J_1(x, u, v) \geq 0$ for all (x, u, v) that are admissible for $P(\mu)$ and $J(x^*, u^*, v^*) = 0$, it is easy to see that the above problem is partially calm.

As seen in Example 1, the calmness condition depends on knowledge of the optimal value of the dynamic bilevel problem. It is therefore important to find sufficient conditions for the calmness condition. For the static case, [17] identifies the existence of a uniformly weak sharp minimum as a sufficient condition for the calmness. It is shown in that paper that the bilevel programming problem in which the lower-level problem is linear is always calm, and sufficient conditions for the calmness of the bilevel problem where the lower-level problem is a linear quadratic problem are given.

To extend the definition of a uniform weak sharp minimum to our dynamic setting, we introduce the following notation. Given u, a control function for the upper level, let $\Omega(u)$ denote

$$\Omega(u) = \{(x, v) \in C([t_0, t_1], R^d) \times \mathcal{V} : \dot{x} = \phi(t, x, u, v), x(t_0) = x_0\}.$$

Let $S(u)$ denote the set of all solutions to problem $P_2(u)$. We say that the family of optimal control problems $\{P_2(u) : u \in L^2([t_0, t_1], U)\}$ has a uniformly weak sharp minimum with modulus $\alpha > 0$ if

$$d_{S(u)}(x, v) \leq \alpha(J_2(x, u, v) - V(u)) \qquad \forall (x, v) \in \Omega(u), u \in L^2([t_0, t_1], U),$$

where $d_{S(u)}(x, v)$ denotes the distance from (x, v) to the set $S(u)$. As in [17], we can show that a uniformly weak sharp minimum is a sufficient condition for partial calmness.

PROPOSITION 3.4. *In addition to* (A1) and (A7), *assume that for any* $u(\cdot)$ *there exists* $k(\cdot) \in L^1([t_0, t_1])$ *such that*

$$|F(t, x', u(t), v') - F(t, x'', u(t), v'')| \leq k(t)\|(x', v') - (x'', v'')\| \qquad \forall t \in [t_0, t_1], x', x'' \in R^d, v', v'' \in R^m$$

and that f *is Lipschitz continuous with constant* $L_f > 0$. *That* $\{P_2(u) : u \in L^2([t_0, t_1], U)\}$ *has a uniformly weak sharp minimum with modulus* α *implies that* $\widetilde{P}_1$ *is partially calm with modulus* $\mu \geq \alpha(\|k\|_1 + L_f)$ *at any solution of the problem.*

Proof. By the definition of a uniformly weak sharp minimum, there exists $\alpha > 0$ such that $\forall\ (x,v) \in \Omega(u), u \in L^2([t_0,t_1],U)$,

$$\begin{aligned} J_2(x,u,v) - V(u) &\geq (1/\alpha) d_{S(u)}(x,v) \\ &= (1/\alpha)|(x,v) - (x(u),v(u))|, \end{aligned}$$

where $(x(u),v(u))$ is the metric projection of (x,v) onto the set $S(u)$. Let (x^*,u^*,v^*) be any solution of the problem P_1. The assumptions imply that $J_1(x,u,v)$ is Lipschitz continuous in (x,v) uniformly in u with constant $L_1 = \|k\|_1 + L_f$. It follows that

$$\begin{aligned} J_2(x,u,v) - V(u) &\geq \frac{1}{\alpha} d_{S(u)}(x,v) \\ &= \frac{1}{\alpha}|(x,v) - (x(u),v(u))| \\ &\geq \frac{1}{\alpha L_1}(J_1(x,u,v) - J_1(x(u),u,v(u))) \\ &\geq \frac{1}{\alpha L_1}(J_1(x,u,v) - J_1(x^*,u^*,v^*)) \\ &\geq \frac{1}{\mu}(J_1(x,u,v) - J_1(x^*,u^*,v^*)). \end{aligned}$$

Therefore, we see that $\widetilde{P}_1$ is partially calm at any solution of the problem with modulus $\mu \geq \alpha L_1$. □

The following result is a sufficient condition for a uniformly weak sharp minimum. The proof technique follows from a result about regular points due to Ioffe (Theorem 1 and Corollary 1.1 of [7]).

PROPOSITION 3.5. *Suppose that $J_2(x,u,v)$ is Lipschitz continuous in (x,v) uniformly in u with constant $L > 0$. If there exists a constant $c > 0$ such that $\|\xi + \eta\| \geq c$ whenever $\xi \in \partial_{(x,v)} J_2(x,u,v)$, $\eta \in (L+1)\partial d_{\Omega(u)}(x,v)$ (or $\eta \in N_{\Omega(u)}(x,v)$)$\forall (x,v) \in \Omega(u)$ such that $(x,v) \notin S(u)\ \forall$ admissible controls u, then*

$$d_{S(u)}(x,v) \leq (1/c)(J_2(x,u,v) - V(u)) \forall (x,v) \in \Omega(u).$$

Proof. Assume that the statement is false. Then there is $u \in L^2([t_0.t_1],U)$ and $(x,v) \in \Omega(u)$ such that

$$d_{S(u)}(x,v) > \frac{1}{c}(J_2(x,u,v) - V(u)).$$

We can obviously choose $\delta > 1$ to make the following inequality valid:

$$d_{S(u)}(x,v) > \frac{\delta}{c}(J_2(x,u,v) - V(u)) := \gamma. \tag{29}$$

It is also obvious that

$$J_2(x,u,v) - V(u) \leq \inf_{(x,v)\in\Omega(u)} (J_2(x,u,v) - V(u)) + \frac{c\gamma}{\delta}.$$

Let δ_S denote the indicator function of set S. Applying the Ekeland variational principle [3, Theorem 7.5.1] with $F(x', v') := J_2(x', u, v') - V(u) + \delta_{\Omega(u)}(x', v')$, $\epsilon = \gamma c/\delta$, and $\lambda = \gamma$, we find $(\widetilde{x}, \widetilde{v}) \in \Omega(u)$ such that

$$\|(\widetilde{x}, \widetilde{v}) - (x, v)\| \leq \gamma \tag{30}$$

and

$$\phi(x', v') := J_2(x', u, v') - V(u) + (c/\delta)\|(x', v') - (\widetilde{x}, \widetilde{v})\|$$

attains its minimum on $\Omega(u)$ at $(\widetilde{x}, \widetilde{v})$. It follows that

$$\begin{aligned} 0 &\in \partial\phi(\widetilde{x}, \widetilde{v}) + (L+1)\partial d_{S(u)}(\widetilde{x}, \widetilde{v}) \\ &\subset \partial_{(x,v)} J_2(\widetilde{x}, u, \widetilde{v}) + (c/\delta)B + (L+1)\partial d_{S(u)}(\widetilde{x}, \widetilde{v}). \end{aligned}$$

Thus there exist

$$\xi \in \partial_{(x,v)} J_2(\widetilde{x}, u, \widetilde{v}), \quad \eta \in (L+1)\partial d_{S(u)}(\widetilde{x}, \widetilde{v})$$

such that

$$\|\xi + \eta\| \leq c/\delta < c. \tag{31}$$

According to (29), (30), and $(\widetilde{x}, \widetilde{v}) \in \Omega(u)$, we have that

$$(\widetilde{x}, \widetilde{v}) \notin S(u).$$

Therefore (31) contradicts the assumption. The proof of the proposition is then complete. □

We now use an example to illustrate the application of the above result. It is different from Example 1 only in the lower-level objective function.

Example 2. Consider the following bilevel dynamic problem:

$$\begin{aligned} &\min\ (x_1(1))^2 + (x_2(1))^2 \\ &\text{s.t. } u(t) \geq 0, (x, v) \in S(u), \end{aligned}$$

where $S(u)$ is the solution set of

$$\begin{aligned} &\min\ x_1(1) + x_2(1) + (x_1(1) + x_2(1))^3 \\ &\text{s.t. } \dot{x}_1(t) = u(t), \\ &\qquad \dot{x}_2(t) = v(t),\ v(t) \geq 0, \\ &\qquad x_1(0) = x_2(0) = 0. \end{aligned}$$

It is easy to see that $\Omega(u) = \{x_1 : x_1(t) = \int_0^t u(s)ds\} \times \{x_2 : x_2(t) \geq 0\} \times \{v : v(t) \geq 0\}$ and $S(u) = \{(x, v) : x_1(t) = \int_0^t u(s)ds, x_2 \equiv 0, v \equiv 0\}\ \forall\ u(t) \geq 0$. Since

$$\begin{aligned} \partial_{(x,v)} J_2(x, u, v) = \{(\xi_1, \xi_2, 0) :& \langle \xi_1, h(\cdot)\rangle = ((1 + 3(x_1(1) + x_2(1))^2)h(1), \\ & \langle \xi_2, h(\cdot)\rangle = (1 + 3(x_1(1) + x_2(1))^2)h(1)\ \forall\ h \in C[0,1]\}, \end{aligned}$$

and $N_{\Omega(u)}(x, v) = N_{\{x_1 : x_1(t) = \int_0^t u(s)ds\}}(x_1) \times \{0\} \times N_{\{v : v(t) \geq 0\}}(v)$ for any $(x_1, x_2, v) \notin S(u)$, it is easy to see that the assumptions in Proposition 3.5 are satisfied.

We now calculate that

$$H_1(t,x,u,v,p_1;1,\mu) = p_1^1 u + p_1^2 v, \qquad H_2(t,x,u,v,p_2) = \sup\{p_2^1 u + p_2^2 v : v \geq 0\}.$$

Since H_2 is independent of x, (28) implies that there exists an arc p_2 such that

$$\dot{p}_2(t) = 0, \tag{32}$$

$$-p_2(1) = (1 + 3(x_1^*(1) + x_2^*(1))^2, 1 + 3(x_1^*(1) + x_2^*(1))^2), \tag{33}$$

$$p_1^1 - \mu p_2^1 \in N_{\{u \in C[0,1]: u \geq 0\}}(u^*). \tag{34}$$

Observing that $x_1(0) = x_2(0) = 0$ and both $x_1(t)$ and $x_2(t)$ are nondecreasing, we derive from (32) and (33) that $p_2^1 = p_2^2 \leq -1$ are constants. Hence $H_2 = p_2^1 u$, which implies from (28) that $\dot{x}_2^*(t) = 0$. That is $x_2^* \equiv 0$. If $u^* \not\equiv 0$ then (34) implies that

$$p_1^1 = \mu p_2^1.$$

But by (25) and (27), p_1^1 and p_1^2 are nonpositive constants and

$$-2x_1^*(1) - \mu(1 + 3[x_1^*(1) + x_2^*(1)]^2) = -\mu(1 + 3[x_1^*(1) + x_2^*(1)]^2),$$

which implies that $x_1^*(1) = 0$. But this is a contradiction. Therefore $u^* \equiv 0, v^* \equiv 0$ is a candidate for an optimal solution since $x_1(0) = x_2(0) = 0$ and both $x_1(t)$ and $x_2(t)$ are nondecreasing. It is not hard to check that it is indeed a solution. Notice that in Example 2 the lower-level problem is not convex and hence is out of the scope of any currently available control theory.

Finally, we use another example to illustrate applications of Theorem 3.2 in solving bilevel dynamic problems in the absence of the calmness condition. Example 3 shows that even without the calmness condition, the necessary condition that we derived may be used to find condition for the existence of a normal multiplier.

Example 3. Consider the following bilevel dynamic problem with linear-quadratic cost functions on the interval $[0,1]$, where

$$F(t,x,u,v) = \frac{1}{2}[x^\top Q_1 x + u^\top R_{11} u + v^\top R_{12} v],$$

$$f(x) = \frac{1}{2} x^\top K_1 x,$$

$$G(t,x,u,v) = \frac{1}{2}[x^\top Q_2 x + u^\top R_{21} u + v^\top R_{22} v],$$

$$g(x) = \frac{1}{2} x^\top K_2 x,$$

$$\phi(t,x,u,v) = A(t)x + B(t)u + C(t)v,$$

where $x \in R^d$, $u \in R^n$, $v \in R^m$, Q_1, Q_2, K_1, K_2 are positive semidefinite matrices and $R_{22}, R_{11}, rR_{22} + R_{12}$, where $r \geq 0$ is any constant, are positive definite matrices with appropriate order; R_{21} is a $n \times n$ matrix; $A(t), B(t)$, and $C(t)$ are matrices with continuous components.

We can calculate

$$\begin{aligned}
H_1(t,x,u,v,p_1;1,\mu) &= p_1^\top \phi - \mu G - F \\
&= p_1^\top (A(t)x + B(t)u + C(t)v) \\
&\quad -\frac{1}{2}\mu[x^\top Q_2 x + u^\top R_{21} u + v^\top R_{22} v] \\
&\quad -\frac{1}{2}[x^\top Q_1 x + u^\top R_{11} u + v^\top R_{12} v], \\
H_2(t,x,u,p_2) &= \sup_v \{p_2^\top \phi - G\} \\
&= \sup_v \{p_2^\top (A(t)x + B(t)u + C(t)v) - \frac{1}{2}[x^\top Q_2 x + u^\top R_{21} u + v^\top R_{22} v]\} \\
&= p_2^\top (A(t)x + B(t)u + C(t)R_{22}^{-1} C(t)^\top p_2) \\
&\quad -\frac{1}{2}[x^\top Q_2 x + u^\top R_{21} u + p_2^\top C(t) R_{22}^{-1} C(t)^\top p_2].
\end{aligned}$$

Suppose that (u^*, v^*) is an optimal control pair and x^* is the corresponding trajectory. If the conclusion of Theorem 3.3 holds, then there exist adjoint arcs p_1, p_2 and constant $\mu \geq 0$ such that

$$\begin{aligned}
-\dot{p}_1 &= A(t)^\top p_1 - [\mu Q_2 + Q_1] x^*, \\
-p_1(1) &= [\mu K_2 + K_1] x^*(1), \\
-\dot{p}_2 &= A(t)^\top p_2 - Q_2^\top x^*, \\
-p_2(1) &= K_2 x^*(1),
\end{aligned}$$

$$\dot{x}^* = A(t)x^* + B(t)u^* + C(t)v^*, \tag{35}$$

$$B(t)^\top p_1 - R_{11} u^* = \mu B(t)^\top p_2, \tag{36}$$

$$v^*(t) = R_{22}^{-1} C(t)^\top p_2 = [\mu R_{22} + R_{12}]^{-1} C(t)^\top p_1. \tag{37}$$

Equation (36) implies that

$$u^*(t) = R_{11}^{-1} B(t)^\top (p_1 - \mu p_2). \tag{38}$$

Substituting (37) and (38) into (35) yields

$$\dot{x}^* = A(t)x^* + B(t)R_{11}^{-1} B(t)^\top (p_1 - \mu p_2) + C(t) R_{22}^{-1} C(t)^\top p_2. \tag{39}$$

Thus, for any $\mu \geq 0$ that satisfies (37), i.e.,

$$R_{22}^{-1} C(t)^\top p_2 = [\mu R_{22} + R_{12}]^{-1} C(t)^\top p_1, \tag{40}$$

we obtain a set of $3d$ equations with equal numbers of unknowns.

$$\begin{aligned}
\dot{x}^* &= A(t)x^* + B(t)R_{11}^{-1} B(t)^\top (p_1 - \mu p_2) + C(t) R_{22}^{-1} C(t)^\top p_2, \\
-\dot{p}_1 &= A(t)^\top p_1 - [\mu Q_2^\top + Q_1^\top] x^*, \\
-\dot{p}_2 &= A(t)^\top p_2 - Q_2^\top x^*.
\end{aligned}$$

Assume that

$$p_1(t) = \psi_1(t)x^*(t),$$
$$p_2(t) = \psi_2(t)x^*(t),$$

where ψ_i are matrices that satisfy the end point conditions

$$\psi_1(1) = -[K_1 + \mu K_2], \quad \psi_2(1) = -K_2$$

to be determined. Differentiating them with respect to t gives

$$\dot{p}_1 = \dot{\psi}_1 x^*(t) + \psi_1 \dot{x}^*(t),$$
$$\dot{p}_2 = \dot{\psi}_2 x^*(t) + \psi_2 \dot{x}^*(t).$$

Substituting for $\dot{x}^*, \dot{p}_1$, and $\dot{p}_2$ gives

$$\dot{\psi}_1 = -A(t)^\top \psi_1 - \psi_1 A(t) + \mu Q_2 + Q_1 - \psi_1 B(t) R_{11}^{-1} B(t)^\top (\psi_1 - \mu\psi_2) - \psi_1 C(t) R_{22}^{-1} C(t)^\top \psi_2,$$
$$\dot{\psi}_2 = -A(t)^\top \psi_2 - \psi_2 A(t) + Q_2 - \psi_2 B(t) R_{11}^{-1} B(t)^\top (\psi_1 - \mu\psi_2) - \psi_2 C(t) R_{22}^{-1} C(t)^\top \psi_2.$$

Moreover,

$$u^*(t) = R_{11}^{-1} B(t)^\top (\psi_1(t) - \mu\psi_2(t))x(t),$$
$$v^*(t) = R_{22}^{-1} C(t)^\top \psi_2(t) x(t).$$

Let $\psi_3 = \psi_1 - \mu\psi_2$. Then provided that there exists $\mu \geq 0$ that satisfies

$$R_{22}^{-1} C(t)^\top \psi_2 = [\mu R_{22} + R_{12}]^{-1} C(t)^\top (\psi_3 + \mu\psi_2) \tag{41}$$

we obtain

$$u^*(t) = R_{11}^{-1} B(t)^\top \psi_3(t) x(t), \tag{42}$$
$$v^*(t) = R_{22}^{-1} C(t)^\top \psi_2(t) x(t), \tag{43}$$

where ψ_3 and ψ_2 are solutions to

$$\dot{\psi}_3 = -A(t)^\top \psi_3 - \psi_3 A(t) + Q_1 - \psi_3 B(t) R_{11}^{-1} B(t)^\top \psi_3 - \psi_3 C(t) R_{22}^{-1} C(t)^\top \psi_2,$$
$$\dot{\psi}_2 = -A(t)^\top \psi_2 - \psi_2 A(t) + Q_2 - \psi_2 B(t) R_{11}^{-1} B(t)^\top \psi_3 - \psi_2 C(t) R_{22}^{-1} C(t)^\top \psi_2,$$

with end point conditions

$$\psi_3(1) = -K_1, \quad \psi_2(1) = -K_2.$$

It is clear that the existence of $\mu \geq 0$ that satisfies the equality (41) is a constraint qualification for ensuring the existence of normal multipliers for the class of linear-quadratic bilevel problems. Such $\mu \geq 0$ exists, for example, when

$$K_1 = 0, \quad Q_1 = 0, \quad R_{12} = 0$$

or

$$K_1 = K_2 = 0, \qquad Q_1 = Q_2 = 0.$$

Acknowledgments. The author would like to thank Qiji Zhu for suggestions which led to improvements in Theorem 2.3 of this paper. The author would also like to thank anonymous referees for comments on an early version of this paper that helped to improve the exposition.

A PREDICTOR-CORRECTOR ALGORITHM FOR A CLASS OF NONLINEAR SADDLE POINT PROBLEMS*

JIE SUN†, JISHAN ZHU‡, AND GONGYUN ZHAO§

Abstract. An interior path-following algorithm is proposed for solving the nonlinear saddle point problem

$$\text{minimax } c^T x + \phi(x) + b^T y - \psi(y) - y^T A x$$
$$\text{subject to } (x, y) \in \mathcal{X} \times \mathcal{Y} \subset R^n \times R^m,$$

where $\phi(x)$ and $\psi(y)$ are smooth convex functions and $\mathcal{X}$ and $\mathcal{Y}$ are boxes (hyperrectangles). This problem is closely related to the models in stochastic programming and optimal control studied by Rockafellar and Wets (*Math. Programming Studies*, 28 (1986), pp. 63–93; *SIAM J. Control Optim.*, 28 (1990), pp. 810–822). Existence and error-bound results on a central path are derived. Starting from an initial solution near the central path with duality gap $O(\mu)$, the algorithm finds an ϵ-optimal solution of the problem in $O(\sqrt{m+n}\,|\log \mu/\epsilon|)$ iterations if both $\phi(x)$ and $\psi(y)$ satisfy a scaled Lipschitz condition.

Key words. interior point methods, nonlinear complementarity problem, optimal control, saddle point problem, stochastic programming

1. Introduction.

We discuss an interior path-following scheme for solving a class of nonlinear saddle point problems in the following form:

$$\text{(1.1)} \quad \begin{cases} \text{Find a saddle point for} & l(x,y) \equiv c^T x + \phi(x) + b^T y - \psi(y) - y^T A x \\ \text{subject to} & x \in \mathcal{X} \subset R^n, y \in \mathcal{Y} \subset R^m, \end{cases}$$

where $\phi(x)$ and $\psi(y)$ are C^2-convex functions, $c \in R^n$, $b \in R^m$, $A \in R^{m\times n}$, and the superscript T represents transpose. The sets of $\mathcal{X}$ and $\mathcal{Y}$ are boxes (hyperrectangles).

According to convex analysis [17], problem (1.1) has a pair of associated optimization problems: the primal problem

$$\text{(1.2)} \qquad \text{minimize}_{x\in\mathcal{X}}\ f(x) \equiv c^T x + \phi(x) + \sup_{y\in\mathcal{Y}}\{(b - Ax)^T y - \psi(y)\}$$

and the dual problem

$$\text{(1.3)} \qquad \text{maximize}_{y\in\mathcal{Y}}\ g(y) \equiv b^T y - \psi(y) - \sup_{x\in\mathcal{X}}\{(A^T y - c)^T x - \phi(x)\}.$$

Note that the function $f(x)$ (called the primal objective function) is convex, the function $g(y)$ (called the dual objective function) is concave, and both are nondifferentiable in general. (For a detailed analysis for the case that both $\phi(x)$ and $\psi(y)$ are quadratic,

see [18], where $f(x)$ and $-g(y)$ turn out to be "piecewise quadratic" convex functions.) Therefore, problems (1.1)–(1.3) can be categorized as nonsmooth convex programming problems. Some fundamental duality relationships among (1.1), (1.2), and (1.3) have been established in [17] which include existence results on the saddle point(s) of (1.1) and the saddle point value—the common optimal value of (1.2) and (1.3).

Problems (1.1)–(1.3) stem from a development beyond the conventional formulation of optimization problems. These models provide a framework that allows penalty representations of constraints as well as accommodates other sources of nonsmoothness such as objectives produced by multistage optimization problems. For instance, linearly constrained convex optimization problems are usually posed in the form

$$\text{minimize } \ \phi(x) \ \text{ subject to } Ax \geq b, x \geq 0.$$

The corresponding Lagrangian saddle point problem is

$$\text{minimax}_{x\geq 0, y\geq 0} \ \phi(x) + y^T(b - Ax),$$

which is a special case of (1.1). Now let $\psi(y)$ be a convex function such that $\psi(0) = 0$ and $\psi(y) \geq 0$ and add $-\psi(y)$ to the Lagrangian function. Then the corresponding primal program becomes

$$\text{minimize } \ \phi(x) + \sup_{y\geq 0}\{y^T(b - Ax) - \psi(y)\} \ \text{ subject to } x \geq 0,$$

where the function $\sup_{y\geq 0}\{y^T(b-Ax)-\psi(y)\}$ is equal to zero for x satisfying $Ax \geq b$ and is greater or equal to zero for all x. Thus in this formulation the exact constraint $Ax \geq b$ is replaced by a penalty representation that allows the modeler to deal with $Ax \geq b$ more flexibly by selecting suitable $\psi(y)$ and $\mathcal{Y}$.

As an example of how multistage optimization could fit into the form of (1.1), we consider a two-stage stochastic programming model studied by Rockafellar and Wets [23]. At the first (current) stage, a decision $x \in R^n$ has to be made, incurring a direct cost $c^T x + \phi(x)$, subject to $x \in \mathcal{X}$, where $\mathcal{X}$ is a box. At the second (future) stage, a random event is observed with outcome $\omega \in \Omega$, where Ω is a probability space. The decision x and the outcome ω then determine an additional "recourse cost" $\rho_\omega(x)$. Under the practical circumstances such as soft constraints [18, 20] and simple recourse [31], the function $\rho_\omega(x)$ is expressed by an optimal value function as follows:

$$\rho_\omega(x) = \sup_{y_\omega \in \mathcal{Y}_\omega} \{y_\omega^T(b_\omega - A_\omega x) - \psi_\omega(y_\omega)\}. \tag{1.4}$$

In principle, the set $\mathcal{Y}_\omega$, the vector b_ω, the matrix A_ω, and the function ψ_ω are allowed to be random. The objective in this model is to make the best decision x with respect to the present cost and constraints as well as the expected cost $E_\omega[\rho_\omega(x)]$ and certain induced constraints. Assuming finite discrete distribution for ω, the decision problem can be described by

$$\text{minimize } \ c^T x + \phi(x) + \sum_{\omega\in\Omega} \pi_\omega \rho_\omega(x) \text{ subject to } x \in \mathcal{X}, \tag{1.5}$$

where π_ω is the probability of the random event ω. Now let

$$\mathcal{Y} = \prod_{\omega\in\Omega} \mathcal{Y}_\omega, \ b = \begin{bmatrix} \cdot \\ \cdot \\ \pi_\omega b_\omega \\ \cdot \\ \cdot \end{bmatrix}, \ A = \begin{bmatrix} \cdot \\ \cdot \\ \pi_\omega A_\omega \\ \cdot \\ \cdot \end{bmatrix}, \text{ and } \psi(y) = \sum_{\omega\in\Omega} \pi_\omega \psi_\omega(y_\omega).$$

Then problem (1.5) takes the form of (1.2).

More about the motivation of models (1.1)–(1.3) and their applications in stochastic programming and optimal control can be found in a series of pioneer papers of Rockafellar and Wets [18, 19, 20, 21, 23, 24].

Algorithms for linear-quadratic cases of problem (1.1) in which both $\phi(x)$ and $\psi(y)$ are linear or quadratic have been studied extensively. Among them are the L-shaped method [30], the decomposition methods [1, 5], the finite generation method [23], the projected gradient method [37], the steepest descent method [36], the sequential quadratic programming method [16], and some interior point methods [2, 3, 27, 32, 33]. For the special case where both $\mathcal{X}$ and $\mathcal{Y}$ are boxes and both $\phi(x)$ and $\psi(y)$ are separable quadratic functions, a simplex–active-set method has been developed [22]. The more general convex case of (1.1), however, has not yet received enough attention in algorithmic development, although the problem can be traced back to the extended Fenchel duality model in the 1970s [17].

The predictor-corrector algorithm studied in this paper is rooted in the primal-dual path-following algorithm of Kojima, Mizuno, and Yoshise [10] for linear complementarity problems and the predictor-corrector method of Mizuno, Todd, and Ye [14] for linear programming. The algorithms in [10] and [14] and their variants have been extensively studied on their global, local, and computational behaviors in the context of linear complementarity problems. It is not possible for us to point out all references on this method; the interested reader may look into the tutorial paper of Gonzaga [6] and recent papers such as [9, 11, 12, 25, 34, 35] and the references therein.

The purpose of writing this paper is threefold.

(i) We develop a predictor-corrector algorithm for problem (1.1) together with existence and error-bound results on a central path. In particular we show that if functions $\phi(x)$ and $\psi(y)$ satisfy a scaled Lipschitz condition, then starting from an initial solution near the central path, the algorithm converges to an ϵ-optimal solution of the problem in $O\left(\sqrt{m+n}\,|\log \mu_0/\epsilon|\right)$ iterations, where μ_0 is a number related to the initial duality gap.

(ii) To the research community in stochastic programming and optimal control, we demonstrate that the interior point method can be used as one of the theoretically efficient methods for convex-concave saddle point problems. We also suggest ways to take computational advantage of the special structure of problem (1.1) arising from stochastic programming and optimal control.

(iii) To the research community of interior point methods, this paper contributes a polynomial algorithm for a class of monotone complementarity problems (MCP). To our knowledge, only few algorithms for nonlinear MCP have been shown to have polynomial complexity (Nesterov and Nemirovskii [15] and Tseng [28]) under different conditions. The scaled Lipschitz condition used in this paper, as shown in [38], is satisfied by a fairly large class of convex functions.

This paper is organized as follows. In section 2 we discuss the conditions for the existence of the optimal solution(s) and the central path. We establish an estimate on the duality gap if (x, y) is near the central path. These results form a foundation for the interior path-following method for problem (1.1). Section 3 is devoted to the proof of polynomial convergence of the predictor-corrector algorithm. Finally, section 4 contains some concluding remarks.

2. Results on feasibility, existence, and error bounds related to the central path. In the following analysis, we assume that both $\mathcal{X}$ and $\mathcal{Y}$ are nonnegative orthants in order to simplify the statements. This is not an essential change from assuming that $\mathcal{X}$ and $\mathcal{Y}$ are boxes. We will elaborate this point at the end of section 3.

Suppose that a saddle point (x^*, y^*) of (1.1) exists; that is,

$$l(x^*, y) \le l(x^*, y^*) \le l(x, y^*) \text{ for all } x \in \mathcal{X} \text{ and } y \in \mathcal{Y}.$$

It can be shown [17] that x^* and y^* must be optimal solutions of (1.2) and (1.3), respectively, and that $f(x^*) = l(x^*, y^*) = g(y^*)$ and vice versa. In addition, the saddle point condition is equivalent to the following variational relationships:

$$-\nabla_x l(x^*, y^*) \in N_{\mathcal{X}}(x^*) \text{ and } \nabla_y l(x^*, y^*) \in N_{\mathcal{Y}}(y^*), \tag{2.1}$$

where $N_{\mathcal{X}}(x^*)$ stands for the normal cone of $\mathcal{X}$ at x^*. The notation $N_{\mathcal{Y}}(y^*)$ has a similar meaning. We assume that both $\phi(x)$ and $\psi(y)$ are finite and twice continuously differentiable on $\mathcal{X}$ and $\mathcal{Y}$, respectively. By introducing auxiliary vectors w^* and s^*, conditions (2.1) can be written in an explicit form as follows:

$$\begin{cases} \nabla\phi(x^*) - A^T y^* - w^* = -c, \\ Ax^* + \nabla\psi(y^*) - s^* = b, \\ (x^*)^T w^* = (y^*)^T s^* = 0, \\ x^*, y^*, w^*, s^* \ge 0. \end{cases} \tag{2.2}$$

The proposed algorithm finds a point $(x, y) \in \mathcal{X} \times \mathcal{Y}$ such that $f(x) - g(y) \le \epsilon$ by finding a sequence of approximate solutions of the following system as $\mu \downarrow 0$:

$$\begin{cases} \nabla\phi(x) - A^T y - w = -c, \\ Ax + \nabla\psi(y) - s = b, \\ x_j w_j = \mu, \quad j = 1, ..., n, \\ y_i s_i = \mu, \quad i = 1, ..., m, \\ x, w, y, s \ge 0. \end{cases} \tag{2.3}$$

Similar to the deduction of system (2.2), it can be shown that (x, y, w, s) is a solution to (2.3) if and only if (x, y) is a saddle point of

$$l_\mu(x, y) \equiv c^T x + \phi(x) + b^T y - \psi(y) - y^T A x - \mu \sum_{j=1}^{n} \log x_j + \mu \sum_{i=1}^{m} \log y_i$$

over $\mathcal{X} \times \mathcal{Y}$.

Naturally, as an interior point method, the proposed algorithm needs some kind of interior points from which to start. We make the following assumption.

Assumption 2.1. There is a quadruple $(x, y, w, s) > 0$ such that the first two equations of system (2.3) are satisfied.

Under this assumption, we can prove that the iterates generated by our algorithm are feasible solutions to problems (1.2) and (1.3) and that the solutions to problem (2.3) exist for all $\mu \ge 0$.

We first discuss the feasibility problem. An x is *feasible* to (1.2) if $x \ge 0$ and $f(x) < \infty$; a y is *feasible* to (1.3) if $y \ge 0$ and $g(y) > -\infty$. We have the following result under an assumption weaker than Assumption 2.1.

PROPOSITION 2.2. *Suppose that the following relations are valid:*

$$\begin{cases} \nabla\phi(x^k) - A^T y^k - w^k = -c, \\ Ax^k + \nabla\psi(y^k) - s^k = b, \\ x^k, w^k, y^k, s^k \ge 0. \end{cases} \tag{2.4}$$

Then x^k is a feasible solution to problem (1.2) *and y^k is a feasible solution to problem* (1.3).

Proof. The second equation of (2.4) and the convexity of $\psi(y)$ imply that for any $y \in \mathcal{Y}$,

$$\begin{aligned}(b - Ax^k)^T y - \psi(y) &= [\nabla\psi(y^k) - s^k]^T y - \psi(y) \\ &= \nabla\psi(y^k)^T(y - y^k) + \nabla\psi(y^k)^T y^k - y^T s^k - \psi(y) \\ &\le \nabla\psi(y^k)^T y^k - \psi(y^k) - y^T s^k.\end{aligned}$$

Since $y \ge 0$ and $s^k \ge 0$, we have

$$\begin{aligned}f(x^k) &= c^T x^k + \phi(x^k) + \sup_{y\ge 0}\{(b - Ax^k)^T y - \psi(y)\} \\ &\le c^T x^k + \phi(x^k) + \sup_{y\ge 0}\{\nabla\psi(y^k)^T y^k - \psi(y^k) - y^T s^k\} \\ &\le c^T x^k + \phi(x^k) + \nabla\psi(y^k)^T y^k - \psi(y^k) < \infty.\end{aligned}$$

Thus the second equation of (2.4), $s^k \ge 0$, and $x^k \ge 0$ imply that x^k is feasible to (1.2). Similarly, the first equation of (2.4), $w^k \ge 0$, and $y^k \ge 0$ imply that y^k is feasible to (1.3). □

Because our algorithm will ensure that (2.4) is valid for all iterates (see details below), the algorithm will generate a feasible sequence $\{(x^k, y^k)\}$ to problems (1.2) and (1.3) according to Proposition 2.2.

Now we discuss the existence of the saddle points of $l_\mu(x, y)$. Unlike the linear-quadratic case, the feasibility of both primal and dual problems is not enough for the existence of a saddle point. However, we will show that under Assumption 2.1 for any $\mu \ge 0$ a saddle point of $l_\mu(x, y)$ exists. We first prove a lemma.

LEMMA 2.3. *Suppose that the following relations are valid:*

$$\mathcal{P} \equiv \cap_{y>0}\{p \in R^n_+ | c^T p + (\phi 0^+)(p) - y^T A p \le 0\} = \{0\}, \tag{2.5}$$

$$\mathcal{Q} \equiv \cap_{x>0}\{q \in R^m_+ | - b^T q + (\psi 0^+)(q) + x^T A^T q \le 0\} = \{0\}, \tag{2.6}$$

where $(\phi 0^+)(p)$ and $(\psi 0^+)(q)$ are the recession functions of $\phi(x)$ and $\psi(y)$, respectively:

$$(\phi 0^+)(p) \equiv \lim_{\lambda\to 0^+} \lambda\phi(x + \lambda^{-1} p),$$

$$(\psi 0^+)(q) \equiv \lim_{\lambda\to 0^+} \lambda\psi(y + \lambda^{-1} q).$$

(The two recession functions are invariant regardless of the choice of $x \in \mathcal{X}$ and $y \in \mathcal{Y}$.) Then $l_\mu(x, y)$ has a saddle point on $\mathcal{X} \times \mathcal{Y}$.

Proof. According to convex analysis [17, Theorem 37.6], a sufficient condition for $l_\mu(x, y)$ to have a saddle point on $\mathcal{X} \times \mathcal{Y}$ is that the convex functions $l_\mu(\cdot, y)$ have no common direction of recession for $y \in \operatorname{ri}\mathcal{Y}$ and that the convex functions $-l_\mu(x, \cdot)$ have no common direction of recession for $x \in \operatorname{ri}\mathcal{X}$, where "ri" stands for the relative interior. Denote by R^n_+ and R^m_+ the nonnegative orthants of R^n and R^m, respectively. Now for fixed $y \in \operatorname{ri}\mathcal{Y}$, the set of directions of recession of $l_\mu(\cdot, y)$ is given by

$$\begin{aligned}\mathcal{P}_y &\equiv \{p \in R^n_+ | \lim_{\lambda\to 0^+} \lambda l_\mu(x+\lambda^{-1}p, y) \le 0\} \\ &= \left\{ p \in R^n_+ | \lim_{\lambda\to 0^+} \lambda\phi(\lambda^{-1}p) - \lim_{\lambda\to 0^+} \lambda\mu \sum_{j=1}^n \log(x_j + \lambda^{-1}p_j) + (c - A^T y)^T p \le 0 \right\} \\ &= \{p \in R^n_+ | (\phi 0^+)(p) + (c - A^T y)^T p \le 0\}.\end{aligned}$$

Similarly, for fixed $x \in \operatorname{ri}\mathcal{X}$, the set of directions of recession of $-l(x,\cdot)$ is

$$\mathcal{Q}_x \equiv \{q \in R^m_+ | (\psi 0^+)(q) - (b - Ax)^T q \le 0\}.$$

The statement "for $y \in \operatorname{ri}\mathcal{Y}$ there is no common direction of recession" is then interpreted as (2.5). We also get (2.6) in the same fashion. □

PROPOSITION 2.4. *Under Assumption* 2.1 *for any* $\mu \ge 0$, $l_\mu(x,y)$ *has a saddle point on* $\mathcal{X}\times\mathcal{Y}$.

Proof. Suppose that Assumption 2.1 is satisfied by a quadruple $(x^0, y^0, w^0, s^0) > 0$. Note that

$$(\phi 0^+)(p) = \lim_{\lambda\to 0^+} \lambda\phi(x^0 + \lambda^{-1}p) = \lim_{\lambda\to 0^+} \lambda[\phi(x^0 + \lambda^{-1}p) - \phi(x^0)] \ge \nabla\phi(x^0)^T p.$$

We have, for any $p \in \mathcal{P}_{y^0}$,

$$(w^0)^T p = c^T p + \nabla\phi(x^0)^T p - (y^0)^T A p \le c^T p + (\phi 0^+)(p) - (y^0)^T A p \le 0.$$

Since $w^0 > 0$ and $p \ge 0$, the above inequality implies $p = 0$. Therefore we have $\mathcal{P}_{y^0} = \{0\}$. Analogously we have $\mathcal{Q}_{x^0} = \{0\}$. By Lemma 2.3, $l_\mu(x,y)$ has a saddle point on $\mathcal{X}\times\mathcal{Y}$. □

Proposition 2.4 says that Assumption 2.1 is sufficient for the existence of optimal solutions of problems (1.1)–(1.3) as well as for the existence of the solutions of (2.3) for any $\mu > 0$. From the strict convexity of $\sup_{y\ge 0} l_\mu(x,y)$ and $-\inf_{x\ge 0} l_\mu(x,y)$, it can be seen that $(x(\mu), y(\mu))$ is unique for $\mu > 0$. We call the set $\{(x(\mu), y(\mu)) | \mu > 0\}$ the *central path* of problem (1.1) if $(x(\mu), y(\mu))$ is a saddle point of $l_\mu(x,y)$ on $\mathcal{X}\times\mathcal{Y}$.

It should be noted that system (2.2) can be viewed as an MCP of the mapping

$$F : R^{m+n} \to R^{m+n}, \quad F(x,y) = \begin{bmatrix} \nabla\phi(x) - A^T y + c \\ Ax + \nabla\psi(y) - b \end{bmatrix}.$$

Several conditions have been discussed in the literature for the existence of the central path under various situations. For example Güler [7] studies conditions for MCPs. It can be shown that his conditions are equivalent to Assumption 2.1 in the context of mapping F. The conditions involving recession functions stated in Lemma 2.3 appear to be new in the literature.

We now estimate the error if the solution of system (2.3) is used as an approximate solution to the saddle point problem (1.1). We prove that the duality gap of the solutions on the central path converges to zero as μ goes to zero. This is the basic fact that justifies interior path-following algorithms.

PROPOSITION 2.5. *Under Assumption* 2.1, *given any* $\mu \ge 0$ *we have*

$$0 \le f(x(\mu)) - g(y(\mu)) \le (m+n)\mu. \tag{2.7}$$

Proof. The assumption implies the existence of $(x(\mu), y(\mu))$, which together with a certain $(w(\mu), s(\mu))$ satisfies system (2.4). By definitions of $f(x)$ and $g(y)$, we always have $f(x) \geq g(y)$ for all $(x, y) \in \mathcal{X} \times \mathcal{Y}$ (the weak duality). Therefore we only need to prove the second inequality. Analogous to the proof of Proposition 2.2, we have

$$\begin{aligned} f(x(\mu)) &\leq c^T x(\mu) + \phi(x(\mu)) - \psi(y(\mu)) + \nabla\psi(y(\mu))^T y(\mu) \\ &= c^T x(\mu) + \phi(x(\mu)) - \psi(y(\mu)) + [b - Ax(\mu)]^T y(\mu) + s(\mu)^T y(\mu). \end{aligned} \tag{2.8}$$

The last equality above is based on the second equation of (2.4). A symmetric argument for the dual problem implies

$$g(y(\mu)) \geq b^T y(\mu) - \psi(y(\mu)) + \phi(x(\mu)) - [A^T y(\mu) - c]^T x(\mu) - w(\mu)^T x(\mu). \tag{2.9}$$

Proposition 2.5 is proved by subtracting (2.9) from (2.8):

$$f(x(\mu)) - g(y(\mu)) \leq w(\mu)^T x(\mu) + s(\mu)^T y(\mu) = (m+n)\mu. \qquad \square$$

Proposition 2.5 provides the estimation on the duality gap for the points on the central path. Denote the positive diagonal matrices $\mathrm{diag}(x_1, \ldots, x_n)$, $\mathrm{diag}(y_1, \ldots, y_m)$, $\mathrm{diag}(w_1, \ldots, w_n)$, and $\mathrm{diag}(s_1, \ldots, s_m)$ by X, Y, W, and S, respectively. For any $\mu > 0$, we do not have to obtain $x(\mu)$ and $y(\mu)$ exactly. In practice a path-following algorithm generates a sequence of (x^k, y^k) close to $(x(\mu^k), y(\mu^k))$. The closeness is defined by a proximity function

$$\delta(x, y, w, s, \mu) = \left(\left\| \frac{Wx}{\mu} - e \right\|^2 + \left\| \frac{Sy}{\mu} - e \right\|^2 \right)^{1/2}, \tag{2.10}$$

where e is a vector of ones of compatible dimension and $\|\cdot\|$ is the Euclidean norm. Notice that $\delta(x, y, w, s, \mu) = 0$ implies that (x, y) is on the central path; i.e., $(x, y) = (x(\mu), y(\mu))$. With a little abuse of the notations, the same e is used in (2.10) and below regardless of the dimension. The following result provides an error bound for an approximate solution of (2.3) which satisfies (2.4) but may not satisfy the other equations of (2.3).

PROPOSITION 2.6. *If (x, y, w, s) satisfies (2.4) and $\delta(x, y, w, s, \mu) \leq \alpha$, then*

$$0 \leq f(x) - g(y) \leq (1 + \alpha/\sqrt{n+m})(n+m)\mu.$$

Proof. Notice that the proof of inequalities (2.8) and (2.9) uses only the relationships in (2.4). Thus by following the proof of Proposition 2.5, we have

$$f(x) - g(y) \leq w^T x + s^T y.$$

On the other hand,

$$w^T x + s^T y = e^T W x + e^T S y = e^T \begin{bmatrix} Wx - \mu e \\ Sy - \mu e \end{bmatrix} + (m+n)\mu$$

$$\leq \|e\| \cdot \left\| \begin{bmatrix} Wx - \mu e \\ Sy - \mu e \end{bmatrix} \right\| + (m+n)\mu \leq \alpha\mu\sqrt{n+m} + (n+m)\mu.$$

Hence

$$f(x) - g(y) \leq (1 + \alpha/\sqrt{n+m})(n+m)\mu. \qquad \square$$

Proposition 2.6 provides an estimation of the duality gap for the solutions in a neighborhood of the central path. With this estimation, in order to find a pair of ϵ-optimal solution to (1.1) in the following sense

$$x \text{ is feasible to (1.2), } y \text{ is feasible to (1.3), and } 0 \le f(x) - g(y) \le \epsilon,$$

we only need to find a pair of primal and dual feasible solutions in a neighborhood of the central path satisfying $\delta(x, y, w, s, \mu) \le \alpha$, where $\mu = \epsilon/[(1+\alpha/\sqrt{n+m})(n+m)]$.

3. Convergence analysis of the predictor-corrector algorithm. Given any point $(x, y, w, s) > 0$ and any number $\mu > 0$ satisfying (2.4) and $\delta(x, y, w, s, \mu) \le \alpha$, we consider a path-following method for problem (1.1). A typical iteration in the algorithm applies one step of Newton's method to the system

$$\begin{cases} \nabla\phi(x) - A^T y - w = -c, \\ Ax + \nabla\psi(y) - s = b, \\ Wx = \lambda\mu e, \\ Sy = \lambda\mu e, \end{cases} \tag{3.1}$$

where λ is a certain constant. From the Newton approximation of system (3.1), the improving direction $(\Delta x, \Delta y, \Delta w, \Delta s)$ is determined by

$$\begin{cases} \Delta w = \nabla^2\phi(x)\Delta x - A^T\Delta y, \\ \Delta s = A\Delta x + \nabla^2\psi(y)\Delta y, \\ W\Delta x + X\Delta w = -Xw + \lambda\mu e, \\ S\Delta y + Y\Delta s = -Sy + \lambda\mu e. \end{cases} \tag{3.2}$$

The associated direction is called the predictor (affine-scaling) direction if $\lambda = 0$ and is called the corrector (centering) direction if $\lambda = 1$. The following algorithm moves a solution from a tight neighborhood of the central path to a loose one in each predictor step in order to reduce the central path parameter μ. It then draws a solution from the loose neighborhood back to the tight one in each corrector step. The algorithm terminates when $\mu \le \epsilon/[(1+\alpha/\sqrt{n+m})(n+m)]$. We now present the algorithm.

ALGORITHM 3.1 (a predictor-corrector algorithm for problem (1.1)).

Step 0 *(Initialization) Let* $k = 0$. *Choose* $(x^0, y^0, w^0, s^0) > 0$, $\mu_0 > 0$, $0 < \alpha < 1 < t$, *where* $\alpha t < 1$, *such that the first two equations of* (3.1) *are satisfied by* (x^0, y^0, w^0, s^0) *and such that* $\delta(x^0, y^0, w^0, s^0, \mu_0) \le \alpha$.

Step 1 **For** $k = 0, 1, \ldots,$ **until** $\mu_k \le \epsilon/[(1+\alpha/\sqrt{n+m})(n+m)]$ *(where* ϵ *is the user assigned tolerance),* **do**

Step 1.1 *Solve* (3.2) *with* $x = x^k$, $y = y^k$, $w = w^k$, $s = s^k$, $\mu = \mu_k$, *and* $\lambda = 0$. *Denote by* Δx^p, Δy^p, Δw^p, *and* Δs^p *the resulting directions. Let* θ *be a suitable positive number such that*

$$\delta(x(\theta), y(\theta), w(\theta), s(\theta), \mu(\theta)) \le t\alpha,$$

where

$$x(\theta) = x^k + \theta\Delta x^p, \quad y(\theta) = y^k + \theta\Delta y^p,$$
$$w(\theta) = w^k + \theta\Delta w^p + \nabla\phi(x^k + \theta\Delta x^p) - \nabla\phi(x^k) - \theta\nabla^2\phi(x^k)\Delta x^p,$$
$$s(\theta) = s^k + \theta\Delta s^p + \nabla\psi(y^k + \theta\Delta y^p) - \nabla\psi(y^k) - \theta\nabla^2\psi(y^k)\Delta y^p,$$

and

$$\mu(\theta) = (1-\theta)\mu_k.$$

This is the predictor step.

Step 1.2 *Solve* (3.2) *with* $x = x(\theta), y = y(\theta), w = w(\theta), s = s(\theta), \mu = \mu(\theta)$, *and* $\lambda = 1$, *resulting in* $\Delta x^c,\ \Delta y^c,\ \Delta w^c$, *and* Δs^c. *Let*

$$x^{k+1} = x(\theta) + \Delta x^c, \quad y^{k+1} = y(\theta) + \Delta y^c,$$
$$w^{k+1} = w(\theta) + \Delta w^c + \nabla\phi(x(\theta) + \Delta x^c) - \nabla\phi(x(\theta)) - \nabla^2\phi(x(\theta))\Delta x^c,$$
$$s^{k+1} = s(\theta) + \Delta s^c + \nabla\psi(y(\theta) + \Delta y^c) - \nabla\psi(y(\theta)) - \nabla^2\psi(y(\theta))\Delta y^c,$$

and

$$\mu_{k+1} = \mu(\theta).$$

This is the corrector step. Update k *and go to next iteration of Step* 1.

The steplength θ in Step 1.1 can be computed by an explicit formula which will be discussed in Proposition 3.6 below. It will become apparent at the end of our analysis that all (x^k, y^k) are feasible to (1.2) and (1.3).

Algorithm 3.1 can be generalized to find an approximate solution (u^*, v^*) of the following MCP:

$$\text{(MCP)} \qquad u, v \in R^{m+n},\ u \geq 0,\ v = F(u) \geq 0,\ u^T v = 0$$

in the sense of

$$u^*, v^* \in R^{m+n},\ u^* \geq 0,\ v^* = F(u^*) \geq 0,\ \delta(u^*, v^*, \mu) \leq \alpha,$$

where $0 < \alpha < 1$, μ is any preassigned small positive number, and $\delta(u, v, \mu)$ is defined similarly to $\delta(x, y, w, s, \mu)$. In order to facilitate comparisons of Algorithm 3.1 with existing interior point algorithms for nonlinear complementarity problems, we will prove our convergence result for the following algorithm for (MCP) which generalizes Algorithm 3.1.

ALGORITHM 3.2 (a predictor-corrector algorithm for problem (MCP)).

Step 0 *(Initialization) Let* $k = 0$. *Choose* $(u^0, v^0) > 0$, $\mu_0 > 0$, $0 < \alpha < 1 < t$, *where* $\alpha t < 1$, *such that the first equation of*

$$\begin{cases} F(u) - v = 0, \\ Vu = \lambda\mu e \end{cases} \tag{3.3}$$

is satisfied by (u^0, v^0) *and such that* $\delta(u^0, v^0, \mu_0) \leq \alpha$.

Step 1 **For** $k = 0, 1, \ldots,$ **until** $\mu_k \leq \epsilon/[(1 + \alpha/\sqrt{n+m})(n+m)]$ *(where* ϵ *is the user-assigned tolerance),* **do**

Step 1.1 *Solve*

$$\begin{cases} \Delta v = F'(u)\Delta u, \\ V\Delta u + U\Delta v = -Vu + \lambda\mu e, \end{cases} \tag{3.4}$$

with $u = u^k$, $v = v^k$, $\mu = \mu_k$, *and* $\lambda = 0$, *where* $F'(u)$ *represents the Jacobian of* F *at* u. *Denote by* Δu^p *and* Δv^p *the resulting directions. Let* θ *be a suitable positive number such that*

$$\delta(u(\theta), v(\theta), \mu(\theta)) \leq t\alpha,$$

where

$$u(\theta) = u^k + \theta \Delta u^p,$$

$$v(\theta) = v^k + \theta \Delta v^p + F(u^k + \theta \Delta u^p) - F(u^k) - \theta F'(u^k)\Delta u^p,$$

and

$$\mu(\theta) = (1-\theta)\mu_k.$$

This is the predictor step.

Step 1.2 *Solve* (3.4) *with* $u = u(\theta), v = v(\theta), \mu = \mu(\theta)$, *and* $\lambda = 1$, *resulting in* Δu^c *and* Δv^c. *Let*

$$u^{k+1} = u(\theta) + \Delta u^c,$$

$$v^{k+1} = v(\theta) + \Delta v^c + F(u(\theta) + \Delta u^c) - F(u(\theta)) - F'(u(\theta))\Delta u^c,$$

and

$$\mu_{k+1} = \mu(\theta).$$

This is the corrector step. Update k *and go to next iteration of Step* 1.

It is not hard to verify that by assigning

$$u = \begin{bmatrix} x \\ y \end{bmatrix}, \quad v = \begin{bmatrix} w \\ s \end{bmatrix}, \quad \text{and } F(u) = \begin{bmatrix} \nabla\phi(x) - A^T y + c \\ Ax + \nabla\psi(y) - b, \end{bmatrix}$$

Algorithm 3.2 specializes to Algorithm 3.1.

We now proceed to show that Algorithm 3.2 is of polynomial complexity. We take notations such as U and V in the same way as X, Y, W, and S. The following assumption is used in our proof.

The scaled Lipschitz condition (SLC) for $F(u)$.

Given $0 < \beta < 1$, *there exists* $M > 0$ *such that*

$$\|U[F(u+\Delta u) - F(u) - F'(u)\Delta u]\| \le M\Delta u^T F'(u)\Delta u$$

holds for any $u > 0$ *and* Δu *satisfying* $\|U^{-1}\Delta u\| \le \beta$.

Back to the saddle point problem, this condition is equivalent to

$$\left\|X[\nabla\phi(x+\Delta x) - \nabla\phi(x) - \nabla^2\phi(x)\Delta x]\right\| \le M\Delta x^T\nabla^2\phi(x)\Delta x$$

and

$$\left\|Y[\nabla\psi(y+\Delta y) - \nabla\psi(y) - \nabla^2\psi(y)\Delta y]\right\| \le M\Delta y^T\nabla^2\psi(y)\Delta y$$

for any $x > 0, \Delta x, y > 0$, and Δy satisfying $\left\|X^{-1}\Delta x\right\| \le \beta$ and $\left\|Y^{-1}\Delta y\right\| \le \beta$.

SLC has been employed in the analysis of interior point methods for convex programs [38]. Functions satisfying this condition include many useful functions such as $\phi(x) = \sum \phi_j(x_j)$ (similarly for $\psi(y) = \sum \psi_i(y_i)$), where $\phi_j(x_j)$ could be

$$-\log x_j,\ x_j \log x_j,\quad x_j^\alpha (\alpha < 0 \text{ or } \alpha > 1).$$

Note that $\phi(x)$ is not necessarily separable in general. For instance, the SLC is satisfied by the quadratic functions $\phi(x) = x^T Q x$ with Q being positive semidefinite. The same can be said about $\psi(y)$.

Denote the diagonal matrices

$$\mathrm{diag}(\Delta u_1, \ldots, \Delta u_{m+n}) \text{ and } \mathrm{diag}(\Delta v_1, \ldots, \Delta v_{m+n})$$

by ΔU and ΔV, respectively. We use the conventional notations such as $U^\nu = \mathrm{diag}(u_1^\nu, \ldots, u_{m+n}^\nu)$, $\Delta U^\nu = \mathrm{diag}(\Delta u_1^\nu, \ldots, \Delta u_{m+n}^\nu)$ and $u^\nu = (u_1^\nu, \ldots, u_{m+n}^\nu)^T$ for any real number ν. In the derivations below, we frequently use relationships defined by (3.4) and the following simple inequality:

For all u, v such that $\delta(u, v, \mu) \le \tau$ there holds

$$(1-\tau)\mu \le u_j v_j \le (1+\tau)\mu, \quad j = 1, \ldots, m+n. \tag{3.5}$$

Analysis on the predictor step. Given

$$\delta(u, v, \mu) \le \alpha$$

(the superscript k is omitted), we want to know how to choose θ such that

$$\delta(u(\theta), v(\theta), \mu(\theta)) \le t\alpha.$$

This will give us important information on the complexity of the algorithm because the algorithm sets $\mu_{k+1} = (1-\theta)\mu_k$ and stops when $\mu_k \le \epsilon/[(1+\alpha/\sqrt{n+m})(n+m)]$. An explicit formula for θ will be given following our analysis. Let

$$\xi = (I + \theta U^{-1}\Delta U)U[F(u + \theta\Delta u) - F(u) - \theta F'(u)\Delta u],$$

where I stands for the identity matrix. Note that

$$\begin{aligned}
&\|V(\theta)u(\theta) - (1-\theta)\mu e\| \\
&= \left\|Vu + \theta(V\Delta u + U\Delta v) + \theta^2 \Delta U\Delta v - (1-\theta)\mu e + \xi\right\| \\
&= \left\|(1-\theta)Vu - (1-\theta)\mu e + \theta^2\Delta U\Delta v + \xi\right\| \\
&\le (1-\theta)\,\|Vu - \mu e\| + \theta^2\,\|\Delta U\Delta v\| + \|\xi\| \\
&\le (1-\theta)\alpha\mu + \theta^2\,\|\Delta U\Delta v\| + \|\xi\| \qquad (3.6)
\end{aligned}$$

and that

$$\|\xi\| \le 2M\theta^2 \Delta u^T F'(u)\Delta u,$$

if $\|\theta U^{-1}\Delta u\| \le \beta < 1$ is satisfied. Let

$$\eta_1 \equiv \|\Delta U\Delta v\| \quad \text{and} \quad \eta_2 \equiv \Delta u^T F'(u)\Delta u.$$

Now we estimate η_1 and η_2 separately.

LEMMA 3.3.

$$\eta_1 \equiv \|\Delta U\Delta v\| \le (1+\alpha)(m+n)\mu.$$

Proof. Let

$$r_1 = (UV)^{-1/2} V\Delta u,$$

$$r_2 = (UV)^{-1/2} U\Delta v,$$

and

$$R_1 = (UV)^{-1/2} V\Delta U.$$

Then by (3.4) we have

$$r_1 + r_2 = -(Uv)^{1/2}$$

and

$$r_1{}^T r_2 = \Delta u^T \Delta v = \Delta u^T F'(u)\Delta u \geq 0.$$

Therefore we get

$$\eta_1 = \|\Delta U \Delta v\| = \|R_1 r_2\| \leq \max\{\|r_1\|^2, \|r_2\|^2\}$$
$$\leq \|r_1 + r_2\|^2 = \left\|(Uv)^{1/2}\right\|^2 \leq (1+\alpha)(m+n)\mu \qquad \text{(by (3.5))}. \qquad \square$$

Since we will apply the SLC in the estimate of η_2, we need to prove the following lemma.

LEMMA 3.4. *In the predictor step, if*

$$\theta \leq \sqrt{\frac{(1-\alpha)\beta}{(1+\alpha)(m+n)}},$$

then $\left\|\theta U^{-1}\Delta u\right\| \leq \beta$.

Proof. Multiplying both sides of

$$V\Delta u + U\Delta v = -Uv$$

by $U^{-1/2}V^{-1/2}$, we have

$$U^{-1/2}V^{1/2}\Delta u + U^{1/2}V^{-1/2}\Delta v = -U^{1/2}v^{1/2}.$$

Therefore by using (3.5) and noting that the inner product of the two terms on the left-hand side is nonnegative, we have

$$\left\|U^{-1/2}V^{1/2}\Delta u\right\|^2 \leq \left\|U^{1/2}v^{1/2}\right\|^2 \leq (1+\alpha)(m+n)\mu.$$

It in turn implies

$$(1+\alpha)(m+n)\mu \geq \left\|U^{-1/2}V^{1/2}\Delta u\right\|^2 = \left\|U^{1/2}V^{1/2}U^{-1}\Delta u\right\|^2 \geq (1-\alpha)\mu\left\|U^{-1}\Delta u\right\|^2.$$

Thus we have

$$\left\|\theta U^{-1}\Delta u\right\|^2 \leq (1+\alpha)(m+n)\theta^2/(1-\alpha) \leq \beta$$

as long as

$$\theta \leq \sqrt{\frac{(1-\alpha)\beta}{(1+\alpha)(m+n)}}. \qquad \square$$

The estimate related to η_2 is given in the following lemma.

LEMMA 3.5. *In the predictor step,*

$$\eta_2 \equiv \Delta u^T F'(u)\Delta u \le (1+\alpha)(m+n)\mu/4.$$

Proof. Setting $\lambda = 0$ in (3.4), we have

$$V\Delta u + U(F'(u)\Delta u) = -Uv.$$

Multiply both sides of the equation by $\Delta u^T U^{-1}$, and we get

$$\Delta u^T U^{-1} V\Delta u + \Delta u^T F'(u)\Delta u = -\Delta u^T v.$$

Hence

$$\begin{aligned}
&\Delta u^T F'(u)\Delta u \\
&= -\Delta u^T v - \Delta u^T U^{-1} V\Delta u \\
&= -\Delta u^T (U^{-1/2}V^{1/2})(U^{1/2}v^{1/2}) - \left\|U^{-1/2}V^{1/2}\Delta u\right\|^2 \\
&\le \left\|U^{1/2}v^{1/2}\right\| \cdot \left\|U^{-1/2}V^{1/2}\Delta u\right\| - \left\|U^{-1/2}V^{1/2}\Delta u\right\|^2 \\
&\le \left\|U^{1/2}v^{1/2}\right\|^2/4 \\
&\le (1+\alpha)(m+n)\mu/4.
\end{aligned}$$

The second to last inequality above is due to the fact that

$$bt - t^2 \le b^2/4$$

for any real numbers b and t. □

PROPOSITION 3.6. *Taking*

$$\theta = \min\left\{\sqrt{\frac{(1-\alpha)\beta}{(1+\alpha)(m+n)}}, \frac{2}{1+\left[1+\frac{(4+2M)(1+\alpha)(m+n)}{(t-1)\alpha}\right]^{1/2}}\right\} = O\left[(m+n)^{-1/2}\right],$$

we have

$$\|V(\theta)u(\theta) - (1-\theta)\mu e\| \le t\alpha(1-\theta)\mu.$$

Proof. From (3.6), Lemmas 3.3, 3.4, and 3.5 we have

$$\begin{aligned}
&\|V(\theta)u(\theta) - (1-\theta)\mu e\| \\
&\le (1-\theta)\alpha\mu + \theta^2\|\Delta U\Delta v\| + \|\xi\| \\
&\le (1-\theta)\alpha\mu + \eta_1\theta^2 + 2M\theta^2\eta_2.
\end{aligned}$$

This quantity will be not greater than $t\alpha(1-\theta)\mu$ as long as

$$0 \le \theta \le \frac{2}{1+\left[1+\frac{4(\eta_1+2M\eta_2)}{(t-1)\alpha\mu}\right]^{1/2}}$$

by simply solving a quadratic equation and picking the large root.

Replacing η_1 and η_2 by the estimates in Lemmas 3.3 and 3.5, we obtain an explicit upper bound for θ:

$$\theta \le \frac{2}{1+\left[1+\frac{(4+2M)(1+\alpha)(m+n)}{(t-1)\alpha}\right]^{1/2}}.$$

This, together with the condition of Lemma 3.4, results in the proposition. ∎

COROLLARY 3.7. *In each predictor step the central path parameter μ can be reduced at least by a factor of $1-\tau/\sqrt{m+n}$, where τ is a positive constant depending on the choices of α, β, t, and the smooth coefficient M in the SLC.*

Analysis on the corrector step. We begin the corrector step with $\delta(u(\theta), v(\theta), \mu(\theta)) \le t\alpha$. Our target is to show that after the step we will have

$$\delta(u^{k+1}, v^{k+1}, \mu_{k+1}) \le \alpha,$$

where

$$u^{k+1} = u(\theta) + \Delta u^c, \quad \mu_{k+1} = \mu(\theta),$$

and

$$v^{k+1} = v(\theta) + \Delta v^c + F(u(\theta) + \Delta u^c) - F(u(\theta)) - F'(u(\theta))\Delta u^c.$$

We will follow the same clue used in the analysis of the predictor step. Omitting the θ in the parentheses, we estimate

$$\eta_3 \equiv \|\Delta U \Delta v\| \quad \text{and} \quad \eta_4 \equiv \Delta u^T F'(u)\Delta u$$

in Lemmas 3.8 and 3.10, while Lemma 3.9 will guarantee the use of the SLC.

LEMMA 3.8. *If $\delta(u, v, \mu) \le t\alpha$ then*

$$\eta_3 \equiv \|\Delta U \Delta v\| \le \frac{(t\alpha)^2}{1-t\alpha}\mu.$$

Proof. Let

$$r_3 = (UV)^{-1/2} V \Delta u$$

and

$$r_4 = (UV)^{-1/2} U \Delta v.$$

Then

$$r_3 + r_4 = (UV)^{-1/2}(-Uv + \mu e).$$

Since $r_3^T r_4 = \Delta u^T \Delta v = \Delta u^T F'(u)\Delta u \ge 0$, similar to the proof of Lemma 3.3, we have

$$\|\Delta U \Delta v\| \le \|r_3 + r_4\|^2 \le \frac{(t\alpha\mu)^2}{(1-t\alpha)\mu} = \frac{(t\alpha)^2}{1-t\alpha}\mu. \qquad \blacksquare$$

LEMMA 3.9. *In the corrector step if $t\alpha \le \beta/(1+\beta)$, then*

$$\|U^{-1}\Delta u\| \le \beta.$$

Proof. Set $\lambda = 1$ in (3.4), and we get

$$V\Delta u + U\Delta v = -Uv + \mu e. \tag{3.7}$$

Let

$$D = U^{1/2}V^{-1/2}.$$

Multiply both sides of (3.7) by $U^{-1/2}V^{-1/2}$, and we obtain

$$D^{-1}\Delta u + D\Delta v = -U^{-1/2}V^{-1/2}\left(Uv - \mu e\right).$$

Since $\Delta u^T \Delta v = \Delta u^T F'(u)\Delta u \geq 0$, we have

$$\left(D^{-1}\Delta u\right)^T \left(D\Delta v\right) \geq 0$$

and

$$\begin{aligned}\|D^{-1}\Delta u\|^2 &\leq \|D^{-1}\Delta u + D\Delta v\|^2 \\ &\leq \|U^{-1/2}V^{-1/2}\|^2\|Uv - \mu e\|^2 \\ &\leq \left[((1-t\alpha)\mu)^{-1/2}\right]^2 (t\alpha\mu)^2 = \frac{(t\alpha)^2\mu}{1-t\alpha}.\end{aligned}$$

On the other hand,

$$\begin{aligned}\|D^{-1}\Delta u\|^2 &= \|U^{1/2}V^{1/2}U^{-1}\Delta u\|^2 \\ &\geq (1-t\alpha)\mu\|U^{-1}\Delta u\|^2.\end{aligned}$$

Hence we get

$$\|U^{-1}\Delta u\| \leq \frac{t\alpha}{1-t\alpha} \leq \beta. \qquad \square$$

LEMMA 3.10. *If $\delta(u, v, \mu) \leq t\alpha$, then*

$$\eta_4 \equiv \Delta u^T F'(u)\Delta u \leq \frac{(t\alpha)^2}{4(1-t\alpha)}\mu.$$

Proof. The proof is very similar to the proof of Lemma 3.5, so we omit the details. The only changes we have to make are to replace Uv and $U^{1/2}v^{1/2}$ with $Uv - \mu e$ and $\left(U^{-1/2}V^{-1/2}\right)(Uv - \mu e)$, respectively, and to use the fact that

$$\frac{\left(U^{-1/2}V^{-1/2}\right)(Uv - \mu e)}{4} \leq \frac{\|Uv - \mu e\|^2}{4(1-t\alpha)\mu} \leq \frac{(t\alpha)^2}{4(1-t\alpha)}\mu. \qquad \square$$

PROPOSITION 3.11. *If the parameters α, t, and M satisfy*

$$\frac{(t\alpha)^2}{1-t\alpha} + \frac{M(t\alpha)^2}{2(1-t\alpha)} \leq \alpha,$$

for example, we can choose

$$t = 2 \text{ and } 0 < \alpha \leq \frac{1}{6+2M};$$

then we have $(u^{k+1}, v^{k+1}) > 0$, and $\delta(u^{k+1}, v^{k+1}, \mu_{k+1}) \leq \alpha$.

Proof. Using similar derivations to that of (3.6) and invoking Lemmas 3.8–3.10, we have

$$\begin{aligned}
&\left\|V_{k+1}u^{k+1} - \mu_{k+1}e\right\| \\
&\le \|\Delta U \Delta v\| + 2M\left[\Delta u F'(u)\Delta u\right] \\
&= \eta_3 + 2M\eta_4 \\
&\le \frac{(t\alpha)^2\mu}{1-t\alpha} + \frac{M(t\alpha)^2\mu}{2(1-t\alpha)} \le \alpha\mu = \alpha\mu_{k+1}.
\end{aligned}$$

Thus we have $\delta(u^{k+1}, v^{k+1}, \mu_{k+1}) \le \alpha$, which further implies $(u^{k+1}, v^{k+1}) > 0$. ∎

Back to the saddle point algorithm 3.1, it is easy to see that $(x^k, y^k, w^k, s^k) > 0$ for all k because $\delta(x^k, y^k, w^k, s^k, \mu_k) < 1$. In addition, the choices of $(x^{k+1}, y^{k+1}, w^{k+1}, s^{k+1})$ in the algorithm ensure that condition (2.4) is satisfied for all k. Thus, by Proposition 2.2, x^k and y^k are feasible to problems (1.1) and (1.2), respectively, for all k.

In summary, the algorithm keeps $(x^k, y^k, w^k, s^k) > 0$ and $\delta(x^k, y^k, w^k, s^k, \mu^k) \le \alpha$ for each k while reducing μ at a linear rate of $1 - O[(m+n)^{-1/2}]$. From Proposition 2.6, it is readily to see that, in order to find an ϵ-optimal solution (x^k, y^k) of problem (1.1) satisfying $f(x^k) - g(y^k) \le \epsilon$, only $O\left[\sqrt{m+n}\,|\log(m+n)\mu_0/\epsilon|\right]$ iterations are necessary. Since μ_0/ϵ is usually larger than $m+n$, the algorithm has polynomial complexity of $O\left(\sqrt{m+n}|\log \mu_0/\epsilon|\right)$.

Remarks on taking advantage of the problem structure. Practical problems formulated as problem (1.1) often have special structures. For instance, in the two-stage model of stochastic programming mentioned in section 1, the matrix $\nabla^2\psi(y)$ is very large and block diagonal, whereas the matrix $\nabla^2\phi(x)$ is of ordinary size. So the key point is how to reduce the amount of work for solving system (3.2). The special feature of system (3.2) allows us to reduce the amount of computations substantially. Let us elucidate this point in some detail.

Problems with large, block-diagonal $\nabla^2\psi(y)$ and small $\nabla^2\phi(x)$. Substituting Δw and Δs into the last two equations and canceling Δy, we obtain an equivalent system to (3.2):

$$\begin{cases}
\left\{\nabla^2\phi(x) + X^{-1}W + A^T\left[\nabla^2\psi(y) + Y^{-1}S\right]^{-1}A\right\}\Delta x \\
\quad = A^T\left[\nabla^2\psi(y) + Y^{-1}S\right]^{-1}\left(-s + \lambda\mu Y^{-1}e\right) - w + \lambda\mu X^{-1}e, \\
\left[\nabla^2\psi(y) + Y^{-1}S\right]\Delta y = -A\Delta x - s + \lambda\mu Y^{-1}e, \\
\Delta w = \nabla^2\phi(x)\Delta x - A^T\Delta y, \\
\Delta s = A\Delta x + \nabla^2\psi(y)\Delta y.
\end{cases} \tag{3.8}$$

The principal work is to solve the first equation in (3.8). Since the dimension of x is low (less than 100, say), we can solve system (3.8) exactly even if the dimension of y is high. Notice that the matrix $(\nabla^2\psi(y) + Y^{-1}S)$ has a block-diagonal structure. Hence $A^T[\nabla^2\psi(y) + Y^{-1}S]^{-1}A$ can be computed blockwise. In particular the computation can proceed in parallel. The solution of the first equation in (3.8) can be obtained by a factorization of $\nabla^2\phi(x) + X^{-1}W + A^T[\nabla^2\psi(y) + Y^{-1}S]^{-1}A$, which might be a dense matrix but must be a low-dimensional and symmetric positive definite matrix. After Δx is obtained from the first equation, Δy can be calculated through the second

equation of (3.8) using $[\nabla^2\psi(y)+Y^{-1}S]^{-1}$ computed in the first step. As a matter of fact, we may store the block factorizations of $\nabla^2\psi(y)+Y^{-1}S$ in the first step for later use in the second step. Subsequently, we get Δw and Δs.

Problems with large, block-diagonal $\nabla^2\psi(y)$, $\nabla^2\phi(x)$, and block-banded A. Discretized optimal control problems often have large, block-diagonal $\nabla^2\psi(y)$ and $\nabla^2\phi(x)$ as described in [20] and [24]. In addition, the matrix A in problem (1.1) can be partitioned into blocks such that the resulting matrix of blocks is banded [32], [33]. For instance, the dynamic constraint system

$$x_t = A_t x_{t-1} + B_t u_t + b_t \text{ for } t = 0,\dots,T \text{ with } A_0 = 0 \tag{3.9}$$

can be expressed as an additional term in the saddle function (1.1):

$$-\sum_{t=0}^{T}(y_t - z_t)^T(-x_t + A_t x_{t-1} + B_t u_t + b_t), \tag{3.10}$$

where $y_t \ge 0,\ z_t \ge 0$ are some additional dual vectors. By doing this, we generate an infinite penalty for the violation of constraints (3.9) in the primal problem. Let $u = (u_0,\dots,u_T)$ be the primal control vector and $x = (x_0,\dots,x_T)$ be the primal state vector. It can be seen that the submatrix of A in problem (1.1) corresponding to the primal vector (u,x) and the dual vector $(y,z) = (y_0,\dots,y_T,z_0,\dots,z_T)$ is

$$\bar{A} = \begin{bmatrix} B & F \\ -B & -F \end{bmatrix}, \text{ where } B = \begin{bmatrix} B_0 & & \\ & \ddots & \\ & & B_T \end{bmatrix}, \quad F = \begin{bmatrix} -I_0 & & & \\ A_1 & -I_1 & & \\ & \ddots & \ddots & \\ & & A_T & -I_T \end{bmatrix}.$$

The computation of $A^T(\nabla^2\psi(y)+Y^{-1}S)^{-1}A$ in (3.8) will require us to compute the submatrices

$$M_1 \equiv \bar{Y}^{-1}\bar{S}_y,\ M_2 \equiv \bar{Z}^{-1}\bar{S}_z, \text{ and } \bar{A}^T\begin{bmatrix} M_1 & \\ & M_2 \end{bmatrix}^{-1}\bar{A},$$

where $\bar{Y},\ \bar{S}_y,\ \bar{Z}$, and $\bar{S}_z$ are some diagonal matrices. Note that

$$\begin{aligned} \bar{A}^T\begin{bmatrix} M_1 & \\ & M_2 \end{bmatrix}^{-1}\bar{A} &= \begin{bmatrix} B & F \\ -B & -F \end{bmatrix}^T\begin{bmatrix} M_1 & \\ & M_2 \end{bmatrix}^{-1}\begin{bmatrix} B & F \\ -B & -F \end{bmatrix} \\ &= \begin{bmatrix} B^T(M_1^{-1}+M_2^{-1})B & B^T(M_1^{-1}+M_2^{-1})F \\ F^T(M_1^{-1}+M_2^{-1})B & F^T(M_1^{-1}+M_2^{-1})F \end{bmatrix} \\ &\equiv \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix}. \end{aligned}$$

According to the structures of M_1, M_2, B, and F, matrix H_{11} is a block-diagonal matrix, matrix $H_{12} = H_{21}^T$ is a block-band matrix with bandwidth 2, and matrix H_{22} is also a block-band one with bandwidth 3. Therefore it is possible to solve equation system (3.8) by using block operations applied to a banded system.

The case of $\mathcal{X}$ and $\mathcal{Y}$ being boxes. Now we explain why changing $\mathcal{X}$ and $\mathcal{Y}$ into boxes will not complicate the computation. Consider a simple case that both $\mathcal{X}$ and $\mathcal{Y}$ are closed-end boxes:

$$\mathcal{X} = \{x \in R^n | 0 \le x \le u < \infty\} \text{ and } \mathcal{Y} = \{y \in R^m | 0 \le y \le v < \infty\}.$$

By introducing auxiliary variables $x^1 = u - x$, $y^1 = v - y$, s, s^1, w, and w^1 and using the variational relationships, the saddle point condition can be written as follows:

$$\begin{cases} \nabla\phi(x) - A^T y - w + w^1 = -c, \\ Ax + \nabla\psi(y) - s + s^1 = b, \\ x + x^1 = u, \\ y + y^1 = v, \\ x^T w = (x^1)^T w^1 = y^T s = (y^1)^T s^1 = 0, \\ x, x^1, y, y^1, w, w^1, s, s^1 \geq 0. \end{cases}$$

The corresponding Newton equations become

$$\begin{cases} \nabla^2\phi(x)\Delta x - A^T\Delta y + \Delta w^1 - \Delta w = a^1, \\ A\Delta x + \nabla^2\psi(y)\Delta y + \Delta s^1 - \Delta s = a^2, \\ \Delta x + \Delta x^1 = a^3, \\ \Delta y + \Delta y^1 = a^4, \\ X\Delta w + W\Delta x = a^5, \\ Y\Delta s + S\Delta y = a^6, \\ W_1\Delta x^1 + X_1\Delta w^1 = a^7, \\ S_1\Delta y^1 + Y_1\Delta s^1 = a^8, \end{cases} \tag{3.11}$$

where $a^1, \ldots, a^8$ are certain fixed vectors. After canceling all variables with superscript 1, we get a system whose major equations are

$$\begin{cases} \left[\nabla^2\phi(x) + X^{-1}W + X_1^{-1}W_1\right]\Delta x - A^T\Delta y = b^1, \\ A\Delta x + \left[\nabla^2\psi(y) + Y^{-1}S + Y_1^{-1}S_1\right]\Delta y = b^2, \end{cases} \tag{3.12}$$

where b^1 and b^2 are certain fixed vectors. After canceling Δy, system (3.12) becomes a similar system to (3.8). Therefore the computations needed for solving system (3.11) are roughly the same as solving system (3.2). Hence there are no significant changes in the algorithm if $\mathcal{X}$ and $\mathcal{Y}$ are changed into boxes. The case that $\mathcal{X}$ and $\mathcal{Y}$ are half-open-end and half-closed-end boxes can be treated analogously.

4. Conclusions and final remarks. We have shown the polynomiality of a predictor-corrector algorithm for a class of nonlinear saddle point problems. The model is an extension of the traditional Lagrange multiplier model in optimization. The results on existence of the central path and the relationship between the central path and the duality gap established in section 2 are useful in developing other interior path-following algorithms.

Several issues deserve further investigation.

(i) *The smooth condition.* We have proposed the SLC as the smooth condition. In the context of convex programming, various smooth conditions were proposed to characterize the problems which will have polynomial interior point algorithms. We refer the reader to references [4] and [15] for more details. A direction of future studies is to identify different classes of practical saddle point problems which will have polynomial interior point algorithms under smooth conditions other than the SLC.

(ii) *Infeasible starting point.* Algorithm 3.1 requires a starting point near the central path. It could be an obstacle if such a starting point is not provided. Recently,

much research has been done on interior point algorithms starting from an *infeasible* interior point; see [8, 12, 13, 29, 33, 35] for examples. The algorithms reduce both infeasibility and duality gap simultaneously. Some of the algorithms use large neighborhoods of the central path and have been tested, e.g., Wright and Ralph [33]. It makes practical sense to develop infeasible interior point methods with large stepsizes for saddle point problems like (1.1).

(iii) *Computation-related developments.* Primary studies [26, 32, 33] show that interior point methods might be fairly effective in solving linear-quadratic problems, but comparison studies between interior point methods and other existing methods have not been conducted fully. In addition, for large-scale problems, it is crucial to reduce the amount of computations for matrix inverse and Hessian evaluation. It is meaningful to develop algorithms that, for instance, can use inexact directions, inaccurate Hessians, and parallelizations in predictor and corrector steps.

THE SYNTHESIS OF UNIVERSAL FEEDBACK PURSUIT STRATEGIES IN DIFFERENTIAL GAMES*

F. H. CLARKE†, YU. S. LEDYAEV‡, AND A. I. SUBBOTIN§

Abstract. We show how any (generalized) supersolution of the Hamilton–Jacobi equation can be used to construct a feedback pursuit strategy which guarantees (to any given tolerance) a capture time not exceeding the solution's value. If the supersolution is the value function, then a near-optimal pursuit strategy is obtained in this way. An important feature of the construction is its "universal" nature, i.e., the fact that the feedback law is uniformly effective on compact sets of initial conditions. This implies in particular that the feedback construction is one that exploits nonoptimal behavior on the part of the evader.

Key words. pursuit, differential game, feedback, synthesis, proximal analysis, Hamilton–Jacobi equation

AMS subject classification. 93B52

PII. S0363012995283972

Introduction. The differential equation bearing the names of Hamilton and Jacobi and of Bellman and Isaacs has been the essential ingredient of the dynamic programming approach to solving differential games. When the value function is smooth, it constitutes a classical solution of that equation; further, its derivatives give rise easily to optimal strategies in feedback form (we recall this familiar argument in section 1). Of course, it is now understood that it is essential to consider the value function as a solution in some generalized sense (minimax or viscosity, for example) via constructs of nonsmooth analysis [3]: derivates, generalized gradients, subdifferentials, etc. (see [5] for an overview of this topic). In this more realistic setting, the issue of effective feedback synthesis is a more subtle one; it is the one we focus upon in this article.

The particular tool of nonsmooth analysis used here is the *proximal subdifferential* $\partial_P f$ of a lower semicontinuous function f mapping $\mathbb{R}^n$ to $(-\infty, \infty]$. An element ζ of $\mathbb{R}^n$ belongs to $\partial_P f(x)$ (for a given x at which f is finite) iff there exists $\sigma \geq 0$ and a neighborhood $N(x)$ of x such that

$$f(y) - f(x) + \sigma \|y - x\|^2 \geq \langle \zeta, y - x \rangle \quad \forall y \in N(x).$$

Supersolutions of the Hamilton–Jacobi equation can be defined in terms of the proximal subdifferential in a manner akin to the well-known approaches of Subbotin [14] and of Crandall and Lions [6] (see section 2 and [4] for a comparison of these solution concepts). As shown in [5], the proximal approach is particularly well suited to

the construction of (set) invariant feedbacks; that same property is what lies at the heart of the present article. Experts will recognize our basic constructs in part as especially simple yet powerful variants of the extremal aiming techniques introduced by Krasovskii and Subbotin [10]. The simplicity of the approach is underlined by the fact that the main result (Theorem 2.1) is completely self-contained, although we do cite a few other results in the next section for the purpose of situating the present contribution.

The context of this article is that of a general differential game of pursuit and evasion. Starting with any supersolution of the associated Hamilton–Jacobi equation, Theorem 2.1 constructs an explicit feedback pursuit strategy which guarantees (to any specified tolerance) a capture time no greater than the value of the supersolution at the starting point x_0. When the supersolution is the value function, the ε-optimal feedback strategies are obtained.

An important feature of this feedback is its "universality," i.e., the property of remaining uniformly effective for all starting positions x_0 in a given compact set. In practical terms, this implies that the feedback strategy is one that exploits nonoptimal behavior: if the evader makes a bad move, this is equivalent to starting over from a new position from which the capture time is less, but then the given feedback pursuit strategy is effective from this new starting point. Similarly, a universal strategy is one that has robustness properties in the presence of jumps or uncertainties in state position.

1. The time-optimal differential game. We proceed to formulate precisely a time-optimal differential game whose payoff is the elapsed time before the state reaches a prescribed terminal set. The value function of the game may be discontinuous and extended valued.

Main assumptions. Let the motion of the controlled system be described by the equation

$$\dot{x}(t) = f(x(t), p(t), q(t)), \tag{1.1}$$

where $x(t) \in \mathbb{R}^n$ is the state, $p(t) \in P$ and $q(t) \in Q$ are the controls of the pursuer and the evader, and P and Q are compact sets. It is assumed that the function $f : \mathbb{R}^n \times P \times Q \mapsto \mathbb{R}^n$ is continuous and satisfies the Lipschitz condition

$$\|f(x,p,q) - f(y,p,q)\| \le \lambda \|x - y\| \tag{1.2}$$

for all $x, y \in \mathbb{R}^n$, $p \in P$, $q \in Q$. Suppose for the moment that

$$\min_{p\in P}\max_{q\in Q}\langle s, f(x,p,q)\rangle = \max_{q\in Q}\min_{p\in P}\langle s, f(x,p,q)\rangle =: H(x,s) \tag{1.3}$$

for all $s \in \mathbb{R}^n$ and $x \in \mathbb{R}^n$. This local saddle point condition is a familiar one frequently referred to as the *Isaacs condition*. The function $H(x,s)$ defined by the equality (1.3) is called the Hamiltonian.

Under the above assumptions, for any initial point $x_0 \in \mathbb{R}^n$ and any choice of measurable controls $p(\cdot) : \mathbb{R}^+ \mapsto P$, $q(\cdot) : \mathbb{R}^+ \mapsto Q$, the corresponding solution of equation (1.1) exists, is unique, and can be extended over the whole semiaxis $\mathbb{R}^+ := [0, \infty)$.

Let a closed set $M \subset \mathbb{R}^n$ be given. We define τ the payoff functional on the space $\mathcal{C}(\mathbb{R}^+; \mathbb{R}^n)$ of continuous functions $x(\cdot) : \mathbb{R}^+ \mapsto \mathbb{R}^n$ by the equality

$$\tau(x(\cdot)) := \min\{t \in \mathbb{R}^+ : x(t) \in M\}. \tag{1.4}$$

If $x(t) \notin M$ for all $t \in \mathbb{R}^+$, then we put $\tau(x(\cdot)) = \infty$.

Feedback strategies and value. An arbitrary function $U : \mathbb{R}^n \mapsto P$ (a function $V : \mathbb{R}^n \mapsto Q$) will be called a feedback strategy of the pursuer (the evader). Let an initial point $x_0 \in \mathbb{R}^n$ be given. Let a feedback strategy U and a partition Δ of $[0, \infty)$,

$$\Delta := \{0 = t_0 < t_1 < \cdots\}, \quad t_i \to \infty \quad \text{as } i \to \infty,$$

be chosen by the pursuer. Denote by $\mathbf{X}(x_0, U, \Delta)$ the set of "step-by-step" trajectories of the differential inclusion

$$\dot{x}(t) \in \operatorname{co}\{f(x(t), U(x(t_i)), q) : q \in Q\}, \tag{1.5}$$

$t_i \le t < t_{i+1}$, $i = 0, 1, 2, \ldots$. Specifically, the elements of the set $\mathbf{X}(x_0, U, \Delta)$ are continuous functions $x(\cdot)\colon \mathbb{R}^+ \mapsto \mathbb{R}^n$ which satisfy the initial condition $x(0) = x_0$; for any $\theta > 0$ their restrictions to $[0, \theta]$ are absolutely continuous and satisfy the differential inclusion (1.5) for almost all $t \in [0, \theta]$.

Similarly, let a feedback strategy $V : \mathbb{R}^n \mapsto Q$ and a partition Δ be chosen by the evader. By the symbol $\mathbf{X}(x_0, V, \Delta)$ we denote the set of step-by-step trajectories of the differential inclusion

$$\dot{x}(t) \in \operatorname{co}\{f(x(t), p, V(x(t_i)))\colon p \in P\}, \tag{1.6}$$

$t_i \le t < t_{i+1}$, $i = 0, 1, 2, \ldots$. It is obvious that any pair (U, V) of feedback strategies of the pursuer and the evader is compatible in the following sense: for arbitrary partitions $\Delta^{(1)}$ and $\Delta^{(2)}$ chosen by the pursuer and the evader there exists a unique trajectory of (1.1) corresponding to the controls given by

$$p(t) = U(x(t_i^{(1)})), \quad t_i^{(1)} \le t < t_{i+1}^{(1)}, \quad t_i^{(1)} \in \Delta^{(1)},\ i = 0, 1, 2, \ldots,$$
$$q(t) = V(x(t_j^{(2)})), \quad t_j^{(2)} \le t < t_{j+1}^{(2)},\ t_j^{(2)} \in \Delta^{(2)},\ j = 0, 1, 2, \ldots.$$

Therefore $\mathbf{X}(x_0, U, \Delta^{(1)}) \cap \mathbf{X}(x_0, V, \Delta^{(2)}) \ne \emptyset$.

Below we will use the notation

$$\operatorname{diam}(\Delta) := \sup_i (t_{i+1} - t_i) \quad \text{for } i = 0, 1, 2, \ldots. \tag{1.7}$$

Since the payoff functional (1.4) may in general be discontinuous, we need some additional constructions in order to define the value. Consider the functional

$$\tau_\varepsilon(x(\cdot)) := \min\{t \in \mathbb{R}^+ : x(t) \in M^\varepsilon\}. \tag{1.8}$$

If $x(t) \notin M^\varepsilon$ for all $t \in \mathbb{R}^+$, then we put $\tau_\varepsilon(x(\cdot)) := \infty$. Here ε is a positive number and M^ε is the ε-neighborhood of the terminal set M; that is,

$$M^\varepsilon := \{x + y : x \in M,\ \|y\| \le \varepsilon\}.$$

Further we introduce the values

$$T_1^\varepsilon(x_0, U, \Delta) := \sup\{\tau_\varepsilon(x(\cdot)) : x(\cdot) \in \mathbf{X}(x_0, U, \Delta)\},$$
$$T_1^\varepsilon(x_0, U) := \limsup_{\operatorname{diam}(\Delta) \downarrow 0} T_1^\varepsilon(x_0, U, \Delta),$$
$$T_1^\varepsilon(x_0) := \inf_U T_1^\varepsilon(x_0, U),$$
$$T_1^0(x_0) := \lim_{\varepsilon \downarrow 0} T_1^\varepsilon(x_0).$$

It is evident that $T_1^{\varepsilon'}(x_0) \geq T_1^{\varepsilon''}(x_0)$ for $\varepsilon' \leq \varepsilon''$. From this monotonicity we have that the last limit exists.

The quantity $T_1^0(x_0)$ is called the optimal result for the pursuer in the class of feedback strategies. Assume that $T_1^0(x_0) < \infty$. From the definition we obtain immediately that for any $\varepsilon > 0$ and $\theta > T_1^0(x_0)$ a feedback strategy U_* and a number $\delta > 0$ can be found such that for any step-by-step motion $x(\cdot) \in \mathbf{X}(x_0, U_*, \Delta)$, where $\operatorname{diam}(\Delta) \leq \delta$ the point $x(t)$ reaches the ε-neighborhood of the set M no later than at time θ.

Similarly we define the optimal result for the evader. We set

$$\begin{aligned} T_2^\varepsilon(x_0, V, \Delta) &:= \inf\{\tau_\varepsilon(x(\cdot)) : x(\cdot) \in \mathbf{X}(x_0, V, \Delta)\}, \\ T_2^\varepsilon(x_0, V) &:= \liminf_{\operatorname{diam}(\Delta)\downarrow 0} T_2^\varepsilon(x_0, V, \Delta), \\ T_2^\varepsilon(x_0) &:= \sup_V T_2^\varepsilon(x_0, V), \\ T_2^0(x_0) &:= \lim_{\varepsilon\downarrow 0} T_2^\varepsilon(x_0). \end{aligned}$$

The quantity $T_2^0(x_0)$ is called the optimal result for the evader in the class of feedback strategies. From the definitions we have that for any $\theta < T_2^0(x_0)$ there exist an $\varepsilon > 0$, a feedback strategy V_*, and a $\delta > 0$ such that any step-by-step motion $x(\cdot) \in \mathbf{X}(x_0, V_*, \Delta)$ on the time interval $[0, \theta]$ will avoid the ε-neighborhood of the set M, provided $\operatorname{diam}(\Delta) \leq \delta$.

For arbitrary step-by-step control choices $(U, \Delta^{(1)})$ and $(V, \Delta^{(2)})$ of the pursuer and the evader we have the inequalities

$$T_1^\varepsilon(x_0, U, \Delta^{(1)}) \geq \tau_\varepsilon(x_*(\cdot)) \geq T_2^\varepsilon(x_0, V, \Delta^{(2)}),$$

where

$$x_*(\cdot) \in \mathbf{X}(x_0, U, \Delta^{(1)}) \cap \mathbf{X}(x_0, V, \Delta^{(2)}).$$

Therefore $T_1^0(x_0) \geq T_2^0(x_0)$.

It is known [10] that under our assumptions the value $\operatorname{Val}(x_0)$ of the time-optimal differential game exists; that is, the equality

$$\operatorname{Val}(x_0) := T_1^0(x_0) = T_2^0(x_0) \tag{1.9}$$

holds.

The framework presented here is that of Krasovskii and Subbotin [10]. Of course, other well-known approaches have been developed; see, for example, [1], [2], [7], [8], [12].

The Bellman–Isaacs equation. Consider the following boundary value problem:

$$H(x, Dv(x)) + 1 = 0, \qquad x \in G := \mathbb{R}^n \setminus M, \tag{1.10}$$

$$v(x) = 0, \qquad x \in \partial G, \tag{1.11}$$

where $H(x, s)$ is the Hamiltonian defined by (1.3). For the differential game under consideration, equation (1.10) is called the Bellman–Isaacs equation. Let us recall some well-known facts.

Let a continuous function $v : \overline{G} \mapsto \mathbb{R}^+$ satisfy the boundary condition (1.11). Let this function be continuously differentiable in the domain G and satisfy equation (1.10). Then the function $v(\cdot)$ coincides with the value function $\mathrm{Val}(\cdot)$ of the time-optimal differential game. Moreover, in this case optimal feedback strategies U_0 and V_0 of the pursuer and the evader can be constructed with the help of v as follows. Introduce *extremal prestrategies* [10] which are defined by the relations

$$p_0(x,s) \in \operatorname{Arg}\min_{p\in P}[\max_{q\in Q}\langle s, f(x,p,q)\rangle], \tag{1.12}$$

$$q_0(x,s) \in \operatorname{Arg}\max_{q\in Q}[\min_{p\in P}\langle s, f(x,p,q)\rangle]. \tag{1.13}$$

We construct feedback strategies U_0 and V_0 as compositions of the prestrategies and the gradient Dv; that is,

$$U_0(x) := p_0(x, Dv(x)), \quad V_0(x) := q_0(x, Dv(x)). \tag{1.14}$$

It is well known, however, that the value function is differentiable only in rare situations. We will show that in the general case, optimal or suboptimal strategies of the pursuer can still be defined via v by relations of the form (1.14), but instead of the gradient $Dv(x)$, proximal subgradients of v are utilized.

2. The main result. Since it is unrealistic to suppose that v is smooth, a generalized solution concept is required. For our present purposes, we consider *proximal solutions*. We stress that as a solution concept, this is entirely equivalent (see [4]) to the earlier formulations of minimax [13], [14] or viscosity solutions [6], but certain advantages derive from using the proximal formulation: the calculus is more natural than that of Dini subderivates (used in minimax solutions) or that of comparison functions (used in viscosity solutions), and the geometric interpretation of a proximal subgradient lends itself to the dualization of results in either set terms or functional terms. To put this another way, the proximal formulation leads to a generalized solution concept that is well integrated with both the theory of nonsmooth analysis and a body of results in control theory bearing on many other issues, as opposed to standing alone. The survey paper [5] is in part a demonstration of this point.

A lower semicontinuous function $v\colon \overline{G} \to [0,\infty]$ is called a *proximal supersolution* of (1.10) provided that

$$H(x,\zeta) + 1 \le 0 \quad \forall x \in G, \qquad \forall \zeta \in \partial_P v(x). \tag{2.1}$$

Note that the inequality (2.1) holds vacuously at points x for which $\partial_P v(x)$ is empty (among which are the points x at which $v(x) = \infty$).

Given any nonnegative lower semicontinuous proximal supersolution v, we associate with it for any $\alpha \in (0, 1/2)$ a certain feedback strategy U_α^P of the pursuer, as follows. For $x \in \overline{G}$, select any minimizer $y_\alpha(x)$ over $\overline{G}$ of the function

$$y \mapsto \frac{|x-y|^2}{2\alpha^2} - \exp\{-2\lambda v(y)\}.$$

This minimum over $\overline{G}$ is attained, as is easily seen. Thus we have

$$y_\alpha(x) \in \operatorname{Arg}\min_{y\in\overline{G}}\left\{\frac{|x-y|^2}{2\alpha^2} - \exp(-2\lambda v(y))\right\}. \tag{2.2}$$

Subsequently, set

$$\zeta_\alpha(x) := \frac{x - y_\alpha(x)}{\alpha^2} \tag{2.3}$$

and define

$$U_\alpha^P(x) := p_0(x, \zeta_\alpha(x)), \tag{2.4}$$

where p_0 is an extremal prestrategy (1.12). Observe that the specification of U_α^P is quite explicit.

In what follows, we posit the hypotheses of the previous section on the data of the problem, except that the Isaacs condition (1.3) is *not* required. In its absence, and without having recourse to relaxed (mixed) control strategies or counterstrategies of the evader, the existence of the value cannot be asserted. However, this has no bearing on the theorem below, which simply provides a feedback strategy for one player (the pursuer) furnishing (up to a specified tolerance) a guaranteed result corresponding to any supersolution. In this one-sided setting, the Hamiltonian H appearing in (2.1) is given by

$$H(x, \zeta) := \min_{p \in P} \max_{q \in Q} \langle \zeta, f(x, p, q) \rangle.$$

THEOREM 2.1. *Let $v: \overline{G} \to [0, \infty]$ be a lower semicontinuous proximal supersolution of the Bellman–Isaacs equation (i.e., v satisfies (2.1)). Let D be a compact subset of G upon which v is bounded. Then for any $\varepsilon > 0$, there exist $\alpha > 0$ and $\delta > 0$ such that*

$$x_0 \in D,\ \operatorname{diam}(\Delta) < \delta \Rightarrow T_1^\varepsilon(x_0, U_\alpha^P, \Delta) \le v(x_0) + \varepsilon, \tag{2.5}$$

where U_α^P is the feedback strategy constructed from v as described above.

Remark 2.2.

(a) The feedback strategy U_α^P is defined independently of D, and the theorem asserts that it is "universal"; i.e., that within the specified tolerance and for α small enough (this does depend on D), it provides the guaranteed upper bound associated with v uniformly for all initial points in D.

(b) It follows from the results in [14] that in the presence of the Isaacs condition the value function $\operatorname{Val}(\cdot)$ is a supersolution of the Bellman–Isaacs equation. In fact, it is the minimal supersolution satisfying the boundary condition $v(x) = 0$, $x \in \partial G$. With $v(\cdot) = \operatorname{Val}(\cdot)$, the theorem then provides a universal ε-optimal feedback strategy. Note, however, that we do not suppose here that v coincides with Val and that (surprisingly) no boundary condition on ∂G enters into the theorem. The theorem evidently implies $T_1^0 \le v$.

(c) The construction of U_α^P corresponds to a functional version of the geometric approach called "proximal aiming" in [5]; it can also be viewed as a variant of the extremal aiming method of [9], [10]. We stress that the proof of the theorem is completely self-contained and elementary and that specific criteria for α and $\operatorname{diam}(\Delta)$ to be "small enough" can be inferred from it. Thus the feedback U_α^P is implementable at least conceptually. Let us stress that "small enough" here corresponds to picking α small *first* and *then* $\delta = \operatorname{diam}(\Delta)$ small in accordance with the order of the iterated limit appearing in (2.12) below.

(d) We remark that the construction of an explicit universal feedback strategy for the evader appears to be an essentially different problem, one that we do not address

here. It is known [10] that in the presence of the Isaacs condition, an appropriate pair of pursuit/evasion strategies would give rise to an approximate saddle point.

Proof of Theorem 2.1. We define a new lower semicontinuous $u\colon \overline{G} \to [0,1]$ via the Kruzhkov transformation:

$$u(x) := 1 - \exp(-2\lambda v(x)). \tag{2.6}$$

Then we claim that $u(\cdot)$ satisfies

$$H(x,\zeta) - 2\lambda(u(x)-1) \le 0 \quad \forall x \in G, \qquad \forall \zeta \in \partial_P u(x). \tag{2.7}$$

This is straightforward from (2.1), (2.6) when $u(x) < 1$, since then $v(x) < \infty$ and $\partial_P u(x)$ and $\partial_P v(x)$ are related in an evident way. When $u(x) = 1$, the only possible element ζ of $\partial_P u(x)$ is $\zeta = 0$, as follows readily from the definition of $\partial_P u(x)$ and the fact that $u \le 1$ everywhere. But then (2.7) holds, since $H(x,0) = 0$.

We define u_α on $\mathbb{R}^n$ by

$$u_\alpha(x) := \min_{y \in \overline{G}} \left\{ u(y) + \frac{|x-y|^2}{2\alpha^2} \right\}, \tag{2.8}$$

an inf-convolution familiar in many settings, notably convex and functional analysis (Moreau–Yosida approximations) and partial differential equations (see, for example, [11], [15]).

Note that by (2.2) the minimum is attained at $y_\alpha(x)$ and that we have $0 \le u_\alpha(x) \le u(x) \le 1$. In addition, the minimum must be attained at points y for which $|x-y|^2/(2\alpha^2)$ is no greater than 1, whence

$$|x - y_\alpha(x)| \le 2\alpha. \tag{2.9}$$

Finally, when $y_\alpha(x) \in G$ (open), then the stationarity condition holds at $y_\alpha(x)$: zero is a proximal subgradient of the function of y appearing in (2.8); i.e., we have

$$y_\alpha(x) \in G \Rightarrow \zeta_\alpha(x) \in \partial_P u(y_\alpha(x)) \tag{2.10}$$

(recall that ζ_α is defined by (2.3)).

Denote by $X(x_0)$ the family of all trajectories $x(\cdot)$ on $[0,\infty)$ of the differential inclusion

$$\dot{x}(t) \in \operatorname{co}\{f(x(t),p,q)\colon p \in P, q \in Q\}$$

satisfying the initial condition $x(0) = x_0$. Let T_0 be an upper bound for $v(\cdot)$ on D, and define

$$K := \{x(t) \in \mathbb{R}^n\colon x(\cdot) \in X(x_0), t \in [0, T_0+1]\},$$
$$m := \sup\{|f(x,p,q)|\colon x \in K, p \in P, q \in Q\}.$$

Note that K is bounded and $m < \infty$. Choose numbers $\alpha \in (0,1/2)$ and $\delta_0 > 0$ such that

$$3\alpha \le \varepsilon. \tag{2.11}$$

Choose any $x_0 \in D$ and set $\theta := v(x_0) + \varepsilon$. Without loss of generality we may assume $\varepsilon \le 1$, so that $\theta \le T_0 + 1$.

We now construct a certain function h which will provide the estimate (2.5) of the theorem. □

LEMMA 2.3. *There is a nonnegative function $h(\alpha,\delta)$ depending only on α and δ (and not on $x_0 \in D$ nor on $x(\cdot) \in X(x_0, U_\alpha^P, \Delta)$) such that*

$$\lim_{\alpha\downarrow 0}(\lim_{\delta\downarrow 0} h(\alpha,\delta)) = 0 \tag{2.12}$$

and having the following property: for any $x(\cdot) \in X(x_0, U_\alpha^P, \Delta)$ let $t_i \in \Delta$, $t_i < \theta$ and suppose $\operatorname{dist}(x(t_i), M) > 3\alpha$. *Then for any $\tau \in [t_i, t_{i+1}] \cap [0,\theta]$ we have*

$$u_\alpha(x(\tau)) \le 1 + e^{2\lambda(\tau-t_i)}[u_\alpha(x(t_i)) - 1] + (\tau - t_i)e^{2\lambda(\tau-t_i)}h(\alpha, \operatorname{diam}(\Delta)). \tag{2.13}$$

To prove this, let f^* be defined by

$$f^* := \frac{x(\tau) - x(t_i)}{\tau - t_i} = \frac{1}{\tau - t_i}\int_{t_i}^{\tau} \dot{x}(t)\,dt.$$

Note that $\dot{x}(t) \in \operatorname{co}\{f(x(t), U_\alpha^P(x(t_i)), q)\colon q \in Q\}$ and $|f^*| \le m$. Below we use the notation

$$\xi := x(t_i), \qquad \zeta_\alpha := \zeta_\alpha(\xi), \qquad \eta_\alpha := y_\alpha(x(t_i)), \qquad \mu := \tau - t_i.$$

Note that $\zeta_\alpha = (\xi - \eta_\alpha)/\alpha^2$ and $u_\alpha(x(\tau)) = u_\alpha(\xi + \mu f^*)$. We observe from (2.8) and the definition of $\eta_\alpha = y_\alpha(\xi)$ that

$$\begin{aligned} u_\alpha(\xi + \mu f^*) &\le u(\eta_\alpha) + |\xi + \mu f^* - \eta_\alpha|^2/(2\alpha^2) \\ &= u(\eta_\alpha) + |\xi - \eta_\alpha|^2/(2\alpha^2) + \langle \xi - \eta_\alpha, \mu f^*\rangle/\alpha^2 + \frac{\mu^2}{2\alpha^2}|f^*|^2 \\ &= u_\alpha(\xi) + \mu\langle \zeta_\alpha, f^*\rangle + \frac{\mu^2}{2\alpha^2}|f^*|^2. \end{aligned} \tag{2.14}$$

We now require a bound for the middle term in this last expression.

By definition (i.e., (2.4)) we have

$$\max_{q\in Q}\langle \zeta_\alpha, f(\xi, U_\alpha^P(\xi), q)\rangle = \min_{p\in P}\max_{q\in Q}\langle \zeta_\alpha, f(\xi, p, q)\rangle = H(\xi, \zeta_\alpha),$$

whence

$$\langle \zeta_\alpha, f\rangle \le H(\xi, \zeta_\alpha) \quad \forall f \in \operatorname{co}\{f(\xi, U_\alpha^P(\xi), q)\colon q \in Q\}.$$

Also, we have $|\xi - \eta_\alpha| \le 2\alpha$ and $|\zeta_\alpha| \le 2/\alpha$ by (2.9) and (2.3). Invoking the positive homogeneity of $H(x,s)$ in s and its Lipschitz continuity in x, we derive

$$\begin{aligned} H(\xi, \zeta_\alpha) &\le H(\eta_\alpha, \zeta_\alpha) + \lambda|\xi - \eta_\alpha|\,|\zeta_\alpha| \\ &= H(\eta_\alpha, \zeta_\alpha) + \lambda|\xi - \eta_\alpha|^2/\alpha^2. \end{aligned} \tag{2.15}$$

We note the existence of $\tilde{f} \in \operatorname{co}\{f(\xi, U_\alpha^P(\xi), q)\colon q \in Q\}$ such that $|f^* - \tilde{f}| \le \gamma(\mu)$, where $\gamma(\mu) \to 0$ as $\mu \downarrow 0$. Hence

$$\langle \zeta_\alpha, f^*\rangle \le \langle \zeta_\alpha, \tilde{f}\rangle + \tilde{h}(\alpha, \mu), \tag{2.16}$$

where $\tilde{h}(\alpha,\mu) := 2\gamma(\mu)/\alpha$. Combining (2.15), (2.16) gives

$$\langle \zeta_\alpha, f^* \rangle \le H(\eta_\alpha, \zeta_\alpha) + \lambda|\xi - \eta_\alpha|^2/\alpha^2 + \tilde{h}(\alpha,\mu),$$

where $\lim_{\alpha\downarrow 0}(\lim_{\mu\downarrow 0} \tilde{h}(\alpha,\mu)) = 0$.

We now invoke the above estimates together with (2.14) to deduce

$$u_\alpha(\xi + \mu f^*) \le u_\alpha(\xi) + \mu[H(\eta_\alpha,\zeta_\alpha) + \lambda|\xi-\eta_\alpha|^2/\alpha^2] + \frac{\mu^2}{2\alpha^2}|f^*|^2 + \mu\tilde{h}(\alpha,\mu).$$

Since $\operatorname{dist}(\xi, M) > 3\alpha$ by assumption and since $|\xi - \eta_\alpha| \le 2\alpha$, it follows that η_α lies in G. Thus $\zeta_\alpha \in \partial_P u_\alpha(\eta_\alpha)$ by (2.10). We may therefore use (2.7) to write

$$\begin{aligned} H(\eta_\alpha,\zeta_\alpha) + \lambda|\xi-\eta_\alpha|^2/\alpha^2 &\le 2\lambda u(\eta_\alpha) - 2\lambda + \lambda|\xi-\eta_\alpha|^2/\alpha^2 \\ &= 2\lambda\left\{u(\eta_\alpha) + \frac{|\xi-\eta_\alpha|^2}{2\alpha^2}\right\} - 2\lambda = 2\lambda u_\alpha(\xi) - 2\lambda. \end{aligned}$$

Substituting in the previous estimate gives

$$\begin{aligned} u_\alpha(\xi+\mu f^*) &\le u_\alpha(\xi) + 2\lambda\mu[u_\alpha(\xi) - 1] + \frac{\mu^2}{2\alpha^2}|f^*|^2 + \mu\tilde{h}(\alpha,\mu) \\ &= (1+2\lambda\mu)u_\alpha(\xi) - 2\lambda\mu + \frac{\mu^2}{2\alpha^2}|f^*|^2 + \mu\tilde{h}(\alpha,\mu) \\ &\le e^{2\lambda\mu}u_\alpha(\xi) - 2\lambda\mu + \frac{\mu^2}{2\alpha^2}m^2 + \mu\tilde{h}(\alpha,\mu) \\ &= 1 + e^{2\lambda\mu}[u_\alpha(\xi) - 1] + \mu e^{2\lambda\mu}h(\alpha,\mu), \end{aligned}$$

where

$$h(\alpha,\mu) := \left[\tilde{h}(\alpha,\mu) + \frac{\mu}{2\alpha^2}m^2 - 2\lambda + \frac{e^{2\lambda\mu}-1}{\mu}\right]e^{-2\lambda\mu}$$

is nonnegative and has the required limiting property. The lemma is proved.

We now require of the parameters α and δ $(= \operatorname{diam}(\Delta))$ that they satisfy

$$\theta e^{2\lambda\theta}h(\alpha,\delta) < e^{2\lambda\varepsilon} - 1. \tag{2.17}$$

If for every such Δ and $x(\cdot)$ as in the lemma there exists $t_i \in \Delta$ such that $t_i < \theta$ and $\operatorname{dist}(x(t_i), M) \le 3\alpha$, then (since $3\alpha \le \varepsilon$ by (2.11)) the conclusion (2.5) of Theorem 2.1 follows immediately. Let us suppose the contrary (for some such Δ and x) and derive a contradiction.

By iterating (2.13) as a recurrent inequality for $u_\alpha - 1$ we easily derive

$$u_\alpha(x(\theta)) - 1 \le [u_\alpha(x_0) - 1]e^{2\lambda\theta} + \theta e^{2\lambda\theta}h(\alpha,\delta).$$

It is clear that $e^{2\lambda\theta} = e^{2\lambda\varepsilon}(1 - u(x_0))^{-1}$, and we have $u_\alpha(x_0) \le u(x_0)$. This yields

$$u_\alpha(x(\theta)) \le 1 - e^{2\lambda\varepsilon} + \theta e^{2\lambda\theta}h(\alpha,\delta) < 0 \qquad \text{(by (2.17))},$$

which cannot be since u_α is nonnegative by construction. This completes the proof of Theorem 2.1.

Remark 2.4. It is a familiar observation that the Lipschitz condition on $f(x,p,q)$ in the x variable can be weakened by requiring it to hold for x in any given compact set K (with the Lipschitz constant λ depending on K), if one postulates the linear growth (in x) condition on f.

BRACHISTOCHRONE WITH COULOMB FRICTION*

STEPHEN C. LIPP†

Abstract. This paper formulates and solves in closed form the problem of finding the minimum-time path of a particle between two points in a uniform gravitational field when motion of the particle is resisted by a force proportional to the normal force exerted on the particle by the path. This resistance to motion is the common mathematical form for Coulomb friction. The problem solution involves the reformulation of the classical brachistochrone of Bernoulli in terms of a singular control problem in which the time derivative of the heading angle of the particle is the control parameter. As such, this solution provides a unique approach to the solution of minimum-time path problems.

Key words. brachistochrone, singular control, extremal control, minimum-time control, corner conditions, optimal control

1. Introduction.

Minimum-time optimal control problems are a common research area in analytical and numerical control system synthesis. Current research in robotics and automation is fraught with minimum-time optimization problems [4, 8, 16, 20]. Some of the earliest work in optimal control theory was concerned with minimum-time optimization [3]. Perhaps the earliest problem proposed in minimum-time optimization was the brachistochrone of Bernoulli [1]. This problem may be stated as follows: A bead slides on a frictionless wire between points A and B in a constant-gravity field. The bead has an initial speed V_0 at point A. What is the shape of the wire that will produce a minimum-time path between the two points? Assuming the positive y axis points upward with $A = (x_0, y_0)$ and $B = (0, 0)$, the optimal path is a portion of a cycloid [2], the path generated by a point on the circumference of a circle as it rolls in the direction of the x axis. The minimum-time solution in this case requires that the time rate of change of heading angle of the bead is constant [2].

Euler proposed an extension to this problem. As quoted from Goldstine [7], Euler "... takes up the elegant problem of finding the shape of the brachystochrone [sic] curve in case the medium through which the heavy particle falls resists the motion depending only on the velocity v. Here he assumes that the resistance function R is proportional to v^{2n}." Euler's solution to this problem is an implicit solution [5]. Due to the fact that the friction is proportional to a function of the velocity only, this problem may be solved using the calculus of variations.

Current research into the brachistochrone has been primarily focused on different approaches to solving the classical brachistochrone problem. For example, Roomany [19] uses a graph theoretical approach to solve the classical brachistochrone problem. This technique is efficient and convergent but is only useful if the field through which the particle moves is derivable from a potential. In a similar manner, Razzaghi and Elnagar solve the classical brachistochrone problem using interpolating polynomials of appropriate degree [18]. Szarkowicz approaches the solution of the brachistochrone

problem with use of multistage Monte Carlo methods [22]. Some extensions of the classical brachistochrone problem have been discussed in the current literature as well. Hoskins extended and solved the classical brachistochrone problem, where the change in direction is allowed only along circles of a given radius R [9]. Perlick solved the classical brachistochrone problem extended to a stationary Lorentzian space-time [14].

The present paper examines the brachistochrone problem in which the friction force on the particle is a resistance proportional to the force exerted by the particle by its path (the normal force). This formulation is the equivalent of determining minimum-time paths in a uniform gravitational field with Coulomb friction resisting the motion. With this choice of motion resistance, the penalty for curvature in the path is high. In fact, the dynamics to be derived will demand that there be no abrupt changes in curvature. Therefore, if the optimal control problem is reformulated with an intermediate point as the initial point and the corresponding speed at that point as the initial speed, a *different* optimal path will result. This again differs from the classical brachistochrone result in that the position and speed at any point on an optimal cycloidal path determine the cycloid. It is the position and *velocity* which uniquely determine the time-optimal path when Coulomb friction is present in the brachistochrone problem.

A discretization of this problem was formulated and solved using a Davidon–Fletcher–Powell algorithm in 1990 [17]. A number of important points in this result were left unsolved, including the question of whether a solution exists and how close a solution is to the actual minimum-time solution. Some interesting features of the minimum-time path were not illustrated in the discretized solution. This paper will present the closed-form solution for the minimum-time path. Therefore, it will demonstrate the validity of the discretized approach and provide further insight into the limitations of that generic approach in its application to this problem.

2. Optimal control formulation. The classical brachistochrone problem may be formulated as an optimal control problem with the heading angle θ as the control variable. In the formulation of any optimal control problem, the first step is the formation of the scalar Hamiltonian [15]. The Hamiltonian is defined by

$$\mathcal{H} = \langle \boldsymbol{\lambda}, \boldsymbol{f}(\boldsymbol{x}, u) \rangle + L(\boldsymbol{x}, u), \tag{2.1}$$

where $\dot{\boldsymbol{x}} = \boldsymbol{f}(\boldsymbol{x}, u)$ are the state dynamics, $\dot{\boldsymbol{\lambda}} = -\frac{\partial \mathcal{H}}{\partial \boldsymbol{x}}$ are the "costate" dynamics, $L(\boldsymbol{x}, u)$ is the scalar function whose time integral is to be minimized, u is the control variable, and $\langle \cdot, \cdot \rangle$ denotes the scalar inner (dot) product. For minimum-time control problems, the scalar cost function $L(\boldsymbol{x}, u) \equiv 1$, since the minimization of the time integral of one corresponds to the minimization of the final time.

Pontryagin's "minimum" principle [15] states that the optimal control is the control u which minimizes the Hamiltonian almost everywhere. When the Hamiltonian is convex in the control variable u, the optimal control necessarily satisfies Euler's condition (the first variation) $\frac{\partial \mathcal{H}}{\partial u} = 0$ and sufficiency is guaranteed with the "strict" Legendre–Clebsch condition (the second variation) $\frac{\partial^2 \mathcal{H}}{\partial u^2} > 0$. The strict Legendre–Clebsch condition is guaranteed in the case of the classical brachistochrone.

The state dynamics for the standard brachistochrone may be derived in x and y coordinates using Newton's laws. Assume that positive x is to the right and positive y is up. Additionally, assume that a first quadrant heading angle θ corresponds to negative x-speed and y-speed. The particle speed is denoted by V. A diagram of the geometry is shown in Figure 2.1.

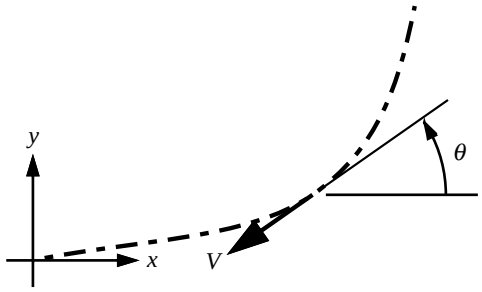

FIG. 2.1. *State-variable geometry.*

Using dimensionless variables

$$\begin{aligned} \dot{x} &= -V\cos\theta, \\ \dot{y} &= -V\sin\theta, \\ \dot{V} &= \frac{1}{2}\sin\theta\,. \end{aligned} \tag{2.2}$$

The dimensionless variables chosen were

$$x = \frac{x^*}{x^*(0)}, \qquad y = \frac{y^*}{x^*(0)}, \qquad V = \frac{V^*}{\sqrt{2gx^*(0)}}, \qquad t = t^*\sqrt{\frac{2g}{x^*(0)}}\,, \tag{2.3}$$

where the superscript $*$ indicates dimensional variables. Treating θ as the control variable, the initial and final conditions on the states are

$$x(0) = 1, \quad y(0) = y_0, \quad V(0) = V_0, \quad x(t_f) = 0, \quad y(t_f) = 0\,. \tag{2.4}$$

Setting

$$\boldsymbol{\lambda} = \left\{ \begin{array}{c} \lambda_x \\ \lambda_y \\ \lambda_V \end{array} \right\}, \tag{2.5}$$

the Hamiltonian may be written as

$$\mathcal{H} = -\lambda_x V\cos\theta - \lambda_y V\sin\theta + \frac{1}{2}\lambda_V\sin\theta + 1\,. \tag{2.6}$$

The costate dynamics as obtained from $\dot{\boldsymbol{\lambda}} = -\frac{\partial\mathcal{H}}{\partial \boldsymbol{x}}$ are

$$\begin{aligned} \dot{\lambda}_x &= \dot{\lambda}_y = 0, \\ \dot{\lambda}_V &= \lambda_x\cos\theta + \lambda_y\sin\theta\,. \end{aligned} \tag{2.7}$$

With the state boundary conditions given, the costates $\boldsymbol{\lambda}$ have free (unknown) boundary conditions except at the boundary where $\boldsymbol{x}$ is unconstrained. Thus the only boundary condition satisfied by $\boldsymbol{\lambda}$ is

$$\lambda_V(t_f) = 0\,. \tag{2.8}$$

This means that there are six differential equations and seven unknowns ($V(t_f)$, $\lambda_x(0)$, $\lambda_y(0)$, $\lambda_V(0)$, $\lambda_x(t_f)$, $\lambda_y(t_f)$, and t_f).

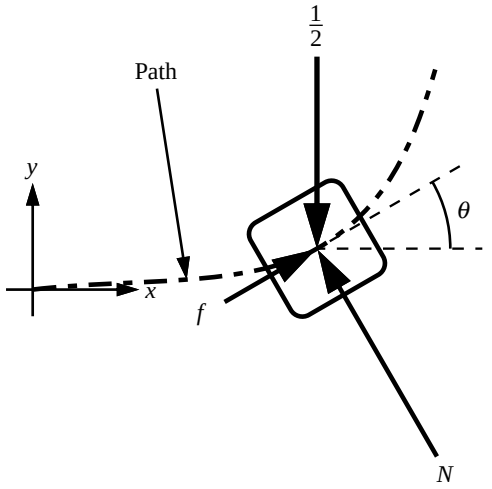

FIG. 2.2. *Free-body diagram of bead on path with Coulomb friction resisting motion.*

The final condition for determination of the optimal control is the transversality condition [15], which states that

$$\mathcal{H}(t_f) = \frac{\partial L(\boldsymbol{x}, u)}{\partial t} = 0\,. \tag{2.9}$$

With the Hamiltonian having no explicit time dependence, this means that $\mathcal{H}(t) \equiv 0$. Simple integration demonstrates that the first and second variation conditions hold for a cycloidal path. Therefore, the cycloidal path is the optimal minimum-time path for control.

When Coulomb friction is added as a resisting force to the motion, the dimensionless equations of motion may be determined from a free-body diagram of the particle (see Figure 2.2). In the figure, the dimensionless normal force N and dimensionless friction force f are given by

$$N = \frac{N^*}{2mg} \qquad \text{and} \qquad f = \frac{f^*}{2mg}\,. \tag{2.10}$$

Coulomb friction resistance has the constitutive law $f = \mu|N|$, where μ is the coefficient of friction. The normal force exerted by the path on the particle is equal to the component of the weight of the particle (1/2 in dimensionless terms) in the direction of the normal force minus the mass of the particle multiplied by the centripetal acceleration caused by the particle's speed and the curvature of the path. In dimensionless terms, this is $V\dot{\theta}$. Therefore, the dimensionless equations of motion are

$$\begin{aligned} \dot{x} &= -V\cos\theta, \\ \dot{y} &= -V\sin\theta, \\ \dot{V} &= \frac{1}{2}\sin\theta - \mu\left|\frac{1}{2}\cos\theta - V\dot{\theta}\right|\,. \end{aligned} \tag{2.11}$$

Unlike the classical or Euler's brachistochrone problem, $\dot{\theta}$ has entered the dynamics. In order to formulate the problem as an optimal control problem, θ will be adjoined as an extra state with $\dot{\theta} = \Omega$ as the control variable.

This formulation is troublesome due to the fact that the control objective and the state dynamics are not convex in the control variable. The second derivative of the Hamiltonian with respect to the control being zero is not sufficient for optimality. In fact, Euler's necessary condition is not satisfied initially for nonzero initial velocity. Recourse to Pontryagin's minimum principle yields extremal control initially but yields no information about the control when the system equations simplify with Euler's condition being satisfied. This problem requires the theory of singular control [10, 11].

When the partial derivative of the Hamiltonian with respect to the control variable equals zero but yields a relation in which there is no explicit control variable, then a singular control solution may exist for the system. Singular control methods yield the following constraint equations for determining the control:

$$\begin{aligned} &\frac{d^i}{dt^i}\left[\frac{\partial \mathcal{H}}{\partial u}\right] = 0, \qquad i = 0, 1, \ldots, m-1, \\ &\frac{d^m}{dt^m}\left[\frac{\partial \mathcal{H}}{\partial u}\right] = g(\boldsymbol{x}, \boldsymbol{\lambda}, u) = 0. \end{aligned} \tag{2.12}$$

The first $m-1$ derivatives are independent of the control u. The mth derivative determines the control u as a function of the states/costates. A result obtainable from this theory is [11]: (1) m is always even; (2) if the number of states is n, the singular control restricts state/costate space to dimension $2n-m$ (the singular hypersurface); and (3) it is necessary that

$$(-1)^{\frac{m}{2}} \frac{\partial}{\partial u}\left(\frac{d^m}{dt^m}\left[\frac{\partial \mathcal{H}}{\partial u}\right]\right) \geq 0\,.$$

The final condition is a generalized Legendre–Clebsch condition, a *necessary* condition for optimality. In general there are no sufficiency conditions for optimality of a singular control arc. Even the strict inequality does not guarantee optimality. Nevertheless, this method will prove invaluable in generating control trajectories for the brachistochrone with Coulomb friction. Furthermore, since the classical brachistochrone can be derived as a singular control problem and the Coulomb friction brachistochrone simplifies to the classical brachistochrone when the coefficient of friction $\mu \to 0$, the necessarily optimal path derived by singular control methods is sufficient in the limit.

3. Reformulation of the classical brachistochrone problem. The classical brachistochrone problem can also be formulated as a singular control problem where the control variable is Ω, the time rate of change of the slope of the time-optimal path. In this case, the state equations are

$$\begin{aligned} \dot{x} &= -V\cos\theta, \\ \dot{y} &= -V\sin\theta, \\ \dot{V} &= \frac{1}{2}\sin\theta, \\ \dot{\theta} &= \Omega\,. \end{aligned} \tag{3.1}$$

The dimensionless Hamiltonian is thus

$$\mathcal{H} = -\lambda_x V\cos\theta - \lambda_y V\sin\theta + \frac{1}{2}\lambda_V \sin\theta + \lambda_\theta \Omega + 1\,. \tag{3.2}$$

The costate equations are

$$\begin{aligned}
\dot{\lambda}_x &= -\frac{\partial \mathcal{H}}{\partial x} = 0,\\
\dot{\lambda}_y &= -\frac{\partial \mathcal{H}}{\partial y} = 0,\\
\dot{\lambda}_V &= -\frac{\partial \mathcal{H}}{\partial V} = \lambda_x \cos\theta + \lambda_y \sin\theta,\\
\dot{\lambda}_\theta &= -\frac{\partial \mathcal{H}}{\partial \theta} = V(\lambda_y \cos\theta - \lambda_x \sin\theta) - \frac{1}{2}\,\lambda_V \cos\theta
\end{aligned} \tag{3.3}$$

with the boundary conditions

$$\lambda_V(t_f) = 0, \qquad \lambda_\theta(0) = \lambda_\theta(t_f) = 0, \qquad \mathcal{H}(t_f) = 0\,. \tag{3.4}$$

With the Hamiltonian being linear in the control variable Ω, the optimal control will be singular control. The singular control is determined with the following conditions:

$$\begin{aligned}
\frac{\partial \mathcal{H}}{\partial \Omega} &= \lambda_\theta = 0,\\
\frac{d}{dt}\,\frac{\partial \mathcal{H}}{\partial \Omega} &= V(\lambda_y \cos\theta - \lambda_x \sin\theta) - \frac{1}{2}\,\lambda_V \cos\theta = 0,\\
\frac{d^2}{dt^2}\,\frac{\partial \mathcal{H}}{\partial \Omega} &= -\frac{1}{2}\,\lambda_x + \left(\frac{1}{2}\,\lambda_V \sin\theta - V(\lambda_x \cos\theta + \lambda_y \sin\theta)\right)\Omega = 0\,.
\end{aligned} \tag{3.5}$$

These conditions restrict state/costate space to dimension six. This restriction in the dimensionality of the state/costate dynamics is known as the singular surface; the trajectory defined on this surface is known as the singular arc. The generalized Legendre–Clebsch condition for this singular control problem is

$$-\frac{\partial}{\partial \Omega}\left[\frac{d^2}{dt^2}\left(\frac{\partial \mathcal{H}}{\partial \Omega}\right)\right] = V(\lambda_x \cos\theta + \lambda_y \sin\theta) - \frac{1}{2}\,\lambda_V \sin\theta \geq 0\,. \tag{3.6}$$

Solving the differential equations for the states/costates and choosing θ as the independent parameter yields (see section 4.2 for more details)

$$\begin{aligned}
x(\theta) &= \frac{V_f^2}{2\cos^2\theta_f}\,(2(\theta - \theta_f) + \sin 2\theta - \sin 2\theta_f), & \lambda_x(\theta) &= \frac{\cos\theta_f}{V_f},\\
y(\theta) &= \frac{V_f^2}{2\cos^2\theta_f}\,(\cos 2\theta_f - \cos 2\theta), & \lambda_y(\theta) &= \frac{\sin\theta_f}{V_f},\\
V(\theta) &= V_f\,\frac{\cos\theta}{\cos\theta_f}, & \lambda_V(\theta) &= -\frac{2\sin(\theta - \theta_f)}{\cos\theta_f},\\
t(\theta) &= t_f - \frac{2V_f}{\cos\theta_f}\,(\theta - \theta_f), & \lambda_\theta(\theta) &= 0\,.
\end{aligned} \tag{3.7}$$

The values of V_f, θ_f, and θ_0 are determined from the initial conditions on x, y, and V. The fact that $\lambda_\theta(\theta) \equiv 0$ indicates the singular solution for the control exists throughout the control trajectory. The optimal control is

$$\Omega = -\frac{\cos\theta_f}{2V_f}, \tag{3.8}$$

satisfying the necessary generalized Legendre–Clebsch condition

$$V(\lambda_x \cos\theta + \lambda_y \sin\theta) - \frac{1}{2}\,\lambda_V \sin\theta = 1 > 0\,.$$

These results will serve as a check for the brachistochrone problem with Coulomb friction. When $\mu = 0$, the Coulomb friction results should reduce to the above results.

4. Brachistochrone with Coulomb friction.

4.1. The equations of motion. The dimensionless equations of motion for the brachistochrone with Coulomb friction are obtained from (2.11) with $\dot\theta = \Omega$ appended. The boundary conditions for the states are

$$(x(\,0\,), y(\,0\,), V(\,0\,), \theta(\,0\,)) = (1, y_0, V_0, \theta_0)\,, \tag{4.1}$$

$$(x(t_f), y(t_f), V(t_f), \theta(t_f)) = (0,\ 0\,, V_f, \theta_f)\,, \tag{4.2}$$

where θ_0, V_f, and θ_f are unknown parameters.

The Hamiltonian for the system is

$$\mathcal{H} = -\lambda_x V\cos\theta - \lambda_y V\sin\theta + \lambda_V\left(\frac{1}{2}\,\sin\theta - \mu\left|\frac{1}{2}\,\cos\theta - V\Omega\right|\right) + \lambda_\theta\Omega + 1\,. \tag{4.3}$$

Therefore, the equations for the costates are

$$\begin{aligned}
\dot\lambda_x &= 0,\\
\dot\lambda_y &= 0,\\
\dot\lambda_V &= \lambda_x\cos\theta + \lambda_y\sin\theta - \mu s\lambda_V\Omega,\\
\dot\lambda_\theta &= -\lambda_x V\sin\theta + \lambda_y V\cos\theta - \frac{1}{2}\,\lambda_V(\cos\theta + \mu s\sin\theta)
\end{aligned} \tag{4.4}$$

with the boundary conditions

$$(\lambda_x(\,0\,), \lambda_y(\,0\,), \lambda_V(\,0\,), \lambda_\theta(\,0\,)) = (\lambda_{x_0}, \lambda_{y_0}, \lambda_{V_0}, 0)\,, \tag{4.5}$$

$$(\lambda_x(t_f), \lambda_y(t_f), \lambda_V(t_f), \lambda_\theta(t_f)) = (\lambda_{x_f}, \lambda_{y_f},\ \ 0\ \ , 0)\,, \tag{4.6}$$

where λ_{x_0}, λ_{y_0}, λ_{V_0}, λ_{x_f}, and λ_{y_f} are unknown. In the above equations

$$s = \operatorname{sgn}\left(\frac{1}{2}\,\cos\theta - V\Omega\right) = \operatorname{sgn}(N)\,. \tag{4.7}$$

Note that for $N = 0$, the above differential equations for λ_V and λ_θ are not properly defined. This case will be considered in section 4.3.

4.2. The singular control arc. The first step in synthesizing the singular control arc for this problem is to derive the constraint equations. To simplify the following analysis, three parameters will be introduced to replace three parameters in the state/costate equations. These parameters are defined as follows:

$$\sin\theta_\mu = \frac{s\mu}{\sqrt{1+\mu^2}},\quad \cos\theta_\mu = \frac{1}{\sqrt{1+\mu^2}},\quad \lambda_x = L\cos\theta_\lambda,\quad \lambda_y = L\sin\theta_\lambda \tag{4.8}$$

with $L > 0$. Noting that the time derivatives of λ_x and λ_y are both zero, the reduced set of six state/costate equations is

$$\begin{aligned}
\dot{x} &= -V\cos\theta,\\
\dot{y} &= -V\sin\theta,\\
\dot{V} &= \frac{1}{2\cos\theta_\mu}\sin(\theta-\theta_\mu) + \tan\theta_\mu V\Omega,\\
\dot{\theta} &= \Omega,\\
\dot{\lambda}_V &= L\cos(\theta-\theta_\lambda) - \tan\theta_\mu\lambda_V\Omega,\\
\dot{\lambda}_\theta &= -LV\sin(\theta-\theta_\lambda) - \frac{1}{2\cos\theta_\mu}\lambda_V\cos(\theta-\theta_\mu)\,.
\end{aligned} \tag{4.9}$$

The seven unknown parameters for these six equations are θ_0, θ_f, V_f, L, θ_λ, λ_{V_0}, and t_f. There is also θ_μ, which is unknown because of s being unknown. In forthcoming equations, s is assumed constant; its sign will be determined from the generalized Legendre–Clebsch condition. The seventh condition is the transversality condition which, for minimum-time optimization, states that the Hamiltonian is zero at time $t = t_f$. Using the final conditions of the states and costates, equations (4.2) and (4.6), respectively, in the Hamiltonian, (4.3), with use of the parameter equations (4.8), the transversality condition may be written as

$$LV_f\cos(\theta_f-\theta_\lambda) = 1\,. \tag{4.10}$$

For this problem, the constraints for singular control may be written as

$$\begin{aligned}
\frac{\partial\mathcal{H}}{\partial\Omega} &= \lambda_\theta + \tan\theta_\mu V\lambda_V = 0,\\
\cos\theta_\mu\frac{d}{dt}\frac{\partial\mathcal{H}}{\partial\Omega} &= -LV\sin(\theta-\theta_\mu-\theta_\lambda) - \frac{1}{2\cos\theta_\mu}\lambda_V\cos\theta = 0,\\
\cos^2\theta_\mu\frac{d^2}{dt^2}\frac{\partial\mathcal{H}}{\partial\Omega} &= \frac{L}{2}(\sin\theta_\mu\sin(2\theta-\theta_\mu-\theta_\lambda) - \cos\theta_\lambda)\\
&\quad - LV\Omega\cos(\theta-2\theta_\mu-\theta_\lambda) + \frac{1}{2\cos\theta_\mu}\lambda_V\Omega\sin(\theta+\theta_\mu) = 0\,.
\end{aligned} \tag{4.11}$$

With the condition that $\lambda_V(t_f) = \lambda_\theta(t_f) = 0$, it is evident that singular control will lead the system to the final state.

The generalized Legendre–Clebsch condition for the existence of singular arcs is

$$-\frac{\partial}{\partial\Omega}\left[\frac{d^2}{dt^2}\left(\frac{\partial\mathcal{H}}{\partial\Omega}\right)\right] > 0\,.$$

For this problem, this is equivalent to the condition

$$-\frac{1}{2\cos\theta_\mu}\lambda_V\sin(\theta+\theta_\mu) + LV\cos(\theta-2\theta_\mu-\theta_\lambda) > 0\,. \tag{4.12}$$

The assumptions upon which the singular control derivation is based are that (1) the speed, including the parameter V_f, is positive; (2) the parameter L is positive; (3) the heading angle θ lies in the interval $(-\pi/2, \pi/2)$; (4) the variable s as manifested in the parameter θ_μ is constant; and (5) the generalized Legendre–Clebsch condition holds.

The derivation will proceed assuming these conditions hold. When the singular-control state trajectories are finally derived, these assumptions will be verified.

The control as determined from the final condition is

$$\Omega = \frac{\frac{L}{2}(\sin\theta_\mu \sin(2\theta - \theta_\mu - \theta_\lambda) - \cos\theta_\lambda)}{LV\cos(\theta - 2\theta_\mu - \theta_\lambda) - \frac{1}{2\cos\theta_\mu}\lambda_V \sin(\theta + \theta_\mu)}\,. \tag{4.13}$$

If the second equation is solved for λ_V, the result is

$$\lambda_V = -\frac{2V}{\cos\theta}\, L\cos\theta_\mu \sin(\theta - \theta_\mu - \theta_\lambda)\,. \tag{4.14}$$

Substituting this result into the control equation,

$$\Omega = \frac{\cos\theta}{2V}\,\frac{\sin\theta_\mu \sin(2\theta - \theta_\mu - \theta_\lambda) - \cos\theta_\lambda}{\sin\theta_\mu \sin(2\theta - \theta_\mu - \theta_\lambda) + \cos(2\theta_\mu + \theta_\lambda)}\,. \tag{4.15}$$

Notice the equations are identical to the singular control equations for the classical brachistochrone when $\theta_\mu = 0$.

With λ_V obtained from (4.14), the generalized Legendre–Clebsch condition becomes

$$\frac{LV}{\cos\theta}\,(\sin\theta_\mu \sin(2\theta - \theta_\mu - \theta_\lambda) + \cos(2\theta_\mu + \theta_\lambda)) > 0\,. \tag{4.16}$$

With $-\pi/2 < \theta < \pi/2$, the constraint that $\lambda_V(t_f) = 0$ implies that if (4.14) is evaluated at t_f then

$$\theta_f = \theta_\mu + \theta_\lambda + k\pi,$$

where k is an integer. Substituting $\theta = \theta_f$ in the generalized Legendre–Clebsch condition yields

$$\frac{LV}{\cos\theta}\,(\sin\theta_\mu \sin(2\theta - \theta_\mu - \theta_\lambda) + \cos(2\theta_\mu + \theta_\lambda))\Big|_{t=t_f} = (-1)^k LV_f \cos\theta_\mu > 0\,.$$

Therefore, k must be an even integer. Without loss of generality, $k = 0$ and

$$\theta_\lambda = \theta_f - \theta_\mu\,. \tag{4.17}$$

Hereafter, the variable θ_λ will be replaced by the right-hand side of (4.17). Rewriting the generalized Legendre–Clebsch condition in terms of θ_f,

$$\frac{LV}{\cos\theta}\,\{\sin\theta_\mu \sin(2\theta - \theta_f) + \cos(\theta_\mu + \theta_f)\} > 0\,. \tag{4.18}$$

With L and V positive, and $-\pi/2 < \theta < \pi/2$, the generalized Legendre–Clebsch condition holds if the term in the braces is positive.

The dimensionless normal force in the system is

$$N = \frac{1}{2}\,\cos\theta - V\Omega = \cos\theta\,\frac{\cos\theta_\mu \cos\theta_f}{\sin\theta_\mu \sin(2\theta - \theta_f) + \cos(\theta_\mu + \theta_f)}\,. \tag{4.19}$$

The generalized Legendre–Clebsch condition explicitly requires $s = \mathrm{sgn}(N) = +1$. In other words, there is no way of picking an optimal singular control for which $N < 0$ at

some point in the singular arc. Furthermore, the assumption of s constant is justified. Hereafter, the parameter θ_μ will be defined by the relations (4.8) with $s \equiv +1$.

It will be helpful to express the generalized Legendre–Clebsch condition, and other relationships in the equations, in a different form. First,

$$\begin{aligned}(4.20)\qquad &\frac{LV}{\cos\theta}\left(\sin\theta_\mu \sin(2\theta-\theta_f)+\cos(\theta_\mu+\theta_f)\right)\\ &= LV\cos\theta\cos\theta_f\cos\theta_\mu((\tan\theta+\tan\theta_\mu)^2-(\tan\theta_f+\tan\theta_\mu)^2+\sec^2\theta_f)>0\,.\end{aligned}$$

The dimensionless normal force may be written as

$$(4.21)\qquad N=\frac{\sec\theta}{(\tan\theta+\tan\theta_\mu)^2-(\tan\theta_f+\tan\theta_\mu)^2+\sec^2\theta_f}\,.$$

Similarly, (4.15) may be written as

$$(4.22)\qquad \Omega=-\frac{\cos\theta}{2V}\,\frac{(\tan\theta-\tan\theta_\mu)^2-(\tan\theta_f-\tan\theta_\mu)^2+\sec^2\theta_f}{(\tan\theta+\tan\theta_\mu)^2-(\tan\theta_f+\tan\theta_\mu)^2+\sec^2\theta_f}\,.$$

Using this last relationship and writing the differential equation for $V(\theta)$,

$$(4.23)\qquad \frac{dV}{d\theta}=-V\,\frac{\tan^3\theta+(1-2\tan\theta_f\tan\theta_\mu)\tan\theta-2\tan\theta_\mu}{(\tan\theta-\tan\theta_\mu)^2-(\tan\theta_f-\tan\theta_\mu)^2+\sec^2\theta_f}\,.$$

The solution of this differential equation is

$$(4.24)\qquad V_+(\theta)=\frac{V_f\sec\theta_f\sec\theta}{(\tan\theta-\tan\theta_\mu)^2-(\tan\theta_f-\tan\theta_\mu)^2+\sec^2\theta_f}\,.$$

The subscript + indicates that this and subsequent formulas are valid for θ near θ_f (singular control). The beauty of this result is its simplicity. With $\theta_\mu = 0$,

$$V(\theta)=V_f\,\frac{\sec\theta_f}{\sec\theta}=V_f\,\frac{\cos\theta}{\cos\theta_f},$$

which is the result for the classical brachistochrone.

With $V_+ > 0$, $\cos\theta > 0$, and the generalized Legendre–Clebsch condition, $\Omega(\theta) < 0$, which implies that θ decreases as a function of time. This means that $\theta \geq \theta_f$, where θ represents the heading angle at time $t \leq t_f$. The implicit assumption in the analysis to this point has been that $V_+ > 0$. In order for this to be true,

$$\begin{aligned}V_+(\theta)&=\frac{V_f\sec\theta_f\sec\theta}{(\tan\theta-\tan\theta_\mu)^2-(\tan\theta_f-\tan\theta_\mu)^2+\sec^2\theta_f}\\ &=V_f\,\frac{\cos\theta_f}{\cos\theta}\,\frac{1}{f^2(\theta)-f^2(\theta_f)+1}>0,\end{aligned}$$

where

$$(4.25)\qquad f(x)=\frac{\tan x-\tan\theta_\mu}{\sec\theta_f}=\cos\theta_f(\tan x-\mu)\,.$$

Given that θ and θ_f are each bounded between $-\pi/2$ and $\pi/2$, this implies that $f^2(\theta)-f^2(\theta_f)+1>0$. If $1-f^2(\theta_f)>0$, then the constraint holds regardless of the value of θ. If $1-f^2(\theta_f)<0$, then θ must be constrained. The fact that $V_+ > 0$ and

$\Omega(\theta) < 0$ translates to the following constraints on θ and θ_f:

$$\begin{aligned} &\theta_f > 2\theta_\mu - \frac{\pi}{2}\,, && \theta_f < \theta < \frac{\pi}{2}\,, \\ &\theta_f \le 2\theta_\mu - \frac{\pi}{2}\,, && \theta_f < \theta < \tan^{-1}\left(\tan\theta_\mu - \sqrt{(\tan\theta_f - \tan\theta_\mu)^2 - \sec^2\theta_f}\right). \end{aligned} \tag{4.26}$$

This constraint on the range of θ also implies the generalized Legendre–Clebsch condition is satisfied in general for the state trajectories to be computed.

The differential equations satisfied by x, y, and t are as follows:

$$\begin{aligned} \frac{dx}{d\theta} &= 2V_f^2\cos\theta_f\,\frac{f^2(\theta) - 4f_0 f(\theta) - f^2(\theta_f) + 4f_0 f(\theta_f) + 1}{(f^2(\theta) - f^2(\theta_f) + 1)^3}\,f'(\theta)\,, \\ \frac{dy}{d\theta} &= 2V_f^2\,\frac{(f(\theta) - f_0)(f^2(\theta) - 4f_0 f(\theta) - f^2(\theta_f) + 4f_0 f(\theta_f) + 1)}{(f^2(\theta) - f^2(\theta_f) + 1)^3}\,f'(\theta)\,, \end{aligned} \tag{4.27}$$

and

$$\frac{dt}{d\theta} = -2V_f\,\frac{f^2(\theta) - 4f_0 f(\theta) - f^2(\theta_f) + 4f_0 f(\theta_f) + 1}{(f^2(\theta) - f^2(\theta_f) + 1)^2}\,f'(\theta),$$

where $f_0 = f(0) = -\mu\cos\theta_f$.

The solution of each differential equation differs with θ_f greater than, equal to, or less than $2\theta_\mu - \pi/2$. The value for $\theta_f > 2\theta_\mu - \pi/2$ is presented first. The value for $\theta_f < 2\theta_\mu - \pi/2$ is obtained from this result by replacing each term $\sqrt{1 - f^2(\theta_f)}$ with $i\sqrt{f^2(\theta_f) - 1}$, and $\tan^{-1}(ix)$ with $i\coth^{-1}(x)$. For each solution the corresponding formula for $\theta_f = 2\theta_\mu - \pi/2$ is also presented. The solutions of the differential equations are

$$\begin{aligned} \frac{x_+(\theta)}{V_f^2} = \cos\theta_f \Bigg[&\frac{1 - f^2(\theta_f) + 3f(\theta_f)f_0}{(1 - f^2(\theta_f))^2}\left(\frac{f(\theta)}{f^2(\theta) - f^2(\theta_f) + 1} - f(\theta_f)\right. \\ &\left. + \frac{1}{\sqrt{1 - f^2(\theta_f)}}\left(\tan^{-1}\left(\frac{f(\theta)}{\sqrt{1 - f^2(\theta_f)}}\right) - \tan^{-1}\left(\frac{f(\theta_f)}{\sqrt{1 - f^2(\theta_f)}}\right)\right)\right) \\ &+ \frac{2f_0 f(\theta_f)}{1 - f^2(\theta_f)}\left(\frac{f(\theta)}{(f^2(\theta) - f^2(\theta_f) + 1)^2} - f(\theta_f)\right) \\ &- 2f_0\left(1 - \frac{1}{(f^2(\theta) - f^2(\theta_f) + 1)^2}\right)\Bigg], \end{aligned} \tag{4.28}$$

$$\begin{aligned} \frac{y_+(\theta)}{V_f^2} = 1 &- \frac{1}{f^2(\theta) - f^2(\theta_f) + 1} + 2f_0(f(\theta_f) + f_0)\left(1 - \frac{1}{(f^2(\theta) - f^2(\theta_f) + 1)^2}\right) \\ &+ \frac{2f_0(1 - f^2(\theta_f) - f(\theta_f)f_0)}{1 - f^2(\theta_f)}\left(\frac{f(\theta)}{(f^2(\theta) - f^2(\theta_f) + 1)^2} - f(\theta_f)\right) \\ &- \frac{f_0(2 - 2f^2(\theta_f) + 3f(\theta_f)f_0)}{(1 - f^2(\theta_f))^2}\left(\frac{f(\theta)}{f^2(\theta) - f^2(\theta_f) + 1} - f(\theta_f)\right. \\ &\left. + \frac{1}{\sqrt{1 - f^2(\theta_f)}}\left(\tan^{-1}\left(\frac{f(\theta)}{\sqrt{1 - f^2(\theta_f)}}\right) - \tan^{-1}\left(\frac{f(\theta_f)}{\sqrt{1 - f^2(\theta_f)}}\right)\right)\right), \end{aligned} \tag{4.29}$$

and

$$\frac{t_+(\theta)}{2V_f} = \frac{t_f}{2V_f} - \frac{2f_0 f(\theta_f)}{1-f^2(\theta_f)}\left(\frac{f(\theta)}{f^2(\theta)-f^2(\theta_f)+1} - f(\theta_f)\right)$$
$$+\ 2f_0\left(1 - \frac{1}{f^2(\theta)-f^2(\theta_f)+1}) - (1 + \frac{2f_0 f(\theta_f)}{1-f^2(\theta_f)}\right)$$
$$\cdot \frac{1}{\sqrt{1-f^2(\theta_f)}}\left(\tan^{-1}\left(\frac{f(\theta)}{\sqrt{1-f^2(\theta_f)}}\right) - \tan^{-1}\left(\frac{f(\theta_f)}{\sqrt{1-f^2(\theta_f)}}\right)\right). \tag{4.30}$$

The solutions of the differential equations for $f(\theta_f) = -1$ ($\theta_f = 2\theta_\mu - \pi/2$) are

$$\frac{x_+(\theta)}{V_f^2} = \sin 2\theta_\mu\left[-\frac{2}{3}\left(\frac{1}{f^3(\theta)}+1\right) + 2f_0\left(\frac{1}{f^4(\theta)}-1\right) + \frac{8f_0}{5}\left(\frac{1}{f^5(\theta)}+1\right)\right], \tag{4.31}$$

$$\frac{y_+(\theta)}{V_f^2} = 1 - \frac{1}{f^2(\theta)} + 2f_0(1-f_0)\left(\frac{1}{f^4(\theta)}-1\right)$$
$$+\ \frac{10f_0}{3}\left(\frac{1}{f^3(\theta)}+1\right) - \frac{8f_0^2}{5}\left(\frac{1}{f^5(\theta)}+1\right), \tag{4.32}$$

and

$$\frac{t_+(\theta)}{2V_f} = \frac{t_f}{2V_f} + \frac{1}{f(\theta)} + 1 + 2f_0\left(1 - \frac{1}{f^2(\theta)}\right) - \frac{4f_0}{3}\left(\frac{1}{f^3(\theta)}+1\right). \tag{4.33}$$

When $\theta_\mu = 0$, the equations simplify to

$$x(\theta) = \frac{V_f^2}{2\cos^2\theta_f}\left(2(\theta-\theta_f) + \sin 2\theta - \sin 2\theta_f\right),$$

$$y(\theta) = \frac{V_f^2}{2\cos^2\theta_f}\left(\cos 2\theta_f - \cos 2\theta\right),$$

and

$$t(\theta) = t_f - \frac{2V_f}{\cos\theta_f}\left(\theta - \theta_f\right).$$

Admittedly, the results were presented without exposition, but the fact that the results yielded are identical to classical brachistochrone results when $\mu = 0$ is at least reassuring.

4.3. The extremal control arc. With the derivation of the singular control arc, the optimal control has yet to be completely described. For one, each of the expressions derived contains two unknowns, V_f and θ_f. There must be relations connecting the states in the singular arc with states starting at time $t = 0$.

Initially the control will be extremal control, that is, control which lies at the boundary of the admissible domain of control. As demonstrated earlier, the optimal control for initial conditions in the first or fourth quadrant (x_0 positive) is control in which the normal force is nonnegative. Therefore

$$\frac{1}{2}\cos\theta - V\Omega \geq 0. \tag{4.34}$$

This constraint will yield the initial extremal control.

The partial derivative of the Hamiltonian with respect to the control variable Ω is given by

$$\frac{\partial \mathcal{H}}{\partial \Omega} = \lambda_\theta + s\mu V \lambda_V \,. \tag{4.35}$$

Examining this term at time $t = 0$, if $V_0 = V(0) \neq 0$ then this term is nonzero. Furthermore, the time derivative of the Hamiltonian is

$$\frac{d\mathcal{H}}{dt} = (\lambda_\theta + s\mu V \lambda_V)\dot{\Omega} - \mu \lambda_V \left(\frac{1}{2} \cos\theta - V\Omega \right) \dot{s} = 0 \,. \tag{4.36}$$

There are thus two options for the initial control Ω if $V_0 \neq 0$: (1) choose Ω constant with s constant (either + or − 1), or (2) choose $\Omega = \frac{\cos\theta}{2V}$ such that the normal force is zero and define $s = -\frac{\lambda_\theta}{\mu V \lambda_V}$ so that the coefficient of $\dot{\Omega}$ in the time derivative of the Hamiltonian is also zero.

Choosing case (1), the *constant* extremal control which "minimizes" the Hamiltonian must be $\Omega = \pm\infty$; that is, the initial control will be a jump change in the direction of the particle. By Pontryagin's principle [15], the optimal control is the control which extremizes the Hamiltonian. In this case, extremization of the Hamiltonian occurs with $\Omega = \pm\infty$ if and only if

$$\left| \frac{\lambda_\theta}{\mu V \lambda_V} \right| \geq 1 \,. \tag{4.37}$$

This constraint follows from the fact that λ_V, from (4.14), is less than zero and that λ_θ, from the first equation of (4.11), is greater than zero at the corner between singular control and extremal control. Thus, in order for constant control to be extremal control, the control reduces to a jump change in slope. After the jump in the control trajectory, the velocity is now zero and singular control yields the constraints. Intuitively, this possibility is trivial as setting the initial normal force infinite makes this problem identical to a zero-initial-velocity problem. All that is gained from having nonzero initial energy is lost immediately.

Therefore, the extremal control will be to let

$$\Omega = \frac{\cos\theta}{2V} \,. \tag{4.38}$$

This control minimizes the Hamiltonian if and only if

$$s = -\frac{\lambda_\theta}{\mu V \lambda_V} \qquad \text{with} \qquad |s| \leq 1 \,. \tag{4.39}$$

This initial extremal control is different from the singular control derived earlier. Due to the order of the singularity, the control *must* be discontinuous [21] at the corner between extremal control and singular control. Setting the normal force equal to zero means that the curve described by the motion of the particle is that of a particle in "free fall."

Starting with the free-fall equation for velocity,

$$\frac{dV}{d\theta} = V \tan\theta \,.$$

Integrating this result yields

$$V_-(\theta) = V_0 \frac{\cos\theta_0}{\cos\theta}\,. \tag{4.40}$$

The subscript $-$ indicates that this and subsequent formulas are valid for θ near θ_0 (extremal control). Using this result in the differential equations for x, y, and t yields

$$\begin{aligned} \frac{dx}{d\theta} &= -2V_0^2 \cos^2\theta_0 \sec^2\theta\,, \\ \frac{dy}{d\theta} &= -2V_0^2 \cos^2\theta_0 \sec^2\theta \tan\theta\,, \end{aligned} \tag{4.41}$$

and

$$\frac{dt}{d\theta} = 2V_0 \cos\theta_0 \sec^2\theta\,.$$

The solution of this set of differential equations is

$$\begin{aligned} x_-(\theta) &= 1 - 2V_0^2 \cos^2\theta_0(\tan\theta - \tan\theta_0) \\ &= 1 - 2V_0^2 \frac{\cos^2\theta_0}{\cos^2\theta_f} \cos\theta_f(f(\theta) - f(\theta_0))\,, \end{aligned} \tag{4.42}$$

$$\begin{aligned} y_-(\theta) &= y_0 - V_0^2 \cos^2\theta_0(\tan^2\theta - \tan^2\theta_0) \\ &= y_0 - V_0^2 \frac{\cos^2\theta_0}{\cos^2\theta_f}(f^2(\theta) - 2f(\theta)f_0 - f^2(\theta_0) + 2f(\theta_0)f_0), \end{aligned} \tag{4.43}$$

and

$$t_-(\theta) = 2V_0 \cos\theta_0(\tan\theta - \tan\theta_0) = 2V_0 \frac{\cos\theta_0}{\cos\theta_f}(f(\theta) - f(\theta_0))\,. \tag{4.44}$$

If θ is the heading angle at the time at which the control switches, then letting $x_+(\theta)$ from (4.28) equal $x_-(\theta)$ from (4.42), $y_+(\theta)$ from (4.29) equal $y_-(\theta)$ from (4.43), and $V_+(\theta)$ from (4.24) equal $V_-(\theta)$ from (4.40) yields three equations in unknowns θ_0, θ_f, V_f, and θ. Therefore it is necessary to derive a fourth equation in these unknowns. The fourth equation will come from meeting the first two conditions for the existence of a singular arc at heading angle θ.

In order to derive the two necessary conditions for a singular arc, the differential equations for λ_V and λ_θ need to be solved. Using the costate time differential equations (4.4) with $s = -\frac{\lambda_\theta}{\mu V \lambda_V}$ yields

$$\begin{aligned} \dot\lambda_V &= L\cos(\theta - \theta_f + \theta_\mu) + \frac{1}{2}\frac{\lambda_\theta \cos\theta}{V_-^2(\theta)}, \\ \dot\lambda_\theta &= -LV_-(\theta)\sin(\theta - \theta_f + \theta_\mu) - \frac{1}{2}\lambda_V \cos\theta + \frac{1}{2}\frac{\lambda_\theta \sin\theta}{V_-(\theta)}\,. \end{aligned} \tag{4.45}$$

Rewriting these time differential equations, with a change of dependent variable, in terms of θ

$$\begin{aligned} \frac{d\lambda_V}{d\theta} &= \frac{2LV_0 \cos\theta_0 \cos(\theta - \theta_f + \theta_\mu)}{\cos^2\theta} + \frac{\lambda_\theta}{V_-}, \\ \frac{d}{d\theta}\frac{\lambda_\theta}{V_-} &= -\frac{2LV_0 \cos\theta_0 \sin(\theta - \theta_f + \theta_\mu)}{\cos^2\theta} - \lambda_V\,. \end{aligned} \tag{4.46}$$

Furthermore, the first two necessary conditions for a singular solution may be written as

$$\lambda_\theta + \tan\theta_\mu V_-(\theta)\lambda_V = \frac{V_-(\theta)}{\cos\theta_\mu}\left(\frac{\lambda_\theta}{V_-(\theta)}\cos\theta_\mu + V_-(\theta)\lambda_V \sin\theta_\mu\right) = 0\,, \tag{4.47}$$

$$-LV_-(\theta)\sin(\theta-\theta_f) - \frac{1}{2\cos\theta_\mu}\lambda_V\cos\theta = 0\,. \tag{4.48}$$

Solving the differential equations for λ_V and λ_θ/V_- yields

$$\lambda_V(\theta) = \lambda_{V_0}\cos(\theta-\theta_0) + 2L(V_0\sin(\theta-\theta_0-\theta_f+\theta_\mu) + V_-(\theta)\sin(\theta_f-\theta_\mu))$$

and

$$\frac{\lambda_\theta(\theta)}{V_-(\theta)} = -\lambda_{V_0}\sin(\theta-\theta_0) + 2L(V_0\cos(\theta-\theta_0-\theta_f+\theta_\mu) - V_-(\theta)\cos(\theta_f-\theta_\mu)),$$

where $\lambda_{V_0} = \lambda_V(0)$.

With these two quantities determined, the value of the switching function given by (4.47) and the constraint given by (4.48) is

$$-\frac{V_-(\theta)}{\cos\theta_\mu}\left(\lambda_{V_0}\sin(\theta-\theta_0-\theta_\mu) + 2LV_0\,\frac{\sin(\theta-\theta_0)\sin(\theta-\theta_f)}{\cos\theta}\right) = 0\,, \tag{4.49}$$

$$-\frac{1}{2\cos\theta_\mu}\left[\lambda_{V_0}\cos(\theta-\theta_0)\cos\theta + L\left(\frac{\cos\theta_f\cos\theta_\mu + \cos\theta\cos(\theta-\theta_f+\theta_\mu)}{\cos\theta}\sin(\theta-\theta_0)\right.\right.$$

$$\left.\left. + \frac{\cos\theta_0\cos\theta_\mu + \cos\theta\cos(\theta-\theta_0+\theta_\mu)}{\cos\theta}\sin(\theta-\theta_f)\right)V_0\right] = 0\,. \tag{4.50}$$

These two linear equations have a nontrivial solution in λ_{V_0} and L if and only if the determinant of the coefficient matrix is zero. The coefficients of λ_{V_0} and L in the second equation are *not* (scaled) time derivatives of the corresponding coefficients in the first equation, despite the derivation given for the conditions in the singular solution. This is due to the fact that the costates on the (constrained) extremal trajectory have different governing equations than the singular trajectory paths (s is *not* constant here). Expanding and simplifying the determinant of the coefficient matrix yield

$$\frac{V_0^2\cos\theta_0}{\cos^2\theta}[\sin(\theta-\theta_0)(\sin(\theta-\theta_0)-\mu\cos(\theta-\theta_0))\cos\theta_f - \mu\sin(\theta-\theta_f)\cos\theta] = 0\,. \tag{4.51}$$

Provided that the (dimensionless) initial velocity V_0 is not zero, the term in brackets being zero is the fourth equation that must hold. The constraints on these four equations come from the fact that $\theta > \theta_0$, $\theta > \theta_f$, and $V_f > 0$ and the restrictions on θ given with the states, inequality (4.26).

4.4. Abnormal trajectories. The derivation up to this point has implicitly assumed "normality" of the minimum-time trajectories. The complete formulation of an optimal control problem in the calculus of variations requires the formation of the Hamiltonian as

$$\mathcal{H} = \langle \boldsymbol{\lambda}, \boldsymbol{f}(\boldsymbol{x}, u)\rangle + \lambda_0 L(\boldsymbol{x}, u), \tag{4.52}$$

where λ_0 is a nonnegative constant. To this point the assumption has been that λ_0 was strictly positive. Thus equation (2.1) is obtained by scaling the remaining costates by the positive constant λ_0.

If, however, λ_0 is zero, then a degenerate condition exists which may yield optimal trajectories. For example, as noted in a novel case in [13], a completely controllable optimal control system with k linear controls and n states, $k < n$, and a cost function L which is quadratic positive-definite in the controls yields an optimal solution which is abnormal. The full definition of the optimal control problem is as follows [12, 23]:

(1) For any t, $\boldsymbol{\lambda}(t)$ and λ_0 are not both zero.

(2) At $(t, \boldsymbol{x}(t), \boldsymbol{\lambda}(t), \lambda_0)$, the function of u,

$$\mathcal{H} = \langle \boldsymbol{\lambda}, \boldsymbol{f}(\boldsymbol{x}, u) \rangle + \lambda_0 L(\boldsymbol{x}, u),$$

assumes for $u = u(t)$ its minimum. With the cost and the state dynamics having no explicit time dependence, the minimum value of the function $\mathcal{H}$ is constant.

(3) For the arguments $t, \boldsymbol{x}(t), \boldsymbol{\lambda}(t), \lambda_0$ the canonical Euler equations

$$\dot{\boldsymbol{x}} = \frac{\partial \mathcal{H}}{\partial \boldsymbol{\lambda}}, \qquad \dot{\boldsymbol{\lambda}} = -\frac{\partial \mathcal{H}}{\partial \boldsymbol{x}}$$

hold.

(4) If T_0 and T_f are the tangent spaces to the state manifold at $t = t_0$ and $t = t_f$, respectively, then

$$\boldsymbol{\lambda}(t_0) \perp T_0 \qquad \text{and} \qquad \boldsymbol{\lambda}(t_f) \perp T_f \,.$$

This is the *transversality* condition.

The abnormal case corresponds to choosing $\lambda_0 = 0$ and finding nontrivial $\boldsymbol{\lambda}(t)$ which satisfy the Euler equations everywhere except possibly at points where the state dynamics $\boldsymbol{f}$ are discontinuous [6]. An equivalent definition of abnormality [23] is that for an n-dimensional system $\boldsymbol{x}(t)$, there do not exist $2n$ linearly independent permissible variations $\delta P, \delta Q$, where

$$(P, Q) = ((t_0, \boldsymbol{x}(t_0)), (t_f, \boldsymbol{x}(t_f))) \,.$$

This second definition indicates the nature of abnormal trajectories; they are trajectories where the states/control cannot be admissibly varied about a given trajectory.

The singular control trajectory or the extremal control trajectory limits the admissible variations of the states and control about the given trajectory. For example, the extremal control trajectory requires that the normal force, given by

$$\frac{1}{2} \cos\theta - V\Omega,$$

be zero along the entire path. This specifies the control Ω as a function of the states V and θ. If V or θ is varied, the control varies. The control itself does *not* restrict the variation of V and θ. If it did, this would indicate an abnormal trajectory.

Similarly, the singular control trajectory requires the states/costates/control to satisfy the three constraints (4.11), thus restricting the state/costate manifold to dimension six, rather than the unconstrained eight. Thus in the singular trajectory, there are only six admissible variations in the states/costates, rather than the eight

of the unconstrained system. Nevertheless, the derivation of the singular control relies upon the cost function L in that the generalized Legendre–Clebsch condition (4.18) implicitly uses the transversality condition for admissible variations of t_f to ensure positive definiteness. With $\lambda_0 = 0$, there are no admissible variations of t_f and the generalized Legendre–Clebsch condition is trivial (zero). The singular paths therefore require "normal" trajectories, that is, those in which all seven unconstrained parameters are allowed to vary in order to realize a minimum.

The question then remains: is there a control strategy such that the states/costates may not be admissibly varied to the full dimension of the space. This question may be answered by examining the "smoothness" of the state manifold. The state manifold consists of two smooth submanifolds joined at the corner where

$$\frac{1}{2}\cos\theta - V\Omega = 0\,.$$

The corner is defined by the control Ω. Furthermore, there are no stationary points in the state-space for $V > 0$. Thus with $V > 0$, the states and the cost may be varied on the corner and on both sides of the corner due to the definition of the corner in terms of the control Ω. The minimization of the final time t_f trivially requires $V > 0$ at all interior points in a state trajectory. Thus at every point in the interior of a state trajectory, there exist admissible variations in the states/costates allowing the normal minimization.

5. The brachistochrone when the initial velocity is zero. If $V_0 = 0$, then the solution of the optimization problem is much simpler than the general case. In this case $\theta_0 = \theta = \pi/2$. The optimal control becomes the solution of the two equations

$$x_+(\pi/2) = 1 \qquad \text{and} \qquad y_+(\pi/2) = y_0\,.$$

The velocity equation and (4.51) both hold. Furthermore,

$$f(\theta) = f(\pi/2) \to \infty \qquad \text{and} \qquad \theta_f > 2\theta_\mu - \pi/2\,.$$

Taking the ratio of y_+ to x_+ will eliminate V_f from the equations, yielding one equation in one unknown, θ_f. When this is solved, the corresponding value of V_f can be solved for in either of the two equations as a positive scaling factor.

The one equation in θ_f can be used to obtain θ_f as a function of y_0 and μ. Expressing this relationship in one equation,

$$\begin{aligned} &1 + \frac{f_0(2f(\theta_f) - f_0)}{1 - f^2(\theta_f)} + \frac{3f_0^2}{(1 - f^2(\theta_f))^2} - f_0\left(\frac{2}{1 - f^2(\theta_f)}\right. \\ &\quad \left. + \frac{3f(\theta_f)f_0}{(1 - f^2(\theta_f))^2}\right)\frac{1}{\sqrt{1 - f^2(\theta_f)}}\cos^{-1}(f(\theta_f)) = y_0\cos\theta_f\left[\frac{f_0 - f(\theta_f)}{1 - f^2(\theta_f)}\right. \\ &\quad \left. - \frac{3f_0}{(1 - f^2(\theta_f))^2} + \left(\frac{1}{1 - f^2(\theta_f)} + \frac{3f(\theta_f)f_0}{(1 - f^2(\theta_f))^2}\right)\frac{1}{\sqrt{1 - f^2(\theta_f)}}\cos^{-1}(f(\theta_f))\right]. \end{aligned} \tag{5.1}$$

Expanding this equation in a power series in θ_f about $\theta_f = 2\theta_\mu - \pi/2$ will yield y_0 as a function of θ_f. Then, reverting this power series will yield θ_f as a function of y_0.

The result of this analysis is

$$\theta_f = 2\theta_\mu - \frac{\pi}{2} + 3\,\frac{y_0-\mu}{1+\mu^2} + \frac{3}{\mu}\,(1-2\mu^2)\left(\frac{y_0-\mu}{1+\mu^2}\right)^2 - \frac{3\sqrt{6}}{\pi\sqrt{\mu}}\,(3-\mu^2)\left(\frac{y_0-\mu}{1+\mu^2}\right)^{\frac{5}{2}} + O((y_0-\mu)^3). \tag{5.2}$$

Immediately apparent from this series expansion is that $y_0 = \mu$ corresponds to a final angle $\theta_f = 2\theta_\mu - \pi/2$. If this angle is substituted into equation (4.30), it is evident that the time-to-go $t_f - t(\theta)$ is infinite. Furthermore, the gradient $\frac{\partial \theta_f}{\partial y_0}$ is positive. Thus initial conditions for y_0 which are less than or equal to μ will not yield the origin in any time. This may also be argued on the grounds of the energy content of the system.

A further point to be noted is that the formal power series derived for θ_f does not converge if $\mu = 0$. This is due to the fact that the power series was expanded about $\theta_f = 2\theta_\mu - \pi/2$. In order to obtain a convergent power series for $\mu = 0$, (5.1) would need to be solved about $\mu = 0$. In this case a power series expansion for θ_f in terms of μ with y_0 as a parameter would be obtained. The initial value for θ_f would be the solution for θ_f in the classical frictionless brachistochrone. Due to the difficulty of the solution of these implicit transcendental equations, this power series solution will not be attempted.

An examination of the brachistochrones computed for $V_0 = 0$, $y_0 = 1$, and varying values of μ (Figure 5.1) demonstrates that the curves cross. The crossing occurs because near the starting point $(x, y) = (1, 1)$, the curvature of the brachistochrones is an increasing function of μ, with the curvature being infinite for $\theta = \pi/2$ and $\mu = 1$. With the increasing curvature, the brachistochrones lie closer to the line $y = y_0 x$, which, in the limit, is the "curve" for $\mu = y_0 = 1$. However, at the final point $(x, y) = (0, 0)$ of each brachistochrone, the slope $\tan\theta_f$ is a *decreasing* function of μ. This observation was not predicted correctly by Ramamani, Lu, and Tabarrok [17] in their discretization of this problem.

The final heading θ_f, the final velocity V_f, and the time-to-go t_f as a function of the coefficient of friction μ are plotted in Figure 5.2. The figure uses an initial condition of $y_0 = 1$. Although the trends displayed in the figures are consistent with different values of y_0, there is no linear relationship between figures with different values of y_0. Demonstrated in the figure is that θ_f is a decreasing function of μ. Furthermore, this function also has negative concavity. This negative concavity, which becomes infinite as $\mu \to y_0^-$, means that $t_f \to \infty$ "slowly" as $\mu \to y_0^-$. The slowness of this approach to infinity can be determined by substituting the power series for θ_f into the relationship for t_f, and by noting the implicit relationship for V_f in this expression. The result is

$$t_f = 4\sqrt{\frac{\pi}{3}}\left(\frac{6(y_0-\mu)}{\mu(1+\mu^2)}\right)^{-\frac{1}{4}} + O((y_0-\mu)^{\frac{3}{4}}). \tag{5.3}$$

This slow divergence is demonstrated in Figure 5.2.

A point not immediately apparent in Figure 5.2 is that although V_f decreases with increasing μ, its concavity has an inflection point around $\mu = 0.65$. Referring to the differential equation for $V(\theta)$, (4.23), for a given value of y_0, there is a value

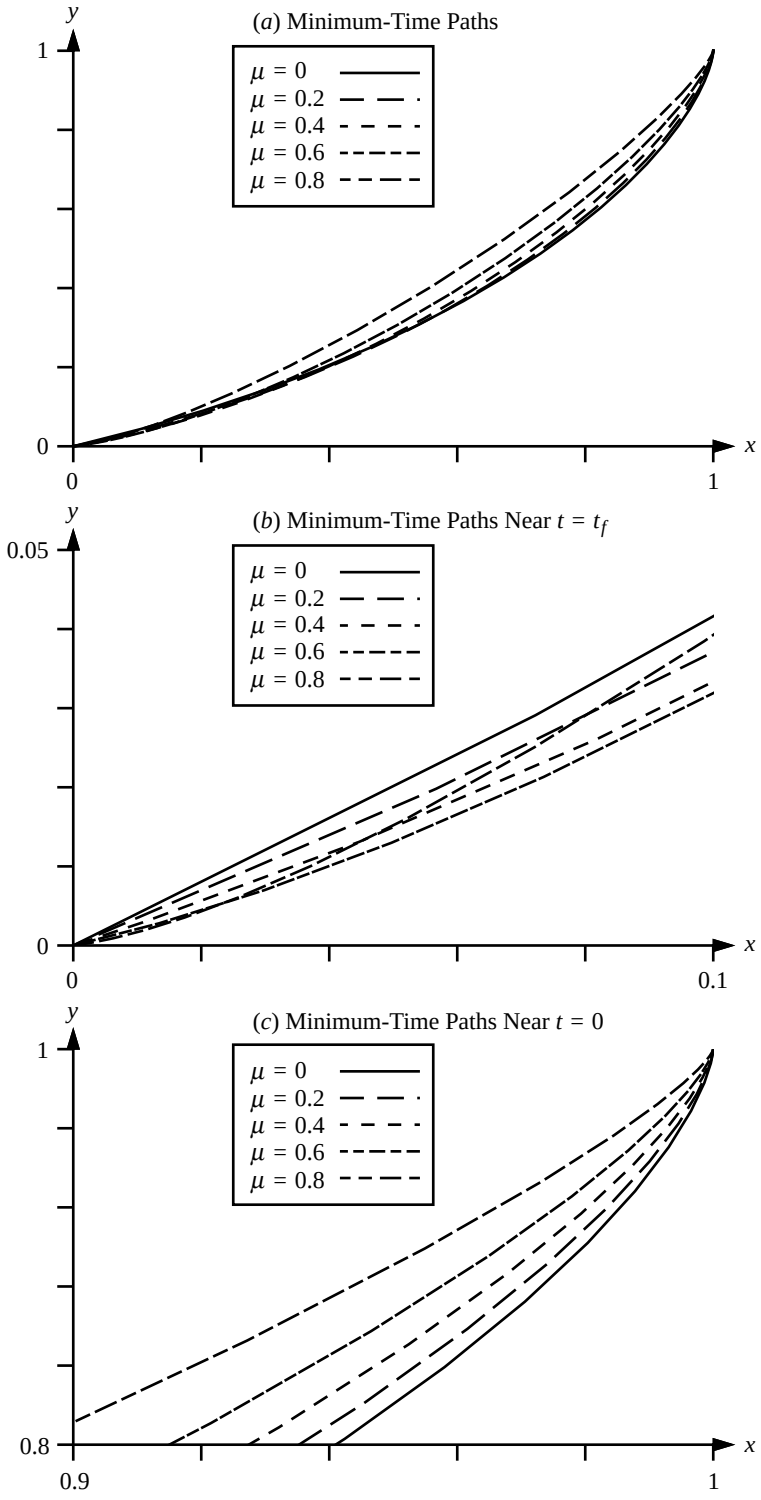

FIG. 5.1. *Coulomb friction brachistochrones with* $V_0 = 0$, $y_0 = 1$, *and differing values for* μ.

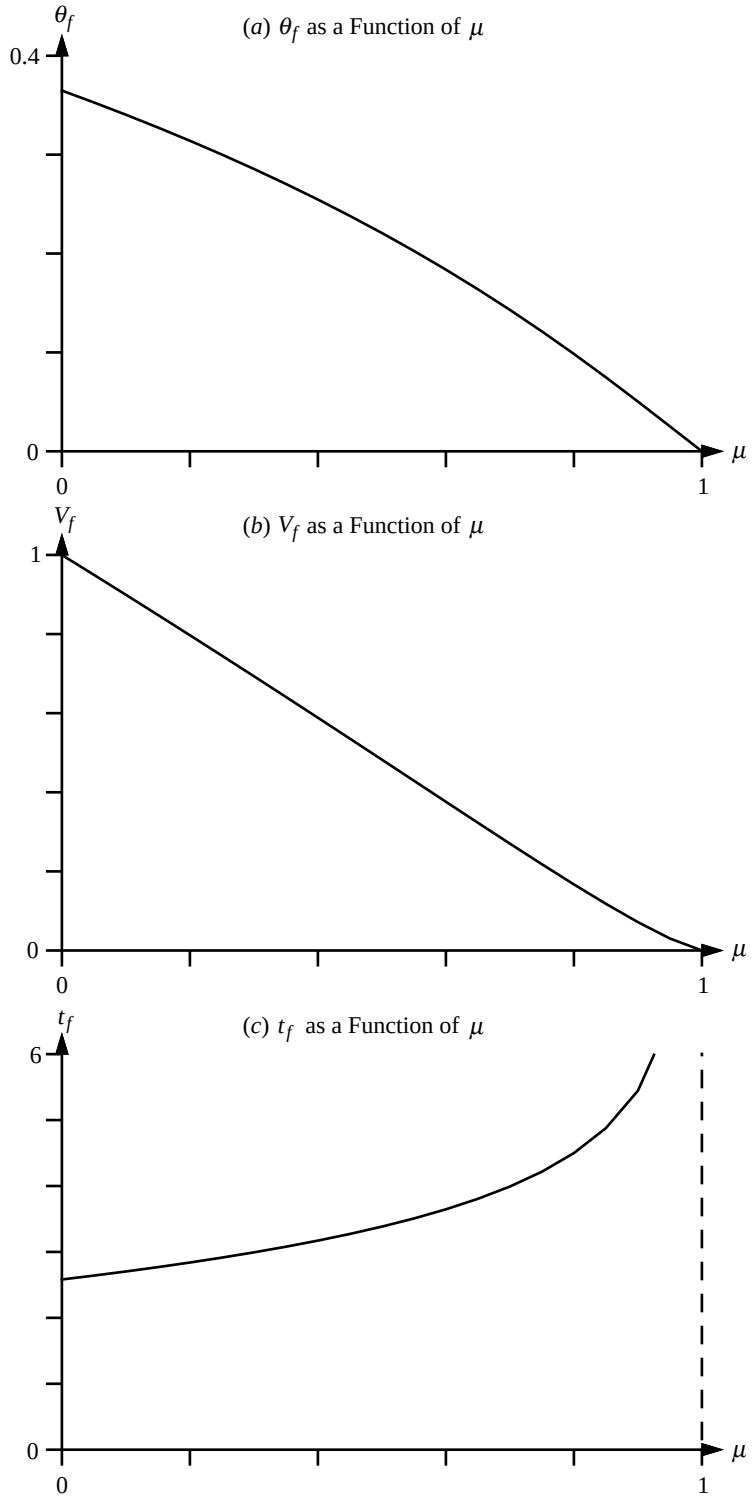

FIG. 5.2. (a) *Final heading angle* θ_f, (b) *final speed* V_f, *and* (c) *minimum time* t_f *for* $V_0 = 0$, $y_0 = 1$, *and variable* μ.

of μ at which the derivative $\frac{dV(\theta_f)}{d\theta} = 0$. This occurs when $\tan\theta_f = 2\mu$. For $y_0 = 1$, this corresponds to $\mu = 0.162\ldots$. Thus, for $y_0 = 1$ and $\mu > 0.162\ldots$, the value of V_f is no longer the largest value of V for the brachistochrone; that is, the speed of the particle initially increases but then decreases as the origin is approached. As the value of μ increases, the point of maximum velocity moves toward $\theta = \pi/2$. Due to the larger difference in angle between $V_{\max}$ and V_f for increasing μ, the plot of V_f as a function of μ will begin concave downward, inflect, and finish concave upward.

6. Some observations about minimum-time paths with nonzero initial velocity. As derived in section 4.3, the minimum-time path for a particle with nonzero initial velocity in a uniform gravitational field with Coulomb friction resisting motion consists of a "free fall" segment followed by a singular arc. The corner conditions joining the two segments are satisfied when (4.51) is satisfied. Setting $\theta = \theta_0$ in (4.51) and solving for θ_0 (and V_0) yields the minimum-time solution for which the entire path is a singular trajectory. The result of this substitution is the zero initial velocity paths presented in the previous section. These paths require $\theta = \theta_0 = \pi/2$.

Setting $\theta = \theta_f$ in (4.51) will yield the solution for a minimum-time path in which the optimal trajectory is entirely a "free fall" trajectory, that is, a trajectory in which the normal force exerted by the path on the particle is zero. Solving for θ_f yields

$$\theta_f = \theta_0 + \theta_\mu \,. \tag{6.1}$$

Substituting this result for θ in (4.42) and (4.43) and solving for θ_0 and V_0 yields

$$\theta_0 = \tan^{-1}\left(y_0 + \mu^{-1} - \sqrt{1 + y_0^2 + \mu^{-2}}\right) \tag{6.2}$$

and

$$V_0 = \sqrt{\frac{\sqrt{1 + y_0^2 + \mu^{-2}} - y_0}{2}} \,. \tag{6.3}$$

The question then is whether velocities greater than this value will yield optimal free-fall trajectories. The answer to this question comes in the solution of $s = -\frac{\lambda_\theta}{\mu V \lambda_V}$ when λ_θ, V, and λ_V are chosen to satisfy the boundary conditions at $t = 0$ and $t = t_f$. The solutions to the differential equations (4.46) with boundary conditions (4.6) are

$$\lambda_V(\theta) = -2\lambda_x V_0 \cos\theta_0 \cos\theta(\tan\theta_f - \tan\theta)(1 + \tan\theta\tan\theta_0) \,, \tag{6.4}$$

$$\frac{\lambda_\theta(\theta)}{V(\theta)} = 2\lambda_x V_0 \cos\theta_0 \cos\theta(\tan\theta_f - \tan\theta)(\tan\theta - \tan\theta_0) \,. \tag{6.5}$$

Thus

$$s = -\frac{\lambda_\theta}{\mu V \lambda_V} = \frac{\tan(\theta - \theta_0)}{\mu} \qquad \text{and} \qquad s_{\max} = \frac{\tan(\theta_f - \theta_0)}{\mu} \,. \tag{6.6}$$

Hence, if a free-fall path were time optimal, $s_{\max} \le 1$. Solving equation (4.42) equals zero and (4.43) equals zero for $\tan\theta_0$ and $\tan\theta_f$,

$$\tan\theta_0 = \sqrt{(2V_0^2 + y_0)^2 - 1 - y_0^2} - 2V_0^2, \quad \tan\theta_f = 2(V_0^2 + y_0) - \sqrt{(2V_0^2 + y_0)^2 - 1 - y_0^2} \,.$$

This means that

$$s_{\max} = \frac{\tan(\theta_f - \theta_0)}{\mu} = \frac{1}{\mu\sqrt{(2V_0^2 + y_0)^2 - 1 - y_0^2}} \le 1 \,. \tag{6.7}$$

Thus for V_0 greater than the critical V_0 given by equation (6.3), the minimum-time path is exclusively a free-fall path.

7. Conclusions. This paper has presented the time-optimal path of a particle between two points in a uniform gravitational field when motion of the particle is resisted by a force proportional to the normal force exerted on the particle by the path. This problem is equivalent to finding a brachistochrone in a uniform gravitational field with Coulomb friction resisting motion. The construction of the brachistochrone in the general case of nonzero initial velocity less than the critical initial velocity given by equation (6.3) becomes the solution of four nonlinear equations in four unknowns. For velocities greater than or equal to the critical initial velocity, the minimum-time path to the origin is a free-fall path. The special case of zero initial velocity is discussed in detail. This case simplifies the analysis to the solution of two transcendental equations in two unknowns. With a simplification, the solution becomes (5.1), which is a single transcendental equation in the unknown θ_f, the final heading angle.

A set of Coulomb friction brachistochrones with zero initial velocity are presented. The features displayed for the specific case plotted are general features of all zero initial velocity Coulomb friction brachistochrones, namely: (1) the (x, y) path is concave upward, (2) the initial heading is always directly downward, (3) the initial curvature is an increasing function of μ for a fixed initial position, (4) the final heading is a concave-downward decreasing function of the coefficient of friction μ for a fixed initial position, (5) the final velocity is a decreasing function of μ with a value of zero at $\mu = y_0$, and (6) the time-to-go is an increasing function of μ with $t_f \to +\infty$ for $\mu \to y_0^-$. Points (3) and (4) above indicate that if two brachistochrones between the same initial and final positions are drawn with different values of μ, the paths cross. This is not a common occurrence in time-optimal path problems. Typically, a change in a parameter in a time-optimal control problem does not produce a path which intersects the original path. The crossing of the paths with a change in the coefficient of friction μ is due to the lack of smoothness in the dynamics of the problem.

BOUNDARY EXACT CONTROLLABILITY OF INTERFACE PROBLEMS WITH SINGULARITIES II: ADDITION OF INTERNAL CONTROLS*

SERGE NICAISE†

Abstract. We prove the exact controllability by boundary action of hyperbolic interface problems with singularities. The two proposed methods consist of acting by a classical boundary control whose support does not contain a neighborhood of the singular points and adding internal controls located near these singular points. (See [M.-T. Niane and O. Seck, *C. R. Acad. Sci. Paris Sér.* I, 318 (1994), pp. 945–948; A. Heibig and M. Moussaoui, *Disc. Cont. Dynam. Syst.*, 2 (1996), pp. 367–386; M.-T. Niane and O. Seck, *C. R. Acad. Sci. Paris Sér.* I, 316 (1993), pp. 695–700], where such a method was introduced.)

1. Introduction.

This paper is the second of two whose purpose is the boundary exact controllability of hyperbolic interface (or transmission) problems presenting singularities at the vertices. For the sake of convenience, we use the notation and definitions from part I [20] without comment.

As we explained in [20], our motivation is twofold: first, various models of multiple-link flexible structures, consisting of finitely many interconnected flexible elements, like strings, beams, plates, or shells, or combinations of them, are of particular interest for mechanical applications and were recently derived in [8, 1, 10, 11, 2]. Second, the problem of controllability, or even stabilizability, of such structures is considered very little. Let us quote the recent works of [22, 9, 10, 21, 6, 15, 16, 6, 7]. In all these works, either no singularity occurs or, if there are some singularities, they are cancelled by an appropriate choice of the multiplier. In both cases, this is possible under strong geometrical conditions.

In order to avoid strong geometrical conditions, Niane and Seck [13, 14] and Heibig and Moussaoui [5] proposed, for the wave equation on domains with slits or with mixed boundary conditions, using classical boundary controls whose support stays far from the singular points and adding internal controls located in a small neighborhood of the singular vertices. Here we show that the method proposed by Niane and Seck [13, 14] and Heibig and Moussaoui [5] also works for transmission problems. We even proposed two strategies: the first is similar to the above authors' [5, 14]; the second consists of adding internal controls with support concentrated on small circles centered at the singular vertices.

Let us recall that for the wave equation on two-dimensional (2-d) networks, we showed [20] how to manage the presence of singularities and the controllability problem using the Hilbert uniqueness method (HUM) of Lions [12]. The strategy consisted of replacing the boundary control by its regular part and adding the coefficients of

the singularities to the space of controls. This led to a classical boundary control but with an internal control, which is a distribution with a support equal to the singular vertices.

The order of part II is the following. In section 2, we formulate the main results of this paper. In sections 3 and 6, we establish different inequalities with multipliers, which will be useful in the application of HUM. These inequalities yield an estimate of the energy. The weak solution of the wave equation is considered in sections 4 and 7, as well as its interpretation in terms of partial differential equations. Sections 5 and 8 are devoted to the setting of the HUM, i.e., to the proof of the boundary exact controllability.

The results of this paper were presented in [19].

2. Main results. On the 2-d polygonal topological network Ω (see [20, section 2]), we consider the following boundary value problem: given $f \in L^2(\Omega)$, let u be a solution of

$$-\triangle u_i = f_i \text{ in } P_i \,\forall i \in \mathcal{I}, \tag{2.1}$$

$$\gamma_{ij} u_i = 0 \text{ on } \Gamma_{ij} \,\forall\, \Gamma_{ij} \in \mathcal{D}, \tag{2.2}$$

$$\gamma_{ij} u_i = \gamma_{kl} u_k \text{ when } \Gamma_{ij} = \Gamma_{kl}, \tag{2.3}$$

$$\sum_{i\in\mathcal{I}:\exists j:\Gamma_{ij}=A} \alpha_i \gamma_{ij} \frac{\partial u_i}{\partial \nu_{ij}} = 0 \text{ on } A \text{ when } A \in \mathcal{N}. \tag{2.4}$$

Recall that the associated self-adjoint operator A on $L^2(\Omega)$ has the property that any $u \in D(A)$ has the singular expansion (2.13) of [20] (see also [3]).

In this paper we are dealing with the boundary exact controllability of the hyperbolic transmission problem associated with (2.1)–(2.4): given $T > 0$ and $(y_0, y_1) \in L^2(\Omega) \times V'$, find controls $v_{i_A}, A \in \mathcal{D}$ and $w_{i_A}, A \in \mathcal{N}_{ext}$ such that the solution y of

$$\left\{\begin{array}{l} y'' + Ay = 0 \text{ in } Q, \\ y(0) = y_0, \qquad y'(0) = y_1, \\ y_{i_A} = v_{i_A} \text{ on } \Sigma_A \,\forall A \in \mathcal{D}, \\ \frac{\partial y_{i_A}}{\partial \nu_{i_A}} = w_{i_A} \text{ on } \Sigma_A \,\forall A \in \mathcal{N}_{ext} \end{array}\right. \tag{2.5}$$

satisfies $y(T) = y'(T) = 0$.

For this problem, the HUM [12] is based on the estimate of the energy

$$E_0 = \frac{1}{2} \int_\Omega \{\alpha |\nabla \varphi_0|^2 + |\varphi_1|^2\}\, dx \tag{2.6}$$

for $(\varphi_0, \varphi_1) \in D(A) \times V$ with respect to the L^2-norms of $\frac{\partial \varphi}{\partial \nu}_{|\Sigma_A}$ for $A \in \mathcal{D}$, $\frac{\partial \varphi}{\partial \tau}_{|\Sigma_A}$, and $\varphi'_{|\Sigma_A}$ for $A \in \mathcal{N}_{ext}$, where φ is the unique solution of the homogeneous hyperbolic transmission problem

$$\left\{\begin{array}{l} \varphi'' + A\varphi = 0 \text{ in } Q, \\ \varphi(0) = \varphi_0, \qquad \varphi'(0) = \varphi_1, \\ \varphi_{i_A} = 0 \text{ on } \Sigma_A \,\forall A \in \mathcal{D}, \\ \frac{\partial \varphi_{i_A}}{\partial \nu_{i_A}} = 0 \text{ on } \Sigma_A \,\forall A \in \mathcal{N}_{ext}. \end{array}\right. \tag{2.7}$$

In our case, the implementation of HUM is not direct due to the presence of the singularities $S^{S,n}$ in the decomposition (2.13) in [20] of φ. Indeed these singularities imply that $\frac{\partial \varphi}{\partial \nu}$ and $\frac{\partial \varphi}{\partial \tau}$ are not square integrable in a neighborhood of the singular vertices (i.e. vertices for which there exists $\lambda_{S,n} \le 1/2$).

As we explained in the introduction, to overcome this difficulty we propose two methods. The first, called addition of surfacial internal control, uses classical boundary controls whose support stays far from the singular points and adds internal controls located in a small neighborhood of the singular vertices. The other consists of adding internal controls with support concentrated on small circles centered at the singular vertices; that is why we call it addition of circular internal controls.

In order to give our two main results, let us introduce the following notation: the set of singular vertices $\mathcal{S}_{sing}$ is the set of vertices S such that there exists at least one $\lambda_{S,n} \in (0, 1/2]$. As in [20, section 4], we also fix points $x_{0i} \in \Pi_i, i \in \mathcal{I}$, define the multiplier m on Ω by $m_i(x) = x - x_{0i}$, and suppose that the geometrical conditions (H1) to (H4) in [20] are satisfied (see Remark 2.3 below). For three positive real numbers δ, γ, T such that $0 < \delta < \gamma$, we set

$$\left\{\begin{array}{l} Q_i = P_i \times (0,T)\, \forall i \in \mathcal{I}, \\ A_\delta = A \setminus \cup_{S \in \mathcal{S}_{sing}} B(S,\delta)\, \forall A \in \mathcal{A}, \\ \Sigma_{A\delta} = A_\delta \times (0,T)\, \forall A \in \mathcal{A}, \\ V_S = (B(S,\gamma) \cap \Omega) \times (0,T)\, \forall S \in \mathcal{S}_{sing}, \\ C_S = (S_1(S,\delta) \cap \Omega) \times (0,T)\, \forall S \in \mathcal{S}_{sing}, \end{array}\right. \tag{2.8}$$

where, as usual, $B(S,\delta)$ (resp., $S_1(S,\delta)$) is the ball (resp., sphere) of center S and radius δ.

THEOREM 2.1. *Suppose that the geometrical conditions* (H1) *to* (H4) [20] *are satisfied. Then there exists $T_0 > 0$ such that for all $T > T_0$ and $(y_0, y_1) \in L^2(\Omega) \times V'$ there exists $(\varphi_0, \varphi_1) \in V \times L^2(\Omega)$ such that the solution y of*

$$\left\{\begin{array}{l} y'' + Ay = \sum_{S \in \mathcal{S}_{sing}} D_S \text{ in } Q, \\ y(0) = y_0, \qquad y'(0) = y_1, \\ y_{i_A} = \left\{\begin{array}{l} \alpha_{i_A}^{-1} \frac{\partial \varphi_{i_A}}{\partial \nu_{i_A}} \text{ on } \Sigma_{A\delta}\, \forall A \in \mathcal{D}^+, \\ 0 \text{ on the remainder of the Dirichlet boundary,} \end{array}\right. \\ \frac{\partial y_{i_A}}{\partial \nu_{i_A}} = \left\{\begin{array}{l} \alpha_{i_A}^{-1} \frac{d}{dt} \varphi'_{i_A} \text{ on } \Sigma_{A\delta}\, \forall A \in \mathcal{N}_{ext}^+, \\ -\alpha_{i_A}^{-1} \frac{\partial^2 \varphi}{\partial \tau_{i_A}^2} \text{ on } \Sigma_{A\delta}\, \forall A \in \mathcal{N}_{ext}^-, \\ 0 \text{ on the rest of the external Neumann boundary} \end{array}\right. \end{array}\right. \tag{2.9}$$

satisfies $y(T) = y'(T) = 0$, where φ is the solution of (2.7) *and $D_S = (\varphi - \frac{d}{dt}\varphi')\chi_{V_S}$.*

THEOREM 2.2. *Under the geometrical assumptions* (H1) *to* (H4) *in* [20]*, there exists $T_0 > 0$ such that for all $T > T_0$ and $(y_0, y_1) \in L^2(\Omega) \times V'$ there exists $(\varphi_0, \varphi_1) \in V \times L^2(\Omega)$ such that if φ is the solution of* (2.7)*, then the solution y of* (2.9) *satisfies $y(T) = y'(T) = 0$. Here D_S is a distribution defined by*

$$\langle D_S, \eta \rangle = - \sum_{j \in \mathcal{I}(S)} \int_{C_{Sj}} \left\{ \varphi'_j \eta'_j + \frac{\partial \varphi_j}{\partial \nu^j} \frac{\partial \eta_j}{\partial \nu^j} + \frac{\partial \varphi_j}{\partial \tau^j} \frac{\partial \eta_j}{\partial \tau^j} \right\} d\sigma dt, \tag{2.10}$$

where $C_S = \cup_{j \in \mathcal{I}(S)} C_{Sj}$, with $C_{Sj} = C_S \cap Q_j$, and on C_{Sj} we have set $\nu^j = (\cos\theta_j, \sin\theta_j)$, $\tau^j = (-\sin\theta_j, \cos\theta_j)$.

Remark 2.3. In Theorems 2.1 and 2.2, the boundary controls are quite classical. The influence of the singularities is balanced by the addition of the internal control

D_S for all singular vertices $S \in \mathcal{S}_{sing}$, which can be seen as a distributional internal control with a support concentrated on V_S in the first case and on C_S in the second one. Their introduction avoids the regularity hypothesis $D(A) \hookrightarrow \mathcal{H}^{3/2+\varepsilon}(\Omega)$ for some $\varepsilon > 0$, leading to strong geometrical conditions on the domains Ω [10, Chaps. 4, 7]. On the other hand, as already explained in part I, the conditions (H1) to (H4) [20] are not related to the singularities but are linked to the multiplier method, since they were introduced to avoid control on internal interfaces (see [20, Remark 6.2]).

3. Estimate of the energy I. The aim of this section is to prove the estimate of the energy with respect to an appropriate norm, leading to the addition of surfacial internal controls with the help of HUM. Usually [12, 4], the energy estimate is based on an identity with multiplier, but here we use two inequalities with multipliers, unlike [13, 5, 14], where an identity with a remainder involving the coefficients of singularities is used. The first multiplier has a support concentrated near the singular points S and vanishes at S in order to balance the singularities, while the second one vanishes in a neighborhood of the singular vertices. More precisely, we prove the following two lemmas.

LEMMA 3.1. *Let $\varphi \in C([0,T], D(A)) \cap C^1([0,T], V) \cap C^2([0,T], H)$ be the solution of (2.7). For any $S \in \mathcal{S}_{sing}$, set $m_i^S(x) = (r_i \cos\theta_i, r_i \sin\theta_i)$ for all $i \in \mathcal{I}(S)$ and $\tilde{m}^S = \eta_S m^S$, where $\eta_S \equiv \eta_S(r)$ is a cut-off function such that $\eta_S \equiv 1$ on $B(S,\delta) \cap \Omega$ with support in $B(S,\delta') \cap \Omega$ for $\delta < \delta' < \gamma$. Then the following identity holds:*

$$\begin{aligned}(3.1)\qquad &\frac{1}{2}\int_Q \operatorname{div}\,\tilde{m}^S\{(\varphi')^2 - \alpha|\nabla\varphi|^2\}\,dxdt\\ &+ \sum_{k,l=1,2}\int_Q \alpha D_k\tilde{m}_l^S D_k\varphi D_l\varphi\,dxdt = -\int_\Omega \varphi'\tilde{m}^S\cdot\nabla\varphi dx|_0^T.\end{aligned}$$

Proof. As $\tilde{m}^S \cong r$ near S and since $\tilde{m}^S$ is identically equal to 0 far from the other vertices, $\tilde{m}^S$ balances the singularities (see [20, Theorem 3.5]), and, therefore, one may apply formula (3.4) of [4]; i.e., the following identity holds on each P_i:

$$\begin{aligned}(3.2)\qquad &\int_{P_i}\triangle\varphi_i\tilde{m}_i^S\cdot\nabla\varphi_i\,dx = -\sum_{k,l=1,2}\int_{P_i} D_k\tilde{m}_{i,l}^S D_k\varphi_i D_l\varphi_i\,dx\\ &+\frac{1}{2}\int_{P_i}\operatorname{div}\,\tilde{m}_i^S|\nabla\varphi_i|^2\,dx + \sum_{j=1}^{N_i}\left\{-\frac{1}{2}\int_{\Gamma_{ij}}\tilde{m}_i^S\cdot\nu_{ij}|\nabla\varphi_i|^2\,d\sigma\right.\\ &\qquad\left.+\int_{\Gamma_{ij}}\frac{\partial\varphi_i}{\partial\nu_{ij}}\tilde{m}_i^S\cdot\nabla\varphi_i\,d\sigma\right\},\end{aligned}$$

where $\tilde{m}_{i,l}^S$ stands for the lth component of $\tilde{m}_i^S$. By the choice of the multiplier $\tilde{m}^S$, we always have

$$(3.3)\qquad \tilde{m}_i^S\cdot\nu_{ij} = 0 \text{ on } \Gamma_{ij}\ \forall j = 1,\dots,N_i.$$

Taking into account this property, multiplying the identity (3.2) by α_i, and summing on $i \in \mathcal{I}$, we get

$$\begin{aligned}(3.4)\qquad &\int_\Omega A\varphi\tilde{m}^S\cdot\nabla\varphi\,dx = \sum_{k,l=1,2}\int_\Omega \alpha D_k\tilde{m}_l^S D_k\varphi D_l\varphi\,dx\\ &-\frac{1}{2}\int_\Omega\alpha\operatorname{div}\,\tilde{m}^S|\nabla\varphi|^2\,dx - \sum_{i\in\mathcal{I}}\sum_{j=1}^{N_i}\int_{\Gamma_{ij}}\alpha_i\frac{\partial\varphi_i}{\partial\nu_{ij}}\tilde{m}_i^S\cdot\tau_{ij}\frac{\partial\varphi_i}{\partial\tau_{ij}}\,d\sigma.\end{aligned}$$

Since $\tilde{m}^S$ is continuous through the edges of Ω, the boundary term of the above identity may be transformed as follows:

$$\sum_{i\in\mathcal{I}}\sum_{j=1}^{N_i}\int_{\Gamma_{ij}}\alpha_i\frac{\partial\varphi_i}{\partial\nu_{ij}}\tilde{m}_i^S\cdot\tau_{ij}\frac{\partial\varphi_i}{\partial\tau_{ij}}\,d\sigma=\sum_{A\in\mathcal{A}}\int_A\left\{\sum_{i\in\mathcal{I}_A}\alpha_i\frac{\partial\varphi_i}{\partial\nu_i}\right\}\tilde{m}^S\cdot\tau\frac{\partial\varphi}{\partial\tau}\,d\sigma.$$

As φ satisfies the "boundary conditions" (2.2) and (2.4), this right-hand side cancels. Accordingly, the identity (3.4) is reduced to

$$\int_\Omega A\varphi\tilde{m}^S\cdot\nabla\varphi\,dx=\sum_{k,l=1,2}\int_\Omega\alpha D_k\tilde{m}_l^S D_k\varphi D_l\varphi\,dx - \frac{1}{2}\int_\Omega\alpha\ \mathrm{div}\ \tilde{m}^S|\nabla\varphi|^2\,dx. \tag{3.5}$$

For the term $\int_Q D_t^2\varphi\tilde{m}^S\cdot\nabla\varphi\ dxdt$, one integration by parts in t and Green's formula directly yield

$$\int_{Q_i}D_t^2\varphi_i\tilde{m}_i^S\cdot\nabla\varphi_i\,dxdt=\int_{P_i}D_t\varphi_i\tilde{m}_i^S\cdot\nabla\varphi_i\,dx|_0^T + \frac{1}{2}\int_{Q_i}\mathrm{div}\ \tilde{m}_i^S(D_t\varphi_i)^2\,dxdt \tag{3.6}$$

because of (3.3).

Integrating (3.5) with respect to $t\in(0,T)$ and summing the result with the sum of (3.6) on $i\in\mathcal{I}$, we arrive at (3.1), since $D_t^2\varphi+A\varphi=0$. □

By the preceding choice of $\tilde{m}^S$, we remark that

$$D_k\tilde{m}_{i,l}^S(x)=\eta_{S,i}(x)\delta_{k,l}+D_k\eta_{S,i}(x)(x-S)_l\ \forall x\in P_i, i\in\mathcal{I}(S).$$

This allows us to rewrite (3.1) in the following way:

$$\int_Q\eta_S(D_t\varphi)^2\,dxdt=R_S, \tag{3.7}$$

where we set

$$R_S=-\frac{1}{2}\int_Q\nabla\eta_S\cdot(x-S)\{(\varphi')^2-\alpha|\nabla\varphi|^2\}\,dxdt - \sum_{k,l=1,2}\int_Q\alpha D_k\eta_S(x-S)_l D_k\varphi D_l\varphi\,dxdt - \int_\Omega\varphi'\tilde{m}^S\cdot\nabla\varphi dx|_0^T. \tag{3.8}$$

The trick, as we shall see later on, is that this remainder is bounded by

$$|R_S|\le C\left[E_0+\int_{V_S}\{\varphi^2+(\varphi')^2\}\,dxdt\right] \tag{3.9}$$

for some positive constant C, depending upon η_S, T, and the geometry of Ω but independent of the initial data φ_0,φ_1.

Accordingly, summing (3.7) on all singular vertices S, we obtain

$$\int_Q \sum_{S\in\mathcal{S}_{sing}} \eta_S (D_t\varphi)^2\, dxdt = \sum_{S\in\mathcal{S}_{sing}} R_S. \tag{3.10}$$

The left-hand side of (3.10) differs from the left-hand side of the classical identity with multiplier (see, e.g., [4, eq. (3.6)] or [12, eq. (I.5.2)]) by the presence of the factor $\sum_{S\in\mathcal{S}_{sing}} \eta_S$ in front of $(D_t\varphi)^2$. Therefore it remains to cover the interior part of Ω. For this part, we take as multiplier $\tilde{m} = (1 - \sum_{S\in\mathcal{S}_{sing}} \eta_S)m$, where m is the multiplier introduced in section 4 of [20].

LEMMA 3.2. *The solution* $\varphi \in C([0,T], D(A)) \cap C^1([0,T], V) \cap C^2([0,T], H)$ *of* (2.7) *satisfies the inequality*

$$\begin{aligned}
&\frac{1}{2}\int_Q \operatorname{div}\tilde{m}\{(\varphi')^2 - \alpha|\nabla\varphi|^2\}\, dxdt + \sum_{k,l=1,2}\int_Q \alpha D_k\tilde{m}_l D_k\varphi D_l\varphi\, dxdt \\
&\le -\int_\Omega \varphi'\tilde{m}\cdot\nabla\varphi dx|_0^T + \frac{1}{2}\sum_{A\in\mathcal{D}}\int_{\Sigma_A} \alpha_{i_A}\tilde{m}_{i_A}\cdot\nu_{i_A}\left(\frac{\partial\varphi_{i_A}}{\partial\nu_{i_A}}\right)^2 d\sigma dt \\
&+ \frac{1}{2}\sum_{A\in\mathcal{N}_{ext}}\int_{\Sigma_A}\tilde{m}_{i_A}\cdot\nu_{i_A}\left\{(D_t\varphi_{i_A})^2 - \alpha_{i_A}(\frac{\partial\varphi_{i_A}}{\partial\tau_{i_A}})^2\right\} d\sigma dt.
\end{aligned} \tag{3.11}$$

Proof. The proof of (3.11) is analogous to the proof of Proposition 4.2 in [20] with $\varphi = \varphi_R$. Indeed, the integrations by parts are allowed since our multiplier $\tilde{m}$ vanishes in a neighborhood of the singular vertices; on the other hand, the continuity of η_S and the property $0 \le \eta_S \le 1$ imply that $\tilde{m}$ still satisfies the conditions (H1) to (H4) in [20]. □

As previously, the multiplier satisfies

$$D_k\tilde{m}_l = \left(1 - \sum_{S\in\mathcal{S}_{sing}}\eta_S\right)\delta_{k,l} - \sum_{S\in\mathcal{S}_{sing}} D_k\eta_S m_l.$$

This allows us to transform (3.11) into

$$\int_Q \left(1 - \sum_{S\in\mathcal{S}_{sing}}\eta_S\right)(D_t\varphi)^2\, dxdt \le R, \tag{3.12}$$

where we define

$$\begin{aligned}
R = &-\int_\Omega \varphi'\tilde{m}\cdot\nabla\varphi dx|_0^T \\
&+ \frac{1}{2}\sum_{A\in\mathcal{N}_{ext}}\int_{\Sigma_A}\tilde{m}_{i_A}\cdot\nu_{i_A}\left\{(D_t\varphi_{i_A})^2 - \alpha_{i_A}\left(\frac{\partial\varphi_{i_A}}{\partial\tau_{i_A}}\right)^2\right\} d\sigma dt \\
&+ \frac{1}{2}\sum_{A\in\mathcal{D}}\int_{\Sigma_A}\alpha_{i_A}\tilde{m}_{i_A}\cdot\nu_{i_A}\left(\frac{\partial\varphi_{i_A}}{\partial\nu_{i_A}}\right)^2 d\sigma dt \\
&+ \frac{1}{2}\int_Q \sum_{S\in\mathcal{S}_{sing}}(\nabla\eta_S\cdot m)\{(\varphi')^2 - \alpha|\nabla\varphi|^2\}\, dxdt \\
&+ \sum_{k,l=1,2}\int_Q \alpha\sum_{S\in\mathcal{S}_{sing}} D_k\eta_S m_l D_k\varphi D_l\varphi\, dxdt.
\end{aligned} \tag{3.13}$$

For any $\{\varphi_0, \varphi_1\} \in D(A) \times V$, let $\varphi \in C([0,T], D(A)) \cap C^1([0,T], V)$ be the solution of (2.7), and define

$$
\begin{aligned}
|||\{\varphi_0, \varphi_1\}|||^2 = & \sum_{A \in \mathcal{D}^+} \int_{\Sigma_{A\delta}} \left(\frac{\partial \varphi_{i_A}}{\partial \nu_{i_A}} \right)^2 d\sigma dt \\
& + \sum_{A \in \mathcal{N}_{ext}^-} \int_{\Sigma_{A\delta}} \left(\frac{\partial \varphi_{i_A}}{\partial \tau_{i_A}} \right)^2 d\sigma dt \\
& + \sum_{A \in \mathcal{N}_{ext}^+} \int_{\Sigma_{A\delta}} \left(D_t \varphi_{i_A} \right)^2 d\sigma dt \\
& + \sum_{S \in \mathcal{S}_{sing}} \int_{V_S} [\varphi^2 + (\varphi')^2] \, dx dt.
\end{aligned} \tag{3.14}
$$

We are now ready to establish the main result of this section.

PROPOSITION 3.3. *Let $\varphi \in C([0,T], D(A)) \cap C^1([0,T], V) \cap C^2([0,T], H)$ be a solution of* (2.7). *Then there exists a minimal time $T_0 > 0$ such that for all $T > T_0$, there exists a constant $C > 0$ (depending on T but not on φ_0, φ_1) such that*

$$
(T - T_0) E_0 \leq C |||\{\varphi_0, \varphi_1\}|||^2. \tag{3.15}
$$

Proof. We first start as in Proposition 4.3 of [20], i.e., by Theorem 4.3 and Remark 4.4 of [20] and the identity (4.24) of [15], we may write

$$
T E_0 = \int_Q |D_t \varphi|^2 dx dt - \frac{1}{2} \int_\Omega D_t \varphi \varphi \, dx \, |_0^T \, . \tag{3.16}
$$

The estimation of the term $\int_\Omega D_t \varphi \varphi \, dx \, |_0^T$ with respect to E_0 is classical (see [12, 4]); therefore, it remains to estimate $\int_Q |D_t \varphi|^2 dx dt$.

The sum of (3.10) and (3.12) yields a positive constant C depending only upon the functions η_S and the geometry of Ω such that

$$
\begin{aligned}
\int_Q |D_t \varphi|^2 dx dt \leq & \, C |||\{\varphi_0, \varphi_1\}|||^2 + C E_0 \\
& + C \sum_{S \in \mathcal{S}_{sing}} \int_0^T \int_{B(S,\delta')} [(\varphi')^2 + \alpha |\nabla \varphi|^2] \, dx dt
\end{aligned} \tag{3.17}
$$

because $\nabla \eta_S \equiv 0$ outside the ball $B(S, \delta')$. We therefore have only to estimate

$$
\int_0^T \int_{B(S,\delta')} \alpha |\nabla \varphi|^2 \, dx dt
$$

for all $S \in \mathcal{S}_{sing}$. This is done using Heibig and Moussaoui's trick [5]. We fix another cut-off function $\tilde{\eta}_S$ similar to η_S but satisfying $\tilde{\eta}_S \equiv 1$ on $B(S, \delta')$ and with a support on $B(S, \gamma)$. Then we multiply the equation

$$
D_t^2 \varphi_i - \alpha_i \triangle \varphi_i = 0
$$

by $\tilde{\eta}_{S,i} \varphi_i$ for all $i \in \mathcal{I}$ and integrate on Q_i, leading to

$$
\int_Q (D_t^2 \varphi - \alpha \triangle \varphi) \tilde{\eta}_S \varphi \, dx dt = 0.
$$

One integration by parts with respect to t and Green's formula on each P_i yields

$$\begin{aligned} 0 = &- \int_Q (D_t\varphi)^2 \tilde{\eta}_S \, dxdt \\ &+ \int_\Omega (D_t\varphi)\varphi\tilde{\eta}_S \, dx|_0^T \\ &+ \int_Q \alpha\nabla\varphi\cdot\nabla(\tilde{\eta}_S\varphi) \, dxdt. \end{aligned}$$

The boundary term on ∂P_i is cancelled due to the continuity of $\tilde{\eta}_S\varphi$ through the edges of Ω and since φ satisfies (2.2)–(2.4). By Leibniz's rule, the above identity may be written as

$$\begin{aligned} \int_Q \alpha|\nabla\varphi|^2\tilde{\eta}_S \, dxdt = &\int_Q (D_t\varphi)^2\tilde{\eta}_S \, dxdt \\ &- \int_\Omega (D_t\varphi)\varphi\tilde{\eta}_S \, dx|_0^T \\ &- \int_Q \alpha\varphi\nabla\varphi\cdot\nabla\tilde{\eta}_S \, dxdt. \end{aligned} \tag{3.18}$$

As $\nabla\tilde{\eta}_S$ is identically equal to 0 near the vertices, Green's formula again leads to

$$\begin{aligned} \int_Q \alpha\varphi\nabla\varphi\cdot\nabla\tilde{\eta}_S \, dxdt = &- \int_Q \alpha\varphi \text{ div } (\varphi\nabla\tilde{\eta}_S) \, dxdt \\ &+ \sum_{i\in\mathcal{I}}\sum_{j=1}^{N_i} \alpha_i \int_0^T \int_{\Gamma_{ij}} (\varphi_i)^2 \frac{\partial\tilde{\eta}_{S,i}}{\partial\nu_{ij}} \, d\sigma dt. \end{aligned}$$

Since $\frac{\partial\tilde{\eta}_{S,i}}{\partial\nu_{ij}} \equiv 0$ on all Γ_{ij}, the previous identity becomes

$$\int_Q \alpha\varphi\nabla\varphi\cdot\nabla\tilde{\eta}_S \, dxdt = -\frac{1}{2}\int_Q \alpha\varphi^2\triangle\tilde{\eta}_S \, dxdt.$$

Inserting this last identity into (3.18), we arrive at

$$\begin{aligned} \int_Q \alpha|\nabla\varphi|^2\tilde{\eta}_S \, dxdt = &\int_Q (D_t\varphi)^2\tilde{\eta}_S \, dxdt \\ &- \int_\Omega (D_t\varphi)\varphi\tilde{\eta}_S \, dx|_0^T \\ &+ \frac{1}{2}\int_Q \alpha\varphi^2\triangle\tilde{\eta}_S \, dxdt. \end{aligned} \tag{3.19}$$

Since $\tilde{\eta}_S \equiv 1$ on $B(S,\delta')$ and has its support on $B(S,\gamma)$, the identity (3.19) yields a positive constant C such that

$$\int_0^T \int_{B(S,\delta')} \alpha|\nabla\varphi|^2 \, dxdt \le C\left[E_0 + \int_{V_S} \{\varphi^2 + (\varphi')^2\} \, dxdt\right]. \tag{3.20}$$

The estimates (3.17) and (3.20) prove (3.15). □

The inverse estimate is only possible under some geometrical conditions. Therefore, we simply note that

$$|||\{\varphi_0,\varphi_1\}|||^2 \le C\{\|\varphi_0\|_{D(A)} + \|\varphi_1\|_V\}, \tag{3.21}$$

which is a consequence of Theorem 3.5 of [20] and the Poincaré estimate

$$\int_\Omega \varphi^2\, dx \le ca(\varphi,\varphi)$$

for some $c > 0$.

We now fix $T > T_0$ such that the inequality (3.15) holds. Then the application

$$D(A)\times V \to \mathbf{R}^+ : \{\varphi_0,\varphi_1\} \to |||\{\varphi_0,\varphi_1\}|||$$

is a norm stronger than the norm induced by $V \times H$ due to Proposition 3.3. As in [12, 4, 15], we define F as the closure of $D(A)\times V$ for this new norm. Due to (3.15) and (3.21) we have the algebraic and topological inclusions:

$$D(A)\times V \hookrightarrow F \hookrightarrow V \times H. \tag{3.22}$$

For the inhomogeneous wave equation (3.1) of [20], we can now state the following result.

PROPOSITION 3.4. *Let $\{\varphi_0,\varphi_1\} \in F$ and $f \in L^1(0,T;V)$. Then the unique solution $\varphi \in C([0,T],V)\cap C^1([0,T],H)$ of* (3.1) *of* [20] *satisfies*

$$\frac{\partial \varphi_{i_A}}{\partial \nu_{i_A}} \in L^2(\Sigma_{A\delta})\,\forall A \in \mathcal{D}^+, \tag{3.23}$$

$$\frac{\partial \varphi_{i_A}}{\partial \tau_{i_A}} \in L^2(\Sigma_{A\delta})\,\forall A \in \mathcal{N}^-_{ext}, \tag{3.24}$$

$$D_t\varphi_{i_A} \in L^2(\Sigma_{A\delta})\,\forall A \in \mathcal{N}^+_{ext}. \tag{3.25}$$

Moreover, there exists a constant $C > 0$ (independent of $\{\varphi_0,\varphi_1\}$ and f) such that

$$\begin{aligned}&\left\{\sum_{A\in\mathcal{D}^+}\int_{\Sigma_{A\delta}}\left(\frac{\partial\varphi_{i_A}}{\partial\nu_{i_A}}\right)^2 d\sigma dt + \sum_{A\in\mathcal{N}^-_{ext}}\int_{\Sigma_{A\delta}}\left(\frac{\partial\varphi_{i_A}}{\partial\tau_{i_A}}\right)^2 d\sigma dt\right.\\ &\left.+\sum_{A\in\mathcal{N}^+_{ext}}\int_{\Sigma_{A\delta}}(D_t\varphi_{i_A})^2\, d\sigma dt + \sum_{S\in\mathcal{S}_{sing}}\int_{V_S}[\varphi^2+(\varphi')^2]\,dxdt\right\}^{1/2}\\ &\le C\left\{|||\{\varphi_0,\varphi_1\}||| + \|f\|_{L^1(0,T;V)}\right\}.\end{aligned} \tag{3.26}$$

Proof. The proof is standard (see [4, Theorem 5.6] or [20, Proposition 4.4]). It is based on the definition of F, Theorem 2.2 of [20] and the usual trace theorems. Indeed the solution $\varphi^{(2)}$ of the wave equation (3.1) of [20] with data $\varphi_0 = \varphi_1 = 0$ and $f \in L^1(0,T;V)$ has the regularity $\varphi^{(2)} \in C([0,T],D(A))\cap C^1([0,T],V)$, as a consequence of Theorem 3.1 of [20]. By Theorem 2.2 and the estimate (3.2) of [20] and the usual trace theorems, it clearly satisfies the estimate (3.26). ∎

4. Weak solutions of the wave equation I. We transpose Proposition 3.4 to get Theorem 4.1.

THEOREM 4.1. *For all $u_0 \in H$, $u_1 \in V'$, $w_A \in L^2(\Sigma_{A\delta})$, where $A \in \mathcal{D}^+ \cup \mathcal{N}^+_{ext} \cup \mathcal{N}^-_{ext}$, and all $w_S \in H^1((0,T);L^2(B(S,\gamma)\cap\Omega)), S \in \mathcal{S}_{sing}$, there exist unique $u \in L^\infty(0,T;V')$, $\{\psi_1,\psi_0\} \in F'$, which satisfy*

$$\begin{aligned}(4.1)\qquad &\int_0^T \langle u(t), f(t)\rangle_{V'-V} dt + \langle\{\psi_1,\psi_0\},\{\varphi_0,-\varphi_1\}\rangle_{F'-F}\\ &= \langle u_1,\varphi(0)\rangle_{V'-V} - \langle u_0,\varphi'(0)\rangle_{H'-H} - \sum_{A\in\mathcal{D}^+}\int_{\Sigma_{A\delta}} w_A \frac{\partial\varphi_{i_A}}{\partial\nu_{i_A}}\, d\sigma dt\\ &- \sum_{A\in\mathcal{N}^-_{ext}}\int_{\Sigma_{A\delta}} w_A \frac{\partial\varphi_{i_A}}{\partial\tau_{i_A}}\, d\sigma dt - \sum_{A\in\mathcal{N}^+_{ext}}\int_{\Sigma_{A\delta}} w_A D_t\varphi_{i_A}\, d\sigma dt\\ &- \sum_{S\in\mathcal{S}_{sing}}\int_{V_S}\{w_S\varphi + w'_S\varphi'\}\, dxdt\end{aligned}$$

for all $f \in L^1(0,T;V)$, $\{\varphi_0,-\varphi_1\} \in F$, where $\varphi \in C([0,T],V)\cap C^1([0,T],H)$ is the unique solution of

$$(4.2)\qquad \begin{cases} \varphi''(t) + A\varphi(t) = f(t), & t\in[0,T],\\ \varphi(T)=\varphi_0, \varphi'(T)=\varphi_1. \end{cases}$$

For the interpretation of (4.1) in terms of partial differential equations, we need the next density result.

LEMMA 4.2. *Let X be a separable Hilbert space and denote by*

$$K = \{w \in H^2((0,T);X) : w'(0) = w'(T) = 0\}.$$

Then K is dense in $H^1((0,T);X)$.

Proof. Let $u \in K^\perp$; then it fulfills

$$(4.3)\qquad \int_0^T \{(u(t),w(t))_X + (u'(t),w'(t))_X\}\, dt = 0\,\forall w \in K,$$

where $(\cdot,\cdot)_X$ denote the inner product of X. Fix an arbitrary element w of X and introduce the function

$$U : t \to (u(t),w)_X.$$

Clearly, it belongs to $H^1((0,T))$ and satisfies

$$U'' - U = 0 \text{ in } \mathcal{D}'((0,T))$$

by taking as test function $w(t)$ in (4.3) the function $w(t) = \varphi(t)w$, where $\varphi \in \mathcal{D}((0,T))$. This implies that U is a linear combination of e^t and e^{-t}. But going back to (4.3) with $w(t) = w\varphi(t)$, where $\varphi \in C^\infty([0,T])$ such that $\varphi'(T) = \varphi'(0) = 0$, we deduce that $U \equiv 0$, because $\varphi(0), \varphi(T)$ are free.

Since w was arbitrary in X, we conclude that $u \equiv 0$. □

We apply Lemma 4.2 with $X = L^2(B(S,\gamma)\cap\Omega)$, for any $S \in \mathcal{S}_{sing}$. Let us then denote by K_S the corresponding space K.

THEOREM 4.3. *Let $u \in L^\infty(0,T;V')$, $\{\psi_1,\psi_0\} \in F'$ be the unique solution of (4.1) with data $u_0 \in V$, $u_1 \in H$, $w_A \in \mathcal{D}(\Sigma_{A\delta})$, where $A \in \mathcal{D}^+ \cup \mathcal{N}^+_{ext} \cup \mathcal{N}^-_{ext}$, and with $w_S \in K_S, S \in \mathcal{S}_{sing}$. Then $u \in C^1([0,T],H)$ satisfies the boundary conditions*

$$u_{i_A} = \begin{cases} \alpha_{i_A}^{-1} w_A \text{ on } \Sigma_{A\delta}\, \forall A \in \mathcal{D}^+, \\ 0 \text{ on } \Sigma_A \setminus \Sigma_{A\delta}\, \forall A \in \mathcal{D}^+, \\ 0 \text{ on } \Sigma_A\, \forall A \in \mathcal{D} \setminus \mathcal{D}^+ \end{cases} \tag{4.4}$$

and (4.5) *to* (4.7) *below:*

$$u_i'' - \alpha_i \triangle u_i = \sum_{S \in \mathcal{S}_{sing}} \{w_{S,i} - w_{S,i}''\}\chi_{V_S,i} \text{ in } \mathcal{D}'(Q_i)\, \forall i \in \mathcal{I}, \tag{4.5}$$

$$u(0) = u_0, \qquad u'(0) = u_1, \tag{4.6}$$

$$u(T) = \psi_0, \qquad u'(T) = \psi_1. \tag{4.7}$$

Proof. We proceed as in Theorem 5.3 of [15] or in Theorem 5.4 of [20] with the necessary adaptations. Let us fix $v \in \mathcal{D}(0,T,\prod_{i\in\mathcal{I}} C^\infty(\overline{P}_i))$ fulfilling (5.3) and (5.4) of [20] (on $\Sigma_A \setminus \Sigma_{A\delta}$, we simply take $w_A = 0$) and obtained in [20, Lemma 5.3]. (v can be chosen equal to 0 in a neighborhood of $S \times [0,T]$ for all $S \in \mathcal{S}_{sing}$; see Lemma 7.2). Define

$$f = v'' - \alpha \triangle v - \sum_{S \in \mathcal{S}_{sing}} \{w_S - w_S''\}\chi_{V_S}.$$

Since $f \in L^2(0,T;H)$, Lemma I.3.4 of [12] guarantees the existence of a unique solution $\psi \in C([0,T],V) \cap C^1([0,T],H) \cap H^2(0,T;V')$ of

$$\begin{cases} \langle \psi''(t), w\rangle + a(\psi(t), w) \\ = -\int_\Omega f(t) w dx, \text{ a.e. } t \in [0,T]\, \forall w \in V, \\ \psi(0) = u_0, \qquad \psi'(0) = u_1. \end{cases} \tag{4.8}$$

Let us now show that

$$u = \psi + v \tag{4.9}$$

is the unique solution of (4.1) when $\psi_0 = u(T), \psi_1 = u'(T)$. We remark that the fact that $v \equiv 0$ near $t = 0$ and $t = T$ leads to the initial conditions (4.6).

From Theorem 4.2 of [15], it suffices to check (4.1) for $\varphi \in C([0,T],D(A)) \cap C^1([0,T],V) \cap C^2([0,T],H)$. Since $u \in H^2(0,T;V')$, the integrations by parts over $(0,T)$ are allowed. Taking into account the initial conditions satisfied by φ and u, we get

$$\begin{aligned} &\int_0^T \langle u(t), \varphi''(t) + A\varphi(t)\rangle dt - \langle u(T), \varphi_1\rangle + \langle u'(T), \varphi_0\rangle \\ &= \langle u_1, \varphi(0)\rangle - \langle u_0, \varphi'(0)\rangle \\ &+ \int_0^T \{\langle \psi''(t), \varphi(t)\rangle + a(\psi(t), \varphi(t)) \\ &\qquad + \langle v''(t), \varphi(t)\rangle + (v(t), A\varphi(t))_H\} dt. \end{aligned} \tag{4.10}$$

As $v(t)$ is identically equal to 0 in a neighborhood of the singular vertices, Green's formula on each P_i is allowed and leads to

$$\begin{aligned}(v(t),A\varphi(t))_H &= (Av(t),\varphi(t))_H \\ &\quad+\sum_{A\in\mathcal{N}_{ext}}\int_A \alpha_{i_A}\frac{\partial v_{i_A}}{\partial\nu_{i_A}}\varphi_{i_A}\,d\sigma \\ &\quad-\sum_{A\in\mathcal{D}}\int_A \alpha_{i_A}v_{i_A}\frac{\partial\varphi_{i_A}}{\partial\nu_{i_A}}\,d\sigma.\end{aligned}$$

Integrating this identity on $(0,T)$ and taking into account (5.3) and (5.4) of [20], we obtain, after integrations by parts on each $\Sigma_{A\delta}$ for all $A\in\mathcal{N}_{ext}^+\cup\mathcal{N}_{ext}^-$,

$$\begin{aligned}\int_0^T (v(t),A\varphi(t))_H\,dt &= \int_0^T (Av(t),\varphi(t))_H\,dt \\ &\quad-\sum_{A\in\mathcal{N}_{ext}^+}\int_{\Sigma_{A\delta}} w_A D_t\varphi_{i_A}\,d\sigma dt \\ &\quad-\sum_{A\in\mathcal{N}_{ext}^-}\int_{\Sigma_{A\delta}} w_A\frac{\partial\varphi_{i_A}}{\partial\tau_{i_A}}\,d\sigma dt \\ &\quad-\sum_{A\in\mathcal{D}^+}\int_{\Sigma_{A\delta}} w_A\frac{\partial\varphi_{i_A}}{\partial\nu_{i_A}}\,d\sigma dt.\end{aligned}$$

Inserting this identity into (4.10), we arrive at the conclusion, because the choice of $w_S\in K_S$ yields

$$\int_{V_S}(w_S-w_S'')\varphi\,dxdt=\int_{V_S}(w_S\varphi+w_S'\varphi')\,dxdt. \qquad \square$$

Roughly speaking, ψ introduced in the above proof satisfies (2.4), and therefore, as v satisfies (5.4), one can say that u satisfies

$$\frac{\partial u_{i_A}}{\partial\nu_{i_A}}=\begin{cases}\alpha_{i_A}^{-1}D_t w_A \text{ on } \Sigma_{A\delta}\,\forall A\in\mathcal{N}_{ext}^+,\\ \alpha_{i_A}^{-1}\frac{\partial w_A}{\partial\tau_{i_A}} \text{ on } \Sigma_{A\delta}\,\forall A\in\mathcal{N}_{ext}^-,\\ 0 \text{ on } \Sigma_A\setminus\Sigma_{A\delta}\,\forall A\in(\mathcal{N}_{ext}^+\cup\mathcal{N}_{ext}^-),\\ 0 \text{ on } \Sigma_A\,\forall A\in\mathcal{N}_{ext}\setminus(\mathcal{N}_{ext}^+\cup\mathcal{N}_{ext}^-)\end{cases} \tag{4.11}$$

in a weak sense.

All these considerations lead us to call the solution u of (4.1) the weak solution of (4.5), (4.6), (4.4), and (4.11). Moreover, with the help of Lemma 4.2, Theorem 5.7 of [20] still holds for u, which allows us to give a meaning to the final conditions (4.7). We even have the following result.

THEOREM 4.4. *Under the assumption of Theorem* 4.1*, let* u*,* $\{\psi_1,\psi_0\}$ *be the solutions of* (4.1)*. Then* $u\in C([0,T],V')\cap C^1([0,T],D(A)')$ *and* u *satisfies the final conditions* (4.7)*.*

5. Addition of surfacial internal controls. The application of the Hilbert uniqueness method of Lions [12] is now standard. First, by Proposition 3.4 for $\{\varphi_0,\varphi_1\}\in F$ there exists a unique solution $\varphi\in C([0,T],V)\cap C^1([0,T],H)$ of (2.7) (or (3.1) of [20] with $f=0$), satisfying (3.26). Second, consider $\psi\in L^\infty(0,T;V')$, $\{\chi_1,-\chi_0\}\in F'$, the unique solution of

$$
\begin{aligned}
(5.1)\qquad & \int_0^T \langle \psi(t), g(t)\rangle dt - \langle \{\chi_1, -\chi_0\}, \{\eta_0, \eta_1\}\rangle \\
&= -\sum_{A\in\mathcal{D}^+} \int_{\Sigma_{A\delta}} \frac{\partial \varphi_{i_A}}{\partial \nu_{i_A}} \frac{\partial \eta_{i_A}}{\partial \nu_{i_A}}\, d\sigma dt - \sum_{A\in\mathcal{N}^-_{ext}} \int_{\Sigma_{A\delta}} \frac{\partial \varphi_{i_A}}{\partial \tau_{i_A}} \frac{\partial \eta_{i_A}}{\partial \tau_{i_A}}\, d\sigma dt \\
&- \sum_{A\in\mathcal{N}^+_{ext}} \int_{\Sigma_{A\delta}} D_t\varphi_{i_A} D_t\eta_{i_A}\, d\sigma dt \\
&- \sum_{S\in\mathcal{S}_{sing}} \int_{V_S} \{\varphi\eta + \varphi'\eta'\}\, dxdt
\end{aligned}
$$

for all $g \in L^1(0,T;V)$, $\{\eta_0, \eta_1\} \in F$, where $\eta \in C([0,T],V) \cap C^1([0,T],H)$ is the unique solution of

$$
(5.2)\qquad \begin{cases} \eta''(t) + A\eta(t) = g(t), & t \in [0,T], \\ \eta(0) = \eta_0, \qquad \eta'(0) = \eta_1. \end{cases}
$$

Its existence comes from Theorem 4.1 by inverting the order of time; moreover, Theorem 4.4 gives a meaning to the initial conditions

$$\psi(0) = \chi_0, \qquad \psi'(0) = \chi_1.$$

Accordingly, the operator

$$\Lambda : F \to F' : \{\varphi_0, \varphi_1\} \to \{\chi_1, -\chi_0\}$$

is well defined and is an isomorphism, because the identity (5.1) with $\eta = \varphi$ yields

$$\langle \Lambda\{\varphi_0, \varphi_1\}, \{\varphi_0, \varphi_1\}\rangle = |||\{\varphi_0, \varphi_1\}|||^2 \ \forall \{\varphi_0, \varphi_1\} \in F.$$

This leads to Theorem 2.1, which we reformulate as follows.

THEOREM 5.1. *For all $u_0 \in H$, $u_1 \in V'$ there exist $w_A \in L^2(\Sigma_{A\delta})$, $A \in \mathcal{D}^+ \cup \mathcal{N}^+_{ext} \cup \mathcal{N}^-_{ext}$, and $v_S \in H^1((0,T); L^2(B(S,\gamma)\cap\Omega)$, $S \in \mathcal{S}_{sing}$, such that the weak solution $u \in C([0,T],V') \cap C^1([0,T],D(A)')$ of the wave equation* (5.3) *below* (*in the sense of* (4.1)) *satisfies $u(T) = u'(T) = 0$:*

$$
(5.3)\qquad \begin{cases} u''(t) + Au(t) = \sum_{S\in\mathcal{S}_{sing}} \{v_S - \frac{d}{dt} v'_S\}\chi_{V_S}, & t \in [0,T], \\ u(0) = u_0, \qquad u'(0) = u_1, \\ u \text{ satisfies (4.4) and (4.11).} \end{cases}
$$

Proof. Since $\{u_1, -u_0\} \in V' \times H \subset F'$, there exists a unique solution $\{\varphi_0, \varphi_1\} \in F$ of

$$\Lambda\{\varphi_0, \varphi_1\} = \{u_1, -u_0\}.$$

We take the solution φ of (2.7) and the solution ψ of (5.1) and set $u = \psi$, $w_A = \frac{\partial \varphi_{i_A}}{\partial \nu_{i_A}}$ for all $A \in \mathcal{D}^+$, $w_A = D_t\varphi_{i_A}$ for all $A \in \mathcal{N}^+_{ext}$, $w_A = \frac{\partial \varphi_{i_A}}{\partial \tau_{i_A}}$ for all $A \in \mathcal{N}^-_{ext}$, $v_S = \varphi$ for all $S \in \mathcal{S}_{sing}$. Because of the time reversibility of the wave equation, the conclusion follows from Proposition 3.4. ∎

6. Estimate of the energy II. The main idea of the second method consists of isolating the singular vertices S by the introduction of an artificial interface C_S. We then use the classical multiplier far from the singular vertices and the multiplier m^S on $B(S,\delta)\cap\Omega$. Namely, we establish the following result.

LEMMA 6.1. *Introduce the multiplier q defined on Ω by $q(x) = m^S(x)$ if $x \in B(S,\delta)\cap\Omega$ for all $S \in \mathcal{S}_{sing}$ and $q(x) = m(x)$ if $x \in \Omega \setminus \cup_{S\in\mathcal{S}_{sing}} B(S,\delta)$. Then the solution $\varphi \in C([0,T], D(A)) \cap C^1([0,T], V)$ of (2.7) satisfies the inequality*

$$
\begin{aligned}
(6.1)\quad \frac{1}{2}\int_Q (\varphi')^2\, dxdt \le & -\int_\Omega \varphi' q\cdot\nabla\varphi dx|_0^T \\
& + \frac{1}{2}\sum_{A\in\mathcal{D}}\int_{\Sigma_{A\delta}} \alpha_{i_A} m_{i_A}\cdot\nu_{i_A}\left(\frac{\partial\varphi_{i_A}}{\partial\nu_{i_A}}\right)^2 d\sigma dt \\
& + \frac{1}{2}\sum_{A\in\mathcal{N}_{ext}}\int_{\Sigma_{A\delta}} m_{i_A}\cdot\nu_{i_A}\left\{(D_t\varphi_{i_A})^2 - \alpha_{i_A}\left(\frac{\partial\varphi_{i_A}}{\partial\tau_{i_A}}\right)^2\right\} d\sigma dt \\
& + \sum_{S\in\mathcal{S}_{sing}}\sum_{j\in\mathcal{I}(S)}\int_{C_{Sj}}\left[\frac{1}{2}(m_j^S - m_j)\cdot\nu^j\left\{(\varphi_j')^2 + \alpha_j\left(\frac{\partial\varphi_j}{\partial\nu_j}\right)^2 - \alpha_j\left(\frac{\partial\varphi_j}{\partial\tau_j}\right)^2\right\}\right. \\
& \qquad \left. + \alpha_j(m_j^S - m_j)\cdot\tau^j\frac{\partial\varphi_j}{\partial\nu_j}\frac{\partial\varphi_j}{\partial\tau_j}\right] d\sigma dt.
\end{aligned}
$$

Proof. We follow the proof of Proposition 4.2 of [20], except that the integration by parts on Ω are here made on $B(S,\delta)\cap\Omega$ for all $S\in\mathcal{S}_{sing}$ and on the remainder, i.e., on $\Omega\setminus\cup_{S\in\mathcal{S}_{sing}} B(S,\delta)$. That explains the presence of the boundary terms on C_S. More precisely, as $m^S \cong r$ near the singular vertices S, m^S balances the singularities (see [20, Theorem 3.5]) and, therefore, one may apply formula (3.4) of [4] in $P_i\cap B(S,\delta)$ and in $P_i\setminus\cup_{S\in\mathcal{S}_{sing}} B(S,\delta)$. Summing the results, we arrive at the following identity on each P_i:

$$
\begin{aligned}
(6.2)\quad \int_{P_i}\triangle\varphi_i q_i\cdot\nabla\varphi_i\, dx = & \sum_{j=1}^{N_i}\left\{-\frac{1}{2}\int_{\Gamma_{ij}} q_i\cdot\nu_{ij}|\nabla\varphi_i|^2\, d\sigma\right. \\
& \qquad \left. + \int_{\Gamma_{ij}}\frac{\partial\varphi_i}{\partial\nu_{ij}} q_i\cdot\nabla\varphi_i\, d\sigma\right\} \\
& + \sum_{S\in\mathcal{S}_{sing}\cap\bar{P}_i}\int_{S_1(S,\delta)\cap P_i}\left[\frac{1}{2}(m_i^S - m_i)\cdot\nu^i\left\{\left(\frac{\partial\varphi_i}{\partial\nu_i}\right)^2 - \left(\frac{\partial\varphi_i}{\partial\tau_i}\right)^2\right\}\right. \\
& \qquad \left. + (m_i^S - m_i)\cdot\tau^i\frac{\partial\varphi_i}{\partial\nu_i}\frac{\partial\varphi_i}{\partial\tau_i}\right] d\sigma dt.
\end{aligned}
$$

As usual, we multiply this identity by α_i and sum on $i\in\mathcal{I}$. Since q is continuous on $B(S,\delta)\cap\Omega$ for $S\in\mathcal{S}_{sing}$ and satisfies

$$
q_i\cdot\nu_{ij} = 0 \text{ on } \Gamma_{ij}\cap B(S,\delta)\ \forall j = 1,\dots,N_i,
$$

the boundary terms are equal to 0 on $\Gamma_{ij}\cap B(S,\delta)$ for all $S\in\mathcal{S}_{sing}$. Moreover, as in Lemma 4.1 of [20], taking into account the conditions (H1) to (H4) [20] satisfied by m, the identity (6.2) implies the estimate

$$
\begin{aligned}
(6.3)\quad \int_\Omega A\varphi q\cdot\nabla\varphi dx \ge & -\frac{1}{2}\sum_{A\in\mathcal{D}}\int_{A_\delta}\alpha_{i_A} m_{i_A}\cdot\nu_{i_A}\left(\frac{\partial\varphi_{i_A}}{\partial\nu_{i_A}}\right)^2 d\sigma \\
& + \frac{1}{2}\sum_{A\in\mathcal{N}_{ext}}\int_{A_\delta}\alpha_{i_A} m_{i_A}\cdot\nu_{i_A}\left(\frac{\partial\varphi_{i_A}}{\partial\tau_{i_A}}\right)^2 d\sigma
\end{aligned}
$$

$$+ \sum_{S\in\mathcal{S}_{sing}} \sum_{i\in\mathcal{I}(S)} \alpha_i \int_{S_1(S,\delta)\cap P_i} \left[\frac{1}{2}(m_i^S - m_i)\cdot\nu^i \left\{ \left(\frac{\partial\varphi_i}{\partial\nu_i}\right)^2 - \left(\frac{\partial\varphi_i}{\partial\tau_i}\right)^2 \right\} + (m_i^S - m_i)\cdot\tau^i \frac{\partial\varphi_i}{\partial\nu_i}\frac{\partial\varphi_i}{\partial\tau_i} \right] d\sigma dt.$$

For the term $\int_Q D_t^2\varphi q\cdot\nabla\varphi\, dxdt$ one integration by parts in t leads to

$$\int_Q D_t^2\varphi q\cdot\nabla\varphi\, dxdt = \int_\Omega D_t\varphi q\cdot\nabla\varphi\, dx\,|_0^T - \int_Q D_t\varphi q\cdot\nabla D_t\varphi\, dxdt. \tag{6.4}$$

The second term of the right-hand side is transformed using Green's formula in $P_i\cap B(S,\delta)$ for any $S\in\mathcal{S}_{sing}$ and in the remainder for all $i\in\mathcal{I}$. This leads to

$$\begin{aligned}\int_Q D_t\varphi q\cdot\nabla D_t\varphi\, dxdt = &-\int_Q (D_t\varphi)^2 dxdt \\ &+ \frac{1}{2}\sum_{A\in\mathcal{A}}\int_{\Sigma_A}(D_t\varphi)^2\left(\sum_{i\in\mathcal{I}_A} q_i\cdot\nu_i\right)d\sigma dt \\ &+ \frac{1}{2}\sum_{S\in\mathcal{S}_{sing}}\sum_{j\in\mathcal{I}(S)}\int_{C_{Sj}}(m_j^S - m_j)\cdot\nu^j(\varphi')^2\, d\sigma dt.\end{aligned}$$

Taking into account the above properties of q and the condition (H1) [20], we arrive at

$$\begin{aligned}\int_Q D_t\varphi q\cdot\nabla D_t\varphi\, dxdt = &-\int_Q (D_t\varphi)^2 dxdt \\ &+ \frac{1}{2}\sum_{A\in\mathcal{N}_{ext}}\int_{\Sigma_{A\delta}}(D_t\varphi)^2 q_{i_A}\cdot\nu_{i_A} d\sigma dt \\ &+ \frac{1}{2}\sum_{S\in\mathcal{S}_{sing}}\sum_{j\in\mathcal{I}(S)}\int_{C_{Sj}}(m_j^S - m_j)\cdot\nu^j(\varphi')^2\, d\sigma dt.\end{aligned} \tag{6.5}$$

Integrating (6.3) on $(0,T)$ and summing the result with (6.5), we obtain the inequality (6.1). □

The right-hand side of (6.1) legitimates the next definition. For any $\{\varphi_0,\varphi_1\}\in D(A)\times V$, let $\varphi\in C([0,T],D(A))\cap C^1([0,T],V)$ be the solution of (2.7) and define

$$\begin{aligned}|||\{\varphi_0,\varphi_1\}|||^2 = &\sum_{A\in\mathcal{D}^+}\int_{\Sigma_{A\delta}}\left(\frac{\partial\varphi_{i_A}}{\partial\nu_{i_A}}\right)^2 d\sigma dt \\ &+ \sum_{A\in\mathcal{N}_{ext}^-}\int_{\Sigma_{A\delta}}\left(\frac{\partial\varphi_{i_A}}{\partial\tau_{i_A}}\right)^2 d\sigma dt \\ &+ \sum_{A\in\mathcal{N}_{ext}^+}\int_{\Sigma_{A\delta}}(D_t\varphi_{i_A})^2\, d\sigma dt \\ &+ \sum_{S\in\mathcal{S}_{sing}}\sum_{j\in\mathcal{I}(S)}\int_{C_{Sj}}\left\{(\varphi_j')^2 + \left(\frac{\partial\varphi_j}{\partial\nu^j}\right)^2 + \left(\frac{\partial\varphi_j}{\partial\tau^j}\right)^2\right\} d\sigma dt.\end{aligned} \tag{6.6}$$

The identity (3.16) and the estimate (6.1) directly lead to the next estimate of the energy.

PROPOSITION 6.2. *Let $\varphi \in C([0,T],D(A)) \cap C^1([0,T],V) \cap C^2([0,T],H)$ be a solution of* (2.7). *Then there exists a minimal time $T_0 > 0$ such that for all $T > T_0$ there exists a constant $C > 0$ (independent upon φ_0, φ_1) such that*

$$(T - T_0)E_0 \leq C|||\{\varphi_0, \varphi_1\}|||^2. \tag{6.7}$$

As in section 3, the inverse estimate (3.21) also holds owing to Theorem 3.5 of [20] and the usual trace theorems. We then define F as the closure of $D(A) \times V$ for the norm (6.6) (F clearly satisfies (3.22)). The analogue of Proposition 3.4 here is Proposition 6.3.

PROPOSITION 6.3. *Let $\{\varphi_0, \varphi_1\} \in F$ and $f \in L^1(0,T;V)$. Then the unique solution $\varphi \in C([0,T],V) \cap C^1([0,T],H)$ of* [20, *eq.* (3.1)] *satisfies* (3.23) *to* (3.25) *and*

$$\varphi_j', \frac{\partial \varphi_j}{\partial \nu^j}, \frac{\partial \varphi_j}{\partial \tau^j} \in L^2(C_{Sj})\, \forall j \in \mathcal{I}(S), S \in \mathcal{S}_{sing}.$$

Moreover, there exists a constant $C > 0$ (independent of $\{\varphi_0, \varphi_1\}$ and f) such that

$$\begin{aligned} &\left\{ \sum_{A \in \mathcal{D}^+} \int_{\Sigma_{A\delta}} \left(\frac{\partial \varphi_{i_A}}{\partial \nu_{i_A}} \right)^2 d\sigma dt + \sum_{A \in \mathcal{N}_{ext}^-} \int_{\Sigma_{A\delta}} \left(\frac{\partial \varphi_{i_A}}{\partial \tau_{i_A}} \right)^2 d\sigma dt \right. \\ &\quad + \sum_{A \in \mathcal{N}_{ext}^+} \int_{\Sigma_{A\delta}} (D_t \varphi_{i_A})^2 \, d\sigma dt \\ &\quad \left. + \sum_{S \in \mathcal{S}_{sing}} \sum_{j \in \mathcal{I}(S)} \int_{C_{Sj}} \left\{ (\varphi_j')^2 + \left(\frac{\partial \varphi_j}{\partial \nu^j} \right)^2 + \left(\frac{\partial \varphi_j}{\partial \tau^j} \right)^2 \right\} d\sigma dt \right\}^{1/2} \\ &\quad \leq C \left\{ |||\{\varphi_0, \varphi_1\}||| + \|f\|_{L^1(0,T;V)} \right\}. \end{aligned} \tag{6.8}$$

Proof. The proof is similar to that of Proposition 3.4, since in the left-hand side of (6.8) derivatives of $\varphi^{(2)}$ appear only far from the singular vertices, and by Theorem 2.2 of [20], they are square integrable. ∎

7. Weak solutions of the wave equation II. The transposition of Proposition 6.3 yields the following theorem.

THEOREM 7.1. *For all $u_0 \in H$, $u_1 \in V'$, $w_A \in L^2(\Sigma_{A\delta})$, where $A \in \mathcal{D}^+ \cup \mathcal{N}_{ext}^+ \cup \mathcal{N}_{ext}^-$ and all $w_{Sj}^k \in L^2(C_{Sj}), j \in \mathcal{I}(S), S \in \mathcal{S}_{sing}, k = 1,2,3$, there exist unique $u \in L^\infty(0,T;V')$, $\{\psi_1, \psi_0\} \in F'$, which satisfy*

$$\begin{aligned} &\int_0^T \langle u(t), f(t) \rangle_{V'-V} dt + \langle \{\psi_1, \psi_0\}, \{\varphi_0, -\varphi_1\} \rangle_{F'-F} \\ &= \langle u_1, \varphi(0) \rangle_{V'-V} - \langle u_0, \varphi'(0) \rangle_{H'-H} - \sum_{A \in \mathcal{D}^+} \int_{\Sigma_{A\delta}} w_A \frac{\partial \varphi_{i_A}}{\partial \nu_{i_A}} \, d\sigma dt \\ &\quad - \sum_{A \in \mathcal{N}_{ext}^-} \int_{\Sigma_{A\delta}} w_A \frac{\partial \varphi_{i_A}}{\partial \tau_{i_A}} \, d\sigma dt - \sum_{A \in \mathcal{N}_{ext}^+} \int_{\Sigma_{A\delta}} w_A D_t \varphi_{i_A} \, d\sigma dt \\ &\quad - \sum_{S \in \mathcal{S}_{sing}} \sum_{j \in \mathcal{I}(S)} \int_{C_{Sj}} \left\{ w_{Sj}^1 \varphi_j' + w_{Sj}^2 \frac{\partial \varphi_j}{\partial \nu^j} + w_{Sj}^3 \frac{\partial \varphi_j}{\partial \tau^j} \right\} d\sigma dt \end{aligned} \tag{7.1}$$

for all $f \in L^1(0,T;V)$, $\{\varphi_0,-\varphi_1\} \in F$, *where* $\varphi \in C([0,T],V) \cap C^1([0,T],H)$ *is the unique solution of* (4.2).

The interpretation of (7.1) in terms of partial differential equations is based on the following trace lifting result, which is easily proved (compare with [20, Lemma 5.3]).

LEMMA 7.2. *Let* $w_A \in \mathcal{D}(\Sigma_{A\delta}), A \in \mathcal{D}^+ \cup \mathcal{N}^+_{ext} \cup \mathcal{N}^-_{ext}$, *and* $w^k_{Sj} \in \mathcal{D}(C_{Sj}), j \in \mathcal{I}(S), S \in \mathcal{S}_{sing}, k = 1,2,3$. *Then there exists a function* v *defined on* Q *and equal to zero in a neighborhood of* $S \times [0,T]$ *for all* $S \in \mathcal{S}_{sing}$ *having the regularity*

$$\begin{cases} v_i \in \mathcal{D}\left(0,T,C^\infty\left(\overline{P_i \setminus \cup_{S\in\mathcal{S}_{sing}} B(S,\delta)}\right)\right) \ \forall i \in \mathcal{I}, \\ v_i \in \mathcal{D}\left(0,T,C^\infty\left(\overline{P_i \cap B(S,\delta)}\right)\right) \ \forall S \in \mathcal{S}_{sing},\ i \in \mathcal{I}(S) \end{cases}$$

and fulfilling (2.3), (2.4) *for all* $A \in \mathcal{N}_{int}$, *the boundary conditions* (4.4) *and* (4.11), *as well as the following interface conditions through* C_S *for all* $S \in \mathcal{S}_{sing}$:

$$\text{(7.2)} \qquad \begin{cases} v^S_j - v^{far}_j = \alpha_j^{-1} w^2_{Sj} \ \text{on } C_{Sj}\ \forall j \in \mathcal{I}(S), \\ \frac{\partial v^S_j}{\partial \nu^j} - \frac{\partial v^{far}_j}{\partial \nu^j} = \alpha_j^{-1}\left(D_t w^1_{Sj} + \frac{\partial w^3_{Sj}}{\partial \tau^j}\right) \ \text{on } C_{Sj}\ \forall j \in \mathcal{I}(S), \end{cases}$$

where v^S_j *(resp.,* v^{far}_j*) stands for the trace on* C_{Sj} *of the restriction of* v_j *to* $\{B(S,\delta) \cap P_j\} \times (0,T)$ *(resp.,* $\{P_j \setminus B(S,\delta)\} \times (0,T)$).

THEOREM 7.3. *Let* $u \in L^\infty(0,T;V')$, $\{\psi_1,\psi_0\} \in F'$ *be the unique solution of* (4.1) *with data* $u_0 \in V$, $u_1 \in H$, $w_A \in \mathcal{D}(\Sigma_{A\delta}), A \in \mathcal{D}^+ \cup \mathcal{N}^+_{ext} \cup \mathcal{N}^-_{ext}$, *and* $w^k_{Sj} \in \mathcal{D}(C_{Sj}), j \in \mathcal{I}(S), S \in \mathcal{S}_{sing}, k = 1,2,3$. *Then* $u \in C^1([0,T],H)$ *satisfies the boundary conditions* (4.4), *the initial conditions* (4.6), *the final conditions* (4.7), *and the hyperbolic equation*

$$\text{(7.3)} \qquad u_i'' - \alpha_i \triangle u_i = \sum_{S\in\mathcal{S}_{sing}} D_{Si} \ \text{in } \mathcal{D}'(Q_i)\ \forall i \in \mathcal{I},$$

where the distribution $D_{Si} \in \mathcal{D}'(Q_i)$ *is defined by*

$$\text{(7.4)} \qquad \langle D_{Si}, \eta\rangle = -\int_{C_{Si}} \left\{ w^1_{Si}\eta' + w^2_{Si}\frac{\partial \eta}{\partial \nu^i} + w^3_{Si}\frac{\partial \eta}{\partial \tau^i}\right\} d\sigma dt$$

if $i \in \mathcal{I}(S)$ *and* $D_{Si} = 0$ *else.*

Proof. Since it is similar to that of Theorem 4.3, we only explain the differences. From the function v obtained in Lemma 7.2, we define the function f on Q by

$$f_i = v_i'' - \alpha_i \triangle v_i \text{ on } Q_i \setminus \cup_{S\in\mathcal{S}_{sing}} C_{Si}\ \forall i \in \mathcal{I}.$$

Note that the Laplacian of v_i is computed outside $\cup_{S\in\mathcal{S}_{sing}} C_{Si}$ because v_i is not necessarily continuous through C_{Si} for $S \in \mathcal{S}_{sing}$ due to (7.2).

As $f \in L^2(0,T;H)$, there exists a unique solution $\psi \in C([0,T],V) \cap C^1([0,T],H) \cap H^2(0,T;V')$ of (4.8). The conclusion follows with $u = \psi + v$ by applying Green's formula on $P_i \setminus \cup_{S\in\mathcal{S}_{sing}} B(S,\delta)$ and on $P_i \cap B(S,\delta)$ for all $S \in \mathcal{S}_{sing}$, as usual.

Let us finally remark that we readily deduce (7.3) from (4.8) and the conditions (7.2) satisfied by v. ∎

As before, we then call the solution u of (7.1) the weak solution of (7.3), (4.6), (4.4), and (4.11). Moreover, from the density of $\mathcal{D}(V)$ in $L^2(V)$ for any open set V, the conclusion of Theorem 4.4 holds for our solution u.

8. Addition of circular internal controls. Theorem 2.2 is now a direct consequence of the HUM of Lions [12]. As Proposition 3.4 is replaced by Proposition 6.3, we then solve (5.1), the right-hand side being unchanged except for the last term, which is replaced by

$$-\sum_{S\in\mathcal{S}_{sing}}\sum_{j\in\mathcal{I}(S)}\int_{C_{Sj}}\left\{\varphi_j'\eta_j'+\frac{\partial\varphi_j}{\partial\nu^j}\frac{\partial\eta_j}{\partial\nu^j}+\frac{\partial\varphi_j}{\partial\tau^j}\frac{\partial\eta_j}{\partial\tau^j}\right\}d\sigma dt.$$

THEOREM 8.1. *For all $u_0\in H$, $u_1\in V'$, there exist $w_A\in L^2(\Sigma_{A\delta})$, $A\in\mathcal{D}^+\cup\mathcal{N}_{ext}^+\cup\mathcal{N}_{ext}^-$, and $w_{Sj}^k\in L^2(C_{Sj}), j\in\mathcal{I}(S), S\in\mathcal{S}_{sing}, k=1,2,3$, such that the weak solution $u\in C([0,T],V')\cap C^1([0,T],D(A)')$ of the wave equation* (8.1) *below* (*in the sense of* (7.1)) *satisfies $u(T)=u'(T)=0$.*

$$\left\{\begin{array}{l} u_i''-\alpha_i\triangle u_i=\sum_{S\in\mathcal{S}_{sing}}D_{Si}\ \text{in}\ \mathcal{D}'(Q_i)\,\forall i\in\mathcal{I},\\ u(0)=u_0,\qquad u'(0)=u_1,\\ u\ \text{satisfies}\ (4.4)\ \text{and}\ (4.11),\end{array}\right.\tag{8.1}$$

where D_{Si} is defined by (7.4).

Proof. Since $\{u_1,-u_0\}\in V'\times H\subset F'$, there exists a unique solution $\{\varphi_0,\varphi_1\}\in F$ of

$$\Lambda\{\varphi_0,\varphi_1\}=\{u_1,-u_0\}.$$

We take the solution φ of (2.7) and then the solution ψ of (5.1) (with the new right-hand side). Because of the time reversibility of the wave equation and Proposition 6.3, the conclusion follows with $u=\psi$, $w_A=\frac{\partial\varphi_{i_A}}{\partial\nu_{i_A}}$ for all $A\in\mathcal{D}^+$, $w_A=D_t\varphi_{i_A}$ for all $A\in\mathcal{N}_{ext}^+$, $w_A=\frac{\partial\varphi_{i_A}}{\partial\tau_{i_A}}$ for all $A\in\mathcal{N}_{ext}^-$, $w_{Si}^1=\varphi_i', w_{Si}^2=\frac{\partial\varphi_i}{\partial\nu^i}, w_{Si}^3=\frac{\partial\varphi_i}{\partial\tau^i}$ for all $S\in\mathcal{S}_{sing}$. □

Let us finally remark that with the above choice of the w_{Si}^k and (7.4), we arrive at the form (2.10) of D_{Si} given in Theorem 2.2. The proof of Theorem 2.2 is then complete.

Acknowledgments. We would like to thank Professor J. E. Lagnese for his interest in this work, as well as his valuable remarks.

INFINITE-DIMENSIONAL LINEAR PROGRAMMING APPROACH TO SINGULAR STOCHASTIC CONTROL*

MICHAEL I. TAKSAR†

Abstract. We consider a multidimensional singular stochastic control problem with state-dependent diffusion matrix and drift vector and control cost depending on the position and direction of displacement of the controlled process. The objective is to minimize the total expected discounted cost. We write an equivalent infinite-dimensional linear programming problem on a subspace of the space conjugate to $\mathcal{C}(\mathbb{R}^n) \times \mathcal{C}(\mathbb{R}^n \times B)$, where B is the unit sphere in $\mathbb{R}^n$. We write a dual linear program and prove absence of duality gap. The dual program characterizes the optimal cost function as a maximal solution to the variational inequality with gradient constraints.

Key words. stochastic control, stochastic differential equations, controlled diffusion processes, primary and dual linear programs, variational inequalities

1. Introduction.

One of the methods to study the optimal control problems is via mathematical programming on suitable spaces. Most probably the earliest result obtained by this approach was Pontryagin's maximum principle (see, e.g., [6]). Recently there was a renewed interest in applying linear and convex programming techniques to deterministic and stochastic optimal control problems (see [31], [17], [30], [8], [9], [16], [14], [15]). A certain duality was established between the problem of minimizing a cost functional over a set of all admissible controls and minimizing a linear or convex functional in the space of measures. The measures in question correspond to occupational measures of the controlled process and are described by linear or convex constraints. The original cost functional can then be represented as an integral with respect to the occupational measure. This gives a possibility to interpret the original control problem as a linear or convex programming problem in an infinite-dimensional space regardless of the structure of the cost function. In [9] convex programming methods were used to study finite horizon and infinite horizon control problems. Infinite-dimensional linear programming methods were employed in studying deterministic continuous-time control problems and discrete-time Markov decision processes with discounted cost (see [14], [15]). The main challenge in the linear programming approach is to show an absence of duality gap between the primal and the dual programs (*strong duality*) and establishing equality of values of the original optimal control problem and its linear programming counterpart.

In this paper we apply linear programming techniques to singular diffusion control. In singular control models the control is described by a functional ν of bounded variation rather than by a classical "input-output" process. We will study a general singular control model with dimension of the control functional being equal to that of the state process.

In classical stochastic control models there is a set $\mathcal{U}$ of controls available at each state $x \in \mathbb{R}^n$. To relate the original control problem to linear or convex programming, one considers measures on $\mathbb{R}^n \times \mathcal{U}$ generated by the controlled process and identifies constraints which these measures must satisfy. If we had chosen to follow the same route for singular control problems then we would have had to make $\mathcal{U}$ the set of values of generalized functions. Defining measures on such a space is technically cumbersome, and thus it would be rather difficult to implement such an approach. Instead we consider a linear space X consisting of pairs (M, N), where M is a linear functional on $\mathcal{C}(\mathbb{R}^n)$ and N is a linear functional on $\mathcal{C}(\mathbb{R}^n \times B)$, where B is a unit sphere in $\mathbb{R}^n$. ($\mathcal{C}(\mathcal{X})$ stands for the set of bounded continuous functions on $\mathcal{X}$.) Any measure on $\mathbb{R}^n$ or $\mathbb{R}^n \times B$ is identified with one such functional. On the other hand, with each admissible control ν we associate two measures M^ν and N^ν on $\mathbb{R}^n$ and $\mathbb{R}^n \times B$, respectively. The measure M^ν is the occupational measure of the controlled process in the state space. To calculate N^ν, we replace real time t by $|\nu|(\cdot)$, where $|\nu|$ is the total variation of the process ν. The measure N^ν is the joint occupational measure of the controlled process and $\frac{d\nu}{d|\nu|}$. The generalized Ito formula yields linear constraints which $(M^\nu, N^\nu) \in X$ must satisfy.

We consider the linear program on X and its dual. We prove strong duality and we also show that the dual program is equivalent to finding the maximal solution to a variational inequality.

The structure of the paper is the following. In the next section we describe notations and outline the main assumptions. In section 3 we formulate the singular control problem, and in section 4 we formulate its linear programming counterpart. Section 5 is devoted to the proof of the main results of the paper: the absence of a duality gap and the equivalence of the values of the linear programming problem and the optimal control problem. In section 6 we summarize the principle results from the infinite-dimensional linear programming used in this paper. Most of the technical issues such as the proof of the generalized Ito formula, the existence of a smooth classical solution to the partial differential equations employed in the paper, and the like are resolved in section 7.

2. Notations and main assumptions. In this section we describe the parameters of the problem and introduce notations used in the paper. We denote by $\mathbb{R}^n$ the n-dimensional Euclidean space and by B a unit sphere in it. The exogenous parameters of the singular control problem are the following:

• a *diffusion matrix* $\sigma(x) = \|\sigma_{ij}(x)\|$ and a drift vector $b(x) = (b_1(x), \dots, b_n(x))$ associated with each $x \in \mathbb{R}^n$.

• a *discount factor* $\alpha > 0$.

• a *holding cost* function $h(x), x \in \mathbb{R}^n$. It corresponds to the rate of increase of the cost when the controlled process is at the point x.

• a *control cost function* $c(x, y), x \in \mathbb{R}^n, y \in B$, which corresponds to the cost of a unit displacement in the direction y when the controlled process is at the point x.

Put

$$a(x) \equiv \|a_{ij}(x)\| = \sigma(x)\sigma(x)^T.$$

The conditions we impose upon the parameters of the problem are the following. (Below K stands for a generic constant which can be different in different formulas. The norm of the matrix $\sigma(x)$ is $(tr[\sigma(x)\sigma(x)^T])^{1/2}$.)

(H1) There exists $K > 0$ such that for all $x, y \in \mathbb{R}^n$,

$$|b(x)| \le K. \tag{2.1}$$

(H2) There exist constants $C_1, C_2 > 0$ such that for each $\xi = (\xi_1, \dots, \xi_n) \in \mathbb{R}^n$ and each x,

$$C_1|\xi|^2 \le \sum_{ij} a_{ij}(x)\xi_i\xi_j \le C_2|\xi|^2. \tag{2.2}$$

(H3) There exist $\beta_1, \beta_2 \ge 0$ such that

$$\|\sigma(x) - \sigma(y)\| \le \beta_1|x - y|, \tag{2.3}$$

$$|b(x) - b(y)| \le \beta_2|x - y|, \tag{2.4}$$

and

$$\beta_1^2/2 + \beta_2 < \alpha. \tag{2.5}$$

(H4) $h(x) \ge 0$ for any $x \in \mathbb{R}^n$. There exist $K > 0$ and $\delta > 0$ such that for all $|x - y| < \delta$,

$$|h(x) - h(y)| \le K|x - y|h(x). \tag{2.6}$$

(H5) There exist constants $\lambda_1, \lambda_2 > 0$, and $K > 0$ such that

$$\lambda_1 \le c(\cdot, \cdot) \le \lambda_2, \tag{2.7}$$

$$|c(x_1, y_1) - c(x_2, y_2)| \le K(|x_1 - x_2| + |y_1 - y_2|). \tag{2.8}$$

The following notations will be used throughout the paper.

$$L = \frac{1}{2}\sum_{ij} a_{ij}(x)\frac{\partial^2}{\partial x_i \partial x_j} + \sum_i b_i(x)\frac{\partial}{\partial x_i} - \alpha. \tag{2.9}$$

If $\mathcal{X}$ is a metric space, then $\mathcal{C}(\mathcal{X})$ stands for the Banach space of bounded continuous functions f on $\mathcal{X}$ with

$$\|f\| = \sup_{x \in \mathcal{X}} |f(x)|.$$

The set of k times continuously differentiable functions on $\mathcal{X}$ with bounded derivatives is denoted by $\mathcal{C}^k(\mathcal{X})$. If g is a continuous strictly positive function on $\mathcal{X}$, then we set

$$\|f\|_g = \sup_{x \in \mathcal{X}} |f(x)|/g(x).$$

The linear space of continuous functions with norm $\|\cdot\|_g$ is denoted by $\mathcal{C}_g(\mathcal{X})$. In the sequel $\mathcal{X}$ will be either $\mathbb{R}^n$ or $\mathbb{R}^n \times B$. Define

$$\mathcal{C}^1(\mathbb{R}^n) = \left\{ f : \frac{\partial f}{\partial x_i} \in \mathcal{C}(\mathbb{R}^n) \forall i \le n \right\},$$

$$\mathcal{C}_g^1(\mathbb{R}^n) = \mathcal{C}_g(\mathbb{R}^n) \cap \mathcal{C}^1(\mathbb{R}^n),$$

$$\mathcal{C}_g^2(\mathbb{R}^n) = \left\{ f \in \mathcal{C}_g^1(\mathbb{R}^n) : \frac{\partial^2 f}{\partial x_i \partial x_j} \in \mathcal{C}_g(\mathbb{R}^n) \forall i, j \le n \right\}.$$

Note that in $\mathcal{C}_g^1(\mathbb{R}^n)$ and $\mathcal{C}_g^2(\mathbb{R}^n)$ we require $\frac{\partial f}{\partial x_i}$ to be bounded while f and its second derivatives are bounded only with respect to the function g. The space $\mathcal{C}_g^2(\mathbb{R}^n)$ is a Banach space with the norm

$$\|f\|_{2,g} = \|f\|_g + \sum_i \left\| \frac{\partial f}{\partial x_i} \right\| + \sum_{i,j} \left\| \frac{\partial^2 f}{\partial x_i \partial x_j} \right\|_g,$$

as are $\mathcal{C}^1(\mathbb{R}^n)$ and $\mathcal{C}_g^1(\mathbb{R}^n)$.

If X is a generic Banach space then we denote by X^* its conjugate, i.e., the set of all bounded continuous functionals on X. Put

$$\mathbb{L}(\mathcal{X}) = \mathcal{C}(\mathcal{X})^*, \mathbb{L}_g(\mathcal{X}) = \mathcal{C}_g(\mathcal{X})^*.$$

Define $\mathcal{M}(\mathcal{X})$ to be the set of all signed measures on $\mathcal{X}$ with finite variation. We use the notation $\langle M, f \rangle$ for the integral of f with respect to M. Let

$$\mathcal{M}_g(\mathcal{X}) = \{M \in \mathcal{M} : |\langle M, g \rangle| < \infty\}.$$

We will identify measures with the functionals they generate on the space of bounded continuous functions. Thus $\mathcal{M}(\mathcal{X}) \subset \mathbb{L}(\mathcal{X})$ and $\mathcal{M}_g(\mathcal{X}) \subset \mathbb{L}_g(\mathcal{X})$.

For a linear space X we denote by X^+ the closed cone of its positive elements. For example, $\mathcal{C}_g(X)^+$ is the set of all nonnegative continuous functions on $\mathcal{X}$ with finite $\|\cdot\|_g$ norm. The set $\mathcal{M}(\mathcal{X})^+$ would be the set of all bounded (nonnegative) measures on $\mathcal{X}$, etc.

If $f \in \mathcal{C}^1(\mathbb{R}^n)$ then $(\nabla f, \cdot)$ is a function on $\mathcal{C}(\mathbb{R}^n, B)$ defined as

$$(\nabla f, \cdot)(x, y) = \frac{\partial f(x)}{\partial y} \equiv \sum_{i=1}^n \frac{\partial f(x)}{\partial x_i} y_i, \qquad x \in \mathbb{R}^n,\ y = (y_1, \dots, y_n) \in B. \tag{2.10}$$

The rest of the section is devoted to the description and properties of vector-valued functions of bounded variation.

A deterministic vector-valued function $l(t) \in \mathbb{R}^n, 0 \le t < \infty$ is called *cadlag* if it is right continuous and has left limits. For any cadlag function l we put $l(0-) = 0$. Let $\|\cdot\|$ be any Minkowski norm in $\mathbb{R}^n$. Set

$$\|l\|(t) = \lim \sum_{i=1}^k \|l(t_i) - l(t_{i_1} -)\|, \tag{2.11}$$

where the limit in (2.11) is taken over divisions $0 = t_0 < t_1 < \cdots < t_k = t$ such that $\max_i |t_i - t_{i-1}| \to 0$. When $\|\cdot\|$ coincides with the ordinary Euclidean metric, (2.11) becomes the definition of the total variation $|l|(t)$ of the function l on $[0, t]$. If $|l|(t) < \infty$ for all $t \le \infty$, then we say that l is a function of *bounded variation*. Since all norms in a finite-dimensional space are equivalent, $\|l\|(t) < \infty$ for any Minkowski norm $\|\cdot\|$ whenever l is a function of bounded variation.

If $f(s)$ is a measurable function and l is a (real or vector-valued) function of bounded variation then it is possible to define a Lebesgue–Stieltjes integral

$$\int_0^t f(s) dl(s).$$

Following the usual convention, we interpret this integral as an integral over $[0-, t]$ with respect to the (vector-valued) measure with distribution function l. Thus when $l(0) \neq 0$ a point mass equal to $l(0)$ is concentrated at $t = 0$.

Set

$$\begin{aligned} \Delta l(s) &= l(s) - l(s-), \\ \Lambda(l) &= \{s : \Delta l(s) \neq 0\}, \\ l^d(t) &= \sum_{s\in\Lambda(l), s\leq t} \Delta l(s), \\ l^c(t) &= l(t) - l^d(t). \end{aligned} \tag{2.12}$$

Obviously, $l^c(t)$ is a continuous process with $l(0) = 0$ and $|l^c|(t) \leq |l|(t)$.

For any function l of bounded variation there exists a vector function $\chi_l(s)$ such that $|\chi_l(s)| = 1$ for all s and

$$l(t) = \int_0^t \chi_l(s) d|l|(s). \tag{2.13}$$

We will use notations $dl(s)/d|l|(s)$ and $\chi_l(s)$ interchangeably. If $s \in \Lambda(l)$ then one can verify that

$$\frac{dl}{d|l|}(s) = \frac{\Delta l(s)}{|\Delta l(s)|}.$$

The vector function $\chi_l(\cdot)$ is unique up to a measure $d|l|(\cdot)$ on the real line. It is also easy to see that if l is a discontinuous functional then it has at most countable number of discontinuities. Thus $\chi_l(\cdot) = \chi_{l^c}(\cdot)$ almost everywhere (a.e.) $d|l^c|(\cdot)$ and

$$l^c(t) = \int_0^t \chi_l(s) d|l^c|(s) = \int_0^t \chi_{l_c}(s) d|l^c|(s). \tag{2.14}$$

3. Formulation of the singular control problem. We start with a probability space $(\Omega, \mathcal{F}, \mathcal{F}_t, P)$ and a standard n-dimensional Brownian motion $w(t)$ on it. An n-dimensional cadlag process $\nu(t)$ is called a *control* if $\nu(t)$ is $\mathcal{F}_t$-measurable for each $t \geq 0$. Given control ν and an initial position $x \in \mathbb{R}^n$ we define the state process $x(\cdot)$ as the solution of the following stochastic differential equation:

$$x(t) = x + \int_0^t \sigma(x(s)) dw(s) + \int_0^t b(x(s)) ds + \nu(t). \tag{3.1}$$

Note that according to our convention $x(0-) = x$ and $x(0) = x + \nu(0)$.

The control ν is called *admissible at point* x if (3.1) has a unique solution and

$$E\left\{\int_0^\infty e^{-\alpha t} d|\nu|(t)\right\} < \infty. \tag{3.2}$$

Obviously (3.2) implies that ν is a process of bounded variation. We denote by $\mathcal{A}(x)$ the set of all controls admissible at x. Given the initial position x and an admissible control ν, we define the cost functional

$$\begin{aligned} J_x(\nu) = E\Bigg\{&\int_0^\infty e^{-\alpha t} h(x(t)) dt + \int_0^\infty e^{-\alpha t} c(x(t), \chi_\nu(t)) d|\nu^c|(t) \\ &+ \sum_{s\in\Lambda(\nu)} e^{-\alpha s} \int_0^{|\Delta\nu(s)|} c(x(s-) + z\chi_\nu(s), \chi_\nu(s)) dz \Bigg\}. \end{aligned} \tag{3.3}$$

The first integral on the right-hand side of (3.3) is called the *holding cost*. The remaining two terms are called the *control cost*. The objective is to find

$$v(x) = \inf_{\nu \in \mathcal{A}(x)} J_x(\nu). \tag{3.4}$$

The usual framework leading to singular control problems appears in the models where the "input" (the control functional) is additive and the control cost is linear. If we consider a particle whose position is represented by the state process of our system then in absence of control the particle's dynamics are governed by a diffusion process. The control (input) corresponds to the displacement of the particle from the original trajectory with the cost proportional to the distance the particle is forced to move due to the exerted control. The coefficient of proportionality, however, may depend on the direction of the displacement as well as the position of the particle. On the right-hand side of (3.3) the "quantity" $d|\nu^c|(s)$ in the second integral corresponds to the length of displacement of the particle while it moves continuously and $\chi_\nu(s) = \frac{d\nu}{d|\nu|}(s)$ is the direction of displacement. The quantity $c(x(s), \chi_\nu(s))$ is the unit cost of moving in the direction $\chi_\nu(s)$ from the point $x(s)$. To understand the last term in (3.3), consider any $s \in \Lambda(\nu)$. This is the moment when the functional $\nu(\cdot)$ as well as the process $x(\cdot)$ are discontinuous. It corresponds to an instantaneous jump of the particle from $x(s-)$ in the direction $\Delta\nu(s)/|\Delta\nu(s)| \equiv \frac{d\nu}{d|\nu|}(s)$ to the position $x(s)$. At this moment of time we assume that the real time stops and the "internal clock" is turned on. During the "internal" time the particle travels the distance $|\nu(s) - \nu(s-)|$ with a constant unit velocity, thus moving from $x(s-)$ to $x(s)$. After z units of "internal" time it reaches the position $x(s-) + z\chi_\nu(s)$. The cost incurred during the time interval $[z, z + dz]$ is then equal to $c(x(s-) + z\chi_\nu(s), \chi_\nu(s))dz$. Integrating this cost yields the last term in (3.3).

In one of the classical situations of an "additive input–linear control cost" problem, the dynamics of the state process are described by

$$dx(t) = \sigma(x(t))dw(t) + (b(x(t)) + u(t))dt,$$

where $u(t)$ is a control functional with values restricted to a compact set. The control cost is given by

$$\int_0^\infty e^{-\alpha t}|u(t)|c(x(t), u(t)/|u(t)|)dt.$$

Suppose that in (3.1) we have a sequence of admissible controls $\nu^n(t)$ which are absolutely continuous with derivatives $d\nu^n(t)/dt = u^n(t)$. Suppose that $x^n(\cdot)$ and $\nu^n(\cdot)$ converge to a stochastic process $x(\cdot)$ and a bounded variation process $\nu(\cdot)$, respectively, in M_1-Skorohod topology. (In this case, M_1-convergence of ν^n to ν corresponds to the convergence of $\nu^n(t)$ to $\nu(t)$ at each point t at which $\nu(t)$ is continuous.) Then one can easily verify that

$$\begin{aligned}\int_0^\infty e^{-\alpha t}|u^n(t)|c(x^n(t), u^n(t)/|u^n(t)|)dt \to \int_0^\infty e^{-\alpha t}c(x(t), \chi_\nu(t))d|\nu^c|(t)\\ + \sum_{s\in\Lambda(\nu)} e^{-\lambda s}\int_0^{|\Delta\nu(s)|} c(x(s-) + z\chi_\nu(s), \chi_\nu(s))dz.\end{aligned} \tag{3.5}$$

This gives another justification for the definition of the control cost in (3.3).

When $c(x,y)$ does not depend on $x \in \mathbb{R}^n (= c(y))$, the expression for the control cost in (3.3) reduces to

$$\int_0^\infty e^{-\alpha t} c(\chi_\nu(t)) d|\nu|(t). \tag{3.6}$$

The most frequently considered case is the one in which $c(\cdot) \equiv \text{const}$ and the holding cost function is convex (e.g., [13], [18], [19], [25], [24], [27], [28], [29]). If $c(y) = \|y\|$, where $\|\cdot\|$ is any Minkowski norm in $\mathbb{R}^n$, then (3.5) becomes

$$\int_0^\infty e^{-\alpha t} d\|\nu\|(t), \tag{3.7}$$

where $\|\nu\|(t)$ is defined by (2.11). The case of $\|(y_1,\dots,y_n)\| = \sum_i (a_i y_i^+ + b_i y_i^-), a_i, b_i > 0$, was studied in [25]. It also appears in diffusion approximation of controlled queues (see [32], [33]).

4. Formulation of the linear programming problem. In this section we formulate linear program (P) and its dual (P*) related to the original singular control problem.

We start by associating two measures $M^\nu \in \mathcal{M}(\mathbb{R}^n)^+$ and $N^\nu \in \mathcal{M}(\mathbb{R}^n \times B)^+$ with each admissible control ν.

$$M^\nu(\Gamma) = E\left\{\int_0^\infty e^{-\alpha t} 1_\Gamma(x(t)) dt\right\}, \quad \Gamma \subset \mathbb{R}^n.$$

$$N^\nu(\Gamma) = E\left\{\int_0^\infty e^{-\alpha t} 1_\Gamma(x(t), \chi_\nu(t)) d|\nu^c|(t) \right. \tag{4.1}$$

$$\left. + \sum_{s\in\Lambda(\nu)} e^{-\alpha s} \int_0^{|\Delta\nu(s)|} 1_\Gamma(x(s-) + z\chi_\nu(s), \chi_\nu(s)) dz \right\}, \qquad \Gamma \subset \mathbb{R}^n \times B.$$

Let $g(x), x \in \mathbb{R}^n$ be a smooth convex function such that

$$\begin{aligned} 1 + |x| \le g(x) \le 2 + |x|, &\qquad x \in \mathbb{R}^n, \\ g(x) = 1 + |x|, &\qquad |x| \ge 1. \end{aligned} \tag{4.2}$$

PROPOSITION 4.1. *For each admissible control ν,*

$$M^\nu \in \mathcal{M}_g(\mathbb{R}^n)^+.$$

The proof of this proposition is given in section 7.

It follows from (3.3) that

$$J_x(\nu) = \langle M^\nu, h\rangle + \langle N^\nu, c\rangle.$$

Expression (4.1) shows that for any admissible control ν, with $J_x(\nu) < \infty$, we have $M^\nu \in \mathcal{M}_h(\mathbb{R}^n)$. Together with Proposition 4.1 this yields

$$M^\nu \in \mathcal{M}_{\tilde g}(\mathbb{R}^n), \tag{4.3}$$

where $\tilde g = g + h$.

To understand the constraints the measures M^ν and N^ν must satisfy, consider $f \in \mathcal{C}_g^2(\mathbb{R}^n)$ and apply Proposition 7.1 to it (below (x, y) stands for the inner product of vectors $x, y \in \mathbb{R}^n$).

$$-f(x) = E\left\{\int_0^\infty e^{-\alpha t} Lf(x(t))dt + \int_0^\infty e^{-\alpha t}\nabla f(x(t))d\nu^c(t) + \sum_{s\in\Lambda(\nu)} e^{-\alpha s}[f(x(s)) - f(x(s-))]\right\} \equiv$$

$$E\left\{\int_0^\infty e^{-\alpha t} Lf(x(t))dt + \int_0^\infty e^{-\alpha t}(\nabla f(x(t)), \chi_\nu(t))d|\nu^c|(t) + \sum_{s\in\Lambda(\nu)} \int_0^{|\Delta\nu(s)|} (\nabla f(x(s-) + z\chi_\nu(s)), \chi_\nu(s))dz\right\}$$

$$= M^\nu(Lf) + N^\nu((\nabla f, \cdot)). \tag{4.4}$$

We introduce a dual pair (X, Y),

$$X = \{(M, N) : \mathcal{M} \in \mathbb{L}_{\tilde{g}}(\mathbb{R}^n), N \in \mathbb{L}(\mathbb{R}^n \times B)\},$$

$$Y = \{(f, j) : f \in \mathcal{C}_{\tilde{g}}(\mathbb{R}^n), j \in \mathcal{C}(\mathbb{R}^n \times B)\}.$$

Define

$$\langle (M, N), (f, j)\rangle = \langle M, f\rangle + \langle N, j\rangle.$$

To write the linear program (P), we need another dual pair (Z, W):

$$W = \mathcal{C}_g^2(\mathbb{R}^n),$$

$$Z = \mathcal{C}_g^2(\mathbb{R}^n)^*.$$

Note that Z contains all the functionals of the form δ_x such that

$$\langle \delta_x, f\rangle = f(x).$$

Let $\mathcal{L} : W \to Y$ be defined as follows

$$\mathcal{L}(f) = (-Lf, -(\nabla f, \cdot)).$$

In a more detailed way $\mathcal{L}f(x) = (F(x), G(x, y))$, where

$$F(x) = -\frac{1}{2}\sum_{i,j=1}^n a_{ij}(x)\frac{\partial^2 f(x)}{\partial x_i \partial x_j} - \sum_{i=1}^n b_i(x)\frac{\partial f(x)}{\partial x_i} + \alpha f(x),$$

$$G(x, y) = -\sum_{i=1}^n \frac{\partial f(x)}{\partial x_i} y_i, \qquad x \in \mathbb{R}^n,\ y = (y_1, \ldots, y_n) \in B.$$

Since $\tilde{g} \geq g$ we have $\mathcal{C}_g(\mathbb{R}^n) \subseteq \mathcal{C}_{\tilde{g}}(\mathbb{R}^n)$; thus the operator $\mathcal{L} : W \to Y$ is well defined for all $f \in W$. Having a dual pair (X, Y), we will always consider the weak topology $\sigma(X, Y)$ on X (see [1] or [26]). The same applies for (Z, W).

For each $\tilde{M} = (M, N) \in X$ consider the following linear functional on W:

$$T_{\tilde{M}}(f) = \langle \tilde{M}, \mathcal{L}f \rangle \equiv -\langle M, Lf \rangle - \langle N, (\nabla f, \cdot) \rangle. \tag{4.5}$$

It follows from (2.1), (2.2), and the definition of $\mathcal{C}_g^2(\mathbb{R}^n)$ that $\mathcal{L}$ is a bounded linear operator from $\mathcal{C}_g^2(\mathbb{R}^n)$ into $\mathcal{C}_{\tilde{g}}(\mathbb{R}^n)$. Since $\tilde{M}$ is a bounded functional on $\mathcal{C}_{\tilde{g}}(\mathbb{R}^n)$ and $\tilde{g} \geq g$, we conclude that $\tilde{M}$ is a bounded functional on $\mathcal{C}_g(\mathbb{R}^n)$ as well. Thus (4.5) implies that $T_{\tilde{M}}$ is a bounded functional on $\mathcal{C}_g^2(\mathbb{R}^n)$ and there exists $\tilde{z} \in Z$ such that $T_{\tilde{M}}(f) = \langle \tilde{z}, f \rangle$. We denote $\tilde{z} = \mathcal{L}^* \tilde{M}$. Standard arguments show that $\mathcal{L}^*$ is a continuous linear map. Let δ_x be a unit measure concentrated at the point x. Formula (4.4) and the definition of the operator $\mathcal{L}^*$ imply that for any admissible control ν and any $f \in \mathcal{C}_g^2(\mathbb{R}^n)$

$$\langle \delta_x, f \rangle = -\langle M^\nu, Lf \rangle - \langle N^\nu, (\nabla f, \cdot) \rangle \equiv \langle \tilde{M}^\nu, \mathcal{L}f \rangle \equiv \langle \mathcal{L}^* \tilde{M}^\nu, f \rangle. \tag{4.6}$$

Relation (4.6) provides linear constraints which all (M^ν, N^ν) must satisfy. This enables us to formulate the linear program. Put $\tilde{h} = (h, c)$ below.

(P) *Minimize* $\langle \tilde{M}, \tilde{h} \rangle \equiv \langle M, h \rangle + \langle N, c \rangle$ *subject to*

$$\tilde{M} \in X^+,$$

$$\mathcal{L}^* \tilde{M} = \delta_x.$$

The dual program (see section 6) is

(P*) *Maximize* $\delta_x(\phi) \equiv \phi(x)$ *subject to*

$$\phi \in W,$$

$$\mathcal{L}\phi \leq \tilde{h}.$$

The dual program can be rewritten in a more conventional way:
Maximize $\phi(x)$ *subject to* $\phi(x) \in \mathcal{C}_g^2(\mathbb{R}^n)$ *and*

$$\frac{1}{2} \sum_{i,j} a_{ij}(x) \frac{\partial^2 \phi(x)}{\partial x_i \partial x_j} + \sum_i b_i(x) \frac{\partial \phi(x)}{\partial x_i} - \alpha \phi(x) + h(x) \geq 0 \quad \forall x \in \mathbb{R}^n, \tag{4.7}$$

$$(\nabla \phi(x), y) + c(x, y) \geq 0 \quad \forall x \in \mathbb{R}^n \forall y \in B. \tag{4.8}$$

If $c(x, y) = \|y\|$, then (4.8) is equivalent to

$$\|\nabla \phi(x)\|^* \leq 1, \tag{4.9}$$

where $\|\cdot\|^*$ is the norm in $\mathbb{R}^n$ dual to the Minkowski norm $\|\cdot\|$. When $c(x, y) \equiv c$, inequality (4.9) becomes a standard gradient constraint variational inequality

$$|\nabla \phi(x)| \leq c \tag{4.10}$$

(see [24], [29]).

5. Consistency and absence of duality gap. The program (P*) is consistent (see the definitions in section 6) since we can take $\phi \equiv 0$ in (4.7). According to

Proposition 7.2, for each x there exists a feasible control ν such that $J_x(\nu) < \infty$. The corresponding pair of measures $\tilde{M}^\nu = (M^\nu, N^\nu)$ is consistent with finite value. Since for any admissible ν, the measure $\tilde{M}^\nu$ satisfies (4.6), we deduce that the program (P) is consistent with finite value and

$$\inf(\mathrm{P}) \le v(x),$$

where $v(x)$ is given by (3.4). Therefore, by virtue of Proposition 6.1,

$$\sup(\mathrm{P})^* \le \inf(\mathrm{P}) \le v(x). \tag{5.1}$$

Our main results are given by the following theorems. They show that the inequalities in (5.1) are tight.

THEOREM 5.1. *There is no duality gap:*

$$\inf(\mathrm{P}) = \sup(\mathrm{P})^*.$$

THEOREM 5.2. *The linear program is consistent with the optimal control problem:*

$$v(x) = \inf(\mathrm{P}).$$

To prove Theorem 5.1, we need to show that the subset D of $Z \times \mathbb{R}$ defined below is closed (see Theorem 6.1).

$$D = \{(\mathcal{L}^*\tilde{M}, \langle \tilde{M}, \tilde{h}\rangle), \tilde{M} \ge 0\}.$$

Let $\gamma \in \mathcal{T}$ be a net and $\tilde{M}_\gamma = (M_\gamma, N_\gamma) \in X^+$ be a family of functionals such that there exist

$$\lim_{\gamma\in\mathcal{T}} \mathcal{L}^*\tilde{M}_\gamma = V, \tag{5.2}$$

$$\lim_{\gamma\in\mathcal{T}} \langle \tilde{M}_\gamma, \tilde{h}\rangle = d. \tag{5.3}$$

We need to show that there exists $\tilde{M} = (M, N)$ such that

$$V = \mathcal{L}^*\tilde{M}, \tag{5.4}$$

$$d = \langle \tilde{M}, \tilde{h}\rangle. \tag{5.5}$$

(We need to use nets in (5.2), (5.3) because the space Z is not separable and to prove closure of D one cannot consider only sequences. See [20] or [3, section I.7] for more details on nets and convergence.) Since M_γ, N_γ are nonnegative functionals and $h, c \ge 0$, relation (5.3) implies that $\langle M_\gamma, h\rangle$ and $\langle N_\gamma, c\rangle$ are bounded. Since $c(\cdot,\cdot) \ge \lambda_1 > 0$ (see (2.5)) we see that $\langle N_\gamma, F\rangle$ are bounded for any $F \in \mathcal{C}(\mathbb{R}^n \times B)^+$. Since the functionals N_γ are positive the latter implies that $\langle N_\gamma, F\rangle \equiv \langle N_\gamma, F^+\rangle - \langle N_\gamma, F^-\rangle$ is bounded for any $F \in \mathcal{C}(\mathbb{R}^n \times B)$. Therefore there exists $N \in \mathbb{L}(\mathbb{R}^n \times B)$ and a subnet $\gamma_1 \in \mathcal{T}_1$ such that

$$\lim_{\gamma_1\in\mathcal{T}_1} N_{\gamma_1} = N. \tag{5.6}$$

Using the definition of the topology in Z and the definition of the operator $\mathcal{L}^*$, we can rewrite (5.2) as

$$\lim_{\gamma\in\mathcal{T}} (-\langle M_\gamma, Lf\rangle - \langle N_\gamma, (\nabla f, \cdot)\rangle) = V(f) \tag{5.7}$$

for all $f \in \mathcal{C}_g^2(\mathbb{R}^n)$. By virtue of Proposition 7.3, there exists a function $f \in \mathcal{C}_g^2(\mathbb{R}^n)$ such that $-Lf = g$. Applying (5.7) to this f, we have

$$\lim_{\gamma\in\mathcal{T}}(\langle M_\gamma, g\rangle - \langle N_\gamma, (\nabla f, \cdot)\rangle) = V(f). \tag{5.8}$$

Since $\frac{\partial f}{\partial x_i} \in \mathcal{C}(\mathbb{R}^n)$, we have $(\nabla f, \cdot) \in \mathcal{C}(\mathbb{R}^n \times B)$. We have already established boundedness of $\langle N_\gamma, F\rangle$ for all $F \in \mathcal{C}(\mathbb{R}^n \times B)$; thus (5.8) implies boundedness of $\langle M_\gamma, g\rangle$. This and the boundedness of $\langle M_\gamma, h\rangle$ show that $\langle M_\gamma, h + g\rangle \equiv \langle M_\gamma, \tilde{g}\rangle$ is bounded as well. Using positivity of the functional M_γ, we conclude that $\langle M_\gamma, G\rangle$ is bounded for all $G \in \mathcal{C}_{\tilde{g}}(\mathbb{R}^n)$. Therefore there exists M and a subnet $\gamma_2 \in \mathcal{T}_2$ of the net $\gamma_1 \in \mathcal{T}_1$ such that

$$\lim_{\gamma_2\in\mathcal{T}_2} M_{\gamma_2} = M. \tag{5.9}$$

Combining (5.9) and (5.6), we conclude

$$\lim_{\gamma_2\in\mathcal{T}_2} \langle (M_{\gamma_2}, N_{\gamma_2}), (h, c)\rangle = \langle (M, N), (h, c)\rangle \tag{5.10}$$

and for any $f \in \mathcal{C}_g^2(\mathbb{R}^n)$

$$\lim_{\gamma_2\in\mathcal{T}_2} \langle (M_{\gamma_2}, N_{\gamma_2}), (-Lf, -(\nabla f, \cdot))\rangle = \langle (M, N), (-Lf, -(\nabla f, \cdot))\rangle. \tag{5.11}$$

Taking $\tilde{M} = (M, N)$, we see that (5.11) implies (5.4) and (5.10) implies (5.5). This proves that D is closed.

Proof of Theorem 5.2. Suppose $\inf(\mathrm{P}) < v(x)$. Then there exists $\tilde{M} = (M, N) \in X^+$ such that $\mathcal{L}^*\tilde{M} = \delta_x$ and

$$\langle M, h\rangle + \langle N, c\rangle < v(x). \tag{5.12}$$

By virtue of Proposition 7.4, there exists a family of functions $h^\epsilon(\cdot) \in \mathcal{C}(\mathbb{R}^n), v^\epsilon(\cdot) \in \mathcal{C}_g^2(\mathbb{R}^n), c^\epsilon(\cdot, \cdot) \in \mathcal{C}(\mathbb{R}^n \times B), \epsilon > 0$ subject to (7.31)–(7.35).

Applying $\mathcal{L}^*\tilde{M}$ to v^ϵ, we get

$$\begin{aligned} v^\epsilon(x) \equiv \delta_x(v^\epsilon) &= \langle \mathcal{L}^*\tilde{M}, v^\epsilon\rangle = \langle \tilde{M}, \mathcal{L}v^\epsilon\rangle \\ &= \langle (M, N), (-Lv^\epsilon, (-\nabla v^\epsilon, \cdot))\rangle = \langle M, -Lv^\epsilon\rangle + \langle N, (\nabla v^\epsilon, \cdot)\rangle \\ &\le \langle M, h^\epsilon\rangle + \langle N, c^\epsilon\rangle. \end{aligned} \tag{5.13}$$

The last inequality in (5.13) is due to (7.31) and (7.32). Letting $\epsilon \to 0$ in (5.13) and applying (7.33), (7.34), and (7.35), we obtain

$$v(x) \le \langle M, h\rangle + \langle N, c\rangle,$$

which contradicts (5.12).

6. Appendix I. Infinite-dimensional linear programming. In this section we present some well-known results from the theory of linear programming in infinite-dimensional spaces. Further details can be found in [1, Chapter 3].

DEFINITION. *Two linear vector spaces X and Y are called a* dual pair *with respect to a bilinear form $\langle\cdot,\cdot\rangle$ on $X \times Y$ if*

(i) *for each $x \in X, x \neq 0$ there exists $y \in Y$ such that $\langle x, y\rangle \neq 0$,*

(ii) *for each $y \in Y, y \neq 0$ there exists $x \in X$ such that $\langle x, y\rangle \neq 0$.*

The space Y is called dual *to X, and X is called dual to Y. If (X,Y) is a dual pair, then by $\sigma(X,Y)$ we denote the weakest topology on X in which $\langle x,y\rangle$ are continuous for all $y\in Y$. Similarly, the topology $\sigma(Y,X)$ is the weakest topology on Y in which $\langle x,y\rangle$ are continuous for all $x\in X$.*

If X^+ is a closed cone of positive elements in X, then the dual cone Y^+ is defined as the set of all $y\in Y$ such that $\langle x,y\rangle\geq 0$.

Let (X,Y) and (W,Z) be two dual pairs and $\mathcal{L}:X\to Z$ be a continuous linear map of X into Z. We define the adjoint map $\mathcal{L}^*:W\to Y$ via the relation

$$\langle \mathcal{L}x,w\rangle=\langle x,\mathcal{L}^*w\rangle \quad \textit{for all } x\in X, w\in W. \tag{6.1}$$

The mapping $\mathcal{L}^*$ is continuous (*see* [26, *section* II.6, *Proposition* 12]).

Consider the linear program

(P) *Minimize $\langle x,c\rangle$ subject to*

$$\mathcal{L}x=b,$$

$$x\in X^+,$$

where $b\in Z$ and $c\in Y$ are given vectors. The *dual* of (P) is

(P*) *Maximize $\langle b,w\rangle$ subject to*

$$w\in W$$

$$-\mathcal{L}^*w+c\in Y^+.$$

DEFINITION. *A linear program is* consistent with finite value (*or just* consistent) *if it has a feasible* (*i.e., satisfying the constraints*) *solution x. If* (P) (*respectively,* (P*)) *is consistent, then its* value *is defined as the infimum of $\langle x,c\rangle$* (*respectively, supremum of $\langle b,w\rangle$*) *over all feasible x* (*respectively, w*) *and is denoted by* inf(P) (*respectively,* sup(P*)).

PROPOSITION 6.1. *If* (P) *and* (P*) *are both consistent, then*

$$\sup(\mathrm{P}^*)\leq\inf(\mathrm{P}).$$

The proof of this proposition can be found in [1].

DEFINITION. *If both* (P) *and* (P*) *are consistent with finite values and*

$$\sup(\mathrm{P})=\inf(\mathrm{P}^*),$$

then it is said that there is no duality gap.

Conditions ensuring absence of a duality gap are given by the following theorem (see [1, Theorems 3.10 and 3.22]).

THEOREM 6.1. *Let D be the subset of $Z\times\mathbb{R}$ defined as*

$$D=\{(\mathcal{L}x,\langle x,c\rangle),x\in X^+\}.$$

If (P) *is consistent with finite value and the set D is closed, then there is no duality gap.*

7. Appendix II. Proofs of auxiliary results. This appendix is devoted to the proof of the technical results used in the previous sections. Below, K stands for a generic constant whose value might differ in different formulas.

Proof of Proposition 4.1. Let ν be an admissible control and $x(\cdot)$ be the solution of (3.1). To show that $\langle M^\nu, g\rangle < \infty$, we need to prove

$$E\left\{\int_0^\infty e^{-\alpha t}(1+|x(t)|)dt\right\} < \infty. \tag{7.1}$$

Obviously the expectation of the first term in the integrand in (7.1) is equal to $1/\alpha$. Let

$$\eta_t = \sup_{u\le t}\left|\int_0^u \sigma(x(s))dw(s)\right|,$$

$$\zeta_t = \sup_{u\le t}\left|\int_0^u b(x(s))ds\right|.$$

The dynamics equation (3.1) implies

$$|x(t)| \le \eta_t + \zeta_t + |\nu|(t).$$

Thus

$$E\left\{\int_0^\infty e^{-\alpha t}|x(t)|dt\right\} \le \int_0^\infty e^{-\alpha t}E\{\eta_t\}dt + \int_0^\infty e^{-\alpha t}E\{\zeta_t\}dt + E\left\{\int_0^\infty e^{-\alpha t}|\nu|(t)dt\right\}. \tag{7.2}$$

We can use (2.2) and Theorem I.9.2 of [23] to get

$$E\{\eta_t\} \le (E\{\eta_t^2\})^{1/2} \le E\left\{\sum_{i=1}^n \sup_{u\le t}\left(\int_0^u \sigma(x(s))dw(s)\right)_i^2\right\}^{1/2}$$

$$\le 2E\left\{\sum_{i=1}^n\left(\int_0^t \sigma(x(s))dw(s)\right)_i^2\right\}^{1/2} \le 2E\left\{\int_0^t \|\sigma(x(s))\|^2 ds\right\}^{1/2} \le Kt^{1/2}. \tag{7.3}$$

Inequality (2.1) implies

$$E\{|\zeta_t|\} \le E\left\{\int_0^t |b(x(s))|ds\right\} \le Kt. \tag{7.4}$$

Integrating by parts, we get

$$E\left\{\int_0^s e^{-\alpha t}d|\nu|(t)\right\} = E\{e^{-\alpha s}|\nu|(s)\} + E\left\{\int_0^s \alpha e^{-\alpha t}|\nu|(t)dt\right\}.$$

Letting $s\to\infty$,

$$E\left\{\int_0^\infty e^{-\alpha t}|\nu|(t)dt\right\} \le \alpha^{-1}E\left\{\int_0^\infty e^{-\alpha t}d|\nu|(t)\right\}. \tag{7.5}$$

The right-hand side of (7.5) is finite for any admissible control ν. Inequalities (7.2)–(7.5) yield (7.1).

PROPOSITION 7.1. *Let ν be an admissible control and $x(\cdot)$ be given by* (3.1) *and $f \in \mathcal{C}_g^2(\mathbb{R}^n)$. Then*

$$-f(x) = E\left\{\int_0^\infty e^{-\alpha t} Lf(x(t))dt + \int_0^\infty e^{-\alpha t}\nabla f(x(t))d\nu^c(t) + \sum_{s\in\Lambda(\nu)} e^{-\alpha s}[f(x(s)) - f(x(s-))]\right\}. \tag{7.6}$$

Proof. Using the generalized Ito's formula (see Theorem VIII.27 in [2]), we can write

$$\begin{aligned} e^{-\alpha T}f(x(T)) - f(x(0-)) &= \int_0^T e^{-\alpha t}\nabla f(x(t))dw(t) + \int_0^T e^{-\alpha t} Lf(x(t-))dt \\ &+ \int_0^T e^{-\alpha t}\nabla f(x(t-))d\nu(t) + \sum_{t\le T, t\in\Lambda(\nu)} e^{-\alpha t}[f(x(t)) - f(x(t-)) - \nabla f(x(t))]. \end{aligned} \tag{7.7}$$

Since $\Delta x(s) = \Delta\nu(s)$, we have

$$\begin{aligned} &\int_0^T e^{-\alpha t}\nabla f(x(t-))d\nu(t) - \sum_{t\le T} e^{-\alpha t}\nabla f(x(t-))\Delta x(t) \\ &= \int_0^T e^{-\alpha t}\nabla f(x(t-))d(\nu^c(t) + \nu^d(t)) - \sum_{t\le T} e^{-\alpha t}\nabla f(x(t-))\Delta\nu(t) \\ &= \int_0^T e^{-\alpha t}\nabla f(x(t-))d\nu^c(t) = \int_0^T e^{-\alpha t}\nabla f(x(t))d\nu^c(t). \end{aligned} \tag{7.8}$$

Since $\nabla f(\cdot)$ is bounded, the first term on the right-hand side of (7.7) is a square integrable martingale and its expectation vanishes. Thus, taking into account (7.8) and recalling that $x(0-) = x$,

$$e^{-\alpha T}E\{f(x(T)\} - f(x) = E\left\{\int_0^T e^{-\alpha t} Lf(x(t))dt + \int_0^T e^{-\alpha t}\nabla f(x(t))d\nu^c(t) + \sum_{s\in\Lambda(\nu), s\le T} e^{-\alpha s}[f(x(s)) - f(x(s-))]\right\}. \tag{7.9}$$

To complete the proof we need only to justify passing to a limit in (7.9) as $T \to \infty$. Since $f \in \mathcal{C}_g^2(\mathbb{R}^n)$, we have

$$f(x), |Lf(x(t))| \le K(1 + |x(t)|) \le K(1 + \eta_t + \zeta_t + |\nu|(t)) \tag{7.10}$$

(see the proof of Proposition 4.1). By virtue of (7.3) and (7.4), the expectation of the absolute value of the first term on the right-hand side of (7.9) does not exceed $\int_0^T e^{-\alpha t}(1 + t + t^{1/2})dt$. Therefore the expectation of the first term on the right-hand side of (7.9) converges to that of the first term on the right-hand side of (7.6) thanks

to the dominated convergence theorem. Due to the boundedness of ∇f, we can write

$$\begin{aligned}\left|\int_0^T e^{-\alpha t}\nabla f(x(t))d\nu^c(t)\right| + \left|\sum_{s\in\Lambda(\nu),s\le T} e^{-\alpha s}[f(x(s)) - f(x(s-))]\right| \\ \le \left|\int_0^T e^{-\alpha t}Kd\nu^c(t)\right| + \sum_{s\in\Lambda(\nu),s\le T} e^{-\alpha s}K|x(s) - x(s-)| \\ \le \int_0^T e^{-\alpha t}Kd|\nu^c|(t) + \sum_{s\in\Lambda(\nu),s\le T} e^{-\alpha s}K|\nu(x(s)) - \nu(x(s-))| \\ = \int_0^T e^{-\alpha t}Kd|\nu|(t). \qquad (7.11)\end{aligned}$$

Inequality (7.11) implies that the expectation of the last two terms on the right-hand side of (7.9) converges to that of the last two terms on the right-hand side of (7.6) thanks to (3.2) and the dominated convergence theorem.

In view of (7.10), (7.3), and (7.4)

$$E\{f(x(T))\} \le K(1 + T + T^{1/2}).$$

Therefore the second term on the left-hand side of (7.9) converges to 0 as $T \to \infty$ and we get (7.6).

PROPOSITION 7.2. *For each $x \in \mathbb{R}^n$ there exists a control ν such that*

$$J_x(\nu) < \infty.$$

Proof. Let D be a closed unit ball in $\mathbb{R}^n$ with the center at x. Consider the solution to the Skorohod problem in D for the stochastic differential equation with normal reflection at the boundary of D. This solution consists of a pair of continuous $\mathcal{F}_t$-adapted processes $(X(t), \nu(t))$ such that $\nu(t)$ is a process of bounded variation and

$$X(t) = x + \int_0^t \sigma(X(s))dw(s) + \int_0^t b(X(s))ds + \nu(t) \in D \text{ for all } t > 0, \qquad (7.12)$$

$$\int_0^\infty 1_{X(s)\ne\partial D} d|\nu|(s) = 0, \qquad (7.13)$$

$$\nu(t) = \int_0^t n(X(s))d|\nu|(s), \qquad (7.14)$$

where $n(y), y \in \partial D$ is a unit inward normal, i.e., $n(y) = x - y$. Existence of such a solution was proved in [22].

Let $f \in \mathcal{C}^2(D)$ be the solution to the following boundary value problem (see [21, section III], where the existence of such a solution is shown)

$$Lf(y) = 0, \qquad y \in D, \qquad (7.15)$$

$$\frac{\partial f}{\partial n}(y) = -1, \qquad y \in \partial D. \qquad (7.16)$$

Applying Ito's formula to $f(X(t))$ and using (7.15), (7.16) together with (7.13) and (7.14), we get

$$f(x) - e^{-\alpha T}E\{f(X(t))\} = E\left\{-\int_0^T Lf(X(t))dt - \int_0^T \nabla f(X(t))e^{-\alpha t}d\nu(t)\right\}$$

$$= E\left\{\int_0^T e^{-\alpha t}\nabla f(X(t))n(X(t))d|\nu|(t)\right\} = E\left\{-\int_0^T e^{-\alpha t}\frac{\partial f}{\partial n}(X(t))d|\nu|(t)\right\}$$

$$= E\left\{\int_0^T e^{-\alpha t}d|\nu|(t)\right\}. \tag{7.17}$$

In view of (7.12), the process $X(\cdot)$ belongs to a compact domain; hence $f(X(T))$ is uniformly bounded in $\mathbb{R}\times\Omega$. Taking limit as $T\to\infty$, we obtain

$$E\left\{\int_0^\infty e^{-\alpha t}d|\nu|(t)\right\} = f(x) < \infty. \tag{7.18}$$

Consider

$$J_x(\nu) = E\left\{\int_0^\infty e^{-\alpha t}h(X(t))dt\right\} + E\left\{\int_0^\infty e^{-\alpha t}c(X(t),\chi_\nu(t))d|\nu|(t)\right\}. \tag{7.19}$$

By virtue of (7.12), the process $h(X(t))$ is uniformly bounded. Thus the first term on the right-hand side of (7.19) is bounded. In view of (2.7) the second term on the right-hand side of (7.19) does not exceed $\lambda_2 E\{\int_0^\infty e^{-\alpha t}d|\nu|(t)\}$, which is finite thanks to (7.18).

PROPOSITION 7.3. *Let g be given by* (4.2). *Then there exists $f\in\mathcal{C}_g^2(\mathbb{R}^n)$ such that*

$$Lf = g. \tag{7.20}$$

Proof. (1) Let $(X(t),P_x)$ be the Markov diffusion process with the infinitesimal generator $L+\alpha$ (see [4], [5], [10]); i.e., for each $x\in\mathbb{R}^n$, the measure P_x is the distribution of the solution to the following stochastic differential equation:

$$X(t) = x + \int_0^t \sigma(X(s))dw(s) + \int_0^t b(X(s))ds. \tag{7.21}$$

Put

$$f(x) = E_x\left\{\int_0^\infty e^{-\alpha t}g(X(t))dt\right\}. \tag{7.22}$$

Since $|X(t)|\le x+\eta_t+\zeta_t$, estimates (7.3) and (7.4) show that $E_x\{g(X(t))\}\le x+\text{const}$, whereas

$$f(x)\le K(1+|x|). \tag{7.23}$$

Therefore $f\in\mathcal{C}_g(\mathbb{R}^n)$. Let D be the unit ball with the center at x and τ be the first hitting time of ∂D by $X(t)$. The strong Markov property of the process $X(t)$ implies

$$f(x) = E\left\{\int_0^\tau e^{-\alpha\tau}g(X(t))dt + e^{-\alpha\tau}f(X(\tau))\right\}.$$

In view of Theorem 5.1 of [11, section 6], the function f given by the above formula is the unique solution in D to the Dirichlet problem (7.20) with the boundary conditions on ∂D given by the same function f. The latter shows that f given by (7.22) satisfies (7.20) in the whole space $\mathbb{R}^n$.

(2) Let D_1, D_2 be two bounded open sets in $\mathbb{R}^n$ such that $\bar{D}_1 \subset D_2$. Then a priori Schauder's inner estimates (see [12, Chapter III]) yield

$$\sup_{x\in D_1}\left(|f(x)|+\sum_i\left|\frac{\partial f(x)}{\partial x_i}\right|+\sum_{i,j}\left|\frac{\partial^2 f(x)}{\partial x_i\partial x_j}\right|\right)\le c\sup_{x\in D_2}\left(|f(x)|+|g(x)|+\sum_i\left|\frac{\partial g(x)}{\partial x_i}\right|\right), \tag{7.24}$$

where c is a constant which depends only on $C_1, C_2, \beta_1, \beta_2$ in (2.2)–(2.4), on the upper bound for $|b|(\cdot)$ in (2.1), on the *diameter* of the set D_2, and on the *distance* between D_1 and D_2. Let D_1 be a ball of radius 1 with the center x and D_2 be a ball of radius 2 with the center x. Then, using (7.23) and (7.24), we deduce the existence of a constant K such that

$$\left(|f(x)|+\sum_i\left|\frac{\partial f(x)}{\partial x_i}\right|+\sum_{i,j}\left|\frac{\partial^2 f(x)}{\partial x_i\partial x_j}\right|\right)\le K(1+|x|). \tag{7.25}$$

(3) To complete the proof we need only to show that $\frac{\partial f}{\partial x_i}$ is bounded in $\mathbb{R}^n$. Assume that $\sigma(x)$ and $b(x)$ are differentiable with

$$\|D_x\sigma(x)\|^2/2+\|D_xb(x)\|\le\beta_1^2/2+\beta_2\equiv\beta<\alpha, \tag{7.26}$$

where $D_xb(x)$ is an $n\times n$ matrix with $(D_xb(x))_{ij}=\frac{\partial b_i(x)}{\partial x_j}$ and $\|D_xb(x)\|^2=\ \mathrm{tr}(D_xb(x)\cdot D_xb(x)^T)$ and with $D_x\sigma(x)$ being an $n\times n\times n$ tensor with

$$D_x\sigma(x)_{ijk}=\frac{\partial\sigma(x)_{ij}}{\partial x_k}$$

and

$$\|D_x\sigma(x)\|^2=\sum_{ijk}D_x\sigma(x)^2_{ijk}.$$

Using the results of section 5.5 of [11], we can show that

$$\frac{\partial f(x)}{\partial x_i}=E\left\{\int_0^\infty e^{-\alpha t}\nabla g(X(t))X^{(i)}(t)dt\right\}, \tag{7.27}$$

where $X^{(i)}(t)$ is the solution to the following stochastic differential equation

$$X^{(i)}(t)=e_i+\int_0^t D_x\sigma(X(s))X^{(i)}(s)dw(s)+\int_0^t D_xb(X(s))X^{(i)}(s)ds, \tag{7.28}$$

where $e_i\in\mathbb{R}^n$ is a vector with $(e_i)_j=\delta_{ij}$ and $X(\cdot)$ is the solution to (7.21). Taking $Z(t)=|X^{(i)}(t)|^2$ and using Ito's formula, we get

$$\begin{aligned}E\{Z(t)\}&=1+\int_0^t E\{2Z(s)D_xb(X(s))+D_x\sigma(X(s))X^{(i)}(s)(D_x\sigma(X(s))X^{(i)}(s))^T\}dt\\&\le 1+\sup_{x\in\mathbb{R}}(2\|D_xb(x)\|+\|D_x\sigma(x)\|^2)\int_0^\infty e^{-\alpha t}E\{Z(t)\}dt\\&\le 1+2\beta\int_0^\infty e^{-\alpha t}E\{Z(t)\}dt.\end{aligned} \tag{7.29}$$

Application of Gronwall's inequality to (7.29) yields

$$E\{|X^{(i)}(t)|^2\} \equiv E\{Z(t)\} \le e^{2\beta t}.$$

Thus $E\{|X^{(i)}(t)|\} \le e^{\beta t}$. Substituting the latter inequality into (7.27), we get

$$\left|\frac{\partial f(x)}{\partial x_i}\right| \le \sup_{y\in\mathbb{R}} |\nabla g(y)| \int_0^\infty e^{-\alpha t} E\{|X^{(i)}(t)|\}dt \le \sup_{y\in\mathbb{R}} ||\nabla g(y)||/(\alpha-\beta) \le K. \tag{7.30}$$

In the case of nondifferentiable $\sigma(\cdot)$ and $b(\cdot)$, we can approximate both functions uniformly by differentiable functions $\sigma_n(\cdot)$ and $b_n(\cdot)$ subject to (7.26). The corresponding cost functions $f_n(\cdot)$ given by (7.22) converge uniformly to $f(\cdot)$ and are subject to (7.30). The latter implies that the limiting function f satisfies (7.30) as well.

PROPOSITION 7.4. *Let v be given by* (3.4). *Then there exists a family of functions $h^\epsilon(\cdot) \in \mathcal{C}(\mathbb{R}^n), v^\epsilon(\cdot) \in \mathcal{C}_g^2(\mathbb{R}^n), c^\epsilon(\cdot,\cdot) \in \mathcal{C}(\mathbb{R}^n \times B), \epsilon > 0$, such that*

$$-Lv^\epsilon \le h^\epsilon, \tag{7.31}$$

$$-(\nabla v^\epsilon, \cdot) \le c^\epsilon, \tag{7.32}$$

$$h^\epsilon \le (1+\delta(\epsilon))h, \tag{7.33}$$

where $\delta(\epsilon) \to 0$ as $\epsilon \to 0$, and

$$\lim_{\epsilon\to 0} \|c - c^\epsilon\| = 0, \tag{7.34}$$

$$\lim_{\epsilon\to 0} \|v^\epsilon(x) - v(x)\| = 0. \tag{7.35}$$

Proof. (1) Assume that σ and b are continuously differentiable with bounded derivatives, satisfying (7.26). Let $(X(t), P_x)$ be the same Markov process as in part 1 of the proof to Proposition 7.3. Let $p(t,x,y), t>0, x, y \in \mathbb{R}^n$ be the transition density of this Markov process. Put

$$v^\epsilon(x) = E_x\{v(X(\epsilon)\} \equiv \int_{\mathbb{R}^n} p(\epsilon,x,y)v(y)dy, \tag{7.36}$$

$$h^\epsilon(x) = E_x\{h(X(\epsilon)\} \equiv \int_{\mathbb{R}^n} p(\epsilon,x,y)h(y)dy. \tag{7.37}$$

The weak dynamic programming principle (see [7]) implies that for any $s > 0$

$$\begin{aligned} v(y) &\le E_y\left\{\int_0^s e^{-\alpha t} h(X(t))dt\right\} + E_y\{e^{-\alpha s} v(X(s))\} \\ &\equiv \int_0^s e^{-\alpha t} E_y\{h(X(t))\}dt \;+\; e^{-\alpha s} E_y\{v(X(s))\}. \end{aligned}$$

Multiplying both sides of the above inequality by $p(\epsilon,x,y)$ and integrating we get

$$\int_{\mathbb{R}^n} p(\epsilon,x,y)v(y)dy$$

$$\le \int_0^s e^{-\alpha t}\left(\int_{\mathbb{R}^n} p(\epsilon,x,y)E_y\{h(X(t))\}dy\right)dt + e^{-\alpha s}\int_{\mathbb{R}^n} p(\epsilon,x,y)E_y\{v(X(t))\}dy$$

$$\equiv \int_0^s e^{-\alpha t} E_x\{h(X(t+\epsilon))\}dt + e^{-\alpha s} E_x\{v(X(t+\epsilon))\}$$

$$\equiv \int_0^s e^{-\alpha t} E_x\{h^\epsilon(X(t))\}dt + e^{-\alpha s} E_x\{v^\epsilon(X(s))\}. \tag{7.38}$$

The last two equalities in (7.38) are due to (7.36), (7.37) and the Chapman–Kolmogorov equation for the transition density p. It is known that the transition density p is the fundamental solution to the parabolic equation with the operator $-\partial/\partial t+(L+\alpha)$ and is twice continuously differentiable in x (see [11], [10], [4]). Therefore v^ϵ is also twice continuously differentiable. Subtracting $v^\epsilon(x)$ from both sides of inequality (7.38), we can apply Ito's formula for $e^{-\alpha s}v^\epsilon(X(s))$ and use (7.21) to get

$$E_x\left\{\int_0^s e^{-\alpha t}[Lv^\epsilon(X(t))+h^\epsilon(X(t))]dt\right\}\geq 0. \tag{7.39}$$

Dividing both parts of (7.39) by s and letting $s\to 0$, we use standard limiting arguments to conclude (7.31).

(2) Extend function $c(x,y)$ to $\mathbb{R}^n\times\mathbb{R}^n$ in a homogeneous way, putting

$$c(x,y)=c(x,y/|y|)|y|, x,y\in\mathbb{R}^n.$$

One can see that the thus extended function $c(\cdot,\cdot)$ remains Lipschitz.

Starting with the initial position $x\in\mathbb{R}^n$ and considering controls ν such that $\nu(0)=\epsilon y, y\in\mathbb{R}^n$, we get

$$v(x)\leq v(x+\epsilon y)+\int_0^\epsilon c(x+zy,y)dz.$$

Subtracting $v(x)$ from both sides and dividing by ϵ, we get

$$\limsup_{\epsilon\to 0}-(v(x+\epsilon y)-v(x))/\epsilon\leq c(x,y). \tag{7.40}$$

Inequalities (7.40) and (2.7) show that v is Lipschitz. Therefore $\nabla v(\cdot)$ exists almost everywhere in $\mathbb{R}^n$ and for almost all $x\in\mathbb{R}^n$ for all $y\in\mathbb{R}^n$:

$$-(\nabla v(x),y)\leq c(x,y). \tag{7.41}$$

Employing the same arguments as in section 5.5 of [11], we can show

$$(\nabla v^\epsilon(x),y)=E_x\{(\nabla v(X(\epsilon)),Y^y(\epsilon))\}, \tag{7.42}$$

where $Y^y(\epsilon)=(Y_1^y(\epsilon),\dots,Y_n^y(\epsilon)), Y_i^y(\epsilon)=(X^{(i)}(\epsilon),y)$, with the process $X^{(i)}(\cdot)$ satisfying the following stochastic differential equation (below δ_{ij} denotes the Kronecker's delta)

$$X_j^{(i)}(t)=\delta_{ij}+\int_0^t\sum_{k=1}^n\sum_{l=1}^n\frac{\partial\sigma_{jk}(X(s))}{\partial x_l}X_l^{(i)}dw_k(s)+\int_0^t\sum_{l=1}^n\frac{\partial b(X(s))}{\partial x_l}X_l^{(i)}(s)ds. \tag{7.43}$$

Put

$$c^\epsilon(x,y)=E_x\{c(X(\epsilon),Y^y(\epsilon))\}.$$

Inequality (7.41) yields

$$(\nabla v^\epsilon(x),y)+c^\epsilon(x,y)=E_x\{(\nabla v(X(\epsilon)),Y^y(\epsilon))+c(X(\epsilon),Y^y(\epsilon))\}\geq 0,$$

whereas (7.32) follows.

(3) Inequality (7.41) implies $v(x) \le K(1+|x|)$. Repeating the arguments of part 1 of the proof to Proposition 7.3, we get $v^\epsilon \le K(1+|x|)$. Since $v^\epsilon(x) = f(x,\epsilon)$, where $f(x,t)$ is the solution to the parabolic equation

$$-\frac{\partial f(x,t)}{\partial t} + (L+\alpha)f(x,t) = 0, \qquad x \in \mathbb{R}^n,\ 0 \le t \le \epsilon,$$

$$f(x,0) = v(x),$$

(see [10], [11]), we can derive that v^ϵ is twice continuously differentiable (see [12]). Applying Schauder-type a priori estimates for the solution of the parabolic equations (see [12, section III]), we conclude that v^ϵ, its first and second derivatives, belong to $\mathcal{C}_g(\mathbb{R}^n)$. To prove $v^\epsilon \in \mathcal{C}_g^2(\mathbb{R}^n)$, we need to show boundedness of ∇v^ϵ in $\mathbb{R}^n$.

Similar to the last section of the previous proposition, we obtain

$$E\{|Y^y(\epsilon)|\} \le e^{\beta\epsilon}, \tag{7.44}$$

where β is the same as in (7.26). Therefore,

$$|\nabla v^\epsilon(x)| \le \lambda_2 e^{\beta\epsilon},$$

thanks to (2.7), (7.41), (7.42), and (7.44).

(4) It is shown in section I.6 of [12] that there exist constants $k > 0$ and $k_1 > 0$ such that

$$p(t,x,y) \le k_1 t^{-n/2} \exp(-k(x-y)^2/t). \tag{7.45}$$

In [14] it was shown that every function h subject to (2.6) satisfies

$$h(y)/h(x) \le \exp(K|x-y|). \tag{7.46}$$

Combining (7.45) and (7.46), we see

$$h^\epsilon(x)/h(x) = \int_{\mathbb{R}^n} p(\epsilon,x,y)h(y)/h(x)dy$$

$$\le \int_{|z|\le\epsilon} p(\epsilon,x,x+z)\exp(Kz)dz + \int_{|z|>\epsilon} k_1\epsilon^{-n/2}\exp(-kz^2/\epsilon)\exp(z)dz$$

$$\le \exp(K\epsilon) + \int_{|z|>\epsilon} k_1\epsilon^{-n/2}\exp(-kz^2/\epsilon)\exp(z)dz \equiv (1+\delta(\epsilon)). \tag{7.47}$$

By inspection, $\delta(\epsilon)$ given in (7.47) converges to 0 as $\epsilon \to 0$. Therefore, (7.33) follows.

Using Lipschitz continuity of v with a constant λ_2 (see (2.7) and (7.40)) and (7.45), we can write

$$v^\epsilon(x) - v(x) = E_x\{v(X(\epsilon)) - v(x)\} \le \lambda_2 E_x\{|X(\epsilon) - x|\}.$$

On the other hand

$$E_x\{|X(\epsilon)-x|\} = \int_{\mathbb{R}^n} p(\epsilon,x,y)|y-x|dy = \left(\int_{|x-y|\le\epsilon} \dots + \int_{|x-y|>\epsilon} \dots\right)$$

$$\le \epsilon + \int_{|z|>\epsilon} k_1\epsilon^{-n/2}\exp(-kz^2/\epsilon)|z|dz = \delta_1(\epsilon) \to 0 \tag{7.48}$$

as $\epsilon \to 0$, whereas (7.35) follows.

From (7.43) it follows that $Y^y(0) = y$. Applying the Lipschitz property of the function c, we get

$$
\begin{aligned}
|c^\epsilon(x,y) - c(x,y)| &= E_x\{|c(X(\epsilon), Y^y(\epsilon)) - c(x, Y^y(0))|\} \\
&\le K E_x\{|X(\epsilon) - x||Y^y(\epsilon) - Y^y(0)|\}.
\end{aligned} \tag{7.49}
$$

From (7.43), (7.44), and (7.48), we imply that the right-hand side of (7.49) converges to 0 as $\epsilon \to 0$. The latter implies (7.34).

Acknowledgment. This research was done while the author was visiting Departamento de Matematicas of the CINVESTAV of the Mexican Institute of Technology, whose hospitality is greatly appreciated. The author would like to thank Dr. O. Hernández-Lerma for the introduction to this field and for a series of helpful and stimulating discussions.

THE DIFFERENTIABILITY OF THE DRAG WITH RESPECT TO THE VARIATIONS OF A LIPSCHITZ DOMAIN IN A NAVIER–STOKES FLOW*

JUAN ANTONIO BELLO†, ENRIQUE FERNÁNDEZ-CARA†, JÉRÔME LEMOINE‡, AND JACQUES SIMON‡

Abstract. This paper is concerned with the computation of the drag T associated with a body traveling at uniform velocity in a fluid governed by the stationary Navier–Stokes equations. It is assumed that the fluid fills a domain of the form $\Omega+u$, where $\Omega \subset \mathbb{R}^3$ is a reference domain and u is a displacement field. We assume only that Ω is a Lipschitz domain and that u is Lipschitz-continuous. We prove that, at least when the velocity of the body is sufficiently small, $u \mapsto T(\Omega + u)$ is a C^∞ mapping (in a ball centered at 0). We also compute the derivative at 0.

Key words. domain optimization, hydrodynamic drag, Navier–Stokes equations, Lipschitz domains, optimal control

1. Introduction.

Formulation of the problem. In this paper, we study the behavior of the drag T associated with a body traveling at uniform velocity γ in a viscous incompressible fluid. It is assumed that the flow of this fluid is governed by the stationary Navier–Stokes equations. We are interested in viewing T as a function of the shape of the body.

More precisely, let B be a reference shape for the body and Ω be the corresponding fluid domain. The body variations are described by a field u, and we search for a formula of the kind

$$T(\Omega + u) = T(\Omega) + T'(\Omega; u) + o(u),$$

where the modified fluid domain is

$$\Omega + u = \{x \in \mathbb{R}^d;\ x = (I + u)(\xi),\ \xi \in \Omega\}.$$

We are thus led to an analysis of the differentiability of the function $u \mapsto T(\Omega + u)$.

The main results. We prove that when Ω is a Lipschitz domain, u is Lipschitz-continuous, and the velocity γ is sufficiently small, the function $u \mapsto T(\Omega + u)$ is differentiable. More precisely (see Theorem 4), we show that it is a C^∞ mapping in a small ball $\mathcal{W}$ whose elements are Lipschitz vector fields. We also compute explicitly $T'(\Omega; u)$, i.e., the derivative at 0 in the direction u.

In the similar but more simple case of an elliptic equation, differentiability results have been established by F. Murat and J. Simon in [9], [10] without any regularity hypothesis on Ω. The proof relies on the change of variables $x = (I+u)(\xi)$, by means of which one is led to a fixed domain. This method has been used for many equations by several authors.

Some difficulties related to incompressibility. The general method in [9], [10] cannot be directly applied to the Stokes and Navier–Stokes cases. This is due to the incompressibility condition

$$\nabla \cdot y(u) = 0 \qquad \text{in } \Omega + u,$$

which has to be satisfied by the velocity field $y(u)$. This difficulty was surmounted when Ω is a $W^{2,\infty}$ domain by J. Simon [17] for Stokes flows and by J. A. Bello, E. Fernández-Cara, and J. Simon [1], [2] for Navier–Stokes flows. In [17], the author uses a variant of the implicit function theorem; in [1], [2], one introduces a family of isomorphisms which allow us to rewrite the equation $\nabla \cdot y(u) = 0$ appropriately. In this paper, the incompressibility equation is rewritten explicitly.

We will assume that Ω is a Lipschitz domain and that u is Lipschitz-continuous. This includes many interesting situations in which $\partial\Omega$ and/or $\partial(\Omega + u)$ possess "corner" points.

Recall that formal computations of the derivative were previously carried out by O. Pironneau [12] (see also [13]) using "normal" variations.

Some difficulties related to weak regularity. The "natural" expression of the derivative $T'(\Omega; u)$ (that is, the right-hand side of (15)) is not defined a priori since y is only $H^1(\Omega)^d$. Nevertheless, we will give a meaning for this expression using the technical result (17).

2. The definition of the drag. Let D and B be bounded open connected sets in $\mathbb{R}^d$, $d = 2$ or 3, with $B \subset\subset D$. Let us set $\Omega = D \backslash \overline{B}$. In the following discussion, it will be assumed that

$$\Omega \text{ is a Lipschitz domain;} \tag{1}$$

that is to say, its boundary $\partial\Omega$ is locally the graph of a Lipschitz-continuous function and Ω is the corresponding epigraph. (This is explained more in detail in the appendix.)

Let $\gamma \in \mathbb{R}^d$ be a given vector. We consider the stationary Navier–Stokes problem [4]

$$\begin{cases} y - g \in H_0^1(\Omega)^d, \\ p \in L^2(\Omega), \qquad \int_\Omega p = 0, \\ -\nu\,\Delta y + (y \cdot \nabla)\, y + \nabla p = 0, \\ \nabla \cdot y = 0. \end{cases} \tag{2}$$

Here, $g \in H^1(\mathbb{R}^d)^d$ and satisfies

$$\nabla \cdot g = 0,\ g = \gamma \text{ in a neighborhood of } \partial D,\ g = 0 \text{ in a neighborhood of } B. \tag{3}$$

When B is small with respect to D, any solution (y, p) to (2) provides good approximations to the velocity field and the pressure distribution of a viscous incompressible fluid in Ω having constant velocity far from B. It can be imagined that we have chosen spatial coordinates fixed with respect to B, D is an approximation to $\mathbb{R}^d$, the fluid is at rest at infinity, and B is the shape of a body traveling at constant velocity $-\gamma$.

The requirement $\int_\Omega p = 0$ provides uniqueness for the pressure p that, otherwise, would be defined up to an additive constant.

If γ is sufficiently small, problem (2) possesses exactly one solution, which is "small" and does not depend on the choice of g. More precisely, Theorem 2.1 in [9] gives the following lemma.

LEMMA 1. *There exists a constant $\alpha > 0$ such that, if $|\gamma| < \alpha\nu$, then* (2) *possesses exactly one solution, $(y, p) \in H^1(\Omega)^d \times L^2(\Omega)$. This solution does not depend on the choice of the function g satisfying* (3). *Furthermore, for each $\epsilon > 0$, the constant α can be chosen in such a way that*

$$\|y\|_{H^1(\Omega)^d} \leq \epsilon\nu.$$

If $\mathcal{O} \subset\subset D$ is given, one can also choose $\alpha = \alpha(\epsilon, \mathcal{O}, D)$ not depending on B, provided $B \subset \mathcal{O}$. Finally, if Ω is a $W^{2,\infty}$ domain, then $(y, p) \in H^2(\Omega)^d \times H^1(\Omega)$.

Thus, at least when γ is small, one can associate with Ω a drag

$$T(\Omega) = \frac{\nu}{2} \int_\Omega \sigma(y)^2, \tag{4}$$

where $\sigma(y)^2 = \sigma(y) \cdot \sigma(y) \equiv \sum_{ij} (\sigma_{ij}(y))^2$.

Remark. If Ω is regular enough, $T(\Omega)$ coincides with the usual hydrodynamical drag, which is given as follows (cf. [14]):

$$\mathcal{T}(\Omega) = -\gamma \cdot \int_{\partial B} (-p\,Id + \nu\,\sigma(y)) \cdot n\,ds.$$

Indeed, using the boundary condition, we obtain

$$\mathcal{T}(\Omega) = -\int_{\partial\Omega} (p\,(y-\gamma) - \nu\,\sigma(y) \cdot (y-\gamma)) \cdot n\,ds.$$

From Gauss formula and incompressibility, this gives

$$\begin{aligned}\mathcal{T}(\Omega) &= -\int_\Omega \nabla \cdot (p\,(y-\gamma) - \nu\,\sigma(y) \cdot (y-\gamma)) \\ &= \int_\Omega ((\nu\,\Delta y - \nabla p) \cdot (y-\gamma) + \nu\,\sigma(y) \cdot \nabla y).\end{aligned}$$

Note that, again using incompressibility,

$$(\nu\,\Delta y - \nabla p) \cdot (y-\gamma) = ((y \cdot \nabla)\,y) \cdot (y-\gamma) = \nabla \cdot (|y-\gamma|^2\,y).$$

Therefore,

$$\int_\Omega (\nu\,\Delta y - \nabla p) \cdot (y-\gamma) = \int_{\partial\Omega} |y-\gamma|^2\,y \cdot n\,ds = 0,$$

and, finally, since $\sigma(y) \cdot \nabla y = \frac{1}{2}\,\sigma(y)^2$, we have $\mathcal{T}(\Omega) = T(\Omega)$. □

3. The domain variations. We will choose fields $u \in W^{1,\infty}(\mathbb{R}^d, \mathbb{R}^d)$ such that $u = 0$ on ∂D. This condition expresses the fact that the outer boundary limiting the fluid is fixed.

We will also assume $\|u\|_{\text{Lip}} < c(\Omega)$, with $c(\Omega)$ being small enough to ensure that $\Omega + u$ is Lipschitzian and also that $B + u$ is included in a fixed open set $\mathcal{O}$ satisfying

$$B \subset\subset \mathcal{O} \subset\subset D.$$

Here, we have denoted by $\|u\|_{\mathrm{Lip}}$ the best Lipschitz constant for u. More precisely, we have the following obvious result (see [8] for a proof).

LEMMA 2. *Assume that $\mathcal{O}$ is as before. There exists $c(\Omega)$, $0 < c(\Omega) < 1$, such that*

$$B + u \subset \mathcal{O} \tag{5}$$

for all $u \in W^{1,\infty}(\mathbb{R}^d, \mathbb{R}^d)$ satisfying $u = 0$ on ∂D and $\|u\|_{\mathrm{Lip}} \leq c(\Omega)$.

We will also use the following result, whose proof is given in the appendix.

LEMMA 3. *There exists $c(\Omega)$, $0 < c(\Omega) < 1$, such that*

$$\Omega + u \quad \textit{is a bounded Lipschitz domain in} \quad \mathbb{R}^d \tag{6}$$

for all $u \in W^{1,\infty}(\mathbb{R}^d, \mathbb{R}^d)$ satisfying $\|u\|_{W^{1,\infty}(\mathbb{R}^d,\mathbb{R}^d)} \leq c(\Omega)$.

Remark. This lemma holds for each bounded Lipschitz domain $\Omega \subset \mathbb{R}^d$. □

For the subsequent discussion, we introduce

$$\mathcal{W} = \{u \in W^{1,\infty}(\mathbb{R}^d, \mathbb{R}^d);\ \|u\|_{W^{1,\infty}(\mathbb{R}^d,\mathbb{R}^d)} < c(\Omega),\ u = 0 \ \text{ on } \ \partial D\},$$

with $c(\Omega)$ being as in Lemmas 2 and 3. Observing that

$$\|u\|_{\mathrm{Lip}} \leq \|u\|_{W^{1,\infty}(\mathbb{R}^d,\mathbb{R}^d)}$$

we see that (5) and (6) are satisfied for all $u \in \mathcal{W}$.

It will also be assumed in the sequel that

$$|\gamma| < \alpha(\epsilon, \mathcal{O}, D)\, \nu, \tag{7}$$

where α is furnished by Lemma 1. The precise value of ϵ will be fixed below. Now, we choose g satisfying (3) and

$$g \equiv 0 \ \text{ in a neighborhood of } \ \mathcal{O}.$$

(Such a choice is always possible; for instance, one can take $g = a \wedge \nabla\psi$, where $a \in \mathbb{R}^3$, $a \,.\, \gamma = 0$, $|a| = 1$, $\psi \in C^\infty(\mathbb{R}^3)$, $\psi = 0$ in $\mathcal{O}$, $\psi(x) = (g \wedge a) \,.\, x$ in a neighborhood of ∂D.) If $u \in \mathcal{W}$, one has $g = 0$ in a neighborhood of $\partial B + u$. The Navier–Stokes problem in $\Omega + u$ can be written as follows:

$$\begin{cases} y(u) - g \in H_0^1(\Omega + u)^d, \\ p(u) \in L^2(\Omega + u), \qquad \displaystyle\int_\Omega p(u) \circ (I + u) = 0, \\ -\nu\, \Delta y(u) + (y(u) \,.\, \nabla)\, y(u) + \nabla p(u) = 0, \\ \nabla \,.\, y(u) = 0. \end{cases} \tag{8}$$

From Lemma 1, we know that (8) possesses exactly one solution $(y(u), p(u))$. Accordingly, the drag associated with $B + u$ can be defined and is given by

$$T(\Omega + u) = \frac{\nu}{2} \int_{\Omega+u} \sigma(y(u))^2. \tag{9}$$

Remark. In principle, it seems more natural to normalize $p(u)$ by imposing that $\int_{\Omega+u} p(u) = 0$. However, it will be seen below that the choice that we have made is more useful when one considers different fields $u \in \mathcal{W}$. (Indeed, it yields $\int_\Omega P(u) = 0$ for the transported pressure $P(u) = p(u) \circ (I + u)$; see (23).) □

4. A differentiability result for the drag. Our main interest in this section to describe the variations of $T(\Omega+u)$ with respect to u. As already mentioned in the introduction, we search for a formula

$$T(\Omega+u) = T(\Omega) + T'(\Omega;u) + o(u), \tag{10}$$

which must hold for all $u \in \mathcal{W}$, with $T'(\Omega;\ .\ )$ being a linear mapping and

$$o(u)/\|u\|_{W^{1,\infty}(\mathbb{R}^d,\mathbb{R}^d)} \to 0 \ \text{ as } \ \|u\|_{W^{1,\infty}(\mathbb{R}^d,\mathbb{R}^d)} \to 0.$$

That such a formula can be obtained stems from the next result, which is the most important in this article.

THEOREM 4. *There exists $\alpha > 0$ such that if $|\gamma| < \alpha\nu$, then $u \mapsto T(\Omega+u)$ is a C^∞ mapping in the set $\mathcal{W}$.*

In addition, the first derivative at 0 can be obtained from any of the expressions (11), (15), or (18).

THEOREM 5. *Assume $|\gamma| < \alpha\nu$.*

(i) *For all $u \in W^{1,\infty}(\mathbb{R}^d,\mathbb{R}^d)$ such that $u|_{\partial D} = 0$, one has*

$$T'(\Omega;u) = \nu \int_\Omega \sum_{ij}\sigma_{ij}(y)\left(\sigma_{ij}(\dot y(u)) - \sum_k (\partial_i u_k\,\partial_k y_j + \partial_j u_k\,\partial_k y_i) + \frac{1}{2}\sigma_{ij}(y)\,\nabla\cdot u\right) \tag{11}$$

with $(\dot y(u), \dot p(u))$ being the unique solution to the linear problem

$$\begin{cases} \dot y(u) \in H_0^1(\Omega)^d, \\ \dot p(u) \in L^2(\Omega), \qquad \displaystyle\int_\Omega \dot p(u) = 0, \\ -\nu\,\Delta \dot y(u) + (\dot y(u)\cdot\nabla)\,y + (y\cdot\nabla)\,\dot y(u) + \nabla \dot p(u) = G(u,y,p), \\ \nabla\cdot \dot y(u) = \sum_{ij}\partial_i u_j\,\partial_j y_i. \end{cases} \tag{12}$$

Here, $y = y(0)$, $p = p(0)$, and $G_k(u,y,p) \in H^{-1}(\Omega)$ is given as follows for $1 \le k \le d$:

$$\begin{aligned} G_k(u,y,p) = &-\nu \sum_{ij}(\partial_j(\partial_i u_j\,\partial_i y_k) + \partial_j(\partial_j u_i\,\partial_i y_k)) + \nu\sum_j \partial_j((\nabla\cdot u)\,\partial_j y_k) \\ &+ \sum_{ij} y_i\,\partial_i u_j\,\partial_j y_k - (y\cdot\nabla)\,y_k\,\nabla\cdot u \\ &+ \sum_j \partial_j(\partial_k u_j\,p) - \partial_k((\nabla\cdot u)\,p). \end{aligned} \tag{13}$$

Moreover, $y \in C^\infty(\Omega)^d$, $p \in C^\infty(\Omega)$, and, consequently,

$$G(u,y,p) = -\nu\,\Delta((u\cdot\nabla)\,y) + (((u\cdot\nabla)\,y)\cdot\nabla)\,y + (y\cdot\nabla)((u\cdot\nabla)\,y) + \nabla(u\cdot\nabla p). \tag{14}$$

(ii) *One also has*

$$T'(\Omega;u) = \nu\int_\Omega \sum_{ij}\left(\sigma_{ij}(y)\,\sigma_{ij}(y'(u)) + \frac{1}{2}\,\nabla\cdot\left(\sigma_{ij}(y)^2 u\right)\right), \tag{15}$$

with $(y'(u), p'(u))$ being the unique solution to

$$\begin{cases} y'(u) + (u\cdot\nabla)\,y \in H_0^1(\Omega)^d, \\ (p'(u) + u\cdot\nabla p) \in L^2(\Omega), \qquad \displaystyle\int_\Omega (p'(u) + u\cdot\nabla p) = 0, \\ -\nu\,\Delta y'(u) + (y'(u)\cdot\nabla)\,y + (y\cdot\nabla)\,y'(u) + \nabla p'(u) = 0, \\ \nabla\cdot y'(u) = 0. \end{cases} \tag{16}$$

Furthermore, $y'(u) \in H^1_{\rm loc}(\Omega)^d$ *and the sum in* (15) *satisfies*

$$\sum_{ij} \left(\sigma_{ij}(y)\, \sigma_{ij}(y'(u)) + \frac{1}{2} \nabla \cdot \left(\sigma_{ij}(y)^2 u \right) \right) \in L^1(\Omega). \tag{17}$$

(iii) *If* B *and* D *are* $W^{2,\infty}$ *domains and* $u \in W^{2,\infty}(\mathbb{R}^d, \mathbb{R}^d)$, *then* $(y,p) \in H^2(\Omega)^d \times H^1(\Omega)$ *and*

$$T'(\Omega; u) = \int_{\partial B} u \cdot n \left(\frac{\partial w}{\partial n} - \frac{\partial y}{\partial n} \right) \cdot \frac{\partial y}{\partial n}\, ds, \tag{18}$$

with (w,q) *being the unique solution to the "adjoint" problem*

$$\begin{cases} w \in H^1_0(\Omega)^d \cap H^2(\Omega)^d, \\ q \in H^1(\Omega), \qquad \displaystyle\int_\Omega q = 0, \\ -\nu\, \Delta w_i + \sum_j \partial_i y_j\, w_j - \sum_j y_j\, \partial_j w_i + \partial_i q = -2\nu\, \Delta y_i\,, \quad 1 \le i \le d, \\ \nabla \cdot w = 0. \end{cases} \tag{19}$$

Remark. In order to compute the derivative of the drag in several directions using (15), one has to solve, for each direction u, the corresponding partial differential problem (16). It is much more interesting to use the identity (18) because it suffices to solve (2) and (19) only once; then, for each u, one has only to compute an integral on ∂B. □

Remark. One can also obtain expressions for the derivatives of higher orders. This must be made with caution; indeed, $T''(\Omega;\, \cdot\,,\, \cdot\,)$ (i.e., the second derivative at 0 of $u \mapsto T(\Omega + u)$) does not coincide with $(T'(\Omega;\, \cdot\,)';\, \cdot\,)$ (i.e., the derivative at 0 of the mapping $u \mapsto T'(\Omega + u;\, \cdot\,)$). In fact, these two quantities are related by the following formula (see [16]):

$$T''(\Omega; u, v) = (T'(\Omega; u)'; v) - T'(\Omega; (u \cdot \nabla)\, v). \qquad \square$$

5. Differentiability results for the velocity and the pressure. In order to prove Theorem 4, we will first show that $u \mapsto y(u)$ is, in a certain sense, a "differentiable" mapping. An important difficulty arises here, because $y(u)$ is a function defined only for $x \in \Omega + u$, a domain which depends on u. This is why we introduce a suitable change of variables and we rewrite the equations satisfied by $y(u)$ and $p(u)$ in the fixed domain Ω. Then, we will have to differentiate the transported variable $Y(u) = y(u) \circ (I + u)$, which is defined in Ω.

In what follows, y and p stand for $y(0)$ and $p(0)$, respectively. We will check the following:

$$\dot{y}(u) = Y'(0) \cdot u \equiv \lim_{t \to 0} \frac{y(tu) \circ (I + tu) - y}{t}\,.$$

This is the "total derivative" of $y(u)$ at 0, used in (11) to give an expression of $T'(\Omega; u)$. We will also have to use the "local derivative." In fact, we will check that

$$y'(u) = \frac{d}{dv} y(v)|_\omega(0) \cdot u \equiv \lim_{t \to 0} \frac{y(tu)|_\omega - y|_\omega}{t} \qquad \text{in } \ \omega.$$

This defines $y'(u)$ in each open set $\omega \subset\subset \Omega$ and, consequently, in the whole domain Ω. The previous local derivative was used in (15) to give an expression of $T'(\Omega; u)$. More precisely, the following result holds.

THEOREM 6. *There exists $\alpha > 0$ such that if $|\gamma| < \alpha\nu$, then*

(i) *The mapping $u \mapsto (y(u), p(u)) \circ (I+u)$ is C^∞ in $\mathcal{W}$, with values in the product space $H^1(\Omega)^d \times L^2(\Omega)$. Its derivative at 0 in the direction u is the unique solution $(\dot{y}(u), \dot{p}(u))$ to (12).*

(ii) *For all $\omega \subset\subset \Omega$, the mapping $u \mapsto y(u)|_\omega$ is differentiable in $\mathcal{W}$, with values in $L^2(\omega)^d$. Its derivative at 0 in the direction u is $y'(u)|_\omega$, where $y'(u)$ is uniquely defined by (16). One also has*

$$y'(u) = \dot{y}(u) - (u \cdot \nabla)\, y. \tag{20}$$

Remark. From general results on local differentiability (see Lemma 2.1 in [15]), (ii) is implied by (i). ∎

Theorems 4, 5, and 6 will be demonstrated in several steps:

— differentiability at 0 of the velocity, the pressure (section 5), and the drag (section 6);

— differentiability at any point in $\mathcal{W}$ (section 7); higher-order differentiability (section 8).

6. Proof of differentiability at 0 of the velocity and the pressure. The goal of this section is to prove the following result.

LEMMA 7. *There exists $\alpha > 0$ such that, if $|\gamma| < \alpha\nu$, then the mapping $u \mapsto (y(u), p(u)) \circ (I+u)$, which is defined in $\mathcal{W}$ and takes values in $H^1(\Omega)^d \times L^2(\Omega)$, is differentiable at 0. Its derivative, denoted by $(\dot{y}(u), \dot{p}(u))$, is uniquely determined by (12).*

The proof is based on the implicit function theorem. We will show that this lemma holds with α being of the form $\alpha(\epsilon, \mathcal{O}, D)$ (as in Lemma 1) for an appropriate constant ϵ. First, we will have to rewrite the equations (8) in the fixed domain Ω. For this, we have to "transport" all the terms, some of which belong to $H^{-1}(\Omega+u)$. But it is not clear for a distribution $f \in H^{-1}(\Omega+u)$ how $f \circ (I+u)$ can be defined. Contrarily, following [10, Definition 4.1], one can give a definition of $(f \circ (I+u))\,\mathrm{Jac}(I+u)$.

DEFINITION 8. *Assume $u \in \mathcal{W}$ and $f \in H^{-1}(\Omega+u)$. Then*

$$(f \circ (I+u))\,\mathrm{Jac}(I+u) \in H^{-1}(\Omega)$$

is defined as follows: for any $\varphi \in H_0^1(\Omega)$, one has

$$\langle (f \circ (I+u))\,\mathrm{Jac}(I+u), \varphi \rangle_{H^{-1}(\Omega)\times H_0^1(\Omega)} = \langle f, \varphi \circ (I+u)^{-1} \rangle_{H^{-1}(\Omega+u)\times H_0^1(\Omega+u)}. \tag{21}$$

Remark. Rigorously speaking, $(f \circ (I+u))\,\mathrm{Jac}(I+u)$ is not a good notation, because $f \circ (I+u)$ is not defined. However, it will be used in subsequent discussion for convenience. ∎

Note that (21) makes sense; indeed, $\varphi \circ (I+u)^{-1} \in H_0^1(\Omega+u)$ (see [10, Lemma 4.1]). It does not change the usual definition of $(f \circ (I+u))\,\mathrm{Jac}(I+u)$ when $f \in L^1_{\mathrm{loc}}(\Omega+u)$.

In order to rewrite (8), we denote by $D(u)$ the operator whose components $D_i(u)$ are given as follows:

$$D_i(u) = \textstyle\sum_j M_{ij}(u)\, \partial_j, \quad M(u) = {}^t\,[\partial_j (I+u)_i]^{-1}. \tag{22}$$

Here, ${}^t\,[\partial_j (I+u)_i]^{-1}$ is the transpose of the inverse of the matrix of components $\partial_j (I+u)_i$. We will use the following three lemmas (see [9] and [10]).

LEMMA 9. *Assume $u \in \mathcal{W}$ and $f \in H^1(\Omega + u)$. Then*

$$(\partial_i f) \circ (I + u) = \textstyle\sum_j M_{ij}(u)\, \partial_j (f \circ (I + u)) = D_i(u)(f \circ (I + u)).$$

LEMMA 10. *If $u \in \mathcal{W}$ and $f \in L^2(\Omega + u)$, then*

$$((\partial_i f) \circ (I + u))\, \mathrm{Jac}(I + u) = \textstyle\sum_j \partial_j (M_{ij}(u)\, (f \circ (I + u))\, \mathrm{Jac}(I + u)).$$

LEMMA 11. *Assume $u \in \mathcal{W}$ and $f \in H^1(\Omega + u)$. Then*

$$((\Delta f) \circ (I + u))\, \mathrm{Jac}(I + u) = \textstyle\sum_{ij} \partial_j (M_{ij}(u)\, \mathrm{Jac}(I + u)\, D_i(u)(f \circ (I + u))).$$

The Navier–Stokes problem (8) can now be written as follows:

$$\text{(23)} \qquad \begin{cases} Y(u) - g \in H^1_0(\Omega)^d, \\ P(u) \in L^2(\Omega), \qquad \displaystyle\int_\Omega P(u) = 0, \\ -\nu \textstyle\sum_{ij} \partial_j (M_{ij}(u)\, \mathrm{Jac}(I + u)\, D_i(u) Y_k(u)) \\ \qquad\qquad + (Y(u) \cdot D(u)) Y_k(u)\, \mathrm{Jac}(I + u) \\ \qquad\qquad + \textstyle\sum_j \partial_j (M_{kj}(u)\, P(u)\, \mathrm{Jac}(I + u)) = 0, \qquad 1 \le k \le d, \\ D(u) \cdot Y(u)\, \mathrm{Jac}(I + u) = 0. \end{cases}$$

Here, we have set $Y(u) = y(u) \circ (I + u)$ and $P(u) = p(u) \circ (I + u)$.

We will also introduce in (23) the new variable $X(u) = Y(u) - g$. This leads to the following system, equivalent to (23) (which is, in turn, equivalent to (8)):

$$\text{(24)} \qquad \begin{cases} X(u) \in H^1_0(\Omega)^d, \\ P(u) \in L^2(\Omega), \qquad \displaystyle\int_\Omega P(u) = 0, \\ -\nu \textstyle\sum_{ij} \partial_j (M_{ij}(u)\, \mathrm{Jac}(I + u)\, D_i(u)(X(u) + g)_k) \\ \qquad\qquad + ((X(u) + g) \cdot D(u))\, (X(u) + g)_k\, \mathrm{Jac}(I + u) \\ \qquad\qquad + \textstyle\sum_j \partial_j (M_{kj}(u)\, P(u)\, \mathrm{Jac}(I + u)) = 0, \qquad 1 \le k \le d, \\ D(u) \cdot (X(u) + g)\, \mathrm{Jac}(I + u) = 0. \end{cases}$$

This equation can be written

$$\text{(25)} \qquad H(u; X(u), P(u)) = 0,$$

where the function H is defined, from $\mathcal{W} \times H^1_0(\Omega)^d \times L^2_0(\Omega)$ into $H^{-1}(\Omega)^d \times L^2_0(\Omega)$, by

$$\text{(26)} \qquad \begin{cases} H(u; \chi, \pi) = (F(u; \chi, \pi), R(u; \chi, \pi)), \quad F = (F_1, \dots, F_d), \\ F_k(u; \chi, \pi) = -\nu \textstyle\sum_{ij} \partial_j (M_{ij}(u)\, \mathrm{Jac}(I + u)\, D_i(u)(\chi + g)_k) \\ \qquad\qquad + ((\chi + g) \cdot D(u))(\chi + g)_k\, \mathrm{Jac}(I + u) \\ \qquad\qquad + \textstyle\sum_j \partial_j (M_{kj}(u)\, \pi\, \mathrm{Jac}(I + u)), \qquad 1 \le k \le d, \\ R(u; \chi, \pi) = D(u) \cdot (\chi + g)\, \mathrm{Jac}(I + u). \end{cases}$$

The fact that $R(u;\chi,\pi) \in L^2_0(\Omega)$ is crucial. This is true because

$$\begin{aligned}\int_\Omega (D(u)\,.\,Y(u))\,\mathrm{Jac}(I+u) &= \int_{\Omega+u} (D(u)\,.\,Y(u))\circ(I+u)^{-1}\\ &= \int_{\Omega+u} \nabla\,.\,(Y(u)\circ(I+u)^{-1})\\ &= 0.\end{aligned}$$

Now, we check that the assumptions of the implicit function theorem are satisfied. First, H is C^1 in a neighborhood of $(0;X,P)$, where we have set $X = X(0) = y - g$, $P = P(0) = p$. Indeed, the coefficients in $D(u)$ and $M(u)$ are C^1 since, according to the results in [10], the mapping $u \mapsto M_{ij}(u)$ is C^1 in a neighborhood of 0 in $W^{1,\infty}(\mathbb{R}^d,\mathbb{R}^d)$, with values in $L^\infty(\mathbb{R}^d,\mathbb{R}^{d^2})$.

On the other hand, let us see that the differential operator $L = D_{(\chi,\pi)}H(0;X,P)$ is an isomorphism from $H^1_0(\Omega)^d \times L^2_0(\Omega)$ onto $H^{-1}(\Omega)^d \times L^2_0(\Omega)$. For each $(\chi,\pi) \in H^1_0(\Omega)^d \times L^2_0(\Omega)$, one has

$$L(\chi,\pi) = (\,-\nu\,\Delta\chi + (\chi\,.\,\nabla)\,y + (y\,.\,\nabla)\,\chi + \nabla\pi\,,\,\nabla\,.\,\chi). \tag{27}$$

The operator L is linear and bounded from $H^1_0(\Omega)^d \times L^2_0(\Omega)$ into $H^{-1}(\Omega)^d \times L^2_0(\Omega)$. Hence, we have to check that, for each $f \in H^{-1}(\Omega)^d$ and $\phi \in L^2_0(\Omega)$, there exists a unique solution $(\chi,\pi) \in H^1_0(\Omega)^d \times L^2_0(\Omega)$ to the system

$$\begin{cases} -\nu\,\Delta\chi + (\chi\,.\,\nabla)\,y + (y\,.\,\nabla)\,\chi + \nabla\pi = f,\\ \nabla\,.\,\chi = \phi \end{cases} \tag{28}$$

and, also, that this solution depends continuously on the data. Since Ω is a Lipschitz domain, Corollary 2.4 in [6] asserts

$$\forall\phi \in L^2(\Omega) \ \text{ such that } \int_\Omega \phi = 0, \ \text{ there exists } \ \psi \in H^1_0(\Omega)^d \ \text{ such that } \ \nabla\,.\,\psi = \phi. \tag{29}$$

Setting $\Phi = \chi - \psi$, system (28) reduces to

$$\begin{cases} \Phi \in V, \quad \pi \in L^2_0(\Omega),\\ -\nu\,\Delta\Phi + (\Phi\,.\,\nabla)\,y + (y\,.\,\nabla)\,\Phi + \nabla\pi = F, \end{cases}$$

where $V = \{v \in H^1_0(\Omega)^d;\ \nabla\,.\,v = 0\}$ and $F = f + \nu\Delta\psi - (\psi\,.\,\nabla)y - (y\,.\,\nabla)\psi$. This equation is elliptic with respect to Φ and possesses a unique solution depending continuously on the data if, for some appropriate $r = r(\mathcal{O},D) > 0$, one has

$$\|y\|_{H^1_0(\Omega)^d} < r\,\nu. \tag{30}$$

Hence, if we choose $\epsilon < r$, $\alpha = \alpha(\epsilon,\mathcal{O},D)$ as in Lemma 1 and

$$|\gamma| < \alpha\nu,$$

this condition holds and L is an isomorphism.

This allows us to apply the implicit function theorem to (25). We deduce that the mapping $u \mapsto (X(u),P(u))$, which takes values in the space $H^1_0(\Omega)^d \times L^2_0(\Omega)$, is

differentiable at 0. Since $y(u)\circ(I+u)=X(u)+g$ and $p(u)\circ(I+u)=P(u)$, the first part of Lemma 7 is proven.

Finally, let us deduce the equations satisfied by $(\dot y(u),\dot p(u))$. In accordance with the implicit function theorem,

$$L(\dot y(u),\dot p(u)) = -D_vH(0;X,P)\,.\,u$$

for all admissible u. Taking into account (26) and also the identities

$$M'_{ik}(0)\,.\,u=-\partial_i u_k \quad\text{and}\quad \frac{d}{dv}\mathrm{Jac}(I+v)(0)\,.\,u=\nabla\,.\,u \tag{31}$$

(see [10]), we find that $(\dot y(u),\dot p(u))$ is a solution to (12). But this problem possesses exactly one solution, since L is an isomorphism. Consequently, Lemma 7 is proven.

Remark. In order to solve (28), we have had to assume that Ω is a Lipschitz domain. The same requirement is found when one writes (28) as a mixed problem and one tries to apply general results concerning mixed variational formulations. □

7. Proof of differentiability at 0 of the drag. The goal of this section is to prove Theorem 5.

Proof of part (i). By definition, one has

$$\begin{aligned} T(\Omega+u) &= \frac{\nu}{2}\int_{\Omega+u}\textstyle\sum_{ij}(\partial_i y_j(u)+\partial_j y_i(u))^2\\ &= \frac{\nu}{2}\int_{\Omega}\textstyle\sum_{ij}(\sum_k(M_{ik}(u)\,\partial_k Y_j(u)+M_{jk}(u)\,\partial_k Y_i(u)))^2\,\mathrm{Jac}(I+u).\end{aligned}$$

We will deduce the differentiability of the mapping $u\mapsto T(\Omega+u)$ from the following result (Theorem 4.1 in [10]).

LEMMA 12. *Assume that $z(u)$ is well defined for all $u\in\mathcal{W}$ and, also, that*

$$u\mapsto z(u)\circ(I+u) \quad \textit{is differentiable at } 0,\ \textit{with values in}\ \ L^1(\Omega). \tag{32}$$

Then the mapping $u\mapsto S(\Omega+u)=\int_\Omega (z(u)\circ(I+u))\,\mathrm{Jac}(I+u)$ is also differentiable at 0. Its derivative at 0 in the direction u is given by

$$S'(\Omega;u)=\int_\Omega(\dot z(u)+z(0)\,\nabla\,.\,u).$$

We will apply this lemma with

$$z(u)\circ(I+u)=\textstyle\sum_{ij}(\sum_k(M_{ik}(u)\,\partial_k Y_j(u)+M_{jk}(u)\,\partial_k Y_i(u)))^2.$$

Obviously, $S(\Omega+u)\equiv T(\Omega+u)$ in this case; also, that (32) holds is deduced from the differentiability at 0 of the $H^1_0(\Omega)^d$-valued mapping $u\mapsto Y(u)$.

Let us compute $T'(\Omega;u)$. From (31) and the fact that $M(0)=Id$, one has

$$\begin{aligned}\dot z(u) &= 2\textstyle\sum_{ij}(\partial_i y_j+\partial_j y_i)(\partial_i\dot y_j(u)+\partial_j\dot y_i(u)-\sum_k\partial_i u_k\,\partial_k y_j-\sum_k\partial_j u_k\,\partial_k y_i)\\ &= 2\textstyle\sum_{ij}\sigma_{ij}(y)(\sigma_{ij}(\dot y(u))-\sum_k\partial_i u_k\,\partial_k y_j-\sum_k\partial_j u_k\,\partial_k y_i).\end{aligned}$$

Since $z(0)=\sum_{ij}\sigma_{ij}(y)^2$, we have

$$T'(\Omega;u)=\nu\int_\Omega\textstyle\sum_{ij}\sigma_{ij}(y)\left(\sigma_{ij}(\dot y(u))-\sum_k(\partial_i u_k\,\partial_k y_j+\partial_j u_k\,\partial_k y_i)+\frac12\,\sigma_{ij}(y)\,\nabla\,.\,u\right).$$

This proves (11). The regularity results are $y \in C^\infty(\Omega)^d$ and $p \in C^\infty(\Omega)$. (This is well known; for instance, see [7].) The identity (14) is then an easy consequence of (13).

Proof of part (ii). Let us set

$$y'(u) = \dot{y}(u) - (u \cdot \nabla)\, y, \quad p'(u) = \dot{p}(u) - u \cdot \nabla p.$$

Using (14) we see that (12) and (16) are equivalent. On the other hand, these definitions provide the following identity:

$$\begin{aligned}&\textstyle\sum_{ij} \left(\sigma_{ij}(y)\, \sigma_{ij}(y'(u)) + \frac{1}{2}\, \nabla \cdot (\sigma_{ij}(y)^2 u) \right) \\ &\quad = \textstyle\sum_{ij} \sigma_{ij}(y) \left(\sigma_{ij}(\dot{y}(u)) - \sum_k (\partial_i u_k\, \partial_k y_j + \partial_j u_k\, \partial_k y_i) + \frac{1}{2}\, \sigma_{ij}(y)\, \nabla \cdot u \right).\end{aligned}$$

Hence, (11) implies (17) and (15).

Proof of part (iii). Let us now suppose that Ω is a $W^{2,\infty}$ domain and $u \in W^{2,\infty}(\mathbb{R}^d, \mathbb{R}^d)$. According to Lemma 1, one has $y \in H^2(\Omega)^d$ and $p \in H^1(\Omega)$. Consequently, one obtains from (15)

$$T'(\Omega; u) = \nu \int_\Omega \textstyle\sum_{ij} \sigma_{ij}(y)\, \sigma_{ij}(y'(u)) + \frac{\nu}{2} \int_{\partial\Omega} \sum_{ij} \sigma_{ij}(y)^2\, u \cdot n\, ds. \tag{33}$$

Since $\dot{y}(u) = 0$ and $y \equiv$ const. on $\partial\Omega$, $y'(u) = -u \cdot n\, \frac{\partial y}{\partial n}$ on $\partial\Omega$. Therefore,

$$\begin{aligned}&\nu \int_\Omega \textstyle\sum_{ij} \sigma_{ij}(y)\, \sigma_{ij}(y'(u)) \\ &\qquad = -2\nu \int_\Omega \Delta y \cdot y'(u) - 2\nu \textstyle\sum_{ij} \int_{\partial\Omega} u \cdot n\, (\partial_i y_j + \partial_j y_i)\, \frac{\partial y_i}{\partial n}\, n_j\, ds.\end{aligned}$$

In addition, $\sum_i \partial_i y_i = 0$ imply $\sum_{ij} (\partial_i y_j + \partial_j y_i)\, \frac{\partial y_i}{\partial n} n_j = |\frac{\partial y}{\partial n}|^2$, whence

$$T'(\Omega; u) = -2\nu \int_\Omega \Delta y \cdot y'(u) - \nu \int_{\partial\Omega} \left| \frac{\partial y}{\partial n} \right|^2 u \cdot n\, ds.$$

If w and q are given by (19), after some manipulation, one obtains

$$\begin{aligned}T'(\Omega; u) = &\int_\Omega \textstyle\sum_i (-\nu\, \Delta w_i\, y_i'(u) + \sum_j (\partial_i y_j\, w_j - y_j \partial_j w_i) y_i'(u) + \partial_i q\, y_i'(u)) \\ &\qquad - \nu \int_{\partial\Omega} \left| \frac{\partial y}{\partial n} \right|^2 u \cdot n\, ds \\ = &\langle -\nu\, \Delta y'(u) + (y'(u) \cdot \nabla)\, y + (y \cdot \nabla)\, y'(u) + \nabla p'(u), w \rangle_{H^{-1}(\Omega)^d \times H^1_0(\Omega)^d} \\ &\qquad + \nu \int_{\partial\Omega} u \cdot n \left(\frac{\partial w}{\partial n} - \frac{\partial y}{\partial n} \right) \cdot \frac{\partial y}{\partial n}\, ds.\end{aligned}$$

Using (16) satisfied by $(y'(u), p'(u))$, one sees that the duality product on the right-hand side cancels. This proves (18), since $u = 0$ on ∂D. ∎

8. Proof of differentiability at any point in $\mathcal{W}$ of the velocity, the pressure, and the drag. In this section, we prove the following result.

LEMMA 13. *The mapping $u \mapsto (y(u), p(u)) \circ (I + u)$, which takes values in $H^1(\Omega)^d \times L^2(\Omega)$, is differentiable at any point $u_0 \in \mathcal{W}$. The mapping $u \mapsto T(\Omega + u)$ is also differentiable at any $u_0 \in \mathcal{W}$.*

Proof. Let $u_0 \in \mathcal{W}$ be given. We have

$$\Omega + (u_0 + v) = (\Omega + u_0) + v \circ (I + u_0)^{-1} \tag{34}$$

for $v \in \mathcal{W}$ small enough in order to have $u_0 + v \in \mathcal{W}$. According to the results in section 6, the mapping $w \mapsto T((\Omega + u_0) + w)$ is differentiable at 0. The mapping $v \mapsto v \circ (I + u_0)^{-1}$ is linear and bounded (therefore differentiable) from $W^{1,\infty}(\mathbb{R}^d, \mathbb{R}^d)$ into itself. Consequently,

$$v \mapsto T((\Omega + u_0) + v \circ (I + u_0)^{-1}) \quad \text{is differentiable at 0;}$$

i.e., $u \mapsto T(\Omega + u)$ is differentiable at u_0.

Now we will apply the previous results to some new reference domains different from Ω. So we introduce the more explicit notation $(y(\Omega; v), p(\Omega; v))$ for the solution to the Navier–Stokes problem in $\Omega + v$. We see from (34) that, for small v,

$$y(\Omega; u_0 + v) \circ (I + (u_0 + v)) = y(\Omega + u_0; v \circ (I + u_0)^{-1}) \circ (I + u_0 + v). \tag{35}$$

On the other hand, from Lemma 7, we know that the $H^1(\Omega + u_0)^d$-valued mapping $w \mapsto y(\Omega + u_0; w) \circ (I + w)$ is differentiable at 0. Thus, $v \mapsto y(\Omega; u_0 + v) \circ (I + u_0 + v)$ is differentiable at 0; i.e., $u \mapsto y(\Omega; u) \circ (I + u)$ is differentiable at u_0. A similar argument holds for the function $u \mapsto p(\Omega; u) \circ (I + u)$. ∎

Remark. Theorem 4.1 in [1] asserts that, when Ω is a $W^{2,\infty}$ domain, the mapping $u \mapsto (y(u), p(u)) \circ (I + u)$ is well defined for $u \in W^{2,\infty}(\mathbb{R}^d, \mathbb{R}^d) \cap \mathcal{W}$ and differentiable at 0, with values in $H^2(\Omega)^d \times H^1(\Omega)$. Adapting the previous argument, we can deduce differentiability at each point in a $W^{2,\infty}$-open ball centered at 0. ∎

9. Higher-order differentiability. In this section, we will prove Theorems 6 and 4.

Proof of part (i) *of Theorem* 6. It remains to prove that $u \mapsto (Y(u), P(u))$ is a C^∞ mapping. (The remainder of part (i) has already been proven in section 6, Lemma 7.)

Observe that the mapping H, introduced in section 5 and defined from $\mathcal{W} \times H_0^1(\Omega)^d \times L_0^2(\Omega)$ into $H^{-1}(\Omega)^d \times L_0^2(\Omega)$, is C^∞. This is a consequence of the fact that $u \mapsto M_{ij}(u)$ and $u \mapsto \mathrm{Jac}(I + u)$ are C^∞ mappings. In turn, this stems from the following:

(a) The mapping $u \mapsto \mathrm{Jac}(I + u)$ is multilinear and, consequently, is of class C^∞.

(b) The mapping $u \mapsto M(u) = {}^t[\partial_i (I + u)_j]^{-1}$ is C^∞ on $\mathcal{W}$, because the inversion operator is indefinitely differentiable in the set of the nonsingular matrices.

From the implicit function theorem, we deduce that $u \mapsto (Y(u), P(u))$ possesses derivatives of all orders at 0. Again using (35), which can be written in the form

$$Y(\Omega; u_0 + u) = Y(\Omega + u_0; u \circ (I + u_0)^{-1}) \circ (I + u_0),$$

one also sees that $u \mapsto Y(\Omega; u)$ is C^∞ at each point $u_0 \in \mathcal{W}$. The same is true for $u \mapsto P(\Omega; u)$. ∎

Proof of part (ii). The differentiability of the mapping $u \mapsto y(u)|_\omega$ at 0 in $L^2(\omega)^d$ and the identity (20) are consequences of the differentiability of $u \mapsto y(u) \circ (I + u)$

given in Lemma 7. This is a consequence of general results on differentiation with respect to domains (see Lemma 2.1 in [15]). On the other hand, (12) and (20) together imply (16). ∎

Proof of Theorem 4. We have to check that $u \mapsto T(\Omega+u)$ is a C^∞ mapping. This is deduced from the above results and the following equality, which has already been used in section 6:

$$T(\Omega+u) = \frac{\nu}{2}\int_\Omega \sum_{ij}\Big(\sum_k (M_{ik}(u)\,\partial_k Y_j(\Omega;u) + M_{jk}(u)\,\partial_k Y_i(\Omega;u))\Big)^2 \mathrm{Jac}(I+u). \qquad \blacksquare$$

10. Miscellaneous remarks. *The case of a non-Lipschitz domain.* Until now, we have assumed that Ω is a Lipschitz domain in order to ensure, among other things, that (29) is true. Actually, this assumption on Ω can be replaced by (29) itself:

$$\forall \phi \in L^2(\Omega) \ \text{ such that } \ \int_\Omega \phi = 0, \ \text{ there exists } \ \psi \in H_0^1(\Omega)^d \ \text{ such that } \ \nabla \cdot \psi = \phi;$$

i.e., the divergence operator maps $H_0^1(\Omega)^d$ onto $L_0^2(\Omega)$.

Under this weaker hypothesis, the results in the previous sections hold again with minor changes. Instead of $p \in C^\infty(\Omega) \cap L^2(\Omega)$, we now have only

$$p \in C^\infty(\Omega), \quad \nabla p \in H^{-1}(\Omega)^d. \tag{36}$$

On the other hand, we cannot normalize p and $\dot{p}(u)$ as before. Instead, a possibility is to fix a nonempty open set $\omega \subset\subset \Omega$ and to impose

$$\int_\omega p = 0, \quad \int_\omega \dot{p}(u) = 0.$$

Remark. The condition (29) requires some regularity on Ω, which is probably not far from being Lipschitz. ∎

Remark. It is important to note that, here, the difficulty is not related to nonlinearity. Even if we were concerned with Stokes flows (the term $(y \cdot \nabla)\, y$ disappears), (36) could not be improved unless a regularity assumption is required for Ω. This difficulty is connected with the fact that the equations are coupled by the incompressibility condition $\nabla \cdot y = 0$. ∎

Remark. For more simple (scalar) problems, we can obtain a result similar to Theorem 4, without any regularity hypothesis for Ω. For example, let y be the unique solution to

$$-\Delta y = f \ \text{ in } \ \Omega, \qquad y - g \in H_0^1(\Omega)^d, \tag{37}$$

and let us set

$$S(\Omega) = \int_\Omega |\nabla(y-z)|^2,$$

where $f \in L^2(\Omega)^d$, $g \in H^2(\mathbb{R}^d)$, and $z \in H^1(\mathbb{R}^d)$ are given and Ω is an arbitrary bounded open set in $\mathbb{R}^d$. Then, $u \mapsto S(\Omega+u)$ is well defined and differentiable in a neighborhood of 0 in $W^{1,\infty}(\mathbb{R}^d,\mathbb{R}^d)$ [10, Theorem 5.2, p. V.10]. ∎

The particular case of a polygonal two-dimensional body. Assume that B is a two-dimensional polygonal domain with vertices $s_1, s_2, \ldots, s_n$. Let us set $s = (s_1, \ldots, s_n)$,

and let us assume that the corresponding polygonal line, ∂B, does not cross itself. Thus, using the notation $s_{n+1} = s_1$, one has

$$[s_i, s_{i+1}[\bigcap [s_j, s_{j+1}[= \emptyset \quad \text{if} \quad 1 \leq i < j \leq n. \tag{38}$$

Also, assume that

$$B \subset\subset \mathcal{O} \subset\subset D. \tag{39}$$

It is then obvious that $\Omega_s = D \backslash \overline{B}$ satisfies (1). In this situation, the following is not difficult to prove:

The mapping $s \mapsto T(\Omega_s)$ is C^∞ at each point $s \in \mathbb{R}^{2n}$ satisfying (38) *and* (39).

Other examples. Above, the polygonal domain can be replaced by a spline depending on a finite number of parameters. In such a way, we obtain similar results for "NACA profiles" or other piecewise C^1 boundaries. Similar results hold for three-dimensional domains.

11. Appendix. In order to prove Lemma 3, we need some previous definitions and results.

DEFINITION 14. *Let Ω be a bounded open set in $\mathbb{R}^d$.*

(i) *We say that* Ω is a Lipschitz domain (*also that Ω is Lipschitzian; see* [11], [5]) *if there exist constants $a > 0$ and $b > 0$ such that, for each $z \in \partial\Omega$, one can find*

— *coordinates $(x_1, \ldots, x_d)$,*

— *a Lipschitz-continuous real-valued function ψ in Θ_* with best Lipschitz constant smaller than b, where $\Theta_* = \{x_*;\ |x_* - z_*| < a\}$, $x_* = (x_1, \ldots, x_{d-1})$, and $z_* = (z_1, \ldots, z_{d-1})$,*

such that, for each $x \in \Theta = \{x \in \mathbb{R}^d;\ |x_* - z_*| < a,\ |x_d - \psi(x_*)| < a\}$, one has

$$x \in \Omega \Longleftrightarrow x_d > \psi(x_*).$$

(ii) *We say that* Ω satisfies the cone property uniformly *if there exist constants $\alpha > 0$ and $b > 0$ such that, for each $z \in \partial\Omega$, one can find coordinates such that*

$$x \in \Omega \cap B(z; \alpha) \Longrightarrow x + \mathcal{C}_{b,\alpha} \subset \Omega.$$

Here, we have set $B(z; \alpha) = \{x \in \mathbb{R}^d;\ |x - z| < \alpha\}$ and

$$\mathcal{C}_{b,\alpha} = \{x \in \mathbb{R}^d;\ x_d > b\,|x_*|,\ |x| < \alpha\}.$$

The properties (i) and (ii) are equivalent. More precisely, we have the following result (see [3]).

LEMMA 15. *A bounded open set in $\mathbb{R}^d$ is Lipschitzian if and only if it satisfies the cone property uniformly.*

The following result was also used in the proof of Lemma 3.

LEMMA 16. *Assume that $\alpha > 0$ and $b > 0$ are given. There exist $\alpha' > 0$, $b' > 0$, and $l \in (0, 1)$ such that, whenever $v \in W^{1,\infty}(\mathbb{R}^d, \mathbb{R}^d)$, $\|v\|_{W^{1,\infty}(\mathbb{R}^d,\mathbb{R}^d)} \leq l$, and $v(0) = 0$, one has*

$$\mathcal{C}_{b',\alpha'} \subset (I + v)\,\mathcal{C}_{b,\alpha}.$$

Proof of Lemma 3. From Lemma 15, there exist $\alpha > 0$ and $b > 0$ such that, for each $z \in \partial\Omega$, one has

$$x \in \Omega \cap B(z; \alpha) \Longrightarrow x + \mathcal{C}_{b,\alpha} \subset \Omega. \tag{40}$$

Again from Lemma 15, it is enough to find α' and b' such that, for each $z' \in \partial(\Omega+u)$,

$$x' \in (\Omega+u) \cap B(z';\alpha') \Longrightarrow x' + \mathcal{C}_{b',\alpha'} \subset \Omega + u. \tag{41}$$

Given such an x', let $\xi' \in \mathcal{C}_{b',\alpha'}$, and define x and z by $x' = x + u(x)$, $z' = z + u(z)$. Lemma 16 with $v(\xi) = u(\xi + x) - u(x)$ gives the existence of $\xi \in \mathcal{C}_{b,\alpha}$ such that $\xi' = \xi + u(\xi + x) - u(x)$. Then

$$x' + \xi' = x + \xi + u(x + \xi).$$

This gives (41), provided that $x + \xi \in \Omega$. By (40), it is enough to check that $x \in \Omega$ (which is obvious) and $|x - z| \leq \alpha$, which is satisfied for $\alpha' \leq \alpha(1 - c)$ (indeed, $x' - z' = x - z + u(x) - u(z)$ implies $|x' - z'| \geq |x - z|(1 - c)$). □

PARTIAL EXACT CONTROLLABILITY FOR SPHERICAL MEMBRANES*

PAOLA LORETI† AND VANDA VALENTE†

Abstract. In this paper the partial exact controllability of an elastic spherical membrane is proved. The reachability problem for the integrodifferential equation, introduced for the vibrations of the meridional displacement, is solved. The main result is a generalization of a Ingham's theorem on nonharmonic Fourier series.

Key words. partial exact controllability, reachability problem, almost periodic functions

PII. S0363012994269624

Introduction. Following Love's and Koiter's linear shell theory [17], [10], in previous works [3], [4], [5], [6] we studied the problem of exact controllability for a thin elastic shell. The mathematical model is a system of partial differential equations where the unknown is the displacement vector $\mathbf{v}$ of the middle shell surface. We denoted by $\mathbf{A}^m$ and $\mathbf{A}^f$ the operators associated with the membrane energy and flexion energy, respectively, and by ε a small parameter depending on h (shell thickness) with $\lim_{h\to 0}\varepsilon = 0$. The spectrum behavior of $\mathbf{A} = \mathbf{A}^m + \varepsilon\mathbf{A}^f$ can be utilized to prove some results of exact controllability for the vibrations of thin shells. In the particular case of an hemispherical shell, the existence of an asymptotic gap for the eigenvalues λ_j of $\mathbf{A}$ allowed us to give a controllability time (depending on ε) and to prove exact controllability in suitable initial data spaces. In the general case we pointed out that when the thickness of the shell goes to zero, the number of eigenvalues of $\mathbf{A}$ less than a fixed $\lambda \geq \lambda^0$ goes to infinity; that is,

$$N_\lambda(\mathbf{A}) = \sum_{\lambda_j<\lambda} 1 \to \infty \quad \text{as} \quad h \to 0.$$

It suggests therefore that an accumulation point for the eigenvalues of the limit problem $\varepsilon = 0$ (the so-called membrane approximation) may occur; moreover, we proved that exact controllability of the limit problem generally fails, and an example of nonexact controllability is constructed in the case of hemispherical membrane approximation (see [6]).

In this paper we give a result of partial controllability for a spherical membrane; i.e., we want to control only one of the displacement components without conditions for the other components. The axially symmetric vibrations of a spherical membrane are described in section 1 by a pair of partial differential equations in the meridional and radial displacements u and w. The partial exact controllability problem is given in terms of the reachability problem for the integrodifferential equation for the vibrations of the meridional displacement. We propose the reverse or reachability Hilbert uniqueness method (RHUM) [11], [14], [15], [16] to construct our control function. In section 2, the well posedness of the corresponding homogeneous problem is proved. In section 4 we give a result of partial exact controllability (PEC) taking into account
